NATIONAL MARINE FISHERIES SERVICE REPORT ON GROUNDFISH MANAGEMENT

National Marine Fisheries Service (NMFS) Northwest Region will briefly report on recent regulatory developments relevant to groundfish fisheries and issues of interest to the Council.

NMFS Northwest Fisheries Science Center will also briefly report on groundfish-related science and research activities.

Council Task:

Discussion.

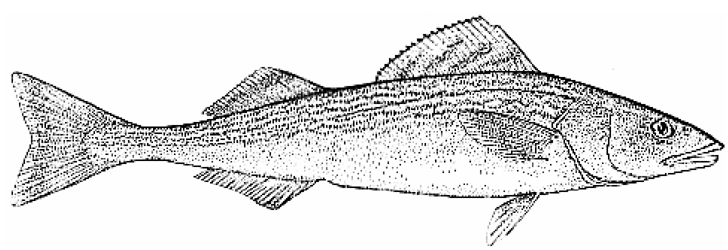
SMALL ENTITY COMPLIANCE GUIDE

PACIFIC COAST GROUNDFISH FISHERY
SABLEFISH PERMIT STACKING PROGRAM

This guide is designed for fishermen participating in the limited entry fixed gear sablefish fishery during the primary season. It provides useful information that will assist fishermen in understanding regulations implementing additional requirements for the sablefish permit stacking program in waters off Washington, Oregon, and California from Amendment 14 to the Pacific Coast Groundfish Fishery Management Plan.

March 31, 2006



CONTENTS

This guide was prepared pursuant to section 212 of the Small Business Regulatory Enforcement Fairness Act of 1996 (SBREFA), Pub. L. 104-121. The statements in this document are intended solely as guidance. This document is intended to provide a plain-language summary of how small businesses can comply with the regulations further implementing the sablefish permit stacking program (71 FR 10614, March 2, 2006).

WHO SHOULD READ THIS GUIDE?

If you currently own a limited entry permit with a sablefish endorsement, are interested in purchasing or leasing a limited entry permit with a sablefish endorsement, and/or own or operate a vessel that participates in the limited entry, primary sablefish fishery – you should read this guide.

INTRODUCTION

Amendment 14 to the Pacific Coast Groundfish Fishery Management Plan (FMP) introduced a permit stacking program to the limited entry, fixed gear primary sablefish fishery off Washington, Oregon, and California. Under this permit stacking program, a vessel owner may register up to 3 sablefish-endorsed permits for use with their vessel to harvest each of the primary season sablefish cumulative limits associated with the stacked permits. Amendment 14 also provided for a fishing season up to 7 months long, from April 1 - October 31, which allows time for vessels to pursue their primary season limits.

Portions of Amendment 14 were implemented for the 2001 primary sablefish season. The extended sablefish season was fully implemented in 2002. In 2006, NMFS is implementing additional regulations for Amendment 14. In the future, NMFS will implement a permit stacking program fee system as required by the Magnuson-Stevens Fishery Conservation and Management Act.

Stages of Implementation

- Beginning in 2001, NMFS implemented the initial permit stacking provisions (66 FR 41152, August 7, 2001). The following provisions were put in place in 2001:
  (1) up to 3 sablefish-endorsed permits may be registered for use with a single vessel;
  (2) the limited entry, primary sablefish season is from August 15 - October 31, 2001;
  (3) a vessel may fish for sablefish during the primary season with any of the gears specified on at least one of the limited entry sablefish-endorsed permits registered for use with that vessel;
  (4) no person may own or hold[1] more than 3 sablefish-endorsed limited entry permits unless that person owned more than 3 permits as of November 1, 2000;
  (5) no partnership or corporation may own a sablefish-endorsed limited entry permit unless that partnership or corporation owned a permit as of November 1, 2000;
  (6) cumulative limits for species other than sablefish and for the sablefish daily trip limit fishery remain per vessel limits and are not affected by permit stacking; and
  (7) the limited entry daily trip limit fishery for sablefish is open during the primary season for vessels not participating in the primary season.

- Beginning in 2002, NMFS extended the fishing season to April 1 - October 31 as part of the Pacific Coast groundfish final specifications and management measures (67 FR 10490; March 7, 2002).

- Beginning in 2006, NMFS is implementing further permit stacking regulations that include the following provisions (71 FR 10614, March 2, 2006):
  (1) permit owners and permit holders are required to document their ownership interests in their permits to ensure that no person holds or has ownership interest in more than 3 permits;

[1] The permit holder is the vessel owner.

(2) an owner-on-board requirement for permit owners who did not own sablefish-endorsed permits as of November 1, 2000;
(3) an opportunity for permit owners to add a spouse as co-owner;
(4) vessels that do not meet minimum frozen sablefish historic landing requirements are not allowed to process sablefish at sea;
(5) permit transferors are required to certify sablefish landings during mid-season transfers; and,
(6) a definition of the term “base permit.”

This guide pertains to those provisions implemented beginning in 2006. Information on these provisions and compliance timelines are included under the chapters describing each provision.

Why is the date November 1, 2000, in the new regulations?

Throughout this compliance guide, you’ll notice reference to the date November 1, 2000. This date, also called the control date, was established to distinguish permit owners who participated in the sablefish fishery before that date from those that are newer to the fishery. The participants before that date are also referred to as “grandfathered” or “first generation” permit owners. Grandfathered or first generation limited entry sablefish-endorsed permit owners are those permit owners who owned a sablefish-endorsed limited entry permit prior to November 1, 2000. These first generation permit owners are exempt from certain requirements of the sablefish permit stacking program, such as the owner-on-board requirement. NMFS announced this November 1, 2000, control date in an Advance Notice of Proposed Rulemaking on April 3, 2001 (66 FR 17681).

1 Declaration of Permit Ownership Interest

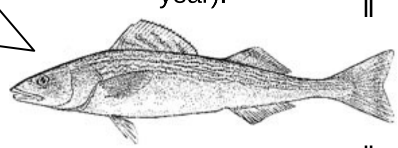
Background: Amendment 14 restricts the number of permits each person can have ownership interest in or hold to 3 permits, unless the person is grandfathered. This provision allows NMFS to track the number of permits owned and held by individuals.

Who must submit ownership interest information? All corporations or partnerships that currently own a sablefish-endorsed permit.

What are the ownership interest requirements?

- No partnership or corporation may own a sablefish-endorsed limited entry permit unless they owned a sablefish-endorsed permit as of November 1, 2000 (Partnerships or corporations that owned permits on or before that date, may continue to have ownership interest in those same permits and may purchase or hold additional permits up to the 3-permit limit; however, partnerships or corporations that owned a permit before November 1, 2000, and subsequently sell all of their sablefish-endorsed permits, will lose the privilege of continuing to own sablefish-endorsed permits if they do not buy another permit within one year).

Permit owners and permit holders are required to document their ownership interests in their permits to ensure that no person holds or has ownership interest in more than 3 permits.



- Any permit sold after November 1, 2000, may only be sold to an individual person or to partnerships or corporations that had ownership interest in a sablefish-endorsed permit before that date.

COMPLIANCE TIMELINE

Effective: **April 3, 2006**

Application Process:

- ✍ **In April 2006**, forms will be sent to corporations and partnerships that currently own or hold sablefish-endorsed permits. **The form will ask for a list of all shareholders or partners as of November 1, 2000, and a second listing of that same information as of the current date in 2006.** NMFS may require a copy of the USCG Abstract of Title as proof of vessel ownership for permit holders and/or owners and may require articles of incorporation or other documentation deemed necessary for proof of corporate or partnership ownership.
- ✍ **By July 1, 2006**, corporations or partnerships must return the completed form to NMFS.
- ✍ NMFS will send a second written notice to those entities who have not responded.
- ✍ **By August 1, 2006**, the completed form must be returned to NMFS. Otherwise, NMFS will void your existing permit(s) and reissue the permit(s) with a vessel registration given as "unidentified" until such time that the completed form is provided to NMFS.
- ✍ To track future changes, NMFS will send the form to corporations and partnerships as part of the annual permit renewal process and whenever a change in permit owner, permit holder, and/or vessel registration occurs.

- No individual person, partnership, or corporation in combination may own or hold more than 3 permits with sablefish endorsements either simultaneously or cumulatively over the primary season. The only exception to this requirement is if the person, partnership, or corporation had an ownership interest in more than 3 permits before November 1, 2000. An individual person, partnership, or corporation that had ownership interest in 3 or more permits with sablefish endorsements as of November 1, 2000, may not acquire additional permits beyond those particular permits owned on November 1, 2000. The term “cumulatively” means that an individual, corporation, or partnership may only be associated with up to 3 permits during the entire primary season.

- If, at some future time, an individual person, partnership, or corporation that owned more than 3 permits as of November 1, 2000, sells or otherwise permanently transfers (not holding through a lease arrangement) some of its originally owned permits, such that they then own fewer than 3 permits, they may acquire additional permits, but may not have ownership interest in or hold more than 3 permits.

- A partnership or corporation will lose their exemptions (the ability to own a sablefish permit and/or own more than 3 permits) when any “change” in the ownership of a corporation or partnership from that which existed on November 1, 2000, takes place. A “change” means the addition of any person (including family member) with an ownership interest in the corporation or partnership since November 1, 2000. A “change” is not considered to have occurred if an existing member of a corporation or partnership dies; becomes legally incapacitated; the ownership of shares among existing members changes; or a member leaves the corporation or partnership. Changes in the partnership or corporation must be reported to NMFS’ Sustainable Fisheries Division (SFD) within 15 calendar days of the addition of a new partner or shareholder.

What is the process to provide ownership interest information?

The process for declaring a permit’s ownership interest is described in the “compliance timeline” box on the previous page.

What will NMFS do with the ownership information?

- **Determine whether a partnership or corporation has changed**. If any of the corporations or partnerships have added one or more individuals as shareholder or partners since November 1, 2000, the corporation or partnership will no longer be able to own a permit. NMFS will void their existing permit, and reissue their permit in “unidentified” status, meaning that it cannot be fished. In order for the permit to be fished, the corporation or partnership will be required to permanently transfer the permit to another qualified individual, corporation, or partnership.

- **Recalculate the number of permits owned and/or held by each individual**. Those individuals who own or hold more than the allowable number of permits will be notified in writing. All permits owned or held by the individual will be registered as “unidentified” until such time that the individual divests themselves of the excess permits.

> **EXAMPLE:**
>
> **Do you own/hold more than 3 permits?**
>
> If a person is found to have ownership interest in 5 permits, 3 of which were owned as of November 1, 2000, NMFS will issue all 5 permits, including any permits shared with other individuals, partnerships, or corporations, into “unidentified” status until that person sells at least 2 of their permits so that they own or hold no more than 3 permits. If a person had ownership interest in 5 permits as of November 1, 2000, and still has ownership interest in those 5 permits and does not own or hold additional permits, none of the permits would be moved into the “unidentified” status.

How will the permit count be calculated?

NMFS counts as owning or holding a permit those individuals who are:

- listed as owner of a permit,
- listed as holder of a permit,
- listed as having an ownership interest in a permit as part of a corporation or partnership.

Each individual who is identified as owning or holding a permit as part of a corporation or partnership will be credited with owning one permit. If a person owns or holds other sablefish permits as an individual, those permits will also be figured in as part of the total count.

Is this a one-time collection of the information?

No. NMFS will require corporations or partnerships to complete this form:

- prior to July 1, 2006 (detailing the individuals with an ownership interest as of November 1, 2000 and as of the current date);
- as part of the annual renewal of their limited entry permit (starting in the Fall, 2006);
- everytime a partnership or corporation is part of a transfer request.

2 ADDITION OF A SPOUSE AS CO-OWNER ON A PERMIT

COMPLIANCE TIMELINE

Effective: **April 3, 2006**

Application Process:

- **In April 2006**, forms will be sent to permit owners with one individual listed as of November 1, 2000, to allow them to add their spouse on their permit. Applicants will be required to submit a copy of their marriage certificate as evidence of marriage.
- **By July 1, 2006**, the form must be returned to NMFS or the permit name on record with NMFS as of November 1, 2000, will remain on the permit.
- NMFS will not accept any declarations to add a spouse as co-owner after the deadline.

Background: Permit owners may not have predicted the implications of not listing their spouse under the detailed provisions of the permit stacking program. For example, if a couple was married as of November 1, 2000, but only one spouse was listed as the permit owner at that time, their spouse would not be exempt from the owner-on-board requirement should they inherit the permit (see Provision 3 below). However, for this one-time application, permit owners may add a not-listed spouse as a co-owner without losing their grandfathered status.

Who is eligible to make this change?
This provision applies only to permit owners who:
1) owned a sablefish-endorsed permit before November 1, 2000, and
2) who were married to their current spouse before November 1, 2000.
Existing partnerships and corporations may not add a spouse as co-owner.

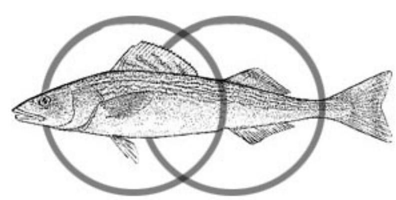
What is the requirement? Permit owners who were married as of November 1, 2000, and who owned a sablefish-endorsed permit as of that date, may wish to add their spouse as co-owner on their permit(s) and retroactively in NMFS' permit ownership records.

If I add my spouse as co-owner, will both of us be exempt from the owner-on-board requirement as individuals?
No. If you add your spouse as co-owner, your grandfathered status will be as a partnership, not as individuals. An individual within the married couple will not be able to retain their exemption from the owner-on-board requirement if they choose to buy another permit as an individual and did not own a permit as an individual as of November 1, 2000, in NMFS "corrected" records (i.e., NMFS records after allowing a not-listed spouse to be added as co-owner). The only way either person can have grandfathered status as an individual is if they continue to own a sablefish permit as an individual since November 1, 2000.

How will the permit count be calculated?
When a couple, married as of November 1, 2000, is listed as co-owners of the same permit, both individuals will be counted as owning one permit each.

Why you might want to do this-
To exempt your spouse from owner-on-board

Why you might NOT want to do this-
To maximize the permit count between you and your spouse



3 Owner-on-Board Requirement

Background: The sablefish permit stacking program is considered an individual fishing quota (IFQ) program. A concern about IFQ programs is that if fishing privileges are for sale, individuals or business entities who do not fish could buy those privileges. To encourage only fishers to buy into the sablefish fleet, Amendment 14 includes an "owner-on-board" provision.

COMPLIANCE TIMELINE

Effective: **January 1, 2007**

Application Process:

- All permit owners who are subject to the owner-on-board requirement will be notified in a letter from NMFS in 2006 and as part of the permit renewal process prior to the start of the primary sablefish season on April 1, 2007.
- Permits issued for the 2007 fishing season will designate which permits are subject to or exempt from the owner-on-board requirement.
- **In April 2006**, all individuals, partnerships or corporations who owned a permit as of November 1, 2000, and who no longer own a permit, will be notified in a letter from NMFS that they would qualify as a grandfathered permit owner if they choose to buy a permit by **March 2, 2007**.

Who is subject to the requirement?

An individual person who owns sablefish-endorsed permits currently but who did not have an ownership interest in a sablefish-endorsed permit as an individual as of November 1, 2000, will be required to be on board the vessel registered for use with that permit while that vessel is fishing for that permit's primary sablefish season limits. Persons subject to owner-on-board must carry government issued photo identification while onboard the vessel.

Who is exempt from the owner-on-board requirement?

A person, partnership, or corporation that had ownership interest in a limited entry permit with a sablefish endorsement prior to November 1, 2000, and continues to own a sablefish permit is considered grandfathered (or a first generation permit owner) and is exempt from the owner-on-board requirement. (See Examples on next page.)

There is also an emergency exemption that permit owners subject to the owner-on-board requirement may request in cases of death, illness, or injury of the permit owner. Please contact NMFS for details on how to apply for an emergency exemption.

Can an individual, corporation, or partnership lose their exemption?

Yes. A grandfathered entity will lose their exemption if:

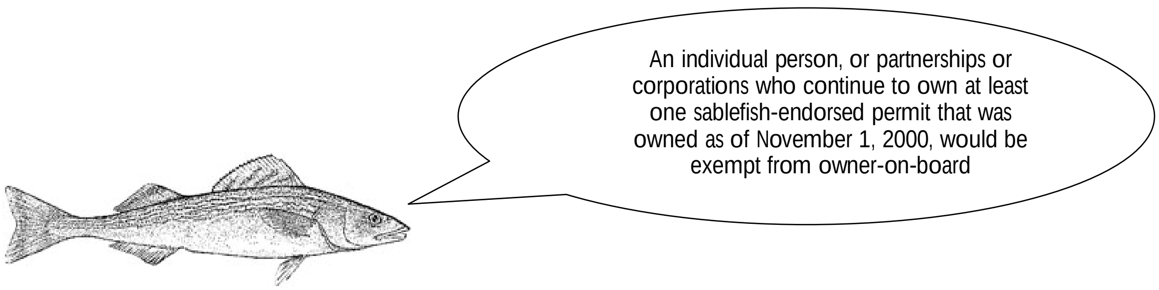
- A corporation or partnership "changes" (adds a partner or individual since November 1, 2000), or
- An individual, corporation, or partnership that owned a permit(s) as of November 1, 2000, sells all of their sablefish permits and does not purchase another permit within one year.

Is a permit holder subject to the owner-on-board requirement?

No. An individual person, partnership, or corporation may continue to hold sablefish-endorsed permits (e.g., through a lease arrangement) from any permit owner (exempt from owner-on-board or not) and remain exempt from the owner-on-board requirements, even if their membership has changed or they did not hold a sablefish-endorsed permit as of November 1, 2000. However, if you hold a sablefish-endorsed permit from a permit owner who is subject to the owner-on-board requirement, they must be onboard your vessel while that permit is being fished during the primary sablefish season.

Do I have to record my permit number on fish tickets?

Yes. Because only non-exempt permits owners are required to be onboard while their permit is being fished, enforcement agents must be able to determine which permits are being fished and which owner should be onboard. In order to aid enforcement of the owner-on-board provision, NMFS and the states are requiring the groundfish Federal limited entry sablefish-endorsed permit number to be written on state fish landing receipts (i.e., fish tickets) beginning in 2007.



EXAMPLES:

Grandfathered and selling all your permits?

If a person, partnership, or corporation that is exempt from the owner-on-board requirement no longer owns at least 1 sablefish-endorsed permit for a period greater than one year, that permit owner would no longer be exempt from the owner-on-board requirement. However, a person, partnership, or corporation that is exempt from the owner-on-board requirement could sell all of its permits, buy another sablefish-endorsed permit within one year of the date the last permit was approved for transfer, and retain its exemption from the owner-on-board requirements. In order to be allowed to obtain a permit during the one year grace period, the partnership or corporation could not have added or changed individuals, excluding individuals that have left the partnership or corporation or who have died.

Grandfathered in a corporation/partnership and buying another permit as an individual?

A person who has ownership interest in a partnership or corporation that owned a sablefish-endorsed permit as of November 1, 2000, but who did not individually own a sablefish-endorsed limited entry permit as of that date, is not exempt from the owner-on-board requirement when he/she leaves the partnership or corporation and purchases another permit individually.

Last remaining member of a grandfathered corporation/partnership?

A person who is part of a grandfathered partnership or corporation and did not own a permit as an individual before November 1, 2000 could buy additional permits as an individual, up to the limit of 3 per individual, but the individual would not be exempt from the owner-on-board requirements with the new permit. However, if the individual was part of a grandfathered partnership or corporation in which they were the only remaining individual (for example, all other individuals with ownership interest had left the partnership or corporation), this individual would still be considered as a grandfathered partnership or corporation in NMFS records. Thus, permits owned under the partnership or corporation now controlled by a single individual would be exempt from the owner-on-board requirements. This individually controlled partnership or corporation could also buy additional permits under the partnership or corporation name, up to the limit of 3 per individual, and would remain exempt from the owner-on-board requirements with the additional permits.

MORE EXAMPLES:

Do you qualify to be grandfathered but no longer own a permit?
A person, partnership, or corporation that qualified for the owner-on-board exemption, but later divested their interest in a permit or permits, may retain rights to an owner-on-board exemption as long as that person, partnership, or corporation purchases another permit by March 2, 2007. A partnership or corporation could only purchase a permit if it has not added or changed individuals since November 1, 2000, excluding individuals that have left the partnership or corporation or who have died.

Have you added members to your corporation/partnership since November 1, 2000?
If the individuals who have an ownership interest in the corporation or partnership change from those owning the partnership or corporation as of November 1, 2000, by adding another individual(s), that partnership or corporation will lose its exemption from both the owner-on-board requirement and from the provision that allows only an individual person to own a sablefish-endorsed permit.

> **Example A**, a husband and wife who own a permit could not add a sibling or child to the permit without losing their first generation status and losing their exemption from the provision that only allows an individual person to own permits.
> **Example B**, a fisherman who wants to take on a new partner because an existing partner is retiring could not add that new partner without losing his first generation status and his exemption from the provision that only allows an individual to own permits.
> **Example C**, in the case of a grandfathered corporation such as "Smith, Inc. and Jones, Inc.," viewed as one corporation in NMFS records, Jones, Inc. could not add a new member without causing "Smith, Inc. and Jones, Inc." to lose its grandfathered status.

Are you a married, grandfathered individual who would like to protect your spouse from owner-on-board?
If a couple was married as of November 1, 2000, but only one spouse was listed as the permit owner at that time, the spouse of the listed permit owner would not be exempt from the owner-on-board requirement if they inherit the permit. NMFS will allow an opportunity for those grandfathered permit owners who wish to add their spouses as co-owners on their permits to correct NMFS' permit ownership records as of November 1, 2000 (See Provision 2).

4 CERTIFICATION FOR MID-SEASON TRANSFERS

Background: With the longer sablefish primary season, there are more opportunities for permit owners to transfer their permits mid-season. Currently, when a sablefish permit is transferred mid-season, there is no indication by the transferor of how much sablefish has been landed against the tier amount for a particular permit. The mid-season certification is required for enforcement purposes as a way to associate specific amounts of landings to date with a total amount reported on fish tickets for a particular permit. The existing transfer form has been amended to include a section to provide this information.

Under already existing regulations, the transferee is required to retain onboard the vessel any fish tickets associated with landings made against that transferred permit, including any landings made previously on the permit during the primary sablefish season. Primary sablefish season fish tickets continue to be required onboard the vessel from April 1 – October 31 and for 15 days thereafter.

COMPLIANCE TIMELINE

Effective: **January 1, 2007**

Application Process:

- ✍ **Beginning January 1, 2007**, if a permit owner transfers a sablefish-endorsed permit mid-season, he/she will have to certify the cumulative amount of sablefish taken to date with that permit on a permit transfer form.
- ✍ The individual either leasing or buying the permit (the transferee) must acknowledge the cumulative amount of sablefish landed to date by signing the transfer form and maintaining the permit onboard the vessel.

Who is subject to this provision? This provision only applies to permit owners transferring their permits between vessels or between permit owners during the April-October primary season.

What is the requirement?
If a permit owner wishes to transfer a sablefish-endorsed permit mid-season, he/she will have to certify the cumulative amount of sablefish taken to date with that permit on a NMFS permit transfer form. In addition, the individual either leasing or buying the permit (the transferee) must acknowledge the cumulative amount of sablefish landed to date by signing the transfer form and maintaining the permit onboard the vessel. This certified amount should match the total amount of primary season sablefish landings reported on state fish tickets.

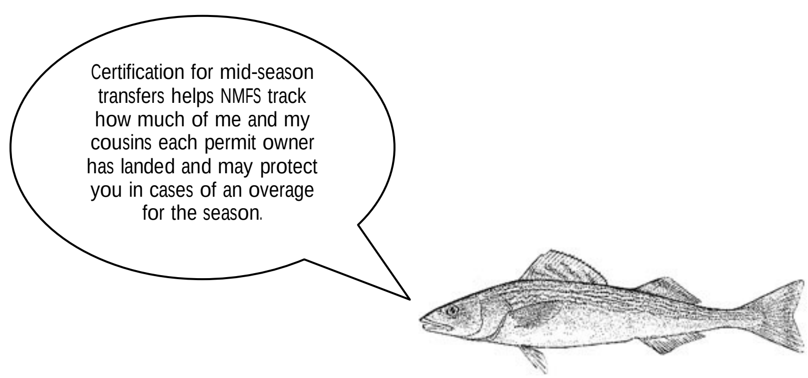
Does this certification occur with any type of transfer?
Yes, for transfers involving sablefish-endorsed permits during the primary season. Regardless of whether there is a change in the vessel registered to the permit and the permit owner/holder or just a change in the permit owner/holder, any of these actions will require a certification from the permit owner of the amount of sablefish landings to date.

How will enforcement use the information reported on a transfer form?
If during a post-season audit of landings associated with a sablefish-endorsed permit, the landings exceed the amount available to be landed on the permit, enforcement measures may be taken against any party that had ownership interest in the permit during the calendar year. The vessel owner or operator may also be held liable. It is a violation of both state and Federal law to give false or incomplete information on fish tickets.

Does the certification of sablefish landings impact other transfer requirements?
No. Permit transfers will still be constrained by limited entry program regulations, which allow a permit to be transferred between vessels only once per calendar year, and which make all permit transfers effective on the first day of a major cumulative limit period. Major cumulative limit periods will continue to begin on January 1, March 1, May 1, July 1, September 1 and November 1. While permits may only be transferred between vessels once per calendar year, changes in the permit owner or holder may occur at any time during the calendar year and as often as necessary.

How will NMFS be able to track the amount of sablefish on a permit?
In order to aid enforcement of mid-season transfers, NMFS and the states are requiring the groundfish Federal limited entry sablefish-endorsed permit number to be written on state fish landing receipts (i.e., fish tickets) beginning in 2007.

Why is the permit sale price and lease price requested?
In addition to the certification of sablefish landings to date, a space will be provided on the landings certification portion of the permit transfer form that requests the sale or lease price of the permit. Providing this sale or lease price to NMFS is optional. This information is being requested so that NMFS may build a database on permit sale prices. This database will be useful in analyzing economic trends and the value of the sablefish fishery.



5 PROHIBITION ON AT-SEA PROCESSING OF SABLEFISH

Background: The at-sea processing prohibition is to ensure that shoreside processing plants continue to have access to sablefish from the primary sablefish season. To acknowledge the investment that some vessels owners may have made in on-board freezing and processing equipment, the regulations allow a one-time opportunity to apply for an exemption from the prohibition on at-sea processing.

COMPLIANCE TIMELINE

Effective: **January 1, 2007**

Application Process:

- ✍ **In April 2006**, applications for an exemption to the prohibition on at-sea processing will be sent to sablefish-endorsed permit owners and/or fixed gear vessel owners.
- ✍ **By July 1, 2006**, permit and/or vessel owners must submit an application and supporting evidence to NMFS.
- ✍ NMFS has 30 days to review the application and make a decision.
- ✍ Those who qualify will be issued a letter from NMFS to carry onboard their vessel.
- ✍ There is an appeals process if you disagree with NMFS determination. For more details on the appeals process, please contact NMFS.

Who is eligible to apply for the exemption?

Any vessel owner that currently owns a sablefish-endorsed permit and whose vessel processed frozen sablefish in any one year from 1998 to 2000.

What is the general requirement?

Beginning January 1, 2007, vessels will be prohibited from processing sablefish at sea that were caught in the primary season, unless the vessel has an exemption from this prohibition.

What is the definition of processing?

"Processing" is defined as, "the preparation or packaging of groundfish to render it suitable for human consumption, retail sale, industrial uses or long-term storage, including, but not limited to, cooking, canning, smoking, salting, drying, filleting, freezing, or rendering into meal or oil, but does not mean heading and gutting unless additional preparation is done."

What are the qualifying criteria for an exemption?

The vessel must have:

- processed at least 2,000 pounds (round weight) of frozen sablefish in any one year during 1998, 1999 or 2000. Processing in 2000 would have to have occurred before November 1, 2000.
- The vessel must currently have a sablefish-endorsed permit.
- The vessel owner must have had a valid sablefish-endorsed permit at the time the qualifying fish were landed.

- The sablefish must have been caught during the primary season in waters 0-200 miles off Washington, Oregon and California.

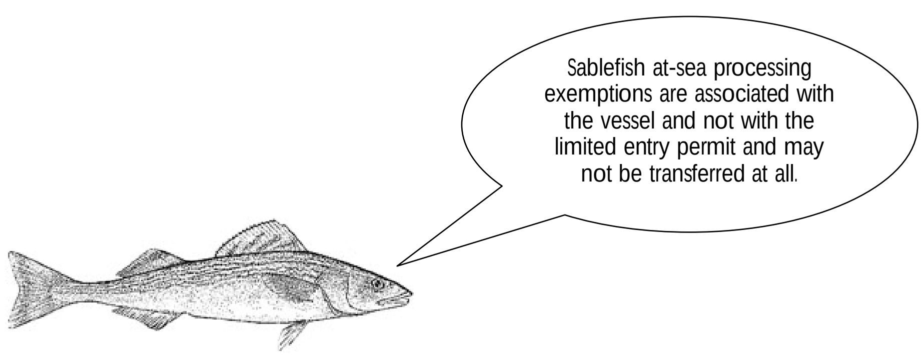
Do I need to prove that the vessel actually processed sablefish?
Yes. An applicant must provide documentation (i.e., sales agreements, bills of lading) that demonstrates the amount of frozen sablefish produced during the qualifying years. The best evidence of a vessel having made frozen sablefish landings are state fish tickets for landed sablefish accompanied by receipts for frozen sablefish from fish buyers or exporters. Evidence of having purchased freezing equipment will not in itself serve to support an application.

How will I know if my application is approved?
NMFS will send a letter to the vessel owner indicating whether your application was approved or disapproved. NMFS will also publish a list of vessels that qualified for the exemption in the Federal Register.

Is the exemption part of the sablefish permit?
No. The exemption, if approved, will be granted through a letter from NMFS and must be carried on the vessel during the primary season. This exemption would apply only to the vessel while the vessel is registered for use with a sablefish-endorsed limited entry permit. The exemption would not be associated with any of the permits registered for use with the vessel and would not be transferable to any other vessel, including other vessels belonging to that same permit and/or vessel owner.

Is the at-sea processing vessel exemption transferable? No.

When does the exemption expire?
When the vessel is totally lost or the vessel is sold or is otherwise transferred to another owner.



6 DESIGNATION OF A BASE PERMIT

The base permit is the limited entry permit registered for use with a vessel that meets the permit length (size) endorsement requirements appropriate to that vessel. A limited entry permit endorsed for pot or longline gear (i.e., any gear other than trawl gear) may be registered for use with a vessel up to 5 ft longer than, the same length as, or any length shorter than, the size endorsed on the existing permit without requiring a combination of permits or a change in the size endorsement. The Groundfish FMP describes a base permit in a permit stacking program as the initial permit needed to participate in the limited entry fishery, and subject to all of the requirements for limited entry permit ownership qualifications, and permit gear and length endorsements.

The permit registered for use with a vessel that is appropriate to that vessel's length is considered the base permit. The process for designating the base permit is described in the "compliance timeline" box at right. Each vessel must be registered for use with at least one permit with a length endorsement appropriate to that vessel. Any additional stacked sablefish-endorsed permits do not need to match the vessel's length.

Outside of the primary season, the vessel would operate under the per vessel cumulative limit restrictions appropriate to the gear of the base permit.

COMPLIANCE TIMELINE

Effective: **January 1, 2007**

Application Process:

- **Fall 2006**, with the limited entry permit renewal process, if more than one permit registered for use with a vessel has an appropriate length endorsement for that vessel, NMFS will designate a base permit by selecting the permit that has been registered to the vessel for the longest time. This designation will appear on the renewed permit.
- If the permit owner objects to NMFS's selection of the base permit, the permit owner may send a letter to NMFS requesting the change and the reasons for the request. If the permit requested to be changed to the base permit is appropriate for the length of the vessel, NMFS will reissue the permit with the new base permit.

ATTACHMENT A: GLOSSARY

Base permit, with respect to a limited entry permit stacking program, means a limited entry permit registered for use with a vessel that meets the permit length endorsement requirements appropriate to that vessel.

Change in partnership or corporation means the addition of a new shareholder or partner to the corporate or partnership membership. This definition of a “change” will apply to any person added to the corporate or partnership membership since November 1, 2000, including any family member of an existing shareholder or partner. A change in membership is not considered to have occurred if a member dies or becomes legally incapacitated and a trustee is appointed to act on his behalf, nor if the ownership of shares among existing members changes, nor if a member leaves the corporation or partnership and is not replaced. Changes in the ownership of publicly held stock will not be deemed changes in ownership of the corporation.

Corporation is a legal, business entity, including incorporated (INC) and limited liability corporations (LLC).

Grandfathered or first generation, when referring to a limited entry sablefish-endorsed permit owner, means those permit owners who owned a sablefish-endorsed limited entry permit prior to 11/1/ 2000, and are, therefore, exempt from certain requirements of the sablefish permit stacking program within the parameters of the regulations.

Hold, with respect to a permit holder, means a vessel owner as identified on the United States Coast Guard (USCG) form 1270 or state motor vehicle licensing document.

Partnership is two or more individuals, partnerships, or corporations, or combinations thereof, who have ownership interest in a permit, including married couples and legally recognized trusts and partnerships, such as limited partnerships (LP), general partnerships (GP), and limited liability partnerships (LLP).

Permit holder means a vessel owner as identified on the United States Coast Guard (USCG) form 1270 or state motor vehicle licensing document.

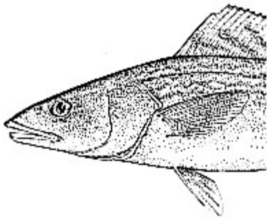
Regional Administrator means the Director, Northwest Region, NMFS.

Sustainable Fisheries Division (SFD) means the Chief, Sustainable Fisheries Division, Northwest Regional Office, NMFS, or a designee.

Spouse means a person who is legally married to another person as recognized by state law (i.e., one’s wife or husband).

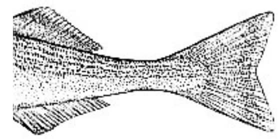
Stacking is the practice of registering more than one limited entry permit for use with a single vessel.

ATTACHMENT B:
SUMMARY SHEET OF PROVISIONS AND EFFECTIVE DATES



ATTENTION: Primary Season Sablefish Fishermen

Additional Sablefish Permit Stacking Regulations
(aka: Amendment 14b)



The final rule implementing additional provisions for the sablefish permit stacking program published in the *Federal Register* on March 2, 2006 (71 FR 10614), and will be effective beginning April 3, 2006. Below is a list of provisions implemented through this rulemaking, along with general effective dates.

Provisions implemented through Amendment 14b

1. declaration of permit ownership interest
2. addition of a spouse as co-owner on a permit
3. owner-on-board (OOB) requirement
4. certification for mid-season transfers
5. prohibition on at-sea processing of sablefish
6. designation of a base permit

Effective April 2006:

- Ownership interest form must be filled out for all permit transfers
- NMFS will send a compliance guide to the fleet about these provisions.
- NMFS will also send letters, forms, & applications to the fleet on:
  - addition of a spouse as co-owner on a permit
  - ownership interest in permit as of 11/1/2000 and as of the current date
  - exemption from the at-sea processing prohibition
  - notification for those permit owners who will be subject to OOB

Effective January 2007:

- Permit owners must be onboard the vessel when that vessel is fishing for sablefish in the primary season against that permit's tier, unless the permit owner is grandfathered (i.e., exempt from OOB).
- During mid-season transfers, the transferor must certify the quantity of sablefish landed on the permit and the transferee must acknowledge the amount of landings to date.
- At-sea processing of sablefish will be prohibited, unless the vessel and permit owner have previously qualified for an exemption.
- A base permit will be designated among the stacked permits with the permit renewal process in the fall of 2006.
- WA, OR and CA will require the sablefish-endorsed permit number to be written on the fish ticket.

Effective April 2007:

- Previously grandfathered permit owners (i.e., exempt from OOB) who no longer qualified as grandfathered upon publication of the final rule and have not gotten back to their original grandfathered configuration, will no longer be exempt from OOB.

DATE: June 9, 2006
TO: DISTRIBUTION
FROM: F/NWR2 -Becky Renko
SUBJECT: PRELIMINARY Report #3 -- 2006 Pacific Whiting Fishery

This report consolidates preliminary state, federal, and tribal data for the 2006 Pacific whiting fishery. Due to concerns about the incidental catch of overfished species, bycatch limits are in place for canary (4.7 mt) and widow rockfish (200 mt) taken in the non-tribal sectors of the fishery. If either bycatch limit is reached, the primary whiting seasons for the non-tribal fisheries will end regardless of the amount of whiting allocation remaining.

	Allocation		Whiting Catch* (mt)	Overfished Species and Chinook salmon catch	Thru [date]	Status	Percent of alloca-tion taken
	Percentages	Metric Tons					
California (south of 42 N lat.)	(5% shore alloc'n; included in WOC shore allocation)	4,873	5,241		5/25	started 4/1, closed 1800 5/25	107.5%
Oregon	--	NA	0				
Washington	--	NA	0				
WOC shore-based	42% commercial OY	**97,469**	5,241	Canary - 0.00 mt Widow -3.38 mt Darkblotched - 2.12 mt Chinook # 210	--	starts 6/15	5.3%
Mothership (n. of 42 N. lat.)	24% commercial OY	**55,696**	35,896	Canary - 0.55 mt Widow - 64.47 mt Darkblotched - 3.94 mt Chinook # 546	6/8	started 5/15	64.4%
Catcher/ processor (n. of 42 N. lat.)	34% commercial OY	**78,903**	23,207	Canary - 0.07 mt Widow - 27.80 mt Darkblotched - 0.91 mt Chinook - #108	6/8	started 5/15	29.4%
Total nontribal	commercial OY	232,069	64,344	Canary - 0.62 mt Widow - 95.65 mt Darkblotched - 6.97 mt Chinook - # 864	--	--	27.7%
Tribal (Makah)		**35,000**	175	Canary - 0. 00 mt Widow - 0.00 mt Darkblotched - 0.00 mt Chinook - #173			0.5%
Total directed fishing		267,069	64,519	Canary - 0.62 mt Widow - 95.65 mt Darkblotched - 6.97 -mt Chinook - # 1,037	--		24.1%

* Catch includes: discards from at-sea processors; weigh-backs from shore-based vessels; and catch landed under trip limits prior to the season. The values for at-sea processing sectors are based on NMFS observer data. Data for shore-based vessels were provided by the States. Data for the at-sea processing portion of the Makah fishery are based on preliminary NMFS observers data and shore-based catch was provided by tribal samplers. All weights are in metric ton (2,204.6 pounds).

2006 WEST COAST GROUNDFISH STOCK ASSESSMENT WORKSHOPS

Three workshops will be hosted by the NW Fisheries Center (NWFSC) during this off-year assessment cycle. The workshops include: 1) The Data and Modeling Workshop, 2) The Pre-recruit Survey Workshop co-hosted with the Southwest Fisheries Science Center, and 3) The NWFSC Bottom Trawl Survey Workshop. These workshops have been identified as being critical in support of the upcoming 2007 assessments.

The Data and Modeling workshop will be held August 8-10 in Seattle, Washington. The workshop will address a number of topics relating to the treatment of data in assessments and other modeling issues, including a review of the features and functionality of the SS2 modeling platform. Additional topics that are likely to be covered in this workshop include:

- A general review of available data sources for west coast groundfish (detailed reviews of data to be used in individual stock assessments are envisioned to occur during pre-assessment workshops in early 2007);
- Standardized methods for constructing age and length compositions and ageing-error matrices, and the treatment of sample-size issues;
- Dealing with uncertainty in parameter values (use of priors).

Organized in cooperation with the SW Fisheries Science Center (SWFSC), the Pre-recruit Survey workshop will be held September 13-15 in Santa Cruz, California to address issues relating to young-of-the-year groundfish surveys. The workshop will focus on:

- Review and finalization of protocols for an integrated, coastwide pre-recruit survey, to be conducted by the SWFSC and the NWFSC, in cooperation with the Pacific Whiting Conservation Cooperative;
- Evaluation of methods for including existing pre-recruit survey data in groundfish stock assessments, based on several case studies;
- Evaluation of the usefulness of pre-recruit abundance indices in assessing the status of groundfish stocks.

The NWFSC Bottom Trawl Survey workshop will be held October 31-November 2 in Seattle, Washington. The workshop will address the integration of the NWFSC shelf-slope survey into groundfish assessments. The major topics to be covered in this workshop include:

- Review of data collected by the NWFSC survey;
- Discussion of methods for developing biomass estimates and summaries of biological data;
- Comparison of survey selectivity and catchability between the NWFSC and Alaska Fisheries Center (AFSC) triennial surveys, for a set of shelf species;
- Comparison of results from including these surveys as separate or continuous time series, for the same set of shelf species.

The three workshops are open to the public. For more information on the workshops or the 2007 west coast groundfish stock assessments, please contact Ms. Stacey Miller, Northwest Fisheries Science Center Stock Assessment Coordinator, at (206) 860-3480 or by email at Stacey.Miller@noaa.gov.

SUMMARY OF WEST COAST GROUNDFISH OBSERVER PROGRAM DATA COLLECTION AND QUALITY CONTROL PROCESS NORTHWEST FISHERIES SCIENCE CENTER

Summary

The Northwest Fisheries Science Center's West Coast Groundfish Observer Program regularly provides the Pacific Fishery Management Council with discard and bycatch rate information. The rates are determined from data collected by at-sea observers deployed on commercial fishing vessels operating in west coast fisheries catch and retain groundfish. Before use, observer data passes through four phases, which take a total of three and a half to four months. This document details these processes, their timelines and suggests possibilities for reducing the amount of time required to complete them and summarizes difficulties in moving toward in-season catch accounting.

The first phase, data collection, entry and initial quality control, takes two months from the collection of the last observed trip of a period. This time could be reduced somewhat if fewer observers were deployed and instead resources were used for staff to quality control data. Since this would reduce existing coverage levels of groundfish fisheries this is not considered an option

The second phase, identifying and attaching corresponding fish ticket with observer data, takes about 10 weeks from the last observed trip of a period. Currently, the program waits two months after the last observed trip of a period for ~90% fish ticket completion rate in the PacFIN system to begin locating and attaching fish ticket and observer data. The time required for this phase could be shortened if fish ticket data were available more rapidly.

The third phase, data processing and analysis, takes about four weeks for each fishery for which discard and bycatch rates are produced. The time needed to complete this phase could be reduced if the fish ticket data set was entirely complete in PacFIN data system sooner, each landing could be easily attributed to a specific fishery, and there were greater consistency in recording catch categories in fish ticket and logbook records. Production of reports that focus solely on summarizing new data, rather than also evaluating changes from previous reports, would also expedite this phase.

Within the fourth phase, final preparation of the data and updating of projection models for use in management, takes about two weeks for the trawl fleet and an additional week for each of the other fleets. Estimation of total discard mortality for each fleet during the previous year requires an additional two weeks for the trawl fleet and another week for each of the other fleets.

In summary, the principal objective of the observer program is the documentation of discards and is not to duplicate the other existing data systems that estimate the catch that is retained. Accordingly, observer data represent only a portion of the information required to estimate total fishing mortality. Discard information must be combined with data from other sources such as fish tickets and vessel logbooks (where available), in order to document total catch. While some internal steps can be taken to reduce the data turnaround time in releasing observer data, because

of its connection with other data sets, other programs and agencies must also take steps in order to reduce the turnaround time.

There are many issues that complicate the potential for processing observer data on a more real-time basis and using those data for in-season management of fleet or vessel total catch caps. In addition to the availability of auxiliary data, substantial concerns about how data would be applied to unobserved vessels would need to be addressed. Existing methods for pooling observer data to protect confidentiality and achieve reasonable sample sizes would not function well in real-time mode, given existing levels of observer coverage. Changes in the sampling design used to distribute observer coverage might improve the extent to which all fleet fishing strategies are observed within any particular 2-month period. However, further analysis is required in order to evaluate the degree to which gaps in coverage would create problems for reporting and applying rates from observed to unobserved vessels over short time periods throughout the year.

Overview

The Pacific Fishery Management Council manages the fisheries off the coasts of California, Oregon and Washington. To aid in Council decisions, the Northwest Fisheries Science Center (NWFSC) provides fisheries research and data on species populations, bycatch rates and economic impacts. The West Coast Groundfish Observer Program (WCGOP) is responsible for collecting the main source of groundfish bycatch data provided to Council. This document describes how the bycatch data is produced for management use. The multifaceted process and the steps involved in final production of data are described and suggestions are made on actions that could be taken to reduce the time to produce the final bycatch and discard information.

The WCGOP deploys trained fishery observers in the limited entry bottom trawl, limited entry fixed gear and the 'open access' fleets (which currently includes the California sablefish open access fleet, Oregon and California near-shore fleets and a portion of the California halibut trawl fishery). Observers' primary responsibility is to monitor the composition and volume of discarded catch on each tow/set. The program randomly selects portions of each fleet for coverage based on geographical area, fishery, vessel activity, and the availability of observer resources.

Vessels participating in the limited entry trawl, limited entry zero tier fixed gear, near-shore and/or California halibut fisheries are selected for observer coverage for all trips taken during a two-month trip limit period. As the limited entry fleets land the majority of groundfish, they are a higher priority and typically all limited entry trawl and zero tier fixed gear trips are observed during their selected period. Coverage of the near-shore and California halibut fisheries are given at this time a lower priority, therefore observers cover these vessels only if a limited entry vessel is not active. Vessels participating in the limited entry sablefish endorsed fishery are selected for all trips during the sablefish season where the vessel lands sablefish against a tiered quota. Typically, all trips with sablefish tiered landings are observed.

The following section highlights the major steps or phases the data goes through before it is submitted for use by the Council. Figures 1 and 2 provide a visual illustration of these phases as well. Figure 3 provides an example timeline of the entire process for one fishery.

Phase 1 - Data Collection, Entry and Initial Quality Control

Observers collect fishing effort information, estimate total catch weight, estimate discard weight, and take species composition and biological samples from the discard (sampling details are available from the WCGOP Observer Training Manual at: http://www.nwfsc.noaa.gov/research/divisions/fram/observer/index.cfm). This information is recorded on waterproof deck forms and upon completion of a trip; the observer enters the data into the observer database. Once an entire trip is entered, the observer runs a data integrity check program consisting of approximately 170 data error checks. At the end of each month, the observer sends the hardcopies of their data to their debriefer. The debriefer, a staff member, then reviews sampling methods and checks for any calculation or data form errors. The data is returned to the observer who corrects errors on the hardcopies and in the database. After a two-month period is completed and a debriefer has checked all data, the observer is interviewed. During the interview, a last check is done for any more data or sampling method errors, species identifications are verified, all biological samples are logged and verified, and the observer's performance is evaluated. After the interview, the debriefer evaluates the data quality, either passing or failing a trip or a segment of trip based upon standard evaluation criteria. The debriefer performs a final verification to confirm that the hard copies of the data match the data in the computer. Finally, the debriefer runs a data error check for the data set, updates any errors found, and closes the trip to prevent further updates.

Time needed:
It typically requires two-months from the end of the data collection period to complete this phase.

Suggestions for reducing the time needed for phase 1:
Currently, the observer program does not release any preliminary data. As the data is from a sub-sample of the fishery, the program must ensure the highest data quality. Accelerating the schedule may impact data quality and the ability to maximize sea time as observers may have to forego trips for debriefing.

Phase 2: Identify and Attach Corresponding Fish Ticket Data with Observer Data

Once phase one is completed, the database manager runs a final quality control check on the entire data set to be analyzed. The quality control can be done by fishery or as a combination of all data collected from all fisheries during a given time period. A debriefer reviews all data that was flagged from the data error check and makes updates when necessary.

After the quality control, the observer data is matched with fish tickets (downloaded from PacFIN) on a per trip basis. To estimate total catch on observed vessels and to relate the data to the unobserved portion of the fleet, observer data and fish ticket(s) data are matched (i.e. the fish ticket(s) data produced for every observed trip is collected from PacFIN). Although locating fish tickets for all observed trips seems a relatively straightforward process, it is not. The state agencies are responsible for delivering the fish ticket information to PacFIN and there is a delay between fish ticket production at the time of landing and when that information is available for observer program use in PacFIN. Currently, it takes approximately two months to have a 90% fish ticket completion rate.

To aid in identifying the correct ticket data, observers record fish tickets number(s) for all trips observed. Using this information, most observed trips can be easily matched with the correct fish tickets. However, observers often only have one fish ticket number from trips that had multiple fish tickets generated as additional fish tickets can be created due to weighbacks, etc.

The database manager searches through the fish ticket list by vessel and using the landing date recorded by the observer, ensures that all fish tickets generated from a trip are located. Cancelled tickets are another complicating factor. For example, there are some ports where a fish ticket is generated at the dock but then the fish are taken by van to a processing facility or market. It appears that sometimes when the transportation of fish occurs, the processor completes a second fish ticket, making the first fish ticket obsolete. Finding the correct tickets can be especially difficult, as there are many days in between vessel landing and the fish ticket being generated. The database manager has created a query to make this process more efficient, however it still takes two weeks to complete this second phase and phase two can not begin until at least a significant portion of the fish tickets from the trip limit periods of the data set are available in PacFIN. Currently, the observer program waits for ~90% fish ticket completion rate or about two months.

Time needed:
Two months and two weeks.

Suggestions for reducing time needed for phase 2:
If the time to submit tickets were reduced, then the time needed to accomplish this phase would also be reduced. Electronic fish tickets are being investigated by at least one state as a viable option to decrease upload time to the PacFIN data system.

Phase 3: Data Processing and Analysis

After the data have gone through quality control, error checking and all fish tickets are located for observed trips, the data are processed by the analyst and then used to estimate discard rates. As fish ticket data are collected on a trip basis and observer data are collected on a set/haul basis, the data sets must be processed to relate to each other.

First, the analyst estimates haul-level weights of species or species groups. As the observer often subsamples hauls/sets, the analyst uses the weights of the species in the each subsample to estimate the weight of the species in the haul/set. For details on methodology, please see the observer data reports available online at:
http://www.nwfsc.noaa.gov/research/divisions/fram/observer/index.cfm).

As previously mentioned, the observer data set and the fish ticket data set use different coding and have different levels of detail. Before the data sets can be joined, the analyst must assign consistent species, catch categories, port and port group coding to the two datasets.

Once the two data sets have consistent coding, the next step is to match catch categories on the fish tickets to retained catch categories in the observer data. The catch categories are species or species groups. The first part of this step involves calculating the trip-level weights of retained for each catch category for both observer data and fish ticket data. The fish ticket and observer data are then matched by catch category and trip. Next the two datasets are joined and the values from the observer data and fish ticket data are compared. At this point, discrepancies between the observer data and the fish ticket data will become obvious.

The analyst works to identify and resolve gross discrepancies between the observer data and the fish ticket data, such as extreme differences in total retained catch and missing fish tickets. The data are also examined for extreme differences in the weight of the landed catch between fish ticket and observer data. Another issue is that catch categories will appear in only one of the datasets; this discrepancy often occurs when catch categories are combined (i.e. other flatfish) in one dataset and specified in the other dataset (i.e. other flatfish vs. butter sole, sand sole, and curlfin sole). For each one of these discrepancies, an attempt is made to determine the cause of the discrepancy to resolve it.

For the gross discrepancies, the analyst attempts to determine the cause. Investigating the discrepancies may involve searching for additional fish tickets for a trip and looking at comments by haul in the observer data. Finally, decisions are made on the course of action for each discrepancy that does not have a clear cause. This matching process is very labor intensive and time consuming, as each discrepancy must be handled individually.

After the causes of the discrepancies are corrected, the two datasets are then joined again. Another check for discrepancies is repeated and if necessary a third or fourth check is conducted.

Once the observer data and fish ticket data are satisfactorily joined by category and trip, the weight of the observer retained catch is adjusted so that the total weight by trip for each catch category in the observer data matches the weights in the fish ticket data. Also for the catch categories only in the fish ticket data, the weight of the catch category landed in each haul/set is estimated. At this point, the data are ready to be analyzed.

For the observer program data reports, the analyst estimates coverage, total discarded catch for observed trips, and discard and bycatch rates for observed trips. To calculate the coverage of a fishery by weight, the total landings made by the fishery are determined by adding together fish ticket weights associated with the fishery. The PacFIN system is queried for this data, but determining total landings for each fishery can be problematic, as the fish ticket does not identify the fishery in which a vessel was participating. Associating landings with limited entry trips is not too problematic for the limited entry fleets as these vessels fish almost exclusively in only one of the limited entry fisheries. In contrast, the open access fishers often participate in many different fisheries, sometimes in the same trip. For the open access fisheries, the program has yet to identify a method to estimate total cumulative landing by fishery. WCGOP is currently working with the states to attempt to estimate the landings by fishery. The inability to estimate total landings for a fishery results in the program being unable to estimate the percent coverage by weight or determine how well observer data matches normal fleet spatial and temporal activity. Also, discard and bycatch rates can be determined for observed trips but any extrapolation to a fishery as a whole can be challenging and utilize multiple assumptions.

For the most part, estimating total discarded catch and discard and bycatch rates of observed trips for each species/species complex is relatively straightforward. Total discard for over 30 species is determined for multiple strata (see Table 4 from observer program trawl report, Sept 2005 at: http://www.nwfsc.noaa.gov/research/divisions/fram/observer/datareport/trawl/datareportsep2005.cfm) by using a ratio estimator to relate the discard and bycatch to hours of towing and/or total retained catch. However, the process is lengthy due to the sheer number of species and strata. A report typically contains 60-80 tables.

Finally, the data and tables are summarized and the reports are written. Due to the fishery-specific differences, the data processing, analysis and writing has to be done separately. Currently four, fishery-specific reports are produced by the observer program.

Time needed:
Four weeks per fishery.

Suggestions for reducing time needed for phase 3:
A complete set of fish tickets would eliminate the need for the analyst to search for missing tickets. A mechanism to denote on a fish ticket which fishery each fish is being landed in would make it easier to determine total landings in a fishery. In particular an identifier added to fish tickets and logbooks to identify when EFP fishing was occurring would be helpful because bycatch rates observed in the general fishery should not be applied to fishing experimental fishing where either retention is required or discards are documented separately. There should be consistency in recording catch category labels on fish tickets between states/processors. This would help data turnaround since the larger the number of differences on how a species is recorded on a fish ticket, the more discrepancies during the matching process that the analyst must investigate.

Phase 4: Development and delivery of discard data and modeling for use in management

Observer data are used in management in two ways: for estimating past amounts of fleet discard, and for projecting discard and bycatch amounts expected in future periods.

For the groundfish trawl fleet, discard in the previous year is estimated using vessel-level data from fish tickets and logbooks, along with observer data from that year. Logbook and observer data are stratified by depth, area, and season. The amount and distribution of fleet effort, obtained from logbook data, is combined with observed discard rates to estimate overall amounts of discard for trips included in logbook records. Because logbooks do not capture 100% of groundfish trawl trips, ratios of fish ticket-to-logbook retained catches are used to expand the discard estimates to the entire trawl fleet. Since non-trawl fisheries lack comparable logbook programs, estimation of past discard relies primarily upon observer and fish-ticket data. Observer data have been incorporated in a depth-specific manner in the sablefish fishery, based on closed-area boundaries, and in the near-shore fisheries, based on state estimates of the distribution of fishing effort. Computation of the best estimates of past discard requires that all of these components be available before the analyses can be conducted.

It must be stressed that discard estimates from WCGOP-observed fisheries represent only a portion of the information needed to estimate total fishing mortality. Fish tickets are needed to document retained groundfish catch in commercial and tribal fisheries. Data from recreational fisheries are needed to document both retained catch and discard mortality in those fisheries. Additionally, estimates of groundfish discard mortality from unobserved fisheries must also be accounted for. Estimates of mortality from this last category, as well as catches attributable to research fishing and exempted fishing permits are typically compiled by the GMT.

The Council is most commonly presented with <u>projections</u> of total catch and discard, as part of GMT evaluation of alternative management measures. The model employed by the GMT (and developed by the NWFSC) to project total catch for the trawl fleet uses 4-year, weighted averages of fish-ticket, logbook, and observer data, where the most recent data are assigned the greatest weight. The data are stratified into depth zones and areas that are consistent with regional and closed-area options commonly considered for Council management action. Projection models for fixed-gear sablefish and near-shore fisheries utilize expected regional landed catches of target species in those fisheries (based on OY allocations or other harvest targets) and prior observer data.

Current time requirements for preparing updated data for projection models:
2 weeks for trawl; 1 week each for other observed fleets.

Current time requirements for developing estimates of the previous year's discard:
2 weeks for trawl; 1 week each for other observed fleets.

Impediments to in-season catch accounting and suggested next steps to be taken by WCGOP to improve data turn around.

Moving towards a more real-time accounting of total catch, whether at the fleet or vessel level, is complicated by a number of issues. With the existing level of observer coverage, discard data are currently pooled across depths, seasons, and large areas in order to ensure that discard rates applied to unobserved vessels are based on reasonable sample sizes. Because the distribution of observers is achieved through a stratified random sample based on only on gear, port group, and 2-month period, and the actual distribution of fishing effort is uncertain, there is no guarantee that observed vessels will fish within specific depth zones or shorter time intervals in which unobserved vessels fish. To protect the confidentiality of observed vessels, current national policy does not even permit discard rates to be reported for strata in which fewer than 3 vessels have been observed. The current schedule for evaluating fleet discard permits observer data to be stratified in a manner that accounts for reporting and statistical criteria after the actual temporal and spatial distribution of observed fishing effort during a year is known.

Applying observed data to the unobserved fleet on an ongoing basis throughout the year, for the most recent week, month, or even 2-month period, would not permit this sort of data-pooling. Aggregating observer data on a coast-wide basis, or across all depths, in order to achieve adequate sample sizes is not an acceptable option, as existing data clearly indicate vastly different rates of encounters and discard for most species across these dimensions. Over some duration of time—likely at least 2 months—gaps in observer data could be reduced, through additional stratification of observer sampling effort, in order to increase the likelihood of collecting data from the full cross-section of fishing activities in which the fleet is likely to engage during that period. But such an effort would need to be based either on prior vessel participation or on an advance declaration process. Neither option would carry a guarantee that an adequate number of observations would be made within a stratum, and the latter would require vessels to commit, at least 4-6 months in advance of a particular period, to conduct at least some of whatever fishing they did within a specified depth stratum. These approaches also imply that vessels participating in strata with fewer total participants are likely to be observed more frequently than is the case with the current sampling strategy.

Without much higher levels of observer coverage, shorter periods of catch accounting would be associated with increasing likelihood that an inadequate number of observations would occur to permit a reasonable analytical stratification of fleet effort to be employed. **New analysis of existing observer and logbook data could be conducted to reveal the likelihood that, with existing levels of coverage, gaps in observer data for specific depth and area stratifications, over a range of time periods, would prevent reasonable application of discard rates to unobserved vessels.** Protocols would also need to be evaluated and agreed upon for revising estimates of discard, in-season, based on pooling accumulated observer data.

The program can also investigate the time taken by observers to submit their data. Currently, observers submit their data within five days of end of a trip. The program can test whether this time can be shortened without missing sea days or overburdening observers. In addition, the program can investigate how many mistakes are made in an observer's original submission of data before data quality control steps. This would give an indication as to the frequency and type of mistakes observers may be making and the steps that would have to be taken to reduce them.

In addition to these types of changes within the program for collecting observer data, fish ticket, and preferably also logbook, data would need to be available on the same schedule as the observer data. Electronic fish tickets would facilitate an accelerated ability to document the landings of observed and unobserved vessels. However, without equally rapid documentation of fishing depths, the estimation of discard would require the development of new models dependent upon algorithms for estimating the depth of fishing based on past participation and/or species composition. Use of an algorithm in place of logbook information could lead to larger error in the initial bycatch estimates, and increase the need for re-estimation once logbook data become available.

Agenda Item F.2
Situation Summary
June 2006

TENTATIVE ADOPTION OF 2007-2008 GROUNDFISH FISHERY SPECIFICATIONS/MANAGEMENT MEASURES AND AMENDMENT 16-4

Under this agenda item, the Council is scheduled to take tentative final action to: 1) adopt 2007-2008 optimum yields (OYs) and rebuilding plans for depleted groundfish species; 2) consider setting aside bycatch caps for proposed 2007 Exempted Fishing Permits (EFPs) (2007 EFP applications are included as Informational Reports in this briefing book); 3) adopt 2007-2008 groundfish management measures; and 4) adopt Groundfish Fishery Management Plan (FMP) Amendment 16-4 amendatory language. This tentative adoption will be followed by review and analysis by the Groundfish Management Team (GMT) and the Groundfish Advisory Subpanel (GAP) with opportunity for clarification under Agenda Item F.5 on Thursday followed by final adoption under Agenda Item F.6 on Friday.

A preliminary draft environmental impact statement (DEIS) is provided to help the Council understand the interconnected consequences of these decisions: biological – effects on living marine resources; physical – effects on habitats and the marine ecosystem; and socioeconomic – effects on fishermen, processors and, fishing communities. Excerpted sections of the preliminary DEIS are provided as Agenda Item F.2.a, Attachment 1. These excerpted sections include: Chapter 2 in its entirety, which describes the 2007-2008 OY alternatives, rebuilding alternatives, and 2007-2008 management measure alternatives; portions of Chapter 4, which describes effects of these alternatives on West Coast marine species; and portions of Chapter 7, which describes the effects of these alternatives on West Coast fishing communities. Agenda Item F.2.a, Attachment 2 is a CD copy of the preliminary DEIS with all the sections completed as of the May 24 briefing book deadline. The DEIS will be formally submitted for public review in mid-July, after the Council's final, preferred alternatives are recommended and analyzed.

Draft FMP Amendment 16-4 amendatory language has been updated with the Council's recommended modifications from the April meeting and is provided as Agenda Item F.2.a, Attachment 3. This draft is complete except for section 4.5.4, which describes the species-specific groundfish rebuilding plans. Alternate versions of section 4.5.4, which will describe rebuilding plans under the Preferred Low OY and Preferred High OY alternatives set by the Council for overfished species in April, will be supplemental attachments under this agenda item. The Council should adopt the relevant version of these species-specific rebuilding plans, consistent with the final preferred OYs it sets for the seven overfished species.

State and tribal entities have provided recommendations for 2007-2008 groundfish management and Amendment 16-4 rebuilding plans. California Department of Fish and Game's recommendations are included in Agenda Item F.2.b, CDFG Report. Oregon Department of Fish and Wildlife presents their recommendations in Agenda Item F.2.b, ODFW Report and ODFW Report 2, and Washington Department of Fish and Wildlife's recommendations are provided in Agenda Item F.2.b, WDFW Report. Additionally, public comments that were received at the Council office by the June briefing book deadline are included in Agenda Item F.2.d, Public Comments.

The Council should consider the state and tribal proposals and preliminary DEIS analyses, as well as advice from advisory bodies and the public before adopting final 2007-2008 OYs and management measures, final rebuilding plans, and the FMP Amendment 16-4 language codifying the Council's rebuilding plans. The Council may want to request additional analyses by the GMT and GAP under this agenda item. Results for any requested analyses can be provided on Thursday under Agenda Item F.5. Final Council action on 2007-2008 OYs and management measures, and Amendment 16-4 rebuilding plans is scheduled for Friday under Agenda Item F.6.

Council Action:

1. **Adopt Preferred 2007-2008 Optimum Yields for Depleted Groundfish Species.**
2. **Consider Setting Aside EFP Bycatch Caps for 2007 EFPs.**
3. **Adopt Tentative Final 2007-2008 Management Measures.**
4. **Adopt Final Amendment 16-4 FMP Language.**

e. **Council Action:** Tentative Adoption of 2007-2008 Final Acceptable Biological Catches (ABCs), Optimum Yields (OYs), Management Measures, and Revised Rebuilding Plans for Overfished Species (Amendment 16-4)

PFMC
05/26/06

2.0 ALTERNATIVES INCLUDING THE PROPOSED ACTION

There are two suites of alternatives analyzed in this EIS. The first suite of alternatives is the range of 2007-2008 harvest specifications or acceptable biological catches (ABCs) and optimum yields (OYs) considered for groundfish stocks and stock complexes managed under the Groundfish FMP. The range of harvest specifications for depleted groundfish species is also analyzed to understand the potential conservation and socioeconomic consequences of alternative depleted species' rebuilding plans. Therefore, the Council's preferred 2007-2008 OY alternative serves two purposes: both as the harvest specifications for the years 2007 and 2008 and, for depleted species, as the next step in the longer term mortality schedules for rebuilding plans. The target rebuilding year for each depleted species under rebuilding is also set in this decision step as the most likely year to rebuild under the Council-preferred OY and mortality schedule. Harvest specification (and rebuilding plan) alternatives are described in section 2.1.

The second suite of alternatives analyzed in this EIS is alternative 2007-2008 management measures. Alternative management measures adopted for analysis are designed to illustrate the potential efficacy and tradeoffs of management strategies and allocations considered for the next biennial management period by the Council. The overarching objectives of 2007-2008 management measures are to stay within the Council-preferred annual OYs for groundfish stocks and stock complexes and to equitably allocate fishing opportunities and other fishery benefits across fishing sectors and regions under Council jurisdiction. Alternative 2007-2008 management measures are described in section 2.2.

2.1 Alternative Harvest Specifications

Table 2-1 depicts the alternative harvest specifications for groundfish stocks and stock complexes managed under the FMP and considered by the Council for the 2007-2008 management period. The Council decided to average projected 2007 and 2008 OYs from adopted assessments and rebuilding analyses with the intent to specify an average OY, which is applied to both years. In some cases, and only for stocks with quantitative assessments, the Council also decided to average projected ABCs for the 2007-2008 management period (see FMP §4.3.1). In cases where the OY might exceed an ABC in any one year, the OY is capped at that ABC since an ABC cannot legally be exceeded.

2.1.1 Depleted Groundfish Species

Depleted groundfish species are those with spawning biomasses that have dropped below the Council's depletion or overfished threshold of 25% of initial spawning biomass (or $B_{25\%}$). The Groundfish FMP mandates these stocks need to be rebuilt through harvest restrictions and other conservation measures to 40% of unfished biomass (or $B_{40\%}$). Furthermore, the MSA mandates these rebuilding periods need to be the shortest time possible while taking into account the status and biology of the depleted stock, the needs of fishing communities, and the interaction of the depleted stock within the marine ecosystem. This mandate was underscored in an August 2005 ruling by the Ninth Circuit Court of Appeals in a challenge to the Council's darkblotched rockfish rebuilding plan. In accordance with that ruling, the Council decided to reconsider all adopted rebuilding plans to ensure they comply with the MSA as interpreted by the courts. Therefore, the range of harvest specifications for depleted groundfish species under rebuilding and analyzed in this EIS has been expanded to more effectively analyze what it means to "rebuild in the shortest time possible, taking into account the needs of fishing communities" by considering the impacts of allowing some access to healthy fish stocks. Access to healthy fish stocks would mean some mortality of depleted species that are caught as bycatch in these fisheries would be allowed. Any harvest of depleted groundfish stocks is anticipated to be unavoidable bycatch. The Council-preferred harvest specifications for depleted species are the mortality limits for these species that the Council recommends under rebuilding to avoid disastrous short-term socioeconomic impacts to West Coast fishing communities. Rebuilding periods for depleted species are coincident with the Council's recommendation for OYs for these species and defined in the Council's rebuilding framework, as specified in the Groundfish FMP, as the median time to attain the target spawning biomass of $B_{40\%}$ under a given harvest rate or mortality schedule.

Prior to the new groundfish assessments conducted, reviewed, and adopted in 2005 under Council procedures, the depleted groundfish species under rebuilding were bocaccio (in waters south of 40°10' N latitude), canary rockfish, cowcod, darkblotched rockfish, lingcod, Pacific ocean perch, widow rockfish, and yelloweye rockfish. However, the 2005 lingcod assessment {Jagielo 2006} indicates that the coastwide lingcod stock has attained (and exceeded) the $B_{40\%}$ spawning biomass threshold and is now considered successfully rebuilt. No new species were declared depleted from the 23 groundfish assessments conducted in 2005. Therefore, the Council is continuing rebuilding plans for the other seven species only and reconsidering those plans in response to a Ninth Circuit Court of Appeals ruling discussed above and in Chapter 1. To fully analyze both the conservation needs of each depleted stock and the socioeconomic effects of alternative rebuilding plans, a wide range of OYs have been specified for analysis for each depleted species (Table 2-2a). Each of these OY alternatives is based on the best available science as recommended by Stock Assessment Review (STAR) panels and the Council's Scientific and Statistical Committee (SSC). Section 2.1.1 describes the scientific basis for each depleted species' OY alternative and describes the strategic analyses of these alternatives that are presented in more detail in subsequent chapters of this EIS.

In considering potential rebuilding alternatives, first, the consequences of each depleted species' OY alternative was examined in isolation to understand the tradeoff between the amount of allowable harvest and alternative rebuilding periods and to identify the West Coast fisheries that are affected by the constraints posed by alternative rebuilding plans for each particular depleted species. The predicted rebuilding periods and the annual OYs that describe the alternative rebuilding schedules, each of which define a rebuilding plan, are estimated using the SSC's endorsed rebuilding program {Punt 2005}. The rebuilding program is a probabilistic population simulator that explores alternative harvest rates and predicts the total mortality and duration of rebuilding for each depleted species under a range of harvest rates. The depleted species' OY alternatives analyzed in this EIS, based on harvest rates estimated from the rebuilding simulation program, are calculated using an instantaneous rate of fishing mortality (F), which may be converted to a Spawning Potential Ratio. For ease of comparison among stocks and to standardize the basis of rebuilding calculations, it is useful to express any specific fishing mortality rate in terms of its effect on Spawning Potential Ratio (SPR = spawning per recruit at the current population level relative to that at the stock's unfished condition). Given fishery selectivity patterns and basic life history parameters, there is a direct inverse relationship between F and SPR (Figure 2-1). When there is no fishing, each new female recruit is expected to achieve 100% of its spawning potential. As fishing intensity increases, expected lifetime reproduction declines due to this added source of mortality. Conversion of F into the equivalent SPR has the benefit of standardizing for differences in growth, maturity, fecundity, natural mortality, and fishery selectivity patterns and, as a consequence, the Council's SSC recommends it be used routinely. The rebuilding program is more thoroughly described in Chapter 6. The OY alternatives for depleted species are described in section 2.1.1.1.

Table 2-1. Council-adopted alternatives for acceptable biological catches (ABCs) and total catch optimum yields (OYs) (mt) for 2007 and 2008. (Overfished stocks in CAPS; Stocks with new assessments in bold).

a/ The Council elected to average OY projections for 2007 and 2008 and analyze/specify the average OYs for each year. ABCs, in some cases, are specified similarly for some species with quantitative assessments. Otherwise, ABCs are year-specific.

b/ Council ABC and Council OY represent the Council's preferred harvest alternative for 2007 and 2008.

c/ Area OYs/HGs are stratified according to the assessment areas and alternatively adjusted by management areas for lingcod and petrale sole.

d/ The Council specified a coastwide 2007-2008 sablefish OY (Alt. 2 OY). However, sector allocations are based on the portion of the OY north of 36 deg. N. lat.

e/ A coastwide OY was not adopted for longspine and shortspine thornyheads. Separate OYs north and south of Pt. Conception at 34deg.27' N. lat. were specified.

f/ The preferred OY is for the Conception and Monterey areas combined.

g/ The yelloweye OY alternatives originally specified for analysis in Nov. 2005 were based on the 2005 assessment. The revised 2006 assessment and rebuilding analysis, adopted in Mar. 2006, projects a range of allowable 2007-2008 OYs under a constant harvest rate strategy of <=15 mt. Therefore, alternatives 3-6 were eliminated from further analysis.

h/ The yelloweye ramp-down strategy ramps the harvest rate down from the status quo harvest rate and resumes a constant harvest rate strategy in 2011. The 2007-2010 OYs are 23 mt, 20 mt, 17 mt, and 14 mt, respectively under the ramp-down strategy.

i/ The Remaining Rockfish and Other Rockfish categories are shown to understand how the Minor Rockfish complex harvest specifications are derived. These are not management targets.

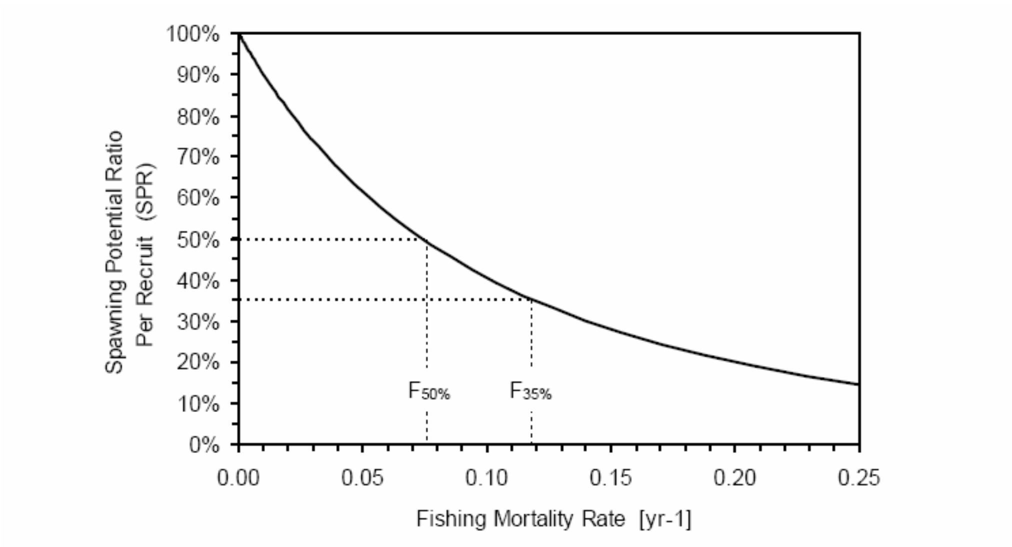

Figure 2-1. Relationship between spawning potential ratio (SPR) and instantaneous fishing mortality rate (F) for a hypothetical rockfish.

Next, rebuilding alternatives were developed by arranging the depleted species' OYs in various combinations (Table 2-2b) and then modeling changes to the current management regime to understand how rebuilding plans for different species interact to constrain fishing opportunities. The OYs in these rebuilding alternatives are strategically arrayed to illuminate how each species might differentially constrain fishing opportunities by sector (or gear type) and region along the West Coast, depending on the amount of allowable harvest of each species. It is important to note that the full range of OY alternatives described in Table 2-2a are not used to structure these rebuilding alternatives. Some of the higher OY alternatives in Table 2-2a are not used to structure the rebuilding alternatives in Table 2-2b. For example, the highest OY alternative for widow rockfish (OY Alternative 5) was not included among the rebuilding alternatives because it represents an amount of bycatch not observed in the current management regime. Prior to 2003, when there was a directed midwater trawl fishery for yellowtail and widow rockfish, catches of widow rockfish approached the level of mortality consistent with the OY Alternative 5 in Table 2-2a. However, the current understanding of the association of the more constraining canary rockfish stock with yellowtail rockfish leads to the conclusion that the available potential harvest of canary rockfish (as described by the range of OYs in Table 2-2a) would constrain any directed midwater trawl opportunities for yellowtail rockfish before the widow rockfish bycatch would approach the higher available OYs for that stock. Therefore, the rebuilding alternatives in Table 2-2b are structured using a narrower range of depleted species' OYs than those depicted in Table 2-2a. The rebuilding alternatives are described in detail below, in Section 2.1.1.2.

At their April 2006 meeting, the Council selected a preferred OY alternative for all managed groundfish species and species complexes except for the seven depleted species (Table 2-1). For the depleted species, the Council selected two preferred OY alternatives for further analysis for each stock. A final preferred OY and rebuilding plan for each depleted species will be decided at the June 2006 Council meeting. As discussed above, the Council's preferred OY alternative for the 2007-2008 fisheries must be consistent with any intent to modify depleted species rebuilding plans. Therefore, the choice of a preferred OY alternative involves consideration of both short-term effects (during 2007-2008) and long-term effects (the future application of rebuilding plans as revised by Amendment 16-4).

2.1.1.1 Optimum Yield Alternatives for Depleted Species

Table 2.2a depicts the range of depleted species' OY alternatives specified for analysis by the Council in November 2005 and April 2006. The numbered OY alternatives in Table 2-2a correspond to the alternative harvest levels that the Council originally selected for analysis in November 2005. In April 2006, the Council decided that the Preferred Low OY and High OY alternatives would represent the range of OYs that should be the focus of more detailed analysis. These preferred OY alternatives will be the range the Council will select from in June 2006 when final depleted species' OYs and rebuilding plans will be adopted. Table 2-3 and Figure 2-2 indicate the median time to rebuild under each 2007-2008 OY alternative.

Table 2-2a. Range of 2007-2008 OYs for depleted groundfish species decided at the November 2005 and April 2006 Council meetings.

		2007-2008 OYs (mt)							
Stock	**Association**	**OY Alt. 1**	**OY Alt. 2**	**OY Alt. 3**	**OY Alt. 4**	**OY Alt. 5**	**OY Alt. 6**	**Pref. Low OY Alt.**	**Pref. High OY Alt.**
Yelloweye a/	Northern Shelf	0	12	~~17~~	~~21~~	~~24~~	~~27~~	12.6	Ramp-down b/
Canary		0	24	44	68			32	44
Cowcod c/	Southern Shelf	0	8	14	18	22		4	8
Bocaccio		0	149	218	315	424		40	218
Darkblotched	Northern Slope	0	130	229	330	472		130	229
POP		0	87	405	514	749		44	100
Widow	Midwater	0	329	456	917	1,369		120	368

a/ A 2007-2008 OY >= 15 mt for yelloweye would result in a less than a 50% probability of rebuilding before Tmax, which is not legally viable. OY Alternatives 3-6 are discussed further in section 2.1.5 of the EIS.

b/ The yelloweye ramp-down strategy ramps the harvest rate down from the status quo harvest rate and resumes a constant harvest rate strategy in 2011. The 2007-2010 OYs are 23 mt, 20 mt, 17 mt, and 14 mt, respectively under the ramp-down strategy.

c/ OY alternatives for Conception and Monterey areas combined.

Table 2-2b. Amendment 16-4 rebuilding alternatives.

		2007-2008 OYs (mt)					
Stock	**Association**	**"Status Quo" Reb. Alt. a/**	**Reb. Alt. 1**	**Reb. Alt. 2**	**Reb. Alt. 3**	**Reb. Alt. 4**	**Reb. Alt. 5**

POP		87	405	87	749	405	44
Widow	Midwater	329	456	329	917	329	120

a/ The species' OYs described in the "status quo" rebuilding alternative are determined by calculating the effective SPR harvest rate from the November 2005 bycatch scorecard and projecting this harvest rate forward to 2007.

b/ OY alternatives for Conception and Monterey areas combined.

			~~5~~	~~2080~~	~~24~~					
			~~6~~	~~2099~~	~~27~~					

a/ The numbered OY alternatives were specified for analysis by the Council in Nov. 2005. The Preferred OY alternatives were specified for analysis by the Council in April 2006.

b/ Darkblotched OY alternatives cannot exceed the ABC (456 mt in 2007 and 486 mt in 2008). Therefore, OY Alt. 5 can only be considered in 2008.

c/ A 2007-2008 OY >= 15 mt for yelloweye would result in a less than a 50% probability of rebuilding before Tmax, which is not legally viable. Alternatives 3-6 are discussed further in section 2.1.5 of the EIS.

d/ The yelloweye ramp-down strategy ramps the harvest rate down from the status quo harvest rate and resumes a constant harvest rate strategy in 2011. The 2007-2010 OYs are 23 mt, 20 mt, 17 mt, and 14 mt, respectively under the ramp-down strategy.

Bocaccio (in Waters off California South of 40°10' N Latitude)

The OY alternatives specified for analysis for the bocaccio stock south of 40°10' N latitude are 0 mt, 40 mt, 149 mt, 218 mt, 315 mt, and 424 mt (Tables 2-1 and 2-2a). This compares to the status quo OYs of 307 mt in 2005 and 309 mt in 2006.

The zero harvest alternative would rebuild the stock by 2021, which is the shortest possible time to rebuild ($T_{F=0}$) given our current understanding of stock productivity.

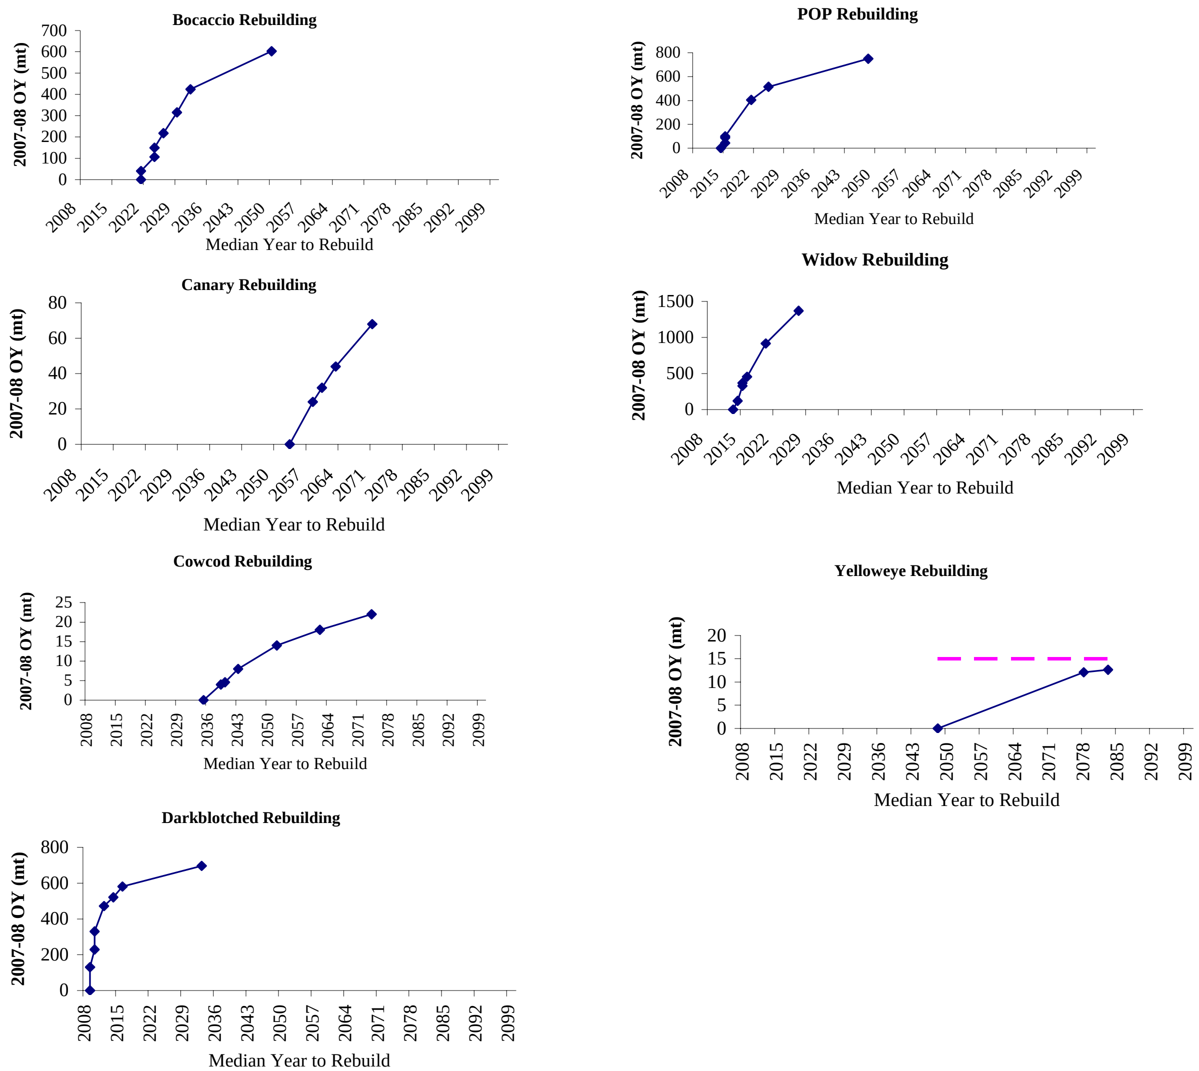

Figure 2-2. Predicted rebuilding duration vs. allowable 2007-2008 harvests for seven depleted West Coast groundfish species.

The 40 mt alternative is the Council's **Preferred Low OY Alternative** specified by the Council in April 2006. The median time to rebuild the stock under this alternative is 2021.9, or about 10 months longer than $T_{F=0}$ (Table 2-3 and Figure 2-2).

The 149 mt alternative is based on the effective harvest rate in 2005 projected forward to 2007 and 2008. The GMT determined the effective harvest rate by applying the best estimate of total mortality in 2005 divided by the exploitable biomass in 2005. The GMT then applied the resulting rate to the projected exploitable biomass in 2007 and 2008 {MacCall 2006a} to determine projected OYs, which were then averaged for those years. The median time to rebuild the stock under this alternative would be 2024, or 3 years longer than $T_{F=0}$ (Table 2-3 and Figure 2-2).

The 218 mt OY alternative is the Council's **Preferred High OY Alternative** and represents the OY under an 80% rebuilding probability (P_{MAX} or the probability of successfully rebuilding the stock in the maximum allowable time under the current National Standard 1 Guidelines) from the 2003 rebuilding analysis {MacCall 2003b}. The median time to rebuild the stock under this alternative would be 2026, or 5 years longer than $T_{F=0}$ (Table 2-3 and Figure 2-2).

The 315 mt OY alternative represents the current SPR harvest rate of 69.2% applied to the 2007 and 2008 projections of exploitable biomass. This is the harvest rate used to establish the status quo 2005 and 2006 OYs. The median time to rebuild the stock under this alternative would be 2029, or 8 years longer than $T_{F=0}$ (Table 2-3 and Figure 2-2).

The 424 mt OY alternative represents the OY under a re-estimated P_{MAX} of 50% from the new rebuilding analysis {MacCall 2006}. This is the highest OY that can be considered for bocaccio in that it is based on the best available science and is at the 50% rebuilding probability threshold established in litigation (*Natural Resources Defense Council v. Daley*, April 25, 2000, U.S. Court of Appeals for the District of Columbia Circuit). The median time to rebuild the stock under this alternative would be 2032, or 11 years longer than $T_{F=0}$ (Table 2-3 and Figure 2-2).

Canary Rockfish

The OY alternatives specified for analysis for the coastwide canary rockfish stock are 0 mt, 24 mt, 32 mt, 44 mt, and 68 mt (Tables 2-1 and 2-2a). This compares to the status quo OY of 47 mt in 2005 and 2006.

The zero harvest alternative would rebuild the stock by 2053, which is the shortest possible time to rebuild ($T_{F=0}$) given our current understanding of stock productivity.

The 24 mt OY alternative represents the OY under a 60% rebuilding probability (the status quo P_{MAX}) from the new rebuilding analysis {Methot 2006}. The median time to rebuild the stock under this alternative would be 2058, or 5 years longer than $T_{F=0}$ (Table 2-3 and Figure 2-2).

The 32 mt alternative is the Council's **Preferred Low OY Alternative**. The median time to rebuild the stock under this alternative is 2060, or 7 years longer than $T_{F=0}$ (Table 2-3 and Figure 2-2).

The 44 mt OY alternative is the Council's **Preferred High OY Alternative** and applies the current SPR harvest rate of 88.7% to the 2007 and 2008 projections of exploitable biomass. This is the harvest rate used to establish the status quo 2005 and 2006 OYs. The median time to rebuild the stock under this alternative would be 2063, or 10 years longer than $T_{F=0}$ (Table 2-3 and Figure 2-2).

The 68 mt OY alternative represents the OY under a re-estimated P_{MAX} of 50% from the new rebuilding analysis {Methot 2006}. This is the highest OY that can be considered for canary rockfish in that it is based on the best available science and is at the 50% rebuilding probability threshold. The median time to rebuild the stock under this alternative would be 2071, or 18 years longer than $T_{F=0}$ (Table 2-3 and Figure 2-2).

Cowcod

The OY alternatives specified for analysis for the cowcod stock occurring in the Conception and Monterey INPFC areas are 0 mt, 8 mt, 14 mt, 18 mt, and 22 mt (Tables 2-1 and 2-2a). This compares to the status quo OY of 4.2 mt in 2005 and 2006.

The zero harvest alternative would rebuild the stock by 2035, which is the shortest possible time to rebuild ($T_{F=0}$) given our current understanding of stock productivity.

The 4 mt alternative is the Council's **Preferred Low OY Alternative** specified by the Council in April 2006. The median time to rebuild the stock under this alternative is 2039, or 4 years longer than $T_{F=0}$ (Table 2-3 and Figure 2-2).

The 8 mt OY alternative is the Council's **Preferred High OY Alternative** and represents the OY under a re-estimated 80% rebuilding probability from the new rebuilding analysis {Piner 2006}. The median time to rebuild the stock under this alternative would be 2043, or 8 years longer than $T_{F=0}$ (Table 2-3 and Figure 2-2).

The 14 mt OY alternative represents the OY under a re-estimated 70% rebuilding probability from the new rebuilding analysis {Piner 2006}. The median time to rebuild the stock under this alternative would be 2052, or 17 years longer than $T_{F=0}$ (Table 2-3 and Figure 2-2).

The 18 mt OY alternative represents the OY under a re-estimated 60% rebuilding probability (the status quo P_{MAX}) from the new rebuilding analysis {Piner 2006}. The median time to rebuild the stock under this alternative would be 2062, or 27 years longer than $T_{F=0}$ (Table 2-3 and Figure 2-2).

The 22 mt OY alternative represents the OY under a re-estimated P_{MAX} of 50% from the new rebuilding analysis {Piner 2006}. This is the highest OY that can be considered for canary rockfish in that it is based on the best available science and is at the 50% rebuilding probability threshold. The median time to rebuild the stock under this alternative would be 2074, or 39 years longer than $T_{F=0}$ (Table 2-3 and Figure 2-2).

Darkblotched Rockfish

The OY alternatives specified for analysis for the coastwide darkblotched rockfish stock are 0 mt, 130 mt, 229 mt, 330 mt, and 424 mt (Tables 2-1 and 2-2a). This compares to the status quo OYs of 269 mt in 2005 and 200 mt in 2006.

The zero harvest alternative would rebuild the stock by 2009.5, which is the shortest possible time to rebuild ($T_{F=0}$) given our current understanding of stock productivity.

The 130 mt OY alternative is the Council's **Preferred Low OY Alternative** and represents the OY specified in 2001. The Ninth Circuit court ruling compelling the Council and NMFS to consider Amendment 16-4 disputed the 2002 darkblotched harvest specification, which had changed this 2001 OY to a higher value. The median time to rebuild the stock under this alternative would be 2009.9, or approximately 5 months longer than $T_{F=0}$ (Table 2-3 and Figure 2-2).

The 229 mt OY alternative is the Council's **Preferred High OY Alternative** and is based on the effective harvest rate in 2005 (F = 0.0216) projected forward to 2007 and 2008. The GMT determined the effective harvest rate by applying its best estimate of total mortality in 2005 divided by the exploitable biomass in 2005. The GMT then applied the resulting harvest rate to the projected exploitable biomass in 2007 and 2008 {Rogers 2006a} to determine projected OYs, which were then averaged for those years. The median time to rebuild the stock under this alternative would be 2010.2, or approximately 8 months longer than $T_{F=0}$ (Table 2-3 and Figure 2-2).

The 330 mt OY alternative applies the harvest rate used to set the 2005 OY (F = 0.032) to the 2007 and 2008 projections of exploitable biomass (OYs averaged and applied to each year). The median time to rebuild the stock under this alternative would be 2010.5, or 1 year longer than $T_{F=0}$ (Table 2-3 and Figure 2-2).

The 472 mt OY alternative represents the OY capped at the average 2007-2008 ABC specification. This is the highest OY that can be considered for darkblotched rockfish in that the ABC cannot be legally exceeded. The re-estimated P_{MAX} under this alternative is 97%. The median time to rebuild the stock under this alternative would be 2012, or 2.5 years longer than $T_{F=0}$ (Table 2-3 and Figure 2-2).

Pacific Ocean Perch

The OY alternatives specified for analysis for the coastwide Pacific ocean perch (POP) stock are 0 mt, 44 mt, 87 mt, 100 mt, 405 mt, 514 mt, and 749 mt (Tables 2-1 and 2-2a). This compares to the status quo OY of 447 mt in 2005 and 2006.

The zero harvest alternative would rebuild the stock by 2014.6, which is the shortest possible time to rebuild ($T_{F=0}$) given our current understanding of stock productivity.

The 44 mt alternative is the Council's **Preferred Low OY Alternative** specified by the Council in April 2006. The median time to rebuild the stock under this alternative is 2015, or about half a year longer than $T_{F=0}$ (Table 2-3 and Figure 2-2).

The 87 mt OY alternative is based on the effective harvest rate in 2005 projected forward to 2007 and 2008. The GMT determined the effective harvest rate by applying its best estimate of total mortality in 2005 divided by the exploitable biomass in 2005. The GMT then applied the resulting harvest rate to the projected exploitable biomass in 2007 and 2008 {Hamel 2006b} to determine projected OYs, which were then averaged for those years. The median time to rebuild the stock under this alternative would be 2015.4, or about 1 year longer than $T_{F=0}$ (Table 2-3 and Figure 2-2).

The 100 mt OY alternative is the Council's **Preferred High OY Alternative**. The median time to rebuild the stock under this alternative would be 2015.6, or 1 year longer than $T_{F=0}$ (Table 2-3 and Figure 2-2).

The 405 mt OY alternative represents the OY under a re-estimated 80% rebuilding probability from the new rebuilding analysis {Hamel 2006b}. The estimated SPR harvest rate under this alternative is 69.6%. The median time to rebuild the stock under this alternative would be 2021, or approximately 7 years longer than $T_{F=0}$ (Table 2-3 and Figure 2-2).

The 514 mt OY alternative represents the OY under a re-estimated 70% rebuilding probability (the status quo P_{MAX}) from the new rebuilding analysis {Hamel 2006b}. The median time to rebuild the stock under this alternative would be 2025, or 11 years longer than $T_{F=0}$ (Table 2-3 and Figure 2-2).

The 749 mt OY alternative represents the OY under a re-estimated P_{MAX} of 50% from the new rebuilding analysis {Hamel 2006b}. This is the highest OY that can be considered for POP in that it is based on the best available science and is at the 50% rebuilding probability threshold. The median time to rebuild the stock under this alternative would be 2048, or 34 years longer than $T_{F=0}$ (Table 2-3 and Figure 2-2).

Widow Rockfish

The OY alternatives specified for analysis for the coastwide widow rockfish stock are 0 mt, 120 mt, 329 mt, 368 mt, 456 mt, 917 mt, and 1,369 mt (Tables 2-1 and 2-2a). This compares to the status quo OYs of 285 mt in 2005 and 289 mt in 2006.

The zero harvest alternative would rebuild the stock by 2013, which is the shortest possible time to rebuild ($T_{F=0}$) given our current understanding of stock productivity.

The 120 mt alternative is the Council's **Preferred Low OY Alternative** and is predicted to rebuild the stock by 2014, which is 1 year longer than $T_{F=0}$ (Table 2-3 and Figure 2-2).

The 329 mt OY alternative is based on the effective harvest rate in 2005 projected forward to 2007 and 2008. The GMT determined the effective harvest rate by applying its best estimate of total mortality in 2005 divided by the exploitable biomass in 2005. The GMT then applied the resulting harvest rate to the projected exploitable biomass in 2007 and 2008 {He et al. 2006b} to determine projected OYs, which were then averaged for those years. The median time to rebuild the stock under this alternative would be 2015, or 2 years longer than $T_{F=0}$ (Table 2-3 and Figure 2-2).

The 368 mt alternative is the Council's **Preferred High OY Alternative** and is predicted to rebuild the stock by 2015, which is 2 years longer than $T_{F=0}$ (Table 2-3 and Figure 2-2).

The 456 mt OY alternative applies the current SPR harvest rate of 93.6% to the 2007 and 2008 projections of exploitable biomass. This is the harvest rate used to establish the status quo 2005 and 2006 OYs. The median time to rebuild the stock under this alternative would be 2016, or approximately 3 years longer than $T_{F=0}$ (Table 2-3 and Figure 2-2).

The 917 mt OY alternative represents the OY under a re-estimated 80% rebuilding probability from the new rebuilding analysis {He et al. 2006b}. The SPR harvest rate under this alternative is estimated to be 88.6%. The median time to rebuild the stock under this alternative would be 2020, or 7 years longer than $T_{F=0}$ (Table 2-3 and Figure 2-2).

The 1,369 mt OY alternative represents the OY under a re-estimated P_{MAX} of 60% from the new rebuilding analysis {He et al. 2006b}. The median time to rebuild the stock under this alternative would be 2027, or 14 years longer than $T_{F=0}$ (Table 2-3 and Figure 2-2).

Yelloweye Rockfish

The OY alternatives originally specified for analysis for the coastwide yelloweye rockfish stock were 0 mt, 12 mt, 17 mt, 21 mt, 24 mt, and 27 mt (Tables 2-1 and 2-2a). The first five yelloweye OY alternatives were derived from the 2005 yelloweye assessment and rebuilding analysis. However, in November 2005 the Council requested a new yelloweye assessment be done over the winter when numerous assessment data issues became known. The Council also specified the status quo 27 mt OY alternative for analysis in case a new, more optimistic assessment and rebuilding analysis were approved in 2006.

A new yelloweye stock assessment {Wallace et al. 2006} and rebuilding analysis {Tsou and Wallace 2006} were approved in March 2006. The new 2006 assessment was more pessimistic than the 2005 assessment and one implication of the new rebuilding analysis was that the projected range of allowable 2007-2008 OYs under a constant harvest rate strategy is ≤ 15 mt. That is, higher OYs would result in rebuilding probabilities ≤ 50%, which is not legally viable. Therefore, yelloweye OY Alternatives 3-6 in Table 2-2a were eliminated from further detailed study (see section 2.1.5).

The Council adopted for analysis a new OY alternative of 12.6 mt for 2007-2008 and consideration of a yelloweye harvest rate ramp-down strategy, which is explained in more detail below. Therefore, the full range of viable yelloweye OY alternatives analyzed for 2007-2008 and Amendment 16-4 are 0 mt, 12 mt, 12.6 mt, and the harvest rate ramp-down strategy, which specifies OYs of 23 mt and 20 mt for 2007 and 2008, respectively. This compares to the status quo OYs of 26 mt in 2005 and 27 mt in 2006.

The zero harvest alternative would rebuild the stock by 2048, which is the shortest possible time to rebuild ($T_{F=0}$) given our current understanding of stock productivity.

The 12 mt OY alternative would rebuild the stock by 2078, or 30 years longer than $T_{F=0}$ (Table 2-3 and Figure 2-2).

The 12.6 mt alternative is the Council's **Preferred Low OY Alternative** and is based on a re-estimated 80% rebuilding probability from the new rebuilding analysis {Tsou and Wallace 2006}. This is the rebuilding probability from the status quo rebuilding plan and the SPR harvest rate under this alternative is estimated to be 71.9%. The median time to rebuild the stock under this alternative would be 2083, or 35 years longer than $T_{F=0}$ (Table 2-3 and Figure 2-2).

The yelloweye harvest rate ramp-down strategy is the Council's **Preferred High OY Alternative** and is designed to provide the Council time to develop management strategies to reduce current yelloweye impacts by more than 50%. The ramp-down strategy would sequentially lower the yelloweye harvest rate in the next four years before resuming a constant harvest rate rebuilding strategy in 2011. The OYs would be 23 mt, 20 mt, 17 mt, and 14 mt in 2007-2010. Under this strategy, the constant harvest rate would be the same as for the Preferred Low OY Alternative (SPR harvest rate = 71.9%) beginning in 2011. The median time to rebuild the stock under this alternative would be 2083.5, or 35.5 years longer than $T_{F=0}$ and about a half a year longer than the Preferred Low OY Alternative (Table 2-3 and Figure 2-2).

2.1.1.2 Rebuilding Alternatives

There are six rebuilding alternatives analyzed in this EIS (Table 2-2b). Each alternative was strategically developed to better compare and contrast the tradeoffs associated with alternative rebuilding strategies. These alternatives are analyzed by predicting the effect on the status quo management regime. Multiple suboptions are presented for each alternative to explore potential effects under different allocation scenarios.

The "status quo" rebuilding alternative is comprised of OY alternatives based on the effective harvest rates for each of the depleted stocks in 2005 projected forward to 2007 and 2008. The effective harvest rates were determined by applying the GMT's best estimate of total mortality in 2005 divided by the exploitable biomass of each stock in 2005. These harvest rates were then applied to the projected best exploitable biomasses in 2007 and 2008 to determine projected OYs.

Rebuilding alternative 1 would result in an increase in slope and midwater trawl fishing opportunities with the higher darkblotched, POP, and widow OYs; and a corresponding decrease in shelf fishing opportunities with the lower OYs for bocaccio, canary, cowcod, and yelloweye.

Rebuilding alternative 2 would result in higher southern shelf fishing opportunities with the higher bocaccio and cowcod OYs; lower northern recreational and limited entry and open access fixed gear opportunities with the lower yelloweye OY; and close to status quo for northern bottom and midwater trawl fishing opportunities with the "status quo" OYs for darkblotched, POP, and widow.

Rebuilding alternative 3 would result in higher shelf fish opportunities north and south with the higher bocaccio, cowcod, canary, and yelloweye OYs; and higher slope and midwater trawl fishing opportunities with the higher OYs for darkblotched, POP, and widow.

Rebuilding alternative 4 would dramatically lower northern shelf opportunities and some additional constraints in southern shelf fisheries north of Point Conception with the lower canary and yelloweye OYs; higher shelf fishing opportunities south of Pt. Conception with the higher bocaccio and cowcod OYs; and higher slope and midwater trawl opportunities with the higher darkblotched, POP, and widow OYs.

Rebuilding alternative 5 would dramatically lower shelf fishing opportunities coastwide with the lower bocaccio, cowcod, canary, and yelloweye OYs; and dramatically lower slope and midwater trawl fishing opportunities with the lower darkblotched, POP, and widow OYs.

2.1.2 Precautionary Zone Groundfish Species

Cabezon (in Waters off California)

The Council has identified one OY alternative, 69 mt, to be analyzed for the cabezon stock in waters off California (Table 2-1) for 2007 and 2008. This is the same as the status quo OY alternative. The ABC alternative identified for analysis is 94 mt for both 2007 and 2008; this alternative is based on the sum of average 2007-2008 ABCs for the northern and southern substocks (north and south of Pt. Conception), as determined in the 2005 stock assessment.

Pacific Whiting

Pacific whiting are managed based on an annual assessment prepared jointly by U.S. and Canadian scientists. Pacific whiting harvest specifications are based on annual assessments and are only analyzed in this EIS to understand the potential bycatch implications of future whiting fisheries. The 2007 ABC and OY will be adopted by the Council at its March 2007 meeting. As placeholders, the Council specified a range of coastwide ABC and OY alternatives for analysis as follows: an OY range of 134,534 mt to 403,604 mt (Table 2-1). This compares to the status quo U.S. OY of 269,069 mt for 2006. The range of 2007 and 2008 ABC alternatives specified for analysis are 244,425 mt to 733,275 mt. The status quo 2006 ABC is 488,850 mt.

Petrale Sole

Three 2007-2008 OY alternatives for petrale sole (coastwide) have been analyzed for Council decision: 1,921 mt, 2,499 mt, and 2,883 mt (Table 2-1). This compares to the status quo OY of 2,762 mt in 2005 and 2006. The OYs are also subdivided by INPFC regions (Columbia and US-Vancouver areas and Eureka, Monterey, and Conception areas) and by latitude (north and south of 40°10' N latitude).

The OY alternatives for the Columbia and US-Vancouver areas were identified by applying the following rationale: OY Alternative 1 is based on the low spawning biomass model from the 2005 stock assessment {Lai et al. 2005}; OY Alternatives 2 and 3 are the same, and are the result of a reduction from the ABC using the 40-10 rule. The ABC alternatives identified for analysis are 2,917 mt for 2007 and 2,919 mt for 2008. Using results from the 2005 stock assessment, each ABC was calculated by summing the north ABC and the south ABC/OY.

Sablefish

The Council identified the following alternatives to be analyzed for the coastwide sablefish stock (Table 2-1): 4,574 mt and 5,934 mt. This compares to the status quo OY of 7,761 mt in 2005 and 7,634 mt in 2006. 2007 and 2008 ABCs identified for analysis are 6,210 mt and 6,058 mt, respectively. OY Alternative 1 is calculated by applying the 40-10 adjustment to the ABC derived from the low stock/production model in the 2005 sablefish assessment {Schirripa and Colbert 2005}; OY Alternative 2 is calculated by applying the 40-10 adjustment using the assessment's base case model.

Each coastwide OY alternative is also divided north and south of 36^{o} N latitude using status quo proportions. Alternative methods for apportioning the OY were not considered because the STAR Panel {Barnes et al. 2005} recommended calculating coastwide biomass without including Conception area survey data.

2.1.3 Healthy Groundfish Species

Arrowtooth Flounder

As arrowtooth flounder is a healthy stock, the Council has identified a single ABC/OY alternative, 5,800 mt, to be analyzed (Table 2-1). This is the same as the status quo ABC/OY for 2005 and 2006; the stock has not been assessed since the previous harvest specifications process, and therefore there is no basis for identifying a value other than that of the status quo.

Black Rockfish (in Waters off Oregon and California)

The Council has specified one OY alternative for analysis for the black rockfish stock in waters off Oregon and California, 722 mt (Table 2-1), based on a projection from the base model in the 2003 assessment {Ralston 2003}. These projected ABCs (725 mt in 2007 and 719 mt in 2008) were averaged and specified for each year (722 mt). Since this is a healthy stock with a spawning biomass above $B_{40\%}$, the OYs were set equal to the ABC. This compares to the status quo OYs of 753 mt in 2005 and 736 mt in 2006, both of which had been set equal to the ABC for that year. Management of the southern black rockfish stock is divided at the California/Oregon border.

Black Rockfish (in Waters off Washington)

The northern black rockfish stock in waters off Washington is healthy. Therefore, the Council has identified a single ABC/OY alternative, 540 mt, to be analyzed (Table 2-1). This is the same as the status quo ABC/OY for 2005 and 2006 since the stock has not been assessed since the previous harvest specifications process; therefore, there is no basis for selecting a value other than the status quo. This value is based on 88% of the northern ABC for the assessed stock north of Cape Falcon, Oregon.

California Scorpionfish

California scorpionfish was first assessed in 2005 {Maunder et al. 2006}, and therefore 2007 will be the first year in which it is not managed as part of the Minor Nearshore Rockfish South complex and the first time that the Council adopts an ABC and an OY for the stock. The Council has specified two

ABC/OY alternatives for analysis: 137 mt and 219 mt (Table 2-1). The first alternative, 137 mt, was derived using the recreational portion from the ABC/OY (based on the 2007-2008 average), multiplying it by 53%, dividing it by 88%, and then adding this modified value to the commercial portion of the ABC/OY (based on the 2007-2008 average). The second alternative provides an ABC/OY of 219 mt based on an average of the 2007 and 2008 ABC/OYs from the stock assessment {Maunder et al. 2005}.

The GMT recommends OY Alternative 1 (137 mt) a modified ABC/OY. This approach utilizes the full recreational data in determining the OY and allows California to track catches inseason with the CRFS program. By incorporating the ability to make inseason adjustments, the risk of either not achieving or overshooting the OY is reduced. The GMT refers the Council to "CDFG Draft Report on Background Information for Selection of 2007/2008 OYs for Gopher Rockfish, California Scorpionfish and Minor Nearshore Rockfish" for further explanation of the calculation of this OY Alternative.

Chilipepper Rockfish

The Council has specified status quo alternatives for chilipepper rockfish for 2007 and 2008 ABCs and OYs, as there is no new stock assessment from which to base new harvest specifications. These alternatives are an ABC of 2,700 mt and an OY of 2,000 mt for 2007-2008 (Table 2-1). The lower OY alternative is a precautionary specification to control the bycatch of bocaccio. The higher OY alternative equals the status quo ABC, since the stock is considered healthy. The rationale for considering this alternative is depth-based management may be an adequate bocaccio bycatch control mechanism.

Chilipepper rockfish within the Eureka INPFC region are managed within the Minor Rockfish North category, and therefore are not included within the ABC and OY alternative values.

Dover Sole

The OY alternatives specified for analysis for Dover sole stock are 16,500 mt and 28,482 mt (Table 2-1). This compares to the status quo OYs of 7,476 mt in 2005 and 7,564 mt in 2007. The first OY alternative is equal to the equilibrium MSY from the 2005 stock assessment {Sampson 2005}; the second alternative is set to the ABC alternative. The Council identified an ABC alternative of 28,522 mt for 2007 and 28,442 mt for 2008. These ABCs were calculated using the $F_{40\%}$ proxy harvest rate and represent the combined total of the south and the north portions of the stock.

English Sole

The OY alternative specified for analysis for English sole stock is 6,237 mt (Table 2-1). This compares to the status quo OY of 3,100 mt for 2005 and 2006. The Council identified an ABC alternative of 6,773 mt for 2007 and 5,701 mt for 2008. The OY alternative was determined by averaging of the 2007 and 2008 ABC alternatives. Projections from the 2005 stock assessment of English sole {Stewart 2005} were used to identify the ABC alternatives.

Lingcod

The OY alternatives specified for analysis for lingcod are 6,280 mt and 6,088 mt (Table 2-1). This compares to the status quo OY of 2,414 mt for 2005 and 2006; these 2005-2006 specifications were adopted by the Council with the lingcod rebuilding plan prior to the stock being declared rebuilt from its overfished status in November 2005. The first alternative was calculated by setting the OY equal to the coastwide ABC, as lingcod is a healthy stock. The second alternative is the sum of LCN and LCS (northern and southern lingcod substocks) OYs; the LCS OY was derived using a 40-10 adjustment. The OYs are also subdivided by INPFC regions (Columbia and US-Vancouver areas and Eureka, Monterey, and Conception areas) and by latitude (North of 42° and South of 42 °). The Council's specified ABC alternatives for 2007 and 2008 are 6,706 mt and 5,853 mt, respectively.

Longspine Thornyhead

The OY alternatives specified for analysis for longspine thornyhead are 2,696 mt and 3,930 mt (Table 2-1). This compares to the status quo OY of 2,656 mt for 2005 and 2006. The first alternative, 2,696 mt, is based on assuming constant density throughout the Conception area and the proportion of the area north and south of Pt. Conception (21% of the Conception area) with a 25% precautionary reduction. The second alternative, 3,930 mt, is based on assuming constant density throughout the Conception area and the proportion of the area north and south of Pt. Conception (21% of the Conception area). As a healthy stock, the OY can be set equal to the ABC, which is how the second alternative was calculated. The OYs are also subdivided by latitude based on a GMT-recommended alternative where harvest guidelines north and south of 34°27' N latitude are analyzed. However the status quo alternative OYs for 2005 and 2006 were specified north and south of 36° N latitude. The Council's specified ABC alternatives for 2007 and 2008 are 3,953 mt and 3,860 mt, respectively.

Shortbelly Rockfish

Shortbelly rockfish is unexploited due to its small size, except as infrequent incidental catch. The 13,900 mt ABC/OY is a continuation of a conservative Council policy for this species based on its last assessment in 1989. Since that assessment, the peak one-year shortbelly landings have been <100 mt.

Shortspine Thornyhead

The shortspine thornyhead OY alternatives specified for analysis are 1,661 mt and 2,476 mt (Table 2-1). This compares to the status quo OY of 1,055 mt for 2005 and 1,077 mt for 2006. The coastwide OYs are the sum of OYs determined for north and south of Pt. Conception (34°27' N latitude). The Council's specified ABC alternatives for 2007 and 2008 are 2,488 mt and 2,463 mt, respectively.

For alternative 1, the OY for the area south of Pt. Conception is based on the base case assessment scenario in the 2005 stock assessment {Hamel 2005}, which indicated that 34% of the coastwide biomass is in this area, and with a 50% reduction to account for the paucity of survey data south of Pt. Conception. The 50% reduction is due to the SSC conclusion the assessment is marginally sufficient to estimate resource status given the short duration and density of survey data south of Pt. Conception. The base case model assumed h = 0.6 and q = 1.0. The OY alternative 1 for the area north of Pt. Conception based on the base case assessment result indicating 66% of the coastwide biomass is in this area with a 25% precautionary reduction. The 25% precautionary reduction is due to the SSC conclusion the assessment is marginally sufficient to estimate resource status. The base case model assumed h = 0.6 and q = 1.0.

Alternative 2 OYs (for north and south of 34°27' N latitude) are based on the same biomass estimates from the 2005 stock assessment base case model, but with no precautionary reduction. Therefore, the OY alternative for the area south of Pt. Conception (841 mt) is based on an estimate of 34% coastwide biomass is in this area and the OY alternative for the north portion (1,634 mt) is based on an estimate of the remaining 66% of the coastwide biomass.

Splitnose Rockfish

As in 2005-2006, the ABC of 615 mt is reduced to an OY of 461 mt based on the Council's policy of making a 25% precautionary OY adjustment for species with less rigorous stock assessments. These harvest specifications are for south of 40°10' N latitude since splitnose rockfish are managed as part of the northern minor slope rockfish complex north of 40°10' N latitude.

Starry Flounder

Starry flounder was assessed for the first time in 2005 and is now proposed to be managed with a separate ABC and OY. Previously the stock has been managed as a component stock of the Other Flatfish complex. Therefore, there are no status quo ABC or OY alternatives for the stock. The Council requested the following two OY alternatives for analysis: 890 mt and 1,186 mt (Table 2-1). Alternative 1 (890 mt) is based on a 25% reduction of the combined area OYs from the base model in the stock assessment {Ralston 2005} as a result of the 25% precautionary reduction for data poor stocks. Alternative OY 2 (1,186 mt) is based on the combined area OYs from the based model in the stock assessment. The ABC alternatives identified by the Council are 1,221 mt for 2007 and 1,395 mt for 2008.

Yellowtail Rockfish

Yellowtail rockfish is a healthy rockfish stock that had a new stock assessment in 2005{Lai 2006}. Year-specific ABCs were projected following the Council's policy of using an $F_{50\%}$ harvest rate as a proxy for F_{MSY} for rockfish; the 2007 ABC for this species is 4,585 mt and the 2008 ABC is 4,510 mt. These ABCs were averaged (4,548 mt) and specified for both years. The OYs were set equal to ABC because the stock is above $B_{40\%}$. The GMT notes that the fisheries have not been attaining yellowtail rockfish harvest levels in recent years because its harvest has been constrained to protect co-occurring depleted species.

2.1.4 Unassessed Groundfish Species and Those Managed as Part of a Stock Complex

2.1.4.1 Minor Rockfish South

The Council has identified four minor rockfish south OY alternatives for analysis: 1,753 mt, 1,855 mt, 1,898 mt, and 2,006 mt (Table 2-1). The OY alternatives calculated for nearshore species, shelf species, and slope species sum to equal the overall minor rockfish south value. The overall OY alternatives for 2007-2008 compare to the status quo OY of 1,968 mt.

The ABC alternative identified by the Council for analysis is 3,403 mt; this compares to a status quo ABC alternative of 3,412 mt for 2005 and 2006. The ABC alternative for 2007 and 2008 reflects three adjustments to account for the reassessment of blackgill rockfish and the new assessments for gopher rockfish and California scorpionfish. First, the status quo contribution of blackgill rockfish to the ABC (343 mt) was removed from the complex ABC and replaced with the new blackgill ABC/OY of 292 mt (based on the 2007-2008 average ABC/OY); this results in an overall reduction of 51 mt. Second, the status quo contribution of gopher rockfish (97 mt) was removed and replaced with the new gopher ABC/OY of 302 mt (based on the 2007-2008 average ABC/OY), resulting in an overall increase of 205 mt. Third, the status quo contribution of California scorpionfish (163 mt) was removed from the ABC as this species will now be managed under its own ABC/OY.

Minor Nearshore Rockfish Species

The complex, Minor Nearshore Rockfish south of 40°10' N latitude, is further subdivided into the following management categories: 1) shallow nearshore rockfish [comprised of black and yellow rockfish (*S. chrysomelas*); China rockfish (*S. nebulosus*); gopher rockfish (*S. carnatus*); grass rockfish (*S. rastrelliger*), and kelp rockfish (*S. atrovirens*)]; 2) deeper nearshore rockfish: [comprised of black rockfish (*S. melanops*), blue rockfish (*S. mystinus*); brown rockfish (*S. auriculatus*); calico rockfish (*S. dalli*); copper rockfish (*S. caurinus*); olive rockfish (*S. serranoides*); quillback rockfish (*S. maliger*); and treefish (*S. serriceps*)] and 3) California scorpionfish (*Scorpaena guttata*).

The Council adopted a southern minor nearshore rockfish species OY for 2003 of 541 mt. This OY was based upon the Groundfish FMP policy for specifying OYs for unassessed species using 50% of recent landings, and was recalculated from the 2001-2002 OY of 662 mt using updates estimates of recreational and commercial harvest. For the 2004 southern minor nearshore rockfish species OY, an adjustment was made to account for removal of black rockfish; however this adjustment started with the 2002 OY of 662 mt and not the 2003 OY of 541 mt. The resulting OY of 615 mt was adopted by the Council for 2004 for the 2005-2006 management cycles. For the 2007-2008 management cycle, the Minor Nearshore Rockfish South is corrected by subtracting the black rockfish OY of 47 mt from the 541 mt OY, resulting in a value of 494 mt.

This initial value for the southern minor nearshore rockfish species OY is then adjusted to account for the new California scorpionfish and gopher rockfish assessments. The current contribution for California scorpionfish of 81.5 mt is removed from the combined OY. Because gopher rockfish cannot be managed separately from other nearshore rockfish species without significantly increasing bycatch and because of uncertainty regarding the assessment because of its poor data quality, gopher rockfish will remain in the southern minor nearshore rockfish species OY and will have a point of concern set at a level determined appropriate to the adopted OY. The following four alternatives different methods for accounting for these changes.

The 413 mt OY alternative includes the 48.5 mt contribution of gopher rockfish (494 mt minus the California scorpionfish contribution of 81.5 mt equals 413 mt). OY alternative 2 is determined by removing the current contribution for gopher rockfish (48.5 mt) from the OY and then increasing the OY by 50% of the new gopher ABC/OY of 302 mt (based on the 2007-2008 average ABC/OY; 2007 = 340 mt, 2008 = 264 mt); this calculation leads to a value of 515 mt. The 558 mt OY alternative is determined by removing the current contribution for gopher rockfish (48.5 mt) from the OY and then increasing the OY by 75% of the new gopher ABC/OY of 302 mt (based on the 2007-2008 average ABC/OY; 2007 = 340 mt, 2008 = 264 mt). OY alternative 4 is determined by removing the current contribution for gopher rockfish (48.5 mt) from the OY and then increasing the OY by the new gopher ABC/OY of 302 mt (based on the 2007-2008 average ABC/OY; 2007 = 340 mt, 2008 = 264 mt); this calculation leads to an OY value of 666 mt. These four OY alternatives compare to the status quo OY alternative of 615 mt for 2004-2005, for which the calculation is discussed earlier.

Minor Shelf Rockfish Species

The minor shelf rockfish complex south of 40°10' N latitude is composed of the following species: bronzespotted rockfish (*S. gilli*); chameleon rockfish (*S. phillipsi*); dusky rockfish (*S. ciliatus*); dwarf-red rockfish (*S. rufianus*); flag rockfish (*S. rubrivinctus*); freckled rockfish (*S. lentiginosus*); greenblotched rockfish (*S. rosenblatti*); greenspotted rockfish (*S. chlorostictus*); greenstriped rockfish (*S. elongatus*); halfbanded rockfish (*S. semicinctus*); harlequin rockfish (*S. variegatus*); honeycomb rockfish (*S. umbrosus*); Mexican rockfish (*S. macdonaldi*); pink rockfish (*S. eos*); pinkrose rockfish (*S.

simulator); pygmy rockfish (*S. wilsoni*); redstripe rockfish (*S. proriger*); rosethorn rockfish (*S. helvomaculatus*); rosy rockfish (*S. rosaceus*); silvergray rockfish (*S. brevispinis*); speckled rockfish (*S. ovalis*); squarespot rockfish (*S. hopkinsi*); starry rockfish (*S. constellatus*); stripetail rockfish (*S. saxicola*); swordspine rockfish (*S. ensifer*); tiger rockfish (*S. nigrocinctus*); vermilion rockfish (*S. miniatus*); and yellowtail rockfish (*S. flavidus*).

The Council has identified the status quo ABC and OY as the only alternative to be analyzed for 2007-2008 management cycle. The OY is set to the ABC; therefore, the ABC alternative and OY alternative for analysis are both 714 mt.

Minor Slope Rockfish Species

The minor slope rockfish complex south of 40°10' N latitude is composed of the following species: aurora rockfish (*S. aurora*); bank rockfish (*S. rufus*); blackgill rockfish (*S. melanostomus*); Pacific ocean perch (*S. alutus*); redbanded rockfish (*S. babcocki*); rougheye rockfish (*S. aleutianus*); sharpchin rockfish (*S. zacentrus*); shortraker rockfish (*S. borealis*); and yellowmouth rockfish (*S. reedi*).

The Council identified one ABC/OY alternative for this complex: 626 mt. This value was determined by the following calculation: the status quo contribution of blackgill (305 mt) was removed from the complex and replaced with the new blackgill ABC/OY of 292 mt (based on the 2007-2008 average ABC/OY; 2007 = 294 mt, 2008 = 290 mt). This alternative compares to the status quo alternative ABC/OY of 639 mt.

2.1.4.2 Minor Rockfish North

The Council has identified three minor rockfish north OY alternatives for analysis: 2,250 mt, 2,270 mt, and 2,290 mt (Table 2-1). The OY alternatives calculated for nearshore species, shelf species, and slope species sum to equal the overall minor rockfish north values. The overall OY alternatives for 2007-2008 compare to the status quo OY of 2,250 mt. The Council identified the status quo ABC alternative, 3,680 mt, to be evaluated for the 2007-2008 management cycle.

Minor Nearshore Rockfish Species

The minor nearshore rockfish complex north of 40°10' N latitude is composed of the following species: black and yellow rockfish (*S. chrysomelas*); blue rockfish (*S. mystinus*); brown rockfish (*S. auriculatus*); calico rockfish (*S. dalli*); China rockfish (*S. nebulosus*); copper rockfish (*S. caurinus*); gopher rockfish (*S. carnatus*); grass rockfish (*S. rastrelliger*); kelp rockfish (*S. atrovirens*); olive rockfish (*S. serranoides*); quillback rockfish (*S. maliger*); and treefish (*S. serriceps*).

When black rockfish was originally removed from the northern minor nearshore rockfish OY, a ratio of black to blue rockfish catch was used to determine what proportion of that OY was attributable to black rockfish. However, due to the variability of blue rockfish catches, there is some concern that this ratio (92%:8% black to blue rockfish) under-represents blue rockfish catch and therefore the resulting OY (since black rockfish is managed separately). To account for this uncertainty (that is, a range of possible levels of black rockfish removal from the OY), three alternatives have been identified by the Council. OY alternative 1 is equal to the status quo OY alternative of 122 mt. OY alternative 2 (142 mt) is equal to the status quo OY alternative plus 20 mt. OY alternative 3 (162 mt) is equal to the status quo OY alternative plus 40 mt.

Minor Shelf Rockfish Species

The minor shelf rockfish complex north of 40°10' N latitude is composed of the following species: bronzespotted rockfish (*S. gilli*); bocaccio (*Sebastes paucispinis*); chameleon rockfish (*S. phillipsi*); chilipepper rockfish (*S. goodei*); cowcod (*S. levis*); dusky rockfish (*S. ciliatus*); dwarf-red rockfish (*S. rufianus*); flag rockfish (*S. rubrivinctus*); freckled rockfish (*S. lentiginosus*); greenblotched rockfish (*S. rosenblatti*); greenspotted rockfish (*S. chlorostictus*); greenstriped rockfish (*S. elongatus*); halfbanded rockfish (*S. semicinctus*); harlequin rockfish (*S. variegatus*); honeycomb rockfish (*S. umbrosus*); Mexican rockfish (*S. macdonaldi*); pink rockfish (*S. eos*); pinkrose rockfish (*S. simulator*); pygmy rockfish (*S. wilsoni*); redstripe rockfish (*S. proriger*); rosethorn rockfish (*S. helvomaculatus*); rosy rockfish (*S. rosaceus*); silvergray rockfish (*S. brevispinis*); speckled rockfish (*S. ovalis*); squarespot rockfish (*S. hopkinsi*); starry rockfish (*S. constellatus*); stripetail rockfish (*S. saxicola*); swordspine rockfish (*S. ensifer*); tiger rockfish (*S. nigrocinctus*); and vermilion rockfish (*S. miniatus*).

No change from status quo was identified by the Council for analysis; therefore the status quo ABC/OY alternative for northern minor shelf rockfish species, 968 mt, is analyzed for the 2007-2008 management cycle (Table 2-1).

Minor Slope Rockfish Species

The minor slope rockfish complex north of 40°10' N latitude is composed of the following species: aurora rockfish (*S. aurora*); bank rockfish (*S. rufus*); blackgill rockfish (*S. melanostomus*); redbanded rockfish (*S. babcocki*); rougheye rockfish (*S. aleutianus*); sharpchin rockfish (*S. zacentrus*); shortraker rockfish (*S. borealis*); splitnose rockfish (*S. diploproa*); and yellowmouth rockfish (*S. reedi*).

No change from status quo is identified by the Council for analysis; therefore the status quo ABC/OY alternative for northern minor slope rockfish species, 1,160 mt, is analyzed for the 2007-2008 management cycle (Table 2-1).

2.1.4.3 Other Unassessed Species

Pacific Cod

No change from status quo is identified by the Council for analysis. As in 2005-2006, the Pacific cod ABC of 3,200 mt is based on historic landings levels, with the 1,600 mt OY representing the Council’s precautionary 50% adjustment for unassessed species (Table 2-1).

Other Fish

The Other Fish stock complex contains all the unassessed Groundfish FMP species that are neither rockfish (family *Scorpaenidae*) nor flatfish. These species include big skate (*Raja binoculata*), California skate (*Raja inornata*), leopard shark (*Triakis semifasciata*), longnose skate (*Raja rhina*), soupfin shark (*Galeorhinus zyopterus*), spiny dogfish (*Squalus acanthias*), finescale codling (*Antimora microlepis*), Pacific rattail (*Coryphaenoides acrolepis*), ratfish (*Hydrolagus colliei*), cabezon (*Scorpaenichthys marmoratus*) (north of the California-Oregon border at 42° N latitude), and kelp greenling (*Hexagrammos decagrammus*).

No change from status quo is identified by the Council for analysis. The OY alternative is 7,300 mt and the ABC alternative is 14,600 mt (Table 2-1).

Other Flatfish

The Other Flatfish complex contains all the unassessed flatfish species in the Groundfish FMP. These species include butter sole (*Isopsetta isolepis*), curlfin sole (*Pleuronichthys decurrens*), flathead sole (*Hippoglossoides elassodon*), Pacific sanddab (*Citharichthys sordidus*), rex sole (*Glyptocephalus zachirus*), rock sole (*Lepidopsetta bilineata*), and sand sole (*Psettichthys melanostictus*).

The Council has identified an OY alternative of 4,884 mt to be analyzed. This OY is based on the ABC with a 25% precautionary reduction for sanddabs and rex sole and a 50% precautionary reduction for the remaining species. The starry flounder contribution is removed (25 mt). The status quo OY alternative is 4,909 mt for 2005 and 2006.

The Council has identified an ABC alternative of 6,731 mt to be analyzed for 2007 and 2008. This ABC alternative is based on the following historical catch levels: the highest landings of Pacific sanddabs (in 1995) and rex sole (in 1982) for the 1981-2003 period and on average landings during 1994-1998 for the remaining Other Flatfish species. The starry flounder contribution is removed (50 mt). The status quo ABC alternative is 6,781 mt for 2005 and 2006.

2.1.5 Alternative Harvest Levels Considered, But Eliminated From Detailed Study

The new darkblotched rebuilding analysis indicates some otherwise viable OY alternatives exceed the ABC, which is based on a proxy F_{MSY} harvest rate. However, a stock's OY cannot legally exceed the ABC, which for darkblotched is 456 mt and 486 mt in 2007 and 2008, respectively. Therefore, OY Alt. 5 (472 mt) can only be considered in 2008 as a year-specific OY. Since the Council intends to average the darkblotched OY from rebuilding analysis projections and specify the same average OY for 2007 and 2008, OY Alternative 5 is eliminated from detailed study.

Yelloweye OY Alternatives specified by the Council in November 2005 for analysis were based on the 2005 rebuilding analysis by Tsou and Wallace (2005)[1]. However, a new yelloweye assessment and rebuilding analysis were adopted as the best available science by the Council in 2006. The new rebuilding analysis {Tsou and Wallace 2006} indicates a 2007-2008 OY ≥ 15 mt for yelloweye would result in a less than a 50% probability of rebuilding by T_{MAX}, which is not legally viable. Therefore, OY Alternatives 3-6 under a constant harvest rate rebuilding strategy are eliminated from further study in this EIS.

2.2 Alternative Management Measures

2.2.1 Catch Sharing Options

2.2.1.1 Research Catches

Under the Magnuson-Stevens Act and the Pacific Coast Groundfish FMP, the term fishing refers to the catching, taking, or harvesting of fish; the attempted catching, taking, or harvesting of fish; any other activity which can reasonably be expected to result in the catching, taking, or harvesting of fish; or any

1 Since the 2005 yelloweye assessment (Wallace et al. 2005) and rebuilding analysis (Tsou and Wallace 2005) were superseded by the 2006 assessment (Wallace et al. 2006) and rebuilding analysis (Tsou and Wallace 2006), they were not published in a Stock Assessment and Fishery Evaluation document. However, these documents are posted on the Council's web site at pcouncil.org for those who are interested.

operations at sea in support of, or in preparation for the catching, taking, or harvesting of fish. Activity by a vessel conducting authorized scientific research is not considered fishing under the Magnuson-Stevens Act or the Pacific Coast Groundfish FMP. However, nothing within the Magnuson-Stevens Act or the Pacific Coast Groundfish FMP is intended to inhibit or prevent any scientific research activity conducted by a scientific research vessel.

The federal regulations, § 600.310 (f)(4)(iii) require that fishing mortality be counted against the OY, including that resulting from bycatch, scientific research, and other fishing activities. In past years, prior to the establishing harvest guidelines for fishing activities, the Council has set aside a portion of the OY for each stock of stock complex projected to be taken by vessels conducting scientific research. The projected amounts were based on the most recent years' research catch summaries and were modified to account for changes in research activities between years. Because the research catch amounts are projections, the catch levels have on occasion been modified during the year when the catch of a constraining overfished species was higher than originally projected.

Table 2-4 summarizes the scientific research catch for 2005. Research catch projections for the overfished species are presented in the estimated mortality impact tables (i.e., bycatch scorecards) that have been prepared for each alternative. For 2007 and 2008, the depleted species' research catch projections are held constant under the different alternatives with the exception of yelloweye rockfish. Yelloweye rockfish values are increased over previous years in response to an increase in survey stations in the IPHC's annual Pacific Halibut longline survey. The additional survey stations are in yelloweye rockfish habitat and are expected to provide much needed fishery independent biological data on yelloweye. However, under the Preferred Low OY alternatives for depleted species, the new IPHC survey stations are not included. The values for bocaccio, widow and canary rockfish are based on the summary of research catch in 2005. These values were rounded up given the understanding that the biomass levels for these stocks are increasing and therefore, they will be more likely to be taken in research catches. Cowcod projections are also based on the summary of 2005 research catch. Although the total research catch in 2005 for darkblotched rockfish and POP was lower than originally projected, the research catch amounts for 2007 and 2008 are the same as those set aside at the beginning of 2005. The catch of these species varies considerably between years (darkblotched rockfish: 5.14 mt in 2003, 0.08 in 2004, and 2.08 mt in 2005; POP: 5.0 mt in 2003, 0.35 mt in 2004, 1.84 mt in 2005). In addition, the biomass levels for these stocks are increasing and they are more likely to be taken in research catches.

2.2.1.2 Exempted Fishing Permit Catches

This section will be completed after 2007 EFP applications are received by the Council in June 2006, at which time the Council may decide to specify EFP bycatch caps or a set-aside yield of groundfish species to allow 2007 EFPs to proceed.

2.2.2 New Management Lines

New management lines being considered for 2007-2008 include a 10 fm line in Washington to manage recreational fisheries, a 20 fm line in Washington and Oregon for managing recreational and nearshore commercial fisheries[2], a 25 fm line in Washington Marine Areas 1 and 2 (from the Oregon/Washington border to the Queets River) for managing the Washington recreational fishery, a 180 fm line modified for petrale sole fishing areas in California (south of 42º N latitude to US/Mexico border) to provide for winter petrale fishing, a 250 fm line south of 38º N latitude for use in managing commercial slope fisheries, and an accompanying 250 fm line modified for petrale sole fishing areas south of 38º N latitude.

The Oregon Department of Fish and Wildlife is proposing a 25 fm RCA line for Council adoption. This line would replace the current 27 fm RCA line in regulation. Due to the geography of the coast, and the methods by which these lines were drawn, there is little difference in area between the 25 fm RCA line and the 27 fm RCA line. This would, however, provide consistency in groundfish regulations between Washington and Oregon, as there would be a continuous 25 fm RCA line beginning at the Queets River and continuing to the Oregon/California border, thus simplifying regulations and providing RCA line consistency to the fishing community.

Additionally, the GMT intends to review the existing petrale sole fishing areas used to manage limited entry trawl fisheries during periods 1 and 6 and may recommend modifications to the boundaries defining these Groundfish Fishing Areas. Any coordinates defining new management lines are anticipated to be provided at the June 2006 Council meeting in Foster City, California.

2 The new 20 fm line in Washington and Oregon is expected to be formally defined with waypoints for 2007-2008 to better enforce any 20 fm depth restriction that might be implemented. California has been managing their recreational and nearshore commercial fisheries with a 20 fm depth restriction regionally, but this regulation is specified referencing depth contours rather than a defined line using latitude/longitude coordinates or waypoints. This was adopted because the majority of the 20 fm depth contour is within state waters, with the exception of an area off of San Francisco over sandy habitat where depleted rockfish (e.g., bocaccio) are not expected to be encountered. This nearshore depth contour winds along a rugged coastline and is considered by CDFG enforcement to be more successfully enforced as a depth contour. Therefore, CDFG intends to continue managing the 20 fm depth restriction by contours.

2.2.3 Description of the Management Measure Alternatives

2.2.3.1 The No Action Alternative

The No Action Alternative is described by the 2005 and 2006 management measures specified in federal and state regulations. All of the action alternatives described in this chapter will be compared to the No Action Alternative. Some of these management measures were changed beginning in 2006 in reaction to problems that arose in managing the 2005 fishery. While 2005 management measures, including inseason adjustments, will be described in detail, the 2006 management measures and projected impacts will be the central focus when comparing all action alternatives to the No Action Alternative. Projected impacts of depleted groundfish species under the No Action Alternative are depicted in Table 2-5.

Table 2-5. Projected mortality (mt) of depleted groundfish species by fishing sector in 2006.

Difference	174.3	2.7	0.8	18.2	373.3	31.7	6.7
Percent of OY	43.6%	94.2%	81.0%	90.9%	16.5%	89.0%	75.1%
Key		= either not applicable; trace amount (<0.01 mt); or not reported in available data sources.					

a/ South of 40°10' N. lat.

b/ Mortality estimates are not hard numbers; based on the GMT's best professional judgment.

c/ Bycatch amounts by species unavailable, but bocaccio occurred in 0.1% of all port samples and other rockfish in another 0.1% of all port samples (and squid fisheries usually land their whole catch). In 2001, out of 84,000 mt total landings 1 mt was groundfish. This suggests that total bocaccio was caught in trace amounts.

d/ Values for canary and yelloweye rockfish represent specified harvest guidelines.

e/ Values are proposed EFP bycatch caps, not estimates of total mortality. The EFP is terminated inseason if the cap is projected to be attained early.

2.2.3.1.1 Limited Entry Trawl Fisheries

Non-Whiting Trawl Fishery

The 2006 trawl trip limits and seasonal RCA configurations (as of May 2006) describe the No Action Alternative and are shown in Tables 2-6a (north of 40°10' N latitude) and 2-6b (south of 40°10' N latitude).

A new management measure implemented in 2005 was mandating the use of selective flatfish trawls shoreward of the trawl RCA north of 40°10' N latitude. The selective flatfish trawl, configured with a cut-back headrope, a low rise, and a small (≤ 8 in. diameter) footrope, is designed to reduce rockfish bycatch while efficiently catching flatfish. The selective flatfish trawl works by allowing rockfish to escape by swimming upward when they encounter the trawl. Flatfish tend to dive down when disturbed, which accounts for the differential selectivity of these trawls to rockfish and flatfish.

In 2005 the non-whiting bottom trawl fishery was constrained with lower slope rockfish trip limits and a larger RCA with a seaward boundary of 200 fm north of 40°10' N latitude in response to a problem with early attainment of the darkblotched rockfish OY in 2004. The period 6 opportunity to harvest petrale sole was also lost in 2004 when the fishery was closed out to 250 fm to minimize further darkblotched rockfish impacts. One consequence of these 2004 management actions was a pent-up demand for petrale sole when the fishery re-opened in 2005. Coupled with this market demand, there was fair winter weather in the north and an abnormal distribution of petrale sole in 2005, which led to an early attainment and exceedance of the petrale sole OY. In response, there was a trip limit imposed on petrale sole in period 1 of 2006, which, in previous years, had been unlimited in periods 1 and 6. The more conservative slope rockfish trip limits and trawl RCA configuration were also re-specified for 2006 to avoid the darkblotched rockfish impacts observed in 2004. And, in a good faith effort to respond to the Ninth Circuit Court of Appeals ruling in a challenge to the darkblotched rockfish rebuilding plan (see section 1.3.1), the Council and NMFS adopted a lower 200 mt darkblotched rockfish OY for 2006 in an emergency rulemaking. This compares to the previously specified darkblotched rockfish OY of 294 mt.

Another change in limited entry trawl management measures from 2005 was the specification of cumulative trip limits for Pacific cod and spiny dogfish beginning in March 2006 (period 2). The Pacific cod ABC of 3,200 mt was based on historical landings since the stock has not been formally assessed. The Pacific cod OY was reduced by half from the ABC beginning in 2005 on the GMT's recommendation and in accordance with the precautionary policy for unassessed stocks {Restrepo et al. 1998 /ft "see FMP §4.6.2"}. In 2004, prior to the precautionary OY reduction, the total mortality of Pacific cod was greater than the current OY of 1,600 mt. Therefore, the Council and NMFS adopted a Pacific cod trip limit beginning in 2006 (Tables 2-6a and 2-6b); previously allowable landings were unlimited. A spiny dogfish trip limit was also specified beginning in 2006 to address conservation concerns and the depleted species' bycatch implications associated with targeting this stock in the open access fishery (see section 2.2.3.1.3 below for more details). Tables 2-6a and 2-6b depict the 2006 spiny dogfish trip limits.

Although not much bottom trawling is done south of Pt. Conception at 34°27' N latitude in the Southern California Bight, bottom trawling and other bottom fishing activities are prohibited in two discrete areas called the Cowcod Conservation Areas (Figure 2-3).

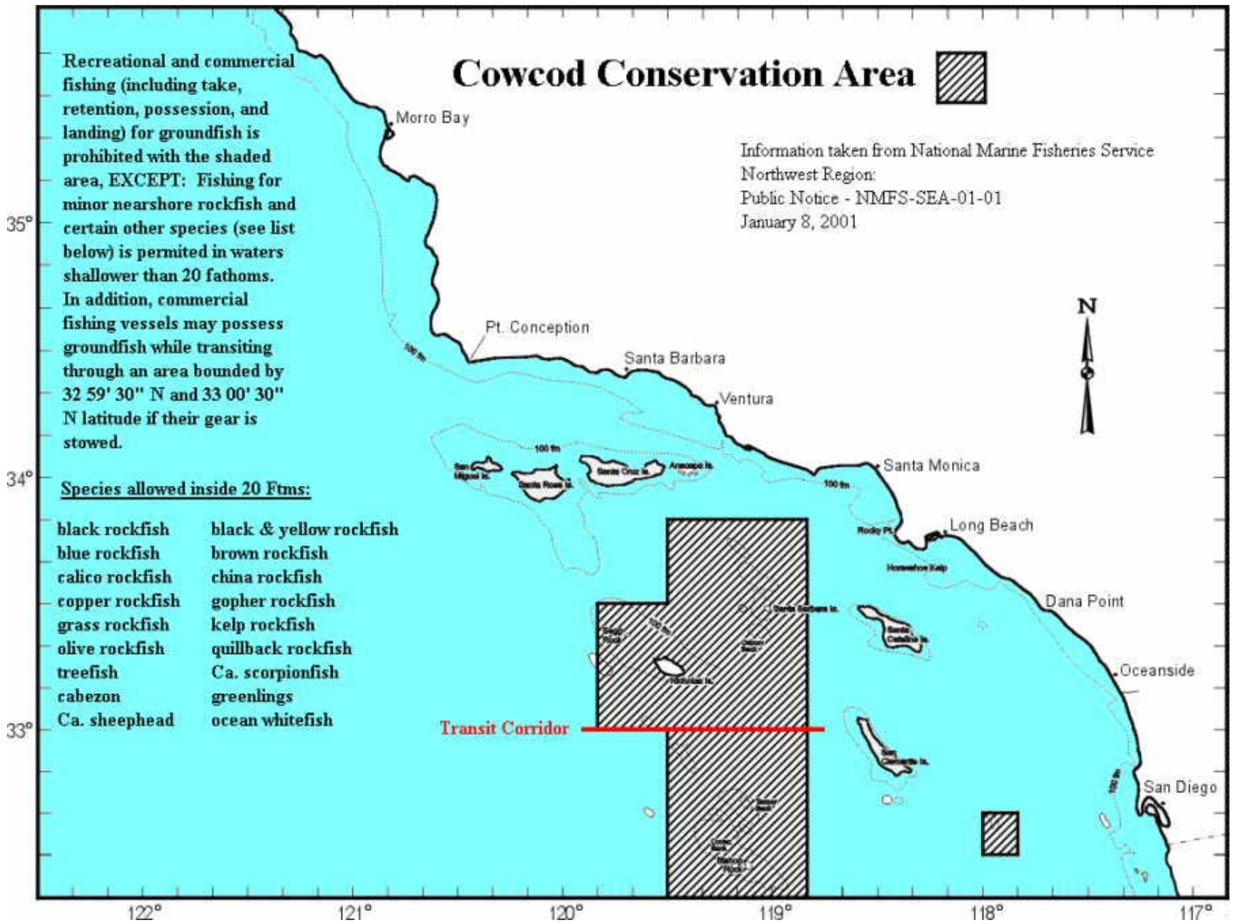

Figure 2-3. The current Cowcod Conservation Areas located in the Southern California Bight.

Whiting Trawl Fishery

The Pacific whiting OY of 269,069 mt, used to manage the 2005 and 2006 West Coast whiting fisheries, forms the basis for the No Action Alternative. The specific 2006 whiting harvest specifications are a coastwide (U.S. + Canada) ABC of 661,680 mt, a coastwide (U.S. + Canada) OY of 364,842 mt, and a U.S. OY of 269,069 mt. The U.S. OY of 269,069 mt is divided by first setting aside the tribal allocation

Table 2-6a. 2006 Trip limits for limited entry trawl gears north of 40°10' N latitude.

Other Limits and Requirements Apply -- Read § 660.301 - § 660.390 before using this table

		JAN	FEB	MAR-APR	MAY-JUN	JUL-AUG	SEP-OCT	NOV-DEC
	Rockfish Conservation Area (RCA)[6/]: North of 40°10' N. lat.	75 fm - modified 200 fm [7/]		75 - 200 fm		100 - 200 fm	75 fm - 200 fm	75 fm - modified 200 fm [7/]
	Selective flatfish trawl gear is required shoreward of the RCA; all trawl gear (large footrope, selective flatfish trawl, and small footrope trawl gear) is permitted seaward of the RCA. Midwater trawl gear is permitted only for vessels participating in the primary whiting season.							
	See § 660.370 and § 660.381 for Additional Gear, Trip Limit, and Conservation Area Requirements and Restrictions. See §§ 660.390-660.394 for Conservation Area Descriptions and Coordinates (including RCAs, YRCA, CCAs, Farallon Islands, and Cordell Banks).							
	State trip limits may be more restrictive than federal trip limits, particularly in waters off Oregon and California.

44	midwater trawl	Before the primary whiting season: CLOSED -- During primary whiting season: In trips of at least 10,000 lb of whiting: combined widow and yellowtail limit of 500 lb/ trip, cumulative yellowtail limit of 2,000 lb/ month. Mid-water trawl permitted in the RCA. See §660.373 for primary whiting season and trip limit details. -- After the primary whiting season: CLOSED						
45	large & small footrope gear	150 lb/ month		300 lb/ 2 months				
46	selective flatfish trawl gear	1,000 lb/ month		2,000 lb/ 2 months				
47	multiple bottom trawl gear [8/]	150 lb/ month		300 lb/ 2 months				
48	**Minor nearshore rockfish & Black rockfish**							
49	large & small footrope gear	CLOSED						
50	selective flatfish trawl gear	300 lb/ month						
51	multiple bottom trawl gear [8/]	CLOSED						
52	**Lingcod[4/]**							
53	large & small footrope gear	600 lb/ month		1,200 lb/ 2 months				
54	selective flatfish trawl gear	600 lb/ month		1,200 lb/ 2 months				
55	multiple bottom trawl gear [8/]	600 lb/ month		1,200 lb/ 2 months				
56	**Pacific cod**	Not limited		30,000 lb/ 2 months	70,000 lb/ 2 months			30,000 lb/ 2 months
57	**Spiny dogfish**	Not limited		200,000 lb/ 2 months	150,000 lb/ 2 months	100,000 lb/ 2 months		
58	**Other Fish [5/]**	Not limited						

1/ Bocaccio, chilipepper and cowcod are included in the trip limits for minor shelf rockfish.
2/ Splitnose rockfish is included in the trip limits for minor slope rockfish.
3/ "Other flatfish" are defined at § 660.302 and include butter sole, curlfin sole, flathead sole, Pacific sanddab, rex sole, rock sole, sand sole, and starry flounder.
4/ The minimum size limit for lingcod is 24 inches (61 cm) total length.
5/ "Other fish" are defined at § 660.302 and include sharks, skates, ratfish, morids, grenadiers, and kelp greenling. Cabezon is included in the trip limits for "other fish."
6/ The Rockfish Conservation Area is a gear and/or sector specific closed area generally described by depth contours but specifically defined by lat/long coordinates set out at § 660.390.
7/ The "modified 200 fm" line is modified to exclude certain petrale sole areas from the RCA.
8/ If a vessel has both selective flatfish gear and large or small footrope gear on board during a cumulative limit period (either simultaneously or successively), the most restrictive cumulative limit for any gear on board during the cumulative limit period applies for the entire cumulative limit period.

To convert pounds to kilograms, divide by 2.20462, the number of pounds in one kilogram.

Table 2-6b. 2006 Trip limits for limited entry trawl gears south of 40°10' N latitude.

Other Limits and Requirements Apply -- Read § 660.301 - § 660.390 before using this table

44	**Other Fish[5/] & Cabezon**	Not limited						

1/ Yellowtail is included in the trip limits for minor shelf rockfish.
2/ POP is included in the trip limits for minor slope rockfish
3/ "Other flatfish" are defined at § 660.302 and include butter sole, curlfin sole, flathead sole, Pacific sanddab, rex sole, rock sole, sand sole, and starry flounder.
4/ The minimum size limit for lingcod is 24 inches (61 cm) total length.
5/ Other fish are defined at § 660.302 and include sharks, skates, ratfish, morids, grenadiers, and kelp greenling.
6/ The Rockfish Conservation Area is a gear and/or sector specific closed area generally described by depth contours but specifically defined by lat/long coordinates set out at § 660.390.
7/ The "modified 200 fm" line is modified to exclude certain petrale sole areas from the RCA.

of 35,000 mt, and then setting aside 1,800 mt for incidental bycatch in non-whiting fisheries and 200 mt for research catch. The resulting yield is then allocated between factory trawlers or catcher-processors (34%), vessels delivering to at-sea processors or motherships (24%), and vessels delivering to shore-based processing plants (42%). Table 2-7 indicates the set asides and allocations for 2006 fisheries.

Table 2-7. Pacific whiting set-asides and allocations by fishing sector specified in 2006.

Sector	Set-aside or allocation (mt)
Tribal whiting	35,000
Non-whiting fisheries	1,800
Research	200
Catcher-processors	78,903
Motherships	55,697
Shore-based whiting	97,469
Total	269,069

The GMT recommended exploring overfished species' bycatch implications in the Pacific whiting fishery using a 4-year weighted average bycatch model (the years 2001-2004 were used to project 2005 impacts and the years 2002-2005 were used to project 2006 impacts- see chapter 4 for more details). The rates used to project 2006 whiting fishery impacts were applied to the 2006 OY under this alternative (these same rates are used to explore bycatch implications in 2007 and 2008 Pacific whiting fisheries- see below). The Council again specified bycatch caps for stocks that could potentially constrain opportunities in the Pacific whiting and other West Coast fishing sectors in 2006. The two overfished West Coast groundfish stocks that are incidentally caught in the whiting-directed trawl fishery and for which bycatch caps have been specified in 2006 regulations are canary and widow rockfish. The Council and NMFS decided to set aside 4.7 mt of canary rockfish and 200 mt of widow rockfish for the 2006 non-tribal whiting-directed fisheries. The non-tribal sectors of the whiting fishery would close prior to reaching their whiting allocations if these caps were reached inseason. However, the Council reserved the ability to change these caps inseason if there was unused yield available and it was needed to keep whiting fisheries open.

2.2.3.1.2 Limited Entry Fixed Gear Fisheries

Limited entry fixed gear trip limits and the nontrawl RCA configuration as of May 2006 describe the No Action Alternative and are shown in Tables 2-8a (north of 40°10' N latitude) and 2-8b (south of 40°10' N latitude). Under the No Action Alternative, the nontrawl RCA is defined by management lines specified with waypoints at roughly 30 fm to 100 fm in waters off northern California (north of 40°10' N latitude) and Oregon; and zero fm to 100 fm in waters off Washington. The nontrawl RCA south of 40°10' N latitude and north of Point Conception at 34°27' N latitude under the No Action Alternative is defined by management lines specified with waypoints at roughly 30 fm to 150 fm during periods 1, 2, 5, and 6 and 20 fm to 150 fm during periods 3 and 4. There is an additional closure between zero fm and 10 fm around the Farallon Islands to reduce impacts on shallow nearshore rockfish in that area. The nontrawl RCA south of Point Conception is defined by management lines specified with waypoints at roughly 60 fm to 150 fm. This more liberal RCA can be accommodated by the minimal occurrence of canary rockfish in the Southern California Bight. Canary and yelloweye rockfish are not allowed to be landed in the limited entry fixed gear fishery under the No Action Alternative.

The primary sablefish fishery, open to limited entry fixed gear permit holders that have a sablefish endorsement, runs from April 1 through October 31. Permit stacking is allowed in this fishery, where

30 **Lingcod[3/]**	CLOSED		800 lb/ 2 months			CLOSED
31 **Pacific cod**	Not limited	1,000 lb/ 2 months				
32 **Spiny dogfish**	Not limited	200,000 lb/ 2 months	150,000 lb/ 2 months	100,000 lb/ 2 months		
33 **Other fish[4/] & Cabezon**	Not limited					

1/ "Other flatfish" are defined at § 660.302 and include butter sole, curlfin sole, flathead sole, Pacific sanddab, rex sole, rock sole, sand sole, and starry flounder.
2/ POP is included in the trip limits for minor slope rockfish. Yellowtail is included in the trip limits for minor shelf rockfish.
3/ The minimum size limit for lingcod is 24 inches (61 cm) total length.
4/ "Other fish" are defined at § 660.302 and include sharks, skates, ratfish, morids, grenadiers, and kelp greenling.
5/ The Rockfish Conservation Area is a gear and/or sector specific closed area generally described by depth contours but specifically defined by lat/long coordinates set out at § 660.390.
To convert pounds to kilograms, divide by 2.20462, the number of pounds in one kilogram.

more than one and up to three permits may be used on a single vessel during the primary sablefish season. Limited entry permits with sablefish endorsements are assigned to one of three different cumulative trip limit tiers, based on the qualifying catch history of the permit. The 2006 sablefish limits are as follows: tier 1 = 62,700 lb, tier 2 = 28,500 lb, and tier 3 = 16,300 lb.

The Council and NMFS adopted a similar change in cumulative trip limits for Pacific cod and spiny dogfish for limited entry fixed gear fisheries as they did for limited entry trawl fisheries beginning in March 2006 (period 2). While the spiny dogfish limits for limited entry fixed gear fisheries were the same for spiny dogfish as in the limited entry trawl fishery, the Pacific cod limits were much lower since Pacific cod are less frequently caught by fixed gears. Tables 2.7a and 2.7b depict the 2006 Pacific cod and spiny dogfish trip limits for limited entry fixed gear fisheries.

Limited entry fixed gears are not allowed to be fished in the Cowcod Conservation Areas (Figure 2-3) under the No Action Alternative, except for some nearshore commercial fishing opportunities described in section 2.2.3.1.4.

2.2.3.1.3 Open Access Fisheries

Open access fisheries are those West Coast commercial fisheries comprised of vessels without a federal limited entry trawl or limited entry fixed gear permit that catch groundfish either as target species (directed groundfish fisheries) or incidentally while targeting non-groundfish species (incidental groundfish fisheries).

Open access gears that fish the bottom and any of the gears used in the directed groundfish fisheries are not allowed to be fished in the Cowcod Conservation Areas (Figure 2-3) under the No Action Alternative, except for some nearshore commercial fishing opportunities described in section 2.2.3.1.4.

Directed Groundfish Fisheries

There are directed groundfish fisheries that target nearshore species (see the following section 2.2.3.1.4) and those operating on the shelf and slope primarily targeting sablefish (daily-trip-limit fishery) and slope rockfish species. This section describes the No Action management measures associated with the latter category of open access vessels targeting groundfish offshore in federal waters.

Open access trip limits and estimated impacts of 2006 management measures as of May 2006 describe the No Action Alternative and are shown in Tables 2-9a (north of 40°10' N latitude) and 2-9b (south of 40°10' N latitude). The same nontrawl RCA described for limited entry fixed gears under the No Action

Table 2-9a. 2006 trip limits for open access gears north of 40°10' N latitude.

Table 2-9a. 2006 trip limits for open access gears north of 40°10' N latitude (continued).

21	**PINK SHRIMP NON-GROUNDFISH TRAWL** *(not subject to RCAs)*	
22	North	**Effective April 1 - October 31:** groundfish 500 lb/day, multiplied by the number of days of the trip, not to exceed 1,500 lb/trip. The following sublimits also apply and are counted toward the overall 500 lb/day and 1,500 lb/trip groundfish limits: lingcod 300 lb/month (minimum 24 inch size limit); sablefish 2,000 lb/month; canary, thornyheads and yelloweye rockfish are PROHIBITED. All other groundfish species taken are managed under the overall 500 lb/day and 1,500 lb/trip groundfish limits. Landings of these species count toward the per day and per trip groundfish limits and do not have species-specific limits. The amount of groundfish landed may not exceed the amount of pink shrimp landed.
23	**SALMON TROLL**	
24	North	Salmon trollers may retain and land up to 1 lb of yellowtail rockfish for every 2 lbs of salmon landed, with a cumulative limit of 200 lb/month, both within and outside of the RCA. This limit is within the 200 lb per month combined limit for minor shelf rockfish, widow rockfish and yellowtail rockfish, and not in addition to that limit. All groundfish species are subject to the open access limits, seasons and RCA restrictions listed in the table above.

1/ Bocaccio, chilipepper and cowcod rockfishes are included in the trip limits for minor shelf rockfish.
Splitnose rockfish is included in the trip limits for minor slope rockfish.
2/ "Other flatfish" are defined at § 660.302 and include butter sole, curlfin sole, flathead sole, Pacific sanddab, rex sole, rock sole, sand sole, and starry flounder.
3/ For black rockfish north of Cape Alava (48°09.50' N. lat.), and between Destruction Is. (47°40' N. lat.) and Leadbetter Pnt. (46°38.17' N. lat.), there is an additional limit of 100 lbs or 30 percent by weight of all fish on board, whichever is greater, per vessel, per fishing trip.
4/ The size limit for lingcod is 24 inches (61 cm) total length.
5/ "Other fish" are defined at § 660.302 and include sharks, skates, ratfish, morids, grenadiers, and kelp greenling.
Cabezon is included in the trip limits for "other fish."
6/ The Rockfish Conservation Area is a gear and/or sector specific closed area generally described by depth contours but specifically defined by lat/long coordinates set out at § 660.390.
To convert pounds to kilograms, divide by 2.20462, the number of pounds in one kilogram.

Alternative above would also apply for those open access fisheries not exempt from the RCA restrictions.

In 2005, a factory longliner from Alaska announced plans to target spiny dogfish in West Coast waters under the open access limits, which were unlimited for species such as spiny dogfish in the Other Fish complex. Fixed gear fisheries targeting spiny dogfish are known to incidentally catch canary and yelloweye rockfish. This unanticipated entrant to the open access fishery was of particular concern since the volume of dogfish that could be landed could incur a significant bycatch of canary and yelloweye rockfish, especially for vessel operators unfamiliar with the West Coast distribution of these species and the techniques employed to avoid them. Therefore, on May 2, 2005, NMFS implemented an emergency rule to specify canary and yelloweye rockfish bycatch caps for the directed open access fishery of 1.0 mt and 0.6 mt, respectively. All directed open access fisheries (those fisheries targeting groundfish species) would close if any of these caps were projected to be attained early in the fishing season. The Council and NMFS increased these caps to 3.0 mt for each of the species later in the year (implemented on July 1) based on increased availability of canary and yelloweye rockfish. While the factory longliner never did implement plans to target spiny dogfish on the West Coast, the Council and NMFS did by decide to change the spiny dogfish limits for limited entry and open access fisheries from unlimited to specified bimonthly trip limits for the open access fishery beginning in March 2006 (Tables 2-9a and 2-9b). While this action did not wholly address the particular vulnerability of lack of effort controls in the open access fishery, it did address bycatch concerns for targeting spiny dogfish in open access (and limited entry) fisheries.

The same 2006 change in Pacific cod management measures adopted for the limited entry fixed gear fishery was made for open access fisheries by adopting new bimonthly trip limits for this stock in March 2006 (Tables 2-9a and 2-9b).

The sablefish daily trip limit (DTL) fishery north of 36° N latitude has caught less than their allocation in recent years. In 2005, the DTL limits for January-September were 300 pounds per day, or one landing per week up to 900 pounds, not to exceed 3,600 pounds per two months. These DTL limits were increased for October through December to 500 pounds per day, or one landing per week up to

1,500 pounds, not to exceed 9,000 pounds per two months. The Council recommended maintaining the previously scheduled daily limit of 300 pounds per day, raising the weekly limit to 1,000 pounds, and raising the two month limit to 5,000 pounds for December 2005. The Council considered a more liberal increase in daily and weekly DTL limits, but was concerned with the inability to control effort in this fishery and therefore recommended a cautious approach to liberalizing this fishery. In April 2006, the Council addressed an increased interest in the DTL sablefish fishery and was especially concerned given the reduced salmon fishing opportunities available. The concern was the open access sablefish quota may be attained early in 2006 without an effective open access effort control mechanism. Therefore, the Council adopted a decreased DTL bimonthly limit for sablefish of 3,000 pounds and tasked the GMT to review effort shifts into this fishery and consider increased DTL limits in June.

Incidental Groundfish Fisheries

West Coast commercial fishing vessels targeting non-groundfish species, but landing groundfish under open access limits are included in the category of incidental open access fisheries. In some cases, such as the ridgeback prawn trawl fishery south of 34°27' N latitude, the northern pink shrimp fishery, and the salmon troll fishery, there are specific exemptions from non-trawl RCA restrictions while landing some groundfish species.

Under the No Action Alternative, the ridgeback prawn trawl fishery south of 34°27' N latitude is allowed to operate out to the 100 fm line regardless of the non-trawl RCA configuration south of Pt. Conception. This exemption is allowed because ridgeback prawn trawling occurs over soft mud substrates where depleted rockfish species do not occur and ridgeback prawns are found largely adjacent to the 100 fm isobath in this area. The pink shrimp trawl fishery is not restricted by an RCA, but approved bycatch reduction devices or fish excluders in shrimp trawls are mandated to minimize incidental groundfish bycatch. The salmon troll fishery is exempted from RCA restrictions, but groundfish species, including lingcod, are not allowed to be retained while fishing in the non-trawl RCA. The only exemption to this regulation under the No Action Alternative is an incidental landing allowance of up to 1 lb of yellowtail rockfish per 2 lbs of salmon landed with a cumulative monthly landing limit of 200 lbs of yellowtail rockfish, both within and outside the RCA. Otherwise, non-trawl RCA restrictions apply to incidental groundfish fisheries if groundfish are to be legally retained and landed under the open access limits.

2.2.3.1.4 Nearshore Commercial Fisheries

The majority of vessels participating in nearshore commercial fisheries do not hold federal limited entry permits, and the most common gear used is jig gear. However, some vessels use longline gear to target nearshore species and, in rare instances, pots or traps are used in the nearshore fishery. California and Oregon limit entry to the nearshore groundfish fishery by requiring a state limited entry permit to take commercial quantities of nearshore groundfish species (see sections 2.1.4.1 and 2.1.4.2 for the lists of nearshore rockfish species targeted in nearshore commercial fisheries north and south of 40°10' N latitude). Washington does not allow a nearshore commercial fishery. More conservative state harvest targets or guidelines than those specified in federal regulations exist for most nearshore species and state trip limits supersede federal limits in these cases. State trip limits are designed to stay within nearshore species harvest caps (Tables 2-10 and 2-11) while providing a year-round opportunity, if possible. Federal management measures for West Coast nearshore commercial groundfish fisheries are typically stratified north and south of 40°10' N latitude.

Table 2-10. Nearshore groundfish species' harvest limits, including harvest targets, OYs, and harvest guidelines by West Coast region, 2002-2006.

Black Rockfish[5]	114	17	131	101	25	126	99	25	124

1/ Non-bolded numbers are harvest targets; bolded numbers are either OYs or harvest guidelines

2/ Minor Nearshore Rockfish includes a reserve of 22 mt in 2004, 14 mt in 2005, and 14 mt in 2006; 2004 OY corrected from 615 mt (in 2004 Fed. Reg.) to 494 mt so does not include the 121 mt that was removed from this group in 2003 when the OY was calculated as 50% of recent landings; the confusion exists because the 121 mt was kept as a reserve in the overall Minor Rockfish OY and was accidentally added back into the NS RF OY in 2004.

3/ Starting in 2004, Deeper Nearshore does not include black rockfish.

4/ Black Rockfish north of 40º 30' to 43º 00' had an ABC of 500 mt in 2003.

5/ The black rockfish OY south of 46º16' N Lat. is subdivided with separate HGs being set for the area north (58 percent of OY) and south (42 percent of OY) of 42º N Lat. For the area south of 42º N Lat., 60 percent of the HG is to be applied to the area north of 40º10' N Lat. and 40 percent applied to the area south of 40º10' N Lat.

Nearshore Commercial Fisheries North of 40°10' N latitude

There are nearshore commercial fisheries north of 40°10' N latitude to the Oregon-Washington border at 46°10' N latitude; Washington does not allow nearshore commercial fisheries in their state waters. A depiction of the season duration for northern nearshore commercial fisheries and predicted black, canary, and yelloweye rockfish impacts under the No Action and action alternatives is provided in Table 2-12a.

Table 2-11. State and federal harvest guidelines specified for state-managed groundfish fisheries in California in 2006.

Species or Species complex	Sector	Harvest guideline in mt (or pounds)
Canary Rockfish	Rec.	9.3
Yelloweye Rockfish	Rec.	3.7
Black Rockfish	NS Comm.	139
	Rec.	170
	Total	309
Minor Nearshore Rockfish	NS Comm.	97
	Rec.	383
	Total	480
Cabezon	NS Comm.	42.1 (92,800)
	Rec.	26.9 (59,300)
	Total	69 (152,100)
Greenlings	NS Comm.	1.5 (3,400)
	Rec.	15.5 (34,200)
	Total	17.1 (37,600)
Lingcod	Rec.	422

Table 2-12a. Season structure and expected yelloweye rockfish and canary rockfish impacts under the 2007-2008 No Action and action alternatives for nearshore commercial fisheries north of 40°10' N latitude.

Alternative	Season Duration	Black Rockfish Reduction (%)	Shoreward RCA (fm)	Estimated Impact (mt) to Yelloweye Rockfish	Estimated Impact (mt) to Canary Rockfish
No Action	12 month season	0	30	2.1	1.7
1	<6 month season	60	20	0.8	0.7
2	12 month season	10	20	1.3	1.2
3a	12 month season	0	20	1.4	1.3
3b	12 month season	0	30	2.1	1.7

Under the No Action Alternative, the nontrawl RCA is defined by management lines specified with waypoints at roughly 30 fm to 100 fm in waters off northern California (north of 40°10' N latitude) and Oregon; and zero fm to 100 fm in waters off Washington. In Oregon, those limited entry permit holders may land commercial quantities of black and blue rockfish under state trip limits, with an additional 15 lbs per day of other nearshore groundfish species. Vessels that also have a nearshore endorsement, in addition to the black/blue limited entry permit may land commercial quantities of other nearshore rockfish (which includes two rockfish with a federal designation as shelf rockfish - tiger and vermilion rockfish), cabezon, and greenling under state trip limits. For vessels that do not hold a state permit or endorsement, an incidental landing limit of no more than 15 pounds per day of any combination of black rockfish, blue rockfish, and/or other nearshore fish is allowed, with a few exceptions. Salmon trollers with a valid troll permit may land 100 pounds of black rockfish, blue rockfish, or a combination thereof in the same landing in which a salmon is landed. These rockfish may only be landed dead. If the cumulative landing of black and blue rockfish combined in the salmon troll fishery reaches 3,000 pounds in any calendar year, then each salmon troll vessel is limited to 15 pounds of black rockfish, blue rockfish, or a combination thereof per troll landing for the remaining calendar year. Trawlers may land up to 1,000 pounds of black rockfish, blue rockfish, or a combination thereof per calendar year and these fish must be 25 percent or less of the total poundage of each landing and must be landed dead.

The 2006 federal trip limit for nearshore species north of 40°10' N latitude to 42° N latitude is 6,000 lb/ 2 months, no more than 1,200 lb of which may be species other than black or blue rockfish. The 2006 federal trip limit for nearshore species north of 42° N latitude is 5,000 lb/ 2 months, no more than 1,200 lb of which may be species other than black or blue rockfish. This listed limit has been superseded by the more conservative Oregon state limits for the last several years.

Nearshore Commercial Fisheries South of 40°10' N latitude

In California, those limited entry permit holders who also have either a shallow nearshore fishery or deeper nearshore fishery permit administered by CDFG may land minor nearshore rockfish from either the shallow nearshore or deeper nearshore complexes. Trip limits for shallow nearshore rockfish, deeper nearshore rockfish, and California scorpionfish vary by period (Table 2-8b).

A depiction of the season duration for southern nearshore commercial fisheries and predicted nearshore rockfish, canary, and yelloweye rockfish impacts under the No Action and action alternatives is provided in Table 2-12b for the area 40°10' N. latitude to 34°27' N. latitude.

Table 2-12b. Season structure and expected yelloweye rockfish and canary rockfish impacts under the 2007-2008 No Action and action alternatives for nearshore commercial fisheries south of 40°10' N latitude to 34°27' N. latitude .

Alternative	Season Duration	Nearshore Rockfish Reduction (%)	Shoreward RCA (fm)	Estimated Impact (mt) to Yelloweye Rockfish	Estimated Impact (mt) to Canary Rockfish
No Action	10 month season	0	30 (Jan-Apr, Sep-Dec) 20 (May-Aug)	0.0	0.33
1	8 month season	15	20	0.0	0.26
2	10 month season	5	20	0.0	0.30
3a	10 month season	5	30	0.0	0.31
3b	10 month season	0	30	0.0	0.56

Under the No Action Alternative, the nontrawl RCA south of 40°10' N latitude and north of Point Conception at 34°27' N latitude is defined by management lines specified with waypoints at roughly 30 fm to 150 fm during periods 1, 2, 5, and 6 and at 20 fm to 150 fm during periods 3 and 4. There is an additional closure between zero fm and 10 fm around the Farallon Islands to reduce impacts on shallow nearshore rockfish in that area. The nontrawl RCA south of Point Conception is defined by management lines specified with waypoints at roughly 60 fm to 150 fm. This more liberal RCA can be accommodated by the minimal occurrence of canary rockfish in the Southern California Bight. Status quo management is proposed south of Point Conception under action alternatives 2 and 3 due to the low incidence rate of overfished species; a nontrawl RCA line of 40 fm is proposed under action alternative 1 due to impacts to bocaccio rockfish. Canary and yelloweye rockfish are not allowed to be landed in the fixed gear fisheries, including those targeting nearshore groundfish species, under the No Action Alternative.

Trip limits for shallow nearshore rockfish, deeper nearshore rockfish, and California scorpionfish vary by period (Table 2-8b). However, period 2 is closed for these species north and south of Point Conception, and shelf rockfish is closed at this time to minimize discard of nearshore species during the closed period. There is also a small and variable trip limit for bocaccio during the open nearshore periods to allow some incidental bycatch to be landed rather than discarded dead at sea. Species' harvest guidelines for California nearshore commercial fisheries are depicted in Table 2-11.

There is some nearshore commercial fishing allowed in the Cowcod Conservation Areas (Figure 2-3) in depths shallower than 20 fm under the No Action Alternative. Only southern minor nearshore rockfish, (both shallow and deeper nearshore rockfish- see section 2.1.4.1 for the list of species in this complex), California scorpionfish, cabezon, greenlings, California sheephead, and ocean whitefish are allowed to be retained in depths <20 fm in the CCAs.

2.2.3.1.5 Tribal Fisheries

The Washington coastal tribes (Makah, Quileute, Hoh, and Quinault) prosecuted their groundfish fisheries in 2005-2006 with the following allocations and trip limits. The 2006 sablefish allocation was 10% of the total catch OY (for the portion of the stock north of 36° N latitude) of 7,363 mt. This provided an allocation of 736.3 mt of sablefish, which is further reduced after deducting an assumed 2.3% discard mortality for a landed catch allocation of 719.4 mt. The tribal commercial harvest of black rockfish was managed with a harvest guideline of 20,000 lbs north of Cape Alava, Washington at 48°09'30" N latitude, and 10,000 lbs between Destruction Island, Washington at 47°40' N latitude and Leadbetter Point, Washington at 46°38'10" N latitude. There were no harvest restrictions on black rockfish between Cape Alava and Destruction Island. Thornyheads were subject to a 300 lb trip limit as were canary rockfish. Yelloweye rockfish were subject to a 100 lb trip limit. For yellowtail rockfish the entire Makah tribal fleet (the only tribal fleet that participated in a midwater fishery) was subject to a cumulative landing limit of 180,000 lbs/two months. Widow rockfish landings were limited to 10% of the weight of yellowtail rockfish landed in any two-month period. These midwater landing limits were subject to inseason adjustments to minimize the take of canary and widow rockfish. Other rockfish, including species in the minor nearshore, minor shelf, and minor slope rockfish complexes were subject to either a 300 lb trip limit per species or complex, or to the non-tribal limited entry trip limit for those species if those limits were less restrictive. Rockfish taken during the open competition tribal commercial fisheries for Pacific halibut were not subject to trip limits. A full rockfish retention program, as well as a tribal observer program, was in place to provide catch accountability. Lingcod were subject to a 600 pound per day and 1,800 pound per week limit for all tribal fisheries except for the treaty troll fishery which was limited to 1,000 pounds per day and 4,000 pounds per week. A petrale sole trip limit of 50,000 lbs/two months for the Makah bottom trawl fleet was specified for the entire year. Trip limits for Pacific cod, English sole, rex sole, arrowtooth flounder, and other flatfish in the tribal bottom trawl fishery were the same as for non-tribal limited entry trawl fishery at the start of the season (Table 2-6a) using the same Council-approved gear. The tribal plan was not to reduce these limits inseason because of the low expected catch unless catch statistics indicated that the tribes would attain more than half the harvest of these species in their usual and accustomed (U and A) fishing areas. The tribal allocation of Pacific whiting in 2006 was 35,000 mt based on the sliding scale allocation formula that specifies the tribal whiting OY based on the total U.S. whiting OY (Table 2-7). The Makah tribe was the only one of the four tribes prosecuting a whiting-directed fishery in 2006, or proposing a whiting-directed fishery for 2007-2008.

2.2.3.1.6 Washington Recreational Fisheries

In 2005 and 2006, the Washington recreational fishery was open year round for groundfish except lingcod, which was open from the Saturday closest to March 15 through the Saturday closest to October 15 in Marine Areas 1-3 (from the Oregon/Washington border at 46º16' N latitude north to Cape Alava at 48º10' N latitude), and from April 15 through the Saturday closest to October 15 or October 15, whichever date is earlier, in Marine Area 4 (Cape Alava to the U.S./Canada border). In 2005, Marine

Areas 1-3 were open from March 12 through October 15, and Marine Area 4 was open from April 15 through October 15. In 2006, Marine Areas 1-3 are open from March 17 through October 14, and Marine Area 4 is open from April 15 through October 14.

Under the No Action Alternative, in 2007 and 2008, the following lingcod seasons would apply:

- Marine Areas 1-3: Open the Saturday closest to March 15 (which is March 17 in 2007 and March 15 in 2008) through the Saturday closest to October 15 (which is October 13 in 2007 and October 18 in 2008).

- Marine Area 4: Open April 15 through October 13 in 2007 and open April 15 through October 15 in 2008.

Washington has a recreational groundfish bag limit of 15 fish per day including rockfish and lingcod. Of the 15 recreational groundfish allowed to be landed per day, only 10 could be rockfish, with no retention of canary or yelloweye rockfish, and a sublimit of two lingcod with a 24-inch minimum size during the open lingcod season.

Recreational groundfish and recreational halibut fishing is prohibited within the "C-shaped" Yelloweye Rockfish Conservation Area (YRCA) (Figure 2-4). Coordinates defining the YRCA are provided in federal regulations at 50 CFR 660.390.

Washington and Oregon prosecuted their 2005 and 2006 recreational fisheries with shared harvest guidelines for canary rockfish, lingcod, and yelloweye rockfish. If the recreational harvest guideline for canary rockfish, lingcod, or yelloweye specified for the Washington/Oregon area was projected to be exceeded inseason, the Washington Department of Fish and Wildlife (WDFW) would consult with the Oregon Department of Fish and Wildlife (ODFW) and take action inseason to close all or portions of the recreational fishery deeper than 30 fm or adjust seasons, bag limits, or size limits, as needed. In 2005, the shared Washington and Oregon harvest guidelines for recreational fisheries were 8.5 mt, 234 mt, and 6.7 mt for canary rockfish, lingcod, and yelloweye rockfish, respectively. In 2006, the shared recreational harvest guidelines for canary and yelloweye remain the same, and lingcod is increased to 271 mt.

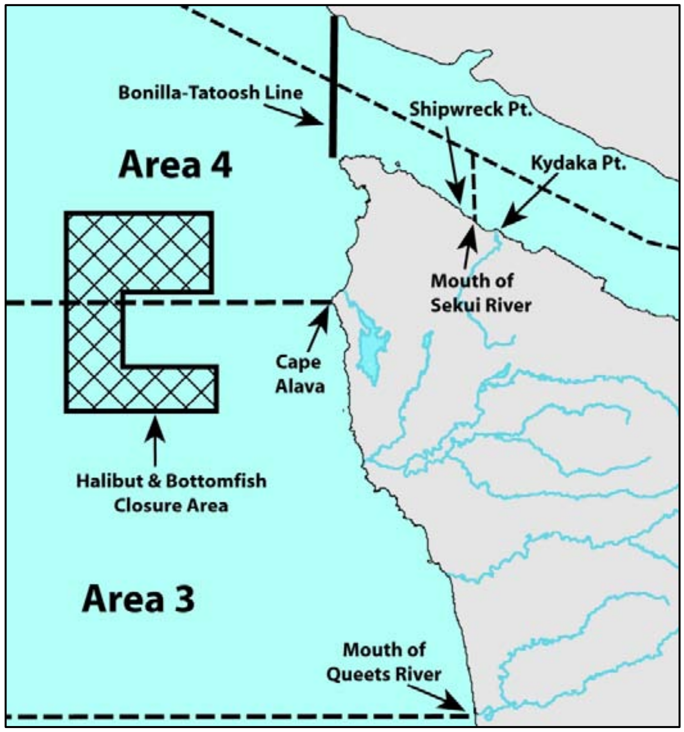

Figure 2-4. The current "C-shaped" Yelloweye Rockfish Conservation Area in waters off northern Washington where recreational groundfish and Pacific halibut fishing is prohibited.

The Washington portion of the shared canary rockfish harvest guideline was 1.7 mt and its portion of the shared yelloweye harvest guideline was 3.5 mt. These total catch amounts or harvest targets, if projected to be attained inseason by the Washington recreational fishery, were the triggers to consult with ODFW and consider an inseason action to slow or eliminate further canary or yelloweye rockfish mortality in this fishery. In 2005, WDFW projected that the yelloweye harvest target would be attained prematurely prompting such a consultation. That consultation indicated the shared yelloweye harvest guideline would be attained early, resulting in a WDFW action implemented on August 5 to close the recreational groundfish fishery outside of 30 fm in waters off Washington north of Leadbetter Pt. at 46º38'10" N latitude. The Council and NMFS adopted conforming federal regulations that were implemented on October 1, 2005.

New Washington recreational management measures were adopted for 2006 to avoid early canary and yelloweye rockfish harvest guideline attainment problems. To reduce the catch of yelloweye rockfish to stay within the Washington recreational harvest target, WDFW proposed, and the Council and NMFS adopted, the following modifications to the 2006 Washington recreational fishery:

- Prohibition of retention of rockfish and lingcod seaward of a line approximating the 20 fm depth contour from May 22, 2006, through September 30, 2006, in Marine Areas 3 and 4 (waters off Washington north of the Queets River at 47º31'42" N latitude where canary and yelloweye catches are highest) on days that halibut fishing is closed.

- Prohibition of retention of rockfish and lingcod seaward of a line approximating the 30 fm depth contour from March 18, 2006, through June 15, 2006, in Marine Area 2 (waters off Washington between Leadbetter Pt. and the Queets River).

Because the 20 fm line had not been previously analyzed, the following modification was made: where the line approximating the 20 fm depth contour extends beyond state waters and into the EEZ, the line will follow the seaward boundary of the state coastal waters.

Halibut fishery regulations for the 2006 Washington fishery became effective March 5, 2006. Therefore, it was necessary to modify the recreational groundfish regulations to conform to the new halibut regulations:

- South of Leadbetter Point to the Washington/Oregon border, when Pacific halibut are onboard the vessel, groundfish may not be taken and retained, possessed or landed, except sablefish and Pacific cod.

2.2.3.1.7 Oregon Recreational Fisheries

In 2005 (and 2006), the Oregon recreational groundfish fishery was (or is expected to be in 2006) open year round with no depth restrictions except during June through September when the fishery was open only inside 40 fm. Catches at the onset of 2005 were also managed using an 8 marine fish daily bag limit[3] including rockfish, greenling (*Hexagrammos* spp.), cabezon, and other groundfish species, but excluding salmon, lingcod, Pacific halibut, perch species, sturgeon, sanddabs, striped bass, tuna, and baitfish. There was no retention of canary and yelloweye rockfish. There was an additional daily bag limit of 25 Pacific sanddabs. Anglers could keep two lingcod with a 24 inch minimum size. Additionally, there was a minimum size limit of 16 inches for cabezon and a 10 inch minimum size limit for greenling species.

The Oregon recreational fishery was managed in 2005 and 2006 with harvest guidelines for black rockfish and widow rockfish, state harvest caps for other nearshore rockfish (including vermilion and tiger rockfish), greenlings, combined black and blue rockfish, and cabezon; and the shared Washington and Oregon harvest guidelines for canary rockfish, lingcod, and yelloweye rockfish discussed above in section 2.2.3.1.5 (Table 2-10). The state harvest caps were set using 2000 harvest as a proxy, and have only ocean boat landings applied against the harvest cap. The black rockfish harvest guideline was shared with Oregon nearshore commercial fisheries; the state allocated the guideline to these sectors as part of their authority. The Oregon black rockfish harvest guidelines for the recreational fishery was 332 mt in 2005 and 324.5 mt in 2006. The state harvest cap for cabezon was 15.8 mt in both 2005 and 2006. ODFW used their Oregon Recreational Boat Survey (ORBS) Program to monitor groundfish catches inseason. If the shared Washington and Oregon recreational harvest guideline for canary, yelloweye, or lingcod was projected to be exceeded, ODFW would consult with WDFW, and consider inseason action to close all or portions of the recreational fishery deeper than 20 fm or 30 fm or adjust seasons, bag limits, or size limits, as needed. Similar actions were considered to manage the black rockfish harvest guideline.

The Oregon Fish and Wildlife Commission (OFWC) also adopted 2005 regulations to prohibit retention of all marine fish (except sablefish, herring, anchovy, smelt, sardine, striped bass, hybrid bass, and offshore pelagic species) when Pacific halibut is retained by the vessel during open days for the all-depth sport fishery for Pacific halibut in the area between lines extending west of Oregon-Washington border and Humbug Mountain, Oregon at 42º40’30” N latitude to the EEZ boundary. This management

3 The Council originally adopted a 10 marine fish daily bag limit for Oregon recreational fisheries. However, subsequent to the Council’s final decision on 2005 and 2006 management measures in June 2004, but prior to January 1, 2005, the Oregon Fish and Wildlife Commission adopted an 8 marine fish daily bag limit. The Council and NMFS adopted conforming federal regulations that were implemented on April 1, 2005.

measure adjustment was expected to provide additional harvest reduction of overfished species and other species with harvest guidelines such as black rockfish by discouraging secondary targeting of such species. This provision also applied during all-depth halibut days in June through September when groundfish retention was prohibited seaward of the RCA boundary approximating the 40 fm depth contour.

In July 2005, ODFW took action to reduce the marine fish daily bag limit from 8 marine fish to 5 marine fish for the remainder of the year to slow the harvest of black rockfish. ODFW took additional action in August 2005 to prohibit retention of cabezon in the recreational ocean boat fishery, due to attainment of the annual state harvest cap for cabezon, and again in October 2005 to close the ocean boat groundfish fishery in waters shoreward of the 40 fathom RCA line, and prohibit retention of black rockfish, as the black rockfish harvest guideline was projected to be attained.

In December 2005, the OFWC refined management measures for the 2006 Oregon recreational groundfish fishery, based on the angler effort patterns observed in 2005. Because there was a significant increase in angler effort targeting groundfish in 2005, due primarily to the poor salmon season in the waters off Oregon, the OFWC adopted a marine fish bag limit of 6 fish in aggregate. The reduced bag limit was necessary to keep the fishery within the 2006 Oregon harvest guideline for black rockfish and to provide a 12 month fishing season. All other management measures (i.e., length restrictions for lingcod, cabezon, and kelp greenling, >40 fm closure during June-September) remain as they were specified for 2005. If the federal and state harvest guidelines are approached in 2006, ODFW would take inseason actions similar in nature to those taken in 2005. Federal conforming regulations were implemented on April 1, 2006.

In 2005 and 2006, ODFW closed the high relief areas of Stonewall Banks to the Pacific halibut fishery during the all-depth Pacific halibut season. Targeting and retention of Pacific halibut was prohibited in the area, and vessels that have retained Pacific halibut while fishing another area, were then prohibited from targeting any species within the closed area. The coordinates for the Stonewall Banks closure implemented in the Pacific halibut fishery are as follows:

1	44º37.46 N latitude	124º24.92 W longitude
2	44º37.46 N latitude	124º23.63 W longitude
3	44º28.71 N latitude	124º21.80 W longitude
4	44º28.71 N latitude	124º24.10 W longitude
5	44º31.42 N latitude	124º25.47 W longitude

Returning to the first point (Figure 2-5).

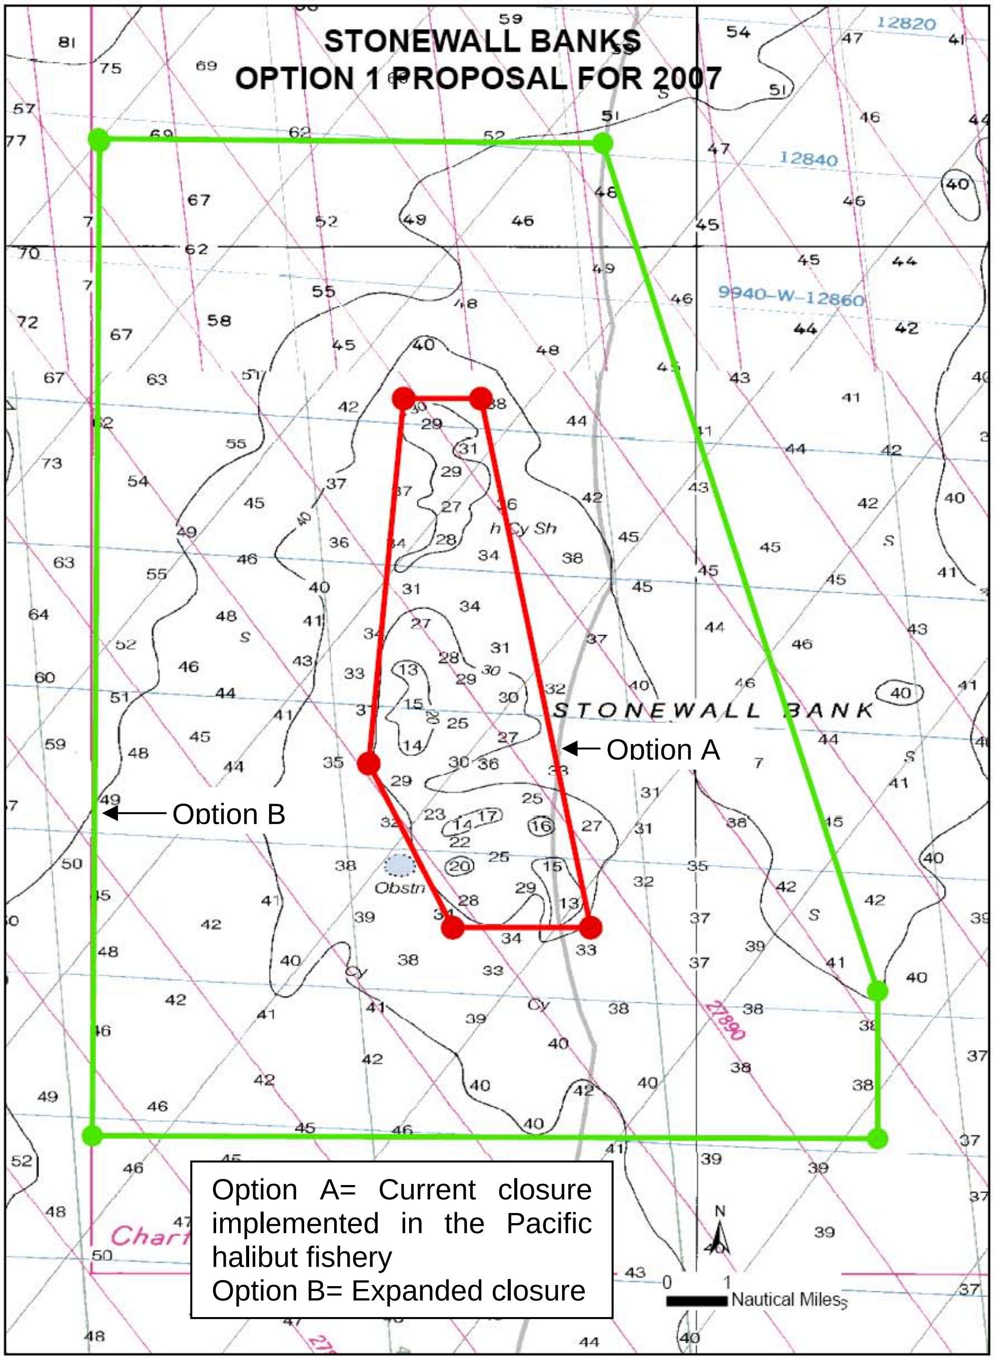

Figure 2-5. The current area closure on Stonewall Banks off the Oregon coast where Pacific halibut retention is prohibited during the all-depth fishery under the No Action Alternative (denoted Option A in figure) and the expanded closed area under Action Alternatives 1 and 3 (denoted Option B in figure).

Halibut regulations for the 2006 fishery became effective March 5, 2006. Therefore it was necessary to modify the recreational groundfish regulations to conform to the new halibut regulations:

- South of the Washington/Oregon border to Cape Falcon, OR, when Pacific halibut are onboard the vessel, groundfish may not be taken and retained, possessed or landed, except sablefish and Pacific cod.
- South of the Cape Falcon, OR, to Humbug Mountain, OR, when Pacific halibut are onboard the vessel, groundfish may not be taken and retained, possessed or landed, except sablefish, during days open to the Oregon Central Coast "all-depth" sport halibut fishery.

2.2.3.1.8 California Recreational Fisheries

For management of California's nearshore recreational groundfish fishery in 2005 and 2006, the California Fish and Game Department (CDFG) divided the coastline into five regional areas, although some regions had the same management measures and were therefore managed as a larger combined region. The five management areas, termed Rockfish/Lingcod Management Areas (RLMAs), are as follows: 1) Southern RLMA (U.S./Mexico Border to Point Conception at 34°27' N latitude), 2) Southern South-Central RLMA (Point Conception to Lopez Point at 36° N latitude), 3) Northern South-Central RLMA (Lopez Point to Pigeon Point at 37º11' N latitude), 4) Northern Central RLMA (Pigeon Point to Cape Mendocino at 40°10' N latitude), and 5) Northern RLMA (Cape Mendocino to the California/Oregon Border at 42° N latitude). The RLMAs between Lopez Point and Cape Mendocino were combined in 2005-2006 management with the intent to specify separate management measures in each of these RLMAs as needed to stay within state and federal harvest guidelines.

The Council and NMFS adopted 2005-2006 California recreational management measures as follows:

- Regulations apply to groundfish (with sanddab fishery exception) and associated state-managed species (rock greenling, California sheephead, and ocean whitefish).
- The sport fishery for sanddabs, using gear specified in federal and state regulations (size #2 hooks or smaller), is exempt from the season closures and depth restrictions placed on other federally-managed groundfish.
- Retention of species in the Other Flatfish complex is allowed when fishing with size #2 hooks or smaller (≤ 11 mm from point to shank) for Pacific sanddabs.
- Lingcod size limit of 24 inches with a daily bag limit of two fish.
- Within a general bag limit of 20 fish, a combined rockfish + cabezon + greenling (RCG) complex daily bag limit of 10 fish of which one can be a cabezon and one can be a greenling of the genus *Hexagrammos*[4].
- A two-fish bag limit for bocaccio in the northern RLMA (north of 40°10' N latitude to the Oregon/California border at 42° N latitude) and a one-fish bag limit south of 40°10' N latitude to the U.S./Mexico border within the 10-fish RCG daily bag limit.
- No retention of cowcod, canary, or yelloweye rockfish.
- Notwithstanding other fishing opportunities for groundfish, lingcod may not be retained during January, February, March, and December.
- All divers (use of boats is permitted while diving for rockfish or other closed species during closed periods provided no hook and line gear on board or in possession while diving to catch rockfish) and shore-based anglers would be exempt from the seasonal closures and depth restrictions for rockfish, greenlings, California scorpionfish, California sheephead, and ocean whitefish.

---

4 The cabezon daily bag sublimit was changed from three fish to one fish and the greenling daily bag sublimit was changed from 2 fish to 1 fish in a California Fish and Game Commission action in October 2004 subsequent to the Council's final decision in June 2004. The Council and NMFS adopted conforming federal regulations that were implemented on April 1, 2005.

The California recreational fishery was managed with federal and state harvest guideline for various groundfish species. Federal annual harvest guidelines were specified for canary rockfish (9.3 mt), yelloweye rockfish (3.7 mt), black rockfish (316 mt for recreational and nearshore commercial fisheries combined in 2005, of which 175 mt were allocated to the recreational fishery by CDFG; in 2006, the combined harvest guideline was 309 mt and the recreational harvest guideline was 170 mt), and lingcod (422 mt) (Table 2-11). State harvest guidelines were specified by CDFG for cabezon, greenlings, and minor nearshore rockfish (both shallow and deeper nearshore rockfish species; see section 2.1.4.1 for the list of species in these complexes). If the recreational harvest guideline for canary rockfish, yelloweye rockfish, or lingcod specified for California was projected to be exceeded, or if the state harvest guideline for black rockfish was projected to be exceeded when combining recreational harvest projections and annual commercial projections, CDFG and/or the Council and NMFS would take action to close all or part of the recreational fishery in all or part of the state regions in all or part of the remainder of the year. Any closure may pertain to closure of specific groundfish species or specific depths in different regions to achieve catch limitation. In the northern RLMA (north of 40°10' N latitude to the Oregon/California border at 42° N latitude), CDFG would take action to close all or part of the recreational fishery deeper than the 30 fm management line if the canary or yelloweye rockfish harvest guideline was attained early in the season.

The 2005 and 2006 adopted management measures included depth bands where fishing for rockfish and associated species was allowed only between 20 and 40 fm (Southern South-Central RLMA) or 30 to 60 fm (Southern RLMA). California took inseason action in 2005 to remove the shoreward boundaries of these depth bands and allow boat-based fishing inside the seaward boundaries originally adopted in the Southern and Southern South-Central RLMAs. These actions were initiated to address concerns related to the ability to enforce fishing restrictions shoreward of adopted depth bands. In addition, final 2004 recreational CRFS projections of impacts showed that additional opportunity could be allowed shoreward of the adopted boundaries, as well as in additional months in the North, North-Central and Northern South-Central RLMAs that would not be likely to exceed harvest guidelines for overfished species targets.

The 2005-2006 seasons and depth restrictions by California management region (Table 2-13) were as follows:

Table 2-13. Summary of 2006 California recreational groundfish seasons and depth restrictions by region under the No Action Alternative.

</table>

NOTES AND KEY:

Shore fishing allowed in all waters in all months

RCG = Rockfish, cabezon, greenlings

--- = Closed to boat-based fishing for RCG

LINGCOD SEASON IS OPEN **ONLY** WHEN RCG IS OPEN, EXCEPT CLOSED DEC, JAN, FEB, MAR FOR SPAWNING

Southern RLMA (U.S./Mexico Border to Point Conception at 34°27' N latitude)

The California recreational groundfish fishery regulations south of Point Conception under the No Action Alternative were the same as described above except for the following changes:

- Groundfish other than California scorpionfish, but including select nongroundfish species (California sheephead and ocean whitefish) open March through August and November through December shoreward of 60 fm; open September through October shoreward of 30 fm; and closed January and February.
- California scorpionfish can only be retained during October and November shoreward of 40 fm and December shoreward of 20 fm (closed January through September).
- Fishing is allowed within the Cowcod Conservation Areas (Figure 2-3) shoreward of the 20 fm line when fishing is open for groundfish other than California scorpionfish, but including select nongroundfish species (California sheephead and ocean whitefish).

Southern South-Central RLMA (Point Conception to Lopez Point at 36° N latitude)

The California recreational groundfish fishery regulations for the area between Point Conception and Lopez Point under the No Action Alternative would be the same as described above except for the following changes:

- Groundfish including select nongroundfish species (California sheephead and ocean whitefish) open May through September shoreward of 40 fm (closed January through April and October through December).

Northern South-Central RLMA (Lopez Point to Pigeon Point at 37°11' N latitude)

The California recreational groundfish fishery regulations for the area between Lopez Point and Cape Mendocino under the No Action Alternative would be the same as described above except for the following changes:

- Groundfish including select nongroundfish species (California sheephead and ocean whitefish) open July through December shoreward of 20 fm (closed January through June).

Northern Central RLMA (Pigeon Point to Cape Mendocino at 40°10' N latitude)

Same regulations as in the Northern South-Central RLMA, except:

- Recreational fishing for groundfish prohibited between the shoreline and the 10 fm (18 m) depth contour around the Farallon Islands and Noonday Rock.
- Waters of Cordell Bank less than 100 fm in depth are closed to fishing at all times.

Northern RLMA (Cape Mendocino to the California/Oregon Border at 42° N latitude)

The California recreational groundfish fishery regulations for the area between Cape Mendocino and the California/Oregon border under the No Action Alternative would be the same as described above except for the following changes:

- Groundfish and ocean whitefish open in May through December shoreward of 40 fm (closed January through June through April).

2.2.3.2 Action Alternative 1

Action Alternative 1 describes the suite of 2007-2008 management measures adopted by the Council for analysis in April 2006 which are the most conservative analyzed in this EIS and therefore tend to constrain fishing opportunities more than the other action alternatives analyzed. They are designed to stay within the Preferred Low OY Alternative for depleted groundfish species (see section 2.1.1.1). Table 2-14 depicts the impacts to depleted groundfish species by sector in 2007 and 2008 associated with the suite of management measures under Action Alternative 1.

2.2.3.2.1 Limited Entry Trawl Fisheries

Table 2-15 depicts the 2007-2008 limited entry trawl management measures under Action Alternative 1. Under this alternative, the trawl RCA is the largest considered for 2007-2008 extending out to the 250 fm in the north and 200 fm in the south (north of 38º N latitude) to stay within the Low Preferred OYs for darkblotched rockfish and Pacific ocean perch. The shoreward RCA line is also extended in to 75 fm in the north and 60-75 fm in the south to reduce mortalities on depleted shelf rockfish, such as bocaccio and canary rockfish, which is responsive to the Low Preferred OYs for those species.

Table 2-14. Projected mortality (mt) of depleted groundfish species by fishing sector under Action Alternative 1.

note: splitnose limits are the same as slope rock limits south of 40 degrees 10 minutes N latitude

* indicates petrale areas

Action Alternative 1 would reduce the lingcod minimum size limit from 24 inches to 20 inches north of 40°10' N latitude under this alternative.

Under Action Alternative 1, Yelloweye RCAs would be added, which would be closed to limited entry trawl fisheries, including midwater trawl, as defined by the following coordinates:

Washington Extension to the "C-Shaped" YRCA

Washington Department of Fish and Wildlife is proposing an extension to the status quo "C-Shaped" YRCA in waters off northern Washington, which is described as follows:

Beginning at 48°00.00' N latitude, 125°16.00' W longitude;
Then to 48°06.00' N latitude, 125°16.00' W longitude;
Then to 48°00.00' N latitude, 124°54.00' W longitude;
Then to 48°06.00' N latitude, 124°54.00' W longitude;
Then to 48°00.00' N latitude, 125°16.00' W longitude;
and back to the point of origin (Figure 2-6).

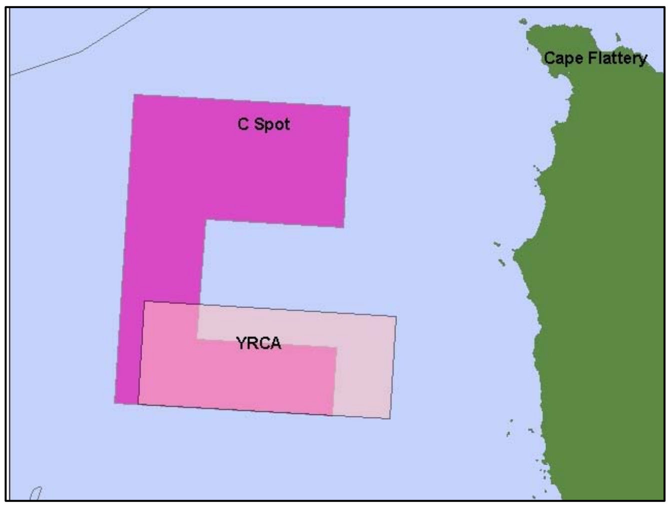

Figure 2-6. A proposed extension to the status quo Yelloweye Rockfish Conservation Area in waters off the Washington north coast where all fishing would be prohibited in 2007-2008 under Action Alternatives 1-3.

WA North Coast A

Beginning at 48°02.23’ N latitude; 125°17.87’ W longitude
Then to 48°01.42’ N latitude; 125°15.89’ W longitude
Then to 47°59.11’ N latitude; 125°18.03’ W longitude
Then to 47°59.97’ N latitude; 125°19.92’ W longitude
and back to the point of origin (Figure 2-7).

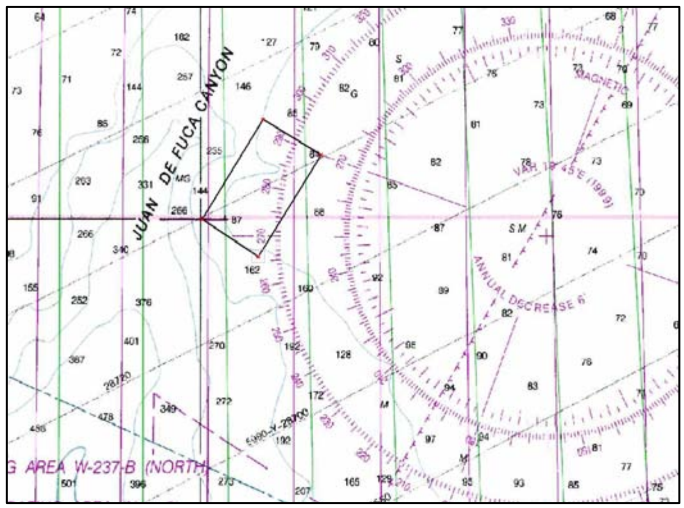

Figure 2-7. A proposed Yelloweye Rockfish Conservation Area (WA North Coast A) in waters off the Washington north coast where all fishing would be prohibited in 2007-2008 under Action Alternatives 1-3.

WA North Coast B

Beginning at 48º11.77’ N latitude by 125º13.03’ W longitude
Then to 48º16.43’ N latitude by 125º07.55’ W longitude
Then to 48º14.72’ N latitude by 125º01.84’ W longitude
Then to 48º13.36’ N latitude by 125º03.20’ W longitude
Then to 48º12.74’ N latitude by 125º05.83’ W longitude
Then to 48º11.55’ N latitude by 125º04.99’ W longitude
Then to 48º09.96’ N latitude by 125º06.63’ W longitude
Then to 48º09.68’ N latitude by 125º08.75’ W longitude
and back to the point of origin (Figure 2-8).

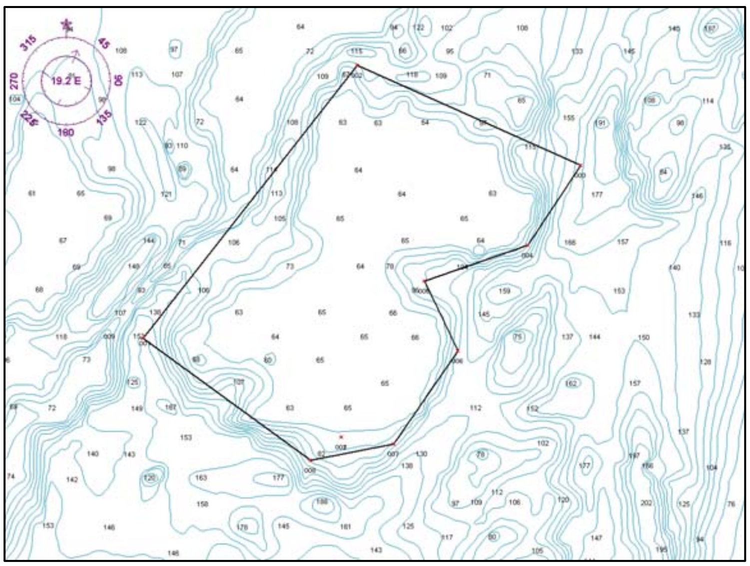

Figure 2-8. A proposed Yelloweye Rockfish Conservation Area (WA North Coast B) in waters off the Washington north coast where all fishing would be prohibited in 2007-2008 under Action Alternatives 1-3.

WA South Coast A

Beginning at 47°05.00’ N latitude; 124°46.50’ W longitude
Then to 47°04.00’ N latitude; 124°46.50’ W longitude
Then to 47°05.00’ N latitude; 124°48.00’ W longitude
and back to the point of origin (Figure 2-9).

WA South Coast B

Beginning at 46°58.00’ N latitude; 124°48.00’ W longitude
Then to 46°55.00’ N latitude; 124°48.00’ W longitude
Then to 46°58.00’ N latitude; 124°49.00’ W longitude
and back to the point of origin (Figure 2-9).

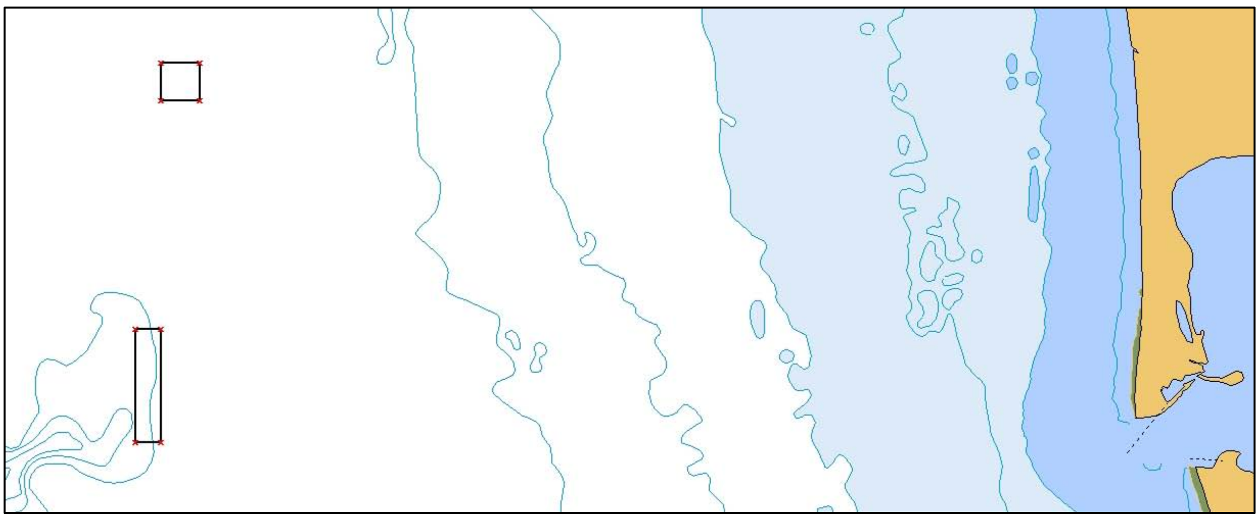

Figure 2-9. Two proposed Yelloweye Rockfish Conservation Areas (WA South Coast A and B) in waters off the Washington south coast where all fishing would be prohibited in 2007-2008 under Action Alternatives 1-3.

Non-Whiting Trawl Fishery

There are no additional management measures than those described above for non-whiting trawl fisheries in 2007 and 2008 under Action Alternative 1.

Whiting Trawl Fishery

Predicted impacts to depleted groundfish species in 2007-2008 whiting-directed fisheries under Action Alternatives 1-3 are depicted in Table 2-16. Higher whiting OYs are not possible given the bycatch constraints imposed by depleted groundfish species under the preferred OYs. However, it is important to note that an alternative strategy for managing 2007-2008 whiting fisheries would be to impose bycatch caps for these species and allow the fleet flexibility to avoid these species while attempting to attain their whiting quotas.

Table 2-16. Predicted impacts to depleted groundfish species using a weighted average of observed bycatch rates in 2002-2005, sector whiting allocations, and estimated exvessel revenues for the 2007-2008 whiting fishery under Action Alternatives 1-3.

Action Alternatives	US Catch	Fathom Line	Sector	Allocation	Canary	Darkblotched	POP	Widow	Yelloweye	Exvessel Rev
Alt. 3	260,000	none	Tribal	35,000	1.6	0.0	0.6	6.0	-	$4,089,570.1
			Mothership	53,520	3.2	4.5	0.9	27.7	0.0	$6,253,536.9
			CP	75,820	0.7	6.0	2.8	48.1	0.0	$8,859,177.3
			Shoreside	93,660	1.3	5.0	1.7	41.0	0.0	$10,943,689.6
			Total		6.8	15.5	6.1	122.8	0.0	$30,145,973.9

			Mothership	29,520	1.8	2.5	0.5	15.3	0.0	$3,449,260.3
			CP	41,820	0.4	3.3	1.6	26.5	0.0	$4,886,452.0
			Shoreside	51,660	0.7	2.8	0.9	22.6	0.0	$6,036,205.5
			Total		4.0	8.6	3.5	68.7	0.0	$17,293,039.3

2.2.3.2.2 Limited Entry Fixed Gear Fisheries

Under Action Alternative 1, the seaward line of the non-trawl RCA is extended out to 150 fm north of Pt. Conception at 34°27' N latitude to the U.S.-Canada border to provide additional canary and yelloweye rockfish protection. The proposed yelloweye RCAs off the Washington coast would also be closed to limited entry fixed gear fisheries under this alternative (Figures 2-5, 2-6, 2-7, and 2-8).

South of Pt. Conception, the non-trawl RCA would be extended shoreward to 40 fm and seaward to 180 fm to reduce canary, cowcod, yelloweye, and particularly bocaccio mortality under this alternative.

The seaward boundary of the western Cowcod Conservation Area would be modified under this alternative to allow limited entry fixed gear vessels access to fish in four distinct Groundfish Fishing Areas (GFAs) deeper than 175 fm (Figure 2-10).

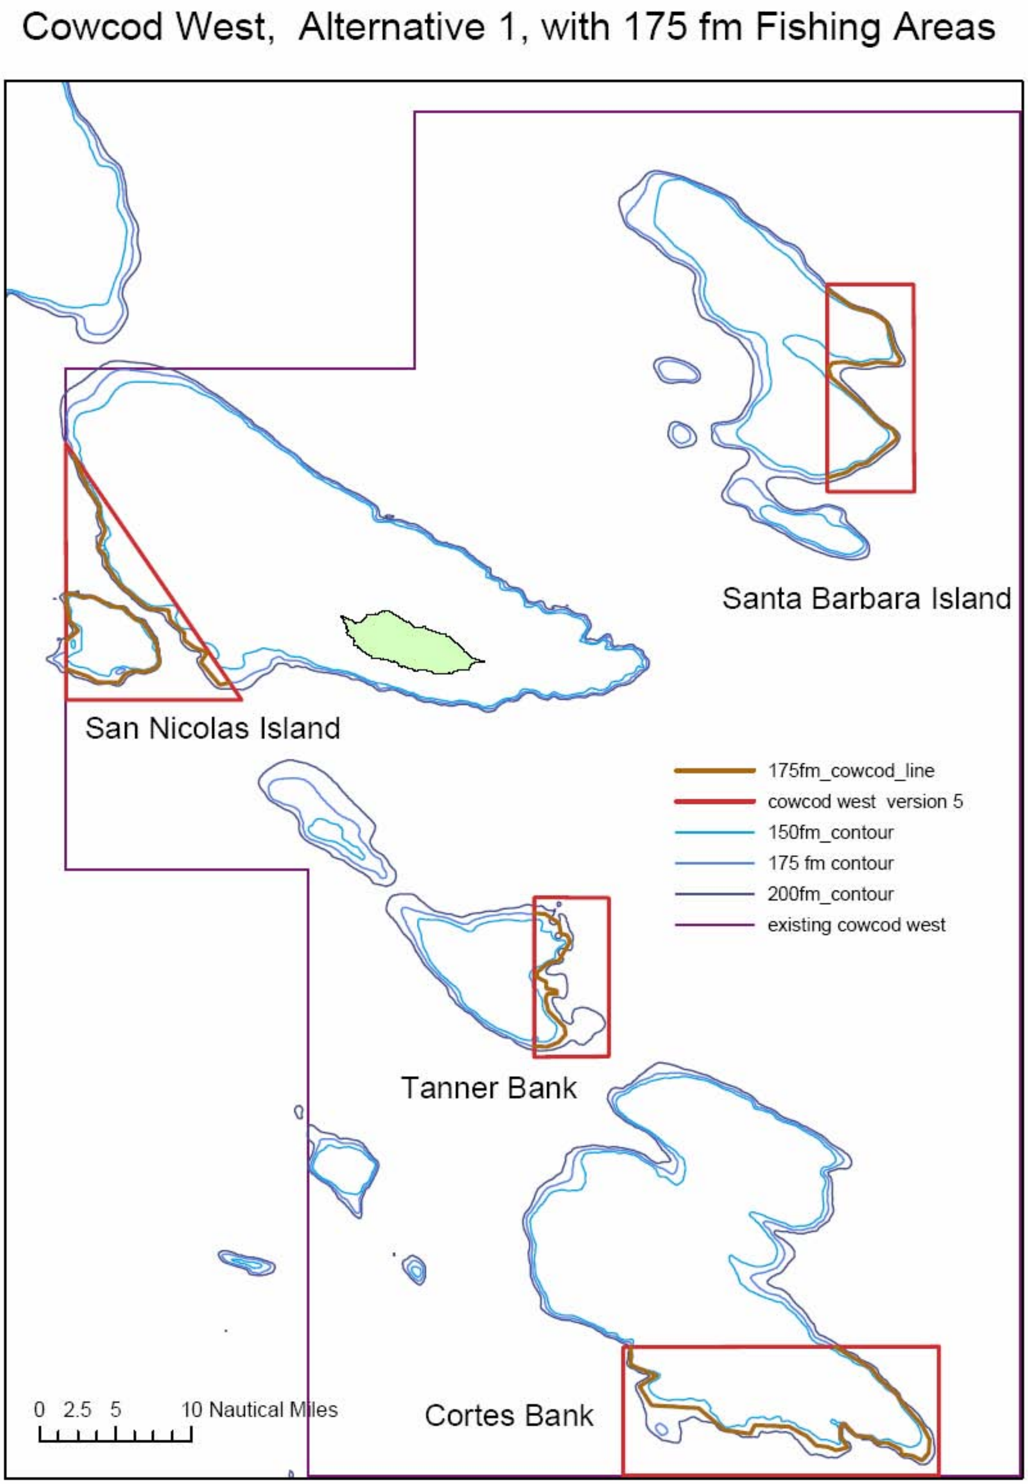

Figure 2-10. Modifications proposed for the western Cowcod Conservation Area in the Southern California Bight under Action Alternative 1 to allow limited entry fixed gear and open access fishing in four distinct Groundfish Fishing Areas (inside red polygons) in depths greater than 175 fm (brown contour).

.2.3.2.3 Open Access Fisheries

Under Action Alternative 1, the seaward line of the non-trawl RCA is extended out to 150 fm north of Pt. Conception at 34°27' N latitude to the U.S.-Canada border to provide additional canary and yelloweye rockfish protection. The proposed yelloweye RCAs off the Washington coast would also be closed to open access fisheries under this alternative (Figures 2-5, 2-6, 2-7, and 2-8).

South of Pt. Conception, the non-trawl RCA would be extended shoreward to 40 fm and seaward to 180 fm to reduce canary, cowcod, yelloweye, and particularly bocaccio mortality under this alternative.

Directed Groundfish Fisheries

The seaward boundary of the western Cowcod Conservation Area would be modified under this alternative to allow open access vessels targeting groundfish using fixed gears access to fish in four distinct Groundfish Fishing Areas (GFAs) deeper than 175 fm (Figure 2-10).

Incidental Groundfish Fisheries

An additional yelloweye RCA is considered under Action Alternative 1 (as well as Action Alternatives 2 and 3) where commercial salmon trolling would be prohibited (Figure 2-11). This salmon troll RCA is defined by the following coordinates:

Beginning at 48°00.00’ N latitude by 125°14.00’ W longitude
Then to 48°02.00’ N latitude by 125°14.00’ W longitude
Then to 48°00.00’ N latitude by 125°16.50’ W longitude
and back to the point of origin.

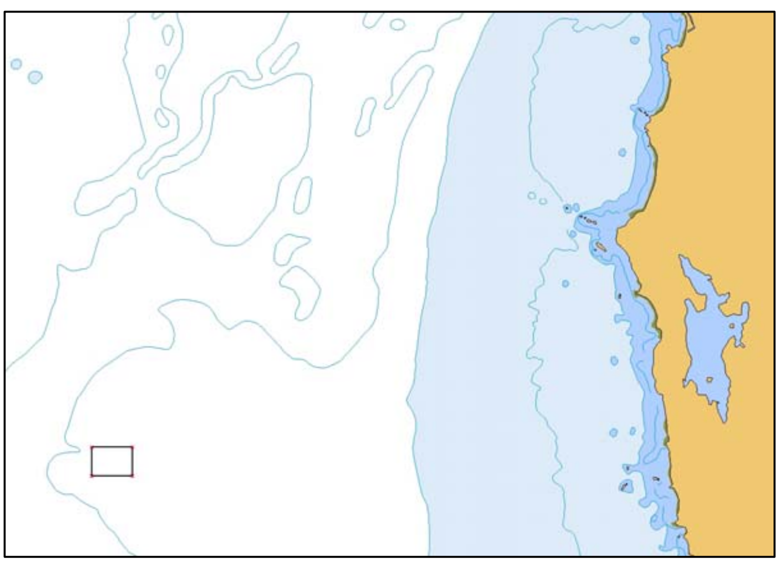

Figure 2-11. A yelloweye RCA off the north Washington coast where commercial salmon trolling would be prohibited under Action Alternatives 1-3.

Under Action Alternative 1, the following management measures would also apply to the commercial salmon troll fishery north of 40°10' N latitude:

- Consistent with the salmon troll regulations off Oregon, allow the retention of lingcod in the salmon troll fishery when fishing shoreward of a line approximating 30 fm.
- As a canary rockfish bycatch reduction measure, prohibit the use of "hoochies" on the bottom spread.

2.2.3.2.4 Nearshore Commercial Fisheries

Nearshore Commercial Fisheries North of 40°10' N latitude

Under Action Alternative 1, the shoreward non-trawl RCA boundary is adjusted from 30 fm (status quo) to 20 fm from 40°10' N latitude to the Oregon-Washington border at 46°16' N latitude (Table 2-12). In addition, the harvestable amount of black rockfish available to this fishery is reduced from status quo levels by 60%. As current trip limits are at the minimum level deemed viable by the fishery participants, a 60 % reduction in target catch would result in a 60% reduction in season duration (< than a 6 month season). The same magnitude of reduced catch may also be attained by utilizing one, or a combination of, the following options: 1) restricting the fishery to waters shoreward of 10 or 15 fm; 2) reducing the duration of the fishery, resulting in a very short season; 3) a fishery closure in some or all areas; and/or 4) reduced harvest of target species.

Nearshore Commercial Fisheries South of 40°10' N latitude

Under Action Alternative 1 from 40°10' N latitude 34°27' N latitude, the shoreward non-trawl RCA boundary is adjusted from 30 fm during periods 1, 2, 5, and 6 and 20 fm during periods 3 and 4 (status quo) to 20 fm during all periods (Table 2-12b). In addition, the harvestable amount of shallow and deeper nearshore rockfish available to this fishery is reduced from status quo levels by 15%. As current trip limits are at the minimum level deemed viable by the fishery participants, a 15% reduction in target catch would result in a 15% reduction in season duration (i.e., an 8 month season). The same magnitude of reduced catch may also be attained by utilizing one, or a combination of, the following options: 1) restricting the fishery to waters shoreward of 10 or 15 fm; 2) reducing the duration of the fishery, resulting in a very short season; 3) a fishery closure in some or all areas; and/or 4) further reduced harvest of target species. Under Action Alternative 1 from 34°27' N latitude to the U.S./Mexico border, the shoreward non-trawl RCA boundary is adjusted from 60 fm (status quo) to 40 fm. The same magnitude of reduced catch may also be attained by utilizing one, or a combination of, the following options: 1) restricting the fishery to waters shoreward of 30 or 20 fm; 2) reducing the duration of the fishery, resulting in a very short season; 3) a fishery closure in some or all areas; and/or 4) reduced harvest of target species.

2.2.3.2.5 Tribal Fisheries

Under all the action alternatives, the following regulations will apply to 2007-2008 tribal groundfish fisheries.

Black Rockfish - The 2007 and 2008 tribal harvest guidelines will be set at 20,000 pounds for the management area between the US/Canada border and Cape Alava, and 10,000 pounds for the management area located between Destruction Island and Leadbetter Point. No tribal harvest restrictions are proposed for the management area between Cape Alava and Destruction Island.

Sablefish - The 2007 and 2008 tribal set asides for sablefish will be set at 10 percent of the Monterey through Vancouver area OY minus 1.9 percent to account for estimated discard mortality. Allocations among tribes and among gear types, if any, will be determined by the tribes.

Pacific cod - The tribes will be subject to a 400 mt harvest guideline for 2007 and 2008.

For all other tribal groundfish fisheries the following trip limits will apply:

Thornyheads - Tribal fisheries will be restricted to the Limited Entry trip limits in place at the beginning of the year for both shortspine and longspine thornyheads.

Canary Rockfish - Tribal fisheries will be restricted to a 300 pound per trip limit.

Other Minor Nearshore, Shelf and Slope Rockfish - Tribal fisheries will be restricted to a 300 pound per trip limit for each species group, or the limited entry trip limits if they are less restrictive than the 300 pound per trip limit.

Yelloweye Rockfish - The tribes will continue developing depth, area, and time restrictions in their directed Pacific halibut fishery to minimize impacts on yelloweye rockfish. Tribal fisheries will be restricted to 100 pounds per trip.

Spiny Dogfish - The Makah Tribe is proposing a directed longline fishery for spiny dogfish for 2007 and 2008. The fishery would be restricted to the Limited Entry trip limits. Increased landings of dogfish by treaty fishermen in 2007 and 2008 would be dependent on successful targeting in 2006 while staying within current estimates of impacts on overfished species.

Full Retention - The tribes will require full retention of all overfished rockfish species as well as all other marketable rockfishes during treaty fisheries.

Tribal Proposals Regarding Makah Trawl fisheries for 2007 and 2008

Midwater Trawl Fishery - Treaty midwater trawl fishermen will be restricted to a cumulative limit of yellowtail rockfish, based on the number of vessels participating, not to exceed 180,000 pounds per two month period for the entire fleet. Their landings of widow rockfish must not exceed 10 percent of the poundage of yellowtail rockfish landed in any given period. The tribe may adjust the cumulative limit for any two-month period to minimize the incidental catch of canary and widow rockfish, provided the average cumulative limit does not exceed 180,000 pounds for the fleet.

Bottom Trawl Fishery - Treaty fishermen using bottom trawl gear will be subject to the trip limits applicable to the limited entry fishery for Dover sole, English sole, rex sole, arrowtooth flounder, and other flatfish. For petrale sole, fishermen would be restricted to 50,000 pounds per two month period for the entire year. Because of the relatively modest expected harvest, the trip limits for the tribal fishery will be those in place at the beginning of the season in the limited entry fishery and will not be adjusted downward, nor will time restrictions or closures be imposed, unless in-season catch statistics demonstrate that the tribe has taken half of the harvest in the tribal area. Fishermen will be restricted to small footrope ($\leq$ 8 inches) trawl gear. Exploration of the use of selective flatfish trawl gear will be conducted in 2006.

Observer Program - The Makah Tribe has an observer program in place to monitor and enforce the limits proposed above.

2.2.3.2.6 Washington Recreational Fisheries

Under Action Alternative 1, WDFW is not proposing any changes to the bottomfish bag limit, minimum size limits, or lingcod season dates described under the No Action Alternative. However, the proposed yelloweye RCAs off the Washington coast would also be closed to Washington recreational fisheries under this alternative (Figures 2-5, 2-6, 2-7, and 2-8). These additional yelloweye RCAs would require a change to the Pacific Halibut Catch Sharing Plan. Other new management measures are considered under Action Alternative 1 as follows:

Management Measures for Marine Areas 3 and 4 (Queets River to the U.S./Canada border)

Under Action Alternative 1, WDFW would prohibit retention of rockfish and lingcod seaward of a line approximating 10 fm during the months of May, August, and September; close the North Coast to halibut fishing, except in Area 4B; and prohibit retention of rockfish and lingcod seaward of a line approximating 20 fm from June 1 through July 31. This alternative would require a change to the Pacific Halibut Catch Sharing Plan.

Management Measures for Marine Area 2 (Leadbetter Pt. to the Queets River)

Under Action Alternative 1, WDFW would prohibit retention of rockfish and lingcod seaward of a line approximating 30 fm from lingcod opening day through July 31; prohibit retention of rockfish and lingcod seaward of a line approximating 20 fm from August 1 through September 30.

Management Measures for Marine Area 1 (Oregon/Washington border to Leadbetter Pt.)

There is very little yelloweye and canary rockfish (0.03 mt and 0.02 mt, respectively, in 2005) caught in Marine Area 1; therefore, WDFW proposes to keep the status quo (No Action) bottomfish fishing regulations in place through 2007 and 2008.

2.2.3.2.7 Oregon Recreational Fisheries

Under Action Alternative 1a (there are two suboptions for the 2007-2008 Oregon recreational fishery under Action Alternative 1), the Oregon recreational groundfish fishery would only be open in depths ≤20 fm from July 1 through Labor Day. The minimum size limit for lingcod would be 20-inches, and anglers would be allowed to retain 3 lingcod per day. Minimum size limits for cabezon and greenling species would be the same as for the No Action Alternative. However, under this alternative the marine fish daily bag limit would increase to 10 marine fish, with all other regulations the same as in the No Action Alternative, except for the following expansion of the Stonewall Banks closure in the Pacific halibut fishery. The additional closure, designed to reduce yelloweye rockfish mortality and hence termed a yelloweye RCA (YRCA), is defined by the following coordinates:

1	44º41.71 N latitude	124º29.99 W longitude
2	44º41.68 N latitude	124º21.60 W longitude
3	44º27.66 N latitude	124º17.01 W longitude
4	44º25.22 N latitude	124º17.01 W longitude
5	44º25.27 N latitude	124º30.11 W longitude

Returning to the first point (Figure 2-5).

This expanded Stonewall Banks closure would only apply to the Pacific halibut fishery since this area is seaward of the 20 fm line and, under this alternative, all groundfish retention is prohibited seaward of the 20 fm line.

Under Action Alternative 1b, the Oregon recreational groundfish fishery would be open from April through September shoreward of the 20 fm line. A 30% reduction in yelloweye rockfish impacts would be achieved by reducing Pacific halibut quota and time on the water in that fishery. The marine fish daily bag limit would be the same as under the No Action Alternative, or 6 marine fish daily. The minimum size limit for lingcod would be 20 inches, and anglers would be allowed to retain 3 lingcod per day. All other groundfish regulations would be the same as under the No Action Alternative except for the expansion of the Stonewall Banks closure in the Pacific halibut fishery described under Action Alternative 1a.
This expanded Stonewall Banks closure would only apply to the Pacific halibut fishery since this area is seaward of the 20 fm line and, under this alternative, all groundfish retention is prohibited seaward of the 20 fm line.

Predicted yelloweye rockfish impacts under both alternatives 1a and 1b are similar (see section 4.3.1.7).

2.2.3.2.8 California Recreational Fisheries

Under Action Alternative 1, the five RLMAs described under the No Action Alternative will be used to manage 2007-2008 California recreational groundfish fisheries. The status quo (No Action) California recreational management measures under Action Alternative 1 include the following:

- Regulations apply to groundfish (with sanddab fishery exception) and associated state-managed species (rock greenling, California sheephead, and ocean whitefish).
- The sport fishery for sanddabs, using gear specified in federal and state regulations (size #2 hooks or smaller), is exempt from the season closures and depth restrictions placed on other federally-managed groundfish.
- Retention of species in the Other Flatfish complex is allowed when fishing with size #2 hooks or smaller (≤ 11 mm from point to shank) for Pacific sanddabs.
- Within a general bag limit of 20 fish, a combined rockfish + cabezon + greenling (RCG) complex daily bag limit of 10 fish, of which one can be a cabezon and one can be a greenling of the genus *Hexagrammos*.
- No retention of cowcod, canary, or yelloweye rockfish.
- Notwithstanding other fishing opportunities for groundfish, lingcod may not be retained during January, February, March, and December.
- Waters of Cordell Bank less than 100 fm in depth are closed to fishing at all times.
- All divers (boats permitted while diving for rockfish or other closed species during closed periods provided no hook and line gear on board or in possession while diving to catch rockfish) and shore-based anglers would be exempt from the seasonal closures and depth restrictions for rockfish, greenlings, California scorpionfish, California sheephead, and ocean whitefish.

California recreational groundfish management measures that differ from status quo under Action Alternative 1 include the following:

- A statewide one-fish bocaccio sublimit is included in the 10-fish RCG daily bag limit.
- Lingcod daily bag limit of 1 fish, but with a minimum size limit of 22 inches.

Additionally, seasons and depth restrictions by RLMA under Action Alternative 1 are described below and summarized in Table 2-17.

- Fishing is allowed within the Cowcod Conservation Areas shoreward of the 20 fm line when fishing is open for groundfish other than California scorpionfish, but including select nongroundfish species (California sheephead and ocean whitefish).

Table 2-17. Summary of 2007-2008 California recreational groundfish seasons and depth restrictions by region under Action Alternative 1.

RCG SEASON BY REGION:

Region	Jan	Feb	Mar	Apr	May	Jun	July	Aug	Sep	Oct	Nov	Dec
North region	---	---	---	---	> 20fm Closed							
North Central	---	---	---	---	---	---	> 20fm Closed			---	> 20fm Closed	
South Central - Monterey	---	---	---	---	---	---	> 20fm Closed					
South Central - Morro Bay	---	---	---	---	> 20fm Closed					---	---	---
South Region*	---	---	> 30fm Closed									

NOTES AND KEY:

Shore fishing allowed in all waters in all months

RCG = Rockfish, cabezon, greenlings

--- = Closed to boat-based fishing for RCG

LINGCOD SEASON IS OPEN **ONLY** WHEN RCG IS OPEN, EXCEPT CLOSED DEC, JAN, FEB, MAR FOR SPAWNING

*In the South Region, CA scorpionfish is open 12 months: 0-40 fm in January-February and 0-30 fm March-December.

Southern RLMA (U.S./Mexico Border to Point Conception)

The California recreational groundfish fishery regulations south of Point Conception under Action Alternative 1 are the same as described above except for the following changes:

- Groundfish other than California scorpionfish, but including select nongroundfish species (California sheephead and ocean whitefish) open March through December shoreward of the 30 fm line and otherwise closed.
- California scorpionfish is open year-round, but restricted to depths ≤40 fm during January and February, and ≤30 fm during March through December.

Southern South-Central RLMA (Point Conception to Lopez Point)

The California recreational groundfish fishery regulations for the area between Point Conception and Lopez Point under Action Alternative 1 would be the same as described above except for the following changes:

- Groundfish including select nongroundfish species (California sheephead and ocean whitefish) open May through September shoreward of the 20 fm line and otherwise closed.

Northern South--Central RLMA (Lopez Point to Pigeon Point)

The California recreational groundfish fishery regulations for the area between Lopez Point and Pigeon Point under the Action Alternative 1 would be the same as described above except for the following changes:

- Groundfish including select nongroundfish species (California sheephead and ocean whitefish) open July through December shoreward of 20 fm and otherwise closed.

Northern Central RLMA (Pigeon Point to Cape Mendocino)

The California recreational groundfish fishery regulations for the area between Pigeon Point and Cape Mendocino under the Action Alternative 1 would be the same as described above except for the following changes:

- Groundfish including select nongroundfish species (California sheephead and ocean whitefish) open July through September and November through December shoreward of 20 fm and otherwise closed.

Northern RLMA (Cape Mendocino to the California/Oregon Border)

The California recreational groundfish fishery regulations for the area between Cape Mendocino and the California/Oregon border under the Action Alternative 1 would be the same as described above except for the following changes:

- Groundfish and ocean whitefish open in May through December shoreward of 20 fm and otherwise closed.

2.2.3.3 Action Alternative 2

Action Alternative 2 is intermediate to Action Alternatives 1 and 3 in constraints to 2007 and 2008 fishing opportunities and intermediate in terms of impacts to depleted and target groundfish species. Table 2-19 depicts the impacts to depleted groundfish species by sector in 2007 and 2008 associated with the suite of management measures under Action Alternative 2.

2.2.3.3.1 Limited Entry Trawl Fisheries

Table 2-18 depicts the 2007-2008 limited entry trawl management measures under Action Alternative 2. The proposed yelloweye RCAs off the Washington coast would also be closed to limited entry trawl fisheries under this alternative (Figures 2-5, 2-6, 2-7, and 2-8).

Table 2-18. Cumulative bimonthly limits and RCA configurations by area and species for the West Coast limited entry trawl fishery in 2007-2008 under Action Alternative 2.

		RCA Configurations		Cumulative Limits							
SUBAREA	Period	INLINE	OUTLINE	SABLEFISH	LONGSPN	SHORTSPN	DOVER	OTHER FLAT	PETRALE	ARROWTH	SLOPE ROCK

Key		= either not applicable; trace amount (<0.01 mt); or not reported in available data sources.						

a/ South of 40°10' N. lat.
b/ Mortality estimates are not hard numbers; based on the GMT's best professional judgment.

c/ Bycatch amounts by species unavailable, but bocaccio occurred in 0.1% of all port samples and other rockfish in another 0.1% of all port samples (and squid fisheries usually land their whole catch). In 2001, out of 84,000 mt total landings 1 mt was groundfish.

d/ Values are proposed EFP bycatch caps, not estimates of total mortality. The EFP is terminated inseason if the cap is projected to be attained early.

Non-Whiting Trawl Fishery

There are no additional management measures than those described above for non-whiting trawl fisheries in 2007 and 2008 under Action Alternative 2.

Whiting Trawl Fishery

Predicted impacts to depleted groundfish species in 2007-2008 whiting-directed fisheries under Action Alternatives 1-3 are depicted in Table 2-16. Higher whiting OYs are not possible given the bycatch constraints imposed by depleted groundfish species under the preferred OYs. However, it is important to note that an alternative strategy for managing 2007-2008 whiting fisheries would be to impose bycatch caps for these species and allow the fleet flexibility to avoid these species while attempting to attain their whiting quotas.

2.2.3.3.2 Limited Entry Fixed Gear Fisheries

Under Action Alternative 2, the seaward line of the non-trawl RCA is extended out to 125 fm north of Cape Mendocino at 40°10' N latitude to the U.S.-Canada border to provide additional canary and yelloweye rockfish protection relative to status quo management measures. The proposed yelloweye RCAs off the Washington coast would also be closed to limited entry fixed gear fisheries under this alternative (Figures 2-5, 2-6, 2-7, and 2-8).

The seaward boundary of the western Cowcod Conservation Area would be modified under this alternative to allow limited entry fixed gear vessels access to fish in depths deeper than 175 fm (Figure 2-12).

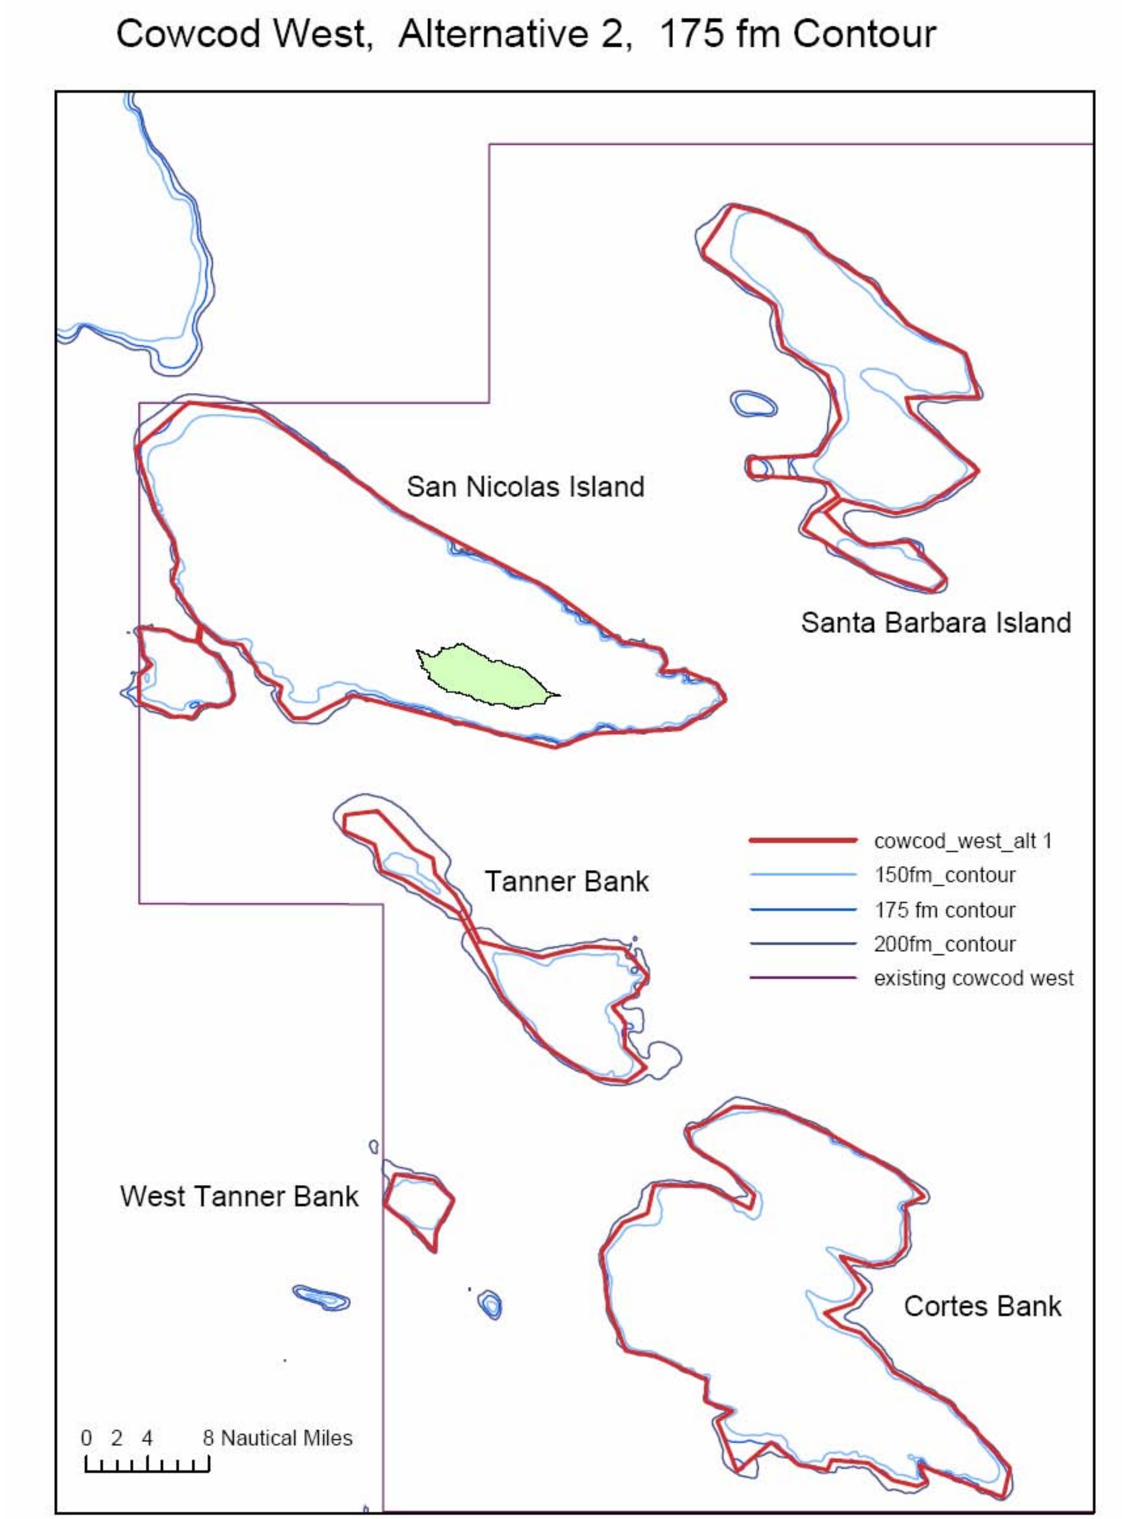

Figure 2-12. Modifications proposed for the western Cowcod Conservation Area in the Southern California Bight under Action Alternative 2 to allow limited entry fixed gear and open access fishing in depths greater than 175 fm (red contour).

2.2.3.3.3 Open Access Fisheries

Under Action Alternative 2, the seaward line of the non-trawl RCA is extended out to 125 fm north of Cape Mendocino at 40°10' N latitude to the U.S.-Canada border to provide additional canary and yelloweye rockfish protection relative to status quo management measures. The proposed yelloweye RCAs off the Washington coast would also be closed to open access fisheries under this alternative (Figures 2-5, 2-6, 2-7, and 2-8).

Directed Groundfish Fisheries

The seaward boundary of the western Cowcod Conservation Area would be modified under this alternative to allow open access vessels targeting groundfish using fixed gears access to fish in depths deeper than 175 fm (Figure 2-12).

Incidental Groundfish Fisheries

Additional management measures to those described above considered for open access fisheries that incidentally catch groundfish species under this alternative apply to the commercial salmon troll fishery north of 40°10' N latitude as follows:
Under Action Alternative 1, the following management measures would also apply to the commercial salmon troll fishery north of 40°10' N latitude:

- Prohibit commercial salmon trolling in the proposed yelloweye RCA in waters off northern Washington described under Action Alternative 1 (Figure 2-11).
- Prohibit the retention of lingcod in the salmon troll fishery shoreward of the non-trawl RCA seaward boundary (e.g., shoreward of 100 fm north of 40°10’ N latitude, under status quo).
- As a canary rockfish bycatch reduction measure, prohibit the use of “hoochies” on the bottom spread.

2.2.3.3.4 Nearshore Commercial Fisheries

Nearshore Commercial Fisheries North of 40°10' N latitude

Under Action Alternative 2, the shoreward RCA boundary is adjusted from 30 fm (status quo) to 20 fm from 40°10' N latitude to the Oregon-Washington border at 46°16' N latitude (Table 2-12). In addition, the harvestable amount of black rockfish available to this fishery is reduced from status quo levels by 10%. The same amount of savings may occur by further adjustment of the shoreward RCA boundary (i.e. 15 fm), resulting in status quo harvest of target species.

Nearshore Commercial Fisheries South of 40°10' N latitude

Under Action Alternative 2, from 40°10' N latitude 34°27’ N latitude, the shoreward non-trawl RCA boundary is adjusted from 30 fm during periods 1, 2, 5, and 6 and 20 fm during periods 3 and 4 (status quo) to 20 fm during all periods (Table 2-12b). In addition, the harvestable amount of shallow and deeper nearshore rockfish available to this fishery is reduced from status quo levels by 5%. The same amount of savings may occur by further adjustment of the shoreward RCA boundary (i.e. 15 fm), or reducing the season duration (9 months), resulting in status quo harvest of target species. Action Alternative 2 from 34°27’ N latitude to the US/Mexico border represents status quo management. CDFG would have the ability to manage harvest at more conservative levels, if deemed appropriate by the Director of CDFG or by the California Fish and Game Commission. Catches would be monitored, and the fishery managed to ensure harvest impacts of both target species and associated overfished rockfish did not exceed adopted levels.

2.2.3.3.5 Tribal Fisheries

Groundfish management measures are the same as described for tribal fisheries under Action Alternative 1. The tribes proposed only one action alternative for analysis.

2.2.3.3.6 Washington Recreational Fisheries

Under Action Alternative 2, WDFW is not proposing any changes to the bottomfish bag limit, minimum size limits, or lingcod season dates described under the No Action Alternative. However, the proposed yelloweye RCAs off the Washington coast would also be closed to Washington recreational fisheries under this alternative (Figures 2-5, 2-6, 2-7, and 2-8). These additional yelloweye RCAs would require a change to the Pacific Halibut Catch Sharing Plan. Other new management measures are considered under Action Alternative 2 as follows:

Management Measures for Marine Areas 3 and 4 (Queets River to the U.S./Canada border)

Under Action Alternative 2, WDFW would prohibit retention of rockfish and lingcod seaward of a line approximating 10 fm during the months of May and September; close the North Coast to halibut fishing, except in Area 4B; and prohibit retention of rockfish and lingcod seaward of a line approximating 20 fm from June 1 through August 31. This alternative would require a change to the Pacific Halibut Catch Sharing Plan.

Management Measures for Marine Area 2 (Leadbetter Pt. to the Queets River)

Under Action Alternative 2, WDFW would prohibit retention of rockfish and lingcod seaward of a line approximating 30 fm from lingcod opening day through August 31.

Management Measures for Marine Area 1 (Oregon/Washington border to Leadbetter Pt.)

There is very little yelloweye and canary rockfish (0.03 mt and 0.02 mt, respectively, in 2005) caught in Marine Area 1; therefore, WDFW proposes to keep the status quo (No Action) bottomfish fishing regulations in place through 2007 and 2008.

2.2.3.3.7 Oregon Recreational Fisheries

Under Action Alternative 2, the Oregon recreational groundfish fishery would be open all year shoreward of the 20 fm line. The marine fish daily bag limit would be reduced to 5 marine fish. Other changes to status quo (No Action) management measures under this alternative include a decrease in the lingcod minimum size limit to 22 inches. All other management measures, including the current Stonewall Banks closure for the Pacific halibut fishery under this alternative are the same as under the No Action Alternative. The additional YRCA contemplated under Action Alternative 1 would not apply to the directed recreational groundfish fishery under this alternative since the proposed closed area is seaward of the 20 fm line.

2.2.3.3.8 California Recreational Fisheries

Under Action Alternative 2, the five RLMAs described under the No Action Alternative will be used to manage 2007-2008 California recreational groundfish fisheries. The status quo (No Action) California recreational management measures under Action Alternative 2 include the following:

- Regulations apply to groundfish (with sanddab fishery exception) and associated state-managed species (rock greenling, California sheephead, and ocean whitefish).
- The sport fishery for sanddabs, using gear specified in federal and state regulations (size #2 hooks or smaller), is exempt from the season closures and depth restrictions placed on other federally-managed groundfish.
- Retention of species in the Other Flatfish complex is allowed when fishing with size #2 hooks or smaller (≤ 11 mm from point to shank) for Pacific sanddabs.
- Combined rockfish + cabezon + greenling (RCG) complex daily bag limit of 10 fish.
- No retention of cowcod, canary, or yelloweye rockfish.
- Lingcod size limit of 24 inches with a daily bag limit of two fish.
- A two-fish bocaccio sublimit included in the 10-fish RCG daily bag limit.
- Notwithstanding other fishing opportunities for groundfish, lingcod may not be retained during January, February, March, and December.
- Waters of Cordell Bank less than 100 fm in depth are closed to fishing at all times.
- All divers (boats permitted while diving for rockfish or other closed species during closed periods provided no hook and line gear on board or in possession while diving to catch rockfish) and shore-based anglers would be exempt from the seasonal closures and depth restrictions for rockfish, greenlings, California scorpionfish, California sheephead, and ocean whitefish.

California recreational groundfish management measures that differ from status quo under Action Alternative 2 include the following:

- Two cabezon and two greenling of the genus *Hexagrammos* sublimit is included in the 10-fish RCG daily bag limit.

Additionally, seasons and depth restrictions by RLMA under Action Alternative 2 are described below and summarized in Table 2-20.

Table 2-20. Summary of 2007-2008 California recreational groundfish seasons and depth restrictions by region under Action Alternative 2.

RCG SEASON BY REGION

Region	**Jan**	**Feb**	**Mar**	**Apr**	**May**	**Jun**	**July**	**Aug**	**Sep**	**Oct**	**Nov**	**Dec**
North region	---	---	---	---	>30fm Closed							
North Central	---	---	---	---	---	---	> 20fm Closed					
South Central - Monterey	---	---	---	---	---	---	> 20fm Closed					
South Central - Morro Bay	---	---	---	> 20fm Closed						---	---	---
South Region*	---	---	> 40fm Closed						> 30fm Closed		> 60fm Closed	

NOTES AND KEY:

Shore fishing allowed in all waters in all months

RCG = Rockfish, cabezon, greenlings

--- = Closed to boat-based fishing for RCG

LINGCOD SEASON IS OPEN **ONLY** WHEN RCG IS OPEN, EXCEPT CLOSED DEC, JAN, FEB, MAR FOR SPAWNING

*In the South Region, CA scorpionfish is open 12 months: 0-40 fm in January-August, 0-30 fm September-October and 0-60 fm November-December.

Southern RLMA (U.S./Mexico Border to Point Conception)

The California recreational groundfish fishery regulations south of Point Conception under Action Alternative 2 are the same as described above except for the following changes:

- Groundfish other than California scorpionfish, but including select nongroundfish species (California sheephead and ocean whitefish) open March through August shoreward of the 40 fm line, September through October shoreward of the 30 fm line, November and December shoreward of the 60 fm line, and otherwise closed.
- California scorpionfish is open year-round, but restricted to depths ≤40 fm during January-August, ≤30 fm during September and October, and ≤60 fm during November and December.

Southern South-Central RLMA (Point Conception to Lopez Point)

The California recreational groundfish fishery regulations for the area between Point Conception and Lopez Point under Action Alternative 2 would be the same as described above except for the following changes:

- Groundfish including select nongroundfish species (California sheephead and ocean whitefish) open April through September shoreward of the 20 fm line and otherwise closed.

Northern South--Central RLMA (Lopez Point to Pigeon Point)

The California recreational groundfish fishery regulations for the area between Lopez Point and Cape Mendocino under the Action Alternative 2 would be the same as described above except for the following changes:

- Groundfish including select nongroundfish species (California sheephead and ocean whitefish) open July through December shoreward of 20 fm and otherwise closed.

Northern Central RLMA (Pigeon Point to Cape Mendocino)

The California recreational groundfish fishery regulations for the area between Pigeon Point and Cape Mendocino under the Action Alternative 2 would be the same as described above except for the following changes:

- Groundfish including select nongroundfish species (California sheephead and ocean whitefish) open July through December shoreward of 20 fm and otherwise closed.

Northern RLMA (Cape Mendocino to the California/Oregon Border)

The California recreational groundfish fishery regulations for the area between Cape Mendocino and the California/Oregon border under the Action Alternative 2 would be the same as described above except for the following changes:

- Groundfish and ocean whitefish open in May through December shoreward of 30 fm and otherwise closed.

2.2.3.4 Action Alternative 3

Action Alternative 3 is the most liberal action alternative analyzed in this EIS. More fishing opportunities, and hence greater impacts to groundfish species, are predicted under this alternative. The only other alternative analyzed that may be less constraining to 2007-2008 fishing opportunities may be the No Action Alternative, if those management measures were implemented in the next management cycle. Table 2-21 depicts the impacts to depleted groundfish species by sector in 2007 and 2008 associated with the suite of management measures under Action Alternative 3.

2.2.3.4.1 Limited Entry Trawl Fisheries

Table 2-22 depicts the 2007-2008 limited entry trawl management measures under Action Alternative 3. The proposed yelloweye RCAs off the Washington coast would also be closed to limited entry trawl fisheries under this alternative (Figures 2-5, 2-6, 2-7, and 2-8).

Under Action Alternative 3, the boundaries of the Cowcod Conservation Areas in the Southern California Bight would be eliminated and the depth-based RCAs specified for south of Pt. Conception would instead be implemented in this area.

Non-Whiting Trawl Fishery

There are no additional management measures than those described above for non-whiting trawl fisheries in 2007 and 2008 under Action Alternative 3.

Whiting Trawl Fishery

Predicted impacts to depleted groundfish species in 2007-2008 whiting-directed fisheries under Action Alternatives 1-3 are depicted in Table 2-16. Higher whiting OYs are not possible given the bycatch constraints imposed by depleted groundfish species under the preferred OYs. However, it is important to note that an alternative strategy for managing 2007-2008 whiting fisheries would be to impose bycatch caps for these species and allow the fleet flexibility to avoid these species while attempting to attain their whiting quotas.

2.2.3.4.2 Limited Entry Fixed Gear Fisheries

Status quo management measures are specified for limited entry fixed gear fisheries under this alternative, except the proposed yelloweye RCAs off the Washington coast would also be closed to limited entry fixed gear fisheries under this alternative (Figures 2-5, 2-6, 2-7, and 2-8).

Under Action Alternative 3, the boundaries of the Cowcod Conservation Areas in the Southern California Bight would be eliminated and the depth-based RCAs specified for south of Pt. Conception would instead be implemented in this area.

Table 2-21. Projected mortality (mt) of depleted groundfish species by fishing sector under Action Alternative 3.

	6	100	150	15,000	22,000	7,000	60,000	110,000	80,000	10,000	40,000

note: splitnose limits are the same as slope rock limits south of 40 degrees 10 minutes N latitude

* indicates petrale areas

2.2.3.4.3 Open Access Fisheries

Status quo management measures are specified for open access fisheries under this alternative, except the proposed yelloweye RCAs off the Washington coast would also be closed to open access fisheries under this alternative (Figures 2-5, 2-6, 2-7, and 2-8) and the following:

Under Action Alternative 3, the boundaries of the Cowcod Conservation Areas in the Southern California Bight would be eliminated and the depth-based RCAs specified for south of Pt. Conception would instead be implemented in this area.

Directed Groundfish Fisheries

There are no additional management measures considered for open access fisheries targeting groundfish species than those described above under this alternative.

Incidental Groundfish Fisheries

Additional management measures to those described above considered for open access fisheries that incidentally catch groundfish species under this alternative apply to the commercial salmon troll fishery north of 40°10' N latitude as follows:

- Prohibit commercial salmon trolling in the proposed yelloweye RCA in waters off northern Washington described under Action Alternative 1 (Figure 2-11).
- Allow the retention of lingcod in the salmon troll fishery, subject to an incidental landing ratio of one lingcod per ten Chinook salmon (Option 3a), or
- Allow the retention of lingcod in the salmon troll fishery, subject to an incidental landing ratio of one lingcod per ten Chinook salmon, north of the Oregon/Washington border at 46°16.00' N latitude (Option 3b).
- As a canary rockfish bycatch reduction measure, prohibit the use of "hoochies" on the bottom spread.

2.2.3.4.4 Nearshore Commercial Fisheries

Nearshore Commercial Fisheries North of 40°10' N latitude

There are two suboptions (Action Alternatives 3a and 3b) for nearshore commercial fisheries from 40°10' N latitude to the Oregon-Washington border at 46°16' N latitude.

Under Action Alternative 3a, the shoreward RCA boundary is adjusted from 30 fm (status quo) to 20 fm with no reduction to the amount of target catch (Table 2-12). Target species harvest levels would be set at levels consistent with adopted ABC/OY levels for those species. ODFW would have the ability to manage harvest at more conservative levels, if deemed appropriate by the Oregon Fish and Wildlife Commission. Catches would be monitored, and the fishery managed to ensure harvest impacts of both target species and associated overfished rockfish did not exceed adopted levels.

Action Alternative 3b represents a near status quo fishery (Table 2-12). The shoreward RCA boundary is established at 30 fm (status quo). Target species harvest levels would be set at levels consistent with adopted ABC/OY levels for those species. ODFW would have the ability to manage harvest at more conservative levels, if deemed appropriate by the Oregon Fish and Wildlife Commission. Catches would be monitored, and the fishery managed to ensure harvest impacts of both target species and associated overfished rockfish did not exceed adopted levels.

Nearshore Commercial Fisheries South of 40°10' N latitude

There are two suboptions (Action Alternatives 3a and 3b) for nearshore commercial fisheries from 40°10' N latitude to 34°27' N latitude.

Under Action Alternative 3a, the shoreward RCA boundary is adjusted from 30 fm during periods 1, 2, 5, and 6 and 20 fm during periods 3 and 4 (status quo) to 30 fm during all periods. In addition, the harvestable amount of shallow and deeper nearshore rockfish available to this fishery is reduced from status quo levels by 5% (Table 2-12b). This represents near-status quo impacts to canary rockfish.

Under Action Alternative 3b, from 40°10' N latitude 34°27' N latitude, the shoreward non-trawl RCA boundary is adjusted from 30 fm during periods 1, 2, 5, and 6 and 20 fm during periods 3 and 4 (status quo) to 30 fm during all periods (Table 2-12b). Target species harvest levels would be set at levels consistent with adopted ABC/OY levels for those species.

In both cases, CDFG would have the ability to manage harvest at more conservative levels, if deemed appropriate by the Director of CDFG or by the California Fish and Game Commission. Catches would be monitored, and the fishery managed to ensure harvest impacts of both target species and associated overfished rockfish did not exceed adopted levels.

Action Alternative 3 from 34°27’ N latitude to the US/Mexico border represents status quo management. CDFG would have the ability to manage harvest at more conservative levels, if deemed appropriate by the Director of CDFG or by the California Fish and Game Commission. Catches would be monitored, and the fishery managed to ensure harvest impacts of both target species and associated overfished rockfish did not exceed adopted levels.

2.2.3.4.5 Tribal Fisheries

Groundfish management measures are the same as described for tribal fisheries under Action Alternative 1. The tribes proposed only one action alternative for analysis.

2.2.3.4.6 Washington Recreational Fisheries

Under Action Alternative 3, WDFW is not proposing any changes to the bottomfish bag limit, minimum size limits, or lingcod season dates described under the No Action Alternative. Under this alternative, WDFW would reduce the lingcod minimum size limit to 20 inches in Marine Areas 1-4. The proposed yelloweye RCAs off the Washington coast would also be closed to Washington recreational fisheries under this alternative (Figures 2-5, 2-6, 2-7, and 2-8). These additional yelloweye RCAs would require a change to the Pacific Halibut Catch Sharing Plan. Other new management measures are considered under Action Alternative 3 as follows:

Management Measures for Marine Areas 3 and 4 (Queets River to the U.S./Canada border)

Under Action Alternative 3, WDFW would prohibit retention of rockfish and lingcod seaward of a line approximating 20 fm from May 1 through June 30, except on days that halibut fishing is open, and from August 1 through September 30; and prohibit retention of rockfish and lingcod seaward of a line approximating 10 fm during the month of July.

Management Measures for Marine Area 2 (Leadbetter Pt. to the Queets River)

Under Action Alternative 3, WDFW would prohibit retention of rockfish and lingcod seaward of a line approximating 30 fm from the lingcod opening day through July 31.

Management Measures for Marine Area 1 (Oregon/Washington border to Leadbetter Pt.)

There is very little yelloweye and canary rockfish (0.03 mt and 0.02 mt, respectively, in 2005) caught in Marine Area 1; therefore, WDFW proposes to keep the status quo (No Action) bottomfish fishing regulations in place through 2007 and 2008.

2.2.3.4.7 Oregon Recreational Fisheries

Under Action Alternative 3a (there are two suboptions for the 2007-2008 Oregon recreational fishery under Action Alternative 3), the Oregon recreational groundfish fishery would be open all year, but restricted to depths shoreward of the 40 fm line from January 1 through May 31 and September 1 through December 31, and shoreward of the 25 fm line from June 1 through August 31. The marine fish daily bag limit would be reduced to 5 marine fish; however flatfish, including Pacific sanddabs, would be managed under a separate 25 fish daily bag limit for all flatfish species. Other changes to status quo (No Action) management measures under this alternative include a decrease in the lingcod minimum size limit to 22 inches and the expanded Stonewall Banks closure described under Action Alternative 1 would apply to the recreational Pacific halibut fishery, restricting targeting of Pacific halibut in this area. Additionally, retention of groundfish would be prohibited in this area, regardless of trip target. All other management measures under this alternative are the same as under the No Action Alternative.

Under Action Alternative 3b, the Oregon recreational groundfish fishery would be open all year shoreward of the 40 fm line. The marine fish daily bag limit would be reduced to 5 marine fish; however flatfish, including Pacific sanddabs, would be managed under a separate 25 fish daily bag limit for all flatfish species. Other changes to status quo (No Action) management measures under this alternative include a decrease in the lingcod minimum size limit to 22 inches and the expanded Stonewall Banks closure described under Action Alternative 1 would apply to the recreational Pacific halibut fishery, restricting targeting of Pacific halibut in this area. Additionally, retention of groundfish would be prohibited in this area, regardless of trip target. All other management measures under this alternative are the same as under the No Action Alternative.

2.2.3.4.8 California Recreational Fisheries

Under Action Alternative 3, the five RLMAs described under the No Action Alternative will be used to manage 2007-2008 California recreational groundfish fisheries. The status quo (No Action) California recreational management measures under Action Alternative 3 include the following:

- Regulations apply to groundfish (with sanddab fishery exception) and associated state-managed species (rock greenling, California sheephead, and ocean whitefish).
- The sport fishery for sanddabs, using gear specified in federal and state regulations (size #2 hooks or smaller), is exempt from the season closures and depth restrictions placed on other federally-managed groundfish.
- Retention of species in the Other Flatfish complex is allowed when fishing with size #2 hooks or smaller (≤ 11 mm from point to shank) for Pacific sanddabs.
- A two-fish bocaccio sublimit is included in the 10-fish RCG daily bag limit.
- No retention of cowcod, canary, or yelloweye rockfish.
- Notwithstanding other fishing opportunities for groundfish, lingcod may not be retained during January, February, March, and December.
- Waters of Cordell Bank less than 100 fm in depth are closed to fishing at all times.
- All divers (boats permitted while diving for rockfish or other closed species during closed periods provided no hook and line gear on board or in possession while diving to catch rockfish) and shore-based anglers would be exempt from the seasonal closures and depth restrictions for rockfish, greenlings, California scorpionfish, California sheephead, and ocean whitefish.

California recreational groundfish management measures that differ from status quo under Action Alternative 3 include the following:

- Combined rockfish + cabezon + greenling (RCG) complex daily bag limit of 10 fish, of which two can be a cabezon and two can be a greenling of the genus *Hexagrammos*.
- Lingcod daily bag limit of 3 fish, but with a minimum size limit of 22 inches.

Additionally, seasons and depth restrictions by RLMA under Action Alternative 3 are described below and summarized in Table 2-23.

Table 2-23. Summary of 2007-2008 California recreational groundfish seasons and depth restrictions by region under Action Alternative 3.

RCG SEASON BY REGION

Region	Jan	Feb	Mar	Apr	May	Jun	July	Aug	Sep	Oct	Nov	Dec
North region	---	---	---	---	> 40fm Closed							
North Central	---	---	---	---	---		> 40fm Closed					
South Central - Monterey	---	---	---	---	> 40fm Closed							
South Central - Morro Bay	---	---	---	> 40fm Closed							---	---
South Region*	---	---	> 60fm Closed									

NOTES AND KEY:

Shore fishing allowed in all waters in all months

RCG = Rockfish, cabezon, greenlings

--- = Closed to boat-based fishing for RCG

Only half of month is open

*In the South Region, CA scorpionfish is open 12 months: 0-40 fm in January-February and 0-60 fm March-December.

Southern RLMA (U.S./Mexico Border to Point Conception)

The California recreational groundfish fishery regulations south of Point Conception under Action Alternative 3 are the same as described above except for the following changes:

- Groundfish other than California scorpionfish, but including select nongroundfish species (California sheephead and ocean whitefish) open March through December shoreward of the 60 fm line and otherwise closed.
- California scorpionfish open year-round, but restricted to depths ≤40 fm in January and February, and ≤60 fm during March through December.

Southern South-Central RLMA (Point Conception to Lopez Point)

The California recreational groundfish fishery regulations for the area between Point Conception and Lopez Point under Action Alternative 3 would be the same as described above except for the following changes:

- Groundfish including select nongroundfish species (California sheephead and ocean whitefish) open April through mid-October shoreward of the 40 fm line and otherwise closed.

Northern South--Central RLMA (Lopez Point to Pigeon Point)

The California recreational groundfish fishery regulations for the area between Lopez Point and Pigeon Point under the Action Alternative 3 would be the same as described above except for the following changes:

- Groundfish including select nongroundfish species (California sheephead and ocean whitefish) open May through December shoreward of 40 fm and otherwise closed.

Northern Central RLMA (Pigeon Point to Cape Mendocino)

The California recreational groundfish fishery regulations for the area between Pigeon Point and Cape Mendocino under the Action Alternative 3 would be the same as described above except for the following changes:

- Groundfish including select nongroundfish species (California sheephead and ocean whitefish) open mid-June through December shoreward of 40 fm and otherwise closed.

Northern RLMA (Cape Mendocino to the California/Oregon Border)

The California recreational groundfish fishery regulations for the area between Cape Mendocino and the California/Oregon border under the Action Alternative 3 would be the same as described above except for the following changes:

- Groundfish and ocean whitefish open in May through December shoreward of 40 fm and otherwise closed.

2.2.3.5 The Council-Preferred Action Alternative

This alternative will be decided at the June Council meeting in Foster City, CA.

2.2.3.5.1 Limited Entry Trawl Fisheries

2.2.3.5.2 Limited Entry Fixed Gear Fisheries

2.2.3.5.3 Open Access Fisheries

2.2.3.5.4 Nearshore Commercial Fisheries

2.2.3.5.5 Tribal Fisheries

2.2.3.5.6 Washington Recreational Fisheries

2.2.3.5.7 Oregon Recreational Fisheries

2.2.3.5.8 California Recreational Fisheries

2.2.3.6 Alternatives Considered, But Eliminated From Detailed Study

2.3 Comparison of the Environmental Consequences

To be completed after June 2006 when the Council will adopt a preferred alternative.

2.4 Social Net Benefit Analysis

To be completed after June 2006 when the Council will adopt a preferred alternative.

4.2 Criteria Used to Evaluate Impacts

A primary goal of the groundfish FMP is to rebuild to or maintain spawning stock biomass of groundfish stocks and stock complexes at B_{MSY}. Two critical considerations in evaluating alternative harvest levels relative to accomplishing this goal are the uncertainty of management measures to limit total fishing-related mortality to prescribed levels and the uncertainty in our understanding of stock status and productivity. In other words, the risks of allowing higher harvests to provide increased socioeconomic benefits (see Chapter 7 for an evaluation of socioeconomic impacts) need to be evaluated by the effectiveness of harvest monitoring systems to accurately determine total fishing-related mortality and assessment uncertainty. An additional consideration for depleted stocks is the tradeoff of duration of rebuilding vs. the amount of allowable harvest or total fishing-related mortality. All of these considerations are used to develop criteria for evaluating biological impacts to groundfish stocks.

Systems for monitoring groundfish mortalities (landings plus discard mortalities) on the West Coast vary in their effectiveness depending on whether the species is primarily caught in commercial or recreational fisheries and how well at-sea discards are monitored. In general, fishing-related mortalities of commercially caught species are better known than those for stocks primarily caught by recreational fisheries. This is because commercial landings are recorded on fish receiving tickets, which are used to document the weight and ex-vessel value of landed catch, while recreational catches are mostly monitored using a random, stratified census of anglers. The degree of at-sea monitoring of discards also varies by fishing sector with the limited entry at-sea whiting trawl sector having the highest at-sea observer rates; followed by limited entry bottom trawl (including shoreside whiting); limited entry fixed gear; open access; California commercial passenger fishing vessels (CPFV or California recreational charter); and California (non-CPFV), Oregon, and Washington recreational. The treaty tribes report that their fisheries are observed at a high rate because their fisheries are full retention fisheries for rockfish species.

Assessment uncertainty is another evaluation criterion for evaluating stock impacts. In general, assessments of species that are adequately sampled by a reliable source of fishery independent abundance information tend to be more robust with respect to estimating stock trends and abundance {NRC, 1998}. On the West Coast, groundfish surveys have typically been conducted using bottom trawl gear randomly stratified over latitudinal and depth strata along the continental shelf and slope {Lauth 2000, Weinberg et al. 2002}[2]. The results from these surveys are typically the key inputs to the stock assessments for West Coast groundfish stock assessments. For example, indices of abundance from the triennial trawl survey were used in 15 of the 22 assessments in Table 4-2, and 7 assessments used slope survey data. These surveys are also often the source of the biological data used to estimate life history parameters. For species that are not well sampled by traditional survey data, such as cowcod and yelloweye rockfish, other temporal indices of abundance are used to tune assessments. Many such indices, particularly fishery-dependent indices such as commercial or recreational catch per unit effort (CPUE) trends, tend to be associated with higher levels of uncertainty. Fishery-dependent data are often less reliable than fishery-independent data for a variety of reasons; for example, catch rates may be

2 The NMFS Alaska Fisheries Science Center originally implemented a full trawl survey completed every three years on the West Coast and hence called the "triennial" survey, data from this survey span from 1977 to 2004. The Alaska Center also conducted slope surveys beginning in 1984, although these surveys had varying temporal and spatial coverage. Since 1998, the NMFS Northwest Fisheries Science Center has conducted an annual bottom trawl survey of the West Coast slope, and since 2003 this survey has sampled both shelf and slope habitats. This survey (referred to as the "combined" survey) will be the key source of fishery independent information in the future. Currently, information from all of these surveys are typically used to tune West Coast groundfish stock assessments.

stable in the face of stock declines as a result of increasing fishing power or changing spatial patterns in effort {Hilborn and Walters 1992, Walters 2003}. Furthermore, management measures can substantially alter the integrity of fishery-dependent data, particularly in response to actions by managers to reduce or control effort. Consequently, assessments for data-poor species such as cowcod and yelloweye rockfish, which are based on highly uncertain catch reconstructions and recreational CPUE time series to inform biomass trends, are associated with much greater levels of uncertainty relative to other groundfish species' assessments.

As illustrated throughout section 4.1, model uncertainty is also a key factor in considering how the results of stock assessments are used. The perception of stock status and productivity for many stocks, particularly those for rebuilding species, often changes substantially between stock assessments. Such changes can be a result of a range of technical factors, including how a given assessment model is structured, the assumptions used to fix or estimate key parameters (i.e., whether parameters such as natural mortality and steepness are fixed, estimated freely, or estimated with an informative prior), and the evolution of methods for developing time series and estimates of uncertainty from different sources of raw data. As the population dynamics of target species themselves are responsive to a mix of complex (and typically poorly understood) biological, oceanographic and interspecific interactions, new sources of information (e.g., new data sets, extensions of existing data sets, incorporation of environmental factors into assessments) can also result in changes in parameter estimates and model outputs. Consequently, estimates of depletion levels and stock status can vary substantially between assessment cycles; as illustrated by the increase in the estimated OY of bocaccio from ≤20 mt to 250 mt between 2002 and 2003, and the perception from the most recent widow rockfish assessment that this stock may not have ever been below the overfished threshold of 25% of initial biomass. In such cases, the most plausible result from the assessment should still be viewed as highly uncertain and the risks associated with management decision-making should account for this uncertainty.

A logical conclusion for evaluating potential management decisions using highly uncertain assessment results is more precaution may be needed to avoid future problems if assumptions regarding stock status are overly optimistic. For example, Punt {2003} developed a simulation model to evaluate how well a particular set of management rules actually achieved management goals in the face of measurement error, process error, and model uncertainty. The study simulating the outcomes under a given set of rules for assessing progress, with regard to the number of times a rebuilding plan was revised, the average catch during the years that the resource was being rebuilt, and the ratio of the number of years that it took for a stock to rebuild over the number of years it was expected to take a stock to rebuild based on the original rebuilding plan. In general, results indicated that greater stability tended to be associated with smaller OYs (which were based on more conservative criteria for achieving success), and that frequent revisions to harvest rates that accompanied new assessments could lead to both a less stable management regime and longer overall rebuilding times.

The predicted times to rebuild the seven depleted species subject to FMP Amendment 16-4 relative to the amount of allowable harvest (to avoid significant or disastrous socioeconomic impacts to fishing communities) are determined in new rebuilding analyses recommended by the SSC in 2005 or, in the case of yelloweye rockfish, in 2006. These rebuilding analyses probabilistically evaluate allowable harvest vs. rebuilding duration relative to the maximum allowable time to rebuild (T_{MAX}) under the current National Standard Guidelines. T_{MAX} is defined as the minimum estimated time to rebuild with no allowable fishing-related mortality (T_{MIN}) plus one mean generation time. The soundness in defining T_{MAX} this way is that one mean generation, or the number of years predicted for a spawning female to replace herself in the population, is a relative biological index of stock productivity. Therefore, the range of allowable rebuilding periods is bounded by the biological limit of T_{MIN} or $T_{F=0}$[3], where all stock

3 T_{MIN} and $T_{F=0}$ are both predicted rebuilding periods in the absence of fishing-related mortality to the stock.

mortality is natural mortality and a scientifically-derived upper limit linked to stock productivity. Stocks exhibiting low productivity will necessarily have longer predicted rebuilding periods due to longer mean generation times. The probability of rebuilding by T_{MAX} (P_{MAX}) is therefore one of the criteria used to evaluate risk of alternative harvest levels for depleted species, since it is a metric that relates management risk (i.e., risk of not meeting the rebuilding target by T_{MAX}) to a stock's relative productivity.

However, given the guidance from the Ninth Circuit District Court not to follow a formulaic approach for deciding a stock's rebuilding plan, another criterion for evaluating alternative rebuilding plans is to use the extended duration of the predicted rebuilding period relative to $T_{F=0}$. This criterion may be more responsive to the court order to rebuild as quickly as possible (i.e., $T_{F=0}$) while considering the needs of fishing communities. The needs of fishing communities are considered by allowing some harvest of a depleted species as unavoidable bycatch while targeting healthy stocks. Any allowable harvest of a depleted species predicts a longer rebuilding period than $T_{F=0}$. How much longer rebuilding is extended from $T_{F=0}$ is therefore a sensible evaluation criterion.

4.3 Discussion of Direct and Indirect Impacts

This section evaluates and discusses direct and indirect impacts of OY alternatives and action alternatives (management measures) on affected species. A retrospective analysis of past management actions and resulting impacts is critical in this exercise to understand potential future impacts. To that end, final total catch estimates by fishing sector are provided for 2004 West Coast groundfish fisheries (Table 4-6) and "near-final" 2005 total catch estimates (Table 4-7). The reason 2005 catches are not considered final is that the full year of WCGOP observation data is not yet available and analyzed to reconcile at-sea discards; a process which has been completed for 2004 fisheries. In lieu of these data, projected impacts from the various sector bycatch models employed by the GMT to track discards relative to known landings is used. It is anticipated that final 2005 catch estimates will be available by the end of 2006, which is too late to be incorporated in the final EIS.

Impacts of OY alternatives are also compared between action alternatives and with the No Action Alternative and evaluated using the criteria described in section 4.2.

These terms are distinguished by when the F=0 strategy is considered. T_{MIN} is the predicted time to rebuild if all fishing-related mortality is eliminated from the onset of rebuilding (usually the year after the stock is declared overfished) and $T_{F=0}$ is the predicted duration of rebuilding if all fishing-related mortality to the stock is eliminated starting at the onset of the next available management cycle. $T_{F=0}$ is typically longer than T_{MIN} since some fishing-related mortality is typically allowed under a Council's rebuilding plan to avoid disastrous short term economic impacts from eliminating harvest. However, unless the stock has just been declared overfished, $T_{F=0}$ is the shortest possible time to rebuild the stock given our current understanding of the stock's productivity.

Table 4-5. Estimated total mortality (mt) of major West Coast groundfish species from commercial, tribal, and recreational fishing during 2003.

a/ Preliminary estimates of total catch mortality based on species discard assumptions used when the OYs were set. These assumptions are currently being revised using data from the West Coast Groundfish Observer Program.
b/ Preliminary estimated discard mortality in the commercial fishery. Preliminary trawl discard calculated by applying discard mortality rates from combined 2001-03 West Coast Groundfish Observer data to 2002 trawl logbook data, by area and depth strata. Discard totals estimated for tows recorded in logbooks is expanded using state-specific ratios of fish ticket landings to retained logbook catch. Because tows conducted under Exempted Fishing Permits could not currently be completely removed from logbooks and fish tickets, applying fleetwide discard rates to these tows may overstate discard for some shelf species. In an effort to minimize this problem, rockfish discard from target tonnage caught within the RCA off Oregon was estimated using bycatch rates from that EFP. Since the Washington EFP included full retention of shelf rockfish, no at-sea discard of these species was estimated for tows occurring within the RCA off Washington, or on tows that exceeded the 2-month allowance of arrowtooth flounder outside the EFP. This column also includes at-sea discards of rebuilding species. Preliminary fixed-gear discard in the directed sablefish fisheries is calculated by applying discard mortality rates from combined 2001-03 West Coast Groundfish Observer data to northern sablefish landings data. No logbooks are available for fixed-gear vessels. Because of limited geographic coverage of available data, fixed-gear discard amounts for species off central California are not well estimated at this time.
c/ Includes shoreside commercial and tribal landings from PacFIN, observed total catch including estimated discards in the at-sea whiting fishery, and RecFIN recreational catch plus observed discard mortality (A+B1).
d/ Discards of whiting are estimated from observer data and counted towards the OY inseason.
e/ Includes "unspecified thornyheads" allocated based on ratios estimated from California landings and At Sea north/south ABCs.

a/ Non-trawl discard includes estimates for the fixed gear nearshore and sablefish fisheries. Sablefish fishery estimates are based on observations of the primary limited entry, fixed gear season. Since few observations were made in this fishery south of Ft. Bragg, CA, discard estimates for southern species, such as bocaccio and cowcod, should not be viewed as complete.

b/ The Pacific Council's Groundfish Management Team produces a bycatch scorecard with the purpose to account for all sources of expected mortality for species that are managed under rebuilding plans. Remaining values are estimates of total mortality in EFPs and research catches.

4.3.1 *Depleted Groundfish Species*

4.3.1.1 Impacts of Optimum Yield Alternatives

Each OY alternative analyzed for depleted groundfish is evaluated using the criteria discussed above in section 4.2. In summation, these evaluation criteria are relative catch monitoring uncertainty, relative assessment uncertainty, the estimated rebuilding probability, and the extended duration of rebuilding. The tradeoff of available harvest under alternative OYs for depleted species and predicted rebuilding times for these species (i.e., the extended duration of rebuilding) is also described in section 2.1.1.1 and depicted in Table 2-3 and Figure 2-2.

This section also describes the types of strategies that should be considered in a groundfish species' rebuilding plan. As OYs decrease across the range of alternatives, more precautionary management measures and risk-averse strategies need to be employed to reduce total fishing-related mortality to prescribed levels.

General Rebuilding Strategies

Harvest Limits (Harvest Guidelines or Quotas)

The Council sets OYs for each depleted stock (among other managed species). Although resulting OYs are considered harvest guidelines, the Council has treated them as hard limits on total fishing mortality for overfished species. For example, they have closed fisheries late in the year if a depleted species' OY is projected to be exceeded. In some cases, OYs for co-occurring healthy groundfish stocks are reduced to limit the incidental mortality of one or more depleted groundfish species.

Permits, Licenses, and Endorsements

Participation in the Washington, Oregon, and California commercial groundfish fishery was partially limited beginning in 1994 when the federal vessel license limitation program was implemented (Amendment 6). Subsequently, Amendment 9 further limited participation in the fixed-gear sablefish fishery by establishing a sablefish endorsement. There is currently no federal permit requirement for other commercial participants (fishers or processors) or recreational participants (private recreational or charter). A buyback of vessels in the limited entry trawl fishery, and associated permits, was completed in 2003. This reduced participation in this sector by roughly one-third.

Trip Landing and Frequency Limits

Cumulative trip limits have been a key fixture of groundfish management for many years. Currently, these limits set for stocks, stock complexes, and species groups dictate the total amount of fish that may be landed during a one- or two-month period. Separate limits are established for the limited entry trawl, limited entry fixed gear, and open access sectors. Landing limits on target species may be adjusted in order to limit coincident catch of depleted species. A limited entry trawl trip limit of 100 pounds per month was established in 2004 for large footrope gear, which may only be used seaward of the Rockfish Conservation Area (RCA).

Seasons

Specification of different seasonal fishing opportunities by region is a management tool increasingly used to limit fishing mortality in West Coast recreational groundfish fisheries. Seasons can be adjusted inseason and often vary by the depths open to fishing to fine tune the balance between fishing opportunities and conservation of depleted species.

Area Closures

Beginning in 2002, RCAs came into use as a way of decreasing bycatch of depleted species. The sector-specific RCAs encompass the depth ranges where bycatch of depleted species is most likely to occur, based on information retrieved from log books, the at-sea observer program, catch records, and trawl survey data; and fishing by designated groundfish fishery sectors is prohibited within its boundaries. The boundaries vary by season and fishery sector, and may be modified in response to new information about the geographic and seasonal distribution of bycatch. Additionally, there are discrete RCAs designed to protect certain species such as cowcod and yelloweye rockfish (two Cowcod Conservation Areas exist south of 34°27' N latitude and one Yelloweye RCA exists in waters off northern Washington). These "species-specific" RCAs also provide a measure of protection for other co-occurring depleted groundfish species.

Gear Restrictions in Trawl Fisheries

Definitions of legal gear types and restrictions on mesh size in trawl gear have been part of the FMP since its inception. A cod end 4.5 inch minimum mesh size has been specified for groundfish trawl gear for many years to reduce the bycatch mortality of juvenile groundfish species and fish that are too small to be marketable. Since 2000, restrictions have been put on the use of trawl nets equipped with large footropes. By using large footropes with heavy roller gear, bottom trawlers can access rocky habitat on the continental shelf. In areas shoreward of the RCA large footrope gear is prohibited, preventing trawlers from accessing rocky habitat in these shallower depths. In areas seaward of the RCA, either small or large footrope gear may be used, although large footrope gear is the preferred gear type in these depths since small footropes tend to dig into the softer sediments of the slope and abyssal plain. In addition, cumulative trip limits have been structured in recent years to encourage vessels to fish exclusively in deep water where some overfished species are less likely to be encountered. Trawl vessels were allowed to use all these legal gear configurations during any given cumulative limit period. However, in 2004 trawl vessels which used the small footrope configuration were restricted to lower cumulative trip limits for target species in comparison to vessels using large footrope configurations. These measures encouraged fishing exclusively in deeper water to take advantage of the higher limits afforded this gear type. In 2005 and 2006, trawl vessels were not restricted with respect to gear-specific cumulative landing limits in any one period, but they were restricted to the area they could fish, either shoreward or seaward of the RCA, in any one period. Large or small footrope trawls were allowed seaward of the RCA, while only small footrope trawls were allowed shoreward of the RCA south of 40°10' N latitude and selective flatfish trawls allowed shoreward of the RCA north of 40°10' N latitude (selective flatfish trawls were also allowed to be used south of 40°10' N latitude, but were not mandated shoreward of the RCA as they were in the north). The selective flatfish trawl net is configured with a cut back headrope, low rise, and a small footrope, a design shown to substantially reduce catches of some rockfish species while more efficiently catching target flatfish species. This is because most rockfish species rise to escape an approaching trawl net, while flatfish species tend to dive. The rockfish escape due to the low rise and cut back headrope. While this gear has been tested and mandated shoreward of the RCA since 2005 in waters north of 40°10' N latitude, it has not been fully tested in waters south of 40°10' N latitude. Therefore, the behavior and bycatch rates of southern rockfish species, such as bocaccio, when encountering a selective flatfish trawl are unknown at this time. However, this gear may also be effective at reducing bycatch of southern rockfish species in the bottom trawl fishery and should be explored further.

Bycatch reduction devices (BRDs), also known as fish excluders, are mandated for the exempt trawl fishery targeting pink shrimp. Pink shrimp trawls historically had a high bycatch of rockfish. ODFW researched various BRD configurations to determine those devices that significantly reduced rockfish bycatch without an overall reduction in pink shrimp catch efficiency. Now specific hard grate BRDs and other accepted configurations are mandated for West Coast pink shrimp trawls and resulting rockfish bycatch has been reduced dramatically.

Gear Restrictions in Fixed Gear Fisheries

Limited entry and open access fixed gear fisheries on the West Coast use hook and line gears, longlines (both vertically and horizontally deployed on the bottom or suspended off the bottom), and pots/traps to target groundfish. Rockfish bycatch has been shown through WCGOP observations to be much lower in pots and traps targeting groundfish than line gears. While a substantial portion of the fixed gear fleets use pots and traps, a significant amount of line gear is used to target nearshore groundfish species and sablefish. Five of the seven rockfish species currently managed under rebuilding plans are shelf species vulnerable to capture using line gears. The two depleted slope species, darkblotched rockfish and POP, are rarely caught using fixed gears. Therefore, measures that would reduce the use of line gears in West Coast shelf areas, where these depleted rockfish species occur, should be considered when developing long term rebuilding strategies. Alternatively, how line gears are fished should be explored more thoroughly since some line gear configurations and fishing strategies may also reduce the bycatch of depleted groundfish species.

Size and Bag Limits

Minimum size limits are specified for many depleted groundfish species to protect recruiting and premature fish from targeted harvest.

Bag limits are a daily limit of species allowed to be retained by anglers. These measures are used for recreational fisheries to limit mortality of depleted groundfish species. In some cases, no retention is allowed for depleted groundfish species as a means to eliminate any potential targeting that might otherwise occur.

Fishery Monitoring and Bycatch Estimation

All commercial groundfish landings are monitored through a fish ticket system requiring reporting by buyers and processors. Bycatch has become a crucial component of total fishing mortality for depleted species. In the last five years, harvest limits or OYs have evolved from an allowed landing limit to a total mortality limit where at-sea dead discards are also counted against the OY. NMFS implemented the West Coast Groundfish Observer Program (WCGOP) in August 2001, and these data were first used to estimate total fishing mortality beginning in mid-2003. The limited entry trawl sector was the first commercial sector to be managed using WCGOP data to estimate discards. In 2004 bycatch modeling was expanded to the primary sablefish fishery prosecuted by limited entry fixed gear vessels as WCGOP data became available for that sector. In 2005 WCGOP data was used to model bycatch of groundfish species in nearshore commercial fisheries in California and Oregon. As more observer data from different fishery sectors become available, further model extensions will be developed to more accurately estimate bycatch of depleted species in these sectors.

Recreational fishery monitoring and bycatch estimation is a state responsibility and each West Coast state employs a different system. Washington and Oregon employ a random, stratified census of anglers to estimate catch and effort with relative precision. In California, where the coastline is much longer, recreational participation much greater, and the larger number of ports, recreational monitoring and catch estimation was done through a federal census known as Marine Recreational Fisheries Statistical Survey (MRFSS). The MRFSS survey, designed to look only at national trends of marine angler participation, is not precise enough to manage the low harvest guidelines used in recreational fishery management to help rebuild depleted stocks. Therefore, in recent years, efforts have been made to improve recreational fishery sampling in California. For instance, in 2001 the Pacific States Marine Fisheries Commission (PSMFC), with support from NMFS, began a new survey to estimate party/charter boat (commercial passenger fishing vessel [CPFV]) fishing effort in California. This survey differed from the traditional MRFSS telephone survey of anglers to determine CPFV trips by two-month period. The survey sampled 10% of the active CPFV fleet each week to determine the number of trips taken and the anglers carried on each trip. This 10% sample was then expanded to make estimates of total angler trips for Southern California and Northern California. However, the requisite precision for managing the low OYs of overfished species like canary rockfish and bocaccio was still lacking. Fishery scientists from the CDFG and the PSMFC designed a new program for sampling California's recreational fisheries, incorporating both the comprehensive coverage of the MRFSS program and the high quality sampling of CDFG's Ocean Salmon Project. The goal of this new program, the California Recreational Fisheries Survey (CRFS), was to produce in a timely manner marine recreational, fishery-based data needed to sustainably manage California's marine recreational fishery resources. The CRFS program, implemented in January 2004, increased the timeliness and accuracy of recreational fisheries data to more effectively monitor catches inseason, estimate take of species of concern, develop harvest guidelines, produce higher quality fishery-dependent indices for stock assessments, and provide other information critical to management decisions.

Bocaccio (in Waters off California South of 40°10' N Latitude)

Specific Bocaccio Rebuilding Strategies

Bocaccio OYs, compliant with the adopted rebuilding plan, have been specified for managing this stock. In most years (with the exception of a slight overage in 2003 when the OY was ≤20 mt, or about 6.5% of the 2006 OY), bocaccio total mortality has been well below the specified OY (Tables 4-5, 4-6 and 4-7). The Council and NMFS have also adopted the practice of reducing the chilipepper rockfish OY from the ABC, despite the healthy abundance of this stock, as a precautionary measure to reduce the incidental mortality of co-occurring bocaccio. Reducing the chilipepper rockfish OY for the purpose of reducing bocaccio mortality may be less necessary given the advent of managing fisheries using depth-based RCAs.

Commercial bocaccio fishery impacts are managed using a combination of area closures (discussed below) and variable cumulative landing or trip limits. A limited entry trawl trip limit of 100 pounds of bocaccio per month was established in 2004 for large footrope gear to accommodate unavoidable bycatch, which may only be used seaward of the RCA. Limited entry fixed gear and open access limits vary by two-month period and north and south of Point Conception within a range of being closed in some periods to 300 pounds per two-month period. Under the No Action Alternative, trip limits for co-occurring southern shelf rockfish species, including chilipepper rockfish, have been adjusted to limit the incidental harvest of bocaccio.

Recreational bocaccio impacts are managed using a combination of area closures (discussed below), minimum size and daily bag limits (discussed below), and seasons. California manages its recreational fisheries according to five sub-areas (referred to as Rockfish/Lingcod Management Areas) defined by latitudinal boundaries. Different closed seasons have been applied, and modified inseason, primarily to limit canary rockfish catches, the most constraining of the overfished species; but these actions also serve to limit recreational catches of bocaccio.

Area closures or RCAs are one of the more effective rebuilding strategies for reducing bocaccio mortalities. South of 40°10' N latitude, the seaward boundary of the RCA or the limited entry trawl sector is 150 fm in 2006, and the shoreward boundary varies between 75 fm and 100 fm, depending on period. Around offshore islands south of 34°27' N latitude the inner boundary extends to the shoreline. The seaward boundary is the same for limited entry fixed gear and open access sectors; the shoreward boundary either 20 fm, 30 fm, or 60 fm, depending on area and period. California has implemented, and modified inseason, closed areas in their recreational management, restricting fisheries to areas shoreward of boundaries at 20 fm, 30 fm, or 60 fm, depending on sub-area and month. Additionally, the existing Cowcod Conservation Areas south of 34°27' N latitude, where sport and commercial bottom fishing is prohibited, provide significant protection for bocaccio. Any additional RCAs south of 40°10' N latitude in the 15-180 fm zone will provide some additional protection of bocaccio. The greatest density of bocaccio occurs south of 34°27' N latitude in the 54-82 fm zone; therefore, any new RCAs in the Southern California Bight in these depths should provide the most conservation benefit. However, bocaccio are less sedentary than rockfish species such as cowcod and yelloweye. Smaller, discrete RCAs may therefore provide incrementally less conservation benefit for bocaccio relative to more sedentary species.

Minimum size and daily bag limits are used to restrict targeting of juvenile bocaccio and total take of bocaccio, respectively. A 10-inch minimum size limit is applicable to bocaccio in waters off California. Under the No Action Alternative, California has implemented a 10-fish bag limit for the rockfish-cabezon-greenling stock complex. Within the 10-fish bag limit there are bocaccio sub-limits of two fish north of 40°10' N latitude and one fish south of 40°10' N latitude.

Evaluation of Optimum Yield Alternatives

Bocaccio rebuilding schedules across the analyzed OY alternatives range from 0-11 years relative to the shortest predicted time to rebuild the stock of 2021 (i.e., 2021-2032) (Table 4-8). Rebuilding probabilities range from 50% for the highest OY alternative of 424 mt, which is the legal upper limit of possible OYs that can be considered, to 95.8% for the zero-harvest alternative. A significant amount of the total mortality of bocaccio now occurs in the California recreational fishery, the sector with the largest bocaccio take in recent years (Tables 4-5, 4-6 and 4-7), which leads to a high catch monitoring uncertainty. While California recreational catch time series are important fishery-dependent indices in the bocaccio stock assessment, the MacCall {2006} assessment is considered relatively certain given generally good data quality and consistency.

The range of preferred OYs specified by the Council in April 2006 of 40-218 mt compares to the status quo 2006 OY of 309 mt. Rebuilding is extended by less than a year from the shortest possible time ($T_{F=0}$) under the harvest rate used to determine the 40 mt alternative to 5 years under the preferred High OY alternative of 218 mt, which is 3 years shorter than under the status quo harvest rate. The range of rebuilding probabilities (P_{MAX}, or the probability of successful rebuilding in the maximum allowable time under National Standard 1 guidelines) for these preferred OYs are 77.7% to 94.3%. Last year, the SSC recommended a general rebuilding policy of establishing harvest rates that lead to rebuilding probabilities of about 80%[4]. The preferred OY range for bocaccio approximates this P_{MAX} "target".

---

4 This recommendation came under the consideration of rebuilding revision rules the Council and its advisors crafted in 2005. The Ninth Circuit Court of Appeals ruling on the challenge to the darkblotched rebuilding plan may have obviated the need for these revision rules by imposing a standard of specifying the shortest possible rebuilding periods while considering the needs of fishing communities. However, as described in section 4.2, P_{MAX} is still a reasonable criterion for evaluating future risks of overharvest given a stock's relative productivity.

Table 4-8. Evaluation of alternative 2007-2008 bocaccio OYs relative to the criteria described in section 4.2.

Evaluation Criterion	OY (mt)						
	No Action OY Alt. (2006 OY)	**OY Alt. 1**	**Pref. Low OY Alt.**	**OY Alt. 2**	**OY Alt. 3 (Pref. High OY)**	**OY Alt. 4**	**OY Alt. 5**
	309	0	**40**	149	**218**	315	424
Catch monitoring uncertainty	High uncertainty due to a significant recreational catch component using MRFSS data (prior to 2004). [a/]						
Assessment Uncertainty	Relatively certain due to generally good data quality and consistency.						
Rebuilding Probability (P_{MAX})	68.4%	95.8%	94.3%	84.4%	77.7%	67.8%	50%
Rebuilding Duration Beyond $T_{F=0}$ (yrs.)	8	0	0.8	3	5	8	11

a/ Catch monitoring uncertainty has improved with the implementation of the California Recreational Fisheries Survey (CRFS) in 2004. However, until CRFS is fully evaluated and catch estimates are provided in a more timely fashion, catch monitoring uncertainty is still regarded as relatively high.

The recent history of bocaccio assessments is one marked with volatile swings in our understanding of stock status and productivity driven largely by infrequent recruitment events. MacCall {2002} characterized the stock as severely depleted and unlikely to rebuild within T_{MAX} under a zero-harvest strategy. However, evidence of a significant recruitment of the 1999 year class was validated in the bocaccio assessment conducted the following year {MacCall 2003}. The emerging understanding is stock productivity may better be characterized as one driven by rare large recruitments. Minimizing the mortality of these large year classes promises to rebuild the stock fastest. In the current regime of depth-based management, the stock is most vulnerable in the juvenile phase when they occur in shallow waters and are incidentally caught in nearshore commercial and recreational fisheries. However, as bocaccio mature, they migrate to deeper waters where the current RCA restricts those fisheries which are most likely to take adult bocaccio and other co-occurring depleted rockfish. There is some indication that bocaccio recruitment typically occurs from Santa Barbara to Santa Cruz, and is rare south of Ventura, with no evidence of separate southern California recruitment events {MacCall 2003}. Therefore, if this recruitment pattern persists in the future, large recruitment events may be indicated by large incidental catches in central California nearshore fisheries. As recent management experience also indicates, avoiding juvenile bocaccio in these waters during such times is difficult.

Given this recruitment dynamic, what harvest rate provides the best balance of conservation needs without overly restricting California commercial and recreational fisheries? The new bocaccio assessment {MacCall 2006} shows exploitation rates have favored rebuilding since 1998. Those OYs fall within the preferred 2007-2008 OY range of 40-218 mt; however, only in 2003, when fisheries were severely restricted due to the pessimistic 2002 assessment result, was the annual total mortality of bocaccio ≤40 mt. The Preferred Low OY may still be difficult to manage with the same restrictive management measures used in 2003 in the event of another large recruitment. Clearly, a significant negative economic impact would be felt in California fishing communities under the Preferred Low OY harvest rate for a rebuilding "cost" of about four additional years of rebuilding under the Preferred High OY harvest rate. Even under the Preferred High OY of 218 mt, management measures would have to be restrictive, especially for nearshore commercial and recreational fisheries in central California, to stay within that harvest rate during years of large recruitments.

Evaluation of Action Alternatives

All the action alternatives contemplate a liberalization of the Cowcod Conservation Areas in the Southern California Bight. The CCAs currently protect more than just cowcod. An ongoing analysis of larval abundance data suggest that the current western CCA is a region of high abundance of bocaccio (S. Ralston, unpublished data), with the recent density particularly high relative to the long term (historical) distribution of bocaccio. Although the CCA was not implemented to protect bocaccio, the potential to increase catches of other rebuilding species that could result from modifications to CCA boundaries is presumably non-trivial.

Action Alternative 1 is the only action alternative estimated to stay within the Preferred Low OY Alternative for bocaccio. Most of the southern nearshore and shelf groundfish fisheries are constrained by the Preferred bocaccio Low OY, but especially those fisheries south of Pt. Conception. Action Alternatives 2 and 3 stay within the Preferred High OY Alternative for bocaccio.

As recent experience has shown, a strong year class will initially be caught in nearshore fisheries and hard to avoid. Higher OYs or a rebuilding framework that allows one-year overages if the long term harvest rate is not exceeded should be considered for this stock due to its episodic recruitment pattern.

Canary Rockfish

Specific Canary Rockfish Rebuilding Strategies

All of the rebuilding strategies used to reduce mortality of depleted species on the West Coast are used to help rebuild canary rockfish. Management of this stock tends to constrain more West Coast fisheries than any other groundfish stock since canary rockfish are distributed coastwide, are found in a variety of habitats, and are caught by a variety of different fishing gears. Canary rockfish are distributed from nearshore areas as juveniles out to about 150 fm as adults and are found at times suspended off the bottom or in atypical soft-bottom habitats for rockfish.

Management of canary rockfish under the harvest rates specified in the current rebuilding plan has been difficult and OYs have been exceeded in two of the last three years. The canary rockfish OY was exceeded by 4.5 mt in 2003, 11 mt in 2004, but, in 2005, total estimated mortality was less than the OY by about 7 mt. Tailoring the management regime to stay within the low harvest rates specified for canary and other depleted rockfish has been an evolutionary process of adaptive management. Better impact modeling with an increasing sample of depth-based discard rates from the WCGOP, gear restrictions (described below), capacity reduction of the limited entry trawl fleet, educational outreach to anglers to avoid canary and other depleted rockfish, restrictive limits and non-retention regulations, and, most importantly, depth-based RCA management have all contributed to improved performance of the management regime in managing canary rockfish.

Canary rockfish are not allowed to be retained in commercial and recreational hook and line or fixed gear fisheries and a small, incidental landing limit is allowed in the limited entry trawl fishery to account for unavoidable incidental bycatch. However, mandating the use of the selective flatfish trawl shoreward of the RCA north of 40°10' N latitude has helped reduce trawl bycatch. Attempts to test selective flatfish trawls south of 40°10' N latitude through implementation of Exempted Fishing Permits have not been successful due to lack of participation. Nevertheless, while these trawls are legal small footrope gear in the south and are volitionally used, experience with these trawls in the north compels consideration of mandating their use shoreward of the RCA south of 40°10' N latitude. At-sea monitoring of their efficacy in southern fisheries through the WCGOP may eventually validate their use in the south. Midwater trawls also catch canary rockfish. The directed midwater trawl fishery for yellowtail rockfish was discontinued in 2002 due to high bycatch of canary and widow rockfish. The midwater trawl fishery for whiting, which is not currently restricted in the trawl RCA, also catches canary rockfish. Implementation of a canary rockfish bycatch cap, where, if attained, the non-tribal fishery would close inseason even if whiting quotas have not been attained, has successfully reduced canary rockfish mortality. This strategy works for the whiting fishery because of near real-time bycatch reporting and open communication to the rest of the fleet when bycatch of canary occurs in any one area.

Use of broad based RCA configurations has had the most effect in reducing canary rockfish mortality and the concept of depth-based RCA management was largely compelled by this need. Figure 4-2 shows the catch per tow of canary rockfish in the NMFS bottom trawl survey, which can be used as an index of the stock's depth and latitudinal distribution. While there are some instances of canary rockfish occurring south of Pt. Conception at 34°27' N latitude, they are largely distributed north of Conception with the greatest density in northern waters off Washington. They are most often found in depths from 50-100 fm, but as can be seen in Figure 4-2 and from Table 4-1, they can occur in the 27-150 fm depth range. The core depth range of the trawl RCA is 100-150 fm, with both shoreward and seaward extensions of the RCA boundaries depending on seasonal conservation needs (canary rockfish and other depleted species tend to make seasonal shoreward-seaward migrations with more shallow distributions in the summer months). Most of the incidental trawl take of canary rockfish occurs shoreward of the RCA since the seaward boundary is often extended out to 200 fm to reduce mortality of darkblotched and POP. The non-trawl RCA extends out to 100 fm north of Cape Mendocino and 150 fm south. Most of the incidental non-trawl take of canary rockfish occurs seaward of the RCA in the north. More discrete area closures, such as those used to reduce mortality of cowcod and yelloweye rockfish, may also help reduce canary mortality, but will likely prove to be less effective for canary rockfish due to their mobility and apparent lack of site fidelity.

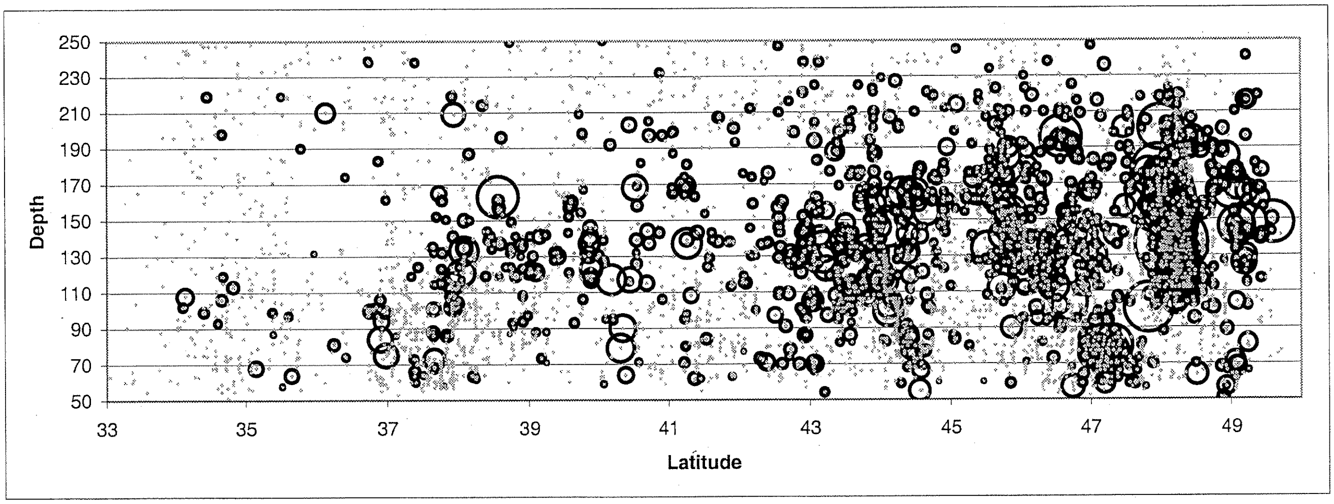

Figure 4-2. Catch per tow of canary rockfish in the bottom trawl survey. Dots are tows with zero catch. Circle size is proportional to the square root of catch per tow. Depth is in meters. Figure from the 2005 canary rockfish assessment (Methot and Stewart 2006)

Evaluation of Optimum Yield Alternatives

Table 4-9 shows the results of the evaluation of alternative canary rockfish OYs analyzed for 2007-2008 using the criteria described in section 4.2.

The canary rockfish OYs considered for 2007-2008 are based on a relatively certain stock assessment, despite the fact that recent recruitments are unknown due to a lack of recent fishery-dependent information (since the fishery has been structured to avoid canary) and the most recent years of the NMFS Northwest Fishery Science Center combined shelf/slope bottom trawl survey were not used. The second, "mop-up" STAR Panel, which reviewed the assessment in September 2005, also recognized the bottom trawl surveys may not provide an adequate index of abundance for shelf rockfish. For canary rockfish, the particular concern is that the level of stock depletion in trawlable habitat may not be reflective of overall population status. However, the historical data inputs to the assessment are more certain than for many of the other West Coast stocks and the 2005 assessment received a particularly high level of scientific scrutiny.

The relative certainty of the assessment result is tempered by a relatively uncertain total catch monitoring component, particularly since there is a significant portion of the total annual catch taken in recreational fisheries. Precautionary management of recreational fisheries to stay within the low canary OYs analyzed in this EIS will still be a predominant theme in rebuilding this stock and managing West Coast fisheries in the coming years. Uncertain total catch estimates will also lead to increasing assessment uncertainty as total removals become less certain and fishery-dependent trends used as assessment indicators of recruitment and biomass are less reliable.

Rebuilding probabilities (P_{MAX}) for alternative canary rockfish OYs are all low ranging from 66% for the zero-harvest alternative to 50% for the highest OY considered. The harvest rates for the Preferred Low and High OYs have a 55% and 58% probability of rebuilding by T_{MAX}, respectively, while the No Action OY predicts about a 55% probability of successful rebuilding by T_{MAX}. Such low rebuilding probabilities infer increased risk in canary stock rebuilding, a condition which recommends a precautionary management approach.

The estimated median time to rebuild the canary rockfish stock under the zero-harvest alternative is 2053. An additional 7 years of rebuilding is predicted under the harvest rate used to determine the Preferred Low OY of 24 mt and 10 years under the Preferred High OY of 44 mt. This compares to slightly more than 11 years under the status quo OY and an additional 18 years under the highest OY of 68 mt. Given that canary rockfish is the most constraining stock in the West Coast groundfish fishery, this tradeoff in canary OY vs. rebuilding duration will be one of the more important considerations for the Council and NMFS.

Table 4-9. Evaluation of alternative 2007-2008 canary rockfish OYs relative to the criteria described in section 4.2.

Evaluation Criterion	OY (mt)					
	No Action OY Alt. (2006 OY)	OY Alt. 1	OY Alt. 2	Pref. Low OY Alt.	OY Alt. 3 (Pref. High OY)	OY Alt. 4
	47	0	24	**32**	**44**	68
Catch monitoring uncertainty	High uncertainty due to a significant recreational catch component.					
Assessment Uncertainty	Relatively certain due to generally good data quality and consistency.					
Rebuilding Probability (P_{MAX})	54.8%	66%	60%	58.3%	55.4%	50%
Rebuilding Duration Beyond $T_{F=0}$ (yrs.)	11.4	0	5	7	10	18

Evaluation of Action Alternatives

Action Alternative 1 is the only action alternative estimated to stay within the Preferred Low OY Alternative for canary rockfish. Most of the current northern fisheries primarily constrained by canary rockfish OYs, such as recreational groundfish fisheries, are predicted to be more constrained by the Preferred Low OY for yelloweye under Action Alternative 1 (Table 2-14). Likewise, the Preferred Low OY for bocaccio tends to constrain southern fisheries historically constrained by canary rockfish more than the Preferred Low OY for canary rockfish. Action Alternatives 2 and 3 stay within the Preferred High OY Alternative for canary rockfish. While yelloweye rockfish OYs will be increasingly more constraining under the Preferred High OY ramp-down strategy, canary rockfish OYs will continue to be the most constraining to fisheries, especially in the four-year yelloweye harvest rate ramp-down transition period under that alternative.

Cowcod

Specific Cowcod Rebuilding Strategies

The prevailing management strategy for rebuilding cowcod is complete avoidance and allowing fisheries with only a "de minimus" fishing-related mortality. Historically, cowcod, due to their large size and superior flesh quality, were targeted in commercial and recreational fisheries. Non-retention regulations have been implemented for all West Coast fisheries to eliminate any possible targeting. Most importantly, all the critical cowcod habitat known through area-specific fishery information and other site-specific survey data have been closed to any type of bottom fishing that might take cowcod. These critical habitats are encompassed in two areas in the Southern California Bight south of Point Conception called the Cowcod Conservation Areas (CCAs, Figure 2-3). Area management is a particularly effective strategy for protecting cowcod given their sedentary life style and site fidelity. Piner et al. {2006} determined these management measures have been effective in keeping total mortality well under the low OYs used to manage this stock since the implementation of the CCAs and no retention regulations in 2001.

Evaluation of Optimum Yield Alternatives

It is particularly difficult to evaluate the cowcod OY alternatives given the great uncertainty in actual total catch and stock status. Both of these factors compel a very precautionary approach in rebuilding this very unproductive stock. OY alternatives 3-5 may be risky given this high uncertainty and the longer rebuilding periods (17-39 years beyond $T_{F=0}$) predicted by those harvest rates. The preferred OY range of 4-8 mt in the Conception and Monterey areas have much shorter predicted rebuilding periods, extending the duration of rebuilding 4-8 years beyond the time predicted under a zero-harvest strategy. The estimated rebuilding probabilities under the preferred Low and High OYs are also reasonably high ($P_{MAX} \geq 80\%$), which helps mitigate the risk of managing stock rebuilding with such high uncertainty.

Table 4-10. Evaluation of alternative 2007-2008 cowcod OYs relative to the criteria described in section 4.2.

Evaluation Criterion	OY (mt)						
	No Action OY Alt. (2006 OY)	OY Alt. 1	Pref. Low OY Alt.	OY Alt. 2 (Pref. High OY)	OY Alt. 3	OY Alt. 4	OY Alt. 5
	4.2	0	**4**	**8**	14	18	22
Catch monitoring uncertainty	Very high uncertainty due to a paucity of at-sea observations.						
Assessment Uncertainty	Very high uncertainty due to poor data quality.						
Rebuilding Probability (P_{MAX})	90.2%	100%	90.6%	80%	70%	60%	50%
Rebuilding Duration Beyond $T_{F=0}$ (yrs.)	4.1	0	4	8	17	27	39

Evaluation of Action Alternatives

All the action alternatives contemplate a liberalization of the Cowcod Conservation Areas in the Southern California Bight. The most significant risk of altering the perimeters of the CCA is the possibility that incidental catches of cowcod would increase, either as a result of incidental catches at the boundary of the fathom lines, or from incidental catches resulting from inadvertent incursions of vessels into shallower depth in the boundary lines. Such risks are associated with all of the potential alterations to both the outer and inner perimeters. Although this risk is difficult to evaluate, the steep and complex topography of the continental shelf and slope in these regions, and the corresponding complexity of the perimeter line alternatives that would be developed to exclude fishing from those depths in which cowcod are most abundant, suggests that there is significant potential for such incursions.

It is worth noting that while most cowcod are found within the 40 to 150 fm depth range, commercial catch and resource survey data demonstrate that cowcod can be found as shallow as 20 fm, in low-moderate numbers to 220 fm, and infrequently to at least 270 fm {Butler et al. 1999; Love et al. 2002; unpublished survey data}. Consequently, even with precise adherence by commercial fishermen to the outer perimeter of 175 fm under action alternatives 1 and 2, and similar performance by recreational fishermen to the inner perimeters of either 30 fm (Alt. 1) or 40 fm (Alt 2), bycatch of cowcod would be expected to increase by some amount under any of the alternatives. Although Action Alternative 1 (the four-area alternative) would presumably have less of an impact with respect to the potential for increased cowcod mortality, all of the areas proposed in this alternative are described as areas of moderate to high densities based on CDFG fishing block catch rate data (figures 5 and 6 in Appendix IV of Piner et al. 2006). Additionally, Potato Bank (west of San Nicolas Island), as well as Cortes Bank were both observed to have high densities of adult cowcod in the recent submersible survey {Yoklavich et al., in prep}. Alternatives 2 and 3 could be expected to have increasingly higher impacts on cowcod as they increase the areal extent of cowcod habitat open to fishing significantly to substantially.

Both Potato Bank and the Santa Barbara Island areas, that would be open in all alternatives but the No Action Alternative, were also recently described as areas with high concentrations of newly described species of black corals {Tissot et al. 2006}, for which nearly all of the high concentrations were observed within the current boundaries of the CCA. Independent of the above concerns, it is worth noting that a growing amount of habitat information in the Southern California Bight may be informative with respect to altering the CCA boundaries in the near future. Additional analysis of such data, and associated habitat preferences by cowcod and other species, could more adequately ensure that habitat known to be optimal for cowcod is protected in future CCA revisions.

With respect to monitoring stock abundance and recovery, changing the boundaries of the CCA could undermine the ability to replicate recent resource surveys, such as the submersible survey and the enhanced CalCOFI ichthyoplankton survey. In particular, the submersible survey conducted by Yoklavich et al. (in prep) was used in the last assessment as a single point estimate of abundance of a given year within the CCAs, expanded by a scaling factor developed based on catch rate data in recreational fisheries. Both the STAR Panel and the SSC report on the cowcod assessment stressed the paucity of data available for this stock, highlighted the potential of this survey for monitoring cowcod trends, and emphasized the need for a consistent time series in order for this survey to be relied upon with confidence for detecting trends. Specifically, alterations to the boundaries of the CCA could undermine the assumptions necessary to replicate this survey in order to develop a second data point for monitoring stock trends. In other words, a second survey may not be comparable with the first, if the conditions (exploitation rates) within the survey area had changed.

This is a particularly important factor given that the four fishing areas proposed under Alternative 1 include three of the eight banks upon which the 2002 visual survey was based; Potato Bank, Santa Barbara Island, and Cortes Bank. The cowcod assessment represents one of the most data-poor assessments in the recent assessment cycle, such that only three free parameters (R_0, steepness and the catchability coefficient for the visual survey) were actually estimated in the model. Aside from the submersible survey, there are no fishery independent data to inform the assessment (in the most recent assessment review, the STAR Panel recommended removal of the CalCOFI time series that was used in the first assessment), nor are there length-frequency data or other information to estimate recruitment variability. As catch rate data were effectively the most important time series index in the assessment, the submersible survey offers one of very few potentially available data series for monitoring stock trends and recovery. Given the paucity of data available for the cowcod assessment, it will be important to attempt to maintain consistency in management measures (to the extent practicable) until an effective monitoring system is in place.

The magnitude of fishing that could take place under any of the action alternatives, and the extent to which such fishing could increase mortality on cowcod and other rebuilding species, will be particularly difficult to assess without adequate observer coverage on vessels that fish within these closed areas. The current cowcod OY could potentially be entirely harvested in a small number of "disaster sets", and the extent to which any observer data that was collected would over, or under, estimate cowcod mortality is difficult to detect with the limited observer coverage for this region. Consideration of the challenges associated with adequately monitoring total mortality that could result from any modification to the CCA should be a high priority in selecting a preferred alternative, including some evaluation of the amount of observer coverage that might be expected from the WCGOP under any of the alternative scenarios.

Enforcement issues are presumably challenging under the proposed alternatives to the status quo. The current boundaries have been shown to be easily understandable to fishermen and enforcement personnel, thus meeting their objectives in rebuilding the cowcod (and other) resources. The practicability of enforcement using VMS data, particularly with respect to the legal issues surrounding the ability of states to use proprietary VMS data for enforcement purposes, is another complicating factor that has yet to be resolved for the purposes of implementing the Alternatives. This, and additional challenges to enforcement that could be associated with any perimeter modification, should also be carefully considered prior to any adoption of proposed alternatives to status quo.

Darkblotched Rockfish

Specific Darkblotched Rockfish Rebuilding Strategies

Darkblotched rockfish are caught almost exclusively by groundfish trawl gear and predominantly bottom trawls operating on the outer continental shelf and slope north of 38° N latitude between 100 and 200 fm (Figure 4-3). The two most significant strategies used to control darkblotched fishing mortality are limited entry trawl trip limits for the southern and northern minor slope rockfish complexes, the complexes in which darkblotched are managed, and implementation of the trawl RCA, where modifications to the seaward boundary tend to have the greatest effect on darkblotched take. As an example, in 2004 the Council and NMFS decided to provide more opportunity to harvest healthy Dover sole, thornyheads, sablefish (DTS), and flatfish stocks in the limited entry trawl fishery while staying within the darkblotched OY of 240 mt. In May the trawl RCA was decreased by moving the seaward boundary inshore to 150 fm and increasing DTS and flatfish limits. By September it was apparent the darkblotched OY would be exceeded without a significant adjustment to the trawl fishery. The trawl RCA was then extended from the shoreline (primarily to address over-attainment of canary rockfish) out to 250 fm north of 40°10' N latitude, from the shoreline out to 200 fm between 38° N latitude and 40°10'

N latitude, and trip limits were severely reduced. The very important winter petrale sole fishery was foregone among other important fishing opportunities. By the end of the year, the darkblotched OY was exceeded, but only by 1.6 mt (Table 4-6). This indicates the sensitivity of RCA boundary adjustments when managing fisheries to stay within low darkblotched rockfish rebuilding OYs.

Area management beyond adjustment of the seaward boundary of the trawl RCA may be an effective rebuilding strategy for darkblotched rockfish. Figure 4-3 indicates an apparent clustered distribution of darkblotched as evidenced by area-specific catch per tow data in past NMFS trawl surveys. While the clustered distribution of darkblotched in Figure 4-3 is informative, the apparent distribution is also affected by the survey sampling regime in that not all of the combined survey data is shown, 0-catch hauls are not shown, and that the depths and latitudes sampled by all surveys have been irregular over time. In 2004, observers noted two very large catches (8,000-15,000 lbs), which were partially discarded {Rogers 2006}. They were both from an area that also had large survey catches at approximately 40.5° N latitude in 200 fm (Figure 4-3). These large catches tended to contain larger than average fish {Rogers 2006}. Closure of those areas might provide additional darkblotched conservation benefits.

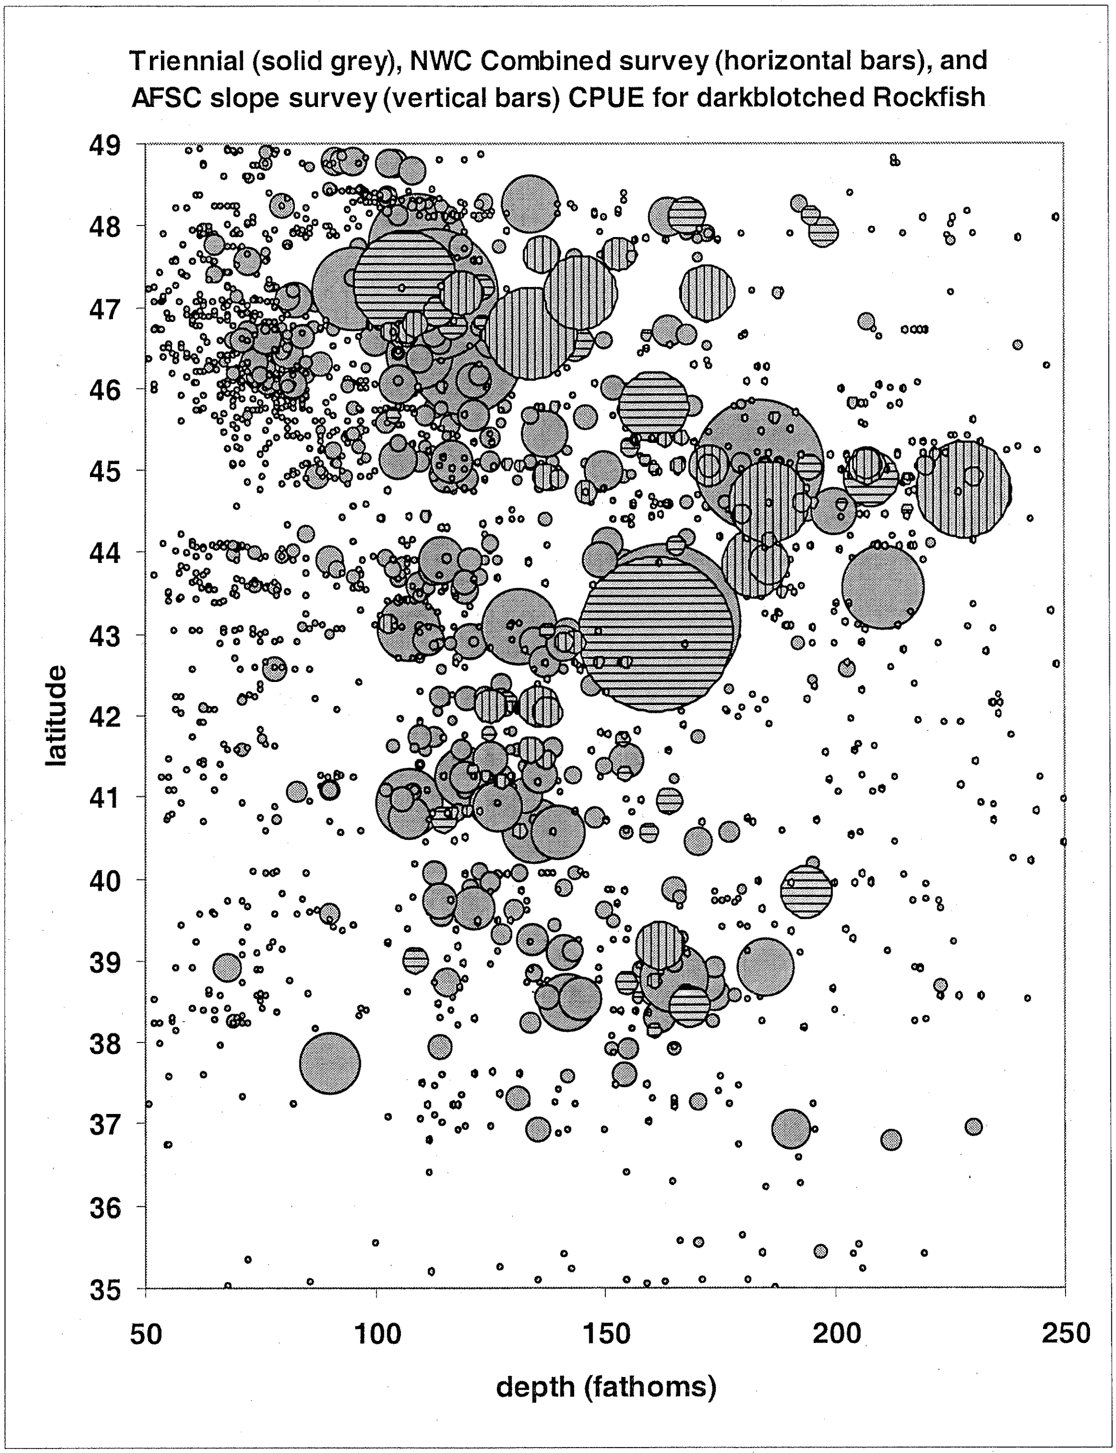

Figure 4-3. Index of West Coast distribution of darkblotched rockfish by latitude and depth as determined by catch per tow in NMFS trawl surveys. Size of circle is proportional to darkblotched rockfish density at that location. Data from NOAA Northwest Fisheries Science Center's West Coast Groundfish Survey Database and the NOAA Alaska Fisheries Science Center Triennial Shelf and Slope Survey Database.

Evaluation of Optimum Yield Alternatives

Table 4-11 shows the results of the evaluation of alternative darkblotched rockfish OYs analyzed for 2007-2008 using the criteria described in section 4.2.

The much more optimistic 2005 darkblotched assessment is largely based on validation of strong recent recruitments. These recruitments are relatively certain in the assessment input data despite the inconsistency in assigned ages of darkblotched in the sample data, which leads to the ranking of "moderate" assessment uncertainty.

The catch monitoring of darkblotched is relatively certain since the limited entry bottom trawl fishery takes the vast majority of the total annual take while targeting DTS and flatfish species on the slope. Estimation of at-sea discards of darkblotched and other species in the trawl fishery has become increasingly certain with the increased observations from the WCGOP. The overfishing of darkblotched that occurred in 2004 (Table 4-6) may be prevented in the near future since model projections using WCGOP discard rates are better informed and landings plus discard are now tracked in near-real time in PacFIN's Quota Monitoring Species (QSM) reports[5].

All the darkblotched OY alternatives have exceptionally high rebuilding probabilities at or approaching 100%. The range of most depleted species' OYs analyzed in this EIS have an OY alternative at or close to 50% P_{MAX}. Conversely, the highest darkblotched OY alternative has a very high 97% P_{MAX} since it is capped at the ABC, which is determined using a proxy harvest rate. Therefore, all the harvest rates used to determine alternative darkblotched OYs and rebuilding strategies are considered risk-averse using this evaluation criterion.

The rebuilding periods associated with alternative darkblotched OYs are relatively short for a depleted rockfish. Under the zero-harvest alternative, rebuilding is predicted to occur by 2009.5. The Preferred Low OY Alternative of 130 mt extends this rebuilding duration by less than half a year, while the Preferred High OY Alternative of 229 mt extends rebuilding by slightly more than half a year. This compares to rebuilding duration beyond $T_{F=0}$ under the status quo OY of slightly more than half a year (equivalent to that under the Preferred High OY) and 2.5 years of extended rebuilding under the largest OY considered of 472 mt. The tradeoff in rebuilding duration vs. allowable darkblotched harvest shows that a greater harvest rate than has been sustained in recent years can still successfully rebuild the darkblotched rockfish stock with a small incremental increase in the rebuilding period. While these strong, incoming year-classes to the spawning stock biomass favor expeditious rebuilding, fishery interceptions of darkblotched will likely increase making it more difficult to manage the low status quo OYs using status quo management measures.

5 The GMT uses the PacFIN QSM report to track OY attainment inseason for recommending adjustments to fisheries to stay within OYs. In 2005, the GMT started incorporating projections of discard mortality in association with landings in the QSM report to better track total fishing-related mortality of managed species.

Table 4-11. Evaluation of alternative 2007-2008 darkblotched rockfish OYs relative to the criteria described in section 4.2.

Evaluation Criterion	OY (mt)					
	No Action OY Alt. (2006 OY)	**OY Alt. 1**	**OY Alt. 2 (Pref. Low OY)**	**OY Alt. 3 (Pref. High OY)**	**OY Alt. 4**	**OY Alt. 5**
	200	0	**130**	**229**	330	472
Catch monitoring uncertainty	Relatively certain due to a predominant trawl catch component.					
Assessment Uncertainty	Moderate uncertainty due to data inconsistency (ageing uncertainty).					
Rebuilding Probability (P_{MAX})	100%	100%	100%	100%	100%	97.2%
Rebuilding Duration Beyond $T_{F=0}$ (yrs.)	0.6	0	0.4	0.7	1	2.5

Evaluation of Action Alternatives

All of the action alternatives analyzed for 2007-2008 contemplate more conservative management of slope trawl fisheries than status quo. Action Alternative 1 is the only alternative estimated to stay within the Preferred Low OY Alternative for darkblotched, but as can be seen in Table 2-14, the Preferred Low OY Alternative for POP is even more constraining to slope trawl fisheries. Action Alternative 2 and 3 stay within the Preferred High OY for darkblotched, but the Preferred High OY for POP is again more constraining (Tables 2-19 and 2-21).

The more effective and accurate catch monitoring and tracking mechanisms used to manage slope trawl fisheries should significantly improve inseason management adjustments to future trawl fisheries and thus avoid the overfishing problem encountered in 2004. Inseason adjustments are anticipated to be fundamental in managing trawl fisheries to stay within whatever darkblotched OY is chosen for 2007-2008 as increased encounter rates of darkblotched are expected with the strong recruitments observed in the latest assessment.

Pacific Ocean Perch

Specific Pacific Ocean Perch Rebuilding Strategies

Pacific ocean perch have been under rebuilding since 1981. The population off the northern U.S. West Coast (Columbia and U.S./Vanc. areas) is at the southern extreme of the stock and rebuilding potential may be more effected by mortalities in waters north of the U.S./Canada border. Nevertheless, the trawl RCA configuration used to reduce darkblotched mortalities, which has been the more constraining stock in slope trawl fisheries since implementation of rebuilding measures in 2001, has significantly reduced POP mortalities. Continued use of RCA management coupled with precautionary slope rockfish trawl trip limits may be the most effective combination of strategies available to the Council and NMFS for rebuilding this stock. Given the stock's overall distribution in the Northeast Pacific, a collaborative U.S./Canada research and management plan needs to be explored.

Evaluation of Optimum Yield Alternatives

Table 4-12 shows the results of the evaluation of alternative POP OYs analyzed for 2007-2008 using the criteria described in section 4.2.

Both catch monitoring uncertainty and assessment uncertainty are relatively low for this species given the fact that the vast majority of total fishing-related mortality occurs in limited entry bottom trawl efforts.

Rebuilding probabilities range from 50% to 100% across the range of analyzed POP OYs and are especially high (>95%) for the Preferred Low and High OY Alternatives. This compares to a 73% P_{MAX} under the status quo OY of 447 mt, which is almost 4.5 times higher than the Preferred High OY Alternative.

The shortest possible time to rebuild the West Coast POP stock under a zero-harvest strategy is 2014.6. The Preferred Low OY Alternative extends rebuilding by less than half a year longer and the Preferred High OY Alternative extends rebuilding by approximately one year. This compares to about 8 years of extended rebuilding under the status quo OY and over 30 years under the harvest rate used to determine the highest OY considered (OY Alternative 5).

Table 4-12. Evaluation of alternative 2007-2008 Pacific ocean perch OYs relative to the criteria described in section 4.2.

Evaluation Criterion	OY (mt)							
	No Action OY Alt. (2006 OY)	**OY Alt. 1**	**Pref. Low OY Alt.**	**OY Alt. 2**	**Pref. High OY Alt.**	**OY Alt. 3**	**OY Alt. 4**	**OY Alt. 5**
	447	0	**44**	87	**100**	405	514	749
Catch monitoring uncertainty	Relatively certain due to a predominant trawl catch component.							
Assessment Uncertainty	Relatively certain due to generally good data quality and consistency.							
Rebuilding Probability (P_{MAX})	73%	100%	99.5%	96.7%	95.8%	80%	70%	50%
Rebuilding Duration Beyond $T_{F=0}$ (yrs.)	7.9	0	0.4	0.4	1	6	10	33

Evaluation of Action Alternatives

In recent years, the effective harvest rate of POP in trawl slope fisheries has been much less than that specified in the POP rebuilding plan because darkblotched OYs were more constraining. The Preferred Low and High OY alternatives are much lower than the No Action OY and, depending on the harvest rate decided for the darkblotched rockfish rebuilding plan, could become the constraining stock in future trawl slope fisheries in waters off Oregon and Washington.

Only Action Alternative 1 constrains fisheries enough to stay within the Preferred Low OY Alternative for POP, while Action Alternatives 2 and 3 stay within the Preferred High OY.

Widow Rockfish

Specific Widow Rockfish Rebuilding Strategies

The Council chose to eliminate the non-tribal midwater trawl fishery targeting yellowtail and widow rockfish in 2003 to reduce widow rockfish exploitation {PFMC 2003}. The WDFW sponsored a midwater trawl EFP in 2002 and 2003 to attempt to shape a fishery that effectively targeted yellowtail while avoiding widow. However, this EFP was discontinued prematurely in 2003 because about 28% of the catch was widow rockfish (B. Culver, personal communication). There is still a tribal midwater trawl fishery that targets yellowtail rockfish, but incidentally catches some widow rockfish. The 2005-2006 limits for this fishery were a fleet-wide (the Makah Tribe was the only tribe prosecuting a midwater trawl fishery) cumulative landing limit of 180,000 lbs of yellowtail rockfish/two months. Widow rockfish landings were limited to 10% of the weight of yellowtail rockfish landed in any two-month period. These midwater landing limits were subject to inseason adjustments to minimize the take of canary and widow rockfish. Management of the tribal midwater trawl fishery is designed to minimize impacts to canary and widow rockfish through avoidance. Observer data is analyzed daily and vessels are told which areas to avoid when these species are encountered.

The Council also chose to manage widow rockfish bycatch beginning in 2004 by precautionary management of midwater trawl fisheries that target Pacific whiting. This has traditionally been the fishery with the greatest incidental bycatch of widow rockfish, excluding the directed yellowtail/widow midwater trawl fishery which was discontinued in 2002. While the shoreside whiting sector has exhibited a clear recent trend of reduced widow rockfish bycatch, widow bycatch in the at-sea sectors has been more random. All whiting trawl sectors showed a significant decrease in widow rockfish bycatch in 2003 (Figure 4-4). The at-sea vessels receive daily reports of bycatch by vessels in their fishery, where there is 100% observer coverage, and actively avoid areas where there has been a high bycatch of salmonids, widow, and yellowtail rockfish. Another contributing factor to the lower widow bycatch in 2003 was a significantly increased abundance of whiting in 2003 which resulted in shorter tows to fill trawls. In years when whiting are less abundant and more dispersed, widow bycatch can become an increasing concern as vessels extend their search for whiting schools and have longer tow times (D. Myer, personal communication). Shorter tows on aggregated whiting schools would sensibly reduce widow bycatch since whiting tows are made in daylight hours when widow rockfish are dispersed. There was also a greater abundance of whiting off the north Washington coast in 2003 that kept at-sea whiting vessels more northerly and away from Oregon and southern Washington coastal areas where widow are more abundantly distributed.

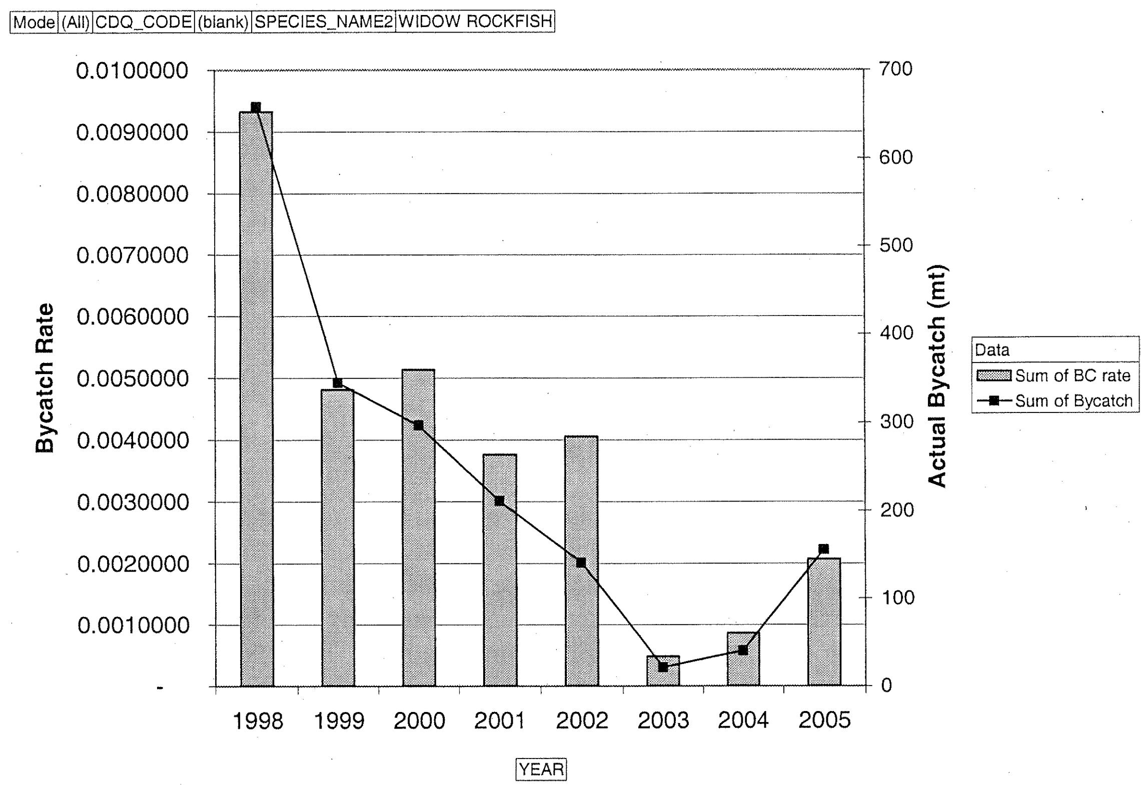

Figure 4-4. Annual Widow Rockfish Bycatch Rate and Bycatch in the Non-tribal Sectors of Whiting-directed Midwater Trawl Fisheries.

In recent years, the GMT has recommended consideration of the following management strategies to reduce widow rockfish bycatch in whiting fisheries: 1) a precautionary reduction in whiting OYs, 2) hard widow rockfish bycatch caps by sector in the whiting fisheries or a hard cap imposed for all sectors combined, 3) establishing avoidance strategies by timely reporting of widow bycatch rates by area that would compel the fleet to move away from such areas, and 4) prohibiting the whiting fishery in areas of highest widow rockfish densities.

As stated above, the Council has elected to specify hard widow rockfish bycatch caps on the non-tribal sectors of the whiting fishery. It is noted that the majority of widow rockfish bycatch in whiting fisheries occurs infrequently in "disaster tows" that may be due to inexperience on the part of the skipper or an unpredictable encounter. Since each sector has a different season, it is conceivable that one sector could pre-empt fishing opportunities for another by experiencing a few "disaster tows." Originally, in 2004, the Council recommended hard bycatch caps for both canary and widow rockfish for all whiting sectors combined, including the tribal sector. However, in 2005, these hard caps were adjusted and implemented only for the non-tribal shoreside and at-sea sectors combined. The specified widow rockfish bycatch cap was originally 200 mt, but adjusted inseason to 212 mt. The 2006 cap was set at 200 mt. Managing the whiting fishery with hard bycatch caps has forced active avoidance of widow and, as Figure 4-4 indicates, has successfully reduced widow bycatch to desired levels. The strategy works due to timely reporting to the rest of the fleet of areas where higher widow bycatch occurred. The at-sea fleets (catcher-processors and motherships) have 100% observer coverage. They also have an independent contractor collect at-sea bycatch information daily, who reports back to the fleet when the bycatch of any particular species of concern rises in any one area. The fleet then moves to areas where whiting can be more cleanly targeted.

The shoreside sector has a similar mechanism for minimizing bycatch. This sector operates under an EFP that mandates full retention of species and landing of all the catch. This allows full sampling of the total catch upon landing. The buyer reports back to the fleet if a landing from a particular area shows a higher than desired bycatch. However, catch can be discarded at sea if landing the bag poses an immediate threat to vessel safety. Since the shoreside fleet does not operate with 100% observer coverage, there may be an incentive to discard at sea if a larger than expected bycatch of widow rockfish occurs. The NMFS started placing cameras on all shoreside whiting vessels in 2004 as an experimental effort to determine if discarding occurs on otherwise unobserved trips. In 2004, a total of 1,003 trips and 1,030 sets were observed using deck-mounted cameras. Non-retention occurred in 19% of sets observed. Most of this non-retention was from fish bled from the codend of the trawl, although some discard occurred from fish dumped off the deck. Most of the observed discards occurred during the last haul of the trip and most discards were < 45 kg total estimated weight. [2005 results?] Starting in 2006, camera monitoring is mandated in the Shoreside Whiting EFP.

An innovative government-industry collaboration coordinated by the NMFS Northwest Fishery Science Center, the Pacific Whiting Conservation Cooperative, and the Fisherman's Marketing Association was launched in 2004 to explore the development of an abundance index methodology specifically for widow rockfish. The goal of this effort was an exploration of non-extractive techniques using acoustics and cameras. This feature was viewed as particularly important owing to the depleted status of this species. As proof of concept, pilot survey work off Newport, Oregon in March 2005 confirmed the ability to reliably locate, observe, and quantitatively measure widow rockfish schools with conventional single frequency fishery acoustics techniques in combination with underwater video cameras. The sites sampled off central Oregon, a subset of those identified by fishermen in the ad hoc working group, were found to contain widow rockfish aggregations, which supports the strategy to rely on use of local fisherman's knowledge of fishing grounds as a sampling framework. The acoustics data collected with the scientific echosounder installed on a fishing vessel was of good scientific quality, which allowed a detailed examination of patterns of variability in widow rockfish populations (see report entitled "Update on the Development of a Commercial Vessel-Based Stock Assessment Survey Methodology for U.S. West Coast Widow Rockfish: A Report to the ad hoc Working Group" by P. Ressler, G. Fleischer and V. Wespestad). The success of the pilot work indicated that the acoustic surveys could be a successful monitoring tool but should be expanded to include other study sites along the West Coast in order to provide coastwide monitoring of the species. Such research is critical for determining a much needed, reliable index of widow rockfish abundance as the established NMFS bottom trawl is ineffective for this semi-pelagic species and fishery-dependent indices no longer reliably track abundance since the fisheries avoid widow rockfish. A reliable, fishery-independent survey will be a very important contribution to our understanding of stock status and trends, which should lead to better area management strategies for widow rockfish, as well as holding potential for other depleted rockfish.

Evaluation of Optimum Yield Alternatives

Table 4-13 shows the results of the evaluation of alternative widow rockfish OYs analyzed for 2007-2008 using the criteria described in section 4.2.

Catch monitoring of widow rockfish is relatively certain given that the stock is mostly caught as bycatch in trawl fisheries and is predominantly caught in whiting-directed trawl fisheries where at-sea observation rates are highest on the West Coast.

Conversely, the assessment result is relatively uncertain due to the lack of a reliable widow abundance index. In past assessments, widow bycatch in whiting-directed trawl fisheries has been used to understand biomass trends. However, with the need for whiting fleets to reduce their widow bycatch, that index is no longer recommended for assessing stock trends. The promise of an effective and useable hydroacoustic survey index is still many years off. The survey would have to be proven through continued research before managers and scientists invest in these resources. And, if that happens, multiple years of survey data would be needed before temporal biomass trends can be discerned and used in assessment. Therefore, assessment uncertainty is relatively uncertain, which should be considered when the Council determines a final rebuilding plan. (In fact, this uncertainty was taken into account when the Council decided not to pursue "delisting" widow rockfish as an overfished species given the assessment result that the stock never did reach a threshold of depletion below $B_{25\%}$. The Council understood there was very little new data informing this new assessment and acknowledged the uncertainty was too great to depart from the rebuilding plan.)

Most of the widow rockfish OY alternatives analyzed in this EIS have high rebuilding probabilities (P_{MAX} at or above 80%). Only OY Alternative 5 (1,369 mt) has a P_{MAX} less than the SSC "target" of ≥80%. The Preferred Low and High OY alternatives have very high rebuilding probabilities of 98% and 95%, respectively. In terms of the P_{MAX} criterion, the harvest rates used to determine these OYs are risk-averse rebuilding specifications.

The strong, year classes recruiting to the widow rockfish spawning stock are evidenced by the short rebuilding times predicted across a large range of OYs (Table 2-3 and Figure 2-2). The shortest possible time to rebuild the stock under a zero-harvest strategy is 2013. The Preferred Low OY harvest rate is predicted to extend rebuilding about a year longer than this and the Preferred High OY harvest rate extends rebuilding by yet another year. This compares to slightly less than two years of extended rebuilding under the status quo OY, which is intermediate to the Preferred Low and High OY Alternatives.

Table 4-13. Evaluation of alternative 2007-2008 widow rockfish OYs relative to the criteria described in section 4.2.

Evaluation Criterion	OY (mt)							
	No Action OY Alt. (2006 OY)	**OY Alt. 1**	**Pref. Low OY Alt.**	**OY Alt. 2**	**Pref. High OY Alt.**	**OY Alt. 3**	**OY Alt. 4**	**OY Alt. 5**
	289	0	**120**	329	**368**	456	917	1,369
Catch monitoring uncertainty	Relatively certain due to a predominant trawl catch component.							
Assessment Uncertainty	Relatively uncertain due to lack of a reliable abundance index.							
Rebuilding Probability (P_{MAX})	96.2%	100%	98.4%	95.7%	95.2%	94%	80%	60%
Rebuilding Duration Beyond $T_{F=0}$ (yrs.)	1.8	0	1	2	2	3	7	14

Evaluation of Action Alternatives

All the action alternatives assume the same basic strategy of reducing widow rockfish mortalities by specifying caps in non-tribal fisheries targeting whiting. While other sectors may be able to reduce their impacts with widow avoidance strategies, the impacts in directed midwater trawl fisheries for whiting promise to most substantially reduce widow mortalities. The large recruitments of widow rockfish predicted in the new stock assessment may be a significant management challenge for the whiting fishery, depending on the widow harvest rate and OY selected for the widow rockfish rebuilding plan and the bycatch caps specified in future whiting fisheries.

Only Action Alternative 1 is conservative enough to stay within the Preferred Low OY Alternative for widow, while all the action alternatives stay within the Council's Preferred High OY Alternative. Managing for a 120 mt OY (Preferred Low OY) will most certainly constrain future whiting fisheries significantly given the OY is less than the status quo bycatch caps specified for 2005 and 2006 whiting fisheries. It will prove difficult, if not impossible for the whiting sectors to fully attain future whiting allocations if the cap is as low as it would have to be under the Preferred Low OY Alternative.

Yelloweye Rockfish

Specific Yelloweye Rockfish Rebuilding Strategies

Of all the new groundfish stock assessments conducted in 2005-2006, the yelloweye rockfish assessment shows the most pessimistic change from status quo. A significant adjustment of status quo management is needed to rebuild this stock given the much lower OYs projected from the new rebuilding analysis. While status quo management of yelloweye has relied on a similar avoidance strategy as is used to minimize cowcod mortalities (i.e., no retention regulations and specific area closures), there are still some fisheries, such as recreational and commercial fisheries in the north targeting Pacific halibut, that will need to be further constrained to stay within the lower OYs analyzed in this EIS. A more comprehensive area management strategy, where more of the critical habitats where yelloweye reside are closed to fishing efforts known to take yelloweye, may be most effective at further reducing mortalities and should be seriously considered. Other mechanisms, such as season and depth restrictions, should also be considered to reduce yelloweye mortality.

Yelloweye rockfish have a similar life history pattern as cowcod. They are sedentary and exhibit more side fidelity than most rockfish species. Prohibiting fishing activities that are prone to catch yelloweye in areas they frequently occur is likely to be one of the best strategies for minimizing total mortality. Broad, depth-based RCAs are effective at reducing fishing-related mortality, and, in fact, the seaward boundary of the non-trawl RCA north of 40°10' N latitude is configured to reduce mortality of yelloweye by fixed gears. However, specific yelloweye RCAs, like the existing one off the north Washington coast (Figure 2-3), are likely to be most effective at reducing incidental mortality in hook and line fisheries. Figure 4-5 depicts the relative density of yelloweye by depth and latitude as indicated by catch per tow in West Coast trawl surveys. Assuming the composite trawl survey CPUEs accurately represent yelloweye distribution, yelloweye RCAs north of 39° N latitude in depths out to 100-125 fm should provide the most protection for yelloweye against incidental exploitation.
Gear restrictions have been shown to be effective at reducing yelloweye mortality as well. Mandating small footrope and selective flatfish trawls shoreward of the trawl RCA has significantly reduced yelloweye mortality.

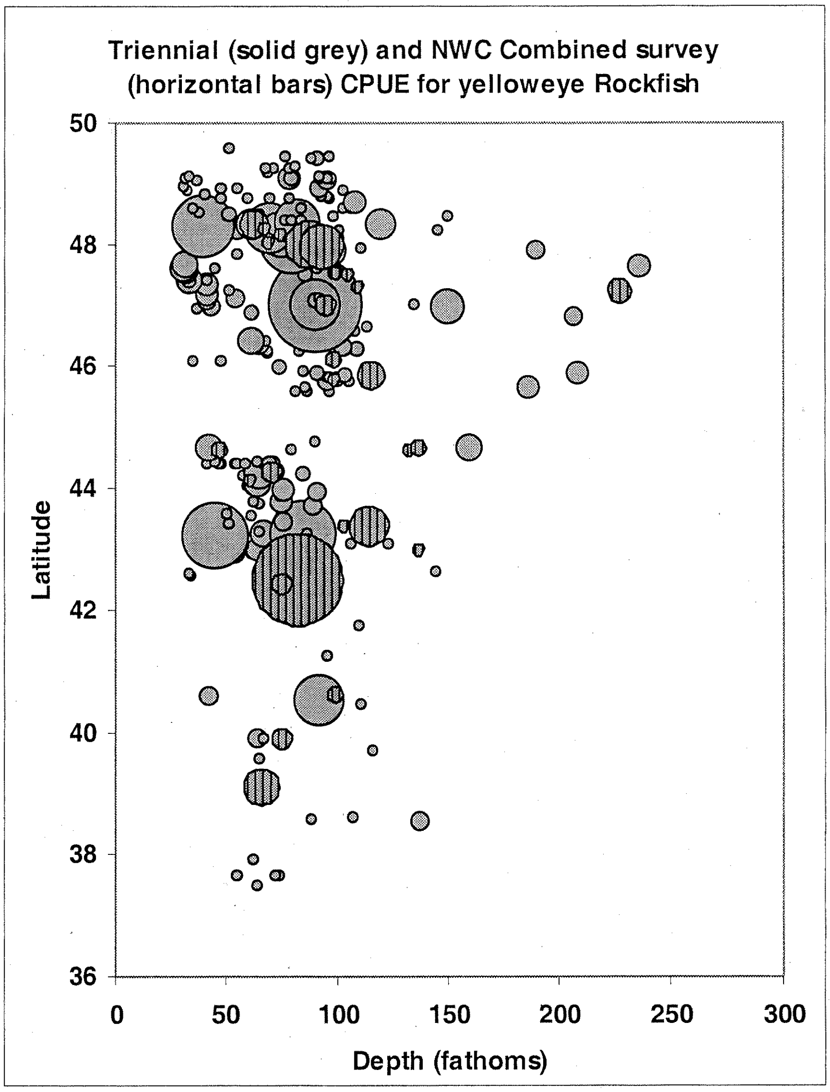

Figure 4-5. Index of West Coast distribution of yelloweye rockfish by latitude and depth as determined by catch per tow in NMFS trawl surveys. Size of circle is proportional to yelloweye rockfish density at that location. Data from NOAA Northwest Fisheries Science Center's West Coast Groundfish Survey Database and the NOAA Alaska Fisheries Science Center Triennial Shelf and Slope Survey Database.

Evaluation of Optimum Yield Alternatives

Table 4-14 shows the results of the evaluation of alternative yelloweye rockfish OYs analyzed for 2007-2008 using the criteria described in section 4.2.

There is considerable uncertainty in catch monitoring systems for tracking total catches of yelloweye. The sector currently taking the most yelloweye through unavoidable bycatch is the recreational sector targeting groundfish and Pacific halibut and, as pointed out in section 4.2, recreational catch monitoring is relatively uncertain. However, catch monitoring uncertainty is even more extreme for yelloweye since it is a rare species in the catch for any sector and, of the commercial sectors currently taking yelloweye, the fixed gear fisheries take the most and WCGOP at-sea observations are more sparse for fixed gear fisheries (particularly in the south). Precautionary management is called for with such high catch monitoring uncertainty.

The yelloweye rockfish assessment is also one of the more uncertain assessments done for West Coast groundfish since the fishery-dependent catch data are sparse and not well known and there is a significant lack of fishery-independent data in the assessment since survey bottom trawls do not catch yelloweye particularly well. The assessment is therefore tuned to highly uncertain recreational CPUE indices that may be more affected by past management restrictions and catch monitoring uncertainty than trends in stock biomass. This high uncertainty calls for precautionary management of stock rebuilding since the true state of nature may be more pessimistic (or optimistic) than the current assessment indicates.

Rebuilding probabilities are relatively high for the yelloweye OY alternatives considered for 2007-2008, ranging from 100% under the zero-harvest alternative to 80% for the Preferred Low OY and High OY alternatives. These preferred OYs are within the "target" range of 80% recommended by the SSC. This compares to about a 46% P_{MAX} under the status quo OY, which is under the lower legal limit of 50%. Of the two preferred OYs adopted for detailed analysis by the Council in April 2006, the Preferred High OY "ramp-down" strategy is slightly more risky in that it assumes a four-year transition from the current management regime before adopting a constant harvest rate strategy equal to that under the Preferred Low OY Alternative. Assuming the 2007-2010 OYs are not exceeded under the ramp-down strategy, there is no effective difference in P_{MAX} between the Preferred Low and High OY alternatives.

The relatively low productivity of the West Coast yelloweye stock predicts very long rebuilding periods. The shortest possible time to rebuild the stock under a zero-harvest strategy would be 2048 (Table 2-3). The harvest rate used to determine the 12 mt alternative (OY Alternative 2) is estimated to extend rebuilding an additional 30 years beyond that, while the Preferred Low OY and High OY alternatives are estimated to extend rebuilding an additional 35 and 35.5 years, respectively. This compares to over 71 additional years of rebuilding under the status quo harvest rate currently specified for rebuilding the yelloweye stock. The effect of a four-year transition from the status quo harvest rate to the low harvest rate under the Preferred Low OY Alternative is about a half a year of additional rebuilding under the ramp-down strategy.

Table 4-14. Evaluation of alternative 2007-2008 yelloweye rockfish OYs relative to the criteria described in section 4.2.

Evaluation Criterion	OY (mt)				
	No Action OY Alt. (2006 OY)	**OY Alt. 1**	**OY Alt. 2**	**Pref. Low OY Alt.**	**Pref. High OY Alt.**
	27	0	12	**12.6**	**Ramp down** a/
Catch monitoring uncertainty	Very high uncertainty due to a paucity of at-sea observations and a significant recreational catch component.				
Assessment Uncertainty	Very high uncertainty due to poor data quality.				
Rebuilding Probability (P_{MAX})	45.7%	100%	81%	80%	80% b/
Rebuilding Duration Beyond $T_{F=0}$ (yrs.)	71.5	0	30	35	35.5
a/ The yelloweye ramp-down strategy ramps the harvest rate down from the status quo harvest rate and resumes a constant harvest rate strategy in 2011. The 2007-2010 OYs are 23 mt, 20 mt, 17 mt, and 14 mt, respectively under the ramp-down strategy.					
b/ P_{MAX} (and the harvest rate beginning in 2011) are the same as for the Preferred Low OY Alternative.					

Evaluation of Action Alternatives

The very conservative management measures described under Action Alternative 1 in Chapter 2 are the only suite of management measures that are predicted to stay within the Council's Preferred Low OY Alternative. Management measures under Action Alternatives 2 and 3 stay within the OYs under the Council's Preferred High OY alternative, or the ramp-down strategy. Every action alternative specifies the implementation of a number of new Yelloweye RCAs to reduce mortality, but there is no quantifiable impact savings determined in this EIS from those proposed area closures. While it is unknown how overall total yelloweye mortality may be reduced by these YRCAs, some reduced mortality is anticipated and should be realized in 2007-2008 if these area closures are implemented. Reduced mortality should first be evidenced in decreased encounters in recreational fisheries in Washington and Oregon and reduced bycatch observed in the WCGOP, particularly in the limited entry and open access fixed gear sectors.

An important aspect of the YRCAs proposed for 2007-2008 is that comprehensive fishery and survey data are unavailable for understanding the distribution of critical yelloweye habitats. The proposed YRCAs under the 2007-2008 action alternatives emerged in consultation with fishermen in potentially affected commercial and recreational sectors as areas where they have traditionally encountered yelloweye. Many of these proposed RCAs are within the habitats of greatest yelloweye density as inferred from trawl survey CPUEs (Figure 4-5). A larger, less fragmented area management strategy may ultimately be more effective for rebuilding the yelloweye stock since it would likely reduce mortalities by protecting the most critical habitats yelloweye reside and will be easier to enforce. However, the YRCAs currently proposed is a good first start in transitioning to a significantly lower harvest rate. If closing only these proposed areas is deemed insufficient for getting to lower OYs, then conservative inseason depth and season restrictions will be needed to stay within these rebuilding limits.

All the action alternatives contemplate stringent yelloweye harvest guidelines, which would force conservative inseason adjustments to those sectors experiencing difficulty avoiding yelloweye impacts.

4.3.1.2 Impacts of Rebuilding Alternatives

As explained in 2.1.1, rebuilding alternatives (Table 2-2b) were developed by arranging the depleted species' OYs in various combinations in order to understand how the rebuilding plans for different species interact to cumulatively constrain fishing opportunities. The description of each rebuilding alternative's impacts, below, is predominantly qualitative, as these suites of OYs were not crafted so that the Council would choose its depleted species OYs wholly from one of the alternatives. Rather, the function of the discussion below is to highlight, through its panoramic view across all depleted species, how each species might differentially constrain fishing opportunities by sector (or gear type) and region along the West Coast. Another point made in this section is that one depleted species (such as canary rockfish, which has a coastwide distribution and affects nearly all fishing sectors) can constrain opportunity in many sectors even if high OYs are selected for other co-occurring depleted species.

Rebuilding Alternative 1

Under Rebuilding Alternative 1, canary rockfish is a constraining species limiting both the commercial and recreational sectors. For limited entry bottom trawl, the canary rockfish OY limits the catch of target species, such as petrale and Dover sole in the summer months, as well as English sole, arrowtooth flounder, and Other Flatfish on the continental shelf. Applying depth restrictions is the primary management tool to reduce the impact of limited entry fixed gear and open access fisheries on depleted species. The canary rockfish OY, as well as the yelloweye rockfish OY, could cause these fisheries to be restricted to depths greater than 100 fm north of 40°10' N latitude (rather than 100 fm under status quo).

Although the canary rockfish OY is the primary constraint on the recreational sector, yelloweye rockfish is also a constraining species for the sector, especially for recreational fisheries in Washington and Oregon. For California recreational fisheries, the bocaccio OY also substantially constrains opportunity. Affected recreational fisheries include those targeting black rockfish, blue rockfish, cabezon, lingcod, Pacific halibut, and greenling. In general, management measures that would be needed under this alternative, in order to restrict encounters with canary rockfish, would be similar to those under Action Alternative 1 (see section 4.3.1.1). However, a greater impact to yelloweye rockfish would be possible under this alternative than is expected under Action Alternative 1. This could allow for less restrictive management measures in some sectors, particularly Washington and Oregon recreational fisheries.

Canary rockfish also constrains the whiting fishery. Given recent bycatch rates, canary rockfish could constrain the whiting fishery to a catch at a level approximately two thirds of the 2006 Pacific whiting OY. However, the whiting fleets have avoided many of the impacts to depleted or protected species through innovative bycatch reduction techniques, such as near real-time reporting of bycatch and voluntary fleet mobilization when bycatch in a particular area is high. In the past two years, setting bycatch caps for the non-tribal whiting sectors has effectively minimized the bycatch of depleted groundfish species.

The bottom trawl fisheries on the continental slope become more liberalized under this alternative. As a result, the available OYs for two of the main deepwater target species, petrale sole and sablefish, are able to be nearly or fully achieved. Given this more liberal scenario, it is the precautionary species, petrale sole and sablefish, which become constraining to fishing opportunities for other target species in limited entry bottom trawl, such as Dover sole and thornyheads. Nevertheless, the catch of Dover sole and thornyheads can still occur at levels equal to or higher than status quo levels. Species that have a high degree of co-occurrence with darkblotched rockfish (particularly those within the slope rockfish complex) are caught at levels that are substantially less than the available OY for those species. As has been the case in recent years, the POP OY is greater than that which can be accessed by these fisheries, given the constraints of other co-occurring species.

This alternative contains a widow rockfish OY that is higher than status quo; the OY is also greater than the estimated impact from the whiting fishery, the primary sector to catch widow incidentally. However, a midwater yellowtail rockfish and widow rockfish fishery cannot be re-introduced because the fishery's anticipated bycatch of canary rockfish could not be accommodated under this alternative's canary rockfish OY.

Rebuilding Alternative 2

Under Rebuilding Alternative 2, the northern fisheries that operate along the continental shelf and in nearshore areas are particularly constrained. The canary rockfish OY is set at a status quo level within this alternative, and therefore the impacts to fisheries would be expected to be similar to that seen under the current management. The yelloweye rockfish OY in this alternative, however, is set to a level lower than status quo (and also lower than under Rebuilding Alternative 1). Since yelloweye rockfish is caught almost exclusively by line gear, this alternative is particularly constraining to northern fixed gear and recreational fisheries. In order to lower the incidental catch of yelloweye within the recreational sector, the groundfish and, in northern waters, the Pacific halibut fishery would have to be restricted to shallower depths (potentially ≤20 fm) and/or new yelloweye RCAs would need to be established in areas of high yelloweye density where recreational bottom fishing would be prohibited. One possibility to reduce the limited entry and open access fixed gear impact on yelloweye rockfish would be to extend the non-trawl RCA seaward north of 40°10' N latitude, although establishing yelloweye RCAs could also help reduce impacts. The management measures to restrict impacts to canary rockfish and yelloweye rockfish under this alternative would be similar to those under Action Alternative 3.

Pacific ocean perch and darkblotched rockfish constrain bottom trawl fisheries along the northern slope areas to the same extent as under status quo management. Management measures under this alternative would also be similar to those described in Action Alternative 3. Similar to the case in Rebuilding Alternative 1, petrale sole and sablefish somewhat constrain the catch of other target species in the deepwater bottom trawl fisheries, such as Dover sole and thornyheads. However, the catch of these species is equal to or higher than the amount of catch occurring under status quo management. The whiting fishery operates as it would under status quo because its constraining bycatch species (canary rockfish, widow rockfish, and darkblotched rockfish) do not change under this alternative.

This alternative liberalizes the southern fisheries by increasing the bocaccio and cowcod OYs relative to status quo, although nearshore and shelf fisheries would still be constrained by canary rockfish, given the species coastwide distribution. Recreational fishermen in California, for example, might be able to fish at deeper depths or have a slightly longer season under this alternative. However, given the bocaccio OY is only slightly higher than the status quo impacts of about 150 mt of bocaccio in all fisheries combined, these increased opportunities might be slight. This is especially true if a strong year class of bocaccio is caught at a higher rate in nearshore fisheries, creating a temporary increase in bocaccio mortality until the fish mature and move to deeper depths.

Rebuilding Alternative 3

Rebuilding Alternative 3 is the most liberal of all of the rebuilding alternatives. Only the yelloweye rockfish OY specified within this alternative is less than that under status quo (although not much different than the realized status quo total mortality); some of the other OYs are substantially greater than those under status quo. This alternative provides for greater opportunities than those found in any of the Action Alternatives or in status quo management measures.

This alternative has the highest attainment of target species for most of the commercial sectors compared to other rebuilding alternatives, although current constraints on fisheries posed by low yelloweye OYs would not be lifted. Nevertheless, multiple target species OYs are not fully attained because the catch of precautionary zone target species caught in the commercial fishery (i.e., petrale sole and sablefish) limits the catch of healthy target species such as Dover sole and thornyheads. Commercial fixed gear fisheries, on the other hand, would continue to be constrained by the yelloweye rockfish OY.

Additional target opportunities could be accommodated under this alternative. For example, a midwater trawl fishery for yellowtail rockfish is possible, given that the widow rockfish OY is large enough to allow targeting and the canary rockfish OY is high enough to account for impacts that would be expected due to the co-occurrence of the three species. Only under this alternative would catch of widow rockfish approach the level of the OY; under the other alternatives (as well as under status quo) the widow rockfish OY is too low to allow this yellowtail rockfish target opportunity. The highest widow rockfish OY that could be considered in the new rebuilding analysis (1,369 mt) cannot be considered since canary rockfish would constrain midwater trawl opportunities, even under the higher amount under this rebuilding alternative (68 mt) before that amount of widow rockfish would be incidentally caught. The whiting fishery, which currently takes the greatest amount of widow rockfish, would be much less constrained by widow rockfish or canary rockfish under this alternative.

Northern recreational fisheries are still constrained by the yelloweye rockfish OY under this alternative. However, the effect on the fisheries may be mitigated by the higher canary rockfish OY in that management measures could direct fisheries away from areas with high yelloweye bycatch even if this increased the bycatch of canary rockfish. Depending on the management measures used to constrain the fisheries, fisheries directed toward black rockfish, Pacific halibut, lingcod, and greenling, amongst others, could be affected. Since yelloweye is rarely caught south of Cape Mendocino (40°10' N latitude), southern recreational fisheries are more liberalized under this alternative than under any of the other alternatives.

Rebuilding Alternative 4

Rebuilding Alternative 4 constrains the catch of target species for northern fisheries. Like in Rebuilding Alternative 1, the canary rockfish OY is almost one-half of status quo; however, the yelloweye OY is less than half of status quo, a more significant reduction than that analyzed under Rebuilding Alternative 1.

The OY for darkblotched rockfish is about double that of status quo and the OY for POP is nearly five times status quo. Given this scenario, the trawl fishery would need to shift away from the nearshore and shelf, where bycatch of canary rockfish is high, and into deeper waters where darkblotched encounters are greater (but are accommodated under this alternative). The result of this shift is to limit the catch of many commercially caught shelf and nearshore target species such as petrale and Dover sole in the summer months, English sole, arrowtooth flounder, and Other Flatfish. The midwater trawl fishery for Pacific whiting is similarly constrained under this alternative as it would be under Rebuilding Alternative 1. With a low canary rockfish bycatch cap, it is possible for the non-tribal sectors of the fishery to be closed before reaching their whiting allocations. However, the fishery's demonstrated ability to reduce its bycatch of overfished species in recent years suggests that such a situation may be averted.

Commercial fixed gear and open access fisheries coastwide are constrained significantly by this alternative, due to their encounters with canary and yelloweye rockfish. Management measures would likely be similar to those described under Action Alternative 1, in which the seaward boundary of the non-trawl RCA is extended from 100 to 150 fm north of 40°10' N latitude.

Recreationally fisheries are restricted substantially or eliminated completely under this alternative due to the low canary rockfish and yelloweye rockfish OYs. This affects both bottomfish fisheries (such as black rockfish, blue rockfish, cabezon, and lingcod) as well as other recreational fisheries that catch canary rockfish and yelloweye rockfish incidentally (such as Pacific halibut). In all instances, the OYs for these target species remain largely uncaught. Although yelloweye rockfish is generally only encountered north of Cape Mendocino, canary rockfish is caught nearly coastwide (it is rarely encountered south of Point Conception). Only for these most southern fisheries, can a more liberal season be considered given the higher bocaccio and cowcod OYs.

Unlike the southern commercial fixed gear fisheries, bottom trawl fisheries in the south are relatively unconstrained under this alternative, as the bocaccio OY is approximately twice that of status quo. As a result, the attainment of target species by the southern trawl fishery is largely limited by the attainment of precautionary zone target species OYs (petrale sole and sablefish).

Rebuilding Alternative 5

The OYs under Rebuilding Alternative 5 constrain all sectors of the groundfish fishery coastwide. Yelloweye rockfish, Pacific ocean perch, canary rockfish, darkblotched rockfish, and bocaccio all constrain the catch of more abundant species as well as the remaining two rebuilding species, widow rockfish and cowcod. No target species are constraints under this alternative, and none of the target species' OYs are attained.

The complexity of managing the fisheries increases substantially under this alternative. For example, it is difficult for managers to shift a fishery from an area where the catch of a depleted species has been exceeded into another other area where less constraining depleted species are found because nearly all of the depleted species are equally constraining. This type of situation would likely bring about the early closure of some fisheries in order to avoid exceeding the rebuilding OYs.

4.4 Discussion of Cumulative Impacts

A number of natural and human-induced factors affect the status of a stock. Through data such as commercial and recreational catch estimates, length at age distributions, and larval distribution and abundance, past effects on a stock's productivity and mortality are incorporated into stock assessments and their associated rebuilding analyses. That is, a final estimate of a stock's biomass reflects the wide number of human and natural effects on the stock, both in the past and at the present time, even if these factors are not estimated explicitly in the model. (Although uncertainty with respect to the estimates in the assessments (see section 4.2) and only nascent understanding of the relationship between environmental conditions and stock status increases an assessment's overall uncertainty.) Given that the findings from a stock assessment provide the scientific basis upon which harvest specification decisions are made, it is assumed here that that the impacts of the effects found within stock assessment models are already adequately accounted for within the analysis of this action. This section, therefore, addresses factors that may impact affected species, but which are not explicitly accounted for in the stock assessments. These factors may affect a species in a number of ways, including contributing to the uncertainty that a harvest specification will maintain or rebuild the affected species' population levels and changing the genetic structure of a stock.

The actions discussed below are divided into two categories, *internal* and *external*. *Internal* refers to actions implemented as part of the management regime, while *external* refers to actions of other agencies, organizations and individuals, including broad natural or socioeconomic effects.

4.4.1 Internal Factors

4.4.1.1 VMS Implementation

In order to enforce compliance with depth-based and area-based restrictions, a common tool in management under the Groundfish FMP, a Vessel Monitoring System (VMS) program has been implemented over the past few years. In 2004, NMFS initiated a pilot program requiring all limited entry trawl and fixed gear vessels operating under the Groundfish FMP to carry and use Vessel Monitoring System (VMS) units. Beginning in 2007, this program will be expanded to include all commercial vessels that take and retain, possess, or land federally-managed groundfish species taken in federal waters or in state waters prior to transiting federal waters. Because the vessels must utilize VMS, compliance by limited entry vessels is assumed in the analysis of impacts of depth-based restrictions on affected species; therefore, the effects of the limited entry sectors' used of VMS are already considered under the current action.

The expansion of VMS into the directed open access sector in 2007, however, is considered to be a future action that may affect West Coast groundfish species. VMS deters mixed fishing strategies where vessels alter gear to catch groundfish within the RCAs. As a result, under VMS the risk of the actual catch exceeding the OYs for overfished species due to illegal fishing in the RCAs is reduced. Nevertheless, the behavior of the open access fleet under VMS can only be speculated; for example, the requirement may encourage additional targeting of groundfish by certain vessels in order to compensate for the cost of the VMS equipment. A potential indirect impact of VMS expansion is that fishing effort and location data from the vessels may improve the understanding of groundfish mortality. Data can be combined with observer, survey, and fish ticket data to better estimate total fishing mortality, impacts on juveniles and other fishery resources related to changes in fishing locations and intensity, fishing intensity (amount of time vessels are in an area), and changes in fishing location and intensity over time.

4.4.1.2 Bycatch (Amendment 18)

The Council has undertaken a number of actions in response to the 1996 amendment to the Magnuson-Stevens Act requiring measures to reduce bycatch in U.S. fisheries, as well as to a related court case, *Pacific Marine Conservation Council v. Evans*. Amendment 18 will establish catch caps and increased monitoring policies in the Groundfish FMP in order to minimize bycatch in West Coast groundfish fisheries to the extent practicable, minimize the mortality of unavoidable bycatch, and ensure that bycatch is reported and monitored as required by law. Amendment 18 was approved by NMFS in 2006. By reducing bycatch and bycatch mortality and by increasing the accuracy of total fishing mortality estimates, these new policies complement ongoing actions to rebuild depleted species. As fishing mortality is decreased through more stringent harvest restrictions, the cumulative adverse effects of fishing and its associated bycatch diminish for both depleted and healthy groundfish stocks. Therefore, it is for the less conservative harvest specification alternatives that these bycatch minimization efforts will be particularly important in providing mitigation against adverse effects.

Bycatch minimization efforts should indirectly affect West Coast groundfish stocks by improving the data used in stock assessments. Assessment models will be tuned to more precise estimates of total catch levels, which will then benefit the management specification process that uses these findings. Given that Amendment 18 will not be implemented in time to influence the 2005-2006 stock assessment cycle, the concern that unreported bycatch may adversely impact the affected species is not fully addressed within this action.

4.4.1.3 Changes to the Management Regime: Open Access Sector License Limitation and Trawl Individual Quota System

The Council is currently considering alternatives that would establish at Trawl Individual Quota (TIQ) program, with an expected implementation date of 2010. In a related action, the Council is considering transitioning the open access directed groundfish sector into a permit system for landing groundfish. Both changes to the West Coast groundfish management structure are expected to improve the accounting of fishing mortality to assure that catches do not exceed harvest specifications. More accurate catch data also would be expected to bring about improvements to stock assessments by reducing the uncertainty surrounding catch data.

4.4.1.3 Area restrictions

Since 1998, progressively restrictive depth-based and area closures (most notably RCAs) have constrained fishing activity within smaller areas of state and federal waters. Though these closures are considered to be effective tools in limiting fishing interactions with depleted species, they are also responsible for shifting additional fishing pressure into other areas and onto other species.

For example, the Oregon recreational groundfish fishery has been closed offshore of 40-fm from June through September since 2004. It is likely that due to these closures, most anglers who would have fished offshore during the closure periods instead relocated their activities inshore. The effort shift onto nearshore species that resulted contributed to the early attainment of the black rockfish harvest cap in 2004 and 2005 and to the early closure of the recreational fishery in both years. A similar effect is noted in the California recreational fishery, in which the combined effects of federal RCAs and state marine protected areas have increased the pressure on nearshore stocks. For many of these nearshore stocks, there is little data to support an assessment of its stock status, suggesting that the effect of this effort shift is difficult to monitor.

It is expected that the effects of area restrictions will persist into the future; the effects may also become more acute if depleted species' OYs are further reduced in order to rebuild the species as quickly as possible. Furthermore, in addition to the possible future expansion of RCAs, the implementation of Amendment 19 (Essential Fish Habitat) will bring about other area closures in order to protect sensitive habitat from fishing impacts. For Washington recreational fisheries, for example, a closure of fisheries seaward of 10 fm would reduce the area available (inside 60 fm) by 84%, and a 20-fathom closure would reduce the area inside 60 fm by 74%. Allowing fishing only in these smaller areas could reduce the ability of anglers to target healthy fish stocks in traditional fishing areas. Analogously, fishing pressure on groundfish stocks that may have previously been spread over a broad area could become more concentrated, increasing the potential for localized depletion of some species.

4.4.2 External Factors

4.4.2.1 Short-term and Long-term Climate Variability: ENSO (El Niño) and PDO

Most commercially important fish and shellfish stocks in the California Current system, including many groundfish, are widely acknowledged to experience moderate to substantial variability in year-to-year recruitment success. Nearly all of these stocks (particularly those of winter-spawning shelf species) experienced high (positive) recruitment anomalies in 1999, and a great many of these stocks experienced high recruitment in 2000 as well. For many stocks, these year classes are a primary factor behind the increased abundance trends presented in Table 4-2. For example, the 1999 bocaccio year class was the largest since 1989, resulting in a near doubling of stock spawning biomass between 1999 and 2005.

Similarly, many stocks also demonstrated strong recruitment in 1970, 1980, 1984 and 1990, with weak year classes tending to occur in 1976, 1982-83, 1992-93 and 1997. Multivariate analysis of the stocks' recruitment deviations suggests that a significant amount of the observed variability in recruitment for West Coast groundfish can be explained by environmental conditions that have a very similar impact to a broad range of species across a fairly broad spatial scale. Such a conclusion is also supported by survey data; for example, the Southwest Fisheries Science Center's rockfish pre-recruit survey (1983-2005) detected a strong degree of covariance in the relative abundance of pelagic juvenile rockfish from 1983 through 2005. Although this survey failed to detect the magnitude of the 1999 year class, it does show strong interannual variability throughout the 1980s, followed by a precipitous decline in relative juvenile abundance through most of the 1990s, followed in turn by a return to highly variable (but often strong) recruitment in the post-1999 era.

The timing of these recruitment synchrony events maps well onto short-term and long-term changes in ocean conditions (for further background on the relationship between El Nino events and the Pacific Decadal Oscillation and ocean conditions, see section 3.1.3. Following an intensive 1997-1998 El Nino event, ocean conditions changed dramatically, and 1999 has been described as a year of transition in long-term (decadal scale, as associated with the Pacific Decadal Oscillation, or PDO) ocean conditions by climatologists {Schwing and Peterson 2003}. The mechanisms by which climate affects recruitment are not known with certainty; however, strong recruitment years are generally associated with high southward transport in the winter period, low ocean temperatures, and high zooplankton production; these conditions parallel those present in 1999 and the years that immediately followed. Indeed, the connection between productivity and transport has long been recognized {e.g., Chelton et al. 1982}; recent observations are consistent with this finding; for example, Swartzman and Hickey {2003} describe an increase in euphausiid biomass following the 1999 shift in much of the California Current (generally south of Cape Blanco), and Feinberg and Peterson {2003} describe a dramatic increase in the duration and intensity of euphausiid spawning off Oregon between 1996 and 2001.

In that stock assessments estimate spawning biomass of a stock over time, it is reasonable to conclude that the effects of climatological events, such as El Nino and PDO, on groundfish species are accounted for within the analyses. However, with one exception, current stock assessments do not explicitly account for their effect on stock status, such as changes in fishing mortality. Only Schirripa and Colbert {2005; 2006} have integrated relative sea level (a proxy for transport) into the sablefish stock assessment as an environmental factor related to recruitment variability.

Future effects of ocean conditions on the status of affected species, on the other hand, are not encompassed within the analysis of the present action. Most notably, the criteria used to analyze impacts on depleted species, such as the time to rebuild under a constant harvest rate and the probability of successfully rebuilding the stock by T_{max}, do not account explicitly for the effects of climatological events. Indeed, although the development of statistical indices of climate variability across multiple time scales has improved our understanding of how climate has affected North Pacific ecosystems and productivity in the past, the future remains subject to poor predictability. Such uncertainty, with respect how fish productivity and the climate regime interact and with respect what and when short- and long-term climate changes will occur, brings about greater uncertainty surrounding stock assessment projections of future biomass: since predictions about future productivity are based on past relationships, between stock size and recruitment for example, if underlying conditions change, these predictions may under- or over-estimate population growth and sustainable fishery removals. For depleted species in particular, errors in prediction may lead to the need to decrease fishing effort below levels specified in the rebuilding plan in order to achieve a rebuilt stock by the target date. On the other hand, unanticipated increases in recruitment strength may allow for a quicker time to rebuild. In either case, amendments to the stock's rebuilding plan may be necessary. This environmentally-related uncertainty pertains more specifically to some depleted species (such as bocaccio, explained above) rather than to others; for species such as cowcod and widow rockfish, recruitment trends are better explained by the deterministic stock-recruitment relationship that is modeled within a stock assessment.

4.4.2.2 Spatial Effects

Under the current groundfish FMP, most stocks are managed under a coastwide OY. However, there is increasing evidence that for some stocks, a greater consideration of spatial dynamics could be appropriate, particularly with respect to minimizing the potential for localized depletion.

Berkeley et al. {2004} review examples of complex population structure in rockfish populations that suggests that only a small fraction of the spawners in a given stock contribute to successful recruitment. This can be attributed to high temporal and spatial variability in the coastal ocean that provides only limited opportunities for optimal environmental conditions that are required for successful recruitment for those species for which recruitment variability is high. Consequently, there could be increased recruitment variability, or some potential for recruitment failure, if the most reproductively important elements of a stock are depleted below target levels.

Similarly, for stocks with limited genetic exchange, overfishing of isolated population units could be possible where current stock assessments do not take such population structure into account. For example, Miller et al. {2005} found significant genetic differences among black rockfish adults collected 340–460 km apart, despite the assumption that prolonged larval duration led to widespread dispersal and minimal population structure in this species.

The risk to a species of reduced reproductive success or the depletion of genetic sub-populations is likely to increase with higher levels of fishing mortality. Alternative 3, therefore, poses the greatest risk of adverse spatial effects to depleted species, while Alternative 1 poses the least risk. In addition, alternative management measures may contribute to adverse spatial effects for a given species, as these could change the spatial and/or temporal concentration of catch (at a local and a coastwide scale) from that observed under current conditions. In all alternatives, however, the low OYs for depleted species constrain the catch of many healthy stocks to levels below their OYs, bringing about a reduction in the risk of adverse spatial effects for healthy stocks.

Many Pacific groundfish harvest specifications are structured following biogeographic zones (such as north-south divisions at Cape Mendocino and at Point Conception; see section 3.1.3 for more information). However there is not yet the science available to support spatial management at the resolution that may be necessary to reduce the risks discussed above; data limitations for stock assessment models preclude such advancement for most, if not all, West Coast groundfish species in the near term. Pelletier and Mahevas {2005} compiled a comprehensive review of fisheries and marine ecosystem simulation models and approaches that incorporated spatial dynamics, and rated the potential for each approach to address a range of ecological and fisheries related effects described as important elements of the success (or lack thereof) of implementing spatial management measures. These included restoring spawning biomass within closed areas, restoring demographic structure, increasing fecundity, enhancing fisheries yield, improving population stability and resilience, protecting biodiversity, and effecting changes in community structure. Such issues will be integral elements of fisheries science and management in the future, and advances in both assessment methods and simulation techniques should provide the means to better cope with the challenges of incorporating such complexity in the face of changing management regimes.

4.5 Summary of Impacts

4.5.1 Documentation of Impact Analysis Modeling

4.5.1.1 Modeling Limited Entry Trawl Impacts

Fleet-wide discard estimates associated with groundfish trawling are derived from WCGOP observer data and logbook and fish ticket data obtained from the Pacific Fisheries Information Network (PacFIN). Observer data are stratified by area, depth, and season. The management line at 40°10' N latitude is used to partition northern and southern areas. Bi-monthly cumulative limit periods are combined to form two seasons, representing winter (January-April and November-December) and summer (May-October). The northern area includes five depth strata, however, only four are used in the south, due to the paucity of observed trips in depths shallower than 100 fm. The number of observed tows and retained catch of target species within each stratum are reported in Table 4-15 for the 2004 fishery. For this analysis, target species include all flatfish, sablefish, and thornyheads, and also slope rockfish in the area south of 40°10' N latitude. Since regulations severely limit or eliminate the retention of rebuilding species, estimating fleet discard for those species by applying a ratio of discarded-to-landed catch to landings is not reliable. Consequently for rebuilding or bycatch species, retained target-species catch is used as a measure of effort for expanding discard from observed trips. Table 4-16 shows aggregate discard ratios for several species in each stratum. For bycatch species (upper panel), the discard ratios represent the discarded poundage for each species divided by the retained target species poundage. For target species (lower panel), the ratio of discarded-to-retained pounds is presented for each species.

Logbook data are then stratified in the same manner as observer data, and the retained amounts of individual target species are aggregated for each stratum (Table 4-17). For each target species, an initial estimate of discard is calculated by multiplying the retained poundage by the appropriate discard ratio reported in Table 4-15. For bycatch species, estimated discard is calculated by multiplying aggregate target species poundage in each stratum by the corresponding discard ratio. Logbook data do not include records for all trawl trips, and for purposes of this analysis, records without recorded depth or latitude-longitude coordinates are not included. To adjust for these factors, the discard amounts are expanded to reflect the difference in landed catch reported in fish tickets and logbooks. For target species, the expansion ratio is equal to fish ticket pounds for each species divided by the logbook pounds for each state and 2-month period. For bycatch species, the ratio of fish ticket-to-logbook poundage for combined target species is used.

Table 4-15. Number of limited entry trawl tows and retained target species poundage observed by the West Coast Groundfish Observer Program in 2004, by depth interval, area and season.

Area	Depth intervals (fm)	Winter [a/] Number of observed tows	target species [b/] retained (lbs)	Summer [a/] Number of observed tows	target species [b/] retained (lbs)

b/ Target species are defined as all flatfish, sablefish and thornyheads in both areas and also slope rockfish in the southern area.

4.5.1.2 Modeling Limited Entry Fixed Gear Impacts

Two major strategies for the limited entry fixed gear fleet are targeting of nearshore groundfish species and targeting sablefish in both the primary fishery and the daily-trip-limit (DTL) fishery. Nearshore impact modeling methodology is described in section 4.5.1.4. Impacts in the sablefish targeting strategies are modeled as follows.

Fleet-wide discard estimates associated with fixed-gear sablefish fishing are derived from WCGOP observer data and fish ticket data obtained from PacFIN . WCGOP observation of fixed-gear vessels targeting sablefish began in 2001 and has focused on those participating in the limited-entry primary fishery. Due to the limited numbers of trips observed south of 40°10' N latitude, discard ratios are calculated through pooling all observations for 2004 within each gear group (longline and pot). Few vessels (limited entry or open access) were observed while fishing for sablefish under the "daily-trip-limit" provisions. However, in this analysis, observations from the primary fishery are assumed to be representative of bycatch and discard occurrences associated with all fixed-gear sablefish fishing north of 36° N latitude. Because there are no logbook data indicating the depth of fishing, it is not possible to apply the same depth-stratified approach used for the trawl fleet. Consequently, the coast-wide observer data are summarized, by gear, across the two depth zones where the fishery was permitted to take place in 2004: greater than 100 fm, north of 40°10' N latitude, and greater than 150 fm, south of 40°10' N latitude. As presented in Table 4-18, discarded amounts of sablefish are calculated for each gear and area, using fish ticket landings and the corresponding discard ratios. Since only a fraction of discards die, an assumed mortality percentage is applied. In accordance with the rate of survival assumed by the GMT, 20% of the discarded poundage is assumed to represent mortality. For rebuilding species, observed discard ratios relative to retained sablefish, are then used to calculate estimated amounts of mortality for each.

Table 4-18. Estimated discard of rebuilding species and sablefish associated with all fixed-gear sablefish landings north of 36° N latitude during 2004.

	South of 40°10' (seaward boundary of the RCA at 150 fm)			North of 40°10' (seaward boundary of the RCA at 100 fm)			Summary for area north of 36° N. Lat.

Pacific ocean perch	0.0	0.0	**0.0**	0.0	0.0	0.0	**0.0**
Darkblotched rockfish	0.1	0.0	**0.1**	0.3	0.0	0.4	**0.5**

a/ As assumed by the Groundfish Management Team, the rate of mortality for discarded sablefish in the fixed gear fishery is assumed to be 20%.

b/ Discard ratios are calculated by dividing the total discarded weight of each species by the retained catch weight of sablefish, and are derived from data collected by the West Coast Groundfish Observer Program during the 2004 limited entry fixed gear primary fishery.

c/ Please note that the observer data include few observations from south of Ft. Bragg, CA, so these rates may underestimate the true bycatch of these species.

4.5.1.3 Modeling Open Access Impacts

Open access impacts are modeled using the limited entry fixed gear sablefish impact methodology described in the previous section for the directed open access strategies targeting sablefish (i.e., the daily-trip-limit fishery). Modeling impacts for that portion of the open access fishery targeting nearshore groundfish species is described in the following section.

4.5.1.4 Modeling Nearshore Commercial Impacts

Fleet-wide discard estimates associated with near-shore groundfish fishing are derived from observer data, fish ticket data obtained from PacFIN, and other parameters developed by the GMT. WCGOP began pilot coverage of vessels targeting near-shore rockfish and associated species, such as cabezon and kelp greenling, in 2003. Data collected from these vessels from January 2003 through August 2004 were summarized in a report published on the NWFSC web site in May of 2005 (http://www.nwfsc.noaa.gov/research/divisions/fram/observer/datareport/nearshore/datareport_nearshore_may2005.cfm). Data from the remainder of 2004 have not yet been released. It should be noted that the coverage of observed trips and tonnage reported in Table 4-19 reflect lower levels of coverage than for other fleets, and in turn greater uncertainty in estimating discard relationships. Table 4-20 summarizes bycatch ratios for rebuilding species and the number of observed gear sets used to calculate them. Table 4-21 summarizes the observed catch weight of target and rebuilding species, and the percentage of each species or species-group's catch that was discarded.

Table 4-19. Number of observed open access, fixed gear trips occurring at less than 50 fm and associated landed tonnage, by port group and gear from January 1, 2003 to August 31, 2004.

Port Group	Hook and Line [a/]		Pot [a/]	
	Number of trips	Landed catch (mt)	Number of trips	Landed catch (mt)
Astoria	16	1.2	b/	
S Oregon	71	7.3		
Crescent City	114	14.6		
Fort Bragg	12	0.3	10	0.3
Monterey	24	1.2		
Morro Bay	77	3.9	12	2.5
Santa Barbara	15	0.6	15	1.8
Los Angeles	31	0.7	32	3.2
ALL PORTS	360	29.7	b/	

a/ Since both gear groups were used on some trips, the total number of observed trips is less than the sum of the numbers shown for each gear group in this table.

b/ Data not reported because of confidentiality issues.

Table 4-20. Ratios of bycatch, for eight[a/] rebuilding species, per 100 pounds of retained nearshore target species, by area and depth, from open access fixed gear sets observed between January 1, 2003 and August 31, 2004 by the West Coast Groundfish Observer Program.

a/ The percentage discarded is calculated as the discard poundage divided by the total catch weight for each species.

b/ Lingcod was declared rebuilt in 2005.

In May 2005, the values presented in Tables 4-20 and 4-21 were used by the GMT, in conjunction with other information provided by Team members, in constructing the framework for evaluating discard in the nearshore fisheries presented in Tables 4-22 and 4-23. For the purposes of estimating 2004 discard in nearshore groundfish fisheries, the framework and parameters developed by the GMT have not been updated, except for the target species landed catch amounts. However, an overview of the process embodied in these two tables is presented below for purposes of clarity. Table 4-22 summarizes the calculation of discard for target species. Landed weights for each species/group are expanded to total catch estimates, using all-depth retention rates. Using observer and state-agency information, total catch is then distributed among 3 depth intervals: 0-10 fm, 11-20 fm, and 21-50 fm. Within each of those strata, depth-specific gross discard and mortality estimates are calculated using observed discard ratios and assumed rates of discard survival. The estimated retained catch of all target species within each area/depth stratum is used with observer-derived discard ratios to estimate the discard mortality of rebuilding species in these fisheries (Table 4-23).

4.5.1.5 Modeling Tribal Fishery Impacts

Background

From 1991 to 2002, Makah fishermen have employed trawl gear on a limited, exploratory basis. Recently, trawl fisheries have been developed to diversify harvest strategies and maximize fisheries production (vessels must choose between trawling and longlining and cannot engage in both). The trawl fleet had eight vessels in 2003 and expanded to the current fleet limit of 10 vessels in 2004. They pursue two basic strategies – bottom (small footrope) and midwater (pelagic) trawl. The majority of the fleet participates in both strategies though some specialize in one or the other. The bottom trawl fishery targets flatfish (primarily Dover, English, and petrale soles and arrowtooth flounder) and Pacific cod, while the midwater fishery targets yellowtail rockfish. In an agreement with the National Marine Fisheries Service and the Pacific Fishery Management Council, the Makah Tribe implemented an observer program in 2003 to monitor maximum retention compliance in the newly developed trawl fisheries. The observer program has a monthly (and overall annual) sampling rate target of 15% of all trips and is administered by a cooperative agreement between the Makah Tribe, Northwest Indian Fisheries Commission, and Washington Department of Fish and Wildlife.

Current Management

Makah Fisheries Management has developed trip limits for the trawl fleet for each of two strategies – bottom and midwater – that maximize production, while discouraging both interactions with overfished species and conflicts (i.e., preempting another fleet's opportunity) with their groundfish directed longline fleet (Tables 4-24 and 4-25). While trip limits are in place to discourage targeting on several species, especially overfished rockfishes (e.g., canary), maximum retention is required. Maximum retention in this case is defined as full retention of all marketable species, with particular emphasis on canary and widow rockfishes. Any trip limit overages are sold and the proceeds forfeited to the Tribe.

Table 4-24. Trip limits for the tribal midwater trawl fishery for both 2003 and 2004.

SPECIES	TRIP LIMITS
Yellowtail rockfish	≤ 30,000 lbs/trip
Widow rockfish	≤ 10% of yellowtail
Canary rockfish	300 lbs/trip
Minor shelf rockfish	300 lbs/trip
Minor slope rockfish	300 lbs/trip
Minor nearshore rockfish	300 lbs/trip
Thornyheads (long- and shortspine combined)	300 lbs/trip
Other species	Same as initial Limited Entry (LE) trawl N of 40° 10'

Table 4-25. Trip and/or cumulative limits for the tribal bottom trawl fishery for 2003 and 2004.

SPECIES	2003 LIMITS	2004 LIMITS
Petrale sole	30,000 lbs/2 mo	30,000 lbs/2 mo
Arrowtooth flounder	60,000 lbs/2 mo	30,000 lbs/trip
All other flatfish	100,000 lbs/2 mo	100,000 lbs/2 mo
Lingcod	300 lbs/day (not to exceed 900 lbs/week)	450 lbs/day (not to exceed 1,350 lbs/wk)
Sablefish	6,000 lbs/yr dressed wt	6,000 lbs/yr dressed wt
Yellowtail rockfish	5,000 lbs/mo	3,000 lbs/trip
Widow rockfish	$\leq$ 10% of yellowtail/trip	$\leq$ 10% of yellowtail/trip
Canary rockfish	300 lbs/trip	300 lbs/trip
Minor shelf rockfish	300 lbs/trip	300 lbs/trip
Minor slope rockfish	300 lbs/trip	300 lbs/trip
Minor nearshore rockfish	300 lbs/trip	300 lbs/trip
Thornyheads (long- and shortspine combined)	300 lbs/trip	300 lbs/trip
Other species	Same as initial LE trawl N of 40° 10'	Same as initial LE trawl N of 40° 10'

Since canary rockfish is the primary constraint in both strategies, management centers on its avoidance. The two strategies may be open simultaneously (though most fishermen with midwater nets will prosecute that strategy when available) and are closed whenever bycatch rates appear elevated. The bottom trawl fishery has a small footrope requirement ($\leq$ 8 inches) that reduces rockfish interactions by preventing access to reefs, rocky substrate, and other high-relief areas. The midwater fishery uses pelagic nets and is managed with a combination of time and area closures to minimize impacts on canary and widow rockfishes.

Midwater trawl areas are defined by latitudinal and longitudinal coordinates in regulations. An area is opened after two vessels with full observer coverage make exploratory trips to verify that bycatch rates are low enough to prosecute the fishery. An area is closed whenever bycatch rates appear elevated. The fishery is also closed June-August based on anecdotal evidence from fishermen that canary rockfish bycatch is highest in these months. Trip limits are usually 30,000 pounds/2 month period, but may be adjusted upwards to a maximum of 30,000 pounds/trip if bycatch appears minimal and few vessels are participating.

Methods

Observations are conducted by the port sampler operating out of Neah Bay, WA. Vessels must contact an observer hotline 24 hours prior to departure stating the date and time of departure and expected duration of the trip. Vessels are selected in a quasi-random manner based on availability of the observer in coordination with his other duties (i.e., dockside sampling and data entry). Data collected include gear type, tow duration, average depth, start and end location, and pounds discarded and retained. Priority is given, in decreasing order, to verifying maximum retention, quantifying discard of halibut and their disposition (not covered in this report), and quantifying all other discard species.

Bycatch rates were measured as total catch (retained + discard, if any) of bycatch species divided by landed catch of target species in pounds – similar to the method employed by the West Coast Groundfish Observer Program. While tow-by-tow data are collected by the observer, corresponding information is not available for unobserved trips making it difficult to attribute bycatch to a particular bottom trawl target strategy. Instead, bycatch rates for bottom trawl are reported for primary flatfish targets combined (petrale, English, and Dover soles and arrowtooth flounder), all flatfish combined, Pacific cod, and all targets combined (i.e., Pacific cod plus all flatfish). Target species are divided into these categories to help determine if bycatch of canary can more readily be attributed to flatfish fishing or Pacific cod fishing. The midwater trawl fishery targets only yellowtail rockfish. Bycatch of canary rockfish is measured for both bottom and midwater trawl fisheries. Bycatch of widow rockfish in midwater trawl is also examined.

Comparisons of observed versus unobserved landings by year were conducted for each strategy to test for differences in retention of select overfished species. Separate analyses were performed for vessels that carried an observer (paired *t* test) and all vessels combined (i.e. including those vessels that had no observer coverage during the year). For all vessels combined the assumption of equal variance was tested and the appropriate *t* test performed. Comparisons of canary rockfish associated with primary flatfish, Pacific cod, and all target species combined were conducted for bottom trawl. Comparisons based on all flatfish landings were not performed, since other flatfish (i.e., non-primary species) are not specifically targeted and change bycatch rates very little. Both widow and canary rockfish associated with yellowtail rockfish were examined for midwater trawl. Comparisons across years were not performed to avoid confusion of interannual variation in species availability or targeting strategy with fishing behavior associated with carrying an observer.

Results

Bottom Trawl

In 2003 there were 23 sampled trips out of 175 total trips (13.1%). Coincidentally, 23 of 221 total trips (10.4%) were also sampled in 2004. Discard in both years consisted primarily of Pacific whiting, spiny dogfish, unmarketable flatfish, and other unmarketable fishes (Table 4-26). Bycatch rates for all landings by target and year are provided in Table 4-27.

Table 4-26. Observed tribal bottom trawl discard in pounds by species or species group by year.

Species	2003	2004
Pacific whiting	11,000	5,097
Spiny dogfish	9,534	9,231
Arrowtooth flounder	1,982	6,250
Unspecified skates	1,485	4,723
Unspecified sole	1,219	1,484
Ratfish	1,180	3,361
Pollock	120	503
Minor shelf rockfish	30	104

Table 4-27. Total fleet bycatch rates (measured as pounds of canary rockfish in the tribal bottom trawl fishery divided by pounds of target category) by year.

Target	2003	2004
Primary flatfish	0.00138	0.00223
All flatfish	0.00131	0.00212
Pacific cod	0.00137	0.00249
All targets	0.00067	0.00115

Two-tailed paired t tests found no significant difference between observed and unobserved trips for vessels that carried an observer during the season for either year (Table 4-28). Canary catches per combined primary flatfish landings were not significantly different. Similarly, canary catches associated with Pacific cod and all targets combined were not significantly different.

Table 4-28. Yearly comparisons of canary rockfish bycatch rates (measured as pounds of canary rockfish divided by pounds of target category) for tribal bottom trawl vessels that carried an observer at least once during a season.

Year	Target Species	Mean Bycatch Rates		d.f.	t	p
		Observed	Unobserved			
2003	Primary flatfish	0.00121	0.00198	6	0.79	0.46
	Pacific cod	0.00202	0.00344	6	-0.60	0.57
	All Targets	0.00059	0.00113	6	-0.89	0.41
2004	Primary flatfish	0.00772	0.00343	5	0.79	0.47
	Pacific cod	0.03807	0.00312	5	1.19	0.29
	All Targets	0.00619	0.00127	5	1.15	0.30

Two-tailed t tests also found no significant difference between all observed and unobserved trips in either year (Table 4-29). Canary bycatch rates associated with primary flatfish were not significantly different. For Pacific cod, observed versus unobserved trips in 2004 had unequal variances $F\ (5, 9) = 23.62$, $p < 0.01$ and were not significantly different in either year. Bycatch rates of canary for all targets combined also were not significantly different.

Table 4-29. Yearly comparisons of canary rockfish bycatch rates (measured as pounds of canary rockfish divided by pounds of target category) for all observed and unobserved tribal bottom trawl vessels.

Year	Target Species	Mean Bycatch Rates		d.f.	t	p
		Observed	Unobserved			
2003	Primary flatfish	0.00106	0.00143	16	-0.43	0.67
	Pacific cod	0.00176	0.00245	16	-0.38	0.71
	All Targets	0.00052	0.00085	16	-0.68	0.50
2004	Primary flatfish	0.00772	0.00750	14	0.03	0.98
	Pacific cod	0.03807	0.00663	5	1.07	0.33
	All Targets	0.00619	0.00330	14	0.64	0.53

Midwater Trawl

The observer sampled 5 out of 34 trips (16.0%) in 2003, and 11 of 53 trips (20.8%) in 2004. Discard consisted of Pacific whiting, minor shelf rockfish, minor slope rockfish, and dogfish (Table 4-30). Bycatch rates of widow and canary in all landings are provided in Table 4-31.

Table 4-30. Observed tribal midwater trawl discard in pounds by species or species group by year.

Species	2003	2004
Pacific whiting	3270	0
Minor shelf rockfish	450	1175
Minor slope rockfish	63	575
Spiny dogfish	0	70

Table 4-31. Total fleet bycatch rates (measured as pounds of canary or widow rockfish divided by pounds of yellowtail rockfish) in the tribal midwater trawl fishery by year.

Species	2003	2004
Canary	0.00168	0.00350
Widow	0.04263	0.06767

Two-tailed paired *t* tests found no significant difference in bycatch between observed and unobserved trips on vessels that carried an observer at some point in the season (Table 4-32). In 2003 there was no significant difference for canary or widow. There was also no significant difference in 2004 for either canary or widow.

Table 4-32. Yearly comparisons of canary and widow rockfish bycatch rates (measured as pounds of bycatch divided by pounds of yellowtail) for tribal midwater trawl vessels that carried an observer at least once during a season.

Year	Species	Mean Bycatch Rates		d.f.	*t*	*p*
		Observed	Unobserved			
2003	Canary	0.00351	0.00289	2	0.27	0.81
	Widow	0.05353	0.03335	2	0.60	0.61
2004	Canary	0.00651	0.00213	5	1.81	0.13
	Widow	0.07209	0.06719	2	0.30	0.78

In comparisons of all observed versus unobserved trips, two-tailed *t* tests detected no significant differences in bycatch (Table 4-33). Variances for canary bycatch were unequal in observed and unobserved trips for 2003 and 2004 $F(2, 7) = 9.57$, $p < 0.01$ and $F(5, 10) = 5.90$, $p < 0.01$ respectively. The difference in canary bycatch was not significantly different in either year, though in 2004 the difference is characterized as being of "borderline" significance. No significant differences were detected for widow bycatch in either year.

Table 4-33. Yearly comparisons of canary and widow rockfish bycatch rates (measured as pounds of bycatch divided by pounds of yellowtail) for all observed and unobserved tribal midwater trawl vessels.

Year	Species	Mean Bycatch Rates		d.f.	*t*	*p*
		Observed	Unobserved			
2003	Canary	0.00351	0.00124	2	0.72	0.55
	Widow	0.05353	0.07671	9	-0.39	0.70
2004	Canary	0.00651	0.00175	6	2.13	0.08*
	Widow	0.07209	0.05421	15	1.16	0.26

* Difference in canary bycatch rates in 2004 was of borderline significance.

Discussion

Bycatch rates for a particular species can vary considerably within a fleet and for a variety of reasons. Annual variations in distribution or abundance can affect encounters, as can effort and the times and areas fished. This is especially true for patchily distributed animals such as canary and widow rockfishes. In both bottom and midwater trawl fisheries the encounter rate of canary was considerably higher in 2004 than in 2003 (71.6% and 108.3% respectively). The bycatch rate of widow rockfish in the midwater fishery was 58.7% higher in 2004. These increases may also reflect expanding effort (though not capacity) within the trawl fleet as a whole. Some level of increasing impacts may be due to what has been termed the "rebuilding paradox." The paradox is that as overfished species rebuild, they are more likely to be encountered by fishermen trying to avoid them. Estimating the relative influence of these factors will require more data collection and further, detailed analyses.

One interesting effect of increased occurrences of canary rockfish in the 2004 midwater fishery was the prosecution of more observed, exploratory trips to determine if bycatch rates were low enough to conduct the fishery in a given area. Observed vessels engaged in exploratory trips can be expected to have higher bycatch rates than unobserved vessels operating in verified low bycatch areas. This is likely what led to the borderline significant low *p*-value for observed versus unobserved that year. Differentiating observed exploratory trips from other observed trips may lead to more comparable observed versus unobserved bycatch rates. Despite large interannual variation of bycatch rates for these two years, the values measured can still inform management. Examination of bycatch rates over many years could detect patterns, and averages across years weighted toward more recent years can mitigate some of the negative effects of the rebuilding paradox on the fishery as well as reflecting changes in fleet behavior (i.e., if more recent years are likely to be more similar to the upcoming season, preseason planning is improved). If preseason planning is based on accurate expectations of bycatch, inseason management (e.g., time and area restrictions) is likely to be more effective at staying within estimated impacts.

Combining maximum or full retention policies with an observer program to verify the accuracy of bycatch accounting can greatly benefit both the fleet and the resource. In other words, if observed bycatch rates are not significantly different than unobserved bycatch rates, managers can be reasonably certain that landings reflect total mortality for overfished species and fishermen can continue to access healthy stocks. This combination can also prove very cost effective where other programs might not be economically feasible (e.g., full observer coverage). With this method, estimates of total removals can be verified, bycatch rate estimates refined, and better preseason and inseason management can be achieved. In this case, the lack of significant differences between bycatch rates in observed versus unobserved trips shows that the maximum retention program is working and landings are a reasonable estimation of actual impacts.

4.5.1.6 Modeling Washington Recreational Impacts

Washington Recreational Fishery Sampling and Catch Estimates

The Washington Ocean Sampling Program (OSP) generates catch and effort estimates for the recreational boat-based groundfish fishery which are provided to Pacific States Marine Fisheries Commission (PSMFC) and incorporated directly into RecFIN. The OSP provides catch in total numbers of fish, and also collects biological information on average fish size, which is provided to RecFIN to enable conversion of numbers of fish to total weight of catch. Boat egress from the Washington coast is essentially limited to four major ports, which enables a sampling approach to strategically address fishing effort from these ports. Effort estimates are generated from exit-entrance counts of boats leaving coastal ports while catch per effort is generated from angler intercepts at the conclusion of their fishing trip. The goal of the program is to provide information to RecFIN on a monthly basis with a one-month delay to allow for inseason estimates. For example, estimates for the month of May would be provided at the end of June. Some specifics of the program are:

Exit/Entrance Count

Boats are counted either leaving the port (4:30 AM - end of the day) or entering the port (approximately 8:00 AM through end of the day) to give a total count of sport boats for the day.

Interview

Boats are encountered systematically as they return to port; anglers are interviewed for target species, number of anglers, area fished, released catch data and depth of fishing (non-fishing trips are recorded as such and included in the effort expansion). The OSP only collects information on released catch and does not collect information on the condition of the released fish. Therefore, released catches must be post-stratified as live or dead based upon an assumed discard mortality rated. Onboard observers are deployed throughout the sampling season primarily to observe hatchery salmon mark rates but also collect rockfish discard information for halibut charter trips.

Examination of Catch

Catch is counted and speciated by the sampler. Salmon are electronically checked for coded wire tags and biodata is collected from other species.

Sampling Rates

Sampling rates vary by port and boat type. Generally, at boat counts less than 30, the goal is 100% coverage. The sampling rate goal decreases as boat counts increase (e.g., at an exit count of 100, sample rate goal is 30%; over 300, sample rate goal is 20%). Overall sampling rates average approximately 50% coastwide through March-October season.

Sampling Schedules

Due to differences in effort patterns, weekdays/weekend days are stratified. Usually, both weekend days and a random 3 of 5 weekdays are sampled.

Personnel

OSP sampling staff include two permanent biologists coordinating data collection, approximately twenty-two port samplers, four on-board observers and one data keypuncher.

Volume of Data

Between 20,000 and 30,000 boat interviews completed per season coastwide.

Data Expansion

Algorithm for expanding sampled days:

$$\frac{\text{Exit Count}}{\text{Total boats sampled}} * P_s \text{ sampled} = P_t$$

where P_s = any parameter (anglers, fish retained, fish released) within a stratum,
and P_t = total of any parameter with stratum for the sample day

Algorithm for expanding for non-sampled days:

$$\text{Total Weekday Catch} = \frac{\Sigma(P_t) \text{ on sampled weekdays}}{\text{number weekdays sampled}} * \text{no. of weekdays in stratum}$$

$$\text{Total Weekend Catch} = \frac{\Sigma(P_t) \text{ on sampled weekend days}}{\text{number weekend days sampled}} * \text{no. weekend days in stratum}$$

Total weekend catch + total weekday catch = total catch in stratum

Notes on Data Expansion:
Salmon and halibut catches are stratified by week; all other species are stratified by month. All expansions are stratified by boat type (charter or private), port, area and target species trip type (e.g., salmon, halibut, groundfish, and albacore).

Washington Recreational Fishery Impact Modeling

Pre-Season Catch Projections

Projected impacts for Washington's recreational fishery are essentially based upon the previous season's harvest estimated by the Ocean Sampling Program (OSP) and incorporated in RecFIN. This is especially true if recreational regulations remain consistent.

However, in 2005, the Washington Department of Fish and Wildlife implemented a depth restriction of 30 fm for a portion of the Washington coast. Since 2002, the OSP program began collecting fishing depth as well as discard information. This information is keypunched and analyzed on an annual basis with respect to depth of catch for species of concern. Beginning in 2006, and carrying through 2007 and 2008, we have modified our pre-season catch projections, based on the use of depth restrictions, by sub-area and fishery. The Washington recreational management measures include prohibiting fishing deeper than 10, 20, or 30 fm (depending upon time and management sub-area); therefore, the depth analysis was re-structured to determine the catch and mortality of discarded fish relative to these depths, as follows:

Canary Rockfish

- Apply 100% mortality rate to canary rockfish caught on all recreational fishing trips targeting Pacific halibut, when there is no depth restriction in place
- Apply 66% mortality rate to canary rockfish on recreational fishing trips targeting species other than Pacific halibut, when there is no depth restriction in place
- When a 20-fm depth restriction is in place, apply a 50% mortality rate to canary rockfish caught on all recreational fishing trips (based on research by Albin and Karpov, 1995).
- When a 10-fm depth restriction is in place, apply a 10% mortality rate to canary rockfish caught on all recreational fishing trips.
- When a 10- or 20-fm depth restriction is in place, there may be a reduced encounter rate of canary rockfish, but this is not included in the model.

Yelloweye Rockfish

- Apply 100% mortality rate to yelloweye rockfish caught on all recreational fishing trips, when there is no depth restriction in place
- When a 20-fm depth restriction is in place, apply a 50% mortality rate to yelloweye rockfish caught on all recreational fishing trips (based on research by Albin and Karpov, 1995).
- When a 20-fm depth restriction is in place, apply an encounter rate reduction of 25% (based on 2005 OSP catch-by-depth data) as yelloweye tend to inhabit deeper depths.
- When a 10-fm depth restriction is in place, apply a 10% mortality rate to yelloweye rockfish caught on all recreational fishing trips.
- When a 10-fm depth restriction is in place, the yelloweye encounter rate is likely reduced from the rate inside 20 fm, but this is not included in the model.

Inseason Catch Projections

Inseason catch projections are based upon the most recent OSP estimates (with a one-month time lag) with subsequent months extrapolated from the pre-season catch projections. This includes producing inseason reports of discard information for prohibited species such as yelloweye and canary. However, it should be noted that the precision of recreational groundfish catch estimates based upon previous seasons will continue to be influenced by factors such as the length and success of salmon and halibut seasons, weather and other unforeseen factors.

4.5.1.7 Modeling Oregon Recreational Impacts

Data Source for Base Model

Modeling of estimated impacts in the 2007-2008 Oregon recreational groundfish fishery was based on recent year estimates of landings and discards. For the ocean boat fishery, the data source was the Oregon Department of Fish and Wildlife's (ODFW) Ocean Recreational Boat Survey (ORBS). For the shore and estuary fishery, the data source was the Marine Recreational Fishery Statistical Survey (MRFSS). Analyzed species include black, blue, brown, canary, china, copper, grass, quillback, vermilion, tiger, widow, and yelloweye rockfishes; as well as kelp and rock greenlings, cabezon and lingcod.

Landings and discards for the ocean boat fishery (in numbers of fish) were initially based on normalized 2004 and 2005 landings and discards because these data most closely reflect regulations expected in 2007-2008 (i.e., bag limits, effort shifts to avoid overfished and harvest capped species, etc.). The 2004 season reflected very good salmon opportunity, while the 2005 season reflected reduced salmon opportunity. As work progressed on the model and the outlook for salmon opportunity in the near future appeared likely to be reduced from recent years it was decided to model estimated 2007-2008 impacts based solely on the 2005 season (reduced salmon opportunity). Groundfish directed effort has been shown to be affected by salmon opportunity (i.e. groundfish directed effort increases when salmon opportunity is poor due to anglers pursuing other species). Concern was expressed that adopting an overly optimistic groundfish season would result in inseason action to slow catch rates, and anglers would rather have regulations relaxed inseason rather than opportunities curtailed. If salmon opportunity improves in 2007-2008, the recreational groundfish opportunity could be expanded inseason.

Landings and discards for the shore and estuary fishery (in weight), largely not affected by management of overfished species, reflect the most recent 5-year average, 1998-2002 as the MRFSS program is designed for trends and not annual accurate estimates of catch. Only annual weights for greenling and cabezon were adjusted to reflect changes in minimum length requirements.

Normalizing 2005 Catch and Angler Trip Data

To facilitate providing maximum flexibility in modeling 2007-2008 management measure alternatives, landings in 2005 were normalized to a 10-fish marine bag limit and a year round season with no offshore closures.

From 2000 through 2002, the rockfish bag limit had been 10 fish per angler per day. Starting in 2003 a 10-fish marine bag limit was implemented that included species other than lingcod, salmon, steelhead, Pacific halibut, sanddab, surfperch, sturgeon, striped bass, pelagic tuna and mackerel species, and bait fish such as herring, anchovy, sardine and smelt. In response to an early closure in 2004, the 2005 marine bag limit started at 8 fish on January 1 and was reduced to 5 fish on July 16.

Normalization of the marine bag limit was accomplished by comparing the average catch per angler trip (CPUE) observed in 2005 (8 and 5 fish marine bag limits in place) with comparable periods in 2003-2004 (10 fish marine bag limit). The average reduction in CPUE observed by adjusting the marine bag limit from 10 to 8 fish was 10.9 percent. A 38.2 percent reduction was observed when the marine bag limit was adjusted from 10 to 5 fish. The same methodology was applied to discards per angler trip, as the number discarded for many species for which retention was allowed increased as the marine bag limit was reduced. Canary and yelloweye rockfish impacts were not adjusted, as the data suggested little change to the duration of groundfish trips, resulting in little savings of those two species.

Landings and discards were normalized to reflect a fishery without depth restrictions. In both 2004 and 2005, during the period from June through September the groundfish fishery was closed shoreward of the 40-fathom line. The expected increase in encounter rates for species residing offshore was based on data from 2001 and 2003-2005 at-sea observations on Oregon charter vessels (360 trips were observed). The observer study was not conducted in 2002. The following increased encounter rates were applied to appropriate months when normalizing to an all-depth fishery: canary rockfish = 1.32; yelloweye rockfish = 1.69; lingcod = 1.3; and widow rockfish = 3.57.

Landings and discards were normalized to a year round season. In both 2004 and 2005 regulations were changed inseason (starting in early September in 2004 and mid-October in 2005). Because of the inseason closures in 2004-2005, the 2003 fishery was used as a template for seasonal catch and effort pattern in the groundfish fishery as it was open January through December. Estimated catch for October through December was calculated by applying the monthly temporal pattern observed in 2003 to the normalized January through September 2005 estimates.

The expected average weight of landed fish was based on those observed in the 2005 ocean boat fishery. The expected average weight of discarded fish in the ocean boat fishery was based on at-sea observations in 2003-2005 with attention paid to matching samples with depth closure regulations. Observations indicate that yelloweye rockfish and canary rockfish caught shoreward of the 40 fm line were considerably smaller than the average size of those caught offshore, due to a higher abundance of juveniles nearshore. Due to small sample sizes observed at-sea, the average weight of fish landed in 2003 was used to represent the average weight of yelloweye rockfish caught during periods of no depth restrictions. For widow rockfish and nearshore rockfish other than black rockfish and blue rockfish, again due to small sample sizes (most are retained), a 25 percent reduction from average landed weight was assumed for discards of these species. This was thought to be conservative as the observed average size of discarded black rockfish and blue rockfish were on the order of a 50 percent reduction from average landed weight.

Annual groundfish directed angler effort for the ocean boat fishery is expected to be similar to levels observed in 2005. Effort data was also normalized using the 2003 temporal pattern to estimate groundfish effort during October through December when the nearshore fishery was closed in 2005. Angler effort in shore and estuary areas is assumed to be similar to the base period of 1998-2002. Groundfish angler trips in the shore and estuary fishery are not available, only total angler trips of all trips types. During closures seaward of 40-fm, ocean boat effort and catch were shifted from the offshore closure areas to open nearshore areas. The estimated effort increase in nearshore waters is 5 percent, which reflects the fact that approximately 5% of the total effort in 2001-2003 was in offshore waters. This effort shift was addressed when normalizing the 2005 fishery.

Estimating Discard Mortality in the Oregon Recreational Groundfish Fishery

An approach similar to that used for the commercial open-access nearshore fishery to determine mortality of discarded groundfish was used to develop appropriate discard mortality rates to be applied to the recreational fishery. The approach incorporates at-sea observations of catch by species, stratified by depth, with angler reported discard, and stratum based mortality rates by species.

At-sea observations were conducted on recreational charter vessels off Oregon during 2001, 2003-2005. A total of 360 vessels trips were conducted. Each year the observations were distributed across the state in an effort to represent the relative magnitude of catch by area. The annual goal was to conduct 100 observations, but that goal was not always achieved due to inseason closures. The number of rockfish observed by species or species group, discarded in the nearshore recreational fishery is reported in Table 4-34.

Table 4-34. Count of released fish observed by depth bin (fm) during 2001, and 2003-2005. Canary and yelloweye data from open all depth periods only; black, blue, and other nearshore rockfish data from all

periods. Other nearshore rockfish includes brown, copper, quillback and china rockfishes (no discards of other nearshore rockfish species were observed).

Species	≤10 fm	11-20 fm	21-25 fm	26-30 fm	31-40 fm	> 40 fm	Sample Size
Black rockfish	296	372	18	2	0	0	688
Blue rockfish	183	622	48	5	0	0	858
Other nearshore rockfish	1	8	2	5	0	0	16
Canary rockfish	13	107	29	2	5	52	208
Yelloweye rockfish	0	5	1	1	0	13	20

The species of rockfish caught inside of 20-fm, and for which mortality rates are derived, include black, blue, other nearshore rockfish, canary, and yelloweye. The distribution of discarded fish by species and depth bin (fm) based on at-sea observations are identified in Tables 4-35a-e. Observed distributions are presented for all-depth fisheries, and predicted distributions are presented for fisheries closed seaward of 40-fm, 30-fm, 20-fm, and 10-fm.

Table 4-35a. Distribution of released fish observed by depth bin (fm) when open all depths.

Species	≤10 fm	11-20 fm	21-25 fm	26-30 fm	31-40 fm	> 40 fm	Sample Size
Black rockfish	43%	54%	3%	0%	0%	0%	688
Blue rockfish	21%	72%	6%	1%	0%	0%	858
Other nearshore rockfish	9%	73%	18%	45%	0%	0%	16
Canary rockfish	6%	51%	14%	1%	2%	25%	208
Yelloweye rockfish	0%	25%	5%	5%	0%	65%	20

Table 4-35b. Predicted distribution of released fish when closed outside 40 fm.

Species	≤10 fm	11-20 fm	21-25 fm	26-30 fm	31-40 fm	Sample Size
Black rockfish	43%	54%	3%	0%	0%	688
Blue rockfish	21%	72%	6%	1%	0%	858
Other nearshore rockfish	6%	50%	13%	31%	0%	16
Canary rockfish	8%	69%	19%	1%	3%	156
Yelloweye rockfish	0%	71%	14%	14%	0%	7

Table 4-35c. Predicted distribution of released fish when closed outside 30 fm.

Species	≤10 fm	11-20 fm	21-25 fm	Sample Size
Black rockfish	43%	54%	3%	686
Blue rockfish	21%	73%	6%	853
Other nearshore rockfish	9%	73%	18%	11
Canary rockfish	9%	72%	19%	149
Yelloweye rockfish	0%	83%	17%	6

Table 4-35e. Predicted distribution of released fish when closed outside 20 fm.

Species	≤10 fm	11-20 fm	Sample Size
Black rockfish	44%	56%	668
Blue rockfish	23%	77%	805
Other nearshore rockfish	11%	89%	9
Canary rockfish	11%	89%	120
Yelloweye rockfish	0%	100%	5

Mortality rates for fish discarded by depth strata are detailed in Table 4-36. A mortality rate of 100% would be applied to all rockfish caught and discarded in waters deeper than 20-fm. These mortality rates were applied to the species distributions (Table 4-35) to determine the comprehensive mortality rates detailed in Table 4-37. These comprehensive mortality rates are applied to estimated discard, calculating estimated discard mortality.

Table 4-36. Mortality rates developed by the GMT for use in the Oregon recreational fishery.

Mortality rate	≤10 fm	11-20 fm	21-25 fm	26-30 fm	31-40 fm	> 40 fm
Black rockfish	10%	40%	100%	100%	100%	100%
Blue rockfish	10%	40%	100%	100%	100%	100%
Other nearshore rockfish	10%	50%	100%	100%	100%	100%
Canary rockfish	10%	50%	100%	100%	100%	100%
Yelloweye rockfish	10%	50%	100%	100%	100%	100%

Table 4-37. Recommended mortality rates for all-depth fisheries and fisheries closed outside of 40 fm, 30 fm, 25 fm, 20 fm and 10 fm.

Species	<=10 fm	<= 20 fm	<= 25 fm	<= 30 fm	<= 40 fm	All depth
Black rockfish	10%	27%	29%	29%	29%	29%
Blue rockfish	10%	33%	37%	37%	37%	37%
Other nearshore rockfish	10%	46%	55%	69%	69%	69%
Canary rockfish	10%	46%	56%	57%	58%	69%
Yelloweye rockfish	10%	50%	58%	64%	64%	88%

A 7 percent mortality rate is applied in the Oregon recreational groundfish fishery for discarded lingcod, cabezon, and greenling species. In addition, a 7 percent mortality rate is used for the shore and estuary boat fisheries for all species discarded because, as barotrauma is not an issue, mortality is mostly related to hook location.

Model Inputs

Daily bag limits, offshore closures, minimum length changes, effort increases, and abundance trends are the basic input factors applied to the standardized 2005 model.

Bag limits were modeled to range from 5 to 10 marine fish and 2 to 3 lingcod. The expected reduction in CPUE from reducing the marine bag limit from 10 fish is based on the same comparison used to normalize the 8 and 5 fish marine bag limits observed in the 2005 fishery. A linear relationship was assumed using the observations in going from 10 to 8 and 10 to 5 fish. The following rates (in percent) of decline in CPUE were used when reducing the bag from 10 fish: 9 = 5.5; 8 = 10.9; 7 = 20.0; 6 = 29.1; 5 = 38.2. As assumed in normalizing the model no effect on CPUE was expected for yelloweye rockfish and canary rockfish (no retention allowed).

The effect of increasing the lingcod bag limit from 2 to 3 fish was also analyzed. In the ocean boat fishery, sample data from 2005 was used to determine the proportion of anglers that had achieved their 2 fish bag limit in 2005 (6.3%). An increase of 10.6 percent of the estimated landings resulted, assuming the same anglers would achieve a 3 fish bag limit. Applying the same approach to discard data results in a reduction of the estimated discard of 15.6 percent. Similar adjustments were made to the estimated landings in the shore and estuary fisheries to reflect an increase in the bag limit (8.5 percent increase in landings). No reductions were made to the estimated discards in the shore and estuary fisheries as most anglers quit fishing when they achieve their lingcod bag limit. No adjustments were made for increased targeting due to the increased bag limit. Discussions with anglers and charter operators indicate any likely increase in targeting lingcod would occur in offshore areas, for which opportunity is drastically reduced due to offshore closures.

The effect of lingcod minimum length reductions from 24-inches to 22 and 20-inches were analyzed for both the ocean boat and shore and estuary fisheries. The length profile of discards was developed from at-sea observations in the 2005 ocean boat fishery. These were applied to the estimated proportion of fish discarded in 2005 (42 percent of total fish caught based on ORBS estimates). It was assumed that all fish between 20 to 24-inches, and 22 to 24-inches would have been retained under the respective regulations. This resulted in an estimated increase in number of fish retained under minimum length regulations of 20 and 22-inches of 53.6 and 35.8 percent respectively. The estimated decrease in the amount of discarded fish under minimum length regulations of 20 and 22-inches was 72.3 and 58.3 percent respectively. The profile of discarded fish in the ocean boat fishery was used as a proxy for the shore and estuary fishery, as there exists no profile of the length of fish discarded in that fishery. This data was applied to the estimated proportion of fish discarded in the shore and estuary fishery (78 percent of total fish caught based on MRFSS estimates). As in the ocean boat fishery it was assumed that all fish now of legal size would have been retained as very few anglers attain the 2-fish bag limit. Because modeling of the shore and estuary fishery is based on past landings in metric tons, no estimate of additional landings in number of fish was calculated, only an expected increase in metric tons. The increase in landings estimated under the 20 and 22-inch minimum length requirements is 10 mt (equating to a discard reduction of 10 mt) and 7 mt (equating to a discard reduction of 7 mt) respectively.

Expected encounter rate reductions by species normally encountered in offshore waters (widow rockfish, canary rockfish, yelloweye rockfish and lingcod) were developed for offshore closures outside of 40, 30, 25, and 20 fm. For retention species (widow rockfish and lingcod) these include expected reduction rates for landed fish (Table 4-38) and discarded fish (Table 4-39). For non-retention species (yelloweye rockfish and canary rockfish) these include expected reduction rates for both discarded and the few illegally retained fish (Table 4-40). They were based on the same at-sea observations mentioned earlier in the report. Offshore effort (5 percent of total groundfish directed effort) was assumed to move to open areas nearshore during offshore closure periods.

Table 4-38. Percent reductions in landed widow rockfish and lingcod due to depth closures.

2001, 2003-2005 count of landed fish by depth bin (fm), open all depths							
Species	<=10 fm	11-20 fm	21-25 fm	26-30 fm	31-40 fm	>40 fm	Total
Widow rockfish	0	1	9	3	54	174	241
Lingcod	115	320	77	16	6	161	695
2001, 2003-2005 distribution of landed fish by depth bin (fm), open all depths							
Species	<=10 fm	11-20 fm	21-25 fm	26-30 fm	31-40 fm	>40 fm	Total
Widow rockfish	0%	0%	4%	1%	23%	72%	100%
Lingcod	17%	46%	11%	2%	1%	23%	100%
Percent reduction in landed fish from open all depth to depth closure							
Species	Closed >10 fm	Closed >20 fm	Closed >25 fm	Closed >30 fm	Closed >40 fm		
Widow rockfish	100%	100%	96%	95%	72%		
Lingcod	83%	37%	26%	24%	23%		

Because smaller lingcod would be legal to retain under the proposed regulations reducing the minimum length to 22 and 20-inches, the average weight of both landed and discarded fish in the ocean boat fishery was also adjusted. The estimated number of fish at 22 and 20-inches that now would be landed was factored by the appropriate average weight (kg) resulting in a revised total metric tons landed. This new weight was divided by the estimated number of fish landed (landings in 2005 plus additional fish, reflecting the appropriate minimum length regulation) to determine a revised average weight. This resulted in a 13.3 percent reduction in average size under the 22-inch regulation and a 19.6 percent under the 20-inch regulation. This same process was used for the discarded fish resulting in a 59.1 percent reduction under the 22-inch regulation and a 78.7 percent reduction under the 20-inch regulation. There was no adjustment in the shore and estuary fishery as the number of fish and average weight are not part of the calculation of metric tons landed.

Table 4-39. Percent reductions in released widow rockfish and lingcod due to depth closures.

2001, 2003-2005 count of released fish by depth bin (fm), open all depths							
Species	<=10 fm	11-20 fm	21-25 fm	26-30 fm	31-40 fm	>40 fm	Total

Table 4-40. Percent total encounter reductions in yelloweye rockfish and canary rockfish due to depth closures.

2001, 2003-2005 count of total encounters (released + landed) by depth bin (fm), open all depth							
Species	<=10 fm	11-20 fm	21-25 fm	26-30 fm	31-40 fm	>40 fm	Total
Canary rockfish	33	244	65	25	20	120	507
Yelloweye rockfish	1	19	11	6	4	29	70
2001, 2003-2005 distribution of total encounters (released + landed) by depth bin (fm), open all depth							
Species	<=10 fm	11-20 fm	21-25 fm	26-30 fm	31-40 fm	>40 fm	Total
Canary rockfish	7%	48%	13%	5%	4%	24%	100%
Yelloweye rockfish	1%	27%	16%	9%	6%	41%	100%
Percent reduction in total encounters (released + landed) from open all depth to depth closure							
Species	Closed >10 fm	Closed >20 fm	Closed >25 fm	Closed >30 fm	Closed >40 fm		
Canary rockfish	93%	45%	33%	28%	24%		
Yelloweye rockfish	99%	71%	56%	47%	41%		

Abundance trends were only developed for lingcod. The average annual increase in impacts used was 1.17 percent and continues the same rate used for modeling the 2004-2006 fisheries. This increase was applied on a yearly basis. Thus for 2007 a 1.37 increase was used (2005 normalized catch x 1.17 x 1.17 representing increases from 2005 to 2006 and to 2007) and for 2008 a 1.6 increase was used (2005 normalized catch x 1.17 x 1.17 x 1.17).

Groundfish directed angler effort was assumed to remain equal to normalized 2005 under a 6 to 12 month season even during periods of offshore closures. For action alternative 1a, it was assumed that 33 percent of the angler effort from the closed period would shift to the open period resulting in 60 percent of annual effort (40 percent of annual effort normally occurs in the July through Labor Day period).

Angler effort in the directed Pacific halibut fishery was assumed to increase in 2007-2008 so as to harvest the complete halibut allocation. The halibut allocation was assumed to be equal to the 2006 allocation, which is four percent higher than in 2005. For action alternative 1b, having the lowest estimated yelloweye rockfish impact (1.5 mt), it was assumed that halibut effort and catch would be reduced by 30 percent.

Model Description

The model was divided into landed and discarded fish sections. Each section had similar components although the discarded section also had components to apply both mortality rates and changes in average size due to offshore closures. Groundfish impacts on yelloweye rockfish and canary rockfish in the Pacific halibut fishery were modeled separately.

The normalized 2005 impact model (all ocean boat fishery sources, excluding the targeted Pacific halibut fishery), include the following components for each species by month: (1) standardized catch; (2) bag limit affects; (3) offshore fishery effects on encounter rates; (4) 5 percent effort shifts to the nearshore fishery due to offshore closures; (5) average size; and (6) minimum length changes for lingcod. For landed and discarded fish the methodology to address the affects of various marine bag limits and offshore closures on (a) encounter rates and (b) shifting effort nearshore, were discussed earlier in the Normalization section. For landed and discarded lingcod, the methodology to address the affects of bag limits and changes in minimum length were discussed earlier in the Model Input section. Average weight was based on 2005 landed weight and at-sea observations for discarded fish as discussed earlier also in the Normalization section. Discarded fish mortality rates by rockfish species and depth were developed from at-sea observer data for catch distribution using mortality rates by species and depth.

Expected impacts on yelloweye rockfish and canary rockfish in the Pacific halibut fishery were addressed separately. The 2005 encounter rate per halibut pound landed, and the 2002-2003 average weight of fish caught shoreward of 30-fm, was applied to the 2006 Oregon central coast all-depth halibut sport allocation to address expected impacts on both species. This assumes similar Pacific halibut allocations in 2007-2008.

Landings and discard impacts for shore and estuary caught species were modeled on a season total basis using the 1998-2002 average impacts (mt). This fishery will be managed for a year round season as it does not impact yelloweye rockfish and canary rockfish. The impacts were adjusted to reflect length limits applied to cabezon and greenling since that period. Sublegal cabezon and greenling that were landed in the 1998-2002 period were now considered discards. A mortality rate of 7 percent was applied to all species discarded in the shore and estuary fishery to represent hooking mortality as the waters are not deep enough to cause mortality from barotrauma.

4.5.1.8 Modeling California Recreational Impacts

The CDFG revised their impact projection model that was reviewed by the GMT at their February 2006 meeting. The GMT recommends this updated model for use in projecting impacts of groundfish species in 2007-2008 California recreational fisheries. This model is described below and is used in impact analyses in this EIS.

Introduction

Recreational fisheries management for multispecies assemblages in California presents many challenges. In recent years, declining stocks of several rockfish species have dictated recreational groundfish management seasons and depths in California. Increasingly complex restrictions have been necessary to provide fishing opportunities that keep total catch of overfished species within the reduced limits that are necessary to rebuild the stocks.

Prior to 2000, the recreational daily bag limit for rockfish was 15 fish per angler and there were no closed months or depths. Beginning in 2000, the daily bag limit was reduced to 10 fish. Regulations have changed each year since 2000, making analysis of the effect of particular regulations difficult to determine. In addition, regulations have become more region-specific, adding to the difficulty of modeling projected catches.

Methodology Used to Project Recreational Catches for 2007-2008

Background

The recreational catch model incorporates a number of parameters and assumptions, all of which are either risk-neutral or risk-adverse. The basic analytical approach is the same as that used for 2005-2006, with new data from the California Recreational Fishery Survey (CRFS) program to serve as a baseline. Model output predicts expected catch under any combination of season and depth fishing restrictions by region.

Management Region Definitions:

North Region:	North of 40°10' N latitude to CA/OR border
North-Central Region:	South of 40°10' N latitude to 37°11' N latitude (Pigeon Pt.)
South-Central Monterey Region:	South of Pigeon Pt. to 36° N latitude (Lopez Pt.)
South-Central Morro Bay Region:	South of Lopez Pt. to 34°27' N latitude (Pt. Conception)
South Region:	South of Pt. Conception to CA/Mexico Border

CDFG/California Recreational Groundfish Model Assumptions

Effort Shift Inshore: The model includes a 27.6% increase in expected landings when fishing is restricted to less than 30 fm and a 39.3% increase in expected landings when fishing is restricted to less than 20 fm. The increase, or effort shift, is to account for increased effort in a smaller fishing area.

Discard Mortality: 1) Canary, cowcod, and yelloweye are non-retention species which have high mortality rates when caught and released. Therefore, expected mortality estimates for these species also include B2 fish (fish reported to be released live) with hooking mortality rates as follows:
10.5 % for the depth range 0-10 fm; 42% for 10-20 fm; and 100% for depths greater than 20 fm.
2) CA Scorpionfish hooking mortality rate is assumed to be 5%. This rate is applied to expected landings of CA Scorpionfish when fishing is allowed for species which associate with CA scorpionfish, but fishing for CA Scorpionfish is not allowed.

Inputs and Key Parameters for the Model

Weighting of Base Years: Base year catches from 2004 and 2005 are combined together in this version of the model using a 0.67 decay function (which translates into a weighting of 60% for 2005 and 40% for 2004). Model output predicts expected catch under any combination of season and depth fishing restrictions by region. *Reasons for weighting the 2005 estimates more heavily than the 2004 estimates include:* the recognition that constraints placed on salmon fishing in 2005 will likely persist over the next several years; and the acknowledgement that the expanded distribution and greater abundance of blue rockfish (as well as other groundfish species) due to cooler oceanographic conditions will also likely persist into 2007 and 2008. *Reasons for using 2004 data include:* the recognition that oceanographic conditions in 2005 were unusual while conditions in 2004 are more in line with what might be expected in 2007-2008 under a colder water regime; and the expectation that the bulk of blue rockfish take (and potentially brown and olive rockfish take) will occur within deeper nearshore waters as was observed in 2004 rather than in the shallow nearshore waters as in 2005.

Base Year Catch: Initially, CRFS catch estimates in WEIGHT of fish were summed for caught and retained (CRFS "A" catch), filleted/caught and released dead (CRFS "B1" catch), and for species of concern, a proportion of CRFS "B2" catch (released alive) derived using depth-based mortality estimates. Base year catch estimates are assumed to be for an unrestricted fishing year with no months closed and no depths closed. Therefore, for each year, a back calculation method was used to add a catch estimate for what the catch would have been if all months and all depths had been open. This back calculation uses percent catch by month and depth derived from historical catch estimates.

Historical Catch By Month: Estimates of historical percent catch by two-month period were calculated for each region based on RecFIN Marine Recreational Fisheries Statistics Survey (MRFSS) data (weight of A+B1) from 1993-1999, which was a time period when seasons and depths were unconstrained.

Proxies were considered on a species by species basis for regions where there was a lack of catch data for that area. Monthly estimates of percent catch then were divided equally (50:50) for each pair of months.

Historical Catch By Depth: Estimates of percent catch by depth were calculated for each region based on RecFIN MRFSS depth sample data (numbers caught A+B1 for CPFV and A+B1+B2 for PR) from 1999-2000, which was a time period when depths were unconstrained. Proxies were considered on a species by species basis for regions where there was a lack of catch data for that area.

Methodology used to Calculate Annual Unrestricted Catch

1. Pull (A + B1) Catch for each year from the RecFIN CRFS data web site: http://www.psmfc.org/recfin/forms/est2004.html.
   Specify species, and select the parameters: month and district under Define Table Layout.
2. Pull historical catch by depth (1999-2000, most recent years unregulated by depth) from the RecFIN boatdepth2 site:
   http://www.psmfc.org/recfin/forms/boatdepth2.html
   Add PC and PR fish caught together for each separate region and species, maintaining combined depth totals for each depth strata. Calculate average percentage of total fish caught within each 10 fm depth stratum (= "Depth Profile") by dividing 10 fm depth strata totals by combined total sum of all strata for the region. Assign proxies as needed for data-poor areas, using adjacent regions, similar species, etc.
3. Pull historical catch through time (1993-1999, the most recent years unregulated by monthly closure) from RecFIN web site:
   http://www.psmfc.org/recfin/forms/est.html
   Calculate average wave %'s over combined years 1993-1999 by dividing individual wave totals by sum of all waves for each region. Assign proxies as needed for data-poor areas using the other region (North or South) as the proxy.
4. For each management region and species, calculate total regulated catch based on months each set of regulations was in effect. For example, if fishing was only open from 0-60 fm for March-December, sum total catch for those months only. If using B2 (reported catch released live) mortality, add calculated B2 mortality to these catch totals. Each management region should now have catch data for all species grouped by the different sets of management regulations (MR sets) in effect for the year so that the identical calculations can easily be performed on identically restricted species.
5. **Expanding to All Depths**. For each MR set: If there was **no** depth restriction, use the unmodified total regulated catch as the expected catch for all depths for that period of the year. If a depth restriction was in place, use total regulated catch to expand out each species in each MR set to all depths: from the Depth Profile, divide total regulated catch by sum of proportion of catch represented by the depths where fishing was open. This is the total expected catch for all depths. For example, if fishing for a MR set was open < 20 fm, divide the total catch by the percentage of the catch < 20 fm using the appropriate Depth Profile (historical unregulated catch data) for each species and region.
6. **Effort Shift**. If the depth restriction is confined to a 20 or 30 fm band, we assume increased effort occurred for these months. To remove this effect, apply an Effort Shift factor to remove the increased fishing (and increased catch) for the constrained depth zone. For example, if a 0-20 fm restriction was in effect, divide the total expected catch for all depths by 1.393 to get final total expected catch for those months. Similarly, use a factor of 1.276 if fishing was restricted within a 30 fm range. No Effort Shift is applied for depth restrictions > 30 fm.

7. **Accounting for Closed Months**. After expanding to all depths and removing Effort Shift (if needed), sum all the final expected catch values across all the MR sets for the year for each management region and species. Divide this sum by the % catch for the year that these regulated months represent (from the wave %'s for the year). In other words, divide the calculated catch for all open months by the percentage of the catch for the year these months historically represent. This results in the expected annual unregulated catch, expanded out from the regulated catch, for each region and species.
8. Input expected annual unregulated catch for each region-species into the Catch by Year Table in the RecFIN Model database. The weighting of the different years' data to be used by the model in projecting catch can be selected at the model-user interface.

Estimates of Total Mortality for Canary and Yelloweye Rockfish Using Two Different Methods for Estimating Discarded Catch

The California recreational catch projection model accounts for total mortality by combining A (sampler examined), B1 (discarded dead/filleted) and a portion of B2 (discarded alive) catch. To calculate the portion of B2 to include in the total mortality estimate, California staff apply mortality rates to the B2 catch component in the following manner: 10.5% for fish caught between 0-10 fm, 42% for fish caught between 10-20 fm, and 100% mortality for all other depths. Oregon and Washington account for total mortality by combining A (sampler examined) and a portion of a combined B catch (catch discarded dead or alive, or catch otherwise unavailable to be examined). Staff from these states apply a 50% mortality rate to the B catch component for fish caught between 0-20 fm and 100% mortality to the B fish caught at all other depths.

To determine which of these methods was more conservative in estimating total mortality, a comparison of the methods was made for canary and yelloweye rockfish taken by California anglers statewide using 2004 and 2005 CRFS A, B1, and B2 annual catch estimates. For this comparison, the type B and B1 fish included catch used as bait, given to other anglers, or otherwise not available for examination.

The total mortality estimates calculated by these two different methods are provided in Table 4-41.

Table 4-41. Total Mortality Estimates (mt) Calculated from Two Different Methods Using 2004 and 2005 California Recreational Fisheries Survey A, B1, and B2 Annual Catch Estimates.

Species	Year	Total Mortality (mt)	
		Combined B[a/] Method	B1 & B2[b/] Method
Canary	2004	NA	NA
	2005	6.8	7.1
Yelloweye	2004	2.7	3
	2005	5.1	5.6

a/ Mortality estimate includes A catch + mortality rates applied to discarded catch combined together (Combined B).

b/ Mortality estimate includes A catch + B1 catch + mortality rates applied to B2 catch (discarded catch (B1 &B2) treated separately).

The "Combined B" method consistently results in lower total mortality catch estimates; that is, it results in lower discard mortality than the "B1 & B2" method. Thus, the California recreational catch projection model uses a more conservative estimate for discard mortality, leading to a higher estimate of overall mortality. However, more analyses may be needed after the PFMC RecFIN Workshop in August, when further discussions will be held on what constitutes the discard catch (type "B") for Washington, Oregon, and California.

Estimation of Impacts

The CDFG is proposing the seasons described under Action Alternatives 1-3 in Chapter 2. The estimated impacts to select groundfish species in 2007 and 2008 California recreational fisheries by region are described in section 4.5.4.

Action Alternative 3 includes an increase in the greenling bag limit from one to two fish. CDFG used the RECFIN methodology for Hypothetical Bag Limit Analyses available at http://www.psmfc.org/recfin/forms/bfreq.html to determine increased impacts on greenlings resulting from this change. The program uses the A+B1+B2 fish from 2004 for estimating the increased impact based on all fish encountered. The A fish are sampled dead fish. CDFG assumes for greenling that B1 includes filets and there were no fish thrown back dead as kelp greenling usually survive release. B2 includes live fish over the bag limit or under the size limit of 12". Since there is no way to estimate the proportion of fish that were undersized, this analysis also assumes there were no fish thrown back as sublegal and assumes that all B2 fish would be available if the bag limit were increased as the most conservative estimate. All bags over the hypothetical limit are then set to the hypothetical limit to calculate increased take. The increased estimated impact on greenlings would be 15% based on this analysis. Even with the increase in catch, landings are expected to stay within the CDFG recreational allocation as greenling landings in 2005 were 37% of the allocation.

Action Alternative 1 includes a reduction in the bocaccio bag limit from Cape Mendocino to the Oregon border from 2 to 1 fish to protect bocaccio under the lower OY. The estimated saving in bocaccio as a result of this change is not possible to determine because the data cannot be summarized for only this region. Bocaccio is at the northern end of its distribution in this part of the state and the fishing effort is low relative to other regions. The estimated take of bocaccio in 2005 was minimal in this region, therefore some small but undetermined amount of savings would be expected. Action Alternative 3 includes an increase in the bocaccio bag limit from one to two fish for the area south of Cape Mendocino so that the statewide bag limit would be two fish. CDFG used the RECFIN methodology for Hypothetical Bag Limit Analyses available at http://www.psmfc.org/recfin/forms/bfreq.html to determine increased impacts on bocaccio resulting from this change. The program uses the A+B1 fish from 2004 and 2005 for estimating the increased impact. The A fish are sampled dead fish. CDFG assumes for bocaccio that B1 includes filets and fish thrown back dead (over the bag limit) as bocaccio do not usually survive release. There is no way to estimate the proportion of B2 fish that were undersized or the proportion thrown back alive. Therefore, B2 fish were not included as CDFG assumed most of the B2 fish were sublegal and there would be very few legal fish released alive. All bags over the hypothetical limit are then set to the hypothetical limit to calculate increased take. The increased estimated impact on bocaccio would be 27% based on this analysis. Landings are still expected to stay within the CDFG recreational allocation as bocaccio landings in 2005 were 64% of the allocation.

There have been anecdotal suggestions that there has been good bocaccio recruitment in southern California during 2003 and/or 2004. Those fish would be expected to recruit first to the recreational fishery in 2006 or 2007, so that additional unknown and unquantified impacts from new recruits could also occur, however, CDFG reviewed the 2005 and 2006 CRFS sample data to look for a spike in small fish with no success.

Action Alternative 1 includes a reduction in the lingcod bag and size limit from the No Action Alternative of two fish at 24" to one fish at 22" to reduce fishing effort for lingcod, thereby reducing impacts on associated rebuilding species. The estimated increase in lingcod take as a result of reducing the size limit from 24" to 22" would be 26% using the formula:
Total Catch from 24" /(1 - 0.207) = Adjusted Catch

Reducing the bag limit from two to one fish at 22" would reduce this estimated increase by 27% based on the formula:
Adjusted Catch x (1 - 0.27) = Estimated Catch under a one fish bag limit.

Using the Total Catch estimate (300 mt) from 2005, the overall reduction in catch would be 24 mt or eight percent. Data from 1995 – 1997 were used to estimate size reduction increases and bag limit decreases when a 22" size limit was in effect.

Lingcod Bag and Minimum Size

CDFG is continuing to propose alternatives to fishery closure as an inseason management response to projected over harvest of lingcod if it occurs. If the CDFG determines that more restrictive management measures are necessary to slow the harvest of lingcod, an increase in the minimum size limit, or a reduction in the bag limit from two to one, may be implemented. Projected harvest for each upcoming month may be multiplied according to the coefficients for size and/or bag limit to identify the management response necessary to keep projected catch within the recreational harvest guideline.

Coefficients to modify projected catch of lingcod from a two-fish bag limit to a one-fish bag limit, or from 24" to a smaller or larger minimum size are shown in Table 4-42.

Table 4-42. Coefficients used to model lingcod bag and size limits in the California recreational groundfish fishery.

Size Limit (inches)	Size Coefficient	Bag Limit Coefficient
22	0.207	0.27
24 (status quo)	0	0.214
25	0.169	0.18
26	0.304	0.15
27	0.43	0.12
28	0.521	0.1
29	0.581	0.07
30	0.641	0.039
31	0.685	0.025
32	0.723	0.011

4.5.2 Allocating Depleted Species' Impacts

The three action alternatives discussed in sections 2.2.3.2 - 2.2.3.4 indicate ways in which the allowable impacts to depleted species may be divided between sectors. Under increasingly low OYs, such ad hoc allocations become even more critical, as the values selected may significantly constrain fisheries' access to healthy stocks and target OYs. In order to explore hypothetical allocation scenarios under the high and low OYs, the Council requested that the GMT produce a number of tables (called "bycatch scorecards") in which depleted species impacts are attributed to sectors following different allocation strategies. Each of these eight scorecards is discussed below, in addition to the assumptions and methodology employed to construct them.

Past relationships between sectors (i.e., their relative contribution toward the total mortality impact for a particular species) provide instructive templates for these hypothetical allocation scenarios. Therefore, at the Council's request, the scorecard of final 2005 mortality estimates and the scorecard projecting impacts in 2006 were used as the starting points from which to explore allocation options. As explained in the description of the No Action Alternative (section 2.2.3.1), factors such as the behavior of fishery participants and natural conditions caused certain sectors to exceed their expected harvest, while other sectors accounted for less mortality than had been originally estimated. For example, in 2005 the Washington and Oregon recreational fisheries exceeded their harvest guideline for yelloweye rockfish. These kinds of situations are captured in the 2005 scorecard, so that the relationships between sectors reflect what actually happened (rather than what was anticipated); this suggests that such proportions may be highly dependent on the particular circumstances that occurred in 2005 and so may not apply accurately to future conditions. The relationships between sectors within the 2006 scorecard represent those initially intended by the Council from the 2005-2006 harvest specifications process (in addition adjustments made to correct problems, such as those encountered in 2005); however these projections contain uncertainty as to how well management measures will operate to correctly constrain the fisheries.

In constructing these scorecards, numerous assumptions were made, following Council guidance. First, it was assumed that the impacts associated with the incidental groundfish open access sector and the tribal sector would not change under the Council's action, as these sectors are managed through separate regulations. The impacts associated with research were maintained at status quo, or in the cases of bocaccio, widow rockfish, and yelloweye rockfish, the anticipated research take was increased to provide for additional studies on depleted and co-occurring species. The low yelloweye rockfish OY scenario, however, does not accommodate this increase in the amount reserved for research. The impacts associated with these three sources were therefore held constant across all of the scorecards.

4.5.2.1 High OY Alternatives

For most species, the impact estimates attributed to each sector in 2005 and in 2006 can be directly applied to the high OY alternatives (Table 4-43 and Table 4-44, respectively). For example, limited entry bottom trawl accounted for 46.6 mt of bocaccio mortality in 2005; 46.6 mt of bocaccio mortality can still be accommodated under the 2007-2008 high OY alternative of 218 mt. Continuing with the example of bocaccio, the 2005-2006 OY is nearly 100 mt greater than the high OY alternative for that stock. However the total estimated catch in 2005 was far less than the OY, which resulted in a large residual amount; by carrying over the same mortality estimates for the sectors, the 2007-2008 high OY alternatives can also provide for a residual to buffer against uncertainty, but it is a smaller value. Although this situation holds true for most of the depleted species, there are two exceptions. For the canary rockfish OY alternative, the impact estimates in both 2005 and 2006 are greater than what can be accommodated under the canary rockfish high OY alternative of 44 mt. Therefore, following Council guidance, each sector's canary rockfish impact was reduced proportionately in order to create a 0.5 mt set-aside. Similarly, the 2008 yelloweye rockfish OY alternative (20 mt) is too small to maintain past mortality impacts; to resolve this, the necessary proportional reductions were made to each sector's impacts, however no set-aside was created.

4.5.2.2 Low OY alternatives

In order to constrain fisheries below the OYs under the low alternatives, Action Alternative 1 management measures are more stringent than those under status quo (Action Alternative 1 is explained in section 2.2.3.2).

As was done for the high OY alternatives, scorecards were produced in which the 2005 and 2006 mortality impact estimates were reduced proportionately in order to be constrained to the low OY alternatives (Table 4-45 and Table 4-46, respectively). With the exception of cowcod, there are no residuals associated with any of the species; setting aside a portion of the OY to buffer against uncertainty would create even more extreme effects for sectors than those already anticipated under full utilization of the OYs (see chapter 7 for further discussion of the socio-economic impacts of a suite of low OYs).

Table 4-45. 2007-2008 estimated total mortality: Low OY applied to the status quo 2006 scorecard (each sector's projected impact is reduced proportionately).

Employing proportional reductions to constrain to the low OYs, as described above, continues status quo Council policy to provide fishing opportunities across regions and sectors; this is consistent with guidance in the Groundfish FMP that "overfishing restrictions and recovery benefits should be fairly and equitably allocated among sectors of the fishery" {PFMC 2004}. However, there are numerous other allocation strategies that could be adopted (through revision of the Groundfish FMP), depending on the management objective sought by the Council; under the constraints of low OYs, such as those within these alternatives, these strategies may provide for a more viable fishery at a coastwide level. Other sections in this EIS also discuss allocation strategies, each of which is based on alternative management objectives. In chapter 7, for example, it is noted that under a highly constrained fishery, allocation could optimize coastwide revenue by allowing mortality impacts only for fisheries that account for the greatest amount of ex vessel revenue, eliminating the fisheries that account for the lowest ex vessel revenue. In this section, another scenario is depicted, in accordance with Council guidance: all of the mortality impacts are associated with either the recreational sector (Tables 4-47 and 4-48) or the commercial sector and (Tables 4-49 and 4-50). These are extreme scenarios that depict a situation that the Council might consider under OYs so constraining that all sectors operating under status quo could not be maintained.

Like the scorecards discussed above, those representing the "all recreational" and "all commercial" scenarios are based on the 2005 scorecard and the 2006 scorecard. That is, for example, the relationships between the commercial sectors are maintained at 2005 proportions (Table 4-50), while zero mortality impacts are estimated for the three recreational groundfish fisheries. Under the "all recreational" scenarios (Tables 4-47 and 4-48) however, the Council provided guidance that commercial fisheries should be constructed using OYs of the species for which there is no recreational fishery mortality. As such, POP and darkblotched rockfish were divided between the LE bottom trawl and whiting sectors using 2005 or 2006 scorecard proportions, as these two sectors are judged to be the only commercial fisheries that can be executed without mortality of other depleted species.

Table 4-47. 2007-2008 estimated total mortality: Low OY, applied to the status quo 2006 scorecard (all relevant projected impacts allocated to the recreational fishery).

4.5.2.3 Comparing Allocation Scorecards with Action Alternatives

Management measures alternatives are developed based on the specific conditions of each fishery, such as what tools are available to managers and how the fishery is constrained by other depleted species; the relationships between sectors' mortality impacts estimates are not necessarily held constant from year to year. Similarly, the Action Alternatives detailed in Chapter 2 result in impact estimates that create different relationships between sectors than those that occurred in 2005 and projected for 2006 (Table 4-51). For example, the 2006 scorecard projects that canary rockfish mortality impacts will be shared between commercial and recreational sectors at a ratio approximating 48:52, while under Action Alternative 2, this relationship changes to approximately 59:41. These kinds of changes in proportions are also present within the commercial sector and within the recreational sector. For example, while the California recreational fishery accounts for approximately 52% of the total recreational impacts in 2006, under Action Alternative 2 the fishery's impacts are projected to account for 68%.

Table 4-51. Percent of impact by sector as a proportion of total impact (2005 and 2006).

4.5.3 No Action Alternative

[To be completed after the June Council meeting. For quantitative impact analysis of the No Action alternative, see 4.5.4.]

4.5.3.1 Limited Entry Trawl Impacts

4.5.3.2 Limited Entry Fixed Gear Impacts

4.5.3.3 Open Access Impacts

4.5.3.4 Nearshore Commercial Impacts

4.5.3.5 Tribal Fishery Impacts

4.5.3.6 Washington Recreational Impacts

4.5.3.7 Oregon Recreational Impacts

4.5.3.8 California Recreational Impacts

4.5.4 The Action Alternatives

When evaluating the impacts associated with the action alternatives, there are several general points that may be important to bear in mind.

First, as a depleted species' spawning stock biomass nears a rebuilt level ($B_{40\%}$), the probability of fishing encounters with that species increases. When more of the stock is available to the fishery but the allowable catch remains at a low level, there is a greater chance that the OY could be reached early in the season or exceeded. This is particularly relevant with respect to darkblotched rockfish, Pacific ocean perch, and widow rockfish. Given that these species are primarily caught incidentally in trawl fisheries, concerns of increased encounters are most notable for those fleets. Furthermore, the proposed management measures under all action alternatives bring about impact estimates at or just below the proposed OY for Pacific ocean perch (Tables 2-14, 2-19 and 2-21). Without an excess of allowable impacts to buffer against the uncertainty associated with a biomass near a rebuilt level, there is a risk under each action alternative that the Pacific ocean perch OY could be exceeded. A similar situation may occur under Action Alternative 1 with respect to widow rockfish, as there is only a very small residual (3% of OY or 3.8 mt). In the scorecards that explore the different allocation scenarios (Tables 4-43 through 4-50), the residual is maintained for these three depleted species under the high OY scenario. Under the low OY scenarios, there is no residual for any of these depleted species.

Second, as the discard estimates from WCGOP improve, it is likely that discard rates used to manage those fisheries with a lesser amount of at-sea observations (i.e., southern limited entry and open access fixed gear fisheries) will change dramatically. This is a particular concern if new discard rates prove to be much higher than currently assumed based on limited at-sea observations. As this information is used to better inform managers about catch of depleted species, inseason action may be necessary to correct management measures that had been crafted according to current discard rates.

Variability in a stock's recruitment success is another source of uncertainty (see section 4.4.2.1). Such variability is most common among winter-spawning shelf and slope groundfish, such as bocaccio, lingcod, and Pacific whiting. For these species, improved population trajectories over recent years can be aligned with climate shifts; for other species, such as cowcod and widow, the improvement in population trends is primarily due to deterministic recruitment trends and reduced harvest rates. The uncertainty surrounding the recruitment success of these species may provide additional support for managing fishing impacts to a value lower than the OY.

The considerations discussed above bring about a cumulative risk of exceeding the OY for certain depleted species. Much of this risk can be attributed to numerous sources of uncertainty, which are discussed further in section 4.2.

General Action Alternative 1 Considerations

The management measures proposed in Action Alternative 1 all constrain fisheries below the Council preferred low OYs for depleted species (Table 2-14). However, for some species (i.e., Pacific ocean perch, widow rockfish, and bocaccio), there is little or no residual available to managers to buffer against uncertainty.

Under these low OYs, the Council must evaluate whether viable fisheries can be maintained. If it is determined that the management measures under Action Alternative 1 do not allow for viable fisheries, then other allocation scenarios may be considered by the Council (see discussion in 4.5.2.2 on allocating the entire OYs to the recreational fishery or to the commercial fishery).

The Council preferred low OYs bring about a similar situation to what is portrayed under Rebuilding Alternative 5. Under both of these, the management measures could result in fisheries that are equally constrained by most, if not all, of the depleted species' OYs. Though this suggests the need for additional room to buffer against management uncertainty, this is countered against the severe social and economic consequences that would be made even more acute by managing to a mortality impact lower than the OY.

General Action Alternative 2 Considerations

The management measures proposed in Action Alternative 2 are projected to constrain the depleted species impacts of all fisheries to levels that are intermediate between the Council preferred low and high OYs (Table 2-19). For some species (i.e., bocaccio, cowcod, and widow rockfish) under this action alternative, there is a large difference between the projected impacts and the high OY alternative. For Pacific ocean perch, on the other hand, the projected impact is nearly equal to the Council preferred high OY value. Unlike Action Alternative 1, this alternative allows for the higher values of research impacts for all depleted species.

General Action Alternative 3 Considerations

The management measures proposed in Action Alternative 3 are projected to constrain the depleted species impacts of all fisheries to levels at or below the Council preferred high OYs (Table 2-21). The anticipated impact to Pacific ocean perch, however, is equal to the high OY under this alternative. This alternative allows for the higher values of research impacts for all depleted species.

4.5.4.1 Limited Entry Trawl Impacts

The estimated impacts of the non-whiting limited entry trawl sector on depleted species and on target species under the action alternatives are displayed in Table 4-52. In 2005 a new management measure was implemented mandating the use of selective flatfish trawls shoreward of the trawl RCA north of 40°10' N latitude; Table 4-53 projects impacts to depleted and target species that would be expected if selective flatfish trawl gear were used by vessels south of 40°10' N latitude.

Table 4-52. Estimates of impacts (mt) to depleted species and total target catch associated with the limited entry non-whiting trawl fishery under the alternatives, without use of selective flatfish trawl gear in the south.

Note: * indicates that differences in bycatch for these species may occur, but the degree of change is unknown

The bycatch analysis for the Pacific whiting trawl fishery (Table 4-54) assumes that the total US Pacific whiting catch will decrease in accordance with the allowable impacts to depleted species. An alternative strategy for managing 2007-2008 whiting fisheries would be to impose bycatch caps for these species and allow the fleet flexibility to avoid these species while attempting to attain their whiting quotas.

Table 4-54. Estimates of impacts to depleted species and total target catch associated with the Pacific whiting fishery under the alternatives.

4.5.4.2 Limited Entry Fixed Gear Impacts

Sablefish Alternatives

The impacts associated with the action alternatives for sablefish (Table 4-55) are arrayed by A) holding the allocations for sablefish constant for the limited entry and open access fixed gear sectors under the Council's preferred sablefish OY and moving the fixed gear RCA line north of 40°10' N latitude from 100 to 125 and 150 fm respectively, and B) by lowering the OY for sablefish to achieve the same reductions in bycatch as by moving the fishery in the north out to the 125 fathom line and the 150 fathom line. These results show that savings in bycatch are achieved by advancing the line further seaward, or by lowering the sablefish allocation to these sectors, but either case creates an economic cost to sablefish fishers.

A review of West Coast groundfish observer data shows that sablefish vessels currently fish at depths deeper than 150 fm north of 40 degrees 10 minutes latitude, but for vessels that homeport in the Puget sound region of Washington, a 150 fathom line eliminates their fishing areas and would require vessels to fish substantially further south and further out to sea. This is because the shelf and slope areas off northern Washington are comprised of multiple canyons and broad areas with relatively the same depth. In other areas of the coast the bottom depths get deeper in a more continuous fashion as one moves further out to sea. Those vessels that don't home port in the Puget sound region and that currently don't fish at depths outside of 150 fm would need to travel further out to sea, however the additional distance required of these vessels to fish outside 150 fm is minor compared to vessels that home port in the Puget sound area.

Reducing the sablefish allocation is shown to give a comparison between area closures and reductions in target species catch that would achieve the same levels of bycatch. Reducing the sablefish allocation for these sectors would decrease bycatch because vessels would fish less and thereby exert less effort on the areas where overfished species are found. While reducing the sablefish allocations for limited entry and open access fixed gear vessels would decrease the catch and revenues to these vessels, it would allow vessels to fish closer to shore and decrease the cost of accessing that sablefish when compared to imposing fathom restrictions that achieve the same reductions.

	Pacific halibut	923,295	249,290	923,295	923,295

4.5.4.3 Open Access Impacts

Like with the limited entry fixed gear fisheries, the primary means to constrain impacts of the open access sector on depleted species is by changing the non-trawl RCA boundaries. The specific impacts under each of the action alternatives have been quantitatively assessed for only some portions of this diverse sector, however. Table 4-56 depicts the projected impacts for all sablefish fisheries (limited entry and open access) and section 4.5.4.3 discusses the impacts of the open access nearshore commercial fisheries.

4.5.4.4 Nearshore Commercial Impacts

Table 4-57 depicts the estimated total mortality of nearshore commercial fisheries under each action alternative. The management measures proposed within Action Alternative 3 are the same as the No Action alternative, and therefore the estimated impacts for these two alternatives are equal. Under the most restrictive management measures (Action Alternative 1), the catch of black rockfish north of 40°10' N latitude is projected to drop by 60% from status quo, while the catch of other target species is projected to be maintained at SQ levels. South of 40°10' N latitude catch of shallow and deeper nearshore species, cabezon, and kelp greenling under Action Alternative 1are all expected to reduce by about 15% due to the proposed area and depth restrictions.

Table 4-57. Open access nearshore commercial fisheries' estimated total mortality (mt) and its percent reduction from status quo under each alternative.

		No Action	Action Alt. 1		Action Alt. 2		Action Alt. 3	
		Mortality (mt)	Mortality (mt)	Reduction (%)	Mortality (mt)	Reduction (%)	Mortality (mt)	Reduction (%)
South of 40 10, North of 34 27	Canary	0.28	0.26	21%	0.30	7%	0.28	0%
	Shallow nearshore species	47	47	16%	55	1%	47	0%

	Other minor nearshore rockfish	36	10	0%	10	0%	36	0%
	Cabezon	33	31	0%	31	0%	33	0%
	Kelp Greenling	21	23	0%	23	0%	21	0%
Depleted Species Total	Canary	2.11	0.98	50%	1.47	25%	2.11	0%
	Yelloweye	2.41	0.81	62%	1.32	38%	2.41	0%
	Widow	0.08	0.03	53%	0.05	24%	0.08	0%

4.5.4.5 Tribal Fishery Impacts

Table 4-58 depicts the projected impacts to the depleted and target species associated with all tribal groundfish fisheries. The estimated impacts to depleted species are the same across all action alternatives (and are the same as the No Action alternative).

The projected catch of spiny dogfish is significantly higher under the action alternatives than under no action. The Makah Tribe is proposing a directed longline fishery for spiny dogfish for 2007 and 2008. The fishery would be restricted to the Limited Entry trip limits. Increased landings of dogfish by treaty fishermen in 2007 and 2008 would be dependent on successful targeting in 2006 while staying within current estimates of impacts on overfished species. The projected value for spiny dogfish landings in Table 4-58 (600,000 lbs or 272.2 mt) is a placeholder provided by Makah Fisheries Management; impacts will not be known until the test fishery is prosecuted. In addition, flatfish and rockfish impacts under all action alternatives are expected to increase by 25% due to increased effort (though not capacity) in Makah trawl fisheries.

Table 4-58. Estimates of impacts to species associated with the Tribal fishery under the alternatives.

		Alternatives			
		No Action	Action Alt. 1	Action Alt. 2	Action Alt. 3

4.5.4.6 Washington Recreational Impacts

Management measures proposed under the action alternatives serve to constrain the Washington recreational fishery to impacts on canary rockfish and yelloweye rockfish lower than those under the No Action alternative (Table 4-59).

Table 4-59. Estimates of impacts to depleted species associated with the Washington recreational fishery under the alternatives.

4.5.4.7 Oregon Recreational Impacts

Management measures proposed under the action alternatives serve to constrain the Oregon recreational fishery to depleted species impacts lower than those under the No Action alternative (Table 4-60). These measures also restrict the catch of target species (with the exception of lingcod), which are projected to be equal or lower to No Action levels under all alternatives.

7.0 SOCIOECONOMIC

7.1 Affected Environment

7.1.1 Introduction

The Pacific Coast groundfish fishery is a multi-species fishery (over 90 groundfish species) taking place off the coasts of Washington, Oregon, and California where groundfish are harvested as target catch or indirectly as bycatch in other fisheries. Groundfish fishermen themselves participate in other fisheries as well. These other fisheries include salmon, highly migratory species, coastal pelagic species, shrimp, and crab, amongst others. All of these fisheries contribute to a wide range of commercial, recreational, and tribal activities that have economic, social, and cultural significance to those engaged in harvesting fish resources. Fish buyers and processors, suppliers of commercial and recreational fishing equipment and services, and fishing communities depend on these fisheries. The aim of this chapter is to describe these activities and relate them to the conservation and management measures being proposed, particularly in the context of the effects of reducing the bycatch of the seven overfished species. Information will also be provided that relates to another FMP objective of maintaining year-round groundfish fishing.

The information and organization of this discussion of the socio-economic environment draws upon the following documents—in many instances repeating or summarizing the relevant information, and, in other instances, updating the information provided:

> The Groundfish EFH document {NMFS (National Marine Fisheries Service) 2005. Pacific Coast Groundfish Fishery Management Plan, Essential Fish Habitat Designation and Minimization of Adverse Impacts, Final Environmental Impact Statement. National Marine Fisheries Service, Seattle, WA, December 2005},
>
> The Bycatch EIS {NMFS (National Marine Fisheries Service), the Pacific Coast Groundfish Fishery Management Plan, Bycatch Mitigation Final Environmental Impact Statement, NMFS, Seattle, WA, September 2004}
>
> The final EIS for the 2005-06 specification document {PFMC (Pacific Fishery Management Council) 2004. Final Environmental Impact Statement for the Proposed Groundfish Acceptable Biological Catch and Optimum Yield Specifications and Management Measures for the 2005-06 Pacific Coast Groundfish Fishery. Pacific Fishery Management Council. Portland, OR, October 2004.}
>
> The analyses and concepts developed for assessing the needs of fishing communities that were presented at the April 2006 Council meeting {Agenda F.1 Groundfish Item F.1 Supplemental Attachments 6-8)}

7.1.1.1 Management Context

The industry and community descriptions and impact analyses found in this chapter are shaped by the typical analyses undertaken to address the setting of harvest quotas and associated management measures, but also by the recent ruling of the Ninth Circuit Court of Appeals concerning rebuilding plans for overfished species. Therefore, it will be useful to summarize the basic context of the current FMP and the important directions for management provided by the Ninth Circuit.

Current FMP

The Council allocates harvest specifications (OYs) between the limited entry and open access categories. Most of the Pacific coast commercial groundfish harvest is taken by the limited entry fleet. Commercial harvest rates of groundfish are constrained by annual harvest guidelines, two-month or one-month cumulative period landing limits, individual trip limits, size limits, species-to-species ratio restrictions, area closures, and other measures. This program is designed to control effort so that the allowable catch is taken at a slow enough rate to stretch the season over the full year. Cumulative period catch limits are set by comparing current and previous landings rates with the year's total available catch and predicted participation

The groundfish limited entry program applies to bottom and midwater trawl, longline, and trap (or pot) gears. Each limited entry permit is endorsed for a particular gear type and that gear endorsement cannot be changed, so the distribution of permits among gear types has been fairly stable. Each permit also has a vessel length endorsement. The total number of permits has typically changed only when multiple permits have been combined to create a new permit with a longer length endorsement. However, in December 2003, a buyback program permanently retired 91 trawl permits, roughly 35% of the total. Limited entry permits can be sold and leased out by their owners, so the distribution of permits among the three states often shifts. At the beginning of 2003, roughly 39% of the limited entry permits were assigned to vessels making landings in California, 37% to vessels making landings in Oregon, and 23% to vessels making landings in Washington.

Other non-tribal commercial fisheries, which either target groundfish or catch them incidentally, but do not hold groundfish limited entry permits, are considered "open access." Gears used by participants in open access commercial fisheries include longline, vertical hook-and-line, troll, pot, setnet, trammel net, shrimp and prawn trawl, California halibut trawl, and sea cucumber trawl gears. Open access trawl gear may not target groundfish, but may land incidental groundfish caught while targeting other species. Open access trap/pot and longline vessels may target groundfish under certain restrictions. Open access vessels may possess limited entry licenses for other, state-managed nongroundfish fisheries such as pink shrimp or Dungeness crab.

Members of the Makah, Quileute, Hoh, and Quinault tribes participate in tribal commercial, ceremonial and subsistence fisheries for groundfish off the Washington coast according to their treaty rights. Participants in the tribal commercial fishery use similar gear to non-tribal commercial fishers who operate off Washington, and groundfish caught in the tribal commercial fishery is typically sold through the same markets as non-tribal commercial groundfish catch. There are set tribal allocations for sablefish and Pacific whiting, while the other groundfish species' allocations are determined through the Council process in coordination with the tribes, states, and NMFS. Management of tribal fisheries is done by the individual tribes in accordance with their tribal practices.

In addition to commercial and tribal fisheries, there are recreational fisheries associated with the groundfish fishery. Marine recreational fisheries consist of charter vessels, private vessels, and shore anglers. Charter vessels are larger vessels for hire, which typically can fish farther offshore than most vessels in the private recreational fleet. Shore-based anglers often fish in intertidal areas, within the surf, or off jetties. Recreational fisheries are managed by a series of seasons, area closures, and bag limits.

Ninth Circuit

Since 2000, the management of West Coast groundfish fisheries has been heavily centered on the need to rebuild overfished groundfish species. A species is considered overfished when its biomass is below 25% of its estimated unfished biomass level. West Coast groundfish stocks are highly inter-mixed, meaning that overfished species co-occur and are caught in common with more abundant groundfish stocks. This inter-mixed nature of groundfish stocks means that eliminating the directed targeting of overfished species usually does not achieve the catch reductions needed to meet rebuilding goals. To adequately constrain total catch of overfished species, management must also constrain targeted fishing on healthy stocks that co-occur with overfished species in order to reduce incidental overfished species catch. This need to constrain harvest of healthy stocks has economic implications to sectors and communities engaged in fish harvesting and processing, because of the loss in landings and revenue that could have been derived from both overfished species and many target species that co-occur with those overfished species. The reader is referred to Chapter 2 Table 2-1 for a full presentation of the levels of overfished species and target species being considered in this EIS along with the relevant associated conservation and management measures that exist to constrain harvests so that these levels are not exceeded as well to equitably distribute the burden of conservation and management across the various harvest groups. These user groups are listed in tables such as Table 2-4, which are otherwise frequently referred to as Bycatch Scorecards."

According to the Magnuson-Stevens Fishery Conservation and Management Act, when a fishery is overfished, any fishery management plan, amendment, or proposed regulations shall:

A) *specify a time period for ending overfishing and rebuilding the fishery that shall—*
   i) *be as short as possible, taking into account the status and biology of any overfished stocks of fish, the needs of fishing communities, recommendations by international organizations in which the United States participates, and the interaction of the overfished stock of fish within the marine ecosystem; and*
   ii) *not exceed 10 years, except in cases where the biology of the stock of fish, other environmental conditions, or management measures under an international agreement in which the United States participates dictate otherwise;*

B) *allocate both overfishing restrictions and recovery benefits fairly and equitably among sectors of the fishery*

As indicated in Chapter 2 (Section 2.1.1), in response to the August 2005 ruling by the Ninth Circuit Court of Appeals, the Council though this EIS is reconsidering its rebuilding plans for all overfished species to ensure they comply with the MSA as interpreted by the Court. The Court's interpretation of the rebuilding requirements of the MSA can be summarized to include the following directions: 1) the rebuilding periods must be as short as possible; 2) that short-term needs of fishing communities may be taken into account in setting rebuilding periods; and 3) to avoid disastrous short-term consequences, limited quotas may be set that allow for some fishing of plentiful species, despite the inevitability of bycatch.

For purposes of assessing the needs of fishing communities, the Council adopted the following general definition at its April 2006 meeting: DBD—need to check language against the actual motion:

> Fishing Communities need a sustainable fishery that is safe, well managed, and profitable, that provides jobs and incomes, that contributes to the local social fabric, culture, and image of the community, and helps market the community and its services and products.

Therefore, in comparison, to previous EISs undertaken for the Pacific Groundfish Fishery Management Plan, this chapter where appropriate, in addition to the typical approaches undertaken, will provide more detailed and focused socio-economic information and analyses relating to rebuilding species and fishing communities.

Overview of General Trends

In addition to the management context, it is important to understand the fisheries context that underlies the determination of the conservation and management measures being developed through this EIS. For purposes of discussion, the Groundfish Fishery will be described in terms of overall landings as a means of describing recent trends and for describing alternative ways that various groundfish sectors are classified. As groundfish fishermen fish in fisheries other than groundfish and groundfish communities depend on other fisheries as well, it is also important to the groundfish fishery in relation to other West Coast fisheries.

Groundfish Fishery

Harvest Sectors and Sub-sectors, Landings and Revenues

As discussed above, the Groundfish fishery is made up by many components. Table 7-1 shows sector trends in harvests from 1995 to 2004. These components are often summed in various ways depending on the management issue. For example, the non-tribal whiting fishery is comprised of three sectors—At-sea catcher processors, at-sea motherships, and shoreside whiting limited entry trawl. The total whiting fishery is made up of the non-tribal whiting sector and the tribal shorebased and at-sea whiting fisheries. Shorebased landings can be estimated by summing Shoreside Whiting Limited Entry Trawl, Shorebased Non-Whiting Limited Entry Trawls, Shoreside Limited Entry Line Gear, Shoreside Limited Entry Pot Gear, Shoreside Directed Open Access, and Shoreside Incidental Open Access landings. Throughout the remainder of this chapter, the discussion will involve one or more of these components.

Some trends should be noted. For this period, whiting harvests by the at-Sea catcher processors and shoreside whiting limited entry trawl fisheries reached a peak in 2004. Tribal shoreside landing also reached a peak in 2004 of 8,698 tons reflecting the recent introduction of a new shorebased tribal whiting fishery. Tribal whiting fisheries were first instituted in 1996 with advent of the at-sea tribal fishery. Harvests by shoreside non-whiting fishery limited entry trawl fleet and recreational fleets reached their lowest levels in 2004 a harvests. When combined, all non-whiting and non-tribal sectors reached a period low of commercial shoreside sectors by the shoreside non-whiting limited entry trawl fleet were at their lowest as was the recreational catch. As Pacific whiting is a highly variable species, often times analysts focus on the non-tribal commercial shoreside landings other than whiting. When this is done, landings shoreside by non-whiting non-tribal commercial sectors also reached a low in 2004, approximately 25,000 tons compared with the 59,000 and 60,000 tons of landings in 1995 and 1996, respectively. The decline in such landings mirrors status of the stocks and Council efforts to rebuild overfished species.

Table 7-1 also shows the percentage shares of each sector of the total fishery. In terms of total non-whiting-non-tribal harvests, there has been a small decline in non-whiting limited entry trawl share from past levels of greater than 75% to the current level of 71%. This has been matched by a slight increase in the recreational share, from 4% to 5% in 1995 and 1996 respectively to current levels of 7 and 8 percent. (The sharp temporary increases in recreational harvests in 1998 and 2003 are due to increases in Central and Northern California recreational harvests of lingcod, widow rockfish, and rockfish contained in the category "minor rockfish south.)

Tables 7-2a, 7-2b, and 7-2c list 1981 through 2005 commercial landings by round weight, exvessel revenue in current dollars, and exvessel revenue in inflation-adjusted dollars for commercially important species on the West Coast. These tables echo the trends discussed above but from a more historical perspective. Table 7-2a shows the large volume of Pacific whiting landings and the emergence of shore-based processing in the early 1990s. (Note that the at-sea sector includes joint venture fisheries occurring in the 1980s. "Americanization" ultimately replaced foreign processors with domestic ones.) While total groundfish landings peaked in 1994, landings of species other than whiting continued a long-term declining trend during this period. Total groundfish landings measured by weight peaked in 1994 at 305,312 mt and have declined by nearly half since. Flatfish, sablefish, and rockfish landings all peaked in 1982, the first full year under Groundfish FMP management. (Note that some decline in landings is to be expected as standing stocks are "fished down" to MSY biomass.) Landings in all groundfish species categories declined steeply after 1998, when species began to be designated overfished. Rockfish landings fell by about three-quarters from 1998 to 2002.

Table7-2b shows total groundfish exvessel value peaking in 1997 at $101.2 million, three years after the peak in total groundfish landings. The difference between these trends is partly explained by the observed run up in exvessel prices for sablefish between 1994 and 1997 at a time when total sablefish landings were pretty stable. Total exvessel value of groundfish landings declined 43% to about $58 million in 2003.

Table 7-2c adjusts the values in Table 7-2b for inflation, allowing a more direct comparison of the real value of landings between years. Low-value whiting is a much less prominent component of landings when measured this way. Measured in constant 2005 dollars, the change in the value of rockfish landings between 1998 and 2003 fell by more than two thirds. The inflation-adjusted value of sablefish and flatfish landings remained fairly stable during this period. Measured in constant 2003 dollars, total groundfish landings value was greatest in the late 1980s, peaking in 1989 at almost $132 million. By 2003, the inflation adjusted value of total groundfish landings had fallen by more than half.

Whiting harvests reached an all time high in 2005 at about 260,000 tons whereas for the other groundfish species there are significant declines starting in 1998 with 2005 showing very slight increases in harvests compared to 2004. In terms of ex-vessel revenues, since the whiting fishery was at an all time high, total groundfish revenues showed an increase significant increase in 2005 to $73 million which is still below the 1981-1997 average of $115 million. (Note that whiting and the other categories include tribal harvests.) In terms of non-whiting groundfish revenues, 2005 showed a slight increase over 2004 to $43 million due to increased sablefish revenues but is still below the 1981-1997 inflation adjusted average of $91 million. (1981-1997 is used as a basis of comparison because the downward trends in lingcod and rockfish started their sharp declines in 1998 and thus the beginning of rebuilding efforts.)

Groundfish Fishery In Relation to Other West Coast Fisheries

Tables 7-2.a through 7-2.c also show the other west coast fisheries harvests and revenues.

Total west coast harvests reached 440,000 tons in 2005 worth $281 million. Of these amounts, groundfish fisheries accounted for 50% of the harvests and 25% of the revenues. In terms of total exvessel revenues, Dungeness Crab was the only fishery that had higher revenues in 2005. Note that squid was the only major fishery that had a significant increase as the Dungeness Crab, salmon, and HMS fisheries all had significant declines in 2005 compared to 2004 adding up to a total West Coast decline in non-groundfish revenues of about 12%. Declines in non-groundfish fisheries make groundfish communities, who are already facing declining groundfish revenues, more vulnerable while often leading to increase effort in groundfish fisheries. As described below, many of these non-groundfish fisheries are part of the groundfish "open access" fleets. (As most of these fisheries are "shoreside fisheries" see 7.1.2.1 for additional discussion.)

Bycatch and Fisheries

Table 7-3 shows for these sectors or their subcomponents, the various bycatch associations; To identify likely distributional affects of reductions in overfished species mortality, NMFS Northwest Region working with members of the GMT constructed a relational database. This database used available data on the interaction of fishery sectors with overfished species, and historical management actions that have been taken to achieve management targets of overfished species. Information from the 2005 groundfish stock assessments was used to identify the distributional range of various overfished species, and then analyzed in conjunction with the size of fishing sectors on a regional basis. The resulting combined effect of relative stock size and relative fleet size helps identify the risk that a regional component of a fishing sector poses to a stock of an overfished species. In this case, "risk" is the potential catch that a particular regional sector has the potential to attain relative to the OY and relative to the capability of other sectors operating in the same area. Using this information on the relationship of groundfish stock and fleet sizes, a data set was constructed that identifies sectors that have high, med-high, med-low, and low or no impact on each overfished species, within a coastwide series of latitude-bounded management areas. Fishing sectors that were analyzed include:

1. limited entry bottom trawl – deep
2. limited entry bottom trawl –shelf
3. limited entry midwater trawl – Pacific whiting
4. limited entry fixed gear – sablefish
5. limited entry fixed gear – nearshore
6. limited entry fixed gear – dogfish
7. open access fixed gear – sablefish
8. open access fixed gear – nearshore
9. open access fixed gear – dogfish
10. California recreational-bottomfish
11. Oregon recreational-bottomfish
12. Washington recreational-bottomfish
13. Washington recreational-halibut
14. Oregon recreational-halibut

Although other commercial sectors arguably exist, one can reasonably assume that these other sectors are minor compared to those listed, or can be considered a component of one of those sectors listed. Our data set further divided sectors by coastal management area where different overfished species commonly occur: north of 40° 10' N. lat., between 40° 10' N. lat. and 38° N. lat., between 38° N. lat. and 36° N. lat., and south of 36° N. lat.. The area north of 40° 10' N. lat. is a traditional area used for management of commercial fisheries and tends to have the highest degree of impact for several overfished species, including darkblotched rockfish, yelloweye rockfish, and Pacific ocean perch. In the area between 38° N. lat. and 40° 10' N. lat., darkblotched rockfish populations are more moderate, Pacific ocean perch is nearly non-existent, and the area, and the northern portion the assessed portion of bocaccio rockfish begins. The area south of 38° N. lat. and north of 36° N. lat. contains few, if any, of the more northern overfished species such as darkblotched rockfish, but canary rockfish still tend to be caught in the area, as well as more southern oriented stocks such as bocaccio rockfish. Few canary rockfish occur south of 36° N. lat., but this area contains both bocaccio rockfish and cowcod.

Bycatch and Communities

Inspection of Tables 7-4a and Tables 7-4b shows that every community is touched in some way by the management of overfished species. (Although this table applies to the commercial sectors, recreational fisheries in the communities listed would encounter similar bycatch species.)

How the Rest of This Chapter Is Organized

The rest of this chapter provides detailed descriptions of the various sectors that make of the non-tribal commercial sectors including discussions of participation, landings, revenues, seasonality, and major fishing communities. Tribal and recreational fisheries are discussed in similar fashion. Seasonality information is presented to address considerations associated with promoting a year round fishery. In addition, the processing sector, non-consumptive users, and fishing communities are also described. After these descriptions, the next major section 7.2 describes the economic impacts of the alternatives. These impacts include direct and indirect impacts and cumulative effects.

7.1.2 Commercial and Tribal Fisheries

7.1.2.1 Overview: Total Non-Tribal Shoreside All Fisheries

Participation

Active participation in West Coast shore-based commercial fisheries has generally declined over the years 2000 to 2005 (Table 7-5). In 2005, 1,292 vessels landed West Coast groundfish, 261 landed coastal pelagic species, 1,084 landed crab, 721 landed highly migratory species, 1,339 landed salmon, and 170 landed shrimp. Groundfish vessels accounted for roughly one-third of the west coast fleet. As evidenced by the state permits purchased in the Groundfish Buyback Program, groundfish fishermen participate in these other fisheries as well, especially, the crab and shrimp fisheries. (The estimates, as they are based on fish tickets, exclude estimates of the tribal fleet and at-sea fleet which are discussed below.)

Landings and Revenues

Commercial fisheries make up the largest portion of West Coast landed catch by weight. Coastal pelagic species, followed by groundfish, crab, and highly migratory species have made up the largest landings by weight since 2000. Crab, followed by groundfish, coastal pelagic species, and highly migratory species comprise the highest-value groups from 2000–2005 (Table 7-6). The four largest gear groups by weight have been gill and trammel net, trawl, trap/pot, and troll gear (Table 7-7).

Limited entry trawlers take the vast majority of the groundfish harvest measured by weight but somewhat less if measured by value. In 2003, groundfish trawlers landed over 95% of total groundfish harvest by weight but only 64% by value (Table 7-8). The difference in trawl weight and revenue proportions is mostly due to the catch of Pacific whiting. Since whiting are caught almost exclusively by limited entry trawl vessels, they skew the overall value per unit weight calculations for this sector.

Distribution of Effort and Major Ports

See discussion below of the various subsectors (limited entry trawl, limited entry fixed gear, and open access). As discussed below, trawl vessels make most of their landings in Oregon. Newport, Astoria, and Charleston (Coos Bay), Oregon are three of the largest four ports for landed weight and exvessel revenue. Westport and Ilwaco, WA, Eureka and Crescent City, CA, Brookings, OR, and Bellingham Bay and Neah Bay, WA comprise the remaining top 10 largest ports for trawl vessel landings.

7.1.2.2 Limited Entry Groundfish Trawl Sector

Participation

West Coast limited entry trawl vessels use midwater trawl gear, and small and large footrope bottom trawl gear (defined at 50 CFR 660.302 and 660.322(b)). Midwater trawl gear is not designed to touch the ocean bottom and is therefore used to target groundfish species–such as Pacific whiting and yellowtail rockfish–that ascend above the ocean floor. Small and large footrope trawl gear are designed to remain in contact with the ocean floor and are used to target species that reside along the ocean bottom such as flatfish on the continental shelf and slope, or DTS species (Dover sole, thornyhead and sablefish complex) in deep water. Fishers generally use small footrope trawl gear in areas that have a regular substrate–few rocks or outcroppings–and more widely on the continental shelf than on the continental slope (due in large part to regulatory requirements). Fishers use large footrope trawl gear most commonly in areas that may have an irregular substrate, and along the continental slope and in deeper water.

The limited-entry shore-based trawl vessels primarily deliver their catch to processors and buyers located along the coasts of Washington, Oregon, and California, and tend to have their homeports located in towns within the same general area where they make deliveries. Larger vessels in the shore-based limited entry trawl sector focus more heavily on the DTS complex in deep water, while smaller trawl vessels focus more heavily on the shelf. Large trawl vessels also tend to participate in the trawl fishery for more months of the year than small trawl vessels. The shore-based vessels range in size from less than 40 feet to over 90 feet in length (Table 7-9).

In 2003, a fishing capacity reduction program (buyback) was implemented off the Pacific coast which retired 91 vessels from the limited entry trawl sector. These 91 vessels represented less than 40 percent of the number of boats actively engaged in the limited entry trawl sector, but approximately 50 percent of historic catch. The purpose of the program was to reduce the number of vessels and permits endorsed for the operation of groundfish trawl gear in order to increase and stabilize economic revenues for vessels remaining in the groundfish fishery and conserve and manage depleted groundfish species. Vessels that participated in the buyback program were sold, scrapped, or converted to nonfishing purposes, and those vessels cannot be used for fishing again.

The impact of the trawl vessel buyback appears to have been positive in terms of exvessel revenue per vessel. Average trawl exvessel revenues generated by non-Pacific Hake groundfish increased from approximately $108,000 to $151,000 in the years 2003 to 2004 respectively even though total exvessel revenues for the fleet decreased from approximately $25,000,000 to $22,000,000 during the same period (Figure 7-1). Declining total bottom trawl revenues in 2005 resulted in a slight decline in average revenue per vessel compared to 2004.

The impact of the trawl vessel buyback differed by region. Some ports lost a disproportionate share of their trawl fleet, while others lost relatively few trawl vessels (Table 7-10). The number of trawl landings in the major trawl ports of Eureka, Crescent City, and Avila declined by 50 percent or more.

7.1.2.2.1 Landings and Revenues from Groundfish Trawl Vessels

Trawlers catch a wide range of species. By weight, the following species account for the bulk of landings (other than Pacific whiting): Dover sole, arrowtooth flounder, petrale sole, sablefish, thornyheads, and yellowtail rockfish. Management measures intended to reduce the directed and incidental catch of overfished rockfish and other depleted species have significantly reduced rockfish catches in recent years substantially below historical levels. Of the three states, landings and revenues by non-tribal trawlers are significantly larger than the other two states (Table 7-11)

By weight, the vast majority of trawl vessel groundfish is caught with midwater trawl gear. This is due to the fact that Pacific whiting is targeted with midwater trawl gear. In contrast, the majority of trawl exvessel revenues are attributed to the bottom trawl sector). (Table 7-12)

Limited entry trawlers take the vast majority of the groundfish harvest measured by weight but somewhat less if measured by value. In 2003, groundfish trawlers landed over 95% of total groundfish harvest by weight but only 64% by value (Table 7-13). The difference in trawl weight and revenue proportions is mostly due to the catch of Pacific whiting. Since whiting are caught almost exclusively by limited entry trawl vessels, they skew the overall value per unit weight calculations for this sector.

7.1.2.2.2 Distribution of Effort by Limited Entry Groundfish Trawl Vessels

Limited entry trawl vessels focus much of their effort on DTS species along the slope, flatfish species along the shelf, and Pacific whiting above the seafloor. Historically, much effort was focused on rockfish species, but recent regulatory requirements–such as RCAs and various cumulative limits - have curtailed rockfish opportunities to protect overfished stocks. In 2005, a specific small footrope trawl designed to avoid rockfish (the selective flatfish trawl) will work to further avoid the catch of rockfish along the shelf while increasing opportunities for flatfish north of 40° 10' latitude. Opportunities to harvest DTS and flatfish species–largely in the form of differential cumulative limits and RCAs–dictate the location of much of the trawl effort, though not all effort is dictated by regulation. Vessels differ in size and technical capacity. For example, small vessels may find it more difficult to fish during the winter months because of weather and other vessels may not have the capacity to fish in deep water where DTS species primarily reside. In other cases, some vessel captains may be more knowledgeable and more successful in certain areas. This knowledge would also influence the location and timing of effort by certain vessels. Furthermore, some species are known to migrate and aggregate during certain months of the year. For example, Petrale and Dover sole are known to aggregate for spawning during the winter months, and several types of flatfish are known to migrate onto the shelf during the summer months. Fishers may target the location of their efforts according to species aggregations and the tendencies of certain fish species to migrate. Differences in knowledge, capital constraint, fish migration, and the regulatory environment can–in large part–affect the location and time of effort by commercial fishing vessels.

Table7-14 shows the depth-based annual distribution of catch made by non-shrimp trawl vessels and Table 7-15 shows the monthly distribution of catch as recorded in trawl logbook data within PacFIN. These data include bottom trawl and midwater trawl gear.

By weight, because of the buyback program, some ports appear to have lost relatively more groundfish catch than other ports. Not surprisingly, those ports that lost relatively more trawl vessels also appear to have lost relatively more catch of groundfish (Table 7-16).

Trawl vessels make most of their landings in Oregon. Newport, Astoria, and Charleston (Coos Bay), Oregon make up three of the largest four ports for landed weight and exvessel revenue during the 2000–2003 period (Table 7-17). Westport and Ilwaco, WA, Eureka and Crescent City, CA, Brookings, OR, and Bellingham Bay and Neah Bay, WA comprise the remaining top 10 largest ports for trawl vessel landings.

7.1.2.3 At-Sea Limited Entry Sector

Participation

In addition to the shore-based limited entry trawl fishery, an at-sea limited entry trawl fishery exists off the coast of Washington, Oregon, and California. The high-volume at-sea fishery targets Pacific whiting with the use of midwater trawls. Pacific whiting commands a relatively low price per pound in the market place. The limited entry at-sea sector is made up of a catcher-processor fleet and a mothership/catcher vessel fleet. A catcher-processor participates in both catching and processing; a mothership engages only in the processing of a particular catch, and relies on catch made by catcher vessels. Many of the catcher vessels that deliver to the West Coast mothership sector may also fish as West Coast shore-based trawl vessels outside the Pacific whiting season; other catcher vessels fish in West Coast waters only during Pacific whiting fishery and return to North Pacific fisheries when the Pacific whiting season closes.

The catcher/processor sector is comprised of vessels that harvest and process whiting (the fleet has typically been 6 to 7 vessels since the formation of the Pacific Whiting Conservation Cooperative in 1997). The mothership sector is comprised of catcher vessels that harvest whiting for delivery to motherships (typically 3-5 motherships operate in the fishery, with one mothership also servicing the tribal fleet). Motherships are vessels that process, but do not harvest, whiting.

According to PacFIN data, the at-sea sector annually catches over 100 million pounds of Pacific whiting, as well as several hundred thousand pounds of other types of West Coast groundfish

Unfortunately, readily available data do not exist for estimating the value of at-sea
According to PacFIN data, the at-sea sector annually catches over 100 million pounds of Pacific whiting, as well as several hundred thousand pounds of other types of West Coast groundfish Harvests of non-whiting groundfish are largely composed of harvests of yellowtail rockfish, widow rockfish and rockfish that make up the category "minor rockfish north."

Harvests and Revenue

Depending on the OY, at-sea harvests by non-tribal motherships and catcher processors have ranged since 1998 from 63,000 tons to the 128,000 tons harvested in 2005 (Table 7-18) worth $14 million (Table 7-19). The amount of non-whiting groundfish harvested by this fleet is quite small, often in the range of less than half of percent.

Distribution of Effort

The catcher-processor fleet and mothership fleet over recent years, typically harvests a major portion of their allocations in May and June. After June, most of the fleets moves on to fish off Alaska, and returns in late August or September where to fish the remainder of their allocations. During the summer months, a few catcher processors may remain to fish whiting.

Major Ports

As the majority of whiting harvested by the non-tribal at-sea fleet is processed into finished product and then transshipped at sea to foreign markets, there are no key at-sea ports, other than Seattle and Anacortes where the corporate headquarters for these companies are located.

7.1.2.4 Limited Entry Groundfish Fixed Gear Sector

Participation

Vessels deploying longlines and traps (pots) comprise the limited entry fixed gear sector. These gear types also may be used by vessels in the open access sector, but preferential harvest limits favor license holders. West Coast limited entry fixed gear vessels typically use longline and fish pots (traps) for catching groundfish. Groundfish longline activities involve anchoring a stationary line with multiple baited hooks attached to it (groundline) to the ocean floor. A buoy line attaches the groundline to a surface float, usually a buoy and pole. Fishermen leave the longline in the water for several hours to a day. The vessel returns to the gear, retrieves the buoy, and hauls the line to the surface to retrieve the gear and fish. Fish pots or traps used to harvest groundfish are generally square and have mesh or twine encompassing the exterior Fishermen drop baited traps to the bottom of the ocean connected to a surface pole or buoy with a vertical line. The fish enter the trap through a door, but cannot exit the trap unless they are small enough to escape through the mesh, or back out the door. These pots are retrieved by the vessel several hours after being set. Both longlines and fish pots can be set across diverse ocean bottom types, though longlines can get hooked on rocky areas or reefs, causing some gear loss. Limited entry fixed gear fishers typically use shore-based vessels that range in size from 30 feet to 65 feet in length, with some vessels exceeding 100 feet, and some as small as 23 feet (Table 7-21). Limited entry fixed gear vessels may also participate in open access fisheries or in the limited entry trawl fishery. Like the limited entry trawl fleet, limited entry fixed gear vessels deliver their catch to ports along the Washington, Oregon, and California coast.

This sector has been plagued by overcapacity, although a series of management initiatives have largely addressed the problem. In the early to mid 1990s the fishery was a "derby" managed by very short seasons of two weeks or less. Two Groundfish FMP amendments have helped to alleviate the symptoms of over capacity in the fixed gear sablefish fishery, effectively eliminating the short, derby season. Amendment 9 required a permit endorsement to participate in the primary sablefish fishery, and Amendment 14 introduced permit stacking. Permit stacking allows up to three sablefish-endorsed permits to be used per vessel. Through a tier system, landing limits vary with the number and type of permits held.

7.1.2.4.1 Landings and Revenue from Limited Entry Fixed Gear Vessels

Fixed gear vessels primarily target the high-value sablefish; this species accounts for a large share of landings, especially when measured by exvessel value. According to PacFIN data, the majority of limited entry fixed gear landings occur in Oregon and Washington. Oregon and Washington also have a higher price per pound for sablefish, while California has a higher price per pound for other types of groundfish. This is most likely representative of the higher amount of high valued live fish landings that occur in California, as opposed to Oregon and Washington (Table 7-22).

7.1.2.4.2 Distribution of Effort by Limited Entry Fixed Gear Vessels

Limited entry fixed gear vessels principally target sablefish, a species that tends to reside in relatively deep water (Table 7-23). The limited entry fixed gear sector is subject to rockfish conservation areas; however, the boundaries are somewhat different from those of the limited entry trawl sector. Fixed gear vessels are more prone than trawl vessels to catching some overfished rockfish species, such as yelloweye rockfish, and are therefore restricted from fishing on the continental shelf. Limited entry fixed gear vessels exert most of their effort during the late spring, summer, and early fall. The monthly distribution of effort has become more spread out over the year, and the number of vessels participating has declined as the tier system and permit stacking provisions were put in place in 1998 and 2001 respectively

Major Ports

Table 7-24 shows the top 15 ports (of the 62 receiving landings) for limited entry fixed gear landings and exvessel revenue from 2000–2003. The largest ports for limited entry fixed gear landings and exvessel revenue, located within Washington, Oregon, and northern California, differ only slightly in the order of landings by rate and of exvessel revenue. The top five ports for landings make up approximately 54% of total landings, while the top five ports for revenue make up approximately 49% of total exvessel revenues for limited entry fixed gear vessels.

7.1.2.5 Open Access Groundfish

7.1.2.5.1 The Groundfish Open Access Sector

The open access sector consists of vessels that do not hold a federal groundfish limited entry permit and target (Open Access Directed Fisheries) or incidentally (Open Access Incidental Fisheries) catch groundfish using a variety of gears. The open access appellation can be confusing because vessels in this sector may hold limited entry permits for other, nongroundfish fisheries issued by the federal or state governments. However, groundfish catches by these vessels are regulated under the groundfish FMP. For example, open access vessels must comply with cumulative trip limits established for the open access sector and are subject to the other operational restrictions imposed in the regulations, including general exclusion from the RCA.

Open Access Directed Fisheries

Participation in the directed open access fishery segment varies between years. Participants may move into other, more profitable fisheries, or they may have taking time off from fishing, or they may quit fishing altogether. Fishers use various non-trawl gears to target particular groundfish species or species groups. Longline and hook-and-line gear are the most common open access gear types used by vessels directly targeting groundfish and is generally used to target sablefish, rockfish, and lingcod. Pot gear is used for targeting sablefish, thornyheads and rockfish. Though largely restricted from use under current regulations, in the past in Southern and Central California setnet gear was used to target rockfish, including chilipepper, widow rockfish, bocaccio, yellowtail rockfish, and olive rockfish, and to a lesser extent vermillion rockfish.

Within the directed open access fishery, fishers are further grouped into the "dead" and/or "live" fish fisheries. The terms dead and live fish fisheries refers to the state of the fish when it's landed. The dead fish fishery has historically been the most common way to land fish. In 2001, the dead fish fishery made up 80% of the directed open access landings. However, more recently, the market value for live fish has resulted in increased landings in the live fish fishery. In 2001, 20% of fish landed (by weight, coastwide) by directed open access fishers was landed alive as compared to only 6% in 1996 {(PFMC 2004 PFMC 2004. Proposed Acceptable Biological Catch and Optimum Yield Specifications and Management Measures for 2005-2006 for the Pacific Coast Groundfish Fishery. Pacific Fishery Management Council, Portland, OR, August 2004)}.

In the live-fish fishery, groundfish are primarily caught with hook and line gear (rod-n-reel), with limited entry longline gear and with limited entry pot gear, and a variety of other hook gears (e.g. stick gear). The fish are kept alive in a seawater tank on board the vessel. California halibut and rockfish taken in gill and trammel nets have increasingly appeared in the live fish fishery {(CDFG 2001) CDFG. 2001. California Marine Living Resources: A Status Report, December 2001. Sacramento, California. (Available on-line: www.dfg.ca.gov/mrd/status)}.. Live fish are sold at a premium price to food fish markets and restaurants, primarily in Asian communities in California. Only limited information exists on the distribution of effort by open access vessels. Because the open access sector has an increasingly large live-fish fishery component with nearshore species making up most of the live fish landings, effort located near shore likely accounts for most live fish landings.

In California, hook and line gear for the live-fish fishery has been limited, since 1995, to a maximum of 150 hooks per vessel and 15 hooks per line within one mile of the mainline shore {(CDFG 2001) CDFG. 2001. California Marine Living Resources: A Status Report, December 2001. Sacramento, California. (Available on-line: www.dfg.ca.gov/mrd/status)}.. Traps are limited to 50 per fisherman. In Washington, it is illegal to possess live bottom fish taken under a commercial fishing license. In Oregon, nearshore rockfish and species such as cabezon and greenling are the primary target of the live fish fishery. Sablefish and rockfish are also landed alive in Oregon, and are managed under limits which count against the federally set limited-entry allocations. The Oregon live fish fishery occurs in waters of ten fathoms or less (18 m). Only legal gears are allowed to be used to catch nearshore live fish. In early 2002, an Oregon Development Fisheries Permit was required for fishermen landing live fish species (e.g. Cabezon, greenling (except kelp greenling), brown, gopher, copper, black and yellow, kelp, vermilion, and grass rockfish (among others), buffalo sculpin, Irish lords, and many surfperch species). However, commercial fishing for food fish is prohibited in Oregon bays and estuaries and within 600 feet (183 m) seaward of any jetty.

Participation

Many fishers catch groundfish incidentally when targeting other species, because of the kind of gear they use and the co-occurrence of target and groundfish species in a given area. Managers classify vessels as being in the open access incidental fishery if groundfish comprises 50% or less of their landings, measured by dollar value. These incidental open access fisheries may also account for substantial amounts of bycatch, especially for overfished groundfish species. Fisheries targeting pink shrimp, spot prawn, ridgeback prawn, California and Pacific halibut, Dungeness crab, salmon, sea cucumber, coastal pelagic species, California sheephead (California nearshore fishery), highly migratory species, and the mix of species caught in net fisheries comprise this incidental segment of the open access sector. These fisheries and associated target species are described below.

The open access groundfish fishery consists of many vessels that predominately fish for other non-groundfish species where they inadvertently catch and land groundfish. Because these incidental vessels do not necessarily depend on their revenue from the groundfish fishery as their major source of income, understanding the level of dependency that such participants have on the open access groundfish fishery must be considered in light of their overall fisheries revenues. Table 7-25 shows the number of open access vessels by vessel length and level of dependency on the groundfish fishery (proportion of annual revenue that is from groundfish). Between November 2000 and October 2001, 1,287 vessels landed groundfish in the open access sector of the groundfish fishery. Of these vessels, 771 vessels (60%) had a greater than 5% dependency on the groundfish fishery with 345 of these vessels having a 95-100% level of dependency of groundfish. The open access fishery is dominated by vessels under 40 feet in length. About 78 percent of the vessels that landed open access groundfish between November 2000 and October 2001 were less than 40 feet on length. It is assumed that a portion of these smaller vessels fish exclusively in state waters, and thus would be excluded from the VMS requirements. However, the data is not available to identify the proportion of vessels that fish only in state waters. Approximately 36 percent of the open access vessels had a greater than 65 percent dependency on groundfish, with 56 percent of the most dependent vessels having less than $5,000 in gross fishing income. A greater proportion of vessels with lower levels of dependency on groundfish fell within income categories greater than $5,000. However, increases in higher valued groundfish catch in 2003 (primarily sablefish) may reduce the proportion of open access vessels in the lowest (<$5,000) income category.

As discussed above, fishery managers divide the open access sector into directed and incidental categories. The directed fishery comprises vessels targeting groundfish while the incidental fishery category applies to vessels targeting other groundfish, but landing some groundfish in the process. However, it is difficult to segregate vessels into these two categories because the choice depends on the intention of the fisher. Over the course of a year or during a single trip, a fisher may engage in different strategies and they may switch between directed and incidental fishing categories. Such changes in strategy are likely the result of a variety of factors, including the potential economic return from landing a particular mix of species. Table 7-26 provides recent information on open access participants for the 2000- 2003 period and is taken from the VMS EA.

7.1.2.5.2 Landings and Revenue from Groundfish Open Access Vessels

Rockfish, thornyheads, and sablefish make up most of the open access landings and revenue and hook and line accounts for the largest gear type for open access landings (Table 7-27). Fixed gear catch most open access groundfish, although non-shrimp trawl gear and net gear also make substantial landings (Table 7-28). Open access landings in the state of California have a large live fish component, which is made evident by the relatively high unit value of rockfish in that state compared to the unit value of rockfish in Oregon and Washington.

7.1.2.5.3 Distribution of Effort by Groundfish Open Access Vessels

Limited information exists on the distribution of effort by open access vessels. The open access sector is made up of many different gear types, along with directed and incidental catch, which makes it difficult to discern the location of effort, though based on the diversity of this sector, it is reasonable to assume that effort is widespread across the West Coast. The open access sector has an increasing large live-fish fishery component; because nearshore species make up most of the live fish landings, effort located near shore likely accounts for most live fish landings. The live fish fishery is a quickly growing component of the open access sector and will likely continue to grow in the nearshore areas.

As shown in Table 7-29, open access landings and revenue tend to occur primarily during the spring, summer, and fall months. Assuming that landed catch represents directed open access, and that landed catch is a function of effort, then more open access related fishing activity occurs during the spring, summer, and fall months than winter months.

Fishing Communities

Table 7-30 shows that the top open access ports are Moss Landing, Port Orford, Morrow Bay, Fort Bragg and Gold Beach.

7.1.2. 6 Tribal Fisheries

7.1.2.6.1 The Tribal Fisheries Sector

West Coast treaty tribes in Washington have formal groundfish allocations for sablefish, black rockfish, and Pacific whiting. Members of four coastal treaty tribes participate in commercial, ceremonial, and subsistence fisheries off the Washington coast. Participants in the tribal commercial fisheries use similar gear to non-tribal fishers. Fish caught in the tribal commercial fishery are distributed through the same markets as non-tribal commercial catch.

Participation

Tribal treaty fisheries are place-oriented—limited to the adjudicated U&A areas. This results in immobile fisheries that cannot move to a new location if the resources or habitat are depleted. In addition, the Tribe and its fishermen have a view of ownership of their fishing grounds rooted in centuries of use and control of these grounds. This sense of ownership influences the fishing practices of the tribes and these practices are used by the tribes to develop tribal rules and regulations to stay within the harvest limits established by the council for overfished and abundant stocks. Tribal fisheries take several species for which they have no formal allocations, and some species for which no specific allocation has been determined (7-31). Rather than try to reserve specific allocations of these species, the tribes biennially recommend trip limits for some species to the Council, which tries to accommodate these fisheries.

Groundfish fishing by the tribes occurs primarily with hook and line and trawl (7-32). All tribes participating in groundfish fisheries have longline vessels in their fleets, but as discussed below only the Makah has trawlers; and only the Makah has participated in the Pacific whiting fishery. Makah has the majority of longline vessels, followed by Quinault, Quileute, and Hoh. Since 1996, a portion of the U.S. whiting OY has been allocated to the West Coast treaty tribes. The tribal allocation is subtracted from the whiting OY before allocation to the non-tribal sectors. Since 1999, the tribal allocation has been based on a sliding scale related to the U.S. whiting OY. To date, only the Makah tribe has fished on the tribal whiting allocation. Makah vessels fish with mid-water trawl gear have also been targeting widow rockfish and yellowtail rockfish in recent years.

As the Makah Tribe has the largest tribal fleet, what follows is a detailed description of Makah groundfish fisheries and management practices. Currently, the Makah fleet is composed of 43 boats, an increase of two vessels from 2004 (Table 7-35). Twenty-nine of the boats fish for salmon, sablefish, and halibut. These boats primarily fish from March to October. Ten of the boats are small bottom trawlers. The trawl fishery is open from January to December, but primarily the fishing is done from June to October. The mid-water whiting fleet is composed of 4 mid-water trawlers who deliver to shoreside plants and to two at-sea motherships one of which also participates in the non-tribal mothership whiting fishery. Their season is from May to September. Full retention of rockfish bycatch is required (as is the case in all Makah groundfish fisheries); the bycatch is processed for human consumption and forfeited to the Tribe for distribution to food banks and similar programs. This program avoided wastage and discards of bycatch species, created a disincentive to both the catcher vessels and processor and provides full accounting of bycatch in the fishery. This in turn has reduced bycatch levels of nearly all species.

In the Makah bottom trawl fishery, the Tribe adopted the small foot rope restrictions as a means to reduce rockfish bycatch and avoid areas where higher incidences of rockfish occur. In addition, the bottom trawl fishery is limited by overall foot rope length as a means of conducting a more controlled fishery. Harvest is restricted by time and area to focus on harvestable species while avoiding bycatch of other species. If bycatch of rockfish is above a set limit, the fishery is modified to stay within the bycatch limit. The midwater trawl fishery has similar control measures. A trawl area must first be tested to determine the incidence of overfished rockfish species prior to opening the area to harvest. Vessels are provided guidelines for fishing techniques and operation of their net. Fishing effort is closely monitored by the on-board observer and harvest manager and changes or restrictions are implemented as needed to stay within the bycatch limits. Full retention of rockfish bycatch is required (as is the case in all Makah groundfish fisheries); the bycatch is processed for human consumption and forfeited to the Tribe for distribution to food banks and similar programs. This program avoided wastage and discards of bycatch species, created a disincentive to both the catcher vessels and processor and provides full accounting of bycatch in the fishery. This in turn has reduced bycatch levels of nearly all species. In developing these trawl fisheries, the Makah management practices include testing of gear, area, vessels, and catch composition before the fishery can proceed from one level to the next. In addition, a new or developing fishery must show that it can be conducted in a manner that protects existing fisheries.

Tribal Harvests and Revenues

Tables 7-33 and 7-34 shows recorded landings of groundfish species by treaty tribes from 1995 to 2003as developed by the Northwest Indian Fisheries Commission {Rob Jones, personal communication to John Devore May 18?DVB?-}. Since 1996, Pacific whiting have comprised the vast bulk of tribal landings, even though in 2000 and 2001 whiting landings were relatively low due to reduced coastwide allocations. As shown in Table 7-34, in addition to increases in Pacific whiting harvests, there has been a growth in tribal landings of flatfish and rockfish to bring total tribal groundfish revenues to a level of $7.5 million in 2005.

Distribution of Effort

The bulk of tribal groundfish landings occur during the March through April Pacific halibut and sablefish fisheries. Most continental shelf species taken in the tribal groundfish fisheries are taken during the halibut fisheries, and most slope species are similarly taken during the tribal sablefish fisheries. Approximately one-third of the tribal sablefish allocation is taken during an open competition fishery, in which vessels from the four tribes on the Washington coast have access to this portion of the overall tribal sablefish allocation. The open competition portion of the allocation tends to be taken during the same period as the major tribal commercial halibut fisheries in March and April. The remaining two-thirds of the tribal sablefish allocation is split between the tribes according to a mutually agreed-upon allocation scheme. Specific sablefish allocations are managed by the individual tribes. The fishery begins in March and goes until some time in the autumn, depending on the number of vessels participating in the fishery. Participants in the halibut and sablefish fisheries tend to use hook-and-line gear, as required by the IPHC. For equity reasons, the tribes have agreed to also use snap-line gear in the fully competitive halibut and sablefish fisheries. So a vessel that participated in a fully competitive sablefish fishery, but that did not land any halibut (and therefore was not subject to IPHC requirements), would still be required by tribal regulations to use snap-line gear.

Major Ports

Table 7-35 shows the distribution of vessels engaged in Tribal groundfish fisheries by major port. These ports are Westport, Neah Bay, and La Push.

7.1.3 Recreational Fisheries

In 2004, there was a major change in how recreational statistics are collected for West Coast fisheries, especially for the collection of statistics on California recreational anglers as the methodologies employed under the Marine Recreational Fisheries Statistics Survey (MRFSS) were replaced by those of a California Recreational Fisheries Survey. The California Recreational Fisheries Survey (CRFS) is the new method for estimating total marine recreational finfish catch and effort in California. The CRFS is a coordinated sampling survey designed to gather catch and effort data from anglers in all modes of marine recreational finfish fishing. This program incorporates and updates the comprehensive sampling methodologies of the former Marine Recreational Fisheries Statistics Survey (MRFSS) and the California Department of Fish and Game's (CDFG) Ocean Salmon Project. This program was fully implemented state-wide in January 2004.

The direct comparability of pre-2004 data with data collected under the new system is still being evaluated. So the discussion below replicates the discussion of recreational fisheries and 1996-2003 trends found in: Pacific Fishery Management Council. 2004. Acceptable Biological Catch and Optimum Yield Specifications and Management Measures for the 2005-2006 West Coast Groundfish Fishery Final Environmental Impact Statement as it is still the best available overview of West Coast recreational fisheries. This discussion is then followed by presentation of 2004-2005 recreational data provided by the States through the Council's Groundfish Management Team process. The California estimates reported below are still under review for there are indications that the preliminary data provided significantly underestimate charterboat effort. However, it is believed that when better estimates are corrected, the results will not alter the relative ranking of economic consequences of the alternatives.

Participation

Demand for recreational trips and estimates of the economic impacts resulting from recreational fishing are related to numbers of anglers. In the U.S., over nine million anglers took part in 76 million marine recreational fishing trips in 2000. The West Coast accounted for about 22% of these participants and 12% of trips. 70% of West Coast trips were made off California, 19% off Washington, and 11% from Oregon {Gentner 2001}.

Recreational fishing is an important economic contributor to the west coast in general, and to some communities specifically. The recreational fishing sector can be divided into two groups; the charter fleet and the private fleet. The private fleet is typically made up of vessels owned by residents living in or near areas where they fish. The charter fleet is a for-hire fleet that plays a large role in the tourism sector of many west coast communities, and opportunities to fish on a charter vessel can be a substantial draw for tourists considering a visit to the coast.

The distribution of resident and non-resident ocean anglers among the West Coast states in 2000, 2001, and 2002 demonstrates the importance of recreational fishing, especially in Southern California (Table 7-36). Southern California has more than twice the number of resident recreational marine anglers than the next most numerous region, Washington State. While most of the recreational anglers were residents of those states where they fished, a significant share was also non-residents. Oregon had the largest share of non-resident ocean anglers in all three years.

In terms of vessels, about 750 charterboats make up the charterboat fleet (Table 7-37); estimates of private boats are unavailable. In terms of proportion, Table7-38 shows the distribution of trips by boat mode and region in 2003. Approximately 80% of the trips taken are from private vessels. Almost 90 percent of all trips taken and half of the charter vessel trips are associated with California.

Recreational fishing in the open ocean has generally been declining slightly since 1996 (Table 7-39); however, charter effort has decreased while private effort increased during that period. Part of this increase likely resulted from longer salmon seasons associated with increased abundance. Some effort shift from salmon to groundfish for example likely occurred prior to 1996 when salmon seasons were shortened.

Distribution of Effort

Fishing effort is related to weather, with relatively more effort occurring in the milder months of summer, and relatively less in winter (Table7-38). As might be expected, this effect is more pronounced in higher latitudes, although the reasons include opportunity as well as climate. Salmon seasons are longer in California than in Oregon, which in turn are longer than in Washington. Until recently, groundfish seasons were also more restrictive in Washington, with the lingcod season being closed from November through March.

7.1.3.1 2004-2005 State Recreational Estimates

Through the Pacific Fishery Management Council's Groundfish Management Team process, total angler trips by mode and by target were developed by each of the States for years 2004 and 2005. In terms of total trips, there was a decline from 1.6 million trips to 1.2 million trips, with all states and modes in decline, particularly the California charter boat mode. (As indicated above, these latter estimates may be underestimates.)

The following estimates of trips where groundfish was a target was provided through the GMT process (Table 7-41). Unlike the total anger trips, total groundfish trips increased by 20 percent in 2005 over 2004. Except for Coos Bay which showed a decline in charter boat trips, this pattern is consistent across all states, areas and ports, and by mode. These estimates suggest that anywhere from 25% (2004) to 40% (2005) of West Coast angler trips are trips targeted on groundfish. It should be noted that groundfish are caught incidentally when other species, such as salmon, are targeted. While the contribution of groundfish catches to the overall incentive to engage in a recreational fishing trip is uncertain, it seems likely that the possibility or frequency of groundfish catch on a trip adds to overall enjoyment and perceived value of the trip.

7.1.4 Buyers, Processors, and Seafood Markets

7.1.4.1 Processors and Buyers

Excluding Pacific whiting delivered to at-sea processors, vessels participating in Pacific groundfish fisheries deliver to shore-based processors within Washington, Oregon, and California. Buyers are located along the entire coast; however, processing capacity has been consolidating in recent years. Several companies have left the West Coast or have chosen to quit the business entirely. Remaining companies have purchased some former plants {Research Group 2003}, but other plants have remained inactive. This has led to trucking groundfish from certain ports to another community for processing. Therefore, landings do not necessarily indicate processing activity in those communities. However, examination of the species composition of landed catch by state can lead to inferences of some processor characteristics.

According to PacFIN data, in 2002 Oregon had the largest amount of groundfish landings (56%), followed by Washington (28%), and California (16%). In contrast, Oregon has the largest amount of exvessel revenue (40%), followed by California (32%) and Washington (22%), respectively. Oregon accounts for the majority of Pacific whiting landings, which creates a large difference between the percentage of landed catch and exvessel revenue because Pacific whiting has a relatively low price per pound. The relatively high amount of Pacific whiting being landed in Oregon may create a case where many processors must generate capacity to handle large quantities at a time. Groundfish processors in Washington may receive landings from Alaska fisheries. Depending on the amount of catch Washington processors can draw from Alaska fisheries, some groundfish processors may require the capacity to process large amounts of product. California processors concentrating on West Coast fisheries may focus on relatively smaller throughput of groundfish.

The seafood distribution chain begins with deliveries by the harvesters (exvessel landings) to the shoreside networks of buyers and processors, and includes the linkage between buyers and processors and seafood markets. In addition to shoreside activities, processing of certain species (e.g., Pacific whiting) also occurs offshore on factory ships.

According to data from the Bureau of Labor Statistics, the number of seafood processing establishments along the west coast has declined in recent years. Further examination of PacFIN data shows the number of companies buying groundfish along the West Coast has also generally declined in recent years. When buyers are classified on a species basis—How many buyers purchased groundfish—we can see slight evidence of a decline in California and Washington (Table 7-42). When buyers are classified on a groundfish gear basis—how many buyers purchased sablefish from fixed gear-sablefish fishermen---evidence of decline is stronger (Table 7-43). Because of the multi-species basis of most buyers it is hard to develop unique counts of buyers by either of these two methods on a state basis. However, the total number of buyers from all fisheries can be uniquely determined. In California, the number of unique buyers in 2005 is estimated to be 465, a decrease of 21 percent from 2004. The number of Oregon buyers fell by 10% and the number of Washington buyers fell by 8% over the same time period.

7.1.4.1.1 Processing Companies Purchasing Groundfish

In terms of quantity, the processing of west coast groundfish is dominated by a small number of companies. For this section, an estimate of unique groundfish companies was derived by grouping PacFIN information on groundfish buyers. Buyers with like names were assumed to be individual companies. For example, a hypothetical buyer with the name ZZZ seafood – Astoria was assumed to belong to the same company as a buyer with the name ZZZ seafood – Ilwaco. Using this approach, the results show that the three largest companies bought approximately 78% of commercially caught groundfish landed on the west coast in the years 2004 and 2005 (Table 7-44, Figure 7-2). When a similar analysis is done based on ex-vessel revenues, the top three companies purchase about 56% of the groundfish sold. (For more accurate estimates, analysts would have to compile lists of affiliated companies and then map them to the PacFIN buyer codes. In addition, estimates of fish purchased by non-affiliated buyers and sold to a company for processing would also have to be developed.)

Supportive of this analysis is a description of the top 10 Seafood suppliers in the United States according to Seafood Business (May 2006); three of which participate in Pacific Groundfish Fisheries. Their corporate strategies affect the Pacific Groundfish fishery. Employment and location of facilities will vary as companies pursue profits, market share, and efficiencies. For example, the build up of Arctic Alaska Company (an Alaska based company who built a surimi plant and fish meal plant in Newport Oregon while bring down catcher processors from Alaska to fish whiting, its eventual sale to Tysons (a major poultry company who wanted to add seafood to its product line), and the selling out of Tyson's fishing business assets (including the shoreside surimi and fish meal plants, and several catcher-processors) to companies like Trident (who before the purchase had little involvement in Pacific groundfish) has indirectly reshaped the Pacific groundfish fishery. Below are the Seafood Business descriptions of Pacific Seafood Group (a shorebased company), Trident Seafoods Corporation (shorebased and at-sea), and American Seafoods Group (at-sea).

> Pacific Seafood Group #1 Sales-$874 million—Key Species: Dungeness crab, halibut, king crab, Pollock, salmon, shrimp. "With 2005 sales of $874 million, Pacific Seafood Group slid into the No. 1 spot on the Seafood Business Top 25 list for the first time this year. After an active 2003 and 2004, Pacific wasn't involved in any acquisitions or mergers last year or early this year. Instead the company grew organically, picking up new customers and increasing sales by approximately $174 million from 2004 to 2005. In 2004, Pacific acquired Seacliff Seafoods, a distributor with facilities in Houston, San Antonio and Wilmington, California. In 2003, the company purchased Starfish, a Bellevue Washington seafood processor and distributor and Craig & Hamiliton, a Stockton, California value-added meat processor. Now Pacific operates 15 processing facilities along the West Coast and 10 distribution facilities in Washington, Oregon, California, Idaho, Montana, Nevada and Utah."
>
> Trident Seafood Corporations #3-Sales-$800 million—Key Species: cod, halibut, whiting, Pollock, king crab, salmon, snow crab. "Trident Seafoods Corp. has been busy growing over the past two months. In March, the company acquired Louis Kemp Seafood, which markets the No. 1 retail surimi-seafood brand, from Con-Agra Foods one of the nation's largest public conglomerates....Then, in April, Trident purchased Ocean Beauty Seafoods' seven Alaska processing facilities and merged its distribution and smoked-fish business with its Seattle rival. The acquisition of Louis Kemp and the deal with Ocean Beauty will surely push Trident's 2006 sales over the $1 billion mark. Trident's prior major acquisition occurred in 2004 when it bought Norquest Seafoods of Seattle and its Portlock and Silver Lining brands. Trident operates 25 fishing vessels and at-sea processors and 18 processing plants throughout Alaska, British Columbia, Washington and Oregon." (Note—In early May 2006 the proposed purchase of Ocean Beauty Seafoods was called off.)
>
> American Seafoods Group #10-Sales $514 million. Key species: catfish, cod, hake, Pollock, scallops, yellowfin sole. "In February, Centre Partners Management sold its remaining 23 percent equity interest in American Seafoods Group to Coastal Villages Region Fund and a management group led by Chairman Berndt Bodal, increasing their ownership to 45 percent and 51 percent respectively of the company's voting equity. The buyers dished out nearly $82 million for the balance of Centre Partners' stake. Centre Partners is the New York investment Group that formed American Seafoods Group with Bodal in 2000, acquiring American Seafoods Co. and Frionor USA's New Bedford, Mass., processing facility from Norway Seafoods. The purchase came two years after the adoption of the American Fisheries Act, which forced many foreign owned fishing fleets out of U.S. waters. American Seafoods expanded in 2002 when it bought Southern Pride Catfish of Greensboro, Ala. Two years later, the company ditched a year and-a-half-long bid for an initial public offering.

7.1.4.1.2 Processing Labor, Processing Capital and the Groundfish Fishery

Processing Labor

Employment and wage information from the Bureau of Labor Statistics shows that seafood processing along the west coast generates approximately $380 to $420 million dollars in the form of wages annually to seafood product preparation and packaging employees, and in most years this sector employs over 10,000 workers (Table 7-45). The largest state in terms of processing wages and employees is Washington state, followed by California, and Oregon respectively. Washington benefits from the large degree of participation in Alaska-based fisheries which make up a substantial portion of nationwide catch, while processing in Oregon and California is dominated by catch occurring in west coast fisheries.

In support of this EIS, the Report: "Trends in Fishing and Seafood Processing Related Employment Statistics" which is attached, was developed in an attempt to mine all available federal data on seafood processing and on employment (Attachment 7-1). Its conclusions also support the analysis above. This report also has shed some light on seasonality of employment, age and gender of seafood workers. For the seafood processing industry, the 35-44 age group is the predominant workforce in al three states with this category representing 30-35%.of workers employed. The next largest group is the 45-54 age group. The gender distribution of employees in the seafood processing industry differs across states. California is the most evenly distributed with some counties where female employees outnumber males. In Oregon and Washington males workers are the majority with ~ 60 and 70% respectively.

Processing labor can be generally divided into two types; specialized labor and unspecialized labor. Unspecialized labor is characterized as workers that can easily transition their skills to other industries and employers. For example, a forklift driver could be characterized as an employee within the unspecialized labor category. That worker can easily transition between a seafood processing employer and another employer that may be involved in office supplies for example. Specialized workers are those workers that have a particular skill set which is not easily converted to other industries. Workers in this category include those that fillet fish. Filleting is a skill that is specific to the seafood industry.

Workers within the unspecialized category are typically in higher supply and are relatively easy to hire if there happens to be a shortage of workers in that category. These workers require less training than specialized workers and new laborers in the unspecialized category are unlikely to negatively impact productivity for any given amount of time. Specialized workers on the other hand are relatively short in supply, and if there is a shortage of workers in this category, newly hired specialized labor is likely to require training and will have relatively low productivity in the early stages of their career. In the seafood processing industry, many laborers are transient and their employment is often temporary in nature due to the cyclical nature of fisheries. However, processors are more likely to try to retain specialized laborers on a year round basis as re-hiring and re-training new workers in the specialized category will reduce productivity. This makes the groundfish fishery one of the most important fisheries for many seafood processors.

According to the PFMC Groundfish FMP, the Council attempts to manage the groundfish fishery on a year-round basis. This year round nature of the fishery is important to those processors that try to keep specialized labor employed on a year round basis. A year round fishery keeps product volume flowing through the plants, gives the fish filleters product to process, and ultimately keeps specialized laborers employed. Without a year round fishery, these laborers often find work elsewhere and this negatively affects processing revenue and product quality. Other fisheries are typically not managed on a year round basis because of several reasons including availability (salmon and albacore for example) and seasonal quality of the harvested species (Dungeness crab for example). Groundfish on the other hand can be available to fishers and marketable by processors on a year round basis.

Figure 7-3 depicts the monthly purchases by major buyers of groundfish—each line is a buyer. The lines reflect the percent of total purchases by the buyer that are comprised of groundfish. From this graph, it can be determined that there isn't a single month where there is not at least one major buyer that isn't making a major purchase of groundfish.

Processing Capital

Unlike many forms of processing labor, the capital involved in fish processing is not easily substitutable for use in other industries. Capital tends to be fixed in its location and designed to handle fish products as opposed to some other type of food product. A processing facility is constructed to handle seafood and produce some output product that may be fillets, surimi, head and gutted fish, or some combination of products. The size of these facilities is typically constructed around some expectation of what the future holds-in terms of quantity-for commercial fisheries landings.

Many fisheries are characterized by swings in available product due to seasonality and year to year fluctuations in species abundance. This means that during the off-season, or years when there are declines in species abundance, processor capital is idle. Groundfish (outside of Pacific whiting) was historically one of the more stable fisheries on the west coast, and is a fishery that is prosecuted on a year round basis. This sense of stability combined with an expectation of year round landings historically gave managers of processing plants some increased degree of certainty when planning for the future and investing in capital in an otherwise highly variable and uncertain industry. The recent decline in landings of traditional groundfish species has eliminated much of that certainty and meant that increasing amounts of processing capital have been left idle. Idle capital increases the cost of producing a unit of output, so naturally, some plants reliant on groundfish have closed down and consolidation has occurred within portions of the processing industry {The Research Group. 2003}. This is verified by the decrease in number of processing establishments over the past several years as reported by the Bureau of Labor Statistics (7-45).

7.1.4.2 Markets and Prices

Much of this discussion will be updated after the Council Meeting. Updated or revised sections are marked with a "*". Unless otherwise noted discussion below is taken from the 2005-2006 Groundfish Specifications EIS.

7.1.4.2.1 Live Fish Markets

An important and growing share of groundfish harvest is delivered live. These deliveries help feed the growing trade in live seafood consumed in restaurants. Groundfish delivered live were primarily nearshore rockfish and perch, but also included thornyheads, sablefish and lingcod. About 86% of live fish landings were in California with the remainder in Oregon {PFMC 2004b}. There were no recorded live fish landings in Washington. Significantly higher exvessel price was paid for live product. The coastwide average price for live product was nearly four dollars per pound, compared with under one dollar for other deliveries of the same species.

7.1.4.2.2 West Coast Groundfish and the World Market

West Coast groundfish compete in a global market, not only with similar species produced in other regions of the world, but also with other fish species such as salmon and tuna. In addition, fish compete with other sources of protein in consumers' budgets. More than 4.7 million mt of fish and other seafood were landed in the U.S. in 2000, approximately the same amount landed in each of the prior two years (DOC 2001). West Coast groundfish contributed about 0.14 million mt, 0.13 million mt, and 0.12 million mt to this total in 1998, 1999 and 2000, respectively. Pacific whiting, a relatively abundant but low price species, comprises about two-thirds of West Coast groundfish landings by weight, but only around 10% of groundfish exvessel revenue.

Production of farm-raised fish has increased rapidly in recent years. In 2000, more than 0.4 million mt of cultured fishery products were produced in the U.S., and more than 45 million mt were raised worldwide. Salmon aquaculture demonstrates the emerging importance of farmed species. While commercial salmon harvest is still near the 1980 to 1997 annual average, world salmon supply has tripled since 1980 due to a nine-fold increase in farmed salmon to 1.5 million mt in 2000.

An objective of groundfish management has been to spread harvest of the annual OY over as much of the year as possible. Consequently, groundfish harvesting occurs in every month, although beginning in the late 1990s, it took on increased importance during the summer months when sablefish harvest peaked during the primary limited entry fixed gear fishery. The bulk of whiting fishery also occurs during the summer.

Groundfish have historically provided West Coast commercial fisheries participants with a relatively steady source of income over the year, supplementing the other more seasonal fisheries. Although groundfish contributed only about 17% of total annual exvessel revenue in 2000, seasonally groundfish played a more significant role, providing one-fifth to one-third of monthly exvessel revenue coastwide during April and the three summer months. The peak value contribution by the groundfish fishery in 2000 was sablefish during August (20% of exvessel revenue). Flatfish harvest supplied between 3% and 9% of monthly exvessel revenue throughout the year, and rockfish contributed an additional 2.5% to 6.8% to monthly exvessel revenue. For northern parts of the coast, groundfish is particularly important just before the start of the December crab fishery.

7.1.4.2.3 Exvessel and Fuel Prices*

Table 7-46 lists ex-vessel prices for several west coast species, total groundfish excluding whiting, fuel, and estimates of bottom trawl revenue per hour fished for the period 1999-2005. The period was chosen based on available fuel prices collected by the PSMFC. All prices are averages except the fuel price. Fuel prices are June prices as reported by Newport Oregon fuel docks. The trends in these prices give the following perspectives:

Whiting—prices appear to range very little from year to year
Flatfish—prices declined in 2004 and 2005 but not to the 1999 level,
Rockfish—After a major increase in 2004, price fell significantly in 2005
Total Groundfish—prices in 2004 and 2005 similar but not as low as 1999.
Bottom trawl Revenue per hour—Increased significantly in 2003 and 2004. 2004 increase may be due to the buyback as fleet reduced by 1/3.
Fuel—2004 and 2005 fuel prices significantly higher while total groundfish prices declined

The implications from there trends are that all sectors are facing rising fuel prices; and, some sectors, particularly the bottom trawl sector may also be facing declining ex-vessel prices.

7.1.4.2.4 Exprocessor and Wholesale Prices

While producer prices for groundfish products have not fared quite as badly as for other frozen fish (including salmon), they still are significantly below recent highs. The trend may be flat or still lower in the future {(2005-2006 EIS, Appendix A Table7-9)}. Increasing production of farmed salmon is partly responsible for a continuing slump in salmon commodity prices. Producer prices for meat products in general have been relatively weak, thereby helping to hold down prices for competitive fish protein. Preliminary 2003 estimates of producer price indices for fish and meat products were higher than seen in recent years, possibly due to the continuing improvement in the world economic outlook.

7.1.4.2.5 Trade and Domestic Demand

Most West Coast groundfish compete in the fresh and frozen fish product markets. In 2000 the U.S. imported 1.8 million mt of edible fishery products, including 1.5 million mt of edible fresh and frozen fish products. In 2000 the U.S. exported about one million mt of edible fishery products, including 190,000 mt of edible, fresh or frozen flatfish and groundfish products. One third of edible fishery exports were to Japan. While surimi was the single largest component of total fresh and frozen exports by weight, salmon was the most valuable export, generating $353 million on the 100,000 mt of fresh and frozen product shipped, and another $146 million from exports of canned product. Asia was the largest export region, absorbing 61% of U.S. fishery exports by volume. Japan alone bought 34% of total fishery exports, and South Korea and China took 11% and 10%, respectively {2005-06 EIS, Appendix A Section 7.1}.

From 1910 through the early 1970s, annual per-capita fish consumption in the U.S. generally ran between 10 pounds and 12 pounds edible weight. Beginning in the early 1970s, per-capita consumption increased, and in the mid 1980s began shifting upward again to the 15-pound to 16-pound range where it has generally remained since 1985. In 2000 annual per-capita U.S. fish consumption was estimated to be 15.2 pounds. U.S, Seafood Consumption reached a record 16.6 pounds per capita in 2004.

7.1.4.2.6 Market and Non-market Consumer Goods

For goods exchanged in markets where a consumer price can be determined (for example seafood), price and quantity information can be used to estimate the benefits consumers derive from consumption activities. A given regulatory action may have little or no impact on consumers if changes in the quantity of fish available are insufficient to have an effect on prices. This is especially true if imports or other protein substitutes are readily available. In the market for recreational experiences, individuals pay fees to participate in recreational fishing trips on charterboats. Price and quantity information from these trips might allow estimation of the benefits participants derive from this type recreational fishing. However, charter trips may often be purchased as part of a bundle of goods and services that include nonfishing recreational activities. Therefore, the estimation of benefits from recreational charter activities is less straightforward than for marketed consumer goods.

For other consumer goods, especially bundles of goods and services such as a recreational fishing trip taken on a private vessel, the prices and quantities associated with each transaction are much more difficult to determine. For the private recreationalist, the amount spent on fishing gear, licenses, and other goods necessary to carry out a particular fishing trip is difficult to isolate. The term "private" is used here to designate a recreational fisher fishing from a private vessel, the shore, bank or a public pier, as opposed to using a charter vessel. Depending on the value a particular individual places on alternatives to fishing, the maximum benefit associated with a fishing trip may far exceed actual trip expenditures.

7.1.4.3 Consumptive versus Nonconsumptive Activities

The sectors benefiting from a resource can generally be placed into one of three groups: consumptive users (e.g., recreational fishers, commercial harvesters, and processors), nonconsumptive users (e.g., wildlife viewers), and nonusers (e.g., members of the general public who derive value from knowing that a species is being maintained at a healthy biomass level). The following table displays the general relationship between use/non-use and consumptive/nonconsumptive types of activities.

Relationship between Use/Nonuse and Consumptive/Nonconsumptive Activities

	Consumptive	Nonconsumptive
Use	Commercial and Recreational Fishing, Processing.	Wildlife Viewing
Nonuse	N/A	Existence Value, Options Value, Bequeathal Value

In economic terms, renewable resource management entails a fundamental tradeoff between current and future costs and benefits. When management needs call for a substantial reduction in allowable harvests, additional costs may be born by the direct consumptive users, who may be left with much smaller harvests than they had been accustomed to. While this near-term sacrifice may create much greater harvest opportunities in the future once the stock has been replenished—depending on the duration of the rebuilding period—many fishers and processors may be unable to weather a long down period, opting instead to go out of business.

Nonconsumptive users may benefit from the use and nonuse values provided by the resource. Wildlife viewing and the derivation of secondary benefits from ecosystem services are examples of non-consumptive use values. One or more of the following nonuse benefits may accrue from the preservation of fish stocks at higher levels of abundance: (1) existence value derived from knowing a fish population or ecosystem is protected without intent to harvest the resource; (2) option value placed on knowing a fish population, habitat, or ecosystem has been protected and is available for use, regardless of whether the resources are actually used; and (3) bequeathal value placed on knowing a fish population, habitat, or ecosystem is protected for the benefit of future generations. Offsite nonconsumptive uses of resources are public in nature in that no one is excluded from deriving the identified benefits, and one person's enjoyment does not affect another's potential benefit.

The existence of coastal fishing communities in themselves may have intrinsic social value. For example, the Newport Beach (California) dory fishing fleet, founded in 1891, is a historical landmark designated by the Newport Beach Historical Society. The city grants the dory fleet use of the public beach in return for the business and tourism this unique fishery generates.

Value may also be placed on biological diversity. The value of biological diversity may be part of the total value placed on a site by nonconsumptive users (onsite or offsite). Three levels of biological diversity have been identified, (1) genetic diversity within a species, (2) species diversity (richness, abundance, and taxonomic diversity), and (3) ecosystem diversity. Ecosystem diversity encompasses the variety of habitats, biotic communities, and ecological processes (Caribbean Fishery Management Council 1998). Healthy ecosystems characterized by high biological diversity are generally able to provide a wider range of ecosystem services than are available from damaged or less diverse ecological communities. Examples of such ecosystem services include the nutrient recycling and filtering capabilities of wetlands, and the CO_2 sequestration function provided by the ocean (which is an important carbon sink).

The total societal value placed on offsite nonconsumptive use of a stock or component of the ecosystem will also depend on: (1) the size of the human population, (2) the level of income, (3) education levels, and (4) environmental perceptions and preferences (Caribbean Fishery Management Council 1998).

The above relationships imply that as human populations and the affluence of those populations increase, and as fish stocks and their ecosystems are depleted, nonconsumptive values associated with maintaining ocean resources are likely to increase. Another implication of these relationships is that once the basic integrity of ecosystem processes and marine fisheries components are preserved, the likely additional benefit from incremental increases biomass will decrease.

Non-Consumptive Users

7.1.5 Fishing Communities

Figure 7-4 and Table 7-47 are provide to the reader as aids in for reviewing references to ports, communities, counties, and recreational areas.

The Magnuson Stevens Act requires among other things that the time period for rebuilding an overfished species "be as short as possible, taking into account the status and biology of any overfished stocks of fish, the needs of fishing communities, recommendations by international organizations in which the United States participates, and the interaction of the overfished stock within the marine ecosystem;..."

7.1.5.1 Community Descriptions

Many documents were used to develop the discussion found in this section. For more detail on the relationship of bycatch species to fisheries sector, port and community, the reader is directed to the attached: "Economic Revenue and Distributional Impacts Associated with Overfished Species Management in West Coast Commercial Groundfish Fisheries" In addition the reader is directed to Tables 7-4a and 7-4b. For additional reference, Section 8.1.6 of the 2005-2006 EIS and its associated Chapter 8 of Appendix-A contains information on fishing communities as well. For a much more expansive discussion of fishing communities, the reader is referred to the NMFS Northwest Fisheries Science Center website where detailed descriptions of fishing communities: http://www.nwfsc.noaa.gov/research/divisions/sd/communityprofiles/index.cfm. The reader is also referred to the Environmental Justice discussion found below, which contains a discussion of identifying communities of concern with respect to minority and low income populations.

In addition to this data, PacFIN data tables developed by NMFS SWFSC that describe by port and sector, the number of dealers, vessels, revenues, landings, vessel trips were used to develop the groundfish sector summaries found in Attachment 7-3 To synthesize the information found in all of the tables described above, the key analysis done for this EIS is the Fishing Community Engagement, Dependence, Resilience and Identification of Potentially Vulnerable Communities which is also attached.(Attachment 7-4of Appendix?) The key results of this study follow.

7.1.5.2 Fishing Community Engagement, Dependence, Resilience and Identification of Potentially Vulnerable Communities

To help the Council with determining the needs of fishing communities, numerous indicators were developed to characterize and rank communities and counties to the degree that a community or county was:

"engaged"—level of involvement in fishing
"dependent"—involved in the groundfish fishery
"resilient"—able to adapt to change
"vulnerable"—"highly dependent" and "having low resilience"
"most vulnerable" – "highest dependence" and "least resilient"

The methodology and results are presented in Attachment 7-4; Attachment 7-4 contains the following tables;

Table 1. Socioeconomic and cultural indicators
Table 2. Determining dependence
Table 3. Methodologies used in past research to identify dependence
Table 4. Determining resilience
Table 5. Linking dependence and resilience to identify vulnerable areas
Table 6. Distressed areas
Table 7. Commercial indicators and rankings city
Table 8. Commercial indicators and rankings by county
Table 9. Commercial fishing engagement scores by city
Table 10. Commercial fishing engagement scores by county
Table 11. Groundfish dependency scores by city
Table 12. Groundfish dependency scores by county

Below are the conclusions of the study.

7.1.5.2.1 Vulnerable Commercial Communities and Counties

With regard to engagement in commercial fishing, twenty-nine cities are identified as "vulnerable" or "most vulnerable" areas. The "most vulnerable" area label indicates the highest levels of engagement (or dependence) and the lowest levels of resilience. Ilwaco and Moss Landing are most vulnerable with regards to engagement in commercial fishing. Ilwaco and Moss Landing have the highest levels of engagement in fishing (score of four and three, respectively) and resiliency (score of three and four, respectively). Other vulnerable areas include Astoria, Bellingham, Coos Bay, Crescent City, Eureka, Fort Bragg, Ilwaco, Moss Landing, Port Orford, Santa Cruz and Winchester. All have high fishing engagement scores (two or greater) and low resiliency scores (two or greater). Newport, San Pedro and Westport all have high fishing engagement (score of four) but lower resiliency scores (score of one).

With regard to dependency on the commercial groundfish fishery, thirty-two cities are identified as vulnerable areas. Neah Bay is identified as a most vulnerable area. Other vulnerable areas include Astoria, Bellingham, Coos Bay, Crescent City, Eureka, Fort Bragg, Moss Landing, Pacific City, and Port Orford. All have high groundfish dependency scores (two or greater) and low resiliency scores (two or greater). Morro Bay, Newport, and Oceanside all have high groundfish dependency (score of three) but lower resiliency scores (score of one). Chinook, Garibaldi, La Push, and Ilwaco all have higher groundfish dependence (score of one) and the lowest resiliency scores (three or more). Several vulnerable areas that are cities are identified as highly engaged and highly dependent (see Table 22).

Astoria, Garibaldi, Gold Beach, and Westport rank in all city categories: commercial and recreational engagement and dependency as well as low resiliency.

Sixteen counties are identified as vulnerable areas with regards to commercial fishing engagement. Six counties are labeled as most vulnerable areas and include Coos, Grays Harbor, Humboldt, Lincoln, Mendocino, and Pacific counties. All have high commercial fishing engagement scores (three or more) and low resiliency scores (three or more). Grays Harbor and Lincoln counties score highest in fishing engagement (scores of four) and lowest in resiliency (scores of four).

Seventeen counties are identified as vulnerable areas with regard to groundfish dependence. Clatsop, Coos, Curry, Grays Harbor, Lincoln, and Los Angeles counties score as most highly dependent (scores of two or more) and least resilient (scores of two or more). Several vulnerable areas that are counties are identified as highly engaged and highly dependent (see Table 23).

7.1.5.2.2 Recreational fishery

Ten cities are identified as vulnerable areas with regard to recreational fishing in Oregon and Washington. These cities are bolded in Table 22 under the recreational column. Astoria, Depoe Bay, and Garibaldi are all highly engaged in the recreational fishery (score of two or more) and least resilient (score of two or more). Garibaldi is the only city labeled as "most vulnerable" due to its high scores in both engagement/dependence on recreational fisheries and low resiliency.

Other recreational vulnerable cities include Gold Beach, La Push, Neah Bay, Newport, Pacific City, Westport, and Winchester. Newport has very high score in recreational engagement (score of five) but a lower resiliency score (score of one). La Push, Neah Bay and Winchester all have lower recreational engagement scores (scores of one) but very low resiliency scores (score of four or more).

It was not possible to identify recreationally engaged vulnerable areas in California due to the two-county and regional level recreational data that was available with regard to recreational fishing, compared to city and county level data available for the resiliency indicators. However, we were able to identify some California communities as potential vulnerable areas based on commercial engagement in and dependency on the groundfish fishery. Table 16 shows that San Luis Obispo through Santa Cruz counties and San Diego through Los Angeles counties are most engaged in recreational fishing and dependent on the groundfish recreational fishery. Los Angeles, San Luis Obispo and Santa Barbara counties are all ranked as least resilient in Table 23.

7.1.5.2.3 Summary

In summary, thirty-eight cities and eighteen counties are identified as commercial and/or recreational vulnerable areas (areas with high engagement or dependence on commercial or recreational fisheries and low resilience to change). Tables 22 and 23 display the results of the analysis. To qualify as a vulnerable area, a city or county must be listed in the top one-third of ranked indicator values for at least one engagement or dependency indicator and one resiliency indicator. When stricter ranking requirements are applied so that a community has to be ranked in the top one-third of an indicator twice under engagement and/or dependence and resilience, a smaller pool of cities and counties qualify. These seventeen cities include Astoria, Bellingham, Bodega Bay, Coos Bay, Crescent City, Depoe Bay, Eureka, Fort Bragg, Garibaldi, Ilwaco, Moss Landing, Neah Bay, Newport, Pacific City, Port Orford, Santa Cruz, and Winchester Bay. The fifteen counties include: Clatsop, Coos, Curry, Del Norte, Grays Harbor, Humboldt, Lincoln, Los Angeles, Mendocino, Monterey, Pacific, San Luis Obispo, Tillamook, Wahkiakum, and Whatcom counties. If even stricter ranking requirements are applied so that a community must be ranked in the top one-third of an indicator three times under engagement and/or dependence and resilience, four cities and six counties are identified as vulnerable. These cities and counties are labeled "most vulnerable". The cities include: Garibaldi, Ilwaco, Moss Landing, and Neah Bay. The counties include: Coos, Grays Harbor, Humboldt, Lincoln, Mendocino, and Pacific counties.

7.1.5.3 Environmental Justice Communities of Concern

This Section repeats the discussion found in The final EIS for the 2005-06 specification document {PFMC (Pacific Fishery Management Council) 2005?DBD Final Environmental Impact Statement for the Proposed Groundfish Acceptable Biological Catch and Optimum Yield Specifications and Management Measures for the 2005-06 Pacific Coast Groundfish Fishery. Pacific Fishery Management Council. Portland, OR, January 2005? DBD}

Environmental Justice Considerations

7.1.5.3.1 Identifying Communities of Concern

Executive Order 12898, Federal Actions to Address Environmental Justice in Minority Populations and Low-Income Populations, requires federal agencies to identify and address "disproportionately high adverse human health or environmental effects of its programs, policies, and activities on minority and low-income populations in the United States." Fishery management actions promulgated by the Pacific Council and implemented by NMFS can have environmental and socioeconomic impacts over a very wide area; the affected area of many actions covers all West Coast waters and adjacent coastal communities involved in fishing. This makes it difficult to identify minority and low-income populations that may be disproportionately affected.

Section 8.5 in Appendix A (PFMC, 2005) describes a methodology, using 2000 U.S. Census data, to identify potential "communities of concern" because their populations have a lower income or a higher proportion of minorities than comparable communities in their region. West Coast ports identified in the PacFIN database were examined in this way. These ports were evaluated using five criteria: the percentage nonwhite population, percentage Native American population, percentage Hispanic population, average income, and the poverty rate. Data were evaluated for both census places and census block groups corresponding to the area around these census places. The values for these statistics were compared to the average value for one of three regions, covering coastal block groups in Washington, Oregon, and northern California; central California; and southern California. For each of the five statistics potential communities of concern were identified. These are communities that have a significantly higher percentage minority population and poverty rate or lower average income than the surrounding reference region.

About two-thirds of the port communities analyzed are above the cutoff threshold for one or more of the statistics, measured either by the census place value or the equivalent block groups. This suggests that additional criteria need to be applied to more realistically identify which ports should be of concern. It should be noted that the population affected by the proposed action, which would be predominantly fishers and those involved in allied industries (e.g., marine supplies, fish processing, recreational charter and equipment) is a small percentage of the population in most communities. It stands to reason that in larger communities and more urban areas, fishery participants are a smaller and potentially less representative component of the population. In isolated rural communities there are usually fewer alternative employment alternatives, making it harder to find work or switch from one occupation to another in response to changes in one economic sector such as fisheries. Given these conditions, another criterion to focus on communities of concern would be population size and urbanization. Eliminating ports with a population greater than 50,000 and of those ports with a population less than 50,000, those for which the block group area is more than 75% urban leaves the following ports as potential communities of concern:

It should be noted that fishery participants usually make up a small component of the population and fisheries may be a small part of the local economy in many places. Thus, even if a community has a high proportion of minority or low income residents, these people might not participate in fisheries and are thus minimally affected by the proposed action. Furthermore, within the affected population some segments are more likely to be low income and minority than others. For example, employees in a fishing processing plant may be predominantly from a minority group, and crew on vessels are likely to have a lower earnings than the skipper or vessel owner, making them more likely to be low income. Unfortunately, the kind of detailed population data necessary to determine the characteristics of the population affected by the proposed action are not available. For this reason, the ports identified in Table 7-48 represent an initial screening. Note that Moss Landing, Port Orford, Neah Bay, and Winchester Bay are also described as "vulnerable communities" (see 7.1.5.2.3).

7.2 The Economic Impacts of the Alternatives

7.2.1 Introduction

7.2.1.1 Criteria Used to Evaluate Impacts

When an agency is evaluating reasonably foreseeable significant adverse effects, there is incomplete or unavailable information, and the costs of obtaining it are exorbitant or the means unknown, the agency must (1) so state, (2) describe the importance of the unavailable information to the assessment, (3) summarize any existing scientific information, and (4) evaluate impacts based on generally accepted scientific principals, which may accord with the best professional judgment of agency staff (40 CFR Part 1502.22). NMFS acknowledges that the information necessary to fully evaluate net national benefits associated with socio-economic impacts described below cannot be reasonably obtained at this time. Available information includes historic data on commercial vessel landings and exvessel revenue gleaned from fish tickets, projections of limited entry trawl vessel participation (landings and revenue) under the alternatives provided by the GMT's trawl bycatch model, rough projections of nontrawl fisheries response (landings and revenue) under the alternatives produced by the Council's commercial fisheries data model, tribal fisheries projections (landings and revenue) under the alternatives provided by the GMT, estimates of recreational angler trips in recent years and under the alternatives provided by the GMT, and estimates of local personal income and employment impacts resulting under the alternatives generated using the Council's commercial and recreational fisheries economic assessment models (FEAM)[1/].

Additional information that is necessary to perform the required net benefits analysis includes production cost information for vessels; production cost, product volume and price information for processors; trip cost, trip volume and price information for charter operators; and angler willingness to pay information for recreational fishing experience. As noted below, efforts are underway to collect representative production cost information from participating commercial fishing vessels. However that information will not be available in time for use in this analysis, nor will the other information mentioned in this paragraph. Therefore the following evaluation is based on best professional judgment of NMFS and Council staff.

7.2.2 Commercial Fisheries

Changes in exvessel revenue are used to indicate the directions of change expected in net economic benefits derived from harvest by the commercial seafood vessels. Subgroups of the groundfish fleet are examined to determine if any particular group is experiencing greater effects than others. The primary divisions are between the limited entry trawl, limited entry fixed gear and open access fishery.

A complete assessment of the expected change in net revenue requires an assessment of changes in fishing costs[1/]. Comprehensive information on fishing costs for the West Coast groundfish fishery is not currently available. An effort is underway by NMFS and PSMFC to fill this gap by collecting data on fixed and variable cost structures of vessels engaged in groundfish and other major West Coast fisheries. A simple analysis of expected change in vessel cost structure associated with implementation of selective flatfish trawl fishery is included. Changes in operational flexibility resulting from regulatory constraints will be addressed qualitatively as an indicator of impacts on production costs. Effects on human health and safety will be discussed primarily in terms of the effect of revenue changes on vessel maintenance and the effect of changes in the RCA on travel distances to fishing ports.

The discussion of cumulative impacts will include the effects of the trawl vessel buyback program and possible future implementation of an ITQ program. These regulatory changes will be discussed in terms

---

1/ FEAM includes estimates of industry (commercial vessels, processors and recreational angling businesses) cost and output parameters that have been adopted from informal surveys over the past 20 years. The Council's economic modeling methodologies are discussed in Appendix D of 2005-2006 EIS.

2/ In order to estimate net economic benefits, fishing costs must be adjusted by appropriate shadow prices to determine real opportunity costs. For example, expenditures for crew would not count as an economic opportunity cost if the labor would otherwise have been unemployed. Or if the labor would have been employed, but at a lower wage, then the difference between the wages in the fishery and the wage in the next best alternative employment would not be counted as an economic cost (i.e., only the next best available wage is counted as a cost).

of their likely effects on vessel revenue and operational costs. Changes in revenue will also be used as an indicator of the magnitude of likely harvest pressure that may affect adjacent fisheries as a result of changes in opportunity in the groundfish fishery.

7.2.3 Buyers, Processors, and Seafood Markets

Due to the lack of data on prices, costs and profitability of buyers and processors, much the same indicators as used for the harvesting sectors are used for comparing impacts on the buyer/processing sector. Specifically, as a proxy for profits, exvessel revenue is used as an indicator of activity level. From the buyer's' perspective, exvessel revenue represents expenditures for a primary production input. Projected change in exvessel revenue under the alternatives can be stratified by different categories to examine impacts by buyer/processors' relative size and level of involvement in or dependence on groundfish purchases.

Substitutability of other products, or the same product imported from elsewhere, greatly affects regional seafood markets. Flatfish are generally lower priced than rockfish, and production is more constrained by markets than by availability of the resource itself. Rockfish are higher priced in West Coast fresh markets. However, similar products from South America, Mexico, Canada, and Alaska readily substitute for West Coast production. Whiting, which is processed into surimi, a generic fish product, competes with other sources of supply such as Alaska pollock.

7.2.4 Tribal Fisheries

The criteria used to compare 2005-2006 management alternatives for the tribal groundfish fisheries are total annual projected groundfish landings and resulting exvessel revenue.

7.2.5 Recreational Fisheries

7.2.5.1 Private Recreational Anglers

Recreational experiences generate economic value for individual anglers, as determined by their willingness to pay for the experience. The sum of anglers' net willingness to pay (minus actual expenditures) represents the net economic value contributed by the recreational fishery to the national economy. However estimates of these parameters are not currently available. As a proxy, partial estimates of the change in total trips and indicators of the probable direction and degree of change in the average value per trip are considered. The following discussion highlights some of the issues involved in estimating the net economic value of the recreational fishing experience.

7.2.5.1.1 Estimating Net Economic Value

The net value of a recreational fishing trip is a function of the willingness of potential anglers to pay for the experience.[1/] While expected catch (species, number and size) probably doesn't affect the value of a

3/ Arguments that might be used to estimate willingness to pay include, among others, attractiveness of the location and distance traveled by the fisher.

trip once it is undertaken, it may affect the likelihood of taking a given trip in the first place. Reduced bag limits, while reducing the number of trips per time period, may also allow for a longer season and an increased total number of angler trips. This could provide angling opportunities to a greater number of anglers, potentially increasing the marginal value of each fish. While the marginal value per angler of each additional fish caught decreases with increasing bag limits, so too does the cost per unit of catch. So the net effect of a change in bag limit on the value of recreational experiences is ambiguous.

While a loss of fishing opportunity may translate into a direct reduction in trip-related expenditures, the resulting change in net economic value will be considerably less than the change in expenditure. Presumably the recreationalist will still pursue another activity, even though this alternative experience may be somewhat inferior than what the person originally had in mind. Substitution of one activity for another in time and/or place may still involve a similar level of expenditures, although not of the same kind or necessarily in the same place. While analysis of the local impact would interpret the reduction in revenue of the recreational fishing-related businesses as a direct loss in local income, analysis of net economic value would treat only the difference in the intrinsic value to the individual between the two types of experience as a net change in value.

An ideal model would allow us to measure the effect on total recreational effort (quantity and location of trips) and marginal value per trip resulting from changes in different management variables. Unfortunately, the data to populate such a model are lacking because the specific surveys to collect the required data have not been done.

7.2.5.1.2 Change in Recreational Effort

Conceptually, effort may change in response to caps on total landings (although if a cap is non-binding it may have no direct effect), change in seasons, or change in area or depth closures. Estimates of the change in the number of angler trips in each state's recreational ocean fishery under each management alternative are derived. Also considered are the proposed closure periods compared with the seasonal effort pattern observed, and the effect of shifts in the inshore closed area under the alternatives.

It should be noted that these estimates probably do not adequately project the effect of management changes on the distribution of effort, nor do they incorporate the impact of other changes on demand for recreational fishing experience. However this is the best available approach for evaluating impacts given the data limitations.

7.2.5.1.3 Change in Quality (Value) of Trips

Management measures may affect the perceived value of the recreational experience as well as the amount of effort. Those anglers forced to change their desired fishing patterns will probably experience a reduction in economic value from the trip. While change in bag limits probably does affect the decision of whether or not to fish, historically West Coast groundfish managers have observed little change in recreational effort in response to changes in bag limits. However continued reductions in bag limits would be expected to eventually lead to reduced demand and lower levels of angler participation once some critical threshold had been crossed.

7.2.5.1.4 Change in Quantity of Trips

Greater restrictions (e.g., lower bag limits) on individual trips may allow a greater number of anglers to fish by spreading the recreational harvest out over a longer season. However if current bag limits are constraining retained catch, then lower bag limits may also reduce the likelihood that a given individual will choose to go fishing in the first place. An increase in the number of trips results in increased total expenditures by recreational anglers. However, especially in the short term, these expenditures may represent dollars taken away from other places and other types of activities rather than "new" activity. Therefore even though net benefits may be unchanged, there may be a redistribution of expenditures among local businesses.

7.2.5.2 Charter Boat Businesses

Demand for charter trips is affected by some of the same factors that affect demand for private recreational fisheries, including bag limits, weather conditions during open seasons, and coincidental timing of open seasons with traditional vacation periods. For example, a closure during the months of July and August, the peak summer vacation period, will have a more adverse impact on charter operators than will closures during any other two-month period of the year. Impacts on charter boats under the alternatives are assessed based on estimated changes in total effort and timing of closure periods.

7.2.6 General Public

Directly measuring individuals' nonconsumptive and nonuse values for a marine resource is beyond the scope of this analysis. The metric used as a proxy is relative size of the RCAs. At current relative biomass levels for sensitive fish species this measure is assumed to be proportional to enhanced nonconsumptive and nonuse values.

7.2.7 Communities

Impacts on communities will be assessed according to the commercial and recreational impacts described below. "Vulnerable" communities will be also discussed.

7.2.7.1 Commercial Fisheries and Recreational Impacts

Projected commercial landings under the alternatives are compared against recent landings to estimate change in landings by port area. Income multipliers generated by the FEAM and differentiated by species, vessel category, gear type, processing mode, and landing port are applied to the projected landings to estimate change in total personal income impacts resulting from the estimated change in harvest and processing activity under each alternative. A description of FEAM is found in {Jensen 1996}. A recent update to the model is described in {Davis 2003}. Also see Appendix D of the 2005-06 EIS for further discussion of income impact estimating methodology. These impacts will be reviewed against the list of "vulnerable communities as described above." Annual recreational fishing effort under the alternatives is estimated by region and compared against recent data. Change in effort is assumed to be roughly proportional to the change in estimated harvest. Regional income multipliers derived from the recreational FEAM, and average trip expenditures for recreational fishers in the four regions derived from a recent study {Gentner 2001} are applied to the estimated change in effort to generate the change in regional income resulting from the level of recreational fishing activity expected under each alternative.

7.2.7.2 Community Vulnerability

The commercial and recreational impacts will be compared against the list of "vulnerable" communities and "communities of concern"—see discussion under 7.1.5.2.

7.2.7.3 Safety

Changes in vessel net income can have effects beyond economic effects. Reduced investment in maintenance and safety equipment can increase hazard associated with fishing. Reduced income opportunity could cause dislocation for crew members and their families. Individuals willing to work for lower paying jobs are generally less skilled and have fewer alternative employment opportunities. In addition to reduced operational efficiency, these factors could lead to deterioration in vessel safety conditions.

Safety of fishing vessels is also affected by the seasons and depth zones or areas open to fishing under the alternatives. Seasonal closures that push commercial and/or recreational vessels out to sea during poor weather months will increase the likelihood of safety problems for those vessels.

RCA boundaries and depth or area closures that pack vessels into shallow nearshore areas will also increase the likelihood of safety problems. Limits that push commercial and recreational fleets to fish in the same waters increase the risk of collisions, especially in bad weather. Recreational boaters tend to be less experienced and have less safety equipment than commercial skippers, and are often unfamiliar with bottom contours, wave dynamics, tides, and currents. This combination of increased vessel density, the inherent risks of navigating shallow waters, and relatively inexperienced skippers, increases the risks to vessels.

Effects on vessel safety under the alternatives are evaluated by comparing revenue earning opportunities for commercial vessels, and the pattern of season and depth/area closures for both commercial and recreational vessels.

7.2.7.4 Key Impact Indicators

As discussed above assessing the impacts of the alternatives will be primarily through the prediction of changes in landings, ex-vessel revenues, and personal income impacts for commercial fisheries. Total estimates are provided by Alternative and then by sector and community (e.g. Shoreside Limited Entry Trawl, Astoria Tillamook) and by state. For recreational fisheries, the key indicators are trips, angler expenditures and income impacts. In evaluating the alternatives, two different approaches are undertaken. The first approach attempts to develop ex-vessel impact estimates on a on a finer scale with respect to gear groups and fisheries than the second approach. The second approach provides information on personal income and other variables. Both discuss recreational fisheries

First Approach –A: Commercial sectors are nearshore groundfish, limited entry trawl, whiting, fixed gear sablefish north of the Conception area, fixed gear south of Point Conception, and Total. The First Approach uses 2005 as a reference point. Whereas the Second approach uses the No-Action Alternative as a reference point.

Second Approach –B: Commercial sectors are Limited Entry trawl (including or excluding whiting), tribal shoreside, tribal at sea, open access groundfish, and total limited entry sablefish.

The methodology and groupings of tribal and commercial sectors differs slightly between each approach, but recreational fisheries are analyzed the same way. Approach B provides commercial estimates and projections by alternatives on landing, revenues, and personal income and recreational estimates and projections of trips, angler expenditures, and personal income. Approach A provides estimates of ex-vessel values and recreational trips. Approach B provides information on a port and community basis; Approach A provides information on a regional basis. Approach A analyzes the five rebuilding alternatives discussed in Chapter 2 and brought before the Council in April. Approach B focuses only the three action alternatives, the no action alternative, and provides estimates of 05 and 06. Approach A does not address O6 or the no-action alternative; however, it does address the "No Fishing" option.

For this document, both analyses will be used. Because it addresses the link between management and economic impact, Approach A Analyses will be used to walk through the alternatives. This discussion will then be followed by a summary of the Second Approach's estimates.

Since both approaches discuss the Action Alternatives, Table 7-49 has been developed to provide the reader with a quick reference to the major changes in OYs from 05-06 levels.

7.2.8 Economic Impact of Management Measures Designed to Achieve the OY Alternatives—Discussion of Approach A

This section discusses the economic impact of management measures that were designed and analyzed with the intention of achieving the OYs described in chapter 2 of this EIS. The alternatives discussed in chapter 2 show a set of alternatives originally considered during the winter of 2006 which led to the council's selection of preliminary preferred alternatives for target species, and a high and low preliminary preferred alternative for rebuilding species. The initial set of OY alternatives pertaining to overfished species described in chapter 2 are referred to here as "rebuilding alternatives" and the second set of alternatives that were selected by the council during the April 2006 meeting are referred to as "preliminary preferred alternatives" or "action alternatives". The action alternatives focus on the council's preliminary preferred OYs for target and rebuilding species. While the council may continue to consider, and ultimately adopt, one or more of the rebuilding alternatives not considered a preliminary preferred alternative, this analysis concentrates on the action alternatives based on the notion that the council has given an indication as to what OYs it feels are close to those it wishes to adopt.

7.2.8.1 Overview

The OYs for target and rebuilding species differ from 2005 and 2006 OYs. In some cases these differences are substantial, and in other cases the difference in minimal. The relative OYs of target and rebuilding species ultimately influences the management measures that are crafted in response to those OYs, and estimates of exvessel revenue, recreational effort, and the distribution and source of those economic effects differ in response.

For the 2007 and 2008 season, the OY of several key target species will differ relative to the 2005 and 2006 season. The OYs for Dover sole, English sole, and shortspine thornyheads will increase substantially based on the council's preliminary preferred alternative (Table 7-49). In response, management measures could be crafted which allow fisheries to harvest more of these species, however, the take of these target species is constrained by rebuilding species, and in some cases, other target species. Some target species will have a decrease in the OY compared to the OYs that were in place for 2005 and 2006. Petrale sole and sablefish for example will have a 22% and 10% reduction respectively, and these OYs are expected to constrain the take of other target species to some degree under the council's preliminary preferred alternatives 2 and 3.

The OY for rebuilding species differ from 2006. Under action alternative 1, all OYs are reduced compared to 2006 levels. Under action alternative 2 and 3, the OY of most overfished species are reduced compared to 2006 levels, but the OY for widow, cowcod, and darkblotched would increase. However, the OY for darkblotched is equivalent to 2006 levels when the OY is measured relative to the size of stock biomass, and analysis shows that this OY is expected to constrain some fisheries more than the 2006 OY based on expectations pertaining to increases in the bycatch rate of darkblotched.

Table 7-49 provides information on the difference and change in OYs for rebuilding species and some of the key target species. This information is useful for showing why exvessel revenue can change under some of the alternatives, the source for those changes, and insight into some of the management responses anticipated to stay within the OY that is ultimately adopted by the council.

A summary comparison of exvessel revenue calculations by sector and alternative provides a glance of the economic impacts of each alternative (Table 7-50). Compared to coastwide 2005 exvessel revenues generated by commercial vessels in directed groundfish sectors, action alternative 3 has the least degree of difference, action alternative 1 has the largest degree of difference, and action alternative 2 is best described as more moderate. The five rebuilding alternatives originally analyzed range from exvessel revenues that are slightly higher than status quo, to revenues that are slightly lower than action alternative 1. On a sector specific basis, all alternatives negatively impact the fixed gear sablefish sector because the OY for sablefish is lower in 2007 and 2008 compared to 2005 and 2006. The nearshore groundfish sector is most impacted by action alternative 1, least impacted by action alternative 3, and more moderately impacted by action alternative 2. The LE bottom trawl sector is most impacted by action alternative 1, has slightly higher revenues than status quo under action alternative 2, and even higher revenues under action alternative 3. The LE whiting sector is most negatively impacted by action alternative 1, but action alternative 3 allows this sector to attain higher revenues than status quo if the whiting OY allows those catch levels to be attained4. Action alternative 2 constrains the whiting sector to revenues that are somewhat less than status quo. Fixed gear fisheries south of point Conception are negatively impacted by action alternative 1, but remain at status quo for action alternatives 2 and 3.

Table 7-51 does a similar analysis for recreational fisheries. Action Alternative 3 leads to an increase in recreational effort over 2005 levels while Action Alternative 1 shows a 35 % decline in angler trips and Alternative 2, a 22% decline.

7.2.8.2 Action Alternative 1

Action alternative 1 reduces overfished species OYs compared to status quo catch levels, and as a result, revenues generated by commercial and recreational fisheries are reduced compared to 2005 levels. Under this alternative, many of the target species OYs are not attained, and fishing area is decreased for all sectors as the size of groundfish conservation areas is expanded to encompass more area where

4 The Pacific whiting ABC and OY levels are estimated and adopted by the Council in the spring of each year.

overfished species are found. While groundfish conservation areas are a useful tool for protecting overfished species while allowing fishing opportunity where those same overfished species are less abundant, having less fishing area makes it more difficult to access target species in many cases, and may also increase the cost of traveling to areas remaining open.

7.2.8.2.1 Impacts to Limited Entry Bottom Trawl

The impacts to the non-whiting limited entry trawl sector under action alternative 1 are largely driven by the OYs for canary rockfish, bocaccio rockfish, darkblotched rockfish, cowcod, and Pacific ocean perch. While the OYs for yelloweye and widow rockfish are also reduced under action alternative 1, the non-whiting limited entry trawl sector does not encounter these species to the same degree as other sectors and therefore the management measures crafted for this sector are not driven by those species.

Regulations for the non-whiting limited entry trawl sector include an expansion of the trawl rockfish conservation area compared to status quo, and a decrease in cumulative limits for target species compared to status quo. Of particular note, this alternative puts in place a 250 fathom seaward boundary in the northern areas (north of 40° 10 minutes N latitude) for the entire year, a 200 fathom seaward boundary in the area between 40° 10 minutes N latitude and 38° N latitude for the entire year, and a 60 fathom shoreward boundary for areas south of 40° 10 minutes N latitude for most of the year. This is a noticeable reduction in fishing area compared to 2006 configurations.

Cumulative limits for target species under this alternative are reduced for all of the major target species including Dover sole, sablefish, thornyheads, other flatfish, arrowtooth flounder, and petrale sole. As a result, none of the OYs for major target species are attained under this alternative.

The combined effect of area closures and reductions in cumulative limits results in a decrease in exvessel revenues from the no-action alternative. Exvessel revenues to this sector are approximately 59% of 2005 levels, representing a decrease of approximately 41% (Table 7-50). Table 7-52 shows projected revenues by two month period.

7.2.8.2.2 Impacts to the Limited Entry Whiting Trawl Fishery

The impacts to the limited entry whiting trawl sector under action alternative 1 are largely driven by the OYs for canary rockfish, widow rockfish, and to a lesser extent, darkblotched rockfish and Pacific ocean perch. Other species are not caught in the whiting sectors to the same degree as other sectors, so management measures necessary to protect species such as bocaccio, yelloweye, and cowcod do not influence the whiting fishery to the same degree as other sectors.

While many sectors benefit from the use of groundfish conservation areas, or more specifically, the rockfish conservation areas, it is estimated that the whiting sector would not benefit as much from imposing a rockfish conservation area in the same manner as the bottom trawl sector. Depths restrictions necessary to achieve reductions in the catch of canary, widow, darkblotched, and POP are generally the same depths where Pacific whiting are found and caught effectively. Closing these areas would also eliminate the ability to target whiting effectively, except in the years of largest whiting abundance when the population is spread more densely over a wider range of depths. Therefore, the most effective means of reducing the bycatch of overfished species in this sector while continuing to allow a fishery is likely to be a decrease in the amount of whiting catch allowed to the commercial sectors. Assuming the whiting sector is allowed to take the same percentage of the widow, canary, darkblotched, and POP OYs as under the 2005 and 2006 fisheries, it is estimated that the commercial catch amounts and exvessel value of Pacific whiting would decrease by 42.5% (Table 7-50) Table 7-53 shows projected revenues by two month period.

7.2.8.2.3 Impacts to Nearshore Groundfish Fisheries

Economic impacts to the nearshore groundfish sector are largely driven by canary and yelloweye rockfish. In areas south of 40° 10 minutes N latitude, observer data has not shown an interaction with yelloweye rockfish, so in these areas, canary rockfish is the driving constraint. Action alternative 1 brings the nearshore groundfish sectors in to depths less than 20 fathoms for the entire year. Depth restrictions are regarded as a useful tool for managing the catch of overfished species in the nearshore groundfish sectors while allowing fishing of healthy target species, however, imposing a more restrictive depth restriction is expected to result in some reduction in the catch of target species as some nearshore target species are not as available at depths less than 20 fathoms. Although some reduction in the catch of target species is expected from a 20 fathom restriction, additional reductions on some of the lesser valued target species are were analyzed under this alternative to achieve the necessary reductions in the bycatch of canary and yelloweye rockfish. Analysis of alternative 1 shows that exvessel revenues are expected to decline by approximately $450,000 from 2005 levels which represents a decrease of approximately 16.5% (Tables 7-50, 7-54).

7.2.8.2.4 Impacts to Fixed Gear Sablefish Sectors North of 36° North Latitude

Economic impacts to the fixed gear sablefish sectors are largely driven by yelloweye and, to a lesser extent, canary rockfish. Management measures designed to reduce the bycatch of these species in the fixed gear sablefish sectors are limited to depth restrictions of varying degrees of restrictiveness depending on the alternative. Changes in the catch of sablefish which are lower than the OY are not considered in the management measures which pertain to reductions in the catch of overfished species because under all alternatives the sablefish OY is reduced compared to 2005 and 2006 levels, and this reduction achieves reductions in the bycatch of overfished species on it's own. The reduction in the sablefish OY occurs as a result of the 2005 sablefish stock assessment, and the council's policies regarding species that fall within the precautionary zone (sablefish is a precautionary zone species).

While exvessel revenues are expected to be the same across all action alternatives ($8.7 million, Table 7-50), action alternative 1 is expected to have a substantial impact to vessels that home port near the northern Washington coast and Puget Sound. Under action alternative 1, the fixed gear sablefish sectors would be restricted to fishing deeper than depths of 150 fathoms, and off the northern Washington coast, the 150 fathom line closes off most of the fishing grounds currently used by those vessels. Imposing a 150 fathom line would require vessels that home port in the northern Washington ports and Puget Sound ports to travel much further distances to reach fishing grounds. This may result in increased travel cost, or some vessels may choose to change their homeport, thereby affecting processors and support businesses relying on vessels in their current home ports in the northern Washington coast and Puget Sound.

7.2.8.2.5 Impacts to Groundfish Fixed Gear Sectors South of 34° 27 North Latitude

The economic impact to fixed gear fisheries operating south of point Conception are largely influenced by the OYs for bocaccio and cowcod. Depth restrictions are viewed as an effective mechanism for achieving reductions in the bycatch of overfished species in this area (primarily bocaccio and cowcod), however depth restrictions are likely to reduce the catch of target species as well since vessels in this area occasionally target species that are found in areas proposed to be closed under action alternative 1. Under status quo management measures, vessels can fish at depths less than 60 fathoms or more than 150 fathoms. Under action alternative 1, vessels would be restricted to fishing shallower than 40 fathoms or deeper than 180 fathoms. Based on the relative abundance of the main target species in the area across those depths, imposing a shoreward boundary of 40 fathoms and a seaward boundary of 180 fathoms is expected to reduce exvessel revenues by approximately $620,000, or approximately 29% compared to 2005 revenues (Table 7-50).

7.2.8.2.6 Impacts to Recreational Sectors

The impact to recreational sectors under action alternative 1 are driven by the OY for yelloweye rockfish and canary rockfish. The yelloweye rockfish OY under this alternative represents a substantial decrease in the OY from status quo levels, and management measures designed to achieve catch levels that meet this reduction in the OY are sufficient to achieve the necessary reductions in the canary rockfish OY. Management measures used to achieve the reductions in the bycatch of yelloweye rockfish include restricting recreational fisheries to 10 and 20 fathoms, reduced bag limits for target species, and shorter seasons. The coastwide impact of these management measures results in a 35% decline in recreational bottomfish fishing effort (Table 7-51).

7.2.8.3 Action Alternative 2

Action alternative 2 brings overfished species OYs to levels that are near status quo catch amounts for many overfished species except for yelloweye rockfish. When applying the portion of the OY currently being caught by status quo catch levels to the predicted biomass of overfished species in 2007 and 2008, the OYs for some overfished species under action alternative 2 are even closer to status quo catch levels. While OYs for overfished species are near status quo, negative economic impacts are less than alternative 1, but more restrictive than action alternative 3. The result is a larger portion of the OY that remains unattributed to any particular sector5.

While many of the OYs for overfished species are not attained under this alternative, coastwide exvessel revenues are estimated to be higher for many sectors of the fishery as the population of target species such as Dover sole and petrale sole increase and become more widely found in the fishery (Table 7-50).

7.2.8.3.1 Impacts to the Limited Entry Bottom Trawl Fishery

The impacts to the non-whiting limited entry trawl sector under action alternative 2 are largely driven by the OYs for canary rockfish, bocaccio rockfish, darkblotched rockfish, cowcod, and Pacific ocean perch.

Regulations for the non-whiting limited entry trawl sector under this alternative mostly include an expansion of the trawl rockfish conservation area compared to status quo. While catch levels of overfished species are predicted to be close to status quo in this sector for many overfished species, it is predicted that the bycatch of several overfished species, darkblotched rockfish in particular, will increase over time and that rate of increase is sufficient to warrant increasing restrictions on the fishery to stay within the OY. Exvessel revenues for the bottom trawl sector are predicted to be marginally higher compared to status quo, however, the distribution of impacts is likely to be different than status

5 see chapter 2 scorecards which estimate catch of overfished species by sector and alternative.

quo. Under this alternative the rockfish conservation area boundaries are set at deeper depths for some periods of the year when compared to status quo, and this has impacts on vessels that are less able to fish at deeper depths because some vessels may be unable to fish in these areas, vessels may need to travel further to fishing grounds, or additional vessels may choose to fish in the nearshore areas, thus impacting small trawl vessels that routinely fish nearer to the shore. Table 7-55 provides projections of revenues by region and two month period. (Note there are no Tables 56 or 57)

7.2.8.3.2 Impacts to the Limited Entry Whiting Trawl Fishery

The impacts to the limited entry whiting trawl sector under action alternative 2 are largely driven by the OYs for canary rockfish and widow rockfish. While many sectors benefit from the use of groundfish conservation areas, or more specifically, the rockfish conservation areas, it is estimated that the whiting sector would not benefit as much from imposing a rockfish conservation area in the same manner as the bottom trawl sector. Depths restrictions necessary to achieve reductions in the catch of canary, widow, darkblotched, and POP are generally the same depths where Pacific whiting are found and caught effectively. Closing these areas would also eliminate the ability to target whiting effectively, except in the years of largest whiting abundance when the population is spread more densely over a wider range of depths. Therefore, the most effective means of reducing the bycatch of overfished species in this sector while continuing to allow a fishery is likely to be a decrease in the amount of whiting catch allowed to the commercial sectors. Assuming the whiting sector is allowed to take the same percentage of the widow, canary, darkblotched, and POP OYs as under the 2005 and 2006 fisheries, it is estimated that the commercial catch amounts and exvessel value of Pacific whiting would decrease by 22%. Table 7-58 shows projected revenues by two month period.

7.2.8.3.3 Impacts to Nearshore Groundfish Fisheries

Economic impacts to the nearshore groundfish sector are largely driven by canary and yelloweye rockfish. In areas south of 40° 10 minutes N latitude, observer data has not shown an interaction with yelloweye rockfish, so in these areas, canary rockfish is the driving constraint. Action alternative 2 brings the nearshore groundfish sectors in to depths less than 20 fathoms for the entire year. Depth restrictions are regarded as a useful tool for managing the catch of overfished species in the nearshore groundfish sectors while allowing fishing of healthy target species, however, imposing a more restrictive depth restriction is expected to result in some reduction in the catch of target species as some nearshore target species are not as available at depths less than 20 fathoms. While some reduction in target species catch is expected under this alternative, the catch of yet other target species that are available at these depths can be increased under this alternative compared to status quo and the impact of increasing the catch of these target species is a slight increase in exvessel revenues. Analysis of alternative 2 shows that exvessel revenues are expected to increase by approximately $90,000 from 2005 levels, but revenues are expected to decrease in the northern areas while increasing in the southern areas (Table 7-59).

7.2.8.3.4 Impacts to Fixed Gear Sablefish Sectors North of 36° North Latitude

Economic impacts to the fixed gear sablefish sectors are largely driven by yelloweye and, to a lesser extent, canary rockfish. Management measures designed to reduce the bycatch of these species in the fixed gear sablefish sectors are limited to depth restrictions of varying degrees of restrictiveness depending on the alternative. Changes in the catch of sablefish which are lower than the OY are not considered in the management measures which pertain to reductions in the catch of overfished species because under all alternatives the sablefish OY is reduced compared to 2005 and 2006 levels, and this reduction achieves reductions in the bycatch of overfished species on it's own. The reduction in the sablefish OY occurs as a result of the 2005 sablefish stock assessment, and the council's policies regarding species that fall within the precautionary zone (sablefish is a precautionary zone species).

While exvessel revenues are expected to be the same across all action alternatives ($8.7 million, Table 7-50), action alternative 2 could have a relatively large impact to vessels that home port near the northern Washington coast and Puget Sound. Under action alternative 2, the fixed gear sablefish sectors would be restricted to fishing deeper than depths of 125 fathoms in areas north of 40° 10 minutes north latitude, and off the northern Washington coast, the 125 fathom line may close off much of the fishing area currently used by those vessels. Imposing a 125 fathom line could require vessels that home port in the northern Washington ports and Puget Sound ports to travel much further distances to reach fishing grounds. This may result in increased travel cost, or some vessels may choose to change their homeport, thereby affecting processors and support businesses relying on vessels in their current home ports in the northern Washington coast and Puget Sound.

7.2.8.3.5 Impacts to Groundfish Fixed Gear Sectors South of 34° 27 North Latitude

The economic impact to fixed gear fisheries operating south of point Conception are largely influenced by the OYs for bocaccio and cowcod. While the fixed gear sectors south of point Conception encounter bocaccio and cowcod, reductions in the catch of these species necessary to stay within the OY are achieved by management measures in other sectors, and therefore, status quo management for fixed gear vessels in the area south of point Conception is sufficient to stay within the OY of overfished species.

7.2.8.3.6 Impacts to Recreational Sectors

The impact to recreational sectors under action alternative 2 are driven by the OY for yelloweye rockfish and canary rockfish. The yelloweye rockfish OY under this alternative is based on a strategy which "ramps down" catch levels from current amounts in order to give managers and industry time to adapt and develop more refined tools for decreasing the catch of yelloweye while allowing some access to healthier target species. It is anticipated that management measures designed to reduce the bycatch of yelloweye rockfish will also result in reductions of canary rockfish, and therefore, management measures which are motivated by reductions in the yelloweye OY are expected to be sufficient to achieve the necessary reductions in the canary rockfish OY. Management measures used to achieve the reductions in the bycatch of yelloweye rockfish include restricting recreational fisheries to varying depth restrictions, imposing site-specific area closures where industry and available data suggests yelloweye are found, and bag limits for target species which don't allow attainment of target species OYs. The coastwide impact of these management measures results in a 22% decline in recreational bottomfish fishing effort (Table 7-51).

7.2.8.4 Action Alternative 3

Action alternative 3 brings overfished species OYs to levels that are near status quo catch amounts for many overfished species except for yelloweye rockfish. When applying the portion of the OY currently being caught by status quo catch levels to the predicted biomass of overfished species in 2007 and 2008, the OYs for some overfished species under action alternative 3 are even closer to status quo catch levels than action alternative 2. The overall economic impact of action alternative 3 is that many sectors are expected to be managed to levels that are similar to status quo.

7.2.8.4.1 Impacts to the Limited Entry Bottom Trawl Fishery

The impacts to the non-whiting limited entry trawl sector under action alternative 3 are largely driven by the OYs for canary rockfish, bocaccio rockfish, darkblotched rockfish, cowcod, and Pacific ocean perch. Under this alternative, the OY for petrale sole (a target species) is also expected to be attained, the OY for sablefish is expected to be nearly attained (due in large part to a decrease in the OY for sablefish), and the catch of Dover sole is expected to be higher than status quo because of the increasing abundance of this species.

Regulations for the non-whiting limited entry trawl sector under this alternative mostly include an expansion of the trawl rockfish conservation area compared to status quo. While catch levels of overfished species are predicted to be close to status quo in this sector for many overfished species, it is predicted that the bycatch of several overfished species, darkblotched rockfish in particular, will increase over time and that rate of increase is sufficient to warrant increasing restrictions on the fishery to stay within the OY. Exvessel revenues for the bottom trawl sector are predicted to be marginally higher compared to alternative 2, and higher still than status quo, however, the distribution of impacts is likely to be different than status quo. Under this alternative the rockfish conservation area boundaries are set at deeper depths for some periods of the year when compared to status quo, and this has impacts on vessels that are less able to fish at deeper depths because some vessels may be unable to fish in these areas, vessels may need to travel further to fishing grounds, or additional vessels may choose to fish in the nearshore areas, thus impacting small trawl vessels that routinely fish nearer to the shore. Table 7-60 shows projected revenues by two month period.

7.2.8.4.2 Impacts to the Limited Entry Whiting Trawl Fishery

The impacts to the limited entry whiting trawl sector under action alternative 3 are largely driven by the OYs for canary rockfish and widow rockfish, but equally driven by the ability of the whiting sectors to catch an amount of Pacific whiting which corresponds to the available OY of canary and widow rockfish. That is, under this alternative, the catch of whiting is expected to be largely unconstrained by overfished species, assuming there are no "disaster tow events" where a single tow of a trawl net catches a large amount of an overfished species. Assuming the whiting sector is allowed to take the same percentage of the widow, canary, darkblotched, and POP OYs as under the 2005 and 2006 fisheries, it is estimated that the commercial catch amounts and exvessel value of Pacific whiting would be the same as status quo, or approximately $30 million (Table 7-50) Table 7-61 shows projected revenues by two month period.

7.2.8.4.3 Impacts to Nearshore Groundfish Fisheries

Economic impacts to the nearshore groundfish sector are largely driven by canary and yelloweye rockfish. In areas south of 40° 10 minutes N latitude, observer data has not shown an interaction with yelloweye rockfish, so in these areas, canary rockfish is the driving constraint. Management measures in the nearshore fisheries under this alternative are designed to be equivalent to status quo, and therefore, exvessel revenues are expected to be the same as status quo.

7.2.8.4.4 Impacts to Fixed Gear Sablefish Sectors North of 36° North Latitude

Management measures imposed on the fixed gear sablefish sectors that are designed to reduce the catch of overfished species largely center on the impacts to yelloweye and, to a lesser extent, canary rockfish. Management measures designed to reduce the bycatch of these species in the fixed gear sablefish sectors are limited to depth restrictions of varying degrees of restrictiveness depending on the alternative. Changes in the catch of sablefish which are lower than the OY are not considered in the management measures which pertain to reductions in the catch of overfished species because under all alternatives the sablefish OY is reduced compared to 2005 and 2006 levels, and this reduction achieves reductions in the bycatch of overfished species on it's own. The reduction in the sablefish OY occurs as a result of the 2005 sablefish stock assessment, and the council's policies regarding species that fall within the precautionary zone (sablefish is a precautionary zone species).

While exvessel revenues are expected to be the same across all action alternatives ($8.7 million), action alternative 3 has the same rockfish conservation area boundaries for the sablefish sectors as under status quo, and therefore, reductions in exvessel revenue for these sectors are not driven by overfished species concerns, but are instead driven by the reduction in the OY of sablefish.

7.2.8.4.5 Impacts to Groundfish Fixed Gear Sectors South of 34° 27 North Latitude

The economic impact to fixed gear fisheries operating south of point Conception are highly influenced by the OYs for bocaccio and cowcod. While the fixed gear sectors south of point Conception encounter bocaccio and cowcod, reductions in the catch of these species necessary to stay within the OY are achieved by management measures in other sectors, and therefore, status quo management for fixed gear vessels in the area south of point Conception is sufficient to stay within the OY of overfished species.

7.2.8.4.6 Impacts to Recreational Sectors

The impact to recreational sectors under action alternative 3 are driven by the OY for yelloweye rockfish and canary rockfish. The yelloweye rockfish OY under this alternative is based on a strategy which "ramps down" catch levels from current amounts in order to give managers and industry time to adapt and develop more refined tools for decreasing the catch of yelloweye while allowing some access to healthier target species. It is anticipated that management measures designed to reduce the bycatch of yelloweye rockfish will also result in reductions of canary rockfish, and therefore, management measures which are motivated by reductions in the yelloweye OY are expected to be sufficient to achieve the necessary reductions in the canary rockfish OY. Management measures used to achieve the reductions in the bycatch of yelloweye rockfish include restricting recreational fisheries to varying depth restrictions, imposing site-specific area closures where industry and available data suggests yelloweye are found, and bag limits for target species which don't allow attainment of target species OYs. The coastwide impact of these management measures results in a 9% increase in recreational bottomfish fishing effort, though only recreational fisheries off California experience an increase in effort. Washington and Oregon are expected to achieve no change in effort under action alternative 3 when compared to status quo.

7.2.9 Net Economic Impact of Alternatives – Approach B

What follows is a walk through the tables. Table 7-62a shows projected exvessel revenue for different groupings of commercial fisheries under the alternatives, and the change in exvessel revenue relative to No Action. The table shows significant differences between the alternatives. For example, Alternative 3 has the smallest difference from No Action with a 2.7% decline associated with Alternative 3, a 10% percent decline with Alternative 2, a 37 % decline in exvessel revenues should Alternative 1 be implemented for non-tribal groundfish including at-sea vessels.

Table 7-62b shows the equivalent estimates for same groupings in terms of landed weight (thousand mt) rather than revenue while Table 7-62c does the same for comparison but using personal income impacts as the impact variable. It should be noted that "Total West Coast Landings (includes at-sea and tribal) is an estimate for all West Coast fisheries including groundfish..

Here is a list of all the commercial related tables:

7-62a Ex-vessel revenue projections by major sector
7-62b Commercial harvest projection by major sector
7-62c Commercial Income Impacts by major sector
7-63a Ex-vessel revenue projections by State, port area and major sector
7-63b Change in ex-vessel revenue projections by State, port area, and major sector
7-64a Estimated income impact projections by State, port area, and major sector
7-64b Change in estimated income impact projections by State, port area, and major sector

Recreational Fisheries Impacts

In a similar manner to those developed for the commercial fishery, the following tables have developed. Shortened titles for these tables are:

7-65a Projected recreational effort by region in 2004 and 2005 and by alternative
7-65b Change in projected effort across alternatives
7-66a Projected angler expenditures by region in 2004 and 2005 and by alternatives.
7-66b Change in projected angler expenditures across alternatives
7-67a Projected recreational income impacts by region in 2004 and 2005, and by alternatives
7-67b Change in recreational income impacts by region by alternative
7-68a Projected recreation employment impacts by region by alternative
7-68b Change in recreation employment impacts by region by area
7-68c Projected recreational Employment impacts by trip target, region, mode, state and alternative
7-68d Projected West Coast Recreational Income by state, boat type and alternative
7-68e Summary of total three State Recreational Impacts (trips, expenditures, income) by boat type and trip target.

Commercial and Recreational Fisheries Impacts Combined

7-68f Combined recreational and income impacts by region and alternative
7-68g Change in combined recreational and commercial impacts by region and alternative

7-68h Combined recreational and commercial employment impacts by region and alternative
7.59i Change in combined recreational and commercial employment impacts by region and alternative

Commercial Impact Comparison

Under the no action alternative, total West Coast landings from all fisheries including groundfish would yield 510,000 mt of fish and shellfish landed or delivered at sea, generating about $280 million in ex-vessel revenues which in turn would lead to $625 million in income impacts and at an income level of $26,000 per year would yield 24,000 jobs. The 2005 estimates are quite similar to the No-Action Alternative. However, Alternative 1 would lead to a level $567 million in personal income, roughly a 10% decrease in income impacts whereas Alternatives 3 would have less than 1% decline in income and Alternative 3, a 4% decline. For non-tribal income impacts, the No-Action and 2005 levels of personal income are about $140 million. Implementation of Alternative 1 would lead to a decline of $56 million in groundfish fishery generated income, for a 40% decline in the groundfish fishery. Alternative 2 would lead to a 15% decline in Non-tribal income impacts including at-sea fisheries and Alternative 1, 2 percent decline.

Recreational Impact Comparison

It is estimated that under the no Action Alternative, 1.2 million angler trips would be taken and the estimated $113 million that these anglers would spend on fishing would generate, $89 million in personal income or the equivalent of 3,422 jobs. These estimates are similar to the ones generated for 2005 but differ significantly with Alternative 1. Under Alternative 1, one million trips would be undertaken leading to $92 million in expenditures, 73 million in income and 2,802 jobs. A difference of $16 million or 18 percent decline. These estimates are for all fisheries including groundfish.. With respect to groundfish targeted trips, the No action alternative leads to $40 million in personal income impacts compared to a 2005 level of $35 million. If Alternative 1 were implemented, the recreational groundfish fishery would generate $25 million, approximately a 30 percent decline. Alternative 3 would generate $45 million in personal income impacts and Alternative 2, $30 million in impacts.

7.2.10 Other Management Measure Analyses

7.2.10.1 Economic Impacts of Management Measures Designed to Reduce the Mortality of Yelloweye Rockfish

The 2002 yelloweye stock assessment was more optimistic than the 2006 stock assessment. The 2006 stock assessment estimated biomass – or status of the stock – to be at a 17.7% depletion level (percent of unfished biomass), and the 2002 assessment estimated the depletion level to be 24%. This does not mean that the population has been declining, only that the re-estimated stock size is smaller than previously thought. While the difference in the depletion level between the two assessments was a difference of approximately 6.3%, one of the more major changes to the stock assessment pertains to the assumed life history characteristics of yelloweye. The characteristics used in the 2002 rebuilding analysis resulted in estimates that showed the species to be more productive than the 2006 assessment. The result of findings and assumptions used in the 2006 assessment means that the estimates from the

2002 assessment allowed for shorter rebuilding times and/or larger harvests when compared to the 2006 assessment. For example, the 2006 OY for yelloweye was set at 27 metric tons, and the results of the 2002 rebuilding analysis estimated that the stock would be rebuilt by 2023 under the SPR harvest rate that corresponds to a 27 metric ton OY in 2006. Estimates from the 2006 assessment, show that a 2007 OY of 12 metric tons would rebuild the stock in 2078. That is, if the council and NMFS adopted a 66% reduction in the yelloweye OY compared to status quo, the rebuilding period would still be 55 years longer than the previous T_{TARGET}, and 30 years longer than $T_{F=0}$.

This dramatic change in the assessment results will have dramatic implications to management measures designed to protect yelloweye rockfish. Management measures ultimately adopted will likely need to result in a smaller harvest of yelloweye than previous measures, and such management measures will also have negative economic consequences to fishing communities. Under status quo management, the sectors that take the largest amount of yelloweye rockfish are the recreational groundfish and halibut sectors, followed by directed open access groundfish, and limited entry fixed gear and tribal sectors. In order to achieve reductions in the bycatch of overfished groundfish, the council has, in the past, restricted to the greatest extent those sectors that have the largest impact on that particular species. However, in many instances the tribal fisheries are left unaffected. Based on past approaches to management, the largest source of reduction in yelloweye rockfish bycatch is likely to come from the recreational and directed open access sectors. At the end of 2005, the recreational sectors were estimated to take 13.1 metric tons of yelloweye, and all other sectors (including tribal and non-groundfish fisheries) were estimated to take 8.9 metric tons.

Several alternatives were analyzed pertaining to yelloweye rockfish OYs. These OYs include zero harvest, a 2007 OY of 12 mt, 12.6 mt, 17 mt, 21 mt, 24 mt, 27 mt, and a ramp-down strategy which has a 2007 OY of 23 mt, 20 mt in 2008, 17 mt in 2009, and 14 mt in 2010 respectively. Implicit in the ramp down strategy is the development of additional management tools in order to allow some harvest of more abundant target species while reducing the catch of yelloweye over time. It is likely that new management tools would not be able to be developed without a ramp-down strategy because the development of additional tools inherently relies on some additional bycatch in order to test the effectiveness of those tools.

7.2.10.1.1 Economic Impact of a $T_{F=0}$ Yelloweye OY

Under the zero harvest alternative ($T_{F=0}$), the cost to the fishing industry is expected to be substantial. The $T_{F=0}$ harvest alternative is estimated to result in a loss of over $100 million in exvessel revenues and approximately 1,150,000 recreational angler trips. These figures represent a complete closure of multiple sectors including, but not limited to, all bottom-tending commercial fishing gears (outside of selective gears like dive gear) for groundfish species, shrimp species, and other bottom dwelling species like Pacific halibut, California halibut, and sea urchins; the complete closure of Chinook salmon troll fisheries; the complete closure of tribal groundfish fisheries; and the complete closure of recreational fisheries for groundfish, Pacific halibut, and Chinook salmon. This alternative is expected to have substantial negative economic consequences to communities, and these closures would be in place until 2048 – the year yelloweye is estimated to be rebuilt.

7.2.10.1.2 Economic Impact of a 12 metric ton Yelloweye OY in 2007

Under the alternative which puts in place a 12 metric ton yelloweye OY in 2007, multiple sectors and communities are estimated to be negatively impacted to a large degree. Analysis of commercial management measures designed to achieve a suite of OYs for all overfished species which included the

12 mt yelloweye OY showed that exvessel revenues would be reduced by nearly 40%. However, this is likely an overestimate of what would occur if only yelloweye were to be reduced to 12 mt and other overfished species were to remain at status quo levels. In terms of recreational fisheries however, it is estimated that recreational fishing effort for groundfish and Pacific halibut off Washington would decrease by 30% under the 12 metric ton yelloweye alternative. Off Oregon, it is estimated that recreational fishing effort for groundfish and Pacific halibut would decrease by 32%, and recreational fishing effort for groundfish off California would decrease by over 33%. In addition, fishing seasons would be shortened which would have additional implications as fewer tourists would be drawn to communities during times when fishing closures are in place. This means that economic impacts will be larger than indicated by just examining changes in angler trips.

Under the 12 mt 2007 OY alternative, it is believed that commercial fixed gear vessels that homeport along the northern Washington coast and Puget Sound would experience a complete closure of traditional fishing grounds for sablefish. Some of these vessels may choose to move further south along the coast and homeport in different locations in order to access other fishing grounds, however, this would have repercussions to those communities where fixed gear vessels currently homeport, and many of these communities are described as being resource-dependent. This means those communities would be negatively impacted to a larger degree than communities that are not as dependent on resource-based industries. It is estimated that these impacts would be in place until 2078, or 30 years longer than T_{MIN}. It is important to note that state managers of recreational fisheries have stated that multiple recreational fisheries cannot operate if the 2007 OY for yelloweye is less than 12 mt. In order to achieve the necessary reductions in yelloweye mortality, managers would need to completely close multiple sectors of recreational fisheries off Washington, Oregon, and northern California, meaning that for many recreational sectors, the economic impact of T_{MIN} is equivalent to an OY that is several tons higher.

Under a 12.6 metric ton yelloweye OY in 2007 the impacts to commercial fisheries, recreational fisheries, and fishing communities is expected to be nearly equivalent to a 12 metric ton OY.

7.2.10.1.3 Economic Impact of the Ramp-Down Strategy

The yelloweye ramp-down OY results in economic impacts to recreational fisheries that range from near status quo, to reductions in angler effort of approximately 22% in 2007 compared to 2005 levels. Commercial exvessel revenues for alternatives corresponding to the yelloweye ramp-down strategy show that revenues would range from near status quo, to reductions of 13% in 2007 compared to 2005 levels. Beyond 2007, the impacts are less clear as the impact of tools that will be developed will not be fully known until after they have been implemented. However, it is expected that the economic implications will be less than the 12 mt and 12.6 mt 2007 OY alternatives. It is estimated that these impacts would be in place until 2083.5, or 35.5 years longer than $T_{F=0}$.

7.2.10.1.4 Consideration of Other Yelloweye OY Alternatives

Optimum yields that are equivalent to an SPR harvest rate of 17 metric tons or greater in 2007 exceed Tmax according to the 2006 rebuilding analysis, and therefore are not further considered. However, negative economic consequences for these alternatives are far less than SPR harvest rates that correspond to a 12 mt or 12.6 mt OY in 2007.

7.2.10.2 Economic Impacts of Zero Harvest Alternatives for Rebuilding Species

The analysis of zero harvest alternatives examined the economic impacts of setting similar overfished species OYs to zero, where similarity was determined based on the correlation of species across latitude and depths. Species that were considered similar under this definition include canary and yelloweye rockfish; bocaccio and cowcod; and Pacific ocean perch and darkblotched rockfish. Widow rockfish was analyzed independently since it tends to be caught in a more pelagic environment compared to other overfished species.

Sectors were analyzed in this case based on the known associations of those sectors with overfished species under currently in place (2006) management measures. These include existing allocations between sectors and regions, area closures that are currently in place, and current patterns of fishery effort. The analysis shows two columns indicating sectors, where one column is titled "major sector" and another column "sub-sector or area-based stratification". If a sector is not known to catch a particular overfished species at certain latitudes, then the portion or area of the sector that would need to be closed to keep the particular species catch at a zero harvest is listed specifically. For example, in order to reduce yelloweye and canary rockfish catch to zero, the fixed gear sablefish sector would need to be severely restricted, however west coast groundfish observer data shows this sector encounters those species north of Point Conception, so the affected sector is identified as "fixed gear sablefish north of Point Conception". The notion that an entire sector would need to be closed to protect an overfished species is based in the multi-species nature of the fishery. In many cases it is not possible to catch abundant stocks of target species without incidentally catching overfished species, and therefore, eliminating the catch of overfished species also requires eliminating the catch of target species that co-occur with those overfished species. In this analysis, figures represent the loss in revenue that occurs as a result of zero landings from overfished species as well as zero landings from target species that co-occur with those overfished species.

In this analysis, 2005 revenues are used as an indicator of revenue that would be lost if a sector were to be closed or restricted to reach a zero harvest of a particular overfished species. Table7-69 shows the amount of exvessel revenue that would be lost for each sector within each overfished species grouping, and the total revenue from 2005 for that entire sector is shown for comparison purposes to understand the magnitude of loss.

Based on this analysis, setting the OY of canary and yelloweye to zero would have the largest impact across recreational and commercial fisheries when compared to the other species groupings. The distribution of these impacts would be felt coastwide and across all sectors of the fishery. The second largest impact to commercial and recreational fisheries would be to set the widow OY to zero. This species would impact most sectors across the coast, but some fisheries off the Washington coast, non-groundfish trawl fisheries, and coastal pelagic species south of 40° 10 minutes North latitude would be unaffected. The species grouping with the third largest impact to commercial fisheries on an exvessel revenue basis is darkblotched and POP, whereas the species grouping with the third largest impact to recreational fisheries would be bocaccio and cowcod. Each of these groupings have very different regional and distributional impacts. Darkblotched and POP would impact most commercial sectors that are oriented toward the north, whereas bocaccio and cowcod would impact most commercial and recreational sectors that operate south of 40° 10 minutes North latitude. Finally, if the OY for all overfished species were to be set to zero, all sectors listed in the analysis would be impacted, and the total economic impact would be greater than any of the individual species groupings.

7.2.11 Other Analyses

Vulnerable Commercial Communities

Table 7-70 shows the percentage change in estimated commercial fishery income impacts by port group compared to the No Action Alternative for shoreside landings.

Under Alternative 1, the port groups with the greatest percentage decrease in estimated income from all Council managed commercial fisheries compared to the No Action alternative are Eureka (21.6%), Newport (20.2%) and Fort Bragg (20.0%). All three port groups consist of counties that were identified as three of the six "most vulnerable" counties (Lincoln, Humboldt, and Mendocino counties) in the Engagement, Dependence, Resiliency and Identification of Vulnerable Areas Analysis (Identification of Vulnerable Areas Analysis). These "most vulnerable" areas were identified for the purpose of ranking those counties and ports most reliant upon the commercial and recreational fishery resource but least able to adjust to additional decreases in harvest levels. The analysis identified six commercially "most vulnerable" counties and four "most vulnerable" cities based on commercial fishing data and one recreationally "most vulnerable" city based on recreational data. The analysis also identified several other vulnerable counties and cities that are considered potentially at risk but to a lesser degree than the "most vulnerable" areas.

Morro Bay (13%), Puget Sound (13%) and South and Central Washington Coast (10%) also have large decreases estimated under Alternative 1. The South and Central Washington Coast port group is comprised of three counties, two of which were identified as two of the six most vulnerable counties (Grays Harbor and Pacific counties). The port group also contains one of four cities identified as most vulnerable areas in the Identification of Vulnerable Areas Analysis (Ilwaco). Morro Bay and Puget Sound port groups also encompass some vulnerable areas, but to a lesser degree than the other port groups named above.

The greatest percentage decrease in estimated income from commercial groundfish fisheries compared to the No Action Alternative are Newport (43.5%), Astoria-Tillamook (41%), South and Central Washington Coast (39.9%), Coos Bay (35.9%), Eureka (35.5%), and Fort Bragg (33.3%). As mentioned above, Newport, South and Central Washington Coast, Eureka, and Fort Bragg port groups consist of five of the six counties identified as most vulnerable counties in the Identification of Vulnerable Areas Analysis (Lincoln, Grays Harbor, Pacific, Humboldt, and Mendocino counties). The Coos Bay port group also consists of one of the six counties identified as most vulnerable counties (Coos County). Astoria-Tillamook and Coos Bay encompass counties identified as vulnerable areas to a lesser degree than the ones mentioned above. However, the Astoria-Tillamook contains one of the four ports identified as most vulnerable ports (Garibaldi).

Under Alternative 2, the port groups with the greatest percentage decrease in estimated income from all Council managed commercial fisheries and groundfish fisheries compared to the No Action alternative are Newport (9.7% and 20.8% respectively) and South and Central Washington Coast (6% and 23.6% respectively). As mentioned above, these port groups consist of counties identified as most vulnerable areas.

Under Alternative 3, the port groups with the greatest percentage decrease in estimated income from all Council managed commercial fisheries and groundfish fisheries compared to the No Action alternative are North Washington Coast (4.2%) and Puget Sound (2.6%). Unidentified areas in Washington and North Washington Coast port groups are estimated to experience the largest decreases (14.3% and 9% respectively) in income. North Washington Coast contains one of the four most vulnerable ports (Neah Bay). Neah Bay and La Push are both located in the North Washington Coast port group and both are ranked as least resilient according to the Identification of Vulnerable Areas Analysis. That is, both are ranked in the top one-third of all cities on the West Coast with regard to low resiliency indicators (population levels, percentage of population living below the poverty level, unemployment rate, and industry diversification). Both were identified in a 2004 study by PSMFC as "isolated cities" or cities not located on a major highway and fell outside of a 35-mile buffer of cities over 20,000.

Vulnerable Recreational Communities

Table 7-71 shows the percentage change in estimated recreational income impacts compared to the No Action Alternative.

Under Alternative 1, the regions with the greatest percentage decrease in estimated income from total charter boat trips compared to the No Action alternative are CA South-Central Coast (53.7%), North Central Coast: San Mateo up through Marin County (47.4%), and North-Central Coast: Sonoma and Mendocino counties (47.1%). Brookings (36.1%), North Washington Coast (32.7%), and Newport (30.6%) are also expected to experience relatively large decreases. The South–Central Coast ties with the South Coast: San Diego through LA region as the most highly recreationally engaged area in California according to the Identification of Vulnerable Areas Analysis. The South–Central Coast region encompasses Moss Landing and Santa Cruz, two cities with low resiliency according to the Identification of Vulnerable Areas Analysis and two counties (Monterey and San Luis Obispo) with low resiliency. North-Central Coast: San Mateo up through Marin County contains one city with low resiliency (Oakland). The North-Central Coast: Sonoma and Mendocino region encompasses two cities (Fort Bragg and Bodega Bay) and one county (Mendocino) with low resiliency. The Brookings region contains one recreational vulnerable area (Gold Beach). North Washington Coast contains two recreational vulnerable areas (Neah Bay and La Push) and Newport contains two recreational vulnerable areas (Depoe Bay and Newport). With regard to private boat trips, North Washington Coast (27.3%), Brookings (22.1%), and South Coast: Ventura and Santa Barbara counties (20.4%) are estimated to experience the largest decreases in income. The North Washington Coast contains two recreational vulnerable cities (Neah Bay and La Push), and Brookings contains one recreational vulnerable city (Gold Beach).

The regions predicted to experience the greatest percentage decrease in estimated income under Alternative 1 from recreational groundfish charter boat fisheries compared to the No Action Alternative are the two North Central CA Coast regions (57.6% for San Mateo up through Marin County and 57.1% for Sonoma and Mendocino Counties), South Central Coast (55%) and North Washington Coast (50%). All Oregon regions are estimated to experience decreases above 39% and South CA Coast ports are estimated to experience decreases of about 35%. With regard to private trips, the South Coast regions (57.9% for Ventura and Santa Barbara counties and 57.5% for San Diego through Los Angeles County) are predicted to experience the greatest percentage decrease in income. All Oregon regions are estimated to experience decreases of above 37%.

Under Alternative 2, with regard to total charter boat trips, the regions with the greatest percentage decrease in estimated income compared to the No Action Alternative are South-Central Coast: San Luis Obispo County through Santa Cruz (52.5%), North-Central Coast: San Mateo up through Marin County (44.2%), North-Central Coast: Sonoma and Mendocino counties (43.5%), and North Washington Coast (27.9%). As mentioned previously, the South-Central Coast: San Luis Obispo County through Santa Cruz contains two counties and two cities with low resiliency. North-Central Coast: San Mateo up through Marin County contains one city with low resiliency. North-Central Coast: Sonoma and Mendocino counties contain two cities and one county with low resiliency. The North Washington Coast region contains two recreational vulnerable cities. With regard to total private trips, North Washington Coast (22%) and South Coast: Ventura and Santa Barbara counties (13%) are estimated to experience the largest decreases in income from recreational fishing.

The regions predicted to experience the greatest percentage decrease in estimated income under Alternative 2 from recreational groundfish charter boat fisheries compared to the No Action Alternative are the CA North Central regions (54.3% for Sonoma and Mendocino counties and 53.8% for San

Mateo up through Marin County), the CA South Central region (53.7%), and the North Washington Coast (41.7%). With regard to private recreational groundfish trips, the South Coast regions (34.9% for San Diego County through Los Angeles County and 34.2% for Ventura and Santa Barbara counties) and North Washington Coast (31.7%) are estimated to experience the largest decreases in income from recreational fishing.

Under Alternative 3, the regions with the greatest percentage decrease in estimated income from total recreational charter boat trips compared to the No Action Alternative are South-Central Coast (21%) and North Washington Coast (7.7%). With regard to private groundfish trips, South-Central Coast (22.1%) and South Coast: Ventura and Santa Barbara counties (10.2%) are estimated to experience the largest decreases in income from recreational fishing.

The regions predicted to experience the greatest percentage decrease in estimated income under Alternative 3 from recreational groundfish charter boat trips compared to the No Action Alternative are CA South-Central Coast (21.4%) and North Washington Coast (16.7%). With regard to private trips for groundfish, the South CA Coast (30.2% for San Diego County through LA County, and 28.9% for Ventura and Santa Barbara counties), South Central CA Coast (25.2%), and North Washington coast (24.4%) are estimated to experience the largest decreases in income from recreational fishing.

Cumulative Effects

The Council on Environmental Quality's regulations implementing the procedural provisions of the National Environmental Policy Act defines cumulative effects as

> The impact on the environment which results from the incremental impact of the action when added to other past, present, and reasonably foreseeable future actions regardless of what agency (Federal or non-Federal) or person undertakes such other actions.

Past actions affecting the socioeconomic environment have included catch restrictions and declining revenue for vessels participating in groundfish fisheries, increasing regulatory complexity, the requirement to carry vessel monitoring systems, the imposition of area closures to protect essential fish habitat, restrictions on fishing gear to protect essential fish habitat, a trawl vessel buyback, growth and change in the demographic and economic nature of coastal communities, and consolidation in the shore-based processing sector amongst others. Reasonably foreseeable future effects include continued restrictions on catch levels to protect overfished species, continued development of tools that reduce the bycatch of overfished species, and continued growth and change in the population of coastal communities. These concepts will be discussed in relation to the alternatives considered and adopted by the council in more detail following the June meeting of the Pacific Fishery Management Council.

JUNE 2006

This document is published by the Pacific Fishery Management Council pursuant to National Oceanic and Atmospheric Administration Award Number FNA03NMF4410067 and FNA17FC1641.

Changes to the FMP Since the Version Published in July 1993

The last generally available version of the Groundfish FMP was produced in July 1993 and incorporated changes made through Amendment 7. In addition to adding material required by the 1996 Sustainable Fisheries Act, Amendment 11 included a general editorial clean-up of Chapters 1–6. However, a revised version of the full document was never produced. Major changes to the content and organization of the FMP, since Amendment 7 and aside from the overall revisions of Chapters 1–6 made by Amendment 11, are summarized here to help clarify references to parts of the FMP in other Council documents.

Chapters in July 1993 FMP	Changes Made Through the Current Version of the FMP
Chapter 1 Introduction	No changes since Amendment 11
Chapter 2 Goals and Objectives	Amendments and additions, no substantial change in organization. (Amendments 12, 13, 16-1, and 17.)
Chapter 3 Areas and Stocks Involved	Amendments and additions, no substantial change in organization. (Amendment 16-1.)
Chapter 4 Optimum Yield	Substantially changed and expanded by Amendment 16-1, which moved and revised material on determining ABC, OY, precautionary thresholds, and rebuilding overfished species that was in Chapter 5 into this chapter. Amendments 16-2 and 16-3 add rebuilding plan summaries to section 4.5.4
Chapter 5 Specification and Apportionment of Harvest Levels	Substantially changed by Amendment 16-1, which moved material to Chapter 4, as noted above. Discussion of DAH, DAP, JVP, and TALFF deleted. (Also Amendments 12, 13, and 17.)
Chapter 6 Management Measures	Amendments and additions, no substantial change in organization. (Amendments 10, 11, 13, 16-1, 17.)
Chapter 7 Experimental Fisheries	No Changes
Chapter 8 Scientific Research	No Changes
Chapter 9 Restrictions on Other Fisheries	No Changes
Chapter 10 Procedures for Reviewing State Regulations	No Changes
Chapter 11 Appendices	This material is now produced under separate cover. An unnumbered section at the end of the FMP, “Appendices Contents,” summarizes the topic areas in the Appendices. It is intended that the unnumbered sections (also References, see below) will always appear at the end of the document. (Amendment 11 added material on essential fish habitat.)
Chapter 12 Management Measures that Continue	This chapter is renumbered Chapter 11. No other

in Effect With Implementation of Amendment 4	changes have been made.
Chapter 13 References	This chapter has been moved to an unnumbered section at the end of the document. (Amendment 16-1.)
Chapter 14 Groundfish Limited Entry	This chapter is renumbered Chapter 12. (Amendments 13 and 14.)

TABLE OF CONTENTS

LIST OF FIGURES

LIST OF TABLES

LIST OF ACRONYMS AND ABBREVIATIONS

ABC	acceptable biological catch
DAH	domestic annual harvest
DAP	domestic annual processing
EEZ	exclusive economic zone
EFH	essential fish habitat
EFP	experimental fishing permit
ESA	Endangered Species Act
MARPOL	International Convention for the Prevention of Pollution from Ships
Magnuson-Stevens Act	Magnuson-Stevens Fishery Conservation and Management Act
FMP	fishery management plan
GAP	Groundfish Advisory Subpanel
GMT	Groundfish Management Team
HG	harvest guideline
IFQ	individual fishing quota
INPFC	International North Pacific Fisheries Commission
JV	joint-venture
JVP	joint-venture processing
LE	limited entry
MLR	minimum landing requirement
mt	metric ton
MSY	maximum sustainable yield
NMFS	National Marine Fisheries Service
OY	optimum yield
POP	Pacific ocean perch
PRA	Paperwork Reduction Act
PSMFC	Pacific States Marine Fisheries Commission
Regional Director	Regional Director, National Marine Fisheries Service
SAFE	Stock Assessment and Fishery Evaluation
Secretary	U.S. Secretary of Commerce
SPR	spawning biomass per recruit
SSC	Scientific and Statistical Committee
TALFF	total allowable level of foreign fishing

<u>A note on annotations</u>: Amended parts of the FMP are denoted at the end of chapters or second-level

sections by amendment number. If applicable, changes to lower-level subsections are also noted at the end of second-level sections. Amendments subsequent to Amendment 4, which substantially revised the original FMP are so noted.

1.0 INTRODUCTION

1.1 Evolution of the Management Plan

The Pacific Coast Groundfish Fishery Management Plan (FMP) was approved by the U.S. Secretary of Commerce (Secretary) on January 4, 1982, and implemented on October 5, 1982. Prior to implementation of the FMP, management of domestic groundfish fisheries was under the jurisdiction of the states of Washington, Oregon, and California. State regulations have been in effect on the domestic fishery for more than 100 years with each state acting independently in both management and enforcement. Furthermore, many fisheries overlapped state boundaries and participants often operated in more than one state. Management and a lack of uniformity of regulations had become a difficult problem, which stimulated the formation of the Pacific States Marine Fisheries Commission (PSMFC) in 1947. PSMFC had no regulatory power but acted as a coordinating entity with authority to submit specific recommendations to states for their adoption. The 1977 Fishery Conservation and Management Act (later amended and renamed the Magnuson-Stevens Fishery Conservation and Management Act (or Magnuson-Stevens Act,) established eight regional fishery management Councils, including the Pacific Council. Between 1977 and the implementation of the groundfish FMP in 1982, state agencies worked with the Council to address conservation issues. Specifically, in 1981, managers proposed a rebuilding program for Pacific ocean perch. To implement this program, the states of Oregon and Washington established landing limits for Pacific ocean perch in the Vancouver and Columbia management areas.

Management of foreign fishing operations began in February 1967 when the U.S. and U.S.S.R. signed the first bilateral fishery agreement affecting trawl fisheries off Washington, Oregon, and California. The U.S. later signed bilateral agreements with Japan and Poland for fishing off the U.S. West Coast. Each of these agreements was renegotiated to reduce the impact of foreign fishing on important West Coast stocks, primarily rockfish, Pacific whiting, and sablefish. When the U.S. extended its jurisdiction to 200 miles (upon signing the Fishery Conservation and Management Act of 1976), the National Marine Fisheries Service (NMFS) developed and the Secretary implemented the preliminary management plan for the foreign trawl fishery off the Pacific Coast. From 1977 to 1982, the foreign fishery was managed under that plan. Many of these regulations were incorporated into the FMP, which provided for continued management of the foreign fishery.

Joint-venture fishing, where domestic vessels caught the fish to be processed aboard foreign vessels, began in 1979 and by 1989 had entirely supplanted directed foreign fishing. These joint ventures primarily targeted Pacific whiting. Joint-venture fisheries were then rapidly replaced by wholly domestic processing; by 1991 foreign participation had ended and U.S.-flagged motherships, catcher-processors, and shore-based vessels had taken over the Pacific whiting fishery. Since then U.S. fishing vessels and seafood processors have fully utilized Pacific Coast fishery resources. Although the Council may entertain applications for foreign or joint venture fishing or processing at any time, provisions for these activities have been removed from the FMP. Re-establishing such opportunities would require another FMP amendment.

Since it was first implemented in 1982, the Council has amended the groundfish FMP 20 times in response to changes in the fishery, reauthorizations of the Magnuson-Stevens Act, and litigation that invalidated provisions incorporated by earlier amendments. During the first ten years of plan implementation, up to 1992, the Secretary approved six amendments. Amendment 4, approved in 1990, was the most significant early amendment; in addition to a comprehensive update and reorganization of the FMP, it established additional framework procedures for establishing and modifying management measures. Another important change was implemented in 1992 with Amendment 6, which established a license limitation (limited entry) program intended to address overcapitalization by restricting further participation in groundfish trawl, longline, and trap fisheries.

The next decade, through 2002, saw the approval of another seven amendments. Amendment 9 modified the limited entry program by establishing a sablefish endorsement for longline and pot permits. Amendments 11, 12, 13 were responses to changes in the Magnuson-Stevens Act due to the 1996 Sustainable Fisheries Act. These changes required FMPs to identify essential fish habitat (EFH), more actively reduce bycatch and bycatch mortality, and strengthen conservation measures to both prevent fish stocks from becoming overfished~~,~~ and promote rebuilding of any stocks that had become overfished. Amendment 14, implemented in 2001, built on Amendment 9 to further refine the limited entry permit system for the economically important fixed gear sablefish fishery. It allowed a vessel owner to "stack" up to three limited entry permits on one vessel along with associated sablefish catch limits. This in effect established a limited tradable quota system for participants in the primary sablefish fishery.

Most of the amendments adopted since 2001 deal with legal challenges to the three SFA-related amendments mentioned above, which were remanded in part by the Federal Court. These have required new amendments dealing with overfishing, bycatch monitoring and mitigation, and essential fish habitat. In relation to the first of these three issues, the Magnuson-Stevens Act now requires FMPs to identify thresholds for both the fishing mortality rate constituting overfishing and the stock size below which a stock is considered overfished. Once the Secretary determines a stock is overfished, the Council must develop and implement a plan to rebuild it to a healthy level. Since these thresholds were established for Pacific Coast groundfish, nine stocks have been declared overfished. The Court found that the rebuilding plan framework adopted by Amendment 12 did not comply with the Magnuson-Stevens Act. In response, Amendments 16-1, 16-2, and 16-3 established the current regime for managing these overfished species.[1] Amendment 16-1, approved in 2003, incorporated guidelines for developing and adopting rebuilding plans and substantially revised Chapters 4 and 5. Amendments 16-2 and 16-3, approved in 2004, incorporated key elements of rebuilding plans into Section 4.5.4. In 2005, a Court of Appeals ruling refined court interpretation of the Magnuson-Stevens Act rebuilding period requirements. Amendment 16-4, approved in [2006], revised the FMP to specify that rebuilding periods will be as short as possible, taking into account the status and biology of the stocks, the needs of fishing communities, and interactions of overfished stocks with the marine

[1] Although the Secretary declared Pacific whiting overfished in 2002, a 2004 stock assessment found that it had recovered to its rebuilt level. Thus, a rebuilding plan for this species was not adopted by these amendments.

ecosystem. As a result of this ruling, Amendment 16-4 also revised the rebuilding periods for [list stocks].

Amendment 17 modified the periodic process the Council uses to establish and modify harvest specifications and management measures for the groundfish fishery. Although not an SFA-related issue, this change did solve a procedural problem raised in litigation. The Council now establishes specifications and management measures every two years, allowing more time for them to be developed during the Council's public meetings.

Amendment 18, approved in 2006, addresses a remand of elements in Amendment 11 related to bycatch monitoring and mitigation. It incorporates a description of the Council's bycatch-related policies and programs into Chapter 6. It also effected a substantial reorganization and update of the FMP, so that it better reflects the Council's and the NMFS's evolving framework approach to management. Under this framework, the Council may recommend a range of broadly defined management measures for NMFS to implement. In addition to the range of measures, this FMP specifies the procedures the Council and NMFS must follow to establish and modify these measures. When first implemented, the FMP specified a relatively narrow range of measures, which were difficult to modify in response to changes in the fishery. The current framework allows the Council to effectively respond when faced with the dynamic challenges posed by the current groundfish fishery.

Amendment 19, also approved in 2006, revises the definition of groundfish EFH, identified habitat areas of particular concern, and describes management measures intended to mitigate the adverse effects of fishing on EFH. This amendment supplants the definition of EFH added to the FMP by Amendment 11.

1.2 How This Document is Organized

The groundfish FMP is organized into 11 chapters

Chapter 1 (this chapter) describes the development of the FMP and how it is organized.

Chapter 2 describes the goals and objectives of the plan and defines key terms and concepts.

Chapter 3 specifies the geographic area covered by this plan and lists the species managed by it, referred to as the fishery management unit, or FMU.

Chapter 4 describes how the Council determines harvest levels. These harvest limits are related to the maximum sustainable yield (MSY) and allowable biological catch (ABC) for FMU species. Precautionary reductions from these thresholds may be applied, depending on the management status of a given stock. If, according to these thresholds, a stock is determined to be overfished, the Council must recommend measures to end overfishing and develop a rebuilding plan, as specified in this chapter. Based on the thresholds, criteria and procedures described in this chapter, the Council specifies an optimum yield (OY), or harvest limit, for managed stocks or stock complexes.

Chapter 5 describes how the Council periodically specifies harvest levels and the management measures needed to prevent catches from exceeding those levels. Currently, the Council develops these specifications over the course of three meetings preceding the start of a two-year management period. (Separate OYs are specified for each of the two years in this period.) This chapter also describes how the stock assessment/fishery evaluation (SAFE) document, which provides information important to management, is developed.

Chapter 6 describes the management measures used by the Council to meet the objectives of the Magnuson-Stevens Act and this FMP. As noted above, this FMP is a framework plan; therefore, the range of management measures is described in general terms while the processes necessary to establish or modify different types of management measures are detailed. Included in the description of management measures is the Council's program for monitoring total catch (which includes bycatch) and minimizing bycatch.

Chapter 7 identifies EFH for groundfish FMU species and the types of measures that may be used to mitigate adverse impacts to essential fish habitat from fishing.

Chapter 8 describes procedures followed by the Council to evaluate and recommend issuing exempted fishing permits (EFPs). Permitted vessels are authorized, for limited experimental purposes, to harvest groundfish by means or in amounts that would otherwise be prohibited by this FMP and its implementing regulations. These permits allow experimentation in support of FMP goals and objectives. EFPs have been used, for example, to test gear types that result in less bycatch.

Chapter 9 provides criteria for determining what activities involving groundfish would qualify as scientific research and could therefore qualify for special treatment under the management program.

Chapter 10 describes the procedures used to review state regulations in order to ensure that they are consistent with this FMP and its implementing regulations.

Chapter 11 describes the groundfish limited entry program.

Appendix A contains descriptions of the biological, economic, social, and regulatory characteristics of the groundfish fishery.

Appendix B contains detailed information on groundfish EFH.

Appendix C describes the effects of fishing on groundfish EFH.

Appendix D describes the effects of activities other than fishing on groundfish EFH.

The appendices contain supporting information for the management program. Because these appendices do not describe the management framework or Council groundfish management policies and procedures, and only supplement the required and discretionary provisions of the FMP described in §303 of the Magnuson-Stevens Act, they may be periodically updated without being subjected to the Secretarial review and approval process described in §304(a) of the Magnuson-Stevens Act. These appendices are published under separate cover.

[Amended: 11, 16-4, 18,19]

2.0 GOALS AND OBJECTIVES

2.1 Goals and Objectives for Managing the Pacific Coast Groundfish Fishery

The Council is committed to developing long-range plans for managing the Washington, Oregon, and California groundfish fisheries that will promote a stable planning environment for the seafood industry, including marine recreation interests, and will maintain the health of the resource and environment. In developing allocation and harvesting systems, the Council will give consideration to maximizing economic benefits to the United States, consistent with resource stewardship responsibilities for the continuing welfare of the living marine resources. Thus, management must be flexible enough to meet changing social and economic needs of the fishery as well as to address fluctuations in the marine resources supporting the fishery. The following goals have been established in order of priority for managing the West Coast groundfish fisheries, to be considered in conjunction with the national standards of the Magnuson-Stevens Fishery Conservation and Management Act (Magnuson-Stevens Act).

Management Goals.

> Goal 1 - Conservation. Prevent overfishing and rebuild overfished stocks by managing for appropriate harvest levels and prevent, to the extent practicable, any net loss of the habitat of living marine resources.
>
> Goal 2 - Economics. Maximize the value of the groundfish resource as a whole
>
> Goal 3 - Utilization. Within the constraints of overfished species rebuilding requirements, achieve the maximum biological yield of the overall groundfish fishery, promote year-round availability of quality seafood to the consumer, and promote recreational fishing opportunities.

Objectives.

To accomplish these management goals, a number of objectives will be considered and followed as closely as practicable:

Conservation.

> Objective 1. Maintain an information flow on the status of the fishery and the fishery resource which allows for informed management decisions as the fishery occurs.
>
> Objective 2. Adopt harvest specifications and management measures consistent with resource stewardship responsibilities for each groundfish species or species group. Achieve a level of harvest capacity in the fishery that is appropriate for a sustainable harvest and low discard rates, and which results in a fishery that is diverse, stable, and profitable. This reduced capacity should lead to more effective management for many other fishery problems.
>
> Objective 3. For species or species groups that are overfished, develop a plan to rebuild the stock as soon as possible, taking into account the status and biology of the stock, the needs of fishing communities, recommendations by international organizations in which the United States participates, and the interaction of the overfished stock within the marine ecosystem. ~~required by the Magnuson-Stevens Act.~~

Objective 4. Where conservation problems have been identified for nongroundfish species and the best scientific information shows that the groundfish fishery has a direct impact on the ability of that species to maintain its long-term reproductive health, the Council may consider establishing management measures to control the impacts of groundfish fishing on those species. Management measures may be imposed on the groundfish fishery to reduce fishing mortality of a nongroundfish species for documented conservation reasons. The action will be designed to minimize disruption of the groundfish fishery, in so far as consistent with the goal to minimize the bycatch of nongroundfish species, and will not preclude achievement of a quota, harvest guideline, or allocation of groundfish, if any, unless such action is required by other applicable law.

Objective 5. Describe and identify essential fish habitat (EFH), adverse impacts on EFH, and other actions to conserve and enhance EFH, and adopt management measures that minimize, to the extent practicable, adverse impacts from fishing on EFH.

Economics.

Objective 6. Within the constraints of the conservation goals and objectives of the FMP, a~~A~~ttempt to achieve the greatest possible net economic benefit to the nation from the managed fisheries.

Objective 7. Identify those sectors of the groundfish fishery for which it is beneficial to promote year-round marketing opportunities and establish management policies that extend those sectors fishing and marketing opportunities as long as practicable during the fishing year.

Objective 8. Gear restrictions to minimize the necessity for other management measures will be used whenever practicable. Encourage development of practicable gear restrictions intended to reduce regulatory and/or economic discards through gear research regulated by exempted fishing permits.

Utilization.

Objective 9. Develop management measures and policies that foster and encourage full utilization (harvest and processing), in accordance with conservation goals, of the Pacific Coast groundfish resources by domestic fisheries.

Objective 10. Recognize~~ing~~ the multispecies nature of the fishery and establish a concept of managing by species and gear or by groups of interrelated species.

Objective 11. Develop management programs that reduce regulations-induced discard and/or which reduce economic incentives to discard fish. Develop management measures that minimize bycatch to the extent practicable and, to the extent that bycatch cannot be avoided, minimize the mortality of such bycatch. Promote and support monitoring programs to improve estimates of total fishing-related mortality and bycatch, as well as those to improve other information necessary to determine the extent to which it is practicable to reduce bycatch and bycatch mortality.

Social Factors.

Objective 12. When conservation actions are necessary to protect a stock or stock assemblage, attempt to develop management measures that will affect users equitably.

Objective 13. Minimize gear conflicts among resource users.

Objective 14. When considering alternative management measures to resolve an issue, choose the measure that best accomplishes the change with the least disruption of current domestic fishing practices, marketing procedures, and the environment.

Objective 15. Avoid unnecessary adverse impacts on small entities.

Objective 16. Consider the importance of groundfish resources to fishing communities, provide for the sustained participation of fishing communities, and minimize adverse economic impacts on fishing communities to the extent practicable.

Objective 17. Promote the safety of human life at sea.

[Amended; 7, 11, 13, 16-1, 16-4, 18]

2.2 Operational Definition of Terms

Acceptable Biological Catch (ABC) is a biologically based estimate of the amount of fish that may be harvested from the fishery each year without jeopardizing the resource. It is a seasonally determined catch that may differ from MSY for biological reasons. It may be lower or higher than MSY in some years for species with fluctuating recruitment. The ABC may be modified to incorporate biological safety factors and risk assessment due to uncertainty. Lacking other biological justification, the ABC is defined as the MSY exploitation rate multiplied by the exploitable biomass for the relevant time period.

Biennial fishing period is defined as a 24-month period beginning January 1 and ending December 31.

Bottom (or flatfish bottom) trawl is a trawl in which the otter boards or the footrope of the net are in contact with the seabed. It includes roller (or bobbin) trawls, Danish and Scottish seine gear, and pair trawls fished on the bottom.

Bottom-contact gear types by design and through normal use make contact with the sea floor. Such contact is more than intermittent in duration and areal extent.

Bycatch means fish which are harvested in a fishery, but which are not sold or kept for personal use and includes economic discards and regulatory discards. Such term does not include fish released alive under a recreational catch and release fishery management program.

Chafing gear is webbing or other material attached to the codend of a trawl net to protect the codend from wear.

Charter fishing means fishing from a vessel carrying a passenger for hire (as defined in section 2101(21a) of title 46, United States Code) who is engaged in recreational fishing.

Closure, when referring to closure of a fishery, means that taking and retaining, possessing or landing the particular species or species complex is prohibited.

Council means the Pacific Fishery Management Council, including its Groundfish Management Team (GMT), Scientific and Statistical Committee (SSC), Groundfish Advisory Subpanel (GAP), and any other committee established by the Council.

Commercial fishing is (1) fishing by a person who possesses a commercial fishing license or is required by law to possess such license issued by one of the states or the federal government as a prerequisite to taking, landing, and/or sale; or (2) fishing which results in or can be reasonably expected to result in sale, barter, trade, or other disposition of fish for other than personal consumption.

Density dependence is the degree to which recruitment declines as spawning biomass declines. Typically we assume that a Beverton-Holt form is appropriate and that the level of density-dependence is such that the recruitment only declines by ten percent when the spawning biomass declines by 50%.

Double-walled codend is a codend constructed of two walls of webbing.

$F_{x\%}$ is the rate of fishing mortality that will reduce female spawning biomass per recruit to x percent of its unfished level. $F_{100\%}$ is zero, and $F_{35\%}$ is a reasonable proxy for F_{MSY}.

Economic discards means fish which are the target of a fishery, but which are not retained because they are of an undesirable size, sex, quality, or for other economic reasons.

Essential fish habitat means those waters and substrate necessary to fish for spawning, breeding, feeding, or growth to maturity.

Exploitable biomass is the biomass that is available to a unit of fishing effort. Defined as the sum of the population biomass at age (calculated as the mean within the fishing year) multiplied by the age-specific availability to the fishery. Exploitable biomass is equivalent to the catch biomass divided by the instantaneous fishing mortality rate.

F is the instantaneous rate of fishing mortality. F typically varies with age, so the F values are presented for the age with maximum F. Fish of other ages have less availability to the fishery, so a unit of effort applies a lower relative level of fishing mortality to these fish.

F_{MSY} is the fishing mortality rate that maximizes catch biomass in the long term.

$F_{0.1}$ is the fishing mortality rate at which a change in fishing mortality rate will produce a change in yield per recruit that is ten percent of the slope of the yield curve at nil levels of fishing mortality.

F_{OF} is the rate of fishing mortality defined as overfishing.

Fishing means (1) the catching, taking, or harvesting of fish; (2) the attempted catching, taking, or harvesting of fish; (3) any other activity which can reasonably be expected to result in the catching, taking, or harvesting of fish; or (4) any operations at sea in support of, or in preparation for, any activity described above. This term does not include any activity by a vessel conducting authorized scientific research.

Fishing year is defined as January 1 through December 31.

Fishing community means a community which is substantially dependent on or substantially engaged in the harvest or processing of fishery resources to meet social and economy needs and includes fishing vessel owners, operators, crew, and recreational fishers and United States fish processors that are based in such community.

Fixed gear (anchored nontrawl gear) includes longline, trap or pot, set net, and stationary hook-and-line gear (including commercial vertical hook-and-line) gears.

Gillnet is a single-walled, rectangular net which is set upright in the water.

Harvest guideline (HG) is an specified numerical harvest objective which is not a quota. Attainment of a HG does not require closure of a fishery.

Hook-and-line means one or more hooks attached to one or more lines. Commercial hook-and-line fisheries may be mobile (troll) or stationary (anchored).

Incidental catch or incidental species means groundfish species caught when fishing for the primary purpose of catching a different species.

Individual fishing quota (IFQ) means a federal permit under a limited access system to harvest a quantity of fish expressed by a unit or units representing a percentage of the total allowable catch of a fishery that may be received or held for exclusive use by a person.

Longline is a stationary, buoyed, and anchored groundline with hooks attached, so as to fish along the seabed.

Maximum sustainable yield is an estimate of the largest average annual catch or yield that can be taken over a significant period of time from each stock under prevailing ecological and environmental conditions. It may be presented as a range of values. One MSY may be specified for a group of species in a mixed-species fishery. Since MSY is a long-term average, it need not be specified annually, but may be reassessed periodically based on the best scientific information available.

Midwater (pelagic or off-bottom) trawl is a trawl in which the otter boards may contact the seabed, but the footrope of the net remains above the seabed. It includes pair trawls if fished in midwater. A midwater trawl has no rollers or bobbins on the net.

MSY stock size means the largest long-term average size of the stock or stock complex, measured in terms of spawning biomass or other appropriate units, that would be achieved under an MSY control rule in which the fishing mortality rate is constant. The proxy typically used in this fishery management plan is 40% of the estimated unfished biomass, although other values based on the best scientific information are also authorized.

Nontrawl gear means all legal commercial gear other than trawl gear.

Optimum yield means the amount of fish which will provide the greatest overall benefit to the U.S., particularly with respect to food production and recreational opportunities, and taking into account the protection of marine ecosystems, is prescribed as such on the basis of the maximum sustainable yield from the fishery as reduced by any relevant economic, social, or ecological factor; and in the case of an overfished fishery, provides for rebuilding to a level consistent with producing the maximum sustainable yield in such fishery.

Overfished describes any stock or stock complex whose size is sufficiently small that a change in management practices is required to achieve an appropriate level and rate of rebuilding. The term generally describes any stock or stock complex determined to be below its overfished/rebuilding threshold. The default proxy is generally 25% of its estimated unfished biomass; however, other scientifically valid values are also authorized.

Overfishing means fishing at a rate or level that jeopardizes the capacity of a stock or stock complex to produce MSY on a continuing basis. More specifically, overfishing is defined as exceeding a maximum allowable fishing mortality rate. For any groundfish stock or stock complex, the maximum allowable mortality rate will be set at a level not to exceed the corresponding MSY rate (F_{MSY}) or its proxy (e.g., $F_{35\%}$).

Processing or to process means the preparation or packaging of groundfish to render it suitable for human consumption, retail sale, industrial uses, or long-term storage, including, but not limited to, cooking, canning, smoking, salting, drying, filleting, freezing, or rendering into meal or oil, but does not mean heading and gutting unless additional preparation is done.

Processor means a person, vessel, or facility that (1) engages in processing, or (2) receives live groundfish directly from a fishing vessel for sale without further processing.

Prohibited species are those species and species groups which must be returned to the sea as soon as is practicable with a minimum of injury when caught and brought aboard except when their retention is authorized by other applicable law. Exception may be made in the implementing regulations for tagged fish, which must be returned to the tagging agency, or for examination by an authorized observer.

Quota means a specified numerical harvest objective, the attainment (or expected attainment) of which causes closure of the fishery for that species or species group. Groundfish species or species groups under this FMP for which quotas have been achieved shall be treated in the same manner as prohibited species.

Recreational fishing means fishing for sport or pleasure, but not for sale.

Regulatory discards are fish harvested in a fishery which fishermen are required by regulation to discard whenever caught or are required by regulation to retain, but not sell.

Roller (or bobbin) trawl is a bottom trawl that has footropes equipped with rollers or bobbins made of wood, steel, rubber, plastic, or other hard material which keep the footrope above the seabed, thereby protecting the net.

Set net is a stationary, buoyed, and anchored gillnet or trammel net.

Stock Assessment and Fishery Evaluation (SAFE) document is a document prepared by the Council that provides a summary of the most recent biological condition of species in the fishery management unit, and the social and economic condition of the recreational and commercial fishing industries, and the fish processing industry. It summarizes, on a periodic basis, the best available information concerning the past, present, and possible future condition of the stocks and fisheries managed by the FMP.

Target fishing means fishing for the primary purpose of catching a particular species or species group (the target species).

A total catch limit is a portion of the OY for a groundfish FMU species, stock, or stock complex assigned to a defined fishery sector or to an individual vessel. Total catch is defined as landed catch plus bycatch (discard) mortality. The Council may specify total catch limits that are transferable or nontransferable among sectors or tradable or nontradable between vessels.

Trammel net is a gillnet made with two or more walls joined to a common float line.

Trap (or pot) is a portable, enclosed device with one or more gates or entrances and one or more lines attached to surface floats.

Spawning biomass is the biomass of mature female fish at the beginning of the year. If the production of eggs is not proportional to body weight, then this definition should be modified to be proportional to expected egg production.

Spawning biomass per recruit is the expected egg production of a female fish over its lifetime. Alternatively, this is the mature female biomass of an equilibrium stock divided by the mean level of recruitment that produced this stock.

Spear is a sharp, pointed, or barbed instrument on a shaft. Spears may be propelled by hand or by mechanical means.

Vertical hook-and-line gear (commercial) is hook-and-line gear that involves a single line anchored at the bottom and buoyed at the surface so as to fish vertically.

[Amended: 5, 11, 13, 17, 18, 19]

3.0 AREAS AND STOCKS INVOLVED

No changes in this chapter.

4.0 PREVENTING OVERFISHING AND ACHIEVING OPTIMUM YIELD

National Standard 1 requires that "Conservation and management measures shall prevent overfishing while achieving, on a continuing basis, the OY from each fishery for the U.S. fishing industry." (50 CFR 600.310(a))

"The determination of OY is a decisional mechanism for resolving the Magnuson-Stevens Act's multiple purposes and policies, implementing an FMP's objectives and balancing the various interests that comprise the national welfare. OY is based on MSY, or on MSY as it may be reduced ... [in consideration of social, economic or ecological factors].... The most important limitation on the specification of OY is that the choice of OY and the conservation and management measures proposed to achieve it must prevent overfishing." (50 CFR Section 600.310(b))

This chapter addresses the essential considerations suggested for National Standard 1, as identified in the NMFS guidelines on the standard (600.310):

- Estimating MSY, estimated the MSY biomass and setting the MSY control rule (50 CFR 600.310(c); Section 4.2 of this Chapter).
- Specifying stock status determination criteria (maximum fishing mortality threshold and minimum stock size threshold, or reasonable proxies thereof) (50 CFR 600.310(d); Section 4.4 of this Chapter).
- Actions for ending overfishing and rebuilding overfished stocks (including the development and adoption of rebuilding plans) (50 CFR 600.310(e); Section 4.5 of this Chapter).
- Setting OY and apportionment of harvest levels (50 CFR 600.310(f); Section 4.6 of this Chapter).

In establishing OYs for West Coast groundfish, this FMP uses the interim step of calculating ABCs for major stocks or management units (groups of species). ABC is the MSY harvest level associated with the current stock abundance. Over the long term, if ABCs are fully harvested, the average of the ABCs would be MSY.

OY is set and apportioned under the procedures outlined in Chapter 5. As provided by Section 303(b)(11) of the Magnuson-Stevens Fishery Conservation and Management Act, the Council may establish a research reserve for any stock, that is within the ABC but above and separate from the OY for that stock.

[Added: 16-1]

4.1 Species Categories

BMSY, ABC and the overfished/rebuilding stock size threshold cannot be precisely defined for all species, because of the absence of available information for many species managed under the FMP. For the purpose of setting MSY, ABC, the maximum fishing mortality threshold (MFMT), the minimum stock size threshold (MSST), OY and rebuilding standards, three categories of species are identified. The first are the relatively few species for which a quantitative stock assessment can be conducted on the basis of catch-at-age or other data. ABCs and overfished/rebuilding thresholds can generally be calculated for these species. The second category includes a large number of species for which some biological indicators are available, but a quantitative analysis cannot be conducted. It is difficult to estimate overfished and overfishing thresholds for the second category of species a priori, but indicators of long-term, potential overfishing can be identified. ABCs for species in this category are typically set at a constant level and some monitoring is necessary to determine if this level of catch is causing a slow decline in stock abundance. The third category includes minor species which are caught, but for which there is, at best, only information on landed biomass. For species in this category, it is impossible to determine MSY, ABC, or an overfished threshold

[Amended: 16-1]

4.2 Determination of MSY, or MSY Proxy, and B_{MSY}

Harvest policies are to be specified according to standard reference points such as MSY (MSY, interpreted as a maximum average achievable catch under prevailing ecological and environmental conditions over a prolonged period). The long-term average biomass associated with fishing at F_{MSY} is B_{MSY}. In this FMP, MSY generally refers to a constant F control rule that is assumed to produce the maximum average yield over time while protecting the spawning potential of the stock. Thus the constant F control rule is generally the proxy for the MSY control rule. Fishing rates above F_{MSY} eventually result in biomass smaller than B_{MSY} and produce less harvestable fish on a sustainable basis. The biomass level that produces MSY (i.e., B_{MSY}) is generally unknown and assumed to be variable over time due to long-term fluctuations in ocean conditions, so that no single value is appropriate. During periods of unfavorable environmental conditions it is important to account for reduced sustainable yield levels.

The problem with an F_{MSY} control rule is that it is tightly linked to an assumed level of density-dependence in recruitment, and there is insufficient information to determine the level of density-dependence in recruitment for many West Coast groundfish stocks. Therefore, the use of approximations or proxies is necessary. Absent a more accurate determination of F_{MSY}, the Council will apply default MSY proxies. The current (2001) proxies are: F40% for flatfish and whiting, $F_{50\%}$ for rockfish (including thornyheads) and $F_{45\%}$ for all species such as sablefish and lingcod. However, values ($F_{40\%}$, $F_{45\%}$, and $F_{50\%}$) are provided here as examples only and are expected to be modified from time to time as scientific knowledge improves. If available information is sufficient, values of F_{MSY}, B_{MSY}, and more appropriate harvest control rules may be developed for any species or species group.

At this time, it is generally believed that, for many species, $F_{45\%}$ strikes a balance between obtaining a large fraction of the MSY if recruitment is highly insensitive to reductions in spawning biomass and preventing a rapid depletion in stock abundance if recruitment is found to be extremely sensitive to reductions in spawning biomass. The long-term expected yield under an $F_{45\%}$ policy depends upon the (unknown) level of density-dependence in recruitment. The recommended level of harvest will reduce the average lifetime egg production by each female entering the stock to 45% of the lifetime egg production for females that are unfished.

Because the level of recruitment is expected to decline somewhat as a stock is fished at $F_{45\%}$, the expected B_{MSY} proxy is less than 45% of the unfished biomass. A biomass level of 40% is a reasonable proxy for BMSY. The short-term yield under an $F_{45\%}$ policy will vary as the abundance of the exploitable stock varies. This is true for any fishing policy that is based on a constant exploitation rate. The abundance of the stock will vary, because of the effects of fishing, and because of natural variation in recruitment. When stock abundance is high (i.e., near its average unfished level), short-term annual yields can be approximately two to three times greater than the expected long-term average annual yield. For many of the long-lived groundfish species common on the West Coast, this "fishing down" transition can take decades. Many of the declines in ABC that occurred during the 1980s were the result of this transition from a lightly exploited, high abundance stock level to a fully exploited, moderately abundant stock level. Further declines below the overfished levels in the 1990s were due in large part to harvest rate policies that were later discovered to not be sustainable. More recent stock assessments indicate that West Coast groundfish stocks likely have lower levels of productivity than other similar species worldwide. Based on this retrospective information, harvest rate policies in the 1990s were too high to maintain stocks at B_{MSY}. The Council revised its harvest rate policies for lower levels of production, described below.

Scientific information as of 1997 (Clark 1993; Ianelli and Heifetz 1995; Mace 1994) indicated that $F_{35\%}$ may not be the best approximation of FMSY, given more realistic information about recruitment than was initially used by Clark in 1991. In his 1993 publication Clark extended his 1991 results by improving the realism of his simulations and analysis. In particular he (1) modeled stochasticity into the recruitment process, (2) introduced serial correlation into recruitment time series, and (3) performed separate analyses for the Ricker and Beverton-Holt spawner-recruit functions. For rockfish, these changes improved the realism of his spawning biomass per recruit (SPR) harvest policy calculations, because these species are known to have stochastic recruitment and they appear to display serial correlation in recruitments (especially on interdecadal time scales), and because the Beverton-Holt spawner-recruit curve may be biologically the most plausible recruitment model. The effect of each of these changes, in isolation and in aggregate, was to decrease FMSY. Consequently, the estimated SPR reduction needed to provide an optimal F_{MSY} proxy (defined as that level of fishing which produces the largest assured proportion of MSY), must necessarily be increased. Clark concluded that $F_{40\%}$ is the optimal rate for fish stocks exhibiting recruitment variability similar to Alaska groundfish stocks. Likewise, Mace (1994) recommended the use of $F_{40\%}$ as the target mortality rate when the stock-recruitment relationship is unknown. Lastly, Ianelli and Heifitz (1995) determined that F44% was a good F_{MSY} proxy for Gulf of Alaska Pacific ocean perch, although he subsequently indicated that a recent recruitment to that stock was larger than expected and that $F_{44\%}$ may be too conservative in that case.

Based on this information and advice by its Groundfish Management Team, in 1997 the Council concluded that $F_{40\%}$ should be used as the proxy for FMSY for rockfish in the absence of specific knowledge of recruitment or life history characteristics which would allow a more accurate determination of FMSY. This proxy was later revised based on further Scientific and Statistical Committee (SSC) investigation into the appropriate FMSY proxies in 2000.

In the spring of 2000, the Council's SSC sponsored a workshop to review the Council's groundfish exploitation rate policy. The workshop explored the historic use of different fishing mortality (F) rates and found that the Council's past practices have generally changed in response to new information from the scientific community. Starting in the early 1990s, the Council used a standard harvest rate of F35%. The SSC's workshop participants reported that new scientific studies in 1998 and 1999 had shown that the $F_{35\%}$ and $F_{40\%}$ rates used by the Council had been too aggressive for Pacific Coast groundfish stocks, such that some groundfish stocks could not maintain a viable population over time. A 1999 study, The Meta-Analysis of the Maximum Reproductive Rate for Fish Populations to Estimate Harvest Policy; a Review (Myers, *et al.* 2000) showed that Pacific Coast groundfish stocks, particularly rockfish, have very low productivity compared to other, similar species worldwide. One prominent theory about the reason for this low productivity is the large-scale North Pacific climate shifts that are thought to cycle Pacific Coast waters through warm and cool phases of 20-30 years duration. Pacific Coast waters shifted to a warm phase around 1977-1978, with ocean conditions less favorable for Pacific Coast groundfish and other fish stocks. Lower harvest rates are necessary to guard against steep declines in abundance during these periods of low productivity (low recruitment). After an intensive review of historic harvest rates, and current scientific literature on harvest rates and stock productivity, the SSC workshop concluded that $F_{40\%}$ is too aggressive for many Pacific Coast groundfish stocks, particularly for rockfish. For 2001 and beyond, the Council adopted the SSC's new recommendations for harvest policies of: $F_{40\%}$ for flatfish and whiting, $F_{50\%}$ for rockfish (including thornyheads) and $F_{45\%}$ for other groundfish such as sablefish and lingcod.

In the past, F_{MSY} fishing rates were treated by the Council (as intended) as targets. Under the Magnuson-Stevens Act as amended in 1996, these fishing rates are more appropriately considered to be thresholds that should not be exceeded (see Section 4.4).

The Council will consider any new scientific information relating to calculation of MSY or MSY proxies and may adopt new values based on improved understanding of the population dynamics and harvest of any species or group of species.

While BMSY may be set based on the averaged unfished abundance ($B_{unfished}$) there are many possible approximations and estimates of mean $B_{unfished}$. If the necessary data exist, the following standard methodology is the preferred approach:

$$\text{mean } B_{unfished} = \text{mean } R * SPR(F=0)$$

Where mean R is the average estimated recruitment expected under unfished conditions, and SPR(F=0) is the spawning potential per recruit at zero fishing mortality rate. SPR(F=0) is normally available as part of the calculation leading to determination of $F_{45\%}$ and is equivalent to $F_{100\%}$.

[Amended: 5, 11, 16-1]

4.3 Determination of ABC

In establishing OYs for West Coast groundfish, this FMP utilizes the interim step of calculating ABCs for major stocks or management units (groups of species). ABC is the MSY harvest level associated with the current stock abundance. Over the long term, if ABCs are fully harvested, the average of the ABCs would be MSY.

4.3.1 Stocks with Quantitative Assessments, Category 1

The stocks with quantitative assessments are those that have recently been assessed by a catch-at-age analysis. Annual evaluation of the appropriate MSY proxy (e.g., F45%) for species in this category will require some specific information in the SAFE document. Estimated age-specific maturity, growth, and availability to the fishery (with evaluation of changes over time in these characteristics) are sufficient to determine the relationship between fishing mortality and yield-per-recruit and spawning biomass-per-recruit. The estimated time series of recruitment, spawning biomass, and fishing mortality are also required to determine whether recent trends indicate a point of concern. In general, ABC will be calculated by applying $F_{45\%}$ (or F40%, F50%, or other established MSY proxy) to the best estimate of current biomass. This current biomass estimate may be for a single year or the average of the present and several future years. Thus, ABC may be intended to remain constant over a period of three or more years.

4.3.2 Stocks with ABC Set by Nonquantitative Assessment, Category 2

These stocks with ABC set by nonquantitative assessments typically do not have a recent, quantitative assessment, but there may be a previous assessment or some indicators of the status of the stock. Detailed biological information is not routinely available for these stocks, and ABC levels have typically been established on the basis of average historical landings. Typically, the spawning biomass, level of recruitment, or the current fishing mortality rate for Category 2 stocks are unknown. The Council places high priority on improving the information for managing these stocks so that they may be moved to

Category 1 status.

4.3.3 Stocks Without ABC Values, Category 3

Of the 80-plus groundfish species managed under the FMP, ABC values have been established for only about 25. The remaining species are incidentally landed and usually are not listed separately on fish landing receipts. Information from fishery independent surveys are often lacking for these stocks, because of their low abundance or they are not vulnerable to survey sampling gear. Until sufficient quantities of at-sea observer program data are available or surveys of other fish habitats are conducted, it is unlikely that there will be sufficient data to upgrade the assessment capabilities or to evaluate the overfishing potential of these stocks. Interim ABC values may be established for these stocks based on qualitative information, including advice from the Council's advisory entities.

[Amended: 11, 12, 16-1]

4.4 Precautionary Thresholds and Overfishing Status Determination Criteria

The National Standard Guidelines define two thresholds that are necessary to maintain a stock at levels capable of producing MSY: the maximum fishing mortality threshold (MFMT) and a minimum stock size threshold (MSST). These two limits are intended for use as benchmarks to decide if a stock or stock complex is being overfished or is in an overfished state. The MFMT and MSST are intrinsically linked through the MSY control rule, which specifies how fishing mortality or catches could vary as a function of stock biomass in order to achieve yields close to MSY.

4.4.1 Determination of Precautionary Thresholds

The precautionary threshold is the biomass level at which point the harvest rate will be reduced to help the stock return to the MSY level (see Section 4.5.1 “Default Precautionary and Interim Rebuilding OY Calculation”). The precautionary biomass threshold is in addition to the overfishing and overfished/rebuilding thresholds required under ths Magnuson-Stevens Act (MFMT and MSST). The precautionary biomass threshold is higher than the overfished biomass (MSST). Because BMSY is a long term average, biomass will by definition be below BMSY in some years and above BMSY in other years. Thus, even in the absence of overfishing, biomass may decline to levels below BMSY due to natural fluctuation. By decreasing harvest rates when biomass is below BMSY but maintaining MSY control rule (or proxy control rule) harvest rates for biomass levels above MSY, the precautionary threshold and accompanying response effectively constitute a control rule that manages for harvests lower than MSY and an average biomass above MSY.

The precautionary threshold is established only for category 1 species. The precautionary threshold will be the BMSY level, if known. The default precautionary threshold will be 40% of the estimated unfished biomass level. The Council may recommend different precautionary thresholds for any species or species group based on the best scientific information about that species or group. It is expected the threshold will be between 25% and 50% of the estimated unfished biomass level.

4.4.2 Determination of Overfishing Threshold

In this FMP, for Category 1 species, the term “overfishing” is used to denote situations where catch exceeds or is expected to exceed the established ABC or MSY proxy ($F_{x\%}$). This can also be expressed as where catch exceeds or is expected to exceed the MFMT. The term “overfished” describes a stock whose abundance is below its overfished/rebuilding threshold, or MSST. Overfished/rebuilding thresholds, in general, are linked to the same productivity assumptions that determine the ABC levels. The default value of this threshold is 25% of the estimated unfished biomass level or 50% of B_{MSY}, if known. The MFMT is simply the value(s) of fishing mortality in the MSY control rule. Technically, exceeding FMSY constitutes overfishing.

For Category 2 species, the following may be evaluated as potential indicators of overfishing:

- catch per effort from logbooks
- catch area from logbooks
- index of stock abundance from surveys
- stock distribution from surveys
- mean size of landed fish

If declining trends persist for more than three years, then a focused evaluation of the status of the stock, its ABC, and overfishing threshold will be quantified. If data are available, such an evaluation should be conducted at approximately five year intervals even when negative trends are not apparent. In fact, many stocks are in need of re-evaluation to establish a baseline for monitoring of future trends. Whenever an evaluation indicates the stock may be declining and approaching an overfished state, the Council should:

1. Improve data collection for this species so it can be moved to Category 1.

2. Determine the rebuilding rate that would allow the stock to return to MSY in no longer than ten years.

Information from fishery independent surveys is often lacking for Category 3 species because of their low abundance or because they are not vulnerable to survey sampling gear. Until sufficient data become available from the at-sea observer program, the risk of overfishing these species cannot be fully evaluated.

4.4.3 Determination of Overfished/Rebuilding Thresholds

The MSST (overfished/rebuilding threshold) is the default value of 25% of the estimated unfished biomass level or 50% of B_{MSY}, if known. The overfished/rebuilding threshold (also referred to as $B_{rebuild}$), is generally in the range of 25% to 40% of $B_{unfished}$, and may also be written as

$B_{rebuild}$ = x% * mean R * SPR(F=0)

The default overfished/rebuilding threshold for category 1 groundfish is $0.25B_{unfished}$. The Council may establish different thresholds for any species based on information provided in stock assessments, the SAFE document, or other scientific or groundfish management-related report. For example, if B_{MSY} is known, the overfished threshold may be set equal to 50% of that amount. The Council may also specify a lower level of abundance where catch or fishing effort is reduced to zero. This minimum abundance threshold (B_{MIN}) would correspond to an abundance that severely jeopardizes the stock's ability to recover to B_{MSY} in a reasonable length of time.

[Amended: 11, 12, 16-1]

4.5 Ending Overfishing and Rebuilding

4.5.1 Default Precautionary and Interim Rebuilding OY Calculation

The precautionary threshold, defined in Section 4.4.1, is used to trigger a precautionary management approach. If biomass declines to a level that requires rebuilding (below the MSST), the precautionary management approach also provides an interim rebuilding harvest control policy to guide ~~the~~ setting the OY until the Council sets a new rebuilding policy specific to the conditions of the stock and fishery. The default OY/rebuilding policy can be described as an "ICES-type catch-based approach" that consists of a modification of the catch policy, where catch (C) declines from $C(F_{MSY})$ at the precautionary threshold in a straight line to F=0 at the minimum abundance threshold of ten percent of the estimated mean unfished biomass (sometimes called pristine or virgin biomass or reproductive potential). This approach could also be described as an OY based on a variable FSPR that is progressively more conservative at low biomass levels. The abbreviated name for this is the "40-10" default adjustment. In most cases, there is inadequate information to estimate FMSY; in such cases, the best proxy for F_{MSY} will be used. The default proxy values will be $F_{40\%}$ for flatfish and whiting, $F_{50\%}$ for rockfish in the Sebastes complex and $F_{45\%}$ for other species such as sablefish and lingcod. The Council anticipates scientific information about the population dynamics of the various stocks will improve over time and that this information will result in improved estimates of appropriate harvest rates and MSY proxies. Thus, these initial default proxy values will be replaced from time to time. Such changes will not require amendment to the FMP, but the scientific basis for new values must be documented.

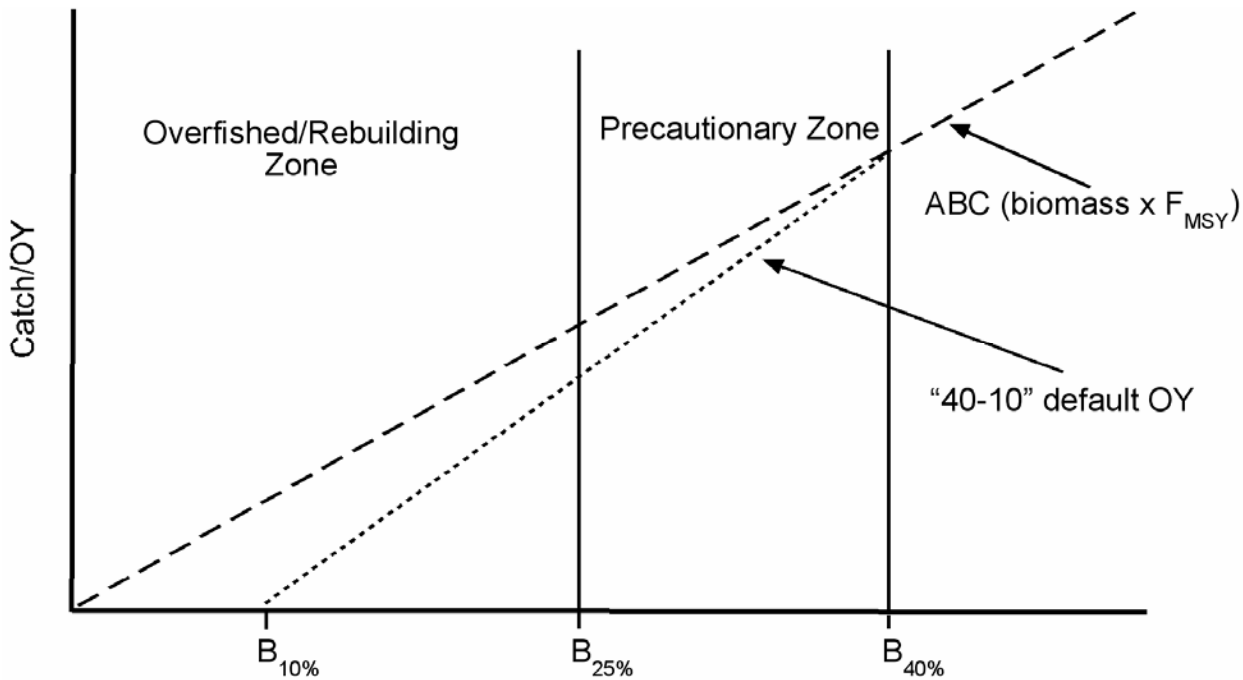

FIGURE 4-1. Illustration of default OY rule compared to ABC.

The greater amount of catch reduction applied below the precautionary threshold will foster quicker return to the MSY level. If a stock falls below its overfished/rebuilding threshold, this line would be used as the interim rebuilding plan during the year until the Council develops a formal rebuilding plan. The point at which the line intersects the horizontal axis does not necessarily imply zero catch would be allowed, but rather is for determining the slope of the line.

In order to apply this default approach, a minimal amount of information is necessary; only stocks in Category 1 can be managed in this way. For stocks with inadequate information to apply this approach, the Council will consider other methods of ensuring that overfishing will be avoided. The Council will consider the approaches discussed in the National Standard Guidelines in developing such recommendations for stocks in Categories 2 and 3.

4.5.2 Procedures For Calculating Rebuilding Parameters

The Magnuson-Stevens Act and National Standard Guidelines provide a descriptive framework for developing strategies to rebuild overfished stocks. This framework identifies three parameters: a minimum time in which an overfished stock ~~may~~ can rebuild to its target biomass (denoted T_{MIN}), a maximum permissible time period for rebuilding the stock to its target biomass (T_{MAX}), and a target year, falling within the time period ~~represented~~ between T_{MIN} and T_{MAX} and representing the ~~best of estimate of~~ the year by which the stock ~~will~~ can be rebuilt, as soon possible, taking into account the status and biology of the stock, the needs of fishing communities, and the interaction of the stock of fish within the marine ecosystem (T_{TARGET}).

T_{MIN}, the lower limit of the specified time period for rebuilding, will be determined by the status and biology of the stock or stock complex and its interactions with other components of the marine ecosystem or environmental conditions, and is defined as the amount of time that would be required for rebuilding if fishing mortality were eliminated entirely.

If ~~the lower limit~~ T_{MIN} is less than ten years, then the specified time period for rebuilding may be adjusted upward so that the rebuilding period is as short as possible, taking into account the status and biology of the stock, the needs of fishing communities, and the interaction of the stock of fish within the marine ecosystem, ~~to the extent warranted by the needs of fishing communities and recommendations by international organizations in which the United States participates,~~ except that no such upward adjustment may result in the specified time period exceeding ten years (which would then constitute T_{MAX}), unless management measures under an international agreement in which the United States participates dictate otherwise.

If the ~~lower limit~~ T_{MIN} is ten years or greater, then the specified time period for rebuilding may be adjusted upward so that the rebuilding period is as short as possible, taking into account the status and biology of the stock, the needs of fishing communities, and the interaction of the stock of fish within the marine ecosystem, ~~to the extent warranted by the needs of fishing communities and recommendations by international organizations in which the United States participate~~s, except that no such upward adjustment can exceed the rebuilding period calculated in the absence of fishing mortality, plus one mean generation time or equivalent period based on the species' life-history characteristics. For example, if a stock could be rebuilt within 12 years in the absence of any fishing mortality, and has a mean generation time of eight years, the maximum allowable time to rebuild would be ~~the rebuilding period could be as long as~~ 20 years, which is T_{MAX}.

The Council may consider a number of factors in determining the time period for rebuilding, including:

1. The status and biology of the stock or stock complex.

2. Interactions between the stock or stock complex and other components of the marine ecosystem or environmental conditions.

3. The needs of fishing communities.

4. Recommendations by international organizations in which the United States participates.

5. Management measures under an international agreement in which the United States participates.

Calculating Rebuilding Probabilities

Stock assessment results form the basis of a rebuilding analysis, which in turn is used to develop rebuilding policies and choose the rebuilding parameters identified in each rebuilding plan. The elements of rebuilding analyses are described in the SSC Terms of Reference for Rebuilding Analyses (SSC 2001). This guidance has been incorporated into a computer program (Punt 2002). In the analysis the probability that the overfished stock will reach its target biomass is determined with respect to T_{MIN}, T_{MAX}, and T_{TARGET}. The methods for calculating the values of these parameters are described below. This is a simplified explanation of the current methodology; for example, equations and technical specifications are omitted. The SSC may revise their terms of reference in the future and the computer program undergoes continued refinement and elaboration.

The rebuilding analysis program uses "Monte Carlo simulation" to derive a probability estimate for a given rebuilding strategy. This method projects population growth many times in separate simulations. It accounts for possible variability by randomly choosing the value of a key variable—in this case total recruitment or recruits per spawner—from a range of values. These values can be specified empirically, by listing some set of historical values, or by a relationship based on a model. The SSC recommends that the rebuilding analyses use historical values. Because of this variability in a key input value, each simulation will show a different pattern of population growth. As a result, a modeled population may reach the target biomass that defines a rebuilt stock (B_{MSY}) in a different year in each of the simulations.

This technique ~~can be used~~ ~~is~~ first used to calculate T_{MIN} in probabilistic terms, which is defined as the time needed to reach the target biomass in the absence of fishing with a 50% probability. In other words, in half the simulations the target biomass was reached in some year up to and including the computed T_{MIN}. Given T_{MIN}, T_{MAX} is computed as 10 years or by adding the value of one mean generation time to T_{MIN}, if T_{MIN} is greater than or equal to 10 years.

~~After determining T_{MAX}, multiple Monte Carlo simulations are conducted, varying the fishing mortality rate. This determines the relationship between F and the probability of the stock being rebuilt by T_{MAX} (denoted P_{MAX}). Since a higher P_{MAX} probability must be achieved by lowering the fishing mortality rate (other things being equal) there is a tradeoff between fishery harvests and rebuilding speed in probabilistic terms. As fishing mortality is reduced, the likelihood that the stock will recover in this maximum time period increases.~~

A target year, T_{TARGET}, is ~~then computed as the median rebuilding year for each related F and P_{MAX}. The median year is simply the year by which half of all cases have already rebuilt, and is unique for a given F and P_{MAX}.~~ set as a year at T_{MIN} or greater, which does not exceed T_{MAX} ,and which is as short as possible, taking into account the status and biology of the stock, the needs of fishing communities, and the interaction of the stock of fish within the marine ecosystem. Prior to Amendment 16-4, the Council set T_{TARGET} in part by considering the probability of rebuilding the stock by T_{MAX}. The Council may continue to review the probability of rebuilding the stock by T_{MAX} given differing F rates, a reference parameter known as "P_{MAX}." The Magnuson-Stevens Act, however, simply requires that rebuilding periods be as short as possible, taking into account:

- the status and biology of any overfished stocks of fish;
- the needs of fishing communities;
- recommendations by international organizations in which the United States participates;
- the interaction of the overfished stock of fish within the marine ecosystem. (§304(e)(4)(A)(i))

It is important to recognize that some of the terms introduced and described above represent policy decisions at the national level and the Council **does not have a choice** in setting their values. The dates for T_{MIN} and T_{MAX} are determined based on guidelines established at the national level. Mean generation time is a biological characteristic that cannot be chosen by policymakers. Thus, the Council cannot choose these values and then use them as a basis for management. Defined in national guidelines, T_{MIN} is a consequence of the productivity of the fish stock and is calculated by fishery biologists based on information they get from a particular stock. Similarly, T_{MAX}, which is calculated from T_{MIN}, does not represent a Council choice.

Policy flexibility comes into play in determining T_{TARGET}, or the time by which the stock is projected to rebuild. As explained earlier, the time to rebuild must be as short as possible, taking into account the status and biology of the stock, the needs of fishing communities, and the interaction of the stock of fish within the marine ecosystem. ~~Fundamentally,~~ W~~w~~hen developing a management strategy, the Council **can** choose a fishing mortality rate and corresponding annual level of fishing. However, when rebuilding overfished species, the choice of F ~~can be~~ is based on ~~either~~ the value of T_{TARGET} ~~or P_{MAX}~~, keeping in mind that these ~~three~~ values cannot be chosen independently of one another. In other words, the Council may choose one ~~of these~~ value~~s~~ and derive the other ~~two~~ from it, but they cannot choose these values ~~for two of these terms~~ independently of ~~the third~~ each other.

4.5.3 Stock Rebuilding Plans

As required by the Magnuson-Stevens Act, within one year of being notified by the Secretary that a stock is overfished or approaching a condition of being overfished, the Council will prepare a recommendation to end the overfished condition and rebuild the stock(s) or to prevent the overfished condition from occurring. For a stock that is overfished, the rebuilding plan will specify a time period for ending the overfished condition and rebuilding the stock. Overfishing restrictions and recovery benefits should be fairly and equitably allocated among sectors of the fishery.

Certain elements of a rebuilding plan developed by the Council, as specified in Section 4.5.3.2 (Contents of Rebuilding Plans), will be submitted to the Secretary as an FMP amendment and implementing regulations. Changes to key rebuilding plan elements will be accomplished through full (notice and comment) rulemaking. Once approved by the Secretary, a rebuilding plan will remain in effect for the specified duration of the rebuilding program, or until modified. The Council will make all approved rebuilding plans available in the annual SAFE document or by other means. The Council may recommend that the Secretary implement interim measures to reduce overfishing until the Council's program has been developed and implemented.

The Council intends its stock rebuilding plans to provide targets, checkpoints, and guidance for rebuilding overfished stocks to healthy and productive levels. They should provide a clear vision of the intended results and the means to achieve those results. They will provide the strategies and objectives that regulations are intended to achieve, and proposed regulations and results will be measured against the rebuilding plans. It is likely that rebuilding plans will be revised over time to respond to new information, changing conditions, and success or lack of success in achieving the rebuilding schedule and other goals. If, in response to these revisions, the Council recommends changes to the management target for a particular stock, such changes will be published through full (notice and comment) rulemaking as described in Section 6.2 of this FMP. As with all Council activities, public participation is critical to the development, implementation and success of management programs.

4.5.3.1 Goals and Objectives of Rebuilding Plans

The overall goals of rebuilding programs are to (1) achieve the population size and structure that will support the maximum sustainable yield within a ~~the~~ specified time period that is as short as possible, taking into account the status and biology of the stock, the needs of fishing communities, and the interaction of the stock of fish within the marine ecosystem; (2) minimize, to the extent practicable, the adverse social and economic impacts associated with rebuilding, including adverse impacts on fishing communities; (3) fairly and equitably distribute both the conservation burdens (overfishing restrictions) and recovery benefits among commercial, recreational, and charter fishing sectors; (4) protect the quantity and quality of habitat necessary to support the stock at healthy levels in the future; and (5) promote widespread public awareness, understanding and support for the rebuilding program. More specific goals and objectives may be developed in the rebuilding plan for each overfished species.

To achieve the rebuilding goals, the Council will strive to (1) explain the status of the overfished stock, pointing out where lack of information and uncertainty may require that conservative assumptions be made in order to maintain a risk-averse management approach; (2) identify present and historical harvesters of the stock; (3) where adequate harvest sharing plans are not already in place, develop harvest sharing plans for the rebuilding period and for when rebuilding is completed; (4) set harvest levels that will achieve the specified rebuilding schedule; (5) implement any necessary measures to allocate the resource in accordance with harvest sharing plans; (6) promote innovative methods to reduce bycatch and bycatch mortality of the overfished stock; (7) monitor fishing mortality and use available stock assessment information to evaluate the condition of the stock; (8) identify any critical or important habitat areas and implement measures to ensure their protection; and (9) promote public education regarding these goals, objectives, and the measures intended to achieve them.

4.5.3.2 Contents of Rebuilding Plans

Generally, rebuilding plans will contain:

1. A description of the biology and status of the overfished stock and fisheries affected by stock rebuilding measures.

2. A description of how rebuilding parameters for the overfished stock were determined (including any calculations that demonstrate the scientific validity of parameters).

3. Estimates of rebuilding parameters ($B_{UNFISHED}$, B_{MSY}, T_{MIN}, T_{MAX}, ~~and the probability of reaching target biomass by this date~~, and T_{TARGET}) at the time of rebuilding plan adoption.

4. A description of the fishing communities' needs that were considered at the time of adoption of the plan.

~~4.~~ 5. The process, and any applicable standards, that will be used during periodic review to evaluate progress in rebuilding the stock to the target biomass (see Section 4.5.3.5).

~~5.~~ 6. Any management measures the Council may wish to specifically describe in the FMP, which facilitate stock rebuilding in the specified period. (These measures would be in addition to any existing measures typically implemented through annual or biennial management. See Section 4.5.3.4 for more information.)

~~6.~~ 7. Any goals and objectives in addition to or different from those listed in the preceding section.

~~7.~~ 8. Potential or likely allocations among sectors.

~~8.~~ 9. For fisheries managed under international agreement, a discussion of how the rebuilding plan will reflect traditional participation in the fishery, relative to other nations, by fishermen of the United States.

~~9.~~ 10. Any other information that may be useful to achieve the rebuilding plan's goals and objectives.

The following questions also serve as a guide in developing rebuilding plans:

1. What is the apparent cause of the current condition (historical fishing patterns, a declining abundance or recruitment trend, a change in assessment methodology, or other factors)?

2. Is there a downward trend in recruitment that may indicate insufficient compensation in the spawner-recruitment relationship?

3. Based on ~~an~~ a comparison of historical harvest levels (including discards) relative to recommended ABC levels, has there been chronic over-harvest?

4. Is human-induced environmental degradation implicated in the current stock condition? Have natural environmental changes been observed that may be affecting growth, reproduction, and/or survival?

5. Would reduction in fishing mortality be likely to improve the condition of the stock?

6. What types of fishing communities rely on catch of this particular stock, or on catch of stocks that co-occur with this stock?

~~6.~~ 7. Is the particular species caught incidentally with other species? Is it a major or minor component in a mixed-stock complex?

~~7.~~ 8. What types of management measures are anticipated and/or appropriate to achieve the biological, social, economic, and community goals and objectives of the rebuilding plan?

Rebuilding plan documents are distinct from the analytical documents required by the National Environmental Policy Act and other legal mandates, although they will reflect the contents of those analyses in a much briefer form. Rebuilding plan elements incorporated into the FMP (in Section 4.5.4) summarize the contents enumerated in this section. Rebuilding plans as a whole will be published in the next annual SAFE document after their approval.

Any new rebuilding program will commence as soon as the first measures to rebuild the stock or stock complex are implemented.

Fishing communities need a sustainable fishery that: is safe, well-managed, and profitable; provides jobs and incomes; contributes to the local social fabric, culture, and image of the community; and helps market the community and its services and products.

4.5.3.3 Process for Development and Approval of Rebuilding Plans

Upon receiving notification that a stock is overfished, the Council will identify one or more individuals to draft the rebuilding plan. A draft of the plan will be reviewed and preliminary action taken (tentative adoption or identification of preferred alternatives), followed by final adoption at a subsequent meeting. The tentative plan or alternatives will be made available to the public and considered by the Council at a minimum of two meetings, unless stock conditions suggest more immediate action is warranted. Upon completing its final recommendations, the Council will submit the proposed rebuilding plan or revision to an existing plan to NMFS for concurrence. A rebuilding plan will be developed following the standard procedures for considering and implementing an FMP amendment under the Magnuson-Stevens Act and other applicable law.

The following elements in each rebuilding plan will be incorporated into the FMP in Section 4.5.4:

1. A brief description of the status of the stock and fisheries affected by stock rebuilding measures at the time the rebuilding plan was prepared.

2. The methods used to calculate stock rebuilding parameters, if substantially different from those described in Section 4.5.2.

3. An estimate at the time the rebuilding plan was prepared of:
   - unfished biomass (Bunfished) and target biomass (BMSY);
   - the year the stock would be rebuilt in the absence of fishing (T_{MIN});
   - T_{MIN} plus one mean generation time (T_{MAX}); and
   - ~~the year the stock would be rebuilt if the maximum time period permissible under National Standard Guidelines were applied (T_{MAX}) and the estimated probability that the stock would be rebuilt by this date based on the application of stock rebuilding measures; and~~
   - the year in which the stock would be rebuilt based on the application of stock rebuilding measures that achieve rebuilding as soon as possible, taking into account the status and biology of the stock, the needs of fishing communities, and the interaction of the overfished stock within the marine ecosystem (T_{TARGET}).

4. A description of the harvest control rule (e.g., constant catch or harvest rate) and the specification of this parameter. The types of management measures that will be used to constrain harvests to the level required ~~implied~~ by the control rule will also be described (see also Section 4.5.3.4). These two elements, the harvest control rule and a description of management measures, represents the rebuilding strategy intended to rebuild the stock by the target year.

It is likely that over time the parameters listed above will change. It must be emphasized that the values enumerated in the FMP represent estimates at the time the rebuilding plan is prepared. Therefore, the FMP need not be amended if new estimates of these values are calculated. The values for these parameters found in the FMP are for reference, so that managers and the public may track changes in the strategy used to rebuild an overfished stock. However, any new estimates of the parameters listed above will be published in the SAFE documents as they become available.

4.5.3.4 Updating Key Rebuilding Parameters

In addition to an initial specification in the FMP, the target year (T_{TARGET}) and the harvest control rule (type and numerical value) will also be specified in regulations. If new information indicates a need to change the value of either of these two parameters, such a change will be accomplished through full (notice and comment) rulemaking as described in Section 6.2 of this FMP. The target year is the year by which the stock would be rebuilt to its target biomass. Therefore, if a subsequent analysis identifies an earlier target year for the current fishing mortality rate (based on the harvest control rule), there is no obligation to change in regulations either the target year (to the computed earlier year) or the harvest control rule (to delay rebuilding to the original target year). Stock assessments for overfished species are typically conducted every two years. Stock assessments and rebuilding analyses use mathematical models to predict a stock's current abundance, as well as project future abundance and recruitment. In any mathematical model that uses a variety of data sources, as the stock assessments do, model results tend to vary from one assessment to the next within some range of values. This expected variation means that, when the Council and SSC review a new overfished species stock assessment and rebuilding model, they must also consider whether the result of that model or models show a rebuilding trajectory that varies from the previously-predicted trajectory to a significant degree. If the variation between the stock assessments and rebuilding analyses for a particular species do not show significant differences in the rebuilding trajectory for that species, they are mathematically considered to be essentially the same. In that circumstance, the Council will likely not need to revise the T_{TARGET} or harvest control rule for that species. Since the target year is ~~a~~ the key rebuilding parameter, it should only be changed after careful deliberation. For example, the Council might recommend that the target year be changed if, based on new information about the status and/or biology of the stock, they determine that the existing target year is later than the recomputed maximum rebuilding time (T_{MAX}) or if a recomputed harvest control rule would result in such a low optimum yield as to cause substantial socioeconomic impacts. These examples are not definitive: the Council may elect to change the target year because of other circumstances. However, any change to the target year or harvest control rule must be supported by commensurate analysis that demonstrates that the new target year is a target to rebuild the stock as soon as possible, taking into account the status and biology of the stock, the needs of fishing communities, and the interaction of the stock within the marine ecosystem.

4.5.3.5 Implementation of Actions Required Under the Rebuilding Plan

NMFS will implement or adjust, with the adoption of the rebuilding plan, any management measures not already in effect that are necessary to implement the rebuilding plan. Many necessary measures may already be in place through the standard management process. Because of the complex nature of the fishery and the interaction of various stocks, regulations will need to be adjusted over the periods of the rebuilding plans. Management measures will be adjusted, or new measures will be developed and implemented in the future, in order to best implement each rebuilding plan throughout the life of that plan.

Once a rebuilding plan is adopted, certain measures required in the rebuilding plan may need to be implemented through authorities and processes already described in the FMP. Management actions to achieve OY harvest, and objectives related to rebuilding requirements of the Magnuson-Stevens Act and goals and objectives of the FMP (each of which may require a slightly different process) include: automatic actions, notices, abbreviated rulemaking actions, and full rulemaking actions. (These actions are detailed in Section 4.6, Chapter 5, and Section 6.2.) Allocation proposals require consideration as specified in the allocation framework (see Section 6.2.3.1). Any proposed regulations to implement the rebuilding plan will be developed in accordance with the framework procedures of this FMP.

Any rebuilding management measures that are not already authorized under the framework of the existing FMP, or specified in the FMP consequent of rebuilding plan adoption, will be implemented by further FMP amendments. These plan amendments may establish the needed measures or expand the framework to allow the implementation of the needed measures under framework procedures.

The Council may designate a state or states to take the lead in working with its citizens to develop management proposals to achieve stock rebuilding.

4.5.3.6 Periodic Review of Rebuilding Plans

Rebuilding plans will be reviewed periodically, but at least every two years, although the Council may propose revisions to an adopted rebuilding plan at any time. These reviews will take into account the goals and objectives listed in Section 4.5.3.1, recognizing that progress towards the first goal, to achieve the population size and structure that will support MSY within the specified time period, will only be evaluated on receipt of new information from the most recent stock assessment. ~~In evaluating progress towards achieving target biomass, the Council will use the standard identified in the rebuilding plan. When drafting a rebuilding plan one of the following standards, or a standard similar in kind to the following, may be chosen:~~

- ~~If the probability of achieving the target biomass within the maximum permissible time period (T_{MAX}) falls below 50% (the required minimum value), then progress will be considered inadequate.~~

- ~~If the probability of achieving the target biomass within the maximum permissible time period (T_{MAX}) falls below the value identified in the rebuilding plan, then progress will be considered inadequate.~~

The Council, in consultation with the SSC and GMT, will determine on a case-by-case basis whether there has been a significant change in a parameter such that the chosen management target must be revised. If, based on this review, the Council decides that the harvest control rule or target year must be changed, the procedures outlined in Section 4.5.3.3 will be followed. Regardless of the Council's schedule for reviewing overfished species rebuilding plans, the Secretary of Commerce, through NMFS, is required to review the progress of overfished species rebuilding plans toward rebuilding goals every two years, per Magnuson-Stevens Act at 16 U.S.C. §304(e)(7).

4.5.3.7 Precedence of a Recovery Plan or "No Jeopardy" Standard Issued Pursuant to the Endangered Species Act

Like rebuilding plans pursuant to National Standard 1 in the Magnuson-Stevens Act, a recovery plan pursuant to the Endangered Species Act outlines measures for the conservation and survival of the designated species. Under Section 7 of the Endangered Species Act an agency must consult NMFS when any activity permitted, funded, or conducted by that agency may affect a listed marine species or its designated critical habitat. (In the case of fishery management actions, NMFS is both the action and consulting agency.) As part of these consultations, a biological opinion is produced describing standards that must be met when permitting or implementing the action to ensure that the action is not likely to jeopardize the continued existence of the listed species; these are referred to as "no jeopardy" standards.

Measures under a recovery plan or "no jeopardy" standards in a biological opinion will supercede rebuilding plan measures and targets if they will result in the stock rebuilding to its target biomass by an earlier date than the target year identified in the current rebuilding plan. (If expressed probabilistically, any ESA standard expressed as a combination of date and probability that constitutes a higher standard will take precedence over the equivalent target and probability in the rebuilding plan. For example, an ESA standard requiring recovery by the rebuilding plan target year, but with a higher probability, would take precedence over the rebuilding plan.) If a stock is de-listed before reaching its target biomass, the rebuilding plan will come back into effect until such time as the stock is fully rebuilt.

4.5.4 Summary of Rebuilding Plan Contents

As noted in Section 4.5.3.3, this section summarizes the contents of rebuilding plans, including the values for rebuilding parameters, at the time of their adoption. The specified numerical values for these parameters are likely to change over time. This section will not be amended to incorporate any revised values. As described in Section 4.5.3.4, if the numerical specification of the harvest control rule or target year for a given overfished species is changed, the new value will be published in federal groundfish regulations. In addition, subsequent SAFE documents may include updated values for the parameters listed in Section 4.5.3.3 and Table 4-1.

In 1999, NMFS notified the Council that the coastwide lingcod stock was considered overfished. Amendment 16-2 to the FMP included a rebuilding plan for lingcod that set a T_{TARGET} rebuilding date of 2009. However, the lingcod stock rebuilt faster than the Council had initially anticipated. The 2005 lingcod stock assessment showed that the coastwide stock had rebuilt to a level exceeding statutory requirements, B_{MSY} or B_{40}. Amendment 16-4, therefore, removed the lingcod rebuilding plan from the FMP.

4.5.4.1 Darkblotched Rockfish

Status of the Darkblotched Stock and Fisheries Affected by Stock Rebuilding Measures at the Time of the Council's Rebuilding Plan Adoption (June 2003)

Historically, darkblotched rockfish were managed as part of a coastwide Sebastes complex, which was later segregated into north and south management units divided at 40°30' N latitude. As a result, fishery-dependent data from this period are generally unavailable. The first darkblotched rockfish stock assessment estimated the proxy MSY harvest rate and overfishing rate for the stock (Lenarz 1993).

Rogers et al. (2000) assessed darkblotched stock status in 2000 and determined the stock was at 14% to 31% of its unfished level. This range in biomass estimates encompasses the MSST threshold of 25%; uncertainty in past catches by foreign vessels, which targeted Pacific ocean perch and also caught darkblotched rockfish, was the most important contributor to this wide range for the biomass estimate. A larger unfished biomass (B_0) is computed using larger historic catch estimates. Since the MSST is expressed as a percent of unfished biomass, a larger B_0 increases the absolute value of this threshold, making an overfished determination more likely. Without definitive information on foreign catches, managers assumed darkblotched comprised 10% of this catch, leading to the conclusion that the spawning stock biomass was 22% of its unfished level. Because this is below the MSST, the stock was declared overfished in 2000.

The Council adopted a rebuilding plan for darkblotched rockfish at its June 2003 meeting, as described by the parameter values listed in Table 4-1. These values are based on a rebuilding analysis conducted by Methot and Rogers (2001).

Darkblotched rockfish occur on the outer continental shelf and continental slope, mainly north of Point Reyes. Because of this distribution they are caught exclusively by commercial vessels. Most landings have been made by bottom trawl vessels targeting flatfish on the continental shelf, rockfish on the continental slope, and the Dover sole–thornyhead–sablefish complex, also on the slope.

Methods Used to Calculate Stock Rebuilding Parameters

The methods used by Methot and Rogers in their rebuilding analysis do not differ substantially from the approach described in Section 4.5.2.

Rebuilding Parameter Values at the Time of Rebuilding Plan Adoption

Table 4-1 lists the numerical values for B_0, B_{MSY}, T_{MIN}, T_{MAX}, P_{MAX}, T_{TARGET} and F. The values of B_0, B_{MSY}, T_{MIN}, and T_{MAX} are derived from the rebuilding analysis used in formulating the rebuilding plan (Methot and Rogers 2001). The Council chose a value of 80% for P_{MAX}, based on a harvest control rule of F = 0.027. This results in a target year of 2030.

Darkblotched Rockfish Rebuilding Strategy

As shown in Table 4-1, at the inception of the rebuilding plan the harvest control rule for darkblotched rockfish was a fishing mortality rate of 0.027. Based on the 2001 rebuilding analysis, this harvest rate is likely to rebuild the stock by the target year of 2030. This value is likely to change over time as stock size and structure changes. Any updated value will be published in federal groundfish regulations. The fishing mortality rate is applied to the exploitable biomass estimate to determine the OY for a given fishing period.

Management measures are implemented through the biennial harvest specification and management process described in Chapter 5. The types of management measures that may be implemented through this process are described in Chapter 6. In 2003, at the time of rebuilding plan adoption, measures intended to limit bycatch of overfished species included prohibiting retention of certain overfished species during some parts of the year, reducing landing limits (cumulative trip limits) on co-occurring species, establishing extensive time/area closures, and restricting the use of trawl nets equipped with large footropes. (By using large footropes with heavy roller gear, bottom trawlers can access rocky habitat on the continental shelf. This is the preferred habitat for some overfished species.)

Beginning in 2002 time/area closures, referred to as Groundfish Conservation Areas (GCAs), came into use as a way of decreasing bycatch of overfished species. GCAs enclose depth ranges where bycatch of overfished species is most likely to occur, based on information retrieved from log books and the at-sea observer program. The boundaries vary by season and fishery sector, and may be modified in response to new information about the geographic and seasonal distribution of bycatch.

To limit darkblotched rockfish bycatch, an outer boundary of the GCA was set to move fishing activity into deeper water, away from the depth range of higher abundance for this species. In 2003 this outer boundary was modified during the winter months to allow targeting of petrale sole and other flatfish in shallower depths while still minimizing bycatch. The cumulative trip limits for minor slope rockfish north of Cape Mendocino, the species complex that darkblotched rockfish are managed under, and for splitnose rockfish, a co-occurring target species, were also lowered. Trip limits for other target species also may be adjusted to reduce darkblotched rockfish bycatch.

4.5.4.2 Pacific Ocean Perch

Status of the Pacific Ocean Perch Stock and Fisheries Affected by Stock Rebuilding Measures at the Time of the Council's Rebuilding Plan Adoption (June 2003)

Pacific Ocean Perch (POP) were targeted by Soviet and Japanese factory trawlers between 1965 and 1975. Their large catches during this period substantially contributed to a decline in the West Coast stock. In 1981, just before this FMP was implemented, the Council declared the POP stock depleted and recommended conservative harvest policies. Although management measures discouraged targeting POP while allowing continued fishing on other species, the stock did not recover and the Council recommended still more restrictive measures. A 1998 stock assessment (Ianelli and Zimmerman 1998) estimated POP biomass was 13% of the unfished level, leading NMFS to declare the stock overfished in 1999.

The Council adopted a rebuilding plan for POP at its June 2003 meeting, as described by the parameter values listed in Table 4-1. These values are based on a 2000 stock assessment (Ianelli, *et al.* 2000) and subsequent rebuilding analysis (Punt and Ianelli 2001). A retrospective analysis of foreign fleet catches, underway at the time of rebuilding plan adoption, may change the rebuilding period estimates on which the rebuilding plan is based.

POP tend to occur at similar depths as darkblotched rockfish, although they have a more northerly geographic distribution. As a result, POP are caught in similar fisheries as darkblotched rockfish, but only north of Cape Mendocino. At the time the rebuilding plan was adopted, limited entry trawl vessels targeting flatfish, including petrale sole and arrowtooth flounder, accounted for more than 90% of all POP landings. POP are not an important component of the recreational fishery.

Methods Used to Calculate Stock Rebuilding Parameters

The methods used in the rebuilding analysis used to develop the rebuilding plan (Punt and Ianelli 2001) do not differ substantially from the approach described in Section 4.5.2.

Rebuilding Parameter Values at the Time of Rebuilding Plan Adoption

Table 4-1 lists the numerical values for B_0, B_{MSY}, T_{MIN}, T_{MAX}, P_{MAX}, T_{TARGET} and F. The values of B_0, B_{MSY}, T_{MIN}, and T_{MAX} are derived from the rebuilding analysis used in formulating the rebuilding plan (Punt and Ianelli 2001). The Council chose a value of 70% for P_{MAX}, based on a harvest control rule of F = 0.0082. This results in a target year of 2027.

Pacific Ocean Perch Rebuilding Strategy

As shown in Table 4-1, at the inception of the rebuilding plan the harvest control rule for POP was a fishing mortality rate of 0.0082. Based on the 2001 POP rebuilding analysis (Punt and Ianelli 2001), this harvest rate is likely to rebuild the stock by the target year of 2027. This value is likely to change over time as stock size and structure changes. Any updated value will be published in federal groundfish regulations. The fishing mortality rate is applied to the exploitable biomass estimate to determine the OY for a given fishing period.

Management measures are implemented through the biennial harvest specification and management process described in Chapter 5. The types of management measures that may be implemented through this process are described in Chapter 6. In 2003, at the time of rebuilding plan adoption, measures intended to limit bycatch of overfished species included prohibiting retention of certain overfished species during some parts of the year, reducing landing limits (cumulative trip limits) on co-occurring species, establishing extensive time/area closures, and restricting the use of trawl nets equipped with large footropes. (By using large footropes with heavy roller gear, bottom trawlers can access rocky habitat on the continental shelf. This is the preferred habitat for some overfished species.)

Beginning in 2002 time/area closures, referred to as Groundfish Conservation Areas (GCAs), came into use as a way of decreasing bycatch of overfished species. GCAs enclose depth ranges where bycatch of overfished species is most likely to occur, based on information retrieved from log books and the at-sea observer program. The boundaries vary by season and fishery sector, and may be modified in response to new information about the geographic and seasonal distribution of bycatch.

Because POP tend to co-occur with darkblotched rockfish, management measures applicable to that species also serve to constrain catches of POP. These measures include configuring the outer boundary of the GCA so that vessels fish in deeper water, where POP are less abundant. A cumulative trip limit, which represents the maximum amount of an identified species or species group that may be landed within the cumulative limit period (in 2003, two months) is also established for this species. Trip limits for overfished species are intended to discourage targeting on them while permitting any incidental catch to be landed. (Bycatch discarded at sea is more difficult to monitor.) As with darkblotched rockfish, trip limits for target species also may be adjusted in order to minimize bycatch of overfished species.

4.5.4.3 Canary Rockfish

<u>Status of the Canary Rockfish Stock and Fisheries Affected by Stock Rebuilding Measures at the Time of the Council's Rebuilding Plan Adoption (June 2003)</u>

Canary rockfish exploitation began in the early 1940s when World War II increased demand for protein (Alverson, *et al.* 1964; Browning 1980). Through this decade the trawl fishery expanded in Oregon and Washington, accounting for most of the canary rockfish catch; in California longlines were mainly used to target rockfish during this period. Other gear historically used to catch canary rockfish include hook-and-line (primarily vertical longline), shrimp trawls, and pots and traps. From 1966 until 1976 foreign trawlers were responsible for most of the harvest. After passage of the Magnuson Act in 1977 domestic vessels became the dominant harvesters of this species. In recent years canary rockfish have become an important recreational target north of Cape Mendocino.

Overfishing, or exceeding the MFMT, was detected by a 1994 stock assessments and subsequent update (Sampson 1996; Sampson and Stewart 1994). In both cases the harvest rate exceeded the F20% threshold. In 1999 two age-based stock assessments showed that the stock was overfished in a northern area comprising the Columbia and U.S. Vancouver management zones (Crone, *et al.* 1999) and in a southern area comprising Conception, Monterey, and Eureka management zones (Williams, *et al.* 1999). Based on these assessments, the stock was declared overfished in January 2000.

The first rebuilding analysis (Methot 2000a) used results from the northern area assessment to project rates of potential stock recovery. The stock was found to have extremely low productivity, defined as production of recruits in excess of the level necessary to maintain the stock at its current low level. According to the anlaysis, rates of recovery are highly dependent on the level of recent recruitment, which could not be estimated with high certainty.

A subsequent assessment (Methot and Piner 2002c) treated the stock as a single coastwide unit (covering the area from the Monterey zone through the U.S. Vancouver zone). This differed from past assessments, where northern and southern areas were treated separately. The lack of older, mature females in surveys and other assessment indices was another consideration in this assessment. Older females may simply have a higher natural mortality rate, or survey and fishing gear may be less effective at catching them. If these fish are in fact un-sampled, productivity estimates should be higher because older, larger fish are more fecund. Methot and Piner (2002c) combined these two hypotheses in a single age-structured version of the SSC-endorsed stock synthesis assessment model (Methot 2000b). They estimated the 2002 abundance of canary rockfish coastwide was about 8% of B_0.

The Canary rockfish rebuilding plan was adopted by the Council at its June 2003 meeting and is based on a 2002 rebuilding analysis (Methot and Piner 2002a). The 2002 rebuilding analysis updated the first rebuilding analysis for canary rockfish, completed in 2000, using information from the aforementioned stock assessment. The Council's rebuilding strategy, when combined with the results of this rebuilding analysis, required a substantial reduction in the OY for 2003. As a result, fisheries must be managed for canary rockfish bycatch, often limiting the amount of target species that may be harvested.

Canary rockfish are encountered in a relatively wide variety of both commercial and recreational fisheries. However, limited entry trawlers targeting flatfish and arrowtooth flounder account for a large proportion of the landed catch, mainly north of Cape Mendocino. Much smaller amounts are caught in the whiting and DTS limited entry trawl fisheries, and by fixed gear vessels targeting groundfish on the continental shelf. Charter vessels account for most of recreationally-caught canary rockfish, mainly off of Northern California and Oregon.

Methods Used to Calculate Stock Rebuilding Parameters

The methods used in the rebuilding analysis used to develop the rebuilding plan (Methot and Piner 2002a) do not differ substantially from the approach described in Section 4.5.2.

Rebuilding Parameter Values at the Time of Rebuilding Plan Adoption

Table 4-1 lists the numerical values for B_0, B_{MSY}, T_{MIN}, T_{MAX}, P_{MAX}, T_{TARGET} and F. The values of B_0, B_{MSY}, T_{MIN}, and T_{MAX} are derived from the rebuilding analysis used in formulating the rebuilding plan (Methot and Piner 2002a). The Council chose a value of 60% for P_{MAX}, based on a harvest control rule of F = 0.022. This results in a target year of 2074.

Canary Rockfish Rebuilding Strategy

As shown in Table 4-1, at the inception of the rebuilding plan the harvest control rule for canary rockfish was a fishing mortality rate of 0.022. Based on the 2002 canary rockfish rebuilding analysis (Methot and Piner 2002a), this harvest rate is likely to rebuild the stock by the target year of 2074. This value is likely to change over time as stock size and structure changes. Any updated value will be published in federal groundfish regulations. The fishing mortality rate is applied to the exploitable biomass estimate to determine the OY for a given fishing period.

Management measures are implemented through the biennial harvest specification and management process described in Chapter 5. The types of management measures that may be implemented through this process are described in Chapter 6. In 2003, at the time of rebuilding plan adoption, measures intended to limit bycatch of overfished species included prohibiting retention of certain overfished species during some parts of the year, reducing landing limits (cumulative trip limits) on co-occurring species, establishing extensive time/area closures, and restricting the use of trawl nets equipped with large footropes. (By using large footropes with heavy roller gear, bottom trawlers can access rocky habitat on the continental shelf. This is the preferred habitat for some overfished species.)

Beginning in 2002 time/area closures, referred to as Groundfish Conservation Areas (GCAs), came into use as a way of decreasing bycatch of overfished species. GCAs enclose depth ranges where bycatch of overfished species is most likely to occur, based on information retrieved from log books and the at-sea observer program. The boundaries vary by season and fishery sector, and may be modified in response to new information about the geographic and seasonal distribution of bycatch.

Canary rockfish prefer rocky areas on the continental shelf so management measures in use at the time of rebuilding plan adoption were intended to discourage fishing in these areas. Under the regulations in place during 2003, bottom trawling is prohibited in the GCA, which encompasses depth ranges where canary rockfish are most frequently caught. In addition, the aforementioned restrictions on the use of trawl nets equipped with large footropes discourage fishing in the rocky habitat preferred by this species. In areas shoreward of the GCA large footrope gear is prohibited, preventing trawlers from assessing rocky habitat in these shallower depths. In areas deeper than the GCA, either small or large footrope gear may be used, although large footrope gear is the preferred type in these depths. In addition, cumulative trip limits are structured to encourage vessels to fish exclusively in deep water where canary rockfish (as well as some other overfished species) are not encountered. Vessels are allowed to use all gear configurations during any given cumulative limit period (currently two months). However, vessels which use the small footrope configuration are restricted to lower cumulative trip limits than vessels using large footrope configurations. Since the large footrope configuration may only be used offshore of the GCA, these measures encourage fishing exclusively in deeper water to take advantage of the higher limits afforded this gear type.

Recreational fisheries are managed mainly through bag limits, size limits, and fishing seasons established for each West Coast state. Bag and size limits have been established for canary rockfish. In addition, managers have the option of closing areas to recreational fishing if needed to prevent the canary rockfish OY from being exceeded.

~~4.5.4.4 Lingcod~~

~~Status of the Lingcod Stock and Fisheries Affected by Stock Rebuilding Measures at the Time of the Council's Rebuilding Plan Adoption (June 2003)~~

~~A 1997 stock assessment concluded that the lingcod stock in the Columbia and Vancouver zones (including the Canadian portion of the Vancouver management zone) was less than 10% of B_0, below the B25% MSST (Jagielo, *et al.* 1997). The Council responded by imposing substantial harvest reductions coastwide, reducing the harvest targets for the Eureka, Monterey, and Conception areas by the same percentage as in the north. In 1999, scientists assessed the southern portion of the stock and concluded the condition of the southern stock was similar to the northern stock, thus confirming the Council had taken appropriate action to reduce harvest coastwide (Adams, *et al.* 1999). Based on these assessments,~~

~~the lingcod stock was declared overfished in 1999.~~

~~Subsequently, Jagielo (2000) conducted a coastwide lingcod assessment, which showed substantial increase in stock size and suggested that the stock was younger and more productive than previously thought. A revised rebuilding analysis of coastwide lingcod (Jagielo and Hastie 2001) was adopted by the Council in September 2001. It confirmed the major conclusions of the 2000 assessment and rebuilding analysis, but slightly modified recruitment projections to stay on the rebuilding trajectory that reaches target biomass in 2009. The rebuilding plan adopted by the Council at is June 2003 meeting is based on this 2001 update of the original rebuilding analysis produced by the same author. Because the minimum time period within which lingcod could be rebuilt is less than 10 years, the maximum allowable rebuilding period (T_{MAX}) is 10 years. The Council chose a target year equal to T_{MAX}, with the stock expected to rebuild by 2009.~~

~~Lingcod are encountered in a diverse array of commercial fisheries. Historically, limited entry trawl and limited entry fixed gear vessels accounted for the majority of lingcod landings. The open access sector, comprising many different gear types and fishing strategies, also lands a significant amount coastwide in nearshore and continental shelf areas. Lingcod are an important species in recreational fisheries, which account for an increasing portion of overall lingcod mortality as commercial landings declined drammatically beginning in 1998. Although recreational lingcod catches are reported coastwide, most of the recreational catch occurs off central and Northern California, with private boats making most of this catch.~~

~~Methods Used to Calculate Stock Rebuilding Parameters~~

~~The methods used in the rebuilding analysis used to develop the rebuilding plan (Jagielo and Hastie 2001) do not differ substantially from the approach described in Section 4.5.2.~~

~~Rebuilding Parameter Values at the Time of Rebuilding Plan Adoption~~

~~Table 4-1 lists the numerical values for B_0, B_{MSY}, T_{MIN}, T_{MAX}, P_{MAX}, T_{TARGET} and F. The values of B_0, B_{MSY}, T_{MIN}, and T_{MAX} are derived from the rebuilding analysis used in formulating the rebuilding plan (Jagielo and Hastie 2001). The Council chose a value of 60% for P_{MAX}, based on a harvest control rule of F = 0.0531 for the northern portion of the stock and F = 0.061 for the southern portion of the stock. This results in a target year of 2009.~~

~~Lingcod Rebuilding Strategy~~

~~As shown in Table 4-1, at the inception of the rebuilding plan the harvest control rule for canary rockfish was a fishing mortality rate of 0.0531 for the northern portion of the stock and 0.061 for the southern portion of the stock. Based on the 2001 lingcod rebuilding analysis (Jagielo and Hastie 2001), this harvest rate is likely to rebuild the stock by the target year of 2009. This value is likely to change over time as stock size and structure changes. Any updated value will be published in federal groundfish regulations. The fishing mortality rate is applied to the exploitable biomass estimate to determine the OY for a given fishing period.~~

~~Management measures are implemented through the biennial harvest specification and management process described in Chapter 5. The types of management measures that may be implemented through this process are described in Chapter 6. In 2003, at the time of rebuilding plan adoption, measures~~

~~intended to limit bycatch of overfished species included prohibiting retention of certain overfished species during some parts of the year, reducing landing limits (cumulative trip limits) on co-occurring species, establishing extensive time/area closures, and restricting the use of trawl nets equipped with large footropes. (By using large footropes with heavy roller gear, bottom trawlers can access rocky habitat on the continental shelf. This is the preferred habitat for some overfished species.)~~

~~Beginning in 2002 time/area closures, referred to as Groundfish Conservation Areas (GCAs), came into use as a way of decreasing bycatch of overfished species. GCAs enclose depth ranges where bycatch of overfished species is most likely to occur, based on information retrieved from log books and the at-sea observer program. The boundaries vary by season and fishery sector, and may be modified in response to new information about the geographic and seasonal distribution of bycatch.~~

~~In addition to the more general measures described above, which are intended to reduce bycatch of all overfished species, lingcod landings by the limited entry fixed gear and open access sectors were prohibited during the winter months in 2003. Lingcod are more vulnerable in shallow depths (where vessels in these sectors are more likely to fish) during the winter because of their spawning behavior. For the same reason, retention of lingcod by recreational fishermen during winter months was prohibited in Washington and California during 2003. Recreational bag and size limits are also used to manage total lingcod fishing mortality.~~

4.5.4.~~5~~ 4 Bocaccio Rockfish

Status of the Bocaccio Stock and Fisheries Affected by Stock Rebuilding Measures at the Time of Rebuilding Plan Adoption (April 2004)

Assessment scientists and managers have treated West Coast bocaccio as independent stocks north and south of Cape Mendocino. The southern stock, which has been declared overfished, occurs south of Cape Mendocino and the northern stock north of 48° N latitude in northern Washington (off Cape Flattery). The overfished southern bocaccio rockfish stock occurs in Central and Southern California waters, on the continental shelf and in nearshore areas, often in rocky habitat. They are caught in both commercial and recreational fisheries in approximately equal amounts. Commercial catches mainly occur in limited entry trawl fisheries.

Bocaccio have long been an important component of California rockfish fisheries. Catches increased to high levels in the 1970s and early 1980s as relatively strong year-classes recruited to the stock. The Council began to recommend increasingly restrictive regulations after an assessment of the southern stock in 1990 (Bence and Hightower 1990) indicated that fishing rates were too high. The southern stock has been assessed six times (Bence and Hightower 1990; Bence and Rogers 1992; MacCall 2002; MacCall 2003b; MacCall, *et al.* 1999; Ralston, *et al.* 1996) and has suffered poor recruitment during the warm water conditions that have prevailed off Southern California since the late 1980s. The 1996 assessment (Ralston, *et al.* 1996) indicated the stock was in severe decline. NMFS formally declared the stock overfished in March 1999 after the groundfish FMP was amended to incorporate the tenets of the Sustainable Fisheries Act. MacCall et al. (1999) confirmed the overfished status of bocaccio and estimated spawning output of the southern stock to be 2.1% of its unfished biomass and 5.1% of the maximum sustainable yield (MSY) level. The northern stock of bocaccio has not been assessed.

While previous assessments only used data from Central and Northern California, an assessment in 2002 (MacCall and He 2002) also included data for southern California. While relative abundance increased slightly from the last assessment (4.8% of unfished biomass), potential productivity appears lower than previously thought, making for a more pessimistic outlook. The Council assumed a medium recruitment scenario for the 1999 year class, which was not assessed (MacCall, *et al.* 1999). The 2002 assessment revealed the 1999 year class experienced relatively lower recruitment. Therefore, although the 1999 year class contributed a substantial quantity of fish to the population, it did not contribute as much to rebuilding as was previously thought.

The 2003 bocaccio assessment differs greatly from the 2002 assessment. It is driven by the strength of the incoming 1999 year class that had not recruited into the indices used for the 2002 assessment and by a revised lower estimate of natural mortality (MacCall 2003b). In addition to the 2001 Triennial Survey data, the 2003 assessment used larval abundance data from recent CalCOFI surveys as well as length and catch per unit effort (CPUE) data from recreational fisheries. In calculating the recreational CPUE information, a new method was used that identifies relevant fishing trips by species composition and adjusts the catch history for regulatory changes that affect the level of discard and avoidance. The results of these calculations suggest that recreational CPUE has increased dramatically in recent years and is at a record high level in Central California north of Pt. Conception. The STAR Panel recommended the use of two assessment models as a means of bracketing uncertainty from the very different signals between the Triennial Survey and the recreational CPUE data. Following the Stock Assessment Review (STAR) Panel meeting, MacCall presented a third "hybrid" model that incorporated the data from all of the indices. The Scientific and Statistical Committee (SSC) recommended, and the Council approved, the use of this third modeling approach. This resulted in modest improvement in estimated stock size, but significantly affected the estimated productivity of the stock. These results had substantial effects on the rebuilding outlook for bocaccio which, under the 2002 assessment, was not expected to rebuild within T_{MAX} even with no fishing related mortality. Total mortality in 2003 fisheries was restricted to less than 20 mt as a means of conserving the stock while minimizing adverse socioeconomic impacts to communities. The current rebuilding analysis (MacCall 2003a), using the "hybrid" model, suggests the stock could rebuild to BMSY within 25 years while sustaining an optimum yield (OY) of approximately 300 mt in 2004.

The Council adopted a rebuilding plan for bocaccio rockfish at its April 2004 meeting, as described by the parameter values listed in Table 4-1. These values are based on a rebuilding analysis conducted by MacCall (2003b).

Fisheries in central and southern California are affected by the bocaccio rebuilding plan because the overfished population occurs in these waters. Recreational and limited entry trawl fisheries in this region have accounted for the bulk of landings in recent years.

Methods Used to Calculate Stock Rebuilding Parameters

The methods used by MacCall in his rebuilding analysis (MacCall 2003a) do not differ substantially from the approach described in Section 4.5.2.

Rebuilding Parameter Values at the Time of Rebuilding Plan Adoption

Table 4-1 lists the numerical values for B_0, B_{MSY}, T_{MIN}, T_{MAX}, P_{MAX}, T_{TARGET} and F. The values of B_0, B_{MSY}, T_{MIN}, and T_{MAX} are derived from the rebuilding analysis used in formulating the rebuilding plan (MacCall 2003a). Using the STATc base model from the most recent stock assessment (MacCall 2003b), the Council chose a value of 70% for P_{MAX}, based on a harvest control rule of F = 0.0498. This results in a target year of 2023.

Bocaccio Rockfish Rebuilding Strategy

As shown in Table 4-1, at the inception of the rebuilding plan the harvest control rule for bocaccio rockfish was a fishing mortality rate of 0.0498. Based on the 2003 rebuilding analysis, this harvest rate is likely to rebuild the stock by the target year of 2023. This value is likely to change over time as stock size and structure changes. Any updated value will be published in federal groundfish regulations. The fishing mortality rate is applied to the exploitable biomass estimate to determine the OY for a given fishing period.

Management measures are implemented through the biennial harvest specification and management process described in Chapter 5. The types of management measures that may be implemented through this process are described in Chapter 6. In 2004, at the time of rebuilding plan adoption, measures intended to limit bycatch of overfished species included prohibiting retention of certain overfished species during some parts of the year, reducing landing limits (cumulative trip limits) on co-occurring species, establishing extensive time/area closures, and restricting the use of trawl nets equipped with large footropes. (By using large footropes with heavy roller gear, bottom trawlers can access rocky habitat on the continental shelf. This is the preferred habitat for some overfished species.)

Beginning in 2002, time/area closures known as GCAs came into use as a way of decreasing bycatch of overfished species. GCAs enclose depth ranges where bycatch of overfished species is most likely to occur, based on information retrieved from logbooks and the at-sea observer program. The boundaries vary by season and fishery sector, and may be modified in response to new information about the geographic and seasonal distribution of bycatch.

As noted, a large proportion of bocaccio catch occurs in recreational fisheries in Central and Southern California. Recreational depth closures, restricting fishing to shallow waters, bag limits, and seasonal closures have been used to reduce recreational bocaccio catches.

4.5.4.~~6~~5 Cowcod

Status of the Cowcod and Fisheries Affected by Stock Rebuilding Measures at the Time of Rebuilding Plan Adoption (April 2004)

Relatively little is known about cowcod, a species of large rockfish that ranges from Ranger Bank and Guadalupe Island in central Baja California to Usal, Mendocino County, California (Miller and Lea 1972), and may infrequently occur as far north as Newport, Oregon. Cowcod have been assessed only once (Butler, *et al.* 1999). Adult cowcod are primarily found over high relief rocky areas (Allen 1982). They are generally solitary, but occasionally aggregate (Love, *et al.* 1990).

While cowcod are not a major component of the groundfish fishery, they are highly desired by both recreational and commercial fishers because of their bright color and large size. In recent years small amounts have been caught by limited entry trawl vessels and recreational anglers in Southern California. The cowcod stock south of Cape Mendocino has experienced a long-term decline. The cowcod stock in the Conception area was assessed in 1998 (Butler, *et al.* 1999). Abundance indices decreased approximately tenfold between the 1960s and the 1990s, based on commercial passenger fishing vessel (CPFV) logs (Butler, *et al.* 1999). Recreational and commercial catch also declined substantially from peaks in the 1970s and 1980s, respectively.

B_0 was estimated to be 3,370 mt, and 1998 spawning biomass was estimated at 7% of B_0, well below the

25% overfishing threshold. As a result, NMFS declared cowcod in the Conception and Monterey management areas overfished in January 2000. Large areas off Southern California (the Cowcod Conservation Areas [CCAs]) have been closed to fishing for cowcod. The stock's low productivity and declined spawning biomass also necessitates an extended rebuilding period, estimated at 62 years with no fishing-related mortality (T_{MIN}), to achieve a 1,350 mt BMSY for the Conception management area.

There is relatively little information about the cowcod stock, and there are major uncertainties in the one assessment that has been conducted. The assessment authors needed to make estimates of early landings based on more recent data and reported total landings of rockfish. Age and size composition of catches are poorly sampled, population structure is unknown, and the assessment was restricted to Southern California waters.

A cowcod rebuilding review was completed in 2003, which validated the assumption that non-retention regulations and area closures have been effective in constraining cowcod fishing mortality (Butler, *et al.* 2003). These results, although encouraging, are based on cowcod fishery-related removals from CPFV observations and angler reported discards. Non-retention regulations and limited observation data have increased the need for fishery independent population indices.

The Council adopted a rebuilding plan for cowcod at its April 2004 meeting, as described by the parameter values listed in Table 4-1. These values are based on a rebuilding analysis conducted by Butler and Barnes (2000).

Methods Used to Calculate Stock Rebuilding Parameters

The Cowcod rebuilding analysis (Butler and Barnes 2000) was completed before the SSC default rebuilding analysis methodology (Punt 2002), described in Section 4.5.2 , had been developed. Instead, it uses a surplus production model using a log-normal distribution fitted to recruitment during 1951-1998. At the time of rebuilding plan adoption (2004) a new cowcod stock assessment and rebuilding analysis had not been completed. In April 2004 the SSC recommended that future cowcod stock assessments use a model whose output can be used in the default rebuilding analysis methodology.

Rebuilding Parameter Values at the Time of Rebuilding Plan Adoption

Table 4-1 lists the numerical values for B_0, B_{MSY}, T_{MIN}, T_{MAX}, P_{MAX}, T_{TARGET} and F. The values of B_0, B_{MSY}, T_{MIN}, and T_{MAX} are derived from the rebuilding analysis (Butler and Barnes 2000) used in formulating the rebuilding plan. The Council chose a value of 60% for P_{MAX}, based on a harvest control rule of F = 0.009. This results in a target year of 2090.

Cowcod Rebuilding Strategy

As shown in Table 4-1, at the inception of the rebuilding plan the harvest control rule for cowcod was a fishing mortality rate of 0.009. Based on the 2000 cowcod rebuilding analysis (Butler and Barnes 2000), this harvest rate is likely to rebuild the stock by the target year of 2090. This value is likely to change over time as stock size and structure changes. Any updated value will be published in federal groundfish regulations. The fishing mortality rate is applied to the exploitable biomass estimate to determine the OY for a given fishing period.

Management measures are implemented through the biennial harvest specification and management process described in Chapter 5. The types of management measures that may be implemented through this process are described in Chapter 6. In 2004, at the time of rebuilding plan adoption, measures intended to limit bycatch of overfished species included prohibiting retention of certain overfished species during some parts of the year, reducing landing limits (cumulative trip limits) on co-occurring species, establishing extensive time/area closures, and restricting the use of trawl nets equipped with large footropes. (By using large footropes with heavy roller gear, bottom trawlers can access rocky habitat on the continental shelf. This is the preferred habitat for some overfished species.)

Beginning in 2002, time/area closures known as GCAs came into use as a way of decreasing bycatch of overfished species. GCAs enclose depth ranges where bycatch of overfished species is most likely to occur, based on information retrieved from logbooks and the at-sea observer program. The boundaries vary by season and fishery sector, and may be modified in response to new information about the geographic and seasonal distribution of bycatch.

Because cowcod is a fairly sedentary species, establishment of a marine protected area, considered one of the GCAs, is the key strategy for limiting cowcod fishing mortality. The CCAs in the Southern California Bight encompasses two areas of greatest cowcod density, as estimated in 2000, based on historical cowcod catch and catch rates in commercial and recreational fisheries. To aid in enforcement, the CCAs are bounded by straight lines enclosing simple polygons. Butler, et al. (2003) concluded that the CCAs have been effective in reducing bycatch to levels projected to allow stock rebuilding. Estimated fishery removals have been at levels sufficient to rebuild the stock, since the CCAs were implemented, except in 2001 when 5.6 mt was caught in the Conception management area. Most of this catch occurred in the spot prawn trawl fishery, which subsequently has been phased out.

Given the particular life history characteristics of cowcod, the Council will continue to use species-specific area closures to protect cowcod. As new information becomes available on cowcod behavior and fisheries interactions with cowcod, the boundaries or related regulations concerning the current CCAs may change, and additional CCAs may be established by regulation.

4.5.4.~~7~~ 6 Widow Rockfish

Status of the Widow Rockfish Stock and Fisheries Affected by Stock Rebuilding Measures at the Time of Rebuilding Plan Adoption (April 2004)

Widow rockfish are an important commercial species from British Columbia to central California, particularly since 1979, when an Oregon trawl fisherman demonstrated the ability to make large catches at night using midwater trawl gear. Since that time, many more participants entered the fishery and landings of widow rockfish increased rapidly (Love, *et al.* 2002). Because widow rockfish are commonly distributed in the mesopelagic (midwater) zone they are most commonly caught in with midwater trawl gear, which sweeps this zone (in contrast to bottom trawl gear used to target most groundfish species). Historically, widow rockfish were a major target species. Landings peaked at 12,473 mt in 1989 and as recently as 2000 stood at 3,866 mt (PFMC 2002). Target fisheries were eliminated after widow rockfish were declared overfished in 2001. Currently, the Pacific whiting fishery accounts for about three-quarters of widow rockfish catches; a small directed fishery for yellowtail rockfish, prosecuted by Washington treaty Indian Tribes, and the limited entry fixed gear sector account for almost all of the remaining incidental catches. Most catches occur in the U.S.-Vancouver, Columbia, and Eureka management areas.

Williams, et al. (2000) assessed the widow rockfish in 2000. The spawning output level (8,223 mt), based on that assessment and a revised rebuilding analysis (Punt and MacCall 2002) adopted by the Council in June 2001, was at 23.6% of the unfished level (33,490 mt) in 1999. This result was computed using the average recruitment from 1968 to 1979 multiplied by the spawning output-per-recruit at F = 0. The analysis concluded the rebuilding period in the absence of fishing is 22 years, and with a mean generation time of 16 years, the maximum allowable time to rebuild (T_{MAX}) is 38 years. Widow rockfish were declared overfished in 2001 based on these analyses.

The most recent assessment (He, *et al.* 2003b) concluded that the widow rockfish stock size is 22.4% of the unfished biomass, but indicates stock productivity is considerably lower than previously thought. Data sparseness was a significant problem in this widow rockfish assessment (Conser, *et al.* 2003; He, *et al.* 2003b). Limited logbook data prior to 1990 is available from bottom trawl fisheries, a questionable data source for a midwater species. The NMFS laboratory at Santa Cruz conducts a midwater trawl survey from which a juvenile index is derived. This index has been highly variable in its ability to predict recruitment, in part, due to the survey's limited geographical area relative to the overall distribution of widow rockfish. The widow rockfish rebuilding analysis considered a wide range of model formulations that investigated different hypothesis on natural mortality, stock-recruitment variability, and the use of a power coefficient to reduce variability of the Santa Cruz midwater juvenile survey. The SSC recommended model formulations that pre-specify the recruitment for 2003-2005, do not use a stock-recruitment relationship (recruits per spawner ratios were used instead to project future recruitment), and vary the power coefficient between two and four in the Santa Cruz midwater juvenile survey. The SSC did not recommend a power coefficient higher than four because the relationship between the Santa Cruz midwater survey recruitment index and other recruitment indices changed dramatically with higher powers. The previous rebuilding analysis (Punt and MacCall 2002) had used a power coefficient of 10 that dampened the estimate of recruitment variability and suggested much higher stock productivity.

Many of the rebuilding parameters for widow rockfish did not change dramatically with the new rebuilding analysis. The rebuilding period in the absence of fishing increased to 25 years and, with a mean generation time of 16 years; the maximum allowable time to rebuild (T_{MAX}) is 41 years. However, the harvest rate associated with different rebuilding strategies dropped significantly in response to the new understanding of decreased stock productivity. Thus, the interim rebuilding OY for 2003 using the 2000 rebuilding analysis was 832 mt, while in 2004, using the 2003 rebuilding analysis (He, *et al.* 2003a), the OY was 284 mt (using the base model, Model 8, which uses a power coefficient of three).

The Council adopted a rebuilding plan for widow rockfish at its April 2004 meeting, as described by the parameter values listed in Table 4-1. These values are based on a rebuilding analysis conducted by He, et al. (He, *et al.* 2003a).

Methods Used to Calculate Stock Rebuilding Parameters

The methods used in the rebuilding analysis He, et al. (He, *et al.* 2003a) used to develop the rebuilding plan do not differ substantially from the approach described in Section 4.5.2.

Rebuilding Parameter Values at the Time of Rebuilding Plan Adoption

Table 4-1 lists the numerical values for B_0, B_{MSY}, T_{MIN}, T_{MAX}, P_{MAX}, T_{TARGET}, and F. The values of B_0, B_{MSY}, T_{MIN}, and T_{MAX} are derived from the rebuilding analysis used in formulating the rebuilding plan (He, *et al.* 2003a). Using Model 8, the base model from the 2003 stock assessment (He, *et al.* 2003b), the Council chose a value of 60% for P_{MAX}, based on a harvest control rule of F = 0.0093. This results in a target year of 2038.

Widow Rockfish Rebuilding Strategy

As shown in Table 4-1, at the inception of the rebuilding plan the harvest control rule for canary rockfish was a fishing mortality rate of 0.0093. Based on the 2003 widow rockfish rebuilding analysis (He, et al. 2003a), this harvest rate is likely to rebuild the stock by the target year of 2038. This value is likely to change over time as stock size and structure changes. Any updated value will be published in federal groundfish regulations. The fishing mortality rate is applied to the exploitable biomass estimate to determine the OY for a given fishing period.

Management measures are implemented through the biennial harvest specification and management process described in Chapter 5. The types of management measures that may be implemented through this process are described in Chapter 6. In 2004, at the time of rebuilding plan adoption, measures intended to limit bycatch of overfished species included prohibiting retention of certain overfished species during some parts of the year, reducing landing limits (cumulative trip limits) on co-occurring species, establishing extensive time/area closures, and restricting the use of trawl nets equipped with large footropes. Because widow rockfish are mainly caught in the water column, bottom trawl gear restrictions have little effect on widow rockfish catch rates.

Beginning in 2002, time/area closures known as GCAs came into use as a way of decreasing bycatch of overfished species. GCAs enclose depth ranges where bycatch of overfished species is most likely to occur, based on information retrieved from logbooks and the at-sea observer program. The boundaries vary by season and fishery sector, and may be modified in response to new information about the geographic and seasonal distribution of bycatch.

Because widow rockfish occur in midwater and aggregate at night, elimination of target fishery opportunities is a relatively easy way of reducing widow rockfish bycatch. The Council has taken a policy approach of establishing management measures to reduce incidental catch in the Pacific whiting fishery sufficient to constrain total mortality below harvest levels (OYs) needed to rebuild the stock. At the time of rebuilding plan adoption, catch in other fisheries is sufficiently small so that rebuilding targets can be met without applying any special measures, beyond those needed to discourage targeting, to reduce widow rockfish fishing mortality in these fishery sectors.

Widow rockfish catches in recreational fisheries are relatively modest. Catches in this sector are managed mainly through bag limits, size limits, and fishing seasons established for each West Coast state. No recreational bag and size limits have been established for widow rockfish. However, general bag limits for rockfish may have some constraining effect on widow recreational catches.

4.5.4.~~8~~ 7 Yelloweye Rockfish

Status of the Yelloweye Rockfish Stock and Fisheries Affected by Stock Rebuilding Measures at the Time of Rebuilding Plan Adoption (April 2004)

Yelloweye rockfish are common from Central California northward to the Gulf of Alaska. They are bottom-dwelling, generally solitary, rocky reef fish, found either on or just over reefs (Eschmeyer, *et al.* 1983; Love 1991; Miller and Lea 1972; O'Connell and Funk 1986). Boulder areas in deep water (>180 m) are the most densely populated habitat type, and juveniles prefer shallow-zone broken-rock habitat

(O'Connell and Carlile 1993). They also reportedly occur around steep cliffs and offshore pinnacles (Rosenthal, *et al.* 1982). The presence of refuge spaces is an important factor affecting their occurrence (O'Connell and Carlile 1993). Yelloweye rockfish are potentially caught in a range of both commercial and recreational fisheries. Because of their preference for rocky habitat, they are more vulnerable to hook and line gear.

The first ever yelloweye rockfish stock assessment was conducted in 2001 (Wallace 2002). This assessment incorporated two area assessments: one from Northern California using CPUE indices constructed from Marine Recreational Fisheries Statistical Survey (MRFSS) sample data and California Department of Fish and Game (CDFG) data collected on board commercial passenger fishing vessels, and the other from Oregon using Oregon Department of Fish and Wildlife (ODFW) sampling data. The assessment concluded current yelloweye rockfish stock biomass is about 7% of unexploited biomass in Northern California and 13% of unexploited biomass in Oregon. The assessment revealed a thirty-year declining biomass trend in both areas with the last above average recruitment occurring in the late 1980s. The assessment's conclusion that yelloweye rockfish biomass was well below the 25% of unexploited biomass threshold for overfished stocks led to this stock being separated from the rockfish complexes in which it was previously listed. Until 2002, when yelloweye rockfish were declared overfished, they were listed in the "remaining rockfish" complex on the shelf in the Vancouver, Columbia, and Eureka management areas and the "other rockfish" complex on the shelf in the Monterey and Conception areas. As with the other overfished stocks, yelloweye rockfish harvest is now tracked separately.

In June 2002 the SSC recommended that managers should conduct a new assessment incorporating Washington catch and age data. This recommendation was based on evidence that the biomass distribution of yelloweye rockfish on the West Coast was centered in waters off Washington and that useable data from Washington were available. Based on that testimony, the Council recommended completing a new assessment in the summer of 2002, before a final decision was made on 2003 management measures. Methot et al. (2002b) did the assessment, which was reviewed by a STAR Panel in August 2002. The assessment result was much more optimistic than the one prepared by Wallace (2002), largely due to the incorporation of Washington fishery data. While the overfished status of the stock was confirmed (24% of unfished biomass), Methot et al. (2002b) provided evidence of higher stock productivity than originally assumed. The assessment also treated the stock as a coastwide assemblage. This assessment was reviewed and approved by the SSC and the Council at the September 2002 Council meeting. Methot and Piner (2002) prepared a rebuilding analysis based on this assessment.

The Council adopted a rebuilding plan for yelloweye rockfish at its April 2004 meeting, as described by the parameter values listed in Table 4-1. These values are based on a rebuilding analysis conducted by Methot and Piner (2002a).

Because yelloweye rockfish prefer rocky reef habitat on the continental shelf, they are most vulnerable to recreational and commercial fixed gear fisheries. In the past, the groundfish trawl sector has accounted for a large proportion of the catch: from 1990 to 1997 trawlers took an average of 46% of the catch coastwide (although most catches occur in Washington and Oregon waters). (This discussion is based on data in the table on page 3 of Methot, *et al.* 2003.) Trip limit reductions after 1997 and the imposition of restrictions on large footrope trawl gear in 2000 have substantially diminished the amount of yelloweye rockfish caught by the trawl sector. (Large footrope gear had made it possible for trawlers to access the rocky habitat where yelloweye live.) Trawl vessels accounted for only 14% of the catch on average from 1998 to 2001. Commercial fixed gear catches have also taken a significant share of the catch, 38% in the years 1990-1997. However, the implementation of the nontrawl RCA, which encloses much yelloweye habitat, has resulted in their share falling also. Open access directed groundfish fisheries and the Pacific halibut longline fleet also catch small amounts of yelloweye rockfish. Recreational catches have become more significant with the reduction in commercial catches. Comparing the 1990-1997 and 1998-2001 periods, their share of the total coastwide catch almost doubled to 30%, although actual average catches declined slightly. Most recreational catches occur in Washington State waters.

Methods Used to Calculate Stock Rebuilding Parameters

The methods used in the rebuilding analysis (Methot and Piner 2002a) used to develop the rebuilding plan do not differ substantially from the approach described in Section 4.5.2.

Rebuilding Parameter Values at the Time of Rebuilding Plan Adoption

Table 4-1 lists the numerical values for B_0, B_{MSY}, T_{MIN}, T_{MAX}, P_{MAX}, T_{TARGET}, and F. The values of B_0, B_{MSY}, T_{MIN}, and T_{MAX} are derived from the rebuilding analysis used in formulating the rebuilding plan (Methot and Piner 2002a). The Council chose a value of 80% for P_{MAX}, based on a harvest control rule of F = 0.0153. This results in a target year of 2058.

Yelloweye Rockfish Rebuilding Strategy

As shown in Table 4-1, at the inception of the rebuilding plan the harvest control rule for canary rockfish was a fishing mortality rate of 0.0153. Based on the 2002 rebuilding analysis (Methot and Piner 2002), this harvest rate is likely to rebuild the stock by the target year of 2058. This value is likely to change over time as stock size and structure changes. Any updated value will be published in federal groundfish regulations. The fishing mortality rate is applied to the exploitable biomass estimate to determine the OY for a given fishing period.

Management measures are implemented through the biennial harvest specification and management process described in Chapter 5. The types of management measures that may be implemented through this process are described in Chapter 6. In 2004, at the time of rebuilding plan adoption, measures intended to limit bycatch of overfished species included prohibiting retention of certain overfished species during some parts of the year, reducing landing limits (cumulative trip limits) on co-occurring species, establishing extensive time/area closures, and restricting the use of trawl nets equipped with large footropes. (By using large footropes with heavy roller gear, bottom trawlers can access rocky habitat on the continental shelf. This is the preferred habitat for some overfished species.)

Beginning in 2002, time/area closures known as GCAs came into use as a way of decreasing bycatch of overfished species. GCAs enclose depth ranges where bycatch of overfished species is most likely to occur, based on information retrieved from logbooks and the at-sea observer program. The boundaries vary by season and fishery sector, and may be modified in response to new information about the geographic and seasonal distribution of bycatch.

In addition to the more general measures described above, which are intended to reduce bycatch of all overfished species, the Yelloweye Rockfish Conservation Area (YRCA), a C-shaped closed area off the Washington coast, near Cape Flattery, prevents recreational groundfish and halibut anglers from targeting this species in an area where they are concentrated. Recreational bag and size limits are also used to manage total yelloweye rockfish fishing mortality.

Given the particular life history characteristics of yelloweye rockfish, the Council will continue to use a species-specific area closure or closures to protect yelloweye rockfish. As new information becomes available on yelloweye rockfish behavior and fisheries interactions with yelloweye rockfish, the boundaries or related regulations concerning the current YRCA may change, and additional YRCAs may be established by regulation.

TABLE 4-1. Specified rebuilding plan parameters at the time of plan adoption. (Page 1 of 1).

Species	Year Stock Declared Overfished	Year Rebuilding Plan Adopted	B_0	B_{MSY}	T_{MIN}	T_{MAX}	P_{MAX}	T_{TARGET}	Harvest Control Rule
Darkblotched Rockfish	2000	2003	29,044 mt	11,618 mt	2014	2047	80%	2030	F = 0.027

[Amended: 11, 12, 16-1, 16-2, 16-3]

4.6 Determination of OY

Optimum yield (OY) is defined in the Magnuson-Stevens Fishery Conservation and Management Act (Magnuson-Stevens Act) as the amount of fish which will provide the greatest overall benefit to the Nation. The Magnuson-Stevens Act also specifies that OY is based on maximum sustainable yield (MSY), and may be equal to or less than MSY. The fishery management plan (FMP) authorizes establishment of a numerical or non-numerical OY for any groundfish species or species group and lays out the procedures the Council will follow in determining appropriate numerical OY values. An OY may be specified for the fishery management area as a whole or for specific subareas. Numerical one-year OYs will be specified biennially, based on acceptable biological catches (ABCs) for major species or species groups, which are in turn based on quantitative or qualitative stock assessments. "Control rules" for determining the numerical values of OYs ensure they will not exceed the ABCs except under tightly limited conditions.

Most of the 80-plus species managed by the FMP have never been assessed in either a quantitative or qualitative manner. In some cases even basic catch statistics are unavailable, because many species (rockfish, for example) are not sorted unless specifically required by regulation. Species of this type have generally not been subject to numerical harvest limits, but rather harvest is limited by gear restrictions and market demand. Other management measures which determine the total amount of harvest each year include trip landing and frequency limits. Those species without a specified OY and not included in a multi-species OY will be included in a non-numerical OY, which is defined as all the fish that can be taken under the regulations, specifications, and management measures authorized by the FMP and promulgated by the U.S. Secretary of Commerce. This non-numerical OY is not a predetermined numerical value, but rather the harvest that results from regulations, specifications, and management measures as they are changed in response to changes in the resource and the fishery. In many cases, the absence of a numerical specification reflects the absence of basic management information, such as abundance estimates and catch statistics. The non-numerical OY concept allows for a variable amount of groundfish to be harvested annually, limited by such constraints as gear restrictions, management measures for other species, and/or absence of consumer acceptance or demand.

The close spatial relationship of many groundfish species throughout the management area results in commercial and recreational catches often consisting of mixtures of several species. This is especially the case in the trawl fishery where fishermen may target on one species, but unavoidably harvest several other species. In such cases, the optimum harvest strategy often is to target on a group (complex or assemblage) of groundfish species.

The Council will avoid allowing overfishing individual stocks and control harvest mortality to allow overfished stocks to rebuild to the MSY level. In the event the Council determines that greater long-term benefits will be gained from the groundfish fishery by overfishing individual stocks or by preventing a stock from recovering to its MSY level, it will justify the action in writing in accordance with the procedures and standards identified in this section and the National Standard Guidelines (50 CFR 600.310(d)). Conversely, the Council may determine that greater benefits will accrue from protecting an individual stock by constraining the multiple species complex or specific components of that complex.

Prior to implementation of the FMP in 1982, the states of Washington, Oregon, and California managed the groundfish fishery without the use of quotas. State regulations since the mid-1940s took the form of area closures (such as San Francisco Bay), legal gear definitions, minimum codend mesh regulations, size limits, bag limits, and other nonquota management measures. Implementation of the FMP built upon those historical management practices by increasing the level of catch monitoring, improving the assessment of stock conditions, and establishing other mechanisms for responding to management needs. It provides for continuation of the historical fishery on traditionally harvested groundfish species while allowing for the development of new fisheries for underutilized species. The FMP, as amended, provides for the establishment of resource conservation measures such as harvest guidelines or quotas through the annual specification procedure and annual and inseason management measures through the "points of concern" and socioeconomic framework mechanisms.

Reduction in catches or fishing rates for either precautionary or rebuilding purposes is an important component of converting values of ABC to values of OY. This relationship is specified by the harvest control rule. All OYs will remain in effect until revised, and, whether revised or not, will be announced at the beginning of the fishing period along with other specifications (see Chapter 5).

Groundfish stock assessments generally provide the following information to aid in determination of ABC and OY.

1. Current biomass (and reproductive potential) estimate.

2. FMSY or proxy, translated into exploitation rate.

3. Estimate of MSY biomass (BMSY), or proxy, unfished biomass (based on average recruitment), precautionary threshold, and/or overfished/rebuilding threshold.

4. Precision estimate (e.g., confidence interval) for current biomass estimate.

4.6.1 Determination of Numerical OYs If Stock Assessment Information Is Available (Category 1)

The Council will follow these steps in determining numerical OYs. The recommended numerical OY values will include any necessary adjustments to harvest mortality needed to rebuild any stock determined to be below its overfished/rebuilding threshold and may include adjustments to address uncertainty in the status of the stock.

1. ABC: Multiply the current fishable biomass estimate times the FMSY exploitation rate or its proxy to get ABC.

2. Precautionary adjustment: If the abundance is above the specified precautionary threshold, OY may be equal to or less than ABC. If current biomass estimate is less than the precautionary threshold (Section 4.4.1), the harvest rate will be reduced according to the harvest control rule specified in Section 4.5.1 in order to accelerate a return of abundance to optimal levels. If the abundance falls below the overfished/rebuilding threshold (Section 4.4.2), the harvest control rule will generally specify a greater reduction in exploitation as an interim management response toward rebuilding the stock while a formal rebuilding plan is being developed. The rebuilding plan will include a specific harvest control rule designed to rebuild the stock, and that control rule will be used in this stage of the determination of OY.

3. Uncertainty adjustments: In cases where there is a high degree of uncertainty about the biomass estimate and other parameters, OY may be further reduced accordingly.

4. Other adjustments to OY: Adjustments to OY for other social, economic, or ecological

considerations may be made. OY will be reduced for anticipated bycatch mortality (i.e. mortality of discarded fish). Amounts of fish harvested as compensation for private vessels participating in NMFS resource survey activities will also be deducted from ABC prior to setting OY.

5. OY recommendations will be consistent with established rebuilding plans and achievement of their goals and objectives.
   (a) In cases where overfishing is occurring, Council action will be sufficient to end overfishing.
   (b) In cases where a stock or stock complex is overfished, Council action will specify OY in a manner that complies with rebuilding plans developed in accordance with Section 4.5.2.
   (c) For fisheries managed under an international agreement, Council action must reflect traditional participation in the fishery, relative to other nations, by fishermen of the United States.
   (d) For any stock that has been declared overfished, the open access/limited entry allocation shares may be temporarily revised for the duration of the rebuilding period by amendment to the regulations in accordance with the normal allocation process described in this FMP. However, the Council may at any time recommend the shares specified in chapter 12 of this FMP be reinstated without requiring further analysis. Once reinstated, any change may be made only through the allocation process.
   (e) For any stock that has been declared overfished, any vessel with a limited entry permit may be prohibited from operating in the open access fishery when the limited entry fishery has been closed.

6. Adjustments to OY could include increasing OY above the default value up to the overfishing level as long as the management still allows achievement of established rebuilding goals and objectives. In limited circumstances, these adjustments could include increasing OY above the overfishing level as long as the harvest meets the standards of the mixed stock exception in the National Standard Guidelines:
   (a) The Council demonstrates by analysis that such action will result in long-term net benefits to the Nation.
   (b) The Council demonstrates by analysis that mitigating measures have been considered and that a similar level of long-term net benefits cannot be achieved by modifying fleet behavior, gear selection/ configuration, or other technical characteristic in a manner such that no overfishing would occur.
   (c) The resulting rate or level of fishing mortality will not cause any species or evolutionarily significant unit thereof to require protection under the Endangered Species Act.

7. For species complexes (such as Sebastes complex), the OY will generally be set equal to the sum of the individual component ABCs, HGs, and/or OYs, as appropriate.

4.6.2 Determination of a Numerical OY If ABC Is Based on Nonquantitative Assessment (Category 2)

1. ABC may be based on average of past landings, previous nonquantitative assessment, or other qualitative information.

2. Precautionary adjustments, if any, would be based on relevant information. In general, the Council will follow a risk-averse approach and may recommend an OY below ABC if there is a perception the stock is below its MSY biomass level. If a declining trend persists for more than

three years, then a focused evaluation of the status of the stock, its ABC, and the overfishing parameters will be quantified. If data are available, such an evaluation should be conducted at approximately five-year intervals even when negative trends are not apparent. In fact, many stocks are in need of re-evaluation to establish a baseline for monitoring of future trends. Whenever an evaluation indicates the stock may be declining and approaching an overfished state, then the Council should:

a. Recommend improved data collection for this species.

b. Determine the rebuilding rate that would increase the multispecies value of the fishery.

3. Uncertainty adjustment: In cases where there is a high degree of uncertainty about the condition of the stock or stocks, OY may be reduced accordingly.

4. Amounts of fish harvested as compensation for industry research activities will also be deducted.

5. These adjustments could include increasing OY above the default value as indicated for Category 1 stocks, items 5 and 6 above.

4.6.3 Non-numerical OY for Stocks with No ABC Values (Category 3)

Fish of these species are incidentally landed and usually are not listed separately in fish landing receipts. Information from fishery-independent surveys are often lacking for these stocks, because of their low abundance or they are not vulnerable to survey sampling gear. Until sufficient quantities of at-sea observer program data are available or surveys of other fish habitats are conducted and/or requirements that landings of all species be recorded separately, it is unlikely that there will be to sufficient data to upgrade the assessment capabilities or to evaluate the overfishing potential of these stocks.

These species typically may be included in a non-numerical OY that is defined as all the fish that can be taken under the regulations, specifications, and management measures authorized by the FMP and promulgated by the Secretary. Such an OY may not be a predetermined numerical value, but rather that harvest that results from regulations, specifications, and management measures as they are changed in response to changes in the resource and the fishery. Nothing in this FMP prevents inclusion of these species in a numerical OY if the Council believes that is more appropriate.

[Amended: 11, 16-1, 17]

5.0 PERIODIC SPECIFICATION AND APPORTIONMENT OF HARVEST LEVELS
6.0 MANAGEMENT MEASURES
7.0 ESSENTIAL FISH HABITAT
8.0 EXPERIMENTAL FISHERIES
9.0 SCIENTIFIC RESEARCH
10.0 PROCEDURE FOR REVIEWING STATE REGULATIONS
11.0 GROUNDFISH LIMITED ENTRY

Draft Amendment 16-4 proposes no changes to the remaining chapters of the FMP (Chapters 5-11,) except, when referring to the number of overfished species, to refer to there being seven, not eight, overfished groundfish species. For example, a sentence that reads "Six of the eight overfished species are continental shelf species…," would be revised to read "Five of the seven overfished species are continental shelf species…" This change is proposed in light of the 2005 recovery of the coastwide lingcod stock to above B_{40}.

APPENDICES CONTENTS

N.B. In the last published version of the FMP (July 1993) the Appendices appeared as Chapter 11.0, and have not been revised or updated since that time. This original material provides descriptive information on the following topics:

- Biological and Environmental Characteristics of the Resource
- Description of the Fishery
- Social and Economic Characteristics of the Fishery
- History of Management
- History of Research
- Weather-Related Vessel Safety
- Relationship of this FMP to Existing Laws and Policies
- Management and Enforcement Costs
- Groundfish Landings Data, 1981 - 1988 from PacFIN

References cited in the July 1993 version of Chapter 11.0 appear in Chapter 13.0 of that version of the FMP, which is entitled "References" and has not been revised or updated since that time.

A portion of Amendment 11 (1998) addressing Essential Fish Habitat added numbered Section 11.10 to the Appendices chapter of the FMP.

More detailed species accounts of groundfish EFH are compiled in the West Coast Groundfish Essential Fish Habitat Appendix, which is available on the NMFS Northwest Region website.1/

In summary, the FMP Appendices consist of the following material: Chapter 11.0 of the July 1993 version of the FMP, Section 11.10 added by FMP Amendment 11, the West Coast Essential Fish Habitat Appendix, and Chapter 13.0 of the July 1993 version. These materials are available under separate cover.

COVER SHEET
2007-2008 Groundfish Specifications and Management Measures
Amendment 16-4: Rebuilding Plans
Environmental Impact Statement

Proposed Action:	Specify harvest levels (acceptable biological catch and optimum yield values) for species and species complexes in the fishery management unit and establish management measures to constrain total fishing mortality to these specifications for the calendar years 2007-2008. Revise rebuilding plans for seven depleted groundfish species.
Type of Statement:	Final Environmental Impact Statement

Abstract:
The *Pacific Coast Groundfish Fishery Management Plan* establishes a framework authorizing the range and type of measures that may be used to manage groundfish fisheries, enumerates 18 objectives that management measures must satisfy (organized under three broad goals), and describes more specific criteria for determining the level of harvest that will provide the greatest overall benefit to the nation, or optimum yield. Fisheries subject to management measures include limited entry trawl fisheries, limited entry fixed gear (pot and longline) fisheries, and a variety of other fisheries catching groundfish, either as target species or incidentally, but not license limited under the management framework established in the Groundfish Fishery Management Plan. Allocations to tribal fisheries off Washington State are also identified. Seven groundfish species are currently declared overfished and measures to prevent overfishing and rebuild these overfished stocks are a central element of this action. In addition, rebuilding plans for these species, which establish targets for long-term recovery, are re-evaluated and revised. The proposed action establishes harvest guidelines for groundfish species, species groups, and geographic subunits. In order to constrain fisheries to these harvest guidelines, management measures for commercial and recreational fisheries are identified. Management measures considered for commercial fisheries include two-month cumulative landing limits for species, species groups, and geographic subunits for limited entry trawl and fixed gear sectors, and fisheries not license limited under the *Pacific Coast Groundfish Fishery Management Plan*, and gear restrictions to reduce bycatch of overfished species and reduce habitat impacts. Management measures considered for recreational fisheries include bag limits, size limits, and fishing seasons; which vary by state. In addition, area closures based on depth and intended to reduce bycatch of species apply to both commercial and recreational fisheries that are likely to catch these species. These closures vary by geographic area and time of year.

1.0 INTRODUCTION

1.1 How This Document is Organized

This document provides background information about, and analyses for two related actions. The first action is to establish 2007-2008 biennial harvest specifications and management measures for fisheries covered by the *Pacific Coast Groundfish Fishery Management Plan* (FMP), which are developed by the Pacific Fishery Management Council (hereafter, the Council) in collaboration with the National Marine Fisheries Service (NMFS). The second action is to consider revising rebuilding plans for seven depleted (overfished) groundfish species. This action requires a potential amendment to the groundfish FMP, which contains the current overfished species rebuilding plans. The two actions are related because the rebuilding plans determine the range of harvest levels that may be considered for depleted species. These actions must conform to the Magnuson-Stevens Fishery Conservation and Management Act (MSA), the principal legal basis for fishery management within the Exclusive Economic Zone (EEZ), which extends from the outer boundary of the territorial sea to a distance of 200 nautical miles from shore. These actions must also conform to a recent court ruling in the Ninth Circuit Court of Appeals, which held that, among other things, the purpose of the MSA is to give conservation of fisheries priority over short-term economic interests. The Court interpreted the rebuilding requirements of the MSA as: 1) the rebuilding periods must be as short as possible; 2) short-term needs of fishing communities may be taken into account in setting rebuilding periods, even when the biology of the species dictates exceeding the 10-year statutory cap. As an example, the Court noted that in order to avoid disastrous short-term consequences, NMFS may set limited quotas that allow for some fishing of plentiful species, despite the inevitability of bycatch.

In addition to addressing MSA mandates, this document is an environmental impact statement (EIS), pursuant to the National Environmental Policy Act (NEPA) of 1969, as amended. According to NEPA (Sec. 102(2)(C)), any "major federal action significantly affecting the quality of the human environment" must be evaluated in an EIS. Based on a preliminary determination by Council and NMFS staff, implementing the two actions referenced above may have significant impacts. Therefore, rather than preparing an environmental assessment (EA), which provides "sufficient evidence and analysis for determining whether to prepare an environmental impact statement," NMFS and the Council have decided to proceed directly to preparation of an EIS. This document is organized so that it contains the analyses required under NEPA, the Regulatory Flexibility Act (RFA), and Executive Order (EO) 12866, which mandates an analysis similar to the RFA. For the sake of brevity, this document is referred to as an EIS, although it contains required elements of an Initial Regulatory Flexibility Analysis (IRFA) pursuant to the RFA and a Regulatory Impact Review (RIR) pursuant to EO 12866.

Federal regulations (40 CFR 1502.9) require agencies to prepare and circulate a draft EIS (DEIS), which "must fulfill and satisfy to the fullest extent possible the requirements established for final statements in Section 102(2)(C) of the Act" (i.e., NEPA). Federal regulations (40 CFR 1506.10(c)) and agency guidelines (NOAA Administrative Order 216-6.5.01.b.1(i)) stipulate a minimum 45-day public comment period on the DEIS. At the end of this period a final EIS (FEIS) is prepared, responding to comments and revising the document accordingly. After the EIS is completed, a 30-day "cooling off" period ensues before the responsible official may sign a record of decision (ROD) and implement the proposed action.

Environmental impact analyses have four essential components: a description of the purpose and need for the proposed action, a range of alternatives, including the proposed action, that represent different ways of accomplishing the purpose and need, a description of the human environment affected by the proposed action, and an evaluation of the predicted direct, indirect, and cumulative impacts of the alternatives.[1] (The human environment is interpreted comprehensively to include the natural and physical environment and the relationship of people with that environment, 40 CFR 1508.14.) These elements allow the decision maker to look at different approaches to accomplishing a stated goal and understand the likely consequences of each choice or alternative. EISs are commonly organized around four chapters covering each of these topics. This EIS is organized differently; Chapters 1 and 2 cover the purpose and need for the action and describe the alternatives, and the next five chapters focus on parts of the biological, physical, and human environments potentially affected by the proposed action. These chapters describe both the status quo environment potentially affected by the proposed action and the predicted impacts of each of the alternatives. Based on this structure, the document is organized in 14 chapters:

The rest of this chapter, Chapter 1, discusses the reasons for federal regulation of West Coast groundfish fisheries in 2007-2008 and for considering revisions to established groundfish rebuilding plans. This description of purpose and need defines the scope of the subsequent analysis.

- Chapter 2 outlines different alternatives that have been considered to address the purpose and need. The Council will choose their preferred alternatives from among these alternatives. The preferred alternative covering revisions to the six rebuilding plans will be submitted to NMFS as an FMP amendment. The preferred alternative for harvest specifications and management measures provides the basis for establishing the regulations governing groundfish fisheries in 2007-2008.

- Chapter 3 describes West Coast marine ecosystems and essential fish habitat (EFH) potentially affected by the proposed action and discloses the predicted impacts of the alternatives on that segment of the physical and biological environment.

- Chapter 4 describes fish species affected by the proposed action and discloses the predicted impacts of the alternatives on that segment of the biological environment. These include target and non-target groundfish fishery management unit species and non-target, non-groundfish species.

- Chapter 5 describes protected species potentially affected by the proposed action and discloses the predicted impacts of the alternatives on that segment of the biological environment.

- Chapter 6 describes the fisheries management regime. Impacts, considered in terms of public sector costs, are evaluated in Chapter 7.

- Chapter 7 describes the socioeconomic environment, which includes commercial, tribal, and recreational fisheries and coastal communities in the action area and how they would be affected by the different alternatives.

- Chapter 8 addresses additional requirements of NEPA and implementing regulations, including the identification of any measures that will be implemented to mitigate significant impacts of the proposed action.

- Chapter 9 details how this amendment meets 10 National Standards set forth in the MSA (§301(a)) and Groundfish FMP goals and objectives.

---

[1] Federal regulations at 40 CFR 1502 detail the required contents of an EIS. Although there are several additional components, this list is of the core elements.

- Chapter 10 provides information on those laws and EOs, in addition to the MSA and NEPA, that an action must be consistent with, and how this action has satisfied those mandates.

- Chapters 11 through 14 include required supporting information: the list of preparers, who received copies of the document, a glossary and acronym list, and the bibliography.

1.2 Purpose and Need for the Proposed Actions

The proposed actions fall within the management framework described in the Groundfish FMP, which enumerates 18 objectives that management measures must satisfy (organized under three broad goals), describes more specific criteria for determining the level of harvest that will provide the greatest overall benefit to the Nation (defined as optimum yield [OY]), and authorizes the range and type of measures that may be used to achieve OY. The management regime described in the Groundfish FMP is itself consistent with 10 National Standards described in the MSA. Harvest specifications (OYs) and management measures must be consistent with the goals, objectives, and management framework described in the Groundfish FMP.

1.2.1 The Proposed Actions

The Council's/NMFS' *proposed actions*, evaluated in this document, are:

1. Re-evaluate and revise, if necessary, adopted rebuilding plans for seven depleted (overfished) groundfish species, so that the rebuilding periods are as short as possible, taking into account the status and biology of the depleted species, and the socioeconomic needs of West Coast fishing communities, and the interaction of the depleted stocks within the marine ecosystem.

2. Specify acceptable biological catch (ABC) and OY values for species and species' complexes in the fishery management unit and establish management measures to constrain total fishing mortality to these specifications. These specifications and management measures will be established for calendar years 2007 and 2008, although they are considered within the context of past management and long-term sustainability of managed fish stocks.

The harvest specifications (OYs) established for 2007 and 2008 are in part determined by potential revisions to rebuilding plans, the first proposed action. Management measures are intended to keep total fishing mortality during each year within the OY established for that year. Specifications include new harvest levels for species with new stock assessments and projected harvest levels for species with stock assessments completed in prior years. Management measures may be modified during the biennial period, so total fishing mortality is constrained to the OYs identified in the preferred alternative. The environmental impacts of any such changes in management measures are expected to fall within the range of impacts evaluated in this EIS. Federally-managed Pacific groundfish fisheries occurring off the coasts of Washington, Oregon, and California (WOC) establish the geographic context for the proposed action.

1.2.2 Need (Problems for Resolution)

The proposed actions are needed because:

1. The Council's policies for rebuilding depleted groundfish species, as described in rebuilding plans, must be re-evaluated and potentially adjusted so that they are consistent with guidelines

pursuant to National Standard 1 (50 CFR 660.310) and a recent opinion rendered in the Ninth District Court in the matter of *Natural Resources Defense Council, Inc., and Oceana, Inc. vs. National Marine Fisheries Service, et al.*, 421 F.3d 872 (9th Cir.2005)..

2. Commercial and recreational harvests in 2007 and 2008 must be constrained to levels that will ensure groundfish stocks are maintained at, or restored to, sizes and structures that will produce the highest net benefit to the nation, while balancing environmental and social values.

1.2.3 Purposes of the Proposed Actions

The purposes of the actions are:

1. Rebuild depleted groundfish stocks to a size and structure capable of supporting MSY according to the requirements of the MSA. The MSA mandates rebuilding periods "be as short as possible, taking into account the status and biology of any overfished stocks of fish, the needs of fishing communities, recommendations by international organizations in which the United States participates, and the interaction of the overfished stock of fish within the marine ecosystem" (§304(e).)

2. Ensure Pacific Coast groundfish subject to federal management are harvested at OY during 2007 and 2008 and in a manner consistent with the aforementioned Groundfish FMP and National Standards Guidelines (NSGs) (50 CFR 600 Subpart D), using routine management tools available to the specifications and management measures process (FMP at 6.2.1, 50 CFR 660.323(b)). Chapter 10 of this EIS describes how the proposed action (preferred alternative) is consistent with the FMP and MSA.

1.3 Background

1.3.1 Revising Groundfish Rebuilding Plans

National Standard 1 Guidelines establish criteria for rebuilding depleted or overfished[2] stocks that the Council used when it adopted rebuilding plans for the eight groundfish stocks[3] the Secretary of Commerce had formally declared as overfished. One of these stocks, lingcod (*Ophiodon elongatus*) has been subsequently rebuilt to its MSY stock size; the remaining seven stocks still managed under Council rebuilding plans are: bocaccio (*Sebastes paucispinis*), canary rockfish (*S. pinniger*), cowcod (*S. levis*), darkblotched rockfish (*S. crameri*), Pacific ocean perch (*S. alutus*), widow rockfish (*S. entomelas*), and yelloweye rockfish (*S. ruberrimus*). According to NSG 1, rebuilding should bring stocks back to a population size that can support MSY (B_{MSY}). In order to do this, a rebuilding plan must specify a target year (T_{TARGET}) based on the time required for the stock to reach B_{MSY}. This target is bounded by a lower limit (T_{MIN}) defined as the time needed for rebuilding in the absence of fishing (i.e., a zero fishing mortality rate, F = 0). T_{MIN} is the shortest possible rebuilding period given the stock's estimated productivity. According to NSG 1, rebuilding plans for stocks with a T_{MIN} less than

2 The MSA and NSGs use the term "overfished" to describe stocks whose biomass has fallen below the minimum stock size threshold (MSST), triggering a management response to rebuild the stock. However, the concept of an overfished stock, defined by biomass, is frequently confused with the concept of "overfishing," or a situation where the fishing mortality rate has exceeded a threshold, which, if sustained, could lead to the stock becoming overfished. In order to make a clearer distinction between these two concepts, in this document the term "depleted" is used to mean overfished, or a biomass level below the MSST.

3 Nine groundfish stocks were formally declared overfished by the Secretary of Commerce; however, one of those stocks, Pacific whiting, was subsequently found not overfished before the Council could recommend a rebuilding plan to the Secretary of Commerce.

10 years must have a target less than or equal to 10 years. If, as is the case with all of the groundfish stocks currently managed under Council rebuilding plans, the biology of a particular species dictates a T_{MIN} of 10 years or greater, then, again according to NSG 1, the maximum allowable rebuilding time, T_{MAX}, is the rebuilding time in the absence of fishing (T_{MIN}) plus "one mean generation time." Mean generation time is a measure of the time required for a female to produce a reproductively-active female offspring {Pielou, 1977 #653; and especially \Restrepo, 1998 #462} calculated as the mean age of the net maternity function (product of survivorship and fecundity at age). An important distinction is the difference between T_{MIN} and the shortest time to rebuild stocks currently managed under Council rebuilding plans. T_{MIN} is the shortest time to rebuild from the onset of the rebuilding plan or from the first year of a rebuilding plan, which is usually the year after the stock was declared overfished. T_{MIN} is therefore the median time predicted to attain the target spawning biomass (for West Coast groundfish stocks, this value is 40% of initial, unexploited biomass) with no fishing-related mortality from the first year of a rebuilding strategy. Over time, estimated T_{MIN} can vary based on assessment results that better inform the stock's growth rate and relative productivity. However, for the seven species managed under West Coast groundfish rebuilding plans, the shortest possible time to rebuild from this point forward is not T_{MIN}, since some harvest has been allowed under Council rebuilding plans. The shortest possible time to rebuild the stocks with rebuilding plans under consideration in Amendment 16-4 is $T_{F=0}$, which is the median time to rebuild the stock if all fishing-related mortality were eliminated beginning in 2007.

Because of the uncertainty surrounding stock assessments and future population trends (due, for example, to variable recruitment), the rebuilding period limits and the target need to be expressed probabilistically. In past years, the Council's approach at the outset of the rebuilding period had been to set T_{TARGET} so there was at least a 50% probability of achieving B_{MSY} within the T_{MAX}.[4]

Although this approach gave some flexibility for the Council to choose a target rebuilding year falling anywhere between the T_{MIN} and T_{MAX} by considering tradeoffs between biological and socioeconomic impacts, a recent Ninth Circuit Court of Appeals decision requires a reconsideration of this approach and emphasizes the need to rebuild stocks in as short a time as possible, taking into account: (1) the status and biology of the stocks, (2) the needs of fishing communities, and (3) interactions of depleted stocks within the marine ecosystem. The current action responds to this by reconsidering the targets and parameters in previously-established rebuilding plans with more emphasis placed on swift rebuilding.

Historically, the Council has focused on the first factor, noted above, and modified rebuilding periods to accommodate targeted fishing for healthy stocks that co-occur with depleted species. The depleted species' stock assessments and rebuilding analyses describe the status and biology of the stocks, and their anticipated rebuilding trajectories. Amendment 16-4, and groundfish harvest analyses in 2007 and beyond will include more analysis of the latter two factors.

This EIS, which includes an IRFA and an RIR, analyzes the connections between depleted species and fishing communities. Different fishery sectors rely on opportunities to fish for various healthy groundfish stocks, almost all of which occur in mixed stock complexes that include both healthy and depleted groundfish stocks. The EIS shows which fishing communities tend to be reliant on which sectors of the groundfish fishery, and whether those sectors encounter depleted stocks while targeting more healthy stocks. It reviews the effects of varying potential groundfish-related income on the duration of depleted stocks' rebuilding periods. For some stocks, a small sacrifice in near-term groundfish-related income may result in notable gains in the swiftness of the rebuilding period. For other stocks, large sacrifices in groundfish-related income could be required to gain even a few months

4 The use of a low bound 50% probability is not specified in regulations; it is the result of litigation (*Natural Resources Defense Council v. Daley*, April 25, 2000, U.S. Court of Appeals for the District of Columbia Circuit).

difference in rebuilding period durations.

Amendment 16-4 is also intended to better take into account the interactions of depleted stocks within the marine ecosystem. Amendment 19 to the FMP, approved in March 2006, addressed how all groundfish species interact within the marine ecosystem and essential fish habitat. For the action considered in this EIS, the more thorough communities-effects review has necessitated a closer look at how depleted stocks interact with target stocks and each other. Where the need to rebuild one depleted stock constrains the annual harvestable amount of a second depleted stock, the rebuilding period for the second stock will be constrained by the rebuilding needs of the first stock. This is a shift from past practices, where rebuilding periods were set for each species individually.

In addition, rebuilding plans also may have to be revised in response to new information about a stock. This new information is typically derived from stock assessments, which use the most recent available scientific information about a stock to estimate various characteristics of the stock relating to its size and productivity. These characteristics largely determine what portion of the stock can be harvested on an annual basis while maintaining the stock at, or rebuilding it to, B_{MSY}; this harvestable amount is the OY for a given stock. An important intermediate step in determining the OY for an overfished stock is the preparation of a rebuilding analysis. The rebuilding analysis, using information from the stock assessment, computes the values of the various parameters used to describe the rebuilding plan.

The rebuilding framework described in the FMP anticipates the likelihood that rebuilding plans will need revision in light of new information about stock characteristics. In order to alleviate the need for frequent FMP amendments, which describes the rebuilding plan for each depleted stock, the FMP states that two key rebuilding parameters, the target year and the harvest control rule (typically expressed as a fishing mortality rate, which is then translated into the harvestable amount, or OY) will be published in federal regulations. Upon receipt of new information that NMFS and the Council determine requires adjustment of these parameters, a regulatory amendment would be made to change the published values through a full rulemaking. The FMP would not normally be amended to update changes in the values of other parameters that are part of the rebuilding plan descriptions in the FMP. However, the Council has elected to pursue an FMP amendment (Amendment 16-4) in this case since they will be considering changes to all seven species' rebuilding plans, within the FMP at Section 4.5.

In considering potential alternatives to revise the seven groundfish rebuilding plans, this EIS used a two-step analysis to develop a range of "vertically-integrated" OY alternatives. First, the alternative OYs specified by the Council for each depleted species were analyzed individually to understand how each OY alternative, which corresponds to a longer-term mortality schedule defining the rebuilding strategy, affects the estimated duration of rebuilding (T_{TARGET}) and affects the various fisheries/fishing sectors. Second, the OY alternatives for each of the seven depleted species were analyzed "vertically", or across the different species, to better understand the interactions between the different rebuilding strategies for the overfished species, and the tradeoffs to the various fishing sectors and communities affected by alternative rebuilding plans. This vertical cross-species analysis of alternative OYs is important since future management regimes are most directly affected by the collective constraints of all rebuilding plans. Vertically integrated OY alternatives are strategically developed by comparing and contrasting relatively higher and lower OY alternatives for each species in turn. This analytical treatment is designed to show, to the extent practicable, how each stock under rebuilding might differentially constrain fishing opportunities by fishing sector, area, and time. Guidance from the Council and the Council's Groundfish Allocation Committee is to assume a status quo management regime (i.e., continuance of similar depth-based closed areas specific to each fishing sector (RCAs), similar intersector allocations of groundfish species, etc.) as a primary working assumption in these analyses. However, the status quo management regime is significantly perturbed under some of these OY scenarios. In these cases, alternative management regimes result and examples are presented under different base assumptions.

1.3.2 The Process for Establishing Harvest Specifications (OYs) and Management Measures

In accordance with the Groundfish FMP, beginning in 1990 the Council set Pacific Coast groundfish harvest specifications annually, with harvest specifications and management measures in effect for the calendar year January 1 to December 31. Amendment 17 to the Groundfish FMP, approved in 2003, shifted decision-making to a two-year, or biennial, cycle. Under the biennial management cycle, harvest specifications and management measures are established for the two-year period in advance of the biennium. Separate ABCs and OYs are established for each calendar year in the two-year cycle. The first biennial harvest specifications were established for 2005–2006; the current action represents the second round of biennial specifications.

Council decision-making for this action occurs over three meetings, culminating in June of the year preceding the biennium. For the 2007-2008 biennium, the Council identified a preliminary range of ABCs and OYs at their November 2005 meeting; at their April 2006 meeting they selected preferred alternatives for the rebuilding plan revisions and, directly related to that, preferred ABCs and OYs that will be used as harvest limits during the 2007-2008 period. At this meeting the Council also approved a range of management measures' alternatives for analysis. The final decision point for the Council occurs at their June 2006 meeting when they finalize the full package of harvest specifications and management measures, choosing a preferred suite of management measures for 2007-2008.

Although Council decision-making is complete by June 2006, there are additional opportunities for public comment under NEPA and the rulemaking process. A DEIS will be released for public review and comment after the June Council meeting. Shortly thereafter, NMFS will publish a proposed rule to implement the 2007-2008 harvest specifications and management measures and Amendment 16-4, which will also include a public comment period. Changes to the rebuilding plans, which would be made via Amendment 16-4 to the groundfish FMP, will also be submitted to NMFS for Secretarial review. Subsequent to the public review periods on the proposed rule and on Amendment 16-4 itself, the approved changes to rebuilding plans will then be incorporated into the FMP. NMFS anticipates completing the Amendment 16-4 Secretarial review period in advance of implementing the 2007-2008 groundfish harvest specifications and management measures.

The choice of harvest specifications and the development of management measures are two separate sets of alternatives, which form the basis of the impact analysis. The OYs for 19 stocks or stock complexes differ among the harvest specification action alternatives. OYs for the remaining stocks are the same across all the action alternatives. (The No Action Alternative represents the status quo, or re-application of 2005-2006 harvest specifications. OYs for additional stocks are different under No Action in comparison to the action alternatives.) The differences among the harvest specification action alternatives reflect policy decisions based on various factors, such as scientific uncertainty in stock assessments (e.g., petrale sole), requirements of rebuilding plans, and whether to apply a precautionary reduction for stocks co-occurring with depleted species (e.g., chilipepper rockfish), among other factors.

The Council process for setting groundfish harvest specifications depends on periodic assessments of the status of groundfish stocks, rebuilding analyses of those stocks that are depleted and managed under rebuilding plans, and a report from an established assessment review body or a Stock Assessment Review (STAR) panel. As appropriate, the Council's Scientific and Statistical Committee (SSC) recommends the best available science for groundfish management decision-making in the Council process. The SSC reviews new assessments, rebuilding analyses, and STAR panel reports and recommends the data and analyses that should be used to set groundfish harvest levels and other specifications for the following biennial management period. A total of 23 groundfish stock assessments were conducted and approved in support of the process for setting 2007-2008 groundfish harvest specifications and management measures. This includes the 2005 Pacific whiting assessment, which was used to set 2005 harvest specifications and management measures for trawl fisheries targeting this stock. The 2005 assessment also forms the basis for ranging 2007-2008 Pacific whiting ABC/OY alternatives for analysis, primarily to understand the bycatch implications of potential future fisheries targeting Pacific whiting. However, new annual assessments of the West Coast Pacific whiting stock are anticipated for setting future Pacific whiting harvest specifications and management measures. The remaining 22 groundfish stock assessments conducted in 2005 are explicitly used for deciding 2007 and 2008 harvest specifications and management measures. An overview of the status of groundfish stocks and stock complexes is found in Chapter 4. How results from each of the current and past stock assessments are used to decide new harvest specifications is also discussed in Chapter 4.

1.3.3 The Range of Management Measures Considered by the Council

Management measure alternatives combine different management tools available to the Council and NMFS as specified in the FMP and in federal regulations. Each of these management measure alternatives (except for No Action) is intended to constrain fishing mortality to or below the Council-preferred OY levels determined by the choice among the ABC/OY alternatives mentioned above. (The action alternatives were crafted before performing the detailed analysis necessary to determine total fishing mortality for each stock. Therefore, one or more of the action alternatives may be projected to exceed the Council-preferred OY for one or more stocks. However, the Council-preferred alternative, chosen at the June Council meeting, must be projected to keep total fishing mortality for all stocks within their respective OYs.) This approach also makes it possible to compare the performance of alternative management measures against one standard: the Council-preferred ABC/OY levels chosen from the first set of alternatives.

The types of management measures included in the alternatives are likely to be substantially the same as those used during the 2005-2006 biennium, although their application will change so that they are suitable to available 2007-2008 harvest levels. Those which may be considered for modification include:

- Two-month or monthly cumulative landing limits frequently referred to as “trip limits.” These are separately established for the limited entry trawl sector, and the limited entry fixed gear and open access sectors.[5] Cumulative limits are established for species or species groups and specify an amount, by weight which a vessel may land during a two-month or monthly period.

- Gear requirements, principally relating to trawl gear. Since 2001 footrope restrictions have been in place for limited entry trawl gear. Footrope size limits the type of bottom habitat a trawl gear may operate in; trawlers with small footrope gear cannot operate in rocky areas, important habitat for some depleted groundfish. After extensive testing, beginning in 2005 selective flatfish trawl gear was required in the area shoreward of the trawl RCA in waters north of a management line at 40°10' N latitude (near Cape Mendocino, California). This modified bottom trawl gear reduces bycatch of most depleted rockfish species while maintaining or increasing catch efficiency for target flatfish species. (The modified trawl nets use a cutback headrope, which allows some species, including some rockfish species, to swim upward when disturbed, thus evading the net entrance. Bottom-hugging species like flatfish are still caught.)

---

[5] These sectors are defined by the requirement to possess a gear-endorsed limited entry permit, which is required to engage in specified types of groundfish fisheries. The “open access” sector refers to those vessels targeting or incidentally catching groundfish without a limited entry permit, although they may hold permits required for other federally- or state-managed fisheries.

- For recreational gear, size limits and bag limits. Bag limits are a number of fish, sometimes enumerated by type, that an angler may retain or land on a per-trip basis. Recreational measures are principally administered by state governments since most of this fishing occurs within state waters. Through the Council process, state-specific measures are developed. Bag limits may differ by zone or management subareas established by the states.

- Time/area closures for commercial vessels, particularly Rockfish Conservation Areas (RCAs). RCAs have been in place since 2002 to prohibit vessels from fishing in depths where depleted groundfish species are more abundant. Separate RCAs are established for the limited entry trawl and non-trawl (limited entry fixed gear and open access) sectors. RCAs for recreational vessels have been in place since 2004. For both commercial and recreational fisheries, RCAs are intended to reduce the incidental catch of these species. Their boundaries may vary seasonally and may be re-specified as part of the biennial management process. In both commercial and recreational fisheries, time/area closures may include seasons of varying durations. Amendment 18 to the FMP, under Secretarial review, specified that depth-based management measures, like RCAs, could also be used either to prevent overfishing a healthy groundfish stock and/or to constrain incidental catch of protected species other than groundfish (salmon, halibut, Dungeness crab.)

1.3.4 Key Management Issues in 2007 and 2008

Certain depleted species will continue to constrain harvest opportunities for healthier stocks. Harvest limits for depleted stocks may change dramatically and constrain fisheries by gear, time, or area much differently than in the recent past, depending on revisions to species' rebuilding plans. In response, various combinations of sector-specific trip limits and closed area configurations will be a central management feature. The most recent available fishery observer data will be used to adjust the bycatch rates used in modeling projected total fishing mortality. Although preventing overfishing and rebuilding depleted stocks is a paramount concern, management measures are intended to allow fishers access to healthy stocks by reducing bycatch rates. This addresses competing goals in the Groundfish FMP to maximize the value of the groundfish resource and rebuild overfished stocks. Striking this balance between conservation of and direct social benefit from groundfish is another way to understand the purpose of this action.

Inseason management of California recreational fisheries to constrain mortality of depleted groundfish and stay within other harvest allocations made to that sector will again play an important role in the formulation of management measures for the 2007-2008 period. Data from a new recreational catch estimation program, the California Recreational Fisheries Survey (CRFS), will be used in preseason and inseason recreational harvest projections. Since CRFS has only been used since 2004, only two years of catch estimates are incorporated in the California recreational impact model used to project harvests for this fishery.

As mentioned above, regionalizing recreational fisheries management will continue as an important management tool. Historically, the recreational fisheries have had some degree of regional management based on differing state regulations and the geographic distribution of groundfish stocks caught in the sport fishery. For 2007-2008, the Council, along with the states, is now considering more explicit regional allocations in the form of harvest guidelines or targets. The concern that a given sector or region could harvest a disproportionate share of the very low coastwide OYs for certain depleted groundfish, such as canary rockfish, has sparked this discussion.

Two large areas in the Southern California Bight south of Pt. Conception have been closed to bottom fishing since 2000 to minimize mortality of cowcod, a severely depleted groundfish stock under rebuilding. Termed the Cowcod Conservation Areas (CCAs), these areas are bounded with regular, rectangular lines to ease enforcement of fishing prohibitions. Some members of the fishing industry have asked that the boundaries of the CCAs be modified to allow fishing in areas that are not considered cowcod habitat, but where healthy slope species, such as blackgill rockfish, are more abundant. The Council agreed to consider modifying the CCAs. This EIS analyzes alternative CCA boundaries with respect to cowcod conservation needs and enforceability of fishing prohibitions.

Successful rebuilding of the coastwide lingcod stock has prompted consideration for higher trip and bag limits by commercial and recreational fishing interests. This EIS analyzes the effect of higher lingcod harvest limits in 2007 and 2008 with respect to the estimated bycatch of co-occurring rockfish species (with particular concern for the bycatch of depleted species) and the potential of localized depletion of lingcod in some areas south of Cape Mendocino, California where the stock is less abundant. One proposal by the Washington Trollers Association, that the Council agreed to consider, is to allow a landing limit of lingcod by salmon trollers who are exempt from RCA restrictions. The potential risks and benefits of this proposal are analyzed in this EIS.

Salmon bycatch in directed groundfish fisheries will receive a greater focus in this EIS than in the past. An ESA consultation is required for determining salmon bycatch limits in groundfish fisheries, particularly in directed Pacific whiting fisheries where there is a salmon bycatch of any significance (relative to other directed groundfish fisheries). Chinook salmon bycatch limits were exceeded in the 2005 whiting fishery prompting a re-initiation of ESA consultation. That experience, a more pessimistic outlook for future salmon returns, and a greater federal focus on the role of harvest in salmon recovery compels a closer look at salmon bycatch in this EIS.

Constraining environmental impacts in West Coast open access fisheries has become increasingly difficult with the small OYs in place for some depleted stocks under rebuilding. As an example, in 2005 a large factory longliner announced plans to target spiny dogfish in the unlimited open access fishery in waters off Washington. This proposed fishery threatened the balance of intersector allocations for species such as canary and yelloweye rockfish, which could have led to an early exceedance of OYs and early termination/cancellation of planned fishing activities across all sectors. In response, NMFS adopted emergency annual bycatch caps (or total mortality limits) for canary and yelloweye rockfish for all open access fisheries in 2005, which would have conceivably limited early closures to only that sector had bycatch exceeded those limits. While the proposed dogfish longline fishery did not occur, this does serve as an example of the difficulty of limiting participation and impacts in the open access fishery. Small limits alone may not adequately control this fishery, which is why this fishery needs more scrutiny in this EIS.

An implication of managing for lower OYs under some of the alternative harvest specifications analyzed in this EIS is the potential need to further constrain tribal groundfish fisheries. Ad hoc tribal/non-tribal allocations[6] under the status quo management regime have been worked out in the Council process. However, some of the lower OY alternatives for northern depleted species, such as canary and yelloweye rockfish, may prompt formal government to government negotiations in the ongoing *U.S. vs. Washington* district court venue to resolve how allowable harvests will be allocated between tribal and non-tribal fisheries, as well as how to effectively constrain tribal fisheries to stay within whatever allocations are ultimately decided. This is an added step in the process of deciding

[6] Ad hoc tribal/non-tribal allocations exist for the depleted species and many target groundfish species. However, such allocations do not include those for sablefish and Pacific whiting, which are long-term allocations frameworked in the Groundfish FMP and specified in federal regulations.

revised rebuilding plans under Amendment 16-4 and the 2007-2008 harvest specifications and management measures. It is unclear how any delay in this allocation decision, if it occurs in the more formal *U.S. vs. Washington* process, will affect final decisions on the actions contemplated in this EIS.

1.3.5 Changes to the FMP Affecting Annual Management

In 2005 the Council took final action on two amendments to the groundfish FMP that will affect management in the 2007-2008 seasons. Amendment 18 incorporates into the FMP the preferred alternative in the September 2004 Pacific Coast Groundfish Fishery Management Plan Bycatch Mitigation Program Final Environmental Impact Statement {NMFS, 2004 1074 /id}. The preferred alternative from that EIS includes the use of sector-specific total catch limits as a way of motivating fishery participants to reduce bycatch, especially of depleted groundfish species. The Council has already used total catch limits in certain circumstances, such as the at-sea whiting sector, where real-time monitoring systems are sufficient to make this approach workable. The amendment would also reorganize and update some of the chapters in the FMP to better describe the current management framework. This includes a description of current standardized bycatch monitoring methodologies and other measures for bycatch reduction. Amendment 19 incorporates the preferred alternative adopted by the Council for the identification and mitigation of essential fish habitat in a FEIS prepared by NMFS {NMFS, 2005 1073 /id}. Mitigation measures will have a direct effect on management in the 2007-2008 cycle. These measures include 43 areas closed to bottom trawling in waters off of all three West Coast states and 17 areas off of Oregon and California closed to all bottom-contact gear. Furthermore, all waters deeper than 700 fathoms would be closed to bottom trawling. An existing measure prohibiting the use of large footrope trawl gear shoreward of a line approximating the 100 fm depth contour; footrope gear larger than 19 inches is prohibited, as is dredge and beam trawl gear. NMFS approval of these amendments, along with implementation of any related regulations is expected to occur in advance of the 2007-2008 season.

1.4 Scoping Summary

1.4.1 Background to Scoping

According to the NEPA, the public and other agencies must be involved in the decision-making process for agency actions. “Scoping” is an important part of this process. Scoping is designed to provide interested citizens, government officials, and tribes an opportunity to help define the range of issues and alternatives that should be evaluated in the EIS. NEPA regulations stress that agencies should provide public notice of NEPA-related proceedings and hold public hearings whenever appropriate during EIS development (40 CFR 1506.6).

The scoping process is designed to ensure all significant issues are properly identified and fully addressed during the course of the EIS process. The main objectives of the scoping process are to provide stakeholders with a basic understanding of the proposed action; explain where to find additional information about the project; provide a framework for the public to ask questions, raise concerns, identify issues, and recommend options other than those being considered by the agency conducting the scoping; and ensure those concerns are included within the scope of the EIS.

1.4.2 Council and Agency NEPA Scoping

On October 25, 2005 (70 FR 61595), NMFS and the Council published a Notice of Intent (NOI) in the *Federal Register* announcing their intent to prepare an EIS in accordance with NEPA for the 2007-2008

ABC and OY specifications and management measures for the Pacific Coast groundfish fishery.[7] The NOI described the proposed action and the way in which alternatives to be analyzed in the EIS would be formulated; it also enumerated a preliminary list of potentially significant impacts that could result from implementing the proposed action. A period for accepting written public comments on the scope of the EIS ended on November 25, 2005, as announced in the NOI.

The Council process, which is based on stakeholder involvement and allows for public participation and public comment on fishery management proposals during Council, subcommittee, and advisory body meetings, is the principal mechanism to scope the EIS. The advisory bodies involved in groundfish management include the Groundfish Management Team (GMT), with representation from state, federal, and tribal fishery scientists; and the Groundfish Advisory Subpanel (GAP), whose members are drawn from the commercial, tribal, and recreational fisheries, fish processors, and environmental advocacy organizations. The Ad Hoc Allocation Committee, a subpanel of the whole Council, provides advice on allocating harvest opportunity among the various fishery sectors. Meetings of the Council and its advisory bodies constitute the Council scoping process, involving the development of alternatives and consideration of the impacts of the alternatives.

The Council and its advisory bodies considered 2007-2008 specifications and management measures at four meetings in November 2005, March 2006, April 2006, and June 2006. The Ad Hoc Groundfish Allocation Committee and the GMT met on February 6–9, 2006, to review the range of harvest specifications and provide guidance on allocation of harvest opportunity among different fishery sectors for 2007-2008. When the Council considers groundfish management at their meetings, the GMT and GAP provide advice and guidance on the development of harvest specifications and management measures. The GMT also meets outside of Council meetings to develop management recommendations. For the 2005-2006 harvest specifications process, they met in October 2003, and February, May, and June 2004. All these meetings are open to the public and are duly noticed.

In addition, both the Oregon and California state fish and game departments hold public hearings to solicit input on the formulation of management measures. Comments made at these hearings are summarized and will be made available to the Council in advance of their June 2006 meeting.

1.4.3 Summary of Comments Received

To gauge public attitudes toward the effects of management on fishing communities, all written and oral public comment on inseason management and inseason adjustments between March 2002 and April 2006 were reviewed. Any comments relating to communities were excerpted in Table 1-1. (Most oral comments were recorded in handwritten notes by staff officers during Council meetings, although some were transcribed from tapes of the meetings). In addition, the table includes comments summarized for the 2004 and 2005/2006 groundfish annual specifications environmental impact statements.

The text below merely summarizes comments made, and makes no claims as to their validity. *[Note that some 2002 comments may be missing]*.
Many comments referred to specific geographic locations. Those are summarized below, from north to south. Comments that did not specifically refer to geographic locations are not included in the summary immediately below, but are summarized later in this section.

[7] On March 14, 2006, an amended NOI was published to include revision of rebuilding plans as part of the proposed actions (71 FR 13097).

1.4.3.1 Washington Comments

Northern Washington

Comments from 12 different people referred to northern Washington communities, including Bellingham, Forks, LaPush, Neah Bay, Port Angeles, Sammamish and Westport. The comments are summarized here.

- A Bellingham processor was concerned about the effect of potentially moving a management line to 150 fathoms (April 2004). He was concerned that this depth restriction would eliminate or sharply reduce the harvest of dogfish and the setline blackcod fishery, resulting in economic hardship.
- Recreational fishers in LaPush were concerned about the lack of regional management in relation to a potential closure of groundfish fisheries. They noted "Groundfish fisheries are critically important to our coastal economy and tourism." (April 2004)
- Recreational fishers from Neah Bay noted that the community had invested heavily in a new marina and other facilities that were dependent on recreational fisheries. (April 2004)
- Recreational CPFV businesses in Westport called for regional management of fisheries and said they depended upon groundfish and halibut for a major part of their livelihood. (April 2004). Recreational interests emphasized that a phased-in approach to cuts in yelloweye quotas would be less damaging to the community than immediate cuts (March and April 2006).
- Commercial fishers from Neah Bay were concerned that their small boat fishery was being discriminated against, as small boats could only fish during certain seasons due to safety concerns. They emphasized the importance of the small trawl fishery to local communities and expressed frustration at the delay in making management decisions. They noted "We have already lost so much with the cable crossing, the Vessel Traffic Lane Change, and other inseason adjustments that we have no reserves left to fall back on…." And that "many of us have been fishing our small family boats for generations. But sadly, many of us do not encourage our children to partake of our tradition of being a fisherman...competition and politics have put an end to that dream" (June 2002 and June 2003). In April 2006, a recreational representative voiced support for a phased-in approach to closures.
- The mayor of Forks, Washington and the Quileute Tribe both wrote to support proposed changes in the Halibut Catch Sharing Plan that were important to the recreational fishery. The Forks mayor noted that "would greatly benefit the Washington North coast communities." (November 2003)
- A CPFV business owner in Sammamish noted that a sport groundfish closure in late 2004 would "require that I cancel all my trips and let my customers also cancel all hotel and dinner plans for October and November of 2004…"

Southern Washington

Three comments from three different people were received from Ilwaco and elsewhere in southern Washington. In sum, they said that Ilwaco had been negatively affected by recreational groundfish closures, that there was a perception that the system favored other states over Washington, and that regional management was needed; and commenters described the importance of recreational fisheries to small coastal communities (April 2004).

1.4.3.2 Oregon Comments

Comments were recorded from approximately 75 individuals from Oregon (some of these were provided to the Council in the form of a Sea Grant study that did not differentiate between individual commenters). Forty-four comments did not specify a location in Oregon. Of these, recreational commenters expressed concerns about the economic impacts of fewer recreational fishers coming to the Oregon coast. They named hotels, restaurants, tackle shops, boat repair shops, charter companies, guides, gas stations, and shopping malls as potentially suffering from cuts in recreational fishing, and noted that many communities were already suffering economic distress. They called for more data on the economic impacts of recreational fisheries, and several expressed the belief that recreational fisheries created more economic benefits and fewer environmental impacts than commercial fisheries.

Commercial fishermen and people commenting on commercial fishing expressed distrust of the management process ("Many no longer go to meetings because they feel it makes no difference, they won't be listened to anyway and decisions have been made ahead of time"), and some believed that management was determined to do away with commercial fishing. They expressed concern about neglect, reduced maintenance, and lack of insurance for fishing vessels ("Many fishermen are going on a 3-year haul out schedule instead of a 1-year schedule"); and lack of support services such as ice plants, fuel docks, gar suppliers and processors. In addition, they noted that cutbacks in other fisheries, like salmon, led to more community dependence on groundfish. They expressed frustration over the difficulty in planning for business purposes and the loss of family-wage jobs. A fisherman's wife reported on an increase in divorce in her social circle ("The financial stress was too much - that and husbands always being angry, moody, and withdrawn. After four years of that, they couldn't take it anymore.") Processors reported layoffs and reductions in the type of species purchased from fishermen ("I quit buying groundfish because I couldn't get the mix I needed for my market").

Non-fishing businesses also reported losses. (These reports were part of the Oregon Sea Grant study presented to the Council in September 2002). An auto dealer said he hadn't sold a car to a fisherman in two years; a radio station owner said advertising was down due to a loss of family wage jobs in his community; a jewelry store owner was said to have laid off four workers; a trucking company reported on cutbacks in hours; a grocery store was said to be keeping fewer accounts for fishing vessels; and gear store managers reported on lost revenue due to fishing regulations and feared that thousands of dollars worth netting they had ordered months in advance would be obsolete by the time it arrived.

Community members in Oregon who were not affiliated with the fishing industry also expressed concerns about crumbling infrastructure, loss of family wage jobs, and impacts on families from economic stress and uncertainty.

Northern Oregon Coast

There was one comment each from the commercial sector in Warrenton and Astoria. One comment described the economic impacts of a potential closure on Warrenton. The speaker noted that there were 30 trawl vessels fishing out of Warrenton, with an average gross exvessel value per vessel of $60,000. He noted that these 30 vessels produced an impact of $1.8 million in exvessel value for Warrenton alone (September 2003). A commenter from Astoria noted that local vessels were not benefiting from the northern Oregon sardine fishery, but that most of the benefits were going out of state (September 2002).

Central Oregon Coast

Comments were received from 18 individuals from the communities of Garibaldi, Pacific City, Depoe Bay, Newport, Toledo, Seal Rock, and Florence.

- A commenter from Depoe Bay voiced concern over the economic and social impacts of a potential sport fishery closure. She noted, "The closure would not only impact the owners of the boats, as they lose their business, but it would also affect from one degree to another all businesses that are touched by charter fishing. Any business that benefits from the tourism generated by the fishing fleet to the marine supply, to fuel docks, restaurants and motels, just to name a few..." She also expressed concern over the fate of the Memorial Day Fleet of Flowers, a 57-year-old tradition in which the charter boat and commercial fleet pay respects to fishermen lost at sea, and other impacts of a weakened charter fleet: "It will mean that no longer will the handicapped, the blind, the deaf, the mentally challenged be able to go ocean fishing. It will mean that many of elderly will not be able to continue with the pleasure of ocean fishing, because there will be no one to take them..." (June 2002)

- The Port of Siuslaw (Florence) wrote with concerns about possible recreational closures outside of 50 fathoms. They noted that "Recreational angling provides a great economic stimulus for Florence and the surrounding area" and expressed concern over the ripple effect of a fishery closure. (September 2003)
- The Garibaldi fishing community was concerned about a recent Labor Day groundfish closure. A processor wrote "that had a tremendous economic impact … [and] a very large psychological impact on my community. It was kind of like a kick in the face...all these people from all over the country who had plans to come to the Oregon coast to go fishing, to spend their money, those plans were stopped with 72 hour notice [or less]." A Garibaldi port commissioner wrote that the pre-Labor Day closure had cost Garibaldi $529,000. Both commercial and recreational fishers in Garibaldi stressed the economic impacts of management decisions on their community: "You have hurt us financially, putting our [three] boats… into dry dock because of the low quotas... You've made us ready to quit and sell our boats than to keep our profession of [fishing]." (November 2005)
- Commenters in Newport pointed out that the coastal economy had been depressed for quite some time. A joint letter from Senators Gordon Smith and Ron Wyden to the Secretary of Commerce noted, "the fishing communities of Oregon are in their worst financial condition in recent history and are depending upon you to carefully craft a balanced management plan…" (September 2002), and a commercial fishing family member wrote "be aware that the West Coast fishery as a whole is experiencing an overall depression. Depressed prices for salmon, shrimp, crab and tuna are adding to the general poor outlook for fisheries" (November 2002). A petition with 43 co-signers notified the Council that "the reduction in fish harvest levels [has] had a drastic impact to our community and that further reduction in groundfish harvest levels will continue to adversely affect every business and family in Newport. The reduction in harvest levels means direct jobs are lost, not only in the commercial fishing industry but also in the recreation fishing industry, processing plants, boat repair businesses and gear shops… The repercussions trickle down to the lodging, restaurant, attraction, entertainment, and retail industries. And when these tourism-based businesses lay off employees due to reduced revenues, this has an effect on other local businesses... It would be difficult to measure the number of jobs and revenues lost to the whole business community." A net shop owner noted "[We] plead the case here for expanding some fishing grounds or quotas to the draggers deploying this year.... A year from now, if these quotas and closed zones stay in effect, we will be having to turn fishermen away for fears of not being paid. Inventories at shoreside services are dwindling and the entire market infrastructure seems ready to collapse..." (June 2003). Another commenter wrote, "All over Oregon, our skippers and deckhands depend on the ground fishery to make a living and feed their families. Winter months through early Spring especially, all they were allowed to catch was bottom fish, to carry them through until salmon season starts again. This is the cycle you have put us in. Now you have ruled to take this away from us leaving nothing to make a living with this winter" (September 2004). The Embarcadero Resort Hotel & Marina estimated 1650 occupied rooms would be lost to the Resort with severe cuts or complete stoppage of groundfish fishing, and estimated total economic loss at $421,887 per

year (September 2002). A processor expressed alarm over whiting being listed as overfished, saying "80-90 people will be laid off [as result of whiting being listed as overfished]."

- In Toledo, a recreational fisher wrote "When [ODFW] shut down bottom fishing it devastated the Oregon coast economy. Not only was the sport industry affected; restaurants, hotels, gas stations, public sector, police, firemen (because of the tax base) - we lost a lot of money on the Oregon coast because of this. It is heartwrenching, because there [were] people on the Oregon coast who... lost their families, who lost their businesses. There were businesses reported losing $1400 per week... that had a devastating affect on our tax bases..."
- A commercial fisher from Pacific City, which hosts a dory fleet, expressed concern that VMS would force small vessels with limited income out of the fishery.
- A Seal Rock resident spoke in favor of potential closures, saying "I realize the importance of fishing to this community. However, I am also aware that no single species can be lost without contributing to the loss of another, eventually impacting the very quality of human life that we are all eager to maintain."

Southern Oregon Coast

Comments were received from 10 different people in Winchester Bay, Bandon, Coos Bay, Charleston, Port Orford, and Brookings-Harbor. (One comment was gathered as part of a Sea Grant study presented during public comment in September 2002).

- In Winchester Bay, a recreational fisher recalled the impacts of an earlier salmon closure on this primarily recreational port: "Many fishing related businesses closed and this area lost all our charter fishing businesses. We currently have only four charter offices providing offshore angling opportunities for our visitors." He noted, "Recreational angling provides a great economic stimulus for Winchester Bay and the surrounding area. If recreational angling were stopped, we would experience the ripple effect from another loss of fishing species." (September 2003)
- The Port Orford Port Manager commented, "Port Orford fishermen, the Port and the community of Port Orford have long derived economic benefit from groundfish landings from around our area. All are now suffering hardship because of declining stocks and harvest regulations." (March 2005)
- The Coos Bay Trawlers' Association expressed concern about the cumulative effect of management measures, including the trawl buy-back program, prohibitions on large roller gear, other gear restrictions, observer requirements, VMS, the Rockfish Conservation Area, and ITQs, which "reduced time on the water by 75 to 80 percent; reduced our earnings by at least 75%" (June 2005). The cost of VMS was problematic: "The state that has the highest unemployment rate, the state with the highest poverty level…has to pay for the system themselves..." (March 2004). In addition, trawlers were frustrated by frequent changes in management direction: "Changing the process again, midstream…is taking all these small [trawl] businesses by surprise, and will hurt many coastal communities… How can any business effectively operate in this kind of environment?..." (September 2003).
- In Charleston, a processor pointed out the difficulty in planning a business when faced with unexpected cuts: "Without proper notice the RCA zone was moved out to 250 fm, which causes a devastating ripple effect within our company. Over the past several months our company has invested approximately $80,000 to develop our new fillet room with the anticipation of Petrale season opening in October of this year. We are a small company just starting out in this business and this has made an enormous impact on our financial situation... Last year during the months of October, November and December we purchased several thousands pounds of Petrale, which made it possible for us to continue doing business by compensating enough income to keep

paying wages of our employees." (November 2004) Another processor emphasized the seasonal importance of the Petrale fishery: "The fall Petrale sole fishery has been a valuable economic asset to both the fishermen and processors at a time when both the weather and the late year limits put an economic hardship on the industry. By the current position of the 250 fm line the Petrale fishery has been eliminated. The Petrale fishery has become an established holiday season marketing item for the processors, brokers, wholesalers, restaurants, and grocery stores." (November 2004)

- Commenters from Brookings-Harbor were concerned about impacts to the recreational fishery. Responding to a sport groundfish closure, one commenter wrote, "The impact is being felt already by this community and is expected to multiply extensively in the next few days. Southern Oregon is struggling to create employment opportunities and keep this one key element of the tourism industry alive, which is our recreational fishing industry. This is a blow to our economy that is unexpected and, plainly speaking, should be justified to the general public…" (September 2004). Another commented that the on-again, off-again regulatory pattern "tears families apart, making it impossible to hire, train, and keep good employees, not to mention maintaining boats, trucks, fishing gear, and montages [sic]. It also tears at the social fabric of coastal communities, ports, fuel docks, suppliers, banks, and restaurants and other support industries, and the employees and families of those businesses" (November 2005). An RV park manager noted that when there are closures in California, it should be made clear to the public that they do not necessarily affect recreational fisheries out of Brookings (September 2002).

1.4.3.3 California Comments

Comments were received from 56 individuals in California. Of these, 15 did not specify a city or town in California. Nine were form letters from an angling organization which promoted angling's economic importance and lack of environmental impact. Two other comments from recreational anglers echoed the same concerns.

Four comments from commercial fishers expressed concern about the economic impacts of restrictions on sanddabs, California halibut, and the possibility of being restricted to fishing outside 200 fathoms. Another fisherman noted that "Over the last several years most of the hook and line fishermen have gone out of business because restrictive regulations have made fishing in this manner economically unrealistic."

<u>Northern California</u>

Comments were received from 15 individuals in northern California (defined as San Francisco and points north). Comments came from people located in Crescent City, McKinleyville, Samoa, Newport and Fort Bragg.

- In Crescent City, commercial fishermen expressed concern about protecting markets for "beach fish" (sanddabs, sole, and flounder) and other nearshore markets. A fisherman noted, "We badly need to have an increase in the black and blue rockfish component of our catch allowances. Without the seasonal increases in these fish, some of the last nearshore markets will be lost along with the infrastructure that supports them. Many fishermen, especially those who fish outside of the areas that can supply the live market, cannot make enough money to support their fishing efforts…" (June 2003) Another commercial fisherman was concerned about the effect of VMS requirements on blackcod fishermen (March 2005). The Crescent City Harbor District expressed concern over recreational seasons, saying "the reduction in our groundfish season will have a devastating impact on our port and local community...." Other recreational fishers noted that the recreational fishing season had been cut in 2004 to seven months, leading to economic losses; and the season was cut in 2005 to four months: "with the offshore weather we have here at Crescent City in the summer, the season will be less than [four months]...This is pure and simple economic damage caused by the federal government to our small community…" (April 2005). The mayor of Crescent City wrote with similar concerns, saying "The recent development of the recreational groundfish regulations is of much concern to the City of Crescent City and its residents. As you know, we have a deep and strong interest in both the commercial and sport fishing activities in our area. Any reduction in this season would have a detrimental effect on our economy and way of life" (April 2005).

- In Samoa, a groundfish trawl gear supplier said that his business had been cut in half during the past five years, that processing and supply infrastructure had contracted, and that fishermen were putting off maintenance on their vessels: "A blanket closure would mean the loss to the nation of these fisheries and the loss of the participants' livelihoods...." (June 2002). A recreational fisher in nearby McKinleyville wrote that a black rockfish closure would hurt California both economically and socially (June 2004).
- In Newport, a commenter said that a thornyheads/sablefish closure had "killed" the Newport dory fleet (September 2002).
- In Fort Bragg, a series of alarming newspaper articles in June 2002 led to a letter from the mayor saying, "This raises concerns in the City of Fort Bragg, because fishing is an important part of the economy. In addition, there are many residents who depend on local fish as a source of food." A charter business commented that "our community has been hit with several extreme newspaper articles… claiming that all fishing, sport and commercial, will be prohibited as of Jan 03 from Mexico to Canada. Our entire community is up in arms." In November 2005, salmon trollers in Fort Bragg expressed concern about increased fuel costs, asking for higher weekly and daily limits for sablefish.
- In June 2003, a recreational fisher passed along an editorial saying "We are already seeing several party boat operations being sold or forced out of business…many boats and supporting businesses (tackle shops, fuel docks, hotels etc.) depend on rockfish for winter their income. It's not a large part of their annual total but enough to pay their employees, insurance and berthing fees until the more lucrative salmon season opens. We are literally one bad salmon season away from losing most of the party boat operations along the Central coast. In a good salmon season these small businesses can scratch out a living but if the salmon don't show the cost of running a boat and paying its crew becomes impossible. Most at risk are boats and businesses in the smaller ports. Two of the largest party boat operations in Bodega Bay are currently selling out or closing down and more are sure to follow from Ft. Bragg to Bodget Bay…"
- In April 2006, a recreational fishing representative said that "If we reach the ABC/OY and have an early closure of any sort at all, we'll have economic effects that will be staggering to the CPFV fleet. Many, many businesses will close; families will be torn apart."
- A commercial representative encouraged the use of baseline data to measure socioeconomic impacts of fishery management actions (April 2006).

Central California – Moss Landing Area

Three comments were received from individuals in the Moss Landing area. Two were in response to potential cutbacks to protect bocaccio. One fisherman said there were no bocaccio where he fished for sablefish, and commented, "Have pity on us. There are no other job opportunities" (June 2002). A commercial fish buyer said his business had lost $1.5 million in potential business during the last three years, and that 40 restaurants had gone out of business due to management restrictions (June 2002). The Harbormaster wrote "There is a synergy that occurs which is unmeasurable in terms of cash value that needs to be considered in the development of fishing regulations, including the designation of essential fish habitats on the west coast. The public comes to the ports and harbors and enjoys getting their fresh seafood while watching the boats offload their catch. Without that, these small craft harbors become stagnant and turn into yacht harbors for the rich. The little guys are forced out and the working harbors cease to exist. We have seen this in southern California harbors and hope that that does not happen here. …" (June 2005).

Southern California – Morro Bay Area

Comments were received from five individuals in the Morro Bay area.

- In response to concerns raised by the Essential Fish Habitat Environmental Impact Statement (June 2005), the Mayor wrote that "Many of the alternatives in the [EFH] DEIS would appear to close fishing grounds to the extent that would eliminate landings in Morro Bay and finally put an end to our commercial fishing harbor…" and that "our harbor and its commercial fishing businesses depend on groundfish landings to support the harbor infrastructure, since many of our fishermen are mainly albacore, crab or salmon permittees with actual landings in the ports north of Morro Bay. Our City has suffered from the reductions in groundfish quotas, seasonal restrictions and area closures to the extent that the local groundfish market has almost collapsed and just a few of the traditional shore side support businesses are still hanging on." She noted that "In the last two years we have seen some hope as groundfish prices have gone up a little, quotas increased slightly, (but typically not what was promised) due to the federal buy-back program and Class A permittees have started to see a reasonable economic return for fishing again. We are hopeful that some uncertainty can be relieved for these local businesses and for the City." Others from Morro Bay also wrote with concerns about potential regulations resulting from the EFH EIS.
- In Port San Luis, the Harbor Master wrote (also in response to the EFH EIS) that "there are many small ports and harbors that have a symbiotic relationship with the fisheries industries, both sport and commercial, within the [EFH] EIS study region. These small craft harbors rely on the fisheries to provide steady jobs and act as an economic engine, keeping the community vibrant. In the case of central California harbors, the past few years of increased regulatory actions have had a drastic effect on the ability of the fishing fleets to continue making a profit. This decline, in turn, has had a direct effect on coastal host community (harbors and marinas). The implementation of regulatory closures or restrictions will have a deleterious economic effect on these local coastal communities..." (June 2005)

Southern California – Los Angeles/Santa Barbara Area

Comments were received from 16 different sources in this region, including a study conducted by the United Anglers of Southern California that was presented during public comment in June 2003 and recorded comments by recreational fishing business owners. Comments came from Balboa, Channel Islands Harbor, Long Beach, Oxnard, Port Hueneme, Port Wainimi, Santa Barbara Channel, Santa Barbara County, Ventura County, and other points in Southern California.

Recreational fishers made the following comments:

- A sportfishing business in Balboa, California noted that several state and federal closures had "contributed to what can only be described as a catastrophic situation for the sportfishing industry in southern California. A lack of catchable species is now being recognized by our attending and prospective customers and their interest and participation is at an all-time low for this time of year." He noted that groundfish are a staple for recreational fishing businesses during the winter months when migratory species are absent, and went on to say "Those who will be affected directly include boat and landing owners, captains, crewmembers, bait haulers, landing office personnel, etc. The businesses indirectly impacted would be tackle providers, fuel docks, boat maintenance and repair facilities (shipyards), manufacturers of fishing electronic equipment, vessel food and beverage vendors, and the list goes on" (June 2003).

- Another sportfishing business owner (in the UASC study) said she had reduced payroll by half and cut back hours to stay in business. She said "The regulations in place take away any chance of making any money…I don't know what else to do." Other business owners in the UASC study reported on lost clients, declines in charter bookings, lower revenues, layoffs, difficulty in paying harbor fees, and other challenges to their businesses (June 2003).
- A saltwater lure manufacturer (in the UASC study) said that December 2002 was the worst December in 42 years of business, and that dealers were reluctant to spend money on fishing lures (June 2003).
- Recreational fishermen were very concerned over limits on rockfish. A charterboat owner in Channel Islands Harbor wrote, "We have been regulated and pushed into shorter bag limits, depth restrictions, tackle cut backs, and an extremely short rockfish season in 2005. The toll of these regs have pushed many of us to borderline bankruptcy. Many of us depend upon groundfish to survive. We have been crippled by the extremely conservative approach... many of our livelihoods may lie in the balance of the Council's decision..." (April 2005)
- Concerns were noted all along the southern California coast. One commenter said, "Ten fathom restrictions would cause a major economic impact [to sport fishers in California south of Pt. Conception]" (June 2002). Another recreational fisher noted at a Council meeting, "[There has been] economic harm to the southern California sport fishery. It's a disaster. The further north you go, the greater the dependence on rockfish" (June 2003).

Commercial fishermen expressed concerns about fisheries infrastructure and cumulative effects:

- A letter from the Southern California Trawlers Association noted, "A significant concern relates to the cumulative impacts of these closures on the essential infrastructure required to sustain viable commercial "working" fishing ports and harbors along the 1,100 mile coastline of California. ... How much fishing area, how many fishing boats, are necessary to maintain the year-round sustainable infrastructure of buying stations, ice houses, hoists, fish processing plants, wholesalers and retailers, that can provide fresh California seafood to seafood consumers?" (June 2005)
- A fixed gear fisherman commented, "In Southern California, with the Cowcod Conservation Area, Rockfish Conservation Area, deeper nearshore permit, nearshore permit, marine sanctuary, whatever, we're running out of stuff to do. And we can't afford to lose this fishery... if we implement this [observer] data, it's going to kill us" (September 2003).
- Others were concerned about small artisanal fisheries in Santa Barbara Channel: "There are small, local, artisanal fisheries that have been fishing sustainably with little bycatch in the Santa Barbara Channel for decades that are going to be eliminated with most of the alternative regulation packages you are considering for resolving the canary, yelloweye, and bocaccio rockfish problems" (June 2002).
- One fisherman commented on the difficulty in planning for business: "How do fish businesses…[recreational boats], processors, buyers, restaurants, fish markets, how do they function and pay taxes and keep the port working if they're not allowed to catch their allocated OY? How do they do their financial planning? Some folks are considering marketing campaigns [to sell] the fish that are caught - to get the highest value added, and certain marketing campaigns go out - and then all of a sudden the season's closed, and people have spent a great deal in marketing their fish... or in the case of the recreational fishermen, putting out ads for their season..." (March 2004)

Southern California – San Diego Area

There were comments from three individuals in the San Diego area.

- A manufacturer of plastic baits (in the UASC study) noted that business was down 20% in 2002 compared to 2001. He said he had considered moving his business out of state or to Mexico to lower costs, and had cut back on his employee's hours. He also noted that historically his business had participated in "every underprivileged kids' fishing trip out there. Is stopping all of this - he can no longer afford it." (June 2003)
- A commercial live fish fisherman wrote, "I and others had been able to maintain a sustainable [live fish] fishery as well as keep a successful business - with employees! That was when we were allowed to fish all year (with quotas) and target more than one species. Now, we have been regulated to fish only four months of the year! … Regulations are putting me out of business..." (June 2003)

1.4.3.4 Comments from coastwide organizations

A large number of comments originated with coastwide or national organizations. Many of these were part of email or postcard campaigns. Although they were primarily focused on environmental protection, they are included here because they also make reference to socioeconomic impacts (additional comments from environmental organizations are described in section X).

- Managers received 19,343 comments originating from Oceana and 8,266 originating from Environment California with the following wording, or a variation thereof: "A healthy Pacific Ocean is crucial for our way of life including our economy and recreation. For more than three years, Oceana has been bringing science and information to the PFMC and NOAA regarding the importance of protecting deep sea corals and sponges from bottom trawling. I support protecting ecologically sensitive areas of the Pacific seafloor such as corals and sponges, and special places such as seamounts, biogenic areas, and deep sea canyons from destructive commercial fishing. As you consider the [EFH EIS], please adopt Alternative 12, which protects habitat and maintains vibrant fisheries" (June 2005).
- Managers received 382 comments saying "...Pacific groundfish are in trouble. Years of heavy fishing have taken their toll so that today both the fish and the fishermen are suffering. We must take steps today to restore our oceans so that our marine wildlife and our fisheries can thrive in the future. Protecting EFH is one of the most important steps on this path" (June 2005).

In addition, there were four comments from other organizations:

- The Fishing Heritage Group, made up of representatives of Environmental Defense, the City of Morro Bay, and the City of Monterey, presented a list of their goals and a consensus map of no-trawl zones to the Council. They wrote that "Starting in the early 1990s, fishing opportunities for west coast groundfish…have become increasingly constrained as a result of reductions in total allowable catch. Efforts to keep the fishing open year-round resulted in reductions in smaller and smaller trip limits, making it difficult for fishermen to make a living, and for ports to maintain revenues. The establishment of very large areas closed to rockfishing resulted in further economic distress. As a result, the working harbors of the central California coast have become fragile - their health linked to declining fish landings and revenues…" (June 2005)
- The Pacific Marine Conservation Council (PMCC) wrote, "PMCC has consistently testified to the Council that we believe that it is important to assess whether disparate adverse economic

impacts may accrue to individual communities if important opportunities are lost due to restricted access. NOAA Fisheries can determine this to some degree using economic and spatial effort data regarding the trawl fishery, but it remains essential to engage fishermen in this process… PMCC believes that NOAA Fisheries' outreach in coastal communities with regard to the [EFH] DEIS should have been more extensive. Additional constructive input from people who make their living on or near the water would have resulted in a more comprehensive EFH EIS, and in superior protection of sensitive marine habitats with minimal impact on fishing communities" (June 2005)

- A representative from the Natural Resources Defense Council said, "The 9th Circuit case reaffirms the Magnuson Act requirements to rebuild depleted species as quickly as possible… That language doesn't mean that the Council and NMFS should balance biological and economic needs; on the contrary, the decision reaffirms earlier ones in holding that… "the purpose of the act is clearly to give conservation of fish priority over short-term economic issues." …Without immediate efforts to rebuild, the long term survival of fishing communities is in doubt. The court also affirmed that Congress wanted to leave leeway to allow fishing on healthy stocks and avoid disastrous short term effects…" (April 2006)
- A representative of Pacific Seafood Group, which operates throughout the West Coast states, said "If the OYs are overly restrictive, the negative economic consequences could occur in the tens of millions of dollars. Many coastal communities are struggling now. An economic impact of this magnitude would create a depression in some areas. Lastly, the Council management teams and industry have crafted innovative and creative management tools in the last few years. Let us use those tools now to find solutions that avoid economic tragedy."

1.4.3.5 Comments from unidentified locations

Forty-five comments (some of which were multiple comments by the same person) did not specify a geographic origin. Many repeated the themes in the comments listed above. Seventeen comments dealt with general socioeconomic impacts to communities, calling for managers to consider effects on communities, to develop better information on community impacts, to consider the economic impacts of recreational fisheries, and to consider cumulative impacts of regulations on communities. Fourteen comments dealt with the effects of regulations on businesses, saying that if certain closures were to take place, there would layoffs, closures, or other hardships. Four comments dealt with processors, marketing, and infrastructure. Three comments called for long-term environmental protection, including ecosystem management, despite short-term economic consequences.

One comment each said businesses need better information for planning; that more EFPs should be implemented; that marine sanctuaries would harm the fishing industry; that sportfishing caused less ecological damage and more economic benefit than commercial fishing; and that closing the recreational fishery during the warmer months would not cause as much hardship as closing it during the winter months, when there are fewer fishing options. One comment questioned the use of 2000-2002 as a baseline for socioeconomic impacts; one called for real-time observer data; and one said that nearshore closures can pose safety risks to small trawlers.

1.4.3.6 Comments from nongovernmental organizations

Most of the comments described above focused exclusively on socioeconomic impacts. Some referred to the balance between short-term economic impacts and long-term environmental protection. The comments below came directly from nongovernmental organizations (the letters are included in their entirety in Appendix B).

Natural Resources Defense Council, the Ocean Conservancy, and Oceana together wrote (March 30,

2006) commenting on the 2007-2008 specifications proposed for yelloweye rockfish. The authors take issue with the GMT's proposal to increase the OY above that identified by the SSC. The letter calls for the Council to rebuild yelloweye as quickly as possible, and to follow the SSC's advice regarding rebuilding periods for yelloweye. The letter expresses concern that the GMT proposal would create a risk of serial depletion of yelloweye, and notes that uncertainty levels are very high for this species. The authors call for the Council and NMFS to develop a systematic approach for identifying the shortest time possible for rebuilding overfished species, before the next round of revisions to rebuilding plans, and to pursue steps to reduce yelloweye effort and catch, similar to those taken to reduce cowcod effort quickly in 2003. They also call for regional management of this species, since depletion levels vary significantly by state, and calls for increased observer coverage on the commercial halibut fleet and funding for fishery-independent surveys.

The letter suggests taking quick action to identify and close yelloweye hotspots to reduce bycatch, and mining observer data to develop spatial management tools, noting "the more quickly such action is taken to rebuild populations like yelloweye, the faster fishing communities will reap the benefits of healthier stocks." The authors note that "a recent study of the economic implications of rebuilding depleted rockfish populations found that the catch of overfished Pacific groundfish is worth three times as much (net present value) once they are rebuilt as in their current depleted state…These findings underscore the economic benefits of staying the course of rebuilding and of tools like protected areas that can help avoid overfishing in the first place."

In addition, Oceana wrote (April 5, 2006):

- "We request that [NOAA Fisheries] immediately review, analyze, and present a comprehensive report of salmon bycatch in the Pacific groundfish fisheries, in particular the whiting fishery and bottom trawl fisheries, to the [PFMC] and the public… We recommend this information include the estimated interception of Klamath River Chinook salmon."
- "We recommend...[including] a description of the methodology of salmon bycatch accounting presently used, and a discussion of any deficiencies… [by the April or June 2006 meeting]."

1.4.3.7 Other scoping comments

In addition to the comments listed above, we received a scoping letter from the Environmental Protection Agency that is included in Appendix B.

1.4.4 Criteria Used to Evaluate the Impacts of the Proposed Action

Council and NMFS staff began their work by assessing the proposed actions in order to identify environmental impacts and narrow the scope of the present analysis to the significant issues that will be analyzed in depth and eliminating from detailed study the issues which are not significant (40 CFR 1501.7). They used 16 factors listed in enumerated in National Oceanic and Atmospheric Administration (NOAA) National Environmental Policy Act (NEPA) guidance (NAO 216-6) §6.01, which reproduces the factors defining "significant" listed at 40 CFR 1508.27, and §6.02, specific guidance on fishery management actions, in order to screen for potentially significant impacts and determine the scope of the analysis. The §6.02 criteria are listed first below and generally focus on components of the human environment potentially affected by a fishery management action. The §6.01 criteria are related to the intensity—or severity—of the impact, which were considered in the context of the environmental components listed in §6.02. As part of this process NMFS and Council staff reviewed the 2005-2006 groundfish harvest specifications and management measures EIS. This review assessed whether the impacts of the current proposed action would differ substantially from those of the interim allocation, increasing the likelihood of significant impacts.

1-2) Can the proposed action be reasonably expected to jeopardize the sustainability of any target or non-target species that may be affected by the action?

The proposed actions have both short- and long-term effects resulting from establishing ABC and OY values for the 2007–08 biennium and, for depleted species, related long-term rebuilding targets. Short-term impacts resulting from harvests during the biennial period will not be significant if total fishing mortality is constrained at or below OYs or other biologically based harvest limits and these limits will allow stocks to remain at or above, or rebuild to, the B_{MSY} proxy, based on stock assessment and rebuilding analyses, which are the best available scientific information. However, there are several sources of uncertainty, which increase the risk that significant impacts could occur. This uncertainty includes measurement error and future natural environmental variation affecting stock productivity. Underestimating actual total fishing mortality, based on landings and observer data, is an example of measurement error that increases the risk of significant impacts. Future adverse environmental conditions affecting recruitment is an example of environmental variation that could delay rebuilding a depleted stock beyond the designated target year. (For a lengthier discussion of sources of risk refer to Appendix A to the 2005–06 groundfish harvest specifications EIS, pages A-28–A-30.) Thus, although a primary objective of the management regime is to constrain fishing mortality to non-significant levels, these sources of risk require a detailed evaluation of sources and levels of fishing mortality and the risks associated with both short-term OYs and long-term rebuilding targets. Chapter 4 evaluates fishing-related impacts to target and nontarget groundfish and other incidentally caught fish species.

3) Can the proposed action be reasonably expected to cause substantial damage to the ocean and coastal habitats and/or essential fish habitat (EFH) as defined under the Magnuson-Stevens Act and identified in FMPs?

Disturbance of benthic habitat by fishing gear is the principal impact of the proposed actions. In particular, there is concern about the effect of bottom trawl gear in high relief areas hosting complex biogenic benthic habitat such as cold water corals and large sponges. Given that the amount of fishing effort occurring in 2007–08 is unlikely to increase beyond levels seen in the recent benthic disturbance will not likely increase. Furthermore, NMFS and the Council recently completed a multi-year project to reevaluate the groundfish EFH identification and implement new mitigation measures for fishing-related impacts. These mitigation measures, which include closing areas thought to encompass sensitive habitat to bottom trawling, will likely result in reduced fishing-related impacts to EFH. Chapter 3 describes these mitigation measures and evaluates the impact of the proposed action.

4) Can the proposed action be reasonably expected to have a substantial adverse impact on public health or safety?

Health and safety related concerns focus on management measures that make it more likely vessels will fish in bad weather or hazardous ocean conditions. For example, Rockfish Conservation Areas—depth-based closed areas established to reduce depleted species bycatch—could require vessels to fish farther offshore in order to access target stocks. Pages A-35–A-38 in Appendix A to the 2005–06 groundfish harvest specifications EIS contains a general discussion of vessel safety. Management measures included under the proposed action are not anticipated to substantially affect vessel safety in a way different from the 2005–06 biennium and these effects are not evaluated further in this EIS.

5) Can the proposed action be reasonably expected to adversely affect endangered or threatened species, marine mammals, or critical habitat of these species?

Groundfish fisheries do incidentally catch species listed under the ESA and marine mammals, but at levels that have been determined not to jeopardize the continued existence ESA-listed species or contribute substantially to mortality of marine mammals not listed under the ESA. Listed stocks of salmon taken in the groundfish trawl fisheries are of principal concern. Pursuant to the ESA NMFS initiated section 7 consultations eight times on the groundfish FMP to address bycatch of listed salmon stocks. The most recent consultation was concluded with the signing of a supplemental biological opinion on March 11, 2006, {NMFS, 2006 1075 /id} because expected bycatch in previous incidental take statements had been exceeded three times from 2002 through 2005. Chapter 5 in this EIS evaluates impacts to ESA-listed salmon stocks based on information provided in the supplemental biological opinion.

6) Can the proposed action be expected to have a substantial impact on biodiversity and ecosystem function within the affected area (e.g., benthic productivity, predator-prey relationships, etc.)?

The proposed action will primarily affect biodiversity and ecosystem function through the removal of target, non-target, and protected species. These are considered cumulative effects and evaluated as such.

7) Are significant social or economic impacts interrelated with significant natural or physical environmental effects?

Groundfish landings translate into exvessel revenue and generate income for fishery participants, fish processors, and others in fishing communities. Over the long term depletion of some groundfish species has been a significant natural environmental effect and measures to rebuild these stocks could have significant adverse socioeconomic effects resulting from setting low OYs for these species. Low OYs for depleted species can constrain catches of target species resulting in substantial declines in overall revenue. As discussed previously in this chapter, a recent court decision has emphasized the need to demonstrate the stock rebuilding will occur in the shortest time possible while taking into account the short-term needs of fishing communities. This suggests that significant adverse socioeconomic impacts should be avoided; but some unavoidable significant adverse impacts (for example, to certain fishing communities) could occur in order to rebuild depleted groundfish stocks. Chapter 7 evaluate impacts to fishery sectors and fishing communities.

8) To what degree are the effects on the quality of the human environment likely to be highly controversial?

Past decisions on stock rebuilding and setting harvest specifications has been subject to litigation. As noted, the reconsideration of current rebuilding plans is in response to a court decision. These factors indicate that the effects are considered controversial.

9) Can the proposed action be reasonably expected to result in substantial impacts to unique areas, such as historic or cultural resources, park land, prime farmlands, wetlands, wild and scenic rivers or ecologically critical areas?

Given the nature of the activities authorized under the proposed action, the principal effect to unique areas would be in the context of EFH. These effects are evaluated in Chapter 3.

10) To what degree are the effects on the human environment likely to be highly uncertain or involve unique or unknown risks?

There is uncertainty about whether short-term harvest limits will result in stock rebuilding by the target year identified in the rebuilding plan. The nature of these risks was summarized in the discussion of factors 1 and 2.

11) Is the proposed action related to other actions with individually insignificant, but cumulatively significant impacts?

This EIS considers cumulative effects to the environmental components evaluated in Chapters 3–7.

12) Is the proposed action likely to adversely affect districts, sites, highways, structures, or objects listed in or eligible for listing in the National Register of Historic Places or may cause loss or destruction of significant scientific, cultural or historical resources?

The proposed action will not affect historic places or result in the loss or destruction of significant scientific, cultural, or historical resources. As noted above, the primary adverse impact of the proposed action is the removal of target and nontarget finfish species, potential adverse effects to EFH, and the incidental take of protected species. To the extent these may be construed as scientific or cultural resources, the proposed actions are not expected to result in a significant level of loss or destruction. The proposed actions could have indirect and cumulative adverse impacts to fishing communities, which might affect cultural resources such as the local social fabric, culture, and image of affected communities.

13) Can the proposed action be reasonably expected to result in the introduction or spread of a non-indigenous species?

The proposed actions do not involve the transport of non-indigenous species. Fishing vessels participating in the proposed action are located in local ports and will not increase the risk of introduction through ballast water or hull fouling.

14) Is the proposed action likely to establish a precedent for future actions with significant effects or represents a decision in principle about a future consideration?

The adoption of new rebuilding targets sets a precedent for establishing future harvest specifications consistent with those targets. Rebuilding plans revised by Amendment 16-4 may be further revised by future FMP amendments in response to new information, changes in the law or regulations, or future court decisions. Future effects are likely to be similar to those described in this EIS and past EISs evaluating harvest specifications (in 2003, 2004, and for the 2005-2006 biennium). But the intensity of these effects are hard to predict, and could be significant.

15) Can the proposed action be reasonably expected to threaten a violation of Federal, State, or local law or requirements imposed for the protection of the environment?

Chapter 9 describes potentially applicable cross-cutting mandates; the proposed actions will be implemented in such a way as to address applicable requirements of these laws and executive orders.

16) Can the proposed action be reasonably expected to result in beneficial impacts, not otherwise identified and described above?

The proposed actions are intended to have a beneficial effect by establishing harvest limits consistent with MSY, including targets to rebuilding depleted stocks to a biomass capable of supporting MSY. This will have both beneficial natural environmental and socioeconomic effects.

Table 1-1. Scoping comments related to community impacts.

Comment	Council meeting	Community impacted (when noted)	Sector (when noted)
2002: April			
Pt. Adams Packing Co. will not operate; 80-90 people will be laid off [as result of whiting being listed as overfished]	April 2002	Hammond, OR	Commercial
[Talked about impacts to Crescent City]	April 2002	Crescent City, CA	Commercial
2002: June			
Losing rockfish would be catastrophic. [Sportfishing business]	June 2002	Long Beach, CA	Recreational
Closing rockfish would put us out of business. [Charter skipper]	June 2002	Oxnard, CA	Recreational
Closing the shelf will kill us. [Sportfishing business]	June 2002	Los Angeles, CA	Recreational
Neah Bay trawlers need to fish in July-August; can't fish later in our small boats. Can only fish on the shelf. Seven ninths of the Neah Bay fleet are small boats.	June 2002	Neah Bay, WA	Commercial
Ten fathom restrictions would cause a major economic impact [to sport fishers in California south of Pt. Conception].	June 2002	Southern California	Recreational
Licenses would be cut by 80% by having to fish in less than 10 fathoms. Might make a living fishing at less than 20 fm. [Sport fishing operator]	June 2002		Recreational
Consider economic impacts [Sport fishing operator]	June 2002	Oxnard, CA	Recreational
Concerned with restrictions in less than 10 fm. Lots of communities will be put out of business. [Charter operator]	June 2002	Port Wainimi, CA	Recreational
[There are no bocaccio where we fish for sablefish.] Have pity on us. There are no other job opportunities. [Commercial fisherman]	June 2002	Moss Landing, CA	Commercial
There has been $1.5 million in foregone benefits in the last three years in my business. Forty restaurants have gone out of business due to these restrictions. [Commercial fish buyer]	June 2002	Moss Landing, CA	Fishing-related business
The northern ports in southern California depend heavily on groundfish. People are scared. [There have been] $2.5 billion in recreational impacts in California.	June 2002	Northern California	Recreational
There has been recent publicity in regional papers that the Council may impose severe measures on commercial and sport fishing for 2003. This raises concerns in the City of Fort Bragg, because fishing is an important part of the economy. In addition, there are many residents who depend on local fish as a source of food.	June 2002	Fort Bragg, CA	Community

Comment	Council meeting	Community impacted (when noted)	Sector (when noted)
We are in the commercial fishing industry and in the paper we read that we could face worse cutbacks next year [than] we already have. … Someone needs to get their head out of the sand and really see what is happening. … We are all having to be put out of business because of someone's assumptions. Why not let the fishermen show what is out there? We all have to sit back and wait while you drive us into bankruptcy when we see the stocks are there. ... It's time to check [your data] or give us a way out without going totally broke!!!!!	June 2002		Commercial
…The Pacific Fishery Management Council is recommending eliminating all bottom fishing by January 2003. If this passes through the Council and is adopted, it will be a disaster for Oregon's coastal economy, as well as a huge disappointment for all sports fishermen. ... I think the economic impact of this decision must be balanced with any concern for the fish.... if there is anything you can do to help keep the sport fishing open, it will keep the charter boats, the guides and the private fishermen on the water. If bottom fishing is eliminated for sportsmen, all the ocean charters will cease to exist... sportsmen make a huge contribution to the local economy. Depending on the area, we are talking about millions and millions of dollars, from gas stations to shopping malls to hotels and restaurants, etc. ... Sportsmen generate 40 times as much money per pound of fish caught than commercially caught fish for the economy...	June 2002	Oregon	Recreational
We operate a charter boat business in Fort Bragg, California. Our community has been hit with several extreme newspaper articles… claiming that all fishing, sport and commercial, will be prohibited as of Jan 03 from Mexico to Canada. Our entire community is up in arms. For several years, we have asked for biologists to board our vessels and actually document what fish we are catching...	June 2002	Fort Bragg, CA	Recreational
I implore you NOT to implement closures. Closures are unwarranted. Closures are not needed to help the fish populations. Closures destroy industries. … Those of us who spend time on the water constantly are opposed to closures because we know they are not needed for the fish, and because we know the impact on our industry and related industries will be totally devastating. ...	June 2002	Santa Barbara, CA	Recreational

Comment	Council meeting	Community impacted (when noted)	Sector (when noted)
… I urge you to make a thorough study of the anecdotal experiences of long time recreational anglers and sportboat captains on a regional basis. In California, we are talking about a constituency of nearly 1 million anglers that pay to use and conserve the resource, not exploit and profit from it. You will find that our reality, times several hundred million dollars of economic impact, differs widely from those who craft research to gain grants, and those who fish for profit alone. [This wording appeared in 9 different emails from anglers]	June 2002	California	Recreational
Please try to see all sides of the story before making any decisions. The angling community is a large one that contributes to our economy as well as the well being of our oceans.	June 2002		Recreational
You are certain to hear the many economic reasons of how the closure of the sport fishing industry would impact our already failing economy. The closure would not only impact the owners of the boats, as they lose their business, but it would also affect from one degree to another all businesses that are touched by charter fishing. Any business that benefits from the tourism generated by the fishing fleet to the marine supply, to fuel docks, restaurants and motels, just to name a few. The loss in dollars to the oil companies who supply the fuel and oil for the fleets will not be insignificant, and will certainly spell doom for many of their business[es].	June 2002	Depoe Bay, OR	Recreational
I would like to address a more finite aspect of a possible loss of the charter fishing fleet. Memorial Day; for the past 57 years the small community of Depoe Bay, Oregon has paid tribute to those lost at sea… Without a charter fleet there will be no Memorial Day Fleet of Flowers. For those of us who have someone "at sea," who have no grave to go to, this one day has deep meaning for us...	June 2002	Depoe Bay, OR	Recreational
The loss of the charter fleet spells other things as well. It will mean that no longer will the handicapped, the blind, the deaf, the mentally challenged be able to go ocean fishing. It will mean that many of elderly will not be able to continue with the pleasure of ocean fishing, because there will be no one to take them...	June 2002	Depoe Bay, OR	Recreational
The charter fishing industry is unique; it is not something that can be shut down with the expectation that we can import it from another country. It will be the loss of an important part of a special way of life, of private enterprise; and, more to the point, the loss of a large part of the coastal economy.	June 2002	Depoe Bay, OR	Recreational
The economic impact of the elimination of the rockfish fishery off the California coast will be devastating, and will surely lead to bankruptcy for many and to major dislocation for others.	June 2002	California	Recreational

Comment	Council meeting	Community impacted (when noted)	Sector (when noted)
…The closure, if it comes, will have a devastating effect on the small businesses operating charter and open party sportfishing boats in [Congressman Gallegly's district], and appears to be in direct conflict with the overwhelming view of the fishermen that the stocks are, in fact, in better shape that just three years ago!	June 2002	California	Recreational
My business has been supplying trawl gear to the groundfish fleet on this coast since 1979. In the past five years, we have seen our business cut in half as a result of the starvation policy you have carried out in an attempt to manage the fisheries on this coast. I feel that a closure of the shelf would mean we could no longer remain in business. The Council's policy of ever-decreasing trip limits has reached its final conclusion; the resource has been wasted, the processing and supply infrastructure has contracted, the fishing vessels have become unsafe and in some cases, completely unseaworthy. These vessels are now faced with fishing for less fish and less money, while paying more for the necessary supplies with which to do so. ... A blanket closure would mean the loss to the nation of these fisheries and the loss of the participants' livelihoods.... Systematically destroying the economic viability of commercial fishing and thus precipitating a Final Full Closure is not a management method.	June 2002	Samoa, CA	Fishing-related business
Let me list the fisheries which my business supplies and which will be impacted by this closure: ... Petrale and English sole, sand dabs, pink shrimp, California halibut, and cucumber...hake and chilipepper...prawns.	June 2002	Samoa, CA	Fishing-related business
There are small, local, artisanal fisheries that have been fishing sustainably with little bycatch in the Santa Barbara Channel for decades that are going to be eliminated with most of the alternative regulation packages you are considering for resolving the canary, yelloweye, and bocaccio rockfish problems.	June 2002	Santa Barbara Channel, CA	Commercial
2002: September			
Businesses need to plan - need information. Don't hide [information]. Provide some information early on.	September 2002	[Coastwide organization]	General

Comment	Council meeting	Community impacted (when noted)	Sector (when noted)
The Embarcadero Resort Hotel & Marine (Newport, OR) estimates 1650 occupied rooms would be lost to the Resort with severe cuts or complete stoppage of ground fishing. This would further impact the restaurant with local fishing families no longer being able to have a night out, come for Sunday brunch, or have banquets. In addition, the transient tourist who does charter fishing would not be dining either, nor would some of the groups come who focus on fishing as their extracurricular activity. ... Total economic loss [is estimated at] $421,887 [per year]. Quite an impact to what you know will devastate the economy of Newport, Lincoln County, the Oregon Coast, Oregon, the Northwest, and the West Coast. It is obvious the disaster ahead and the many who will suffer.	September 2002	Newport, OR	Non-fishing business
We, the undersigned citizens and business people of the City of Newport and members of the Greater Newport Chamber of Commerce, notify the PFMC that the reduction in fish harvest levels have had a drastic impact to our community and that further reduction in groundfish harvest levels will continue to adversely effect every business and family in Newport. The reduction in harvest levels means direct jobs are lost, not only in the commercial fishing industry but also in the recreation fishing industry, processing plants, boat repair businesses and gear shops. However, the impact doesn't end there. The repercussions trickle down to the lodging, restaurant, attraction, entertainment, and retail industries. And when these tourism based businesses lay off employees due to reduced revenues, this has an effect on other local businesses... It would be difficult to measure the number of jobs and revenues lost to the whole business community. We urge the PFMC to seriously reconsider the social and economic impacts their decision will have to coastal communities depending on the fishing industry. [43 co-signers]	September 2002	Newport, OR	Community
…Oregon's commercial fishing industry helped build our state and continues to employ thousands of people involved in catching, processing and distributing high quality seafood across the country. But that industry, its workers and families, are being threatened by drastic reductions to the amount of fish that can be caught off the Oregon coast - reductions that may be made with little regard to the economic consequences. ... We remind you that the fishing communities of Oregon are in their worst financial condition in recent history and are depending upon you to carefully craft a balanced management plan. ... We urge you to direct NMFS to adopt reasonable 2003 groundfish catch guidelines made by the Council that consider sound science and the economic impact to coastal communities.	September 2002	Newport, OR	Commercial

Comment	Council meeting	Community impacted (when noted)	Sector (when noted)
Significant socioeconomic impacts are already occurring. Community fisheries infrastructure is eroding and all fisheries are being impacted by the reductions in groundfish. Trickle down effects should be considered and are already occurring. The Council should assess the impacts to secondary and tertiary businesses.	September 2002	Oregon	Community
Landings and value should not be the only data considered in any socioeconomic impact analysis. This will not give you an accurate picture of what is happening at the ground level in coastal communities as a result of management decisions. Landings and value data alone do not reflect the negative impacts to individuals and businesses.	September 2002	Oregon	Community
Many fishermen fervently feel that fisheries management agencies have an agenda to close down the fishery. Many no longer go to meetings because they feel it makes no difference, they won't be listened to anyway and decisions have been made ahead of time. ... Most fishermen and their families cannot afford the travel time and expense away from home.	September 2002	Oregon	Commercial
People need information so they can make adjustments to their business strategies now rather than after all their resources are used up trying to hang on.	September 2002	Oregon	General
I haven't sold a vehicle to a fisherman in 2 years. [Salesman, auto dealer]	September 2002	Oregon	Non-fishing business
We are losing family wage jobs on the coast and we can't afford to do that. Consider the trickle down effect that is now occurring. Advertising is down at my radio station due to the shrinking base of family wage jobs - fishing is critical to our communities. [Radio station owner]	September 2002	Oregon	Non-fishing business
How will the full range of economic impacts be considered? We've had a fire disaster in our region this summer and we're already hurting badly from that. [County commissioner]	September 2002	Oregon	Community
Coast communities don't have many opportunities for family wage jobs like we see in the valley. Fishing is critical to us here. [Mayor]	September 2002	Oregon	Community
The Council and NMFS should try harder to do a better job of releasing information to the media. People think that because there are recreational closures in California, that Brookings is closed also - not true… [RV park manager]	September 2002	Brookings, OR	Non-fishing business
We need to fight to save coastal family wage jobs. [Mayor]	September 2002	Oregon	Community

Comment	Council meeting	Community impacted (when noted)	Sector (when noted)
More vessels are now operating without insurance. That could easily ruin the family business. Ports and communities will have to respond and pay for things like cleanup. Plus, there are significant costs associated with Coast Guard search and rescue. When maintenance is put off, more accidents happen and taxpayers will have to cover the costs. [Port manager]	September 2002	Oregon	Commercial
The local jewelry store laid off four workers. They don't have the business they need anymore from fishermen and their families. [Port commissioner]	September 2002	Oregon	Non-fishing business
The industry isn't collapsing but we need help right now with readjustment initiatives. We are a community of survivors. Rural communities need to remain independent. Don't take that away. [Port manager]	September 2002	Oregon	Community
There are limited jobs you can retrain for in our community which will support a family. [Port manager]	September 2002	Oregon	Community
A buyback program will help some fishermen but won't help other businesses. [Radio station owner]	September 2002	Oregon	Non-fishing business
Shipyard business is way down. Many fishermen are going on a 3-year haul out schedule instead of a 1-year schedule. We are concerned about safety. [Insurance agent]	September 2002	Oregon	Non-fishing business
The local fuel dock is ready to shut down. [Fishing family member]	September 2002	Oregon	General
Consider the time and goods and services involved in getting ready for fishing seasons that don't happen. This is significant lost revenue for my store. [Gear store manager]	September 2002	Oregon	Fishing-related business
I couldn't get ice this summer so even though we had a good salmon fishery, we couldn't get the ice to hold the fish. My fish plant closed. [Salmon troller]	September 2002	Oregon	Commercial
My firm is cutting back and may go out of business. I can hardly afford to keep working because of the reduced demand for trucking. There's now only a few months of work. [Trucker for firm that transports product from fish plants]	September 2002	Oregon	Fishing-related business
Our fish plant closed and we couldn't get a market with another plant. So we've moved our fishing business out of state. [Fisherman's wife]	September 2002	Oregon	Commercial
I quit buying groundfish because I couldn’t get the mix I needed for my market. I laid off 15 workers. [Fish buyer]	September 2002	Oregon	Processing
The local grocery store used to carry lots of boat accounts - those are way down now and there are more and more accounts in arrears.	September 2002	Oregon	Non-fishing business
In fact, lots of associated businesses are being hit - marine electronics included. Business is down and what business they have, it's hard to get folks to keep their accounts current.	September 2002	Oregon	Fishing-related business

Comment	Council meeting	Community impacted (when noted)	Sector (when noted)
It isn't reasonable for NMFS to seek to enact regulations that will eradicate family businesses without a specific economic plan in place to assist those businesses and replace those jobs. And I'm not talking about 10 dollar an hour jobs - I'm talking about jobs for crewmen who earn between $35,000 and $40,000 per year. [Fisherman's wife]	September 2002	Oregon	Commercial
Families are so frustrated - we feel we never know what's next. No one can plan a successful fishing business with so many unknowns. Who will be in, who will be out. If you are out then what - nothing. Nothing is clear-cut. We won't even know next year's restrictions until just before the season actually starts - and that's if we are lucky. Our financial reserves are gone - what can we do? [Fisherman's wife]	September 2002	Oregon	Commercial
Two of my friends are now getting divorces. The financial stress was too much - that and husbands always being angry, moody, and withdrawn. After four years of that, they (the wives) couldn’t take it any more. [Fisherman's wife]	September 2002	Oregon	Commercial
I'm very concerned about the crumbling infrastructure - it's worse in some ports than others but all are experiencing it. Processors, fuel docks, gear suppliers - they are shutting down. Once that happens, I fear we won't be able to go back and rebuild. There may well be no infrastructure left to support the industry of the future. [Gear store owner]	September 2002	Oregon	Fishing-related business
I have $90,000 worth of netting on order - I had to place the order 6-8 months ago in order for it to be here for the 2003 season (needs one year lead time). The order has been shipped - it's on a ship in a container. I fear once it gets here it will be illegal and I won't be able to sell it. I can't send it back - it's happened to me before. I need to be able to plan my business better than the current management system allows. Seems like I could at least get a tax credit for merchandise I can no longer sell. I have to assume full liability. [Gear store owner]	September 2002	Oregon	Fishing-related business
Economic data mainly focuses on the commercial sector, not recreational. We need more recreational data. [Charter boat owner]	September 2002	Oregon	Recreational
Oregon's economy is a mess and the coastal economy is even worse. If you'd just let us work, we have a lot to contribute. [Fisherman]	September 2002	Oregon	Commercial
Other fisheries are already being negatively impacted by the groundfish crisis - more pressure in albacore tuna specialty markets for example - only so much room on the shelf and existing businesses are being pushed aside. [fisherman]	September 2002	Oregon	Commercial

Comment	Council meeting	Community impacted (when noted)	Sector (when noted)
Groundfish issues are of great concern to crabbers. There already have been impacts. There's now more pressure on the resource and there may be gear and habitat conflicts when we start implementing area closures. We're losing processing capacity. [Commodity commission manager]	September 2002	Oregon	Processing
What are the community impacts of fish businesses using less water and power? This translates to less income for the city/county. [Processor representative]	September 2002	Oregon	Community
Fishermen are treated as criminals by NMFS for even small overages. And this on top of everything else! Decriminalize the system and us! [Fisherman]	September 2002	Oregon	Commercial
The Magnuson Act should be the Sustainable Fishing Community Act. [Fisherman's wife]	September 2002	Oregon	Community
I'm very concerned about our crumbling infrastructure - once existing support facilities like fueling stations and fish processing plants are gone, environmental rules will make it hard for new ones to come in, even when fishing improves. [Sea Grant marine agent]	September 2002	Oregon	Community
The local women's shelter is full - families are breaking up - this thing has gone on so long and there are so many uncertainties that it's tearing some families apart. You can imagine how it gets at home when money is tight. [Groundfish Disaster Outreach Program staff]	September 2002	Oregon	Community
How will NMFS gather community impact data such as business impacts? [GDOP staff]	September 2002	Oregon	Community
You'd think that all the news about sardines is helping the local [Astoria] fleet - no - no local fishermen have the gear or permits to benefit from the fishery. Much of the benefit from that fishery is going out of state. [GDOP staff]	September 2002	Astoria, OR	Commercial
[Relayed socioeconomic impacts in his area.] Council needs to rectify these problems	September 2002	El Granada, CA	Commercial
Thornyheads and sablefish [were] closed this summer - it killed the Newport dory fleet.	September 2002	Newport, CA	Commercial
Work quickly [on EFPs]; the industry needs help fast.	September 2002		Commercial
Economics of fishing should be given greater emphasis.	September 2002	California	Commercial
California recreational fisheries will suffer. Economic [impacts] are underestimated.	September 2002	California	Recreational
2002: November			
Keep flatfish species in the California halibut fishery. We need every dime we can get.	November 2002	California	Commercial

Comment	Council meeting	Community impacted (when noted)	Sector (when noted)
Although the Council is primarily concerned with groundfish, and the effect of restrictions in the groundfish fleet, be aware that the West Coast fishery as a whole is experiencing an overall depression. Depressed prices for salmon, shrimp, crab and tuna are adding to the general poor outlook for fisheries. There will be a smaller fleet regardless of what this Council does, and regardless of what happens in groundfish. This proposal [fixed gear permit stacking] will provide some economic relief both to those who choose to leave, and those who choose to stay.	November 2002	Newport, OR	Commercial
2003: April			
We need real time [observer] data. Need to observe where fishermen fish [now], not where they once fished. Closing down coastal communities. We need economic analyses of port impacts.	April 2003	California	Community
Consider community effects of rebuilding plans.	April 2003	[Coastwide organization]	Community
Small trawlers are fighting to survive. If we try to go offshore, there are safety risks.	April 2003	Neah Bay, WA	Commercial
We urge the Council not to adopt this change to the CCA boundaries…especially when the effects of this kind of change under the MSA must be looked at in a balanced view considering also the social and economic impacts to members of our Association, all of whom are individual family fishermen... We have been eking out market orders by adhering to all of the groundfish conservation measures, but barely. Now, with the proposed changes to the CCA, our last few spot prawn areas would be halved...	April 2003	Santa Barbara Channel, CA	Commercial
2003: June			
[Change the bocaccio OY.] The Morro Bay economy is down 10% overall. The fishery-dependent industry is really hammered.	June 2003	Morro Bay	Community
[There has been] economic harm to the southern California sport fishery. It's a disaster. The further north you go, the greater the dependence on rockfish.	June 2003	Southern California	Recreational
Recreational fishing businesses, particularly landings and bait and tackle operations, do not benefit from the various programs designed to ease impacts of regulations on the commercial fishing community.	June 2003	Huntington Beach, CA	Recreational
Rockfishing regulations over the recent past has been dramatically affecting recreational fishing opportunities in Northern Los Angeles, Ventura, and Santa Barbara counties.	June 2003	Southern California	Recreational

Comment	Council meeting	Community impacted (when noted)	Sector (when noted)
In 1999, two landings, Hornet Sportfishing and Sea Landing, operated here [Santa Barbara Harbor]. Since then, the former has closed with no subsequent information available. Sea Landing had three sportfishing vessels available throughout the year. Now, it has one with a second available in October and November for offshore fishing... Essentially, Sea Landing had 437 fewer passengers in 2002 than 2001 for the three corresponding months (Oct-Dec).	June 2003	Santa Barbara County	Recreational
The one landing here [Ventura County] that had three vessels operating from it has closed its doors and no records are available. [A landing in Channel Islands harbor had 25.5% fewer passengers in Oct-Dec 2002 than in 2001]	June 2003	Ventura County	Recreational
Cisco's Sportfishing Landing [Channel Islands Harbor] has been in business and open 24 [hours] per day since 1964. It is the largest landing in the region… The following points are from a conversation with Marlene Wilcox, owner (Feb. 1, 2003): Lack of passengers most apparent on open party boats; overnight boats not getting out at all; [partial day] boats going light; running a two-for-one program; ... business is off a minimum of 25%; ... "The regulations in place take away any chance of making any money"; is reducing everything to stay alive; payroll has been cut in half...used to stay open 24 hours per day - now only 8-12 hours, which is the minimum necessary to stay in business; has cut all corners and still just falling further and further behind; can't pay bills; "I don't know what else to do."	June 2003	Channel Islands Harbor	Recreational
Captain Hook's Sportfishing [Channel Islands Harbor] opened in 1998 with a half-million-dollar investment… They enjoyed a 15% growth in 1999 and 2000. The downturn started in 2001, and Debbie reports that financially, her business is down 21% and between 45-55% behind on her original business model for the same time frame. ... There's been steady decline in business since May 2002. If the pattern continues or some form of relief isn't forthcoming, they'll be forced into bankruptcy. They never would have invested in the business if they had known this would happen.	June 2003	Channel Islands Harbor	Recreational

Comment	Council meeting	Community impacted (when noted)	Sector (when noted)
Port Hueneme Sportfishing reflects the same downturn in business that the others in the area show. The owner reports his November and December 2002, and January 2003, were 50% of what he did the previous year. He also reports that he experienced 50% cancellation of charters for the same three months that had been previously booked, and bookings for 2003 are running 75% behind last year. He can't make his monthly lease payments to the Harbor Department. He used to employ two part-time and two full-time employees. He has now laid everyone off.	June 2003	Port Hueneme, CA	Recreational
Booking of charters for upcoming year [is] over 20% off from last year, and last year was poor.	June 2003	Channel Islands Harbor	Recreational
New business is substantially curtailed.	June 2003	Channel Islands Harbor	Recreational
Between the 20 fm closure and island closures, where am I supposed to fish? Give us out to 30 or 40 fm or buy me out. Give me a long-term, low interest loan to fund my boats' transition to ecotourism and I'll never fish again. Right now I'm in the middle of a county sponsored engines, generator re-power that's costing me $200,000, so I can be eco-emission compliant. I'm doing this because they want me to; it's not required. While I'm doing this, other parts of government are putting me out of business.	June 2003	Southern California	Recreational
Going into savings to keep business afloat. Saltwater fishing business way off; freshwater helping to keep doors open. Sluggish economy not helping, but fishing restrictions most damaging. [Tackle shop owner]	June 2003	Southern California	Recreational
As of October 15th, bottom fell out of business. November 2002 did 50% of November 2001. December was OK. Attributes [this] to excellent fishing in Santa Monica Bay that month. Laid off an employee of five years in October (shop had three; now has two). Spent less than 50% of what he spent last year at early season trade shows. Bought store six years ago. Retired to this business and loves it. Now he wants to sell. He can't stand the political uncertainty of future. He feels victimized; has no voice. He feels nobody is really listening. [Interview with tackle shop owner]	June 2003	Southern California	Recreational

Comment	Council meeting	Community impacted (when noted)	Sector (when noted)
Sales for December 2002 not even 50% of December 2001. Worst December in 42 years of business. November 2002 and January 2003 reflect similar trends. Dealers are scared and pulling in horns. They won't spend now. Historically, the industry depended on the quality of the bite, volume of fish that migrate into the region, water temperatures that controlled how eagerly resident fish bite. Now, the business is dependent on political issues. [Interview with saltwater lure manufacturer]	June 2003	Southern California	Recreational
Business down 20% overall in 2002 as compared to 2001. Considered moving manufacturing out of state (perhaps to Mexico) to lower costs. Has cut back employees' total hours; they are all part time now. These are all ESL employees who have been with him 4 to 8 years. Historically, Fishtrap Lures has contributed and partaken in every underprivileged kids' fishing trip out there. Is stopping all of this - he can no longer afford it. [Manufacturer of plastic baits]	June 2003	San Diego	Recreational
My concern is with a small footrope I can harvest 20,000 lbs of beach fish [sand dabs, Petrale, English, sand, and flounder sole], which may sustain the markets until we are able to harvest more, but [is] not enough to operate a fishing vessel on… The only option that I can see is to fish a large footrope, which 99% of the fleet will choose to do and the market for beach fish will go away. And that market will take years to get back and will not be there if or when you ever let us catch the beach fish... I will lose my markets and be forced to fish in an area that will be over fished and unsafe for my boat over a fish I do not catch. I believe this inseason management plan will devastate the trawl industry. Markets will be lost and large numbers of boats will be forced to fish in a small area which compromises the safety of the smaller vessels.	June 2003	Crescent City	Commercial

Comment	Council meeting	Community impacted (when noted)	Sector (when noted)
We need to know what is happening with the current closure for the west coast groundfish. We are getting killed out here! When you first talked about closing the fishery…you said a two week closure…at the most three weeks. Well, we are on week four now...we still have not heard one word from the Council on how things are progressing. ... Do we all need to declare bankruptcy right now?? The appearance of discrimination against those of us that use small footropes nearshore is looking more and more as a fact. Some of us are not capable of fishing with big gear that can operate outside of 200 fathoms...you need to take that into consideration. As I write this, the large vessels continue to tow away... still making a living... they haven't missed a day of fishing. We (small boats) have been shut down for almost a month now...many of us will soon be in jeopardy of losing assets, like our homes or boats. We have already lost so much with the cable crossing, the Vessel Traffic Lane Change, and other inseason adjustments that we have no reserves left to fall back on. ...	June 2003	Neah Bay, WA	Commercial
The Council's action or lack thereof [has] real human impact. You are literally killing us off out here. ... PLEASE come up with some different restrictions for us that will still allow us to survive...we want a viable sustainable fishery that we can continue our livelihood into the future...many of us have been fishing our small family boats for generations. But sadly, many of us do not encourage our children to partake of our tradition of being a fisherman...competition and politics have put an end to that dream.	June 2003	Neah Bay, WA	Commercial
I have been told this OY [June 2003] is not large enough to allow the seasonal upward catch adjustments the fishermen need to take advantage of the good weather and strong market of the summer months. This has created a situation that threatens long established markets and infrastructure up and down the coast... We badly need to have an increase in the black and blue rockfish component of our catch allowances. Without the seasonal increases in these fish, some of the last nearshore markets will be lost along with the infrastructure that supports them. Many fishermen, especially those who fish outside of the areas that can supply the live market, cannot make enough money to support their fishing efforts...	June 2003	Crescent City	Commercial
The management regime for 2003 virtually ended groundfishing by recreational anglers.	June 2003	Southern California	Recreational

Comment	Council meeting	Community impacted (when noted)	Sector (when noted)
[We] plead the case here [Newport, OR] for expanding some fishing grounds or quotas to the draggers deploying this year, as the value of the fish the quotas allow right now would force our net shop out of business, much less a drag boat. A year from now, if these quotas and closed zones stay in effect, we will be having to turn fishermen away for fears of not being paid. Inventories at shoreside services are dwindling and the entire market infrastructure seems ready to collapse...	June 2003	Newport, OR	Fishing-related business
If we do not get back some grounds or quotas in the next couple of catch periods, I am sure there will be some fishermen dangerously close to losing their ability to survive. Look at the value of the fish that you have left us and go through the economics of running a trawler. It does not add up to viable business.	June 2003		Commercial
…We are already seeing several party boat operations being sold or forced out of business…many boats and supporting businesses (tackle shops, fuel docks, hotels etc.) depend on rockfish for winter their income. It's not a large part of their annual total but enough to pay their employees, insurance and berthing fees until the more lucrative salmon season opens. We are literally one bad salmon season away from losing most of the party boat operations along the Central coast. In a good salmon season these small businesses can scratch out a living but if the salmon don't show the cost of running a boat and paying its crew becomes impossible. Most at risk are boats and businesses in the smaller ports. Two of the largest party boat operations in Bodega Bay are currently selling out or closing down and more are sure to follow from Ft. Bragg to Bodget Bay. ...A blown motor or other major breakdown can cost upwards of $40,000 and quickly force the owner to sell out or into bankruptcy.	June 2003	Central California	Recreational
I and others had been able to maintain a sustainable [live fish] fishery as well as keep a successful business - with employees! That was when we were allowed to fish all year (with quotas) and target more than one species. Now, we have been regulated to fish only four months of the year! And the license fees are going up! With more licenses! (Deeper nearshore rockfish - a cruel slap in the face to nearshore fishermen not levied on the sportfishing fleet). This situation is unacceptable to this open access participant... Regulations are putting me out of business, by a conspiracy of anti-fishing management staffing... Something must be done to put the commercial fishing industry back to a common sense, profitable state. ...	June 2003	San Diego, CA	Commercial

Comment	Council meeting	Community impacted (when noted)	Sector (when noted)
…These current species, area and seasonal limitations will, in a relatively short time, cause the ultimate demise of the sportfishing industry. We have already realized a significant decline in our passenger loads and revenue since the most current stringent closure went into effect, i.e. [the] sculpin closure (March 1). This closure, in conjunction with the ongoing whitefish restriction, the "non-opening" for any species of rockfish and the 20 fathom...depth limitation have all contributed to what can only be described as a catastrophic situation for the sportfishing industry in southern California. A lack of catchable species is now being recognized by our attending and prospective customers and their interest and participation is at an all-time low for this time of year.	June 2003	Balboa, CA	Recreational
…The net result…of the closures has been that the sportfishing industry is now crippled by the limitations of allowable catch which has had a devastating effect on our potential customers' participation in the fishing activity. In other words, people are not going fishing because they can keep next to nothing that they catch! To pay to go fishing is not money well spent since the trips result in something more akin to simply a "boat ride."	June 2003	Balboa, CA	Recreational
Over the past 50 years of recreational sportfishing, we have been able to offer our customers a variety of species in the winter and spring months. Since migratory species, such as tuna, yellowtail, barracuda, etc., are not in our area during these months we have relied on whitefish, sculpin and rockfish (groundfish) as the mainstay of our trips. Needless to say both winter and spring seasons have been disastrous in terms of participation and catch due to the fact that we are unable to fish for any type of groundfish other than sheephead.	June 2003	Balboa, CA	Recreational
The demise of recreational sportfishing will also have a severe economic impact on those who derive their livelihood from sportfishing. Those who will be affected directly include boat and landing owners, captains, crewmembers, bait haulers, landing office personnel, etc. The businesses indirectly impacted would be tackle providers, fuel docks, boat maintenance and repair facilities (shipyards), manufacturers of fishing electronic equipment, vessel food and beverage vendors, and the list goes on.	June 2003	Balboa, CA	Recreational
2003: September			
If trawling is closed for three months, the filleters I have would have to get a new job; the truck drivers would leave, and I'd be out of business. It's that serious and that simple.	September 2003	California	Processing

Comment	Council meeting	Community impacted (when noted)	Sector (when noted)
If we implement this observer data inseason, it's not only going to shut down the trawl fishery; it's going to take the fixed gear fishery also. In Southern California, with the Cowcod Conservation Area, Rockfish Conservation Area, deeper nearshore permit, nearshore permit, marine sanctuary, whatever, we're running out of stuff to do. And we can't afford to lose this fishery... if we implement this data, it's going to kill us.	September 2003	Southern California	Commercial
Changing the process again, midstream…is taking all these small [trawl] businesses by surprise, and will hurt many coastal communities. …How do us small business owners tell our bankers that our government's inseason adjustment has ruined our business plan for the year? How can any business effectively operate in this kind of environment?...	September 2003	Coos Bay, OR	Commercial
I think a lot of this…is centered on biology rather than thinking about the fishing community… Fishing, fishermen, and fishing communities are all businesses… Communities should be considered. There are a lot of rural communities out there…that are all hurting. This closure could really impact rural communities, if not devastate them. Socioeconomic and drastic impacts must be considered in this decision. Businesses depend on a yearly revenue cycle to make decisions...an inseason adjustments makes no business sense... I can't fathom making decisions every two weeks in another kind of business...	September 2003		Commercial
If this season is shut down, the economic effect in Port San Luis, Morro Bay, and San Luis County in general is gonna take a real hit. The only processor in Port San Luis…will be out of business… There are approximately 15 trawl vessels that will be out of business in both ports...	September 2003	Port San Luis and Morro Bay, CA	Commercial
In terms of some of the economic impacts…In Warrenton, Oregon, last year...in period 6 (teh whole period that would be closed under on scenario here) the exvessel gross averaged about $60,000 per vessel for the trawl fleet. There are about 30 vessels fishing in Warrenton, so that comes out to about a $1.8 million impact. And if you use a conservative...multiplier (2.5), that's about a $4.5 million impact on the community of Warrenton.	September 2003	Warrenton, OR	Commercial
Please consider alternatives to protect fisheries who have taken drastic measures in their commitment to save and conserve fish. These changes create scenarios where fishermen cannot function as a business.	September 2003	Central California	Commercial
[Only 28 of 545 metric tons of shortspine thornyheads are caught in Washington]. You're now taking somebody who's not creating a problem, and trying to put us out of business. I don't understand…	September 2003	Neah Bay, WA	Commercial

Comment	Council meeting	Community impacted (when noted)	Sector (when noted)
The effects of a total closure could be pretty devastating to some people, and given the doubts about the science that's being used, I think you need to weight that very carefully.	September 2003	Fort Bragg, CA	Commercial
… One of my landings, Cisco Sportfishing, is out of business, bankrupt, because of the closure of the rockfish fishery.	September 2003	Southern California	Recreational
Keep the B platoon; it helps the industry. The trawl industry is on its knees.	September 2003	Oregon	Commercial
If areas outside of the 50 fm line are closed to recreational anglers, we would not have any opportunity to fish for groundfish [due to unique geology of area.] Recreational angling provides a great economic stimulus for Winchester Bay and the surrounding area. If recreational angling were stopped, we would experience the ripple effect from another loss of fishing species. We experienced this in the 80s and 90s with the closure of coho salmon fishing along the Oregon coast. Many fishing related businesses closed and this area lost all our charter fishing businesses. We currently have only four charter offices providing offshore angling opportunities for our visitors. [Received 2 copies from different people]	September 2003	Winchester Bay, OR	Recreational
The Port of Siuslaw [Florence, Oregon]…is greatly concerned about any pending recreational groundfish closures outside of the 50 fm line… We do not have any coastal reefs that support groundfish. The closest reefs to Florence are at Heceta Banks thirty miles offshore...Recreational angling provides a great economic stimulus for Florence and the surrounding area. If recreational angling for groundfish were stopped, we would experience the ripple effect from the loss of fishing. We experienced this in the 80s and 90s with the closure of coho salmon fishing on the Oregon coast. Many fishing related businesses closed and we lost all our charter fishing businesses.	September 2003	Florence, OR	Recreational
2003: November			
Closing the [sanddab fishery] makes it hard to pay for VMS.	November 2003	California	Commercial
I would catch 30% of what I could if forced out to 200 fm.	November 2003	California	Commercial
We are writing on behalf of Forks, Washington…to support the proposed changes to the Pacific Halibut Catch Sharing Plan… Our community has been struggling with a declining economy for the past fifteen years. We have been actively pursuing methods to improve all aspects of local commerce, including recreational fishing impacts. ... [Changes to the catch sharing plan] would greatly benefit the Washington North coast communities.	November 2003	Forks, WA	Recreational

Comment	Council meeting	Community impacted (when noted)	Sector (when noted)
The Quileute Tribe at LaPush, Washington is writing in support of the letter you have received from the City of Forks…Like Forks, our community has been struggling financially for many years. Having the only major recreational harbor for many miles, recreational fishing is extremely important to us as well. ...	November 2003	LaPush, WA	Tribal
2004: March			
Please don't push me out into 120 fm. It's not going to help the yelloweye, and it's going to be very hard on my economics.	March 2004	Port Angeles, WA	Commercial
I was talking to our harbor manager, and he says he's facing some revenue cuts. How do fish businesses…[recreational boats], processors, buyers, restaurants, fish markets, how do they function and pay taxes and keep the port working if they're not allowed to catch their allocated OY? How do they do their financial planning? Some folks are considering marketing campaigns [to sell] the fish that are caught - to get the highest value added, and certain marketing campaigns go out - and then all of a sudden the season's closed, and people have spent a great deal in marketing their fish... or in the case of the recreational fishermen, putting out ads for their season...	March 2004	South/Central California	Commercial
Sport fishermen come to the coast, rent a hotel, eat dinners out, buy tackle at the local shop, get their boat serviced/repaired in town… who supports the local economy more with the least impact on fish stocks???	March 2004	Oregon coast	Recreational
It seems strange to us that the hardest hit west coast fleet is the only U.S. fleet to have to pay for [VMS]… The state that has the highest unemployment rate, the state with the highest poverty level, the state with the most strict and radical regulations in the world and the state with much less powerful Senators has to pay for the system themselves. We now are forced to fish beside vessels who are using government paid for VMS units while we have to borrow money to pay for them. ...	March 2004	Coos Bay, OR	Commercial

2004: April			
… It has…come to the attention of Arrowac Fisheries that this depth management fisheries approach may result in the fishing depth restriction being moved to 150 fm perhaps as early as June. This depth restriction will be financially devastating to Arrowac Fisheries Inc., [its] employees...and the fishermen who derive their livelihood from the longline fishery off the coast of Washington. It appears the tradeoff for this devastation of the local economy would be to enable the Council to find additional rockfish bycatch biomass to be allocated to another user group... Arrowac Fisheries depends heavily on the dogfish harvest...moving the depth restriction to 150 fm would virtually eliminate the harvest of dogfish...[we also depend] on the set line blackcod fishery that takes place off the Washington Coast. With a depth restriction of 150 fm...an additional negative economic hardship would be experienced... Most likely Arrowac would see a reduction in blackcod pounds delivered...generating less dollar return and reduced work hours...	April 2004	Bellingham, WA	Processor
With respect to the blackcod fishery of the Washington coast the real negative economic impact would be borne by the setline fishermen. Moving the depth restriction to 150 fm would result in the harvest of small blackcod, generating an average revenue of about a dollar less per pound...	April 2004	Bellingham, WA	Processor
… I represent the LaPush Area Recreational fisheries in the North of Falcon and PMFC process. …We are extremely concerned about the lack of regional management…There is no fairness in allowing one state's excessive catch to preclude fishing in the other states. Groundfish fisheries are critically important to our coastal economy and tourism.	April 2004	Forks, WA	Recreational
Our city has been severely impacted by the decline of the groundfish. … The current system appears to favor other states over Washington.	April 2004	Ilwaco, WA	Community
…I represent the Ilwaco Charter Association. … We are extremely concerned about the lack of regional management on weak groundfish stocks… Groundfish fisheries are critically important for our coastal economies.	April 2004	Ilwaco, WA	Recreational
…The 30 vessel owner/operators that are members of our association depend upon groundfish and halibut for a major part of their livelihood. …[A call for regional management]	April 2004	Westport, WA	Recreational
…I am writing on behalf of Southwest Washington Anglers. … These various fisheries are of extreme economic value to our small coastal communities. [A call for regional management]	April 2004	Oregon and Washington	Recreational

… The Port of Neah Bay has invested heavily in the newly constructed Makah Marina and additional upland facilities that both support and are reliant on the recreational fisheries. A vibrant groundfish and halibut fishery are critically important to Neah Bay's economy, as it is to other coastal communities relying on recreational fishing to survive. We are extremely concerned about the lack of regional management...	April 2004	Neah Bay, WA	Recreational
2004: June			
[California recreational fishery] needs a 10 month season to survive. About to lose [my] business.	June 2004	Southern California	Recreational
This [black rockfish] closure hurts California economically and socially while it does nothing to protect California's environment.	June 2004	McKinleyville, CA	Recreational
I believe you are completely wrong in recommending the closure of the bottom fishing season with all the implications for people who depend on the sea for their food and income…When you close the seasons as you often recommend, it puts an extreme hardship on businesses and their employees.	June 2004		General
2004: September			
All over Oregon, our skippers and deckhands depend on the ground fishery to make a living and feed their families. Winter months through early Spring especially, all they were allowed to catch was bottom fish, to carry them through until salmon season starts again. This is the cycle you have put us in. Now you have ruled to take this away from us leaving nothing to make a living with this winter. How can you sleep at night??? ... Your inaccurate estimates are interfering with peoples' lives and should be stopped. We have all worked with you, allowing observers to go out on our boats (no charge) and fish checkers to come down to our privately owned docks, to help them do their job. How and what would they feel and you, yourself, if we say - no more!!! ...Give us back our fishing rights.	September 2004	Newport, OR	Recreational
As the news of the sports ground fishery closure moves like a storm through Brookings Harbor, numerous individuals have contacted the Port… The impact is being felt already by this community and is expected to multiply extensively in the next few days. Southern Oregon is struggling to create employment opportunities and keep this one key element of the tourism industry alive, which is our recreational fishing industry. This is a blow to our economy that is unexpected and, plainly speaking, should be justified to the general public, as each of our fishermen knows very well that there is a tremendous abundance of groundfish available in this area.	September 2004	Brookings, OR	Recreational

This [sport groundfish closure] will require that I cancel all my trips and let my customers also cancel all hotel and dinner plans for October and November of 2004. … I will now plan on leaving the northern Oregon coast upon the closure of the 2004 salmon season. ... It is sad that the few commercial interests far outdistance the revenue generated by public visiting and spending tourist dollars in these hard hit local coastal towns.	September 2004	Sammamish, WA	Recreational
[VMS] will force small vessels with limited income out of the fishery.	September 2004	Pacific City, OR	Commercial
2004: November			
[Wants specific Petrale areas opened.] Petrale is important to the limited entry trawl sector. [We] may not survive a closure. [My] career is probably over without a Petrale season.	November 2004		Commercial
The fall Petrale sole fishery has been a valuable economic asset to both the fishermen and processors at a time when both the weather and the late year limits put an economic hardship on the industry. By the current position of the 250 fm line the Petrale fishery has been eliminated. The Petrale fishery has become an established holiday season marketing item for the processors, brokers, wholesalers, restaurants, and grocery stores. We all traditionally look forward to this unique fishery opportunity, over the past years, to sell the best available sole we have to offer our customers and the general public. The loss of income produced by this fishery will not only affect the fishermen, their crews, and processing community, but the coastal communities as well.	November 2004	Charleston, OR	Processing
…Without proper notice the RCA zone was moved out to 250 fm, which causes a devastating ripple effect within our company. Over the past several months our company has invested approximately $80,000 to develop our new fillet room with the anticipation of Petrale season opening in October of this year. We are a small company just starting out in this business and this has made an enormous impact on our financial situation... Last year during the months of October, November and December we purchased several thousands pounds of Petrale, which made it possible for us to continue doing business by compensating enough income to keep paying wages of our employees. Currently we employ 11 employees...in the fillet room; if we continue to lose the upcoming months of Petrale season this number will dramatically decrease, leaving our employees without jobs. In order to help with Petrale season we also employ additional dock crew [and a supervisor].	November 2004	Charleston, OR	Processing

Taking away access to Petrale...obviously affects more than just the fishermen. It affects many jobs...and it has already taken a serious toll on our small company... By moving the RCA zone we have also lost access to rex sole, English sole, sanddabs, and shallow water dover, which is a smaller market but still provides income to local families that our company employs.	November 2004	Charleston, OR	Processing
2005: March			
Since a seven month recreational groundfish season in 2004 did not result in a catch exceeding the target harvest, it is difficult to understand why our fishing season has been reduced to four months in 2005. … Because the reduction in our groundfish season will have a devastating impact on our port and local community, and because we have significant new information indicating the reduced season is neither justified nor needed, the Board of Harbor Commissioners of the Crescent City Harbor District respectfully requests that you open the season for recreational rockfish on May 1 and allow it to remain open until October 31.	March 2005	Crescent City, CA	Recreational
Port Orford fishermen, the Port and the community of Port Orford have long derived economic benefit from groundfish landings from around our area. All are now suffering hardship because of declining stocks and harvest regulations. [Request for TIQC to consider fixed gear vessels and keep Port Orford informed.] We believe any groundfish planning should include all gears and harvesters and provide information to communities and a process for communities to participate in the decision-making that will affect their futures.	March 2005	Port Orford, OR	Commercial
2005: April			
…Blackcod fishermen will be affected [by VMS requirements]. It's going to be a situation where, according to this economic information, which may or may not be true, there's over a million dollars being brought in by those fishermen in our northern area. I don't believe there's been a multiplier applied to that to tell you what the true value is to our communities; it would be at least three times that much. ...I see the VMS being a much larger economic issue than what is being presented to you...	April 2005	Crescent City, CA	Commercial

In 2004 the [California] Department of Fish and Game cut our fishing season to seven months, with this shortened season Crescent City and Del Norte County suffered some tourism and revenue losses that year. In 2005 the CDFG cut our season to just four months...with the offshore weather we have here at Crescent City in the summer, the season will be less than [four months]...This is pure and simple economic damage caused by the federal government to our small community. This county cannot afford to let this continue. ...	April 2005	Crescent City, CA	Recreational
… I have a lot of friends here in Crescent City that fish the ocean waters, this year they are all taking their business to Brookings, Oregon. As you know, tourism is the largest part of Del Norte County's revenue, this county can not afford to let this continue, Crescent City used to be a destination point, not so these days, every business in Crescent City will lose more revenue this year than they did last year, it will be the same in 2006 with another four month fishing season if they're not stopped...	April 2005	Crescent City, CA	Recreational
The recent development of the recreational groundfish regulations is of much concern to the City of Crescent City and its residents. As you know, we have a deep and strong interest in both the commercial and sport fishing activities in our area. Any reduction in this season would have a detrimental effect on our economy and way of life.	April 2005	Crescent City, CA	Community
I am a charter boat owner/operator that operates out of Port Hueneme CA. I am writing to convey the urgency for more groundfish opportunity when you are considering inseason adjustments… I ask the members of the Council to consider the fact that I have been driven to near bankruptcy by the extremely cautious approach you have taken in regard to this so-called groundfish crisis. Me and many others that rely on groundfish to survive have been mentally and financially torched by the MRFS data...	April 2005	Port Hueneme, CA	Recreational
…I own and operate the Seabiscuit (CPFV) out of Channel Islands Harbor… We have been regulated and pushed into shorter bag limits, depth restrictions, tackle cut backs, and an extremely short rockfish season in 2005. The toll of these regs have pushed many of us to borderline bankruptcy. Many of us depend upon groundfish to survive. We have been crippled by the extremely conservative approach... many of our livelihoods may lie in the balance of the Council's decision...	April 2005	Channel Islands Harbor, CA	Recreational

2005: June			
There are many small ports and harbors that have mutually beneficial relationships with fisheries industries, both sport and commercial, within the [EFH EIS] study region. These small craft harbors rely on the fisheries to provide steady jobs and act as an economic engine to keep the community vibrant. In the case of several central California harbors, the past few years of increased regulatory actions have had a drastic negative effect on the ability of the fishing fleets to continue making a profit, which has a direct effect on coastal host community (harbors and marinas). The implementation of yet another...closure will have a great economically adverse effect on these local communities...	June 2005	Moss Landing, CA	Community
There is a synergy that occurs which is unmeasurable in terms of cash value that needs to be considered in the development of fishing regulations, including the designation of essential fish habitats on the west coast. The public comes to the ports and harbors and enjoys getting their fresh seafood while watching the boats offload their catch. Without that, these small craft harbors become stagnant and turn into yacht harbors for the rich. The little guys are forced out and the working harbors cease to exist. We have seen this in southern California harbors and hope that that does not happen here. ...	June 2005	Moss Landing, CA	Community
There are many small ports and harbors that have a symbiotic relationship with the fisheries industries, both sport and commercial, within the [EFH] EIS study region. These small craft harbors rely on the fisheries to provide steady jobs and act as an economic engine, keeping the community vibrant. In the case of central California harbors, the past few years of increased regulatory actions have had a drastic effect on the ability of the fishing fleets to continue making a profit. This decline, in turn, has had a direct effect on coastal host community (harbors and marinas). The implementation of regulatory closures or restrictions will have a deleterious economic effect on these local coastal communities...	June 2005	Port San Luis, CA	Community

There is a synergy that occurs which is unmeasurable in terms of cash value that needs to be considered in the development of fishing regulations, including the designation of essential fish habitats on the west coast. The public visits the ports and harbors and loves to get their fresh seafood while watching the boats offload their catch. Without community interest, these small craft harbors become stagnant and turn into yacht harbors for the wealthy, or marine malls selling plastic sharks and T-shirts. The small independent business persons (fishermen) are forced out and the working harbors cease to exist. We have seen this in southern California harbors and hope that that does not happen here. ...	June 2005	Port San Luis, CA	Community
[Comments on EFH EIS]: Consideration of the buyout program and the unintended effects to the local harbors should be considered and offset with mitigation measures to insure the continued infrastructure is in place, new markets are explored, funding for new shore side fisheries support facilities are provided and the economic synergy is maintained for the shoreside businesses in the local coastal communities.	June 2005	Port San Luis, CA	Community
…The extreme weather combined with the extreme and rapid harvest controls have made a large portion of the traditional groundfish fisheries economically unviable for the dominant sport charter fleet and small scale fixed gear rockfish fleet.	June 2005	Santa Barbara, CA	Commercial
Status quo here means a continuation of heavy management measures while the resources continue to rebuilding. For the trawl fleet, this has meant: fleet reduction via the buy-back program; prohibited large roller gear use…[other gear restrictions]…forced to carry observers for data collection activities; coerced to operate under "house arrest" with the unfunded mandatory VMS program; forced to develop the RCA and boundary modifications; engaged in collaborative research to help improve the science; current development of ITQ program to reduce discards with industry funding; reduced time on the water by 75 to 80 percent; reduced our earnings by at least 75%.	June 2005	Coos Bay, OR	Commercial
Fishermen feel that the Council is operating in fear of environmental group lawsuits and are willing to sacrifice every coastal community to appease them… The fleet in particular has made the most extreme sacrifices to ensure a healthy sustainable resource... It's our community's jobs at stake, not NMFS', that these environmental groups are willing to sacrifice. The nation needs to address the frustration level environmental groups are placing on our fishing communities. The nation needs to weigh the stress these groups are placing on our hard working families...	June 2005	Coos Bay, OR	Commercial

Under options C13 and C14 [of the EFH EIS], the area designated as it is would have devastating effects on the rest of the commercial and recreational fleets in both Coos Bay and Bandon as well as both ports. The Port of Bandon strongly urges the Council to revisit this map and remove the hard bottom designation that we were singled out with.	June 2005	Bandon, OR	Community
Many [of the alternatives in the EFH EIS] have large economic impacts to the downside on fishing sectors and communities.	June 2005	Oregon	Recreational
The City of Morro Bay treasures its fishing heritage and local commercial fishing fleet that provides fresh seafood for this country in a highly regulated and sustainable environment. Our harbor and its commercial fishing businesses depend on groundfish landings to support the harbor infrastructure, since many of our fishermen are mainly albacore, crab or salmon permittees with actual landings in the ports north of Morro Bay. Our City has suffered from the reductions in groundfish quotas, seasonal restrictions and area closures to the extent that the local groundfish market has almost collapsed and just a few of the traditional shore side support businesses are still hanging on.	June 2005	Morro Bay, CA	Community
Currently there are 5 Class A permittees who operate out of our port… Each Class A permittee generally fishes between 5-8 days to make up their 60 day quota; so on most of the days of the year there is no longer even one deep water complex trawler operating on this two hundred miles of coastline. Yet, the port still does get groundfish, and these are the consistent landings that allow our one remaining full service fish buying dock to keep employees working and pay the bills. The City is dedicated to supporting this remaining fish buying dock...	June 2005	Morro Bay, CA	Community
Clearly the policy of subsidizing more and bigger trawlers in the 1970s was a disaster, but just as clearly the resource for 15 years now has been very lightly harvested compared to historic levels. Many of our local restaurants no longer can get local fresh fish and have turned, like most of the country, to frozen fish which is oftentimes harvested in environmentally damaging ways in unregulated countries.	June 2005	Morro Bay, CA	Community
In the last two years we have seen some hope as groundfish prices have gone up a little, quotas increased slightly, (but typically not what was promised) due to the federal buy-back program and Class A permittees have started to see a reasonable economic return for fishing again. We are hopeful that some uncertainty can be relieved for these local businesses and for the City.	June 2005	Morro Bay, CA	Community

Many of the alternatives in the [EFH] DEIS would appear to close fishing grounds to the extent that would eliminate landings in Morro Bay and finally put an end to our commercial fishing harbor. We do not believe it is the intent of [NMFS] to eliminate fresh seafood landings in our area and decimate our City...	June 2005	Morro Bay, CA	Community
Extend the timelines for adoption of groundfish EFH so that the coastal communities/fishing industry can fully engage the discussion with NMFS and the environmental community. Improve the outreach to community and fishing businesses by considering an ombudsman program, enhancing your sustainable fisheries outreach effort or some mechanism to empower local fishermen to give input and build trust with NMFS and the environmental community.	June 2005	Morro Bay, CA	Community
I would close by pointing out that virtually 100% of our commercial fishermen are owner operated small businesses. We don't have the corporate interests that can hire lobbyists… It is tremendously difficult for a small business owner/operator or a small city for that matter to take the time to become informed on these issues, much less to attend the many meetings that are needed to have an impact. Thus are voices are often not heard or we find that decisions are made at meetings we are unable to attend. ...All of the above facts lead to a feeling of lack of empowerment and even distrust of the process...	June 2005	Morro Bay, CA	Commercial
Any viable economic analysis of minimization measures should include not only the short-term direct costs of management measures, but also the long-term costs of continued habitat damage, as well as the long-term benefits of habitat protection.	June 2005	[Organization]	Environmental
With the array of closures already implemented along the California coastline, a significant concern relates to the cumulative impacts of these closures on the essential infrastructure required to sustain viable commercial "working" fishing ports and harbors along the 1,100 mile coastline of California. ...Which additional layer of no-fishing regulation will cross the threshold of cutbacks to the number of boats required to harvest a sustainable yield from California's ocean resources, the number of buying stations still left in Morro Bay, San Pedro or Santa Barbara Harbors, the number of fish processors and/or retailers that can keep their doors open in order to serve the remaining few fishing boats that still go out? The cultural value of working ports and harbors is measured in both cultural heritage and tourism value: it is common knowledge that what attracts tourist dollars to the Morro Bay or Santa Barbara Harbor is "the quaint fishing boats" that still number in the tens, at least, in each harbor...	June 2005	Southern California	Commercial

At some point, an additional regulation will be the last one necessary to remove the infrastructure, more or less permanently (due to the failure of the commercial fishing industry to recruit young people among its numbers), that supports this cultural heritage in California ports and harbors. It behooves the Council to carefully consider whether or not further draconian measures are actually required to effectively protect groundfish EFH, or whether these further measures are, in fact, "the last straw" for fisheries culture and infrastructure in these ports and harbors. ...How much fishing area, how many fishing boats, are necessary to maintain the year-round sustainable infrastructure of buying stations, ice houses, hoists, fish processing plants, wholesalers and retailers, that can provide fresh California seafood to seafood consumers?	June 2005	Southern California	Commercial
[Pacific Marine Conservation Council] believes that NOAA Fisheries' outreach in coastal communities with regard to the [EFH] DEIS should have been more extensive. Additional constructive input from people who make their living on or near the water would have resulted in a more comprehensive EFH EIS, and in superior protection of sensitive marine habitats with minimal impact on fishing communities.	June 2005	[Organization]	Community
PMCC has consistently testified to the Council that we believe that it is important to assess whether disparate adverse economic impacts may accrue to individual communities if important opportunities are lost due to restricted access. NOAA Fisheries can determine this to some degree using economic and spatial effort data regarding the trawl fishery, but it remains essential to engage fishermen in this process.	June 2005	[Organization]	Community
A healthy Pacific Ocean is crucial for our way of life including our economy and recreation. For more than three years, Oceana has been bringing science and information to the PFMC and NOAA regarding the importance of protecting deep sea corals and sponges from bottom trawling. I support protecting ecologically sensitive areas of the Pacific seafloor such as corals and sponges, and special places such as seamounts, biogenic areas, and deep sea canyons from destructive commercial fishing. As you consider the [EFH EIS], please adopt a management alternative that protects habitat and maintains vibrant fisheries.	June 2005	Form postcard (755 comments)	Environmental

A healthy Pacific Ocean is crucial for our way of life including our economy and recreation. For more than three years, Oceana has been bringing science and information to the PFMC and NOAA regarding the importance of protecting deep sea corals and sponges from bottom trawling. I support protecting ecologically sensitive areas of the Pacific seafloor such as corals and sponges, and special places such as seamounts, biogenic areas, and deep sea canyons from destructive commercial fishing. As you consider the [EFH EIS], please adopt a management alternative that protects habitat and maintains vibrant fisheries.	June 2005	Form postcard (8,266 comments)	Environmental
...Pacific groundfish are in trouble. Years of heavy fishing have taken their toll so that today both the fish and the fishermen are suffering. We must take steps today to restore our oceans so that our marine wildlife and our fisheries can thrive in the future. Protecting EFH is one of the most important steps on this path. ...	June 2005	Form email (382 comments)	Environmental
A healthy Pacific Ocean is crucial for our way of life including our economy and recreation. I support protecting ecologically sensitive areas of the Pacific seafloor such as corals and sponges, and special places such as seamounts, biogenic areas, and deep sea canyons from destructive commercial fishing. As you consider the [EFH EIS], please adopt Alternative 12, which protects habitat and maintains vibrant fisheries..	June 2005	Form email (18,529 comments)	Environmental
A healthy Pacific Ocean is crucial for our way of life including our economy and recreation. A key to keeping the Pacific Ocean healthy is the protection of marine habitat necessary to support its diverse assemblage of ocean life... As you consider the [EFH EIS], please adopt a management alternative that protects these ecologically sensitive habitats necessary to maintain vibrant fisheries.	June 2005	Form email (58 comments)	Environmental
Closing the [recreational] bottom fishing in the warm months would not impact the industry nearly as bad as closing it in the cold months. The sportfishing landings are suffering, trying to find anything to fish for during the winter months with the closures to bottom fishing. ...	June 2005	California	Recreational

In the middle of listening to all the rhetoric regarding the implementation of the [Marine Life Protection Act]…we receive your notice of further attacks on the fishing community. Honestly, does anyone consider that if this continues we will be importing all our fish from disease ridden fish farms, or unregulated fisheries of foreign countries. California has vast resources that are being wasted...Many fishermen are going out of business, there was a 50% reduction in fishermen just in our local Morro Bay community. We lost our local weather buoy and weather station recently with no effort to replace them. I feel the state/feds are too biased towards the environmental community and letting the fishing communities die on the vine. Ten years from now, after the current older fishermen retire, there will not be commercial fishing in California at the rate we are going because it will be economically impossible to survive, but maybe that is what everyone seems to want.	June 2005	Morro Bay, CA	Commercial
I am writing because a healthy Pacific Ocean is crucial for our way of life, which includes our economy and recreation. [Support for Oceana's efforts] … As you consider the EFH EIS, please adopt Alternative 12, which protects habitat and maintains vibrant fisheries.	June 2005	New York, NY	Environmental
It is not acceptable to close habitat areas to all fishing because some types of fishing have little or no impact on the habitat. Option C.3.1 or C.3.2 is a much more rational approach to the problem, and would have the least economic impact on the coastal communities. Alternative D3 - this could be the economic straw that breaks the back of the small vessel operators. The impact of these vessels is minimal or nonexistent, but more people work on the small vessels than on the larger ones in this area. Do you really want to put all those people out of work? Do you really want to turn off the lights of the small coastal communities? I know the main thrust of this draft proposal is environmental, but I would like to remind you that Homo Sapiens is also part of the environment...	June 2005	Newport, OR	Recreational
We have experienced some huge changes in the last few years. We have seen the bottom fish fleet reduced and their area reduced drastically. …I think it is time for the industry, the Council and the environmentalists to stop making rules that will harm the fishing community. ...	June 2005		Commercial
The economic impact these closures would inflict to the coastal economies will be devastating. The demise of the commercial industries have already made a mark on the coastal community and caused them to focus more efforts on sport fishing. The closures proposed would kill not only the local fishers but also the thousands and thousands of tourists drawn to the area for that very reason. ...	June 2005		Community

I respectfully recommend that your office consider the economic disaster of imposing these new unproven regulations on the coastal communities that thrive on tourists visiting and recreating in these public areas. … I believe [NMFS] needs to better evaluate the impacts of these proposals and preserve fishing opportunities for future generations of anglers. I also believe that this plan is an economic disaster waiting to happen to the already economically depressed coastal communities.... I for one will review my monies spent on the Oregon Coast and all the clients that I draw to the coast to fish the waters off Oregon and Washington. I will better manage my assets and tax dollars and reinvest in areas that are not impacted by these inappropriate regulations.	June 2005		Recreational
… There are not huge numbers of sport fishermen, but the numbers represent a much bigger number of visitors to the coast of Oregon to do other activities. If the fishing is restricted unnecessarily, it will have a large negative impact on the economies of the coastal towns that are already in poor economic condition...	June 2005	Longview, WA	Recreational
…The (positive) economic factors in rural communities should be given priority.	June 2005	Shelton, WA	Recreational
Please do not continue to bow to special interest groups who are pressuring you to consider marine sanctuaries. This is the last thing we need on the west coast to continue our economic slide into oblivion. … I would urge all of you to think this proposal through carefully and weigh the ramifications both economically and recreationally...	June 2005	Portland, OR	Recreational
… Sport fishing has been the lifeblood of many small communities along the Oregon coast and represents a substantial infusion of money to local and the state economy… Please take into account when you consider the current closure proposals that the sport fishing fleet does represent a major influence on the economy and does virtually no harm to the ecology or the fishery.	June 2005	Oregon	Recreational
Under Alternative C.12, C.13 and C.14 there is only one near shore area listed for Oregon… This area is rarely trawled… but this area is the only area available to recreational groundfish fleet and a small number of hook and line groundfish commercial vessels. Alternative C.13 would eliminate those fisheries, a real blow to Coos Bay and Bandon. Alternative C.14 would also cut out a large portion of very productive salmon trolling grounds out of Coos Bay and Bandon. A double blow to the communities. ...	June 2005	Coos Bay and Bandon, OR	Commercial

In our area, where groundfish are particular important, the fishing industry is already hurting and has been in serious decline for years. Overfishing and the use of bottom trawl nets and other heavy fishing gear have depleted fish stocks and caused much damage to the marine habitats the fish depend on... Effective measures to protect those critical habitats and to regenerate and restore fish populations are essential if commercial fishing is to have a future here along the Pacific Coast. ...We believe that an ecosystem-based management plan that truly protects the long-term health of the marine environment offers the only promise for the future of fishing here on the West Coast, both as an important local industry, and as an essential economic resource for the country as a whole.	June 2005	Bandon, OR	Commercial
For many years, a large percentage of my income was derived from fishing vertical gear for chilipepper rockfish, working from about the Cordell Banks to the Channel Islands; that fishery is now virtually closed to me forever. In order to replace this lost income, in recent years I have fished the same type of vertical hook-and-line gear for blackgill rockfish...The only fishing grounds accessible to me [from Morro Bay]...is the Santa Lucia Banks. I have already been displaced from all closer grounds... Please do not close the last place I have left to fish this highly selective gear type.	June 2005	Morro Bay, CA	Commercial
…Since most sportfishing probably does have less impact than most commercial fishing, and in many cases an equal or greater community economic impact, it seems clear that one way to minimize the impact on EFH would be to allocate more fish to sportfishers. This would have the added benefit of extracting a greater economic benefit from the limited allowable catches of some of the more constraining species of groundfish. ...	June 2005	Oregon	Recreational
Being a lifelong resident [of Seal Rock, OR]…means I realize the importance of fishing to this community. However, I am also aware that no single species can be lost without contributing to the loss of another, eventually impacting the very quality of human life that we are all eager to maintain. ...	June 2005	Seal Rock, OR	General
The base years of 2000-2002 are questionable measures of fishing. One must remember that the fishery in those years was already significantly impacted by trip limits and area closures. In fact the entire west coast trawl fishery is much different today than in the past. Since 1994 75% of trawl effort has been removed by limited entry permit retirement, vessel buyback program and migration of part of the fleet to Alaska. ...	June 2005	Toledo, OR	Commercial

As a retired marine ecologist, I'm aware that, for decades, protection, even when intended, has fallen victim to more immediate economic pleas from fishermen. Please do protect the habitat of groundfish and manage the resource for the long run. …	June 2005	Eugene, OR	General
The fishing heritage of central California's harbors is iconic, inextricably woven into the state's history and culture. Moreover, this heritage is alive today--commercial fishing and working harbors provide significant benefits to society, including fresh seafood, tax revenue, tourist attractions, economic benefits that ripple through coastal communities, and a strong voice for conservation (e.g. opposition to pollution). Commercial fishing in this region has a long and colorful history and creates a culture worth sustaining for its own sake. Some communities have been almost entirely dependent on fishing for generations. But California's fishing heritage is at risk.	June 2005	[Organization]	General
Starting in the early 1990s, fishing opportunities for west coast groundfish…have become increasingly constrained as a result of reductions in total allowable catch. Efforts to keep the fishing open year-round resulted in reductions in smaller and smaller trip limits, making it difficult for fishermen to make a living, and for ports to maintain revenues. The establishment of very large areas closed to rockfishing resulted in further economic distress. As a result, the working harbors of the central California coast have become fragile - their health linked to declining fish landings and revenues. ...[Presented goals of the Fishing Heritage Group and consensus map of no-trawl zones]	June 2005	[Organization]	General
The Del Norte County Board of Supervisors has been approached by the near-shore sport fishing community concerning shortened sport fishing seasons ordered by the PFMC. The public expressed frustration and concern regarding the impacts associated with shortened seasons...	June 2005	Del Norte County, CA	Recreational
Over the last several years most of the hook and line fishermen have gone out of business because restrictive regulations have made fishing in this manner economically unrealistic. …Since one of the mandates of the Magnuson Act is to preserve the economic stability of the industry, I urge you to formulate groundfish regulations which are realistic in providing me, and other fixed gear fishermen, with a meaningful opportunity to engage in our method of fishing.	June 2005	California	Commercial

2005: September			
When [ODFW] shut down bottom fishing it devastated the Oregon coast economy. Not only was the sport industry affected; restaurants, hotels, gas stations, public sector, police, firemen (because of the tax base) - we lost a lot of money on the Oregon coast because of this. It is heartwrenching, because there was people on the Oregon coast who... lost their families, who lost their businesses. There were businesses reported losing $1400 per week... that had a devastating affect on our tax bases... so, dealing with that was horrifying, when the general public was told that they were not allowed to go out and fish to provide food for their families... We shouldn't let the guessing game [of counting fish] [cause] economic damages to the community or destroy families.	September 2005	Toledo, OR	Recreational
…At least one week [of fishing] would have made sure they had… electricity, heating oil, stuff like to that to get them through the winter, pay their rent… their basic needs and their basic local taxes… it does have a tremedous effect all the way around.	September 2005	Toledo, OR	Recreational
2005: November			
Fort Bragg is one of the major DTL ports. Our concern has been with the increased fuel cost, it's considerably more beneficial to us to have higher daily and weekly limits on the sablefish… [With the lower limits and higher fuel costs,] it doesn't leave a lot of money left.	November 2005	Fort Bragg, CA	Commercial
[Re: black rockfish]. What happened in Oregon, just before Labor Day, all groundfishing was stopped. That had a tremendous economic impact on my community, but… it had a very large psychological impact on my community. It was kind of like a kick in the face...all these people from all over the country who had plans to come to the Oregon coast to go fishing, to spend their money, those plans were stopped with 72 hour notice [or less]... And then again this year, [black rockfish was closed in October]. This is not a very safe thing for some of these sports fishermen [who may be tempted to go further out into unsafe waters]... I'm here to beg the [Council] to explore ways of increasing the ABC/OY for black rockfish in Oregon and California. ...	November 2005	Garibaldi, OR	Processor
The PFMC management style over the last few years has been off and on again more than I can count. This tears families apart, making it impossible to hire, train, and keep good employees, not to mention maintaining boats, trucks, fishing gear, and montages [sic]. It also tears at the social fabric of coastal communities, ports, fuel docks, suppliers, banks, and restaurants and other support industries, and the employees and families of those businesses. ...	November 2005	Brookings-Harbor, OR	Commercial

The decision of NMFS last year to cut off groundfish days before Labor Day, the largest tourist day on our coastline, was devastating. Over $529,000 was lost to Garibaldi alone. This kind of timing decisions are truly uncalled for and are based on speculation at best. As a Port commissioner to Garibaldi, it is difficult to see the economic impact on an already struggling portal city. Council members demand the facts, review the economic impact - lives are at stake.	November 2005	Garibaldi, OR	Processor
[In regard to sport canary and black rockfish regulations] - Please consider the economic effects you impose on our communities before you make any more mistakes.	November 2005	Garibaldi, OR	Recreational
We are northwest fishermen that have been severely affected by your recent change in the bottomfishing quotas. You have hurt us financially, putting our boats (three) into dry dock because of the low quotas. Someone is not properly assessing the fish stocks which we have complained of on numerous occasions...several times we've offered our services to show you fellows the multiple fish schools out there with no response... we feel it's not financially [beneficial] to sit around all summer to catch our few...quotas you've allowed us. You've made us ready to quit and sell our boats than to keep our profession of [fishing].	November 2005	Garibaldi, OR	Commercial
In past years we've created laws to protect the fishing fleet and industry. The reality today is that it's now slowly eliminating the small fisherman… Fishing areas are not being regulated evenly. The scientific data is wrong.	November 2005	Garibaldi, OR	Processor
My wife and I have been hook and line fishing commercially for over the past 11 years, for black rockfish. We fish out of Garibaldi, Oregon. We do this primarily to supplement our social security.	November 2005	Garibaldi, OR	Commercial
2006: March			
I'd like to give support for the stepped-down approach concerning yelloweye rockfish… Buy adopting this approach, we can spare possibly complete closures off the Washington coast and Oregon [in the halibut, bottomfish and salmon recreational fisheries].... The Washington coast recreational halibut fishery…is [worth] at least $1.6 million…	March 2006	Westport, WA	Recreational
2006: April			
The 9th Circuit case reaffirms the Magnuson Act requirements to rebuild depleted species as quickly as possible… That language doesn't mean that the Council and NMFS should balance biological and economic needs; on the contrary, the decision reaffirms earlier ones in holding that… "the purpose of the act is clearly to give conservation of fish priority over short-term economic issues." …Without immediate efforts to rebuild, the long term survival of fishing communities is in doubt. The court also affirmed that Congress wanted to leave leeway to allow fishing on healthy stocks and avoid disastrous short term effects…	April 2006	[National organization]	Environmental
We realize it is critical to rebuild the overfished stocks; it	April	[Coastwide organization]	Processing

is also critical that we don't precipitate economic disaster. If the OYs are overly restrictive, the negative economic consequences could occur in the tens of millions of dollars. Many coastal communities are struggling now. An economic impact of this magnitude would create a depression in some areas. Lastly, the Council management teams and industry have crafted innovative and creative management tools in the last few years. Let us use those tools now to find solutions that avoid economic tragedy.	2006		
…If the [canary rockfish] OY was lowered to 44 metric tons, there's a very real possibility that the trawl survey could potentially shut down the shelf, severely impacting our coastal communities. … With the recreational and commercial salmon fishery all but gone this year, and the Dungeness crab landings tapering off, our coastal communities will be depending on groundfish more than ever... Curtailment of the groundfish fishery not only has a negative short term impact; there's a long-term effect as well... Ask any processor how it is to buy back into the market when farm-raised products and imports have taken the place of our products. These interruptions in product flow almost always result in lower exvessel prices to the fleet, and are detrimental to the entire coastal supply chain… With respect to the health of our coastal communities, I believe that while we are still alive, we are far from healthy. While the cuts each year have been necessary, they have been extremely onerous. Each year the fleet has left millions of dollars of healthy species in the water due to the constraints of overfished species…	April 2006	Oregon	Commercial
I think the rampdown is a very sensible way to … avoid unnecessary impacts on small businesses. In the north where yelloweye impacts are the greatest, most open access and recreational businesses are small businesses, and they are the ones that are going to be impacted … the most. They're more susceptible to quick economic downturns, due to smaller profit margins… and they have smaller reserves. … Due to past reductions, most small business fisheries have been at or near the tipping point—that's the point where you're not making enough profit to be able to justify your effort…and I think a rampdown might even be a way to allow some fishermen to plan their exit from the fishery… giving someone a few years to plan his exit is a way to keep him from just facing a disastrous event all at once… [Quoted from "Trends in Fishing and Seafood Processing-Related Establishments and Employment in West Coast Fishing Communities," pp. 11, 15; noted that the five most dependent communities were all on the northern California and Oregon coast.] This is the area which is going to be hit hardest. This is the area where ports and people are more dependent on rockcod than other fisheries… We don't have a lot of other industries besides our ports.	April 2006	Crescent City, CA	Commercial
The fishing community is basically on life support… As you make your decisions today, think about how the fishing community is being impacted. …Specifically, each	April 2006	South/Central California	Commercial

metric ton that you allow the nearshore minor south to take… that's a lot of money. Considering what's going on with the salmon… these folks, all of us, are basically on life support. You're talking about short term needs—we need these fish…			
We are continuing to work with state and federal agencies to quantify the socioeconomic impacts of changes to the groundfish fishery on our community. The use of 12-13 metric tons of yelloweye for 2007-2008 would put and end, pretty much, to the positive changes we're making, and we think a minor disruption in the time to rebuild caused by a phase-in is far preferable to the major economic disruption caused by a drastic cut. We need the flexibility in the phase-in to continue what we've been doing.	April 2006	Westport, WA	Recreational
If we do start out at 12.0 or 12.6 metric tons, instead of the phased in, stepped down approach, it will close our halibut fishery in the ocean, and that would be devastating, it would be a disaster. So we have to support the stepped down approach.	April 2006	Neah Bay, WA	Recreational
Even with or without a normal salmon season, we need our rockfish. If we reach the ABC/OY and have an early closure of any sort at all, we'll have economic effects that will be staggering to the CPFV fleet. Many, many businesses will close; families will be torn apart. In one month alone, October for example, if [it's] closed in the north central, it'll cost a minimum of $2 million in just lost fares alone on the CPFV boats. … Every pound of fish not accessible can be directly translated into lost dollars. Alternative 4 will not hurt the fishery or the resource, but it will help to support those who make their living in the nearshore [fishery], by helping to give us as long a season as possible to avoid economic disaster.	April 2006	Northern California	Recreational
… Adopt the highest OYs possible; anything less represents an economic hardship that really would be excruciating, so much so it would cause myself and others to be on the brink of, if not already have, filed bankruptcy, especially in light of the salmon situation… This is a burden that's going to be too big for a lot of us to bear, and we're all going to end up… facing losing a business and a livelihood that I have been in for virtually all of my life. I'm not young; for me to go do something else at this time of my life is getting to be pretty hard…	April 2006		Recreational
[To evaluate socioeconomic impacts, we need baselines for measuring these changes. Referred to Moss Landing harbor report by Dr. Carrie Pomeroy & Dr. Mike Dalton as a good example of baseline information.]	April 2006		Commercial
[Supports stepped down yelloweye plan]. At the 12 metric ton level, we determine that in the Oregon recreational [fishery] that the season would be so short that dramatic, catastrophic monetary losses would occur. ...I would hope that the economic numbers could move up on the priority list, because of some of these conditions that are actually not even the fault of fishermen.	April 2006	Oregon	Recreational

2.0 ALTERNATIVES INCLUDING THE PROPOSED ACTION

There are two suites of alternatives analyzed in this EIS. The first suite of alternatives is the range of 2007-2008 harvest specifications or acceptable biological catches (ABCs) and optimum yields (OYs) considered for groundfish stocks and stock complexes managed under the Groundfish FMP. The range of harvest specifications for depleted groundfish species is also analyzed to understand the potential conservation and socioeconomic consequences of alternative depleted species' rebuilding plans. Therefore, the Council's preferred 2007-2008 OY alternative serves two purposes: both as the harvest specifications for the years 2007 and 2008 and, for depleted species, as the next step in the longer term mortality schedules for rebuilding plans. The target rebuilding year for each depleted species under rebuilding is also set in this decision step as the most likely year to rebuild under the Council-preferred OY and mortality schedule. Harvest specification (and rebuilding plan) alternatives are described in section 2.1.

The second suite of alternatives analyzed in this EIS is alternative 2007-2008 management measures. Alternative management measures adopted for analysis are designed to illustrate the potential efficacy and tradeoffs of management strategies and allocations considered for the next biennial management period by the Council. The overarching objectives of 2007-2008 management measures are to stay within the Council-preferred annual OYs for groundfish stocks and stock complexes and to equitably allocate fishing opportunities and other fishery benefits across fishing sectors and regions under Council jurisdiction. Alternative 2007-2008 management measures are described in section 2.2.

2.1 Alternative Harvest Specifications

Table 2-1 depicts the alternative harvest specifications for groundfish stocks and stock complexes managed under the FMP and considered by the Council for the 2007-2008 management period. The Council decided to average projected 2007 and 2008 OYs from adopted assessments and rebuilding analyses with the intent to specify an average OY, which is applied to both years. In some cases, and only for stocks with quantitative assessments, the Council also decided to average projected ABCs for the 2007-2008 management period (see FMP §4.3.1). In cases where the OY might exceed an ABC in any one year, the OY is capped at that ABC since an ABC cannot legally be exceeded.

2.1.1 Depleted Groundfish Species

Depleted groundfish species are those with spawning biomasses that have dropped below the Council's depletion or overfished threshold of 25% of initial spawning biomass (or $B_{25\%}$). The Groundfish FMP mandates these stocks need to be rebuilt through harvest restrictions and other conservation measures to 40% of unfished biomass (or $B_{40\%}$). Furthermore, the MSA mandates these rebuilding periods need to be the shortest time possible while taking into account the status and biology of the depleted stock, the needs of fishing communities, and the interaction of the depleted stock within the marine ecosystem. This mandate was underscored in an August 2005 ruling by the Ninth Circuit Court of Appeals in a challenge to the Council's darkblotched rockfish rebuilding plan. In accordance with that ruling, the Council decided to reconsider all adopted rebuilding plans to ensure they comply with the MSA as interpreted by the courts. Therefore, the range of harvest specifications for depleted groundfish species under rebuilding and analyzed in this EIS has been expanded to more effectively analyze what it means to "rebuild in the shortest time possible, taking into account the needs of fishing communities" by considering the impacts of allowing some access to healthy fish stocks. Access to healthy fish stocks would mean some mortality of depleted species that are caught as bycatch in these fisheries would be allowed. Any harvest of depleted groundfish stocks is anticipated to be unavoidable bycatch. The Council-preferred harvest specifications for depleted species are the mortality limits for these species that the Council recommends under rebuilding to avoid disastrous short-term socioeconomic impacts to

West Coast fishing communities. Rebuilding periods for depleted species are coincident with the Council's recommendation for OYs for these species and defined in the Council's rebuilding framework, as specified in the Groundfish FMP, as the median time to attain the target spawning biomass of $B_{40\%}$ under a given harvest rate or mortality schedule.

Prior to the new groundfish assessments conducted, reviewed, and adopted in 2005 under Council procedures, the depleted groundfish species under rebuilding were bocaccio (in waters south of 40°10' N latitude), canary rockfish, cowcod, darkblotched rockfish, lingcod, Pacific ocean perch, widow rockfish, and yelloweye rockfish. However, the 2005 lingcod assessment {Jagielo 2006} indicates that the coastwide lingcod stock has attained (and exceeded) the $B_{40\%}$ spawning biomass threshold and is now considered successfully rebuilt. No new species were declared depleted from the 23 groundfish assessments conducted in 2005. Therefore, the Council is continuing rebuilding plans for the other seven species only and reconsidering those plans in response to a Ninth Circuit Court of Appeals ruling discussed above and in Chapter 1. To fully analyze both the conservation needs of each depleted stock and the socioeconomic effects of alternative rebuilding plans, a wide range of OYs have been specified for analysis for each depleted species (Table 2-2a). Each of these OY alternatives is based on the best available science as recommended by Stock Assessment Review (STAR) panels and the Council's Scientific and Statistical Committee (SSC). Section 2.1.1 describes the scientific basis for each depleted species' OY alternative and describes the strategic analyses of these alternatives that are presented in more detail in subsequent chapters of this EIS.

In considering potential rebuilding alternatives, first, the consequences of each depleted species' OY alternative was examined in isolation to understand the tradeoff between the amount of allowable harvest and alternative rebuilding periods and to identify the West Coast fisheries that are affected by the constraints posed by alternative rebuilding plans for each particular depleted species. The predicted rebuilding periods and the annual OYs that describe the alternative rebuilding schedules, each of which define a rebuilding plan, are estimated using the SSC's endorsed rebuilding program {Punt 2005}. The rebuilding program is a probabilistic population simulator that explores alternative harvest rates and predicts the total mortality and duration of rebuilding for each depleted species under a range of harvest rates. The depleted species' OY alternatives analyzed in this EIS, based on harvest rates estimated from the rebuilding simulation program, are calculated using an instantaneous rate of fishing mortality (F), which may be converted to a Spawning Potential Ratio. For ease of comparison among stocks and to standardize the basis of rebuilding calculations, it is useful to express any specific fishing mortality rate in terms of its effect on Spawning Potential Ratio (SPR = spawning per recruit at the current population level relative to that at the stock's unfished condition). Given fishery selectivity patterns and basic life history parameters, there is a direct inverse relationship between F and SPR (Figure 2-1). When there is no fishing, each new female recruit is expected to achieve 100% of its spawning potential. As fishing intensity increases, expected lifetime reproduction declines due to this added source of mortality. Conversion of F into the equivalent SPR has the benefit of standardizing for differences in growth, maturity, fecundity, natural mortality, and fishery selectivity patterns and, as a consequence, the Council's SSC recommends it be used routinely. The rebuilding program is more thoroughly described in Chapter 6. The OY alternatives for depleted species are described in section 2.1.1.1.

Kelp Greenling HG (OR)									No Fed HG	fed HG = state HG							No Fed HG

a/ The Council elected to average OY projections for 2007 and 2008 and analyze/specify the average OYs for each year. ABCs, in some cases, are specified similarly for some species with quantitative assessments. Otherwise, ABCs are year-specific.

b/ Council ABC and Council OY represent the Council's preferred harvest alternative for 2007 and 2008.

c/ Area OYs/HGs are stratified according to the assessment areas and alternatively adjusted by management areas for lingcod and petrale sole.

d/ The Council specified a coastwide 2007-2008 sablefish OY (Alt. 2 OY). However, sector allocations are based on the portion of the OY north of 36 deg. N. lat.

e/ A coastwide OY was not adopted for longspine and shortspine thornyheads. Separate OYs north and south of Pt. Conception at 34deg.27' N. lat. were specified.

f/ The preferred OY is for the Conception and Monterey areas combined.

g/ The yelloweye OY alternatives originally specified for analysis in Nov. 2005 were based on the 2005 assessment. The revised 2006 assessment and rebuilding analysis, adopted in Mar. 2006, projects a range of allowable 2007-2008 OYs under a constant harvest rate strategy of <=15 mt. Therefore, alternatives 3-6 were eliminated from further analysis.

h/ The yelloweye ramp-down strategy ramps the harvest rate down from the status quo harvest rate and resumes a constant harvest rate strategy in 2011. The 2007-2010 OYs are 23 mt, 20 mt, 17 mt, and 14 mt, respectively under the ramp-down strategy.

i/ The Remaining Rockfish and Other Rockfish categories are shown to understand how the Minor Rockfish complex harvest specifications are derived. These are not management targets.

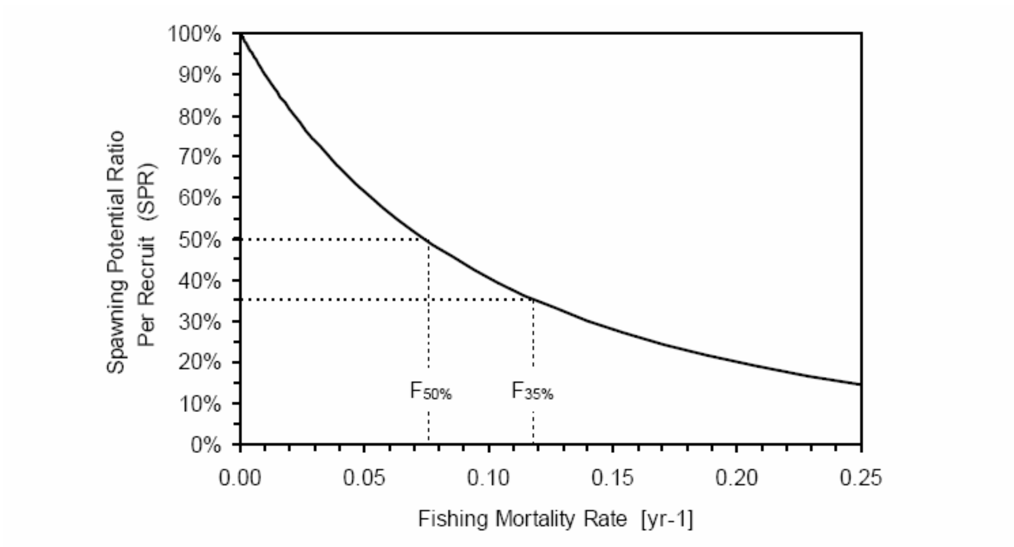

Figure 2-1. Relationship between spawning potential ratio (SPR) and instantaneous fishing mortality rate (F) for a hypothetical rockfish.

Next, rebuilding alternatives were developed by arranging the depleted species' OYs in various combinations (Table 2-2b) and then modeling changes to the current management regime to understand how rebuilding plans for different species interact to constrain fishing opportunities. The OYs in these rebuilding alternatives are strategically arrayed to illuminate how each species might differentially constrain fishing opportunities by sector (or gear type) and region along the West Coast, depending on the amount of allowable harvest of each species. It is important to note that the full range of OY alternatives described in Table 2-2a are not used to structure these rebuilding alternatives. Some of the higher OY alternatives in Table 2-2a are not used to structure the rebuilding alternatives in Table 2-2b. For example, the highest OY alternative for widow rockfish (OY Alternative 5) was not included among the rebuilding alternatives because it represents an amount of bycatch not observed in the current management regime. Prior to 2003, when there was a directed midwater trawl fishery for yellowtail and widow rockfish, catches of widow rockfish approached the level of mortality consistent with the OY Alternative 5 in Table 2-2a. However, the current understanding of the association of the more constraining canary rockfish stock with yellowtail rockfish leads to the conclusion that the available potential harvest of canary rockfish (as described by the range of OYs in Table 2-2a) would constrain any directed midwater trawl opportunities for yellowtail rockfish before the widow rockfish bycatch would approach the higher available OYs for that stock. Therefore, the rebuilding alternatives in Table 2-2b are structured using a narrower range of depleted species' OYs than those depicted in Table 2-2a. The rebuilding alternatives are described in detail below, in Section 2.1.1.2.

At their April 2006 meeting, the Council selected a preferred OY alternative for all managed groundfish species and species complexes except for the seven depleted species (Table 2-1). For the depleted species, the Council selected two preferred OY alternatives for further analysis for each stock. A final preferred OY and rebuilding plan for each depleted species will be decided at the June 2006 Council meeting. As discussed above, the Council's preferred OY alternative for the 2007-2008 fisheries must be consistent with any intent to modify depleted species rebuilding plans. Therefore, the choice of a preferred OY alternative involves consideration of both short-term effects (during 2007-2008) and long-term effects (the future application of rebuilding plans as revised by Amendment 16-4).

2.1.1.1 Optimum Yield Alternatives for Depleted Species

Table 2.2a depicts the range of depleted species' OY alternatives specified for analysis by the Council in November 2005 and April 2006. The numbered OY alternatives in Table 2-2a correspond to the alternative harvest levels that the Council originally selected for analysis in November 2005. In April 2006, the Council decided that the Preferred Low OY and High OY alternatives would represent the range of OYs that should be the focus of more detailed analysis. These preferred OY alternatives will be the range the Council will select from in June 2006 when final depleted species' OYs and rebuilding plans will be adopted. Table 2-3 and Figure 2-2 indicate the median time to rebuild under each 2007-2008 OY alternative.

Table 2-2a. Range of 2007-2008 OYs for depleted groundfish species decided at the November 2005 and April 2006 Council meetings.

		2007-2008 OYs (mt)							
Stock	**Association**	**OY Alt. 1**	**OY Alt. 2**	**OY Alt. 3**	**OY Alt. 4**	**OY Alt. 5**	**OY Alt. 6**	**Pref. Low OY Alt.**	**Pref. High OY Alt.**
Yelloweye a/	Northern	0	12	~~17~~	~~21~~	~~24~~	~~27~~	12.6	Ramp-down b/
Canary	Shelf	0	24	44	68			32	44
Cowcod c/	Southern	0	8	14	18	22		4	8
Bocaccio	Shelf	0	149	218	315	424		40	218
Darkblotched	Northern	0	130	229	330	472		130	229
POP	Slope	0	87	405	514	749		44	100
Widow	Midwater	0	329	456	917	1,369		120	368

a/ A 2007-2008 OY >= 15 mt for yelloweye would result in a less than a 50% probability of rebuilding before Tmax, which is not legally viable. OY Alternatives 3-6 are discussed further in section 2.1.5 of the EIS.

b/ The yelloweye ramp-down strategy ramps the harvest rate down from the status quo harvest rate and resumes a constant harvest rate strategy in 2011. The 2007-2010 OYs are 23 mt, 20 mt, 17 mt, and 14 mt, respectively under the ramp-down strategy.

c/ OY alternatives for Conception and Monterey areas combined.

Table 2-2b. Amendment 16-4 rebuilding alternatives.

		2007-2008 OYs (mt)					
Stock	**Association**	**"Status Quo" Reb. Alt. a/**	**Reb. Alt. 1**	**Reb. Alt. 2**	**Reb. Alt. 3**	**Reb. Alt. 4**	**Reb. Alt. 5**

Widow	Midwater	329	456	329	917	329	120

a/ The species' OYs described in the "status quo" rebuilding alternative are determined by calculating the effective SPR harvest rate from the November 2005 bycatch scorecard and projecting this harvest rate forward to 2007.

b/ OY alternatives for Conception and Monterey areas combined.

			~~5~~	~~2080~~	~~24~~					
			~~6~~	~~2099~~	~~27~~					

a/ The numbered OY alternatives were specified for analysis by the Council in Nov. 2005. The Preferred OY alternatives were specified for analysis by the Council in April 2006.

b/ Darkblotched OY alternatives cannot exceed the ABC (456 mt in 2007 and 486 mt in 2008). Therefore, OY Alt. 5 can only be considered in 2008.

c/ A 2007-2008 OY >= 15 mt for yelloweye would result in a less than a 50% probability of rebuilding before Tmax, which is not legally viable. Alternatives 3-6 are discussed further in section 2.1.5 of the EIS.

d/ The yelloweye ramp-down strategy ramps the harvest rate down from the status quo harvest rate and resumes a constant harvest rate strategy in 2011. The 2007-2010 OYs are 23 mt, 20 mt, 17 mt, and 14 mt, respectively under the ramp-down strategy.

Bocaccio (in Waters off California South of 40°10' N Latitude)

The OY alternatives specified for analysis for the bocaccio stock south of 40°10' N latitude are 0 mt, 40 mt, 149 mt, 218 mt, 315 mt, and 424 mt (Tables 2-1 and 2-2a). This compares to the status quo OYs of 307 mt in 2005 and 309 mt in 2006.

The zero harvest alternative would rebuild the stock by 2021, which is the shortest possible time to rebuild ($T_{F=0}$) given our current understanding of stock productivity.

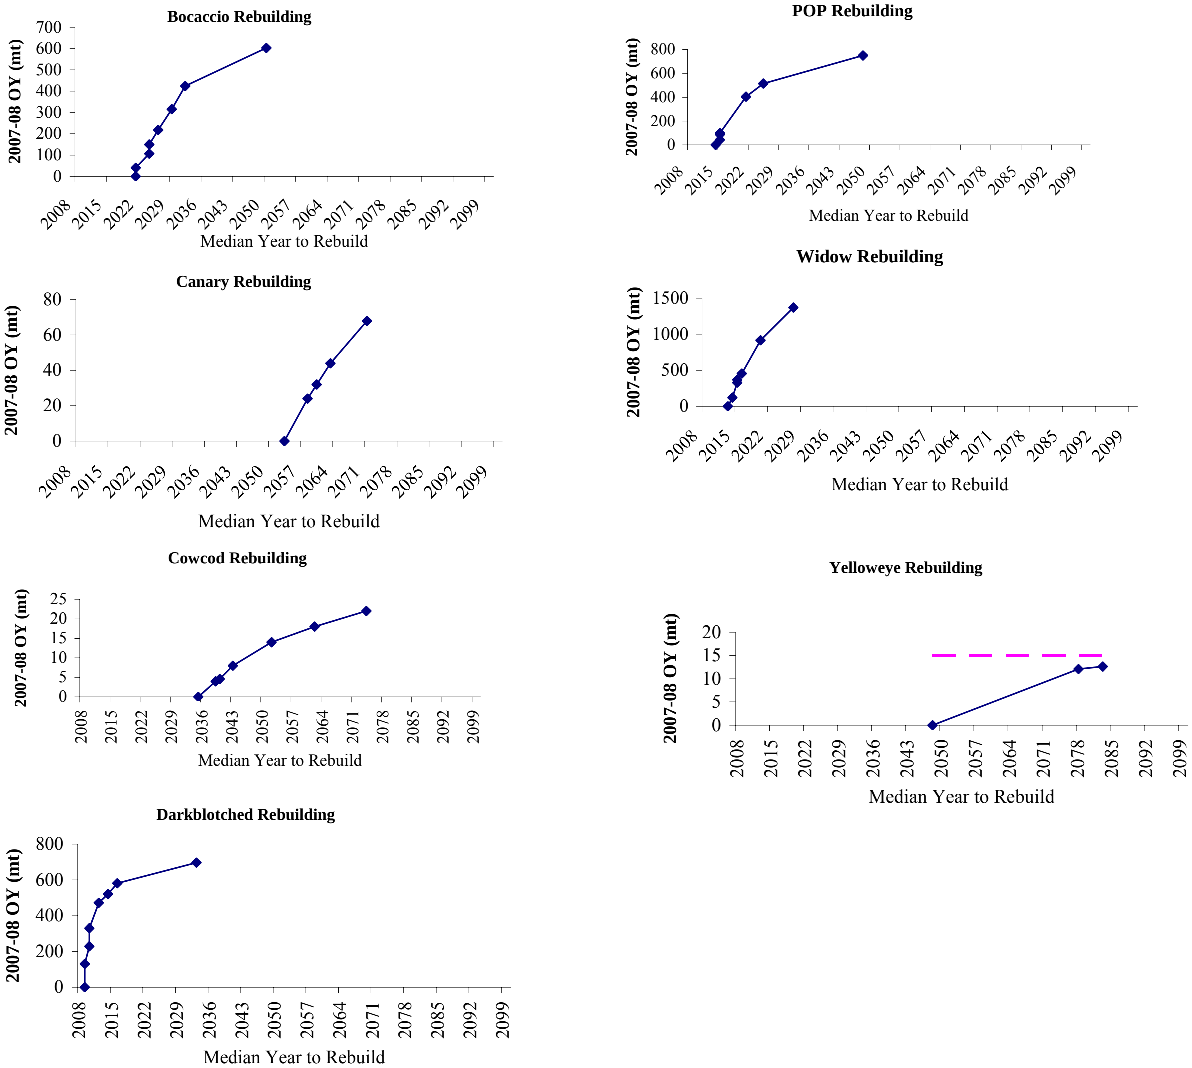

Figure 2-2. Predicted rebuilding duration vs. allowable 2007-2008 harvests for seven depleted West Coast groundfish species.

The 40 mt alternative is the Council's **Preferred Low OY Alternative** specified by the Council in April 2006. The median time to rebuild the stock under this alternative is 2021.9, or about 10 months longer than $T_{F=0}$ (Table 2-3 and Figure 2-2).

The 149 mt alternative is based on the effective harvest rate in 2005 projected forward to 2007 and 2008. The GMT determined the effective harvest rate by applying the best estimate of total mortality in 2005 divided by the exploitable biomass in 2005. The GMT then applied the resulting rate to the projected exploitable biomass in 2007 and 2008 {MacCall 2006a} to determine projected OYs, which were then averaged for those years. The median time to rebuild the stock under this alternative would be 2024, or 3 years longer than $T_{F=0}$ (Table 2-3 and Figure 2-2).

The 218 mt OY alternative is the Council's **Preferred High OY Alternative** and represents the OY under an 80% rebuilding probability (P_{MAX} or the probability of successfully rebuilding the stock in the maximum allowable time under the current National Standard 1 Guidelines) from the 2003 rebuilding analysis {MacCall 2003b}. The median time to rebuild the stock under this alternative would be 2026, or 5 years longer than $T_{F=0}$ (Table 2-3 and Figure 2-2).

The 315 mt OY alternative represents the current SPR harvest rate of 69.2% applied to the 2007 and 2008 projections of exploitable biomass. This is the harvest rate used to establish the status quo 2005 and 2006 OYs. The median time to rebuild the stock under this alternative would be 2029, or 8 years longer than $T_{F=0}$ (Table 2-3 and Figure 2-2).

The 424 mt OY alternative represents the OY under a re-estimated P_{MAX} of 50% from the new rebuilding analysis {MacCall 2006}. This is the highest OY that can be considered for bocaccio in that it is based on the best available science and is at the 50% rebuilding probability threshold established in litigation (*Natural Resources Defense Council v. Daley*, April 25, 2000, U.S. Court of Appeals for the District of Columbia Circuit). The median time to rebuild the stock under this alternative would be 2032, or 11 years longer than $T_{F=0}$ (Table 2-3 and Figure 2-2).

Canary Rockfish

The OY alternatives specified for analysis for the coastwide canary rockfish stock are 0 mt, 24 mt, 32 mt, 44 mt, and 68 mt (Tables 2-1 and 2-2a). This compares to the status quo OY of 47 mt in 2005 and 2006.

The zero harvest alternative would rebuild the stock by 2053, which is the shortest possible time to rebuild ($T_{F=0}$) given our current understanding of stock productivity.

The 24 mt OY alternative represents the OY under a 60% rebuilding probability (the status quo P_{MAX}) from the new rebuilding analysis {Methot 2006}. The median time to rebuild the stock under this alternative would be 2058, or 5 years longer than $T_{F=0}$ (Table 2-3 and Figure 2-2).

The 32 mt alternative is the Council's **Preferred Low OY Alternative**. The median time to rebuild the stock under this alternative is 2060, or 7 years longer than $T_{F=0}$ (Table 2-3 and Figure 2-2).

The 44 mt OY alternative is the Council's **Preferred High OY Alternative** and applies the current SPR harvest rate of 88.7% to the 2007 and 2008 projections of exploitable biomass. This is the harvest rate used to establish the status quo 2005 and 2006 OYs. The median time to rebuild the stock under this alternative would be 2063, or 10 years longer than $T_{F=0}$ (Table 2-3 and Figure 2-2).

The 68 mt OY alternative represents the OY under a re-estimated P_{MAX} of 50% from the new rebuilding analysis {Methot 2006}. This is the highest OY that can be considered for canary rockfish in that it is based on the best available science and is at the 50% rebuilding probability threshold. The median time to rebuild the stock under this alternative would be 2071, or 18 years longer than $T_{F=0}$ (Table 2-3 and Figure 2-2).

Cowcod

The OY alternatives specified for analysis for the cowcod stock occurring in the Conception and Monterey INPFC areas are 0 mt, 8 mt, 14 mt, 18 mt, and 22 mt (Tables 2-1 and 2-2a). This compares to the status quo OY of 4.2 mt in 2005 and 2006.

The zero harvest alternative would rebuild the stock by 2035, which is the shortest possible time to rebuild ($T_{F=0}$) given our current understanding of stock productivity.

The 4 mt alternative is the Council's **Preferred Low OY Alternative** specified by the Council in April 2006. The median time to rebuild the stock under this alternative is 2039, or 4 years longer than $T_{F=0}$ (Table 2-3 and Figure 2-2).

The 8 mt OY alternative is the Council's **Preferred High OY Alternative** and represents the OY under a re-estimated 80% rebuilding probability from the new rebuilding analysis {Piner 2006}. The median time to rebuild the stock under this alternative would be 2043, or 8 years longer than $T_{F=0}$ (Table 2-3 and Figure 2-2).

The 14 mt OY alternative represents the OY under a re-estimated 70% rebuilding probability from the new rebuilding analysis {Piner 2006}. The median time to rebuild the stock under this alternative would be 2052, or 17 years longer than $T_{F=0}$ (Table 2-3 and Figure 2-2).

The 18 mt OY alternative represents the OY under a re-estimated 60% rebuilding probability (the status quo P_{MAX}) from the new rebuilding analysis {Piner 2006}. The median time to rebuild the stock under this alternative would be 2062, or 27 years longer than $T_{F=0}$ (Table 2-3 and Figure 2-2).

The 22 mt OY alternative represents the OY under a re-estimated P_{MAX} of 50% from the new rebuilding analysis {Piner 2006}. This is the highest OY that can be considered for canary rockfish in that it is based on the best available science and is at the 50% rebuilding probability threshold. The median time to rebuild the stock under this alternative would be 2074, or 39 years longer than $T_{F=0}$ (Table 2-3 and Figure 2-2).

Darkblotched Rockfish

The OY alternatives specified for analysis for the coastwide darkblotched rockfish stock are 0 mt, 130 mt, 229 mt, 330 mt, and 424 mt (Tables 2-1 and 2-2a). This compares to the status quo OYs of 269 mt in 2005 and 200 mt in 2006.

The zero harvest alternative would rebuild the stock by 2009.5, which is the shortest possible time to rebuild ($T_{F=0}$) given our current understanding of stock productivity.

The 130 mt OY alternative is the Council's **Preferred Low OY Alternative** and represents the OY specified in 2001. The Ninth Circuit court ruling compelling the Council and NMFS to consider Amendment 16-4 disputed the 2002 darkblotched harvest specification, which had changed this 2001 OY to a higher value. The median time to rebuild the stock under this alternative would be 2009.9, or approximately 5 months longer than $T_{F=0}$ (Table 2-3 and Figure 2-2).

The 229 mt OY alternative is the Council's **Preferred High OY Alternative** and is based on the effective harvest rate in 2005 (F = 0.0216) projected forward to 2007 and 2008. The GMT determined the effective harvest rate by applying its best estimate of total mortality in 2005 divided by the exploitable biomass in 2005. The GMT then applied the resulting harvest rate to the projected exploitable biomass in 2007 and 2008 {Rogers 2006a} to determine projected OYs, which were then averaged for those years. The median time to rebuild the stock under this alternative would be 2010.2, or approximately 8 months longer than $T_{F=0}$ (Table 2-3 and Figure 2-2).

The 330 mt OY alternative applies the harvest rate used to set the 2005 OY (F = 0.032) to the 2007 and 2008 projections of exploitable biomass (OYs averaged and applied to each year). The median time to rebuild the stock under this alternative would be 2010.5, or 1 year longer than $T_{F=0}$ (Table 2-3 and Figure 2-2).

The 472 mt OY alternative represents the OY capped at the average 2007-2008 ABC specification. This is the highest OY that can be considered for darkblotched rockfish in that the ABC cannot be legally exceeded. The re-estimated P_{MAX} under this alternative is 97%. The median time to rebuild the stock under this alternative would be 2012, or 2.5 years longer than $T_{F=0}$ (Table 2-3 and Figure 2-2).

Pacific Ocean Perch

The OY alternatives specified for analysis for the coastwide Pacific ocean perch (POP) stock are 0 mt, 44 mt, 87 mt, 100 mt, 405 mt, 514 mt, and 749 mt (Tables 2-1 and 2-2a). This compares to the status quo OY of 447 mt in 2005 and 2006.

The zero harvest alternative would rebuild the stock by 2014.6, which is the shortest possible time to rebuild ($T_{F=0}$) given our current understanding of stock productivity.

The 44 mt alternative is the Council's **Preferred Low OY Alternative** specified by the Council in April 2006. The median time to rebuild the stock under this alternative is 2015, or about half a year longer than $T_{F=0}$ (Table 2-3 and Figure 2-2).

The 87 mt OY alternative is based on the effective harvest rate in 2005 projected forward to 2007 and 2008. The GMT determined the effective harvest rate by applying its best estimate of total mortality in 2005 divided by the exploitable biomass in 2005. The GMT then applied the resulting harvest rate to the projected exploitable biomass in 2007 and 2008 {Hamel 2006b} to determine projected OYs, which were then averaged for those years. The median time to rebuild the stock under this alternative would be 2015.4, or about 1 year longer than $T_{F=0}$ (Table 2-3 and Figure 2-2).

The 100 mt OY alternative is the Council's **Preferred High OY Alternative**. The median time to rebuild the stock under this alternative would be 2015.6, or 1 year longer than $T_{F=0}$ (Table 2-3 and Figure 2-2).

The 405 mt OY alternative represents the OY under a re-estimated 80% rebuilding probability from the new rebuilding analysis {Hamel 2006b}. The estimated SPR harvest rate under this alternative is 69.6%. The median time to rebuild the stock under this alternative would be 2021, or approximately 7 years longer than $T_{F=0}$ (Table 2-3 and Figure 2-2).

The 514 mt OY alternative represents the OY under a re-estimated 70% rebuilding probability (the status quo P_{MAX}) from the new rebuilding analysis {Hamel 2006b}. The median time to rebuild the stock under this alternative would be 2025, or 11 years longer than $T_{F=0}$ (Table 2-3 and Figure 2-2).

The 749 mt OY alternative represents the OY under a re-estimated P_{MAX} of 50% from the new rebuilding analysis {Hamel 2006b}. This is the highest OY that can be considered for POP in that it is based on the best available science and is at the 50% rebuilding probability threshold. The median time to rebuild the stock under this alternative would be 2048, or 34 years longer than $T_{F=0}$ (Table 2-3 and Figure 2-2).

Widow Rockfish

The OY alternatives specified for analysis for the coastwide widow rockfish stock are 0 mt, 120 mt, 329 mt, 368 mt, 456 mt, 917 mt, and 1,369 mt (Tables 2-1 and 2-2a). This compares to the status quo OYs of 285 mt in 2005 and 289 mt in 2006.

The zero harvest alternative would rebuild the stock by 2013, which is the shortest possible time to rebuild ($T_{F=0}$) given our current understanding of stock productivity.

The 120 mt alternative is the Council's **Preferred Low OY Alternative** and is predicted to rebuild the stock by 2014, which is 1 year longer than $T_{F=0}$ (Table 2-3 and Figure 2-2).

The 329 mt OY alternative is based on the effective harvest rate in 2005 projected forward to 2007 and 2008. The GMT determined the effective harvest rate by applying its best estimate of total mortality in 2005 divided by the exploitable biomass in 2005. The GMT then applied the resulting harvest rate to the projected exploitable biomass in 2007 and 2008 {He et al. 2006b} to determine projected OYs, which were then averaged for those years. The median time to rebuild the stock under this alternative would be 2015, or 2 years longer than $T_{F=0}$ (Table 2-3 and Figure 2-2).

The 368 mt alternative is the Council's **Preferred High OY Alternative** and is predicted to rebuild the stock by 2015, which is 2 years longer than $T_{F=0}$ (Table 2-3 and Figure 2-2).

The 456 mt OY alternative applies the current SPR harvest rate of 93.6% to the 2007 and 2008 projections of exploitable biomass. This is the harvest rate used to establish the status quo 2005 and 2006 OYs. The median time to rebuild the stock under this alternative would be 2016, or approximately 3 years longer than $T_{F=0}$ (Table 2-3 and Figure 2-2).

The 917 mt OY alternative represents the OY under a re-estimated 80% rebuilding probability from the new rebuilding analysis {He et al. 2006b}. The SPR harvest rate under this alternative is estimated to be 88.6%. The median time to rebuild the stock under this alternative would be 2020, or 7 years longer than $T_{F=0}$ (Table 2-3 and Figure 2-2).

The 1,369 mt OY alternative represents the OY under a re-estimated P_{MAX} of 60% from the new rebuilding analysis {He et al. 2006b}. The median time to rebuild the stock under this alternative would be 2027, or 14 years longer than $T_{F=0}$ (Table 2-3 and Figure 2-2).

Yelloweye Rockfish

The OY alternatives originally specified for analysis for the coastwide yelloweye rockfish stock were 0 mt, 12 mt, 17 mt, 21 mt, 24 mt, and 27 mt (Tables 2-1 and 2-2a). The first five yelloweye OY alternatives were derived from the 2005 yelloweye assessment and rebuilding analysis. However, in November 2005 the Council requested a new yelloweye assessment be done over the winter when numerous assessment data issues became known. The Council also specified the status quo 27 mt OY alternative for analysis in case a new, more optimistic assessment and rebuilding analysis were approved in 2006.

A new yelloweye stock assessment {Wallace et al. 2006} and rebuilding analysis {Tsou and Wallace 2006} were approved in March 2006. The new 2006 assessment was more pessimistic than the 2005 assessment and one implication of the new rebuilding analysis was that the projected range of allowable 2007-2008 OYs under a constant harvest rate strategy is ≤ 15 mt. That is, higher OYs would result in rebuilding probabilities ≤ 50%, which is not legally viable. Therefore, yelloweye OY Alternatives 3-6 in Table 2-2a were eliminated from further detailed study (see section 2.1.5).

The Council adopted for analysis a new OY alternative of 12.6 mt for 2007-2008 and consideration of a yelloweye harvest rate ramp-down strategy, which is explained in more detail below. Therefore, the full range of viable yelloweye OY alternatives analyzed for 2007-2008 and Amendment 16-4 are 0 mt, 12 mt, 12.6 mt, and the harvest rate ramp-down strategy, which specifies OYs of 23 mt and 20 mt for 2007 and 2008, respectively. This compares to the status quo OYs of 26 mt in 2005 and 27 mt in 2006.

The zero harvest alternative would rebuild the stock by 2048, which is the shortest possible time to rebuild ($T_{F=0}$) given our current understanding of stock productivity.

The 12 mt OY alternative would rebuild the stock by 2078, or 30 years longer than $T_{F=0}$ (Table 2-3 and Figure 2-2).

The 12.6 mt alternative is the Council's **Preferred Low OY Alternative** and is based on a re-estimated 80% rebuilding probability from the new rebuilding analysis {Tsou and Wallace 2006}. This is the rebuilding probability from the status quo rebuilding plan and the SPR harvest rate under this alternative is estimated to be 71.9%. The median time to rebuild the stock under this alternative would be 2083, or 35 years longer than $T_{F=0}$ (Table 2-3 and Figure 2-2).

The yelloweye harvest rate ramp-down strategy is the Council's **Preferred High OY Alternative** and is designed to provide the Council time to develop management strategies to reduce current yelloweye impacts by more than 50%. The ramp-down strategy would sequentially lower the yelloweye harvest rate in the next four years before resuming a constant harvest rate rebuilding strategy in 2011. The OYs would be 23 mt, 20 mt, 17 mt, and 14 mt in 2007-2010. Under this strategy, the constant harvest rate would be the same as for the Preferred Low OY Alternative (SPR harvest rate = 71.9%) beginning in 2011. The median time to rebuild the stock under this alternative would be 2083.5, or 35.5 years longer than $T_{F=0}$ and about a half a year longer than the Preferred Low OY Alternative (Table 2-3 and Figure 2-2).

2.1.1.2 Rebuilding Alternatives

There are six rebuilding alternatives analyzed in this EIS (Table 2-2b). Each alternative was strategically developed to better compare and contrast the tradeoffs associated with alternative rebuilding strategies. These alternatives are analyzed by predicting the effect on the status quo management regime. Multiple suboptions are presented for each alternative to explore potential effects under different allocation scenarios.

The "status quo" rebuilding alternative is comprised of OY alternatives based on the effective harvest rates for each of the depleted stocks in 2005 projected forward to 2007 and 2008. The effective harvest rates were determined by applying the GMT's best estimate of total mortality in 2005 divided by the exploitable biomass of each stock in 2005. These harvest rates were then applied to the projected best exploitable biomasses in 2007 and 2008 to determine projected OYs.

Rebuilding alternative 1 would result in an increase in slope and midwater trawl fishing opportunities with the higher darkblotched, POP, and widow OYs; and a corresponding decrease in shelf fishing opportunities with the lower OYs for bocaccio, canary, cowcod, and yelloweye.

Rebuilding alternative 2 would result in higher southern shelf fishing opportunities with the higher bocaccio and cowcod OYs; lower northern recreational and limited entry and open access fixed gear opportunities with the lower yelloweye OY; and close to status quo for northern bottom and midwater trawl fishing opportunities with the "status quo" OYs for darkblotched, POP, and widow.

Rebuilding alternative 3 would result in higher shelf fish opportunities north and south with the higher bocaccio, cowcod, canary, and yelloweye OYs; and higher slope and midwater trawl fishing opportunities with the higher OYs for darkblotched, POP, and widow.

Rebuilding alternative 4 would dramatically lower northern shelf opportunities and some additional constraints in southern shelf fisheries north of Point Conception with the lower canary and yelloweye OYs; higher shelf fishing opportunities south of Pt. Conception with the higher bocaccio and cowcod OYs; and higher slope and midwater trawl opportunities with the higher darkblotched, POP, and widow OYs.

Rebuilding alternative 5 would dramatically lower shelf fishing opportunities coastwide with the lower bocaccio, cowcod, canary, and yelloweye OYs; and dramatically lower slope and midwater trawl fishing opportunities with the lower darkblotched, POP, and widow OYs.

2.1.2 Precautionary Zone Groundfish Species

Cabezon (in Waters off California)

The Council has identified one OY alternative, 69 mt, to be analyzed for the cabezon stock in waters off California (Table 2-1) for 2007 and 2008. This is the same as the status quo OY alternative. The ABC alternative identified for analysis is 94 mt for both 2007 and 2008; this alternative is based on the sum of average 2007-2008 ABCs for the northern and southern substocks (north and south of Pt. Conception), as determined in the 2005 stock assessment.

Pacific Whiting

Pacific whiting are managed based on an annual assessment prepared jointly by U.S. and Canadian scientists. Pacific whiting harvest specifications are based on annual assessments and are only analyzed in this EIS to understand the potential bycatch implications of future whiting fisheries. The 2007 ABC and OY will be adopted by the Council at its March 2007 meeting. As placeholders, the Council specified a range of coastwide ABC and OY alternatives for analysis as follows: an OY range of 134,534 mt to 403,604 mt (Table 2-1). This compares to the status quo U.S. OY of 269,069 mt for 2006. The range of 2007 and 2008 ABC alternatives specified for analysis are 244,425 mt to 733,275 mt. The status quo 2006 ABC is 488,850 mt.

Petrale Sole

Three 2007-2008 OY alternatives for petrale sole (coastwide) have been analyzed for Council decision: 1,921 mt, 2,499 mt, and 2,883 mt (Table 2-1). This compares to the status quo OY of 2,762 mt in 2005 and 2006. The OYs are also subdivided by INPFC regions (Columbia and US-Vancouver areas and Eureka, Monterey, and Conception areas) and by latitude (north and south of 40°10' N latitude).

The OY alternatives for the Columbia and US-Vancouver areas were identified by applying the following rationale: OY Alternative 1 is based on the low spawning biomass model from the 2005 stock assessment {Lai et al. 2005}; OY Alternatives 2 and 3 are the same, and are the result of a reduction from the ABC using the 40-10 rule. The ABC alternatives identified for analysis are 2,917 mt for 2007 and 2,919 mt for 2008. Using results from the 2005 stock assessment, each ABC was calculated by summing the north ABC and the south ABC/OY.

Sablefish

The Council identified the following alternatives to be analyzed for the coastwide sablefish stock (Table 2-1): 4,574 mt and 5,934 mt. This compares to the status quo OY of 7,761 mt in 2005 and 7,634 mt in 2006. 2007 and 2008 ABCs identified for analysis are 6,210 mt and 6,058 mt, respectively. OY Alternative 1 is calculated by applying the 40-10 adjustment to the ABC derived from the low stock/production model in the 2005 sablefish assessment {Schirripa and Colbert 2005}; OY Alternative 2 is calculated by applying the 40-10 adjustment using the assessment's base case model.

Each coastwide OY alternative is also divided north and south of 36^{o} N latitude using status quo proportions. Alternative methods for apportioning the OY were not considered because the STAR Panel {Barnes et al. 2005} recommended calculating coastwide biomass without including Conception area survey data.

2.1.3 Healthy Groundfish Species

Arrowtooth Flounder

As arrowtooth flounder is a healthy stock, the Council has identified a single ABC/OY alternative, 5,800 mt, to be analyzed (Table 2-1). This is the same as the status quo ABC/OY for 2005 and 2006; the stock has not been assessed since the previous harvest specifications process, and therefore there is no basis for identifying a value other than that of the status quo.

Black Rockfish (in Waters off Oregon and California)

The Council has specified one OY alternative for analysis for the black rockfish stock in waters off Oregon and California, 722 mt (Table 2-1), based on a projection from the base model in the 2003 assessment {Ralston 2003}. These projected ABCs (725 mt in 2007 and 719 mt in 2008) were averaged and specified for each year (722 mt). Since this is a healthy stock with a spawning biomass above $B_{40\%}$, the OYs were set equal to the ABC. This compares to the status quo OYs of 753 mt in 2005 and 736 mt in 2006, both of which had been set equal to the ABC for that year. Management of the southern black rockfish stock is divided at the California/Oregon border.

Black Rockfish (in Waters off Washington)

The northern black rockfish stock in waters off Washington is healthy. Therefore, the Council has identified a single ABC/OY alternative, 540 mt, to be analyzed (Table 2-1). This is the same as the status quo ABC/OY for 2005 and 2006 since the stock has not been assessed since the previous harvest specifications process; therefore, there is no basis for selecting a value other than the status quo. This value is based on 88% of the northern ABC for the assessed stock north of Cape Falcon, Oregon.

California Scorpionfish

California scorpionfish was first assessed in 2005 {Maunder et al. 2006}, and therefore 2007 will be the first year in which it is not managed as part of the Minor Nearshore Rockfish South complex and the first time that the Council adopts an ABC and an OY for the stock. The Council has specified two ABC/OY alternatives for analysis: 137 mt and 219 mt (Table 2-1). The first alternative, 137 mt, was derived using the recreational portion from the ABC/OY (based on the 2007-2008 average), multiplying it by 53%, dividing it by 88%, and then adding this modified value to the commercial portion of the ABC/OY (based on the 2007-2008 average). The second alternative provides an ABC/OY of 219 mt based on an average of the 2007 and 2008 ABC/OYs from the stock assessment {Maunder et al. 2005}.

The GMT recommends OY Alternative 1 (137 mt) a modified ABC/OY. This approach utilizes the full recreational data in determining the OY and allows California to track catches inseason with the CRFS program. By incorporating the ability to make inseason adjustments, the risk of either not achieving or overshooting the OY is reduced. The GMT refers the Council to "CDFG Draft Report on Background Information for Selection of 2007/2008 OYs for Gopher Rockfish, California Scorpionfish and Minor Nearshore Rockfish" for further explanation of the calculation of this OY Alternative.

Chilipepper Rockfish

The Council has specified status quo alternatives for chilipepper rockfish for 2007 and 2008 ABCs and OYs, as there is no new stock assessment from which to base new harvest specifications. These alternatives are an ABC of 2,700 mt and an OY of 2,000 mt for 2007-2008 (Table 2-1). The lower OY alternative is a precautionary specification to control the bycatch of bocaccio. The higher OY alternative equals the status quo ABC, since the stock is considered healthy. The rationale for considering this alternative is depth-based management may be an adequate bocaccio bycatch control mechanism.

Chilipepper rockfish within the Eureka INPFC region are managed within the Minor Rockfish North category, and therefore are not included within the ABC and OY alternative values.

Dover Sole

The OY alternatives specified for analysis for Dover sole stock are 16,500 mt and 28,482 mt (Table 2-1). This compares to the status quo OYs of 7,476 mt in 2005 and 7,564 mt in 2007. The first OY alternative is equal to the equilibrium MSY from the 2005 stock assessment {Sampson 2005}; the second alternative is set to the ABC alternative. The Council identified an ABC alternative of 28,522 mt for 2007 and 28,442 mt for 2008. These ABCs were calculated using the $F_{40\%}$ proxy harvest rate and represent the combined total of the south and the north portions of the stock.

English Sole

The OY alternative specified for analysis for English sole stock is 6,237 mt (Table 2-1). This compares to the status quo OY of 3,100 mt for 2005 and 2006. The Council identified an ABC alternative of 6,773 mt for 2007 and 5,701 mt for 2008. The OY alternative was determined by averaging of the 2007 and 2008 ABC alternatives. Projections from the 2005 stock assessment of English sole {Stewart 2005} were used to identify the ABC alternatives.

Lingcod

The OY alternatives specified for analysis for lingcod are 6,280 mt and 6,088 mt (Table 2-1). This compares to the status quo OY of 2,414 mt for 2005 and 2006; these 2005-2006 specifications were adopted by the Council with the lingcod rebuilding plan prior to the stock being declared rebuilt from its overfished status in November 2005. The first alternative was calculated by setting the OY equal to the coastwide ABC, as lingcod is a healthy stock. The second alternative is the sum of LCN and LCS (northern and southern lingcod substocks) OYs; the LCS OY was derived using a 40-10 adjustment.

The OYs are also subdivided by INPFC regions (Columbia and US-Vancouver areas and Eureka, Monterey, and Conception areas) and by latitude (North of 42° and South of 42 °). The Council's specified ABC alternatives for 2007 and 2008 are 6,706 mt and 5,853 mt, respectively.

Longspine Thornyhead

The OY alternatives specified for analysis for longspine thornyhead are 2,696 mt and 3,930 mt (Table 2-1). This compares to the status quo OY of 2,656 mt for 2005 and 2006. The first alternative, 2,696 mt, is based on assuming constant density throughout the Conception area and the proportion of the area north and south of Pt. Conception (21% of the Conception area) with a 25% precautionary reduction. The second alternative, 3,930 mt, is based on assuming constant density throughout the Conception area and the proportion of the area north and south of Pt. Conception (21% of the Conception area). As a healthy stock, the OY can be set equal to the ABC, which is how the second alternative was calculated. The OYs are also subdivided by latitude based on a GMT-recommended alternative where harvest guidelines north and south of 34°27' N latitude are analyzed. However the status quo alternative OYs for 2005 and 2006 were specified north and south of 36° N latitude. The Council's specified ABC alternatives for 2007 and 2008 are 3,953 mt and 3,860 mt, respectively.

Shortbelly Rockfish

Shortbelly rockfish is unexploited due to its small size, except as infrequent incidental catch. The 13,900 mt ABC/OY is a continuation of a conservative Council policy for this species based on its last assessment in 1989. Since that assessment, the peak one-year shortbelly landings have been <100 mt.

Shortspine Thornyhead

The shortspine thornyhead OY alternatives specified for analysis are 1,661 mt and 2,476 mt (Table 2-1). This compares to the status quo OY of 1,055 mt for 2005 and 1,077 mt for 2006. The coastwide OYs are the sum of OYs determined for north and south of Pt. Conception (34°27' N latitude). The Council's specified ABC alternatives for 2007 and 2008 are 2,488 mt and 2,463 mt, respectively.

For alternative 1, the OY for the area south of Pt. Conception is based on the base case assessment scenario in the 2005 stock assessment {Hamel 2005}, which indicated that 34% of the coastwide biomass is in this area, and with a 50% reduction to account for the paucity of survey data south of Pt. Conception. The 50% reduction is due to the SSC conclusion the assessment is marginally sufficient to estimate resource status given the short duration and density of survey data south of Pt. Conception. The base case model assumed $h = 0.6$ and $q = 1.0$. The OY alternative 1 for the area north of Pt. Conception based on the base case assessment result indicating 66% of the coastwide biomass is in this area with a 25% precautionary reduction. The 25% precautionary reduction is due to the SSC conclusion the assessment is marginally sufficient to estimate resource status. The base case model assumed $h = 0.6$ and $q = 1.0$.

Alternative 2 OYs (for north and south of 34°27' N latitude) are based on the same biomass estimates from the 2005 stock assessment base case model, but with no precautionary reduction. Therefore, the OY alternative for the area south of Pt. Conception (841 mt) is based on an estimate of 34% coastwide biomass is in this area and the OY alternative for the north portion (1,634 mt) is based on an estimate of the remaining 66% of the coastwide biomass.

Splitnose Rockfish

As in 2005-2006, the ABC of 615 mt is reduced to an OY of 461 mt based on the Council's policy of making a 25% precautionary OY adjustment for species with less rigorous stock assessments. These harvest specifications are for south of 40°10' N latitude since splitnose rockfish are managed as part of the northern minor slope rockfish complex north of 40°10' N latitude.

Starry Flounder

Starry flounder was assessed for the first time in 2005 and is now proposed to be managed with a separate ABC and OY. Previously the stock has been managed as a component stock of the Other Flatfish complex. Therefore, there are no status quo ABC or OY alternatives for the stock. The Council requested the following two OY alternatives for analysis: 890 mt and 1,186 mt (Table 2-1). Alternative 1 (890 mt) is based on a 25% reduction of the combined area OYs from the base model in the stock assessment {Ralston 2005} as a result of the 25% precautionary reduction for data poor stocks. Alternative OY 2 (1,186 mt) is based on the combined area OYs from the based model in the stock assessment. The ABC alternatives identified by the Council are 1,221 mt for 2007 and 1,395 mt for 2008.

Yellowtail Rockfish

Yellowtail rockfish is a healthy rockfish stock that had a new stock assessment in 2005{Lai 2006}. Year-specific ABCs were projected following the Council's policy of using an $F_{50\%}$ harvest rate as a proxy for F_{MSY} for rockfish; the 2007 ABC for this species is 4,585 mt and the 2008 ABC is 4,510 mt. These ABCs were averaged (4,548 mt) and specified for both years. The OYs were set equal to ABC because the stock is above $B_{40\%}$. The GMT notes that the fisheries have not been attaining yellowtail rockfish harvest levels in recent years because its harvest has been constrained to protect co-occurring depleted species.

2.1.4 Unassessed Groundfish Species and Those Managed as Part of a Stock Complex

2.1.4.1 Minor Rockfish South

The Council has identified four minor rockfish south OY alternatives for analysis: 1,753 mt, 1,855 mt, 1,898 mt, and 2,006 mt (Table 2-1). The OY alternatives calculated for nearshore species, shelf species, and slope species sum to equal the overall minor rockfish south value. The overall OY alternatives for 2007-2008 compare to the status quo OY of 1,968 mt.

The ABC alternative identified by the Council for analysis is 3,403 mt; this compares to a status quo ABC alternative of 3,412 mt for 2005 and 2006. The ABC alternative for 2007 and 2008 reflects three adjustments to account for the reassessment of blackgill rockfish and the new assessments for gopher rockfish and California scorpionfish. First, the status quo contribution of blackgill rockfish to the ABC (343 mt) was removed from the complex ABC and replaced with the new blackgill ABC/OY of 292 mt (based on the 2007-2008 average ABC/OY); this results in an overall reduction of 51 mt. Second, the status quo contribution of gopher rockfish (97 mt) was removed and replaced with the new gopher ABC/OY of 302 mt (based on the 2007-2008 average ABC/OY), resulting in an overall increase of 205 mt. Third, the status quo contribution of California scorpionfish (163 mt) was removed from the ABC as this species will now be managed under its own ABC/OY.

Minor Nearshore Rockfish Species

The complex, Minor Nearshore Rockfish south of 40°10' N latitude, is further subdivided into the following management categories: 1) shallow nearshore rockfish [comprised of black and yellow rockfish (*S. chrysomelas*); China rockfish (*S. nebulosus*); gopher rockfish (*S. carnatus*); grass rockfish (*S. rastrelliger*), and kelp rockfish (*S. atrovirens*)]; 2) deeper nearshore rockfish: [comprised of black rockfish (*S. melanops*), blue rockfish (*S. mystinus*); brown rockfish (*S. auriculatus*); calico rockfish (*S. dalli*); copper rockfish (*S. caurinus*); olive rockfish (*S. serranoides*); quillback rockfish (*S. maliger*); and treefish (*S. serriceps*)] and 3) California scorpionfish (*Scorpaena guttata*).

The Council adopted a southern minor nearshore rockfish species OY for 2003 of 541 mt. This OY was based upon the Groundfish FMP policy for specifying OYs for unassessed species using 50% of recent landings, and was recalculated from the 2001-2002 OY of 662 mt using updates estimates of recreational and commercial harvest. For the 2004 southern minor nearshore rockfish species OY, an adjustment was made to account for removal of black rockfish; however this adjustment started with the 2002 OY of 662 mt and not the 2003 OY of 541 mt. The resulting OY of 615 mt was adopted by the Council for 2004 for the 2005-2006 management cycles. For the 2007-2008 management cycle, the Minor Nearshore Rockfish South is corrected by subtracting the black rockfish OY of 47 mt from the 541 mt OY, resulting in a value of 494 mt.

This initial value for the southern minor nearshore rockfish species OY is then adjusted to account for the new California scorpionfish and gopher rockfish assessments. The current contribution for California scorpionfish of 81.5 mt is removed from the combined OY. Because gopher rockfish cannot be managed separately from other nearshore rockfish species without significantly increasing bycatch and because of uncertainty regarding the assessment because of its poor data quality, gopher rockfish will remain in the southern minor nearshore rockfish species OY and will have a point of concern set at a level determined appropriate to the adopted OY. The following four alternatives different methods for accounting for these changes.

The 413 mt OY alternative includes the 48.5 mt contribution of gopher rockfish (494 mt minus the California scorpionfish contribution of 81.5 mt equals 413 mt). OY alternative 2 is determined by removing the current contribution for gopher rockfish (48.5 mt) from the OY and then increasing the OY by 50% of the new gopher ABC/OY of 302 mt (based on the 2007-2008 average ABC/OY; 2007 = 340 mt, 2008 = 264 mt); this calculation leads to a value of 515 mt. The 558 mt OY alternative is determined by removing the current contribution for gopher rockfish (48.5 mt) from the OY and then increasing the OY by 75% of the new gopher ABC/OY of 302 mt (based on the 2007-2008 average ABC/OY; 2007 = 340 mt, 2008 = 264 mt). OY alternative 4 is determined by removing the current contribution for gopher rockfish (48.5 mt) from the OY and then increasing the OY by the new gopher ABC/OY of 302 mt (based on the 2007-2008 average ABC/OY; 2007 = 340 mt, 2008 = 264 mt); this calculation leads to an OY value of 666 mt. These four OY alternatives compare to the status quo OY alternative of 615 mt for 2004-2005, for which the calculation is discussed earlier.

Minor Shelf Rockfish Species

The minor shelf rockfish complex south of 40°10' N latitude is composed of the following species: bronzespotted rockfish (*S. gilli*); chameleon rockfish (*S. phillipsi*); dusky rockfish (*S. ciliatus*); dwarf-red rockfish (*S. rufianus*); flag rockfish (*S. rubrivinctus*); freckled rockfish (*S. lentiginosus*); greenblotched rockfish (*S. rosenblatti*); greenspotted rockfish (*S. chlorostictus*); greenstriped rockfish (*S. elongatus*); halfbanded rockfish (*S. semicinctus*); harlequin rockfish (*S. variegatus*); honeycomb rockfish (*S. umbrosus*); Mexican rockfish (*S. macdonaldi*); pink rockfish (*S. eos*); pinkrose rockfish (*S. simulator*); pygmy rockfish (*S. wilsoni*); redstripe rockfish (*S. proriger*); rosethorn rockfish (*S. helvomaculatus*); rosy rockfish (*S. rosaceus*); silvergray rockfish (*S. brevispinis*); speckled rockfish (*S. ovalis*); squarespot rockfish (*S. hopkinsi*); starry rockfish (*S. constellatus*); stripetail rockfish (*S.

saxicola); swordspine rockfish (*S. ensifer*); tiger rockfish (*S. nigrocinctus*); vermilion rockfish (*S. miniatus*); and yellowtail rockfish (*S. flavidus*).

The Council has identified the status quo ABC and OY as the only alternative to be analyzed for 2007-2008 management cycle. The OY is set to the ABC; therefore, the ABC alternative and OY alternative for analysis are both 714 mt.

Minor Slope Rockfish Species

The minor slope rockfish complex south of 40°10' N latitude is composed of the following species: aurora rockfish (*S. aurora*); bank rockfish (*S. rufus*); blackgill rockfish (*S. melanostomus*); Pacific ocean perch (*S. alutus*); redbanded rockfish (*S. babcocki*); rougheye rockfish (*S. aleutianus*); sharpchin rockfish (*S. zacentrus*); shortraker rockfish (*S. borealis*); and yellowmouth rockfish (*S. reedi*).

The Council identified one ABC/OY alternative for this complex: 626 mt. This value was determined by the following calculation: the status quo contribution of blackgill (305 mt) was removed from the complex and replaced with the new blackgill ABC/OY of 292 mt (based on the 2007-2008 average ABC/OY; 2007 = 294 mt, 2008 = 290 mt). This alternative compares to the status quo alternative ABC/OY of 639 mt.

2.1.4.2 Minor Rockfish North

The Council has identified three minor rockfish north OY alternatives for analysis: 2,250 mt, 2,270 mt, and 2,290 mt (Table 2-1). The OY alternatives calculated for nearshore species, shelf species, and slope species sum to equal the overall minor rockfish north values. The overall OY alternatives for 2007-2008 compare to the status quo OY of 2,250 mt. The Council identified the status quo ABC alternative, 3,680 mt, to be evaluated for the 2007-2008 management cycle.

Minor Nearshore Rockfish Species

The minor nearshore rockfish complex north of 40°10' N latitude is composed of the following species: black and yellow rockfish (*S. chrysomelas*); blue rockfish (*S. mystinus*); brown rockfish (*S. auriculatus*); calico rockfish (*S. dalli*); China rockfish (*S. nebulosus*); copper rockfish (*S. caurinus*); gopher rockfish (*S. carnatus*); grass rockfish (*S. rastrelliger*); kelp rockfish (*S. atrovirens*); olive rockfish (*S. serranoides*); quillback rockfish (*S. maliger*); and treefish (*S. serriceps*).

When black rockfish was originally removed from the northern minor nearshore rockfish OY, a ratio of black to blue rockfish catch was used to determine what proportion of that OY was attributable to black rockfish. However, due to the variability of blue rockfish catches, there is some concern that this ratio (92%:8% black to blue rockfish) under-represents blue rockfish catch and therefore the resulting OY (since black rockfish is managed separately). To account for this uncertainty (that is, a range of possible levels of black rockfish removal from the OY), three alternatives have been identified by the Council. OY alternative 1 is equal to the status quo OY alternative of 122 mt. OY alternative 2 (142 mt) is equal to the status quo OY alternative plus 20 mt. OY alternative 3 (162 mt) is equal to the status quo OY alternative plus 40 mt.

Minor Shelf Rockfish Species

The minor shelf rockfish complex north of 40°10' N latitude is composed of the following species:

bronzespotted rockfish (*S. gilli*); bocaccio (*Sebastes paucispinis*); chameleon rockfish (*S. phillipsi*); chilipepper rockfish (*S. goodei*); cowcod (*S. levis*); dusky rockfish (*S. ciliatus*); dwarf-red rockfish (*S. rufianus*); flag rockfish (*S. rubrivinctus*); freckled rockfish (*S. lentiginosus*); greenblotched rockfish (*S. rosenblatti*); greenspotted rockfish (*S. chlorostictus*); greenstriped rockfish (*S. elongatus*); halfbanded rockfish (*S. semicinctus*); harlequin rockfish (*S. variegatus*); honeycomb rockfish (*S. umbrosus*); Mexican rockfish (*S. macdonaldi*); pink rockfish (*S. eos*); pinkrose rockfish (*S. simulator*); pygmy rockfish (*S. wilsoni*); redstripe rockfish (*S. proriger*); rosethorn rockfish (*S. helvomaculatus*); rosy rockfish (*S. rosaceus*); silvergray rockfish (*S. brevispinis*); speckled rockfish (*S. ovalis*); squarespot rockfish (*S. hopkinsi*); starry rockfish (*S. constellatus*); stripetail rockfish (*S. saxicola*); swordspine rockfish (*S. ensifer*); tiger rockfish (*S. nigrocinctus*); and vermilion rockfish (*S. miniatus*).

No change from status quo was identified by the Council for analysis; therefore the status quo ABC/OY alternative for northern minor shelf rockfish species, 968 mt, is analyzed for the 2007-2008 management cycle (Table 2-1).

Minor Slope Rockfish Species

The minor slope rockfish complex north of 40°10' N latitude is composed of the following species: aurora rockfish (*S. aurora*); bank rockfish (*S. rufus*); blackgill rockfish (*S. melanostomus*); redbanded rockfish (*S. babcocki*); rougheye rockfish (*S. aleutianus*); sharpchin rockfish (*S. zacentrus*); shortraker rockfish (*S. borealis*); splitnose rockfish (*S. diploproa*); and yellowmouth rockfish (*S. reedi*).

No change from status quo is identified by the Council for analysis; therefore the status quo ABC/OY alternative for northern minor slope rockfish species, 1,160 mt, is analyzed for the 2007-2008 management cycle (Table 2-1).

2.1.4.3 Other Unassessed Species

Pacific Cod

No change from status quo is identified by the Council for analysis. As in 2005-2006, the Pacific cod ABC of 3,200 mt is based on historic landings levels, with the 1,600 mt OY representing the Council's precautionary 50% adjustment for unassessed species (Table 2-1).

Other Fish

The Other Fish stock complex contains all the unassessed Groundfish FMP species that are neither rockfish (family *Scorpaenidae*) nor flatfish. These species include big skate (*Raja binoculata*), California skate (*Raja inornata*), leopard shark (*Triakis semifasciata*), longnose skate (*Raja rhina*), soupfin shark (*Galeorhinus zyopterus*), spiny dogfish (*Squalus acanthias*), finescale codling (*Antimora microlepis*), Pacific rattail (*Coryphaenoides acrolepis*), ratfish (*Hydrolagus colliei*), cabezon (*Scorpaenichthys marmoratus*) (north of the California-Oregon border at 42° N latitude), and kelp greenling (*Hexagrammos decagrammus*).

No change from status quo is identified by the Council for analysis. The OY alternative is 7,300 mt and the ABC alternative is 14,600 mt (Table 2-1).

Other Flatfish

The Other Flatfish complex contains all the unassessed flatfish species in the Groundfish FMP. These species include butter sole (*Isopsetta isolepis*), curlfin sole (*Pleuronichthys decurrens*), flathead sole (*Hippoglossoides elassodon*), Pacific sanddab (*Citharichthys sordidus*), rex sole (*Glyptocephalus zachirus*), rock sole (*Lepidopsetta bilineata*), and sand sole (*Psettichthys melanostictus*).

The Council has identified an OY alternative of 4,884 mt to be analyzed. This OY is based on the ABC with a 25% precautionary reduction for sanddabs and rex sole and a 50% precautionary reduction for the remaining species. The starry flounder contribution is removed (25 mt). The status quo OY alternative is 4,909 mt for 2005 and 2006.

The Council has identified an ABC alternative of 6,731 mt to be analyzed for 2007 and 2008. This ABC alternative is based on the following historical catch levels: the highest landings of Pacific sanddabs (in 1995) and rex sole (in 1982) for the 1981-2003 period and on average landings during 1994-1998 for the remaining Other Flatfish species. The starry flounder contribution is removed (50 mt). The status quo ABC alternative is 6,781 mt for 2005 and 2006.

2.1.5 Alternative Harvest Levels Considered, But Eliminated From Detailed Study

The new darkblotched rebuilding analysis indicates some otherwise viable OY alternatives exceed the ABC, which is based on a proxy F_{MSY} harvest rate. However, a stock's OY cannot legally exceed the ABC, which for darkblotched is 456 mt and 486 mt in 2007 and 2008, respectively. Therefore, OY Alt. 5 (472 mt) can only be considered in 2008 as a year-specific OY. Since the Council intends to average the darkblotched OY from rebuilding analysis projections and specify the same average OY for 2007 and 2008, OY Alternative 5 is eliminated from detailed study.

Yelloweye OY Alternatives specified by the Council in November 2005 for analysis were based on the 2005 rebuilding analysis by Tsou and Wallace (2005)[8]. However, a new yelloweye assessment and rebuilding analysis were adopted as the best available science by the Council in 2006. The new rebuilding analysis {Tsou and Wallace 2006} indicates a 2007-2008 OY ≥ 15 mt for yelloweye would result in a less than a 50% probability of rebuilding by T_{MAX}, which is not legally viable. Therefore, OY Alternatives 3-6 under a constant harvest rate rebuilding strategy are eliminated from further study in this EIS.

2.2 Alternative Management Measures

2.2.1 Catch Sharing Options

2.2.1.1 Research Catches

Under the Magnuson-Stevens Act and the Pacific Coast Groundfish FMP, the term fishing refers to the catching, taking, or harvesting of fish; the attempted catching, taking, or harvesting of fish; any other activity which can reasonably be expected to result in the catching, taking, or harvesting of fish; or any operations at sea in support of, or in preparation for the catching, taking, or harvesting of fish. Activity by a vessel conducting authorized scientific research is not considered fishing under the Magnuson-Stevens Act or the Pacific Coast Groundfish FMP. However, nothing within the Magnuson-Stevens Act or the Pacific Coast Groundfish FMP is intended to inhibit or prevent any scientific research activity

[8] Since the 2005 yelloweye assessment (Wallace et al. 2005) and rebuilding analysis (Tsou and Wallace 2005) were superseded by the 2006 assessment (Wallace et al. 2006) and rebuilding analysis (Tsou and Wallace 2006), they were not published in a Stock Assessment and Fishery Evaluation document. However, these documents are posted on the Council's web site at pcouncil.org for those who are interested.

conducted by a scientific research vessel.

The federal regulations, § 600.310 (f)(4)(iii) require that fishing mortality be counted against the OY, including that resulting from bycatch, scientific research, and other fishing activities. In past years, prior to the establishing harvest guidelines for fishing activities, the Council has set aside a portion of the OY for each stock of stock complex projected to be taken by vessels conducting scientific research. The projected amounts were based on the most recent years' research catch summaries and were modified to account for changes in research activities between years. Because the research catch amounts are projections, the catch levels have on occasion been modified during the year when the catch of a constraining overfished species was higher than originally projected.

Table 2-4 summarizes the scientific research catch for 2005. Research catch projections for the overfished species are presented in the estimated mortality impact tables (i.e., bycatch scorecards) that have been prepared for each alternative. For 2007 and 2008, the depleted species' research catch projections are held constant under the different alternatives with the exception of yelloweye rockfish. Yelloweye rockfish values are increased over previous years in response to an increase in survey stations in the IPHC's annual Pacific Halibut longline survey. The additional survey stations are in yelloweye rockfish habitat and are expected to provide much needed fishery independent biological data on yelloweye. However, under the Preferred Low OY alternatives for depleted species, the new IPHC survey stations are not included. The values for bocaccio, widow and canary rockfish are based on the summary of research catch in 2005. These values were rounded up given the understanding that the biomass levels for these stocks are increasing and therefore, they will be more likely to be taken in research catches. Cowcod projections are also based on the summary of 2005 research catch. Although the total research catch in 2005 for darkblotched rockfish and POP was lower than originally projected, the research catch amounts for 2007 and 2008 are the same as those set aside at the beginning of 2005. The catch of these species varies considerably between years (darkblotched rockfish: 5.14 mt in 2003, 0.08 in 2004, and 2.08 mt in 2005; POP: 5.0 mt in 2003, 0.35 mt in 2004, 1.84 mt in 2005). In addition, the biomass levels for these stocks are increasing and they are more likely to be taken in research catches.

2.2.1.2 Exempted Fishing Permit Catches

This section will be completed after 2007 EFP applications are received by the Council in June 2006, at which time the Council may decide to specify EFP bycatch caps or a set-aside yield of groundfish species to allow 2007 EFPs to proceed.

2.2.2 New Management Lines

New management lines being considered for 2007-2008 include a 10 fm line in Washington to manage recreational fisheries, a 20 fm line in Washington and Oregon for managing recreational and nearshore commercial fisheries[9], a 25 fm line in Washington Marine Areas 1 and 2 (from the Oregon/Washington border to the Queets River) for managing the Washington recreational fishery, a 180 fm line modified for petrale sole fishing areas in California (south of 42º N latitude to US/Mexico border) to provide for winter petrale fishing, a 250 fm line south of 38º N latitude for use in managing commercial slope fisheries, and an accompanying 250 fm line modified for petrale sole fishing areas south of 38º N latitude.

The Oregon Department of Fish and Wildlife is proposing a 25 fm RCA line for Council adoption. This line would replace the current 27 fm RCA line in regulation. Due to the geography of the coast, and the methods by which these lines were drawn, there is little difference in area between the 25 fm RCA line and the 27 fm RCA line. This would, however, provide consistency in groundfish regulations between Washington and Oregon, as there would be a continuous 25 fm RCA line beginning at the Queets River and continuing to the Oregon/California border, thus simplifying regulations and providing RCA line consistency to the fishing community.

Additionally, the GMT intends to review the existing petrale sole fishing areas used to manage limited entry trawl fisheries during periods 1 and 6 and may recommend modifications to the boundaries defining these Groundfish Fishing Areas. Any coordinates defining new management lines are anticipated to be provided at the June 2006 Council meeting in Foster City, California.

9 The new 20 fm line in Washington and Oregon is expected to be formally defined with waypoints for 2007-2008 to better enforce any 20 fm depth restriction that might be implemented. California has been managing their recreational and nearshore commercial fisheries with a 20 fm depth restriction regionally, but this regulation is specified referencing depth contours rather than a defined line using latitude/longitude coordinates or waypoints. This was adopted because the majority of the 20 fm depth contour is within state waters, with the exception of an area off of San Francisco over sandy habitat where depleted rockfish (e.g., bocaccio) are not expected to be encountered. This nearshore depth contour winds along a rugged coastline and is considered by CDFG enforcement to be more successfully enforced as a depth contour. Therefore, CDFG intends to continue managing the 20 fm depth restriction by contours.

2.2.3 Description of the Management Measure Alternatives

2.2.3.1 The No Action Alternative

The No Action Alternative is described by the 2005 and 2006 management measures specified in federal and state regulations. All of the action alternatives described in this chapter will be compared to the No Action Alternative. Some of these management measures were changed beginning in 2006 in reaction to problems that arose in managing the 2005 fishery. While 2005 management measures, including inseason adjustments, will be described in detail, the 2006 management measures and projected impacts will be the central focus when comparing all action alternatives to the No Action Alternative. Projected impacts of depleted groundfish species under the No Action Alternative are depicted in Table 2-5.

Table 2-5. Projected mortality (mt) of depleted groundfish species by fishing sector in 2006.

Difference	174.3	2.7	0.8	18.2	373.3	31.7	6.7
Percent of OY	43.6%	94.2%	81.0%	90.9%	16.5%	89.0%	75.1%
Key		= either not applicable; trace amount (<0.01 mt); or not reported in available data sources.					

a/ South of 40°10' N. lat.

b/ Mortality estimates are not hard numbers; based on the GMT's best professional judgment.

c/ Bycatch amounts by species unavailable, but bocaccio occurred in 0.1% of all port samples and other rockfish in another 0.1% of all port samples (and squid fisheries usually land their whole catch). In 2001, out of 84,000 mt total landings 1 mt was groundfish. This suggests that total bocaccio was caught in trace amounts.

d/ Values for canary and yelloweye rockfish represent specified harvest guidelines.

e/ Values are proposed EFP bycatch caps, not estimates of total mortality. The EFP is terminated inseason if the cap is projected to be attained early.

2.2.3.1.1 Limited Entry Trawl Fisheries

Non-Whiting Trawl Fishery

The 2006 trawl trip limits and seasonal RCA configurations (as of May 2006) describe the No Action Alternative and are shown in Tables 2-6a (north of 40°10' N latitude) and 2-6b (south of 40°10' N latitude).

A new management measure implemented in 2005 was mandating the use of selective flatfish trawls shoreward of the trawl RCA north of 40°10' N latitude. The selective flatfish trawl, configured with a cut-back headrope, a low rise, and a small (≤ 8 in. diameter) footrope, is designed to reduce rockfish bycatch while efficiently catching flatfish. The selective flatfish trawl works by allowing rockfish to escape by swimming upward when they encounter the trawl. Flatfish tend to dive down when disturbed, which accounts for the differential selectivity of these trawls to rockfish and flatfish.

In 2005 the non-whiting bottom trawl fishery was constrained with lower slope rockfish trip limits and a larger RCA with a seaward boundary of 200 fm north of 40°10' N latitude in response to a problem with early attainment of the darkblotched rockfish OY in 2004. The period 6 opportunity to harvest petrale sole was also lost in 2004 when the fishery was closed out to 250 fm to minimize further darkblotched rockfish impacts. One consequence of these 2004 management actions was a pent-up demand for petrale sole when the fishery re-opened in 2005. Coupled with this market demand, there was fair winter weather in the north and an abnormal distribution of petrale sole in 2005, which led to an early attainment and exceedance of the petrale sole OY. In response, there was a trip limit imposed on petrale sole in period 1 of 2006, which, in previous years, had been unlimited in periods 1 and 6. The more conservative slope rockfish trip limits and trawl RCA configuration were also re-specified for 2006 to avoid the darkblotched rockfish impacts observed in 2004. And, in a good faith effort to respond to the Ninth Circuit Court of Appeals ruling in a challenge to the darkblotched rockfish rebuilding plan (see section 1.3.1), the Council and NMFS adopted a lower 200 mt darkblotched rockfish OY for 2006 in an emergency rulemaking. This compares to the previously specified darkblotched rockfish OY of 294 mt.

Another change in limited entry trawl management measures from 2005 was the specification of cumulative trip limits for Pacific cod and spiny dogfish beginning in March 2006 (period 2). The Pacific cod ABC of 3,200 mt was based on historical landings since the stock has not been formally assessed. The Pacific cod OY was reduced by half from the ABC beginning in 2005 on the GMT's recommendation and in accordance with the precautionary policy for unassessed stocks {Restrepo et al. 1998 /ft "see FMP §4.6.2"}. In 2004, prior to the precautionary OY reduction, the total mortality of Pacific cod was greater than the current OY of 1,600 mt. Therefore, the Council and NMFS adopted a Pacific cod trip limit beginning in 2006 (Tables 2-6a and 2-6b); previously allowable landings were unlimited. A spiny dogfish trip limit was also specified beginning in 2006 to address conservation concerns and the depleted species' bycatch implications associated with targeting this stock in the open access fishery (see section 2.2.3.1.3 below for more details). Tables 2-6a and 2-6b depict the 2006 spiny dogfish trip limits.

Although not much bottom trawling is done south of Pt. Conception at 34°27' N latitude in the Southern California Bight, bottom trawling and other bottom fishing activities are prohibited in two discrete areas called the Cowcod Conservation Areas (Figure 2-3).

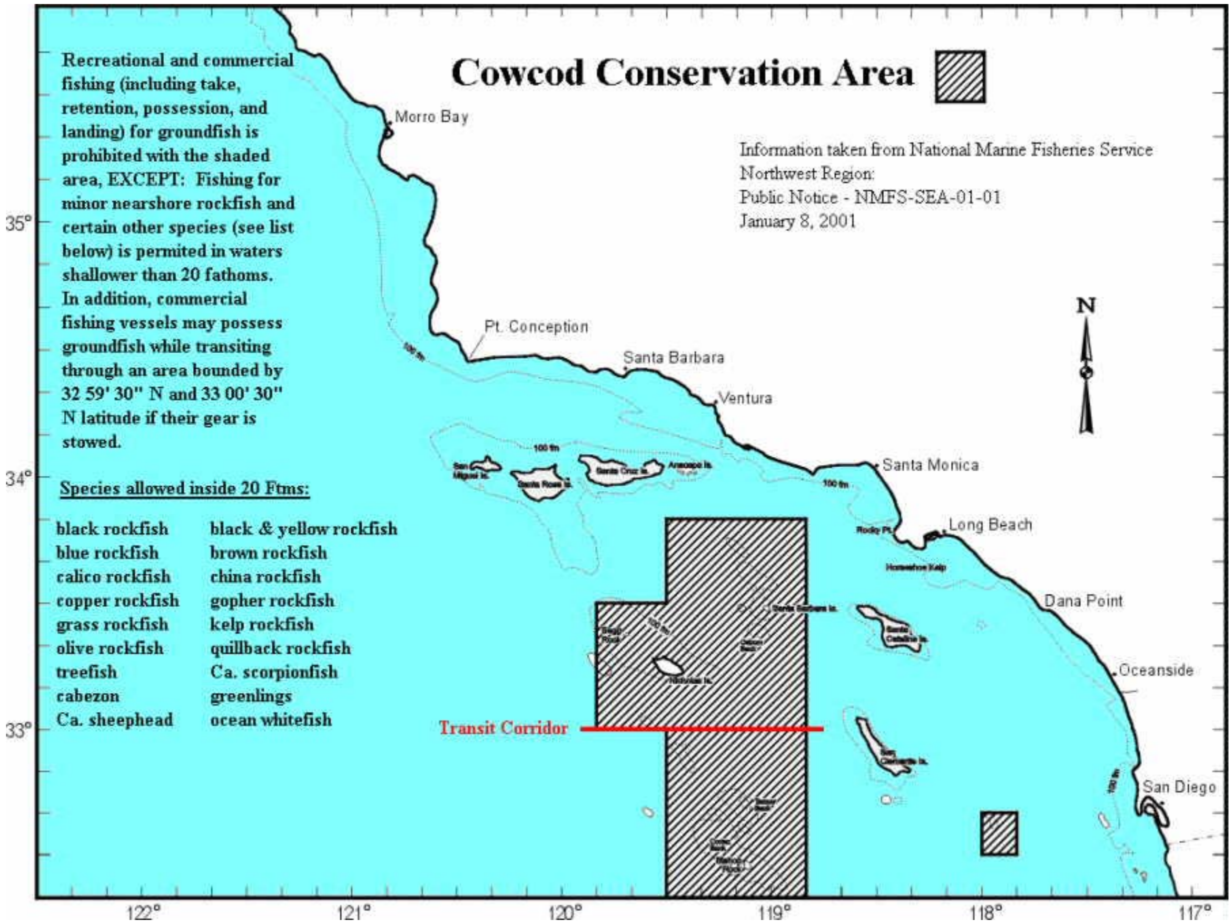

Figure 2-3. The current Cowcod Conservation Areas located in the Southern California Bight.

Whiting Trawl Fishery

The Pacific whiting OY of 269,069 mt, used to manage the 2005 and 2006 West Coast whiting fisheries, forms the basis for the No Action Alternative. The specific 2006 whiting harvest specifications are a coastwide (U.S. + Canada) ABC of 661,680 mt, a coastwide (U.S. + Canada) OY of 364,842 mt, and a U.S. OY of 269,069 mt. The U.S. OY of 269,069 mt is divided by first setting aside the tribal allocation

Table 2-6a. 2006 Trip limits for limited entry trawl gears north of 40°10' N latitude.

43	**Yellowtail**							
44	midwater trawl	Before the primary whiting season: CLOSED -- During primary whiting season: In trips of at least 10,000 lb of whiting: combined widow and yellowtail limit of 500 lb/ trip, cumulative yellowtail limit of 2,000 lb/ month. Mid-water trawl permitted in the RCA. See §660.373 for primary whiting season and trip limit details. -- After the primary whiting season: CLOSED						
45	large & small footrope gear	150 lb/ month		300 lb/ 2 months				
46	selective flatfish trawl gear	1,000 lb/ month		2,000 lb/ 2 months				
47	multiple bottom trawl gear [8/]	150 lb/ month		300 lb/ 2 months				
48	**Minor nearshore rockfish & Black rockfish**							
49	large & small footrope gear	CLOSED						
50	selective flatfish trawl gear	300 lb/ month						
51	multiple bottom trawl gear [8/]	CLOSED						
52	**Lingcod[4/]**							
53	large & small footrope gear	600 lb/ month		1,200 lb/ 2 months				
54	selective flatfish trawl gear							
55	multiple bottom trawl gear [8/]							
56	**Pacific cod**	Not limited		30,000 lb/ 2 months	70,000 lb/ 2 months			30,000 lb/ 2 months
57	**Spiny dogfish**	Not limited		200,000 lb/ 2 months	150,000 lb/ 2 months	100,000 lb/ 2 months		
58	**Other Fish [5/]**	Not limited						

1/ Bocaccio, chilipepper and cowcod are included in the trip limits for minor shelf rockfish.
2/ Splitnose rockfish is included in the trip limits for minor slope rockfish.
3/ "Other flatfish" are defined at § 660.302 and include butter sole, curlfin sole, flathead sole, Pacific sanddab, rex sole, rock sole, sand sole, and starry flounder.
4/ The minimum size limit for lingcod is 24 inches (61 cm) total length.
5/ "Other fish" are defined at § 660.302 and include sharks, skates, ratfish, morids, grenadiers, and kelp greenling. Cabezon is included in the trip limits for "other fish."
6/ The Rockfish Conservation Area is a gear and/or sector specific closed area generally described by depth contours but specifically defined by lat/long coordinates set out at § 660.390.
7/ The "modified 200 fm" line is modified to exclude certain petrale sole areas from the RCA.
8/ If a vessel has both selective flatfish gear and large or small footrope gear on board during a cumulative limit period (either simultaneously or successively), the most restrictive cumulative limit for any gear on board during the cumulative limit period applies for the entire cumulative limit period.

To convert pounds to kilograms, divide by 2.20462, the number of pounds in one kilogram.

Table 2-6b. 2006 Trip limits for limited entry trawl gears south of 40°10' N latitude.

Other Limits and Requirements Apply -- Read § 660.301 - § 660.390 before using this table

44	**Other Fish[5/] & Cabezon**	Not limited						

1/ Yellowtail is included in the trip limits for minor shelf rockfish.
2/ POP is included in the trip limits for minor slope rockfish
3/ "Other flatfish" are defined at § 660.302 and include butter sole, curlfin sole, flathead sole, Pacific sanddab, rex sole, rock sole, sand sole, and starry flounder.
4/ The minimum size limit for lingcod is 24 inches (61 cm) total length.
5/ Other fish are defined at § 660.302 and include sharks, skates, ratfish, morids, grenadiers, and kelp greenling.
6/ The Rockfish Conservation Area is a gear and/or sector specific closed area generally described by depth contours but specifically defined by lat/long coordinates set out at § 660.390.
7/ The "modified 200 fm" line is modified to exclude certain petrale sole areas from the RCA.

of 35,000 mt, and then setting aside 1,800 mt for incidental bycatch in non-whiting fisheries and 200 mt for research catch. The resulting yield is then allocated between factory trawlers or catcher-processors (34%), vessels delivering to at-sea processors or motherships (24%), and vessels delivering to shore-based processing plants (42%). Table 2-7 indicates the set asides and allocations for 2006 fisheries.

Table 2-7. Pacific whiting set-asides and allocations by fishing sector specified in 2006.

Sector	Set-aside or allocation (mt)
Tribal whiting	35,000
Non-whiting fisheries	1,800
Research	200
Catcher-processors	78,903
Motherships	55,697
Shore-based whiting	97,469
Total	269,069

The GMT recommended exploring overfished species' bycatch implications in the Pacific whiting fishery using a 4-year weighted average bycatch model (the years 2001-2004 were used to project 2005 impacts and the years 2002-2005 were used to project 2006 impacts- see chapter 4 for more details). The rates used to project 2006 whiting fishery impacts were applied to the 2006 OY under this alternative (these same rates are used to explore bycatch implications in 2007 and 2008 Pacific whiting fisheries- see below). The Council again specified bycatch caps for stocks that could potentially constrain opportunities in the Pacific whiting and other West Coast fishing sectors in 2006. The two overfished West Coast groundfish stocks that are incidentally caught in the whiting-directed trawl fishery and for which bycatch caps have been specified in 2006 regulations are canary and widow rockfish. The Council and NMFS decided to set aside 4.7 mt of canary rockfish and 200 mt of widow rockfish for the 2006 non-tribal whiting-directed fisheries. The non-tribal sectors of the whiting fishery would close prior to reaching their whiting allocations if these caps were reached inseason. However, the Council reserved the ability to change these caps inseason if there was unused yield available and it was needed to keep whiting fisheries open.

2.2.3.1.2 Limited Entry Fixed Gear Fisheries

Limited entry fixed gear trip limits and the nontrawl RCA configuration as of May 2006 describe the No Action Alternative and are shown in Tables 2-8a (north of 40°10' N latitude) and 2-8b (south of 40°10' N latitude). Under the No Action Alternative, the nontrawl RCA is defined by management lines specified with waypoints at roughly 30 fm to 100 fm in waters off northern California (north of 40°10' N latitude) and Oregon; and zero fm to 100 fm in waters off Washington. The nontrawl RCA south of 40°10' N latitude and north of Point Conception at 34°27' N latitude under the No Action Alternative is defined by management lines specified with waypoints at roughly 30 fm to 150 fm during periods 1, 2, 5, and 6 and 20 fm to 150 fm during periods 3 and 4. There is an additional closure between zero fm and 10 fm around the Farallon Islands to reduce impacts on shallow nearshore rockfish in that area. The nontrawl RCA south of Point Conception is defined by management lines specified with waypoints at roughly 60 fm to 150 fm. This more liberal RCA can be accommodated by the minimal occurrence of canary rockfish in the Southern California Bight. Canary and yelloweye rockfish are not allowed to be landed in the limited entry fixed gear fishery under the No Action Alternative.

The primary sablefish fishery, open to limited entry fixed gear permit holders that have a sablefish endorsement, runs from April 1 through October 31. Permit stacking is allowed in this fishery, where

33	**Other fish**[4/] **& Cabezon**	Not limited					

1/ "Other flatfish" are defined at § 660.302 and include butter sole, curlfin sole, flathead sole, Pacific sanddab, rex sole, rock sole, sand sole, and starry flounder.
2/ POP is included in the trip limits for minor slope rockfish. Yellowtail is included in the trip limits for minor shelf rockfish.
3/ The minimum size limit for lingcod is 24 inches (61 cm) total length.
4/ "Other fish" are defined at § 660.302 and include sharks, skates, ratfish, morids, grenadiers, and kelp greenling.
5/ The Rockfish Conservation Area is a gear and/or sector specific closed area generally described by depth contours but specifically defined by lat/long coordinates set out at § 660.390.
To convert pounds to kilograms, divide by 2.20462, the number of pounds in one kilogram.

more than one and up to three permits may be used on a single vessel during the primary sablefish season. Limited entry permits with sablefish endorsements are assigned to one of three different cumulative trip limit tiers, based on the qualifying catch history of the permit. The 2006 sablefish limits are as follows: tier 1 = 62,700 lb, tier 2 = 28,500 lb, and tier 3 = 16,300 lb.

The Council and NMFS adopted a similar change in cumulative trip limits for Pacific cod and spiny dogfish for limited entry fixed gear fisheries as they did for limited entry trawl fisheries beginning in March 2006 (period 2). While the spiny dogfish limits for limited entry fixed gear fisheries were the same for spiny dogfish as in the limited entry trawl fishery, the Pacific cod limits were much lower since Pacific cod are less frequently caught by fixed gears. Tables 2.7a and 2.7b depict the 2006 Pacific cod and spiny dogfish trip limits for limited entry fixed gear fisheries.

Limited entry fixed gears are not allowed to be fished in the Cowcod Conservation Areas (Figure 2-3) under the No Action Alternative, except for some nearshore commercial fishing opportunities described in section 2.2.3.1.4.

2.2.3.1.3 Open Access Fisheries

Open access fisheries are those West Coast commercial fisheries comprised of vessels without a federal limited entry trawl or limited entry fixed gear permit that catch groundfish either as target species (directed groundfish fisheries) or incidentally while targeting non-groundfish species (incidental groundfish fisheries).

Open access gears that fish the bottom and any of the gears used in the directed groundfish fisheries are not allowed to be fished in the Cowcod Conservation Areas (Figure 2-3) under the No Action Alternative, except for some nearshore commercial fishing opportunities described in section 2.2.3.1.4.

Directed Groundfish Fisheries

There are directed groundfish fisheries that target nearshore species (see the following section 2.2.3.1.4) and those operating on the shelf and slope primarily targeting sablefish (daily-trip-limit fishery) and slope rockfish species. This section describes the No Action management measures associated with the latter category of open access vessels targeting groundfish offshore in federal waters.

Open access trip limits and estimated impacts of 2006 management measures as of May 2006 describe the No Action Alternative and are shown in Tables 2-9a (north of 40°10' N latitude) and 2-9b (south of 40°10' N latitude). The same nontrawl RCA described for limited entry fixed gears under the No Action

Table 2-9a. 2006 trip limits for open access gears north of 40°10' N latitude.

20	**Other Fish[5/]**	Not limited					

Table 2-9a. 2006 trip limits for open access gears north of 40°10' N latitude (continued).

21	**PINK SHRIMP NON-GROUNDFISH TRAWL** *(not subject to RCAs)*	
22	North	**Effective April 1 - October 31:** groundfish 500 lb/day, multiplied by the number of days of the trip, not to exceed 1,500 lb/trip. The following sublimits also apply and are counted toward the overall 500 lb/day and 1,500 lb/trip groundfish limits: lingcod 300 lb/month (minimum 24 inch size limit); sablefish 2,000 lb/month; canary, thornyheads and yelloweye rockfish are PROHIBITED. All other groundfish species taken are managed under the overall 500 lb/day and 1,500 lb/trip groundfish limits. Landings of these species count toward the per day and per trip groundfish limits and do not have species-specific limits. The amount of groundfish landed may not exceed the amount of pink shrimp landed.
23	**SALMON TROLL**	
24	North	Salmon trollers may retain and land up to 1 lb of yellowtail rockfish for every 2 lbs of salmon landed, with a cumulative limit of 200 lb/month, both within and outside of the RCA. This limit is within the 200 lb per month combined limit for minor shelf rockfish, widow rockfish and yellowtail rockfish, and not in addition to that limit. All groundfish species are subject to the open access limits, seasons and RCA restrictions listed in the table above.

1/ Bocaccio, chilipepper and cowcod rockfishes are included in the trip limits for minor shelf rockfish.
Splitnose rockfish is included in the trip limits for minor slope rockfish.
2/ "Other flatfish" are defined at § 660.302 and include butter sole, curlfin sole, flathead sole, Pacific sanddab, rex sole, rock sole, sand sole, and starry flounder.
3/ For black rockfish north of Cape Alava (48°09.50' N. lat.), and between Destruction Is. (47°40' N. lat.) and Leadbetter Pnt. (46°38.17' N. lat.), there is an additional limit of 100 lbs or 30 percent by weight of all fish on board, whichever is greater, per vessel, per fishing trip.
4/ The size limit for lingcod is 24 inches (61 cm) total length.
5/ "Other fish" are defined at § 660.302 and include sharks, skates, ratfish, morids, grenadiers, and kelp greenling.
Cabezon is included in the trip limits for "other fish."
6/ The Rockfish Conservation Area is a gear and/or sector specific closed area generally described by depth contours but specifically defined by lat/long coordinates set out at § 660.390.
To convert pounds to kilograms, divide by 2.20462, the number of pounds in one kilogram.

Alternative above would also apply for those open access fisheries not exempt from the RCA restrictions.

In 2005, a factory longliner from Alaska announced plans to target spiny dogfish in West Coast waters under the open access limits, which were unlimited for species such as spiny dogfish in the Other Fish complex. Fixed gear fisheries targeting spiny dogfish are known to incidentally catch canary and yelloweye rockfish. This unanticipated entrant to the open access fishery was of particular concern since the volume of dogfish that could be landed could incur a significant bycatch of canary and yelloweye rockfish, especially for vessel operators unfamiliar with the West Coast distribution of these species and the techniques employed to avoid them. Therefore, on May 2, 2005, NMFS implemented an emergency rule to specify canary and yelloweye rockfish bycatch caps for the directed open access fishery of 1.0 mt and 0.6 mt, respectively. All directed open access fisheries (those fisheries targeting groundfish species) would close if any of these caps were projected to be attained early in the fishing season. The Council and NMFS increased these caps to 3.0 mt for each of the species later in the year (implemented on July 1) based on increased availability of canary and yelloweye rockfish. While the factory longliner never did implement plans to target spiny dogfish on the West Coast, the Council and NMFS did by decide to change the spiny dogfish limits for limited entry and open access fisheries from unlimited to specified bimonthly trip limits for the open access fishery beginning in March 2006 (Tables 2-9a and 2-9b). While this action did not wholly address the particular vulnerability of lack of effort controls in the open access fishery, it did address bycatch concerns for targeting spiny dogfish in open access (and limited entry) fisheries.

The same 2006 change in Pacific cod management measures adopted for the limited entry fixed gear fishery was made for open access fisheries by adopting new bimonthly trip limits for this stock in March 2006 (Tables 2-9a and 2-9b).

The sablefish daily trip limit (DTL) fishery north of 36° N latitude has caught less than their allocation in recent years. In 2005, the DTL limits for January-September were 300 pounds per day, or one landing per week up to 900 pounds, not to exceed 3,600 pounds per two months. These DTL limits were increased for October through December to 500 pounds per day, or one landing per week up to

1,500 pounds, not to exceed 9,000 pounds per two months. The Council recommended maintaining the previously scheduled daily limit of 300 pounds per day, raising the weekly limit to 1,000 pounds, and raising the two month limit to 5,000 pounds for December 2005. The Council considered a more liberal increase in daily and weekly DTL limits, but was concerned with the inability to control effort in this fishery and therefore recommended a cautious approach to liberalizing this fishery. In April 2006, the Council addressed an increased interest in the DTL sablefish fishery and was especially concerned given the reduced salmon fishing opportunities available. The concern was the open access sablefish quota may be attained early in 2006 without an effective open access effort control mechanism. Therefore, the Council adopted a decreased DTL bimonthly limit for sablefish of 3,000 pounds and tasked the GMT to review effort shifts into this fishery and consider increased DTL limits in June.

Incidental Groundfish Fisheries

West Coast commercial fishing vessels targeting non-groundfish species, but landing groundfish under open access limits are included in the category of incidental open access fisheries. In some cases, such as the ridgeback prawn trawl fishery south of 34°27' N latitude, the northern pink shrimp fishery, and the salmon troll fishery, there are specific exemptions from non-trawl RCA restrictions while landing some groundfish species.

Under the No Action Alternative, the ridgeback prawn trawl fishery south of 34°27' N latitude is allowed to operate out to the 100 fm line regardless of the non-trawl RCA configuration south of Pt. Conception. This exemption is allowed because ridgeback prawn trawling occurs over soft mud substrates where depleted rockfish species do not occur and ridgeback prawns are found largely adjacent to the 100 fm isobath in this area. The pink shrimp trawl fishery is not restricted by an RCA, but approved bycatch reduction devices or fish excluders in shrimp trawls are mandated to minimize incidental groundfish bycatch. The salmon troll fishery is exempted from RCA restrictions, but groundfish species, including lingcod, are not allowed to be retained while fishing in the non-trawl RCA. The only exemption to this regulation under the No Action Alternative is an incidental landing allowance of up to 1 lb of yellowtail rockfish per 2 lbs of salmon landed with a cumulative monthly landing limit of 200 lbs of yellowtail rockfish, both within and outside the RCA. Otherwise, non-trawl RCA restrictions apply to incidental groundfish fisheries if groundfish are to be legally retained and landed under the open access limits.

2.2.3.1.4 Nearshore Commercial Fisheries

The majority of vessels participating in nearshore commercial fisheries do not hold federal limited entry permits, and the most common gear used is jig gear. However, some vessels use longline gear to target nearshore species and, in rare instances, pots or traps are used in the nearshore fishery. California and Oregon limit entry to the nearshore groundfish fishery by requiring a state limited entry permit to take commercial quantities of nearshore groundfish species (see sections 2.1.4.1 and 2.1.4.2 for the lists of nearshore rockfish species targeted in nearshore commercial fisheries north and south of 40°10' N latitude). Washington does not allow a nearshore commercial fishery. More conservative state harvest targets or guidelines than those specified in federal regulations exist for most nearshore species and state trip limits supersede federal limits in these cases. State trip limits are designed to stay within nearshore species harvest caps (Tables 2-10 and 2-11) while providing a year-round opportunity, if possible. Federal management measures for West Coast nearshore commercial groundfish fisheries are typically stratified north and south of 40°10' N latitude.

Table 2-10. Nearshore groundfish species' harvest limits, including harvest targets, OYs, and harvest guidelines by West Coast region, 2002-2006.

1/ Non-bolded numbers are harvest targets; bolded numbers are either OYs or harvest guidelines

2/ Minor Nearshore Rockfish includes a reserve of 22 mt in 2004, 14 mt in 2005, and 14 mt in 2006; 2004 OY corrected from 615 mt (in 2004 Fed. Reg.) to 494 mt so does not include the 121 mt that was removed from this group in 2003 when the OY was calculated as 50% of recent landings; the confusion exists because the 121 mt was kept as a reserve in the overall Minor Rockfish OY and was accidentally added back into the NS RF OY in 2004.

3/ Starting in 2004, Deeper Nearshore does not include black rockfish.

4/ Black Rockfish north of 40º 30' to 43º 00' had an ABC of 500 mt in 2003.

5/ The black rockfish OY south of 46º16' N Lat. is subdivided with separate HGs being set for the area north (58 percent of OY) and south (42 percent of OY) of 42º N Lat. For the area south of 42º N Lat., 60 percent of the HG is to be applied to the area north of 40º10' N Lat. and 40 percent applied to the area south of 40º10' N Lat.

Nearshore Commercial Fisheries North of 40°10' N latitude

There are nearshore commercial fisheries north of 40°10' N latitude to the Oregon-Washington border at 46°10' N latitude; Washington does not allow nearshore commercial fisheries in their state waters. A depiction of the season duration for northern nearshore commercial fisheries and predicted black, canary, and yelloweye rockfish impacts under the No Action and action alternatives is provided in Table 2-12a.

Table 2-11. State and federal harvest guidelines specified for state-managed groundfish fisheries in California in 2006.

Species or Species complex	Sector	Harvest guideline in mt (or pounds)
Canary Rockfish	Rec.	9.3
Yelloweye Rockfish	Rec.	3.7
Black Rockfish	NS Comm.	139
	Rec.	170
	Total	309
Minor Nearshore Rockfish	NS Comm.	97
	Rec.	383
	Total	480
Cabezon	NS Comm.	42.1 (92,800)
	Rec.	26.9 (59,300)
	Total	69 (152,100)
Greenlings	NS Comm.	1.5 (3,400)
	Rec.	15.5 (34,200)
	Total	17.1 (37,600)
Lingcod	Rec.	422

Table 2-12a. Season structure and expected yelloweye rockfish and canary rockfish impacts under the 2007-2008 No Action and action alternatives for nearshore commercial fisheries north of 40°10' N latitude.

Alternative	Season Duration	Black Rockfish Reduction (%)	Shoreward RCA (fm)	Estimated Impact (mt) to Yelloweye Rockfish	Estimated Impact (mt) to Canary Rockfish
No Action	12 month season	0	30	2.1	1.7
1	<6 month season	60	20	0.8	0.7
2	12 month season	10	20	1.3	1.2
3a	12 month season	0	20	1.4	1.3
3b	12 month season	0	30	2.1	1.7

Under the No Action Alternative, the nontrawl RCA is defined by management lines specified with waypoints at roughly 30 fm to 100 fm in waters off northern California (north of 40°10' N latitude) and Oregon; and zero fm to 100 fm in waters off Washington. In Oregon, those limited entry permit holders may land commercial quantities of black and blue rockfish under state trip limits, with an additional 15 lbs per day of other nearshore groundfish species. Vessels that also have a nearshore endorsement, in addition to the black/blue limited entry permit may land commercial quantities of other nearshore rockfish (which includes two rockfish with a federal designation as shelf rockfish - tiger and vermilion rockfish), cabezon, and greenling under state trip limits. For vessels that do not hold a state permit or endorsement, an incidental landing limit of no more than 15 pounds per day of any combination of black rockfish, blue rockfish, and/or other nearshore fish is allowed, with a few exceptions. Salmon trollers with a valid troll permit may land 100 pounds of black rockfish, blue rockfish, or a combination thereof in the same landing in which a salmon is landed. These rockfish may only be landed dead. If the cumulative landing of black and blue rockfish combined in the salmon troll fishery reaches 3,000 pounds in any calendar year, then each salmon troll vessel is limited to 15 pounds of black rockfish, blue rockfish, or a combination thereof per troll landing for the remaining calendar year. Trawlers may land up to 1,000 pounds of black rockfish, blue rockfish, or a combination thereof per calendar year and these fish must be 25 percent or less of the total poundage of each landing and must be landed dead.

The 2006 federal trip limit for nearshore species north of 40°10' N latitude to 42° N latitude is 6,000 lb/ 2 months, no more than 1,200 lb of which may be species other than black or blue rockfish. The 2006 federal trip limit for nearshore species north of 42° N latitude is 5,000 lb/ 2 months, no more than 1,200 lb of which may be species other than black or blue rockfish. This listed limit has been superseded by the more conservative Oregon state limits for the last several years.

Nearshore Commercial Fisheries South of 40°10' N latitude

In California, those limited entry permit holders who also have either a shallow nearshore fishery or deeper nearshore fishery permit administered by CDFG may land minor nearshore rockfish from either the shallow nearshore or deeper nearshore complexes. Trip limits for shallow nearshore rockfish, deeper nearshore rockfish, and California scorpionfish vary by period (Table 2-8b).

A depiction of the season duration for southern nearshore commercial fisheries and predicted nearshore rockfish, canary, and yelloweye rockfish impacts under the No Action and action alternatives is provided in Table 2-12b for the area 40°10’ N. latitude to 34°27’ N. latitude.

Table 2-12b. Season structure and expected yelloweye rockfish and canary rockfish impacts under the 2007-2008 No Action and action alternatives for nearshore commercial fisheries south of 40°10' N latitude to 34°27’ N. latitude .

Alternative	Season Duration	Nearshore Rockfish Reduction (%)	Shoreward RCA (fm)	Estimated Impact (mt) to Yelloweye Rockfish	Estimated Impact (mt) to Canary Rockfish
No Action	10 month season	0	30 (Jan-Apr, Sep-Dec) 20 (May-Aug)	0.0	0.33
1	8 month season	15	20	0.0	0.26
2	10 month season	5	20	0.0	0.30
3a	10 month season	5	30	0.0	0.31
3b	10 month season	0	30	0.0	0.56

Under the No Action Alternative, the nontrawl RCA south of 40°10' N latitude and north of Point Conception at 34°27' N latitude is defined by management lines specified with waypoints at roughly 30 fm to 150 fm during periods 1, 2, 5, and 6 and at 20 fm to 150 fm during periods 3 and 4. There is an additional closure between zero fm and 10 fm around the Farallon Islands to reduce impacts on shallow nearshore rockfish in that area. The nontrawl RCA south of Point Conception is defined by management lines specified with waypoints at roughly 60 fm to 150 fm. This more liberal RCA can be accommodated by the minimal occurrence of canary rockfish in the Southern California Bight. Status quo management is proposed south of Point Conception under action alternatives 2 and 3 due to the low incidence rate of overfished species; a nontrawl RCA line of 40 fm is proposed under action alternative 1 due to impacts to bocaccio rockfish. Canary and yelloweye rockfish are not allowed to be landed in the fixed gear fisheries, including those targeting nearshore groundfish species, under the No Action Alternative.

Trip limits for shallow nearshore rockfish, deeper nearshore rockfish, and California scorpionfish vary by period (Table 2-8b). However, period 2 is closed for these species north and south of Point Conception, and shelf rockfish is closed at this time to minimize discard of nearshore species during the closed period. There is also a small and variable trip limit for bocaccio during the open nearshore periods to allow some incidental bycatch to be landed rather than discarded dead at sea. Species' harvest guidelines for California nearshore commercial fisheries are depicted in Table 2-11.

There is some nearshore commercial fishing allowed in the Cowcod Conservation Areas (Figure 2-3) in depths shallower than 20 fm under the No Action Alternative. Only southern minor nearshore rockfish, (both shallow and deeper nearshore rockfish- see section 2.1.4.1 for the list of species in this complex), California scorpionfish, cabezon, greenlings, California sheephead, and ocean whitefish are allowed to be retained in depths <20 fm in the CCAs.

2.2.3.1.5 Tribal Fisheries

The Washington coastal tribes (Makah, Quileute, Hoh, and Quinault) prosecuted their groundfish fisheries in 2005-2006 with the following allocations and trip limits. The 2006 sablefish allocation was 10% of the total catch OY (for the portion of the stock north of 36° N latitude) of 7,363 mt. This provided an allocation of 736.3 mt of sablefish, which is further reduced after deducting an assumed 2.3% discard mortality for a landed catch allocation of 719.4 mt. The tribal commercial harvest of black rockfish was managed with a harvest guideline of 20,000 lbs north of Cape Alava, Washington at 48°09'30" N latitude, and 10,000 lbs between Destruction Island, Washington at 47°40' N latitude and Leadbetter Point, Washington at 46°38'10" N latitude. There were no harvest restrictions on black rockfish between Cape Alava and Destruction Island. Thornyheads were subject to a 300 lb trip limit as were canary rockfish. Yelloweye rockfish were subject to a 100 lb trip limit. For yellowtail rockfish the entire Makah tribal fleet (the only tribal fleet that participated in a midwater fishery) was subject to a cumulative landing limit of 180,000 lbs/two months. Widow rockfish landings were limited to 10% of the weight of yellowtail rockfish landed in any two-month period. These midwater landing limits were subject to inseason adjustments to minimize the take of canary and widow rockfish. Other rockfish, including species in the minor nearshore, minor shelf, and minor slope rockfish complexes were subject to either a 300 lb trip limit per species or complex, or to the non-tribal limited entry trip limit for those species if those limits were less restrictive. Rockfish taken during the open competition tribal commercial fisheries for Pacific halibut were not subject to trip limits. A full rockfish retention program, as well as a tribal observer program, was in place to provide catch accountability. Lingcod were subject to a 600 pound per day and 1,800 pound per week limit for all tribal fisheries except for the treaty troll fishery which was limited to 1,000 pounds per day and 4,000 pounds per week. A petrale sole trip limit of 50,000 lbs/two months for the Makah bottom trawl fleet was specified for the entire year. Trip limits for Pacific cod, English sole, rex sole, arrowtooth flounder, and other flatfish in the tribal bottom trawl fishery were the same as for non-tribal limited entry trawl fishery at the start of the season (Table 2-6a) using the same Council-approved gear. The tribal plan was not to reduce these limits inseason because of the low expected catch unless catch statistics indicated that the tribes would attain more than half the harvest of these species in their usual and accustomed (U and A) fishing areas. The tribal allocation of Pacific whiting in 2006 was 35,000 mt based on the sliding scale allocation formula that specifies the tribal whiting OY based on the total U.S. whiting OY (Table 2-7). The Makah tribe was the only one of the four tribes prosecuting a whiting-directed fishery in 2006, or proposing a whiting-directed fishery for 2007-2008.

2.2.3.1.6 Washington Recreational Fisheries

In 2005 and 2006, the Washington recreational fishery was open year round for groundfish except lingcod, which was open from the Saturday closest to March 15 through the Saturday closest to October 15 in Marine Areas 1-3 (from the Oregon/Washington border at 46º16' N latitude north to Cape Alava at 48º10' N latitude), and from April 15 through the Saturday closest to October 15 or October 15, whichever date is earlier, in Marine Area 4 (Cape Alava to the U.S./Canada border). In 2005, Marine

Areas 1-3 were open from March 12 through October 15, and Marine Area 4 was open from April 15 through October 15. In 2006, Marine Areas 1-3 are open from March 17 through October 14, and Marine Area 4 is open from April 15 through October 14.

Under the No Action Alternative, in 2007 and 2008, the following lingcod seasons would apply:

- Marine Areas 1-3: Open the Saturday closest to March 15 (which is March 17 in 2007 and March 15 in 2008) through the Saturday closest to October 15 (which is October 13 in 2007 and October 18 in 2008).

- Marine Area 4: Open April 15 through October 13 in 2007 and open April 15 through October 15 in 2008.

Washington has a recreational groundfish bag limit of 15 fish per day including rockfish and lingcod. Of the 15 recreational groundfish allowed to be landed per day, only 10 could be rockfish, with no retention of canary or yelloweye rockfish, and a sublimit of two lingcod with a 24-inch minimum size during the open lingcod season.

Recreational groundfish and recreational halibut fishing is prohibited within the "C-shaped" Yelloweye Rockfish Conservation Area (YRCA) (Figure 2-4). Coordinates defining the YRCA are provided in federal regulations at 50 CFR 660.390.

Washington and Oregon prosecuted their 2005 and 2006 recreational fisheries with shared harvest guidelines for canary rockfish, lingcod, and yelloweye rockfish. If the recreational harvest guideline for canary rockfish, lingcod, or yelloweye specified for the Washington/Oregon area was projected to be exceeded inseason, the Washington Department of Fish and Wildlife (WDFW) would consult with the Oregon Department of Fish and Wildlife (ODFW) and take action inseason to close all or portions of the recreational fishery deeper than 30 fm or adjust seasons, bag limits, or size limits, as needed. In 2005, the shared Washington and Oregon harvest guidelines for recreational fisheries were 8.5 mt, 234 mt, and 6.7 mt for canary rockfish, lingcod, and yelloweye rockfish, respectively. In 2006, the shared recreational harvest guidelines for canary and yelloweye remain the same, and lingcod is increased to 271 mt.

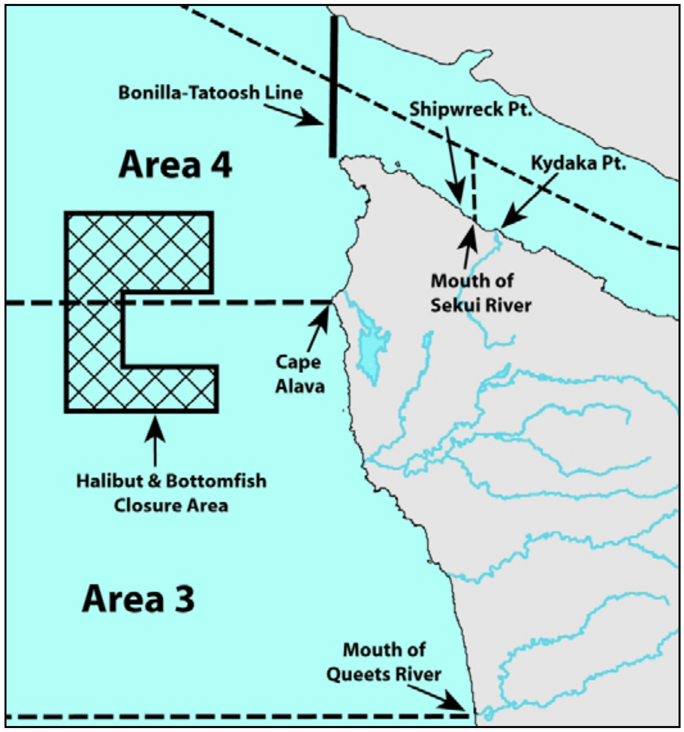

Figure 2-4. The current "C-shaped" Yelloweye Rockfish Conservation Area in waters off northern Washington where recreational groundfish and Pacific halibut fishing is prohibited.

The Washington portion of the shared canary rockfish harvest guideline was 1.7 mt and its portion of the shared yelloweye harvest guideline was 3.5 mt. These total catch amounts or harvest targets, if projected to be attained inseason by the Washington recreational fishery, were the triggers to consult with ODFW and consider an inseason action to slow or eliminate further canary or yelloweye rockfish mortality in this fishery. In 2005, WDFW projected that the yelloweye harvest target would be attained prematurely prompting such a consultation. That consultation indicated the shared yelloweye harvest guideline would be attained early, resulting in a WDFW action implemented on August 5 to close the recreational groundfish fishery outside of 30 fm in waters off Washington north of Leadbetter Pt. at 46º38'10" N latitude. The Council and NMFS adopted conforming federal regulations that were implemented on October 1, 2005.

New Washington recreational management measures were adopted for 2006 to avoid early canary and yelloweye rockfish harvest guideline attainment problems. To reduce the catch of yelloweye rockfish to stay within the Washington recreational harvest target, WDFW proposed, and the Council and NMFS adopted, the following modifications to the 2006 Washington recreational fishery:

- Prohibition of retention of rockfish and lingcod seaward of a line approximating the 20 fm depth contour from May 22, 2006, through September 30, 2006, in Marine Areas 3 and 4 (waters off Washington north of the Queets River at 47º31'42" N latitude where canary and yelloweye catches are highest) on days that halibut fishing is closed.

- Prohibition of retention of rockfish and lingcod seaward of a line approximating the 30 fm depth contour from March 18, 2006, through June 15, 2006, in Marine Area 2 (waters off Washington between Leadbetter Pt. and the Queets River).

Because the 20 fm line had not been previously analyzed, the following modification was made: where the line approximating the 20 fm depth contour extends beyond state waters and into the EEZ, the line will follow the seaward boundary of the state coastal waters.

Halibut fishery regulations for the 2006 Washington fishery became effective March 5, 2006. Therefore, it was necessary to modify the recreational groundfish regulations to conform to the new halibut regulations:

- South of Leadbetter Point to the Washington/Oregon border, when Pacific halibut are onboard the vessel, groundfish may not be taken and retained, possessed or landed, except sablefish and Pacific cod.

2.2.3.1.7 Oregon Recreational Fisheries

In 2005 (and 2006), the Oregon recreational groundfish fishery was (or is expected to be in 2006) open year round with no depth restrictions except during June through September when the fishery was open only inside 40 fm. Catches at the onset of 2005 were also managed using an 8 marine fish daily bag limit[10] including rockfish, greenling (*Hexagrammos* spp.), cabezon, and other groundfish species, but excluding salmon, lingcod, Pacific halibut, perch species, sturgeon, sanddabs, striped bass, tuna, and baitfish. There was no retention of canary and yelloweye rockfish. There was an additional daily bag limit of 25 Pacific sanddabs. Anglers could keep two lingcod with a 24 inch minimum size. Additionally, there was a minimum size limit of 16 inches for cabezon and a 10 inch minimum size limit for greenling species.

The Oregon recreational fishery was managed in 2005 and 2006 with harvest guidelines for black rockfish and widow rockfish, state harvest caps for other nearshore rockfish (including vermilion and tiger rockfish), greenlings, combined black and blue rockfish, and cabezon; and the shared Washington and Oregon harvest guidelines for canary rockfish, lingcod, and yelloweye rockfish discussed above in section 2.2.3.1.5 (Table 2-10). The state harvest caps were set using 2000 harvest as a proxy, and have only ocean boat landings applied against the harvest cap. The black rockfish harvest guideline was shared with Oregon nearshore commercial fisheries; the state allocated the guideline to these sectors as part of their authority. The Oregon black rockfish harvest guidelines for the recreational fishery was 332 mt in 2005 and 324.5 mt in 2006. The state harvest cap for cabezon was 15.8 mt in both 2005 and 2006. ODFW used their Oregon Recreational Boat Survey (ORBS) Program to monitor groundfish catches inseason. If the shared Washington and Oregon recreational harvest guideline for canary, yelloweye, or lingcod was projected to be exceeded, ODFW would consult with WDFW, and consider inseason action to close all or portions of the recreational fishery deeper than 20 fm or 30 fm or adjust seasons, bag limits, or size limits, as needed. Similar actions were considered to manage the black rockfish harvest guideline.

The Oregon Fish and Wildlife Commission (OFWC) also adopted 2005 regulations to prohibit retention of all marine fish (except sablefish, herring, anchovy, smelt, sardine, striped bass, hybrid bass, and offshore pelagic species) when Pacific halibut is retained by the vessel during open days for the all-depth sport fishery for Pacific halibut in the area between lines extending west of Oregon-Washington border and Humbug Mountain, Oregon at 42º40’30” N latitude to the EEZ boundary. This management

[10] The Council originally adopted a 10 marine fish daily bag limit for Oregon recreational fisheries. However, subsequent to the Council’s final decision on 2005 and 2006 management measures in June 2004, but prior to January 1, 2005, the Oregon Fish and Wildlife Commission adopted an 8 marine fish daily bag limit. The Council and NMFS adopted conforming federal regulations that were implemented on April 1, 2005.

measure adjustment was expected to provide additional harvest reduction of overfished species and other species with harvest guidelines such as black rockfish by discouraging secondary targeting of such species. This provision also applied during all-depth halibut days in June through September when groundfish retention was prohibited seaward of the RCA boundary approximating the 40 fm depth contour.

In July 2005, ODFW took action to reduce the marine fish daily bag limit from 8 marine fish to 5 marine fish for the remainder of the year to slow the harvest of black rockfish. ODFW took additional action in August 2005 to prohibit retention of cabezon in the recreational ocean boat fishery, due to attainment of the annual state harvest cap for cabezon, and again in October 2005 to close the ocean boat groundfish fishery in waters shoreward of the 40 fathom RCA line, and prohibit retention of black rockfish, as the black rockfish harvest guideline was projected to be attained.

In December 2005, the OFWC refined management measures for the 2006 Oregon recreational groundfish fishery, based on the angler effort patterns observed in 2005. Because there was a significant increase in angler effort targeting groundfish in 2005, due primarily to the poor salmon season in the waters off Oregon, the OFWC adopted a marine fish bag limit of 6 fish in aggregate. The reduced bag limit was necessary to keep the fishery within the 2006 Oregon harvest guideline for black rockfish and to provide a 12 month fishing season. All other management measures (i.e., length restrictions for lingcod, cabezon, and kelp greenling, >40 fm closure during June-September) remain as they were specified for 2005. If the federal and state harvest guidelines are approached in 2006, ODFW would take inseason actions similar in nature to those taken in 2005. Federal conforming regulations were implemented on April 1, 2006.

In 2005 and 2006, ODFW closed the high relief areas of Stonewall Banks to the Pacific halibut fishery during the all-depth Pacific halibut season. Targeting and retention of Pacific halibut was prohibited in the area, and vessels that have retained Pacific halibut while fishing another area, were then prohibited from targeting any species within the closed area. The coordinates for the Stonewall Banks closure implemented in the Pacific halibut fishery are as follows:

1	44º37.46 N latitude	124º24.92 W longitude
2	44º37.46 N latitude	124º23.63 W longitude
3	44º28.71 N latitude	124º21.80 W longitude
4	44º28.71 N latitude	124º24.10 W longitude
5	44º31.42 N latitude	124º25.47 W longitude

Returning to the first point (Figure 2-5).

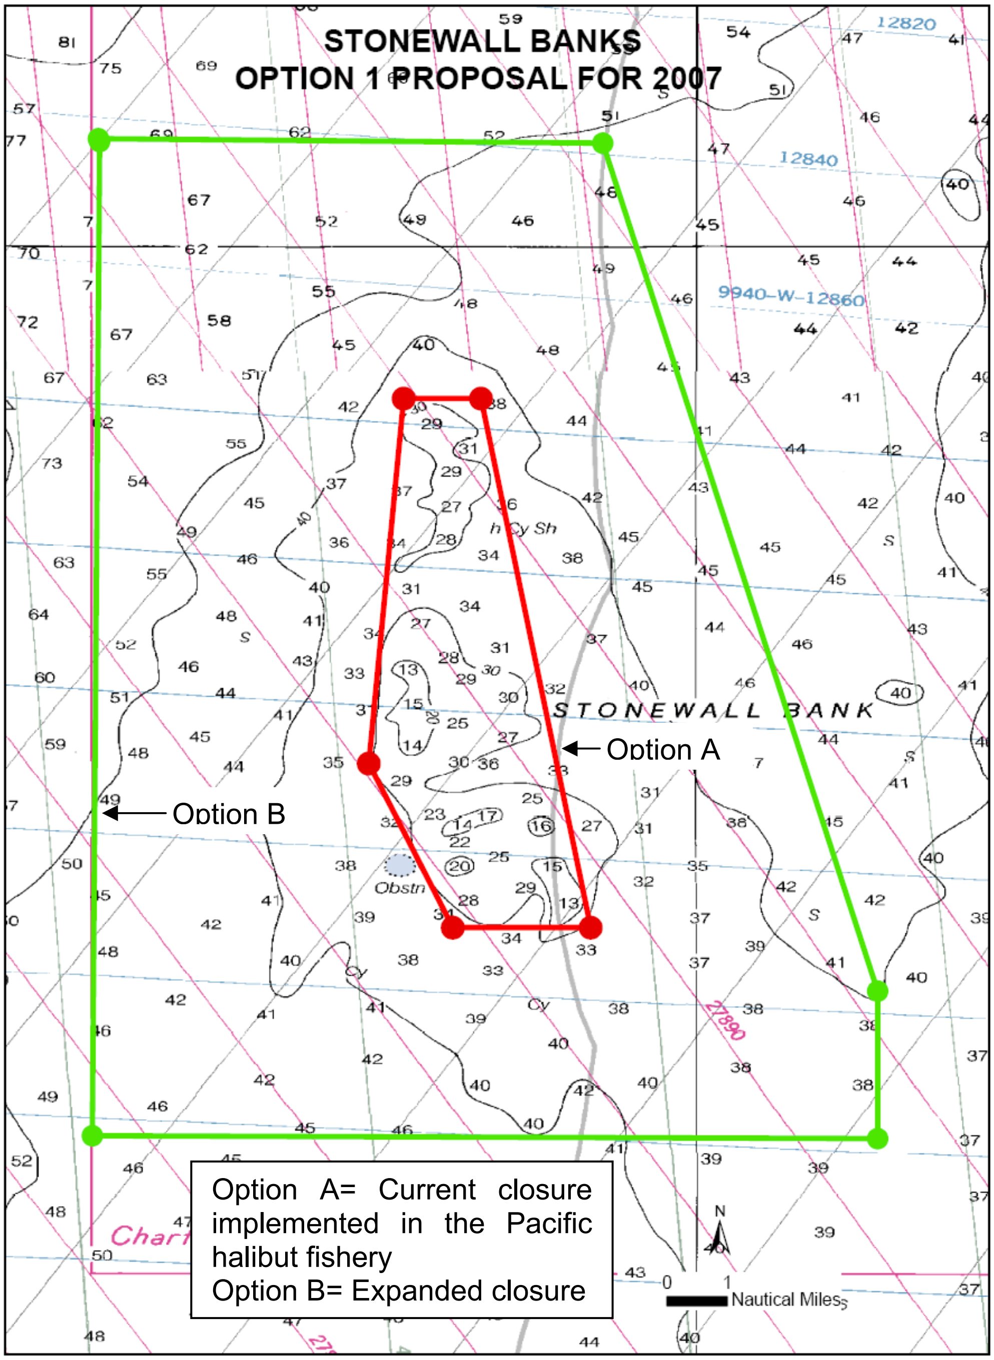

Figure 2-5. The current area closure on Stonewall Banks off the Oregon coast where Pacific halibut retention is prohibited during the all-depth fishery under the No Action Alternative (denoted Option A in figure) and the expanded closed area under Action Alternatives 1 and 3 (denoted Option B in figure).

Halibut regulations for the 2006 fishery became effective March 5, 2006. Therefore it was necessary to modify the recreational groundfish regulations to conform to the new halibut regulations:

- South of the Washington/Oregon border to Cape Falcon, OR, when Pacific halibut are onboard the vessel, groundfish may not be taken and retained, possessed or landed, except sablefish and Pacific cod.
- South of the Cape Falcon, OR, to Humbug Mountain, OR, when Pacific halibut are onboard the vessel, groundfish may not be taken and retained, possessed or landed, except sablefish, during days open to the Oregon Central Coast "all-depth" sport halibut fishery.

2.2.3.1.8 California Recreational Fisheries

For management of California's nearshore recreational groundfish fishery in 2005 and 2006, the California Fish and Game Department (CDFG) divided the coastline into five regional areas, although some regions had the same management measures and were therefore managed as a larger combined region. The five management areas, termed Rockfish/Lingcod Management Areas (RLMAs), are as follows: 1) Southern RLMA (U.S./Mexico Border to Point Conception at 34°27' N latitude), 2) Southern South-Central RLMA (Point Conception to Lopez Point at 36° N latitude), 3) Northern South-Central RLMA (Lopez Point to Pigeon Point at 37º11' N latitude), 4) Northern Central RLMA (Pigeon Point to Cape Mendocino at 40°10' N latitude), and 5) Northern RLMA (Cape Mendocino to the California/Oregon Border at 42° N latitude). The RLMAs between Lopez Point and Cape Mendocino were combined in 2005-2006 management with the intent to specify separate management measures in each of these RLMAs as needed to stay within state and federal harvest guidelines.

The Council and NMFS adopted 2005-2006 California recreational management measures as follows:

- Regulations apply to groundfish (with sanddab fishery exception) and associated state-managed species (rock greenling, California sheephead, and ocean whitefish).
- The sport fishery for sanddabs, using gear specified in federal and state regulations (size #2 hooks or smaller), is exempt from the season closures and depth restrictions placed on other federally-managed groundfish.
- Retention of species in the Other Flatfish complex is allowed when fishing with size #2 hooks or smaller (≤ 11 mm from point to shank) for Pacific sanddabs.
- Lingcod size limit of 24 inches with a daily bag limit of two fish.
- Within a general bag limit of 20 fish, a combined rockfish + cabezon + greenling (RCG) complex daily bag limit of 10 fish of which one can be a cabezon and one can be a greenling of the genus *Hexagrammos*[11].
- A two-fish bag limit for bocaccio in the northern RLMA (north of 40°10' N latitude to the Oregon/California border at 42° N latitude) and a one-fish bag limit south of 40°10' N latitude to the U.S./Mexico border within the 10-fish RCG daily bag limit.
- No retention of cowcod, canary, or yelloweye rockfish.
- Notwithstanding other fishing opportunities for groundfish, lingcod may not be retained during January, February, March, and December.
- All divers (use of boats is permitted while diving for rockfish or other closed species during closed periods provided no hook and line gear on board or in possession while diving to catch rockfish) and shore-based anglers would be exempt from the seasonal closures and depth restrictions for rockfish, greenlings, California scorpionfish, California sheephead, and ocean whitefish.

[11] The cabezon daily bag sublimit was changed from three fish to one fish and the greenling daily bag sublimit was changed from 2 fish to 1 fish in a California Fish and Game Commission action in October 2004 subsequent to the Council's final decision in June 2004. The Council and NMFS adopted conforming federal regulations that were implemented on April 1, 2005.

The California recreational fishery was managed with federal and state harvest guideline for various groundfish species. Federal annual harvest guidelines were specified for canary rockfish (9.3 mt), yelloweye rockfish (3.7 mt), black rockfish (316 mt for recreational and nearshore commercial fisheries combined in 2005, of which 175 mt were allocated to the recreational fishery by CDFG; in 2006, the combined harvest guideline was 309 mt and the recreational harvest guideline was 170 mt), and lingcod (422 mt) (Table 2-11). State harvest guidelines were specified by CDFG for cabezon, greenlings, and minor nearshore rockfish (both shallow and deeper nearshore rockfish species; see section 2.1.4.1 for the list of species in these complexes). If the recreational harvest guideline for canary rockfish, yelloweye rockfish, or lingcod specified for California was projected to be exceeded, or if the state harvest guideline for black rockfish was projected to be exceeded when combining recreational harvest projections and annual commercial projections, CDFG and/or the Council and NMFS would take action to close all or part of the recreational fishery in all or part of the state regions in all or part of the remainder of the year. Any closure may pertain to closure of specific groundfish species or specific depths in different regions to achieve catch limitation. In the northern RLMA (north of 40°10' N latitude to the Oregon/California border at 42° N latitude), CDFG would take action to close all or part of the recreational fishery deeper than the 30 fm management line if the canary or yelloweye rockfish harvest guideline was attained early in the season.

The 2005 and 2006 adopted management measures included depth bands where fishing for rockfish and associated species was allowed only between 20 and 40 fm (Southern South-Central RLMA) or 30 to 60 fm (Southern RLMA). California took inseason action in 2005 to remove the shoreward boundaries of these depth bands and allow boat-based fishing inside the seaward boundaries originally adopted in the Southern and Southern South-Central RLMAs. These actions were initiated to address concerns related to the ability to enforce fishing restrictions shoreward of adopted depth bands. In addition, final 2004 recreational CRFS projections of impacts showed that additional opportunity could be allowed shoreward of the adopted boundaries, as well as in additional months in the North, North-Central and Northern South-Central RLMAs that would not be likely to exceed harvest guidelines for overfished species targets.

The 2005-2006 seasons and depth restrictions by California management region (Table 2-13) were as follows:

Table 2-13. Summary of 2006 California recreational groundfish seasons and depth restrictions by region under the No Action Alternative.

RCG SEASON BY REGION

Region	Jan	Feb	Mar	Apr	May	Jun	July	Aug	Sep	Oct	Nov	Dec
North region	---	---	---	---	> 30fm Closed							
North Central	---	---	---	---	---	---	> 20fm Closed					
South Central - Monterey	---	---	---	---	---	---	> 20fm Closed					
South Central - Morro Bay	---	---	---	---	> 40fm Closed					---	---	---
South Region	---	---	> 60fm Closed						>30 fm Closed		> 60fm Closed	

NOTES AND KEY:

Shore fishing allowed in all waters in all months

RCG = Rockfish, cabezon, greenlings

--- = Closed to boat-based fishing for RCG

LINGCOD SEASON IS OPEN **ONLY** WHEN RCG IS OPEN, EXCEPT CLOSED DEC, JAN, FEB, MAR FOR SPAWNING

Southern RLMA (U.S./Mexico Border to Point Conception at 34°27' N latitude)

The California recreational groundfish fishery regulations south of Point Conception under the No Action Alternative were the same as described above except for the following changes:

- Groundfish other than California scorpionfish, but including select nongroundfish species (California sheephead and ocean whitefish) open March through August and November through December shoreward of 60 fm; open September through October shoreward of 30 fm; and closed January and February.
- California scorpionfish can only be retained during October and November shoreward of 40 fm and December shoreward of 20 fm (closed January through September).
- Fishing is allowed within the Cowcod Conservation Areas (Figure 2-3) shoreward of the 20 fm line when fishing is open for groundfish other than California scorpionfish, but including select nongroundfish species (California sheephead and ocean whitefish).

Southern South-Central RLMA (Point Conception to Lopez Point at 36° N latitude)

The California recreational groundfish fishery regulations for the area between Point Conception and Lopez Point under the No Action Alternative would be the same as described above except for the following changes:

- Groundfish including select nongroundfish species (California sheephead and ocean whitefish) open May through September shoreward of 40 fm (closed January through April and October through December).

Northern South-Central RLMA (Lopez Point to Pigeon Point at 37°11' N latitude)

The California recreational groundfish fishery regulations for the area between Lopez Point and Cape Mendocino under the No Action Alternative would be the same as described above except for the following changes:

- Groundfish including select nongroundfish species (California sheephead and ocean whitefish) open July through December shoreward of 20 fm (closed January through June).

Northern Central RLMA (Pigeon Point to Cape Mendocino at 40°10' N latitude)

Same regulations as in the Northern South-Central RLMA, except:

- Recreational fishing for groundfish prohibited between the shoreline and the 10 fm (18 m) depth contour around the Farallon Islands and Noonday Rock.
- Waters of Cordell Bank less than 100 fm in depth are closed to fishing at all times.

Northern RLMA (Cape Mendocino to the California/Oregon Border at 42° N latitude)

The California recreational groundfish fishery regulations for the area between Cape Mendocino and the California/Oregon border under the No Action Alternative would be the same as described above except for the following changes:

- Groundfish and ocean whitefish open in May through December shoreward of 40 fm (closed January through June through April).

2.2.3.2 Action Alternative 1

Action Alternative 1 describes the suite of 2007-2008 management measures adopted by the Council for analysis in April 2006 which are the most conservative analyzed in this EIS and therefore tend to constrain fishing opportunities more than the other action alternatives analyzed. They are designed to stay within the Preferred Low OY Alternative for depleted groundfish species (see section 2.1.1.1). Table 2-14 depicts the impacts to depleted groundfish species by sector in 2007 and 2008 associated with the suite of management measures under Action Alternative 1.

2.2.3.2.1 Limited Entry Trawl Fisheries

Table 2-15 depicts the 2007-2008 limited entry trawl management measures under Action Alternative 1. Under this alternative, the trawl RCA is the largest considered for 2007-2008 extending out to the 250 fm in the north and 200 fm in the south (north of 38º N latitude) to stay within the Low Preferred OYs for darkblotched rockfish and Pacific ocean perch. The shoreward RCA line is also extended in to 75 fm in the north and 60-75 fm in the south to reduce mortalities on depleted shelf rockfish, such as bocaccio and canary rockfish, which is responsive to the Low Preferred OYs for those species.

Table 2-14. Projected mortality (mt) of depleted groundfish species by fishing sector under Action Alternative 1.

Fishery	Bocaccio *a/*	Canary	Cowcod	Dkbl	POP	Widow	Yelloweye

note: splitnose limits are the same as slope rock limits south of 40 degrees 10 minutes N latitude

* indicates petrale areas

Action Alternative 1 would reduce the lingcod minimum size limit from 24 inches to 20 inches north of 40°10' N latitude under this alternative.

Under Action Alternative 1, Yelloweye RCAs would be added, which would be closed to limited entry trawl fisheries, including midwater trawl, as defined by the following coordinates:

Washington Extension to the "C-Shaped" YRCA

Washington Department of Fish and Wildlife is proposing an extension to the status quo "C-Shaped" YRCA in waters off northern Washington, which is described as follows:

Beginning at 48°00.00' N latitude, 125°16.00' W longitude;
Then to 48°06.00' N latitude, 125°16.00' W longitude;
Then to 48°00.00' N latitude, 124°54.00' W longitude;
Then to 48°06.00' N latitude, 124°54.00' W longitude;
Then to 48°00.00' N latitude, 125°16.00' W longitude;
and back to the point of origin (Figure 2-6).

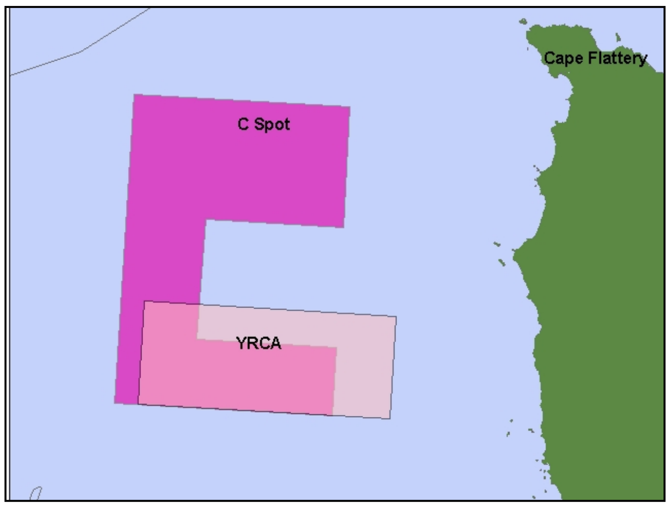

Figure 2-6. A proposed extension to the status quo Yelloweye Rockfish Conservation Area in waters off the Washington north coast where all fishing would be prohibited in 2007-2008 under Action Alternatives 1-3.

WA North Coast A

Beginning at 48°02.23' N latitude; 125°17.87' W longitude
Then to 48°01.42' N latitude; 125°15.89' W longitude
Then to 47°59.11' N latitude; 125°18.03' W longitude
Then to 47°59.97' N latitude; 125°19.92' W longitude
and back to the point of origin (Figure 2-7).

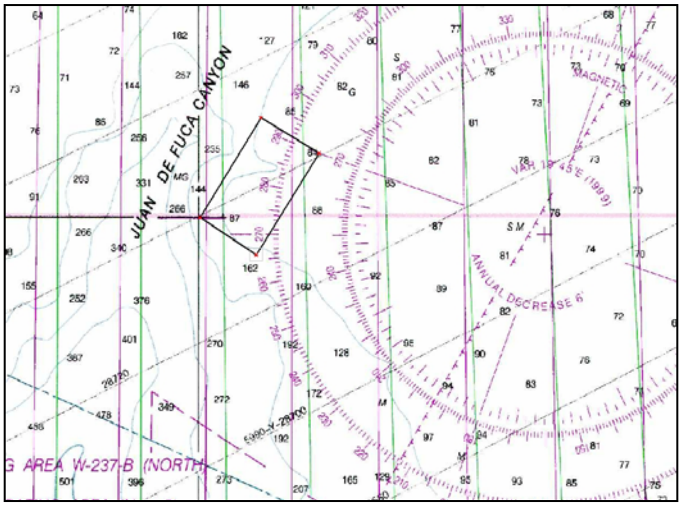

Figure 2-7. A proposed Yelloweye Rockfish Conservation Area (WA North Coast A) in waters off the Washington north coast where all fishing would be prohibited in 2007-2008 under Action Alternatives 1-3.

WA North Coast B

Beginning at 48º11.77’ N latitude by 125º13.03’ W longitude
Then to 48º16.43’ N latitude by 125º07.55’ W longitude
Then to 48º14.72’ N latitude by 125º01.84’ W longitude
Then to 48º13.36’ N latitude by 125º03.20’ W longitude
Then to 48º12.74’ N latitude by 125º05.83’ W longitude
Then to 48º11.55’ N latitude by 125º04.99’ W longitude
Then to 48º09.96’ N latitude by 125º06.63’ W longitude
Then to 48º09.68’ N latitude by 125º08.75’ W longitude
and back to the point of origin (Figure 2-8).

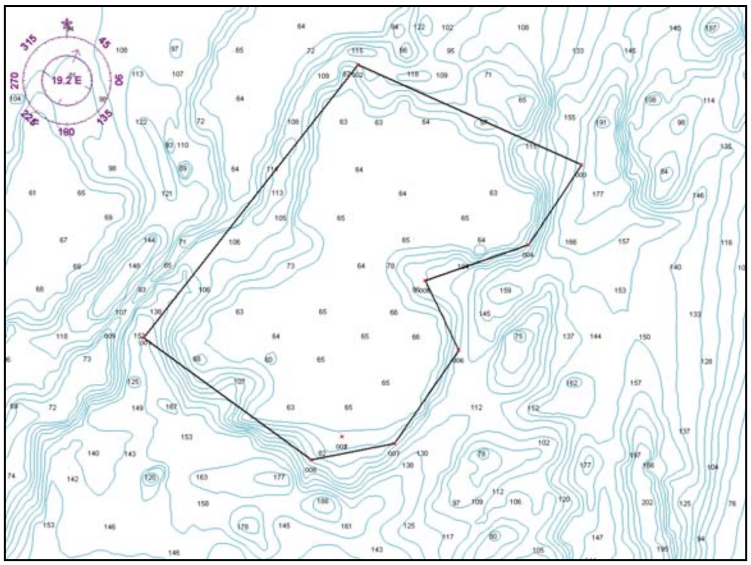

Figure 2-8. A proposed Yelloweye Rockfish Conservation Area (WA North Coast B) in waters off the Washington north coast where all fishing would be prohibited in 2007-2008 under Action Alternatives 1-3.

WA South Coast A

Beginning at 47°05.00' N latitude; 124°46.50' W longitude
Then to 47°04.00' N latitude; 124°46.50' W longitude
Then to 47°05.00' N latitude; 124°48.00' W longitude
and back to the point of origin (Figure 2-9).

WA South Coast B

Beginning at 46°58.00' N latitude; 124°48.00' W longitude
Then to 46°55.00' N latitude; 124°48.00' W longitude
Then to 46°58.00' N latitude; 124°49.00' W longitude
and back to the point of origin (Figure 2-9).

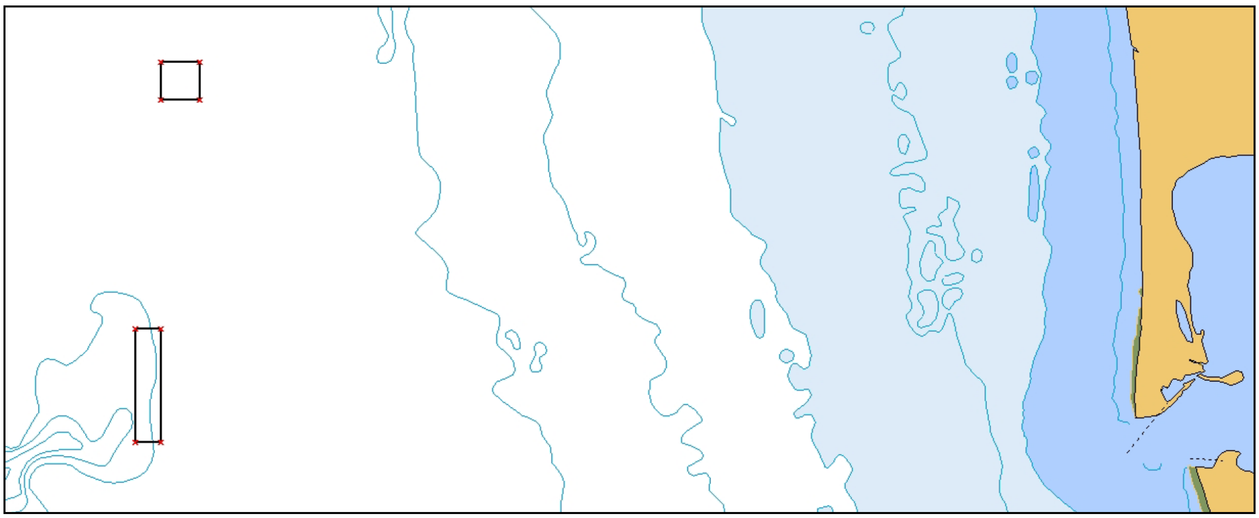

Figure 2-9. Two proposed Yelloweye Rockfish Conservation Areas (WA South Coast A and B) in waters off the Washington south coast where all fishing would be prohibited in 2007-2008 under Action Alternatives 1-3.

Non-Whiting Trawl Fishery

There are no additional management measures than those described above for non-whiting trawl fisheries in 2007 and 2008 under Action Alternative 1.

Whiting Trawl Fishery

Predicted impacts to depleted groundfish species in 2007-2008 whiting-directed fisheries under Action Alternatives 1-3 are depicted in Table 2-16. Higher whiting OYs are not possible given the bycatch constraints imposed by depleted groundfish species under the preferred OYs. However, it is important to note that an alternative strategy for managing 2007-2008 whiting fisheries would be to impose bycatch caps for these species and allow the fleet flexibility to avoid these species while attempting to attain their whiting quotas.

Table 2-16. Predicted impacts to depleted groundfish species using a weighted average of observed bycatch rates in 2002-2005, sector whiting allocations, and estimated exvessel revenues for the 2007-2008 whiting fishery under Action Alternatives 1-3.

Action Alternatives	US Catch	Fathom Line	Sector	Allocation	Canary	Darkblotched	POP	Widow	Yelloweye	Exvessel Rev
Alt. 3	260,000	none	Tribal	35,000	1.6	0.0	0.6	6.0	-	$4,089,570.1

			Total		4.0	8.6	3.5	68.7	0.0	$17,293,039.3

2.2.3.2.2 Limited Entry Fixed Gear Fisheries

Under Action Alternative 1, the seaward line of the non-trawl RCA is extended out to 150 fm north of Pt. Conception at 34°27' N latitude to the U.S.-Canada border to provide additional canary and yelloweye rockfish protection. The proposed yelloweye RCAs off the Washington coast would also be closed to limited entry fixed gear fisheries under this alternative (Figures 2-5, 2-6, 2-7, and 2-8).

South of Pt. Conception, the non-trawl RCA would be extended shoreward to 40 fm and seaward to 180 fm to reduce canary, cowcod, yelloweye, and particularly bocaccio mortality under this alternative.

The seaward boundary of the western Cowcod Conservation Area would be modified under this alternative to allow limited entry fixed gear vessels access to fish in four distinct Groundfish Fishing Areas (GFAs) deeper than 175 fm (Figure 2-10).

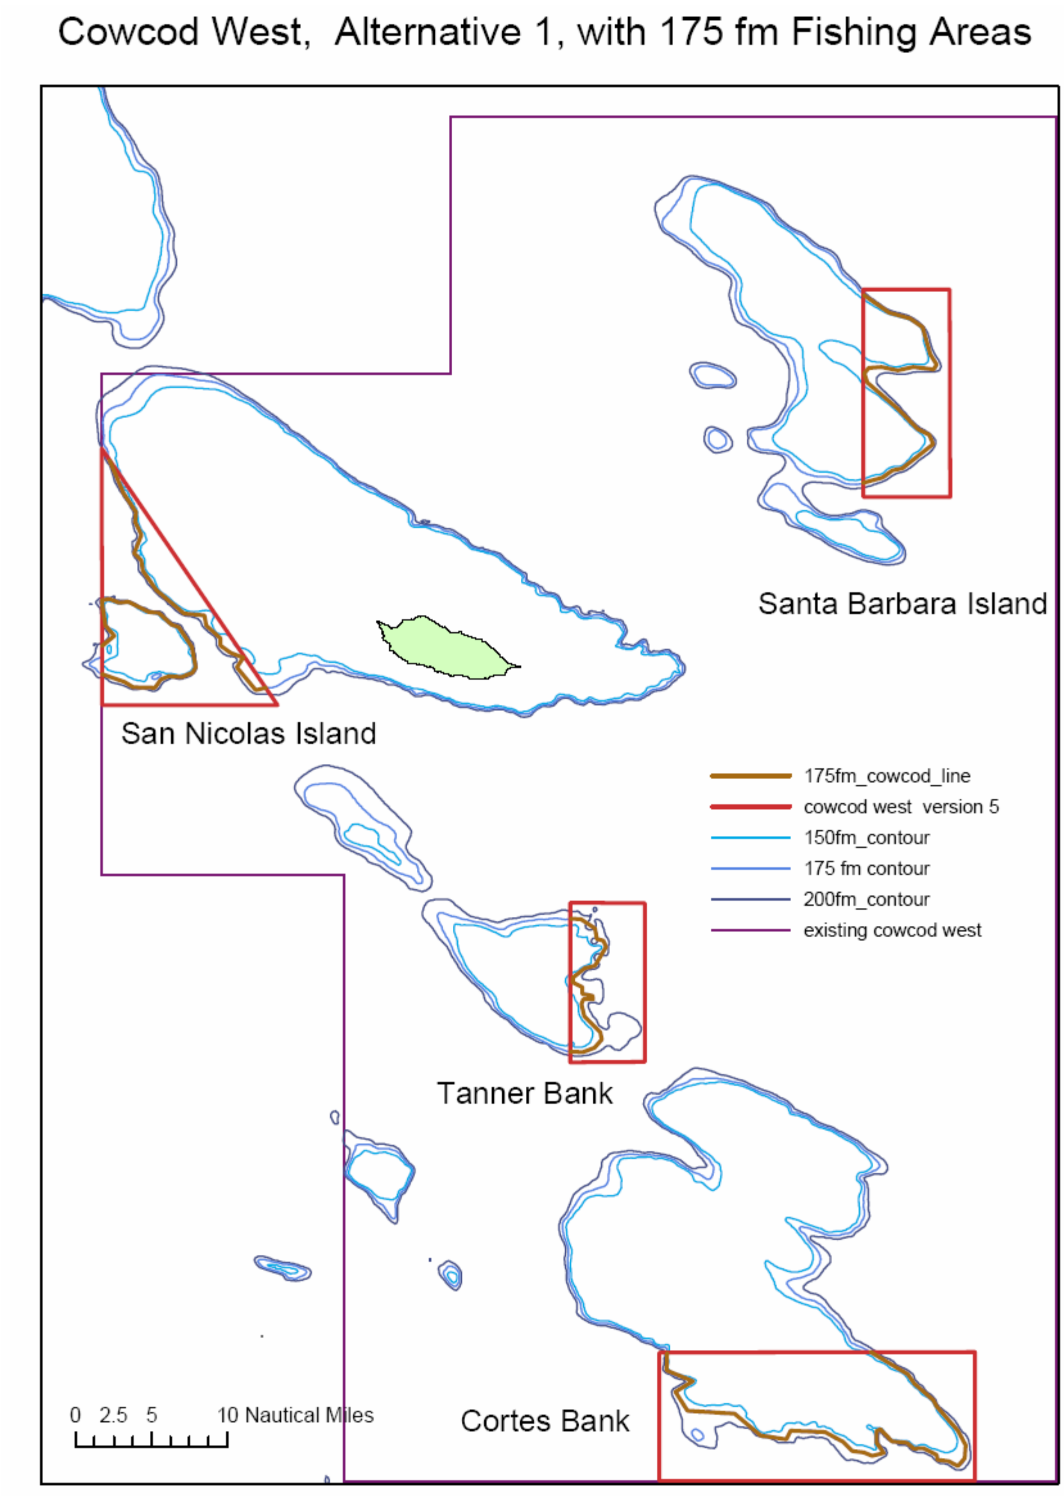

Figure 2-10. Modifications proposed for the western Cowcod Conservation Area in the Southern California Bight under Action Alternative 1 to allow limited entry fixed gear and open access fishing in four distinct Groundfish Fishing Areas (inside red polygons) in depths greater than 175 fm (brown contour).

.2.3.2.3 Open Access Fisheries

Under Action Alternative 1, the seaward line of the non-trawl RCA is extended out to 150 fm north of Pt. Conception at 34°27' N latitude to the U.S.-Canada border to provide additional canary and yelloweye rockfish protection. The proposed yelloweye RCAs off the Washington coast would also be closed to open access fisheries under this alternative (Figures 2-5, 2-6, 2-7, and 2-8).

South of Pt. Conception, the non-trawl RCA would be extended shoreward to 40 fm and seaward to 180 fm to reduce canary, cowcod, yelloweye, and particularly bocaccio mortality under this alternative.

Directed Groundfish Fisheries

The seaward boundary of the western Cowcod Conservation Area would be modified under this alternative to allow open access vessels targeting groundfish using fixed gears access to fish in four distinct Groundfish Fishing Areas (GFAs) deeper than 175 fm (Figure 2-10).

Incidental Groundfish Fisheries

An additional yelloweye RCA is considered under Action Alternative 1 (as well as Action Alternatives 2 and 3) where commercial salmon trolling would be prohibited (Figure 2-11). This salmon troll RCA is defined by the following coordinates:

Beginning at 48°00.00’ N latitude by 125°14.00’ W longitude
Then to 48°02.00’ N latitude by 125°14.00’ W longitude
Then to 48°00.00’ N latitude by 125°16.50’ W longitude
and back to the point of origin.

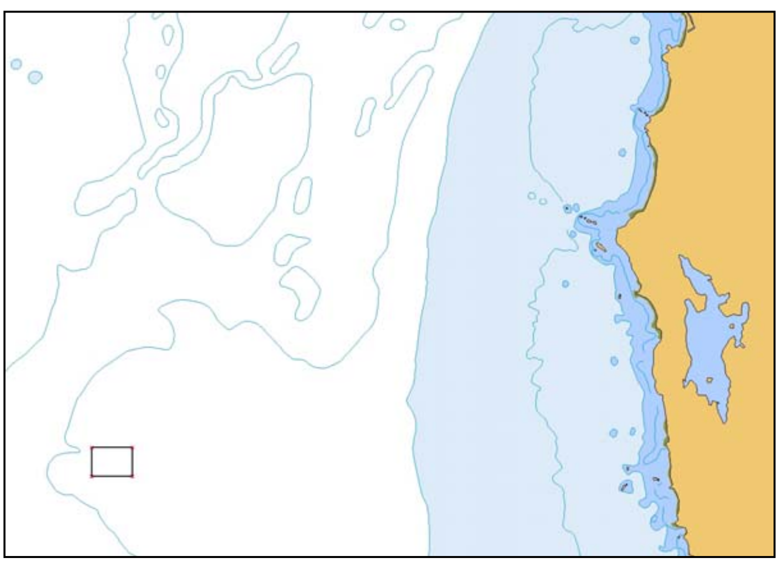

Figure 2-11. A yelloweye RCA off the north Washington coast where commercial salmon trolling would be prohibited under Action Alternatives 1-3.

Under Action Alternative 1, the following management measures would also apply to the commercial

salmon troll fishery north of 40°10' N latitude:
- Consistent with the salmon troll regulations off Oregon, allow the retention of lingcod in the salmon troll fishery when fishing shoreward of a line approximating 30 fm.
- As a canary rockfish bycatch reduction measure, prohibit the use of "hoochies" on the bottom spread.

2.2.3.2.4 Nearshore Commercial Fisheries

Nearshore Commercial Fisheries North of 40°10' N latitude

Under Action Alternative 1, the shoreward non-trawl RCA boundary is adjusted from 30 fm (status quo) to 20 fm from 40°10' N latitude to the Oregon-Washington border at 46°16' N latitude (Table 2-12). In addition, the harvestable amount of black rockfish available to this fishery is reduced from status quo levels by 60%. As current trip limits are at the minimum level deemed viable by the fishery participants, a 60 % reduction in target catch would result in a 60% reduction in season duration (< than a 6 month season). The same magnitude of reduced catch may also be attained by utilizing one, or a combination of, the following options: 1) restricting the fishery to waters shoreward of 10 or 15 fm; 2) reducing the duration of the fishery, resulting in a very short season; 3) a fishery closure in some or all areas; and/or 4) reduced harvest of target species.

Nearshore Commercial Fisheries South of 40°10' N latitude

Under Action Alternative 1 from 40°10' N latitude 34°27' N latitude, the shoreward non-trawl RCA boundary is adjusted from 30 fm during periods 1, 2, 5, and 6 and 20 fm during periods 3 and 4 (status quo) to 20 fm during all periods (Table 2-12b). In addition, the harvestable amount of shallow and deeper nearshore rockfish available to this fishery is reduced from status quo levels by 15%. As current trip limits are at the minimum level deemed viable by the fishery participants, a 15% reduction in target catch would result in a 15% reduction in season duration (i.e., an 8 month season). The same magnitude of reduced catch may also be attained by utilizing one, or a combination of, the following options: 1) restricting the fishery to waters shoreward of 10 or 15 fm; 2) reducing the duration of the fishery, resulting in a very short season; 3) a fishery closure in some or all areas; and/or 4) further reduced harvest of target species. Under Action Alternative 1 from 34°27' N latitude to the U.S./Mexico border, the shoreward non-trawl RCA boundary is adjusted from 60 fm (status quo) to 40 fm. The same magnitude of reduced catch may also be attained by utilizing one, or a combination of, the following options: 1) restricting the fishery to waters shoreward of 30 or 20 fm; 2) reducing the duration of the fishery, resulting in a very short season; 3) a fishery closure in some or all areas; and/or 4) reduced harvest of target species.

2.2.3.2.5 Tribal Fisheries

Under all the action alternatives, the following regulations will apply to 2007-2008 tribal groundfish fisheries.

Black Rockfish - The 2007 and 2008 tribal harvest guidelines will be set at 20,000 pounds for the management area between the US/Canada border and Cape Alava, and 10,000 pounds for the management area located between Destruction Island and Leadbetter Point. No tribal harvest restrictions are proposed for the management area between Cape Alava and Destruction Island.

Sablefish - The 2007 and 2008 tribal set asides for sablefish will be set at 10 percent of the Monterey through Vancouver area OY minus 1.9 percent to account for estimated discard mortality. Allocations among tribes and among gear types, if any, will be determined by the tribes.

Pacific cod - The tribes will be subject to a 400 mt harvest guideline for 2007 and 2008.

For all other tribal groundfish fisheries the following trip limits will apply:

Thornyheads - Tribal fisheries will be restricted to the Limited Entry trip limits in place at the beginning of the year for both shortspine and longspine thornyheads.

Canary Rockfish - Tribal fisheries will be restricted to a 300 pound per trip limit.

Other Minor Nearshore, Shelf and Slope Rockfish - Tribal fisheries will be restricted to a 300 pound per trip limit for each species group, or the limited entry trip limits if they are less restrictive than the 300 pound per trip limit.

Yelloweye Rockfish - The tribes will continue developing depth, area, and time restrictions in their directed Pacific halibut fishery to minimize impacts on yelloweye rockfish. Tribal fisheries will be restricted to 100 pounds per trip.

Spiny Dogfish - The Makah Tribe is proposing a directed longline fishery for spiny dogfish for 2007 and 2008. The fishery would be restricted to the Limited Entry trip limits. Increased landings of dogfish by treaty fishermen in 2007 and 2008 would be dependent on successful targeting in 2006 while staying within current estimates of impacts on overfished species.

Full Retention - The tribes will require full retention of all overfished rockfish species as well as all other marketable rockfishes during treaty fisheries.

Tribal Proposals Regarding Makah Trawl fisheries for 2007 and 2008

Midwater Trawl Fishery - Treaty midwater trawl fishermen will be restricted to a cumulative limit of yellowtail rockfish, based on the number of vessels participating, not to exceed 180,000 pounds per two month period for the entire fleet. Their landings of widow rockfish must not exceed 10 percent of the poundage of yellowtail rockfish landed in any given period. The tribe may adjust the cumulative limit for any two-month period to minimize the incidental catch of canary and widow rockfish, provided the average cumulative limit does not exceed 180,000 pounds for the fleet.

Bottom Trawl Fishery - Treaty fishermen using bottom trawl gear will be subject to the trip limits applicable to the limited entry fishery for Dover sole, English sole, rex sole, arrowtooth flounder, and other flatfish. For petrale sole, fishermen would be restricted to 50,000 pounds per two month period for the entire year. Because of the relatively modest expected harvest, the trip limits for the tribal fishery will be those in place at the beginning of the season in the limited entry fishery and will not be adjusted downward, nor will time restrictions or closures be imposed, unless in-season catch statistics demonstrate that the tribe has taken half of the harvest in the tribal area. Fishermen will be restricted to small footrope (≤ 8 inches) trawl gear. Exploration of the use of selective flatfish trawl gear will be conducted in 2006.

Observer Program - The Makah Tribe has an observer program in place to monitor and enforce the limits proposed above.

2.2.3.2.6 Washington Recreational Fisheries

Under Action Alternative 1, WDFW is not proposing any changes to the bottomfish bag limit, minimum size limits, or lingcod season dates described under the No Action Alternative. However, the proposed yelloweye RCAs off the Washington coast would also be closed to Washington recreational fisheries under this alternative (Figures 2-5, 2-6, 2-7, and 2-8). These additional yelloweye RCAs would require a change to the Pacific Halibut Catch Sharing Plan. Other new management measures are considered under Action Alternative 1 as follows:

Management Measures for Marine Areas 3 and 4 (Queets River to the U.S./Canada border)

Under Action Alternative 1, WDFW would prohibit retention of rockfish and lingcod seaward of a line approximating 10 fm during the months of May, August, and September; close the North Coast to halibut fishing, except in Area 4B; and prohibit retention of rockfish and lingcod seaward of a line approximating 20 fm from June 1 through July 31. This alternative would require a change to the Pacific Halibut Catch Sharing Plan.

Management Measures for Marine Area 2 (Leadbetter Pt. to the Queets River)

Under Action Alternative 1, WDFW would prohibit retention of rockfish and lingcod seaward of a line approximating 30 fm from lingcod opening day through July 31; prohibit retention of rockfish and lingcod seaward of a line approximating 20 fm from August 1 through September 30.

Management Measures for Marine Area 1 (Oregon/Washington border to Leadbetter Pt.)

There is very little yelloweye and canary rockfish (0.03 mt and 0.02 mt, respectively, in 2005) caught in Marine Area 1; therefore, WDFW proposes to keep the status quo (No Action) bottomfish fishing regulations in place through 2007 and 2008.

2.2.3.2.7 Oregon Recreational Fisheries

Under Action Alternative 1a (there are two suboptions for the 2007-2008 Oregon recreational fishery under Action Alternative 1), the Oregon recreational groundfish fishery would only be open in depths ≤20 fm from July 1 through Labor Day. The minimum size limit for lingcod would be 20-inches, and anglers would be allowed to retain 3 lingcod per day. Minimum size limits for cabezon and greenling species would be the same as for the No Action Alternative. However, under this alternative the marine fish daily bag limit would increase to 10 marine fish, with all other regulations the same as in the No Action Alternative, except for the following expansion of the Stonewall Banks closure in the Pacific halibut fishery. The additional closure, designed to reduce yelloweye rockfish mortality and hence termed a yelloweye RCA (YRCA), is defined by the following coordinates:

1	44º41.71 N latitude	124º29.99 W longitude
2	44º41.68 N latitude	124º21.60 W longitude
3	44º27.66 N latitude	124º17.01 W longitude
4	44º25.22 N latitude	124º17.01 W longitude
5	44º25.27 N latitude	124º30.11 W longitude

Returning to the first point (Figure 2-5).

This expanded Stonewall Banks closure would only apply to the Pacific halibut fishery since this area is seaward of the 20 fm line and, under this alternative, all groundfish retention is prohibited seaward of the 20 fm line.

Under Action Alternative 1b, the Oregon recreational groundfish fishery would be open from April through September shoreward of the 20 fm line. A 30% reduction in yelloweye rockfish impacts would be achieved by reducing Pacific halibut quota and time on the water in that fishery. The marine fish daily bag limit would be the same as under the No Action Alternative, or 6 marine fish daily. The minimum size limit for lingcod would be 20 inches, and anglers would be allowed to retain 3 lingcod per day. All other groundfish regulations would be the same as under the No Action Alternative except for the expansion of the Stonewall Banks closure in the Pacific halibut fishery described under Action Alternative 1a.
This expanded Stonewall Banks closure would only apply to the Pacific halibut fishery since this area is seaward of the 20 fm line and, under this alternative, all groundfish retention is prohibited seaward of the 20 fm line.

Predicted yelloweye rockfish impacts under both alternatives 1a and 1b are similar (see section 4.3.1.7).

2.2.3.2.8 California Recreational Fisheries

Under Action Alternative 1, the five RLMAs described under the No Action Alternative will be used to manage 2007-2008 California recreational groundfish fisheries. The status quo (No Action) California recreational management measures under Action Alternative 1 include the following:

- Regulations apply to groundfish (with sanddab fishery exception) and associated state-managed species (rock greenling, California sheephead, and ocean whitefish).
- The sport fishery for sanddabs, using gear specified in federal and state regulations (size #2 hooks or smaller), is exempt from the season closures and depth restrictions placed on other federally-managed groundfish.
- Retention of species in the Other Flatfish complex is allowed when fishing with size #2 hooks or smaller (≤ 11 mm from point to shank) for Pacific sanddabs.
- Within a general bag limit of 20 fish, a combined rockfish + cabezon + greenling (RCG) complex daily bag limit of 10 fish, of which one can be a cabezon and one can be a greenling of the genus *Hexagrammos*.
- No retention of cowcod, canary, or yelloweye rockfish.
- Notwithstanding other fishing opportunities for groundfish, lingcod may not be retained during January, February, March, and December.
- Waters of Cordell Bank less than 100 fm in depth are closed to fishing at all times.
- All divers (boats permitted while diving for rockfish or other closed species during closed periods provided no hook and line gear on board or in possession while diving to catch rockfish) and shore-based anglers would be exempt from the seasonal closures and depth restrictions for rockfish, greenlings, California scorpionfish, California sheephead, and ocean whitefish.

California recreational groundfish management measures that differ from status quo under Action Alternative 1 include the following:

- A statewide one-fish bocaccio sublimit is included in the 10-fish RCG daily bag limit.
- Lingcod daily bag limit of 1 fish, but with a minimum size limit of 22 inches.

Additionally, seasons and depth restrictions by RLMA under Action Alternative 1 are described below and summarized in Table 2-17.

- Fishing is allowed within the Cowcod Conservation Areas shoreward of the 20 fm line when fishing is open for groundfish other than California scorpionfish, but including select nongroundfish species (California sheephead and ocean whitefish).

Table 2-17. Summary of 2007-2008 California recreational groundfish seasons and depth restrictions by region under Action Alternative 1.

RCG SEASON BY REGION:

Region	Jan	Feb	Mar	Apr	May	Jun	July	Aug	Sep	Oct	Nov	Dec
North region	---	---	---	---	> 20fm Closed							
North Central	---	---	---	---	---	---	> 20fm Closed			---	> 20fm Closed	
South Central - Monterey	---	---	---	---	---	---	> 20fm Closed					
South Central - Morro Bay	---	---	---	---	> 20fm Closed					---	---	---
South Region*	---	---	> 30fm Closed									

NOTES AND KEY:

Shore fishing allowed in all waters in all months

RCG = Rockfish, cabezon, greenlings

--- = Closed to boat-based fishing for RCG

LINGCOD SEASON IS OPEN **ONLY** WHEN RCG IS OPEN, EXCEPT CLOSED DEC, JAN, FEB, MAR FOR SPAWNING

*In the South Region, CA scorpionfish is open 12 months: 0-40 fm in January-February and 0-30 fm March-December.

Southern RLMA (U.S./Mexico Border to Point Conception)

The California recreational groundfish fishery regulations south of Point Conception under Action Alternative 1 are the same as described above except for the following changes:

- Groundfish other than California scorpionfish, but including select nongroundfish species (California sheephead and ocean whitefish) open March through December shoreward of the 30 fm line and otherwise closed.
- California scorpionfish is open year-round, but restricted to depths ≤40 fm during January and February, and ≤30 fm during March through December.

Southern South-Central RLMA (Point Conception to Lopez Point)

The California recreational groundfish fishery regulations for the area between Point Conception and Lopez Point under Action Alternative 1 would be the same as described above except for the following changes:

- Groundfish including select nongroundfish species (California sheephead and ocean whitefish) open May through September shoreward of the 20 fm line and otherwise closed.

Northern South--Central RLMA (Lopez Point to Pigeon Point)

The California recreational groundfish fishery regulations for the area between Lopez Point and Pigeon Point under the Action Alternative 1 would be the same as described above except for the following changes:

- Groundfish including select nongroundfish species (California sheephead and ocean whitefish) open July through December shoreward of 20 fm and otherwise closed.

Northern Central RLMA (Pigeon Point to Cape Mendocino)

The California recreational groundfish fishery regulations for the area between Pigeon Point and Cape Mendocino under the Action Alternative 1 would be the same as described above except for the following changes:

- Groundfish including select nongroundfish species (California sheephead and ocean whitefish) open July through September and November through December shoreward of 20 fm and otherwise closed.

Northern RLMA (Cape Mendocino to the California/Oregon Border)

The California recreational groundfish fishery regulations for the area between Cape Mendocino and the California/Oregon border under the Action Alternative 1 would be the same as described above except for the following changes:

- Groundfish and ocean whitefish open in May through December shoreward of 20 fm and otherwise closed.

2.2.3.3 Action Alternative 2

Action Alternative 2 is intermediate to Action Alternatives 1 and 3 in constraints to 2007 and 2008 fishing opportunities and intermediate in terms of impacts to depleted and target groundfish species. Table 2-19 depicts the impacts to depleted groundfish species by sector in 2007 and 2008 associated with the suite of management measures under Action Alternative 2.

2.2.3.3.1 Limited Entry Trawl Fisheries

Table 2-18 depicts the 2007-2008 limited entry trawl management measures under Action Alternative 2. The proposed yelloweye RCAs off the Washington coast would also be closed to limited entry trawl fisheries under this alternative (Figures 2-5, 2-6, 2-7, and 2-8).

Table 2-18. Cumulative bimonthly limits and RCA configurations by area and species for the West Coast limited entry trawl fishery in 2007-2008 under Action Alternative 2.

		RCA Configurations		Cumulative Limits

Key		= either not applicable; trace amount (<0.01 mt); or not reported in available data sources.						

a/ South of 40°10' N. lat.
b/ Mortality estimates are not hard numbers; based on the GMT's best professional judgment.

c/ Bycatch amounts by species unavailable, but bocaccio occurred in 0.1% of all port samples and other rockfish in another 0.1% of all port samples (and squid fisheries usually land their whole catch). In 2001, out of 84,000 mt total landings 1 mt was groundfish.

d/ Values are proposed EFP bycatch caps, not estimates of total mortality. The EFP is terminated inseason if the cap is projected to be attained early.

Non-Whiting Trawl Fishery

There are no additional management measures than those described above for non-whiting trawl fisheries in 2007 and 2008 under Action Alternative 2.

Whiting Trawl Fishery

Predicted impacts to depleted groundfish species in 2007-2008 whiting-directed fisheries under Action Alternatives 1-3 are depicted in Table 2-16. Higher whiting OYs are not possible given the bycatch constraints imposed by depleted groundfish species under the preferred OYs. However, it is important to note that an alternative strategy for managing 2007-2008 whiting fisheries would be to impose bycatch caps for these species and allow the fleet flexibility to avoid these species while attempting to attain their whiting quotas.

2.2.3.3.2 Limited Entry Fixed Gear Fisheries

Under Action Alternative 2, the seaward line of the non-trawl RCA is extended out to 125 fm north of Cape Mendocino at 40°10' N latitude to the U.S.-Canada border to provide additional canary and yelloweye rockfish protection relative to status quo management measures. The proposed yelloweye RCAs off the Washington coast would also be closed to limited entry fixed gear fisheries under this alternative (Figures 2-5, 2-6, 2-7, and 2-8).

The seaward boundary of the western Cowcod Conservation Area would be modified under this alternative to allow limited entry fixed gear vessels access to fish in depths deeper than 175 fm (Figure 2-12).

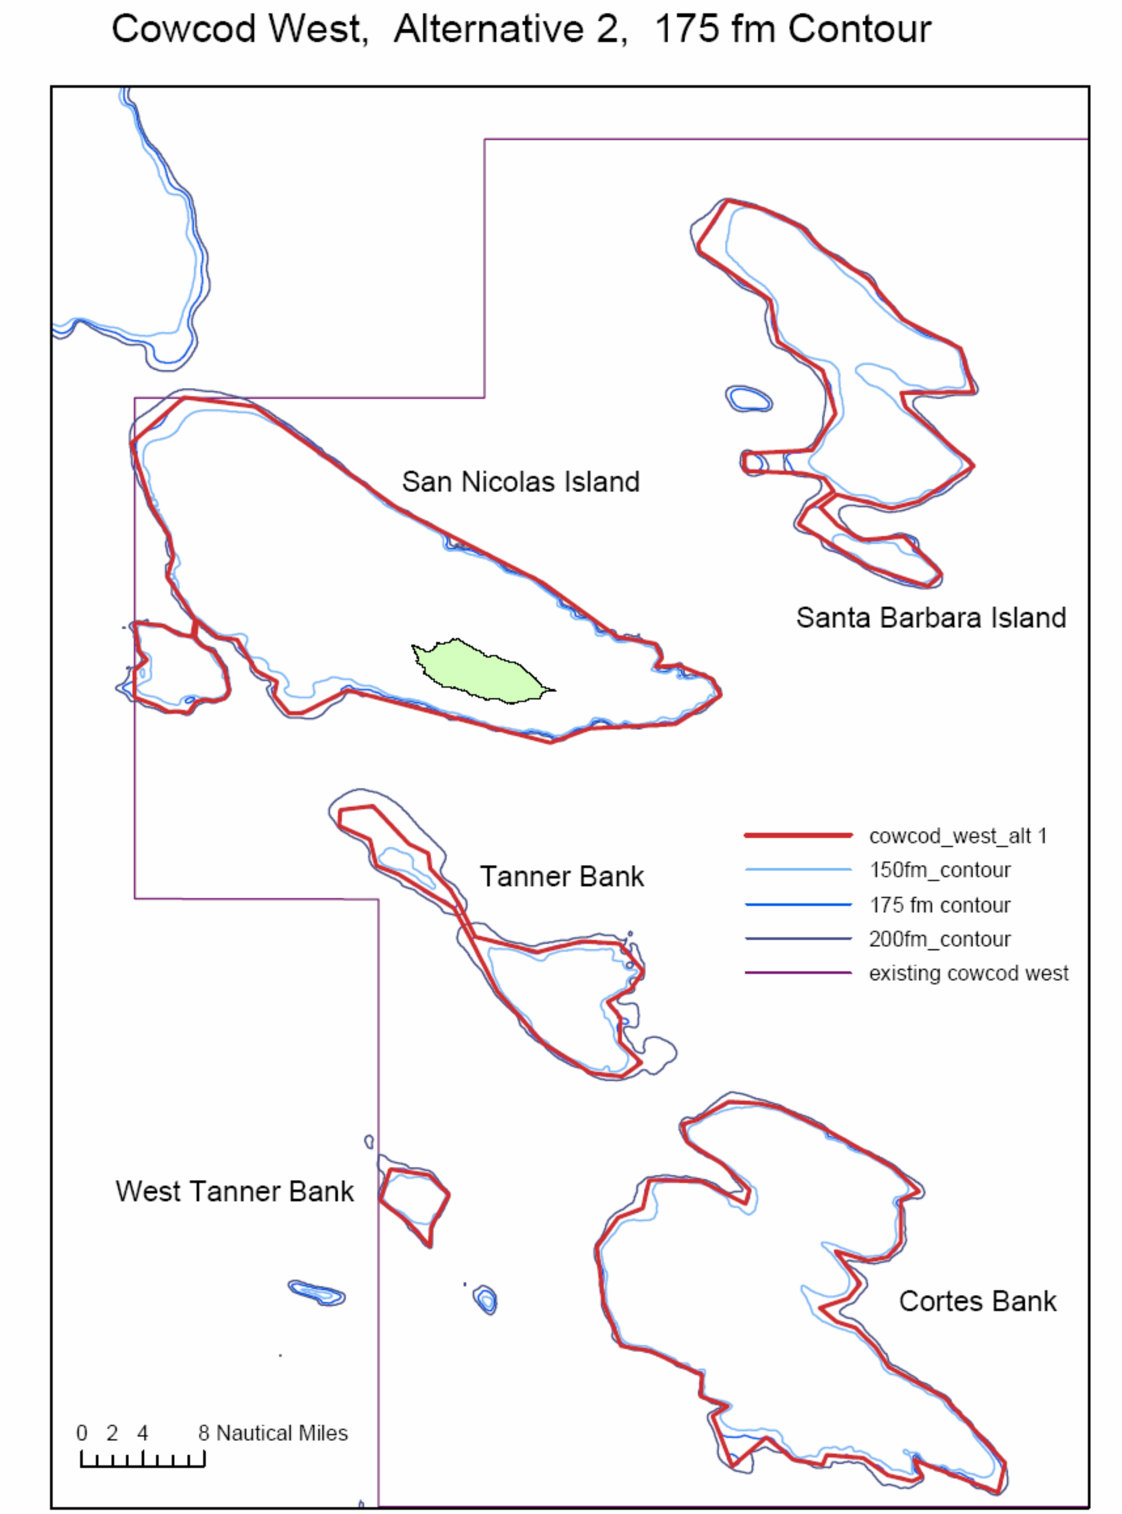

Figure 2-12. Modifications proposed for the western Cowcod Conservation Area in the Southern California Bight under Action Alternative 2 to allow limited entry fixed gear and open access fishing in depths greater than 175 fm (red contour).

2.2.3.3.3 Open Access Fisheries

Under Action Alternative 2, the seaward line of the non-trawl RCA is extended out to 125 fm north of Cape Mendocino at 40°10' N latitude to the U.S.-Canada border to provide additional canary and yelloweye rockfish protection relative to status quo management measures. The proposed yelloweye RCAs off the Washington coast would also be closed to open access fisheries under this alternative (Figures 2-5, 2-6, 2-7, and 2-8).

Directed Groundfish Fisheries

The seaward boundary of the western Cowcod Conservation Area would be modified under this alternative to allow open access vessels targeting groundfish using fixed gears access to fish in depths deeper than 175 fm (Figure 2-12).

Incidental Groundfish Fisheries

Additional management measures to those described above considered for open access fisheries that incidentally catch groundfish species under this alternative apply to the commercial salmon troll fishery north of 40°10' N latitude as follows:
Under Action Alternative 1, the following management measures would also apply to the commercial salmon troll fishery north of 40°10' N latitude:

- Prohibit commercial salmon trolling in the proposed yelloweye RCA in waters off northern Washington described under Action Alternative 1 (Figure 2-11).
- Prohibit the retention of lingcod in the salmon troll fishery shoreward of the non-trawl RCA seaward boundary (e.g., shoreward of 100 fm north of 40°10’ N latitude, under status quo).
- As a canary rockfish bycatch reduction measure, prohibit the use of “hoochies” on the bottom spread.

2.2.3.3.4 Nearshore Commercial Fisheries

Nearshore Commercial Fisheries North of 40°10' N latitude

Under Action Alternative 2, the shoreward RCA boundary is adjusted from 30 fm (status quo) to 20 fm from 40°10' N latitude to the Oregon-Washington border at 46°16' N latitude (Table 2-12). In addition, the harvestable amount of black rockfish available to this fishery is reduced from status quo levels by 10%. The same amount of savings may occur by further adjustment of the shoreward RCA boundary (i.e. 15 fm), resulting in status quo harvest of target species.

Nearshore Commercial Fisheries South of 40°10' N latitude

Under Action Alternative 2, from 40°10' N latitude 34°27’ N latitude, the shoreward non-trawl RCA boundary is adjusted from 30 fm during periods 1, 2, 5, and 6 and 20 fm during periods 3 and 4 (status quo) to 20 fm during all periods (Table 2-12b). In addition, the harvestable amount of shallow and deeper nearshore rockfish available to this fishery is reduced from status quo levels by 5%. The same amount of savings may occur by further adjustment of the shoreward RCA boundary (i.e. 15 fm), or reducing the season duration (9 months), resulting in status quo harvest of target species. Action Alternative 2 from 34°27’ N latitude to the US/Mexico border represents status quo management. CDFG would have the ability to manage harvest at more conservative levels, if deemed appropriate by the Director of CDFG or by the California Fish and Game Commission. Catches would be monitored, and the fishery managed to ensure harvest impacts of both target species and associated overfished rockfish did not exceed adopted levels.

2.2.3.3.5 Tribal Fisheries

Groundfish management measures are the same as described for tribal fisheries under Action Alternative 1. The tribes proposed only one action alternative for analysis.

2.2.3.3.6 Washington Recreational Fisheries

Under Action Alternative 2, WDFW is not proposing any changes to the bottomfish bag limit, minimum size limits, or lingcod season dates described under the No Action Alternative. However, the proposed yelloweye RCAs off the Washington coast would also be closed to Washington recreational fisheries under this alternative (Figures 2-5, 2-6, 2-7, and 2-8). These additional yelloweye RCAs would require a change to the Pacific Halibut Catch Sharing Plan. Other new management measures are considered under Action Alternative 2 as follows:

Management Measures for Marine Areas 3 and 4 (Queets River to the U.S./Canada border)

Under Action Alternative 2, WDFW would prohibit retention of rockfish and lingcod seaward of a line approximating 10 fm during the months of May and September; close the North Coast to halibut fishing, except in Area 4B; and prohibit retention of rockfish and lingcod seaward of a line approximating 20 fm from June 1 through August 31. This alternative would require a change to the Pacific Halibut Catch Sharing Plan.

Management Measures for Marine Area 2 (Leadbetter Pt. to the Queets River)

Under Action Alternative 2, WDFW would prohibit retention of rockfish and lingcod seaward of a line approximating 30 fm from lingcod opening day through August 31.

Management Measures for Marine Area 1 (Oregon/Washington border to Leadbetter Pt.)

There is very little yelloweye and canary rockfish (0.03 mt and 0.02 mt, respectively, in 2005) caught in Marine Area 1; therefore, WDFW proposes to keep the status quo (No Action) bottomfish fishing regulations in place through 2007 and 2008.

2.2.3.3.7 Oregon Recreational Fisheries

Under Action Alternative 2, the Oregon recreational groundfish fishery would be open all year shoreward of the 20 fm line. The marine fish daily bag limit would be reduced to 5 marine fish. Other changes to status quo (No Action) management measures under this alternative include a decrease in the lingcod minimum size limit to 22 inches. All other management measures, including the current Stonewall Banks closure for the Pacific halibut fishery under this alternative are the same as under the No Action Alternative. The additional YRCA contemplated under Action Alternative 1 would not apply to the directed recreational groundfish fishery under this alternative since the proposed closed area is seaward of the 20 fm line.

2.2.3.3.8 California Recreational Fisheries

Under Action Alternative 2, the five RLMAs described under the No Action Alternative will be used to manage 2007-2008 California recreational groundfish fisheries. The status quo (No Action) California recreational management measures under Action Alternative 2 include the following:

- Regulations apply to groundfish (with sanddab fishery exception) and associated state-managed species (rock greenling, California sheephead, and ocean whitefish).
- The sport fishery for sanddabs, using gear specified in federal and state regulations (size #2 hooks or smaller), is exempt from the season closures and depth restrictions placed on other federally-managed groundfish.
- Retention of species in the Other Flatfish complex is allowed when fishing with size #2 hooks or smaller (≤ 11 mm from point to shank) for Pacific sanddabs.
- Combined rockfish + cabezon + greenling (RCG) complex daily bag limit of 10 fish.
- No retention of cowcod, canary, or yelloweye rockfish.
- Lingcod size limit of 24 inches with a daily bag limit of two fish.
- A two-fish bocaccio sublimit included in the 10-fish RCG daily bag limit.
- Notwithstanding other fishing opportunities for groundfish, lingcod may not be retained during January, February, March, and December.
- Waters of Cordell Bank less than 100 fm in depth are closed to fishing at all times.
- All divers (boats permitted while diving for rockfish or other closed species during closed periods provided no hook and line gear on board or in possession while diving to catch rockfish) and shore-based anglers would be exempt from the seasonal closures and depth restrictions for rockfish, greenlings, California scorpionfish, California sheephead, and ocean whitefish.

California recreational groundfish management measures that differ from status quo under Action Alternative 2 include the following:

- Two cabezon and two greenling of the genus *Hexagrammos* sublimit is included in the 10-fish RCG daily bag limit.

Additionally, seasons and depth restrictions by RLMA under Action Alternative 2 are described below and summarized in Table 2-20.

Table 2-20. Summary of 2007-2008 California recreational groundfish seasons and depth restrictions by region under Action Alternative 2.

RCG SEASON BY REGION

Region	Jan	Feb	Mar	Apr	May	Jun	July	Aug	Sep	Oct	Nov	Dec
North region	---	---	---	---	>30fm Closed							
North Central	---	---	---	---	---	---	> 20fm Closed					
South Central - Monterey	---	---	---	---	---	---	> 20fm Closed					
South Central - Morro Bay	---	---	---	> 20fm Closed						---	---	---
South Region*	---	---	> 40fm Closed						> 30fm Closed		> 60fm Closed	

NOTES AND KEY:

Shore fishing allowed in all waters in all months

RCG = Rockfish, cabezon, greenlings

--- = Closed to boat-based fishing for RCG

LINGCOD SEASON IS OPEN **ONLY** WHEN RCG IS OPEN, EXCEPT CLOSED DEC, JAN, FEB, MAR FOR SPAWNING
*In the South Region, CA scorpionfish is open 12 months: 0-40 fm in January-August, 0-30 fm September-October and 0-60 fm November-December.

Southern RLMA (U.S./Mexico Border to Point Conception)

The California recreational groundfish fishery regulations south of Point Conception under Action Alternative 2 are the same as described above except for the following changes:

- Groundfish other than California scorpionfish, but including select nongroundfish species (California sheephead and ocean whitefish) open March through August shoreward of the 40 fm line, September through October shoreward of the 30 fm line, November and December shoreward of the 60 fm line, and otherwise closed.
- California scorpionfish is open year-round, but restricted to depths ≤40 fm during January-August, ≤30 fm during September and October, and ≤60 fm during November and December.

Southern South-Central RLMA (Point Conception to Lopez Point)

The California recreational groundfish fishery regulations for the area between Point Conception and Lopez Point under Action Alternative 2 would be the same as described above except for the following changes:

- Groundfish including select nongroundfish species (California sheephead and ocean whitefish) open April through September shoreward of the 20 fm line and otherwise closed.

Northern South--Central RLMA (Lopez Point to Pigeon Point)

The California recreational groundfish fishery regulations for the area between Lopez Point and Cape Mendocino under the Action Alternative 2 would be the same as described above except for the following changes:

- Groundfish including select nongroundfish species (California sheephead and ocean whitefish) open July through December shoreward of 20 fm and otherwise closed.

Northern Central RLMA (Pigeon Point to Cape Mendocino)

The California recreational groundfish fishery regulations for the area between Pigeon Point and Cape Mendocino under the Action Alternative 2 would be the same as described above except for the following changes:

- Groundfish including select nongroundfish species (California sheephead and ocean whitefish) open July through December shoreward of 20 fm and otherwise closed.

Northern RLMA (Cape Mendocino to the California/Oregon Border)

The California recreational groundfish fishery regulations for the area between Cape Mendocino and the California/Oregon border under the Action Alternative 2 would be the same as described above except for the following changes:

- Groundfish and ocean whitefish open in May through December shoreward of 30 fm and otherwise closed.

2.2.3.4 Action Alternative 3

Action Alternative 3 is the most liberal action alternative analyzed in this EIS. More fishing opportunities, and hence greater impacts to groundfish species, are predicted under this alternative. The only other alternative analyzed that may be less constraining to 2007-2008 fishing opportunities may be the No Action Alternative, if those management measures were implemented in the next management cycle. Table 2-21 depicts the impacts to depleted groundfish species by sector in 2007 and 2008 associated with the suite of management measures under Action Alternative 3.

2.2.3.4.1 Limited Entry Trawl Fisheries

Table 2-22 depicts the 2007-2008 limited entry trawl management measures under Action Alternative 3. The proposed yelloweye RCAs off the Washington coast would also be closed to limited entry trawl fisheries under this alternative (Figures 2-5, 2-6, 2-7, and 2-8).

Under Action Alternative 3, the boundaries of the Cowcod Conservation Areas in the Southern California Bight would be eliminated and the depth-based RCAs specified for south of Pt. Conception would instead be implemented in this area.

Non-Whiting Trawl Fishery

There are no additional management measures than those described above for non-whiting trawl fisheries in 2007 and 2008 under Action Alternative 3.

Whiting Trawl Fishery

Predicted impacts to depleted groundfish species in 2007-2008 whiting-directed fisheries under Action Alternatives 1-3 are depicted in Table 2-16. Higher whiting OYs are not possible given the bycatch constraints imposed by depleted groundfish species under the preferred OYs. However, it is important to note that an alternative strategy for managing 2007-2008 whiting fisheries would be to impose bycatch caps for these species and allow the fleet flexibility to avoid these species while attempting to attain their whiting quotas.

2.2.3.4.2 Limited Entry Fixed Gear Fisheries

Status quo management measures are specified for limited entry fixed gear fisheries under this alternative, except the proposed yelloweye RCAs off the Washington coast would also be closed to limited entry fixed gear fisheries under this alternative (Figures 2-5, 2-6, 2-7, and 2-8).

Under Action Alternative 3, the boundaries of the Cowcod Conservation Areas in the Southern California Bight would be eliminated and the depth-based RCAs specified for south of Pt. Conception would instead be implemented in this area.

	6	100	150	15,000	22,000	7,000	60,000	110,000	80,000	10,000	40,000

note: splitnose limits are the same as slope rock limits south of 40 degrees 10 minutes N latitude

* indicates petrale areas

2.2.3.4.3 Open Access Fisheries

Status quo management measures are specified for open access fisheries under this alternative, except the proposed yelloweye RCAs off the Washington coast would also be closed to open access fisheries under this alternative (Figures 2-5, 2-6, 2-7, and 2-8) and the following:

Under Action Alternative 3, the boundaries of the Cowcod Conservation Areas in the Southern California Bight would be eliminated and the depth-based RCAs specified for south of Pt. Conception would instead be implemented in this area.

Directed Groundfish Fisheries

There are no additional management measures considered for open access fisheries targeting groundfish species than those described above under this alternative.

Incidental Groundfish Fisheries

Additional management measures to those described above considered for open access fisheries that incidentally catch groundfish species under this alternative apply to the commercial salmon troll fishery north of 40°10' N latitude as follows:

- Prohibit commercial salmon trolling in the proposed yelloweye RCA in waters off northern Washington described under Action Alternative 1 (Figure 2-11).
- Allow the retention of lingcod in the salmon troll fishery, subject to an incidental landing ratio of one lingcod per ten Chinook salmon (Option 3a), or
- Allow the retention of lingcod in the salmon troll fishery, subject to an incidental landing ratio of one lingcod per ten Chinook salmon, north of the Oregon/Washington border at 46°16.00’ N latitude (Option 3b).
- As a canary rockfish bycatch reduction measure, prohibit the use of “hoochies” on the bottom spread.

2.2.3.4.4 Nearshore Commercial Fisheries

Nearshore Commercial Fisheries North of 40°10' N latitude

There are two suboptions (Action Alternatives 3a and 3b) for nearshore commercial fisheries from 40°10' N latitude to the Oregon-Washington border at 46°16' N latitude.

Under Action Alternative 3a, the shoreward RCA boundary is adjusted from 30 fm (status quo) to 20 fm with no reduction to the amount of target catch (Table 2-12). Target species harvest levels would be set at levels consistent with adopted ABC/OY levels for those species. ODFW would have the ability to manage harvest at more conservative levels, if deemed appropriate by the Oregon Fish and Wildlife Commission. Catches would be monitored, and the fishery managed to ensure harvest impacts of both target species and associated overfished rockfish did not exceed adopted levels.

Action Alternative 3b represents a near status quo fishery (Table 2-12). The shoreward RCA boundary is established at 30 fm (status quo). Target species harvest levels would be set at levels consistent with adopted ABC/OY levels for those species. ODFW would have the ability to manage harvest at more conservative levels, if deemed appropriate by the Oregon Fish and Wildlife Commission. Catches would be monitored, and the fishery managed to ensure harvest impacts of both target species and associated overfished rockfish did not exceed adopted levels.

Nearshore Commercial Fisheries South of 40°10' N latitude

There are two suboptions (Action Alternatives 3a and 3b) for nearshore commercial fisheries from 40°10' N latitude to 34°27’ N latitude.

Under Action Alternative 3a, the shoreward RCA boundary is adjusted from 30 fm during periods 1, 2, 5, and 6 and 20 fm during periods 3 and 4 (status quo) to 30 fm during all periods. In addition, the harvestable amount of shallow and deeper nearshore rockfish available to this fishery is reduced from status quo levels by 5% (Table 2-12b). This represents near-status quo impacts to canary rockfish.

Under Action Alternative 3b, from 40°10' N latitude 34°27’ N latitude, the shoreward non-trawl RCA boundary is adjusted from 30 fm during periods 1, 2, 5, and 6 and 20 fm during periods 3 and 4 (status quo) to 30 fm during all periods (Table 2-12b). Target species harvest levels would be set at levels consistent with adopted ABC/OY levels for those species.

In both cases, CDFG would have the ability to manage harvest at more conservative levels, if deemed appropriate by the Director of CDFG or by the California Fish and Game Commission. Catches would be monitored, and the fishery managed to ensure harvest impacts of both target species and associated overfished rockfish did not exceed adopted levels.

Action Alternative 3 from 34°27' N latitude to the US/Mexico border represents status quo management. CDFG would have the ability to manage harvest at more conservative levels, if deemed appropriate by the Director of CDFG or by the California Fish and Game Commission. Catches would be monitored, and the fishery managed to ensure harvest impacts of both target species and associated overfished rockfish did not exceed adopted levels.

2.2.3.4.5 Tribal Fisheries

Groundfish management measures are the same as described for tribal fisheries under Action Alternative 1. The tribes proposed only one action alternative for analysis.

2.2.3.4.6 Washington Recreational Fisheries

Under Action Alternative 3, WDFW is not proposing any changes to the bottomfish bag limit, minimum size limits, or lingcod season dates described under the No Action Alternative. Under this alternative, WDFW would reduce the lingcod minimum size limit to 20 inches in Marine Areas 1-4. The proposed yelloweye RCAs off the Washington coast would also be closed to Washington recreational fisheries under this alternative (Figures 2-5, 2-6, 2-7, and 2-8). These additional yelloweye RCAs would require a change to the Pacific Halibut Catch Sharing Plan. Other new management measures are considered under Action Alternative 3 as follows:

Management Measures for Marine Areas 3 and 4 (Queets River to the U.S./Canada border)

Under Action Alternative 3, WDFW would prohibit retention of rockfish and lingcod seaward of a line approximating 20 fm from May 1 through June 30, except on days that halibut fishing is open, and from August 1 through September 30; and prohibit retention of rockfish and lingcod seaward of a line approximating 10 fm during the month of July.

Management Measures for Marine Area 2 (Leadbetter Pt. to the Queets River)

Under Action Alternative 3, WDFW would prohibit retention of rockfish and lingcod seaward of a line approximating 30 fm from the lingcod opening day through July 31.

Management Measures for Marine Area 1 (Oregon/Washington border to Leadbetter Pt.)

There is very little yelloweye and canary rockfish (0.03 mt and 0.02 mt, respectively, in 2005) caught in Marine Area 1; therefore, WDFW proposes to keep the status quo (No Action) bottomfish fishing regulations in place through 2007 and 2008.

2.2.3.4.7 Oregon Recreational Fisheries

Under Action Alternative 3a (there are two suboptions for the 2007-2008 Oregon recreational fishery under Action Alternative 3), the Oregon recreational groundfish fishery would be open all year, but restricted to depths shoreward of the 40 fm line from January 1 through May 31 and September 1 through December 31, and shoreward of the 25 fm line from June 1 through August 31. The marine fish daily bag limit would be reduced to 5 marine fish; however flatfish, including Pacific sanddabs, would be managed under a separate 25 fish daily bag limit for all flatfish species. Other changes to status quo (No Action) management measures under this alternative include a decrease in the lingcod minimum size limit to 22 inches and the expanded Stonewall Banks closure described under Action Alternative 1 would apply to the recreational Pacific halibut fishery, restricting targeting of Pacific halibut in this area. Additionally, retention of groundfish would be prohibited in this area, regardless of trip target. All other management measures under this alternative are the same as under the No Action Alternative.

Under Action Alternative 3b, the Oregon recreational groundfish fishery would be open all year shoreward of the 40 fm line. The marine fish daily bag limit would be reduced to 5 marine fish; however flatfish, including Pacific sanddabs, would be managed under a separate 25 fish daily bag limit for all flatfish species. Other changes to status quo (No Action) management measures under this alternative include a decrease in the lingcod minimum size limit to 22 inches and the expanded Stonewall Banks closure described under Action Alternative 1 would apply to the recreational Pacific halibut fishery, restricting targeting of Pacific halibut in this area. Additionally, retention of groundfish would be prohibited in this area, regardless of trip target. All other management measures under this alternative are the same as under the No Action Alternative.

2.2.3.4.8 California Recreational Fisheries

Under Action Alternative 3, the five RLMAs described under the No Action Alternative will be used to manage 2007-2008 California recreational groundfish fisheries. The status quo (No Action) California recreational management measures under Action Alternative 3 include the following:

- Regulations apply to groundfish (with sanddab fishery exception) and associated state-managed species (rock greenling, California sheephead, and ocean whitefish).
- The sport fishery for sanddabs, using gear specified in federal and state regulations (size #2 hooks or smaller), is exempt from the season closures and depth restrictions placed on other federally-managed groundfish.
- Retention of species in the Other Flatfish complex is allowed when fishing with size #2 hooks or smaller (≤ 11 mm from point to shank) for Pacific sanddabs.
- A two-fish bocaccio sublimit is included in the 10-fish RCG daily bag limit.
- No retention of cowcod, canary, or yelloweye rockfish.
- Notwithstanding other fishing opportunities for groundfish, lingcod may not be retained during January, February, March, and December.
- Waters of Cordell Bank less than 100 fm in depth are closed to fishing at all times.
- All divers (boats permitted while diving for rockfish or other closed species during closed periods provided no hook and line gear on board or in possession while diving to catch rockfish) and shore-based anglers would be exempt from the seasonal closures and depth restrictions for rockfish, greenlings, California scorpionfish, California sheephead, and ocean whitefish.

California recreational groundfish management measures that differ from status quo under Action Alternative 3 include the following:

- Combined rockfish + cabezon + greenling (RCG) complex daily bag limit of 10 fish, of which two can be a cabezon and two can be a greenling of the genus *Hexagrammos*.
- Lingcod daily bag limit of 3 fish, but with a minimum size limit of 22 inches.

Additionally, seasons and depth restrictions by RLMA under Action Alternative 3 are described below and summarized in Table 2-23.

Table 2-23. Summary of 2007-2008 California recreational groundfish seasons and depth restrictions by region under Action Alternative 3.

RCG SEASON BY REGION

Region	Jan	Feb	Mar	Apr	May	Jun	July	Aug	Sep	Oct	Nov	Dec
North region	---	---	---	---	> 40fm Closed							
North Central	---	---	---	---	---		> 40fm Closed					
South Central - Monterey	---	---	---	---	> 40fm Closed							
South Central - Morro Bay	---	---	---	> 40fm Closed							---	---
South Region*	---	---	> 60fm Closed									

NOTES AND KEY:

Shore fishing allowed in all waters in all months

RCG = Rockfish, cabezon, greenlings

--- = Closed to boat-based fishing for RCG

Only half of month is open

*In the South Region, CA scorpionfish is open 12 months: 0-40 fm in January-February and 0-60 fm March-December.

Southern RLMA (U.S./Mexico Border to Point Conception)

The California recreational groundfish fishery regulations south of Point Conception under Action Alternative 3 are the same as described above except for the following changes:

- Groundfish other than California scorpionfish, but including select nongroundfish species (California sheephead and ocean whitefish) open March through December shoreward of the 60 fm line and otherwise closed.
- California scorpionfish open year-round, but restricted to depths ≤40 fm in January and February, and ≤60 fm during March through December.

Southern South-Central RLMA (Point Conception to Lopez Point)

The California recreational groundfish fishery regulations for the area between Point Conception and Lopez Point under Action Alternative 3 would be the same as described above except for the following changes:

- Groundfish including select nongroundfish species (California sheephead and ocean whitefish) open April through mid-October shoreward of the 40 fm line and otherwise closed.

Northern South--Central RLMA (Lopez Point to Pigeon Point)

The California recreational groundfish fishery regulations for the area between Lopez Point and Pigeon Point under the Action Alternative 3 would be the same as described above except for the following changes:

- Groundfish including select nongroundfish species (California sheephead and ocean whitefish) open May through December shoreward of 40 fm and otherwise closed.

Northern Central RLMA (Pigeon Point to Cape Mendocino)

The California recreational groundfish fishery regulations for the area between Pigeon Point and Cape Mendocino under the Action Alternative 3 would be the same as described above except for the following changes:

- Groundfish including select nongroundfish species (California sheephead and ocean whitefish) open mid-June through December shoreward of 40 fm and otherwise closed.

Northern RLMA (Cape Mendocino to the California/Oregon Border)

The California recreational groundfish fishery regulations for the area between Cape Mendocino and the California/Oregon border under the Action Alternative 3 would be the same as described above except for the following changes:

- Groundfish and ocean whitefish open in May through December shoreward of 40 fm and otherwise closed.

2.2.3.5 The Council-Preferred Action Alternative

This alternative will be decided at the June Council meeting in Foster City, CA.

2.2.3.5.1 Limited Entry Trawl Fisheries

2.2.3.5.2 Limited Entry Fixed Gear Fisheries

2.2.3.5.3 Open Access Fisheries

2.2.3.5.4 Nearshore Commercial Fisheries

2.2.3.5.5 Tribal Fisheries

2.2.3.5.6 Washington Recreational Fisheries

2.2.3.5.7 Oregon Recreational Fisheries

2.2.3.5.8 California Recreational Fisheries

2.2.3.6 Alternatives Considered, But Eliminated From Detailed Study

2.3 Comparison of the Environmental Consequences

To be completed after June 2006 when the Council will adopt a preferred alternative.

2.4 Social Net Benefit Analysis

To be completed after June 2006 when the Council will adopt a preferred alternative.

3.0 WEST COAST MARINE ECOSYSTEMS AND ESSENTIAL FISH HABITAT

3.1 Affected Environment

3.1.1 West Coast Marine Ecosystems

The term ecosystem is generally defined as a "functional unit of the environment" within which the basic processes of energy flow and cycling are identifiable and can be (relatively) localized. In this sense, marine ecosystems are extremely difficult to identify, as most are relatively open systems, with poorly defined boundaries and strong interactions across broad spatial scales. The California Current ecosystem, like other Eastern boundary current ecosystems, are especially difficult to define, as they are characterized by tremendous fluctuations in physical conditions and productivity over multiple time scales {Parrish et al. 1981, Mann and Lazier 1996}. Food webs tend to be structured around coastal pelagic species that exhibit boom-bust cycles over decadal time scales {Bakun 1996, Schwartzlose et al. 1999}. Similarly, the top trophic levels of such ecosystems are often dominated by highly migratory species such as salmon, albacore tuna, sooty shearwaters, fur seals and baleen whales, whose dynamics may be partially or wholly driven by processes in entirely different ecosystems, even different hemispheres. For this analysis, the ecosystem is considered in terms of physical and biological oceanography, climate, biogeography, essential fish habitat (EFH) marine protected areas, and the role of depleted species' rebuilding in the marine ecosystem.

3.1.2 Physical and Biological Oceanography

The California Current is essentially the eastern limb of the Central Pacific Gyre, and begins where the west wind drift (or the North Pacific Current) reaches the North American Continent. This occurs near the northern end of Vancouver Island, roughly between 45° and 50° N latitude and 130° to 150° W longitude {Ware and McFarlane 1989}. A divergence in the prevailing wind patterns causes the west wind drift to split into two broad coastal currents, the California Current to the south and the Alaska Current to the north. As there are really several dominant currents in the region, all of which vary in geographical location, intensity, and direction with the seasons, this region is often referred to as the California Current System {Hickey 1979}.

The California Current itself is a year-round feature consisting of a massive southward flow of the cool waters of the west wind drift. The current is best characterized as a shallow, wide, and slow-moving body of water, ranging from the shelf break to 1,000 km offshore, with the strongest flows at the sea surface, and in the summertime {Dodimead et al. 1963, Hickey 1979, Lynn and Simpson 1987}. This surface current is matched in the summer by the California Undercurrent, which moves water northward from the south in a deep yet narrow band of subtropical water typically found just off of the shelf break at depths of 100 to 300 m. The undercurrent flows from Baja California to Vancouver Island, transporting warmer, saltier southern water north along the coast {Hickey 1979}. On average, the California Current flow volume reaches a maximum in spring and summer, when the flow moves inshore, closer to the shelf break. The California Undercurrent develops in late spring through early summer and persists into the fall. During late summer and fall, there is considerably more mesoscale variability in flow patterns, with fields of cyclonic and anticyclonic eddies and considerable mixing of water masses between shelf and offshore waters {Brink and Cowles 1991}. Beginning in the fall, and through the winter, the northward flowing Davidson Current is the dominant feature over the shelf and beyond the shelf break {Hickey 1998}.

Current dynamics over the continental shelf are generally forced by regional wind fields, which tend to be southerly in the spring and summer, and northerly in the winter. Spring and summer winds drive offshore Ekman transport of surface waters, which is balanced by the upwelling of deeper waters that tend to be cooler and nutrient rich. Between the Strait of Juan de Fuca and Cape Blanco, summer upwelling leads to the development of a southward flowing upwelling jet over the continental shelf {Hickey 1998, Barth et al. 2000}. The shelf narrows as it approaches Cape Blanco, intensifying the energy of the jet {Bateen 1997, Barth et al. 2000}. As this jet reaches Cape Blanco it turns sharply offshore, mixing the cool, nutrient rich waters of the jet with the warmer, less productive waters of the slow-moving California Current. These interactions lead to the development of eddy fields and mesoscale variability in primary and secondary productivity that distinguish the region south of Cape Blanco from that to the north {Strub et al. 1991}. All these currents, countercurrents, undercurrents, jets and meanders transport water masses of different origins and characteristics, as well as the nutrients and organisms entrained within them, to the California Current System.

Wickett {1967} demonstrated that secondary productivity off southern California was influenced by the advection of northern water from the west wind drift, such that interannual differences in southern Ekman transport explained 50 to 60 percent of the variance in zooplankton biomass. Chelton et al. {1982} followed up these observations by observing that when the bulk of the divergent flow is to the south, the California Current experiences greater southward transport, more productive source waters and higher secondary production in the region off of southern California. Fulton and LeBrasseur {1985} further demonstrated that the zooplankton biomass, and even the mean size of copepods, was greater in the northern portion of the California Current when transport was high. Ongoing research has continued to demonstrate that climate-driven changes in transport and ocean conditions dramatically affect both the species composition and productivity of zooplankton in the northern California Current {Peterson et al. 2002, Peterson and Schwing 2003, Mackas et al. 2004}. Thus, while local wind fields and coastal upwelling ultimately drive much of the primary production at the base of the food web, growing evidence suggests that large-scale physical processes and associated changes in the community composition of zooplankton is a significant factor in determining the overall productivity of the ecosystem {Peterson and Keister 2003, Swartzman and Hickey 2003, Feinberg and Peterson 2003}.

3.1.3 Interannual and Interdecadal Climate Forcing

The effects of climate on the biota of the California Current ecosystem have been recognized for some time. Hubbs {1948} believed so strongly in the correlation between water temperature and fish distributions that he felt “justified in drawing inferences, from the known data on fish distribution, regarding ocean temperatures of the past.” It is worth noting that Hubbs had already drawn distinctions between eras that seemed to be associated with the establishment of warm-water populations over long time periods, and the occasional warm years (generally associated with stronger El Niño events) that brought irregular tropical or subtropical fish much further north along the coast.

Currently, the El Niño/Southern Oscillation (ENSO) is widely recognized to be the dominant mode of interannual variability in the equatorial Pacific, with impacts throughout the rest of the Pacific basin and the globe {Mann and Lazier 1996}. During the negative (El Niño) phase of the ENSO cycle, jet stream winds are typically diverted northward, often resulting in increased exposure of the West Coast of the U.S. to subtropical weather systems. Concurrently, coastally trapped waves propagate the equatorial ENSO signal northward along the West Coast of Central and North America as far as the subarctic, resulting in increased northern advection, warmer sea surface (and subsurface) temperatures, elevated coastal sea levels, and deepened thermoclines {Bakun 1996}. The impacts of these events to the coastal ocean generally include reduced upwelling winds, deepening of the thermocline, intrusion of offshore (subtropical) waters, dramatic declines in primary and secondary production, poor recruitment, reduced growth and survival of many resident species (such as salmon and groundfish), and northward extensions in the range of many tropical species {Wooster and Fluharty 1985, Pearcy and Schoener 1987, McGowan et al. 1998, Pearcy 2002}. There is reduced availability of many forage species, particularly market squid, and juvenile survival of most rockfish is extremely low. Concurrently, top predators such as seabirds and pinnipeds often exhibit reproductive failure.

In addition to interannual variability in ocean conditions, the North Pacific seems to exhibit substantial interdecadal variability. Mantua et al. {1997} first defined what is now commonly referred to as the Pacific (inter)Decadal Oscillation, or PDO, which is defined as the leading principal component of North Pacific (above 20°N latitude) sea surface temperatures between 1900 and 1993, and superficially resembles ENSO over a decadal time scale. During positive regimes, coastal sea surface temperatures in both the Gulf of Alaska and the California Current tend to be higher, while those in the North Pacific Gyre tend to be lower; the converse is true in negative regimes. Evidence suggests that there have been two full PDO cycles in the 20th century. Cool (negative PDO) regimes occurred between 1890 and 1924, and from 1947 to 1976, while warm (positive PDO) regimes from 1925 to 1946 and again from 1977 to 1999. Variation in the productivity of salmon stocks throughout the Northeast Pacific seems to track these changes in ocean temperature, such that positive PDO regimes are associated with increased productivity of salmon stocks from western Alaska to northern British Columbia, and negative regimes favor stocks from California to southern British Columbia {Mantua et al. 1997, Hare et al. 1999}.

Although the precise mechanism for the PDO remains elusive, the pattern is clearly linked to variability in atmospheric conditions. The average wintertime Aleutian low both deepened and moved eastward in the post-1977 regime {Mantua et al. 1997}, resulting in considerably stronger eastward wind stress {Parrish et al. 2001}. This increase in wind stress has been tied to the observed cooling (and increased productivity) of the waters in the central North Pacific[?]and Alaska Gyre {Brodeur and Ware 1992, Polovina et al. 1995}, and the consequent warming of coastal waters in the Gulf of Alaska and California Current {Mantua et al. 1997}. In a more recent effort to quantify the broad scale impacts of the PDO on Northeast Pacific ecosystems, Hare and Mantua {2000} compiled 100 physical and biological time series throughout the Northeast Pacific, including time series of recruitment and abundance for commercially important coastal pelagics, groundfish and invertebrates. They found that the dominant principal component of these 100 time series has the same trajectory as the PDO, consistent with anecdotal accounts of covariance between the PDO and many other physical and biological indices.

Growing evidence also suggests that the PDO may have shifted from a positive to negative regime since 1999, as the period between 1999 and 2002 was associated with a negative PDO signal, cool coastal ocean temperatures, high southward transport, and tremendous salmon productivity {Peterson and Schwing 2003}. However, since that period there has been considerable confusion with respect to whether a shift in the PDO did actually occur, or even whether the PDO remains a dominant mode of variability in North Pacific Climate {Bond et al. 2003, Goericke et al. 2004, Goericke et al. 2005}. The degree to which long-term warming is affecting the world's oceans and its ecosystems relative to other forms of variability is currently a major concern, and the consequent interactions between monotonic (global change), interdecadal (PDO) and interannual (ENSO) climate variability are difficult to disentangle. Although a great many processes drive changes in sea surface temperature trends over multiple time scales, there is growing consensus that the integrated heat content of the global oceans has been increasing, and can only be adequately accounted for by atmospheric forcing attributed to the accumulation of greenhouse gasses in the atmosphere {Levitus et al. 2000; Barnett et al. 2001; 2005}.

Within the California Current itself, Mendelssohn, et al. {2003} described long-term warming trends in the upper 50 to 75 m of the water column using subsurface temperature records in the California Current over the past 50 years. McGowan et al. {1998} attributed significant long term declines in zooplankton populations in the California Current over the same period to increased water temperatures that resulted in an intensification of stratification and a reduction of nutrient regeneration into surface waters. Recent paleoecological studies from marine sediments also indicate that 20th century warming trend in the California Current have exceeded natural variability in ocean temperatures over the last 1400 years {Field et al. 2006a}. All of this evidence suggests that although the development of statistical indices of climate variability across multiple time scales have improved our understanding of how climate has affected North Pacific ecosystems and productivity in the past, the future remains subject to extremely poor predictability.

3.1.3 Biogeography

Biogeography describes spatial patterns of biological distribution. Along the U.S. West Coast within the California Current system, such patterns have been observed to be influenced by various factors including depth, ocean conditions, and latitude. Each are discussed in the remainder of this section.

At the scale of the ecosystem, the most widely recognized patterns are distinct zoogeographic provinces extending North and South of Point Conception, California, known as the Oregonian and San Diego Provinces. The Oregonian Province extends from the Straight of Juan de Fuca in the North to Point Conception in the South. The San Diego Province begins at Point Conception and runs south past the terminus of the EEZ {NMFS 2004 OLO}.

Patterns of adult groundfish distribution based on depth have been observed to occur between nearshore, continental shelf, and the continental slope and have been used to form discrete management units. This information is detailed in (INSERT SECTION). Botsford and Lawrence {2002} showed considerable spatial and temporal synchrony in coho salmon and Dungeness crab catches among ports and regions in the California Current between 1950 and 1990; interestingly, they also found that Chinook landings did not have spatial coherence. Similarly, Field and Ralston {2005} showed that 51-72 percent of the year-to-year variability in recruitment for three winter spawning rockfish (yellowtail, widow and chilipepper) seems to be shared coastwide, over a spatial scale of 500-1,000 km. The major differences in recruitment strength seemed to be associated with Cape Blanco and/or Cape Mendocino, and some evidence suggests differences in relative year class strength north and south of Point Conception as well. With respect to genetic evidence for biogeographic boundaries, Hedgecock {1994} found that fish and invertebrates with planktonic larvae generally maintain low spatial genetic variance over large (500-2000 km) regions in the California Current. Analysis of a range of *Sebastes* species also suggests little genetic differentiation within the California Current region {Wishard et al. 1980; McGauley and Mulligan 1995; Rocha-Olivares and Vetter 1999}, although some nearshore species may exhibit greater spatial patterns of population substructure, particularly north and south of Cape Mendocino {Cope 2004}.

Williams and Ralston {2002} found that Cape Mendocino (and the Mendocino Escarpment) was one of the most noteworthy barriers to the latitudinal distribution of rockfish species diversity. Most stock assessments for groundfish tend to be either coastwide assessments, or are relative to the stocks north or south of Cape Mendocino (occasionally Cape Blanco). Both Cape Mendocino and Point Conception are key management boundaries for the Council. In general, evidence suggests wide to very wide dispersal of larvae and juveniles for most groundfish, with modest to limited movement of adults (general on the scale of thousands of kilometers for most species, with limited examples of small numbers of some populations moving in the hundreds of kilometers). There are strong seasonal inshore and offshore migrations for many species, particularly flatfish, and some evidence for ontogenetic movement in some species by both/either depth and latitude. Pacific hake are the only confirmed highly migratory groundfish species in the FMP, with a clear seasonal migration from southern spawning grounds off of northern Mexico and Southern California to northern foraging habitat off of Oregon, Washington, and British Columbia {Bailey et al. 1982}. There is an ontogenetic component to this migration, as juveniles tend to be found off of central and northern California, with larger, older fish tending to travel further north. Similarly, the distribution of hake tends to be more northerly in warm years {Dorn 1995, Swartzman and Hickey 2003}, reflecting interannual shifts in marine habitat conditions.

While the physical and bathymetric features associated with these general biogeographic boundaries are fixed in space, the physical characteristics of water masses and associated plankton communities are clearly highly dynamic in space and time (as discussed in sections 3.1.2 and 3.1.3). Fulton and LeBrasseur {1985} described a transport-driven shifting subarctic domain in the northern reaches of the California Current System, the margin of which was characterized by abrupt declines in zooplankton biomass south of the subarctic boundary. Although the physical dynamics are now thought to be more complex than their model, it is clear that climate driven changes in transport and ocean conditions dramatically alter both the species composition and productivity of zooplankton throughout the California Current to a considerably greater extent than static boundaries based on geography {McGowan et al. 1998, Peterson et al. 2002, Peterson and Schwing 2003; Mackas et al. 2004}.

For example, in the late 1960s and early 1970s, the dominant copepod species in the Northern California Current during the summer tended to be subarctic (or boreal) types such as *Pseudocalanus mimus*, *Calanus marshallae* and *Arcatioa longiremis*; species that are commonly found over shelf waters throughout the Gulf of Alaska {Peterson and Miller 1977}. Data suggest that northern species became relatively less abundant, while southern (subtropical) species such as *Paracalanus parvus* and *Calanus pacificus* were more abundant through the 1980s and early 1990s. These southern species were almost completely dominant during the 1997-98 El Niño, at which time standing biomass was near all time lows {Peterson et al. 2002}. Since 1999, northern species have again dominated numerically during spring and summer, and the standing biomass of zooplankton has been roughly double that observed prior to 1999 {Peterson and Schwing 2003}.

3.1.4 Essential Fish Habitat

Essential Fish Habitat (EFH) has been described within the project area for highly migratory species, coastal pelagic species, salmon, and groundfish. The MSA defines EFH to mean "those waters and substrate necessary to fish for spawning, breeding, feeding or growth to maturity" (16 U.S.C. 1802 sec. 3(10)). Regulatory guidelines elaborate that the words "essential" and "necessary" mean EFH should be sufficient to "support a population adequate to maintain a sustainable fishery and the managed species' contributions to a healthy ecosystem." The regulatory guidelines also establish authority for Councils to designate Habitat Areas of Particular Concern (HAPC) based on the vulnerability and ecological value of specific habitat types. Councils are required to minimize to the extent practicable the adverse of fishing on EFH. NMFS works through a consultation process to minimize adverse effects of non-fishing activities (50 CFR 600 subpart J).

3.1.4.1 Coastal Pelagic Species

The coastal pelagic species (CPS) fishery includes four finfish (Pacific sardine, Pacific (chub) mackerel, northern anchovy and jack mackerel), and market squid. CPS finfish generally live nearer to the surface than the sea floor. The definition of EFH for CPS is based on the temperature range where they are found, and on the geographic area where they occur at any life stage. This range varies widely according to ocean temperatures. The EFH for CPS also takes into account where these species have been found in the past, and where they may be found in the future.

The east-west boundary of EFH for CPS includes all marine and estuary waters from the coasts of California, Oregon, and Washington to the limits of the EEZ (the 200-mile limit) and above the thermocline where sea surface temperatures range between 10 and 26 °C. (A thermocline is an area where water temperatures change rapidly, usually from colder at the bottom to warmer on top). The southern boundary is the U.S.-Mexico maritime boundary. The northern boundary is more changeable, and is defined as the position of the 10° C isotherm, which varies seasonally and annually. (The 10° C isotherm is a rough estimate of the lowest temperature where finfish are found, and thus represents their northern boundary). In years with cold winter sea surface temperatures, the 10° C isotherm during February is around 43° N latitude offshore, and slightly further south along the coast. In August, this northern boundary moves up to Canada or Alaska. A more complete description of Coastal Pelagic Species and associated EFH is contained in the Coastal Pelagics FMP, which is incorporated herein by reference.

3.1.4.2 Salmon

Salmon range from more than 1,000 miles inland to thousands of miles out at sea. Although the waters off Canada are salmon habitat, they are also not included in the description of salmon EFH because they are outside of U.S. jurisdiction. However, waters off Alaska are included in the description.

In estuaries and marine areas, salmon habitat extends from the shoreline to the 200-mile limit of the EEZ and beyond. In freshwater, salmon EFH includes all the lakes, streams, ponds, rivers, wetlands, and other bodies of water that have been historically accessible to salmon. The description of EFH also includes areas above artificial barriers, except for certain barriers and dams that fish cannot pass. However, activities that occur above these barriers and that are likely to affect salmon below the barriers may be affected by court rulings from ongoing EFH-related litigation.

The Council is required to minimize the negative impacts of fishing activities on essential salmon habitat. The ocean activities that the Council is concerned with include the effects of fishing gear, removal of salmon prey by other fisheries, and the effect of salmon fishing on reducing nutrients in streams due to fewer salmon carcasses in the spawning grounds. The Council may use gear restrictions, time and area closures, and harvest limits to reduce negative impacts on salmon EFH.

The Council is also required to comment and make recommendations regarding other agencies' actions that may effect salmon EFH. This usually takes the form of endorsing an enhancement program or other type of program, requesting information and justification for actions that might effect salmon habitat, and promoting the needs of the salmon fisheries. The Council works with many other agencies to identify cumulative impacts on salmon habitat, to encourage conservation, and to take other actions to protect salmon habitat. A more complete description of Salmon and associated EFH is contained in the Salmon FMP, which is incorporated herein by reference.

3.1.4.3 Highly Migratory Species

These species (tuna, swordfish and sharks) range widely in the ocean, both in terms of area and depth. Highly migratory species (HMS) are usually not associated with the features that are typically considered fish habitat (such as seagrass beds, rocky bottoms, or estuaries). Their habitat may be defined by temperature ranges, salinity, oxygen levels, currents, shelf edges, and sea mounts. Little is known about why highly migratory species frequent particular areas. Nevertheless, these species may be affected by actions close to shore or on land, such as fishing, dredging, wastewater discharge, oil and gas exploration and production, aquaculture, water withdrawals, release of hazardous materials, and coastal development. A more complete description of HMS and associated EFH is contained in the HMS FMP which is incorporated herein by reference.

3.1.4.4 Groundfish

The Council first identified groundfish EFH in 1998 via Amendment 11 to the FMP. Because information about each groundfish species' habitat was limited, EFH was defined as the whole West Coast Exclusive Economic Zone. However, in 2000, based on the *American Oceans Campaign* v. *Daley* court case, the Council was directed to revisit the question of groundfish EFH. In 2001, NMFS Northwest Region staff began work on an environmental impact statement (EIS) for groundfish EFH off Washington, Oregon, and California, which after several years of work was finalized in 2005. The Council's preferred alternative in the final EIS became Amendment 19 to the Groundfish Fishery Management Plan in 2006.

EFH for groundfish is described as all waters from the high tide line (and parts of estuaries) to 3,500 meters (1,914 fathoms) in depth. "Habitat areas of particular concern," or HAPCs, are a subset of EFH used to focus management and restoration efforts. The current HAPC types are: estuaries, canopy kelp, seagrass, rocky reefs, and "areas of interest" (a variety of submarine features, such as banks, seamounts, and canyons, along with Washington State waters.) (INSERT FIGIRE)

In addition to identifying EFH and describing HAPCs, the Council also adopted mitigation measures directed at the adverse impacts of fishing on groundfish EFH. Principal among these are closed areas to protect sensitive habitats. There are three types of closed areas: bottom trawl closed areas, bottom contact closed areas, and a bottom trawl footprint closure. The bottom trawl closed areas are closed to all types of bottom trawl fishing gear. The bottom trawl footprint closure closes areas in the EEZ between 1,280 m (700 fm) and 3,500 m (1,094 fm), which is the outer extent of groundfish EFH. The bottom contact closed areas are closed to all types of bottom contact gear intended to make contact with bottom during fishing operations, which includes fixed gear, such as longline and pots. A more complete description of groundfish and associated EFH is contained in the Groundfish FMP, which is incorporated herein by reference.

3.1.5 Marine Protected Areas

In addition to the closed areas described above, there are marine protected areas distributed throughout the project area. The EIS for Pacific Coast Groundfish EFH contains a complete analysis of these sites and is incorporated here by reference. The following is a brief summary of these areas.

Federally designated marine managed areas:

- Twenty-eight National Wildlife Refuges, covering approximately 89,000 ha. Regulations vary by refuge, but generally, commercial fishing is not allowed in most refuges.

- Seven National Parks, covering approximately 570,000 ha (although only a small fraction of this area is the marine portion of the parks). Regulations vary by park.

- Five National Marine Sanctuaries covering approximately 3,000,000 ha. Regulations vary by sanctuary, but in general, all types of fishing are allowed in federal waters of the sanctuaries.

- Four National Estuarine Research Reserves (NERR), covering approximately 8,000 ha. All fishing and fishing gear are prohibited from the Tijuana River NERR and the Elkhorn Slough NERR (which doesn't include the Slough's main channel). All other NERR sites allow or do not address specific fishing regulations.

Other Federal Areas:

These are some additional areas under federal jurisdiction that may have restrictions to vessel access, rather than specific regulations having to do with fishing or fishing gear. These data were developed in 1998 by Al Didier for the Pacific States Marine Fisheries Commission (PSMFC), so the total number of areas may have changed since these data were compiled.

- Twenty-two Regulated Navigation Areas (33CFR165) cover approximately 17,000 ha, and are located generally in urban areas such as Puget Sound, Columbia River, San Francisco Bay, Los Angeles, and San Diego.

- Forty-nine Danger Zones and Restricted Areas (33CFR334) cover approximately 170,000 ha. These are located in Puget Sound, San Francisco Bay, Monterey Bay, between Morro Bay and Point Conception, off some of the Channel Islands, and a few additional southern California locations.

- Twenty-seven weather and scientific buoys. Two buoys are located off the Washington coast, one is located off the Oregon coast, twenty buoys are located off the California coast, with six of these located off Monterey Bay. Four of these buoys are located outside the EEZ.

Fishing regulated areas established by the Pacific Fishery Management Council:

- Rockfish Conservation Area (RCA): These areas have changed over time, as well as having a seasonal component to their locations. In addition, there are specific areas for trawl gear and non-trawl gear. Not all of the historical RCA areas have been developed into GIS data, but most of the areas from 2003 are mapped as an example (Figures 3-20 through 3-25). A chronology of changing trawl and non-trawl RCAs for the year 2003 is included below.

- Cowcod Conservation Areas (CCA): Sections of the CCA cover a total area of 1,372,447 ha (Figure 3-26).

- Darkblotched Conservation Area (DBCA): The Dark Blotched Conservation Area covered 1,029,415 ha (Figure 3-26).

- Yelloweye Rockfish Conservation Area (YRCA): This area encompasses 59,285 ha (Figure 3-26).

- Two National Marine Fisheries sites (Pacific Whiting Salmon Conservation Zones), covering approximately 44,000 ha. These two sites, one off the Columbia River and one off the Klamath River, prohibit fishing for Pacific Whiting with commercial mid-water trawl gear.

Trawl RCA Chronology:

- April 2003: 2,380,610 ha.

- May 2003: 5,530,861 ha; North of 40°10’ N latitude, the eastern boundary moved to shore. Other boundaries same as April.

- June 2003: 3,850,239 ha; South of 40°10’, the western boundary was moved further west. North of 40°10’, the eastern boundary moved away from shore to a location between the April’s eastern boundary and May’s eastern boundary.

- July–August 2003: 2,865,640 ha; North of 40°10’, the eastern boundary was moved away from shore.
- September–October 2003: 3,592,844 ha.
- November 2003: 3,590,423 ha.

Non-Trawl RCA Chronology:

- April 2003: 4,864,260 ha.
- May 2003: 4,864,260 ha; same boundaries as April 2003.
- June 2003: 4,864,491 ha; same depth boundaries as May 2003 with a small change in coordinate locations.
- July–August 2003: 4,855,405 ha; same boundaries as June 2003, with modification in southern California for Newport/South Jetty open area.
- September–October 2003: 4,956,611 ha; south of Point Conception, eastern boundary moved towards slightly towards shore. Additional areas added around Channel Islands.
- November 2003: 4,956,611 ha; same area as September–October.

State marine protected areas:

California: MPA boundaries for sites in California were downloaded from the California Department of Fish and Game website. In these data, there are 79 sites covering approximately 59,000 hectares. The California sites have been categorized into 13 designations. California is currently renaming and recategorizing these sites into three designations (marine reserve, marine park, and marine conservation area); however, the existing designations are used here for descriptive purposes (Figure 3-27).

- Ten State Marine Reserves: These areas are located adjacent to the Channel Islands. No commercial or recreational fishing is allowed in these areas.
- Two State Marine Conservation Areas: These areas are also located adjacent to the Channel Islands. Most commercial fishing, except for spiny lobster fishing, is prohibited in these areas.
- Seven State Parks: five of these coastal state parks are located north of San Francisco, one is south of Monterey, and one is near Irvine. Fishing regulations vary by park.
- Four State Beaches: One is located north of San Francisco and the other three are south of Point Conception. Fishing regulations vary by site.
- One State Historic Park: This site is located north of San Francisco. There are no prohibitions on fishing gear of any type.
- Nine Reserves: Several areas in, near or north of San Francisco Bay. A few areas in southern California. Regulations are highly variable by site—some prohibit all fishing, and some allow all fishing.

- Twenty-two Ecological Reserves: These sites are located all along the coast. Regulations are highly variable by site—some are designated as no-take reserves, meaning all fishing is prohibited, and some are designated to prohibit certain type of fishing. Some allow all fishing, but prohibit take of other types of resources.

- Four MRPA Ecological Reserves: three sites are located along the central California coast, and one is north of San Francisco. Recreational and commercial fishing is prohibited at all sites.

- One Invertebrate Reserve: This site is located on the central coast. Recreational fishing is allowed for finfish. Commercial fishing is allowed for finfish, lobster, abalone and crab.

- One Natural Preserve: This site is located in northern California. No access allowed to the site.

- Three Clam Preserves: These sites are located on the central coast, just north of Point Conception. No clams may be taken, but all commercial and recreational fishing and fishing gear are allowed.

- One Marine Gardens Fish Refuge: This site is located in Monterey Bay. Most commercial fishing gear is prohibited, except nets. Recreational pot gear is prohibited, other recreational gear is allowed.

- Fourteen Marine Life Refuges: These sites are located primarily along the central and southern coast. Most commercial gear, except pot and "other" gear, is prohibited from these sites. All recreational gear types are allowed.

Oregon: MPA boundaries for three types of sites in Oregon were provided by Oregon Department of Fish and Wildlife. These are all small intertidal sites encompassing approximately 460 ha (Figure 3-31).

- Seven Marine Gardens: Generally, commercial and recreational pot gear is prohibited, other gear types not restricted.

- Six Research Reserves: Generally, commercial pot gear is prohibited

- One Habitat Refuge: All commercial and recreational fishing activities are prohibited.

Washington: The Washington State GIS data for MPAs contain 68 individual sites covering approximately 28,000 ha. The areas are managed by one of the following organizations: WDFW, Washington Department of Natural Resources (WDNR), San Juan County Marine Resource Committee (MRC), Washington State Parks and Recreation Commission (WSPRC), or The Nature Conservancy (TNC). The total area figure is a bit of an overestimate because some of the areas, such as state parks and TNC areas, include the upland portions of the sites as well as the marine portions (Figures 3-32 and 3-33).

- Nine WDFW Marine Preserves: generally prohibit most types of commercial fishing gear.

- Two WDFW Wildlife Refuges; generally closed to all access.

- Nine WDFW Conservation Areas: most restrictive of fishing—all fishing and gear are prohibited from nearly all of these sites.

- Two WDFW Sea Cucumber Closures: closed to commercial harvest of sea cucumbers and urchins.

- Six WDNR Aquatic Reserves: no restrictions on commercial or recreational fishing

- Seven WDNR Natural Areas Preserves: highest level of restriction–only allowable activities are scientific or education functions. Therefore, no commercial or recreational fishing allowed.

- Two WDNR Natural Resource Conservation Areas: No specific prohibition of fishing activities.

- Eight San Juan County MRC Bottomfish Recovery Zones: These are voluntary bottomfish no-take zones–no specific prohibition of fishing activities.

- Seven State Parks: Prohibited to take non-game invertebrates and seaweed. No specific prohibition of fishing activities.

- Two TNC Conservation Easements.

- Fourteen TNC Nature Preserves: limitation on public access and all fishing activities.

3.1.6 The Role of Rebuilding Species in the Marine Ecosystem

Under Section 304 of the Magnuson-Stevens Fishery Conservation and Management Act (104-297), fishery management plans, plan amendments, or proposed regulations for overfished species must take into account status and biology of any overfished stocks of fish as well as the interaction of overfished stocks within the marine ecosystem. This section was developed to consider the relevant aspects of these stocks with respect to their interaction with other biotic elements of the ecosystem.[12] The intent is not to replicate the evaluation of status, life history, and productivity of the stocks themselves, which is discussed in more detail in Chapters 2 and 4, but rather to focus on the role of these species in the environment, and to attempt to evaluate the relative impacts of alternative management decisions analyzed in this document with respect to the long-term consequences on other elements of the ecosystem (noting that the likely or expected impacts on the stocks themselves are discussed in detail in the stock-specific summaries in Chapter 4).

The rebuilding rockfish stocks, and indeed all rockfish more generally, occupy a broad range of ecological niches and trophic roles, and some analysis of their principal predators, prey, and competitors is an important consideration with respect to the impacts that rebuilding decisions may have on the larger ecosystem. Larval rockfish (and larval fish more generally), have been shown to play a minor role in the macrozooplankton community, which is dominated by a wide range of predators and competitors {McGowan and Miller 1980}. However, both juvenile and adult rockfish are important prey items to a wide range of other rockfish, other piscivorous fishes, seabirds, and marine mammals. Most food habits studies do not reliably or consistently report rockfish to the species level. Therefore, a summary of key predators here is focused more generally the role of rockfish as prey, rather than the

[12] Many marine organisms (such as many types of plankton, structure-forming invertebrates, and burrowing or bioturbating organisms) can and do interact with abiotic (physical and chemical) characteristics of an ecosystem that could have broader-scale impacts to marine communities and ecosystems. However, such interactions are neither known nor suspected for the rebuilding species evaluated in this section, and consequently are not explicitly considered here.

role of individual rebuilding species as prey. Although it is not possible to assess potential impacts to predators that may or may not result from the depletion of rockfish populations, particularly with respect to the level of depletion beyond target levels or the natural population variability exhibited by unfished species {Moser et al. 2000; Miller and Sydeman 2004}, it is clear that rockfish in general (particularly juveniles) represent a significant trophic linkage throughout the ecosystem.

For example, Merkel {1957} reported that juvenile rockfish were particularly important prey of Chinook salmon along the central California coast, representing on the order of 22 percent of prey by volume throughout the year, with most predation occurring between May and July, when pelagic juveniles move inshore to settle. Brodeur and Pearcy {1990} also found heavy predation on larval and juvenile rockfish by coho and Chinook salmon along the Oregon and southwest Washington coasts. The importance of rockfish as prey to piscivorous rockfish such as bocaccio, cowcod and yelloweye is summarized below; many nearshore rockfish species also predate heavily on other rockfish, particularly juveniles {Lea et al. 1999; Hobson et al.; Love et al. 2002}. Lingcod are among the most voracious predators of both juvenile and adult rockfish; Phillips {1959} reported that a 54-lb lingcod in Monterey, California had been found with a 12-inch starry rockfish and an 18½-inch canary rockfish in its stomach. Additional studies have confirmed that rockfish are important prey items for both California {Shaw et al. 1989} and Oregon lingcod {Steiner 1979}. Sablefish are also significant predators of both juvenile and adult rockfish, with rockfish representing between 20 and 60 percent of sablefish prey by volume {McFarlane and Beamish 1983; Cailliet et al. 1988; Laidig et al. 1997; Buckley et al. 1999}. However, for most depth ranges sablefish prey primarily on longspine thornyheads. Although Pacific hake are known predators of juvenile rockfish, juvenile rockfish represent significantly less than 1 percent of their diet by both volume and frequency of occurrence. Pacific halibut, soupfin sharks, dogfish sharks, and albacore tuna are other known rockfish predators {Rankin 1915; Ripley 1946; Bonham 1954}, and many other fishes are likely to feed on rockfish (particularly juveniles) as well.

A wide range of seabirds also prey heavily on juvenile rockfish {Wiens and Scott 1975, Chu 1984}. For many species, as much as 90 percent of their diet comprises juvenile rockfish during the late spring and early summer, which coincides with the breeding season for many resident species {Ainley et al. 1993, Miller and Sydeman 2004}. However, there is considerable interannual, and interdecadal variability in the frequency of rockfish in seabird diets, related primarily to the availability of juveniles to seabirds. While many studies have not attempted to identify juvenile *Sebastes* to species, for those that have (largely off of the central and southern California coasts,) unexploited species such as shortbelly rockfish generally account for more than two-thirds of the juvenile rockfish identified {Merkel 1957, Ainley et al. 1996, Miller and Sydeman 2004}. Throughout the 1990s, declines in juvenile rockfish predation by central California seabirds occurred in both exploited and unexploited rockfish species {Sydeman et al. 2001, Miller and Sydeman 2004, Mills et al. in press}. It is reasonable to expect that fisheries removals have contributed to overall declines in juvenile production, with proportionately greater declines in production for stocks that have been historically overfished and are now rebuilding.

As seabirds have a success-failure breeding response, rather than a response that is proportional to food supply, there is a potential for seabird populations to be highly sensitive to changes in food abundance {MacCall 1984; Furness and Tasker 2000; Sydeman et al. 2001}. This may be particularly true for seabirds in which juvenile rockfish have been shown to be a preferred prey item. Research has shown that common murres prefer to forage locally for juvenile rockfish during their breeding season (May-June, when juvenile rockfish are most abundant), since the close proximity to the breeding grounds reduces foraging trip duration. In years when juvenile rockfish are less abundant, murres forage in coastal waters for northern anchovy and other forage fishes {Ainley and Boekelheide 1990, Miller and Sydeman 2004}. Consequently, it is difficult to determine whether declines in overfished species could have had a notable impact on seabird reproductive success or other predators above and beyond that which has occurred as a result of fishing stocks to target levels and natural variability. These declines are coincident with the poor recruitment observed in many exploited species (described in section **4.2.XX**), as well as poor reproductive performance for many seabird species that depend heavily on juvenile rockfish in the breeding season (Sydeman et al. 2001). However, the observation that declines were observed in the consumption by seabirds of juveniles of both unexploited and exploited species suggests that ocean conditions were a major factor in the low abundance of juvenile rockfish.

Both juvenile and adult rockfish are typically a modest, but significant, component in the diets of most California Current pinnipeds and many cetaceans; however, rockfish prey are rarely identified to the species level {Morejohn et al. 1978; Stroud et al. 1981; Perez and Bigg 1986}. Morejohn et al. {1978} did identify bocaccio rockfish to species in diets of harbor seals and elephant seals, but other rockfish were listed solely as *Sebastes sp*. Lowry and Carretta {1999} reported that shortbelly rockfish were among the most frequently encountered prey items for California sea lion at San Nicolas, San Clemente, and Santa Barbara Islands. Lowry et al. {1991} also suggested that California sea lion food habits tend to be temporally dynamic and related to the relative availability of prey. Off of central California, some rockfish taken in food habits studies have been identified using otoliths, with those identified to species including shortbelly, bocaccio, splitnose, vermillion, and canary rockfish.[13]

Given that most marine mammal populations in the California Current exhibit either stable or increasing abundance trends over the last several decades, it seems unlikely that the depletion of overfished rockfish or any alteration to their expected recovery trajectories that might result from management decisions would have a negative impact on marine mammals. However, the converse situation, in which increasing marine mammal populations might slow or prevent the recovery of rebuilding species (a depensatory impact), may be plausible. For example, Bundy {2001} used a multispecies model of the Newfoundland-Labrador ecosystem to evaluate such potential interactions between harp seals and cod. Her results suggest that although the decline of cod was the result of overfishing, the recovery may be hindered by the increasing natural mortality rate associated with a nearly constant per capita consumption of cod by harp seals and concurrent increases in seal abundance. Such factors, which are know as depensatory processes that could complicate recovery efforts for some species, are difficult to quantify, and consequently are not explicitly considered in the analysis of rebuilding trajectories. However, since most rockfish are characterized by low growth, low metabolic rates, and low natural mortality rates, they are likely to be less tightly coupled with the dynamics of either their predators or their prey over most temporal and spatial scales.

With respect to the food habits of the depleted species themselves, accurate quantification of food habits is poor. Most rockfish are notoriously difficult to sample for food habits studies due to the eversion of their air bladder upon capture in sampling gear, usually resulting in regurgitation of any stomach contents. Thus, while several quantitative studies exist for widow, canary, yelloweye, and darkblotched rockfish, anecdotal accounts of food habits are the primary source of information for cowcod and bocaccio rockfish. For all of these species, general patterns of prey preferences are evident from the literature; however, prey preferences may also vary substantially over time (seasons, years), space (depth, latitude, habitat) and life history stage (most species tend to exhibit some ontogenetic shift in prey preferences with size).

Available food habits studies tend to confirm that POP, darkblotched, canary, and widow rockfish are primarily planktivorous, with the vast majority of the diets of the first three of these being euphausiids. For example, Brodeur and Pearcy {1984} found that euphausiids comprised 85 percent of prey by volume for Pacific Ocean Perch, 92 percent by volume for Canary rockfish, and roughly 75 percent by

[13] M. Weise, University of California Santa Cruz, unpublished data, but see Weise and Harvey {2005} for an overview of the study and methods.

volume (of identifiable remains) for a small number of darkblotched rockfish (for which most prey remains were unidentifiable). All three of these species also fed to some extent on smaller amounts of pelagic shrimp, cephalopods, mesopelagic fishes, and other prey. Lee {2002} also found that canary rockfish relied heavily on euphausiids, which accounted for over 98 percent of prey by volume. By contrast, widow rockfish have a more varied range of prey items, including a heavy reliance on gelatinous zooplankton. Phillips {1964} reported that widow rockfish, which tend to occupy semi-pelagic habitat, feed on macrozooplankton, particularly amphipods. Adams {1987} found that widow rockfish diets in northern California were dominated by four key groups of prey items; salps and other gelatinous zooplankton, euphausiids, pelagic shrimp, and small fishes (primarily mesopelagic fishes, juvenile hake, and forage fishes such as anchovy and smelt). Lee {2002} found that nearly 75 percent of the diet by volume of widow rockfish off of Oregon and Washington was composed of salps and other gelatinous predators, with smaller fractions of euphausiids, pelagic shrimps, and small fishes.

Although quantitative food habits studies do not exist for either cowcod or bocaccio rockfish, both Phillips {1964} and Love, et al. {2002} described bocaccio rockfish as almost exclusively piscivorous. Love, et al. {2002} include other rockfish, hake, sablefish, anchovy, mesopelagic fishes, and squid as the key prey for large juvenile and adult bocaccio, while cowcod are described by Love et al. {2002}as feeding on "anything that is not bolted down," but primarily fishes and cephalopods. Limited data is reported in the literature for yelloweye rockfish. Steiner {1979} reported on the stomach contents of 28 yelloweye caught on rocky reefs off of the central Oregon coast, which preyed primarily on benthic epifauna, flatfish, other rockfish and shrimp. Rosenthal, et al. {1987} found that yelloweye rockfish in southeast Alaska were primarily piscivorous, preying primarily on herring, other rockfish, and sand lance. Thus, the general patterns that emerge for these seven species are that three are higher trophic level piscivores that tend to be found on rocky or highly structured habitat (cowcod, bocaccio, and yelloweye rockfish), three are primarily planktivores associated with shelf and slope benthic habitat (POP and canary and darkblotched rockfish) and one is an omnivorous species that occurs and feeds primarily in midwater, and primarily on gelatinous zooplankton (widow rockfish).

As higher trophic level predators, cowcod, bocaccio, and yelloweye rockfish have a greater potential to play a structuring role in the ecosystem, particularly over smaller spatial scales. Despite their overall rarity throughout the marine environment relative to more abundant omnivorous or planktivorous rockfish,[14] submersible surveys have found that these piscivorous species can be found at relatively high levels of abundance in many rocky reef habitats isolated and presumably lightly fished reefs {Yoklavich et al. 2000, Yoklavich et al. 2002, Jagielo et al. 2003}. In surveys of reefs that had high piscivores density, the concentration of smaller, fast-growing and early maturing *Sebastes* species was considerably lower (such as greenstripe, rosethorn, splitnose, and pygmy rockfish). By contrast, in rocky reef habitats known or suspected to be subject to heavier fishing pressure, the abundance of such small, fast-growing, and early-maturing species was considerably greater. For example, Stein et al. {1992} found that reefs with small numbers of piscivorous rockfish (such as yelloweye) had very high numbers (as much as three orders of magnitude greater) of smaller species. Yet the scarcity of data on spatial patterns of abundance and fishing pressure, and a lack of all but qualitative food habits data for most these species, makes demonstrating and quantifying such interactions extremely challenging.

Additional empirical support for either intraguild competition or top-down impacts of fishing that may

---

[14] Estimates of unfished biomass (B_0) for cowcod and yelloweye are on the order of 3,000 and 7,500 mt respectively. By contrast, estimates of unfished biomass for bocaccio and widow and canary rockfish are on the order of 70,000, 90,000, and 230,000 mt respectively. Similarly, cowcod have always been among the rarest of *Sebastes* spp. larvae identifiable to species in the standard CalCOFI survey area (nearshore to offshore waters south of Point Piedras Blancas off California) between 1951 and 1998, with estimates of abundance as much as two orders of magnitude less than more abundant species {Moser et al. 2000}.

have resulted in either localized or large-scale community changes is presented in Levin, et al. {in press}, who found some evidence for broad-scale changes in the taxonomic composition of benthic marine fishes in the California Current. Their analysis focused on 16 species of rockfish, eight species of flatfish, and seven species of cartilaginous fishes that were sampled by bottom trawl surveys on the continental shelf between 1977 and 2001 (including all of the rebuilding species except for cowcod). For the species they included in their analysis, rockfish declined from over 60 percent of the catch in 1977 to less than 17 percent of the catch in 2001, with flatfish catches increasing by a similar magnitude. Additionally, populations of larger rockfish (including primarily the rebuilding species) had fallen at high rates (as reflected by stock assessments), while those of smaller species, particularly those associated with soft substrate, had generally increased in abundance. These authors also note that the potential for smaller species of rockfish to consume or outcompete recruiting juveniles of larger species highlights the potential that fishing could shift the community composition of the rockfish assemblage, or the benthic groundfish assemblage more generally, into an alternate state.

The potential for intraguild competition or top-down forcing, in both small-scale rocky reef systems and throughout the larger ecosystem, is also supported by theoretical considerations and simulation models. Walters and Kitchell {2001} as well as MacCall {2002} have demonstrated the potential for strong interactions among the adults of higher trophic level piscivores and their prey, such that adults crop down forage species that may be potential predators or competitors of their own juveniles, with consequent negative impacts on higher trophic level predators when their populations are reduced by fishing {see also Swain and Sinclair 2000}. Baskett et al. {2006} have explored the potential for such interactions as well, with a community interactions model based on rocky reef habitat and juvenile and adult life history stages of rockfish parameterized to represent yelloweye and pygmy rockfish. Their model sought to evaluate interspecific dynamics among rocky reef rockfish within a marine reserve, and considered the interactions among fishing, population recovery following cessation of fishing mortality, juvenile predation and competition.

Without interspecific interactions, the model developed by Baskett, et al. {2006} predicted that larger piscivores would recover given minimal levels of dispersal and reserve size. However, when community interactions were taken into account, initial conditions such as the relative abundance of the piscivores and the size of the reserve became more important with respect to the ultimate stable state, and the models predicted that under some circumstances recovery could be unlikely. Due to lack of adequate information on abundance and plausible parameter values for many of the interactions, the model was simplistic in the sense of modeling a single predator (with two life history stages) and a single prey/competitor, with little evaluation of the complicating impacts of climate variation, variability in recruitment, multiple alternative prey items, and other factors. Despite this, their results were consistent with similar simulations of the potential consequences of community interactions in marine systems {Walters and Kitchell 2001, MacCall 2002, Mangel and Levin 2005}, and speak to the importance of considering such interactions in the design, implementation and monitoring of recovery efforts for rebuilding species.

3.2 Criteria Used to Evaluate Impacts

3.2.1 Discussion of Direct and Indirect Impacts

The sections above provide a conceptual framework, based on trophic considerations and the basic structure and function of marine food webs, for considering the plausible impacts of the removal of both overfished (rebuilding) stocks as well as healthy stocks from the marine ecosystem. The impact associated with both the status quo and the action alternatives are the removals of these species from the ecosystem, at various levels depending upon the OY alternatives. Biogeography and EFH are presented for consideration of other elements of the ecosystem along with current measures to protect EFH.

Although far from conclusive, the empirical evidence and theoretical considerations discussed in section 3.1.3 suggest some potential for top-down impacts or intraguild competition, as a result of declines in higher trophic level species such as cowcod, bocaccio, and yelloweye rockfish over small spatial scales. It is reasonable to expect that similar impacts could potentially be associated with fishery-induced declines in stocks of healthy species (those reduced from their equilibrium abundance, but not to levels below overfishing limits), such as sablefish, Pacific halibut, petrale sole, shortspine thornyhead, Pacific hake, and other piscivorous or higher trophic level species. Such impacts are often referred to as trophic cascades, in which declines of high trophic level species (keystone predators) have cascading impacts through food webs to the abundance, productivity, and species diversity of lower trophic levels. Empirical examples of trophic cascades tend to be more common for semi-enclosed ecosystems such as lakes, or highly structured (two dimensional) environments, such as intertidal or sub-tidal ecosystems {Paine 1969, Simenstad et al. 1978, Tegner and Dayton 2000}. As one ventures further from these environments, the evidence for top-down control, or trophic cascades, becomes considerably spottier, although Van der Elst {1979} reported a classic example of top-down control of a coastal ecosystem off of the Natal coast in South Africa.[15]

However, in coastal upwelling ecosystems such as the California Current, most evidence suggest that the primary forcing factor for ecosystem productivity and structure over the scale of the entire system tends to be either "bottom-up" (based on the amount and variability of primary or secondary production) or "middle-out." For example, Ware and Thomson {2005} proposed that the carrying capacity of north Pacific coastal ecosystems was primarily determined by bottom-up control, based on correlations between latitudinal variability in primary production and commercial fisheries yields. Alternatively, bottom-up control in these ecosystems could be a function of secondary production, through variability in the productivity and species composition of the zooplankton community. As discussed in section 3.1.1, the California Current seems to experience higher secondary production during periods of stronger southward transport and cooler sea surface temperatures. Zooplankton, particularly euphausiids, are the principal prey item for most of the mid-trophic level organisms in the California Current, including Pacific hake and most rockfish.

An alternative to bottom-up control is "middle-out" control, also referred to as "wasp-waist" control, in which a small number of key mid-trophic level species represent a bottleneck of energy flow between lower and higher trophic levels. It has long been noted that food webs in coastal upwelling ecosystems tend to be structured around coastal pelagic species, such as krill, sardine, anchovy, and hake, that exhibit boom-bust cycles of abundance over decadal time scales {Bakun 1996, Schwartzlose et al. 1999}. Such dynamics have long been thought to be a consequence of the energetic and highly variable oceanographic processes that shape the physical environment and drive production throughout pelagic and benthic food webs in coastal upwelling ecosystems (such as the California Current system) over a range of time scales {Parrish et al. 1981, Mann and Lazier 1996}. The idea of wasp-waist control was first suggested by Rice {1995} and developed in greater detail in Cury et al. {2000}. The premise is that the low species diversity often observed in the middle of many upwelling ecosystems results in a vast majority of the energy in the food web flowing through coastal pelagic species such as sardine, anchovy, and mackerel. Many of these seem to feature "weak links" in their life cycles related to sensitivity to climate forcing, such that climate conditions determine the productivity of these stocks,

15 In this case, increased mortality of large sharks resulted from the use of shark nets to protect bathers, which subsequently caused an apparent increase in the abundance of smaller dusky and milk sharks on which they preferentially fed. This increase of smaller sharks resulted in a substantial decline in catch per unit effort of several populations of teleost fishes that were both commercially and recreationally important to coastal communities in the region.

and indirectly drive the dynamics of both higher and lower trophic levels.

Empirical evidence for any of these types of control is typically limited for large marine ecosystems {Hunt and McKinnell 2006}. However, where trophic interactions among exploited species are documented or suspected, ecosystem modeling can provide a template to evaluate both the magnitude and consequences of removals of either predators or prey in the system of interest {Hollowed et al. 2000, Christensen et al. 2004}. Although such models are unavoidably constrained by conceptual shortcomings and data limitations, most critical reviews of multispecies modeling approaches agree that ecosystem models can augment contemporary single species models by confronting an array of interactions and dynamics that are more difficult to address with single-species models, such as competition, predation and environmental variability {Hollowed et al. 2000, Fulton et al. 2003, Plagányi and Butterworth 2004}. For example, Walters, et al. {2005} used the results from a number of existing ecosystem models to demonstrate that widespread application of contemporary (MSY proxy) single-species management approaches could lead to dramatic impacts on ecosystem structure, particularly where such approaches are applied to forage species. Their results add considerable weight to the perceived need to consider forage species as resources whose value is derived from their role as prey to commercially and recreationally important stocks, a consideration consistent with recent the Council determination to place a precautionary ban on krill (euphausiid) harvests throughout the West Coast EEZ.

Dynamic simulations of an ecosystem model of the Northern California Current were developed by Field et al. {2006b}, who modeled the continental shelf and slope ecosystem between Cape Mendocino and Cape Flattery between 1960 and 2004. The model was based on, and tuned to, biomass estimates from stock assessments and surveys, consumption and production rates estimated from empirical studies or the literature, historical estimates of landings and discard rates, and the limited food habits data that were available in this region. The model was run forward first under the assumption of a constant environment, then forced dynamically with several climate indices. They found that most of the variability observed in single species models and dynamics can be replicated with a multi-species modeling approach, despite significant changes in food web structure and the abundance of both predators and prey in this ecosystem over time. In general, these results imply that over the macro-scale, there do not appear to be obvious changes in ecological structure that have resulted in strong interspecific interactions (predation, competition) between most of these species. One large exception to this generalization was Pacific hake, which by virtue of their large biomass and high consumption of forage species in the model were shown to have potential competitive interactions. Agostini {2005} found that most model components (particularly pandalid shrimp, rockfish, salmon, seabirds and marine mammals) benefited from a reduction in hake biomass, primarily as a result of increases in the availability of euphausiids, forage fish and other prey.

These results are consistent with what is known of the life histories for many of the rockfish, roundfish and longer-lived flatfish in the California Current, where low mortality rates are indicative of low predation rates and presumably weakly coupled trophic interactions. In other words, species with a low natural mortality rate are unlikely to be a “key prey species” for higher trophic level predators, and are consequently less likely to effect significant bottom-up control in the energy flow or structure of the ecosystem. Consequently, the effects of severe declines in the overfished species that were explicitly included in this model (canary rockfish, widow rockfish, and POP) to other elements of the ecosystem were minimal. The model found considerably stronger interspecific interactions in species such as shrimp, salmon, and small flatfish where there is high turnover and high predation coupled with substantial changes in many of their key predators (such as hake, sablefish, marine mammals) over the last forty years. There were, of course, other exceptions to this generalization; in fact one of the strongest interactions appeared to be among several of the slowest growing species; sablefish, shortspine thornyhead, and longspine thornyhead. Essentially, the model suggested that natural mortality rates for longspine thornyheads may have fallen by nearly fourfold over recent decades as a result of substantial declines in sablefish and shortspine thornyheads, their key predators. As a result, the expectation would be that longspine thornyhead abundance would increase over time, a prediction consistent with recent trawl survey results.

However, this work focused on integrating a broad array of species and habitats, and the piscivorous species of rockfish described in the previous section were not modeled as independent populations. For example, as the fauna and environmental conditions along the continental slope differ tremendously from those on the shelf and near the shelf break, evaluating these interactions more carefully is likely to require development of spatially explicit modeling efforts, coupled with more appropriate consideration of age and/or size based bioenergetic requirements and predation interactions. A comparable, but considerably more complex model, with greater population (demographic) structure, spatial complexity and explicit physical forcing {Fulton et al. 2004}, is currently under development by researchers at the NMFS Northwest Fisheries Science Center. As baseline knowledge and modeling abilities increase, such models will hold greater promise for successfully identifying the processes and mechanism of ecosystem change, and guiding decisions that might hasten the recovery of both individual species and sustain the community and ecosystem in which they reside.

Other theoretical considerations point to the potential for an important role for rebuilding species in the California Current over broad spatial and temporal scales, particularly the stocks that were historically more abundant. By virtue of their slow growth and low mortality rate, these stocks may fill a role in stabilizing highly dynamic ecosystems, by dampening what might otherwise be even greater ecological responses by high turnover species to rapid changes or short-term bursts in production {Apollonio 1994}. However, the same could be said of any ecosystem for which all stocks were at their "target" levels. The premise of nearly all contemporary fisheries management is that reducing stocks to target levels results is sustainable from a single species perspective, but there is little or no theoretical or empirical basis on which to conclude that this approach is optimal from the perspective of other, codependent elements of the ecosystem {Mangel et al. 2000, Goodman et al. 2002}. As Goodman et al. {2002} discuss, fishing to achieve any MSY-related objectives inevitably shifts the equilibrium biomass, age and size structure of a population from that which occurred in the unfished condition, and any such changes have the potential to propagate through the food web and effect consequent changes on other species.

The action considered in this EIS would authorize harvest of groundfish within EFH. The action is within the scope of fishery management actions analyzed in the EIS for groundfish EFH. Those analyses are incorporated by reference. A Record of Decision for Pacific Coast Groundfish EFH was issued on March 8, 2006 and concluded that partial approval of Amendment 19 to the FMP would minimize to the extent practicable adverse impacts to EFH from fishing. Amendment 19, approved on March 8, 2006, provides for a comprehensive strategy to conserve EFH, including its identification, designation of Habitat Areas of Particular Concern, and the implementation of measures to minimize to the extent practicable adverse impacts to EFH from fishing. The final rule implementing Amendment 19 will provide measures necessary to conserve EFH. Therefore, provided that the final alternative for this EIS is within the scope of Amendment 19, no additional EFH recommendations are necessary for this proposed action.

3.4 Discussion of Cumulative Impacts

"Cumulative impact" is the impact on the environment which results from the incremental impact of the action when added to other past, present, and reasonably foreseeable future actions regardless of what agency (Federal or non-Federal) or person undertakes such other actions. Cumulative impacts can

result from individually minor but collectively significant actions taking place over a period of time. (40 CFR 1508.7).

While contemporary approaches to fisheries science focus on estimating surplus production, stock-recruit relationships and maximum sustainable yields, it is worth noting that from a purely "holistic" perspective, the fishing down of any species removes or alters energy pathways and ecological structure from either other species (such as seabirds and marine mammals) or other ecosystem processes {Aydin 2004}, although this observation does not invalidate the logic of surplus production from a single-species perspective. It has long been assumed that fish stocks and populations, and subsequently the ecosystems in which they exist, are healthy if they are maintained close to the levels that provide MSY. However, there is a growing body of ecological, genetic and theoretical evidence that suggests that this may not necessarily be a fair assumption, neither for the exploited species themselves nor the ecosystems in which they exist. A growing body of literature suggests that fisheries have the potential to effect substantial changes in both genetic and demographic characteristics of fish populations; as Stokes and Law {2000} suggest "to an evolutionary biologist, fishing is a massive uncontrolled experiment in evolutionary selection." Selection by fisheries has clearly been demonstrated to result in changes in size at age,[16] changes in size and age at maturity, changes in natural mortality and increased total fecundity {Mangel et al. 1993; Stokes and Law 2000; Mangel and Stamps 2001; Conover and Munch 2002; Stergieu 2002}; and some examples even suggest changes in body shape, alterations in heritable patterns of distribution and migration and even changes in avoidance behavior {Ricker 1981; Heino and Godø 2002}.

Their results speak not only to the necessity to consider evolutionary consequences, but also to the observation that the consequences could be detrimental to humans as well as fish. Quite simply, these evolutionary consequences can reduce the sustainable yield of a population by decreasing the age at maturity and consequently reducing the relative amount of somatic growth in a population relative to reproductive effort. As Conover {2000} suggests, "Yield… is not a currency that is crucial to fitness. From the fishes' point of view, the goal is maximizing the relative contribution of genes (not biomass) to succeeding generations." The current National Standard guidelines recognize the significance of such factors on both populations and ecosystems, as they state that the benefits of protecting marine ecosystems include "maintaining viable populations (including those of unexploited species), maintaining evolutionary and ecological processes (e.g., disturbance regimes, hydrological processes, nutrient cycles), maintaining the evolutionary potential of species and ecosystems, and accommodating human use" (50 C.F.R. 600.310). Such observations demonstrate that maintaining the role of species in an ecosystem, and minimizing the selective role of fishing on marine fish diversity on multiple levels, are both key challenges and crucial element to any future ecosystem-based approach to the management of marine resources.

From an idealistic perspective, an ecosystem-based approach to managing fisheries is clearly a common goal that would be in the interests of both the resources being managed and the resource users. A truly integrated ecosystem approach might make management decisions based on accurate indices of ecosystem productivity, the needs of other predators (such as seabirds and marine mammals), and the consequences of fishing on habitat and ecological structure. Unfortunately, the data necessary to develop and adequately parameterize multispecies models are lacking for most ecosystems, including

---

16 As early as 1912 it was noticed that fish caught in the early or developing years of a fishery tended to be larger at age than those caught in more recent years, and it is now known that when mortality increases as a result of size-selected fishing; faster-growing individuals are removed at higher rates than slower-growing individuals. The result is that slower-growing animals make up a greater percentage of their age group; and the population in question is selected to be smaller at a given age over time. The same logic applies to the selection of earlier ages at maturity and to other selective factors.

the California Current. Even with adequate data, the ability of multispecies models to make meaningful predictions regarding the consequences of decisions is limited. Although multispecies models are capable of providing insight regarding potential or likely interspecific interactions, and can provide long term (strategic) guidance regarding likely ecosystem impacts of fishing, there are still far too many unanswered basic ecological questions to expect that the ecological consequences of fishing at alternative harvest rates can be described or quantified. For example, May {1999} reminds us that even basic mechanisms responsible for density-dependent or density independent regulatory mechanisms continue to be unresolved for many populations, an issue of particular importance for rockfish, for which stock assessment models estimate a wide spectrum between strong density dependence and strong density independence. It may be that the only certainty that managers can expect is that decisions will have to continue to be made with imperfect information.

3.5 Summary of Impacts

While considerable research has been undertaken to better understand trophic interactions and other ecosystem considerations throughout the U.S. and the world, and to consider the cumulative, large-scale effects of fishing on marine ecosystems from a more holistic perspective, there is no clear consensus on what would actually constitute precautionary harvest policies or rates from a multispecies or ecosystem perspective. As a result, there is no fundamental foundation upon which to consider the consequences of historical overfishing, or alternative strategies in rebuilding depleted species, with respect to the potential impacts or trade-offs to ecological integrity and future sustainability.

From a basic ecological perspective, all species have a role to fill in the system, and the loss or severe reduction of any stock or species could have reverberations throughout the food web. Even the reduction of fished populations to their target levels affects the flow of energy through the marine ecosystem, and has the potential to either modestly or massively alter the structure and integrity of the communities that either prey on, are preyed upon, or otherwise interact with those species. As discussed in section 3.1.6, some seabirds that depend on juvenile rockfish have undergone declines in breeding success, and declines in the availability of prey have been implicated as potential causes. However, ocean conditions and the effects of fishing are likely to be compounded, and the trends themselves are difficult to discern. Based on the observation that most resident or migratory marine mammal populations in the California Current have been increasing at modest to substantial rate over the past several decades (including California sea lions, harbor seals, elephant seals, gray whales, and humpback whales), it is similarly difficult to expect that the cumulative impacts of fishing have been detrimental for these guilds (independent of the incidental mortality resulting from fishing activity, described in section XXX).

Based on what is known or suspected about the large-scale nature of energy flow in upwelling environments, it is reasonable to expect that the cumulative impacts that have resulted from overfishing, and may continue to result from any delay in rebuilding, are modest to negligible when integrated across the entire California Current ecosystem. This is particularly true when considering the potential cumulative impact of depleting these populations below target levels (e.g., 10 percent to 25 percent of historical abundance) relative to depleting such populations to precisely their target levels (e.g., ~40 percent of historical abundance). However, for several rebuilding species, particularly those at higher trophic levels, these impacts may be more significant at smaller spatial scales for some habitat types and regions, since severe depletion may well have resulted in substantial shifts in the community composition of some benthic habitat. Furthermore, clearly identifying and evaluating the potential consequences to the ecosystem of modest changes in population trends and abundance that may result from deviations in rebuilding trajectories, above and beyond those that would have resulted from fishing stocks down precisely to target levels, is an analysis beyond the scope of existing data and capacity. The empirical data, either from visual or trawl surveys, are limited in their resolution, and although theoretical (simulated) studies suggest that thresholds between alternative stable states may exist, identifying such thresholds is beyond the realm of existing capacity.

What can be said is that the management measures that have been implemented over recent years by the Council do appear to have resulted in increasing abundance and productivity levels for rebuilding (and other) species, although such improvement may be a factor of climate and other unmanageable contributors as well. Moreover, the existing management approach is highly dependent on spatial closures, which effectively eliminate fishing mortality from broad areas of habitat that are optimal for both the rebuilding species and other, healthier groundfish stocks in the California Current. The protection of intact functional patches of habitat was identified by Baskett, et al. {2006} as one of the management measures that had the greatest potential to avoid or reverse changes in species composition on small rocky reef habitats. Moreover, recent action taken under the EFH amendments to the Groundfish FMP will not only protect additional habitat areas from trawl fishing impacts into the foreseeable future, but limit the ability to use large-footrope gear in nearshore habitat, further reducing the potential to impact high relief reef communities in those areas that remain shoreward of the 100 fm depth contour.

Consequently, the ability to say anything meaningful about the broad-scale ecosystem impacts associated with adopting one of the preferred alternatives above the other is by all measures an intractable question. Clearly the three OY options for rebuilding species differ in the trajectories they set for rebuilding populations, and clearly those options that rebuild stocks the most rapidly have the greatest potential to minimize the long-term ecological impacts to the ecosystem that may have resulted from their removal. However, there exists no meaningful way of quantitatively assessing the potential difference with respect to the risk of undesirable consequences of choosing one OY alternative over the other. To the extent that the two alternatives differ among each other (or from the status quo) with respect to area closures, there again might be some unquantifiable generalization that would suggest that the greater the protection of stocks from area closures, the lighter are the potential consequences of fishing to ecological structure and function.

3.5.1 No Action Alternative

In general, there is no empirical or theoretical evidence that declines in these stocks of West Coast rockfish have had impacts on predators or higher trophic level species, particularly impacts above and beyond those which might be expected by reduction of biomass to their target levels. However, there is potential evidence, largely theoretical, that among those rebuilding species that are higher trophic level predators there could be cascading ecological consequences to some benthic communities resulting from severe depletion and potential replacement by more opportunistic species. Again, the extent to which such impacts (if real) might be of a greater magnitude than those that would be expected under scenarios in which biomass declined to target levels is impossible to quantify.

The management measures currently in place for rebuilding groundfish rely primarily on the use of spatial management measures (area closures) in those depth zones and habitats in which these species are most frequently encountered. As such, these areas tend to represent the optimal habitat for these species, and are either known or suspected (from catch rate data, trawl surveys, ROV surveys, and other means) to sustain the highest densities of depleted species. Consequently, this approach would be expected to effectively maintain functioning habitat areas and/or metapopulations of rebuilding species with an extremely high degree of protection. The extent the no action alternative differs from the action alternatives is the extent to which the selected action alternative results in greater area closures and greater reductions in fishing mortality for rebuilding species.

3.5.2 The Action Alternatives

With respect to potential differences between the action alternative and the no action alternative (independent of the consequences of the different alternatives to the recovery trajectories of the stocks themselves), the broad scale, cumulative impacts to the ecosystem of different OY alternatives are for all intensive purposes beyond are ability to monitor and test. As discussed above, it is intuitive that the lower the fishing mortality rate, and the greater the extent of spatial closures, the greater the potential for rebuilding species to fill their niche or role in the ecosystem relative to the risk of changes or shifts in equilibrium or ecosystem states. The precision and abilities of multispecies or ecosystem models to accurately reflect the potential cumulative impacts to the ecosystem that result in slightly differing rebuilding trajectories is extremely low, particularly with respect to any ability to detect thresholds that may exist with respect to alternative stable states within either small or broad scale habitats and ecosystems.

This section will be summarized in greater detail following the June meeting...

4.0 AFFECTED SPECIES

4.1 Species Description and Status

There are over 90 species of groundfish managed under the groundfish FMP. These species include over 60 species of rockfish in the family Scorpaenidae, 7 roundfish species, 12 flatfish species, assorted shark, skate, and a few miscellaneous bottom-dwelling marine fish species. Table 4-1 depicts the latitudinal and depth distributions of groundfish species managed under the groundfish FMP.

The following sections contain information on the life histories of a subset of the groundfish managed under the groundfish FMP. While reading these sections, it is important to keep in mind how certain life history traits of the species have important implications on how the stocks are sustainably managed.

In contrast to the highly variable, and often volatile, population cycles of many coastal pelagic and invertebrate populations in the California Current, many of the resident groundfish in the California Current have evolved entirely different life history approaches to coping with environmental variability. Sablefish, Dover sole, spiny dogfish and a large number of rockfish (*Sebastes* and *Sebastolobus*) species have lifespans that typically span decades, and in some extreme examples may reach ages of 100 or greater (Beamish, *et al.* 2006; Love, *et al.* 2002). Although large initial catches of many rockfish had given the impression that these stocks were also highly productive, a growing body of scientific evidence soon made it clear that many of these species were incapable of sustaining high intensity fishing pressure using modern fishing methods (Francis 1986; Gunderson 1977; Gunderson 1984; Leaman and Beamish 1984).

Among the concerns raised in some of the early research and analyses were that the large standing stocks of older individuals were simply maintaining themselves within the dynamic bounds of their ecosystem, and that the failure to consider the role of such longevity in Northeast Pacific groundfish could lead to management challenges. Factors such as extreme longevity, low natural mortality, increasing fecundity with age, and infrequent reproductive success (recruitment) were explicitly considered when initial harvest rate strategies were developed for the Council (e.g., (Clark 1991)). However, the paucity of data and magnitude of some of these factors as related to the low productivity of many species were not fully appreciated in many early studies, and are now known to be important considerations in developing harvest rate guidelines and management policies (Clark 2002; Dorn 2002). Consequently, harvest rates for many species have been reduced repeatedly in recent years to account for the improved knowledge regarding the overall productivity of these stocks. As new information continues to emerge regarding the significance of diverse age structures and other factors in sustaining groundfish resources (Berkeley 2004; Berkeley, *et al.* 2004; Bobko and Berkeley 2004), such information continues to be evaluated and incorporated into the stock assessment and assessment review processes that provide the scientific basis upon which management decisions are made.

Management of these groundfish species is based on principles outlined in the MSA, groundfish FMP, and national standard guidelines, which provide guidance on the 10 national standards in the MSA. Stock assessments are based on resource surveys, catch trends in West Coast fisheries, and other data sources. Section 6.1.4 describes, in general terms, how stock assessments are conducted and reviewed before they are applied in West Coast groundfish management.

Table 4-1. Latitudinal and depth distributions of groundfish species (adults) managed under the Pacific Coast Groundfish Fishery Management Plan. [a/]

Common name	Scientific name	Latitudinal Distribution		Depth Distribution (fm)	
		Overall	Highest Density	Overall	Highest Density

Table 4-1. Latitudinal and depth distributions of groundfish species (adults) managed under the Pacific Coast Groundfish Fishery Management Plan (continued). [a/]

a/ Data from Casillas et al. 1998, Eschmeyer et al. 1983, Hart 1973, Miller and Lea 1972, Love et al. 2002, and NMFS survey.
data. Depth distributions refer to offshore distributions, not vertical distributions in the water column.
b/ The category "rockfish" includes all genera and species of the family Scorpaenidae, even if not listed, that occur in the Washington, Oregon, and California area.
c/ Only the southern stock of bocaccio south of 40°10' N. lat. is listed as overfished.
d/ Dusky rockfish do not occur on the U.S. West Coast south of 49° N. lat. The species needs to be removed from the FMP.
e/ Only two occurrences of harlequin rockfish south of 51° N. lat. (off Newport, OR and La Push, WA; Casillas et al. 1998).

The passage of the Sustainable Fisheries Act in 1996 incorporated the current conservation and rebuilding mandates into the MSA. These mandates—including abundance-based standard reference points for declaring the status of a stock (overfished; in a "precautionary" status; or at levels that can support MSY (healthy or "rebuilt"))—were subsequently incorporated in the groundfish FMP with adoption of Amendments 11 and 12. These reference points are determined relative to an estimate of "virgin" or unexploited spawning biomass of the stock, denoted as $SB_{0,}$ which is defined as the average equilibrium abundance of a stock's spawning biomass before it is affected by fishing-related mortality.[17] SB_0 is then used to estimate MSY, as identified in the Magnuson-Stevens Act and national standard guidelines. MSY represents a theoretical maximum surplus production from a population of constant size; national standard guidelines define it as "the largest long-term average catch or yield that can be taken from a stock or stock complex under prevailing ecological and environmental conditions." For a given population and set of ecological conditions, there is a biomass that produces MSY (denoted as B_{MSY}), which is less than the equilibrium size in the absence of fishing (B_0). (Generally, population sizes above B_{MSY} are assumed to be less productive, because of competition for resources or other density dependent factors.) The harvest rate used to achieve or sustain B_{MSY} is referred to as the Maximum Fishing Mortality Threshold (MFMT, denoted as F_{MSY}). Two harvest specification reference points, defined in the groundfish FMP, provide guidance in setting the harvest rate: a total catch OY and an ABC. The Council identifies the OY as the management target for each species or species complex. When the stock biomass is determined to be lower than $B_{MSY,}$ the OY is set to less than the ABC in order to rebuild the stock to a healthy level (see the following discussion). The ABC, which is the maximum allowable harvest, is calculated by applying an estimated or proxy F_{MSY} harvest rate to the estimated abundance of the exploitable stock.

The biomass level that produces MSY (i.e. B_{MSY}) is generally unknown and assumed to be variable over time due to long-term fluctuations in ocean conditions, so that no single value is appropriate. Furthermore, F_{MSY} is tightly linked to an assumed level of density dependence in recruitment, and there is insufficient information to determine that level for many West Coast groundfish stocks. Therefore, the use of approximations or proxies is necessary; absent of a more accurate determination of $F_{MSY,}$ the Council applies default MSY proxies. The Council-specified proxy MSY abundance for most West Coast groundfish species is 40% of B_0 (denoted as $B_{40\%}$), meaning that the Council adopts management actions aimed to maintain abundance of each stock at or above approximately 40% of its virgin biomass.

[17] The current abundance of a stock relative to its unfished level is commonly written as a percentage or a proportion; this value represents the stock's depletion level. In addition to using a comparison between current spawning biomass and unfished spawning biomass to determine this reference point, some stock assessment authors compare current and unfished levels of spawning output or of total stock biomass (B), depending on the information that is available.

The Council-specified threshold for declaring a stock overfished or depleted is when the stock's spawning biomass declines to less than 25% of B_0 (denoted as $B_{25\%}$). The MSA and national standard guidelines refer to this threshold as the Minimum Stock Size Threshold or MSST. A rebuilding plan that specifies how total fishing-related mortality is constrained to achieve an MSY abundance level within the legally allowed time is required by the MSA and groundfish FMP when a stock is declared depleted.

Stocks estimated to be above the depletion threshold, yet below an abundance level that supports MSY, are considered to be in the "precautionary zone." The Council has specified precautionary reductions in harvest rate for such stocks in order to increase abundance to $B_{40\%}$. The methodology for determining this precautionary reduction is described in the groundfish FMP and is referred to as the 40-10 adjustment. As the stock declines below $B_{40\%}$, the total catch OY is reduced from the ABC until, at 10% of B_0, the OY is set to zero. However, in practice the 40-10 adjustment only applies to stocks above $B_{25\%}$ (the MSST) because once a stock falls below this level, an adopted rebuilding plan supplants it. Most stocks with an estimated abundance greater than $B_{40\%}$ are managed by setting harvest to the ABC. Figure 4-1 presents this framework graphically.

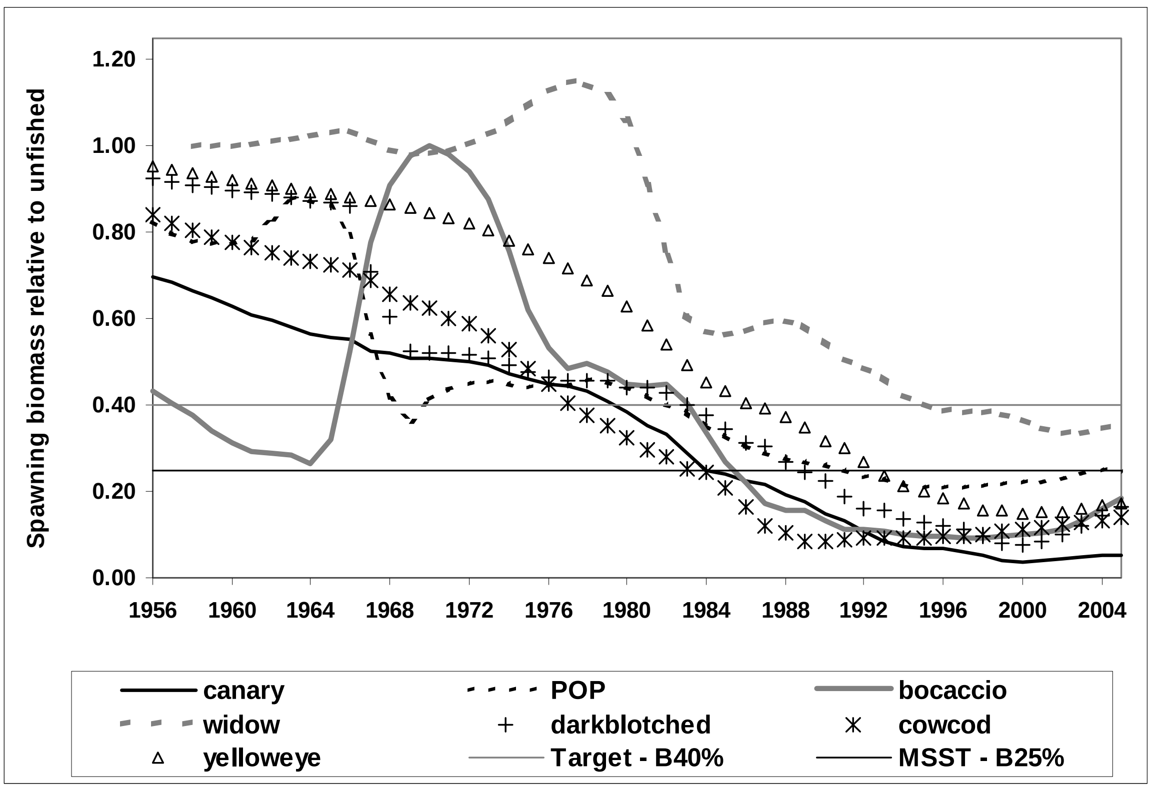

Figure 4-1. Relative depletion trends for rebuilding rockfish species

Sections 4.1.1, 4.1.2 and 4.1.3 describe groundfish stocks according to the categories just described: overfished, precautionary zone, and healthy. However, it is important to realize that of the more than 90 species in the management unit, only a portion is individually managed. Thus, the remaining species are managed and accounted for in groupings or stock complexes (discussed in section 4.1.4) because individually they comprise a small part of the landed catch and insufficient information exists to develop the stock assessments necessary to set an OY based on yield estimates. (The groundfish FMP identifies the OY for these species as an average of historical catch, based on the assumption that this is below MSY.)

Twenty-three stock assessments were performed in the 2005 stock assessment cycle, and two of these assessments (Pacific whiting, *Merluccius productus* and yelloweye rockfish, *Sebastes ruberrimus*) were redone in early 2006. One assessment, that for vermillion rockfish (*Sebastes miniatus*), was not accepted by the Scientific and Statistical Committee (SSC) as being suitable for the provision of quantitative management advice. Table 4-2 presents a summary of the results of the twenty-two assessments that were accepted as being suitable bases for management, including depletion (the estimated spawning biomass or output relative to the unfished condition), and the associated current and unfished spawning biomass, recent trends in abundance, and the estimated catch level at MSY. Table 4-3 lists life history parameters from the twenty-two stock assessments; steepness of the spawner-recruitment curve (h), the von Bertalanffy Equation growth constant (k), and natural mortality (M) are each important contributors to the understanding of the productivity and resiliency of a species.

Complimentary to this overview, Table 4-4 provides a general overview of the data that were available for each of these assessments, including a qualitative description of the extent to which assessments might be considered data-rich or data-poor, and the estimated or assumed value used in the stock assessment for the steepness of the spawner/recruit curve (generally an indicator of the productivity of the stock). Of these full assessments, only 14 of the 23 conducted in 2005 and 2006 had what might be considered moderate to good information (although these are generally the species that account for the vast majority of groundfish catches in the California Current). In general, stock assessments for nearshore species tend to lack fishery-independent trend information, and rely primarily on catch-per-unit-effort (CPUE) data and demographic data from recreational fisheries. By contrast, assessments for most shelf and slope species are informed by fisheries independent surveys and demographic information from commercial fisheries, and as such tend to be more data rich than those for nearshore species. Although fishery-dependent CPUE data exist for many commercial groundfish species, for most species such series have been truncated to the period prior to 2000, as a result of the difficulties interpreting catch rates given marked changes in management measures for West Coast fisheries in recent years.

* This refers solely to the richness of data and the internal consistency of the data within the assessment, as interpreted subjectively from the assessments, STAR Panel reports, SSC reports, and GMT discussions; in no way is this intended to be a reflection of the abilities of assessment authors or teams

** The use of age composition data infers that sufficient age data were available to be used to tune the age composition of the modeled population, this does not include age data used to fit growth curves or estimate natural mortality rates

*** Larval surveys refer to indices of larval abundance from California Cooperative Oceanic Fisheries Investigations (CalCOFI) plankton surveys, generally used as a relative index of spawning biomass, pre recruit surveys are from the Southwest Fisheries Science Center's juvenile rockfish survey or other sources, and submersible surveys refer to biomass estimates derived from visual observations.

4.1.1 Depleted Groundfish Species

4.1.1.1 Bocaccio

Distribution and Life History

Bocaccio (*Sebastes paucispinis*) is a rockfish species that ranges from Krozoff and Kodiak Islands in the Gulf of Alaska to central Baja California, Mexico (Hart 1988; Miller and Lea 1972). Love, et al. (Love, *et al.* 2002) and Thomas and MacCall (Thomas and MacCall. 2001) describe bocaccio distribution and life history. Bocaccio are historically most abundant in waters off central and southern California. The southern bocaccio stock is most prevalent at the 54-82 fm depth zone (Casillas, *et al.* 1998).

Bocaccio are found in a wide variety of habitats, often on or near bottom features, but sometimes over muddy bottoms. They are found both nearshore and offshore (Sakuma and Ralston 1995). Larvae and small juveniles are pelagic (Garrison and Miller 1982) and are commonly found in the upper 100 m of the water column, often far from shore (MBC 1987). Large juveniles and adults are semi-demersal and are most often found in shallow coastal waters over rocky bottoms associated with algae (Sakuma and Ralston 1995). Adults are commonly found in eelgrass beds, or congregated around floating kelp beds (Love, *et al.* 1990; Sakuma and Ralston 1995). Young and adult bocaccio also occur around artificial structures, such as piers and oil platforms (MBC 1987). Although juveniles and adults are usually found around vertical relief, adult aggregations also occur over firm sand-mud bottoms (MBC 1987). Bocaccio move into shallow waters during their first year of life (Hart 1988), then move into deeper water with increased size and age (Garrison and Miller 1982).

Bocaccio are ovoviviparous (live young are produced from eggs that hatch within the female's body) (Garrison and Miller 1982; Hart 1988). Love et al. (Love, *et al.* 1990) reported the spawning season to last nearly an entire year (>10 months). Parturition occurs during January to April off Washington, November to March off Northern and Central California, and October to March off Southern California (MBC 1987). Fecundity ranges from 20,000 to 2,300,000 eggs. In California, two or more broods may be born per year (Love, *et al.* 1990). The spawning season is not well known in northern waters. Males mature at three to seven years, with about half maturing in four to five years. Females mature at three to eight years, with about half maturing in four to six years (MBC 1987).

Maximum age of bocaccio was radiometrically determined to be at least 40 years, and perhaps more than 50 years. Bocaccio are difficult to age, and stock assessments used length measurement data and growth curves to estimate the age composition of the stock. Although recent assessments have described the true natural mortality rate as a key unknown for estimating stock status, recent assessments have used a value of 0.15 (which is associated with an 86% adult annual survival rate in the absence of fishing mortality).

Larval bocaccio eat diatoms, dinoflagellates, tintinnids, and cladocerans (Sumida and Moser 1984). Copepods and euphausiids of all life stages (adults, nauplii and egg masses) are common prey for juveniles (Sumida and Moser 1984). Both Phillips (1964) and Love et al. (2002) described bocaccio rockfish as almost exclusively piscivorous, and include other rockfish, Pacific whiting, sablefish, anchovy, mesopelagic fishes and squid as the key prey for large juvenile and adult bocaccio. Bocaccio are eaten by sharks, salmon, other rockfishes, lingcod, albacore, sea lions, porpoises, and whales (MBC 1987). Adult bocaccio are often caught with chilipepper rockfish and have been observed schooling with speckled, vermilion, widow, and yellowtail rockfish (Love, *et al.* 2002). As pelagic juveniles, they may compete with chilipepper, widow, yellowtail, shortbelly and other pelagic juvenile rockfishes for both food and habitat (Reilly, *et al.* 1992).

Stock Status and Management History

There are two separate West Coast bocaccio populations. The southern stock exists south of Cape Mendocino and the northern stock north of 48° N latitude in northern Washington (off Cape Flattery). It is unclear whether this stock separation implies stock structure. The distribution of the two populations and evidence of lack of genetic intermixing suggests stock structure, although MacCall (MacCall 2002) sees some recent evidence for limited genetic mixing of the two populations. Nonetheless, assessment scientists and managers have treated the two populations as independent stocks north and south of Cape Mendocino. The northern stock of bocaccio has not been assessed.

Bocaccio have long been an important component of California rockfish fisheries. Catches increased to high levels in the 1970s and early 1980s as relatively strong year-classes recruited to the stock. The Council began to recommend increasingly restrictive regulations after an assessment of the southern stock in 1990 (Bence and Hightower 1990) indicated that fishing rates were too high. The southern stock suffered poor recruitment during the warm water conditions that prevailed off Southern California beginning in the late 1980s. The 1996 assessment (Ralston, *et al.* 1996) indicated the stock was in severe decline. NMFS formally declared the stock overfished in March 1999 after the groundfish FMP was amended to incorporate the tenets of the Sustainable Fisheries Act. MacCall et al. (MacCall, *et al.* 1999) confirmed the overfished status of bocaccio and estimated spawning output of the southern stock to be 2.1% of its unfished biomass.

While previous assessments only used data from central and northern California, the assessment in 2002 (MacCall and He 2002) also included data for southern California. Although relative abundance increased slightly from the previous assessment (4.8% of unfished biomass), potential productivity (as evidenced from the steepness of the spawner/recruit relationship, which reflects the level of compensatory production at low stock sizes) appeared lower than previously thought, making for a more pessimistic outlook. Furthermore, the 2002 assessment revealed that although the 1999 year class was the strongest in several years, it was weak relative to the range of possibilities considered in the 1999 assessment.

The 2003 bocaccio assessment differed greatly from the 2002 assessment. It was affected by additional CalCOFI data that suggested an increasing abundance trend, more complete understanding of the 1999 year class and by a revised (lower) estimate of the natural mortality rate (MacCall 2003b). The results of these calculations suggested that recreational CPUE had increased dramatically in recent years and was at a record high level in central California north of Pt. Conception. The STAR Panel recommended the use of two assessment models as a means of bracketing uncertainty from the very different signals between the Triennial Survey and the recreational CPUE data. Following the STAR Panel meeting, MacCall presented a third "hybrid" model (STATc) that incorporated the data from all of the indices. The SSC recommended and the Council approved the use of this third modeling approach. This resulted in modest improvement in estimated stock size, but significantly affected the estimated productivity of the stock. These results had substantial effects on the rebuilding outlook for bocaccio, which, under the 2002 assessment, was not expected to rebuild within T_{MAX} even with no fishing related mortality. Total mortality in 2003 fisheries was restricted to less than 20 mt as a means of conserving the stock while minimizing adverse socioeconomic impacts to communities. The 2003 rebuilding analysis (MacCall 2003a), using the "hybrid" model, suggested the stock could rebuild to B_{MSY} within 25 years while sustaining an OY of approximately 300 mt in 2004.

The 2003 assessment was updated in 2005 (MacCall 2006b). The assessment used the original Stock Synthesis model (SS1), and did not develop an equivalent new Stock Synthesis 2 (SS2) version of the assessment. In addition to new length frequency data, new data points were included from both the triennial survey and the CALCOFI larval abundance index, both of which suggested an increasing upwards trajectory for the stock. The updated base-case (STATc) model forecasts a slow increase in biomass (spawning output), with depletion (current spawning output divided by unfished spawning output) increasing from a current value of 10.7% to approximately 20% over the coming decade. The estimated 2005 total biomass (age1+) was 8,561 mt. The 2004 exploitation rate of 0.0103 was well below the maximum fishing mortality threshold (F_{MSY}). The 2003 OY was set at 20 mt and the retained catch was about 12 mt. Including mortality of estimated discards, estimated total catch was 22 mt. The 2004 OY was set at 199 mt, but due to constraints of co-occurring depleted stocks, realized catch was 78 mt. Thus, recent management has shown substantial improvement in performance.

A bocaccio rebuilding plan was adopted by the Council at its April 2004 and submitted for incorporation in the groundfish FMP under Amendment 16-3. The rebuilding plan established a target rebuilding year of 2023 and the harvest control rule of F = 0.0498 (with a P_{MAX} of 70%). (It was later clarified in the 2005 Rebuilding Analysis (MacCall 2006a) that the target rebuilding year had been incorrectly stated in the rebuilding plan to be 2023; since the 2003 rebuilding analysis indicated that a 50% probability rebuilding would require 23 years, and that this assumed a beginning date of 2004 (the first simulated year), the correct value of T_{targ} is 2027.) Revision to the bocaccio rebuilding plan is under consideration by the Council and such changes to the groundfish FMP would be enacted through Amendment 16-4; the analysis of the action is a purpose of this EIS.

4.1.1.2 Canary Rockfish

Distribution and Life History

Canary rockfish (*Sebastes pinniger*) range from northern Baja California, Mexico, to southeastern Alaska (Boehlert and Kappenman 1980; Hart 1988; Love 1991; Miller and Lea 1972; Richardson and Laroche 1979). There is a major population concentration of canary rockfish off Oregon (Richardson and Laroche 1979). Canary rockfish primarily inhabit waters 91 m to 183 m (50 fm to 100 fm) deep (Boehlert and Kappenman 1980). In general, they inhabit shallow water when they are young, and deep water as adults (Mason 1995). Adult canary rockfish are associated with pinnacles and sharp drop-offs (Love, *et al.* 1991) and are most abundant above hard bottoms (Boehlert and Kappenman 1980). In the southern part of their range, canary rockfish appear to be associated with reefs (Boehlert 1980). In Central California, newly settled canary rockfish are first observed at the seaward sand-rock interface and farther seaward in deeper water (18 m to 24 m).

Canary rockfish off the West Coast exhibit a protracted spawning period from September through March, probably peaking in December and January off Washington and Oregon (Hart 1988; Johnson, *et al.* 1982). Female canary rockfish reach sexual maturity at roughly eight years of age. Like many members of Sebastes, canary rockfish are ovoviviparous, whereby eggs are internally fertilized within females, and hatched eggs are released as live young (Bond 1979; Golden and Demory 1984; Kendall, Jr. and Lenarz 1986). Canary rockfish are a relatively fecund species, with egg production being correlated with size (e.g., a 49-cm female can produce roughly 0.8 million eggs, and a female that has realized maximum length (approximately 60 cm) produces approximately 1.5 million eggs (Gunderson 1971)).

Very little is known about the early life history strategies of canary rockfish. The limited research that has been conducted indicates that larvae are strictly pelagic (near the ocean surface) for a short period of time and begin to migrate to demersal waters during the summer of their first year of life. Larvae develop into juveniles around nearshore rocky reefs, where they may congregate for up to three years (Boehlert 1980; Sampson 1996). Evaluations of length distributions by depth demonstrate an increasing trend in mean size of fish with depth (Methot and Stewart 2006). Since 1990, stock assessments have assumed a base natural mortality rate of 0.06 (94% adult annual survival when there is no fishing mortality). Due to the rarity of old females in both survey and catch data, female canary rockfish have long been assumed to have increasing natural mortality rates with age (Golden and Wood 1990).

Little is known about ecological relationships between canary rockfish and other organisms. Adult canary rockfish are often caught with bocaccio, sharpchin, yelloweye, and yellowtail rockfishes, and lingcod. Researchers have also observed canary rockfish associated with silvergray and widow rockfish. Young-of-the-year feed on copepods, amphipods, and young stages of euphausiids. Adult canary rockfish feed primarily on euphausiids, as well as pelagic shrimp, cephalopods, mesopelagic fishes and other prey {Phillips 1964; Brodeur and Pearcy 1984; Lee 2002}. Small canary rockfish are consumed by seabirds, Chinook salmon, lingcod, and marine mammals.

Stock Status and Management History

Canary rockfish have long been an important component of rockfish fisheries. The Council began to recommend increasingly restrictive regulations after an assessment in 1994 (Sampson and Stewart 1994) indicated that fishing rates were too high. In hindsight, work has estimated that the abundance of the canary rockfish stock dropped below $B_{40\%}$ (an abundance level used as a proxy for MSY) in about 1980, at which time the annual catch was more than double the current estimate of the MSY level. Harvest rates in excess of the current fishing mortality target for rockfish ($SPR_{50\%}$) is estimated to have begun in the late 1970s and persisted through 1999. Recent management actions appear to have curtailed the rate of removal such that overfishing has not occurred since 1999, and recent SPR values are in excess of 90%.

A 1999 stock assessment showed the stock had declined below the overfished level ($B_{25\%}$) in the northern area (Columbia and U.S. Vancouver management areas), (Crone, *et al.* 1999) and in the southern area (Conception, Monterey, and Eureka areas, (Williams, *et al.* 1999). The stock was declared overfished in January 2000. The first rebuilding analysis (Methot 2000) used results from the northern area assessment to project rates of potential stock recovery. The stock was found to have extremely low productivity, defined as production of recruits in excess of the level necessary to maintain the stock at its current, low level. Rates of recovery were highly dependent upon the level of recent recruitment, which could not be estimated with high certainty. The initial rebuilding OY for 2001 and 2002 was set at 93 mt based upon a 50% probability of rebuilding by the year 2057, a medium level for these recent recruitments, and maintaining a constant annual catch of 93 mt through 2002.

In 2002, a coastwide assessment of canary rockfish was conducted (Methot and Piner 2002), treating the stock as a single unit from the Monterey management area north through the U.S. Vancouver area. This was a departure from the methodologies of past assessments. Although there is some evidence of genetic separation of the northern and southern stocks (Boehlert and Kappenman 1980; Wishard, *et al.* 1980), the observed variability in growth rate by sex and area was not significantly different at small versus large spatial scales.

A critical uncertainty in past and current canary rockfish assessments is the lack of older, mature females in surveys and other assessment indices. There are two competing explanations for this observation. Older females could have a higher natural mortality rate, resulting in their disproportionate disappearance from the population. Alternatively, survey and fishing gears may be less effective at catching them, perhaps because older females are associated with habitat inaccessible to most trawl gear. If this is the case, then these fish (which, because of their higher spawning output, may make an important contribution to future recruitment) are part of the population, but remain poorly sampled. The most recent assessment assumed a linear increase in female natural mortality from 0.06 at age 6 to approximately 0.09 at age 14 (Methot and Stewart 2006). . The 2005 assessment was based on two equally plausible assessment models (as recommended by the SSC); one with differential male and female gear selectivities and one without gender-specific selectivities. The approved canary rockfish rebuilding analysis blended the two models by alternately re-sampling between the two input parameter sets. Both laboratory-based physiological studies and habitat-specific studies of the distribution of older male and female canary rockfish could better inform managers of the significance of these patterns and assumptions.

A full canary rockfish assessment was done in 2005 (Methot and Stewart 2006). As explained above, the assessment was based on two equally plausible models. In the base model (differential male-female selectivity) SB_0 is estimated to be 34,798 mt, resulting in a depletion level of 5.7%. In the alternate model (no difference in selectivity) SB_0 is estimated to be 33,872 mt, with a depletion level of 11.3%. The steepness of the spawner-recruitment relationship, which largely determines the rate of increase in recruitment as the stock rebuilds, was estimated to be 0.33 in the base model, and 0.45 in the alternate model,

A new rebuilding analysis was also completed in 2005 (Methot 2006). Using the integrated ("blended") model explained above, the analysis estimated SB_0 to be 34,155 mt of female spawning biomass at the beginning of 2005 (corresponding to a depletion level of 9.4%). In this analysis, it was noted that following the constant harvest rate established under the canary rockfish rebuilding plan would produce an OY of 43 mt in 2007 and has a 57.4% probability of rebuilding by the current Ttarget (2074) and a 58.5% probability of rebuilding by the current Tmax (2076). The new structure of the analysis allowed for the incorporation of three sources of uncertainty, rather than one; the result of this is that it would take a large change in the constant harvest rate harvest rate (and short-term OY) to make a large change in the probability of rebuilding. For example, the harvest rate that would produce a 50% probability of rebuilding by the target rebuilding year (2074) is twice the level that would produce a 60% probability of rebuilding by T_{max} (2076).

A canary rockfish rebuilding plan was adopted by the Council in June 2003 and submitted for incorporation in the groundfish FMP under Amendment 16-2. The rebuilding plan established a target rebuilding year of 2074 and the harvest control rule of F = 0.022 (with a P_{MAX} of 60%). Revision to the canary rockfish rebuilding plan is under consideration by the Council and such changes to the groundfish FMP would be enacted through Amendment 16-4; the analysis of the action is a purpose of this EIS.

4.1.1.3 Cowcod

Distribution and Life History

Relatively little is known about cowcod (*Sebastes levis*), a species of large rockfish that ranges from Ranger Bank and Guadalupe Island in central Baja California to Usal, Mendocino County, California (Miller and Lea 1972), and may infrequently occur as far north as Newport, Oregon.

Love et al. (Love, *et al.* 2002) and Barnes (Barnes 2001) described cowcod distribution and life history. Cowcod are most abundant in waters off central and southern California. They range from 22-491 m in depth and are considered to be parademersal (transitional between a midwater pelagic and benthic species). Adults are commonly found at depths of 180 m to 235 m and juveniles are most often found in 30 m to 149 m of water (Love, *et al.* 1990).

MacGregor (MacGregor 1986) found that larval cowcod are almost exclusively found in Southern

California and may occur many miles offshore. Cowcod have always been among the rarest of *Sebastes* species larvae identifiable to species in the southern California Bight (the core CalCOFI survey area), with estimates of abundance as much as two orders of magnitude less than more abundant species (Moser, *et al.* 2000). Juveniles occur over sandy bottom areas, and solitary ones have been observed resting within a few centimeters of soft-bottom areas where gravel or other low relief was found (Allen 1982). Young-of-the-year have been observed on fine sand and clay sediment as well as oil platform shell mounds and other complex bottom features at depths ranging from 22-122 fm (40-224 m). Adult cowcod are primarily found over high relief rocky areas (Allen 1982). They are generally solitary, but occasionally aggregate (Love, *et al.* 1990). Although cowcod are generally not migratory, they may move, to some extent, to follow food (Love 1991).

Cowcod can live to be at least 55 years old. Maximum size is 94 cm (37 in) and 13 kg (28.5 lb). The instantaneous rate of natural mortality is believed to be 0.08 (92% adult annual survival when there is no fishing mortality) (Butler, *et al.* 1999). Average size at age of mature females is similar to males. Females reach 90% of their maximum expected size by 40 years (Butler, *et al.* 1999).

Cowcod are ovoviviparous, and large females may produce up to three broods per season (Love, *et al.* 1990). Spawning peaks in January in the Southern California Bight (MacGregor 1986). Fecundity is dependent on size and ranges from 181,000 to 1,925,000 eggs. Larvae emerge at about 5.0 mm (MacGregor 1986).

Little is known about ecological relationships between cowcod and other organisms. Small cowcod feed on planktonic organisms such as copepods. Juveniles eat shrimp and crabs, and adults eat fish, octopus, and squid (Allen 1982). Adults consume a wide range of prey items, but are primarily piscivorous (Love, *et al.* 2002).

<u>Stock Status and Management History</u>

While cowcod are not a major component of the groundfish fishery, they are highly desired by both recreational and commercial fishers because of their bright color and large size. The cowcod stock in the Conception area was first assessed in 1998 (Butler, *et al.* 1999). Abundance indices decreased approximately tenfold between the 1960s and the 1990s, based on commercial passenger fishing vessel (CPFV) logs (Butler, *et al.* 1999). Recreational and commercial catch also declined substantially from peaks in the 1970s and 1980s, respectively.

NMFS declared cowcod in the Conception and Monterey management areas overfished in January 2000, after Butler et al. (Butler, *et al.* 1999) estimated the 1998 spawning biomass to be at 7% of B_0, well below the 25% overfishing threshold. Because cowcod is a fairly sedentary species, closed areas were established in 2002 to reduce cowcod mortality. These Cowcod Conservation Areas, located in the Southern California Bight, were selected due to their high density of cowcod; while fishing for nearshore rockfish and pelagic species is allowed within the CCAs, fishing with most gear types that could catch cowcod is prohibited.

A cowcod rebuilding analysis was completed in 2003 which validated the assumption that non-retention regulations and area closures had been effective in constraining cowcod fishing mortality (Butler, *et al.* 2003). These encouraging results were based on cowcod fishery-related landings in recreational and commercial fisheries, although the assessment included discard information only with respect to CPFV observations (which indicated negligible discards in that sector). This rebuilding review pointed out a common problem among the analyses of depleted species: reliance on landings (fishery-dependent) data for providing relative abundance values becomes increasingly difficult as the allowable catch is decreased and fishery observer data remains low. Monitoring stock status and recovery thus becomes increasingly difficult in the absence of fishery-independent surveys.

As in the 1999 assessment, the 2005 cowcod assessment (Piner, *et al.* 2006) considered only the cowcod population in Southern California Bight (from the US-Mexico border north to Point Conception) population, as this is the area in which cowcod are most abundant, adult habitat is most common, and catches are highest.. The 2005 assessment used only two data sources, the CPFV time series and the visual survey estimate data. The model was developed in Stock Synthesis 2, and although the base model estimated only three parameters (two of which were "nuisance parameters," the other was equilibrium recruitment), the STAR Panel determined that this simplicity was appropriate given the paucity of data. The assessment provides a set of results corresponding to three different values for assumed steepness (h), the key parameter in the S-R relationship (h=0.4, 0.5, and 0.6). Although the model with assumed h=0.5 was deemed the most likely by the STAR panel, there is still considerable uncertainty around both this value and the overall results of the assessment itself. The assessment estimated that the 2005 spawning biomass was 18% of unfished levels, within a range of 14 to 21% depending on the value assumed for steepness, a considerably more optimistic result than the 1999 assessment.

The rebuilding analysis (Piner 2006) estimated a new T_{max} of 2074, 25 years earlier than the 2099 date estimated previously (Butler and Barnes 2000). It is noted in the rebuilding analysis, however, that rebuilding scenarios are extremely uncertain for this data-poor species, particularly with respect to steepness. Moreover, there is widespread concern about the ability to monitor the stock, and consequently to evaluate progress towards rebuilding in the future.

A cowcod rebuilding plan was adopted by the Council in April 2004 and submitted for incorporation in the groundfish FMP under Amendment 16-3. The rebuilding plan established a target rebuilding year of 2090 and the harvest control rule of F = 0.009 (with a P_{MAX} of 60%). Revision to the cowcod rebuilding plan is under consideration by the Council and such changes to the groundfish FMP would be enacted through Amendment 16-4; the analysis of the action is a purpose of this EIS.

4.1.1.4 Darkblotched Rockfish

<u>Distribution and Life History</u>

Darkblotched rockfish (*Sebastes crameri*) are found from Santa Catalina Island off Southern California to the Bering Sea (Miller and Lea 1972; Richardson and Laroche 1979). They are most abundant from Oregon to British Columbia. Off Oregon, Washington, and British Columbia, darkblotched rockfish occur primarily on the outer shelf and upper slope (Richardson and Laroche 1979). Distinct population groups have been found off the Oregon coast between 44°30' N latitude and 45°20' N latitude (Richardson and Laroche 1979).

Young-of-the-year recruit to bottom at depths ranging from 55-200 m after spending up to five months as pelagic larvae and juveniles in offshore waters (Love, *et al.* 2002). Off central California, young darkblotched rockfish recruit to soft substrate and low (<1 m) relief reefs (Love 1991). Darkblotched rockfish make limited migrations after they become adults (Gunderson 1977). Adults occur in depths of 25 m to 600 m, and 95% are found between 50 m and 400 m (Allen and Smith 1988). Adults are often found on mud near cobble or boulders. Fish tend to move to deeper waters as they age.

Maximum age of darkblotched rockfish is 64 years, and maximum size is 58 cm (23 in) and 2.3 kg (5.1 lb). Rogers, et al. (Rogers, *et al.* 2000) estimated that the instantaneous rate of natural mortality was about 0.05 (95% adult annual survival when there is no fishing mortality). Females tend to be larger than males of the same age, and reach 90% of their maximum expected size by 13 years (Rogers, *et al.* 2000).

Darkblotched rockfish are ovoviviparous (Nichol and Pikitch 1994). Insemination of female darkblotched rockfish occurs from August to December, and fertilization and parturition occur from December to March off Oregon and California, and primarily in February off Oregon and Washington (Hart 1988; Nichol and Pikitch 1994; Richardson and Laroche 1979). Fecundity is dependent on size and ranges from 20,000 to 610,000 eggs.

Little is known about ecological relationships between darkblotched rockfish and other organisms. Pelagic juveniles feed on planktonic organisms such as copepods. Adults are often caught with other fish such as Pacific ocean perch and splitnose rockfish. Midwater animals such as euphausiids and amphipods dominate the diet of adult fish. Albacore and Chinook salmon consume pelagic juveniles (Hart 1988). Little is known about predation of adults.

Stock Status and Management History

Darkblotched rockfish has always been caught primarily with commercial trawl gear, as part of a complex of slope rockfish. Catch of darkblotched rockfish very likely first became significant in the mid-to-late 1940's, during which time it accelerated dramatically due to increases in gear efficiency and demand (Harry and Morgan 1963; Scofield 1948). During the mid 1960's to mid 1970's darkblotched rockfish were caught by both domestic and foreign fleets (Rogers 2003b). Domestic landings rose from late 1970's until the late 1980's, although limits on rockfish catch were first instituted in 1983, when darkblotched was rockfish managed as part of a group of around 50 species (designated as the Sebastes complex) (Rogers, *et al.* 2000). During the 2000's, progressive steps have been taken to reduce the catch of darkblotched rockfish, following the declaration of its overfished status in 2001. However, management goals (ABC or OY) for darkblotched rockfish were exceeded from 1997 through 2002. Although the 1996 assessment produced an ABC calculation for darkblotched, from 1997 through 2000 that amount was combined with yields for other species for purposes of managing a complex of species to combined ABC and OY amounts. Separate ABCs and OYs for darkblotched have been specified since 2001; however the species continues to be managed as part of a slope rockfish trip limit. Based on discard estimates now available from observer and logbook data for 2000-2003, the species-specific ABC was exceeded during 1997-2000 and the OY was exceeded in 2001 and 2002. However in 2004, the OY was not exceeded (based on the final estimate of total mortality, including discards).

Rogers et al. (Rogers, *et al.* 2000) completed an assessment in 2000 that employed a more extensive length-based stock synthesis modeling than had been used in the previous (1996) assessment (which had followed a simple F=M methodology verified by limited modeling using length based stock synthesis). This assessment determined the stock was at 14-31% of its unfished level, depending on assumptions regarding the historic catch of darkblotched rockfish in the foreign fishery from 1965-1978. More than any other issue of uncertainty, the uncertainty of historical foreign catch compositions had the greatest influence on the assessment model's calculation of stock status; as the proportion of the overall catch assumed to be composed of darkblotched was increased in the model, the estimates of B_0 also increased, bringing the current stock size estimate closer to a overfished level. Four accepted model runs varied the assumed foreign catch proportion from 0%-20%, which resulted in significant differences in B_0 and the spawning index. Only one of those model runs (assuming 0% foreign catch of darkblotched) estimated the stock was not overfished. The STAR Panel (PFMC 2000) and the GMT were unable to resolve the uncertainty in foreign catch composition. Therefore, the Stock Assessment Team's (STAT) assumption that 10% of foreign catch was comprised of darkblotched (Rogers, *et al.* 2000) was accepted, leading to the conclusion that the spawning stock biomass was 22% of its unfished level.

Given that the stock was estimated to be below the overfished threshold ($B_{25\%}$), NMFS declared darkblotched rockfish to be overfished in 2001; the same year, the Council adopted a rebuilding analysis for the stock (Methot and Rogers 2001). On the earlier recommendation of the SSC (June 2001 Council meeting), the authors incorporated results of the 2000 triennial slope trawl survey conducted by the Alaska Fishery Science Center and modeled a more recent time series of recruitments. Incorporating these data resulted in a downward revision of the estimated recruitment and abundance, throughout the time series, compared to what had been used in the Rogers et al. (Rogers, *et al.* 2000) assessment. For example, the mean recruitment in the 1983-1996 period was estimated to be about 67% of earlier estimates. Overall, this led to a revised estimate of spawning stock biomass at the beginning of 2002 of 14% of its unfished level. The minimum time to rebuild (T_{MIN}) in the absence of fishing was estimated to be 14 years with a median rebuilding year of 2014. The maximum time to rebuild (T_{MAX}) in accordance with the National Standard 1 Guidelines was 47 years (2047).

An assessment update for darkblotched rockfish, completed in 2003, suggested that the stock had not changed significantly from the previous assessment, but there was evidence of strong recent recruitment (Rogers 2003a). However these high numbers of fish added to the exploitable stock had not been validated by indices used in the assessment, so the spawning stock biomass was determined to be at 11% of it unfished level ($B_{11\%}$). New information in this update included revised estimates of the darkblotched rockfish catch in historical foreign fisheries, new fishery length and age composition information, a new Triennial Survey data point, and new slope survey data. Unresolved data discrepancies between these data sources, related to length and age composition, limited the amount of new data used in this assessment update. The SSC STAR Lite Panel requested progressive inclusion of 1997-1999, 2000, and 2001 recruitment estimates (Ralston, *et al.* 2003). Risk of error progressively increased from including those recruitment estimates because they were based on increasingly limited data. Rebuilding results were sensitive to the high 2000 and 2001 recruitment estimates and including them allowed much greater 2004 OYs because those recruits enter the fishery and help rebuild the stock before the maximum allowable year; based on the recommendations of the SSC STAR Lite Panel, the assessment was amended to include the recruitment estimate for 2000.

The 2005 assessment (Rogers 2006) was a full assessment. It incorporated data from a large number of sources, allowing for the estimation of landings back to 1928. The major sources of uncertainty in this stock assessment include: 1) the assumed natural mortality rate (M), 2) the age-length relationship, 3) noisy survey indices and length compositions due to a few large survey catches which tend to have larger than average fish, 4) steepness (h) parameter for the spawner-recruit curve, and 5) the amount of historical landings prior to 1978. Uncertainty in the model results were explored primarily through examination of alternative natural mortality values. Estimates for M varied depending on the calculation method chosen, ranging from 0.025-0.5 (based on Hoenig's method (Hoenig 1983)) to 0.107 (from a linear relationship with reproductive effort). Investigating the range from 0.05 to 0.10, Rogers found that the best fitting M value conflicted among the different data sources; the primary source of this conflict was the AFSC slope survey. The STAR panel determined that the confidence intervals produced within the models underestimated uncertainty (Ralston, *et al.* 2006). The Panel concluded that uncertainty could be bracketed by assuming that an M value of 0.07 is likely (base model), while 0.05 and 0.09 are the unlikely extremes.

Higher natural mortality values bring about calculations of smaller historical declines in stock abundance and larger current biomass levels. Applying the STAR Panel selected value of M=0.07, the assessment determined the biomass of age 1+ darkblotched rockfish to have declined by 84% from 1928 to 1999; since 1999, the age 1+ biomass has more than doubled. There were several strong recruitments in recent years, even though spawning stock has been at a low level. The 1999 year class is the strongest since the 1980 year class. The estimated spawning stock biomass depletion at the beginning of 2005 was 16% of unfished biomass ($B_{16\%}$).

A darkblotched rockfish rebuilding plan was first adopted by the Council in June 2003 and submitted for incorporation in the groundfish FMP under Amendment 16-2. The rebuilding plan established a target rebuilding year of 2030 and the harvest control rule (constant fishing rate) of F = 0.027 (with a probability of rebuilding by T_{MAX} of 80%). Applying the results from the 2003 rebuilding analysis {(Rogers 2003a)}, the harvest control rule was changed beginning in 2004 via a regulatory amendment. The new harvest control rule of F = 0.032 was used to set annual darkblotched OYs in 2004-2006 and resulted in an updated P_{MAX} of >90%. Revision to the darkblotched rockfish rebuilding plan is under consideration by the Council and such changes to the groundfish FMP would be enacted through Amendment 16-4; the analysis of the action is a purpose of this EIS.

4.1.1.5 Pacific Ocean Perch

Distribution and Life History

Pacific ocean perch (POP, *Sebastes alutus*) are found from La Jolla, California to the western boundary of the Aleutian Archipelago (Eschmeyer, *et al.* 1983; Gunderson 1971; Ito, *et al.* 1986; Miller and Lea 1972), but are common from Oregon northward (Eschmeyer, *et al.* 1983). They primarily inhabit waters of the upper continental slope (Dark and Wilkins 1994) and are found along the edge of the continental shelf (Archibald, *et al.* 1983). Pacific ocean perch occur as deep as 825 m, but usually are at 100 m to 450 m and along submarine canyons and depressions (NOAA 1990). Throughout their range, POP are generally associated with gravel, rocky, or boulder type substrate (Ito 1986). Larvae and juveniles are pelagic; subadults and adults are benthopelagic (living and feeding on the bottom and in the water column). Adults form large schools 30 m wide, to 80 m deep, and as much as 1,300 m long (NOAA 1990). They also form spawning schools (Gunderson 1971). Juvenile POP form ball-shaped schools near the surface or hide in rocks (NOAA 1990).

Pacific ocean perch winter and spawn in deeper water (>275 m). In the summer (June through August) they move to feeding grounds in shallower water (180 m to 220 m) to allow gonads to ripen (Archibald, *et al.* 1983; Gunderson 1971; NOAA 1990). They are slow-growing and long-lived; the maximum age has been estimated at about 98 years (Heifetz, *et al.* 2000). The can grow up to about 54 cm and 2 kg (Archibald, *et al.* 1983; Beamish 1979; Eschmeyer, *et al.* 1983; Ito, *et al.* 1986; Mulligan and Leaman 1992; NOAA 1990). POP are carnivorous. Larvae eat small zooplankton. Small juveniles eat copepods, and larger juveniles feed on euphausiids (krill). Adults eat euphausiids, shrimps, squids, and small fishes. Immature fish feed throughout the year, but adults feed only seasonally, mostly April through August (NOAA 1990). POP predators include sablefish and Pacific halibut.

Stock Status and Management History

POP were harvested exclusively by U.S. and Canadian vessels in the Columbia and Vancouver INPFC areas prior to 1965. Large Soviet and Japanese factory trawlers began fishing for POP in 1965 in the Vancouver area and in the Columbia area a year later. Intense fishing pressure by these foreign fleets occurred from 1966 to 1975. The MSA, passed by Congress in 1976, ended foreign fishing within 200 miles of the United States coast.

The POP resource off the West Coast was overfished before implementation of the groundfish FMP in 1982, and Council actions to conserve the resource likewise predate the FMP. Large removals of POP in the foreign trawl fishery, followed by significant declines in catch and abundance, led the Council to limit harvest beginning in 1979. A 20-year rebuilding plan for POP was adopted in 1981. Rebuilding under this original plan was largely influenced by a cohort analysis of 1966-1976 catch and age composition data (Gunderson 1979), updated with 1977-1980 data (Gunderson 1981), and an evaluation of trip limits as a management tool (Tagart, *et al.* 1980). This was the first time trip limits were used by the Council to discourage targeting and overharvest of an overfished stock, and it remains a management strategy in use today in the West Coast groundfish fishery. In addition to trip limits, the Council significantly lowered the OY for POP. After twenty years of rebuilding under the original plan, the stock stabilized at a lower equilibrium than estimated in the pre-fishing condition. While continuing stock decline was abated, rebuilding was not achieved as the stock failed to increase in abundance to B_{MSY}.

Ianelli (Ianelli and Zimmerman 1998) estimated POP female spawning biomass in 1997 to be at 13% of its unfished level, thereby confirming that the stock was overfished. NMFS formally declared POP overfished in March 1999 after the groundfish FMP was amended to incorporate the tenets of the Sustainable Fisheries Act. The Council adopted and NMFS enacted more conservative management measures in 1999 as part of a redoubled rebuilding effort.

A 2000 POP assessment suggested the stock was more productive than originally thought (Ianelli, *et al.* 2000). A revised POP rebuilding analysis was completed and adopted by the Council in 2001 (Punt and Ianelli 2001). This analysis estimated a T_{MIN} of 12 years and a T_{MAX} of 42 years. It was noted in the rebuilding analysis that the ongoing retrospective analysis of historic foreign fleet catches was likely to change projections of POP rebuilding.

The 2003 POP assessment (Hamel, *et al.* 2003) incorporating updated survey and fishery data including the retrospective of foreign fleet catches (Rogers 2003b). The assessment covered areas from southern Oregon to the U.S. border with Canada, the southern extent of POP distribution. The overall conclusion was that the stock was relatively stable at approximately 28% of its unfished biomass ($B_{28\%}$). Of all the changes and additions to the data, the historical catch estimates had the greatest effect, resulting in lower estimates of both equilibrium unfished biomass (B_0) and maximum sustainable yield.

Many cases were presented in the 2003 rebuilding analysis and, based on SSC advice, the Council chose the one based on the full Bayesian posterior distribution, in which recruits were re-sampled to project future recruitment. Re-sampling recruits rather than recruits per spawner was recommended because only the southern fringe of the stock occurs in waters off the U.S. West Coast. One would want to resample recruits per spawner if measured recruitment is a function of measured stock size. However, it is unlikely that the recruitment measured off the U.S. West Coast is wholly from the portion of the parental stock occurring in these same waters.

The 2005 assessment (Hamel 2006) is an update and uses the same model as in the 2003 assessment, a forward projection age-structured model (Hamel, *et al.* 2003). The assessment incorporates new data and changes to the data used in the previous assessment. As was the case in the previous assessment, a number of sources of uncertainty are explicitly accounted for, such as that associated with natural mortality, the parameters of the stock-recruitment relationship, and catchability coefficients for the different surveys. However, sensitivity analyses based upon alternative model structures/data set choices suggested that the overall uncertainty may be greater than that predicted by a single model specification, as was also the case in the 2003 assessment. There are also other sources of uncertainty that are not included in the current model. These include the degree of connection between the stocks of Pacific ocean perch off British Columbia and those in PFMC waters; the effect of the PDO, ENSO and other climatic variables on recruitment, growth and survival of Pacific ocean perch; gender differences in growth and survival; a possible non-linear relationship between individual spawner biomass and effective spawning output and more complicated relationship between age and maturity. In order to provide the Council with a means to incorporate this uncertainty into its decision making, Hamel undertook the following analysis: he estimated, based on a reference case, the Bayesian posterior distributions for key management and rebuilding variables. These distributions best reflect the uncertainty of the assessment's analysis, and are suitable for probabilistic decision making. The assessment estimated the following values based on the maximum of the posterior density function (MPD) point estimate: spawning biomass depletion at the start of 2005 equal to 23.4% and a 2007 ABC equal to 746 mt. Overfishing for POP is considered to be occurring when F is above F_{MSY} = 0.0310 according to the current assessment base model. The 2005 rebuilding analysis (Hamel and Hame 2006) re-estimated T_{MIN} to be 2015.

A Pacific ocean perch rebuilding plan was adopted by the Council in June 2003 and submitted for incorporation in the groundfish FMP under Amendment 16-2 (approved by NMFS in January 2004). The rebuilding plan established a target rebuilding year of 2027 and a harvest control rule of F = 0.0082 (with a P_{MAX} of 70%). The 2003 assessment (Hamel, *et al.* 2003) and rebuilding analysis (Punt, *et al.* 2003) was used to amend the harvest control rule and set annual POP OYs for the 2004-2006 period. The amended harvest control rule was F = 0.0257, which increased the estimated P_{MAX} to slightly greater than 70%. Revision to the Pacific ocean perch rebuilding plan is under consideration by the Council and such changes to the groundfish FMP would be enacted through Amendment 16-4; the analysis of the action is a purpose of this EIS.

4.1.1.6 Widow Rockfish

Distribution and Life History

Widow rockfish (*Sebastes entomelas*) range from Albatross Bank off Kodiak Island to Todos Santos Bay, Baja California, Mexico (Eschmeyer, *et al.* 1983; Miller and Lea 1972; NOAA 1990). They occur over hard bottoms along the continental shelf (NOAA 1990) and prefer rocky banks, seamounts, ridges near canyons, headlands, and muddy bottoms near rocks. Large widow rockfish concentrations occur off headlands such as Cape Blanco, Cape Mendocino, Point Reyes, and Point Sur. Adults form dense, irregular, midwater and semi-demersal schools deeper than 100 m at night and disperse during the day (Eschmeyer, *et al.* 1983; NOAA 1990; Wilkins 1986). All life stages are pelagic, but older juveniles and adults are often associated with the bottom (NOAA 1990). All life stages are fairly common from Washington to California (NOAA 1990). Pelagic larvae and juveniles co-occur with yellowtail rockfish, chilipepper, shortbelly rockfish, and bocaccio larvae and juveniles off Central California (Reilly, *et al.* 1992).

Widow rockfish are ovoviviparous, have internal fertilization, and brood their eggs until released as larvae {NOAA 1990; Ralston et al. 1996a; Reilly et al. 1992}. Mating occurs from late fall-early winter. Larval release occurs from December through February off California, and from February through March off Oregon. Juveniles are 21 mm to 31 mm at metamorphosis, and they grow to 25 cm to 26 cm over three years. Age and size at sexual maturity varies by region and sex, generally increasing northward and at older ages and larger sizes for females. Some mature in three years (25 cm to 26 cm), 50% are mature by four years to five years (25 cm to 35 cm), and most are mature in eight years (39 cm to 40 cm) (NOAA 1990). The maximum age of widow rockfish is 28 years, but rarely over 20 years for females and 15 years for males (NOAA 1990). The largest size is 53 cm and about 2.1 kg (Eschmeyer, *et al.* 1983; NOAA 1990).

Widow rockfish are carnivorous. Adults feed on small pelagic crustaceans, midwater fishes (such as age-one or younger Pacific whiting), salps, caridean shrimp, and small squids (Adams 1987; NOAA 1990). During spring, the most important prey item is salps, during the fall fish are more important, and during the winter widow rockfish primarily eat sergestid shrimp (Adams 1987). Feeding is most intense in the spring after spawning (NOAA 1990). Pelagic juveniles are opportunistic feeders, and their prey consists of various life stages of calanoid copepods, and euphausiids (Reilly, *et al.* 1992).

Stock Status and Management History

Widow rockfish are an important commercial species from British Columbia to central California, particularly since 1979, when Oregon trawl fisherman demonstrated the ability to make large catches at night using midwater trawl gear. Many more participants have entered the fishery since that time, and landings of widow rockfish have increased rapidly (Love, *et al.* 2002). Widow rockfish are a minor component of the recreational groundfish fisheries.

Williams (Williams, *et al.* 2000) assessed the coastwide stock of widow rockfish in 2000. The spawning output level (8,223 mt eggs), based on that assessment and a revised rebuilding analysis (Punt and MacCall 2002) adopted by the Council in June 2001, was at 23.6% of the unfished level (33,490 mt eggs) in 1999.

The 2003 assessment (He, *et al.* 2003b) concluded that the widow rockfish stock size was at 24.65% of the unfished biomass, but indicated that stock productivity was considerably lower than previously thought. Data sparseness was a significant problem in this widow rockfish assessment (Conser, *et al.* 2003; He, *et al.* 2003b).

A full assessment was completed in 2005 for widow rockfish (He, *et al.* 2006). In addition to including the new data from 2003 to 2004, this assessment added an index of relative abundance based on the triennial survey data and estimated the power coefficient of the midwater juvenile survey index instead of using a fixed value. The base model estimated that spawning biomass declined steadily since the early 1980s and that spawning output in 2004 was 31% of the unexploited level, above the Council's overfished threshold. Further, spawning output in the base model was estimated to have never dropped below the 25% overfished threshold. Alternative model runs, which were considered to be only slightly less plausible than the base model, however, indicated that the stock had been below $B_{25\%}$. The 2005 rebuilding analysis indicated that the stock was much closer to reaching a rebuilt biomass than previously estimated: under the current rebuilding analysis T_{MIN} is estimated to be 2013, compared to a T_{MIN} of 2026 in the 2003 analysis (He, *et al.* 2003a).

Using estimates from the 2003 widow rockfish rebuilding analysis (He, *et al.* 2003a), the Council adopted a rebuilding plan in April 2004 that was subsequently incorporated into the groundfish FMP under Amendment 16-3. The rebuilding plan established a target rebuilding year of 2038 and a harvest control rule of F = 0.0093 (with a P_{MAX} of 60%). Revision to the widow rockfish rebuilding plan is under consideration by the Council and such changes to the groundfish FMP would be enacted through Amendment 16-4; the analysis of the action is a purpose of this EIS.

4.1.1.7 Yelloweye Rockfish

Distribution and Life History

Yelloweye rockfish (*Sebastes ruberrimus*) range from the Aleutian Islands, Alaska, to northern Baja California, Mexico, and are common from Central California northward to the Gulf of Alaska (Eschmeyer, *et al.* 1983; Hart 1988; Love 1991; Miller and Lea 1972; O'Connell and Funk 1986). Yelloweye rockfish occur in water 25 m to 550 m deep with 95% of survey catches occurring from 50 m to 400 m (Allen and Smith 1988). Yelloweye rockfish are bottom dwelling, generally solitary, rocky reef fish, found either on or just over reefs (Eschmeyer, *et al.* 1983; Love 1991; Miller and Lea 1972;

O'Connell and Funk 1986). Boulder areas in deep water (>180 m) are the most densely populated habitat type, and juveniles prefer shallow-zone broken-rock habitat (O'Connell and Carlile 1993). They also reportedly occur around steep cliffs and offshore pinnacles (Rosenthal, *et al.* 1982). The presence of refuge spaces is an important factor affecting their occurrence (O'Connell and Carlile 1993).

Yelloweye rockfish are ovoviviparous and give birth to live young in June off Washington (Hart 1988). The age of first maturity is estimated at six years and all are estimated to be mature by eight years (Wyllie Echeverria 1987). They can grow to 91 cm (Eschmeyer, *et al.* 1983; Hart 1988) and males and females probably grow at the same rates (Love 1991; O'Connell and Funk 1986). The growth rate levels off at approximately 30 years of age (O'Connell and Funk 1986) but they can live to be 114 years old (Love 1991; O'Connell and Funk 1986). Yelloweye rockfish are a large predatory reef fish that usually feeds close to the bottom (Rosenthal, *et al.* 1982). They have a widely varied diet, including fish, crabs, shrimps and snails, rockfish, cods, sand lances, and herring (Love 1991). Yelloweye rockfish have been observed underwater capturing smaller rockfish with rapid bursts of speed and agility. Off Oregon the major food items of the yelloweye rockfish include cancroid crabs, cottids, righteye flounders, adult rockfishes, and pandalid shrimps (Steiner 1978). Quillback and yelloweye rockfish have many trophic features in common (Rosenthal, *et al.* 1982).

Stock Status and Management History

The first ever yelloweye rockfish stock assessment was conducted in 2001 (Wallace 2002). This assessment incorporated two area assessments: one from Northern California using CPUE indices constructed from Marine Recreational Fisheries Statistical Survey (MRFSS) sample data and CDFG data collected on board commercial passenger fishing vessels, and the other from Oregon using Oregon Department of Fish and Wildlife (ODFW) sampling data. The assessment concluded yelloweye rockfish stock biomass in 2001 was at about 7% of unexploited biomass in Northern California and 13% of unexploited biomass in Oregon. The assessment revealed a thirty-year declining biomass trend in both areas with the last above average recruitment occurring in the late 1980s. The assessment's conclusion that yelloweye rockfish biomass was well below the 25% of unexploited biomass threshold for overfished stocks led to this stock being separated from the rockfish complexes in which it was previously listed. Until 2002, when yelloweye rockfish were declared overfished, they were listed in the "remaining rockfish" complex on the shelf in the Vancouver, Columbia, and Eureka INPFC areas and the "other rockfish" complex on the shelf in the Monterey and Conception areas. As with the other overfished stocks, yelloweye rockfish harvest is now tracked separately.

In June 2002 the SSC recommended that managers should conduct a new assessment incorporating Washington catch and age data. This recommendation was based on evidence that the biomass distribution of yelloweye rockfish on the West Coast was centered in waters off Washington and that useable data from Washington were available. Based on that testimony, the Council recommended completing a new assessment in the summer of 2002, before a final decision was made on 2003 management measures. Methot et al. (Methot, *et al.* 2003) did the assessment, which was reviewed by a STAR Panel in August 2002. The assessment result was much more optimistic than the one prepared by Wallace (Wallace 2002), largely due to the incorporation of Washington fishery data. While the overfished status of the stock was confirmed (24% of unfished biomass), Methot et al. (Methot, *et al.* 2003) provided evidence of higher stock productivity than originally assumed. The assessment also treated the stock as a coastwide assemblage. This assessment was reviewed and approved by the SSC and the Council at the September 2002 Council meeting.

A yelloweye rockfish assessment was among those completed as part of the 2005 assessment cycle (Wallace, *et al.* 2005). While the assessment was scheduled to be an update, it migrated to a new modeling platform, which is allowed only in full assessments. At their November 2005 meeting, the

Council heard testimony that there were additional data sources that might inform a yelloweye assessment, but had not been included due to the terms of reference constraints on update assessments. Therefore, the Council asked the assessment team to undertake a further, full assessment effort that would include all possible sources of information.

The re-assessment of the stock (Wallace, *et al.* 2006) used the Stock Synthesis 2 model that had been introduced in the 2005 assessment. The assessment updated all data sources in the previous model, including a substantial effort to examine multiple data sources to further define and extend the historical catch stream. New data sources were also included (WDFW 2002 submersible survey and the International Pacific Halibut Commission annual longline survey). Further revisions in the assessment included reducing natural mortality from 0.045 to 0.036 and increasing steepness from 0.437 to 0.45. The assessment model treated the West Coast population of yelloweye rockfish in two different ways: as a single coastwide stock (consistent with the 2002 and 2005 assessments) and as separate and distinct sub-populations for the States of California, Oregon and Washington. The assessment is considered to be data poor, however the sparseness of data is particularly acute in the Washington model. As such, the SSC recommended to the Council that the coastwide model be used for setting the optimum yield (OY) of the stock. During the March 2006 meeting, the Council deliberated over which of the past assessments represented the best available science for use in decision-making; the Council selected the coastwide model from the 2006 assessment. Under this model, the 2006 coastwide biomass is calculated to be at 17.7% of the unfished level (with depletion rates of 8.5%, 21.8% and 20.8% for California, Oregon and Washington respectively). The rebuilding analysis (Tsou and Wallace 2006) re-estimated other parameters: Tmax increased to 2096 with a harvest control rule of F=0.0101, and a projected OY in 2007 of 12.6 mt.

The yelloweye assessment can be categorized as quite data poor; it relies primarily on recreational CPUE information with varying data gaps even in those data series among the three states. Very little fishery independent information exists. Additionally, since retention of yelloweye has been prohibited in recreational fisheries; even the limited CPUE series that do exist were truncated in 2001. In order to resolve the uncertainty in the current assessment as well as to track rebuilding, it will be necessary to implement additional strategies to collect yelloweye abundance information.

In 2004, a yelloweye rebuilding plan was adopted by the Council and submitted for incorporation in the groundfish FMP under Amendment 16-3. The rebuilding plan established a target rebuilding year of 2058 and a harvest control rule of F = 0.0153 (with a P_{MAX} of 80%). Revision to the yelloweye rockfish rebuilding plan is under consideration by the Council and such changes to the groundfish FMP would be enacted through Amendment 16-4; the analysis of the action is a purpose of this EIS.

4.1.2 Precautionary Zone Groundfish Species

Groundfish species managed under the FMP with an estimated spawning stock biomass less than 40% of its unfished level, but greater than 25% of its unfished level are categorized as species managed in the "precautionary zone". A depleted species is managed under its rebuilding plan even if it has partially rebuilt to above $B_{25\%}$; it remains under its rebuilding plan until it is assessed to have attained the B_{MSY} abundance level of 40% of unfished biomass. Precautionary zone species are managed using the 40-10 adjustment in which the OY is set less than the ABC, as described earlier in this chapter; depleted species are managed under the mortality schedule specified in rebuilding plans.

4.1.2.1 Cabezon (in Waters off California)

Distribution and Life History

Cabezon (*Scorpaenichthys marmoratus*) are distributed along the entire West Coast of the continental United States. They range from central Baja California north to Sitka, Alaska {Quast 1968; Miller and Lea 1972; Love et al. 1996}. Cabezon are primarily a nearshore species found intertidally and among jetty rocks, out to depths of greater than 100 m {Miller and Lea 1972; Love et al. 1996}.

Cabezon are known to spawn in recesses of natural and manmade objects, and males are reported to show nest-guarding behavior (Garrison and Miller 1982). Spawning is protracted, and there appears to be a seasonal progression of spawning that begins off California in winter and proceeds northward to Washington by spring. Spawning off California peaks in January and February {O'Connell 1953} while spawning in Puget Sound (Washington State) occurs for up to 10 months (November-August), peaking in March–April {Lauth 1987}. Laid eggs are sticky and adhere to the surface where deposited. After hatching, the young of the year spend 3–4 months as pelagic larvae and juveniles. Settlement takes place after the young fish have attained 3–5 cm in length {O'Connell; 1953; Lauth 1987}. It is apparent that females lay multiple batches in different nests, but whether these eggs are temporally distinct enough to qualify for separate spawning events is not understood {O'Connell 1953; Lauth 1987}.

Stock Status and Management History

The status and future prospects of cabezon were first assessed in 2003 (Cope, *et al.* 2004). The assessment delineated two stocks (north and south) at the Oregon-California border, a distinction based on differences in the catch history, CPUE trends and biological parameters (mainly growth) between the two areas. Due to the lack of data on the northern population, the assessment focused on only the southern population. As with most nearshore groundfish stocks, this assessment lacked a fishery-independent index of abundance, and consequently relied on recreational CPUE indices and information about larval abundance. The 2003 depletion level of cabezon off California was estimated at 34.7% (under the base-case posterior density function, or MPD, point estimate).

In the 2005 assessment (Cope and Punt 2006), the California cabezon stock was further divided north and south of Point Conception into the northern California substock (NCS) and the southern California substock (SCS). Historically, the recreational fishery has been the primary source of removals of cabezon in California; however commercial catches have become a major source of removals in the last ten years because of the developing live-fish fishery. Recreational removals were reconstructed back to 1916, when the commercial fishery began. When investigating the uncertainty related to the various data sources, Cope and Punt determined that excluding the mean weight value for the recreational man-made fleet for 2000 led to a major reduction in the status of the SCS (to 5.8% of virgin biomass in 2005); the use of this data point may be the most important uncertainty of the SCS assessment. The unfished spawning biomass of the California cabezon substocks were estimated to be 1110 (NCS) and 251 (SCS) mt, with estimated reproductive outputs of 445 (NCS) and 71 (SCS) mt in 2005; this leads to an estimated depletion level of 40.1% (NCS) and 28.3% (SCS). Although the assessment provides information on two substocks within California, cabezon are managed on a coastwide basis for the state. The assessment authors noted that regional management is an important consideration for relatively sedentary nearshore reef species such as cabezon and that future assessments should continue to provide scientific analyses on increasingly finer spatial scales in order to investigate such a potential shift in management.

4.1.2.2 Petrale Sole

Distribution and Life History

Petrale sole (*Eopsetta jordani*) are found from Cape Saint Elias, Alaska to Coronado Island, Baja California, Mexico. The range may possibly extend into the Bering Sea, but the species is rare north and west of southeast Alaska and in the inside waters of British Columbia (Garrison and Miller 1982; Hart 1988). Nine separate breeding stocks have been identified, although stocks intermingle on summer feeding grounds (Hart 1988; NOAA 1990). Of these nine, one occurs off British Columbia, two off Washington, two off Oregon, and four off California. Adults are found from the surf line to 550 m depth, but their highest abundance is deeper than 300 m. Adults migrate seasonally between deepwater winter spawning areas to shallower spring feeding grounds. They show an affinity to sand, sandy mud, and occasionally muddy substrates (NOAA 1990).

Spawning occurs over the continental shelf and continental slope to as deep as 550 m. Spawning occurs in large spawning aggregations in the winter. Eggs are pelagic and juveniles and adults are demersal (Garrison and Miller 1982). Eggs and larvae are transported from offshore spawning areas to nearshore nursery areas by oceanic currents and wind. Larvae metamorphose into juveniles at six months (22 cm) and settle to the bottom of the inner continental shelf (Pearcy, *et al.* 1977). Petrale sole tend to move into deeper water with increased age and size. Petrale sole begin maturing at three years. Half of males mature by seven years (29 cm to 43 cm) and half of the females are mature by eight years (>44 cm) {Pearcy et al. 1977; Pedersen 1975a; Pedersen 1975b}. Near the Columbia River, petrale sole mature one to two years earlier {Pedersen 1975a; Pedersen 1975b}.

Larvae are planktivorous. Small juveniles eat mysids, sculpins, and other juvenile flatfishes. Large juveniles and adults eat shrimps and other decapod crustaceans, as well as euphausiids, pelagic fishes, ophiuroids, and juvenile petrale sole {Garrison and Miller 1982; Hart 1988; Pearcy et al. 1977; Pedersen 1975a; Pedersen 1975b}. Petrale sole eggs and larvae are eaten by planktivorous invertebrates and pelagic fishes. Juveniles are preyed upon (sometimes heavily) by adult petrale sole, as well as other large flatfishes. Adults are preyed upon by sharks, demersally feeding marine mammals, and larger flatfishes and pelagic fishes (NOAA 1990). Petrale sole competes with other large flatfishes. It has the same summer feeding grounds as lingcod, English sole, rex sole, and Dover sole (NOAA 1990).

Stock Status and Management History

Petrale sole are harvested almost exclusively by bottom trawls in the U.S. West Coast groundfish fisheries. Petrale sole fishing grounds range from Cape Flattery off northern Washington, to Point Conception off southern California. Recent petrale sole catch statistics exhibit marked seasonal variation, with substantial portions of the annual harvest taken from the spawning grounds in December and January. Petrale sole off the U.S. West Coast have been managed historically using a coastwide ABC which represents the sum of ABCs calculated for the four INPFC areas.

In 2005, an assessment of the petrale sole stock in U.S. waters off California, Oregon, and Washington was completed {Lai et al. 2005}. Previous assessments of petrale sole in the U.S. Vancouver and Columbia INPFC areas had been conducted by Demory {1984}, Turnock et al. {1993}, and Sampson and Lee {1999}. In this assessment, petrale sole in the Eureka, Monterey and Conception INPFC areas (the Southern assessment area) are assessed separately from those in the U.S. Vancouver and Columbia areas (the Northern assessment area). Although genetic information and stock structure are not well known for this species, the available data on growth, CPUE, and geographical distribution along the U.S. Pacific coast support the use of two separate assessment areas. The assessment used the length-and-age structured Stock Synthesis 2 (SS2) Model.

Petrale sole in the north was estimated to be at 34% of unfished spawning stock biomass in 2005. In the south, the stock was estimated to be at 29% of unfished spawning stock biomass. Biomass trends were qualitatively similar in both areas, and also showed consistency with petrale sole trends in Canadian waters. Both stocks were estimated to have been below the Pacific Council's overfished threshold of 25% of unfished biomass from the mid-1970s until very recently. Estimated harvest rates were in excess of the target fishing mortality rate of F40% during this period as well. Petrale sole in both areas showed large recent increases in stock size, which is consistent with the strong upward trend in the shelf survey biomass index. In comparison to previous assessments of petrale sole, this assessment represents a significant change in our perception of petrale sole stock status. For example, in the 1999 assessment, spawning biomass stock biomass in 1998 was estimated to be at 39% of unfished stock biomass. The current assessment now estimates biomass in 1998 to have been at 12% of unfished stock biomass.

4.1.2.3 Sablefish

Distribution and Life History

Sablefish, or black cod, (*Anoplopoma fimbria*) are distributed in the Northeastern Pacific Ocean from the southern tip of Baja California, northward to the north-central Bering Sea and in the Northwestern Pacific Ocean from Kamchatka, southward to the northeastern coast of Japan. Although few studies have critically evaluated issues regarding the stock structure of this species, it appears there may exist at least three different stocks of sablefish along the West Coast of North America: (1) a stock that exhibits relatively slow growth and small maximum size that is found south of Monterey Bay {Phillips and Imamura 1954; Cailliet et al. 1988}; (2) a stock that is characterized by moderately fast growth and large maximum size that occurs from northern California to Washington {Fujiwara and Hankin 1988a; Methot 1994, 1995}; and (3) a stock that grows very quickly and contains individuals that reach the largest maximum size of all sablefish in the Northeastern Pacific Ocean, distributed off British Columbia, Canada and in the Gulf of Alaska {Mason et al. 1983; McFarlane and Beamish 1990; Methot 1995}. Large adults are uncommon south of Point Conception {Hart 1988; Love 1991; McFarlane and Beamish 1983a; McFarlane and Beamish 1983b; NOAA 1990}. Adults are found as deep as 1,900 m, but are most abundant between 200 m and 1,000 m {Beamish and McFarlane 1988; Kendall and Matarese 1987; Mason et al. 1983}. Off Southern California , sablefish are abundant to depths of 1,500 m (MBC 1987). Adults and large juveniles commonly occur over sand and mud {McFarlane and Beamish 1983a; NOAA 1990} in deep marine waters. They were also reported on hard-packed mud and clay bottoms in the vicinity of submarine canyons (MBC 1987).

Spawning occurs annually in the late fall through winter in waters greater than 300 m (Hart 1988; NOAA 1990). Sablefish are oviparous with external fertilization (NOAA 1990). Eggs hatch in about 15 days {Mason et al. 1983; NOAA 1990} and are demersal until the yolk sac is absorbed {Mason et al. 1983}. Age-zero juveniles become pelagic after the yolk sac is absorbed. Older juveniles and adults are benthopelagic. Larvae and small juveniles move inshore after spawning and may rear for up to four years {Boehlert and Yoklavich 1985; Mason et al. 1983}. Older juveniles and adults inhabit progressively deeper waters. Estimates indicate that 50% of females are mature at five years to six years (24 inches) and 50% of males are mature at five years (20 inches).

Sablefish larvae prey on copepods and copepod nauplii. Pelagic juveniles feed on small fishes and cephalopods—mainly squids {Hart 1988; Mason et al. 1983}. Demersal juveniles eat small demersal fishes, amphipods, and krill (NOAA 1990). Adult sablefish feed on fishes like rockfishes and octopus {Hart 1988; McFarlane and Beamish 1983a}. Larvae and pelagic juvenile sablefish are heavily preyed upon by seabirds and pelagic fishes. Juveniles are eaten by Pacific cod, Pacific halibut, lingcod, spiny dogfish, and marine mammals, such as Orca whales {Cailliet et al. 1988; Hart 1988; Love 1991; Mason et al. 1983; NOAA 1990}. Sablefish compete with many other co-occurring species for food, mainly Pacific cod and spiny dogfish (Allen 1982).

Stock Status and Management History

Formal stock assessments of sablefish began in 1984. The first coastwide-established regulations on the sablefish fishery off the U.S. Pacific coast were implemented as trip limits in October 1982. Since 1982, the sablefish fishery has been managed intensively, with limited-entry and open-access programs used in various manners to limit catches.

In 2001, two assessments were completed and reviewed by a STAR panel: one by NMFS (Schirripa and Methot 2001) and one by the Pacific Groundfish Conservation Trust (Hilborn, *et al.* 2001). The two assessments were in agreement, and the Council adopted the NMFS assessment for management purposes. The Schirripa and Methot assessment focused on evaluating the sensitivity of the model and the outcomes to changes in the survey data. These changes include the combining of the AFSC slope survey data and the NWFSC Industry Co-operative Survey data using a statistical GLM procedure. This analysis made it possible to extend the southern boundary of the assessment south to Point Conception (34°27' N latitude) rather than 36° N latitude, used in previous assessments. The assessment indicated a normal decline in biomass since the late 1970s due to the fishing down of the unfished stock and an unexpected decline in recruitment during the early 1990s. It introduced, for the first time, the possibility that sablefish recruitment may be linked to environmental factors. A seemingly meaningful relationship was demonstrated between changes in northern and southern copepod abundances and sablefish recruitment. Conditions and projections in the model considered two competing "states of nature" to calculate the mean virgin recruitment: a "density-dependent" state that used the average of 1975-1991 recruitments, and a "regime shift" state that used the 1975-2000 recruitments. To account for this uncertainty, the Council adopted a 2002 ABC based on the proxy harvest rate ($F_{45\%}$,) adjusted to reflect the distribution north and south of 36° N. This was done because a plan amendment would be needed to change the management area since groundfish FMP Amendment 14, permit stacking, specified only the area north of 36° N latitude.

The Council also wanted to verify industry reports of a large abundance of juvenile sablefish, an observation that was confirmed to some extent by preliminary results from the 2001 NMFS slope survey. Based on these considerations, the Council recommended a new expedited assessment be done in 2002. This update assessment (Schirripa 2002), by definition, sought to document changes in the estimates of the status of the stock by only considering newly available data for 2001 while not considering any new changes in the model structure or model assumptions. The expedited assessment confirmed fishermen's anecdotal reports of a large 1999 year class, which was also apparent in the preliminary results of the 2001 slope survey. This assessment also suggested that a relatively strong year class was produced in 2000.

The 2005 assessment (Schirripa 2006) made several changes to the format used in the previous full assessment. Landings were either taken from written records or reconstructed back to the year 1900 (the assumed model start date of the fishery). Inspection of length compositions from the AFSC and the NWFSC slope surveys led to the conclusion that the two surveys had different gear selectivities. Consequently, a separation of the data was maintained and the surveys used individually. Sufficient observer data was available in which to estimate discards from all three fisheries. To compliment these discards rates, a release mortality function based on sea surface temperature was developed from which to estimate dead discards by each of the three fisheries. Pursuing the connection between ocean conditions and recruitment, the model fit a relationship between sea level and recruitment deviations for the period 1973-2003 and used that relationship to hindcast recruitment variability back to 1925. The

2005 assessment found that spawning stock biomass has steadily declined since 1900 and suggested that there is little evidence that recruitment from 2001-2005 was as high as that for the strong 1999 and 2000 year classes. As a result, the assessment's biomass projections indicate a short-term increase, followed by a continued decline. With an estimate of current spawning biomass of 75,070 mt (compared to an unfished spawning biomass of 218,860 mt), the 2005 depletion is estimated to be 34.3%

4.1.3 Healthy Groundfish Species

4.1.3.1 Arrowtooth Flounder

Distribution and Life History

Arrowtooth flounder (*Atheresthes stomias*) range from the southern coast of Kamchatka to the northwest Bering Sea and Aleutian Islands to San Simeon, California. Arrowtooth flounder is the dominant flounder species on the outer continental shelf from the western Gulf of Alaska to Oregon. Eggs and larvae are pelagic; juveniles and adults are demersal (Garrison and Miller 1982; NOAA 1990). Juveniles and adults are most commonly found on sand or sandy gravel substrates, but occasionally occur over low-relief rock-sponge bottoms. Arrowtooth flounder exhibit a strong migration from shallow water summer feeding grounds on the continental shelf to deep water spawning grounds over the continental slope (NOAA 1990). Depth distribution may vary from as little as 50 m in summer to more than 500 m in the winter (Garrison and Miller 1982; NOAA 1990; Rickey 1995).

Arrowtooth flounder are oviparous with external fertilization. Spawning may occur deeper than 500 m off Washington (Rickey 1995). Larvae eat copepods, their eggs, and copepod nauplii (Yang 1995; Yang and Livingston 1985). Juveniles and adults feed on crustaceans (mainly ocean pink shrimp and krill) and fish (mainly gadids, herring, and pollock) (Hart 1988; NOAA 1990). Arrowtooth flounder exhibit two feeding peaks, at noon and midnight.

Stock Status and Management History

The West Coast stock of arrowtooth flounder was last assessed in 1993 {Rickey 1993}. The stock is scheduled for a full assessment in the 2007-2008 stock assessment cycle, which will inform the 2009-2010 management specifications process.

4.1.3.2 Bank Rockfish

Distribution and Life History

Bank rockfish (*Sebastes rufus*) are found from Newport, Oregon, to central Baja California, Mexico, most commonly from Fort Bragg southward (Love 1992). Bank rockfish occur offshore (Eschmeyer, *et al.* 1983) from depths of 31 m to 247 m (Love 1992), although adults prefer depths over 210 m (Love, *et al.* 1990). Observations of commercial catches indicate juveniles occupy the shallower part of the species range (Love et al. 1990). Bank rockfish are a midwater, aggregating species and are found over hard bottoms (Love 1992), over high relief or on bank edges (Love, *et al.* 1990), and along the ledge of Monterey Canyon (Sullivan 1995). They also frequent deep water over muddy or sandy bottoms {Miller and Lea 1972a}. Spawning occurs from December to May (Love, *et al.* 1990). Peak spawning of bank rockfish in the Southern California Bight occurs in January and a month later in Central and Northern California. Off California, bank rockfish are multiple brooders (Love, *et al.* 1990). Females grow to a larger maximum size (50 cm) than males (44 cm), but grow at a slightly slower rate (Cailliet, *et al.* 1996). Males reach first maturity at 28 cm, 50% maturity at 31 cm, and 100% at 38 cm. Females reach first maturity at 31 cm, 50% at 36 cm, and 100% maturity at 39 cm (Love, *et al.* 1990). Bank rockfish are midwater feeders, eating mostly gelatinous planktonic organisms such as tunicates, but also preying on small fishes and krill (Love 1992).

4.1.3.3 Black Rockfish

Distribution and Life History

Black rockfish (*Sebastes melanops*) are found from Southern California (San Miguel Island) to the Aleutian Islands (Amchitka Island) and they occur most commonly from San Francisco northward {Hart 1988; Miller and Lea 1972a; Phillips 1957; Stein and Hassler 1989}. Black rockfish occur from the surface to greater than 366 m; however, they are most abundant at depths less than 54 m (Stein and Hassler 1989). Off California, black rockfish are found along with the blue, olive, kelp, black-and-yellow, and gopher rockfishes (Hallacher and Roberts 1985). The abundance of black rockfish in shallow water declines in the winter and increases in the summer (Stein and Hassler 1989). Densities of black rockfish decrease with depth during both the upwelling and non-upwelling seasons (Hallacher and Roberts 1985; PFMC 1996). Off Oregon, larger fish seem to be found in deeper water (20 m to 50 m) (Stein and Hassler 1989). Black rockfish off the northern Washington coast and outer Strait of Juan de Fuca exhibit no significant movement. However, fish appear to move from the Central Washington coast southward to the Columbia River, but not into waters off Oregon. Movement displayed by black rockfish off the northern Oregon coast is primarily northward to the Columbia River (Culver 1986). Black rockfish form mixed sex, midwater schools, especially in shallow water (Hart 1988; Stein and Hassler 1989). Black rockfish larvae and young juveniles (<40 mm to 50 mm) are pelagic, but are benthic at larger sizes (Laroche and Richardson 1980).

Black rockfish have internal fertilization and annual spawning (Stein and Hassler 1989). Parturition occurs from February through April off British Columbia, January through March off Oregon, and January through May off California (Stein and Hassler 1989). Spawning areas are unknown, but spawning may occur in offshore waters because gravid (egg-carrying) females have been caught well offshore (Dunn and Hitz 1969; Hart 1988; Stein and Hassler 1989). Black rockfish can live to be more than 20 years in age. The maximum length attained by the black rockfish is 60 cm (Hart 1988; Stein and Hassler 1989). Off Oregon, black rockfish primarily prey on pelagic nekton (anchovies and smelt) and zooplankton such as salps, mysids, and crab megalops. Off Central California, juveniles eat copepods and zoea, while adults prey on juvenile rockfish, euphausiids, and amphipods during upwelling periods. During periods without upwelling they primarily consume invertebrates. Black rockfish feed almost exclusively in the water column (Culver 1986). Black rockfish are known to be eaten by lingcod and yelloweye rockfish (Stein and Hassler 1989).

Stock Status and Management History

The most recent black rockfish assessment was completed in 2003 and pertains to the portion of the coastwide stock occurring off the coasts of Oregon and California {Ralston and Dick 2003}. Previous assessments had been completed for the portion of the stock occurring in waters between Cape Falcon (Oregon) and the US-Canada border. Alternative harvest levels in the 2003 assessment were ranged to capture the major uncertainty of historical landings prior to 1978. Black rockfish catches prior to 1945 were assumed to be zero in the assessment. Many gaps in historical landings of black rockfish since 1945 were evident, and these landings were reconstructed using a variety of data sources. The base model assumed cumulative landings of black rockfish from all fisheries was 17,100 mt from 1945 to

1977. The projected 2005-2006 harvest specifications for black rockfish in the waters off Oregon and California used this base case catch scenario. The northern California-Oregon stock of black rockfish was concluded to be in healthy condition; its 2002 spawning output, estimated to be at 49% of its unexploited spawning level, meant that the stock as well above the management target level of $B_{40\%}$.

Black rockfish are scheduled to be assessed in the 2007-2008 stock assessment cycle, which will inform the 2009-2010 management specifications process.

4.1.3.5 California Scorpionfish

Distribution and Life History

California scorpionfish (*Scorpaena guttata*), also known locally as sculpin, is a generally benthic species found from central California to the Gulf of California in depths between the inter-tidal and about 170 m {Eschmeyer et al., 1983; Love et al., 1987}. It generally inhabits rocky reefs, but in certain areas and seasons it aggregates over sandy or muddy substrate {Frey, 1971; Love et al., 1987}. Catch rate analysis and tagging studies show that most, but not all, California scorpionfish migrate to deeper water to spawn during May-September {Love et al., 1987}. Tagging data suggest that they return to the same spawning site {Love et al. 1987}, but information is not available on non-spawning season site fidelity. California scorpionfish are quite mobile and may not be permanently tied to a particular reef {Love et al. 1987}.

California scorpionfish spawn from May through August, peaking in July {Love et al. 1987}. The species is oviparous, producing floating, gelatinous egg masses in which the eggs are embedded in a single layer {Orton 1955}. California scorpionfish utilize the "explosive breeding assemblage" reproductive mode in which fish migrate to, and aggregate at traditional spawning sites for brief periods {Love et al. 1987}. These spawning aggregations have been targeted by fishermen. Few California scorpionfish are mature at 1 year of age, but over 50% are mature by age two and most are mature by age three {Love et al. 1987}.

The species feeds on a wide variety of foods, including crabs, fishes, octopi, isopods and shrimp, but juvenile *Cancer* crabs are the most important prey {Limbaugh, 1955; Love et al., 1987}.

Stock Status and Management History

Before the 2005 assessment (Maunder et al. 2006), no assessment had been carried out for California scorpionfish. Given that in most years, 99% or more of the landings occur in the southern California ports, only the stock off of southern California is assessed. Although a substantial, but unknown, proportion of the stock is in Mexican waters, this assessment truncates the stock to the south at the international border. Data used in the model (SS2 version 1.18) included commercial and recreational landings, a fishery dependent CPUE statistic determined from analysis of CPFV logbook trip data from 1980-1999, a fishery independent index of abundance determined from trawl surveys carried out by the sanitation districts, and length-frequency data from the hook and line and trawl commercial fisheries, the recreational fishery, and the sanitation district trawl surveys. Based on the life history characteristics of the species (e.g. using "explosive" breeding assemblages), and limited information on related species, a steepness value of 0.7 was assumed for the assessment. The assessment noted that there is a large amount of variation in recruitment levels and recent recruitments are estimated to be substantially higher than average. Predictions of future biomass will be dependent on what recruitment level is assumed in the future. The estimate of the 2004 stock status was sensitive to the inclusion of the sanitation index in the stock assessment; removing the sanitation index reduced the current biomass level. The STAR Panel and STAT Team gave relative probabilities to models including and excluding the sanitation index of 74% and 26%, respectively. Including the sanitation index, the assessment estimated the 2005 biomass to be at 80% of its unfished level.

4.1.3.6 Chilipepper Rockfish

Distribution and Life History

Chilipepper rockfish (*Sebastes goodei*) are found from Magdalena Bay, Baja California, Mexico, to as far north as the northwest coast of Vancouver Island, British Columbia {Allen 1982; Hart 1988; Miller and Lea 1972a}. Chilipepper have been taken as deep as 425 m, but nearly all in survey catches were taken between 50 and 350 m (Allen and Smith 1988). Adults and older juveniles usually occur over the shelf and slope; larvae and small juveniles are generally found near the surface. In California, chilipepper are most commonly found associated with deep, high relief rocky areas and along cliff drop-offs (Love, *et al.* 1990), as well as on sand and mud bottoms (MBC 1987). They are occasionally found over flat, hard substrates (Love, *et al.* 1990). Love {1991} does not consider this to be a migratory species. Chilipepper may travel as far as 45 m off the bottom during the day to feed {Love 1991}.

Chilipeppers are ovoviviparous and eggs are fertilized internally (Reilly, *et al.* 1992). Chilipepper school by sex just prior to spawning (MBC 1987). In California, fertilization of eggs begins in October and spawning occurs from September to April (Oda 1992) with the peak occurring during December to January (Love, *et al.* 1990). Chilipepper may spawn multiple broods in a single season (Love, *et al.* 1990). Females of the species are significantly larger, reaching lengths of up to 56 cm (Hart 1988). Males are usually smaller than 40 cm (Dark and Wilkins 1994). Males mature at two years to six years of age, and 50% are mature at three years to four years. Females mature at two years to five years with 50% mature at three years to four years (MBC 1987). Females may attain an age of about 27 years, whereas the maximum age for males is about 12 years (MBC 1987).

Larval and juvenile chilipepper eat all life stages of copepods and euphausiids, and are considered to be somewhat opportunistic feeders (Reilly, *et al.* 1992). In California, adults prey on large euphausiids, squid, and small fishes such as anchovies, lanternfish, and young Pacific whiting (Hart 1988; Love, *et al.* 1990). Chilipepper are found with widow rockfish, greenspotted rockfish, and swordspine rockfish (Love, *et al.* 1990). Juvenile chilipepper compete for food with bocaccio, yellowtail rockfish, and shortbelly rockfish (Reilly, *et al.* 1992).

Stock Status and Management History

Chilipepper rockfish were last assessed in 1998 {Ralston et al. 1998}, at which time the stock was estimated to be at 46% to 61% of unfished biomass. Due to constraints of co-occurring overfished species, the catch of chilipepper rockfish has reduced to incidental levels. Chilipepper rockfish is scheduled for a full assessment in the 2008-2009 stock assessment cycle.

4.1.3.7 Dover Sole

Distribution and Life History

Dover sole (*Microstomus pacificus*) are distributed from the Navarin Canyon in the northwest Bering Sea and westernmost Aleutian Islands to San Cristobal Bay, Baja California, Mexico (Hagerman 1952; Hart 1988; NOAA 1990). Dover sole are a dominant flatfish on the continental shelf and slope from Washington to Southern California. Adults are demersal and are found from 9 m to 1,450 m, with highest abundance below 200 m to 300 m (Allen and Smith 1988). Adults and juveniles show a high affinity toward soft bottoms of fine sand and mud. Juveniles are often found in deep nearshore waters. Dover sole are considered to be a migratory species. In the summer and fall, mature adults and juveniles can be found in shallow feeding grounds, as shallow as 55 m off British Columbia (Westrheim and Morgan 1963). By late fall, Dover sole begin moving offshore into deep waters (400 m or more) to spawn. Although there is an inshore-offshore seasonal migration, little north-south coastal migration occurs (Westrheim and Morgan 1963).

Spawning occurs from November through April off Oregon and California (Hart 1988; NOAA 1990; Pearcy, *et al.* 1977) in waters 80 m to 550 m depth at or near the bottom (Hagerman 1952; Hart 1988; Pearcy, *et al.* 1977). Dover sole are oviparous and fertilization is external. Larvae are planktonic and are transported to offshore nursery areas by ocean currents and winds for up to two years. Settlement to benthic living occurs mid-autumn to early spring off Oregon, and February through July off California (Markle, *et al.* 1992). Juvenile fish move into deeper water with age and begin seasonal spawning and feeding migrations upon reaching maturity.

Dover sole larvae eat copepods, eggs, and nauplii, as well as other plankton. Juveniles and adults eat polychaetes, bivalves, brittlestars, and small benthic crustaceans. Dover sole feed diurnally by sight and smell (Dark and Wilkins 1994; Gabriel and Pearcy 1981; Hart 1988; NOAA 1990). Dover sole larvae are eaten by pelagic fishes like albacore, jack mackerel and tuna, as well as sea birds. Juveniles and adults are preyed upon by sharks, demersally feeding marine mammals, and to some extent by sablefish (NOAA 1990). Dover sole compete with various eelpout species, rex sole, English sole, and other fishes of the mixed species flatfish assemblage (NOAA 1990).

Stock Status and Management History

Dover sole have been the target of trawl operations along the West Coast of North America since World War II and were almost certainly caught prior to the war as incidental take in directed fisheries for English sole and petrale sole. Almost all of the harvests have been taken by groundfish trawl, and in particular as part of the DTS (Dover sole, shortspine thornyhead, longspine thornyhead, and sablefish) trawl fishery. Annual landings from U.S. waters averaged 6,700 mt during the 1960s, 12,800 mt during the 1970s, 18,400 mt during the 1980s, 12,400 mt during the 1990s, and 7,200 mt since 2000. Discarding of small, unmarketable fish is an important, but poorly documented feature of the fishery.

The 1997 Dover sole stock assessment (Brodziak, *et al.* 1997) treated the entire population from the Monterey area through the U.S./Vancouver area as a single stock based on research addressing the genetic structure of the population. Under a range of harvest policies and recruitment scenarios, the 1997 model projected that spawning biomass would increase from the estimated year-end level in 1997 through the year 2000 due to growth of the exceptionally large 1991 year class and to the lower catches observed in the fishery since 1991.Dover sole were next assessed in 2001, resulting in an estimated spawning stock size of 29% of the unexploited biomass (Sampson and Wood 2001). Although there was no clear trend in abundance, stocks steadily declined from the 1950s until the mid-1990s. The 1991 year class was the last strong one, consistent with the 1997 assessment. The 2001 assessment authors projected five years of Dover sole harvest levels based on preferred, optimistic, and pessimistic projections of recruitment. These options varied the harvest rate from $F_{40\%}$ (the current F_{MSY} proxy) to $F_{50\%}$. The Council adopted an ABC of 8,510 mt and an OY of 7,440 mt in 2005 and 2006, which was calculated using the current F_{MSY} proxy and the 40-10 adjustment.

A new Dover sole assessment was done in 2005 {Sampson 2006} which indicated the stock was above target levels and had an increasing abundance trend. The final base model estimated the unexploited spawning stock biomass to be slightly less than 300,000 mt and spawning biomass at the start of 2005 was estimated to be about 189,000 mt, equivalent to 63% of the unexploited level. Spawning biomass and age 5+ biomass (roughly corresponding to the exploitable biomass) were estimated to have reached their lowest points in the mid-1990s and have been rising steadily since. The estimated increases in biomass since the mid-1990s are due primarily to strong year classes in 1990 and 1991, and exceptionally strong year classes in 1997 and 2000.

4.1.3.8 English Sole

Distribution and Life History

English sole (*Parophrys vetulus*) are found from Nunivak Island in the southeast Bering Sea and Agattu Island in the Aleutian Islands, to San Cristobal Bay, Baja California Sur, Mexico (Allen and Smith 1988). In research survey data, nearly all occurred at depths greater than 250 m (Allen and Smith 1988). Adults and juveniles prefer soft bottoms composed of fine sands and mud (Ketchen 1956), but also occur in eelgrass habitats (Pearson and Owen 1992). English sole use nearshore coastal and estuarine waters as nursery areas (Krygier and Pearcy 1986; Rogers, *et al.* 1988). Adults make limited migrations. Those off Washington show a northward post-spawning migration in the spring on their way to summer feeding grounds and a southerly movement in the fall (Garrison and Miller 1982). Tagging studies have identified separate stocks based on this species' limited movements and meristic characteristics (Jow 1969).

Spawning occurs over soft-bottom mud substrates (Ketchen 1956) from winter to early spring, depending on the stock. Eggs are neritic and buoyant, but sink just before hatching (Hart 1988); juveniles and adults are demersal (Garrison and Miller 1982). Small juveniles settle in the estuarine and shallow nearshore areas all along the coast, but are less common in southerly areas, particularly south of Point Conception. Large juveniles commonly occur up to depths of 150 m. Although many postlarvae may settle outside of estuaries, most will enter estuaries during some part of their first year of life (Gunderson, *et al.* 1990). Some females mature as three-year-olds (26 cm), but all females over 35 cm long are mature. Males mature at two years (21 cm).

Larvae are planktivorous. Juveniles and adults are carnivorous, eating copepods, amphipods, cumaceans, mysids, polychaetes, small bivalves, clam siphons, and other benthic invertebrates {Allen 1982; Becker 1984; Hogue and Carey 1982; Simenstad et al. 1979}. English sole feed primarily by day, using sight and smell, and sometimes dig for prey (Allen 1982; Hulberg and Oliver 1979). A juvenile English sole's main predators are probably piscivorous birds such as great blue heron (*Ardia herodias*), larger fishes, and marine mammals. Adults may be eaten by marine mammals, sharks, and other large fishes.

Stock Status and Management History

English sole have been captured by the bottom trawl fishery operating off the western coast of North

America for over a century. Stewart {2006} found that peak catches from the southern area occurred in the 1920s with a maximum of 3,976 mt of English sole landed in 1929, and peak catches from the northern area occurred in the 1940s to the 1960s with a maximum of 4,008 mt landed in 1948. Landings from both areas have generally declined since the mid 1960s and have been at nearly historical lows in recent years

The most recent stock assessment of English sole prior the current 2005 assessment was performed in 1993 {Sampson 1993}, using an earlier version of the Stock Synthesis program {Methot 1989}. That assessment considered the female portion of the stock off Oregon and Washington during the years 1977-1993. The English sole spawning biomass was found to be increasing and it was concluded that the fishery was sustainable at (then) contemporary harvest levels.

The 2005 assessment of English sole {Stewart 2006} modeled a single coastwide stock, although both commercial and fishery independent data sources were treated separately for a southern (INPFC Conception and Monterey) and a northern (INPFC Eureka, Columbia and U.S. Vancouver) area. The assessment found that English sole spawning biomass has increased rapidly over the last decade after a period of poor recruitments from the mid 1970s to the mid 1990s, which left the stock at nearly historically low levels. Strong year classes were estimated for 1995, 1996, and 1999. The data indicate that the 1999 year class may be the largest in the time-series, although the magnitude is somewhat uncertain because the assessment contains no age data subsequent to 2000. There is substantial uncertainty related to certain parameters in the assessment, specifically biomass, recruitment, and relative depletion, as indicated by the wide confidence intervals for those parameters. Nevertheless, sensitivity analyses indicated that the conclusion that current spawning biomass exceeds the target level ($B_{40\%}$) was robust to all three of these sources of uncertainty. The spawning biomass at the beginning of 2005 was estimated to be 31,379 mt, which corresponds to 91.5% of the unexploited equilibrium level. Current (2004) total catches were estimated to be 1,341 mt, of which 950 mt were landed.

4.1.3.9 Lingcod

Distribution and Life History

Lingcod (*Ophiodon elongatus*), a top order predator of the family Hexagrammidae, ranges from Baja California, Mexico, to Kodiak Island in the Gulf of Alaska. Lingcod are demersal at all life stages (Allen and Smith 1988; NOAA 1990; Shaw and Hassler 1989). Adult lingcod prefer two main habitat types: slopes of submerged banks 10 m to 70 m below the surface with seaweed, kelp, and eelgrass beds and channels with swift currents that flow around rocky reefs (Emmett, *et al.* 1991; Giorgi and Congleton 1984; NOAA 1990; Shaw and Hassler 1989). Juveniles prefer sandy substrates in estuaries and shallow subtidal zones (Emmett, *et al.* 1991; Forrester and Thomson 1969; Hart 1988; NOAA 1990). As the juveniles grow they move to deeper waters. Adult lingcod are considered a relatively sedentary species, but there are reports of migrations of greater than 100 km by sexually immature fish {Jagielo 1990; Mathews and LaRiviere 1987; Matthews 1992; Smith et al. 1990}.

Mature females live in deeper water than males and move from deep water to shallow water in the winter to spawn {Forrester 1969; Hart 1988; Jagielo 1990; LaRiviere et al. 1980; Mathews and LaRiviere 1987; Matthews 1992; Smith et al. 1990}. Mature males may live their whole lives associated with a single rock reef, possibly out of fidelity to a prime spawning or feeding area (Allen and Smith 1988; Shaw and Hassler 1989). Spawning generally occurs over rocky reefs in areas of swift current {Adams 1986; Adams and Hardwick 1992; Giorgi and Congleton 1984; LaRiviere et al. 1980}. After the females leave the spawning grounds, the males remain in nearshore areas to guard the nests until the eggs hatch. Hatching occurs in April off Washington, but as early as January and as late as

June at the geographic extremes of the lingcod range. Males begin maturing at about two years (50 cm), whereas females mature at three plus years (76 cm). In the northern extent of their range, fish mature at an older age and larger size {Emmett et al. 1991; Hart 1988; Mathews and LaRiviere 1987; Miller and Geibel 1973; Shaw and Hassler 1989}. The maximum age for lingcod is about 20 years (Adams and Hardwick 1992).

Lingcod are a visual predator, feeding primarily by day. Larvae are zooplanktivores (NOAA 1990). Small demersal juveniles prey upon copepods, shrimps, and other small crustaceans. Larger juveniles shift to clupeids and other small fishes (Emmett, *et al.* 1991; NOAA 1990). Adults feed primarily on demersal fishes (including smaller lingcod), squids, octopi, and crabs {Hart 1988; Miller and Geibel 1973; Shaw and Hassler 1989}. Lingcod eggs are eaten by gastropods, crabs, echinoderms, spiny dogfish, and cabezon. Juveniles and adults are eaten by marine mammals, sharks, and larger lingcod {Miller and Geibel 1973; NOAA 1990}.

Stock Status and Management History

Lingcod have been a target of commercial fisheries since the early 1900's in California, and since the late 1930's in Oregon and Washington waters. Recreational fishermen have targeted lingcod since the 1920's in California. A smaller recreational fishery has taken place in Washington and Oregon since at least the 1970's. Although historically the catches of lingcod have been greater in the commercial sector than in the recreational sector, this pattern has been reversed since the late 1990's.

In 1997, U.S. scientists assessed the size and condition of the portion of the stock in the Columbia and Vancouver areas (including the Canadian portion of the Vancouver management area), and concluded the stock had fallen to below 10% of its unfished size (Jagielo, *et al.* 1997). The Council responded by imposing substantial harvest reductions coastwide, reducing the harvest targets for the Eureka, Monterey, and Conception areas by the same percentage as in the north. In 1999, scientists assessed the southern portion of the stock and concluded the condition of the southern stock was similar to the northern stock, thus confirming the Council had taken appropriate action to reduce harvest coastwide (Adams, *et al.* 1999). Based on these assessments, the lingcod stock was declared overfished in 1999.

Jagielo {2000} conducted a coastwide lingcod assessment and determined the total biomass increased from 6,500 mt in the mid-1990s to about 8,900 mt in 2000. In the south, the population had also increased slightly from 5,600 mt in 1998 to 6,200 mt in 2000. In addition, the assessment concluded previous aging methods portrayed an older population; whereas new aging efforts showed the stock to be younger and more productive. Therefore, the ABC and OY were increased in 2001 on the basis of the new assessment. A revised rebuilding analysis of coastwide lingcod (Jagielo and Hastie 2001) was adopted by the Council in September 2001. It confirmed the major conclusions of the 2000 assessment and rebuilding analysis, but slightly modified recruitment projections to stay on the rebuilding trajectory to reach target biomass in 2009. This modification resulted in a slight decrease in the 2002 ABC and OY.

A coastwide assessment for lingcod was completed in 2003 {Jagielo et al. 2003} and approved by the Council in March 2004 for use in setting harvest specifications for the 2005-2006 biennium. This assessment updated the previous coastwide lingcod assessment {Jagielo 2000}. As in the previous assessment, separate age-structured assessment models were constructed for northern areas (Columbia and U.S.-Vancouver areas) and southern areas (Conception, Monterey, and Eureka areas). Results from these two models were combined to obtain coastwide estimates of spawning biomass, the depletion level, and other relevant assessment outputs. This assessment indicated that the lingcod stock had achieved the rebuilding objective of $B_{40\%}$ in the north (actually 28% above $B_{40\%}$), but was at $B_{31\%}$ in the south. However, the adopted lingcod rebuilding plan specified a coastwide rebuilding objective. The

Council's SSC, working in concert with the lead assessment author, recalculated the coastwide lingcod stock status in March 2004 using actual 2003 harvests (the assessment, which was completed during 2003, assumed harvest would be equal to the specified OY in 2003). Their calculations indicated that the spawning biomass at the start of 2004 was within 99.3% of B_{MSY} (or $B_{40\%}$) on a coastwide basis. Therefore, the Council could not recommend to NMFS that the stock should be declared rebuilt. The lingcod rebuilding plan was adopted by the Council and incorporated into the groundfish FMP under Amendment 16-2. The rebuilding plan had established a target rebuilding year of 2009 and the harvest control rule of F = 0.0531 for fisheries in the northern areas and F = 0.0610 for fisheries in the southern areas (with a PMAX of 60%). However the 2003 assessment {Jagielo et al. 2003} was then used to recalculate the harvest control rule .to be F = 0.17 for fisheries in the northern areas and F = 0.15 for fisheries in the southern areas.

The 2005 assessment {Jagielo and Wallace 2005} used the Stock Synthesis II program and, as in previous lingcod assessments, constructed separate models of the stock for northern and southern areas. With respect to uncertainty within the assessment, the authors pointed in particular to the estimation of assessment parameters for the southern (LCS) model due to the sparseness of data (in particular, the short time series of fishery age data and small sample sizes). On a coastwide basis, the lingcod population was concluded to be fully rebuilt, given that the spawning biomass in 2005 was estimated to be 64% of its unfished level (B_{2005}=34,017 mt; B_0= 52,850 mt). Within the separate area models, current biomass is closer to unfished biomass in the north (87% of B_0) than in the south (24% of B_0). Given that the lingcod stock is managed on a coastwide basis, the Council announced the lingcod stock to be fully rebuilt in 2005, which is four years earlier than the target rebuilding year established in the rebuilding plan.

4.1.3.10 Longspine Thornyhead

Distribution and Life History

Longspine thornyhead (*Sebastolobus altivelis*) are found from the southern tip of Baja California, Mexico, to the Aleutian Islands {Eschmeyer et al. 1983; Jacobson and Vetter 1996; Love 1991; Miller and Lea 1972; Smith and Brown 1983}, but are abundant from Southern California northward {Love 1991}. Juvenile and adult longspine thornyhead are demersal and occupy the benthic surface (Smith and Brown 1983). Off Oregon and California, longspine thornyhead mainly occur at depths of 400 m to 1,400 plus m, most between 600 m and 1,000 m in the oxygen minimum zone (Jacobson and Vetter 1996). Thornyhead larvae (*Sebastolobus* spp.) have been taken in research surveys up to 560 km off the California coast (Cross 1987; Moser, *et al.* 1993). Juveniles settle on the continental slope at about 600 m to 1,200 m (Jacobson and Vetter 1996). Longspine thornyhead live on soft bottoms, preferably sand or mud {Eschmeyer et al. 1983, Jacobson and Vetter 1996, Love 1991}. Longspine thornyheads neither school nor aggregate (Jacobson and Vetter 1996).

Spawning occurs in February and March at 600 m to 1,000 m {Jacobson and Vetter 1996, Wakefield and Smith 1990}. Longspine thornyhead are oviparous and are multiple spawners, spawning two to four batches per season {Love 1991, Wakefield and Smith 1990}. Eggs rise to the surface to develop and hatch. Floating egg masses can be seen at the surface in March, April, and May (Wakefield and Smith 1990). Juveniles (<5.1 cm long) occur in midwater (Eschmeyer, *et al.* 1983). After settling, longspine thornyhead are completely benthic (Jacobson and Vetter 1996). Longspine thornyhead can grow to 38 cm {Eschmeyer et al. 1983, Jacobson and Vetter 1996, Miller and Lea 1972} and live more than 40 years (Jacobson and Vetter 1996). Longspine thornyhead reach the onset of sexual maturity at 17 cm to 19 cm total length (10% of females mature) and 90% are mature by 25 cm to 27 cm (Jacobson and Vetter 1996).

Longspine thornyhead are ambush predators (Jacobson and Vetter 1996). They consume fish fragments, crustaceans, bivalves, and polychaetes and occupy a tertiary consumer level in the food web. Pelagic juveniles prey largely on herbivorous euphausiids and occupy a secondary consumer level in the food web {Love 1991, Smith and Brown 1983}. Longspine thornyhead are commonly found in shortspine thornyhead stomachs. Cannibalism in newly settled longspine thornyhead may occur, because juveniles settle directly onto adult habitat (Jacobson and Vetter 1996). Sablefish commonly prey on longspine thornyhead.

Stock Status and Management History

Longspine thornyhead are exploited in the limited entry deep-water trawl fishery operating on the continental slope that also targets shortspine thornyhead, Dover sole and sablefish (called the DTS fishery). A very small proportion of longspine landings is due to non-trawl gears (gillnet, hook and line). Longspine and shortspine thornyhead make up a single market category, however they have been managed under separate harvest specifications since 1992. The thornyhead fishery developed in Northern California during the 1960s. The fishery then expanded north and south, and the majority of the landings of longspine thornyhead have since been in the Monterey, Eureka, and Columbia INPFC areas, with some increase in landings from the Conception (southern CA) and Vancouver (northern WA) INPFC areas in recent years (Fay 2006).

Longspine thornyhead were assessed for the fourth time in 2005 (Fay 2006); the previous assessment was conducted in 1997 {Rogers et al. 1997}. The model assumed one coastwide stock with one coastwide trawl fishery. Data sources included commercial landings and length composition, three sources of discard rates, and biomass indices and length composition information from the Alaska Fisheries Science Center and Northwest Fisheries Science Center slope surveys. Results from the base model suggested that the length compositions from the slope surveys were influencing recruitment in the model, such that the model estimated slightly higher recruitment in the early 1990s, which then declined in the mid to late 1990s. The spawning biomass in 2005 was approximately 71% of unfished spawning biomass, but this estimate is highly uncertain as is evident in the comparatively large 95% confidence interval for the spawning biomass. A suite of sensitivity analyses bracketed some of the areas of uncertainty in catchability, selectivity, mortality and steepness that formed a basis for considering and discussing major areas of uncertainty for the decision table.

4.1.3.11 Pacific Whiting

Distribution and Life History

Pacific whiting (*Merluccius productus*), also known as Pacific hake, are a semi-pelagic merlucciid (a cod-like fish species) that range from Sanak Island in the western Gulf of Alaska to Magdalena Bay, Baja California Sur, Mexico. They are most abundant in the California Current System {Bailey 1982; Hart 1988; Love 1991; NOAA 1990}. Smaller populations of Pacific whiting occur in several of the larger semi-enclosed inlets of the northeast Pacific Ocean, including the Strait of Georgia, Puget Sound, and the Gulf of California {Bailey et al. 1982; Stauffer 1985}. The highest densities of Pacific whiting are usually between 50 m and 500 m, but adults occur as deep as 920 m and as far offshore as 400 km {Bailey 1982; Bailey et al. 1982; Dark and Wilkins 1994; Dorn 1995; Hart 1988; NOAA 1990}. Pacific whiting school at depth during the day, then move to the surface and disband at night for feeding (McFarlane and Beamish 1986; Sumida and Moser 1984; Tanasich, *et al.* 1991). Coastal stocks spawn off Baja, California in the winter, then the mature adults begin moving northward and inshore following food supply and Davidson Currents (NOAA 1990). Pacific whiting reach as far north as southern British Columbia by fall. They then begin a southern migration to spawning grounds further offshore {Bailey et al. 1982; Dorn 1995; Smith 1995; Stauffer 1985}.

Spawning occurs from December through March, peaking in late January {Smith 1995}. Pacific whiting are oviparous with external fertilization. Eggs of the Pacific whiting are neritic and float to neutral buoyancy {Bailey 1982; Bailey et al. 1982; NOAA 1990}. Hatching occurs in five days to six days, and within three months to four months juveniles are typically 35 mm (Hollowed 1992). Juveniles move to deeper water as they get older (NOAA 1990). Females mature at three years to four years (34 cm to 40 cm) and nearly all males are mature by three years (28 cm). Females grow more rapidly than males after four years; growth ceases for both sexes at 10 years to 13 years {Bailey et al. 1982}.

All life stages feed near the surface late at night and early in the morning (Sumida and Moser 1984). Larvae eat calanoid copepods, as well as their eggs and nauplii (McFarlane and Beamish 1986; Sumida and Moser 1984). Juveniles and small adults feed chiefly on euphausiids (NOAA 1990). Large adults also eat amphipods, squid, herring, smelt, crabs, and sometimes juvenile whiting {Bailey 1982; Dark and Wilkins 1994; McFarlane and Beamish 1986; NOAA 1990}. Eggs and larvae of Pacific whiting are eaten by pollock, herring, invertebrates, and sometimes Pacific whiting. Juveniles are eaten by lingcod, Pacific cod, and rockfish species. Adults are preyed on by sablefish, albacore, pollock, Pacific cod, marine mammals, soupfin sharks, and spiny dogfish (Fiscus 1979; McFarlane and Beamish 1986; NOAA 1990).

Stock Status and Management History

The history of the coastal whiting fishery is characterized by rapid changes brought about by the development of foreign fisheries in 1966, joint-venture fisheries in the early 1980s, and domestic fisheries in 1990s. The coastwide (U.S. and Canada) whiting stock is assessed annually by a joint technical team of scientists from both countries. The 2001 assessment (Helser, *et al.* 2002) incorporated 2001 hydroacoustic survey data and showed the spawning stock biomass declined substantially and had been lower during the past several years than previously estimated. The stock assessment estimated the biomass in 2001 was 0.7 million mt, and the female spawning biomass was less than 20% of the unfished biomass. This was substantially lower than indicated in the 1998 assessment (Dorn, *et al.* 1999), which estimated the biomass to be at 39% of its unfished biomass. Therefore, NMFS declared the whiting stock overfished in April 2002. The stock was projected to be near 25% of the unfished biomass in 2002 and above $B_{25\%}$ in 2003.

The 2004 whiting stock assessment (Helser, *et al.* 2004), incorporating new data from the 2003 hydro-acoustic survey, estimated the spawning stock biomass at the beginning of 2004 between 47% and 51% of unfished biomass; the stock was therefore declared rebuilt. Furthermore, because the 1999 year class was larger than previously estimated, estimates of the 2001 biomass in this assessment ranged from 27% to 33% of unfished biomass, indicating that the stock approached, but never fell below, the $B_{25\%}$ minimum stock size threshold (Whiting STAR Panel 2004).

The 2005 whiting stock assessment considered two alternative and equally plausible models based on the value for the catchability coefficient (q) for the hydroacoustic survey, q=1 and q=0.6. Within a stock assessment model, a higher catchability coefficient brings about a lower the estimate of current biomass. Under the base model (q=1), which the Council adopted, the 2004 coastwide depletion level was estimated to be 0.50 (given that age 3+ biomass was estimated to be 2.5 million mt in 2004).

Unlike the 2005 assessment, the 2006 assessment was based on the stock assessment package Stock Synthesis 2. The assessment considered two alternative and equally plausible models based on the value for the catchability coefficient (*q*) for the hydroacoustic survey, q=1 and q=0.69. One of these values (*q*=1) is the same as that included in the 2005 assessment. The second value, q=0.69, was estimated taking into account a prior distribution on *q* selected by the STAR Panel. Although the SSC endorsed the option of combining of results from both models (giving each model equal weight) to form the basis for management advice, the Council adopted 2006 ABC and OY values based on the base model that used the more conservative q=1 value. The base model estimated the depletion level of the coastwide stock to be 31%. The assessment reinforced the importance of the 1999 year class, noting that it was the single most dominate cohort since the late 1980s and it in large part supported fishery catches during the last few years; over the coming years its proportion within the overall stock will decrease, however, and therefore the spawning biomass is predicted to decline in the future for almost any level of harvest.

4.1.3.12 Shortbelly Rockfish

Distribution and Life History

Shortbelly rockfish (*Sebastes jordani*) are found from San Benito Islands, Baja California, Mexico, to La Perouse Bank, British Columbia (Eschmeyer, *et al.* 1983; Lenarz 1980). The habitat of the shortbelly rockfish is wide ranging (Eschmeyer, *et al.* 1983). Shortbelly rockfish inhabit waters from 50 m to 350 m in depth (Allen and Smith 1988) on the continental shelf (Chess, *et al.* 1988) and upper-slope (Stull and Tang 1996). Adults commonly form very large schools over smooth bottoms near the shelf break (Lenarz 1992). Shortbelly rockfish have also been observed along the Monterey Canyon ledge (Sullivan 1995). During the day shortbelly rockfish are found near the bottom in dense aggregations. At night they are more dispersed (Chess, *et al.* 1988). During the summer shortbelly rockfish tend to move into deeper waters and to the north as they grow, but they do not make long return migrations to the south in the winter to spawn (Lenarz 1980).

Shortbelly rockfish are viviparous, bearing advanced yolk sac larvae {Ralston et al. 1996a}. Shortbelly rockfish spawn off California during January through April (Lenarz 1992). Larvae metamorphose to juveniles at 27 mm and appear to begin forming schools at the surface at that time (Laidig, *et al.* 1991; Lenarz 1980). A few shortbelly rockfish mature at age two, while 50% are mature at age three, and nearly all are mature by age four (Lenarz 1992). They live to be about ten years old (Lenarz 1980; MacGregor 1986) with the maximum recorded age being 22 years (Lenarz 1992).

Shortbelly rockfish feed primarily on various life stages of euphausiids and calanoid copepods both during the day and night {Chess et al. 1988; Lenarz et al. 1991}. Shortbelly rockfish play a key role in the food chain as they are preyed upon by Chinook and coho salmon, lingcod, black rockfish, Pacific whiting, bocaccio, chilipepper, pigeon guillemots, western gull, marine mammals, and other taxa (Chess, *et al.* 1988; Eschmeyer, *et al.* 1983; Hobson and Howard 1989; Lenarz 1980).

4.1.3.13 Shortspine Thornyhead

Distribution and Life History

Shortspine thornyhead (*Sebastolobus alascanus*) are found from northern Baja California, Mexico, to the Bering Sea and occasionally to the Commander Islands north of Japan (Jacobson and Vetter 1996). They are common from Southern California northward {Love 1991}. Shortspine thornyhead inhabit areas over the continental shelf and slope (Erickson and Pikitch 1993; Wakefield and Smith 1990). Although they can occur as shallow as 26 m (Eschmeyer, *et al.* 1983), shortspine thornyhead mainly occur in depths between 100 m and 1,400 m off Oregon and California, most commonly between 100 m to 1,000 m (Jacobson and Vetter 1996).

Spawning occurs in February and March off California (Wakefield and Smith 1990). Shortspine thornyhead are thought to be oviparous (Wakefield and Smith 1990), although there is no clear evidence to substantiate this (Erickson and Pikitch 1993). Eggs rise to the surface to develop and hatch. Larvae are pelagic for about 12 months to 15 months. During January to June, juveniles settle onto the continental shelf and then move into deeper water as they become adults (Jacobson and Vetter 1996). Off California, they begin to mature at five years; 50% are mature by 12 years to 13 years; and all are mature by 28 years (Owen and Jacobson 1992). Although it is difficult to determine the age of older individuals, Owen and Jacobson {1992} report that off California, they may live to over 100 years of age. The mean size of shortspine thornyhead increases with depth and is greatest at 1,000 m to 1,400 m (Jacobson and Vetter 1996).

Benthic individuals are ambush predators that rest on the bottom and remain motionless for extended periods of time (Jacobson and Vetter 1996). Off Alaska, shortspine thornyhead eat a variety of invertebrates such as shrimps, crabs, and amphipods, as well as fishes and worms (Owen and Jacobson 1992). Longspine thornyhead are a common item found in the stomachs of shortspine thornyhead. Cannibalism of newly settled juveniles is important in the life history of thornyheads (Jacobson and Vetter 1996).

Stock Status and Management History

Shortspine thornyhead are a major component of the deepwater fishery on the continental slope, especially the trawl fishery for Dover sole, thornyheads, and sablefish (referred to as the DTS complex). The species is one of the most numerous components of the slope ecosystem; however, this is an especially long-lived species and cannot sustain aggressive harvest rates. It is taken coincidentally with Dover sole, sablefish, and longspine thornyhead, especially in the upper slope and lower shelf; in deeper water, longspine thornyhead is a more predominate species. The two thornyhead species are often difficult to distinguish, and historical landings data combine the two into a single category; nevertheless, the species have been managed under separate harvest specifications since 1992.

The assessment of shortspine thornyhead in 1997 covered the area from Central California at 36° N latitude to the U.S./Canada border {Rogers et al. 1997}. The STAR Panel expressed concern that management requires more detailed information on thornyheads than could be obtained from the available data. In 1998, two separate stock assessments covering the area north of 36°N latitude were prepared and accepted by the Council(NMFS STAT and OT STAT 1998; Rogers, *et al.* 1998). A synthesis of these two assessments was used to set the harvest specifications 1999 and 2000; given that the synthesis estimated 1999 depletion at 32% of virgin biomass, the Council used the precautionary 40-10 policy to set the OYs for those two years.

There were a range of uncertainties in the 2001 assessment of shortspine thornyhead, in 2001, not the least of which was the estimated biomass {Piner and Methot 2001}. The assessment was extended south to Point Conception (in contrast to past surveys, which were limited to stocks north of the 36° N latitude management area boundary). The authors concluded the 2001 spawning biomass ranged between 25% and 50% of unexploited spawning biomass. As was also the case in the 1998 assessment (Rogers, *et al.* 1998), the uncertainty in abundance largely revolved around the uncertainty in recruitment and survey *q*, or catchability, of shortspine thornyhead in slope surveys. The authors also concluded that the trend in stock biomass was increasing and the stock was not overfished. Based on estimated biomass and application of the GMT-recommended F=0.75M principle (which approximates an $F_{50\%}$ proxy harvest rate for shortspine thornyhead), the assessment authors and GMT recommended a slight increase in the ABC and OY for 2002. They also recommended that the harvest specifications be set for two areas divided by Pt. Conception (34°27'N latitude), rather than the previous policy to separate the management areas at the Conception-Monterey border (36°N latitude). Despite the uncertainty in biomass estimates and determination of whether shortspine thornyhead should be treated as a precautionary zone" stock, these recommendations did treat the stock as such by applying the 40-10 adjustment.

The 2005 assessment {Hamel 2006} extended the southern border of the assessment area from Pt. Conception to the Mexican border (32.5ºN). Including the entire Conception area resulted in a larger basis for unfished biomass, given that this area was estimated to contain nearly half of the stock's total West Coast biomass. Another key modeling change from the previous assessment was to model the slope surveys as having dome-shaped selectivity. Because of the sparseness and quality of the data, natural mortality, steepness and the catchability coefficient were all fixed. The catchability coefficient for the slope survey was fixed at q=1 based on findings by Lauth et al {2004}. The STAR Panel {Barnes et al. 2006} noted that because the supporting data and subsequent assessment were just marginally sufficient to estimate the resource status, the biological reference points (e.g. biomass levels) should be considered with caution. The assessment estimated the spawning biomass for 2005 to be 63% of unfished abundance, with a weakly falling recent trend. It was also noted that there could be regional management concerns with this stock because while the assessment OY is coastwide, there are differences in historic exploitation rates north and south of Point Conception.

4.1.3.14 Splitnose Rockfish

Distribution and Life History

Splitnose rockfish (*Sebastes diploproa*) occur from Prince William Sound, Alaska to San Martin Island, Baja California, Mexico {Miller and Lea 1972}). Splitnose rockfish occur from zero m to 800 m, with most survey catches occurring in depths of 100 m to 450 m (Allen and Smith 1988). The relative abundance of juveniles (<21 cm) is quite high in the 91 m to 272 m depth zone and then decreases sharply in the 274 m to 475 m depth zone {Boehlert 1980}. Splitnose rockfish have a pelagic larval stage, a prejuvenile stage, and a benthic juvenile stage {Boehlert 1977}. Benthic splitnose rockfish associate with mud habitats {Boehlert 1980}. Young occur in shallow water, often at the surface under drifting kelp (Eschmeyer, *et al.* 1983). The major types of vegetation juveniles are found under are *Fucus* spp. (dominant), eelgrass, and bull kelp (Shaffer, *et al.* 1995). Juvenile splitnose rockfish off Southern California are the dominant rockfish species found under drifting kelp {Boehlert 1977}.

Splitnose rockfish are ovoviviparous and release yolk sac larvae {Boehlert 1977}. They may have two parturition seasons, or may possibly release larvae throughout the year {Boehlert 1977}. In general, the main parturition season get progressively shorter and later toward the north {Boehlert 1977}. Splitnose rockfish growth rates vary with latitude, being generally faster in the north. Splitnose rockfish mean sizes increase with depth in a given latitudinal area. Mean lengths of females are generally greater than males {Boehlert 1980}. Off California, 50% maturity occurs at 21 cm, or five years of age, whereas off British Columbia 50% of males and females are mature at 27 cm (Hart 1988). Adults can achieve a maximum size of 46 cm {Boehlert 1980, Eschmeyer et al. 1983, Hart 1986}. Females have surface ages to 55 years and section ages to 81 years.

Adult splitnose rockfish off Southern California feed on midwater plankton, primarily euphausiids (Allen 1982). Juveniles feed mainly on planktonic organisms, including copepods and cladocerans during June and August. In October, their diets shift to larger epiphytic prey and are dominated by a single amphipod species. Juvenile splitnose rockfish actively select prey (Shaffer, *et al.* 1995) and are probably diurnally active (Allen 1982). Adults are probably nocturnally active, at least in part (Allen 1982).

4.1.3.15 Starry Flounder

Distribution and Life History

Starry flounder have a very broad geographic distribution around the rim of the north Pacific Ocean and have been recorded from Los Angeles to the Aleutian Islands, although they are rare south of Point Conception (Kramer and O'Connell 1995; Orcutt 1950). Off the West Coast of the United States starry flounder are found commonly in nearshore waters, especially in the vicinity of estuaries (Baxter 1999; Kimmerer 2002; NOAA 1991; Orcutt 1950; Pearson 1989; Sopher 1974). It has a quite shallow bathymetric distribution, with most individuals occurring in waters less than 80 m, although specimens have been collected off the continental shelf in excess of 350 m {Orcutt 1950, Kramer et al. 1995}. They are most often found on gravel, clean shifting sand, hard stable sand, and mud substrata.

Spawning occurs primarily during the winter months of December and January, at least in central California (Orcutt 1950); it may occur somewhat later in the year (February-April) off British Columbia and Washington {Hart 1973; Love 1996}. Egg/larval development apparently takes about 2-3 months to occur. Offspring principally remain within the estuaries until age 2, when many have migrated to the adjacent ocean habitats (Baxter 1999; Kimmerer 2002; Orcutt 1950). Reproductive maturity occurs at age-2 yr for males and age-3 yr for females, when the fish are 28 cm and 35 cm, respectively. Tagging studies have shown that fish are relatively sedentary and move little during their adult lives {Love 1996}, however there is little information on regional variation in stock structure.

Starry flounder consume crabs, shrimps, worms, clams and clam siphons, other small mollusks, small fishes, nemertean worms, and brittle stars (Hart 1973).

Stock Status and Management History

The U.S. West Coast starry flounder stock was first assessed in 2005 {Ralston 2006}. The assessment is based on the assumption of separate biological populations north and south of the CA / OR border; it uses catch data, relative abundance indices derived from trawl logbook data, and an index of age-1 abundance from trawl surveys in the San Francisco Bay and Sacramento-San Joaquin River estuary. Unlike most other groundfish stock assessments, no age- or length-composition data are directly used in the assessment. Both the northern and southern populations are estimated to be above the target level of 40% of virgin spawning biomass (44% of SB_0 in Washington-Oregon and 62% in California), although the status of this data-poor species remains fairly uncertain compared to that of many other groundfish species. One of the most significant areas of uncertainty in the assessment is the estimate of natural mortality rate, which was quite high (0.30 yr^{-1} for females and 0.45 yr^{-1} for males).

4.1.3.16 Yellowtail Rockfish

Distribution and Life History

Yellowtail rockfish (*Sebastes flavidus*) range from San Diego, California, to Kodiak Island, Alaska {Fraidenburg 1980; Gotshall 1981; Lorz et al. 1983; Love 1991; Miller and Lea 1972a; Norton and MacFarlane 1995}. The center of yellowtail rockfish abundance is from Oregon to British Columbia

(Fraidenburg 1980). Yellowtail rockfish are a common, demersal species abundant over the middle shelf {Carlson and Haight 1972; Fraidenburg 1980; Tagart 1991; Weinberg 1994}. Yellowtail rockfish are most common near the bottom, but not on the bottom {Love 1991; Stanley et al. 1994}. Yellowtail rockfish adults are considered semi-pelagic {Stanley et al. 1994; Stein et al. 1992} or pelagic, which allows them to range over wider areas than benthic rockfish (Pearcy 1992). Adult yellowtail rockfish occur along steeply sloping shores or above rocky reefs {Hart 1986}. They can be found above mud with cobble, boulder and rock ridges, and sand habitats; they are not, however, found on mud, mud with boulder, or flat rock {Love 1991, Stein et al. 1992}. Yellowtail rockfish form large (sometimes greater than 1,000 fish) schools and can be found alone or in association with other rockfishes {Love 1991, Pearcy 1992, Rosenthal et al. 1982, Stein et al. 1992, Tagart 1991}. These schools may persist at the same location for many years (Pearcy 1992).

Yellowtail rockfish are viviparous (Norton and MacFarlane 1995) and mate from October to December. Parturition peaks in February and March and from November to March off California {Westrheim 1975}. Young-of-the-year pelagic juveniles often appear in kelp beds beginning in April and live in and around kelp in midwater during the day, descending to the bottom at night {Love 1991, Tagart 1991}. Male yellowtail rockfish are 34 cm to 41 cm in length (five years to nine years) at 50% maturity, females are 37 cm to 45 cm (six years to ten years) (Tagart 1991). Yellowtail rockfish are long-lived and slow-growing; the oldest recorded individual was 64 years old {Fraidenburg 1981, Tagart 1991}. Yellowtail rockfish have a high growth rate relative to other rockfish species (Tagart 1991). They reach a maximum size of about 55 cm in approximately 15 years (Tagart 1991). Yellowtail rockfish feed mainly on pelagic animals, but are opportunistic, occasionally eating benthic animals as well (Lorz, *et al.* 1983). Large juveniles and adults eat fish (small Pacific whiting, Pacific herring, smelt, anchovies, lanternfishes, and others), along with squid, krill, and other planktonic organisms (euphausiids, salps, and pyrosomes) {Love 1991, Phillips 1964, Rosenthal et al. 1982, Tagart 1991}.

Stock Status and Management History

Until the late 1990's, yellowtail rockfish were harvested as part of a directed midwater trawl fishery. However because it co-occurs with several other rockfishes, including the overfished species canary rockfish and widow rockfish {Nagtegaal 1983; Tagart 1987; Rogers and Pikitch 1992}, yellowtail rockfish fishing opportunity has been substantially curtailed. Since the end of 2002, there have been no landings limits that provide directed mid-water fishing opportunities for yellowtail rockfish in non-tribal trawl fisheries.

The stock assessment of yellowtail rockfish was most recently updated in 2005 (Wallace and Lai 2006). The last full assessment of the northern stock areas was conducted in 2000 {Tagart et al. 2000}, and it was then updated in 2003 {Lai et al. 2003}. The Council manages the U.S. fishery as two stocks separated at Cape Mendocino, California; as in the past, the 2005 update assessment includes only the northern stock (which is divided for assessment purposes into three areas: South Vancouver, Northern Columbia, and Eureka/South Columbia). The purpose of an assessment update is to add the most recent data into the model used in the full assessment. This update, therefore, continued the use of the age-structured model written with AD Model Builder software and extended the various data time series. Abundance trends were estimated to be somewhat different by area (little trend in South Vancouver and declining trends in the other areas). However following the recommendations of the SSC and 2003 STAR panel, the coastwide estimates of biomass and ABC/OY are the summation of estimates from the three assessed areas. The estimated age4+ biomass in year 2004 was 72,152 mt with a 26% CV, which is an increase from 58,025 mt in 2003. Since 1995 the spawning biomass has remained above 40% of unfished levels.

4.1.4 Unassessed Groundfish Species and Those Managed as Part of a Stock Complex

4.1.4.1 Minor Rockfish South

Southern Nearshore Species

The complex, Minor Nearshore Rockfish south of 40°10' N latitude, is further subdivided into the following management categories: 1) shallow nearshore rockfish [comprised of black and yellow rockfish (*S. chrysomelas*); China rockfish (*S. nebulosus*); gopher rockfish (*S. carnatus*); grass rockfish (*S. rastrelliger*), and kelp rockfish (*S. atrovirens*)]; 2) deeper nearshore rockfish: [comprised of black rockfish (*S. melanops*), blue rockfish (*S. mystinus*); brown rockfish (*S. auriculatus*); calico rockfish (*S. dalli*); copper rockfish (*S. caurinus*); olive rockfish (*S. serranoides*); quillback rockfish (*S. maliger*); and treefish (*S. serriceps*)] and 3) California scorpionfish (*Scorpaena guttata*).

Of the species listed above, two were assessed for the first time in 2005, gopher rockfish, and California scorpionfish. Because of this new information, California scorpionfish has been removed from the stock complex and will be managed under its individual harvest specifications beginning in 2007. However gopher rockfish cannot be managed separately from other nearshore rockfish species without significantly increasing bycatch; in addition, the assessment is considered uncertain due to its poor data quality. Gopher rockfish, therefore, will continue to be managed from within the southern minor nearshore rockfish species complex, but the information provided in the stock assessment will be used to inform the harvest specifications set for that complex.

Gopher rockfish was assessed for the first time in 2005 (Key, *et al.* 2006). Although the distribution of gopher rockfish extends south into the Southern California Bight, the assessment was restricted to the stock north of Pt. Conception. The assessment is based on landings and length composition data from commercial and recreational fisheries (primarily hook and line gear) and an index of relative abundance (catch per unit effort or CPUE) from the commercial passenger fishing vessel (CPFV) Sportfish Survey database. These data sources were used to estimate population trends from 1965 to 2004. There are no fishery-independent indices of stock biomass for gopher rockfish. Assessment results indicate an upward trend in gopher rockfish biomass since the 1980s and estimates of 2005 abundance ranged between 60% and 110% of average unfished stock size; this range of depletion levels is the result of alternative emphases in the model given to the CPFV in the CPUE index, a data element identified as a major source of uncertainty. Recent exploitation rates are estimated to have been well below the F_{MSY} proxy for rockfish.

Southern Shelf Species

The minor shelf rockfish complex south of 40°10' N latitude is composed of the following species: bronzespotted rockfish (*S. gilli*); chameleon rockfish (*S. phillipsi*); dusky rockfish (*S. ciliatus*); dwarf-red rockfish (*S. rufianus*); flag rockfish (*S. rubrivinctus*); freckled rockfish (*S. lentiginosus*); greenblotched rockfish (*S. rosenblatti*); greenspotted rockfish (*S. chlorostictus*); greenstriped rockfish (*S. elongatus*); halfbanded rockfish (*S. semicinctus*); harlequin rockfish (*S. variegatus*); honeycomb rockfish (*S. umbrosus*); Mexican rockfish (*S. macdonaldi*); pink rockfish (*S. eos*); pinkrose rockfish (*S. simulator*); pygmy rockfish (*S. wilsoni*); redstripe rockfish (*S. proriger*); rosethorn rockfish (*S. helvomaculatus*); rosy rockfish (*S. rosaceus*); silvergray rockfish (*S. brevispinis*); speckled rockfish (*S. ovalis*); squarespot rockfish (*S. hopkinsi*); starry rockfish (*S. constellatus*); stripetail rockfish (*S. saxicola*); swordspine rockfish (*S. ensifer*); tiger rockfish (*S. nigrocinctus*); vermilion rockfish (*S. miniatus*); and yellowtail rockfish (*S. flavidus*).

In 2005, vermilion rockfish was assessed for the first time. However there were significant concerns about the reliability of the assessment. Given these concerns, the SSC did not endorse the results as being suitable for setting OYs and the Council did not accept the assessment for use in management. Vermilion rockfish, therefore, is still managed within the southern minor shelf rockfish complex

Southern Slope Species

The minor slope rockfish complex south of 40°10' N latitude is composed of the following species: aurora rockfish (*S. aurora*); bank rockfish (*S. rufus*); blackgill rockfish (*S. melanostomus*); Pacific ocean perch (*S. alutus*); redbanded rockfish (*S. babcocki*); rougheye rockfish (*S. aleutianus*); sharpchin rockfish (*S. zacentrus*); shortraker rockfish (*S. borealis*); and yellowmouth rockfish (*S. reedi*).

Although blackgill rockfish has been formally assessed, it is still managed as part of the southern Sebastes complex; aggregate ABCs and OYs are established from this complex using the harvest targets of some component individual species, such as blackgill rockfish.

Blackgill rockfish landings can be attributed almost entirely to the commercial fishery in California. Since the late 1970's, hook and line has accounted for 56% of total landings in California, set nets has accounted for 12%; and trawl has accounted for 32%. The first assessment for blackgill rockfish was conducted in 1998 (Butler, *et al.* 1999). That assessment assumed a unit stock in southern and central California (Conception INPFC area) and was based on a stock reduction analysis assuming constant recruitment. The dynamics of the simple model were tuned to average mortality rates from catch curves and landings data. Fishery selectivity was assumed to mirror maturity at size/age; trends in fishable/mature biomass were then estimated.

In 2005, the second and most recent stock assessment of blackgill rockfish was completed {Helser 2006}. This assessment expanded the geographic range of that in Butler et al. {1999}, including both the Monterey and Conception INPFC areas, where over 90% of the landings have occurred. The assessment is based on catch and length composition data from commercial fisheries and indices of relative abundance and size composition from the AFSC shelf trawl survey and the AFSC slope survey. The modeling approach, Stock Synthesis 2 (Ver. 1.19), takes advantage of fishery and survey length compositions to explicitly estimate selectivity. The base model estimated depletion to be 52.3% of the unfished spawning biomass, within a range of 36% to 67% depending upon the assumed natural mortality rate (identified as a key axis of uncertainty for this stock). Assessment results indicate that recent exploitation rates have been slightly below the F_{MSY} proxy for rockfish.

4.1.4.2 Minor Rockfish North

Northern Nearshore Species

The minor nearshore rockfish complex north of 40°10' N latitude is composed of the following species: black and yellow rockfish (*S. chrysomelas*); blue rockfish (*S. mystinus*); brown rockfish (*S. auriculatus*); calico rockfish (*S. dalli*); China rockfish (*S. nebulosus*); copper rockfish (*S. caurinus*); gopher rockfish (*S. carnatus*); grass rockfish (*S. rastrelliger*); kelp rockfish (*S. atrovirens*); olive rockfish (*S. serranoides*); quillback rockfish (*S. maliger*); and treefish (*S. serriceps*).

Northern Shelf Species

The minor shelf rockfish complex north of 40°10' N latitude is composed of the following species:

bronzespotted rockfish (*S. gilli*); bocaccio (*Sebastes paucispinis*); chameleon rockfish (*S. phillipsi*); chilipepper rockfish (*S. goodei*); cowcod (*S. levis*); dusky rockfish (*S. ciliatus*); dwarf-red rockfish (*S. rufianus*); flag rockfish (*S. rubrivinctus*); freckled rockfish (*S. lentiginosus*); greenblotched rockfish (*S. rosenblatti*); greenspotted rockfish (*S. chlorostictus*); greenstriped rockfish (*S. elongatus*); halfbanded rockfish (*S. semicinctus*); harlequin rockfish (*S. variegatus*); honeycomb rockfish (*S. umbrosus*); Mexican rockfish (*S. macdonaldi*); pink rockfish (*S. eos*); pinkrose rockfish (*S. simulator*); pygmy rockfish (*S. wilsoni*); redstripe rockfish (*S. proriger*); rosethorn rockfish (*S. helvomaculatus*); rosy rockfish (*S. rosaceus*); silvergray rockfish (*S. brevispinis*); speckled rockfish (*S. ovalis*); squarespot rockfish (*S. hopkinsi*); starry rockfish (*S. constellatus*); stripetail rockfish (*S. saxicola*); swordspine rockfish (*S. ensifer*); tiger rockfish (*S. nigrocinctus*); and vermilion rockfish (*S. miniatus*).

Northern Slope Species

The minor slope rockfish complex north of 40°10' N latitude is composed of the following species: aurora rockfish (*S. aurora*); bank rockfish (*S. rufus*); blackgill rockfish (*S. melanostomus*); redbanded rockfish (*S. babcocki*); rougheye rockfish (*S. aleutianus*); sharpchin rockfish (*S. zacentrus*); shortraker rockfish (*S. borealis*); splitnose rockfish (*S. diploproa*); and yellowmouth rockfish (*S. reedi*).

4.1.4.3 Pacific Cod

Distribution and Life History

Pacific cod (*Gadus macrocephalus*) are widely distributed in the coastal north Pacific, from the Bering Sea to Southern California in the east, and to the Sea of Japan in the west. Adult Pacific cod occur as deep as 875 m (Allen and Smith 1988), but the vast majority occurs between 50 m and 300 m {Allen and Smith 1988, Hart 1986, Love 1991, NOAA 1990}. Along the West Coast, Pacific cod prefer shallow, soft-bottom habitats in marine and estuarine environments (Garrison and Miller 1982), although adults have been found associated with coarse sand and gravel substrates (Garrison and Miller 1982; Palsson 1990). Larvae and small juveniles are pelagic; large juveniles and adults are parademersal (Dunn and Matarese 1987; NOAA 1990). Adult Pacific cod are not considered to be a migratory species. There is, however, a seasonal bathymetric movement from deep spawning areas of the outer shelf and upper slope in fall and winter to shallow middle-upper shelf feeding grounds in the spring (Dunn and Matarese 1987; Hart 1988; NOAA 1990; Shimada and Kimura 1994).

Pacific cod have external fertilization {Hart 1986, NOAA 1990} with spawning occurring from late fall to early spring. Their eggs are demersal. Larvae may be transported to nursery areas by tidal currents (Garrison and Miller 1982). Half of females are mature by three years (55 cm) and half of males are mature by two years (45 cm) {Dunn and Matarese 1987, Hart 1986}. Juveniles and adults are carnivorous and feed at night (Allen and Smith 1988; Palsson 1990) with the main part of the adult Pacific cod diet being whatever prey species is most abundant (Kihara and Shimada 1988; Klovach, *et al.* 1995). Larval feeding is poorly understood. Pelagic fish and sea birds eat Pacific cod larvae, while juveniles are eaten by larger demersal fishes, including Pacific cod. Adults are preyed upon by toothed whales, Pacific halibut, salmon shark, and larger Pacific cod {Hart 1986, Love 1991, NOAA 1990, Palsson 1990}. The closest competitor of the Pacific cod for resources is the sablefish (Allen 1982).

4.1.4.4 Other Fish

The Other Fish stock complex contains all the unassessed Groundfish FMP species that are neither rockfish (family *Scorpaenidae*) nor flatfish. These species include big skate (*Raja binoculata*), California skate (*Raja inornata*), leopard shark (*Triakis semifasciata*), longnose skate (*Raja rhina*), soupfin shark (*Galeorhinus zyopterus*), spiny dogfish (*Squalus acanthias*), finescale codling (*Antimora microlepis*), Pacific rattail (*Coryphaenoides acrolepis*), ratfish (*Hydrolagus colliei*), cabezon (*Scorpaenichthys marmoratus*) (north of the California/Oregon border at 42° N latitude), and kelp greenling (*Hexagrammos decagrammus*).

Kelp greenling was assessed for the first time in 2005. Although the assessment covered both California and Oregon, the Council adopted only the Oregon substock assessment for use in management. Due to the considerable uncertainty associated with the assessment, the Council furthermore decided not to set independent harvest specifications for kelp greenling.

The first and only assessment of kelp greenling was completed in 2005 by Cope and MacCall {2006}. The assessment treated the stock as two completely independent sub-stocks divided at the California-Oregon border (excluding Washington, as there have been no substantial fisheries off its coast). There are substantial differences between the two assessments with respect to assessment period, model assumptions, results, and uncertainties. An important difference between the two sub-stocks is the first year for which historical catch data are available (1916 for California and 1981 for Oregon). The Oregon sub-stock has some age-at-length data, which were included in the assessment. The estimate of depletion for the Oregon sub-stock (the current biomass is at 49% of its unfished) is more certain than estimates of absolute abundance, which are highly imprecise. For the California sub-stock, substantial uncertainty could not be resolved regarding growth and natural mortality rates, as well as the shape of the selectivity pattern for the shore mode fishery. Due to these factors, it was not possible to formulate a model for California.

Longnose skate and spiny dogfish are each scheduled to be assessed in 2007; this will be the first stock assessment for each of these species.

4.1.4.5 Other Flatfish

The Other Flatfish complex contains all the unassessed flatfish species in the Groundfish FMP. These species include butter sole (*Isopsetta isolepis*), curlfin sole (*Pleuronichthys decurrens*), flathead sole (*Hippoglossoides elassodon*), Pacific sanddab (*Citharichthys sordidus*), rex sole (*Glyptocephalus zachirus*), rock sole (*Lepidopsetta bilineata*), and sand sole (*Psettichthys melanostictus*).

Starry flounder (*Platichthys stellatus*) has been managed as part of the Other Flatfish complex (through 2006). However, with the first assessment of starry flounder in 2005 {Ralston 2006}, the Council intends to manage this species, under the current action, with its own stock-specific ABC and OY.

4.1.5 Non-Groundfish Species

Non-groundfish species and the fisheries that target them often need to be considered in groundfish management for two reasons. First, these species may be caught incidentally in directed groundfish fisheries. Thus, management measures that change total fishing effort in groundfish fisheries could increase or decrease fishing mortality on the incidentally-caught species. Second, those fisheries targeting non-groundfish species may also incidentally catch groundfish. This source of groundfish mortality cannot be directly regulated through the groundfish FMP, as such vessels do not hold federal groundfish permits; however, its impact still must be subtracted from the overall OY for that groundfish species. Such catch accounting is particularly critical for depleted species. This section briefly describes these non-groundfish species and associated fisheries, and for certain fisheries, notes mitigation measures that have been introduced to decrease their incidental take of groundfish.

Since vessels operating within the incidental groundfish Open Access fleet do not hold licenses under the Groundfish FMP, it has been difficult to assure their compliance with closed areas established to protect depleted rockfish species (i.e. the Rockfish Conservation Areas). However a new technology adopted by the PFMC has made this accounting easier. Beginning in 2007, all commercial vessels that take and retain, possess, or land federally-managed groundfish species taken in federal waters or in state waters prior to transiting federal waters must employ Vessel Monitoring Systems (VMS). VMS is further discussed in Chapter 6.

Observer programs within the groundfish fishery are important contributions toward the accurate monitoring and recording of incidental take, including that of non-groundfish species. Standardized bycatch reporting methodologies are discussed in section 6.1.2. However one program, the Shoreside Whiting Observer Program (SWOP), is of particular relevance here. SWOP was established in 1992 to examine bycatch in the directed Pacific whiting fishery. Participating vessels must carry an exempted fishing permit (EFP) issued by NMFS, and are required to retain all catch and to land unsorted catch at designated shoreside processing plants. In return, permitted vessels are not penalized for landing prohibited species (e.g., Pacific salmon, Pacific halibut, Dungeness crab), nor are they held liable for exceeding groundfish trip limits.

4.1.5.1 Salmon

Salmon are anadromous fish, spending a part of their life in ocean waters, but returning to freshwater rivers and streams to spawn and then die. Council-managed ocean salmon fisheries mainly catch Chinook and coho salmon (*Oncorhynchus tshawytscha* and *O. kisutch*); pink salmon (*O. gorbuscha*) are also caught in odd-numbered years, principally off of Washington. For further information on the species, as well as management actions and harvest levels, see the *Review of 2005 Ocean Salmon Fisheries* {PFMC 2006}.

The salmon troll fishery has an incidental catch of Pacific halibut and groundfish; this is of particular significance with respect to canary rockfish catch and is further discussed in Section 4.3.5.1. In addition, to account for yellowtail rockfish landed incidentally while not promoting targeting on the species, a federal regulation was adopted in 2001 that allowed salmon trollers to land up to one pound of yellowtail per two pounds of salmon, not to exceed 300 pounds per month (north of Cape Mendocino).

Groundfish fisheries catch salmon incidentally. Chapter 5 (Protected Species) discusses the impacts on salmon in further detail. For both ESA-listed and non ESA-listed salmon species, incidental catch is highest in the limited entry groundfish trawl (whiting and non-whiting) sector. Bycatch of salmon by the groundfish trawl fleet is generally restricted to encounters with Chinook. Data from the West Coast Groundfish Observer Program indicated an order of magnitude drop in coastwide Chinook bycatch for non-whiting LE trawl between 2003 to 2004; the reduction can be attributed to a large degree to a decrease in nearshore trawl effort, where salmon bycatch is usually highest(Hastie 2005). On the other hand, there was an order of magnitude increase in bycatch by the whiting fishery between 2004 and 2005.

4.1.5.2 Pacific Halibut

Pacific halibut (*Hippoglossus stenolepis*) belong to a family of flounders called *Pleuronectidae*. Pacific halibut are managed by the bilateral (U.S./Canada) International Pacific Halibut Commission (IPHC) with implementing regulations set by Canada and the U.S. in their own waters. The Pacific Halibut Catch Sharing Plan for waters off Washington, Oregon, and California (Area 2A) specifies IPHC management measures for Pacific halibut on the West Coast. Implementation of IPHC catch levels and regulations is the responsibility of the Council, the states of Washington, Oregon, and California, and the Pacific halibut treaty tribes.

Of groundfish fisheries, the fixed gear sablefish fishery is responsible for the most catch of Pacific halibut. To allow landing of these halibut, the Catch Sharing Plan stipulates that when the Area 2A total allowable catch (TAC) is above 900,000 pounds, halibut may be retained in the limited entry primary sablefish fishery north of Point Chehalis, Washington (46° 53' 18" N latitude). Rockfish have been commonly caught historically in the halibut fishery. However, encounters have been significantly reduced over recent years by restricting the fishery to set depth greater than 100 fm.

4.1.5.3 Coastal Pelagic Species

Coastal Pelagic Species (CPS) are schooling fish, not associated with the ocean bottom, that migrate in coastal waters. These species include: northern anchovy (*Engraulis mordax*), Pacific sardine (*Sardinops sagax*), Pacific (chub) mackerel (*Scomber japonicus*), jack mackerel (*Trachurus symmetricus*), and market squid (Decapoda spp.). For further information on the species, as well as management actions and harvest levels, see the 2005 CPS SAFE document {PFMC 2005}.

The catch of groundfish in CPS fisheries is negligible, and retention is prohibited. The whiting fishery accounts for a minor proportion of the catch of Pacific mackerel and jack mackerel; the federal harvest guideline for these mackerel species has not been met in recent years.

4.1.5.4 Highly Migratory Species

Highly migratory species (HMS) include tunas, billfish, dorado, and sharks—species that range great distances during their lifetime, extending beyond national boundaries into international waters and among the EEZs of many nations in the Pacific. In 2003, the Council adopted a Highly Migratory Species FMP to federally regulate the take of HMS within and outside the U.S. West Coast EEZ. The FMP {PFMC 2003c} describes management unit species in detail; these are five tuna species, five shark species, striped marlin, swordfish, and dorado (dolphinfish).

The catch of HMS in groundfish fisheries are considered to be negligible.

Using federal observer data, it was concluded that bycatch of Pacific whiting and yellowtail rockfish in the drift gillnet fishery is considered "major" (greater than ten individuals per 100 sets observed) for the period of 2001-2004 {PFMC 2006}. Also, a notable source of groundfish species mortality within the HMS fishery has been due to "mixed trips," in which a vessel operating under a VMS license also targets groundfish during a single trip. The expansion of VMS coverage into the Open Access sector has contributed significantly to the reduction of mixed trip impact on depleted species. Without the VMS requirement (which will go into effect in 2007), the activity of vessels under HMS permits within rockfish conservation areas is unknown, and it is possible that the vessels are targeting groundfish within these restricted areas. VMS is discussed in further detail in Chapter 6.

4.1.5.5 Dungeness Crab

The Dungeness crab (*Cancer magister*) is distributed from the Aleutian Islands, Alaska, to Monterey Bay, California. It lives in bays, inlets, around estuaries, and on the continental shelf. Dungeness crab is found to a depth of about 180 m. Although it is found at times on mud and gravel, this crab is most abundant on sand bottoms; frequently it occurs among eelgrass. It is typically harvested using traps (crab pots), ring nets, by hand (scuba divers), or dip nets. Dungeness crab are managed by the states of Oregon and California, and by the State of Washington in cooperation with Washington Coast treaty tribes, and with inter-state coordination through the Pacific States Marine Fisheries Commission.

Dungeness crab is taken incidentally, or harmed unintentionally, by groundfish gears. In some areas, encounter with Dungeness crab by nearshore flatfish trawls is common. These encounter rates were one of criteria the Council considered when deciding to set the nearshore RCA boundary as seaward as possible. The incidental catch of depleted groundfish species is considered to be negligible.

4.1.5.6 Greenlings, Ocean Whitefish, and California Sheephead

California sheephead (*Semicossyphus pulcher*) are a large member of the wrasse family *Labridae*. They range from Monterey Bay south to Guadalupe Island in central Baja California and the Gulf of California, in Mexico, but are uncommon north of Point Conception. They are associated with rocky bottom habitats, particularly in kelp beds to 55 m, but more commonly at depths of 3 m to 30 m. They can live to 50 years of age and a maximum length of 91 cm (16 kg). Like some other wrasse species, California sheephead change sex starting first as a female, but changing to a male at about 30 cm in length.

Ocean whitefish (*Caulolatilus princeps)* occur as far north as Vancouver Island in British Columbia, but are rare north of Central California. A solitary species, they inhabit rocky bottoms and are also found on soft sand and mud bottoms. Whitefish dig into the substrate for food.

In California, California sheephead and ocean whitefish are each managed by CDFG. Both are predominantly caught by the recreational fishery. Catch of California sheephead and ocean whitefish in the recreational fishery are restricted within the Cowcod Conservation Area to minimize interaction with cowcod.

While kelp greenling, managed under the groundfish FMP, represents the majority of the greenling that are caught; the other species, rock, painted, and white spotted greenling, are managed by the states. Minimal take of rock greenling occurs in the commercial and recreational fisheries in California. It is often taken in conjunction with fishing for federally managed groundfish, primarily nearshore rockfish and cabezon.

4.1.5.7 Pink Shrimp

Pacific pink shrimp (*Pandalus jordani*) are found from Unalaska in the Aleutian Islands to San Diego, California, at depths of 25 fm to 200 fm (46 m to 366 m). Off the U.S. West Coast these shrimp are harvested with trawl gear from Northern Washington to Central California, with the majority of the catch taken off the coast of Oregon. Pacific shrimp fisheries are managed by the states of Washington, Oregon, and California; the Council has no direct management authority.

Concentrations of pink shrimp are associated with well-defined areas of green mud and muddy-sand bottoms. Shrimp trawl nets are usually constructed with net mesh sizes smaller than the net mesh sizes for legal groundfish trawl gear. Thus, it is shrimp trawlers that commonly take groundfish in association with shrimp, rather than the reverse. In the past, the pink shrimp fishery had been responsible in some years for a significant proportion of canary rockfish incidental catch. However, such impact has been reduced to a negligible amount because of bycatch reduction devices (BRDs) that are now required on all vessels in this fishery. BRDs are added to the trawl net and divert finfish out of the codend of the net, where the shrimp catch is accumulated.

4.1.5.8 California Halibut

California halibut (*Paralichthys californicus*) are a left-eyed flatfish of the family *Bothidae*. They range from Northern Washington to southern Baja California, Mexico, (Eschmeyer, *et al.* 1983), but are most common south of Oregon. The species can be targeted by trawl vessels south of Pt. Arena, CA (38°57.50' N latitude). It is a state-managed species, and participation in the open-access fishery for California halibut does not require specific permits. California halibut is, at most, an ancillary fishery for limited-entry trawlers in California (Hastie 2005). The California halibut fishery is known to take only minimal amounts of depleted groundfish species; for example, the PFMC Groundfish Management Team estimated that, in 2005, the fishery was responsible for 0.1 mt mortality of bocaccio rockfish and 0.0 mt of all other depleted groundfish species.

4.1.5.9 Ridgeback and Spot Prawns

Ridgeback prawns (*Sicyonia ingentis*) are found from Monterey, California south to Baja California, Mexico, in depths of 145 metric feet to 525 metric feet {Sunada *et al.* 2001}. They are more abundant south of Point Conception and are the most common invertebrate appearing in trawls. Their preferred habitat is sand, shell and green mud substrate, and relatively sessile. They are prey for sea robins, rockfish, and lingcod. The Ridgeback prawn fishery occurs exclusively in California, centered in the Santa Barbara Channel and off Santa Monica Bay. The ridgeback prawn fishery is managed by the State of California and, similar to spot prawn and pink shrimp, is considered an “exempted” trawl gear in the federal open access groundfish fishery, entitling the fishery to groundfish trip limits. However, the catch of depleted groundfish in the ridgeback prawn fishery is considered to be negligible.

Spot prawn (*Pandalus platyceros*) are the largest of the pandalid shrimp and range from Baja California, Mexico, north to the Aleutian Islands and west to the Korean Strait {Larson 2001}. They inhabit rocky or hard bottoms including coral reefs, glass sponge reefs, and the edges of marine canyons. They have a patchy distribution, which may result from active habitat selection and larval transport. Spot prawn are Hermaphroditic. Spot prawn fisheries are state-managed. The use of trawl gear to target spot prawn has been banned in all three states; the spot prawn pot fishery that remains is considered to have no incidental bycatch of depleted groundfish species.

4.1.5.10 Sea Cucumbers

Two sea cucumber species are targeted commercially: the California sea cucumber (*Parastichopus californicus*), also known as the giant red sea cucumber, and the warty sea cucumber (*P. parvimensis*) (Rogers-Bennett and Ono 2001). These species are tube-shaped Echinoderms, a phylum that also includes sea stars and sea urchins. The California sea cucumber occurs as far north as Alaska, while the warty sea cucumber is uncommon north of Point Conception and does not occur north of Monterey. Both species are found in the intertidal zone to as deep as 300 feet and are bottom-dwelling organisms.

Along the West Coast, sea cucumbers are harvested by diving or trawling, and the fisheries are managed by the states. The warty sea cucumber is fished almost exclusively by divers. The California sea cucumber is caught principally by trawling in Southern California, but is targeted by divers in Northern California. The sea cucumber trawl fishery occurs over sandy flat habitat off of Santa Barbara (south of Pt. Conception), an area with no rocky outcroppings. Given that habitat, the fishery is considered to have negligible bycatch of depleted species.

4.2 Criteria Used to Evaluate Impacts

A primary goal of the groundfish FMP is to rebuild to or maintain spawning stock biomass of groundfish stocks and stock complexes at B_{MSY}. Two critical considerations in evaluating alternative harvest levels relative to accomplishing this goal are the uncertainty of management measures to limit total fishing-related mortality to prescribed levels and the uncertainty in our understanding of stock status and productivity. In other words, the risks of allowing higher harvests to provide increased socioeconomic benefits (see Chapter 7 for an evaluation of socioeconomic impacts) need to be evaluated by the effectiveness of harvest monitoring systems to accurately determine total fishing-related mortality and assessment uncertainty. An additional consideration for depleted stocks is the tradeoff of duration of rebuilding vs. the amount of allowable harvest or total fishing-related mortality. All of these considerations are used to develop criteria for evaluating biological impacts to groundfish stocks.

Systems for monitoring groundfish mortalities (landings plus discard mortalities) on the West Coast vary in their effectiveness depending on whether the species is primarily caught in commercial or recreational fisheries and how well at-sea discards are monitored. In general, fishing-related mortalities of commercially caught species are better known than those for stocks primarily caught by recreational fisheries. This is because commercial landings are recorded on fish receiving tickets, which are used to document the weight and ex-vessel value of landed catch, while recreational catches are mostly monitored using a random, stratified census of anglers. The degree of at-sea monitoring of discards also varies by fishing sector with the limited entry at-sea whiting trawl sector having the highest at-sea observer rates; followed by limited entry bottom trawl (including shoreside whiting); limited entry fixed gear; open access; California commercial passenger fishing vessels (CPFV or California recreational charter); and California (non-CPFV), Oregon, and Washington recreational. The treaty tribes report that their fisheries are observed at a high rate because their fisheries are full retention fisheries for rockfish species.

Assessment uncertainty is another evaluation criterion for evaluating stock impacts. In general, assessments of species that are adequately sampled by a reliable source of fishery independent abundance information tend to be more robust with respect to estimating stock trends and abundance {NRC, 1998}. On the West Coast, groundfish surveys have typically been conducted using bottom trawl gear randomly stratified over latitudinal and depth strata along the continental shelf and slope {Lauth 2000, Weinberg et al. 2002}[18]. The results from these surveys are typically the key inputs to the stock assessments for West Coast groundfish stock assessments. For example, indices of abundance from the triennial trawl survey were used in 15 of the 22 assessments in Table 4-2, and 7 assessments used slope survey data. These surveys are also often the source of the biological data used to estimate life history parameters. For species that are not well sampled by traditional survey data, such as cowcod and yelloweye rockfish, other temporal indices of abundance are used to tune assessments. Many such indices, particularly fishery-dependent indices such as commercial or recreational catch per unit effort (CPUE) trends, tend to be associated with higher levels of uncertainty. Fishery-dependent data are often less reliable than fishery-independent data for a variety of reasons; for example, catch rates may be

[18] The NMFS Alaska Fisheries Science Center originally implemented a full trawl survey completed every three years on the West Coast and hence called the "triennial" survey, data from this survey span from 1977 to 2004. The Alaska Center also conducted slope surveys beginning in 1984, although these surveys had varying temporal and spatial coverage. Since 1998, the NMFS Northwest Fisheries Science Center has conducted an annual bottom trawl survey of the West Coast slope, and since 2003 this survey has sampled both shelf and slope habitats. This survey (referred to as the "combined" survey) will be the key source of fishery independent information in the future. Currently, information from all of these surveys are typically used to tune West Coast groundfish stock assessments.

stable in the face of stock declines as a result of increasing fishing power or changing spatial patterns in effort {Hilborn and Walters 1992, Walters 2003}. Furthermore, management measures can substantially alter the integrity of fishery-dependent data, particularly in response to actions by managers to reduce or control effort. Consequently, assessments for data-poor species such as cowcod and yelloweye rockfish, which are based on highly uncertain catch reconstructions and recreational CPUE time series to inform biomass trends, are associated with much greater levels of uncertainty relative to other groundfish species' assessments.

As illustrated throughout section 4.1, model uncertainty is also a key factor in considering how the results of stock assessments are used. The perception of stock status and productivity for many stocks, particularly those for rebuilding species, often changes substantially between stock assessments. Such changes can be a result of a range of technical factors, including how a given assessment model is structured, the assumptions used to fix or estimate key parameters (i.e., whether parameters such as natural mortality and steepness are fixed, estimated freely, or estimated with an informative prior), and the evolution of methods for developing time series and estimates of uncertainty from different sources of raw data. As the population dynamics of target species themselves are responsive to a mix of complex (and typically poorly understood) biological, oceanographic and interspecific interactions, new sources of information (e.g., new data sets, extensions of existing data sets, incorporation of environmental factors into assessments) can also result in changes in parameter estimates and model outputs. Consequently, estimates of depletion levels and stock status can vary substantially between assessment cycles; as illustrated by the increase in the estimated OY of bocaccio from ≤20 mt to 250 mt between 2002 and 2003, and the perception from the most recent widow rockfish assessment that this stock may not have ever been below the overfished threshold of 25% of initial biomass. In such cases, the most plausible result from the assessment should still be viewed as highly uncertain and the risks associated with management decision-making should account for this uncertainty.

A logical conclusion for evaluating potential management decisions using highly uncertain assessment results is more precaution may be needed to avoid future problems if assumptions regarding stock status are overly optimistic. For example, Punt {2003} developed a simulation model to evaluate how well a particular set of management rules actually achieved management goals in the face of measurement error, process error, and model uncertainty. The study simulating the outcomes under a given set of rules for assessing progress, with regard to the number of times a rebuilding plan was revised, the average catch during the years that the resource was being rebuilt, and the ratio of the number of years that it took for a stock to rebuild over the number of years it was expected to take a stock to rebuild based on the original rebuilding plan. In general, results indicated that greater stability tended to be associated with smaller OYs (which were based on more conservative criteria for achieving success), and that frequent revisions to harvest rates that accompanied new assessments could lead to both a less stable management regime and longer overall rebuilding times.

The predicted times to rebuild the seven depleted species subject to FMP Amendment 16-4 relative to the amount of allowable harvest (to avoid significant or disastrous socioeconomic impacts to fishing communities) are determined in new rebuilding analyses recommended by the SSC in 2005 or, in the case of yelloweye rockfish, in 2006. These rebuilding analyses probabilistically evaluate allowable harvest vs. rebuilding duration relative to the maximum allowable time to rebuild (T_{MAX}) under the current National Standard Guidelines. T_{MAX} is defined as the minimum estimated time to rebuild with no allowable fishing-related mortality (T_{MIN}) plus one mean generation time. The soundness in defining T_{MAX} this way is that one mean generation, or the number of years predicted for a spawning female to replace herself in the population, is a relative biological index of stock productivity. Therefore, the range of allowable rebuilding periods is bounded by the biological limit of T_{MIN} or $T_{F=0}$[19], where all

[19] T_{MIN} and $T_{F=0}$ are both predicted rebuilding periods in the absence of fishing-related mortality to the stock.

stock mortality is natural mortality and a scientifically-derived upper limit linked to stock productivity. Stocks exhibiting low productivity will necessarily have longer predicted rebuilding periods due to longer mean generation times. The probability of rebuilding by T_{MAX} (P_{MAX}) is therefore one of the criteria used to evaluate risk of alternative harvest levels for depleted species, since it is a metric that relates management risk (i.e., risk of not meeting the rebuilding target by T_{MAX}) to a stock's relative productivity.

However, given the guidance from the Ninth Circuit District Court not to follow a formulaic approach for deciding a stock's rebuilding plan, another criterion for evaluating alternative rebuilding plans is to use the extended duration of the predicted rebuilding period relative to $T_{F=0}$. This criterion may be more responsive to the court order to rebuild as quickly as possible (i.e., $T_{F=0}$) while considering the needs of fishing communities. The needs of fishing communities are considered by allowing some harvest of a depleted species as unavoidable bycatch while targeting healthy stocks. Any allowable harvest of a depleted species predicts a longer rebuilding period than $T_{F=0}$. How much longer rebuilding is extended from $T_{F=0}$ is therefore a sensible evaluation criterion.

4.3 Discussion of Direct and Indirect Impacts

This section evaluates and discusses direct and indirect impacts of OY alternatives and action alternatives (management measures) on affected species. A retrospective analysis of past management actions and resulting impacts is critical in this exercise to understand potential future impacts. To that end, final total catch estimates by fishing sector are provided for 2004 West Coast groundfish fisheries (Table 4-6) and "near-final" 2005 total catch estimates (Table 4-7). The reason 2005 catches are not considered final is that the full year of WCGOP observation data is not yet available and analyzed to reconcile at-sea discards; a process which has been completed for 2004 fisheries. In lieu of these data, projected impacts from the various sector bycatch models employed by the GMT to track discards relative to known landings is used. It is anticipated that final 2005 catch estimates will be available by the end of 2006, which is too late to be incorporated in the final EIS.

Impacts of OY alternatives are also compared between action alternatives and with the No Action Alternative and evaluated using the criteria described in section 4.2.

These terms are distinguished by when the F=0 strategy is considered. T_{MIN} is the predicted time to rebuild if all fishing-related mortality is eliminated from the onset of rebuilding (usually the year after the stock is declared overfished) and $T_{F=0}$ is the predicted duration of rebuilding if all fishing-related mortality to the stock is eliminated starting at the onset of the next available management cycle. $T_{F=0}$ is typically longer than T_{MIN} since some fishing-related mortality is typically allowed under a Council's rebuilding plan to avoid disastrous short term economic impacts from eliminating harvest. However, unless the stock has just been declared overfished, $T_{F=0}$ is the shortest possible time to rebuild the stock given our current understanding of the stock's productivity.

a/ Preliminary estimates of total catch mortality based on species discard assumptions used when the OYs were set. These assumptions are currently being revised using data from the West Coast Groundfish Observer Program.
b/ Preliminary estimated discard mortality in the commercial fishery. Preliminary trawl discard calculated by applying discard mortality rates from combined 2001-03 West Coast Groundfish Observer data to 2002 trawl logbook data, by area and depth strata. Discard totals estimated for tows recorded in logbooks is expanded using state-specific ratios of fish ticket landings to retained logbook catch. Because tows conducted under Exempted Fishing Permits could not currently be completely removed from logbooks and fish tickets, applying fleetwide discard rates to these tows may overstate discard for some shelf species.
In an effort to minimize this problem, rockfish discard from target tonnage caught within the RCA off Oregon was estimated using bycatch rates from that EFP. Since the Washington EFP included full retention of shelf rockfish, no at-sea discard of these species was estimated for tows occurring within the RCA off Washington, or on tows that exceeded the 2-month allowance of arrowtooth flounder outside the EFP. This column also includes at-sea discards of rebuilding species. Preliminary fixed-gear discard in the directed sablefish fisheries is calculated by applying discard mortality rates from combined 2001-03 West Coast Groundfish Observer data to northern sablefish landings data. No logbooks are available for fixed-gear vessels. Because of limited geographic coverage of available data, fixed-gear discard amounts for species off central California are not well estimated at this time.
c/ Includes shoreside commercial and tribal landings from PacFIN, observed total catch including estimated discards in the at-sea whiting fishery, and RecFIN recreational catch plus observed discard mortality (A+B1).
d/ Discards of whiting are estimated from observer data and counted towards the OY inseason.
e/ Includes "unspecified thornyheads" allocated based on ratios estimated from California landings and At Sea north/south ABCs.

4.3.1 Depleted Groundfish Species

4.3.1.1 Impacts of Optimum Yield Alternatives

Each OY alternative analyzed for depleted groundfish is evaluated using the criteria discussed above in section 4.2. In summation, these evaluation criteria are relative catch monitoring uncertainty, relative assessment uncertainty, the estimated rebuilding probability, and the extended duration of rebuilding. The tradeoff of available harvest under alternative OYs for depleted species and predicted rebuilding times for these species (i.e., the extended duration of rebuilding) is also described in section 2.1.1.1 and depicted in Table 2-3 and Figure 2-2.

This section also describes the types of strategies that should be considered in a groundfish species' rebuilding plan. As OYs decrease across the range of alternatives, more precautionary management measures and risk-averse strategies need to be employed to reduce total fishing-related mortality to prescribed levels.

<u>General Rebuilding Strategies</u>

Harvest Limits (Harvest Guidelines or Quotas)

The Council sets OYs for each depleted stock (among other managed species). Although resulting OYs are considered harvest guidelines, the Council has treated them as hard limits on total fishing mortality for overfished species. For example, they have closed fisheries late in the year if a depleted species' OY is projected to be exceeded. In some cases, OYs for co-occurring healthy groundfish stocks are reduced to limit the incidental mortality of one or more depleted groundfish species.

Permits, Licenses, and Endorsements

Participation in the Washington, Oregon, and California commercial groundfish fishery was partially limited beginning in 1994 when the federal vessel license limitation program was implemented (Amendment 6). Subsequently, Amendment 9 further limited participation in the fixed-gear sablefish fishery by establishing a sablefish endorsement. There is currently no federal permit requirement for other commercial participants (fishers or processors) or recreational participants (private recreational or charter). A buyback of vessels in the limited entry trawl fishery, and associated permits, was completed in 2003. This reduced participation in this sector by roughly one-third.

Trip Landing and Frequency Limits

Cumulative trip limits have been a key fixture of groundfish management for many years. Currently, these limits set for stocks, stock complexes, and species groups dictate the total amount of fish that may be landed during a one- or two-month period. Separate limits are established for the limited entry trawl, limited entry fixed gear, and open access sectors. Landing limits on target species may be adjusted in order to limit coincident catch of depleted species. A limited entry trawl trip limit of 100 pounds per month was established in 2004 for large footrope gear, which may only be used seaward of the Rockfish Conservation Area (RCA).

Seasons

Specification of different seasonal fishing opportunities by region is a management tool increasingly used to limit fishing mortality in West Coast recreational groundfish fisheries. Seasons can be adjusted inseason and often vary by the depths open to fishing to fine tune the balance between fishing opportunities and conservation of depleted species.

Area Closures

Beginning in 2002, RCAs came into use as a way of decreasing bycatch of depleted species. The sector-specific RCAs encompass the depth ranges where bycatch of depleted species is most likely to occur, based on information retrieved from log books, the at-sea observer program, catch records, and trawl survey data; and fishing by designated groundfish fishery sectors is prohibited within its boundaries. The boundaries vary by season and fishery sector, and may be modified in response to new information about the geographic and seasonal distribution of bycatch. Additionally, there are discrete RCAs designed to protect certain species such as cowcod and yelloweye rockfish (two Cowcod Conservation Areas exist south of 34°27' N latitude and one Yelloweye RCA exists in waters off northern Washington). These "species-specific" RCAs also provide a measure of protection for other co-occurring depleted groundfish species.

Gear Restrictions in Trawl Fisheries

Definitions of legal gear types and restrictions on mesh size in trawl gear have been part of the FMP since its inception. A cod end 4.5 inch minimum mesh size has been specified for groundfish trawl gear for many years to reduce the bycatch mortality of juvenile groundfish species and fish that are too small to be marketable. Since 2000, restrictions have been put on the use of trawl nets equipped with large footropes. By using large footropes with heavy roller gear, bottom trawlers can access rocky habitat on the continental shelf. In areas shoreward of the RCA large footrope gear is prohibited, preventing trawlers from accessing rocky habitat in these shallower depths. In areas seaward of the RCA, either small or large footrope gear may be used, although large footrope gear is the preferred gear type in these depths since small footropes tend to dig into the softer sediments of the slope and abyssal plain. In addition, cumulative trip limits have been structured in recent years to encourage vessels to fish exclusively in deep water where some overfished species are less likely to be encountered. Trawl vessels were allowed to use all these legal gear configurations during any given cumulative limit period. However, in 2004 trawl vessels which used the small footrope configuration were restricted to lower cumulative trip limits for target species in comparison to vessels using large footrope configurations. These measures encouraged fishing exclusively in deeper water to take advantage of the higher limits afforded this gear type. In 2005 and 2006, trawl vessels were not restricted with respect to gear-specific cumulative landing limits in any one period, but they were restricted to the area they could fish, either shoreward or seaward of the RCA, in any one period. Large or small footrope trawls were allowed seaward of the RCA, while only small footrope trawls were allowed shoreward of the RCA south of 40°10' N latitude and selective flatfish trawls allowed shoreward of the RCA north of 40°10' N latitude (selective flatfish trawls were also allowed to be used south of 40°10' N latitude, but were not mandated shoreward of the RCA as they were in the north). The selective flatfish trawl net is configured with a cut back headrope, low rise, and a small footrope, a design shown to substantially reduce catches of some rockfish species while more efficiently catching target flatfish species. This is because most rockfish species rise to escape an approaching trawl net, while flatfish species tend to dive. The rockfish escape due to the low rise and cut back headrope. While this gear has been tested and mandated shoreward of the RCA since 2005 in waters north of 40°10' N latitude, it has not been fully tested in waters south of 40°10' N latitude. Therefore, the behavior and bycatch rates of southern rockfish species, such as bocaccio, when encountering a selective flatfish trawl are unknown at this time. However, this gear may also be effective at reducing bycatch of southern rockfish species in the bottom trawl fishery and should be explored further.

Bycatch reduction devices (BRDs), also known as fish excluders, are mandated for the exempt trawl fishery targeting pink shrimp. Pink shrimp trawls historically had a high bycatch of rockfish. ODFW researched various BRD configurations to determine those devices that significantly reduced rockfish bycatch without an overall reduction in pink shrimp catch efficiency. Now specific hard grate BRDs and other accepted configurations are mandated for West Coast pink shrimp trawls and resulting rockfish bycatch has been reduced dramatically.

Gear Restrictions in Fixed Gear Fisheries

Limited entry and open access fixed gear fisheries on the West Coast use hook and line gears, longlines (both vertically and horizontally deployed on the bottom or suspended off the bottom), and pots/traps to target groundfish. Rockfish bycatch has been shown through WCGOP observations to be much lower in pots and traps targeting groundfish than line gears. While a substantial portion of the fixed gear fleets use pots and traps, a significant amount of line gear is used to target nearshore groundfish species and sablefish. Five of the seven rockfish species currently managed under rebuilding plans are shelf species vulnerable to capture using line gears. The two depleted slope species, darkblotched rockfish and POP, are rarely caught using fixed gears. Therefore, measures that would reduce the use of line gears in West Coast shelf areas, where these depleted rockfish species occur, should be considered when developing long term rebuilding strategies. Alternatively, how line gears are fished should be explored more thoroughly since some line gear configurations and fishing strategies may also reduce the bycatch of depleted groundfish species.

Size and Bag Limits

Minimum size limits are specified for many depleted groundfish species to protect recruiting and premature fish from targeted harvest.

Bag limits are a daily limit of species allowed to be retained by anglers. These measures are used for recreational fisheries to limit mortality of depleted groundfish species. In some cases, no retention is allowed for depleted groundfish species as a means to eliminate any potential targeting that might otherwise occur.

Fishery Monitoring and Bycatch Estimation

All commercial groundfish landings are monitored through a fish ticket system requiring reporting by buyers and processors. Bycatch has become a crucial component of total fishing mortality for depleted species. In the last five years, harvest limits or OYs have evolved from an allowed landing limit to a total mortality limit where at-sea dead discards are also counted against the OY. NMFS implemented the West Coast Groundfish Observer Program (WCGOP) in August 2001, and these data were first used to estimate total fishing mortality beginning in mid-2003. The limited entry trawl sector was the first commercial sector to be managed using WCGOP data to estimate discards. In 2004 bycatch modeling was expanded to the primary sablefish fishery prosecuted by limited entry fixed gear vessels as WCGOP data became available for that sector. In 2005 WCGOP data was used to model bycatch of groundfish species in nearshore commercial fisheries in California and Oregon. As more observer data from different fishery sectors become available, further model extensions will be developed to more accurately estimate bycatch of depleted species in these sectors.

Recreational fishery monitoring and bycatch estimation is a state responsibility and each West Coast state employs a different system. Washington and Oregon employ a random, stratified census of anglers to estimate catch and effort with relative precision. In California, where the coastline is much longer, recreational participation much greater, and the larger number of ports, recreational monitoring and catch estimation was done through a federal census known as Marine Recreational Fisheries Statistical Survey (MRFSS). The MRFSS survey, designed to look only at national trends of marine angler participation, is not precise enough to manage the low harvest guidelines used in recreational fishery management to help rebuild depleted stocks. Therefore, in recent years, efforts have been made to improve recreational fishery sampling in California. For instance, in 2001 the Pacific States Marine Fisheries Commission (PSMFC), with support from NMFS, began a new survey to estimate party/charter boat (commercial passenger fishing vessel [CPFV]) fishing effort in California. This survey differed from the traditional MRFSS telephone survey of anglers to determine CPFV trips by two-month period. The survey sampled 10% of the active CPFV fleet each week to determine the number of trips taken and the anglers carried on each trip. This 10% sample was then expanded to make estimates of total angler trips for Southern California and Northern California. However, the requisite precision for managing the low OYs of overfished species like canary rockfish and bocaccio was still lacking. Fishery scientists from the CDFG and the PSMFC designed a new program for sampling California's recreational fisheries, incorporating both the comprehensive coverage of the MRFSS program and the high quality sampling of CDFG's Ocean Salmon Project. The goal of this new program, the California Recreational Fisheries Survey (CRFS), was to produce in a timely manner marine recreational, fishery-based data needed to sustainably manage California's marine recreational fishery resources. The CRFS program, implemented in January 2004, increased the timeliness and accuracy of recreational fisheries data to more effectively monitor catches inseason, estimate take of species of concern, develop harvest guidelines, produce higher quality fishery-dependent indices for stock assessments, and provide other information critical to management decisions.

Bocaccio (in Waters off California South of 40°10' N Latitude)

Specific Bocaccio Rebuilding Strategies

Bocaccio OYs, compliant with the adopted rebuilding plan, have been specified for managing this stock. In most years (with the exception of a slight overage in 2003 when the OY was ≤20 mt, or about 6.5% of the 2006 OY), bocaccio total mortality has been well below the specified OY (Tables 4-5, 4-6 and 4-7). The Council and NMFS have also adopted the practice of reducing the chilipepper rockfish OY from the ABC, despite the healthy abundance of this stock, as a precautionary measure to reduce the incidental mortality of co-occurring bocaccio. Reducing the chilipepper rockfish OY for the purpose of reducing bocaccio mortality may be less necessary given the advent of managing fisheries using depth-based RCAs.

Commercial bocaccio fishery impacts are managed using a combination of area closures (discussed below) and variable cumulative landing or trip limits. A limited entry trawl trip limit of 100 pounds of bocaccio per month was established in 2004 for large footrope gear to accommodate unavoidable bycatch, which may only be used seaward of the RCA. Limited entry fixed gear and open access limits vary by two-month period and north and south of Point Conception within a range of being closed in some periods to 300 pounds per two-month period. Under the No Action Alternative, trip limits for co-occurring southern shelf rockfish species, including chilipepper rockfish, have been adjusted to limit the incidental harvest of bocaccio.

Recreational bocaccio impacts are managed using a combination of area closures (discussed below), minimum size and daily bag limits (discussed below), and seasons. California manages its recreational fisheries according to five sub-areas (referred to as Rockfish/Lingcod Management Areas) defined by latitudinal boundaries. Different closed seasons have been applied, and modified inseason, primarily to limit canary rockfish catches, the most constraining of the overfished species; but these actions also serve to limit recreational catches of bocaccio.

Area closures or RCAs are one of the more effective rebuilding strategies for reducing bocaccio mortalities. South of 40º10' N latitude, the seaward boundary of the RCA or the limited entry trawl sector is 150 fm in 2006, and the shoreward boundary varies between 75 fm and 100 fm, depending on period. Around offshore islands south of 34°27' N latitude the inner boundary extends to the shoreline. The seaward boundary is the same for limited entry fixed gear and open access sectors; the shoreward boundary either 20 fm, 30 fm, or 60 fm, depending on area and period. California has implemented, and modified inseason, closed areas in their recreational management, restricting fisheries to areas shoreward of boundaries at 20 fm, 30 fm, or 60 fm, depending on sub-area and month. Additionally, the existing Cowcod Conservation Areas south of 34°27' N latitude, where sport and commercial bottom fishing is prohibited, provide significant protection for bocaccio. Any additional RCAs south of 40°10' N latitude in the 15-180 fm zone will provide some additional protection of bocaccio. The greatest density of bocaccio occurs south of 34°27' N latitude in the 54-82 fm zone; therefore, any new RCAs in the Southern California Bight in these depths should provide the most conservation benefit. However, bocaccio are less sedentary than rockfish species such as cowcod and yelloweye. Smaller, discrete RCAs may therefore provide incrementally less conservation benefit for bocaccio relative to more sedentary species.

Minimum size and daily bag limits are used to restrict targeting of juvenile bocaccio and total take of bocaccio, respectively. A 10-inch minimum size limit is applicable to bocaccio in waters off California. Under the No Action Alternative, California has implemented a 10-fish bag limit for the rockfish-cabezon-greenling stock complex. Within the 10-fish bag limit there are bocaccio sub-limits of two fish north of 40º10' N latitude and one fish south of 40º10' N latitude.

Evaluation of Optimum Yield Alternatives

Bocaccio rebuilding schedules across the analyzed OY alternatives range from 0-11 years relative to the shortest predicted time to rebuild the stock of 2021 (i.e., 2021-2032) (Table 4-8). Rebuilding probabilities range from 50% for the highest OY alternative of 424 mt, which is the legal upper limit of possible OYs that can be considered, to 95.8% for the zero-harvest alternative. A significant amount of the total mortality of bocaccio now occurs in the California recreational fishery, the sector with the largest bocaccio take in recent years (Tables 4-5, 4-6 and 4-7), which leads to a high catch monitoring uncertainty. While California recreational catch time series are important fishery-dependent indices in the bocaccio stock assessment, the MacCall {2006} assessment is considered relatively certain given generally good data quality and consistency.

The range of preferred OYs specified by the Council in April 2006 of 40-218 mt compares to the status quo 2006 OY of 309 mt. Rebuilding is extended by less than a year from the shortest possible time ($T_{F=0}$) under the harvest rate used to determine the 40 mt alternative to 5 years under the preferred High OY alternative of 218 mt, which is 3 years shorter than under the status quo harvest rate. The range of rebuilding probabilities (P_{MAX}, or the probability of successful rebuilding in the maximum allowable time under National Standard 1 guidelines) for these preferred OYs are 77.7% to 94.3%. Last year, the SSC recommended a general rebuilding policy of establishing harvest rates that lead to rebuilding probabilities of about 80%[20]. The preferred OY range for bocaccio approximates this P_{MAX} "target".

[20] This recommendation came under the consideration of rebuilding revision rules the Council and its advisors crafted in 2005. The Ninth Circuit Court of Appeals ruling on the challenge to the darkblotched rebuilding plan may have obviated the need for these revision rules by imposing a standard of specifying the shortest possible rebuilding periods while considering the needs of fishing communities. However, as described in section 4.2, P_{MAX} is still a reasonable criterion for evaluating future risks of overharvest given a stock's relative productivity.

Table 4-8. Evaluation of alternative 2007-2008 bocaccio OYs relative to the criteria described in section 4.2.

Evaluation Criterion	OY (mt)						
	No Action OY Alt. (2006 OY)	**OY Alt. 1**	**Pref. Low OY Alt.**	**OY Alt. 2**	**OY Alt. 3 (Pref. High OY)**	**OY Alt. 4**	**OY Alt. 5**
	309	0	**40**	149	**218**	315	424
Catch monitoring uncertainty	High uncertainty due to a significant recreational catch component using MRFSS data (prior to 2004). [a/]						
Assessment Uncertainty	Relatively certain due to generally good data quality and consistency.						
Rebuilding Probability (P_{MAX})	68.4%	95.8%	94.3%	84.4%	77.7%	67.8%	50%
Rebuilding Duration Beyond $T_{F=0}$ (yrs.)	8	0	0.8	3	5	8	11
a/ Catch monitoring uncertainty has improved with the implementation of the California Recreational Fisheries Survey (CRFS) in 2004. However, until CRFS is fully evaluated and catch estimates are provided in a more timely fashion, catch monitoring uncertainty is still regarded as relatively high.							

The recent history of bocaccio assessments is one marked with volatile swings in our understanding of stock status and productivity driven largely by infrequent recruitment events. MacCall {2002} characterized the stock as severely depleted and unlikely to rebuild within T_{MAX} under a zero-harvest strategy. However, evidence of a significant recruitment of the 1999 year class was validated in the bocaccio assessment conducted the following year {MacCall 2003}. The emerging understanding is stock productivity may better be characterized as one driven by rare large recruitments. Minimizing the mortality of these large year classes promises to rebuild the stock fastest. In the current regime of depth-based management, the stock is most vulnerable in the juvenile phase when they occur in shallow waters and are incidentally caught in nearshore commercial and recreational fisheries. However, as bocaccio mature, they migrate to deeper waters where the current RCA restricts those fisheries which are most likely to take adult bocaccio and other co-occurring depleted rockfish. There is some indication that bocaccio recruitment typically occurs from Santa Barbara to Santa Cruz, and is rare south of Ventura, with no evidence of separate southern California recruitment events {MacCall 2003}. Therefore, if this recruitment pattern persists in the future, large recruitment events may be indicated by large incidental catches in central California nearshore fisheries. As recent management experience also indicates, avoiding juvenile bocaccio in these waters during such times is difficult.

Given this recruitment dynamic, what harvest rate provides the best balance of conservation needs without overly restricting California commercial and recreational fisheries? The new bocaccio assessment {MacCall 2006} shows exploitation rates have favored rebuilding since 1998. Those OYs fall within the preferred 2007-2008 OY range of 40-218 mt; however, only in 2003, when fisheries were severely restricted due to the pessimistic 2002 assessment result, was the annual total mortality of bocaccio ≤40 mt. The Preferred Low OY may still be difficult to manage with the same restrictive management measures used in 2003 in the event of another large recruitment. Clearly, a significant negative economic impact would be felt in California fishing communities under the Preferred Low OY harvest rate for a rebuilding "cost" of about four additional years of rebuilding under the Preferred High OY harvest rate. Even under the Preferred High OY of 218 mt, management measures would have to be restrictive, especially for nearshore commercial and recreational fisheries in central California, to stay within that harvest rate during years of large recruitments.

Evaluation of Action Alternatives

All the action alternatives contemplate a liberalization of the Cowcod Conservation Areas in the Southern California Bight. The CCAs currently protect more than just cowcod. An ongoing analysis of larval abundance data suggest that the current western CCA is a region of high abundance of bocaccio (S. Ralston, unpublished data), with the recent density particularly high relative to the long term (historical) distribution of bocaccio. Although the CCA was not implemented to protect bocaccio, the potential to increase catches of other rebuilding species that could result from modifications to CCA boundaries is presumably non-trivial.

Action Alternative 1 is the only action alternative estimated to stay within the Preferred Low OY Alternative for bocaccio. Most of the southern nearshore and shelf groundfish fisheries are constrained by the Preferred bocaccio Low OY, but especially those fisheries south of Pt. Conception. Action Alternatives 2 and 3 stay within the Preferred High OY Alternative for bocaccio.

As recent experience has shown, a strong year class will initially be caught in nearshore fisheries and hard to avoid. Higher OYs or a rebuilding framework that allows one-year overages if the long term harvest rate is not exceeded should be considered for this stock due to its episodic recruitment pattern.

Canary Rockfish

Specific Canary Rockfish Rebuilding Strategies

All of the rebuilding strategies used to reduce mortality of depleted species on the West Coast are used to help rebuild canary rockfish. Management of this stock tends to constrain more West Coast fisheries than any other groundfish stock since canary rockfish are distributed coastwide, are found in a variety of habitats, and are caught by a variety of different fishing gears. Canary rockfish are distributed from nearshore areas as juveniles out to about 150 fm as adults and are found at times suspended off the bottom or in atypical soft-bottom habitats for rockfish.

Management of canary rockfish under the harvest rates specified in the current rebuilding plan has been difficult and OYs have been exceeded in two of the last three years. The canary rockfish OY was exceeded by 4.5 mt in 2003, 11 mt in 2004, but, in 2005, total estimated mortality was less than the OY by about 7 mt. Tailoring the management regime to stay within the low harvest rates specified for canary and other depleted rockfish has been an evolutionary process of adaptive management. Better impact modeling with an increasing sample of depth-based discard rates from the WCGOP, gear restrictions (described below), capacity reduction of the limited entry trawl fleet, educational outreach to anglers to avoid canary and other depleted rockfish, restrictive limits and non-retention regulations, and, most importantly, depth-based RCA management have all contributed to improved performance of the management regime in managing canary rockfish.

Canary rockfish are not allowed to be retained in commercial and recreational hook and line or fixed gear fisheries and a small, incidental landing limit is allowed in the limited entry trawl fishery to account for unavoidable incidental bycatch. However, mandating the use of the selective flatfish trawl shoreward of the RCA north of 40°10' N latitude has helped reduce trawl bycatch. Attempts to test selective flatfish trawls south of 40°10' N latitude through implementation of Exempted Fishing Permits have not been successful due to lack of participation. Nevertheless, while these trawls are legal small footrope gear in the south and are volitionally used, experience with these trawls in the north compels consideration of mandating their use shoreward of the RCA south of 40°10' N latitude. At-sea monitoring of their efficacy in southern fisheries through the WCGOP may eventually validate their use in the south. Midwater trawls also catch canary rockfish. The directed midwater trawl fishery for yellowtail rockfish was discontinued in 2002 due to high bycatch of canary and widow rockfish. The midwater trawl fishery for whiting, which is not currently restricted in the trawl RCA, also catches canary rockfish. Implementation of a canary rockfish bycatch cap, where, if attained, the non-tribal fishery would close inseason even if whiting quotas have not been attained, has successfully reduced canary rockfish mortality. This strategy works for the whiting fishery because of near real-time bycatch reporting and open communication to the rest of the fleet when bycatch of canary occurs in any one area.

Use of broad based RCA configurations has had the most effect in reducing canary rockfish mortality and the concept of depth-based RCA management was largely compelled by this need. Figure 4-2 shows the catch per tow of canary rockfish in the NMFS bottom trawl survey, which can be used as an index of the stock's depth and latitudinal distribution. While there are some instances of canary rockfish occurring south of Pt. Conception at 34°27' N latitude, they are largely distributed north of Conception with the greatest density in northern waters off Washington. They are most often found in depths from 50-100 fm, but as can be seen in Figure 4-2 and from Table 4-1, they can occur in the 27-150 fm depth range. The core depth range of the trawl RCA is 100-150 fm, with both shoreward and seaward extensions of the RCA boundaries depending on seasonal conservation needs (canary rockfish and other depleted species tend to make seasonal shoreward-seaward migrations with more shallow distributions in the summer months). Most of the incidental trawl take of canary rockfish occurs shoreward of the RCA since the seaward boundary is often extended out to 200 fm to reduce mortality of darkblotched and POP. The non-trawl RCA extends out to 100 fm north of Cape Mendocino and 150 fm south. Most of the incidental non-trawl take of canary rockfish occurs seaward of the RCA in the north. More discrete area closures, such as those used to reduce mortality of cowcod and yelloweye rockfish, may also help reduce canary mortality, but will likely prove to be less effective for canary rockfish due to their mobility and apparent lack of site fidelity.

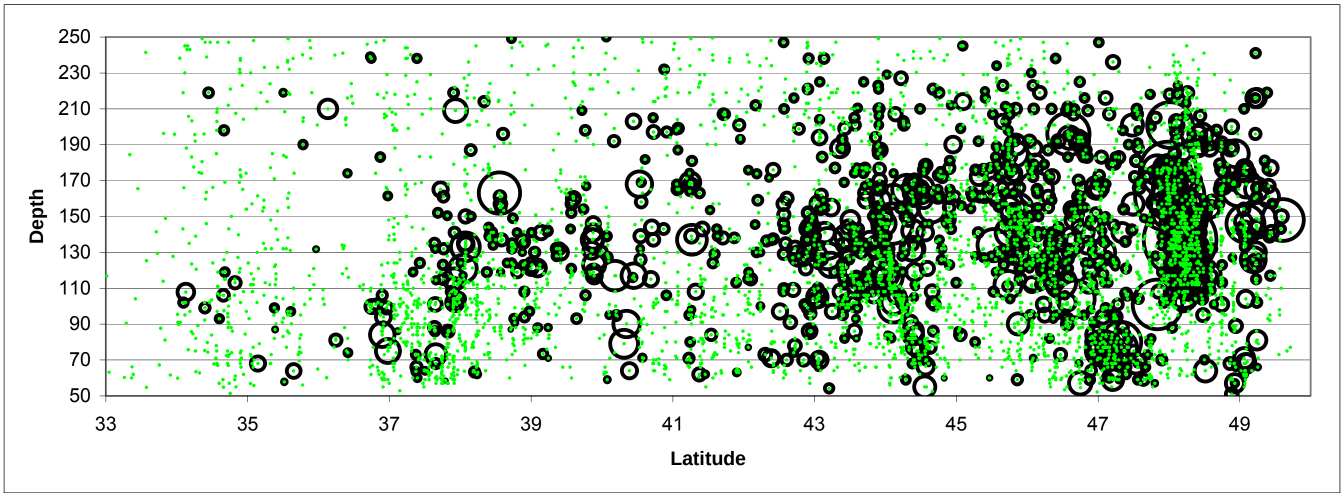

Figure 4-2. Catch per tow of canary rockfish in the bottom trawl survey. Dots are tows with zero catch. Circle size is proportional to the square root of catch per tow. Depth is in meters. Figure from the 2005 canary rockfish assessment (Methot and Stewart 2006)

Evaluation of Optimum Yield Alternatives

Table 4-9 shows the results of the evaluation of alternative canary rockfish OYs analyzed for 2007-2008 using the criteria described in section 4.2.

The canary rockfish OYs considered for 2007-2008 are based on a relatively certain stock assessment, despite the fact that recent recruitments are unknown due to a lack of recent fishery-dependent information (since the fishery has been structured to avoid canary) and the most recent years of the NMFS Northwest Fishery Science Center combined shelf/slope bottom trawl survey were not used. The second, "mop-up" STAR Panel, which reviewed the assessment in September 2005, also recognized the bottom trawl surveys may not provide an adequate index of abundance for shelf rockfish. For canary rockfish, the particular concern is that the level of stock depletion in trawlable habitat may not be reflective of overall population status. However, the historical data inputs to the assessment are more certain than for many of the other West Coast stocks and the 2005 assessment received a particularly high level of scientific scrutiny.

The relative certainty of the assessment result is tempered by a relatively uncertain total catch monitoring component, particularly since there is a significant portion of the total annual catch taken in recreational fisheries. Precautionary management of recreational fisheries to stay within the low canary OYs analyzed in this EIS will still be a predominant theme in rebuilding this stock and managing West Coast fisheries in the coming years. Uncertain total catch estimates will also lead to increasing assessment uncertainty as total removals become less certain and fishery-dependent trends used as assessment indicators of recruitment and biomass are less reliable.

Rebuilding probabilities (P_{MAX}) for alternative canary rockfish OYs are all low ranging from 66% for the zero-harvest alternative to 50% for the highest OY considered. The harvest rates for the Preferred Low and High OYs have a 55% and 58% probability of rebuilding by T_{MAX}, respectively, while the No Action OY predicts about a 55% probability of successful rebuilding by T_{MAX}. Such low rebuilding probabilities infer increased risk in canary stock rebuilding, a condition which recommends a precautionary management approach.

The estimated median time to rebuild the canary rockfish stock under the zero-harvest alternative is 2053. An additional 7 years of rebuilding is predicted under the harvest rate used to determine the Preferred Low OY of 24 mt and 10 years under the Preferred High OY of 44 mt. This compares to slightly more than 11 years under the status quo OY and an additional 18 years under the highest OY of 68 mt. Given that canary rockfish is the most constraining stock in the West Coast groundfish fishery, this tradeoff in canary OY vs. rebuilding duration will be one of the more important considerations for the Council and NMFS.

Table 4-9. Evaluation of alternative 2007-2008 canary rockfish OYs relative to the criteria described in section 4.2.

Evaluation Criterion	OY (mt)					
	No Action OY Alt. (2006 OY)	OY Alt. 1	OY Alt. 2	Pref. Low OY Alt.	OY Alt. 3 (Pref. High OY)	OY Alt. 4
	47	0	24	**32**	**44**	68
Catch monitoring uncertainty	High uncertainty due to a significant recreational catch component.					
Assessment Uncertainty	Relatively certain due to generally good data quality and consistency.					
Rebuilding Probability (P_{MAX})	54.8%	66%	60%	58.3%	55.4%	50%
Rebuilding Duration Beyond $T_{F=0}$ (yrs.)	11.4	0	5	7	10	18

Evaluation of Action Alternatives

Action Alternative 1 is the only action alternative estimated to stay within the Preferred Low OY Alternative for canary rockfish. Most of the current northern fisheries primarily constrained by canary rockfish OYs, such as recreational groundfish fisheries, are predicted to be more constrained by the Preferred Low OY for yelloweye under Action Alternative 1 (Table 2-14). Likewise, the Preferred Low OY for bocaccio tends to constrain southern fisheries historically constrained by canary rockfish more than the Preferred Low OY for canary rockfish. Action Alternatives 2 and 3 stay within the Preferred High OY Alternative for canary rockfish. While yelloweye rockfish OYs will be increasingly more constraining under the Preferred High OY ramp-down strategy, canary rockfish OYs will continue to be the most constraining to fisheries, especially in the four-year yelloweye harvest rate ramp-down transition period under that alternative.

Cowcod

Specific Cowcod Rebuilding Strategies

The prevailing management strategy for rebuilding cowcod is complete avoidance and allowing fisheries with only a “de minimus” fishing-related mortality. Historically, cowcod, due to their large size and superior flesh quality, were targeted in commercial and recreational fisheries. Non-retention regulations have been implemented for all West Coast fisheries to eliminate any possible targeting. Most importantly, all the critical cowcod habitat known through area-specific fishery information and other site-specific survey data have been closed to any type of bottom fishing that might take cowcod. These critical habitats are encompassed in two areas in the Southern California Bight south of Point Conception called the Cowcod Conservation Areas (CCAs, Figure 2-3). Area management is a particularly effective strategy for protecting cowcod given their sedentary life style and site fidelity. Piner et al. {2006} determined these management measures have been effective in keeping total mortality well under the low OYs used to manage this stock since the implementation of the CCAs and no retention regulations in 2001.

Evaluation of Optimum Yield Alternatives

It is particularly difficult to evaluate the cowcod OY alternatives given the great uncertainty in actual total catch and stock status. Both of these factors compel a very precautionary approach in rebuilding this very unproductive stock. OY alternatives 3-5 may be risky given this high uncertainty and the longer rebuilding periods (17-39 years beyond $T_{F=0}$) predicted by those harvest rates. The preferred OY range of 4-8 mt in the Conception and Monterey areas have much shorter predicted rebuilding periods, extending the duration of rebuilding 4-8 years beyond the time predicted under a zero-harvest strategy. The estimated rebuilding probabilities under the preferred Low and High OYs are also reasonably high (P_{MAX}≥80%), which helps mitigate the risk of managing stock rebuilding with such high uncertainty.

Table 4-10. Evaluation of alternative 2007-2008 cowcod OYs relative to the criteria described in section 4.2.

Evaluation Criterion	**OY (mt)**						
	No Action OY Alt. (2006 OY)	**OY Alt. 1**	**Pref. Low OY Alt.**	**OY Alt. 2 (Pref. High OY)**	**OY Alt. 3**	**OY Alt. 4**	**OY Alt. 5**
	4.2	0	**4**	**8**	14	18	22
Catch monitoring uncertainty	Very high uncertainty due to a paucity of at-sea observations.						
Assessment Uncertainty	Very high uncertainty due to poor data quality.						
Rebuilding Probability (P_{MAX})	90.2%	100%	90.6%	80%	70%	60%	50%
Rebuilding Duration Beyond $T_{F=0}$ (yrs.)	4.1	0	4	8	17	27	39

Evaluation of Action Alternatives

All the action alternatives contemplate a liberalization of the Cowcod Conservation Areas in the Southern California Bight. The most significant risk of altering the perimeters of the CCA is the possibility that incidental catches of cowcod would increase, either as a result of incidental catches at the boundary of the fathom lines, or from incidental catches resulting from inadvertent incursions of vessels into shallower depth in the boundary lines. Such risks are associated with all of the potential alterations to both the outer and inner perimeters. Although this risk is difficult to evaluate, the steep and complex topography of the continental shelf and slope in these regions, and the corresponding complexity of the perimeter line alternatives that would be developed to exclude fishing from those depths in which cowcod are most abundant, suggests that there is significant potential for such incursions.

It is worth noting that while most cowcod are found within the 40 to 150 fm depth range, commercial catch and resource survey data demonstrate that cowcod can be found as shallow as 20 fm, in low-moderate numbers to 220 fm, and infrequently to at least 270 fm {Butler et al. 1999; Love et al. 2002; unpublished survey data}. Consequently, even with precise adherence by commercial fishermen to the outer perimeter of 175 fm under action alternatives 1 and 2, and similar performance by recreational fishermen to the inner perimeters of either 30 fm (Alt. 1) or 40 fm (Alt 2), bycatch of cowcod would be expected to increase by some amount under any of the alternatives. Although Action Alternative 1 (the four-area alternative) would presumably have less of an impact with respect to the potential for increased cowcod mortality, all of the areas proposed in this alternative are described as areas of moderate to high densities based on CDFG fishing block catch rate data (figures 5 and 6 in Appendix IV of Piner et al. 2006). Additionally, Potato Bank (west of San Nicolas Island), as well as Cortes Bank were both observed to have high densities of adult cowcod in the recent submersible survey {Yoklavich et al., in prep}. Alternatives 2 and 3 could be expected to have increasingly higher impacts on cowcod as they increase the areal extent of cowcod habitat open to fishing significantly to substantially.

Both Potato Bank and the Santa Barbara Island areas, that would be open in all alternatives but the No Action Alternative, were also recently described as areas with high concentrations of newly described species of black corals {Tissot et al. 2006}, for which nearly all of the high concentrations were observed within the current boundaries of the CCA. Independent of the above concerns, it is worth noting that a growing amount of habitat information in the Southern California Bight may be informative with respect to altering the CCA boundaries in the near future. Additional analysis of such data, and associated habitat preferences by cowcod and other species, could more adequately ensure that habitat known to be optimal for cowcod is protected in future CCA revisions.

With respect to monitoring stock abundance and recovery, changing the boundaries of the CCA could undermine the ability to replicate recent resource surveys, such as the submersible survey and the enhanced CalCOFI ichthyoplankton survey. In particular, the submersible survey conducted by Yoklavich et al. (in prep) was used in the last assessment as a single point estimate of abundance of a given year within the CCAs, expanded by a scaling factor developed based on catch rate data in recreational fisheries. Both the STAR Panel and the SSC report on the cowcod assessment stressed the paucity of data available for this stock, highlighted the potential of this survey for monitoring cowcod trends, and emphasized the need for a consistent time series in order for this survey to be relied upon with confidence for detecting trends. Specifically, alterations to the boundaries of the CCA could undermine the assumptions necessary to replicate this survey in order to develop a second data point for monitoring stock trends. In other words, a second survey may not be comparable with the first, if the conditions (exploitation rates) within the survey area had changed.

This is a particularly important factor given that the four fishing areas proposed under Alternative 1 include three of the eight banks upon which the 2002 visual survey was based; Potato Bank, Santa Barbara Island, and Cortes Bank. The cowcod assessment represents one of the most data-poor assessments in the recent assessment cycle, such that only three free parameters (R_0, steepness and the catchability coefficient for the visual survey) were actually estimated in the model. Aside from the submersible survey, there are no fishery independent data to inform the assessment (in the most recent assessment review, the STAR Panel recommended removal of the CalCOFI time series that was used in the first assessment), nor are there length-frequency data or other information to estimate recruitment variability. As catch rate data were effectively the most important time series index in the assessment, the submersible survey offers one of very few potentially available data series for monitoring stock trends and recovery. Given the paucity of data available for the cowcod assessment, it will be important to attempt to maintain consistency in management measures (to the extent practicable) until an effective monitoring system is in place.

The magnitude of fishing that could take place under any of the action alternatives, and the extent to which such fishing could increase mortality on cowcod and other rebuilding species, will be particularly difficult to assess without adequate observer coverage on vessels that fish within these closed areas. The current cowcod OY could potentially be entirely harvested in a small number of “disaster sets”, and the extent to which any observer data that was collected would over, or under, estimate cowcod mortality is difficult to detect with the limited observer coverage for this region. Consideration of the challenges associated with adequately monitoring total mortality that could result from any modification to the CCA should be a high priority in selecting a preferred alternative, including some evaluation of the amount of observer coverage that might be expected from the WCGOP under any of the alternative scenarios.

Enforcement issues are presumably challenging under the proposed alternatives to the status quo. The current boundaries have been shown to be easily understandable to fishermen and enforcement personnel, thus meeting their objectives in rebuilding the cowcod (and other) resources. The practicability of enforcement using VMS data, particularly with respect to the legal issues surrounding the ability of states to use proprietary VMS data for enforcement purposes, is another complicating factor that has yet to be resolved for the purposes of implementing the Alternatives. This, and additional challenges to enforcement that could be associated with any perimeter modification, should also be carefully considered prior to any adoption of proposed alternatives to status quo.

Darkblotched Rockfish

Specific Darkblotched Rockfish Rebuilding Strategies

Darkblotched rockfish are caught almost exclusively by groundfish trawl gear and predominantly bottom trawls operating on the outer continental shelf and slope north of 38° N latitude between 100 and 200 fm (Figure 4-3). The two most significant strategies used to control darkblotched fishing mortality are limited entry trawl trip limits for the southern and northern minor slope rockfish complexes, the complexes in which darkblotched are managed, and implementation of the trawl RCA, where modifications to the seaward boundary tend to have the greatest effect on darkblotched take. As an example, in 2004 the Council and NMFS decided to provide more opportunity to harvest healthy Dover sole, thornyheads, sablefish (DTS), and flatfish stocks in the limited entry trawl fishery while staying within the darkblotched OY of 240 mt. In May the trawl RCA was decreased by moving the seaward boundary inshore to 150 fm and increasing DTS and flatfish limits. By September it was apparent the darkblotched OY would be exceeded without a significant adjustment to the trawl fishery. The trawl RCA was then extended from the shoreline (primarily to address over-attainment of canary rockfish) out to 250 fm north of 40°10' N latitude, from the shoreline out to 200 fm between 38° N latitude and 40°10' N latitude, and trip limits were severely reduced. The very important winter petrale sole fishery was foregone among other important fishing opportunities. By the end of the year, the darkblotched OY was exceeded, but only by 1.6 mt (Table 4-6). This indicates the sensitivity of RCA boundary adjustments when managing fisheries to stay within low darkblotched rockfish rebuilding OYs.

Area management beyond adjustment of the seaward boundary of the trawl RCA may be an effective rebuilding strategy for darkblotched rockfish. Figure 4-3 indicates an apparent clustered distribution of darkblotched as evidenced by area-specific catch per tow data in past NMFS trawl surveys. While the clustered distribution of darkblotched in Figure 4-3 is informative, the apparent distribution is also affected by the survey sampling regime in that not all of the combined survey data is shown, 0-catch hauls are not shown, and that the depths and latitudes sampled by all surveys have been irregular over time. In 2004, observers noted two very large catches (8,000-15,000 lbs), which were partially discarded {Rogers 2006}. They were both from an area that also had large survey catches at approximately 40.5° N latitude in 200 fm (Figure 4-3). These large catches tended to contain larger than average fish {Rogers 2006}. Closure of those areas might provide additional darkblotched conservation benefits.

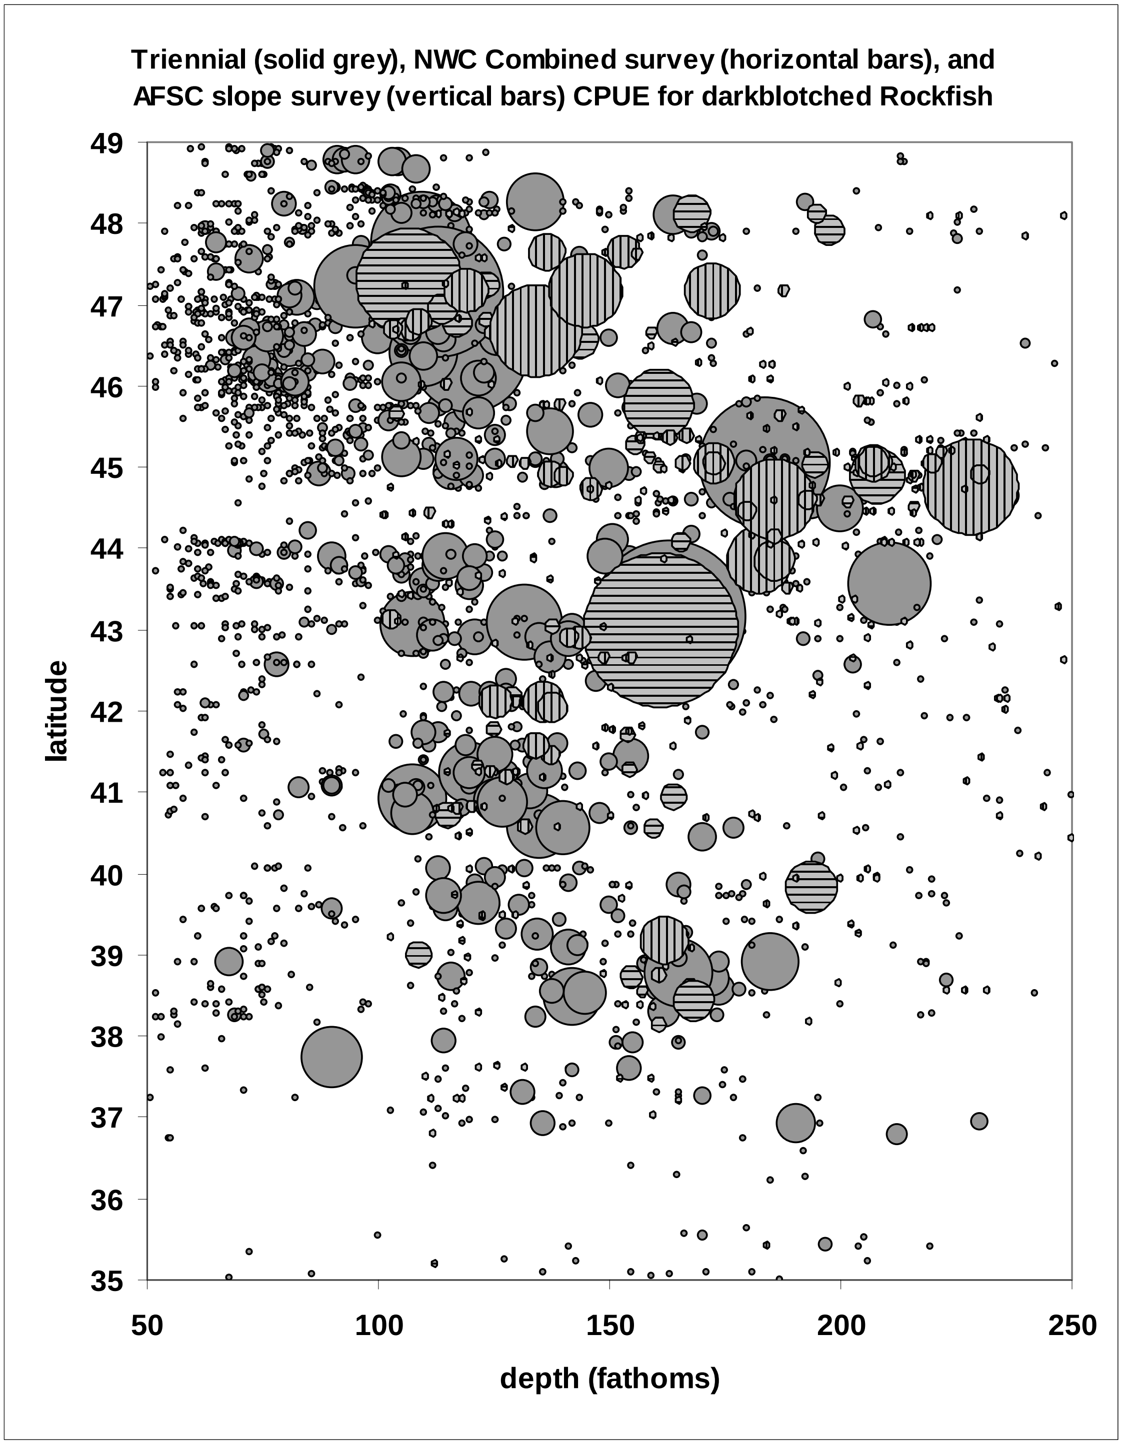

Figure 4-3. Index of West Coast distribution of darkblotched rockfish by latitude and depth as determined by catch per tow in NMFS trawl surveys. Size of circle is proportional to darkblotched rockfish density at that location. Data from NOAA Northwest Fisheries Science Center's West Coast Groundfish Survey Database and the NOAA Alaska Fisheries Science Center Triennial Shelf and Slope Survey Database.

Evaluation of Optimum Yield Alternatives

Table 4-11 shows the results of the evaluation of alternative darkblotched rockfish OYs analyzed for

2007-2008 using the criteria described in section 4.2.

The much more optimistic 2005 darkblotched assessment is largely based on validation of strong recent recruitments. These recruitments are relatively certain in the assessment input data despite the inconsistency in assigned ages of darkblotched in the sample data, which leads to the ranking of "moderate" assessment uncertainty.

The catch monitoring of darkblotched is relatively certain since the limited entry bottom trawl fishery takes the vast majority of the total annual take while targeting DTS and flatfish species on the slope. Estimation of at-sea discards of darkblotched and other species in the trawl fishery has become increasingly certain with the increased observations from the WCGOP. The overfishing of darkblotched that occurred in 2004 (Table 4-6) may be prevented in the near future since model projections using WCGOP discard rates are better informed and landings plus discard are now tracked in near-real time in PacFIN's Quota Monitoring Species (QSM) reports[21].

All the darkblotched OY alternatives have exceptionally high rebuilding probabilities at or approaching 100%. The range of most depleted species' OYs analyzed in this EIS have an OY alternative at or close to 50% P_{MAX}. Conversely, the highest darkblotched OY alternative has a very high 97% P_{MAX} since it is capped at the ABC, which is determined using a proxy harvest rate. Therefore, all the harvest rates used to determine alternative darkblotched OYs and rebuilding strategies are considered risk-averse using this evaluation criterion.

The rebuilding periods associated with alternative darkblotched OYs are relatively short for a depleted rockfish. Under the zero-harvest alternative, rebuilding is predicted to occur by 2009.5. The Preferred Low OY Alternative of 130 mt extends this rebuilding duration by less than half a year, while the Preferred High OY Alternative of 229 mt extends rebuilding by slightly more than half a year. This compares to rebuilding duration beyond $T_{F=0}$ under the status quo OY of slightly more than half a year (equivalent to that under the Preferred High OY) and 2.5 years of extended rebuilding under the largest OY considered of 472 mt. The tradeoff in rebuilding duration vs. allowable darkblotched harvest shows that a greater harvest rate than has been sustained in recent years can still successfully rebuild the darkblotched rockfish stock with a small incremental increase in the rebuilding period. While these strong, incoming year-classes to the spawning stock biomass favor expeditious rebuilding, fishery interceptions of darkblotched will likely increase making it more difficult to manage the low status quo OYs using status quo management measures.

21 The GMT uses the PacFIN QSM report to track OY attainment inseason for recommending adjustments to fisheries to stay within OYs. In 2005, the GMT started incorporating projections of discard mortality in association with landings in the QSM report to better track total fishing-related mortality of managed species.

Table 4-11. Evaluation of alternative 2007-2008 darkblotched rockfish OYs relative to the criteria described in section 4.2.

Evaluation Criterion	**OY (mt)**					
	No Action OY Alt. (2006 OY)	**OY Alt. 1**	**OY Alt. 2 (Pref. Low OY)**	**OY Alt. 3 (Pref. High OY)**	**OY Alt. 4**	**OY Alt. 5**
	200	0	**130**	**229**	330	472
Catch monitoring uncertainty	Relatively certain due to a predominant trawl catch component.					
Assessment Uncertainty	Moderate uncertainty due to data inconsistency (ageing uncertainty).					
Rebuilding Probability (P_{MAX})	100%	100%	100%	100%	100%	97.2%
Rebuilding Duration Beyond $T_{F=0}$ (yrs.)	0.6	0	0.4	0.7	1	2.5

Evaluation of Action Alternatives

All of the action alternatives analyzed for 2007-2008 contemplate more conservative management of slope trawl fisheries than status quo. Action Alternative 1 is the only alternative estimated to stay within the Preferred Low OY Alternative for darkblotched, but as can be seen in Table 2-14, the Preferred Low OY Alternative for POP is even more constraining to slope trawl fisheries. Action Alternative 2 and 3 stay within the Preferred High OY for darkblotched, but the Preferred High OY for POP is again more constraining (Tables 2-19 and 2-21).

The more effective and accurate catch monitoring and tracking mechanisms used to manage slope trawl fisheries should significantly improve inseason management adjustments to future trawl fisheries and thus avoid the overfishing problem encountered in 2004. Inseason adjustments are anticipated to be fundamental in managing trawl fisheries to stay within whatever darkblotched OY is chosen for 2007-2008 as increased encounter rates of darkblotched are expected with the strong recruitments observed in the latest assessment.

Pacific Ocean Perch

Specific Pacific Ocean Perch Rebuilding Strategies

Pacific ocean perch have been under rebuilding since 1981. The population off the northern U.S. West Coast (Columbia and U.S./Vanc. areas) is at the southern extreme of the stock and rebuilding potential may be more effected by mortalities in waters north of the U.S./Canada border. Nevertheless, the trawl RCA configuration used to reduce darkblotched mortalities, which has been the more constraining stock in slope trawl fisheries since implementation of rebuilding measures in 2001, has significantly reduced POP mortalities. Continued use of RCA management coupled with precautionary slope rockfish trawl trip limits may be the most effective combination of strategies available to the Council and NMFS for rebuilding this stock. Given the stock's overall distribution in the Northeast Pacific, a collaborative U.S./Canada research and management plan needs to be explored.

Evaluation of Optimum Yield Alternatives

Table 4-12 shows the results of the evaluation of alternative POP OYs analyzed for 2007-2008 using the criteria described in section 4.2.

Both catch monitoring uncertainty and assessment uncertainty are relatively low for this species given the fact that the vast majority of total fishing-related mortality occurs in limited entry bottom trawl efforts.

Rebuilding probabilities range from 50% to 100% across the range of analyzed POP OYs and are especially high (>95%) for the Preferred Low and High OY Alternatives. This compares to a 73% P_{MAX} under the status quo OY of 447 mt, which is almost 4.5 times higher than the Preferred High OY Alternative.

The shortest possible time to rebuild the West Coast POP stock under a zero-harvest strategy is 2014.6. The Preferred Low OY Alternative extends rebuilding by less than half a year longer and the Preferred High OY Alternative extends rebuilding by approximately one year. This compares to about 8 years of extended rebuilding under the status quo OY and over 30 years under the harvest rate used to determine the highest OY considered (OY Alternative 5).

Table 4-12. Evaluation of alternative 2007-2008 Pacific ocean perch OYs relative to the criteria described in section 4.2.

Evaluation Criterion	OY (mt)							
	No Action OY Alt. (2006 OY)	**OY Alt. 1**	**Pref. Low OY Alt.**	**OY Alt. 2**	**Pref. High OY Alt.**	**OY Alt. 3**	**OY Alt. 4**	**OY Alt. 5**
	447	0	**44**	87	**100**	405	514	749
Catch monitoring uncertainty	Relatively certain due to a predominant trawl catch component.							
Assessment Uncertainty	Relatively certain due to generally good data quality and consistency.							
Rebuilding Probability (P_{MAX})	73%	100%	99.5%	96.7%	95.8%	80%	70%	50%
Rebuilding Duration Beyond $T_{F=0}$ (yrs.)	7.9	0	0.4	0.4	1	6	10	33

Evaluation of Action Alternatives

In recent years, the effective harvest rate of POP in trawl slope fisheries has been much less than that specified in the POP rebuilding plan because darkblotched OYs were more constraining. The Preferred Low and High OY alternatives are much lower than the No Action OY and, depending on the harvest rate decided for the darkblotched rockfish rebuilding plan, could become the constraining stock in future trawl slope fisheries in waters off Oregon and Washington.

Only Action Alternative 1 constrains fisheries enough to stay within the Preferred Low OY Alternative for POP, while Action Alternatives 2 and 3 stay within the Preferred High OY.

Widow Rockfish

Specific Widow Rockfish Rebuilding Strategies

The Council chose to eliminate the non-tribal midwater trawl fishery targeting yellowtail and widow rockfish in 2003 to reduce widow rockfish exploitation {PFMC 2003}. The WDFW sponsored a midwater trawl EFP in 2002 and 2003 to attempt to shape a fishery that effectively targeted yellowtail while avoiding widow. However, this EFP was discontinued prematurely in 2003 because about 28% of the catch was widow rockfish (B. Culver, personal communication). There is still a tribal midwater trawl fishery that targets yellowtail rockfish, but incidentally catches some widow rockfish. The 2005-2006 limits for this fishery were a fleet-wide (the Makah Tribe was the only tribe prosecuting a midwater trawl fishery) cumulative landing limit of 180,000 lbs of yellowtail rockfish/two months. Widow rockfish landings were limited to 10% of the weight of yellowtail rockfish landed in any two-month period. These midwater landing limits were subject to inseason adjustments to minimize the take of canary and widow rockfish. Management of the tribal midwater trawl fishery is designed to minimize impacts to canary and widow rockfish through avoidance. Observer data is analyzed daily and vessels are told which areas to avoid when these species are encountered.

The Council also chose to manage widow rockfish bycatch beginning in 2004 by precautionary management of midwater trawl fisheries that target Pacific whiting. This has traditionally been the fishery with the greatest incidental bycatch of widow rockfish, excluding the directed yellowtail/widow midwater trawl fishery which was discontinued in 2002. While the shoreside whiting sector has exhibited a clear recent trend of reduced widow rockfish bycatch, widow bycatch in the at-sea sectors has been more random. All whiting trawl sectors showed a significant decrease in widow rockfish bycatch in 2003 (Figure 4-4). The at-sea vessels receive daily reports of bycatch by vessels in their fishery, where there is 100% observer coverage, and actively avoid areas where there has been a high bycatch of salmonids, widow, and yellowtail rockfish. Another contributing factor to the lower widow bycatch in 2003 was a significantly increased abundance of whiting in 2003 which resulted in shorter tows to fill trawls. In years when whiting are less abundant and more dispersed, widow bycatch can become an increasing concern as vessels extend their search for whiting schools and have longer tow times (D. Myer, personal communication). Shorter tows on aggregated whiting schools would sensibly reduce widow bycatch since whiting tows are made in daylight hours when widow rockfish are dispersed. There was also a greater abundance of whiting off the north Washington coast in 2003 that kept at-sea whiting vessels more northerly and away from Oregon and southern Washington coastal areas where widow are more abundantly distributed.

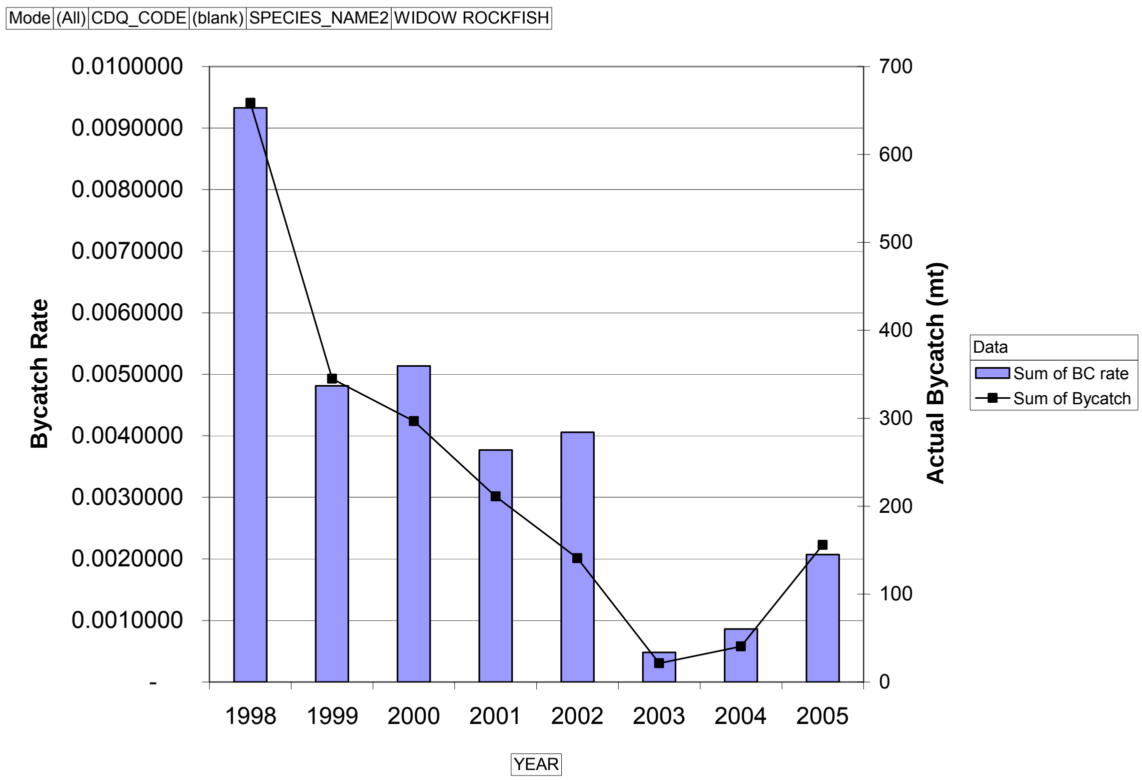

Figure 4-4. Annual Widow Rockfish Bycatch Rate and Bycatch in the Non-tribal Sectors of Whiting-directed Midwater Trawl Fisheries.

In recent years, the GMT has recommended consideration of the following management strategies to reduce widow rockfish bycatch in whiting fisheries: 1) a precautionary reduction in whiting OYs, 2) hard widow rockfish bycatch caps by sector in the whiting fisheries or a hard cap imposed for all sectors combined, 3) establishing avoidance strategies by timely reporting of widow bycatch rates by area that would compel the fleet to move away from such areas, and 4) prohibiting the whiting fishery in areas of highest widow rockfish densities.

As stated above, the Council has elected to specify hard widow rockfish bycatch caps on the non-tribal sectors of the whiting fishery. It is noted that the majority of widow rockfish bycatch in whiting fisheries occurs infrequently in "disaster tows" that may be due to inexperience on the part of the skipper or an unpredictable encounter. Since each sector has a different season, it is conceivable that one sector could pre-empt fishing opportunities for another by experiencing a few “disaster tows.” Originally, in 2004, the Council recommended hard bycatch caps for both canary and widow rockfish for all whiting sectors combined, including the tribal sector. However, in 2005, these hard caps were adjusted and implemented only for the non-tribal shoreside and at-sea sectors combined. The specified widow rockfish bycatch cap was originally 200 mt, but adjusted inseason to 212 mt. The 2006 cap was set at 200 mt. Managing the whiting fishery with hard bycatch caps has forced active avoidance of widow and, as Figure 4-4 indicates, has successfully reduced widow bycatch to desired levels. The strategy works due to timely reporting to the rest of the fleet of areas where higher widow bycatch occurred. The at-sea fleets (catcher-processors and motherships) have 100% observer coverage. They also have an independent contractor collect at-sea bycatch information daily, who reports back to the fleet when the bycatch of any particular species of concern rises in any one area. The fleet then moves to areas where whiting can be more cleanly targeted.

The shoreside sector has a similar mechanism for minimizing bycatch. This sector operates under an EFP that mandates full retention of species and landing of all the catch. This allows full sampling of the total catch upon landing. The buyer reports back to the fleet if a landing from a particular area shows a higher than desired bycatch. However, catch can be discarded at sea if landing the bag poses an immediate threat to vessel safety. Since the shoreside fleet does not operate with 100% observer coverage, there may be an incentive to discard at sea if a larger than expected bycatch of widow rockfish occurs. The NMFS started placing cameras on all shoreside whiting vessels in 2004 as an experimental effort to determine if discarding occurs on otherwise unobserved trips. In 2004, a total of 1,003 trips and 1,030 sets were observed using deck-mounted cameras. Non-retention occurred in 19% of sets observed. Most of this non-retention was from fish bled from the codend of the trawl, although some discard occurred from fish dumped off the deck. Most of the observed discards occurred during the last haul of the trip and most discards were < 45 kg total estimated weight. [2005 results?] Starting in 2006, camera monitoring is mandated in the Shoreside Whiting EFP.

An innovative government-industry collaboration coordinated by the NMFS Northwest Fishery Science Center, the Pacific Whiting Conservation Cooperative, and the Fisherman's Marketing Association was launched in 2004 to explore the development of an abundance index methodology specifically for widow rockfish. The goal of this effort was an exploration of non-extractive techniques using acoustics and cameras. This feature was viewed as particularly important owing to the depleted status of this species. As proof of concept, pilot survey work off Newport, Oregon in March 2005 confirmed the ability to reliably locate, observe, and quantitatively measure widow rockfish schools with conventional single frequency fishery acoustics techniques in combination with underwater video cameras. The sites sampled off central Oregon, a subset of those identified by fishermen in the ad hoc working group, were found to contain widow rockfish aggregations, which supports the strategy to rely on use of local fisherman's knowledge of fishing grounds as a sampling framework. The acoustics data collected with the scientific echosounder installed on a fishing vessel was of good scientific quality, which allowed a detailed examination of patterns of variability in widow rockfish populations (see report entitled "Update on the Development of a Commercial Vessel-Based Stock Assessment Survey Methodology for U.S. West Coast Widow Rockfish: A Report to the ad hoc Working Group" by P. Ressler, G. Fleischer and V. Wespestad). The success of the pilot work indicated that the acoustic surveys could be a successful monitoring tool but should be expanded to include other study sites along the West Coast in order to provide coastwide monitoring of the species. Such research is critical for determining a much needed, reliable index of widow rockfish abundance as the established NMFS bottom trawl is ineffective for this semi-pelagic species and fishery-dependent indices no longer reliably track abundance since the fisheries avoid widow rockfish. A reliable, fishery-independent survey will be a very important contribution to our understanding of stock status and trends, which should lead to better area management strategies for widow rockfish, as well as holding potential for other depleted rockfish.

Evaluation of Optimum Yield Alternatives

Table 4-13 shows the results of the evaluation of alternative widow rockfish OYs analyzed for 2007-2008 using the criteria described in section 4.2.

Catch monitoring of widow rockfish is relatively certain given that the stock is mostly caught as bycatch in trawl fisheries and is predominantly caught in whiting-directed trawl fisheries where at-sea observation rates are highest on the West Coast.

Conversely, the assessment result is relatively uncertain due to the lack of a reliable widow abundance index. In past assessments, widow bycatch in whiting-directed trawl fisheries has been used to understand biomass trends. However, with the need for whiting fleets to reduce their widow bycatch, that index is no longer recommended for assessing stock trends. The promise of an effective and useable hydroacoustic survey index is still many years off. The survey would have to be proven through continued research before managers and scientists invest in these resources. And, if that happens, multiple years of survey data would be needed before temporal biomass trends can be discerned and used in assessment. Therefore, assessment uncertainty is relatively uncertain, which should be considered when the Council determines a final rebuilding plan. (In fact, this uncertainty was taken into account when the Council decided not to pursue "delisting" widow rockfish as an overfished species given the assessment result that the stock never did reach a threshold of depletion below $B_{25\%}$. The Council understood there was very little new data informing this new assessment and acknowledged the uncertainty was too great to depart from the rebuilding plan.)

Most of the widow rockfish OY alternatives analyzed in this EIS have high rebuilding probabilities (P_{MAX} at or above 80%). Only OY Alternative 5 (1,369 mt) has a P_{MAX} less than the SSC "target" of ≥80%. The Preferred Low and High OY alternatives have very high rebuilding probabilities of 98% and 95%, respectively. In terms of the P_{MAX} criterion, the harvest rates used to determine these OYs are risk-averse rebuilding specifications.

The strong, year classes recruiting to the widow rockfish spawning stock are evidenced by the short rebuilding times predicted across a large range of OYs (Table 2-3 and Figure 2-2). The shortest possible time to rebuild the stock under a zero-harvest strategy is 2013. The Preferred Low OY harvest rate is predicted to extend rebuilding about a year longer than this and the Preferred High OY harvest rate extends rebuilding by yet another year. This compares to slightly less than two years of extended rebuilding under the status quo OY, which is intermediate to the Preferred Low and High OY Alternatives.

Table 4-13. Evaluation of alternative 2007-2008 widow rockfish OYs relative to the criteria described in section 4.2.

Evaluation Criterion	**OY (mt)**							
	No Action OY Alt. (2006 OY)	**OY Alt. 1**	**Pref. Low OY Alt.**	**OY Alt. 2**	**Pref. High OY Alt.**	**OY Alt. 3**	**OY Alt. 4**	**OY Alt. 5**
	289	0	**120**	329	**368**	456	917	1,369
Catch monitoring uncertainty	Relatively certain due to a predominant trawl catch component.							
Assessment Uncertainty	Relatively uncertain due to lack of a reliable abundance index.							
Rebuilding Probability (P_{MAX})	96.2%	100%	98.4%	95.7%	95.2%	94%	80%	60%
Rebuilding Duration Beyond $T_{F=0}$ (yrs.)	1.8	0	1	2	2	3	7	14

Evaluation of Action Alternatives

All the action alternatives assume the same basic strategy of reducing widow rockfish mortalities by specifying caps in non-tribal fisheries targeting whiting. While other sectors may be able to reduce their impacts with widow avoidance strategies, the impacts in directed midwater trawl fisheries for whiting promise to most substantially reduce widow mortalities. The large recruitments of widow rockfish predicted in the new stock assessment may be a significant management challenge for the whiting fishery, depending on the widow harvest rate and OY selected for the widow rockfish rebuilding plan and the bycatch caps specified in future whiting fisheries.

Only Action Alternative 1 is conservative enough to stay within the Preferred Low OY Alternative for widow, while all the action alternatives stay within the Council's Preferred High OY Alternative. Managing for a 120 mt OY (Preferred Low OY) will most certainly constrain future whiting fisheries significantly given the OY is less than the status quo bycatch caps specified for 2005 and 2006 whiting fisheries. It will prove difficult, if not impossible for the whiting sectors to fully attain future whiting allocations if the cap is as low as it would have to be under the Preferred Low OY Alternative.

Yelloweye Rockfish

Specific Yelloweye Rockfish Rebuilding Strategies

Of all the new groundfish stock assessments conducted in 2005-2006, the yelloweye rockfish assessment shows the most pessimistic change from status quo. A significant adjustment of status quo management is needed to rebuild this stock given the much lower OYs projected from the new rebuilding analysis. While status quo management of yelloweye has relied on a similar avoidance strategy as is used to minimize cowcod mortalities (i.e., no retention regulations and specific area closures), there are still some fisheries, such as recreational and commercial fisheries in the north targeting Pacific halibut, that will need to be further constrained to stay within the lower OYs analyzed in this EIS. A more comprehensive area management strategy, where more of the critical habitats where yelloweye reside are closed to fishing efforts known to take yelloweye, may be most effective at further reducing mortalities and should be seriously considered. Other mechanisms, such as season and depth restrictions, should also be considered to reduce yelloweye mortality.

Yelloweye rockfish have a similar life history pattern as cowcod. They are sedentary and exhibit more side fidelity than most rockfish species. Prohibiting fishing activities that are prone to catch yelloweye in areas they frequently occur is likely to be one of the best strategies for minimizing total mortality. Broad, depth-based RCAs are effective at reducing fishing-related mortality, and, in fact, the seaward boundary of the non-trawl RCA north of 40º10' N latitude is configured to reduce mortality of yelloweye by fixed gears. However, specific yelloweye RCAs, like the existing one off the north Washington coast (Figure 2-3), are likely to be most effective at reducing incidental mortality in hook and line fisheries. Figure 4-5 depicts the relative density of yelloweye by depth and latitude as indicated by catch per tow in West Coast trawl surveys. Assuming the composite trawl survey CPUEs accurately represent yelloweye distribution, yelloweye RCAs north of 39º N latitude in depths out to 100-125 fm should provide the most protection for yelloweye against incidental exploitation.

Gear restrictions have been shown to be effective at reducing yelloweye mortality as well. Mandating small footrope and selective flatfish trawls shoreward of the trawl RCA has significantly reduced yelloweye mortality.

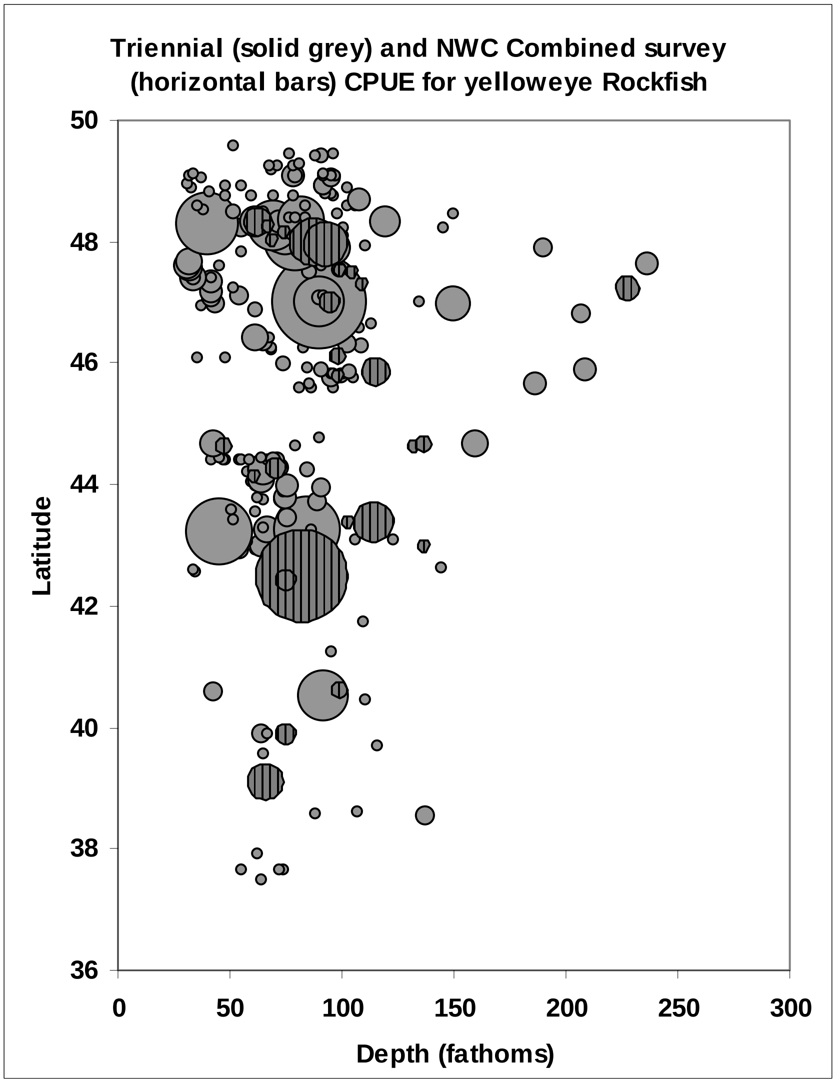

Figure 4-5. Index of West Coast distribution of yelloweye rockfish by latitude and depth as determined by catch per tow in NMFS trawl surveys. Size of circle is proportional to yelloweye rockfish density at that location. Data from NOAA Northwest Fisheries Science Center's West Coast Groundfish Survey Database and the NOAA Alaska Fisheries Science Center Triennial Shelf and Slope Survey Database.

Evaluation of Optimum Yield Alternatives

Table 4-14 shows the results of the evaluation of alternative yelloweye rockfish OYs analyzed for 2007-2008 using the criteria described in section 4.2.

There is considerable uncertainty in catch monitoring systems for tracking total catches of yelloweye. The sector currently taking the most yelloweye through unavoidable bycatch is the recreational sector targeting groundfish and Pacific halibut and, as pointed out in section 4.2, recreational catch monitoring is relatively uncertain. However, catch monitoring uncertainty is even more extreme for yelloweye since it is a rare species in the catch for any sector and, of the commercial sectors currently taking yelloweye, the fixed gear fisheries take the most and WCGOP at-sea observations are more sparse for fixed gear fisheries (particularly in the south). Precautionary management is called for with such high catch monitoring uncertainty.

The yelloweye rockfish assessment is also one of the more uncertain assessments done for West Coast groundfish since the fishery-dependent catch data are sparse and not well known and there is a significant lack of fishery-independent data in the assessment since survey bottom trawls do not catch yelloweye particularly well. The assessment is therefore tuned to highly uncertain recreational CPUE indices that may be more affected by past management restrictions and catch monitoring uncertainty than trends in stock biomass. This high uncertainty calls for precautionary management of stock rebuilding since the true state of nature may be more pessimistic (or optimistic) than the current assessment indicates.

Rebuilding probabilities are relatively high for the yelloweye OY alternatives considered for 2007-2008, ranging from 100% under the zero-harvest alternative to 80% for the Preferred Low OY and High OY alternatives. These preferred OYs are within the "target" range of 80% recommended by the SSC. This compares to about a 46% P_{MAX} under the status quo OY, which is under the lower legal limit of 50%. Of the two preferred OYs adopted for detailed analysis by the Council in April 2006, the Preferred High OY "ramp-down" strategy is slightly more risky in that it assumes a four-year transition from the current management regime before adopting a constant harvest rate strategy equal to that under the Preferred Low OY Alternative. Assuming the 2007-2010 OYs are not exceeded under the ramp-down strategy, there is no effective difference in P_{MAX} between the Preferred Low and High OY alternatives.

The relatively low productivity of the West Coast yelloweye stock predicts very long rebuilding periods. The shortest possible time to rebuild the stock under a zero-harvest strategy would be 2048 (Table 2-3). The harvest rate used to determine the 12 mt alternative (OY Alternative 2) is estimated to extend rebuilding an additional 30 years beyond that, while the Preferred Low OY and High OY alternatives are estimated to extend rebuilding an additional 35 and 35.5 years, respectively. This compares to over 71 additional years of rebuilding under the status quo harvest rate currently specified for rebuilding the yelloweye stock. The effect of a four-year transition from the status quo harvest rate to the low harvest rate under the Preferred Low OY Alternative is about a half a year of additional rebuilding under the ramp-down strategy.

Table 4-14. Evaluation of alternative 2007-2008 yelloweye rockfish OYs relative to the criteria described in section 4.2.

Evaluation Criterion	OY (mt)				
	No Action OY Alt. (2006 OY)	**OY Alt. 1**	**OY Alt. 2**	**Pref. Low OY Alt.**	**Pref. High OY Alt.**
	27	0	12	**12.6**	**Ramp down** [a]
Catch monitoring uncertainty	Very high uncertainty due to a paucity of at-sea observations and a significant recreational catch component.				
Assessment Uncertainty	Very high uncertainty due to poor data quality.				
Rebuilding Probability (P_{MAX})	45.7%	100%	81%	80%	80% [b]
Rebuilding Duration Beyond $T_{F=0}$ (yrs.)	71.5	0	30	35	35.5
a/ The yelloweye ramp-down strategy ramps the harvest rate down from the status quo harvest rate and resumes a constant harvest rate strategy in 2011. The 2007-2010 OYs are 23 mt, 20 mt, 17 mt, and 14 mt, respectively under the ramp-down strategy.					
b/ P_{MAX} (and the harvest rate beginning in 2011) are the same as for the Preferred Low OY Alternative.					

Evaluation of Action Alternatives

The very conservative management measures described under Action Alternative 1 in Chapter 2 are the only suite of management measures that are predicted to stay within the Council's Preferred Low OY Alternative. Management measures under Action Alternatives 2 and 3 stay within the OYs under the Council's Preferred High OY alternative, or the ramp-down strategy. Every action alternative specifies the implementation of a number of new Yelloweye RCAs to reduce mortality, but there is no quantifiable impact savings determined in this EIS from those proposed area closures. While it is unknown how overall total yelloweye mortality may be reduced by these YRCAs, some reduced mortality is anticipated and should be realized in 2007-2008 if these area closures are implemented. Reduced mortality should first be evidenced in decreased encounters in recreational fisheries in Washington and Oregon and reduced bycatch observed in the WCGOP, particularly in the limited entry and open access fixed gear sectors.

An important aspect of the YRCAs proposed for 2007-2008 is that comprehensive fishery and survey data are unavailable for understanding the distribution of critical yelloweye habitats. The proposed YRCAs under the 2007-2008 action alternatives emerged in consultation with fishermen in potentially affected commercial and recreational sectors as areas where they have traditionally encountered yelloweye. Many of these proposed RCAs are within the habitats of greatest yelloweye density as inferred from trawl survey CPUEs (Figure 4-5). A larger, less fragmented area management strategy may ultimately be more effective for rebuilding the yelloweye stock since it would likely reduce mortalities by protecting the most critical habitats yelloweye reside and will be easier to enforce. However, the YRCAs currently proposed is a good first start in transitioning to a significantly lower harvest rate. If closing only these proposed areas is deemed insufficient for getting to lower OYs, then conservative inseason depth and season restrictions will be needed to stay within these rebuilding limits. All the action alternatives contemplate stringent yelloweye harvest guidelines, which would force conservative inseason adjustments to those sectors experiencing difficulty avoiding yelloweye impacts.

4.3.1.2 Impacts of Rebuilding Alternatives

As explained in 2.1.1, rebuilding alternatives (Table 2-2b) were developed by arranging the depleted species' OYs in various combinations in order to understand how the rebuilding plans for different species interact to cumulatively constrain fishing opportunities. The description of each rebuilding alternative's impacts, below, is predominantly qualitative, as these suites of OYs were not crafted so that the Council would choose its depleted species OYs wholly from one of the alternatives. Rather, the function of the discussion below is to highlight, through its panoramic view across all depleted species, how each species might differentially constrain fishing opportunities by sector (or gear type) and region along the West Coast. Another point made in this section is that one depleted species (such as canary rockfish, which has a coastwide distribution and affects nearly all fishing sectors) can constrain opportunity in many sectors even if high OYs are selected for other co-occurring depleted species.

Rebuilding Alternative 1

Under Rebuilding Alternative 1, canary rockfish is a constraining species limiting both the commercial and recreational sectors. For limited entry bottom trawl, the canary rockfish OY limits the catch of target species, such as petrale and Dover sole in the summer months, as well as English sole, arrowtooth flounder, and Other Flatfish on the continental shelf. Applying depth restrictions is the primary management tool to reduce the impact of limited entry fixed gear and open access fisheries on depleted species. The canary rockfish OY, as well as the yelloweye rockfish OY, could cause these fisheries to be restricted to depths greater than 100 fm north of 40°10' N latitude (rather than 100 fm under status quo).

Although the canary rockfish OY is the primary constraint on the recreational sector, yelloweye rockfish is also a constraining species for the sector, especially for recreational fisheries in Washington and Oregon. For California recreational fisheries, the bocaccio OY also substantially constrains opportunity. Affected recreational fisheries include those targeting black rockfish, blue rockfish, cabezon, lingcod, Pacific halibut, and greenling. In general, management measures that would be needed under this alternative, in order to restrict encounters with canary rockfish, would be similar to those under Action Alternative 1 (see section 4.3.1.1). However, a greater impact to yelloweye rockfish would be possible under this alternative than is expected under Action Alternative 1. This could allow for less restrictive management measures in some sectors, particularly Washington and Oregon recreational fisheries.

Canary rockfish also constrains the whiting fishery. Given recent bycatch rates, canary rockfish could constrain the whiting fishery to a catch at a level approximately two thirds of the 2006 Pacific whiting OY. However, the whiting fleets have avoided many of the impacts to depleted or protected species through innovative bycatch reduction techniques, such as near real-time reporting of bycatch and voluntary fleet mobilization when bycatch in a particular area is high. In the past two years, setting bycatch caps for the non-tribal whiting sectors has effectively minimized the bycatch of depleted groundfish species.

The bottom trawl fisheries on the continental slope become more liberalized under this alternative. As a result, the available OYs for two of the main deepwater target species, petrale sole and sablefish, are able to be nearly or fully achieved. Given this more liberal scenario, it is the precautionary species, petrale sole and sablefish, which become constraining to fishing opportunities for other target species in limited entry bottom trawl, such as Dover sole and thornyheads. Nevertheless, the catch of Dover sole and thornyheads can still occur at levels equal to or higher than status quo levels. Species that have a high degree of co-occurrence with darkblotched rockfish (particularly those within the slope rockfish complex) are caught at levels that are substantially less than the available OY for those species. As has been the case in recent years, the POP OY is greater than that which can be accessed by these fisheries, given the constraints of other co-occurring species.

This alternative contains a widow rockfish OY that is higher than status quo; the OY is also greater than the estimated impact from the whiting fishery, the primary sector to catch widow incidentally. However, a midwater yellowtail rockfish and widow rockfish fishery cannot be re-introduced because the fishery's anticipated bycatch of canary rockfish could not be accommodated under this alternative's canary rockfish OY.

Rebuilding Alternative 2

Under Rebuilding Alternative 2, the northern fisheries that operate along the continental shelf and in nearshore areas are particularly constrained. The canary rockfish OY is set at a status quo level within this alternative, and therefore the impacts to fisheries would be expected to be similar to that seen under the current management. The yelloweye rockfish OY in this alternative, however, is set to a level lower than status quo (and also lower than under Rebuilding Alternative 1). Since yelloweye rockfish is caught almost exclusively by line gear, this alternative is particularly constraining to northern fixed gear and recreational fisheries. In order to lower the incidental catch of yelloweye within the recreational sector, the groundfish and, in northern waters, the Pacific halibut fishery would have to be restricted to shallower depths (potentially ≤20 fm) and/or new yelloweye RCAs would need to be established in areas of high yelloweye density where recreational bottom fishing would be prohibited. One possibility to reduce the limited entry and open access fixed gear impact on yelloweye rockfish would be to extend the non-trawl RCA seaward north of 40°10' N latitude, although establishing yelloweye RCAs could also help reduce impacts. The management measures to restrict impacts to canary rockfish and yelloweye rockfish under this alternative would be similar to those under Action Alternative 3.

Pacific ocean perch and darkblotched rockfish constrain bottom trawl fisheries along the northern slope areas to the same extent as under status quo management. Management measures under this alternative would also be similar to those described in Action Alternative 3. Similar to the case in Rebuilding Alternative 1, petrale sole and sablefish somewhat constrain the catch of other target species in the deepwater bottom trawl fisheries, such as Dover sole and thornyheads. However, the catch of these species is equal to or higher than the amount of catch occurring under status quo management. The whiting fishery operates as it would under status quo because its constraining bycatch species (canary rockfish, widow rockfish, and darkblotched rockfish) do not change under this alternative.

This alternative liberalizes the southern fisheries by increasing the bocaccio and cowcod OYs relative to status quo, although nearshore and shelf fisheries would still be constrained by canary rockfish, given the species coastwide distribution. Recreational fishermen in California, for example, might be able to fish at deeper depths or have a slightly longer season under this alternative. However, given the bocaccio OY is only slightly higher than the status quo impacts of about 150 mt of bocaccio in all fisheries combined, these increased opportunities might be slight. This is especially true if a strong year class of bocaccio is caught at a higher rate in nearshore fisheries, creating a temporary increase in bocaccio mortality until the fish mature and move to deeper depths.

Rebuilding Alternative 3

Rebuilding Alternative 3 is the most liberal of all of the rebuilding alternatives. Only the yelloweye rockfish OY specified within this alternative is less than that under status quo (although not much different than the realized status quo total mortality); some of the other OYs are substantially greater than those under status quo. This alternative provides for greater opportunities than those found in any of the Action Alternatives or in status quo management measures.

This alternative has the highest attainment of target species for most of the commercial sectors compared to other rebuilding alternatives, although current constraints on fisheries posed by low yelloweye OYs would not be lifted. Nevertheless, multiple target species OYs are not fully attained because the catch of precautionary zone target species caught in the commercial fishery (i.e., petrale sole and sablefish) limits the catch of healthy target species such as Dover sole and thornyheads. Commercial fixed gear fisheries, on the other hand, would continue to be constrained by the yelloweye rockfish OY.

Additional target opportunities could be accommodated under this alternative. For example, a midwater trawl fishery for yellowtail rockfish is possible, given that the widow rockfish OY is large enough to allow targeting and the canary rockfish OY is high enough to account for impacts that would be expected due to the co-occurrence of the three species. Only under this alternative would catch of widow rockfish approach the level of the OY; under the other alternatives (as well as under status quo) the widow rockfish OY is too low to allow this yellowtail rockfish target opportunity. The highest widow rockfish OY that could be considered in the new rebuilding analysis (1,369 mt) cannot be considered since canary rockfish would constrain midwater trawl opportunities, even under the higher amount under this rebuilding alternative (68 mt) before that amount of widow rockfish would be incidentally caught. The whiting fishery, which currently takes the greatest amount of widow rockfish, would be much less constrained by widow rockfish or canary rockfish under this alternative.

Northern recreational fisheries are still constrained by the yelloweye rockfish OY under this alternative. However, the effect on the fisheries may be mitigated by the higher canary rockfish OY in that management measures could direct fisheries away from areas with high yelloweye bycatch even if this increased the bycatch of canary rockfish. Depending on the management measures used to constrain the fisheries, fisheries directed toward black rockfish, Pacific halibut, lingcod, and greenling, amongst others, could be affected. Since yelloweye is rarely caught south of Cape Mendocino ($40^{o}10'$ N latitude), southern recreational fisheries are more liberalized under this alternative than under any of the other alternatives.

Rebuilding Alternative 4

Rebuilding Alternative 4 constrains the catch of target species for northern fisheries. Like in Rebuilding Alternative 1, the canary rockfish OY is almost one-half of status quo; however, the yelloweye OY is less than half of status quo, a more significant reduction than that analyzed under Rebuilding Alternative 1.

The OY for darkblotched rockfish is about double that of status quo and the OY for POP is nearly five times status quo. Given this scenario, the trawl fishery would need to shift away from the nearshore and shelf, where bycatch of canary rockfish is high, and into deeper waters where darkblotched encounters are greater (but are accommodated under this alternative). The result of this shift is to limit the catch of many commercially caught shelf and nearshore target species such as petrale and Dover sole in the summer months, English sole, arrowtooth flounder, and Other Flatfish. The midwater trawl fishery for Pacific whiting is similarly constrained under this alternative as it would be under Rebuilding Alternative 1. With a low canary rockfish bycatch cap, it is possible for the non-tribal sectors of the fishery to be closed before reaching their whiting allocations. However, the fishery's demonstrated ability to reduce its bycatch of overfished species in recent years suggests that such a situation may be averted.

Commercial fixed gear and open access fisheries coastwide are constrained significantly by this alternative, due to their encounters with canary and yelloweye rockfish. Management measures would likely be similar to those described under Action Alternative 1, in which the seaward boundary of the non-trawl RCA is extended from 100 to 150 fm north of 40°10' N latitude.

Recreationally fisheries are restricted substantially or eliminated completely under this alternative due to the low canary rockfish and yelloweye rockfish OYs. This affects both bottomfish fisheries (such as black rockfish, blue rockfish, cabezon, and lingcod) as well as other recreational fisheries that catch canary rockfish and yelloweye rockfish incidentally (such as Pacific halibut). In all instances, the OYs for these target species remain largely uncaught. Although yelloweye rockfish is generally only encountered north of Cape Mendocino, canary rockfish is caught nearly coastwide (it is rarely encountered south of Point Conception). Only for these most southern fisheries, can a more liberal season be considered given the higher bocaccio and cowcod OYs.

Unlike the southern commercial fixed gear fisheries, bottom trawl fisheries in the south are relatively unconstrained under this alternative, as the bocaccio OY is approximately twice that of status quo. As a result, the attainment of target species by the southern trawl fishery is largely limited by the attainment of precautionary zone target species OYs (petrale sole and sablefish).

Rebuilding Alternative 5

The OYs under Rebuilding Alternative 5 constrain all sectors of the groundfish fishery coastwide. Yelloweye rockfish, Pacific ocean perch, canary rockfish, darkblotched rockfish, and bocaccio all constrain the catch of more abundant species as well as the remaining two rebuilding species, widow rockfish and cowcod. No target species are constraints under this alternative, and none of the target species' OYs are attained.

The complexity of managing the fisheries increases substantially under this alternative. For example, it is difficult for managers to shift a fishery from an area where the catch of a depleted species has been exceeded into another other area where less constraining depleted species are found because nearly all of the depleted species are equally constraining. This type of situation would likely bring about the early closure of some fisheries in order to avoid exceeding the rebuilding OYs.

4.3.2 Precautionary Zone Groundfish Species

[To be completed after the June Council meeting. See chapter 2 for a description of the OY alternatives for these species and Table 2-1 for the 2007-2008 Preferred OYs decided at the April Council meeting.]

4.3.2.1 Cabezon (in Waters off California)

4.3.2.2 Pacific Whiting

4.3.2.3 Petrale Sole

4.3.2.4 Sablefish

4.3.3 Healthy Groundfish Species

[To be completed after the June Council meeting. See chapter 2 for a description of the OY alternatives for these species and Table 2-1 for the 2007-2008 Preferred OYs decided at the April Council meeting.]

4.3.3.1 Arrowtooth Flounder

4.3.3.2 Bank Rockfish

4.3.3.3 Black Rockfish

4.3.3.4 Blackgill Rockfish

4.3.3.5 California Scorpionfish

4.3.3.6 Chilipepper Rockfish

4.3.3.7 Dover Sole

4.3.3.8 English Sole

4.3.3.9 Lingcod

4.3.3.10 Longspine Thornyhead

4.3.3.11 Shortbelly Rockfish

4.3.3.12 Shortspine Thornyhead

4.3.3.13 Splitnose Rockfish

4.3.3.14 Starry Flounder

4.3.3.15 Yellowtail Rockfish

4.3.4 Unassessed Groundfish Species and Those Managed as Part of a Stock Complex

[To be completed after the June Council meeting. See chapter 2 for a description of the OY alternatives for these species and Table 2-1 for the 2007-2008 Preferred OYs decided at the April Council meeting.]

4.3.4.1 Minor Rockfish South

4.3.4.1.1 Southern Nearshore Species

4.3.4.1.2 Southern Shelf Species

4.3.4.1.3 Southern Slope Species

4.3.4.2 Minor Rockfish North

4.3.4.2.1 Northern Nearshore Species

4.3.4.2.2 Northern Shelf Species

4.3.4.2.3 Northern Slope Species

4.3.4.3 Pacific Cod

4.3.4.4 Other Fish

4.3.4.5 Other Flatfish

4.3.5 Non-Groundfish Species

[To be completed after the June Council meeting.]

4.3.5.1 Salmon

[See chapter 5 for a description of salmon bycatch in groundfish fisheries]

4.3.5.2 Pacific Halibut

4.3.5.3 Coastal Pelagic Species

4.3.5.4 Highly Migratory Species

4.3.5.5 Dungeness Crab

4.3.5.6 Greenlings, Ocean Whitefish, and California Sheephead

4.3.5.7 Pink Shrimp

4.3.5.8 California Halibut

4.3.5.9 Ridgeback and Spot Prawns

4.3.5.10 Sea Cucumbers

4.4 Discussion of Cumulative Impacts
