A number of natural and human-induced factors affect the status of a stock. Through data such as commercial and recreational catch estimates, length at age distributions, and larval distribution and abundance, past effects on a stock's productivity and mortality are incorporated into stock assessments and their associated rebuilding analyses. That is, a final estimate of a stock's biomass reflects the wide number of human and natural effects on the stock, both in the past and at the present time, even if these factors are not estimated explicitly in the model. (Although uncertainty with respect to the estimates in the assessments (see section 4.2) and only nascent understanding of the relationship between environmental conditions and stock status increases an assessment's overall uncertainty.) Given that the findings from a stock assessment provide the scientific basis upon which harvest specification decisions are made, it is assumed here that that the impacts of the effects found within stock assessment models are already adequately accounted for within the analysis of this action. This section, therefore, addresses factors that may impact affected species, but which are not explicitly accounted for in the stock assessments. These factors may affect a species in a number of ways, including contributing to the uncertainty that a harvest specification will maintain or rebuild the affected species' population levels and changing the genetic structure of a stock.

The actions discussed below are divided into two categories, *internal* and *external*. *Internal* refers to actions implemented as part of the management regime, while *external* refers to actions of other agencies, organizations and individuals, including broad natural or socioeconomic effects.

4.4.1 Internal Factors

4.4.1.1 VMS Implementation

In order to enforce compliance with depth-based and area-based restrictions, a common tool in management under the Groundfish FMP, a Vessel Monitoring System (VMS) program has been implemented over the past few years. In 2004, NMFS initiated a pilot program requiring all limited entry trawl and fixed gear vessels operating under the Groundfish FMP to carry and use Vessel Monitoring System (VMS) units. Beginning in 2007, this program will be expanded to include all commercial vessels that take and retain, possess, or land federally-managed groundfish species taken in federal waters or in state waters prior to transiting federal waters. Because the vessels must utilize VMS, compliance by limited entry vessels is assumed in the analysis of impacts of depth-based restrictions on affected species; therefore, the effects of the limited entry sectors' used of VMS are already considered under the current action.

The expansion of VMS into the directed open access sector in 2007, however, is considered to be a future action that may affect West Coast groundfish species. VMS deters mixed fishing strategies where vessels alter gear to catch groundfish within the RCAs. As a result, under VMS the risk of the actual catch exceeding the OYs for overfished species due to illegal fishing in the RCAs is reduced. Nevertheless, the behavior of the open access fleet under VMS can only be speculated; for example, the requirement may encourage additional targeting of groundfish by certain vessels in order to compensate for the cost of the VMS equipment. A potential indirect impact of VMS expansion is that fishing effort and location data from the vessels may improve the understanding of groundfish mortality. Data can be combined with observer, survey, and fish ticket data to better estimate total fishing mortality, impacts on juveniles and other fishery resources related to changes in fishing locations and intensity, fishing intensity (amount of time vessels are in an area), and changes in fishing location and intensity over time.

4.4.1.2 Bycatch (Amendment 18)

The Council has undertaken a number of actions in response to the 1996 amendment to the Magnuson-Stevens Act requiring measures to reduce bycatch in U.S. fisheries, as well as to a related court case, *Pacific Marine Conservation Council v. Evans*. Amendment 18 will establish catch caps and increased monitoring policies in the Groundfish FMP in order to minimize bycatch in West Coast groundfish fisheries to the extent practicable, minimize the mortality of unavoidable bycatch, and ensure that bycatch is reported and monitored as required by law. Amendment 18 was approved by NMFS in 2006. By reducing bycatch and bycatch mortality and by increasing the accuracy of total fishing mortality estimates, these new policies complement ongoing actions to rebuild depleted species. As fishing mortality is decreased through more stringent harvest restrictions, the cumulative adverse effects of fishing and its associated bycatch diminish for both depleted and healthy groundfish stocks. Therefore, it is for the less conservative harvest specification alternatives that these bycatch minimization efforts will be particularly important in providing mitigation against adverse effects.

Bycatch minimization efforts should indirectly affect West Coast groundfish stocks by improving the data used in stock assessments. Assessment models will be tuned to more precise estimates of total catch levels, which will then benefit the management specification process that uses these findings. Given that Amendment 18 will not be implemented in time to influence the 2005-2006 stock assessment cycle, the concern that unreported bycatch may adversely impact the affected species is not fully addressed within this action.

4.4.1.3 Changes to the Management Regime: Open Access Sector License Limitation and Trawl Individual Quota System

The Council is currently considering alternatives that would establish at Trawl Individual Quota (TIQ) program, with an expected implementation date of 2010. In a related action, the Council is considering transitioning the open access directed groundfish sector into a permit system for landing groundfish. Both changes to the West Coast groundfish management structure are expected to improve the accounting of fishing mortality to assure that catches do not exceed harvest specifications. More accurate catch data also would be expected to bring about improvements to stock assessments by reducing the uncertainty surrounding catch data.

4.4.1.3 Area restrictions

Since 1998, progressively restrictive depth-based and area closures (most notably RCAs) have constrained fishing activity within smaller areas of state and federal waters. Though these closures are considered to be effective tools in limiting fishing interactions with depleted species, they are also responsible for shifting additional fishing pressure into other areas and onto other species.

For example, the Oregon recreational groundfish fishery has been closed offshore of 40-fm from June through September since 2004. It is likely that due to these closures, most anglers who would have fished offshore during the closure periods instead relocated their activities inshore. The effort shift onto nearshore species that resulted contributed to the early attainment of the black rockfish harvest cap in 2004 and 2005 and to the early closure of the recreational fishery in both years. A similar effect is noted in the California recreational fishery, in which the combined effects of federal RCAs and state marine protected areas have increased the pressure on nearshore stocks. For many of these nearshore stocks, there is little data to support an assessment of its stock status, suggesting that the effect of this effort shift is difficult to monitor.

It is expected that the effects of area restrictions will persist into the future; the effects may also become more acute if depleted species' OYs are further reduced in order to rebuild the species as quickly as possible. Furthermore, in addition to the possible future expansion of RCAs, the implementation of Amendment 19 (Essential Fish Habitat) will bring about other area closures in order to protect sensitive habitat from fishing impacts. For Washington recreational fisheries, for example, a closure of fisheries seaward of 10 fm would reduce the area available (inside 60 fm) by 84%, and a 20-fathom closure would reduce the area inside 60 fm by 74%. Allowing fishing only in these smaller areas could reduce the ability of anglers to target healthy fish stocks in traditional fishing areas. Analogously, fishing pressure on groundfish stocks that may have previously been spread over a broad area could become more concentrated, increasing the potential for localized depletion of some species.

4.4.2 External Factors

4.4.2.1 Short-term and Long-term Climate Variability: ENSO (El Niño) and PDO

Most commercially important fish and shellfish stocks in the California Current system, including many groundfish, are widely acknowledged to experience moderate to substantial variability in year-to-year recruitment success. Nearly all of these stocks (particularly those of winter-spawning shelf species) experienced high (positive) recruitment anomalies in 1999, and a great many of these stocks experienced high recruitment in 2000 as well. For many stocks, these year classes are a primary factor behind the increased abundance trends presented in Table 4-2. For example, the 1999 bocaccio year class was the largest since 1989, resulting in a near doubling of stock spawning biomass between 1999 and 2005.

Similarly, many stocks also demonstrated strong recruitment in 1970, 1980, 1984 and 1990, with weak year classes tending to occur in 1976, 1982-83, 1992-93 and 1997. Multivariate analysis of the stocks' recruitment deviations suggests that a significant amount of the observed variability in recruitment for West Coast groundfish can be explained by environmental conditions that have a very similar impact to a broad range of species across a fairly broad spatial scale. Such a conclusion is also supported by survey data; for example, the Southwest Fisheries Science Center's rockfish pre-recruit survey (1983-2005) detected a strong degree of covariance in the relative abundance of pelagic juvenile rockfish from 1983 through 2005. Although this survey failed to detect the magnitude of the 1999 year class, it does show strong interannual variability throughout the 1980s, followed by a precipitous decline in relative juvenile abundance through most of the 1990s, followed in turn by a return to highly variable (but often strong) recruitment in the post-1999 era.

The timing of these recruitment synchrony events maps well onto short-term and long-term changes in ocean conditions (for further background on the relationship between El Nino events and the Pacific Decadal Oscillation and ocean conditions, see section 3.1.3. Following an intensive 1997-1998 El Nino event, ocean conditions changed dramatically, and 1999 has been described as a year of transition in long-term (decadal scale, as associated with the Pacific Decadal Oscillation, or PDO) ocean conditions by climatologists {Schwing and Peterson 2003}. The mechanisms by which climate affects recruitment are not known with certainty; however, strong recruitment years are generally associated with high southward transport in the winter period, low ocean temperatures, and high zooplankton production; these conditions parallel those present in 1999 and the years that immediately followed. Indeed, the connection between productivity and transport has long been recognized {e.g., Chelton et al. 1982}; recent observations are consistent with this finding; for example, Swartzman and Hickey {2003} describe an increase in euphausiid biomass following the 1999 shift in much of the California Current (generally south of Cape Blanco), and Feinberg and Peterson {2003} describe a dramatic increase in the duration and intensity of euphausiid spawning off Oregon between 1996 and 2001.

In that stock assessments estimate spawning biomass of a stock over time, it is reasonable to conclude that the effects of climatological events, such as El Nino and PDO, on groundfish species are accounted for within the analyses. However, with one exception, current stock assessments do not explicitly account for their effect on stock status, such as changes in fishing mortality. Only Schirripa and Colbert {2005; 2006} have integrated relative sea level (a proxy for transport) into the sablefish stock assessment as an environmental factor related to recruitment variability.

Future effects of ocean conditions on the status of affected species, on the other hand, are not encompassed within the analysis of the present action. Most notably, the criteria used to analyze impacts on depleted species, such as the time to rebuild under a constant harvest rate and the probability of successfully rebuilding the stock by T_{max}, do not account explicitly for the effects of climatological events. Indeed, although the development of statistical indices of climate variability across multiple time scales has improved our understanding of how climate has affected North Pacific ecosystems and productivity in the past, the future remains subject to poor predictability. Such uncertainty, with respect how fish productivity and the climate regime interact and with respect what and when short- and long-term climate changes will occur, brings about greater uncertainty surrounding stock assessment projections of future biomass: since predictions about future productivity are based on past relationships, between stock size and recruitment for example, if underlying conditions change, these predictions may under- or over-estimate population growth and sustainable fishery removals. For depleted species in particular, errors in prediction may lead to the need to decrease fishing effort below levels specified in the rebuilding plan in order to achieve a rebuilt stock by the target date. On the other hand, unanticipated increases in recruitment strength may allow for a quicker time to rebuild. In either case, amendments to the stock's rebuilding plan may be necessary. This environmentally-related uncertainty pertains more specifically to some depleted species (such as bocaccio, explained above) rather than to others; for species such as cowcod and widow rockfish, recruitment trends are better explained by the deterministic stock-recruitment relationship that is modeled within a stock assessment.

4.4.2.2 Spatial Effects

Under the current groundfish FMP, most stocks are managed under a coastwide OY. However, there is increasing evidence that for some stocks, a greater consideration of spatial dynamics could be appropriate, particularly with respect to minimizing the potential for localized depletion.

Berkeley et al. {2004} review examples of complex population structure in rockfish populations that suggests that only a small fraction of the spawners in a given stock contribute to successful recruitment. This can be attributed to high temporal and spatial variability in the coastal ocean that provides only limited opportunities for optimal environmental conditions that are required for successful recruitment for those species for which recruitment variability is high. Consequently, there could be increased recruitment variability, or some potential for recruitment failure, if the most reproductively important elements of a stock are depleted below target levels.

Similarly, for stocks with limited genetic exchange, overfishing of isolated population units could be possible where current stock assessments do not take such population structure into account. For example, Miller et al. {2005} found significant genetic differences among black rockfish adults collected 340–460 km apart, despite the assumption that prolonged larval duration led to widespread dispersal and minimal population structure in this species.

The risk to a species of reduced reproductive success or the depletion of genetic sub-populations is likely to increase with higher levels of fishing mortality. Alternative 3, therefore, poses the greatest risk of adverse spatial effects to depleted species, while Alternative 1 poses the least risk. In addition, alternative management measures may contribute to adverse spatial effects for a given species, as these could change the spatial and/or temporal concentration of catch (at a local and a coastwide scale) from that observed under current conditions. In all alternatives, however, the low OYs for depleted species constrain the catch of many healthy stocks to levels below their OYs, bringing about a reduction in the risk of adverse spatial effects for healthy stocks.

Many Pacific groundfish harvest specifications are structured following biogeographic zones (such as north-south divisions at Cape Mendocino and at Point Conception; see section 3.1.3 for more information). However there is not yet the science available to support spatial management at the resolution that may be necessary to reduce the risks discussed above; data limitations for stock assessment models preclude such advancement for most, if not all, West Coast groundfish species in the near term. Pelletier and Mahevas {2005} compiled a comprehensive review of fisheries and marine ecosystem simulation models and approaches that incorporated spatial dynamics, and rated the potential for each approach to address a range of ecological and fisheries related effects described as important elements of the success (or lack thereof) of implementing spatial management measures. These included restoring spawning biomass within closed areas, restoring demographic structure, increasing fecundity, enhancing fisheries yield, improving population stability and resilience, protecting biodiversity, and effecting changes in community structure. Such issues will be integral elements of fisheries science and management in the future, and advances in both assessment methods and simulation techniques should provide the means to better cope with the challenges of incorporating such complexity in the face of changing management regimes.

4.5 Summary of Impacts

4.5.1 Documentation of Impact Analysis Modeling

4.5.1.1 Modeling Limited Entry Trawl Impacts

Fleet-wide discard estimates associated with groundfish trawling are derived from WCGOP observer data and logbook and fish ticket data obtained from the Pacific Fisheries Information Network (PacFIN). Observer data are stratified by area, depth, and season. The management line at 40°10' N latitude is used to partition northern and southern areas. Bi-monthly cumulative limit periods are combined to form two seasons, representing winter (January-April and November-December) and summer (May-October). The northern area includes five depth strata, however, only four are used in the south, due to the paucity of observed trips in depths shallower than 100 fm. The number of observed tows and retained catch of target species within each stratum are reported in Table 4-15 for the 2004 fishery. For this analysis, target species include all flatfish, sablefish, and thornyheads, and also slope rockfish in the area south of 40°10' N latitude. Since regulations severely limit or eliminate the retention of rebuilding species, estimating fleet discard for those species by applying a ratio of discarded-to-landed catch to landings is not reliable. Consequently for rebuilding or bycatch species, retained target-species catch is used as a measure of effort for expanding discard from observed trips. Table 4-16 shows aggregate discard ratios for several species in each stratum. For bycatch species (upper panel), the discard ratios represent the discarded poundage for each species divided by the retained target species poundage. For target species (lower panel), the ratio of discarded-to-retained pounds is presented for each species.

Logbook data are then stratified in the same manner as observer data, and the retained amounts of individual target species are aggregated for each stratum (Table 4-17). For each target species, an initial estimate of discard is calculated by multiplying the retained poundage by the appropriate discard ratio reported in Table 4-15. For bycatch species, estimated discard is calculated by multiplying aggregate target species poundage in each stratum by the corresponding discard ratio. Logbook data do not include records for all trawl trips, and for purposes of this analysis, records without recorded depth or latitude-longitude coordinates are not included. To adjust for these factors, the discard amounts are expanded to reflect the difference in landed catch reported in fish tickets and logbooks. For target species, the expansion ratio is equal to fish ticket pounds for each species divided by the logbook pounds for each state and 2-month period. For bycatch species, the ratio of fish ticket-to-logbook poundage for combined target species is used.

Table 4-15. Number of limited entry trawl tows and retained target species poundage observed by the West Coast Groundfish Observer Program in 2004, by depth interval, area and season.

Area	Depth intervals (fm)	Winter [a/] Number of observed tows	target species [b/] retained (lbs)	Summer [a/] Number of observed tows	target species [b/] retained (lbs)

4.5.1.2 Modeling Limited Entry Fixed Gear Impacts

Two major strategies for the limited entry fixed gear fleet are targeting of nearshore groundfish species and targeting sablefish in both the primary fishery and the daily-trip-limit (DTL) fishery. Nearshore impact modeling methodology is described in section 4.5.1.4. Impacts in the sablefish targeting strategies are modeled as follows.

Fleet-wide discard estimates associated with fixed-gear sablefish fishing are derived from WCGOP observer data and fish ticket data obtained from PacFIN . WCGOP observation of fixed-gear vessels targeting sablefish began in 2001 and has focused on those participating in the limited-entry primary fishery. Due to the limited numbers of trips observed south of 40°10' N latitude, discard ratios are calculated through pooling all observations for 2004 within each gear group (longline and pot). Few vessels (limited entry or open access) were observed while fishing for sablefish under the "daily-trip-limit" provisions. However, in this analysis, observations from the primary fishery are assumed to be representative of bycatch and discard occurrences associated with all fixed-gear sablefish fishing north of 36° N latitude. Because there are no logbook data indicating the depth of fishing, it is not possible to apply the same depth-stratified approach used for the trawl fleet. Consequently, the coast-wide observer data are summarized, by gear, across the two depth zones where the fishery was permitted to take place in 2004: greater than 100 fm, north of 40°10' N latitude, and greater than 150 fm, south of 40°10' N latitude. As presented in Table 4-18, discarded amounts of sablefish are calculated for each gear and area, using fish ticket landings and the corresponding discard ratios. Since only a fraction of discards die, an assumed mortality percentage is applied. In accordance with the rate of survival assumed by the GMT, 20% of the discarded poundage is assumed to represent mortality. For rebuilding species, observed discard ratios relative to retained sablefish, are then used to calculate estimated amounts of mortality for each.

Table 4-18. Estimated discard of rebuilding species and sablefish associated with all fixed-gear sablefish landings north of 36^{o} N latitude during 2004.

Pacific ocean perch	0.0	0.0	**0.0**	0.0	0.0	0.0	**0.0**
Darkblotched rockfish	0.1	0.0	**0.1**	0.3	0.0	0.4	**0.5**

a/ As assumed by the Groundfish Management Team, the rate of mortality for discarded sablefish in the fixed gear fishery is assumed to be 20%.

b/ Discard ratios are calculated by dividing the total discarded weight of each species by the retained catch weight of sablefish, and are derived from data collected by the West Coast Groundfish Observer Program during the 2004 limited entry fixed gear primary fishery.
c/ Please note that the observer data include few observations from south of Ft. Bragg, CA, so these rates may underestimate the true bycatch of these species.

4.5.1.3 Modeling Open Access Impacts

Open access impacts are modeled using the limited entry fixed gear sablefish impact methodology described in the previous section for the directed open access strategies targeting sablefish (i.e., the daily-trip-limit fishery). Modeling impacts for that portion of the open access fishery targeting nearshore groundfish species is described in the following section.

4.5.1.4 Modeling Nearshore Commercial Impacts

Fleet-wide discard estimates associated with near-shore groundfish fishing are derived from observer data, fish ticket data obtained from PacFIN, and other parameters developed by the GMT. WCGOP began pilot coverage of vessels targeting near-shore rockfish and associated species, such as cabezon and kelp greenling, in 2003. Data collected from these vessels from January 2003 through August 2004 were summarized in a report published on the NWFSC web site in May of 2005 (http://www.nwfsc.noaa.gov/research/divisions/fram/observer/datareport/nearshore/datareport_nearshore_may2005.cfm). Data from the remainder of 2004 have not yet been released. It should be noted that the coverage of observed trips and tonnage reported in Table 4-19 reflect lower levels of coverage than for other fleets, and in turn greater uncertainty in estimating discard relationships. Table 4-20 summarizes bycatch ratios for rebuilding species and the number of observed gear sets used to calculate them. Table 4-21 summarizes the observed catch weight of target and rebuilding species, and the percentage of each species or species-group's catch that was discarded.

Table 4-19. Number of observed open access, fixed gear trips occurring at less than 50 fm and associated landed tonnage, by port group and gear from January 1, 2003 to August 31, 2004.

Port Group	Hook and Line [a/]		Pot [a/]	
	Number of trips	Landed catch (mt)	Number of trips	Landed catch (mt)
Astoria	16	1.2	b/	
S Oregon	71	7.3		
Crescent City	114	14.6		
Fort Bragg	12	0.3	10	0.3
Monterey	24	1.2		
Morro Bay	77	3.9	12	2.5
Santa Barbara	15	0.6	15	1.8
Los Angeles	31	0.7	32	3.2
ALL PORTS	360	29.7	b/	

a/ Since both gear groups were used on some trips, the total number of observed trips is less than the sum of the numbers shown for each gear group in this table.

b/ Data not reported because of confidentiality issues.

Table 4-20. Ratios of bycatch, for eight[a/] rebuilding species, per 100 pounds of retained nearshore target species, by area and depth, from open access fixed gear sets observed between January 1, 2003 and August 31, 2004 by the West Coast Groundfish Observer Program.

a/ The percentage discarded is calculated as the discard poundage divided by the total catch weight for each species.

b/ Lingcod was declared rebuilt in 2005.

In May 2005, the values presented in Tables 4-20 and 4-21 were used by the GMT, in conjunction with other information provided by Team members, in constructing the framework for evaluating discard in the nearshore fisheries presented in Tables 4-22 and 4-23. For the purposes of estimating 2004 discard in nearshore groundfish fisheries, the framework and parameters developed by the GMT have not been updated, except for the target species landed catch amounts. However, an overview of the process embodied in these two tables is presented below for purposes of clarity. Table 4-22 summarizes the calculation of discard for target species. Landed weights for each species/group are expanded to total catch estimates, using all-depth retention rates. Using observer and state-agency information, total catch is then distributed among 3 depth intervals: 0-10 fm, 11-20 fm, and 21-50 fm. Within each of those strata, depth-specific gross discard and mortality estimates are calculated using observed discard ratios and assumed rates of discard survival. The estimated retained catch of all target species within each area/depth stratum is used with observer-derived discard ratios to estimate the discard mortality of rebuilding species in these fisheries (Table 4-23).

4.5.1.5 Modeling Tribal Fishery Impacts

Background

From 1991 to 2002, Makah fishermen have employed trawl gear on a limited, exploratory basis. Recently, trawl fisheries have been developed to diversify harvest strategies and maximize fisheries production (vessels must choose between trawling and longlining and cannot engage in both). The trawl fleet had eight vessels in 2003 and expanded to the current fleet limit of 10 vessels in 2004. They pursue two basic strategies – bottom (small footrope) and midwater (pelagic) trawl. The majority of the fleet participates in both strategies though some specialize in one or the other. The bottom trawl fishery targets flatfish (primarily Dover, English, and petrale soles and arrowtooth flounder) and Pacific cod, while the midwater fishery targets yellowtail rockfish. In an agreement with the National Marine Fisheries Service and the Pacific Fishery Management Council, the Makah Tribe implemented an observer program in 2003 to monitor maximum retention compliance in the newly developed trawl fisheries. The observer program has a monthly (and overall annual) sampling rate target of 15% of all trips and is administered by a cooperative agreement between the Makah Tribe, Northwest Indian Fisheries Commission, and Washington Department of Fish and Wildlife.

Current Management

Makah Fisheries Management has developed trip limits for the trawl fleet for each of two strategies – bottom and midwater – that maximize production, while discouraging both interactions with overfished species and conflicts (i.e., preempting another fleet's opportunity) with their groundfish directed longline fleet (Tables 4-24 and 4-25). While trip limits are in place to discourage targeting on several species, especially overfished rockfishes (e.g., canary), maximum retention is required. Maximum retention in this case is defined as full retention of all marketable species, with particular emphasis on canary and widow rockfishes. Any trip limit overages are sold and the proceeds forfeited to the Tribe.

Table 4-24. Trip limits for the tribal midwater trawl fishery for both 2003 and 2004.

SPECIES	TRIP LIMITS
Yellowtail rockfish	≤ 30,000 lbs/trip
Widow rockfish	≤ 10% of yellowtail
Canary rockfish	300 lbs/trip
Minor shelf rockfish	300 lbs/trip
Minor slope rockfish	300 lbs/trip
Minor nearshore rockfish	300 lbs/trip
Thornyheads (long- and shortspine combined)	300 lbs/trip
Other species	Same as initial Limited Entry (LE) trawl N of 40° 10'

Table 4-25. Trip and/or cumulative limits for the tribal bottom trawl fishery for 2003 and 2004.

SPECIES	2003 LIMITS	2004 LIMITS
Petrale sole	30,000 lbs/2 mo	30,000 lbs/2 mo
Arrowtooth flounder	60,000 lbs/2 mo	30,000 lbs/trip
All other flatfish	100,000 lbs/2 mo	100,000 lbs/2 mo
Lingcod	300 lbs/day (not to exceed 900 lbs/week)	450 lbs/day (not to exceed 1,350 lbs/wk)
Sablefish	6,000 lbs/yr dressed wt	6,000 lbs/yr dressed wt
Yellowtail rockfish	5,000 lbs/mo	3,000 lbs/trip
Widow rockfish	≤ 10% of yellowtail/trip	≤ 10% of yellowtail/trip
Canary rockfish	300 lbs/trip	300 lbs/trip
Minor shelf rockfish	300 lbs/trip	300 lbs/trip
Minor slope rockfish	300 lbs/trip	300 lbs/trip
Minor nearshore rockfish	300 lbs/trip	300 lbs/trip
Thornyheads (long- and shortspine combined)	300 lbs/trip	300 lbs/trip
Other species	Same as initial LE trawl N of 40° 10’	Same as initial LE trawl N of 40° 10’

Since canary rockfish is the primary constraint in both strategies, management centers on its avoidance. The two strategies may be open simultaneously (though most fishermen with midwater nets will prosecute that strategy when available) and are closed whenever bycatch rates appear elevated. The bottom trawl fishery has a small footrope requirement (≤ 8 inches) that reduces rockfish interactions by preventing access to reefs, rocky substrate, and other high-relief areas. The midwater fishery uses pelagic nets and is managed with a combination of time and area closures to minimize impacts on canary and widow rockfishes.

Midwater trawl areas are defined by latitudinal and longitudinal coordinates in regulations. An area is opened after two vessels with full observer coverage make exploratory trips to verify that bycatch rates are low enough to prosecute the fishery. An area is closed whenever bycatch rates appear elevated. The fishery is also closed June-August based on anecdotal evidence from fishermen that canary rockfish bycatch is highest in these months. Trip limits are usually 30,000 pounds/2 month period, but may be adjusted upwards to a maximum of 30,000 pounds/trip if bycatch appears minimal and few vessels are participating.

Methods

Observations are conducted by the port sampler operating out of Neah Bay, WA. Vessels must contact an observer hotline 24 hours prior to departure stating the date and time of departure and expected duration of the trip. Vessels are selected in a quasi-random manner based on availability of the observer in coordination with his other duties (i.e., dockside sampling and data entry). Data collected include gear type, tow duration, average depth, start and end location, and pounds discarded and retained. Priority is given, in decreasing order, to verifying maximum retention, quantifying discard of halibut and their disposition (not covered in this report), and quantifying all other discard species.

Bycatch rates were measured as total catch (retained + discard, if any) of bycatch species divided by landed catch of target species in pounds – similar to the method employed by the West Coast Groundfish Observer Program. While tow-by-tow data are collected by the observer, corresponding information is not available for unobserved trips making it difficult to attribute bycatch to a particular bottom trawl target strategy. Instead, bycatch rates for bottom trawl are reported for primary flatfish targets combined (petrale, English, and Dover soles and arrowtooth flounder), all flatfish combined, Pacific cod, and all targets combined (i.e., Pacific cod plus all flatfish). Target species are divided into these categories to help determine if bycatch of canary can more readily be attributed to flatfish fishing or Pacific cod fishing. The midwater trawl fishery targets only yellowtail rockfish. Bycatch of canary rockfish is measured for both bottom and midwater trawl fisheries. Bycatch of widow rockfish in midwater trawl is also examined.

Comparisons of observed versus unobserved landings by year were conducted for each strategy to test for differences in retention of select overfished species. Separate analyses were performed for vessels that carried an observer (paired *t* test) and all vessels combined (i.e. including those vessels that had no observer coverage during the year). For all vessels combined the assumption of equal variance was tested and the appropriate *t* test performed. Comparisons of canary rockfish associated with primary flatfish, Pacific cod, and all target species combined were conducted for bottom trawl. Comparisons based on all flatfish landings were not performed, since other flatfish (i.e., non-primary species) are not specifically targeted and change bycatch rates very little. Both widow and canary rockfish associated with yellowtail rockfish were examined for midwater trawl. Comparisons across years were not performed to avoid confusion of interannual variation in species availability or targeting strategy with fishing behavior associated with carrying an observer.

Results

Bottom Trawl

In 2003 there were 23 sampled trips out of 175 total trips (13.1%). Coincidentally, 23 of 221 total trips (10.4%) were also sampled in 2004. Discard in both years consisted primarily of Pacific whiting, spiny dogfish, unmarketable flatfish, and other unmarketable fishes (Table 4-26). Bycatch rates for all landings by target and year are provided in Table 4-27.

Table 4-26. Observed tribal bottom trawl discard in pounds by species or species group by year.

Species	2003	2004
Pacific whiting	11,000	5,097
Spiny dogfish	9,534	9,231
Arrowtooth flounder	1,982	6,250
Unspecified skates	1,485	4,723
Unspecified sole	1,219	1,484
Ratfish	1,180	3,361
Pollock	120	503
Minor shelf rockfish	30	104

Table 4-27. Total fleet bycatch rates (measured as pounds of canary rockfish in the tribal bottom trawl fishery divided by pounds of target category) by year.

Target	2003	2004
Primary flatfish	0.00138	0.00223
All flatfish	0.00131	0.00212
Pacific cod	0.00137	0.00249
All targets	0.00067	0.00115

Two-tailed paired *t* tests found no significant difference between observed and unobserved trips for vessels that carried an observer during the season for either year (Table 4-28). Canary catches per combined primary flatfish landings were not significantly different. Similarly, canary catches associated with Pacific cod and all targets combined were not significantly different.

Table 4-28. Yearly comparisons of canary rockfish bycatch rates (measured as pounds of canary rockfish divided by pounds of target category) for tribal bottom trawl vessels that carried an observer at least once during a season.

Year	Target Species	Mean Bycatch Rates		d.f.	*t*	*p*
		Observed	Unobserved			
2003	Primary flatfish	0.00121	0.00198	6	0.79	0.46
	Pacific cod	0.00202	0.00344	6	-0.60	0.57
	All Targets	0.00059	0.00113	6	-0.89	0.41
2004	Primary flatfish	0.00772	0.00343	5	0.79	0.47
	Pacific cod	0.03807	0.00312	5	1.19	0.29
	All Targets	0.00619	0.00127	5	1.15	0.30

Two-tailed *t* tests also found no significant difference between all observed and unobserved trips in either year (Table 4-29). Canary bycatch rates associated with primary flatfish were not significantly different. For Pacific cod, observed versus unobserved trips in 2004 had unequal variances $F\ (5, 9) = 23.62$, $p < 0.01$ and were not significantly different in either year. Bycatch rates of canary for all targets combined also were not significantly different.

Table 4-29. Yearly comparisons of canary rockfish bycatch rates (measured as pounds of canary rockfish divided by pounds of target category) for all observed and unobserved tribal bottom trawl vessels.

Year	Target Species	Mean Bycatch Rates		d.f.	*t*	*p*
		Observed	Unobserved			
2003	Primary flatfish	0.00106	0.00143	16	-0.43	0.67
	Pacific cod	0.00176	0.00245	16	-0.38	0.71
	All Targets	0.00052	0.00085	16	-0.68	0.50
2004	Primary flatfish	0.00772	0.00750	14	0.03	0.98
	Pacific cod	0.03807	0.00663	5	1.07	0.33
	All Targets	0.00619	0.00330	14	0.64	0.53

Midwater Trawl

The observer sampled 5 out of 34 trips (16.0%) in 2003, and 11 of 53 trips (20.8%) in 2004. Discard consisted of Pacific whiting, minor shelf rockfish, minor slope rockfish, and dogfish (Table 4-30). Bycatch rates of widow and canary in all landings are provided in Table 4-31.

Table 4-30. Observed tribal midwater trawl discard in pounds by species or species group by year.

Species	2003	2004
Pacific whiting	3270	0
Minor shelf rockfish	450	1175
Minor slope rockfish	63	575
Spiny dogfish	0	70

Table 4-31. Total fleet bycatch rates (measured as pounds of canary or widow rockfish divided by pounds of yellowtail rockfish) in the tribal midwater trawl fishery by year.

Species	2003	2004
Canary	0.00168	0.00350
Widow	0.04263	0.06767

Two-tailed paired *t* tests found no significant difference in bycatch between observed and unobserved trips on vessels that carried an observer at some point in the season (Table 4-32). In 2003 there was no significant difference for canary or widow. There was also no significant difference in 2004 for either canary or widow.

Table 4-32. Yearly comparisons of canary and widow rockfish bycatch rates (measured as pounds of bycatch divided by pounds of yellowtail) for tribal midwater trawl vessels that carried an observer at least once during a season.

Year	Species	Mean Bycatch Rates		d.f.	*t*	*p*
		Observed	Unobserved			
2003	Canary	0.00351	0.00289	2	0.27	0.81
	Widow	0.05353	0.03335	2	0.60	0.61
2004	Canary	0.00651	0.00213	5	1.81	0.13
	Widow	0.07209	0.06719	2	0.30	0.78

In comparisons of all observed versus unobserved trips, two-tailed *t* tests detected no significant differences in bycatch (Table 4-33). Variances for canary bycatch were unequal in observed and unobserved trips for 2003 and 2004 $F\ (2, 7) = 9.57$, $p < 0.01$ and $F\ (5, 10) = 5.90$, $p < 0.01$ respectively. The difference in canary bycatch was not significantly different in either year, though in 2004 the difference is characterized as being of "borderline" significance. No significant differences were detected for widow bycatch in either year.

Table 4-33. Yearly comparisons of canary and widow rockfish bycatch rates (measured as pounds of bycatch divided by pounds of yellowtail) for all observed and unobserved tribal midwater trawl vessels.

Year	Species	Mean Bycatch Rates		d.f.	*t*	*p*
		Observed	Unobserved			
2003	Canary	0.00351	0.00124	2	0.72	0.55
	Widow	0.05353	0.07671	9	-0.39	0.70
2004	Canary	0.00651	0.00175	6	2.13	0.08*
	Widow	0.07209	0.05421	15	1.16	0.26

* Difference in canary bycatch rates in 2004 was of borderline significance.

Discussion

Bycatch rates for a particular species can vary considerably within a fleet and for a variety of reasons. Annual variations in distribution or abundance can affect encounters, as can effort and the times and areas fished. This is especially true for patchily distributed animals such as canary and widow rockfishes. In both bottom and midwater trawl fisheries the encounter rate of canary was considerably higher in 2004 than in 2003 (71.6% and 108.3% respectively). The bycatch rate of widow rockfish in the midwater fishery was 58.7% higher in 2004. These increases may also reflect expanding effort (though not capacity) within the trawl fleet as a whole. Some level of increasing impacts may be due to what has been termed the “rebuilding paradox.” The paradox is that as overfished species rebuild, they are more likely to be encountered by fishermen trying to avoid them. Estimating the relative influence of these factors will require more data collection and further, detailed analyses.

One interesting effect of increased occurrences of canary rockfish in the 2004 midwater fishery was the prosecution of more observed, exploratory trips to determine if bycatch rates were low enough to conduct the fishery in a given area. Observed vessels engaged in exploratory trips can be expected to have higher bycatch rates than unobserved vessels operating in verified low bycatch areas. This is likely what led to the borderline significant low *p*-value for observed versus unobserved that year. Differentiating observed exploratory trips from other observed trips may lead to more comparable observed versus unobserved bycatch rates. Despite large interannual variation of bycatch rates for these two years, the values measured can still inform management. Examination of bycatch rates over many years could detect patterns, and averages across years weighted toward more recent years can mitigate some of the negative effects of the rebuilding paradox on the fishery as well as reflecting changes in fleet behavior (i.e., if more recent years are likely to be more similar to the upcoming season, preseason planning is improved). If preseason planning is based on accurate expectations of bycatch, inseason management (e.g., time and area restrictions) is likely to be more effective at staying within estimated impacts.

Combining maximum or full retention policies with an observer program to verify the accuracy of bycatch accounting can greatly benefit both the fleet and the resource. In other words, if observed bycatch rates are not significantly different than unobserved bycatch rates, managers can be reasonably certain that landings reflect total mortality for overfished species and fishermen can continue to access healthy stocks. This combination can also prove very cost effective where other programs might not be economically feasible (e.g., full observer coverage). With this method, estimates of total removals can be verified, bycatch rate estimates refined, and better preseason and inseason management can be achieved. In this case, the lack of significant differences between bycatch rates in observed versus unobserved trips shows that the maximum retention program is working and landings are a reasonable estimation of actual impacts.

4.5.1.6 Modeling Washington Recreational Impacts

<u>Washington Recreational Fishery Sampling and Catch Estimates</u>

The Washington Ocean Sampling Program (OSP) generates catch and effort estimates for the recreational boat-based groundfish fishery which are provided to Pacific States Marine Fisheries Commission (PSMFC) and incorporated directly into RecFIN. The OSP provides catch in total numbers of fish, and also collects biological information on average fish size, which is provided to RecFIN to enable conversion of numbers of fish to total weight of catch. Boat egress from the Washington coast is essentially limited to four major ports, which enables a sampling approach to strategically address fishing effort from these ports. Effort estimates are generated from exit-entrance counts of boats leaving coastal ports while catch per effort is generated from angler intercepts at the conclusion of their fishing trip. The goal of the program is to provide information to RecFIN on a monthly basis with a one-month delay to allow for inseason estimates. For example, estimates for the month of May would be provided at the end of June. Some specifics of the program are:

Exit/Entrance Count

Boats are counted either leaving the port (4:30 AM - end of the day) or entering the port (approximately 8:00 AM through end of the day) to give a total count of sport boats for the day.

Interview

Boats are encountered systematically as they return to port; anglers are interviewed for target species, number of anglers, area fished, released catch data and depth of fishing (non-fishing trips are recorded as such and included in the effort expansion). The OSP only collects information on released catch and does not collect information on the condition of the released fish. Therefore, released catches must be post-stratified as live or dead based upon an assumed discard mortality rated. Onboard observers are deployed throughout the sampling season primarily to observe hatchery salmon mark rates but also collect rockfish discard information for halibut charter trips.

Examination of Catch

Catch is counted and speciated by the sampler. Salmon are electronically checked for coded wire tags and biodata is collected from other species.

Sampling Rates

Sampling rates vary by port and boat type. Generally, at boat counts less than 30, the goal is 100% coverage. The sampling rate goal decreases as boat counts increase (e.g., at an exit count of 100, sample rate goal is 30%; over 300, sample rate goal is 20%). Overall sampling rates average approximately 50% coastwide through March-October season.

Sampling Schedules

Due to differences in effort patterns, weekdays/weekend days are stratified. Usually, both weekend days and a random 3 of 5 weekdays are sampled.

Personnel

OSP sampling staff include two permanent biologists coordinating data collection, approximately twenty-two port samplers, four on-board observers and one data keypuncher.

Volume of Data

Between 20,000 and 30,000 boat interviews completed per season coastwide.

Data Expansion

Algorithm for expanding sampled days:

$$\frac{\text{Exit Count}}{\text{Total boats sampled}} * P_s \text{ sampled} = P_t$$

where P_s = any parameter (anglers, fish retained, fish released) within a stratum,
and P_t = total of any parameter with stratum for the sample day

Algorithm for expanding for non-sampled days:

$$\text{Total Weekday Catch} = \frac{\Sigma(P_t) \text{ on sampled weekdays}}{\text{number weekdays sampled}} * \text{ no. of weekdays in stratum}$$

$$\text{Total Weekend Catch} = \frac{\Sigma(P_t) \text{ on sampled weekend days}}{\text{number weekend days sampled}} * \text{ no. weekend days in stratum}$$

Total weekend catch + total weekday catch = total catch in stratum

Notes on Data Expansion:
Salmon and halibut catches are stratified by week; all other species are stratified by month. All expansions are stratified by boat type (charter or private), port, area and target species trip type (e.g., salmon, halibut, groundfish, and albacore).

Washington Recreational Fishery Impact Modeling

Pre-Season Catch Projections

Projected impacts for Washington's recreational fishery are essentially based upon the previous season's harvest estimated by the Ocean Sampling Program (OSP) and incorporated in RecFIN. This is especially true if recreational regulations remain consistent.

However, in 2005, the Washington Department of Fish and Wildlife implemented a depth restriction of 30 fm for a portion of the Washington coast. Since 2002, the OSP program began collecting fishing depth as well as discard information. This information is keypunched and analyzed on an annual basis with respect to depth of catch for species of concern. Beginning in 2006, and carrying through 2007 and 2008, we have modified our pre-season catch projections, based on the use of depth restrictions, by sub-area and fishery. The Washington recreational management measures include prohibiting fishing deeper than 10, 20, or 30 fm (depending upon time and management sub-area); therefore, the depth analysis was re-structured to determine the catch and mortality of discarded fish relative to these depths, as follows:

Canary Rockfish

- Apply 100% mortality rate to canary rockfish caught on all recreational fishing trips targeting Pacific halibut, when there is no depth restriction in place
- Apply 66% mortality rate to canary rockfish on recreational fishing trips targeting species other than Pacific halibut, when there is no depth restriction in place
- When a 20-fm depth restriction is in place, apply a 50% mortality rate to canary rockfish caught on all recreational fishing trips (based on research by Albin and Karpov, 1995).
- When a 10-fm depth restriction is in place, apply a 10% mortality rate to canary rockfish caught on all recreational fishing trips.
- When a 10- or 20-fm depth restriction is in place, there may be a reduced encounter rate of canary rockfish, but this is not included in the model.

Yelloweye Rockfish

- Apply 100% mortality rate to yelloweye rockfish caught on all recreational fishing trips, when there is no depth restriction in place
- When a 20-fm depth restriction is in place, apply a 50% mortality rate to yelloweye rockfish caught on all recreational fishing trips (based on research by Albin and Karpov, 1995).
- When a 20-fm depth restriction is in place, apply an encounter rate reduction of 25% (based on 2005 OSP catch-by-depth data) as yelloweye tend to inhabit deeper depths.
- When a 10-fm depth restriction is in place, apply a 10% mortality rate to yelloweye rockfish caught on all recreational fishing trips.
- When a 10-fm depth restriction is in place, the yelloweye encounter rate is likely reduced from the rate inside 20 fm, but this is not included in the model.

Inseason Catch Projections

Inseason catch projections are based upon the most recent OSP estimates (with a one-month time lag) with subsequent months extrapolated from the pre-season catch projections. This includes producing inseason reports of discard information for prohibited species such as yelloweye and canary. However, it should be noted that the precision of recreational groundfish catch estimates based upon previous seasons will continue to be influenced by factors such as the length and success of salmon and halibut seasons, weather and other unforeseen factors.

4.5.1.7 Modeling Oregon Recreational Impacts

Data Source for Base Model

Modeling of estimated impacts in the 2007-2008 Oregon recreational groundfish fishery was based on recent year estimates of landings and discards. For the ocean boat fishery, the data source was the Oregon Department of Fish and Wildlife's (ODFW) Ocean Recreational Boat Survey (ORBS). For the shore and estuary fishery, the data source was the Marine Recreational Fishery Statistical Survey (MRFSS). Analyzed species include black, blue, brown, canary, china, copper, grass, quillback, vermilion, tiger, widow, and yelloweye rockfishes; as well as kelp and rock greenlings, cabezon and lingcod.

Landings and discards for the ocean boat fishery (in numbers of fish) were initially based on normalized 2004 and 2005 landings and discards because these data most closely reflect regulations expected in 2007-2008 (i.e., bag limits, effort shifts to avoid overfished and harvest capped species, etc.). The 2004 season reflected very good salmon opportunity, while the 2005 season reflected reduced salmon opportunity. As work progressed on the model and the outlook for salmon opportunity in the near future appeared likely to be reduced from recent years it was decided to model estimated 2007-2008 impacts based solely on the 2005 season (reduced salmon opportunity). Groundfish directed effort has been shown to be affected by salmon opportunity (i.e. groundfish directed effort increases when salmon opportunity is poor due to anglers pursuing other species). Concern was expressed that adopting an overly optimistic groundfish season would result in inseason action to slow catch rates, and anglers would rather have regulations relaxed inseason rather than opportunities curtailed. If salmon opportunity improves in 2007-2008, the recreational groundfish opportunity could be expanded inseason.

Landings and discards for the shore and estuary fishery (in weight), largely not affected by management of overfished species, reflect the most recent 5-year average, 1998-2002 as the MRFSS program is designed for trends and not annual accurate estimates of catch. Only annual weights for greenling and cabezon were adjusted to reflect changes in minimum length requirements.

Normalizing 2005 Catch and Angler Trip Data

To facilitate providing maximum flexibility in modeling 2007-2008 management measure alternatives, landings in 2005 were normalized to a 10-fish marine bag limit and a year round season with no offshore closures.

From 2000 through 2002, the rockfish bag limit had been 10 fish per angler per day. Starting in 2003 a 10-fish marine bag limit was implemented that included species other than lingcod, salmon, steelhead, Pacific halibut, sanddab, surfperch, sturgeon, striped bass, pelagic tuna and mackerel species, and bait fish such as herring, anchovy, sardine and smelt. In response to an early closure in 2004, the 2005 marine bag limit started at 8 fish on January 1 and was reduced to 5 fish on July 16.

Normalization of the marine bag limit was accomplished by comparing the average catch per angler trip (CPUE) observed in 2005 (8 and 5 fish marine bag limits in place) with comparable periods in 2003-2004 (10 fish marine bag limit). The average reduction in CPUE observed by adjusting the marine bag limit from 10 to 8 fish was 10.9 percent. A 38.2 percent reduction was observed when the marine bag limit was adjusted from 10 to 5 fish. The same methodology was applied to discards per angler trip, as the number discarded for many species for which retention was allowed increased as the marine bag limit was reduced. Canary and yelloweye rockfish impacts were not adjusted, as the data suggested little change to the duration of groundfish trips, resulting in little savings of those two species.

Landings and discards were normalized to reflect a fishery without depth restrictions. In both 2004 and 2005, during the period from June through September the groundfish fishery was closed shoreward of the 40-fathom line. The expected increase in encounter rates for species residing offshore was based on data from 2001 and 2003-2005 at-sea observations on Oregon charter vessels (360 trips were observed). The observer study was not conducted in 2002. The following increased encounter rates were applied to appropriate months when normalizing to an all-depth fishery: canary rockfish = 1.32; yelloweye rockfish = 1.69; lingcod = 1.3; and widow rockfish = 3.57.

Landings and discards were normalized to a year round season. In both 2004 and 2005 regulations were changed inseason (starting in early September in 2004 and mid-October in 2005). Because of the inseason closures in 2004-2005, the 2003 fishery was used as a template for seasonal catch and effort pattern in the groundfish fishery as it was open January through December. Estimated catch for October through December was calculated by applying the monthly temporal pattern observed in 2003 to the normalized January through September 2005 estimates.

The expected average weight of landed fish was based on those observed in the 2005 ocean boat fishery. The expected average weight of discarded fish in the ocean boat fishery was based on at-sea observations in 2003-2005 with attention paid to matching samples with depth closure regulations. Observations indicate that yelloweye rockfish and canary rockfish caught shoreward of the 40 fm line were considerably smaller than the average size of those caught offshore, due to a higher abundance of juveniles nearshore. Due to small sample sizes observed at-sea, the average weight of fish landed in 2003 was used to represent the average weight of yelloweye rockfish caught during periods of no depth restrictions. For widow rockfish and nearshore rockfish other than black rockfish and blue rockfish, again due to small sample sizes (most are retained), a 25 percent reduction from average landed weight was assumed for discards of these species. This was thought to be conservative as the observed average size of discarded black rockfish and blue rockfish were on the order of a 50 percent reduction from average landed weight.

Annual groundfish directed angler effort for the ocean boat fishery is expected to be similar to levels observed in 2005. Effort data was also normalized using the 2003 temporal pattern to estimate groundfish effort during October through December when the nearshore fishery was closed in 2005. Angler effort in shore and estuary areas is assumed to be similar to the base period of 1998-2002. Groundfish angler trips in the shore and estuary fishery are not available, only total angler trips of all trips types. During closures seaward of 40-fm, ocean boat effort and catch were shifted from the offshore closure areas to open nearshore areas. The estimated effort increase in nearshore waters is 5 percent, which reflects the fact that approximately 5% of the total effort in 2001-2003 was in offshore waters. This effort shift was addressed when normalizing the 2005 fishery.

Estimating Discard Mortality in the Oregon Recreational Groundfish Fishery

An approach similar to that used for the commercial open-access nearshore fishery to determine mortality of discarded groundfish was used to develop appropriate discard mortality rates to be applied to the recreational fishery. The approach incorporates at-sea observations of catch by species, stratified by depth, with angler reported discard, and stratum based mortality rates by species.

At-sea observations were conducted on recreational charter vessels off Oregon during 2001, 2003-2005. A total of 360 vessels trips were conducted. Each year the observations were distributed across the state in an effort to represent the relative magnitude of catch by area. The annual goal was to conduct 100 observations, but that goal was not always achieved due to inseason closures. The number of rockfish observed by species or species group, discarded in the nearshore recreational fishery is reported in Table 4-34.

Table 4-34. Count of released fish observed by depth bin (fm) during 2001, and 2003-2005. Canary and yelloweye data from open all depth periods only; black, blue, and other nearshore rockfish data from all periods. Other nearshore rockfish includes brown, copper, quillback and china rockfishes (no discards of other nearshore rockfish species were observed).

Species	≤10 fm	11-20 fm	21-25 fm	26-30 fm	31-40 fm	> 40 fm	Sample Size

Black rockfish	296	372	18	2	0	0	688
Blue rockfish	183	622	48	5	0	0	858
Other nearshore rockfish	1	8	2	5	0	0	16
Canary rockfish	13	107	29	2	5	52	208
Yelloweye rockfish	0	5	1	1	0	13	20

The species of rockfish caught inside of 20-fm, and for which mortality rates are derived, include black, blue, other nearshore rockfish, canary, and yelloweye. The distribution of discarded fish by species and depth bin (fm) based on at-sea observations are identified in Tables 4-35a-e. Observed distributions are presented for all-depth fisheries, and predicted distributions are presented for fisheries closed seaward of 40-fm, 30-fm, 20-fm, and 10-fm.

Table 4-35a. Distribution of released fish observed by depth bin (fm) when open all depths.

Species	≤10 fm	11-20 fm	21-25 fm	26-30 fm	31-40 fm	> 40 fm	Sample Size
Black rockfish	43%	54%	3%	0%	0%	0%	688
Blue rockfish	21%	72%	6%	1%	0%	0%	858
Other nearshore rockfish	9%	73%	18%	45%	0%	0%	16
Canary rockfish	6%	51%	14%	1%	2%	25%	208
Yelloweye rockfish	0%	25%	5%	5%	0%	65%	20

Table 4-35b. Predicted distribution of released fish when closed outside 40 fm.

Species	≤10 fm	11-20 fm	21-25 fm	26-30 fm	31-40 fm	Sample Size
Black rockfish	43%	54%	3%	0%	0%	688
Blue rockfish	21%	72%	6%	1%	0%	858
Other nearshore rockfish	6%	50%	13%	31%	0%	16
Canary rockfish	8%	69%	19%	1%	3%	156
Yelloweye rockfish	0%	71%	14%	14%	0%	7

Table 4-35c. Predicted distribution of released fish when closed outside 30 fm.

Species	≤10 fm	11-20 fm	21-25 fm	26-30 fm	Sample Size
Black rockfish	43%	54%	3%	0%	688
Blue rockfish	21%	72%	6%	1%	858
Other nearshore rockfish	6%	50%	13%	31%	16
Canary rockfish	9%	71%	19%	1%	151
Yelloweye rockfish	0%	71%	14%	14%	7

Table 4-35d. Predicted distribution of released fish when closed outside 27 fm.

Species	≤10 fm	11-20 fm	21-25 fm	Sample Size
Black rockfish	43%	54%	3%	686
Blue rockfish	21%	73%	6%	853
Other nearshore rockfish	9%	73%	18%	11
Canary rockfish	9%	72%	19%	149
Yelloweye rockfish	0%	83%	17%	6

Table 4-35e. Predicted distribution of released fish when closed outside 20 fm.

Species	≤10 fm	11-20 fm	Sample Size

Black rockfish	44%	56%	668
Blue rockfish	23%	77%	805
Other nearshore rockfish	11%	89%	9
Canary rockfish	11%	89%	120
Yelloweye rockfish	0%	100%	5

Mortality rates for fish discarded by depth strata are detailed in Table 4-36. A mortality rate of 100% would be applied to all rockfish caught and discarded in waters deeper than 20-fm. These mortality rates were applied to the species distributions (Table 4-35) to determine the comprehensive mortality rates detailed in Table 4-37. These comprehensive mortality rates are applied to estimated discard, calculating estimated discard mortality.

Table 4-36. Mortality rates developed by the GMT for use in the Oregon recreational fishery.

Mortality rate	≤10 fm	11-20 fm	21-25 fm	26-30 fm	31-40 fm	> 40 fm
Black rockfish	10%	40%	100%	100%	100%	100%
Blue rockfish	10%	40%	100%	100%	100%	100%
Other nearshore rockfish	10%	50%	100%	100%	100%	100%
Canary rockfish	10%	50%	100%	100%	100%	100%
Yelloweye rockfish	10%	50%	100%	100%	100%	100%

Table 4-37. Recommended mortality rates for all-depth fisheries and fisheries closed outside of 40 fm, 30 fm, 25 fm, 20 fm and 10 fm.

Species	<=10 fm	<= 20 fm	<= 25 fm	<= 30 fm	<= 40 fm	All depth
Black rockfish	10%	27%	29%	29%	29%	29%
Blue rockfish	10%	33%	37%	37%	37%	37%
Other nearshore rockfish	10%	46%	55%	69%	69%	69%
Canary rockfish	10%	46%	56%	57%	58%	69%
Yelloweye rockfish	10%	50%	58%	64%	64%	88%

A 7 percent mortality rate is applied in the Oregon recreational groundfish fishery for discarded lingcod, cabezon, and greenling species. In addition, a 7 percent mortality rate is used for the shore and estuary boat fisheries for all species discarded because, as barotrauma is not an issue, mortality is mostly related to hook location.

Model Inputs

Daily bag limits, offshore closures, minimum length changes, effort increases, and abundance trends are the basic input factors applied to the standardized 2005 model.

Bag limits were modeled to range from 5 to 10 marine fish and 2 to 3 lingcod. The expected reduction in CPUE from reducing the marine bag limit from 10 fish is based on the same comparison used to normalize the 8 and 5 fish marine bag limits observed in the 2005 fishery. A linear relationship was assumed using the observations in going from 10 to 8 and 10 to 5 fish. The following rates (in percent) of decline in CPUE were used when reducing the bag from 10 fish: 9 = 5.5; 8 = 10.9; 7 = 20.0; 6 = 29.1; 5 = 38.2. As assumed in normalizing the model no effect on CPUE was expected for yelloweye rockfish and canary rockfish (no retention allowed).

The effect of increasing the lingcod bag limit from 2 to 3 fish was also analyzed. In the ocean boat fishery, sample data from 2005 was used to determine the proportion of anglers that had achieved their 2 fish bag limit in 2005 (6.3%). An increase of 10.6 percent of the estimated landings resulted, assuming the same anglers would achieve a 3 fish bag limit. Applying the same approach to discard data results in a reduction of the estimated discard of 15.6 percent. Similar adjustments were made to the estimated landings in the shore and estuary fisheries to reflect an increase in the bag limit (8.5 percent increase in landings). No reductions were made to the estimated discards in the shore and estuary fisheries as most anglers quit fishing when they achieve their lingcod bag limit. No adjustments were made for increased targeting due to the increased bag limit. Discussions with anglers and charter operators indicate any likely increase in targeting lingcod would occur in offshore areas, for which opportunity is drastically reduced due to offshore closures.

The effect of lingcod minimum length reductions from 24-inches to 22 and 20-inches were analyzed for both the ocean boat and shore and estuary fisheries. The length profile of discards was developed from at-sea observations in the 2005 ocean boat fishery. These were applied to the estimated proportion of fish discarded in 2005 (42 percent of total fish caught based on ORBS estimates). It was assumed that all fish between 20 to 24-inches, and 22 to 24-inches would have been retained under the respective regulations. This resulted in an estimated increase in number of fish retained under minimum length regulations of 20 and 22-inches of 53.6 and 35.8 percent respectively. The estimated decrease in the amount of discarded fish under minimum length regulations of 20 and 22-inches was 72.3 and 58.3 percent respectively. The profile of discarded fish in the ocean boat fishery was used as a proxy for the shore and estuary fishery, as there exists no profile of the length of fish discarded in that fishery. This data was applied to the estimated proportion of fish discarded in the shore and estuary fishery (78 percent of total fish caught based on MRFSS estimates). As in the ocean boat fishery it was assumed that all fish now of legal size would have been retained as very few anglers attain the 2-fish bag limit. Because modeling of the shore and estuary fishery is based on past landings in metric tons, no estimate of additional landings in number of fish was calculated, only an expected increase in metric tons. The increase in landings estimated under the 20 and 22-inch minimum length requirements is 10 mt (equating to a discard reduction of 10 mt) and 7 mt (equating to a discard reduction of 7 mt) respectively.

Expected encounter rate reductions by species normally encountered in offshore waters (widow rockfish, canary rockfish, yelloweye rockfish and lingcod) were developed for offshore closures outside of 40, 30, 25, and 20 fm. For retention species (widow rockfish and lingcod) these include expected reduction rates for landed fish (Table 4-38) and discarded fish (Table 4-39). For non-retention species (yelloweye rockfish and canary rockfish) these include expected reduction rates for both discarded and the few illegally retained fish (Table 4-40). They were based on the same at-sea observations mentioned earlier in the report. Offshore effort (5 percent of total groundfish directed effort) was assumed to move to open areas nearshore during offshore closure periods.

Table 4-38. Percent reductions in landed widow rockfish and lingcod due to depth closures.

2001, 2003-2005 count of landed fish by depth bin (fm), open all depths							
Species	<=10 fm	11-20 fm	21-25 fm	26-30 fm	31-40 fm	>40 fm	Total
Widow rockfish	0	1	9	3	54	174	241
Lingcod	115	320	77	16	6	161	695
2001, 2003-2005 distribution of landed fish by depth bin (fm), open all depths							
Species	<=10 fm	11-20 fm	21-25 fm	26-30 fm	31-40 fm	>40 fm	Total
Widow rockfish	0%	0%	4%	1%	23%	72%	100%
Lingcod	17%	46%	11%	2%	1%	23%	100%
Percent reduction in landed fish from open all depth to depth closure							
Species	Closed >10 fm	Closed >20 fm	Closed >25 fm	Closed >30 fm	Closed >40 fm		
Widow rockfish	100%	100%	96%	95%	72%		
Lingcod	83%	37%	26%	24%	23%		

Because smaller lingcod would be legal to retain under the proposed regulations reducing the minimum length to 22 and 20-inches, the average weight of both landed and discarded fish in the ocean boat fishery was also adjusted. The estimated number of fish at 22 and 20-inches that now would be landed was factored by the appropriate average weight (kg) resulting in a revised total metric tons landed. This new weight was divided by the estimated number of fish landed (landings in 2005 plus additional fish, reflecting the appropriate minimum length regulation) to determine a revised average weight. This resulted in a 13.3 percent reduction in average size under the 22-inch regulation and a 19.6 percent under the 20-inch regulation. This same process was used for the discarded fish resulting in a 59.1 percent reduction under the 22-inch regulation and a 78.7 percent reduction under the 20-inch regulation. There was no adjustment in the shore and estuary fishery as the number of fish and average weight are not part of the calculation of metric tons landed.

Table 4-39. Percent reductions in released widow rockfish and lingcod due to depth closures.

2001, 2003-2005 count of released fish by depth bin (fm), open all depths							
Species	<=10 fm	11-20 fm	21-25 fm	26-30 fm	31-40 fm	>40 fm	Total

Species	Closed >10 fm	Closed >20 fm	Closed >25 fm	Closed >30 fm	Closed >40 fm		
Canary rockfish	93%	45%	33%	28%	24%		
Yelloweye rockfish	99%	71%	56%	47%	41%		

Abundance trends were only developed for lingcod. The average annual increase in impacts used was 1.17 percent and continues the same rate used for modeling the 2004-2006 fisheries. This increase was applied on a yearly basis. Thus for 2007 a 1.37 increase was used (2005 normalized catch x 1.17 x 1.17 representing increases from 2005 to 2006 and to 2007) and for 2008 a 1.6 increase was used (2005 normalized catch x 1.17 x 1.17 x 1.17).

Groundfish directed angler effort was assumed to remain equal to normalized 2005 under a 6 to 12 month season even during periods of offshore closures. For action alternative 1a, it was assumed that 33 percent of the angler effort from the closed period would shift to the open period resulting in 60 percent of annual effort (40 percent of annual effort normally occurs in the July through Labor Day period).

Angler effort in the directed Pacific halibut fishery was assumed to increase in 2007-2008 so as to harvest the complete halibut allocation. The halibut allocation was assumed to be equal to the 2006 allocation, which is four percent higher than in 2005. For action alternative 1b, having the lowest estimated yelloweye rockfish impact (1.5 mt), it was assumed that halibut effort and catch would be reduced by 30 percent.

Model Description

The model was divided into landed and discarded fish sections. Each section had similar components although the discarded section also had components to apply both mortality rates and changes in average size due to offshore closures. Groundfish impacts on yelloweye rockfish and canary rockfish in the Pacific halibut fishery were modeled separately.

The normalized 2005 impact model (all ocean boat fishery sources, excluding the targeted Pacific halibut fishery), include the following components for each species by month: (1) standardized catch; (2) bag limit affects; (3) offshore fishery effects on encounter rates; (4) 5 percent effort shifts to the nearshore fishery due to offshore closures; (5) average size; and (6) minimum length changes for lingcod. For landed and discarded fish the methodology to address the affects of various marine bag limits and offshore closures on (a) encounter rates and (b) shifting effort nearshore, were discussed earlier in the Normalization section. For landed and discarded lingcod, the methodology to address the affects of bag limits and changes in minimum length were discussed earlier in the Model Input section. Average weight was based on 2005 landed weight and at-sea observations for discarded fish as discussed earlier also in the Normalization section. Discarded fish mortality rates by rockfish species and depth were developed from at-sea observer data for catch distribution using mortality rates by species and depth.

Expected impacts on yelloweye rockfish and canary rockfish in the Pacific halibut fishery were addressed separately. The 2005 encounter rate per halibut pound landed, and the 2002-2003 average weight of fish caught shoreward of 30-fm, was applied to the 2006 Oregon central coast all-depth halibut sport allocation to address expected impacts on both species. This assumes similar Pacific halibut allocations in 2007-2008.

Landings and discard impacts for shore and estuary caught species were modeled on a season total basis using the 1998-2002 average impacts (mt). This fishery will be managed for a year round season as it does not impact yelloweye rockfish and canary rockfish. The impacts were adjusted to reflect length limits applied to cabezon and greenling since that period. Sublegal cabezon and greenling that were landed in the 1998-2002 period were now considered discards. A mortality rate of 7 percent was applied to all species discarded in the shore and estuary fishery to represent hooking mortality as the waters are not deep enough to cause mortality from barotrauma.

4.5.1.8 Modeling California Recreational Impacts

The CDFG revised their impact projection model that was reviewed by the GMT at their February 2006 meeting. The GMT recommends this updated model for use in projecting impacts of groundfish species in 2007-2008 California recreational fisheries. This model is described below and is used in impact analyses in this EIS.

Introduction

Recreational fisheries management for multispecies assemblages in California presents many challenges. In recent years, declining stocks of several rockfish species have dictated recreational groundfish management seasons and depths in California. Increasingly complex restrictions have been necessary to provide fishing opportunities that keep total catch of overfished species within the reduced limits that are necessary to rebuild the stocks.

Prior to 2000, the recreational daily bag limit for rockfish was 15 fish per angler and there were no closed months or depths. Beginning in 2000, the daily bag limit was reduced to 10 fish. Regulations have changed each year since 2000, making analysis of the effect of particular regulations difficult to determine. In addition, regulations have become more region-specific, adding to the difficulty of modeling projected catches.

Methodology Used to Project Recreational Catches for 2007-2008

Background

The recreational catch model incorporates a number of parameters and assumptions, all of which are either risk-neutral or risk-adverse. The basic analytical approach is the same as that used for 2005-2006, with new data from the California Recreational Fishery Survey (CRFS) program to serve as a baseline. Model output predicts expected catch under any combination of season and depth fishing restrictions by region.

Management Region Definitions:

North Region:	North of 40°10' N latitude to CA/OR border
North-Central Region:	South of 40°10' N latitude to 37°11' N latitude (Pigeon Pt.)

South-Central Monterey Region:	South of Pigeon Pt. to 36° N latitude (Lopez Pt.)
South-Central Morro Bay Region:	South of Lopez Pt. to 34°27' N latitude (Pt. Conception)
South Region:	South of Pt. Conception to CA/Mexico Border

CDFG/California Recreational Groundfish Model Assumptions

Effort Shift Inshore: The model includes a 27.6% increase in expected landings when fishing is restricted to less than 30 fm and a 39.3% increase in expected landings when fishing is restricted to less than 20 fm. The increase, or effort shift, is to account for increased effort in a smaller fishing area.

Discard Mortality: 1) Canary, cowcod, and yelloweye are non-retention species which have high mortality rates when caught and released. Therefore, expected mortality estimates for these species also include B2 fish (fish reported to be released live) with hooking mortality rates as follows:
10.5 % for the depth range 0-10 fm; 42% for 10-20 fm; and 100% for depths greater than 20 fm.
2) CA Scorpionfish hooking mortality rate is assumed to be 5%. This rate is applied to expected landings of CA Scorpionfish when fishing is allowed for species which associate with CA scorpionfish, but fishing for CA Scorpionfish is not allowed.

Inputs and Key Parameters for the Model

Weighting of Base Years: Base year catches from 2004 and 2005 are combined together in this version of the model using a 0.67 decay function (which translates into a weighting of 60% for 2005 and 40% for 2004). Model output predicts expected catch under any combination of season and depth fishing restrictions by region. *Reasons for weighting the 2005 estimates more heavily than the 2004 estimates include:* the recognition that constraints placed on salmon fishing in 2005 will likely persist over the next several years; and the acknowledgement that the expanded distribution and greater abundance of blue rockfish (as well as other groundfish species) due to cooler oceanographic conditions will also likely persist into 2007 and 2008. *Reasons for using 2004 data include:* the recognition that oceanographic conditions in 2005 were unusual while conditions in 2004 are more in line with what might be expected in 2007-2008 under a colder water regime; and the expectation that the bulk of blue rockfish take (and potentially brown and olive rockfish take) will occur within deeper nearshore waters as was observed in 2004 rather than in the shallow nearshore waters as in 2005.

Base Year Catch: Initially, CRFS catch estimates in WEIGHT of fish were summed for caught and retained (CRFS “A” catch), filleted/caught and released dead (CRFS “B1” catch), and for species of concern, a proportion of CRFS “B2” catch (released alive) derived using depth-based mortality estimates. Base year catch estimates are assumed to be for an unrestricted fishing year with no months closed and no depths closed. Therefore, for each year, a back calculation method was used to add a catch estimate for what the catch would have been if all months and all depths had been open. This back calculation uses percent catch by month and depth derived from historical catch estimates.

Historical Catch By Month: Estimates of historical percent catch by two-month period were calculated for each region based on RecFIN Marine Recreational Fisheries Statistics Survey (MRFSS) data (weight of A+B1) from 1993-1999, which was a time period when seasons and depths were unconstrained. Proxies were considered on a species by species basis for regions where there was a lack of catch data for that area. Monthly estimates of percent catch then were divided equally (50:50) for each pair of months.

Historical Catch By Depth: Estimates of percent catch by depth were calculated for each region based on RecFIN MRFSS depth sample data (numbers caught A+B1 for CPFV and A+B1+B2 for PR) from 1999-2000, which was a time period when depths were unconstrained. Proxies were considered on a species by species basis for regions where there was a lack of catch data for that area.

Methodology used to Calculate Annual Unrestricted Catch

1. Pull (A + B1) Catch for each year from the RecFIN CRFS data web site: http://www.psmfc.org/recfin/forms/est2004.html.
   Specify species, and select the parameters: month and district under Define Table Layout.
2. Pull historical catch by depth (1999-2000, most recent years unregulated by depth) from the RecFIN boatdepth2 site:
   http://www.psmfc.org/recfin/forms/boatdepth2.html
   Add PC and PR fish caught together for each separate region and species, maintaining combined depth totals for each depth strata. Calculate average percentage of total fish caught within each 10 fm depth stratum (= "Depth Profile") by dividing 10 fm depth strata totals by combined total sum of all strata for the region. Assign proxies as needed for data-poor areas, using adjacent regions, similar species, etc.
3. Pull historical catch through time (1993-1999, the most recent years unregulated by monthly closure) from RecFIN web site:
   http://www.psmfc.org/recfin/forms/est.html
   Calculate average wave %'s over combined years 1993-1999 by dividing individual wave totals by sum of all waves for each region. Assign proxies as needed for data-poor areas using the other region (North or South) as the proxy.
4. For each management region and species, calculate total regulated catch based on months each set of regulations was in effect. For example, if fishing was only open from 0-60 fm for March-December, sum total catch for those months only. If using B2 (reported catch released live) mortality, add calculated B2 mortality to these catch totals. Each management region should now have catch data for all species grouped by the different sets of management regulations (MR sets) in effect for the year so that the identical calculations can easily be performed on identically restricted species.
5. **Expanding to All Depths**. For each MR set: If there was **no** depth restriction, use the unmodified total regulated catch as the expected catch for all depths for that period of the year. If a depth restriction was in place, use total regulated catch to expand out each species in each MR set to all depths: from the Depth Profile, divide total regulated catch by sum of proportion of catch represented by the depths where fishing was open. This is the total expected catch for all depths. For example, if fishing for a MR set was open < 20 fm, divide the total catch by the percentage of the catch < 20 fm using the appropriate Depth Profile (historical unregulated catch data) for each species and region.
6. **Effort Shift**. If the depth restriction is confined to a 20 or 30 fm band, we assume increased effort occurred for these months. To remove this effect, apply an Effort Shift factor to remove the increased fishing (and increased catch) for the constrained depth zone. For example, if a 0-20 fm restriction was in effect, divide the total expected catch for all depths by 1.393 to get final total expected catch for those months. Similarly, use a factor of 1.276 if fishing was restricted within a 30 fm range. No Effort Shift is applied for depth restrictions > 30 fm.
7. **Accounting for Closed Months**. After expanding to all depths and removing Effort Shift (if needed), sum all the final expected catch values across all the MR sets for the year for each management region and species. Divide this sum by the % catch for the year that these regulated months represent (from the wave %'s for the year). In other words, divide the

calculated catch for all open months by the percentage of the catch for the year these months historically represent. This results in the expected annual unregulated catch, expanded out from the regulated catch, for each region and species.

8. Input expected annual unregulated catch for each region-species into the Catch by Year Table in the RecFIN Model database. The weighting of the different years' data to be used by the model in projecting catch can be selected at the model-user interface.

Estimates of Total Mortality for Canary and Yelloweye Rockfish Using Two Different Methods for Estimating Discarded Catch

The California recreational catch projection model accounts for total mortality by combining A (sampler examined), B1 (discarded dead/filleted) and a portion of B2 (discarded alive) catch. To calculate the portion of B2 to include in the total mortality estimate, California staff apply mortality rates to the B2 catch component in the following manner: 10.5% for fish caught between 0-10 fm, 42% for fish caught between 10-20 fm, and 100% mortality for all other depths. Oregon and Washington account for total mortality by combining A (sampler examined) and a portion of a combined B catch (catch discarded dead or alive, or catch otherwise unavailable to be examined). Staff from these states apply a 50% mortality rate to the B catch component for fish caught between 0-20 fm and 100% mortality to the B fish caught at all other depths.

To determine which of these methods was more conservative in estimating total mortality, a comparison of the methods was made for canary and yelloweye rockfish taken by California anglers statewide using 2004 and 2005 CRFS A, B1, and B2 annual catch estimates. For this comparison, the type B and B1 fish included catch used as bait, given to other anglers, or otherwise not available for examination.

The total mortality estimates calculated by these two different methods are provided in Table 4-41.

Table 4-41. Total Mortality Estimates (mt) Calculated from Two Different Methods Using 2004 and 2005 California Recreational Fisheries Survey A, B1, and B2 Annual Catch Estimates.

Species	Year	Total Mortality (mt)	
		Combined B[a/] Method	B1 & B2[b/] Method
Canary	2004	NA	NA
	2005	6.8	7.1
Yelloweye	2004	2.7	3
	2005	5.1	5.6

a/ Mortality estimate includes A catch + mortality rates applied to discarded catch combined together (Combined B).

b/ Mortality estimate includes A catch + B1 catch + mortality rates applied to B2 catch (discarded catch (B1 &B2) treated separately).

The "Combined B" method consistently results in lower total mortality catch estimates; that is, it results in lower discard mortality than the "B1 & B2" method. Thus, the California recreational catch projection model uses a more conservative estimate for discard mortality, leading to a higher estimate of overall mortality. However, more analyses may be needed after the PFMC RecFIN Workshop in

August, when further discussions will be held on what constitutes the discard catch (type “B”) for Washington, Oregon, and California.

Estimation of Impacts

The CDFG is proposing the seasons described under Action Alternatives 1-3 in Chapter 2. The estimated impacts to select groundfish species in 2007 and 2008 California recreational fisheries by region are described in section 4.5.4.

Action Alternative 3 includes an increase in the greenling bag limit from one to two fish. CDFG used the RECFIN methodology for Hypothetical Bag Limit Analyses available at http://www.psmfc.org/recfin/forms/bfreq.html to determine increased impacts on greenlings resulting from this change. The program uses the A+B1+B2 fish from 2004 for estimating the increased impact based on all fish encountered. The A fish are sampled dead fish. CDFG assumes for greenling that B1 includes filets and there were no fish thrown back dead as kelp greenling usually survive release. B2 includes live fish over the bag limit or under the size limit of 12". Since there is no way to estimate the proportion of fish that were undersized, this analysis also assumes there were no fish thrown back as sublegal and assumes that all B2 fish would be available if the bag limit were increased as the most conservative estimate. All bags over the hypothetical limit are then set to the hypothetical limit to calculate increased take. The increased estimated impact on greenlings would be 15% based on this analysis. Even with the increase in catch, landings are expected to stay within the CDFG recreational allocation as greenling landings in 2005 were 37% of the allocation.

Action Alternative 1 includes a reduction in the bocaccio bag limit from Cape Mendocino to the Oregon border from 2 to 1 fish to protect bocaccio under the lower OY. The estimated saving in bocaccio as a result of this change is not possible to determine because the data cannot be summarized for only this region. Bocaccio is at the northern end of its distribution in this part of the state and the fishing effort is low relative to other regions. The estimated take of bocaccio in 2005 was minimal in this region, therefore some small but undetermined amount of savings would be expected. Action Alternative 3 includes an increase in the bocaccio bag limit from one to two fish for the area south of Cape Mendocino so that the statewide bag limit would be two fish. CDFG used the RECFIN methodology for Hypothetical Bag Limit Analyses available at http://www.psmfc.org/recfin/forms/bfreq.html to determine increased impacts on bocaccio resulting from this change. The program uses the A+B1 fish from 2004 and 2005 for estimating the increased impact. The A fish are sampled dead fish. CDFG assumes for bocaccio that B1 includes filets and fish thrown back dead (over the bag limit) as bocaccio do not usually survive release. There is no way to estimate the proportion of B2 fish that were undersized or the proportion thrown back alive. Therefore, B2 fish were not included as CDFG assumed most of the B2 fish were sublegal and there would be very few legal fish released alive. All bags over the hypothetical limit are then set to the hypothetical limit to calculate increased take. The increased estimated impact on bocaccio would be 27% based on this analysis. Landings are still expected to stay within the CDFG recreational allocation as bocaccio landings in 2005 were 64% of the allocation.

There have been anecdotal suggestions that there has been good bocaccio recruitment in southern California during 2003 and/or 2004. Those fish would be expected to recruit first to the recreational fishery in 2006 or 2007, so that additional unknown and unquantified impacts from new recruits could also occur, however, CDFG reviewed the 2005 and 2006 CRFS sample data to look for a spike in small fish with no success.

Action Alternative 1 includes a reduction in the lingcod bag and size limit from the No Action

Alternative of two fish at 24” to one fish at 22” to reduce fishing effort for lingcod, thereby reducing impacts on associated rebuilding species. The estimated increase in lingcod take as a result of reducing the size limit from 24” to 22” would be 26% using the formula:
Total Catch from 24" /(1 - 0.207) = Adjusted Catch

Reducing the bag limit from two to one fish at 22” would reduce this estimated increase by 27% based on the formula:
Adjusted Catch x (1 - 0.27) = Estimated Catch under a one fish bag limit.

Using the Total Catch estimate (300 mt) from 2005, the overall reduction in catch would be 24 mt or eight percent. Data from 1995 – 1997 were used to estimate size reduction increases and bag limit decreases when a 22” size limit was in effect.

Lingcod Bag and Minimum Size

CDFG is continuing to propose alternatives to fishery closure as an inseason management response to projected over harvest of lingcod if it occurs. If the CDFG determines that more restrictive management measures are necessary to slow the harvest of lingcod, an increase in the minimum size limit, or a reduction in the bag limit from two to one, may be implemented. Projected harvest for each upcoming month may be multiplied according to the coefficients for size and/or bag limit to identify the management response necessary to keep projected catch within the recreational harvest guideline.

Coefficients to modify projected catch of lingcod from a two-fish bag limit to a one-fish bag limit, or from 24” to a smaller or larger minimum size are shown in Table 4-42.

Table 4-42. Coefficients used to model lingcod bag and size limits in the California recreational groundfish fishery.

Size Limit (inches)	Size Coefficient	Bag Limit Coefficient
22	0.207	0.27
24 (status quo)	0	0.214
25	0.169	0.18
26	0.304	0.15
27	0.43	0.12
28	0.521	0.1
29	0.581	0.07
30	0.641	0.039
31	0.685	0.025
32	0.723	0.011

4.5.2 Allocating Depleted Species’ Impacts

The three action alternatives discussed in sections 2.2.3.2 - 2.2.3.4 indicate ways in which the allowable impacts to depleted species may be divided between sectors. Under increasingly low OYs, such ad hoc allocations become even more critical, as the values selected may significantly constrain fisheries’ access to healthy stocks and target OYs. In order to explore hypothetical allocation scenarios under the high and low OYs, the Council requested that the GMT produce a number of tables (called “bycatch scorecards”) in which depleted species impacts are attributed to sectors following different allocation strategies. Each of these eight scorecards is discussed below, in addition to the assumptions and methodology employed to construct them.

Past relationships between sectors (i.e., their relative contribution toward the total mortality impact for a particular species) provide instructive templates for these hypothetical allocation scenarios. Therefore, at the Council's request, the scorecard of final 2005 mortality estimates and the scorecard projecting impacts in 2006 were used as the starting points from which to explore allocation options. As explained in the description of the No Action Alternative (section 2.2.3.1), factors such as the behavior of fishery participants and natural conditions caused certain sectors to exceed their expected harvest, while other sectors accounted for less mortality than had been originally estimated. For example, in 2005 the Washington and Oregon recreational fisheries exceeded their harvest guideline for yelloweye rockfish. These kinds of situations are captured in the 2005 scorecard, so that the relationships between sectors reflect what actually happened (rather than what was anticipated); this suggests that such proportions may be highly dependent on the particular circumstances that occurred in 2005 and so may not apply accurately to future conditions. The relationships between sectors within the 2006 scorecard represent those initially intended by the Council from the 2005-2006 harvest specifications process (in addition adjustments made to correct problems, such as those encountered in 2005); however these projections contain uncertainty as to how well management measures will operate to correctly constrain the fisheries.

In constructing these scorecards, numerous assumptions were made, following Council guidance. First, it was assumed that the impacts associated with the incidental groundfish open access sector and the tribal sector would not change under the Council's action, as these sectors are managed through separate regulations. The impacts associated with research were maintained at status quo, or in the cases of bocaccio, widow rockfish, and yelloweye rockfish, the anticipated research take was increased to provide for additional studies on depleted and co-occurring species. The low yelloweye rockfish OY scenario, however, does not accommodate this increase in the amount reserved for research. The impacts associated with these three sources were therefore held constant across all of the scorecards.

4.5.2.1 High OY Alternatives

For most species, the impact estimates attributed to each sector in 2005 and in 2006 can be directly applied to the high OY alternatives (Table 4-43 and Table 4-44, respectively). For example, limited entry bottom trawl accounted for 46.6 mt of bocaccio mortality in 2005; 46.6 mt of bocaccio mortality can still be accommodated under the 2007-2008 high OY alternative of 218 mt. Continuing with the example of bocaccio, the 2005-2006 OY is nearly 100 mt greater than the high OY alternative for that stock. However the total estimated catch in 2005 was far less than the OY, which resulted in a large residual amount; by carrying over the same mortality estimates for the sectors, the 2007-2008 high OY alternatives can also provide for a residual to buffer against uncertainty, but it is a smaller value. Although this situation holds true for most of the depleted species, there are two exceptions. For the canary rockfish OY alternative, the impact estimates in both 2005 and 2006 are greater than what can be accommodated under the canary rockfish high OY alternative of 44 mt. Therefore, following Council guidance, each sector's canary rockfish impact was reduced proportionately in order to create a 0.5 mt set-aside. Similarly, the 2008 yelloweye rockfish OY alternative (20 mt) is too small to maintain past mortality impacts; to resolve this, the necessary proportional reductions were made to each sector's impacts, however no set-aside was created.

Table 4-43. 2007-2008 estimated total mortality: High OY applied to the status quo 2006 scorecard.

Fishery	Bocaccio a/	Canary	Cowcod	Dkbl	POP	Widow	Y'eye 2007	Y'eye 2008
Limited Entry Trawl- Non-whiting	47.4	7.5	2.7	160.3	63.3	1.0	0.3	0.3
Limited Entry Trawl- Whiting

4.5.2.2 Low OY alternatives

In order to constrain fisheries below the OYs under the low alternatives, Action Alternative 1 management measures are more stringent than those under status quo (Action Alternative 1 is explained in section 2.2.3.2).

As was done for the high OY alternatives, scorecards were produced in which the 2005 and 2006 mortality impact estimates were reduced proportionately in order to be constrained to the low OY alternatives (Table 4-45 and Table 4-46, respectively). With the exception of cowcod, there are no residuals associated with any of the species; setting aside a portion of the OY to buffer against uncertainty would create even more extreme effects for sectors than those already anticipated under full utilization of the OYs (see chapter 7 for further discussion of the socio-economic impacts of a suite of low OYs).

Table 4-45. 2007-2008 estimated total mortality: Low OY applied to the status quo 2006 scorecard (each sector's projected impact is reduced proportionately).

Employing proportional reductions to constrain to the low OYs, as described above, continues status quo Council policy to provide fishing opportunities across regions and sectors; this is consistent with guidance in the Groundfish FMP that "overfishing restrictions and recovery benefits should be fairly and equitably allocated among sectors of the fishery" {PFMC 2004}. However, there are numerous other allocation strategies that could be adopted (through revision of the Groundfish FMP), depending on the management objective sought by the Council; under the constraints of low OYs, such as those within these alternatives, these strategies may provide for a more viable fishery at a coastwide level. Other sections in this EIS also discuss allocation strategies, each of which is based on alternative management objectives. In chapter 7, for example, it is noted that under a highly constrained fishery, allocation could optimize coastwide revenue by allowing mortality impacts only for fisheries that account for the greatest amount of ex vessel revenue, eliminating the fisheries that account for the lowest ex vessel revenue. In this section, another scenario is depicted, in accordance with Council guidance: all of the mortality impacts are associated with either the recreational sector (Tables 4-47 and 4-48) or the commercial sector and (Tables 4-49 and 4-50). These are extreme scenarios that depict a situation that the Council might consider under OYs so constraining that all sectors operating under status quo could not be maintained.

Like the scorecards discussed above, those representing the "all recreational" and "all commercial" scenarios are based on the 2005 scorecard and the 2006 scorecard. That is, for example, the relationships between the commercial sectors are maintained at 2005 proportions (Table 4-50), while zero mortality impacts are estimated for the three recreational groundfish fisheries. Under the "all recreational" scenarios (Tables 4-47 and 4-48) however, the Council provided guidance that commercial fisheries should be constructed using OYs of the species for which there is no recreational fishery mortality. As such, POP and darkblotched rockfish were divided between the LE bottom trawl and whiting sectors using 2005 or 2006 scorecard proportions, as these two sectors are judged to be the only commercial fisheries that can be executed without mortality of other depleted species.

Table 4-47. 2007-2008 estimated total mortality: Low OY, applied to the status quo 2006 scorecard (all relevant projected impacts allocated to the recreational fishery).

4.5.2.3 Comparing Allocation Scorecards with Action Alternatives

Management measures alternatives are developed based on the specific conditions of each fishery, such as what tools are available to managers and how the fishery is constrained by other depleted species; the relationships between sectors' mortality impacts estimates are not necessarily held constant from year to year. Similarly, the Action Alternatives detailed in Chapter 2 result in impact estimates that create different relationships between sectors than those that occurred in 2005 and projected for 2006 (Table 4-51). For example, the 2006 scorecard projects that canary rockfish mortality impacts will be shared between commercial and recreational sectors at a ratio approximating 48:52, while under Action Alternative 2, this relationship changes to approximately 59:41. These kinds of changes in proportions are also present within the commercial sector and within the recreational sector. For example, while the California recreational fishery accounts for approximately 52% of the total recreational impacts in 2006, under Action Alternative 2 the fishery's impacts are projected to account for 68%.

Table 4-51. Percent of impact by sector as a proportion of total impact (2005 and 2006).

4.5.3 No Action Alternative

[To be completed after the June Council meeting. For quantitative impact analysis of the No Action alternative, see 4.5.4.]

4.5.3.1 Limited Entry Trawl Impacts

4.5.3.2 Limited Entry Fixed Gear Impacts

4.5.3.3 Open Access Impacts

4.5.3.4 Nearshore Commercial Impacts

4.5.3.5 Tribal Fishery Impacts

4.5.3.6 Washington Recreational Impacts

4.5.3.7 Oregon Recreational Impacts

4.5.3.8 California Recreational Impacts

4.5.4 The Action Alternatives

When evaluating the impacts associated with the action alternatives, there are several general points that may be important to bear in mind.

First, as a depleted species' spawning stock biomass nears a rebuilt level ($B_{40\%}$), the probability of fishing encounters with that species increases. When more of the stock is available to the fishery but the allowable catch remains at a low level, there is a greater chance that the OY could be reached early in the season or exceeded. This is particularly relevant with respect to darkblotched rockfish, Pacific ocean perch, and widow rockfish. Given that these species are primarily caught incidentally in trawl fisheries, concerns of increased encounters are most notable for those fleets. Furthermore, the proposed management measures under all action alternatives bring about impact estimates at or just below the proposed OY for Pacific ocean perch (Tables 2-14, 2-19 and 2-21). Without an excess of allowable impacts to buffer against the uncertainty associated with a biomass near a rebuilt level, there is a risk under each action alternative that the Pacific ocean perch OY could be exceeded. A similar situation may occur under Action Alternative 1 with respect to widow rockfish, as there is only a very small residual (3% of OY or 3.8 mt). In the scorecards that explore the different allocation scenarios (Tables 4-43 through 4-50), the residual is maintained for these three depleted species under the high OY scenario. Under the low OY scenarios, there is no residual for any of these depleted species.

Second, as the discard estimates from WCGOP improve, it is likely that discard rates used to manage those fisheries with a lesser amount of at-sea observations (i.e., southern limited entry and open access fixed gear fisheries) will change dramatically. This is a particular concern if new discard rates prove to be much higher than currently assumed based on limited at-sea observations. As this information is used to better inform managers about catch of depleted species, inseason action may be necessary to correct management measures that had been crafted according to current discard rates.

Variability in a stock's recruitment success is another source of uncertainty (see section 4.4.2.1). Such variability is most common among winter-spawning shelf and slope groundfish, such as bocaccio, lingcod, and Pacific whiting. For these species, improved population trajectories over recent years can be aligned with climate shifts; for other species, such as cowcod and widow, the improvement in population trends is primarily due to deterministic recruitment trends and reduced harvest rates. The uncertainty surrounding the recruitment success of these species may provide additional support for managing fishing impacts to a value lower than the OY.

The considerations discussed above bring about a cumulative risk of exceeding the OY for certain depleted species. Much of this risk can be attributed to numerous sources of uncertainty, which are discussed further in section 4.2.

General Action Alternative 1 Considerations

The management measures proposed in Action Alternative 1 all constrain fisheries below the Council preferred low OYs for depleted species (Table 2-14). However, for some species (i.e., Pacific ocean perch, widow rockfish, and bocaccio), there is little or no residual available to managers to buffer against uncertainty.

Under these low OYs, the Council must evaluate whether viable fisheries can be maintained. If it is determined that the management measures under Action Alternative 1 do not allow for viable fisheries, then other allocation scenarios may be considered by the Council (see discussion in 4.5.2.2 on allocating the entire OYs to the recreational fishery or to the commercial fishery).

The Council preferred low OYs bring about a similar situation to what is portrayed under Rebuilding Alternative 5. Under both of these, the management measures could result in fisheries that are equally constrained by most, if not all, of the depleted species' OYs. Though this suggests the need for additional room to buffer against management uncertainty, this is countered against the severe social and economic consequences that would be made even more acute by managing to a mortality impact lower than the OY.

General Action Alternative 2 Considerations

The management measures proposed in Action Alternative 2 are projected to constrain the depleted species impacts of all fisheries to levels that are intermediate between the Council preferred low and high OYs (Table 2-19). For some species (i.e., bocaccio, cowcod, and widow rockfish) under this action alternative, there is a large difference between the projected impacts and the high OY alternative. For Pacific ocean perch, on the other hand, the projected impact is nearly equal to the Council preferred high OY value. Unlike Action Alternative 1, this alternative allows for the higher values of research impacts for all depleted species.

General Action Alternative 3 Considerations

The management measures proposed in Action Alternative 3 are projected to constrain the depleted species impacts of all fisheries to levels at or below the Council preferred high OYs (Table 2-21). The anticipated impact to Pacific ocean perch, however, is equal to the high OY under this alternative. This alternative allows for the higher values of research impacts for all depleted species.

4.5.4.1 Limited Entry Trawl Impacts

The estimated impacts of the non-whiting limited entry trawl sector on depleted species and on target species under the action alternatives are displayed in Table 4-52. In 2005 a new management measure was implemented mandating the use of selective flatfish trawls shoreward of the trawl RCA north of 40°10' N latitude; Table 4-53 projects impacts to depleted and target species that would be expected if selective flatfish trawl gear were used by vessels south of 40°10' N latitude.

Table 4-52. Estimates of impacts (mt) to depleted species and total target catch associated with the limited entry non-whiting trawl fishery under the alternatives, without use of selective flatfish trawl gear in the south.

Note: * indicates that differences in bycatch for these species may occur, but the degree of change is unknown

The bycatch analysis for the Pacific whiting trawl fishery (Table 4-54) assumes that the total US Pacific whiting catch will decrease in accordance with the allowable impacts to depleted species. An alternative strategy for managing 2007-2008 whiting fisheries would be to impose bycatch caps for these species and allow the fleet flexibility to avoid these species while attempting to attain their whiting quotas.

Table 4-54. Estimates of impacts to depleted species and total target catch associated with the Pacific whiting fishery under the alternatives.

4.5.4.2 Limited Entry Fixed Gear Impacts

Sablefish Alternatives

The impacts associated with the action alternatives for sablefish (Table 4-55) are arrayed by A) holding the allocations for sablefish constant for the limited entry and open access fixed gear sectors under the Council's preferred sablefish OY and moving the fixed gear RCA line north of 40°10' N latitude from 100 to 125 and 150 fm respectively, and B) by lowering the OY for sablefish to achieve the same reductions in bycatch as by moving the fishery in the north out to the 125 fathom line and the 150 fathom line. These results show that savings in bycatch are achieved by advancing the line further seaward, or by lowering the sablefish allocation to these sectors, but either case creates an economic cost to sablefish fishers.

A review of West Coast groundfish observer data shows that sablefish vessels currently fish at depths deeper than 150 fm north of 40 degrees 10 minutes latitude, but for vessels that homeport in the Puget sound region of Washington, a 150 fathom line eliminates their fishing areas and would require vessels to fish substantially further south and further out to sea. This is because the shelf and slope areas off northern Washington are comprised of multiple canyons and broad areas with relatively the same depth. In other areas of the coast the bottom depths get deeper in a more continuous fashion as one moves further out to sea. Those vessels that don't home port in the Puget sound region and that currently don't fish at depths outside of 150 fm would need to travel further out to sea, however the additional distance required of these vessels to fish outside 150 fm is minor compared to vessels that home port in the Puget sound area.

Reducing the sablefish allocation is shown to give a comparison between area closures and reductions in target species catch that would achieve the same levels of bycatch. Reducing the sablefish allocation for these sectors would decrease bycatch because vessels would fish less and thereby exert less effort on the areas where overfished species are found. While reducing the sablefish allocations for limited entry and open access fixed gear vessels would decrease the catch and revenues to these vessels, it would allow vessels to fish closer to shore and decrease the cost of accessing that sablefish when compared to imposing fathom restrictions that achieve the same reductions.

	Pacific halibut	923,295	249,290	923,295	923,295

4.5.4.3 Open Access Impacts

Like with the limited entry fixed gear fisheries, the primary means to constrain impacts of the open access sector on depleted species is by changing the non-trawl RCA boundaries. The specific impacts under each of the action alternatives have been quantitatively assessed for only some portions of this diverse sector, however. Table 4-56 depicts the projected impacts for all sablefish fisheries (limited entry and open access) and section 4.5.4.3 discusses the impacts of the open access nearshore commercial fisheries.

4.5.4.4 Nearshore Commercial Impacts

Table 4-57 depicts the estimated total mortality of nearshore commercial fisheries under each action alternative. The management measures proposed within Action Alternative 3 are the same as the No Action alternative, and therefore the estimated impacts for these two alternatives are equal. Under the most restrictive management measures (Action Alternative 1), the catch of black rockfish north of 40°10' N latitude is projected to drop by 60% from status quo, while the catch of other target species is projected to be maintained at SQ levels. South of 40°10' N latitude catch of shallow and deeper nearshore species, cabezon, and kelp greenling under Action Alternative 1are all expected to reduce by about 15% due to the proposed area and depth restrictions.

Table 4-57. Open access nearshore commercial fisheries' estimated total mortality (mt) and its percent reduction from status quo under each alternative.

		No Action	Action Alt. 1		Action Alt. 2		Action Alt. 3

	Widow	0.08	0.03	53%	0.05	24%	0.08	0%

4.5.4.5 Tribal Fishery Impacts

Table 4-58 depicts the projected impacts to the depleted and target species associated with all tribal groundfish fisheries. The estimated impacts to depleted species are the same across all action alternatives (and are the same as the No Action alternative).

The projected catch of spiny dogfish is significantly higher under the action alternatives than under no action. The Makah Tribe is proposing a directed longline fishery for spiny dogfish for 2007 and 2008. The fishery would be restricted to the Limited Entry trip limits. Increased landings of dogfish by treaty fishermen in 2007 and 2008 would be dependent on successful targeting in 2006 while staying within current estimates of impacts on overfished species. The projected value for spiny dogfish landings in Table 4-58 (600,000 lbs or 272.2 mt) is a placeholder provided by Makah Fisheries Management; impacts will not be known until the test fishery is prosecuted. In addition, flatfish and rockfish impacts under all action alternatives are expected to increase by 25% due to increased effort (though not capacity) in Makah trawl fisheries.

Table 4-58. Estimates of impacts to species associated with the Tribal fishery under the alternatives.

5.0 PROTECTED SPECIES

Four different laws designate a species or stock as "protected" within U.S. waters: the Endangered Species Act (ESA), the Marine Mammal Protection Act (MMPA), the Migratory Bird Treaty Act (MBTA), and EO 13186. Briefly, the substance of these mandates is as follows:

- The ESA protects species in danger of extinction throughout all or a significant part of their range and mandates the conservation of the ecosystems on which they depend. "Species" is defined by the Act to mean a species, a subspecies, or—for vertebrates only—a distinct population. Under the ESA, a species is listed as "endangered" if it is in danger of extinction throughout a significant portion of its range and "threatened" if it is likely to become an endangered species within the foreseeable future throughout all, or a significant part, of its range.
- The MMPA guides marine mammal species protection and conservation policy off the U.S. West Coast. NMFS is responsible for MMPA-based management of cetaceans and pinnipeds, while the USFWS is responsible for sea otter management. Stock assessment reports review new information every year for strategic stocks and every three years for non-strategic stocks. "Strategic stocks" are those whose human-caused mortality and injury exceeds the potential biological removal level. (At 50 CFR 229.2, "potential biological removal level" is defined as, "the maximum number of animals, not including natural mortalities, that may be removed from a marine mammal stock while allowing that stock to reach or maintain its optimum sustainable population…") Marine mammals, whose abundance falls below the optimum sustainable population, are listed as "depleted" under the MMPA. All marine mammal species are protected under the MMPA, regardless of whether a particular species or stock is listed as threatened or endangered under the ESA.
- The MBTA implements various treaties and conventions between the U.S. and Canada, Japan, Mexico, and the former Soviet Union for the protection of migratory birds. Under the Act, taking, killing, or possessing migratory birds is unlawful. In addition to the MBTA, an Executive Order, *Responsibilities of Federal Agencies to Protect Migratory Birds*, (EO 13186), directs federal agencies to negotiate Memoranda of Understanding with the USFWS that would obligate agencies to evaluate the impact on migratory birds as part of any NEPA process. All migratory seabird species are protected under the MBTA and EO 13186, regardless of whether a particular species or stock is listed as threatened or endangered under the ESA.

NMFS and PFMC have published recent NEPA documents that describe protected species found in the West Coast EEZ. The December 2005 Final EIS on "Pacific Coast Groundfish Fishery Management Plan Essential Fish Habitat Designation and Minimization of Adverse Impacts" (EFH EIS) {NMFS, 2005 1073 /id} provided descriptions of West Coast EEZ species protected under the ESA, the MMPA, and the MBTA and EO 13186 at Section 3.4 and provided information on fisheries interactions, where available and applicable. The December 2004 Final EIS on "Proposed Acceptable Biological Catch and Optimum Yield Specifications and Management Measures for the 2005-2006 Pacific Coast Groundfish Fishery" (2005-2006 Specifications EIS) {PFMC, 2004 916 /id} provided descriptions of West Coast EEZ species protected under these same laws at Chapter 6, and analyzed the effects of the groundfish fisheries on these species.

- No new scientific analyses on the interactions between the groundfish fisheries and marine mammals have been completed since the publication of either the EFH EIS or the 2005-2006 Specifications EIS. NMFS publishes an annual list of fisheries in the Federal Register separating commercial fisheries into one of three categories based on the level of serious injury and mortality of marine mammals occurring incidentally in that fishery. The categorization of a fishery in the list of fisheries determines whether participants in that fishery are subject to certain provisions of the MMPA, such as registration, observer coverage, and take reduction plan requirements. West Coast groundfish fisheries are designated as Category III fisheries, denoting a remote likelihood of, or no known, serious injuries or mortalities to marine mammals (71 FR 247, January 4, 2006).

- No new scientific analyses on the interactions between the groundfish fisheries and seabirds have been completed since the publication of either the EFH EIS or the 2005-2006 Specifications EIS. NMFS is compiling observer data on fisheries interactions with seabirds to develop a long-term assessment of the effects of the groundfish fisheries on migratory seabirds. This assessment is part of NMFS's work with the USFWS on a Memorandum of Understanding concerning seabirds and the groundfish fisheries, as required under EO 13168.
- No new scientific analyses on the interactions between the groundfish fisheries and sea turtles have been completed since the publication of either the EFH EIS or the 2005-2006 Specifications EIS {PFMC, 2004 1077 /id}. Four sea turtle species have been sighted off the U.S. West Coast: loggerhead (*Caretta caretta*), green (*Chelonia mydas*), leatherback (*Dermochelys coriacea*), and olive ridley (*Lepidochelys olivacea*). Under the ESA, green, leatherback, and olive ridely sea turtles are listed as endangered; loggerheads are listed as threatened. NMFS has reviewed WCGOP data for fisheries interactions with sea turtles and WCGOP has not observed any sea turtle interactions in the groundfish fisheries.

Under the CEQ implementing regulations for NEPA at 40 CFR 1502.21, *Incorporation by Reference*, "Agencies shall incorporate material into an environmental impact statement by reference when the effect will be to cut down on bulk without impeding agency and public review of the action. The incorporated material shall be cited in the statement and its content briefly described. No material may be incorporated by reference unless it is reasonably available for inspection by potentially interested persons within the time allowed for comment. Material based on proprietary data which is itself not available for review and comment shall not be incorporated by reference." Based on these NEPA implementing regulations, the relevant content of the aforementioned EISs is incorporated by reference.

The 2005–06 groundfish harvest specifications EIS did not find that the proposed action would result in significant impacts to protected species, based on a qualitative evaluation of the alternatives. Although there was insufficient spatio-temporal information to predict interactions under different alternatives, projected catch, as a gross proxy for overall fishing effort, was used to comparatively evaluate the alternatives. It is important to note that groundfish trawl fishing effort as reported in logbooks has fallen over the past few years; for example, 110,512 tow-hours were reported in 2000 while 64,763 tow hours were logged in 2004. Declining groundfish trawl effort is a predictable response to lowered OYs and more restrictive management measures imposed to reduce bycatch of depleted groundfish and it is reasonable to conclude that non-trawl sectors experienced similar declines. Furthermore, because OYs for some depleted species—principally canary and yelloweye rockfish—have not increased, it is likely that fishing effort in 2005 and 2006, and the 2007–08 biennium is likely to continue a declining trend. Combined with the conclusion of no significant impact in the previous EIS, and the lack of new information suggesting otherwise, it is reasonable to conclude that the range of alternatives in the current EIS will not result in significant impacts to protected species. For this reason effects to sea turtles, marine mammals, and seabirds are not evaluated in further detail. However, given the new information contained in the 2006 supplemental biological opinion, this EIS focuses on impacts of the alternatives on the ESA-listed salmon ESUs identified in that opinion.

5.1 Affected Environment

According to the ESA, NMFS may conduct a "section 7 consultation" on a federally-authorized activity, such as fishing in EEZ waters, in order to determine whether that activity is likely to jeopardize the continued existence of an ESA-listed species. In 1990, NMFS conducted its first ESA section 7 consultation on Chinook salmon take in the groundfish FMP. Subsequent NMFS section 7 consultations in 1991, 1992, and 1993 concluded that Chinook was the ESA-listed salmon species most likely to be affected by the groundfish fisheries. Groundfish fishery interception of salmon species other than Chinook is negligible and infrequent {NMFS, 2006 1075 /id}. Of the ESA-listed Chinook evolutionarily significant units (ESUs,) NMFS has concluded that the ESUs most likely to be affected by the groundfish fisheries include: Snake River fall Chinook (threatened), Upper Willamette River Chinook (threatened), Lower Columbia River Chinook (threatened), Puget Sound Chinook (threatened), Sacramento River winter-run Chinook (endangered), California coastal Chinook (threatened), and Central Valley spring-run Chinook (threatened). The 1992 Biological Opinion also concluded that groundfish gears other than trawl gear are either unlikely to affect salmon, or to have no salmon bycatch at all {NMFS, 1992 1076 /id}. The incidental take statements for this and subsequent section 7 consultations established a consultation standard of 11,000 Chinook salmon caught in Pacific whiting fisheries. In other words, Chinook salmon bycatch exceeding this number in a given year would be a basis for re-initiating consultation to determine whether this new information indicates the action would jeopardize the continued existence of listed ESUs and considering further mitigation measures to reduce bycatch. The 1992 biological opinion estimated the take of salmon in other, non-whiting groundfish trawl fisheries at 6,000–9,000 fish annually, with most of these taken in waters north of 43° N latitude. As with the whiting fishery, almost all of these were estimated to be Chinook salmon. Historically the non-whiting groundfish trawl sector has not been comprehensively monitored for protected species bycatch and no similar re-initiation standard was established for this sector. However, with the implementation of the WCGOP it has become possible to estimate salmon bycatch in the non-whiting groundfish trawl sector more precisely.

The 11,000 fish threshold for re-initiation has been breached three times since 1991, most recently in 2005. In response, the latest supplemental biological opinion {NMFS, 2006 1075 /id} was prepared. The evaluation of impacts to protected species (focusing on listed Chinook salmon ESUs) substantially relies on this and previous opinions. Like the biological opinion, effects are considered in terms of two sectors: whiting and non-whiting groundfish trawl. Other groundfish fishery sectors are not considered, based on the conclusion in this and previous biological opinions that salmon bycatch is negligible in these sectors.

5.1.1 The Whiting Fishery

Salmon bycatch has generally been well below 11,000 fish consultation standard (averaging 7,281 since 1991); although, as noted, above it has been exceeded three times (see Table 5-1), in 1995 (14,533 fish), 2000 (11,513 fish), and 2005 (11,916 fish). Figure 5-1 breaks out the Chinook bycatch by the various whiting sectors over time.

Both the absolute and relative effects of the different whiting subsectors may considered in describing past impacts. Table 5-2 shows, for the whole 1991–2005 period, both the bycatch rate (number of Chinook/mt whiting) and the percent of all Chinook caught for each subsector (number of Chinook caught by subsector/number caught in all sectors). The rate can be considered a measure of relative impact, or the intensity of the impact of a given subsector, while the percent of total indicates the absolute magnitude of impact for each subsector. It can be seen that tribal mothership sector has the highest relative impact (0.1171 Chinook/mt) but ranks second to last in terms of absolute impact. The nontribal mothership sector has had the highest absolute impact (31.73 percent) and the second-highest relative impact (0.0506 Chinook/mt). The catcher/processor sector has the lowest overall bycatch rate for the period followed (0.0219 Chinook/mt) and accounted for the third-lowest proportion of overall bycatch (22.81 percent). The tribal shorebased sector has only operated since 2003 and thus accounts for a very small share of total bycatch for the period.

Table 5-1. Annual bycatch of salmonids in the whiting fishery.

	Salmonid Species							
Year	Chinook	Coho	Pink	Chum	Sockeye	Steelhead	Unidentified	Total
1991	6,206	138	24	8	0	0	NA	6,376
1992	5,353	193	0	48	0	0	NA	5,594
1993	5,262	17	3397	58	116	0	NA	8,850

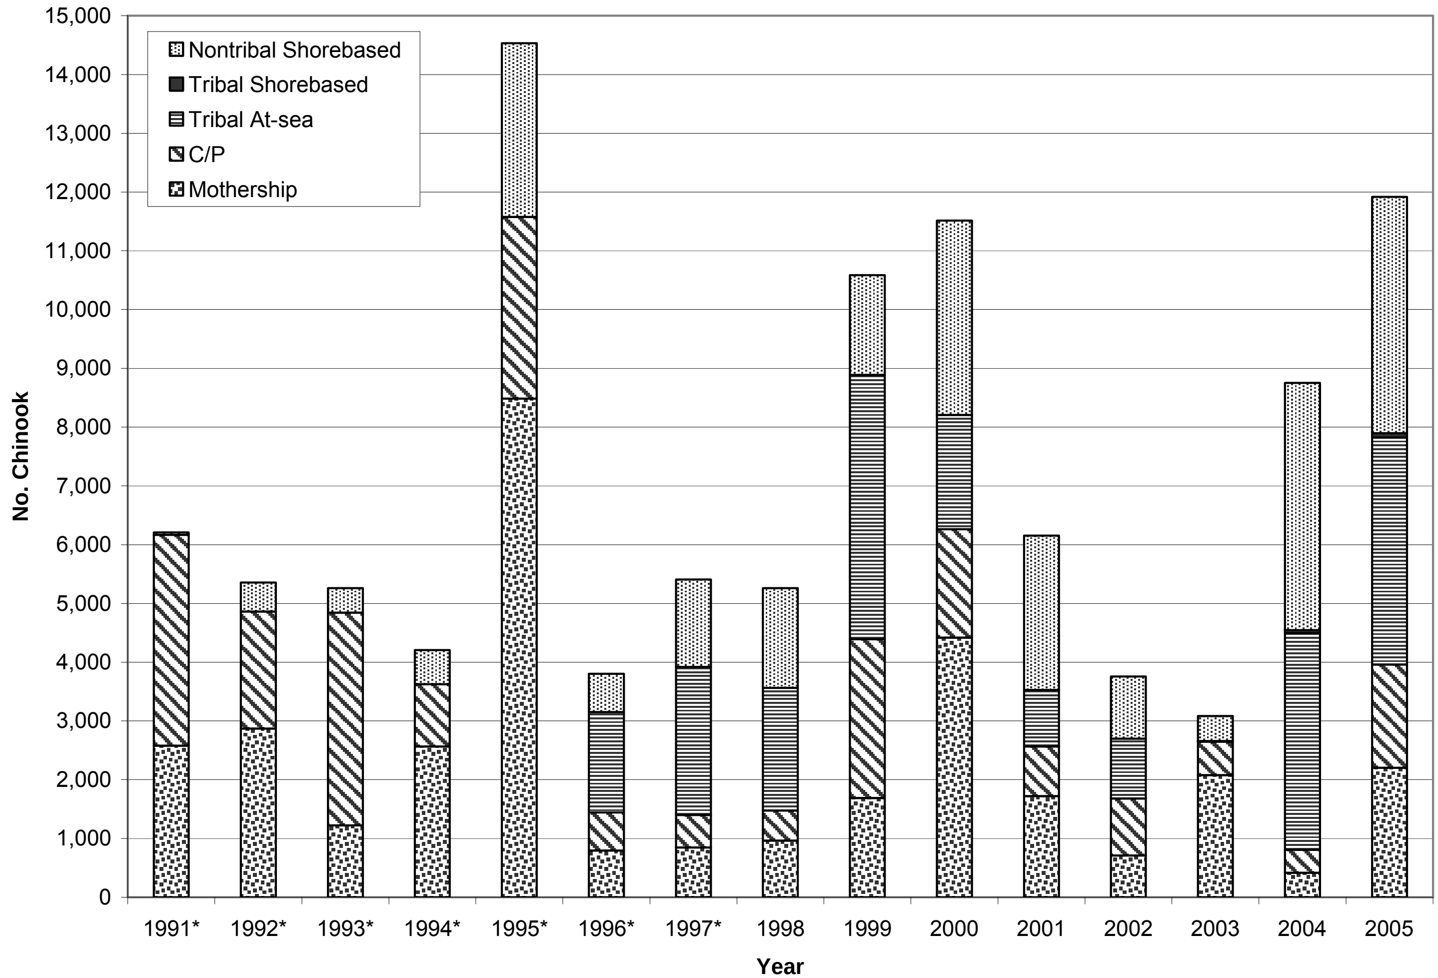
Figure 5-1. Summary of Chinook salmon bycatch in the Pacific whiting Fishery by sector in number of fish, 1991-2005. {“Data from Table 4 in” /pt NMFS, 2006 1075 /id “.” /ft}



* NOTE: 1991-1997 is based final inseason data files and may vary from estimates derived from NORPAC data. Shoreside data updated from Nottage and Parker 2005.
2002 shore-based landings does not include 432 mt of whiting or salmon taken in trip limit fishery
2003 shore-based landings does not include 195 mt of whiting or salmon taken in trip limit fishery
2004 shore-based landings does not include 1,644 mt of whiting or salmon taken in trip limit fishery - first year of video monitoring at-sea 2005 shore-based landings does not include 310 mt of whiting or salmon taken in trip limit fishery

Table 5-2. Relative impact (average Chinook salmon/mt whiting) and absolute impact (percent of all Chinook caught 1991–2005) by whiting sector.

	Relative Impact (rate)	Absolute Impact (% all Chinook)
Mothership	0.0506	31.73%
Catcher/Processor	0.0219	22.81%
Nontribal Shorebased	0.0246	24.25%
Tribal Mothership	0.1171	21.07%
Tribal Shorebased	0.0066	0.13%

The supplemental biological opinion summarizes previous work to identify causative factors that would account for variations in salmon bycatch. On an annual basis there is some temporal and spatial variation in bycatch that can be accounted for by the behavior and biology of Chinook salmon and Pacific whiting. Bycatch rates send to higher closer to shore and earlier in the season. This may explain, for example, the high bycatch rate for the tribal mothership sector, since these vessels fish within the U&As, and thus have less flexibility to make spatial adjustments in response to salmon bycatch. Similarly, the shorebased sector, for cost and operational reasons, tends to fish closer to shore. However, no such factors adequately account for inter-annual variation in bycatch. Pervious work found no "obvious or consistent correlation" between annual Chinook abundance and bycatch {NMFS, 2006 1075 /id " , page 19" /ft}. Ocean conditions may play a role but specific causative factors, at least any that can be used predicatively, cannot be identified.

Although the 11,000 fish threshold is used a trigger to re-initiate consultations, the biological opinions produced in the course of these consultations have not concluded that occasionally exceeding this threshold (as occurred in 1995, 2000, and 2005) is not by itself a basis for making a jeopardy determination. In its 2006 supplemental biological opinion, NMFS reaffirmed this conclusion with respect to the 2005 fishery. In reaffirming this conclusion, the supplemental biological opinion notes that on average bycatch has been well below this threshold, averaging about 7,300 Chinook over the last 15 years. Furthermore, the status of the Chinook ESUs most likely to be affected by the whiting fishery has generally improved since the 1999 section 7 consultation.[22]

During the 2005 fishery, when it became apparent to NMFS that the whiting fishery could exceed the 11,000 Chinook level, the agency took emergency action to close the fishery shoreward of a boundary line approximating the 100 fm depth contour (70 FR 51682, August 31, 2005). This may prove to be a valuable mitigation measure and for 2006 EFP for the shore-based whiting sector allows NMFS to invoke a similar closure if bycatch threatens to exceed the 11,000 fish threshold. At the same time the Council has not recommended a blanket nearshore area closure throughout the whiting season because such a closure would force the whiting fishery into offshore waters where canary and darkblotched rockfish bycatch may be high. The more flexible approach of applying this mitigation measure in response to conditions in the fishery allows industry and NMFS tradeoff the impacts of salmon bycatch (more prevalent in inshore waters) and bycatch of the two depleted rockfish species (which occur more often in offshore waters).

During the 2005 fishery, when it became apparent to NMFS that the whiting fishery could exceed the 11,000 Chinook level, the agency took emergency action to establish a new salmon conservation zone. The new zone was referred to as the Ocean Salmon Conservation Zone and was defined as all waters shoreward of a boundary line approximating the 100-fm (183-m) depth contour (70 FR 51682, August 31, 2005). Fishing for whiting during the remaining portion of the 2005 primary season was prohibited

[22] The 1999 re-initiation was in response to the listing of 22 additional salmonid ESUs since the previous consultation.

within the Ocean Salmon Conservation Zone. For 2006, NMFS will continue to monitor Chinook catch in the whiting fishery. If the 11,000 Chinook threshold is projected to be reached before the whiting allocation is projected to be reached, provisions within the terms and conditions of the EFPs that are issued to the shore-based participants would allow the Ocean Salmon Conservation Zone to be reinstated for the shore-based sector. If the Ocean Salmon Conservation Zone is reinstated for the shore-based sector, the at-sea sectors will be asked to voluntarily fish deeper than the 100 fm depth contour for the remainder of the 2006 primary whiting season. A substantial portion of the shore-based whiting fishery has occurred inside the 100 fm depth contour in recent years, while the at-sea sectors have voluntarily fished in deeper waters to avoid Chinook salmon. Having the Ocean Salmon Conservation Zone in effect throughout the whiting season was not recommended by the Council because such a closure could shift effort into offshore waters between 100 fm and 150 fm where historical data indicates there are higher catch rates for canary and darkblotched rockfish. Maintaining the ability to close the whiting fishery in the nearshore area inseason provides the fishery participants with flexibility to avoid overfished species, but maintains a mechanism for reducing the incidental take of Chinook salmon.

5.1.2 Limited Entry Bottom Trawl Fishery

As noted above, estimates of Chinook salmon bycatch for the (non-whiting) bottom trawl fishery have only recently become available. Data from the WCGOP were used to estimate 18,120 salmon caught in 2002, 13,862 fish in 2003, and 1,978 fish in 2004. Virtually all of the salmon caught were Chinook salmon (see Table 11 in NMFS 2006). Since these bycatch levels exceed the previous estimate of 6,000–9,000 Chinook specified in previous incidental take statements, NMFS also reinitiated its consultation on the Groundfish FMP and included an evaluation in the most recent, 2006 supplemental biological opinion. The previous estimates of salmon bycatch in the bottom trawl fishery were extrapolated from two coastwide research studies, one related to discards conducted from 1985 to 1987, and a second related to mesh size conducted from 1988 to 1990 {NMFS, 1992 1076 /id}. These were the only relevant data sources until NMFS began placing observers on bottom trawl vessels in August 2001.

The magnitude and distribution of bycatch in the trawl fishery from 2002 to 2004 was affected by significant changes in regulation and management of the fishery to protect overfished groundfish stocks. Between 1999 and 2002, NMFS declared eight groundfish species as overfished pursuant to the MSA (see Chapter 1). In response, one of the Council's major tools for reducing incidental interception of overfished groundfish has been the RCAs, large-scale marine area closures. The last several years has been a period of significant change for the fishery as it has had to adjust to the need to manage under the strict harvest limits for a complex of overfished species. The evolution and testing of RCAs and other regulatory strategies is ongoing, but fishery management and regulation substantially changed in the 2002–04 time period. Because of changing regulations, shifts in fishing areas, reductions in trawl fishery effort from the December 2003 trawl vessel and permit buyback program, and gear innovations (including the new selective flatfish trawl gear) coastwide, it is difficult to pinpoint which of these various factors may be affecting Chinook bycatch negatively or positively.

The supplemental biological opinion evaluates Chinook salmon bycatch by latitudinal and depth strata based on estimates from WCGOP data. Figure 5-2 aggregates this information (Table 12 in the supplemental biological opinion) across the three years of available data. The highest bycatch occurs in depths less than 125 fm across all latitudinal strata with the highest overall bycatch occurring off the Oregon coast from Cape Falcon to Cape Blanco, followed by the region to the south to Cape Mendocino in northern California. Looking at latitudinal differences alone, over the three years 56% of estimated Chinook bycatch occurred in the Cape Falcon-Cape Blanco region; in 2003 two-thirds of estimated bycatch was from that region. The 2006 supplemental biological opinion notes that "more bycatch, in the bottom trawl fishery in particular, was shifted south into northern California than was previously thought" (page 30). As a result Sacramento winter-run Chinook, California coastal Chinook, and Central Valley spring-run Chinook may be disproportionately affected. However, component ESUs for these stocks have increased or remained stable over the past 10 years.

	US/Canada Border to Cape Falcon	Cape Falcon to Cape Blanco	C. Blanco to C. Mendocino	C. Mendocino to US/Mex Border
> 250 fm	30	37	47	0
125-250 fm	724	8,264	4,713	57
< 125 fm	4,975	8,907	5,332	875

Area

Figure 5-2. Aggregated estimate of Chinook bycatch 2002–04 in the groundfish bottom trawl sector. (Data from Table 12 in NMFS 2006.)

Take of Chinook salmon in the trawl fishery is a relatively rare event with a few tows accounting for a disproportionate share of the estimates of catch. Thus, in terms of salmon bycatch, the distribution of effects is highly skewed. As a result, comparing tows within a given spatio-temporal sampling stratum, approximately 45 percent of all observed Chinook bycatch occurs in the single largest tow for any given stratum. For example, in the 2002 Cape Falcon-Cape Blanco and less-than-125-fathom-depth stratum there were 341 observed tows. One or more salmon was observed in only 24 of these tows while a single tow accounted for 179 salmon, which was 56 percent of all the observed salmon used to derive the estimate of 2,207 Chinook for that stratum.

This skewed distribution in the occurrence of salmon also affects the reliability of estimates derived from subsamples. In the groundfish bottom trawl sector only a portion of tows are observed. Even in the whiting fishery, where there is 100 percent observer coverage, observers may subsample some hauls rather than counting all fish brought aboard.

Although the estimated bycatch in 2002 and 2003 was substantially above the 6,000–9,000 expected salmon bycatch range articulated in the incidental take statement from the 1999 consultation, in the 2006 supplemental biological opinion NMFS reaffirmed 9,000 Chinook as a benchmark for making a jeopardy determination. As in the whiting fishery, exceeding this value in any one year is not by itself a reason for concluding jeopardy. NMFS therefore reaffirmed its prior determination that implementation of the Groundfish FMP is not likely to jeopardize the continued existence of any of the affected ESUs. However, in response to the larger than expected bycatch in two of three sample years NMFS will continue to monitor and collect data to analyze take levels.

5.2 Criteria Used to Evaluate Impacts

Focusing on potentially significant impacts, the impact of incidental catches of ESA-listed Chinook is evaluated in this chapter, using the supplemental biological opinion {NMFS, 2006 1075 /id} and previous opinions to provide a framework for evaluating impacts. Broadly, the threshold for significant impacts can be correlated with the thresholds used to assess jeopardy: 11,000 Chinook salmon in the whiting fishery and 9,000 fish in the non-whiting groundfish bottom trawl fishery. As noted, occasional bycatch over these thresholds is not by itself a reason to conclude jeopardy, and by the same token would not be a basis for concluding that a given alternative is likely to result in significant impacts to a listed Chinook salmon ESU. The supplemental biological opinion also proposes a variety of management measures, which would be implemented through this harvest specifications process, to reduce Chinook bycatch. This suggests that Chinook bycatch in any one year as high as 14,000 in the whiting fishery, which approximates the maximum bycatch, observed in 1995, would not be a significant impact but the likelihood that the 11,000 Chinook threshold will be exceeded several years could be considered a significant impact. This suggests the following criterion and threshold that could be used to evaluate the impacts on listed Chinook salmon ESUs:

- Is the alternative likely to result in bycatch in the whiting fishery of more than 14,000 Chinook in either 2007 or 2008 or would the average bycatch for the 2005–08 period exceed 11,000 fish?

A similar criterion could be developed for the groundfish bottom trawl sector, based on the incidental take statement estimate and recent estimates of single-year bycatch. However, given that the 2002 maximum bycatch value is almost double the 9,000 fish benchmark, that the data series is very limited, and there are wide confidence limits on the estimates due to the skewed nature of bycatch occurrence on a tow-by-tow basis, it would not be reasonable to use the maximum bycatch value in a similar fashion. However, the 1995 maximum in the whiting fishery is approximately one-third above the 11,000 fish consultation standard. This suggests a parallel criterion would be:

- Is the alternative likely to result in bycatch in the groundfish bottom trawl fishery of more than 12,000 Chinook in either 2007 or 2008 or would the average bycatch in the 2005–08 period exceed 9,000 fish?

Using these criteria in a quantitative fashion, however, is not possible because no methods are available to predict the number of Chinook salmon that will be caught in either fishery. For example, the bycatch rate varies independently from the amount harvested and, as discussed in the supplemental biological opinion, is likely influenced by the interaction between ocean conditions and fishery response in terms of fishing strategy. Instead, the alternatives can be evaluated qualitatively based on the inclusion of management measures that may directly or indirectly mitigate the bycatch of Chinook salmon. The supplemental biological opinion discusses a number of management measures that should be adopted as part of this harvest specifications process to mitigate Chinook bycatch. These include:

- For the whiting fishery, implement a hard bycatch limit that would couple a four-year running average of 11,000 with a year-specific cap of 14,000 or some similar construction. Under such a limit, the bycatch may be as high as 14,000 in any one year, but would also be constrained such that the average bycatch in the current year and previous three years may not exceed 11,000.

- For the whiting fishery, authorize inseason action to immediately close fishing for whiting shoreward of 100 fm if and when NMFS determines that Chinook bycatch is likely to exceed the 11,000 fish threshold.

It should be noted that establishing the harvest specification and management measures for the whiting fishery is a separate although related action that occurs on an annual basis. For example, the development of harvest specifications and management measures for the 2007 whiting fishery will occur during the March–April 2007 time frame in the Council process. Therefore, these types of management measures are not considered for adoption as part of the proposed action evaluated in this EIS. Bycatch information for the groundfish bottom trawl sector, gathered through the WCGOP, does not become available inseason as is the case for the whiting fishery; currently they become available in September or October of the following year. Thus, it is not possible to use the current incidental take statement benchmark of 9,000 fish as a trigger for inseason action. Instead, the alternatives can be evaluated based on possible direct or indirect effects of management measures on salmon bycatch. Given the current information on the spatio-temporal distribution of salmon bycatch, the following evaluation criteria are applied:

- Will the alternative likely result in an increase or decrease in the groundfish bottom trawl shoreward of the inner RCA boundary? In the 2005–06 period these boundaries varied seasonally and geographically between either 100 or 75 fm while the seaward boundary varied between 150 and 200 fm. This makes the RCA boundaries a good proxy for a zone where Chinook bycatch is likely to be higher versus a zone where bycatch is likely to be low.

- Will the alternative likely result in an increase or decrease in groundfish bottom trawl effort in the area between Cape Falcon and Cape Mendocino? Current data indicate higher bycatch rates in this region.

- Does the alternative expand the selective flatfish trawl requirement? The supplemental biological opinion notes that this gear type may reduce Chinook salmon bycatch rates, although there is not enough observer data to confirm such an effect. Selective flatfish trawl gear is currently required shoreward of the RCA north of 40°10’ N. latitude, which encompasses the areas with the highest salmon bycatch rates. This requirement may be expanded to the areas south of 40°10’ N. latitude in 2007–08. Although bycatch rates in this region are substantially lower, such a measure could have a modest effect on overall salmon bycatch.

- Is the alternative likely to result in an overall increase or decrease in groundfish trawl effort? Other things being equal (such as the spatio-temporal distribution of effort) reductions in overall fishing effort are likely to result in less salmon bycatch. Currently, it is not possible to predict fishing effort directly. As noted above, catch, which is projected in the modeling of alternatives, can be used as a gross proxy for fishing effort. Although the least precise, this criterion is the most concrete tool for evaluating effects because it employs one of the few metrics for which projected estimates are available.

5.3 Discussion of Direct and Indirect Impacts

5.3.1 Harvest Limits (OY Alternatives)

Chapter 2 describes two sets of harvest limit alternatives, the rebuilding alternatives and the 2007–08 OY alternatives. The rebuilding alternatives principally serve a heuristic function; there is no expectation that any one of them would by itself be chosen as the set of harvest limits (in combination with target species OYs) for the 2007–08 period. Nonetheless, they deserve discussion because they provide a high degree of contrast in terms of overall strategy and as a consequence the overall distribution of fishing. As discussed above, the timing and geographic distribution of fishing are two factors that have a demonstrable relation to salmon bycatch. Furthermore, the general distribution of depleted species indirectly affects the distribution of fishing effort because management measures are crafted to discourage fishing in times and areas where incidental catch of these species is likely to be higher. Section 2.1.1.2 describes the effect of the alternatives on regional and sectoral fishing opportunity, which is used below to describe the likely effect on the incidental take of Chinook salmon.

The status quo rebuilding alternatives comprise depleted species OYs based on estimated 2005 harvests projected forward to account for changes in exploitable biomass. The distribution of fishing effort is thus likely to be similar as occurred in 2005–06. Although the resulting incidental take of Chinook salmon cannot be predicted, in 2007-08 it is likely to be within the range of incidental take experienced in the recent past. Depending on what mitigation measures are adopted, the consultation standards discussed above could be exceeded in the whiting and bottom groundfish fishery sectors.

Rebuilding alternative 1 would result in an increase in slope and midwater trawl fishing opportunities. Subject to target species harvest limits this alternative would result in more fishing opportunity in the whiting fishery; however, more fishing effort would occur offshore. This could reduce the incidental take of Chinook salmon in comparison to the status quo.

Rebuilding alternative 2 would result in higher southern shelf fishing opportunities, and close to status quo fishing opportunity for northern bottom and midwater trawl sectors. This alternative could result in increased incidental take of Chinook salmon in comparison to status quo if fishing effort increases on the southern shelf.

Rebuilding alternative 3 would result in higher shelf fishing opportunities coastwide and also higher slope and midwater fishing opportunities. This alternative could result in increased incidental take of Chinook salmon in comparison to status quo and alternatives 1 and 2. Absent mitigation measures, there would be an increased risk of exceeding the consultation thresholds for both the whiting and groundfish bottom trawl fisheries.

Rebuilding alternative 4 would dramatically lower northern shelf fishing opportunities while also constraining southern shelf fisheries north of Point Conception. It would allow increased slope and midwater trawl opportunities. This alternative could result in lower incidental take of Chinook salmon in comparison to status quo and alternatives 1–4 because of the reduction in shelf fishing opportunity.

Rebuilding alternative 5 would dramatically lower shelf, slope, and midwater fishing opportunities coastwide. This alternative could result in the lowest incidental take of Chinook salmon in comparison to all of the other rebuilding alternatives.

The 2007–08 ABC/OY alternatives include the No Action alternative, which would establish the same OYs that were established for 2005–06, six action alternatives, and the Council-preferred alternative, which as of this writing has not been fully specified. No one of the six action alternatives (Alternatives 2–5) is by itself a viable alternative; they function to capture ranges of OYs for each of the stocks or stock complexes. Thus, in Table 2–5 it is possible to read across by row to see these ranges but reading down any one column for an alternative does not result in a meaningful set of OYs across all stocks. For depleted species several intermediate values are presented, which are related to possible long-term rebuilding targets. In addition, and again more as a heuristic device, the low end of the ranges for depleted species is zero, in order to demonstrate the overall effect of rebuilding in the shortest possible time period. Finally, as of this writing the Council-preferred alternative contains a generally more restricted range of OYs for depleted species; final action by the Council will determine the specific OY for each of these stocks. Given this structure of the OY alternatives, it is not possible to simply compare each of the six action alternatives against each other or with the No Action or Council-preferred alternatives. For this reason, the discussion below focuses on the No Action alternative, the effects of rebuilding in the shortest time possible (establishing zero OYs for depleted species), and the low and high range for depleted species in the Council-preferred alternative. Although OYs are ranged for target species, these differences are not likely to have a discernable effect on Chinook salmon at the level of analysis possible in the EIS. The one possible exception is the OY for Pacific whiting. However, selecting an OY for Pacific whiting is not part of the proposed action. A maximum likely range of potential OYs, based on the recent past, is included within the OY alternatives primarily as an aid for forecasting possible impacts to depleted species and revenue projection for the groundfish fisheries as a whole. The effects of differences in the magnitude and distribution of fishing effort related to this range of the potential Pacific whiting OY is likely to be slight, considering other mitigation factors, such as strategies to minimize depleted species bycatch and mitigation measures that may be implemented to reduce Chinook salmon bycatch (see below).

The No Action alternative would continue 2005–06 OYs into the next biennium. They would be implemented along with existing management measures, thus resulting in fishing opportunity experienced in the current biennium. Chinook incidental take would likely be similar to the recent past.

Any alternative that sets the OYs for one or more depleted species to zero or near zero would have a variable effect, depending on which depleted species harvests are so constrained. Table 2–4 shows the projected total catch of depleted groundfish species across groundfish sectors in 2006. Note that the non-tribal whiting fisheries are operating under a total catch limit (cap) for canary and widow rockfish. The principal depleted species caught in the Pacific whiting fishery are canary, darkblotched, and widow rockfish, and POP, although in much smaller quantities than the bottom trawl sector as a whole. Further constraints on harvest limits for these species, moving toward zero, would first tend to change fishing behavior in order to avoid bycatch and at still lower levels require reductions in the target species quota to minimize bycatch. The response in terms of fishing behavior, and resulting effects on Chinook incidental take would depend on which species were constrained. Darkblotched rockfish and POP are shelf species, so avoidance strategies could involve moving closer inshore, and/or a change in fishing strategy, for example from the DTS fishery to targeting flatfish. This could increase the risk of

Chinook take. Widow rockfish are semi-pelagic but favor rocky outcrops on the shelf while canary rockfish although in both cases there distribution can be variable. For that reason there may be a less clear cut changes in fishing strategy associated with low or no OY for these species, and thus less effect on Chinook incidental take. The depleted bocaccio stock and cowcod are principally encountered in central and southern California waters and thus eliminating catch of these species would principally affect bottom trawl fisheries in those areas while the whiting fishery would be largely unaffected. Changes in Chinook incidental take would therefore likely be minimal. Obviously, setting zero OYs for all depleted species would likely require closure of most, if not all, groundfish fisheries (and other fisheries with groundfish incidental catch). In that case incidental take of Chinook salmon would be effectively eliminated.

The Council's preliminary preferred low OY alternative would establish depleted species OYs well below the projected 2006 catch of these species shown in Table 2–4. If all were adopted it would be necessary to severely constrain all groundfish fisheries or selectively close certain sectors. The preliminary preferred high OY alternative are, with the exception of the canary and yelloweye rockfish OYs, above projected 2006 catches. The management measure alternatives have been developed to fall within the range of these OYs in terms of projected depleted species catch. Therefore, the projected catches under these alternatives, discussed below, combined with any mitigating measures identified, provide a clearer picture of the likely impacts of the proposed action on Chinook salmon.

Target species OYs also have some influence on fishing opportunity, although less so than the constraining OYs of the depleted species. In particular, the OY for Pacific whiting is relevant to Chinook take in the whiting fishery. Selection of this OY, and associated management measures, is not part of the proposed action, but a range of possible OYs, represented by the values under alternatives 1 and 2 are presented for analytical purposes. Subject to constraints imposed by depleted species OYs, particularly canary and widow rockfish, a higher Pacific whiting OY would allow greater fishing opportunity in this sector, contributing to the potential for Chinook salmon incidental take.

5.3.2 2007–08 Management Measure Alternatives

Management measure alternatives can affect Chinook bycatch in two ways. First, for the groundfish bottom trawl sector trip limits and other management measures can affect the overall amount of fishing effort. This is not an issue in the whiting fishery, because target catch is managed by quota. But the size of total catch limits (bycatch caps) for selected depleted species, as were applied in 2005–06, could act as constraint on overall fishing effort if they force early closure of the fishery. Second, depending on the mix of trip limits, and for the whiting fishery bycatch caps, fishing behavior in terms of timing and location could be affected.

As discussed in the supplemental biological opinion and in Section 5.1, historically there has been no clear correlation between fishing opportunity, harvest and Chinook take in the whiting fishery. Similarly, the limited data available from the groundfish bottom trawl sector show a large difference between the 2002–03 estimates and the 2004 estimate that cannot be obviously correlated with characteristics of the fishery in those years. The 2007–08 management measure alternatives have been structured to meet the range of preliminary preferred OY alternatives identified by the Council. It is not possible to predict any differential effect of the management measure alternatives in terms of Chinook take. Take is likely to be consistent with levels experienced in the recent past, with some unquantified likelihood that the consultation standards established for the two sectors could be exceeded during the 2007–-08 period. Additional mitigation measures, discussed below, could be implemented to address the risk of higher Chinook take.

Although not part of the proposed action, the adoption of additional mitigation measures to reduce

Chinook incidental take in the whiting fishery could be considered when establishing management measures for that fishery. This a separate, connected action that occurs in March of each year based on the most recent annual stock assessment for Pacific whiting. Thus, for 2007, the Council will take action to adopt a whiting OY and appropriate management measures at their March 2007 meeting.

For 2007 and beyond, automatic action authority could be established under 50 CFR 660.370 (d) to implement an Ocean Salmon Conservation Zone, as discussed in Section 5.1.1 in relation to the 2005 and 2006 seasons, for the whiting fishery in response to high salmon take. When NMFS projects the catch of Chinook salmon in the Pacific whiting fishery will exceed the 11,000 fish threshold, the Ocean Salmon Conservation Area could be put in place for all sectors of the whiting fishery though a single Federal Register notice.

As needed to stay within the available OY for overfished species, each of the management alternatives other than status quo could contain additional depth closures or provisions to create additional closures that are imposed on the whiting fishery mid-season, if an Ocean Salmon Conservation Area becomes effective. Shifts in fishing effort between 100 and 150 fm may need to be restricted under some alternatives.

There remains considerable uncertainty about bycatch of salmon in the bottom trawl fishery. The magnitude and distribution of bycatch in the trawl fishery since 2002 has been affected by significant changes in management measures to protect overfished groundfish stocks and changes in fishing effort as a result of the trawl buyback program. The uncertainty will remain until more years of observer data are available and changes in groundfish fishery management and effort distribution are analyzed in relation to the incidental take of salmon. Until 2005 observer data are available and can be analyzed, and until coded wire tag data is analyzed in relation to observer data and listed stocks, maintaining the seaward line of the Trawl RCA between Cascade Head (45° 03.83' N. lat.) and the north/south management line (40° 10.00' N. lat.) at 250 fm for the winter periods (January-April and November-December) would be a precautionary measure that could be taken in 2007 to reduce the incidental take of Chinook salmon in the bottom trawl fishery.

5.4 Discussion of Cumulative Impacts

"Cumulative impact" is the impact on the environment which results from the incremental impact of the action when added to other past, present, and reasonably foreseeable future actions regardless of what agency (Federal or non-Federal) or person undertakes such other actions. Cumulative impacts can result from individually minor but collectively significant actions taking place over a period of time. (40 CFR 1508.7)

Based on this definition, this section briefly identifies two categories of actions that have effects that when combined with the effects of the proposed action, could result in significant impacts to ESA-listed Chinook salmon. First are actions occurring in the past or the present (which is defined as the period through December 31, 2006) that will have effects persisting into the period when the proposed action is implemented (i.e., January 1, 2007) and possibly beyond. Second are reasonably foreseeable effects, which will be implemented on or after January 1, 2007 and combine with the direct and indirect effects of the proposed action to produce potentially significant cumulative effects. Section 5.5 then describes the overall or cumulative effect on protected species resulting from the direct, indirect, and external effects on protected species.

Past and present actions with persistent effects:

- Groundfish harvest specifications and management measures, 1998-2006: Past management measures authorized fishing, indirectly affecting the incidental take of Chinook salmon, as described in Section 5.1. The 1998–2006 period is identified because it marks a substantial reduction in groundfish harvest limits in comparison to earlier years. During this period rebuilding plans were developed and adopted for depleted groundfish species. Selection of a rebuilding strategy for each stock narrows the range of OYs that may be chosen for those stocks and has required the implementation of various constraining management measures to limit catches of these stocks. Given the life cycle of Chinook salmon, fishing mortality in more recent years would have a much greater contributory effect on population status.

- West Coast non-groundfish fisheries: Commercial and recreational salmon fisheries target non-listed salmon but incidentally take listed Chinook. All fisheries have a similar persistent effect, contributing to total fishing mortality and attendant effects on stock productivity. Commercial and recreational salmon fisheries are managed to optimize harvest of hatchery-produced fish while keeping the take of wild, ESA-listed stocks within limits that will ensure their continued existence. Thus, in managing these stocks, all sources of fishing mortality are estimated or accounted for, including incidental take in groundfish fisheries.

- Nonfishing actions: Salmon are vulnerable to human-caused degradation of freshwater habitat used for spawning. These effects are generally well known and diverse. They include physical barriers to migration (dams), changes in water flow and temperature (often a secondary effect of dams or water diversion projects), and degradation of spawning environments due to increased silt in the water due to adjacent land use. A very large proportion of the long-term, and often permanent, declines in salmon stocks is attributable to this class of impacts. For a detailed summary of nonfishing impacts to salmon habitat see Section 3.2.5 of the EFH Appendix in Amendment 14 to the Pacific Coast Salmon FMP.

Reasonably foreseeable future actions:

- Groundfish harvest specifications and management measures, 2009–10 and beyond: As with past harvest specifications, future harvest specifications are likely to have an indirect effect on the incidental take of listed Chinook salmon, which in combination with incidental take during 2007–08 will have cumulative effects on year classes intercepted by the fisheries during that time. This cumulative effect will only persist as long as the affected year classes. For 2007–08 harvest specifications and management measures this is of relatively short duration. Projected rebuilding times for depleted species are much longer and rebuilding alternative are thus likely to affect groundfish harvest levels, and thus indirectly incidental take of Chinook salmon, for decades. However, it is likely that rebuilding strategies will continue to be modified in the future based on new information, so it is probably unrealistic to expect that any strategy adopted as part of this proposed action will remain unchanged for the duration of a given rebuilding period. Nonetheless, in very general terms groundfish fishing effort is likely to constrained to mitigate depleted species catch for the foreseeable future.

- West Coast non-groundfish fisheries: Similar to groundfish fisheries, future take in non-groundfish fisheries (i.e., on or after January 1, 2007) contributes to year-class-specific total fishing mortality.

- Non-fishing actions: Adverse impacts to freshwater habitat are likely to continue for the foreseeable future.

5.5 Summary of Impacts

5.5.1 Harvest Limits (OY Alternatives)

This section is intended summarize in comparative fashion the overall impact of each of the alternatives considering both direct and indirect impacts and the effects of other past, present, and reasonably foreseeable future actions. Previous harvest specifications and harvest specifications established in periods beyond the next biennium are likely to have a modest or negligible effect on total fishing mortality for a given Chinook stock year class or cohort over and above the direct and indirect effects of fishing in 2007–08. This is because Chinook salmon are relatively short-lived species so the year classes intercepted in 2007–08 would only experience fishing mortality from groundfish fisheries in the bienniums immediately preceding and following 2007–08. Furthermore, most of the Chinook taken in the groundfish trawl fisheries are 2-year olds; mortality on this age class has less effect on stock productivity than the removal of mature fish.

Modification of rebuilding plans has a long-term effect on fishing opportunity because adopted targets determine harvest levels in future years. As stocks rebuild constraining OYs for depleted species will increase, allowing more fishing opportunity. However, it is not possible to predict what effect this will have on Chinook take.

As discussed above, in-river habitat modifications affecting reproductive success and fishing mortality in other fisheries have a large cumulative effect on Chinook salmon. Generally, these effects are assessed through Council management of directed harvest of non-listed salmon and other processes at the state and federal level.

It is not possible to distinguish how the various actions described above would interact differentially with the alternatives to produce relatively different effects in comparison to the description of direct/indirect effects described in Section 5.3.1.

5.5.2 2007–08 Management Measure Alternatives

As with the OY alternatives, there is no information to indicate how other actions contributing to cumulative effects might combine with indirect/effects to produce relative differences in effects among the alternatives.

6.0 DESCRIPTION OF THE FISHERIES MANAGEMENT REGIME

6.1 Management Data Systems

This chapter addresses policy, science, and management entities directly affected by changes to the current management regime, but does not include participants in the fishery or the fishing communities of the West Coast (see Chapter 7 for a description of the socioeconomic environment). The management regime is an important issue because it generates direct and indirect impacts. The regime is also itself affected by changes in law and policy, which can cumulatively affect the environment. This section describes stock assessments, catch accounting, observer programs and research fisheries, all crucial components in the process of determining sustainable fishery yields; uncertainty, which underlies the range of alternatives evaluated in this EIS; and enforcement, which affects the efficacy of prescribed management measures. Impacts, considered in terms of public sector costs, are evaluated in Chapter 7.

Uncertainty in fishery management and constraining OYs combine to create a potentially intensive inseason management burden on the management regime. As discussed in this chapter, ongoing research, existing observer programs, and revised fishery sampling programs could provide new information during the 2006-2007 management cycle. Entities and documents including the Pacific Coast Groundfish FMP, the Council and its Ad Hoc Groundfish Information Policy Committee, and NEPA all provide rules and guidance on inseason use of new information.

6.1.1 Catch Monitoring and Accounting

Various state, federal, and tribal catch monitoring systems are used in West Coast groundfish management. These are coordinated through the Pacific States Marine Fisheries Commission (PSMFC). PacFIN (Pacific Fisheries Information Network) is the commercial catch monitoring database, and RecFIN (Recreational Fishery Information Network) is the database for recreational fishery catch monitoring. There are two components to total catch, (1) catch landed in port, and (2) catch discarded at sea. Discards occur for regulatory reasons (i.e., catch in excess of trip and/or landing limits) and market reasons (i.e., catch of unmarketable species or size). A description of the relevant data systems used to monitor total catch and discards in commercial, recreational, and research fisheries follows. A description of how these data sources are used in modeling fishery impacts see Section 4.5.

6.1.1.1 Monitoring Commercial Landings

Sorting requirements are now in place for all species with trip limits, harvest guidelines, or OYs, including all depleted species. This provides accounting for the weight of landed depleted species when catches are hailed at sea or landed. Limited entry groundfish trawl fishermen are also required to maintain logbooks to record the start and haul locations, time, and duration of trawl tows, as well as the total catch by species market category (i.e., those species and complexes with sorting requirements). Landings are recorded on state fish receiving tickets. Fishtickets are designed by the individual states, but there is an effort to coordinate record-keeping requirements with state and federal managers. Poundage by sorted species category, area of catch, vessel identification number, and other data elements are required on fishtickets. Landings are also sampled in port by state personnel to collect species composition data, otoliths for ageing, lengths, and other biological data. Sample rates vary between fishery and state, but there is an effort to sample about 20% of the landed catch. A suspension of at-sea sorting requirements coupled with full retention of catch is allowed in the whiting fishery (by FMP Amendment 10 and an annual EFP in the Shoreside Whiting sector). The at-sea whiting fishery has 100% on-board observer coverage, while the shoreside whiting sector brings most of their catch to port for sampling. Landings, logbook data, and state port sampling data are reported inseason to the

PacFIN database managed by the PSMFC (www.psmfc.org/pacfin/index.html). The GMT and PSMFC manage the Quota Species Monitoring (QSM) dataset reported in PacFIN. All landings of groundfish stocks of concern (depleted stocks and stocks below BMSY) and target stocks and stock complexes in West Coast fisheries are tracked in QSM reports of landed catch. The GMT recommends prescribed landing limits and other inseason management measures to the Council to attain, but not exceed, total catch OYs of QSM species. Stock and complex landing limits are modified inseason to control total fishing-related mortality; QSM reports and landed catch forecasts are used to control the landed catch component.

6.1.1.2 Monitoring Recreational Catch

Recreational catch is monitored by the states as it is landed in port. These data are compiled by the PSMFC in the RecFIN database. The types of data compiled in RecFIN include sampled biological data, estimates of landed catch plus discards, and economic data. Descriptions of the RecFIN program, state recreational fishery sampling programs in Oregon and Washington, and the most recent data available to managers, assessment scientists, and the general public, can be found on the PSMFC web site at www.psmfc.org/recfin.

The Marine Recreational Fisheries Statistics Survey (MRFSS) has been an integral part of the RecFIN program. Traditionally, there are two primary components of the survey; field intercept surveys (administered under supervision of PSMFC) and a random phone survey of coastal populations (administered by a third party contracted by NMFS). The field intercept surveys was used to estimate catch, and the phone survey was used to estimate effort. The results of these two efforts are combined in the RecFIN data system maintained by PSMFC, and estimates of total effort and fishing mortality are produced along with other data potentially useful for management and stock assessments. However, MRFSS was not designed to estimate catch and effort at the level of precision needed for management or assessment; it was designed to provide a broad picture look of national fisheries. Comparison with independent and more precise estimation procedures has shown wide variance in catch estimates. Inseason management of recreational fisheries using MRFSS has been compromised by inseason variance of catch estimates.

In recent years, efforts have been made to improve MRFSS. Observing a growing concern with the use of MRFSS program data on the West Coast, California and policy representatives from the West Coast recommended the development of a new program to replace MRFSS. In response, staff from the CDFG and the PSMFC designed the California Recreational Fisheries Survey (CRFS), a new program for sampling California's recreational fisheries which incorporated both the comprehensive coverage of the MRFSS program and the high frequency on-site sampling of CDFG's Ocean Salmon Project. Additionally, in 2001 PSMFC, with support from NMFS, began a new survey to estimate party/charter boat (CPFV) fishing effort in California.

Washington and Oregon use the MRFSS system as a supplement to their extensive port sampling programs from which most of their recreational catch estimates are derived. The Washington Ocean Sampling Program and the Oregon Boat Survey both operate annually from approximately April through October and focus on recreational finfish (including salmon, groundfish, halibut, and tuna) from private and charter fishing vessels.

A primary goal of West Coast recreational survey programs is to produce timely marine recreational, fishery-based data needed for sustainable management of marine recreational fishery resources. Continuing improvements to West Coast recreational fishery surveys should reduce uncertainty in recreational harvest estimates and improve preseason and inseason management processes, two important components of coastwide groundfish fishery management under constraining OYs.

6.1.1.3 Management Response to Catch Monitoring

Management measures are normally imposed, adjusted, or removed at the beginning of the biennial fishing period, but may, if the Council determines it necessary, be imposed, adjusted, or removed at any time during the period. As described in Section 6.2 of the Groundfish FMP, four different categories of management actions are authorized, ranging from automatic actions initiated by NMFS to full rulemaking actions requiring a minimum of two Council meetings. Inseason adjustments typically fall under the category of notice actions that are routine (as defined by the FMP) in nature and usually require one Council meeting and one *Federal Register* notice. Federal and/or state responses to management goals varies according to the specification of the harvest targets and are largely governed by the definitions in the FMP and federal regulations as follows:

> <u>Acceptable Biological Catch (ABC)</u> *is a biologically based estimate of the amount of fish that may be harvested from the fishery each year without jeopardizing the resource. It is a seasonally determined catch that may differ from MSY for biological reasons. It may be lower or higher than MSY in some years for species with fluctuating recruitment. The ABC may be modified to incorporate biological safety factors and risk assessment due to uncertainty. Lacking other biological justification, the ABC is defined as the MSY exploitation rate multiplied by the exploitable biomass for the relevant time period.*
>
> <u>Optimum yield</u> *means the amount of fish which will provide the greatest overall benefit to the U.S., particularly with respect to food production and recreational opportunities, and taking into account the protection of marine ecosystems, is prescribed as such on the basis of the maximum sustainable yield from the fishery as reduced by any relevant economic, social, or ecological factor; and in the case of an overfished fishery, provides for rebuilding to a level consistent with producing the maximum sustainable yield in such fishery (Federal regulations adds final sentence: OY may be expressed numerically (as a harvest guideline, quota, or other specification) or non-numerically).*
>
> <u>Quota</u> *means a specified numerical harvest objective, the attainment (or expected attainment) of which causes closure of the fishery for that species or species group. Groundfish species or species groups under this FMP for which quotas have been achieved shall be treated in the same manner as prohibited species*
> *(the second sentence is not included in Federal Regulations).*
>
> <u>Harvest guideline</u> *is a specified numerical harvest objective which is not a quota. Attainment of a harvest guideline does not require closure of a fishery. (Identical language in Federal Regulations 50 CFR Part 660, Subpart G).*

California

California has three possible courses of regulatory action for recreational fisheries when a harvest limit is reached.

1. Closure of recreational fisheries for any federal groundfish, greenlings (of the genus *Hexagrammos*), California sheephead, and ocean whitefish when a federal annual harvest limit for lingcod, rockfish, cabezon, or a subgroup of rockfish, and/or California scorpionfish has been exceeded or is projected to be exceeded (Section 27.82 of Title 14, California Code of Regulations).

The CFGC has given CDFG the authority to close the following recreational fisheries when an annual harvest limit (OY or harvest guideline) established in regulation by NMFS for lingcod, rockfish, cabezon, or a subgroup of rockfish, and/or California scorpionfish has been exceeded or is projected to be exceeded: lingcod, rockfish, a subgroup of rockfish, California scorpionfish, cabezon, greenlings (of the genus *Hexagrammos*), California sheephead, ocean whitefish, and any federal groundfish. Closures may encompass all state waters or specific areas, and may be for all or part of the calendar year. The CDFG must provide the public with a notice of the closure (via press release) at least 10 days before the closure is to take effect.

2. Closure of recreational fisheries for California sheephead, cabezon or greenlings (of the genus *Hexagrammos*) when a state-established total allowable catch (TAC) or allocation is reached or is projected to be reached (Section 52.10 of Title 14, California Code of Regulations).

Statewide TACs are established in regulation for California sheephead, cabezon, or greenlings (of the genus Hexagrammos). The regulation sets allocations for recreational and commercial fisheries. CFGC has given the CDFG the authority to close the recreational and commercial fisheries for these species when an allocation or TAC is reached or is projected to be reached prior to the end of the calendar year. For the closure of a recreational fishery, CDFG is required to provide the public with at least 10 days notice (via press release) prior to the closure.

3. Emergency action by CFGC (Section 240 of the Fish and Game Code).

The California State Legislature has authorized CFGC to adopt or repeal regulations on an emergency basis, provided the action is necessary for (1) the immediate conservation, preservation, or protection of birds, mammals, reptiles, or fish, including, but not limited to, any nests or eggs thereof, or (2) the immediate preservation of the public peace, health and safety, or general welfare. CFGC may adopt emergency regulations for recreational fisheries and for those commercial fisheries the Legislature has given CFGC the authority to regulate.

The law requires CFGC hold at least one hearing before taking emergency action, and the action is subject to the review of the Office of Administrative Law (OAL). Once CFGC takes action and submits the rulemaking file to OAL, OAL has 10 days to review the file and approve or disapprove the regulation. If OAL approves the regulation, then it is filed with the Secretary of State and is in effect for 120 days (unless the regulation specifies a shorter time period).

Emergency regulation lapses by operation of law unless CFGC files a completed rulemaking for a permanent regulation with OAL or OAL approves a re-adoption of the emergency regulation. The rulemaking for the permanent regulation must follow the normal rulemaking provisions of the Administrative Procedures Act. This includes a 45-day public notice.

Oregon

The Oregon State Legislature granted the Oregon Fish and Wildlife Commission (OFWC) the authority to adopt regulations under the Oregon Administrative Rules (OAR). The OFWC delegates the authority to adopt temporary rules to the Director of ODFW (Director). Temporary rules may be considered for various reason, including the achievement of quotas, optimum yields, harvest limits or harvest guidelines, and to conform to federal regulations. Temporary regulations can be adopted, filed and in effect within a single business day, but in practice, 72 hours public notice is usually provided. A temporary rule approved by the Director is ratified by the OFWC at its next meeting, usually within 30 days.

Once filed, copies of the temporary rule are distributed to all marine related ODFW and Oregon State Police offices. The ODFW information and education program creates and distributes a general public news release. Additionally, specific industry notices are developed distributed throughout local fishing communities.

Once adopted, temporary regulations are in effect for 180 days. If the regulations needs to remain in place for a longer duration, ODFW can adopt a permanent rule through the full OFWC process. This two-meeting process includes public notice of the intent for rulemaking, an economic analysis, and adequate public review.

Washington

The Washington State Legislature has granted the Washington Fish and Wildlife Commission (WFWC) the authority to adopt emergency regulations under the Revised Code of Washington (RCW) 77.04.090. WFWC has delegated the authority to adopt emergency regulations to the Director of WDFW. Emergency regulations may be considered for various reasons, including the achievement of quotas, optimum yields, harvest limits or harvest guidelines, and to conform with federal regulations. The parameters for approving emergency regulations are not specified in the authority language. Emergency regulations can be adopted, filed, and in effect within 24 hours of being drafted.

Once adopted, emergency regulations are in effect for 120 days. During this time, if the regulation needs to remain in place for a longer duration, WDFW may consider adopting a permanent rule. Depending on the nature of the rule, it may have to go through the WFWC approval process. Once the permanent rule process has been initiated, a second emergency regulation may be filed to extend the time period. For example, an emergency regulation filed on March 1 that must remain in effect for the calendar year would expire on June 28. Provided a permanent rule process has been initiated, a subsequent emergency regulation can be filed on June 29 that would remain in effect through October 26, in order to accommodate the time needed for the permanent rule process to be finalized.

Washington Administrative Code (WAC) 220-28-010 strengthens state's the ability to enforce emergency regulations, by stating, "It shall be unlawful to take, fish for or possess food fish or shellfish taken contrary to the provisions of any special season or emergency closed period prescribed in this chapter." A note at the end of the rule language also clarifies, "The department of fish and wildlife frequently adopts emergency rules of limited duration that relate to seasons, closures, gear, and other special matters concerning the industry...."

Once filed, copies of the emergency regulation are faxed to all WDFW regional offices and enforcement staff. WDFW also uses its Outreach and Education Program to inform the public of emergency regulations. Typically, a Fishing Rule Change Notice is distributed to local media and WDFWs sportfishing hotlines are updated within 24 hours of the rule adoption.

6.1.2 Standardized Bycatch Reporting Methodologies

Establishing a standardized bycatch reporting methodology and limiting bycatch to the extent practicable are MSA mandates. Effective bycatch accounting and control mechanisms are also critical for staying within target total catch OYs. The first element in limiting bycatch is accurately measuring bycatch rates by time, area, depth, gear type, and fishing strategy. This section describes West Coast programs designed to achieve these goals.

At its November 2005 meeting, the Council approved Amendment 18 to the Groundfish FMP. The Council recommendation addresses National Standard 9 and Section 303(a)(11) of the MSA, which require practicable means to minimize bycatch and bycatch mortality a standardized bycatch reporting methodology. The purpose of FMP Amendment 18 is to clearly and comprehensively describe measures that address these requirements, which have been established through long-term regulations and the biennial management process. The amendment also describes new measures that could be implemented by future regulatory or amendment actions. For additional information on Amendment 18 see the Council web page (www.pcouncil.org/groundfish/gffmp/gfa18.html).

6.1.2.1 West Coast Groundfish Observer Program

The WCGOP includes the Observer Team and collaborators from the PSMFC that direct the program, train new observers, and manage and analyze the bycatch data. On May 24, 2001, NMFS established the WCGOP to implement the *Pacific Coast Groundfish Fishery Management Plan* (50 CFR Part 660). This regulation requires all vessels that participate in commercial groundfish fisheries to carry an observer when notified to do so by NMFS or its designated agent. These observers monitor and record catch data, including species composition of retained and discarded catch. Observers also collect critical biological data such as fish length, sex, and weight. The program currently deploys observers coastwide on the permitted trawl and fixed-gear groundfish fleet, as well as on some vessels that are part of the open-access groundfish fleet.

The WCGOP is designed to provide estimates of fleet-wide discards in commercial fisheries; fishtickets are the mandated landings accounting mechanism. Logbook data need to be available to fully use observer data because observers initially record hail weights and logbook data for retained catch, and these values need to be adjusted by fishticket information to achieve total catch estimates. One difficulty is the need for a statistically significant number of observations of discard across all strata to determine representative bycatch rates for these strata. Implementation of depth-based management further exacerbated the data-sparseness of observations, since areas where many observations occurred in the first year of the WCGOP are now closed to fishing.

NMFS first implemented the WCGOP in August 2001 to make direct observations of commercial groundfish discards. Given the skewed distribution of bycatch in West Coast groundfish fisheries, many observations in each sampling strata (i.e.,target effort by gear type by area) are needed to estimate representative bycatch rates of depleted groundfish species. The seasonality of bycatch is an important management consideration. Target opportunities for healthy flatfish and DTS species vary seasonally and geographically. It is reasonable to expect bycatch rates of depleted groundfish species to vary in accordance with the co-occurrence of target species and depleted species.

The he WCGOP has released annual reports beginning in 2003 which describe the analysis of observer data for various fishery sectors and species collected under the program. These reports and background materials on the WCGOP are available on the Northwest Fisheries Science Center website at: www.nwfsc.noaa.gov/research/divisions/fram/observer/datareport/index.cfm.

NMFS continually reviews the program and has gradually expanded the programs coverage since its inception. Additionally, the NWFSC has worked closely with the Council and NMFS-NWR to coordinate the availability of WCGOP results into the management regime. A description of how data from the WCGOP is being used in the modeling of commercial fishery impacts can be found in Section 4.5.

6.1.2.2 At-Sea Pacific Whiting Observer Program

To increase the utilization of bycatch otherwise discarded as a result of trip limits, Amendment 13 to the Groundfish FMP implemented an increased utilization program on June 1, 2001, which allows catcher/processors and motherships in the whiting fishery to exceed groundfish trip limits without penalty, providing specific conditions are met. These conditions include provisions for 100% observer coverage, non-retention of prohibited species, and either donation of retained catch in excess of cumulative trip limits to a bona fide hunger relief agency or processing of retained catch into mince, meal, or oil products.

Vessels participating in the at-sea Pacific whiting fisheries have been carrying observers voluntarily since 1991. NMFS made observer coverage mandatory for at-sea processors in July 2004 (65 FR 31751). These provisions have not only given fishery managers the tools necessary to allow the At-Sea Pacific Whiting Program to operate efficiently while meeting management goals, but have also provided scientists, through the observer coverage, an extensive amount of information on bycatch species. This dataset has not only provided valuable information in the management of Pacific whiting, but has also been used as a stock assessment data source.

6.1.2.3 Shore-based Pacific Whiting Observation Program

The Shoreside Hake Observation Program (SHOP) was established in 1992 to provide information for evaluating bycatch in the directed Pacific whiting fishery and for evaluating conservation measures adopted to limit the catch of salmon, other groundfish, and prohibited species. Though instituted as an experimental monitoring program, it has been continued annually to account for all catch in targeted whiting trip landings, enumerate potential discards, and accommodate the landing and disposal of non-sorted catch from these trips. Initially, the SHOP included at-sea samplers aboard shore-based whiting vessels. However, when an ODFW analysis of bycatch determined no apparent difference between vessels with and without samplers, sampler coverage was reduced to shoreside processing plants. In 1995, the SHOP's emphasis changed from a high observation rate (50% of landings), to a lower rate (10% of landings), and increased emphasis on collection of biological information (e.g., otoliths, length, weight, sex, and maturity) from Pacific whiting and selected bycatch species (yellowtail rockfish, widow rockfish, sablefish, chub (Pacific) mackerel (*Scomber japonicus*), and jack mackerel (*Trachurus symmetricus*). The required observation rate was decreased as studies indicated that fishtickets were a good representation of what was actually landed. Focus shifted again due to 1997 changes in the allocation of yellowtail rockfish and increases in yellowtail bycatch rates. Since then, yellowtail and widow bycatch in the shoreside whiting fishery has been dramatically reduced because of increased awareness by fishermen of the bycatch and allocation issues involved in the SHOP program.

The SHOP is a cooperative effort between the fishing industry and state and federal management agencies to sample and collect information on directed Pacific whiting landings at shoreside processing plants. Participating vessels apply for and carry an EFP issued by NMFS. Permit terms require vessels to retain all catch and land unsorted catch at designated shoreside processing plants. Permitted vessels are not penalized for landing prohibited species (e.g., Pacific salmon, Pacific halibut, Dungeness crab), nor are they held liable for overages of groundfish trip limits. For additional information and complete reports go to: www.dfw.state.or.us/MRP/hake/.

Since inception, an EFP has been adopted annually allowing suspension of at-sea sorting requirements in the shore-based whiting fishery enabling full retention and subsequent port sampling of the entire catch. However, EFPs are intended to provide for limited testing of a fishing strategy, gear type, or monitoring program that may eventually be implemented on a larger fleet-wide scale and are not a permanent solution to the monitoring needs of the shore-based Pacific whiting fishery. A permanent monitoring program for the shore-based Pacific whiting fleet is being developed because of the specification in the Pacific Coast Salmon and Groundfish FMPs and the 1992 BO analyzing the effects of the groundfish fishery on salmon stocks listed under the ESA. The issue of salmon retention in the groundfish trawl fisheries was brought before the Council in 1996 in the form of Amendment 10 to the

Pacific Coast Groundfish FMP and Amendment 12 to the Pacific Coast Salmon FMP.

The Council and NMFS are currently working to adopt a monitoring program to provide a full retention opportunity without the use of the EFP process and the Council adopted a preliminary range of alternatives for public review in June 2004. However, a number of issues on how a monitoring program would operate could not be resolved and NMFS worked with the states and industry to prepare a revised range of alternatives for Council consideration. Council action is now scheduled for September and November 2006. If the Council takes final action according to this schedule NMFS will then develop the regulations needed to implement the program in 2007.

6.1.2.4 Central California Marine Sport Fish Project

The CDFG has been collecting angler catch data from the CPFV industry intermittently for several decades in order to assess the status of the nearshore California recreational fishery. The project has focused primarily on rockfish and lingcod angling and has not sampled salmon trips. Reports and analyses from these projects document trends by port area in species composition, angler effort, catch, and, for selected species, CPUE, mean length, and length frequency. In addition, total catch and effort estimates are made based on adjustments of logbook data by sampling information.

Before 1987, catch information was primarily obtained on a general port basis from dockside sampling of CPFVs, also called party boats. This did not allow documentation of specific areas of importance to recreational anglers and was not sufficient to assess the status of rockfish populations at specific locations.

CPFV operators are required by law to record total catch and location for all fishing trips in logbooks provided by the CDFG. However, the required information is too general for use in assessing the status of the multi species rockfish complex on a reef by reef basis. Rockfish catch data are not reported by species and information on location is only requested by block number (a block is an area of 100 square miles). Many rockfishes tend to be residential, underscoring the need for site specific data. Thus, there is a strong need to collect catch information on board CPFVs at sea. However, locations of specific fishing sites are often not revealed for reasons of confidentiality.

In May 1987 the Central California Marine Sport Fish Project began on board sampling of the CPFV fleet. Data collection continued until June 1990, when state budgetary constraints temporarily precluded further sampling, resumed in August 1991, and continued through 1994. The program depends on the voluntary cooperation of CPFV owners and operators. Angler catches on board central and northern California CPFVs were sampled from fourteen ports, ranging from Crescent City in the north to Port San Luis (Avila Beach) in the south. For additional information on this program, see the PSMFC website at: (www.psmfc.org/recfin/ccmsp.htm).

6.1.2.5 Oregon Marine Recreational Observation Program

In response to depleted species declarations and increasing concerns about fishery interactions with these species, ODFW started this program to improve understanding of recreational impacts. There were three objectives to this program; (1) document the magnitude of canary rockfish discard in the Oregon recreational fishery; (2) improve the biological database for several rockfish and groundfish species; and (3) gather reef location information for future habitat mapping. A seasonal sampler was stationed in each of the ports of Garibaldi, Newport, and Charleston to ride recreational groundfish charter vessels coastwide in Oregon from July through September, 2001. The Garibaldi sampler covered boats out of Garibaldi, the Newport sampler covered both Newport and Depoe Bay, and the Charleston sampler covered Charleston, Bandon, and Brookings charter vessels. During a typical day the sampler would ride a five to eight hour recreational groundfish charter trip and spend the remainder of the day gathering biological and genetic data dockside from several rockfish and groundfish species for which little is known mostly due to their infrequency in the catch. When allowed by the captain, the sampler also obtained Global Positioning System (GPS) locations of fishing sites for future use by the Habitat Mapping Project of the ODFW Marine Resources Program. Results from this program have been incorporated into recreational fishery modeling by ODFW. This program has continued and expanded to document the magnitude of discard of all groundfish species, not just canary rockfish. For more information on this program as well as other fishery research and survey programs see the ODFW Marine Program website at: www.dfw.state.or.us/MRP/.

6.1.2.6 WDFW Groundfish At-Sea Data Collection Program

The WDFW At-Sea Data Collection Program was initiated in 2001 to allow fishery participants access to healthier groundfish stocks while meeting the rebuilding targets of depleted stocks and to collect bycatch data through an at-sea sampler program. The data collected in these programs could assist with future fishery management by producing valuable and accurate data on the amount, location, and species composition of the bycatch of rockfish associated with these fisheries, rather than using calculated bycatch assumptions. These data could also allow the Council to establish trip limits in the future that maximize fishing opportunities on healthy stocks while meeting conservation goals for depleted stocks.

In recent years, WDFW has implemented its At-Sea Data Collection Program through the use of federal EFPs. In 2001, 2002, 2003, and 2004, WDFW sponsored and administered a trawl EFP for arrowtooth flounder and petrale sole, and in 2002, WDFW also sponsored a midwater trawl EFP for yellowtail rockfish. The primary objective for these experimental fisheries was to measure bycatch rates for depleted rockfish species associated with these trawl fisheries. Fishery participants were provided access to healthier groundfish stocks and were constrained by individual vessel bycatch caps. State-sponsored samplers were used to collect data on the amount of rockfish bycatch caught on a per tow basis and to ensure the vessel complied with the bycatch cap; therefore, vessels participating in the EFP were required to have 100% sampler coverage. In 2003 and 2004, WDFW sponsored a longline EFP for spiny dogfish that also required 100% sampler coverage to measure the bycatch rate of depleted rockfish species associated with directed dogfish fishing. Research scientists have analyzed the preliminary data from these EFPs and have finalized summary reports.

6.1.2.7. WDFW Ocean Sampling Program

In addition to the At-Sea Data Collection Program, WDFW collects at-sea data through the Ocean Sampling Program. The at-sea portion is not intended to be an observer program for the purposes of enumerating the bycatch alone, but is coupled with shore-based sampling of anglers to calculate an estimated discard weight. At-sea samplers record biological information from discarded species. Shore-based creel surveys of anglers provide the estimate of total number of discards. Combining these two data sources yields estimates of the weight of total fishery discard by species.

6.1.2.8 Tribal Observer Program

Tribal directed groundfish fisheries are subject to full rockfish retention. For some rockfish species where the tribes do not have formal allocations, trip limits proposed by the tribes are adopted by the Council to accommodate incidental catch in directed fisheries (i.e., Pacific halibut, sablefish, and yellowtail rockfish). These trip limits are intended to constrain direct catches while allowing for small incidental catches. Incidental catch and discard of depleted species is minimized through the use of full rockfish retention, shore based sampling, observer coverage, and shared information throughout the fleets regarding areas of known interactions with species of concern. Makah trawl vessels often participate in paired tows in close proximity where one vessel has observer coverage. If landings on the observed vessel indicate higher than anticipated catches of depleted species, the vessels relocate and inform the rest of the fleet of the results (Steve Joner, Makah Fisheries Management, pers. comm., February, 2004). Fleet communication in order to avoid depleted species is practiced by all tribal fleets.

6.1.3 Research Fisheries

The reduction in directed fisheries and overall landings has resulted in less information available to fishery managers compromising efforts to assess stock abundance and recovery. There is an increasing reliance on fishery-independent sources of information such as research fisheries and surveys. This is particularly true for depleted species such as widow rockfish, yelloweye rockfish, cowcod, bocaccio, and canary rockfish as fisheries are designed to avoid areas inhabited by these species. There is a relatively sparse amount of data available for widow rockfish because widow rockfish directed fisheries have been essentially eliminated and the Pacific whiting sectors have modified their behavior to avoid encounters with widow rockfish. Assessment scientists will continue to rely on research fisheries as landings, age composition, and logbook catch rate data from many fishery sources decreases. A summary of long-term research fisheries and resource surveys can be found in Appendix A, Section 1.1.1.3. of the 2005-2006 groundfish harvest specifications FEIS {PFMC, 2004 1127 /id}.

6.1.4 The Stock Assessment Process

The Council process for setting groundfish harvest levels and other specifications depends on periodic assessments of the status of groundfish stocks, rebuilding analyses of those stocks that are depleted and managed under rebuilding constraints, and a report from an established assessment review body or a STAR Panel. As appropriate, the SSC recommends the best available science for groundfish management decision-making in the Council process. The SSC reviews new assessments, rebuilding analyses, and STAR Panel reports and recommends the data and analyses that should be used to set groundfish harvest levels and other specifications for the following biennial management period.

NMFS is currently planning the next round of stock assessments for completion and review in 2007 for use in developing management measures and harvest specifications for the 2009-2010 biennial management cycle. Rebuilding plans and stock assessments for depleted species are subject to review every two years. NMFS will also hold a series of workshops in 2006 focusing on data needs and available data sources for the list of stock assessments being considered for 2007. More information on the stock assessment process can be found in Appendix A, Section 1.1.1.1 of the 2005-2006 groundfish harvest specifications FEIS {PFMC, 2004 1127 /id}.

6.1.5 Rebuilding Analyses

In the case of depleted species, stock assessment results form the basis of a rebuilding analysis, which in turn is used to develop rebuilding policies and choose the rebuilding target identified in each rebuilding plan. The elements of rebuilding analyses are described in the SSC Terms of Reference for Rebuilding Analyses{SSC, 2005 1334 /id}. This guidance has been incorporated into a computer program for conducting rebuilding analyses developed by Dr. Andre Punt and the Marine Population Assessment & Management Group (MPAM) at the School of Aquatic & Fishery Sciences, University of Washington. Copies of the computer software and documentation can be found at the MPAM web page at: fish.washington.edu/research/MPAM/Rebuild.htm.

In a rebuilding analysis the probability the depleted stock will reach the target biomass defining a rebuilt stock (B_{MSY} or $B_{40\%}$) is determined in the absence of fishing (T_{MIN}) and the maximum permissible rebuilding time under National Standard Guidelines (T_{MAX}). The target rebuilding year (T_{TARGET}) is determined based on these limits and the probability of achieving the target biomass by T_{MAX} (denoted P_{MAX}). Probability statements are an estimate that something may happen (in this case, that stocks will reach a given size in a specified time period) and thus also the level of risk associated with a given action. Additional information on rebuilding analysis and interpretation of results can be found in Section 3.2.2.2 of Amendment 16-1 to the Pacific Coast Groundfish FMP{PFMC, 2003 1066 /id}.

The MSA mandates these rebuilding periods need to be the shortest time possible while taking into account the status and biology of the depleted stock, the needs of fishing communities, and the interaction of the depleted stock within the marine ecosystem. This mandate was underscored in an August 2005 ruling by the Ninth Circuit Court of Appeals in a challenge to the Council's darkblotched rockfish rebuilding plan. In accordance with that ruling, the Council decided to reconsider all adopted rebuilding plans to ensure they comply with the MSA as interpreted by the courts. In addition to the court ruling, federal legislation has been introduced to reauthorize the MSA and NMFS is currently considering revisions to the National Standard Guidelines regarding the prevention of overfishing while achieving sustainable yield. Therefore, in the near future, the SSC is likely to review and revise the Terms of Reference for Rebuilding Analyses accordingly.

6.1.6 License Limitation, Capacity Reduction, and Fleet Rationalization

Declining fishing opportunity and increased importance in stock rebuilding and sustainable fisheries since the late 1990s have created the need for smaller, more efficient fishing fleets and more responsive management tools and monitoring programs. NMFS recently completed a capacity reduction program for the limited entry trawl sector and the Council is in the process of rationalizing the remaining trawl fleet through the developing intersector allocations and a limited access privilege program. A full discussion of these long-term management strategies is presented in Appendix A, Section 1.2.4. of the 2005-2006 groundfish harvest specifications FEIS {PFMC, 2004 1127 /id}.

6.2 Enforcement

Enforcement of fishery regulations has become increasingly complex with the addition of large closed areas, smaller cumulative trip limits and bag limits, and depth-based closures for commercial and recreational fisheries. At the same time, decreased OYs and the need to rebuild depleted stocks has placed additional importance on controlling and monitoring fishery related mortality. Enforcement agencies continue to use traditional methods to ensure compliance with groundfish fishery regulations including dockside sampling, at-sea patrols, and air surveillance. VMS dramatically enhances, rather than replaces, traditional enforcement techniques. Recent declines in enforcement agency budgets, combined with increased regulatory complexity, have stressed the ability to adequately monitor fisheries for regulatory compliance. In response, NMFS implemented a VMS, which includes satellite tracking of vessel positions and a declaration system for those vessels legally fishing within an RCA. VMS was initially implemented on January 1, 2004 and is currently required on all vessels participating in the groundfish fishery with a limited entry permit. In November 2005, the Council recommended expansion of VMS requirements to all commercial vessels that take and retain, possess or land federally-managed groundfish species taken in federal waters or in state waters prior to transiting federal waters. Additionally, to enhance enforcement of closed areas for the protection of groundfish essential fish habitat, the Council recommends requiring VMS on all non-groundfish trawl vessels including those targeting pink shrimp, California halibut, sea cucumber, and ridgeback prawn. Implementation of expanded VMS requirements is recommended to coincide with implementation of regulations for the protection of groundfish habitat but, no sooner than January 1, 2007.

6.4 Education and Outreach

California, Oregon, and Washington have actively engaged in education and outreach programs to help recreational fisherman learn ways to minimize bycatch and fishery impacts on depleted species. Efforts include publication of fish identification guides and posters and identification of areas to be avoided due to relatively high abundance of depleted species. Additionally, research programs have been implemented to develop release techniques which reduce mortality and, once developed, educate fisherman in the application of these techniques. Education can be an effective way to reduce bycatch thereby reducing the need for intensive inseason management and frequent fishery closures due to the constraints of depleted species.

6.5 Managing with Risk and Uncertainty

Uncertainty in fishery management exists for many reasons including imperfect sources of data from the past, inaccurate or inadequate monitoring of current fisheries, and unknown future environmental conditions. All of these factors contribute to the risks associated with the assessment of stock status, the estimation of impacts to fish stocks due to fishery management measures, and the projections of future stock health under varying long-term management alternatives. Appendix A of the 2005-2006 groundfish harvest specification FEIS includes discussions of risk in fishery management {PFMC, 2004 1127 /id}; a detailed discussion of short-term costs versus long-term risk may be found in Section 1.2.1. For more information on the assessment of risk in long-term stock population projections see Section 1.1.1.2.

7.0 SOCIOECONOMIC

7.1 Affected Environment

7.1.1 Introduction

The Pacific Coast groundfish fishery is a multi-species fishery (over 90 groundfish species) taking place off the coasts of Washington, Oregon, and California where groundfish are harvested as target catch or indirectly as bycatch in other fisheries. Groundfish fishermen themselves participate in other fisheries as well. These other fisheries include salmon, highly migratory species, coastal pelagic species, shrimp, and crab, amongst others. All of these fisheries contribute to a wide range of commercial, recreational, and tribal activities that have economic, social, and cultural significance to those engaged in harvesting fish resources. Fish buyers and processors, suppliers of commercial and recreational fishing equipment and services, and fishing communities depend on these fisheries. The aim of this chapter is to describe these activities and relate them to the conservation and management measures being proposed, particularly in the context of the effects of reducing the bycatch of the seven overfished species. Information will also be provided that relates to another FMP objective of maintaining year-round groundfish fishing.

The information and organization of this discussion of the socio-economic environment draws upon the following documents—in many instances repeating or summarizing the relevant information, and, in other instances, updating the information provided:

> The Groundfish EFH document {NMFS (National Marine Fisheries Service) 2005. Pacific Coast Groundfish Fishery Management Plan, Essential Fish Habitat Designation and Minimization of Adverse Impacts, Final Environmental Impact Statement. National Marine Fisheries Service, Seattle, WA, December 2005},
>
> The Bycatch EIS {NMFS (National Marine Fisheries Service), the Pacific Coast Groundfish Fishery Management Plan, Bycatch Mitigation Final Environmental Impact Statement, NMFS, Seattle, WA, September 2004}
>
> The final EIS for the 2005-06 specification document {PFMC (Pacific Fishery Management Council) 2004. Final Environmental Impact Statement for the Proposed Groundfish Acceptable Biological Catch and Optimum Yield Specifications and Management Measures for the 2005-06 Pacific Coast Groundfish Fishery. Pacific Fishery Management Council. Portland, OR, October 2004.}
>
> The analyses and concepts developed for assessing the needs of fishing communities that were presented at the April 2006 Council meeting {Agenda F.1 Groundfish Item F.1 Supplemental Attachments 6-8)}

7.1.1.1 Management Context

The industry and community descriptions and impact analyses found in this chapter are shaped by the typical analyses undertaken to address the setting of harvest quotas and associated management measures, but also by the recent ruling of the Ninth Circuit Court of Appeals concerning rebuilding plans for overfished species. Therefore, it will be useful to summarize the basic context of the current FMP and the important directions for management provided by the Ninth Circuit.

Current FMP

The Council allocates harvest specifications (OYs) between the limited entry and open access categories. Most of the Pacific coast commercial groundfish harvest is taken by the limited entry fleet. Commercial harvest rates of groundfish are constrained by annual harvest guidelines, two-month or one-month cumulative period landing limits, individual trip limits, size limits, species-to-species ratio restrictions, area closures, and other measures. This program is designed to control effort so that the allowable catch is taken at a slow enough rate to stretch the season over the full year. Cumulative period catch limits are set by comparing current and previous landings rates with the year's total available catch and predicted participation

The groundfish limited entry program applies to bottom and midwater trawl, longline, and trap (or pot) gears. Each limited entry permit is endorsed for a particular gear type and that gear endorsement cannot be changed, so the distribution of permits among gear types has been fairly stable. Each permit also has a vessel length endorsement. The total number of permits has typically changed only when multiple permits have been combined to create a new permit with a longer length endorsement. However, in December 2003, a buyback program permanently retired 91 trawl permits, roughly 35% of the total. Limited entry permits can be sold and leased out by their owners, so the distribution of permits among the three states often shifts. At the beginning of 2003, roughly 39% of the limited entry permits were assigned to vessels making landings in California, 37% to vessels making landings in Oregon, and 23% to vessels making landings in Washington.

Other non-tribal commercial fisheries, which either target groundfish or catch them incidentally, but do not hold groundfish limited entry permits, are considered "open access." Gears used by participants in open access commercial fisheries include longline, vertical hook-and-line, troll, pot, setnet, trammel net, shrimp and prawn trawl, California halibut trawl, and sea cucumber trawl gears. Open access trawl gear may not target groundfish, but may land incidental groundfish caught while targeting other species. Open access trap/pot and longline vessels may target groundfish under certain restrictions. Open access vessels may possess limited entry licenses for other, state-managed nongroundfish fisheries such as pink shrimp or Dungeness crab.

Members of the Makah, Quileute, Hoh, and Quinault tribes participate in tribal commercial, ceremonial and subsistence fisheries for groundfish off the Washington coast according to their treaty rights. Participants in the tribal commercial fishery use similar gear to non-tribal commercial fishers who operate off Washington, and groundfish caught in the tribal commercial fishery is typically sold through the same markets as non-tribal commercial groundfish catch. There are set tribal allocations for sablefish and Pacific whiting, while the other groundfish species' allocations are determined through the Council process in coordination with the tribes, states, and NMFS. Management of tribal fisheries is done by the individual tribes in accordance with their tribal practices.

In addition to commercial and tribal fisheries, there are recreational fisheries associated with the groundfish fishery. Marine recreational fisheries consist of charter vessels, private vessels, and shore anglers. Charter vessels are larger vessels for hire, which typically can fish farther offshore than most vessels in the private recreational fleet. Shore-based anglers often fish in intertidal areas, within the surf, or off jetties. Recreational fisheries are managed by a series of seasons, area closures, and bag limits.

Ninth Circuit

Since 2000, the management of West Coast groundfish fisheries has been heavily centered on the need to rebuild overfished groundfish species. A species is considered overfished when its biomass is below 25% of its estimated unfished biomass level. West Coast groundfish stocks are highly inter-mixed, meaning that overfished species co-occur and are caught in common with more abundant groundfish stocks. This inter-mixed nature of groundfish stocks means that eliminating the directed targeting of overfished species usually does not achieve the catch reductions needed to meet rebuilding goals. To adequately constrain total catch of overfished species, management must also constrain targeted fishing on healthy stocks that co-occur with overfished species in order to reduce incidental overfished species catch. This need to constrain harvest of healthy stocks has economic implications to sectors and communities engaged in fish harvesting and processing, because of the loss in landings and revenue that could have been derived from both overfished species and many target species that co-occur with those overfished species. The reader is referred to Chapter 2 Table 2-1 for a full presentation of the levels of overfished species and target species being considered in this EIS along with the relevant associated conservation and management measures that exist to constrain harvests so that these levels are not exceeded as well to equitably distribute the burden of conservation and management across the various harvest groups. These user groups are listed in tables such as Table 2-4, which are otherwise frequently referred to as Bycatch Scorecards."

According to the Magnuson-Stevens Fishery Conservation and Management Act, when a fishery is overfished, any fishery management plan, amendment, or proposed regulations shall:

A) *specify a time period for ending overfishing and rebuilding the fishery that shall—*
- *i)* *be as short as possible, taking into account the status and biology of any overfished stocks of fish, the needs of fishing communities, recommendations by international organizations in which the United States participates, and the interaction of the overfished stock of fish within the marine ecosystem; and*
- *ii)* *not exceed 10 years, except in cases where the biology of the stock of fish, other environmental conditions, or management measures under an international agreement in which the United States participates dictate otherwise;*

B) *allocate both overfishing restrictions and recovery benefits fairly and equitably among sectors of the fishery*

As indicated in Chapter 2 (Section 2.1.1), in response to the August 2005 ruling by the Ninth Circuit Court of Appeals, the Council though this EIS is reconsidering its rebuilding plans for all overfished species to ensure they comply with the MSA as interpreted by the Court. The Court's interpretation of the rebuilding requirements of the MSA can be summarized to include the following directions: 1) the rebuilding periods must be as short as possible; 2) that short-term needs of fishing communities may be taken into account in setting rebuilding periods; and 3) to avoid disastrous short-term consequences, limited quotas may be set that allow for some fishing of plentiful species, despite the inevitability of bycatch.

For purposes of assessing the needs of fishing communities, the Council adopted the following general definition at its April 2006 meeting: DBD—need to check language against the actual motion:

> Fishing Communities need a sustainable fishery that is safe, well managed, and profitable, that provides jobs and incomes, that contributes to the local social fabric, culture, and image of the community, and helps market the community and its services and products.

Therefore, in comparison, to previous EISs undertaken for the Pacific Groundfish Fishery Management Plan, this chapter where appropriate, in addition to the typical approaches undertaken, will provide more detailed and focused socio-economic information and analyses relating to rebuilding species and fishing communities.

Overview of General Trends

In addition to the management context, it is important to understand the fisheries context that underlies the determination of the conservation and management measures being developed through this EIS. For purposes of discussion, the Groundfish Fishery will be described in terms of overall landings as a means of describing recent trends and for describing alternative ways that various groundfish sectors are classified. As groundfish fishermen fish in fisheries other than groundfish and groundfish communities depend on other fisheries as well, it is also important to the groundfish fishery in relation to other West Coast fisheries.

Groundfish Fishery

Harvest Sectors and Sub-sectors, Landings and Revenues

As discussed above, the Groundfish fishery is made up by many components. Table 7-1 shows sector trends in harvests from 1995 to 2004. These components are often summed in various ways depending on the management issue. For example, the non-tribal whiting fishery is comprised of three sectors—At-sea catcher processors, at-sea motherships, and shoreside whiting limited entry trawl. The total whiting fishery is made up of the non-tribal whiting sector and the tribal shorebased and at-sea whiting fisheries. Shorebased landings can be estimated by summing Shoreside Whiting Limited Entry Trawl, Shorebased Non-Whiting Limited Entry Trawls, Shoreside Limited Entry Line Gear, Shoreside Limited Entry Pot Gear, Shoreside Directed Open Access, and Shoreside Incidental Open Access landings. Throughout the remainder of this chapter, the discussion will involve one or more of these components.

Some trends should be noted. For this period, whiting harvests by the at-Sea catcher processors and shoreside whiting limited entry trawl fisheries reached a peak in 2004. Tribal shoreside landing also reached a peak in 2004 of 8,698 tons reflecting the recent introduction of a new shorebased tribal whiting fishery. Tribal whiting fisheries were first instituted in 1996 with advent of the at-sea tribal fishery. Harvests by shoreside non-whiting fishery limited entry trawl fleet and recreational fleets reached their lowest levels in 2004 a harvests. When combined, all non-whiting and non-tribal sectors reached a period low of commercial shoreside sectors by the shoreside non-whiting limited entry trawl fleet were at their lowest as was the recreational catch. As Pacific whiting is a highly variable species, often times analysts focus on the non-tribal commercial shoreside landings other than whiting. When this is done, landings shoreside by non-whiting non-tribal commercial sectors also reached a low in 2004, approximately 25,000 tons compared with the 59,000 and 60,000 tons of landings in 1995 and 1996, respectively. The decline in such landings mirrors status of the stocks and Council efforts to rebuild overfished species.

Table 7-1 also shows the percentage shares of each sector of the total fishery. In terms of total non-whiting-non-tribal harvests, there has been a small decline in non-whiting limited entry trawl share from past levels of greater than 75% to the current level of 71%. This has been matched by a slight increase in the recreational share, from 4% to 5% in 1995 and 1996 respectively to current levels of 7 and 8 percent. (The sharp temporary increases in recreational harvests in 1998 and 2003 are due to increases in Central and Northern California recreational harvests of lingcod, widow rockfish, and rockfish contained in the category “minor rockfish south.)

Tables 7-2a, 7-2b, and 7-2c list 1981 through 2005 commercial landings by round weight, exvessel revenue in current dollars, and exvessel revenue in inflation-adjusted dollars for commercially important species on the West Coast. These tables echo the trends discussed above but from a more historical perspective. Table 7-2a shows the large volume of Pacific whiting landings and the emergence of shore-based processing in the early 1990s. (Note that the at-sea sector includes joint venture fisheries occurring in the 1980s. “Americanization” ultimately replaced foreign processors with domestic ones.) While total groundfish landings peaked in 1994, landings of species other than whiting continued a long-term declining trend during this period. Total groundfish landings measured by weight peaked in 1994 at 305,312 mt and have declined by nearly half since. Flatfish, sablefish, and rockfish landings all peaked in 1982, the first full year under Groundfish FMP management. (Note that some decline in landings is to be expected as standing stocks are “fished down” to MSY biomass.) Landings in all groundfish species categories declined steeply after 1998, when species began to be designated overfished. Rockfish landings fell by about three-quarters from 1998 to 2002.

Table7-2b shows total groundfish exvessel value peaking in 1997 at $101.2 million, three years after the peak in total groundfish landings. The difference between these trends is partly explained by the observed run up in exvessel prices for sablefish between 1994 and 1997 at a time when total sablefish landings were pretty stable. Total exvessel value of groundfish landings declined 43% to about $58 million in 2003.

Table 7-2c adjusts the values in Table 7-2b for inflation, allowing a more direct comparison of the real value of landings between years. Low-value whiting is a much less prominent component of landings when measured this way. Measured in constant 2005 dollars, the change in the value of rockfish landings between 1998 and 2003 fell by more than two thirds. The inflation-adjusted value of sablefish and flatfish landings remained fairly stable during this period. Measured in constant 2003 dollars, total groundfish landings value was greatest in the late 1980s, peaking in 1989 at almost $132 million. By 2003, the inflation adjusted value of total groundfish landings had fallen by more than half.

Whiting harvests reached an all time high in 2005 at about 260,000 tons whereas for the other groundfish species there are significant declines starting in 1998 with 2005 showing very slight increases in harvests compared to 2004. In terms of ex-vessel revenues, since the whiting fishery was at an all time high, total groundfish revenues showed an increase significant increase in 2005 to $73 million which is still below the 1981-1997 average of $115 million. (Note that whiting and the other categories include tribal harvests.) In terms of non-whiting groundfish revenues, 2005 showed a slight increase over 2004 to $43 million due to increased sablefish revenues but is still below the 1981-1997 inflation adjusted average of $91 million. (1981-1997 is used as a basis of comparison because the downward trends in lingcod and rockfish started their sharp declines in 1998 and thus the beginning of rebuilding efforts.)

Groundfish Fishery In Relation to Other West Coast Fisheries

Tables 7-2.a through 7-2.c also show the other west coast fisheries harvests and revenues.

Total west coast harvests reached 440,000 tons in 2005 worth $281 million. Of these amounts, groundfish fisheries accounted for 50% of the harvests and 25% of the revenues. In terms of total exvessel revenues, Dungeness Crab was the only fishery that had higher revenues in 2005. Note that squid was the only major fishery that had a significant increase as the Dungeness Crab, salmon, and HMS fisheries all had significant declines in 2005 compared to 2004 adding up to a total West Coast decline in non-groundfish revenues of about 12%. Declines in non-groundfish fisheries make groundfish communities, who are already facing declining groundfish revenues, more vulnerable while often leading to increase effort in groundfish fisheries. As described below, many of these non-groundfish fisheries are part of the groundfish “open access” fleets. (As most of these fisheries are “shoreside fisheries” see 7.1.2.1 for additional discussion.)

Bycatch and Fisheries

Table 7-3 shows for these sectors or their subcomponents, the various bycatch associations; To identify likely distributional affects of reductions in overfished species mortality, NMFS Northwest Region working with members of the GMT constructed a relational database. This database used available data on the interaction of fishery sectors with overfished species, and historical management actions that have been taken to achieve management targets of overfished species. Information from the 2005 groundfish stock assessments was used to identify the distributional range of various overfished species, and then analyzed in conjunction with the size of fishing sectors on a regional basis. The resulting combined effect of relative stock size and relative fleet size helps identify the risk that a regional component of a fishing sector poses to a stock of an overfished species. In this case, “risk” is the potential catch that a particular regional sector has the potential to attain relative to the OY and relative to the capability of other sectors operating in the same area. Using this information on the relationship of groundfish stock and fleet sizes, a data set was constructed that identifies sectors that have high, med-high, med-low, and low or no impact on each overfished species, within a coastwide series of latitude-bounded management areas. Fishing sectors that were analyzed include:

1. limited entry bottom trawl – deep
2. limited entry bottom trawl –shelf
3. limited entry midwater trawl – Pacific whiting
4. limited entry fixed gear – sablefish
5. limited entry fixed gear – nearshore
6. limited entry fixed gear – dogfish
7. open access fixed gear – sablefish
8. open access fixed gear – nearshore
9. open access fixed gear – dogfish
10. California recreational-bottomfish
11. Oregon recreational-bottomfish
12. Washington recreational-bottomfish
13. Washington recreational-halibut
14. Oregon recreational-halibut

Although other commercial sectors arguably exist, one can reasonably assume that these other sectors are minor compared to those listed, or can be considered a component of one of those sectors listed. Our data set further divided sectors by coastal management area where different overfished species commonly occur: north of 40˚ 10’ N. lat., between 40˚ 10’ N. lat. and 38˚ N. lat., between 38˚ N. lat. and 36˚ N. lat., and south of 36˚ N. lat.. The area north of 40˚ 10’ N. lat. is a traditional area used for management of commercial fisheries and tends to have the highest degree of impact for several overfished species, including darkblotched rockfish, yelloweye rockfish, and Pacific ocean perch. In the area between 38˚ N. lat. and 40˚ 10’ N. lat., darkblotched rockfish populations are more moderate, Pacific ocean perch is nearly non-existent, and the area, and the northern portion the assessed portion of bocaccio rockfish begins. The area south of 38˚ N. lat. and north of 36˚ N. lat. contains few, if any, of the more northern overfished species such as darkblotched rockfish, but canary rockfish still tend to be caught in the area, as well as more southern oriented stocks such as bocaccio rockfish. Few canary rockfish occur south of 36˚ N. lat., but this area contains both bocaccio rockfish and cowcod.

Bycatch and Communities

Inspection of Tables 7-4a and Tables 7-4b shows that every community is touched in some way by the management of overfished species. (Although this table applies to the commercial sectors, recreational fisheries in the communities listed would encounter similar bycatch species.)

How the Rest of This Chapter Is Organized

The rest of this chapter provides detailed descriptions of the various sectors that make of the non-tribal commercial sectors including discussions of participation, landings, revenues, seasonality, and major fishing communities. Tribal and recreational fisheries are discussed in similar fashion. Seasonality information is presented to address considerations associated with promoting a year round fishery. In addition, the processing sector, non-consumptive users, and fishing communities are also described. After these descriptions, the next major section 7.2 describes the economic impacts of the alternatives. These impacts include direct and indirect impacts and cumulative effects.

7.1.2 Commercial and Tribal Fisheries

7.1.2.1 Overview: Total Non-Tribal Shoreside All Fisheries

Participation

Active participation in West Coast shore-based commercial fisheries has generally declined over the years 2000 to 2005 (Table 7-5). In 2005, 1,292 vessels landed West Coast groundfish, 261 landed coastal pelagic species, 1,084 landed crab, 721 landed highly migratory species, 1,339 landed salmon, and 170 landed shrimp. Groundfish vessels accounted for roughly one-third of the west coast fleet. As evidenced by the state permits purchased in the Groundfish Buyback Program, groundfish fishermen participate in these other fisheries as well, especially, the crab and shrimp fisheries. (The estimates, as they are based on fish tickets, exclude estimates of the tribal fleet and at-sea fleet which are discussed below.)

Landings and Revenues

Commercial fisheries make up the largest portion of West Coast landed catch by weight. Coastal pelagic species, followed by groundfish, crab, and highly migratory species have made up the largest landings by weight since 2000. Crab, followed by groundfish, coastal pelagic species, and highly migratory species comprise the highest-value groups from 2000–2005 (Table 7-6). The four largest gear groups by weight have been gill and trammel net, trawl, trap/pot, and troll gear (Table 7-7).

Limited entry trawlers take the vast majority of the groundfish harvest measured by weight but somewhat less if measured by value. In 2003, groundfish trawlers landed over 95% of total groundfish harvest by weight but only 64% by value (Table 7-8). The difference in trawl weight and revenue proportions is mostly due to the catch of Pacific whiting. Since whiting are caught almost exclusively by limited entry trawl vessels, they skew the overall value per unit weight calculations for this sector.

Distribution of Effort and Major Ports

See discussion below of the various subsectors (limited entry trawl, limited entry fixed gear, and open access). As discussed below, trawl vessels make most of their landings in Oregon. Newport, Astoria, and Charleston (Coos Bay), Oregon are three of the largest four ports for landed weight and exvessel revenue. Westport and Ilwaco, WA, Eureka and Crescent City, CA, Brookings, OR, and Bellingham Bay and Neah Bay, WA comprise the remaining top 10 largest ports for trawl vessel landings.

7.1.2.2 Limited Entry Groundfish Trawl Sector

Participation

West Coast limited entry trawl vessels use midwater trawl gear, and small and large footrope bottom trawl gear (defined at 50 CFR 660.302 and 660.322(b)). Midwater trawl gear is not designed to touch the ocean bottom and is therefore used to target groundfish species–such as Pacific whiting and yellowtail rockfish–that ascend above the ocean floor. Small and large footrope trawl gear are designed to remain in contact with the ocean floor and are used to target species that reside along the ocean bottom such as flatfish on the continental shelf and slope, or DTS species (Dover sole, thornyhead and sablefish complex) in deep water. Fishers generally use small footrope trawl gear in areas that have a regular substrate–few rocks or outcroppings–and more widely on the continental shelf than on the continental slope (due in large part to regulatory requirements). Fishers use large footrope trawl gear most commonly in areas that may have an irregular substrate, and along the continental slope and in deeper water.

The limited-entry shore-based trawl vessels primarily deliver their catch to processors and buyers located along the coasts of Washington, Oregon, and California, and tend to have their homeports located in towns within the same general area where they make deliveries. Larger vessels in the shore-based limited entry trawl sector focus more heavily on the DTS complex in deep water, while smaller trawl vessels focus more heavily on the shelf. Large trawl vessels also tend to participate in the trawl fishery for more months of the year than small trawl vessels. The shore-based vessels range in size from less than 40 feet to over 90 feet in length (Table 7-9).

In 2003, a fishing capacity reduction program (buyback) was implemented off the Pacific coast which retired 91 vessels from the limited entry trawl sector. These 91 vessels represented less than 40 percent of the number of boats actively engaged in the limited entry trawl sector, but approximately 50 percent of historic catch. The purpose of the program was to reduce the number of vessels and permits endorsed for the operation of groundfish trawl gear in order to increase and stabilize economic revenues for vessels remaining in the groundfish fishery and conserve and manage depleted groundfish species. Vessels that participated in the buyback program were sold, scrapped, or converted to nonfishing purposes, and those vessels cannot be used for fishing again.

The impact of the trawl vessel buyback appears to have been positive in terms of exvessel revenue per vessel. Average trawl exvessel revenues generated by non-Pacific Hake groundfish increased from approximately $108,000 to $151,000 in the years 2003 to 2004 respectively even though total exvessel revenues for the fleet decreased from approximately $25,000,000 to $22,000,000 during the same period (Figure 7-1). Declining total bottom trawl revenues in 2005 resulted in a slight decline in average revenue per vessel compared to 2004.

The impact of the trawl vessel buyback differed by region. Some ports lost a disproportionate share of their trawl fleet, while others lost relatively few trawl vessels (Table 7-10). The number of trawl landings in the major trawl ports of Eureka, Crescent City, and Avila declined by 50 percent or more.

7.1.2.2.1 Landings and Revenues from Groundfish Trawl Vessels

Trawlers catch a wide range of species. By weight, the following species account for the bulk of landings (other than Pacific whiting): Dover sole, arrowtooth flounder, petrale sole, sablefish, thornyheads, and yellowtail rockfish. Management measures intended to reduce the directed and incidental catch of overfished rockfish and other depleted species have significantly reduced rockfish catches in recent years substantially below historical levels. Of the three states, landings and revenues by non-tribal trawlers are significantly larger than the other two states (Table 7-11)

By weight, the vast majority of trawl vessel groundfish is caught with midwater trawl gear. This is due to the fact that Pacific whiting is targeted with midwater trawl gear. In contrast, the majority of trawl exvessel revenues are attributed to the bottom trawl sector). (Table 7-12)

Limited entry trawlers take the vast majority of the groundfish harvest measured by weight but somewhat less if measured by value. In 2003, groundfish trawlers landed over 95% of total groundfish harvest by weight but only 64% by value (Table 7-13). The difference in trawl weight and revenue proportions is mostly due to the catch of Pacific whiting. Since whiting are caught almost exclusively by limited entry trawl vessels, they skew the overall value per unit weight calculations for this sector.

7.1.2.2.2 Distribution of Effort by Limited Entry Groundfish Trawl Vessels

Limited entry trawl vessels focus much of their effort on DTS species along the slope, flatfish species along the shelf, and Pacific whiting above the seafloor. Historically, much effort was focused on rockfish species, but recent regulatory requirements–such as RCAs and various cumulative limits - have curtailed rockfish opportunities to protect overfished stocks. In 2005, a specific small footrope trawl designed to avoid rockfish (the selective flatfish trawl) will work to further avoid the catch of rockfish along the shelf while increasing opportunities for flatfish north of 40º 10' latitude. Opportunities to harvest DTS and flatfish species–largely in the form of differential cumulative limits and RCAs–dictate the location of much of the trawl effort, though not all effort is dictated by regulation. Vessels differ in size and technical capacity. For example, small vessels may find it more difficult to fish during the winter months because of weather and other vessels may not have the capacity to fish in deep water where DTS species primarily reside. In other cases, some vessel captains may be more knowledgeable and more successful in certain areas. This knowledge would also influence the location and timing of effort by certain vessels. Furthermore, some species are known to migrate and aggregate during certain months of the year. For example, Petrale and Dover sole are known to aggregate for spawning during the winter months, and several types of flatfish are known to migrate onto the shelf during the summer months. Fishers may target the location of their efforts according to species aggregations and *the tendencies of certain fish species to migrate. Differences in knowledge, capital constraint, fish migration, and the regulatory environment can–in large part–affect the location and time of effort by commercial fishing vessels.*

Table7-14 shows the depth-based annual distribution of catch made by non-shrimp trawl vessels and Table 7-15 shows the monthly distribution of catch as recorded in trawl logbook data within PacFIN. These data include bottom trawl and midwater trawl gear.

By weight, because of the buyback program, some ports appear to have lost relatively more groundfish catch than other ports. Not surprisingly, those ports that lost relatively more trawl vessels also appear to have lost relatively more catch of groundfish (Table 7-16).

Trawl vessels make most of their landings in Oregon. Newport, Astoria, and Charleston (Coos Bay), Oregon make up three of the largest four ports for landed weight and exvessel revenue during the 2000–2003 period (Table 7-17). Westport and Ilwaco, WA, Eureka and Crescent City, CA, Brookings, OR, and Bellingham Bay and Neah Bay, WA comprise the remaining top 10 largest ports for trawl vessel landings.

7.1.2.3 At-Sea Limited Entry Sector

Participation

In addition to the shore-based limited entry trawl fishery, an at-sea limited entry trawl fishery exists off the coast of Washington, Oregon, and California. The high-volume at-sea fishery targets Pacific whiting with the use of midwater trawls. Pacific whiting commands a relatively low price per pound in the market place. The limited entry at-sea sector is made up of a catcher-processor fleet and a mothership/catcher vessel fleet. A catcher-processor participates in both catching and processing; a mothership engages only in the processing of a particular catch, and relies on catch made by catcher vessels. Many of the catcher vessels that deliver to the West Coast mothership sector may also fish as West Coast shore-based trawl vessels outside the Pacific whiting season; other catcher vessels fish in West Coast waters only during Pacific whiting fishery and return to North Pacific fisheries when the Pacific whiting season closes.

The catcher/processor sector is comprised of vessels that harvest and process whiting (the fleet has typically been 6 to 7 vessels since the formation of the Pacific Whiting Conservation Cooperative in 1997). The mothership sector is comprised of catcher vessels that harvest whiting for delivery to motherships (typically 3-5 motherships operate in the fishery, with one mothership also servicing the tribal fleet). Motherships are vessels that process, but do not harvest, whiting.

According to PacFIN data, the at-sea sector annually catches over 100 million pounds of Pacific whiting, as well as several hundred thousand pounds of other types of West Coast groundfish

Unfortunately, readily available data do not exist for estimating the value of at-sea
According to PacFIN data, the at-sea sector annually catches over 100 million pounds of Pacific whiting, as well as several hundred thousand pounds of other types of West Coast groundfish Harvests of non-whiting groundfish are largely composed of harvests of yellowtail rockfish, widow rockfish and rockfish that make up the category “minor rockfish north.”

Harvests and Revenue

Depending on the OY, at-sea harvests by non-tribal motherships and catcher processors have ranged since 1998 from 63,000 tons to the 128,000 tons harvested in 2005 (Table 7-18) worth $14 million (Table 7-19). The amount of non-whiting groundfish harvested by this fleet is quite small, often in the range of less than half of percent.

Distribution of Effort

The catcher-processor fleet and mothership fleet over recent years, typically harvests a major portion of their allocations in May and June. After June, most of the fleets moves on to fish off Alaska, and returns in late August or September where to fish the remainder of their allocations. During the summer months, a few catcher processors may remain to fish whiting.

Major Ports

As the majority of whiting harvested by the non-tribal at-sea fleet is processed into finished product and then transshipped at sea to foreign markets, there are no key at-sea ports, other than Seattle and Anacortes where the corporate headquarters for these companies are located.

7.1.2.4 Limited Entry Groundfish Fixed Gear Sector

Participation

Vessels deploying longlines and traps (pots) comprise the limited entry fixed gear sector. These gear types also may be used by vessels in the open access sector, but preferential harvest limits favor license holders. West Coast limited entry fixed gear vessels typically use longline and fish pots (traps) for catching groundfish. Groundfish longline activities involve anchoring a stationary line with multiple baited hooks attached to it (groundline) to the ocean floor. A buoy line attaches the groundline to a surface float, usually a buoy and pole. Fishermen leave the longline in the water for several hours to a day. The vessel returns to the gear, retrieves the buoy, and hauls the line to the surface to retrieve the gear and fish. Fish pots or traps used to harvest groundfish are generally square and have mesh or twine encompassing the exterior Fishermen drop baited traps to the bottom of the ocean connected to a surface pole or buoy with a vertical line. The fish enter the trap through a door, but cannot exit the trap unless they are small enough to escape through the mesh, or back out the door. These pots are retrieved by the vessel several hours after being set. Both longlines and fish pots can be set across diverse ocean bottom types, though longlines can get hooked on rocky areas or reefs, causing some gear loss. Limited entry fixed gear fishers typically use shore-based vessels that range in size from 30 feet to 65 feet in length, with some vessels exceeding 100 feet, and some as small as 23 feet (Table 7-21). Limited entry fixed gear vessels may also participate in open access fisheries or in the limited entry trawl fishery. Like the limited entry trawl fleet, limited entry fixed gear vessels deliver their catch to ports along the Washington, Oregon, and California coast.

This sector has been plagued by overcapacity, although a series of management initiatives have largely addressed the problem. In the early to mid 1990s the fishery was a "derby" managed by very short seasons of two weeks or less. Two Groundfish FMP amendments have helped to alleviate the symptoms of over capacity in the fixed gear sablefish fishery, effectively eliminating the short, derby season. Amendment 9 required a permit endorsement to participate in the primary sablefish fishery, and Amendment 14 introduced permit stacking. Permit stacking allows up to three sablefish-endorsed permits to be used per vessel. Through a tier system, landing limits vary with the number and type of permits held.

7.1.2.4.1 Landings and Revenue from Limited Entry Fixed Gear Vessels

Fixed gear vessels primarily target the high-value sablefish; this species accounts for a large share of landings, especially when measured by exvessel value. According to PacFIN data, the majority of limited entry fixed gear landings occur in Oregon and Washington. Oregon and Washington also have a higher price per pound for sablefish, while California has a higher price per pound for other types of groundfish. This is most likely representative of the higher amount of high valued live fish landings that occur in California, as opposed to Oregon and Washington (Table 7-22).

7.1.2.4.2 Distribution of Effort by Limited Entry Fixed Gear Vessels

Limited entry fixed gear vessels principally target sablefish, a species that tends to reside in relatively deep water (Table 7-23). The limited entry fixed gear sector is subject to rockfish conservation areas; however, the boundaries are somewhat different from those of the limited entry trawl sector. Fixed gear vessels are more prone than trawl vessels to catching some overfished rockfish species, such as yelloweye rockfish, and are therefore restricted from fishing on the continental shelf. Limited entry fixed gear vessels exert most of their effort during the late spring, summer, and early fall. The monthly distribution of effort has become more spread out over the year, and the number of vessels participating has declined as the tier system and permit stacking provisions were put in place in 1998 and 2001 respectively

Major Ports

Table 7-24 shows the top 15 ports (of the 62 receiving landings) for limited entry fixed gear landings and exvessel revenue from 2000–2003. The largest ports for limited entry fixed gear landings and exvessel revenue, located within Washington, Oregon, and northern California, differ only slightly in the order of landings by rate and of exvessel revenue. The top five ports for landings make up approximately 54% of total landings, while the top five ports for revenue make up approximately 49% of total exvessel revenues for limited entry fixed gear vessels.

7.1.2.5 Open Access Groundfish

7.1.2.5.1 The Groundfish Open Access Sector

The open access sector consists of vessels that do not hold a federal groundfish limited entry permit and target (Open Access Directed Fisheries) or incidentally (Open Access Incidental Fisheries) catch groundfish using a variety of gears. The open access appellation can be confusing because vessels in this sector may hold limited entry permits for other, nongroundfish fisheries issued by the federal or state governments. However, groundfish catches by these vessels are regulated under the groundfish

FMP. For example, open access vessels must comply with cumulative trip limits established for the open access sector and are subject to the other operational restrictions imposed in the regulations, including general exclusion from the RCA.

Open Access Directed Fisheries

Participation in the directed open access fishery segment varies between years. Participants may move into other, more profitable fisheries, or they may have taking time off from fishing, or they may quit fishing altogether. Fishers use various non-trawl gears to target particular groundfish species or species groups. Longline and hook-and-line gear are the most common open access gear types used by vessels directly targeting groundfish and is generally used to target sablefish, rockfish, and lingcod. Pot gear is used for targeting sablefish, thornyheads and rockfish. Though largely restricted from use under current regulations, in the past in Southern and Central California setnet gear was used to target rockfish, including chilipepper, widow rockfish, bocaccio, yellowtail rockfish, and olive rockfish, and to a lesser extent vermillion rockfish.

Within the directed open access fishery, fishers are further grouped into the “dead” and/or “live” fish fisheries. The terms dead and live fish fisheries refers to the state of the fish when it’s landed. The dead fish fishery has historically been the most common way to land fish. In 2001, the dead fish fishery made up 80% of the directed open access landings. However, more recently, the market value for live fish has resulted in increased landings in the live fish fishery. In 2001, 20% of fish landed (by weight, coastwide) by directed open access fishers was landed alive as compared to only 6% in 1996 {(PFMC 2004 PFMC 2004. Proposed Acceptable Biological Catch and Optimum Yield Specifications and Management Measures for 2005-2006 for the Pacific Coast Groundfish Fishery. Pacific Fishery Management Council, Portland, OR, August 2004)}.

In the live-fish fishery, groundfish are primarily caught with hook and line gear (rod-n-reel), with limited entry longline gear and with limited entry pot gear, and a variety of other hook gears (e.g. stick gear). The fish are kept alive in a seawater tank on board the vessel. California halibut and rockfish taken in gill and trammel nets have increasingly appeared in the live fish fishery {(CDFG 2001) CDFG. 2001. California Marine Living Resources: A Status Report, December 2001. Sacramento, California. (Available on-line: www.dfg.ca.gov/mrd/status)}.. Live fish are sold at a premium price to food fish markets and restaurants, primarily in Asian communities in California. Only limited information exists on the distribution of effort by open access vessels. Because the open access sector has an increasingly large live-fish fishery component with nearshore species making up most of the live fish landings, effort located near shore likely accounts for most live fish landings.

In California, hook and line gear for the live-fish fishery has been limited, since 1995, to a maximum of 150 hooks per vessel and 15 hooks per line within one mile of the mainline shore {(CDFG 2001) CDFG. 2001. California Marine Living Resources: A Status Report, December 2001. Sacramento, California. (Available on-line: www.dfg.ca.gov/mrd/status)}.. Traps are limited to 50 per fisherman. In Washington, it is illegal to possess live bottom fish taken under a commercial fishing license. In Oregon, nearshore rockfish and species such as cabezon and greenling are the primary target of the live fish fishery. Sablefish and rockfish are also landed alive in Oregon, and are managed under limits which count against the federally set limited-entry allocations. The Oregon live fish fishery occurs in waters of ten fathoms or less (18 m). Only legal gears are allowed to be used to catch nearshore live fish. In early 2002, an Oregon Development Fisheries Permit was required for fishermen landing live fish species (e.g. Cabezon, greenling (except kelp greenling), brown, gopher, copper, black and yellow, kelp, vermilion, and grass rockfish (among others), buffalo sculpin, Irish lords, and many surfperch species). However, commercial fishing for food fish is prohibited in Oregon bays and estuaries and within 600 feet (183 m) seaward of any jetty.

Participation

Many fishers catch groundfish incidentally when targeting other species, because of the kind of gear they use and the co-occurrence of target and groundfish species in a given area. Managers classify vessels as being in the open access incidental fishery if groundfish comprises 50% or less of their landings, measured by dollar value. These incidental open access fisheries may also account for substantial amounts of bycatch, especially for overfished groundfish species. Fisheries targeting pink shrimp, spot prawn, ridgeback prawn, California and Pacific halibut, Dungeness crab, salmon, sea cucumber, coastal pelagic species, California sheephead (California nearshore fishery), highly migratory species, and the mix of species caught in net fisheries comprise this incidental segment of the open access sector. These fisheries and associated target species are described below.

The open access groundfish fishery consists of many vessels that predominately fish for other non-groundfish species where they inadvertently catch and land groundfish. Because these incidental vessels do not necessarily depend on their revenue from the groundfish fishery as their major source of income, understanding the level of dependency that such participants have on the open access groundfish fishery must be considered in light of their overall fisheries revenues. Table 7-25 shows the number of open access vessels by vessel length and level of dependency on the groundfish fishery (proportion of annual revenue that is from groundfish). Between November 2000 and October 2001, 1,287 vessels landed groundfish in the open access sector of the groundfish fishery. Of these vessels, 771 vessels (60%) had a greater than 5% dependency on the groundfish fishery with 345 of these vessels having a 95-100% level of dependency of groundfish. The open access fishery is dominated by vessels under 40 feet in length. About 78 percent of the vessels that landed open access groundfish between November 2000 and October 2001 were less than 40 feet on length. It is assumed that a portion of these smaller vessels fish exclusively in state waters, and thus would be excluded from the VMS requirements. However, the data is not available to identify the proportion of vessels that fish only in state waters. Approximately 36 percent of the open access vessels had a greater than 65 percent dependency on groundfish, with 56 percent of the most dependent vessels having less than $5,000 in gross fishing income. A greater proportion of vessels with lower levels of dependency on groundfish fell within income categories greater than $5,000. However, increases in higher valued groundfish catch in 2003 (primarily sablefish) may reduce the proportion of open access vessels in the lowest (<$5,000) income category.

As discussed above, fishery managers divide the open access sector into directed and incidental categories. The directed fishery comprises vessels targeting groundfish while the incidental fishery category applies to vessels targeting other groundfish, but landing some groundfish in the process. However, it is difficult to segregate vessels into these two categories because the choice depends on the intention of the fisher. Over the course of a year or during a single trip, a fisher may engage in different strategies and they may switch between directed and incidental fishing categories. Such changes in strategy are likely the result of a variety of factors, including the potential economic return from landing a particular mix of species. Table 7-26 provides recent information on open access participants for the 2000- 2003 period and is taken from the VMS EA.

7.1.2.5.2 Landings and Revenue from Groundfish Open Access Vessels

Rockfish, thornyheads, and sablefish make up most of the open access landings and revenue and hook and line accounts for the largest gear type for open access landings (Table 7-27). Fixed gear catch most open access groundfish, although non-shrimp trawl gear and net gear also make substantial landings (Table 7-28). Open access landings in the state of California have a large live fish component, which is made evident by the relatively high unit value of rockfish in that state compared to the unit value of rockfish in Oregon and Washington.

7.1.2.5.3 Distribution of Effort by Groundfish Open Access Vessels

Limited information exists on the distribution of effort by open access vessels. The open access sector is made up of many different gear types, along with directed and incidental catch, which makes it difficult to discern the location of effort, though based on the diversity of this sector, it is reasonable to assume that effort is widespread across the West Coast. The open access sector has an increasing large live-fish fishery component; because nearshore species make up most of the live fish landings, effort located near shore likely accounts for most live fish landings. The live fish fishery is a quickly growing component of the open access sector and will likely continue to grow in the nearshore areas.

As shown in Table 7-29, open access landings and revenue tend to occur primarily during the spring, summer, and fall months. Assuming that landed catch represents directed open access, and that landed catch is a function of effort, then more open access related fishing activity occurs during the spring, summer, and fall months than winter months.

Fishing Communities

Table 7-30 shows that the top open access ports are Moss Landing, Port Orford, Morrow Bay, Fort Bragg and Gold Beach.

7.1.2. 6 Tribal Fisheries

7.1.2.6.1 The Tribal Fisheries Sector

West Coast treaty tribes in Washington have formal groundfish allocations for sablefish, black rockfish, and Pacific whiting. Members of four coastal treaty tribes participate in commercial, ceremonial, and subsistence fisheries off the Washington coast. Participants in the tribal commercial fisheries use similar gear to non-tribal fishers. Fish caught in the tribal commercial fishery are distributed through the same markets as non-tribal commercial catch.

Participation

Tribal treaty fisheries are place-oriented—limited to the adjudicated U&A areas. This results in immobile fisheries that cannot move to a new location if the resources or habitat are depleted. In addition, the Tribe and its fishermen have a view of ownership of their fishing grounds rooted in centuries of use and control of these grounds. This sense of ownership influences the fishing practices of the tribes and these practices are used by the tribes to develop tribal rules and regulations to stay within the harvest limits established by the council for overfished and abundant stocks. Tribal fisheries take several species for which they have no formal allocations, and some species for which no specific allocation has been determined (7-31). Rather than try to reserve specific allocations of these species, the tribes biennially recommend trip limits for some species to the Council, which tries to accommodate these fisheries.

Groundfish fishing by the tribes occurs primarily with hook and line and trawl (7-32). All tribes participating in groundfish fisheries have longline vessels in their fleets, but as discussed below only the Makah has trawlers; and only the Makah has participated in the Pacific whiting fishery. Makah has the majority of longline vessels, followed by Quinault, Quileute, and Hoh. Since 1996, a portion of the U.S. whiting OY has been allocated to the West Coast treaty tribes. The tribal allocation is subtracted from the whiting OY before allocation to the non-tribal sectors. Since 1999, the tribal allocation has been based on a sliding scale related to the U.S. whiting OY. To date, only the Makah tribe has fished on the tribal whiting allocation. Makah vessels fish with mid-water trawl gear have also been targeting widow rockfish and yellowtail rockfish in recent years.

As the Makah Tribe has the largest tribal fleet, what follows is a detailed description of Makah groundfish fisheries and management practices. Currently, the Makah fleet is composed of 43 boats, an increase of two vessels from 2004 (Table 7-35). Twenty-nine of the boats fish for salmon, sablefish, and halibut. These boats primarily fish from March to October. Ten of the boats are small bottom trawlers. The trawl fishery is open from January to December, but primarily the fishing is done from June to October. The mid-water whiting fleet is composed of 4 mid-water trawlers who deliver to shoreside plants and to two at-sea motherships one of which also participates in the non-tribal mothership whiting fishery. Their season is from May to September. Full retention of rockfish bycatch is required (as is the case in all Makah groundfish fisheries); the bycatch is processed for human consumption and forfeited to the Tribe for distribution to food banks and similar programs. This program avoided wastage and discards of bycatch species, created a disincentive to both the catcher vessels and processor and provides full accounting of bycatch in the fishery. This in turn has reduced bycatch levels of nearly all species.

In the Makah bottom trawl fishery, the Tribe adopted the small foot rope restrictions as a means to reduce rockfish bycatch and avoid areas where higher incidences of rockfish occur. In addition, the bottom trawl fishery is limited by overall foot rope length as a means of conducting a more controlled fishery. Harvest is restricted by time and area to focus on harvestable species while avoiding bycatch of other species. If bycatch of rockfish is above a set limit, the fishery is modified to stay within the bycatch limit. The midwater trawl fishery has similar control measures. A trawl area must first be tested to determine the incidence of overfished rockfish species prior to opening the area to harvest. Vessels are provided guidelines for fishing techniques and operation of their net. Fishing effort is closely monitored by the on-board observer and harvest manager and changes or restrictions are implemented as needed to stay within the bycatch limits. Full retention of rockfish bycatch is required (as is the case in all Makah groundfish fisheries); the bycatch is processed for human consumption and forfeited to the Tribe for distribution to food banks and similar programs. This program avoided wastage and discards of bycatch species, created a disincentive to both the catcher vessels and processor and provides full accounting of bycatch in the fishery. This in turn has reduced bycatch levels of nearly all species. In developing these trawl fisheries, the Makah management practices include testing of gear, area, vessels, and catch composition before the fishery can proceed from one level to the next. In addition, a new or developing fishery must show that it can be conducted in a manner that protects existing fisheries.

Tribal Harvests and Revenues

Tables 7-33 and 7-34 shows recorded landings of groundfish species by treaty tribes from 1995 to 2003as developed by the Northwest Indian Fisheries Commission {Rob Jones, personal communication to John Devore May 18?DVB?-}. Since 1996, Pacific whiting have comprised the vast bulk of tribal landings, even though in 2000 and 2001 whiting landings were relatively low due to reduced coastwide allocations. As shown in Table 7-34, in addition to increases in Pacific whiting harvests, there has been a growth in tribal landings of flatfish and rockfish to bring total tribal groundfish revenues to a level of $7.5 million in 2005.

Distribution of Effort

The bulk of tribal groundfish landings occur during the March through April Pacific halibut and sablefish fisheries. Most continental shelf species taken in the tribal groundfish fisheries are taken during the halibut fisheries, and most slope species are similarly taken during the tribal sablefish fisheries. Approximately one-third of the tribal sablefish allocation is taken during an open competition fishery, in which vessels from the four tribes on the Washington coast have access to this portion of the overall tribal sablefish allocation. The open competition portion of the allocation tends to be taken during the same period as the major tribal commercial halibut fisheries in March and April. The remaining two-thirds of the tribal sablefish allocation is split between the tribes according to a mutually agreed-upon allocation scheme. Specific sablefish allocations are managed by the individual tribes. The fishery begins in March and goes until some time in the autumn, depending on the number of vessels participating in the fishery. Participants in the halibut and sablefish fisheries tend to use hook-and-line gear, as required by the IPHC. For equity reasons, the tribes have agreed to also use snap-line gear in the fully competitive halibut and sablefish fisheries. So a vessel that participated in a fully competitive sablefish fishery, but that did not land any halibut (and therefore was not subject to IPHC requirements), would still be required by tribal regulations to use snap-line gear.

Major Ports

Table 7-35 shows the distribution of vessels engaged in Tribal groundfish fisheries by major port. These ports are Westport, Neah Bay, and La Push.

7.1.3 Recreational Fisheries

In 2004, there was a major change in how recreational statistics are collected for West Coast fisheries, especially for the collection of statistics on California recreational anglers as the methodologies employed under the Marine Recreational Fisheries Statistics Survey (MRFSS) were replaced by those of a California Recreational Fisheries Survey. The California Recreational Fisheries Survey (CRFS) is the new method for estimating total marine recreational finfish catch and effort in California. The CRFS is a coordinated sampling survey designed to gather catch and effort data from anglers in all modes of marine recreational finfish fishing. This program incorporates and updates the comprehensive sampling methodologies of the former Marine Recreational Fisheries Statistics Survey (MRFSS) and the California Department of Fish and Game's (CDFG) Ocean Salmon Project. This program was fully implemented state-wide in January 2004.

The direct comparability of pre-2004 data with data collected under the new system is still being evaluated. So the discussion below replicates the discussion of recreational fisheries and 1996-2003 trends found in: Pacific Fishery Management Council. 2004. Acceptable Biological Catch and Optimum Yield Specifications and Management Measures for the 2005-2006 West Coast Groundfish Fishery Final Environmental Impact Statement as it is still the best available overview of West Coast recreational fisheries. This discussion is then followed by presentation of 2004-2005 recreational data provided by the States through the Council's Groundfish Management Team process. The California estimates reported below are still under review for there are indications that the preliminary data provided significantly underestimate charterboat effort. However, it is believed that when better estimates are corrected, the results will not alter the relative ranking of economic consequences of the alternatives.

Participation

Demand for recreational trips and estimates of the economic impacts resulting from recreational fishing are related to numbers of anglers. In the U.S., over nine million anglers took part in 76 million marine recreational fishing trips in 2000. The West Coast accounted for about 22% of these participants and 12% of trips. 70% of West Coast trips were made off California, 19% off Washington, and 11% from Oregon {Gentner 2001}.

Recreational fishing is an important economic contributor to the west coast in general, and to some communities specifically. The recreational fishing sector can be divided into two groups; the charter fleet and the private fleet. The private fleet is typically made up of vessels owned by residents living in or near areas where they fish. The charter fleet is a for-hire fleet that plays a large role in the tourism sector of many west coast communities, and opportunities to fish on a charter vessel can be a substantial draw for tourists considering a visit to the coast.

The distribution of resident and non-resident ocean anglers among the West Coast states in 2000, 2001, and 2002 demonstrates the importance of recreational fishing, especially in Southern California (Table 7-36). Southern California has more than twice the number of resident recreational marine anglers than the next most numerous region, Washington State. While most of the recreational anglers were residents of those states where they fished, a significant share was also non-residents. Oregon had the largest share of non-resident ocean anglers in all three years.

In terms of vessels, about 750 charterboats make up the charterboat fleet (Table 7-37); estimates of private boats are unavailable. In terms of proportion, Table7-38 shows the distribution of trips by boat mode and region in 2003. Approximately 80% of the trips taken are from private vessels. Almost 90 percent of all trips taken and half of the charter vessel trips are associated with California.

Recreational fishing in the open ocean has generally been declining slightly since 1996 (Table 7-39); however, charter effort has decreased while private effort increased during that period. Part of this increase likely resulted from longer salmon seasons associated with increased abundance. Some effort shift from salmon to groundfish for example likely occurred prior to 1996 when salmon seasons were shortened.

Distribution of Effort

Fishing effort is related to weather, with relatively more effort occurring in the milder months of summer, and relatively less in winter (Table7-38). As might be expected, this effect is more pronounced in higher latitudes, although the reasons include opportunity as well as climate. Salmon seasons are longer in California than in Oregon, which in turn are longer than in Washington. Until recently, groundfish seasons were also more restrictive in Washington, with the lingcod season being closed from November through March.

7.1.3.1 2004-2005 State Recreational Estimates

Through the Pacific Fishery Management Council’s Groundfish Management Team process, total angler trips by mode and by target were developed by each of the States for years 2004 and 2005. In terms of total trips, there was a decline from 1.6 million trips to 1.2 million trips, with all states and modes in decline, particularly the California charter boat mode. (As indicated above, these latter estimates may be underestimates.)

The following estimates of trips where groundfish was a target was provided through the GMT process (Table 7-41). Unlike the total anger trips, total groundfish trips increased by 20 percent in 2005 over 2004. Except for Coos Bay which showed a decline in charter boat trips, this pattern is consistent across all states, areas and ports, and by mode. These estimates suggest that anywhere from 25% (2004) to 40% (2005) of West Coast angler trips are trips targeted on groundfish. It should be noted that groundfish are caught incidentally when other species, such as salmon, are targeted. While the contribution of groundfish catches to the overall incentive to engage in a recreational fishing trip is uncertain, it seems likely that the possibility or frequency of groundfish catch on a trip adds to overall enjoyment and perceived value of the trip.

7.1.4 Buyers, Processors, and Seafood Markets

7.1.4.1 Processors and Buyers

Excluding Pacific whiting delivered to at-sea processors, vessels participating in Pacific groundfish fisheries deliver to shore-based processors within Washington, Oregon, and California. Buyers are located along the entire coast; however, processing capacity has been consolidating in recent years. Several companies have left the West Coast or have chosen to quit the business entirely. Remaining companies have purchased some former plants {Research Group 2003}, but other plants have remained inactive. This has led to trucking groundfish from certain ports to another community for processing. Therefore, landings do not necessarily indicate processing activity in those communities. However, examination of the species composition of landed catch by state can lead to inferences of some processor characteristics.

According to PacFIN data, in 2002 Oregon had the largest amount of groundfish landings (56%), followed by Washington (28%), and California (16%). In contrast, Oregon has the largest amount of exvessel revenue (40%), followed by California (32%) and Washington (22%), respectively. Oregon accounts for the majority of Pacific whiting landings, which creates a large difference between the percentage of landed catch and exvessel revenue because Pacific whiting has a relatively low price per pound. The relatively high amount of Pacific whiting being landed in Oregon may create a case where many processors must generate capacity to handle large quantities at a time. Groundfish processors in Washington may receive landings from Alaska fisheries. Depending on the amount of catch Washington processors can draw from Alaska fisheries, some groundfish processors may require the capacity to process large amounts of product. California processors concentrating on West Coast fisheries may focus on relatively smaller throughput of groundfish.

The seafood distribution chain begins with deliveries by the harvesters (exvessel landings) to the shoreside networks of buyers and processors, and includes the linkage between buyers and processors and seafood markets. In addition to shoreside activities, processing of certain species (e.g., Pacific whiting) also occurs offshore on factory ships.

According to data from the Bureau of Labor Statistics, the number of seafood processing establishments along the west coast has declined in recent years. Further examination of PacFIN data shows the number of companies buying groundfish along the West Coast has also generally declined in recent years. When buyers are classified on a species basis—How many buyers purchased groundfish—we can see slight evidence of a decline in California and Washington (Table 7-42). When buyers are classified on a groundfish gear basis—how many buyers purchased sablefish from fixed gear-sablefish fishermen---evidence of decline is stronger (Table 7-43). Because of the multi-species basis of most buyers it is hard to develop unique counts of buyers by either of these two methods on a state basis. However, the total number of buyers from all fisheries can be uniquely determined. In California, the number of unique buyers in 2005 is estimated to be 465, a decrease of 21 percent from 2004. The number of Oregon buyers fell by 10% and the number of Washington buyers fell by 8% over the same time period.

7.1.4.1.1 Processing Companies Purchasing Groundfish

In terms of quantity, the processing of west coast groundfish is dominated by a small number of companies. For this section, an estimate of unique groundfish companies was derived by grouping PacFIN information on groundfish buyers. Buyers with like names were assumed to be individual companies. For example, a hypothetical buyer with the name ZZZ seafood – Astoria was assumed to belong to the same company as a buyer with the name ZZZ seafood – Ilwaco. Using this approach, the results show that the three largest companies bought approximately 78% of commercially caught groundfish landed on the west coast in the years 2004 and 2005 (Table 7-44, Figure 7-2). When a similar analysis is done based on ex-vessel revenues, the top three companies purchase about 56% of the groundfish sold. (For more accurate estimates, analysts would have to compile lists of affiliated companies and then map them to the PacFIN buyer codes. In addition, estimates of fish purchased by non-affiliated buyers and sold to a company for processing would also have to be developed.)

Supportive of this analysis is a description of the top 10 Seafood suppliers in the United States according to Seafood Business (May 2006); three of which participate in Pacific Groundfish Fisheries. Their corporate strategies affect the Pacific Groundfish fishery. Employment and location of facilities will vary as companies pursue profits, market share, and efficiencies. For example, the build up of Arctic Alaska Company (an Alaska based company who built a surimi plant and fish meal plant in Newport Oregon while bring down catcher processors from Alaska to fish whiting, its eventual sale to Tysons (a major poultry company who wanted to add seafood to its product line), and the selling out of Tyson's fishing business assets (including the shoreside surimi and fish meal plants, and several catcher-processors) to companies like Trident (who before the purchase had little involvement in Pacific groundfish) has indirectly reshaped the Pacific groundfish fishery. Below are the Seafood Business descriptions of Pacific Seafood Group (a shorebased company), Trident Seafoods Corporation (shorebased and at-sea), and American Seafoods Group (at-sea).

> Pacific Seafood Group #1 Sales-$874 million—Key Species: Dungeness crab, halibut, king crab, Pollock, salmon, shrimp. "With 2005 sales of $874 million, Pacific Seafood Group slid into the No. 1 spot on the Seafood Business Top 25 list for the first time this year. After an active 2003 and 2004, Pacific wasn't involved in any acquisitions or mergers last year or early this year. Instead the company grew organically, picking up new customers and increasing sales by approximately $174 million from 2004 to 2005. In 2004, Pacific acquired Seacliff Seafoods, a distributor with facilities in Houston, San Antonio and Wilmington, California. In 2003, the company purchased Starfish, a Bellevue Washington seafood processor and distributor and Craig & Hamiliton, a Stockton, California value-added meat processor. Now Pacific operates 15 processing facilities along the West Coast and 10 distribution facilities in Washington, Oregon, California, Idaho, Montana, Nevada and Utah."
>
> Trident Seafood Corporations #3-Sales-$800 million—Key Species: cod, halibut, whiting, Pollock, king crab, salmon, snow crab. "Trident Seafoods Corp. has been busy growing over the past two months. In March, the company acquired Louis Kemp Seafood, which markets the No. 1 retail surimi-seafood brand, from Con-Agra Foods one of the nation's largest public conglomerates….Then, in April, Trident purchased Ocean Beauty Seafoods' seven Alaska processing facilities and merged its distribution and smoked-fish business with its Seattle rival. The acquisition of Louis Kemp and the deal with Ocean Beauty will surely push Trident's 2006 sales over the $1 billion mark. Trident's prior major acquisition occurred in 2004 when it bought Norquest Seafoods of Seattle and its Portlock and Silver Lining brands. Trident operates 25 fishing vessels and at-sea processors and 18 processing plants throughout Alaska, British Columbia, Washington and Oregon." (Note—In early May 2006 the proposed purchase of Ocean Beauty Seafoods was called off.)
>
> American Seafoods Group #10-Sales $514 million. Key species: catfish, cod, hake, Pollock, scallops, yellowfin sole. "In February, Centre Partners Management sold its remaining 23 percent equity interest in American Seafoods Group to Coastal Villages Region Fund and a management group led by Chairman Berndt Bodal, increasing their ownership to 45 percent and 51 percent respectively of the company's voting equity. The buyers dished out nearly $82 million for the balance of Centre Partners' stake. Centre Partners is the New York investment Group that formed American Seafoods Group with Bodal in 2000, acquiring American Seafoods Co. and Frionor USA's New Bedford, Mass., processing facility from Norway Seafoods. The purchase came two years after the adoption of the American Fisheries Act, which forced many foreign owned fishing fleets out of U.S. waters. American Seafoods expanded in 2002 when it bought Southern Pride Catfish of Greensboro, Ala. Two years later, the company ditched a year and-a-half-long bid for an initial public offering.

7.1.4.1.2 Processing Labor, Processing Capital and the Groundfish Fishery

Processing Labor

Employment and wage information from the Bureau of Labor Statistics shows that seafood processing along the west coast generates approximately \$380 to \$420 million dollars in the form of wages annually to seafood product preparation and packaging employees, and in most years this sector employs over 10,000 workers (Table 7-45). The largest state in terms of processing wages and employees is Washington state, followed by California, and Oregon respectively. Washington benefits from the large degree of participation in Alaska-based fisheries which make up a substantial portion of nationwide catch, while processing in Oregon and California is dominated by catch occurring in west coast fisheries.

In support of this EIS, the Report: “Trends in Fishing and Seafood Processing Related Employment Statistics” which is attached, was developed in an attempt to mine all available federal data on seafood processing and on employment (Attachment 7-1). Its conclusions also support the analysis above. This report also has shed some light on seasonality of employment, age and gender of seafood workers. For the seafood processing industry, the 35-44 age group is the predominant workforce in al three states with this category representing 30-35%.of workers employed. The next largest group is the 45-54 age group. The gender distribution of employees in the seafood processing industry differs across states. California is the most evenly distributed with some counties where female employees outnumber males. In Oregon and Washington males workers are the majority with ~ 60 and 70% respectively.

Processing labor can be generally divided into two types; specialized labor and unspecialized labor. Unspecialized labor is characterized as workers that can easily transition their skills to other industries and employers. For example, a forklift driver could be characterized as an employee within the unspecialized labor category. That worker can easily transition between a seafood processing employer and another employer that may be involved in office supplies for example. Specialized workers are those workers that have a particular skill set which is not easily converted to other industries. Workers in this category include those that fillet fish. Filleting is a skill that is specific to the seafood industry.

Workers within the unspecialized category are typically in higher supply and are relatively easy to hire if there happens to be a shortage of workers in that category. These workers require less training than specialized workers and new laborers in the unspecialized category are unlikely to negatively impact productivity for any given amount of time. Specialized workers on the other hand are relatively short in supply, and if there is a shortage of workers in this category, newly hired specialized labor is likely to require training and will have relatively low productivity in the early stages of their career. In the seafood processing industry, many laborers are transient and their employment is often temporary in nature due to the cyclical nature of fisheries. However, processors are more likely to try to retain specialized laborers on a year round basis as re-hiring and re-training new workers in the specialized category will reduce productivity. This makes the groundfish fishery one of the most important fisheries for many seafood processors.

According to the PFMC Groundfish FMP, the Council attempts to manage the groundfish fishery on a year-round basis. This year round nature of the fishery is important to those processors that try to keep specialized labor employed on a year round basis. A year round fishery keeps product volume flowing through the plants, gives the fish filleters product to process, and ultimately keeps specialized laborers employed. Without a year round fishery, these laborers often find work elsewhere and this negatively affects processing revenue and product quality. Other fisheries are typically not managed on a year round basis because of several reasons including availability (salmon and albacore for example) and seasonal quality of the harvested species (Dungeness crab for example). Groundfish on the other hand can be available to fishers and marketable by processors on a year round basis.

Figure 7-3 depicts the monthly purchases by major buyers of groundfish—each line is a buyer. The lines reflect the percent of total purchases by the buyer that are comprised of groundfish. From this graph, it can be determined that there isn't a single month where there is not at least one major buyer that isn't making a major purchase of groundfish.

Processing Capital

Unlike many forms of processing labor, the capital involved in fish processing is not easily substitutable for use in other industries. Capital tends to be fixed in its location and designed to handle fish products as opposed to some other type of food product. A processing facility is constructed to handle seafood and produce some output product that may be fillets, surimi, head and gutted fish, or some combination of products. The size of these facilities is typically constructed around some expectation of what the future holds-in terms of quantity-for commercial fisheries landings.

Many fisheries are characterized by swings in available product due to seasonality and year to year fluctuations in species abundance. This means that during the off-season, or years when there are declines in species abundance, processor capital is idle. Groundfish (outside of Pacific whiting) was historically one of the more stable fisheries on the west coast, and is a fishery that is prosecuted on a year round basis. This sense of stability combined with an expectation of year round landings historically gave managers of processing plants some increased degree of certainty when planning for the future and investing in capital in an otherwise highly variable and uncertain industry. The recent decline in landings of traditional groundfish species has eliminated much of that certainty and meant that increasing amounts of processing capital have been left idle. Idle capital increases the cost of producing a unit of output, so naturally, some plants reliant on groundfish have closed down and consolidation has occurred within portions of the processing industry {The Research Group. 2003}. This is verified by the decrease in number of processing establishments over the past several years as reported by the Bureau of Labor Statistics (7-45).

7.1.4.2 Markets and Prices

Much of this discussion will be updated after the Council Meeting. Updated or revised sections are marked with a "*". Unless otherwise noted discussion below is taken from the 2005-2006 Groundfish Specifications EIS.

7.1.4.2.1 Live Fish Markets

An important and growing share of groundfish harvest is delivered live. These deliveries help feed the growing trade in live seafood consumed in restaurants. Groundfish delivered live were primarily nearshore rockfish and perch, but also included thornyheads, sablefish and lingcod. About 86% of live fish landings were in California with the remainder in Oregon {PFMC 2004b}. There were no recorded live fish landings in Washington. Significantly higher exvessel price was paid for live product. The coastwide average price for live product was nearly four dollars per pound, compared with under one dollar for other deliveries of the same species.

7.1.4.2.2 West Coast Groundfish and the World Market

West Coast groundfish compete in a global market, not only with similar species produced in other regions of the world, but also with other fish species such as salmon and tuna. In addition, fish compete with other sources of protein in consumers' budgets. More than 4.7 million mt of fish and other seafood were landed in the U.S. in 2000, approximately the same amount landed in each of the prior two years (DOC 2001). West Coast groundfish contributed about 0.14 million mt, 0.13 million mt, and 0.12 million mt to this total in 1998, 1999 and 2000, respectively. Pacific whiting, a relatively abundant but low price species, comprises about two-thirds of West Coast groundfish landings by weight, but only around 10% of groundfish exvessel revenue.

Production of farm-raised fish has increased rapidly in recent years. In 2000, more than 0.4 million mt of cultured fishery products were produced in the U.S., and more than 45 million mt were raised worldwide. Salmon aquaculture demonstrates the emerging importance of farmed species. While commercial salmon harvest is still near the 1980 to 1997 annual average, world salmon supply has tripled since 1980 due to a nine-fold increase in farmed salmon to 1.5 million mt in 2000.

An objective of groundfish management has been to spread harvest of the annual OY over as much of the year as possible. Consequently, groundfish harvesting occurs in every month, although beginning in the late 1990s, it took on increased importance during the summer months when sablefish harvest peaked during the primary limited entry fixed gear fishery. The bulk of whiting fishery also occurs during the summer.

Groundfish have historically provided West Coast commercial fisheries participants with a relatively steady source of income over the year, supplementing the other more seasonal fisheries. Although groundfish contributed only about 17% of total annual exvessel revenue in 2000, seasonally groundfish played a more significant role, providing one-fifth to one-third of monthly exvessel revenue coastwide during April and the three summer months. The peak value contribution by the groundfish fishery in 2000 was sablefish during August (20% of exvessel revenue). Flatfish harvest supplied between 3% and 9% of monthly exvessel revenue throughout the year, and rockfish contributed an additional 2.5% to 6.8% to monthly exvessel revenue. For northern parts of the coast, groundfish is particularly important just before the start of the December crab fishery.

7.1.4.2.3 Exvessel and Fuel Prices*

Table 7-46 lists ex-vessel prices for several west coast species, total groundfish excluding whiting, fuel, and estimates of bottom trawl revenue per hour fished for the period 1999-2005. The period was chosen based on available fuel prices collected by the PSMFC. All prices are averages except the fuel price. Fuel prices are June prices as reported by Newport Oregon fuel docks. The trends in these prices give the following perspectives:

Whiting—prices appear to range very little from year to year
Flatfish—prices declined in 2004 and 2005 but not to the 1999 level,
Rockfish—After a major increase in 2004, price fell significantly in 2005
Total Groundfish—prices in 2004 and 2005 similar but not as low as 1999.
Bottom trawl Revenue per hour—Increased significantly in 2003 and 2004. 2004 increase may be due to the buyback as fleet reduced by 1/3.
Fuel—2004 and 2005 fuel prices significantly higher while total groundfish prices declined

The implications from there trends are that all sectors are facing rising fuel prices; and, some sectors, particularly the bottom trawl sector may also be facing declining ex-vessel prices.

7.1.4.2.4 Exprocessor and Wholesale Prices

While producer prices for groundfish products have not fared quite as badly as for other frozen fish (including salmon), they still are significantly below recent highs. The trend may be flat or still lower in the future {(2005-2006 EIS, Appendix A Table7-9)}. Increasing production of farmed salmon is partly responsible for a continuing slump in salmon commodity prices. Producer prices for meat products in general have been relatively weak, thereby helping to hold down prices for competitive fish protein. Preliminary 2003 estimates of producer price indices for fish and meat products were higher than seen in recent years, possibly due to the continuing improvement in the world economic outlook.

7.1.4.2.5 Trade and Domestic Demand

Most West Coast groundfish compete in the fresh and frozen fish product markets. In 2000 the U.S. imported 1.8 million mt of edible fishery products, including 1.5 million mt of edible fresh and frozen fish products. In 2000 the U.S. exported about one million mt of edible fishery products, including 190,000 mt of edible, fresh or frozen flatfish and groundfish products. One third of edible fishery exports were to Japan. While surimi was the single largest component of total fresh and frozen exports by weight, salmon was the most valuable export, generating $353 million on the 100,000 mt of fresh and frozen product shipped, and another $146 million from exports of canned product. Asia was the largest export region, absorbing 61% of U.S. fishery exports by volume. Japan alone bought 34% of total fishery exports, and South Korea and China took 11% and 10%, respectively {2005-06 EIS, Appendix A Section 7.1}.

From 1910 through the early 1970s, annual per-capita fish consumption in the U.S. generally ran between 10 pounds and 12 pounds edible weight. Beginning in the early 1970s, per-capita consumption increased, and in the mid 1980s began shifting upward again to the 15-pound to 16-pound range where it has generally remained since 1985. In 2000 annual per-capita U.S. fish consumption was estimated to be 15.2 pounds. U.S, Seafood Consumption reached a record 16.6 pounds per capita in 2004.

7.1.4.2.6 Market and Non-market Consumer Goods

For goods exchanged in markets where a consumer price can be determined (for example seafood), price and quantity information can be used to estimate the benefits consumers derive from consumption activities. A given regulatory action may have little or no impact on consumers if changes in the quantity of fish available are insufficient to have an effect on prices. This is especially true if imports or other protein substitutes are readily available. In the market for recreational experiences, individuals pay fees to participate in recreational fishing trips on charterboats. Price and quantity information from these trips might allow estimation of the benefits participants derive from this type recreational fishing. However, charter trips may often be purchased as part of a bundle of goods and services that include nonfishing recreational activities. Therefore, the estimation of benefits from recreational charter activities is less straightforward than for marketed consumer goods.

For other consumer goods, especially bundles of goods and services such as a recreational fishing trip taken on a private vessel, the prices and quantities associated with each transaction are much more difficult to determine. For the private recreationalist, the amount spent on fishing gear, licenses, and other goods necessary to carry out a particular fishing trip is difficult to isolate. The term "private" is used here to designate a recreational fisher fishing from a private vessel, the shore, bank or a public pier, as opposed to using a charter vessel. Depending on the value a particular individual places on alternatives to fishing, the maximum benefit associated with a fishing trip may far exceed actual trip expenditures.

7.1.4.3 Consumptive versus Nonconsumptive Activities

The sectors benefiting from a resource can generally be placed into one of three groups: consumptive users (e.g., recreational fishers, commercial harvesters, and processors), nonconsumptive users (e.g., wildlife viewers), and nonusers (e.g., members of the general public who derive value from knowing that a species is being maintained at a healthy biomass level). The following table displays the general relationship between use/non-use and consumptive/nonconsumptive types of activities.

Relationship between Use/Nonuse and Consumptive/Nonconsumptive Activities

	Consumptive	Nonconsumptive
Use	Commercial and Recreational Fishing, Processing.	Wildlife Viewing
Nonuse	N/A	Existence Value, Options Value, Bequeathal Value

In economic terms, renewable resource management entails a fundamental tradeoff between current and future costs and benefits. When management needs call for a substantial reduction in allowable harvests, additional costs may be born by the direct consumptive users, who may be left with much smaller harvests than they had been accustomed to. While this near-term sacrifice may create much greater harvest opportunities in the future once the stock has been replenished—depending on the duration of the rebuilding period—many fishers and processors may be unable to weather a long down period, opting instead to go out of business.

Nonconsumptive users may benefit from the use and nonuse values provided by the resource. Wildlife viewing and the derivation of secondary benefits from ecosystem services are examples of non-consumptive use values. One or more of the following nonuse benefits may accrue from the preservation of fish stocks at higher levels of abundance: (1) existence value derived from knowing a fish population or ecosystem is protected without intent to harvest the resource; (2) option value placed on knowing a fish population, habitat, or ecosystem has been protected and is available for use, regardless of whether the resources are actually used; and (3) bequeathal value placed on knowing a fish population, habitat, or ecosystem is protected for the benefit of future generations. Offsite nonconsumptive uses of resources are public in nature in that no one is excluded from deriving the identified benefits, and one person's enjoyment does not affect another's potential benefit.

The existence of coastal fishing communities in themselves may have intrinsic social value. For example, the Newport Beach (California) dory fishing fleet, founded in 1891, is a historical landmark designated by the Newport Beach Historical Society. The city grants the dory fleet use of the public beach in return for the business and tourism this unique fishery generates.

Value may also be placed on biological diversity. The value of biological diversity may be part of the total value placed on a site by nonconsumptive users (onsite or offsite). Three levels of biological diversity have been identified, (1) genetic diversity within a species, (2) species diversity (richness, abundance, and taxonomic diversity), and (3) ecosystem diversity. Ecosystem diversity encompasses the variety of habitats, biotic communities, and ecological processes (Caribbean Fishery Management Council 1998). Healthy ecosystems characterized by high biological diversity are generally able to provide a wider range of ecosystem services than are available from damaged or less diverse ecological communities. Examples of such ecosystem services include the nutrient recycling and filtering capabilities of wetlands, and the CO_2 sequestration function provided by the ocean (which is an important carbon sink).

The total societal value placed on offsite nonconsumptive use of a stock or component of the ecosystem will also depend on: (1) the size of the human population, (2) the level of income, (3) education levels, and (4) environmental perceptions and preferences (Caribbean Fishery Management Council 1998).

The above relationships imply that as human populations and the affluence of those populations increase, and as fish stocks and their ecosystems are depleted, nonconsumptive values associated with maintaining ocean resources are likely to increase. Another implication of these relationships is that once the basic integrity of ecosystem processes and marine fisheries components are preserved, the likely additional benefit from incremental increases biomass will decrease.

Non-Consumptive Users

7.1.5 Fishing Communities

Figure 7-4 and Table 7-47 are provide to the reader as aids in for reviewing references to ports, communities, counties, and recreational areas.

The Magnuson Stevens Act requires among other things that the time period for rebuilding an overfished species "be as short as possible, taking into account the status and biology of any overfished stocks of fish, the needs of fishing communities, recommendations by international organizations in which the United States participates, and the interaction of the overfished stock within the marine ecosystem;…"

7.1.5.1 Community Descriptions

Many documents were used to develop the discussion found in this section. For more detail on the relationship of bycatch species to fisheries sector, port and community, the reader is directed to the attached: "Economic Revenue and Distributional Impacts Associated with Overfished Species Management in West Coast Commercial Groundfish Fisheries" In addition the reader is directed to Tables 7-4a and 7-4b. For additional reference, Section 8.1.6 of the 2005-2006 EIS and its associated Chapter 8 of Appendix-A contains information on fishing communities as well. For a much more expansive discussion of fishing communities, the reader is referred to the NMFS Northwest Fisheries Science Center website where detailed descriptions of fishing communities: http://www.nwfsc.noaa.gov/research/divisions/sd/communityprofiles/index.cfm. The reader is also referred to the Environmental Justice discussion found below, which contains a discussion of identifying communities of concern with respect to minority and low income populations.

In addition to this data, PacFIN data tables developed by NMFS SWFSC that describe by port and sector, the number of dealers, vessels, revenues, landings, vessel trips were used to develop the groundfish sector summaries found in Attachment 7-3 To synthesize the information found in all of the tables described above, the key analysis done for this EIS is the Fishing Community Engagement, Dependence, Resilience and Identification of Potentially Vulnerable Communities which is also attached.(Attachment 7-4of Appendix?) The key results of this study follow.

7.1.5.2 Fishing Community Engagement, Dependence, Resilience and Identification of Potentially Vulnerable Communities

To help the Council with determining the needs of fishing communities, numerous indicators were developed to characterize and rank communities and counties to the degree that a community or county was:

"engaged"—level of involvement in fishing
"dependent"—involved in the groundfish fishery
"resilient"—able to adapt to change
"vulnerable"—"highly dependent" and "having low resilience"
"most vulnerable" – "highest dependence" and "least resilient"

The methodology and results are presented in Attachment 7-4; Attachment 7-4 contains the following tables;

Table 1. Socioeconomic and cultural indicators
Table 2. Determining dependence
Table 3. Methodologies used in past research to identify dependence
Table 4. Determining resilience
Table 5. Linking dependence and resilience to identify vulnerable areas
Table 6. Distressed areas
Table 7. Commercial indicators and rankings city
Table 8. Commercial indicators and rankings by county
Table 9. Commercial fishing engagement scores by city
Table 10. Commercial fishing engagement scores by county
Table 11. Groundfish dependency scores by city
Table 12. Groundfish dependency scores by county
Table 13. California charter vessels ranked by region
Table 14. California recreational indicator values and rankings by region
Table 15. Oregon and Washington recreational indicator values and rankings by city
Table 16. California recreational engagement scores by region
Table 17. Oregon and Washington recreational engagement scores by city
Table 18. Resiliency indicator values and rankings by city
Table 19. Resiliency indicator values and rankings by county
Table 20. Resiliency scores by city
Table 21. Resiliency scores by county
Table 22. Commercial and recreational scores and identification of vulnerable cities
Table 23. Commercial and recreational scores and identification of vulnerable counties

Below are the conclusions of the study.

7.1.5.2.1 Vulnerable Commercial Communities and Counties

With regard to engagement in commercial fishing, twenty-nine cities are identified as "vulnerable" or "most vulnerable" areas. The "most vulnerable" area label indicates the highest levels of engagement (or dependence) and the lowest levels of resilience. Ilwaco and Moss Landing are most vulnerable with regards to engagement in commercial fishing. Ilwaco and Moss Landing have the highest levels of engagement in fishing (score of four and three, respectively) and resiliency (score of three and four, respectively). Other vulnerable areas include Astoria, Bellingham, Coos Bay, Crescent City, Eureka, Fort Bragg, Ilwaco, Moss Landing, Port Orford, Santa Cruz and Winchester. All have high fishing engagement scores (two or greater) and low resiliency scores (two or greater). Newport, San Pedro and Westport all have high fishing engagement (score of four) but lower resiliency scores (score of one).

With regard to dependency on the commercial groundfish fishery, thirty-two cities are identified as vulnerable areas. Neah Bay is identified as a most vulnerable area. Other vulnerable areas include Astoria, Bellingham, Coos Bay, Crescent City, Eureka, Fort Bragg, Moss Landing, Pacific City, and Port Orford. All have high groundfish dependency scores (two or greater) and low resiliency scores (two or greater). Morro Bay, Newport, and Oceanside all have high groundfish dependency (score of three) but lower resiliency scores (score of one). Chinook, Garibaldi, La Push, and Ilwaco all have higher groundfish dependence (score of one) and the lowest resiliency scores (three or more). Several vulnerable areas that are cities are identified as highly engaged and highly dependent (see Table 22).

Astoria, Garibaldi, Gold Beach, and Westport rank in all city categories: commercial and recreational engagement and dependency as well as low resiliency.

Sixteen counties are identified as vulnerable areas with regards to commercial fishing engagement. Six counties are labeled as most vulnerable areas and include Coos, Grays Harbor, Humboldt, Lincoln, Mendocino, and Pacific counties. All have high commercial fishing engagement scores (three or more) and low resiliency scores (three or more). Grays Harbor and Lincoln counties score highest in fishing engagement (scores of four) and lowest in resiliency (scores of four).

Seventeen counties are identified as vulnerable areas with regard to groundfish dependence. Clatsop, Coos, Curry, Grays Harbor, Lincoln, and Los Angeles counties score as most highly dependent (scores of two or more) and least resilient (scores of two or more). Several vulnerable areas that are counties are identified as highly engaged and highly dependent (see Table 23).

7.1.5.2.2 Recreational fishery

Ten cities are identified as vulnerable areas with regard to recreational fishing in Oregon and Washington. These cities are bolded in Table 22 under the recreational column. Astoria, Depoe Bay, and Garibaldi are all highly engaged in the recreational fishery (score of two or more) and least resilient (score of two or more). Garibaldi is the only city labeled as “most vulnerable” due to its high scores in both engagement/dependence on recreational fisheries and low resiliency.

Other recreational vulnerable cities include Gold Beach, La Push, Neah Bay, Newport, Pacific City, Westport, and Winchester. Newport has very high score in recreational engagement (score of five) but a lower resiliency score (score of one). La Push, Neah Bay and Winchester all have lower recreational engagement scores (scores of one) but very low resiliency scores (score of four or more).

It was not possible to identify recreationally engaged vulnerable areas in California due to the two-county and regional level recreational data that was available with regard to recreational fishing, compared to city and county level data available for the resiliency indicators. However, we were able to identify some California communities as potential vulnerable areas based on commercial engagement in and dependency on the groundfish fishery. Table 16 shows that San Luis Obispo through Santa Cruz counties and San Diego through Los Angeles counties are most engaged in recreational fishing and dependent on the groundfish recreational fishery. Los Angeles, San Luis Obispo and Santa Barbara counties are all ranked as least resilient in Table 23.

7.1.5.2.3 Summary

In summary, thirty-eight cities and eighteen counties are identified as commercial and/or recreational vulnerable areas (areas with high engagement or dependence on commercial or recreational fisheries and low resilience to change). Tables 22 and 23 display the results of the analysis. To qualify as a vulnerable area, a city or county must be listed in the top one-third of ranked indicator values for at least one engagement or dependency indicator and one resiliency indicator. When stricter ranking requirements are applied so that a community has to be ranked in the top one-third of an indicator twice under engagement and/or dependence and resilience, a smaller pool of cities and counties qualify. These seventeen cities include Astoria, Bellingham, Bodega Bay, Coos Bay, Crescent City, Depoe Bay, Eureka, Fort Bragg, Garibaldi, Ilwaco, Moss Landing, Neah Bay, Newport, Pacific City, Port Orford, Santa Cruz, and Winchester Bay. The fifteen counties include: Clatsop, Coos, Curry, Del Norte, Grays Harbor, Humboldt, Lincoln, Los Angeles, Mendocino, Monterey, Pacific, San Luis Obispo, Tillamook, Wahkiakum, and Whatcom counties. If even stricter ranking requirements are applied so that a community must be ranked in the top one-third of an indicator three times under engagement and/or dependence and resilience, four cities and six counties are identified as vulnerable. These cities and counties are labeled "most vulnerable". The cities include: Garibaldi, Ilwaco, Moss Landing, and Neah Bay. The counties include: Coos, Grays Harbor, Humboldt, Lincoln, Mendocino, and Pacific counties.

7.1.5.3 Environmental Justice Communities of Concern

This Section repeats the discussion found in The final EIS for the 2005-06 specification document {PFMC (Pacific Fishery Management Council) 2005?DBD Final Environmental Impact Statement for the Proposed Groundfish Acceptable Biological Catch and Optimum Yield Specifications and Management Measures for the 2005-06 Pacific Coast Groundfish Fishery. Pacific Fishery Management Council. Portland, OR, January 2005? DBD}

Environmental Justice Considerations

7.1.5.3.1 Identifying Communities of Concern

Executive Order 12898, Federal Actions to Address Environmental Justice in Minority Populations and Low-Income Populations, requires federal agencies to identify and address "disproportionately high adverse human health or environmental effects of its programs, policies, and activities on minority and low-income populations in the United States." Fishery management actions promulgated by the Pacific Council and implemented by NMFS can have environmental and socioeconomic impacts over a very wide area; the affected area of many actions covers all West Coast waters and adjacent coastal communities involved in fishing. This makes it difficult to identify minority and low-income populations that may be disproportionately affected.

Section 8.5 in Appendix A (PFMC, 2005) describes a methodology, using 2000 U.S. Census data, to identify potential "communities of concern" because their populations have a lower income or a higher proportion of minorities than comparable communities in their region. West Coast ports identified in the PacFIN database were examined in this way. These ports were evaluated using five criteria: the percentage nonwhite population, percentage Native American population, percentage Hispanic population, average income, and the poverty rate. Data were evaluated for both census places and census block groups corresponding to the area around these census places. The values for these statistics were compared to the average value for one of three regions, covering coastal block groups in Washington, Oregon, and northern California; central California; and southern California. For each of the five statistics potential communities of concern were identified. These are communities that have a significantly higher percentage minority population and poverty rate or lower average income than the surrounding reference region.

About two-thirds of the port communities analyzed are above the cutoff threshold for one or more of the statistics, measured either by the census place value or the equivalent block groups. This suggests that additional criteria need to be applied to more realistically identify which ports should be of concern. It should be noted that the population affected by the proposed action, which would be predominantly fishers and those involved in allied industries (e.g., marine supplies, fish processing, recreational charter and equipment) is a small percentage of the population in most communities. It stands to reason that in larger communities and more urban areas, fishery participants are a smaller and potentially less representative component of the population. In isolated rural communities there are usually fewer alternative employment alternatives, making it harder to find work or switch from one occupation to another in response to changes in one economic sector such as fisheries. Given these conditions, another criterion to focus on communities of concern would be population size and urbanization. Eliminating ports with a population greater than 50,000 and of those ports with a population less than 50,000, those for which the block group area is more than 75% urban leaves the following ports as potential communities of concern:

It should be noted that fishery participants usually make up a small component of the population and fisheries may be a small part of the local economy in many places. Thus, even if a community has a high proportion of minority or low income residents, these people might not participate in fisheries and are thus minimally affected by the proposed action. Furthermore, within the affected population some segments are more likely to be low income and minority than others. For example, employees in a fishing processing plant may be predominantly from a minority group, and crew on vessels are likely to have a lower earnings than the skipper or vessel owner, making them more likely to be low income. Unfortunately, the kind of detailed population data necessary to determine the characteristics of the population affected by the proposed action are not available. For this reason, the ports identified in Table 7-48 represent an initial screening. Note that Moss Landing, Port Orford, Neah Bay, and Winchester Bay are also described as “vulnerable communities” (see 7.1.5.2.3).

7.2 The Economic Impacts of the Alternatives

7.2.1 Introduction

7.2.1.1 Criteria Used to Evaluate Impacts

When an agency is evaluating reasonably foreseeable significant adverse effects, there is incomplete or unavailable information, and the costs of obtaining it are exorbitant or the means unknown, the agency must (1) so state, (2) describe the importance of the unavailable information to the assessment, (3) summarize any existing scientific information, and (4) evaluate impacts based on generally accepted scientific principals, which may accord with the best professional judgment of agency staff (40 CFR Part 1502.22). NMFS acknowledges that the information necessary to fully evaluate net national benefits associated with socio-economic impacts described below cannot be reasonably obtained at this time. Available information includes historic data on commercial vessel landings and exvessel revenue gleaned from fish tickets, projections of limited entry trawl vessel participation (landings and revenue) under the alternatives provided by the GMT's trawl bycatch model, rough projections of nontrawl fisheries response (landings and revenue) under the alternatives produced by the Council's commercial fisheries data model, tribal fisheries projections (landings and revenue) under the alternatives provided by the GMT, estimates of recreational angler trips in recent years and under the alternatives provided by the GMT, and estimates of local personal income and employment impacts resulting under the alternatives generated using the Council's commercial and recreational fisheries economic assessment models (FEAM)[1/].

Additional information that is necessary to perform the required net benefits analysis includes production cost information for vessels; production cost, product volume and price information for processors; trip cost, trip volume and price information for charter operators; and angler willingness to pay information for recreational fishing experience. As noted below, efforts are underway to collect representative production cost information from participating commercial fishing vessels. However that information will not be available in time for use in this analysis, nor will the other information mentioned in this paragraph. Therefore the following evaluation is based on best professional judgment of NMFS and Council staff.

7.2.2 Commercial Fisheries

Changes in exvessel revenue are used to indicate the directions of change expected in net economic benefits derived from harvest by the commercial seafood vessels. Subgroups of the groundfish fleet are examined to determine if any particular group is experiencing greater effects than others. The primary divisions are between the limited entry trawl, limited entry fixed gear and open access fishery.

A complete assessment of the expected change in net revenue requires an assessment of changes in fishing costs[1/]. Comprehensive information on fishing costs for the West Coast groundfish fishery is not currently available. An effort is underway by NMFS and PSMFC to fill this gap by collecting data on fixed and variable cost structures of vessels engaged in groundfish and other major West Coast fisheries. A simple analysis of expected change in vessel cost structure associated with implementation of selective flatfish trawl fishery is included. Changes in operational flexibility resulting from regulatory constraints will be addressed qualitatively as an indicator of impacts on production costs. Effects on human health and safety will be discussed primarily in terms of the effect of revenue changes on vessel maintenance and the effect of changes in the RCA on travel distances to fishing ports.

The discussion of cumulative impacts will include the effects of the trawl vessel buyback program and possible future implementation of an ITQ program. These regulatory changes will be discussed in terms of their likely effects on vessel revenue and operational costs. Changes in revenue will also be used as an indicator of the magnitude of likely harvest pressure that may affect adjacent fisheries as a result of changes in opportunity in the groundfish fishery.

---

[23]/ FEAM includes estimates of industry (commercial vessels, processors and recreational angling businesses) cost and output parameters that have been adopted from informal surveys over the past 20 years. The Council's economic modeling methodologies are discussed in Appendix D of 2005-2006 EIS.

[24]/ In order to estimate net economic benefits, fishing costs must be adjusted by appropriate shadow prices to determine real opportunity costs. For example, expenditures for crew would not count as an economic opportunity cost if the labor would otherwise have been unemployed. Or if the labor would have been employed, but at a lower wage, then the difference between the wages in the fishery and the wage in the next best alternative employment would not be counted as an economic cost (i.e., only the next best available wage is counted as a cost).

7.2.3 Buyers, Processors, and Seafood Markets

Due to the lack of data on prices, costs and profitability of buyers and processors, much the same indicators as used for the harvesting sectors are used for comparing impacts on the buyer/processing sector. Specifically, as a proxy for profits, exvessel revenue is used as an indicator of activity level. From the buyer's' perspective, exvessel revenue represents expenditures for a primary production input. Projected change in exvessel revenue under the alternatives can be stratified by different categories to examine impacts by buyer/processors' relative size and level of involvement in or dependence on groundfish purchases.

Substitutability of other products, or the same product imported from elsewhere, greatly affects regional seafood markets. Flatfish are generally lower priced than rockfish, and production is more constrained by markets than by availability of the resource itself. Rockfish are higher priced in West Coast fresh markets. However, similar products from South America, Mexico, Canada, and Alaska readily substitute for West Coast production. Whiting, which is processed into surimi, a generic fish product, competes with other sources of supply such as Alaska pollock.

7.2.4 Tribal Fisheries

The criteria used to compare 2005-2006 management alternatives for the tribal groundfish fisheries are total annual projected groundfish landings and resulting exvessel revenue.

7.2.5 Recreational Fisheries

7.2.5.1 Private Recreational Anglers

Recreational experiences generate economic value for individual anglers, as determined by their willingness to pay for the experience. The sum of anglers' net willingness to pay (minus actual expenditures) represents the net economic value contributed by the recreational fishery to the national economy. However estimates of these parameters are not currently available. As a proxy, partial estimates of the change in total trips and indicators of the probable direction and degree of change in the average value per trip are considered. The following discussion highlights some of the issues involved in estimating the net economic value of the recreational fishing experience.

7.2.5.1.1 Estimating Net Economic Value

The net value of a recreational fishing trip is a function of the willingness of potential anglers to pay for the experience.[1/] While expected catch (species, number and size) probably doesn't affect the value of a trip once it is undertaken, it may affect the likelihood of taking a given trip in the first place. Reduced bag limits, while reducing the number of trips per time period, may also allow for a longer season and an increased total number of angler trips. This could provide angling opportunities to a greater number of anglers, potentially increasing the marginal value of each fish. While the marginal value per angler of each additional fish caught decreases with increasing bag limits, so too does the cost per unit of catch. So the net effect of a change in bag limit on the value of recreational experiences is ambiguous.

---

[25]/ Arguments that might be used to estimate willingness to pay include, among others, attractiveness of the location and distance traveled by the fisher.

While a loss of fishing opportunity may translate into a direct reduction in trip-related expenditures, the resulting change in net economic value will be considerably less than the change in expenditure. Presumably the recreationalist will still pursue another activity, even though this alternative experience may be somewhat inferior than what the person originally had in mind. Substitution of one activity for another in time and/or place may still involve a similar level of expenditures, although not of the same kind or necessarily in the same place. While analysis of the local impact would interpret the reduction in revenue of the recreational fishing-related businesses as a direct loss in local income, analysis of net economic value would treat only the difference in the intrinsic value to the individual between the two types of experience as a net change in value.

An ideal model would allow us to measure the effect on total recreational effort (quantity and location of trips) and marginal value per trip resulting from changes in different management variables. Unfortunately, the data to populate such a model are lacking because the specific surveys to collect the required data have not been done.

7.2.5.1.2 Change in Recreational Effort

Conceptually, effort may change in response to caps on total landings (although if a cap is non-binding it may have no direct effect), change in seasons, or change in area or depth closures. Estimates of the change in the number of angler trips in each state's recreational ocean fishery under each management alternative are derived. Also considered are the proposed closure periods compared with the seasonal effort pattern observed, and the effect of shifts in the inshore closed area under the alternatives.

It should be noted that these estimates probably do not adequately project the effect of management changes on the distribution of effort, nor do they incorporate the impact of other changes on demand for recreational fishing experience. However this is the best available approach for evaluating impacts given the data limitations.

7.2.5.1.3 Change in Quality (Value) of Trips

Management measures may affect the perceived value of the recreational experience as well as the amount of effort. Those anglers forced to change their desired fishing patterns will probably experience a reduction in economic value from the trip. While change in bag limits probably does affect the decision of whether or not to fish, historically West Coast groundfish managers have observed little change in recreational effort in response to changes in bag limits. However continued reductions in bag limits would be expected to eventually lead to reduced demand and lower levels of angler participation once some critical threshold had been crossed.

7.2.5.1.4 Change in Quantity of Trips

Greater restrictions (e.g., lower bag limits) on individual trips may allow a greater number of anglers to fish by spreading the recreational harvest out over a longer season. However if current bag limits are constraining retained catch, then lower bag limits may also reduce the likelihood that a given individual will choose to go fishing in the first place. An increase in the number of trips results in increased total expenditures by recreational anglers. However, especially in the short term, these expenditures may represent dollars taken away from other places and other types of activities rather than "new" activity. Therefore even though net benefits may be unchanged, there may be a redistribution of expenditures among local businesses.

7.2.5.2 Charter Boat Businesses

Demand for charter trips is affected by some of the same factors that affect demand for private recreational fisheries, including bag limits, weather conditions during open seasons, and coincidental timing of open seasons with traditional vacation periods. For example, a closure during the months of July and August, the peak summer vacation period, will have a more adverse impact on charter operators than will closures during any other two-month period of the year. Impacts on charter boats under the alternatives are assessed based on estimated changes in total effort and timing of closure periods.

7.2.6 General Public

Directly measuring individuals' nonconsumptive and nonuse values for a marine resource is beyond the scope of this analysis. The metric used as a proxy is relative size of the RCAs. At current relative biomass levels for sensitive fish species this measure is assumed to be proportional to enhanced nonconsumptive and nonuse values.

7.2.7 Communities

Impacts on communities will be assessed according to the commercial and recreational impacts described below. “Vulnerable” communities will be also discussed.

7.2.7.1 Commercial Fisheries and Recreational Impacts

Projected commercial landings under the alternatives are compared against recent landings to estimate change in landings by port area. Income multipliers generated by the FEAM and differentiated by species, vessel category, gear type, processing mode, and landing port are applied to the projected landings to estimate change in total personal income impacts resulting from the estimated change in harvest and processing activity under each alternative. A description of FEAM is found in {Jensen 1996}. A recent update to the model is described in {Davis 2003}. Also see Appendix D of the 2005-06 EIS for further discussion of income impact estimating methodology. These impacts will be reviewed against the list of “vulnerable communities as described above.” Annual recreational fishing effort under the alternatives is estimated by region and compared against recent data. Change in effort is assumed to be roughly proportional to the change in estimated harvest. Regional income multipliers derived from the recreational FEAM, and average trip expenditures for recreational fishers in the four regions derived from a recent study {Gentner 2001} are applied to the estimated change in effort to generate the change in regional income resulting from the level of recreational fishing activity expected under each alternative.

7.2.7.2 Community Vulnerability

The commercial and recreational impacts will be compared against the list of “vulnerable” communities and “communities of concern”—see discussion under 7.1.5.2.

7.2.7.3 Safety

Changes in vessel net income can have effects beyond economic effects. Reduced investment in maintenance and safety equipment can increase hazard associated with fishing. Reduced income opportunity could cause dislocation for crew members and their families. Individuals willing to work for lower paying jobs are generally less skilled and have fewer alternative employment opportunities. In addition to reduced operational efficiency, these factors could lead to deterioration in vessel safety conditions.

Safety of fishing vessels is also affected by the seasons and depth zones or areas open to fishing under the alternatives. Seasonal closures that push commercial and/or recreational vessels out to sea during poor weather months will increase the likelihood of safety problems for those vessels.

RCA boundaries and depth or area closures that pack vessels into shallow nearshore areas will also increase the likelihood of safety problems. Limits that push commercial and recreational fleets to fish in the same waters increase the risk of collisions, especially in bad weather. Recreational boaters tend to be less experienced and have less safety equipment than commercial skippers, and are often unfamiliar with bottom contours, wave dynamics, tides, and currents. This combination of increased vessel density, the inherent risks of navigating shallow waters, and relatively inexperienced skippers, increases the risks to vessels.

Effects on vessel safety under the alternatives are evaluated by comparing revenue earning opportunities for commercial vessels, and the pattern of season and depth/area closures for both commercial and recreational vessels.

7.2.7.4 Key Impact Indicators

As discussed above assessing the impacts of the alternatives will be primarily through the prediction of changes in landings, ex-vessel revenues, and personal income impacts for commercial fisheries. Total estimates are provided by Alternative and then by sector and community (e.g. Shoreside Limited Entry Trawl, Astoria Tillamook) and by state. For recreational fisheries, the key indicators are trips, angler expenditures and income impacts. In evaluating the alternatives, two different approaches are undertaken. The first approach attempts to develop ex-vessel impact estimates on a on a finer scale with respect to gear groups and fisheries than the second approach. The second approach provides information on personal income and other variables. Both discuss recreational fisheries

First Approach –A: Commercial sectors are nearshore groundfish, limited entry trawl, whiting, fixed gear sablefish north of the Conception area, fixed gear south of Point Conception, and Total. The First Approach uses 2005 as a reference point. Whereas the Second approach uses the No-Action Alternative as a reference point.

Second Approach –B: Commercial sectors are Limited Entry trawl (including or excluding whiting), tribal shoreside, tribal at sea, open access groundfish, and total limited entry sablefish.

The methodology and groupings of tribal and commercial sectors differs slightly between each approach, but recreational fisheries are analyzed the same way. Approach B provides commercial estimates and projections by alternatives on landing, revenues, and personal income and recreational estimates and projections of trips, angler expenditures, and personal income. Approach A provides estimates of ex-vessel values and recreational trips. Approach B provides information on a port and community basis; Approach A provides information on a regional basis. Approach A analyzes the five rebuilding alternatives discussed in Chapter 2 and brought before the Council in April. Approach B focuses only the three action alternatives, the no action alternative, and provides estimates of 05 and 06. Approach A does not address O6 or the no-action alternative; however, it does address the "No Fishing" option.

For this document, both analyses will be used. Because it addresses the link between management and economic impact, Approach A Analyses will be used to walk through the alternatives. This discussion will then be followed by a summary of the Second Approach's estimates.

Since both approaches discuss the Action Alternatives, Table 7-49 has been developed to provide the reader with a quick reference to the major changes in OYs from 05-06 levels.

7.2.8 Economic Impact of Management Measures Designed to Achieve the OY Alternatives—Discussion of Approach A

This section discusses the economic impact of management measures that were designed and analyzed with the intention of achieving the OYs described in chapter 2 of this EIS. The alternatives discussed in chapter 2 show a set of alternatives originally considered during the winter of 2006 which led to the council's selection of preliminary preferred alternatives for target species, and a high and low preliminary preferred alternative for rebuilding species. The initial set of OY alternatives pertaining to overfished species described in chapter 2 are referred to here as "rebuilding alternatives" and the second set of alternatives that were selected by the council during the April 2006 meeting are referred to as "preliminary preferred alternatives" or "action alternatives". The action alternatives focus on the council's preliminary preferred OYs for target and rebuilding species. While the council may continue to consider, and ultimately adopt, one or more of the rebuilding alternatives not considered a preliminary preferred alternative, this analysis concentrates on the action alternatives based on the notion that the council has given an indication as to what OYs it feels are close to those it wishes to adopt.

7.2.8.1 Overview

The OYs for target and rebuilding species differ from 2005 and 2006 OYs. In some cases these differences are substantial, and in other cases the difference in minimal. The relative OYs of target and rebuilding species ultimately influences the management measures that are crafted in response to those OYs, and estimates of exvessel revenue, recreational effort, and the distribution and source of those economic effects differ in response.

For the 2007 and 2008 season, the OY of several key target species will differ relative to the 2005 and 2006 season. The OYs for Dover sole, English sole, and shortspine thornyheads will increase substantially based on the council's preliminary preferred alternative (Table 7-49). In response, management measures could be crafted which allow fisheries to harvest more of these species, however, the take of these target species is constrained by rebuilding species, and in some cases, other target species. Some target species will have a decrease in the OY compared to the OYs that were in place for 2005 and 2006. Petrale sole and sablefish for example will have a 22% and 10% reduction respectively, and these OYs are expected to constrain the take of other target species to some degree under the council's preliminary preferred alternatives 2 and 3.

The OY for rebuilding species differ from 2006. Under action alternative 1, all OYs are reduced compared to 2006 levels. Under action alternative 2 and 3, the OY of most overfished species are reduced compared to 2006 levels, but the OY for widow, cowcod, and darkblotched would increase. However, the OY for darkblotched is equivalent to 2006 levels when the OY is measured relative to the size of stock biomass, and analysis shows that this OY is expected to constrain some fisheries more than the 2006 OY based on expectations pertaining to increases in the bycatch rate of darkblotched.

Table 7-49 provides information on the difference and change in OYs for rebuilding species and some of the key target species. This information is useful for showing why exvessel revenue can change under some of the alternatives, the source for those changes, and insight into some of the management responses anticipated to stay within the OY that is ultimately adopted by the council.

A summary comparison of exvessel revenue calculations by sector and alternative provides a glance of the economic impacts of each alternative (Table 7-50). Compared to coastwide 2005 exvessel revenues generated by commercial vessels in directed groundfish sectors, action alternative 3 has the least degree of difference, action alternative 1 has the largest degree of difference, and action alternative 2 is best described as more moderate. The five rebuilding alternatives originally analyzed range from exvessel revenues that are slightly higher than status quo, to revenues that are slightly lower than action alternative 1. On a sector specific basis, all alternatives negatively impact the fixed gear sablefish sector because the OY for sablefish is lower in 2007 and 2008 compared to 2005 and 2006. The nearshore groundfish sector is most impacted by action alternative 1, least impacted by action alternative 3, and more moderately impacted by action alternative 2. The LE bottom trawl sector is most impacted by action alternative 1, has slightly higher revenues than status quo under action alternative 2, and even higher revenues under action alternative 3. The LE whiting sector is most negatively impacted by action alternative 1, but action alternative 3 allows this sector to attain higher revenues than status quo if the whiting OY allows those catch levels to be attained[26]. Action alternative 2 constrains the whiting sector to revenues that are somewhat less than status quo. Fixed gear fisheries south of point Conception are negatively impacted by action alternative 1, but remain at status quo for action alternatives 2 and 3.

Table 7-51 does a similar analysis for recreational fisheries. Action Alternative 3 leads to an increase in recreational effort over 2005 levels while Action Alternative 1 shows a 35 % decline in angler trips and Alternative 2, a 22% decline.

7.2.8.2 Action Alternative 1

Action alternative 1 reduces overfished species OYs compared to status quo catch levels, and as a result, revenues generated by commercial and recreational fisheries are reduced compared to 2005 levels. Under this alternative, many of the target species OYs are not attained, and fishing area is decreased for all sectors as the size of groundfish conservation areas is expanded to encompass more area where overfished species are found. While groundfish conservation areas are a useful tool for protecting overfished species while allowing fishing opportunity where those same overfished species are less abundant, having less fishing area makes it more difficult to access target species in many cases, and may also increase the cost of traveling to areas remaining open.

7.2.8.2.1 Impacts to Limited Entry Bottom Trawl

The impacts to the non-whiting limited entry trawl sector under action alternative 1 are largely driven by the OYs for canary rockfish, bocaccio rockfish, darkblotched rockfish, cowcod, and Pacific ocean perch. While the OYs for yelloweye and widow rockfish are also reduced under action alternative 1, the non-whiting limited entry trawl sector does not encounter these species to the same degree as other sectors

[26] The Pacific whiting ABC and OY levels are estimated and adopted by the Council in the spring of each year.

and therefore the management measures crafted for this sector are not driven by those species.

Regulations for the non-whiting limited entry trawl sector include an expansion of the trawl rockfish conservation area compared to status quo, and a decrease in cumulative limits for target species compared to status quo. Of particular note, this alternative puts in place a 250 fathom seaward boundary in the northern areas (north of 40° 10 minutes N latitude) for the entire year, a 200 fathom seaward boundary in the area between 40° 10 minutes N latitude and 38° N latitude for the entire year, and a 60 fathom shoreward boundary for areas south of 40° 10 minutes N latitude for most of the year. This is a noticeable reduction in fishing area compared to 2006 configurations.

Cumulative limits for target species under this alternative are reduced for all of the major target species including Dover sole, sablefish, thornyheads, other flatfish, arrowtooth flounder, and petrale sole. As a result, none of the OYs for major target species are attained under this alternative.

The combined effect of area closures and reductions in cumulative limits results in a decrease in exvessel revenues from the no-action alternative. Exvessel revenues to this sector are approximately 59% of 2005 levels, representing a decrease of approximately 41% (Table 7-50). Table 7-52 shows projected revenues by two month period.

7.2.8.2.2 Impacts to the Limited Entry Whiting Trawl Fishery

The impacts to the limited entry whiting trawl sector under action alternative 1 are largely driven by the OYs for canary rockfish, widow rockfish, and to a lesser extent, darkblotched rockfish and Pacific ocean perch. Other species are not caught in the whiting sectors to the same degree as other sectors, so management measures necessary to protect species such as bocaccio, yelloweye, and cowcod do not influence the whiting fishery to the same degree as other sectors.

While many sectors benefit from the use of groundfish conservation areas, or more specifically, the rockfish conservation areas, it is estimated that the whiting sector would not benefit as much from imposing a rockfish conservation area in the same manner as the bottom trawl sector. Depths restrictions necessary to achieve reductions in the catch of canary, widow, darkblotched, and POP are generally the same depths where Pacific whiting are found and caught effectively. Closing these areas would also eliminate the ability to target whiting effectively, except in the years of largest whiting abundance when the population is spread more densely over a wider range of depths. Therefore, the most effective means of reducing the bycatch of overfished species in this sector while continuing to allow a fishery is likely to be a decrease in the amount of whiting catch allowed to the commercial sectors. Assuming the whiting sector is allowed to take the same percentage of the widow, canary, darkblotched, and POP OYs as under the 2005 and 2006 fisheries, it is estimated that the commercial catch amounts and exvessel value of Pacific whiting would decrease by 42.5% (Table 7-50) Table 7-53 shows projected revenues by two month period.

7.2.8.2.3 Impacts to Nearshore Groundfish Fisheries

Economic impacts to the nearshore groundfish sector are largely driven by canary and yelloweye rockfish. In areas south of 40° 10 minutes N latitude, observer data has not shown an interaction with yelloweye rockfish, so in these areas, canary rockfish is the driving constraint. Action alternative 1 brings the nearshore groundfish sectors in to depths less than 20 fathoms for the entire year. Depth restrictions are regarded as a useful tool for managing the catch of overfished species in the nearshore groundfish sectors while allowing fishing of healthy target species, however, imposing a more restrictive depth restriction is expected to result in some reduction in the catch of target species as some nearshore target species are not as available at depths less than 20 fathoms. Although some reduction in the catch of target species is expected from a 20 fathom restriction, additional reductions on some of the lesser valued target species are were analyzed under this alternative to achieve the necessary reductions in the bycatch of canary and yelloweye rockfish. Analysis of alternative 1 shows that exvessel revenues are expected to decline by approximately $450,000 from 2005 levels which represents a decrease of approximately 16.5% (Tables 7-50, 7-54).

7.2.8.2.4 Impacts to Fixed Gear Sablefish Sectors North of 36° North Latitude

Economic impacts to the fixed gear sablefish sectors are largely driven by yelloweye and, to a lesser extent, canary rockfish. Management measures designed to reduce the bycatch of these species in the fixed gear sablefish sectors are limited to depth restrictions of varying degrees of restrictiveness depending on the alternative. Changes in the catch of sablefish which are lower than the OY are not considered in the management measures which pertain to reductions in the catch of overfished species because under all alternatives the sablefish OY is reduced compared to 2005 and 2006 levels, and this reduction achieves reductions in the bycatch of overfished species on it's own. The reduction in the sablefish OY occurs as a result of the 2005 sablefish stock assessment, and the council's policies regarding species that fall within the precautionary zone (sablefish is a precautionary zone species).

While exvessel revenues are expected to be the same across all action alternatives ($8.7 million, Table 7-50), action alternative 1 is expected to have a substantial impact to vessels that home port near the northern Washington coast and Puget Sound. Under action alternative 1, the fixed gear sablefish sectors would be restricted to fishing deeper than depths of 150 fathoms, and off the northern Washington coast, the 150 fathom line closes off most of the fishing grounds currently used by those vessels. Imposing a 150 fathom line would require vessels that home port in the northern Washington ports and Puget Sound ports to travel much further distances to reach fishing grounds. This may result in increased travel cost, or some vessels may choose to change their homeport, thereby affecting processors and support businesses relying on vessels in their current home ports in the northern Washington coast and Puget Sound.

7.2.8.2.5 Impacts to Groundfish Fixed Gear Sectors South of 34° 27 North Latitude

The economic impact to fixed gear fisheries operating south of point Conception are largely influenced by the OYs for bocaccio and cowcod. Depth restrictions are viewed as an effective mechanism for achieving reductions in the bycatch of overfished species in this area (primarily bocaccio and cowcod), however depth restrictions are likely to reduce the catch of target species as well since vessels in this area occasionally target species that are found in areas proposed to be closed under action alternative 1. Under status quo management measures, vessels can fish at depths less than 60 fathoms or more than 150 fathoms. Under action alternative 1, vessels would be restricted to fishing shallower than 40 fathoms or deeper than 180 fathoms. Based on the relative abundance of the main target species in the area across those depths, imposing a shoreward boundary of 40 fathoms and a seaward boundary of 180 fathoms is expected to reduce exvessel revenues by approximately $620,000, or approximately 29% compared to 2005 revenues (Table 7-50).

7.2.8.2.6 Impacts to Recreational Sectors

The impact to recreational sectors under action alternative 1 are driven by the OY for yelloweye rockfish and canary rockfish. The yelloweye rockfish OY under this alternative represents a substantial decrease in the OY from status quo levels, and management measures designed to achieve catch levels that meet this reduction in the OY are sufficient to achieve the necessary reductions in the canary rockfish OY. Management measures used to achieve the reductions in the bycatch of yelloweye rockfish include restricting recreational fisheries to 10 and 20 fathoms, reduced bag limits for target species, and shorter seasons. The coastwide impact of these management measures results in a 35% decline in recreational bottomfish fishing effort (Table 7-51).

7.2.8.3 Action Alternative 2

Action alternative 2 brings overfished species OYs to levels that are near status quo catch amounts for many overfished species except for yelloweye rockfish. When applying the portion of the OY currently being caught by status quo catch levels to the predicted biomass of overfished species in 2007 and 2008, the OYs for some overfished species under action alternative 2 are even closer to status quo catch levels. While OYs for overfished species are near status quo, negative economic impacts are less than alternative 1, but more restrictive than action alternative 3. The result is a larger portion of the OY that remains unattributed to any particular sector[27].

While many of the OYs for overfished species are not attained under this alternative, coastwide exvessel revenues are estimated to be higher for many sectors of the fishery as the population of target species such as Dover sole and petrale sole increase and become more widely found in the fishery (Table 7-50).

7.2.8.3.1 Impacts to the Limited Entry Bottom Trawl Fishery

The impacts to the non-whiting limited entry trawl sector under action alternative 2 are largely driven by the OYs for canary rockfish, bocaccio rockfish, darkblotched rockfish, cowcod, and Pacific ocean perch.

Regulations for the non-whiting limited entry trawl sector under this alternative mostly include an expansion of the trawl rockfish conservation area compared to status quo. While catch levels of overfished species are predicted to be close to status quo in this sector for many overfished species, it is predicted that the bycatch of several overfished species, darkblotched rockfish in particular, will increase over time and that rate of increase is sufficient to warrant increasing restrictions on the fishery to stay within the OY. Exvessel revenues for the bottom trawl sector are predicted to be marginally higher compared to status quo, however, the distribution of impacts is likely to be different than status quo. Under this alternative the rockfish conservation area boundaries are set at deeper depths for some periods of the year when compared to status quo, and this has impacts on vessels that are less able to fish at deeper depths because some vessels may be unable to fish in these areas, vessels may need to travel further to fishing grounds, or additional vessels may choose to fish in the nearshore areas, thus impacting small trawl vessels that routinely fish nearer to the shore. Table 7-55 provides projections of revenues by region and two month period. (Note there are no Tables 56 or 57)

[27] see chapter 2 scorecards which estimate catch of overfished species by sector and alternative.

7.2.8.3.2 Impacts to the Limited Entry Whiting Trawl Fishery

The impacts to the limited entry whiting trawl sector under action alternative 2 are largely driven by the OYs for canary rockfish and widow rockfish. While many sectors benefit from the use of groundfish conservation areas, or more specifically, the rockfish conservation areas, it is estimated that the whiting sector would not benefit as much from imposing a rockfish conservation area in the same manner as the bottom trawl sector. Depths restrictions necessary to achieve reductions in the catch of canary, widow, darkblotched, and POP are generally the same depths where Pacific whiting are found and caught effectively. Closing these areas would also eliminate the ability to target whiting effectively, except in the years of largest whiting abundance when the population is spread more densely over a wider range of depths. Therefore, the most effective means of reducing the bycatch of overfished species in this sector while continuing to allow a fishery is likely to be a decrease in the amount of whiting catch allowed to the commercial sectors. Assuming the whiting sector is allowed to take the same percentage of the widow, canary, darkblotched, and POP OYs as under the 2005 and 2006 fisheries, it is estimated that the commercial catch amounts and exvessel value of Pacific whiting would decrease by 22%. Table 7-58 shows projected revenues by two month period.

7.2.8.3.3 Impacts to Nearshore Groundfish Fisheries

Economic impacts to the nearshore groundfish sector are largely driven by canary and yelloweye rockfish. In areas south of 40° 10 minutes N latitude, observer data has not shown an interaction with yelloweye rockfish, so in these areas, canary rockfish is the driving constraint. Action alternative 2 brings the nearshore groundfish sectors in to depths less than 20 fathoms for the entire year. Depth restrictions are regarded as a useful tool for managing the catch of overfished species in the nearshore groundfish sectors while allowing fishing of healthy target species, however, imposing a more restrictive depth restriction is expected to result in some reduction in the catch of target species as some nearshore target species are not as available at depths less than 20 fathoms. While some reduction in target species catch is expected under this alternative, the catch of yet other target species that are available at these depths can be increased under this alternative compared to status quo and the impact of increasing the catch of these target species is a slight increase in exvessel revenues. Analysis of alternative 2 shows that exvessel revenues are expected to increase by approximately $90,000 from 2005 levels, but revenues are expected to decrease in the northern areas while increasing in the southern areas (Table 7-59).

7.2.8.3.4 Impacts to Fixed Gear Sablefish Sectors North of 36° North Latitude

Economic impacts to the fixed gear sablefish sectors are largely driven by yelloweye and, to a lesser extent, canary rockfish. Management measures designed to reduce the bycatch of these species in the fixed gear sablefish sectors are limited to depth restrictions of varying degrees of restrictiveness depending on the alternative. Changes in the catch of sablefish which are lower than the OY are not considered in the management measures which pertain to reductions in the catch of overfished species because under all alternatives the sablefish OY is reduced compared to 2005 and 2006 levels, and this reduction achieves reductions in the bycatch of overfished species on it's own. The reduction in the sablefish OY occurs as a result of the 2005 sablefish stock assessment, and the council's policies regarding species that fall within the precautionary zone (sablefish is a precautionary zone species).

While exvessel revenues are expected to be the same across all action alternatives ($8.7 million, Table 7-50), action alternative 2 could have a relatively large impact to vessels that home port near the northern Washington coast and Puget Sound. Under action alternative 2, the fixed gear sablefish sectors would be restricted to fishing deeper than depths of 125 fathoms in areas north of 40º 10 minutes north latitude, and off the northern Washington coast, the 125 fathom line may close off much of the fishing area currently used by those vessels. Imposing a 125 fathom line could require vessels that home port in the northern Washington ports and Puget Sound ports to travel much further distances to reach fishing grounds. This may result in increased travel cost, or some vessels may choose to change their homeport, thereby affecting processors and support businesses relying on vessels in their current home ports in the northern Washington coast and Puget Sound.

7.2.8.3.5 Impacts to Groundfish Fixed Gear Sectors South of 34° 27 North Latitude

The economic impact to fixed gear fisheries operating south of point Conception are largely influenced by the OYs for bocaccio and cowcod. While the fixed gear sectors south of point Conception encounter bocaccio and cowcod, reductions in the catch of these species necessary to stay within the OY are achieved by management measures in other sectors, and therefore, status quo management for fixed gear vessels in the area south of point Conception is sufficient to stay within the OY of overfished species.

7.2.8.3.6 Impacts to Recreational Sectors

The impact to recreational sectors under action alternative 2 are driven by the OY for yelloweye rockfish and canary rockfish. The yelloweye rockfish OY under this alternative is based on a strategy which “ramps down” catch levels from current amounts in order to give managers and industry time to adapt and develop more refined tools for decreasing the catch of yelloweye while allowing some access to healthier target species. It is anticipated that management measures designed to reduce the bycatch of yelloweye rockfish will also result in reductions of canary rockfish, and therefore, management measures which are motivated by reductions in the yelloweye OY are expected to be sufficient to achieve the necessary reductions in the canary rockfish OY. Management measures used to achieve the reductions in the bycatch of yelloweye rockfish include restricting recreational fisheries to varying depth restrictions, imposing site-specific area closures where industry and available data suggests yelloweye are found, and bag limits for target species which don’t allow attainment of target species OYs. The coastwide impact of these management measures results in a 22% decline in recreational bottomfish fishing effort (Table 7-51).

7.2.8.4 Action Alternative 3

Action alternative 3 brings overfished species OYs to levels that are near status quo catch amounts for many overfished species except for yelloweye rockfish. When applying the portion of the OY currently being caught by status quo catch levels to the predicted biomass of overfished species in 2007 and 2008, the OYs for some overfished species under action alternative 3 are even closer to status quo catch levels than action alternative 2. The overall economic impact of action alternative 3 is that many sectors are expected to be managed to levels that are similar to status quo.

7.2.8.4.1 Impacts to the Limited Entry Bottom Trawl Fishery

The impacts to the non-whiting limited entry trawl sector under action alternative 3 are largely driven by the OYs for canary rockfish, bocaccio rockfish, darkblotched rockfish, cowcod, and Pacific ocean perch. Under this alternative, the OY for petrale sole (a target species) is also expected to be attained, the OY for sablefish is expected to be nearly attained (due in large part to a decrease in the OY for sablefish), and the catch of Dover sole is expected to be higher than status quo because of the increasing abundance of this species.

Regulations for the non-whiting limited entry trawl sector under this alternative mostly include an expansion of the trawl rockfish conservation area compared to status quo. While catch levels of overfished species are predicted to be close to status quo in this sector for many overfished species, it is predicted that the bycatch of several overfished species, darkblotched rockfish in particular, will increase over time and that rate of increase is sufficient to warrant increasing restrictions on the fishery to stay within the OY. Exvessel revenues for the bottom trawl sector are predicted to be marginally higher compared to alternative 2, and higher still than status quo, however, the distribution of impacts is likely to be different than status quo. Under this alternative the rockfish conservation area boundaries are set at deeper depths for some periods of the year when compared to status quo, and this has impacts on vessels that are less able to fish at deeper depths because some vessels may be unable to fish in these areas, vessels may need to travel further to fishing grounds, or additional vessels may choose to fish in the nearshore areas, thus impacting small trawl vessels that routinely fish nearer to the shore. Table 7-60 shows projected revenues by two month period.

7.2.8.4.2 Impacts to the Limited Entry Whiting Trawl Fishery

The impacts to the limited entry whiting trawl sector under action alternative 3 are largely driven by the OYs for canary rockfish and widow rockfish, but equally driven by the ability of the whiting sectors to catch an amount of Pacific whiting which corresponds to the available OY of canary and widow rockfish. That is, under this alternative, the catch of whiting is expected to be largely unconstrained by overfished species, assuming there are no "disaster tow events" where a single tow of a trawl net catches a large amount of an overfished species. Assuming the whiting sector is allowed to take the same percentage of the widow, canary, darkblotched, and POP OYs as under the 2005 and 2006 fisheries, it is estimated that the commercial catch amounts and exvessel value of Pacific whiting would be the same as status quo, or approximately $30 million (Table 7-50) Table 7-61 shows projected revenues by two month period.

7.2.8.4.3 Impacts to Nearshore Groundfish Fisheries

Economic impacts to the nearshore groundfish sector are largely driven by canary and yelloweye rockfish. In areas south of 40° 10 minutes N latitude, observer data has not shown an interaction with yelloweye rockfish, so in these areas, canary rockfish is the driving constraint. Management measures in the nearshore fisheries under this alternative are designed to be equivalent to status quo, and therefore, exvessel revenues are expected to be the same as status quo.

7.2.8.4.4 Impacts to Fixed Gear Sablefish Sectors North of 36° North Latitude

Management measures imposed on the fixed gear sablefish sectors that are designed to reduce the catch of overfished species largely center on the impacts to yelloweye and, to a lesser extent, canary rockfish. Management measures designed to reduce the bycatch of these species in the fixed gear sablefish sectors are limited to depth restrictions of varying degrees of restrictiveness depending on the alternative. Changes in the catch of sablefish which are lower than the OY are not considered in the management measures which pertain to reductions in the catch of overfished species because under all alternatives the sablefish OY is reduced compared to 2005 and 2006 levels, and this reduction achieves reductions in the bycatch of overfished species on it's own. The reduction in the sablefish OY occurs as a result of the 2005 sablefish stock assessment, and the council's policies regarding species that fall within the precautionary zone (sablefish is a precautionary zone species).

While exvessel revenues are expected to be the same across all action alternatives ($8.7 million), action alternative 3 has the same rockfish conservation area boundaries for the sablefish sectors as under status quo, and therefore, reductions in exvessel revenue for these sectors are not driven by overfished species concerns, but are instead driven by the reduction in the OY of sablefish.

7.2.8.4.5 Impacts to Groundfish Fixed Gear Sectors South of 34° 27 North Latitude

The economic impact to fixed gear fisheries operating south of point Conception are highly influenced by the OYs for bocaccio and cowcod. While the fixed gear sectors south of point Conception encounter bocaccio and cowcod, reductions in the catch of these species necessary to stay within the OY are achieved by management measures in other sectors, and therefore, status quo management for fixed gear vessels in the area south of point Conception is sufficient to stay within the OY of overfished species.

7.2.8.4.6 Impacts to Recreational Sectors

The impact to recreational sectors under action alternative 3 are driven by the OY for yelloweye rockfish and canary rockfish. The yelloweye rockfish OY under this alternative is based on a strategy which "ramps down" catch levels from current amounts in order to give managers and industry time to adapt and develop more refined tools for decreasing the catch of yelloweye while allowing some access to healthier target species. It is anticipated that management measures designed to reduce the bycatch of yelloweye rockfish will also result in reductions of canary rockfish, and therefore, management measures which are motivated by reductions in the yelloweye OY are expected to be sufficient to achieve the necessary reductions in the canary rockfish OY. Management measures used to achieve the reductions in the bycatch of yelloweye rockfish include restricting recreational fisheries to varying depth restrictions, imposing site-specific area closures where industry and available data suggests yelloweye are found, and bag limits for target species which don't allow attainment of target species OYs. The coastwide impact of these management measures results in a 9% increase in recreational bottomfish fishing effort, though only recreational fisheries off California experience an increase in effort. Washington and Oregon are expected to achieve no change in effort under action alternative 3 when compared to status quo.

7.2.9 Net Economic Impact of Alternatives – Approach B

What follows is a walk through the tables. Table 7-62a shows projected exvessel revenue for different groupings of commercial fisheries under the alternatives, and the change in exvessel revenue relative to No Action. The table shows significant differences between the alternatives. For example, Alternative 3 has the smallest difference from No Action with a 2.7% decline associated with Alternative 3, a 10% percent decline with Alternative 2, a 37 % decline in exvessel revenues should Alternative 1 be implemented for non-tribal groundfish including at-sea vessels.

Table 7-62b shows the equivalent estimates for same groupings in terms of landed weight (thousand mt) rather than revenue while Table 7-62c does the same for comparison but using personal income impacts as the impact variable. It should be noted that “Total West Coast Landings (includes at-sea and tribal) is an estimate for all West Coast fisheries including groundfish..

Here is a list of all the commercial related tables:

7-62a Ex-vessel revenue projections by major sector
7-62b Commercial harvest projection by major sector
7-62c Commercial Income Impacts by major sector
7-63a Ex-vessel revenue projections by State, port area and major sector
7-63b Change in ex-vessel revenue projections by State, port area, and major sector
7-64a Estimated income impact projections by State, port area, and major sector
7-64b Change in estimated income impact projections by State, port area, and major sector

Recreational Fisheries Impacts

In a similar manner to those developed for the commercial fishery, the following tables have developed. Shortened titles for these tables are:

7-65a Projected recreational effort by region in 2004 and 2005 and by alternative
7-65b Change in projected effort across alternatives
7-66a Projected angler expenditures by region in 2004 and 2005 and by alternatives.
7-66b Change in projected angler expenditures across alternatives
7-67a Projected recreational income impacts by region in 2004 and 2005, and by alternatives
7-67b Change in recreational income impacts by region by alternative
7-68a Projected recreation employment impacts by region by alternative
7-68b Change in recreation employment impacts by region by area
7-68c Projected recreational Employment impacts by trip target, region, mode, state and alternative
7-68d Projected West Coast Recreational Income by state, boat type and alternative
7-68e Summary of total three State Recreational Impacts (trips, expenditures, income) by boat type and trip target.

Commercial and Recreational Fisheries Impacts Combined

7-68f Combined recreational and income impacts by region and alternative
7-68g Change in combined recreational and commercial impacts by region and alternative
7-68h Combined recreational and commercial employment impacts by region and alternative
7.59i Change in combined recreational and commercial employment impacts by region and alternative

Commercial Impact Comparison

Under the no action alternative, total West Coast landings from all fisheries including groundfish would yield 510,000 mt of fish and shellfish landed or delivered at sea, generating about $280 million in ex-vessel revenues which in turn would lead to $625 million in income impacts and at an income level of

$26,000 per year would yield 24,000 jobs. The 2005 estimates are quite similar to the No-Action Alternative. However, Alternative 1 would lead to a level $567 million in personal income, roughly a 10% decrease in income impacts whereas Alternatives 3 would have less than 1% decline in income and Alternative 3, a 4% decline. For non-tribal income impacts, the No-Action and 2005 levels of personal income are about $140 million. Implementation of Alternative 1 would lead to a decline of $56 million in groundfish fishery generated income, for a 40% decline in the groundfish fishery. Alternative 2 would lead to a 15% decline in Non-tribal income impacts including at-sea fisheries and Alternative 1, 2 percent decline.

Recreational Impact Comparison

It is estimated that under the no Action Alternative, 1.2 million angler trips would be taken and the estimated $113 million that these anglers would spend on fishing would generate, $89 million in personal income or the equivalent of 3,422 jobs. These estimates are similar to the ones generated for 2005 but differ significantly with Alternative 1. Under Alternative 1, one million trips would be undertaken leading to $92 million in expenditures, 73 million in income and 2,802 jobs. A difference of $16 million or 18 percent decline. These estimates are for all fisheries including groundfish.. With respect to groundfish targeted trips, the No action alternative leads to $40 million in personal income impacts compared to a 2005 level of $35 million. If Alternative 1 were implemented, the recreational groundfish fishery would generate $25 million, approximately a 30 percent decline. Alternative 3 would generate $45 million in personal income impacts and Alternative 2, $30 million in impacts.

7.2.10 Other Management Measure Analyses

7.2.10.1 Economic Impacts of Management Measures Designed to Reduce the Mortality of Yelloweye Rockfish

The 2002 yelloweye stock assessment was more optimistic than the 2006 stock assessment. The 2006 stock assessment estimated biomass – or status of the stock – to be at a 17.7% depletion level (percent of unfished biomass), and the 2002 assessment estimated the depletion level to be 24%. This does not mean that the population has been declining, only that the re-estimated stock size is smaller than previously thought. While the difference in the depletion level between the two assessments was a difference of approximately 6.3%, one of the more major changes to the stock assessment pertains to the assumed life history characteristics of yelloweye. The characteristics used in the 2002 rebuilding analysis resulted in estimates that showed the species to be more productive than the 2006 assessment. The result of findings and assumptions used in the 2006 assessment means that the estimates from the 2002 assessment allowed for shorter rebuilding times and/or larger harvests when compared to the 2006 assessment. For example, the 2006 OY for yelloweye was set at 27 metric tons, and the results of the 2002 rebuilding analysis estimated that the stock would be rebuilt by 2023 under the SPR harvest rate that corresponds to a 27 metric ton OY in 2006. Estimates from the 2006 assessment, show that a 2007 OY of 12 metric tons would rebuild the stock in 2078. That is, if the council and NMFS adopted a 66% reduction in the yelloweye OY compared to status quo, the rebuilding period would still be 55 years longer than the previous T_{TARGET}, and 30 years longer than $T_{F=0}$.

This dramatic change in the assessment results will have dramatic implications to management measures designed to protect yelloweye rockfish. Management measures ultimately adopted will likely need to result in a smaller harvest of yelloweye than previous measures, and such management measures will also have negative economic consequences to fishing communities. Under status quo management, the sectors that take the largest amount of yelloweye rockfish are the recreational groundfish and halibut sectors, followed by directed open access groundfish, and limited entry fixed gear and tribal sectors. In order to achieve reductions in the bycatch of overfished groundfish, the council has, in the past, restricted to the greatest extent those sectors that have the largest impact on that particular species. However, in many instances the tribal fisheries are left unaffected. Based on past approaches to management, the largest source of reduction in yelloweye rockfish bycatch is likely to come from the recreational and directed open access sectors. At the end of 2005, the recreational sectors were estimated to take 13.1 metric tons of yelloweye, and all other sectors (including tribal and non-groundfish fisheries) were estimated to take 8.9 metric tons.

Several alternatives were analyzed pertaining to yelloweye rockfish OYs. These OYs include zero harvest, a 2007 OY of 12 mt, 12.6 mt, 17 mt, 21 mt, 24 mt, 27 mt, and a ramp-down strategy which has a 2007 OY of 23 mt, 20 mt in 2008, 17 mt in 2009, and 14 mt in 2010 respectively. Implicit in the ramp down strategy is the development of additional management tools in order to allow some harvest of more abundant target species while reducing the catch of yelloweye over time. It is likely that new management tools would not be able to be developed without a ramp-down strategy because the development of additional tools inherently relies on some additional bycatch in order to test the effectiveness of those tools.

7.2.10.1.1 Economic Impact of a $T_{F=0}$ Yelloweye OY

Under the zero harvest alternative ($T_{F=0}$), the cost to the fishing industry is expected to be substantial. The $T_{F=0}$ harvest alternative is estimated to result in a loss of over $100 million in exvessel revenues and approximately 1,150,000 recreational angler trips. These figures represent a complete closure of multiple sectors including, but not limited to, all bottom-tending commercial fishing gears (outside of selective gears like dive gear) for groundfish species, shrimp species, and other bottom dwelling species like Pacific halibut, California halibut, and sea urchins; the complete closure of Chinook salmon troll fisheries; the complete closure of tribal groundfish fisheries; and the complete closure of recreational fisheries for groundfish, Pacific halibut, and Chinook salmon. This alternative is expected to have substantial negative economic consequences to communities, and these closures would be in place until 2048 – the year yelloweye is estimated to be rebuilt.

7.2.10.1.2 Economic Impact of a 12 metric ton Yelloweye OY in 2007

Under the alternative which puts in place a 12 metric ton yelloweye OY in 2007, multiple sectors and communities are estimated to be negatively impacted to a large degree. Analysis of commercial management measures designed to achieve a suite of OYs for all overfished species which included the 12 mt yelloweye OY showed that exvessel revenues would be reduced by nearly 40%. However, this is likely an overestimate of what would occur if only yelloweye were to be reduced to 12 mt and other overfished species were to remain at status quo levels. In terms of recreational fisheries however, it is estimated that recreational fishing effort for groundfish and Pacific halibut off Washington would decrease by 30% under the 12 metric ton yelloweye alternative. Off Oregon, it is estimated that recreational fishing effort for groundfish and Pacific halibut would decrease by 32%, and recreational fishing effort for groundfish off California would decrease by over 33%. In addition, fishing seasons would be shortened which would have additional implications as fewer tourists would be drawn to communities during times when fishing closures are in place. This means that economic impacts will be larger than indicated by just examining changes in angler trips.

Under the 12 mt 2007 OY alternative, it is believed that commercial fixed gear vessels that homeport along the northern Washington coast and Puget Sound would experience a complete closure of traditional fishing grounds for sablefish. Some of these vessels may choose to move further south along the coast and homeport in different locations in order to access other fishing grounds, however, this would have repercussions to those communities where fixed gear vessels currently homeport, and many of these communities are described as being resource-dependent. This means those communities would be negatively impacted to a larger degree than communities that are not as dependent on resource-based industries. It is estimated that these impacts would be in place until 2078, or 30 years longer than T_{MIN}. It is important to note that state managers of recreational fisheries have stated that multiple recreational fisheries cannot operate if the 2007 OY for yelloweye is less than 12 mt. In order to achieve the necessary reductions in yelloweye mortality, managers would need to completely close multiple sectors of recreational fisheries off Washington, Oregon, and northern California, meaning that for many recreational sectors, the economic impact of T_{MIN} is equivalent to an OY that is several tons higher.

Under a 12.6 metric ton yelloweye OY in 2007 the impacts to commercial fisheries, recreational fisheries, and fishing communities is expected to be nearly equivalent to a 12 metric ton OY.

7.2.10.1.3 Economic Impact of the Ramp-Down Strategy

The yelloweye ramp-down OY results in economic impacts to recreational fisheries that range from near status quo, to reductions in angler effort of approximately 22% in 2007 compared to 2005 levels. Commercial exvessel revenues for alternatives corresponding to the yelloweye ramp-down strategy show that revenues would range from near status quo, to reductions of 13% in 2007 compared to 2005 levels. Beyond 2007, the impacts are less clear as the impact of tools that will be developed will not be fully known until after they have been implemented. However, it is expected that the economic implications will be less than the 12 mt and 12.6 mt 2007 OY alternatives. It is estimated that these impacts would be in place until 2083.5, or 35.5 years longer than $T_{F=0}$.

7.2.10.1.4 Consideration of Other Yelloweye OY Alternatives

Optimum yields that are equivalent to an SPR harvest rate of 17 metric tons or greater in 2007 exceed Tmax according to the 2006 rebuilding analysis, and therefore are not further considered. However, negative economic consequences for these alternatives are far less than SPR harvest rates that correspond to a 12 mt or 12.6 mt OY in 2007.

7.2.10.2 Economic Impacts of Zero Harvest Alternatives for Rebuilding Species

The analysis of zero harvest alternatives examined the economic impacts of setting similar overfished species OYs to zero, where similarity was determined based on the correlation of species across latitude and depths. Species that were considered similar under this definition include canary and yelloweye rockfish; bocaccio and cowcod; and Pacific ocean perch and darkblotched rockfish. Widow rockfish was analyzed independently since it tends to be caught in a more pelagic environment compared to other overfished species.

Sectors were analyzed in this case based on the known associations of those sectors with overfished species under currently in place (2006) management measures. These include existing allocations between sectors and regions, area closures that are currently in place, and current patterns of fishery effort. The analysis shows two columns indicating sectors, where one column is titled “major sector” and another column “sub-sector or area-based stratification”. If a sector is not known to catch a particular overfished species at certain latitudes, then the portion or area of the sector that would need to be closed to keep the particular species catch at a zero harvest is listed specifically. For example, in order to reduce yelloweye and canary rockfish catch to zero, the fixed gear sablefish sector would need to be severely restricted, however west coast groundfish observer data shows this sector encounters those species north of Point Conception, so the affected sector is identified as "fixed gear sablefish north of Point Conception". The notion that an entire sector would need to be closed to protect an overfished species is based in the multi-species nature of the fishery. In many cases it is not possible to catch abundant stocks of target species without incidentally catching overfished species, and therefore, eliminating the catch of overfished species also requires eliminating the catch of target species that co-occur with those overfished species. In this analysis, figures represent the loss in revenue that occurs as a result of zero landings from overfished species as well as zero landings from target species that co-occur with those overfished species.

In this analysis, 2005 revenues are used as an indicator of revenue that would be lost if a sector were to be closed or restricted to reach a zero harvest of a particular overfished species. Table7-69 shows the amount of exvessel revenue that would be lost for each sector within each overfished species grouping, and the total revenue from 2005 for that entire sector is shown for comparison purposes to understand the magnitude of loss.

Based on this analysis, setting the OY of canary and yelloweye to zero would have the largest impact across recreational and commercial fisheries when compared to the other species groupings. The distribution of these impacts would be felt coastwide and across all sectors of the fishery. The second largest impact to commercial and recreational fisheries would be to set the widow OY to zero. This species would impact most sectors across the coast, but some fisheries off the Washington coast, non-groundfish trawl fisheries, and coastal pelagic species south of 40° 10 minutes North latitude would be unaffected. The species grouping with the third largest impact to commercial fisheries on an exvessel revenue basis is darkblotched and POP, whereas the species grouping with the third largest impact to recreational fisheries would be bocaccio and cowcod. Each of these groupings have very different regional and distributional impacts. Darkblotched and POP would impact most commercial sectors that are oriented toward the north, whereas bocaccio and cowcod would impact most commercial and recreational sectors that operate south of 40° 10 minutes North latitude. Finally, if the OY for all overfished species were to be set to zero, all sectors listed in the analysis would be impacted, and the total economic impact would be greater than any of the individual species groupings.

7.2.11 Other Analyses

Vulnerable Commercial Communities

Table 7-70 shows the percentage change in estimated commercial fishery income impacts by port group compared to the No Action Alternative for shoreside landings.

Under Alternative 1, the port groups with the greatest percentage decrease in estimated income from all Council managed commercial fisheries compared to the No Action alternative are Eureka (21.6%), Newport (20.2%) and Fort Bragg (20.0%). All three port groups consist of counties that were identified as three of the six "most vulnerable" counties (Lincoln, Humboldt, and Mendocino counties) in the Engagement, Dependence, Resiliency and Identification of Vulnerable Areas Analysis (Identification of Vulnerable Areas Analysis). These "most vulnerable" areas were identified for the purpose of ranking those counties and ports most reliant upon the commercial and recreational fishery resource but least able to adjust to additional decreases in harvest levels. The analysis identified six commercially "most vulnerable" counties and four "most vulnerable" cities based on commercial fishing data and one recreationally "most vulnerable" city based on recreational data. The analysis also identified several other vulnerable counties and cities that are considered potentially at risk but to a lesser degree than the "most vulnerable" areas.

Morro Bay (13%), Puget Sound (13%) and South and Central Washington Coast (10%) also have large decreases estimated under Alternative 1. The South and Central Washington Coast port group is comprised of three counties, two of which were identified as two of the six most vulnerable counties (Grays Harbor and Pacific counties). The port group also contains one of four cities identified as most vulnerable areas in the Identification of Vulnerable Areas Analysis (Ilwaco). Morro Bay and Puget Sound port groups also encompass some vulnerable areas, but to a lesser degree than the other port groups named above.

The greatest percentage decrease in estimated income from commercial groundfish fisheries compared to the No Action Alternative are Newport (43.5%), Astoria-Tillamook (41%), South and Central Washington Coast (39.9%), Coos Bay (35.9%), Eureka (35.5%), and Fort Bragg (33.3%). As mentioned above, Newport, South and Central Washington Coast, Eureka, and Fort Bragg port groups consist of five of the six counties identified as most vulnerable counties in the Identification of Vulnerable Areas Analysis (Lincoln, Grays Harbor, Pacific, Humboldt, and Mendocino counties). The Coos Bay port group also consists of one of the six counties identified as most vulnerable counties (Coos County). Astoria-Tillamook and Coos Bay encompass counties identified as vulnerable areas to a lesser degree than the ones mentioned above. However, the Astoria-Tillamook contains one of the four ports identified as most vulnerable ports (Garibaldi).

Under Alternative 2, the port groups with the greatest percentage decrease in estimated income from all Council managed commercial fisheries and groundfish fisheries compared to the No Action alternative are Newport (9.7% and 20.8% respectively) and South and Central Washington Coast (6% and 23.6% respectively). As mentioned above, these port groups consist of counties identified as most vulnerable areas.

Under Alternative 3, the port groups with the greatest percentage decrease in estimated income from all Council managed commercial fisheries and groundfish fisheries compared to the No Action alternative are North Washington Coast (4.2%) and Puget Sound (2.6%). Unidentified areas in Washington and North Washington Coast port groups are estimated to experience the largest decreases (14.3% and 9% respectively) in income. North Washington Coast contains one of the four most vulnerable ports (Neah Bay). Neah Bay and La Push are both located in the North Washington Coast port group and both are ranked as least resilient according to the Identification of Vulnerable Areas Analysis. That is, both are ranked in the top one-third of all cities on the West Coast with regard to low resiliency indicators (population levels, percentage of population living below the poverty level, unemployment rate, and industry diversification). Both were identified in a 2004 study by PSMFC as “isolated cities” or cities not located on a major highway and fell outside of a 35-mile buffer of cities over 20,000.

Vulnerable Recreational Communities

Table 7-71 shows the percentage change in estimated recreational income impacts compared to the No Action Alternative.

Under Alternative 1, the regions with the greatest percentage decrease in estimated income from total charter boat trips compared to the No Action alternative are CA South-Central Coast (53.7%), North Central Coast: San Mateo up through Marin County (47.4%), and North-Central Coast: Sonoma and Mendocino counties (47.1%). Brookings (36.1%), North Washington Coast (32.7%), and Newport (30.6%) are also expected to experience relatively large decreases. The South–Central Coast ties with the South Coast: San Diego through LA region as the most highly recreationally engaged area in California according to the Identification of Vulnerable Areas Analysis. The South–Central Coast region encompasses Moss Landing and Santa Cruz, two cities with low resiliency according to the Identification of Vulnerable Areas Analysis and two counties (Monterey and San Luis Obispo) with low resiliency. North-Central Coast: San Mateo up through Marin County contains one city with low resiliency (Oakland). The North-Central Coast: Sonoma and Mendocino region encompasses two cities (Fort Bragg and Bodega Bay) and one county (Mendocino) with low resiliency. The Brookings region contains one recreational vulnerable area (Gold Beach). North Washington Coast contains two recreational vulnerable areas (Neah Bay and La Push) and Newport contains two recreational vulnerable areas (Depoe Bay and Newport). With regard to private boat trips, North Washington Coast (27.3%), Brookings (22.1%), and South Coast: Ventura and Santa Barbara counties (20.4%) are estimated to experience the largest decreases in income. The North Washington Coast contains two recreational vulnerable cities (Neah Bay and La Push), and Brookings contains one recreational vulnerable city (Gold Beach).

The regions predicted to experience the greatest percentage decrease in estimated income under Alternative 1 from recreational groundfish charter boat fisheries compared to the No Action Alternative are the two North Central CA Coast regions (57.6% for San Mateo up through Marin County and 57.1% for Sonoma and Mendocino Counties), South Central Coast (55%) and North Washington Coast (50%). All Oregon regions are estimated to experience decreases above 39% and South CA Coast ports are estimated to experience decreases of about 35%. With regard to private trips, the South Coast regions (57.9% for Ventura and Santa Barbara counties and 57.5% for San Diego through Los Angeles County) are predicted to experience the greatest percentage decrease in income. All Oregon regions are estimated to experience decreases of above 37%.

Under Alternative 2, with regard to total charter boat trips, the regions with the greatest percentage decrease in estimated income compared to the No Action Alternative are South-Central Coast: San Luis Obispo County through Santa Cruz (52.5%), North-Central Coast: San Mateo up through Marin County (44.2%), North-Central Coast: Sonoma and Mendocino counties (43.5%), and North Washington Coast (27.9%). As mentioned previously, the South-Central Coast: San Luis Obispo County through Santa Cruz contains two counties and two cities with low resiliency. North-Central Coast: San Mateo up through Marin County contains one city with low resiliency. North-Central Coast: Sonoma and Mendocino counties contain two cities and one county with low resiliency. The North Washington Coast region contains two recreational vulnerable cities. With regard to total private trips, North Washington Coast (22%) and South Coast: Ventura and Santa Barbara counties (13%) are estimated to experience the largest decreases in income from recreational fishing.

The regions predicted to experience the greatest percentage decrease in estimated income under Alternative 2 from recreational groundfish charter boat fisheries compared to the No Action Alternative are the CA North Central regions (54.3% for Sonoma and Mendocino counties and 53.8% for San Mateo up through Marin County), the CA South Central region (53.7%), and the North Washington Coast (41.7%). With regard to private recreational groundfish trips, the South Coast regions (34.9% for San Diego County through Los Angeles County and 34.2% for Ventura and Santa Barbara counties) and North Washington Coast (31.7%) are estimated to experience the largest decreases in income from recreational fishing.

Under Alternative 3, the regions with the greatest percentage decrease in estimated income from total recreational charter boat trips compared to the No Action Alternative are South-Central Coast (21%) and North Washington Coast (7.7%). With regard to private groundfish trips, South-Central Coast (22.1%) and South Coast: Ventura and Santa Barbara counties (10.2%) are estimated to experience the largest decreases in income from recreational fishing.

The regions predicted to experience the greatest percentage decrease in estimated income under

Alternative 3 from recreational groundfish charter boat trips compared to the No Action Alternative are CA South-Central Coast (21.4%) and North Washington Coast (16.7%). With regard to private trips for groundfish, the South CA Coast (30.2% for San Diego County through LA County, and 28.9% for Ventura and Santa Barbara counties), South Central CA Coast (25.2%), and North Washington coast (24.4%) are estimated to experience the largest decreases in income from recreational fishing.

Cumulative Effects

The Council on Environmental Quality's regulations implementing the procedural provisions of the National Environmental Policy Act defines cumulative effects as

> The impact on the environment which results from the incremental impact of the action when added to other past, present, and reasonably foreseeable future actions regardless of what agency (Federal or non-Federal) or person undertakes such other actions.

Past actions affecting the socioeconomic environment have included catch restrictions and declining revenue for vessels participating in groundfish fisheries, increasing regulatory complexity, the requirement to carry vessel monitoring systems, the imposition of area closures to protect essential fish habitat, restrictions on fishing gear to protect essential fish habitat, a trawl vessel buyback, growth and change in the demographic and economic nature of coastal communities, and consolidation in the shore-based processing sector amongst others. Reasonably foreseeable future effects include continued restrictions on catch levels to protect overfished species, continued development of tools that reduce the bycatch of overfished species, and continued growth and change in the population of coastal communities. These concepts will be discussed in relation to the alternatives considered and adopted by the council in more detail following the June meeting of the Pacific Fishery Management Council.

a/ multiple records exist for landings with HKL gear that do not have an associated vessel id. The vessel count in this case is an estimate

b/ annual revenue of $2,500 is used as a proxy for vessels that had efforts directed at groundfish

c\ if ≥20% of revenue was from groundfish, a vessel was assumed to have target groundfish at some point during the year

8.0 SUMMARY OF OTHER ENVIRONMENTAL MANAGEMENT ISSUES

Based on the environmental impacts disclosed in Chapters 3 through 7, this chapter summarizes a range of issues that an EIS must address. These issues are identified at 40 CFR 1502.16, describing the analysis of environmental consequences in an EIS. The last two sections in this chapter describe mitigation measures (as required by 40 CFR 1502.16(h)) and identify unavoidable adverse impacts (as required by 40 CFR 1502.16).

8.1 Short-Term Uses Versus Long-Term Productivity

The tradeoff between short-term costs versus long-term risk in setting OYs is possibly the most important tradeoff governing the management of renewable resources. Balancing short-term use and long-term productivity is the essence of the range of harvest specification (OY) alternatives. Short-term uses generally affect the present quality of life for the public, in contrast to long-term productivity, which affects the quality of life for future generations, based on environmental sustainability. The proposed actions indirectly affect the sustainability of marine resources by constraining fishing mortality in 2007–08 consistent with the best available science contained in stock assessments or other information sources. These harvest rates are also consistent with rebuilding plans, as modified according to the proposed actions. The MSA and NSGs establish a framework for rebuilding overfished stocks─establishing long-term productivity─while recognizing short-term use as reflected in the needs of fishing communities. Taken together these actions represent a tradeoff between short-term benefits, reflected in revenue generated from fishing in 2005 and 2006, and long-term productivity of fish stocks, which determines the abundance of fish in the future, and thus future harvests. Managers must respond to changes in resource status, whether a result of harvests or other, environmental factors; this requires effective monitoring of total fishing mortality. A better understanding of the role of environmental and ecological factors play in affecting stock productivity would also enhance managers' ability to predict future stock response to current harvest levels.

Multi year management is based on the framework in the FMP, which dictates how harvest control rules should be set in order to produce sustainable harvests over the long term. While each species' harvest in any one year affects long-term productivity, these harvests are part of an ongoing activity, fishing over many years, which cumulatively affects productivity.

8.2 Irreversible Resource Commitments

An irreversible commitment represents some permanent loss of an environmental attribute or service. The use of non-renewable resources is irreversible; unsustainable renewable resource use may be irreversible if future production is permanently reduced or, at the extreme, is extinguished.

The use of non-renewable energy resources, such as fossil fuel, represents a pervasive irreversible commitment associated with the proposed action because fishing vessels are mechanically powered. The use of energy is discussed below in Section 9.4.

However the proposed action, implemented under the alternatives, does not by itself represent an irreversible commitment, because harvest levels under the Council-preferred OYs are specified for each year in the biennium, and management measures are projected to constrain total fishing mortality to these levels. Inseason monitoring combined with adjustments to the management measures will be used if catch projections indicate harvest levels may be exceeded during either of the two years in the biennial management period. Cumulatively, past, current, and future specifications could result in an irreversible commitment if a stock were to be extirpated or if population size is reduced to such a degree that even if harvesting stopped completely the stock would not recover. Theoretical work, for example, suggests that ecological factors can inhibit recovery of stocks that are reduced to very low biomass levels {MacCall, 2002 597 /id;Walters, 2001 545 /id}. Although several overfished stocks, such as cowcod, bocaccio, canary rockfish, and yelloweye rockfish, are at low biomasses relative to B_{MSY} (the biomass capable of supporting MSY), there can be considerable uncertainty about the likelihood of recovery. For example, the 2002 bocaccio stock assessment and rebuilding analysis {MacCall, 2002 406 /id;MacCall, 2002 407 /id}, used as the basis for setting harvest specifications for 2003, concluded that the stock was unlikely to recover within the rebuilding framework time period (T_{MAX}) even if fishing mortality was reduced to zero. Subsequent stock assessments {MacCall, 2003 663 /id;MacCall, 2006 1207 /id} painted a quite different picture. Detection of a strong 1999 year class in more recent data sets, along with other factors, resulted in a substantial increase in the OYs for 2004 onward in comparison to 2003 (from under 20 mt in 2003 to 309 mt in 2006), based on the Council's rebuilding plan. Given this variability in assessment results, there is not enough information to determine a definite threshold below which population decline is irreversible.

8.3 Irretrievable Resource Commitments

A resource is irretrievably committed if its use is lost for time, but is not actually or practically lost permanently. The analysis of direct, indirect and cumulative impacts in Chapters 3 through 7 generally describe irretrievable resource commitments, and in the case of renewable resources, these parallel the tradeoff between short-term use and long-term productivity. Alternatives that constrain fish harvests to a level related to the harvest specifications and adopted rebuilding plans are predicted to allow future sustainable harvests. The fish that are harvested represent an irretrievable resource commitment, as do the inputs in terms of capital and labor (including energy and resources) needed to harvest and market these fish. In addition, the difference between the current sustainable yield for a stock and the long-term MSY (recognizing this may be only a theoretical optimum) would represent an irretrievable resource commitment.

8.4 Energy Requirements and Conservation Potential of the Alternatives

The proposed action indirectly affects energy use primarily in the form of fossil fuels used to power surveillance craft and fishing vessels. Energy used in at-sea and aerial monitoring and enforcement activities is a direct effect. Change in the level of this type of monitoring is hard to predict because it depends on the types of management measures that will be implemented biennially and inseason. Generally, the RCA, which was first implemented in late 2002, would require more surveillance to be effective. However, the VMS requirement implemented at the beginning of 2004 will compensate for the increased surveillance need because vessel positions can be remotely monitored. Finally, the availability of ships and aircraft to conduct surveillance, which is partly contingent on U.S. Coast Guard mission priorities, will also dictate the level and the number of patrols, affecting energy use. For these reasons, it is difficult to predict how energy use would change from baseline conditions. The proposed action affects fishing activity and thus the consumption of fuel by fishing vessels. Fuel consumption is likely to correlate with projected harvest levels, which are a consequence of the different types of management measures in the alternatives. However, there are a variety of other factors that could affect overall energy use and efficient utilization. Changes in fuel prices, for example, could affect the level of fishing vessel operations independent of the constraining effect of management measures under the alternatives.

8.5 Urban Quality, Historic Resources, and the Design of the Built Environment

The direct and indirect impacts on the urban quality, historic resources, and the built environment will be minimal. Cumulative impacts could be greater. Fishing income has already fallen in many coastal communities, both because of declines in groundfish landings and in other fisheries such as salmon. Cumulative loss of income could lead to a fall in private investment that could curtail maintenance of buildings and other private infrastructure. Public investment, which includes shoreside amenities and marine-related infrastructure such as docks, boat basins, jetties, and navigable channels, is sensitive to changes in tax revenue. By itself, changes in fishing-related revenue may not have an overwhelming impact on local tax revenues, but external factors such as changes in the broader economy could act cumulatively. It is also possible that as private investment shrinks so that, for example, there are fewer fishing vessels using shoreside infrastructure, there will be less political motivation to devote public resources to these uses. In large urban centers, such as Seattle, San Francisco, and the Los Angeles area, the relative impact would be slight and probably not result in changes in urban quality substantially different from the baseline. For small communities, and especially those likely to be more hard hit by declining revenues, the effect on urban quality could be noticeable, especially over the long term (again, depending on external economic factors). These changes could also affect cultural and historic resources as fishing and fishing-dependent activities are supplanted or simply disappear, changing the character of a coastal community. Since the effects described above are speculative; it is not possible to compare the effects of the alternatives beyond projected changes in revenue. No direct impacts of the proposed actions on cultural historic resources protected under the National Historical Preservation Act are expected. Because indirect or cumulative impacts are too speculative, these impacts cannot be predicted.

8.6 Possible Conflicts Between the Proposed Action and Other Plans and Policies For the Affected Area

Overfished groundfish species are caught incidentally in fisheries managed under other Council FMPs (salmon, CPS, and HMS). More restrictive measures are likely to affect these fisheries and thus conflict with some of the objectives of these FMPs. (FMPs try to strike a balance between conservation and utilization, so they include objectives related to resource use.)

8.7 Significant and Unavoidable Adverse Impacts

The EIS must include a discussion of those adverse effects that cannot be avoided (40 CFR 1502.16). This discussion focuses on potentially significant adverse impacts of the proposed action, as implemented by the preferred alternative. Council on Environmental Quality (CEQ) regulations at 40 CFR 1508.27 define “significantly” in terms of both context and intensity, and provide ten factors to consider when evaluating the intensity of an impact. National Oceanic and Atmospheric Administration (NOAA) provides agency guidance in determining significant impacts of fishery management actions in NOAA administrative order (NAO) 216-6 at §6.02, which expands on the CEQ definition. These criteria focus on the components of the human environment most likely to be affected by these types of actions. Based on the guidance in these two sources, the proposed action could result in the following *potentially* significant impacts.

This section to be completed after the Council chooses a preferred alternative.

8.8 Mitigation

An EIS must discuss “means to mitigate the adverse environmental impacts” stemming from the proposed action (40 CFR 1502.16(h)), even if the adverse impacts are not by themselves significant. Alternatives are mitigative to the degree that management measures constrain fishing mortality to levels below the harvest specifications. Further mitigation measures could address the adverse impacts that would still occur with implementation of any of the action alternatives.

This section to be completed after the Council chooses a preferred alternative.

8.9 Environmentally Preferred Alternative and Rationale for Preferred Alternative

NEPA regulations, at 40 CFR 1505.2(b), state that the ROD will identify an alternative or alternatives considered "environmentally preferable." Guidance, in the form of *Forty Most Asked Questions Concerning CEQ's NEPA Regulations*, states that the environmentally preferable alternative is "the alternative that will promote the national environmental policy as expressed in NEPA's Section 101. Ordinarily, this means the alternative that causes the least damage to the biological and physical environment; it also means the alternative which best protects, preserves, and enhances historic, cultural, and natural resources" (Question 6.A).

This section to be completed after the Council chooses a preferred alternative.

9.0 CONSISTENCY WITH THE GROUNDFISH FMP AND MSA NATIONAL STANDARDS

To be completed after June 2006 Council meeting.

9.1 FMP Goals and Objectives

The Groundfish FMP goals and objectives are listed below. The way in which the harvest specifications and management measures for 2007 and 2008 addresses each objective is briefly described in italics below the relevant statement.

Management Goals.

Goal 1 - Conservation. Prevent overfishing and rebuild overfished stocks by managing for appropriate harvest levels, and prevent, to the extent practicable, any net loss of the habitat of living marine resources.

Goal 2 - Economics. Maximize the value of the groundfish resource as a whole.

Goal 3 - Utilization. Achieve the maximum biological yield of the overall groundfish fishery, promote year-round availability of quality seafood to the consumer, and promote recreational fishing opportunities.

Objectives. To accomplish these management goals, a number of objectives will be considered and followed as closely as practicable:

Conservation.

Objective 1. Maintain an information flow on the status of the fishery and the fishery resource which allows for informed management decisions as the fishery occurs.

Objective 2. Adopt harvest specifications and management measures consistent with resource stewardship responsibilities for each groundfish species or species group.

Objective 3. For species or species groups which are below the level necessary to produce MSY, consider rebuilding the stock to the MSY level and, if necessary, develop a plan to rebuild the stock.

Objective 4. Where conservation problems have been identified for nongroundfish species, and the best scientific information shows the groundfish fishery has a direct impact on the ability of that species to maintain its long-term reproductive health, the Council may consider establishing management measures to control the impacts of groundfish fishing on those species. Management measures may be imposed on the groundfish fishery to reduce fishing mortality of a nongroundfish species for documented conservation reasons. The action will be designed to minimize disruption of the groundfish fishery, in so far as consistent with the goal to minimize the bycatch of nongroundfish species, and will not preclude achievement of a quota, harvest guideline, or allocation of groundfish, if any, unless such action is required by other applicable law.

None of the alternatives include new measures intended to control the impacts of groundfish fishing on nongroundfish stocks.

Objective 5. Describe and identify EFH, adverse impacts on EFH, and other actions to conserve and enhance EFH, and adopt management measures that minimize, to the extent practicable, adverse impacts from fishing on EFH.

Economics.

Objective 6. Attempt to achieve the greatest possible net economic benefit to the nation from the managed fisheries.

Objective 7. Identify those sectors of the groundfish fishery for which it is beneficial to promote year-round marketing opportunities and establish management policies that extend those sectors' fishing and marketing opportunities as long as practicable during the fishing year.

Objective 8. Gear restrictions to minimize the necessity for other management measures will be used whenever practicable.

Utilization.

Objective 9. Develop management measures and policies that foster and encourage full utilization (harvesting and processing) of the Pacific Coast groundfish resources by domestic fisheries.

There has been no foreign fishing on the West Coast for more than a decade, so all of the alternatives meet this objective.

Objective 10. Recognizing the multispecies nature of the fishery and establish a concept of managing by species and gear or by groups of interrelated species.

As in past years, management measures in all of the alternatives use species groups related to particular fisheries or gear to structure trip limits.

Objective 11. Strive to reduce the economic incentives and regulatory measures that lead to wastage of fish. Also, develop management measures that minimize bycatch to the extent practicable and, to the extent that bycatch cannot be avoided, minimize the mortality of such bycatch. In addition, promote and support monitoring programs to improve estimates of total fishing-related mortality and bycatch, as well as those to improve other information necessary to determine the extent to which it is practicable to reduce bycatch and bycatch mortality.

GCAs are meant to reduce bycatch of overfished species by prohibiting fishing that generates significant bycatch in areas where these species are most abundant. (GCAs are included in all the alternatives.) In addition, trip limits under all the alternatives are set through model projections that include estimated bycatch, based on data derived from the WCGOP. This provides the best estimates of total fishing-related mortality and bycatch currently available.

Objective 12. Provide for foreign participation in the fishery, consistent with the other goals to take that portion of the OY not utilized by domestic fisheries while minimizing conflict with domestic fisheries.

This objective is no longer relevant, since all stocks are fully utilized by domestic fishers.

Social Factors.

Objective 13. When conservation actions are necessary to protect a stock or stock assemblage, attempt to develop management measures that will affect users equitably.

The Council process facilitates input from resource user groups, state and federal agencies, and the general public. This promotes the formulation of equitable management measures.

Objective 14. Minimize gear conflicts among resource users.

Although redistribution of fishing effort because of GCA closures could increase crowding in nearshore areas, this has not emerged as an issue voiced during scoping for this EIS or through other public comment opportunities during Council meetings.

Objective 15. When considering alternative management measures to resolve an issue, choose the measure that best accomplishes the change with the least disruption of current domestic fishing practices, marketing procedures, and the environment.

Management measures proposed for 2007 and 2008 do not differ substantially in kind from those used since 2004. GCAs have been in use since 2002, and this base of experience has allowed managers to propose configurations that vary less over the course of the year, simplifying their application.

Objective 16. Avoid unnecessary adverse impacts on small entities.

Section 10.3.2 evaluates the impact of the proposed action on small entities, as required by the Regulatory Flexibility Act, based on information and analyses in the EIS.

Objective 17. Consider the importance of groundfish resources to fishing communities, provide for the sustained participation of fishing communities, and minimize adverse economic impacts on fishing communities to the extent practicable.

The impacts of all the alternatives on communities are evaluated in Sections 7.3.6, 7.4.6, and 7.5.6.

Objective 18. Promote the safety of human life at sea.

GCAs could affect safety if more vessels elect to fish seaward of the closed areas and are more exposed to bad weather conditions. If smaller vessels traditionally fishing in the areas now part of GCAs, or shoreward elect to fish seaward of the GCAs weather-related safety issues could arise. Use of selective flatfish trawl gear north of 40°10' N latitude has not only provided increased trip limits for target species, but has also decreased the size of the trawl RCAs. This provides increased opportunity shoreward of the RCA and decreased incentive for smaller vessels to fish seaward of the RCA. Implementation of a vessel monitoring system capable of sending distress calls could mitigate this safety issue.

9.2 National Standards

An FMP or plan amendment and any pursuant regulations must be consistent with ten national standards contained in the MSA (§301). These are:

National Standard 1 states that conservation and management measures shall prevent overfishing while achieving, on a continuing basis, the optimum yield from each fishery for the United States fishing industry.

The harvest specification action alternatives all include OY values that reflect harvest rates below the overfishing threshold and include precautionary reductions to rebuild overfished stocks and other stocks that, while not overfished, are at a biomass below the level necessary to produce MSY. The No Action Alternative is not based on the best available science for all stocks and, in some cases, would specify harvest limits that are not sufficiently precautionary.

National Standard 2 states that conservation and management measures shall be based on the best scientific information available.

OY values in the harvest specification action alternatives, including the Council-preferred Alternative, are based on the most recent stock assessments, developed through the peer-review STAR process. This represents the best available science. The No Action Alternative OY values are based on stock assessments conducted in 2004 for management in 2005-2006, the years to which the No Action Alternative management measures apply. Given that more recent stock assessments are available, the No Action Alternative does not use the best available science.

National Standard 3 states that, to the extent practicable, an individual stock of fish shall be managed as a unit throughout its range, and interrelated stocks of fish shall be managed as a unit or in close coordination.

Some groundfish stocks are managed as individual units with specific trip limits. However, given the multi-species nature of many groundfish fisheries, other stocks are grouped in stock complexes and managed accordingly. This generally applies to non-target species for which no individual stock assessments have been performed. Until recently, landings of many species in groundfish fisheries were not recorded individually. Nongroundfish fisheries also may not report incidental groundfish catches at the species level. This limits the amount of time-series data available for individual species stock assessments. However, whenever possible individual stocks are assessed. Stocks are managed throughout the range of that stock (as opposed to the species), although issues do arise in the case of stocks straddling international borders. For this reason, allocation of the harvestable surplus of Pacific whiting between the U.S. and Canada is subject to a negotiated agreement.

National Standard 4 states that conservation and management measures shall not discriminate between residents of different states. If it becomes necessary to allocate or assign fishing privileges among various United States fishers, such allocation shall be (A) fair and equitable to all such fishers; (B) reasonably calculated to promote conservation; and (C) carried out in such manner that no particular individual, corporation, or other entity acquires an excessive share of such privileges. The proposed measures will not discriminate between residents of different states.

Management measures are developed through the Council process, which facilitates substantial participation by state representatives. Generally, state proposals are brought forward when alternatives are crafted and integrated to the degree practicable. Decisions about catch allocation between different sectors or gear groups are also part of this participatory process, and emphasis is placed on equitable division while ensuring conservation goals. None of the management measures in the alternatives would allocate specific shares or privileges to one individual or corporation.

National Standard 5 states that conservation and management measures shall, where practicable, consider efficiency in the utilization of fishery resources; except that no such measure shall have economic allocation as its sole purpose.

Management measures in the groundfish fishery are not designed specifically for the purpose of efficient utilization. However, lower OY levels and other restrictions are likely to result in further fleet capacity reduction as fishing becomes economically unviable for more vessels. There is broad consensus that capacity reduction in some sectors is needed to rationalize fisheries. In response, the Council and NMFS implemented a fixed gear permit stacking program through Amendment 14 to the FMP. NMFS has also completed a trawl vessel buyback program to reduce the size of the limited entry fleet. Additionally, the Council has begun to explore the potential for individual quotas, in part, as a means of providing regulatory flexibility and economically viable fishing communities.

National Standard 6 states that conservation and management measures shall take into account and allow for variations among, and contingencies in, fisheries, fishery resources, and catches.

Management measures reflect differences in catch, and in particular bycatch of overfished species, among different fisheries. Because of the low harvest specifications for overfished species, management measures are proposed for nongroundfish fisheries to minimize bycatch of these species. Each alternative was evaluated in terms of the probable bycatch of overfished species, based on the proposed management measures. (See Chapter 2 and Chapter 4.) This allows comparison between the proposed OY and a judgement of whether management measures will constrain fisheries sufficiently.

National Standard 7 states that conservation and management measures shall, where practicable, minimize costs and avoid unnecessary duplication.

The alternatives do not explicitly address this standard. Generally, by coordinating management, monitoring, and enforcement activities between the three West Coast states duplication, and thus cost, is minimized. Necessary monitoring and enforcement programs, such as the use of fishery observers and implementation of VMS, increase management costs. But these efforts are necessary to effective management.

National Standard 8 states that conservation and management measures shall, consistent with the conservation requirements of this Act (including the prevention of overfishing and rebuilding of overfished stocks), take into account the importance of fishery resources to fishing communities in order to (A) provide for the sustained participation of such communities, and (B) to the extent practicable, minimize adverse economic impacts on such communities.

This document evaluates the effects of the alternatives on fishing communities (see Sections 7.3.6, 7.4.6, and 7.5.6), and these effects were taken into account in choosing the preferred harvest specification and management measure alternatives. The preferred alternatives represent the Council's judgment of the best tradeoff between the need to conserve and rebuild fish stocks and the economic impacts of the necessary management measures. Generally, this tradeoff is resolved by structuring management measures to allow communities to access healthy, harvestable stocks while minimizing catch of overfished stocks.

National Standard 9 states that conservation and management measures shall, to the extent practicable, (A) minimize bycatch and (B) to the extent bycatch cannot be avoided, minimize the mortality of such bycatch.

Minimizing bycatch, of all species and overfished species in particular, is an important component of the alternatives. GCAs are meant to keep fishing away from areas where overfished species are most abundant, and therefore reduce bycatch. Trip limits are structured to discourage directed and incidental catch of these species, but where bycatch is unavoidable, to allow some minimal retention. Integration of observer data into the management process allows more accurate estimates of bycatch rates, and thus *total catch estimates. Selective flatfish trawl gear has demonstrated reduce bycatch rates for several overfished rockfish species and is required north of 40 °10' N latitude shoreward of the RCA.*

National Standard 10 states that conservation and management measures shall, to the extent practicable, promote the safety of human life at sea.

RCAs could affect safety if more vessels elect to fish seaward of the closed areas and are more exposed to bad weather conditions. Use of selective flatfish trawl gear north of 40 °10' N latitude has not only provided increased trip limits for target species, but has also decreased the size of the trawl RCAs thereby providing additional opportunity shoreward of the RCA and decreased incentive for smaller vessels to fish seaward of the RCA. For vessels electing to increase the amount of time fishing seaward of RCAs, implementing a VMS capable of sending distress calls could provide some mitigation. Although units with this capability have been approved for use, vessel owners are not required to purchase a unit with this capability. Also, by providing near real-time vessel position data, VMS could aid in search and rescue operations.

9.3 Other Applicable MSA Provisions

Harvest specifications are set based on targets established in overfished species rebuilding plans, which conform to Section 304(e)–Rebuild Overfished Fisheries. Rebuilding plans contain the elements required by Section 304(e)(4) and discussed in the NSGs (50 CFR 600.310).

Chapter 3 in this EIS constitutes an EFH assessment of the proposed action's impacts, as required by 50 CFR 600.920 (e)(3). NMFS prepared an EIS evaluating programmatic measures designed to identify and describe West Coast groundfish EFH, and minimize potential fishing impacts on West Coast groundfish EFH. The Council took final action amending the groundfish FMP to incorporate new EFH provisions in November 2005. NMFS partially approved the amendment in March 2006. Implementing regulations became effective in June 2006.

10.0 CROSS-CUTTING MANDATES

10.1 Other Federal Laws

10.1.1 Coastal Zone Management Act

Section 307(c)(1) of the federal Coastal Zone Management Act (CZMA) of 1972 requires all federal activities that directly affect the coastal zone be consistent with approved state coastal zone management programs to the maximum extent practicable. The *Council-preferred Alternative* would be implemented in a manner that is consistent to the maximum extent practicable with the enforceable policies of the approved coastal zone management programs of Washington, Oregon, and California. This determination has been submitted to the responsible state agencies for review under Section 307(c)(1) of the CZMA. The relationship of the groundfish FMP with the CZMA is discussed in Section 11.7.3 of the Groundfish FMP. The Groundfish FMP has been found to be consistent with the Washington, Oregon, and California coastal zone management programs. The recommended action is consistent and within the scope of the actions contemplated under the framework FMP.

Under the CZMA, each state develops its own coastal zone management program which is then submitted for federal approval. This has resulted in programs which vary widely from one state to the next. Harvest specifications and management measures for 2007-2008 are not expected to affect any state's coastal management program.

10.1.2 Endangered Species Act

NMFS issued BOs under the ESA on August 10, 1990, November 26, 1991, August 28, 1992, September 27, 1993, May 14, 1996, December 15, 1999, and a supplemental BO on March, 11, 2006, pertaining to the effects of the groundfish fishery on Chinook salmon (Puget Sound, Snake River spring/summer, Snake River fall, upper Columbia River spring, lower Columbia River, upper Willamette River, Sacramento River winter, Central Valley spring, California coastal), coho salmon (Central California coastal, southern Oregon/northern California coastal), chum salmon (Hood Canal summer, Columbia River), sockeye salmon (Snake River, Ozette Lake), and steelhead (upper, middle and lower Columbia River, Snake River Basin, upper Willamette River, central California coast, California Central Valley, south-central California, northern California, southern California). During the 2000 Pacific whiting season, the whiting fisheries exceeded the Chinook bycatch amount specified in the Pacific whiting fishery BO (December 15, 1999) incidental take statement estimate of 11,000 fish, by approximately 500 fish. In the 2001 whiting season, however, the whiting fishery's Chinook bycatch was about 7,000 fish, which approximates the long-term average. The whiting fishery again exceeded the incidental take statement level of 11,000 fish in 2005 when almost 12,000 Chinook salmon were caught. In addition, new information became available about the bycatch of salmon in the groundfish bottom trawl sector. The March 11, 2006, supplemental BO evaluated this information and proposes measures to mitigate this bycatch. NMFS has concluded that implementation of the FMP for the Pacific Coast groundfish fishery is not expected to jeopardize the continued existence of any endangered or threatened species under the jurisdiction of NMFS, or result in the destruction or adverse modification of critical habitat. The proposed action is within the scope of these consultations. Chapter 5 in this EIS evaluates the impacts of the proposed action on protected species.

10.1.3 Marine Mammal Protection Act

The MMPA of 1972 is the principle federal legislation that guides marine mammal species protection and conservation policy in the United States. Under the MMPA, NMFS is responsible for the management and conservation of 153 stocks of whales, dolphins, porpoise, as well as seals, sea lions, and fur seals;

while the U.S. Fish and Wildlife Service is responsible for walrus, sea otters, and the West Indian manatee.

Off the West Coast, the Steller sea lion (*Eumetopias jubatus*) eastern stock, Guadalupe fur seal (*Arctocephalus townsendi*), and Southern sea otter (*Enhydra lutris*) California stock are listed as threatened under the ESA. The sperm whale (*Physeter macrocephalus*) Washington, Oregon, and California stock, humpback whale (*Megaptera novaeangliae*) Washington, Oregon, and California - Mexico Stock, blue whale (*Balaenoptera musculus*) eastern north Pacific stock, and Fin whale (*Balaenoptera physalus*) Washington, Oregon, and California stock are listed as depleted under the MMPA. Any species listed as endangered or threatened under the ESA is automatically considered depleted under the MMPA.

The West Coast groundfish fisheries are considered a Category III fishery, indicating a remote likelihood of or no known serious injuries or mortalities to marine mammals, in the annual list of fisheries published in the *Federal Register*. Based on its Category III status, the incidental take of marine mammals in the West Coast groundfish fisheries does not significantly impact marine mammal stocks. The proposed action will affect the intensity, duration, and location of groundfish fisheries through implemented management measures. But these changes would not change the effects of the groundfish fisheries on marine mammals.

10.1.4 Migratory Bird Treaty Act

The MBTA of 1918 was designed to end the commercial trade of migratory birds and their feathers that, by the early years of the 20th century, had diminished the populations of many native bird species. The MBTA states that it is unlawful to take, kill, or possess migratory birds and their parts (including eggs, nests, and feathers) and is a shared agreement between the United States, Canada, Japan, Mexico, and Russia to protect a common migratory bird resource. The MBTA prohibits the directed take of seabirds, but the incidental take of seabirds does occur. The proposed action is unlikely to affect the incidental take of seabirds protected by the MBTA.

10.1.5 Paperwork Reduction Act

The proposed action, as implemented by any of the alternatives considered in this EIS, does not require collection-of-information subject to the Paperwork Reduction Act.

10.1.6 Regulatory Flexibility Act

The purpose of the RFA is to relieve small businesses, small organizations, and small governmental entities of burdensome regulations and record-keeping requirements. Major goals of the RFA are; (1) to increase agency awareness and understanding of the impact of their regulations on small business, (2) to require agencies communicate and explain their findings to the public, and (3) to encourage agencies to use flexibility and to provide regulatory relief to small entities. The RFA emphasizes predicting impacts on small entities as a group distinct from other entities and the consideration of alternatives that may minimize the impacts while still achieving the stated objective of the action. An IRFA is conducted unless it is determined that an action will not have a "significant economic impact on a substantial number of small entities." The RFA requires that an IRFA include elements that are similar to those required by EO 12866 and NEPA. Therefore, the IRFA has been combined with the RIR and NEPA analyses. Section 10.3 (below) summarizes the analytical conclusions specific to the RFA and EO 12866.

10.2 Executive Orders

10.2.1 EO 12866 (Regulatory Impact Review)

EO 12866, Regulatory Planning and Review, was signed on September 30, 1993, and established guidelines for promulgating new regulations and reviewing existing regulations. The EO covers a variety of regulatory policy considerations and establishes procedural requirements for analysis of the benefits and costs of regulatory actions. Section 1 of the EO deals with the regulatory philosophy and principles that are to guide agency development of regulations. It stresses that in deciding whether and how to regulate, agencies should assess all of the costs and benefits across all regulatory alternatives. Based on this analysis, NMFS should choose those approaches that maximize net benefits to society, unless a statute requires another regulatory approach.

The RIR and IRFA determinations are part of the combined summary analysis in Section 11.3 of this document.

11.2.2 EO 12898 (Environmental Justice)

EO 12898 obligates federal agencies to identify and address "disproportionately high adverse human health or environmental effects of their programs, policies, and activities on minority and low-income populations in the United States" as part of any overall environmental impact analysis associated with an action. NOAA guidance, NAO 216-6, at §7.02, states that "consideration of EO 12898 should be specifically included in the NEPA documentation for decision-making purposes." Agencies should also encourage public participation—especially by affected communities—during scoping, as part of a broader strategy to address environmental justice issues.

The environmental justice analysis must first identify minority and low-income groups that live in the project area and may be affected by the action. Typically, census data are used to document the occurrence and distribution of these groups. Agencies should be cognizant of distinct cultural, social, economic, or occupational factors that could amplify the adverse effects of the proposed action. (For example, if a particular kind of fish is an important dietary component, fishery management actions affecting the availability, or price of that fish, could have a disproportionate effect.) In the case of Indian tribes, pertinent treaty or other special rights should be considered. Once communities have been identified and characterized, and potential adverse impacts of the alternatives are identified, the analysis must determine whether these impacts are disproportionate. Because of the context in which environmental justice is developed, health effects are usually considered, and three factors may be used in an evaluation: whether the effects are deemed significant, as the term is employed by NEPA; whether the rate or risk of exposure to the effect appreciably exceeds the rate for the general population or some other comparison group; and whether the group in question may be affected by cumulative or multiple sources of exposure. If disproportionately high adverse effects are identified, mitigation measures should be proposed. Community input into appropriate mitigation is encouraged.

Section 8.5 in Appendix A to the 2005–06 groundfish harvest specifications EIS describes a methodology, using 2000 U.S. Census data, to identify potential "communities of concern" because their populations have a lower income or a higher proportion of minorities than comparable communities in their region. Based on this information, but focusing on more isolated, rural coastal communities, Section 7.5.7 of this document discusses the potential effects of the proposed action on minority and low income populations. It should be noted that fishery participants make up a small proportion of the total population in these communities, and their demographic characteristics may be different from the community as a whole. However, information specific to fishery participants is not available. Furthermore, different segments of the fishery-involved population may differ demographically. For example, workers in fish processing plants may be more often from a minority population while deckhands may be more frequently low income in comparison to vessel owners.

Participation in decisions about the proposed action by communities that could experience disproportionately high and adverse impacts is another important principle of the EO. The Council offers a range of opportunities for participation by those affected by its actions and disseminates information to affected communities about its proposals and their effects through several channels. In addition to Council membership, which includes representatives from the fishing industries affected by Council action, the GAP, a Council advisory body, draws membership from fishing communities affected by the proposed action. While no special provisions are made for membership to include representatives from low income and minority populations, concerns about disproportionate effects to minority and low income populations could be voiced through this body or to the Council directly. Although Council meetings are not held in isolated coastal communities for logistical reasons, they are held in different places up and down the West Coast to increase accessability. In addition, fishery management agencies in Oregon and California sponsored public hearings in coastal communities to gain input on the proposed action. The comments were made available to the Council in advance of their decision to choose a preferred alternative.

The Council disseminates information about issues and actions through several media. Although not specifically targeted at low income and minority populations, these materials are intended for consumption by affected populations. Materials include a newsletter, describing business conducted at Council meetings, notices for meetings of all Council bodies, and fact sheets intended for the general reader. The Council maintains a postal and electronic mailing list to disseminate this information. The Council also maintains a website (www.pcouncil.org) providing information about the Council, its meetings, and decisions taken. Most of the documents produced by the Council, including NEPA documents, can be downloaded from the website.

10.2.3 EO 13132 (Federalism)

EO 13132, which revoked EO 12612, an earlier federalism EO, enumerates eight "fundamental federalism principles." The first of these principles states "Federalism is rooted in the belief that issues that are not national in scope or significance are most appropriately addressed by the level of government closest to the people." In this spirit, the EO directs agencies to consider the implications of policies that may limit the scope of or preempt states' legal authority. Preemptive action having such "federalism implications" is subject to a consultation process with the states; such actions should not create unfunded mandates for the states; and any final rule published must be accompanied by a "federalism summary impact statement."

The Council process offers many opportunities for states (through their agencies, Council appointees, consultations, and meetings) to participate in the formulation of management measures. This process encourages states to institute complementary measures to manage fisheries under their jurisdiction that may affect federally-managed stocks.

The proposed action does not have federalism implications subject to EO 13132.

10.2.4 EO 13175 (Consultation and Coordination With Indian Tribal Government)

EO 13175 is intended to ensure regular and meaningful consultation and collaboration with tribal officials in the development of federal policies that have tribal implications, to strengthen the United States government-to-government relationships with Indian tribes, and to reduce the imposition of unfunded mandates upon Indian tribes.

The Secretary recognizes the sovereign status and co-manager role of Indian tribes over shared federal and tribal fishery resources. At Section 302(b)(5), the Magnuson-Stevens Act reserves a seat on the Council for a representative of an Indian tribe with federally-recognized fishing rights from California, Oregon, Washington, or Idaho.

The U.S. government formally recognizes the four Washington coastal tribes (Makah, Quileute, Hoh, and Quinault) have treaty rights to fish for groundfish. In general terms, the quantification of those rights is 50% of the harvestable surplus of groundfish available in the tribes' U and A fishing areas (described at 50 CFR 660.324). Each of the treaty tribes has the discretion to administer their fisheries and to establish their own policies to achieve program objectives.

Accordingly, harvest specifications and management measures for 2007-2008 have been developed in consultation with the affected tribe(s) and, insofar as possible, with tribal consensus.

10.2.5 EO 13186 (Responsibilities of Federal Agencies to Protect Migratory Birds)

EO 13186 supplements the MBTA (above) by requiring federal agencies to work with the USFWS to develop memoranda of agreement to conserve migratory birds. NMFS is in the process of implementing a memorandum of understanding. The protocols developed by this consultation will guide agency regulatory actions and policy decisions in order to address this conservation goal. The EO also directs agencies to evaluate the effects of their actions on migratory birds in environmental documents prepared pursuant to the NEPA.

The FEIS for the 2005-2006 groundfish harvest specifications and management measures evaluated impacts to seabirds and concluded that the proposed action will not significantly impact seabirds. There is no new information to indicate that the current proposed action would result in greater impacts to seabirds and the previous evaluation is incorporated by reference.

10.3 Regulatory Impact Review and Regulatory Flexibility Analysis

In order to comply with EO 12866 and the RFA, this document also serves as an RIR and an IRFA. A summary of these analyses is presented below.

10.3.1 EO 12866 (Regulatory Impact Review)

EO 12866, Regulatory Planning and Review, was signed on September 30, 1993, and established guidelines for promulgating new regulations and reviewing existing regulations. The EO covers a variety of regulatory policy considerations and establishes procedural requirements for analysis of the benefits and costs of regulatory actions. Section 1 of the EO deals with the regulatory philosophy and principles that are to guide agency development of regulations. It stresses that in deciding whether and how to regulate, agencies should assess all of the costs and benefits across all regulatory alternatives. Based on this analysis, NMFS should choose those approaches that maximize net benefits to society, unless a statute requires another regulatory approach.

The regulatory principles in EO 12866 emphasize careful identification of the problem to be addressed. The agency is to identify and assess alternatives to direct regulation, including economic incentives such as user fees or marketable permits, to encourage the desired behavior. Each agency is to assess both the costs and the benefits of the intended regulation and, recognizing that some costs and benefits are difficult to quantify, propose or adopt a regulation only after reasoned determination the benefits of the intended regulation justify the costs. In reaching its decision agency must use the best reasonably obtainable information, including scientific, technical and economic data, about the need for and consequences of the intended regulation.

NMFS requires the preparation of an RIR for all regulatory actions of public interest; implementation of rebuilding plans includes the publication of strategic rebuilding parameters in federal regulations. The RIR provides a comprehensive review of the changes in net economic benefits to society associated with proposed regulatory actions. The analysis also provides a review of the problems and policy objectives prompting the regulatory proposals and an evaluation of the major alternatives that could be used to solve the problems. The purpose of the analysis is to ensure the regulatory agency systematically and comprehensively considers all available alternatives, so the public welfare can be enhanced in the most efficient and cost-effective way. The RIR addresses many of the items in the regulatory philosophy and principles of EO 12866.

The RIR analysis and an environmental analyses required by NEPA have many common elements and they have been combined in this document. The following table shows where the elements of an RIR, as required by EO 12866, are located.

Required RIR Elements	Corresponding Sections
Description of management objectives	Sections 1.2 & 1.3
Description of the fishery[a/]	Chapter 7
Statement of the problem	Section 1.2.2
Description of each alternative considered in the analysis	Chapter 2
An analysis of the expected economic effects of each alternative	Chapter 7

a/ In addition to the information in this document, basic economic information is provided annually in the Council's Stock Assessment and Fishery Evaluation document.

The RIR is designed to determine whether the proposed actions could be considered "significant regulatory actions" according to EO 12866. The EO 12866 test requirements used to assess whether or not an action would be a "significant regulatory action" and the expected outcomes of the proposed management alternative are discussed below. A regulatory program is "economically significant" if it is likely to result in the following effects:

1.a. Have an annual effect on the economy of $100 million or more, or adversely affect in a material way the economy, a sector of the economy, productivity, competition, jobs, the environment, public health or safety, or state, local, or tribal governments or communities.

1.b. Present a risk to long term productivity:

2. Create a serious inconsistency or otherwise interfere with action taken or planned by another agency.

3. Materially alter the budgetary impact of entitlement, grants, user fees, or loan programs or the rights and obligations of recipients thereof.

4. Raise novel legal or policy issues arising out of legal mandates, the President's priorities, or the principles set forth in this EO.

10.3.2 Impacts on Small Entities (Regulatory Flexibility Act, RFA)

The RFA requires government agencies to assess the effects that regulatory alternatives would have on small entities, including small businesses, and to determine ways to minimize those effects. A fish-harvesting business is considered a "small" business by the Small Business Administration (SBA) if it has annual receipts not in excess of $3.5 million. For related fish-processing businesses, a small business is one that employs 500 or fewer persons. For wholesale businesses, a small business is one that employs not more than 100 people. For marinas and charter/party boats, a small business is one with annual receipts not in excess of $5 million.

The data available for this analysis are based on data sets that have vessel and buyer/processor identifiers. The commercial data are from the PacFIN data system, and the recreational data were provided by the states. The vessel and processor counts are based on unique vessel and buyer/processor identifiers. However, it is known that in many cases a single firm may own more than one vessel, or a buyer/processing facility may include more than one profit center. Therefore, the counts should be considered upper bound estimates. Additionally, businesses owning vessels and/or buyers and processors may have revenue from fisheries in other geographic areas, such as Alaska, or from nonfishing activities. Therefore, it is likely that when all operations of a firm are aggregated, some of the small entities identified here are actually larger than indicated.

Council-preferred Alternative

Seafood Harvesters -

Buyers/Processors -

Recreational Fishery

Section 603 (b) of the RFA identifies the elements that should be included in the IRFA. These are bulleted below, followed by information that addresses each element.

- A description of the reasons why action by the agency is being considered.

The purpose and need for the proposed action are discussed in Section 1.2.

- A succinct statement of the objectives of, and legal basis for, the proposed rule.

The description of purpose and need in Section 1.2 also outlines the objectives of the proposed action. The introductory paragraph in Chapter 1 and Section 1.3, background to the purpose and need, provide information on the legal basis for the proposed action (proposed rule).

- A description and, where feasible, an estimate of the number of small entities to which the proposed rule will apply.

- A description of the projected reporting, record-keeping, and other compliance requirements of the proposed rule, including an estimate of the classes of small entities that will be subject to the requirements of the report or record.

There are no new reporting or record-keeping requirements that are proposed as part of this action.

- An identification, to the extent practicable, of all relevant federal rules, which may duplicate, overlap, or conflict with the proposed rule.

No federal rules have been identified that duplicate, overlap, or conflict with the alternatives. Public comment is hereby solicited, identifying such rules.

- A description of any significant alternatives to the proposed rule that accomplish the stated objectives that would minimize any significant economic impact of the proposed rule on small entities.

This EIS includes a range of alternatives, which were considered by the Council.

11.0 LIST OF PREPARERS

Council Staff

Name	Position	Participation
Mr. Mike Burner	Groundfish Staff Officer	Principal author, Chapter 6
Ms. Laura Bozzi		
Dr. Christopher Kit Dahl	NEPA Staff Officer	Principal author, Executive Summary; co-author, Chapters 1 and 5
Mr. John DeVore	Groundfish Staff Officer	Project lead; principal author, Chapters 2 and 4; co-author, Chapter 1

NMFS Northwest Region Staff

Name	Position	Participation
Dr. Stephen Freese		
Ms Yvonne DeReynier		Contributing author, Chapter 5
Mr. Steve Copps		Contributing author, Chapter 3

Groundfish Management Team

The Groundfish Management Team worked with the Council to develop the details of the alternatives and provided catch and bycatch projections. State and tribal representatives put forward proposals for allocations and management measures. Additional contributions are noted below, as appropriate.

Name	Affiliation	Participation
Ms. Deborah Aseltine-Neilson	California Department of Fish and Game	
Ms. Susan Ashcraft	California Department of Fish and Game	
Mr. Merrick Burden	NMFS, Northwest Region	
Mr. Brian Culver	Washington Department of Fish and Wildlife	
Ms. Michele Culver	Washington Department of Fish and Wildlife	
Dr. John Field	NMFS Southwest Fisheries Science Center	
Dr. James Hastie	NMFS Northwest Fisheries Science Center	
Mr. Robert F. Jones	Northwest Indian Fisheries Commission	
Ms. Becky Renko	NMFS, Northwest Region	
Ms. Gway Rogers-Kirchner	Oregon Department of Fish and Wildlife	
Mr. Mark Saelens	Oregon Department of Fish	

Name	Affiliation	Participation
	and Wildlife	
Mr. John Wallace	NMFS Northwest Fisheries Science Center	

Other Contributors

12.0 AGENCIES, ORGANIZATIONS, AND PERSONS TO WHOM COPIES OF THIS STATEMENT WERE SENT

The Council makes both the DEIS and FEIS available on its website, so anyone with computer access may download an electronic copy. Electronic copies on CD-ROM and paper copies are made available upon request. The Council distributes a notice of availability for the DEIS and FEIS through its electronic mailing list, which include state and federal agencies, tribes, and individuals. Copies of the FEIS are sent to anyone who comments on the DEIS. In addition, NMFS distributes copies of the DEIS to the following agencies:

Department of Interior
Department of State
U.S. Coast Guard, Commander Pacific Area
Marine Mammal Commission
Pacific States Marine Fisheries Commission
Washington Coastal Zone Management Program, Shoreline Environmental Assistance, Department of Ecology, Washington State
Ocean-Coastal Management Program, Department of Land Conservation and Development, State of Oregon
California Coastal Commission

13.0 ACRONYMS AND GLOSSARY

Acronym	Definition
ABC	Acceptable biological catch. See below.
acceptable biological catch	The ABC is a scientific calculation of the sustainable harvest level of a fishery and is used to set the upper limit of the annual total allowable catch. It is calculated by applying the estimated (or proxy) harvest rate that produces maximum sustainable yield to the estimated exploitable stock biomass (the portion of the fish population that can be harvested).
ADFG	Alaska Department of Fish and Game
AIS	Automated Information System
ALD	Angler license database
allocation	Distribution of fishing opportunity among user groups or individuals. Shares are sometimes based on historic harvest amounts.
alternatives	In the context of an environmental impact statement for annual fisheries management measures, alternatives are different suites of optimum yields and management measures that could be used to manage fisheries.
anadromous	Fish that spend their adult life in the sea, but swim upriver to freshwater spawning grounds in order to reproduce.
angler	A person catching fish or shellfish with no intent to sell; includes people releasing the catch.
annuli	Annual variations in the pattern of growth rings on fish scales or otoliths (ear bones).
APA	Administrative Procedures Act
$B_{25\%}$	25% of unfished biomass (size of fish stock without fishing). For groundfish, this is the threshold for being designated as overfished.
$B_{40\%}$	40% of unfished biomass (size of fish stock without fishing). This is the Council's threshold for declaring a stock rebuilt, or the size of the stock estimated to produce maximum sustainable yield. This is also referred to as B_{MSY}.
BA	Biological assessment. See below.
barotrauma	Physical trauma or injury to a fish due to pressure change. When a fish is rapidly brought from deep water to the surface, the drop in pressure can cause a variety of physical problems, such as severe expansion of the swim bladder and gas bubbles in the blood.
bathymetry	The science of measuring the ocean's depth.
Bathypelagic Zone	The zone of the ocean that extends from 1,000 to 4,000 meters below the ocean surface.
BB	Beach and Bank

Acronym	Definition
benthic	Refers to organisms that live on or in the ocean floor.
best available science	The term “best available science” comes from the second National Standard listed in the Magnuson-Stevens Act and is the informational standard mandated for decision making.
bioaccumulation	The build-up over time of substances (like metals) that cannot be excreted by an organism.
biological assessment (BA)	An assessment conducted as part of the Endangered Species Act process.
Biological Opinion (BO)	A scientific assessment issued by the National Marine Fisheries Service or U.S. Fish and Wildlife Service, as required by the Endangered Species Act for listed species. Determines the likelihood of an action to jeopardize the existence of a species listed under the Endangered Species Act.
biomass	The total weight of a stock of fish.
BiOp	Biological opinion. See above.
biota	Refers to any and all living organisms and the ecosystems in which they exist.
BLM	Bureau of Land Management. Administers 261 million acres of public lands, mainly in the West.
blocked quota shares	Quota shares that must be transferred together, and cannot be divided.
BMP	Best Management Practices
B_{MSY}	The biomass that allows maximum sustainable yield to be taken. Also see $B_{40\%}$.
BO	Biological opinion. See above.
B_o	Unfished biomass; the estimated size of a fish stock in the absence of fishing.
BOR	U.S. Bureau of Reclamation. Responsible for managing water distribution in the West.
BPA	Bonneville Power Administration. BPA markets electricity from 31 federally-owned dams in the Columbia River basin.
BRD	Bycatch reduction device. See below.
BSAI	Bering Sea Aleutian Islands
bycatch	Fish that are captured in a fishery, but that are discarded (returned to the sea) rather than being sold, kept for personal use, or donated to a charitable organization. Bycatch plus landed catch equals the total catch or total estimated fishing mortality.
bycatch reduction device	Devices (such as finfish excluders) incorporated info fishing gears designed to reduce the take of non-target species.

Acronym	Definition
C&S	Ceremonial and subsistence. See below.
CA	California
CAGEAN	Catch-at-age analysis. An analysis used to reconstruct the population history of long-lived fish stocks. They provide an estimate of the current “exploitable biomass” (the part of the population that can be fished) upon which the harvest rate is based.
CalCOFI	California Cooperative Oceanic Fisheries Investigations
California bight	The region of concave coastline off Southern California between the headland at Point Conception and the U.S./Mexican border, and encompassing various islands, shallow banks, basins, and troughs extending from the coast roughly 200 km offshore.
California Rockfish Conservation Area	The California Rockfish Conservation Area (CRCA) is defined as (1) ocean waters 20 fm to 250 fm between Cape Mendocino and Point Reyes and 20 fm to 150 fm between Point Reyes and the U.S./Mexico Border, and (2) the Cowcod Conservation Areas. The purpose of the CRCA is to regulate all gear types that have a potentially significant affect on rebuilding of overfished rockfish species south of Cape Mendocino.
CAM	Coho Assessment Model
CANSAR-TAM	Catch-at-age Analysis for Sardine - Two Area Model (see CAGEAN)
catch per unit of effort	The quantity of fish caught (in number or weight) with one standard unit of fishing effort. For example, the number of fish taken per 1,000 hooks per day, or the weight of fish, in tons, taken per hour of trawling. CPUE is often considered an index of fish biomass (or abundance). Sometimes referred to as catch rate. CPUE may be used as a measure of economic efficiency of fishing as well as an index of fish abundance.
CBFWA	Columbia Basin Fish and Wildlife Authority
CCA	Cowcod Conservation Area(s). See below.
CDFG	California Department of Fish and Game
CDQ	Community development quota
CEQ	Council on Environmental Quality
CEQA	California Environmental Quality Act
ceremonial and subsistence	A harvest category specific to native American tribes.
CERT	Community Economic Revitalization Teams
cetaceans	Marine mammals of the order Cetacea. Includes whales, dolphins and porpoises.

Acronym	Definition
CFGC	California Fish and Game Commission
CFR	Code of Federal Regulations. See below.
CFZ	Contiguous fishery zone. The area from 3-12 miles offshore.
Channel Islands National Marine Sanctuary	A 1,252-square-nautical-mile area of the Santa Barbara Channel designated as a marine sanctuary in 1980. It encompasses an area out to six nautical miles around the islands of San Miguel, Santa Rosa, Santa Cruz, Anacapa, and Santa Barbara. CINMS is one of 13 National Marine Sanctuaries around the country.
CIE	Committee of independent experts
CINMS	Channel Islands National Marine Sanctuary. See above.
CITES	Convention of International Trade in Endangered Species
cm	Centimeter
coastal pelagic species	Coastal pelagic species are schooling fish, not associated with the ocean bottom, that migrate in coastal waters. They usually eat plankton and are the main food source for higher level predators such as tuna, salmon, most groundfish, and humans. Examples are herring, squid, anchovy, sardine, and mackerel.
Coastal Zone Management Act	The main objective of the CZMA is to encourage and assist states in developing coastal zone management programs, to coordinate state activities, and to safeguard the regional and national interests in the coastal zone. It requires that any federal activity (including fishery management regulations) directly affecting the coastal zone of a state be consistent with that state's approved coastal zone management program, since activities that take place beyond the territorial sea may affect the coastal zone.
Code of Federal Regulations	A codification of the regulations published in the *Federal Register* by the executive departments and agencies of the federal government. The CFR is divided into 50 titles that represent broad areas subject to federal regulation. Title 50 contains wildlife and fisheries regulations.

Acronym	Definition
coded-wire tag	Coded-wire tags are small pieces of stainless steel wire that are injected into the snouts of juvenile salmon and steelhead. Each tag is etched with a binary code that identifies its release group.
cod-end	The end of a trawl net, which retains the catch.
COE	(U.S. Army) Corps of Engineers. Among other things, the COE manages hydropower facilities, conducts dredging operations, and builds breakwaters and jetties.
cohort	In a stock, a group of fish born during the same time period.
cohort replacement rate	The rate at which each subsequent cohort, or generation, replaces the previous one.
commercial fishing	Fishing in which the fish harvested, either whole or in part, are intended to enter commerce through sale, barter, or trade.
COMPASS	Communication Partnership for Science and the Sea
co-occurring stocks	Different stocks of fish that swim or school near one another and may be caught together.
COP	Council Operating Procedures
Council	Pacific Fishery Management Council
Cowcod Conservation Area(s)	Two areas located in the Southern California Bight southwest of Santa Monica to the California/Mexico border that encompass roughly 4,300 square nautical miles of habitat where the highest densities of cowcod occur. These areas are closed to bottom fishing in order to rebuild the cowcod stock.
CPFD	Catch per fishing day
CPFV	Commercial passenger fishing vessel (charter boat)
CPS	Coastal pelagic species. See above.
CPUE	Catch per unit of effort. See above.
CRCA	California Rockfish Conservation Area. See above.
CRFD	Coastal Fisheries Resources Division
CRFS	California Recreational Fisheries Survey
CRITFC	Columbia River Inter-Tribal Fish Commission
CRP	Conservation Reserve Program
CRR	Cohort replacement rate. See above.
CRTAC	Columbia River Technical Advisory Committee

Acronym	Definition
CSP	Halibut Catch Sharing Plan
cumulative limit	The total allowable amount of a species or species group, by weight, that a vessel may take and retain, possess, or land during a period of time. Fishers may take as many landings of a species or species complex as they like as long as they do not exceed the cumulative limit that applies to the vessel or permit during the designated period.
cumulative limit stacking	The association of cumulative limits with permits, rather than with vessels, allowing a vessel with multiple limited entry permits to harvest multiple cumulative limits. Also known as “permit stacking.”
CV	Coefficient of variation
CWT	Coded-wire tag. See above.
CZMA	Coastal Zone Management Act. See above.
DAH	Domestic annual harvest. See below.
DAP	Domestic annual processing. See below.
DBCA	Darkblotched (rockfish) Conservation Area
DEIS	Draft Environmental Impact Statement (see EIS, NEPA)
demersal	Living near, and depending on, the sea floor. For example, cods, groupers, and halibut are demersal. (Pronounced “deMERsal”).
density dependence	The degree to which spawning biomass effects recruitment of a fish stock.
DEPM	Daily egg production method
derby fishery	A fishery of brief duration during which fishers race to take as much catch as they can before the fishery closes.
DFO	(Canada) Department of Fisheries and Oceans
DFOP	Detailed Fishery Operating Plan
DFW	Department of Fish and Wildlife
DGN	Drift gillnet
DOC	Department of Commerce. Parent organization of the National Marine Fisheries Service.
DOI	Department of Interior
DOJ	Department of Justice. DOJ attorneys represent the Secretary of Commerce in litigation on fishery management plans.
DOM	Domestic catch
domestic annual harvest	The domestic annual fishing capacity, modified by other factors (such as economic factors), which will determine estimates of what the fleets will harvest.

Acronym	Definition
domestic annual processing	The amount that will be domestically processed, based not only on physical capacity, but on a demonstrated intent, and the effects of domestic harvesting, markets, and other fisheries.
DOS	Department of State
downwelling	The process whereby prevailing seasonal winds create surface currents that cause surface water to sink, bringing nutrient-poor ocean surface water into an area.
DTL	Daily-trip-limit
DTS	Dover sole, thornyhead, and trawl-caught sablefish complex
EA	Environmental assessment (see NEPA, EIS). See below.
EC	Enforcement Consultants. See below.
ED	Environmental Defense (formerly the Environmental Defense Fund)
ED	Executive Director
EDCP	Enhanced Data Collection Project
EDF	Environmental Defense Fund
EDM	Estimated discard mortality. See below.
EEZ	Exclusive Economic Zone. See below.
EFH	Essential fish habitat. See below.
EFIN	Economic Fishery Information Network, administered by the Pacific States Marine Fisheries Commission.
EFP	Exempted fishing permit. See below.
EIA	Environmental impact assessment. A set of activities designed to identify and predict the impacts of proposed action on the environment, and on human health and well being, and to interpret and communicate information about the impacts, including mitigation measures likely to eliminate the risks.
EIR	Environmental impact review
EIS	Environmental impact statement. See below.

Acronym	Definition
El Niño Southern Oscillation	Abnormally warm ocean climate conditions, which in some years affect the eastern coast of Latin America (centered on Peru) often around Christmas time. The anomaly is accompanied by dramatic changes in species abundance and distribution, higher local rainfall and flooding, and massive deaths of fish and their predators. Many other climactic anomalies around the world are attributed to consequences of *El Niño*.
Endangered Species Act	An act of federal law that provides for the conservation of endangered and threatened species of fish, wildlife, and plants. When preparing fishery management plans, councils are required to consult with the National Marine Fisheries Service and the U.S. Fish and Wildlife Service to determine whether the fishing under a fishery management plan is likely to jeopardize the continued existence of an ESA-listed species or to result in harm to its critical habitat.
endorsement	A designation on a limited entry permit that authorizes the use of the permit for a particular gear, length of vessel, or in a particular segment of the fishery.
Enforcement Consultants	A Council committee that provides advice on enforcement of fishery regulations.
ENSO	*El Niño* Southern Oscillation. See above.
environmental assessment	As part of the National Environmental Policy Act (NEPA) process, an EA is a concise public document that provides evidence and analysis for determining whether to prepare an environmental impact statement (EIS) or a Finding of No Significant Impact.
Environmental impact statement	As part of the National Environmental Policy Act (NEPA) process, an EIS is an analysis of the expected impacts resulting from the implementation of a fisheries management or development plan (or some other proposed action) on the environment. EISs are required for all fishery management plans as well as significant amendments to existing plans. The purpose of an EIS is to ensure the fishery management plan gives appropriate consideration to environmental values in order to prevent harm to the environment.
EO	Executive Order
EO 12866	A Federal executive order that, among other things, requires agencies to assess the economic costs and benefits of all regulatory proposals and complete a Regulatory Impact Analysis (RIA) that describes the costs and benefits of the proposed rule and alternative approaches, and justifies the chosen approach. See RIR.
EPA	Environmental Protection Agency
EPO	Eastern Pacific Ocean
equilibrium yield	The harvest that would maintain a stock at its current level, apart from the effects of environmental conditions.

Acronym	Definition
ESA	Endangered Species Act. See above.
escapement	The number or proportion of fish surviving (escaping from) a given fishery at the end of the fishing season and reaching the spawning grounds. Term generally used for salmon management.
essential fish habitat	Those waters and substrate necessary to fish for spawning, breeding, feeding or growth to maturity.
Estimated discard mortality	Estimates of discards can be made in a variety of ways, including samples from observers and logbook records. Fish (or parts of fish) can be discarded for a variety of reasons such as having physical damage, being a non-target species for the trip, and compliance with management regulations like minimum size limits or quotas.
ESU	Evolutionarily significant unit
ETP	Eastern tropical Pacific
evolutionarily significant unit	An Evolutionarily Significant Unit or "ESU" is a distinctive group of Pacific salmon, steelhead, or sea-run cutthroat trout that is uniquely adapted to a particular area or environment and cannot be replaced.
Exclusive Economic Zone	A zone under national jurisdiction (up to 200 nautical miles wide) declared in line with the provisions of the 1982 United Nations Convention of the Law of the Sea, within which the coastal State has the right to explore and exploit, and the responsibility to conserve and manage, the living and non-living resources.
exempted fishing permit	A permit issued by National Marine Fisheries Service that allows exemptions from some regulations in order to study the effectiveness, bycatch rate, or other aspects of an experimental fishing gear. Previously known as an "experimental fishing permit."
exploitable biomass	The biomass that is available to a unit of fishing effort. Defined as the sum of the population biomass at age (calculated as the mean within the fishing year) multiplied by the age-specific availability to the fishery. Exploitable biomass is equivalent to the catch biomass divided by the instantaneous fishing mortality rate.
EY	Equilibrium yield. See above.

Acronym	Definition
F	The instantaneous rate of fishing mortality. The term "fishing mortality rate" is a technical fishery science term that is often misunderstood. It refers to the rate at which animals are removed from the stock by fishing. The fishing mortality rate can be confusing because it is an "instantaenous" rate that is useful in mathematical calculations, but is not easily translated into the more easily understood concept of "percent annual removal."
F=0	Fishing mortality equals zero (no fishing).
FAD	Fish aggregating device. See below.
FAO	Food & Agriculture Organization of the United Nations
fathom	Used chiefly in measuring marine depth. A fathom equals six feet.
FCRA	Federal Credit Reform Act
FCZ	Fishery Conservation Zone. The area over which the U.S. asserts exclusive fishery management authority. The FCZ extends from the seaward boundary of the coastal states' territorial seas to 200 nautical miles from the baseline where the territorial sea is measured (roughly, 3 to 200 miles offshore). Similar to the EEZ, or Exclusive Economic Zone.
FEAM	Fishery economic assessment model. See below.
Fecundity	The potential to produce offspring.
Federal Register	The Federal Register is the official daily publication for Rules, Proposed Rules, and Notices of Federal agencies and organizations, as well as Executive Orders and other Presidential documents. Fisheries regulations are not considered final until they are published in the Federal Register.
FEIS	Final Environmental Impact Statement (see EIS, NEPA).
FERC	Federal Energy Regulatory Commission. Regulates hydropower operations.
FFA	(South Pacific) Forum Fishery Agency
Finding of no significant impact	As part of the National Environmental Policy Act (NEPA) process, a finding of no significant impact (FONSI) is a document that explains why an action that is not otherwise excluded from the NEPA process, and for which an environmental impact statement (EIS) will not be prepared, will not have a significant effect on the human environment.
Fish aggregating device	Artificial or natural floating objects placed on the ocean surface, often anchored to the bottom, to attract several schooling fish species underneath, thus increasing their catchability.

Acronym	Definition
Fish stock	A population of a species of fish from which catches are taken in a fishery. Use of the term “fish stock” usually implies that the particular population is more or less isolated from other stocks of the same species, and hence self-sustaining.
Fishery economic assessment model	FEAM uses historical landings data, information on industry cost and margin structure (vessels and processors), and income multipliers generated by IMPLAN to produce estimates of “regionalized” local income impact after deducting for leakage of payments to non-residents and to non-local suppliers, wholesalers, and manufactures.
Fishery management council	A fisheries management body established by the Magnuson-Stevens Act to manage fishery resources in designated regions of the United States. Membership varies in size depending on the number of states involved. There are eight regional Councils, including the Pacific Council.
Fishery management plan	A plan, and its amendments, that contains measures for conserving and managing specific fisheries and fish stocks.
Fishery management unit	The species or stocks of fish managed under a fishery management plan.
Fishing	The catching, taking, or harvesting of fish; the attempted catching, taking, or harvesting of fish; any other activity that can reasonably be expected to result in the catching, taking, or harvesting of fish; any operations at sea in support of, or in preparation for, any of these activities. This term does not include any activity by a vessel conducting authorized scientific research.
Fishing community	A community which is substantially dependent on or substantially engaged in the harvest or processing of fishery resources to meet social and economic needs. Includes fishing vessel owners, fishing families, operators, crew, recreational fishers, fish processors, gear suppliers, and others in the community who depend on fishing.
Fixed gear	Fishing gear that is stationary after it is deployed (unlike trawl or troll gear which is moving when it is actively fishing). Within the context of the groundfish limited entry fleet, “fixed gear” means longline and fishpot (trap) gear. Within the context of the entire groundfish fishery, fixed gear includes longline, fishpot, and any other gear that is anchored at least at one end.
FL	Fork length. See below.
Fm	Fathom (6 feet)
FMA	Fishery management area
FMC	Fishery Management Council. See above.
FMP	Fishery management plan. See above.

Acronym	Definition
F_{MSY}	The fishing mortality rate that maximizes catch biomass in the long term.
FMU	Fishery management unit
FONSI	Finding of no significant impact. See above.
Footrope	The rope along the bottom of a trawl net's opening. Small footropes can get caught or tangled in rocky reef areas, so regulations that require small footropes protect these rocky areas by encouraging skippers to fish elsewhere.
Fork length	A measurement used frequently for fish length when the tail has a fork shape. Projected straight distance between the tip of the fish and the fork of the tail.
FR	Federal Register. See above.
FRFA	Final Regulatory Flexibility Analysis. The FRFA includes all the information from the initial regulatory flexibility analysis. Additionally, it provides a summary of significant issues raised by the public, a statement of any changes made in the proposed rule as a result of such comments, and a description of steps taken to minimize the significant adverse economic impact on small entities consistent with stated objectives.
FRO	Fishery Resource Office
FTE	Full time employee
FWS	U.S. Fish and Wildlife Service
$F_{X\%}$	The rate of fishing mortality that will reduce female spawning biomass per recruit to x percent of its unfished level. F100% is zero, and F35% is a reasonable proxy for FMSY. (All figures after "F" should be subscript.)
GAC	Groundfish Allocation Committee
GAO	General Accounting Office
GAP	Groundfish Advisory Subpanel. See below.
GCA	Groundfish Conservation Area
GCG	Gene Conservation Group. A genetically distinct group within a species that forms when a group does not mix with other populations of the same species.
GDOP	Groundfish Disaster Outreach Program (Oregon Sea Grant)
GDP	Gross Domestic Product
GF	Groundfish
GFNMS	Gulf of the Farallones National Marine Sanctuary
GFSP	Groundfish Fishery Strategic Plan

Acronym	Definition
GIFA	Governing International Fishery Agreement. Foreign vessels fishing within the fishery conservation zone must have a permit issued by the Secretary of Commerce. In order to receive a permit, each foreign nation must enter into a formal GIFA which binds them to comply with U.S. regulations and allows for vessel inspection and enforcement of regulations.
GIPC	Groundfish Information Policy Committee
GIS	Geographic Information System
GLM	Generalized Linear Models
GMMC	Ad Hoc Groundfish Multi-Year Management Committee
GMT	Groundfish Management Team. See below.
GPS	Global Positioning System
Groundfish Advisory Subpanel	The Council established the GAP to obtain the input of the people most affected by, or interested in, the management of the groundfish fishery. This advisory body is made up of representatives with recreational, trawl, fixed gear, open access, tribal, environmental, and processor interests. Their advice is solicited when preparing fishery management plans, reviewing plans before sending them to the Secretary, reviewing the effectiveness of plans once they are in operation, and developing annual and inseason management.
Groundfish Management Team	Groundfish management plans and annual and inseason management recommendations are prepared by the Council's GMT, which consists of scientists and managers with specific technical knowledge of the groundfish fishery.
GSA	General Services Administration
GSI	Genetic stock identification
Habitat areas of particular concern	Subsets of essential fish habitat (see EFH) containing particularly sensitive or vulnerable habitats that serve an important ecological function, are particularly sensitive to human-induced environmental degradation, are particularly stressed by human development activities, or comprise a rare habitat type.

Acronym	Definition
Habitat TRC	Ad Hoc Groundfish Habitat Technical Review Committee
HAPC	Habitat areas of particular concern. See above.
Harvest guideline(s)	A numerical harvest level that is a general objective, but not a quota. Attainment of a harvest guideline does not require a management response, but it does prompt review of the fishery.
Harvest specifications	The detailed regulations that make up management measures – for example, trawl footrope size, depth limits, net mesh size, etc.
HAS	Halibut Advisory Subpanel
HC	Habitat Committee
HCP	Habitat Conservation Plan
HG	Harvest guideline(s). See above.
High seas	All waters beyond the EEZ (3-200 mile zone) of the United States and beyond any foreign nation's EEZ.
Highly migratory species	In the Council context, highly migratory species in the Pacific Ocean include species managed under the HMS Fishery Management Plan: tunas, sharks, billfish/swordfish, and dorado or dolphinfish.
HMG	Halibut Managers Group
HMS	Highly migratory species. See above.
HMS FMP	Highly Migratory Species Fishery Management Plan. This is the fishery management plan (and its subsequent revisions) for the Washington, Oregon, and California Highly Migratory Species Fisheries developed by the PFMC and approved by the Secretary of Commerce.
HMSAS	Highly Migratory Species Advisory Subpanel
HMSMT	Highly Migratory Species Management Team
HMSPDT	Highly Migratory Species Plan Development Team
HRM	Harvest Rate Model
HSFCA	High Seas Fisheries Compliance Act
IATTC	Inter-American Tropical Tuna Commission
IBQ	Individual bycatch quota. IBQs are used to control the catch of prohibited species.
ICA	Initial catch allowance (related to individual quotas)
ICB	Information Collection Budget
ICCAT	International Convention for the Conservation of Atlantic Tunas
ICES	International Convention for the Exploration of the Sea
IFQ	Individual fishing quota. See below.

Acronym	Definition
IGH	Iron Gate Hatchery
IMPLAN	IMpact Analysis for PLANning - a regional economic impact model
Incidental catch or incidental species	Species caught when fishing for the primary purpose of catching a different species.
Incidental take	The "take" of protected species (such as listed salmon, marine mammals, sea turtles, or sea birds) during fishing. "Take" is defined as to harass, harm, pursue, hunt, shoot, wound, kill, trap, capture or collect, or to attempt to engage in any such conduct.
Individual transferable (or tradeable) quota	A type of quota (a part of a total allowable catch) allocated to individual fishermen or vessel owners and which can be transferred (sold, leased) to others.
Initial regulatory flexibility analysis	An analysis required by the Regulatory Flexibility Act.
INMARSAT	International Marine Satellite
INPFC	International North Pacific Fishery Commission. See below.
Inseason adjustments	Regulatory changes that affect an ongoing fishery.
International North Pacific Fishery Commission	International North Pacific Fisheries Commission (INPFC) areas are used to define fishing areas. The INPFC was established in 1952 and dissolved in 1993, but the areas defined by the Commission are still commonly used in marine fisheries management.
International Pacific Halibut Commission	A Commission responsible for studying Pacific halibut stocks and the halibut fishery. The IPHC makes proposals to the U.S. and Canada concerning the regulation of the halibut fishery.
Invertebrate	An animal, such as a mollusk, with no spinal column
IPA	Intergovernmental Personnel Act. An IPA Agreement permits the temporary assignment of personnel between Federal agencies, state, local, and Indian tribal governments, colleges and universities, and certain other organizations.
IPHC	International Pacific Halibut Commission. See above.
IPOA	International Plan of Action
IPQ	Individual processing quota
IQ	Individual quota
IRFA	Initial regulatory flexibility analysis. See above.
ISC	Interim Scientific Committee
ITQ	Individual Transferable (or Tradable) Quota. See above.
JV	Joint Venture

Acronym	Definition
KFMC	Klamath Fishery Management Council
kg	kilogram
KMZ	Klamath management zone (ocean zone between Humbug Mountain and Horse Mountain where management emphasis is on Klamath River fall chinook)
LCN	Lingcod - North
LCS	Lingcod - South
LE	Limited entry fishery. See below.
Length requirement	The requirement that specifies that permits may not be registered for use with vessels more than five feet longer (in overall length) than the length endorsed on the permit.
Limited entry fishery	A fishery for which a fixed number of permits have been issued in order to limit participation.
Local depletion	Local depletion occurs when localized catches take more fish than can be replaced either locally or through fish migrating into the catch area. Local depletion can occur apart from the status of the overall stock, and can be greater than decreases in the entire stock.
LOS	Law of the Sea
M	Instantaneous rate of natural mortality (as opposed to F, fishing mortality)
m	Meter(s)
Magnuson-Stevens Act	Magnuson-Stevens Fishery Conservation and Management Act. See below.
Magnuson-Stevens Fishery Conservation and Management Act	The MSFCMA, sometimes known as the "Magnuson-Stevens Act," established the 200-mile fishery conservation zone, the regional fishery management council system, and other provisions of U.S. marine fishery law.
Marine Mammal Protection Act	The MMPA prohibits the harvest or harassment of marine mammals, although permits for incidental take of marine mammals while commercial fishing may be issued subject to regulation. (See "incidental take" for a definition of "take").
Marine Recreational Fisheries Statistical Survey	A national survey conducted by National Marine Fisheries Service to estimate the impact of recreational fishing on marine resources.

Acronym	Definition
MARPOL	International Convention for the Prevention of Pollution from Ships
MAX CAT	Maximum Allowable Catch
Maximum fishing mortality threshold	A limit identified in the National Standard Guidelines. A fishing mortality rate above this threshold constitutes overfishing.
Maximum sustainable yield	An estimate of the largest average annual catch or yield that can be continuously taken over a long period from a stock under prevailing ecological and environmental conditions. Since MSY is a long-term average, it need not be specified annually, but may be reassessed periodically based on the best scientific information available.
mb	megabyte
MBTA	Migratory Bird Treaty Act
MCB	Mid-Columbia River brights (bright hatchery fall chinook released in the Columbia River downstream from McNary Dam.)
MCMC	Monte Carlo Markov Chain (analysis)
mean generation time	A measure of the time required for a female to produce a reproductively-active female offspring.
MERRP	Marine Ecological Reserves Research Program
MFCMA	Magnuson Fishery Conservation and Management Act. The Fishery Conservation and Management Act was renamed the "Magnuson Fishery Conservation and Management Act" in 1980. The MFCMA established the 200-mile fishery conservation zone and the regional fishery management council system.
MFMT	Maximum fishing mortality threshold. See above.
MHHW	Mean higher high water level (high tide line)
MHLC	Multilateral High-Level Conference
Minimum stock size threshold	A threshold biomass used to determine if a stock is overfished. The Council proxy for MSST is B25%.

Acronym	Definition
Mixed stock exception	In “mixed-stock complexes,” many species of fish swim together and are caught together. This becomes a problem when some of these stocks are healthy and some are overfished, because even a sustainable harvest of the healthy stocks can harm the depleted stock. In order to avoid having to shut down all fisheries to protect one particular overfished stock, the national standard guidelines allow a “mixed-stock” exception to the “overfished” definition. This would allow higher catches of some overfished species than ordinarily allowed in order to avoid severe hardship to fishing communities.
MLR	Minimum landing requirement
mm	Millimeter
MM	Man made
MMPA	Marine Mammal Protection Act. See above.
MOA	Memorandum of Agreement
MOC	Mid-Oregon coast
MOU	Memorandum of Understanding
MPA	Marine protected areas
MPRSA	Marine Protection Research and Sanctuaries Act. The MPRSA authorizes the Secretary of Commerce (with Presidential approval) to designate ocean marine sanctuaries.
MRFSS	Marine Recreational Fisheries Statistics Survey. See above.
MRPZ	Marine resources protection zone
MRWG	Marine Reserve Work Group
MSA	Magnuson-Stevens Fishery Conservation and Management Act. See above.
MSFCMA	Magnuson-Stevens Fishery Conservation and Management Act. See above.
MSP	Maximum sustainable production
MSST	Minimum stock size threshold. See above.
MSY	Maximum sustained yield. See above.
mt	Metric ton. 1000 kilos or 2,204.62 pounds. (A “short ton” is 2000 lbs.)
MUS	Management Unit Species
NA	Not available
NAO	NOAA Administrative Order

Acronym	Definition
National Environmental Policy Act	Passed by Congress in 1969, NEPA requires Federal agencies to consider the environment when making decisions regarding their programs. Section 102(2)(C) requires Federal agencies to prepare an Environmental Impact Statement (EIS) before taking major Federal actions that may significantly affect the quality of the human environment. The EIS includes: the environmental impact of the proposed action, any adverse environmental effects which cannot be avoided should the proposed action be implemented, alternatives to the proposed action, the relationship between local short-term uses of the environment and long-term productivity, and any irreversible commitments of resources which would be involved in the proposed action should it be implemented.
National Marine Fisheries Service	A division of the U.S. Department of Commerce, National Ocean and Atmospheric Administration (NOAA). NMFS is responsible for conservation and management of offshore fisheries (and inland salmon). The NMFS Regional Director is a voting member of the Council.
National standard guidelines	Guidelines issued by National Marine Fisheries Service to provide comprehensive guidance for the development of fishery management plans and amendments that comply with the national standards of the Magnuson-Stevens Act. These guidelines are found in Title 50, Code of Federal Regulations, part 600.
NBS	National Bureau of Standards
NCEAS	National Center for Ecological Analysis and Synthesis
NCRS	National Resource Conservation Service
NE	Northeast
Nearshore	"Nearshore" is defined (by the California Nearshore Fishery Management Plan) as the area from the high-tide line offshore to a depth of 120 ft (20 fm).
NEPA	National Environmental Policy Act. See above.
Neritic	Inhabiting coastal waters primarily over the continental shelf, generally over bottom depths equal to or less than 183 meters (100 fm) deep.
NEV	Net economic value(s)
NFCC	National Fisheries Conservation Center
NGO	Nongovernmental organization
nm	Nautical mile
NMFS	National Marine Fisheries Service. See above.
NMFS NWFSC	National Marine Fisheries Service Northwest Fisheries Science Center
NMFS NWR	National Marine Fisheries Service Northwest Region
NMFS SWR	National Marine Fisheries Service Southwest Region
NMSA	National Marine Sanctuaries Act

Acronym	Definition
NMSP	National Marine Sanctuaries Program
NNB	Net National Benefits
NOAA	National Oceanic & Atmospheric Administration. The parent agency of National Marine Fisheries Service.
NOC	North Oregon coast
NOF	North of (Cape) Falcon, Oregon
NOI	Notice of Intent
Nontrawl	Within the context of the groundfish limited fleet, “nontrawl” and “fixed gear” are the same, i.e. longline and fishpot gear. Within the context of the entire groundfish fishery, nontrawl gear includes longline, fishpot, and any other gear that is not trawl gear (troll, gillnet, vertical hook-and-line, etc.).
NORPAC	North Pacific Database Program
NOS	National Ocean Service
NPCC	Northwest Power and Conservation Council (formerly known as the Northwest Power Planning Council)
NPFMC	North Pacific Fishery Management Council. The NPFMC consists of the state of Alaska, with representation by Washington and Oregon.
NPOA	National Plan of Action
NPTZ	North Pacific Transition Zone
NRC	National Research Council
NRC	National Resource Consultants
NRDC	Natural Resources Defense Council
NS	Nearshore. See above.
NSF	National Science Foundation
NSG	National Standards Guidelines. See above.
NURP	National Undersea Research Program
NWAFC	Northwest and Alaska Fisheries Centers (two separate science centers)
NWFSC	Northwest Fisheries Science Center (in Seattle; a division of NMFS).
NWIFC	Northwest Indian Fisheries Commission
NWR	Northwest Region
OA	Open access fishery. See below.
OC	Oregon Coast (coho)
Oceanic	Inhabiting the open sea, ranging beyond the continental and insular shelves, beyond the neritic zone.

Acronym	Definition
OCZMA	Oregon Coast Zone Management Act
ODFW	Oregon Department of Fish and Wildlife
OMB	Office of Management and Budget
OPAC	(Oregon) Ocean Policy Advisory Council
Open-access fishery	The segment of the groundfish fishery or any other fishery for which entry is not controlled by a limited entry permitting program.
Optimum yield	The amount of fish that will provide the greatest overall benefit to the Nation, particularly with respect to food production and recreational opportunities, and taking into account the protection of marine ecosystems. The OY is developed on the basis of the Maximum Sustained Yield from the fishery, taking into account relevant economic, social, and ecological factors. In the case of overfished fisheries, the OY provides for rebuilding to a level that is consistent with producing the Maximum Sustained Yield for the fishery.
OR	Oregon
Oregon production index (OPI)	A measure of the abundance of adult coho salmon produced in the Columbia River and Oregon coastal hatcheries and streams. It is the sum of ocean sport and troll catches off the Columbia River, Oregon, and California; Oregon coastal hatchery returns; and the inriver gillnet catch, Bonneville Dam counts, and hatchery returns to the Columbia River below Bonneville Dam.
OSP	Optimum sustainable production
OSP	Oregon State Police
OTC	Oregon Trawl Commission
Overcapacity	A level of fishing pressure that threatens to reduce a stock or complex below the abundance necessary to support maximum sustainable yield and allow an economically sustainable fishing industry.
Overfished	Any stock or stock complex whose size is sufficiently small that a change in management practices is required to achieve an appropriate level and rate of rebuilding. The term generally describes any stock or stock complex determined to be below its overfished/rebuilding threshold. The default proxy is generally 25% of its estimated unfished biomass; however, other scientifically valid values are also authorized.
Overfishing	Fishing at a rate or level that jeopardizes the capacity of a stock or stock complex to produce MSY on a continuing basis. More specifically, overfishing is defined as exceeding a maximum allowable fishing mortality rate. For any groundfish stock or stock complex, the maximum allowable mortality rate will be set at a level not to exceed the corresponding MSY rate (FMSY) or its proxy.
Overhead	The amount by which the allocation of a fishery would be exceeded if every vessel took the available cumulative limit.

Acronym	Definition
OY	Optimum yield. See above.
PacFIN	Pacific Coast Fisheries Information Network. Provides commercial fishery information for Washington, Oregon, and California. Maintained by the Pacific States Marine Fisheries Commission.
Pacific decadal oscillation	A long-term, El Nino-like pattern of Pacific Ocean climate variability.
Pacific States Marine Fisheries Commission	The PSMFC is a non-regulatory agency that serves Alaska, California, Idaho, Oregon and Washington. PSMFC (headquartered in Portland) provides a communication exchange between the Pacific Fishery Management Council and the North Pacific Fishery Management Council, and a mechanism for federal funding of regional fishery projects. The PSMFC provides information in the form of data services for various fisheries.
PBR	Potential biological removal. See below.
PCFFA	Pacific Coast Federation of Fishermen's Associations
PDO	Pacific decadal oscillation. See above.
PEIS	Programmatic Environmental Impact Statement. An EIS that applies to an entire program or management regime, rather than a specific action.
Pelagic	Inhabiting the water column as opposed to being associated with the sea floor; generally occurring anywhere from the surface to 1000 meters (547 fm). See also epipelagic and mesopelagic.
Permit stacking	The registration of more than one limited entry permit for a single vessel, where a vessel is allowed additional catch for each additional permit registered for use with the vessel.
PFMC	Pacific Fishery Management Council
PGPs	Programmatic General Permits
P_{MAX}	The estimated probability of reaching $T_{MAX.}$ May not be less than 50%.
PMCC	Pacific Marine Conservation Council
POCTRT	Pacific Offshore Cetacean Take Reduction Team
POP	Pacific Ocean perch. A rockfish species that was declared overfished in 1999.
Potential biological removal	The maximum number of animals, not including natural mortalities, that may be removed from a marine mammal stock while allowing that stock to reach or maintain its optimum sustainable population.
PRA	Paperwork Reduction Act
Preferred alternative	The alternative that is identified as preferred by the authors of an environmental impact statement or environmental assessment. It is identified to indicate which alternative is likely to be selected, thereby helping the public focus its comments.

Acronym	Definition
Processing	The preparation or packaging of fish to render it suitable for human consumption, retail sale, industrial uses, or long-term storage, including but not limited to cooking, canning, smoking, salting, drying, filleting, freezing, or rendering into meal or oil, but not heading and gutting unless additional preparation is done.
Proposed alternatives	Alternatives proposed by the Council for a proposed management action (such as annual management specifications). The alternatives are presented to the public for comment, and are voted upon at a subsequent Council meeting. The options always include a "status quo" alternative (for example the current season's ABCs and OYs).
PSC	Pacific Salmon Commission
PSEIS	Programmatic Supplemental Environmental Impact Statement
PSMFC	Pacific States Marine Fisheries Commission. See above.
Q	The relation between selectivity of survey fishing and actual (commercial) fishing. Selectivity is a measure of the proportion of fish encountered by gear to those that are actually caught.
QS	Quota share(s)
QS	Quota shares (related to individual fishing quotas)
QSM	Quota species monitoring. See below.
Quota	A specified numerical harvest objective, the attainment (or expected attainment) of which causes closure of the fishery for that species or species group.
Quota shares	A share of the Total Allowable Catch (TAC) allocated to an operating unit such as a vessel, a company or an individual fisherman (individual quota) depending on the system of allocation. Quotas may or may not be transferable, inheritable, and tradable. While generally used to allocate total allowable catch, quotas could be used also to allocate fishing effort or biomass.
Quota species monitoring	Quota species monitoring is a PacFIN database that monitors the cumulative landings of species managed either with individual OYs or OYs prescribed for a species complex (grouping of species in a single management unit). The GMT uses quota species monitoring to develop inseason groundfish fishery management recommendations to attempt to attain, but not exceed, prescribed OYs.
R	Recruits or recruitment.
R/S	Recruits per spawner
R_0	Level of unfished recruitment
RCA	Rockfish Conservation Area (Depends on how it is used)
RCA	Riparian conservation area
RD	Regional Director. Usually, the Regional Director of the National Marine Fisheries Service.

Acronym	Definition
Rebuilding	Implementing management measures that increase a fish stock to its target size.
Rebuilding analysis	An analysis that uses biological information to describe the probability that a stock will rebuild within a given timeframe under a particular management regime.
Rebuilding plan	A document that describes policy measures that will be used to rebuild a fish stock that has been declared overfished.
RecFin	Recreational Fishery Information Network. A database managed by the Pacific States Marine Fisheries Commission that provides recreational fishery information for Washington, Oregon, and California.
Recruits	Recruits are a group ("cohort") of young fish that enter a fish stock in one year.
Recruits/recruitment	The estimated production of new members to a fish population as measured at a specific life stage.
Regulatory Flexibility Analysis (or Act)	Regulatory Flexibility Act (see IRFA and FRFA above). See below. The Regulatory Flexibility Act (5 U.S.C. 601-612) requires federal agencies to consider the effects of their regulatory actions on small businesses and other small entities and to minimize any undue disproportionate burden.
Regulatory Impact Review	RIRs are prepared to determine whether a proposed regulatory action is "major." The RIR examines alternative management measures and their economic impacts.
RER	Recovery Exploitation Rates
RF	Rockfish
RFA	Regulatory Flexibility Analysis, or Regulatory Flexibility Act. See above.
Riparian area	A land area adjacent to water. Technical definition: "riparian area" means an area of land that (a) is adjacent to a stream, river, lake or wetland, and (b) contains vegetation that, due to the presence of water, is distinctly different from the vegetation of adjacent upland areas. (Code of British Columbia)
RIR	Regulatory Impact Review. See above.
ROD	Record of Decision
ROV	Remotely operated vehicle (submarine)
RPAs	Reasonable and prudent alternatives
Rulemaking	The process of developing Federal regulations which occurs in several steps, including publishing proposed rules in the Federal Register, accepting comments on the proposed rule, and publishing the final rule. An "advanced notice of proposed rulemaking" is published when dealing with especially important or controversial rules.
SAFE	Stock assessment and fishery evaluation. See below.

Acronym	Definition
Saltonstall-Kennedy Act	The Saltonstall-Kennedy Act allocates 30% of the duties for imported fishery products to technological, biological, marketing, and other research and services in order to promote the free flow of domestically-produced fishery products and to develop markets for domestic fishery products.
SAP	Sanctuary Advisory Subpanel
SAS	Salmon Advisory Subpanel
SBA	Small Business Administration
SCB	Southern California Bight
Scientific and Statistical Committee	An advisory committee of the PFMC made up of scientists and economists. The Magnuson-Stevens Act requires that each council maintain an SSC to assist in gathering and analyzing statistical, biological, ecological, economic, social, and other scientific information that is relevant to the management of Council fisheries.
SDC	Status Determination Criteria
SEA	Socioeconomic Analysis
Secretary	U.S. Secretary of Commerce
SEIS	Supplemental Environmental Impact Statement (see Environmental Impact Statement)
SFA	Sustainable Fisheries Act of 1996. Amended the MSFCMA.
SFO	Sustainable Fisheries Office (NMFS)
Shelf rockfish	Rockfish that live on the continental shelf
SIA	Social impact analysis
SIC	Standard Industrial Classifications
S-K	Saltonstall-Kennedy. See above.
Slope rockfish	Rockfish that live on the continental slope
SOC	Secretary of Commerce. The Secretary has responsibility for reviewing, approving, and implementing a fishery management plan.
SOPP	Statement of Organization, Practices, and Procedures
Southern California bight	See California Bight, above.
Spawning biomass	The biomass of mature female fish at the beginning of the year. If the production of eggs is not proportional to body weight, then this definition is construed to be proportional to expected egg production.
SPR	Spawning biomass per recruit
SRS	Stratified Random Sampling
SSB	Spawning stock biomass

Acronym	Definition
SSC	Scientific and Statistical Committee. See above.
SST	Sea surface temperature
STAR	Stock assessment review
STAR Panel	Stock Assessment Review Panel. A panel set up to review stock assessments for particular fisheries. In the past there have been STAR panels for sablefish, rockfish, squid, and other species.
STAT	Stock Assessment Team. Develops stock assessments.
Stock Assessment and Fishery Evaluation	A SAFE document is a document prepared by the Council that provides a summary of the most recent biological condition of species in the fishery management unit, and the social and economic condition of the recreational and commercial fishing industries, including the fish processing sector. It summarizes, on a periodic basis, the best available information concerning the past, present, and possible future condition of the stocks and fisheries managed in the FMP.
STT	Salmon Technical Team
SWFSC	Southwest Fisheries Science Center (NMFS)
TAC	Total allowable catch. See below.
TALFF	Total allowable level of foreign fishing
Target fishing	Fishing for the primary purpose of catching a particular species or species group (the target species).
Territorial sea	The territorial sea of the United States extends 12 nautical miles offshore. States exercise authority over marine fisheries in waters from the coastline to 3 miles offshore.
TES	Threatened and Endangered Species
TIN	Tax Identification Number
TIQC	Ad Hoc Groundfish Trawl Individual Quota Committee
T_{MAX}	The maximum time period to rebuild an overfished stock, according to National Standard Guidelines. Depends on biological, environmental, and legal/policy factors.
T_{MIN}	The minimum time period to rebuild an overfished stock, according to National Standard Guidelines. Technically, this is the minimum amount of time in which a fish stock will have a 50% chance of rebuilding if no fishing occurs (depends on biological and environmental factors).
Total allowable catch	The total regulated catch from a stock in a given time period, usually a year. (NMFS)
Total catch OY	Total catch optimum yield. The landed catch plus discard mortality.
T_{TARGET}	The target year, set by policy, for a fish stock to be completely rebuilt.

Acronym	Definition
U/A	Usual and accustomed (usually used when referring to tribal fishing, hunting or gathering areas)
ULS	Unconstrained Least Squares
USC	United States Code
USCG	U.S. Coast Guard. A representative of the USCG is a non-voting member of the Council.
USDA	U.S. Department of Agriculture
USFS	U.S. Forest Service
USFWS	U.S. Fish and Wildlife Service. A representative of USFWS is a non-voting member of the Council.
USGS	U.S. Geological Survey
Vessel Monitoring System	A satellite communications system used to monitor fishing activities—for example, to ensure that vessels stay out of prohibited areas. The system is based on electronic devices (transceivers), which are installed on board vessels. These devices automatically send data to shore-based "satellite" monitoring system.
VMS	Vessel monitoring system. See above.
VPA	Virtual population analysis. A modeling method used in conducting stock assessments.
VSI	Visual stock identification
WA	Washington
WCGOP	West Coast Groundfish Observer Program
WCSPA	West Coast Seafood Processors Association
WCVI	West Coast Vancouver Island
WDFW	Washington Department of Fish and Wildlife. A representative of WDFW sits on the Council.
WOC	Washington, Oregon and California
Yield per recruit	A model that estimates yield in terms of weight, but more often as a percentage of the maximum sustainable yield, for various combinations of natural mortality, fishing mortality and time exposed to the fishery (NOAA).
YPR	Yield per recruit. See above.
YRCA	Yelloweye Rockfish Conservation Area
ZMRG	Zero Mortality Rate Goal. A goal stated in the Marine Mammal Protection Act that the "incidental kill or incidental serious injury of marine mammals permitted in the course of commercial fishing operations be reduced to insignificant levels approaching a zero mortality and serious injury rate."

14.0 LITERATURE CITED

15.0 INDEX

To be completed for final DEIS.

Agenda Item F.2.b
ODFW Report 2
June 2006

OREGON DEPARTMENT OF FISH AND WILDLIFE REPORT ON THE PROPOSED STONEWALL BANKS YELLOWEYE ROCKFISH CONSERVATION AREA

The Oregon Department of Fish and Wildlife (ODFW) recommends consideration of a third option (Figure 1) for the implementation of a recreational Yelloweye Rockfish Conservation Area (YRCA) located at Stonewall Banks, off the coast of Newport, Oregon. This third option is within the range of options for development of a recreational Stonewall Banks YRCA, previously adopted by the Pacific Fishery Management Council (PFMC) at its April 2006 meeting.

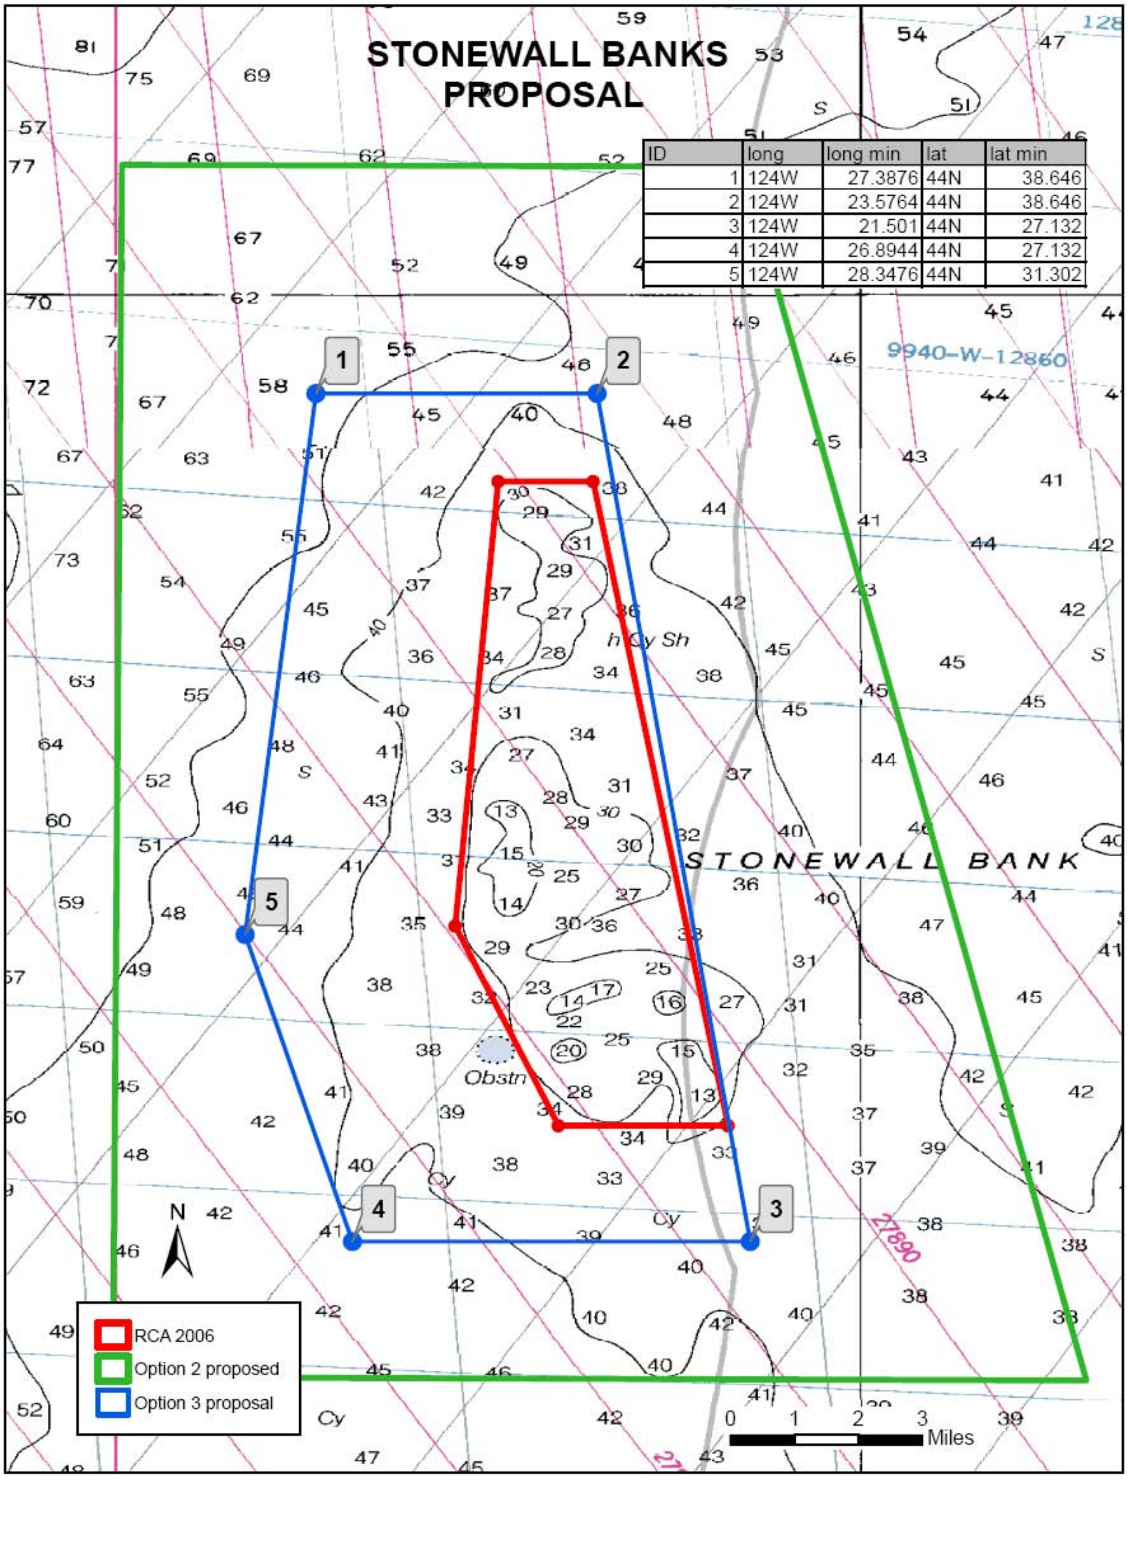
ODFW met with recreational fishery participants in Newport, Oregon on May 17, 2006 to discuss the range of management measures for the 2007-2008 recreational groundfish fisheries that were adopted by the PFMC at its April 2006 meeting. One of the topics at that meeting was the development of the recreational Stonewall Banks YRCA. Anglers fishing in this area would be prohibited from retaining groundfish, regardless of target species. This area may also be implemented in the Pacific halibut fishery beginning in 2007 as an area closed to the retention of Pacific halibut, replacing the closure that currently exists in that fishery. Adjustments to the 2007 Pacific halibut Catch Sharing Plan would be made as appropriate. Consideration may be given to allow vessels that have retained Pacific halibut (from outside the closed area) to troll (mooching prohibited) for salmon within the closed area.

The fishery participants that were present at the Newport meeting crafted the area proposed as Option 3, based on long-term knowledge of the area. Additionally, in 2005, ODFW conducted a research project, scoping the viability of employing external acoustic tags on yelloweye rockfish to determine site fidelity characteristics, and discard mortality. Tags were placed on 6 yelloweye rockfish; all were intercepted outside of the south-east border of the Option 1 closure area; area that is included in Option 3 boundaries.

A management alternative that was introduced at the Newport meeting was to require vessels within the closure area to troll only, regardless of target species, or retained catch. This means that any vessel fishing within this area would be required to have the vessel in gear at all times while in the closure area. Anglers would be able to retain any species of fish (i.e. groundfish, Pacific halibut, salmon, etc.) caught while in the area. This alternative requires further consideration.

The northern boundary of Option 3 is currently under review, and is awaiting further discussion with fishery participants. ODFW staff is currently working with fishery participants to determine an appropriate northern boundary, as data collected in the International Pacific Halibut Commission stock assessment survey indicates presence of yelloweye rockfish further north than the current northern boundary within Option 3. Adjusted coordinates will be provided to the PFMC at its June 2006 meeting.

Figure 1. Each of the three options for the implementation of a recreational Stonewall Banks YRCA. Option 1 is the smallest box and represents the current closure in the Pacific halibut fishery. Option 2 is the largest box, and Option 3 is the box in between.



SUMMARY OF THE BIOLOGICAL AND SOCIOECONOMIC EFFECTS OF THE 2007-2008 ACTION ALTERNATIVES

Introduction

The preliminary draft environmental impact statement (DEIS), "Proposed Acceptable Biological Catch and Optimum Yield Specifications and Management Measures for the 2007- 2008 Pacific Coast Groundfish Fishery and Amendment 16-4: Rebuilding Plans for Seven Depleted Pacific Coast Groundfish Species – Preliminary Draft Environmental Impact Statement" (Agenda Item F.2.a, Attachment 4), includes extensive analysis of the effects of rebuilding the seven depleted groundfish species subject to revised rebuilding plans under Amendment 16-4. These rebuilding analyses explore the time to rebuild under various levels of harvest (i.e., alternative optimum yields (OYs)), including a "no fishing" scenario (F=0); and the corresponding economic implications to groundfish sectors, ports, and fishing communities; and the interaction of depleted species within the marine ecosystem.

Alternative 2007-2008 groundfish management measures, referred to as Action Alternatives in the preliminary DEIS, are designed to provide fishing opportunities to harvest healthy, target species within the constraints of alternative depleted species' OYs. The three Action Alternatives decided by the Council in April 2006 follow a gradient of conservatism, with Action Alternative 1 being the most conservative in that these management measures constrain fishing opportunities the most, but result in faster rebuilding. Conversely, Action Alternative 3 has the most liberal management measures and provides the most fishing opportunity at a cost of longer rebuilding times. Action Alternative 2 is intermediate in the predicted effects to fishing opportunities and rebuilding times.

The Council decided preferred 2007-2008 OYs for all non-depleted species and two OY alternatives (a preferred Low OY Alternative and a preferred High OY Alternative) for detailed analysis at their April 2006 meeting. Action Alternative 1 management measures are designed to stay within the preferred Low OYs for depleted species and Action Alternative 3 management measures are designed to stay within the preferred High OYs for depleted species in 2007-2008. Action Alternative 2 has intermediate effects, staying within the preferred Low OY for some depleted species and otherwise staying within the preferred High OY. Table 1 depicts the estimated take of depleted species in Action Alternatives 1-3, respectively.

This document summarizes the key effects of the No Action Alternative, the three action alternatives, and the F=0 scenario in terms of impacts to rebuilding periods for depleted species and socioeconomic impacts. These summary effects are depicted in Table 1 of this document. Table 2 summarizes the combined recreational and commercial income impacts of the No Action and action alternatives by West Coast region. Figure 1 depicts trends in groundfish exvessel revenues since 1981, with projections through 2008 under each of the action alternatives. Table 3 lists the most vulnerable counties associated with changes in groundfish management measures. These tables and Figure 1 provide a "snapshot" of the bottom line biological and socioeconomic effects of the action alternatives.

The F=0 Alternative
The shortest possible rebuilding times are predicted for depleted species under the F=0 alternative (denoted $T_{F=0}$, the time to rebuild in the absence of fishing-related mortality) since fishing-related mortality is eliminated beginning in 2007. This alternative is a comparison "benchmark" in this preliminary DEIS since the Council has decided to allow some harvest under groundfish rebuilding plans to avoid disastrous short-term socioeconomic impacts.

Under the F=0 alternative, multiple sectors are closed and fishing communities experience substantial losses of commercial fishing-related revenue and recreational fishing effort and expenditures (Table 7-69 of the preliminary DEIS). Compared to 2005 revenues, commercial fishery exvessel revenue would be decreased by over $177 million, and the number of recreational angler trips would decrease by over 1.1 million. These figures represent a closure of all groundfish-related commercial revenues, all groundfish-related recreational angler trips, and multiple non-groundfish sectors.

Action Alternative 1
Action Alternative 1 constrains fisheries to the preferred Low OYs for depleted species and therefore results in the shortest rebuilding times considered by the Council for Amendment 16-4 rebuilding plans. Rebuilding is extended by less than five years relative to $T_{F=0}$ for bocaccio, cowcod, darkblotched rockfish, Pacific ocean perch, and widow rockfish. Canary and yelloweye rockfish rebuilding periods are extended by an estimated 7 and 35 years, respectively under Action Alternative 1.

Action Alternative 1 reduces rebuilding species OYs compared to status quo catch levels, and as a result, revenues generated by commercial fisheries directed at groundfish are lower than status quo levels, and the number of recreational bottomfish trips is lower than status quo. Under this alternative, many of the target species OYs are not attained, and fishing area is decreased for all sectors as the size of groundfish conservation areas is expanded to encompass more area where rebuilding species are found. Under this alternative, exvessel revenues for the major directed groundfish sectors are estimated to be approximately $42.8 million, and the number of recreational angler trips for bottomfish is estimated to be 350,690. These figures represent approximately 62% of exvessel revenues generated in 2005, and 65% of the number of angler trips in 2005.

Action Alternative 2
Action Alternative 2 effects are intermediate to the other action alternatives. Alternative 2 management measures explore different ways to constrain fishing-related mortality of depleted species and reveal distributional effects to fishing sectors and regions resulting from these alternative measures. Table 1 shows the estimated impacts to depleted species under Action Alternative 2 management measures are within the preferred Low OY for cowcod, but within the preferred High OY for the other six depleted species. Predicted rebuilding times under Action Alternative 2 are likewise intermediate to those under the other action alternatives and proportional to the amount of allowable harvest if that harvest rate is maintained during the entire rebuilding period.

Action Alternative 2 brings rebuilding species OYs to levels that are near status quo catch amounts for many rebuilding species except for yelloweye rockfish. While OYs for rebuilding species are near status quo, negative economic impacts are greater than alternative 1, but less than Action Alternative 3. In addition, a larger portion of the OY remains unattributed to any particular sector.

While many of the OYs for rebuilding species are near status quo, and there are relatively large amounts of OYs not attributed to any particular sector, the amount of exvessel revenues are different for certain sectors and regions of the fishery when compared to 2005 and 2006 revenues. While some sectors have higher exvessel revenues than 2005 or 2006, others have lower exvessel revenues. The difference in the distribution of revenues is directly attributed to changes in target species abundance and OYs. For example, the increase in the 2007 OY for Dover sole results in larger exvessel revenue for the bottom trawl sector as a whole, while the decrease in the 2007 OY for sablefish results in lower coastwide exvessel revenues for the fixed gear sablefish sectors.

On a coastwide basis, combined exvessel revenues for the major directed groundfish sectors are estimated to be approximately $59.7 million, and the number of recreational angler trips for bottomfish is estimated to be 421,271. These figures represent approximately 87% of 2005 exvessel revenues, and 78% of 2005 bottomfish angler trips.

Action Alternative 3
Action Alternative 3 constrains fisheries to the preferred High OYs for depleted species and therefore results in longer rebuilding times relative to the other action alternatives. Rebuilding is extended by five years or less relative to $T_{F=0}$ for bocaccio, darkblotched rockfish, Pacific ocean perch, and widow rockfish. Cowcod, canary and yelloweye rockfish rebuilding periods are extended by an estimated 8, 10, and 36 years, respectively under Action Alternative 3.

Action Alternative 3 brings rebuilding species OYs to levels that are near status quo catch amounts for many rebuilding species except for yelloweye rockfish. The overall economic impact of Action Alternative 3 is that many sectors are expected to achieve social and economic benefits that are similar to status quo levels. However, like Action Alternative 2, there are differences in the distribution of exvessel revenue and angler trips on a regional basis and on a sector-by-sector basis. This change is driven by changes in the abundance and OYs for target species, as well as changes in the yelloweye OY. The change in the yelloweye OY negatively impacts recreational fisheries in the northern areas, but recreational fisheries in the southern areas are able to attain a higher number of angler trips than under 2005 and 2006 regulations. In the case of commercial fisheries, the bottom trawl sector is able to attain higher levels of exvessel revenues when compared to 2005 and 2006, primarily as a result of the increase in the Dover sole OY. Alternatively, the fixed gear sablefish sectors achieve lower levels of revenue because of a decrease in the sablefish OY.

On a coastwide basis, commercial exvessel revenues for the major directed groundfish sectors are estimated to be approximately $64.9 million, and the number of recreational bottomfish trips is estimated to be 587,873. These figures represent 94% of 2005 exvessel revenues, and 109% of 2005 recreational angler trips.

The Economic Implications of Uncertainty and Management Flexibility
The economic impact estimates in the preliminary DEIS are based on management measures that achieve some level of target and non-target species catch or recreational fishing opportunity. Catch projections, revenue estimates, and recreational effort projections are, as with any

projection or estimate, subject to varying degrees of accuracy. While they do in fact represent the best estimate of catch and socioeconomic impacts, these estimates will inherently differ from what actually occurs in the fishery when the 2007 fishing year progresses. These differences can be due to such things as changes in catch per unit effort, unexpected weather patterns, unexpected ocean conditions, changes in the behavior or availability of the fish stocks, or changes in effort on the part of fishermen, amongst other things. Empirical evidence and past experience has shown that catch projections will ultimately differ to some degree from what actually occurs. Some projections will be less than what occurs and some will be higher than what actually occurs. Rebuilding species catch estimates that end up being less than what actually occurs in the fishery have the potential to negatively impact fishing sectors if an inseason management response is necessary to keep the catch of that rebuilding species within the OY. While the catch of rebuilding species that are higher than expected may provide for some amount of revenue or angler satisfaction, rebuilding species provide little social and economic benefit because they represent a small portion of the fishery, but constrain abundant target species. This is because of the mixed stock nature of the fishery. When an inseason action is necessary to stay within a rebuilding species OY because of unexpectedly high catch, that inseason action will typically result in a loss of social and economic benefits as the fishery becomes constrained to minimize further catch of that rebuilding species. While it is impossible to know which species are likely to have higher or lower actual catches than predicted, it can almost always be expected that it will occur to some degree. That is, it is a matter of when catches will differ from predictions and for what species, not a matter of if actual catches will differ from predictions.

The amount of uncertainty related to the catch projections of rebuilding species is directly related to the economic impacts of management measures designed to achieve a given catch level. If OYs are constructed in a manner that takes into account the reality that catch predictions have a certain level of uncertainty (that is, if OYs are higher than predicted total catch) then the economic impact that is predicted prior to the start of the season for a given set of management measures becomes more certain. As the difference between the OY of rebuilding species and predicted catch increases, the economic impacts resulting from management measures becomes increasingly more certain. Inversely, as the difference, or “buffer” between the OY of a rebuilding species and predicted catch decreases, the certainty of the economic impacts predicted for that particular management scheme is reduced. If the OY for all rebuilding species is determined from predicted catch, it can be guaranteed that the actual economic impacts resulting from that suite of OYs will be lower than what is predicted because the actual catch of one or more rebuilding species will be higher than expected and some constraining management response will be necessary at some point during the year. A management system designed in a manner where each stock is equally constraining has no flexibility to respond to likely departures from predictions.

Management of groundfish fisheries throughout much of the 2002-2006 period have relied on some degree of management flexibility to keep rebuilding species catch levels within their respective OYs while maintaining some amount of social and economic benefits. For example, a typical review of inseason catches will reveal that the catch of one or more rebuilding species is higher than what was anticipated. The response has often been to implement a change in management regulations which shifts major portions of the fishery to areas where rebuilding species that are experiencing higher than anticipated catch levels may not be as abundant, but other rebuilding species may be found in greater abundance. This effectively reduces catches of rebuilding species that may be tracking ahead of projections, but it may increase the catch of other rebuilding species. The social and economic impact of restricting the fishery in some areas is often mitigated by the ability to move the fishery to other areas. Without a buffer between predicted catch of rebuilding species and rebuilding species OYs, this type of management flexibility would not be possible, and the actual social and economic impact associated with particular catch levels is likely to be lower than what was expected. Therefore, if it is an objective to maintain some certainty that a level of social and economic benefit related to fishing activities will occur over the course of a year, then a buffer between predicted catches of rebuilding species and the OY of rebuilding species is necessary.

Effects on West Coast Fishing Communities

A consideration in deciding groundfish rebuilding plans is the effect of management measures on West Coast fishing communities. Chapter 7 and Appendix A of the preliminary DEIS explores the socioeconomic impacts of alternative harvest levels and corresponding management measures on West Coast fishing sectors, ports, and communities. This report summarizes these effects at the county level by listing those counties that are considered "vulnerable" and "most vulnerable" to changes in management measures by ranking those counties that are most engaged in fishing or dependent on the groundfish fishery and least resilient to negative socioeconomic impacts (Table 3).

In this analysis, a county is "commercially engaged" in fishing if it ranks among the top one-third of all coastal counties in at least one of four indicators (number of vessels, permits, dealers, or revenue). A county is "commercially dependent" on groundfish resources if it ranks among the top one-third of all coastal counties in at least one of three indicators (groundfish permits and two groundfish revenue measurements). A county is "recreationally engaged or dependent" on fishing if it ranks among the top one-third of all coastal counties in at least one of four indicators (four measurements of the number of angler and charter trips). A county is "least resilient" if it ranks among the top one-third of all coastal counties in at least one of four indicators (industry diversification, unemployment rate, percentage of the population living below the poverty level, and population) used as proxies for economic resiliency. A county is listed as "vulnerable" if it is commercially engaged and least resilient, commercially dependent and least resilient, or recreationally engaged or dependent and least resilient. A county is listed as "most vulnerable" if it is listed among the top one-third of "commercially engaged", "commercially dependent", or "recreational engaged or dependent" indicators at least three times and is listed among the top one-third of resiliency indicators at least three times.

Table 1. Estimated rebuilding duration for depleted groundfish fisheries and predicted socioeconomic impacts under 2007-2008 Action Alternatives and a "no fishing" scenario.

Action Alternative	Depleted Species	OY (mt)	Estimated Impacts[a/] (mt)	Median Time to Rebuild[b/]	Exvessel Revenue for Major Groundfish Sectors[c/]	Recreational Effort[d/] (no. of trips)
No Action Alternative (2006 specifications and management measures)	Bocaccio	309	135	2029

	Yelloweye	Ramp-down[e/]	14.3	2084		
	Socioeconomic Impacts				$59,654,000	421,271
Action 3 (Constrains fisheries to the preferred High OYs for depleted species)	Bocaccio	218	186	2026		
	Canary	44	41	2063		
	Cowcod	8	3.5	2043		
	Darkblotched	229	203	2010		
	Pacific Ocean Perch	100	100	2016		
	Widow	368	191	2015		
	Yelloweye	Ramp-down[e/]	18.3	2084		
	Socioeconomic Impacts				$64,861,000	587,873

a/ Estimated impacts are from the GMT's bycatch scorecards for each alternative. The No Action Alternative represents impacts with inseason adjustments implemented in May 2006.

b/ Median rebuilding time is the estimated time to rebuild the stock if the entire OY is taken and the harvest rate is maintained after 2008 and through the entire course of rebuilding (i.e., harvest is taken at the rate used to determine the OY).

c/ "Major groundfish sectors" includes nearshore groundfish, limited entry bottom trawl, limited entry whiting, fixed gear sablefish, and fixed gear groundfish south of Pt. Conception.

d/ Recreational effort includes only bottomfish trips.

e/ The yelloweye ramp-down strategy ramps the harvest rate down from the status quo harvest rate and resumes a constant harvest rate strategy in 2011. The 2007-2010 OYs are 23 mt, 20 mt, 17 mt, and 14 mt, respectively under the ramp-down strategy.

Table 2. Change (from No Action) in combined estimated commercial and recreational income impacts by region under the action alternatives (million $).

PFMC
06/13/06

At the April Meeting the Council Adopted the Following:

- Fishing Communities need a sustainable fishery that is safe, well managed, and profitable, that provides jobs and incomes, that contributes to the local social fabric, culture, and image of the community, and helps market the community and its services and products.

Table 7-1 Total Commercial, Tribal, and Recreational Landings and Deliveries by Sector

California Department of Fish and Game (CDFG) Report on Rockfish Conservation Area Management Alternatives for 2007-2008 Groundfish Management

Cowcod Conservation Area (CCA) Perimeters

Options for Consideration

The California Department of Fish and Game (CDFG) has received requests from both commercial and recreational fishermen to modify the boundaries of the Cowcod Conservation Area (CCA) for 2007-2008. Recreational fishermen have requested a modification to the inner perimeter to allow access to additional fishing areas nearshore. Commercial fixed gear fishermen have requested access to deeper waters within the current CCA boundaries to restore access to former slope rockfish target opportunities, primarily for blackgill rockfish.

Background and Purpose of CCA

The Cowcod Conservation Area (CCA) closures in the area south of 34°27’ N. latitude were established in 2001 in response to an overfished determination for the cowcod rockfish stock, and a federal requirement to restore the population to a healthy status. The intent of the CCAs was to reduce the cowcod catch so that the rebuilding Optimum Yield/Total Allowable Catch (OY/TAC) will not be exceeded. Rebuilding analyses suggest that recovery would be jeopardized if rebuilding OY/TACs are exceeded by any significant amount. The cowcod stock was reassessed in 2005, which indicated that cowcod biomass size is in slightly better shape than the last assessment (18% versus 7% of unfished biomass). This was reflected in a higher Conception area ABC for 2007-2008, though results of the new rebuilding analysis confirm suggestions from previous analysis that rebuilding of cowcod may take several decades. A new series of annual rebuilding OY/TACs have been calculated for future years, beginning in 2007-2008.

The CCA closures are primarily located far offshore where cowcod catches and catch rates remained historically high, but where total groundfish effort had been much lower than for fishing grounds closer to the mainland shore. Therefore, the CCA closures were initially adopted because they were less disruptive to southern California fisheries than alternative measures that would have been applied across the board to all shelf fishing grounds. These area closures were established prior to the implementation of depth-based RCAs along the coast that provided new protection to the primary depths of overfished shelf species, such as cowcod. The biggest difference between the RCAs and the CCAs was that the CCAs were expected to remain unchanged for many years based on the need to keep cowcod mortality within the rebuilding limits from the first stock assessment, although they were never intended to serve as reserves or marine protected areas (MPAs). Given that the recent assessment shows a more optimistic rebuilding picture, this proposal provides consideration for adjustment of the CCA boundaries.

When the CCAs were first established, enforcement concerns dictated the outer boundaries to be long, straight lines rather than following irregular depth contours so that enforcement by aircraft could be effective. This resulted in inclusion of deep water (slope) habitat in the closure, where cowcod are less commonly found, and thus access to slope fishing grounds was omitted. Since the CCA's adoption, an electronic Vessel Monitoring System (VMS) has been adopted by the Pacific Fishery Management Council (PFMC) for commercial groundfish vessels, which is intended to provide effective enforcement without the need for long straight boundaries for offshore area closures. VMS should allow for more effective enforcement of irregular offshore boundaries. And, the overly-precautionary area management should be able to accommodate some risk of bycatch on the deeper fringes of cowcod depth distribution. .

Outer CCA Perimeter Alternatives

For the 2007-2008 management cycle, alternative outer boundaries for the CCAs are proposed for consideration, to preserve the original intent of maintaining cowcod fishing mortality levels within the rebuilding OY/TAC while restoring fishing access to target species generally outside of cowcod depth zones for non-trawl vessels only. Prior to implementation of the CCAs, the area was accessed by vessels fishing with hook and line gear to target primarily blackgill rockfish, along with other slope rockfish.

Three alternatives to status quo are presented for consideration.

<u>Option 1 (= "Action Alternative 2" Chapter 2, DEIS): modify depth boundaries to allow fishing deeper than 175 fm.</u>

For non-trawl vessels that employ VMS, the CCA closure areas would be limited to the primary depth range that is utilized by cowcod, which would remove current bottom fishing restrictions from a large area of fishing grounds that are too deep to be considered primary cowcod habitat. Alternative 1 redefines the CCA outer perimeters as a series of waypoints that fall within (or beyond) the cowcod depth range, centering on the 175 fathom contour. This alternative refines the area management of cowcod intended when the CCA was established while preserving the original intent of the CCA with less impact to fisheries for other healthy stocks. Some additional considerations would be necessary to provide effective enforcement for this alternative:

- Only vessels with VMS would be eligible to fish between the current CCA boundaries and the new outer perimeter lines. For all vessels except those carrying VMS, the current boundaries and restrictions for the CCAs would be maintained.
- CDFG enforcement of Alternative 1 waypoints would rely on timely access to VMS information, and the ability to use that information in state court to prosecute violations. Without VMS access, or federal enforcement of boundaries, effective enforcement and thus management integrity could not be ensured.
- Vessels intending to fish using Alternative 1 boundaries would be required to declare their intent prior to departure from port for each trip.
- End buoys for longline sets would be required to employ radar reflectors and strobe lights. Also, the practicality of employing transponders (or other technologies) similar to VMS for the end buoys would be considered as a regulatory requirement.

Option 2 (= "Action Alternative 1", Chapter 2, DEIS): establish specific rockfish fishing areas within the CCA.

Four deep-water rockfish fishing areas (RFAs) within the existing CCA boundaries would be specified for commercial fishing with hook and line gear. This is similar to Alternative 1, except areas open to fishing would be limited to fishing grounds within four new defined RFAs and, within those RFAs, to areas that are deeper than the 175 fathom contour, as approximated by a series of waypoints within the RFA polygons. All other conditions would be as specified under Alternative 1. The limited number of fishing locations in Alternative 2 are intended to improve enforceability of the regulations compared to Alternative 1 while providing some access to slope target species deeper than habitat preferred by cowcod.

Option 3 (= "Action Alternative 3" Chapter 2, DEIS). Eliminate the CCAs and employ depth-based management under normal Rockfish Conservation Area (RCA) regulations.

This alternative would provide for management of the CCA areas as part of the routine groundfish management process. Any depth and area restrictions would be developed and adopted under the RCA regulations, which are currently closed to 150 fm in the area south of 34°27' N latitude.

Option 4. Status quo (no action alternative)

Maintain the current boundaries and restrictions for the CCAs. This alternative provides boundaries that have been shown to be easily understandable to fishers and enforcement. Conservation for cowcod and other overfished groundfish that are found within the area is achieved. However, fishing opportunities previously afforded to fixed gear vessels for target slope species are not realized.

Analysis of Impacts for Outer Perimeter Alternatives

Available depth distribution information for cowcod and blackgill rockfish are provided in Table 4-1 in Chapter 4 of the 2007-2008 DEIS contained in the June 2006 Briefing Book. The provided depth range of highest cowcod density is 100 -130 fm with an overall depth range of 22 - 203 fm. Depth distribution information for blackgill, the primary slope target species, is 125 - 300 fm for common depth (or highest density). While there is some overlap of the proposed open depths with the deeper ranges where cowcod has been observed, all of the outer perimeter alternatives would be expected to maintain the total cowcod catch within the rebuilding OY for 2007-2008. Prior to adoption of the CCA, less than ten vessels fished for blackgill rockfish in these areas. While CDFG recognizes there is no way to predict the likelihood of increased open access opportunity in areas reopened to the hook and line fishery under these alternatives, few open access vessels currently participate in slope rockfish fishing in areas open outside the non-trawl RCA boundaries.

All of the Outer Perimeter Alternatives would be expected to maintain the total cowcod catch within the rebuilding OY for 2007/2008. In 2000, an OY of 2.4 mt was established for the Conception area, which was roughly one-half the level of the total commercial catch from trawl and non-trawl vessels during the preceding years when there were few if any constraints on cowcod fishing. Since then, access to shelf habitat has been restricted by implementation of depth-based Rockfish Conservation Areas (RCAs), and the cowcod bycatch mortality has been coming in under the current rebuilding OY of 2.1 mt.. The majority of catch has come from the trawl sector north of Pt. Conception, which currently has a separate OY of 2.1 mt. When comparing current catch estimates from the non-trawl commercial sectors to the OYs combined from both areas are 0.2 mt, representing 5% of the two area OYs combined (=4.2mt). For 2007-08, the Council-preferred OY alternatives combine the two OY management areas for a single OY that includes a near-status quo level and a higher level (4.0 mt or 8.0 mt for both areas combined). The trawl and non-trawl RCAs have provided protection of cowcod in addition to the CCA and total catch for cowcod in all commercial and recreational sectors has successfully reduced impact to approximately 20% below the current OYs, with an RCA boundary at 150 fm. A combination of 150 fm RCA boundaries and maintained CCA closure in waters less than 175 fm (under Action Alternatives 1 and 2) should therefore preserve successful management of bycatch levels of cowcod rockfish below the proposed low OY option for 2007-08. From a biological perspective, any of the alternatives to status quo meet the intent of the CCAs; however, from an implementation perspective, the option contained in Option 2 (Action Alternative 1) best achieves enforcement goals. Relative to concerns expressed over the potential impact on continued fishery-independent research within the CCA, a new survey using submersibles to survey cowcod within the CCA was conducted and used as a survey source in the 2005 cowcod stock assessment. Some areas contained in alternatives may overlap with survey areas, although we have not compared to actual transect locations. Depending on the alternative chosen, CDFG recognizes that it might affect comparability of the one past survey with future surveys repeated in the area.

The actual impact to cowcod of any changes could be evaluated in the future to consider whether the blackgill fishery should continue in that areas, if new observer data from fishing deeper than 175 fm in the CCA became available. While the West Coast Groundfish Observer Program was implemented after the closure of the CCA, observations south of Pt. Conception have been minimal to this point.

Inner CCA Perimeter Alternatives

For 2007-08, constituents have requested the opportunity for recreational fishing deeper than the currently-specified 20 fm depth closure.

Alternative 1: Extend fishing depth from 20 fm to 30 fm.

Alternative 2: Extend fishing depth from 20 fm to 40 fm.

Sub-options for Alternatives 1 and 2: Consider allowing retention of shelf rockfish species

Alternative 3 (CDFG preferred alternative): Status quo (no action). Maintain the current boundaries and depth and species restrictions for the CCAs.

Analysis of Impacts from Inner Perimeter Alternatives

The current 0-20 fathom shallow fishing opportunity within the CCA is limited to nearshore species and does not provide for retention of shelf species. Both of these provisions were established to eliminate the risk of interactions with cowcod. Fishing deeper than 20 fathoms would not provide additional fishing opportunities unless we allowed retention of shelf species. .Allowing retention of shelf species would increase the likelihood that an unquantifiable amount of cowcod would be discarded, thus undermining the intent of the CCAs. Allowing increased fishing opportunities for the recreational and commercial fisheries in an area of expected cowcod interactions is not supportable given the continued low OY options. Therefore, the CDFG does not recommend any change from status quo for inner CCA boundaries.

Proposed Creation of Darkblotched Rockfish Conservation Areas (DRCAs) between 40°10' N latitude and 38° N latitude for Limited Entry Trawl Groundfish in 2007-2008

Background:
California Department of Fish and Game (CDFG) is proposing two areas for possible new Darkblotched Rockfish Rockfish Conservation Areas (DRCAs) between 40°10' N. latitude and 38° N. latitude. This area represents the southern end of the distribution of this rebuilding species. Although catch rates are lower in this area when compared to catch rates in the area north of 40°10' N. latitude, some large catches have occurred in past years, and as a result there is uncertainty in predictability of catches in this area. Slope rockfish represents an important target species group for trawl vessels operating in this area, and cumulative trip limits previously were the same from 40°10' N. latitude to the US/Mexico border. However, due to uncertainty relative to possible darkblotched rockfish in this area when targeting slope rockfish, cumulative trip limits have been reduced to a level intermediary between low levels N. of 40°10' and limits south of 38° N. latitude. Available data was analyzed to evaluate whether specific areas of higher concentration (i.e., catch-per-unit-effort) could be identified for potential closure to provide a reasonable expectation of lower bycatch than current rates being assumed for the area.

Data Reviewed:
Data from several sources were reviewed through a collaborative effort between NMFS and CDFG. Fishery-independent data from the triennial, slope, and combined surveys were provided by AFSC and NWFSC, and analysis conducted by John Field, NMFS Santa Cruz and Jan Mason, NMFS Pacific Grove. Fishery-dependent location data were derived from trawl logbook data and analyzed by Jan Mason and Gerry Kobylinski, CDFG. Data from identified areas was compared to observer data from the West Coast Groundfish Observer Program (WCGOP) by Jim Hastie. A complete review of the analysis will be provided at the June Council meeting.

Proposal:
Five areas reflecting higher concentrations of darkblotched rockfish in one or more years from 2000-2005 were identified and analyzed. Of these, two areas appeared to have the greatest amount of overlapping data between data sources. WCGOP data did not conflict with these finding. Should the areas be adopted for use in 2007-2008 groundfish management, their appropriate application needs to be explored. The areas could be used year-round, or part of the year, or used when needed inseason. The two areas for consideration are as follows:

Alternative 1: DRCA at Spanish Canyon near Shelter Cove (Figure 1)

Coordinates for Area 1 (Map attached):

#	Latitude Degrees	Decimal Minutes	Longitude Degrees	Decimal Minutes
1	40	6.22	124	17.78
2	40	2.96	124	15.49
3	40	2.42	124	13.69
4	40	2.23	124	13.66
5	40	2.57	124	16.53
6	40	4.85	124	17.99
7	40	6.22	124	17.78

Alternative 3: DRCA west of Pt Arena (Figure 2)

Coordinates for area 3 are as follows (Map Attached):

#	Latitude Degrees	Decimal Minutes	Longitude Degrees	Decimal Minutes
1	38	56.36	123	59.33
2	38	56.98	123	56.73
3	38	53.7	123	56.35
4	38	50.07	123	53.6
5	38	50.02	123	55.32
6	38	56.36	123	59.33

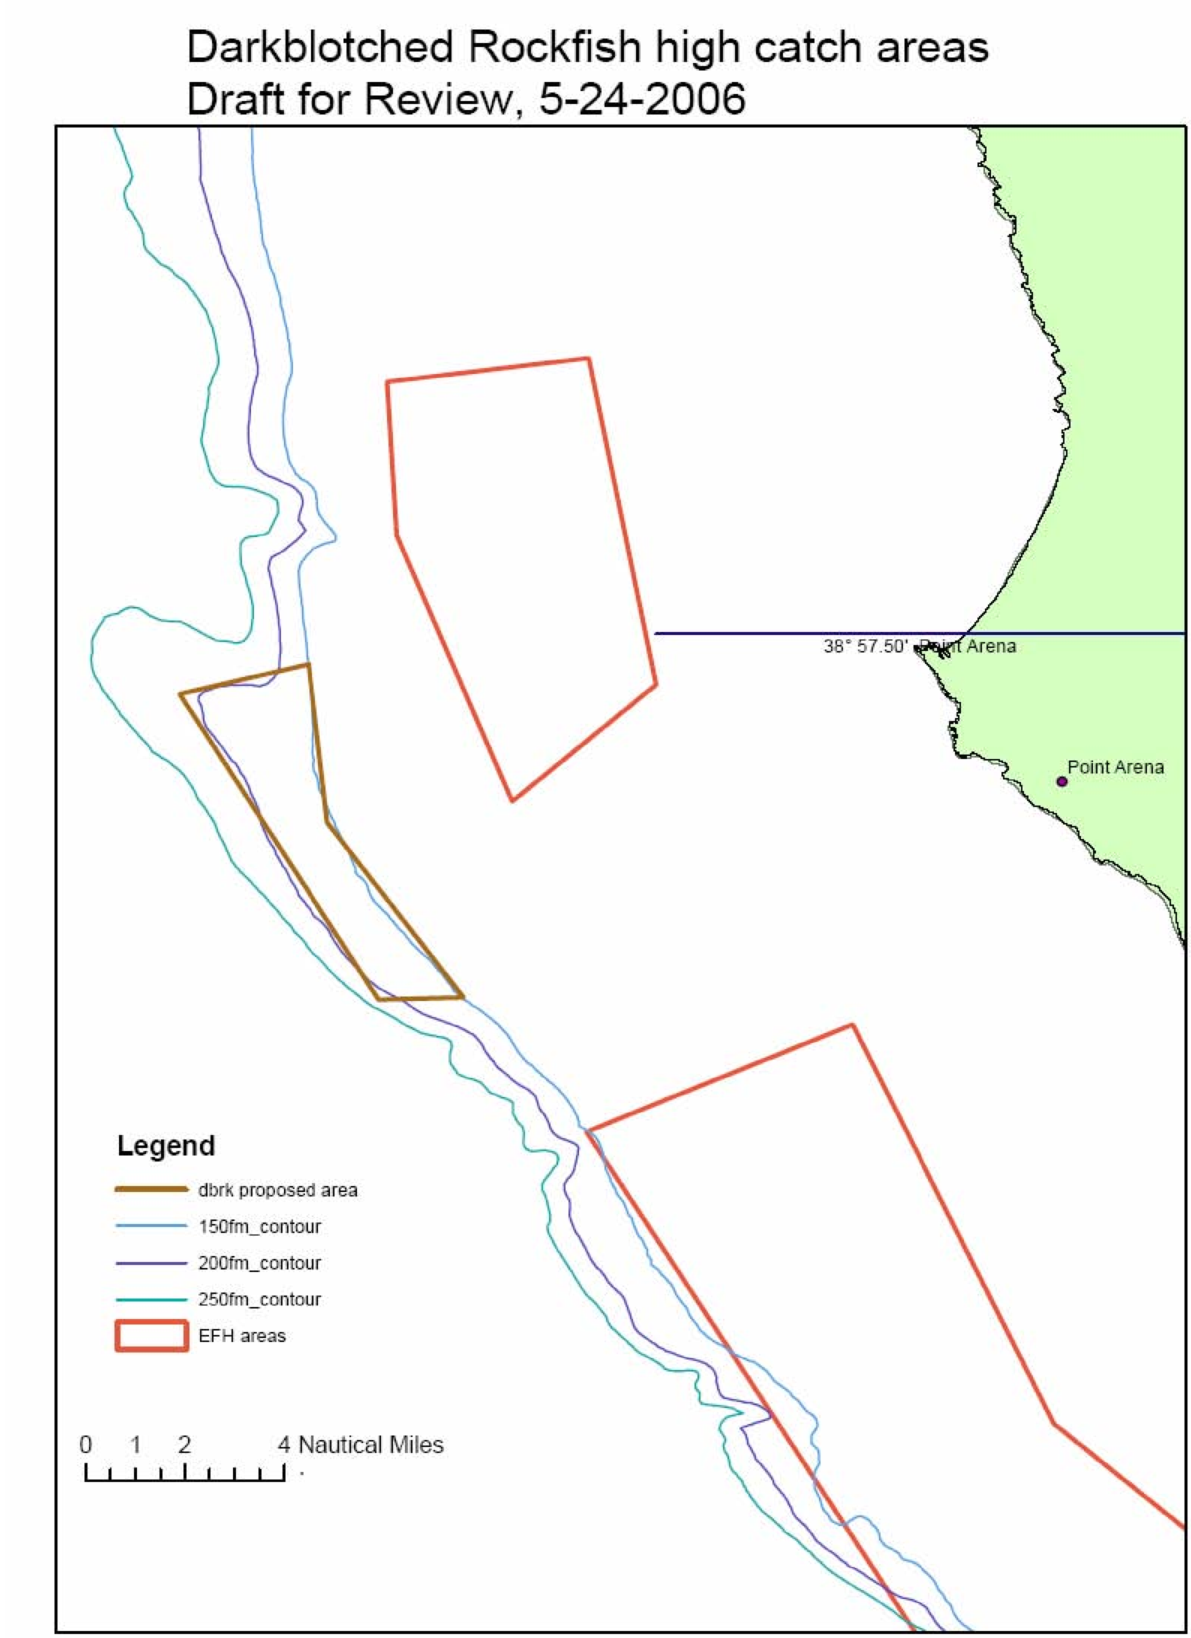

Figure 2. Proposed darkblotched RCA west of Point Arena.

OREGON DEPARTMENT OF FISH AND WILDLIFE REPORT SUMMARIZING PUBLIC COMMENT RECEIVED REGARDING 2007-2008 GROUNDFISH MANAGEMENT

The Oregon Department of Fish and Wildlife held a series of public meetings to gather public input on the range of management measures adopted by the Pacific Fishery Management Council for each of the 2007-2008 groundfish fisheries (commercial and recreational). Meetings were conducted coastwide on 4 consecutive days; beginning in Brookings, Oregon, and moving north to Coos Bay, Newport, and Astoria, and consisted of a joint session to discuss regulation setting processes and harvest levels, and break-out sessions to separately discuss the harvest levels and management measures specific to the recreational or commercial fisheries.

Recreational

Table 1 details the majority opinions from each meeting as well as a listing of individual comments regarding proposed recreational management measures for the 2007-2008 groundfish fisheries. Overall, attendees were very concerned about the proposed low level of yelloweye rockfish, and were adamant that the groundfish fishery would not be sustainable under the management structure of Action Alternatives 1a and 1b (Figure 1). If forced to determine a preference between Action Alternatives 1a and 1b, most felt that a reduction in the Pacific halibut fishery would have a less severe impact than a 2-month groundfish fishery.

Both the north and south coasts (Astoria and Brookings) preferred having a reduction in season duration over a reduction in the daily marine bag limit. The central coast (Coos Bay and Newport) preferred maintaining a year round fishery, though meeting attendees cautioned that reducing the marine fish daily bag limit further would greatly curtail fishing interest. Nearly all participants confirmed the desire to maintain a marine fish daily bag limit of no fewer than 5 fish.

Overall, attendees were supportive of creating a flatfish daily bag limit of 25 fish in aggregate, consisting of all soles and flounders except Pacific halibut. Currently, all flatfish except Pacific sanddab and Pacific halibut are managed within the marine fish daily bag limit.

Reactions to increased lingcod opportunity were mixed. There was no support for a minimum size limit of 20-inches, some support for a minimum size limit of 22-inches, and most support for the status quo minimum size limit of 24-inches. Most attendees did not endorse an increase in the lingcod daily bag limit, unless there were dramatic changes in either the season structure or depth restrictions.

Commercial

Bottom Trawl

Overall bottom trawl fishermen understood and accepted the rationale behind the suite of high, medium and low OY alternatives. At the low end (particularly for nearshore selective flatfish trawl) the level of trip limits presented might not even cover operational cost (high price of fuel). Deepwater fishermen were also concerned about high fuel costs, and indicated they might then elect to fish closer to home – which would increase nearshore trawl effort. An option to allow only one trawl net type per 2-month cumulative catch period is intended to prevent increased effort nearshore (which could result in early season closure). Fishermen were split regarding support for such an option. Bottom trawl fishermen also indicated that the trip limit ratios are not aligned with actual ratios of one species to another in actual catches, and will result in unnecessary discard. Dover sole trip limits should be increased relative to sablefish and petrale sole. Finally, some fishermen indicated that using state-wide or even region-wide estimates for bycatch mortality penalized fishermen that do not catch canary rockfish or yelloweye rockfish in their area. They felt that a move towards sub-regional, or even sub-state management would be a fair approach.

Midwater-trawl

No Pacific whiting fishery participants attended, and no comments were received.

Fixed-gear sablefish

Fixed-gear fishermen were universal in their belief that the sablefish OY was set too low. If Action Alternative 2 (fish outside 125 fm) or Action Alternative 1 (fish outside 150 fm) is implemented it should only apply to longline gear (pot bycatch is nearly non-existent compared to longline). Longline fishermen were not well represented. Fisherman understood that the FMP would need to be amended to make this change (separate pot and longline management options), but felt it would be worthwhile.

Nearshore Hook & Line

The majority felt that season structure and shallower depth restrictions would be preferable to reduced target species harvest levels. Fishing inside 20 fm was accepted by nearly all (a minority felt that 10 or 15 fm would be acceptable). Fishing in less than 20 fm during the winter was inadvisable because fish disperse and safety issues are a great concern.

Figure 1. Season structure along with expected yelloweye rockfish and canary rockfish impacts for various 2007-08 Oregon recreational fishery action alternatives, compared to the no action alternative.

* Status quo marine bag species.

**Marine bag limit excludes flatfish which have a separate 25 fish daily bag limit.

Table 1. Major Sport Issues Discussed at Public Meetings reviewing 2007-08 Management Measures *

	Brookings	**Coos Bay**	**Newport**	**Astoria**
Number of Public Participants	8	6	10	6
Issues:				
Year round season	Suggest April 1 - October 15 fishery.	Year round fishery. Opposed to fishery inside of 40 fm all year (Action Alternatives 3a and 2 are not feasible).	Year round fishery at expense of offshore opportunity. No depth closure inside of 25 fm (Action Alternative 2 is not feasible).	Suggest March 15 - October 15 or April 1 -October 15. No depth closure inside of 25 fm (Action Alternative 2 is not feasible).
Marine bag limit		No less than 5 (or 6) marine bag.	No less than 5 marine bag.	Higher marine bag with less than year round season.
Separate flatfish bag limit	Yes (unanimous)	Yes. (concern for starry flounder and California halibut)	Yes. Less confusing for anglers as not need to identify species (except P. halibut) and less citations.	Yes, but maybe reduce bag limit from 25. Remain open year round.
Lingcod bag limit	2 (status quo)	If fishery open > 40 fm =2. If fishery open < 40 fm =2 or 3.	If fishery open > 40 fm =2. If fishery open < 40 fm =2 or 3. Concern for increased yelloweye rockfish impacts.	If year round season =2. If reduced season and/or reduced marine bag limit =3.
Lingcod minimum length (inches)	22 or 24 (most preferred status quo)	24	24	22
Reduce Pacific halibut season to achieve longer groundfish season of at least six months	Not an issue in this area (little P. halibut opportunity)	Neither reduced Pacific halibut opportunity (Action Alternative 1b) or 2 month groundfish season (Action Alternative 1a) are feasible. Action Alternative 1b would have less impact to the fishery.	Neither reduced Pacific halibut opportunity (Action Alternative 1b) or 2 month groundfish season (Action Alternative 1a) are feasible. Action Alternative 1b would have less impact to the fishery.	Neither reduced Pacific halibut opportunity (Action Alternative 1b) or 2 month groundfish season (Action Alternative 1a) are feasible.

Other Related Proposals/ Issues	1. Weekly or annual limits on rockfish (tags?) 2. Regional mgt within OR on nearshore species (north vs south coast)	1. Allow incidental take of lingcod in P. halibut fishery (especially if Stonewall Bank is closed). 2. Regional mgt within OR. 3. Manage yelloweye rf on state status (regional).	Viable economic impact statement needed to address various options and effect on fishing industry, coastal economy, and state.	Columbia R. subarea would like an increase in the OR/CA sport P. halibut allocation as they have little incidental yelloweye rf impacts.

* Comments reflect majority opinion. All were informed the shore fishery would be managed for a year round season as yelloweye rf and canary rf are not impacted in the shore fishery.

Individual or minority observations on Major Sport Issues by Port

Year round season (Confirm: year round fishery at expense of offshore opportunity and reduced marine bag)

- Newport
  - Values fish more in winter
  - March - October 15 season
  - Move the fishery inside 15-fathoms all year and avoid yelloweye rockfish
  - No less than 5 fish marine bag limit
  - No less than 8 fish marine bag limit
- Coos Bay
  - No less than 6 fish marine bag limit
  - No less than 5 fish marine bag limit
- Brookings
  - A few participants favored year round season
  - March should be left open as lingcod fishing is good
  - Inseason closures and bag limit changes discourages anglers from coming to the coast
  - The is a good biological reason for closing in winter as lingcod are guarding nests

Lingcod bag limit

- Astoria
  - Leave it alone for a few years
  - Ask for 3 fish bag to negotiate from
- Newport
  - Concerned that increasing the lingcod bag limit may result in increased yelloweye rockfish catch
  - Increase lingcod catch so as to reduce abundance and overall predation on rockfish
  - Concern over the effect of raising the bag limit on the abundance status of lingcod in 10 years
  - Close the winter fishery except allow 3 lingcod and implement gear size restrictions
- Coos Bay

- Let's get something back (3 fish)
- Leave it at 2 fish
- Adopt tag with either 12 or 24 fish per year
- Will allowing 3 lingcod increase the rockfish impact?
- Brookings
  - One angler preferred 3 fish bag

Lingcod minimum length (inches)

- Astoria
  - Leave it alone for a few years
  - Ask for 20-inches to negotiate from
- Newport
  - Why would we want to reduce the minimum size limit? No less than 24 inches!
- Brookings
  - How about reinstating the upper length limit on lingcod?
  - One angler recommended a 22-inch minimum length
  - Enforcement representative (Oregon State Police) felt that a change in lingcod minimum length would cause confusion

Separate flatfish bag limit

- Newport
  - Increased opportunity
  - One participant opposed

Reduce Pacific halibut season to achieve longer groundfish season of at least 6 months

- Astoria
  - July through Labor Day fishery inside of 20-fathoms is not feasible
  - Newport needs to find a way of reducing yelloweye rf impacts or else reduce catch in Newport and allow increased halibut catch in other area
- Newport
  - We can afford to loose 30% of the P. halibut quota
  - July through Labor Day fishery inside of 20-fathoms is not feasible
  - Increase Stonewall RCA, allow troll gear only and restrict weight to avoid catching yelloweye rockfish
  - Several participants suggest allowing fishing for salmon in RCA with halibut on vessel
  - Impacts are in Stonewall Banks area and need to be reduced by RCA or gear restrictions. Suggest enlarged RCA and consider troll gear (barbless hooks, weight limits?)
- Coos Bay
  - July through Labor Day fishery inside of 20-fathoms is not feasible
  - Close Stonewall Banks or find other method to maintain longer groundfish season. Troll gear only in Stonewall Banks may result in lingcod and halibut targeting and thus incidental yelloweye rf catch
  - Two halibut bag limit may reduce rockfish impacts.

Other Comments

- Newport

- Add a subsistence definition allowing the estuary boat fishery to be open year round
- Brookings
  - Need clarification in the regulations on when a gaff may be used
  - Commercial crab pots near port are a gear conflict with sport salmon trolling
  - Is ODFW spending money on inland fisheries that comes from ocean fisher's licenses?
  - Use rockfish tag dollars for rockfish assessments
  - Concerned about sea lion predation on rockfish (especially yelloweye rockfish)

Table 2. Major Commercial Issues Discussed at Public Meetings reviewing 2007-08 Management Measures

May, 2006

	Brookings	**Coos Bay**	**Newport**	**Astoria**
Number of Public Participants	11	4	3	8
Issues:				
LE Trawl				
Trawl Trip Limits		Dover / Sablefish ratios create sablefish discard. Dover limits should be higher		Alternative 1: Too much Dover will go to waste. Petrale limits should be lower than Dover. Better quality Dover in the summer. Alternative 2: Better than Alt. 1 but still want more Dover. Selective Flatfish gear can't go out to 100 fm; can catch the limit too quickly. May not get to Pacific Cod. Alternative 3: No canary bycatch by Astoria nearshore trawl.
Darkblotched Rockfish		Current regulations are causing a lot of discard mortality		
LE and OA Sablefish				
Sablefish Stock Assessment	Stock is healthy - assessment is wrong	Stock is healthy - assessment is wrong		Stock is healthy - assessment is wrong

Nearshore				
Reduced Black Rockfish Harvest Cap	A better idea is to eliminate gear that has higher bycatch of yelloweye (e.g., longline)		Work on season structure and depth restrictions rather than reduced harvest caps	
Shallower Depth Restriction	A 20 fm restriction was reasonable	Concerned over gear conflicts - Recreational Charter / OA H+L	15 or 20 fathoms OK during the summer. Not OK during the winter as fish disperse and there are safety concerns	
Increase Lincod Trip Limit	Yes	Yes - Dinglebar gear fishes lingcod cleanly	Yes - spawning period closure is inconsistent with management of other species (petrale sole)	
Lingcod Minimum Size Limit		Retain the 24" minimum.		
Open access sole limit should be more generous			Lots of sole available nearshore for open access trap gear	
Open Access				
Salmon Troll Lingcod Allowance		Yes		Concerned about Salmon trollers targeting Lingcod

Other Comments

Astoria

- Who is pushing to have longnose skates assessed and why?
- Why is the money from the overages, in particular hake, going to the state's general fund?
- The hake fishery's bycatch is impacting the bottom trawlers.
- Fishers using hook & line can easily avoid yelloweye so why are they being "punished" by the limitations of longline gear?

Newport

- Need more regional management - even subregions of a state
- Identify preferred gear (low bycatch) for nearshore fishery
- Yelloweye are not caught in traps
- Stock assessments for darkblotched rockfish and sablefish need to factor in mandatory excluder devices in the shrimp fishery.

Coos Bay

- Comment that sablefish traps fish cleaner than longline. Discussion of Amendment 6 and what it would take to separate out traps.

- Need to overhaul of trawl logbooks or all logbooks to make them ‘Total Catch’ logbooks more similar to Alaska.
- Petrale grounds in Southern Oregon haven’t been fished very hard in several years.
- Discussion about splitting the trawlers into two fleets: Big boat / Small boat or beach / deep?
- OA H+L is really two fleets. The lingcod fishermen 25-40 fm and the live fish boats <20 fm
- Low weights of shallow water yelloweye RF catch don’t reflect that it’s the recruitment (small/young) yelloweye being caught at shallow depths

Brookings

- Black rockfish OY is being stepped down while recruitment curve should be going up if current population models are accurate.
- Large foot rope bottom trawl net designed with an overhang and section of 5” (across diagonal) square mesh at cod end will drastically reduce if not eliminate the catch of small sablefish and rockfish

Agenda Item F.2.b
Supplemental CDFG Report
June 2006

Supplemental CDFG Report on Corrections to California Recreational Alternatives in Chapter 2.0 of the 2007-2008 Groundfish Management Specifications Draft EIS

Corrected text is submitted by CDFG on sections of Chapter 2.0 “Alternatives Including the Proposed Action” related to California recreational fishery alternatives. Underlined statements are additions and deleted items are in ~~strikeout~~.

2.2.3.1 The No Action Alternative

2.2.3.1.8 California Recreational Fisheries

For management of California’s nearshore recreational groundfish fishery in 2005 and 2006, the California Fish and Game Department (CDFG) divided the coastline into five regional areas, although some regions had the same management measures and were therefore managed as a larger combined region. The five management areas, termed Rockfish/Lingcod Management Areas (RLMAs), are as follows: 1) Southern RLMA (U.S./Mexico Border to Point Conception at 34°27' N latitude), 2) Southern South-Central RLMA (Point Conception to Lopez Point at 36° N latitude), 3) Northern South-Central RLMA (Lopez Point to Pigeon Point at 37º11’ N latitude), 4) Northern Central RLMA (Pigeon Point to Cape Mendocino at 40°10' N latitude), and 5) Northern RLMA (Cape Mendocino to the California/Oregon Border at 42° N latitude). The RLMAs between Lopez Point and Cape Mendocino were combined in 2005-2006 management with the intent to specify separate management measures in each of these RLMAs as needed to stay within state and federal harvest guidelines.

The Council and NMFS adopted 2005-2006 California recreational management measures as follows:

- Regulations apply to groundfish (with sanddab fishery exception) and associated state-managed species (rock greenling, California sheephead, and ocean whitefish).
- The sport fishery for sanddabs, using gear specified in federal and state regulations (size #2 hooks or smaller), is exempt from the season closures and depth restrictions placed on other federally-managed groundfish.
- Retention of species in the Other Flatfish complex is allowed when fishing with size #2 hooks or smaller (≤ 11 mm from point to shank) for Pacific sanddabs.
- Lingcod size limit of 24 inches with a daily bag limit of two fish.
- Within a general bag limit of 20 fish, a combined rockfish + cabezon + greenling (RCG) complex daily bag limit of 10 fish of which one can be a cabezon and one can be a greenling of the genus *Hexagrammos*[1].
- A two-fish bag limit for bocaccio in the northern RLMA (north of 40°10' N latitude to the Oregon/California border at 42° N latitude) and a one-fish bag limit south of 40°10' N latitude to the U.S./Mexico border within the 10-fish RCG daily bag limit.
- No retention of cowcod, canary, or yelloweye rockfish.
- Notwithstanding other fishing opportunities for groundfish, lingcod may not be retained during January, February, March, and December.

1 The cabezon daily bag sublimit was changed from three fish to one fish and the greenling daily bag sublimit was changed from 2 fish to 1 fish in a California Fish and Game Commission action in October 2004 subsequent to the Council’s final decision in June 2004. The Council and NMFS adopted conforming federal regulations that were implemented on April 1, 2005.

- All divers (use of boats is permitted while diving for rockfish or other closed species during closed periods provided no hook and line gear on board or in possession while diving to catch rockfish) and shore-based anglers would be exempt from the seasonal closures and depth restrictions for rockfish, greenlings, California scorpionfish, California sheephead, and ocean whitefish.

The California recreational fishery was managed with federal and state harvest guideline for various groundfish species. Federal annual harvest guidelines were specified for canary rockfish (9.3 mt), yelloweye rockfish (3.7 mt), black rockfish (316 mt for recreational and nearshore commercial fisheries combined in 2005, of which 175 mt were allocated to the recreational fishery by CDFG; in 2006, the combined harvest guideline was 309 mt and the recreational harvest guideline was 170 mt), and lingcod (422 mt) (Table 2-11). State harvest guidelines were specified by CDFG for cabezon, greenlings, and minor nearshore rockfish (both shallow and deeper nearshore rockfish species; see section 2.1.4.1 for the list of species in these complexes). If the recreational harvest guideline for canary rockfish, yelloweye rockfish, or lingcod specified for California was projected to be exceeded, or if the state harvest guideline for black rockfish was projected to be exceeded when combining recreational harvest projections and annual commercial projections, CDFG and/or the Council and NMFS would take action to close all or part of the recreational fishery in all or part of the state regions in all or part of the remainder of the year. Any closure may pertain to closure of specific groundfish species or specific depths in different regions to achieve catch limitation. In the northern RLMA (north of 40°10' N latitude to the Oregon/California border at 42° N latitude), CDFG would take action to close all or part of the recreational fishery deeper than the 30 fm management line if the canary or yelloweye rockfish harvest guideline was attained early in the season.

The 2005 and 2006 adopted management measures included depth bands where fishing for rockfish and associated species was allowed only between 20 and 40 fm (Southern South-Central RLMA) or 30 to 60 fm (Southern RLMA). California took inseason action in 2005 to remove the shoreward boundaries of these depth bands and allow boat-based fishing inside the seaward boundaries originally adopted in the Southern and Southern South-Central RLMAs. These actions were initiated to address concerns related to the ability to enforce fishing restrictions shoreward of adopted depth bands. In addition, final 2004 recreational CRFS projections of impacts showed that additional opportunity could be allowed shoreward of the adopted boundaries, as well as in additional months in the North, North-Central and Northern South-Central RLMAs that would not be likely to exceed harvest guidelines for overfished species targets.

The 2005-2006 seasons and depth restrictions by California management region (Table 2-13) were as follows:

Table 2-13. Summary of 2006 California recreational groundfish seasons and depth restrictions by region under the No Action Alternative.

RCG SEASON BY REGION

Region	Jan	Feb	Mar	Apr	May	Jun	July	Aug	Sep	Oct	Nov	Dec
North region	---	---	---	---	> 30fm Closed							
North Central	---	---	---	---	---	---	> 20fm Closed					
South Central - Monterey	---	---	---	---	---	---	> 20fm Closed					
South Central - Morro Bay	---	---	---	---	> 40fm Closed					---	---	---
South Region	---	---	> 60fm Closed						>30 fm Closed		> 60fm Closed	

NOTES AND KEY:

Shore fishing allowed in all waters in all months

RCG = Rockfish, cabezon, greenlings

--- = Closed to boat-based fishing for RCG

LINGCOD SEASON IS OPEN **ONLY** WHEN RCG IS OPEN, EXCEPT CLOSED DEC, JAN, FEB, MAR FOR SPAWNING

Southern RLMA (U.S./Mexico Border to Point Conception at 34°27' N latitude)

The California recreational groundfish fishery regulations south of Point Conception under the No Action Alternative were the same as described above except for the following changes:

- Groundfish other than California scorpionfish, but including select nongroundfish species (California sheephead and ocean whitefish) open March through August and November through December shoreward of 60 fm; open September through October shoreward of 30 fm; and closed January and February.
- California scorpionfish can only be retained during October and November shoreward of 40 fm and December shoreward of 20 fm (closed January through September).
- Fishing is allowed within the Cowcod Conservation Areas (Figure 2-3) shoreward of the 20 fm line when fishing is open for groundfish other than California scorpionfish, but including select nongroundfish species (California sheephead and ocean whitefish).

Southern South-Central RLMA (Point Conception to Lopez Point at 36° N latitude)

The California recreational groundfish fishery regulations for the area between Point Conception and Lopez Point under the No Action Alternative would be the same as described above except for the following changes:

- Groundfish including select nongroundfish species (California sheephead and ocean whitefish) open May through September shoreward of 40 fm (closed January through April and October through December).

Northern South-Central RLMA (Lopez Point to Pigeon Point at 37°11' N latitude)

The California recreational groundfish fishery regulations for the area between Lopez Point and Cape Mendocino under the No Action Alternative would be the same as described above except for the following changes:

- Groundfish including select nongroundfish species (California sheephead and ocean whitefish) open July through December shoreward of 20 fm (closed January through June).

Northern Central RLMA (Pigeon Point to Cape Mendocino at 40°10' N latitude)

Same regulations as in the Northern South-Central RLMA, except:

- Recreational fishing for groundfish prohibited between the shoreline and the 10 fm (18 m) depth contour around the Farallon Islands and Noonday Rock.
- Waters of Cordell Bank less than 100 fm in depth are closed to fishing at all times.

Northern RLMA (Cape Mendocino to the California/Oregon Border at 42° N latitude)

The California recreational groundfish fishery regulations for the area between Cape Mendocino and the California/Oregon border under the No Action Alternative would be the same as described above except for the following changes:

- Groundfish and ocean whitefish open in May through December shoreward of 40 fm (closed January ~~through June~~ through April).

2.2.3.2 Action Alternative 1

2.2.3.2.8 California Recreational Fisheries

Under Action Alternative 1, the five RLMAs described under the No Action Alternative will be used to manage 2007-2008 California recreational groundfish fisheries. The status quo (No Action) California recreational management measures under Action Alternative 1 include the following:

- Regulations apply to groundfish (with sanddab fishery exception) and associated state-managed species (rock greenling, California sheephead, and ocean whitefish).
- The sport fishery for sanddabs, using gear specified in federal and state regulations (size #2 hooks or smaller), is exempt from the season closures and depth restrictions placed on other federally-managed groundfish.
- Retention of species in the Other Flatfish complex is allowed when fishing with size #2 hooks or smaller (≤ 11 mm from point to shank) for Pacific sanddabs.
- Within a general bag limit of 20 fish, a combined rockfish + cabezon + greenling (RCG) complex daily bag limit of 10 fish, of which one can be a cabezon and one can be a greenling of the genus *Hexagrammos*.
- No retention of cowcod, canary, or yelloweye rockfish.
- Notwithstanding other fishing opportunities for groundfish, lingcod may not be retained during January, February, March, and December.
- Waters of Cordell Bank less than 100 fm in depth are closed to fishing at all times.
- Recreational fishing for groundfish prohibited between the shoreline and the 10 fm (18 m) depth contour around the Farallon Islands and Noonday Rock.
- All divers (boats permitted while diving for rockfish or other closed species during closed periods provided no hook and line gear on board or in possession while diving to catch rockfish) and

shore-based anglers would be exempt from the seasonal closures and depth restrictions for rockfish, greenlings, California scorpionfish, California sheephead, and ocean whitefish.
- Fishing is allowed within the Cowcod Conservation Areas shoreward of the 20 fm line when fishing is open for groundfish other than California scorpionfish, but including select nongroundfish species (California sheephead and ocean whitefish).

California recreational groundfish management measures that differ from status quo under Action Alternative 1 include the following:
- A statewide one-fish bocaccio sublimit is included in the 10-fish RCG daily bag limit.
- Lingcod daily bag limit of 1 fish, but with a minimum size limit of 22 inches.

Additionally, seasons and depth restrictions by RLMA under Action Alternative 1 are described below and summarized in Table 2-17.
- ~~Fishing is allowed within the Cowcod Conservation Areas shoreward of the 20 fm line when fishing is open for groundfish other than California scorpionfish, but including select nongroundfish species (California sheephead and ocean whitefish).~~

Table 2-17. Summary of 2007-2008 California recreational groundfish seasons and depth restrictions by region under Action Alternative 1.

RCG SEASON BY REGION:

Region	Jan	Feb	Mar	Apr	May	Jun	July	Aug	Sep	Oct	Nov	Dec
North region	---	---	---	---	> 20fm Closed							
North Central	---	---	---	---	---	---	> 20fm Closed			---	> 20fm Closed	
South Central - Monterey	---	---	---	---	---	---	> 20fm Closed					
South Central - Morro Bay	---	---	---	---	> 20fm Closed					---	---	---
South Region*	---	---	> 30fm Closed									

NOTES AND KEY:

Shore fishing allowed in all waters in all months

RCG = Rockfish, cabezon, greenlings

--- = Closed to boat-based fishing for RCG

LINGCOD SEASON IS OPEN **ONLY** WHEN RCG IS OPEN, EXCEPT CLOSED DEC, JAN, FEB, MAR FOR SPAWNING

*In the South Region, CA scorpionfish is open 12 months: 0-40 fm in January-February and 0-30 fm March-December.

Southern RLMA (U.S./Mexico Border to Point Conception)

The California recreational groundfish fishery regulations south of Point Conception under Action Alternative 1 are the same as described above except for the following changes:
- Groundfish other than California scorpionfish, but including select nongroundfish species (California sheephead and ocean whitefish) open March through December shoreward of the 30 fm line and otherwise closed.
- California scorpionfish is open year-round, but restricted to depths shoreward of 40 fm during January and February, and shoreward of 30 fm during March through December.

Southern South-Central RLMA (Point Conception to Lopez Point)

The California recreational groundfish fishery regulations for the area between Point Conception and Lopez Point under Action Alternative 1 would be the same as described above except for the following changes:

• Groundfish including select nongroundfish species (California sheephead and ocean whitefish) open May through September shoreward of the 20 fm line and otherwise closed.

Northern South--Central RLMA (Lopez Point to Pigeon Point)

The California recreational groundfish fishery regulations for the area between Lopez Point and Pigeon Point under the Action Alternative 1 would be the same as described above except for the following changes:

• Groundfish including select nongroundfish species (California sheephead and ocean whitefish) open July through December shoreward of 20 fm and otherwise closed.

Northern Central RLMA (Pigeon Point to Cape Mendocino)

The California recreational groundfish fishery regulations for the area between Pigeon Point and Cape Mendocino under the Action Alternative 1 would be the same as described above except for the following changes:

• Groundfish including select nongroundfish species (California sheephead and ocean whitefish) open July through September and November through December shoreward of 20 fm and otherwise closed.

Northern RLMA (Cape Mendocino to the California/Oregon Border)

The California recreational groundfish fishery regulations for the area between Cape Mendocino and the California/Oregon border under the Action Alternative 1 would be the same as described above except for the following changes:

• Groundfish and ocean whitefish open in May through December shoreward of 20 fm and otherwise closed.

2.2.3.3.8 California Recreational Fisheries

Under Action Alternative 2, the five RLMAs described under the No Action Alternative will be used to manage 2007-2008 California recreational groundfish fisheries. The status quo (No Action) California recreational management measures under Action Alternative 2 include the following:

• Regulations apply to groundfish (with sanddab fishery exception) and associated state-managed species (rock greenling, California sheephead, and ocean whitefish).

• The sport fishery for sanddabs, using gear specified in federal and state regulations (size #2 hooks or smaller), is exempt from the season closures and depth restrictions placed on other federally-managed groundfish.

• Retention of species in the Other Flatfish complex is allowed when fishing with size #2 hooks or smaller (≤ 11 mm from point to shank) for Pacific sanddabs.

• Combined rockfish + cabezon + greenling (RCG) complex daily bag limit of 10 fish.

• No retention of cowcod, canary, or yelloweye rockfish.

• Lingcod size limit of 24 inches with a daily bag limit of two fish.

• ~~A two-fish bocaccio sublimit included in the 10-fish RCG daily bag limit.~~

• A two-fish bag limit for bocaccio in the northern RLMA (north of 40°10' N latitude to the Oregon/California border at 42° N latitude) and a one-fish bag limit south of 40°10' N latitude to the U.S./Mexico border within the 10-fish RCG daily bag limit.

- Notwithstanding other fishing opportunities for groundfish, lingcod may not be retained during January, February, March, and December.
- Waters of Cordell Bank less than 100 fm in depth are closed to fishing at all times.
- Recreational fishing for groundfish prohibited between the shoreline and the 10 fm (18 m) depth contour around the Farallon Islands and Noonday Rock.
- All divers (boats permitted while diving for rockfish or other closed species during closed periods provided no hook and line gear on board or in possession while diving to catch rockfish) and shore-based anglers would be exempt from the seasonal closures and depth restrictions for rockfish, greenlings, California scorpionfish, California sheephead, and ocean whitefish.
- Fishing is allowed within the Cowcod Conservation Areas shoreward of the 20 fm line when fishing is open for groundfish other than California scorpionfish, but including select nongroundfish species (California sheephead and ocean whitefish).

California recreational groundfish management measures that differ from status quo under Action Alternative 2 include the following:

- ~~Two~~ One cabezon and two greenling of the genus *Hexagrammos* sublimit is included in the 10-fish RCG daily bag limit.

Additionally, seasons and depth restrictions by RLMA under Action Alternative 2 are described below and summarized in Table 2-20.

Table 2-20. Summary of 2007-2008 California recreational groundfish seasons and depth restrictions by region under Action Alternative 2.

RCG SEASON BY REGION

Region	Jan	Feb	Mar	Apr	May	Jun	July	Aug	Sep	Oct	Nov	Dec
North region	---	---	---	---	>30fm Closed							
North Central	---	---	---	---	---	---	> 20fm Closed					
South Central - Monterey	---	---	---	---	---	---	> 20fm Closed					
South Central - Morro Bay	---	---	---	> 20fm Closed						---	---	---
South Region*	---	---	> 40fm Closed						> 30fm Closed		> 60fm Closed	

NOTES AND KEY:

Shore fishing allowed in all waters in all months

RCG = Rockfish, cabezon, greenlings

--- = Closed to boat-based fishing for RCG

LINGCOD SEASON IS OPEN **ONLY** WHEN RCG IS OPEN, EXCEPT CLOSED DEC, JAN, FEB, MAR FOR SPAWNING

*In the South Region, CA scorpionfish is open 12 months: 0-40 fm in January-August, 0-30 fm September-October and 0-60 fm November-December.

Southern RLMA (U.S./Mexico Border to Point Conception)

The California recreational groundfish fishery regulations south of Point Conception under Action Alternative 2 are the same as described above except for the following changes:

- Groundfish other than California scorpionfish, but including select nongroundfish species (California sheephead and ocean whitefish) open March through August shoreward of the 40 fm line, September through October shoreward of the 30 fm line, November and December shoreward of the 60 fm line, and otherwise closed.

• California scorpionfish is open year-round, but restricted to depths shoreward of 40 fm during January-August, shoreward of 30 fm during September and October, and shoreward of 60 fm during November and December.

Southern South-Central RLMA (Point Conception to Lopez Point)

The California recreational groundfish fishery regulations for the area between Point Conception and Lopez Point under Action Alternative 2 would be the same as described above except for the following changes:

• Groundfish including select nongroundfish species (California sheephead and ocean whitefish) open April through September shoreward of the 20 fm line and otherwise closed.

Northern South--Central RLMA (Lopez Point to Pigeon Point)

The California recreational groundfish fishery regulations for the area between Lopez Point and Cape Mendocino under the Action Alternative 2 would be the same as described above except for the following changes:

• Groundfish including select nongroundfish species (California sheephead and ocean whitefish) open July through December shoreward of 20 fm and otherwise closed.

Northern Central RLMA (Pigeon Point to Cape Mendocino)

The California recreational groundfish fishery regulations for the area between Pigeon Point and Cape Mendocino under the Action Alternative 2 would be the same as described above except for the following changes:

• Groundfish including select nongroundfish species (California sheephead and ocean whitefish) open July through December shoreward of 20 fm and otherwise closed.

Northern RLMA (Cape Mendocino to the California/Oregon Border)

The California recreational groundfish fishery regulations for the area between Cape Mendocino and the California/Oregon border under the Action Alternative 2 would be the same as described above except for the following changes:

• Groundfish and ocean whitefish open in May through December shoreward of 30 fm and otherwise closed.

2.2.3.4 Action Alternative 3

2.2.3.4.8 California Recreational Fisheries

Under Action Alternative 3, the five RLMAs described under the No Action Alternative will be used to manage 2007-2008 California recreational groundfish fisheries. The status quo (No Action) California recreational management measures under Action Alternative 3 include the following:

• Regulations apply to groundfish (with sanddab fishery exception) and associated state-managed species (rock greenling, California sheephead, and ocean whitefish).

• The sport fishery for sanddabs, using gear specified in federal and state regulations (size #2 hooks or smaller), is exempt from the season closures and depth restrictions placed on other federally-managed groundfish.

- Retention of species in the Other Flatfish complex is allowed when fishing with size #2 hooks or smaller (≤ 11 mm from point to shank) for Pacific sanddabs.
- ~~A two-fish bocaccio sublimit is included in the 10-fish RCG daily bag limit.~~
- No retention of cowcod, canary, or yelloweye rockfish.
- Lingcod size limit of 24 inches with a daily bag limit of two fish.
- ~~Notwithstanding other fishing opportunities for groundfish, lingcod may not be retained during January, February, March, and December~~.
- Waters of Cordell Bank less than 100 fm in depth are closed to fishing at all times.
- Recreational fishing for groundfish prohibited between the shoreline and the 10 fm (18 m) depth contour around the Farallon Islands and Noonday Rock.
- All divers (boats permitted while diving for rockfish or other closed species during closed periods provided no hook and line gear on board or in possession while diving to catch rockfish) and shore-based anglers would be exempt from the seasonal closures and depth restrictions for rockfish, greenlings, California scorpionfish, California sheephead, and ocean whitefish.
- Fishing is allowed within the Cowcod Conservation Areas shoreward of the 20 fm line when fishing is open for groundfish other than California scorpionfish, but including select nongroundfish species (California sheephead and ocean whitefish).

California recreational groundfish management measures that differ from status quo under Action Alternative 3 include the following:

- Combined rockfish + cabezon + greenling (RCG) complex daily bag limit of 10 fish, of which ~~two~~ one can be a cabezon and two can be a greenling of the genus *Hexagrammos*.
- A two-fish bocaccio sublimit is included in the 10-fish RCG daily bag limit.
- Notwithstanding other fishing opportunities for groundfish, lingcod may not be retained during January, February, and March.
- ~~Lingcod daily bag limit of 3 fish, but with a minimum size limit of 22 inches.~~

Additionally, seasons and depth restrictions by RLMA under Action Alternative 3 are described below and summarized in Table 2-23.

Table 2-23. Summary of 2007-2008 California recreational groundfish seasons and depth restrictions by region under Action Alternative 3.

RCG SEASON BY REGION

Region	Jan	Feb	Mar	Apr	May	Jun	July	Aug	Sep	Oct	Nov	Dec
North region	---	---	---	---	> 40fm Closed							
North Central	---	---	---	---	---		> 40fm Closed					
South Central - Monterey	---	---	---	---	> 40fm Closed							
South Central - Morro Bay	---	---	---	> 40fm Closed							---	---
South Region*	---	---	> 60fm Closed									

NOTES AND KEY:

Shore fishing allowed in all waters in all months

RCG = Rockfish, cabezon, greenlings

--- = Closed to boat-based fishing for RCG

Only half of month is open

*In the South Region, CA scorpionfish is open 12 months: 0-40 fm in January-February and 0-60 fm March-December.

Southern RLMA (U.S./Mexico Border to Point Conception)

The California recreational groundfish fishery regulations south of Point Conception under Action Alternative 3 are the same as described above except for the following changes:

- Groundfish other than California scorpionfish, but including select nongroundfish species (California sheephead and ocean whitefish) open March through December shoreward of the 60 fm line and otherwise closed.
- California scorpionfish open year-round, but restricted to depths shoreward of 40 fm in January and February, and shoreward of 60 fm during March through December.

Southern South-Central RLMA (Point Conception to Lopez Point)

The California recreational groundfish fishery regulations for the area between Point Conception and Lopez Point under Action Alternative 3 would be the same as described above except for the following changes:

- Groundfish including select nongroundfish species (California sheephead and ocean whitefish) open April through mid-October shoreward of the 40 fm line and otherwise closed.

Northern South--Central RLMA (Lopez Point to Pigeon Point)

The California recreational groundfish fishery regulations for the area between Lopez Point and Pigeon Point under the Action Alternative 3 would be the same as described above except for the following changes:

- Groundfish including select nongroundfish species (California sheephead and ocean whitefish) open May through December shoreward of 40 fm and otherwise closed.

Northern Central RLMA (Pigeon Point to Cape Mendocino)

The California recreational groundfish fishery regulations for the area between Pigeon Point and Cape Mendocino under the Action Alternative 3 would be the same as described above except for the following changes:

- Groundfish including select nongroundfish species (California sheephead and ocean whitefish) open mid-June through December shoreward of 40 fm and otherwise closed.

Northern RLMA (Cape Mendocino to the California/Oregon Border)

The California recreational groundfish fishery regulations for the area between Cape Mendocino and the California/Oregon border under the Action Alternative 3 would be the same as described above except for the following changes:

- Groundfish and ocean whitefish open in May through December shoreward of 40 fm and otherwise closed.

CALIFORNIA DEPARTMENT OF FISH AND GAME REPORT ON THE TENTATIVE ADOPTION OF 2007-2008 GROUNDFISH FISHERY SPECIFICATIONS/MANAGEMENT MEASURES AND AMENDMENT 16-4

Purpose

In consideration of management measures for the 2007-08 groundfish fishery, the Council has been provided with a substantial amount of economic analysis of alternative management measures. Much of this analysis is compared to the socioeconomic impacts resulting from 2005 and 2006 management. While action alternatives 1 and 2 show negative impacts compared to status quo, the analysis for action alternative 3 shows an increase in the number of recreational angler trips and personal income when compared to status quo, which is largely driven by California recreational fishery options (Agenda Item F.2.a Supplemental Attachment 5). This document is intended to provide a perspective on compounding effects of recent management decisions prior to the status quo season, that have been needed to substantially reduce impacts on overfished species. The CDFG recommends that the resulting cumulative economic impacts that lead to the 2005-06 status quo be kept in mind when considering specifications and management measure alternatives for 2007-08 relative to the status quo.

Past and Present

In 1998 the recreational fishery for rockfish, lingcod and associated species was much less regulated than it is under the Status Quo regulations (Table 2-13, Agenda Item F.2.a Attachment 1). California anglers enjoyed a 15 fish bag limit of rockfish within a 20 fish bag and a year round season. Fishing depths were unconstrained and anglers routinely fished as deep as 100 fms north of Point Conception to the Oregon border and to 120 fms south of Point Conception. This represented an effective area of 29,970 square kilometers available for fishing assuming all areas available were fished for these species (Figures 1 - 4). CDFG recognizes that not all available areas represent appropriate habitat for rockfish, lingcod and the associated species. Beginning in 1999, stricter regulations were adopted following the completion of the bocaccio stock assessment and an overfished status determination to minimize even recreational impacts on this species. Bocaccio are a shelf species found in depths greater than 20 – 40 fms and recreational anglers began losing fishing opportunities in deeper shelf waters.

Between 1998 and 2005, progressively restrictive season and depth changes and area closures were adopted to reduce impacts on overfished shelf species as they were identified, primarily bocaccio, canary rockfish, yelloweye rockfish, cowcod and lingcod. In 2000, the rockfish bag limit was reduced from 15 to 10 fish. In fact, in 2000 due to the number of overfished species and the need to further limit impacts, the West Coast Groundfish Fishery was declared an economic disaster. These changes moved anglers further inshore for more months and away from encounters with overfished shelf species increasing pressure on nearshore stocks as Rockfish Conservation Areas (RCAs) were implemented. To recognize the regional differences on individual overfished stocks and maximize fishing opportunities, the Rockfish and Lingcod Management Areas (RMLAs) were designated so that regulations could be more region specific. During the same period, additional areas were closed to recreational and commercial groundfish fishing when new Marine Protected Areas (MPAs) were adopted in state waters around the

Channel Islands and in the Cowcod Conservation Area (CCA) - also in southern California. An additional factor that contributed to the highly restricted recreational regulations in California was the reliance on the Marine Recreational Fisheries Statistical Survey (MRFSS) data for regulation development and inseason monitoring (not tasks for which the program was designed.) During this period, California's recreational regulations were routinely conservative due to the uncertainties of MRFSS data, the concerns over accuracy of the data, and the repeated need for inseason action when estimates indicated higher catches than expected.

By 2005, the maximum seasons and depths fished were eight months at ≤ 30 fms from the Oregon Border to Cape Mendocino, six months at ≤ 20 fm from Cape Mendocino to Lopez Point, five months at ≤ 40 fms from Lopez Point to north of Point Conception, and 10 months at ≤ 30 fm or ≤ 60 fm south of Point Conception (Figures 1 - 5).

All of the above changes resulted in a reduction of 62% to the area effectively open to California's recreational groundfish fishery by 2005. It also resulted in a reduction of between 17% and 58% of the season length.

Concentrating anglers into shallower waters limits their access to other rockfish species and focuses targeting on nearshore rockfish stocks. Because most of the nearshore species are managed as data-poor, this further constricts the fishery (Table2-CARecSQ).

Reasonably Foreseeable Future

Under Action Alternative 1, in 2007 and 2008 the remaining area open to the recreational groundfish fishery would be further reduced by 12% to increase protection on rebuilding species (Figures 1 - 4) and keep catches within lower harvest targets. This action would result in a 74% overall reduction in available fishing areas since 1998. The season would likely be limited to between five and eight months and maximum allowable depths of ≤ 20 or ≤ 30 fm depending on RLMA.

Fishable areas		
Year	Area (Sq Km)	% of Past 1998 Baseline
1998	29,970	100%
2005	11,472	38%
2007-08	7,890	26%

Direct/Indirect Effects

All reductions in seasons and depth limitations have had direct impacts on anglers including:

- Reductions in seasons have reduced overall opportunities,
- Reduced or eliminated opportunities for target species in deeper water (e.g. large "red" rockfish including bocaccio, yelloweye, canary, cowcod, copper or vermilion rockfish, and to some extent lingcod or associated species like chilipepper rockfish) have reduced participation.
- Direct effects of depth changes (via stricter RCA boundaries) on resources have included increased pressure on nearshore stocks when the status of many of these species is considered "data poor".

Indirect effects experienced by anglers include:

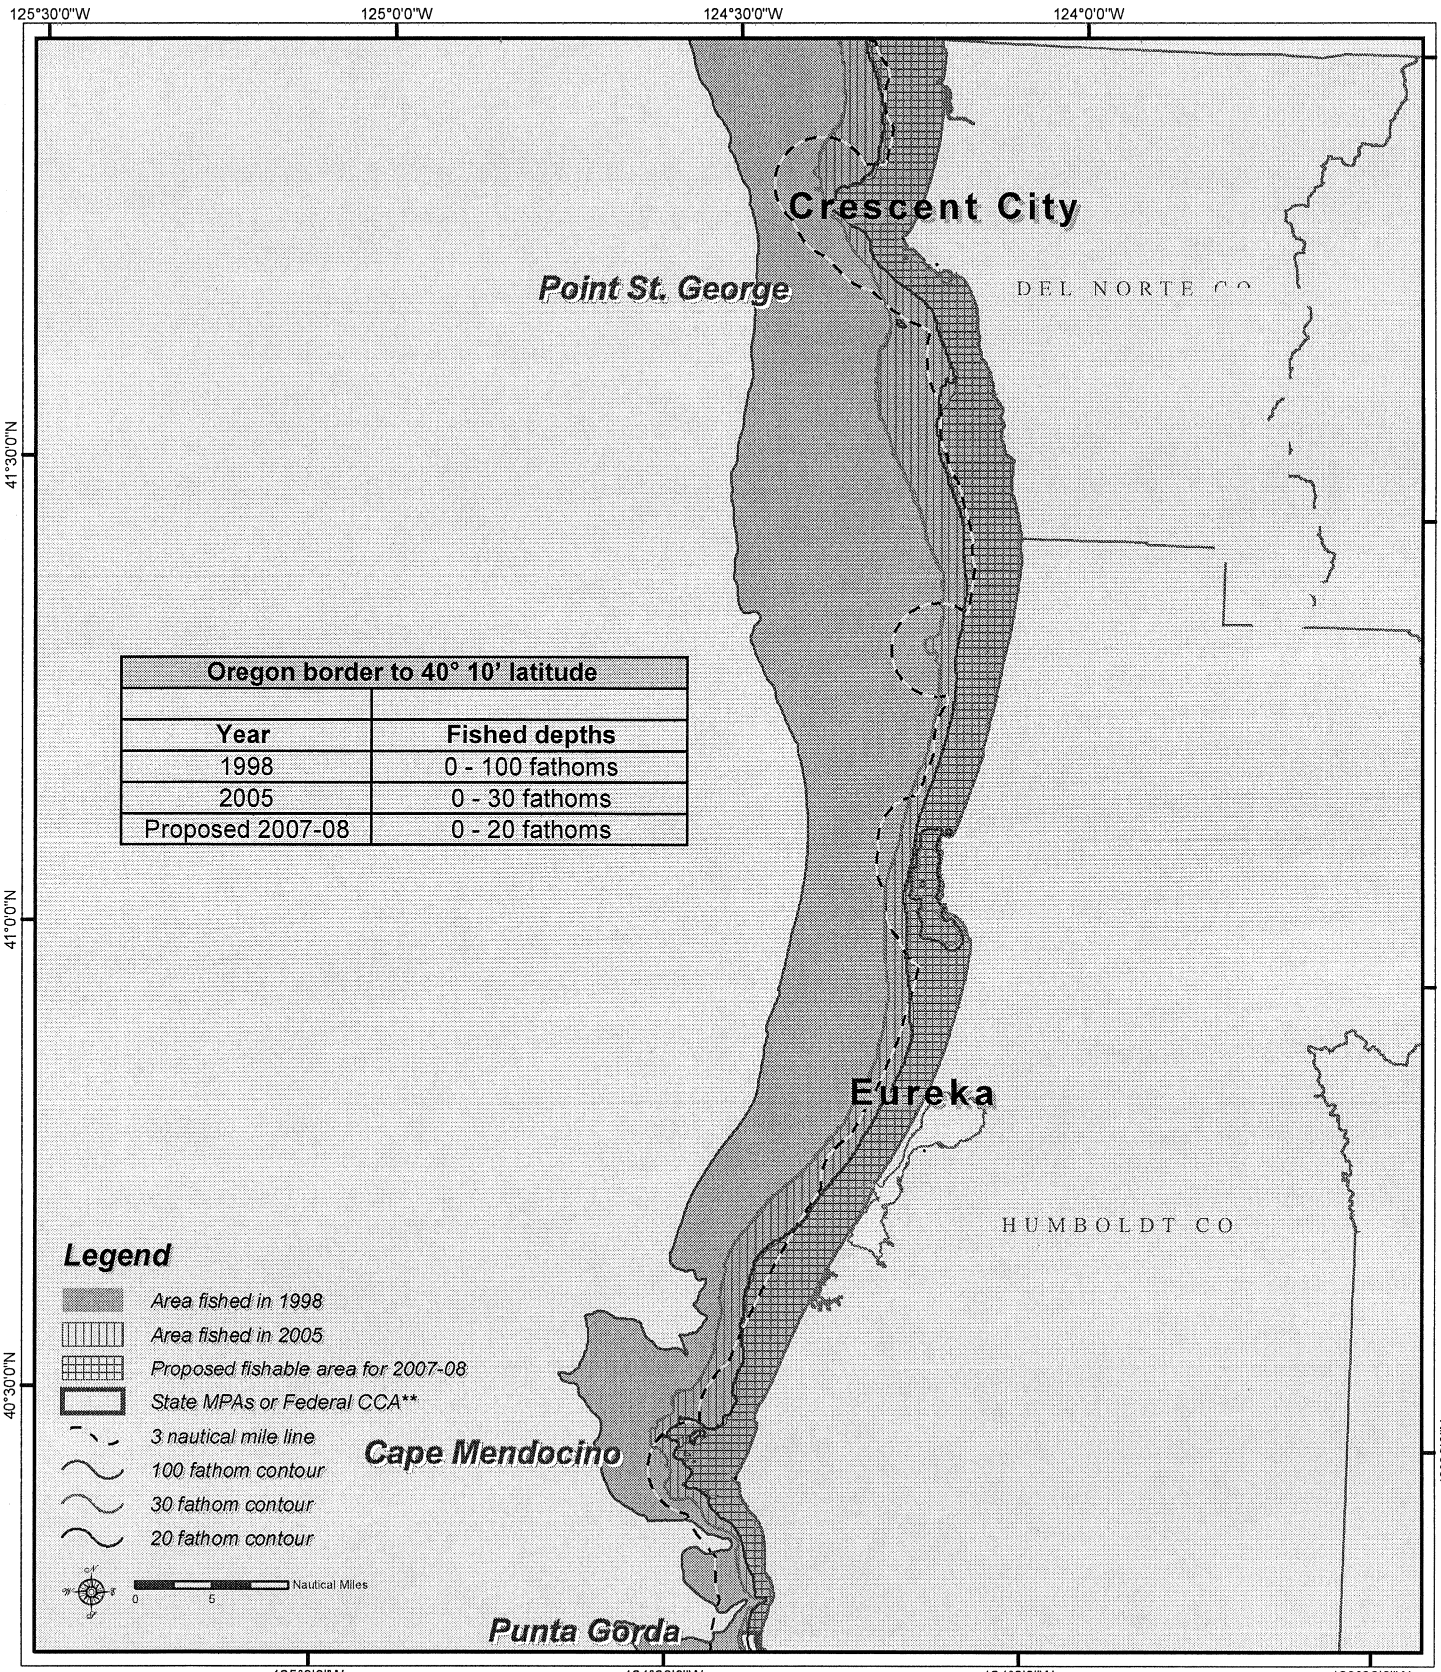
- Increased perception that "there are no fish left" or all species are over fished has also reduced participation.
- Confusion over changes in the regulations and/or resulting citations reducing participation,
- Greater difficulty in predicting fishing behavior leading to inseason closures which:
    - Create additional impacts on the sportfishing public
    - Reduce business for industry (loss of repeat customers)
    - Greater effort by enforcement staff to enforce changing regulations

Impacts on the recreational fishing industry:

- Less fishing trips with shorter seasons and less "target" species available
- Difficulty retaining qualified staff due to increased "down time" when their services are not needed
- Increased costs due to gear restrictions, greater advertising,

Impacts of Regulations on Recreationally Fished Areas for Rockfish and Associated Species

Change in fishable areas shown for 1998, 2005, and proposed 2007 - 08 based on RCA Alternative 1 (Low)



Oregon border to 40° 10' latitude	
Year	Fished depths
1998	0 - 100 fathoms
2005	0 - 30 fathoms
Proposed 2007-08	0 - 20 fathoms

* Survey data suggest that in the past, fishing for rockfish, lingcod and associated species occurred in depths less than 100 fm north of Point Conception and less than 120 fm south of Point Conception.

** Marine Protected Areas (MPAs) or Cowcod Conservation Areas (CCAs) include areas less than 100 or 120 fathoms that were fished prior to their formal designations
(such as in 1998 when the 100 and 120 fathoms depth zones represented fished areas).

OREGON DEPARTMENT OF FISH AND WILDLIFE REPORT ON THE TENTATIVE ADOPTION OF THE 2007-2008 GROUNDFISH FISHERY SPECIFICATIONS/MANAGEMENT MEASURES AND AMAENDMENT 16-4

The Oregon Department of Fish and Wildlife (ODFW) met with members of the Sport Advisory Council (SAC) on June 6, 2006 to discuss the proposed management measures for the 2007-2008 Oregon recreational groundfish fisheries. SAC is an advisory body, providing management advice to ODFW, specific to the sport groundfish and halibut fisheries, and is comprised of representatives of the charter and private sectors of the sport fishery, as well as a representative of the port commissions. Membership is distributed coastwide in an effort to have representation of each of the coastal areas.

At this meeting, ODFW staff summarized the Council preferred harvest levels for species that constrain the Oregon sport groundfish fishery (primarily canary, yelloweye, and black rockfishes) and the range of management measures that are proposed for this fishery. The comments received from the series of public meetings that were held in May 2006 were also detailed, and the same questions posed to the public in those meetings were asked of SAC. A schematic of the management measure alternatives is provided for reference in figure 1. The following summary represents the consensus opinions of SAC:

1) Do you prefer a year round season in preference to a shorter season with less offshore closures and a larger marine bag limit?
    a) The majority of SAC members confirmed the desire for a year round season even if it meant reduced offshore opportunity. A minority preferred a shorter season. SAC confirmed they did not desire a marine bag limit of less than 5 fish.
2) Do you support a separate flatfish bag (excluding Pacific halibut) of 25 fish?
    a) SAC unanimously supported a separate 25 fish flatfish bag limit that excludes Pacific halibut.
3) What do you recommend for the lingcod daily bag limit and minimum length?
    a) The majority of SAC members supported a daily bag limit of 2 fish with a 22-inch minimum size requirement. It was thought a lingcod daily bag limit of 3 fish would increase time on the water and associated take of limiting species (i.e. canary, yelloweye and black rockfishes). A minimum size limit of 22-inches was projected to both increase the total harvest of lingcod and allow anglers to attain the lingcod daily bag limit quicker, reducing the time on the water and subsequent take of limiting species.
4) In the event that the low OY alternative for yelloweye rockfish is adopted by the Council, would (1) a longer groundfish season (6 months) with a reduced halibut quota (reduced by 30%) or (2) a shorter groundfish season (July through Labor Day) and no reduction to the halibut quota be preferable?
    a) SAC discussed the economic importance of the Pacific halibut fishery to the coast especially during the spring months. Pacific halibut opportunity provides income to pay expenses that have accrued during the winter months such as insurance, moorages, rent, and basic requirements of running a business. Additionally, the local ports depend on the Pacific halibut spring fishery for income from moorage and lodging fees. SAC recommended not reducing the halibut opportunity if at all possible. SAC also discussed the importance of the groundfish fishery during months without Pacific halibut or salmon opportunity. Loss of income generated by the groundfish fishery in the non-summer

months would effectively bankrupt many of the active charter vessels in Oregon. SAC was adamant that both alternatives 1a and 1b (figure 1) are very detrimental to the fishery and coastal economy.

5) The issue of expanding the Stonewall Bank closure area was reviewed with SAC. Staff is recommending that the closure area be increase in size. Not only halibut fishing will be closed in the area, but groundfish will also be closed. Some SAC members expressed concern over anglers with a legally caught halibut not being able to troll for salmon over the expanded (and present) closed area. A recommendation of allowing a halibut on the vessel while trolling in the area for salmon, but with an additional gear requirement requiring trolling with either a downrigger or diver was discussed. It was thought this would make illegal targeting of halibut difficult, help enforcement, and minimize the incidental take of yelloweye rockfish.

There have been several public comment letters regarding the 2007-2008 harvest specification and management measures that have been received by ODFW for distribution to the Council.

Those letters are attached.

Figure 1. Season structure along with expected yelloweye rockfish and canary rockfish impacts for various 2007-08 Oregon recreational fishery action alternatives, compared to the no action alternative.

Alternative	Season structure (Month: J F M A M J J A LDay S O N D)	Marine Bag	Ling Bag	Ling Size	Yelloweye Impact (mt)	Canary Impact (mt)
1a	J–J: CLOSED; J–LDay: GF open <20 fm; S–D: CLOSED	10*	3	20	1.6	1.6
1b	J–M: CLOSED; A–S: GF open <20 fm & Halibut fishery reduced by 30%; O–D: CLOSED	6*	3	20	1.5	2.3
2	J–D: GF open <20 fm	5*	2	22	1.9	2.6
3a	J–M: GF open <40 fm; J–LDay: GF open <25 fm; S–D: GF open <40 fm	5**	2	22	2.5	3.7
3b	J–D: GF open <40 fm	5**	2	22	2.9	4.0
No Action	J–M: GF open all depth; J–S: GF open <40 fm; O–D: GF open all depth	6*	2	24	3.6	5.3

* Status quo marine bag species.

**Marine bag limit excludes flatfish which have a separate 25 fish daily bag limit.

Pacific Fisheries Management Council
Chairman David Hansen
Council Members

June 6, 2006

Dear Sirs,

We have reviewed the options for the Oregon recreational fishery presented to us by the ODFW. We would like you to understand what these options mean to our business. In 2005, 37% of our gross was earned from Jan to June and another 10% was earned in Sept and Oct. No small business, charter fishing or any of the other businesses connected to fishing can sustain the type of closure suggested in Option 1a. Since most of that 37% of gross is made from the May-June Halibut fishery, Option 1b is almost as bad. With all of the cutbacks we have had for the last three years, the spring Halibut fishery is all that has been keeping us alive.

Option 2 and Option 3a will put so much pressure on the rock fish that we will could be shut down as early as the first of July which will also put the charter fleet out of business. Even 3b is not a good choice as almost half of our trips from May to June were beyond forty fathoms for either Halibut or Ling Cod. We have only caught six yellow eye so far this year. The Captains are very good at staying away from any Yelloweye areas, and there are no Yelloweye at our 800' all-depth Halibut grounds.

We understand that the GMT came up with a step down program that might help reduce some of the adverse impacts of these drastic actions. Please consider using it. Present time assessments, done on the actual reef habitat where most yellow eye reside, rather than trawl fish data, needs to be done immediately. When the best available science uses old data, statistical theory and has no way to measure age or recruitment, there will never be a recovery! We believe you have come very close to the bottom line for most charter fishing businesses this year. The "No Action Option" is the only acceptable one left. Our family has been charter fishing for over 30 years. All of our children are in the fishing business-two are charter boat Captain's, one works for the ODFW and the youngest helps manage our charter office. Please do not let politics and questionable data ruin our family business, and our community's future!

Sincerely,

Mick & Linda Bull

"have knife…will travel"

Pacific Fishery Management Council
Donald Hansen, Chairman

Mr. Hansen and Fellow Councilors,

As an independent business owner and lifelong lover of the Oregon Coast and Pacific Ocean I applaud your commitment, work and dedication to the issues that affect the present and future of my home and livelihood.

In regards to current proposals for the 2007 and 2008 sports ground fishing regulations and management issues before the council I would like to offer the following opinions and observations.

First of all, most of the problems that I see and am experiencing are related to stock assessments and ABC's/OY's for canary, black and yelloweye rockfishes as well as a perceived ignorance of the social and economic impacts these assessments and council decisions based on these assessments have had on me and my community. These "best available science" studies are inherently flawed as there is no good science or studies as a starting point to draw conclusions from. We must work together to redefine what "best available science" means and how it is used in council decisions and deliberations, we must also work together on a simpler and cheaper approach to data collection that includes more anecdotal evidence and emphasizes acoustic studies over more expensive video technologies.

Ever decreasing bag limits and seasonal depth restrictions have crippled my ability to make a living in my chosen career, following in my father's footsteps as a fish filleter for both sports and commercial fishing enterprises. When I began my business the Oregon bag limit was 15 rockfish it is currently 6 marine fish, the effect this drastic and sudden lowering of sports as well as commercial catch limits has driven nearly all of the seafood workers and managers I know out of the fishing community or into a lowered standard of living. This is only the tip of the social and economic impacts that are occurring; I implore you to consider these hardships before you cut back and restrict my fishing community anymore.

In specific I am referring to the proposals for 2007-08 Oregon Recreational Fisheries proposal from ODFW, of which I have included a copy. Of the options listed the only one I feel that will not fatally wound my fishing community is the "No Action" alternative. We who have survived in the industry have tried our best to be creative and industrious to adapt to the recent "catastrophe" that has befallen us and continue on as a community. Any further restrictions to bag or depth limits would be disastrous to my business as well as my fishing community, I am afraid it cannot take another blow without dying. So please do not ignore the impacts decisions based on flawed conclusions will make to the social and economic dynamics of my fishing community.

Thank You for Your Dedication,

June 7, 2006

PFMC
Chairman- David Hanson
Council Members

To whom it may concern:

I am writing in response to your proposed season structure impacts for the 2007-08 recreational fishery action alternatives, compared to the no action alternative.

As the former owner of Garibaldi Charters and now a employee for the company I have a vested interest in the sport fishing industry in Garibaldi. The only acceptable alternative is the NO ACTION PLAN. Your 1a and 1b plans would by our records cause us to lose 50% of our business. Your plan 2, 3a and 3b are also unacceptable. If 1a and 1b were to be put into effect not only would the charter business be closed, but it would also effect the shops, gas stations, restaurants, grocery store, banks and every other business in Garibaldi. With the gas prices going up, the price of a day of fishing and lodging going up and our fishing seasons less and less our quota's being cut, how much longer do you think anyone can stay in the fishing industry and make a living. Well, let me tell you something, they can't and it's a shame. For the past 15 years we hung in there because we wanted to fish so people could have the experience but we can't much longer, and the sad part about it is that the ocean is full of fish.

Please weigh your options carefully and we can only hope your decision will be the right one as the Charter Companies really don't have too much to say about their future in this matter.

REMEMBER THE NO ACTION PLAN IS THE ONLY ACCEPTABLE ONE.

Thank You

Sharon Davis

Pacific Marine Council

Attention: Dave Hansen and Council Members

Dear Sirs:

It has been brought to my attention that there has been a proposal made to change the fishing guide lines for the year 2007-08, which will impact our fishing community greatly.

As a member of the Chamber of Commerce and a Business owner in Garibaldi, I feel we all depend on the fishing season heavily to support our town. They buy their gas here, stay in our motels, eat at our restaurants and shop at our local retail shops.

I feel adopting measure 1A or 1B would surely put the Charter Boats out of business. Which means I would have to eventually close my doors too.

I would hope you would accept my vote to take no new action.

Sincerely,

Gerry Bales

Gerry Bales

Pacific Fisheries Management Council
Chairman Davis Hanson
Council Members

Dears Sirs,

I have been in the fishing industry since 1968 and owned KERRI LIN CHARTERS since 1975. There have been many changes in regulations, limits and prices during this time. We try to help the local economy by having customers use local motels, food services, and gift shops. We are trying to survive.

The 2007-08 ODFW options was shown to me yesterday. There is only one option to help us stay in business: NO ACTION.

I concentrate on the fish inside 40 fathoms from May to early Sept. Other charters go "out deep" for the halibut and Cod. We should be allowed to do that for a longer period of time. When we are forced inside, the quota goes quickly.

Let us fish. Don't confuse the public with constant changes. Help Garibaldi businesses.

Thank you,
Jon F. Brown

6-8-2006
PFMC
Chairman & Council Members,

Dear Sirs,

We have been informed that you are considering greatly reducing the number of fishing days for the 2007-2008 fishing season. My husband and I have managed the Bayshore Inn in Garibaldi for many years. In the spring, the bulk of our customers come from recommendations of the local charter offices. Many private boat owners stay with us, too. Any reduction in fishing could be devastating to our business.

We understand that some of the options you are considering could actually put charter offices completely out of business. This would seriously affect our whole community as the fishing and related businesses, and the lumber mill are our only employers. Instead of being one of Oregon's true fishing villages, we could become one of Oregon's newer ghost towns. Please consider the economic restrictions these type of regulations would have for all of Oregon's coastal towns. Our fishermen are always amazed by the abundance of fish around here, so it is hard to understand why you would have to shut down a whole industry because you think one species may be endangered.

Sincerely,

James A. Stamm
Alberta R Stamm

Dave Hansen and Council Members
Pacific Marine Fisheries Council

June 8th, 2006

Dear Mr. Hansen and Council Members:

It is with dismay I have learned of possible additional limitations of the charter fishing season in my beloved Garibaldi and other Pacific Coastal areas.

Please consider my concerns in your decision:

- The negative effect on the livelihood of charter businesses in our already economically struggling area
- The negative effect on the spin off business locally, i.e.: motels, restaurants, retail businesses
- Limitations on the opportunity for visiting and local fishermen's family members to experience the lively port area, including educational opportunities of the importance of the bay and estuary
- The negative effect to the Port of Garibaldi, as fewer charter businesses survive to utilize the charter slips

My family and I have been coming to this area since 1982, enjoying the fishing village atmosphere enhanced by the charter boats and the tourist business they attract.

It is my request that no changes be made in the current season and allowable catch.

Please allow the charter industry to survive, as it barely doing at this time. Garibaldi and other coastal communities need the life infused by the fishing industry.

Thank you for your kind consideration of my input into your decision.

Very truly yours,

Loyce B. Bass

Atten: Pacific Fishery Management Council
Don Hansen, Chair and Council Members
Reg: 2007-2008 Ground Fish Regulations

After attending the public meetings held by ODF&W and learning about what the PFMC is considering I felt it necessary to advise you of our situation.

We are a family business operating two six pack charter boats fishing out of Gold Beach and Port Orford. Due to the past and certainly current salmon regulations over 90% of our business is halibut and bottom fish.

We operate year round and depend on this as our livelihood for my wife and myself and our two sons as well as one employee. Any further restrictions i.e. shortened seasons, reduced bag limits or depth restrictions above what we deal with now would severely impact our business in a negative way to the point of putting us out of business.

We understand the conservation issues and practice release techniques developed by the ODF&W using release baskets and fishing shallower water whenever possible.

Our customers, due to the population base, travel a minimum of three hours to fish with us and as a result spend time coming and going in the community which also adds to the economic value of them fishing with us. We are the only charter business out of these two ports that work on a full time basis and this oportunity for cusomters to fish and ourselves make a living in a tourism based economy would be lost in the event further restrictions were put in place.

We ask the PFMC carefully reviews this when they set the regulations as we are not the only ones that will be put out of business as there are others exactly like us up and down the coast.

I thank you for your time and consideration.

Sincerely,

Mark Lottis

Atten: Pacific Fishery Management Council
Don Hansen, Chair and Council Members
Reg: 2007-2008 Ground Fish Regulations

This letter is to convey our Association's position on further restrictions on ground fish i.e. season limits and/or bag limits.

We represent over fifty individuals and local businesses that depend heavily on the recreation and economic value that this brings to the Gold Beach area.

Our fishing grounds are already highly restricted naturally as of result of weather conditions that prevent over fishing. We need a full year round season just to get in a reasonable amount of fishing days. If any further restrictions are put on rock fish and lingcod we will for all practical purposes not have any opportunities at all for this fishery.

Please take this into consideration when making the 2007-2008 regulations.

Sincerely,

Don Foss

Re: Proposed Management Measures for the 2007-08 Oregon Recreational Groundfish Fishery

---

Please consider the following comments and information prior to any final decisions that will affect or change the present groundfish fishery off the Oregon Coast.

It is our recommendation that the no action alternative be taken based on the following:

- In consideration of *Action Alternative 1a*, it should be noted that 48% of all 2005 angler trips out of Newport were for groundfish. This proposed alternative would represent a 20% loss of all angler trips. This represents approximately 20% loss of launch revenue, recreational moorage fees – both long and short term, charter lease fees, as well as visitors to our RV Park. These numbers equate to a 15% loss of revenue to our total annual budget, nearly $344,000 ... just one port on the Oregon Coast.

- Action *Alternative 1b* could have an even larger affect due to the fact that the Department is proposing to reduce the recreational halibut catch and further reduce time on the water. It has taken nearly 10 years to rebuild and bring back the halibut stocks to the point that Oregon recreational fishers rely and look forward to the halibut openers as a relief to the salmon restrictions that keep mounting.

- It is difficult, with such little time to prepare, to place an exact dollar amount on the economic impact that the proposed management measures could have locally, especially given the fact that we are right in the middle of one of the worst salmon disasters to hit the coast since the listing of the coho.

I don't have the answers or another alternative that would further reduce the impacts on the yelloweye rockfish and canary rockfish, but I do know that any further restrictions to bottom fish bag limits or reduced fish days is not a good idea.

The Port of Newport recommends status quo.

OREGON DEPARTMENT OF FISH AND WILDLIFE REPORT ON THE TENTATIVE ADOPTION OF 2207-2008 GROUNDFISH FISHERY SPECIFICATIONS/MANAGEMENT MEASURES AND AMENDMENT 16-4

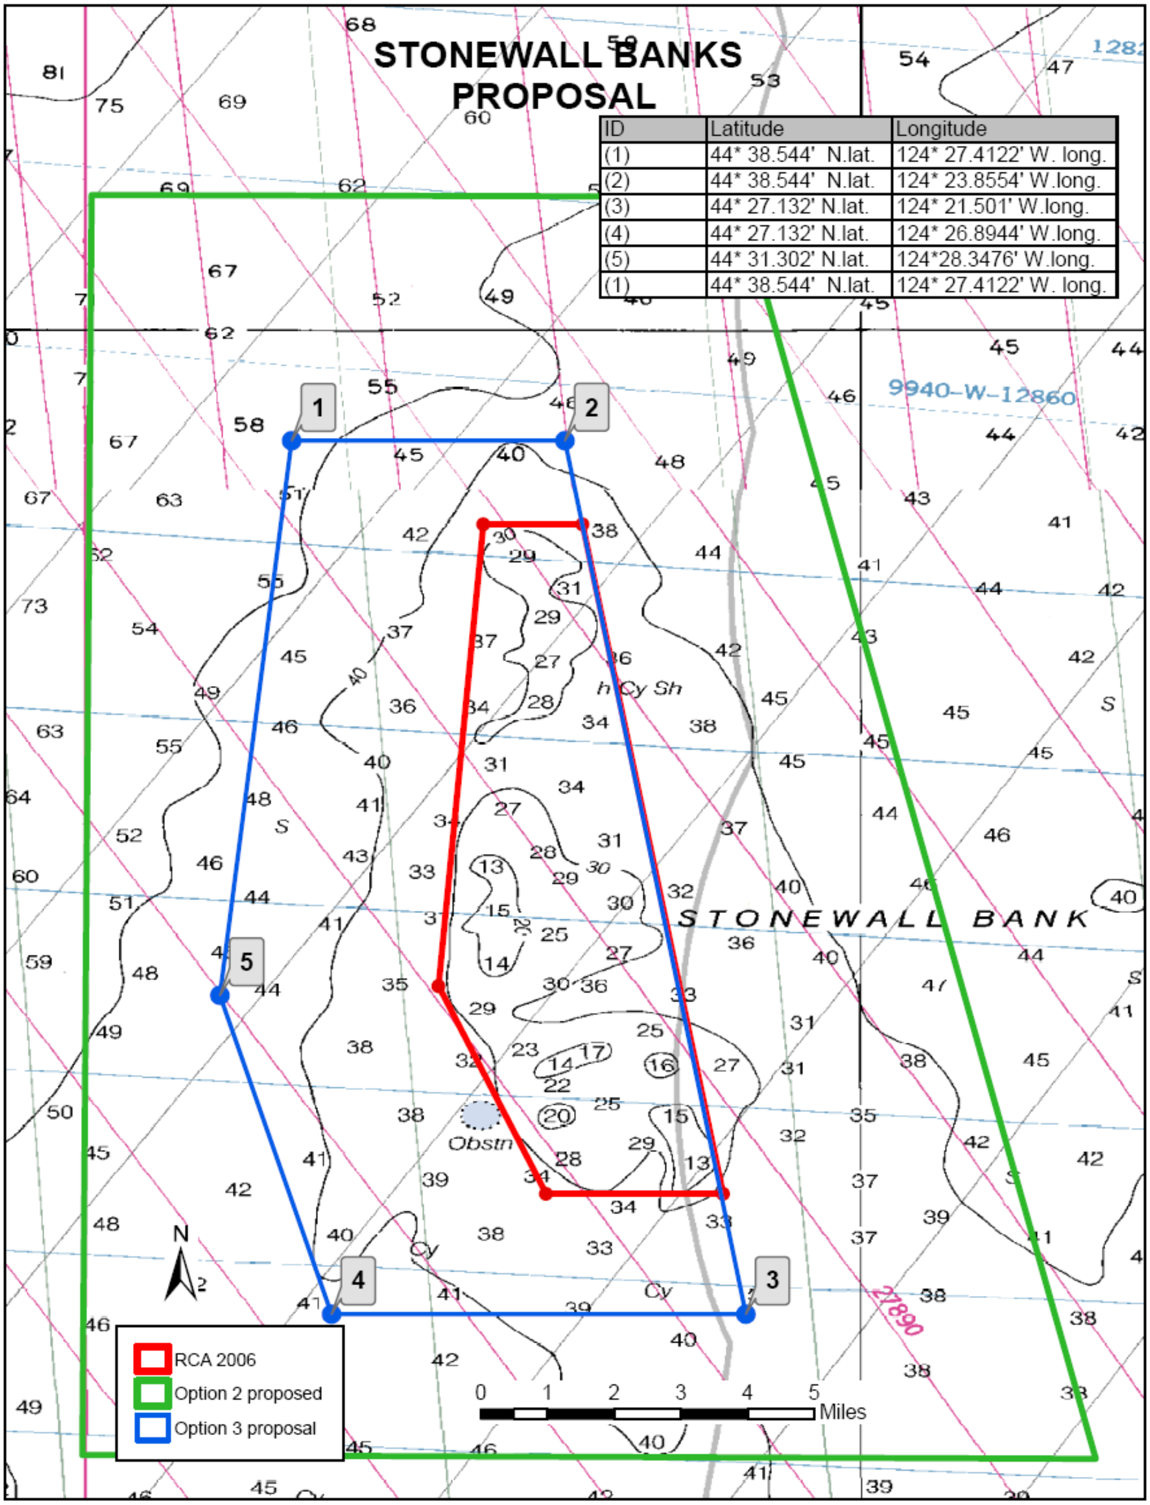
The Oregon Department of Fish and Wildlife (ODFW) worked with fishery participants to determine an appropriate northern line for the proposed Stonewall Bank closure option 3 (ODFW Report 2) for the implementation of a recreational Yelloweye Rockfish Conservation Area (YRCA) located at Stonewall Bank, off the coast of Newport, Oregon. This third option (figure 1) is within the range of options for development of a recreational Stonewall Bank YRCA, previously adopted by the PFMC at its April 2006 meeting.

The coordinates contained in this report replace those contained in ODFW Report 2. Minor adjustments were made to the northern line to provide consistency in the east lines between options 1 (current closure in the Pacific halibut fishery) and 3, as there are no current necessities to adjust the eastern boundary. The northern line was not adjusted further north, as the occurrence of yelloweye rockfish in the area to the north was not consistent, and the habitat is mostly sand or hard bottom, with patchy rock outcroppings.

Stonewall Bank YRCA modified option 3 coordinates:

	Latitude		Longitude	
ID	**Degrees**	**Decimal Minutes**	**Degrees**	**Decimal Minutes**
1	44	38.544	124	27.4122
2	44	38.544	124	23.8554
3	44	27.132	124	21.501
4	44	27.132	124	26.8944
5	44	31.302	124	28.3476
1	44	38.544	124	27.4122

Figure 1. Each of the three options for the implementation of a recreational Stonewall Bank YRCA. Option 1 is the smallest box and represents the current closure in the Pacific halibut fishery. Option 2 is the largest box and represents an analysis area adopted at the April Council meeting, and Option 3 (modified from that detailed in ODFW Report 2) is the box in between, and represents ODFW's preferred alternative.



Agenda Item F.2.b
Supplemental ODFW Report 5
June, 2006

OREGON DEPARTMENT OF FISH AND WILDLIFE REPORT SUPPORTING ADOPTION OF THE "RAMP-DOWN" YELLOWEYE ROCKFISH OPTIMUM YEILD

The Oregon Department of Fish and Wildlife (ODFW) supports adoption of the "ramp-down" yelloweye rockfish optimum yield (OY). ODFW believes this strategy, while extending the rebuilding time for this stock by ~6 months (estimated to rebuild in the year 2083.5) as compared to the Low OY Alternative (estimated to rebuild in the year 2083), will provide the time required for businesses dependant on recreational and commercial groundfish fisheries (both directly and indirectly) to make appropriate adjustments to business plans, and for fishery managers to collect data needed to develop additional management tools to structure meaningful fisheries under the low OY anticipated in 2011 (13.5 metric tons).

Community Vulnerabilities

The Oregon counties among the 15 counties coastwide that were labeled as "vulnerable" areas (high engagement or dependence on commercial or recreational fisheries and low resilience to change) include Clatsop, Coos, Curry, Lincoln, and Tillamook counties (as noted in Chapter 7 of the preliminary draft EIS, section 7.1.5.2.3, p. 31). Of the 6 counties labeled "most vulnerable", 2 are located in Oregon (Coos and Lincoln counties). All of the above counties were identified as "vulnerable" in both the commercial and recreational fishery analysis.

Recreational Fishery

Oregon's marine recreational fisheries are comprised of anglers targeting primarily groundfish, Pacific halibut, salmon, tuna, or a combination thereof. Yelloweye rockfish, deemed most limiting of the depleted species to the recreational fisheries, are impacted in nearly all target strategies, most concentrated in the groundfish and Pacific halibut fisheries. The groundfish and Pacific halibut fisheries have been increasingly restricted for the purposes of reducing impacts to canary and yelloweye rockfishes. Management tools such as time and depth restrictions, non-retention, and area closures have been implemented in both of the key fisheries to conserve depleted species. Additional measures, such as the proposed Stonewall Bank Yelloweye Rockfish Conservation Area, are being considered for implementation in 2007-2008 to further conserve canary and yelloweye rockfishes.

Under the 12 metric ton yelloweye alternative, the Oregon recreational fishing effort for groundfish and Pacific halibut would decrease by 32% (Chapter 7, section 7.2.10.1.2, p. 50), resulting in an estimated impact to income of $2.62 million or 34% (Table 7-68d., p. 151). In addition, fishing seasons would be severely shortened which would have additional implications. Fewer tourists would be drawn to communities during times when fishing closures are in place. Support industries such as charter offices, fuel stations, sporting goods stores, marinas, motels, campgrounds, restaurants, grocery stores, and many other local businesses will lose income, and in some cases, close their business. The economic impacts will be far reaching and much larger than indicated by just examining changes in angler trips.

Under Action Alternative 1, structured to address the Low OY Alternative for yelloweye rockfish of 12.6 metric tons, all Oregon regions are estimated to experience decreases in estimated income generated from recreational groundfish charter boat fisheries that are greater than 39% (Chapter 7, section 7.2.11, p. 53). With regards to income generated by recreational groundfish private trips, all Oregon regions are estimated to experience decreases that are greater than 37%. These reductions are attributed to limited fishery opportunity (fishery open for 2-6 months) and depth restrictions (fishery restricted to waters shoreward of 20-fathoms during the open period). Income loss at these levels will effectively close the recreational groundfish charter boat fishery in Oregon, as the charter industry will not be able to sustain basic operational costs (Supplemental ODFW Report 3, Agenda Item F.2.b, June 2006). Additionally, projected decreases in income would cause undue hardship on Oregon's coastal communities that are already depressed (5 of 7 coastal counties deemed "vulnerable").

To conduct meaningful recreational fisheries with very low impacts of canary and yelloweye rockfishes, ODFW is gathering information related to site fidelity, survivability, effective release methods, and recreational gear selectivity. A variety of research projects are currently being conducted, and are planned to either continue in 2007 and/or be expanded in the future. Results have been summarized for use in public education brochures, scientific journals, and potential inclusion in stock assessments. It is very likely that it will not be feasible to continue this research under the Low OY Alternative for yelloweye rockfish.

Commercial Nearshore Fisheries

Reduced allowable harvest of yelloweye rockfish will also impact various commercial fisheries, including the Oregon commercial nearshore fishery. With regards to the commercial nearshore fishery for the area north of 40° 10' N. Lat., Action Alternative 1, structured to meet allowed impacts under the Low OY Alternative for yelloweye rockfish, would require a 60% reduction of black rockfish harvest. Black rockfish comprise the majority of the catch in this fishery. The fishery is currently operating on very low monthly trip limits (300-600 pounds/month of black and blue rockfish combined). Fishery participants have asserted that the current limits represent the minimum amount of monthly harvest required to be able to maintain business operating costs and viability. Analysis shows that under Action Alternative 1, ex-vessel revenue for the commercial nearshore fishery in the area north of 40° 10' N. Lat. would be reduced by 42% as compared to 2005 revenue (Table 7-54, Chapter 7, p. 124). This estimate is considered to be conservative, as it does not factor in loss to fishery support businesses (i.e. ice plants, fabrication shops, gear manufacturers/suppliers, etc.) and the greater communities. Projected decreases in income would cause undue hardship on Oregon's coastal communities that are already depressed (5 of 7 coastal counties deemed "vulnerable").

Supplemental Tribal Comment
Quileute Indian Tribe
June 2006

Testimony of the Quileute Tribe on Groundfish Management to the PFMC

The Quileute Tribe is very concerned about the future of all west coast groundfish stocks and in particular, the current status of Yelloweye rockfish. For many years, the Tribe has taken substantial measures to insure a minimal impact on this species of concern. We have implemented a full retention fishery with 100 lb/trip/vessel landing limits to ensure that our individual fisherman are having a minimal impact on the stock and to further ensure that we, as co-managers, have a full accounting of total Yelloweye mortality. The Tribe has achieved additional catch reductions actively avoiding Yelloweye "hot spots" and through the reduction of the inter-tribal open-competitive halibut fishery. These management strategies have allowed the Quileute Tribe to keep its total Yelloweye bycatch to less than 1 metric ton per year over the past 5 years and less than 600 pounds in 2005.

Considering the significant difference in catch favoring the non treaty fleet and the pre-conservation measures that the Quileute Tribe has already taken to protect this species the Tribe believes that it would be both a violation of its Treaty with the United States and economically devastating for the Tribe to bear the brunt of any additional conservation measures. In addition, NMFS, as an agent of the Federal government, has a fiduciary duty and primary trust responsibility to protect and preserve the Tribe's treaty-secured fishing rights. The federal government and NMFS would violate both its fiduciary responsibility to the Tribe and the Treaty itself if it were to require the Tribe to further reduce its fisheries below current levels, without, at the very least, first looking to non-Quileute fisheries to bear the burden of additional conservation steps.

Additional conservation measures would have severe economic impacts on the entire Quileute Tribal fishing fleet and the broader Tribal community. The Quileute Indian Reservation is located in La Push, Washington, which is about 15 miles West of Forks on the Washington Coast. It is a rural reservation in an area with very few economic opportunities for tribal members. Other than work in tribal government, fisheries represent the only other significant source of jobs for tribal members on the reservation. There are usually between 5 to 7 tribal boats that participate in the tribal ocean fisheries, which provide jobs for not only the vessel owners but crew members as well. In addition, the Tribe owns a fish processing plant that is dependent in large part on the catch that is brought in by tribal fisherman. This fish processing plant is also an important source of employment for tribal members, as well as an important source of revenue for the Tribe itself. The diminishment or loss of fishing related jobs would have a very significant and potentially devastating impact on the Tribe's economy.

Tribal Proposal Regarding Groundfish Fisheries for 2007 and 2008

Black Rockfish - The 2007 and 2008 tribal harvest guidelines will be set at 20,000 pounds for the management area between the US/Canada border and Cape Alava, and 10,000 pounds for the management area located between Destruction Island and Leadbetter Point. No tribal harvest restrictions are proposed for the management area between Cape Alava and Destruction Island.

Sablefish - The 2007 and 2008 tribal set asides for sablefish will be set at 10 percent of the Monterey through Vancouver area OY minus 1.9 percent to account for estimated discard mortality. Allocations among tribes and among gear types, if any, will be determined by the tribes.

Pacific cod - The tribes will be subject to a 400 mt harvest guideline for 2007 and 2008.

For all other tribal groundfish fisheries the following trip limits will apply:

Thornyheads - Tribal fisheries will be restricted to the Limited Entry trip limits in place at the beginning of the year for both shortspine and longspine thornyheads.

Canary Rockfish - Tribal fisheries will be restricted to a 300 pound per trip limit.

Other Minor Nearshore, Shelf and Slope Rockfish - Tribal fisheries will be restricted to a 300 pound per trip limit for each species group, or the Limited Entry trip limits if they are less restrictive than the 300 pound per trip limit.

Yelloweye Rockfish - The tribes will continue developing depth, area, and time restrictions in their directed Pacific halibut fishery to minimize impacts on yelloweye rockfish. Tribal fisheries will be restricted to 100 pounds per trip.

Spiny Dogfish - The Makah Tribe is proposing a directed longline fishery for spiny dogfish for 2007 and 2008. The fishery would be restricted to the Limited Entry trip limits. Increased landings of dogfish by treaty fishermen in 2007 and 2008 would be dependent on successful targeting in 2006 while staying within current estimates of impacts on overfished species.

Full Retention - The tribes will require full retention of all overfished rockfish species as well as all other marketable rockfishes during treaty fisheries.

Tribal Proposals Regarding
Makah Trawl fisheries for 2007 and 2008

Midwater Trawl Fishery - Treaty midwater trawl fishermen will be restricted to a cumulative limit of yellowtail rockfish, based on the number of vessels participating, not to exceed 180,000 pounds per two month period for the entire fleet. Their landings of widow rockfish must not exceed 10 percent of the poundage of yellowtail rockfish landed in any given period. The tribe may adjust the cumulative limit for any two-month period to minimize the incidental catch of canary and widow rockfish, provided the average cumulative limit does not exceed 180,000 pounds for the fleet.

Bottom Trawl Fishery - Treaty fishermen using bottom trawl gear will be subject to the trip limits applicable to the limited entry fishery for Dover sole, English sole, rex sole, arrowtooth flounder, and other flatfish. For Dover sole and arrowtooth flounder, the limited entry trip limits in place at the beginning of the season will be combined across periods and the fleet to create a cumulative harvest target. The limits available to individual fishermen will then be adjusted inseason to stay within the overall harvest target as well as estimated impacts to overfished species. For petrale sole, fishermen would be restricted to 50,000 pounds per two month period for the entire year. Because of the relatively modest expected harvest, all other trip limits for the tribal fishery will be those in place at the beginning of the season in the limited entry fishery and will not be adjusted downward, nor will time restrictions or closures be imposed, unless in-season catch statistics demonstrate that the tribe has taken ½ of the harvest in the tribal area. Fishermen will be restricted to small footrope ($\leq$ 8 inches) trawl gear. Exploration of the use of selective flatfish trawl gear will be conducted in 2006.

Observer Program - The Makah Tribe has an observer program in place to monitor and enforce the limits proposed above.

WASHINGTON DEPARTMENT FISH AND WILDLIFE JUSTIFICATION FOR APPLYING THE RAMP-DOWN OY APPROACH TO REBUILDING YELLOWEYE ROCKFISH

As noted in the Draft Environmental Impact Statement (EIS) and the Groundfish Management Team report on Agenda Item F.2, the yelloweye is data poor and highly uncertain. All of the yelloweye assessments have been tuned to a recreational catch-per-unit-of-effort (CPUE) index and lack fishery independent trend information. Standardized fishery independent sampling is designed so that changes in sampled indices reflect changes in the population being measured rather than the method of sampling. Fishery CPUE can be prone to those changes being partially reflective of changes in behavior of the fishery (area, gear, target strategies, etc.) rather than changes in the population. As noted by the Center for Independent Experts reviewer of a previous yelloweye assessment, "CPUE data are of fundamental importance in this assessment because this is the only data type which provides direct evidence of biomass trends. However, there is always doubt as to whether any fishery-derived CPUE series is proportional to abundance." The current assessment authors state, "As in the previous assessments, the sparseness of the size and age composition data and the lack of a relevant fishery-independent survey has limited the model's ability to properly assess the status of the resource."

The baseline model assumed a single coast-wide stock and complete mixing. Given the apparently sedentary nature of this species this may be unrealistic. However, even though the approach may be desirable, current data are too sparse to support area-specific models. This is especially problematic in trying to construct the historical population required to model the population off Washington within the Stock Synthesis 2 software employed in the assessment. Although data are too sparse for a specific model off the Washington coast, previous assessment authors have commented on data that may point to a less depleted yelloweye resource in this area (trawl survey abundance, lower historical exploitation, larger average size). "The WA result is for a much lesser degree of stock decline." (Methot, et al. 2002 Yelloweye Assessment). However, until further data are collected, we will be unable to address this uncertainty. As stated in the assessment, "…due to catch restrictions since 2002, catch-per-unit-effort (CPUE) data no longer reflect the real changes in population abundance, and discard estimates are highly uncertain."

Uncertainty in the data and assessment versus the certainty of the major impacts upon industry need to be a consideration in how we proceed with respect to yelloweye rockfish.

One source of information for stocks off Washington might be to collaborate with Department of Fish and Oceans, Canada to draw upon information on the yelloweye stock and management response immediately to the north in British Columbia. Yelloweye catch quotas for the British Columbia fishery for the current year are 83 mt for the commercial fishery off the west coast of Vancouver Island, and 284 mt coastwide. Recreational catches would be in addition. To provide some perspective, this means, that after rebuilding our yelloweye stock over a 70 to 80 year period, the MSY catch level for the entire US coast will still be less than half the total of the current annual commercial catch off the west coast of Vancouver island (less than the length of the Oregon coast).

Efforts to Collect Additional Data

The Washington Department of Fish and Wildlife (WDFW) is working on several initiatives to collect additional biological data and fishery information, including:

- In 2006, WDFW is partnering with the International Pacific Halibut Commission to enhance their longline halibut survey by setting additional stations in "untrawlable" areas off Washington's north coast. WDFW hopes to continue this effort in 2007 and would also like to expand the enhanced survey with additional stations off Oregon.

- WDFW is working with scientists from Alaska and British Columbia to assemble and review data on yelloweye growth and natural mortality; these data could potentially be used to address the assumption for natural mortality (M) in the next stock assessment.

- Collection of biological and species distribution information from federal and state at-sea observer programs.

- In May, WDFW began a voluntary recreational private angler camera project to collect species identification and length data from recreational fishers.

- In May, WDFW began a voluntary logbook program for charter and private recreational boats; these data could help identify the fishing locations of these fisheries and bycatch information on canary and yelloweye rockfish.

- Also in May, WDFW began a voluntary logbook program for limited entry fixed gear participants to collect much-needed fishery location data.

In addition to these efforts, WDFW is continuing to develop a yelloweye occurrence and habitat GIS database, implement a strong public education program, and work with stakeholders from commercial and recreational fishers to refine yelloweye rockfish conservation areas (YRCAs).

Impacts to Washington Recreational Fisheries

Under the $T_{F=0}$ yelloweye OY, the estimated loss to recreational fisheries is about 1,150,000 angler trips (as noted in Chapter 7 of the draft EIS, section 7.2.10.1.1, p. 49). Washington recreational bottomfish and halibut angler trips are estimated to decline by 30% under the yelloweye OY of 12 mt (Chapter 7, section 7.2.10.1.1, p. 50). These projected reductions in angler trips would cause undue hardship on Washington's coastal communities that are already depressed.

For reference, the status of Washington's coastal communities was described in the 2000 U.S. census. In 2000, the population of Neah Bay was 794, which is a 13.3% decline from 1990. There is a 24% unemployment rate in Neah Bay. The per capita income was $11,338 with a median household income of $21,635; these data indicate that 29.9% of the Neah Bay population is below the poverty level. A lot of the employment in Neah Bay is seasonal in nature, with fisheries employing about 300 people per year.

Also according to the 2000 U.S. census, the population of La Push was 371. There is an unemployment rate of 27.4% in La Push. The per capita income was $9,589 with a median household income of $21,750, which indicates that 34.5% of the population is below the poverty level. In 2000, the population of Westport was 2,137. There was a per capita income of

$17,362, and a median household income of $32,037, which indicates that 14.3% of the population is below the poverty level.

In 2006, Washington's recreational fisheries were further constrained by the implementation of depth restrictions off our North Coast and central areas, where yelloweye are caught. These include a 20-fm depth restriction applied to the fisheries operating out of Neah Bay and La Push from late May through the end of September, and a 30-fm depth restriction from mid-March through mid-June to the recreational fishery out of Westport. Given the location of the continental shelf off Neah Bay, the 20-fm depth restriction is about 0.5 to one mile offshore. These depth restrictions, especially in the North Coast area, have severely impacted recreational bottomfish fisheries targeting healthy lingcod and black rockfish stocks, and have resulted in additional economic loss to the coastal communities.

With regard to Action Alternatives 1 and 2, the results of these alternatives would virtually eliminate the Washington North Coast recreational halibut fishery in Neah Bay and La Push. There are 38,985 angler trips taken out of Neah Bay annually, 26% of which (10,166) are halibut trips. There are an additional 7,984 angler trips originating out of La Push, 17% of which (1,389) are halibut trips. Both Neah Bay and La Push are considered to be vulnerable recreational fishing communities and they both have very low resiliency (as noted in Chapter 7 of the draft EIS, section 7.1.5.2.2 on p. 30). Action Alternative 1 would result in a decrease of 33% in recreational charter trips, and a decrease of 27% of private boat trips in the North Coast, and Alternative 2 would reduce charter trips by 42%, and private boat trips by 32% (Chapter 7, section 7.2.11, p. 53). These reductions are the result of fishery closures and increased depth restrictions, but do not include any projected reductions resulting from the proposed area closures for yelloweye conservation; therefore, the estimated reductions are likely low.

Impacts to Washington Commercial Fisheries

Under the TF=0 yelloweye OY, the estimated loss to commercial fisheries is over $100 million in ex-vessel revenues, which would result from complete closures of the tribal groundfish fisheries and closures of Washington longline and pot fisheries (as noted in Chapter 7 of the draft EIS, section 7.2.10.1.1, p. 49). Commercial ex-vessel revenues could decline by as much as 40% under the yelloweye OY of 12 mt (Chapter 7, section 7.2.10.1.1, p. 50). To ensure this low OY was not exceeded, the non-trawl rockfish conservation area would have to expand from the shoreline to 150 fms offshore, precluding access to prime sablefish and dogfish areas that are the backbone of Washington's longline fishery. The economic impacts resulting from these measures, again, would cause undue hardship on Washington's coastal communities that are already depressed. Areas labeled "most vulnerable" with regard to commercial fishing in Washington include Neah Bay and Ilwaco; other commercial vulnerable areas with low resiliency include La Push, Westport and Bellingham.

For the reasons described above, the Washington Department of Fish and Wildlife believes the ramp-down strategy is justified for setting the OY for yelloweye rockfish.

Agenda Item F.2.b
WDFW Report
June 2006

WASHINGTON DEPARTMENT OF FISH AND WILDLIFE REPORT ON 2007-2008 GROUNDFISH FISHERY SPECIFICATIONS/MANAGEMENT MEASURES AND AMENDMENT 16-4

The Washington Department of Fish and Wildlife (WDFW) held public meetings following the April Council meeting to review and discuss proposed closed areas for protection of overfished rockfish, primarily yelloweye. Anecdotal information communicated to WDFW staff indicated that some of the proposed areas, including portions of the current "C-shaped" closed area, have not produced yelloweye rockfish, whereas other areas consistently contain yelloweye.

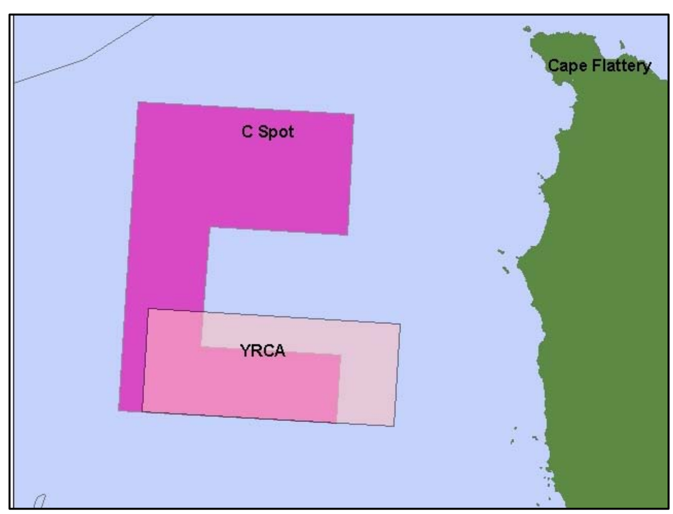
To examine this further, we plotted the coordinates of the closed areas with Geographic Information Systems (GIS) software with overlays of all available yelloweye rockfish encounter data. Data sources included state observer data from recreational, salmon troll, and exempted fisheries for trawl and longline, groundfish trawl logbook data, and data from the annual International Pacific Halibut Commission (IPHC) halibut survey, the National Marine Fisheries Service triennial trawl survey, and the WDFW submersible survey for yelloweye.

The geological structure of the area off the northern coast of Washington is high rocky relief, which yelloweye tend to inhabit, especially across a large area commonly referred to as "the prairie." It is important to note that, while there have been yelloweye caught on "the prairie," the data we have is an artifact of where the data have been collected. For example, the IPHC survey consistently sets on the same locations every year, so we cannot determine whether the catch-per-unit of effort for yelloweye is higher in one location than another, as the entire area has not been randomly surveyed. Additionally, observer data from the salmon troll fishery, as an example, was collected from "the prairie" as that is where a large proportion of the fishery takes place. Over the next two years, WDFW will work with constituents to collect additional data, and review the existing data in more detail, to evaluate additional yelloweye rockfish conservation areas that might be implemented in the future.

However, using the available data, WDFW has developed a new proposal for a yelloweye rockfish conservation area for 2007-08 that overlaps the southern portion of the "C-shaped" area, as depicted by the following coordinates:

Beginning at 48°00.00' N lat.; 125°16.00' W long.
Then to 48°06.00' N lat.; 125°16.00' W long.
Then to 48°00.00' N lat.; 124°54.00' W long.
Then to 48°06.00' N lat.; 124°54.00' W long.
and back to the point of origin.

This proposed yelloweye rockfish conservation area would be closed to all fishing, including trawl, fixed gear, recreational, and all open access fisheries.



Agenda Item F.2.c
Supplemental GAP Report
June 2006

GROUNDFISH ADVISORY SUBPANEL REPORT ON TENTATIVE ADOPTION OF 2007-2008 GROUNDFISH FISHERY SPECIFICATIONS/MANAGEMENT MEASURES AND AMENDMENT 16-4

The Groundfish Advisory Subpanel (GAP) considered options for 2007-2008 optimum yields (OYs) for depleted groundfish species. There are three parts to this statement: the first contains general comments on current and future economic conditions in the groundfish fishery; the second covers OY recommendations for overfished species, including detailed justification rationale; and the third provides sector specific comments with over-arching impacts and respect to more than one species.

The GAP referenced Agenda Item F.2.a, Attachment 2; page 158, Table 7.69, for exvessel values. In addition, the GAP defines “take” in this document as the amount of catch expected to be harvested (including discard mortality). The GAP has also applied a 3:1 multiplier effect when identifying associated community impacts. The income impact multiplier for all groundfish is 2.16. The GAP believes that the community impacts are much more significant than income impacts alone and believes that the 3:1 multiplier is a more accurate depiction of overall community impacts. Recreational information comes from a National Marine Fisheries Service (NMFS) 2001 study “Technical Memorandum NMFS-F-SPO-49 October 2001.”

General Economic Conditions

Members of the GAP representing all sectors of the industry continue to voice their desire to be allowed to fish over the long term. Many interpretations of the Ninth Circuit Court’s ruling have been made. Taking into consideration the needs of fishing communities to avoid short-term disastrous consequences has different meanings to different stakeholders. However, one fact is undisputable: short-and long-term consequences to fishing communities are intrinsically linked. In order for there to be commercial and recreational fishing industries over the long term, short-term management measures must help preserve fishing businesses. More plainly said, if no fishing industry exists into the future because of overly extreme cuts in harvest then the Council has not taken into account the economic needs of fishing communities. If individual businesses continue to become depleted, necessary infrastructure within fishing communities that support commercial and recreational industries also become depleted. Once boats are tied to the dock, doors are closed, markets are lost, it isn’t just one season’s fishing foregone.

The GAP believes that some access to depleted species in order to catch healthy stocks is necessary to avoid disastrous short-term consequences to fishing communities. If communities and fishery sectors cannot survive short-term restrictions, longer-term efforts at sustainability apply only to the biology of fish – not to sustaining communities. The GAP believes the relationship between sustainable fishing communities and stable fisheries stocks is intrinsic, and preserving both for the long-term is not only worthwhile, but a necessity. With this in mind, the GAP notes the following with respect to the level of distress in the current fishery.

Generally from 1981 through 1997 the exvessel value of the commercial non-whiting groundfish fishery ranged from $80 to $100 million. In 1998, the first year of the groundfish disaster, the value of the entire non-whiting groundfish fishery was $61 million. The disaster was officially declared in 2000, and from 2002 through 2005 exvessel value of the fishery ranged from approximately $40 to $45 million. A difference of $40 to $55 million from the earlier period.

During this time of harvest cuts many fishing businesses and several seafood processors have gone out of business. Secondary and tertiary businesses associated with the fishing industry have also suffered. The additional hardship of increased fuel costs has only made it more difficult to maintain business plans.

Taking into consideration the needs of fishing communities goes beyond simple measures of changes in revenue. Socioeconomic effects should also be a major part of the discussion. For example, unemployment rates are higher for older individuals who have a more difficult time transitioning to new employment opportunities. This type of information is difficult to quantify but we know there are detrimental social consequences when businesses are suffering financially and closing their doors.

Incentives for improved science, management, and fishing practices should always be encouraged and explored. However, the one control the Council has for decision-making today on rebuilding plans is controlling fishing effort. Recreational and commercial fisheries have adapted to reduced harvests. Areas are now closed to protect overfished stocks. Essential fish habitat was established to protect spawning grounds and sensitive habitats. These reductions, closures, and other management measures are in place and there is evidence that stocks are rebuilding. Further reductions in harvest will harm the West Coast groundfish fishery and support industries without any meaningful gain in rebuilding times for most overfished species.

On the basis of the current distress in the fishery, the array of tradeoffs between present and future production, the levels of economic activities that each of these OYs affords, and affect on rebuilding times, the GAP has the following specific recommendations.

GAP Recommendations for OYs for Overfished Species

The following is a summary of the GAP recommendations:

Species	2007 OY	2008 OY
Bocaccio	218 mt	218 mt
Canary rockfish	44 mt	44 mt
Cowcod	8 mt	8 mt
Darkblotched rockfish	330 mt	330 mt
Pacific Ocean Perch	217 mt	217 mt
Widow rockfish	456 mt	456 mt
Yelloweye rockfish	Ramp down approach	Ramp down approach

BOCACCIO

Recommendation

The GAP recommends an OY of 218 mt for 2007 and 2008.

Fisheries Involved

Bocaccio is caught in the following fisheries occurring south of 40° 10'.

- Research Fisheries
- Limited Entry Trawl Non-whiting Fisheries
- Limited Entry Fixed-Gear Fisheries
- Open Access Directed Groundfish Fisheries
- Open Access Incidental Fisheries
    - California halibut
    - California gillnet
    - Coastal pelagic species wetfish
    - Pink shrimp
    - Ridgeback prawn
    - Salmon troll
- California Recreational Fisheries

Communities Impacted

There are at least 31 ports that could be impacted with a reduction in the amount of Bocaccio available. These communities are all located south of 40˚ 10' north latitude and include:
Albion, Bodega Bay, Fort Bragg, Point Arena, Point Reyes, Shelter Cover, Big Creek, Elk, Monterey, Moss Landing, Half Moon Bay, San Francisco, Santa Cruz, Avila, Berkeley, Dana Point, Long Beach, Mission Bay, Morro Bay, Newport Beach, Oceanside, Oxnard, Playa Del Rey, Point Loma, San Diego, San Pedro, San Simeon, Santa Barbara, Terminal Island, Ventura, and Wilmington.

Justification for Recommendation

- An OY of 218 mt represents an 80% probability of rebuilding. The median time to rebuild the stock under this alternative would be 2026, or five years longer than if a zero OY alternative were implemented.
- The Bocaccio biomass is increasing at an accelerated rate. Interactions with Bocaccio will continue to increase as the stock continues to rebuild.
- For 2007 and 2008 this represents an OY which is only 36% and 28% of the Council's preferred acceptable biological catch (ABC) of 602 mt and 618 mt, respectively.
- Dr. Alec McCall reports that there is strong evidence that two strong year classes are moving into the fishery.
- This fishery has already constrained or eliminated other fisheries, for example, the spot and ridgeback prawn trawl fisheries, the California halibut fishery, sea cucumber fishery, overall open access California groundfish fisheries, California limited entry trawl fishery and all of the California groundfish recreational fisheries.

Impacts of Lower OY Values

Limited Entry Trawl Non-whiting Fishery

Under a zero OY alternative, there would be no limited entry trawl non-whiting fishery south of 40˚10' N. Lat. This results in a loss of $2,600,000 exvessel value which equates to a $7,800,000 impact to affected communities.

Under the low OY alternative (40 mt), the limited entry trawl non-whiting fishery is expected to take 9.1 mt of Bocaccio (Table 2-14). In 2006, this same fishery is expected to take 47.9 mt of Bocaccio. This is an 80% reduction in catch, resulting in a $2,080,000 loss in exvessel revenues, which equates to $6,240,000 loss to affected communities.

Under the high OY alternative (218 mt), the limited entry trawl non-whiting fishery is expected to take 50.5 mt (Table 2-21). This number is more similar to the expected catch in 2006 and the higher OY allows a fishery similar to the status quo fishery, which is already severely constrained.

Limited Entry Fixed-Gear Fishery

Under a zero OY alternative there would be no limited entry fixed-gear fishery south of 40°10' N. lat. for shelf and nearshore rockfish. This results in a loss of $1,200,000 in exvessel revenue which equates to a $3,600,000 economic impact to the affected communities.

Under the low OY alternative (40 mt), the limited entry fixed gear fishery is expected to take 5.4 mt of Bocaccio (Table 2-14). This same fishery is expected to take 13.4 mt of Bocaccio in 2006. This is a 60% reduction in catch resulting in a loss of $720,000 in exvessel revenue which equates to $2,160,000 impact to affected communities.

Under the high OY alternative (218 mt), the limited entry fixed gear fishery is expected to take 13.4 mt of Bocaccio. The higher OY would allow a fishery similar to the status quo fishery, which is already severely constrained.

Open Access Directed Groundfish Fishery

Under a zero OY alternative the open access directed groundfish fishery south of 40°10' N. Lat. for shelf and nearshore rockfish would be eliminated. This results in a loss of $3,000,000 in exvessel value, which equates to a $9,000,000 economic impact to the affected communities.

Under the low OY alternative (40 mt), the open access directed groundfish fishery is expected to take 4.1 mt (Table 2-14). This is 6.5 mt less than the expected catch for 2006. This is a 37% reduction resulting in a loss of $1,110,000 exvessel values, which equates to a $3,330,000 economic impact to affected communities.

Under the high OY, alternative (218 mt), the open access directed groundfish fishery is expected to take 13.4 mt (Table 2-21). The higher OY option allows a near status quo fishery, which is already severely constrained.

California Recreational Fishery

Under a zero OY alternative all California recreational fisheries that encounter Bocaccio would be eliminated. This results in a loss of more than $1 billion to affected communities.

Under the low OY alternative (40 mt), the California recreational fishery is expected to take 16.0 mt (Table 2-14). This same fishery is expected to take 98.0 mt in 2006. This is an 84% reduction in catch and equates to an $840,000,000 economic impact to California communities.

Under the high OY alternative (218 mt), the California recreational fishery is expected to take 106.8 mt (Table 2-21). The high OY allows a status quo fishery, which is already severely constrained.

Maintaining Bocaccio catches at 2006 levels in order to prosecute fisheries on healthier stocks DOES NOT represent a profitable position for any of the fisheries which interact with Bocaccio. Using 2006 levels as a benchmark for measuring impacts is misleading in that 2006 levels are not reflective of healthy fishing communities. Total Bocaccio catches prior to the groundfish fishery disaster declaration in 2000 were significantly higher with 480 mt landed in 1997. The total catch expected in 2006 is just under 174 mt. This reflects a 64% reduction in Bocaccio catch as well as a higher percentage reduction in catches of associated species.

CANARY ROCKFISH

Recommendation

The GAP recommends a 44 mt OY for 2007 and 2008.

Fisheries Involved

Canary rockfish are caught in essentially all of the major fishery sectors including:

- Research Fisheries
- Tribal Fisheries
- Limited Entry Trawl Non-Whiting Fisheries
- Limited Entry Trawl Whiting Fisheries
- Limited Entry Fixed Gear Fisheries
- Open Access Directed Groundfish Fisheries
- Open Access Directed Incidental Groundfish Fisheries
    - California Halibut
    - Pink Shrimp
    - Salmon Troll
- Washington Recreational Fisheries
- Oregon Recreational Fisheries
- California Recreational Fisheries

Communities Involved

There are at least 46 ports that could be impacted by a reduction in the amount of canary rockfish available for harvest. These ports include: Aberdeen, Astoria, Bandon, Bellingham, Blaine, Brookings, Cathlamet, Charleston, Chinook, Crescent City, Depoe Bay, Eureka, Everett, Fields Landing, Florence, Garibaldi, Gold Beach, Ilwaco, La Push, Mill Creek, Neah Bay, Newport, Pacific City, Port Angeles, Port Orford, Port Townsend, Seattle, Tokeland, Trinidad, Westport, Winchester Bay, Albion, Avila, Bodega Bay, Fort Bragg, Point Arena, Point Reyes, Shelter Cover, Big Creek, Elk, Monterey, Morro Bay, Moss Landing, Half Moon Bay, San Francisco, and Santa Cruz.

Justification for Recommendation

- The most recent canary stock assessment reports that the biomass has been increasing since 2000. As the canary stock continues to rebuild the interaction with canary rockfish during fishing operations will continue to grow.
- Cooperative research currently being conducted indicates that some of the assumptions in the stock assessment surrounding older female fish are inaccurate and that inclusion of the new information would show the stock is actually more productive. Video Trawl research from the same project indicates a higher level of abundance than assumed in the stock assessment.
- The recommended OY is 7% less than the 2006 OY and 26% of the 2007 Council preferred ABC of 172 mt.
- Estimated catch for 2006 (44.3 mt) is higher than the high OY option (44 mt).

Impacts of Lower OY Values

Tribal Fishery

Under a zero OY alternative, the tribal fishery loses all groundfish and salmon fisheries resulting in an economic loss of $11,685,700 in exvessel revenue.

Limited Entry Trawl Non-Whiting Fishery (non-tribal)

Under a zero OY alternative, the limited entry trawl non-whiting fishery would be eliminated. This results in a loss of $6,500,000 in exvessel revenue, which equates to a $19,500,000 economic impact to affected communities.

Under the low OY alternative (32 mt), the limited entry non-whiting fishery is expected to take 3.7 mt (Table 2-14). In 2006 this same fishery is expected to take 7.8 mt. This would result in a 53% reduction in catch and results in a loss of $3,445,000 in exvessel revenue, which equates to a $10,335,000 economic impact to affected communities.

Under the high OY alternative (44 mt), the limited entry non-whiting fishery is expected to take 8.5 mt (Table 2-21). The high OY alternative allows a fishery similar to the status quo fishery, which is already severely constrained.

Limited Entry Trawl Whiting Fishery (non-tribal)

Under a zero OY alternative, the entire whiting fishery could be lost resulting in a $30 million exvessel loss, which equates to a $90 million economic impact to affected communities.

Under the low OY alternative (32 mt), a 3.0 mt hard cap would be imposed on the whiting fishery (Table 2-14). This equates to a 40% reduction from the hard cap in place for 2006. Based on this scenario, it is likely that 50% of the whiting OY would be unattainable, resulting in a $15 million exvessel revenue loss, which equates to a $45 million economic impact to affected communities.

Under the high OY alternative (44 mt), it is projected that the whiting fishery would take 5.5 mt (Table 2-21). If the 2006 hard cap of 4.7 mt is implemented there is the possibility that 15% of the fishery would be foregone if, due to the rebuilding paradox, canary rockfish are encountered at an accelerated rate and the hard cap is reached. 5.0% of the fishery equates to $4.5 million exvessel revenue loss, which equates to a $13.5 million economic impact to affected communities.

Limited Entry Fixed Gear Fishery (non-tribal)
Under a zero OY alternative, the limited entry fixed gear fishery would be eliminated. This results in a loss of $19,000,000 exvessel value and equates to $57,000,000 to affected communities.

Under the low OY alternative (32 mt), the limited entry fixed gear fishery is expected to take 0.1 mt (Table 2-14). This same fishery is expected to take 1.2 mt in 2006, resulting in a 98% reduction and a loss of $18,620,000 in exvessel revenue, which equates to a $55,860,000 economic impact to affected communities.

Under the high OY alternative (44 mt), the limited entry fixed gear fishery is expected to take .9 mt (Table 2-21), which results in a 25% reduction in catch and equates to a loss of $4,700,000 in exvessel value. This loss translates to a $14,250,000 economic impact to affected communities.

Open Access Directed Groundfish Fishery
Under a zero OY alternative, the open access directed groundfish fishery would be eliminated. This represents a loss of $8,000,000 in exvessel revenue, which equates to a $24,000,000 economic impact to affected communities.

Under the low OY alternative (32 mt), the open access directed groundfish fishery is expected to take 1.0 mt (Table 2-14). This same fishery is expected to take 3.0 mt of canary rockfish in 2006 resulting in a 66% reduction in catch and a loss of $5,280,000 in exvessel value which equates to a $15,840,000 economic impact to affected communities.

Under the high OY alternative (44 mt), the open access directed groundfish fishery is expected to take 2.1 mt (Table 2-21). The high OY alternative allows a fishery similar to the status quo fishery, which is already severely constrained.

California Recreational Fishery
Under a zero OY alternative the California recreational fisheries that encountered canary rockfish would be eliminated. This results in a loss of more than $1 billion to affected communities.

Oregon Recreational Fishery
Under a zero OY alternative, the Oregon recreational fisheries that encounter canary rockfish would be completely eliminated. This results in a loss of more than $45 million to affected communities.

Washington Recreational Fishery
Under a zero OY alternative, Washington recreational fisheries that take canary would be eliminated. This results in a loss of $5,000,000 to affected communities (includes total loss of halibut fishery, 50% loss of groundfish fishery, and 25% loss of salmon fishery due to depth restrictions – forced to stay inside of 30 fathoms).

Under the low OY alternative (12.6 mt), the Washington recreational fishery is expected to take 1.6 mt. This same fishery is expected to take 3.1 mt in 2006 which is an 80% reduction in catch which results in a loss of $4,000,000 to affected communities.

Maintaining canary catches at 2006 levels in order to prosecute fisheries on healthier stocks DOES NOT represent a profitable position for any of the fisheries which interact with canary rockfish. Using 2006 levels as a benchmark for measuring impacts is misleading in that 2006 levels are not reflective of healthy fishing communities.

Total canary rockfish catches prior to the groundfish fishery disaster declaration in 2000 were significantly higher with 1,309 mt landed in 1997. The total catch expected in 2006 is just over 44 mt. This represents a 97% reduction in catches of canary rockfish as well as a higher percentage reduction in catches of associated species.

COWCOD

Recommendation

The GAP recommends an OY of 8 mt for 2007 and 2008.

Fisheries Involved

Cowcod are caught in the following fisheries:

- Research Fisheries
- Limited Entry Trawl Non-Whiting Fisheries
- Limited Entry Fixed-Gear Fisheries
- Open Access Directed groundfish Fisheries
- California Recreational Fisheries

Communities Involved

There are at least 31 ports that could be impacted with a reduction in the amount of cowcod available. These communities are all located south of 38˚ 10' N. Lat. and include:
Albion, Bodega Bay, Fort Bragg, Point Arena, Point Reyes, Shelter Cover, Big Creek, Elk, Monterey, Moss Landing, Half Moon Bay, San Francisco, Santa Cruz, Avila, Berkeley, Dana Point, Long Beach, Mission Bay, Morro Bay, Newport Beach, Oceanside, Oxnard, Playa Del Rey, Point Loma, San Diego, San Pedro, San Simeon, Santa Barbara, Terminal Island, Ventura, and Wilmington.

Justification for Recommendation

- The ABC for cowcod more than tripled with the new assessment, from 5 mt to 17 mt. The OY for 2006 was 4.2 mt, 58% below the ABC. With a 17 mt ABC, the status quo rebuilding policy would result in an OY of 5 mt, 71% below the ABC. An OY of 8 mt would be 53% below the ABC, more aggressive rebuilding relative to the 2006 fishery.
- An 8 mt OY for cowcod represents an 80% probability of rebuilding on schedule.
- As this stock continues to be rebuilt, there will be higher incidence of interactions with this stock (rebuilding paradox).

Impacts of Lower OY Values

Limited Entry Trawl Non-Whiting Fisheries

A zero OY alternative would eliminate the limited entry trawl non-whiting fishery south of 40°10' N. Lat. resulting in a loss of $2,600,000 in exvessel value and $7,800,000 to the affected communities.

The low OY alternative (4 mt) results in an expected catch of 0.2 mt for the limited entry trawl non-whiting fishery (Table 2-14). This same fishery is expected to catch 2.7 mt in 2006. This results in a 93% reduction in catch and a loss of $2,418,000 in exvessel values, which equates to a $7,254,000 economic impact to affected communities.

The high OY alternative (8 mt) results in an expected catch of 2.9 mt for the limited entry trawl non-whiting fishery (Table 2-21). The high OY allows a status quo fishery, which is already severely constrained.

<u>Limited Entry Fixed-Gear Fisheries</u>
A zero OY alternative would eliminate the limited entry fixed gear fishery south of 40°10' N. Lat. This results in a loss of $1,200,000 in exvessel revenue and 3,600,000 to the affected communities.

Under the low OY alternative (4 mt) the limited entry fixed gear fishery is expected to take 0.1 mt of cowcod (Table 2-14). This is the same expected catch for 2006.

Under the high OY alternative (8 mt) the limited entry fixed gear fishery is expected to take 0.1 mt of cowcod (Table 2-21). The high OY alternative allows a status quo fishery, which is already severely constrained.

<u>Open Access Directed Groundfish Fisheries</u>
A zero OY alternative would eliminate the southern open access directed groundfish fishery. This results in a loss of $3,000,000 in exvessel value, which equates to a $9,000,000 economic impact to affected communities.

Under the low OY alternative (4 mt), the open access directed groundfish fishery is expected to take 0.1 mt (Table 4-45). This is the same catch expected for 2006.

Under the high OY alternative (8 mt), the open access directed groundfish fishery is expected to take 0.1 mt. This alternative allows for a status quo fishery, which is already severely constrained.

<u>California Recreational Fisheries</u>
Under a zero OY alternative, California recreational fisheries south of Point Conception would have to be eliminated. This results in a loss of approximately $500,000,000 to affected communities.

Under the low OY alternative, California recreational fisheries are expected to take 0.0 mt (Table 2-14). This same fishery is expected to catch 0.4 mt in 2006. This results in a 100% reduction in catch, which equates to a $500 million economic impact to affected communities.

Under the high OY alternative, California recreational fisheries are expected to take 0.3 mt (Table 2-21). The high OY allows a fishery similar to the status quo fishery, which is already severely constrained.

Maintaining cowcod catches at 2006 levels in order to prosecute fisheries on healthier stocks DOES NOT represent a profitable position for any of the fisheries which interact with cowcod rockfish. Using 2006 levels as a benchmark for measuring impacts is misleading in that 2006 levels are not reflective of healthy fishing communities. Total cowcod catches prior to the groundfish fishery disaster declaration in 2000 were higher with 9 mt landed in 1997. The total catch expected in 2006 is 3.4 mt, a reduction in catch of over 62%.

DARKBLOTCHED ROCKFISH

Recommendation

The GAP recommends an OY of 330 mt for 2007 and 2008.

Fisheries Involved

Darkblotched rockfish is currently taken in several West Coast fisheries including:

- Research Fisheries
- Tribal Fisheries
- Limited Entry Trawl Non-Whiting Fisheries
- Limited Entry Trawl Whiting Fisheries
- Limited Entry Fixed-gear Fisheries
- Open Access Directed Groundfish Fisheries

Communities Involved

There are at least 13 communities that could be impacted with a reduction in the amount of darkblotched rockfish available. These communities include Astoria, Bellingham, Blaine, Brookings, Charleston, Crescent City, Eureka, Ft. Bragg, Ilwaco, Neah Bay, Newport, and Westport.

Justification for Recommendation

- An OY of 330 mt is 72% of the Council's preferred ABC of 457 mt. The 330 mt OY results in a rebuilt stock by 2010.5, a 1 year increase from a zero OY alternative.
- As the darkblotched rockfish stock rebuilds, the interactions with these fish will continue to increase (rebuilding paradox).
- The current 200 mt OY was imposed as an interim OY pending the development of a rebuilding plan; it was not intended to be a rebuilding OY.
- Given higher occurrence of darkblotched, the current fishery could catch 284 mt, which is higher than the high OY option (229 mt).
- A 330 mt OY equates to rebuilding six months into the year 2010. A zero harvest OY equates to rebuilding six months into the year 2009. Both options equate to rebuilding during the *same* management cycle. It is estimated that you could set a 432 mt OY and darkblotched rockfish would still be rebuilt within the same management cycle (2010.9).

Impacts of Lower OY Values

<u>Tribal Fishery</u>

Under a zero OY alternative, the tribal bottom trawl fishery would be eliminated, resulting in a direct loss of $693,379 in exvessel revenue.

Limited Entry Trawl Non-Whiting Fishery (non-tribal)
Under a zero OY alternative, the limited entry trawl non-whiting fishery would be eliminated north of 38˚ N. Lat. This results in a loss of $14,300,000 in exvessel revenue which equates to a $42,900,000 economic impact to affected communities.
Under the low OY alternative, the limited entry trawl non-whiting fishery is expected to catch 66.7 mt (Table 2-14). This same fishery is expected to catch 248.9 mt in 2006. This is a 73% reduction in catch and equals $10,439,000 lost in exvessel revenues, which equates to a $31,317,000 economic impact to affected communities.

Under the high OY alternative, the limited entry trawl non-whiting fishery is expected to catch 181.1 mt (Table 2-21). This same fishery is expected to catch 248.9 mt in 2006. This is a 28% reduction in catch and equals a loss of $4,040,000 in exvessel revenues, which equates to a $12,012,000 economic impact on affected communities.

Limited Entry Trawl Whiting Fishery (non-tribal)
Under a zero OY alternative, the entire whiting fishery could be lost resulting in a loss of $30 million in exvessel revenue, which equates to a $90 million economic impact to the affected communities.

Under the low OY alternative (130 mt), the whiting fishery is expected to catch 8.6 mt (Table 2-14). In 2005 the whiting fishery took 16.5 mt of darkblotched rockfish. Under the 8.6 mt a 50% reduction would occur, resulting in a loss of approximately $15,000,000 in exvessel revenue which equates to a $45,000,000 economic impact to affected communities.

Under the high OY alternative (229 mt), the whiting fishery is expected to catch 16.2 mt (Table 2-21). Based on the darkblotched catch from 2005 only a slight loss would occur. However, under the rebuilding paradox, if darkblotched are encountered at an accelerated rate then the fishery could reach its darkblotched hard cap prior to the attainment of the whiting fishery causing economic loss.

Limited Entry Fixed Gear Fishery (non-tribal)
Under a zero OY alternative, the entire limited entry fixed gear fishery would be lost. This results in a loss of $12,000,000 in exvessel value and equates to a $36,000,000 economic impact to affected communities.

Under the low OY alternative (130 mt), the limited entry fixed gear fishery is expected to take 0.0 mt (Table 2-14). This same fishery is expected to take 1.3 mt in 2006. This represents a 100% decrease in catch and a loss of $12,000,000 in exvessel value that equates to a $36,000,000 economic impact to affected communities.

Under the high OY alternative (229 mt), the limited entry fixed gear fishery is expected to take 1.1 mt (Table 2-21). This results in a 16% decrease in catch or a loss of $1,920,000 in exvessel value, which equates to a $5,760,000 economic impact to affected communities.

Open Access Directed Groundfish Fishery
Under a zero OY alternative, the open access directed groundfish fishery on the slope north of 38˚ would be eliminated. This results in a loss of $1,900,000 in exvessel value which equates to a $5,700,000 economic impact to affected communities.

Under the low OY alternative, the open access directed groundfish fishery is expected to take 0.2 mt (Table 2-14). This same fishery is expected to take 0.2 mt in 2006.

Under the high OY alternative, the open access directed groundfish fishery is expected to take 0.2 mt (Table 4-43). The high OY alternative allows a status quo fishery, which is already severely constrained.

Maintaining darkblotched catches at 2006 levels in order to prosecute fisheries on healthier stocks DOES NOT represent a profitable position for any of the fisheries which interact with darkblotched rockfish. Using 2006 levels as a benchmark for measuring impacts is misleading in that 2006 levels are not reflective of healthy fishing communities. Total darkblotched catches prior to the groundfish fishery disaster declaration in 2000 were higher with 747 mt landed in 1997. The 2006 OY is 200 mt, a reduction in catch of about 73% as well as a higher percentage reduction in catches or associated species.

PACIFIC OCEAN PERCH

Recommendation

The GAP recommends an OY of 217 mt for 2007 and 2008.

Fisheries Involved

Pacific Ocean perch (POP) is currently taken in several West Coast fisheries including:

- Research Fisheries
- Tribal Fisheries
- Limited Entry Trawl Non-Whiting Fisheries
- Limited Entry Trawl Whiting Fisheries
- Limited Entry Fixed-Gear Fisheries
- Open Access Directed Groundfish Fisheries

Communities Involved

There are 11 ports that could be impacted by a reduction in the amount of Pacific Ocean Perch available. These communities include: Astoria, Bellingham, Blaine, Brookings, Charleston, Crescent City, Eureka, Ilwaco, Neah Bay, Newport, and Westport.

Justification for Recommendation

- A 217 mt OY is equal to 24% of the Council's preferred sustainable ABC of 900 mt in 2007.
- As POP continues to rebuild, interactions with the stock will continue to increase (rebuilding paradox).
- There are significant problems associated with attempting to rebuild a stock which is occurring on the extreme southern fringe of its geographic range. This stock has been under rebuilding scenarios of one kind or another for about thirty years. The GAP encourages the Council to consider whether we are attempting to manage to incorrect levels by not considering the biomass of the stock over a larger portion of its range.
- Estimated catch in 2006 (116.7 mt) is higher than the high OY alternative (100 mt).
- The high OY alternative (100 mt) results in a rebuilt stock in 2015.6 (just over six months through the year 2015). An OY of 217.5 results in a rebuilt stock in 2016.9. Both options equate to rebuilding during the *same* management cycle.

Impacts of Lower OY Values

Tribal Fishery

Under a zero OY alternative, the tribal bottom trawl fishery would be eliminated, resulting in a direct loss of $693,379 in exvessel revenue.

Limited Entry Trawl Non-Whiting Fishery (non-tribal)

Under a zero OY alternative the limited entry trawl non-whiting fishery would be eliminated north of 40°10'. This results in a loss of $12,000,000 in exvessel value, which equates to a $36,000,000 economic impact to affected communities.

Under the low OY alternative (44 mt) the limited entry trawl non-whiting fishery is expected to take 32.4 mt (Table 2-14). This same fishery is expected to take 102.6 mt in 2006. This results in a 69% reduction in catch and a loss of $8,280,000 in exvessel revenues, which equates to a $24,840,000 economic impact to affected communities.

Under the high OY alternative (100 mt) the limited entry trawl non-whiting fishery is expected to take 85.9 mt (Table 2-21). This results in a 16% reduction in catch and, a loss of $1,920,000 in exvessel revenues which equates to a $5,760,000 economic impact to affected communities.

Limited Entry Trawl Whiting Fishery (non-tribal)

Under a zero OY alternative, the entire whiting fishery could be lost resulting in a $30,000,000 loss to exvessel revenues, which equates to a $90,000,000 economic impact to affected communities.

Under the low OY alternative (44 mt), the whiting fishery is expected to take 3.0 mt of POP (Table 2-14). In 2003 and 2004, the whiting fishery caught 4 mt and 6 mt, respectively. The whiting fishery is expected to take 5.7 mt in 2006. This could result in 33-50% less POP available to the whiting fishery resulting in a loss of $10 to 15 million in exvessel revenues. This equates to a $30 to 45 million dollar economic impact to affected communities.

Under the high OY alternative (100 mt), the whiting fishery is expected to take 5.4 mt (Table 2-21). Based on catches in recent years, this may allow for full attainment of the whiting OY. However, based on implications of the rebuilding paradox and the rate of bycatch in the limited entry bottom trawl fishery, there is the possibility of losing part of the whiting OY.

Limited Entry Fixed-Gear Fishery (non-tribal)

Under a zero OY alternative, the limited entry fixed gear fishery would be eliminated north of 40°10' N. Lat. This results in a loss of $10,000,000 in exvessel value, which equates to a $30,000,000 economic impact to affected communities.

Under the low OY alternative (44 mt), the limited entry fixed gear fishery is expected to take 0.6 mt (Table 2-14). This same fishery is expected to take 0.4 mt in 2006. This results in a 33% reduction in catch and a loss of $3,300,000 in exvessel revenues, which equates to a $9,900,000 economic impact to affected communities.

Under the high OY alternative (100 mt), the limited entry fixed gear fishery is expected to take 0.6 mt (Table 2-21). This results in a 33% reduction in catch and a loss of $3,300,000 in exvessel revenues, which equates to a $9,900,000 economic impact to affected communities.

Open Access Directed Groundfish Fishery
Under a zero OY alternative, the open access directed groundfish fishery slope fishery north of 40°10' N. Lat. would be eliminated. This results in a loss of $1,500,000 in exvessel value and associated loss of $4,500,000 to affected communities.

Under the low OY alternative (44 mt), the open access directed groundfish fishery is expected to take 0.1 mt (Table 2-14). This same fishery is expected to take 0.1 mt in 2006.

Under the high OY alternative (100 mt), the open access directed groundfish fishery is expected to take 0.1 mt (Table 2-21). The high OY value allows a status quo fishery, which is already severely constrained.

Maintaining POP catches at 2006 levels in order to prosecute fisheries on healthier stocks DOES NOT represent a profitable position for any of the fisheries which interact with POP. Using 2006 levels as a benchmark for measuring impacts is misleading in that 2006 levels are not reflective of healthy fishing communities. Total POP catches prior to the groundfish fishery disaster declaration in 2000 were higher with 751 mt caught in 1997. The total catch expected in 2006 is 116.7 mt, a reduction in catch of over 85% as well as a higher percent reduction in catches of associated species.

WIDOW ROCKFISH

Recommendation
The GAP recommends an OY of 456 mt for 2007 and 2008.

Fisheries Involved
Widow rockfish are currently taken in several West Coast fisheries including:

- Research Fisheries
- Tribal Fisheries
- Limited Entry Trawl Non-Whiting Fisheries
- Limited Entry Trawl Whiting Fisheries
- Limited Entry Fixed Gear Fisheries
- Open Access Directed Groundfish Fisheries
- Open Access Incidental Groundfish Fisheries
    - Pink shrimp
    - Salmon troll
- Oregon Recreational Fisheries
- California Recreational Fisheries

Communities Involved
There are at least 11 ports that could be impacted with a reduction in the amount of widow rockfish available. These communities include Astoria, Charleston, Crescent City, Eureka, Fort Bragg, Bodega Bay, San Francisco, Ilwaco, Newport, Seattle and Westport.

Justification for Recommendation

- A 456 mt OY is equal to 8% of the Council's preferred sustainable ABC of 5,334 mt in 2007. This OY corresponds to a rebuilding plan which results in the stock being rebuilt by 2016, 3 years longer than zero harvest.
- The most recent stock assessment revealed that widow rockfish was never overfished and is rebuilding rapidly.
- Interactions with widow rockfish will continue to increase as the stock continues to grow (rebuilding paradox).
- A 456 mt OY equates to rebuilding in 2016. The preferred high OY (368 mt) results in the stock being rebuilt in 2015. Both options equate to rebuilding during the *same* management cycle. It is estimated that an OY of approximately 440 mt would result in a rebuilt stock in 2015.9.
- The 2005 stock assessment indicates that in 2004 the widow stock was not overfished and in 2004 was above the overfished level at 31% of the unfished biomass.

Impacts of Lower OY Values

<u>Tribal Fisheries</u>

Under a zero OY alternative, the mid-water trawl and whiting fishery would be eliminated resulting in a $4,752,058 loss in exvessel revenue.

<u>Limited Entry Trawl Non-Whiting Fishery</u>

Under a zero OY alternative, the entire limited entry trawl non-whiting shelf fishery could be eliminated. This results in a loss of $6,900,000 in exvessel value, which equates to a $20,700,000 economic impact to affected communities.

Under the low OY alternative (120 mt), projected catch of widow rockfish in the limited entry non-whiting fishery would be reduced to 0.1 mt (Table 2-14). This same fishery is expected to take 0.6 mt of widow in 2006. This results in an 83% reduction in catch and a loss of $5,727,000 in exvessel revenue, which equates to a $17,181,000 economic impact to affected communities.

Under the high OY alternative (368 mt), the limited entry trawl non-whiting fishery is expected to take 1.0 mt (Table 2-21). The high OY alternative could allow a status quo fishery, which is already severely constrained.

<u>Limited Entry Trawl Whiting Fishery</u>

Under a zero OY alternative the entire whiting fishery would be lost resulting in a $30 million dollar loss at the exvessel level. This equates to a $90 million dollar economic impact to affected communities.

Under the low OY alternative, the whiting industry hard cap would be reduced to 64.9 mt (Table 2-14). This equates to a 66% reduction from the hard cap in place for 2006. Twenty million in lost exvessel revenues could be associated with the loss of access to the healthy whiting OY based on the reduction in widow rockfish available (66% of a $30 million dollar fishery). This equates to a $60 million dollar economic impact to the affected communities.

Under the higher OY alternatives, it is assumed that the 200 mt hard cap for the whiting fishery would remain in place. It is difficult to predict whether losses would occur under this scenario. While 200 mt is the hard cap in place for 2006, due to the circumstances of the rebuilding paradox it is unclear whether or not a 200 mt hard cap will affect the 2006 fishery. Presumably as the stock continues to rebound, harvesters in the whiting fishery will continue to encounter widow rockfish at higher rates.

Limited Entry Fixed-Gear Fishery

Under a zero OY alternative the limited entry fixed gear fishery would be eliminated. This results in a loss of $1,800,000 in exvessel value, which equates to a $5,400,000 economic impact to affected communities.

Under the low OY alternative (120 mt), the limited entry fixed gear fishery is expected to catch 0.5 mt (Table 2-14). This same fishery is projected to take 0.5 mt in 2006.

Under the high OY alternative (368 mt), the limited entry fixed gear fishery is expected to take 0.5 mt (Table 2-21).

Open Access Directed Groundfish Fishery

Under a zero OY alternative, the open access directed groundfish fishery would be eliminated. This results in a loss of $3,000,000 in exvessel value which equates to a $9,000,000 economic impact to affected communities.

Under the low OY alternative (120 mt), the open access directed groundfish fishery is expected to take 0.1 mt (Table 2-14).

Under the high OY alternative (368 mt), the open access directed groundfish fishery is expected to take 0.1 mt.

Oregon Recreational Fisheries

Under a zero OY alternative, Oregon recreational fisheries associated with widow rockfish would be eliminated resulting in a loss of $3,200,000 to affected communities.

Under the low OY alternative (120 mt), the Oregon recreational fishery is expected to take 0.5 mt. This same fishery is expected to take 1.4 mt in 2006. This equates to a 65% reduction in catch and a loss of $2,080,000 in exvessel value which equates to a $6,240,000 economic impact to affected communities.

Under the high OY alternative (368 mt), the Oregon recreational fishery is expected to take 1.4 mt.

California Recreational Fisheries

Under a zero OY alternative, California recreational fisheries associated with widow rockfish would be eliminated resulting in a loss of $1 billion to affected communities.

Under the low OY alternative (120 mt), the California recreational fishery is expected to take 1.6 mt (Table 2-14). This same fishery is expected to take 8.0 mt in 2006. This results in an 80% reduction in catch and a loss of $800 million to affected communities.

Maintaining widow rockfish catches at 2006 levels in order to prosecute fisheries on healthier stocks DOES NOT represent a profitable position for any of the fisheries which interact with widow rockfish. Using 2006 levels as a benchmark for measuring impacts is misleading in that 2006 levels are not reflective of healthy fishing communities. Total widow catches prior to the groundfish fishery disaster declaration in 2000 were higher with 6,492 mt caught in 1997. The total catch expected in 2006 is 258 mt, a reduction in catch of over 96% as well as a higher percentage reduction in catches of associated species.

YELLOWEYE ROCKFISH

Recommendation

The GAP recommends a ramp-down approach for yelloweye rockfish which results in the following OYs:

- 2007 OY, 23 mt
- 2008 OY, 20 mt
- 2009 OY, 17 mt
- 2010 OY, 15 mt

Fisheries Involved

Yelloweye rockfish are currently caught in several fisheries including:

- Research Fisheries
- Tribal Fisheries
- Limited Entry Trawl – Non Whiting Fisheries
- Limited Entry Fixed Gear Fisheries
- Open Access Directed Groundfish Fisheries
- Open Access Incidental Groundfish Fisheries
    - Pink shrimp
    - Salmon troll
- Washington Recreational Fisheries
- Oregon Recreational Fisheries
- California Recreational Fisheries

Communities Involved

There are at least 31 ports that could be impacted by lower amounts of yelloweye available. These ports include: Aberdeen, Astoria, Bandon, Bellingham, Blaine, Brookings, Cathlamet, Charleston, Chinook, Crescent City, Depoe Bay, Eureka, Everett, Fields Landing, Florence, Garibaldi, Gold Beach, Ilwaco, La Push, Mill Creek, Neah Bay, Newport, Pacific City, Port Angeles, Port Orford, Port Townsend, Seattle, Tokeland, Trinidad, Westport, and Winchester Bay.

Justification for Recommendation

- This "ramp-down" approach incorporates a reduced OY on a yearly basis; however the proposal from the GAP would set 15 mt as the lower bound on the OY. The GAP notes that under the first year of this ramp-down approach the OY would be 23 mt, 36% below the ABC of 36 mt. The 2007 OY also represents a 15% reduction from 2006. Under a ramp-down to 13.5 mt, it is estimated that rebuilding times could increase by approximately 7 months.

- The GAP believes the yelloweye stock will be rebuilding under this scenario in the shortest time possible while taking into consideration the biology of the stock and the needs of the fishing communities

Impacts of Lower OY Values

Tribal Fishery

Under a zero OY alternative, the tribal fishery loses all groundfish and salmon fisheries resulting in an economic loss of $11,685,700 in exvessel revenue.

Limited Entry Trawl – Non Whiting Fisheries

Under a zero OY alternative, the limited entry trawl non-whiting shelf fishery north of 36° N. Lat. would be eliminated. This results in a loss of $6,500,000 in exvessel revenue, which equates to a $19,500,000 economic impact to the affected communities.

Under the low OY alternative (12.6 mt), the limited entry trawl non-whiting fishery is expected to take 0.1 mt (Table 2-14). This same fishery is expected to take 0.1 mt in 2006.

Under the high OY alternative (23 mt in 2007), the limited entry trawl non-whiting fishery is expected to take 0.3 mt (Table 2-21).

Limited Entry Fixed Gear Fisheries

Under a zero OY alternative, the limited fixed gear fishery north of Point Conception would be eliminated. This results in a loss of $15,000,000 in exvessel revenue which equates to a $45,000,000 economic impact to affected communities.

Open Access Directed Groundfish Fisheries

Under a zero OY alternative, the open access directed groundfish fishery north of 40˚10' N. Lat. would be eliminated. This results in a loss of $5,400,000 in exvessel revenue, which equates to a $16,200,000 economic impact to affected communities.

Under the low OY alternative (12.6 mt), the open access directed groundfish fishery is expected to take 0.9 mt (Table 2-14). This same fishery is expected to take 3.0 mt in 2006. This results in a 70% reduction in catch and a loss of $3,780,000 in exvessel revenues, which equates to an $11,340,000 economic impact to affected communities.

Washington Recreational Fisheries

Under a zero OY alternative Washington recreational fisheries that take yelloweye would be eliminated. This results in a loss of $5,000,000 to affected communities (includes total loss of halibut fishery, 50% loss of groundfish fishery, 25% of salmon fishery due to depth restrictions – forced to stay inside of 30 fathoms).

Under the low OY alternative (12.6 mt), the Washington recreational fishery is expected to take 1.6 mt. This same fishery is expected to take 3.1 mt in 2006, an 80% reduction in catch, which results in a loss of $4,000,000 to affected communities.

Oregon Recreational Fisheries

Under a zero OY alternative, Oregon recreational fisheries that take yelloweye would be eliminated. This results in a loss of $45,000,000 to affected communities.

Under the low OY alternative (12.6 mt), the Oregon recreational fishery is expected to take 1.5 mt. This same fishery is expected to take 3.6 mt in 2006 and results in a 59% reduction in catch and a loss of $26,550,000 to affected communities.

California Recreational Fisheries

Under a zero OY alternative, California recreational fisheries that take yelloweye would be eliminated. This results in a loss of $400,000,000 to affected communities.

Under the low OY alternative (12.6 mt), the California recreational fishery is expected to take 1.2 mt (Table 4-45). This same fishery is expected to take 3.7 mt in 2006. This results in a 68% decrease in catch and a loss of $272 million to affected communities.

Sector Specific Comments

California Fixed Gear Fishery

Under the low Bocaccio OY, all recreational and commercial shelf rockfish opportunity would be forced to access shelf species at no deeper than 30 fathoms. This would eliminate access to valued shelf species such as vermillion rockfish as they tend to be in deeper water in the southern California bight. This would also increase pressure on non-assessed nearshore species. The commercial fixed gear impact for directed groundfish fisheries would be $37,500 per limited entry vessel per year. The open access fleet could lose $9,300 per vessel per year. With increasingly smaller profit margins, this amount of a reduction in profit would likely be the end of their businesses.

Northern Open Access Directed Groundfish Fishery

Reducing the catch of midwater schooling black and blue rockfish is the least effective and most expensive way to protect yelloweye stocks. Limiting benthic species that share habitat with yelloweye by moving into shallower water is a much more effective and less costly alterative. The reduction of any catch in open access affects the most impoverished small boats and ports of the northern California and Oregon coast. The ports of Humboldt, Crescent City, Gold Beach, Pacific City and Port Orford all earned vulnerable category status. Garibaldi earned a most vulnerable title. This lost revenue must all come from the profit side of these small businesses. Due to the reduction imposed on our industry over the last six years, any lost income will have a much harsher outcome to open access fishers. Their profit margins have been eroded by raising costs without coinciding price increases. The cost of living has also gone up. This is a critical period for open access fishermen. A reduction in profits would put all open access nearshore fishermen at risk of bankruptcy. In Crescent City alone, 15 fishermen would be displaced. Each of these fishermen rely on rock cod for over ½ their yearly income. Cutting catches would make it impossible to maintain their yearly cash flow.

Southern Open Access

Any reduction in catch of the open access fishery causes a great reduction in profit. Open access boats for the directed groundfish fishery south of 40°10' N. Lat. are generally small vessels run by single family, small businessmen. In some ports, these vessels comprise a large percentage of the fleet.

California Recreational Fishery

It is difficult to estimate the social and economic value of recreational fishing. The groundfish draft environmental impact statement notes that the values they calculated were drawn from the dollars anglers spent pursuing the fishery. In 2005 for example, California Recreational Fisheries

Survey data in northern California records almost 57,000 angler trips for the months of September and October. If "Action Alternative 2" were adopted by the Council, and forced an additional closure for the month of October in north-central, it would lead to a loss of almost $3 million in recreational fishing expenditures.
Another indicator of lost revenue to the state of California is the steady decline of sport fishing license sales. CDFG reports that annual resident licenses sales are down from 2.2 million in 1976 to 1.2 million in 2005. During that time the population of California grew 166%, from 21 to 35 million people, but we lost a million anglers with a drop in sales of 54%. This decline in license sales has cost CDFG over $32 million at a time when budget cuts leave current regulations unenforced because of the lack of wardens in the field.

The fishing public's uncertainty about the allowed species, changing bag limits and seasons remains the prime culprit for this lost revenue. The public has turned away from fishing because they do not understand the rules. The Council should support California Department of Fish and Game (CDFG’s) efforts to simplify the regulations. The main change recreational stakeholders in the north-central region have requested: is expansion of the open depths out to 40 fathoms. We support this mainly for conservation reasons - no additional fish will be taken, despite the estimates in the analysis. The change will merely spread the effort away from minor nearshore rockfish.

The draft DEIS does not include the social value of recreational fishing. Dollar signs cannot describe the value of families fishing for food and fun.

Oregon Recreational Fishery
The charter fleet in Oregon has been reduced from 232 boats in 2001 to 94 boats sampled in 2005. About 25% of the 94 boats are NOT full-time operators – many are small 6-pack boats that are on trailers and may only operate on weekends. Management measures implemented since 2001 have greatly reduced and changed the make-up of the fleet. Many of the full-time operators have already gone out of business. The few full-time operators that are left are barely holding on. As management continues to tighten up it takes less and less restrictions to break the remaining participants.

Under low OY conditions the Oregon recreational fishery stands to lose at least $7.5 million. This equates to 35,187 private trips and 71,427 charter trips lost.

Washington Recreational Fishery
For the Washington recreational fleet, – both private and charter operations are operating under restrictions that are difficult to live with currently and further reductions and restrictions will be devastating. Businesses in all sectors, (hotel/motel, bait and tackle shots, charter offices, etc.) are showing a downturn of as much as 1/3 in revenues from this time last year. This is a cumulative effect of short halibut seasons, fathom restrictions, fuel prices, and a poor economy. Many charter operations have been operating on the margin and any further restrictions are likely to break them and place the stronger businesses into their position. A zero OY on yelloweye, short halibut seasons, reduced salmon opportunity, and bad press involving albacore could result in a fleet reduction similar to the collapse of the salmon in the early eighties. There are no immediately feasible fisheries to fall back on. On Table 7-71 Summary of Percentage Change in Recreational Income Impacts it lists the south and central Washington coasts as 0.0% change, due to the fact that these areas can no longer reduce their take of yelloweye. The assumption that

further restricting opportunity in these areas will result in no change in income is ludicrous. Businesses are substantially reduced because of this year's management measures. Loss of revenue from a zero OY on canary or yelloweye will result in a loss in excess of $5 million.

GROUNDFISH MANAGEMENT TEAM REPORT ON TENTATIVE ADOPTION OF 2007-2008 GROUNDFISH FISHERY SPECIFICATIONS/MANAGEMENT MEASURES AND AMENDMENT 16-4

At its April 2006 meeting, the Council adopted final preferred alternatives for acceptable biological catches (ABCs) for all species and optimum yields (OYs) for non-overfished species. These values are listed in Table 2-1 in the Preliminary Draft Environmental Impact Statement (DEIS) (pages 3-5 in Agenda Item F.2.a, Attachment 1).

In its April 2006 statement for 2007-2008 management specifications (Agenda Item F.1.c., Supplemental GMT Report) the GMT discussed the Council's direction for this management period to "rebuild [overfished species] as quickly as possible, taking into account the status and biology of the stock, the needs of fishing communities, and the interaction of these stocks within the marine ecosystem." The Council provided further direction at that meeting, selecting two suites of preferred overfished species OYs from the lower end of the rebuilding OY range initially slated for analysis. These two alternatives were labeled at that meeting as the "Preferred Low OY" and "Preferred High OY" alternatives.

Under this agenda item, the Council is expected to make final decisions on OYs for overfished species. Additionally, if the Council wants to consider 2007 exempted fishing permits (EFPs), some yield of overfished species needs to be set-aside to accommodate EFP catch. The Council should also provide guidance on recreational harvest guidelines for canary and yelloweye rockfish. These actions will allow the Groundfish Management Team (GMT) and Groundfish Advisory Subpanel (GAP) to focus on recommendations for preferred management measures under Agenda Items F.5 and F.6.

Analytical documents available at this meeting look at the effects of the different OY levels on the environment, focusing on three Action Alternatives. Action Alternative 1 presents a management measures regime based on the Preferred Low OY alternative. Action Alternatives 2 and 3 present management regimes based on the Preferred High OY alternative, but emphasizing different fishing strategies. Summary descriptions of the action alternatives are provided in Agenda Item F.2.a., Supplemental Attachment 5, "Summary of the Biological and Socioeconomic Effects of the 2007-2008 Action Alternatives."

With regard to setting the OYs for overfished species, the Council needs to be aware of the differences in the biology of the different rockfish stocks and, as a result, the varying rebuilding schedules. Table 2-3 and Figure 2-2 in Chapter 2 of the Preliminary DEIS present the rebuilding parameters of the overfished stocks. Figure 2-2 displays the rebuilding yields and the resulting differences in median times to rebuild. Stocks with steep slopes, such as darkblotched, Pacific ocean perch (POP), and widow rockfish, are more productive; stocks with relatively flat lines, such as cowcod and yelloweye, are considerably less productive. Stocks with low productivity will take much longer to rebuild, even in the absence of fishing. Table 2-3, excerpted below, shows a variety of OYs and median times to rebuild, including those for states of no fishing (F=0), and for fishing at the Preferred Low OY and Preferred High OY levels.

	Action Alt. 1 OYs	Rebuilt Date	Action Alts. 2 & 3 OYs	Rebuilt Date	F=0 Rebuilt Date
Bocaccio	40 mt	2021.9	218 mt	2026	2021.1
Canary rockfish	32 mt	2060	44 mt	2063	2053
Cowcod	4 mt	2039	8 mt	2043	2035
Darkblotched rockfish	130 mt	2009.9	229 mt	2010.2	2009.5
Pacific ocean perch	44 mt	2015	100 mt	2015.6	2014.6
Widow rockfish	120 mt	2014	368 mt	2015	2013
Yelloweye rockfish	12.6 mt	2083	23 mt '07 20 mt '08	2083.5	2048

Comparison of years to rebuild (years) for F=0, status quo OY, and OY alternatives for 2007							
	Bocaccio	Canary	Cowcod	DKBL	POP	Widow	Yelloweye
Years to rebuild at F=0	15.1	48.0	29.0	3.5	8.6	7.0	42.0
Years to rebuild at status quo (i.e.: 2006 OY)	23.0	58.4	33.1	4.1	16.5	8.8	113.5
Years to rebuild at Preferred Low OY alternative	15.9	54.0	33.0	3.9	9.0	8.0	77.0
Percent difference in years to rebuild (Preferred Low OY vs. status quo)	-30.9%	-7.5%	-0.3%	-4.9%	-45.4%	-9.1%	-32.2%
Years to rebuild at Preferred High OY alternative	20.0	57.0	37.0	4.2	9.6	9.0	77.5
Percent difference in years to rebuild (Preferred High OY vs. status quo)	-13.0%	-2.4%	11.8%	2.4%	-41.8%	2.3%	-31.7%

Estimates of rebuilt dates for F=0 illustrate **how soon it is possible for each stock to recover to $\mathbf{B_{MSY}}$,** given life history and environmental constraints in the absence of fishing beginning in 2007. These rebuilt date estimates are based on the most recent stock assessments for these species. Depending on data and methods used, the rebuilt dates for these species could be revised in future stock assessments, even in the absence of fishing.

In our April 2006 statement on 2007-2008 harvest levels, we recommended, and we continue to recommend, that the Council **take into account the status and biology of the stocks** by:

- Looking at the depletion rates of each overfished species and the sensitivity of those species to changes in OY to structure suites of OYs that focus protection on the more sensitive species. The species with rebuilding times that are most sensitive to changes in OY are canary rockfish, yelloweye rockfish, and cowcod. We believe that the suites of Preferred Low and Preferred High OYs appropriately focus greater protection on the species more sensitive to OY changes.

- We also recommended that the OYs for overfished species include allowances for research catch, in order to ensure that future information could be gathered on the status and biology of these and other fish stocks. In setting the Preferred High OY alternative, the Council heeded our advice and included research catch amounts in the component overfished species OYs. Extractive scientific research under the Preferred Low OY alternative would come at a cost of further lost fishing opportunity. For the purpose of estimating economic effects of the Preferred Low OY alternative, the GMT assumed that there would be no Exempted Fishing Permits (EFPs) under that alternative.

In order to ensure that overfished species are managed within their rebuilding OYs, projected overfished species mortalities are modeled at the beginning of the year, and subsequent adjustments to management measures are made inseason to keep total catch within the OYs. However, there is uncertainty in both the stock assessments and pre-season projections that need to be considered when setting the rebuilding OYs. Taking this uncertainty into consideration, the GMT makes recommendations below on OYs for specific overfished species.

In its guidance on **taking into account the needs of fishing communities**, the 9th Circuit Court of Appeals stated, “The purpose of the [Magnuson-Stevens] Act is clearly to give conservation of fisheries priority over short-term economic interests. The Act sets this priority in part because the longer-term economic interests of fishing communities are aligned with the conservation goals set forth in the Act.” The 9th Circuit goes on to state “The natural reading of this language, however, is that Congress intended to ensure that overfished species were rebuilt as quickly as possible, but wanted to leave some leeway to avoid disastrous short-term consequences for fishing communities.”

We discussed the three action alternatives and the zero harvest alternative and their effects on fishing communities in terms of: short term economic impacts compared to status quo, short term economic impacts compared to historic economic impacts, short term economic impacts compared to the 2000 disaster declaration by the Secretary of Commerce, and short term economic impacts of each action alternatives when compared to one another. While there is currently no definition that establishes a threshold for identifying “disastrous short term consequences,” there are several precedents that help put the economic impacts of the action alternatives into perspective:

- The Secretary of Commerce’s 2000 commercial fishery disaster declaration for the groundfish fishery;
- The US department of Agriculture defines severe production losses in a county as a reduction countywide of at least 30 percent; and
- The Small Business Administration will make a physical disaster declaration when at least three businesses have uninsured losses of 40% or more of their estimated fair replacement value.

Under the status quo fishery, revenues are lower than when compared to revenues generated in 2000, the year of the disaster declaration. In 2000, 2001, and 2002 groundfish exvessel revenues were approximately $62 million, $52 million, and $43 million respectively. Recreational angler trips numbered an estimated 1,218,000 in 2000, 927,000 in 2001, and 843,000 in 2002.

The action alternatives result in exvessel revenue, recreational angler trips, and income impacts that continue to be lower than when the disaster declaration was made. Changes in personal income are lowest under action alternative 1 and this alternative reduces personal income by $57.6 million from status quo levels (see table 7-68g, page 505 of the Preliminary DEIS). The percent change in income impacts (compared to status quo) under action alternative 1 reduces personal income by more than 40% for many port groups. Action Alternative 2 reduces commercial groundfish fishery income by more than 20% for some port groups. Action Alternative 3 reduces commercial groundfish fishery income by less than 15% for all port groups (see Table 7-70, page 510 of the Preliminary DEIS). Recreational fisheries follow the same general pattern. Action Alternative 1 reduces recreational groundfish personal income by more than 40% for some regions. Action Alternative 2 reduces personal income by more than 40% for some regions. Action Alternative 3 reduces recreational groundfish personal income by more than 25% for several regions, and more than 30% for one region (see Table 7-71, page 511 of the Preliminary DEIS).

In addition to those short-term and large-scale effects of the 2007-2008 action alternatives that are predictable pre-season, the GMT is also concerned with the less predictable effects of the Preferred Low OY alternative, which supports Action Alternative 1. In our April statement on 2007-2008 harvest specifications, we reminded the Council of the uncertainty inherent in inseason groundfish fisheries management, stating "information available on the different fisheries varies in both its quality and abundance – both pre-season, and as we proceed through the seasons." The Preferred Low OY/Action Alternative 1 requires a variety of fisheries to be either severely constrained or closed by January 1, 2007. Any flexibility to respond to management uncertainty would require further closures and constraints upon severely constrained fisheries. It is also expected that the Preferred Low OY/Action Alternative 1 could trigger a host of inseason fishery closures to accommodate fishery information received inseason.

Chapter 3 of the Preliminary DEIS **takes into account the interaction of overfished species within the marine ecosystem**. The rebuilding rockfish stocks on the West Coast and all rockfish more generally, occupy a broad range of ecological niches and trophic roles in the California Current ecosystem, since both juvenile and adult rockfish are important prey items to a wide range of other rockfish, other piscivorous fishes, seabirds and marine mammals. From a holistic perspective, the fishing down of any species, whether to or below target levels, alters energy pathways and has the potential to affect ecological structure. Unfortunately, the research and data necessary to understand such potential impacts, or to develop and adequately parameterize multispecies models to evaluate such impacts reliably, are lacking for most ecosystems, including the California Current.

As a result, there is no foundation upon which to consider the consequences of historical overfishing, or alternative strategies in rebuilding depleted species, with respect to the potential effects or trade-offs to ecological integrity and future sustainability. For several rebuilding species, particularly those at higher trophic levels (piscivorous species such as cowcod, yelloweye and bocaccio), these impacts may be more significant at smaller spatial scales for some habitat types and regions. Existing spatial closures for essential fish habitat protection and overfished species bycatch reduction should provide adequate protection to sustain ecological relationships and interactions. However, there is no meaningful way of quantitatively assessing the risk of undesirable consequences to the ecosystem of choosing one OY alternative over the other. As the estimated impacts to the rebuilding trajectories for most of these species are forecast to be relatively modest, it stands to reason that the potential consequences of the differing OY alternatives to the ecosystem are also relatively modest.

Specific Overfished Species OYs

The results of the most recent round of stock assessments for overfished species were, in general, more optimistic than the prior round of assessments. The exception to this is yelloweye rockfish, which was substantially more pessimistic. As a result of the need to restrict the fisheries based on the new yelloweye assessment, the GMT recommends the OY ramp-down strategy for this species, which results in a lower OY, but would provide time to collect much-needed additional data that could better inform new management measures for greater yelloweye protection.

Cowcod may be viewed as an unproductive stock, similar to yelloweye; however the most recent round of assessments shows this stock is less depleted than previously thought. Because of the more optimistic stock assessment result, a dramatic decrease in the OY may not be necessary like the proposed decrease in the yelloweye OY. The GMT feels that the relatively unproductive nature of these stocks justifies a relatively restrictive management scheme.

Canary rockfish and bocaccio may be viewed as being more productive than yelloweye and cowcod, but less productive than Pacific ocean perch, darkblotched rockfish, and widow rockfish. The GMT recommends adopting OYs for these species that are relatively close to pre-season catch predictions because of the greater depletion and lower productivity of these stocks. While setting an OY close to predicted catch is expected to result in substantial inseason actions to stay within those OYs (because of inseason deviations from pre-season catch predictions), the GMT feels that the productivity of these stocks justifies a relatively more restrictive management scheme.

Pacific ocean perch, darkblotched rockfish, and widow rockfish may be viewed as being less depleted and more productive than the other three depleted species. If the Council wishes to accommodate the GMT's request to allow for uncertainty and management flexibility by building in a difference between the OY and predicted catch, the GMT feels that this difference or "buffer" should be greatest around these species. Doing so would have a relatively small impact on the rebuilding times for these species, but would accommodate management flexibility, reduce the need for inseason adjustments to management, and result in greater stability to the management regime. The GMT would also like to note that when a buffer is set between the expected (scorecard) catch and the adopted OY, the benefits realized in more rapid rebuilding times when actual catches are less than the OY are captured in subsequent stock assessments and assessment updates (as realized catches, rather than OYs, are entered into subsequent assessments as data).

As discussed above, the Council sets harvest levels and management measures pre-season with the expectation that the management measures will adequately constrain harvest to keep total catch within established harvest levels. As each season progresses, new information becomes available, often modifying the assumptions that were made pre-season about catch and bycatch rates. When inseason catch rate estimates vary from pre-season catch rate estimates, the Council takes inseason action to either constrain the fishery to stay within OYs, or liberalize the fishery to achieve OYs for non-overfished species while staying with overfished species OYs. Inseason revisions to management measures are necessary to maintain rebuilding schedules and to prevent overfishing, but the more inseason measures vary from those set pre-season, the less predictable fishing business management becomes for fishery participants.

Species That Are Most Sensitive to Changes in OY

Cowcod While the cowcod stock assessment is data poor, the GMT believes that continued use of closed areas as a management tool would appropriately keeps the catches of cowcod to an acceptable level. The GMT notes that all of the Action Alternatives, including the No Action Alternative, would result in projected cowcod mortalities that are less than the Preferred High OY (by 0.8-4.7 mt). The 8.0 mt Preferred High OY for cowcod is calculated under an 80% probability of rebuilding by T_{MAX}, or a rebuilt date of 2043. Projecting the status quo harvest rate forward would result in an OY of 4.6 for 2007 and 2008, with a rebuilt date of 2040.

Yelloweye Yelloweye rockfish have a life history that illustrates the classic challenge of rebuilding overfished West Coast rockfish stocks – they are slow to mature, have low productivity, and can live in excess of 100 years. Given their low productivity, any incremental change in yelloweye rockfish harvest *levels* can notably change the associated constant harvest *rates*. For example, a 2007 OY of 12 mt would result in a constant harvest rate that would extend the rebuilding period beyond the F=0 rebuilt date by 30 years (from 2048 to 2078), while a 2007 OY of 12.6 mt would result in a constant harvest rate that would extend the rebuilding period beyond the F=0 by 35 years (from 2048 to 2083).

For yelloweye rockfish, the GMT recommends a departure from the Council's practice with other overfished species of setting constant harvest rates that are intended to carry through time to the rebuilt dates. We recommend that yelloweye OYs in 2007-2010 be set at ramping down harvest *levels*, beginning with 23 mt in 2007 and continuing to 20 mt in 2008, ultimately reaching 13.5 mt in 2011. Beginning in 2011, the yelloweye rockfish rebuilding plan would revert to a constant harvest rate of F = 0.0101 through to the rebuilt date of 2083.5. By contrast, an initial 2007 OY based on this harvest rate would result in an OY of 12.6 mt and a rebuilt date of 2083. As points of reference, the 2006 yelloweye OY is 27 mt, with expected total catch currently estimated at 21.1 mt.

By any standards, the yelloweye assessment data are sparse; the assessment is tuned to recreational catch-per-unit-of-effort (CPUE) data with a decreasing period of coverage from south to north, and size and age composition information and fishery independent data are particularly lacking. Additionally, yelloweye rockfish have a low vulnerability to trawl gear (which is why the NMFS trawl survey is a poor index for this stock), and WCGOP data for fixed gear fisheries is minimal. Poor yelloweye rockfish data availability makes provision of a yelloweye research catch allowance critical to future assessment, management and rebuilding efforts. Therefore, the GMT continues to support the ramp-down approach for yelloweye. This approach would provide time for: 1) additional data to be collected through additional and/or enhanced research, such as the International Pacific Halibut Commission survey; 2) fishermen, such as fixed gear fishery participants, and processors who will be affected by the yelloweye rebuilding plan to make decisions that could affect their future businesses; and 3) the Council, its advisory bodies, and the states to identify, explore, and further develop management tools to manage to the lower rebuilding OYs that are anticipated over the next few years.

Yelloweye rockfish are sedentary in nature and tend to favor the high rocky relief, or untrawlable habitat, found off the northern West Coast. Due to their habitat preference, yelloweye rockfish are rarely encountered in trawl fisheries, especially in light of small footrope requirements on the shelf. Most yelloweye harvest occurs in tribal and non-tribal hook and line fisheries, and in recreational fisheries. However, some of the specific rocky relief areas are prime recreational halibut and lingcod fishing areas, while other areas encompass favorite commercial fishing spots. Logbook data, or data on fishing locations by these different fisheries is, for the most part, not collected, and at-sea observations are minimal. Therefore, the states would like to have a series of public meetings with affected stakeholders to develop potential area closures for yelloweye rockfish conservation, which could be in place beginning in 2009, and design and implement a logbook program for fixed gear fisheries. Additionally, further research to examine survivability and recreational gear selectivity may provide information to help design management measures for the 2009-2010 management cycle.

Given the high degree of uncertainty in the assessment, the GMT developed alternatives that target amounts less than the Preferred High OY. For example, the estimated mortalities for Action Alternatives 2 and 3 are 14.3 mt and 18.3 mt, respectively, compared to an initial ramp-down OY of 23 mt, which leaves residual amounts of 4.7-8.7 mt in 2007, and 1.7-5.7 mt in 2008.

Species That Are Moderately Sensitive to Changes in OY

<u>Bocaccio</u> The bocaccio stock assessment demonstrates that recruitment is highly variable and anecdotal evidence suggests there may be a strong incoming year-class. Should this strong year-class become evident, past experience indicates that young bocaccio are difficult to avoid for most fisheries and, consequently, encounter rates would be expected to increase. Additionally, the commercial trawl preseason catch projections for bocaccio have been off by a significant amount (100-200%) as compared to post-season catch estimates in recent years, and fixed gear West Coast Groundfish Observer Program (WCGOP) data, especially for the area south of 40°10'N. lat., is fairly sparse. Therefore, we recommend that the Council consider management measures that would result in preseason catch projections that are significantly less (e.g., around 15-20 mt) than the OY to cover this uncertainty. The GMT notes that Action Alternatives 2 and 3, and the No Action Alternative would result in projected bocaccio mortalities that are significantly less, by 32-107 mt, than the Council's Preferred High OY of 218 mt.

<u>Canary</u> Unavoidable incidental catches of canary rockfish occur in trawl, fixed gear, open access, and recreational fisheries targeting groundfish, as well as commercial and recreational fisheries targeting species other than groundfish. Canary's wide geographic distribution and catchability in all fisheries makes it difficult to manage with species-specific RCAs, like yelloweye rockfish and cowcod. Canary is one of the most constraining stocks in 2007-2008 management. The commercial trawl preseason catch projections have been off by a factor of 75-100% as compared to post-season catch estimates in recent years. WCGOP data for fixed gear is fairly sparse, and there is very little observer data for open access and recreational fisheries. Therefore, the GMT recommends the Council consider management measures that would result in preseason catch projections that are slightly less than the Preferred High OY. All of the Action Alternatives, including the No Action Alternative, would result in projected canary mortalities that are less than the Preferred High OY (by 2.7-10.9 mt).

Species With OYs Affected by the Rebuilding Paradox

Darkblotched In the recent past, the commercial trawl preseason catch projections for darkblotched rockfish have been off by as much as 250% as compared to post-season catch estimates. Darkblotched is rarely caught by fixed gear and recreational fisheries. While the GMT has significantly increased the precision in its catch estimation methodology over the past year, inseason data indicates that actual catches are still about 50% higher than what was projected preseason for 2006. Additionally, this species is nearing its rebuilt level, with particularly strong year classes from 1999 and 2000 that are now entering the fishery. Between 2000 and 2005, both the biomass and the spawning output of darkblotched roughly doubled. The biomass is expected to increase by an additional 40% from current levels by 2010, with spawning output doubling again in that period, at which point the stock is expected to be rebuilt based on the assessment point estimate.

This rapid darkblotched stock increase means that there would likely be increased encounter rates for darkblotched in 2007 and 2008 (i.e., the "rebuilding paradox" of not being able to avoid higher catches as the stock approaches target biomass levels.) Therefore, the GMT recommends the Council consider including a relatively high amount of OY to cover this rebuilding paradox and continued catch projection modeling uncertainty. The GMT notes that, while the Action Alternatives, including the No Action Alternative, all result in projected darkblotched mortalities that are less than the Preferred High OY (by 18.2-32.5 mt,) the amount of residual may not be sufficient to address the high variability in encounter rates as the stock rebuilds. As a potential consequence of variable encounter rates, darkblotched bycatch may jeopardize commercial slope fisheries such as the DTS and winter petrale fisheries. The Council has repeatedly heard testimony from industry on the importance of winter petrale and DTS fisheries in maintaining a permanent work force, and avoiding loss of markets to other supply sources which, once lost, can be difficult to regain.

Pacific ocean perch The commercial trawl preseason catch projections for Pacific ocean perch (POP) have been off by as much as 100% as compared to post-season catch estimates in recent years; however, the GMT has significantly increased the precision in its catch estimation methodology over the past year, especially for trawl. Like darkblotched, POP is rarely caught by fixed gear and recreational fisheries. However, POP is also nearing its rebuilt level, so there would likely be increased encounter rates for POP in 2007 and 2008. Therefore, the Council may wish to consider including a relatively high amount of OY to cover the rebuilding paradox and this uncertainty. Similar to darkblotched, unless there is sufficient OY available to address these items, POP will likely constrain commercial slope fisheries. However, unlike darkblotched and other overfished stocks, there is expected to be hardly any residual for POP (i.e., no residual for Action Alternatives 1 and 3, and a residual of 1.5 mt in Action Alternative 2). This is because the OYs analyzed for the Action Alternatives for POP for 2007 and 2008 (which are 44 mt and 100 mt) are significantly reduced from the 2006 OY level of 447 mt. These reduced OYs were not the result of the recent stock assessment or rebuilding plan, but were proposed from recent catch levels in the commercial slope fisheries, which are more significantly constrained by darkblotched rebuilding levels.

Widow Rockfish For widow, the commercial trawl preseason catch projections have been off by as much as 100% as compared to post-season catch estimates in recent years; however, the GMT has significantly increased the precision in its catch estimation methodology over the past year, especially for trawl, and catches of widow are small in fixed gear and recreational fisheries. However, widow is also nearing its rebuilt level, so there would likely be increased encounter rates for widow in 2007 and 2008. Therefore, the GMT recommends the Council consider management measures, which would result in preseason catch projections that are slightly less than the Preferred High OY. Action Alternatives 2 and 3, would result in projected widow rockfish mortalities that are significantly less than the Preferred High OY (by 176-224 mt); however, Action Alternative 1 with the low OY for widow has little residual (3.8 mt) remaining.

Harvest Guidelines for Canary and Yelloweye Rockfish

The Council needs to set separate harvest guidelines for canary and yelloweye rockfish for the recreational fisheries, to be divided at the Oregon/ California border. Under status quo management the Council had adopted harvest guidelines for canary and yelloweye recreational fisheries. The 2006 scorecard represents these harvest guidelines; the 2005 scorecard reflects the end-of-season fishery impacts that actually occurred. Following Council guidance at its April 2006 meeting, the GMT constructed scorecards representing different allocation scenarios (Tables 4-43 through 4-47 in Agenda Item F.2.a Attachment 2, pages 133-140). The recreational fishery harvest guideline alternatives in the table below are taken from those scorecards. These harvest guidelines represent proportional reductions from the 2005 or the 2006 scorecard in order to constrain total mortality below the Preferred Low or the High OY alternatives. One scenario depicts the harvest guidelines if all of the canary and yelloweye rockfish were allocated to the recreational fisheries.

Canary Rockfish recreational harvest guideline/ target alternatives

			High OY		Low OY			
	2006 scorecard		Using 2006 scorecard	Using 2005 scorecard	Using 2006 scorecard	Using 2005 scorecard	All Rec, w/ 2006 scorecard	All Rec, w/ 2005 scorecard
WA	8.5		1.6	1.4	1.1	1.6	2.1	4.7
OR			6.6	5.4	4.3	4.1	8.3	12.1
CA	9.3		9	2	5.9	1.7	11.4	5

Source: Tables 4-43 to 4-47 in Agenda Item F.2.a Attachment 2, pages 133-140

Yelloweye Rockfish recreational harvest guideline/ target alternatives

			High OY				Low OY			
	2006 scorecard		Using 2006 scorecard		Using 2005 Scorecard		Using 2006 Scorecard	Using 2005 Scorecard	All Rec, w/ 2006 scorecard	All Rec, w/ 2005 scorecard
			2007	2008	2007	2008	2007-8	2007-8	2007-8	2007-8
WA	6.7		3.5	3	5.4	4.4	1.6	2.4	2.6	3.9
OR			3.2	2.7	4.2	3.5	1.5	1.9	2.3	3.1
CA	3.7		3.7	3.1	0.9	0.8	1.7	0.4	2.7	0.7

Source: Tables 4-43 to 4-47 in Agenda Item F.2.a Attachment 2, pages 133-140

** Note that Table 4-61 (p. 154 in F.2.a Attachment 2) gave the California recreational 2006 harvest guidelines, rather than the no action impact estimates. The no action impact estimates should be 6.1 mt for canary rockfish and 1.5 mt for yelloweye rockfish. The no action impact estimates are correctly listed for the other states in Tables 4-59 and 4-60.

HABITAT COMMITTEE REPORT ON TENTATIVE ADOPTION OF 2007-2008 GROUNDFISH FISHERY SPECIFICATIONS/MANAGEMENT MEASURES AND AMENDMENT 16-4

John Field of the Groundfish Management Team briefed the Habitat Committee (HC) on the potential opening of parts of the California Cowcod Conservation Area (CCA) to certain gears. The HC had concerns that the parts of the CCA that may be opened contain black corals, which are highly sensitive to disturbance.

A portion of the CCA (CCA East) has already been identified in the Groundfish Essential Fish Habitat Environmental Impact Statement as an ecologically important area. However, new information described in the groundfish annual specifications for 2007-2008 (Tissot et al. 2006) notes that high concentrations of newly described species of black corals are found in both the Potato Bank and Santa Barbara Island areas. Information is sparse regarding the associations of groundfish with habitat-forming invertebrates and coral. However, given the vulnerability of this habitat and the limited coverage of the Tissot survey, we urge the Council to maintain the status quo. At a minimum, we urge the Council to consider an option that would leave closed the high-density coral areas described in the paper.

Modifying the CCA demonstrates the complexities involved in multi-species management; taking one action, such as opening these areas, would affect a number of rockfish and other species. Maintaining a stable CCA provides an opportunity to develop an ecosystem management approach over time, although this was not the original purpose for creating the CCA.

SCIENTIFIC AND STATISTICAL COMMITTEE REPORT ON TENTATIVE ADOPTION OF 2007-2008 GROUNDFISH FISHERY SPECIFICATIONS/MANAGEMENT MEASURES AND AMENDMENT 16-4

Mr. John DeVore met with the Scientific and Statistical Committee (SSC), and provided an overview of important issues contained in the reference documents under this agenda item. Most of the analytical methods and technical issues associated with the impacts analyses presented in these documents have previously been reviewed by the SSC. Therefore, SSC discussion of the documents focused on a few topics under consideration for 2007 which were either newly developed, required further clarification, or have become of higher importance than in past years.

The SSC notes that among the management proposals in Draft Amendment 16-4 (Agenda Item F.2a, Attachment 3), there is an option on page 27 where "…the Council may establish a research reserve for any stock, that is within the ABC but above and separate from the OY for that stock." If adopted, this would represent a significant change from the way that mortality associated with research activities has been previously accounted for in groundfish management. Potential advantages to this approach are that the fishery would not be subject to early closure due to unexpectedly high research catches, and research could continue unhindered under most situations, thus providing crucial information that is not otherwise available when stocks are under rebuilding constraints. Total catch accounting means that the catch series used for assessment and rebuilding analyses includes research catches.

The evaluation of action alternatives for cowcod (Agenda Item F.2a, Attachment 3, pages 72-73) raises the issue that modifying the current Cowcod Conservation Area (CCA) boundaries could undermine the ability to replicate the recent submersible survey within the CCA. The SSC notes that the methodology used in conjunction with the previous survey to extrapolate the findings over other habitats outside the CCA would not be appropriate for future surveys, and therefore CCA management consistency would not be an issue with respect to future survey work. Of greater importance is that fishing mortality is no longer distributed across all areas, and hence future surveys should be conducted both inside and outside the CCAs, so that the abundance extrapolations may be stratified accordingly. While there may be good reasons to consider not changing the CCA boundaries, possible impacts to future survey work is not one of them.

The economic impact analyses take into consideration current economic effects, but not how these effects may change through time. For example, it is not clear how an economic sacrifice today may be mitigated by increased revenue due to higher abundances at a future date, or how loss of current fishing opportunities may result in loss of port infrastructure that reduces future fishing opportunities. A dynamic benefit-cost analysis would help inform the Council on these trade-offs. However, such an analysis would need to project forward for all fisheries and sectors impacted by overfished species, which would be a complex undertaking.

PFMC
06/13/06

Notes from SSC to John DeVore:

Clarifications and recommendations for reference documents

- *The analyses that report time to rebuild in fractional years imply greater precision than is appropriate. Round rebuilding times to nearest whole year.*
- *Care should be taken to not make value judgments in the analyses. For example, the risk associated with canary rebuilding is not much different among alternatives, and therefore the expected duration of rebuilding should be highlighted among alternatives, rather than risk of not rebuilding.*
- *It would be useful to present the difference in rebuilding times in both absolute years and as percent change. For example, a hypothetical one year increase is negligible if the rebuilding time is 70y, but it is a 50% increase if the rebuilding time is 2Y.*
- *Table 1 in Supplemental Report 5 should be appended to include community impacts.*
- *In Draft Amendment 16-4, it should be clarified that the year that a stock is expected to be rebuilt is not an absolute. Statements such as "the year in which the stock would be rebuilt…(page 39)" should be revised to convey less certainty.*
- *It would be desirable to clarify the notion of a stock. In particular, for a situation such as lingcod where it has a continuous latitudinal distribution but clear geographic differences in progress toward rebuilding, it may be appropriate to have an established mechanism or process to identify a "unit to conserve" that is smaller than the overall stock.*

Re: 2007-2008 Groundfish management

Dear Chairman Hansen;

The Westport Charterboat Association would like to go on record in support of the "phase-in" approach to the rebuilding OY for Yelloweye Rockfish.

Over the past six years our fleet in Westport has reduced it's YE mortality from around 1,400 per year in 1999 to less than 200 in 2005. That's an 85% reduction. This has been accomplished through both regulation and avoidance of areas that are prone to YE encounters. Although further reductions are possible, the social and economic cost becomes quite large. We would lose access to the more abundant species that our livelihoods depend upon.

We understand that a phase in approach would result in a slightly longer rebuilding time. The delay involved in a phase-in gives us precious time to generate more data and even more effective management measures. We are also concerned with a management process that considers Yelloweye coast-wide. Yelloweye are sedentary and live in specific areas virtually all their lives. Although they may be the same critter genetically, they don't migrate up and down the Coast. It makes all the sense in the world to manage these fish regionally. That would go a long way toward reducing localized depletion.

We have always worked in a proactive fashion regarding conservation of Rockfish species. The history of our reduction of impacts on this species speaks for itself and we ask that you adopt a phased-in approach to Yelloweye management to give time for the acquisition of better data and the development of a more appropriate management philosophy.

Thank you for your consideration,

Steve Westrick, President
Westport Charterboat Association

What a waste...
Recreational fisherman are 'harvesting' over 9 metric tons of canary and yellow eye? You're numbers were based on 100% mortality. Even at 66% don't you think you're off the mark? Don't bother answering that. Quit wasting the fish while you can't make a decision to stay away from them. Set a better guideline, a scientifically realistic one. Then keep the incidentally caught fish until the guideline is met then close the area. I've seen the fish returned and not floating after properly deflating the bladder. Address the real issue - COMMERCIAL HARVEST!!!!!   HELLO!!! U.S. and International.
We're getting tired of getting, or not getting what's left over after the state gets done with the commercial harvest interests...

RE: Cow Cod Conservation Area

Mr. John Devore and all Council members,

I would like to provide some new information and clarify a few points I made earlier for the Council members, concerning the possible reconfiguration of the outer boundary of the CCA. I would appreciate these remarks finding their way to the Council briefing book in time for the June meeting.

First off, this issue would not be a subject for discussion had the Point Conception Groundfishermen's Association not gone to the May, 2005 CA Fish and Game Commission in Sacramento. After three years of our members writing numerous letters and making multiple telephone calls to our State representatives regarding the onerous nature and burden the CCA presents to fishermen; the Commission had to direct their Department to get "off their asses" and address this. Fishermen had previously been ignored.

The Council needs to clearly understand the facts of this issue so they can make a decision based on the ***best science available*** and ***their responsibility*** to fishermen under the Regulatory Flexibility Act.

This is not a dispute over the health of cow cod stocks. They may or may not be over fished, but without question the data shows their abundance is increasing exponentially faster than past projections. ***This is*** a dispute about the areas ***closed*** to ***protect*** cow cod.

The West Coast Ground fish Observer program was implemented and touted as a critical tool to get factual information, good or bad for our various ground fisheries. One particularly interesting statistic discovered from this program is that for **6,285 observed sets**, south of 40°10′, between August 2001 and April 2006 for fixed gear deeper than 150 fathoms, there was a total of ***zero*** cow cod taken. Please refer to the enclosed letter from Janell Majewski, WCGOP Lead Debriefer and

Trainer. If no cow cod are being taken, why is 70% of the CCA in depths greater than 150 fathoms?

What the affected fishermen in Southern California are proposing is that the present outer boundary for the CCA be changed to replicate the 175-fathom curve instead of the existing straight line, big block approach that encompasses depths as great as 1000 fathoms. Special conditions that ***only vessels with VMS*** are allowed inside the existing CCA with ground fish aboard. Though the data clearly shows no interaction with cow cod to as shallow as 150 fathoms (the outer boundary of the RCA's in so. Ca.) The fishermen proposed 175 fathoms, leaving a 25-fathom buffer zone.

At this point, it seems the biggest obstacle to this proposal has been the unwillingness of the 'enforcement consultants' to consider at even the smallest level, the benefits this action would have for the fishermen versus their fears of some massive assault on their ability to enforce the proposed CCA boundaries. Lets put the facts out on the table. First of all, the boats fishing in the CCA areas would have VMS. Enforcements arguments about VMS not being adequate because of the lack of data sharing, or the Feds being incompetent just don't hold water. Please take a look at enclosed article from the Chinook Observer, a recent example of the effectiveness of VMS. Furthermore, our proposal has a VMS zone miles from the 175-fathom curve for the entire CCA. Please refer to enclosed chart. We are talking about a very small fleet, a total of nine vessels. The State enforcement personnel have a wide range of tools besides VMS at their disposal. Wouldn't it be great to hear what the Department ***can do*** rather than their persistent whimpering about what they cannot do?

It is time somebody stands up for the fishermen whose livelihoods have been so negatively impacted by this over reaching and unnecessary closure. Please support changing the outer boundary of the ***entire*** CCA to 175-fathoms.

Sincerely,

T. Athens

Mr. Tim Athens
Neptuneabs@aol.com

Hello Mr. Athens,

In April of 2006, you requested information on observed cowcod rockfish catch by fixed gear fishers outside of 150 fathoms and South of Point Conception from the West Coast Groundfish Observer Program. We were able to process this request with one modification.

Currently, the program only stratifies data geographically by North and South of 40°10′N latitude. Therefore, this is the stratification used for your data request.

Results: In the 6,285 observed sets, there have been zero occurrences of cowcod rockfish in the limited entry and open access fixed gear fisheries outside of 150 fathoms, South of 40°10′N Latitude, between August 2001 and April 2006.

As you can see from the results, the modification of your request has no bearing on the outcome.

Thank you for patience in filling this data request. If you have any questions, please don't hesitate to contact me at (206) 860-3293.

Sincerely,

Digitally signed by Janell Majewski

Fisheries bust details found in court documents

Ken Greenfield Jr. allegedly violated laws protecting Pacific ground fish

By NANCY BUTTERFIELD
Observer correspondent

Wednesday, May 10, 2006

CHINOOK — When about 50 state and federal law enforcement officers descended on the Port of Chinook the morning of April 25, they not only arrested suspected illegal immigrants, they also served a search warrant on three fishing vessels at the port, at the Garda Marie Seafood Co. in Chinook and at the Bell Buoy Crab Co. fish-processing plant.

In an application and affidavit for a search warrant filed by Michael Adkins in U.S. District Court in Seattle by the National Oceanic and Atmospheric Administration/National Marine Fisheries Service Office of Law Enforcement dated April 20 and signed by U.S. Magistrate Judge Karen L. Strombom, agents found probable cause of violations of the Lacey Act by the fishing vessels Garda Marie, Renee Maria and Rememberance, the home office of Garda Marie Seafoods and the Bell Buoy processing facility.

Adkins is a special agent with the U.S. Department of Commerce, NOAA and NMFS OLE and is charged with enforcing fish and wildlife laws.

The Lacey Act is a federal statute which prohibits the sale, trade or transportation of wildlife or wildlife products harvested or attained in violation of federal, state, tribal or foreign laws.

The investigation into the fishing practices by the owner of two vessels at the Port of Chinook marina, Kenneth Greenfield Jr., and by Bell Buoy Crab Co. began in September last year. The search warrant was issued to search the three fishing vessels at the Port of Chinook marina, the home office of the owner-operator of the Garda Marie and the Renee Maria, Greenfield, and Bell Buoy, for alleged preparation and submission of false documents related to unlawfully taken sablefish, also known as black cod.

According to the warrant, he investigation centered on fishers operating out of the Chinook marina.and selling catches to Bell Buoy Crab Co. Sablefish, and more than 80 other species, are managed under the Pacific Coast Groundfish Fishery Management Plan.

Regulations require fish receiving faciliities to complete a "fish receiving ticket" immediately upon receipt of federally regulated groundfish from commercial fishers. A copy of the ticket must be given to the commercial fisher at the time of purchase or delivery and a copy must be retained by the dealer. Tickets must be signed under penalty of perjury as being accurate by the dealer and the fisher. Federal and state regulations prohibit the falsification of, or failure to make or file, tickets for groundfish species managed by PCGFMP.

A confidential informant contacted a Washington Department of Fish and Wildlife enforcement officer, according to the warrant, saying that the operator of a commercial fishing vessel operating out of Port of Chinook was exceeding the weekly trip limit — Kenneth Greenfield Jr, operating FV Garda Marie, who had allocated a portion of the catch to the Renee Maria. That vessel allegedly hadn't left the marina on the day in question.

Investigators also looked into additional discrepancies related to the fishing activity last August of Robert T. Greenfield, Kenneth Greenfield's brother, operator of the FV Rememberance, also at Chinook marina, a limited entry vessel, who allegedly recorded catching 884 pounds of black cod on the FV Rememberance, which allegedly didn't leave the port that day.

The informant said Greenfield had allegedly engaged in similar conduct on several occasions throughout the 2005 sablefish season, according to the affidavit.

Adkins said in the affidavit he believed that Bell Buoy was submitting falsified tickets in an apparent effort to under-report sablefish catches.

In November 2005, Adkins said he determined "that Bell Buoy had submitted 17 tickets on which trip limits for sablefish were exceeded [and] none of the overages had been reported to state or federal officials." He said a review of tickets submitted by Bell Buoy "disclosed additional discrepancies related to the fishing activity of Robert Greenfield."

"A ticket dated Aug. 20, 2005, reported that Bell Buoy purchased 884.8 pounds of sablefish from Robert Greenfield off the R/V Remembrance. My review of the Vessel Monitoring System data recorded on Friday, Aug. 19 and Saturday, Aug. 20, indicates that the Rememerance did not leave the marina on either date."

Investigators interviewed numerous people involved at the Port of Chinook and at Bell Buoy about how sablefish catches were being reported at Bell Buoy. The investigation caused a NOAA/NMFS officer to believe "Bell Buoy was submitting falsified tickets in an apparent attempt to underreport sablefish catches. Underreporting allows vessel operators to overfish and then provides Bell Buoy with more fish to process and sell," according to the affidavit..

Additional discrepancies listed in the affidavit related to the fishing activity of Robert T. Greenfield, operator of the FV Rememberance, also at Chinook marina, a limited entry vessel, recorded 884 pounds of fish from the Rememberance, which allegedly didn't leave the port that day in August.

An agent interviewed Robert Greenfield, who said he was sport fishing for salmon on that day and that the records must be wrong. But, according to the affidavit, his signature was on the ticket.

RE: Modify Cowcod Conservation Area

Dear Council Members,

I am writing to support the proposal to modify the Cowcod Conservation Area (CCA) boundaries. This proposal is contained within your upcoming groundfish regulation package. The proposal will modify the CCA to allow fishing in depths greater than 175 fathoms. This modification is an adaptive management action that will provide access to abundant fish stocks that are currently lock up inside the CCA without harming over fished species or their recovery efforts. This action is constant with the PFMC's Strategic Groundfish Plan and will provide need economic relief to our local groundfish fishery and fishing infrastructure.

The decision to modify the CCA to depth shallower than 175f is based on two factors:

1) Biological considerations
2) Enforcement considerations

I request that you ask the following question before you vote on this important action:

Factor 1) Biological considerations:

Question 1. Is there any biological harm to current rebuilding programs or overfished stock that this change would cause?

Question 2. Do we have observer data to support a decision to allow fishing below 175f?

The PFMC Groundfish Fishery Strategic Plan states: *"(b) Strategic Plan Goal for Observer Program"*
"To quantify the amount and species of fish caught by the various gears in the groundfish fishery and account for the total fishery related removals"

The observer program has generated the information required to answer questions relating to factor 1)'Biological Considerations'. Answer-NO HARM

Factor 2) Enforcement Considerations

Question 3.How can we balance enforcement simplification with the economic viability of the fishery?

The strategic plan provides some insight into balancing competing goals. Adaptive management is a high priority goal. VMS and the observer program provide important tools to achieving adaptive management that did not exist when the CCA was originally created.

The PFMC Groundfish strategic Plan states under 'COUNCIL PROCESS AND EFFECTIVE PUBLIC INVOLVEMENT'
(b) STRATEGIC PLAN GOALS for COUNCIL PROCESS:
A. *To establish and maintain a management process that is transparent, participatory, understandable, accessible, consistent, effective credible, and* ***adaptive:***

B. *To provide a public forum that can respond in a timely way to the* ***needs of the*** *resource and the* ***communities*** *and individuals* ***who depend on them****: and*

C. *To establish a long-term view with clear, measurable goals and objectives.*

Question 4. Why has the PFMC adopted the VMS program if it is not intended as in enforcement and monitoring tool to allow this type of adaptive change?

Question 5. How is enforcement able to enforce a depth based modified Rockfish Conservation Area (RCA) North of 40.10. N. lat.for Limited entry Trawl Gear (NMFS-SEA-06-03) but not a depth based modified CCA area for Limited entry Fixed Gear?

Question 6. How is enforcement able to enforce three different depth definitions of the RCA South of 40. 10. N lat. (75fm-150fm along mainland coast, 150fm around islands in JAN and Feb, 100fm-150fm Mar-OCT and 75fm-150fm in Nov-Dec, if they are unable to enforce a 175-depth definition of the CCA?

Question 7. Why didn't the enforcement wing of the CDFG object to enforcing 40 individual boundary lines for the 12 marine reserves and MPA at the Channel Islands, if enforcing changes to the CCA is so difficult?

Question 8. Is enforcement using, "enforceability" of the CCA modification, as a tool to mask a DFG policy preference to retain the current CCA boundaries?

Please use adaptive management and provide us with needed regulatory relief.

Sincerely,

Chris Hoeflinger,
Fishery Representative, Channel Island National Marine Sanctuary, Sanctuary Advisory Council

Re: Draft Amendment 16-4 and 2007-2008 specifications and management measures for the Pacific groundfish fishery

Dear Mr. DeVore:

We are writing on behalf of the Natural Resources Defense Council (NRDC) and NRDC's more than 550,000 members to comment on the draft plans for Amendment 16-4 and the 2007-2008 specifications and management measures (specifications) for the Pacific groundfish fishery. Please include these comments in the June 2006 briefing book.

Overview

We have reviewed the Council's draft proposals from the April briefing book for new rebuilding plans and for the 2007-2008 specifications. We are encouraged by the apparent improvements in the biological condition of a number of the overfished species, and hopeful that the Council will develop a rebuilding approach that applies the shortest time period possible. However, such an approach is not yet clearly in evidence. We are concerned that the Council may use the more optimistic stock assessment results to increase short-term catch levels instead of reducing rebuilding time periods. We also remain concerned that some species (e.g. canary and bocaccio) are still at extremely low levels—in the range of 10% of historic biomass. Although some of the rebuilding alternatives being considered appear to include satisfactorily short rebuilding periods in light of the recent Ninth Circuit decision, NRDC v. NMFS, 421 F.3d 872 (9th Cir. 2005), the fact remains that many of the alternatives do not. Additionally, the proposed plans continue to be based on some of the same fundamentally flawed methodologies as the existing plans, as well as some new ones.

Rebuilding Alternatives

Based on the information available in the April 2006 Briefing Book, many of the proposed rebuilding plan and Optimum Yield (OY) alternatives repeat the problems of the existing plans. Despite ample language to the contrary, the new rebuilding plan alternatives currently under consideration provide no assurances that rebuilding periods will be "as short as possible" or mortality levels as low as possible. Indeed, many of the proposals continue to delay rebuilding beyond what the law requires, and do so by increasing mortality levels.

Rebuilding methodology

The Council acknowledges that NRDC v. NMFS "requires a reconsideration" of the existing rebuilding framework. PFMC, April Briefing Book, Agenda Item F.1.a, Attachment 2, at 5 (April 2006). The existing framework allows the Council to select any target rebuilding date (Ttarget) between the minimum time needed to rebuild in the absence of all fishing (Tmin), and Tmin plus one mean generation time (Tmax), even if that Ttarget is decades longer than Tmin. The Ninth Circuit held that the Magnuson Stevens Act's requirement to rebuild in a time period that is "as short as possible" "cannot be reconciled with a rebuilding period that is from 20 to 33 years longer than the biologically shortest possible rebuilding period...even granting the Agency some leeway in extending rebuilding periods" beyond Tmin. NRDC v. NMFS, 421 F.3d 872, 882 (9th Cir. 2005). Tmax, which is decades longer than Tmin for all of the overfished species, is an impermissibly long time period for rebuilding, and thus inherently illegal.

Nonetheless, many of the rebuilding alternatives being considered in the draft Amendment 16-4 either are pegged to and derived from Tmax, or would set Ttarget decades beyond Tmin, or both. For example, canary rockfish currently has a Ttarget of 2074, which is 17 years longer than the current Tmin. Under the new proposal and according to new stock assessment data, the new Tmin is moved from 2057 to 2048, but the three rebuilding alternatives being considered would establish new Ttargets that are 10, 15, and 23 years longer than the new Tmin, respectively. The longest of these alternatives actually sets Ttarget at Tmax, and so clearly would be illegal if adopted. These alternatives, and the methodology used to develop them, exemplify the potential gap between the Council's statements that the new rebuilding plans will comply with the Ninth Circuit's opinion and the reality of what is being proposed.

While the clear illegality of Tmax sets a definable outer bound for an illegally long rebuilding period, still at issue in the draft of Amendment 16-4 is how much "leeway in extending rebuilding periods" beyond Tmin the Council is allowed and how it must make that decision. The Ninth Circuit explained that the "leeway" was intended "to avoid disastrous short-term consequences for fishing communities." NRDC v. NMFS, 421 F.3d at 880. The Court provided the following example of disastrous consequences:

> "[E]ven if a fishing community is actively seeking not to fish for a certain species, it will inevitably catch some of the overfished species in the process of fishing for other, more plentiful fish-what is known as "bycatch." Because almost no groundfish that are caught as bycatch survive even if they are thrown back into the ocean, an absolute ban on catching any of a species of groundfish could mean *a total moratorium on all fishing in the parts of the fishery containing groundfish*, with obvious adverse consequences for fishing communities. Section 1854(e)(4)(i), then, allows the Agency to set limited quotas that would account for the short-term needs of fishing communities (for example, to allow for some fishing of plentiful species despite the inevitability of bycatch), even though this would mean that the rebuilding period would take longer than it would under a total fishing ban."

Id. (emphasis added). Thus, the court's example of "disastrous short-term consequences for fishing communities" is a total moratorium on all fishing due to an absolute ban on any bycatch of overfished species. NRDC is not suggesting that a complete moratorium on groundfishing is a feasible or desirable outcome.

The Council seems to be interpreting very broadly what economic "leeway" it is permitted to take in extending the lengths of rebuilding plans beyond Tmin. It is currently engaged in a detailed economic analysis that will consider and attempt to quantify the specific cost of different rebuilding periods on individual fishing communities. The analysis looks at two things: (1) what targeted species are caught from which ports, identifying whether the impacts of restricting bycatch on co-occurring overfished species would be High, Medium, or Low/No; and (2) the relationship between exvessel revenue and overfished species mortality. The Council is quantifying the specific economic effects of various mortality levels for overfished species (based on various rebuilding alternatives) but has yet to explain how the two are connected. There is no definable threshold (or even a discussion of the need for one) of what amount of economic impact – either by exvessel, by community, or both – would constitute "disastrous short-term consequences." Absent a threshold and any explanation of how the rebuilding alternatives relate to the economic analysis, the various rebuilding alternatives (and their associated mortality levels) cannot be assessed to determine whether they exceed the amount of economic "leeway" allowed by the Ninth Circuit's decision.

What is clear, however, is that the short-term economic needs of an individual fishing community do not constitute the broad type of "disastrous short-term economic consequences" described by the Court. Taking into account the short-term needs of fishing communities by providing some economic leeway in rebuilding times and mortality levels does not mean that the needs of a particular fishing community that is highly dependent on one or more overfished species can trump the requirement to rebuild as quickly as possible. The economic analysis must factor in the long and short-term economic needs of the entire fishery, and even then, cannot prioritize those needs over the clear priority given to conservation in the Magnuson-Stevens Act. We do not have enough information at this stage to know how the Council intends to use the new analysis. However, a potential use for the results of the analysis - to balance, or arguably prioritize, the needs of the fishing communities over the need to rebuild as soon as possible - conflicts with the Council's own interpretation of the Ninth Circuit's opinion currently contained in draft Amendment 16-4:

> "These actions must also conform to a recent court ruling in the Ninth Circuit Court of Appeals, which held that, among other things, *the purpose of the MSA is to give conservation of fisheries priority over short-term economic interests.* The Court interpreted the rebuilding requirements of the MSA as: 1) the rebuilding periods must be as short as possible; 2) short-term needs of fishing communities may be taken into account in setting rebuilding periods, even when the biology of the species dictates exceeding the 10-year statutory cap. As an example, the Court noted that in order to avoid disastrous short-term consequences, NMFS may set limited quotas that allow for some fishing of plentiful species, despite the inevitability of bycatch."

PFMC, April Briefing Book, Agenda Item F.1.a, Attachment 2, at 1 (April 2006) (emphasis added).

A fundamental question is how low bycatch levels of overfished species can be set without triggering disastrous short-term consequences. The Council has yet to directly address this question, although many of the rebuilding periods and associated mortality rates currently contained in the draft Amendment 16-4 alternatives are longer than what the current rebuilding plans allow and, at any rate, decades longer than Tmin. On that basis alone, many of the alternatives repeat, and some even exacerbate, the problems that exist in the current plans.

The Council may not extend a rebuilding period or Ttarget based on new optimistic stock assessment data. Nor may it use more optimistic data to increase mortality levels while leaving Ttarget alone. "As short as possible," providing some leeway, does not allow for longer periods unless the stock declines unexpectedly in the middle of a rebuilding period and maintaining the same Ttarget would lead to "disastrous short-term consequences." The economic leeway provided under a plan in one year cannot be expanded based on better data without making Ttarget shorter. The leeway remains the same because the "disastrous short-term consequences" that are avoided one year can presumably be avoided the next at the same low catch level.

The Council is developing a new framework for determining rebuilding periods and the annual specifications that flow from rebuilding plans. It cannot replace the existing defective framework with a less formulaic, and thus equally problematic structure. Until the Council adopts rebuilding plans that comply with the law, the Council must adopt mortality levels and accompanying management measures that lead to the shortest rebuilding period, including some leeway to avoid catastrophic economic consequences.

Additional suggestions

We have other suggestions regarding the rebuilding approach described in the draft Amendment 16-4. We urge the Council to include in any new rebuilding approach special consideration for stocks that are at levels approaching 10% of historic biomass or less. NMFS' Technical Guidance for NS1 notes that at levels as low as ½ the minimum stock size threshold—about 12% of historic levels for Pacific groundfish—it "may be necessary to set the fishing mortality rate to as close to zero as possible (i.e. to that associated with unavoidable levels of bycatch)" for a number of years.[1] The Council's own 40:10 policy calls for zero mortality at those low biomass levels. We recommend "as close to zero as possible" as a sensible starting point for setting OYs for species in that category.

We also have concerns about the implications of not fully taking uncertainty into account in stock assessments or rebuilding analyses. Shorter recovery times (i.e., revised times to recovery when F=0) in species such as darkblotched are largely driven by new, steeper stock recruitment curves. We caution against categorical acceptance of these more optimistic predictions due to uncertainties in the estimates of these stock recruitment curves. In some

[1] V.R. Restrepo et al, Technical Guidance on the Use of Precautionary Approaches to Implementing National Standard 1 of the Magnuson-Stevens Fishery Conservation and Magnuson Act, NOAA Tech Mem NMFS-F/SPO-31, 1998, p. 38

cases, such as in the new assessment and rebuilding analysis of darkblotched rockfish, future recruitments are assumed to be almost entirely independent of the stock size. This apparent disconnect between stock size and recruitment seems likely to have significant error associated with it, and is likely to change with improved data. Thus, assuming a constant stock-recruit curve with no error is problematic. Uncertainty in steepness and Bo translate directly into uncertainty in Tmin, in addition to contributing uncertainty to the probability of recovery under different management scenarios. We recommend that that these uncertainties be incorporated into the rebuilding analyses to produce a more realistic range of predictions.

We plan to make additional comments once the new analysis of alternative OYs is available, and will address other topics, such as FMP goals and objectives and standards for evaluating rebuilding success, at that time. Thank you for your consideration of these comments.

Sincerely,

Karen Garrison David Newman

RE: Cow Cod conservation Area outer boundary change

John,
I would like to start off by letting you and the council no how important this issue is to the small fleet that fishes for ground fish in the Southern California Bight. The CCA in its present form should have never been implemented and all were trying to do is reduce the closure to areas that have some relevance in protecting cow cod.

I have enclosed an opinion/editorial piece that I have submitted to several commercial fishing magazines. I would like this passed on to all members of the Council and put in the briefing book for the June meeting. Copies are enclosed. Thank you for any help you can provide in this matter.
If you have any questions I can be contacted at 805 984 5338 and email neptuneobs@aol.com

Sincerely,

Tim Athens

California Department of Fish and Game continues firing in their war on commercial fishing

I am a fixed gear limited entry fisherman based in Southern California and have been involved in fishery politics most of my fishing career. I thought I had seen the worst of the ground fish management bombshells lobbed at our industry, but this latest assault on the 'sacred', Cow Cod Conservation Area, outer boundary change, truly takes the cake.

A little background history is in order. The CCA was implemented in 2001 to protect the 'hastily declared endangered' cow cod. It is commonly acknowledged that the preferred depths range of *sebastes levi* is 60 to 150 fathoms. In my 30 plus year career fishing ground fish with various types of hook and line gear, I've never encountered one deeper than 150 fathoms. Associates of mine, who have comparable experience with ground fish here in Southern California attest to similar findings. In order to protect these slow growing rockfish, the brain trusts involved with managing our fisheries decided to close huge swaths of ocean to all ground fish fishing. The main problem with their methodology was that the vast majority of turf they closed had not one thing to do with cow cod habitat. The percentage of area closed deeper than 150 fathoms was more than 70 percent of all the closed area combined. Our most productive areas for black gill, thornyheads, black cod and other slope associated species were eliminated in one fell swoop. All in the name of protecting a fish that doesn't live there.

One has to ask, why would fisheries managers take such a draconian measure? Think back to 1999/2000 when the prevailing mindset of the agencies involved was not to manage; just close everything. It was literally a feeding frenzy and the chum was our fishing grounds. I asked our State Reps on the PFMC why so much area had to be closed and was told, "Enforcement had concerns about their ability to enforce anything other than large block closures. Without VMS it's the only feasible way". Reluctantly, I accepted our fate, hoping in the years to come we would have enough info from the observer program and VMS implementation. Maybe then we would be able to right the wrong that had been bestowed upon us.

Here we are, six years later and we have a huge amount of information from the observer program. The data shows for 355 observed sets in depths greater than 150 fathoms by the fixed gear limited entry fleet there was a total of ZERO cow cod taken. I'm no schooled academic, but I am reasonably certain these statistics would indicate to any responsible fisheries manager that cow cod by-catch is not an issue with fixed gear at depths greater than 150 fathoms.

Then there's the VMS issue. At out expense, the fixed gear limited entry fleet was selected as the 'test case' and first group required to install VMS on their boats. The test must have went well, because the 'powers that be' are expanding the program to most every commercial vessel that lands or transports ground fish from federal waters. So where does that leave us? It leaves us with depth based, Rockfish Conservation Areas here in the Southern California Bight that try to follow a specific fathom curve. How are they enforced? By a number of methods, but primarily VMS.

Armed with the observer data and emphasizing the VMS program, last May 2005, I went before the California Fish and Game Commission and requested them to ask their Department to ' get the ball rolling on the CCA issue at the Council level'. Namely, change the outer boundary of the CCA to 175 fathoms for fixed gear limited entry, VMS enabled vessels. The Commission was supportive of the request and recognized the absurdity of the existing closure and the hardships it presented. Miraculously, they directed the Department to go ahead with our association's request. The Departments ground fish rep on the Council asked our Association to work with Department personnel and develop a suite of CCA options to be presented to the Council in June 2006, the Council would then choose one at that time. The options consisted of 1) status quo, 2) changing the outer boundary to 175 fathoms, our choice, and 3) maintaining some especially important areas within the existing CCA following the 175-fathom curve, but overall not a significant portion of the slope areas. This last option was adopted as a compromise because CA State enforcement officials, once again, claimed enforcement is a problem. We had made a good faith effort to work with the Department on this issue and thought we were in agreement, even though we knew the decision would ultimately be up to the Council.

It seems that there has been a complete change of attitude and protocol by the State. We were informed in April that the 'enforcement consultants' would have nothing to do with anything but a straight-line, big block approach. To make matters worse, they also said they would choose one option as the 'preferred one' to present to the Council. That doesn't exactly seem like a fair and equitable process, having the entity that wants to put the kibosh on the proposal, pick the option to be presented.

Here is a sample of the questions I've asked the various State council reps and their responses concerning this issue. What about VMS? We have it for the RCA's. It seems to work fine for that. "No, no, no, VMS is not an adequate enforcement tool; the Feds won't share the data with us". Well don't the Feds enforce with VMS? "We don't trust their competency". Can't you get the Feds to share the data with you? "No, we tried; they won't amend the Magnuson Act". What actual effort have you made to amend the Magnuson Act so info can be shared? "None". What about the patrol boats and planes? "We don't have enough money for fuel or crew". Doesn't the Coast Guard enforce federal fisheries regulations? "They don't have the time or resources". I pay my taxes. Should these issues put myself and other fishermen out of business? "That's not my concern".

Why don't they just admit it, it's glaringly obvious. Our State PFMC representatives, who are supposed to be advocates for their State's respective fisheries, don't want us fishing, simply because they're in the pockets of the environmental groups that are driving this 'ground fish jihad'.

RE; Cow Cod Conservation Area

Mr. John DeVore and all Council members,
Would you please support changing the entire CCA borders to the 175-fathom curve. We would prefer 150 fathoms but have compromised to 175.
Ground fish observation data in over **6000** observed sets over 150 fathoms in depth **did not catch a SINGLE cow cod.**

Presently, we have to travel 120 miles (one way) to fish for Black Gill rock fish, and with the price of fuel, the vagaries of the weather (we are a small boat) and the U.S. Navy, we are coming to the point where financial survival is a serious question.

Changing the CCA boundaries to 175 fathoms would open almost all the "old" fishing grounds. It is much closer to home and safety for my boat and crew.

The CCA does not meet California Fish and Game code 7056. Defines sustainability objectives of management systems.

(a) The fishery is conducted sustainable.
(b) The health of marine habitat is maintained and restored.
(c) Depressed fisheries are rebuilt.
(d) The fishery limits bycatch.
(e) Management system allows co-management to prevent or reduce excess effort.
(f) Fishery management systems are adaptive.
(g) The Management decision-making process is open and seeks advice and assistance of interested parties so as to consider relevant information.
(h) The management system observes long-term interests of people dependent on fishing for food, livelihood, or recreation.
(i) The adverse impacts of fishery management on small-scale fisheries, coastal communities, and local economies are minimized.
(j) Collaborative and cooperative approaches to management involve fishery participants and others and are strongly encouraged, and appropriate mechanisms are in place to resolve disputes.
(k) The management system is proactive and responds quickly.
(l) The management system is reviewed for effectiveness in achieving sustainability goals and for fairness and reasonableness in its interaction with people affected by management.

The CCA <u>does not</u> meet the standards of the Magnuson Act.

The CCA <u>does not</u> meet the standards for the Regulatory Flexibility Act.

The CA DFG <u>did not</u> oppose enforcing the 12 new reserves in the Channel Islands.

Will modification of the CCA boundaries have any significant biological impact on cow cod or its rebuilding program? **<u>NO</u>**.

<u>We are all VMS carrying boats; enforcement cannot be an issue.</u>

Dear Sirs;
In 1985 I started deck handing on charter boats thinking it was a great way of making a living I got a Captain's license. In 1991 I bought a 50 foot charter boat and started Santa Cruz Sportfishing Inc.Since then our season opener went from the middle of February to starting April 1'st too almost no season this year.People still think it is closed to all the bad press.Rockcod season was year round with no depth restrictions to a 6 month season with a 120 foot depth restrictions.This has destroyed our business forcing us to sell the big boat and buy a six pack boat and get a part time land job to keep the business going.Now with the MLPA's closing a lot of our shallow water to us maybe unemployment is a option.I understand it is the Canary Rockfish is the issue but in our area I just don't see sport fishermen contributing to the quota all that much but I am sure someone has the stats on that. Opening up the deeper water up and lighting our season could possibly save the remaining businesses(hotels, restruants,tackle stores,marine ,stores,etc.).Thanks for time.

Sincerely,

RE: Groundfish Fisheries Management Measures

As a long time member of the Recreational Sport Fishing Industry, I am writing to express strong concerns regarding the Negative Economical Impact that is being realized due to recent fishery management decisions.

While management is not in dispute, Good Management is needed, it is the decisions made that have had severe repercussions to the industry producing hardships for many. The ability to maintain business and or employment is increasingly threatened as a direct result. Several businesses have closed while others face great struggle and debt to remain in business. The Monterey Bay area party boat fleet has diminished. What was once known as a thriving fleet of close to two dozen licensed vessels is now a struggling fleet of less than ten licensed vessels due to sportsmen declining to partake in a favored activity when numerous inconsistencies and constant revisions exist in the often confusing and stringent regulations. The long term closures and current shallow water restrictions have further diminished participation.
This has also caused a severe decline in License Sales for the State of California

Conservation and Protection of fisheries is important however a better focused plan is needed. Fishing in a concentrated area (120feet or less only) would be of more harm than good. The ability to be able to fish throughout deeper waters will enhance the fisheries by taking pressure off a specific area, additionally Business and employment will once again prosper.

Respectfully Submitted,

Peter Bruno

RE: Groundfish Fisheries Management Measures

I am writing this letter with regards to the devastating impact that overly restrictive regulations on Rockfishing has had upon the charter fishing boat business in Monterey Bay.

Five years ago there was a total of 18 charter fishing boats that regularly fished for rock fish in the Monterey Bay. There was 12 boats in Monterey, 5 in Santa Cruz and 1 in Moss Landing. To break it down further Monterey had 4 Charter Fishing businesses with a total of 12 boats, now there a re 2 business with a total of 5 boats fishing; in Santa Cruz there was 3 businesses, now there is 2 with 2 boats; in Moss Landing there is 1 charter boat operation with 1 boat that is currently for Sale. They are calling it quits after this season.

The numbers of people going rock fishing has been declining every year. The cumulative effect of the shortened and inconsistent periods of time to fish, types of fish, size & bag limits of so many species of fish, regulations changing in the middle of the season are all vary confusing and turns the people off.

This year is quite possibly going to be our worst year ever. With Morro Bay fishing 240 feet and Monterey fishing in 120 feet it is a no brainer. I ask you, would you want to go fishing in Monterey Bay for Blue fish, a few yellow tail, a Gopher cod and a vary few Ling Cod in less than 120 feet or less when you could go to Morro Bay and catch a wide variety of fish that are for the most part bigger then the fish available in the 120 feet or less?

It should also be mentioned that a large part of both Monterey and Morro Bay's clientele comes from Fresno and the surrounding area, so when you have one port fishing in 240 feet and the other fishing 120 feet and both advertising for the same customers, you do not have to be a genius to figure out where a guy is going to spend his money.

All we want is an level playing field. Your consideration in giving Monterey 240 feet in July would be very helpful. What we really need in the future is more time on the water.

Yours Truly

George Lemon

Re: Extending Rockfish Season and Opening fishing in deeper water.

I enjoy fishing for rockfish and would like to see these changes made. This will let the party boats fish the deeper waters and put less pressure in the shallow water where most small boat sports fisherman fish. Thank you for considering this change.

Sincerely,
Ron Semenza

Dear Council Members;

Our Family has been in the Sport Fishing business since 1949. I have been operating this business since 1962. In 1998 we had 8 boats, 8 skippers and 4 shop people. We now have only 3 skippers and 1 shop person.

In 1998 there were 14 boats fishing out of Montery, 6 boats out of Santa Cruz, and 2 from Moss Landing. Out of 22 Party Boats there are now only 8 boats in the South Monterey Bay Region. Two of the Party Boat companies in Monterey and two in Santa Cruz have gone out of business.

Our customer base has been reduced due to the limit restrictions, time on the water and fathom restrictions. The economic impact on our business has been devastating. No salmon and no albacore and all the restrictions we have
tried to do everything in our power to keep our skippers working and our business going. We have fished Sand Dabs, Giant Squid, Crab Combo, gone Whale Watching and have even sold some of our boats. All this in an effort to continue a business of 57 years.

We strongly urge the council ro raise the O.Y. and consider Alternative 3 (high B) for the 2007-2008 season and in July 2006 open to 40 fathoms in the South Central Monterey Bay Region.

Yours truly,

Chris Arcoleo

Dear Sir;

Over the past five plus years, the regulations governing the rockfish fisheries have been a total disaster for the party boat industry. In Monterey we have seen a reduction in the number of fishing party boats from a high of thirteen to a barely surviving five. The number of people going fishing for rockfish has been so greatly reduced that what was once the backbone of the business is now just a side fishery.

The constantly changing, confusing, and restrictive regulations have turned the public off of fishing for rockfish and fishing in general.

People never know when the season is open.

They are unhappy with only being able to fish for shallow water species.

They are not happy with only being able to retain ten fish for their efforts.

We need to conserve and protect our fisheries for now and the future. In the Monterey fishing area there is no shortage of fish in the general populations, deep or shallow. There are more fish available in deep water now because of the long closures. Being allowed to fish in a broader depth of water makes party boat operators better stewards of the fisheries by being able to move around and not focus on any particular area or group of fish.

Bottom line; better quality fish from increased access to deep water will mean more happy fishermen and possibly a regeneration of a sputtering business (especially with the horrible salmon season of 2006, it would be nice to finish the year in the black)

Sincerely,

David Lemon

Randy Fisher, Director
Pacific States Marine Fisheries Commission
205 SE Spokane Street
Portland, OR 97202

Dear Mr. Fisher:

I received the Socioeconomics Program Questionnaire from Ms. Nicole Milne from the National Marine Fisheries Service and shared it with several people in Lincoln County, including the Lincoln County Historical Society. As I mentioned to her in a phone conversation, people who have reviewed the document are tremendously concerned about the inaccuracy of the information. Knowing that she is working on this project alone helps me understand why the information is so. However, I want to stress the value that lies in taking advantage of local resources, such as myself, to assist her in compiling a more detailed list of local contacts to make the document an important database that can be relied upon by numerous agencies, commercial fishermen, and industry scientists.

One glaring example of an inaccuracy is the statement that South Beach and Newport are two separate communities. People who live here consider South Beach and Newport one community. Indeed, South Beach is located within the city limits of the City of Newport. The vessels that she described as being owned by South Beach residents all conduct their business out of the Port of Newport facility on the north side of Yaquina Bay. Any data will be skewed if the information is broken down by individual community and not the general area.

Frankly, the information about our area is so inaccurate that I feel compelled, in the strongest possible terms, to convey my concerns. The need for accurate socio-economic information grows every day. Commercial fishermen are eager to share their knowledge of the sea and local industry, and to work hand-in-hand with the scientific community to integrate what the industry knows with what the scientific community has learned. We have so much to gain through cooperation. In my experience, the National Marine Fisheries Service has only paid lip service to the vital role this type of data can play in modern fisheries management. Getting information directly from the source – the local fishermen – can generate a wealth of data and provide a credible and thorough database on the socioeconomics of fisheries management. Conducting inadequate research which leads to inaccurate information is highly counterproductive. Publishing such information would be a detriment to the communities themselves.

Here are some recommendations that could help achieve a more complete research effort:

1. Contact people on a local level. I will be happy to brainstorm a list of contacts.
2. Split the work up by state since many of the governance structures change from state to state and year to year.
3. Hire a separate person to become an expert on each state and expand and update the database yearly.
4. Prior to publication, submit the data collected with each State Department of Fisheries to check its accuracy.
5. Learn about any programs that are currently underway in which local fishermen are working with the scientific community, such as the Port Liaison Project, Undersea Cable Committee, and the Oregon Sea Grant.

Collecting all the data for this research is an insurmountable job for only one person. I believe additional staff may have to be hired to conduct separate areas of research, or, NMFS needs to strongly consider contracting with local people who have the skills to assemble this information. Publishing and relying upon inaccurate information will lead to greater financial losses over time.

As I explained to Ms. Milne earlier, I cannot enumerate all the errors in the research in a single phone call or letter. I am willing, however, to meet with her and other local contacts to get the project moving in the right direction. This is exciting work. It holds tremendous promise for providing a reference point from which future researchers can build. Lincoln County stands ready to help develop a more complete and accurate picture of the people and history that are the cornerstone of our nation's fisheries.

Sincerely,

Terry N. Thompson

re Rockfishing

I am a recreational fisherman. Fishing is something, which I enjoy immensely.

However, in the past few years my ability to fish in the ocean has been dramatically curtailed, due to the short season in effect for rock fishing.

In addition, I understand the populations of most species is healthy.

So, I would ask that you consider extending the season to target these fishes for as long as possible.

Thank you.

Subject: Ground fish regs.

Upcoming council meeting in June 2006.
Why not allow sportsfishermen to fish a longer season and deeper water. We sportsfishermen really do enjoy the rock cod fishing that we have here in Central California(Monterey Bay area). There some of us that don't have that much more time to fish so it would be great if the council would lengthen the season and allow fishing in deeper waters. Scientifically, I haven't seen where the sportfishing for the rockcod has impacted there numbers.
Thank you for this consideration.
Conway Woo, D.D.S.

Subject: Comment on rock fish regulations
From: "Bill Woods" <bill.woods@earthlink.net>
Date: Tue, 6 Jun 2006 09:33:25 -0700
To: <pfmc.comments@noaa.gov>

I've heard through the grapevine that the PFMC is considering regulations for next year, and that comment at this time is appropriate. I live in Aptos, California. My personal fishing activity is recreational, usually out of Santa Cruz. Thank you for considering the following comments:

1. Most important - Please do whatever is necessary, including complete closures if the science is sound, to protect existing brood stocks from any further decline.
2. Please give appropriate attention to the size and age of brood fish - not just a total biomass measure - in your assessment of population viability. The science does seem clear on the importance of large, old female rock fish in the population.
3. Where harvest opportunities are deemed to exist, please allocate fish in a manner that maximizes public benefit, based on comprehensive analysis. My opinion is that the total utility, enjoyment and economic value per fish is significantly greater when those fish are harvested by recreational fishermen. I am sympathetic to the impacts this shift might have on commercial fishermen, but wild fish are a finite resource. It is consistent with the values of our society to protect wild fish in the same way wild terrestrial creatures are treated. Commercial harvest of wild birds and mammals is completely prohibited everywhere in the United States. In terms of social values, why should commercial fishing be different? (And, yes, I agree there should be compensation to the displaced commercial fishermen.)
4. Reduce "bycatch" tolerances by at least 90%. The magnitude of allowed - and often wasted - bycatch in relation to the restrictions, limits and penalties placed on recreational fishing is ridiculous, appalling, and undermines the credibility of the entire process.
5. Look for more sensible, enforceable, recreational fishing regulations than the ones we have had lately. Determine whether any release of fish caught at depth is feasible. Then make rules that are consistent with those findings - and educate fishermen about proper techniques. Don't force people to waste fish that will not survive release, and don't allow fishing where this is likely to happen.

Again, thank you for considering my input.

Sincerely,

Bill Woods

June 11, 2006

Mr. Donald K Hansen, Chairman
Pacific Fishery Management Council
7700 NE Ambassador Place, Suite 200
Portland OR. 97220-1384

Dear Mr. Hansen:

The Washington Trollers Association (WTA) is made up of approximately 100 members and represents the majority of the salmon trollers that troll for salmon off of the Washington coast. The WTA is aware of the requirements of the Magnuson Act and the Court's interpretation of what actions need to happen in order to demonstrate that Yelloweye groundfish are managed on a recovery schedule. The PFMC is required to consider the effects of even the smallest bycatch encounters of Yelloweye in fisheries such as the salmon troll fishery or demonstrate that the PFMC managed fisheries will allow a recovery of Yelloweye groundfish. WTA representatives have met with WDFW staff and discussed ways that the Washington Trollers can help in the recovery of Yelloweye. However, because of a lack of communication, we were totally surprised by the WDFW Report Agenda Item F.2.b that was released in early June 2006. The WDFW report proposes a no fishing zone of a vast area of prime salmon trolling area that we think is not justified as Yelloweye habitat or abundance.
The following points are made from our understanding of the science and the interaction of salmon trolling and Yelloweye encounters.

- Yelloweye are very sedimentary and live close to the bottom around high relief rocks.
- Bottom trawlers encounter very few Yelloweye because they trawl primarily in flat bottom and avoid rocky reefs. Especially since large foot ropes and rock hopper gear was eliminated in the last few years. (This regulation change should have dramatic affect to help Yelloweye recover.)
- Salmon trollers seldom encounter Yelloweye because of the difficulty trolling close to the bottom around high rocky relief sites.
- The information on salmon troll encounters with Yelloweye was found by the advisory teams not to be statistically ~~usable.~~ unusalbe.
- The Yelloweye protection area proposed by the referenced WDFW Report as a no fishing zone is a high production salmon area that happened to produce most of the salmon trolling opportunity this last month and includes vast areas of flat trawlable terrain that do not include high rocky relief that Yelloweye habitat.

- We have unique rockfish conservation areas designed for each of the major gear types that incidentally encounter rockfish to include longline, trawl, and sport. Salmon troll gear is different and should have unique areas of no salmon troll fishing to protect rockfish as well. It should be reasonably easy for enforcement to determine the difference between vessels trolling with hooks and vessels using other types of gear.
- In the area proposed for "no fishing in 2007-2008 cycle" in the WDFW report referenced above, there has been several observed salmon troll trips in 2005 and 2006. As far as we know, there have been no encounters of Yelloweye while trolling for salmon in the same areas.

Taking the preceding into consideration, and understanding that because of our low encounter rate of Yelloweye in the troll fishery, the models estimating Yelloweye recovery will not be affected by any measures taken by the troll fleet short of completely closing the fishery. WTA is concerned and understands the pressure brought by the environmental community and the courts to do all reasonably possible to ensure that the Yelloweye recovers in the quickest time possible. WTA has reviewed the submersible data from the North Washington Coast and found high abundance of Yelloweye in an area off of Cape Flattery in an area called the "table top" at 48 24' N by 124 53' W. This is in the no trolling area that is commonly called "mushroom closure". Many of our trollers have used other types of gear in past years that targeted Yelloweye and know of several places of good habitat and high abundance of Yelloweye that is protected from trolling in the closed to trolling "mushroom area".

If it is necessary to satisfy the Court Mandate for the recovery of Yelloweye, WTA is forwarding the following alternative for consideration as additional closed to trolling area for 2007-2008. WTA is forwarding for consideration an area bounded by 125 16.5 W, 125 14.0' W, 48 00' N, 48 02' N. This proposed closed area should not be considered for expansion as the submersible data information show this area as extreme high rocky relief with high abundance of Yelloweye and some adjoining areas are flat and not good Yelloweye habitat.

Sincerely,

Doug Fricke

Doug Fricke, WTA President

STAGNARO
Fishing Trips & Bay Cruises
Santa Cruz, California
PO Box 1340, Santa Cruz, CA 95061

Agenda Item F.2.d
6/06

Pacific Fishery Management Council,

MY NAME IS KEN STAGNARO. I AM FROM STAGNARO SPORTFISHING IN SANTA CRUZ AND MONTEREY BAY AREA. MY FAMILY'S BUSINESS HAS BEEN IN EXISTENCE SINCE THE EARLY 1930'S. OUR FLEET ONCE CONSISTED OF AS MANY AS 14 CHARTER BOATS. IN 2006 ONE BOAT IS ALL THAT IS LEFT. IN A BROADER PICTURE IN THE LATE 1990'S THERE WERE APPROXIMATELY 20 COAST GUARD CERTIFIED COMMERCIAL PASSENGER FISHING BOATS IN MONTEREY BAY. NOW THERE ARE SEVEN! AND ONE OF THOSE IS FOR SALE. IN FACT IM SURE THERE ARE OTHERS WHO WOULD SELL JUST TO KEEP THEIR COLLECTIVE SHIRTS. I OFTEN HAVE A SARCASTIC CHUCKLE WHEN I READ AN ECONOMIC IMPACT REPORT AS TO THE LATEST RESTRICTIONS OR SEASON CLOSURE, ESPECIALLY THE PART THAT SAYS "MAY EFFECT SMALL BUSINESS" THERE IS AN UNDERSTATEMENT.

IT IS A FULL TIME JOB TO KEEP UP ON ALL OF THE STUFF YOU LAW MAKERS AND NUMBER CRUNCHERS CAN COME UP WITH. FOR THE MOMENT I HAVE A FULL TIME JOB. BUT AS I SEE IT IF IT WERE NOT FOR THE CANARY, GOLDEN EYE AND BOCACCIO ROCKFISH WE MIGHT STILL HAVE A 12 MONTH SEASON WITHOUT DEPTH RESTRICTIONS. ALTHOUGH I AM SURE IT CAN BE DIFFERENT IN OTHER AREAS AND ON COMMERCIAL TRAWLERS. BUT ON OUR BOATS CANARY'S AND GOLDEN EYE HAVE ALWAYS BEEN A VERY SMALL PERCENTAGE OF OUR CATCH GOING BACK TO THE 1960'S. ON AVERAGE MAYBE 10% OR LESS. EVEN MUCH LESS FOR GOLDEN EYE. IF THE LAW ALLOWED US A LONGER SEASON AND GREATER DEPTH I AM CERTAIN I CAN ACHIEVE VERY CLOSE TO ZERO PERCENT CANARY AND GOLDEN EYE. FURTHER, I MOSTLY FISH FROM ANO NUEVO TO THE NORTH DOWN TO THE MONTEREY CANYON OFF MOSS LANDING TO THE SOUTH. THE REEF'S AND ROCKFISH HABITAT IN THIS AREA AMOUNT TO APPROXIMATELY 90 SQUARE MILES. APPROXIMATELY 75 SQUARE MILES OF THIS AREA IS DEEPER THAN 120 FEET. AND AFTER HAVING ONLY 15 SQ. MILES TO WORK IN FOR SEVERAL YEARS, THE NEW MPA'S THREATEN TO TAKE EVEN MORE AREA FROM US. IN SHORT OUR INDUSTRY WILL NOT SURVIVE WITHOUT A LONGER SEASON AND DEPTH LIMIT. I ASK THAT THE OPTION WHICH PROVIDES FOR THE MOST LIBERAL OF SEASONS AND DEPTH RESTRICTION BE ADOPTED. THANK YOU,

KEN STAGNARO

WASHINGTON DEPARTMENT OF FISH AND WILDLIFE MOTION ON THE TENTATIVE ADOPTION OF THE 2007-2008 GROUNDFISH FISHERY SPECIFICATIONS/MANAGEMENT MEASURES AND AMENDMENT 16-4

I move that the Council tentatively approve the following management measures, as described in the Action Alternatives in the draft Environmental Impact Statement, for preliminary action:

<u>WASHINGTON RECREATIONAL FISHERIES</u>

Statewide Measures:

- Maintain status quo bag limits as described in the No Action Alternative (Chapter 2, p. 52), which include a recreational groundfish bag limit of 15 fish per day, including rockfish and lingcod, with a sublimit of 10 rockfish, and 2 lingcod. Retention of canary and yelloweye rockfish is prohibited.

- Maintain status quo lingcod season as described in the No Action Alternative (Chapter 2, p. 52); in 2007 and 2008, the following lingcod seasons would apply:

  - Marine Areas 1-3: Open the Saturday closest to March 15 (which is March 17 in 2007 and March 15 in 2008) through the Saturday closest to October 15 (which is October 13 in 2007 and October 18 in 2008).

  - Marine Area 4: Open April 15 through October 13 in 2007 and open April 15 through October 15 in 2008.

- Reduce the minimum size for lingcod from 24 inches to 22 inches.

Area-Specific Measures:

Management Measures for Marine Areas 3 and 4 (Queets River to U.S./Canada border)

Action Alternative 3 (Chapter 2, p. 89), with two revisions: Prohibit fishing for, retention, and possession of **<u>groundfish</u>** seaward of a line approximating 20 fm from May 1 through **<u>September 30</u>**, except on days that halibut fishing is open.

Revisions:
1. Change “rockfish and lingcod” to more broadly cover “all groundfish” for ease of regulatory understanding and enforcement of the regulations
2. Move the depth restriction in July from 10 fm seaward to 20 fm

Management Measures for Marine Area 2 (Leadbetter Pt. to the Queets River)

Action Alternative 3 (Chapter 2, p. 89), with one revision: Prohibit fishing for, retention, and possession of **<u>groundfish</u>** seaward of a line approximating 30 fm from the lingcod opening day in March through April 30, and from June 16 through July 31. From May 1 through June 15 (i.e., during the average period of the South Coast halibut fishery), allow the retention of sablefish and Pacific cod seaward of the 30-fm depth restriction.

Revision:

1. Change “rockfish and lingcod” to more broadly cover “all groundfish” for ease of regulatory understanding and enforcement of the regulations, while still allowing the retention of sablefish and Pacific cod, which may be caught incidentally while targeting halibut offshore.

Management Measures for Marine Area 1 (Oregon/Washington border to Leadbetter Pt.)

No Action Alternative (Chapter 2, p. 54), which would prohibit fishing for, retention, and possession of groundfish, except sablefish and Pacific cod, when Pacific halibut are onboard the vessel.

This suite of management measures would result in the following estimated mortalities of overfished rockfish for Washington recreational fisheries:

Bocaccio	Canary	Cowcod	Darkblotched	POP	Widow	Yelloweye
0	1.1	0	0	0	0	3.1

Yelloweye Rockfish Conservation Areas (YRCAs)

- Maintain the “C-shaped” YRCA (Chapter 2, Figure 2-4, p. 53) in the Washington North Coast area, as depicted by coordinates in federal regulations at 50 CFR 660.390. Recreational fishing for, retention, and possession of groundfish and Pacific halibut is prohibited within this area, and this area is defined as a voluntary “area to be avoided” for commercial fixed gear and salmon troll fisheries.

- Add an additional YRCA in the Washington North Coast area, labeled North Coast Area B, under Action Alternative 1 (Chapter 2, Figure 2-8, p. 65), as described by the following coordinates:

  Beginning at 48°11.77’ N lat., 125°13.03’ W long.;
  Then to 48° 16.43’ N lat., 125°07.55’ W long.;
  Then to 48° 14.72’ N lat., 125°01.84’ W long.;
  Then to 48°13.36’ N lat., 125°03.20’ W long.;
  Then to 48°12.74’ N lat., 125°05.83’ W long.;
  Then to 48°11.55’ N lat., 125°04.99’ W long.;
  Then to 48°09.96’ N lat., 125°06.63’ W long.;
  Then to 48°09.68’ N lat., 125°08.75’ W long.;
  And back to the point of origin.

  This area would be closed to commercial limited entry fixed gear and open access groundfish fishing. WDFW notes that this area is already closed to trawl gear with the implementation of the trawl rockfish conservation area and the essential fish habitat trawl closure; most of this area is also closed to salmon troll as a salmon conservation measure.

- Add an additional YRCA in the Washington North Coast area, under Action Alternative 1 (Chapter 2, Figure 2-11, p. 69), as described by the following coordinates:

  Beginning at 48°00.00’ N lat., 125°14.00’ W long.;
  Then to 48°02.00’ N lat., 125°14.00’ W long.;
  Then to 48°00.00’ N lat., 125°16.50’ W long.;
  Then to 48°02.00’ N lat., 125°16.50’ W long.;
  And back to the point of origin.

  This area would be closed to the commercial salmon troll fishery. WDFW would like to point out that this area overlaps a portion of the “C-shaped” YRCA, and is already closed to recreational groundfish and halibut fishing.

- Add an additional YRCA to in the Washington South Coast area, labeled South Coast Area B, under Action Alternative 1 (Chapter 2, Figure 2-9, p. 66), as described by the following coordinates:

  Beginning at 46°58.00’ N lat., 124°48.00’ W long.;
  Then to 46°55.00’ N lat., 124°48.00’ W long.;
  Then to 46°58.00’ N lat., 124°49.00’ W long.;
  Then to 46°55.00’ N lat., 124°49.00’ W long.;
  And back to the point of origin.

  This area would be closed to recreational fishing for groundfish and Pacific halibut and would be a voluntary “area to be avoided” for commercial groundfish fisheries.

We believe these proposed area closures will assist in the conservation and rebuilding of yellowye rockfish and, while the primary purpose for these closures is yelloweye protection, we also believe that there will be additional benefits for canary rockfish as well.

As mentioned in Agenda Item F.2.b, WDFW Report, even though we are not able to quantify the amount of reduced yelloweye rockfish mortality resulting from implementing these conservation areas, the Washington Department of Fish and Wildlife did review available yelloweye rockfish encounter data. We plotted the coordinates of the closed areas with Geographic Information Systems (GIS) software with overlays of state observer data from recreational, salmon troll, and exempted fisheries for trawl and longline, groundfish trawl logbook data, and data from the annual International Pacific Halibut Commission (IPHC) halibut survey, the National Marine Fisheries Service triennial trawl survey, and the WDFW submersible survey for yelloweye. Based on this review, and information communicated from recreational and commercial fishers, we believe that closing these areas to the specified fisheries will help conserve yelloweye rockfish. Over the next 18 months, we will have a series of meetings with recreational and commercial fishers to complete a more comprehensive review of the data and information about fishing locations to further refine and these YRCAs and potentially define new sites.

Agenda Item F.3
Situation Summary
June 2006

TRAWL INDIVIDUAL QUOTA ANALYSIS--REVIEW OF STAGE ONE

The drafting of the analytical document for the trawl individual quota (TIQ) program has been divided into two stages. This two stage process was developed as a response to funding that was not sufficient to cover a complete analytical document. The first stage work product for the analytical document has been carried out under contract and includes specification of the impacts that will be evaluated along with the approach and methods that will be used in the evaluation.

A summary of the current status of this project is provided in Agenda Item F.3.a Attachment 1. Drafting of the analysis has been underway since last fall A workshop to provide an opportunity for public involvement in the drafting process was held April 18-20, 2006 in Portland, Oregon and a report is provided as Agenda Item F.3.b, Workshop Report (*on Council briefing book CD*).

At this meeting the Council will review the contractor work product on the first stage of development of the analysis and determine whether adjustments are needed to the analytical approach or any of the alternatives (Agenda Item F.3.b, Attachment 1—excerpt from Stage I Draft). The contractor has identified some areas for which adjustments may be appropriate at this time, expressed concern about the number of permutations contained in the alternatives, and expressed concern that analysis of some design elements may uncover problems which indicate that other options should have been considered. With respect to these issues, the contractor's primary concern is excessive permutations and the possible need to reconsider some design elements at the end of the process, which may escalate costs. To address these issues Council staff has initiated the following for Council consideration at this meeting:

(1) Reorganization of some of the main elements of the alternatives in order to streamline the analysis.
(2) Adjustments to some of the design elements.
    (Agenda Item F.3.a, Attachment 2 and Agenda Item F.3.c, Supplemental TIQC Report)

The staff will compile the results of Council deliberations from this meeting and ask the Council to confirm any stage one modifications at its September meeting. The confirmation in September will allow the Groundfish Management Team, Groundfish Advisory Subpanel, and others who have been fully subscribed with the biennial specifications process to offer the Council their recommendations on this matter. September confirmation of the stage one actions is not expected to cause any delay in the work on stage two as there are many aspects of the analysis which will not be driven by the types of adjustments that the Council will be considering.

Council Task:

1. **Identify any other impacts that should be considered or problems with the planned approach to the analysis.**
2. **Consider the need for any revisions to the current alternatives.**

Groundfish Trawl Individual Quotas *(TIQ)*
Pacific Fishery Management Council (Council) Status Report
June 2006

Summary of Project Status

Most Recent Actions:

- Council (June 2005)
  - adopted a set of TIQ alternatives for analysis
  - authorized the initiation of scoping for an intersector allocation Environmental Impact Statement **(EIS)**
- Council (November 2005)
  - reviewed provisions and made recommendations for addressing community concerns
  - eliminated an alternative that would have required TIQ for overfished species only
- Allocation Committee (November 2005)
  - met to develop intersector allocation alternatives
- Independent Experts Panel (March 2006)
  - met to review internal review draft of document to be presented at the April 18-20 workshop
- Public workshop held on stage 1 of the analytical process (April18-20, 2006)

Current Activities:

- Drafting of the TIQ analytical package (including EIS) is in progress under a contract with Northern Economics Incorporated **(NEI)**. The stage 1 draft, analytical approaches and methods will be presented for Council review at its June 2006 meeting.
- Public scoping for the intersector allocation is underway and historic harvest data is being summarized by sector. The Council will take up intersector allocation at its September 2006 meeting.

Next Major Events:

Date	Event	Location
June 11-16, 2006	**Council Meeting**: • Review Stage 1 Draft TIQ Analytical Package • Determine need to modify alternatives	Foster City, CA (San Francisco Bay Area)
Summer, 2006	TIQC Meeting to review interim components analysis.	Portland, OR
Sept, 2006	**Council Meeting** • Review interim components analysis. • Confirm June action on Stage 1 draft • Review scoping results on intersector allocation	Foster City, CA

Funding Status (TIQ Program and Intersector Allocation)

The projected Council funding need for full development of a TIQ system includes both deliberations on the design of a TIQ program and the intersector allocations necessary to determine the share of the optimum yield to be allocated to the trawl fishery.

Total Council need:	$2,250,000 (updated December 2005)
Total received:	$555,000
Total remaining need:	$1,695,000

Contract Work Status

Drafting the TIQ Analytical Package. The Council has entered into a contract with NEI in October 2005 to begin work on the TIQ analytical package. Drafting of the analytical package for the TIQ program has been divided into two stages because funding was not available to allow development of a complete package. The analytical package includes an EIS, regulatory impact review, regulatory flexibility analysis, and fishery impact statement, along with other required analyses. Funding for the full analysis will need to be secured prior to the end of the first stage in order for the analytical process to proceed to completion without further interruption.

An outline of the analysis and types of impacts to be evaluated was presented at a public workshop April 18-20, 2006. The document will be further developed and revised in response to information and comments received at the workshop. It will then be presented to the Council at its June 2006 meeting. The second stage of drafting will commence when the first stage is completed and needed funding has been secured.

Data summaries for Intersector Allocation. Summaries of historic harvest data for the commercial and recreational fisheries were compiled under contract with Dr. Edward Waters and presented to the Allocation Committee at its November 2005 meeting.

Committee Activity Status

TIQ Committee (TIQC)

The TIQC is the lead constituent committee advising the Council on development of the TIQ program. The TIQC has met six times, first in October 2003 and last in October 2005. Its first five meetings led to the development of the set of options adopted for analysis by the Council at its June 2005 meeting. At its October 2005 meeting, the TIQC reviewed alternatives developed by the TIQ Analytical Team to address community concerns.

TIQC members were given the opportunity to participate in an internal review of a preliminary draft of the analytical package under development by NEI and participate in the April 18-20, 2006 workshop on the draft stage 1 analysis. Upcoming activities for the TIQC include a one day meeting at the June 2006 Council meeting to review the draft NEI work product and a meeting in the summer of 2006 to review an interim analysis of some of the components of the alternatives.

TIQ Analytical Team (AT)

The AT has met four times, first in June 2004 and last in November 2004. At its November 2004 meeting, a work plan was developed for conducting additional analyses in support of TIQC policy deliberations to occur from January through May 2005. The work plan was only partially implemented due to a shortfall in the funding available for contractors working in support of the AT.

The last major work product of the AT was a set of community related options for Council consideration. The analytical basis for the options was presented to the Scientific and Statistical Committee (SSC) at its September 2005 meeting and the options were reviewed by the Council at its November 2005 meeting.

Establishment of a contract with NEI has resulted in a shift in the roll of the AT. Rather than taking the lead in developing analyses, the AT role is now to provide expert advice to NEI on development of the analyses and to review NEI work products.

AT members attended the meeting of the IEP on March 16, 2006, and participated in the April 18-20, 2006 workshop on the draft stage 1 analysis.

TIQ Independent Experts Panel (IEP)

The IEP met two times, first in June 2004 and last in September 2004. Their first meeting was a joint meeting with the TIQ AT. At their September 2004 meeting, they recommended revisions to the goals and objectives, which were later adopted by the Council. The IEP also specified a process for its review of the draft analysis to be developed by the TIQ AT once the Council adopted alternatives for analysis. Since that time, workload and funding considerations have led to the transfer of the main responsibility for drafting analyses to the outside contractor (NEI).

Recent activities of the IEP included internal review of preliminary drafts developed by NEI prior to the April 18-20, 2006 workshop. IEP members were not available for the April workshop. A special meeting was held March 16, 2006 to provide NEI with an opportunity to receive advice from members of the IEP. A complete draft was not available at that time. The IEP agreed that it would meet again early on in the next stage of the drafting process, after some of the methods had been applied and initial results developed.

TIQ Enforcement Group (EG)

The TIQ EG met two times, first in May 2004 and last in September 2004. The TIQ EG developed enforcement alternatives and estimates of enforcement costs for status quo and management under a generic, catch-based individual quota program.

In December 2005, TIQ EG members were given the opportunity to participate in an internal review of a preliminary draft document developed by NEI. Some EG members participated in the April 18-20, 2006 workshop. The next task for the EG will be to review preliminary results from the analysis, when they become available.

Scientific and Statistical Committee (SSC)

The SSC has been involved in review of the TIQ program only when it has come before the Council for major actions. The SSC reviewed the TIQ program alternatives at its November 2004 meeting and provided comments to the Council. It reiterated those comments at the June 2005 Council meeting. In June 2005, the Council charged the AT to work with the SSC to draft options to address community concerns. The SSC reviewed the technical basis for the options developed by the AT at the September 2005 SSC meeting and provided comments at the November 2005 Council meeting.

SSC members Mike Dalton, Tom Jagielo, Hans Radtke, and David Sampson have agreed to take the lead for the SSC in tracking and reviewing development of the TIQ program. The SSC has been asked to participate in the internal review of preliminary drafts of the analysis developed by NEI. The SSC subgroup participated at the April 18-20, 2006 workshop. The next task for the SSC will be to review and comment to the Council on the contractor stage 1 analysis being provided at the June 2006 Council meeting.

Groundfish Management Team (GMT)

The GMT last reviewed and commented to the Council on the TIQ program at the June 2005 Council meeting. Merrick Burden is the GMT lead on the TIQ process. A GMT representative (Mark Saelens) attended the March 16, 2006 meeting of the IEP and the April 18-20 workshop on the draft stage 1 analysis. Because of other workload related to the 2007-2008 annual specifications process, the GMT will not have had time to review the draft stage 1 analysis for the June Council meeting. They will have an opportunity to review the document over the summer and provide comments at the September 2006 Council meeting.

Groundfish Advisory Panel (GAP)

The GAP reviews TIQ issues as they arise on the Council agenda. The GAP last advised the Council on the TIQ program at the November 2005 Council meeting, at which time, options to address community concerns were considered.

In December 2005, GAP members were given the opportunity to participate in an internal review of a preliminary draft of the analytical package under development by NEI. GAP members were invited to participate at the April 18-20, 2006 workshop. Because of workload related to the 2007-2008 annual specifications process, the GAP will not have had time to review the draft stage 1 analysis at the June Council meeting. They will have an opportunity to review the document and provide comments at the September 2006 Council meeting.

Allocation Committee

The Allocation Committee role is to address aspects of the TIQ system directly impacting other sectors. The main direct impact is the development of the intersector allocations necessary to determine the share of fish that will be available for the TIQ program. The Allocation Committee has requested data summaries and begun development of some approaches for determining the priorities and methods for resolving intersector allocation issues. An initial summary of historic harvest data was presented at the November 2005 Allocation Committee meeting. Data issues need to be resolved pertaining to (1) the source from which the recreational data was drawn and (2) commercial landings that could not be assigned to a sector of the fleet. The next Allocation Committee meeting focusing on the long-term intersector allocation issue may occur over the summer.

Agenda Item F.3.a
Attachment 2
June 2006

STAFF REPORT:
ISSUES FOR COUNCIL CONSIDERATION

There are two main decision areas to be addressed in the trawl individual fishing quota (IFQ) analysis:

1. specification of the broader management regime within which the IFQ program or permit stacking would be implemented, and
2. specification of the IFQ program and permit stacking alternatives.

Proposals are presented here for reorganizing the alternatives addressing each of these decision areas, to facilitate a more efficient and informative analysis. Additionally, with respect to each of these areas, there are a number of design issues which, if addressed at the June and fall 2006 meetings, may facilitate a more targeted and efficient analysis. Resolution in one of these areas, processor definitions and supporting data, is essential in order to proceed with an analysis of an initial allocation of IFQ to processors.

Management Regime Alternatives

Restructuring

TASK: Provide guidance, if the proposed reorganization is not acceptable.

At its June 2005 meeting, the Council was presented with the suite of management regime alternatives identified in the first column of the following table. Council actions in June and November 2005 left the management regime alternatives specified in the second column. In the process of developing plans for the analysis, it became apparent that there were not broad differences between Alternative 3 and Alternative 4 in the second column. Alternative 3 provided an option for low OY management[1] and Alternative 4 did not provide such an option. Maintaining separate alternatives to address these differences would require substantial repetition and not provide more information than could be provided by treating the differences as options within a single alternative. Therefore, Alternatives 3 and 4 have been tentatively combined into a single alternative for Council consideration and are presented as such in the stage one analysis. If the Council would like to maintain separate alternatives to address the low OY management issue, analysts are prepared to make the necessary modifications to the stage one analysis before proceeding.

Alternatives in the Scoping Document, as of June 2005	Alternatives after Council Actions, as of November 2005	Revised Alternatives (Proposed for Consideration June 2006)
1. No Action 2. IFQ for Trawl Target Species and Species for Which There is a Trawl Allocation 3. IFQ for Groundfish Except "Other Fish" 4. IFQ for All Groundfish and Options for Halibut IBQ 5. Cumulative Catch Limits 6. Cumulative Catch Limits and Permit Stacking 7. Cumulative Catch Limits and Permit Stacking with Extended Cumulative Limit Periods	1: No Action 2: IFQs for Trawl Target and Species for Which There is a Trawl Allocation 3: IFQs for All Groundfish Species Except "Other Fish" and Low OY Management 4: IFQs for All Groundfish Species Except "Other Fish" and No Low OY Management 5. IFQs for All Groundfish 6 Permit Stacking with Full Cumulative Catch Limits for Each Stacked Permit (No Extended Periods).	1: No Action 2: IFQs for Trawl Target and Species for Which There is a Trawl Allocation 3: IFQs for All Groundfish Species Except "Other Fish" (options with and without low OY management) 4. IFQs for All Groundfish 5. Permit Stacking with Full Cumulative Catch Limits for Each Stacked Permit (No Extended Periods).

(NOTES: "IFQs Only For Overfished Species" was added as an alternative in June but removed from consideration in November. Alternative 2 also includes low OY management provisions.)

Specification of Design Elements

The IFQ management regime alternatives (Tables 2-1 and 2-3 in Agenda Item F.3.b, Attachment 1) do not completely address the rules that would apply for vessels participating in both the shoreside whiting and shoreside nonwhiting fisheries (Element 2) and in both the limited entry trawl and limited entry fixed gear fishery (Element 3.2). Similarly, the permit stacking alternatives did not completely address these combinations, nor did they address the use of trawl and open access gears (exempted gear and unendorsed longline or fishpot) (Element 3.1). Three other areas not completely specified were whether there should be accumulation caps on transferable cumulative limits (Element 1.3), procedures for rolling over whiting IFQ between whiting sectors (Element 2.3), and the possible extension of the cumulative limit period to longer than 2 months (Element 2.4). Finally, outstanding was the issue of the threshold that might be applied for determining when low OY management measures should be applied (Element 1.4). The TIQC is being asked to review and report recommendations to the Council on each of these issues.

[1] For Alternative 3 in the 2nd column, when a species was determined to be at low biomass levels, management of that species would have switched from IFQs to nontransferable cumulative limits.

Three elements have been added to the end of the management regime alternatives in order to fill out the permit stacking alternative and cover related decisions in one place: Element 4, at-sea monitoring; Element 5, area management; and Element 6, sector allocations. The provisions for these elements are not new and are derived from decision tables in the scoping document.

Vessels Participating in Both the Shoreside Whiting and Shoreside Nonwhiting Fisheries

TASK: Provide guidance, if the proposed options are not acceptable.

Provisions have tentatively been added to the alternatives specifying that a whiting closure for shoreside trips would be implemented by the imposition of a whiting cumulative catch limit (all alternatives) and that such whiting cumulative limits would not be stackable (as part of an Alternative 2 transferable cumulative limit provision or as part of an Alternative 5 permit stacking system). For Alternative 2, whiting may be taken on both shoreside whiting and shoreside nonwhiting trips. Different types of whiting IFQ would be issued for the directed shoreside whiting trips and for incidental whiting catch on shoreside nonwhiting trips. Nonwhiting trips with incidental whiting catch would be constrained by year-round cumulative limits and whiting IFQ issued for nonwhiting trips would be required to cover the incidental catch. Directed shoreside whiting IFQ could not be used outside of the whiting season. Vessels which engage in both directed whiting and nonwhiting trips would have to use directed shoreside whiting IFQ for whiting targeted trips and use incidental whiting IFQ to cover incidental catch on nonwhiting trips. For Alternatives 2, 3, and 4, IFQ would still be required for whiting taken during closures, such that whiting catch would be constrained both by the IFQ requirement and cumulative limits. Also, when a vessel is making a whiting trip, nonwhiting catch taken on the trip would be limited to a single limit for each cumulative limit (Alternative 2) or permit stacked (Alternative 5) (i.e. even if a vessel stacks cumulative limits or permits for the purpose of making nonwhiting trips, while making whiting directed trips it would receive no credit for stacking).

Vessels with Limited Entry Trawl and Limited Entry Fixed Gear Permits

TASK: Provide guidance, if the proposed options are not acceptable.

The alternatives do not specify how catch taken by vessels with limited entry trawl and limited entry fixed gear permits will be treated. Options for consideration are provided under Element 3.2. These options include not requiring IFQ for fixed gear catch (Alternative 2), and not requiring IFQ for catch taken toward limited entry fixed gear cumulative or daily limits but allowing fixed gear catch in excess of such limits, if the catch is covered trawl with IFQs (Alternatives 3 and 4).

For the permit stacking alternative, two initial options are provided for consideration. The first applies the LE fixed gear rules any time a vessel is using fixed gear, the second applies the LE fixed gear rules when the vessel is fishing toward a sablefish tier limit but constrains the vessel to the trawl limits (including stacked limits) when it is not fishing toward the tier limit.

Limited Entry Trawl Vessels Using Open Access Under the Permit Stacking Alternative

TASK: Provide guidance, if the proposed options are not acceptable.

The permit stacking alternative does not specify how catch taken with open access gear (exempted gear longline and fishpot) will be managed. Two options for consideration are provided in Element 3.1. The first would be to continue to apply the open access trip limits. The second is to apply the LE trawl cumulative catch limits and permit stacking provisions along with a requirement that landings be made in compliance with the catch limit monitoring program (In Table 2-1, Element 3.1 and 3.2. In Table 2-3, Element 3.1, Options 3.1.4.1 and 3.1.4.2; and Element 3.2, Options 3.2.3.1 and 3.2.3.2).

Accumulation Caps for Transferable Cumulative Limits

TASK: Indicate whether or not there should be caps on stacking of transferable cumulative limits and if so the level of the caps that should be considered.

Under Alternative 2, species for which there is not a trawl allocation would be managed with transferable cumulative limits. For IFQs and permit stacking, caps have been specified for the amount of fish harvesting opportunity a person or vessel can accumulate. There is no cap specified with respect to the Alternative 2 transferable cumulative limits.

Rolling Over Unused Whiting IFQ Part Way Through the Season Under Alternative 2

TASK: Provide options for analysis.

Under status quo management a roll-over of unused allocation from one sector to another may occur if NMFS determines on September 15th that one sector's allocation is likely to go unused. Management regime Alternative 2 specifies that there be an option for a midseason rollover of IFQ from one sector to another. Two examples of how this might be achieved are provided in Sub-option 2.3.2.2 of Table 2-3. The first approach specifies that the IFQ ownership not change but rather the sector designation be lifted on some segment of the unused quota after a certain point in the year. The main issue under this approach may be that it could effectively eliminate the sector designations if individuals from one sector pay those in another sector not to use their quota so that it can be transferred between sectors toward the end of the year. The second approach specifies that unused IFQ be ceded back to the program for redistribution among other holders equally, via lottery or through other means. The main issue under this approach might be that individuals may apply to receive the redistribution not with the intent of using the redistribution but rather to acquire quota to sell.

Lengthening the Cumulative Limit Period Under Alternative 2

TASK: Provide guidance, if the proposed option is not acceptable.

Alternative 2 specifies that the cumulative limit periods might be lengthened but does not specify an option for the duration of the extension. The option for lengthening the cumulative period has tentatively been specified as a 4-month period, pending TIQC and Council review. The following outlines how management might function under a variety of limit period lengths.

Cumulative Limit Period	Function and Adjustment Under an Extended Cumulative Limit Period
1 year	The fishery would function either as an individual quota fishery in which each permit has one block of quota for each species/species group; or as a derby, if cumulative limits were set higher than the amounts that would constitute a quota.
6 months	The second 6-month period would function similar to the one-year period. Because complete data on the first period would not be available at the start of the second period, the second period would need to be started with low limits that would be increased after the results from the first six months are assessed. The adjustment for the second period could occur in late July (outside the Council meeting) or September (at the Council meeting). Excess catch of a single incidental species in the first period could severely limit opportunities in the second period.
4 months	The second period adjustment would have to occur after its start, therefore cumulative limits would likely need to start low then be increased after the assessment of the first period was complete. The second period adjustment could occur in late May (outside the Council meeting) or June (at the Council meeting). Alternatively, all adjustments could be made in the third period. The second period would end August 31 and the third period adjustment could be made at the September Council meeting. The third 4-month period would function similar to the one-year period.
3 months	A three-month period would require major reconfiguration of models and estimates from the observer program. It might function similar to the two-month cumulative limits, but would likely require either action outside of a Council meeting or mid-period adjustments.

NOTE: These scenarios assume cumulative limit periods of equal length. Other approaches could be constructed with periods of varying length, for example, the periods for a single year might run 4-months, 2-months, 4-months, 2-months.

Threshold for Triggering Low OY Management

TASK: Provide guidance, if the proposed option is not acceptable.

Under Alternative 3, whether or not low OY management would be imposed would be determined during the biennial management process. Under Alternative 2, a threshold would be established below which the switch to low OY management would be automatic. Under low OY management, catch for the low OY species would be controlled through nontransferable cumulative catch limits. (Under Alternative 2, low OY management would apply only to those species managed with transferable cumulative catch limits; under Alternative 3, low OY management would apply to any species managed with IFQ.).

For Alternative 2, only one threshold has been suggested, and that threshold is supplied as an example: "25% of B_{msy}"). Since no other thresholds have been put forward at this time, it is suggested that $B_{25\%}$ be specified as the threshold for the purpose of analysis.

IFQ Program Alternatives

The following table describes the design elements which vary between the IFQ program alternatives. Highlighted edits in the first row indicate the modifications proposed to streamline the analysis (with explanation provided in adjacent shaded area). Other shaded areas indicate provisions that may benefit from additional attention early in the second stage of developing the analysis.

Table. Differences between the IFQ programs, proposed revisions to the initial allocation of quota shares among eligible groups and other provisions which may benefit from some additional attention early in the analytical process.

Program A	Program B	Program C
Initial Allocation of Quota Shares, Section B.1.0		
Eligible Groups: 50% to current permit owners; 50% to processors.	*Eligible Group Suboption B-1:* 100% to current permit owners. ~~*Eligible Group Suboption B-2:*~~ ~~Nonwhiting--100% to current permit owners.~~ ~~Whiting--50% to current permit owners; 50% to processors.~~ ~~*Eligible Group Suboption B-3:*~~ ~~90% to current permit owners; 10% to processors.~~	*Eligible Groups:* 75% to current permit owners; ~~25% to processors.~~ with the remainder to be divided between processors and the community stability holdback (no less than 5% and no more than 20% to either group).
Programs A and B provide a range which, in combination with information from program C would allow the Council to select an IFQ allocation for processors of somewhere between 0% and 50%.	Suboption B-2 was an amalgam of Program A for the whiting fishery and Program B Suboption B-1 for the nonwhiting fishery. The description of the alternatives should identify that an option like Suboption B-2 is being considered. The analysis of the programs should adequately bracket the programs, providing the Council flexibility to adopt an option like Suboption B-2. Suboption B-3, a 10% processor allocation, is in Program C. The spread of allocations to permit holders (50% in Program A, 75% in Program C, and 100% in Program B) should adequately bracket an action in which 90% would go to permit holders.	For the analysis, use 10% to processors and 15% to communities. With this range of alternatives, the analysis should allow the Council to reasonably select options such as a 75/25 permit/processor split, a 75/25 permit/community-stability-holdback split, or a 90/10 permit/processor split.
Processor Definition: Use special IFQ program definition (processors: receive and process unprocessed fish; or catch and process).	*Processor Definition:* Use FMP definition (processors process unprocessed and already processed fish or receive live fish for resale).	*Processor Definition:* Same as Program B.
For June 2006: Issues relating to the definition of processor and qualifying processing history need to be addressed and are discussed in the text. The processors eligible to receive an initial allocation would not necessarily be those listed on the fish tickets. The primary concern is identification of the needed data for the initial allocation and analysis.		

Program A	Program B	Program C
Recent Participation Periods: Harvesters, including catcher processors--1998-2003. Shoreside Processors and Motherships--1999-2004.	*Recent Participation Option B-1:* None. *Recent Participation Option B-2:* 1998-2003.	*Recent Participation Periods:* Same as Program A.
For Fall 2006: The current recent participation requirements leave to the analysis the development of information that will be used to determine the level of activity required to meet the requirement (e.g. number of pounds or landings required to qualify as a recent participant. Information developed early in the second stage of the analysis may help the Council narrow the options, and thus facilitate a more efficient and focused analysis.		
Weighting Among Years: Use pounds from each year to calculate catch history.	*Weighting Among Years:* Use percent of total pounds for the year to calculate catch history for each year.	*Weighting Among Years:* Same as Program B.
For Fall 2006: The issue of weighting among years may be examined quantitatively. If the results of the analysis enable the Council to make a clear determination of preference in this area, it will be possible to efficiently produce a more focused analysis. For Fall 2006: Proxy Species. None of the current options include the possibility of using proxy species to allocate species for which it would have been desirable to minimize incidental catch, or for which the quality of catch history data is poor. Use of proxy species is, however, included in the list of options the Council may want to consider at time of final implementation. If there is a significant chance that the use of proxy species will be considered as part of the final action, it may be worthwhile to provide some preliminary analysis and consider inclusion of the option in one of the main program alternatives.		
IFQ/Permit Holding Requirements and IFQ Acquisition, Section B.2.0		
Rollover to Following Year: 10% for nonoverfished species and 5% for overfished species.	*Rollover to Following Year:* 30% for nonoverfished species and 30% for overfished species.	*Rollover to Following Year:* 5% for nonoverfished species and none for overfished species.
New entrant provisions: No special provisions.	*New entrant provisions:* No special provisions.	*New entrant provisions:* Lottery for new entrants to acquire revoked shares.
Community Stability Holdback: None.	*Community Stability Holdback:* None.	*Community Stability Holdback:* up to 20%.
Leasing: Allowed.	*Leasing:* Prohibited.	*Leasing:* Allowed.
Transfer Period: Year round	*Transfer Period:* January-October	*Transfer Period:* Year round
Accumulation Limits: 50% or none.	*Accumulation Limits:* Consider all limits as suboptions.	*Accumulation Limit Suboption C-1:* 1% or 5% *Accumulation Limit Suboption C-2:* 10% or 25%
For Fall 2006: The current range of accumulation limits is quite broad, even within the individual programs. Accumulation limits may have a significant influence on the long term effects of the IFQ program. Information on the distribution of catch history may allow the Council to narrow these limits.		
Program Administration, Section B.3.0		
Enforcement Program 2: 100% at-sea monitoring (observer), discards allowed. 100% shoreside monitoring. Upgraded bycatch reporting. Electronic state landings tracking system. Licenses required for delivery sites. Unlimited landing hours.	*Enforcement Program 1:* 100% at-sea monitoring (observer), full retention required. 100% shoreside monitoring. Electronic state landings tracking system. Limited ports of landing, no licenses required for delivery sites. Limited landing hours.	*Enforcement Program 3:* 100% at-sea monitoring (video or observer), discards allowed unless monitoring is with video cameras. Upgraded bycatch reporting. Federal electronic landings tracking system parallel to state system. Opportunity to monitor shoreside. Licenses required for delivery sites. Unlimited landing hours.
Central lien registry: Limited to necessary ownership information.	*Central lien registry:* With all ownership information.	*Central lien registry:* With all ownership information.
Cost Recovery: Up to 3%.	*Cost Recovery:* Up to 3%.	*Cost Recovery:* Full.
Data Collection: Expanded voluntary.	*Data Collection:* Expanded mandatory.	*Data Collection:* Expanded mandatory.

Restructuring

TASK: Provide guidance, if the proposed alternatives are not acceptable.

A proposal is made here to restructure the options with respect to the initial allocation of IFQ between harvesters, processors and community stability holdback. The restructuring is intended to simplify the analysis by providing clear sideboards (the Program A 50/50 split between permits and processors, and the Program B 100% allocation of IFQ to permit holders) and placing all the midpoints in Program C. Program C would allocate 75% to permit holders and 25% to be divided between processors and community stability holdback with no less than 5% and no more than 20% going to either. For the purpose of analysis, the Program C division would be 10% to processors and 15% to community stability holdback. This approach then brackets the options by providing analysis of 100%, 75%, and 50% to permit holders, 50%, 10% and 0% to processors, and 15% to community stability holdback. It should be reasonably possible to infer from these alternatives the effects of all mixes previously identified including providing 50% of the whiting IFQ and 0% of the nonwhiting IFQ to processors, and providing up to 20% of the IFQ for community stability holdback.

Note: also embodied in this revision is a modification of the description of the derivation of the community stability holdback. The holdback was previously specified as an annual withholding of quota pounds to be reallocated to cooperatives of IFQ holders coming forward with proposals that benefit communities. This modification would specify the holdback of quota shares rather than quota pounds. The approaches are mathematically equivalent. Specifying community stability holdback in the same section of the program as the initial permit/processor division of quota shares clarifies the eventual distribution of quota shares and pounds.

Specification of Design Elements

The main IFQ design element issue needing attention at this meeting is the definition of processor and the measures of processing history that would be used for an initial allocation of IFQ to processors. It may be possible to conduct analyses over the summer that would provide useful information on formulas for initial allocation (in particular, recent participation requirements, the measurement of catch history as annual proportions of total landings rather than pounds of total landings, and use of proxy species) and accumulation limits. Such information may help the Council ensure that the most relevant options are covered in the final analytical package and facilitate an efficient and focused analysis.

Processors and Processing History

TASK: Determine whether or not data sets have been identified that will be suitable to support an initial allocation to processors.

The IFQ programs include options for an initial allocation of IFQ to processors. After the initial allocation, the IFQ would be freely tradable, i.e. IFQ allocated to permit holders could be owned by processors or anyone else eligible to own IFQ, and IFQ allocated to processors could be owned by permit holders or anyone else eligible to own IFQ. For any allocation to proceed, there must be credible and verifiable documentation of the criteria on which the allocation will be based. In this case, the proposed criterion is processing history.

> "Processing or to process" means the preparation or packaging of groundfish to render it suitable for human consumption, retail sale, industrial uses, or long-term storage, including, but not limited to, cooking, canning, smoking, salting, drying, filleting, freezing, or rendering into meal or oil, <u>but does not mean heading or gutting unless additional preparation is done</u>. [emphasis added]

Using this definition of processing, the TIQC identified two definitions for processor.

	Definition of Processor
Option 1	Using Special IQ Program Definition for Processors: The processor is the entity which - 1. after processing, sells his or her own LE trawl vessel-caught groundfish directly to a wholesale or retail market; OR 2. buys unprocessed trawl-caught groundfish, processes it, and sells it to the wholesale or retail market. The entity is defined as: Suboption 1(a)(i) the processing facility and allocation goes to the current owner, unless leased, in which case it would go to the current lessee. Suboption 1(a)(ii) the processing facility and allocation goes to the current owner. Suboption 1(b) the person processing (individual, partnership, corporation or other entity).
Option 2	FMP Definition. A processor is a- "person, vessel, or facility that engages in processing; or receives live groundfish directly from a fishing vessel for retail sale without further processing." Same suboptions for definition of entities as in Option 1.

In specifying the processing history on which the allocation should be based, the TIQC recommended that processors only receive credit for fish they process (fish passed through to another processor without processing should not be counted). The scoping document noted that information beyond what is on fish tickets will be needed to substantiate processing activities (fish tickets do not indicate whether or not the entity receiving the fish processed it and some processors may not be listed on a ticket for the fish they processed). Under the definitions of processing and processors, qualifying processing history could potentially accrue to the second, third or more handlers of the fish, including restaurants and grocery stores. (Note: the IFQ program prohibits IFQ ownership by any entity not eligible to own a US documented fishing vessel, therefore, foreign owned processors would not qualify for IFQ).

Status of entity as a processor based on the processor definitions.					
				Eligible for an Initial IFQ Allocation as Processor?	
Do they take ownership of the fish?	Is the fish received processed?	Does the entity process it?	Category	Option 1 Definition	Option 2 Definition
Yes	No	Yes	Processor (Including: Operations that Both Harvest and Process AND Operations that Acquire Unprocessed Fish from a Vessel/Receiver/Dealer/Buyer)	Yes	Yes
No	No	Yes	Custom Processor	No	Yes
No	No	No	Buyer	No	No
Yes	No	No	Fish Receiving-Station/Dealer	No	No
Yes	Yes	Yes	Secondary Processor	No	Yes
Yes	Yes	No	Fish Dealer/Wholesaler	No	No

To date we have not been able to identify the data set which would support an allocation to processors based on one of these definitions of processing history. On May 16, 2006, a letter was sent to processor representatives on Council advisory bodies explaining this problem and requesting their help in identifying data sets that could be used for an initial allocation and analysis. The TIQC will be addressing this issue at their June 11, 2006 meeting.

Allocation Formulas and Accumulation Limits

TASK: Schedule consideration for fall Council meeting.

Some additional preliminary analysis of allocation formulas and accumulation limits may enable the Council to narrow the some of the program options, thereby facilitating a more efficient and focused analysis. This work could be conducted and made available for the Council in the fall of 2006. Additional explanation of the issues is provided in shaded sections of the table displaying the differences among IFQ programs.

Staff Report
(F.3.a, Attachment 1)

In response to concerns about analytical effort required to address numerous alternatives and options; and identification of areas where more specificity is required

the staff report provides proposal to consider some adjustments to

- Management Regime Alternatives
- IFQ Program Alternatives

Management Regime Alternatives

- Simplify and eliminate one management regime alternative

11/05 Council
1. No Action
2. IFQ for Trawl Target
3. IFQ for Groundfish Except “Other” and Low OY Mngmnt
4. IFQ for Groundfish Except “Other” and No Low OY Mngmnt
5. IFQ for all Groundfish
6. Cumulative Catch Limits & Stacking

11/05 Council	**06/06 Proposed**
1. No Action	1. No Action
2. IFQ for Trawl Target	2. IFQ for Trawl Target
3. IFQ for Groundfish Except “Other” and Low OY Mngmnt	
4. IFQ for Groundfish Except “Other” and No Low OY Mngmnt	
5. IFQ for all Groundfish	4. IFQ for all Groundfish
6. Cumulative Catch Limits & Stacking	5. Cumulative Catch Limits & Stacikng

11/05 Council	**06/06 Proposed**
1. No Action	1. No Action
2. IFQ for Trawl Target	2. IFQ for Trawl Target
3. IFQ for Groundfish Except "Other" and Low OY Management	**3. IFQ for Groundfish Except "Other" (Option for Low OY Management)**
4. IFQ for Groundfish Except "Other" and No Low OY Management	
5. IFQ for all Groundfish	4. IFQ for all Groundfish
6. Cumulative Catch Limits & Stacking	5. Cumulative Catch Limits & Stacikng

6. Cumulative Catch Limits & Stckng	6. Cumulative Catch Limits & Stckng	7. Cumulative Catch Limits & Stckng	6. Cumulative Catch Limits & Stckng	5. Cumulative Catch Limits & Stckng
7. Cumul Catch Limits and Stacking with Extended Periods	7. Cumul Catch Limits and Stacking with Extended Periods			

Management Regime Alternatives

- Simplify and eliminate one alternative
- Whiting: better define closures, whiting & nonwhiting trips & stacking rules.

Whiting

- Shoreside Whiting Closure: Imposition of a cumulative catch limits (IFQ also required)
- Alternative 2: Shoreside Nonwhiting Trips
  - Incidental whiting IFQ year round cumulative catch limit and
- Alternative 2: Shoreside Whiting Closure
  - Directed whiting IFQ cannot be used outside whiting season
  - Whiting trip >50% whiting (TIQC recommendation)
- Permit and cumulative limit stacking does not apply for whiting trips

Management Regime Alternatives

- Simplify and eliminate one alternative
- Whiting: Better define closures, whiting & nonwhiting trips & stacking rules.
- Vessels with LE Trawl and LE Fixed Gear

LE Trawl & LE Fixed Gear

- IFQ not required for fixed gear catch
  - Alt 2: No opportunity to use IFQ with fixed gear
  - Alt 3 & 4: Allow vessels to use trawl IFQ when using fixed gear to catch in excess of fixed gear limits
- For permit stacking
  - Option a: No opportunity to benefit from stacked trawl limits (LE fixed gear rules apply)
  - Option b: Fixed gear limits apply while fishing toward sablefish tier limits. Otherwise, stacked trawl limits apply.

Management Regime Alternatives

- Simplify and eliminate one alternative
- Whiting: Better define closures, whiting & nonwhiting trips & stacking rules.
- Vessels with LE trawl and LE fixed gear
- LE trawl vessel use of open access gear under permit stacking.

LE Trawl & Open Access Gear (Permit Stacking)

- Option a: No opportunity to benefit from stacked trawl limits (open access trip limits apply)
- Option b: Stacked trawl limits apply.

Management Regime Alternatives

- Simplify and eliminate one alternative
- Whiting: Better define closures, whiting & nonwhiting trips & stacking rules.
- Vessels with LE trawl and LE fixed gear
- LE trawl vessel use of open access gear under permit stacking.
- Accumulation Limits for Transferable Cumulative Limits (Alt 2, unallocated spp)

Transferable Cumulative Limits (Unallocated Species Under Alternative 2)

- Option for a cap is needed
- Analysis to be provided and addressed at next TIQC meeting

Management Regime Alternatives

- Simplify and eliminate one alternative
- Whiting: Better define closures, whiting & nonwhiting trips & stacking rules.
- Vessels with LE trawl and LE fixed gear
- LE trawl vessel use of open access gear under permit stacking.
- Accumulation limits for transferable cumulative limits
- Rollover of unused whiting IFQ

Whiting IFQ Rollover

- Provision to allow such rollover needs more specificity.
- Development of more specific options to be addressed at next TIQC meeting

Management Regime Alternatives

- Simplify and eliminate one alternative
- Whiting: Better define closures, whiting & nonwhiting trips & stacking rules.
- Vessels with LE trawl and LE fixed gear
- LE trawl vessel use of open access gear under permit stacking.
- Accumulation limits for transferable cumulative limits
- Rollover of unused whiting IFQ
- Lengthening the cumulative limit period
- Threshold for low OY management

Threshold for Low OY Management (Alternative 2)

- Under Alternative 2 the low OY transition would be from transferable to nontransferable cumulative limits (for unallocated species)
  - $B_{25\%}$ was provided as the only example. Recommend changing status from “example” to the “provision” that would be used.
  - SSC has now proposed “overfished” status as the threshold.

- Under Alternative 3, the Council decides as part of each cycle whether a species should be managed using low OY management (transition from IFQs to cumulative limits).

Management Regime Alternatives

- Simplify and eliminate one alternative
- Whiting: Better define closures, whiting & nonwhiting trips & stacking rules.
- Vessels with LE trawl and LE fixed gear
- LE trawl vessel use of open access gear under permit stacking.
- Accumulation limits for transferable cumulative limits
- Rollover of unused whiting IFQ
- Lengthening the cumulative limit period

Alternative 2: Lengthening the Cumulative Limit Period

- No option had been provided
- Proposed option: 4 months

- Year round (derby or quota)
- 6 month (second period, derby or quota; adjustment procedure)
- 3 month (data systems not set up for odd number of months)

IFQ Program Alternatives

- Reducing Alternatives

IFQ Program Alternatives

- Reducing Alternatives
- Specification of Elements
  - Processors and Processing History Definition

Processor & Processing Definitions

- Two definition options
  - Under either option processors deep into the marketing chain could qualify
  - Lack of data to implement or analyze
- TIQC proposal to resolve these issues and narrow the definition to one option
- Options remaining:
  - (1) the facility qualifies the current . . .
    - (suboptions owner or lessee),
  - (2) the person owning the facility at the time of processing qualifies

IFQ Program Alternatives

- Reducing Alternatives
- Specification of Elements
  - Processors and Processing History Definition
  - For Fall 2006
    - Recent participation options
    - Weighting among years
    - Use of target species as proxies for incidental
    - Accumulation caps

Agenda Item F.3.b
Attachment 1 ERRATA (Complete)
June, 2006

ERRATA: Replacement Pages 23-36 for
Excerpt from Stage 1 Draft IFQs and Permit Stacking Alternatives in the Limited Entry Trawl Fishery (Chapters 1, 2, 4 and Appendices A-C).

Attached is a revised Table 2-1 (from Agenda Item F.3.b, Attachment 1). The pages immediately preceding and following the table are included to facilitate replacement of the original Table 2-1 with the errata table. The main differences between this and the original version are in the references to the whiting and non-whiting species and segments of the fishery.

PFMC

[This Page Intentionally Blank]

Alternative 4: IFQs for all groundfish species. The distinction between whiting sectors would be eliminated. Reporting of all groundfish catch would be required. At-sea monitoring would be required on all vessels. OYs for each of the Other Species of groundfish would be would be established. If the OY for any species becomes extremely low, the Council may suspend allocations between gear sectors for that species.

Alternative 5: **Permit stacking.** Groundfish would be managed as under the No-Action Alternative, but limited entry trawl permit holders would be allowed to "stack" additional permits. Permit holders would be issued a full complement cumulative trip limit pounds for each permit they own. Whiting seasons and sectors would be maintained. Reporting of all groundfish catch would be required. At-sea monitoring would be required on all vessels. Catches of Other Species would be monitored. If the OY for any species becomes extremely low, the Council may suspend allocations between gear sectors for that species.

In addition to the various management regimes described above, the three IFQ alternatives (Alternatives 2 – 4) differ with respect to the way in which quota shares are allocated. The Council developed three basic allocations and incorporated them into three IFQ programs (currently labeled Program A, Program B, and Program C). The allocations differ primarily in terms of which groups would receive quota and how much each group would receive. These are summarized below:

Program A: Harvesters and processors are initially allocated equal amounts of QS that give them rights to harvest groundfish. Processors are defined as those facilities that take ownership of and process unprocessed groundfish. Program A would be applied to Alternative 3.

Program B: Harvesters and processors are allocated QS that give them rights to harvest groundfish. Split options include: a) 100/0 for all groundfish, b) 100/0 for non-whiting and 50/50 for whiting, and c) 90/10 for all groundfish. Processors are defined as in the FMP—those facilities that process either unprocessed or already processed groundfish or receive live fish for resale. Program B would be applied to Alternative 3.

Program C: Harvesters and processors are allocated QS that give them rights to harvest groundfish. Harvesters would initially receive 75 percent of the QS and processors would receive the remaining 25 percent. Processors are defined as those facilities that take ownership of and process unprocessed groundfish. Program C would be applied to Alternative 2, 3, and 4.

All three of the programs are applied to Alternative 3 as options. In effect, this generates three new alternatives: Alternatives 3A, 3B, and 3C. In addition it should be noted that Program B contains three different allocation schemes, and that these schemes also have the potential to significantly alter the impacts of the alternative. The end result is that Alternative 3 might reasonably be analyzed as five different alternatives: Alternatives 3A, 3Ba, 3Bb, 3Bc, and 3C.

Table 2-1 and Table 2-2, below, present details of the various elements and options that make up each of the alternatives. The tables are similar to those produced for the Council, and contain references to the IFQ Scoping Results Document[6] and various options described within that document.

[6] National Environmental Policy Act Scoping Results Document: Individual Fishing Quotas (A Kind of Dedicated Access Privilege) and Other Catch Control Tools for the Pacific Coast Limited Entry Trawl Groundfish Fishery. Pacific Fishery Management Council, July 2005.

Table 2-1. Management Regime Alternatives for Analysis

Alternatives (Sec 2.1.1.1 Scoping Results[a/])	Alternative 1 No-Action Alternative	Alternative 2 IFQs for Trawl Target Groundfish	Alternative 3 IFQs for All Groundfish Except Other Fish	Alternative 4 IFQs for All Groundfish	Alternative 5 Cumulative Catch Limits and Permit Stacking
COMPONENT 1: CATCH CONTROL TOOLS					
IFQ Program for Non-Whiting and Whiting Trips					
Element 1.1 IFQ Program to Be Applied **(See Table 2-2)**	No IFQ Program.	Program C	Alternative 3A - Program A Alternative 3B - Program B Alternative 3C - Program C	Program C	No IFQ Program.
Additional Control Tools (Sections 2.1.1.2 of the Scoping Results Document).[a]/					
Element 1.2 **Permit Stacking**	-- -- -- -- -- -- -- -- -- -- -- -- -- -- -- None -- -- -- -- -- -- -- -- -- -- -- -- -- -- --				One set of trip limits issued for each of a maximum of 3 permits attached to vessel. Only one of the permits attached to the vessel would need to be of the appropriate length.
Element 1.3 **Cumulative Trip Limits**	Cumulative landing limits. (One set of limits for each vessel to which a permit is assigned.)	Transferable cumulative catch limits.[b]/ Cumulative limits would be transferable on a temporary basis between vessels within the period (full or partial limit transfers would be allowed, depending on length of limit period)	Cumulative catch limits (One set of limits for each vessel to which a permit is assigned.)	None	Cumulative catch limits. (One set of limits for each permit.)

Alternatives (Sec 2.1.1.1 Scoping Results[a/])	Alternative 1 No-Action Alternative	Alternative 2 IFQs for Trawl Target Groundfish	Alternative 3 IFQs for All Groundfish Except Other Fish	Alternative 4 IFQs for All Groundfish	Alternative 5 Cumulative Catch Limits and Permit Stacking
Element 1.4 Adjustments for Low OYs					
Allocation	- -- -- -- -- -- -- -- -- The Council may suspend intersector allocations when a species is overfished -- -- -- -- -- -- -- --				
Catch Control Rules	N/A	Adjust rules for low OY conditions (as specified in Component 2). *IFQ species – No change.* *Non-IFQ species – For species meeting the low OY threshold switch from transferable to* ***non****transferable cumulative catch limits.*[c/]	**Option 1**: Adjust rules for low OY conditions (as specified in Component 2). *For low OY species, except whiting, switch from IFQs for that species and instead manage the sector allocation as a pool using nontransferable cumulative catch limits to control catch.*[d/] **Option 2:** No low OY adjustments.	N/A	N/A
Threshold	N/A	Low OY Threshold: Establish a threshold at which point a species would switch to "Low OY management." ($B_{25\%}$)	Low OY Threshold: Decide on application of "Low OY management" as part of the biennial specifications process.	N/A	N/A
Element 1.5 General Season Closures	-- -- -- -- When all sectors in aggregate reach the overall OY for a species, seasons close for the affected species -- -- -- --				
Element 1.6 Whiting Season Openings	Staggered season openings for each whiting sector.	Possible continuation of spring opening for the season, to control impacts on ESA listed salmon.	Possible continuation of spring opening for the season, to control impacts on ESA listed salmon.	Possible continuation of spring opening for the season, to control impacts on ESA listed salmon.	Same as no action.
Element 1.7 Whiting Season Closings	Whiting season closes for a sector on attainment of whiting allocation. Whiting season closure on attainment of bycatch caps for species with bycatch caps.	Whiting season closure on attainment of bycatch caps for species with bycatch caps.[i/]	Open until end of year.	Open until end of year.	Same as no action

Alternatives (Sec 2.1.1.1 Scoping Results[a/])	Alternative 1 No-Action Alternative	Alternative 2 IFQs for Trawl Target Groundfish	Alternative 3 IFQs for All Groundfish Except Other Fish	Alternative 4 IFQs for All Groundfish	Alternative 5 Cumulative Catch Limits and Permit Stacking
COMPONENT 2					
Sector/Species Group Combinations and the Catch Control Tools To Be Applied (Section 2.1.1.3 & 2.1.1.4 of the scoping results document)					
Element 2.1 Sectors Define Whiting Trip: Opt 1-- >50% non-whiting Opt 2-- >50% or >10,000 lbs non-whiting	Three sectors: ▪ shoreside (SS) deliveries ▪ mothership (MS) deliveries ▪ catcher-processor (CP) deliveries	Four sectors: ▪ SS whiting deliveries ▪ SS non-whiting deliveries ▪ MS deliveries ▪ CP deliveries (FROM Scoping Results Doc: 2.1.1.4 Option 3)	Three sectors: ▪ SS deliveries ▪ MS deliveries ▪ CP deliveries (FROM Scoping Results Doc: 2.1.1.4 Option 2)	One sector (FROM Scoping Results Doc: 2.1.1.4 Option 1)	Three sectors: ▪ SS deliveries ▪ MS deliveries ▪ CP deliveries
Element 2.2 Primary Trawl Target and Allocated Species[e/] **(Except Whiting)**	All sectors: cumulative landing limits. Trawl fishery closes on attainment of cap, guideline or OY. Whiting season closes on attainment of whiting fishery bycatch cap for non-whiting species.	SS non-whiting deliveries: IFQs SS, MS, & CP whiting deliveries: catch caps for these species. A sector's whiting seasons close on attainment of that sector's whiting fishery catch cap for non-whiting species. No cumulative catch limits. Midseason rollovers for excess cap amounts and augmentation of caps thru acquisition of SS IFQ.	Sector specific IFQs (Low OY Conditions: Option 1: switch to nontransferable cumulative catch limits and close on attainment of sector limits; Option 2: continue use of IFQs.)	IFQ	Cumulative catch limits with permit stacking rules applied for non-whiting trips. Whiting season closes on attainment of whiting fishery bycatch cap for non-whiting species. Stacked permits may not be used to cover catch on whiting trips.
Element 2.3 Whiting	All sectors: Whiting season (no vessel landing limits). Outside the whiting season shoreside deliveries allowed under cumulative whiting landing limits. Midseason rollover of excess allocation to another sector.	SS nonwhiting deliveries: Whiting catch must be covered with IFQ and is also constrained year-round by nontransferable cumulative whiting catch limits. SS, MS, & CP whiting deliveries: IFQs during whiting season. Midseason whiting rollover to another sector Opt 1: Not allowed; Opt 2: Allowed following specified procedures.	Sector specific IFQs during the whiting season. If SS whiting is closed SS whiting IFQs may continue to be used, subject to nontransferable cumulative whiting catch limits.	IFQs during the whiting season. IFQs and nontransferable cumulative whiting catch limits for shoreside deliveries outside the whiting season.	All sectors: Whiting season (no vessel landing limits). Outside the whiting season shoreside deliveries allowed under cumulative whiting catch limits. Permit stacking rules do <u>not</u> apply for cumulative whiting limits. Midseason rollover of excess allocation to another sector.

Alternatives (Sec 2.1.1.1 Scoping Results[a/])	Alternative 1 No-Action Alternative	Alternative 2 IFQs for Trawl Target Groundfish	Alternative 3 IFQs for All Groundfish Except Other Fish	Alternative 4 IFQs for All Groundfish	Alternative 5 Cumulative Catch Limits and Permit Stacking
Element 2.4 Unallocated Shared Target and Incidental Species Currently Managed With Cumulative Limits	All sectors: cumulative landing limits Trawl fishery closes on attainment of cap, guideline or OY. Whiting season closes on attainment of whiting fishery bycatch cap for non-whiting species.	SS whiting deliveries Transferable cumulative catch limits. Option for >2 mo cumulative periods and midperiod transfers. (Low OY conditions: switch to nontransferable cumulative catch limits) SS, MS, & CP whiting deliveries For species without caps: non-whiting species catch is limited by to a single cumulative catch limits regardless of the number of transferable limits held by a vessel. For non-whiting species with caps, same as Element 2.2.	Sector specific IFQs. (Low OY Conditions: Same low OY condition options as for "Primary Trawl Target and Allocated Species" (Element 2.2))	IFQ	Cumulative catch limits with permit stacking rules applied for non-whiting trips. Whiting season closes on attainment of whiting fishery bycatch cap for non-whiting species. Stacked permits may not be used to cover catch on whiting trips.
Element 2.5 "Other Fish" Groundfish[f/g/]	Status Quo. Currently: monitoring only. May change to cumulative limits.	Same as status quo.[h/]	Same as status quo.[h/]	IFQ	Same as status quo.[h/]
Component 3: Groundfish Catch of Limited Entry Trawl Vessels Using Gears Other Than Groundfish Trawl (Section 2.1.1.5 of the Scoping Results Document)					
Element 3.1 **Trawl Vessel Exempted Gear Quota Accounting and Catch Control (Includes Exempted Trawl and Exempted Non-trawl Gears)**	**Exempted gea**r catch by LE trawl vessels counts against LE allocation (trawl and fixed gear)[i/] but is subject to open access (OA) trip limits.	**Exempted gear** - IFQ is **not** required. Catch counts against the OA allocation and is managed as part of the OA fishery. Some catch will be allocated from the LE trawl to OA fishery. (FROM Scoping Results Document Section 2.1.1.5 Opt 2C)	**Exempted gear -** IFQ required. Catch counts against LE Trawl. Open access catch control regulations apply. (FROM 2.1.1.5 Scoping Results Document Section Option 1A)	**Exempted gear -** IFQ required. Catch counts against LE Trawl. Open access trip limits **do not** apply. (FRM 2.1.1.5 Scoping Results Doc Option 1B)	**Exempted gea**r catch by LE trawl vessels counts against LE allocation (trawl and fixed gear)[h/] but is subject to open access (OA) trip limits OR Permit stacking applies and vessels must comply with trawl enforcement and monitoring provisions.

Alternatives (Sec 2.1.1.1 Scoping Results[a/])	Alternative 1 No-Action Alternative	Alternative 2 IFQs for Trawl Target Groundfish	Alternative 3 IFQs for All Groundfish Except Other Fish	Alternative 4 IFQs for All Groundfish	Alternative 5 Cumulative Catch Limits and Permit Stacking
Element 3.2 **Trawl Vessel Longline and Fish Pot Without and With LE Endorsement (Fixed Gear Quota Accounting and Catch Control)**	**Unendorsed longline & fishpot** catch by LE trawl vessels counts against LE allocation (trawl and fixed gear) [i/] but is subject to open access trip limits. **LE endorsed fixed gear** - Rules for the LE fixed gear fishery apply when the vessel is using fixed gear. Vessels fish against the limited entry allocation[i/] and are constrained by fixed gear trip limits while using fixed gear.	**Unendorsed longline & fishpot** - IFQ required. Catch counts against LE Trawl. LE fixed gear catch control regulations apply. **LE endorsed fixed gear –** While using fixed gear, IFQ is not required, catch is constrained by LE fixed gear limits and counts toward the LE fixed gear allocation. (FROM 2.1.1.5 Scoping Results Doc, Option 1A)	**Unendorsed longline and fishpot** - IFQ required. Catch counts against LE Trawl. LE fixed catch control regulations **do not** apply. **LE endorsed fixed gear –** While using fixed gear, IFQ is not required for catch taken toward LE fixed gear cumulative or daily limits and such catch counts toward the LE fixed gear allocation. Catch in excess of LE fixed gear trip limits may be taken if covered by trawl IFQ. (FROM 2.1.1.5 Scoping Results Doc, Opt 1B)	**Unendorsed longline & fishpot** - IFQ required. Catch counts against LE Trawl. LE fixed catch control regulations **do not** apply. **LE endorsed fixed gear** - While using fixed gear, IFQ is not required for catch taken toward LE fixed gear cumulative or daily limits and such catch counts toward the LE fixed gear allocation. Catch in excess of LE fixed gear trip limits may be taken if covered by trawl IFQ. (FRM 2.1.1.5 Scoping Results Doc, Opt 1B)	**Unendorsed longline & fishpot** catch by LE trawl vessels counts against LE allocation[i/] (trawl and fixed gear) [i/] but is subject to open access trip limits. OR Permit stacking applies and vessels must comply with trawl enforcement and monitoring provisions. **LE endorsed fixed gear** - When the vessel is using fixed gear catch counts against the LE allocation[i/] and is constrained by fixed gear limits. OR Permit stacking applies and vessels must comply with trawl enforcement and monitoring provisions (except when fishing fixed gear tier limits).
Component 4. Monitoring and Enforcement					
At-sea Observers/ Monitoring	Biological observers on some SS catcher vessel trips, 100% observers for at-sea deliveries (MS and CP)	100% at-sea monitoring. Detailed monitoring and enforcement provisions under each IFQ program (Tables 2-2 and 2-4).	100% at-sea monitoring. Detailed monitoring and enforcement provisions under each IFQ program (Tables 2-2 and 2-4)	100% at-sea monitoring. Detailed monitoring and enforcement provisions under each IFQ program (Tables 2-2 and 2-4)	100% at-sea monitoring.

Alternatives (Sec 2.1.1.1 Scoping Results[a/])	Alternative 1 No-Action Alternative	Alternative 2 IFQs for Trawl Target Groundfish	Alternative 3 IFQs for All Groundfish Except Other Fish	Alternative 4 IFQs for All Groundfish	Alternative 5 Cumulative Catch Limits and Permit Stacking
Component 5. Area Management (Decision Table B from Scoping Results Document)					
	Species divided by areas based on stock assessment information. New area divisions created as stock assessment information indicates need.	Program Option for All Action Alternatives: Plan to establish additional regional management areas as needed at a later time. Provisions are included to allow later subdivision of IFQs by area. Process Option: Task a group to begin considering the need for additional regional management areas (biological or socio-economic) and potential boundaries along with a process for identifying and responding to regional management area issues that may develop or become more apparent in the future. **Decision deferred until additional information is available, e.g. preliminary DEIS is ready.**			
Component 6. Sector Allocation					
Element 6.1 Within Trawl (Decision Table E from Scoping Results Document)	Whiting allocation rules. No other within trawl allocations.	Establish within trawl allocations based on each sector's relative shares during the time period used for initial allocation. If time periods are different for different sectors use only those years in common to all sectors or calculate a percentage based on each sectors period then adjust all sectors proportionally so that the result sums to 100%. Consider applying the IFQ allocation recency requirement (if any) to eliminate from the sector calculation the catch history of any vessel that has not been active in recent years.			Whiting allocation rules. No other within trawl allocations.
Element 6.2 Trawl/All-Other-Gear		Establish needed intersector allocations through the intersector allocation process.			
Element 6.3 Trawl/ Open Access	N/A	Augment the open access allocation to account for trawl vessels fishing with open access gear on the open access allocation (Element 3.1)	N/A	N/A	N/A

Table 2-2. IFQ Program Design Alternatives for Analysis

	IFQ Program A	IFQ Program B	IFQ Program C
B.1.0 IFQ Allocation			
B.1.1 Eligible Groups	Allocate 50% of quota shares to current permit owners and 50% to processors (Option 3b).[7]	Eligible Group Suboption B-1. Allocate 100% of quota shares to current permit owners (Option 1 from Appendix B). Eligible Group Suboption B-2. Allocate 100% of quota shares for non-whiting species to current permit owners and 50% of the quota shares for whiting species to current permit owners. Allocate 50% of the quota shares for whiting species to processors. (New Option, June 2005) Eligible Group Suboption B-3. 90% of quota shares to current permit owners and 10% to processors. (New Option, June 2005).	Allocate 75% of quota shares to current permit owners and 25% to processors (Option 3a).
Processor Definition:	Use special IFQ Program definition (processors: receive and process unprocessed fish; or catch and process) (Option 1).	Use FMP Definition (processors process unprocessed and already processed fish or receive live fish for resale) (Option 2).	Same as Program A.

[7] References to Options refer to options at they were described in the Scoping Results Document, i.e. *National Environmental Policy Act Scoping Results Document: Individual Fishing Quotas (A Kind of Dedicated Access Privilege) and Other Catch Control Tools for the Pacific Coast Limited Entry Trawl Groundfish Fishery*. Pacific Fishery Management Council, July 2005.

	IFQ Program A	IFQ Program B	IFQ Program C
B.1.2 Qualifying Criteria: Recent Participation	**Harvesters (including catcher-processors):** 1998-2003 participation required in order to qualify for an initial allocation of quota shares (number of trips or years to be specified). (Option 2). **For shoreside processors and motherships:** 1999-2004 recent participation requirement (the number of trips or years is yet to be specified). (Option 4).	All Members of Eligible Groups: No recent participation required in order to qualify for an initial allocation of quota shares (Option 1). **OR** All Members of Eligible Groups: 1998-2003 participation required (one trawl groundfish landing/delivery of any groundfish species) in order to qualify for an initial allocation of quota shares. (Option 2).	Same as Program A.
B.1.3 Elements of the Allocation "Formula"			
Vessel/Permit Related Allocation	Catcher vessel permit owners will receive quota shares based on their permit history plus an equal division of the quota that could be attributed to permit history of bought-back permits (catcher-processors permit owners will not receive a portion of the quota shares distributed on an equal sharing basis) (Option 2). Suboptions for incidentally caught overfished species, either: (a) same as for Other Fish OR (b) equally divide quota for incidentally caught overfished species. For catcher-processors permit owners, use an allocation schedule developed by unanimous consent of that sector (to be provided).	Same as Program A, except no special catcher-processor schedule.	Same as Program A.
Processor Allocation	Processors are allocated quota shares based entirely on the processing of groundfish trawl landings received unprocessed (Option 1).		
B.1.4 History: Species/Species Groups to Be Used for Allocation	Allocate Quota Shares Based on Individual Species/Species Groups: Allocate quota shares for each species/species group based on relative amounts of each respective species/species group caught/landed or processed - for permits applies to permit history; for processors applies to amounts processed (Option 2).		

	IFQ Program A	IFQ Program B	IFQ Program C
B.1.5 History: Allocation Periods			
Periods/Years to Drop:	Options are identical under all programs. Vessels: 1994-2003. Drop 2 years for whiting sector fishing (applies to incidental harvest and whiting). Drop 3 years for non-whiting sector fishing. (Option 1, Sub-option B) Shore Processors: 1999-2004. Drop 2 years. (Option 5, Sub-option B) Motherships: 1998-2003. No opportunity to drop worst year. (Option 4, Sub-option A)		
Weighting Among Years:	Absolute pounds - no weighting between years (Sub-option (i)).	Relative pounds (calculate history based on the entity's percent share of each year's total) (Sub-option (ii)).	Same as Program B
B.1.6 History: Combined Permits and Other Exceptional Situations			
Combined permits:	All permits count. History of the permits combined into a single permit goes to the resulting permit (Option 1).		
Illegal landings/catch:	Don't count Illegal landings/catch under any program.		
Landings in excess of trip limits, as authorized under an EFP:	Don't count landings in excess of the cumulative limit in place for the non-EFP fishery under any program		
Compensation fish:	Don't count compensation fish under any program.		
B.1.7 Initial Issuance Appeals Process	Only one provision has been identified: Appeals would occur through processes developed by NMFS. NMFS will develop a proposal for an internal appeals process and bring it to the Council for consideration. Any proposed revisions to fish-tickets would undergo review by state enforcement personnel prior to finalization of the revisions.		
B.1.8 Creating New IFQ Species/Species Groups After initial Implementation	Only one practical option has been identified: When a management unit is subdivided, quota shares for that unit will be subdivided by issuing quota share holders amounts of shares for the subdivisions equivalent to their holdings of the shares being subdivided. If a new management unit is established that is not a subset of an existing unit managed with IFQ, the Council will need to take action at that time to develop criteria for quota share allocation.		
B.2.0 IFQ/Permit Holding Requirements and IFQ Acquisition (After Initial Allocation)			
B.2.1 IFQ and LE Permit Holding Requirements	Catch must be covered with quota pounds within 30 days of the landing (Option 3). Only LE trawl vessels would be allowed to participate in the IFQ fishery. For any vessel with an overage (landings not covered by quota) there would be no more fishing by the vessel until the overage is covered. Additionally, for vessels with an overage, the limited entry permit cannot be sold or transferred until the deficit is cleared. A possible suboption would require some amount of quota pounds be held prior to departure from port (to be analyzed).		
B.2.2 Annual IFQ Issuance			
B.2.2.1 Start-of-Year Quota Pound Issuance	Only one practical option has been identified: Quota pounds are issued annually to share holders based on the amount of quota shares they held. (Quota shares are issued at the time of initial IFQ allocation).		

	IFQ Program A	IFQ Program B	IFQ Program C
B.2.2.2 Rollover (Carryover) of Quota Pounds to a Following Year			
Non-overfished Species	10% rollover for non-overfished species (Option 3)	30% rollover for non-overfished species (Option 5)	5% rollover for non-overfished species (Option 2)
Overfished Species	5% rollover for overfished species (Option 3)	Full (30%) rollover allowance for overfished species (Option 5)	No rollover allowance for overfished species (Option 2)
B.2.2.3 Quota Share Use-or-Lose Provisions	Do not include a use-or-lose provision but evaluate need as part of future program reviews (Option 3).		
B.2.2.4 Entry Level Opportunities for Acquiring Quota Shares and Low Interest Loan Options	No special provisions.	No special provisions.	Provide new entrants an opportunity to qualify for revoked shares and shares lost due to non-use (if such non-use provisions are created) (Element 2)
B.2.2.5 Community Stability Hold Back	No special provisions.	No special provisions.	Set aside up to 20% of the non-whiting shoreside trawl sector allocation each year and allocate to IFQ holders who have submitted proposals, ranked on the basis of objective criteria that evaluate benefits to local communities.
B.2.3 Transfer Rules			
B.2.3.1 Eligible Owners/Holders (Who May Own/Hold)	Any entity eligible to own or operate a US documented fishing vessel. (Option 2) *The Trawl IQ Committee's intent is to preserve opportunity for existing participants*		
B.2.3.2 Duration of Transfer - Leasing and Sale	Permanent transfers and leasing of quota shares and quota pounds allowed. (Option 2)	Permanent quota share transfers only--leasing prohibited. Permanent transfers and leasing of quota pounds allowed. (Option 1)	Same as Program A
B.2.3.3 Limits on Time of Transfer	Allow transfers of quota shares any time during year (Option 1).	Prohibit transfer of quota shares during the last two months of the year.	Same as Program A
B.2.3.4 Divisibility	Only one practical option has been identified: Quota Shares: nearly unrestricted divisibility - "many decimal points." Quota Pounds: divisible to the single pound		
B.2.3.5 Liens	No options have been proposed to restrict liens. Liens can and should be facilitated through a central lien registry. Options for the central lien registry are covered in Section B.3.1.		

	IFQ Program A	IFQ Program B	IFQ Program C
B.2.3.6 Accumulation Limits	50% or No Limits (Option 5).	Consider all limits as sub-options	Most restrictive limits (1% or 5%) **OR** Intermediate level limits (10% or 25%)
B.2.3.7 Vertical Integration Limit	Only one option has been identified: No additional limits on vertical integration beyond those already provided through accumulation limits.		
B.3.0 Program Administration			
Tracking IFQ, Monitoring Landings, and Enforcement (see Table B.3-1)			
Enforcement Program Number	**Enforcement Program 2**	**Enforcement Program 1**	**Enforcement Program 3**
At-Sea Monitoring	100% at-sea monitors (observers)	100% at-sea monitors (observers)	100% at-sea monitors (observers) or cameras
Shoreside Monitoring	Shoreside monitoring opportunity would be provided	100% shoreside monitoring	Shoreside monitoring opportunity would be provided
Retention and Discards	Discards allowed	Full retention required	Discards allowed if at-sea monitor is present (otherwise full retention)
Discard Monitoring and Reporting System	Upgraded discard (bycatch) monitoring and reporting system needed	An upgraded discard monitoring and reporting system is un-needed	Upgraded discard (bycatch) monitoring and reporting system needed
Electronic Reporting	Electronic landings tracking. QS reported electronically.	Electronic landings tracking. QS reported electronically.	Parallel federal electronic landings tracking. QS reported electronically.
Landing Notification	Advance notice of landing required.	Advance notice of landing required	Advance notice of landing required
Potential Landing Times	Unlimited landing hours	Limited landing hours	Unlimited landing hours
Potential Landing Sites	Licenses required for delivery sites	Unlimited landings sites	Licenses required for delivery sites
Vessel Monitoring System (VMS)	VMS Required under all programs	VMS Required under all programs	VMS Required under all programs
Quota Share Tracking	Create a central lien registry but exclude all but essential ownership information. (Option 2).	Create a central lien registry including all related ownership information (Option 1).	Create a central lien registry including all related ownership information (Option 1).

	IFQ Program A	IFQ Program B	IFQ Program C
B.3.2 Cost Recovery/Sharing and Rent Extraction	Cost recovery for management (not enforcement or science). Up to 3% of ex-vessel value, the limit specified in the Magnuson-Stevens Act.	Same as Program A	Full cost recovery: Landings fee plus privatization of elements of the management system. In particular, privatization for monitoring of IFQ landings (e.g., industry pays for their own compliance monitors). Stock assessments should not be privatized and the electronic fish ticket system should not be privatized.
B.3.3 Program Duration and Procedures for Program Performance Monitoring, Review, and Revision (Magnuson-Stevens Act (d)(5)(A))	A four year review process is specified along with review criteria. Among other factors, the review would include evaluation of whether or not there are localized depletion problems and whether or not quota shares are being utilized. Standard fishery management plan and regulatory amendment procedures will be used to modify the program.		
B.3.4 Data Collection	Expanded voluntary submission of economic data (Option 2).	Expanded mandatory submission of economic data (Option 1).	Same as Program B

2.2 Alternatives Considered but Excluded from Detailed Analysis

This section discusses an alternative that was considered but rejected and briefly explains the reasons for its elimination. In addition, this section lists options and sub-options that were considered by the Council and TIQC but were not included in any of the alternatives forwarded for analysis.

An alternative that was initially considered for analysis would issue IFQs for overfished species, maintain cumulative trip limits for all other species, and implement total catch reporting and 100 percent at-sea monitoring. Upon further consideration it was determined that this alternative would not have the potential to create enough benefits to the groundfish fishery to offset the costs of the monitoring and reporting requirements, and questions were raised as to how the program would continue once overfished species recovered. Therefore, the alternative was dropped from further consideration.

In addition to the dropped alternative, a number of options and sub-options were discussed by the Council and TIQC but not included in the alternatives forwarded for analysis. The list below provides an initial summary of these excluded elements and options.

- Species groups that could be managed under an IFQ program but were not explicitly included
    - Overfished Species
    - Prohibited Species
- Stakeholder groups that were not included as recipients of QS
    - Vessel crew members and skippers
    - Vessel owners
    - Communities
- Methods for issuing QS that were not included
    - Auctions
    - Lotteries
    - Equal shares
    - QS based strictly on years of participation
- Types of shares from an IFQ program that might have been forwarded but were not
    - Shares for Processing (as opposed to IFQs for harvesting issued to processors)

While the elements and options listed above were not specifically included in the suite of alternatives that were forwarded for full analysis, all are included in the description of components, elements and options (Section 2.3).

2.3 Components Table

Before the effects of the alternatives on resources and stakeholders of concern can be fully evaluated a number of issues need to be addressed and decisions may need to be made by the Council. The Components Table below highlights these issues by augmenting the basic alternatives forwarded by the Council for detailed analysis. The major goal of the Components Table and the Components Analysis (see Appendix C: Components Analysis) is to ensure that the details of each alternative are adequately considered by clearly specifying how the different elements fit together within an alternative and identifying unknown or unintended potential effects on resources and stakeholders groups. The Components Table and Components Analysis also identify options that were discussed but not brought forward for detailed analysis.

Preface

This document is the Stage I Draft of the *Environment Impact Statement (EIS) of IFQs and Permit Stacking Alternatives in the Limited Entry Trawl Fishery* produced under Contract No. PFMC01IQ02 with the Pacific Fishery Management Council.

This version of the document has been completely reorganized from the draft that was provided in April to the Trawl IFQ Workshop. The reorganization decision was in collaboration with the PFMC. The document should be viewed as a work in progress, and as such the Consulting Team has focused its effort on document content, rather than on formatting. We apologize for any inconvenience this may cause reviewers, and very much appreciate any editing and proofreading comments.

The document is currently over 350 pages long including this front material, and while significant portions of the document contain only section headings, reviewers are encouraged to examine the entire document and to provide comments on the overall structure of the outline.

The Consulting Team has tried to front-load the content of the outline. The bulleted list provides an overview of the various chapters along with an indication of content levels.

- Chapter 1 contains introductory text for the EIS. The content is relatively complete.
- Chapter 2 provide summary of the alternatives for analysis. The Council has forwarded a main suite of 5 Alternatives including the No-Action Alternative. In addition there are numerous options that are also included but which are not part of the main suite of alternatives. The Council has not rejected these options and therefore wishes to include them in the EIS. The Components Table, shown in the second half of Chapter 2, organizes the alternatives forwarded by the Council in a step-by-step manner that allows decision-makers and stakeholders to investigate and understand the ramifications of each of the little decisions that must be made when overhauling the management regime. The PFMC and the Consulting Team are in the process of revising earlier versions of the component table, and consequently the full table is unavailable at this time. The full table will be included in the final draft.
- Chapter 3 contains the annotated outline of the past and baseline conditions of the affected stakeholders and resource groups.
- Chapter 4 contains annotated outline of the direct, indirect, and cumulative effects analysis. In the effects analysis of the alternatives will be examined as whole, and the effects of the alternatives on each group of stakeholders and resources will be documented.
- Chapter 5 contains an outline of the summary of other environmental management Issues
- Chapter 6 describes the 6 consistency between IFQ program, West Coast Groundfish FMP and MSA National Standards and Requirements
- Chapter 7 contains the outline of the analysis of cross-cutting mandates.
- Chapters 8 – 11 are reserved for a list of preparers, a glossary and a list of acronyms, an index and the listed references and cited literature.
- Appendix A contains an annotated outline of the RIR/IRFA

- Appendix B is a technical appendix to the Social Impact Assessment. The appendix contains introductory text and an example of the content that would be provided for affected communities.
- Appendix C contains the beginnings of a components analysis.

Executive Summary

1 Introduction

This introduction discusses the purpose and need for the proposed action. It also provides a historical background and a summary of actions and events that have led to the Council proposals. This introduction also lists the suite of alternatives to be analyzed, including alternatives that were considered but excluded from detailed analysis, and a summary of the scoping process. The introductory chapter ends with a description of how the remainder of the document is organized.

1.1 Purpose and Need for the Proposed Action

The Pacific Fishery Management Council (Council) is considering an individual fishing quota (IFQ) program that would change the primary management tool used to control trawl catch of West Coast groundfish from a system of periodic landing limits to one based on total catch quota shares (QS) where each quota pound (QP) derived from QS could be caught at any time during an open season. The status quo alternative (No Action) is also considered. From the set of alternatives analyzed in this draft EIS, the Council will identify a preferred alternative that will be termed "the proposed action."

In this EIS, QP is the annual catch amount allocated to an individual, whereas QS is the individual's portion as a percentage of the total allocation. IFQs refer to both QS and QP.

1.1.1 Need for Action (Problems for Resolution)

Despite the recently completed buyback program, management of the West Coast limited entry groundfish trawl fishery (West Coast groundfish trawl fishery) is still marked by serious biological, social, and economic concerns, similar to those cited in the US Commission on Ocean Policy's 2004 report. The trawl fishery is currently viewed as economically unsustainable given the current number of participating vessels, the current status of certain groundfish stocks, and the various measures in place to protect those stocks.

One major source of concern stems from the management of bycatch, particularly of overfished species. Over the past several years the Council's groundfish management efforts have been preoccupied with drafting rebuilding plans for overfished species, and general developing management schemes for minimizing bycatch and specific management of overfished species bycatch. Through the groundfish Strategic Plan and the draft Amendment 18 process, the Council has indicated its support for future use of IFQ programs to manage commercial groundfish fisheries. These programs will give individual fishery participants more flexibility in how they participate in the fishery, and more accountability in how individual actions affecting bycatch of overfished species impact the groundfish fishery as a whole.

Upon the recommendations of its Trawl Individual Quota Committee (TIQC), the Council sent the following problem statement out for public review during the public scoping period. The statement summarizes the perceived need for an IFQ-type program on the West Coast:

> As a result of the legal requirement to minimize bycatch of overfished species, considerable harvest opportunity is being forgone in an economically stressed fishery. The West Coast groundfish trawl fishery is a multi-species fishery in which fishermen exert varying and limited control of the mix of species in their catch. The optimum yields (OYs) for many overfished species have been set at low levels, placing a major constraint on the industry's ability to fully

harvest the available OYs of the more abundant target species that co-occur with the overfished species, wasting economic opportunity. Average discard rates for the fleet are applied to projected bycatch of overfished species. These discard rates determine the degree to which managers must constrain the harvest of targeted species that co-occur with overfished species. These discard rates are developed over a long period of time and do not rapidly respond to changes in fishing behavior by individual vessels or for the fleet as a whole. Under this system, there is little direct incentive for individual vessels to do everything possible to avoid take of species for which there are conservation concerns, such as overfished species. In an economically stressed environment, uncertainties about average bycatch rates become highly controversial. As a consequence, members of fishing fleets tend to place pressure on managers to be less conservative in their estimates of bycatch. Given all of these factors, in the current system there are uncertainties about the accuracy of bycatch estimation, few incentives for the individual to reduce personal bycatch rates, and an associated loss of economic opportunity related to the harvest of target species.

The current management regime is not responsive to the wide variety of fishing business strategies and operational concerns. For example, historically the Pacific Council has tried to maintain a year-round groundfish fishery. Such a pattern works well for some business strategies in the industry, but there has been substantial comment from fishermen who would prefer to be able to pursue a more seasonal groundfish fishing strategy. The current management system does not have the flexibility to accommodate these disparate interests. Nor does it have the sophistication, information, and ability to make timely responses necessary to react to changes in market, weather, and harvest conditions that occur during the fishing year. The ability to react to changing conditions is a key factor in conducting an efficient fishery in a manner that is safe for the participants.

Fishery stock depletion and economic deterioration of the fishery are concerns for fishing communities. Communities have a vital interest in the short-term and long-term economic viability of the industry, the income and employment opportunities it provides, and the safety of participants in the fishery.

In summary, management of the fishery is challenged with the competing goals of: minimizing bycatch, taking advantage of the available allowable harvests of more abundant stocks (including conducting safe and efficient harvest activities in a manner that optimizes net benefits over both the short and long term), increasing management efficiency, and responding to community interest.

1.1.2 Purpose of the Proposed Actions

The Council commissioned the TIQC with identifying the elements of a trawl IFQ program and scoping alternatives and potential impacts of those alternatives in support of the requirements of the Magnuson-Stevens Fishery Conservation and Management Act (MSA) and National Environmental Policy Act (NEPA). At its first meeting in October 2003, the TIQC drafted a set of goals and objectives. The Independent Experts Panel (IEP) and TIQC subsequently recommended modifying some of the goals and objectives. The participation of the TIQC, the IEP, and other entities in the scoping process is described below in Section 1.2.

The following list of "goals, objectives, and constraints and guiding principles" outlines the purpose of the proposed action. This list is based on recommendations of the IEP, as modified by the TIQC and Council. The Council adopted this list in June 2005 while recommending moving forward with an Individual Fishing Quota (IFQ) program for the trawl fishery.

1.1.2.1 Goals

1. Increase regional and national net benefits including improvements in economic, social, environmental and fishery management objectives.
2. Achieve capacity rationalization through market forces and create an environment for decision making that can rapidly and efficiently adjust to changing conditions.

1.1.2.2 Objectives

1. Provide for a viable, profitable and efficient groundfish fishery.
2. Minimize negative ecological impact while taking the available harvest.
3. Reduce bycatch and discard mortality.
4. Promote individual accountability – responsibility for catch (landed catch and discards).
5. Increase stability for business planning.
6. Increase operational flexibility.
7. Minimize adverse effects from an IFQ program on fishing communities to the extent practical.
8. Promote measurable economic and employment benefits through the seafood catching, processing, distribution elements, and support sectors of the industry.
9. Provide quality product for the consumer.
10. Increase safety in the fishery.

1.1.2.3 Constraints and Guiding Principles

1. Taking into account the biological structure of the stocks including such factors as populations and genetics.
2. Taking into account the need to ensure that the total OYs and Allowable Biological Catch (ABC) for the trawl and all other sectors are not exceeded.
3. Accounting for total groundfish mortality.
4. Avoiding provisions where the primary intent is a change in marketing power balance between harvesting and processing sectors.
5. Avoiding excessive quota concentration.
6. Providing efficient and effective monitoring and enforcement.
7. Designing a responsive review evaluation and modification mechanism.
8. Take into account the management and administrative costs of implementing and overseeing the IFQ program and complementary catch monitoring programs and the limited state and federal resources available.

The relative performance of each of the alternatives with respect to these "goals, objectives, and constraints and guiding principles" is summarized in Section 6.1. Many of these elements are also addressed elsewhere in the analysis, for example in the Chapter 6 discussion of consistency with the Pacific Coast Groundfish Fishery Management Plan (Groundfish FMP) and MSA national standards;

and in Appendices A and B where impacts on net national benefits, small entities and communities are addressed.

1.1.3 Background to Purpose and Need

This section examines the natural, exploitation, and management history of the West Coast groundfish trawl fishery.

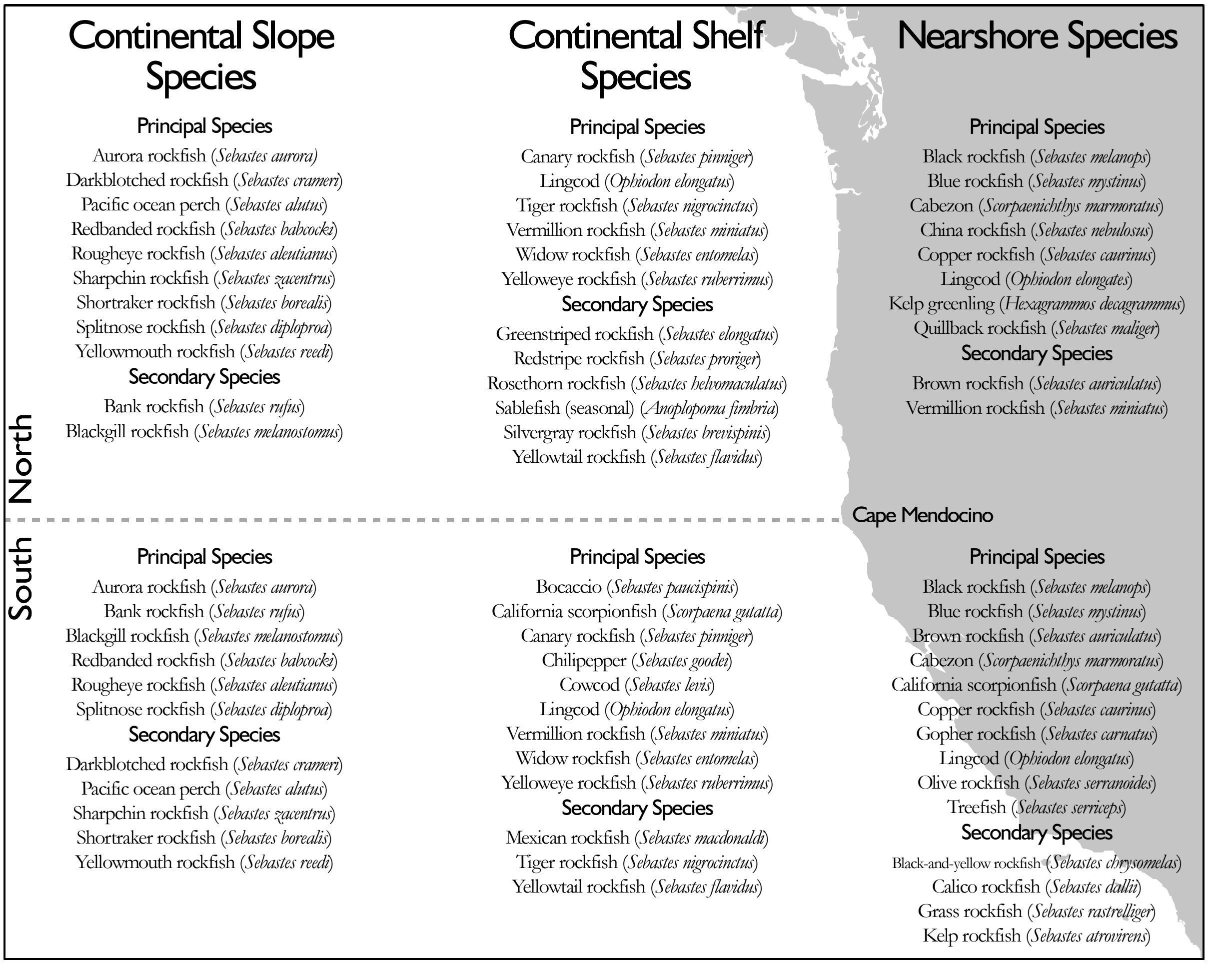
1.1.3.1 Biological Context of West Coast Groundfish

The groundfish covered by the Groundfish FMP include species that live on or near the bottom of the eastern Pacific Ocean within 200 miles of the US West Coast. These include the following species groups:

- **Rockfish.** The FMP covers 64 different species of rockfish, including widow, yellowtail, canary, shortbelly, and vermilion rockfish; bocaccio, chilipepper, cowcod, yelloweye, thornyheads, darkblotched rockfish, and Pacific Ocean perch.
- **Flatfish.** The FMP covers 12 species of flatfish, including various soles, starry flounder, turbot, and sanddab.
- **Roundfish.** The six species of roundfish included in the FMP are lingcod, cabezon, kelp greenling, Pacific cod, Pacific whiting (hake), and sablefish.
- **Sharks and skates.** The six species of sharks and skates in the FMP are leopard shark, soupfin shark, spiny dogfish, big skate, California skate, and longnose skate.
- **Other species.** These include ratfish, finescale codling, and Pacific rattail grenadier.

The list of current trawl target species includes flatfish, roundfish, thornyheads and a few species of rockfish. Primary flatfish target species include petrale sole and Dover sole. Roundfish target species include Pacific whiting, Pacific cod and sablefish. Some rockfish species, especially Pacific Ocean perch and widow rockfish were important trawl targets until the mid 1990s. Rockfish include three genera under the family Scorpaenidae. One genus, *Scorpaena*, forms only a small fishery off southern California. The thornyheads, genus *Sebastolobus*, are occasionally referred to as rockfish, however biologically they are quite different. The genus most commonly referred to as rockfish, *Sebastes*, is a very diverse group. Figure 1-1 shows the distribution of members of the genus *Sebastes* and other groundfish species by latitude and depth association.

Figure 1-1. Latitude and Depth Association of Selected Groundfish Species



West Coast flatfish and roundfish stocks are relatively abundant, short-lived, and productive. Large initial catches of rockfish gave the impression that these stocks were also highly productive. However, increased scientific knowledge of the natural history and stock status of several rockfish species made it clear that most members of the genus *Sebastes* are not able to withstand the level of removals made possible by high intensity fishing pressure using modern fishing methods. There are several reasons for this:

1. Most rockfish are viviparous. Fertilization is internal and the female retains the eggs until they hatch, giving "birth" to live young. This limits the number of eggs that are produced annually.
2. Extreme longevity. Specimens of several rockfish species have been estimated at over 60 years of age, and some over 100 years.
3. Long generation times. Many rockfish species require 10 or more years to reach sexual maturity.
4. Low natural mortality. Rockfish are adapted to relatively slow natural population turnover, unlike species such as Pacific whiting, sablefish and most flatfish.
5. Fecundity increases with age. Evidence shows that older female rockfish actually produce more young than younger ones.

6. Infrequent recruitment success. Ocean conditions or other factors seem to create large variability in recruitment success.
7. Specific habitat requirements vary with life stage. Eggs, larvae, juvenile and adult forms of many rockfish use different types of habitat over their lifecycle.
8. Relatively low mobility of adults. Many rockfish tend to inhabit a particular site for much of their adult life making them particularly susceptible to capture.

The traits of long life, slow growth, viviparity and increasing fecundity with age may have evolved to deal with environmental variability. The ability of Rockfish to live a long time and produce more young with age increases the odds that they will be able to "wait out" poor environmental conditions and produce enough young that a few offspring will likely survive. However, these characteristics also lead to a relatively low productivity for a given biomass and predispose most rockfish to being unable to support large, sustained removals. Low productivity coupled with a tendency to associate with other target species increases management difficulty. This is especially problematic when the associated species differ markedly in life history traits such as generation time, fecundity and natural mortality rate.

1.1.3.2 Groundfish Fisheries Context

The West Coast groundfish trawl fishery consists of a several species of flatfish, roundfish, rockfish, and other species taken using trawl, trap and hook-and-line gears, including recreational gear. The commercial fishery is prosecuted over a wide range of depths, from 20 fathoms for English sole and sanddabs to as deep as 700 fathoms for Dover sole, thornyheads, and sablefish. Fishing may occur on smooth mud/sand substrates, rocky reefs, pinnacles, and canyons. Recreational groundfish fisheries typically occur closer inshore than most commercial fisheries.

West Coast groundfish range from semi-pelagic species like Pacific whiting, shortbelly rockfish, and widow rockfish to demersal species such as Dover sole, lingcod, and thornyheads. Most species primarily inhabit the continental shelf, but Dover sole, thornyheads, rex sole, petrale sole, and some others occur in greatest abundance on the continental slope. The close spatial relationship of certain species often results in large catches of non-target species. This is particularly true in the case of bottom trawl catches. For example, vessels targeting on Dover sole also catch thornyheads, sablefish, and darkblotched rockfish. Several species of rockfish may be caught in a single trawl tow, and the species mix changes from north to south. Historically, widow rockfish, yellowtail rockfish, and canary rockfish were caught in the Vancouver and Columbia management areas, while bocaccio and chilipepper rockfish have been significant catch components in the Monterey and Conception areas. Currently, only a few rockfish species are trawl targets, including yellowtail rockfish in northern midwater fisheries and splitnose rockfish and associated species in the southern slope fishery.

Fishermen can exercise some control over the mix of various species in catches by depth and area shifts in effort as well as modifying the manner in which gear is fished. However, it is often impossible to avoid catch of some non-target species. The fishery's multi-species nature is further complicated by seasonal changes in fish availability, weather, and by market conditions (prices and poundage limits)—factors which may cause a trawler to fish on several species' assemblages in a single fishing trip. Many gear types are used in the commercial groundfish fishery, including trawl nets, traps, and longlines. However, trawl nets (both bottom and midwater types) account for the major portion of the groundfish catch.

In the trawl fishery, some incidental catch of non-targeted groundfish is unavoidable, and for economic or regulatory reasons, some of the catch is discarded. In multi-species fisheries such as this, it is practically impossible to optimize harvests—achieve MSY—for all stocks simultaneously. Optimally harvesting any one stock may result in either under-harvest or over-harvest of co-occurring stocks. While under-harvest is not necessarily a concern from a biological standpoint, it may have economic impacts in terms of forgone revenues and incomes. With the declaration of several species as overfished, over-harvest of co-occurring species has become an acute problem.

Under the Groundfish FMP, when a species is declared overfished, mortality levels for that species must be reduced substantially in order to allow the species to recover to a target biomass capable of supporting MSY. To keep the groundfish fishery within the species-specific catch limits for overfished species (landings plus discard mortality), limits are imposed on the landings of healthy stocks with the goal to reduce the take of the incidentally caught overfished species. The entire fishery may thus be managed based on the constraints imposed by a few species, even if those species are not targeted in any particular fishery, and are only caught incidentally.

The current number of overfished species and their occurrence in different areas and habitats along the West Coast means that virtually all groundfish fisheries are managed in ways that constrain the harvest of the healthy stocks. For this reason, overfished species are sometimes referred to as "constraining stocks," and managing fisheries to prevent overfishing of these stocks is likely to require forgoing substantial potential harvests.

1.1.3.3 Groundfish Management Context

The West Coast groundfish trawl fishery is jointly managed by state and federal authorities under the Magnuson-Stevens Act (MSA), which was passed in 1976 to "Americanize" US fisheries. In addition to establishing eight regional fishery management councils, the MSA extended US fishery management authority in territorial waters from 12 miles out to 200 miles from the shore. On the West Coast, the Council coordinates federal management authority for fisheries occurring in Pacific ocean waters from 3 to 200 miles off California, Oregon and Washington; with the states themselves for fisheries occurring in state waters (i.e., between the shoreline and 3 miles offshore).

Under the MSA, catch by foreign fleets in this "Exclusive Economic Zone" (EEZ) dropped to zero by 1992. However, this decline was more than offset by expansion of the US domestic fleet, which was encouraged by government subsidies. In response to the rapid expansion of the groundfish fishery on the West Coast, the Secretary of Commerce approved the Groundfish FMP in 1982. The Groundfish FMP initially focused on species targeted by the midwater trawl fishery (widow rockfish and Pacific whiting). Over the following decade, several additional species were added to the list of actively managed species, with established optimum yield (OY) catch amounts and, in some cases, sector quotas.

In 1996, the Sustainable Fisheries Act amended and reauthorized the MSA. National standards adopted under the reauthorization include a requirement to prevent overfishing while maintaining, optimum yield (OY). Optimum yield is the harvest amount that will achieve the maximum sustainable yield (MSY), as reduced by relevant economic, social, or ecological factors. Under National Standard 1(d), a stock is considered overfished if current stock biomass is less than 25 percent of the virgin biomass.

The Groundfish FMP currently covers more than 80 species. The Council manages the commercial fishery primarily with bimonthly trip limits set to prevent fishing mortality from exceeding OYs. However, despite increasingly stringent management measures, seven groundfish species are currently overfished as defined under the MSA (bocaccio, canary rockfish, cowcod, darkblotched rockfish, Pacific Ocean perch, widow rockfish and yelloweye rockfish). In January 2000, the Secretary of Commerce declared the West Coast groundfish fishery a federal disaster. In the summer of 2002, the

Council first began implementing depth-based area closures. These measures were designed to exclude fishing effort from those depth zones particularly inhabited by overfished species.

The Council has been developing programs to reduce capacity in the groundfish fisheries since the mid-1980s, culminating with this proposal to move toward an IFQ program. Groundfish FMP Amendments 6, 8, 9 and 14 were drafted specifically to reduce capacity in groundfish fisheries. A vessel buyback program implemented in 2003 reduced the number of groundfish trawl vessels by one-third. Draft FMP Amendment 18 is also expected to lead to capacity reduction by authorizing bycatch accountability conditions. The adoption of a framework and plans for rebuilding overfished species (Amendment 16) has led to the implementation of a vessel monitoring system (VMS) to insure that proscribed fishing does not occur in the RCAs.

1.1.3.4 Limited Entry Fixed Gear Capacity Rationalization

Amendment 8 to the Groundfish FMP was an attempt to implement an IFQ program in the fixed gear sablefish fishery. However this program languished first because of a congressional request for delay and then because of the Magnuson-Stevens Act moratorium on the creation of new IFQ programs. Instead, Amendment 9 was adopted in 1997 establishing limits on this economically valuable fishery. Amendment 9 required that in order to fish in the primary fixed gear sablefish fishery (April 1 to October 31), participating vessels must possess a new sablefish endorsement in addition to a fixed gear limited entry permit. Amendment 14, implemented in 2001, attempted to further rationalize this fishery by establishing a "permit stacking" system. Permit stacking allows a sablefish-endorsed fixed gear permit holder to acquire up to two additional permits and combine them for use on a given vessel. A vessel with stacked permits is assigned to one of three tiers based on the original catch history associated with the permits. Each tier has a different landing limit. A vessel with stacked permits is then eligible to take the landing limit associated with that tier for each permit assigned to the vessel. Thus, a vessel with three permits is eligible to land up to three times as much sablefish as a vessel in the same tier with only one permit.

Since the stacked permits confer fishing eligibility only during the primary sablefish season, the main capacity-reducing effect of Amendment 14 was to remove permits from the other limited entry fixed gear fisheries. Vessels surrendering their permits may still shift to other non-permitted fisheries if a viable opportunity exists. The endorsement and permit stacking regime has also succeeded in eliminating many of the characteristics of a "derby fishery" that plagued this fishery in the past. Derby fisheries result when overcapacity combined with restrictive catch limits serves to concentrate fishing into a very short season. By 1995 the primary sablefish season lasted only one week, which was followed by a brief "mop up" period to reach the established limit or allocation. Permit stacking essentially gives each vessel a fixed quota, which can be caught at any time during the six-month primary season. Although not a freely tradable quota, this system confers a set amount of sablefish harvest opportunity and allows it to be more efficiently allocated among vessels through permit transactions. The permit seller also captures economic rent through the sale. However, since the transferable units are fairly "lumpy", there is no ability to finely divide the amount or timing of quota purchases in this fishery as would be the case under a true transferable quota system.

As of 2002, about one half (83) of the 164 sablefish-endorsed permits were registered to vessels holding more than one permit. Of the vessels with multiple sablefish-endorsed permits, 25 had two permits and 11 had three permits (PFMC 2003b).

1.1.3.4.1 Overfished Species and the Strategic Plan

Under the reauthorized MSA, the National Marine Fisheries Service (NMFS) is required to report to Congress any managed species considered to be overfished or approaching a condition of being overfished. For any fish stock determined to be overfished, the Council is required to prepare a plan to rebuild that stock. The Council developed Amendments 11, 12 and 13 to the FMP to implement this and other new provisions of the 1996 Sustainable Fisheries Act. Following the completion of Amendment 11 in 1998, NMFS declared bocaccio, lingcod, and Pacific Ocean perch to be overfished. Subsequently NMFS declared six additional species to be overfished: canary rockfish and cowcod (in 2000), darkblotched and widow rockfish (in 2001), and yelloweye rockfish and Pacific whiting (in 2002). Pacific whiting was declared rebuilt in 2004, and lingcod was found to be rebuilt following a stock assessment conducted in 2005.

Since the declaration of the first three overfished species in 1999, the Council's groundfish management efforts have largely focused on developing management measures to reduce directed and incidental take of overfished species. To varying degrees, all of the overfished species co-occur with several more healthy and abundant stocks. One of the Council's primary strategies for reducing incidental catch of overfished species has been to limit access to the healthy co-occurring stocks. In response to the consequent severe reductions in available catch, the Secretary of Commerce declared the groundfish fishery to be a commercial fishery failure in January 2000. This declaration freed disaster relief funds for the three West Coast states, and pushed the Council to complete its Strategic Plan on managing the groundfish fisheries in October 2000. One element of the Strategic Plan was an evaluation of overcapacity in the commercial groundfish fleets. This was done by comparing the potential harvest capacity of participating vessels with the amount of fish actually available for harvest. For the non-whiting groundfish trawl fishery, the SSC calculated that 26 to 40 percent of the vessels then participating in the fishery were capable of taking all of the groundfish available for trawl harvest. The Strategic Plan noted that while a reduction of at least 50 percent in the number of trawl vessels was required, rationalization of the West Coast groundfish trawl fishery would not be complete until the capacity level was in balance with the economic value of the resource.

The Strategic Plan recommended a trawl vessel buyback program as a near-term objective, and a trawl IFQ or mandatory permit stacking program[1] as a longer-term objective. An IFQ program for trawlers has been on the Council's official workload list since soon after the adoption of the Strategic Plan. In June 2001, the Council created an Ad Hoc Trawl Permit Stacking Work Group. However, this group met only once on February 26, 2002 before being suspended while the Council addressed other workload priorities and began to develop a vessel buyback program before continuing work on permit stacking.

1.1.3.4.2 Limited Entry Trawl Capacity Rationalization and the Trawl Vessel Buyback

In 1987, the Council appointed an ad hoc Limited Entry Committee to design a groundfish fisheries license limitation program. In 1991, the Council adopted Amendment 6 to the groundfish FMP, a groundfish license limitation program that led to the creation of federal limited entry permits. At that time the Council acknowledged that the license limitation program, while expected to limit the growth of groundfish harvesting capacity, would not resolve the problem of overcapacity in the groundfish fishery. An IFQ program was also considered as a major alternative to the license limitation program. However, at that time there was a great deal of opposition to IFQs across all sectors of industry (vessel owners, operators, crew, processors, and support industries). The license limitation program was seen as a first step toward rationalization of the fleet with further capacity reduction

[1] Mandatory permit stacking reduces capacity in the fishery by requiring permit holders to acquire an additional permit to continue fishing.

measures to follow. NMFS implemented Amendment 6 in 1993, issuing 388 initial limited entry permits with trawl endorsements, in addition to permits issued with endorsements for longline and/or pot (trap) gear. Gear endorsements were used to constrain the number of participants using a particular gear type in the groundfish fishery. As of January 1, 1994, all vessels participating in the limited entry segment of the fishery were required to have permits.

Limited entry permits were issued with capacity endorsements that matched the length of the vessel that originally qualified for the permit. At the recommendation of the Council, NMFS issued a final rule in 1994 allowing permit owners to combine two or more permits to create a permit with a longer length endorsement than any of the original permits. Because a vessel's harvesting capacity increases geometrically (i.e., volumetrically) with an increase in vessel length, NMFS implemented a conversion formula for permit combinations that assigned a certain number of capacity rating points per foot of vessel length. Under this point system, a vessel owner wishing to permit a longer vessel must purchase enough existing permits to create a combined permit with capacity points sufficient for the length of the vessel (See 59 CFR17726, April 14, 1994). By 2003, this permit combination requirement had resulted in the effective removal of 114 trawl permits from the fishery. Of the 388 trawl permits originally issued, there were 274 permits remaining until the 2003 buyback program.

A line item in a 2003 budget bill (PL 108-7) instructed NMFS to implement a fishing capacity reduction program for the non-tribal West Coast groundfish trawl fleet (excluding Pacific whiting catcher-processors). This bill funded the buyback with a $10 million appropriation and a $36 million loan approved by an industry referendum. The loan will be repaid by members of the participating fleets (limited entry groundfish trawl, Dungeness crab pot, and pink shrimp trawl fleets) through landings fees collected over the course of the next 30 years. On August 8, 2005, NMFS published a notice (70FR 45695) announcing that collection for repayment of the loan would commence on September 8, 2005.

Under the buyback program, NMFS retired 91 trawl vessels, their associated state fishing permits, and federal limited entry trawl permits, effective December 4, 2003. The program reduced the available pool of limited entry permits for vessels delivering to shore plants and motherships to 182 permits (including the 10 permits associated with the whiting catcher-processor fleet). Since December 2003, 2 additional permits were retired through permit combination, leaving 180 limited entry trawl permits remaining in the fishery. The 91 vessels retired under the buyback program accounted for 40 percent of the $32 million in ex-vessel revenues delivered by all limited entry groundfish trawlers in 2002 (including deliveries to non-tribal motherships).

Following the completion of the buyback program, NMFS analyzed permit latency in the limited entry trawl fleet to determine whether a significant number of unused or infrequently used permits remained in the fishery. The agency's concern over latent capacity stemmed from public comments observing that permit/vessel owners who had been bought out under the buyback program could rejoin the fishery by simply purchasing a latent permit and vessel. The Council found no need to take remedial action given evidence for relatively low occurrence of highly latent permits and the apparent lack of concern among industry members who bear responsibility for repaying the $36 million loan that funded the buyback.

An IFQ program would obviate the need to address latent permit issues, and is the most efficient way to match capacity with available catch. Consequently, in response to a June 2003 request from members of the groundfish trawl industry, the Council decided to investigate moving forward with a trawl IFQ program as a solution to any remaining permit latency and overcapacity issues in the trawl fishery. The Council authorized appointment of the TIQC, which included representatives from the whiting and non-whiting trawl sectors, shoreside and at-sea processors, environmental organizations and communities. The Council also tasked Council staff with drafting a plan for IFQ program development, identifying budget needs, and pursuing funding options. November 6, 2003 was recommended by TIQC and endorsed by the Council as a control date for IFQ. A *Federal Register Notice* of this control date was published on January 9, 2004 (69FR 1563).

1.1.3.5 Current Groundfish Management System

The groundfish fishery is a multi-species fishery including many species of rockfish, flatfish, sharks and skates, and roundfish. A variety of targeting strategies are pursued using different types of gear, resulting in wide variation in the mix of species caught. Currently the groundfish fishery is divided into sectors: limited entry trawl (further subdivided into the shoreside sector and at-sea whiting sectors); limited entry fixed gear (line gear and pot or trap gear); directed open access using line, pot gear, or other non-groundfish trawl gears; "incidental" open access (vessels targeting non-groundfish species, like crab, salmon, or California halibut, but which occasionally catch groundfish); and a tribal groundfish sector, which includes whiting mothership, trawl and fixed-gear vessels.

Allocating harvest opportunity among different fishery sectors is an integral part of the management process. Some stocks, such as sablefish and Pacific whiting, have fixed or "hard" allocations. Management measures for these species are structured so that particular sectors have the opportunity to catch a fixed percentage of the OY. However, allocations for the majority of groundfish species are determined as part of the process of developing management measures. In these cases, rather than establishing a hard allocation, the Council proposes management measures, evaluates the likely allocations resulting from those measures, and modifies the proposed measures. The proposed modification takes place on the basis of the expected catches, and either establishes an ad hoc allocation (harvest guideline) for the purpose of the period covered by the management measures or a de facto allocation. In this way allocation among sectors is achieved, particularly in deciding harvest allocations between commercial and recreational sectors. The harvest of the four Indian tribes in Washington State is also taken into account when OYs are established. For a few species (sablefish and whiting, for example) a share of the OYs for groundfish species taken in their fisheries is explicitly allocated. For most species, expected tribal harvest levels are taken into account in setting regulations for other sectors but there is not an allocation to the tribes. For the species for which they receive an allocation, the tribes then oversee the prosecution of their fisheries separate from the management of other groundfish fishery sectors.

Since the adoption of FMP Amendment 17 in 2003, groundfish harvest specifications and management measures have been set on a biennial basis. Every even-numbered year the Council adopts OYs and management specifications covering groundfish fisheries for the following two years. The two-year management cycles began with the 2005-2006 fishery. ABCs and OYs are set based on the most recent stock assessments and recommendations from Council advisory bodies and comments from the public. Separate ABCs and OYs are identified for each year in the two-year cycle. Management measures are then crafted to optimize opportunities for commercial and recreational fishers while keeping harvest within the adopted OYs. Recently this process has become a delicate balancing act between the competing demands for groundfish target species from the different sectors, and the additional constraint to minimize mortality of several constraining overfished species, including bycatch (discard) mortality.

Management of commercial fisheries is currently based on four elements: seasons, bimonthly cumulative landings limits, management areas, and exclusion zones or groundfish conservation areas. Landed species can be caught outside of designated exclusion zones that, for commercial fisheries, generally encompass bottom areas on the continental shelf between about 75 fm and 150 fm in depth (varying somewhat with season and year), and are referred to as Rockfish Conservation Areas (RCAs). Landings limits are set based on historical landings of target species from fish tickets, and discard rates for target and incidental catch species obtained from observer sampling of commercial fishing vessels.

1.1.3.5.1 Commercial Fishery Management Measures

1.1.3.5.1.1 Seasons

Most groundfish fisheries are managed to achieve a year-round season. In fact, this is one of the key objectives expressed in the Groundfish FMP because buyers and processors regard a continuous and consistent supply of fish as essential to maintaining markets. Recently, managing fisheries to prevent OYs from being exceeded before the end of the year has become increasingly difficult because of the low harvest limits for some overfished species. Consequently, some fisheries have been closed early. A few groundfish fisheries are managed according to shorter seasons. The Pacific whiting fishery is the most significant example in terms of the volume of landings. Its season usually begins on April 1 and runs until the OY has been caught, usually by late October. The Pacific whiting OY is allocated according to a formula between shore-based, at-sea mothership, at-sea catcher/processor, and tribal fleets. Within a given whiting fleet, participants coordinate fishing behavior to determine how quickly their allocation will be taken or, conversely, how long the season will last. The limited entry fixed gear sablefish fishery is also limited to a “primary season” from April 1 to October 31. While sablefish may be caught by other sectors and fisheries at other times of the year, the allocation and catch limits are smaller.

1.1.3.5.1.2 Cumulative landings limits

Trip limits have been a feature of groundfish management since the inception of the Groundfish FMP. Over time the regime has become more complex, covering a wider range of species and sectors. The basic concept is to set a limit on how much of a given species (or multi-species complex[2]) an individual vessel may land in a fixed time period. Originally, these limits were on a per trip basis. Currently, in order to reduce the likelihood of regulatory discards, the limits are cumulative totals for a two-month period (Jan-Feb, March-Apr, May-June, etc.). Two-month cumulative landings limits are set separately for the limited entry trawl, limited entry fixed gear, and open access sectors. For each of these sectors there are separate limits for US waters north and south of 40°10' N latitude (approximately Cape Mendocino, California). The Pacific whiting fishery is a significant exception to trip limit management. As noted above, it occurs during a season whose length is determined by how quickly the OY is taken.

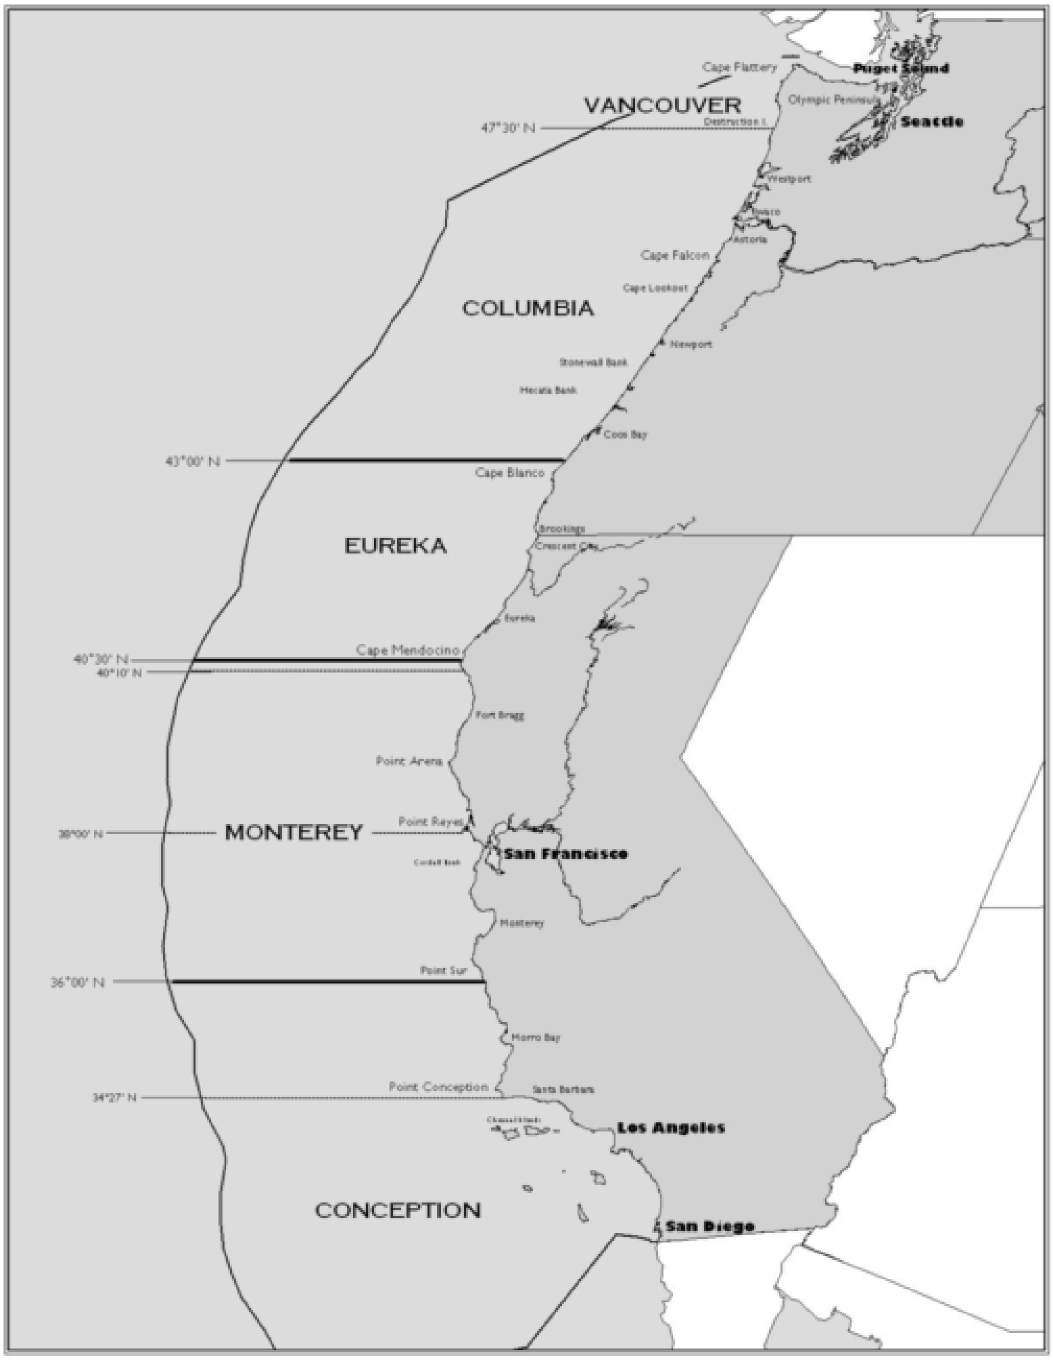
1.1.3.5.1.3 Management Areas

The West Coast EEZ is divided into several, sometimes overlapping, areas, as shown in Figure 1-2. The five named areas (Vancouver, Columbia, Eureka, Monterey, and Conception) were originally devised by the International North Pacific Fishery Commission (INPFC) as statistical areas for cataloguing fish catch. Although still occasionally referred to as “INPFC areas,” this organization is defunct and “management area” is now the preferred term. Landings continue to be reported by these areas in the Groundfish Stock Assessment and Fishery Evaluation (SAFE) document, and these boundaries are sometimes used to demarcate the application of different management measures. The 40°10' N latitude line (near the Eureka-Monterey boundary) is more significant in this respect, as noted above. Landings limits differ north and south of this boundary. Other boundaries in use for

[2] Many commercially less important or less frequently caught species are combined in stock complexes for the purposes of management. These species are not generally differentiated in reported landings, and most have not had stock assessments. Multi-species complexes currently in use include the “minor rockfish” (additionally separated into several sub-categories), “other flatfish”, and “other fish” categories.

management include latitude lines at significant coastal landmarks, such as Point Reyes and Point Conception in California. The latter represents an important marine biogeographic boundary, and is used to bifurcate some stocks (such as sablefish), as well as to differentiate management measures.

Figure 1-2. West Coast Groundfish Management Areas and Other Key Management Lines



1.1.3.5.1.4 Groundfish Conservation Areas

Three different types of closed areas have been implemented to limit bycatch of overfished species. A relatively small Yelloweye Rockfish Conservation Area (YRCA) closes a "hotspot" off the Washington coast. Recreational fishing is prohibited within the YRCA and the area is a designated as a voluntary closure for the limited entry fixed gear sablefish fleet and salmon trollers. The YRCA was first implemented in 2003. There are two areas off the southern California coast designated Cowcod Conservation Areas (CCAs), intended to protect cowcod. Recreational and commercial fishing are prohibited within the CCAs, except that rockfish and lingcod fishing have been permitted shoreward of 20 fathoms. The CCAs were first implemented in 2001. Rockfish Conservation Areas (RCAs) are by far the most extensive and complex closed areas. First implemented in late 2002 as part of an in-season management action, RCAs extend from the Canadian border to the Mexican border of US waters. The RCAs were implemented to reduce bycatch of overfished species. These species are more frequently caught within certain depth ranges. Based on analysis of observer reports and vessel logbooks, the boundaries of the RCAs were set to prohibit bottom fishing within a range of depths where encounters with overfished species were most likely. In order to make enforcement possible, in most cases the actual isobaths—lines of equal depth—are approximated by straight lines between published waypoints. The depths included in RCAs vary by season, latitude, and regulatory sector. Boundaries for limited entry trawl vessels are different than those for the limited entry fixed gear and open access sectors. Figure 1-3 and Figure 1-4 depict the general configuration of the trawl RCA during January and February, and March through October, respectively, of 2005. Note that in Figure 1-4, the width of the RCAs (particularly in the Northern areas) is significantly reduced.

Figure 1-3. Configuration of the trawl RCA and Cowcod Conservation Area during January-February 2005.

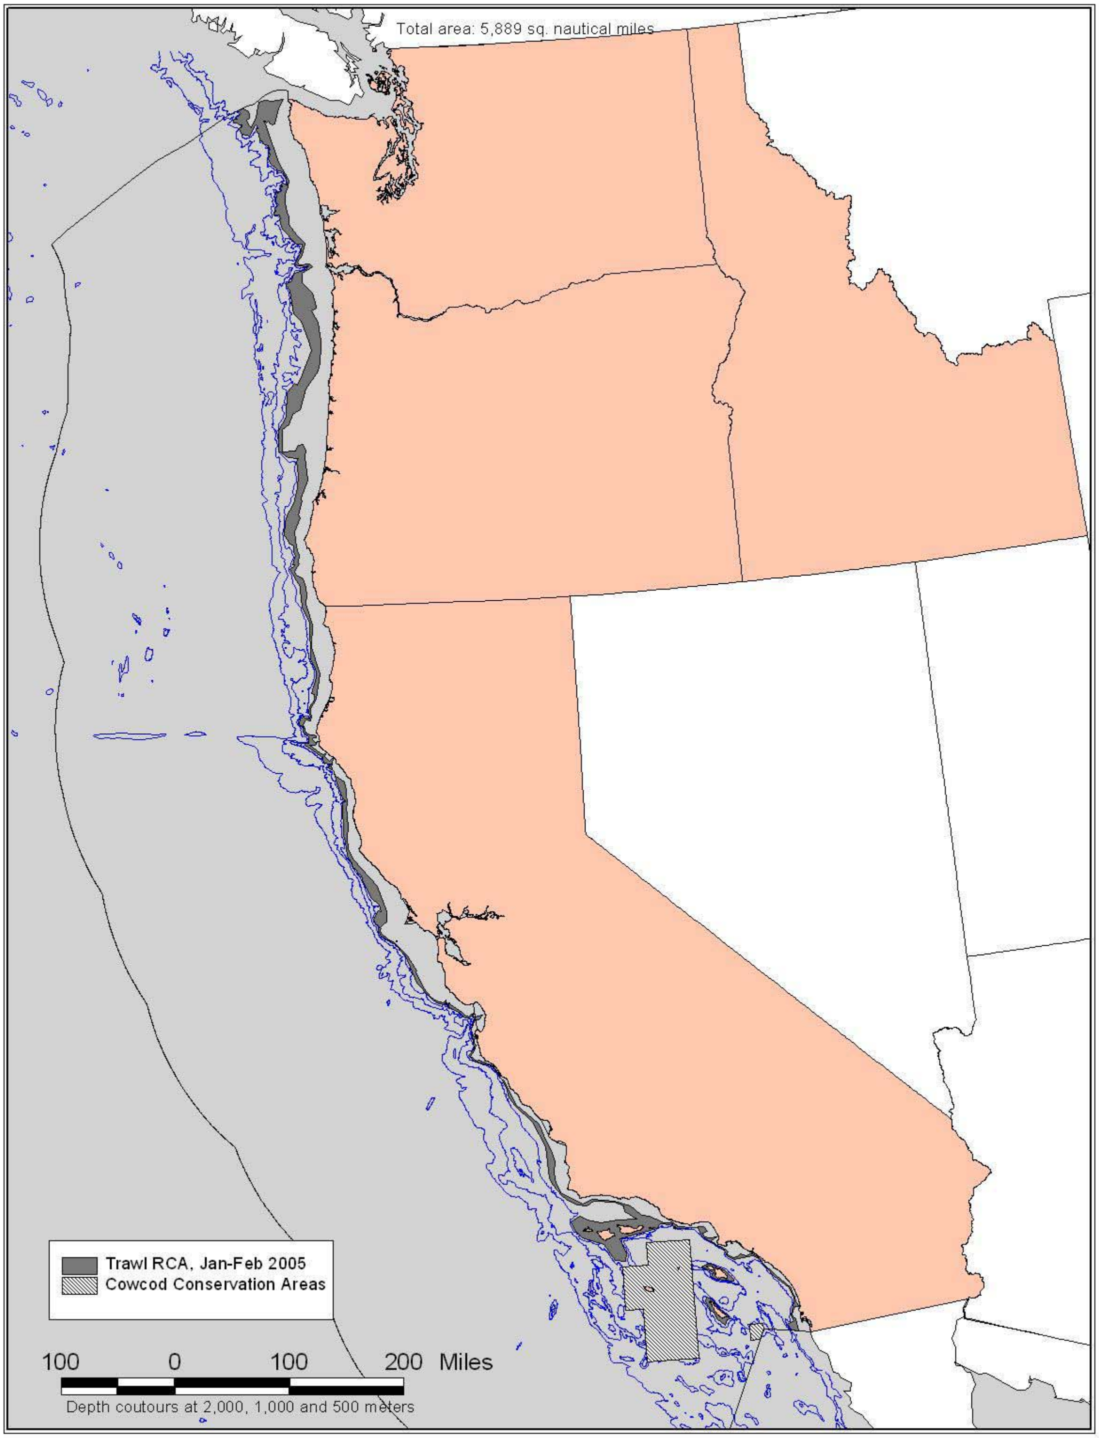


Figure 1-4. Configuration of the trawl RCA and Cowcod Conservation Area during March-October 2005.

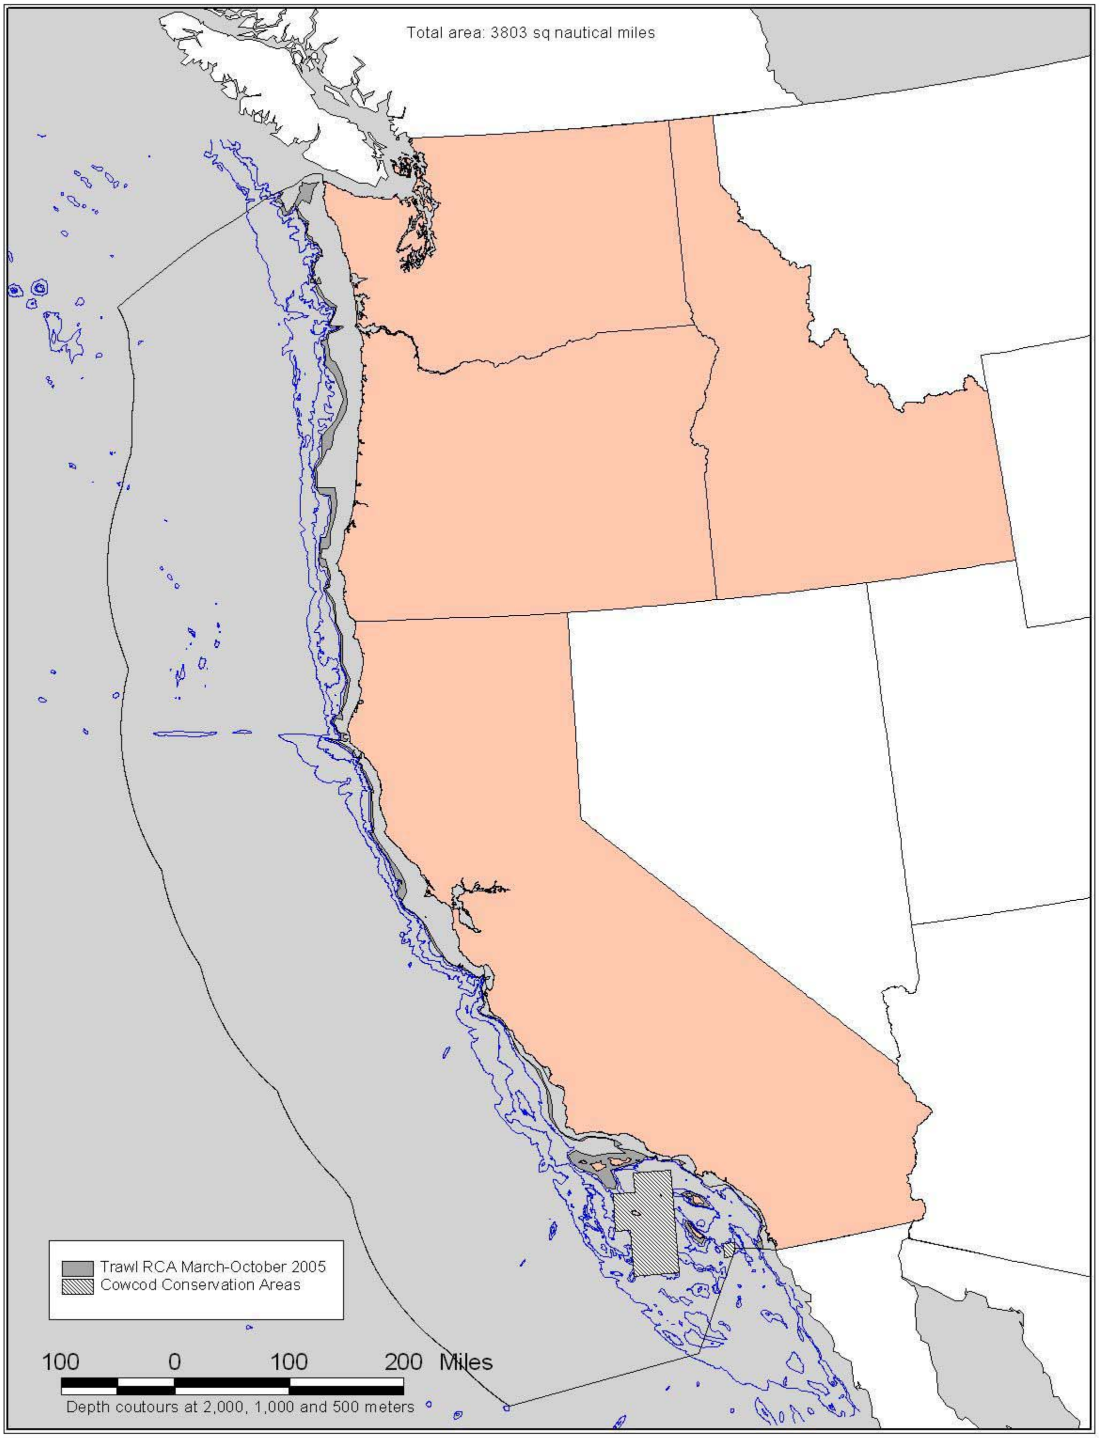

1.1.3.5.1.5 Gear Restrictions

Although various gear restrictions were a key feature of groundfish management even before the FMP was implemented, the most important current measures distinguish between large and small footrope gear. This refers to the size of the roller gear affixed to the bottom leading edge of a bottom trawl net. Large footrope gear can allow the net to be fished over rougher ground. Large footrope gear is also preferred when trawling for Dover sole, thornyheads, and sablefish (DTS species) on the soft bottom areas offshore, while small footropes are more commonly used to fish in areas shoreward of the RCAs. Since rocky habitat areas nearshore and on the continental shelf are important to a range of organisms, including several overfished rockfish species, the Council developed measures to discourage fishing on these sites. Beginning in 2003, vessels using small footrope trawl gear (and therefore more likely to be fishing shoreward of the RCA) at any time during a cumulative limit period are subject to lower DTS species landings limits. So if small footrope gear is used at all during that period, the amount of fish that can be landed during the period is significantly reduced. This restriction is meant to encourage vessels to fish exclusively seaward of the RCA (and using large footrope gear), thereby avoiding bycatch of overfished groundfish species (particularly canary rockfish) that are found on the continental shelf. An exception is selective flatfish trawl (SFT) gear, which can be used shoreward of the RCA in association with relatively higher cumulative trip limits to target flatfish. In order to qualify as SFT gear, the net must have a headrope at least 30 percent longer than the footrope, the rise of the net cannot exceed 3 ft, the headrope must not have any floats along the center 50 percent of its length, it must be a two-seam trawl net, and otherwise qualify as legal small-footrope trawl gear as defined in federal regulations. Also, in some non-groundfish (incidental open access) fisheries, such the pink shrimp fishery, bycatch reduction devices (BRDs) are required. These devices are added to the trawl net and divert finfish (such as canary rockfish) out of the codend of the net, where the shrimp catch is accumulated.

1.1.3.5.1.6 Observer Coverage

With the exception of the Pacific whiting fleets, there has been no consistent and comprehensive monitoring of groundfish total catch or discards on the West Coast. Vessels participating in the at-sea Pacific whiting fisheries have been voluntarily carrying observers since 1991. NMFS made observer coverage mandatory for at-sea processors in July 2004 (65 FR 31751). The Shoreside Whiting Observation Program (SWOP) was established in 1992 to examine bycatch in the directed Pacific whiting fishery. Participating vessels must carry an exempted fishing permit (EFP) issued by NMFS, and are required to retain all catch and to land unsorted catch at designated shoreside processing plants. In return, permitted vessels are not penalized for landing prohibited species (e.g., Pacific salmon, Pacific halibut, Dungeness crab), nor are they held liable for exceeding groundfish trip limits. Beginning in 2001, the West Coast Groundfish Observer Program (WCGOP) has placed observers on selected non-whiting groundfish vessels. NMFS first implemented the WCGOP in August 2001 to directly observe groundfish discards in the commercial fishery. Observers initially covered about 10 percent of the West Coast limited entry trawl fleet effort, selected via a stratified random sample. Coverage has since increased to about 20 percent and has also been expanded to include the limited entry fixed-gear and open access vessels. This WCGOP generates the incidental catch and discard rates currently used to set cumulative trip limits in the non-whiting fisheries.

1.1.3.5.2 Recreational Fishery Management Measures

Recreational fisheries typically occur closer inshore than most commercial fisheries and are actively managed by the states. Thus, recreational management measures, although developed through the Council process, tend to differ between states. The main recreational management measures used are season limitations, bag limits, which restrict the number of groundfish an angler may land, and size (length) restrictions. Since some overfished species are frequently caught in recreational fisheries, species-specific sub-limits are applied within the overall groundfish bag limit. Closed seasons have also been imposed in response to overfishing. The most recent response to recreational take of overfished species has been to establish depth-based area restrictions. Although similar in concept and intent to the RCAs, recreational area restrictions generally limit recreational groundfish fishing to depths less than a specified value (e.g., 30 fm). Boundaries defined by waypoints for these areas generally have not been used.

1.2 Scoping Summary

1.2.1 Background to Scoping

Although a formally announced public scoping on a potential trawl IFQ program EIS under NEPA did not begin until May 24, 2004, the Council began preliminary scoping of alternatives for reducing harvest capacity and bycatch in the trawl fisheries in September 2003.[3] Following the September 2003 meeting, the Council Chair appointed the TIQC from a broad range of constituencies. The TIQC has served as the Council's initial scoping vehicle, conducting public meetings to examine what elements a trawl individual quota program should contain if such a program were implemented. In this role, the TIQC met to discuss and develop proposed alternatives five times: October 28-29, 2003; March 17-18, 2004; October 26-27, 2004; February 23-24, 2005; and May 10-11, 2005.

1.2.2 Council and Agency NEPA Scoping

A number of other Council committees were formed or enlisted to support the TIQC process, including the Council's Enforcement Group, the TIQ Analytical Team, and TIQ Independent Experts Panel. The Enforcement Group developed enforcement program alternatives during meetings on May 25-26, 2004, and September 28, 2004. Analytical Team members from NMFS and California Department of Fish and Game, supported by Council staff and private contractors, worked to supply the analytical demands of the TIQC process throughout the scoping period. The Analytical Team met four times: June 8-9, 2004; July 1-2, 2004; September 7-8, 2004; and November 16-17, 2004.

Trawl IFQ program issues were also discussed by the Council's Allocation Committee at several of its public meetings between September 2003 and November 2005. The Allocation Committee is particularly interested in this issue because implementing an IFQ program for the trawl fleet would, at a minimum, require the Council to allocate catch of groundfish species and species complexes between limited entry trawl and the other fleets. The Allocation Committee is also currently engaged in developing sector allocations for groundfish species in response to the framework adopted under the draft FMP Amendment 18 process.

NMFS published a notice of intent to develop a trawl IFQ program EIS and formally initiate scoping on May 24, 2004 (69 FR 29482). The Council's formally announced NEPA public scoping period ran from May 24, 2004 through August 2, 2004. Three NEPA scoping hearings were held: June 13, 2004 in Foster City, California; July 20, 2004 in Seattle, Washington; and July 27, 2004 in Newport, Oregon.

[3] Note that IFQs were an alternative under the 1991 Amendment 6 groundfish license limitation program, and have been raised in Council discussions about management alternatives before and since that time.

Having received the results from public scoping and input from Council advisory bodies, the Council voted in June 2005 to forward for analysis in a draft EIS, the following draft TIQ alternatives covering trawl harvest and processing of West Coast groundfish, including Pacific whiting:

- Alternative 1: Status quo
- Alternative 2: IFQs for trawl target species and species for which allocations exist
- Alternative 3: IFQs for all groundfish except the "other fish" category of groundfish **with** adjustments at low harvest levels
- Alternative 4: IFQs for all groundfish except the "other fish" category of groundfish **without** adjustments at low harvest levels
- Alternative 5: IFQs for all groundfish
- *Alternative 6: IFQs for overfished species only (this alternative was later dropped)*
- Alternative 7: Permit stacking (one cumulative limit for each permit associated with a vessel)

In November 2005, the Council recommended some changes to the EIS analysis commissioned in June, including: (1) eliminating a provision requiring processor participation[4] in collaboratives of quota share holders competing for quota set aside to benefit communities; (2) creating a community advisory panel as part of the Council process; and (3) dropping Alternative 6, which would have created a trawl individual quota program only for overfished species.

The timeline for progressing on the draft EIS will depend on available funding. In September 2005, the Council selected a contractor to work on Stage 1 of the EIS process, drafting an annotated outline of the EIS and associated documents to be used in phase two of the process, drafting the EIS itself.

1.2.3 Summary of Comments Received

Comments received during the May 24, 2004 through August 2, 2004 NEPA public scoping period are summarized in a separate document, *Staff Summary of Public Comment on Trawl Individual Quotas*, PFMC, September 2004.

1.3 Organization of This Document

This document currently consists of 11 chapters and 3 appendices. Following this introductory chapter, the remaining chapters of this document cover the following material:

- Chapter 2: Provides a description of the proposed alternatives, including a detailed component-by-component breakout, and a discussion of alternatives considered but excluded from detailed analysis.

[4] The Council's November 2005 recommendation eliminated the provision requiring community benefit set-aside QP applicants to submit harvester/processor joint venture proposals, instead opening the community set-aside QP proposal process to any IFQ holder (who may or may not chose to collaborate with another entity). Under those alternatives and options providing for direct allocations of IFQ to processors (or that would otherwise allow processors to become direct IFQ holders), processors holding IFQ could apply for community set-aside QP without taking on a harvester sector partner just as harvesters holding IFQ could apply for community set-aside QP without taking on a processing sector partner.

- Chapter 3: Provides summary profiles of potentially affected resources and stakeholder groups, including descriptions of historical and baseline conditions, mechanisms for change, and indicators used to measure change.
- Chapter 4: Evaluates the direct, indirect and cumulative effects of the alternatives on the resources and stakeholder groups of concern. The analysis uses a “resource-based” approach whereby a single section of the document examines and describes the direct, indirect and cumulative effects of each alternative on a particular resource or stakeholder group.
- Chapter 5: Contains a review of other issues typically found in NEPA documents including short-term uses versus long-term productivity, irreversible resource commitments, and energy requirements and conservation potential of the alternatives.
- Chapter 6: Examines the consistency of the proposed action with the TIQ program goals, objectives, and constraints and guiding principles (listed in Section 1.1.2); the Groundfish FMP goals and objectives; and the national standards and other provisions of the MSA.
- Chapter 7: Examines consistency with other federal laws and Executive Orders.
- Chapter 8: Lists the individual preparers of this document.
- Chapter 9: Presents a glossary of technical terms and a list of acronyms used in this document.
- Chapter 10: Provides a list of the literature cited in this document.
- Chapter 11: Provides a general keyword index to the document.
- Appendix A: Contains the Regulatory Impact Review (RIR) and Initial Regulatory Flexibility Analysis (IRFA).
- Appendix B: Contains the Social Impact Assessment Technical Appendix.
- Appendix C: Contains a detailed analysis of the components, elements and options underlying the Action Alternatives.

2 Description of Proposed Alternatives

2.1 Alternatives Forwarded for Analysis

The Council, with considerable input from the TIQC and TIQ Analytical Team, forwarded an initial suite of six alternatives for analysis. After discussions between the Consulting Team and the Council Staff, it was determined that the differences between two of the alternatives were relatively minor and did not require a full analysis—differences could be discussed as sub-option to a single alternative.[5] As a result of these discussions it was determined that the list of alternatives forwarded for detailed analysis could be reduced from six to five.

The alternatives analyzed include a "no-action" alternative, three alternatives involving IFQs, and an alternative allowing the stacking of permits. These five alternatives are summarized below in terms of the basic management regimes that would be employed:

Alternative 1: The No-Action Alternative. The status quo management regime for groundfish species would be continued. Only limited entry trawl permit holders would fish for groundfish with trawl gear. Whiting would be managed with special seasons and allocations to sectors defined by the processor of the whiting; Non-whiting groundfish with the exception of Other Species would be managed with cumulative landings limits issued to all limited entry trawl permit holders every two months. Catches of Other Species of groundfish—sharks (except spiny dogfish), skates, rays, ratfish, morids, grenadiers, etc. (Note: spiny dogfish, cabezon, and kelp greenling would likely be managed separate from Other Species)—would be monitored but Optimum Yields (OYs) would not be constraining. Reporting of at-sea discards of groundfish would not be required. If the OY for any species becomes extremely low, the Council may suspend allocations between gear sectors.

Alternative 2: IFQs for whiting and Trawl Target Species. Whiting seasons and sectors would be maintained, and an additional non-whiting sector would be established. IFQs are not issued for incidentally caught groundfish—these are managed with transferable, bi-monthly cumulative catch limits. Reporting of all groundfish catch would be required. At-sea monitoring would be required on all vessels. Catches of Other Species of groundfish would be monitored. For IFQ species, management does not change with low OYs. If the OY for a non-IFQ species becomes extremely low (such as for a rebuilding species). The species would be managed with nontransferable cumulative catch limits.

Alternative 3: IFQs for all groundfish species except Other Species. Whiting seasons would be eliminated, but whiting sectors are maintained. Reporting of all groundfish catch would be required. At-sea monitoring would be required on all vessels. Catches of Other Species would be monitored. If the OY for any species becomes extremely low, management would switch from IFQs for that species, and instead the species would be managed under sector allocations as a pool using nontransferable cumulative catch limits to control catch.

[5] The two similar alternatives—Original Alternative 3 and Original Alternative 4—both allocated QS/QP for all but "other species", but differed in way they treated species with Low OYs, and in the basic allocation of QS/QP. However, Original Alternative 5, which allocates QS/QP for all species, used the same Low OY treatment and the same basic QS/QP allocation as Original Alternative 4. Therefore it was determined that dropping Original Alternative 4 would not leave any significant programmatic options unanalyzed. The Alternatives as originally forwarded to Consulting Team can be viewed at http://www.pcouncil.org/groundfish/gfifq.html

Alternative 4: IFQs for all groundfish species. The distinction between whiting sectors would be eliminated. Reporting of all groundfish catch would be required. At-sea monitoring would be required on all vessels. OYs for each of the Other Species of groundfish would be would be established. If the OY for any species becomes extremely low, the Council may suspend allocations between gear sectors for that species.

Alternative 5: **Permit stacking.** Groundfish would be managed as under the No-Action Alternative, but limited entry trawl permit holders would be allowed to "stack" additional permits. Permit holders would be issued a full complement cumulative trip limit pounds for each permit they own. Whiting seasons and sectors would be maintained. Reporting of all groundfish catch would be required. At-sea monitoring would be required on all vessels. Catches of Other Species would be monitored. If the OY for any species becomes extremely low, the Council may suspend allocations between gear sectors for that species.

In addition to the various management regimes described above, the three IFQ alternatives (Alternatives 2 – 4) differ with respect to the way in which quota shares are allocated. The Council developed three basic allocations and incorporated them into three IFQ programs (currently labeled Program A, Program B, and Program C). The allocations differ primarily in terms of which groups would receive quota and how much each group would receive. These are summarized below:

Program A: Harvesters and processors are initially allocated equal amounts of QS that give them rights to harvest groundfish. Processors are defined as those facilities that take ownership of and process unprocessed groundfish. Program A would be applied to Alternative 3.

Program B: Harvesters and processors are allocated QS that give them rights to harvest groundfish. Split options include: a) 100/0 for all groundfish, b) 100/0 for non-whiting and 50/50 for whiting, and c) 90/10 for all groundfish. Processors are defined as in the FMP—those facilities that process either unprocessed or already processed groundfish or receive live fish for resale. Program B would be applied to Alternative 3.

Program C: Harvesters and processors are allocated QS that give them rights to harvest groundfish. Harvesters would initially receive 75 percent of the QS and processors would receive the remaining 25 percent. Processors are defined as those facilities that take ownership of and process unprocessed groundfish. Program C would be applied to Alternative 2, 3, and 4.

All three of the programs are applied to Alternative 3 as options. In effect, this generates three new alternatives: Alternatives 3A, 3B, and 3C. In addition it should be noted that Program B contains three different allocation schemes, and that these schemes also have the potential to significantly alter the impacts of the alternative. The end result is that Alternative 3 might reasonably be analyzed as five different alternatives: Alternatives 3A, 3Ba, 3Bb, 3Bc, and 3C.

Table 2-1 and Table 2-2, below, present details of the various elements and options that make up each of the alternatives. The tables are similar to those produced for the Council, and contain references to the IFQ Scoping Results Document[6] and various options described within that document.

[6] National Environmental Policy Act Scoping Results Document: Individual Fishing Quotas (A Kind of Dedicated Access Privilege) and Other Catch Control Tools for the Pacific Coast Limited Entry Trawl Groundfish Fishery. Pacific Fishery Management Council, July 2005.

Table 2-1. Management Regime Alternatives for Analysis

Alternatives (Sec 2.1.1.1 Scoping Results[a/])	Alternative 1 No-Action Alternative	Alternative 2 IFQs for Trawl Target Groundfish	Alternative 3 IFQs for All Groundfish Except Other Fish	Alternative 4 IFQs for All Groundfish	Alternative 5 Cumulative Catch Limits and Permit Stacking
COMPONENT 1: CATCH CONTROL TOOLS					
IFQ Program for <u>Non-Whiting</u> and <u>Whiting</u> Trips					
Element 1.1 IFQ Program to Be Applied **(See Table 2-2)**	No IFQ Program.	Program C	Alternative 3A - Program A Alternative 3B - Program B Alternative 3C - Program C	Program C	No IFQ Program.
Additional Control Tools (Sections 2.1.1.2 of the Scoping Results Document).[a]/					
Element 1.2 **Permit Stacking**	-- -- -- None -- -- --				One set of trip limits issued for each of a maximum of 3 permits attached to vessel. Only one of the permits attached to the vessel would need to be of the appropriate length.
Element 1.3 **Cumulative Trip Limits**	Cumulative landing limits. (One set of limits for each vessel to which a permit is assigned.)	Transferable cumulative catch limits.[b]/ Cumulative limits would be transferable on a temporary basis between vessels within the period (full or partial limit transfers would be allowed, depending on length of limit period)	Cumulative catch limits (One set of limits for each vessel to which a permit is assigned.)	None	Cumulative catch limits. (One set of limits for each permit.)

Alternatives (Sec 2.1.1.1 Scoping Results[a/])	Alternative 1 No-Action Alternative	Alternative 2 IFQs for Trawl Target Groundfish	Alternative 3 IFQs for All Groundfish Except Other Fish	Alternative 4 IFQs for All Groundfish	Alternative 5 Cumulative Catch Limits and Permit Stacking
Element 1.4 Adjustments for Low OYs					
Allocation	- -- -- -- -- -- -- -- -- The Council may suspend intersector allocations when a species is overfished -- -- -- -- -- -- -- --				
Catch Control Rules	N/A	Adjust rules for low OY conditions (as specified in Component 2). *IFQ species – No change.* *Non-IFQ species – For species meeting the low OY threshold switch from transferable to **non**transferable cumulative catch limits.*[c/]	**Option 1**: Adjust rules for low OY conditions (as specified in Component 2). *For low OY species, except whiting, switch from IFQs for that species and instead manage the sector allocation as a pool using nontransferable cumulative catch limits to control catch.*[d/] **Option 2:** No low OY adjustments.	N/A	N/A
Threshold	N/A	Low OY Threshold: Establish a threshold at which point a species would switch to "Low OY management." (e.g., $B_{25\%}$)	Low OY Threshold: Decide on application of "Low OY management" as part of the biennial specifications process.	N/A	N/A
Element 1.5 General Season Closures	-- -- -- -- When all sectors in aggregate reach the overall OY for a species, seasons close for the affected species -- -- -- --				
Element 1.6 Whiting Season Openings	Staggered season openings for each whiting sector.	Possible continuation of spring opening for the season, to control impacts on ESA listed salmon.	Possible continuation of spring opening for the season, to control impacts on ESA listed salmon.	Possible continuation of spring opening for the season, to control impacts on ESA listed salmon.	Same as no action.
Element 1.7 Whiting Season Closings	Whiting season closes for a sector on attainment of whiting allocation. Whiting season closure on attainment of bycatch caps for species with bycatch caps.	Whiting season closure on attainment of bycatch caps for species with bycatch caps.[i/]	Open until end of year.	Open until end of year.	Same as no action

Alternatives (Sec 2.1.1.1 Scoping Results[a/])	Alternative 1 No-Action Alternative	Alternative 2 IFQs for Trawl Target Groundfish	Alternative 3 IFQs for All Groundfish Except Other Fish	Alternative 4 IFQs for All Groundfish	Alternative 5 Cumulative Catch Limits and Permit Stacking
COMPONENT 2					
Sector/Species Group Combinations and the Catch Control Tools To Be Applied (Section 2.1.1.3 & 2.1.1.4 of the scoping results document)					
Element 2.1 Sectors Define Whiting Trip: Opt 1-- >50% non-whiting Opt 2-- >50% or >10,000 lbs non-whiting	Three sectors: ▪ shoreside (SS) deliveries ▪ mothership (MS) deliveries ▪ catcher-processor (CP) deliveries	Four sectors: ▪ SS non-whiting deliveries ▪ SS non-non-whiting deliveries ▪ MS deliveries ▪ CP deliveries (FROM Scoping Results Doc: 2.1.1.4 Option 3)	Three sectors: ▪ SS deliveries ▪ MS deliveries ▪ CP deliveries (FROM Scoping Results Doc: 2.1.1.4 Option 2)	One sector (FROM Scoping Results Doc: 2.1.1.4 Option 1)	Three sectors: ▪ SS deliveries ▪ MS deliveries ▪ CP deliveries
Element 2.2 Primary Trawl Target and Allocated Species[e/] **(Except Whiting)**	All sectors: cumulative landing limits. Trawl fishery closes on attainment of cap, guideline or OY. Non-whiting season closes on attainment of non-whiting fishery bycatch cap for non-whiting species.	SS non-whiting sector IFQs SS, MS, & CP non-whiting sectors: catch caps for these species. A sector's non-whiting season closes on attainment of that sector's non-whiting fishery catch cap for non-whiting species. No cumulative catch limits. Midseason rollovers for excess cap amounts and augmentation of caps thru acquisition of SS IFQ.	Sector specific IFQs (Low OY Conditions: Option 1: switch to nontransferable cumulative catch limits and close on attainment of sector limits; Option 2: continue use of IFQs.)	IFQ	Cumulative catch limits with permit stacking rules applied for non-whiting trips. Non-whiting season closes on attainment of non-whiting fishery bycatch cap for non-whiting species. Stacked permits may not be used to cover catch on whiting trips.
Element 2.3 Whiting	All sectors: non-whiting season (no vessel landing limits). Outside the non-whiting season shoreside deliveries allowed under cumulative non-whiting landing limits. Midseason rollover of excess allocation to another sector.	Catch covered by SS non-whiting IFQ is also constrained year-round by nontransferable cumulative non-whiting cumulative catch limits. SS, MS, & CP non-whiting sectors: IFQs during non-whiting season. Midseason non-whiting rollover to another sector Opt 1: Not allowed; Opt 2: Allowed following specified procedures.	Sector specific IFQs during the non-whiting season. If SS non-whiting is closed SS whiting IFQs may continue to be used, subject to nontransferable cumulative non-whiting catch limits.	IFQs during the non-whiting season. IFQs and nontransferable cumulative non-whiting catch limits for shoreside deliveries outside the non-whiting season.	All sectors: non-whiting season (no vessel landing limits). Outside the non-whiting season shoreside deliveries allowed under cumulative non-whiting catch limits. Permit stacking rules do not apply for cumulative non-whiting limits. Midseason rollover of excess allocation to another sector.

Alternatives (Sec 2.1.1.1 Scoping Results[a/])	Alternative 1 No-Action Alternative	Alternative 2 IFQs for Trawl Target Groundfish	Alternative 3 IFQs for All Groundfish Except Other Fish	Alternative 4 IFQs for All Groundfish	Alternative 5 Cumulative Catch Limits and Permit Stacking
Element 2.4 Unallocated Shared Target and Incidental Species Currently Managed With Cumulative Limits	All sectors: cumulative landing limits Trawl fishery closes on attainment of cap, guideline or OY. Non-whiting season closes on attainment of non-whiting fishery bycatch cap for non-whiting species.	SS non-non-whiting trips Transferable cumulative catch limits. Option for >2 mo cumulative periods and midperiod transfers. (Low OY conditions: switch to nontransferable cumulative catch limits) SS, MS, & CP non-whiting sectors: For species without caps: non-whiting species catch is limited by to a single cumulative catch limits regardless of the number of transferable limits held by a vessel. For non-whiting species with caps, same as Element 2.3.	Sector specific IFQs. (Low OY Conditions: Same as for "Primary Trawl Target and Allocated Species" (Element 2.2))	IFQ	Cumulative catch limits with permit stacking rules applied for non-whiting trips. Non-whiting season closes on attainment of non-whiting fishery bycatch cap for non-whiting species. Stacked permits may not be used to cover catch on whiting trips.
Element 2.5 "Other Fish" Groundfish[f/g/]	Status Quo. Currently: monitoring only. May change to cumulative limits.	Same as status quo.[h/]	Same as status quo.[h/]	IFQ	Same as status quo.[h/]

Component 3: Groundfish Catch of Limited Entry Trawl Vessels Using Gears Other Than Groundfish Trawl

(Section 2.1.1.5 of the Scoping Results Document)

Element 3.1 **Trawl Vessel Exempted Gear Quota Accounting and Catch Control (Includes Exempted Trawl and Exempted Non-trawl Gears)**	**Exempted gea**r catch by LE trawl vessels counts against LE allocation (trawl and fixed gear)[i/] but is subject to open access (OA) trip limits.	**Exempted gear** - IFQ is **not** required. Catch counts against the OA allocation and is managed as part of the OA fishery. Some catch will be allocated from the LE trawl to OA fishery. (FROM Scoping Results Document Section 2.1.1.5 Opt 2C)	**Exempted gear -** IFQ required. Catch counts against LE Trawl. Open access catch control regulations apply. (FROM 2.1.1.5 Scoping Results Document Section Option 1A)	**Exempted gear -** IFQ required. Catch counts against LE Trawl. Open access trip limits **do not** apply. (FRM 2.1.1.5 Scoping Results Doc Option 1B)	**Exempted gea**r catch by LE trawl vessels counts against LE allocation (trawl and fixed gear)[h/] but is subject to open access (OA) trip limits OR Permit stacking applies and vessels must comply with trawl enforcement and monitoring provisions.

Alternatives (Sec 2.1.1.1 Scoping Results[a/])	Alternative 1 No-Action Alternative	Alternative 2 IFQs for Trawl Target Groundfish	Alternative 3 IFQs for All Groundfish Except Other Fish	Alternative 4 IFQs for All Groundfish	Alternative 5 Cumulative Catch Limits and Permit Stacking
Element 3.2 **Trawl Vessel Longline and Fish Pot Without and With LE Endorsement (Fixed Gear Quota Accounting and Catch Control)**	**Unendorsed longline & fishpot** catch by LE trawl vessels counts against LE allocation (trawl and fixed gear)[i/] but is subject to open access trip limits. **LE endorsed fixed Gear** - Rules for the LE fixed gear fishery apply when the vessel is using fixed gear. Vessels fish against the limited entry allocation[i/] and are constrained by fixed gear trip limits while using fixed gear.	**Unendorsed longline & fishpot** - IFQ required. Catch counts against LE Trawl. LE fixed gear catch control regulations apply. **LE endorsed fixed gear –** While using fixed gear, IFQ is not required, catch is constrained by LE fixed gear limits and counts toward the LE fixed gear allocation. (FROM 2.1.1.5 Scoping Results Doc, Option 1A)	**Unendorsed longline and fishpot** - IFQ required. Catch counts against LE Trawl. LE fixed catch control regulations **do not** apply. **LE endorsed fixed gear –** While using fixed gear, IFQ is not required for catch taken toward LE fixed gear cumulative or daily limits and such catch counts toward the LE fixed gear allocation. Catch in excess of LE fixed gear trip limits may be taken if covered by IFQ. (FROM 2.1.1.5 Scoping Results Doc, Opt 1B)	**Unendorsed longline & fishpot** - IFQ required. Catch counts against LE Trawl. LE fixed catch control regulations **do not** apply. **LE endorsed fixed gear** - While using fixed gear, IFQ is not required for catch taken toward LE fixed gear cumulative or daily limits and such catch counts toward the LE fixed gear allocation. Catch in excess of LE fixed gear trip limits may be taken if covered by IFQ. (FRM 2.1.1.5 Scoping Results Doc, Opt 1B)	**Unendorsed longline & fishpot** catch by LE trawl vessels counts against LE allocation[i/] (trawl and fixed gear)[i/] but is subject to open access trip limits. OR Permit stacking applies and vessels must comply with trawl enforcement and monitoring provisions. **LE endorsed fixed gear** - Rules for the LE fixed gear fishery apply when the vessel is using fixed gear. Vessels fish against the LE allocation[i/] and constrained by fixed gear limits while using fixed gear. Or permit stacking applies and vessels must comply with trawl enforcement and monitoring provisions (except when fishing tier limits).
Component 4. Monitoring and Enforcement					
At-sea Observers/ Monitoring	Biological observers on some SS catcher vessel trips, 100% observers for at-sea deliveries (MS and CP)	100% at-sea monitoring. Detailed monitoring and enforcement provisions under each IFQ program (Tables 2-2 and 2-4).	100% at-sea monitoring. Detailed monitoring and enforcement provisions under each IFQ program (Tables 2-2 and 2-4)	100% at-sea monitoring. Detailed monitoring and enforcement provisions under each IFQ program (Tables 2-2 and 2-4)	100% at-sea monitoring.

Alternatives (Sec 2.1.1.1 Scoping Results[a/])	Alternative 1 No-Action Alternative	Alternative 2 IFQs for Trawl Target Groundfish	Alternative 3 IFQs for All Groundfish Except Other Fish	Alternative 4 IFQs for All Groundfish	Alternative 5 Cumulative Catch Limits and Permit Stacking
Component 5. Area Management (Decision Table B from Scoping Results Document)					
	Species divided by areas based on stock assessment information. New area divisions created as stock assessment information indicates need.	Program Option for All Action Alternatives: Plan to establish additional regional management areas as needed at a later time. Process Option: Task a group to begin considering the need for additional regional management areas (biological or socio-economic) and potential boundaries along with a process for identifying and responding to regional management area issues that may develop or become more apparent in the future. **Decision deferred until additional information is available, e.g. preliminary DEIS is ready.**			
Component 6. Sector Allocation					
Element 6.1 Within Trawl (Decision Table E from Scoping Results Document)	Whiting allocation rules. No other within trawl allocations.	Establish within trawl allocations based on each sectors relative shares during the time period used for initial allocation. If time periods are different for different sectors use only those years in common to all sectors or calculate a percentage based on each sectors period then adjust all sectors proportionally so that the result sums to 100%. Consider applying the IFQ allocation recency requirement (if any) to eliminate from the sector calculation the catch history of any vessel that has not been active in recent years.			Whiting allocation rules. No other within trawl allocations.
Element 6.2 Trawl/All-Other-Gear		Establish needed intersector allocations through the intersector allocation process.			
Element 6.3 Trawl/ Open Access	N/A	Augment the open access allocation to account for trawl vessels fishing with open access gear on the open access allocation (Element 3.1)	N/A	N/A	N/A

Table 2-2. IFQ Program Design Alternatives for Analysis

	IFQ Program A	IFQ Program B	IFQ Program C
B.1.0 IFQ Allocation			
B.1.1 Eligible Groups	Allocate 50% of quota shares to current permit owners and 50% to processors (Option 3b).[7]	Eligible Group Suboption B-1. Allocate 100% of quota shares to current permit owners (Option 1 from Appendix B). Eligible Group Suboption B-2. Allocate 100% of quota shares for non-whiting species to current permit owners and 50% of the quota shares for whiting species to current permit owners. Allocate 50% of the quota shares for whiting species to processors. (New Option, June 2005) Eligible Group Suboption B-3. 90% of quota shares to current permit owners and 10% to processors. (New Option, June 2005).	Allocate 75% of quota shares to current permit owners and 25% to processors (Option 3a).
Processor Definition:	Use special IFQ Program definition (processors: receive and process unprocessed fish; or catch and process) (Option 1).	Use FMP Definition (processors process unprocessed and already processed fish or receive live fish for resale) (Option 2).	Same as Program A.

[7] References to Options refer to options at they were described in the Scoping Results Document, i.e. *National Environmental Policy Act Scoping Results Document: Individual Fishing Quotas (A Kind of Dedicated Access Privilege) and Other Catch Control Tools for the Pacific Coast Limited Entry Trawl Groundfish Fishery*. Pacific Fishery Management Council, July 2005.

	IFQ Program A	IFQ Program B	IFQ Program C
B.1.2 Qualifying Criteria: Recent Participation	**Harvesters (including catcher-processors):** 1998-2003 participation required in order to qualify for an initial allocation of quota shares (number of trips or years to be specified). (Option 2). **For shoreside processors and motherships:** 1999-2004 recent participation requirement (the number of trips or years is yet to be specified). (Option 4).	All Members of Eligible Groups: No recent participation required in order to qualify for an initial allocation of quota shares (Option 1). **OR** All Members of Eligible Groups: 1998-2003 participation required (one trawl groundfish landing/delivery of any groundfish species) in order to qualify for an initial allocation of quota shares. (Option 2).	Same as Program A.
B.1.3 Elements of the Allocation "Formula"			
Vessel/Permit Related Allocation	Catcher vessel permit owners will receive quota shares based on their permit history plus an equal division of the quota that could be attributed to permit history of bought-back permits (catcher-processors permit owners will not receive a portion of the quota shares distributed on an equal sharing basis) (Option 2). Suboptions for incidentally caught overfished species, either: (a) same as for Other Fish OR (b) equally divide quota for incidentally caught overfished species. For catcher-processors permit owners, use an allocation schedule developed by unanimous consent of that sector (to be provided).	Same as Program A, except no special catcher-processor schedule.	Same as Program A.
Processor Allocation	Processors are allocated quota shares based entirely on the processing of groundfish trawl landings received unprocessed (Option 1).		
B.1.4 History: Species/Species Groups to Be Used for Allocation	Allocate Quota Shares Based on Individual Species/Species Groups: Allocate quota shares for each species/species group based on relative amounts of each respective species/species group caught/landed or processed - for permits applies to permit history; for processors applies to amounts processed (Option 2).		

	IFQ Program A	IFQ Program B	IFQ Program C
B.1.5 History: Allocation Periods			
Periods/Years to Drop:	Options are identical under all programs. Vessels: 1994-2003. Drop 2 years for whiting sector fishing (applies to incidental harvest and whiting). Drop 3 years for non-whiting sector fishing. (Option 1, Sub-option B) Shore Processors: 1999-2004. Drop 2 years. (Option 5, Sub-option B) Motherships: 1998-2003. No opportunity to drop worst year. (Option 4, Sub-option A)		
Weighting Among Years:	Absolute pounds - no weighting between years (Sub-option (i)).	Relative pounds (calculate history based on the entity's percent share of each year's total) (Sub-option (ii)).	Same as Program B
B.1.6 History: Combined Permits and Other Exceptional Situations			
Combined permits:	All permits count. History of the permits combined into a single permit goes to the resulting permit (Option 1).		
Illegal landings/catch:	Don't count Illegal landings/catch under any program.		
Landings in excess of trip limits, as authorized under an EFP:	Don't count landings in excess of the cumulative limit in place for the non-EFP fishery under any program		
Compensation fish:	Don't count compensation fish under any program.		
B.1.7 Initial Issuance Appeals Process	Only one provision has been identified: Appeals would occur through processes developed by NMFS. NMFS will develop a proposal for an internal appeals process and bring it to the Council for consideration. Any proposed revisions to fish-tickets would undergo review by state enforcement personnel prior to finalization of the revisions.		
B.1.8 Creating New IFQ Species/Species Groups After initial Implementation	Only one practical option has been identified: When a management unit is subdivided, quota shares for that unit will be subdivided by issuing quota share holders amounts of shares for the subdivisions equivalent to their holdings of the shares being subdivided. If a new management unit is established that is not a subset of an existing unit managed with IFQ, the Council will need to take action at that time to develop criteria for quota share allocation.		
B.2.0 IFQ/Permit Holding Requirements and IFQ Acquisition (After Initial Allocation)			
B.2.1 IFQ and LE Permit Holding Requirements	Catch must be covered with quota pounds within 30 days of the landing (Option 3). Only LE trawl vessels would be allowed to participate in the IFQ fishery. For any vessel with an overage (landings not covered by quota) there would be no more fishing by the vessel until the overage is covered. Additionally, for vessels with an overage, the limited entry permit cannot be sold or transferred until the deficit is cleared. A possible suboption would require some amount of quota pounds be held prior to departure from port (to be analyzed).		
B.2.2 Annual IFQ Issuance			
B.2.2.1 Start-of-Year Quota Pound Issuance	Only one practical option has been identified: Quota pounds are issued annually to share holders based on the amount of quota shares they held. (Quota shares are issued at the time of initial IFQ allocation).		

	IFQ Program A	IFQ Program B	IFQ Program C
B.2.2.2 Rollover (Carryover) of Quota Pounds to a Following Year			
Non-overfished Species	10% rollover for non-overfished species (Option 3)	30% rollover for non-overfished species (Option 5)	5% rollover for non-overfished species (Option 2)
Overfished Species	5% rollover for overfished species (Option 3)	Full (30%) rollover allowance for overfished species (Option 5)	No rollover allowance for overfished species (Option 2)
B.2.2.3 Quota Share Use-or-Lose Provisions	Do not include a use-or-lose provision but evaluate need as part of future program reviews (Option 3).		
B.2.2.4 Entry Level Opportunities for Acquiring Quota Shares and Low Interest Loan Options	No special provisions.	No special provisions.	Provide new entrants an opportunity to qualify for revoked shares and shares lost due to non-use (if such non-use provisions are created) (Element 2)
B.2.2.5 Community Stability Hold Back	No special provisions.	No special provisions.	Set aside up to 20% of the non-whiting shoreside trawl sector allocation each year and allocate to IFQ holders who have submitted proposals, ranked on the basis of objective criteria that evaluate benefits to local communities.
B.2.3 Transfer Rules			
B.2.3.1 Eligible Owners/Holders (Who May Own/Hold)	Any entity eligible to own or operate a US documented fishing vessel. (Option 2) *The Trawl IQ Committee's intent is to preserve opportunity for existing participants*		
B.2.3.2 Duration of Transfer - Leasing and Sale	Permanent transfers and leasing of quota shares and quota pounds allowed. (Option 2)	Permanent quota share transfers only--leasing prohibited. Permanent transfers and leasing of quota pounds allowed. (Option 1)	Same as Program A
B.2.3.3 Limits on Time of Transfer	Allow transfers of quota shares any time during year (Option 1).	Prohibit transfer of quota shares during the last two months of the year.	Same as Program A
B.2.3.4 Divisibility	Only one practical option has been identified: Quota Shares: nearly unrestricted divisibility - "many decimal points." Quota Pounds: divisible to the single pound		
B.2.3.5 Liens	No options have been proposed to restrict liens. Liens can and should be facilitated through a central lien registry. Options for the central lien registry are covered in Section B.3.1.		

	IFQ Program A	IFQ Program B	IFQ Program C
B.2.3.6 Accumulation Limits	50% or No Limits (Option 5).	Consider all limits as sub-options	Most restrictive limits (1% or 5%) **OR** Intermediate level limits (10% or 25%)
B.2.3.7 Vertical Integration Limit	Only one option has been identified: No additional limits on vertical integration beyond those already provided through accumulation limits.		
B.3.0 Program Administration			
Tracking IFQ, Monitoring Landings, and Enforcement (see Table B.3-1)			
Enforcement Program Number	**Enforcement Program 2**	**Enforcement Program 1**	**Enforcement Program 3**
At-Sea Monitoring	100% at-sea monitors (observers)	100% at-sea monitors (observers)	100% at-sea monitors (observers) or cameras
Shoreside Monitoring	Shoreside monitoring opportunity would be provided	100% shoreside monitoring	Shoreside monitoring opportunity would be provided
Retention and Discards	Discards allowed	Full retention required	Discards allowed if at-sea monitor is present (otherwise full retention)
Discard Monitoring and Reporting System	Upgraded discard (bycatch) monitoring and reporting system needed	An upgraded discard monitoring and reporting system is un-needed	Upgraded discard (bycatch) monitoring and reporting system needed
Electronic Reporting	Electronic landings tracking. QS reported electronically.	Electronic landings tracking. QS reported electronically.	Parallel federal electronic landings tracking. QS reported electronically.
Landing Notification	Advance notice of landing required.	Advance notice of landing required	Advance notice of landing required
Potential Landing Times	Unlimited landing hours	Limited landing hours	Unlimited landing hours
Potential Landing Sites	Licenses required for delivery sites	Unlimited landings sites	Licenses required for delivery sites
Vessel Monitoring System (VMS)	VMS Required under all programs	VMS Required under all programs	VMS Required under all programs
Quota Share Tracking	Create a central lien registry but exclude all but essential ownership information. (Option 2).	Create a central lien registry including all related ownership information (Option 1).	Create a central lien registry including all related ownership information (Option 1).

	IFQ Program A	IFQ Program B	IFQ Program C
B.3.2 Cost Recovery/Sharing and Rent Extraction	Cost recovery for management (not enforcement or science). Up to 3% of ex-vessel value, the limit specified in the Magnuson-Stevens Act.	Same as Program A	Full cost recovery: Landings fee plus privatization of elements of the management system. In particular, privatization for monitoring of IFQ landings (e.g., industry pays for their own compliance monitors). Stock assessments should not be privatized and the electronic fish ticket system should not be privatized.
B.3.3 Program Duration and Procedures for Program Performance Monitoring, Review, and Revision (Magnuson-Stevens Act (d)(5)(A))	A four year review process is specified along with review criteria. Among other factors, the review would include evaluation of whether or not there are localized depletion problems and whether or not quota shares are being utilized. Standard fishery management plan and regulatory amendment procedures will be used to modify the program.		
B.3.4 Data Collection	Expanded voluntary submission of economic data (Option 2).	Expanded mandatory submission of economic data (Option 1).	Same as Program B

2.2 Alternatives Considered but Excluded from Detailed Analysis

This section discusses an alternative that was considered but rejected and briefly explains the reasons for its elimination. In addition, this section lists options and sub-options that were considered by the Council and TIQC but were not included in any of the alternatives forwarded for analysis.

An alternative that was initially considered for analysis would issue IFQs for overfished species, maintain cumulative trip limits for all other species, and implement total catch reporting and 100 percent at-sea monitoring. Upon further consideration it was determined that this alternative would not have the potential to create enough benefits to the groundfish fishery to offset the costs of the monitoring and reporting requirements, and questions were raised as to how the program would continue once overfished species recovered. Therefore, the alternative was dropped from further consideration.

In addition to the dropped alternative, a number of options and sub-options were discussed by the Council and TIQC but not included in the alternatives forwarded for analysis. The list below provides an initial summary of these excluded elements and options.

- Species groups that could be managed under an IFQ program but were not explicitly included
    - Overfished Species
    - Prohibited Species
- Stakeholder groups that were not included as recipients of QS
    - Vessel crew members and skippers
    - Vessel owners
    - Communities
- Methods for issuing QS that were not included
    - Auctions
    - Lotteries
    - Equal shares
    - QS based strictly on years of participation
- Types of shares from an IFQ program that might have been forwarded but were not
    - Shares for Processing (as opposed to IFQs for harvesting issued to processors)

While the elements and options listed above were not specifically included in the suite of alternatives that were forwarded for full analysis, all are included in the description of components, elements and options (Section 2.3).

2.3 Components Table

Before the effects of the alternatives on resources and stakeholders of concern can be fully evaluated a number of issues need to be addressed and decisions may need to be made by the Council. The Components Table below highlights these issues by augmenting the basic alternatives forwarded by the Council for detailed analysis. The major goal of the Components Table and the Components Analysis (see Appendix C: Components Analysis) is to ensure that the details of each alternative are adequately considered by clearly specifying how the different elements fit together within an alternative and identifying unknown or unintended potential effects on resources and stakeholders groups. The Components Table and Components Analysis also identify options that were discussed but not brought forward for detailed analysis.

Several key terms used within the Components Table are defined below:

Components: Components focus on major programmatic issues within the alternatives.

Elements: Elements are single decision-points within a component. In order for an alternative to be completely defined, a decision must be made for each element.

Options: Options define the basic choices within each element. Generally options are mutually exclusive of other options, but it is noted when more than one option can be selected.

Sub-options: Sub-options provide further refinement of the options. Decisions with respect to sub-options need only be made if the particular option is chosen.

The PFMC and the Consulting Team are in the process of revising earlier versions of the Component Table, and consequently the full table is unavailable at this time. The full table will be included in the final draft. The Components Table is divided into two sections—the first section (which is included in this draft) identifies components, elements and options pertaining to the day-to-day management regime under each alternative. The second section (which is not yet available) will identify components, elements and options pertaining to the allocation of IFQs under Alternatives 2 – 4.

Table 2-3. Components, Elements, and Options Relating to Alternative Management Regimes

Section 1: Components, Elements, and Options Relating to Management Regimes	Alt. 1	Alt. 2	Alt. 3	Alt. 4	Alt. 5
Component 1 Catch Control Tools *In this component the primary catch control rules are specified but not generally the species to which they apply.*					
Element 1.1 IFQ Program. The specific design elements of each of these IFQ program are provided in Table 22 and 2-4. *Alternative 3 will be analyzed with each IFQ program (Alternative 3A, 3B, and 3C) in order to compare and contrast the differences while holding other aspects of the management regime constant.*					
Option 1.1.1 No IFQ Program	☑	☐	☐	☐	☑
Option 1.1.2 IFQ Program A GENERAL DESCRIPTION (See Tables 2-2 and 2-4)	☐	☑	☑	☐	☐
Option 1.1.3 IFQ Program B GENERAL DESCRIPTION (See Tables 2-2 and 2-4)	☐	☐	☑	☐	☐
Option 1.1.4 IFQ Program C GENERAL DESCRIPTION (See Tables 2-2 and 2-4)	☐	☐	☑	☑	☐
Element 1.2 Permit Stacking.					
Option 1.2.1 No Permit Stacking	☑	☑	☑	☑	☐
Option 1.2.2 Permit Stacking A vessel receives one whole set of trip limits issued for each of a maximum of 3 permits attached to the vessel. Only one of the permits attached to the vessel would need to be of the appropriate length. The cumulative limits would continue to be for 2 months periods.	☐	☐	☐	☐	☑
Element 1.3 Cumulative Trip Limits GENERAL DESCRIPTION					
Option 1.3.1 Cumulative Landing Limits. Vessels reaching their cumulative landing limits may continue to fish but must discard fish in excess of the landing limit. Season closures are be implemented for the affected species when the fleet reaches its cap for that species.	☑	☐	☐	☐	☐

– **Key to Alternatives**

– Alt. 1: No Action; Cumulative trip limits; Whiting season; Only report landings	– Alt. 2: Trawl Target IFQs, Whiting season; Total catch reporting	– Alt. 3: IFQs for all but Other Species, No whiting seasons; Total catch reporting	– Alt. 4: IFQs for all species, No whiting seasons; Total catch reporting	– Alt. 5: Permit stacking; trip limits; Whiting season; Total catch reporting

– **Key to Column Indicators** – ☑ = this option is included in alternative; ☐ = option could be included but is not; **N/A** = option is not applicable to alternative

Section 1: Components, Elements, and Options Relating to Management Regimes	Alt. 1	Alt. 2	Alt. 3	Alt. 4	Alt. 5
Option 1.3.2 Cumulative Catch Limits: Vessels reaching their cumulative catch limits must stop trawling in strategies which may encounter species for which the catch limit has been reached. Within the catch limits, there may be retention limits that vary based on biennial management decisions. A season closure will be implemented for the affected species when the fleet reaches its cap for that species. Note: this option requires 100% catch monitoring. *Under the alternatives that use cumulative catch limits, the limits are not applied to species managed with IFQ (except that whiting taken in non-whiting fisheries may be subject to both the cumulative limit and the IFQ requirement, and under Alternative 3 an IFQ species may be managed with nontransferable cumulative limits instead of IFQ under low OY conditions—see Component 2).*	☐	☑	☑	☑	☑
Sub-Option 1.3.2.1 Transferable separate from the permit, but nontransferable: (1) for whiting; and (2) for low OY species managed with cumulative limits Vessels which reach their cumulative limits may continue fishing if they acquire additional cumulative limits. All cumulative limit transfers are temporary (i.e. a cumulative limit reverts to the original permit at the end of the year). Partial transfers may be allowed if the cumulative limit period is longer than 2 months. Consider the need for a limit on stacking. *(Whiting cumulative limits apply at all times to the non-whiting shoreside sector and to the shoreside whiting sector when the whiting season is closed See Component 2).*	☐	☑	☐	☐	☐
Sub-Option 1.3.2.2 Not transferable except with the transfer of the permit.	☑	☐	☑	☑	☑
Element 1.4 Adjustments for Low OY Management Under status quo and all alternatives, the Council may suspend intersector allocations when a species is overfished. *The option choices are whether or not to adjust the catch control rules under low OY conditions and, if so, the threshold or procedure for determining when to apply low OY adjustments. The adjustments that would be made under low OY conditions are specified in Element 2.2 through Element 2.4. In general the adjustments for low OY conditions are as follows: under Alternative 2, switch from transferable cumulative limits to nontransferable cumulative limits; and, under Alternative 3, switch from IFQ management to management with nontransferable cumulative limits, except for whiting.*	☑	☑	☑	☑	☑

– **Key to Alternatives**

– Alt. 1: No Action; Cumulative trip limits; Whiting season; Only report landings	– Alt. 2: Trawl Target IFQs, Whiting season; Total catch reporting	– Alt. 3: IFQs for all but Other Species, No whiting seasons; Total catch reporting	– Alt. 4: IFQs for all species, No whiting seasons; Total catch reporting	– Alt. 5: Permit stacking; trip limits; Whiting season; Total catch reporting

– **Key to Column Indicators** – ☑ = this option is included in alternative; ☐ = option could be included but is not; **N/A** = option is not applicable to alternative

Section 1: Components, Elements, and Options Relating to Management Regimes	Alt. 1	Alt. 2	Alt. 3	Alt. 4	Alt. 5
Option 1.4.1 **Low OY managemen**t. When the OY is unusually low catch control rules may be changed. [NOTE: Either of the following suboptions can be matched with an alternative that includes low OY management adjustments.]	N/A	☑	☑	☐	N/A
Sub-Option 1.4.1.1 Establish a threshold at which point a species would switch from incidental catch management to "low OY management." ($B_{25\%}$).	N/A	☑	☐	☐	N/A
Sub-Option 1.4.1.2 Decide on application of "low OY management" as part of the biennial specifications process.	N/A	☐	☑	☐	N/A
Option 1.4.2 **No low OY management** provisions, (other than the existing Council discretion to suspend allocations for overfished species).	N/A	☐	☑	☑	N/A
Element 1.5 **General season closure:** When all sectors reach the overall OY for a species, the fisheries catching that species close.	☑	☑	☑	☑	☑
Element 1.6 **Whiting season openings.**					
Option 1.6.1 Staggered season openings for each whiting sector set during the biennial specifications process.	☑	☐	☐	☐	☑
Option 1.6.2 Continuation of spring opening for the season, to control impacts on ESA listed salmon.	☐	☑	☑	☑	☐
Option 1.6.3 Opens January 1.	☐	☑	☑	☑	☐
Element 1.7 **Whiting season closings.** *During closed periods there is generally a whiting cumulative limit of 20,000 pounds per week for shoreside whiting deliveries (no at-sea deliveries are allowed).* *(Note: Under Alternative 2 whiting is controlled by IFQs. Under Alternative 3 and 4 catch of all groundfish species is controlled through IFQs, except "Other Fish" under Alternative 3.)*					
Option 1.7.1 Whiting season closes for a sector on attainment of whiting allocations or on attainment of catch caps for bycatch species with caps.	☑	☐	☐	☐	☑
Option 1.7.2 Whiting season closure on attainment of bycatch caps for species with bycatch cap	☐	☑	☐	☐	☐
Component 2 **Sector Species Combinations Trips** are assigned to a sector based on delivery location and species composition. Whiting trips in the shoreside fishery are those OPTION A: with more than 50% whiting, OR OPTION B more than 50% whiting and greater than 10,000 pound of whiting. *For the remainder of the document it is assumed that Option A applies.*					

– **Key to Alternatives**

– Alt. 1: No Action; Cumulative trip limits; Whiting season; Only report landings	– Alt. 2: Trawl Target IFQs, Whiting season; Total catch reporting	– Alt. 3: IFQs for all but Other Species, No whiting seasons; Total catch reporting	– Alt. 4: IFQs for all species, No whiting seasons; Total catch reporting	– Alt. 5: Permit stacking; trip limits; Whiting season; Total catch reporting

Section 1: Components, Elements, and Options Relating to Management Regimes	Alt. 1	Alt. 2	Alt. 3	Alt. 4	Alt. 5
Element 2.1 Trawl Sectors.					
Option 2.1.1 Specify three sectors: ☐ Shoreside deliveries -- all limited-entry trawl deliveries to shoreside processors ☐ Mothership deliveries -- all limited-entry trawl deliveries to motherships ☐ Catcher-processor deliveries – all harvests by catcher processors	☑	☐	☑	☐	☑
Option 2.1.2 Specify four sectors: ☐ Shoreside whiting deliveries -- all limited-entry trawl deliveries of whiting to shoreside processors. ☐ Shoreside non-whiting deliveries -- all limited-entry trawl deliveries to shoreside processors for trips on which whiting comprises less than 50% of the catch. ☐ Mothership deliveries -- all limited-entry trawl deliveries to motherships ☐ Catcher-processor deliveries -- all harvests by catcher processors *Other elements under this component specify the following catch control rules for the Alternative 2 shoreside whiting and non-whiting landings (summarized here).*	☐	☑	☐	☐	☐
Option 2.1.3 Specify one trawl sector: This sector includes all deliveries and harvests of limited-entry trawl vessels.	☐	☐	☐	☑	☐

Sector	*Trip Classification & Whiting Catch Control*	*Other Species Catch Control*
Shoreside Whiting	*>50% of the catch is whiting. Shoreside whiting sector IFQ is required to cover whiting catch.*	*Sector cap—closure on reaching limit.*
Shoreside Non-whiting	*<50% of the catch is whiting. Shoreside non-whiting sector IFQ is required to cover the whiting catch AND catch in excess of the cumulative landing limits constitutes a violation.*	*IFQ required for trawl target and allocated species. Cumulative limits for unallocated and incidental catch (transferable or nontransferable depending on OY conditions).*

– **Key to Alternatives**

– Alt. 1: No Action; Cumulative trip limits; Whiting season; Only report landings	– Alt. 2: Trawl Target IFQs, Whiting season; Total catch reporting	– Alt. 3: IFQs for all but Other Species, No whiting seasons; Total catch reporting	– Alt. 4: IFQs for all species, No whiting seasons; Total catch reporting	– Alt. 5: Permit stacking; trip limits; Whiting season; Total catch reporting

– **Key to Column Indicators** – ☑ = this option is included in alternative; ☐ = option could be included but is not; **N/A** = option is not applicable to alternative

Section 1: Components, Elements, and Options Relating to Management Regimes		Alt. 1	Alt. 2	Alt. 3	Alt. 4	Alt. 5
Element 2.2 Catch Control for Trawl Target and Allocated Species (Except Whiting) Trawl target species are defined as those species for which trawlers took over 90% of the harvest from 1994 through 2004. Sablefish; Dover sole; Yellowmouth Rockfish; Sharpchin Rockfish; Arrowtooth Flounder Splitnose Rockfish (Monterey and Conception); Petrale Sole; English Sole; Pacific Cod; Pacific Ocean Perch; Other Flatfish Complex Longspine thornyhead; Dark-blotched Rockfish Other species may be targeted by trawl and other sectors or taken incidentally in the trawl fishery. These species are also included in the Element 2.2 management category, if a trawl allocation is established. *For the purpose of analysis the species assumed to fall into this category are specified in Section 2.x.x.*						
Option 2.2.1	All sectors: cumulative landing limits On attainment of a cap, guideline or OY for a particular species, the segments of the trawl fishery that might catch that species are closed. Cumulative limits are adjusted to meet season duration objectives (usually a year-round fishery, except for whiting). Whiting Fishery: Cumulative landings limits for non-whiting species. For non-whiting species for which whiting fishery caps have been established, the whiting season closes on attainment of the non-whiting catch cap. For species without whiting fishery caps, the cumulative limits that apply to all trawl vessels are set taking into account catch projections for the whiting fishery. Greater than expected catch in the whiting fishery may result in the downward adjustment of those limits.	☑	☐	☐	☐	☐
Option 2.2.2	Shoreside non-whiting sector IFQs: No special management under low OY conditions. Whiting fishery: shoreside, mothership, & catcher-processor whiting sectors. Each whiting sector will have a cap for each trawl target and allocated species/species group. A whiting sector will close if its cap is reached for a non-whiting species. For whiting deliveries, there will be no cumulative catch limits for non-whiting species. A procedure will be established under which all or a portion of an unused cap species may be rolled-over/transferred to another sector. More specificity needed (timing and criteria similar to that used for the current whiting rollover, rollover to a non-whiting sector)? Any person may acquire non-whiting IFQ from the shoreside non-whiting sector and designate that it be used to increase the cap for a particular sector of the whiting fishery, for the common benefit of all members of that sector. *NOTE: In the extreme IFQ transfers could lead to whiting sector targeting on a non-whiting species.*	☐	☑	☐	☐	☐

– **Key to Alternatives**

– Alt. 1: No Action; Cumulative trip limits; Whiting season; Only report landings	– Alt. 2: Trawl Target IFQs, Whiting season; Total catch reporting	– Alt. 3: IFQs for all but Other Species, No whiting seasons; Total catch reporting	– Alt. 4: IFQs for all species, No whiting seasons; Total catch reporting	– Alt. 5: Permit stacking; trip limits; Whiting season; Total catch reporting

– **Key to Column Indicators** – ☑ = this option is included in alternative; ☐ = option could be included but is not; **N/A** = option is not applicable to alternative

Section 1: Components, Elements, and Options Relating to Management Regimes	Alt. 1	Alt. 2	Alt. 3	Alt. 4	Alt. 5
Option 2.2.3 All Sectors: sector specific IFQs (i.e. not transferable from one sector to another See Element 1.4)	☐	☐	☑	☐	☐
Sub-Option 2.2.3.1 Under low OY conditions, switch to nontransferable cumulative catch limits. All poundage that would otherwise have been issued to holders of quota shares will be used to create a catch cap. Nontransferable cumulative limits will be used to achieve Council season duration goals. (See Element 1.4)	☐	☐	☑	☐	☐
Sub-Option 2.2.3.2 No special measures for low OY conditions (i.e. continue using IFQs) (See Element 1.4)	☐	☐	☑	☐	☐
Option 2.2.4 IFQs	☐	☐	☐	☑	☐
Option 2.2.5 Cumulative catch limits with permit stacking rules applied for non-whiting trips. For the whiting fishery, same as Option 2.2.1 except that cumulative limits are catch limits rather than landing limits. Permit stacking rules do not apply to non-whiting species taken on whiting trips, i.e. on whiting trips a vessel receives no credit for permit stacking.	☐	☐	☐	☐	☑
Element 2.3 **Whiting.** There would be an annual allocation of whiting for each sector specified under the alternative, except under Option 2.3.4. A vessel is considered to be participating in a shoreside whiting trip if its landing (Alternative 1) or catch (Alternatives 2 through 5) for a trip is composed of more than 50% whiting.					
Option 2.3.1 All sectors: whiting season (no vessel landing limits). Outside the whiting season, cumulative whiting landing limits for shoreside deliveries and no at-sea delivery allowed. Whiting season start dates for each sector are set during the biennial specifications process. Each sector's season closes when that sector's allocation has been caught. If it appears that a sector's whiting allocation will not be caught during the sector's whiting season, then on or after September 15, the portion of the sector's whiting allocation that is projected to go unused may be rolled over for use by other sectors.	☑	☐	☐	☐	☐

– **Key to Alternatives**

– Alt. 1: No Action; Cumulative trip limits; Whiting season; Only report landings	– Alt. 2: Trawl Target IFQs, Whiting season; Total catch reporting	– Alt. 3: IFQs for all but Other Species, No whiting seasons; Total catch reporting	– Alt. 4: IFQs for all species, No whiting seasons; Total catch reporting	– Alt. 5: Permit stacking; trip limits; Whiting season; Total catch reporting

– **Key to Column Indicators** – ☑ = this option is included in alternative; ☐ = option could be included but is not; **N/A** = option is not applicable to alternative

Section 1: Components, Elements, and Options Relating to Management Regimes	Alt. 1	Alt. 2	Alt. 3	Alt. 4	Alt. 5
Option 2.3.2 Shoreside, mothership, & catcher-processor whiting sectors: IFQs during whiting season (season may be year-round, see Element 1.6 and Element 1.7). If needed for salmon ESA or other purposes, whiting season start dates for each sector would be set during the harvest specifications process. When the whiting season is closed, whiting may be delivered shoreside as part of the non-whiting fishery so long as it does not constitute a whiting trip (whiting comprises less than 50% of the catch for the trip), shoreside whiting cumulative catch limits are not violated, and the catch is covered by IFQ issued for the non-whiting shoreside sector. Any other groundfish species caught with the whiting must be caught and landed consistent with all other rules that apply to the shoreside non-whiting sector (Option 2.2.2, Option 2.4.2, and Option 2.5.2).	☐	☑	☐	☐	☐
Sub-Option 2.3.2.1 Whiting IFQ may not be transferred from one sector to another.	☐	☑	☐	☐	☐
Sub-Option 2.3.2.2 Whiting IFQ may not be transferred from one sector to another. However, there may be a midseason transfer of unused IFQ from one sector to another. Criteria for transfers, amount, and sectors to which the transfer would be made need to be specified. **Example 1.** After a certain date (initially September 15, but modifiable as part of the annual specifications process), if more than 25% of the whiting IFQ/quota pounds (see **Table 2-4** for a description of the quota share/quota pound IFQ system) for a sector remain unused, a portion of the quota pounds for the sector may be redesignated for use by any sector (i.e. the IFQ may be transferred to a different owner/vessel, or used by the same vessel operating in a different mode, for example, a catcher vessel switching from mothership to shoreside deliveries). The redesignation will not change the ownership of the quota pounds but quota pounds may be transferred after the redesignation. If a sector qualifies for quota pound redesignation then (OPTION A, up to 50% of the unused quota pounds; OR OPTION, B 50% of the quota pounds for the year) associated with each account may be redesignated for use in any sector. **Example 2.** As of a certain date (initially September 15, but modifiable as part of the annual specifications process), any account in which more than 25% of the whiting quota pounds for the year remain unused will forfeit those pounds in excess of 25% for redistribution (except for non-whiting shoreside quota pounds, i.e. those whiting pounds designated to cover bycatch in the non-whiting fishery). Forfeited quota pounds shall be redistribute (1) equally among other whiting quota pound accounts for vessels with whiting for the same sector, where the holder of such an account has applied for the redistribution; OR (2) proportionally to the whiting quota pounds for the year held in other quota pound accounts for vessels with whiting for the same sector, where the holder of such an account has applied for the redistribution; OR (3) via auction (if auctions are allowed and only if the proceeds are dedicated directly to defrayal of TIQ program costs) or, if auctions are not allowed or funds cannot be dedicated, via a lottery among vessel quota pound accounts registered for the lottery. If there is not sufficient interest in using whiting quota pounds for the sector for which they were originally issued the quota pounds may be redesignated for use by any trawl sector. Whiting quota	☐	☑	☐	☐	☐

– **Key to Alternatives**

– Alt. 1: No Action; Cumulative trip limits; Whiting season; Only report landings	– Alt. 2: Trawl Target IFQs, Whiting season; Total catch reporting	– Alt. 3: IFQs for all but Other Species, No whiting seasons; Total catch reporting	– Alt. 4: IFQs for all species, No whiting seasons; Total catch reporting	– Alt. 5: Permit stacking; trip limits; Whiting season; Total catch reporting

– **Key to Column Indicators** – ☑ = this option is included in alternative; ☐ = option could be included but is not; **N/A** = option is not applicable to alternative

Section 1: Components, Elements, and Options Relating to Management Regimes	Alt. 1	Alt. 2	Alt. 3	Alt. 4	Alt. 5
pounds redistributed, via any means except auction may (may not) be transferred from the vessel account to which they are assigned (but may be voluntarily relinquished for redistribution). [NOTES: "Quota pounds for the year" means all quota pounds used by the account during the year plus any unused quota pounds remaining in the account. To avoid forfeiture, accounts not associated with vessels would have to transfer all of their quota pounds to a vessel account because quota pounds can only be used in association with a vessel account.]					
Option 2.3.3 Sector specific IFQs during the whiting season. Outside the whiting season, cumulative whiting catch limits for shoreside deliveries and no catch for at-sea delivery allowed. If needed for salmon ESA or other purposes, whiting season start dates for each sector would be set during the biennial specifications process.	☐	☐	☑	☐	☐
Option 2.3.4 IFQ (no division of the trawl sectors, see Option 2.1.3). Whiting season. Outside the whiting season, whiting may still be caught using IFQs, but catch is also constrained by whiting cumulative catch limits and at-sea delivery is not allowed. If needed for salmon ESA or other purposes, whiting season start dates for each sector would be set during the harvest specifications process.	☐	☐	☐	☑	☐
Option 2.3.5 Same as Option 2.3.1 except that whiting cumulative limits are catch limits rather than landing limits. Permit stacking rules do not apply to whiting cumulative catch limits.	☐	☐	☐	☐	☑
Element 2.4 Unallocated Shared Target and Incidental Species Currently Managed With Cumulative Limits *For purposes here, "Shared target species" are those for which trawlers take less than 90% of the catch but at greater than incidental levels. Shortspine thornyheads is an example of a currently unallocated shared target species. Because unallocated shared target and unallocated incidental species are grouped together for management, a specific definition of incidental species is not provided here. In general incidental species would be considered those species which do not provide a significant economic incentive for the particular targeting strategy employed by trawl vessels.*					
Option 2.4.1 All sectors: cumulative landing limits (including whiting deliveries) On attainment of a cap, guideline or OY for a particular species, the segments of the trawl fishery that might catch that species are closed. Whiting fishery: Cumulative landing limits apply to non-whiting species. It is unlikely that a whiting fishery cap would be established for an unallocated non-whiting species, however, if that situation were to occur, the whiting season would close on attainment of the non-whiting cap. For species without whiting fishery caps, the cumulative limits that apply to all trawl vessels are set taking into account catch projections for the whiting fishery. Greater than expected catch in the whiting fishery may result in the downward adjustment of those limits.	☑	☐	☐	☐	☐

– **Key to Alternatives**

– Alt. 1: No Action; Cumulative trip limits; Whiting season; Only report landings	– Alt. 2: Trawl Target IFQs, Whiting season; Total catch reporting	– Alt. 3: IFQs for all but Other Species, No whiting seasons; Total catch reporting	– Alt. 4: IFQs for all species, No whiting seasons; Total catch reporting	– Alt. 5: Permit stacking; trip limits; Whiting season; Total catch reporting

– **Key to Column Indicators** – ☑ = this option is included in alternative; ☐ = option could be included but is not; **N/A** = option is not applicable to alternative

Section 1: Components, Elements, and Options Relating to Management Regimes	Alt. 1	Alt. 2	Alt. 3	Alt. 4	Alt. 5
Option 2.4.2 Shoreside non-whiting deliveries: Cumulative catch limits, transferable separate from the permit. Under low OY conditions, the cumulative catch limits will be nontransferable. Whiting fishery: shoreside, mothership, & catcher-processor whiting sectors. If a cap were to be established for an unallocated species, there will be no cumulative catch limits for those non-whiting species with a cap. A procedure will be established under which all or a portion of an unused cap species may be rolled-over/transferred to another sector. More specificity needed (timing and criteria similar to that used for the current whiting rollover, rollover to a non-whiting sector)? For species without a cap, shoreside cumulative catch limits apply to species without a cap, except that even if cumulative limits are stacked non-whiting catch on whiting trips will be constrained to a single cumulative limit. The cumulative limits that apply to all trawl vessels are set based on catch projections for the whiting fishery. Greater than expected catch in the whiting fishery may result in the downward adjustment of those limits. No special management under low OY conditions.	☐	☑	☐	☐	☐
Sub-Option 2.4.2.1 The duration of the cumulative limit periods will remain at two months and mid-period transfers will not be allowed.	☐	☑	☐	☐	☐
Sub-Option 2.4.2.2 The duration of the cumulative limits may be set to four months and mid-period transfers allowed.	☐	☑	☐	☐	☐
Option 2.4.3 Sector specific IFQs (i.e. not transferable from one sector to another.	☐	☐	☑	☐	☐
Sub-Option 2.4.3.1 Under low OY conditions, switch to nontransferable cumulative catch limits. All poundage that would otherwise have been issued to holders of quota shares will be used to create a catch cap. Nontransferable cumulative limits will be used to achieve Council season duration goals. (See Element 1.4)	☐	☐	☑	☐	☐
Sub-Option 2.4.3.2 No special measures for low OY conditions (i.e. continue using IFQs) (See Element 1.4)	☐	☐	☑	☐	☐
Option 2.4.4 IFQs	☐	☐	☐	☑	☐

– **Key to Alternatives**

– Alt. 1: No Action; Cumulative trip limits; Whiting season; Only report landings	– Alt. 2: Trawl Target IFQs, Whiting season; Total catch reporting	– Alt. 3: IFQs for all but Other Species, No whiting seasons; Total catch reporting	– Alt. 4: IFQs for all species, No whiting seasons; Total catch reporting	– Alt. 5: Permit stacking; trip limits; Whiting season; Total catch reporting

– **Key to Column Indicators** – ☑ = this option is included in alternative; ☐ = option could be included but is not; **N/A** = option is not applicable to alternative

Section 1: Components, Elements, and Options Relating to Management Regimes	**Alt. 1**	**Alt. 2**	**Alt. 3**	**Alt. 4**	**Alt. 5**
Option 2.4.5 Cumulative catch limits with permit stacking rules applied for non-whiting trips. On attainment of a cap, guideline or OY for a particular species, the segments of the trawl fishery that might catch that species are closed. For the whiting fishery, cumulative catch apply to non-whiting species. It is unlikely that a whiting fishery cap would be established for an unallocated non-whiting species; however, if that situation were to occur, the whiting season would close on attainment of the non whiting catch cap. Permit stacking rules do not apply to non-whiting species taken on whiting trips, i.e. on whiting trips a vessel receives no credit for permit stacking.	☐	☐	☐	☐	☑
Element 2.5 "Other Fish" Groundfish: sharks (except spiny dogfish), skates, rays, ratfish, morids, and grenadiers. *Under the current management regime these Other Species have an OY but do not have separate OYs and are not managed with cumulative trip limits. However, on occasion some of these species are considered for separate management (e.g. Pacific cod, Spiny Dogfish, cabezon and kelp greenling). As with other species groups, composition of the group will change over time. The group will be analyzed as it was composed for the 2005 fishery. If action Alternative 2, 3 or 5 is implemented the management measures used for groundfish categorized as "Other Fish" will be those in place just prior to the time of implementation, unless than Council follows other procedures to take action (e.g. modifications during the biennial specifications process). If at the time the program is implemented cumulative limits are used to manage these species, then they will be managed the same as "Unallocated Shared Target and Incidental Species" (Element 2.4). In order to accommodate the possible change in status of some members of this group and the possible need for allocation of IFQ an allocation analysis will be provided for the species most likely to be managed separately at the time of program implementation.*					
Option 2.5.1 Status Quo: monitoring only (occasional use of cumulative limits)	☑	☐	☐	☐	☐
Option 2.5.2 Monitoring only or management measures in place just prior to implementation.	☐	☑	☑	☐	☑
Option 2.5.3 IFQs	☐	☐	☐	☑	☐
Component 3 Groundfish Catch of Limited Entry (LE) Trawl Vessels Using Gears Other Than Groundfish Trawl *This component addresses the application of the management measures specified in Component 1, Component 2, and Component 4 to groundfish catch by non-trawl and exempted trawl gear used by vessels with a limited entry trawl permit. Exempted trawl gears are California halibut, Pacific shrimp, sea cucumber trawl and ridgeback prawn trawl.*					

– **Key to Alternatives**

– Alt. 1: No Action; Cumulative trip limits; Whiting season; Only report landings	– Alt. 2: Trawl Target IFQs, Whiting season; Total catch reporting	– Alt. 3: IFQs for all but Other Species, No whiting seasons; Total catch reporting	– Alt. 4: IFQs for all species, No whiting seasons; Total catch reporting	– Alt. 5: Permit stacking; trip limits; Whiting season; Total catch reporting

– **Key to Column Indicators** – ☑ = this option is included in alternative; ☐ = option could be included but is not; **N/A** = option is not applicable to alternative

Section 1: Components, Elements, and Options Relating to Management Regimes	Alt. 1	Alt. 2	Alt. 3	Alt. 4	Alt. 5
Element 3.1 Exempted Gear (Including Exempted Trawl Gear)					
Option 3.1.1 Exempted gear landings by LE trawl vessels counts against the LE allocation (trawl and fixed gear), with the exception of sablefish for which there is a separate LE trawl allocation against which such landings count. Landings are subject to open access (OA) cumulative limits and also count against limited entry trawl cumulative limits.	☑	☐	☐	☐	☐
Option 3.1.2 IFQ is not required for use of exempted gears. Catch counts against the OA allocation and is managed as part of the OA fishery. Some catch will be allocated from the LE trawl to OA fishery.	☐	☑	☐	☐	☐
Option 3.1.3 IFQ is required when exempted gears are used. Catch counts against the LE trawl allocation. For species for which IFQ is not required, catch counts against the trawl cumulative limits. Catch by LE trawl vessels using exempted gear must be taken in compliance with the IFQ enforcement and monitoring system and all other relevant rules applying to the IFQ, including the sector to which deliveries must be made (e.g. shoreside, mothership and catcher-processor designations).	☐	☐	☑	☑	☐
Sub-Option 3.1.3.1 Open access catch control regulations (trip limits) also apply, in addition to the IFQ requirement.	☐	☐	☑	☐	☐
Sub-Option 3.1.3.2 Open access catch control regulations (trip limits) **do not** apply.	☐	☐	☐	☑	☐
Option 3.1.4 Exempted gear catch by LE trawl vessels counts against LE allocation (trawl and fixed gear), with the exception of sablefish for which there is a separate LE trawl allocation against which such catch counts.	☐	☐	☐	☐	☑
Sub-Option 3.1.4.1 Landings are subject to open access (OA) cumulative limits and also count against limited entry trawl cumulative limits.	☐	☐	☐	☐	☑
Sub-Option 3.1.4.2 Landings are not subject open access limits. Vessels may use exempt gear to fish against the limits associated with stacked permits. Enforcement and monitoring regulations for trawl gear also apply to LE trawl vessels using exempted gear.	☐	☐	☐	☐	☑

– **Key to Column Indicators** – ☑ = this option is included in alternative; ☐ = option could be included but is not; **N/A** = option is not applicable to alternative

Section 1: Components, Elements, and Options Relating to Management Regimes	Alt. 1	Alt. 2	Alt. 3	Alt. 4	Alt. 5
Element 3.2 Longline and Fishpot Gear (Fixed Gear)					
Option 3.2.1 Longline or fishpot catch by LE trawl vessels without a longline or pot endorsement counts against LE allocation (trawl and fixed gear), however, for sablefish there is a separate LE trawl allocation against which the sablefish landings count. The catch is subject to open access trip limits. Longline or fishpot catch by LE trawl vessels with a longline or pot endorsement counts against LE allocation (trawl and fixed gear), however, for sablefish there is a separate LE fixed gear allocation against which the sablefish landings count. The catch is subject to fixed gear trip limits.	☑	☐	☐	☐	☐
Option 3.2.2 IFQ is required for LE trawl vessels using longline or fishpot gear to catch species for which IFQ management is used in the trawl fishery. For species for which IFQ is not required in the trawl fishery, longline or fishpot catch counts against the trawl cumulative limits. All groundfish catch counts against the LE trawl allocation (except as noted). Catch by LE trawl vessels using longline or fishpot gear must be taken in compliance with the IFQ enforcement and monitoring system and all other relevant rules applying to the IFQ, including the sector to which deliveries must be made (e.g. shoreside, mothership and catch processor designations). An exception to this rule is provided for vessels that also have a limited entry fixed gear permit. In such case the rules are modified as specified Sub-Option 3.2.2.1 or Sub-Option 3.2.2.2.	☐	☑	☑	☑	☐
Sub-Option 3.2.2.1 For limited entry trawl vessels without a limited entry fixed gear permit, limited entry fixed gear catch control regulations (trip limits) apply and all longline and fishpot gear catch must be covered by IFQ or trawl cumulative limits. For limited entry trawl vessels that also hold a limited entry fixed gear permit, IFQ is not required to cover catch taken toward fixed gear cumulative or daily limits, catch taken toward the limits need not comply with the trawl IFQ monitoring and enforcement system, and such catch or landings count against the limited entry fixed gear allocation (i.e. for vessels with both limited entry trawl and fixed gear permits there is no opportunity to use trawl IFQ to increase harvest using longline or fishpot gear).	☐	☑	☐	☐	☐

– **Key to Alternatives**

– Alt. 1: No Action; Cumulative trip limits; Whiting season; Only report landings	– Alt. 2: Trawl Target IFQs, Whiting season; Total catch reporting	– Alt. 3: IFQs for all but Other Species, No whiting seasons; Total catch reporting	– Alt. 4: IFQs for all species, No whiting seasons; Total catch reporting	– Alt. 5: Permit stacking; trip limits; Whiting season; Total catch reporting

– **Key to Column Indicators** – ☑ = this option is included in alternative; ☐ = option could be included but is not; **N/A** = option is not applicable to alternative

Section 1: Components, Elements, and Options Relating to Management Regimes	Alt. 1	Alt. 2	Alt. 3	Alt. 4	Alt. 5
Sub-Option 3.2.2.2 For limited entry trawl vessels without limited entry fixed gear permits, limited entry fixed gear catch control regulations (trip limits) **do not** apply and IFQ is required for all longline and fishpot gear catch. For limited entry trawl vessels with an LE fixed gear permit, IFQ is not required to cover catch taken toward the fixed gear trip limits; catch taken toward the limits need not comply with the trawl IFQ monitoring and enforcement system, and catch taken toward the limits counts against the limited entry fixed gear allocation. Longline or fishpot catch taken after fixed gear limits have been reached must be covered by IFQ or trawl cumulative limits, and be taken in compliance with the trawl IFQ monitoring and enforcement system and other relevant rules.	☐	☐	☑	☑	☐
Option 3.2.3 Longline or fishpot catch by LE trawl vessels without a longline or pot endorsement counts against LE allocation (trawl and fixed gear), however, for sablefish there is a separate LE trawl allocation against which the sablefish landings count. Longline or fishpot catch by LE trawl vessels with a longline or pot endorsement counts against LE allocation (trawl and fixed gear), however, for sablefish there is a separate LE fixed gear allocation against which the sablefish landings count. The catch is subject to fixed gear trip limits.	☐	☐	☐	☐	☑
Sub-Option 3.2.3.1 The catch is subject to open access trip limits or fixed gear limits, depending on whether or not an LE fixed gear permit is held.	☐	☐	☐	☐	☑
Sub-Option 3.2.3.2 The catch is subject to stacked trawl permit limits, and enforcement and monitoring requirements for the trawl fishery apply, except that vessels with sablefish endorsed fixed gear permits may take their tier sablefish limits and associated incidental catch under the rules which apply to the LE fixed gear fishery. The tiered sablefish limits will not count toward the trawl limits.	☐	☐	☐	☐	☑
Component 4 Monitoring and Enforcement (At-Sea Observers/Monitoring)					
Option 4.1.1 No action (status quo) monitoring and enforcement includes 100-percent observers on catcher-processors and motherships in the whiting fishery. Biological observers from the WCGOP are present for other segments of the limited entry trawl fishery. All limited entry trawl vessels carry VMS.	☑	☐	☐	☐	☐

Section 1: Components, Elements, and Options Relating to Management Regimes		Alt. 1	Alt. 2	Alt. 3	Alt. 4	Alt. 5
Option 4.1.2	Detailed monitoring and enforcement programs are specified in the IFQ Program Alternatives (Programs A, B and C). These monitoring and enforcement programs include 100-percent at-sea monitoring, upgraded bycatch reporting, electronic landings reporting, shoreside monitoring of deliveries, advance notice of landing, limited delivery locations/ports, electronic IFQ tracking and continues use of VMS. Limited entry trawl vessels would be required to be in compliance with such programs any time they are harvesting against limited entry trawl catch limits, including IFQ.	☐	☑	☑	☑	☐
Option 4.1.3	In addition to the no action (status quo) monitoring and enforcement, 100-percent observers (or equivalent means of monitoring) would be required for vessels fishing on trawl cumulative limits, due to the conversion from status quo cumulative landing limits to cumulative catch limits.	☐	☐	☐	☐	☑
Component 5	**Area Management.** Decision deferred until additional information is available, e.g. preliminary DEIS is ready.					
Option 5.1.1	Species divided by areas based on stock assessment information. New area divisions created as stock assessment information indicates need.	☑	☐	☐	☐	☐
Option 5.1.2	Plan to establish additional regional management areas as needed at a later time.	☐	☑	☑	☑	☑
Option 5.1.3	Process Option: Task a group to begin considering the need for additional regional management areas (biological or socio-economic) and potential boundaries along with a process for identifying and responding to regional management area issues that may develop or become more apparent in the future.	☐	☑	☑	☑	☑
Component 6	**Sector Allocation**					
Element 6.1	**Within Trawl Allocation.** Allocation among limited entry trawl sectors.					
Option 6.1.1	Whiting allocation rules. No other within trawl allocations.	☑	☐	☐	☐	☑

– **Key to Alternatives**

– Alt. 1: No Action; Cumulative trip limits; Whiting season; Only report landings	– Alt. 2: Trawl Target IFQs, Whiting season; Total catch reporting	– Alt. 3: IFQs for all but Other Species, No whiting seasons; Total catch reporting	– Alt. 4: IFQs for all species, No whiting seasons; Total catch reporting	– Alt. 5: Permit stacking; trip limits; Whiting season; Total catch reporting

This section of the Components Table [IN PROGRESS, TO BE PROVIDED AS PART OF FINAL REPORT] deals with the initial allocation QS and the annual allocation of QP. QS differ from QP in that QP represent an annual catch amount allocated to a person, whereas a persons' QS represent portions of the total pool of quota shares (QSP).

The allocation of QS is typically based on historical participation. For example, under one option, a harvester's QS would be based on the total of all pounds landed under the permit from 1994 – 2003 after dropping the two worst years. For a given year, QP for a species are an individual's QS as a percent of all quota shares issued for that species, multiplied by the sector allocation for that species for that year. It should be noted that QS need not be based on catch history. For example each participant could be issued 1,000 QS for every year they fished, or each participant might be issued 10 QS of species Y for every 100 pounds of species X. The former method might be used if documentation of historical participation is suspect, while the latter might be used to issue quota shares for incidental species that fishers were trying to avoid.

The West Coast Trawl IFQ Program has several complicating features. One such feature is that multiple groups could be issued QS, and the proportion of QS going to each group may be predetermined. There are also options that would use different catch history periods for the different groups. While this type of allocation is complicated, it should not be considered a stumbling block if decision makers have predetermined the proportion that would go to each group. Assume for example that Group X's QS are allocated based on landings from one set of years—say 1994 – 2003, and Groups Y's QS are based on a different set of years 2000 – 2004. Furthermore, assume that both groups are to be allocated 50 percent of the QS; the total amount of history for a particular species over all members Group A was 10 million pounds, and the total amount for Group B was 4 million pounds. If Group A's history is divided by 10 and Group B's history is divided by 4, and quota shares are issued based on the result, then each group would receive 1 million QS, thus assuring that each group gets 50 percent of the allocation.

Another complicating feature of the Trawl IFQ Program is the fact that the reporting system for shoreside deliveries shows the total amount landed rather than total amount caught. For target species, or for species that are not constraining to the fishery, it is likely that landings are approximately equal to total catch. But for many incidental catch species (e.g., those with low value) or overfished species that constrain the fishery, landings may be a very poor indicator of historical catch. Furthermore, even if all catch of incidental species were reported, it may not be reasonable to award QS of incidental species based on historical catches. Assume for example there are two fishers A and B. Fisher A is very methodical and works hard to avoid incidental catches and lands 100 pounds of incidental catch for every 1,000 pounds of target catch. Fisher B is a less careful fisher and lands 600 pounds of incidental catch for every 1,000 pounds of target. If landing history were used for incidental catch, then Fisher B would get significantly more QS than Fisher A, and in a sense would be rewarded for not fishing cleanly. From this perspective it may be more equitable to consider methods other than historical landings to issue quota shares for incidental or overfished species.

The remainder of this section is structured as a table similar to the previous section. It should be noted that QS are only applicable to Alternatives 2 – 4. It should also be noted that the Council developed three basic programs for issuance of QS—Program A, Program B and Program C. In the main suite of alternatives, Program C was matched with Alternatives 2, 3 or 4 for analysis, while Programs A and B were matched with Alternative 3. The application of each of the programs to Alternative 3 creates three full sub-alternatives for Alternative 3. The intent of was to allow the alternatives to be compared with one another using the same IFQ program, and to allow the various programs to be compared using the same main alternative. With this approach, the Council hopes the information necessary to choose between any combination of management alternatives and IFQ programs will be generated.

Table 2-4. Components, Elements, and Options Relating to the Allocation QS and QP

Table 4 will go here.

2.4 Summary of Direct, Indirect and Cumulative Effects of Alternatives

This section provides an overview of the direct, indirect and cumulative effects of each alternative on the resource and stakeholder groups of concern. The discussion of the impacts of the alternatives is limited to a concise descriptive summary of such impacts in a comparative form, including charts or tables, thus sharply defining the issues and providing a clear basis for choice among alternatives. The information presented is based on the scientific analysis of the direct, indirect and cumulative effects of each of the alternatives presented in Chapter 4.

2.4.1 Alternative 1: The No-Action Alternative

2.4.2 Alternative 2: IFQs for Whiting and Trawl Target Species

2.4.3 Alternative 3: IFQs for All Groundfish except Other Species

Alternative 3 consists of five major options. The options vary by the allocation rules used. Because it is expected that the initial allocation of IFQs will one of the most important impact mechanisms, the Consulting Team believes it is important to treat each of these major options as a stand-alone alternative in the effect analysis. This treatment is exemplified in Table 2-5, in which each of five options for Alternative 3 is included with a separate column.

It should be noted that Alternative 3C was designed by the Council to be somewhat of lynchpin or central cohesive option among the seven IFQ permutations in the main suite of alternatives; each of the Alternative 3 options differ only in the initial allocation rules, while both Alternative 2 and Alternative 4 use the same initial allocation rules as used in Alternative 3C.

2.4.3.1 Alternative 3A: IFQ for all but Other Species with 50/50 QS Allocation Split between Harvesters and Processors

2.4.3.2 Alternative 3Ba: IFQ for all but Other Species with a 100/0 QS Allocation Split between Harvesters and Processors

2.4.3.3 Alternative 3Bb: IFQ for all but Other Species with a 90/10 QS Allocation Split between Harvesters and Processors

2.4.3.4 Alternative 3Bc: IFQ for all but Other Species with a 50/50 QS Allocation Split between Harvesters and Processors for Whiting and a 100/0 Split for Non-whiting

2.4.3.5 Alternative 3C: IFQ for all but Other Species with 75/25 QS Allocation Split between Harvesters and Processors

2.4.4 Alternative 4: IFQs for All Groundfish Species

2.4.5 Alternative 5: Permit Stacking

2.5 Comparison of the Direct, Indirect and Cumulative Effects of the Alternatives

Table 2-5 provides brief narrative descriptions of the major direct and indirect effects of each alternative. The rows in the table list the stakeholder and resource groups that have been initially identified as being possibly affected by the alternatives. The columns in the table list the alternatives. The various options for Alternative 3 are treated independently because the impacts of the initial allocation rules in the IFQ programs may differ. Table 2-6 provides brief narrative descriptions of the cumulative effects of the alternatives.

3 Resource and Stakeholder Profiles

3.1 Introduction

This chapter provides profiles of affected resource and stakeholder groups. Included are definitions of historical and baseline conditions. The profiles document the current conditions and historical context of resource and stakeholder groups as measured by specified quantitative or qualitative indicators. The profiles describe how resource and stakeholder groups have changed, and how they are changing at the time of the analysis. This description of the affected environment will not only provide the needed baseline to evaluate the environmental consequences of the alternatives, but also will help identify past and present actions contributing to cumulative effects.

3.1.1 Historical Conditions

These are conditions of the resources and stakeholder groups as reflected in the indicator values for previous years. Trends in conditions are identified where possible, and the important cause-and-effect relationships between past actions and the condition of resources and stakeholder groups of concern are described to the extent possible.

3.1.2 Baseline Conditions

This description of baseline conditions reflects the status of potentially affected resource and stakeholder groups as of 2005. To the extent feasible, trends data from the description of historical conditions are used to depict baseline conditions more accurately (i.e., by incorporating variation over time). The cumulative past and present effects of groundfish fishery activity, as well as effects external to the groundfish fishery such as other fishery impacts, human-induced impacts, and climatic events influencing the resource and stakeholder groups, all contribute to the state of the baseline condition. In terms of regulations, the baseline includes all existing regulations as modified by actions that the Council has approved, but which have not yet been implemented by NMFS. Thus, any new regulations implementing the Essential Fish Habitat measures approved in Amendment 19 are assumed to be in effect, as are the sector allocations authorized under Amendment 18.

The baseline conditions provide a benchmark against which the effects of the alternatives are compared in Chapter 4.

3.2 Major Fishery Data Sets Used in Describing Historical and Baseline Conditions

This section briefly describes some of the major data sets available for defining the historical and baseline conditions.

3.2.1 Shoreside Non-whiting Commercial Fishery Data

Several harvest monitoring systems are used in West Coast groundfish management. PacFIN (Pacific Fisheries Information Network) is the commercial monitoring database for shoreside landings. Summaries of logbook entries are also available for catch of limited entry trawl fleet. Discards by the shoreside fleets are sampled by the West Coast Groundfish Observer Program (WCGOP). These three data sources are all incorporated into the bycatch models constructed and maintained by the PFMC Groundfish Management Team (GMT). NorPac collects and summarizes catch by the at sea whiting fleets.

3.2.1.1 Landings Data

Commercial landings are recorded on state fish-tickets. Poundage by sorted species category, price, area of catch, vessel identification number, port of landing, buyer and other data elements are recorded on fish-tickets. Landings are sampled in port by state personnel to collect species composition data for aggregated species categories, and other biological data. Species composition ratios are used to disaggregate landings data for certain species categories. Limited entry groundfish trawl vessels are also required to maintain logbooks that record the start location, time, and duration of trawl tows, as well as the total catch by species market category. Data from fish-tickets and logbooks are available at various level of summarization from PacFIN.

3.2.1.2 Discards and Incidental Catch Data

The Groundfish FMP requires all vessels that participate in the groundfish fishery to carry an observer when notified to do so by NMFS or its designated agent. Under the WCGOP, observers monitor and record catch data, including species composition of retained and discarded catch. Observers also collect biological data such as fish length, sex, and weight. The program deploys observers coast wide on permitted trawl and fixed-gear groundfish vessels, as well as on some open-access groundfish vessels. Currently the program samples approximately 20% of limited entry trawl trips and has been expanding coverage of the limited entry fixed-gear and open access sectors.

Estimates derived from the WCGOP reports are used to calibrate incidental catch and discard rates in the bycatch models constructed and maintained by the PFMC Groundfish Management Team (GMT). The first and most developed bycatch model is used for managing of the limited entry trawl fishery. Preliminary bycatch models for the limited entry fixed gear and directed open access fleets have recently been developed.

The trawl bycatch model projects future landings of major trawl target species (excluding Pacific whiting) through use of recent landings data and an array of bimonthly trip limits. Landings projections are then used to estimate total mortality for target species and non-target species of concern through the application of average bycatch ratios. The principal data inputs to the trawl bycatch model are (1) fish tickets (landings), (2) WCGOP bycatch and discard rates, and (3) trawl logbooks (depth association of catch). Logbook data are used to partition observed landings into appropriate depth strata, by summarizing the depth distributions recorded in logbooks for each modeled target species. Bycatch ratios are generally stratified by target fishery; bimonthly period; latitude zone (north of 40°10' N. lat., between 40°10' and 38° N. lat., and south of 38° N. lat.); and depth zone (shoreward of Rockfish Conservation Areas (RCAs), and seaward of RCAs).

3.2.2 Whiting Commercial Fishery Data

The shoreside whiting sector is required to bring 100% of their catch to port for sampling. Landings, logbook data, and state port sampling data for the shoreside whiting sector are reported to PacFIN. (For information on this program see http://hmsc.oregonstate.edu/odfw/reports/hake.html). The at-sea whiting fishery has 100% on-board observer coverage. Total catch by vessels involved in the at-sea whiting fishery is summarized and maintained by NorPac. Since total catch in both the at-sea and shoreside whiting sectors is observed, either by at-sea observers or upon landing, bycatch models are not maintained for these sectors.

3.2.3 Recreational Catch Data

RecFIN (Recreational Fishery Information Network) maintains official estimates of West coast recreational fishery catch. Total annual catch estimates by state, species and fishing mode go back to 1980. The NOAA sponsored Marine Recreational Fishery Statistics Survey (MRFSS) was a major component of this data collection, but these data were also augmented with data collected from state funded sampling programs.

In 2003, it was determined that the States of Oregon and Washington would take over the entire recreational data collection program with funds from MRFSS diverted to sampling programs run by the individual states. This regime shift took place in mid-2003. At the beginning of 2004 in California a new expanded California Recreational Fisheries Survey (CRFS) replaced MRFSS. In Oregon and Washington the existing Ocean Boat Survey program was expanded, while in California the new CRFS is a partnership between PSMFC and CDFG. The new program in California provides much more precise estimates of recreational catch.

Data from these sources are still compiled into the RecFIN database. The new state-based programs allow monthly estimates of total catch and are timelier for in-season management. (See http://www.psmfc.org/recfin/index.html).

3.2.4 Economic Data

3.2.4.1 Ex-vessel Prices

The PacFIN system records deliveries by catcher vessels to shore-based buyers, and includes revenue information by species group for each landing. This data can be used to calculate average ex-vessel prices by species, port, area of catch and month. NorPac data records only delivery tonnage for the at-sea whiting sector. Delivery prices for the at-sea sector therefore must be inferred or imputed based on other information, e.g., shoreside prices.

3.2.4.2 Ex-processor Prices

Unfortunately there is no systematic collection of ex-processor prices for seafood products produced on the West Coast. NOAA Fisheries has periodically surveyed processors to collect production and wholesale price information, but these data have not been considered highly useful (Freese, 2006). Other estimates of these values have been included in the Fisheries Economic Assessment Model (FEAM), which is used by the Council to estimate income impacts attributable to West Coast commercial fisheries. However, ex-processor prices in the FEAM tend to be fairly aggregated, and are not differentiated by month or product form (i.e., frozen vs. fresh). Any detailed information on West

Coast ex-processor prices must be collected through a survey or key informant interviews, or inferred from examination of other sources. The absence of processed product and wholesale price information may limit the types of analysis that can be conducted.

3.2.4.3 Vessel Costs

There are no current, comprehensive estimates of costs for West Coast commercial harvester vessels available. However NWFSC is currently conducting a cost and earnings survey of West Coast trawl vessels. It is assumed that results will be available in time for inclusion in the EIS. FEAM does include average cost estimates for several representative vessel types. However estimates used in the most current version of the FEAM are several years old and predate the recent run-up in fuel prices.

3.2.4.4 Processor Costs

There are no current, comprehensive estimates of costs for West Coast processors available. FEAM does include average cost estimates for several representative types of processors. However, estimates used in the most current version of the model are several years old and predate the recent run-up in fuel prices. Any detailed information on West Coast processor costs must be collected through a survey or key informant interviews, or inferred from examination of other sources.

3.3 List of Potentially Affected Resource and Stakeholder Groups

The Consulting Team is proposing to develop profiles of the following resource and stakeholder groups. The amount of detail in any of the profile will depend on the level of interaction with the groundfish trawl fishery. For example profiles of trawl catcher vessels will be extensive, while profiles of recreational harvesters will be highly aggregated. The Consulting Team does not consider this list final—some groups may be deleted and/or new ones added.

- Limited-entry Trawl Groundfish Catcher Vessels
- Trawl Catcher Processors
- Processors and Buyers of Trawl Groundfish
- Other Non-Trawl Commercial Harvesters
- Processors and Buyers that do Not Purchase Trawl Groundfish
- Recreational Harvesters[8]
- Communities
- Tribes
- Input Suppliers
- Wholesalers and Retailers of Groundfish
- Consumers
- General Public
- Management Agencies
- Groundfish Resources

[8] Recreational harvesters will be profiled in a very general way showing total catch and relative dependence on groundfish.

- Other Fish Resources
- Marine Mammals
- Other Protected Resources
- Seabirds
- Habitat
- Trophic Relationships[9]

3.4 Limited-entry Trawl Groundfish Catcher Vessels

The description of limited-entry trawl groundfish catcher vessels contains the following sub-sections:

- Sub-section 3.4.1describes the classification of potentially affected trawl catcher vessels and permit holders.
- Sub-section 3.4.2 lists the condition indicators used to describe the historical and current status of trawl catcher vessels and permit holders.
- Sub-section 3.4.3 summarizes participation of all trawl catcher vessel classes.

3.4.1 Classification of Potentially Affected Trawl Catcher Vessels

This section discusses the directly affected fish harvester component of the affected environment. The preliminary specification of six trawl catcher vessel classes is shown in Table 3-1, together with an initial description of each class.

Table 3-1. Preliminary Specification of Trawl Catcher Vessel Classes

Vessel Class	Description
Offshore Whiting Trawl CV (OW-TCV)	Whiting deliveries to motherships account for 50 percent or more of West Coast revenue. Whiting deliveries to onshore processors are minimal.
Inshore Whiting Trawl CV (IW-TCV)	Whiting deliveries to onshore processors is 50 percent or more of West Coast revenue. Whiting deliveries to motherships are minimal.
Combination Onshore-Offshore Whiting Trawl CV (CW-TCV)	Whiting deliveries account for 50 percent or more of West Coast revenue. Deliveries to both onshore and offshore processors.
Large Diversified Trawl CV (LD-TCV)	Larger diversified vessels; Whiting revenue is less than 50 percent of West Coast revenue. Fish year-round in both deepwater and near-shore fisheries.
Small Diversified Trawl CV (SD-TCV)	Smaller diversified vessels; Whiting revenue is less than 50 percent of West Coast revenue. Generally fish near shore and not during winter.
Bought-out Trawl CVs (BO-TCV)	This class contains the vessels that where bought out of the fishery in the industry funded buyback in 2003.

Determination of whether a permit and associated vessel(s) are classified into a particular class will be based on landings during the years 1994-2005. Each permit will be assigned to one and only one class regardless of operational changes the operation utilizing the permit may have made. Regardless of

[9] This analysis uses the term Trophic Relationships to specifically represent predator prey relationships. The term "ecosystems" is often used instead, but the Consulting Team believes that the term "ecosystem" comprises all of the resources and stakeholders already listed, and therefore listing it as a separate resource is redundant.

whether a permit might appear to belong to any class, if it was bought out in the 2003 industry funded buyback it will be classified as a Bought-Out Trawl CV.

The Consulting Team notes that feedback received during the Trawl IFQ Workshop held in Portland, OR, April 18-20, 2006, indicated that there may be other ways to classify the diversified trawl vessels. For example it might be that these vessels would be better classified in terms of geographic location—vessels operating out of California and Southern Oregon have a narrow shelf width compared to vessels operating out or Northern Oregon or Washington. The final classification scheme for trawl catcher vessels will be determined during the actual EIS analysis in Phase 2. At that time, a complete assessment of catches and catch patterns will be utilized for classification.

3.4.2 Condition Indicators for Trawl Catcher Vessels

Indicators of the historical and baseline conditions of trawl catcher vessels include but are not necessarily limited to the following:

- Catch by species
- Catch as by species as a percent of optimum yield
- Incidental catch by species by target fisheries
- Discarded catch by species and target fishery
- Distribution of catches by month
- Ex-vessel revenues from groundfish
- Distribution of catches among the trawl fleet and sectors
- Relative dependency on West Coast trawl groundfish
- Relationships with processors
- Operating costs
- Net revenues
- Number of participating trawl catcher vessels
- Number of permit holders
- Distribution of permit holders by community
- Number of trips per year
- Number of fishing days per year
- Number of crew members
- Distribution of crew members by community
- Crew and skipper shares

Some conditions may not be measurable by quantifiable indicators. These include vessel safety, market power vis-à-vis processors, and others.

3.4.3 Summary of Past and Present Conditions of Trawl Catcher Vessels

This section summarizes and compares participation over all trawl catcher vessel classes described in Table 3-1. Detailed descriptions of each vessel class are provided in Sections 3.4.3.4 – 3.4.4.6. This summary highlights the conditions and indicators that are the most important determinants of outcomes under the alternatives—total participation, landings and ex-vessel value by species, landings and ex-vessel value by target strategy, and incidental catches of overfished species by target strategy.

The section compares the situation in 2005 (baseline condition) and historical conditions during the 1994-2005 period.

3.4.3.1 Number of Active Permit Holders and Vessels

This section summarizes participation in terms of the number of limited trawl permits holders during the historical period and in 2005. The section shows the annual number of active number of permits by year and vessel class; the annual number of active number of permits by year and species; the total number of permits by species and catcher vessel class over the historical period, and the number of active permits by species and catcher vessel class in 2005.

A trawl IFQ program is likely to affect the number of active permits in the West Coast groundfish trawl fishery during the initial allocation of IFQs to permit holders and during the fleet consolidation that is likely to follow implementation of the program.

Table 3-2. Active Permits by Trawl CV Class, 1994-2005

	1994	1995	1996	1997	1998	1999	2000	2001	2002	2003	2004	2005	Total
Vessel Class	**Number of Active Permit Holders**

3.4.3.2 Total Landings and Ex-vessel Value

This section summarizes landings and ex-vessel values generated by limited trawl permits holders during the historical period (1994-2005) and in 2005.

A trawl IFQ program is likely to affect the amount and distribution of landings and ex-vessel values across vessel classes. For example, the initial allocation of IFQs will likely be based to some extent on historical landings. To the extent that historical landings patterns match landings patterns in 2005, distributional changes in the fishery caused by the initial allocation will be minimized. Showing the changes in landing patterns over time by vessel class provides insights into the potential effects of the initial allocation and the consolidation of the fleet that is likely to follow. Additional details on landings and ex-vessel values within vessel classes are shown in Sections 3.4.3.4 – 3.4.4.6.

3.4.3.3 Ex-Vessel Value, Landings and Incidental Catch Rates by Target Strategy

This section summarizes fishing of the limited entry trawl fleet by target strategy during the historical period (1994-2005) and in 2005. Target strategies are based on landings by species in individual fish-tickets for shore-based landings. The target strategy for deliveries to motherships is assumed to be Pacific whiting.

Target strategies vary significantly by vessel class—by definition, the three whiting vessel class target Pacific whiting more than any other target, while the diversified vessel classes utilize other strategies more than whiting. Target strategies are important under a trawl IFQ program because incidental catches of overfished species vary by target strategy. For example, if a target strategy has low incidental catch rates of a particular overfished species, vessel classes that utilize that target strategy will have a lower need for IFQs for that species.

This section also provides a summary of incidental catch rates for all limited entry trawl vessels by target strategy from 2001-2005. These tables are derived using a process similar to that used in the NOAA Fisheries Bycatch Model.

3.4.3.4 Distribution of Landings by Species and Month

This section summarizes the distribution of landings of trawl catcher vessels by month. This is an important indicator because under an IFQ program vessels will likely want to change their fishing period to optimize catches of target species relative to catches of overfished species. Section 3.6.3.3 in provides a summary of ex-vessel prices paid by month.

3.4.4 Past and Present Conditions of Trawl Catcher Vessel Classes

3.4.4.1 Offshore Whiting Trawl Catcher Vessels

The Offshore Whiting Trawl Catcher Vessel class (OW-TCV) includes permits and the vessel associated with those permits that have been primarily engaged in the offshore whiting fishery over the years from 1994 – 2005. Vessels that are defined as being in this class will have generated more than 50 percent of their West Coast groundfish revenue in deliveries of whiting to motherships during the period. The offshore whiting fishery is distinct from the Inshore Whiting Fishery in that deliveries are made to motherships by transferring trawl cod-ends at the end of each tow. Because these vessels deliver directly to motherships they do not necessarily need a RSW hold, and may stay out at sea for longer periods than Inshore Whiting Trawl CVs.

3.4.4.1.1 Class Characteristics and Participation

This section describes class behavior and participation, as well as vessel size and design. To shorten this outline document, only table and figure captions and headings are shown.

Table 3-32. Number of Offshore Whiting Trawl Catcher Vessels by Length, 1994-2005

	Vessel Lengths Associated with Permits Assigned to the Class					
Year	60-79’	80’-94’	95’-109’	110’-124’	124’+	Total

The numbers of active vessels in this class by year are graphically depicted in Figure 3-1.

Figure 3-1. Number of Offshore Whiting Catcher Vessels, 1994-2005

Figure 3-2 shows the number of years a permit was active during the historical period. Under a trawl IFQ program, the number of years a permit was active will directly correlate with the amount of IFQs received relative to average catches in active years. For example, if a permit was active for 6 of the 12 years in the quota share historical period, it is likely that the amount of IFQs for a species allocated to the permit will yield IFQs approximately equal to 50 percent of the permit’s average landings during active years, assuming total catch for the species was relatively constant over the historical period.

Figure 3-2. Histogram of Duration of Participation, Offshore Whiting Trawl Catcher Vessels, 1994-2005

3.4.4.1.2 Description of Fishing Operations

This section provides a general background on these vessels, including their history of participation in the West Coast groundfish trawl fishery and other fisheries. While this vessel class by definition is specialized in the whiting fishery, it is possible that vessels in this class have participated in other fisheries during the 1994-2005 period.

3.4.4.1.3 Dependence on West Coast Groundfish Trawl Fishery and Annual Cycle of Operations

Figure 3-3 and Table 3-33 show the relative dependence on limited entry trawl groundfish relative to other West Coast and Alaska fisheries.

Figure 3-3. Ex-Vessel Value of Harvest by Offshore Whiting CVs by Fishery, 1994-2004

3.4.4.1.4 Catch Quantity and Value in West Coast Groundfish Trawl Fishery

This section discusses the harvest amount and value of the Offshore Whiting Trawl CV class in the West Coast groundfish trawl fishery. The following types of information are presented:

- Participation levels by groundfish species
- Participation levels by target strategy
- Incidental catch by target strategy
- Ex-vessel value of deliveries by processor class

Table 3-37 through Table 3-39 show the number of permits, landed tons, and ex-vessel value by species in the Offshore Whiting Trawl CV class from 1994-2005.

Figure 3-4 shows a hypothetical distribution of catch of species X among vessels in the class from 1994-2005 and in 2005. Similar figures will be generated for each groundfish species landed in the limited entry trawl fisheries. The total over all years is shown because it represents the historical distribution of landings among vessels in the class, while the distribution in 2005 is shown because it represents participation in the baseline year.

Figure 3-4. Distribution of Landings of Species X by the Offshore Whiting Trawl CV Class

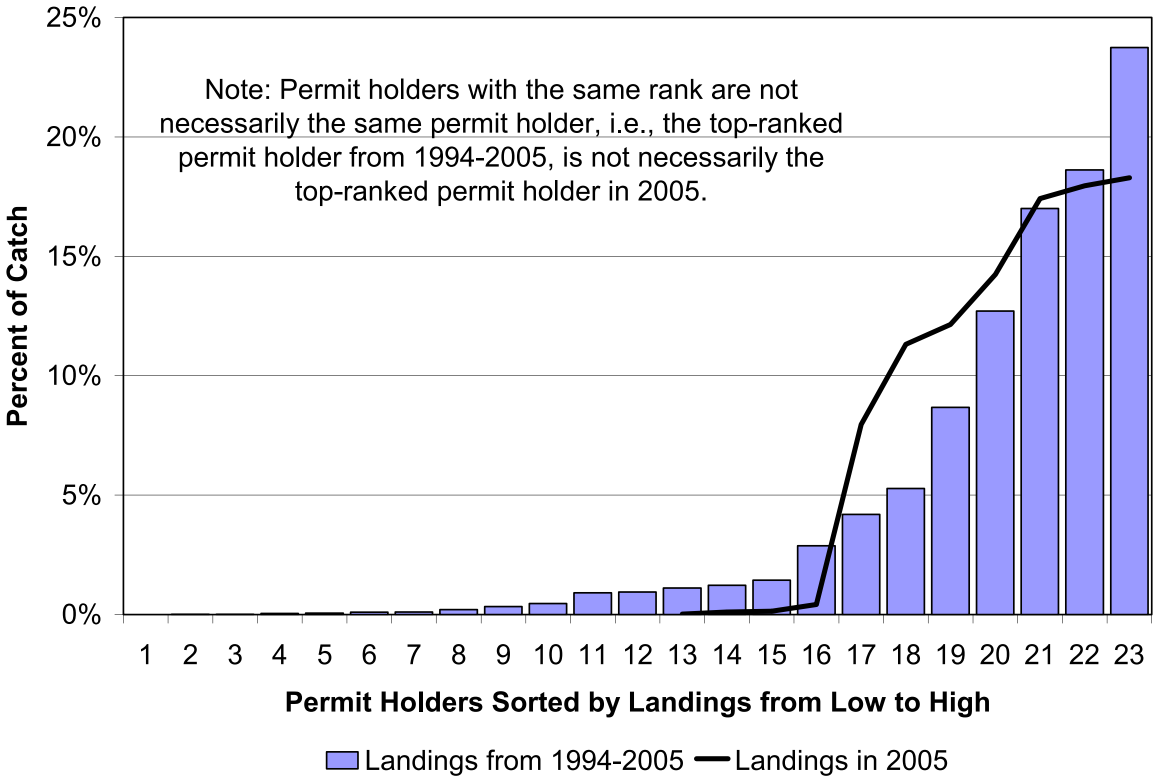

Table 3-40 through Table 3-42 present information on participation by target strategy for the Offshore Whiting Trawl CV class from 1994–2005. Target strategies can provide insights into the participation of the Offshore Whiting Trawl CV in seasonal fisheries, as well as insights into potential opportunities for expansion by the class. In addition, examining participation by target strategy may provide the only means to accurately estimate incidental catch. This is because catch of a particular species can only be considered incidental if it is not intentionally caught but rather taken while targeting other species. It should of course be noted that targeting strategies in three whiting vessel classes are largely pre-determined—i.e., whiting and little else. To the extent they exist, the analysis will document other targeting strategies that have been utilized by vessels in this class over the years.

Defining a target strategy for a particular trip is difficult. The Consulting Team intends to use the algorithms developed by NMFS for the Trawl Bycatch Model to identify a particular strategy for each trip recorded in the fish ticket database.

Table 3-40. Number of Permits for the Offshore Whiting Trawl CV Class by Target Strategy, 1994-2005

Year	Pacific Whiting	DTS Complex:	Petrale Sole	Slope Rockfish	Other Rockfish	Arrowtooth Flounder	Other Flatfish	Other Targets	Total
	Ex-Vessel Value ($1,000 in 2005$)								

Additional information on the targeting strategies of this class is provided in Table 3-43 through Table 3-46.[10] These tables show the intensity of fishing activity during the year. The average number of trips per year and the average length of trip are expected to be affected under a trawl IFQ program. Catch per day is also likely to be an important measure of effectiveness. Additional tables may also be developed to show capacity levels and capacity utilization by target strategy in order to identify potential opportunities for fleet consolidation. Each table will show data for 2000 through 2005 and will show both annual and two-month period data.

	Average Days Per Trip							
Jan-Feb 2000								
Mar-Apr 2000								

[10] In general, vessels in the offshore whiting CV class do not participate in many other target fisheries on the West Coast. However, it is believed that some vessels that are classified as this type of vessel do participate in other West Coast groundfish fisheries. To the extent they do, their efforts will be described here.

3.4.4.1.5 Incidental Catch of Offshore Whiting Trawl CVs in Target Fisheries

One of the primary objectives of a trawl IFQ program is the reduction of incidental catch. By developing tables showing rates of incidental catch under various target strategies, it may be possible to project how effective a trawl IFQ program will be in reducing incidental catch. The Consulting Team believes that incidental catch rates by vessel class can be estimated using observer data over a period of several years. Table 3-47 shows the estimated average incidental catch rate over 2001-2005 for Offshore Whiting Trawl CVs by target strategy. Incidental catch rates are equal to the catch of incidental species as a percent of the total catch of target species. In the case of the DTS complex and Slope Rockfish, the denominator is the total catch of all species in the complex.

Table 3-47. Average Incidental Catch by Target Strategy, 2001-2005

	Pacific Whiting	DTS Complex	Petrale Sole	Slope Rockfish	Other Rockfish	Arrowtooth Flounder	Other Flatfish	Other Targets

Table 3-48 shows estimated total catch by target species for the period 2001-2005 by two-month trip limit period. These data represent the denominator in estimates of incidental catch rates for all species in each target strategy shown in Table 3-49. Table 3-49 shows average incidental catch rates by period over the year 2001-2005 for Offshore Whiting Trawl CVs. Additional tables will be developed for the other target strategies. The Consulting Team believes that if the incidental catch rate for a target species is relatively high during a particular period, it is likely that under an IFQ program catcher vessels will try to shift effort to periods with lower rates. If incidental catch rates do not vary by period, there will be less impetus for temporal shifts.

Table 3-48. Estimated Total Catch of Target Species by Season in Each Target Fishery by Period, 2001-2005

Incidental catch rates are also likely to vary by geographic region. If particular areas generally exhibit comparatively lower incidental catch rates, it is likely that under a trawl IFQ program additional effort will be directed to areas with lower rates. Table 3-50 shows estimated total catches of target species by management area from 2001-2005. These data represent the denominator in estimates of incidental catch rates for all species in each target strategy as shown in Table 3-51.

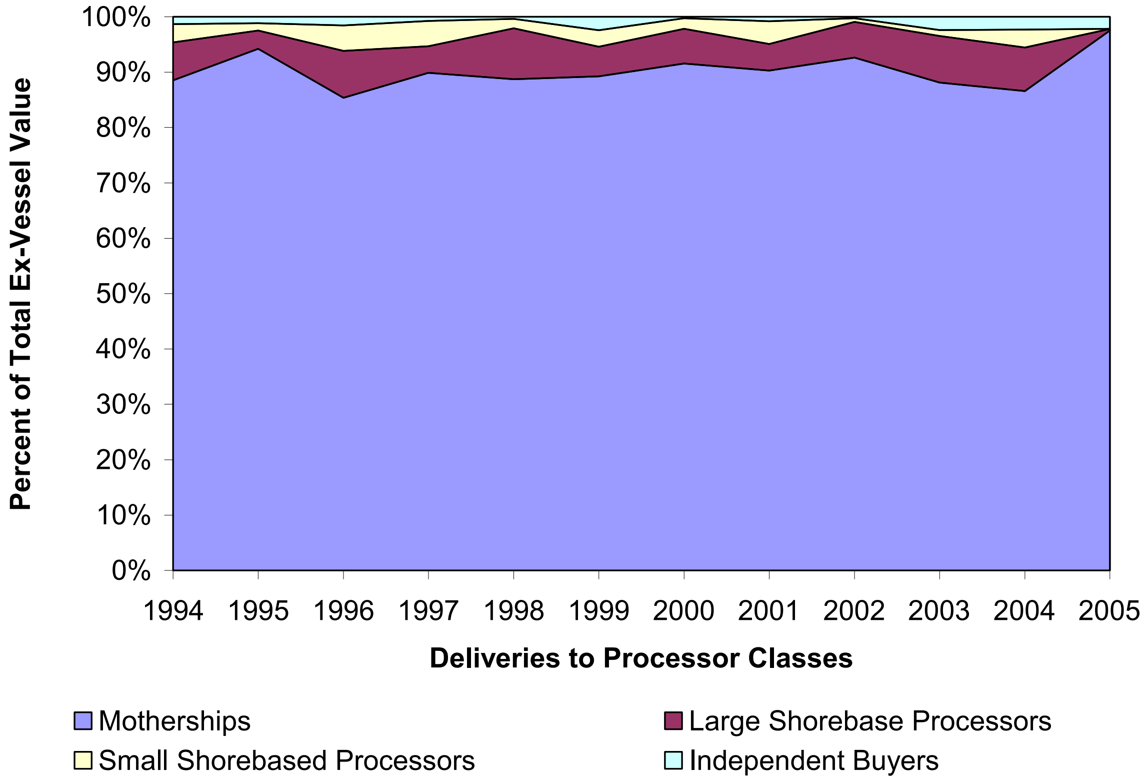
The following figures provide additional information on the geographic distribution of average annual catches of primary target species for Offshore Whiting Trawl CVs. These figures will be derived from log book data.

Figure 3-5. Average Annual Whiting Catch by Offshore Whiting CVs by Lat/Long, 1997-1998

3.4.4.1.6 Relationships with Processors

The Consulting Team believes that a trawl IFQ program could change not only the spatial and temporal distribution of catches, but also the distribution of landings of Offshore Whiting Trawl CVs across processing classes as catcher vessels and processors respond to new opportunities. While this may not be a likely outcome for Offshore Whiting Trawl CVs, some other trawl CV classes are likely to experience changes in the distribution of landings. Figure 3-6 (shown here with hypothetical data) shows the reliance of Offshore Whiting Trawl CVs on various processors of trawl groundfish from 1994 through 2005.

Figure 3-6. Ex-Vessel Value Paid to Offshore Whiting Trawl CVs by Processor Class, 1994-2005 (Hypothetical Data)



Source: Data in figure are hypothetical.

A trawl IFQ program is likely to alter the relationship between harvesters and processors/buyers. One way to measure the stability of these relationships is to examine the number of different processing companies to which catcher vessels deliver their fish. Table 3-54 examines the stability of the relationship between harvesters and processors by year.

Table 3-54. Number of Processors to which Offshore Whiting TCV Deliver, 1994-2005

3.4.4.1.7 Safety

This section discusses maydays, deaths, and sinking's reported from 1994-2004 for Offshore Whiting Trawl CVs. These data are available from the US Coast Guard. The impetus to fish in poor weather may be reduced under a trawl IFQ program, thereby reducing the number of incident calls received by the US Coast Guard.

3.4.4.1.8 Cost and Net Revenue Estimates

This section describes the costs and net revenues of the Offshore Whiting Trawl CV class. Estimates of fixed and variable costs from an ongoing survey of permit holders may be available for use in the analysis of a trawl IFQ program.

Cost estimates will be aggregated/divided into several categories that are likely to be affected by a transition to a trawl IFQ program, including:

- Share of gross revenue paid to crew and skipper
- Crew size
- Fuel costs per day
- Other trip costs per day
- Crew and liability insurance
- Vessel insurance
- Moorage
- Vessel and engine maintenance
- Administrative wages and salaries

- Other annual and fixed cost

Given that the survey of permit holders is currently ongoing, the Consulting Team assumes cost information would be based on estimates from either 2004 or 2005. In order to apply these estimates to historical catch and effort, they could be adjusted for inflation using standard producer price indexes. Fuel costs would be adjusted separately because they have changed more than other costs.

Historical trip, crew, and fixed costs as well as estimates of annual net revenues to permit holders and owners could be calculated by combining inflation adjusted cost estimates with historical trip data based on targeting strategy as described in Table 3-43 and Table 3-44.

3.4.4.1.9 Crew Employment and Income

The average vessel in the Offshore Whiting CV class typically carries a crew of X including the skipper.[11] Table 3-55 shows the estimated total number of crew (including skipper and administrative staff) in this class from 1994 through 2004.

Table 3-55. Number of Crewmembers and Crewmember Months in West Coast Groundfish Trawl Fishery by Offshore Whiting CVs, 1994-2004

Year	Number of Crew Members	Crewmember Months						Total
		Jan-Feb	Mar-Apr	May-Jun	Jul-Aug	Sep-Oct	Nov-Dec	

Note: Employees will be credited to 1 FTE if the vessels takes 4+ trips per month, 0.75 at 3 trips per month, 0.5 FTE at two trips per month, etc.

Crewmembers typically are paid a share of the gross revenue. A share may be calculated as a portion of gross revenue such as gross revenue less food and fuel expenditures or gross revenue less food, fuel, and landing tax expenditures. Individual crew shares are about 6 to 10 percent of the gross revenue after expenditures have been subtracted. This analysis assumes that 40 percent of ex-vessel revenue goes to payments for labor. This share may shift dramatically if a trawl IFQ program rapidly reduces the number of catcher vessels operating in a region. Table 3-56 presents estimated payments to labor in groundfish and non-groundfish fisheries over time.

Table 3-56. Payments to Labor by Species Group by Offshore Whiting CVs in West Coast Groundfish Trawl Fishery by Period, 1994-2004

Year	$ Millions in 2005 $						
	Jan-Feb	Mar-Apr	May-Jun	Jul-Aug	Sep-Oct	Nov-Dec	Total

Note: These will be estimated based on crew factors and crew share estimates from cost data gathered by NOAA Fisheries, or from key informant interviews.

3.4.4.1.10 Regional Residence of Permit Holders

Table 3-57 presents information on the residence of permit holders by region in the Offshore Whiting CV class. Table 3-58 and Table 3-59 show the ex-vessel revenue accruing to each region based on the assumption that a permit holder generally hires crewmembers who reside in the permit holder's region of residence. Table 3-60 shows the estimated crewmember months and payments to labor accruing to each region.

[11] Typical numbers of crewmembers on board will be determined using the NOAA cost survey or will be obtained from key informant interviews

3.4.4.2 Shoreside Whiting Trawl Catcher Vessels

The Shoreside Whiting Trawl Catcher Vessel class (SW-TCV) consists of permit holders whose deliveries of whiting account for 50 percent or more of West Coast revenue. Whiting deliveries to motherships are minimal.

This section will contain a set of tables and figures similar to those provided for the Offshore Whiting Trawl CV class.

3.4.4.3 Combination Whiting Trawl Catcher Vessels

The Combination Whiting Trawl Catcher Vessel class (CW-TCV) consists of permit holders whose deliveries of whiting account for 50 percent or more of West Coast revenue. These vessels make significant deliveries to both onshore and offshore processors.

This section will contain a set of tables and figures similar to those provided for the Offshore Whiting Trawl CV class.

3.4.4.4 Large Diversified Trawl Catcher Vessels

The Large Diversified Trawl Catcher Vessel class (LD-TCV) consists of permit holders and associated vessels, whose revenue from Whiting is less than 50 percent of their West Coast revenue. These permit holders fish year-round in both deepwater and near-shore fisheries.

This section will contain a set of tables and figures similar to those provided for the Offshore Whiting Trawl CV class.

As noted in Section 3.4.1, the final classification of the diversified groundfish trawl vessels may change after the initial analysis of catch and participation data. Other possible classification criteria may include typical fishing patterns or geographic locations.

3.4.4.5 Small Diversified Trawl Catcher Vessels

The Small Diversified Trawl Catcher Vessel class (SD-TCV) consists of permit holders and associated vessels, whose revenue from Whiting is less than 50 percent of their West Coast revenue. These permit holders generally fish near shore and not during winter.

This section will contain a set of tables and figures similar to those provided for the Offshore Whiting Trawl CV class.

3.4.4.6 Bought-out Trawl Catcher Vessels

The Bought-Out Inshore Trawl Catcher Vessel class (BO-TCV) consists of permits holder and vessels that were bought out of the fishery in the industry-funded buyback in 2003. While these permit holders and vessels would not be directly affected by a trawl IFQ program—they are no longer in the West Coast groundfish trawl fishery and, therefore, ineligible to receive IFQs—the allocation formula of an IFQ program would distribute the catch of these vessels on an equal-share basis to permit holders that are eligible to receive IFQs. Therefore the catches of these permit holders are an important indicator of IFQ allocations. In addition, these permit holders and vessels delivered significant quantities of groundfish to various processor classes. After these vessels left the fishery in 2003, some buyers and processors had to seek out new suppliers of groundfish. By providing a summary of these vessels and their activities, the EIS is able to provide a more complete description of the West Coast groundfish trawl fishery.

This section will contain a set of tables and figures similar to those provided for the Offshore Whiting Trawl CV class.

3.5 Trawl Catcher Processors

3.5.1 Potentially Affected Trawl Catcher Processors

The trawl catcher processors that could be potentially affected participate primarily in the offshore whiting fishery and currently operate under the Pacific Whiting Conservation Cooperative.

3.5.2 Condition Indicators for Trawl Catcher Processors

Indicators of the historical and baseline conditions of trawl catcher processors include but are not necessarily limited to the following:

- Catch by species
- Incidental catch by species
- Discarded catch by species

- Distribution of catches by month
- Relative dependency on West Coast trawl groundfish
- Wholesale value of production
- Operating costs
- Net revenues
- Number of participating trawl catcher processors
- Number of trawl catcher processor permit holders
- Number of trips per year
- Number of fishing days per year
- Number of harvesting crew members
- Number of processing crew members
- Harvesting crew and skipper shares
- Product types and amounts by species
- Product recovery rates

Some conditions such as vessel safety may not be measurable by quantifiable indicators.

This section will contain a set of tables and figures similar to those provided for trawl catcher vessel classes. To the extent that information is available, additional tables will document processed product and wholesale value generated by trawl catcher processors.

3.6 Processors of Trawl-Caught Groundfish

Processors would be directly affected by a new management regime if the regime changes the way they currently operate or changes future opportunities. Processors that process groundfish caught with trawl gear would be directly affected by a trawl IFQ program, and could be allocated IFQs under options forwarded by the Council.

3.6.1 Classifications of Potentially Affected Processors

There are two major categories of processors of trawl groundfish—motherships and shore-based processors. In this analysis motherships are treated as a distinct class of processors, while shore-based processors are further subdivided based largely on the requirements of the options to allocate IFQs to processors. Many of the IFQ programs included in the main suite of alternatives would allocate IFQs to processors—companies that cut and package fish or handle live fish—but would not allocate IFQs to buyers that simply transfer unprocessed fish (unless it is live fish) to "processors". Therefore, the processor classification system must differentiate between buyers and processors. The issue is further complicated by the fact that "processors" are not specifically identified in PacFIN fish-tickets—the only reliable source of historical shore-based landings data for both harvesters and processors.[12]

For shorebased deliveries, PacFIN fish-tickets contain a field for the "processor," but this field is required to be completed by the "first receiver" of the fish from the catching vessel. In many cases the

[12] The problem of identification of processors does not apply to motherships because motherships are uniquely identified in the NORPAC At-Sea database.

receiver is not an entity that processes raw fish—some are agents of processors, while others are independent buyers. Furthermore, there does not appear to be a way to determine—short of first-hand knowledge—which receivers are processors, agents of processors, independent buyers that sell to multiple processors, or independent buyers that sell fish directly to the wholesale or retail market. Fortunately, some initial studies identify many of these linkages,[13] and members of the processing industry appear willing and able to assist in the classification process.

An additional difficulty arises from the consolidation that has occurred among processors and buyers in recent years. While it is well known, for example, that the Pacific Seafood Group has experienced considerable growth over the last 25 years,[14] other processors are also expanding through consolidation and acquisition—Bornstein Seafoods, for example, lists ten buying stations and processors on the West Coast on its Web site.[15] Because a relatively small number of firms own or control the majority of groundfish that are delivered to shore, treating individual processing facilities as independent entities would likely result in a misrepresentation of the impacts of a trawl IFQ program. The fact that there are few owners involved also creates data confidentiality issues.

Assuming that sufficient information regarding linkages between buyers and processors is available, the following definitions will be used to classify shore-based processors:

- Receivers of groundfish refer to entities that are listed in the fish-ticket data.
- Processors mean those entities that typically cut and package unprocessed fish for resale.[16] Processors may or may not be receivers of groundfish.
- Secondary Processors are those processors that cut and package fish that has already been processed.
- Buyers are entities that receive groundfish but do not process groundfish.
    - Associated buyers are those buyers that are linked by ownership, contract or employment to a processor or an entity that owns processors.
    - Independent buyers are those buyers that are not linked to a particular processor.

The Consulting Team is still investigating the most appropriate way to classify shore-based processors, but it tentatively proposes the following classification scheme:

1) Identify, to the extent feasible,[17] connections between receivers and primary processing facilities. If a receiver (or multiple receivers) and a particular processing facility (or multiple processing facilities) have a consistent link, they would be identified as a single "processing group". Each independent buyer would be identified as such. All other receivers would be associated with a processing group, either by themselves or with other buyers and processors. For example, all buyers and processors associated with the Pacific Seafood Group would be

[13] An e-mail communication dated March 20, 2005 from Shannon Davis to Jim Seger indicated that Mr. Davis had obtained information about company affiliations for much of the shore-based buying and processing industry..

[14] According to the Pacific Seafood Web site (http://www.pacseafood.com/welcome.html), "since 1983 Pacific Group has expanded from one processing and one distribution facility to over 20 operating units."

[15] http://www.bornstein.com/Locations.html

[16] This section assumes that a definition of "processing" will be developed that unambiguously identifies processors eligible to receive QS. The current definitions included in the alternatives forwarded for analysis do not appear to meet this standard.

[17] Identification of processing groups would be done using secondary data and through the use of key informant interviews.

assigned to a single processing group. All facilities would be assigned based on current relationships.

2) Divide processing groups into two subsets—large and small. For example, large processing units might be defined as those processing groups that account for more than one percent of total ex-vessel trawl groundfish purchases in any year. All receivers that are associated with a group that is defined as large would be considered large for purposes of the EIS analysis regardless of the amount of groundfish the individual facility purchased.
3) Group independent buyers into a single class.

This classification scheme would result in the following four processing classes of trawl-caught groundfish (including motherships):

- Large Shore-based Processing Groups (LSPG)—processing groups (processing facilities and associated buyers) that have accounted for more than X percent[18] of the ex-vessel value of shore-based processing of trawl groundfish in any given year.
- Small Shore-based Processors Groups (SSPG)—processing groups (processing facilities and associated buyers) that have never accounted for more than X percent[18] of the ex-vessel value of shore-based processing of trawl groundfish in any given year.
- Independent Buyers (IB)—receivers of groundfish that do not appear to meet the definition of a "processor" and do not appear to be associated with any processors through contractual or ownership linkages.[19]
- Motherships (MS)—processing vessels that have participated as processor in the mothership allocation of Pacific whiting. They are identified in the NORPAC At-Sea data sets.

Earlier drafts of this document, as well the presentation made to the Trawl IQ Workshop on April 18, 2006, indicated that processing classes would include a geographic component, e.g., Large Washington Processors or Small California Processors. Upon further consideration, the Consulting Team concluded that if IFQ allocations to processors are included in the preferred alternative, the processing classes documented in the EIS should reflect the types of entities that would receive shares. Rather than depicting processors as independent facilities, the analysis should recognize that the majority of processing is undertaken by multi-facility companies with locations distributed throughout the West Coast. Notwithstanding this consideration, the profiles of shore-based processing classes in this chapter show the geographic distribution of processing facilities and buying stations.

3.6.2 Condition Indicators for Processors of Trawl Groundfish

Indicators of the historical and baseline conditions of processors of trawl groundfish, including motherships and shore-based processors, include but are not necessarily limited to the following:

- Number of processors groups, facilities and buying stations
- Total purchases of trawl-caught groundfish by species
- Ex-Vessel Prices Paid
- Distribution of purchases by month
- Relative dependency of West Coast trawl groundfish

[18] This percentage would be fixed after processing group linkages are determined and data using the processing group definitions are examined

[19] Classification as an "independent buyer" would not necessarily be "proof" that the receiver is ineligible to receive QS. Actual eligibility would be determined during the QS application process once a trawl IFQ program was implemented. Nevertheless, the EIS analysis would make a reasonable effort to verify the classification.

- Relationships with harvesters
- Distribution of facilities and buying stations by community
- Wholesale value of production
- Operating costs
- Net revenues
- Product types and amounts by species
- Product recovery rates by product and species
- Operating days per year
- Number of processing crew

3.6.3 Summary of Past and Present Conditions of Trawl Groundfish Processors

This section provides a summary of participation of all processors of trawl groundfish in the West Coast fisheries. Detailed descriptions of each processing class are provided in Sections 3.6.4 – 3.6.4.4. This summary emphasizes total participation and purchases of groundfish in terms of volume and ex-vessel value by species. The section includes comparisons between the situation in 2005 (baseline condition) and conditions in the historical period (1994-2005).

3.6.3.1 Number of Processor Groups, Facilities and Buying Stations

Table 3-61 summarizes the participation of trawl groundfish processors groups by processor class. For shore-based processors the table indicates the number of processor groups as well as the number of processing facilities and associated buyers.

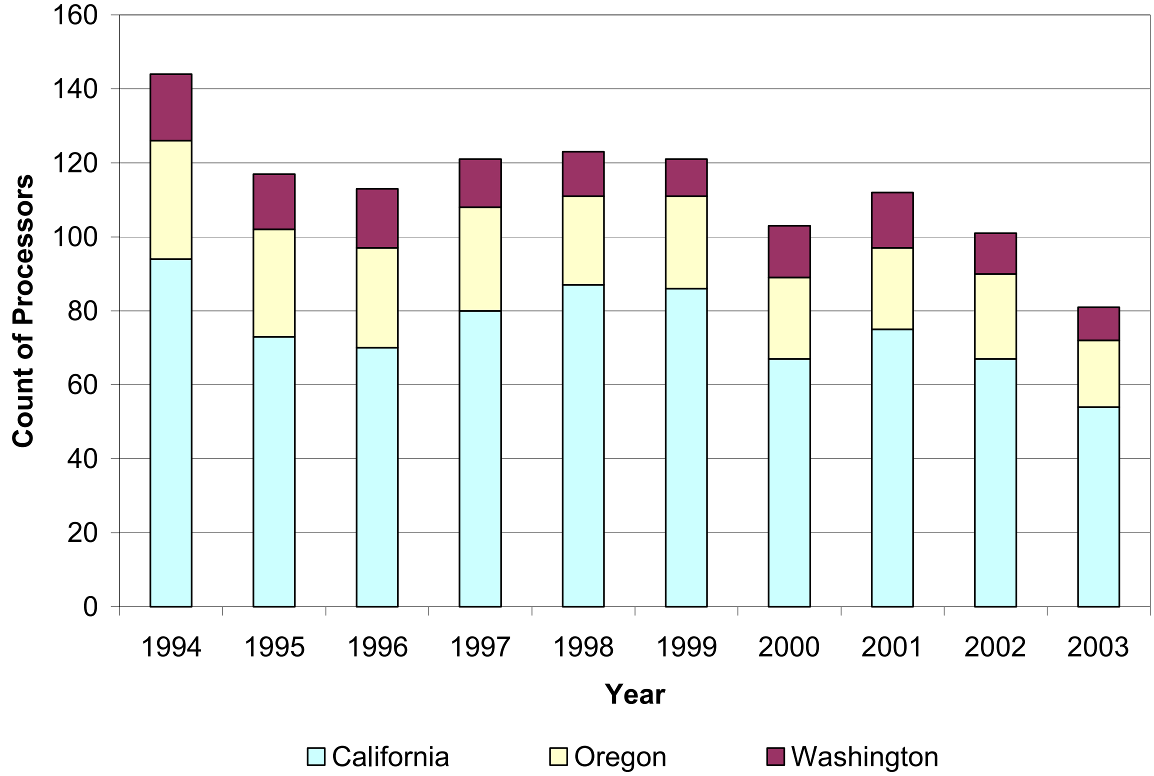
Table 3-61. Active Processors and Buyers by Processor Class, 1994-2005

	1994	1995	1996	1997	1998	1999	2000	2001	2002	2003	2004	2005
Processor Class	Number of Groups or Facilities											
Large Shore-based Processor Groups (LSPG)												
Processing Facilities												
Associated Buyers												
Small Shore-based Processor Groups (LSPG)												
Processing Facilities												
Associated Buyers												
Independent Buyers												
Motherships												

Note: The sum of processing facilities and associated buyers will equal the total number of receivers.

Figure 3-7 shows the number of receivers of trawl groundfish by state. This includes all buyers, but may not include all processors if there are processors that are not also receivers. The figure is included to provide a perspective of the potential magnitude of the groundfish trawl processing sector.

Figure 3-7. Number of Receivers of Trawl Groundfish by State, 1994-2003[20]



Source: Data provided to the Consulting Team by Shannon Davis in October 2005.

3.6.3.2 Total Purchases of Trawl-Caught Groundfish by Species

This section documents the total volume and ex-vessel value of trawl-caught groundfish purchases. Tables show volumes and values by species and year for all processors, and volumes and value by species for the historical period and 2005 by processing class.

[20] Actual data in the EIS would use 1994-2005.

3.6.3.3 Distribution of Purchases

This section summarizes the distribution of trawl groundfish purchases by month over the historical period and in 2005 and summarizes ex-vessel prices paid by month. Section 3.4.3.4 summarizes total landings (volume and value) by month. The distribution of purchases by month is a key indicator because under a trawl IFQ program harvesters will likely change their fishing patterns to minimize incidental catch of overfished species.

3.6.4 Past and Present Conditions of Trawl Groundfish Processor Classes

3.6.4.1 Large Shore-based Processor Groups

Large Shore-based Processing Groups (LSPG) include those processing groups (processing facilities and associated buyers) that have accounted for more than X percent of the ex-vessel value of shore-based processing of trawl groundfish in any given year.

The tables below provide an example of the types of information that will be presented for each processor class.

Table 3-73. Active Large Processors and Associated Buyers, 1994-2005

3.6.4.2 Small Shore-based Processor Groups

Small Shore-based Processors Groups (SSPG) include those processing groups (processing facilities and associated buyers) that have never accounted for more than X percent of the ex-vessel value of shore-based processing of trawl groundfish in any given year.

This section will contain a set of tables and figures similar to those provided for the Large Shore-based Processor Groups.

3.6.4.3 Independent Buyers

Independent buyers include those receivers of groundfish that do not meet the definition of "processor" and are not associated with any processors through contractual or ownership linkages.

This section will contain a set of tables and figures similar to those provided for the Large Shore-based Processor Groups. Because independent buyers do not actually process groundfish, process product information will not be included.

3.6.4.4 Motherships

This section provides a profile of motherships associated with the West Coast groundfish trawl fishery. In addition, processed products and wholesale values are discussed. Sources for some of the information referenced in this section have not yet been identified; consequently, the EIS analysis may have to create and administer instruments for acquiring or estimating the data.

The tables below provide an example of the types of information presented in this section.

3.7 Non-Trawl Commercial Harvesters

While non-trawl vessels and their owners and crew would not be directly affected by a trawl IFQ program, they may be indirectly affected in several ways. The most obvious indirect effects are the economic impacts of spillovers resulting from fleet consolidation. If the trawl fleet consolidates, vessels and crew members no longer employed in trawl fisheries will potentially be able to switch into non-trawl fisheries. Non-trawl fisheries will also be affected indirectly because the management action taken with respect to the trawl fleet is likely to influence future actions taken with respect to non-trawl vessels. The analysis of the non-trawl segment of the fish harvesting component will require further specification of non-trawl categories, e.g., limited entry longline vessels, non-licensed vessels, dive fisheries, etc. Vessel categories previously employed in Council models of the fishery will form the basis of this specification.[21]

3.7.1 Potentially Affected Non-Trawl Commercial Harvesters

Several classes of non-trawl commercial harvesters are included in the analysis based primarily on the non-trawl fisheries in which trawl permit holders currently operate or may potentially operate under a trawl IFQ program. While final specification of the potentially affected non-trawl harvesters will be made in Phase 2, the following represents an initial list of these indirectly affected harvesters.

[21] Radtke and Davis (2003) define 12 non-trawl fish harvesting vessels types in the Fishery Economic Assessment Model (FEAM)

- Limited entry fixed gear harvesters
- Directed open access fixed gear harvesters
- Exempted trawl incidental open access harvesters
- Dungeness crab harvesters
- Coastal pelagic species harvesters
- Salmon troll harvesters
- Highly migratory species harvesters

A trawl IFQ program is likely to lead to fleet consolidation. Those that leave the fishery and are able to keep their vessels may expand their effort in other fisheries to which they access. For example, a limited entry trawl permit holder that also has a limited entry fixed gear permit may choose to sell the initial allocation of IFQs and use the money to expand effort in the limited entry fixed gear fishery. If the total OY available for the limited entry fixed gear fishery is set, this additional investment could have a negative impact on existing participants in the limited entry fixed gear fishery.

3.7.2 Condition Indicators for Non-Trawl Commercial Harvesters

Indicators of the historical and baseline conditions of non-trawl commercial harvesters are similar to those described for trawl catcher vessels, but because these vessels are likely to be only indirectly affected, the number of indicators has been reduced to the following:

- Number of participating catcher vessels
- Landings, ex-vessel revenues and ex-vessel prices by species
- Distribution of landings by month
- Geographic distribution of effort
- Distribution of ex-vessel revenue by permit holder residence

3.7.3 Past and Present Conditions of Non-Trawl Commercial Harvester Classes

3.7.3.1 Limited Entry Fixed Gear Harvesters

Limited entry fixed gear harvesters may be indirectly affected by a trawl IFQ program because many limited entry trawl permit holders also participate in the limited entry fixed gear fishery. In addition, a trawl IFQ program may allow trawl QP to be utilized in the fixed gear fisheries.

3.7.3.1.1 Participation and Landings

Table 3-92 shows the number of active permit holders in the limited entry fixed gear fishery.

3.7.3.1.2 Distribution of Landings

Figure 3-9 through Figure 3-13 show landings by month of major fixed gear species from 1994-2005. On average, over 90 percent of the revenue in the fixed gear fishery is represented in the figures. The temporal distribution of fishing effort will be an important indicator in the ability of trawl IFQ holders to split time between the fixed gear fishery and trawl fishery. If the timings of the fisheries coincide, the probability that vessels will participate in both fisheries diminishes.

Figure 3-9. Sablefish Landings in the Limited Entry Fixed Gear Fishery by Month, 1994-2005

Figure 3-13. Spiny Dogfish Landings in the Limited Entry Fixed Gear Fishery by Month, 1994-2005

3.7.3.1.3 Geographic Distribution of Fishing Effort

This section discusses the geographic distribution of effort in the limited entry fixed gear fishery. It is anticipated that the extent that the geographic distribution of effort in fixed gear fishery overlaps with the geographic distribution of effort in the trawl fishery, the greater the likelihood that the alternatives will affect the limited entry fixed gear fishery.

3.7.3.2 Directed Open Access Fixed Gear Harvesters

This section will describe the directed open access fixed gear harvesting sector. The format of this section and the information provided will be similar to the section for limited entry fixed gear fleet.

3.7.3.3 Exempted Trawl Incidental Open Access Harvesters

This section will describe the exempted trawl open access harvesting sector. The format of this section and the information provided will be similar to the section for limited entry fixed gear fleet

3.7.3.4 Dungeness Crab Harvesters

This section will describe the Dungeness crab harvesting sector. The format of this section and the information provided will be similar to the section for limited entry fixed gear fleet.

3.7.3.5 Highly Migratory Species Harvesters

This section will describe the highly migratory species harvesting sector. The format of this section and the information provided will be similar to the section for limited entry fixed gear fleet.

3.7.3.6 Salmon Troll Harvesters

This section will describe the commercial salmon troll harvesting sector. The format of this section and the information provided will be similar to the section for limited entry fixed gear fleet.

3.8 Buyers and Processors that do Not Purchase Trawl Groundfish

This section describes buyers and processors that do not purchase trawl groundfish (hereafter referred to as Other Buyers and Processors). Because Other Buyers and Processors are not involved in the West Coast groundfish trawl fishery they will not be directly affected by a trawl IFQ program. However, these buyers and processors would be indirectly affected if a trawl IFQ program restricts their ability to enter the trawl-caught groundfish processing market in the future.[22] They would also be affected if higher profits for processors of trawl groundfish encourage these processors to increase their level of activity in non-trawl groundfish fisheries or non-groundfish fisheries.

3.8.1 Condition Indicators for Other Buyers and Processors

Indicators of the historical and baseline conditions of Other Buyers and Processors include but are not necessarily limited to the following:

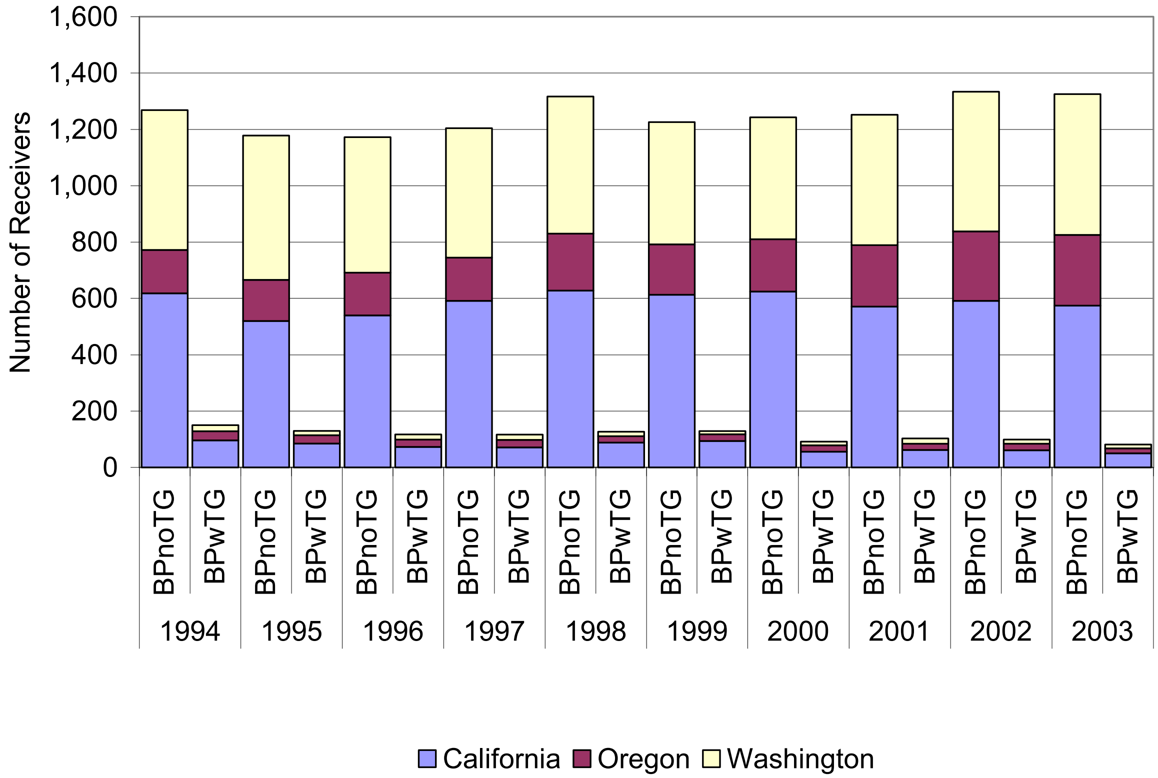
- Number of affected buyers and facilities
- Total purchases by fishery
- Relative market share compared to Trawl Groundfish Processors
- Geographic distribution of participation

3.8.2 Past and Present Conditions of Other Buyers and Processors

Figure 3-14 shows the total number of receivers of West Coast harvests. Other Buyers and Processors (labeled as BPnoTG in the figure) are those receivers that did not purchase trawl groundfish, while trawl receivers (labeled as BPwTG in the figure) include all receivers that purchased trawl groundfish. The number of BPnoTG ranged from 1,172 in 1996 to 1,334 in 2002. The number of BPwTG ranged from 150 in 1994 to 81 in 2003.

[22] Because entry into the trawl fishery by harvesting vessels is already limited, non-trawl vessels are generally only indirectly affected by the alternatives.

Figure 3-14. Buyers and Processors of West-Coast Species, 1994-2003



Note: BPnoTG are buyers and processors that do not purchase trawl groundfish; TGwBP are trawl groundfish buyers and processors.

Although Other Buyers and Processors are discussed as a single group, the information provided shows the geographic distribution of participation. Table 3-101 through Table 3-108 summarize the historical and baseline conditions of Other Buyers and Processors in terms of various indicators.

3.9 Recreational Harvesters of Groundfish

Recreational harvesters of groundfish may be indirectly affected by a trawl IFQ program. Perhaps the most significant way in which recreational harvesters could be affected is through the fishery management process. If trawl groundfish harvesters and processors become more profitable under a trawl IFQ program, their level of participation and influence in Council and NMFS management processes may increase. This additional participation could ultimately result in increased constraints on the growth potential of the recreation fisheries. In addition, the possibility that trawl harvesters will be more flexible in their harvesting pattern under a trawl IFQ program may affect the number of trawl vessels on the grounds at any given time.

3.9.1 Condition Indicators for Recreational Harvesters of Groundfish

Based on the availability of data on the recreational fishery for groundfish, the indicators of the historical and baseline conditions of recreational harvesters will include the following:

- Volume of recreational groundfish landings by species and year
- Distribution of recreational groundfish landings by two-month periods
- Geographic distribution of recreational groundfish landings

3.9.2 Past and Present Conditions of Recreational Harvesters of Groundfish

Table 3-109 shows the volume of landings in the recreational groundfish fishery by species and year. The table indicates data for 1994-2005, but the availability of data may limit the actual amount of information shown. In addition, some groundfish species are not harvested in recreational fisheries. The table will only include those species that are regularly harvested in the groundfish recreational fishery.

3.10 Communities

This section will summarize the community profiles presented in Appendix B: Social Impact Assessment Technical Appendix and will place relevant fishery activity in a community setting. While the community profiles in Appendix B provide a range of descriptive and context information, the profiles in this section are brief (1-2 pages each) and summarize different types of relevant community fisheries engagement information, such as the number of participating vessels by sector, landings, and total revenue, among others, along with information that will provide a quick gauge of fishery dependency by community, including relevant fishery diversity information as well as economic diversity information at the community level.

3.10.1 Potentially Affected Communities

Individual industry sectors outlined in previous sections are distributed across a range of communities. Some communities have marked concentrations of vessel ownership or are homeport to clusters of vessels; some communities are the location of processing effort; and some communities have concentrations of fishery support service businesses and employment. Individual communities may be host to single or multiple sector activities with varying degrees of intensity of activity, may have a greater or lesser degree of engagement in the fishery through employment of residents, and may have a greater or lesser degree of dependency on the fishery as a result of numerous factors, including such fundamental community attributes as relative size and diversity of private sector-driven economic base and/or sources of public revenues. Communities may be directly and/or indirectly affected by the Action Alternatives in a variety of ways.

As described in more detail in Appendix B, the choice of specific communities and regions to be profiled in this section will be driven by data availability (e.g., information on where relevant trawl vessels are located, port landing data, or the like) and by data confidentiality considerations. Looking at trawl vessel distribution as an example, within the state of Washington a couple of different groupings are possible. Only two communities, Port Angeles (with four vessels) and Westport (with seven vessels) have three or more vessels each, allowing community-level data discussions. Only two other Washington communities are listed as having any relevant catcher vessels. Blaine has an additional two vessels, so information from those vessels could be lumped with those from Port Angeles into a Northern Puget Sound area that could then be described as a region if the desired outcome was to include all vessel information from that region. Similarly, information from the only other Washington vessel located in Ilwaco/Chinook could be lumped with those from Westport to provide an all-inclusive Coastal Washington South and Central regional discussion, following the groupings utilized in previous groundfish EIS analyses. The advantage of staying with community-specific data is the ability to ultimately better describe impacts (and variations of impacts) at the community level, while the advantage of utilizing regions is to allow for an analysis that accommodates all available information.

Continuing the vessel-based example, Oregon trawl vessel communities that could be described on an individual community basis include Astoria (32 vessels), Newport (20 vessels), Coos Bay (16 vessels), and Brookings (6 vessels). Florence, with one vessel, could be lumped with Coos Bay, and similarly Tillamook, with two vessels, could be lumped with Astoria for a more regional coverage and for the sake of completeness.

Within California, a total of nine communities feature three or more trawl vessels that would, in turn, allow for community level discussions. These are Crescent City (three vessels), Eureka (nine vessels), Fort Bragg (nine vessels), Princeton/Half Moon Bay (nine vessels), San Francisco (five vessels), Monterey (four vessels), Moss Landing (five vessels), Avila (three vessels), and Morro Bay (three vessels). Only two California communities have less than three vessels, precluding a community level data discussion: Bodega Bay (one vessel) and Santa Cruz (two vessels). These communities could be lumped with others for regional groupings and, if appropriate and desired, some of the other communities could be further be lumped to simplify the analysis (e.g., Avila and Morro Bay have been lumped into a single region in earlier analyses).

Different patterns of community confidentiality restrictions emerge when other data sets or groupings are utilized, such as landings by ports or distribution of permits (as opposed to vessels), as noted in Appendix B. Further, when common ownership is taken into consideration, analytic flexibility declines as confidentiality restrictions expand. Ultimately, we would be seeking analytic power and utility within individual communities or groups of communities with common attributes to allow for a production of the best available information regarding potential community and social impacts for consideration by decision makers. The decision regarding appropriate aggregations of communities will also be informed by community or regional level information on processing and support service entities as well as data on vessels or permit holders or landings themselves. It is likely that after the detailed data runs are produced, classes of communities or a typology of communities will be constructed to reduce analytic complexity while capturing the range of likely social impacts. Individual community variability characterization will be retained, to the extent possible, in the detailed information presented in Appendix B. It will also be important in this section to summarize the community level distribution changes that have occurred since the implementation of the buyback program in order to set the stage for subsequent cumulative impact analysis.

3.10.2 Condition Indicators for Communities

Indicators of the historical and baseline conditions of communities include but are not necessarily limited to the following:

- Community distribution of vessel and permit ownership
- Community distribution of landings and vessel activity
- Community distribution of processing related activity
- Community distribution of fishery related employment by sector
- Community distribution of fishery related income
- Community distribution of fishery related public revenues
- Community distribution of fishery related support service demand (qualitative)

The historical and baseline conditions of communities will also be summarized with respect to the overall engagement and dependency of trawl related fishing communities based on the above indicators.

3.11 Tribes

Tribes are proposed as a separate potentially affected stakeholder group from communities. Tribal groundfish fisheries are regulated by the participating tribes themselves, with the type of overall allocations varying by groundfish species or species group. In the case of sablefish, for example, tribal allocations account for 10 percent of the northern area OY, while whiting tribal allocations are based on a formula subject to a sliding scale adjustment. Other groundfish are allocated on biannual basis in a process that includes Council coordination. In short, while not necessarily directly affected by federal and state management measures, tribal entities are directly involved in the Council process and craft their groundfish management measures in cooperation with federal and state managers. Further, tribes and tribal related entities may be direct participants in the non-tribal fisheries subject to management under the proposed alternatives (as may any other entity) and it is known that at least some tribes are involved with fisheries support service business ventures that rely to at least some degree on potentially affected non-tribal fishing entities.

3.11.1 Potentially Affected Tribes

Four Indian tribes in Western Washington exercise treaty rights to harvest groundfish and other marine species in the Pacific Ocean off the Northwest Coast: the Hoh, Makah, and Quileute Tribes and the Quinault Indian Nation. Each has reservation lands, but their fishing is not confined to the reservation. Each of these tribes has usual and accustomed fishing areas (U & A) that extend into the groundfish fishery management area.

3.11.1.1 The Hoh Tribe

The 443-acre Hoh reservation is located in Jefferson County, on the Pacific Coast of northern Washington. The reservation lies within the boundaries of the Olympic National Park, and in the area of the Hoh River drainage system. The Hoh River empties into the Pacific and serves as the reservation's northern boundary. The Hoh U&A within the FMA is between 47°54'18 N (Quillayute River) and 47°21'00 N (Quinault River) and east of 125°44'00 W. Currently, Hoh tribal members harvest shellfish, smelt, sturgeon, sablefish, rockfish, Dungeness crab, salmon (spring, summer, and fall chinook, and fall coho), steelhead, trout, and halibut within their U & A.

3.11.1.2 The Makah Tribe

The 27,950-acre Makah reservation is located on the northwestern tip of Washington's Olympic Peninsula in Clallam County. It includes Cape Flattery and Koitlah Point. Vancouver Island, Canada is across the Strait of San Juan de Fuca. The reservation lies 70 miles west of Port Angeles, and 17 miles from the nearest neighboring community, Sekiu. Unlike many other tribes in the US, the Makah Tribe still holds title to a substantial portion of their ancestral land base, engendering a high degree of continuity in both place-oriented identity and subsistence practice (Sepez 2000). The Makah U&A includes Washington state statistical area 4B and that portion of the FMA north of 48°02'15 N (Norwegian Memorial) and east of 125°44'00 W. Currently, Makah tribal members harvest halibut, whiting, rockfish, lingcod, sablefish, flatfish, salmon, steelhead, sturgeon, shellfish, other groundfish, and gray whales within their U&A. Makah members currently operate groundfish trawlers and a whiting mothership.

3.11.1.3 The Quileute Tribe

The 694-acre Quileute reservation is located entirely in Clallam County, Washington, on the south banks of the Quillayute River along the Pacific Ocean. It is surrounded on three sides by the Olympic National Park, and the fourth side of the Reservation is on the Pacific Ocean—First Beach. The headquarters for the Tribe is in La Push, and most Quileute live in Clallam County; however, some enrolled members live in other counties of the state (e.g., adjacent Jefferson to the south) and even outside Washington. The Quileute Tribe has regulated its marine and freshwater fishery for many years. The Quileute today commercially harvest groundfish (including halibut, sablefish, lingcod, and rockfish), Dungeness crab, tuna, smelt, salmon, and steelhead from the marine environment. Seals, sea lions, bivalves (California and blue mussels, razor clams, littlenecks, and butter clams), and other invertebrates are harvested ceremonially and for subsistence. In fresh water, they harvest smelt, salmon, trout, and steelhead commercially as well as for ceremony and subsistence. Salmonids include chinook, coho, sockeye, steelhead, sea trout, and cutthroat trout.

3.11.1.4 The Quinault Indian Nation

The 208,150 acre Quinault Reservation is located in Grays Harbor and Jefferson Counties on the western shore of the Olympic Peninsula. The western boundary of the triangular reservation is the Pacific Ocean coastline, stretching about 26 miles. The Quinault Indian Nation has regulated its river fisheries since 1916, both for a commercial and sports fishery. It has regulated its off-reservation river fisheries and ocean fisheries since 1974. As a self-regulating tribe, the Tribe also regulates the fishery and all other activities on Lake Quinault and its Reservation beaches. Along with the rivers and streams that run through the Quinault Reservation, Lake Quinault is entirely within the Reservation. Reservation beaches and Lake Quinault are closed to non-members except by permission of the Quinault government. The Tribe has on occasion closed its waters to all fishing and prohibited certain types of gear in order to conserve fish runs.

3.11.2 Condition Indicators for Tribes

Indicators of the historical and baseline conditions of tribes include but are not necessarily limited to the following:

- Coastal distribution of fishing activity
- Distribution of income derived from fishing activities

3.12 Input Suppliers

Businesses that supply inputs to groundfish trawl harvesters may be indirectly affected by a trawl IFQ program if the program causes behavioral changes in trawl groundfish harvesting operations.[23] However, the indirect effects on input suppliers may be minimal for two reasons. First, the current management regime has already essentially eliminated the race for fish in the West Coast groundfish trawl fishery,[24] and second, input suppliers would likely be much more affected by a change in OY level than by a trawl IFQ program. Notwithstanding these caveats, the implementation of IFQ programs in other fisheries have had significant effects on input suppliers, and therefore this stakeholder group is included.

Estimating impacts on input suppliers is complicated by the fact that many of the vessels and processors in the trawl groundfish sectors are not wholly dependent on the West Coast groundfish trawl fishery. For example, many (if not most) of the vessels that participate in the whiting fishery also participate in the Alaska pollock fishery. Therefore, while a vessel may exit the West Coast groundfish trawl fishery it may remain active in other fisheries and continue to purchase a similar level of fixed or annual inputs. For example, moorage expenditures would only be affected if a vessel that leaves the West Coast groundfish trawl fishery severs all ties with the West Coast. To simplify the analysis, it is assumed here that the only inputs that would be affected by a trawl IFQ program are those related to a vessel's level of fishing production, i.e., variable inputs.

The initial list[25] of variable inputs of trawl vessels likely to be affected by the alternatives includes fuel, food, trawl gear, and observers.[26] For example, fuel expenditures are among the largest expense categories for fishing vessels. Under a trawl IFQ program, fish harvesters are expected to be better able to optimize their fishing activities over the course of the year, thereby decreasing fuel expenditures. As a result, marine fuel suppliers are likely to see a change in the demand for their product. Trawl gear suppliers are likely to be indirectly affected by a trawl IFQ program. If there is considerable consolidation of the fleet, fewer trawl gear sets would be needed. On the other hand, consolidation would also mean that the gear on the vessels remaining in the fishery will see greater use during the year. Finally, if the remaining trawl harvesters become more profitable under a trawl IFQ program, they are more likely to replace and upgrade their gear more often.

Although crew labor is generally considered a variable input, it is discussed in the above descriptions of potentially affected vessels. While fixed inputs are assumed to be unaffected by a trawl IFQ program, it is likely that a program would create demand for the services of permit and IFQ brokers.

3.12.1 Condition Indicators for Input Suppliers

Indicators of the historical and baseline conditions of input suppliers include but are not necessarily limited to the following:

- Estimated fuel sales to trawl groundfish harvesters and processors and the geographic distribution of major marine fuel supply businesses.

[23] The Consulting Team does not anticipate that a trawl IFQ program would have a measurable effect on the demand for inputs by trawl groundfish processors.

[24] A race for fish typically creates an economic advantage for input suppliers.

[25] It could be argued that other inputs would be affected by a trawl IFQ program. This initial list could be augmented if it is determined that the use of other inputs may change significantly.

[26] Observers are included in this section because firms that provide observers are properly considered input suppliers. Inclusion of observers in this section does not imply that vessels would or would not be required to pay for observer coverage.

- Estimated food sales to trawl groundfish harvesters and the geographic distribution of major food supply businesses.
- Estimated annual sales of trawl gear in the West Coast groundfish trawl fishery and the geographic distribution of major trawl gear suppliers.
- Observer expenses, observer counts, and geographic distribution of observer supply businesses.
- Number of permit transactions and the geographic distribution of permit brokerages.

The lack of expenditure data may limit the ability of the analysis to fully describe the conditions of input suppliers.

3.12.2 Past and Present Conditions of Input Suppliers

This section describes the historical and baseline conditions of input suppliers as they relate to the trawl groundfish harvesting and processing sectors. A separate sub-section will be devoted to each of the input supply sectors described in Section 3.12.1.

3.12.2.1 Fuel Suppliers

This section estimates fuel sales by volume and value in recent years. The primary source of information is the NMFS vessel expenditure survey that is currently in progress.

This section also utilizes landings data from PacFIN to describe the geographic distribution of fuel sales based on the assumption that fishing vessel operators purchase the majority of their fuel in the community in which fish are landed.

3.12.2.2 Trawl Gear Suppliers

This section documents past and present conditions of trawl gear suppliers including estimates of sales by year to West-Coast groundfish trawlers and the geographic location of trawl gear suppliers.

3.12.2.3 Suppliers of Groundfish Observers

Currently, most observers are contracted workers of specialized businesses that coordinate with NMFS to supply observers as needed. This section describes the past and present conditions of observer supply companies, including the number of observer days by year in the West Coast groundfish trawl fishery, number of observers used per year, amount paid to observer companies and the geographic location of observer companies.

3.12.2.4 Permit Brokerages

Currently, there are specialized businesses that broker fishing permits. This section describes the past and present conditions of permit brokerages, including the number and geographic location of these businesses.

3.13 Wholesalers and Retailers

Wholesale and retail suppliers of groundfish would be indirectly affected by a trawl IFQ program to the extent that there are changes in groundfish product variety and groundfish product flows generated by trawl groundfish processors.

The transition to an IFQ program in other fisheries has typically created significant changes in the timing of harvests and types of products generated. These impacts are less likely in the West Coast groundfish trawl fishery because the fishery does not currently experience a race for fish. Cumulative trip limits spread harvests out over time, thereby generally preventing market gluts.

It is possible that a trawl IFQ program would create incentives to decrease the period over which the harvest of a particular species take place, and therefore would lead to greater variances in product flow. For example, in an effort to maximize harvests of petrale sole while staying within overfished species constraints, harvesters and processor may choose to limit petrale sole harvest to periods when incidental catch rates are lowest. This type of behavioral change would affect wholesalers and retailers.

It is also possible that wholesalers and retailers, that are also trawl groundfish buyers and processors, may have be able to increase their relative market share because that may experience greater certainty of supplies and increasing profits.

An additional possible impact on wholesale and retail distributors could result from QS allocation options that allocate harvesting quota shares to processors. In general, the options would not provide allocations to independent buyers of groundfish, some of which may be important sources of groundfish for certain wholesalers and retailers. By not receiving shares of the fishery, the ability of independent buyers to buy fish and supply wholesalers and retailers that are currently dependent upon them may be constrained.

3.13.1 Condition Indicators for Wholesalers and Retailers

There are far fewer wholesale businesses that deal with trawl groundfish than retail outlets. Therefore, different indicators are developed for the two groups.

Indicators of the historical and baseline conditions of wholesale businesses include the following:

- Delineation of wholesale businesses dealing with trawl groundfish
- Estimated market share of major wholesale businesses dealing with trawl groundfish
- Relative dependence of major wholesale businesses on trawl groundfish

Indicators of the historical and baseline conditions of retail businesses include the following:

- Types and number of retail businesses selling trawl groundfish

Data documenting the activities of wholesalers and retailers with respect to trawl groundfish are not known to exist. Therefore, the description of the past and present conditions of wholesalers and retailers of trawl groundfish is largely qualitative, and relies largely on key informant interviews.

3.14 Consumers

This section describes the past and present conditions of the retail market for the major species groups harvested in the West Coast groundfish trawl fishery.[27] Consumers of West Coast trawl groundfish may be indirectly affected by a trawl IFQ program if the prices, quality or availability of groundfish products change. As indicated in Section 3.13, cumulative trip limits in the West Coast groundfish trawl fishery already spread out harvests and allow processors to provide a wide variety of products to meet consumer demand. Therefore, the impacts of a trawl IFQ program on the market for trawl groundfish may be minimal.

3.14.1 Condition Indicators for Consumers

Indicators of the historical and baseline conditions of the market for trawl groundfish include the following:

- Product types and amounts by species group
- Retail product prices by species group

Data documenting the market for trawl groundfish are not known to exist. Therefore, the description of the past and present conditions of this market is largely qualitative, and relies largely on key informant interviews.

3.15 General Public

Marine and coastal ecosystems are among the most productive natural systems on earth and provide a wide range of benefits to humans (National Research Council 2001; Wilson et. al. 2005). Full accounting of the values derived from these systems is rapidly gaining the attention of federal, state and local regulatory agencies in the United States (National Research Council 2004).

Economists have developed a widely used taxonomy of ecosystem values, although definitions of specific benefits may vary (National Research Council 2004). Typically, economists divide the total value of an environmental asset into use values and non-use values. Use values involve either in situ contact with the environmental asset in question or personal consumption of products or services derived from the asset. Use values include consumptive use values, non-consumptive use values, and indirect use values (Table 3-111).

Table 3-111. Categories of Possible Economic Values Assigned to a Marine Ecosystem and Associated Species

Economic Value	Description
	Use value
Consumptive direct use value	Value derived from extractive activities
Non-consumptive direct use value	Value gained through activities such as observing a species or ecosystem

[27] Data on product types and product amounts generated in the West Coast groundfish trawl fishery are limited compared to the Alaska groundfish fishery.

Economic Value	Description
Indirect use value	Value of the ecological functions and services of a species or ecosystem that indirectly provides support and protection to people, economic activity, and property
Non-use value	
Bequest value	Value derived from the knowledge that a species or ecosystem will be preserved for future generations
Existence value	Value emanating from the satisfaction of knowing that a particular species or ecosystem survives in a natural state

Sources: Adapted from National Research Council (2004)

Consumptive, direct use values can be further subdivided into commercial value if the purpose of the extractive activity is to sell products to others or recreational value if the purpose is recreational enjoyment and no remuneration is involved. Activities that are engaged in for recreational purposes typically are not produced and traded in the private market economy, but exceptions do exist, including charter fishing and cruise activities.

Non-consumptive direct use activities derived from marine and coastal ecosystems such as tourism, diving, bird and whale watching, and appreciating the aesthetics of wild areas are also valuable to humans. These benefits may or may not be traded in markets, an example of the former being eco-tourism activities.

Considering the high productivity of the US Pacific Coast, it is certain that any significant changes or disturbances in this ecosystem would have a significant impact on human welfare. Marine and coastal ecosystems provide natural goods and services such as flood control, carbon storage; atmospheric gas regulation, particularly by the ocean's enormously productive phytoplankton; nutrient cycling; and transformation, detoxification, and sequestration of pollutants and societal wastes (NMFS 2005). The use values derived from these services are considered indirect, since they are derived from the support and protection of activities that have directly measurable values (e.g., commercial fishing, waste treatment) (National Research Council 2004). A large part of the contributions to human welfare by these ecosystem services are pure public goods (Costanza et al. 1997). In short, they accrue directly to people without passing through the market economy, and in many cases people are not even aware of them.

Non-use values, also referred to as passive-use values, do not involve personal consumption of derived products nor *in situ* contact. They are generated from people's inter-generational altruistic concerns (i.e., bequest value) or from the utility people receive from knowing that a particular asset exists or is being preserved (i.e., existence value). For example, some people may derive pleasure from the knowledge that wildlife exists in the area and would be willing to pay to preserve the structure and integrity of these biological communities even if they never directly “experience” them. Existence value may be highly sensitive to the amount of information acquired, i.e., small changes in information or knowledge about an ecosystem or associated species may produce large shifts in existence value for that ecosystem or species. It follows, therefore, that improvements in communication technology may lead to significant increases in existence value. Given the rich biodiversity of the Pacific as well as the highly-publicized human-induced stress on this marine ecosystem, it is probable that a significant component of the overall benefit of the Pacific may be from existence (non-use) value.

Economists have taken the decomposition of the basic components of value in a species or ecosystem a step further by incorporating uncertainty into an individual's choice. For example, individuals may be willing to pay a premium for retaining an option for future use of a good or service, although they may not currently use it. This so-called 'option value' exists under conditions of uncertainty about the future demand for an environmental asset. An extension of option value known as quasi-option value represents the value derived from postponing a decision about preserving a species or ecosystem in order to gain more knowledge in the future. Less intuitive goods and services derived from marine ecosystems have been recognized only as knowledge of these ecosystems has evolved (National Research Council 2004). Some of these include maintenance of biodiversity, and contributing to biogeochemical cycles and global climate. In addition, new information about medicine, genetics, or other areas of scientific research may result from future study of marine ecosystems and associated species.

In general, the value of an ecosystem good or service will vary with its level of provision (National Research Council 2004). For example, one might feel that access to certain marine ecosystem services, such as fisheries production, has decreased over time as a result of human pressures on natural habitat. Peoples' marginal valuations of these services will increase as their perceived scarcity becomes greater.

3.15.1 Condition Indicators for General Public

A comprehensive economic evaluation exercise would seek to quantify all the benefits of potentially affected marine ecosystems and associated species. On the one hand, the benefits of activities that produce goods and services exchanged in markets are relatively easy to estimate, as the goods and services generated have 'observable' prices. Examples include the seafood produced in the commercial fisheries discussed in this analysis. On the other hand, many of the goods and services derived from marine ecosystems are not exchanged through markets and therefore do not receive market prices. These are referred to by economists as "non-market" goods and services. Examples include recreational fishing experiences as well as less intuitive benefits of ecosystems such as climate regulation and nutrient storage and cycling.

The values of many non-market ecosystem goods and services can be estimated only with stated-preference methods such as contingent valuation, and this is the application in which these methods have been soundly criticized on conceptual and empirical grounds (National Research Council 2004). Moreover, the difficulty of valuing changes in these goods or services is compounded by the underlying complexity of natural ecosystems, which creates a barrier to quantifying the links from ecosystem structure and functions to the goods and services that humans value (National Research Council 2004).

In short, complete estimation of the monetary value of the full range of benefits that marine ecosystems and associated species provide to humans is a challenging task requiring data and models not available and not practicable to develop based on the current state of understanding of these systems. In particular, directly measuring individuals' non-consumptive and non-use values for potentially affected marine ecosystems is beyond the scope of this analysis. Therefore, the direction and degree of change of selected indicators defined in other sections of the analysis are considered as proxy metrics for the non-consumptive and non-use benefits that the general public derives from potentially affected marine ecosystems. In general, it is assumed that positive changes in the status of marine ecosystem and associated species positively affect the flow of non-consumptive and non-use benefits. The proxy metrics for historical and baseline non-consumptive and non-use values include but are not necessarily limited to the following:

- Amount of groundfish bycatch (i.e., the waste associated with fish that are caught and discarded)

- Condition of overfished groundfish species
- Condition of potentially affected marine mammals, seabirds, other protected species, habitat, and predator-prey relationships

3.16 Management agencies

3.16.1 Potentially Affected Management Agencies

Under the Magnuson-Stevens Act, NMFS manages the groundfish fishery in the EEZ. The states retain jurisdiction to manage fisheries in state waters. A state can also regulate vessels registered under the laws of that state in federal waters if the state's laws and regulations are consistent with the FMP and applicable federal law.

In practice, the states and federal government manage the groundfish fishery consistently and cooperatively. For the groundfish fishery, the states, the responsible federal agencies, and the Pacific Fishery Management Council coordinate closely. Each state has a representative of its fishery agency as a voting member on the Council. NMFS has a voting member on the Council, and the US Coast Guard, US Fish and Wildlife Service, and the Pacific States Marine Fisheries Commission have non-voting members on the Council. The states and NMFS also have representatives on the Council Committees that help develop management measures.

Management and enforcement responsibilities include the following: 1) data collection, research, and analysis to prepare stock assessments, 2) the annual groundfish specifications process through which catch caps are established, 3) the ongoing Council and NMFS process of amending FMPs and regulations to implement fishery management measures, 4) monitoring of fishing activities to estimate the total catch of each species and to ensure compliance with fishery laws and regulations, 5) action to adjust management regulations to keep catch within specified caps, and 6) actions taken by NOAA Office of Law Enforcement, the US Coast Guard (USCG), and NOAA General Counsel NW to identify, educate, and in some cases, penalize people who violate the laws and regulations governing the groundfish fisheries

Agencies that have roles in the management of West Coast groundfish stocks are:

- Pacific Fisheries Management Council
- NOAA Fisheries NW Regional Office
- NOAA Fisheries SW Regional Office
- NOAA Office of Law Enforcement
- NOAA General Counsel NW
- Pacific States Marine Fishery Commission
- State of California

3.16.2 Condition Indicators for Management Agencies

Managing fisheries in a cost-effective manner while balancing risks to the resource with socioeconomic benefits is often the objective of public agencies charged with fishery management and enforcement. Therefore, management costs, enforcement feasibility, risk to resources, and reliability of fishery data are the criteria or indicators used in evaluating the historical and baseline conditions of management agencies (Table 3-112):

Table 3-112. Indicators of Historical and Baseline Conditions of Management Agencies

Criteria	Description
Management costs	Costs associated with initial issuance, appeals, quota tracking, and catch monitoring.
Enforcement feasibility	Additional resources required to implement the alternatives.
Reliability of fishery data	Magnitude of modifications to the data collection and management system needed to make the program operational.
Risk to the resources	Integrity of the management and enforcement system is sufficient to ensure that catch quotas and time/area closures are adhered to.

3.16.3 Data

Agency records, as well as, various federal and state reports will be used in the analysis of the effects of the alternatives under consideration. Staff of the NMFS will also be a source of information.

3.16.4 Past and Present Conditions of Management Agencies

The format below for describing historical and baseline conditions will be repeated for all potentially affected management agencies.

3.16.4.1 Pacific Fisheries Management Council

The Pacific Coast Groundfish Fishery Management Plan was approved by the US Secretary of Commerce on January 4, 1982 and implemented on October 5, 1982. The Plan establishes a framework authorizing the range and types of measures that may be used to manage groundfish fisheries, enumerates eighteen objectives that management measures must satisfy, and describes more specific criteria for determining the level of harvest that will provide the greatest overall benefit to the nation. Fisheries subject to management measures include limited entry trawl fisheries, limited entry fixed gear (pot and longline) fisheries, and a variety of other fisheries catching groundfish, either as target species or as incidental catch.

The Council process for setting groundfish harvest levels and other specifications depends on periodic assessment of the status of groundfish stocks, rebuilding analyses of those stocks that are overfished and managed under rebuilding constraints, and reports from an established assessment review body or a Stock Assessment Review Panel (STAR). As appropriate, the SSC recommends the best available science for groundfish management decision making. The Council's Scientific and Statistical

Committee (SSC) reviews new assessments, rebuilding analyses, and STAR Panel reports. It then recommends the data and analyses that should be used to set groundfish harvest levels and other specifications for the following biennial management period.

Prior to implementation of the FMP, management of domestic groundfish fisheries was under the jurisdiction of the states of Washington, Oregon and California. Management and lack of uniformity became difficult problems that stimulated the formation of the Pacific States Marine Fishery Commission (PSMFC) in 1947. PSMFC had no regulatory power but acted as a coordinating entity with authority to submit specific recommendations to states for their adoption. The 1977 Fishery Conservation and Management Act (later amended and renamed the Magnuson-Stevens Fishery Conservation and Management Act or Magnuson-Stevens Act (MSA)) established eight regional fishery management Councils, including the Pacific Council. Between 1977 and the implementation of the FMP, state agencies worked with the Council to address conservation issues. In 1981, managers proposed a rebuilding program for Pacific Ocean perch.

Management of foreign fishing operations began in February 1967, when the US and USS.R. signed the first bilateral fishery agreement affecting trawl fisheries off Washington, Oregon and California. Later bilateral agreements were signed with Japan and Poland. These agreements were negotiated to reduce the impact of foreign fishing on important West Coast stocks, primarily rockfish, Pacific whiting and sablefish.

Joint-venture fishing, where domestic vessels catch the fish to be processed aboard foreign vessels, began in 1979, with Pacific whiting the primary target species. By 1989, this activity entirely supplanted directed foreign fishing. Joint-venture fisheries in turn were supplanted by wholly domestic operations shortly thereafter.

Since it was first implemented in 1982, the Council has amended the groundfish FMP numerous times in response to changes in the fishery and reauthorizations of the MSA.

The current groundfish management program relies heavily on trip limits to control fishing effort, with maintaining commercial production over the year a major goal. Usage of the term "trip limit" has evolved over the past 20 years. It referred initially to the amount of fish a commercial vessel could catch and retain on a single fishing trip. Over time, it was modified to include trip frequency limits and ultimately the amount of groundfish that could be caught and retained during a specified period of time, typically one or two months. A critical feature of status quo trip limits is that they do not directly limit the amount of catch, but rather only the amount of groundfish that can be retained and delivered for sale. Commercial vessels are allowed to discard unusable fish and any fish in excess of a specified limit.

3.17 Groundfish Resources

3.17.1 Potentially Affected Groundfish Resources

Groundfish fisheries regulated under the Groundfish FMP occur on the continental shelf and upper slope off Washington, Oregon and California (Figure 3-17). The continental shelf is narrow, varying in width from less than a mile off the Monterey Peninsula in California to as much as 37 miles over Heceta Bank off southern Oregon. The total shelf area (0 to 100 fathoms) is about 30,000 square miles. By comparison, the area of the central and eastern Bering Sea shelf is an order of magnitude larger, extending approximately 200 miles from shore. The relatively limited continental shelf and upper slope habitat off the West Coast recently produced average groundfish yields of 268,085 mt within the US EEZ in comparison to recent average groundfish yields in the Eastern Bering Sea and Aleutian Islands of 1,775,600 mt within the US EEZ (NMFS 1999). Nevertheless, productivity in West Coast waters is high and groundfish resources in the region sustain major fisheries.

Figure 3-17. Geographic Distribution of Rockfish and Allied Species (Lingcod, Cabezon, Kelp Greenling, and California Scorpionfish)

Source: 2005-2006 Groundfish Spec's EIS, Appendix A, p. A-88

There are over 80 species of groundfish managed under the Groundfish FMP. Over 60 species of rockfish, 7 roundfish species, 12 flatfish species, assorted sharks, skates and a few miscellaneous bottom-dwelling marine fish species. Fish managed under the groundfish FMP, as well as, their distribution are listed in Table 3-113. Management of these groundfish species is based on principles contained in the MSA, Groundfish FMP, and MSA National Standards Guidelines.

Table 3-113. Latitudinal and Depth Distributions of Groundfish Species (Adults) Managed under the Pacific Coast Groundfish Fishery Management Plan

Common name	Scientific name	Latitudinal Distribution		Depth Distribution (fm)	
		Overall	Highest Density	Overall	Highest Density
Rockfish Species					
Roundfish Species					
Shark and Skate Species					
Other Species					

Source: PFMC, 2004, Appendix A, p. A-78

The commercial trawl fishery is prosecuted over a wide range of depths, from 20 fathoms for English sole and sanddabs to as deep as 700 fathoms for Dover sole and sablefish. Fishing also may occur on smooth mud/sand substrates, rocky reefs, pinnacles and canyons.

Mandates incorporated in the MSA as a result of passage of the SFA in1996 included abundance-based standards for declaring a stock overfished. These standards were subsequently incorporated in the Groundfish FMP with adoption of Amendments 11 and 12. The abundance-based reference points for managing West Coast groundfish species are relative to an estimate of “virgin” or unexploited biomass of the stock, which is denoted as B_0 and is defined as the average equilibrium abundance of a stock’s spawning biomass before it is affected by fishing-related mortality. The MSA and NSG employ the Maximum Sustainable Yield (MSY) concept to frame management objectives. MSY represents a theoretical maximum surplus production from a population of constant size. The NSG define it as, “the largest long-term average catch or yield that can be taken from a stock or stock complex under prevailing ecological and environmental conditions.” Thus, for a given population, and set of ecological conditions, there is a biomass that produces MSY (denoted as B_{MSY}), which is less than the equilibrium size in the absence of fishing (B_0). The harvest rate used to specify harvest levels designed to achieve or sustain B_{MSY} is referred to as the Maximum Fishing Mortality Threshold (MFMT, denoted as F_{MSY}). There are two harvest specification reference points defined in the Groundfish FMP, a total catch OY and an ABC. The OY is typically the management target and is usually less than the ABC, based on precautionary adjustments or the need to rebuild stocks to B_{MSY}. The ABC, which is the maximum allowable harvest, is calculated by applying an estimated or proxy F_{MSY} harvest rate to the estimated abundance of the exploitable stock.

The Council-specified proxy MSY abundance for most West Coast groundfish species is 40% of B_0 (denoted as B_{40}). The Council-specified threshold for declaring a stock overfished is when the stock’s spawning biomass declines to less than 25% of B_0 (denoted as B_{25}). The MSA and NSG refer to this threshold as the Minimum Stock Size Threshold or MSST. A rebuilding plan that specifies how total fishing-related mortality is constrained to achieve an MSY abundance level, within the legally allowed time, is required by the MSA and Groundfish FMP when a stock is declared overfished.

Stocks estimated to be above the overfishing threshold, yet below an abundance level that supports MSY, are considered to be in the “precautionary zone.” The Council has specified a precautionary reduction in harvest rates for such stocks to increase abundance to B_{40}. The methodology for determining this precautionary reduction is described in the Groundfish FMP and is referred to as the 40-10 adjustment (Figure 3-18). As the stock declines below B_{40}, the total catch, OY, is reduced from the ABC until, at 10% of B_0, the OY is set to zero. However, in practice the 40-10 adjustment only applies to stocks above B_{25} (MSST) because once a stock falls below this level, an adopted rebuilding plan replaces it. Most stocks with an estimated abundance greater than B_{40} are managed by setting harvest to the ABC. The California Department of Fish and Game (CDFG) uses a precautionary policy analogous to the Council's 40-10 adjustment specified in their nearshore FMP. Called the 60-20 adjustment, the precautionary reduction of OY from the ABC would begin at 60% of $B_{0,}$ until, at 20% of B_0, the OY is set to zero.

Figure 3-18. 40-10 Rule

Source: PFMC, 2004, Appendix A, p. A-78

A significant number of stocks managed under the Groundfish FMP have never been assessed. Stocks assessed over the last 12 years, 1994 through 2005, are listed in Table 3-114. The fishery in 2002 and 2003 was characterized by significant under harvest of available catch (including discards) for many species (Table 3-115 and Table 3-116).

3.17.2 Condition Indicators for Groundfish Resources

Indicators of the historical and baseline conditions of groundfish species in terms of fishery impacts include but are not necessarily limited to the following:

- Fishery Mortality: The rate at which the stock is depleted by direct mortality imposed by removing the fish from the sea.
- Change in Biomass Level: The change over time in the biomass of the stock, as measured in metric tons (mt). Two measures are used: total biomass, which is the estimated biomass of the entire stock, and spawning biomass, which is the estimated biomass of all of the spawning females in the stock.
- Spatial/Temporal Concentration of Catch: The degree to which the fishery will concentrate in a particular geographic area during a particular period of time each season. This pattern in space and time can affect fishing mortality and can also influence habitat suitability for spawning, rearing, and feeding.
- Habitat Suitability: The degree to which habitat has the right characteristics to support the target stock at one or more life-history stages (spawning, rearing of juveniles, availability of food at all stages, availability of refuge area to allow escape from predators at all stages). Habitat suitability can be affected directly, for example by mechanical damage from bottom trawling, or influenced indirectly, for example, by the gradual depletion of corals that provide hard substrate.
- Prey Availability: The extent to which prey species are present in the environment and available as food to the target stock. Like habitat suitability, this measure can be affected directly, for example, by the direct removal of prey species by the fishery, or indirectly, for example, by a change in the structure of the food web.

3.17.3 Data

Detailed information on the species discussed below can be found in the Life History Appendix to the Groundfish FMP, regarding utilization patterns, fisheries that harvest the species, geographic range, migration and movements, reproduction, growth and development, and trophic interactions. Useful information also is contained in the groundfish fishery specification EIS, West Coast Groundfish Bycatch Management Program EIS (Bycatch EIS) and Groundfish Essential Fish Habitat EIS (EFH EIS).

3.17.4 Past and Present Conditions of Overfished Groundfish Species

3.17.4.1 Bocaccio (Sebastes paucispinis)

The format below for describing historical and baseline conditions will be repeated for all Overfished Groundfish Species and Non-Overfished Groundfish Species.

3.17.4.1.1 Life History and Distribution

Bocaccio (*Sebastes paucispinis*) is a rockfish species that ranges from Krozoff and Kodiak Islands in the Gulf of Alaska to central Baja California, Mexico. Historically, they have been abundant in water off central and southern California. There are two separate West Coast populations. The southern stock exists south of Cape Mendocino and the northern stock north of 48 degrees N latitude in northern Washington (off Cape Flattery). It is unclear whether this stock separation implies stock structure. Juveniles settle in nearshore waters after a pelagic stage that lasts several months. Adults are most commonly found at 100-150 m over the outer continental shelf. Bocaccio is found in a wide variety of habitats, often on or near bottom features, but sometimes over muddy bottoms.

Bocaccios are ovoviviparous. Spawning takes place during the entire year.

Maximum age of bocaccio has been radiometrically determined to be at least 40 and perhaps more than 50 years old. They are difficult to age and length measurements serve as a proxy in stock assessments.

3.17.4.1.2 Population Trends

Bocaccio was declared overfished by the Council in the fall of 1999. Catch restrictions were implemented in 2000 to initiate rebuilding. In 2004, a rebuilding plan was enacted as part of Amendment 16-3 to the Groundfish FMP. In response to the 2002 assessment, which indicated very low productivity, the 2003 OY was set at 20 mt, and the retained catch was about 12 mt. Including mortality of estimated discards, estimated 2003 total kill was 22 mt. Based on the 2003 assessment, which showed a much more productive stock, the 2004 OY was set at 250 mt, however, management used an operational target of 199 mt. The final catch was 78 mt. Discards brought the estimated 2004 kill to 83 mt.

3.17.4.1.3 Trophic Interactions

Larval bocaccios eat diatoms, dinoflagellates, tintinnids, and cladocerans. Copepods and euphausiids of all life stages are common prey for juveniles. Adults eat small fishes associated with kelp beds, including other species of rockfishes and occasionally small amounts of shellfish. Bocaccios are eaten by sharks, salmon, other rockfishes, lingcod, Albacore, sea lions, porpoises, and whales. Adult bocaccios are often caught with chilipepper rockfish and have been observed schooling with speckled, vermilion, widow, and yellowtail rockfish. They compete with chilipepper, widow rockfish, yellowtail rockfish and shortbelly rockfishes for both food and habitat resources.

3.17.4.1.4 Management Overview

Assessment scientists and managers have treated West Coast bocaccio as two separate independent stocks north and south of Cape Mendocino. Bocaccios have been an important component of California rockfish fisheries. Catches increased to high levels in the 1970s and early 1980s due to relatively strong recruitment. The Council began implementing increasingly restrictive regulations after an assessment of the southern stock in 1990 indicated that fishing rates were too high. Subsequent assessments have indicated that the stock was in severe decline, and NMFS declared the stock overfished in 1999. MacCall *et al*. (1999) estimated spawning output of the southern stock to be 2.1% of its unfished biomass and 5.1% of the MSY level. The northern stock of bocaccio has not been assessed.

3.17.4.1.5 Past and Present Effects and Management Actions

The following direct and indirect effects were identified as potentially having population-level effects:

3.17.4.1.5.1 Mortality Due to Catch/Bycatch

Catches of this species have declined steeply from the 1970s, reflecting both a long-term decline in abundance and progressive harvest restrictions. The value of catch data since 2000 is imprecise because of management-induced discarding. Recent discards in the trawl fishery have been monitored. Because of the lack of data, discard rates in other commercial fisheries are assumed to be similar to those for the trawl fishery. Discards in the recreational fishery are provided by RecFIN. Catch, both retained and discarded by fishery for years 2000 through 2004 are reported in Table 3-118.

Table 3-118. Retained and Discarded Catch of Bocaccio by Fishery, 2000- 2004 (mt)

YEAR	TRAWL	HOOK & LINE	SETNET	RecSouth	RecNorth	TOTAL

Source: MacCall, Alec D., Status of Bocaccio off California in 2005, Table ES2, p. 3.

Based on the 1996 stock assessment bocaccio was declared formally overfished, thereby requiring development of a rebuilding plan. Rebuilding was initiated through catch restrictions beginning in 2000. The rebuilding OY was set at 100mt for 2000-2002. In response to the 2002 assessment that indicated very low productivity, the 2003 OY was set at 20mt. During the same year the retained catch was 12mt. Including mortality estimated discards, the estimated total kill was 22mt. Based on the 2003 assessment, that revealed a more productive stock, the 2004 OY was set at 250mt. However, management set the operational catch target at 199mt. The final catch was 78mt. Discards brought the estimated 2004 catch to 83mt. In 2004, a formal rebuilding plan was implemented for bocaccio by the Council.

3.17.4.1.5.2 Change in Reproductive Success Due to Removal of Predators, Cannibalism, Spatial/Temporal Concentration of Fishery Catch/Bycatch, Fishery Selectivity of Juveniles

The strong 1999 year class remains dominant. However, the 2003 year class appears stronger than average (Table 3-119). Little is known about factors that affect reproductive success.

Table 3-119. Stock Status Information for Bocaccio Taken from the 2005 Stock Assessment (mt)

Year	Spawning Output (billion eggs)	Relative Abundance	Total Age-1 Biomass(mt)	Recruits at Age-1	Catch(mt)	Exploitation Rate
1995	751	5.6%	4994	755	777	15.6%
……	……..	……	…….	……..	…….	…….
2004	1261	9.4%	8078	1342	83	1.0%
2005	1440	10.7%	8561	885		

Source: MacCall, Alec D., Status of Bocaccio off California in 2005, Table 5, p. 13.

3.17.4.1.5.3 Change in Prey Availability Due to Fishery Catch/Bycatch of Prey Species

Little is known about ecological relationships between bocaccio and other organisms. Larval bocaccios eat diatoms, dinoflagellates, tintinnids, and cladocerans. Copepods and euphausiids of all life stages are common prey for juveniles. Adults eat small fishes associated with kelp beds, including other species of rockfishes and occasionally small amounts of shellfish. They compete with chilipepper, widow rockfish, yellowtail rockfish and shortbelly rockfishes for both food and habitat resources.

3.17.4.1.5.4 Change in Important Habitat Due to Fishery Gear Impacts

Bocaccios are most abundant in waters off central and southern California. Juveniles settle in nearshore waters after a several month pelagic stage. Adults are found at depths of 6.5-261 fm (12-478 m). Most adults are caught off the middle and lower shelf at depths between 27 fm and 137 fm (50 and 250 m). Larger fish tend to be deeper. Bocaccio is found in a wide variety of habitats, often on or near bottom features but sometimes over muddy bottoms. While usually found near the bottom they also have occurred as much as 16.4 fm (30 m) off bottom.

In November 1999, in order to keep trawlers from capturing canary rockfish, bocaccio, cowcod, and lingcod that associate with high relief rocky habitat on the continental shelf, the Council adopted a gear restriction that limits large footrope size. Differential trip limits were assigned to the three categories of trawl gear configurations: large footropes greater than 8 inches (20.5 cm), small footropes less than or equal to eight inches ($\leq$ 20.5 cm), and midwater or pelagic gear. This rule prohibited vessels from delivering nearshore and shelf rockfish species and many flatfish species if they use footropes with rollers larger than eight inches. Large footropes could still be used for deepwater shelf and slope species. Though only preliminary research has been done, it widely is believed that this gear restriction has been effective in keeping boats from being able to fish in high relief habitat.

3.17.4.1.6 Comparative Baseline

Based on the 2005 assessment, the estimated unfished spawning output is 13325 billion eggs (compared with 13387 billion eggs estimated in the 2003 rebuilding analysis), based on the average recruitment from spawning years between 1950 and 1985. Estimated B_{MSY} is 5330 billion eggs (compared with 5355 billon eggs in 2003). According to the 2005 assessment, the current (2005) spawning output is 1419 billion eggs, which is 27% of the estimated B_{MSY}.

Results of stock projections suggest that the stock will be in the state of rebuilding when the TIQ program is implemented. Catch projections provided by both the stock assessment author and the STAR Panel are given in the Table 3-120.

Table 3-120. Projected Abundance of Bocaccio

YEAR	STAR Panel Catch Projections (mt)		Assessment Projections	
	Minimum	Maximum	Catch (mt)	Spawning Output
2005	150	150	281	1430
2010	129	359	327	1711
2012	158	425	423	1962
2015	211	535	511	2594

3.17.5.17 Leopard Shark (Triakis semifasciata)

3.18 Other Fish Resources

3.18.1 Potentially Affected Other Fish Resources

Other affected resources, non-groundfish species, and fisheries that target them often need to be considered in groundfish management for two reasons. First, they may be caught incidentally in fisheries targeting groundfish. Therefore, management measures that change total fishing effort in groundfish fisheries could increase or decrease fishing mortality on incidentally caught species. Second, those fisheries targeting non-groundfish species may be affected by management measures intended to reduce or eliminate incidental catches of overfished groundfish species in these fisheries.

Following an approach used in the Council's Groundfish Bycatch EIS, species listed below (excluding protected species described in other sections) are examined to capture the impacts of the alternatives under consideration. The species are: California halibut, Pacific halibut, pink shrimp, spot prawn, ridgeback prawn, Dungeness crab, jack mackerel, Pacific mackerel, walleye pollock, common thresher shark, and eulachon. These species were selected because they represent the range of impacts likely to be experienced by a broader range of species, but with similar life histories, distributions, and vulnerabilities to bycatch impacts.

3.18.2 Condition Indicators for Other Fish Resources

Indicators of the historical and baseline conditions of Other Fish Resources are similar to those listed for groundfish species in Section 3.17.2.

3.18.3 Data

Information needed to complete the profiles for the selected species can be found in the groundfish fishery specification, Bycatch and EFH EISs.

3.18.4 Past and Present Conditions of Other Affected Fish Resources

The format below for describing historical and baseline conditions will be repeated for all Other Affected Fish Resources.

3.18.4.1 Pacific halibut (*Hippoglossus stenolepis*)

3.18.4.1.1 Life History and Distribution

Pacific halibut is a large flatfish which inhabits the continental shelf of the US and Canada. They are demersal and are caught most often between 90 to 900 feet. Halibut from California through the Bering Sea are considered to form one homogenous population. Halibut off the West Coast are at the extreme southern end of their range. The majority of the stock and all major spawning grounds are in more northern waters off Canada and Alaska. The halibut that inhabit West Coast waters result from the southerly migration of juveniles.

Halibut spawn during the winter in deep water (approximately 1,000 feet). Their eggs and larvae rise and drift with ocean currents in a counter-clockwise direction around the northeast Pacific Ocean. Young fish settle to the bottom in shallow feeding areas. Juvenile migration is usually completed by the age of six. Adult fish tend to remain on the same grounds year after year, making only a seasonal migration from the more shallow feeding grounds in summer to deeper spawning grounds in the winter.

Pacific halibut are the largest of all flatfish, weighing up to about 500 pounds. Females typically grow faster and live longer than males. The oldest halibut on record was 55 years old. Most are less than 25 years old.

3.18.4.1.2 Population Trends

The assessment of the Pacific halibut stock status was revised in 1996 due to the observed changes in individual growth rates that affected fishing gear selectivity. The new analyses showed that the exploitable portion of the stock apparently peaked at 326,520 mt in 1988 (Sullivan and Parma 1998). The population has since declined slightly and has maintained a biomass in the range of 270,000 to 277,000 mt. The long-term average yield was estimated at 26,980 mt (Parma 1998).

Until 2001, the exploitable biomass off the West Coast was estimated as a proportion of the total for the two areas. As a result of a reanalysis and reevaluation of assessment methods for these areas in 2001, the biomass off the West Coast was estimated from survey data and a separate assessment of abundance in British Columbia. This change resulted in about a 5% increase in the biomass estimate for the West Coast (Clark and Hare 2001).

3.18.4.1.3 Trophic Interactions

Halibut are carnivorous. Larval halibut feed on plankton. When they are one to three years old they feed on small crustaceans and small fish. As halibut grow, fish become a larger part of their diet. They prey upon cod, sablefish, pollock, rockfish, sculpins, turbot, and other flatfish. They also leave the bottom to feed on sand lance and herring in the water column. Octopus, crabs, clams, and occasionally small halibut are also eaten. Large juveniles and adult halibut occasionally are eaten by marine mammals but are rarely prey for other fish.

3.18.4.1.4 Management Overview

Pacific halibut are managed by the bilateral (US/Canada) International Pacific Halibut Commission (IPHC). Implementing regulations are set by each country in their own waters. The Pacific Halibut Catch Sharing Plan for waters off Washington, Oregon and California (Area 2A) specifies management measures for the West Coast. Implementing catch levels and regulations are the responsibility of the Council, the states of Washington, Oregon, and California, and the Pacific halibut treaty tribes. A license from the IPHC is required to participate in the commercial fishery. The commercial sector in Area 2A is confined to waters south of Point Chehalis, Washington. In the non-treaty commercial sector, 85% of the harvest is allocated to the directed halibut fishery and 15% to the salmon troll fishery to cover incidental catch. When the Area 2A total allowable catch is above 900,000 pounds, halibut may be retained in the limited entry sablefish fishery north of Point Chehalis.

3.18.4.1.5 Past and Present Effects and Management Actions

The following direct and indirect effects are capable of having population-level effects on Pacific halibut:

3.18.4.1.5.1 Mortality due to Bycatch

Pacific halibut bycatch mortality in groundfish fisheries was relatively low until the 1960s when it increased due to the development of foreign fisheries. Total bycatch mortality for IPHC regulatory areas:

- Peaked in 1965 at approximately 21 million pounds
- Decreased in the late 1960s to approximately 15 million pounds
- Increased to approximately 20 million pounds by the early 1970s
- Decreased through the late 1970s with an increase to approximately 18 million pounds in 1980.

The bycatch of Pacific halibut in groundfish fisheries decreases the amount that can be taken by fishermen in the directed IPHC fishery. Pacific halibut bycatch data for the limited entry trawl fishery are presented in Table 3-121.

Table 3-121. Bycatch of Pacific Halibut taken by Limited Entry Trawl Vessels, 2000-2005

Year	2000	2001	2002	2003	2004	2005
Bycatch (mt)						

Source:

3.18.4.1.5.2 Spawning Disruption

The early directed Pacific halibut fishery took place year-round. Fish caught during spawning season were of poor quality. Bycatch contains both adult (>81 cm) and juvenile fish (<81 cm). A winter season fishery closure was proposed as a result of the 1913 US and Canada discussions on international halibut management. This closure was proposed in order to eliminate a period of fishing when poor quality fish were caught.

Pacific halibut spawn in very deep water (400 to 600m) off the continental shelf edge and negative effects would arise to the degree that fisheries utilize these areas.

3.18.4.1.5.3 Reduced Recruitment: Spatial/Temporal Concentration of Bycatch

Alaska groundfish fisheries take the majority (more than 90%) of Pacific halibut bycatch. Juveniles may or may not have completed their migration from the nursery ground to home areas. Their capture has the potential effect of reducing recruitment to adult stock in the home area where they would have migrated. Adult fish caught as bycatch have completed their migration back to home areas. Therefore, bycatch of adult fish can be expected to affect only the stock in the area where the bycatch is taken. Approximately 50 to 60 percent of the bycatch is below the directed fishery size limit of 81 cm.

3.18.4.1.6 Comparative Baseline

The assessment of the Pacific halibut stock status was revised in 1996 due to observed changes in individual growth rates that affected fishing selectivity. Pacific halibut have shown a decrease in size and age over time. Fish today weigh approximately a third of what fish of the same size weighed 20 years ago. The new analyses indicated that the exploitable portion of the stock apparently peaked at 326,520 mt in 1988. The population has since declined slightly and has maintained a biomass in the range of 270,000 to 277,000 mt. The long-term average yield was estimated at 26,980 mt round weight (Parma 1998).

The nature of the Pacific halibut commercial fishery has changed in recent years. Both Canadian and US fisheries have gone from open access with short season fisheries to IFQ fisheries that last eight months. In addition, quota allocations have been implemented for Native American treaty, commercial, and recreational fisheries for waters from Washington to California. Removals of Pacific halibut for 2002 totaled 44,453 mt (net weight). The breakdown by fishery is: commercial catch 33,749 mt (76%); sport catch 3,946 mt (9%); incidental bycatch mortality, 5,806 mt (13%): personal use, 363mt (1%); and waste, 726 mt (2%).

Currently, the Pacific halibut resource is considered to be healthy. The 2005 estimated total exploitable biomass was 395 million pounds (Clark and Hare, 2005). The total exploitable biomass is predicted to be 382 million pounds in 2006. It is inferred that any direct or indirect effects of past bycatch in groundfish fisheries were taken into account under the IPHC management process.

3.18.4.2 California halibut (Paralichthys californicus)

3.18.4.3 Pink shrimp (Pandalus jordani)

3.18.4.4 Spot prawn (Pandalus platyceros)

3.18.4.5 Ridgeback prawn (*Sicyonia ingentis*)

3.18.4.6 Dungeness crab (*Cancer magister)*

3.18.4.7 Jack mackerel (Trachurus symmetricus)

3.18.4.8 Pacific mackerel (*Scomber japonicus*)

3.18.4.9 Walleye pollock (Theragra chalcogramma)

3.18.4.10 Common thresher shark (*Alopias vulpinus*)

3.18.4.11 Eulachon (thaleichthys pacificus)

3.19 Marine Mammals

3.19.1 Potentially Affected Marine Mammals

The waters off Washington, Oregon and California support a wide variety of marine mammals. Approximately 30 species, including seals and sea lions, sea otters, whales, dolphins, and porpoise, occur within the EEZ. Many marine mammal species seasonally migrate through West Coast waters, while others are year-round residents

The 2005-2006 groundfish fishery specification EIS (PFMC, 2004) reported marine mammal fishery interactions observed during the first year of the West Coast Groundfish Observer Program. Information obtained indicated that lethal interactions occurred in both the trawl and longline fisheries, although the highest mortality was seven California sea lions taken by trawl gear. Trawlers also took two Steller sea lions and an unidentified sea lion. Because marine mammals are diving animals and strong swimmers, they are more likely to be taken in trawl gear than longline gear. Other marine mammals noted to have been taken in West Coast groundfish fisheries are the harbor seal, sea otter, Dall's porpoise, white-sided dolphin, and short-beaked dolphin.

Table 3-122. Interactions between Marine Mammals and West Coast Groundfish Trawl Fishery Documented by West Coast Groundfish Observers between September 2001 and October 2002

Species	Gear Type	Type of Interaction
California Sea Lion	Trawl	7 Individuals Taken
Unidentified Sea Lion	Trawl	1 Individual Taken
Steller sea Lion	Trawl	2 Individuals Taken
California Sea Lion	Trawl and Longline	Feeding on Discard
Steller sea Lion	Trawl and Longline	Feeding on Discard
Pacific white-sided Dolphin	Trawl	Feeding on Discard

Source: PFMC, 2004, p.225. Note – Approximately 10% of the coast-wide limited entry trawl landed weight was observed.

3.19.2 Condition Indicators for Marine Mammals

Indicators of the historical and baseline conditions of marine mammals in terms of fishery impacts include but are not necessarily limited to incidental takes/entanglement, prey availability, spatial and temporal distribution of the fishery catch, and disturbance by fishing vessels.

Fisheries interact with marine mammals either operationally or biologically. Operational effects are direct and occur in the form of incidental takes that may result in disturbance, serious injury or mortality. Operational interactions between marine mammals and fisheries result from entanglement in actively fishing or derelict fishing gear. Marine mammals become entangled when they encounter derelict or active fishing gear. Biological interactions result from disturbance of normal marine mammal foraging behavior.

Some types of fisheries are much more likely to catch marine mammals incidentally than others. Incidental take is a direct source of mortality and NMFS requires all commercial fisheries in the US EEZ to report the incidental take and injury of marine mammals that occur during their operation. Provisions of the MMPA requires that all commercial fisheries be placed into one of three categories, based on the frequency of incidental take (serious injuries and mortalities) relative to the value of potential biological removal (PBR) for each stock or marine mammal. Category 1 fisheries are those fisheries with frequent incidental take, defined as those with takes greater than or equal to 50% of PBR for a particular stock. Category II designates fisheries with occasional serious injuries and mortalities, defined as those with takes between 1% and 50% of PBR. Category III designates fisheries with a remote likelihood or no known serious injuries or mortalities, defined as those with takes less than or equal to 1% of PBR.

In some cases, individual marine mammals may be killed outright by fishing activity. In other cases, individuals are affected in ways that may decrease their chances of surviving natural phenomenon or reproducing successfully. These sub-lethal impacts reduce the overall "fitness" of individuals and may have population-level implications if enough animals are impacted. Although some fisheries have no record of incidental take of marine mammals, some may contribute to the effect of entanglement in lost fishing gear. Evidence of entanglement comes from observations of animals trailing ropes, buoys, nets, or bearing scars from such gear. Sometimes stranded marine mammals also have evidence of entanglement but it may not be possible to ascertain whether the entanglement caused the injury or whether the corpse picked up gear as it floated around after death. Sometimes an animal is observed to become entangled in specific fishing gear, in which case an incidental take or minor injury may be recorded for the particular fishery, but many times the contributions of individual fisheries to the overall effects of entanglement are difficult to document and quantify.

Prey availability to marine mammals depends on a large number of factors and differs by species and season. Among these factors are oceanographic processes such as upwelling, thermal stratification, fronts, gyres, and tidal currents that concentrate prey at particular times and places. Prey availability also depends on the abundance of competing predators and the ecology of prey species, including their natural rates of reproduction, seasonal migration, and movements within the water column. The relative contributions of factors that influence prey availability for particular species and areas are rarely known. Most critical is the lack of information on how events outside an animal's foraging range or in a different season may influence the availability of prey to animals in a particular place and time.

The question of whether commercial fisheries have an effect on the availability of prey to marine mammals may be addressed by examining the degree of direct competition (harvest) for prey and by looking for potential indirect or cascading effects of fisheries on the food web of the mammals. For marine mammals whose diets overlap to some extent with the target or bycatch species of the fisheries, fishery removals could potentially decrease the density of prey fields or cause changes in the distribution of prey such that foraging success of the marine mammals is affected. If alternative prey is not available or is of poorer nutritional quality than the preferred species, or if the animal must spend more time and energy searching for prey, reproductive success and/or survival can be compromised. In the case of marine mammals that do not feed on fish or feed on different species than are taken in the fisheries, the removal of a large numbers of target fish from the ecosystem may alter the predator/prey dynamics and thus the abundance of another species that are eaten by marine mammals. The mechanisms and causal pathways for many potential food web effects are not well documented because they are difficult to study.

The effects of disturbance caused by vessel traffic, fishing operations, engine noise, and sonar pulses on marine mammals are largely unknown. Observed behavior ranges from attraction to the vessel, to course modification or maintenance of distance from the vessel. Dall's porpoise, Pacific white-sided dolphins, and beaked whales have been observed adjacent to vessels for extended periods of time. A small number of fatal collisions with various vessels have been recorded in California and Alaska in the past decade.

3.19.3 Data

Information useful to this analysis is available in various agency reports, and the PFMC's Bycatch and EFH EISs.

3.19.4 Past and Present Effects on Marine Mammals

3.19.4.1 Pinnipeds

The format below for describing historical and baseline conditions will be repeated for all potentially affected marine mammal species.

3.19.4.1.1 Northern elephant seal (*Mirounga angustirostris*)

3.19.4.1.1.1 Life History and Distribution

Elephant seals (*Mirounga angustirostris)* range throughout the northeast Pacific Ocean from central Baja California, Mexico to the GOA and eastern Aleutian Islands, with occasional sightings in the southern Bering Sea. They are polygamous breeders with males forming harems and defending them against other mature males. Breeding occurs on islands from central Baja California north through central Oregon. Pupping and mating occurs on isolated islands and mainland rookeries during January and February. Following the breeding season, adults go to sea and forge until they return to rookery islands to molt in April (females) and July (males). Following the molt adults again return to foraging areas, where they feed until returning for the following breeding season. Elephant seals complete two long distance migrations each year, with males traveling further then females.

3.19.4.1.1.2 Population Trends

The existing population of northern elephant seals is descended from perhaps 100 animals that survived in Mexico after the species was nearly exterminated by commercial hunting in the 19th century. The population has expanded rapidly since hunting was halted. An estimated population of 127,000 animals existed in US and Mexico waters in 1991, with 95,000 animals present in the US Approximately 101,000 animals were estimated to make up the US population in 2001.

3.19.4.1.1.3 Trophic Interactions

Northern elephant seals feed mainly at night in very deep water and consume whiting, skates, rays, sharks cephalopods, shrimp, euphausiids, and pelagic red crab. Males forage in areas close to or over the continental shelf break, during intense feeding. Females tend to forage in deeper waters off the continental shelf. In these waters, elephant seals dive to depths of 400m, apparently feeding on organisms associated with the deep scattering layer. Some adult and sub-adult males occupy more coastal habitats where dive records suggest feeding on or near the bottom. While the proportion of the population using coastal habitats is unknown, most adult males and females appear to feed in the water column over very deep water.

3.19.4.1.1.4 Management Overview

Management of the northern elephant seal is the responsibility of NMFS. Since they are protected under the MMPA, a moratorium exists on the taking of all marine mammals, except for subsistence use by Alaska Natives. Northern elephant seals are not an important species for Alaska Native subsistence hunters. Because their annual human-caused mortality is less than the calculated PRB for this stock, they are not considered a "strategic" stock under the MMPA.

3.19.4.1.1.5 Past and Present Effects and Management Actions

Directed Mortality from Incidental Take by West Coast Groundfish Fisheries

There are no recent estimated incidental kills of Northern elephant seals in groundfish fisheries along Washington, Oregon and California. However, they have been caught in setnet fisheries. On average 86 elephant seals are taken each year in various gillnet fisheries from California to Washington (Carretta et al. 2002).

3.19.4.1.1.6 Comparative Baseline

The population of northern elephant seals in US waters continues to expand and is currently over 100,000 animals. They spend part of the year in Alaska waters, but there is little information on their diet there. Incidental take in groundfish fisheries appears to be a very rare occurrence.

3.19.4.1.2 Northern fur seal (Callorhinus ursinus)

3.19.4.1.2.1 Life History and Distribution

The northern fur seal ranges throughout the North Pacific Ocean from southern California north to the Bering Sea and west to the Okhotsk Sea and Honshu Island, Japan. The species is sexually dimorphic, meaning that mature males and females look very different. They have a highly polygamous mating system, breeding in dense colonies on islands located near highly productive marine areas. Breeding is restricted to only a few sites: the Pribilof Islands, Commander Islands, Bogoslof Island, and San Miguel Island. Most females, pups, and juveniles leave the Bering Sea by late November and are pelagic in the North Pacific during the late fall and winter, migrating south as far as Southern California in the eastern North Pacific and Japan in the western North Pacific, until they begin returning to the rookeries in March.

Two separate stocks of northern fur seals are recognized within US waters: an eastern Pacific stock, that includes all the animals in the BSAI and GOA, and a San Miguel Island (California) stock. Population estimates for the eastern Pacific stock are calculated by estimating the number of pups at rookeries and then multiplying by an expansion factor (4.5) that approximates a life table analysis(Angliss and Lodge 2002).

3.19.4.1.2.2 Population Trends

Until the mid-1970s, northern fur seal population trends could be explained by commercial harvest patterns in the North Pacific Ocean. Large population declines coincided with large harvests of female and juvenile fur seals. The fur seal population has shown a resiliency to sustained harvest of adult males when females and juveniles were not harvested. The history of pelagic sealing (1875-1909), its impact on the fur seal population, and a subsequent treaty banning pelagic sealing is found in Gentry (1998). At the peak of pelagic sealing (1891-1900), more than 42,000 animals were taken annually in the Bering Sea. Because the takes were greatly reducing the stock, Great Britain (for Canada), Japan, Russia and the United States ratified the Treaty for the Preservation and Protection of Fur Seals and Sea Otters in 1911. With the signing of the treaty, commercial pelagic harvests ended. The population grew rapidly after the cessation of pelagic sealing until the mid-1940s.

The Alaska population of fur seals peaked at a high of approximately 2 million animals during the 1950s. In 1957, the signatories to the 1911 Treaty ratified a new agreement. During those negotiations, calculations presented by the US suggested that maximum sustained productivity would occur at lower female population levels than those that existed in the early 1950s. Consistent with that analysis, from 1956 to 1968, a total of about 30,000 to 96,000 juvenile males were harvested each year and a pelagic collection of about 16,000 females were taken for research purposes by the US and Canada. This harvest of females and juveniles caused a large population decline into the late 1960s.

With the cessation of female and juvenile harvests, the population increased only briefly into the mid-1970s. The population then began a steady decline of 6 to 8 percent per year into the 1980s. The cause of this decline has not been determined. By 1983 the population was estimated to be 877,000 seals (Angliss *et al*, 2001). Since 1998, population estimates from pup surveys indicate that the population is declining at a rate of more than five percent per year. The cause of the decline is unknown.

3.19.4.1.2.3 Trophic Interactions

Northern fur seals food habitats studies that were based on the frequency of occurrence indicate that the diet consisted of 67% fish, (34% Pollock, 16% capelin, 6% Pacific herring, 4% deep-sea smelt and lantern fish, 2% salmon, 2% Atka mackerel, and no more than 1% eulachon, Pacific cod, rockfish, sablefish, sculpins, Pacific sand lance, flatfish and other fish) and 33 percent squid (Perez 1990)

3.19.4.1.2.4 Management Overview

Northern fur seals are managed by NMFS and by co-management agreements with Alaska Native Organizations under Section 119 of the MMPA. Northern fur seals were listed as depleted under the MMPA in 1988 because population levels had declined to less than 50% of that observed in the late 1950s.

3.19.4.1.2.5 Past and Present Effects and Management Actions

Direct Mortality from Incidental Take by West Coast MSA Groundfish Fisheries

Incidental take of fur seals from the foreign and joint venture groundfish fisheries averaged 22 animals per year form 1978 to 1988 (Perez and Loughlin 1991). The high seas driftnet fisheries killed thousands of fur seals every year, including an estimated 5,200 fur seals in 1991, the last year before those fisheries were outlawed by United Nations Resolution (46/215) (Hill and DeMaster 1999).

Based on self-reported mortalities, State of Alaska managed salmon fisheries took an average of 15 fur seals per year from 1990 to 1998. Most of these mortalities come from the Bristol Bay salmon drift gillnet fishery.

The incidental take of northern fur seals is uncommon in groundfish fisheries. The last recorded mortality in any Alaska groundfish fishery occurred in 1996. The estimated average take in trawls is less than one seal per year (Angliss *et al*. 2001). During the period 1994-1998 there were no reported mortalities of northern fur seals in any observed fishery along the West Coast of the continental US

The contribution of MSA fisheries to gear and debris that causes entanglement of fur seals is unknown.

Indirect Effects through Changes in Prey Availability

Ecological interactions between northern fur seals and groundfish fisheries are caused by spatial and temporal overlap between fur seal foraging areas and groundfish fisheries. The diet of northern fur seals includes a wide range of fish species.

3.19.4.1.2.6 Comparative Baseline

Northern fur seals are numerous. However, they are listed as a "depleted" stock under the MMPA because of major population declines from 1950 to the late 1960s and again from the mid-1970s through the early 1980s. Subsistence hunts make up the great majority of anthropogenic mortality, but these levels are well below PBR. Incidental take in groundfish fisheries hovers around zero. There still is concern about potential competitive interactions for prey.

3.19.4.1.3 Guadalupe furl seal (*Arctocephalus townsendi*)

3.19.4.1.4 California sea lion (*Zalophus californianus*)

3.19.4.1.5 Pacific harbor seal (*Phoca vitulina richardsi*)

3.19.4.1.6 Northern or Steller sea lion *(Eumetopias jubatus)*

3.19.4.2 Sea otters

3.19.4.2.1 Southern (*Enhydra lutris nereis*)

3.19.4.2.2 Washington (*Enhydra lutris kenyoni*)

3.19.4.3 Cetaceans

3.19.4.3.1 Minke whale (*Balaenoptera acutorostrata*)

3.19.4.3.2 Short-finned pilot whale (*Globicephala macrorhynus*)

3.19.4.3.3 Gray whale (*Eschrilchtius robustus*)

3.19.4.3.4 Harbor porpoise (*Phocoena phocoena*)

3.19.4.3.5 Dall's porpoise (*Phocoenoides dalli*)

3.19.4.3.6 Short-beaked common dolphin Pacific white-sided dolphin (*Delphinus delphis*)

3.19.4.3.7 Long-beaked common dolphin (*Delphinus capensis*)

3.20 Seabirds

3.20.1 Potentially Affected Seabirds

The highly productive California Current System supports more than two million breeding seabirds and at least twice that number of migrant visitors. Over 100 species have been recorded within the EEZ, including albatross, shearwaters, petrels, storm-petrels, cormorants, pelicans, gulls, terns, and alcids (murres, murrelets, guillemots, auklets, and puffins). In addition to these seabirds, millions of other birds are seasonally abundant in this oceanic habitat including: waterfowl, waterbirds (loons and grebes), and shorebirds (phalaropes). Not surprisingly, there is considerable overlap of fishing areas and areas of high bird density in this highly productive upwelling system. The species composition and abundance of birds varies spatially and temporally. The highest seabird biomass is found over the continental shelf, and bird density is highest during the spring and fall when local breeding species and migrants predominate.

The US Fish and Wildlife Service (USFWS) is the primary federal agency responsible for seabird conservation and management. Four species found off the Pacific coast are listed under the ESA

(Short-tail albatross (*Phoebastria albatrus*), California brown pelican (*Pelecanus occidentalis*), California least tern (*Sterna artillarum browni*), and Marbled murrelet (*Brachyramphs marmoratus*)). The USFWS has classified several seabird species that occur off the Pacific Coast as "Species of Conservation Concern." These species include the black-footed albatross (*Phoebastria nigripes*), ashy storm-petrel (*Oceanodroma homochroa*), gull-billed tern (*Sterna nilotica*), elegant tern (*Sterna elegans*), arctic tern (*Sterna paradisaea*), black skimmer (*Rynchops niger*), and Xantus's murrelet (*Synthliboramphus hypoleucus*).

Under the MSA, NMFS must ensure fishery management actions comply with other laws designed to protect seabirds. NMFS also is required to consult with USFWS if fishery management plan actions may affect seabird species listed as endangered or threatened.

3.20.2 Condition Indicators for Seabirds

Indicators of the historical and baseline conditions of seabirds in terms of fishery impacts include but are not necessarily limited to incidental takes mortality from vessel strikes, changes in prey availability, ingestion of processing waste and discards, and habitat suitability.

Seabirds are caught incidentally in all types of fishing operations. Table 3-123 provides observer data for West Coast groundfish fisheries for the time period September 2001 to October 2002. The risk of seabirds getting caught in fishing gear varies with the density and behavior of bird species around the fishing vessel, the type of fishing gear used, and the technique and/or devices used, if any, to deter or avoid the birds. Many factors contribute to the abundance and distribution of birds at sea, including the availability of natural prey, but many species are attracted to fishing vessels in order to forage on bait, offal, discards, and natural prey disturbed by fishing operations.

Table 3-123 Interactions between Seabirds and West Coast Groundfish Fisheries Documented by West Coast Groundfish Observers between September 2001 and October 2002.

Species	Gear Type	Type of Interaction
Unidentified Gull(*Larus species*)	Trawl	1 Individual Taken
Unidentified Seabird	Trawl	4 Individuals Taken
Short-tailed Albatross (*Phoebastria albatrus*)	Longline and Trawl	Feeding on Discard
…	…	…

Source: PFMC Bycatch EIS Table 4.3.16, p 4-137

Although more than 100 species of seabirds occur along the West Coast, little information is available about the incidental take of seabirds in West Coast groundfish fisheries. Observers aboard groundfish vessels off the West Coast during August 2001 –October 2002 reported that four cormorants and one gull were taken by the limited entry trawl fleet.

Catcher processors and motherships participating in the Pacific whiting fishery have had full observer coverage since the mid-1970s. The non-whiting portion of the fishery has had observer coverage only since the fall of 2001. Between September 2001 and October 2002, approximately 10% of the coast wide limited entry trawl landed weight was observed.

Seabirds sometimes strike vessels and fishing gear in flight. Some birds fly away without injury but others are injured.

Seabird species differ greatly from one another in their prey requirements and feeding behavior, leading to substantial differences in their responses to changes in the environment. Diets consist largely of fish and squid less than 15 cm long and large zooplankton. Although they may take a wide variety of prey species during the year, most seabirds in a given area and time depend on one or a few prey species. Diets and foraging ranges are most restricted during the breeding season, when high-energy food must be delivered efficiently to nestlings, and are more flexible during other times of the year. Prey availability may also depend on the ecology of food species, including productivity of other predators, food-web relationships of the prey, and prey behavior, such as migration of fish and zooplankton. Many factors that influence prey availability are completely unknown. Most critical is the lack of information on how events beyond a seabirds foraging range may influence prey availability. Such factors may include environmental changes, fluctuations in region wide stocks of forage and non-forage species, and commercial harvest.

Scavenging of fishery wastes can influence seabird populations in either a negative or positive manner. If populations of large gulls increase as a result of waste and discards, local populations of other species may be reduced through increased competition for nest sites and predation pressure on young birds. Further, sudden withdrawal of discards could cause the predatory species to increase pressure on other species long before the predator populations decline. The seabird species whose normal foraging behavior includes scavenging on dead material, may be at risk of either becoming entangled or being incidentally taken in fishing gear.

Fishing vessels can affect seabird populations whether or not the vessels are engaged in fishing or processing activities. Many surface-feeding birds are attracted to vessels, while others may be displaced from foraging areas. The magnitude of the impact depends on the location, timing, and frequency of vessel traffic and on how closely those factors coincide with important foraging areas.

There is some concern that fishing activity, especially trawling, may have detrimental impacts on seabirds by disrupting the schooling behavior of their prey and therefore decreasing their foraging success. The intensity and longevity of trawling impacts on the structure and distribution of forage fish schools are not known. However, given the large number of variables that influence foraging success for different species and the ability of birds to search for prey over large distances, it is unlikely that any localized disruptions of prey fields could be demonstrated to have specific adverse effects on birds. There is evidence that some forms of trawling may make fish vulnerable to diving birds by disturbing or injuring the fish.

3.20.3 Data

Information useful to this analysis is available in various agency reports, and the PFMC's Bycatch and EFH EISs.

3.20.4 Past and Present Conditions of Seabirds

The format below for describing historical and baseline conditions will be repeated for all potentially affected seabird species.

3.20.4.1 Albatross

3.20.4.1.1 Life History and Distribution

Albatross range extensively throughout waters off the Pacific Coast. In particular, three species, the short-tailed albatross (*Phoebastria albatrus*), the black-footed albatross (*Phoebastria nigripes*), and the Laysan albatross (*Phoebastria immutabilis*) occur in the waters off Washington, Oregon, and California.

Short-tailed albatross

The short-tailed albatross is a very large seabird with narrow, seven-foot-long wings adapted for soaring low over the ocean. Young birds are chocolate brown, gradually turning white as they grow older. Adult short-tailed albatross have an entirely white back, white or pale yellow head and back of the neck, and black and white wings. Their large pink bill is hooked at the end with a blue tip. Presently, these birds nest on two islands in Japan, Torishima and Kinami-kojima. Single eggs are laid in October and November, chicks hatch in December through February, and the young fledge from May to July. Immature birds wander across the North Pacific until they begin breeding at 6 to 9 years of age.

Once considered the most common albatross ranging over the continental shelf, the short-tailed albatross was hunted to near extinction in the early 1900s. It is now thought to be one of the rarest birds in the world. Relatively little is know about seasonal movements or factors determining marine distribution of short-tailed albatross. It is believed that the species was formerly common off China, in the Sea of Japan, the Sea of Okhotsk, the Bering Sea north to the Bering Strait, and throughout the enter temperate North Pacific, from Alaska to Baja California.

Black-footed albatross

Much like the short-tailed albatross, the black-footed albatross ranges throughout the North Pacific. It is the most abundant albatross species along the Pacific Coast and is present throughout the year. Breeding occurs in the Northwestern Hawaiian Islands and Torishima Island, and the species disperses from the Bering Sea south along the West Coast to California

Laysan albatross

The Laysan albatross, also known as the “gooney bird,” is a large white and black seabird with a wingspan that reaches 85 inches. The most abundant North Pacific albatross is the Laysan albatross. The vast majority of the Laysan albatross population breeds in the Northwestern Hawaiian Islands, fewer numbers breed on the Japanese Ogasawara Islands, and fewer pairs breed on islands off Baja California, Mexico. They range, when at sea, from the Bering Sea, to California and to Japan. They are monogamous and if one of the mates should die it may be several years before the survivor can make a new pair bond. Only one egg is laid per year. Similar to the other North Pacific albatross species, Laysan albatross feed on schooling fish and squid at the ocean’s surface.

3.20.4.1.2 Population Trends

Short-tailed albatross

Historical records indicate that there were over 100,000 individuals at the Torishima Island colony at the turn of the century and during 1998 and 1999 just over 400 breeding adults were found at the colony. The population on Torishima Island is now growing at an annual rate of 7.8%. The current estimate of the short-tailed albatross world population is about 1700 individuals.

Black-footed albatross

The global black-footed albatross population is estimated at about 56,600 breeding pairs and thought to be decreasing. This species is classified as vulnerable by the IUCN (International Union for the Conservation of Nature and Natural Resources) based on a 19% population decrease during 1995 to 2000 and a projected future decline of more than 20% over the next 60 years owing to interactions with longline fisheries for tuna, billfish, and groundfish in the North Pacific.

Laysan albatross

The USFWS counts Laysan albatross at Midway Atoll once every four years and counts birds or samples density at French Frigate Shoals and Laysan Island every year. These monitoring sites account for 93% of the world population of about 393,000 breeding pairs. At these three sites breeding populations have declined at an average rate of 3.2% per year since 1992.

3.20.4.1.3 Trophic Interactions

Short-tailed albatross

Short-tailed albatross forage at the water's surface on squid, crustaceans, and various fish species. They forage along the edge of the continental shelf and on the outer shelf where upwelling brings their prey to the surface. They may forage at night, as well as, during the day. Since they range widely over the ocean and are opportunistic feeders, their diet varies with local availability. Albatross are attracted to fishery wastes released from fishing vessels and processors and are vulnerable to being caught in fishing gear, especially on baited hooks longline fisheries.

Black-footed albatross

Black-footed albatross prey on fish, sea urchins, amphipods, and squid. Foraging is done at night and prey is caught at the ocean's surface. This species will follow fishing vessels and consume discards. Besides interactions with longline gear, other threats to black-footed albatross include nest loss due to waves, pollution, introduced predators, oiling, ingestion of plastic and volcanic eruptions on Torishima Island.

Laysan albatross

Cephalopods play a major role in the diet of Laysan albatross. Squid are the most important food item, although which species are eaten is poorly known. Few observations have been published about their feeding in the wild, other than of those birds scavenging near fishing vessels. They take food in the upper meter of the ocean's surface. In addition to squid, other food items include myctophids, other invertebrates and fish. Similar to the other North Pacific albatross species, Laysan albatross feed on schooling fish and squid at the ocean's surface.

3.20.4.1.4 Management Overview

Short-tailed albatross

Management responsibility for the short-tailed albatross is under the jurisdiction of the USFWS. The short-tailed albatross was originally designated as "endangered" under the Endangered Species Conservation Act of 1969 as a foreign-listed species (because they do not nest in US territory). In 1973, when the ESA replaced the 1969 Act, the short-tailed albatross was included as a foreign species but not as a native species. This created an administrative error by listing its status as endangered elsewhere except in the US The USFWS corrected the error by extending the species' endangered status to include its range within the US The proposed and final rules contain extensive information on the species life history, demographics, and population status (USFWS 1998a and 2000c).

At the time a species is proposed for listing under the ESA, critical habitat can also be proposed. Habitats outside the US are not eligible for critical habitat designation. Because the North Pacific Ocean and Bering Sea once supported millions of short-tailed albatross, USFWS scientists believe that this species is nowhere near its habitat carrying capacity. NMFS determined that designation of critical habitat within the US would not be beneficial to the short-tailed albatross (USFWS 1998a and 2000c).

Under the requirements of the ESA, the USFWS is responsible for determining whether proposed federal actions are likely to jeopardize the recovery of the species.

Black-footed albatross

Wildlife management responsibility for the black-footed albatross falls under the jurisdiction of the USFWS. Most research on the species has taken place in their northwest Hawaiian breeding colonies. Black-footed albatross have been assigned "vulnerable" status on the World Conservation Union's Red List of Threatened Species because of reported declines in numbers on their breeding colonies.

Laysan albatross

Wildlife management responsibilities for Laysan albatross fall under the jurisdiction of the USFWS. The species is protected under the US Migratory Bird Treaty Act.

3.20.4.1.5 Past and Present Effects and Management Actions

3.20.4.1.5.1 Direct Mortality from Incidental Takes in West Coast MSA Groundfish Fisheries

Short-tail albatross

No short-tailed albatross have been recorded as being taken in the groundfish trawl fishery. Short-tail albatross have been reported to be taken by vessels using hook-and line gear. Because incidental catch is so small, estimation of the total take is problematic. Uncertainty exists on how the known take should be expanded to the unobserved portion of fisheries.

Black-footed albatross

Laysan albatross

3.20.4.1.5.2 Direct Mortality from Vessel Strikes

Short-tailed albatross

Many trawl vessels deploy a cable ("third wire") from the vessels to the trawl net monitoring device (sonar transducers). These cables are not typically monitored by groundfish observers and any birds killed by such collisions would not be likely to make their way into the trawl net and would therefore not be recorded in the observers haul sample. The distribution and extent of seabird mortalities or injuries by species is therefore unknown.

Black-footed albatross

Laysan albatross

3.20.4.1.5.3 Changes in Prey Availability

Short-tailed albatross

The impacts of groundfish and other fisheries on the availability of prey to short-tailed albatross are unknown. The ability of albatross to forage over huge areas is presumed to lessen the potential impact of localized depletion of prey. The fact that the short-tailed albatross population is growing at or near its theoretical maximum rate and the environment used to support millions of them, it is thought that food availability is not a limited at present (USFWS 2000c).

Black-footed albatross

Laysan albatross

3.20.4.1.5.4 Consumption of Fishery Discards

Short-tailed albatross

Short-tailed albatross are attracted to fishing vessels and processors to eat discards and offal. Benefits of the food source are countered by an increased risk of incidental take.

Black-footed albatross

Laysan albatross

3.20.4.1.6 Comparative Baseline

Short-tailed albatross

Short-tailed albatross were nearly exterminated by commercial hunting about 100 years ago but are making a comeback. The population appears to be increasing at a near-maximum rate. They still are one of the rarest species on earth with an estimated population of only 1600 to 1700 birds. They are listed as “endangered” under the ESA. Recent scientific research indicates that new seabird avoidance techniques can greatly reduce the incidental take of species with similar feeding behavior as short-tailed albatross.

Black-footed albatross

Black-footed albatross is the most numerous albatross species along the Pacific Coast. There were an estimated 300,000 black-footed albatross in the world as of 2001. However, their numbers have declined over the past ten years. This species is classified as “vulnerable” by the IUCN (International Union for the Conservation of Nature and Natural Resources) based on a 19% population decrease during 1995-2000 and a projected future decline of more than 20% over about the next 60 years owing to interactions with longline fisheries. The species faces serious threats from incidental take in longline fisheries throughout its range, especially by foreign tuna and swordfish pelagic longline fisheries in the Central and North Pacific.

Laysan albatross

The most abundant North Pacific albatross species is the Laysan albatross. At three main monitoring sites, Midway Atoll, French Frigate Shoals and Laysan Island, breeding populations have declined at an average rate of 3.2% per year since 1992.

3.20.4.2 California brown pelican

3.20.4.3 Northern Fulmars

3.20.4.4 Shearwaters

3.20.4.5 Cormorants

3.20.4.6 Puffins

3.21 Other Protected Resources

3.21.1 Potentially Affected Other Protected Species

Protected species fall under three overlapping categories reflecting four mandates: the Endangered Species Act of 1973 (ESA), the Marine Mammal Protection Act of 1972 (MMPA), the Migratory Bird Treaty Act (MBTA), and EO 13186. Groundfish fisheries may interact with these species, causing mortality or harming to them. Different protected species are affected by a variety of gear types. For example, ESA-listed salmon stocks are caught in mid-water trawl fisheries targeting Pacific whiting.

Several species of marine mammals, seabirds, sea turtles and salmon on the West Coast have been listed as threatened or endangered under the ESA. A species is listed as “endangered” if it is in danger of extinction throughout a significant portion of its range and “threatened” if it is likely to become an endangered species within the foreseeable future throughout all, or a significant portion, of its range. Species subject to conservation and management requirements of the ESA are identified below.

3.21.2 Condition Indicators for Other Protected Species

Indicators of the historical and baseline conditions of Other Protected Species in terms of fishery impacts include but are not necessarily limited to the following:

It is possible that the effects of management action on protected species correlate with changes in the level of fishing effort. Increased fishing effort, other things held constant, could lead to an increase in interactions between fishing vessels and protected species, while a decrease in fishing effort would have the opposite effect. Thus, changes in fishing effort could be one way to evaluate the relative effects of the alternatives. However, there are limited data available on the distribution, intensity, and duration of fishing effort associated with groundfish. If such data are available, the distribution and intensity level of fishing effort will have to be correlated with the distribution of protected species to determine effects.

In addition to the quantity of effort expended by harvesters, the spatial and temporal distribution of the catch is off interest. This interest stems from the possibility of the fishery moving into areas and taking place during times of the year that alters the characteristics of fishery/other protected resource interactions. Prey availability and habitat suitability are also considered important indicators of change.

3.21.3 Data

Information useful to this analysis is available in various agency reports, and the PFMC's Bycatch and EFH EISs.

3.21.4 Past and Present Conditions of Other Protected Resources

Since marine mammal and seabird species that are protected were discussed in their respective sections of this chapter, attention is focused on salmon and sea turtles.

3.21.4.1 Sea Turtles

Numerous human-induced factors have adversely affected sea turtle populations in the North Pacific and resulted in their threatened or endangered status. Documented incidental capture and mortality by purse seines, gillnets, trawls, longline fisheries, and other types of fishing gear adversely affect sea turtles. However, the relative effect of each of these sources of impacts on sea turtles is difficult to assess. Sea turtle species that might interact with groundfish fisheries are discussed below.

3.21.4.1.1 Leatherback Sea turtles

The format below for describing historical and baseline conditions will be repeated for all Other Protected Species.

3.21.4.1.1.1 Life History and Distribution

Leatherback turtles are the largest sea turtles in the world, reaching a shell length of 1.6 m and a mass of 700 kg. They reach sexual maturity at an estimated age of 13 to 14 years for females and live for more than 30 years. Leatherbacks must surface to breathe air, but can stay submerged for two hours and dive to 1,000 m. Males do not leave the ocean, but females come ashore on open sandy beaches to dig nests and lay eggs. Nestlings emerge from the sand at night and attempt to make their way to the sea. Very little is known about the distribution and natural history of these young turtles after they leave their natal beaches.

Leatherback turtles are widely distributed throughout the world's oceans. In the Pacific Ocean, they range as far north as Alaska and as far south as Chile and New Zealand. The Pacific Coast of Mexico is regarded as the most important breeding ground for nesting leatherback turtles in the world. No nesting is known to occur in US waters of the Pacific.

Leatherback turtles undertake long migrations and exhibit broad thermal tolerances. They have been found in waters ranging from 7 to 27 degrees C. They are typically associated with continental shelf habitats and pelagic environments.

3.21.4.1.1.2 Population Trends

Estimating the population size of this species is especially difficult because individuals are widely dispersed and males never come ashore. Population estimates are usually based on the number of females seen on nesting beaches.

3.21.4.1.1.3 Trophic Interactions

Leatherback turtles feed predominately on jellyfish and other large planktonic species. There is little information available on their diet in subarctic waters. To a large extent, the oceanic distribution may reflect the distribution and abundance of their planktonic prey. Nestling and juvenile turtles fall prey to a host of bird, mammal, and fish species throughout their range.

3.21.4.1.1.4 Management Overview

NMFS and the USFWS share responsibilities at the federal level for the research, management, and recovery of Pacific sea turtle populations under US jurisdiction. The leatherback turtle was listed as endangered under the ESA in June of 1970. NMFS and USFWS have created a joint Pacific Sea Turtle Recovery team to develop a recovery plan for the species. Under the requirements of the ESA, these agencies are responsible for issuing Section 7 consultations for federal action that may impact the species.

Leatherback turtles are classified as Critically Endangered in the *Red List of Threatened Species*, where taxa classified are considered to be "facing an extremely high risk of extinction in the wild in the immediate future." In October of 2000, the US ratified the Inter-American Convention for the Protection and Conservation of Sea Turtles. This treaty is the first international agreement dedicated solely to raising standards for the protection of sea turtles.

3.21.4.1.1.5 Past and Present Effects and Management Actions

Direct and Indirect Effects of External Fisheries

Commercial fisheries have affected leatherback turtles. The primary threats are entanglement in fishing gear (e.g. longlines, driftnets and etc.), boat collisions, and contamination by oil spills, and ingestion of marine debris. Spotila et al. (2000) indicates that a conservative estimate of annual leatherback fishery-related mortality (from longlines, trawls and gillnets) in the Pacific during the 1990s was 1,500 animals. They estimate that this represented about a 23 percent mortality rate.

Direct and Indirect Effects of Groundfish Fisheries

Little is known about the interactions between sea turtles and West Coast fisheries. Directed fishing for sea turtles in West Coast groundfish fisheries is prohibited because of their ESA listings. However, incidental takes of sea turtles by longlines and trawls can occur.

According to NMFS, there have been no direct takes of leatherbacks in the West Coast groundfish fisheries. Further, there is no fishery that is targeting the prey of this species. NMFS has concluded that the direct and indirect effects of commercial fisheries on leatherback turtles are negligible and not likely to jeopardize its survival or recovery.

3.21.4.1.1.6 Comparative Baseline

Leather back turtle populations are in serious decline around the world, largely due to many human-related sources of mortality. All of them must be addressed, if this species is to recover for the brink of extinction. However, some commercial fisheries have played a role in the decline of this species.

3.21.4.1.2 Olive Ridley sea turtle

3.21.4.1.3 Loggerhead sea turtle

3.21.4.1.4 Green sea turtle

3.21.4.2 Salmon

Chinook or king salmon (*Oncorhynchus tshawytscha*) and coho or silver salmon (*O. Kisutch*) are the main species caught in Council-managed ocean salmon fisheries. Therefore the discussion focuses on these two species

3.22 Habitat

3.22.1 Potentially Affected Habitat

Healthy marine habitat is basic to the wellbeing of marine species and their place in the food web (http://www.pcouncil.org/groundfish/gfefheis/chp3affenvi.pdf). The marine habitats of the West Coast support living marine resources at the most fundamental level by providing the conditions necessary for populations to sustain themselves. From a broad perspective, habitat is the geographic area, and the characteristics of that area, where the species occurs at any time during its life. Habitat characteristics comprise a variety of attributes and scales, including physical (geological), biological, and chemical parameters, location, and time. It is the interactions between environmental variables that make up habitat that determine a species' biological niche. These variables include both physical variables such as depth, substrate, temperature range, salinity, and dissolved oxygen, and biological variables such as the presence of competitors, predators, or facilitators.

Habitat use by species subject to trawl fisheries extends out to the deepest depth observed for groundfish, or 3400 m (EFH EIS Ch. 2 http://www.nwr.noaa.gov/Groundfish-Halibut/Groundfish-Fishery-Management/NEPA-Documents/EFH-Final-EIS.cfm). As a result, the habitat resource category covers extensive areas of the Pacific coast. However, not all of this area may have the same value for groundfish or the trawl industry. We have identified two sub categories of habitat that may have interactions with the trawl industry: essential fish habitat (EFH)/habitat areas of particular concern (HAPC), and marine protected areas (MPA)/marine areas closed to trawling. Regulations restrict trawling in some portions of these habitat categories, but fishermen may access them if allowed to change gear under an IFQ system.

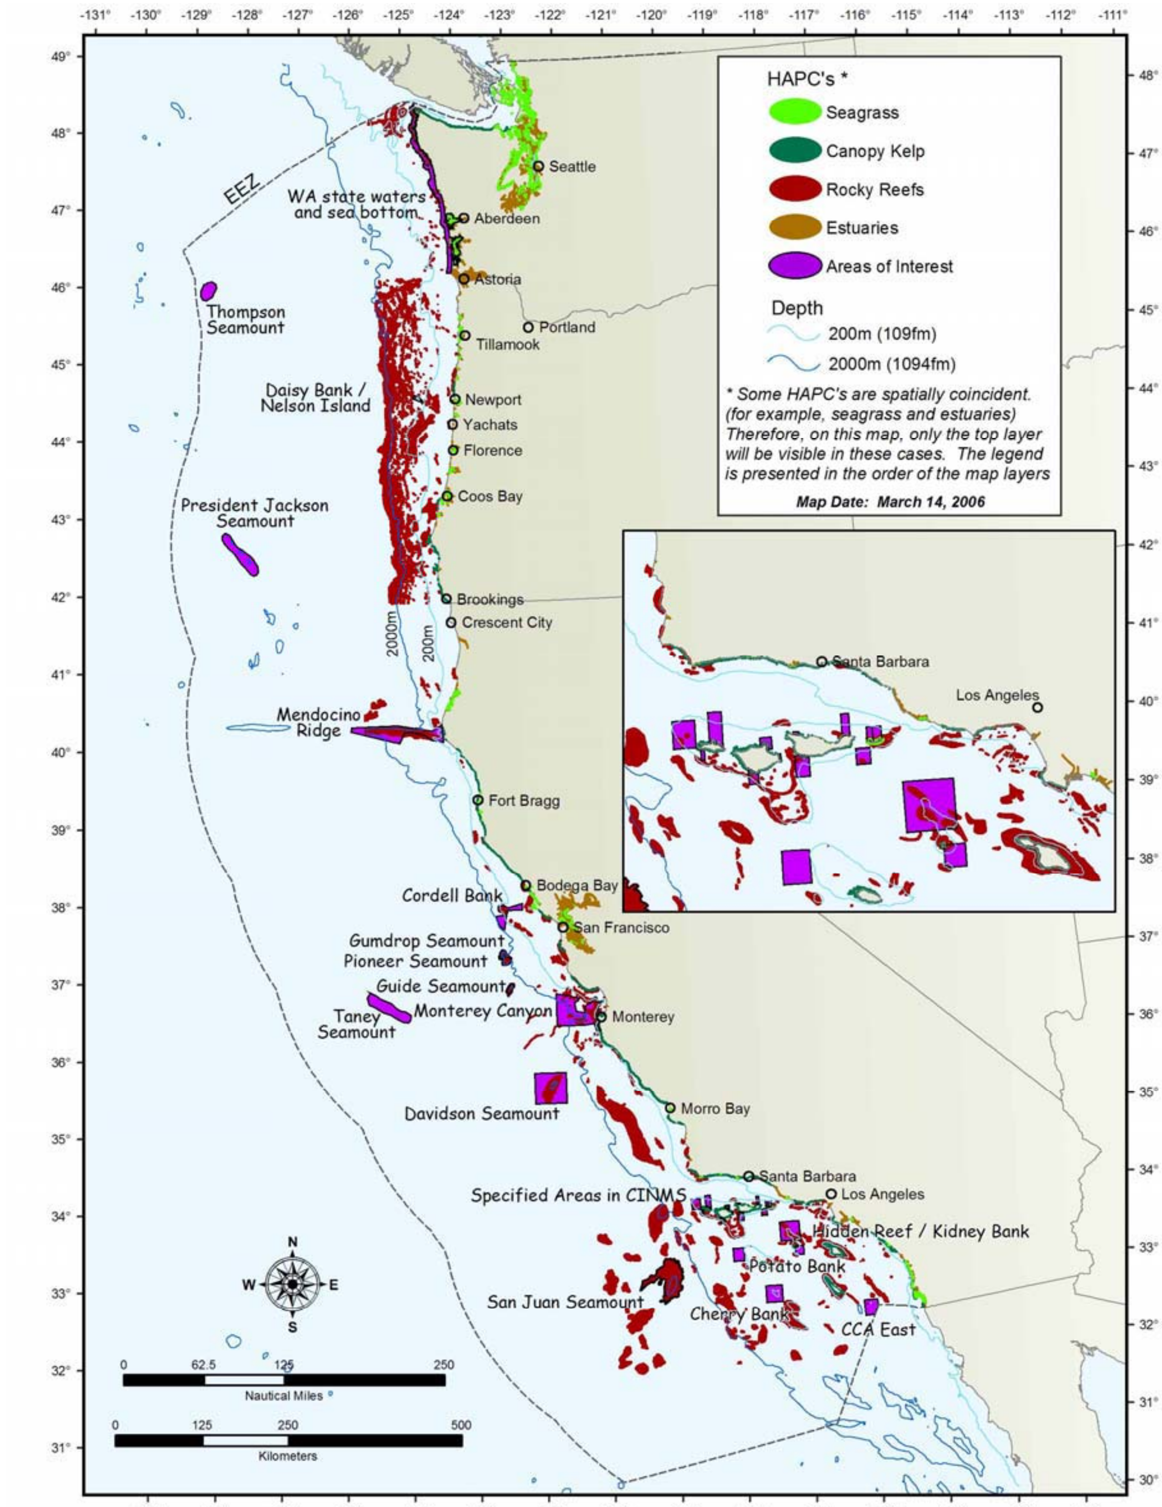
3.22.1.1 Essential Fish Habitat/Habitat Areas of Particular Concern

The MSA establishes a requirement for regional councils and NMFS to describe and identify EFH (Section 303(a)(7), Section 305(b)), and NMFS published regulations to guide Councils in this action (50 CFR part 600; subpart J). The Pacific Council and NOAA Fisheries have prepared an EIS for EFH (http://www.nwr.noaa.gov/Groundfish-Halibut/Groundfish-Fishery-Management/NEPA-Documents/EFH-Final-EIS.cfm) that formed the basis of Amendment 19 that described and identified EFH for the Pacific Region (http://www.pcouncil.org/groundfish/gffmp/gfa19/A18-19Final.pdf). The decision for EFH was based on runs of a model that calculated habitat suitability for species and life stages (EFH EIS); the model calculated a habitat suitability probability (HSP) that formed the basis for various alternatives. The overall extent of groundfish EFH for all FMU species is identified as all waters and substrate within the following areas:

- Depths less than or equal to 3,500 m (1,914 fathoms) to mean higher high water level (MHHW) or the upriver extent of saltwater intrusion, defined as upstream and landward to where ocean-derived salts measure less than 0.5 ppt during the period of average annual low flow.
- Seamounts in depths greater than 3,500 m as mapped in the EFH assessment GIS.
- Areas designated as HAPCs not already identified by the above criteria.

The following subsection describes the five HAPCs established under Amendment 19. Figure 7.2 in the final EIS for Amendment 19 provides a graphic description of the HAPCs and is reproduced here as Figure 3-19. One type of HAPC—the oil platform HAPC—was included in the amendment approved by the Council, but was not approved as part of the final amendment, and therefore is not included in the figure.

Figure 3-19. HAPCs Designated in Amendment 19



Source: This figure is reproduced from Figure 7.2 of the EIS for Amendment 19.

3.22.1.1.1 Estuaries

Estuaries are protected nearshore areas such as bays, sounds, inlets, and river mouths, influenced by ocean and freshwater. Tidal cycles and freshwater runoff varies salinity within estuaries and results in great diversity, offering freshwater, brackish and marine habitats within close proximity (Haertel and Osterberg 1967). Estuaries tend to be shallow, protected, nutrient rich, and biologically productive, providing important habitat for marine organisms, including groundfish. For many fish species, estuaries provide important habitats for reproduction, feeding, and refuge (Gunter 1957). These important ecological functions are vulnerable to damage from a wide range of human activities because estuaries receive runoff from adjacent land areas and are often close to human population centers. Anthropogenic impacts to estuaries may include nutrient loading, introduction of non-native species, changes in water temperature, increased turbidity etc.

3.22.1.1.2 Canopy Kelp

Of the habitats associated with the rocky shelf habitat composite, kelp forests are of primary importance to the ecosystem and serve as important groundfish habitat. Lush kelp forest communities (e.g., giant kelp, bull kelp, elk kelp, and feather boa kelp) are found relatively close to shore along the open coast. On the rocky shelf, these subtidal communities provide vertically-structured habitat through the water column; a canopy of tangled blades from the surface to a depth of 10 feet; a water column, stipe region and the bottom, holdfast region. The stands provide nurseries, feeding grounds and shelter to a variety of groundfish species and their prey (Ebeling, et al. 1980; Feder, et al. 1974). Giant kelp communities are highly productive relative to other habitats, including wetlands, shallow and deep sand bottoms, and rock bottom artificial reefs (Bond *et al.*, 1998). Their net primary production is an important component to the energy flow within food webs. Foster and Schiel (1985) reported that the net primary productivity of kelp beds may be the highest of any marine community. The net primary production of seaweeds in a kelp forest is available to consumers in three forms: living tissue on attached plants; drift in the form of whole plants or detached pieces; and dissolved organic matter exuded by attached and drifting plants (Foster and Schiel 1985).

3.22.1.1.3 Seagrass

Seagrass species found on the West Coast of the US include eelgrass (*Zostera spp*., *Ruppia sp*.) and surfgrass (*Phyllospadix spp*.). These grasses are vascular plants, not seaweeds, forming dense beds of leafy shoots year-round in the lower intertidal and subtidal areas. Eelgrass is found on soft-bottom substrates in intertidal and shallow subtidal areas of estuaries. Surfgrass is found on hard-bottom substrates along higher energy coasts. Studies have shown seagrass beds to be among the areas of highest primary productivity in the world (Herke and Rogers 1993; Hoss and Thayer 1993). High primary production, results in high rates of secondary production (Emmett, et al. 1991; Good 1987; Herke and Rogers 1993; Sogard and Able 1991). Seagrasses also provide habitat for many invertebrates and epiphytes and provide many crustaceans, fish, and birds with protection and food. Several commercially important species use seagrass beds including Dungeness crab (Spencer 1932) and Pacific herring (Taylor, 1964). Pacific coast seagrasses have been shown to be vulnerable to anthropogenically introduced species of seagrasses such as *Spartina alterniflora* (Taylor et al. 2004) and *Zostera japonica* (Harrison and Bigley 1982).

3.22.1.1.4 Rocky Reefs

Rocky habitats are generally categorized as either nearshore or offshore in reference to the proximity of the habitat to the coastline. Rocky habitat may be composed of bedrock, boulders, or smaller rocks such as cobble and gravel. Hard substrates are one of the least abundant benthic habitats, yet they are among the most important habitats for groundfish. Typical shallow water hard bottom fishes include rockfish (e.g. *Sebastes spp*.), lingcod, and sculpins (MMS 2002). Managed species known to use nearshore hard bottom habitat in the coastal zone include black rockfish, black-and-yellow rockfish, brown rockfish, cabezon, calico rockfish, California scorpionfish, chilipepper, copper rockfish, gopher rockfish, kelp greenling, leopard shark, lingcod, olive rockfish, quillback rockfish, redstripe rockfish, rosethorn rockfish, shortbelly rockfish, silvergray rockfish, and spotted ratfish. In the offshore area, many managed species are dependent on hard bottom habitat during some portion of their life cycle. Typically, deeper water hard bottom habitats are inhabited by large, mobile fishes such as rockfish, sablefish, Pacific hake, spotted ratfish, and spiny dogfish (MMS 2002). Cross and Allen (1993) estimated that about 30 percent of the fish species and 40 percent of the families occur over hard substrates. Fishing with certain gear types can modify rocky habitat and have a negative impact on plants and animals found there.

3.22.1.1.5 Areas of interest

Areas of interest are discrete areas that are of special interest due to their unique geological and ecological characteristics. The following areas of interest are designated HAPCs:

- Off of Washington: All waters and sea bottom in state waters shoreward from the three nautical mile boundary of the territorial sea shoreward to MHHW.
- Off of Oregon: Daisy Bank/Nelson Island, Thompson Seamount, President Jackson Seamount.
- Off of California: all seamounts, including Gumdrop Seamount, Pioneer Seamount, Guide Seamount, Taney Seamount, Davidson Seamount, and San Juan Seamount; Mendocino Ridge; Cordell Bank; Monterey Canyon; specific areas in the federal waters of the CINMS; specific areas of the Cowcod Conservation Area.

3.22.1.2 Marine Protected Areas and Areas Closed to Trawling

Marine protected area (MPA) is a broad term describing a managed area in the marine environment that provides some level of resource protection. MPAs are a management tool that may employ a range of strategies to protect the marine environment—from prohibiting the harvesting of all marine life, to allowing the take of only selected marine species, or restricting other kinds of human uses. Besides having different levels of protection and use, MPAs vary dramatically in size and shape, protect a range of natural or cultural resources, and are designated by a variety of authorities. The federal government, individual states, and jurisdictions within states may specify MPAs within their jurisdictions. The national MPA center http://mpa.gov has developed a database of MPAs (http://www.mpa.gov/inventory/inventory.html) that allow searches by jurisdiction. For purposes of this project, we will identify MPAs in federal waters, and indicate whether each MPA restricts fishing activity.

Marine areas closed to trawling are a specific type of MPA. As part of the EFH process to address adverse fishing impacts, the Pacific Council has proposed 41 potential trawl closure areas. Marine Protected Areas and areas closed to trawling or bottom contact gear may also be affected by the changes in the distribution of trawl effort. The three tables below list marine sanctuaries and other protected areas that may be affected. [28]

[28] Closed areas described in Table 3-125 and Table 3-126 were provided in a comment from Merrick Burden to the November 28 *Analytical Framework*.

Table 3-124. Marine Sanctuaries and other Protected Areas

Area Designation	Agency
Olympic Coast National Marine Sanctuary	National Oceanic and Atmospheric Administration
Monterey Bay National Marine Sanctuary	National Oceanic and Atmospheric Administration
Gulf of the Farallones National Marine Sanctuary	National Oceanic and Atmospheric Administration
Channel Islands National Marine Sanctuary	National Oceanic and Atmospheric Administration
Yelloweye Rockfish Conservation Area	NOAA – NMFS
Columbia River Salmon Conservation Zone	NOAA – NMFS
Klamath River Salmon Conservation Zone	NOAA – NMFS
Western and Eastern Cowcod Conservation Areas	NOAA – NMFS

	Carrington Point	Painted Cove	South Point.
	Footprint	Richardson Rock	Davidson Seamount

3.22.2 Condition Indicators for Habitat

Indicators of the historical and baseline conditions of habitat in terms of fishery impacts include but are not necessarily limited to the following:

- Amount of gear interactions with habitat by gear
- Location of interactions with habitat
- Habitat type affected

The conditions of habitat are not likely to be measurable by quantifiable indicators.

3.22.3 Data

The assessment consolidates the best available ecological, environmental, and fisheries information into various databases, including a geographic information system (GIS) and the habitat use database (HUD). The following types of data were used in this process to identify groundfish EFH:

- Geological substrate (GIS)
- Estuaries (GIS)
- Canopy kelp (GIS)
- Seagrass (GIS)
- Structure-forming invertebrate information
- Bathymetric data (GIS)
- Latitude (GIS)
- Information on pelagic habitat
- Data quality (GIS and other databases)
- Information on the functional relationships between fish and habitat (including a literature review consolidated in the HUD).

An expert panel developed the following six habitat categories, each with one or more habitat types:

Habitat Category	Habitat type
Nearshore biogenic	Estuarine macrophyte
	Estuarine shellfish
Nearshore unconsolidated bottom	Soft bottom
Nearshore hard bottom	Hard bottom
Offshore biogenic	Macrophyte
	Shelf shellfish
	Shelf sponge
	Slope sponge
	Shelf coral
	Slope coral
	Ridge
	Basin
	Continental rise
Offshore unconsolidated bottom	Shelf soft bottom
	Shelf canyons, gullies, and ice formed features
	Ridge
	Slope canyons, gullies, and ice formed features
	Continental rise, canyons, gullies, and landslides
Offshore hard bottom	Canyon and ice formed features
	Exposure
	Slope canyons, gullies, landslides, and exposures
	Basin

The EFH EIS describes and maps the various habitats found in the Pacific Region. A GIS database contains the geographical delineation of each parcel of habitat, over which other information may be overlain.

The EFH EIS contains the available information for the use of each habitat parcel by each life stage of the fish species addressed in the Groundfish FMP. Maps of probabilities of habitat use by species and life stages are available through the NOAA Fisheries Northwest Regional Office.

The EIS contains the available information relevant to habitat impacts of fishing activities. The EIS describes the gear types used in the Pacific region and their habitat impacts. Of the suite of gears, trawl (pelagic and non-pelagic) is the primary gear of interest as this document specifically addresses trawling. Hook and line gear, especially longline, and pot gear are also important as some alternatives may allow fishermen to change from trawling to other gears. Longline and pots are the most likely substitute gears for catching species targeted by trawling.

Statistical areas for catch reporting are too large to provide sufficient detail for attributing fishing effort to specific habitat parcels. As a trawl IFQ program could lead fishermen to change fishing locations, a mechanism to estimate the spatial distribution of fishing effort will be necessary to evaluate the impacts of redistribution of fishing effort.

3.22.4 Past and Present Conditions of Habitat

The information available for habitat is provided in the EFH EIS (http://www.nwr.noaa.gov/Groundfish-Halibut/Groundfish-Fishery Management/NEPA-Documents/EFH-Final-EIS.cfm). Geographic information in the Pacific Region consists of parcels of habitat category and habitat type in the GIS database. The available information does not permit evaluation of past conditions or trends in condition. The available information describes the habitat types and their utilization by organisms, but does not assess the quality of the habitats in terms of disturbance or degradation from original condition.

3.23 Trophic Relationships

3.23.1 Potentially Affected Trophic Relationships

3.23.1.1 Predators

Groundfish species may be preyed upon by a number of different organisms depending on the life stage in question (http://www.pcouncil.org/groundfish/gfefheis/chp3affenvi.pdf). The eggs of groundfish species may be consumed by various planktivores and benthic predators (e.g. gastropods, crabs, fishes, echinoderms). Larvae and juveniles are taken by sea birds, porpoises, larger life stages of groundfish, chaetognaths, and invertebrates (e.g. siphonophores, jellyfishes). Adults of managed groundfish species are preyed upon by man, sharks, marine mammals (e.g. sea lions, seals, whales, dolphins, porpoises, and otters), halibut, albacore, salmon, and other larger predatory groundfish such as cabezon, lingcod, and sablefish. These groundfish predators either occupy the same habitats as their groundfish prey or encounter those habitats in the course of hunting over larger areas of ocean territory.

There is some concern that the biological environment has been directly affected by fishing and other marine harvesting activities that remove top-level predators. For example, several recent studies have suggested that removal of whales and other marine mammals has created cascading effects throughout marine food webs. From an ecosystem perspective, human fishing activities might be viewed as large-scale predation that consumes species at a variety of trophic levels and may also affect other trophic levels directly or indirectly. Effects of fishing on species abundance, species diversity, community structure and physical environment have been described in numerous studies. For example, top predators may be removed, resulting in increases of species lower in the food web. Fishing practices can also affect habitats, community structure and biodiversity. The cumulative effects of 100 years of West Coast groundfish fishing (and fishing for other species) have helped shape present day ecosystem structure. Forage species (including groundfish and non-groundfish) captured in the course of groundfish fishing may be removed from the environment. Top-level predator species may also be removed, resulting in increases of their prey species. Or, their competitors may increase, making it difficult to regain their previous position in the hierarchy. In either case, fishing increases the mortality rate of "unfished" populations. These and other changes could alter trophic dynamics, abundance and biodiversity of the ecosystem. It is difficult, however, to separate many of these fisheries-related changes from environmental ones. See the Life History Appendix to the FMP and the Habitat Use Database for detailed information on the known predators of each species in the groundfish FMU.

3.23.1.2 Prey

Major prey items of managed groundfish species include copepod eggs, copepod nauplii, amphipods, diatoms, dinoflagellates, tintinnids, cladocerans, fish and invertebrate eggs and larvae, mysids, ophiuroids, tunicates, worms (e.g. annelids and polychaetes), shrimp, decapod crustaceans, bivalve mollusks, squids and octopi, euphausiids, pelagic fishes (e.g. anchovies, smelt, lanternfishes, and herring), sculpins, juvenile flatfishes, juvenile rockfishes, and other small fishes (http://www.pcouncil.org/groundfish/gfefheis/chp3affenvi.pdf). These prey occupy the same habitats as the groundfish species/life stage that prey upon them. There is usually a dietary progression in groundfish coinciding with ontogeny, which generally begins with the consumption of zooplankton during early life stages and culminates with the consumption of crustaceans, bivalves, cephalopods and/or fishes in the adult life stage. The various species/life stages of groundfish take prey by a wide range of strategies including planktivory, sit and wait predation, and active predation on sedentary or mobile prey items. Some groundfish species feed throughout the diel cycle, some feed diurnally, and others are nocturnal hunters. Groundfish diets may shift in response to seasonal variations in prey abundance. Cannibalism on various life stages is known to occur in some groundfish such as the macrourids, cabezon, kelp greenling, gopher rockfish, Pacific whiting, rock and petrale sole. See the Life History Appendix to the FMP and the Habitat Use Database for detailed information on the trophic interactions of each species in the groundfish FMU.

3.23.2 Condition Indicators for Trophic Relationships

Indicators of the historical and baseline conditions of trophic relationships in terms of fishery impacts include but are not necessarily limited to the following:

- Prey abundance
- Predator abundance
- Average trophic level

The conditions of trophic relationships are not likely to be measurable by quantifiable indicators.

3.23.3 Data

Most research dealing with predator-prey relationships in the Pacific Region deals with coastal survival of salmon, and evaluating how oceanic and climate process affect primary and secondary productivity and the connection to juvenile salmon growth and survival in the California Current (e.g., http://www.nwfsc.noaa.gov/research/divisions/fed/oceanecology.cfm). Various ecosystem modeling approaches, such as Ecopath/Ecosim, have been used for these studies. These models require data on abundance and distribution of lower trophic level species, especially those important to salmon. Similar data for non-coastal-salmon appears less readily available. For example, the EIS for EFH described predators and prey for the west coast groundfish but discussed predator-prey relationships only generally. The Stock Assessment and Fishery Evaluation document for the west coast groundfish did not specifically address ecosystem issues, which would include predator-prey relationships.

3.2.2 Past and Present Condition of Trophic Relationships

A summary of information available for predator-prey interactions is provided in the EFH EIS (http://www.nwr.noaa.gov/Groundfish-Halibut/Groundfish-Fishery-Management/NEPA-Documents/EFH-Final-EIS.cfm. The available information does not permit evaluation of past conditions or trends in condition. The available information describes the predators and prey of Pacific coast groundfish, but does not assess the status of the species involved in terms of disturbance or degradation from the original condition.

4 Effects of Alternatives

This section forms the scientific and analytic basis for the comparison of the effects of the No-Action and Action Alternatives on the resource and stakeholder groups of concern. The Consulting Team proposes that a "resource-based" approach be used to present the effects analysis, whereby a single section of the document describes the effects of all of the alternatives for a particular resource or stakeholder group.

The description of the effects of the alternatives is prefaced by a section that provides an overview of the analytical framework used to guide the analysis. Specifically, the analytical framework includes the following elements:

- Comparative Baseline
- Analytical Timeline
- Types of Effects Analyzed
- Analytical Scenarios
- Significance Criteria and Ratings
- Cumulative Effects Analysis
- Data Collection and Models for Estimating Impacts

4.1 Analytical Framework

4.1.1 Comparative Baseline

Chapter 3 of this document contains a comprehensive assessment of the human (physical, biological, and socioeconomic) environment potentially affected by the alternative actions under consideration. For each of the resource or stakeholder groups used to analyze the impacts of the alternatives in this document, a comparative baseline has been developed. The baseline incorporates the status of the resource or stakeholder group at a given point in time. In general, the baseline condition for this effects analysis is the status of potentially affected resource and stakeholder groups as of 2005. The baseline conditions provide a benchmark against which the specific effects of each alternative, including the No-Action Alternative, are compared.

The baseline does not necessarily represent a static 'snapshot' of the resource and stakeholder groups. To the extent feasible, trends in the data from the description of historical conditions are used to depict baseline conditions more accurately (i.e., by incorporating variation over time). The cumulative past and present effects of groundfish fishery activity, as well as effects external to the groundfish fishery such as other fishery impacts, human-induced impacts, and climatic events influencing the resource and stakeholder groups, all contribute to the state of the baseline condition.

In terms of regulations, the comparative baseline includes all existing regulations as modified by actions that the Council has approved, but which have not yet been implemented by NMFS. The following bulleted list summarizes the assumptions with respect to the regulations that are considered part of the comparative baseline:[29]

- Activity restrictions in areas that are currently defined will remain in place, as will any restrictions resulting from designation of Habitat Areas of Particular Concern (HAPCs) that were approved under Amendment 19.
- Shoreside whiting monitoring and full retention as approved in Amendment 10 will be implemented and enforced.
- Binding sector total catch limits for groundfish, especially for overfished species, will be approved and implemented.[30]
- Improvements in recreational catch statistics, particularly in California, will have been made.
- All other enforcement, monitoring, catch accounting and observer coverage levels are assumed to be equivalent to those seen in 2005.

A critical component of the comparative baseline is the assumption that will be used for the ABC and OY levels for groundfish. Two options exist:

- Use the ABCs and OYs from 2005 and 2006
- Use the ABCs and OYs that will be in effect for 2007 and 2008.

The preliminary 2007/2008 OYs are likely to result in lower landings levels than were seen in 2005 primarily because the OY for sablefish is lower and perhaps more importantly the OY for yelloweye (a constraining overfished species) are also lower. Therefore the use of 2007/2008 may not be consistent with the amount of effort that was actually seen in 2005. For this reason, a decision has been made to use the 2005/2006 OYs for this EIS.

4.1.2 Analytical Timeline

In an EIS, as in any analysis that tries to predict the effects of future actions, it is critical to examine the time periods covered by the available historic and current data, the period in which the analysis will occur, and the period over which the analysts must make projections. In general, there is a significant time lag between the period during which the analysis is undertaken and the period in which the effects of a proposed action will occur. Specifically, Stage 2 of the trawl IFQ program analysis, in which the actual analysis takes place, is scheduled to begin in July 2006 and be completed in June 2007. The effects of the action won't begin to occur until 2010, and most likely will not be fully realized until some years later. The purpose of this section is to provide the Council with an understanding of the timing issues that complicate the trawl IFQ program EIS and to propose an analytical approach that can overcome the potential problems.

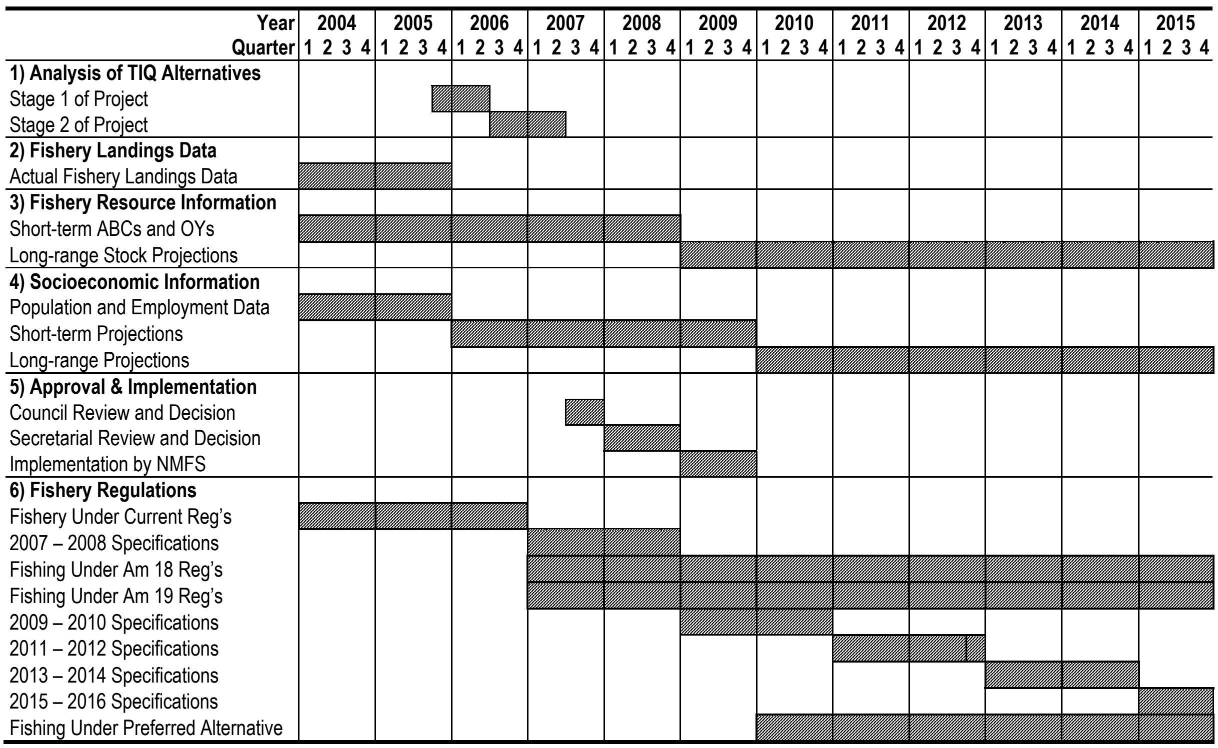
Figure 4-1 provides an overview of the trawl IFQ program analytical and implementation timeline from the perspective of Stage 2 of the trawl IFQ program analysis. The timeline (shown in the columns) is described in quarters and years from 2004 through 2015. The figure is divided into sections of rows that address the sequential elements of the timeline. The first section of the figure, labeled "Analysis of TIQ Alternatives," shows the time frame over which this analysis of the trawl IFQ

[29] This list was developed through discussions between the Consulting Team and staff members from PFMC and NMFS

[30] While groundfish sector allocations were approved in concept in Amendment 18, specific sector allocations have not yet been approved by the Council. Nonetheless PFMC and NMFS staff members believe that sector allocations should be considered part of the comparative baseline.

program takes place. Sections 2 through 4 of the figure show the information availability timeframe for key sets of data that will be necessary for the analysis. Section 5 (Approval & Implementation) shows the timeframe for the Council and Secretarial decision process and implementation of the approved program by NMFS. Finally, the last section of the figure (Fishery Regulations) shows the timing of regulatory changes that are projected to occur between now and the first years of fishing under the program developing from the preferred alternative.

Figure 4-1. Trawl IFQ Program Analytical and Implementation Timeline



Note: Historical data exists for the fishery and for resource and stakeholder groups. The fact that the timeline begins at 2004 is not meant to imply that data from earlier period will not be accessed and used.

As seen in the first section of Figure 4-1, Stage 1 of the analysis (development of the analytical framework and outline) runs approximately one year, from the 4th quarter of 2005 into the 2nd quarter of 2006. The second stage of the trawl IFQ program analysis is currently scheduled to begin in the 3rd quarter of 2006 and run through the 2nd quarter of 2007. It should be reiterated that the figure examines data and information availability from the perspective of the Stage 2 analysis—at least some of the data and information will only be available after Stage 1 is underway or completed.

Section 2 of the figure shows the period over which actual fishery landings data will be available. By the time the Stage 2 analysis is underway, fishery data for 2005 should be available. Information for earlier years will also be available and used to describe historical conditions of potentially affected resource and stakeholder groups, but it is not shown in the figure.

The figure's third section describes the availability of stock assessment information. Under the current management regime, the groundfish stock specifications cover two-year periods and are released in the 2nd or 3rd quarter each even-numbered year. Therefore, in the 3rd quarter of 2006—the beginning of the Stage 2 analysis—the specifications containing Acceptable Biological Catch (ABC) and Optimum Yield (OY) projections for 2007 and 2008 should be available. The specifications are based on periodic Stock Assessment and Fishery Evaluations (SAFE) documents that provide not only an indication of the stock levels and OYs for the near term, but generally also provide longer range projections. As indicated in the figure, these long-range projections of stock sizes are likely to be generally available through at least 2015 for most species.

The fourth section of the figure deals with available socioeconomic information, including two critical data sets, population and employment. In general, population and employment estimates through 2005 will be available at either the community level or the county level by the time Stage 2 of the EIS development is underway. Reasonably reliable projections of the population and employment through 2009 should also be available or can be generated, but projections out beyond 2009 are likely to become increasingly less certain, primarily because population estimates are recalibrated every 10 years to the decennial US census.

Assuming that the analysis of the trawl IFQ program proceeds as currently scheduled, the Council should receive a preliminary DEIS at the end of the 2nd quarter in 2007, and is presumed to make its final recommendations by the end of that year. Following the Council decision, it is presumed that development of a DEIS for Secretarial review will be required. Drafting of plan amendment language, implementation plans, proposed changes to the regulation, and the secretarial review and decision process will require at least a full year (2008) to conclude. Assuming the Secretary of Commerce approves the program, it is anticipated that implementation of the program by NMFS will require an additional year (2009), meaning that fishing under the preferred alternative from the TIQ Program would not realistically begin until 2010.

The sixth and final section of the figure shows the major regulatory regimes under which the fishery will operate between 2004 and 2015. The current regulations are expected to remain in effect through 2006. By then it is anticipated that new groundfish stock and harvest specifications would be in place, and that any regulations developed under Amendments 18 and 19 will have been implemented. It is presumed that fishing would continue under those regulations through 2009. In 2010 it is anticipated that fishing under the Preferred Alternative from the TIQ program would begin and that those regulations would largely replace existing Amendment 18 regulations.

It is also presumed that there will be a period of transition as vessel and processor owners determine how best to prosecute the fisheries under the new management regime. The duration of this transition period is uncertain—it will depend in large part on the configuration of the alternatives, the status of the stocks, and the relative profitability of the fishery. To accommodate this uncertainty, the Consulting Team recommends that the time horizon of the effects analysis be extended to at least 2015—six years after the first fishing is expected to occur under the new regime.

4.1.3 Types of Effects Analyzed

This analysis considers the terms "effects" and "impacts" to be synonymous, and the terms are used interchangeably. The Council on Environment Quality (CEQ) regulations implementing NEPA state that effects or impacts include ecological (such as the effects on natural resources and on the components, structures, and functioning of affected ecosystems), aesthetic, historic, cultural, economic, social, or health, whether direct, indirect or cumulative. CEQ NEPA regulations define direct, indirect or cumulative effects on the human environment as follows:

Direct Effects—are caused by the action and occur at the same time and place.

Indirect Effects—are caused by the action and are later in time or further removed in distance, but are still reasonably foreseeable. Indirect effects may include growth inducing effects and other effects related to induced changes in the pattern of land use, population density or growth rate, and related effects on air and water and other natural systems, including ecosystems.

Cumulative Effects—are the impacts on the environment which result from the incremental impact of the action when added to other past, present and reasonably foreseeable future actions regardless of what agency (federal or non-federal) or person undertakes such actions. Cumulative effects can result from individually minor but collectively significant actions taking place over a period of time.

According to CEQ NEPA regulations, effects may include those resulting from actions which may have both beneficial and detrimental effects, even if on balance the agency believes that the effect will be beneficial.

This EIS utilized a Stakeholder/Resource based approach for describing the effects of the alternatives. In this approach a single section of the document describes the effects of all of the alternatives for a particular resource or stakeholder group. For example in effects analysis for the limited-entry trawl groundfish catcher vessels, there are separate sub-sections for each alternative. Within the assessment of each alternative there will be a subsection that describes the direct and indirect effects. This will subsection will be followed by an assessment of the cumulative effects.

4.1.4 Analytical Scenarios

Given the complexity of the affected environment in which the West Coast groundfish trawl fishery occurs, current conditions of some resource and stakeholder groups are uncertain, and future conditions are always uncertain. To account for this inherent uncertainty, the Consulting Team recommends that a set of "what if" scenarios be developed and included in the effects analysis. The scenarios would be developed as a means to demonstrate differences in the way the various alternatives perform under conditions that are plausible, but that are not necessarily predicted to occur. In some cases, the scenarios might be deemed highly unlikely, but nonetheless may be considered because they create an analytical vehicle to isolate important effects of the proposed alternatives. It should be emphasized that the list of scenarios is not fixed—scenarios could be added or removed as deemed appropriate.

4.1.4.1 Possible Scenarios for Analyzing All of the Alternatives

Projected OYs and ABCs for 2007 and 2008

This analytical scenario shows how the management regimes under the No-Action Alternative and Action Alternatives can affect the behavioral responses of harvesters and processors in the event of Acceptable Biological Catch (ABC) and Optimum Yield (OY) projections for 2007 and 2008.

High Abundance of Groundfish Species

This analytical scenario shows how the management regimes under the No-Action Alternative and Action Alternatives can affect the behavioral responses of harvesters and processors in the event of higher OYs than those likely under baseline conditions.

Low Abundance of Groundfish Species

This analytical scenario shows how the management regimes under the No-Action Alternative and Action Alternatives can affect the behavioral responses of harvesters and processors in the event of lower OYs than those likely under baseline conditions.

A Stock that is Currently Not Overfished Falls into Overfished Status

An analysis of this scenario would reflect differences in the way the alternative management regime and the vessels and processors operating under that regime would respond to imposition of additional incidental catch constraints that would be necessary to rebuild a newly designated overfished stock.

A Stock that is Currently in an Overfished Status is Rebuilt

Under this scenario it is assumed that a species that has been in an overfished status is rebuilt, and that OYs return to levels that may allow targeted harvesting of the species. The likely responses of vessels and processors under the No-Action Alternative and Action Alternatives would be assessed and the difference in impacts discussed.

Alternative Sector Allocations

Scenarios could be added to both the No-Action Alternative and Action Alternatives to show the direct effects of different sector allocations of key groundfish species.

4.1.4.2 Possible Scenarios for Analyzing the No-Action Alternative

Depending on the specification, it may be important to create analytical scenarios for the No-Action Alternative. The following scenarios assume that 100 percent observer coverage is not part of the regulations included under the No-Action Alternative.

Alternative Levels of Observer Coverage on Trawl Vessels

Scenarios could be added to the No-Action Alternative to demonstrate the impacts of increasing levels of observer coverage under the existing management regime.

Alternative Requirements for the Reporting of Bycatch for Trawl Vessels

This scenario could be added to the No-Action Alternative to demonstrate potential impacts of total catch reporting under the existing management regime.

4.1.4.3 Possible Scenarios for Analyzing the Action Alternatives

In general, the proposed alternative management regimes create the potential for two basic types of efficiency gains—individual vessel owners may become more efficient in the way they harvest during the year, and the fleet as a whole may consolidate so that fewer vessels are operating. Analytical scenarios can be used to demonstrate the potential impacts of those changes. Scenarios may also be included that vary the length of the transition period to a consolidated fleet. The scenarios that could be added include the following:

No Transfers of IFQs Occur

If it is assumed for analytical purposes that no transfers occur, it is possible to estimate the potential efficiency gains that can be achieved simply by providing vessel owners the ability to optimize their harvest strategy for the amount of quota they receive.

Moderate Fleet Consolidation

In this scenario it is assumed that IFQs are transferred and vessels drop out of the fishery such that the average vessel remaining in the industry fishes an average of 100 days per year. For this scenario, the average number of fishing days per vessel per year was chosen somewhat arbitrarily, and could be adjusted based on input from the Council and NMFS.

Considerable Fleet Consolidation

In this scenario it is assumed that IFQs are transferred and vessels drop out of the fishery such that the average vessel remaining in the industry fishes an average of 200 days per year. This scenario was chosen based on the assumption that a single vessel is unlikely to be able to fish more than 300 days in a given year.

Quick Transition to a Moderately Consolidated Fleet

In this scenario it is assumed that the fleet undergoes a “moderate” consolidation during the first year of the IFQ program—the average vessel fishes 100 days per year. Theoretically, overall efficiency of the fleet—once it is consolidated—would not be affected by how quickly or gradually it consolidates. However, the impacts on communities and fishing crews are likely to be much more noticeable if the transition to a consolidated fleet is relatively quick.

Gradual Transition to a Moderately Consolidated Fleet

In this scenario is assumed that the fleet undergoes a "moderate" consolidation over the first five years of the IFQ program —the average vessel fishes 100 days per year

4.1.5 Cumulative Effects Analysis

As described in Section 4.1.3, cumulative impacts are those **combined effects** on the condition of the resource and stakeholder groups of concern that result from the incremental impact of each alternative when added to other past, present, and reasonably foreseeable future actions. For a description of the effects of past and present actions, the cumulative effects analysis draws on the historical and baseline conditions of affected resource and stakeholders presented in Chapter 3. Reasonably foreseeable future actions (RFFAs) that have the potential to affect the resource and stakeholder groups of concern were developed by the Consulting Team in consultation with Council staff and NMFS representatives.

RFFAs may be endogenous (external) or exogenous (internal) to the federal fishery management regime. Examples of endogenous RFFAs include changes in ABCs and OYs. Other endogenous RFFAs might include the reauthorization of the MSA with proposed changes to national standards, or a declaration that a particular stock has been rebuilt. Examples of exogenous RFFAs include higher than anticipated population growth in coastal communities, or a declaration of critical habitat for an endangered seabird.

The Consulting Team proposes that the end of 2015 be used as the "end point" for the cumulative effects analysis in terms of identifying RFFAs. Exact specification of the end-point for the cumulative effects analysis is a point of discussion, but the Consulting Team believes the time horizon of the analysis should be more than a few years after implementation of an alternative management regime, thereby including fleet consolidation and other possible effects.

The following initial list of exogenous RFFAs is proposed for inclusion in the cumulative effects analysis:

- Human population increases in affected communities
- Increased tourism and recreational opportunities in affected coastal communities
- Increased demand for retirement destinations in affected coastal communities
- Increased demand for protein
- Continued growth and scope of the aquaculture industry
- Increased public awareness and scrutiny of the fishing industry
- Increased demand for ecosystem-wide fishery management approaches

The Consulting Team, in consultation with Council staff and NMFS representatives, developed the following initial list of endogenous RFFAs:

- The Magnuson-Stevens Act will be reauthorized, which will result in additional regulatory requirements. The specific management changes to be included as RFFAs will be determined in discussions with Agency staff.

- Limited entry will be imposed on all fisheries currently managed under open access, including the fisheries for highly migratory species, coastal pelagic species, and salmon and portions of the groundfish fishery.
- The Monterey Bay trawl buyback program as proposed under the EFH EIS will be completed.
- Technological improvements will make it feasible to require VMS on all fishing vessels regardless of size.
- Real-time reporting of electronic fish tickets and electronic logbook entries will be required.
- Vessel Monitoring Systems (VMS) for all licensed and all open access vessels will be in place, enforced, and monitored.
- Observer coverage will be increased to levels such that 25 percent of all groundfish catches by species are observed.
- POP, darkblotched rockfish, and widow rockfish stocks will be declared rebuilt and will be removed from "overfished" status.
- Annual OYs for lingcod, POP, darkblotched rockfish, and widow rockfish will allow for limited targeting of these species.

4.1.6 Significance Criteria and Ratings

The effects analysis includes a set of criteria for identifying significant effects on the resource and stakeholder groups of concern. These criteria or thresholds are set as specific numerical standards, qualitative standards, and/or desired management goals. The criteria for defining significance are discussed in the individual effects analysis sections.

Following the analysis of effects and determination of significance, the following impact ratings are applied:

Significantly adverse (S-): Significant adverse effect based on ample information and data and the professional judgment of the analysts who addressed the topic.

Conditionally significant adverse (CS-): This determination is lacking in quantitative data or information; however, the professional judgment of the analysts is that the alternative will cause a decline in the condition of the resource.

Not significant (NS): This determination is based on information and data, along with the professional judgment of the analysts that suggest that the effects will not cause a significant change in the condition of the resource.

Conditionally significant beneficial (CS+): This determination is lacking in quantitative data and information; however, the professional judgment of the analysts is that the alternative will cause an improvement in the condition of the resource.

Significantly beneficial (S+): Significant beneficial effect based on ample information and data and the professional judgment of the analysts who addressed the topic.

Unknown (U): This determination is characterized by the absence of information or data sufficient to adequately assess the significance of the impacts, either because the impact is impossible to predict, or because insufficient information is available to determine the condition of the resource.

4.1.7 Data Collection and Models for Estimating Impacts

4.1.7.1 Data Collection

The Consulting Team suggests that an interview-based data collection process from key informants be used to further understand current fishing practices and quantify the likely changes under each alternative. Changes in fishing practices will depend on a number of factors, such as relationships with processors, ex-processor prices, increased/decreased costs, or increased/decreased prices ex-vessel prices. As a result, the interviews will address information needed for a number of components of the overall analysis. The interviews will balance complexity and completion time requirements against the need for information on a number of topics. The contractor for Phase 2 may need to work with the Council staff to prepare an explanation and justification to the Office of Management and Budget for approval of the survey plan.

4.1.7.2 Models

This subsection provides an overview of possible model development for predicting how trawl groundfish harvesters and trawl groundfish processors would respond under each alternative. The choice of models depends upon the amount and quality of information available. The following bullets describe some of the data issues complicating model development for this EIS:

- Cost and earnings data for harvesters are still under development, and at best will be available only for a single year. A comprehensive predictive model would require information showing how costs change different OY levels and exogenous prices.
- Cost data for processors are unavailable and unlikely to become available in the timeframe of the analysis.
- Comprehensive primary data on processed products and product prices are unavailable.
- Final market demands for groundfish products are not well known.
- Data showing the total catch of groundfish by individual vessels are unavailable. Estimates of total catch are currently made in the NMFS Bycatch Model by combining observer data, logbook data, and landings data.

Given these data shortcomings and the advice of individual members of the IEP, the Consulting Team determined that a comprehensive predictive model would not be feasible for use in the EIS. Instead, the Consulting Team proposes to develop a set of models designed to focus on specific issues. These issues include:

- The distributional effects of the initial allocation of IFQs in a trawl IFQ program.
- The potential consolidation of the trawl groundfish harvesting sector following the allocation
- The potential to reduce catches of incidental species.
- The potential to increase profits

These models could be constructed using existing data sources, combined with the interview data discussed above and/or analysts' judgment to fill the numerous data gaps.

4.1.7.2.1 A Model to Project the Effects of the Initial Allocation of IFQ

The Consulting Team believes the initial allocation of IFQs will have a potentially significant effect on the way in which trawl groundfish harvesters and trawl groundfish processors prosecute the fishery. The Consulting Team believes that a careful examination of the initial allocation options, and a determination of how permit holders would fare relative to current participation levels, will provide an indication of the amount of change that may be expected in the fishery as a result of the initial allocations.

The initial allocation model would consist of four modules as follows:

1) **Historical Landings Module**: This module would include landings by year and species from 1994 - 2005 for individual permit holders, including data on participation in fisheries other than the West Coast groundfish trawl fishery. The module would also include data indicating the volume of purchases of trawl groundfish by individual buyers and processors. Finally the module would contain demographic information including vessel class, community of residence, physical location of processing facility, etc., for each potential recipient of IFQ.
2) **Allocation Rules Module**: This module would contain the specific allocation rules included in the alternatives. As described in Table 2-2, there are six different allocation splits between harvesters and processors included in the main suite of alternatives. All of the options in the main suite alternatives would allocate IFQs based on a historical landings basis, but the way that catch history is used varies by program. In addition to the allocation options in the main suite of alternatives, the Council has indicated that other allocation methodologies should be examined. These additional allocation methodologies are detailed in the 2nd half of the Components Table in Chapter 2. Most of these ancillary options merely tweak the allocation rules in the main suite by changing the eligibility years, the minimum landings requirements, or the length of the historical period. However one of the included ancillary options uses a very different methodology for allocating IFQ for overfished species and other incidentally caught groundfish. This methodology allocates IFQs for overfished and incidentally caught groundfish species in proportion to the amount of IFQ issued for target species--the proportions would be based on average incidental catch rates in recent years as estimated in the NMFS Bycatch Model.
3) **Incidental Catch Rate Module**: This module will consist of estimates of incidental catch rates of overfished species and other incidentally caught groundfish species on a target species basis for the years 2001 – 2005.[31] The estimates will be based on the NMFS Bycatch Model. This module will be used for two different purposes: 1) It will be used in conjunction with the Allocation Rules Module to project IFQ allocations under the option that allocates IFQs on the basis of incidental catch rates; 2) The Incidental Catch Rate Module will be used to examine the different allocation outcomes and to assess “winners and losers” among the initial quota recipients.
4) **Comparison Module**: In this module the allocations of IFQs will be compared to actual 2005 landings and ex-vessel values. Initial QS allocations will be translated to QPs based on the OYs and trawl apportionment targets from 2005. Ex-vessels prices from 2005 will be used to assign a “QP proxy value” to the hypothetical QP allocations for 2005. Each individual’s QP proxy value will be compared to the individual’s actual ex-vessel value of landings from 2005. The absolute value of the difference between the QP proxy value and the actual ex-vessel value is a measure of the “neutrality” of the allocation. Allocation options that result in relatively larger values indicate that the option would result in greater change from 2005 conditions.

[31] The WCGOP began collecting bycatch data in August 2001.

A second means of comparison using this module will examine the allocation of QP for overfished species, and compare this allocation to the "overfished species requirements" of each individual. Overfished species requirements would be calculated by applying the Incidental Catch Rate Module to hypothetical 2005 QP allocations of target species. The absolute value of the difference between each hypothetical overfished species QP allocation and estimated overfished species requirements in 2005 will be calculated. The larger this difference, the greater the change relative to 2005 conditions.

4.1.7.2.2 A Model to Assist in the Projections of Consolidation Effects

The Consulting Team believe that consolidation under the IFQ and permit stacking alternatives will be a key impact mechanism. The Consulting Team plans to develop a model to provide rough "order of magnitude" projections of the effects of consolidation. This model will not predict the level of consolidation, but rather will predict which permit holders are most likely to leave the fishery under a given level of consolidation. This information will be then be used in other models and in the community impact analysis. Actual levels of consolidation will be discussed in the context of the scenarios described in Subsection 4.1.4.3.

In general the Consulting Team believes that post-IFQ consolidation of the West Coast groundfish trawl fishery will depend on several factors as listed below:

1) Participation in 2005. The Consulting Team assumes that permit holders that did not participate in 2005, are unlikely to re-enter the West Coast groundfish trawl fishery regardless of their initial allocation. In other words the Consulting Team will assume that all initial quota recipients that did not also fish in 2005 will transfer their allocations and leave the fishery.
2) Ownership linkages to processors. The Consulting Team believes that—all other factors being equal—permit holders that have direct ownership linkages to processors are much more likely to remain in the fishery than other permit holders.
3) Relative efficiency within the vessel class in terms of average catch per day as reflected in log-book data. This will be used as a proxy for relative profitability—the Consulting Team does not believe that cost and earning data being developed in the ongoing NMFS survey will be adequate to measure relative profitability.
4) Relative ranking within the permit holder's vessel class in terms of gross revenue in 2005.
5) Relative ranking within the permit holder's vessel class in terms of the absolute difference between QP proxy value (discussed in the previous section) and actual 2005 ex-vessel value.
6) Relative ranking within the permit holder's vessel class in terms of the absolute difference between the hypothetical allocation of 2005 QP of overfished species (developed in the initial allocation model) and the permit holder's overfished species requirements.
7) Relative ranking within the permit holder's vessel class in terms of the dependence on trawl groundfish revenues as a percentage of all other fish harvesting revenues. The Consulting Team assumes that the greater the dependence on the West Coast groundfish trawl fishery the greater the likelihood of remaining in the fishery.

The consolidation model will calculate a weighted average of these factors and provide an overall ranking of each permit holder within its vessel class. The higher the ranking the greater the likelihood that permit holders within each vessel class would remain in the fishery under the various consolidation scenarios.

The final steps of the consolidation model rely on the assumption that each vessel that remains in the fishery would acquire enough target species QPs such that they end up with the same proportion of target species as they landed in 2005.

4.1.7.2.3 A Model to Estimate Potential Reductions in Incidental Catch Rates of Overfished Species

The need to reduce incidental catch of overfished species is believed to be a major impact mechanism in determining the behavioral changes under the IFQ alternatives. A critical question is whether existing data indicate that incidental catches can actually be reduced. The Consulting Team proposes to use the data developed for the NMFS Bycatch Model to project potential reductions in incidental catch rates and subsequently the levels of target catches that might be attained.

The **Incidental Catch Rate Reduction Model** will utilize observed incidental catch rates by haul, target strategy, and month from 2001 – 2005. Each haul will be ranked on the basis of incidental catch of overfished species relative to the catch of target species with ties going to the haul with the greater amount of target catch. These haul-by-haul records will examined based on specific assumptions about the ability of harvesters to reduce bycatch rates. For example it might be assumed that all hauls ranked at or below the 25th percentile over the course of the year (i.e., the 25% of hauls with the highest incidental catch per target species catch) would be eliminated from each target fishery. After these hauls are eliminated, the remaining hauls would be aggregated and a new incidental catch rate for the target species would be calculated. Next, all target catches would be expanded proportionally until the level of estimated 2005 trawl catch of the overfished species is reached. Finally average ex-vessel prices by month from 2005 would be applied to the catches of target species, and the result compared to the total ex-vessel value attained in 2005.

The following assumption sets are initially proposed:

1) Assume that all hauls ranked in the 25th percentile or less over the course of the year are eliminated from each target fishery.
2) Assume that all hauls ranked in the 50th percentile or less over the course of the year are eliminated from each target fishery.
3) Assume that all hauls ranked in the 25th percentile or less over the course of each two-month period are eliminated from each target fishery.[32]
4) Assume that all hauls ranked in the 50th percentile or less over the course of each two-month period are eliminated from each target fishery.
5) Assume that all hauls ranked in the 25th percentile by vessel class over the course of the year are eliminated from each target fishery
6) Assume that all hauls ranked in the 50th percentile by vessel class over the course of the year are eliminated from each target fishery.

4.1.7.2.4 A Methodology to Assist in the Projections of Ex-Vessel Prices

Ex-vessel prices by species are likely to have a significant influence on all of the potential impacts of the IFQ program. While trend in ex-vessel prices by month of landing or by volume can be thoroughly examined with PacFIN data, in they end, ex-vessel prices are influenced by many additional mechanisms that are not so easily studied. For example, ex-vessel prices are heavily influenced by retail prices and consumer demand, as well as the global substitute products. Unfortunately there do

[32] Under this and the following assumption set, the expansion of remaining hauls would be undertaken such that the proportion of target catches in each month would remain constant.

not appear to be many useful economic analyses in recent years that study consumer demand for groundfish product.

The influence of the market power of processors and harvesters on ex-vessel prices is also important, and IFQ clearly have the ability to shift the balance of power between harvesters and processors. However, the influence of market power is poorly understood, because market power is assumed not to exist in the basic economic theory of pure competition. Using the assumption of pure competition, economic theory is reasonably able to predict outcomes; if on the other hand pure competition cannot be assumed, then standard economic theory is unreliable, and game theory and experimental economics must be used.

The Consulting Team has had discussions with game theorists and practitioners of experimental economics, and there appears to be interest in working on this problem. It should be noted that experimental economic was used by the North Pacific Fishery Management Council in their analysis of processor shares in the IFQ program for crab.

Game theory and experimental economics are likely able to provide insights into the effects of an allocation of harvesting shares to processors, and on the potential affects that the IFQ system could have of ex-vessel prices. This may be a particularly important determinant in ability of harvesters to reduce incidental catch of overfished species.

4.1.7.2.5 A Model to Assess the Likelihood that Additional Profits Could Offset Additional Observer Costs

An important feature of all of the Action Alternatives is the requirement that all vessels in the West Coast groundfish trawl fishery carry observers 100 percent of the time, or use video monitoring equipment approved by NMFS at all times. Under the current management regime, it is considered infeasible to require this level of catch monitoring because the costs of the program could not be supported by the level of profits generated in the fishery. It is presumed that if the alternatives lead to increased profits, then requiring 100 percent observers or video monitoring could be justified.

This section describes the model that would be used to assess the likelihood that profits in the West Coast groundfish trawl fishery under the alternatives could increase enough to offset the increased costs of observers and monitoring.[33] Initial estimates of the cost of an expanded observer program in the West Coast groundfish trawl fishery range from $300-$1,000 per fishing day.

The “observer cost offset model” will utilize the incidental catch rate model in conjunction with the consolidation model to find combinations of: 1) potential revenue increases from higher targets species catches due to lower incidental catch rates of overfished species; and 2) fixed cost savings resulting from fleet consolidation. The combination of these results will be used to assess whether the potential for increase in profits for vessels in the different vessel classes could fully offset the cost of observers under the assumption that average catches per day of target species for the remaining vessel would remain at 2005 levels.

It is acknowledged that this is a relatively simplistic model; however more sophisticated models would require more information and certainty than are likely to be available.

4.1.7.2.6 A Profitability Model

The profit motive is a nearly universal impact mechanism that will be present in all of the alternatives. Potential changes in profits under the alternatives will be estimated using NMFS trawl vessel cost-

[33] It should not necessarily be inferred that the trawl industry would actually be required to cover the additional observer costs.

earnings survey results applied to each vessel class. This information, combined with the models listed above will be used to estimate the marginal revenue attainable on purchased QS based on a range of assumed change in variable costs scenarios. The components of the profitability model include:

- NMFS vessel cost-earnings survey data will be used to estimate the average fixed cost of vessels by vessel class, and the average variable cost per target pound.
- The consolidation model will be use to predict the number of vessels remaining in the fleet at varying levels of consolidation and improvement in incidental catch rates at those consolidation levels.
- The incidental catch rate model will be used to estimate potential additional catches and value of target species for each vessel class
- Fixed cost savings will be estimated based on the number of vessels remaining in each vessel class.
- Variable cost savings per target pound will be assumed. The Consulting Team assumes a priori that the following variable cost savings percentages will be used: 1) no change, a 5 percent reduction, and a 10 percent reduction.

4.2 Summary of the Potential Effects of the Alternatives

This section provides a broad overview of the potential impacts of the alternatives considered. Specifically, it discusses the major incentives that are likely to determine the way in which trawl groundfish harvesters and trawl groundfish processors prosecute the fishery under the different alternatives and highlights the socioeconomic consequences of those incentives.

This section also uses a tabular format to summarize the direct, indirect and cumulative effects of the alternatives. The summary table is shown in Table 4-1 on page 211 will utilize the significance criteria and ratings introduced in Section 4.1.6 for each of the indicators listed.

4.2.1 No-Action Alternative (Alternative 1)

The current management regime utilizes two-month cumulative trip limits to spread harvests out over the year. As a result of the legal requirement to minimize bycatch of overfished species, considerable harvest opportunity is being forgone. The OYs for many overfished species have been set at low levels, placing a major constraint on the industry's ability to fully harvest the available OYs of the more abundant target species that co-occur with the overfished species, wasting potential landings and revenues. Because overfished species are constraining catches of target species, permit holders are compelled to take multiple trips that increase operating costs and that fail to fully utilize vessel capacities.

The use of average discard rates for the fleet to project bycatch of overfished species, together with the absence of a requirement to report catches that are not landed, creates little direct incentive for individual vessels to do everything possible to reduce personal bycatch rates. Overall, the current management regime provides little individual bycatch accountability or opportunity or incentives for individuals to reduce bycatch.

Further, the current management regime is not responsive to the wide variety of fishing business strategies and operational concerns. For example, some fishermen would prefer to be able to pursue a more seasonal groundfish fishing strategy to take advantage of changes in market, weather, and harvest conditions that occur during the fishing year.

4.2.2 IFQ Alternatives (Alternatives 2 - 4)

The following subsection discusses the primary impact mechanism and behavior changes that are likely under the IFQ Alternative. While the alternatives are obviously not identical, they all carry with them the same basic impacts.

4.2.2.1 Potential Effects of Management Measures on Harvesters and Processors

A trawl IFQ program is intended to achieve the IFQ Project goals and objectives (Section 1.1.2) by imposing an alternative system of incentives (a.k.a. impact mechanisms) that would change the way in which trawl groundfish harvesters and trawl groundfish processors prosecute the fishery. The program would accomplish this through management measures that

- allocate annual IFQs;
- grant IFQ transferability; and
- require total catch reporting and monitoring.

The discussion below briefly discusses how these measures are expected to help achieve the ITQ Project goals and objectives, and identifies potential countervailing incentives that may limit the positive impacts.

The allocation of annual IFQs would remove the constraints on the timing of harvest under the current bimonthly cumulative trip limit regime, thereby allowing harvesters to optimize their fishing patterns during the year so as to maximize their net revenue on the amount of fish allocated to them. Removing the constraints on harvest timing would allow permit holders to time their activities so that greater amounts of target species can be harvested for a given amount of incidental catches of constraining overfished species. The removal of harvest timing constraints would also allow harvesters to consolidate their own fishing activities, rather than being forced by regulation to divide their harvesting activities into six two-month periods.

Notwithstanding the new freedom harvesters would have to time their fishing activities, buyers and processors of trawl groundfish are not likely to completely change their groundfish purchasing patterns in order for harvesters to maximize their profits. Buyers and processors would continue to time their purchasing and processing activities to meet their own market and capacity constraints. While harvesters may wish to harvest their entire IFQ of fish in one month, they must still find a buyer that is willing to pay a price for their catch that will cover their expenses.

The granting of transferability would allow harvesters to optimize the size of their allocation by matching their allocation with the harvesting capabilities of their vessels and crew. This, in turn, would lead to higher profits because the fixed costs of the fishing operation could be offset by a greater amount of revenues. Permit holders with an excess of overfished species quota will likely find willing buyers among those who have not been able to reduce their incidental catch of overfished species, or they will find willing sellers of target species quota.

Transferability not only would allow some permit holders to increase the size of their operations in order to increase profitability, it would also allow permit holders to leave the fishery with compensation. In other words, transferability is likely to cause consolidation of the trawl harvesting sector. This consolidation would remove redundant capital from the fishery as more efficient operations purchase the IFQs of less efficient operations.

Imposing a total catch reporting and monitoring requirement would make each vessel responsible and accountable for all groundfish caught, rather than the amounts retained. This increased accountability would provide an incentive for vessels to reduce their incidental catch rates of overfished species—in contrast to the status quo, actions to reduce incidental catch would provide benefits directly to the individual undertaking the change.

4.2.2.2 Potential Effects of Initial Allocation of IFQs on Harvesters and Processors

The specific details of the initial IFQ allocation rule chosen will also be a major impact mechanism. The initial allocation will cause behavioral changes in the trawl groundfish industry because the initial allocation will change the opportunities available to each initial assignee of IFQ. The only situation in which the initial allocation would not cause behavioral changes would be an allocation of IFQ to each permit holder active in the 2005 West Coast groundfish trawl fishery that meets the following conditions:

1) The allocation of pounds of each species is no less than the amount of that species the permit holder actually harvested;
2) Any additional pounds that can be allocated while remaining within the OY of each species would be allocated in proportion to the percentage of that species that each permit holder harvested.

Under such an allocation all of the participants in the 2005 West Coast groundfish trawl fishery could have harvested the amounts they actually harvested—no one would be better or worse off relative to the baseline conditions. Any other allocation would force permit holders to buy and sell quota shares to return to the level of participation they would have attained without the allocation.

An allocation that causes no one to be worse off is not necessarily consistent with the IFQ Program goals and objectives. Assume, for example, that a particular permit holder caught a large amount of an overfished species in 2005, thereby causing the entire fishery to be closed before the OYs of many species were harvested. An allocation that makes no one worse off would provide that permit holder with the ability to again shut down the fishery prematurely.

Permit holders will examine their initial allocation of IFQs to determine if it makes economic sense for them to remain in the fishery or to sell their allocation and leave the fishery. Of particular importance will be the initial allocation of overfished species. Permit holders that receive high allocations of overfished species, relative to their allocation of target species, will be in a better position to remain in the fishery, as they would be less likely to incur the cost of purchasing additional IFQs.

The allocation of harvesting IFQs to processors will also cause behavioral changes, as any such allocation means that harvesters would have to obtain additional IFQ in order to attain pre-allocation harvest levels. On the other hand, it has been argued that if an allocation were not provided to processors, the bargaining power of processors relative to harvesters would be compromised. A change in the relative bargaining positions would allow harvesters to increase their profitability at the expense of processors.

Processors would examine their initial allocation, and the relationships they have with permit holders that remain in the fishery to determine what they do with their harvest IFQs. Potential options for processors include: 1) transferring IFQs to harvesters at no or nominal cost to ensure continued deliveries of raw product; 2) selling or leasing IFQs to harvesters at the prevailing market prices; 3) using them to augment the catches of their own vessels.

Processors would also examine the markets for their groundfish product to determine the volumes the markets can bear. Of particular importance is the seasonality of demand. If periods of high demand correspond with periods of low incidental catch rates of overfished species, processors may encourage harvesters to increase their deliveries during that period. If periods of high demand coincide with periods of high incidental catch rates of overfished species, processor may have to offer harvesters higher prices to encourage larger deliveries.

4.2.2.3 Potential Indirect Effects

Many of the behavioural changes of harvesters and processors discussed above would result in indirect socioeconomic effects on stakeholder groups. For example, the decision of permit holders to leave the West Coast groundfish trawl fishery as a result of the initial allocation could result in:

- Lost employment opportunities for crew members.
- Loss of supplies of raw product to buyers and processors.
- Reduced demand for fishing inputs.
- A shift in fishing effort to other fisheries.
- Changes in the socioeconomic importance of fishing in coastal communities

4.2.3 Permit Stacking (Alternative 5)

The permit stacking alternative would continue the bimonthly cumulative trip limits currently used to manage the West Coast groundfish trawl fishery, but would include the following two differences:

Additional Transferability: Permit holders would be able to acquire additional permits, and each permit held (up to three) would result in an additional trip limit amount. If for example the cumulative trip limit for a species was set at 50,000 lbs, a permit holder with three permits would receive three cumulative trip limits for each period or 150,000 lbs. The additional transferability would allow permit holders to optimize their operations and provides industry funded compensation for those permit holder that wish to exit the fishery.

Total Catch Reporting and Monitoring: As in the IFQ Alternatives total catch reporting would be required as well as observers or video monitoring on all limited-entry trawl groundfish vessels.

4.2.4 Comparative Summary of the Alternatives

Table 4-1 provides a comparative summary table of the direct and indirect effects of the alternatives on resource and stakeholder groups. The table shows the key indicators or measurement criteria used to describe the potential impacts of the alternatives in terms of changes from baseline conditions. The columns in the table list the main suite of alternatives, along with the five different allocation programs associated with Alternative 3. The cells of the table indicate the significance of the predicted changes from baseline conditions using the significance ratings in Section 4.1.6. Table 4-2 is similar to Table 4-1 except that it lists the significance of cumulative effects.

4.3 Limited Entry Trawl Groundfish Catcher Vessels

This section describes the effects of the alternatives on limited-entry trawl groundfish catcher vessels.

The section begins with details of the analytical framework that will be utilized for the trawl groundfish catcher vessel sector (Section 4.3.1). The analytical framework describes the impact mechanisms, the indicators of measures of change and the significance thresholds that will be applied for each indicator.

Section 4.3.2 through Section 4.3.6 focuses successively on each of the alternatives. Section 4.3.4, which addresses Alternative 3 has separate subsection describing the effects of each of the five major options contained in the Alternative.

Each of the effects sections describes the direct, indirect and cumulative effects of the alternatives with respect to limited entry trawl groundfish catcher vessels. Within the assessment of each alternative there is a subsection that describes the direct and indirect effects. This subsection will be followed by an assessment of the cumulative effects for the alternative. Within each effects subsection the analysis has the following basic format:

1) Identifies and describes the impact mechanisms (or RFFAs) that are likely to change the conditions of stakeholders.
2) Projects the conditions of the stakeholder under the alternative using the indicators developed in more detail later in this framework section.
3) Compares the projected conditions with the baseline conditions and determines the significance of the change.

It should noted that because the trawl catcher vessels stakeholder group is the first stakeholder or resources group discussed, the Stage 1 outline shows all of the headings for the effects analysis sections. In order to limit the redundancy, later stakeholder and resource sections do not contain the same list of effects sections.

4.3.1 Analytical Framework for Trawl Catcher Vessels

Table 4-3 provides an overview of 1) potential impacts; 2) mechanisms that relate the proposed action to the impacts; 3) measurement criteria or indicators used in assessing each type of impact; 4) the models and data sets used in the analysis; and 5) the significance criteria or thresholds.

As described in Section 4.2, there are several key impact mechanisms or incentives for change that will affect catcher vessel behavior under all of the alternatives. These are listed below.

- o The economic incentive to increase profits, reduce costs and increase revenues
- o The need to reduce incidental catches of overfished species
- o The regulatory need to have total catch reporting and 100 percent observers or video monitoring

These key incentives manifest themselves in various ways within the different action alternatives.

- Under all of the action alternatives, the **total catch reporting, and observer and monitoring requirements** (all impact mechanisms) will induce changes in the following indicators for the trawl groundfish harvesters:

- Variable costs per fishing day
- Fixed cost per vessel

The following list describes impact mechanisms and indicators they are likely affect under the IFQ Alternatives:

- The **allocation rules specific to each alternative** change the distribution of the dedicated access privilege. Different allocation rules will result in changes in a number of indicators. These indicators are listed below:
  - Number of initial QS recipients, by class and the number that participated in 2005
  - Value of transfers to restore participants to 2005 level
  - Ex-Vessel Value of QPs allocated to 2005 participants
  - Value of QPs allocated to permit holder that did not participate in 2005
- Under an IFQ management regime **the profit motive** (an impact mechanism) will allow harvesters to increase profits (in this case a measure of change) and **reduce incidental catch rates of overfished species** (the need to reduce incidental catch rates is considered both an impact mechanism) by inducing changes in the following indicators:
  - The timing of fishing activities
  - The location of fishing patterns
  - The incidental catch rate of overfished species relative to target species
  - Total catch of target species
  - Total revenue from target species
  - Average variable cost per pound of target catch
- The IFQ system combined with the specific IFQ allocation rules, and the profit motive will allow harvesters to consolidate. Consolidation is also likely under the permit stacking alternative. In this context **consolidation is considered an impact mechanism** that will induce changes in the following indicators:
  - The number of active permit holders and vessels
  - The number of crewmembers
  - The total fixed cost in the trawl groundfish fleet
  - Changes in the number of fishing days per vessel
  - Additional changes in the variable cost per pound of target species
- The IFQ alternatives will also provide harvesters with an **increased amount of certainty** that the actions of other harvesters will not negatively affect their ability to harvest the fish allocated to them. The increased certainty is an impact mechanism that could affect the following indicators:
  - The incidental catch rate of overfished species relative to target species
  - Safety-related incidents & accidents
  - The timing of fishing activities
  - The location of fishing patterns

- The relative bargaining power vis-à-vis processors of trawl groundfish

Table 4-3 provides an overview of the impact mechanism, indicators or measures of impact and the significance thresholds that will be used. For quantitative indicators, this section will utilize a significance threshold of +/- 20 percent to indicate whether the measured change in the indicator from the comparative baseline is significant. The same threshold is used to roughly assess changes in qualitative indicators (e.g., fishing vessel safety). Changes in quantitative indicators will be based on model projections as described in subsection 4.1.7.2 combined with the scenarios described in Subsection 4.1.4; predicted changes in qualitative indicators are based on the judgment of the socioeconomic analysts.

Table 4-3. Impact Mechanisms and Indicators, and Significance Thresholds for Trawl Catcher Vessels

Impact Mechanisms	Indicator or Measure of Impact	Significance Thresholds
IFQ Allocation Rules	Number of initial QS recipients	+/- 20% change
IFQ Allocation Rules	Number of initial QS recipients that participated in 2005	+/- 20% change
IFQ Allocation Rules	Ex-Vessel value of QPs allocated to 2005 participants	+/- 20% change
IFQ Allocation Rules	Ex-vessel value of transfers to restore participants to 2005 level	+/- 20% change
IFQ Allocation Rules	Ex-Vessel value of QPs allocated to permit holders that did not participate in 2005	+/- 20% change
Initial Allocation Rules, Increased Certainty	Relative market power of harvesters & processors	Qualitative judgment of analysts
Profit Motive, Increased Certainty Reduce Incidental Catch Rates, Reporting and Monitoring Requirements	Incidental catch rates of overfished species	+/- 20% change
Reduce Incidental Catch Rates, Profit Motive,	Seasonal distribution of fishing effort	Chi-square tests
Reduce Incidental Catch Rates, Profit Motive, Consolidation	Geographic distribution of effort	Chi-square tests
Reporting and Monitoring Requirements, Profit Motive, Reduce Incidental Catch Rates	Total Discards	+/- 20% change
Profit Motive, Reduce Incidental Catch Rates	Higher target OY utilization rates	+/- 20% change
Profit Motive, Reduce Incidental Catch Rates	Total ex-vessel revenue	+/- 20% change
Consolidation, Increased Certainty	Safety-related incidents & accidents	Qualitative judgment of analysts
Profit Motive	Crew/skipper shares	+/- 20% change
Reduce Incidental Catch Rates, Monitoring Requirements, Profit motive	Variable cost per target pound	+/- 20% change
Monitoring Requirements, Profit Motive	Variable cost per day	+/- 20% change
Profit Motive, IFQ Allocation Rules, Consolidation	Number of active vessels	+/- 20% change
Profit Motive, IFQ Allocation Rules, Consolidation	Number of permit holders	+/- 20% change
Profit Motive, Consolidation, Reduce Incidental Catch Rates, Monitoring Requirements	Number of trips per year	+/- 20% change
Profit Motive, Consolidation, Reduce Incidental Catch Rates, Monitoring Requirements	Number of fishing days per year	+/- 20% change
Profit Motive, Monitoring Requirements	Vessel-level fixed cost	+/- 20% change
Consolidation	Fleet-wide fixed Cost	+/- 20% change
Consolidation, Profit Motive	Number of crew members	+/- 20% change
Profit Motive, Consolidation, Reduce Incidental Catch Rates, Monitoring Requirements	Vessel Level Profitability	+/- 20% change
Consolidation, Profit Motive, Reduce Incidental Catch Rates, Monitoring Requirements	Fleet-wide Profits	+/- 20% change
Reduce Incidental Catch Rates, Profit Motive, Initial Allocation Rules, Reporting and Monitoring Requirements	Market value of QS	+/- 20% change

Table 4-4 provides a comparative summary table of the direct and indirect effect of the alternatives with respect to trawl groundfish catcher vessels. The rows in the table show the indicators of change as described in Table 4-3. The columns in the table list the main suite of alternatives, along with the 5 different allocation programs associated with Alternative 3. The cells of the table will reflect the significance criteria and ratings developed for the indicator in the direct and indirect effects analysis in Section 4.3.2 through Section 4.3.5.1. Table 4-5 is similar to Table 4-4 except that it lists the significance criteria and ratings for the cumulative effects.

Table 4-4. Summary of the Direct and Indirect Effects of the Alternatives on Trawl Groundfish Catcher Vessels

4.3.2 Alternative 1: The No-Action Alternative

The analysis of effect of Alternative 1 will be relatively straight-forward compared to the effects analyses of the Action Alternatives. This is because Alternative 1 is very similar to status quo.

4.3.2.1 Direct and Indirect Effects Analysis

The analysis of effect of Alternative 1 will be relatively straight-forward compared to the effects analyses of the Action Alternatives. This is because Alternative 1 is very similar to status quo.

In general the analysis will describe the overall effects of the bulleted list of items in Section 4.1.1 beginning on page 195.

The analysis will also project the likely potential changes in the indicators that result from the applicable scenarios described in Section 4.1.4 beginning on page 198. In addition the cumulative effect analysis under Alternative 1 will describe and discuss most of the RFFAs that are likely affect the outcomes under all of the alternatives. The initial list of RFFAs is provided in Section 4.1.5.

4.3.2.1.1 Projected Conditions of the Indicators under the Alternative

4.3.2.1.2 Changes from the Baseline Conditions

4.3.2.2 Cumulative Effect Analysis

4.3.2.2.1 Discussion of Likely RFFAs

4.3.2.2.2 Projected Conditions of the Indicators under the Alternative

4.3.2.2.3 Changes from the Baseline Conditions

4.3.3 Alternative 2: IFQs for Whiting and Trawl Target Species

4.3.3.1 Direct and Indirect Effects Analysis

4.3.3.1.1 Projected Conditions of the Indicators under the Alternative

4.3.3.1.2 Changes from the Baseline Conditions

4.3.3.2 Cumulative Effect Analysis

4.3.3.2.1 Discussion of Likely RFFAs

4.3.3.2.2 Projected Conditions of the Indicators under the Alternative

4.3.3.2.3 Changes from the Baseline Conditions

4.3.4 Alternative 3: IFQs for All Groundfish except Other Species

Alternative 3 consists of five major options. The options vary by the allocation rules used. Because it is expected that the initial allocation of IFQ will be one of the most important impact mechanisms the Consulting Team believes it is important to treat each of these major options as a stand-alone alternative in the effects analysis.

4.3.4.1 Alternative 3A: IFQ for all but Other Species with 50/50 QS Allocation Split between Harvesters and Processors

4.3.4.1.1 Direct and Indirect Effects Analysis

4.3.4.1.1.1 Projected Conditions of the Indicators under the Alternative

4.3.4.1.1.2 Changes from the Baseline Conditions

4.3.4.1.2 Cumulative Effect Analysis

4.3.4.1.2.1 Discussion of Likely RFFAs

4.3.4.1.2.2 Projected Conditions of the Indicators under the Alternative

4.3.4.1.2.3 Changes from the Baseline Conditions

4.3.4.2 Alternative 3Ba: IFQ for all but Other Species with a 100/0 QS Allocation Split between Harvesters and Processors

4.3.4.2.1 Direct and Indirect Effects Analysis

4.3.4.2.1.1 Projected Conditions of the Indicators under the Alternative

4.3.4.2.1.2 Changes from the Baseline Conditions

4.3.4.2.2 Cumulative Effect Analysis

4.3.4.2.2.1 Discussion of Likely RFFAs

4.3.4.2.2.2 Projected Conditions of the Indicators under the Alternative

4.3.4.2.2.3 Changes from the Baseline Conditions

4.3.4.3 Alternative 3Bb: IFQ for all but Other Species with a 90/10 QS Allocation Split between Harvesters and Processors

4.3.4.3.1 Direct and Indirect Effects Analysis

4.3.4.3.1.1 Projected Conditions of the Indicators under the Alternative

4.3.4.3.1.2 Changes from the Baseline Conditions

4.3.6 Alternative 5: Permit Stacking

4.3.6.1 Direct and Indirect Effects Analysis

4.3.6.1.1 Projected Conditions of the Indicators under the Alternative

4.3.6.1.2 Changes from the Baseline Conditions

4.3.6.2 Cumulative Effect Analysis

4.3.6.2.1 Discussion of Likely RFFAs

4.3.6.2.2 Projected Conditions of the Indicators under the Alternative

4.3.6.2.3 Changes from the Baseline Conditions

4.4 Trawl Catcher Processors

4.4.1 Analytical Framework for the Assessment of Effects on Trawl Catcher Processors

In general the assessment of the impacts of the alternatives on catcher processors will mirror the assessment of impacts on catcher vessels. A key difference, however, is the fact that with catcher processors there is no uncertainty generated from the relationship between harvesters and processors. Furthermore, the impacts of the IFQ alternative will be minimized by that catcher processors already operate in rationalize manner through their cooperative. Therefore they are unlikely to realize significant changes in incidental catch, the utilization of target species. If is likely, however that the initial allocation rules could have a measurable affect on catcher processors. To the extent that the initial allocation rule provides catcher processors with QS and QP that match their current use, impacts of the IFQ program will be likely be minimal. However, given that catcher processors have used observers on all of their vessels 100 of the time (and therefore all of their catch is reported), it is possible they will receive a disproportionate amount of QS for certain species that other catcher vessel have not reported.

Table 4-6 provides an overview of the impact mechanism, indicators or measures of impact and the significance thresholds that will be used. For quantitative indicators, this section will utilize a significance threshold of +/- 20 percent to indicate whether the measured change in the indicator from the comparative baseline is significant. The same threshold is used to roughly assess changes in qualitative indicators (e.g., fishing vessel safety). Changes in quantitative indicators will be based on model projections as described in subsection 4.1.7.2 combined with the scenarios described in Subsection 4.1.4; predicted changes in qualitative indicators are based on the judgment of the socioeconomic analysts.

Table 4-6. Impact Mechanisms and Indicators, and Significance Thresholds for Trawl Catcher Processors

Impact Mechanisms	Indicator or Measure of Impact	Significance Thresholds
IFQ Allocation Rules	Number of initial QS recipients	+/- 20% change
IFQ Allocation Rules	Number of initial QS recipients that participated in 2005	+/- 20% change
IFQ Allocation Rules	Ex-Vessel value of QPs allocated to 2005 participants	+/- 20% change
IFQ Allocation Rules	Ex-vessel value of transfers to restore participants to 2005 level	+/- 20% change
IFQ Allocation Rules	Ex-Vessel value of QPs allocated to permit holders that did not participate in 2005	+/- 20% change
Profit Motive, Increased Certainty Reduce Incidental Catch Rates, Reporting and Monitoring Requirements	Incidental catch rates of overfished species	+/- 20% change
Reduce Incidental Catch Rates, Profit Motive,	Seasonal distribution of fishing effort	Chi-square tests
Reduce Incidental Catch Rates, Profit Motive, Consolidation	Geographic distribution of effort	Chi-square tests
Reporting and Monitoring Requirements, Profit Motive, Reduce Incidental Catch Rates	Total Discards	+/- 20% change
Profit Motive, Reduce Incidental Catch Rates	Higher target OY utilization rates	+/- 20% change
Profit Motive, Reduce Incidental Catch Rates	Total ex-vessel revenue	+/- 20% change
Consolidation, Increased Certainty	Safety-related incidents & accidents	Qualitative judgment of analysts
Profit Motive	Crew/skipper shares	+/- 20% change
Reduce Incidental Catch Rates, Monitoring Requirements, Profit motive	Variable cost per target pound	+/- 20% change
Monitoring Requirements, Profit Motive	Variable cost per day	+/- 20% change
Profit Motive, IFQ Allocation Rules, Consolidation	Number of active vessels	+/- 20% change
Profit Motive, IFQ Allocation Rules, Consolidation	Number of permit holders	+/- 20% change
Profit Motive, Consolidation, Reduce Incidental Catch Rates, Monitoring Requirements	Number of trips per year	+/- 20% change
Profit Motive, Consolidation, Reduce Incidental Catch Rates, Monitoring Requirements	Number of fishing days per year	+/- 20% change
Profit Motive, Monitoring Requirements	Vessel-level fixed cost	+/- 20% change
Consolidation	Fleet-wide fixed Cost	+/- 20% change
Consolidation, Profit Motive	Number of crew members	+/- 20% change
Profit Motive, Consolidation, Reduce Incidental Catch Rates, Monitoring Requirements	Vessel Level Profitability	+/- 20% change
Consolidation, Profit Motive, Reduce Incidental Catch Rates, Monitoring Requirements	Fleet-wide Profits	+/- 20% change
Reduce Incidental Catch Rates, Profit Motive, Initial Allocation Rules, Reporting and Monitoring Requirements	Market value of QS	+/- 20% change

Two summary tables (not shown but similar to Table 4-4 and Table 4-5) will provide an overview of the indirect effect and cumulative effects of the alternatives. These table will be followed by Sections 4.4.2 through 4.4.6. These sections are not shown, but will be structured in a manner similar to Sections 4.3.2 through 4.3.6.

4.5 Processors of Trawl Groundfish

4.5.1 Analytical Framework for the Assessment of Effects on Processors of Trawl Groundfish

Table 4-7 provides an overview of the analytical approach used to compare baseline and future conditions of processors or Trawl-caught groundfish. The table lists: 1) mechanisms that relate the proposed action to the impacts; 2) potential impacts; 3) measurement criteria or indicators used in assessing each type of impact; 4) significance criteria or thresholds. In general, the Action Alternatives create or enhance mechanisms that have the potential cause behavioral changes on the part of buyers and processors of trawl-caught groundfish, and on the trawl groundfish harvesters. These behavioral changes have the potential to create impacts, which in turn manifest themselves in the form of indicators of change. In general, the indicators of change are measurable with existing or predictable with models or other analytical tools. The extent that indicators change, relative to the baseline conditions, is an indication of the significance of the impact.

Table 4-7. Impact Mechanisms, Indicators and Significance Thresholds for Trawl Groundfish Processors under the Alternatives

Impact Mechanisms	Potential Impacts	Indicator	Significance Threshold
Allocation to Processors	Lack of allocation to independent buyers may force some to exit	Number of processors groups, facilities and buying stations	+/- 20 percent and qualitative judgment of analysts
Reduction in incidental catch rates	Increased Target Species Utilization	Total purchases of trawl-caught groundfish by species	+/- 20 percent and qualitative judgment of analysts
Allocation to Processors	Lack of allocation to independent buyers may force some to exit	Geographic distribution of facilities and buying stations by community	+/- 20 percent plus qualitative judgment of analysts
Allocations to processors	Changes in competition and changing relationships with harvesters		
Increased Certainty and flexibility			
Reduction in incidental catch rates	Geographic redistribution of harvests		
Reduction in incidental catch rates	Increased Target Species Utilization	Ex-Vessel Prices by species	+/- 20 percent and qualitative judgment of analysts
Reduction in incidental catch rates	If timing of harvests change, and supply at certain time change, then processors may same prices to influence supply		
Allocations to Processors	Changes in Market Power (processors may use QP on own vessels)		
Increased certainty and flexibility	New products or Markets may open		
Allocation to processors	Lack of allocation to independent buyers may force some to exit		
Harvester action to reduce incidental catch rates	If timing of harvests change, and supply at certain time change, then processors may same prices to influence supply	Distribution of purchases by month	+/- 20 percent and qualitative judgment of analysts
Increased certainty and flexibility	New products form may be developed and the mix of existing products may change.	Product mix by species	Qualitative judgment of analysts
Increased certainty and flexibility	If timing of harvests change, and	Product recovery rates by	Qualitative judgment of

Impact Mechanisms	Potential Impacts	Indicator	Significance Threshold
	supply at certain time change	product and species	analysts
Increased certainty and flexibility	Processors may be able to tweak processing lines		
Allocation to Processors	Harvester will need to acquire additional shares from Processors	Relationships with harvesters	Qualitative Judgment of Analysts
Allocation to Processors	Drives independent buyers out		
No Allocation to processors	Harvesters more likely to search out and find new markets		
Combination of above mechanisms	Combination of above impacts	Total ex-vessel value of purchases	+/- 20 percent and qualitative judgment of analysts
Combination of above mechanisms	Combination of above impacts	Total wholesale value of production	+/- 20 percent and qualitative judgment of analysts
Combination of above mechanisms	Combination of above impacts	Total operating costs	+/- 20 percent and qualitative judgment of analysts
Combination of above mechanisms	Combination of above impacts	Net revenues	+/- 20 percent and qualitative judgment of analysts
Combination of above mechanisms	Combination of above impacts	Relative dependency of West Coast trawl groundfish	+/- 20 percent and qualitative judgment of analysts
Combination of above mechanisms	Combination of above impacts	Processing employment	+/- 20 percent and qualitative judgment of analysts

4.5.1.1 Analytical Methods

The Consulting Team believes *a priori* that in addition need to increase profits, there are three primary mechanisms through which the IFQ alternatives influence behavior changes on the part of the buyers and processors of trawl groundfish. These mechanisms include: 1) the allocation to processors (or the lack thereof); 2) harvester actions to reduce incidental catch rates; 3) the increased certainty and flexibility inherent in IFQ systems. The impact mechanisms cause processors (and harvesters) to change their behavior. The behavior changes create impacts. In the table, the second column links the impact mechanism to the potential impact. In turn the impact is linked to a measurable indicator of change. Note that there may be several mechanisms that lead to a particular impact. Furthermore there may be several impacts that are manifest in a single indicator.

The following discussion focuses on each of the indicators listed in Table 4-7, and explains the reasoning and assumption employed, and describes the proposed analytical approach the Consulting Team proposes to use in the assessment of effects.

Table 4-8. Analytical Methods for Projecting Changes in Indicators for Processors of Trawl Groundfish

Indicator of Change	Analytical Methods
Number of processors groups, facilities and buying stations	The initial allocation rules will be used in the initial allocation model (described in Section 4.1.7.2) along with data gathered in key interviews to determine the number of independent buyers that will not receive harvesting QS. The Consulting Team believes *a priori* that the magnitude of the impacts will depend on specific allocation rules, specifically on: 1) the amount allocated to processors (options range from 0 percent to 50 percent); and 2) on the definition of processors to whom allocations would be provided. If independent buyers are allocated QS then it is more likely these firms would remain viable. If secondary processors are allocated QS then it is likely that these businesses may become more involved in primary processing and the numbers of buyers would increase.
Total purchases of trawl-caught groundfish by species	The total purchases of trawl caught groundfish will increase relative to the No-Action Alternative, if harvesters can reduce their incidental catch rates of overfished species. The incidental catch rate model described in Section 4.1.7.2, utilizes catch rate data by target species and month, and variance between individual harvesters. The model is not able to take into account the influence of processors on incidental catch rates. The Consulting Team believes that processors can have a major impact on incidental catch rates (and thus overall utilization of target species) through ex-vessel price signals and through other working arrangements with harvesters. Unfortunately there does not appear to be a way to quantify these influences, and therefore the model result will be augmented with qualitative assessments and the use of what-if scenarios
Distribution of facilities and buying stations by community	The distribution of processing facilities under the alternative will by the number of processors—which as discussed above is likely to change as a result of the alternatives. The distribution buyer and processors will also be influenced by the need to reduce incidental catches of overfished species to the extent that harvester will changed their fishing locations. The distribution of buyers and processor will also be influenced by the increased certainty and flexibility inherent in an IFQ system. If multi-location processors are relatively certainty they will receive adequate supplies then they may choose to alter the geographic location of their facilities. Projecting the geographic distribution of facilities will utilize the initial allocation model and the incidental catch rate model, along with data from key informant interviews. While some of the information will be quantifiable other parts will be based on the qualitative judgment of the analyst.

Indicator of Change	Analytical Methods
Ex-Vessel Prices by species	The effects on ex-vessel prices under an IFQ system are of critical importance. Ex-vessel prices paid to harvester by species will be influence by the preceding impacts that have already been discussed. In other words if there are significant changes in the number of buyers and processors, the amount of fish they are buying or their geographic distribution, then there are also likely to be changes in the ex-vessel prices. In addition, the ex-vessel prices paid will be influenced by the needs of harvesters reduce incidental catches. Depending on relative market power processors can influence the timing of harvests through price signals. For example if a particular processors wants to discourage too much harvest in a particular month in which there are relatively low incidental catch rates, then that processor could lower prices for the target species in that month. If the processor has sufficient market power then, even if other processors do not follow suit, that processor would not expect an overall reduction in the amount of deliveries to its facilities. If the market leader is able to maintain those lower prices, then in the long-run it would be expected that other processor (those with less market power) would follow the leader and lower prices as well. As discussed in Subsection 4.1.7.2.4, the Consulting Team is investigation the use of experimental economics to help determine potential affects of the alternatives on ex-vessel price.
Distribution of purchases by month	As indicated in the previous row of the table, the distribution of purchases by month will be influence by consumer demand, relative market of processor and harvesters, and temporal differentials in incidental catch rate of overfished species. The incidental catch rate model, augmented with key informant interviews and, possibly augmented with results from an experimental economic study, will inform the analysis.
Product mix by species	The increased certainty and flexibility of an IFQ system are likely to influence the variety of product types and amounts generated from the groundfish trawl fishery. In other fisheries around the world that moved to an IFQ system, product mix changed significantly. Because the West Coast trawl groundfish fishery cannot be characterized as a race-for-fish, the change in this indicator may not be significant. Key informant interview will be the primary means used to evaluate changes in this indicator.

Indicator of Change	Analytical Methods
Product recovery rates by product and species	The increased certainty and flexibility of an IFQ system are likely to influence product recovery rates generated from the groundfish trawl fishery. In other fisheries around the world that moved to an IFQ system, product recovery rates improved significantly. Because the West Coast trawl groundfish fishery cannot be characterized as a race-for-fish, the change in this indicator may not be significant. Key informant interview will be the primary means used to evaluate changes in this indicator.
Relationships with harvesters	As discussed in previous rows of this table, the relationships between harvesters and processors are likely to be affected by the IFQ allocations. The initial allocation rules will in large part determine the direction of change. If processors are not allocated any harvesting IFQs then it is likely that harvesters will gain bargaining strength relative to processors. If processors are allocated harvesting shares, then the magnitude of the change in bargaining power will shift back to toward processors. At some (currently unknown) level, an allocation of IFQs to processors will lead to an increase in processor bargaining power relative to harvesters. Key informant interview will be a primary source of information. The interview will attempt to delineate the relationship under the baseline conditions to assess potential changes in those relationships under the alternatives. As discussed previously, quantifying the shift in bargaining power will not be easy. Key informant interview will be used, and it is possible that game theory and experimental economics may also be utilized.
Total ex-vessel value of purchases	The total ex-vessel value of purchases will be quantifiable under a set of assumptions about incidental catches, the timing of harvests, and improvements in the utilization of target species OYs. As indicated above however, the Consulting Team fully expects some unquantifiable changes in ex-vessel prices. The analysis will provide a quantitative assessment augmented with qualitative judgments.
Total wholesale value of production	The total wholesale value of production will be quantifiable under a set of the same set of assumptions discussed in the previous row along with data from key informants about production by product types and product prices. As indicated above however, the Consulting Team fully expects some unquantifiable changes in wholesale prices, and product volumes. The analysis will provide a quantitative assessment augmented with qualitative judgments.
Total operating costs	Very little data regarding operating costs of processors are likely to be available. The analysis will provide a qualitative assessment on the basis of findings with respect to number of processors, timing of production, and volume of product.
Net revenues	As with operating costs this will be qualitative assessment relying on findings on the indicator discussed above.

Indicator of Change	Analytical Methods
Relative dependency of West Coast trawl groundfish	This indicator will be based on total ex-vessel purchases of both groundfish and non-groundfish. It will assume that non-groundfish purchases remain constant. The estimates will also influenced by finding with respect to the number and type of processors that remain in the fishery under the alternatives. As with the assessment of changes in total ex-vessel value the analysis will provide both quantitative estimates and qualitative judgments.
Processing employment	Processing employment is expected to change in a similar manner as total wholesale value. The Consulting Team plans to utilize processing employment data from each State's labor department. These data are fairly reliable given that the existence and use of standardize codes that show the show processing employment. These data will be augmented by estimates of processing labor relative to wholesale value on motherships.

Two summary tables (not shown but similar to Table 4-4 and Table 4-5) will provide an overview of the indirect effect and cumulative effects of the alternatives. These table will be followed by Sections 4.5.2 through 4.5.6. These sections are not shown, but will be structured in a manner similar to Sections 4.3.2 through 4.3.6.

4.6 Non-Trawl Commercial Harvesters

4.6.1 Analytical Framework for the Assessment of Effects on Non-Trawl Commercial Harvesters

Table 4-9 provides an overview of 1) potential impacts; 2) mechanisms that relate the proposed action to the impacts; 3) measurement criteria or indicators used in assessing each type of impact; 4) models and data sets used in the analysis; and 5) significance criteria or thresholds.

Table 4-9. Impact Mechanisms, Indicators, and Significance Thresholds for Non-Trawl Commercial Harvesters under the Alternatives

Potential Impacts	Impact Mechanisms	Measurement Criteria	Source Data	Significance Criteria
Change in the participation, fishing patterns and economic performance of non-trawl commercial harvesters	Consolidation of trawl harvest operations results in spillovers in other fisheries. Management of trawl fleet influences management of non-trawl vessels.	Number of participating catcher vessels	Available literature, together with expert opinion and other pertinent information, will play a critical role in the analysis of each criterion	Will not be able to derive quantitative threshold, will discuss qualitatively
		Landings, ex-vessel revenues and ex-vessel prices by species		
		Distribution of landings by month		
		Geographic distribution of effort		
		Distribution of ex-vessel revenue by permit holder residence		

4.6.1.1 Potential Impacts and Impact Mechanisms

While non-trawl vessels, and their owners and crew, would not be directly affected by the three IFQ alternatives (Alternatives 2 – 4), they may be indirectly affected. The most obvious indirect effects are the economic impacts of spillovers resulting from fleet consolidation. If the trawl fleet consolidates, vessels and crew members no longer employed in trawl fisheries will potentially be able to switch into non-trawl fisheries. The increased effort in non-trawl fisheries would likely have a negative impact on the economic performance of the fishers already engaged in those fisheries. These changes in economic performance could, in turn, affect participation levels and fishing patterns. Management action taken with respect to the trawl fleet could influence future actions taken with respect to non-trawl vessels. Any projection of changes in the management regime for non-trawl vessels would be speculative, but future management actions would likely lead to changes in the conditions of these vessels.

4.6.1.2 Measurement Criteria and Significance Criteria

The same measurement criteria used to describe historical and baseline conditions in Chapter 3 are used to evaluate the effects of the alternatives.

Quantitative significance thresholds are inappropriate because of the absence of data and models. Instead, qualitative judgments as to the significance of effects will be made.

4.6.1.3 Methods, Models, and Data Sets

Available literature, together with expert opinion and other pertinent information, will play a critical role in the analysis of each criterion.

Two summary tables (not shown but similar to Table 4-4 and Table 4-5) will provide an overview of the indirect effect and cumulative effects of the alternatives. These table will be followed by Sections 4.6.2 through 4.6.6. These sections are not shown, but will be structured in a manner similar to Sections 4.3.2 through 4.3.6.

4.7 Buyers and Processors that do Not Purchase Trawl Groundfish

4.7.1 Analytical Framework for the Assessment of Effects on Buyers and Processors that do Not Purchase Trawl Groundfish

Table 4-10 provides an overview of 1) potential impacts; 2) mechanisms that relate the proposed action to the impacts; 3) measurement criteria or indicators used in assessing each type of impact; 4) models and data sets used in the analysis; and 5) significance criteria or thresholds.

Table 4-10. Impact Mechanisms, Indicators, and Significance Thresholds for Buyers and Processors that do Not Purchase Trawl Groundfish under the Alternatives

Potential Impacts	Impact Mechanisms	Measurement Criteria	Source Data	Significance Criteria
Change in the processing patterns and economic performance of buyers and processors that do not purchase trawl groundfish	Restrictions in ability to enter the trawl-caught groundfish processing market. Increased competition.	Number of buyers and facilities	Available literature, together with expert opinion and other pertinent information, will play a critical role in the analysis of each criterion	Will not be able to derive quantitative threshold, will discuss qualitatively
		Total purchases by fishery		
		Relative market share		
		Geographic distribution of participation		

4.7.1.1 Potential Impacts and Impact Mechanisms

Because buyers and processors that do not purchase trawl groundfish are not involved in the West Coast groundfish trawl fishery they will not be directly affected by the three IFQ alternatives (Alternatives 2 – 4). However, these buyers and processors would be indirectly affected if a trawl IFQ program restricts their ability to enter the trawl-caught groundfish processing market in the future. They would also be affected if higher profits for processors of trawl groundfish encourages these processors to increase their level of activity in non-trawl groundfish fisheries or non-groundfish fisheries. The potential restrictions on market entry and increased competition could have a negative impact on the economic performance of the buyers and processors in this category, and cause them to adjust their processing patterns.

4.7.1.2 Measurement Criteria and Significance Criteria

The same measurement criteria used to describe historical and baseline conditions in Chapter 3 are used to evaluate the effects of the alternatives.

Quantitative significance thresholds are inappropriate because of the absence of data and models. Instead, qualitative judgments as to the significance of effects will be made.

4.7.1.3 Methods, Models, and Data Sets

Available literature, together with expert opinion and other pertinent information, will play a critical role in the analysis of each criterion.

Two summary tables (not shown but similar to Table 4-4 and Table 4-5) will provide an overview of the indirect effect and cumulative effects of the alternatives. These table will be followed by Sections 4.7.2 through 4.7.6. These sections are not shown, but will be structured in a manner similar to Sections 4.3.2 through 4.3.6.

4.8 Recreational Harvesters

4.8.1 Analytical Framework for the Assessment of Effects on Recreational Harvests

As indicated in Section 3.9, recreational harvesters of groundfish may be indirectly affected by a trawl IFQ program. Perhaps the most significant way in which recreational harvesters could be affected is through in the political balance of power in the fishery management process. If trawl groundfish harvesters and processors become more profitable under a trawl IFQ program, their level of participation and influence in Council and NMFS management processes may increase. This additional participation could ultimately result in increased constraints on the growth potential of the recreation fisheries. This is particularly true if the IFQ Program leads to permanent sector allocations for the trawl groundfish fishery. Finally, the need to for trawl harvester to reduce incidental catch rates of overfished species and consolidation may affect geographic distribution of trawl vessels and the number of trawl groundfish vessels on the ground.

4.8.1.1 Impacts, Mechanisms, and Condition Indicators for Recreational Harvesters of Groundfish

The assessment indirect impacts of the trawl IFQ program on recreational harvests will primarily be qualitative in nature, but will also based in part of changes projected for the alternatives for trawl groundfish harvesters and processors. Table 4-11 summarizes the Impact mechanisms, potential impacts, indicators or measurement criteria and significance thresholds for the effects of the alternative under the alternatives.

Table 4-11. Impact Mechanisms, Indicators and Significance Thresholds for Recreational Harvesters

Impact Mechanisms	Potential Impacts	Indicators / Measurement Criteria	Significance Threshold
Increased profitability of trawl harvesters and processors under IFQs	Change in Political Power	Projected trawl sector profits	+/- 20 percent
Permanent to allocation trawl sector	Limitations on recreational fishing growth	Future apportionment s of OYs to recreational sector the trawl groundfish sector.	Any permanent limit on growth would be deemed significant.
Trawl harvester need to reduce incidental catch, consolidation	Crowding of fishing grounds	Projections of number of trawl groundfish vessels	+/- 20 percent
		Projections of geographic distribution of harvests	+/- 20 percent shift in trawl distributions

Two summary tables (not shown but similar to Table 4-4 and Table 4-5) will provide an overview of the indirect effect and cumulative effects of the alternatives. These table will be followed by Sections 4.6.1.2 through 4.6.1.6. These sections are not shown, but will be structured in a manner similar to Sections 4.3.2 through 4.3.6.

4.9 Communities

4.9.1 Analytical Framework for the Assessment of Effects on Communities

Table 4-12 provides an overview of 1) potential impacts; 2) mechanisms that relate the proposed action to the impacts; 3) measurement criteria or indicators used in assessing each type of impact; 4) models and data sets used in the analysis; and 5) significance criteria or thresholds.

Table 4-12. Overview of Analytical Approach Used to Compare Baseline and Future Conditions of Communities under the Alternatives.

Potential Impacts	Impact Mechanisms	Measurement Criteria	Source Data	Significance Criteria
Change in Vessels/Permits from Community	Consolidation of harvest operations; changes in distribution of harvest operations	Number of active vessels	Vessel count	+/-20% Change
		Number of permit holders	Permit data	+/- 20% Change
Change in Processing in Community	Consolidation of processing operations; changes in distribution of processing operations	Number of active processors	Output from sector analysis	+/- 20% Change
Change in Employment by Sector in Community	Consolidation and change in geographic distribution of sectors	Estimated number of jobs per sector	Output from sector analysis	+/- 20% Change
Change in Income in Community	Change in share based compensation structure for crew; loss of employment income through consolidation	Estimated income per sector	Output from sector analysis	+/- 20% Change
Change in Public Revenues in Community	Shift in geographic patterns of economic activity; changes in raw and processed product cost/value	Estimated revenues	Derived from output from sector analysis	+/- 20% Change
Change in Support Service Sector in Community	Changes in demand related to consolidation of fleet and processing as well as spatial and temporal redistribution of fishery related activity	Can be discussed in qualitative terms only.	Built on assumptions derived from sector analysis	Will not be able to derive quantitative threshold, will discuss qualitatively

4.9.1.1 Potential Impacts

The current economic deterioration of the West Coast groundfish trawl fishery would likely continue under the No-Action Alternative. This continuing deterioration would be a major concern for fishing communities that have a vital interest in the short-term and long-term economic viability of the fishery, the income and employment opportunities it provides, and the safety of participants in the fishery.

If the history of the implementation of other IFQ programs is a guide, the three IFQ alternatives (Alternatives 2 – 4) will result in social impacts being felt in a range of communities, as fewer vessels will participate in the fishery and fewer communities will be the sites of processing effort. In some ways, transition to an IFQ program could be viewed as neutral or a zero-sum exercise from an economic perspective, where presumably similar overall harvest levels will be sustained and potential losses in landings in one area (from a shift in distribution of effort), for example, would be offset by potential gains in landings elsewhere. From a social impact perspective, however, impacts result from at-risk and beneficiary populations or communities being different. Furthermore all things are not equal; there is intended to be an overall gain in value of the fishery with the transition to an IFQ system through an increase in efficiency and the increase in participant's ability to pursue value-added opportunities, among other program aspects. Again, if history is a guide, there will be fewer, if more stable, jobs across a range of sectors as efficiencies are increased and a redistribution of income and revenue opportunities will occur. The mechanisms that relate a trawl IFQ program to various potential social impacts are outlined in more detail below.

4.9.1.2 Impact Mechanisms

Vessel consolidation

- Employment: loss of skipper and crew positions
- Income: change in compensation structure
- Vessel related support service demand decline
- Vessel activity related public revenues decline

Processor consolidation

- Employment and income changes for processing employees
- Processing activity related support service demand changes
- Processing activity related public revenue changes

Changes in spatial distribution of effort

- Changes in the spatial distribution of vessel homeporting and/or other vessel activity or vessel related activity (including support service activity)
- Changes in the distribution of landing patterns
- Changes in the distribution of processing effort
- Changes in temporal distribution of effort
- Changes in timing and duration of harvester related activities
- Changes in timing and duration of processing related activities
- Changes in timing and duration of support services demand

Other economic changes

- Changes in price/value of raw and processed product(s) and therefore related revenue as seen on a localized basis
- Changes in vessel/processor ratios or other changes influencing shifting rent between sectors as seen on a localized basis

4.9.1.3 Measurement Criteria or Indicators

Measurement criteria or indicators are summarized in Table 4-12. These include estimated counts or values associated with the various indicators noted. As important as overall counts or absolute measurements, however, is the potential for redistribution between communities through changes in spatial distribution of effort, not necessarily associated with harvest activity itself, but through shifts brought about by consolidation and the pursuit of efficiency, which may favor particular communities or types of communities over others.

4.9.1.4 Models and Data

Information on likely numbers of harvesters and processors, and related derived measures, such as employment and income, will derive from information developed for the individual sectors as described in the previous sector profile sections of this document. These will then be applied to the community base.

Projections of change will not be made for each individual community. Patterns of redistribution accompanying or following consolidation, which will be important for the ultimate assessment of community impacts, will necessarily be described in qualitative terms, based in experience with previous IFQ programs as informed by the specific alternative attributes.

4.9.1.5 Significance Criteria or Thresholds

Consistent with the significance criteria utilized in the individual sector analyses, it is assumed that a 20 percent change in key indicators at the community level will be significant. Beyond individual sector changes, however, overall community level impact analysis will be driven by the combination of (a) direct fishery related changes and (b) community attributes of dependency and/or vulnerability. Further, indirect or cumulative impacts may prove significant in specific communities based on the combination of fishery engagement through direct participation and support service business participation. In the case of support service engagement, there are no standardized measures of community engagement or dependency, so there are no straightforward ways to establish quantitative thresholds of significance. Where quantitative thresholds are not of practical use, the significance of change will be discussed in terms of the nature, direction, and magnitude of likely impacts.

Two summary tables (not shown but similar to Table 4-4 and Table 4-5) will provide an overview of the indirect effect and cumulative effects of the alternatives. These table will be followed by Sections 4.9.2 through 4.9.6. These sections are not shown, but will be structured in a manner similar to Sections 4.3.2 through 4.3.6.

4.10 Tribes

4.10.1 Analytical Framework for the Assessment of Effects on Tribes

As noted in the existing conditions section, tribal groundfish fisheries are regulated by the participating tribes themselves, with the type of overall allocations varying by groundfish species or species group. While not necessarily directly affected by Federal and state management measures, tribal entities are involved in the Council process and craft their groundfish management measures in cooperation with federal and state managers. Further, tribes and tribal related entities may be direct participants in the non-tribal fisheries subject to management under the proposed alternatives (as may any other entity) and it is known that at least some tribes are involved with fisheries support service business ventures that rely to at least some degree on potentially affected non-tribal fishing entities. Further, tribes may experience impacts resulting from capital spillover, fishing effort spillover, market competition, and processing related impacts. These factors will be addressed primarily in qualitative terms, as will potential impacts to the coastal distribution of fishing activity and potential changes in the distribution of income derived from fishing activities. Tribal comment will be needed during this process.

Two summary tables (not shown but similar to Table 4-4 and Table 4-5) will provide an overview of the indirect effect and cumulative effects of the alternatives. These table will be followed by Sections 4.10.2 through 4.10.6. These sections are not shown, but will be structured in a manner similar to Sections 4.3.2 through 4.3.6.

4.11 Input Suppliers

4.11.1 Analytical Framework for the Assessment of Effects on Input Suppliers

As indicated in Section 3.12, input suppliers to the West Coast limited-entry trawl groundfish fishery may be indirectly affected by a trawl IFQ program. Businesses that supply inputs to groundfish trawl harvesters may be indirectly affected by a trawl IFQ program if the program causes behavioral changes in trawl groundfish harvesting operations. The Consulting Team's *a priori* expectation is that the indirect effects on input suppliers may not be as large as experienced in other IFQ programs because the race for fish in the West Coast groundfish trawl fishery has been virtually eliminated. However, because the implementation of IFQ programs in other fisheries around the world has had significant effects on input suppliers a careful examination of impacts is warranted.

Estimating impacts on input suppliers is complicated by the fact that many of the vessels and processors in the trawl groundfish sectors are not wholly dependent on the West Coast groundfish trawl fishery. Therefore, while a vessel may exit the West Coast groundfish trawl fishery it may remain active in other fisheries and continue to purchase a similar level of fixed or annual inputs. To simplify the analysis, it is assumed here that the only inputs that would be affected by a trawl IFQ program are those related to a vessel's level of fishing production, i.e., variable inputs.

The initial list[34] of variable inputs of trawl vessels that are likely to be affected by the alternatives include fuel, food, trawl gear, and observers.[35] For example, fuel expenditures are among the largest expense categories for fishing vessels. Under a trawl IFQ program, fish harvesters are expected to be better able to optimize their fishing activities over the course of the year, thereby decreasing fuel expenditures. As a result, marine fuel suppliers are likely to see a change in the demand for their product.

If there is considerable consolidation of the fleet, fewer trawl gear sets would be needed. On the other hand, consolidation would also mean that the gear on the vessels remaining in the fishery will see greater use during the year. Finally, if the remaining trawl harvesters become more profitable under a trawl IFQ program, they are more likely to replace and upgrade their gear more often.

[34] It could be argued that other inputs would be affected by a trawl IFQ program. This initial list could be augmented if it is determined that the use of other inputs may change significantly.

[35] Observers are included in this section because firms that provide observers are properly considered input suppliers. Inclusion of observers in this section does not imply that vessels would or would not be required to pay for observer coverage.

While fixed inputs are assumed to be unaffected by a trawl IFQ program, it is likely that a program would create new demands for the services of permit and QS brokers, and therefore effects on these input suppliers are included.

4.11.1.1 Impacts, Mechanisms, and Condition Indicators for Recreational Harvesters of Groundfish

Indicators of the effects of the alternative on input suppliers include but are not necessarily limited to the following:

- Fuel sales to trawl groundfish harvesters
- Estimated food sales to trawl groundfish harvesters
- Estimated annual sales of trawl gear in the West Coast groundfish trawl fishery
- Observer expenses, observer counts, and geographic distribution of observer supply businesses.

The assessment of indirect impacts of the trawl IFQ program on input suppliers will be based primarily on projected changes in the trawl groundfish catcher vessel classes. Because total vessel-level expenditures for the entire West Coast are unknown, it will not be possible to fully quantify impacts. Table 4-16 summarizes the Impact mechanisms, potential impacts, indicators or measurement criteria and significance thresholds for the effects of the alternative under the alternatives. Because the input suppliers for food, fuel are presumed to supply these input to both trawl and non-trawl, and recreational vehicle, the significant threshold used for these input is set at +/- 50 percent. Therefore if a supplier generates 40 percent of its revenue from trawl groundfish harvesters, then a 50 percent reduction in trawl expenditure would result in a 20 percent overall decline in revenue, which would be considered significant. Trawl gear suppliers may be more specialized and more dependent on the trawl fishery, and therefore the significant threshold is set at 20 percent. Similarly observer suppliers and permit brokers are likely to be more dependent on the trawl fishery and therefore a lower threshold may be reasonable.

Table 4-13. Impact Mechanisms, Indicators and Significance Thresholds for Input Suppliers under the Alternatives.

Impact Mechanisms	Potential Impacts	Indicators / Measurement Criteria	Significance Threshold
Consolidation, the profit motive, and the need to reduce incidental catches	Reduction total number of trips reduction in total days fished and increases in CPUE for target species.	Fuel expenditures	+/- 50 percent
		Food expenditures	+/- 50 percent
Consolidation	Reduction in the number of trawl vessels	Trawl gear expenditures	+/- 20 percent
The requirement for 100 percent monitoring	Increase in the number of observer days	Expenditures on Observers	+/- 20 percent
The initial allocation and transferability	Transfers of QS and QP and cumulative trip limits	Ex-vessel value of transfers	+/- 20 percent
Consolidation, the profit motive, and the need to reduce incidental catches	Geographic re-distribution of expenditures	Geographic distribution of permit holders remaining in the fishery	Qualitative judgment of the analysts

Two summary tables (not shown but similar to Table 4-4 and Table 4-5) will provide an overview of the indirect effect and cumulative effects of the alternatives. These table will be followed by Sections 4.11.2 through 4.11.6. These sections are not shown, but will be structured in a manner similar to Sections 4.3.2 through 4.3.6.

4.12 Wholesalers and Retailers

4.12.1 Analytical Framework for the Assessment of Effects on Wholesalers and Retailers

Wholesale and retail suppliers of groundfish would be indirectly affected by a trawl IFQ program to the extent that there are changes in groundfish product variety and groundfish product flows generated by trawl groundfish processors. Wholesale and retail suppliers will also be affected to the extent that the individual firms within the in sector directly benefit from the IFQ program, i.e. vertically integrated firms.

The implementation of IFQ programs in other fisheries around the world has created significant changes in the timing of harvests and types of products generated, but most of those fisheries were characterized by a race for fish management regime. These impacts are less likely in the West Coast groundfish trawl fishery because the fishery does not currently experience a race for fish—cumulative trip limits spread harvests out over time, thereby generally preventing market gluts. It is possible, however, that a trawl IFQ program would create incentives to decrease the period over which the harvest of a particular species take place, and therefore would lead to greater variances in product flow.

It is also possible that wholesalers and retailers, that are also trawl groundfish buyers and processors, may have be able to increase their relative market share because that may experience greater certainty of supplies and increasing profits. Therefore potential effects will report, to the extent possible, on integrated and non-integrated firms.

- Change in total wholesale value of non-integrated wholesalers and retailers
- Change in total wholesale value of integrated wholesalers and retailers
- Estimated market share of non-integrated wholesalers and retailers
- Estimated market share of integrated wholesalers and retailers

Data documenting the activities of wholesalers and retailers with respect to trawl groundfish are not known to exist, nor are reliable comprehensive data on wholesale or retail values. Therefore, the assessment of effects on wholesalers and retailers of trawl groundfish will be largely qualitative, relying largely on key informant interviews, and secondary data.

Table 4-14 shows the impact mechanisms, potential impacts, indicators and significance thresholds for of the effects of the alternatives on wholesalers and retailers.

Table 4-14. Impact Mechanisms, Indicators and Significance Thresholds for Wholesalers and Retailers under the Alternatives

Impact Mechanisms	Potential Impacts	Indicators / Measurement Criteria	Significance Threshold
Initial allocation rules, profit motive, reduction in incidental catch rates, greater utilization of target species, increased certainty and flexibility of harvesters and processors.	Creation of new products and changes in timing of production	Change in wholesale value of integrated firms	Qualitative judgment of analysts
		Change in wholesale value of non-integrated firms	Qualitative judgment of analysts
Initial allocation rules, profit motive	Reduction in competition	Market share of non-integrated firms	Qualitative judgment of analysts
		Market share non-integrated firms	Qualitative judgment of analysts

Two summary tables (not shown but similar to Table 4-4 and Table 4-5) will provide an overview of the indirect effect and cumulative effects of the alternatives. These table will be followed by Sections 4.12.2 through 4.12.6. These sections are not shown, but will be structured in a manner similar to Sections 4.3.2 through 4.3.6.

4.13 Consumers

4.13.1 Analytical Framework for the Assessment of Effects on Consumers

Consumers of West Coast trawl groundfish may be indirectly affected by a trawl IFQ program if the prices, quality or availability of groundfish products change. Currently cumulative trip limits in the West Coast groundfish trawl fishery already spread out harvests and allow processors to provide a wide variety of products to meet consumer demand. Therefore, the impacts of a trawl IFQ program on the market for trawl groundfish may be minimal.

Indicators of the effects of the alternatives on the consumer market for trawl groundfish include the following:

- Changes in product types and amounts by species group
- Changes in retail product prices by product type and species group

Comprehensive data documenting the consumer market for West Coast trawl groundfish are not known to exist. Therefore, the description of the effects on the consumer market will largely qualitative, and will rely largely on key informant interviews, secondary data, and the judgment of the analysts

Table 4-15. Impact Mechanisms, Indicators, and Significance Thresholds for Consumers

Impact Mechanisms	Potential Impacts	Indicators / Measurement Criteria	Significance Threshold
Initial allocation rules, profit motive, greater utilization of target species OYs.	Creation of new products and changes in timing of production	Product types and amounts by species group	Qualitative judgment of analysts
		retail product prices by product type by species group	Qualitative judgment of analysts
		Total estimated retail value of products	Qualitative judgment of analysts

Two summary tables (not shown but similar to Table 4-4 and Table 4-5) will provide an overview of the indirect effect and cumulative effects of the alternatives. These table will be followed by Sections 4.13.2 through 4.13.6. These sections are not shown, but will be structured in a manner similar to Sections 4.3.2 through 4.3.6.

4.14 General Public

4.14.1 Analytical Framework for the Assessment of Effects on the General Public

Table 4-16 provides an overview of 1) potential impacts; 2) mechanisms that relate the proposed action to the impacts; 3) measurement criteria or indicators used in assessing each type of impact; 4) models and data sets used in the analysis; and 5) significance criteria or thresholds.

Table 4-16. Impact Mechanisms, Indicators, and Significance Thresholds for the General Public

Potential Impacts	Impact Mechanisms	Measurement Criteria	Source Data	Significance Criteria
Changes in non-consumptive and non-use benefits	Change in the level of fishery waste and the conditions of marine ecosystems and associated species that have non-consumptive or non-use value	Discards Condition of overfished groundfish species Condition of potentially affected marine mammals, seabirds, other protected species, habitat, and predator-prey relationships	Impact analysis in this document for pertinent resource groups	No quantitative threshold available; will discuss qualitatively in terms of the direction and degree of change

4.14.1.1 Potential Impacts and Impact Mechanisms

Under the No-Action Alternative, the primary management tool would continue to be two-month cumulative landings limits available to vessels with limited entry trawl permits. Reporting of at-sea discards of groundfish would not be required, and uncertainties about the accuracy of bycatch estimation are likely to continue. As a consequence, members of fishing fleets will continue to place pressure on managers to be less conservative in their estimates of bycatch. The management regime would remain unresponsive to the wide variety of fishing business strategies and operational concerns. The inflexibility of this system limits the ability of individual vessels to do everything possible to reduce waste, discard, and collateral damage to marine plants and animals that have non-consumptive or non-use value.

Implementation of an IFQ system under Alternatives 2 - 4 may cause fishermen to change behavior in a way that could affect the level of waste in the West Coast groundfish trawl fishery and the impact of the fishery on marine ecosystems and associated species: fishermen could change the level of fishing effort they employ, the areas they fish, the time of year they fish, and/or the gear with which they fish. Under Alternative 5, permit stacking will allow the creation of larger limits and provide greater flexibility to harvesters, with the end product being possible changes in time and area of fishing.

4.14.1.2 Measurement Criteria and Significance Criteria

No quantitative significance thresholds are available for changes in the non-consumptive and non-use benefits derived from marine ecosystems and associated species of concern. Instead, qualitative judgments as to the significance of effects are made after considering information regarding impacts on 1) discards; 2) overfished groundfish species; and 3) marine mammals, seabirds, other protected species, habitat, and predator-prey relationships .

4.14.1.3 Methods, Models, and Data Sets

Directly measuring changes in individuals' non-consumptive and non-use values for potentially affected marine ecosystems under each alternative is beyond the scope of this analysis. Therefore, the direction and degree of change of selected indicators defined in other sections of the analysis are considered as proxy metrics for the non-consumptive and non-use benefits that the general public derives from marine ecosystems and associated species of concern. In general, it is assumed that positive changes in the status of marine ecosystem and associated species positively affect the flow of non-consumptive and non-use benefits.

Two summary tables (not shown but similar to Table 4-4 and Table 4-5) will provide an overview of the indirect effect and cumulative effects of the alternatives. These table will be followed by Sections 4.14.2 through 4.14.6. These sections are not shown, but will be structured in a manner similar to Sections 4.3.2 through 4.3.6.

4.15 Management Agencies

4.15.1.1 Analytical Framework for the Assessment of Effects on Management Agencies

Table 4-17 provides an overview of 1) potential impacts; 2) mechanisms that relate the proposed action to the impacts; 3) measurement criteria or indicators used in assessing each type of impact; 4) models and data sets used in the analysis; and 5) significance criteria or thresholds.

Table 4-17. Impact Mechanisms, Indicators, and Significance Thresholds for Management Agencies

Potential Impacts	Impact Mechanisms	Measurement Criteria	Source Data	Significance Criteria
Changes in cost-effectiveness of fisheries management	Modification to procedures used to manage the fishery	Management costs	Agency records, various federal and state reports, discussions with NMFS staff	+/- 20% change
		Enforcement feasibility		Level of change to existing program required
		Reliability of fishery data		Degree of modifications required to existing system
		Risk to the resources		Level of management system change required to ensure that fishery catch caps are exceeded

4.15.1.2 Potential Impacts and Impact Mechanisms

Under the No-Action Alternative, the primary management tool would continue to be two-month cumulative landings limits available to vessels with limited entry trawl permits. Reporting of at-sea discards of groundfish would not be required, and uncertainties about the accuracy of bycatch estimation are likely to continue.

The three IFQ alternatives (Alternatives 2 – 4) represent a significant departure from the way the West Coast groundfish trawl fishery has been managed and operated. There are four key operational elements associated with an IQ program: initial issuance of quota, appeals process, quota tracking and catch monitoring. Costs associated with initial issuance will depend upon the number of people or entities issued quota shares, the number of species and area specific allocations, and the availability of complete and accurate historical catch records. The cost of processing appeals will be dependent up the complexity of the initial allocation determination process, the numbers of involved parties and the quality of historical catch records. Quota share tracking involves, for example, monitoring individual harvest quota usage and quota transfers. The current catch monitoring system may require modification to ensure proper functioning of the program. For example, an electronic fish ticket system may provide a faster transmission of data to NMFS allowing for quicker updating of individual quota holdings and, therefore, greater flexibility for fishermen to transfer quota as needed. An observer program is a critical component of a catch monitoring system. In general, these programs are expensive and difficult to operate. However, they provide a way to monitor total removals. Well defined goals and objectives are critical prerequisites of an effective IFQ program. They will facilitate development of the design and operational characteristics of the program.

4.15.1.3 Measurement Criteria and Significance Criteria

The same measurement criteria used to describe historical and baseline conditions in Chapter 3 are used to evaluate the effects of the alternatives.

4.15.1.4 Methods, Models, and Data Sets

To facilitate analysis of the three IFQ alternatives (Alternatives 2 – 4), it will be necessary to contact the NOAA Fisheries Northwest Regional Office to determine the extent of work that already has been initiated. In addition to management costs, it will be necessary to examine enforcement, data reliability and resource risk issues. Observer/monitoring system costs will be a critical issue in the analysis.

Under Alternative 5, all enforcement, monitoring, catch accounting and observer coverage levels are assumed to be equivalent to those under the No-Action Alternative. In will be necessary to determine the nature of program changes that will be needed to accommodate permit stacking. Once these changes are identified, it will be possible to examine impacts associated with such a change. How the remaining effects will be affected by this alternative will be determined by consulting with agency staff.

Two summary tables (not shown but similar to Table 4-4 and Table 4-5) will provide an overview of the indirect effect and cumulative effects of the alternatives. These table will be followed by Sections 4.15.2 through 4.15.6. These sections are not shown, but will be structured in a manner similar to Sections 4.3.2 through 4.3.6.

4.16 Groundfish Resources

4.16.1 Analytical Framework for the Assessment of Effects on Groundfish Resources

Table 4-18 provides an overview of 1) potential impacts; 2) mechanisms that relate the proposed action to the impacts; 3) measurement criteria or indicators used in assessing each type of impact; 4) models and data sets used in the analysis; and 5) significance criteria or thresholds.

Table 4-18. Impact Mechanisms, Indicators, and Significance Thresholds for Groundfish Resources

Potential Impacts	Impact Mechanisms	Measurement Criteria	Source Data	Significance Criteria
Changes in the capacity of a stock to produce MSY on a continuing basis and in the sustainability of a stock	Flexibility of fishermen in selecting the level of fishing effort they employ, the area they fish, the time of year they fish, and the gear with which they fish	Fishing mortality	Available literature, including the FMP, recent stock assessments, and EISs, together with expert opinion, and other pertinent information will play a critical role in the analysis of each criterion	Relation to overfishing mortality rate
		Biomass level		Stock size relative to maximum stock size threshold (MSST)
		Spatial/temporal concentration of catch		Stock size relative to maximum stock size threshold (MSST)
		Prey availability		Stock size relative to maximum stock size threshold (MSST)
		Habitat suitability		Stock size relative to maximum stock size threshold (MSST)

4.16.1.1 Potential Impacts and Impact Mechanisms

Under the No-Action Alternative, the primary management tool would continue to be two-month cumulative landings limits available to vessels with limited entry trawl permits. Reporting of at-sea discards of groundfish would not be required, and uncertainties about the accuracy of bycatch estimation are likely to continue. As a consequence, members of fishing fleets will continue to place pressure on managers to be less conservative in their estimates of bycatch. The management regime would remain unresponsive to the wide variety of fishing business strategies and operational concerns. Under this system, there is little direct incentive for individual vessels to do everything possible to avoid take of species for which there are conservation concerns, such as overfished species.

The most significant impact of the three IFQ alternatives (Alternatives 2 - 4) on the capacity of target species or related species group(s) to produce maximum sustainable yield (MSY) on a continuing basis and on the sustainability of these stocks results from the flexibility that can be exercised in the use of quota shares. Under these alternatives, quota share holders may have greater freedom in determining the level of fishing effort to employ, selecting the area where to fish, picking the time during the year to fish, and choosing the gear with which they fish. During 2002 and 2003, the fishery was characterized by a significant under harvest of available catch quota for many species. A major factor contributing to this phenomenon was the small catch caps for some groundfish species. The ability to adjust operations to current conditions should reduce the number of under harvested species.
Under Alternative 5, permit stacking will allow the creation of larger limits. These larger limits will provide greater flexibility to harvesters, with the end product being possible reductions in incidental catch levels.

4.16.1.2 Measurement Criteria and Significance Criteria

The same measurement criteria used to describe historical and baseline conditions in Chapter 3 will be used to evaluate the effects of the alternatives.

The significance of the effects the are likely to surface as a result of implementation of the alternatives being considered are evaluated as to whether the impacts may be reasonably expected to jeopardize the sustainability of each target species or related species group(s).

Overfishing and stock size thresholds have been developed for key groundfish species. These thresholds are used to evaluate the significance of the effects of the alternative management actions. Fishing mortality rates that exceed the overfishing mortality rate are considered to jeopardize the capacity of the stock to produce MSY on a continuing basis and adversely impact the sustainability of the stock. A related measure of this potential is indicated by change in biomass levels. The significance of effects of the spatial/temporal concentration of the catch, the level of prey availability, and habitat suitability for target species is evaluated with respect to each stock's size relative to its MSST. An action that jeopardizes the stock's ability to sustain itself at or above its MSST is considered to adversely affect the sustainability of the stock. Species or species complexes that do not have reliable estimates of MSST cannot be evaluated for the significance of these effects.

4.16.1.3 Methods, Models, and Data Sets

Information developed in other sections of this EIS, mainly that dealing with predicted changes in fishing practices, will provide insight into how the operation of the fishery might change under the alternatives. Once this information is available, it will be possible to examine each criterion in Table 4-18. Available literature, including the FMP, recent stock assessments, EISs, together with expert opinion and other pertinent information will play a critical role in the analysis of each criterion in the table.

Two summary tables (not shown but similar to Table 4-4 and Table 4-5) will provide an overview of the indirect effect and cumulative effects of the alternatives. These table will be followed by Sections 4.16.2 through 4.16.6. These sections are not shown, but will be structured in a manner similar to Sections 4.3.2 through 4.3.6.

4.17 Other Fish Resources

4.17.1 Analytical Framework for the Assessment of Effects on Other Fish Resources

Table 4-19 provides an overview of 1) potential impacts; 2) mechanisms that relate the proposed action to the impacts; 3) measurement criteria or indicators used in assessing each type of impact; 4) models and data sets used in the analysis; and 5) significance criteria or thresholds.

Table 4-19. Impact Mechanisms, Indicators, and Significance Thresholds for Other Fish Resources

Potential Impacts	Impact Mechanisms	Measurement Criteria	Source Data	Significance Criteria
Changes in the sustainability of a stock	Flexibility of fishermen in selecting the level of fishing effort they employ, the area they fish, the time of year they fish, and the gear with which they fish	Fishing mortality	Available literature, including the FMP, recent stock assessments, and EISs, together with expert opinion, and other pertinent information will play a critical role in the analysis of each criterion	Level of mortality
		Biomass level		Stock size relative to Maximum sustainable yield biomass
		Spatial/temporal concentration of catch		Stock size relative to maximum stock size threshold (MSST)
		Prey availability		Availability relative to historical levels
		Habitat suitability		Level of damage relative to historical levels

4.17.1.1 Potential Impacts and Impact Mechanisms

Under the No-Action Alternative, the primary management tool would continue to be two-month cumulative landings limits available to vessels with limited entry trawl permits. Reporting of at-sea discards of groundfish would not be required, and uncertainties about the accuracy of bycatch estimation are likely to continue. As a consequence, members of fishing fleets will continue to place pressure on managers to be less conservative in their estimates of bycatch. The management regime would remain unresponsive to the wide variety of fishing business strategies and operational concerns. The inflexibility of this system limits the ability of individual vessels to do everything possible to avoid take of species in this resource category.

The most significant impact of the three IFQ alternatives (Alternatives 2 - 4) on the sustainability of Other Fish Resources results from the flexibility that can be exercised in the use of quota shares. Under these alternatives, quota share holders may have greater freedom in determining the level of fishing effort to employ, selecting the area where to fish, picking the time during the year to fish, and choosing the gear with which they fish. With the ability to change fishing operations, the bycatch of species in this category should go down in the West Coast groundfish trawl fishery. The enhanced fishery monitoring will allow improvement in the documentation of the bycatch of these species which will facilitate management of the fishery.

Under Alternative 5, permit stacking will allow quota share holders to increase the size of their limits. This should make it possible to reduce the bycatch of species in this resource category.

4.17.1.2 Measurement Criteria and Significance Criteria

The same measurement criteria used to describe historical and baseline conditions in Chapter 3 are used to evaluate the effects of the alternatives.

Significance of effects is based on the likelihood that population-level changes will result from internal events within the groundfish fishery. An effect that is considered not significant corresponds to a change that is not likely to result in population-level effects on these resources or that lies within the range of natural variability for the species.

4.17.1.3 Methods, Models, and Data Sets

Information developed in other sections of this EIS, mainly that dealing with predicted changes in fishing practices, will provide insight into how the operation of the fishery might change under the alternatives. Once this information is available, it will be possible to examine each criterion in Table 4-19. Available literature, including the FMP, recent stock assessments, EISs, together with expert opinion and other pertinent information will play a critical role in the analysis of each criterion in the table.

Two summary tables (not shown but similar to Table 4-4 and Table 4-5) will provide an overview of the indirect effect and cumulative effects of the alternatives. These table will be followed by Sections 4.17.2 through 4.17.6. These sections are not shown, but will be structured in a manner similar to Sections 4.3.2 through 4.3.6.

4.18 Marine Mammals

4.18.1 Analytical Framework for the Assessment of Effects on Marine Mammals

Table 4-20 provides an overview of 1) potential impacts; 2) mechanisms that relate the proposed action to the impacts; 3) measurement criteria or indicators used in assessing each type of impact; 4) models and data sets used in the analysis; and 5) significance criteria or thresholds.

Table 4-20. Impact Mechanisms, Indicators, and Significance Thresholds for Marine Mammals under the Alternatives

Potential Impacts	Impact Mechanisms	Measurement Criteria	Source Data	Significance Criteria
Changes in the reproduction and/or survival of a marine mammal species group in a way that could affect the population	Flexibility of fishermen in selecting the level of fishing effort they employ, the area they fish, the time of year they fish, and the gear with which they fish	Incidental take/entanglement in marine debris	Available literature, including the FMP, recent stock assessments, and EISs, together with expert opinion, and other pertinent information will play a critical role in the analysis of each criterion	Stock size or recovery time
		Harvest of prey species		Foraging success
		Spatial/temporal concentration of fishery		Survival and/or reproductive success
		Disturbance		Survival and/or reproductive success

4.18.1.1 Potential Impacts and Impact Mechanisms

Under the No-Action Alternative, the primary management tool would continue to be two-month cumulative landings limits available to vessels with limited entry trawl permits. The management regime would remain unresponsive to the wide variety of fishing business strategies and operational concerns. The inflexibility of this system limits the ability of individual vessels to do everything possible to avoid interactions with marine mammals.

The most significant impact of the three IFQ alternatives (Alternatives 2 - 4) on the reproduction and/or survival of marine mammal species groups results from the flexibility that can be exercised in the use of quota shares. Under these alternatives, quota share holders may have greater freedom in determining the level of fishing effort to employ, selecting the area where to fish, picking the time during the year to fish, and choosing the gear with which they fish. With the ability to change fishing operations, the probability of negative fishery/marine mammal interactions should go down. The enhanced fishery monitoring will allow improvement in the documentation of fishery/marine mammal interactions which will facilitate management of the fishery.

Under Alternative 5, permit stacking will allow quota share holders to increase the size of their catch limits. This should make it possible for quota share holders to adjust their fishing activities to reduce the probability of negative fishery/marine mammal interactions.

4.18.1.2 Measurement Criteria and Significance Criteria

The same measurement criteria used to describe historical and baseline conditions in Chapter 3 are used to evaluate the effects of the alternatives.

Potential effects of the alternatives would be estimated in light of the extent of direct take, disturbance by fishing vessels, and competition between the fisheries and marine mammals for food. Two issues to be explored are: 1) do these effects occur or could they occur under each alternative, and 2) if they do occur, do they occur to an extent that would limit the recovery of a listed species or adversely modify critical habitat. If these effects do occur to an extent that would limit the recovery of a listed species or adversely modify critical habitat, then it would be concluded that the action would have significant effects under NEPA. If these effects do not occur or are insignificant under the ESA, then it is concluded that the action would have no significant effects for the purpose of NEPA.

4.18.1.3 Methods, Models, and Data Sets

Information developed in other sections of this EIS, mainly that dealing with predicted changes in fishing practices, will provide insight into how the operation of the fishery might change under the alternatives. Once this information is available, it will be possible to examine each criterion in Table 4-20. Available literature, including the FMP, recent stock assessments, EISs, together with expert opinion and other pertinent information will play a critical role in the analysis of each criterion in the table.

Two summary tables (not shown but similar to Table 4-4 and Table 4-5) will provide an overview of the indirect effect and cumulative effects of the alternatives. These table will be followed by Sections 4.18.2 through 4.18.6. These sections are not shown, but will be structured in a manner similar to Sections 4.3.2 through 4.3.6.

4.19 Seabirds

4.19.1 Analytical Framework for the Assessment of Effects on Seabirds

Table 4-21 provides an overview of 1) potential impacts; 2) mechanisms that relate the proposed action to the impacts; 3) measurement criteria or indicators used in assessing each type of impact; 4) models and data sets used in the analysis; and 5) significance criteria or thresholds.

Table 4-21. Impact Mechanisms, Indicators, and Significance Thresholds for Seabirds under the Alternatives

Potential Impacts	Impact Mechanisms	Measurement Criteria	Source Data	Significance Criteria
Changes in the population trends of species outside the range of natural fluctuations	Flexibility of fishermen in selecting the level of fishing effort they employ, the area they fish, the time of year they fish, and the gear with which they fish	Incidental take in gear and vessel strikes	Available literature, including the FMP, recent stock assessments, and EISs, together with expert opinion, and other pertinent information will play a critical role in the analysis of each criterion	Level of take relative to population level
		Prey availability and fishery wastes		Survival or reproductive success
		Benthic habitat		Survival or reproductive success

4.19.1.1 Potential Impacts and Impact Mechanisms

Under the No-Action Alternative, the primary management tool would continue to be two-month cumulative landings limits available to vessels with limited entry trawl permits. The management regime would remain unresponsive to the wide variety of fishing business strategies and operational concerns. The inflexibility of this system limits the ability of individual vessels to do everything possible to avoid interactions with seabirds.

The most significant impact of the three IFQ alternatives (Alternatives 2 - 4) on the population trends of seabirds results from the flexibility that can be exercised in the use of quota shares. Under these alternatives, quota share holders may have greater freedom in determining the level of fishing effort to employ, selecting the area where to fish, picking the time during the year to fish, and choosing the gear with which they fish. With the ability to change fishing operations, the probability of negative fishery/seabird interactions should go down. The enhanced fishery monitoring will allow improvement in the documentation of fishery/seabird interactions which will facilitate management of the fishery.

Under Alternative 5, permit stacking will allow quota share holders to increase the size of their catch limits. This should make it possible for quota share holders to adjust their fishing activities to reduce the probability of negative fishery/seabird interactions.

4.19.1.2 Measurement Criteria and Significance Criteria

The same measurement criteria used to describe historical and baseline conditions in Chapter 3 will be used to evaluate the effects of the alternatives.

Significance criteria for impacts on seabirds are based on whether the proposed action would be likely to result in population level effects, defined as changes in the population trend outside the range of natural fluctuations. There are a large number of unpredictable variables and gaps in current knowledge about particular species and ecosystem effects. Therefore, it is impossible to ascertain significance on a strictly quantitative basis.

Except for the supplemental food provided by fisheries in the form of offal, the effects of them are considered adverse to individual birds. Low levels of incidental take of seabirds are better for conservation purposes than high levels of take, but no amount of incidental take can be considered beneficial to a seabird population.

4.19.1.3 Methods, Models, and Data Sets

Information developed in other sections of this EIS, mainly that dealing with predicted changes in fishing practices, will provide insight into how the operation of the fishery might change under the alternatives. Once this information is available, it will be possible to examine each criterion in Table 4-21. Available literature, including the FMP, recent stock assessments, EISs, together with expert opinion and other pertinent information will play a critical role in the analysis of each criterion in the table.

Two summary tables (not shown but similar to Table 4-4 and Table 4-5) will provide an overview of the indirect effect and cumulative effects of the alternatives. These table will be followed by Sections 4.19.2 through 4.19.6. These sections are not shown, but will be structured in a manner similar to Sections 4.3.2 through 4.3.6.

4.20 Other Protected Resources

4.20.1 Analytical Framework for the Assessment of Effects on Other Protected Resources

Table 4-22 provides an overview of 1) potential impacts; 2) mechanisms that relate the proposed action to the impacts; 3) measurement criteria or indicators used in assessing each type of impact; 4) models and data sets used in the analysis; and 5) significance criteria or thresholds.

Table 4-22. Impact Mechanisms, Indicators, and Significance Thresholds for Other Protected Resources

Potential Impacts	Impact Mechanisms	Measurement Criteria	Source Data	Significance Criteria
Changes in the sustainability of a stock	Flexibility of fishermen in selecting the level of fishing effort they employ, the area they fish, the time of year they fish, and the gear with which they fish	Level of fishing effort and fishery interactions Spatial/temporal characteristic of catch Prey availability Habitat suitability	Available literature, including the FMP, recent stock assessments, and EISs, together with expert opinion, and other pertinent information will play a critical role in the analysis of each criterion	Stock size relative to historical levels

4.20.1.1 Potential Impacts and Impact Mechanisms

Under the No-Action Alternative, the primary management tool would continue to be two-month cumulative landings limits available to vessels with limited entry trawl permits. The management regime would remain unresponsive to the wide variety of fishing business strategies and operational concerns. The inflexibility of this system limits the ability of individual vessels to do everything possible to avoid interactions with protected species.

The most significant impact of the three IFQ alternatives (Alternatives 2 - 4) on the stock status of Other Protected Resources results from the flexibility that can be exercised in the use of quota shares. Under these alternatives, quota share holders may have greater freedom in determining the level of fishing effort to employ, selecting the area where to fish, picking the time during the year to fish, and choosing the gear with which they fish. With the ability to change fishing operations, the probability of negative fishery/Other Protected Resources interactions should go down. The enhanced fishery monitoring will allow improvement in the documentation of fishery/Other Protected Resources interactions which will facilitate management of the fishery.

Under Alternative 5, permit stacking will allow quota share holders to increase the size of their catch limits. This should make it possible for quota share holders to adjust their fishing activities to reduce the probability of negative fishery/Other Protected Resources interactions.

4.20.1.2 Measurement Criteria and Significance Criteria

The same measurement criteria used to describe historical and baseline conditions in Chapter 3 are used to evaluate the effects of the alternatives.

The significance of these effects is evaluated as to whether the impacts of the proposed action may be reasonably expected to jeopardize the sustainability of each species or species group or its ability to recover over time.

4.20.1.3 Methods, Models, and Data Sets

Information developed in other sections of this EIS, mainly that dealing with predicted changes in fishing practices, will provide insight into how the operation of the fishery might change under the alternatives. Once this information is available, it will be possible to examine each criterion in Table 4-22. Available literature, including the FMP, recent stock assessments, EISs, together with expert opinion and other pertinent information will play a critical role in the analysis of each criterion in the table.

Two summary tables (not shown but similar to Table 4-4 and Table 4-5) will provide an overview of the indirect effect and cumulative effects of the alternatives. These table will be followed by Sections 4.20.2 through 4.20.6. These sections are not shown, but will be structured in a manner similar to Sections 4.3.2 through 4.3.6.

4.21 Habitat

4.21.1 Analytical Framework for the Assessment of Effects on Habitat

Table 4-23 provides an overview of 1) potential impacts; 2) mechanisms that relate the proposed action to the impacts; 3) measurement criteria or indicators used in assessing each type of impact; 4) models and data sets used in the analysis; and 5) significance criteria or thresholds.

Table 4-23. Impact Mechanisms, Indicators, and Significance Thresholds for Habitat under the Alternatives

Potential Impacts	Impact Mechanisms	Measurement Criteria	Source Data	Significance Criteria
Changes in adverse impacts on habitat	Flexibility of fishermen in selecting the level of fishing effort they employ, the area they fish, the time of year they fish, and the gear with which they fish	Amount of gear interactions with habitat by gear Location of interactions with habitat Habitat type affected	Habitat database; interviews to determine changes in time, area, and gear; and available literature, including the FMP, recent stock assessments, and EISs, together with expert opinion, and other pertinent information	+/-20% change or discuss qualitatively in terms of the direction and degree of change

4.21.1.1 Potential Impacts and Impact Mechanisms

Under the No-Action Alternative, the primary management tool will continue to be two-month cumulative landings limits available to vessels with limited entry trawl permits. Trawl fishermen currently affect habitat through gear interactions. Little information has been developed for assessing gear impacts on habitat and fish production associated with habitat. The EFH EIS presents conclusions that trawl gear has greater adverse impacts on biogenic structure and vertical relief than on unconsolidated sediments, especially in high energy environments. Fishermen have little flexibility to change fishing behavior, because doing so would result in additional costs or reduced benefits, given market demands for fish. However, management actions under Amendments 18-19 that implement trawl gear restrictions and time-area closures will reduce adverse impacts from fishing on habitat.

Alternatives 2 - 5 will not directly affect habitat or regulations that manage habitat. However, implementation of an IFQ system under Alternatives 2 - 4 may cause fishermen to change behavior in a way that could affect habitat: fishermen could change the level of fishing effort they employ, the areas they fish, the time of year they fish, and/or the gear with which they fish. Under Alternative 5, permit stacking will allow the creation of larger limits and provide greater flexibility to harvesters, with the end product being possible changes in time and area of fishing. Permit stacking would not allow fishers to change gear. Changes in the fishing practices of particular sectors as a result of an IFQ program or permit stacking could indirectly affect the condition of habitat.

4.21.1.2 Measurement Criteria and Significance Criteria

The same measurement criteria used to describe historical and baseline conditions in Chapter 3 will be used to evaluate the effects of the alternatives. Whether evaluation of significance criteria can occur with quantitative or qualitative analysis will depend on the level of detail of information provided by respondents during interviews (see Section 4.1.7.1).

4.21.1.3 Methods, Models, and Data Sets

As described in Section 4.1.7.1, for each alternative, interview respondents would predict changes in fishing practices: e.g., changes in gear type or configuration; changes in area(s) fished; and changes in fishing effort in area(s) or season. The analysis would examine predicted responses resulting from each alternative relative to the known habitat. For example, if analysis of interviews predicts that a proportion of fishermen will move from a current to a new location for some proportion of the time, new maps of fishing activities would show reduced fishing effort in current areas and increased effort in new areas. Queries of the GIS database would indicate whether the changes in area would translate into changes in distribution of fishing effort on habitat types.

If interviews demonstrate that little change from baseline fishing practices will occur for particular sectors as a result of an IFQ system, little further analysis of fishing impacts on habitat will be required.

Two summary tables (not shown but similar to Table 4-4 and Table 4-5) will provide an overview of the indirect effect and cumulative effects of the alternatives. These table will be followed by Sections 4.21.2 through 4.21.6. These sections are not shown, but will be structured in a manner similar to Sections 4.3.2 through 4.3.6.

4.22 Trophic Relationships

4.22.1 Analytical Framework for the Assessment of Effects on Trophic Relationships

Table 4-24 provides an overview of 1) potential impacts; 2) mechanisms that relate the proposed action to the impacts; 3) measurement criteria or indicators used in assessing each type of impact; 4) models and data sets used in the analysis; and 5) significance criteria or thresholds.

Table 4-24. Impact Mechanisms, Indicators, and Significance Thresholds for Trophic Relationships

Potential Impacts	Impact Mechanisms	Measurement Criteria	Source Data	Significance Criteria
Changes in ecological functions of predators and prey	Flexibility of fishermen in selecting the level of fishing effort they employ, the area they fish, the time of year they fish, and the gear with which they fish	Predator abundance Prey abundance Average trophic level	Habitat database; interviews to determine changes in time, area, and gear; and available literature, including the FMP, recent stock assessments, and EISs, together with expert opinion, and other pertinent information	No quantitative threshold available; will discuss qualitatively in terms of the direction and degree of change

4.22.1.1 Potential Impacts and Impact Mechanisms

Under the No-Action Alternative, the primary management tool will continue to be two-month cumulative landings limits available to vessels with limited entry trawl permits. Trawl fishermen currently affect trophic interactions through adverse impacts on habitat that may affect production of predators and prey, through catch of predators and prey that species composition and relative abundance, and through changes in bio-energetic flow resulting from discards that redistributes food items (e.g., benthic resources redistributed to surface and midwater zones). Little information has been developed for assessing gear impacts on trophic interactions, although the EFH EIS presents summaries on information known for some predators and some prey. Fishermen have little flexibility to change fishing behavior, because doing so would result in additional costs or reduced benefits, given market demands for fish. However, management actions under Amendments 18-19 that implement trawl gear restrictions and time-area closures or change quantities of bycatch discarded could affect some aspects of trophic relationships.

Alternatives 2 - 5 will not directly affect trophic relationships. However, implementation of an IFQ system under Alternatives 2 - 4 may cause fishermen to change behavior in a way that could affect habitat: fishermen could change the level of fishing effort they employ, the areas they fish, the time of year they fish, and/or the gear with which they fish. Under Alternative 5, permit stacking will allow the creation of larger limits and provide greater flexibility to harvesters, with the end product being possible changes in time and area of fishing. Permit stacking would not allow fishers to change gear. Changes in the fishing practices of particular sectors as a result of an IFQ program or permit stacking could indirectly affect the condition of trophic relationships.

4.22.1.2 Measurement Criteria and Significance Criteria

The same measurement criteria used to describe historical and baseline conditions in Chapter 3 will be used to evaluate the effects of the alternatives.

No quantitative significance thresholds are available; qualitative judgments as to the direction and magnitude of effects will be made based on pertinent information and literature review.

4.22.1.3 Methods, Models, and Data Sets

As described in Section 4.1.7.1, for each alternative, respondents would predict changes in fishing practices: e.g., changes in gear type or configuration; changes in area(s) fished; and changes in fishing effort in area(s) or season. The analysis would examine predicted responses resulting from IFQ alternatives relative to the known suite of predator and prey species. For example, if analysis of interviews predicts that a proportion of fishermen would shift from trawls to other gears, the analysis could qualitatively assess the range and amount of species caught and the impact on predator-prey relationships.

If interviews demonstrate that little change from baseline fishing practices will occur for particular sectors as a result of an IFQ system, little further analysis of fishing impacts on trophic relationships will be required.

Two summary tables (not shown but similar to Table 4-4 and Table 4-5) will provide an overview of the indirect effect and cumulative effects of the alternatives. These table will be followed by Sections 4.22.2 through 4.22.6. These sections are not shown, but will be structured in a manner similar to Sections 4.3.2 through 4.3.6.

5 Summary of Other Environmental Management Issues

This chapter summarizes a range of environmental issues that are required under 40 CFR 1502.16. This CEQ regulation describes the analysis of environmental consequences required under an EIS. The discussion in this section follows the environmental impacts disclosed in Chapter 4.

5.1 Short-Term Uses versus Long-Term Productivity

Balancing short-term use and long-term productivity is the essence of fisheries management. Short-term uses generally affect the present quality of life for the public; while long-term productivity is based on environmental sustainability and concerns the quality of life of future generations. While harvest in any one year may or may not affect long-term productivity, harvests are part of an ongoing activity. Fishing over many years cumulatively affects productivity.

This action does not directly affect the process by which sustainable harvest levels are set or enforced. It may however help to improve catch monitoring and bycatch accounting in the groundfish trawl fishery. The proposed action may also indirectly affect the sustainability of marine resources by inducing change in fishing behavior including areas and times fished.

5.2 Irreversible Resource Commitments

A resource is irretrievably committed if its use is lost for a time, but is not actually or practically lost permanently. The analysis of direct, indirect, and cumulative impacts in this document generally addresses any irretrievable resource commitments. Assignment of fishing quotas to particular entities under some of the alternatives considered in this analysis may represent an irretrievable resource commitment, since the quota may be unavailable for use by other participants. Also, fish that are harvested represent an irretrievable resource commitment, as do the inputs in terms of capital and labor (including energy and resources) needed to harvest and market these fish. Nevertheless, these factors are not likely to be adversely affected by any of the alternatives considered in this document.

5.3 Energy Requirements and Conservation Potential of the Alternatives

The proposed action may indirectly affect energy use primarily in the form of fossil fuels used to power fishing vessels. Fuel consumption is likely to correlate with harvest levels, although this was not empirically tested as it is outside the scope of this action. Individual fishing quotas may actually conserve fossil fuel by allowing vessels increased flexibility in where and when to fish; although there are a variety of other factors that could affect overall energy use and efficient utilization. Changes in fuel prices, for example, could greatly affect the level of fishing vessel operations independent of the other regulatory factors under the alternatives.

5.4 Urban Quality, Historic Resources, and the Design of the Built Environment

Public investment in shoreside amenities and marine-related infrastructure such as docks, boat basins, jetties, and navigable channels, is sensitive to changes in tax revenue. By itself, changes in fishing-related revenue may not have an overwhelming impact on local tax revenues, but external factors such as changes in the broader economy could act cumulatively. It is also possible that as private investment shrinks so that, for example, there are fewer fishing vessels, there will be less political motivation to devote public resources to maintaining port infrastructure. Such changes could also affect cultural and historic resources as fishing and fishing-dependent activities are supplanted, changing the character of a coastal community. The effects described above are speculative. No direct impacts of the proposed action on cultural historic resources protected under the National Historical Preservation Act are expected. However further fleet consolidation, which is likely to occur in response to economic incentives under any of the alternatives, may indirectly affect the level of private and public investment in port infrastructure.

5.5 Possible Conflicts between the Proposed Action and Other Plans and Policies for the Affected Area

Groundfish species are caught incidentally in fisheries managed under other Council FMPs (e.g., salmon, coastal pelagic species, and highly migratory species). FMPs try to strike a balance between conservation and utilization and so generally include objectives related to resource use and capacity levels of the fishing fleet. Impacts of this action may affect these fisheries as a result of spillover if displaced groundfish vessels choose to pursue other fishing opportunities, and thus possibly come into conflict with some of the objectives of these FMPs.

5.6 Significant and Unavoidable Adverse Impacts

The EIS must include a discussion of those adverse effects that cannot be avoided (40 CFR 1502.16). This discussion focuses on potentially significant adverse impacts of the proposed action, as implemented by the different alternatives. CEQ regulations at 40 CFR 1508.27 define “significantly” in terms of both context and intensity, and provide ten factors to consider when evaluating the intensity of an impact. NOAA provides agency guidance in determining significant impacts of fishery management actions in administrative order NAO 216-6 at §6.02, which expands on the CEQ definition. These criteria focus on the components of the human environment most likely to be affected by these types of actions. Based on the guidance in these two sources, the proposed action could result in the following potentially significant impacts.

By itself, the proposed action does not have significant social or economic impacts interrelated with the potential significant natural or physical environmental effects discussed above (NAO 216-6 §6.02h). Changes in ex-vessel revenue and personal income are not anticipated to substantially change from levels estimated for the recent past and present.

CEQ regulations also state that “the degree to which the action may establish a precedent for future actions with significant effects or represents a decision in principle about future consideration” (40 CFR 1508.27(b)(6)) should be part of the significance evaluation. Clearly if individual quotas are established for groundfish trawl catch there is likely to be pressure to extend a quota system to other groundfish and non-groundfish fisheries in the future.

5.7 Mitigation

An EIS must discuss “means to mitigate the adverse environmental impacts” stemming from the proposed action (40 CFR 1502.1(h)), even if the adverse impacts are not by themselves significant.

Potential mitigation measures are discussed with respect to the components of the human environment potentially affected by the proposed action.

Habitat and ecosystem: Although adverse impacts to overfished species' habitats may be caused by a range of natural events and human activities, mitigation measures within the scope of NMFS authority would address fishing-related impacts. For example, the existing system of RCAs would not be affected by this action, nor would the ongoing process to establish and manage groundfish EFH. The alternatives do include provisions to allow designation of area-specific fishing quotas, if necessary, to reduce the likelihood of local depletion of harvested fish stocks.

Bycatch reduction: Amendment 18 to the Groundfish FMP includes consideration of bycatch caps and individual fishing quotas. Effective bycatch monitoring will be an important basis for implementing these types of programs. A higher level of observer coverage than under the current WCGOP will likely be necessary. In addition to limiting total mortality, individual quota programs could provide incentives for fishermen to find ways to reduce bycatch rates, since they would more directly bear the cost and reap the benefits of managing their own bycatch.

Socioeconomic sectors: Adverse socioeconomic impacts may result from changes in the geographic distribution of commercial harvests and recreational fishing opportunities. The alternatives considered in this document include Community Stability Holdback provisions that would allow associations of quota holders to engage in cooperative fishing activities. This program is designed to at least partially protect communities from economic impacts of any adverse changes in the geographic distribution of fishing activity under an IFQ program.

6 Consistency with the IFQ program, West Coast Groundfish FMP and with MSA National Standards and Requirements

This section examines the consistency of the proposed action with the IFQ program goals, objectives, constraints and guiding principles, West Coast Groundfish FMP, national standards of the MSA and with other applicable requirements of the MSA.

6.1 Consistency with ITQ Project Goals, Objectives, Constraints and Guiding Principles

The ITQ program goals, objectives, constraints and guiding principles are described in Section 1.1.2. The relative performance of the proposed action with respect to these goals, objectives, and constraints and guiding principles is summarized in this section.

6.2 Consistency with FMP Goals and Objectives

The Groundfish FMP goals and objectives are described below, together with the way in which the proposed action addresses these objectives.

Management Goals.

Goal 1 - Conservation. Prevent overfishing and rebuild overfished stocks by managing for appropriate harvest levels, and prevent, to the extent practicable, any net loss of the habitat of living marine resources.

Goal 2 - Economics. Maximize the value of the groundfish resource as a whole.

Goal 3 - Utilization. Achieve the maximum biological yield of the overall groundfish fishery, promote year-round availability of quality seafood to the consumer, and promote recreational fishing opportunities.

Objectives. To accomplish these management goals, a number of objectives will be considered and followed as closely as practicable:

Conservation.

Objective 1. Maintain an information flow on the status of the fishery and the fishery resource which allows for informed management decisions as the fishery occurs.

Objective 2. Adopt harvest specifications and management measures consistent with resource stewardship responsibilities for each groundfish species or species group.

Objective 3. For species or species groups which are below the level necessary to produce MSY, consider rebuilding the stock to the MSY level and, if necessary, develop a plan to rebuild the stock.

Objective 4. Where conservation problems have been identified for non-groundfish species, and the best scientific information shows the groundfish fishery has a direct impact on the ability of that species to maintain its long-term reproductive health, the Council may consider establishing management measures to control the impacts of groundfish fishing on those species. Management measures may be imposed on the groundfish fishery to reduce fishing mortality of a non-groundfish species for documented conservation reasons. The action will be designed to minimize disruption of the groundfish fishery, in so far as consistent with the goal to minimize the bycatch of non-groundfish species, and will not preclude achievement of a quota, harvest guideline, or allocation of groundfish, if any, unless such action is required by other applicable law.

Objective 5. Describe and identify EFH, adverse impacts on EFH, and other actions to conserve and enhance EFH, and adopt management measures that minimize, to the extent practicable, adverse impacts from fishing on EFH.

Economics.

Objective 6. Attempt to achieve the greatest possible net economic benefit to the nation from the managed fisheries.

Objective 7. Identify those sectors of the groundfish fishery for which it is beneficial to promote year-round marketing opportunities and establish management policies that extend those sectors' fishing and marketing opportunities as long as practicable during the fishing year.

Objective 8. Gear restrictions to minimize the necessity for other management measures will be used whenever practicable.

Utilization.

Objective 9. Develop management measures and policies that foster and encourage full utilization (harvesting and processing) of the Pacific Coast groundfish resources by domestic fisheries.

Objective 10. Recognizing the multi-species nature of the fishery and establish a concept of managing by species and gear or by groups of interrelated species.

Objective 11. Strive to reduce the economic incentives and regulatory measures that lead to wastage of fish. Also, develop management measures that minimize bycatch to the extent practicable and, to the extent that bycatch cannot be avoided, minimize the mortality of such bycatch. In addition, promote and support monitoring programs to improve estimates of total fishing-related mortality and bycatch, as well as those to improve other information necessary to determine the extent to which it is practicable to reduce bycatch and bycatch mortality.

Objective 12. Provide for foreign participation in the fishery, consistent with the other goals to take that portion of the OY not utilized by domestic fisheries while minimizing conflict with domestic fisheries.

Social Factors.

Objective 13. When conservation actions are necessary to protect a stock or stock assemblage, attempt to develop management measures that will affect users equitably.

Objective 14. Minimize gear conflicts among resource users.

Objective 15. When considering alternative management measures to resolve an issue, choose the measure that best accomplishes the change with the least disruption of current domestic fishing practices, marketing procedures, and the environment.

Objective 16. Avoid unnecessary adverse impacts on small entities.

Objective 17. Consider the importance of groundfish resources to fishing communities, provide for the sustained participation of fishing communities, and minimize adverse economic impacts on fishing communities to the extent practicable.

Objective 18. Promote the safety of human life at sea.

6.3 Consistency with MSA National Standards

An FMP or plan amendment and any pursuant regulations must be consistent with ten national standards contained in Sec. 301 of the MSA. The national standards are described below, together with the way in which the proposed action is consistent with these standards.

National Standard 1: Conservation and management measures shall prevent overfishing while achieving, on a continuing basis, the optimum yield from each fishery for the United States fishing industry.

National Standard 2: Conservation and management measures shall be based on the best scientific information available.

National Standard 3: To the extent practicable, an individual stock of fish shall be managed as a unit throughout its range, and interrelated stocks of fish shall be managed as a unit or in close coordination.

National Standard 4: Conservation and management measures shall not discriminate between residents of different states. If it becomes necessary to allocate or assign fishing privileges among various United States fishers, such allocation shall be (A) fair and equitable to all such fishers; (B) reasonably calculated to promote conservation; and (C) carried out in such manner that no particular individual, corporation, or other entity acquires an excessive share of such privileges. The proposed measures will not discriminate between residents of different states.

National Standard 5: Conservation and management measures shall, where practicable, consider efficiency in the utilization of fishery resources; except that no such measure shall have economic allocation as its sole purpose.

National Standard 6: Conservation and management measures shall take into account and allow for variations among, and contingencies in, fisheries, fishery resources, and catches.

National Standard 7: Conservation and management measures shall, where practicable, minimize costs and avoid unnecessary duplication.

National Standard 8: Conservation and management measures shall, consistent with the conservation requirements of this Act (including the prevention of overfishing and rebuilding of overfished stocks), take into account the importance of fishery resources to fishing communities in order to (A) provide for the sustained participation of such communities, and (B) to the extent practicable, minimize adverse economic impacts on such communities.

National Standard 9: Conservation and management measures shall, to the extent practicable, (A) minimize bycatch and (B) to the extent bycatch cannot be avoided, minimize the mortality of such bycatch.

National Standard 10: Conservation and management measures shall, to the extent practicable, promote the safety of human life at sea

6.4 Consistency with MSA Requirements for a Limited Access System

Sec. 303(b)(6) of the MSA states that, in developing a limited access system for a fishery in order to achieve optimum yield, the Council and the Secretary shall take into account

(A) present participation in the fishery,

(B) historical fishing practices in, and dependence on, the fishery,

(C) the economics of the fishery,

(D) the capability of fishing vessels used in the fishery to engage in other fisheries,

(E) the cultural and social framework relevant to the fishery and any affected fishing communities, and

(F) any other relevant considerations.

6.5 Consistency with MSA Requirements for Individual Fishing Quotas

Sec. 303(d)(5) of the MSA states that, in submitting and approving any new individual fishing quota program on or after October 1, 2000, the Councils and the Secretary shall consider the report of the National Academy of Sciences required under section 108(f) of the Sustainable Fisheries Act, and any recommendations contained in such report, and shall ensure that any such program

(A) establishes procedures and requirements for the review and revision of the terms of any such program (including any revisions that may be necessary once a national policy with respect to individual fishing quota programs is implemented), and, if appropriate, for the renewal, reallocation, or reissuance of individual fishing quotas;

(B) provides for the effective enforcement and management of any such program, including adequate observer coverage, and for fees under section 304(d)(2) to recover actual costs directly related to such enforcement and management; and

(C) provides for a fair and equitable initial allocation of individual fishing quotas, prevents any person from acquiring an excessive share of the individual fishing quotas issued, and considers the allocation of a portion of the annual harvest in the fishery for entry level fishermen, small vessel owners, and crew members who do not hold or qualify for individual fishing quotas.

6.6 MSA Fishery Impact Statement

Sec. 303(a)(9) of the MSA requires any fishery management plan or amendment to include a fishery impact statement which shall assess, specify, and describe the likely effects, if any, of the conservation and management measures on--

(A) participants in the fisheries and fishing communities affected by the plan or amendment; and

(B) participants in the fisheries conducted in adjacent areas under the authority of another Council, after consultation with such Council and representatives of those participants.

Information for the fishery impact statement will be abstracted from the detailed information presented in Appendix B and the sector and community analysis presented in the main body of the EIS.

7 Cross-Cutting Mandates

This section examines the consistency of the proposed action with other applicable federal mandates.

7.1 Other Federal Laws

7.1.1 Coastal Zone Management Act

Section 307(c)(1) of the federal Coastal Zone Management Act (CZMA) of 1972 requires all federal activities that directly affect the coastal zone be consistent with approved state coastal zone management programs to the maximum extent practicable. The Council-preferred Alternative would be implemented in a manner that is consistent to the maximum extent practicable with the enforceable policies of the approved coastal zone management programs of Washington, Oregon, and California. This determination has been submitted to the responsible state agencies for review under Section 307(c)(1) of the CZMA. The relationship of the groundfish FMP with the CZMA is discussed in Section 11.7.3 of the Groundfish FMP. The Groundfish FMP has been found to be consistent with the Washington, Oregon, and California coastal zone management programs. The recommended action is consistent and within the scope of the actions contemplated under the framework FMP.

Under the CZMA, each state develops its own coastal zone management program which is then submitted for federal approval. This has resulted in programs which vary widely from one state to the next. The proposed action is not expected to affect any state's coastal management program.

7.1.2 Endangered Species Act

NMFS issued BOs under the ESA on August 10, 1990, November 26, 1991, August 28, 1992, September 27, 1993, May 14, 1996, and December 15, 1999 pertaining to the effects of the groundfish fishery on Chinook salmon (Puget Sound, Snake River spring/summer, Snake River fall, upper Columbia River spring, lower Columbia River, upper Willamette River, Sacramento River winter, Central Valley spring, California coastal), coho salmon (Central California coastal, southern Oregon/northern California coastal), chum salmon (Hood Canal summer, Columbia River), sockeye salmon (Snake River, Ozette Lake), and steelhead (upper, middle and lower Columbia River, Snake River Basin, upper Willamette River, central California coast, California Central Valley, south-central California, northern California, southern California). During the 2000 Pacific whiting season, the whiting fisheries exceeded the chinook bycatch amount specified in the Pacific whiting fishery BO (December 15, 1999) incidental take statement estimate of 11,000 fish, by approximately 500 fish. In the 2001 whiting season, however, the whiting fishery's chinook bycatch was about 7,000 fish, which approximates the long-term average. After reviewing data from, and management of, the 2000 and 2001 whiting fisheries (including industry bycatch minimization measures), the status of the affected listed chinook, environmental baseline information, and the incidental take statement from the 1999 whiting BO, NMFS determined in a letter dated April 25, 2002 that a re-initiation of the 1999 whiting BO was not required. NMFS has concluded that implementation of the FMP for the Pacific Coast groundfish fishery is not expected to jeopardize the continued existence of any endangered or threatened species under the jurisdiction of NMFS, or result in the destruction or adverse modification of critical habitat. The proposed action is within the scope of these consultations.

The analysis of impacts to salmon (see Section 4.19.1.1 Other Fish Resources) and protected resources will be used to evaluate the consistency of the proposed action with the ESA.

7.1.3 Marine Mammal Protection Act

The MMPA of 1972 is the principle federal legislation that guides marine mammal species protection and conservation policy in the United States. Under the MMPA, NMFS is responsible for the management and conservation of 153 stocks of whales, dolphins, porpoise, as well as seals, sea lions, and fur seals; while the US Fish and Wildlife Service is responsible for walrus, sea otters, and the West Indian manatee.

Off the West Coast, the Steller sea lion (*Eumetopias jubatus*) eastern stock, Guadalupe fur seal (*Arctocephalus townsendi*), and Southern sea otter (*Enhydra lutris*) California stock are listed as threatened under the ESA. The sperm whale (*Physeter macrocephalus*) Washington, Oregon, and California stock, humpback whale (*Megaptera novaeangliae*) Washington, Oregon, and California - Mexico Stock, blue whale (*Balaenoptera musculus*) eastern north Pacific stock, and Fin whale (*Balaenoptera physalus*) Washington, Oregon, and California stock are listed as depleted under the MMPA. Any species listed as endangered or threatened under the ESA is automatically considered depleted under the MMPA.

The West Coast groundfish trawl fishery is considered a Category III fishery, indicating a remote likelihood of or no known serious injuries or mortalities to marine mammals, in the annual list of fisheries published in the *Federal Register*. Based on its Category III status, the incidental take of marine mammals in the West Coast groundfish trawl fishery does not significantly impact marine mammal stocks.

The analysis of impacts to marine mammals will be used to evaluate the consistency of the proposed action with the MMPA

7.1.4 Migratory Bird Treaty Act

The MBTA of 1918 was designed to end the commercial trade of migratory birds and their feathers that, by the early years of the 20th century, had diminished the populations of many native bird species. The MBTA states that it is unlawful to take, kill, or possess migratory birds and their parts (including eggs, nests, and feathers) and is a shared agreement between the United States, Canada, Japan, Mexico, and Russia to protect a common migratory bird resource. The MBTA prohibits the directed take of seabirds, but the incidental take of seabirds does occur.

The analysis of impacts to seabirds will be used to evaluate the consistency of the proposed action with the MBTA.

7.1.5 Paperwork Reduction Act

The Paperwork Reduction Act (PRA) (44 USC. 3501, et seq.) is designed “to minimize the paperwork burden for individuals, small businesses, educational and nonprofit institutions, federal contractors, state, local and tribal governments, and other persons resulting from the collection of information by or for the federal government.” In brief, this law is intended to ensure that the government is not overly burdening the public with requests for information. This is accomplished through an information collection budget (ICB). The ICB for each agency is in terms of the total estimated time burden of responding to official inquiries. The President's Office of Management and Budget (0MB) oversees the ICB of each agency. Agencies must annually identify and obtain clearance from 0MB for new or significant revisions to reporting and record keeping requirements.

Procedurally, the PRA requirements constrain what, how, and how frequently information will be collected from the public affected by a rule that requires reporting (e.g., the amount of fish caught during a fishing trip). New collections of information must be submitted to 0MB for clearance before a final rule may take effect. For each rule that requires a collection of information, the agency must describe in detail what data will be collected, how it will be collected and how often, from whom it will be collected, how much time will be spent by each affected person in complying with the information requirements, why the information is necessary and how it will be used. Information collections approved by 0MB have a maximum effectiveness of three years. To be extended beyond that time requires another submission for 0MB clearance. Required collection of information from the public can not be enforced without being included in an approved ICB.

A trawl IFQ program, if adopted, would contain collection of information requirements subject to the PRA. These would include reporting and recordkeeping requirements for vessels and processors for vessels and processors. These reporting and recordkeeping requirements will be submitted to 0MB for review and clearance.

7.1.6 Regulatory Flexibility Act

This section will contain a summary of the IRFA presented in Appendix A

7.2 Executive Orders

7.2.1 EO 12866 (Regulatory Impact Review)

This section contains a summary of the RIR presented in Appendix A

7.2.2 EO 12898 (Environmental Justice)

Executive Order 12898 (*Federal Actions to Address Environmental Justice in Minority and Low-Income Populations,* 59 Fed Reg 7629 [1994]) requires each federal agency to achieve environmental justice by addressing "disproportionately high and adverse human health and environmental effects . . . on minority populations and low-income populations." This section will address the two main components involved in addressing environmental justice considerations: (1) ensuring effective public participation (among populations that may traditionally have been under-represented in the public participation process) and (2) identifying high and adverse impacts that may disproportionately accrue to low-income populations or minority populations. The latter component will itself consist of two steps: (a) identification of the presence of populations that could trigger environmental justice concerns and (b) an analysis of specific effects on those populations.

7.2.2.1 Public Participation among Minority Populations and Low-Income Populations

EO 12898 requires that communities potentially bearing disproportionately high and adverse effects have meaningful input into the decisions being made about the project. This section will describe what was done to inform the communities about the project and the potential impacts it will have on their communities (e.g., notices, mailings, fact sheets, briefings, presentations, news releases, translations, newsletters, reports, community interviews, telephone hotlines, question and answer sessions, stakeholder meetings, and/or the like), what input was received from the communities, and how that input was utilized in the decisions that were made regarding the project during this stage of the analysis.

7.2.2.2 Identification of Affected Minority Populations and Low-Income Populations

The information contained in this section consists to a substantial degree of an additional screening of fishing community demographic information presented in Appendix B to portray minority populations and low-income populations in relevant communities. This section will also include a description of the methodology and criteria utilized for identifying minority populations and low-income populations and the references used for establishing the criteria. In brief, these will consist of:

- Relevant CEQ and NOAA Fisheries specific guidance regarding "meaningfully greater" minority population or low-income population determination versus a larger comparative context.
- Income indicator screening (utilizing poverty level and income data from US Bureau of the Census) for identified geographies, consistent with those utilized for community analysis in earlier report sections, typically screened against county level data as the reference community, where appropriate, given the geographically dispersed nature of this project. The methodology and justification utilized in determining the reference community will be explicitly presented, with the specific approach depending on the results generated from other impact area analyses (that will then be subjected to environmental justice screening). Where "population pocket" screening is possible utilizing standardized demographic data (e.g., resident processing workers in group quarters) this will be pursued.
- Minority indicator screening (total minority population as defined by total population exclusive of the non-Hispanic white population component) for identified geographies, consistent with those utilized for community analysis in earlier report sections, typically screened against county level data (or other appropriate level as noted for low-income populations). Similar as for low-income population screening, where "population pocket" screening for low-income populations is possible utilizing standardized demographic data this will be pursued as well.

7.2.2.3 Effects of the Proposed Actions on Low-Income and Minority Population

This analysis involves, in part, taking the previously identified impacts associated with the various management alternatives and juxtaposing the footprint of those alternatives with the footprint of populations of concern for environmental justice analysis to provide a comprehensive accounting of all impacts on minority populations and low-income populations. In this case, given the nature of the project, few, if any, physical environment impacts are likely to disproportionately accrue to minority populations or low-income populations. Rather, impacts are much more likely to be economic in nature (but they may include direct, indirect, and cumulative impacts). Reference communities utilized in the impact analysis will be consistent with those used in the screening analysis.

Indicators will include:

- Disproportionate loss of employment among low-income populations or minority populations (compared to employment changes among higher-income or non-minority populations)
- Disproportionate loss of economic activity in low-income population or minority population areas (compared to areas associated with higher-income or non-minority populations)
- Disproportionate loss of revenue to communities associated with low-income populations or minority populations (compared to communities associated with higher-income or non-minority populations)

7.2.3 EO 13132 (Federalism)

EO 13132, otherwise known as the Federalism EO, was signed by the President on August 4, 1999, and published August 10, 1999 (64 FR 43255). The EO superseded the previous Federalism EOs (12612 and 13083), but supplements EOs 12372, 12866, and 12988. This EO is intended to guide federal agencies in the formulation and implementation of "policies that have federalism implications." Such policies are regulations, legislative comments or proposed legislation, and other policy statements or actions that have substantial direct effects on the states, on the relationship between the national government and the states, or on the distribution of power and responsibilities among the various levels of government. This EO requires federal agencies to have a process to ensure meaningful and timely input by state and local officials in the development of regulatory policies that have federalism implications. A federalism summary impact statement is also required for rules that have federalism implications.

The EO establishes fundamental federalism principles based on the US Constitution, specifies federalism policy making criteria, and special requirements for preemption of state law. For example, a federal action that limits the policy making discretion of a state is to be taken only where there is constitutional and statutory authority for the action and it is appropriate in light of the presence of a problem of national significance. Also, where a federal statute does not have expressed provisions for preemption of state law, such preemption by federal rule making may be done only when the exercise of state authority directly conflicts with the exercise of federal authority. To preclude conflict between state and federal law on fishery management issues, the Magnuson-Stevens Act explicitly establishes conditions for federal preemption of state regulations (and extension of state fishery management authority into the EEZ). Furthermore, close state-federal consultation on groundfish fisheries measures is provided by the Council process.

7.2.4 EO 13175 (Consultation and Coordination with Indian Tribal Government)

The EO on consultation and coordination with Indian tribal governments was signed by the President on November 6, 2000, and published November 9, 2000 (65 FR 67249). This EO supersedes the previous EO 13084: Consultation and coordination with Indian tribal governments. The purpose of this EO is to establish regular and meaningful consultation and collaboration with Indian tribal governments in the development of federal regulatory practices that significantly or uniquely affect their communities; to reduce the imposition on unfunded mandates on Indian tribal governments; and to streamline the application process for and increase the availability of waivers to Indian tribal governments. This EO requires federal agencies to have an effective process to involve and consult with representatives of Indian tribal governments in developing regulatory policies and prohibits regulations that impose substantial direct compliance costs on Indian tribal communities.

7.2.5 EO 13186 (Responsibilities of Federal Agencies to Protect Migratory Birds)

EO 13186 supplements the MBTA (above) by requiring federal agencies to work with the USFWS to develop memoranda of agreement to conserve migratory birds. NMFS is in the process of implementing a memorandum of understanding. The protocols developed by this consultation will guide agency regulatory actions and policy decisions in order to address this conservation goal. The EO also directs agencies to evaluate the effects of their actions on migratory birds in environmental documents prepared pursuant to NEPA.

The analysis of impacts to seabirds will be used to evaluate the consistency of the proposed action with EO 13186.

12 Appendix A: Regulatory Impact Review/Initial Regulatory Flexibility Analysis

12.1 Regulatory Impact Review

12.1.1 Introduction

EO 12866, Regulatory Planning and Review, was signed on September 30, 1993, and established guidelines for promulgating new regulations and reviewing existing regulations. The EO covers a variety of regulatory policy considerations and establishes procedural requirements for analysis of the benefits and costs of regulatory actions. Section 1 of the EO deals with the regulatory philosophy and principles that are to guide agency development of regulations. It stresses that in deciding whether and how to regulate, agencies should assess all of the costs and benefits across all regulatory alternatives. Based on this analysis, NMFS should choose those approaches that maximize net benefits to society, unless a statute requires another regulatory approach.

The regulatory principles in EO 12866 emphasize careful identification of the problem to be addressed. The agency is to identify and assess alternatives to direct regulation, including economic incentives such as user fees or marketable permits, to encourage the desired behavior. Each agency is to assess both the costs and the benefits of the intended regulation and, recognizing that some costs and benefits are difficult to quantify, propose or adopt a regulation only after reasoned determination the benefits of the intended regulation justify the costs. In reaching its decision agency must use the best reasonably obtainable information, including scientific, technical and economic data, about the need for and consequences of the intended regulation.

NMFS requires the preparation of an RIR for all regulatory actions of public interest; implementation of rebuilding plans includes the publication of strategic rebuilding parameters in federal regulations. The RIR provides a comprehensive review of the changes in net economic benefits to society associated with proposed regulatory actions. The analysis also provides a review of the problems and policy objectives prompting the regulatory proposals and an evaluation of the major alternatives that could be used to solve the problems. The purpose of the analysis is to ensure the regulatory agency systematically and comprehensively considers all available alternatives, so the public welfare can be enhanced in the most efficient and cost-effective way. The RIR addresses many of the items in the regulatory philosophy and principles of EO 12866.

The RIR analysis and an environmental analyses required by NEPA have many common elements and they have been combined in this document. The following table shows where selected elements of an RIR, as required by EO 12866, are located.

Required RIR Element	Corresponding Section
Description of management objectives	Section 1.1.2 Purpose of the Proposed Actions
Description of the fishery	Chapter 3 Resource and Stakeholder Profiles

Statement of the problem	Section 1.1.1 Need for Action (Problems for Resolution)
Description of each alternative considered in the analysis	Chapter 2 Description of Proposed Alternatives

The RIR is designed to determine whether the proposed actions could be considered "significant regulatory actions" according to EO 12866. The EO 12866 test requirements used to assess whether or not an action would be a "significant regulatory action" and the expected outcomes of the proposed management alternative are discussed below. A regulatory program is "economically significant" if it is likely to result in the following effects:

l.a. Have an annual effect on the economy of $100 million or more, or adversely affect in a material way the economy, a sector of the economy, productivity, competition, jobs, the environment, public health or safety, or state, local, or tribal governments or communities.

1.b. Present a risk to long term productivity:

2. Create a serious inconsistency or otherwise interfere with action taken or planned by another agency.

3. Materially alter the budgetary impact of entitlement, grants, user fees, or loan programs or the rights and obligations of recipients thereof.

4. Raise novel legal or policy issues arising out of legal mandates, the President's priorities, or the principles set forth in this EO.

12.1.2 Economic analysis of the Alternatives

This section will provide a quantitative assessment of net benefits and distributional effects, augmented by a qualitative assessment where appropriate.

The information necessary to fully evaluate net national benefits associated with socioeconomic impacts cannot be reasonably obtained at this time. Currently available information includes historic data on commercial vessel landings and ex-vessel revenue gleaned from fish-tickets and projections of limited entry trawl vessel participation (landings and revenue) under the alternatives provided by the NMFS Bycatch Model. Additional information that is necessary to perform a net benefits analysis includes production cost information for vessels and production cost, product volume and price information for processors.

Efforts are underway to collect representative production cost information from participating commercial fishing vessels. The NMFS Northwest Fisheries Science Center is undertaking a cost-earnings survey of the limited entry trawl fleet during the first quarter of 2005. With a satisfactory response rate, this survey will provide improved data for estimating potential efficiency gains from implementation of a trawl IFQ program.

As described in Section 4.1.7 the Consulting Team proposes to use the information bases available at the time of the impact analysis to develop a set of models designed to focus on the following specific issues:

- The distributional effects of the initial allocation of QS in a trawl IFQ program.
- The potential consolidation of the trawl groundfish harvesting sector following the allocation
- The potential to reduce catches of incidental species.

- The likelihood that additional profits could offset additional observer costs
- The potential to increase profits

The output from these models will enable analysts to 1) determine how permit holders would fare under initial IFQ allocation options relative to baseline (2005) participation levels; 2) predict which permit holders are most likely to leave the fishery under a given level of consolidation. This information will be then be used in other models and in the community impact analysis; 3) predict the ability of harvesters to reduce bycatch rates; 4) assess whether the potential for increase in profits for vessels in different vessel classes could fully offset increased costs of observers and monitoring; and 5) estimate the marginal revenue attainable from purchased IFQs based on a range of assumed change in variable costs scenarios.

In the absence of adequate data on prices, costs and profitability of buyers and processors, ex-vessel revenue will be used as a proxy indicator of profits. From the buyers' perspective, ex-vessel revenue represents expenditures for a primary production input. Projected change in ex-vessel revenue under the alternatives will be stratified by different categories to examine impacts by buyer/processors' relative size and level of involvement in or dependence on trawl groundfish purchases.

12.1.2.1 Changes in Net Benefits within a Benefit-Cost Framework

This section will provide a quantitative assessment of net benefits, augmented by a qualitative assessment where appropriate.

For businesses, the change in profit can be used as a measure of the change in net benefits. The change in net benefits to consumers can be measured in terms of the change in consumer surplus. In addition changes in non-market value and ecosystem service will be qualitatively assessed.

12.1.2.2 Changes in the Distributional Effects

Changes in the distribution of benefits and costs reflect changes in the benefits and costs of groups of individuals, businesses of differing sizes, and other entities (including small communities and governmental entities).

12.1.2.3 Changes in Income and Employment

Regional economic models, including input-output models, will be used to estimate the regional income and employment effects of alternative regulatory actions..

12.2 Initial Regulatory Flexibility Analysis

12.2.1 Introduction

When an agency proposes regulations, the Regulatory Flexibility Act (RFA) (5 USC. § 601-612) requires the agency to prepare and make available for public comment an initial regulatory flexibility analysis (IRFA) that describes the impact of the proposed rule on small businesses, nonprofit enterprises, local governments, and other small entities. The IRFA is to aid the agency in considering all reasonable regulatory alternatives that would minimize the economic impact on affected small entities..

The level of detail and sophistication of the analysis should reflect the significance of the impact on small entities. Under 5 USC., Section 603(b) of the RFA, each IRFA is required to address:

1. A description of the reasons why action by the agency is being considered;

2. A succinct statement of the objectives of, and the legal basis for, the proposed rule;

3. A description of and, where feasible, an estimate of the number of small entities to which the proposed rule will apply;

4. A description of the projected reporting, record keeping and other compliance requirements of the proposed rule, including an estimate of the classes of small entities that will be subject to the requirement and the type of professional skills necessary for preparation of the report or record;

5. An identification, to the extent practicable, of all relevant federal rules that may duplicate, overlap or conflict with the proposed rule;

6. A description of any significant alternatives to the proposed rule that accomplish the stated objectives of applicable statutes and that minimize any significant economic impact of the proposed rule on small entities.

12.2.2 Reasons for Considering the Proposed Rule

The reasons for considering the proposed action are discussed in Section 1.1.1 Need for Action (Problems for Resolution).

12.2.3 Objectives and Legal Basis of the Proposed Rule

The objectives of the proposed action are discussed in Section 1.1.2 Purpose of the Proposed Actions. Section 1.1.3.3 Groundfish Management Context provides information on the legal basis for the proposed rule.

12.2.4 Description and Number of Small Entities to which the Proposed Rule will Apply

12.2.4.1 Definition of a Small Entity

Three types of small entities are defined in the RFA:

Small business - Section 601(3) of the RFA defines a small business as having the same meaning as small business concern under section 3 of the Small Business Act. This includes any firm that is independently owned and operated and is not dominant in its field of operation. The US Small Business Administration (SBA) has established size criteria for all major industry sectors in the US, including fish harvesting and fish processing businesses. A business involved in the commercial catching or taking of finfish is a small business if it is independently owned and operated and not dominant in its field of operation (including its affiliates), and if it has combined annual receipts not in excess of $4.0 million for all its affiliated operations worldwide. A seafood processor is a small business if it is independently owned and operated, not dominant in its field of operation (including its affiliates) and employs 500 or fewer persons, on a full-time, part-time, temporary, or other basis, at all its affiliated operations worldwide. A business involved in both the harvesting and processing of seafood products is a small business if it meets the $4.0 million criterion for fish harvesting operations.

Finally, a wholesale business servicing the fishing industry is a small business if it employs 100 or fewer persons on a full-time, part-time, temporary, or other basis, at all its affiliated operations worldwide.

The SBA has established "principles of affiliation" to determine whether a business concern is "independently owned and operated." In general, business concerns are affiliates of each other when one concern controls or has the power to control the other, or a third party controls or has the power to control both. The SBA considers factors such as ownership, management, previous relationships with or ties to another concern, and contractual relationships, in determining whether affiliation exists. Individuals or firms that have identical or substantially identical business or economic interests, such as family members, persons with common investments, or firms that are economically dependent through contractual or other relationships, are treated as one party with such interests aggregated when measuring the size of the concern in question. The SBA counts the receipts or employees of the concern whose size is at issue and those of all its domestic and foreign affiliates, regardless of whether the affiliates are organized for profit, in determining the concern's size. However, business concerns owned and controlled by Indian Tribes, Alaska Regional or Village Corporations organized pursuant to the Alaska Native Claims Settlement Act (43 U. S.C. 1601), Native Hawaiian Organizations, or Community Development Corporations authorized by 42 USC. 9805 are not considered affiliates of such entities, or with other concerns owned by these entities solely because of their common ownership.

Affiliation may be based on stock ownership when (1) A person is an affiliate of a concern if the person owns or controls, or has the power to control 50 percent or more of its voting stock, or a block of stock which affords control because it is large compared to other outstanding blocks of stock, or (2) If two or more persons each owns, controls or has the power to control less than 50 percent of the voting stock of a concern, with minority holdings that are equal or approximately equal in size, but the aggregate of these minority holdings is large as compared with any other stock holding, each such person is presumed to be an affiliate of the concern.

Affiliation may be based on common management or joint venture arrangements. Affiliation arises where one or more officers, directors or general partners control the board of directors and/or the management of another concern. Parties to a joint venture also may be affiliates. A contractor and subcontractor are treated as joint venturers if the ostensible subcontractor will perform primary and vital requirements of a contract or if the prime contractor is unusually reliant upon the ostensible subcontractor. All requirements of the contract are considered in reviewing such relationship, including contract management, technical responsibilities, and the percentage of subcontracted work.

Small organizations - The RFA defines "small organizations" as any not-for-profit enterprise that is independently owned and operated and is not dominant in its field.

Small governmental jurisdictions - The RFA defines small governmental jurisdictions as governments of cities, counties, towns, townships, villages, school districts, or special districts with populations of less than 50,000.

12.2.4.2 Description of Small Entities to Which the Rule will Apply

Federal courts and Congress have indicated that a RFA analysis should be limited to small entities subject to the regulation. As such, small entities to which the rule will not apply are not considered in this analysis.

The proposed alternatives would apply to businesses involved in the harvesting or processing of West Coast groundfish. There do not appear to be any entities that are directly regulated by the proposed action that would qualify as either "small nonprofit" entities, nor "small government jurisdictions."

12.2.4.3 Estimate of the Number of Small Entities to Which the Rule will Apply

[The data presented in this section are preliminary - estimates of the number of small entities will be updated during Stage 2]

The data available for this analysis are based on vessel and buyer/processor identifiers included in the PacF1N data system. The vessel and processor counts are based on unique vessel and buyer/processor identifiers. However, it is known that in many cases a single firm may own more than one vessel, or a buyer/processing facility may include more than one profit center. Therefore, the counts should be considered upper bound estimates. Additionally, businesses owning vessels and/or buyers and processors may have revenue from fisheries in other geographic areas, such as Alaska, or from non-fishing activities. Therefore, it is likely that when all operations of a firm are aggregated, some of the small entities identified here are actually larger than indicated.

Seafood Harvesters - Most of the vessels, processors, and related businesses engaged in the West Coast groundfish trawl fishery would be classified as small businesses under the SBA definition. A total 4,588 commercial vessels fishing from West Coast ports, 1,709 vessels had some involvement in West coast groundfish fisheries. Of these, 421 held groundfish limited entry permits, and an additional 771 participated in open access groundfish fisheries and derived more than 5% of total revenue from groundfish. Ninety-one limited entry trawl vessels, representing 35% of the limited entry trawl fleet, were permanently retired under a recent buyback program. The share of annual groundfish ex-vessel revenue retired under the buyback was somewhat greater, 36% including whiting or 46% of non-whiting ex-vessel revenue. There has been some concern that effective capacity in the fishery will not actually be reduced this much due to reactivation of “latent” permits. There were 24 permits not fished at all during 2001 through 2003, and 40 permits not fished at all in 2002 and 2003. Events have shown that of the 20 limited entry trawl permits that have changed hands since the buyback was completed, 14 of these permits had no recorded landings in 2002. Six buyback participants have reentered the limited entry trawl fishery, purchasing a total of 11 permits.

Buyers/Processors - A total 1,780 fish buyers on the West Coast, 732 bought at least some groundfish from commercial fishermen. All but 19 of these purchased less than $2 million worth of total harvest during the year 2000. A few buyers/processors may not qualify as small businesses under the SBA criterion. Fewer than nine buyers/processors that process groundfish were listed as employing more than 500 people (Warren 2004). However the employee counts for these buyers/processors include operations in Alaska and processing for species other than groundfish. Many of the listed employees are therefore likely in Alaska due to the much higher volumes of fish processing done there. Finally, since most processing employment is seasonal, many of these buyers/processors would not be expected to employ more than 500 employees year round.

12.2.5 Description of the Projected Reporting, Record Keeping and Other Compliance Requirements of the Proposed Rule

12.2.5.1 Description of Compliance Requirements of the Proposed Rule

12.2.5.2 Description of Compliance Costs Associated with the Proposed Rule

12.2.5.3 Estimate of the Regulatory Burden and Distributional Effects

12.2.5.4 Description of Potential Benefits of the Proposed Rule to Small Entities

12.2.6 Identification of Relevant Federal Rules that may Duplicate, Overlap or Conflict with the Proposed Rule

NOAA Fisheries is unaware of any duplicative, overlapping, or conflicting federal rules.

12.2.7 Description of Significant Alternatives to the Proposed Rule

An IRFA must consider all significant alternatives that accomplish the stated objectives of the applicable statues and minimize any significant economic impact of the proposed rule on small entities. "Significant alternatives" are those with potentially lesser impacts on small entities (versus large-scale entities) as a whole. The kinds of alternatives that are possible will vary based on the particular regulatory objective and the characteristics of the regulated industry. However, section 603(c) of the RFA gives agencies some alternatives that they must consider at a minimum:

1. Establishment of different compliance or reporting requirements for small entities or timetables that take into account the resources available to small entities.

2. Clarification, consolidation, or simplification of compliance and reporting requirements for small entities.

3. Use of performance rather than design standards.

4. Exemption for certain or all small entities from coverage of the rule, in whole or in part.

13 Appendix B: Social Impact Assessment Technical Appendix

This technical appendix will consist of a set of detailed community and regional profiles that will build on existing descriptive work as informed by the analysis of fishery-related activity specific to the trawl fishery that will potentially be impacted by the proposed management alternatives. Existing work does not provide the detail at the community level of analysis that we would seek, specifically for the links of particular fishery sectors to individual communities and the relationships of those sectors to larger community engagement and dependency attributes.

13.1 Introduction

For the purposes of social impact assessment, a two-pronged approach to analyzing the community or regional components of potential change associated with the proposed trawl management alternatives will be utilized. First, summary tables based on existing quantitative fishery information (and accompanying narrative discussions) will be developed to illustrate patterns of participation in the various components of the fishery. These will be presented in the main body of the RIR and summarized in the relevant EIS sections, as discussed in Section 3.10 and Section 4.10. This analysis will focus on the fishery sectors (e.g., catcher vessels) and portray the baseline distribution of these sectors across communities and regions (Section 3.10), along with associated activities (e.g., landings). The associated analysis of alternatives section in the EIS (Section 4.10) will look at the potential differential distribution of impacts to communities and regions that would accompany potential changes in the sectors brought about by the various management alternatives.

The second approach to producing a comprehensive SIA involves selecting a set of trawl fishery communities for characterization to describe the range, direction, and likely order of magnitude of social and community level impacts associated with the management alternatives for the trawl fishery. In short, this approach uses the community or region as the primary frame of reference or unit of analysis to assess the nature of engagement or dependency on the fishery in terms of the various sectors present in the community and the relationship of those sectors to the rest of the local social and economic context. This approach will be contained in this technical appendix.

Our starting point for defining affected communities will be the 2005-2006 groundfish fishery specification EIS (PFMC, 2004) and data from Davis (2005) which may be used to provide a list of regions, homeports and landing ports (see Table 13-1).

Table 13-1. Regions, Homeports and Landings Ports with Trawl Activity

State	Region	Trawl Vessel Homeport	Trawl Landings Port
WA	Northern Puget Sound	Bellingham	
WA	Northern Puget Sound	Blaine	Blaine
WA	Coastal Washington North	Neah Bay	Neah Bay
WA	Coastal Washington South and Central	Westport	Westport
WA	Coastal Washington South and Central	Ilwaco/Chinook	Ilwaco
OR	Astoria	Astoria	Astoria
OR	Tillamook	Tillamook/Garibaldi	Garibaldi
OR	Newport	Newport	Newport
OR	Coos Bay	Coos Bay	
OR	Coos Bay	Florence	Florence
OR	Coos Bay		Charleston
OR	Brookings	Brookings	Brookings
CA	Crescent City	Crescent City	Crescent City
CA	Eureka	Eureka	Eureka
CA	Fort Bragg	Fort Bragg	Fort Bragg
CA	Fort Bragg	Other Mendocino County	
CA	Bodega Bay	Bodega Bay	Bodega Bay
CA	San Francisco	San Francisco	San Francisco
CA	San Francisco	Princeton/Half Moon Bay	Princeton
CA	San Francisco	Other SF Area	
CA	Monterey	Monterey	Monterey
CA	Monterey	Santa Cruz	Santa Cruz
CA	Monterey	Moss Landing	Moss Landing
CA	Morro Bay	Morro Bay	Morro Bay
CA	Morro Bay	Avila	Avila
CA	Los Angeles	Los Angeles	
CA	Los Angeles	Long Beach	
CA	San Diego	San Diego	
CA	San Diego	Oceanside	

The choice of specific communities and regions to be profiled in this appendix will be driven by relevant data availability (e.g., information on where are relevant trawl vessels located) and by data confidentiality considerations. Looking at trawl vessel distribution as an example, within the state of Washington only two communities (Port Angeles and Westport, with 4 and 7 vessels, respectively) have three or more vessels each, allowing community level data discussions. Only two other Washington communities are listed as having any relevant catcher vessels (Blaine with 2 vessels and Ilwaco/Chinook with 1 vessel). Neither of these communities can be discussed individually due to confidentiality considerations, so these vessels will either be lumped into larger regional groupings (such as Blaine with Port Angeles into a Northern Puget Sound area and Ilwaco/Chinook with Westport into a Coastal Washington South and Central area), following the groupings utilized in previous groundfish EIS analyses. The advantage of staying with community-specific data is the ability to ultimately better describe impacts (and variations of impacts) at the community level, while the advantage of utilizing regions is to allow for an analysis that accommodates all available information (but at the expense of community level detail).

Oregon trawl vessel communities that could be described on an individual community basis include Astoria (32 vessels), Newport (20 vessels), Coos Bay (16 vessels), and Brookings (6 vessels). Florence, with 1 vessel, could be lumped with Coos Bay and similarly Tillamook, with 2 vessels, could be lumped with Astoria for a more regional coverage and for the sake of completeness.

Within California, a total of nine communities feature three or more trawl vessels that would, in turn, allow for community level discussions. These are Crescent City (3 vessels), Eureka (9 vessels), Fort Bragg (9 vessels), Princeton/Half Moon Bay (9 vessels), San Francisco (5 vessels), Monterey (4 vessels), Moss Landing (5 vessels), Avila (3 vessels), and Morro Bay (3 vessels). Only two California communities have less than three vessels, precluding a community level data discussion: Bodega Bay (1 vessel) and Santa Cruz (2 vessels). These communities could be lumped with others for regional groupings and, if appropriate and desired, some of the other communities could be further be lumped to simplify the analysis (e.g., Avila and Morro Bay have been lumped into a single region in earlier analyses).

If permit data rather than vessel data were chosen, a different set of communities fall out, particularly after common ownership is taken into account to further narrow information that can be released without confidentiality restrictions. If four or more entities are taken as the minimum threshold for release, the following communities could be discussed on an individual basis:

- Oregon: Astoria, Charleston, Clackamas, Coos Bay, Garibaldi, Newport and Warrenton.
- California: Eureka, Fort Bragg, Half Moon Bay, and San Francisco.
- Washington: Seattle.

If port landings data are chosen, yet a different set of communities emerge that could be discussed on an individual basis. Ultimately, as noted in Section 3.10, we would be seeking analytic power and utility within individual communities or groups of communities with common attributes to allow for a production of the best available information regarding potential community and social impacts for consideration by decision makers. The decision regarding appropriate aggregations of communities will also be informed by community or regional level information on processing and support service entities as well as data on vessels themselves.

Linking processing related data to communities is likely to prove difficult for at least two reasons. First, geographically linked processing data are scarce. Second, confidentiality concerns are even more pronounced with processing entities than they are with harvest entities, given the smaller overall number and the specific distribution of participants. It is likely that the processing related aspects of the community based discussions will, as a result of these difficulties, be more qualitative than quantitative in nature. Further complicating this analysis is the fact that it is not uncommon for landed catch to be trucked from the point of landing to processing facilities elsewhere, meaning that the attribution of economic activity to particular locations is inherently challenging. Again, however, we will attempt to qualitatively describe patterns of activity where quantitative information is scarce.

The final selection of communities for profiling will follow an analysis of the data and it is anticipated that different types of information will be developed for different geographic footprints, shaped by confidentiality concerns. The outline of the remainder of the technical appendix is as follows:

13.2 Overview of Trawl Community Socioeconomic Profiles

13.3 Background and Methodology

13.4 Community Variability

13.4.1 Location and Historical Ties to the Fishery

A general literature review will be conducted, but several recent efforts have provided more or less standardized information across a wide range of west coast fishing communities that will be of direct use for the current effort. These include:

- West Coast Marine Fishing Community Descriptions. Jennifer Langdon-Pollock, Pacific States Marine Fisheries Commission, Economic Fisheries Information Network, January 2004.
- Fishing Communities (Appendix A, Section 8.0), Proposed Acceptable Biological Catch and Optimum Yield Specifications and Management Measures: 2005-2006 Pacific Coast Groundfish Fishery EIS. Pacific Fishery Management Council, October 2004.
- Draft Supplemental Community Profiling Document: Community Profiles for West Coast and North Pacific Fisheries – Washington, Oregon, California, and other US States. Norman, Sepez, Lazrus, Milne, Package, Russell, Grant, Petersen, Primo, Styles, Tilt, and Vaccaro, Socioeconomics Program NWFSC and Economics and Social Sciences Research Program AFSC, 2006.

Other recent reports have focused on aspects of the fishery in particular locations. These include:

- Socio-economics of the Moss Landing Commercial Fishing Industry: Report to the Monterey County Office of Economic Development. Pomeroy and Dalton, June 2003.
- Market Channels and Value Added to Fish Landed at Monterey Bay Area Ports. Pomeroy and Dalton, California Sea Grant College Program, 2005.

13.4.2 Community Socioeconomic Structures

This section will lay out a typology of communities based (a) the structure of the communities themselves and (b) on nature and degree of engagement in, and dependence upon, the West Coast groundfish trawl fishery.

13.5 Social Impact Experience with IQ or Other Rationalization Programs

13.5.1 Summary Review of Relevant Literature

In addition to a general literature review on community impacts related to IQ and other fishery rationalization related experience, an additional focus will be put on incorporating recent work has been completed by management entity staff directly related to the currently proposed management alternatives. These include:

- Communities and Individual Quota Programs: Discussion on Community Definitions, Community Eligibility Criteria and Allocation Process in Quota Systems, Suzanne Russell, NWFSC, n.d. (circa 2005)
- Individual Fishing Quotas in Multi-species Fisheries: Objectives, Outcomes, Design Elements and Preliminary Thought on the Challenges for the Pacific Groundfish Fishery, Kate Quigley, NOAA Fisheries NW Region, August 26, 2004.
- Practicability Analysis for Amendment 18: Bycatch Mitigation and Standardized Total Catch Reporting Methodologies (Preliminary Discussion Draft). NMFS Northwest Region, October 2005.
- Update on Trawl Individual Quota Process and Community Concerns (includes Appendix: Community Involvement Programs and Community Impact Control Mechanisms Used in ITQ Systems). PFMC Agenda Item H.11, Situation Summary, November 2005.
- Catch-Quota Balancing in Multi-species Individual Fishing Quotas. Sanchirico, Holland, Quigley and Fina, Resources for the Future, November 2005. (This document is not as directly tied to the current fishery management initiative as the previous three, but is still relevant nonetheless.)

These have also been recent documents generated by a number of groups involved as stakeholders in the ongoing fishery management process that are directed toward aspects of community impact assessment. These documents will also be reviewed for perspectives and data to include in the overall background literature review. These documents include:

- Addressing Community Concerns in the Development of Individual Fishing Quota Program Alternatives for the Pacific Groundfish Trawl Sector: A Survey of Community Stakeholders. Environmental Defense, September 6, 2004
- Coastal Fishing Community Considerations in the Context of Trawl IFQs. Ginny Goblirsch, Community Representative, PFMC Trawl IQ Committee, October 18, 2004.
- The Economic Impacts of Food Plant Closure: Analysis of the Pacific Coast Seafood Plant in Warrenton, Oregon. Globalwise, Inc., for Pacific Seafood Group, February 23, 2004.

13.5.2 Region Specific Experience

This section will include a summary of region-specific experience in other IQ or rationalization programs and the outcomes of those programs that may be brought forward as "lessons learned" to be applied to the current alternatives analysis. This information will, for example, include experience in the offshore whiting co-ops. Further, other recent relevant region-specific management outcome information that may inform prediction of future trawl IQ impacts will be summarized in this section. This will include, for example, the results of the recent buy-back program and the associated changes in patterns of engagement and dependency across communities.

13.5.3 Structure of Proposed Community Options

This section will provide an overview of the proposed options designed to address community impact concerns. These include three main options:

- Community Stability Holdback Option
- Community Involvement Option

- Existing Community Impact Control Mechanism Options

These options have a number of suboptions as well and are listed in outline form below. These sections would provide a general level componential analysis of likely social impact outcomes based on the structure of the options and suboptions themselves.

13.5.3.1 Community Stability Holdback Option

- General
  - Portion of annual QP held back and allocated for proposals submitted by IFQ holders
  - Proposals evaluated with priority on community benefits
  - Shares held back continue to be trawl shares
- Holdback
  - Up to 20 percent [previously 25 percent] of total annual QP for [non-whiting] shoreside component of trawl fishery (but period may be greater than one year)
  - Suboptions of (A) 20 percent, (B) 10 percent, (C) 5 percent, and (D) 5 percent in year one, increasing by 5 percent each year until the total set aside is 20 percent.
- Committee
  - Appointed by the Council, recommendations approved by Council before forwarding to NMFS
  - Role to make recommendations with the purpose of achieving community development, enhancement, or stabilization goals
  - Composed of representatives of West Coast regions, port districts, processors, and fishermen
  - Staffing by NMFS + Council (option A) or Council (option B)
- Eligibility for Participation
  - IFQ holders [previously joint fishermen/processor proposals]; may work together in collaboratives
  - IFQ holders may only participate in one proposal
- Allocation Criteria
  - To be developed, but quantitative in nature for consistent application to proposals
  - Potential criteria may or may not include:
    - Past performance (performance on past commitments)
    - Utilization (indicator of wastage and pollution externalities)
    - Local added value (value of exports divided by landings)
    - Local labor employment (percentage of local employees)
    - Local labor earnings (wages to product value ratio)
    - Public debt related to fisheries investment (fishery infrastructure debt relying on fisheries activity repayment)

- Public investment dedicated to fisheries (total public investments supporting fishing industry)
- Port dependence (proportion of total port revenue derived from fisheries activity)
- Other (to be identified through public comment)

13.5.3.2 Community Involvement Option

- Committee
  - Convened by Council; composed of representatives of West Coast regions, port districts, processors, and fishermen
  - Make recommendations pertaining to IFQ program and its impact to port districts, regions, processors, and fishermen

13.5.3.3 Existing Community Impact Control Mechanism Options

- Allowing communities to hold quota
- Setting limits on quota accumulation
- Allocations of whiting and non-whiting groundfish species for shoreside and at-sea delivery
- Temporarily prohibiting QS transfer after initial allocation (to be analyzed but NOT a part of current alternatives)
- Distribute revoked shares or reclaimed quota to new entrants

13.6 Community Profiles

13.6.1 Community #1

13.6.1.1 Community Demographics

- Total Population, Ethnicity, Age and Sex, Housing
- Occupation, Employment, Income

13.6.1.2 Local Economy and Links to the Trawl Fishery

- Harvesting (fleet characteristics, permits, landings, employment, etc.)
- Processing (buyer/processor characteristics, volumes, patterns of movement between landing and processing, employment, etc.)
- Fishery Support Services (vessel and processor support related activity characterization)
- Other Local Business Activity/Local Economic Base Summary (for baseline of economic dependency analysis)

13.6.1.3 Community Revenues (estimated revenues in community revenue context)

13.6.1.4 Summary of Recent Community Rationalization Experience (including lessons learned)

13.6.1.5 Differential Impacts of Trawl Fishery Management Alternatives (general level discussion)

13.6.2 Community #2 (etc.)

14 Appendix C: Components Analysis

The major goal of the Components Analysis and Components Tables (See Table 2-3 and Table 2-4) is to ensure that the details of each alternative are adequately considered by clearly specifying how the different elements fit together within an alternative; and to identify unknown or unintended potential effects on resources and stakeholders groups. The Components Table and Components Analysis also identify and analyze options that were discussed but not brought forward into the main suite of alternatives.

14.1 Analysis of Components, Elements, and Options

The analysis of the components, elements and options that comprise the Trawl IFQ Program is of critical importance. A thorough analysis of each of the components, elements, options and sub-options can provide the Council with the necessary information to refine their Alternatives, or even to eliminate Alternatives.

The remainder of this section lists the section provides and indication of the section headings proposed for the Components Analysis. In general the components analysis would have a section for each of the components defined in the Components Tables. Within each component section the various elements and options are described, discussed, and analyzed.

14.1.1 Analysis of Elements and Options Contained in Component 1

Component 1

Element 1.1

Option 1.1.1

Sub-Option 1.1.1.1

14.1.2 Analysis of Elements and Options Contained in Component 2

Component 2

Element 2.1

Option 2.1.1

Sub-Option 2.1.1.1

14.2 Preliminary Analysis of Distributions of Catch History and Potential QS by Species

This section contains a further examination of the question of whether allocations QS for incidental species should utilize historical catches. The Consulting Team has included this preliminary analysis for two reasons: 1) it provides insight in the question of how to allocate QS for incidental species, and 2) it provides an example of the type of analysis that would be included in the components analysis.

In this analysis of preliminary analysis of catch history, the Consulting Team examined PacFIN Fish-Ticket from 1994-2003. We combined catch information with permit holder data from the NMFS NW Region. With the permit data analysts were able to examine fish-ticket catches of two major groups of limited entry trawl permits—permit that were bought back during the 2003 buyback and permits that remained at registered permits after the buyback. This distinction is important because all of the options in the alternatives re-distribute the aggregate catch of "bought-back permits" on an equal shares basis to each of the remaining permits that are assigned to catcher vessels.[36]

Table 14-1 shows the shore-based landings from PacFIN Fish tickets of selected species by from 1994-2003. Two groups of permits are shown landings assigned to permits to bought-out permits, and landings assigned to post-buyback permit holders. If the amount landed by the bought-out permit is relatively high, then redistributing that catch in the allocation of QS can add significant amounts of QS to remaining permit holders. This may be particularly important if QS of incidental catch is allocated based on historical landings. If on the other hand, the amount landed by the bought-out permit is relatively low (see cabezon and butter sole as examples), then the re-distribution will have a much smaller impact.

[36] Permits assigned to Catcher Processors would not share in this redistribution.

Table 14-1. Shore-based Landings of Limited Entry Trawl Permit Holder Groups by Species, 1994-2003

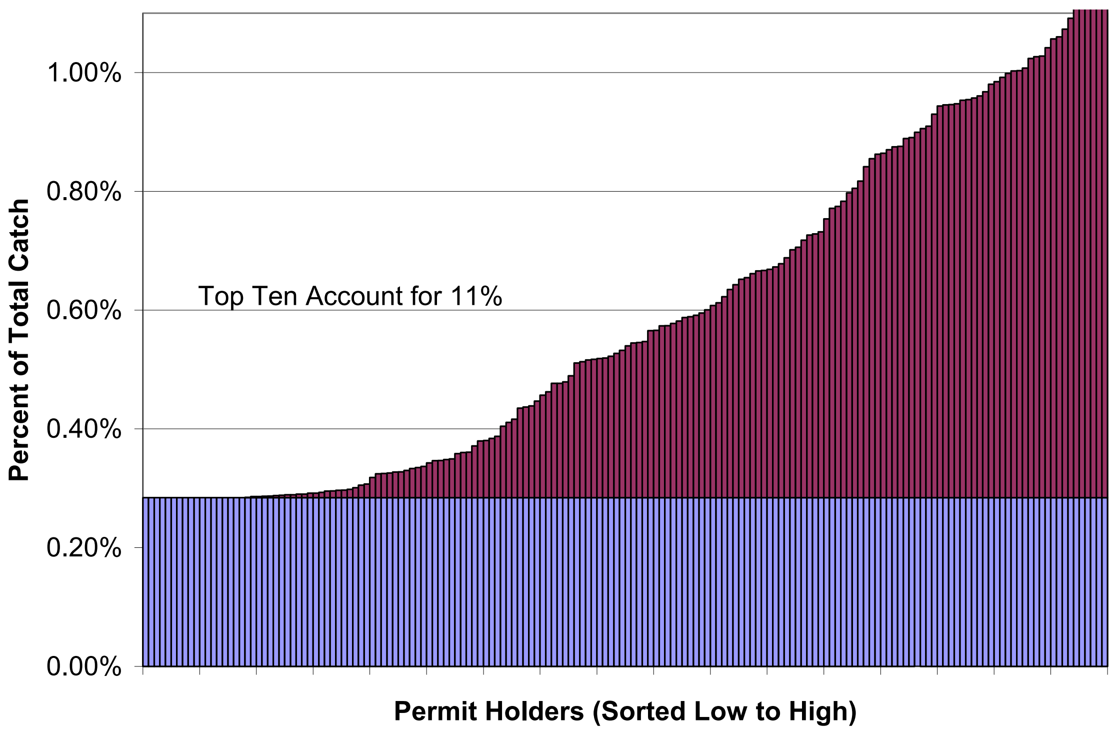
	Bought-out Permits		Post-Buyback Permit Holders		Catch of All Permit Holders
Species	**Lbs (1,000s)**	**Percent**	**Lbs (1,000s)**	**Percent**	**Lbs (1,000s)**
Black Rockfish	37	13.49	238	86.51	275
Butter Sole	5	16.38	24	83.62	28
Cabezon	1	4.69	11	95.31	12
California Scorpionfish	4	24.95	13	75.05	17
Canary Rockfish	4,233	50.52	4,145	49.48	8,378
Curlfin Sole	17	25.76	48	74.24	64
Darkblotched Rockfish	289	48.90	302	51.10	591
Dover Sole	92,664	48.29	99,241	51.71	191,905
English Sole	9,498	41.03	13,652	58.97	23,149
Flathead Sole	38	42.46	52	57.54	90
Lingcod	5,867	48.60	6,205	51.40	12,072
Nearshore Rockfish	24	22.99	81	77.01	106
Pacific Cod	6,472	54.84	5,329	45.16	11,801
Pacific Whiting	138,802	8.44	1,505,495	91.56	1,644,296
Petrale Sole	18,352	49.46	18,750	50.54	37,102
Rex Sole	6,443	42.42	8,746	57.58	15,189
Sablefish	31,128	48.11	33,573	51.89	64,701
Sanddabs	6,350	30.46	14,497	69.54	20,847
Shortbelly Rockfish	74	34.93	138	65.07	211
Spiny Dogfish	6,575	71.30	2,647	28.70	9,222
Thornyheads	43,117	48.56	45,678	51.44	88,795
Walleye Pollock	3,054	33.65	6,020	66.35	9,074
Widow Rockfish	30,974	37.05	52,631	62.95	83,605
Yelloweye Rockfish	22	64.51	12	35.49	34

Figure 14-1 provides a preliminary assessment of an allocation of QS based on 1994-2003 landings for Dover sole. The figure is provided as an illustration and should not be considered official. All post-buyback permit holders were included.[37] In the figure, permits are sorted by landings history from low to high—each small bar represents the catch of a one permit of the 170 remaining after the buyback. The lighter shaded bars represent the equal-share redistribution of landings of bought-out permits. The darker-shaded bars represents landing of remaining permits. A tick-mark horizontal axis is shown for every ten permits. As is readily seen in the figure, the distribution of landings by remaining permit holders is highly skewed—highliners land significantly higher amounts of Dover sole than most permit holders. It should be noted however, that while this distribution appears to be highly skewed, the distribution of Dover sole landing are among the least skewed of all groundfish species. The note inside the figure indicate the percentage of total Including re-distributed catches) of the top ten permits—in the case of Dover sole the top-ten permits accounted for 11 percent of the total landings. A critical finding of this figure is that for many permit holders, the re-distribution of landings from bought-out permits would constitute the majority of their QS.

[37] Actual options may require more recent participation to qualify for QS.

The next five pages show similar figures for other species, including a mix of primary target species, non-constraining incidental catch species, and overfished species. A careful examination of the figures provides insight into the distribution of landings overtime. It should be noted that all of the figures are truncated at the top to protect the confidentiality of the permits with the highest landings.

Figure 14-1. Dover Sole Catch Distribution—Post Buyback Permit Holders 1994-2003



Note: The set of bars at the bottom of the figures, represent the catch of bought out boats evenly distributed to remaining permit holders. The darker shaded bars represent the actual catch of remaining permit holders.

As might be expected, the figures reveal that the distribution of landings for Dover sole, thornyheads and sablefish (see Figure 14-1 through Figure 14-3) are very similar, as is the relative importance of the re-distribution of landings from bought-out permits. Figure 14-4 which shows the distribution of Petrale sole exhibits a higher level skewness—the more concave the distribution means that a greater percentage of the total landings were made by highliners.

Figure 14-5 shows the distribution of shore-based landings of Pacific Whiting. This figure indicates that a over 2/3^{rds} of the permits remaining after the buyback do not participate in the whiting fishery. The figure also indicate that the top-10 permits accounted for 43 percent of the total after the re-distribution of whiting landings by bought-out permits.

Figure 14-6 through Figure 14-9 show the distribution of landings of four species that are (or have been) declared overfished.[38] The figures all show significant levels of skewness—in particular the distribution of yelloweye rockfish is very highly skewed. All four of these figures clearly demonstrate the potential benefit of the re-distribution of landings from bought out boats. The equal-share re-distribution may provide sufficient amounts of QS to cover incidental catches without forcing vessels to purchase QS from those that had high levels of landings. Referring back to Table 14-1, the approximately 50 percent of the total landings canary rockfish would be re-distributed, while only 37 percent of the widow rockfish would be re-distributed. Whether or not the re-distributed amounts are actually sufficient to cover incidental catches is an empirical question. The figures also show however, that allocating these species using historical landings may provide a significant windfall to permit holders that had high levels of catch of these now-constraining species.

[38] Lingcod is not currently considered overfished, but was considered overfished as late as 2005.

Agenda Item F.3.b
Attachment 1 ERRATA
June, 2006

ERRATA: Replacement Pages 23-36 for
Excerpt from Stage 1 Draft IFQs and Permit Stacking Alternatives in the Limited Entry Trawl Fishery (Chapters 1, 2, 4 and Appendices A-C).

Attached is a revised Table 2-1 (from Agenda Item F.3.b, Attachment 1). The pages immediately preceding and following the table are included to facilitate replacement of the original Table 2-1 with the errata table. The main differences between this and the original version are in the references to the whiting and non-whiting species and segments of the fishery.

[This Page Intentionally Blank]

Alternative 4: IFQs for all groundfish species. The distinction between whiting sectors would be eliminated. Reporting of all groundfish catch would be required. At-sea monitoring would be required on all vessels. OYs for each of the Other Species of groundfish would be would be established. If the OY for any species becomes extremely low, the Council may suspend allocations between gear sectors for that species.

Alternative 5: **Permit stacking.** Groundfish would be managed as under the No-Action Alternative, but limited entry trawl permit holders would be allowed to "stack" additional permits. Permit holders would be issued a full complement cumulative trip limit pounds for each permit they own. Whiting seasons and sectors would be maintained. Reporting of all groundfish catch would be required. At-sea monitoring would be required on all vessels. Catches of Other Species would be monitored. If the OY for any species becomes extremely low, the Council may suspend allocations between gear sectors for that species.

In addition to the various management regimes described above, the three IFQ alternatives (Alternatives 2 – 4) differ with respect to the way in which quota shares are allocated. The Council developed three basic allocations and incorporated them into three IFQ programs (currently labeled Program A, Program B, and Program C). The allocations differ primarily in terms of which groups would receive quota and how much each group would receive. These are summarized below:

Program A: Harvesters and processors are initially allocated equal amounts of QS that give them rights to harvest groundfish. Processors are defined as those facilities that take ownership of and process unprocessed groundfish. Program A would be applied to Alternative 3.

Program B: Harvesters and processors are allocated QS that give them rights to harvest groundfish. Split options include: a) 100/0 for all groundfish, b) 100/0 for non-whiting and 50/50 for whiting, and c) 90/10 for all groundfish. Processors are defined as in the FMP—those facilities that process either unprocessed or already processed groundfish or receive live fish for resale. Program B would be applied to Alternative 3.

Program C: Harvesters and processors are allocated QS that give them rights to harvest groundfish. Harvesters would initially receive 75 percent of the QS and processors would receive the remaining 25 percent. Processors are defined as those facilities that take ownership of and process unprocessed groundfish. Program C would be applied to Alternative 2, 3, and 4.

All three of the programs are applied to Alternative 3 as options. In effect, this generates three new alternatives: Alternatives 3A, 3B, and 3C. In addition it should be noted that Program B contains three different allocation schemes, and that these schemes also have the potential to significantly alter the impacts of the alternative. The end result is that Alternative 3 might reasonably be analyzed as five different alternatives: Alternatives 3A, 3Ba, 3Bb, 3Bc, and 3C.

Table 2-1 and Table 2-2, below, present details of the various elements and options that make up each of the alternatives. The tables are similar to those produced for the Council, and contain references to the IFQ Scoping Results Document[6] and various options described within that document.

[6] National Environmental Policy Act Scoping Results Document: Individual Fishing Quotas (A Kind of Dedicated Access Privilege) and Other Catch Control Tools for the Pacific Coast Limited Entry Trawl Groundfish Fishery. Pacific Fishery Management Council, July 2005.

Table 2-1. Management Regime Alternatives for Analysis

Alternatives (Sec 2.1.1.1 Scoping Results[a/])	Alternative 1 No-Action Alternative	Alternative 2 IFQs for Trawl Target Groundfish	Alternative 3 IFQs for All Groundfish Except Other Fish	Alternative 4 IFQs for All Groundfish	Alternative 5 Cumulative Catch Limits and Permit Stacking
			COMPONENT 1: CATCH CONTROL TOOLS		
			IFQ Program for Non-Whiting and Whiting Trips		
Element 1.1 IFQ Program to Be Applied (See Table 2-2)	No IFQ Program.	Program C	Alternative 3A - Program A Alternative 3B - Program B Alternative 3C - Program C	Program C	No IFQ Program.
			Additional Control Tools (Sections 2.1.1.2 of the Scoping Results Document).[a]/		
Element 1.2 Permit Stacking	-- -- -- -- -- -- -- -- -- -- -- -- -- -- -- None -- -- -- -- -- -- -- -- -- -- -- -- -- -- --				One set of trip limits issued for each of a maximum of 3 permits attached to vessel. Only one of the permits attached to the vessel would need to be of the appropriate length.
Element 1.3 Cumulative Trip Limits	Cumulative landing limits. (One set of limits for each vessel to which a permit is assigned.)	Transferable cumulative catch limits.[b]/ Cumulative limits would be transferable on a temporary basis between vessels within the period (full or partial limit transfers would be allowed, depending on length of limit period)	Cumulative catch limits (One set of limits for each vessel to which a permit is assigned.)	None	Cumulative catch limits. (One set of limits for each permit.)

Alternatives (Sec 2.1.1.1 Scoping Results[a/])	Alternative 1 No-Action Alternative	Alternative 2 IFQs for Trawl Target Groundfish	Alternative 3 IFQs for All Groundfish Except Other Fish	Alternative 4 IFQs for All Groundfish	Alternative 5 Cumulative Catch Limits and Permit Stacking
Element 1.4 Adjustments for Low OYs					
Allocation	- -- -- -- -- -- -- -- -- The Council may suspend intersector allocations when a species is overfished -- -- -- -- -- -- -- --				
Catch Control Rules	N/A	Adjust rules for low OY conditions (as specified in Component 2). *IFQ species – No change.* *Non-IFQ species – For species meeting the low OY threshold switch from transferable to* ***non****transferable cumulative catch limits.*[c/]	**Option 1**: Adjust rules for low OY conditions (as specified in Component 2). *For low OY species, except whiting, switch from IFQs for that species and instead manage the sector allocation as a pool using nontransferable cumulative catch limits to control catch.*[d/] **Option 2:** No low OY adjustments.	N/A	N/A
Threshold	N/A	Low OY Threshold: Establish a threshold at which point a species would switch to "Low OY management." ($B_{25\%}$)	Low OY Threshold: Decide on application of "Low OY management" as part of the biennial specifications process.	N/A	N/A
Element 1.5 General Season Closures	-- -- -- -- When all sectors in aggregate reach the overall OY for a species, seasons close for the affected species -- -- -- --				
Element 1.6 Whiting Season Openings	Staggered season openings for each whiting sector.	Possible continuation of spring opening for the season, to control impacts on ESA listed salmon.	Possible continuation of spring opening for the season, to control impacts on ESA listed salmon.	Possible continuation of spring opening for the season, to control impacts on ESA listed salmon.	Same as no action.
Element 1.7 Whiting Season Closings	Whiting season closes for a sector on attainment of whiting allocation. Whiting season closure on attainment of bycatch caps for species with bycatch caps.	Whiting season closure on attainment of bycatch caps for species with bycatch caps.[i/]	Open until end of year.	Open until end of year.	Same as no action

Alternatives (Sec 2.1.1.1 Scoping Results[a/])	Alternative 1 No-Action Alternative	Alternative 2 IFQs for Trawl Target Groundfish	Alternative 3 IFQs for All Groundfish Except Other Fish	Alternative 4 IFQs for All Groundfish	Alternative 5 Cumulative Catch Limits and Permit Stacking
COMPONENT 2					
Sector/Species Group Combinations and the Catch Control Tools To Be Applied (Section 2.1.1.3 & 2.1.1.4 of the scoping results document)					
Element 2.1 Sectors Define Whiting Trip: Opt 1-- >50% non-whiting Opt 2-- >50% or >10,000 lbs non-whiting	Three sectors: ▪ shoreside (SS) deliveries ▪ mothership (MS) deliveries ▪ catcher-processor (CP) deliveries	Four sectors: ▪ SS whiting deliveries ▪ SS non-whiting deliveries ▪ MS deliveries ▪ CP deliveries (FROM Scoping Results Doc: 2.1.1.4 Option 3)	Three sectors: ▪ SS deliveries ▪ MS deliveries ▪ CP deliveries (FROM Scoping Results Doc: 2.1.1.4 Option 2)	One sector (FROM Scoping Results Doc: 2.1.1.4 Option 1)	Three sectors: ▪ SS deliveries ▪ MS deliveries ▪ CP deliveries
Element 2.2 Primary Trawl Target and Allocated Species[e/] **(Except Whiting)**	All sectors: cumulative landing limits. Trawl fishery closes on attainment of cap, guideline or OY. Whiting season closes on attainment of whiting fishery bycatch cap for non-whiting species.	SS non-whiting deliveries: IFQs SS, MS, & CP whiting deliveries: catch caps for these species. A sector's whiting seasons close on attainment of that sector's whiting fishery catch cap for non-whiting species. No cumulative catch limits. Midseason rollovers for excess cap amounts and augmentation of caps thru acquisition of SS IFQ.	Sector specific IFQs (Low OY Conditions: Option 1: switch to nontransferable cumulative catch limits and close on attainment of sector limits; Option 2: continue use of IFQs.)	IFQ	Cumulative catch limits with permit stacking rules applied for non-whiting trips. Whiting season closes on attainment of whiting fishery bycatch cap for non-whiting species. Stacked permits may not be used to cover catch on whiting trips.
Element 2.3 Whiting	All sectors: Whiting season (no vessel landing limits). Outside the whiting season shoreside deliveries allowed under cumulative whiting landing limits. Midseason rollover of excess allocation to another sector.	SS nonwhiting deliveries: Whiting catch must be covered with IFQ and is also constrained year-round by nontransferable cumulative whiting catch limits. SS, MS, & CP whiting deliveries: IFQs during whiting season. Midseason whiting rollover to another sector Opt 1: Not allowed; Opt 2: Allowed following specified procedures.	Sector specific IFQs during the whiting season. If SS whiting is closed SS whiting IFQs may continue to be used, subject to nontransferable cumulative whiting catch limits.	IFQs during the whiting season. IFQs and nontransferable cumulative whiting catch limits for shoreside deliveries outside the whiting season.	All sectors: Whiting season (no vessel landing limits). Outside the whiting season shoreside deliveries allowed under cumulative whiting catch limits. Permit stacking rules do not apply for cumulative whiting limits. Midseason rollover of excess allocation to another sector.

Alternatives (Sec 2.1.1.1 Scoping Results[a/])	Alternative 1 No-Action Alternative	Alternative 2 IFQs for Trawl Target Groundfish	Alternative 3 IFQs for All Groundfish Except Other Fish	Alternative 4 IFQs for All Groundfish	Alternative 5 Cumulative Catch Limits and Permit Stacking
Element 2.4 Unallocated Shared Target and Incidental Species Currently Managed With Cumulative Limits	All sectors: cumulative landing limits Trawl fishery closes on attainment of cap, guideline or OY. Whiting season closes on attainment of whiting fishery bycatch cap for non-whiting species.	SS whiting deliveries Transferable cumulative catch limits. Option for >2 mo cumulative periods and midperiod transfers. (Low OY conditions: switch to nontransferable cumulative catch limits) SS, MS, & CP whiting deliveries For species without caps: non-whiting species catch is limited by to a single cumulative catch limits regardless of the number of transferable limits held by a vessel. For non-whiting species with caps, same as Element 2.2.	Sector specific IFQs. (Low OY Conditions: Same low OY condition options as for "Primary Trawl Target and Allocated Species" (Element 2.2))	IFQ	Cumulative catch limits with permit stacking rules applied for non-whiting trips. Whiting season closes on attainment of whiting fishery bycatch cap for non-whiting species. Stacked permits may not be used to cover catch on whiting trips.
Element 2.5 "Other Fish" Groundfish[f/g/]	Status Quo. Currently: monitoring only. May change to cumulative limits.	Same as status quo.[h/]	Same as status quo.[h/]	IFQ	Same as status quo.[h/]
Component 3: Groundfish Catch of Limited Entry Trawl Vessels Using Gears Other Than Groundfish Trawl (Section 2.1.1.5 of the Scoping Results Document)					
Element 3.1 **Trawl Vessel Exempted Gear Quota Accounting and Catch Control (Includes Exempted Trawl and Exempted Non-trawl Gears)**	**Exempted gea**r catch by LE trawl vessels counts against LE allocation (trawl and fixed gear)[i/] but is subject to open access (OA) trip limits.	**Exempted gear** - IFQ is **not** required. Catch counts against the OA allocation and is managed as part of the OA fishery. Some catch will be allocated from the LE trawl to OA fishery. (FROM Scoping Results Document Section 2.1.1.5 Opt 2C)	**Exempted gear -** IFQ required. Catch counts against LE Trawl. Open access catch control regulations apply. (FROM 2.1.1.5 Scoping Results Document Section Option 1A)	**Exempted gear -** IFQ required. Catch counts against LE Trawl. Open access trip limits **do not** apply. (FRM 2.1.1.5 Scoping Results Doc Option 1B)	**Exempted gea**r catch by LE trawl vessels counts against LE allocation (trawl and fixed gear)[h/] but is subject to open access (OA) trip limits OR Permit stacking applies and vessels must comply with trawl enforcement and monitoring provisions.

Alternatives (Sec 2.1.1.1 Scoping Results[a/])	Alternative 1 No-Action Alternative	Alternative 2 IFQs for Trawl Target Groundfish	Alternative 3 IFQs for All Groundfish Except Other Fish	Alternative 4 IFQs for All Groundfish	Alternative 5 Cumulative Catch Limits and Permit Stacking
Element 3.2 **Trawl Vessel Longline and Fish Pot Without and With LE Endorsement (Fixed Gear Quota Accounting and Catch Control)**	**Unendorsed longline & fishpot** catch by LE trawl vessels counts against LE allocation (trawl and fixed gear)[i/] but is subject to open access trip limits. **LE endorsed fixed gear** - Rules for the LE fixed gear fishery apply when the vessel is using fixed gear. Vessels fish against the limited entry allocation[i/] and are constrained by fixed gear trip limits while using fixed gear.	**Unendorsed longline & fishpot** - IFQ required. Catch counts against LE Trawl. LE fixed gear catch control regulations apply. **LE endorsed fixed gear –** While using fixed gear, IFQ is not required, catch is constrained by LE fixed gear limits and counts toward the LE fixed gear allocation. (FROM 2.1.1.5 Scoping Results Doc, Option 1A)	**Unendorsed longline and fishpot** - IFQ required. Catch counts against LE Trawl. LE fixed catch control regulations **do not** apply. **LE endorsed fixed gear –** While using fixed gear, IFQ is not required for catch taken toward LE fixed gear cumulative or daily limits and such catch counts toward the LE fixed gear allocation. Catch in excess of LE fixed gear trip limits may be taken if covered by trawl IFQ. (FROM 2.1.1.5 Scoping Results Doc, Opt 1B)	**Unendorsed longline & fishpot** - IFQ required. Catch counts against LE Trawl. LE fixed catch control regulations **do not** apply. **LE endorsed fixed gear** - While using fixed gear, IFQ is not required for catch taken toward LE fixed gear cumulative or daily limits and such catch counts toward the LE fixed gear allocation. Catch in excess of LE fixed gear trip limits may be taken if covered by trawl IFQ. (FRM 2.1.1.5 Scoping Results Doc, Opt 1B)	**Unendorsed longline & fishpot** catch by LE trawl vessels counts against LE allocation[i/] (trawl and fixed gear)[i/] but is subject to open access trip limits. OR Permit stacking applies and vessels must comply with trawl enforcement and monitoring provisions. **LE endorsed fixed gear** - When the vessel is using fixed gear catch counts against the LE allocation[i/] and is constrained by fixed gear limits. OR Permit stacking applies and vessels must comply with trawl enforcement and monitoring provisions (except when fishing fixed gear tier limits).
Component 4. Monitoring and Enforcement					
At-sea Observers/ Monitoring	Biological observers on some SS catcher vessel trips, 100% observers for at-sea deliveries (MS and CP)	100% at-sea monitoring. Detailed monitoring and enforcement provisions under each IFQ program (Tables 2-2 and 2-4).	100% at-sea monitoring. Detailed monitoring and enforcement provisions under each IFQ program (Tables 2-2 and 2-4)	100% at-sea monitoring. Detailed monitoring and enforcement provisions under each IFQ program (Tables 2-2 and 2-4)	100% at-sea monitoring.

Alternatives (Sec 2.1.1.1 Scoping Results[a/])	Alternative 1 No-Action Alternative	Alternative 2 IFQs for Trawl Target Groundfish	Alternative 3 IFQs for All Groundfish Except Other Fish	Alternative 4 IFQs for All Groundfish	Alternative 5 Cumulative Catch Limits and Permit Stacking
Component 5. Area Management (Decision Table B from Scoping Results Document)					
	Species divided by areas based on stock assessment information. New area divisions created as stock assessment information indicates need.	Program Option for All Action Alternatives: Plan to establish additional regional management areas as needed at a later time. Provisions are included to allow later subdivision of IFQs by area. Process Option: Task a group to begin considering the need for additional regional management areas (biological or socio-economic) and potential boundaries along with a process for identifying and responding to regional management area issues that may develop or become more apparent in the future. **Decision deferred until additional information is available, e.g. preliminary DEIS is ready.**			
Component 6. Sector Allocation					
Element 6.1 Within Trawl (Decision Table E from Scoping Results Document)	Whiting allocation rules. No other within trawl allocations.	Establish within trawl allocations based on each sector's relative shares during the time period used for initial allocation. If time periods are different for different sectors use only those years in common to all sectors or calculate a percentage based on each sectors period then adjust all sectors proportionally so that the result sums to 100%. Consider applying the IFQ allocation recency requirement (if any) to eliminate from the sector calculation the catch history of any vessel that has not been active in recent years.			Whiting allocation rules. No other within trawl allocations.
Element 6.2 Trawl/All-Other-Gear		Establish needed intersector allocations through the intersector allocation process.			
Element 6.3 Trawl/ Open Access	N/A	Augment the open access allocation to account for trawl vessels fishing with open access gear on the open access allocation (Element 3.1)	N/A	N/A	N/A

Table 2-2. IFQ Program Design Alternatives for Analysis

	IFQ Program A	IFQ Program B	IFQ Program C
B.1.0 IFQ Allocation			
B.1.1 Eligible Groups	Allocate 50% of quota shares to current permit owners and 50% to processors (Option 3b).[7]	Eligible Group Suboption B-1. Allocate 100% of quota shares to current permit owners (Option 1 from Appendix B). Eligible Group Suboption B-2. Allocate 100% of quota shares for non-whiting species to current permit owners and 50% of the quota shares for whiting species to current permit owners. Allocate 50% of the quota shares for whiting species to processors. (New Option, June 2005) Eligible Group Suboption B-3. 90% of quota shares to current permit owners and 10% to processors. (New Option, June 2005).	Allocate 75% of quota shares to current permit owners and 25% to processors (Option 3a).
Processor Definition:	Use special IFQ Program definition (processors: receive and process unprocessed fish; or catch and process) (Option 1).	Use FMP Definition (processors process unprocessed and already processed fish or receive live fish for resale) (Option 2).	Same as Program A.

[7] References to Options refer to options at they were described in the Scoping Results Document, i.e. *National Environmental Policy Act Scoping Results Document: Individual Fishing Quotas (A Kind of Dedicated Access Privilege) and Other Catch Control Tools for the Pacific Coast Limited Entry Trawl Groundfish Fishery*. Pacific Fishery Management Council, July 2005.

	IFQ Program A	IFQ Program B	IFQ Program C
B.1.2 Qualifying Criteria: Recent Participation	**Harvesters (including catcher-processors):** 1998-2003 participation required in order to qualify for an initial allocation of quota shares (number of trips or years to be specified). (Option 2). **For shoreside processors and motherships:** 1999-2004 recent participation requirement (the number of trips or years is yet to be specified). (Option 4).	All Members of Eligible Groups: No recent participation required in order to qualify for an initial allocation of quota shares (Option 1). **OR** All Members of Eligible Groups: 1998-2003 participation required (one trawl groundfish landing/delivery of any groundfish species) in order to qualify for an initial allocation of quota shares. (Option 2).	Same as Program A.
B.1.3 Elements of the Allocation "Formula"			
Vessel/Permit Related Allocation	Catcher vessel permit owners will receive quota shares based on their permit history plus an equal division of the quota that could be attributed to permit history of bought-back permits (catcher-processors permit owners will not receive a portion of the quota shares distributed on an equal sharing basis) (Option 2). Suboptions for incidentally caught overfished species, either: (a) same as for Other Fish OR (b) equally divide quota for incidentally caught overfished species. For catcher-processors permit owners, use an allocation schedule developed by unanimous consent of that sector (to be provided).	Same as Program A, except no special catcher-processor schedule.	Same as Program A.
Processor Allocation	Processors are allocated quota shares based entirely on the processing of groundfish trawl landings received unprocessed (Option 1).		
B.1.4 History: Species/Species Groups to Be Used for Allocation	Allocate Quota Shares Based on Individual Species/Species Groups: Allocate quota shares for each species/species group based on relative amounts of each respective species/species group caught/landed or processed - for permits applies to permit history; for processors applies to amounts processed (Option 2).		

	IFQ Program A	IFQ Program B	IFQ Program C
B.1.5 History: Allocation Periods			
Periods/Years to Drop:	Options are identical under all programs. Vessels: 1994-2003. Drop 2 years for whiting sector fishing (applies to incidental harvest and whiting). Drop 3 years for non-whiting sector fishing. (Option 1, Sub-option B) Shore Processors: 1999-2004. Drop 2 years. (Option 5, Sub-option B) Motherships: 1998-2003. No opportunity to drop worst year. (Option 4, Sub-option A)		
Weighting Among Years:	Absolute pounds - no weighting between years (Sub-option (i)).	Relative pounds (calculate history based on the entity's percent share of each year's total) (Sub-option (ii)).	Same as Program B
B.1.6 History: Combined Permits and Other Exceptional Situations			
Combined permits:	All permits count. History of the permits combined into a single permit goes to the resulting permit (Option 1).		
Illegal landings/catch:	Don't count Illegal landings/catch under any program.		
Landings in excess of trip limits, as authorized under an EFP:	Don't count landings in excess of the cumulative limit in place for the non-EFP fishery under any program		
Compensation fish:	Don't count compensation fish under any program.		
B.1.7 Initial Issuance Appeals Process	Only one provision has been identified: Appeals would occur through processes developed by NMFS. NMFS will develop a proposal for an internal appeals process and bring it to the Council for consideration. Any proposed revisions to fish-tickets would undergo review by state enforcement personnel prior to finalization of the revisions.		
B.1.8 Creating New IFQ Species/Species Groups After initial Implementation	Only one practical option has been identified: When a management unit is subdivided, quota shares for that unit will be subdivided by issuing quota share holders amounts of shares for the subdivisions equivalent to their holdings of the shares being subdivided. If a new management unit is established that is not a subset of an existing unit managed with IFQ, the Council will need to take action at that time to develop criteria for quota share allocation.		
B.2.0 IFQ/Permit Holding Requirements and IFQ Acquisition (After Initial Allocation)			
B.2.1 IFQ and LE Permit Holding Requirements	Catch must be covered with quota pounds within 30 days of the landing (Option 3). Only LE trawl vessels would be allowed to participate in the IFQ fishery. For any vessel with an overage (landings not covered by quota) there would be no more fishing by the vessel until the overage is covered. Additionally, for vessels with an overage, the limited entry permit cannot be sold or transferred until the deficit is cleared. A possible suboption would require some amount of quota pounds be held prior to departure from port (to be analyzed).		
B.2.2 Annual IFQ Issuance			
B.2.2.1 Start-of-Year Quota Pound Issuance	Only one practical option has been identified: Quota pounds are issued annually to share holders based on the amount of quota shares they held. (Quota shares are issued at the time of initial IFQ allocation).		

	IFQ Program A	IFQ Program B	IFQ Program C
B.2.2.2 Rollover (Carryover) of Quota Pounds to a Following Year			
Non-overfished Species	10% rollover for non-overfished species (Option 3)	30% rollover for non-overfished species (Option 5)	5% rollover for non-overfished species (Option 2)
Overfished Species	5% rollover for overfished species (Option 3)	Full (30%) rollover allowance for overfished species (Option 5)	No rollover allowance for overfished species (Option 2)
B.2.2.3 Quota Share Use-or-Lose Provisions	Do not include a use-or-lose provision but evaluate need as part of future program reviews (Option 3).		
B.2.2.4 Entry Level Opportunities for Acquiring Quota Shares and Low Interest Loan Options	No special provisions.	No special provisions.	Provide new entrants an opportunity to qualify for revoked shares and shares lost due to non-use (if such non-use provisions are created) (Element 2)
B.2.2.5 Community Stability Hold Back	No special provisions.	No special provisions.	Set aside up to 20% of the non-whiting shoreside trawl sector allocation each year and allocate to IFQ holders who have submitted proposals, ranked on the basis of objective criteria that evaluate benefits to local communities.
B.2.3 Transfer Rules			
B.2.3.1 Eligible Owners/Holders (Who May Own/Hold)	Any entity eligible to own or operate a US documented fishing vessel. (Option 2) *The Trawl IQ Committee's intent is to preserve opportunity for existing participants*		
B.2.3.2 Duration of Transfer - Leasing and Sale	Permanent transfers and leasing of quota shares and quota pounds allowed. (Option 2)	Permanent quota share transfers only--leasing prohibited. Permanent transfers and leasing of quota pounds allowed. (Option 1)	Same as Program A
B.2.3.3 Limits on Time of Transfer	Allow transfers of quota shares any time during year (Option 1).	Prohibit transfer of quota shares during the last two months of the year.	Same as Program A
B.2.3.4 Divisibility	Only one practical option has been identified: Quota Shares: nearly unrestricted divisibility - "many decimal points." Quota Pounds: divisible to the single pound		
B.2.3.5 Liens	No options have been proposed to restrict liens. Liens can and should be facilitated through a central lien registry. Options for the central lien registry are covered in Section B.3.1.		

	IFQ Program A	IFQ Program B	IFQ Program C
B.2.3.6 Accumulation Limits	50% or No Limits (Option 5).	Consider all limits as sub-options	Most restrictive limits (1% or 5%) **OR** Intermediate level limits (10% or 25%)
B.2.3.7 Vertical Integration Limit	Only one option has been identified: No additional limits on vertical integration beyond those already provided through accumulation limits.		
B.3.0 Program Administration			
Tracking IFQ, Monitoring Landings, and Enforcement (see Table B.3-1)			
Enforcement Program Number	**Enforcement Program 2**	**Enforcement Program 1**	**Enforcement Program 3**
At-Sea Monitoring	100% at-sea monitors (observers)	100% at-sea monitors (observers)	100% at-sea monitors (observers) or cameras
Shoreside Monitoring	Shoreside monitoring opportunity would be provided	100% shoreside monitoring	Shoreside monitoring opportunity would be provided
Retention and Discards	Discards allowed	Full retention required	Discards allowed if at-sea monitor is present (otherwise full retention)
Discard Monitoring and Reporting System	Upgraded discard (bycatch) monitoring and reporting system needed	An upgraded discard monitoring and reporting system is un-needed	Upgraded discard (bycatch) monitoring and reporting system needed
Electronic Reporting	Electronic landings tracking. QS reported electronically.	Electronic landings tracking. QS reported electronically.	Parallel federal electronic landings tracking. QS reported electronically.
Landing Notification	Advance notice of landing required.	Advance notice of landing required	Advance notice of landing required
Potential Landing Times	Unlimited landing hours	Limited landing hours	Unlimited landing hours
Potential Landing Sites	Licenses required for delivery sites	Unlimited landings sites	Licenses required for delivery sites
Vessel Monitoring System (VMS)	VMS Required under all programs	VMS Required under all programs	VMS Required under all programs
Quota Share Tracking	Create a central lien registry but exclude all but essential ownership information. (Option 2).	Create a central lien registry including all related ownership information (Option 1).	Create a central lien registry including all related ownership information (Option 1).

	IFQ Program A	IFQ Program B	IFQ Program C
B.3.2 Cost Recovery/Sharing and Rent Extraction	Cost recovery for management (not enforcement or science). Up to 3% of ex-vessel value, the limit specified in the Magnuson-Stevens Act.	Same as Program A	Full cost recovery: Landings fee plus privatization of elements of the management system. In particular, privatization for monitoring of IFQ landings (e.g., industry pays for their own compliance monitors). Stock assessments should not be privatized and the electronic fish ticket system should not be privatized.
B.3.3 Program Duration and Procedures for Program Performance Monitoring, Review, and Revision (Magnuson-Stevens Act (d)(5)(A))	A four year review process is specified along with review criteria. Among other factors, the review would include evaluation of whether or not there are localized depletion problems and whether or not quota shares are being utilized. Standard fishery management plan and regulatory amendment procedures will be used to modify the program.		
B.3.4 Data Collection	Expanded voluntary submission of economic data (Option 2).	Expanded mandatory submission of economic data (Option 1).	Same as Program B

2.2 Alternatives Considered but Excluded from Detailed Analysis

This section discusses an alternative that was considered but rejected and briefly explains the reasons for its elimination. In addition, this section lists options and sub-options that were considered by the Council and TIQC but were not included in any of the alternatives forwarded for analysis.

An alternative that was initially considered for analysis would issue IFQs for overfished species, maintain cumulative trip limits for all other species, and implement total catch reporting and 100 percent at-sea monitoring. Upon further consideration it was determined that this alternative would not have the potential to create enough benefits to the groundfish fishery to offset the costs of the monitoring and reporting requirements, and questions were raised as to how the program would continue once overfished species recovered. Therefore, the alternative was dropped from further consideration.

In addition to the dropped alternative, a number of options and sub-options were discussed by the Council and TIQC but not included in the alternatives forwarded for analysis. The list below provides an initial summary of these excluded elements and options.

- Species groups that could be managed under an IFQ program but were not explicitly included
    - Overfished Species
    - Prohibited Species
- Stakeholder groups that were not included as recipients of QS
    - Vessel crew members and skippers
    - Vessel owners
    - Communities
- Methods for issuing QS that were not included
    - Auctions
    - Lotteries
    - Equal shares
    - QS based strictly on years of participation
- Types of shares from an IFQ program that might have been forwarded but were not
    - Shares for Processing (as opposed to IFQs for harvesting issued to processors)

While the elements and options listed above were not specifically included in the suite of alternatives that were forwarded for full analysis, all are included in the description of components, elements and options (Section 2.3).

2.3 Components Table

Before the effects of the alternatives on resources and stakeholders of concern can be fully evaluated a number of issues need to be addressed and decisions may need to be made by the Council. The Components Table below highlights these issues by augmenting the basic alternatives forwarded by the Council for detailed analysis. The major goal of the Components Table and the Components Analysis (see Appendix C: Components Analysis) is to ensure that the details of each alternative are adequately considered by clearly specifying how the different elements fit together within an alternative and identifying unknown or unintended potential effects on resources and stakeholders groups. The Components Table and Components Analysis also identify options that were discussed but not brought forward for detailed analysis.

Appendix A: Workshop Presentations

1 Introduction

On April 18 – 20, 2006, the Pacific Fisheries Management Council held a three-day workshop on the proposed approach for analysis of fishery management alternatives and completion of an Environmental Impact Statement (EIS) for members of the harvesting and processing community. The goals were to:

- Provide participants, decision-makers and other members of the public with a better understanding of the potential methods to be used to analyze impacts resulting from implementation of a Trawl Individual Quota Program and assistance to preparers of the EIS to ensure the project is accomplished in full compliance with the National Environmental Protection Act (NEPA) and its implementing regulations,
- Provide participants with an opportunity to share information with the project team that may assist in understanding potential effects of these alternatives.

1.1 Day 1 Overview:

The workshop began with introductions, an overview of the workshop, and a discussion of workshop goals and objectives. After lunch, the consultant team presented an overview of the Stage 1 Draft Report with a particular emphasis on the analytical framework and the Proposed Alternatives. The presentation was structured with opportunities for participants to ask questions and make comments throughout the presentation.

1.2 Day 2 Overview:

The second day of the workshop featured two small group break-out discussions. The morning session focused on Permit Stacking (Alternative 5); while the afternoon session focused on Alternatives 3 and 4. Permit Stacking was chosen as the first topic because it closely resembles the status quo, and thus the changes from status quo will be less noticeable relative to Individual Fishing Quota (IFQ) management. Alternatives 3 and 4 were chosen to address potential results from various management changes involving IFQs. During the small group discussions, workshop participants were divided into 3 groups that discussed these issues. The full workshop then reconvened and each group provided a summary of their discussions to the workshop as a whole. The break-out discussion topics were chosen by the project team with the intent of allowing workshop participants to discuss their views on potential outcomes of the action alternatives.

1.3 Day 3 Overview:

The third day of the workshop featured a large group presentation and discussion of defining the term 'processor' as it relates to each of the proposed alternatives. This session was followed by a large group presentation and discussion on community issues. These topics were prioritized based, in part, on input from workshop participants. The last session of the workshop included a wrap-up session, summarizing the key points that were taken from workshop discussions and finished with a brief overview of the next steps of the project.

Workshop Agenda

From	To	Activity
Tuesday, April 18, 2006		
From	**To**	**Activity**
9:30 AM	10:00 AM	Coffee and greetings
10:00 AM	10: 30 AM	Workshop Begins: Introductions and Project Background
10:30 AM	10:45 PM	Workshop overview and agenda review – Marcus
10:45 AM	11:15	Alternatives as forwarded by Council and as Currently Listed
11:15 AM	12:00 PM	Discussion of workshop goals & objectives
12:00 PM	1:00 PM	Lunch
Discussion Topic: Presentation of Stage 1 Draft by consulting team		
1:00 PM	3:00 PM	Analytical Framework / Affected Stakeholders and Resources
3:00 PM	3:30 PM	Break
3:30 PM	5:00 PM	Components Table and Major Analytical Issues
5:00 PM	5:30 PM	Large Group Discussion, Questions, and Answers
Wednesday, April 19, 2006		
From	**To**	**Activity**
8:00 AM	8:15 AM	Coffee
Discussion Topic: Effects of the No Action Alternative and Permit Stacking (Alternative 5)		
8:15 AM	9:00 AM	Presentation from the Consulting Team on the Analysis of these Alternatives
9:00 AM	9:15 AM	Goal and Objectives for Small Group Discussions
9:15 AM	10:30 AM	Small group discussion re. No-Action Alternative and Permit Stacking
10:30 AM	10:45 AM	Break
10:45 AM	12:00 PM	Small groups report back to entire workshop with large group discussion
12:00 PM	1:00 PM	Lunch
Discussion Topic: Effects of IFQ Alternative 4 (Simplest IFQ program)		
1:00 PM	1:45 PM	Presentation from the Consulting Team on IFQ Alternatives
1:45 AM	2:00 AM	Goal and Objectives for Small Group Discussions
2:00 PM	3:15 PM	Small group discussion re. IFQ Alternatives
3:15 PM	3:30 PM	Break
3:30 PM	5:00 PM	Small groups report back to entire workshop with large group discussion
5:00 PM	5:30 PM	Large Group Discussion, Questions, and Answers
Thursday, April 20, 2006		
From	**To**	**Activity**
8:00 AM	8:15 AM	Coffee
Discussion Topic: Processor Definitions, Allocations, and Impacts		
8:15 AM	8:45 AM	Initial discussion/presentation by Consulting Team
8:45 AM	9:45 AM	Large group discussions
9:45 AM	10:00 AM	Break
Discussion Topic: Community Impacts Consolidation		
10:00 AM	10:30 AM	Initial discussion/presentation by Consulting Team
10:30 AM	11:15 AM	Small group discussions
11:15 AM	12:00 PM	Small groups report back to entire workshop
12:00 PM	1:00 PM	Lunch
Discussion Topic: Consolidation		
1:00 PM	1:30 PM	Initial discussion/presentation by Consulting Team
1:30 PM	2:15 PM	Small group discussions
2:15 PM	3:00 PM	Small groups report back to entire workshop
3:00 PM	3:30 PM	Break
Discussion Topic: Review of Workshop and Next Steps		
3:30 PM	5:00 PM	Wrap-Up Session

1.4 Report Contents:

The workshop report provided here presents a summary of workshop. Most of the workshop sessions consisted of a *Microsoft PowerPoint* presentation by the Consulting Team during which questions were taken and answers provided. The presentations are reproduced in Appendix A, while the questions and comments raised by participants and the responses of project team are contained in the main body of this report.

2 Morning Session, Day 1: Workshop Goals and Objectives/ Presentation of Alternatives

2.1 Introductions of Workshop Participants

Day 1 began with an introduction to the TIQ Project, History, and Project Schedule by Jim Seger, followed by an introduction of the Project Team and Workshop participants. A list of workshop participants is provided in Table 1. The Project team referred to in this document consists of Jim Seger, PFMC project manager the project consulting team.

Table 1. Attendees at the Trawl IQ Workshop

Name	Affiliation	Stakeholder Group	Council Body	Tu.	We.	Th.
Bersch, Joe	Supreme Alaska Seafoods	Mothership	None	Yes	Yes	Yes
Bodnar, Steve	Coos Bay Trawlers Association	Trawl Representative	TIQC	Yes	Yes	Yes
Burke, Denny	F/V Timmy Boay	Trawl/Combo Vessel Owner	None	Yes	Yes	Yes
Campbell, Carl		Commercial Fisherman	None	Yes	Yes	Yes
Carroll, Richard	Ocean Gold Seafoods	Processor	None	Yes	Yes	Yes
Cleary, Dave	Oregon State Police	Enforcement	EC	Yes	Yes	Yes
Cobb Lessa	Port Orford Ocean Resource Team	Community	None	No	No	Yes
Cooper, Mark	Midwater Trawlers Cooperative	Trawl Vessel Owner	None	Yes	Yes	Yes
Corrigan, Brian	USCG	Enforcement	EC	Yes	Yes	No
Craford, Kent	Consultant, WCSPA	Processor	None	Yes	Yes	Yes
Cramer, June		License Owner	None	Yes	Yes	Yes
Cramer, Leo		License Owner	None	Yes	Yes	Yes
Dalton, Mike	CSU, Monterey Bay	Tech – Economist	SSC	Yes	Yes	Yes
Daspit, William	PSMFC	Tech—Data Systems	None	Yes	Yes	Yes
Dooley, Robert		Trawl Vessel Owner	None	No	Yes	Unk.
Dunn, Kevin	F/V Iron Lady	Trawl Vessel Owner	None	Yes	Yes	Yes
Easly, Otha	NMFS, SWR, OLE	Enforcement	EC	Yes	Yes	Yes
Fosmark, Kathy	Nontrawl Vessel Owner	Open Access Gear—Southern	GAP	Yes	Yes	Yes
Fujita, Rod	Environmental Defense	Environmental	None	Yes	Yes	Yes
Garbrick, Chris	United Catcher Boats	Trawl Vessel Owner	TIQC	Yes	Yes	Yes
Ghio, Tom	Ghio Fish Company	Fixed Gear/Buyer	GAP	Yes	No	No
Goblirsch, Ginny	Ex-Sea Grant and Fisherman	Communities	TIQC	Yes	Yes	Yes
Green, Don		Trawl Permit Holder/Fisherman	None	Yes	Yes	Yes
Hightower, Alan		Trawl Vessel Owner	TIQC	Yes	Yes	Yes
Hughes, Steve	NRC/United Catcher Boats	Trawl Representative	None	No	Yes	Yes
Hutala, Peter	Pacific Marine Conservation Coalition	Environmental	None	Yes	Yes	Yes
Jagielo, Tom	WDFW	Tech – Biologist	SSC	Yes	Yes	Yes
Jinks, David	Midwater Trawlers Cooperative	Trawl Vessel Owner	None	Yes	Yes	Unk.

Waters, Ed	Consultant	Yes	Yes	Yes

2.2 Questions on Workshop Agenda

Participants had several questions and comments related to the Workshop agenda. Those questions and comments and, when available, the Project Team's responses, are listed in the following section. Participant questions and comments are indicated with a "P." Project Team responses are indicated with a "T" and are italicized and indented. Project Team Members' names, when available, are provided in parentheses at the beginning of their response. When a discussion continues on a particular comment or question, the participant's reply is also indented.

P: **Community Impacts** are last on last day—is this a reflection of how important it is? How do you see this discussion being a priority? Impacts on communities should be part of every discussion; I'm interested in how you propose doing that analysis.

P: Are we not discussing **Alternatives 2 and 3** at this meeting? I thought we were going to.

P: I'm concerned that if we focus on Alts. 4 and 5 we are diminishing 2 and 3—then we are moving forward with alternatives that haven't been considered enough and it's too late.

2.3 Overview of Alternatives

Marcus Hartley of Northern Economics gave a presentation on the project alternatives. The presentation is included in Appendix A pages 1 – 8.

P: **Alt 4 Question**—Other species—what species are you discussing here that would have OY?

> ***T:*** *Other Species of Groundfish would have OY under Alternative 4—not other species like sharks, skates etc.*

P: **Alt 5—**Gear Sector—when referring gear sectors, are you referring to trawl and fixed gear or are you referring to recreational sector too?

P: **OY**—where is that **threshold level** and what is the motivation for it? Threshold levels would be defined on some level of basic biomass and used for modeling; although this is not currently specified

P: **Trawl Only Options**—what groundfish quota would go to trawl?

> ***T:*** *Council is in the process of determining trawl sector splits; establishment of trawl IFQ program will not set sector allocations*

P: **Historical allocation** is not used in determining allocation under Alt. 5? I assumed Council would look at this as an option rather than becoming part of the program; we must look at historical allocation of permits—needs to be part of analysis

P: Is **cumulative trip limit** the same as annual trip limit?

> ***T:*** *No, it means cumulative trip limit for 2-month trip limits. Assuming 6 trip limits are issued per year.*
>
> **P:** So as part of program alternatives, are you going to look at eliminating the 2-month trip limits and switch to annual limits?
>
> ***T:*** *No, there will still be 2-month trip limits.*

P: **Quota Shares** allocated to trawl? These are reflected in the Programs A-C? Does this include the bycatch species also?

P: Only 1 option is to allocate 100% to harvesters, which is only a sub-option to B. There **should be a stand-alone harvester option** to compare against the others. All options except one allocate shares to processors. How do you fairly analyze the effects of these when they don't appear to be balanced options?

> ***T:*** *These options were developed by the Council and if they need to be changed, the issue must be taken up with the Council.*

P: Program C has an element that held back part of QS for proposals that had both harvesters and processors to help **meet community stability objectives**.

> ***T:*** *Yes, there are options that work toward meeting community stability objectives.*

P: So the way things are structured now, **Option 1 Program B** could never be looked at under Alternative 2 or any other option except under Alternative 3?

> ***T:*** *We would look at what a 90-10% spilt do, etc.*
>
> **P:** But the **Council could pick among different options** among alternatives even if they are only analyzed as part of one alternative?
>
> ***T:*** *(Marcus) yes we are trying to analyze these components separately so that the Council understands their effects.*
>
> ***T:*** *(Jon) Yes—given the complexity of these options, you can simplify the analysis by only analyzing options and sub-options under one alternative but do it in a way that provides the Council with an understanding of the effects so they may mix and match among options and elements if necessary.*

P: Why did you choose **option C** to analyze against all the alternatives?

> ***T:*** *(Marcus) This was the Council's decision to do it this way.*

P: I don't understand what's going on with **processor shares**. Are these shares that would come out of the harvester quotas or would it give processors the right to buy the fish?

> ***T:*** *(Marcus) Shares for processors would be a dedicated access privilege to harvest the fish—not a right to buy fish.*
>
> **P:** Don't we have a limited entry trawl permit? Processors don't have a trawl permit.
>
> ***T:*** *(Jim) This is the heart of the controversy and these options have been taken up by Council and this is where we've come with this issue.*
>
> ***T:*** *(Marcus) Shares that are allocated to processors would have to be harvested on a limited entry vessel.*

P: Are you considering the **shares** that are held by processors (i.e. on processor owned vessels) now into this?

P: **Split between harvesters and processors**—are there caps on how much can be in the processor sector and the harvester sector?

> ***T:*** *(Marcus) There are proposals to have limits on how much any given entity can have.*

P: The only way a harvester is going to have control of what he gets for his product is if he has control of where he sells.

P: Has there been a decision that once these dedicated access privilege are allocated that someone from the environmental community can buy them up. Is there anything in these provisions that tells people how they must be used?

> ***T:*** *(Jim) There are provisions in the Alternatives now is to monitor this issue and if it becomes problem—then address it.*

P: What about **costs to government for enforcing** these alternatives and options?

> ***T:*** *(Rich) We are looking at management costs in 4 components—we are attempting to analyze these programs and their enforcement/management costs so that we can compare that information.*

2.3.1 Goals and Objectives of Workshop

Jon Isaacs (URS, Inc.) gave a presentation and led a discussion on the goals and objectives of the workshop. The presentation can be found in Appendix A, pages 9 – 14. Questions and comments on the goals and objectives of the workshop are presented in the section.

P: Has the Problem Statement already been approved by the Council? P&N?

> ***T:*** *Yes—P&N has already been adopted by the Council and could be subject to change if needed.*

P: If we go forward without looking at **Alternatives 2 and 3,** we will prejudice ourselves against these alternatives for future consideration.

> ***T:*** *(Marcus) The analysis will fully study Alternatives 2 and 3; the intent of the workshop sessions tomorrow is to do a step-wise approach into some of these impacts of the programs so we have a more complete understanding of them. We can address Alternatives 2 and 3 from the analytical perspective, and highlight the primary differences between Alternatives 2 and 3 from Alternative 4.*

P: You are entirely missing the difference in the whiting industry.

> ***T:*** *(Jim) We can incorporate this into the discussion during small group discussions*

P: **Bi-monthly trip limits—**most of the fleet was hoping that would go away with this IFQ program. Could this be incorporated as an option for analysis in the alternatives?

> ***T:*** *(Jon) Are we bound by what Council has developed in the alternatives?*
>
> ***T:*** *(Jim) Analysis must focus on the alternatives proposed by the Council. Alternative 4 does get rid of trip limits. Alternatives 2 and 3 also vary this as sort of hybrids of this management approach. So there is variation for trip limits among the alternatives.*

3 Afternoon Session, Day 1: Presentation of Analyzed Framework

The Marcus Hartley (Northern Economics) provided the Workshop with presentations on the proposed Analytical Framework and on the Affected Stakeholders and Resources. The PowerPoint Presentation on the analytical framework is contained in Appendix A, pages 15 – 48, while the presentation of affected stakeholders and resources is contained in Appendix A, pages 49 - 70. Project team members Rich Marasco, and Bob Trumble also gave brief overviews of biological resources and habitat. Question and comments were taken during the presentations and are summarized below. As in Section 2, above, participant questions and comments are indicated with a "P." Project Team responses are indicated with a "T" and are italicized and indented.

P: When will the Draft EIS (DEIS) be produced?

> ***T:*** *End of the 2nd quarter of 2007.*

P: Why is it one year for Secretarial approval?

> ***T:*** *Once the Council makes the decision, a new DEIS will have to be done, regulations will need to be written and implementation plan must be developed in addition to the review process. All these processes, particularly the regulation-writing process, take a long time.*
>
> **P:** Seems that some of these processes could be done simultaneously.
>
> ***T:*** *(Jon) There are risks associated with overlapping this process and much cannot be done until the ROD is signed.*

P: **Sector Allocations—**2nd Amendment Process isn't reflected in this schedule. These would have to be nailed down.

P: **Communities—**Newport—fishing port of which trawl is a component. Effects in the trawl fishery may have effects on other fisheries. Will the EIS analyze the effects on other fisheries that result from the effects on trawl fisheries? What is the picture? Are we trying to protect existing communities or are we protecting market conditions and future communities?

> ***T:*** *(Mike D.) Under National Std. 8 the analysis must look at what the different alternatives would do to the sustainability of the communities. Engagement vs. dependency—what is the relative importance of this segment of the fishery to the local economy? Part of analysis looks at the overall picture of the community economics. Our job in the analysis is to look at the alternatives that have been developed and provide an analysis of the impacts of those alternatives on the communities in light of existing status quo and future conditions as well.*
>
> **P:** It is important to consider market forces and future conditions in the analysis.
>
> **P:** Some of this should be laid out in terms of the objectives—protection of the communities.

P: Why does **Amendment 18** sunset?

> ***T:*** *If approved by the Secretary—it deals with standardized methodology for dealing with bycatch and non-managed species as well, so Amendment 18 would have provisions that would impact the trawl IFQ program. IFQ program is actually part of the Amendment 18 so the schedule should reflect this.*

P: **Sector Allocations**—If **Secretarial review** goes forward but allocations are not figured out yet, what happens? Also what happens if a new Secretary is put in office in the middle of this process—does the new Secretary have to honor what the previous Secretary had in motion?

> ***T:*** *(Marcus) Is it completely infeasible to have an IFQ system if you don't have hard and fast Sector allocations? That seems to be the general assumption but it seems that you could put something together 'almost'—ranges of OY. Approach could be to issue IFQs in 2 steps—initial IFQs and then the 2nd set.*

P: What are the current operating assumptions?

> ***T:*** *(Jim) Right now Council Staff is working on **intersector** allocation EIS to set these in place. But you could, as part of bi-annual specifications, establish an amount based on that. We may want to refer to the New Zealand sector allocation programs and various options being explored there.*
>
> **P:** So this would be in a holding pattern until allocations happens.
>
> ***T:*** *(Jim) not necessarily; the Council could set allocations to be used in the interim until they are established.*

P: How do you do your analysis without making **assumptions about allocations?** So how are you going to make these assumptions and how are they split out?

> ***T:*** *(Marcus) Assumptions would be based in part on 2005 splits just for analytical purposes. We will be looking at ranges in order to analyze this. We're in the process of rebuilding several stocks and the 2005 numbers don't reflect the best scenario and we would hope that these assumptions would be covered in the analysis.*

P: What is the difference between the **baseline condition and the historical condition** and how will it impact your analysis?

> ***T:*** *(Marcus) The baseline is 2005 data considering historical trends that have occurred and how those trends have impacted the 2005 baseline condition.*
>
> ***T:*** *(Jon) Part of the issue is the challenge in using the most comprehensive data set but in light of the historical trends.*

P: Channel Islands Fishery Management Plan FMP Process—if we had only looked at one year for the baseline for that fishery, you end up with a very skewed representation of the fishery. So instead we used an **average over 20 years** rather than one particular year in order to capture trends. Could this be applied?

> ***T:*** *(Mike D.) This works for some variables but not all—no matter what you choose as your baseline. It is incumbent on the team to capture the trends up to that point.*

P: The amount of fish that's allowed to be caught is based on principles of the stock assessment for that year….all the more reason why you need to average historical data rather than one specific year.

> ***T:*** *(Anne) The difference in analyzing one specific year in light of **historical trends versus using an average number** to do the analysis may not be discernable. In other words, the discussion of impacts will consider historical trends if you were to use an average number or if you used 2005 data in light of historical trends.*

P: Must the NEPA analysis evaluate the **net benefit or net cost** of the potential impacts or just identify them?

> ***T:*** *(Marcus/Jon) Yes, to the extent we can, we must try to evaluate the effect in terms of value or other quantitative measure or significance.*

P: How do you approach estimating **individual effects versus more programmatic effects?** Methodology—how will you approach these questions? Will you use interviews, looking at other programs, etc.?

> ***T:*** *(Marcus) It depends on which action you're looking at, but all of these sources of information will be considered in our analysis. The complexity of this analysis makes it difficult to develop a robust analysis.*

> ***T:*** *(Mike D.) We will be looking at various levels of effects such as community level, individual level, regional level of effects. We will use a tiered approach to evaluating levels of effects.*

P: Council's **Amendment 18** established some catch caps as tools for getting at allocations. Clarity on this issue may be needed?

P: Make sure that ensuring a **steady flow of fish** can work both ways—including when the market doesn't necessarily want it.

P: Even **cumulative trip limits** don't ensure a steady flow of fish in the current system, although it attempts to; make sure this is understood.

P: Cumulative trips limits do **eliminate flexibility.** Fish flow is not that steady either.

P: **Stakeholders—**deficiency of document regarding stakeholders. Can we discuss this today?

> ***T:*** *(Marcus) Yes, this will be part of the presentation.*

P: Might be useful to **interview stock assessment scientists** because they might have some input as far as ups and downs of the stocks.

> ***T:*** *(Marcus) Yes, this has been and will be done.*

> ***T:*** *(Mike D.) Yes this and we also do literature reviews; we also want to take advantage of institutional knowledge of people attending this meeting here today.*

P: Are you looking at market issues in terms of s**ubstitutable species or aquaculture?**

> ***T:*** *(Marcus) Yes we will, especially with regard to the flatfish fishery.*

> ***T:*** *(Jon) We do have to focus on the logical permutations of the alternatives and not anything and everything that could be analyzed.*

P: What about **net revenues?** Is there anything you can use to shed light on this analysis in terms of net revenue?

> ***T:*** *(Marcus) Yes there are cost data; Carl Lian (NMFS) has data that will likely be used in the analysis and anything else that is available.*

P: Is it reasonable to assume that there will be **improved accounting of catch** so that there will be better modeling for the fishery?

> ***T:*** *(Marcus) Yes, we hope that that would be a result of the proposed alternatives.*

P: **Post trade allocation of permits?** Would this be possible to predict and use in the analysis? Allocation will matter and that's my main point.

> ***T:*** *(Marcus) Initial allocation and consolidation across harvesters and processors will be analyzed to the extent that we can. These behavioral changes will really determine the direct and indirect effects of the proposed alternatives.*

P: If QS are only issued to fisherman and not to processors, would effects on processors be indirect or direct?

> ***T:*** *(Marcus) Processors would be directly affected.*

P: **Directly affected stakeholders** are not represented on your slide—such as crew or skippers, owners etc., or are they considered in the harvester group?

> ***T:*** *(Marcus) we are looking at crew members, owners etc. as part of the harvesting sector. Whether they are directly or indirectly affected, they will be looked at in the effects analysis.*

P: Offshore whiting deliver to offshore processors; onshore whiting vessels would be delivering to onshore processors—need to use Council terms **at-sea and shoreside** rather than offshore or onshore.

P: Most people in the industry would think of the **strategy used when fishing rather than the size of their boat** and that's how they would develop categories to analyze, instead of size categories such as Large Diversified Trawl CV or Small Diversified Trawl CV.

P: Is large, small referring to tonnage or length?

> ***T:*** *(Marcus) Length of boats seems to indicate what species they fish for and strategy they use.*
>
> ***T:*** *(Mike D.) The goal of analysis is to capture differences in the fleet, which has to do with relative dependency on the different catch.*

P: **Vessel length is not a good indicator** rather what fisheries they are involved in—themes such as state fisheries, federal fisheries etc. may have more logical breaks.

P: Seems to make a difference to whether you are inshore or offshore; it's an economic thing. So size really doesn't matter.

P: Trawl catcher processors—how will **QS for harvesters versus catcher processors** get allocated?

> ***T:*** *(Jim) QS would be allocated to harvesters and then to processors. It's not a competition between processors and vessels; they are separate allocations. The first step is to split the IFQ into two pieces—the IFQ to be allocated among each group separately. The competition between the two groups happens at the Council level when they initially determine how much percentage is allocated to each group (harvesters/processors).*

P: Indicators for Trawl Harvesters—Why is it operating costs and not capital inputs?

> ***T:*** *(Marcus) We will be looking at capital inputs.*

P: In determining **net revenue**, what data are you using to determine net revenue?

> ***T:*** *(Marcus) Carl Leyan (NMFS) is putting these data together for us.*
>
> **P:** It is critical that this is accurate.
>
> **P:** We do use budgets in our impact modeling but it would be surprising if Carl has anything different than what we are using.
>
> **P:** If you have enough data, you could do a **power analysis** and determine these things rather than using an arbitrary percentage such as 20% but I understand it is difficult to get enough data to do this.

P: **Landings of Bought-Out Permit:** There is another alternative rather than equally dividing landings to boats left, which is to divide it equally among people who are buying it out.

> ***P:*** *Catcher Processors (CPs) are not contributing to buy out so it's those folks that are paying back the loan that would receive shares.*

P: **Classes of Trawl Processors—**I assume you are using the FMP definition of processor?

> ***T:*** *(Marcus) This uses the fish ticket information; processors in the FMP are defined in terms of primary and secondary.*

P: Will you classify processors by fish ticket number or by ownership?

> ***T:*** *(Marcus) Our basic approach is to look at the processing facility; in terms of the allocations, we would need to go through the process of looking at joint ownership etc.*

P: Will you be putting limits in as far as **fish tickets or ownership**?

> ***T:*** *(Marcus) The definition we will be talking about Thursday is the processing facility itself, not, at this point, the buyers. The economic effect takes place where that processing occurs.*

P: **Classification**—will you be distinguishing between **whiting and non-whiting?**

> ***T:*** *(Marcus) We've talked about this and are considering this. There are advantages and disadvantages of doing so.*

P: **Indicators for processors—**the processor tags many fish but none of them get cut there; so if processor gets IQ, he can transfer the fish to another community; that's where the revenue goes?

> ***T:*** *(Marcus) I cannot speak to the why of that question. The allocation would goes to the cutter of the fish; two options—one: take ownership of the fish and you process un-processed groundfish; Two: use definition of FMP—processes un-processed, already processed fish or sells live fish into the market.*

P: **Motherships** will be treated essentially the same although the community effects will be different. Commenter - This is an oversight in your powerpoint. Your **product types** that are listed are very **non-inclusive.**

> ***T:*** *(Marcus) The data we have are limited so our reporting of this is very non-inclusive.*

P: **Communities** - Seattle is missing from the major ports listed in the power point.

P: **Community stability holdback**—where is that being analyzed? Are you going to be doing that?

> ***T:*** *Yes—under Program C, part of Alternatives 2, 3, and 4.*

P: List of communities was just where vessels or processors were stationed; I can imagine communities where trawl fisheries are taking place off shore that may affect the community indirectly even if fish are not processed there. Would you look at these effects?

P: Indirectly Affected Stakeholders—If there is not a lot of reason to break out **recreational harvesters,** we will not be doing so given the difficulty of doing so.

P: When you talk about separating the non-overfished from overfished…could you give me an example, like widow which is currently under a rebuilding plan, and how those types of species would be dealt with?

> ***T:*** *(Rich) They would be dealt with the same as they are now. With respect to overfished species—the analysis will treat them the same as the non-overfished species.*

P: The focus seems to be on habitat, what about non-FMP species? So you would be looking at the whole spectrum of species that might be impacted?

> ***T:*** *(Bob) Yes we would look at the whole spectrum.*

3.1 Day 1 Wrap-Up Session

At the end of Day 1, Jim Seger gave a brief overview of the next day's agenda—the behavioral changes under these proposed Alternatives. Participant comments are recorded below.

P: The Consulting Team appears to have an Alaska mentality where vessels are broken out by shelf or slope—where here it's much smaller, so the break is not so different. The shelf is within 4 miles of the beach—so size of vessel is not really applicable here as it might be in Alaska. Need to totally separate the fallacy of bringing the whiting fleet into the groundfish fleet. Definition of facility processor is based on major amounts of fish; this seems to be a vertical integration of processors where very few control a vast amount of fish. The industry took a big hit as soon as the buy-back program went through. Buy-back power will be lost in this system the way it's set up now. This is a big concern. Need area-specific ITQs to restrict movement.

P: You could plot a 70 to 80-mile radius around a port where a vessel delivers to determine where they fish with a few exceptions. You could construct arcs around ports to determine the likely fishing area.

P: Next species of controversy between harvesters will likely be Shortspine—just as evidenced with the sablefish IFQ program—it was a 'bloodbath' between harvesters.

P: Once the ITQs become sellable—you are going to impact other fisheries.

4 Morning Session, Day 2: Permit Stacking

The second day began with a presentation to the whole group, with a focus and on the No-Action Alternative and on Alternative 5: Permit Stacking. Alternative 5 was chosen as a focus point because it closely resembles the No-Action Alternative, and the Consulting Team felt it was important to address several issues in the context of cumulative trip limits—for example, the relationship between harvesters and processors, and the potential costs of the requirement that 100 percent of catch be observed.

Marcus Hartley provided the PowerPoint presentation which is included in Appendix A, pages 71- 84. Following the large group presentation, participants in the workshop were divided into three small groups for more in-depth discussions. After the small-group sessions, the large group was reconvened and the discussions from each small group were summarized and presented back to large group.

4.1 Questions and Comments during the Large Group Presentation

The participant's questions and comments on the large group presentation are recorded below.

P: How often could the permit be transferred per year?

> ***T:*** *(Jim) Every 2-month period.*

P: There is an emerging market for certified seafood so incentives are created by these programs for changing behavior to increase the value of the catch.

P: Are we to assume that we're managing on a more real-time basis so that there is some consequence or incentive for going over individual caps?

> ***T:*** *(Jim) Yes—some incentive to not exceed caps, but not as much of a need to upgrade monitoring system as in sablefish, for example.*

P: Behavior changes result in leaving the fishery, etc. There needs to be a policy change on the part of Council to address people leaving the fishery for another fishery.

4.2 Permit Stacking Small Breakout Group Summaries

After the presentation to the large group, the participants broke up into three small groups for discussion of particular questions. Each group's Breakout Discussions are summarized in the following sections.

4.2.1 Group 1 Permit Stacking Small Breakout Discussion

What is likely to change with the permit-stacking program?

- Consolidation of the fleet.
    - Yes, this will occur. There are only a set number of permits.
    - Concentration of harvest in a given area.
        - Fewer vessels fishing may result in concentration of fishing effort in certain areas.
        - More difficult to have quality fishing trips because it concentrates effort.
        - Whether this is good or bad is hard to say because it may result in a reduction in incidental catch of certain species in other areas.
        - The better, stronger operators will be the ones left fishing and those that are smaller, weaker will be doing the permit stacking.
        - Latent permits will be the ones bought out first.
        - Rules of stacking—restrictions on permits for stacking certain types of permits. Permits that are not being used at all could be stacked.
        - Issue of latent licenses—how we set up the rules of stacking will make a big difference in driving trip limits down and will dictate by how much.
- If you have a smaller vessel and you have this endorsement, you may be more likely to sell. The amount of overhead in the fishing operation may have greater influence than the amount of revenue.
- Stacking permits and increasing efficiency—limits are going to go down so more people are realizing their entire limits. Total limits will probably go down.

Is permit stacking going to reduce bycatch?

- Bycatch will be reduced—less will be discarded (which may include species that are overfished).
- In the tribal fishery, fewer boats equals a lower bycatch rate. Bycatch is defined by these critical species. So as a result of the permit stacking program, lower bycatch will result.
- Trip limits will be smaller. Permit stacking will likely result in reduction of the base trip limit. There are implications for the cumulative effects of this.
- Ultimately as we maximize the number of permits stacked, the OY/number of permits…
- This assumes that we stay with a stacking of a 2-month period. The trend to switch to longer periods could reduce overhead.

Is it true that some people try to reduce incidental catch and others don't? Why?

- There is cost associated with the time it takes to deal with incidental catch; smaller boats are more likely to not deal with it. So they are more likely to fish cleaner.
- This depends on the boat but generally, smaller boats are making smaller tows, which often have less incidental catch, because they don't want to have to spend the time it takes to deal

with incidental catch. On the other hand, bigger boats can fish deeper which may also be cleaner. So it really just depends. There is a lot of variability with this.

- Is there really any ability to avoid canary rockfish? Yes, to a degree (e.g., bottom trawling), but not every one can avoid them.
- Are there incentives to high-grade with smaller trip limits? Yes.
- There is incentive to retain more and do less high-grading.

Observer Coverage

- What are the implications of 100% Observer coverage?
  - $500 per day is going to cause people to leave the fishery.
- What percentage of the fleet might leave?
- Most trawl vessels can carry an observer.
- Observer costs can be even higher than $500 per day because they can't be taken on or off the boat at will due to weather delays. This is an extremely heavy burden for multi-species groundfish fleets.
- What about using electronic methods to account for catch?
- Cameras can't really tell the number of fish on the deck so using them may not be feasible. Cameras may only indicate whether fish are being discarded and not really provide any information on the amounts of fish.
- Electronic monitoring will result in less time out in the field for enforcement due to the time it will take to have to review tapes.
- Coast Guard Safety Exam—the new observer requirements may result in more people being required to take safety exams and might improve safety.
- Given the cost of the observers, are we obtaining that much more useful information with full monitoring versus the monitoring we do today?
- The Observer Program may allow more biological sampling, which may provide more information on status of stocks.
- Observers up north are used for biological sampling that help in understanding predator-prey relationships etc.
- In this region, there's been a resistance to collect biological information. If this is already collected on shore, the fleet shouldn't have to bear the cost of this. Biological sampling only shoreside may not correctly capture what is being discarded.
- What's the utility of going from 25 to 100% observer coverage? It may allow us to do a power analysis, which is a very a useful tool.
- A compliance monitor is different from a trained observer; there is a difference between hiring a biologist or a technician. The availability of observers also influences this cost. Expenses of observers include airfare, travel expenses, etc.
- What are your alternatives to paying for observers? Don't go fishing. Why should we be responsible for paying for observers, we don't necessarily want them, we want to fish. So why should we have to pay this cost?

- Every case is different; some people have permits for several fisheries, but some do not. Those that only have a few permits would be more likely to not fish. Fuel is triple what it was 5 years ago, profit margins are getting smaller, yet the price of fish is staying the same.
- The cost for observers per day is high because a lot of them are working only 1, 2 or 12 days per month, or maybe not at all. You can't just pay them for the days they work.
- Some fisheries are not conducive to line fisheries, which may reduce the observer costs because you may not need as many observers on deck as with other trawl fisheries.
- Current alternatives are all catch-based programs—not landings based. You can't get around the 100% observer requirement.
- Fixed costs can go down.
- Overall, the observer requirement is going to be a significant problem for many fishermen.

What about the relationship between harvesters and processors with permit stacking?

- You may have to make 2 trips to deliver fish, so you may not make more money because they (processors) may not take more than one delivery.
- Plants may have a smaller number of boats bringing them fish so the volume of what they process may not change as a result of stacking.
- Permit stacking can change where fish are landed.
- Product into the plant—processors would probably want larger deliveries. There may be a benefit of handling the larger flow of product through the plant.
- There is no doubt about the potential for market changes.

What would happen to the price of fish as a result of stacking?

- If the same amount of product is going through the plant, the change shouldn't be there, but it may not work that way. Twice as many fish could mean lower price.
- This one is really an incremental step away from status quo. As we start going to a longer period, deviating from 2-month periods, then we've really begun to mimic a true IFQ program. Why, in other alternatives, is there consideration of allocating shares to fish companies? This seems to be re-allocating.
- Stacking permits may not provide you with more fish. Not everyone fishes the same. There's no benefit to stacking if you can't catch and sell the additional amount of fish.

What about the future behavior of processors with permit stacking?

- They might consolidate too because of larger deliveries.
- Is this different from pressures today? Satellite plants might close because of not being able to deal with larger deliveries.
- There is the likelihood that processing would be more efficient because of economies of scale. The cost of operating over a short span versus a longer span of time.
- Larger deliveries may mean greater efficiency and may not result in lower prices for fish. The quantity of fish is the same but you may get a more efficient scheme.
- Smaller deliveries are not as efficient.

- Larger deliveries would equal better efficiency and therefore higher value.
- Price is a function of demand and supply. Quantities will be the same.
- Will the timing of the supply change? This may be another influence on the price.
- What about product form?
- Yes, in an open-access fishery you end up with whatever product you can put it into as fast as possible. Finished product recoveries increase with rationalization.
- Couldn't reduced trip limits result in efficiencies for both harvesters and processors? This is hard to answer because of timing of deliveries and the size of their deliveries. Processors may dictate when boats can deliver. Companies put the boats on a market limit (whatever they can handle).
- If people have the certainty of regular deliveries, how is this a bad thing—or why doesn't it happen more right now?
- The most valuable fish processed are the last ones processed. You can't cater your capacity to a peak run of 4-5 days, but this is what everyone tries to do.
- Race for fish is gone. So we're just tweaking an existing system with this alternative unless the market changes and we begin developing unique cuts of fish, etc.
- Your 2-month period doesn't result in a mini-race for fish. There are usually fewer landings in the second month than in the first month. This actually seems to be quite variable. Not sure if the data support this.
- There is a possibility of spatial pattern changes.

If you had 150 permits spread up and down the coast—whose permit is going to have more value?

- You are still required to have a license, which have a value, a fixed amount. If you have a permit for a smaller length endorsement, you may have more difficulty financially so you may be more inclined to sell. The market for permits itself has changed because of permit stacking. Vessel length in the south is smaller than in the north and this is not necessarily directly linked to the fishery as much as to geography. Weather is better in the south, so boats are bigger off Washington than Santa Barbara. Length distribution does exist, so if you have this system, smaller permits may take on greater value.
- Market availability further south you go has diminished in recent years and there is no one to sell to. They may make money under this new system because they could sell.

Spatial and Temporal Distribution of Vessels

- Smaller boats are weather constrained but this may not translate into a longitudinal effect but more of a latitudinal effect.
- Oceanographic conditions and market conditions.
- The continental shelf is greater in north so there are more grounds available.

4.2.2 Group 2 Permit Stacking Small Breakout Discussion

Big Picture Questions

- Does stacking apply to a full year or can permits be stacked for fishing periods? More stacking will occur if stacking can be done for each period independently. For example, vessels that fish in Alaska part of the year could stack permits on other vessel while gone. Note: Jim Seger indicated that current regulations allow permit transfers at six-month intervals.
- Will stacking have 100% retention requirement, or allow discarding? Note: the requirement for full catch (rather than landing) reporting could require full retention for video monitoring, but could allow discards if monitored by an observer.
- How would stacking deal with management of overfished species?

Relationship between harvesters and processors

- Importance of continuity?
    - Most vessels have long-term relationships with buying stations/processors.
- Long term relationship/implicit contracts?
    - The relationships between vessels and processors vary considerably, and formal contracts and informal relationships exist among them.
    - Changes in relationships could depend on how stacking changes over time—stacking would likely cause geographic shifts in effort, but boats would tend to maintain existing relationships, or at least use existing relationships as a starting point
    - Effects of latent capacity. If changes in permit stacking can occur often, latent effort will increase, because vessels could take advantage of short-term availability for fishing or could use permits of vessels fishing elsewhere. Transfers of permits only once per year would lead to less use of existing latent capacity.
    - Vessels that stack permits from some other geographic region could strengthen the relationship with their processors, by making more fish available to that processor.

Would the permit stacking system provide any benefits to the whiting fishery?

- Permit stacking would provide little direct benefits to the whiting fishery. However, the availability of overfished species is important to maintaining harvest of target species, and how management develops for the overfished species could have a big impact on the whiting fleet.

How would harvesters change areas in which they fish under a permit stacking program?

- The group agreed that vessels that stack permits will likely stay in the original areas for those vessels. Permits and catch would migrate to the areas of stacking. The group did not determine if particular geographic regions would have a net import or expert of permits.
- The group had a difference of opinion on whether permits would tend to migrate to larger vessels or larger ports. In general, the group agreed with the assumption that permits would travel the path of least resistance, and likely move toward vessels with larger profits.

100% observer/video coverage?

- To understand impacts, we must be able to answer the question "Who pays for the observers or video monitoring, the government or the vessel?" If the government pays, then lower impacts would accrue to the vessel. If vessels pay for observers, then vessels would have to stack permits to generate enough revenue to make the payments.
- Estimating the impacts on vessels of paying for observers requires estimates of actual costs (observer, video) relative to revenues.
- What does the cash flow for multi-species vessels look like relative to cost of observers? Does marginal revenue of stacking add enough to cover costs of observers? If observer costs take up all of revenue generated by stacking, then vessels would have no incentive to stack.
- Small vessels that take 5-6,000 lbs. per day could not afford observers, and would likely have to sell, lease, or otherwise transfer their permits.
- Video monitoring can effectively document whether discarding occurs, but cannot collect biological data. Components of the whiting fleet currently use video monitoring to monitor whether discarding occurs.
- The group expressed concern that the IFQ alternatives and background information did not define how video monitoring would be used and whether the data would have limitations on its use. The group expressed concern that lags in data analysis would lead to difficult enforcement uses.

Stacking over time

- Different effects would occur if vessels can change stacking arrangements every fishing period compared to a single change once each 12-month period
- Multi-period stacking could occur differently in different fisheries –the group predicted that stacking would shift to valuable fisheries, e.g., to sablefish

Could the permit stacking program lead to reduced or increased incidental catches of overfished species? Why or why not?

- The group agreed that bigger limits resulting from stacking would lead to reduced bycatch/discarding
- Larger catch quantities allow vessels to fish more often, stay on the water longer, and vessel operators can learn and stay current with areas of lower bycatch of overfished or undesirable species.

Specialization resulting from permit stacking

- Some vessels that fish in Alaska might stack local permits and forego Alaska pursuits. Staying local would save travel costs. About 20 vessels with high capacity could fall in this group.

Safety

- The group expected little direct change in safety, except that fewer vessels on the ocean mean fewer opportunities for incidents. Vessels that stack permits and remain in the fishery will more likely be profitable, and thereby safer, than vessels that transfer permits.

4.2.3 Group 3 Permit Stacking Small Breakout Discussion

Status Quo/ No Action

- Factors affecting decision to go fishing:
  - How close to the end of cumulative trip limit?
  - Is there an observer on board?
  - Weather
  - Time of year: weather, stock availability and demand conditions
  - What/when the buyer/processor wants to buy
  - Processor schedules deliveries
  - Other fishing opportunities (crab, shrimp, albacore, FG SF, AK)
  - Market price and cost. Seasonal fluctuations in price? (not necessarily) Longer term fluctuations in price driven by demand, world supply and availability of substitutes.
  - Hunting season
  - Not leaving on Friday
  - Availability of crew, ice and supplies
  - Fishing for history (date has been set)

How many permit transfers allowed per year?

- GMT analysis showed fractional trip limits for stacked permits for this reason. Will electronic reporting, total catch accounting mitigate this?

System could be set up to allow higher limits for first/single permits. GMT analysis incorporated this.

- Limit on # permits should be based on ownership, so an owner of multiple vessels can't accumulate too many permits
- This alternative has too many restrictions to be attractive as is. Should include lengthened trip limit period (120 days?)
- Trip limits reduce flexibility for processors.
- Need to neutralize potential effect of latent permits
- Doesn't accomplish goals of IQ program
- PS has been analyzed by GMT(1998-99?)

- Doesn't reduce mgt cost or complexity
- Limits need to be related to fishing history, or some formula (tiers?) Note: This will reduce value of latent permits.
- Stacking will make it harder for new entrants to get in the fishery
- Trip limits per permit would become more restrictive
- Allocative impacts: Number of permits/vessels owned by processors, larger operators should be disclosed. Number of latent permits. These factors will affect outcomes under this alternative.

How would the permit stacking program change relationships between harvesters and processors?

- Reduction in number of vessels increases bargaining power per remaining vessel
- Two month cumulative trip limit imposes artificial market constraints/gluts. Permit stacking may magnify this. Affects market timing and product form.
- Transfers among vessels by owners with multiple vessels would increase deliveries, create gluts
- Single-permit owners would lose out because trip limits per permit would be reduced ("overhead")
- Smaller owners would be closed out by larger operators
- Block of permits could create effects on rest of the fishery, lower the price of product, increase area concentration, close out certain communities. e.g., Canadian experience

Would the permit stacking system provide any benefits to the whiting fishery?

- No benefits to whiting fishery directly
- But would increase opportunity/access to fish for non-whiting groundfish
- When widow recovers enough to be targeted, or allow targeting of yellowtail, stacked trip limits will complicate management of widow trip limits

How would harvesters change the areas in which they fish under a permit stacking program?

- May create incentive to choose low bycatch area/reduce bycatch because 3 times as much will be harvested per trip
- Only affects owners with excess capacity on their vessel

How will processors respond to a permit stacking program? Would they change the timing of their demand for inputs?

- (Not addressed)

What will be the effect having to report 100 percent of the catch, ignoring for the moment the additional cost of the observer/video monitoring program?

- (Not addressed)

Now assume that the combination of video monitoring and observers will cost an average of $500 per day for observers per fishing day. Will it be necessary for harvesters to purchase additional permits to remain viable? How would this change if more emphasis were placed on video monitoring and thereby reducing the costs of the observer/monitoring system?

- (Not addressed)

Could the permit stacking program lead to reduced or increased incidental catches of overfished species? Why or why not?

- Permit stacking would not reduce incidental catch, by itself.

4.3 Questions and Comments on Permit Stacking: Large Group Wrap-Up Session

Following the three breakout sessions, each small group summarized its discussion and presented its findings to the whole workshop.

P: As your trip limits are reduced, you'll retain more fish. As permits are stacked, fewer boats will result in less bycatch.

P: There may be more consolidation towards certain fishing ports but there has already been a lot of consolidation so this program may not cause that much more consolidation.

P: Permit stacking could result in reaching regulatory caps more quickly.

P: How many permits are going to get stacked? What will be the effect on small boats? How many will go out of business?

> ***T:*** *(Marcus) The minimum number of permits would be 57.*

P: Duration of cumulative trip limit period?

> ***T:*** *(Jim) Could go up to a year (more like a quota system).*
>
> **P:** Number of transfers per year?
>
> ***T:*** *One per year. This could be adjusted in the alternative options.*

P: This should be brought to the Council's attention so they can make this modification.

P: Can you lease a permit?

> ***P:*** *Permit just has to be associated with the vessel however that is done as long as it is registered to the vessel. This doesn't really mean that you would be going out of business because permits can be stacked for money.*

P: Latent permits—170 active permits (not all fish). Participation in the fishery—10 years fished is the biggest chunk. Permit holder come in and leave regularly. So in any one year, we should be saying 100—175?

> ***T:*** *We are working through this number and it will be provided in the analysis. This currently does not include the off shore fishery.*

P: I don't see how we've captured a management problem here. Balancing encounters with overfished species…expectation for managing trip limits and encounters with overfished species. If we don't know how behavior is going to change in terms of stacking permits this could be a problem as far as OYs for overfished species.

P: What will permit stacking do as far as reaching caps for overfished species?

P: We're not sure if you're permit stacked whether you would take several days to fish—Processors may not want large volumes of fish but rather smaller deliveries year-round. Several trips versus one trip.

5 Afternoon Session, Day 2: Large Group Presentation of Alternatives 3 and 4

To begin the afternoon session of Day 2, the Marcus Hartley provided a presentation on Alternatives 3 and 4, which is included in Appendix A, pages 85 - 94. There was a brief discussion during the presentation and then the Participants split up into three smaller groups for in-depth discussions.

5.1 Questions and Comments Raised During the Large Group Presentation

P: Under Alternative 3 - Are we to assume overfished species are to be managed under IFQs?

> ***T:*** *Yes.*

P: I am concerned about losing the discussion of the interplay between community stability holdback program and these issues. We need to make sure this is discussed in the EIS.

P: Regarding the idea that processors develop new products—this would fit nicely as part of the intent of the community stability holdback.

> **T:** *Community stability holdback quotas are measured in the number of pounds issued.*

P: Alternative 3 sub-options—whether IFQs would cover overfished species. One sub-option would switch to an OY limit.

> ***T:*** *For this work session, only discuss IFQs for overfished species, not OYs.*

5.2 Alternatives 3 and 4 Small Breakout Discussions

5.2.1 Group 1 Alternatives 3 and 4 Small Breakout Session

5.2.1.1 Issues to be Addressed As Expressed by Participants

- For the EIS—Assumption is that 25% of QS would be given to processors. What sort of discussion will occur in the EIS to support the decision being made? Why are we stopping at the first chain of customers rather than what we might consider secondary customers?
- Processor shares—What is the economic and conservation rationale behind giving processors shares?
    - How will this particular action promote sustainability?
    - What goals are we attempting to be accomplished under this program?
    - Why are we going from no allocation to processors to 25%?
    - How processor shares will hurt the harvesters? Interaction in the marketplace.
    - Different products/product changes
    - Processors have not historically received a share. Why do we have to give them a share now?

5.2.1.2 Breakout Group Discussion

How will the allocations of QS/QP be used by processors? (Assume under this alternative a 75/25% spilt)

- If fish companies control shares—they are likely to make arrangements with certain fisherman to catch those shares.
- Processors may use shares to ensure boats they don't own will fish for them, and as a way of leveraging their access to additional product.
- This question is too big to answer. Processor shares might be the only means of preventing monopolies—they may end up keeping smaller plants alive. They may lease their shares out to others and shut their doors. It may be a good business decision for them to do so. Canada example—after implementing an IFQ system, the three processors that were there were shut down. Shorebased communities may cease to exist unless they have allocations.
- Whiting could move this way under Alternative 4.
- It will likely be difficult for shorebased processors to exist without whiting.
- CPs would likely have the strongest position as a buyer.
- Shorebased processors only have the opportunity to do whiting where CPs may have the ability to move back and forth (to catch Pollock, for example).
- Newer plants may not have the opportunity to start in under this type of program.
- There are differences in opinion about what causes plant closures.
- Under this scenario, an asset is being allocated to a sector (harvesters or processors); unless market forces are controlled, the effects of this are unpredictable unless there are conservation and economic controls to engineer the market.
- As long as there are certain caps on ownership, I don't have an objection to processors owning quota, just the initial allocation of the shares.
- What are the constraints and how should they be implemented rather than trying to predict what the results might be? If this is in place, how should this be structured to protect harvesters, small processors, etc.? How would it protect communities?
- Accumulation caps—do they apply equally across shares? The EIS alternatives will consider accumulation caps.
- Assumptions—are you trying to maintain the existing processor mix and fleet mix? Are you protecting what is status quo or are we moving to more efficiency in certain areas?
- There are trade-offs between efficiency and the social goals of fairness and equity. These need to be clearly laid out in the EIS.

Would the allocation of QS/QP to processors make it more likely that harvesters would try to acquire additional QP? If so, why?

- Depends on what the processors are doing with the other 25% of the shares.
- The less you get, the more you try to acquire.

- This will likely result in a major change. Some are going to have to get greater QS to stay alive and others are going to have to sell to stay alive. People increasing quota and people selling is likely.
- Not everyone will share in the opportunity for processors; people will be acquiring more or selling out.
- Owners of multiple permits/vessels will be in a stronger position than single vessel owners.
- Isn't the point of IFQ to try to reduce capacity?
- Individual accountability (bycatch) seems the primary goal under an IFQ program.

Will processors try to get more?

- Depends on the assumptions for share caps etc.
- Tendency is yes. New Zealand example—accumulation caps are critical. Harvesters there are not happy with the results of the IFQ program.

How would alternative allocation percentages affect harvesters and processors?

- Changing percentages will change the intensity of the behavioral changes.
- This is a huge equity issue—same amount of fish gets landed but fewer people have the opportunity to share in the quota. The problem of equity is exacerbated. This program may have possible cumulative effects with other initial conditions such as trawl buy back. Processor quota would likely reduce opportunity to realize the benefits associated with the buyback.

Is it likely that processors would change the products they produce under an IFQ program? What changes might you make?

- Product form is likely to change radically, particularly in the whiting fishery. Shorebased whiting industry now does one or two products exclusively. Just as under the AFA, there was diversification in product form. You may see additional products that were never produced before. What leads to this? In a rationalized system it's not the timing, it's what you can do with the fixed quantity that you have.
- Would new product forms be more profitable? Goal is what you could do to enhance your product. This is a likely change in all species under this type of system.
- Whiting open access moving toward IFQ may mean more of the product being produced.
- Do you see these results and changes as a result in the IFQ system or is it a result of these certain assumptions of 75/25%
- In general, slowing the fishery down will mean production of more of the product and more types of products.
- Non-whiting sector allocation of 25% of QS to processors will make it difficult for new young startup companies to enter, thus possibly discouraging development of new products.
- Option for gear flexibility? Would different types of product result in different gear types?

- Opportunity to use other gears is limited. Gear types are relatively constrained due to bycatch.
- It would be nice to have the option to use other gear types and should be encouraged if it's a cleaner way to fish; more flexibility would be helpful. You may get better prices by using other gear (e.g. pot for black cod).

Is it likely that processors would change the timing of their purchase demands for particular species in an effort to reduce incidental catch and thereby increase target catches?

- Don't foresee this changing. Timing will shift considerably to better fit fishing in certain areas and to deal with bycatch issues. This is more a function of the flexibility of the relationship then to the availability of fish.

Whiting seasons would be eliminated under Alternative 3. What would the effect of this be?

- Speculation about the nature of the stocks.
- There might be an opportunity to develop a roe market in Japan, China etc.
- Reduction in salmon bycatch and other groundfish species is a major issue in this fishery. Stretching out the season does help address this problem to a certain extent.

Would you expect whiting vessels that don't currently fish for other types of groundfish to change behavior with respect to timing or areas fished to reduce incidental bycatch?

- Being able to time this is a big deal for bycatch. It is nice to have the option.

How would harvesters change timing or areas of fishing under this simplified IFQ compared to permit stacking?

- Seems like market forces influence catch—when you go after catch.
- With an IFQ program, you have the chance to adjust your timing.
- If period became 12 months rather than 2 months, you have more flexibility to avoid bycatch.

With regard to the extra cost of the observer program; Is it likely that harvesters would need to purchase additional QS/QP to cover those additional costs?

- Accumulating shares can be a huge cost. Accumulating shares is not easy but costly.
- Will willingness to pay for additional QS diminish because of cost of having to pay for observer program?
- Getting more QS does not always mean you'll be more profitable, especially initially.
- Weighing various costs—putting constraints on who can own shares.
- Is 100% observer coverage mandatory for this or is 100% monitoring? The idea is to enforce the individual accountability, not necessarily to collect more data.

- A platoon fishing season could reduce the potential cost of observers. Would fishers be open to this? This eliminates the flexibility of fishing (a goal of the IFQ program).
- Cost for observers is spread out over greater amount of time under an IFQ so it may be more costly. How hard your observer costs hits you is directly related to the value of the fish in your hold on those days at sea that you are required to have observers.
- Observer program means more data collection and seems like a service to the government.

How would this change if the emphasis were on video monitoring thereby reducing the costs of the observing program? Is video monitoring a viable alternative?

- There is cost and time associated with viewing tapes. How are you trying to use this information? Would the fear of having video monitoring be enough to encourage cleaner fishing? Are the images good enough to see what's going on?

How do you think the elimination of whiting sectors will affect the distribution of whiting between whiting processing sectors?

- Shorebased processors and motherships would cease to exist.
- CPs are more efficient and would continue to operate.
- If there isn't enough capacity of CPs to deal with the larger amount of fish, shorebased and motherships may continue, but may not for long. This is likely to be short term.
- Communities with shorebased processors would be affected.

5.2.2 Group 2 Alternatives 3 and 4 Small Breakout Session

How will QS be used by processors?

- Will processors give/lease to affiliated harvesters or acquire own fleet?
- Over time, fishermen and processors would work out long-term arrangements—they would need to come to mutual agreement on the use of the processor QS. Business plans of the processors would affect their decision to keep, lease, sell, or give away access to the shares.
- Processors bringing in third party vessels from outside the area to harvest processor held shares would de-stabilize the fishery (contrary to goals of program)
- A 25% loss of shares from harvesters to the processors would eliminate harvesters' profit margin, and they would have to work out a way to recapture that profit under the new system. Harvester access to processor held shares may be a question of how much harvesters are willing to pay for use of processor held shares.
- However used, processor held QS would change the way of bargaining—as would the IFQ program itself. Harvester and processors both have concerns that the other sector could unreasonably drive the price of fish to their detriment—through a "take it or leave it" stance.
- Processor ownership of shares would perhaps accelerate the consolidation of the processing sector that is already taking place, with a limited number of companies gaining larger market share.

Will harvesters try and acquire more QS?

- Yes; acquiring more QS is a natural impact of an IQ system through consolidation over time as seen in other places where IFQs have been implemented. (Previous experience has demonstrated consolidation within harvester sectors; no experience exists with a program that initially allocates harvester shares to processors.)

Will processors try and acquire more QS?

- Yes; the group reached a consensus that processors would acquire more harvester share over time, altering the original allocative split percentage.

Would a 90/10 allocation make a difference?

- The initial allocation would have no long term difference, but would cause a different starting point that could have very different short term impacts. The starting point would likely have an impact on the pace of change, with higher proportions assigned to processors leading to faster changes.

Is it likely that processors would change products under IFQ program? What kinds of changes?

- The flexibility resulting from an IFQ program would allow more of a shift toward filling market needs.
- With an opportunity to fish at a slower pace and in sync with the market, processors could develop new product forms. Whether new products develop, IFQ will drive overall improvement in recovery rates and quality.
- There will be some development of specialty products.
- Processors will have a new opportunity to look at value-added products.
- The whiting C/P fleet has moved to products other than surimi; the rationalization resulting from formation of a co-op has provided this fleet with more opportunity to explore other products.
- In general, analysts need to be careful about attributing causality of product shifts to the IFQ system when the market is already driving product form changes; e.g., some of the C/P product changes were market driven as surimi demand decreased.
- In general, IFQ system will allow for better strategic decision-making and predictability.

Whiting fishery changes—whiting seasons would be eliminated—would whiting vessels change their behavior (timing, areas fished) to reduce bycatch?

- Most participants in the group believed that the whiting fishery would still be driven by seasonal availability. While harvesters and processors may make some seasonal changes, the changes would probably not be major.
- Whiting harvesters would have an opportunity to fish during the periods of low bycatch (Fall) if the change made business sense. However, a regulatory change in the seasons would have to go through Section 7 consultation to examine the impacts of the change on bycatch.

How would harvesters change timing or areas of fishing under this simplified IFQ compared to permit stacking? (Toward where CPUE/incidental catch balance is favorable?)

- The group could not reach consensus on this issue. Some said that processors would want a steady flow of product during the year, while others provided information that processors would want to work around other, more time-constrained fisheries.

What will be the effect of the IFQ program on incidental catches of overfished species?

- Harvesters will have an incentive to save catch of overfished species to the end of the fishing year as a requirement for harvesting desirable target species. This incentive would occur regardless of the form of management of the overfished species.
- Harvesters need a mechanism to save overfished species to the end of the year, or they may lose the opportunity to catch their full allotments of target species.
- Eliminating the race for fish would allow for a slower fishery. Harvesters could take steps to lower bycatch without the competitive disadvantage that would have occurred in open access.
- IFQs would reduce the current amount of discards (of target and overfished species), and make more fish available for retention.

Would observer/monitoring program costs drive QS/QP purchases following initial allocation?

- Fishing could occur over more consecutive days than under permit stacking. If harvesters could have observers on board for longer periods, lower overhead would decrease overall observer costs compared to permit stacking.
- Participants noted that observer coverage would depend on the goals and objectives of the observer program; as data needs increase, observer coverage could also increase (e.g., Community Development Quota vessels in AK have two observers on each vessel to increase accuracy to manage individual species quotas).
- Participants noted that whiting motherships and C/P currently pay for their own observers.
- GF vessels with low QS could have problems paying for observers, which would make them more likely to sell, lease, or otherwise transfer the QS. Vessels with larger QS might need to buy QS to pay for observers.

Under Alternative 4, how would eliminating whiting sectors affect distribution of whiting between whiting processing sectors?

- Motherships and shoreside could lose shares.

Alternative 2 has 4 sectors (shoreside non-whiting, shoreside whiting, CPs, MS)

- If the IQ program has QS or other individual allotment of overfished species, separate allocation of the overfished species would be needed to avoid one shoreside sector shutting down the other.

Alternative 3 has 3 sectors (combined shoreside, CPs, MS)

Community stability hold-back (non-whiting component)

- The hold-back would likely create more management expense, either at the expense of the community or the participating QS holder.
- Even though the hold-back would go to QS holder(s), redistribution of the QP may cause instability in the fleet. The administrator of the hold-back is not identified, and could have a substantial impact in determining whether the instability occurs.
- Most of vessels and processors are currently part of the communities, so what benefits them does benefit the communities.
- Hold-backs could end up pitting one community against another, for example by a buying station or processing facility threatening to leave one community for another unless the community offers a subsidy.
- The impacts of hold-backs have to be considered in the context of changes currently taking place without an IQ program. Consolidation and specialization will happen anyway, as demonstrated by the loss of working waterfronts along the coast. Group members considered that the effects of IFQs on communities will vary more or less depending on characteristics of the communities.
- Have poor data for catch history for processors and communities, but processors and communities can release if want.

Group members pointed out two central concerns related to the effects of IFQs:

- Group members expressed concern about whether the IQ system has caps on ownership. They recommended evaluation of “use it or lose it” provisions so that IFQ could not be bought and shelved by entities that want to reduce the amount of fishing.
- Group members noted that if the IQ program establishes QS or other individual allotments for overfished species, then those QS become the currency for the full fishery. Group members expressed concern for QS for overfished species issued to those who caught the most such that they get the most of the overfished species. QS based on history works against those who avoided overfished species. Any entity that accrued too much QS of overfished species could control the entire fishery.
    - As an alternative, the group recommended consideration of individual bycatch account system or bycatch co-op systems to control distribution and use of overfished species.
    - As an alternative, the group recommended consideration of allocating overfished species in proportion to QS of other target species.

5.2.3 Group 3 Alternatives 3 and 4 Small Breakout Session

How will Processors use their allocations of QS/QP? Give to harvesters? Lease to harvesters? Use with own vessels and use profits to expand fleet?

- Processor QS is of little value to processors, except to negotiate with harvesters to get deliveries, or else could be fished on a processor's vessel.
- On "day 2", sales, purchases and consolidation of QS will have changed the game. Very many possibilities.
- Relationship between processors and harvesters is already very complex, interlinked with other fisheries. Processor QS is another layer of proc control.
- Under the Status Quo there are fewer options, so incentives are less important. With IQ program, options are expanded and changed, so incentives are necessary to maintain flow of product.
- QS represents access to the ocean.
- It is not necessarily a win-win among processors for processors to get QS.
- Processor QS will make it more difficult for new entrants: harvesters and processors.
- Do shoreside processors have responsibility to pay for observers?
- Should examine experience of BC groundfish and East Coast surfclam fisheries.

Would harvesters be more likely to acquire IQ?

- Yes. If they start at 75% they need to acquire more just to stay whole.
- Yes just because it makes good business sense.

Would harvesters be more likely to sell IQ?

- Yes
- (Note: 26 permits are being targeted for purchase by Nature Conservancy)
- QS for overfished species increases likelihood that somebody can corner the market, for whatever purpose.

What about other processor allocations? 10%, 50%

- More of the same…

Will Processors change the products produced?

- Yes. Less freeze, more fresh. Currently do freeze, but not by choice. The market in British Columbia is very responsive to demand.
- Eliminating artificial trip limit deadlines will improve product flow.
- Product recovery rates increase

Will Harvesters change products delivered?

- Maybe.
- Opportunities for harvesters and processors to bargain as co-equals and investigate new options.
- More revenue sharing?

Will Procs adjust timing of deliveries of certain spp to reduce bycatch and increase amounts of target spp?

- Uncertain, because too many other factors involved (markets, price)

What data are available with respect to products and prices?

- This group did not address this issue

What is effect on whiting fishery of eliminating sector-specific seasons?

- Current seasons were designed at least partly to reduce salmon bycatch.
- There is competition to be first with product. This can drive bycatch, but there will no longer be a race for fish.
- There is competition between processors for a limited pool of harvesters.

How would whiting (and non-whiting) harvesters change behavior (timing or areas fished) to reduce bycatch? What will be effect on overfished species?

- There may be a race for fish to avoid being shut down because of somebody else.
- Co-ops may be formed to pool bycatch quota: e.g., hotspot tracking
- How to prevent opportunistic price gauging for QS for the most limiting spp
- Enforcement Consultants recommendation: Must have 1 QP of each species before leaving the dock
- Would need to know when a “sector” is approaching exhaustion of available QP
- Many potential problems with QS for overfished spp
- Incentive to hold canary QS and sell dearly to those in need

Would non-whiting harvesters change behavior (timing or areas fished) to reduce bycatch?

- (see above)

Will harvesters need to buy additional QS/QP in order to afford observer costs @ $500 per day?

- (Note: At-sea MS costs $350 per observer per day, but more days at sea)
- If can't afford $500 per day then would likely sell QS
- Small boat averages $1,500 per day.
- Assuming $350/day and 100 days per year, would need to average at least $75,000 more ex-vessel per year to cover observers and other additional costs.
- 20% coverage is "status quo". What is a minimum coverage level to be "acceptable"

What about video monitoring?

- (not addressed)

Under Alt 4, whiting seasons and sectors are eliminated. How will this affect the distribution of whiting between processing sectors?

- CPs are most efficient, highly mobile so they will overrun the whiting fishery.
- Note: Alternative 2 has 4 sectors (shoreside non-whiting, shoreside whiting, CPs, MS), Alt 3 has 3 sectors (combined shoreside, CPs, MS)

Community Stability Holdback Program: up to 25% of QP will be held back and made available competitively for quota holder ventures based on criteria to be specified.

- May be better associated with a different Harvester-Processor split than Program C (25-75)
- Does this include shoreside QPs only. Yes, shoreside, non-whiting only.
- Review panel with quantitative criteria would need to decide which proposals get QPs. Subdivisions by state?
- Would need to have a processor to qualify as a "community"?
- Ports that currently have trawlers and processing should be eligible
- Are there other ways to mitigate impacts than this type of program?
- Some commercial fishery dependent communities will die without a commercial fishery. This program may keep options open for these communities, and save infrastructure.
- Impact on efficiency should be investigated: dispersion of capital?
- Neither Processor QS nor Harvester QS will stay in a particular community
- Zero sum game…

5.3 Alternatives 3 and 4: Large Group Wrap-Up

P: Discussion on cost per day for observers—boats under 60 ft. split equally with boats over 60ft. in having to pay costs for the observer program.

P: What is the true goal of the observer program? It doesn't necessarily have to be 100% to accomplish some goals.

6 Session 1, Day 3: Large Group Discussion on Allocations to Processors

Day 3 began with Marcus providing a PowerPoint presentation on allocations to processors (Appendix A, pages 95 – 104). The presentation summarized problems in the current definitions of processors with respect to allocations of IFQs and proposed a solution. During the presentation, comments and questions were accepted and discussed. That discussion is summarized in the following section.

P: Who pays the landing taxes?

> ***T:*** *Tax would be paid if you're a purchaser—you'd pay a state revenue tax which solves part of the issue related to receiving products.*

P: A fish ticket does indicate whether it comes in on the round or whether something has been done to it.

P: There are no permits for motherships.

P: Under a trawl IFQ program—don't you only need to identify those plants that purchase trawl caught groundfish?

> ***T:*** *(Marcus) But we don't know from the fish ticket data whether it was delivered live fish. Discussion of delivery of live fish; whether it occurs or not.*

> ***T:*** *(Jim) Not just identifying who the processor is but the issue is if you're allocating based on history which is difficult to gather from fish ticket information. There may be governmental records of some kind but the issue is whether they are in a central repository and whether they could be put there.*

P: With the advent of paying for the buy back—everyone that has landed a live fish; wouldn't there be a record there of this?

P: Clarify point that recording groundfish tickets—only concerned with trawl caught fish.

P: Under this system, could you end up with unprocessed fish that would not go to anyone?

> **T:** Fish don't go away if QS is not award—everyone gets more this way. There may be processors out there who may not apply for QS. It is not NMFS responsibility to seek those people.

P: Consultant definition of on-shore processor—last bullet—the fish ticket is filled out by people that do that. So how does the data set tell you who actually processes?

P: The majority of the species groups who go through the record channels—it's easy to find out who processes, but down in California this becomes much more complicated because of all the different smaller groups. You should focus on the main species that we're fishing for and then the other small groups of other species; by aiming at bigger groups, you won't get lost in this definition.

P: Fundamental question of why QS would be allocated to processors from fisherman customers—this rationale was not addressed in any of the options. Will the EIS describe the basis and philosophy of why this is to occur?

> ***T:*** *(Marcus) To the extent that this is laid out in the Purpose and Need, the better it is. In the future proposed rule, there will likely be a statement that would explain the rationale behind NMFS' decision to allocate to processors.*

P: But the decision-makers will need this rationale in front of them when making the decision about the alternative. When will the rationale be specified?

> ***T:*** *(Jim) This will be presented in the document and will be brought to the forefront.*

P: Agree that this is a policy/political question that the Council staff needs to address. If you are going to do an analysis of this rationale that you analyze allocations to all groups (holistic analysis), not just of allocations to processors.

P: If Council were to set an objective of what their going to do, the Council needs to be aware of the potential consequences of their decision. Regarding allocations to processors, policymakers would need to know the effects of this early on in the decision-making process. Until the Council understands some of the potential impacts of this, how can they define their objective? Analysts should make policymakers aware of the consequences of this decision before making the decision to do this. The question of whether or not to provide preliminary analysis of the potential effects of processor shares and provide this information to the Council before they determine the reasonable range of alternatives or whether to wait and provide this information to the Council as part of the analysis in the EIS should be considered now.

P: Allocations of QS: I don't understand why they are being split up. Why the QS would be distributed? QS belong to the harvesters. Now you're taking our QS away from us. I understand the fleet should be consolidated, but it doesn't make sense to give QS to processors. You want to push this under the table and we're not even taking about it and it's a major issue. Such a big emphasis on processor shares instead of managing the stocks.

> ***T:*** *(Jim) We have a range of options we're looking at, including allocations to processors and not allocating to processors etc. We are obligated to evaluate a range of reasonable alternatives and how the achieve goals and objectives and their associated impacts. When the Council makes their decision on this issue, they will review all of these analyses. Make sure that the things you agree with are on the table so they can be evaluated as part of this decision so the Council members are better informed. The EIS must evaluate these issues and be informative about the potential impacts.*

P: Part of our charge under NEPA is to evaluate all of these economic issues that not only affect on processors, but also on skippers, crews, and others employed in the fishery.

P: There are two components to this issue—analytical component of the economic changes resulting from allocations and then there is the value judgment of who gets the money.

7 Session 2, Day 3: Community Impacts Discussion

Session 2 on Day 3 focused on a discussion of Community Impacts. Mike Downs (EDAW, Inc.) provided a PowerPoint presentation (included in Appendix A on pages 105 - 120) and led a large-group discussion. Several different subtopics were discussed, with each subtopic introducing specific questions for discussion. These questions and their discussions are summarized in the following sections.

7.1 The Nature, Direction, and Magnitude of Impacts

The following questions were put to the Participants for discussion in this session:

1. In general, how would fishery management changes under the proposed IFQ or permit stacking programs result in impacts to communities?
2. How would impacts be distributed among communities? (Who would likely gain/lose)
3. What would cause community impacts? (Fleet or processing consolidation? Change in timing or location of landings?)
4. How would the impact be felt? (What would happen?)
5. How would impacts differ in communities that are home to catcher vessels versus communities that are home to processors?
6. Where are fishery support businesses located and how would they be affected?
7. How substantial would community impacts be and what communities would be most vulnerable?

P: Communities that are not trawl communities (e.g., Port Orford) would be impacted as well by these changes. Many communities feel the impacts of serial depletion of certain species without controls. What do we need to do to get our community included in this analysis?

P: Serial depletion and potential fragmentation—point made for the management of fish on a coast-wide basis, regional management of fisheries. The analysis should contrast the regional management and status quo and the way it is currently split out.

P: Any rationalization scheme has significant impacts. Unalaska, Alaska example post consolidation of the crab fishery; this consolidation has resulted in a slow-down in the support service industry and in people leaving the community. A similar result is likely under this scenario for the west coast.

P: It's important for each of the fishery dependent communities—are you going to analyze what that community feels their ideal needs are? What does the fishery want to see as far as options in their community—ideal fleet size and what is needed to support it. Some areas may have fewer/more boats due to the recent buyback; community quota could be very useful. The trawl fishery IFQ committee had a provision to allow other gear types under an IFQ—could they be used for other gears if they see the need to do so? Communities could acquire IFQs themselves to establish stability and then be able to lease it out. There may be opportunity for communities to take more control through these mechanisms.

P: Has the Council made it clear with regard to area management? Is that going to be folded into the IFQ system?

> ***T:*** *Provisions have been put in place for creation of area management after the initial IFQ (e.g., if the Council decides to split OY, etc.) So redevelopment of allocation process would not have to be done. This would have to be taken into account when Council makes final decision.*

P: How are you planning on gathering community data?

> ***T:*** *Background info will come from ongoing efforts, community profiles, dependence and vulnerability assessment, etc. NWFSC Community Profile project currently going out for review. Available on the website. Short term profiles—baseline info describing dependence on fisheries, how important fisheries are to the communities. Another project—dependency resiliency indicators are being developed—in terms of ways to rank communities based on these indicators to compare communities to each other to understand the importance of fishing to these communities. June briefing on this issue in Council forthcoming.*

P: Long-term impacts to communities—artificial restraints on the market opportunities are not beneficial. IFQ holder / processor team effort to look at new opportunities. Do not want to see restraints on this.

P: During down times—communities are more vulnerable to long term or permanent changes away from the fishing industry (e.g. processing facilities becoming hotels etc.) and there is a permanent loss of working waterfront. There may be unintended consequences with this program as far as losing more of that waterfront infrastructure that could be detrimental to the fishery as a whole.

P: Some communities are not highly visible as far as their dependence on the fishery resulting in the need to travel from these less visible communities to get access, which could take away from other communities. This needs to be part of the analysis (e.g., Neah Bay).

P: A buying station can come and go. Don't see the benefit of giving them harvester shares as part of the allocation to processors.

P: Don't see other industries having to give away 25% of their business. Don't agree with giving processors shares. This adds more constraint. If share gets taken away from the harvesters, it's going to cut back the harvester effort. Regardless of the percentage, it's additional constraint on free market. This has an effect on mobility.

P: Would the Council want to build in an option—for the benefit of communities, would we want to put a constraint on this flow?

P: Constraint was never part of this. Ultimate benefit is that money would come back to the port. No one should be told where they have to land.

P: IFQ program—would affect each sector of whiting separately. Some may be affected, some may not. Mothership sector—has been acting as a rationalized sector but this could change. Don't see a lot of change for processors, may not be much consolidation.

P: Catcher vessels (mothership sector—expansion of vessels and participants to vessels that receive quota and them major consolidation after this. Shoreside sector—most affected. Increase in capacity of harvesting sector—there would have to be some consolidation depending on who receives QS. Whatever system is chosen, consolidation will result. Timing—Don't see an IFQ program affecting timing for catcher-processors or motherships. Shoreside may take fish at a different time but this may be beneficial.

P: Changes will be different by sector and community—mothership sector and CVs—Seattle and Newport—don't see consolidation in these sectors. Likely consolidation in vessels in these areas; crossing between sectors likely. There will likely be consolidation among vessels but not a lot of movement between communities.

P: Shoreside communities are more spread out. Astoria, Westport and Newport.

P: Impacts of IFQ system could result in shore-based processors leaving entirely—Canada example—leaving for other countries because there was no market left after implementation of the IFQ. Off-shore joint venture—fisherman pooled collected quota and built off-shore facilities. Major impact on the coastal communities.

P: Alternative that removes sector splits for whiting—this will result in community impact from processing moving offshore. This will result in a major impact.

P: Potential Data Source—what the fishery means to coastal communities.

P: A processor company has recently done an analysis of their economic impact on their community. This can be provided to you as a template to use for the analysis.

P: Important to analyze the effects of the buyback program on the communities. The buyback program resulted in geographically disproportionate impacts—which we can learn from.

P: Need an analysis of quality of employment. Example, some plants have benefits, 401K, process sharing, unions. When you have various allocation scenarios, consolidation in the fleet resulting in market changes, how will this affect the quality of these jobs?

P: What will consolidation mean for the ability of processors to continue to assume market risks (e.g., custom processing, fee-base processing, etc)? What does this change do to employment in processing and supporting businesses as well?

P: Example of what's happening in crab market. Canada—Opilio market—custom processing market arrangement. Any costs above their processing costs went back to the fleet. Depressed the value of the crab stocks worldwide due to lack of incentive for processors to do anything with the product.

P: Under Program C (75/25%), immediate reaction—how does this compare to other alternatives and status quo. This has not been clearly laid out by Council in terms of what needs to be prepared. Status quo—community profiles being developed; propose to look at community impacts, permit stack, 100% harvest, and high or low processor share. This makes a big difference in terms of the effects. Generically—three options for communities (listed in presentation) need to be evaluated as well. Isn't really a need for a holdback in the communities but the analysis can help show this.

P: Make sure the final analysis includes these issues and presents the outcome.

P: Analysis should evaluate recent consolidation of processing on the coast, what has already taken place as a result of the buyback. Tough to define what the community is. (Little money spent in some smaller communities—rather it's going to larger communities) Need to look at where money is being spent. Profits distributed by crew, vendors, etc. Strictly trawl communities—not very many—impacts have occurred for years. Could be a measure of future impact of status quo. Have varied over years and may not be that different in the future.

P: Neah Bay—Important to recognize as tribal and non-tribal community. Facility and support services available for the non-tribal fleet. Maintained facilities and services that are open for non-tribal fleet, we welcome their business in the community. Currently there is a buying station. Whiting business focus. Looking to expand opportunities in Neah Bay to restore processing and fleet support services. How would consolidation under IFQ work—it may not meet biological objectives, accountability. Could lead to consolidation without safeguards or limitations. Could force smaller vessels out of business. Tribe does not want to see this impact. Fleet has been shrinking over the years. Consolidation could stifle development or redevelopment of processing and fleet support activities. There are communities that only have fishing—it is their only sustainable opportunity. Tribe looking to redeveloping infrastructure in the future and would like the IFQ program to help this, not make it more difficult.

7.2 Community Aggregation for Analysis

The following question was asked of participants

1. What communities should be lumped together for analysis? (Why, what are the common ties?)

P: Landings data along the coast to explore different definitions of community. What are the patterns up and down the coast in terms of this activity? This is another type of analysis ongoing that may be useful. Cindy Thomson—NMFS Santa Cruz is studying landings and permit data—provides info on where people live but may not provide info on where they are spending money on the fishery. Landings patterns may provide more information on the activities. Important to understand that people may be based in one location but their contribution to the fishery may be somewhere else and this needs to be analyzed in the EIS as far as the impacts to communities. Impacts of an IFQ program—especially noted in Moss Landing, maybe in Monterrey but may not in other areas.

P: Analysis—1999-2003—Moss Landing—socioeconomic impacts of the regulations—did analyze all fisheries and the impacts which could provide a snapshot before the buyback program.

P: Map in presentation—Edmonds, WA should be lumped with Seattle.

P: Ports in Oregon—Grouings—Astoria, Seaside, Garibaldi, Warrenton, Newport, South Beach (Toledo), Coos Bay, North Bend, Bandon, Brookings.

P: Port Orford does not want to be lumped with any other community. Is this for needs of the analysis; why lump?

T: When communities are small enough, they must be aggregated with other communities.

P: Is there a way around confidentiality problem? If a community wants to be stand alone in the analysis, could they be required to provide data?

7.3 Environmental Justice Issues

The following questions were asked of the large group.

1. Are there minority populations of concern?
2. Are there low-income populations of concern?

P: Project—interviewed Asian immigrants and their engagement in fishery regulations. They may be a population of concern. Study will be sent to consultant team.

7.4 Community Stability Holdback Option Analysis

1. Likely outcomes of holdback program?
2. Allocation criteria input
   a. Past performance
   b. Utilization
   c. Local added value
   d. Local labor employment
   e. Local labor earnings
   f. Public debt
   g. Public investment
   h. Port dependence
   i. Other (from public input)

P: Community holdback program—Incur new costs of getting extra product.

P: Community programs—processors that do not have facilities—shifts in processors by regions would compete in different markets—needs to be analyzed.

P: Aberdeen is in there—West Port needs to be included—large landings should be noted.

P: Port Townsend—Why is it on the list?

T: *The data in the map represent data on the community of residence of permit holders.*

P: Blaine, WA—not on map?

P: Consolidation may result in increase in property value due to businesses shifting to other things (hotels resorts, etc).

P: Modification of community holdback option—is there a regional option that would devolve that decision making to smaller pieces? This would have to be brought to Council to be addressed.

P: Community holdback—analyze what this could do to marketers obtaining a mass of products to entice buyers. Could create obstacles to obtain critical mass of product thereby resulting in artificial constraints to be able to market.

P: There is a flip side to this—you would have to create incentives for holdback too. There could be a commitment required of buyers to buy the held back pounds.

P: Community concern over losing fishing effort. There is a Corps of Engineers requirement to have a minimum number of vessels in a harbor to justify dredging harbors.

P: Processing plants are where they are due to fishing; where the fish are. What's good for fishermen is good for communities.

P: Community holdback—have you looked at safeguards? Many community budgets do not support administrative responsibilities that may come with ownership of shares.

> ***T:*** *The options allow communities to purchase QS if they want to. Safeguards on these would be whatever the local community safeguards are in place.*

P: Fishing community property shifts to other types of businesses. In the northeast of the U.S., there is a plan to do something to address over-development of hotels etc. buying up fishing industry infrastructure.

P: Clarify the Hold-back—does unclaimed quota goes back into the sector? QS/QP issued each year—allocated back to the holders of QS/QP to use those shares in ways to benefit communities. How would this play out in isolated areas where processors have left (CA). If the communities have a history of processing, do they have access to shares?

P: If there isn't a recent participation requirement, seems like if a processor has left but there is a history of processing, why not use this as an endowment for the community?

P: Is it intended that the whiting allocations for communities would come off the top or off the top by sector? Understanding is that this is not the intent. This program only applies to the shoreside portion.

8 Session 3, Day 3: Consolidation

Marcus Hartley provided the workshop with a PowerPoint presentation on the subject of consolidation and how consolidation is likely to be addressed in the EIS. The presentation is included in Appendix A, pages 121 - 129. Questions and comments were taken and discussed during the presentation and these are summarized below.

P: Fish that are overfished now will be rebuilt in the future—so how would you change your analysis to deal with species whose status might change in the future?

P: Was there consideration to deal with the allocation based on revenues paid rather than catch history?

> ***T***: *Problems associated with accuracy of data collected on ex-vessel revenues paid. Revenues paid is not being considered now as a allocation method.*
>
> ***T***: *Design elements for analysis—looking for sufficient analysis to determine whether it needs to be put back into the alternative elements and fully analyzed.*
>
> ***T***: *Under any of the programs there would still be anti-trust regulations regarding allocations and consolidation.*

P: In an IFQ system—all the fish would be accounted for so unreported bycatch would go away. The net effect—more fish would be available to harvesters and processors in the system.

> ***T:*** *This is a very difficult thing to analyze because we don't have good info on discard amounts.*

P: We may not sell shares, we may instead trade shares for one species to another. Will this be analyzed?

> ***T:*** *Yes. The starting assumption is that fishermen will be trying to get to a level where they will be harvesting the same amount by species they did before the IFQ.*

P: Are you building an assumption in that some harvesters will sell out and leave the fishery?

> ***T:*** *Yes.*

P: It is assumed that quota will migrate to the most efficient. How much conservation benefit can you ascribe to the initial allocation given that the very next day after implementation of IFQ, this will change?

> ***T:*** *Conservation benefit is applied to the overall program, not really related to initial allocations.*
>
> **P:** So whoever has the QS, the same rules regarding bycatch will remain in place? There are arguments made that there are no conservation benefits to processors, but in reality is it not correct that there is a conservation benefit from allocating to anyone, irrespective of who holds the QS?
>
> ***T:*** *Yes, this is the economic theory; if you have a dedicated access privilege, we assume there will be conservation benefits. [Other team members concurred.].*

P: Who is going to broker these shares?

> ***T:*** *It will likely be private businesses, done through same people that broker the other permits.*

P: NMFS would have to know about the transfer before it came into effect.

> ***T:*** *There need not be a broker involved as long as NMFS is notified.*

P: Consolidation Scenario 1—moderate fleet consolidation. Is this a reasonable definition of moderate consolidation? Is 150 days reasonable? 150 days is a lot of days. Moderate may be more like an average of number of days. 50 for the non-whiting fleet is high (now).

> ***T:*** *How many days on average now are people fishing?*
>
> **P:** 50-60 on average; maybe a little more.

P: 2005 OYs might be used as a guide when looking at consolidation. This is what is reflected in the most recent data set and may be more consistent to keep with this level of OY.

> ***T:*** *Will also be looking at the future extended out; but there is such uncertainty in knowing future OYs.*

P: OYs profile seems to change every time there is a Council meeting. How will this be managed? Will an average be used?

> ***T:*** *QP under this program will be assigned on the basis of the pre-season OY. If you are suggesting using an average of OYs as your base case, this has not been considered but might be for this analysis.*

P: 2005—boat made 31 trips of 2-3 days at sea and this is an average for groundfish.

P: 16-4 rebuilding provisions—OYs that emerge in 07-08 really inform what the constraining stocks will be like. Suggest not to go to 2005 as the base case because it is not realistic for the short run. We need to look at conditions when these species are partially or completely rebuilt.

P: It might not take very many vessels to catch everything, but in the future this may still be too many boats. Boats have to be profitable now or they will not be there in the future. Harvesters have to be able to get through a very low period anyway.

P: Are you assuming that allocations would go to permit holders as of the time of the application? So they would go to an individual, LLC or partnership?

> ***T:*** *Whoever registered the permit would get the allocation. So an owner who has more than one boat, can determine where the allocations go. Each permit holder will be assumed to be independent.*

P: Number of days fished may not be a good measure to use for consolidation. Maybe some other measure—how aggregated those shares are in terms of production. Constant number of boats but the steepness of that distribution curve is dramatic. Have you looked at other ways of looking at how to allocate?

> ***T:*** *Yes, we are looking at various ideas for distributing catches after consolidation. It is difficult to estimate how much consolidation would occur. Best option now for the analysis is to contrast high and low amounts of consolidation and compare them. This is a "what if" scenario, not a prediction.*

P: The relative level of consolidation that is going to occur through this program is going to be more significant compared to the example you showed earlier.

P: What if consolidation happens in the first year? What if it happens over the next five years? Impacts seem much more significant if the consolidation happens quickly rather than over longer periods of time.

> ***T:*** *Are these reasonable time ranges for scenarios? (Nodding heads).*

P: It may be necessary for you to analyze this in terms of number of days at sea, this seems reasonable. Make a guess of 100-110 days at sea as a best estimate depending on what area you are from etc. But in the first slide—what is missing here is money. How much you have to consolidate depends on the revenue you can make and how much money is available for people to make choices. Observer monitoring program is a significant cost that will drive accumulation. How much you accumulate is going to depend on revenues and costs on an individual basis but also by how capitalized the fishery is. Crab Fishery (AK) badly capitalized fishery. Pollock—10 to 15% consolidation but most of them probably shouldn't have been there in the first place (minor consolidation). From a revenue standpoint, the boats that will be left will be profitable. Doing this with number of days at sea, better information might be a better way to go.

P: New Zealand—Maori Tribe example—consolidation is a key issue for this trawl IFQ program. The fisherman in New Zealand did not think they would be forced out very quickly but they didn't get enough initial allocation or the processors just kept lowering the price, wait it out over time and could wait until fishermen went out of business. Accumulation limits are options that have been put forth by the Trawl IFQ Committee.

P: When you do the social analysis using no cap on consolidation—will you look at how this will affect communities?

> ***T:*** *Yes.*

P: There may be a biological impact to consolidation too, I assume you would identify spatially where consolidation would occur at different levels; possibility of depletion of subpopulations of fish.

> ***T:*** *Yes, this will be covered in the analysis.*

P: Lessons learned from New Zealand—Have effective accumulation caps, something that could be monitored and enforced, keep shares out of processors hands if possible, put a freeze on transfers in the first year or two so people can get used to the system before trading or selling.

P: The IFQ Committee was using Bruce C. advised to freeze transfers in the first year; this is a good point. This is a side option in the alternatives that would be analyzed.

P: Economic forces—seems that you will have incentive to maximize your efficiency. I'm unclear what the incentive to maintain smaller vessels would be?

P: In terms of consolidation on processing—if you do give shares to processors, first you have processors with fewer vessels to do business. Need an analysis of some kind of rent extraction with this scenario.

P: The suggestion has been made that there is conservation benefit to consolidation—this will not be the case. We need to look carefully at what conservation benefit is to initial allocation, and various allocation scenarios and whether there is a disproportionate impact on those that get certain allocations.

9 Workshop Wrap Up Session

For the Workshop Wrap up, the Project Team asked the Participants two final questions: *What haven't we talked about? What needs more discussion?* The resulting discussion is summarized below.

P: NRC Committee discussion—The term or the length of the property right? This would allow for correcting some of the bad things that could happen--they could be renegotiated and changed in the future.

P: Problem Statement—We didn't talk about this much at all. Shortcoming of this process. Maybe this is more of a Stage 2 issue, but a more in-depth discussion on this is warranted.

P: Some analysis of how we deal with the really low OY species (canary rockfish); how to manage an IFQ over an entire year that could affect the entire fleet.

P: Averaging by Days—geographically—there are areas that fish by days at sea; not really trips at sea. But this varies depending on the area (north versus south) due to continental shelf, fishery, etc…

P: Bycatch discussion—how would this program impact other sectors—also concern of overfished species, what kind of effects of other fisheries going over their limit for overfished species and how that will impact this system.

P: The real issue here is the biological limitations, needs of the resource, how these systems would solve or address these issues and how they would be good or bad. We need to focus on the biological needs of the resource.

P: We discussed status quo a lot—seems that not many or no one would go out of business under status quo. Under this new system, seems like many people would. Why can't we just tweak status quo instead of this radical change? Seem to be too many more questions than there are answers. This has been a good learning process for me as a fisherman to understand what the potential impacts of this might be. Discussing shares like it is not a big deal and it really is.

P: A major option missing—annual allocation to each permit within the context of the current limited entry fishery. There are only five alternatives and this one seems rather simple to analyze and it is missing. This should be sent back to Council.

P: I agree with this comment (above). It would be a shame if we get nothing out of this process. Interim steps to the IFQ program would be better and we need to analyze these as options; they are currently not included for analysis in the EIS.

P: Buy back program taught lessons on what happens. This will be the same situation; it will be important to analyze the effect of having that capital in people's hands and how it can be detrimental to other fisheries. As fleet consolidates and people get laid off there will be a huge impact on the communities and the support infrastructure. (Deck Hand Layoff example)

P: Crab and tuna example—those fisheries are at capacity will lead to limited entry, pot limits; those opportunities are just not there as they were when we first started looking at this. This should be part of the community impact assessment.

P: Senate Bill introduced last year, Congress could approve a whiting IFQ program, how would Council handle two IFQ programs at the same time. Are we wasting our time with this one if the whiting IFQ happens? When Congress finishes work on this, it isn't finished, NEPA analysis would have to take place. So how would this mesh with what we have to analyze for this program?

> ***T:*** *We would do an analysis of how these programs would mesh and the Council would have to look at this separately.*

P: Enforcement for adjacent states would have implications. I have concerns about this. The analysis needs to look at more detail on what the current capacity/infrastructure is for adjacent states. This is going to increase enforcement costs for these states. Some of this would be multiplied when you start issuing different types of shares (vessel shares, processor shares, etc.) There is currently no infrastructure to enforce this IFQ program right now.

> ***T:*** *We do have an enforcement group that is analyzing this issue right now and though it is not currently in the Analytical Document, this will be part of the EIS. Many other studies separate from this analysis will be included in the final EIS.*

P: Those things that have already been rejected; there is potentially meritorious arguments for how they should have been included. How does this stand up to legal challenge. How do you justify them being dismissed?

> ***T:*** *This is difficult to ensure. The best approach is to accurately provide the rationale behind these decisions in the Council record. Nothing is final until the ROD is signed by the Secretary of Commerce. The EIS must clearly document the purpose and need and the reasonable range of alternatives and provide the justification for what is analyzed in the document and what is not.*

P: Was it the Council that decided to put other options aside?

> ***T:*** *The Committee provided their suggestions to Council and then, after review, the Council adopted how to go forward in this process.*

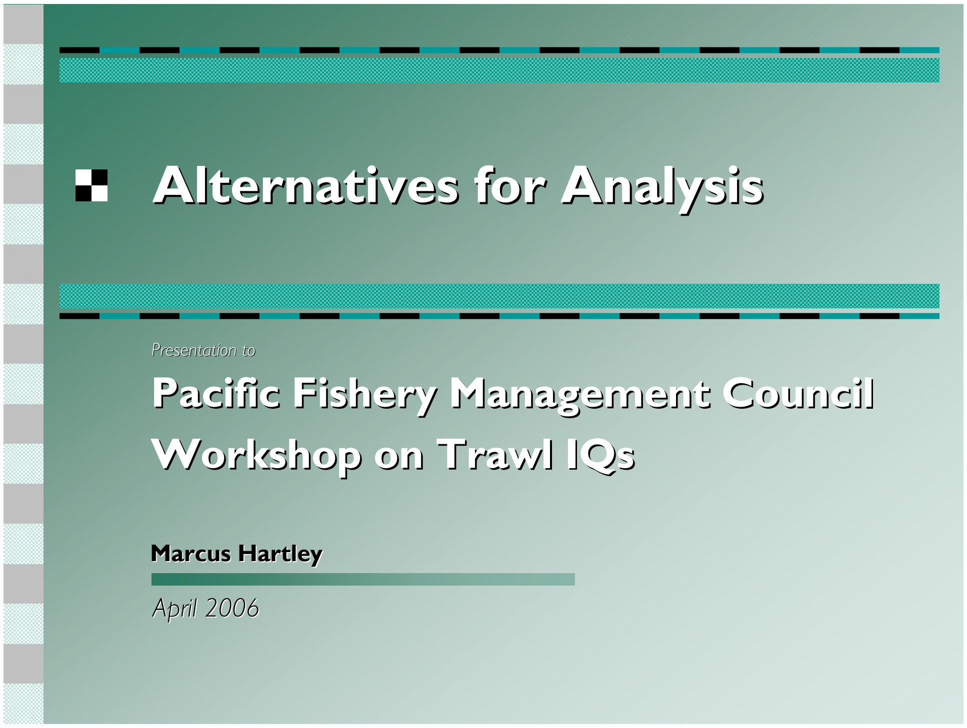
Alternatives for Analysis

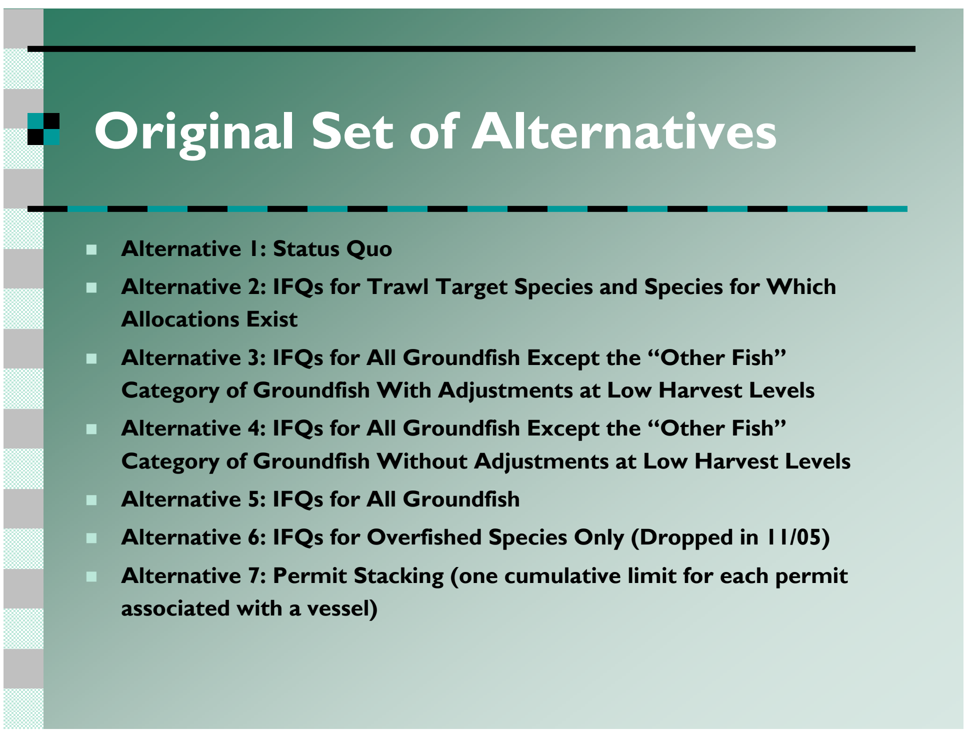
A PowerPoint Presentation Provided to the Trawl IQ Workshop

By Marcus Hartley (Northern Ecconomics) during the

Morning Session on; April 18, 2006



Alternatives for Analysis
Presentation to
Pacific Fishery Management Council
Workshop on Trawl IQs
Marcus Hartley
April 2006



Original Set of Alternatives
Alternative 1: Status Quo
Alternative 2: IFQs for Trawl Target Species and Species for Which Allocations Exist
Alternative 3: IFQs for All Groundfish Except the "Other Fish" Category of Groundfish With Adjustments at Low Harvest Levels
Alternative 4: IFQs for All Groundfish Except the "Other Fish" Category of Groundfish Without Adjustments at Low Harvest Levels
Alternative 5: IFQs for All Groundfish
Alternative 6: IFQs for Overfished Species Only (Dropped in 11/05)
Alternative 7: Permit Stacking (one cumulative limit for each permit associated with a vessel)

Current Set of Alternatives

- **Alternative 1:** No Action Alternative
- **Alternative 2:** Manage with IFQs for Whiting and Trawl Target Species
- **Alternative 3:** Manage with IFQs for all groundfish except Other Species
- **Alternative 4:** Manage with IFQs for all groundfish species
- **Alternative 5:** Manage groundfish as under the No-Action Alternative but allow Permit Stacking

Alternative 1: The No-Action Alternative

- **Continues status quo management of groundfish species.**
- **Only limited entry trawl permit holders may fish for groundfish with trawl gear.**
- **Whiting are managed with special seasons and allocations to sectors defined by the processor of the whiting.**
- **Non-whiting groundfish, with the exception of Other Species, are managed with cumulative landings limits issued to all limited entry trawl permit holders every two months.**
- **Catches of Other Species of groundfish would be monitored. Other species include sharks (except spiny dogfish), skates, rays, ratfish, morids, grenadiers, etc. (Note: spiny dogfish, cabezon, and kelp greenling will likely be managed separately from Other Species)**
- **Reporting of at-sea discards of groundfish would not be required.**
- **If the OY for any species becomes extremely low, the Council may suspend allocations between gear sectors.**

Alternative 2: IFQs for Whiting and Trawl Target Species.

- **IFQs for Whiting and Trawl Target Species.**
- **Target species are those species for which a separate allocation for the trawl limited entry fleet has been approved.**
  - Definitive list of target species is currently unavailable.
- **Whiting seasons and sectors would be maintained, and an additional non-whiting sector would be established.**
- **IFQs are not issued for incidentally caught groundfish (species other than target species)—these are managed with transferable, bi-monthly cumulative catch limits.**
- **Reporting of all groundfish catch would be required. At-sea monitoring would be required on all vessels.**
- **Catches of Other Species of groundfish would be monitored.**
- **For IFQ species, management does not change with low OYs.**
- **If the OY for a non-IFQ species becomes extremely low (such as for a rebuilding species) then the species would be managed with nontransferable cumulative catch limits.**

Alternative 3: IFQs for all Groundfish except Other Species.

- **IFQs for all Groundfish except Other Species.**
- **Whiting seasons would be eliminated, but whiting sectors would be maintained.**
- **Reporting of all groundfish catch would be required. At-sea monitoring would be required on all vessels.**
- **Catches of Other Species would be monitored.**
- **Management if the OY for any species becomes extremely low—two options**
  - Management would switch from IFQs for that species, and instead the species would be managed under sector allocations as a pool using nontransferable cumulative catch limits to control catch.
  - Continue to manage with IFQs in low OY situations

Alternative 4: IFQs for all groundfish species

- IFQs for all groundfish species.
- Whiting Seasons would be eliminated.
- The distinction between whiting sectors would be eliminated.
- Reporting of all groundfish catch would be required. At-sea monitoring would be required on all vessels.
- Other Species of groundfish would be managed with IFQs.
- If the OY for any species becomes extremely low, the Council may suspend allocations between gear sectors for that species.

Alternative 5: Permit Stacking

- Manage groundfish as under the No-Action Alternative, but allow limited entry trawl permit holders to "stack" additional permits.
- Permit holders would be issued a full complement of cumulative trip limit pounds for each permit they own.
- Cumulative Trip Limits would be issued for total catch rather than total landings.
- Reporting of all groundfish catch would be required. At-sea monitoring would be required on all vessels.
- Whiting seasons and sectors would be maintained.
- Catches of Other Species would be monitored.
- If the OY for any species becomes extremely low, the Council may suspend allocations between gear sectors for that species

IFQ Specific Program Options for QS Allocation

- **Program A: Allocate 50 percent of QS to both harvesters and processors**
- **Program B: Three QS allocation options**
  - a) 100% to harvesters, 0% to processors
  - b) 90% to harvesters, 10% to processors
  - c) 100% of non-whiting to harvesters, 50% of whiting to harvesters, 50% of whiting to processors
- **Program C: Allocate 75 percent of QS to harvesters and 25 percent of QS processors**

IFQ Specific Program Options for Defining Processors

- **Program A: Processors are defined as those facilities that take ownership of, and process, unprocessed groundfish.**
- **Program B: Processors are defined as in the FMP—those facilities that process either unprocessed or already processed groundfish, or receive live fish for resale.**
- **Program C: Processors are defined as those facilities that take ownership of, and process, unprocessed groundfish.**

Application of IFQ Programs to Alternatives

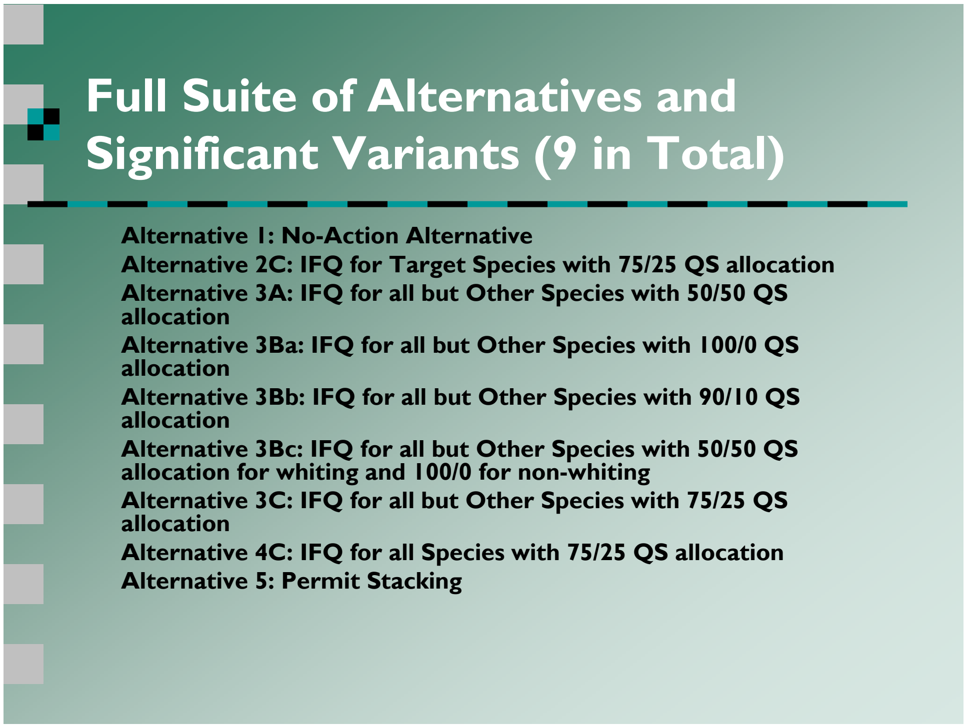
- Program A would be applied to Alternative 3
- Program B would also be applied to Alternative 3
- Program C would be applied to Alt's 2, 3, and 4

Note 1: Applying Program C to all three IFQ Alternatives allows the effects of the 75/25 QS allocation to be studied against three different management regimes.

Note 2: Applying Programs A, B & C independently to Alternative 3 allows the effects of three programs to be studied against a single management regime.

Variants of Alternative 3

- All three allocation programs (A, B, & C) are applied to Alternative 3.
- Program B contains three different QS allocation schemes; each of these has the potential to significantly alter the near-term impacts of the Alternatives.
- The end result is that Alternative 3 should be analyzed as five different Alternatives 3A, 3Ba, 3Bb, 3Bc, and 3C.



Full Suite of Alternatives and Significant Variants (9 in Total)
Alternative 1: No-Action Alternative
Alternative 2C: IFQ for Target Species with 75/25 QS allocation
Alternative 3A: IFQ for all but Other Species with 50/50 QS allocation
Alternative 3Ba: IFQ for all but Other Species with 100/0 QS allocation
Alternative 3Bb: IFQ for all but Other Species with 90/10 QS allocation
Alternative 3Bc: IFQ for all but Other Species with 50/50 QS allocation for whiting and 100/0 for non-whiting
Alternative 3C: IFQ for all but Other Species with 75/25 QS allocation
Alternative 4C: IFQ for all Species with 75/25 QS allocation
Alternative 5: Permit Stacking

Workshop Goals and Objectives

A PowerPoint Presentation Provided to the Trawl IQ Workshop

By Jon Isaacs (URS, Inc.) during the

Morning Session on; April 18, 2006

Fisheries Management and NEPA Compliance

- Changes to a Fishery Management Plan is a major federal action requiring compliance with the National Environmental Policy Act (NEPA)
- Alternatives are usually complex due to the number of species harvested and fishery participants
- This Stage I Analysis and Strategy precedes EIS preparation, but must anticipate needs

NEPA Compliance Objectives

- Supplement the existing authority of federal agencies
- Reform agency procedures to look at consequences of decisions
- Put environmental concerns on an equal footing with technical, social, and economic concerns
- Resolve environmental problems
- Foster intergovernmental coordination and cooperation
- Enhance public participation in government planning and decision making

Components of a NEPA Document

- Purpose and Need
- Alternatives, including the proposed action
- Affected Environment
- Environmental Consequences
- Mitigation Measures

Purpose and Need of Proposed Action

- Explains why the agency or applicant is proposing a specific action
- Must be compelling and make sense to the public
- Alternatives to the proposed action are logically and functionally linked to purpose and need

Alternatives

- Alternatives must meet purpose and need and provide a reasonable range contrast for NEPA analysis
- Need enough detail on proposed action and alternatives to assess environmental consequences
- Alternatives considered but eliminated from further analysis must be documented
- Scoping comments must be considered

Affected Environment

- Physical, biological and social environment
- Content linked to scoping and key issues
- Provides historical baseline information and trends on the affected resources
- Must provide enough information to address direct, indirect and cumulative effects
- Include quantitative information and information on trends
- Avoid unnecessary information

Environmental Consequences

- Organized by alternative or by affected environment topic
- Evaluate impacts on all issues for all alternatives
- Must address direct, indirect, and cumulative effects
- Can focus on certain categories of impacts and dismiss others, but must provide justification

Workshop Goals and Objectives: Council

- Describe the proposed approach suggested for analysis of alternatives and completion of the EIS
- Share it with members of the fishing community for feedback and suggestions for areas of improvement

Workshop Goals and Objectives: Consulting Team

- We want to know if what we are proposing to do is understandable and realistic
- Provide guidance on some key questions, major forces that may shape how the fishery responds to management alternatives
- Small breakout groups are proposed to address these issues

Workshop Goals and Objectives: Workshop Participants

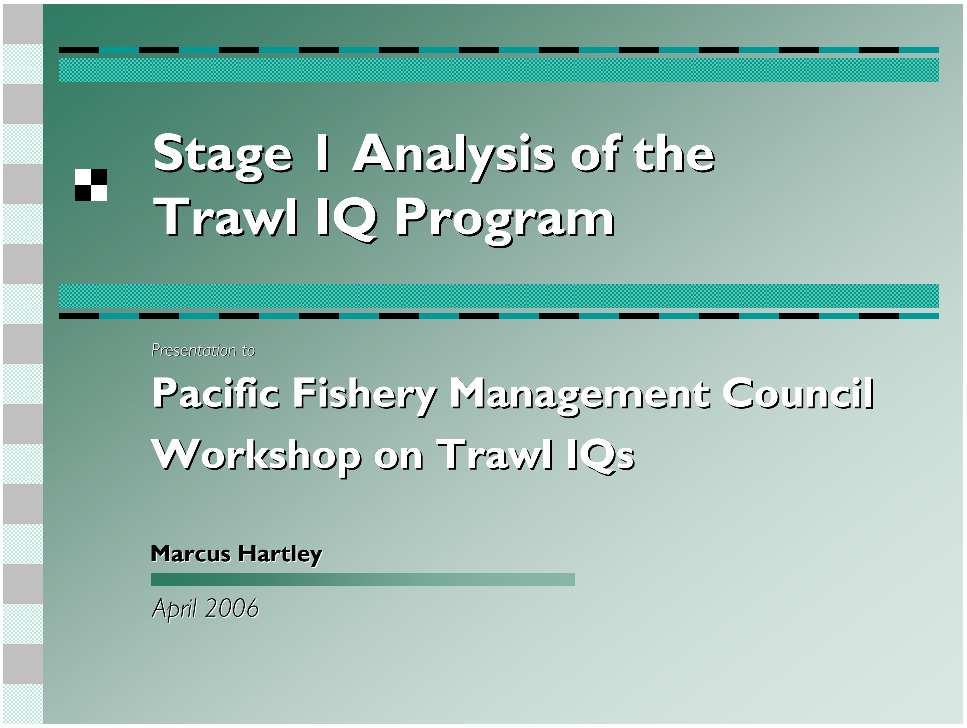
- Participant suggestions on workshop goals and objectives

Analytical Framework for the EIS

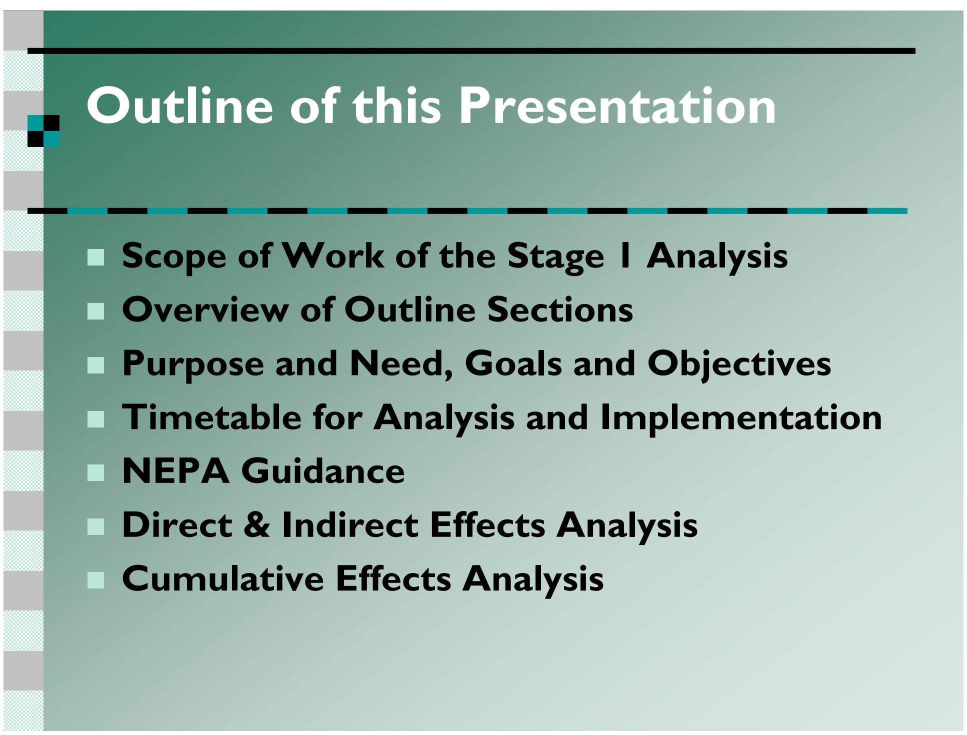
A PowerPoint Presentation Provided to the Trawl IQ Workshop

By Marcus Hartley (Northern Economics) during the

Afternoon Session on; April 18, 2006



Stage I Analysis of the Trawl IQ Program
Presentation to
Pacific Fishery Management Council
Workshop on Trawl IQs
Marcus Hartley
April 2006



Outline of this Presentation
Scope of Work of the Stage I Analysis
Overview of Outline Sections
Purpose and Need, Goals and Objectives
Timetable for Analysis and Implementation
NEPA Guidance
Direct & Indirect Effects Analysis
Cumulative Effects Analysis

Scope of Work for the Stage 1 Analysis

- The first stage entails the development of the introductory chapters, outline, and analytical framework for the EIS/RIR/IRFA/SIA.
- It will entail the gathering of information and sufficient analysis to fully develop a detailed, specific and documented analytical framework approach to address each feature of the alternatives and their likely impacts, along with an assessment of the overall differences in impacts among the alternatives.

Scope of Work for Stage 2

- The second stage will be to complete the EIS, as well as RIR, IRFA and SIA
- Stage 2 will be based on the framework developed in Stage 1

Outline of this Presentation

- Scope of Work of the Stage 1 Analysis
- **Overview of Outline Sections**
- Purpose and Need, Goals and Objectives
- Timetable for analysis and implementation
- NEPA Guidance
- Direct & Indirect Effects Analysis
- Cumulative Effects Analysis

Chapter 1: Introduction

- Need for Action—Problems for Resolution
- Background to Purpose and Need
- Purpose of the Proposed Actions
- Goals
- Objectives
- Constraints and Guiding Principles
- Description of Proposed Alternatives
- Scoping Summary

Chapter 2: Analytical Framework

- Provides a summary of the analytical framework used in the analysis.
- Includes a list of affected resources along with an initial description of indicators and significance criteria.

Chapter 3: Resource and Stakeholder Profiles

- Will provide (in Stage 2) summary profiles of affected resources and stakeholder groups showing historical and baseline conditions

Chapter 4: Components Analysis

- The components table deconstructs the alternatives into component parts consisting of elements, options, and sub-options that combine together to create the proposed alternatives.
- The components analysis will examine (in Stage 2) individual elements, options and sub-options, including some options and sub-options that have not specifically been included in the Alternatives
- In this chapter options and sub-options will be examined (in Stage 2) independent from the Alternatives.

Chapter 5: Direct and Indirect Effects Analysis

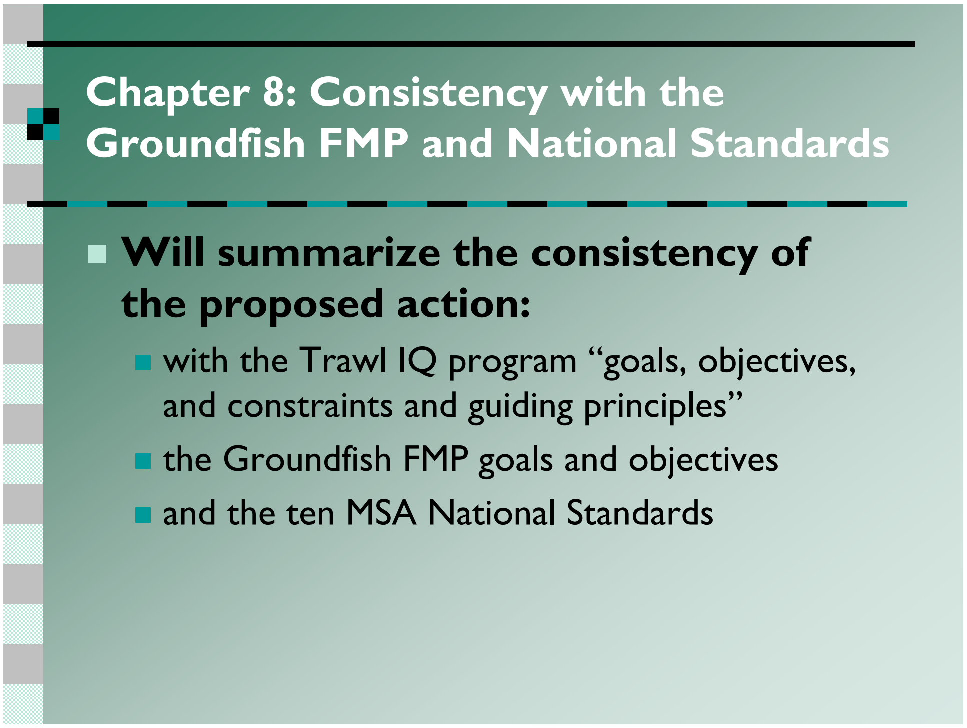
- The Stage 2 analysis will use a "resource-based" approach to examine direct and indirect effects of the Alternatives.
- In a "resource-based" approach, a single section of the document examines and describes the direct and indirect effects of all of the alternatives assessed for a particular resource or stakeholder group.
- The Alternatives will be examined holistically, as opposed to the single issue approach in the components analysis

Chapter 6: Cumulative Effects Analysis

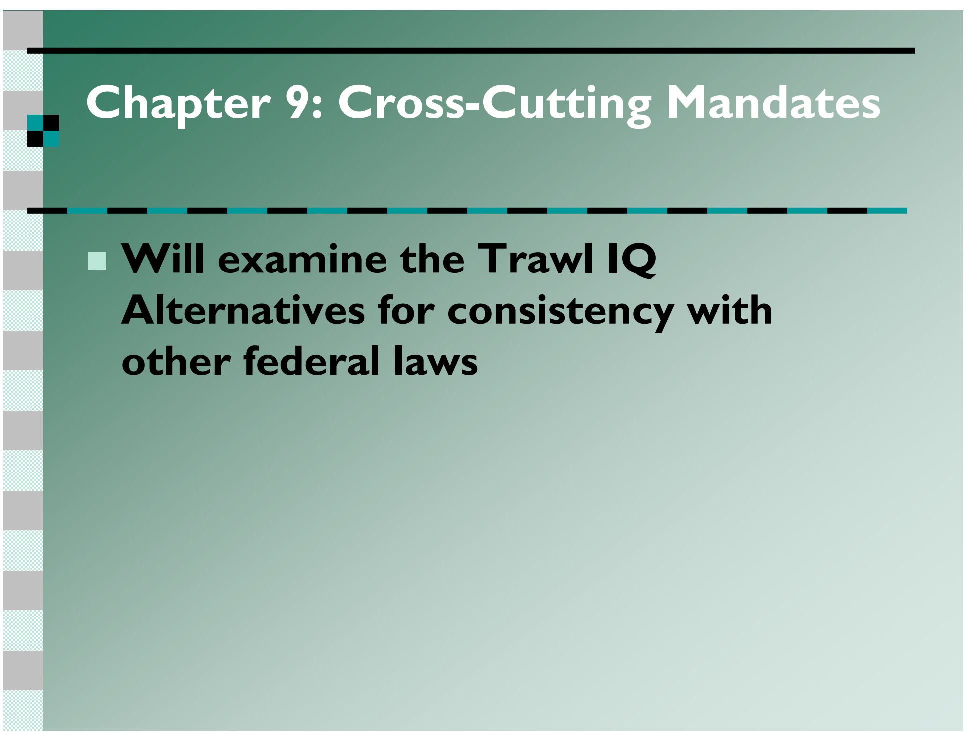
- Will contain the cumulative effects (CE) analysis.
- Will explicitly take into account reasonably foreseeable future events (RFFEs)—both endogenous and exogenous—that have the potential to create effects on affected resources and stakeholders.
- The CE analysis will follow the same general format as the direct and indirect effects analysis looking at the alternatives holistically from the perspective of each stakeholder/resource group.

Chapter 7: Summary of Other Environmental Management Issues

- **Will contain a review of other issues typically found in NEPA documents including:**
  - Short-term uses versus long-term productivity
  - Irreversible resource commitments and energy requirements
  - Conservation potential of the alternatives



Chapter 8: Consistency with the Groundfish FMP and National Standards
Will summarize the consistency of the proposed action:
with the Trawl IQ program "goals, objectives, and constraints and guiding principles"
the Groundfish FMP goals and objectives
and the ten MSA National Standards



Chapter 9: Cross-Cutting Mandates
Will examine the Trawl IQ Alternatives for consistency with other federal laws

Other Required Chapters

- Chapter 10: List of Preparers
- Chapter 11: Acronyms and Glossary
- Chapter 12: Literature Cited
- Chapter 13: Index

Appendix A: RIR

- **Regulatory Impact Review (RIR)**
  - Economic Analysis of the Alternatives
  - Initial Regulatory Flexibility Analysis (IRFA)

Appendix A: RIR (cont.)

- **Economic Analysis of the Alts.**
  - Net Benefits: Benefit-Cost Framework
    - Overall Change in B-Cs
    - Change in Distribution of B-Cs
  - Regional Economic Impacts:
    - Change in Income and Employment by Region

Appendix A: RIR (cont.)

- **Initial Regulatory Flexibility Analysis (IRFA)**
  - Impacts on Small Entities
  - Compliance Requirements/Costs
  - Additional Regulatory Burden
  - Conflicts with Other Federal Rules

Appendix B: Social Impact Assessment Technical Appendix

- **SIA two-pronged approach**
  - Summary tables based on quantitative information; presented in body of EIS/RIR; focuses on distribution of sectors across communities
  - Detailed community context information; presented in technical appendix; focuses on community engagement and dependency

Appendix B: Social Impact Assessment Technical Appendix

- **Balance of quantitative and qualitative**
  - Limits of available information
  - Range, direction, and likely order of magnitude of social and community impacts

SIA Technical Appendix Contents

- Introduction
- Overview of Trawl Community Socioeconomic Profiles
- Background and Methodology

SIA Technical Appendix Contents

- Community Variability
  - Location and Historical Ties to the Fishery
  - Community Socioeconomic Structures
- Social Impact Experience with IFQ or Other Rationalization Programs
  - Summary Review of Relevant Literature
  - Region-Specific Experience

SIA Technical Appendix Contents

- **Community Profiles**
  - Community #1
    - Community Demographics
    - Local Economy and Links to the Trawl Fishery
    - Community Revenues
    - Summary of Recent Community Rationalization Experience
    - Differential Impacts of Trawl Fishery Management Alternatives
  - Community #2 (and so on)

Outline of this Presentation

- **Scope of Work of the Stage 1 Analysis**
- **Overview of Outline Sections**
- **Purpose and Need, Goals and Objectives**
- **Time table for analysis and implementation**
- **NEPA Guidance**
- **Direct & Indirect Effects Analysis**
- **Cumulative Effects Analysis**

Need for Action—Council Problem Statement

- **In summary, management of the fishery is challenged with the competing goals of:**
  - minimizing bycatch,
  - taking advantage of the available allowable harvests of more abundant stocks (including conducting safe and efficient harvest activities in a manner that optimizes net benefits over the short-term and long-term),
  - increasing management efficiency,
  - responding to community interest.

Goals

- **Increase regional and national net benefits including improvements in economic, social, environmental and fishery management objectives.**
- **Achieve capacity rationalization through market forces and create an environment for decision making that can rapidly and efficiently adjust to changing conditions.**

Objectives

- Provide for a viable, profitable and efficient groundfish fishery.
- Minimize negative ecological impact while taking the available harvest.
- Reduce bycatch and discard mortality.
- Promote individual accountability – responsibility for catch (landed catch and discards).
- Increase stability for business planning.

Objectives (continued)

- Increase operational flexibility.
- Minimize adverse effects from an IFQ program on fishing communities to the extent practical.
- Promote measurable economic and employment benefits through the seafood catching, processing, distribution elements, and support sectors of the industry.
- Provide quality product for the consumer.
- Increase safety in the fishery.

Constraints and Guiding Principles

- **The Alternatives should strive to realize the goals and objectives…**
  - Taking into account the biological structure of the stocks including such factors as populations and genetics.
  - Taking into account the need to ensure that the total OYs and ABC for the trawl and all other sectors are not exceeded.
  - Accounting for total groundfish mortality.
  - Avoiding provisions where the primary intent is a change in marketing power balance between harvesting and processing sectors.

Constraints and Guiding Principles (continued)

- **The Alternatives should strive to realize the goal and objectives…**
  - Avoiding excessive quota concentration.
  - Providing efficient and effective monitoring and enforcement.
  - Designing a responsive review evaluation and modification mechanism.
  - Taking into account the management and administrative costs of implementing and overseeing the IFQ program and complementary catch monitoring programs and the limited state and federal resources available.

Outline of this Presentation

- Cumulative Effects Analysis

Timeline for the Analysis Page 35

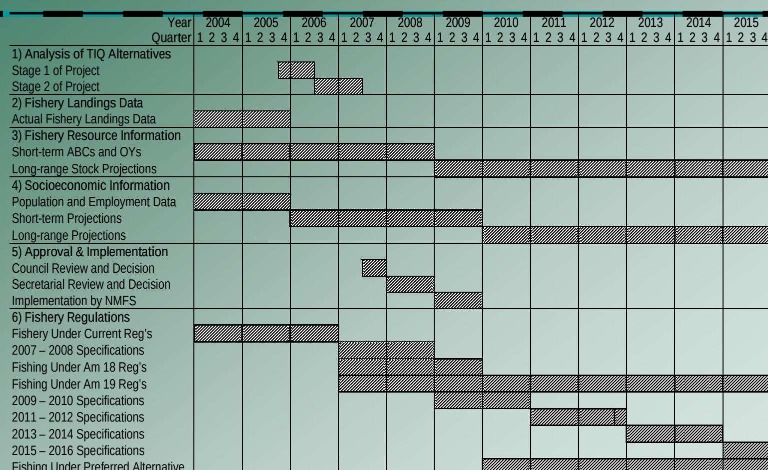

Figure 2.1 Details

- **Stage 1 and Stage 2 analyses take place through 2nd quarter of 2007. Final Council decision in 4th Quarter 2007**
- **Data to be used:**
  - Fishery data from 2005 will be used, along with information from earlier years.
  - The specifications containing ABC and OY projections for 2007 and 2008 will be used.
  - Population and employment estimates through 2005
- **Drafting of final EIS, FMP language, implementation plans, proposed rule, and the secretarial review and decision process will require at least a full year (2008).**
- **Implementation by NMFS will require 1 year, through 2009**
- **Fishing under IFQ Program could begin in 2010**

Outline of this Presentation

- **Purpose and Need, Goals and Objectives**
- **Time table for analysis and implementation**
- **NEPA Guidance**
- **Direct & Indirect Effects Analysis**
- **Cumulative Effects Analysis**

Council on Environment Quality (CEQ) Guidance on NEPA

- Effects include ecological (such as the effects on natural resources and on the components, structures, and functioning of affected ecosystems), aesthetic, historic, cultural, economic, social, or health, whether direct, indirect or cumulative.
- Effects may also include those resulting from actions which may have both beneficial and detrimental effects, even if on balance the agency believes that the effect will be beneficial.

CEQ: Direct and Indirect Effects

- "Effects" include:
- (a) Direct effects which are caused by the action and occur at the same time and place.
- (b) Indirect effects which are caused by the action and later in time or further removed in distance, but which are still reasonably foreseeable. Indirect effects may include growth-inducing effects and other effects related to induced changes in the pattern of land use, population density or growth rate, and related effects on air and water and other natural systems, including ecosystems.

Cumulative Impacts

- Cumulative impacts are the impact(s) on the environment which result from the incremental impact of the actions when added to other past, present and reasonably foreseeable future actions regardless of what agency (federal or non-federal) or person undertakes such actions.
- Cumulative effects can result from individually minor but collectively significant actions taking place over a period of time.

Outline of this Presentation

- Scope of Work of the Stage I Analysis
- Overview of Outline Sections
- Purpose and Need, Goals and Objectives
- Time table for analysis and implementation
- NEPA Guidance
- **Direct & Indirect Effects Analysis**
- Cumulative Effects Analysis

Analytical Conditons

- **Historical conditions**
  - Conditions of the resources and stakeholder groups for previous years
- **Baseline conditons**
  - The status of affected resources as of 2005.
  - Status of stocks, ABCs, OYs,
  - The numbers of vessels and processors, and ownership interests and residences of owners.
  - Community populations and employment reflect 2005 information.
  - The status of other affected resources and stakeholders as of 2005.
  - Trends will also be examined.
- **Differences in the baseline conditions and historical conditions will be noted and discussed**

Assessing direct/indirect effects: 3-Step Process

- **Examine & document the forces that are likely to change the baseline conditions of affected resources**
  - Forces are the aspects of the proposed alternative and how people will react to them
- **Project and predict the conditions of the affected resources after the forces from Step 1 have acted.**
- **Document how conditions have changed from baseline conditions in the case of the No-Action Alternative, or from the No-Action Alternative in the case of Action Alternatives**

Causes of indirect effects

- **Behavior changes of directly affected stakeholders cause indirect effects**
- **Examples:**
  - Harvest timing shifts to a period with lower incidental catches of overfished species, but the shift increases interactions with other species
  - A permit holder sells trawl QS allocation and increases effort in non-trawl fisheries
  - A change in product quality changes consumer willingness to pay

Assumptions under No-Action Alternative

- **No-action Alternative assumes fishery resources at 2007-2008 groundfish harvest specifications.**
- **All other resources, resource users and stakeholders will be assumed to start at baseline levels.**
- **The number of vessels and processors will mirror those seen in 2005,**
- **2005 ex-vessel and wholesale prices, community population etc., will be used**
- **All existing regulations as modified by actions that the Council has approved, but which have not yet been implemented by NMFS**
  - Includes Essential Fish Habitat measures
  - Assume Sector Allocations authorized under Amendment 18 will be in place.

Direct/Indirect Effect Analysis of the No Action Alternative

- **Step 1: Examine the forces that are likely to create changes in the conditions of the resources**

Major forces under the No-Action Alternative

- **Overfished species constraining harvest of target species reducing profits in the fishery**
- **No requirement to report discards so lots of uncertainty**
- **Low harvester profit levels make it difficult for harvesters to pay for observers/monitoring**
- **Cumulative trip limits preclude optimization of harvesting patterns for harvesters**
- **Cumulative trip limits ensure steady flow of fish to processors and consumer markets**
- **Lack of incentives to take individual action to reduce incidental catch**
  - Any savings the individual makes will accrue to the entire harvesting sector and not to the individual
- **Other Sectors can cause seasons to end**

Direct/Indirect Effect Analysis of the No Action Alternative

- **Step 2: Project the conditions of the affected resources after the forces from Step 1 have acted**
- **Methods**
  - Assume continuation of recent trends from baseline conditions
  - Interview harvesters and processors on other potential changes

Direct/Indirect Effect Analysis of the No Action Alternative (continued)

- **Step 3: Document how conditions have changed from baseline conditions**
- **The Stage 2 analysis will show the differences between outcomes under No-Action Alternative and baseline conditions**

Direct/Indirect Effect Analysis of Action Alternatives

- **Step 1: Examine the forces that are likely to create changes in the conditions of the resources.**
  - Changes in OYs—Stage 2 analysis will use 2007-2008 Specifications
  - Total catch reporting
  - Monitoring of catch with observers or video cameras
  - Other changes embedded in the Alternatives

Direct/Indirect Effects—Step 1 Other major forces under IFQs

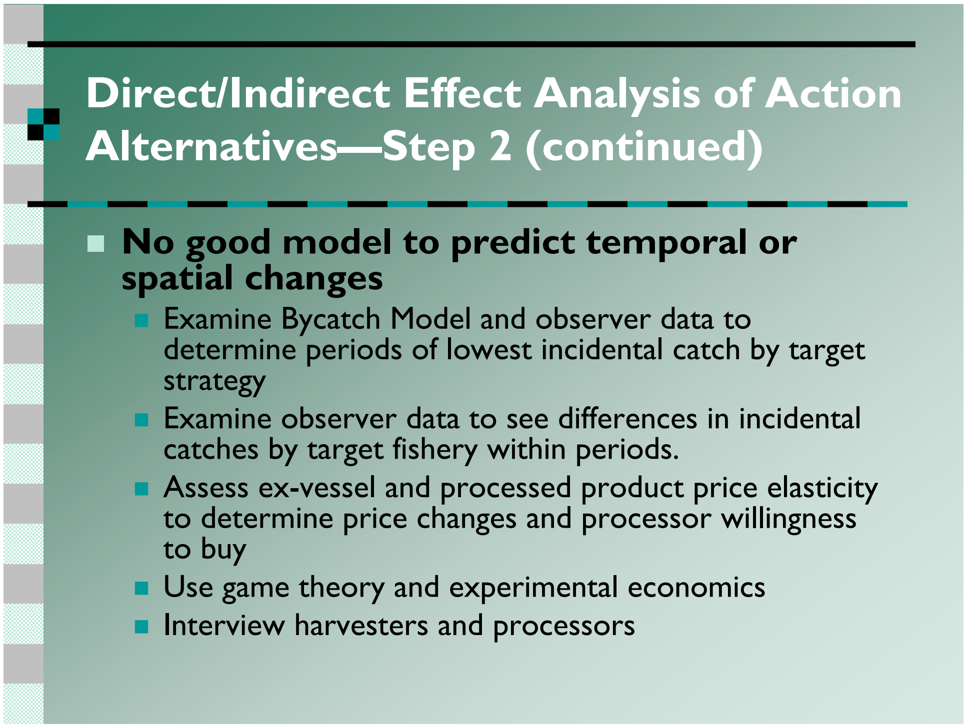
- **Allocation of QS/QP to harvesters and (potentially to processors) grants access to an annually determined quantity of fish**
- **IFQs allow the optimization of harvests of groundfish within the constraints of other regulations and market forces, including:**
  - markets for end products sold to consumers,
  - markets in which harvesters sell their catches to fish buyers and processors,
  - and new markets for QS and QP that are created by the program.

Direct/Indirect Effects of Action Alternatives—Step 2

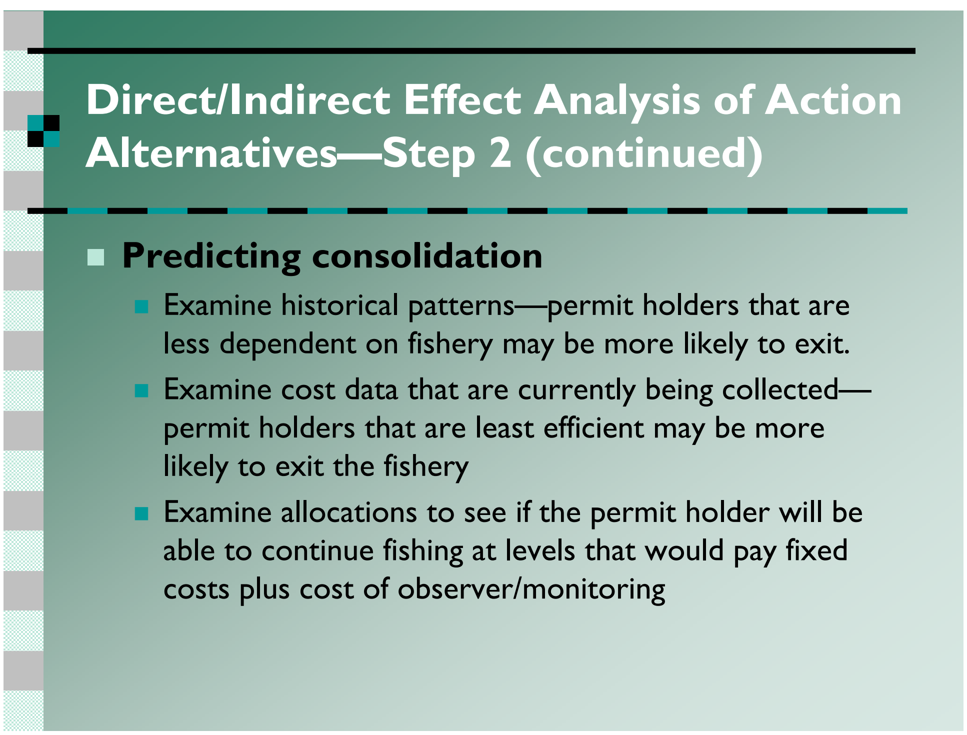
- **Primary forces lead to behavioral changes creating direct and indirect impacts**
  - Incentives to reduce incidental catch so that greater amounts of target species can be harvested
  - Spatial and temporal changes in fishing patterns
  - Changes in the relationships between harvesters and processors
  - Initial allocation and consolidation will also alter fishing patterns and distribution of activities across the harvesting and processing sectors

Direct/Indirect Effect Analysis of Action Alternatives—Step 2 (continued)

- **How to Predict Changes**
  - Allocations are determined by formula
    - Compare Allocations to harvesting and processing patterns
  - Predicting changes in behavior patterns
    - Harvests are likely to shift to periods of lower incidental catch
    - Harvests are likely shift to areas of lower incidental catch
    - But will processors pay the same price for fish if all harvests take place in one period?
    - Will processors be able or willing to purchase and process in condensed periods of time?



Direct/Indirect Effect Analysis of Action Alternatives—Step 2 (continued)
No good model to predict temporal or spatial changes
Examine Bycatch Model and observer data to determine periods of lowest incidental catch by target strategy
Examine observer data to see differences in incidental catches by target fishery within periods.
Assess ex-vessel and processed product price elasticity to determine price changes and processor willingness to buy
Use game theory and experimental economics
Interview harvesters and processors



Direct/Indirect Effect Analysis of Action Alternatives—Step 2 (continued)
Predicting consolidation
Examine historical patterns—permit holders that are less dependent on fishery may be more likely to exit.
Examine cost data that are currently being collected—permit holders that are least efficient may be more likely to exit the fishery
Examine allocations to see if the permit holder will be able to continue fishing at levels that would pay fixed costs plus cost of observer/monitoring

Direct/Indirect Effect Analysis of Action Alternatives—Step 2 (continued)

- **Predicting cost of QS/QP**
  - What is the marginal revenue that can be earned by purchasing additional QS/QP
  - If the lack of QP for an incidental catch species is constraining target catches, then prices may be quite high and will be tied to the marginal revenue the target species, more than they will be tied to the value of the constraining species.

Direct/Indirect Effect Analysis of Action Alternatives—Step 3

- **Compare the projected conditions from Step 2 with the conditions projected from Step 2 of the analysis of the No-Action Alternative.**
- **Direct and indirect effects are the differences between the conditions under the Action Alternative and their respective conditions for the No-Action Alternative.**

Predictions and Scenarios

- The Consulting Team believes that reliable and robust mathematical or theoretical models that predict behavioral changes under the action alternatives will not be possible within the Council's time and budget constraints.
- Interviews with stakeholders may produce the best predictions.
- Analytical Scenarios will be a primary tool that will be used to assess direct/indirect effects.

Analytical Scenarios

- The scenarios would be developed as a means to demonstrate differences in the way the various alternatives perform under plausible conditions
- Scenarios are not predictions, but tools that will be used to demonstrate potential impacts

Scenarios that could be added to the No-Action Alternative

- Alternative Levels of Observer Coverage on Trawl Vessels
- Alternative requirements for the reporting of discards for trawl vessels

Scenarios applicable to both the No-Action and Action Alternatives

- High Abundance of Groundfish Species
- Low Abundance of Groundfish Species
- A stock that is currently not overfished falls into overfished status
- A stock that is currently in an overfished status is rebuilt
- Alternative sector allocations

Scenarios that could be added to the Action Alternatives

- Assume no transfers of QS occur
- Assume a moderate fleet consolidation: QS are transferred and vessels drop out of the fishery such that the average vessel remaining in the industry fishes an average of 150 days per year.
- Assume a high fleet consolidation such that the average vessel fishes 270 days per year
- Assume a very quick transition (1-year) to a moderately consolidated fleet
- Assume a relative slow transition (5-years) to a moderately consolidated fleet

Scenarios that could be added to the Action Alternatives (continued)

- Assume all harvests for primary target species are made in months with lowest incidental catch rates
- Assume all harvests for primary target species made in geographic areas with lowest incidental catch rates
- Assume no shift in temporal/spatial distribution, but assume all catch shifts to above average incidental catch rates

Outline of this Presentation

- Scope of Work of the Stage I Analysis
- Overview of Outline Sections
- Purpose and Need, Goals and Objectives
- Time table for analysis and implementation
- NEPA Guidance
- Direct & Indirect Effects Analysis
- **Cumulative Effects Analysis**

Framework for Cumulative Effects Analysis

- CE analysis takes into account reasonably foreseeable future events (RFFEs)
- Future conditions related to each of the Alternatives will be based on exogenous RFFEs and endogenous RFFEs specific to each of those alternatives.

Step-wise Process for CE Analysis

- Step 1 examines and documents behavioral changing forces including those examined in direct/indirect analysis and RFFEs
- Step 2 projects the future conditions of the affected resources under the alternative after the forces from Step 1 have acted
- Step 3 documents how the future conditions have changed under the alternative.
  - In the case of the No-Action Alternative, the change is measured as the difference from the current conditions.
  - In the case of the Action Alternatives, the change is measured with respect to the Future Conditions under the No-Action Alternative.

Step-wise Process for CE Analysis (continued)

- Step 4 documents whether the status of any of the affected resources or stakeholder groups has, as a result of the combination of past, present, and reasonably foreseeable future events or actions, changed significantly in ways that were not already apparent in the baseline conditions

Affected Stakeholders and Resources

A PowerPoint Presentation Provided to the Trawl IQ Workshop

By Marcus Hartley (Northern Economics) during the

Afternoon Session on; April 18, 2006

Affected Stakeholders and Resources

Presentation to

Pacific Fishery Management Council Workshop on Trawl IQs

Marcus Hartley and Members of the Consulting Team

April 2006

Outline of Presentation

- NEPA Guidance
- Directly Affected Stakeholders
- Indirectly Affected Stakeholders
- Directly Affected Resources
- Indirectly Affected Resources

NEPA Guidance from CEQ

- Direct effects which are caused by the action and occur at the same time and place.
- Indirect effects which are caused by the action and later in time or further removed in distance, but are still reasonably foreseeable. Indirect effects may include growth inducing effects and other effects related to induced changes in the pattern of land use, population density or growth rate, and related effects on air and water and other natural systems, including ecosystems.

Application of CEQ Guidance to this Analysis

- Directly Affected Stakeholders are those stakeholders that would be specifically cited in the regulations
- Directly Affected Resources are those groundfish species for which IFQs or cumulative trip limits would be issued.
- All other stakeholders and resources are considered to be indirectly affected.

Directly Affected Stakeholders

- Limited Entry Trawl Permit Holders
- Processors of Trawl-caught Groundfish
- Managers of the Trawl Groundfish Fishery

Classes of Trawl Harvesters

- Offshore Whiting Trawl CV (OW-TCV)
- Inshore Whiting Trawl CV (IW-TCV)
- Combination Onshore-Offshore Whiting Trawl CV (CW-TCV)
- Large Diversified Trawl CV (LD-TCV)
- Small Diversified Trawl CV (SD-TCV)
- Trawl Catcher Processors (TCP)

Additional Details on Harvester Classifications

- Harvesters are classified because impacts will vary by class
- Classes attempt to group permit holders and vessels that have similar sets of activities.
- Classification will be made based on the landings of the permit holder and the vessel to which the permit is currently attached
- Catcher Processors are included because they would be issued IFQ under Alternatives 2, 3 and 4

Condition Indicators

- Condition Indicators are established for directly and indirectly affected stakeholders and resources
- The effects of the alternatives can generally be quantified by changes in the condition indicators
- The direction and magnitude of change are empirical issues
- Whether the change is significant is typically a judgment made by the analysts

Indicators for Trawl Harvesters

- Catch by species
- Incidental catch by species
- Discarded catch by species
- Distribution of catches by month
- Ex-vessel revenues from groundfish
- Operating costs
- Net revenues

Indicators for Trawl Harvesters (continued)

- Number of participating trawl catcher vessels
- Number of permit holders
- Distribution of permit holders by community
- Number of trips per year
- Number of fishing days per year
- Number of crew members
- Distribution of crew members by community
- Crew and skipper shares

Indicators for Trawl Harvesters (continued)

- Some effects of the alternatives may not be measurable by quantifiable indicators. These include impacts on vessel safety, market power vis-à-vis processors, and others.

Significance Criteria for Trawl Harvesters

- Whether a quantifiable change is significant is typically a judgment of the analyst
- Significance Criteria must be specified
- For trawl harvester indicators, the Consulting Team has made the judgment that a 20 percent change in the indicator will be considered significant

Landings of Bought-out Permit

- **The outline lists Bought-out Trawl Catcher Vessels as a directly affected stakeholder.**
- **Technically this is incorrect. Under the IFQ Alternatives, permit holders that remain in the fishery following the buyout would be allocated the catch history of bought-out permits. While the bought-out permit holders are not directly affected, their landings will be described in the same section as other harvest vessel classes.**

Processors of Trawl-caught Groundfish

- **Issues with Classification**
  - Fish Ticket data indicate first receiver of fish
  - Definition of processor in Alternatives is ambiguous
  - Treatment of Buyers that are not “processors”
  - Number of actual processors is relatively low
  - Confidentiality is an issue
- **Classification still an unresolved issue**
  - A separate workshop session will be held on this issue

Classes of Trawl Groundfish Processors

- Large Washington Processors of Trawl Groundfish
- Small Washington Processors of Trawl Groundfish
- Large Oregon Processors of Trawl Groundfish
- Small Oregon Processors of Trawl Groundfish
- Large California Processors of Trawl Groundfish
- Small California Processors of Trawl Groundfish
- Motherships
- Note that trawl catcher processors are treated as both harvesters and processors

Indicators for Processors of Trawl Groundfish

- Total purchases of trawl-caught groundfish by species
- Number of processors
- Distribution of purchases by month
- Distribution of processors by community
- Wholesale value of production
- Operating costs
- Net revenues

Indicators for Processors of Trawl Groundfish (continued)

- Product types and amounts by species
- Product recovery rates by product and species
- Operating days per year
- Number of processing crew
- Number of ownership entities

Indicators for Processors of Trawl Groundfish (continued)

- Some effects of the alternatives may not be measurable by quantifiable indicators, including impacts on market power vis-à-vis harvesters, and others.

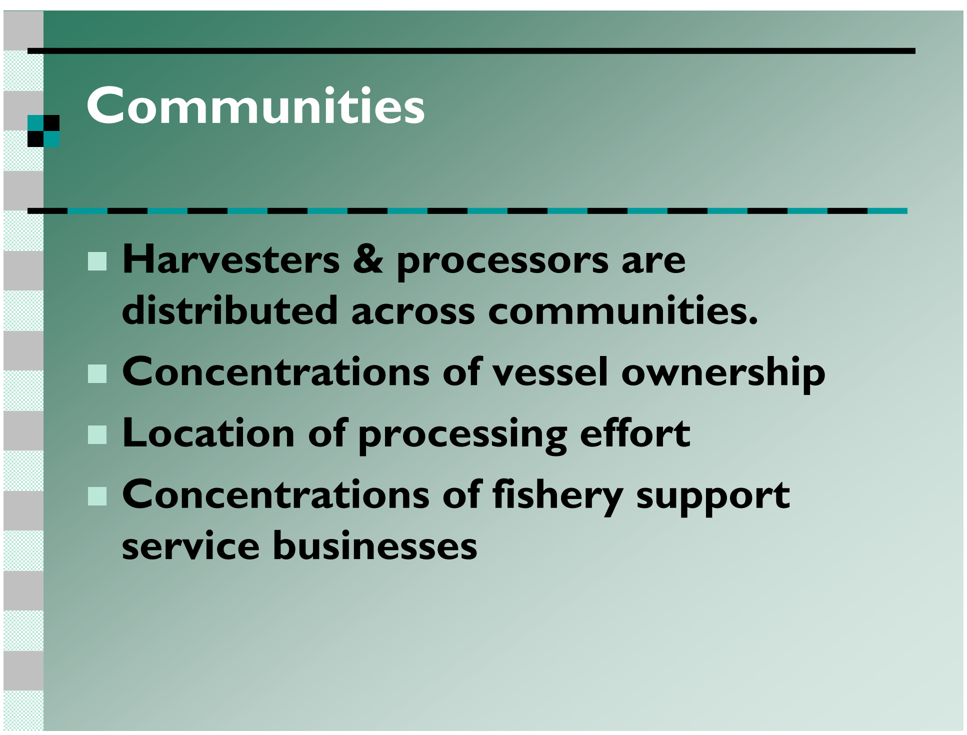
Directly Affected Management Agencies

- Pacific Fisheries Management Council
- NOAA Fisheries PNW Region
- NOAA Fisheries SW Region
- NOAA Fisheries Enforcement
- NOAA General Council
- Pacific States Marine Fishery Commission
- State of California
- State of Oregon
- State of Washington
- U.S. Coast Guard

Indicators for Management Agencies

- Management costs
- Enforcement feasibility
- Reliability of fishery data
- Risk to the resource

Indirectly Affected Stakeholders
Communities
Non-trawl Commercial Harvesters
Processors not involved in the Trawl Groundfish Fishery
Recreational Harvesters
Tribes
Input Suppliers, Wholesalers and Retailers
Consumers of West Coast Groundfish
The General Public



Communities
Harvesters & processors are distributed across communities.
Concentrations of vessel ownership
Location of processing effort
Concentrations of fishery support service businesses

Washington Communities

Region	Trawl Vessel Homeport
Northern Puget Sound	Bellingham
Northern Puget Sound	Blaine
Coastal Washington North	Neah Bay
Coastal WA South & Central	Westport
Coastal WA South & Central	Ilwaco/Chinook

Note: this is an initial listing

Oregon Communities

Region	Trawl Vessel Homeport
Astoria	Astoria
Tillamook	Tillamook & Garibaldi
Newport	Newport
Coos Bay	Coos Bay
Coos Bay	Florence
Brookings	Brookings

Note: this is an initial listing

Northern California Communities

Region	Trawl Vessel Homeport
Crescent City	Crescent City
Eureka	Eureka
Fort Bragg	Fort Bragg
Fort Bragg	Other Mendocino County
Bodega Bay	Bodega Bay
San Francisco	San Francisco
San Francisco	Princeton/Half Moon Bay
San Francisco	Other SF Area

Note: this is an initial listing

Southern California Communities

Region	Trawl Vessel Homeport
Monterey	Monterey
Monterey	Santa Cruz
Monterey	Moss Landing
Morro Bay	Morro Bay
Morro Bay	Avila
Los Angeles	Los Angeles
Los Angeles	Long Beach
San Diego	San Diego
San Diego	Oceanside

Note: this is an initial listing

Indicators of effects on Communities

- Change in distribution of harvesting-related activity
- Change in distribution of processing-related activity
- Change in distribution of fishery-related employment by sector
- Change in distribution of fishery-related income and revenue
- Change in distribution of fishery-related support service demand
- Changes in overall patterns of engagement and dependency based on previous indicators

Non-Trawl Commercial Harvesters

- **Non-Trawl Harvesters**
  - These may be indirectly affected because limited entry trawl harvesters also participate in other fisheries and rationalization of the limited entry trawl fishery may allow LE trawl permit holders to increase their participation in these other fisheries.
  - Limited Entry Fixed Gear Harvesters
  - Open Access Trawl Harvesters
  - Dungeness Crab Harvesters

Effect Indicators for Non-Trawl Harvesters

- Catch by species
- Distribution of catches by month
- Ex-vessel revenues from groundfish
- Number of participating catcher vessels
- Distribution of vessel owners by community
- Number of trips per year

Other Indirectly Affected Stakeholders

- Input Suppliers, Wholesalers and Retailers
  - Could see changes in sales and timing of sales
- Consumers of West Coast Groundfish
  - Changes in products, product quality, prices, availability
- The General Public
  - Non-use and existence value changes

Processors not involved in the Trawl Groundfish Fishery--Indicators

- **Change in total purchases of fish**
- **Change in number of processor facilities**
- **Changes in the relative market shares**
- **Change in average level of purchases**

Other Indirectly Affected Stakeholders

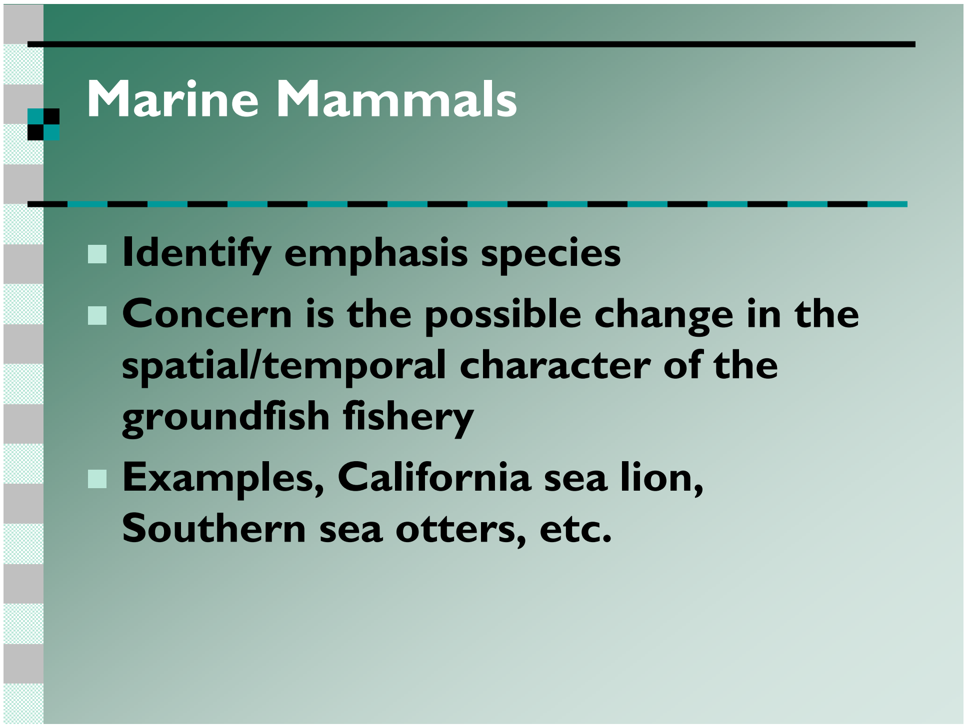
- **Recreational Harvesters**
  - Potential effects have yet to be identified
- **Tribes**
  - While not necessarily directly affected by federal and state management measures, they are directly involved in the Council process and craft their groundfish management measures in cooperation with federal and state managers

Groundfish Species

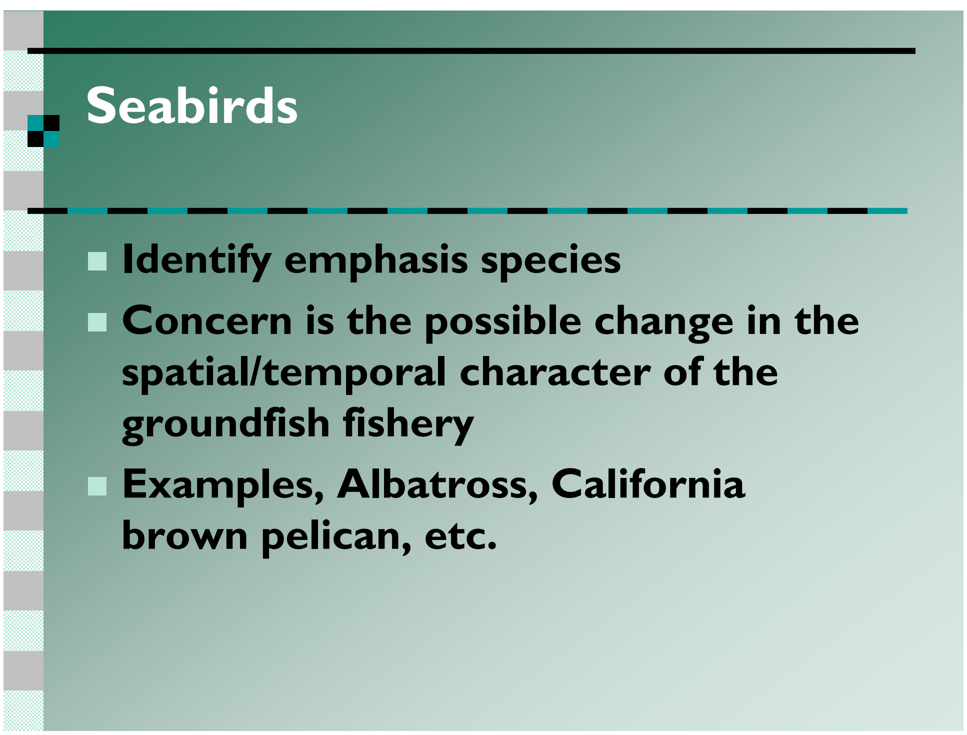
- Species broken up into two categories (overfished and non-overfished)
- Quota setting process will remain unchanged
- Of concern is the spatial/temporal character of the groundfish fishery

Other Affected Fish Resources

- Species caught incidentally in fisheries targeting groundfish
- Identify emphasis species; i.e. Pacific halibut, coastal pelagic species, etc.
- Concern is the possible change in the spatial/temporal character of the groundfish fishery



Marine Mammals
Identify emphasis species
Concern is the possible change in the spatial/temporal character of the groundfish fishery
Examples, California sea lion, Southern sea otters, etc.



Seabirds
Identify emphasis species
Concern is the possible change in the spatial/temporal character of the groundfish fishery
Examples, Albatross, California brown pelican, etc.

Other affected Protected Resources

- Identify emphasis species
- Concern is the possible change in the spatial/temporal character of the groundfish fishery
- Examples, salmon and other species protected by ESA

Habitat Areas

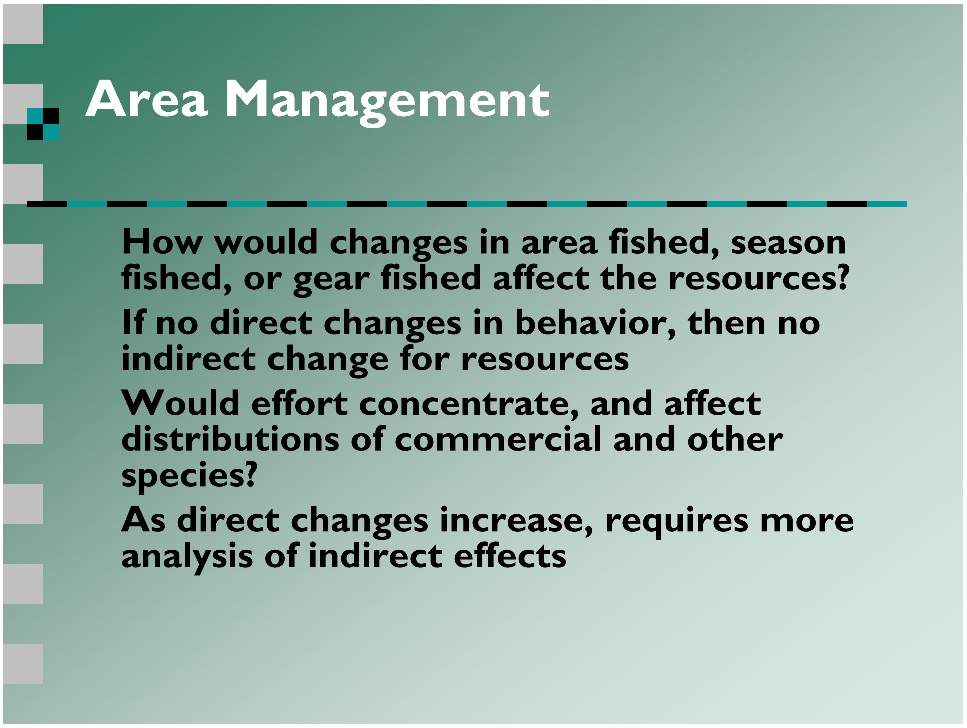
- Identified MPAs and areas closed to trawling
- No direct effects from Trawl IQ
- For areas closed to trawling, no indirect effects of trawling
- If change gear, may have indirect effects

Essential Fish Habitat

- **No direct effect of IQ on EFH**
- **Would fishers change area, gear?**
  - Want to assess indirect impacts relative to status quo?
  - Fish closer to port?
  - Fish farther away in higher CPUE?
  - Switch to longline?

Ecosystem Effects

- **No direct effects**
- **Want to assess relative effects of indirect changes from IQ– predators, prey, protected species, habitat**



Area Management
How would changes in area fished, season fished, or gear fished affect the resources?
If no direct changes in behavior, then no indirect change for resources
Would effort concentrate, and affect distributions of commercial and other species?
As direct changes increase, requires more analysis of indirect effects

No-Action and Permit Stacking Alternatives

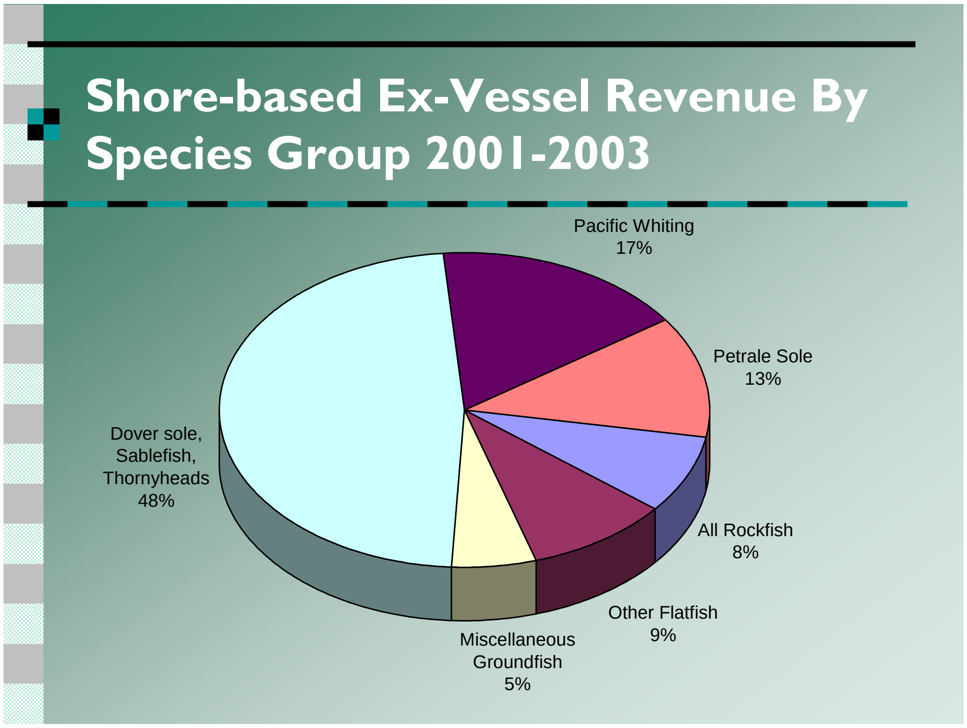
Status Quo Facts

- **After the Buy-back 170 active permits remain.**
- **Since 2001, there have been 135 active permits in shore based data.**
- **The Dover sole, Thornyhead, Sablefish (DTS) fishery is the largest by value among shore-based fisheries.**
- **The Whiting Fishery is largest by volume.**



Shore-based Ex-Vessel Revenue By Species Group 2001-2003
Pacific Whiting 17%
Petrale Sole 13%
Dover sole, Sablefish, Thornyheads 48%
All Rockfish 8%
Other Flatfish 9%
Miscellaneous Groundfish 5%

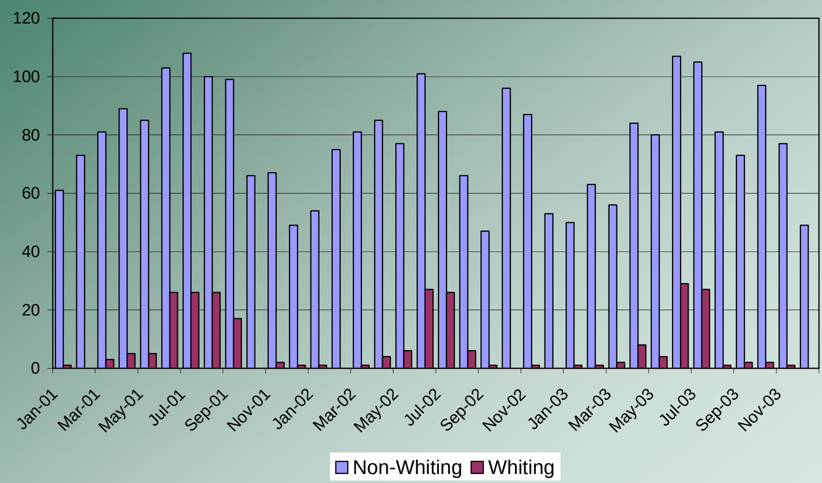
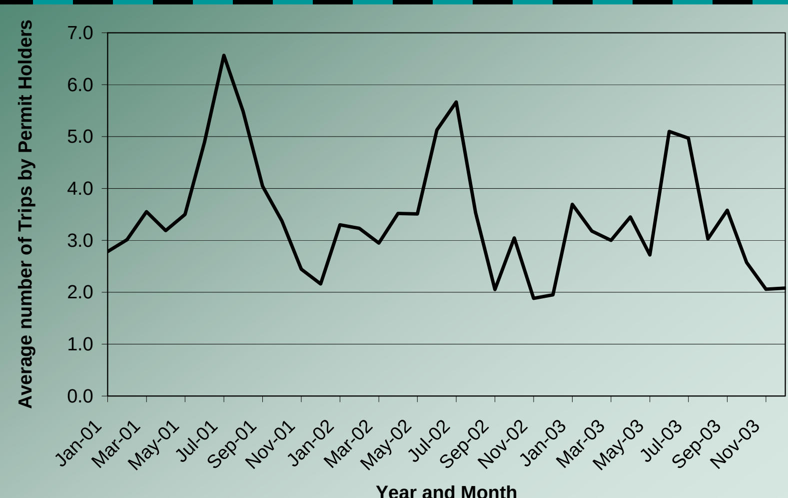
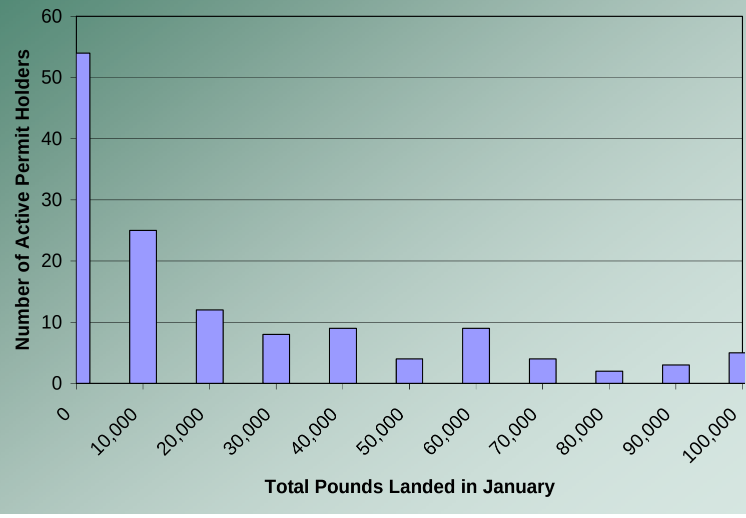
Shore-based Participation by Permit Holders in Whiting and Non-Whiting



Average Trips Per Month of Post-Buy-back Permit Holders in shore-based data



Catch of Active Shore-based Permit Holders in January 2001-2003



Decision to go Fishing

- Gross Revenue Potential
- Variable Cost Potential
- Fixed Costs

Gross Revenue Potential

- How much might be caught?
- Who will the buy the fish that are caught—does the vessel have a market?
- What is the vessel likely to earn in gross revenues?
- If not now, will the opportunity to fish be there tomorrow?
- What other fishing opportunities do I have?

Variable Cost Potential

- Gas / Diesel
- Crew
- Food
- Maintenance on vessel, engine, and gear due to wear and tear
- Time away from other opportunities to earn money
- Insurance
- Risk of injury and death

Fixed Cost—What does it cost to have the option to fish?

- Moorage
- Insurance
- Maintenance on hull and engine because vessel is in the water
- Annual permit charges
- Opportunity cost of capital

Decision of When and Where

- Not all permit holders fish every period
  - The Consulting Team thinks this may be weather related and related to other fishing opportunities—participation in non-whiting fisheries appear to increase during warmer months?
- What drives the decision to fish during a period?

Other Fishing Opportunities

- Dungeness Crab
- Limited Entry Fixed Gear
- Alaska Fisheries
- Open Access Trawl
- Open Access Vertical Hook and Line

Level of Effort and Landings in Month

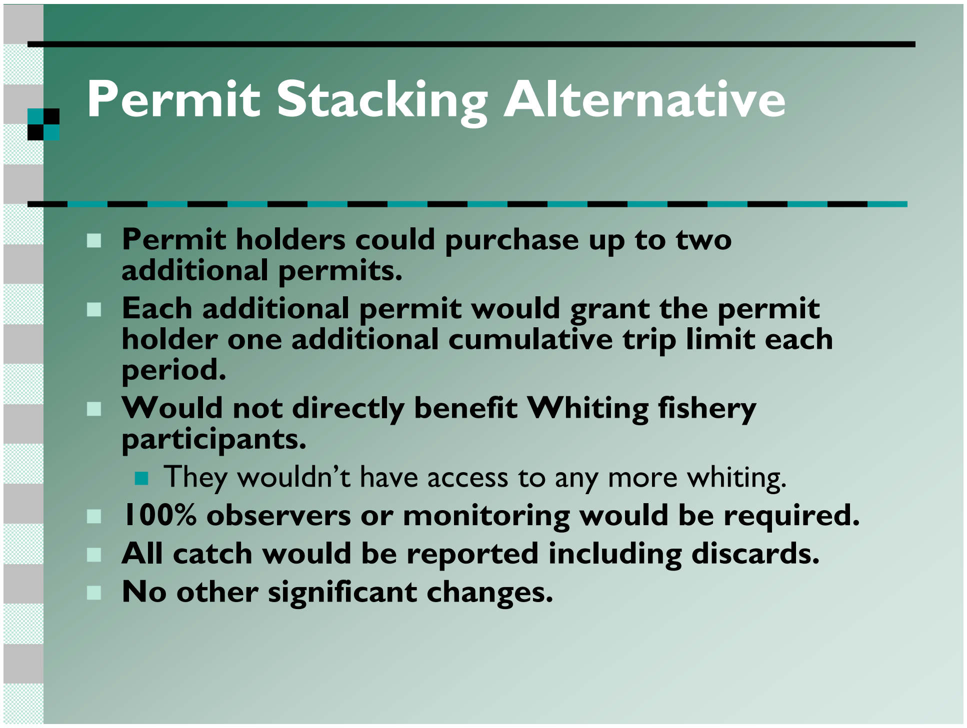
- The level of effort and the amount of Landings appear relatively inconsistent across participants.
- The Consulting Team thinks this may be a reflection of other fishing opportunities
  - Also influenced by innate abilities and drive.
- Difference could also be a lack of markets to sell fish?
- Is the fishing effort affected by homeport?
- Once the decision to fish is made, it doesn't appear that all permit holders fish to the same intensity.

Incidental Catch

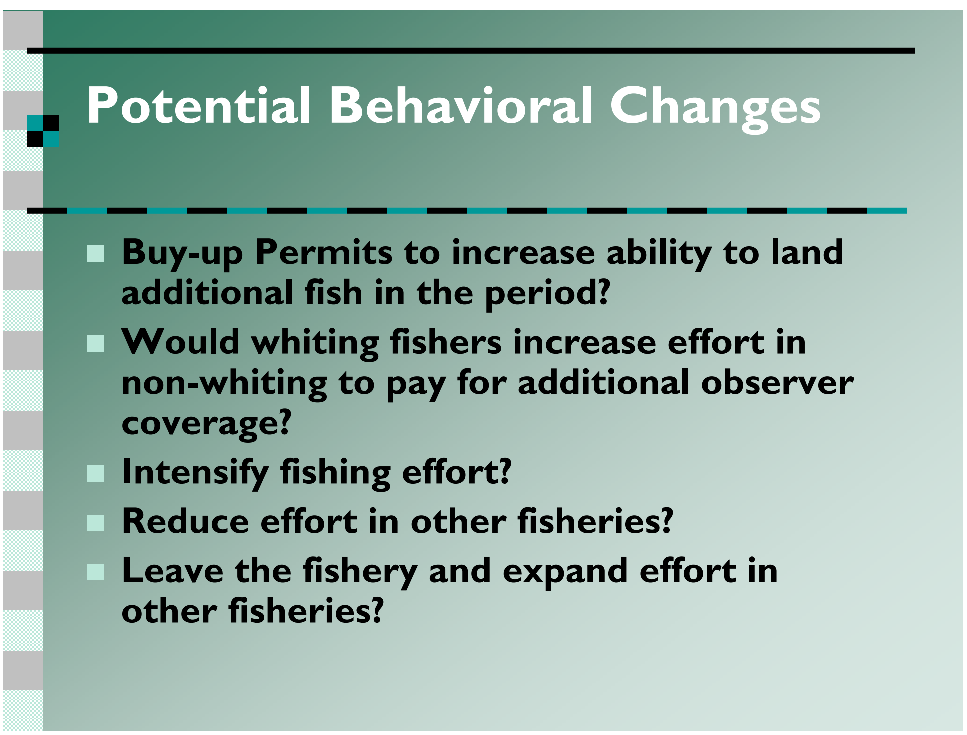
- **The Consulting Team thinks that some make a greater effort to reduce incidental catch than others**
- **Is this the case?**
- **Why?**

Relationship between harvesters and Processors

- **The Consulting Team has heard from some fishers and some processors that the processors place a high value on ensuring that fishers deliver all of their fish to them.**
- **The Consulting Team has heard that processors will often say something like…**
  - Yes, I will buy your low value fish, but in return you have sell me all of your high value fish, including species other than groundfish
  - Or, yes, I will buy your entire load of fish today, even though I don't really need it, but if I do buy it, you must always deliver to me or my company.
- **The Consulting Team has heard that the relationship between harvesters and processors is a long-term relationship—often there are no official contracts, but there are implicit contracts.**



Permit Stacking Alternative
Permit holders could purchase up to two additional permits.
Each additional permit would grant the permit holder one additional cumulative trip limit each period.
Would not directly benefit Whiting fishery participants.
They wouldn't have access to any more whiting.
100% observers or monitoring would be required.
All catch would be reported including discards.
No other significant changes.



Potential Behavioral Changes
Buy-up Permits to increase ability to land additional fish in the period?
Would whiting fishers increase effort in non-whiting to pay for additional observer coverage?
Intensify fishing effort?
Reduce effort in other fisheries?
Leave the fishery and expand effort in other fisheries?

How would the permit stacking program change relationships between harvesters and processors?

- **Describe the current relationship between harvesters and processors**
  - The Consulting Team has heard from some fishers and some processors that the processors place a high value of ensuring that fishers deliver all of their fish to them.
  - The Consulting Team has heard that processors will often say something like—Yes, I will buy your low value fish, but in return you have sell me all of your high value fish, including species other than groundfish

More Questions

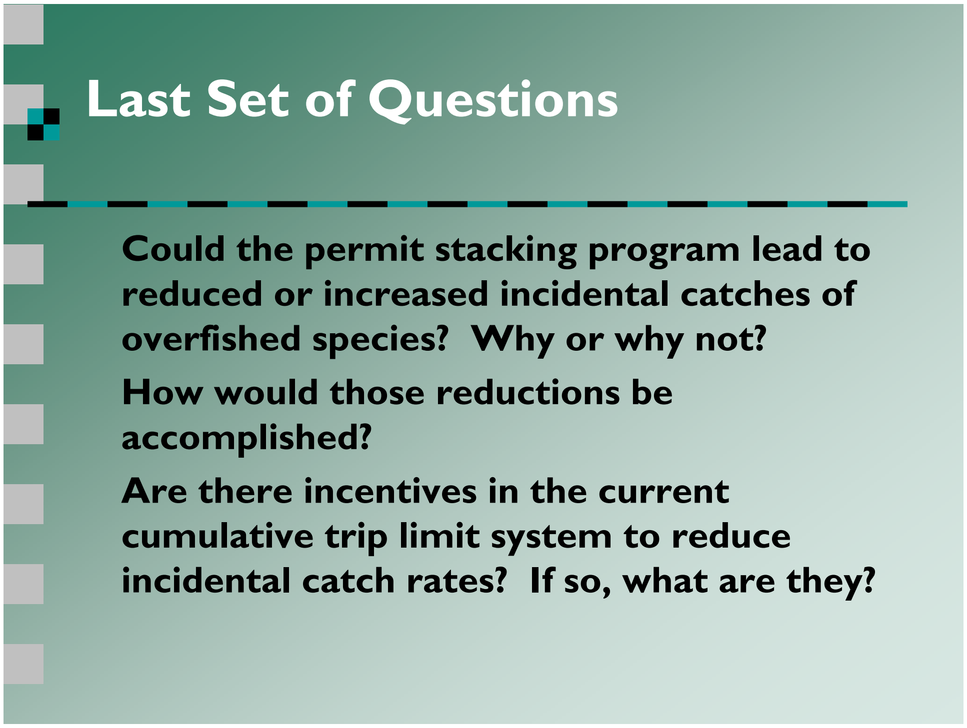
- **Would the permit stacking system provide any benefits to the whiting fishery?**
- **How would harvesters change the areas in which they fish under a permit stacking program?**

More Questions

- How will processors respond to a permit stacking program? Would they change the timing of their demand for inputs?
- What will be the effect of having to report 100 percent of the catch, ignoring for the moment the additional cost of the observer/video monitoring program?

Next to last set of Questions

- Now assume that the combination of video monitoring and observers will cost an average of $500 per fishing day.
  - Will it be necessary for harvesters to purchase additional permits to remain viable?
  - How would this change if more emphasis were placed on video monitoring, thereby reducing the costs of the observer/monitoring system.



Last Set of Questions
Could the permit stacking program lead to reduced or increased incidental catches of overfished species? Why or why not?
How would those reductions be accomplished?
Are there incentives in the current cumulative trip limit system to reduce incidental catch rates? If so, what are they?

IFQ Alternatives

A PowerPoint Presentation Provided to the Trawl IQ Workshop

By Marcus Hartley (Northern Economics) during the

Afternoon Session on; April 19, 2006

Forces and Mechanisms under IFQs

Presentation to

Pacific Fishery Management Council Workshop on Trawl IQs

Marcus Hartley

April 2006

Alternative 3: IFQs for all Groundfish except Other Species.

- **IFQs for all Groundfish except Other Species.**
- **Whiting seasons would be eliminated, but whiting sectors are maintained.**
  - 3 whiting sectors
- **Reporting of all groundfish catch would be required.**
- **At-sea monitoring would be required on all vessels.**

Assume Program C for Each Alternative

- 75 percent of QS to Harvesters
- 25 percent of QS to Processors
- Processors are defined as those facilities that take ownership of, and process, unprocessed groundfish

Processor & Harvester Relationships

- **Processors would be allocated 25 percent of the QP of all species under Alternative 4.**
  - How will these allocations of QS/QP be used by processors?
  - Would the allocation of QS/QP to processors make it more likely that harvesters would try to acquire additional QS?
    - If so, why?
  - How would the discussion change if processors were instead allocated …
    - 50 percent of the QS/QP?
    - 10 percent of the QS/QP?

How will Processors use QS/QP

- **One processor told us…**
  - He would provide the QP to the harvesters that he normally works with free of charge to ensure that they would deliver all their fish (all species) to him.
  - He would not lease them to his harvesters and would not pay a lower ex-vessel price
  - He would prioritize to most efficient vessels

How will Processors use QS/QP

- **One processor told us that…**
  - He would lease them to harvesters at the market rate paid for QP.
  - With IFQs, it's all about profit maximization

How will Processors use QS/QP

- **One processor told use …**
  - He would use them on his own vessels and use the extra profits to expand his fleet

Processor Behavioral Changes

- **Is it likely that processors would change the products they produce under an IFQ program?**
  - What kinds of changes might be made?
- **Is it likely that processors would change the timing of their purchase demands for particular species in an effort to reduce incidental catch and thereby increase target catches?**
- **What data are available with respect to products and product prices?**

Processor Use of QS/QP

- Mainstream economic theory assumes pure competition; therefore, questions of how processors use QS/QP cannot easily be answered.
- We would look at game theory and experimental economics to address these issues.

Whiting Fisheries Changes

- Whiting Seasons would be eliminated under this alternative. What would be the affect of this option on the program?
- Would you expect whiting vessels (that don't fish for other types of groundfish) to change behavior with respect to timing or areas fished to reduce incidental catch? How?

Spatial and Temporal Behavioral Changes

- **How would harvesters change timing or areas of fishing under this IFQ program compared to permit stacking?**
  - The Consulting Team thinks vessels will move to times and areas where the ratio of target CPUE to incidental catch rates is most favorable, subject to constraints of market demand from processors

Incidental Catch Behavioral Changes

- **What will be the effect of the IFQ program on incidental catches of overfished species?**
  - Will the IFQ program allow harvesters to reduce incidental catches?
  - How could these changes be accomplished?

More Whiting Behavioral Changes

- Would you expect whiting vessels that also fish for other types of groundfish to change behavior with respect to timing or areas fished in order to reduce incidental catch?

More on incidental catch

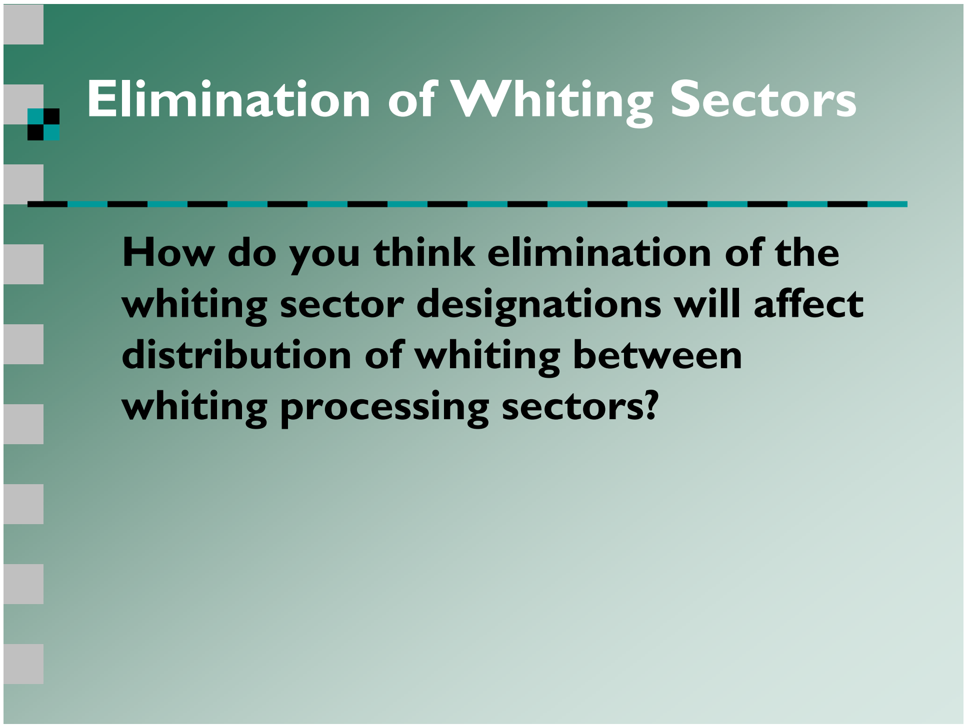
- How do you think groundfish-only vessels would change?
- How will the incentives for reducing incidental catch change?

At-Sea Monitoring Program

- **Remembering that the IFQ program includes an observer and monitoring program (assume a cost of $500 per day), is it likely that harvesters would need to purchase additional QS/QP to cover those additional costs?**
  - How would this change if more emphasis were placed on video monitoring, thereby reducing the costs of the observer/monitoring system?

Alternative 4: IFQs for all groundfish species

- **IFQs for all groundfish species.**
- **Whiting Sector designations would be eliminated.**
- **Whiting Seasons would be eliminated.**
- **Reporting of all groundfish catch would be required.**
- **At-sea monitoring would be required on all vessels.**



Elimination of Whiting Sectors
How do you think elimination of the whiting sector designations will affect distribution of whiting between whiting processing sectors?

Allocations to Processors

A PowerPoint Presentation Provided to the Trawl IQ Workshop

By Marcus Hartley (Northern Economics) during the

Morning Session on; April 20, 2006

Allocations to Processors: Definitions and Impacts

Presentation to

Pacific Fishery Management Council Workshop on Trawl IQs

Marcus Hartley

April 2006

IFQ Specific Program Options for Defining Processors

- **Program A: Processors are defined as those facilities that take ownership of, and process, unprocessed groundfish.**
- **Program B: Processors are defined as in the FMP—those facilities that process either unprocessed or already processed groundfish or receive live fish for resale.**
- **Program C: Processors are defined as those facilities that take ownership of, and process, unprocessed groundfish.**

The Problem

- Official data do not exist to produce a complete or accurate list of the entities that would be entitled to an allocation of QS/QP according to those definitions.
- Without a reliable indication of which entities would be entitled to QS/QP, the analysis of the impacts of the IFQ programs would be incomplete and be susceptible to legal challenge.

Processor-ID in PacFIN

- The term "Processor" developed in the alternatives differs from the way that data have been collected in the PacFIN Fish-Ticket data set.
- PacFIN's "Processor-ID" field, is more correctly described as "First Receiver ID"
- These entities may in fact be the actual processor of the fish, but they may also be agents of processors, independent buyers, restaurants, wholesale distributors, brokers, and possibly other types of entities.

FMP Definitions of Processors and Processing

- Definitions in the Alternatives implicitly rely on the definition of processing in the FMP. Specifically:

  "Processing or to process means the preparation or packaging of groundfish to render it suitable for human consumption, retail sale, industrial uses, or long-term storage, including, but not limited to, cooking, canning, smoking, salting, drying, filleting, freezing, or rendering into meal or oil, but does not mean heading or gutting unless additional preparation is done."

FMP Definition Issues

- In the FMP definition, processors clearly do more than reselling or re-distributing fish.
- The FMP definition appear to disqualify all receivers of fish that simply resell the fish or redistribute the fish.
- However, the FMP definition of processing also specifically states that heading or gutting of a fish does note equate to processing.
- The FMP also implies that simply bleeding, gutting, heading, or selling whole fresh fish does not equate to processing.

Implications of the FMP

- The implication of the previous bullet is that, in order to determine if a fish has been processed, and therefore whether an entity is a processor eligible to receive QS/QP for that fish, NMFS must know specifically what was done to the fish after each entity takes possession of it.
- Those data do not exist!

Potential "Processors"

- Recipients of fresh fish that is whole, bled, gutted, or headed and gutted that undertake additional processing
- Restaurants, Grocery stores and Consumers might qualify, along with the entities that are typically thought of as "processors".
- Under both options, entities that are not located in the US, entities that are not owned by US citizens, and individuals that are not US citizens may actually qualify for QS/QP allocations.
- Finally it appears that under Program B, initial processors, secondary processors, tertiary processors and so-on could all qualify for QS/QP from a single fish.

Concerns from the EIS Perspective

- These concerns may have significant socio-political implications
- the Consulting Team is concerned that the issues have significant implications on the development of an EIS.
- All potential recipients of QS/QP would be considered directly affected, including restaurants and retail outlets that fillet fish and secondary processors.
- The scope of the EIS is significantly expanded by the definition of processors as currently stated in the Alternatives.

Example 1:

- "Joes," a facility in Newport, buys a load of flatfish from a vessel.
- Joes fillets 85 percent of the fish and sells them into the distribution chain.
- Joes fills a special order for whole fish for "Jacks," a high-end white tablecloth restaurant with the remaining 15 percent of the flatfish
- Chefs at Jacks fillet the flatfish at the diner's tables and pan-sear them to perfection.
- A strict interpretation of the FMP would mean that Jacks would be the Processor entitled to 15% of QS, while Joes would get 85% of the QS.

Example 2

- Joes freezes 500 lbs of thornyheads after heading and gutting.
- Joes sell to "Jims" in Bellingham,
- After storing, Jims refreshes and fillets them, and send them down to Jacks.
- Chefs at Jacks skin the fillets and cook them.
- By the definition in Program B, Joes, Jims, and Jacks have all processed the fish and would all qualify for 500 lbs worth of QS.

Consulting Team Option 1

- For purposes of allocation of QS/QP, two types of processors are defined:
  - At-sea Processors are those vessels that operate as Motherships in the Offshore Whiting fishery or those vessels permitted to operate as Catcher Processors in the Catcher Processor Whiting Fishery.
  - Shore-based processors are defined as those entities that are listed in the "Processor-ID" field of Fish-tickets.
- This is a simple and implementable approach that uses official data.

Consulting Team Option 2

- For purposes of allocation of QS/QP, two types of processors are defined:
- An At-Sea Processor is defined as an operation that while at-sea: 1) catches or takes delivery of whole groundfish; and 2) freezes or dries that groundfish; and 3) sells the fish into a wholesale market. All such fish shall be defined as "processed at-sea."
- A Shore-based Processor is an operation, working on US soil, that takes delivery of trawl-caught groundfish that has not been "processed at-sea" or that has not been "processed on-shore"; and that thereafter engages that particular fish in "on-shore processing."

Consulting Team Definition of Onshore Processing

- "On-shore Processing" is defined as any operation that takes place on shore; and that involves: 1) cutting groundfish into smaller portions; or 2) the freezing, cooking, smoking, drying of groundfish; and 3) packaging of groundfish for resale into 100 lb units or smaller for sale or distribution into a wholesale market.
- The purchase and redistribution into a wholesale market of live groundfish from a harvesting vessel is also defined as "on-shore processing."
- Entities that received fish that have not undergone "at-sea processing" or "on-shore processing" (as defined in this paragraph) and sell that fish directly to consumers shall not be considered a "Processor" for purposes of QS/QP allocations.

Implementation of allocation for QS of Processing QS (Part 1)

- NMFS requests applications for QS
- All entities listed in At-Sea data or in PacFIN data in "Processor-ID" or equivalent fields are eligible to apply.
- All entities that believe they have met the definition of processing but which were not listed in the Processor-ID field, may also apply.

Implementation of allocation for QS of Processing QS (Part 2)

- Entities claiming to be a processors, but which were not listed in Processor-ID field, must provide sufficient evidence to NMFS to back up their claim that indeed they were the "Processor" of that fish.
- Therefore the only "unofficial" data that must be supplied is the special case where an independent buyer supplied "unprocessed" fish to the Claimant.
- Otherwise Official Data Sets would be used.

Caveats

The Consulting Team makes no claim that the definitions and concepts provided here would withstand legal challenge.

Community Impacts

A PowerPoint Presentation Provided to the Trawl IQ Workshop

By Mike Downs (EDAW, Inc.) during the

Morning Session on; April 20, 2006

Social/Community Impact Assessment Discussion

Presentation to

Pacific Fishery Management Council Workshop on Trawl IQs

Mike Downs

April 2006

Social/Community Impact Assessment

- **SIA two-pronged approach**
  - Summary tables based on quantitative information; presented in body of EIS/RIR; focuses on distribution of sectors across communities
  - Detailed community context information; presented in technical appendix; focuses on community engagement and dependency

Social/Community Impact Assessment

- **Balance of quantitative and qualitative**
  - Limits of available information
  - Range, direction, and likely order of magnitude of social and community impacts

Social/Community Impact Assessment

Background and Methodology

- NEPA (social and economic effects)
- MSA National Standard 8 (engaged, dependent, sustained)
- Executive Order 12898 (environmental justice)

Social/Community Impact Assessment

- **Community Variability**
  - Location and Historical Ties to the Fishery
  - Community Socioeconomic Structures
  - Engagement, Dependency, Resiliency, Vulnerability

Social/Community Impact Assessment

Social Impact Experience with IFQ or Other Rationalization Programs

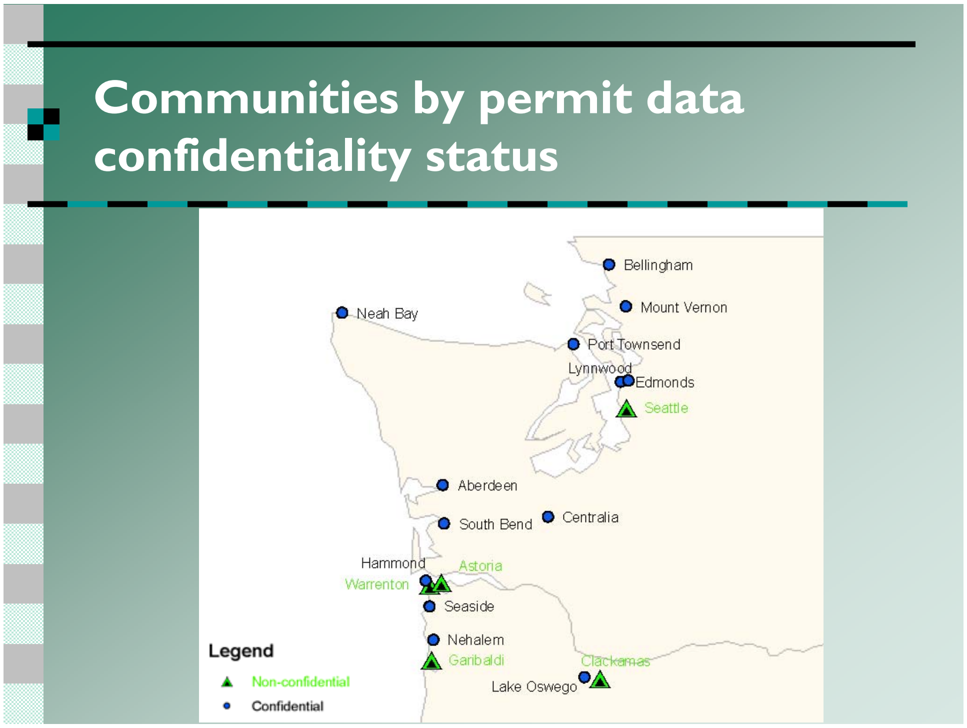
- Summary Review of Relevant Literature – lessons learned
- Region-Specific Experience – applying the lessons learned to the regional and fishery context

Social/Community Impact Assessment

- **Community Profiles**
  - Community #1
    - Community Demographics
    - Local Economy and Links to the Trawl Fishery
    - Community Revenues
    - Summary of Recent Community Rationalization Experience
    - Differential Impacts of Trawl Fishery Management Alternatives
  - Community #2 (and so on)

SIA Analytic Challenge: Data Confidentiality

- **Need to aggregate fisheries data**
  - 4 or more entities
  - Counts versus common ownership



Communities by permit data confidentiality status
Bellingham
Mount Vernon
Neah Bay
Port Townsend
Lynnwood
Edmonds
Seattle
Aberdeen
South Bend
Centralia
Hammond
Astoria
Warrenton

Port Orford
Brookings
Harbor
Crescent City
McKinleyville
Bayside
Eureka
Fields Landing
Ferndale
Legend
Non-confidential
Confidential

Communities by permit data confidentiality status

Confidentiality Example: Limited number of communities without harvester data restrictions

- **Oregon**
  - Astoria
  - Charleston
  - Clackamas
  - Coos Bay
  - Garibaldi
  - Newport
  - Warrenton

Communities without harvester data restrictions (continued)

- California
  - Eureka
  - Fort Bragg
  - Half Moon Bay
  - San Francisco
- Washington
  - Seattle

Data Confidentiality Issues: Processors

- Defining processors
- Confidentiality by location

Communities confidentiality methodological approaches

- Aggregation of communities based on proximity and socioeconomic ties (see map)
- Use of averaged data for communities with fewer than requisite number of entities

Anticipated Community Impact Drivers

- Vessel consolidation
  - Employment: loss of skipper and crew positions
  - Income: change in compensation structure
  - Support service businesses
  - Public revenues
- Processor consolidation
  - Employment/income processing employees
  - Support service businesses
  - Public revenues

Anticipated Community Impact Drivers (cont.)

- **Change in spatial distribution of effort and landing patterns**
  - What is logical to look for at this point?
  - Toward larger communities? Others?
- **Change in temporal distribution of effort**
  - What is logical to anticipate at this point?
  - How would this impact communities and support businesses?

Anticipated Community Impact Drivers (cont.)

- **Change number of vessels**
  - What is logical to look for at this point?
  - Toward larger vessels? Other attributes?
- **Change in number of processors**
  - What is logical to anticipate at this point?
  - Toward larger processors? Change in balance of larger and niche processors?

Community Options to be Analyzed

- Community Stability Holdback Option
- Community Involvement Option
- Existing Community Impact Control Mechanism Options

Community Stability Holdback Option

- **General**
  - Portion of annual QP held back and allocated for proposals submitted by IFQ holders [earlier: joint fishermen/processor venture proposals]
  - Proposals evaluated with priority on community benefits
  - Shares held back continue to be trawl shares

Community Stability Holdback Option (continued)

- **Holdback**
  - Up to 25 percent of total annual QP for [non-whiting] shoreside component of trawl fishery (but period may be greater than one year)

Community Stability Holdback Option (continued)

- **Committee**
  - Appointed by Council, recommendations approved by Council before being forwarded to NMFS
  - Role to make recommendations with the purpose of achieving community development, enhancement, or stabilization goals
  - Composed of representatives of West Coast regions, port districts, processors, and fishermen
  - Staffing by NMFS + Council (option A) or Council (option B)

Community Stability Holdback Option (continued)

- **Eligibility for Participation**
  - IFQ holders [previously joint fishermen/ processor venture proposals]; may work together in collaboratives.
  - IFQ holders may only participate in one proposal

Community Stability Holdback Option (continued)

- **Allocation Criteria**
  - To be developed, but quantitative in nature for consistent application to proposals
  - Potential criteria may or may not include:
    - Past performance (performance on past commitments)
    - Utilization (indicator of wastage and pollution externalities)
    - Local added value (value of exports divided by landings)
    - Local labor employment (percentage of local employees)

Community Stability Holdback Option (continued)

- **Potential Allocation Criteria (Continued)**
  - Local labor earnings (wages to product value ratio)
  - Public debt related to fisheries investment (fishery infrastructure debt relying on fisheries activity repayment)
  - Public investment dedicated to fisheries (total public investments supporting fishing industry)
  - Port dependence (proportion of total port revenue derived from fisheries activity)
  - Other (to be identified through public comment)

Community Involvement Option

- **Committee**
  - Convened by Council; composed of representatives of West Coast regions, port districts, processors, and fishermen
  - Make recommendations pertaining to IFQ program and its impacts to port districts, regions, processors, and fishermen

Existing Community Impact Control Mechanism Options

- Allowing communities to hold quota
- Setting limits on quota accumulation
- Allocations of whiting and non-whiting groundfish species for shoreside and at-sea delivery
- Temporarily prohibiting QS transfer after initial allocation (to be analyzed, but NOT a part of current alternatives)
- Distribute revoked shares or reclaimed quota to new entrants

Environmental Justice Analysis

- High and adverse impacts
- Disproportionately accruing to minority populations or low-income populations
- Populations vs. community (e.g. population pockets)

Consolidation

A PowerPoint Presentation Provided to the Trawl IQ Workshop

By Marcus Hartley (Northern Economics) during the

Afternoon Session on; April 20, 2006

Consolidation

Presentation to

Pacific Fishery Management Council Workshop on Trawl IQs

Marcus Hartley

April 2006

Forces that May Affect Consolidation of the Industry

- Initial Allocation
- Accumulation Caps
- Use Caps or Vertical Integrations Limits (none included)
- Sector Definitions
- Harvesting and Processing Costs
- Observer and Monitoring Costs

Initial Allocation

- **We heard in Small Group Sessions that the allocations to processors will affect consolidation in terms of:**
  - Who will buy QS
  - How fast consolidation will occur
- **If processors get 25% rather than 10%, those processors will be able to purchase more QS in the future.**

Economic Theory

- **Those to whom the QS are issued may be able to capture the extra rents in the fishery—not just in current period, but for all periods in the future.**
  - Note that perfect information of future stock sizes, future input and product prices, etc. would be required to extra all of the extra rent.
- **Purchasers of QS will be able to make normal business profits, but probably won't be able to generate extra rents, unless they made a really good purchase deal on QS.**

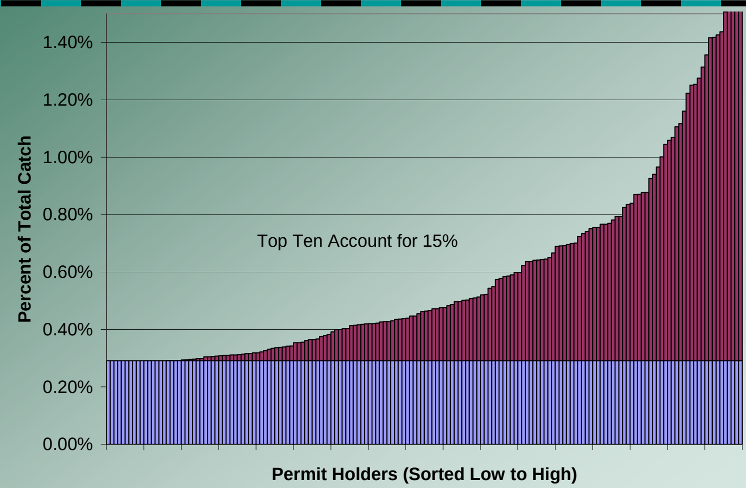
Initial Allocation of Harvest Shares for Catcher Vessels (See Page 26)

- **Catcher vessel permit owners will receive quota shares based on their permit history plus an equal division of the quota that could be attributed to permit history of bought-back permits (catcher-processors permit owners will not receive a portion of the quota shares distributed on an equal sharing basis)**
- **Suboptions for incidentally caught overfished species, either:**
  - (a) same as for OTHER FISH
  - (b) equally divide quota for incidentally caught overfished species

Initial Allocation of QS

- **The graphic below is an initial representation of the potential allocation of QS (shown on a percentage basis) based on Program A—pure catch history allocation, without the recent participation criteria or minimum landings criteria.**

Example Allocation for Petrale Sole



Accumulation Caps

- **Program A: 50% or No Limits**
- **Program B: Consider all limits (1%, 5%, 10%, 25%, or 50%, No limits)**
- **Program C: 1%, 5%, 10%, or 25%**

Whiting Sector Definitions

- **Discussed in Afternoon Session on April 19**
  - Participants indicated a general feeling that whiting would be consolidated to the CP sector if unconstrained by sector designations

Other Factors

- **Harvesting and Processing Costs**
- **Observer and Monitoring Costs**
- **Vessels and Processors with highest net revenue per fish are in the best position to purchase QS\QP**
- **Purchasing QS\QP will increase overall cost per fish and thus reduce net revenue per fish.**
- **Those that have to purchase less QS\QP to get back to pre-IFQ levels, have an advantage, compared to those that have to purchase more QS\QP to get back to pre-IFQ levels.**

Methods to Assess Consolidation

- Examine Initial Allocation
- Conduct key informant interviews
- Examine cost and revenue information
- Factor in accumulation limits
- Make an educated projection
- Bound projections with Scenarios

Consolidation Scenario 1

- ***Assume a moderate fleet consolidation*:**
  - In this scenario it would be assumed that QS are transferred and vessels drop out of the fishery such that the average vessel remaining in the industry fishes an average of 150 days per year. For this scenario, the average number of fishing days per vessel per year was chosen somewhat arbitrarily, and could be adjusted based on comments.
- **Is this scenario reasonable?**

Consolidation Scenario 2

- ***Assume a high fleet consolidation such that the average vessel fishes 270 days per year*:**
  - In this scenario it would be assumed that QS are transferred and vessels drop out of the fishery such that the average vessel remaining in the industry fishes an average of 270 days per year. This scenario was chosen based on the assumption that a single vessel is unlikely to be able to fish more than 300 days in a given year.
- **Is this scenario reasonable?**

Consolidation Scenario 3

- ***Assume a very quick transition to a moderately consolidated fleet*:**
  - In this scenario it is assumed that the fleet undergoes a "moderate" consolidation during the **first year** of the IFQ program—the average vessel fishes 150 days per year.
  - Theoretically, overall efficiency of the fleet—once it is consolidated—would not be affected by how quickly or gradually it consolidates. However, the impacts on communities and fishing crews are likely to be much more noticeable if the transition to a consolidated fleet is relatively quick.
- **Is this scenario reasonable?**

Consolidation Scenario 4

- ***Assume a gradual transition to a moderately consolidated fleet:***
  - In this scenario is assumed that the fleet undergoes a "moderate" consolidation over the **first five years** of the IFQ program —the average vessel fishes 150 days per year.
- **Is this scenario reasonable?**

Other Questions

- **What might be reasonable scenarios for consolidation of processors?**
- **Should other initial allocation options be included for CVs?**

Agenda Item F.3.c
Supplemental SSC Report
June 2006

SCIENTIFIC AND STATISTICAL COMMITTEE REPORT ON TRAWL INDIVIDUAL QUOTA ANALYSIS – REVIEW OF STAGE I DOCUMENT

Jim Seger (PFMC) and Marcus Hartley (Northern Economics Inc.) briefed the Scientific and Statistical Committee (SSC) on the Stage 1 Draft – IFQs and Permit Stacking Alternatives in the Limited Entry Trawl Fishery (Agenda Item F.3.b, Attachment 1 and REVISED Attachment 1 ERRATA).

The SSC has several comments on the proposed methods:

- Analysis of the alternatives is a work in progress and a number of different data sources and approaches are being proposed. This analysis will generate a huge amount of output. To facilitate analysis and eventual consideration of results, it would help to narrow the scope of components and elements under each alternative. In addition, the SSC requests that the Consulting Team narrow the number of indicators being considered. Changes in the RCA boundaries and other aspects of management besides the current system of cumulative trip limits, were not considered, which seems inconsistent with the goal of the IFQ program to reduce bycatch.

- An objective of the IFQ program is to reduce bycatch and discard mortality. However, some elements for each alternative distinguish between low-OY and high-OY situations using thresholds, for example B25%, with quota shares becoming inactive if abundance is less than the threshold. In this case, management of the fishery would revert to cumulative trip limits, which raises a consistency issue. In other words, any benefits of the IFQ program for reducing bycatch would be forfeited for overfished stocks because the incentive for doing so would be lost. In any case, the SSC recommends basing the low-OY situation on whether the stock is considered overfished.

- Instead of basing significance of the effects from the alternatives on an arbitrary level (i.e. 20%), the SSC recommends reporting results in terms of the actual percentage change, or at least indicate the approximate level (20-30%, 30-40%, etc.).

- The Consulting Team suggests that an interview-based approach be used to obtain information from “key informants” to “quantify the likely changes under each alternative.” While this type of information is important for understanding the current structure of the fishery, the SSC is skeptical that such information can be used as a reliable basis for evaluating future changes under hypothetical conditions (i.e. different scenarios and alternatives).

- The Stage 1 Draft document provides an overview of five models (Initial Allocation, Industry Consolidation, Incidental Catch, Observer Cost, and Profitability) that would be developed for an analysis of the alternatives. However, descriptions of these models is rather general, and it was not possible for the SSC to evaluate the structure of these models at this time. Most of the SSC discussion focused on the Incidental Catch model. An important point is that modeling on a tow-by-tow basis may not be reliable and raises the question of how to handle relatively rare "disaster tows" that generate large amounts of bycatch. Regarding the Consolidation and Profitability models, the SSC recommends that effects on employment (e.g. crew shares) should be included as a main component of the analysis.

- The issue of dealing with changes in market power between harvesters and processors is important, and unsettled according to the Consulting Team. The SSC recommends reviewing current literature on this subject [e.g. Matulich, S., and M. Clark. 2003. North Pacific Halibut and Sablefish IFQ Policy Design: Quantifying the Impacts on Processors, Marine Resource Economics, 18(2), 149-166.].

- The SSC discussed potential problems in the initial allocation if healthy and overfished stocks are not treated differently. Specifically, past catch may work well for establishing the initial allocation of permits for healthy stocks. However, this type of allocation rule could create a perverse reward for vessels with the highest levels of catch for overfished species. An alternative is a uniform allocation of quota shares for these stocks.

Finally, the SSC wishes to highlight the complexity of the efficiency and equity trade-offs that are likely to occur under any IFQ program, and for the possibility of unforeseen consequences. The Consulting Team indicated that a range of estimates for potential efficiency gains (i.e. benefits), and costs of implementation, should be available to inform the Council after the analysis proposed in the Stage 1 Draft document is complete.

GROUNDFISH TRAWL INDIVIDUAL QUOTA COMMITTEE REPORT ON TRAWL INDIVIDUAL QUOTA ANALYSIS REVIEW OF STAGE 1 DOCUMENT

The Trawl Individual Quota Committee (TIQC) met Sunday June 11, 2006 and reviewed the proposed restructuring of the management regime alternatives, the individual fishing quota (IFQ) program alternatives, and other areas where the Council staff sought additional guidance (Agenda Item F.3.a, Attachment 2; Staff Report, Issues for Council Consideration). The TIQC recommends the Council modify the specifications provided in the staff report as follows:

1. Restructuring IFQ Program Alternatives

With respect to the three program alternatives, change the section on initial allocation of quota shares to groups of initial participants to the following:

Program A	Program B	Program C
Initial Allocation of Quota Shares, Section B.1.0		
Eligible Groups: 50% to current permit owners; 50% to processors.	*Eligible Group Suboption B-1:* 100% to current permit owners. ~~*Eligible Group Suboption B-2:* Nonwhiting--100% to current permit owners. Whiting--50% to current permit owners; 50% to processors.~~ ~~*Eligible Group Suboption B-3:* 90% to current permit owners; 10% to processors.~~	***Eligible Groups:* 75% to current permit owners, 25% to processors.** **(NOTE: For the nonwhiting shoreside fishery only, up to 20% of the quota pounds will be held back from the allocation (off the top) to support the community stability holdback. Each year, the Council will have the flexibility to determine whether 20% or some lesser amount will be held back.**

2. Specification of Design Elements

For purposes of allocation of QS/QP (quota share/quota pounds), two types of processors are defined for any program which includes an initial allocation of quota share to processors. These definitions will apply only for the initial allocation and not for other purposes (unless otherwise specified):

1. At-sea processors are those vessels that operate as motherships in the at sea whiting fishery or those vessels permitted to operate as catcher-processors in the catcher-processor whiting fishery.
2. A shoreside processor is an operation, working on US soil, that takes delivery of trawl-caught groundfish that has not been "processed at-sea" and that has not been "processed shoreside"; and that thereafter engages that particular fish in "shoreside processing."

    a. "Shoreside Processing" is defined as any operation that takes place shoreside; and that involves:

1) cutting groundfish into smaller portions; OR
2) freezing, cooking, smoking, drying groundfish

and packaging that groundfish for resale into 100 pound units or smaller for sale or distribution into a wholesale market.

b. The purchase and redistribution into a wholesale market of live groundfish from a harvesting vessel is also defined as "shoreside processing."
c. Entities that received fish that have not undergone "at-sea processing" or "shoreside processing" (as defined in this paragraph) and sell that fish directly to consumers shall not be considered a "processor" for purposes of QS/QP allocations.
d. The recipient of the groundfish listed on the fishticket is presumed to be the first processor unless evidence is presented to NMFS that some other entity was the processor as defined in this section.

For the at-sea fishery, observer data and weekly processing reports will be used to document landings. Item d. may potentially result in conflicting claims to the history for a particular landing (e.g. claims by the first receiver and a processing company to the history for same fish ticket). This will create a need for adjudication. Further criteria will need to be developed for use in adjudication.

3. Definition of a Whiting Trip

Two options exist for the definition of a whiting trip. Based on its review of scattergrams showing the pounds of whiting and percent of whiting for trips in 2002, 2003, and 2004, the TIQC recommends that any trip composed of more than 50% whiting be considered a shoreside whiting trip. The rejected alternative would have defined a whiting trip as those trips composed of more the 50% whiting or trips with more than 10,000 pounds of whiting. The TIQC rejected the 10,000 pound option out of concern that different type of IFQ might be required for whiting and nonwhiting trips. If a vessel went out intending to make a whiting trip covered with IFQ for the whiting fishery and the trip was cut short, such that 10,000 pounds was not taken, then the vessel might not have the right type of IFQ to cover the catch.

4. Bycatch in the Whiting Fishery under Alternative 2

The TIQC is concerned about how bycatch in the whiting fishery would be managed under Alternative 2 and would like to explore the possibility of creating co-ops for that alternative. The TIQC would like to address this issue in more detail and report back at the next meeting. It is the TIQC's understanding that taking another meeting to develop this specification will not delay the early part of Stage II of the analysis.

5. Provisions for a Rollover of Unused IFQ from One Whiting Sector to Another

The IFQ program includes the possible provision of a rollover of unused IFQ from one whiting sector to another. Additional detail needs to be developed for this alternative. The TIQC will take this up at its next meeting. Again, it is the TIQC's understanding that taking another meeting to develop this specification will not delay the early part of Stage II of the analysis.

PFMC - 6/13/06

PACIFIC MARINE CONSERVATION COUNCIL

Mr. Donald K. Hansen
Chairman
Pacific Fishery Management Council
7700 NE Ambassador Place, Suite 200
Portland, Oregon 97220-1384

April 14, 2006

Re: Trawl Individual Fishing Quota analysis

Dear Chairman Hansen,

Thank you for the opportunity to comment on behalf of Pacific Marine Conservation Council (PMCC) on the preliminary analysis that might be used as the basis for developing a draft environmental impact statement for a proposed west coast groundfish dedicated access privilege program (DAP). PMCC is a nonprofit fisheries conservation group that includes commercial and sport fishermen, marine scientists, conservationists and community advocates.

PMCC is very concerned about the inadequacy of the range of alternatives currently under analysis, the basic features within the alternatives, and the failure of program developers to fully implement the DAP-related recommendations of the U.S. Commission on Ocean Policy (USCOP). We've expressed these concerns in scoping, in written comments and in oral testimony, and we'll attempt to avoid redundancy here.

We hope that these comments will be useful for those developing the west coast DAP analysis for the Pacific Fishery Management Council (PFMC), as well as useful to members of the PFMC as they direct changes to the content and approach of the analysis.

A suite of alternatives that represent an adequate range of possible actions should be adopted. Apparently this step still requires additional guidance from the PFMC.

Once the alternatives are clear, each alternative should be evaluated relative to each of the goals and objectives as adopted by the PFMC. This step is not adequately explicit in the draft analysis as of this date. PMCC also recommends a concurrent evaluation of each alternative for conformity with the recommendations of the USCOP. It is particularly important to the public interest whether or not substantial and measurable conservation benefits would result from alternatives, as measured against the future baseline.

We feel strongly that it is essential when developing management options for the groundfish fishery, especially new approaches such as DAPs, to assume that area management will need to play a role. We discuss this below in the context of the emerging science that describes spatial limits for sub-populations of some fishes, as well as in the interest of equity benefits of smaller management units. The trend toward area management is obvious and this analysis should acknowledge this reality both in terms of program features and in the description of future baseline conditions.

PO Box 59, Astoria, Oregon 97103 Tel: 503-325-8188 Fax: 503-325-3584 www.pmcc.org

Community impacts objective

As PMCC previously testified at the March 16, 2006, meeting of the Trawl Individual Quota Independent Experts Panel, a modification to Objective 7 (page 27 of the draft analysis) should be made to reflect guidance from the PFMC. This change is significant because it reflects the stronger intention of the PFMC to "Minimize adverse effects from an IFQ program on fishing communities."

On page 30 of the June 2005 PFMC minutes it is recorded:

"Mr. Anderson asked for a friendly amendment to Motion 19, that would modify the goals and objectives on page 2 of C.5.a, Attachment 1 as follows: change goal 1 to read "and attainment of fishery management objectives" and remove the words "to the extent practicable" under Objective 7. The motion was accepted as a friendly amendment."

Motion 19 later passed.

PMCC finds that the tools to mitigate adverse impacts to communities analyzed thus far are deficient to achieve that end. The most basic of tools that should be part of any IFQ program is a conservative and enforceable cap on consolidation of *control* of quota shares.

Additional tools that are reasonable to evaluate include spatial distribution of quota to protect community interests (as well as to avoid local depletion of sub-populations of fish), direct distribution of quota to communities, provisions that allow fishermen and groups representing any type of commercial or recreational effort to own quota, and establishment of stewardship areas prior to or concurrent with implementation of a DAP.

Alternatives Considered but Excluded from Detailed Analysis

PMCC is concerned about what we consider the premature rejection of alternatives and features of alternatives from detailed analysis. Some of these we consider to be within a reasonable range of alternatives that could accomplish the goals and objectives adopted by the PFMC.

We find it somewhat arbitrary to presume, as stated on page 55 of the draft analysis, that "Elements and options that are included in the Components Analysis will be assessed in a both a quantitative and qualitative manner that will include the justification for exclusion."

PMCC is interested, for example, in a full analysis of bycatch sector caps by gear type and geographic area, to provide a fair contrast of this approach with other alternatives. Such an approach has been anticipated as a bycatch reduction system as outlined in Amendment 18 of the Pacific Groundfish Fishery Management Plan.

We also agree with the PFMC that an alternative based on IFQs for overfished species should be included. Again, from page 30 of the June 2005 PFMC minutes:

Mr. Anderson moved (Amendment #4 to Motion 19) to add to the package for analysis recommendation C from the GMT report (IFQs for overfished species only). Mr. Mallet seconded…. Amendment #4 passed.

Consistency with Congressional action

Congress is taking up reauthorization of the Magnuson-Stevens Fishery Conservation and Management Act, and there is a likelihood that such legislation will be passed this year. One bill, S.

PO Box 59, Astoria, Oregon 97103 Tel: 503-325-8188 Fax: 503-325-3584 www.pmcc.org

2021, has passed out of the Senate Commerce Committee. This bill includes basic standards that apply to Limited Access Privilege Programs (LAPP), such as this trawl IFQ. Two bills introduced in the House of Representatives, H.R. 5018 and H.R. 5051, include similar standards.

A stand-alone bill, the Fishing Quota Standards Act or H.R. 3278, has also been introduced in the House. The provisions in this bill closely track the recommendations of the USCOP and the PMCC positions regarding national standards for IFQs.

PMCC believes that it would be wise to craft the quota system alternatives so that they are consistent with standards under consideration by Congress. We realize that there has been discussion of an attempt to exempt this program from national standards designed to protect the environment and our fishing communities. Please consider however, the Congressional intent expressed in the report language which accompanies S. 2021:

> EFFECT ON CERTAIN EXISTING SHARES AND PROGRAMS- New section 303A(h) would ensure that section 303A would not require a reallocation of quota share from any limited access system, including sector allocations, submitted to the Secretary and approved by the Council prior to the date of enactment of this bill.
> However, the LAPP provisions of S. 2012 adopt the recommendations of the U.S. Ocean Commission, and the Committee expects that quota programs now being developed by the Councils will incorporate these recommendations even before enactment of this legislation. The Committee recognizes that Councils must move forward on programs under development and does not intend to cause unwarranted delays by requiring mature plans to be re-drafted wholesale. But Councils should attempt to ensure plans adhere to the spirit of the criteria recommended by the U.S. Ocean Commission and those contained in the bill in order to improve the consistency and fairness of future programs.

Area management in the future of the groundfish fishery

The way that west coast groundfish fisheries are managed is out of balance. The existing coast-wide management approach of West Coast groundfish does not protect the biological structure of fish populations, encourages local area depletion and provides disincentives for conservation-minded fishermen. As a result of this approach, high levels of bycatch in one geographic area can shut down fishing in other geographic areas.

Recent science (reviewed by Berkeley et. al. 2004) concludes that fish stocks may consist of "several reproductively isolated units, and that recruitment may come from only a small and different fraction of the spawning population each year." The authors go on to state that "the age structure of a stock combined with the spatial distribution of recruitment are as important as spawning biomass in maintaining long-term sustainable population levels. In particular, there is an increasing number of examples of complex population structure in species currently managed as a unit stock, and increasing evidence that only a small fraction of spawners in a stock – those that spawn at the right time and place – successfully contribute to each new cohort." None of this variation is currently accounted for in the management of West Coast groundfish populations. Recent modeling efforts also suggest that age structure can have a profound effect on recruitment variability in cod (Begg and Martiensdottier 2002) and sustainable harvest levels in rockfish (Spencer et al. *in press*).

Attempting to manage constraining overfished species on a coastwide basis is an ongoing challenge just in seeking fairness and equity between gear groups and regions. Add to this the evidence that local depletions may lead to stock fragmentations and it starts to become clear that the entire coast is likely too broad a scale for management of at least some species. And it could get worse. Tradable IFQ shares would likely encourage local depletion more than current management, and at the same time could further limit opportunities for fishing in areas where populations are abundant.

Solutions that move toward area management will likely appear at multiple scales in an adaptive process. Precautionary measures such as harvest guidelines by state have already been used, even without stock assessments that explicitly evaluate the relative strength of fish populations by region. Differential trip limits broken by capes or state lines have also been used.

A natural and practical way for this to progress is to cape-to-cape management, which would divide the west coast management unit into smaller areas delineated by Cape Flattery, Cape Blanco, Cape Mendocino, and Point Conception, well-known biogeographic boundaries in fish distributions. Beyond the biological benefits, a thoughtful approach to management on smaller scales could promote local stewardship and benefit communities as well.

It makes good sense to at a minimum provide for distribution of DAP quota shares on a geographic basis. The British Columbia groundfish trawl individual vessel quota program took such an approach, even in the absence of data identifying sub-populations of quota fish. Managers in British Columbia had the foresight to anticipate the disruption a future redistribution of quota by area would have on the fishery.

Even if spatial elements are not included within the DAP alternatives, which we believe would be a grave mistake, the practicality of area management cannot be ignored. First, the science is emerging that will likely necessitate management of some species at smaller geographic scales. Second, there is strong demand in some communities for area management, and for stewardship areas that could provide, among other benefits, local incentives for effective conservation. And, third, the problem of bycatch has not gone away just because a DAP is under consideration. Although Amendment 18 unacceptably lacks a time schedule for action to reduce bycatch, it does express the intent of the PFMC to institute bycatch caps by fishing sector, which could be subdivided geographically.

PMCC believes that all of these trends and expectations should be part of the analysis of future baseline conditions, both for the purpose of evaluating any incremental benefits of each DAP alternative, and for anticipating the management environment at the time when a DAP might be implemented.

Thank you for considering our comments.

Respectfully submitted,

Peter Huhtala
Senior Policy Director

References: *We cited some of these documents in our comments. All of them are incorporated into our comments by reference, because we believe that they each contribute to understanding facets of recent science regarding stock structure and spatial distribution of fish populations. We believe that awareness of this information should compel inclusion of spatial elements within many DAP alternatives, and it also provides insight into the scientific basis for a trend in west coast groundfish fisheries toward area management. Astoria, OR 97103

May 02, 2006

Dear Chairman Hansen;

I am a retired fisherman of 30 years. For 21 of those years I fished in the Alaska Halibut and Black Cod fishery, 9 of those years under the IFQ system. Last year I was asked by local Astoria/Warrenton based groundfish drag fishermen to help them with certain aspects of their Individual Transferable Quota System. After looking into their plan I could see that it was a very good idea. Being able to transfer too much of a certain species to another vessel (on paper) during a given trip would eliminate most bycatch. Making it 100% observer covered would be a major change from the "Good Old Days".

Processor or community quotas are not the way to go. Senator Smith's Two Pie Hake Quota is definitely not the way to go. Making our fishermen into modern day sharecroppers under either processor or community quotas is not the American way. Keeping fishermen as independent as possible is the proper course. I was able to use the quota I received as collateral for two seperate loans. I used that money to refurbish my boat, and acquire more quota. That money made its way to local shipyards, engine dealers, electronic stores, gear stores, and quota brokerages. The days of the company store are over. Lets not go back to that.

Chairman Hansen, I want to thank you and the council members for all the time you give to your community. This time that you give back to your community is a choice that you make. Please allow our fishermen to be able to continue to make decisions and choices. They can do that much better under Private ownership of quota, not under processor or community quotas.

Sincerely;
Bernard Bjork

Mr. Donald K. Hansen, Chairman
Pacific Fishery Management Council
7700 NE Ambassador Place, Suite 200
Portland, OR 97220-1384

RE: Agenda item F.3

Dear Chairman Hansen:

I attended the Trawl workshop in Portland on April 19th to find out how the Contractor intends to analyze the potential impacts of a trawl IQ plan on communities. The community session was held at the end of the workshop, many people had left, and the Contractor decided to change the format and give each person a chance to comment instead of breaking into working groups. I think it is important to note that what many people consider to be the most important issue—how the trawl IQ plan will negatively impact coastal communities and other fisheries—wasn't approached with the same process as the other issues. I believe it is critical that the PFMC not allow community impacts to be pushed aside or given token analysis. The following issues need to be analyzed by the Contractor before the Council moves forward with approving a trawl IQ plan:

--Community impacts: the Contractor proposed to limit analysis of impacts to communities to "trawl communities". **All coastal communities must be considered.** I can list a dozen negative impacts the trawl fishery and trawl management has had on my community, the non-trawl community of Port Orford, Oregon. One major impact is the groundfish harvest reductions brought on by destructive trawl gear that put the Port Orford longline fleet completely out of business. Another example is the influx of capital into the crab fishery from the trawl buyback that brought thousands of crab pots into an already over-capitalized fishery. There is a long list of negative impacts to my community over many years. I anticipate severe impacts to my community if the trawl IQ plan isn't designed with area-based IQs - where the fish was historically landed - the entire trawl IQ could end up being fished right here at Port Orford. Localized, serial depletion of fish stocks is a very real threat to our community.

--Loss of jobs in coastal communities: A major goal of IQs is to promote efficiency which translates to consolidation. Obviously many deckhands are going to lose jobs. I worked for the Oregon Groundfish Disaster Outreach Program and we had a tough time finding jobs in coastal communities for the displaced fishermen. Most people had to leave the coast and move to the I-5 corridor to find family wage jobs. It is devastating to coastal communities to lose working people, to lose families. The Council needs to acknowledge this issue and analyze it, and then decide if efficiency-a trawl IQ plan-is the best way to go.

--Impacts on other fisheries: IQs will make fishermen millionaires overnight. What will be the impact when IQ is sold and the fisherman invests the capital in other fisheries that have latent opportunity? That enormous influx of money into other fisheries will just shift the trawlers problems to other fisheries. For example, while the Oregon crab fishery is considered over-capitalized, at least 100 permits have landed less than 10,000 pounds in any one year of the 5 year window period for pot limits. That's a great deal of latent capacity available for the trawl IQ money.If Oregon does get a pot limit in place, highly efficient fishermen with lots of cash to reinvest buying latent permits, investing in the fastest boats and premium gear will severely impact the crab fishery. The same is true for west coast salmon. All fisheries have been negatively impacted by the trawl buyback money being poured into bigger, faster boats, more gear, purchasing latent permits. Do we need to destroy every fishery so the trawlers can "rationalize" their fishery?

--Impacts on other groundfish fishermen: The Council made a terrific mistake when you moved forward with a trawl only IQ program. The commercial longline fleet and sport and recreation fishermen are left with the unknown; we do not know what to expect for our fishery in the future. How do you intend to manage the other fishers? You should not move a trawl IQ program forward until you acknowledge what you are going to do about all the other groundfish fishermen. You have created incredible instability in the other groundfish sectors so the trawlers can get their IQ pushed through.

It is easy to understand why the trawlers want an IQ program. This is about making men millionaires. What is difficult for me to understand is what's in it for the PFMC that is the steward of the fish and the communities? What's in it for the country—this is a public resource?

Analyzing or scoping options for the IQ plan is important work for the Council to consider. The information generated from a thorough analysis of the impacts of a trawl IQ plan will provide critical guidance for the Council. Please spend the time and money needed to make sure you get the best possible information before you move the trawl IQ program forward.

Sincerely,

Leesa Cobb

Program Director

RE: June 16, 2006, Item F3 Trawl Individual Quota Analysis

Historically, the Central Coast harbors of California have sustained a vibrant trawl fleet whose year-round landings have provided the foundation for fishery-related businesses and harbor economic infrastructure. In recent years, seasonal/area closures, reduced quotas, and increased costs have caused severe stress on the participants in these fisheries and on related businesses, eventually impacting the harbors' ability to provide marine related services such as fuel, ice, chandleries and buyers. This is especially true in the California harbors that have only sporadic landings in other fisheries such albacore, salmon and crab. These harbors and their marine related businesses are dependent on ground fish landings. We now understand that the PFMC is considering a major change in fishery governance and regulations in ground fish with the issues surrounding individual fishing quotas for trawlers.

Small, fishing-dependent harbors, have concerns about IFQs to insure that such a governance change does not further diminish our local businesses' capacity to support harbor infrastructure and our fishing fleets. Earlier this year with the much appreciated support of the PFMC and its staff, the Fishing Heritage Group (FHG), hosted an IFQ workshop in Morro Bay, California to try to evaluate our situation in the context of your current IFQ considerations and attempt to formulate input to the PFMC.

We are concerned that a change to IFQs, without appropriate safeguards, could result in consolidation of buyers and fishing operations into a few harbors on the West Coast. This inevitably will collapse the many small, fishing-dependent harbors that have relied on ground fish for year-round employment and services support. Once traditional fishing uses are eliminated in a coastal community they do not come back, representing a real and permanent loss to the nation's seafood supply, economy, and missed opportunities in promoting sustainable fisheries with improved gear under the umbrella of ecosystem based management.

We encourage you to move carefully in your development of IFQ alternatives and deliberately try to protect existing fragile fishing businesses and small fishing-dependent harbors. Concepts we support and recommend for further thorough analyses are:

1) A Community stabilization holdback allocation or some other mechanism to insure broad participation in fisheries and protect the local economic and cultural values of small fishing-dependent communities on the Central Coast.
2) Consolidation caps or some other mechanism to avoid consolidation of fishing efforts and businesses into a few harbors and a few corporate owners.
3) Provisions that would allow gear switching between gear sectors, in a measured way that will not injure existing participants.
4) Development of an IFQ allocation formula based on years in the fishery, contribution to fishing dependent communities and conservation performance as well as catch history.
5) Stewardship area management that will improve regional management already in place, encourage conservation practices, and take advantage of price and seasonal market opportunities while accessing regionally plentiful fish stocks.
6) Current work effort on community profiles for West Coast fisheries. Collection of this baseline information should be expedited and highlighted. It will be vital to decision

making in the IFQ process to insure that we understand the value and importance of these communities along with the potential impacts of major governance changes.

Concurrently with ongoing analysis of IFQs as a management tool, we ask that the Council support and approve Experimental Fishing Permits (EFPs) that will help to develop bycatch reduction methods and incentives, environmentally friendly gear types and access to those plentiful stocks in the RCA or other under harvested resources that may provide the platform for gear switching programs.

We are a unique voice, representing some environmental protection groups, fishermen and Central Coast communities/harbor managers that provide a forum for the resolution of conflicts associated with a variety of fishery management issues. Trust is being built with the FHG and its diverse stakeholders on developing constructive approaches to the issues that face us, unified by the desire to maintain sustainable fishing businesses, while protecting our ocean environment into the future. We hope we can be a powerful partner with the PFMC as we work together to accomplish mutual goals. We stand ready to assist the PFMC in working through the complex issues associated with ground fish trawl IFQ programs, especially as it affects fisheries and communities of the Central Coast of California. Thank you for your consideration.

On behalf of the Fishing Heritage Group -

NATURAL RESOURCES DEFENSE COUNCIL

June 6, 2006

Agenda Item F.3
June 2006

Dr. Donald McIsaac, Executive Director
Pacific Fishery Management Council
7700 NE Ambassador Place, Suite 200
Portland, OR 97220-1384

Dear Dr. McIsaac and members of the Council:

On behalf of the Natural Resources Defense Council (NRDC) and our more than one million members and activists, we are writing to offer our comments on the Groundfish Trawl Individual Quota Stage I Analysis.

NRDC has a long-standing interest in the conservation of the Pacific groundfish fishery. While IFQs are an economic tool, they can be used to achieve conservation goals. If the Council determines that an IFQ system is necessary and appropriate for this fishery, the program should be done in a way that maximizes the conservation of groundfish populations and the protection of critical habitats and minimizes bycatch. After reviewing the Stage I analysis, we are concerned that many conservation tools are absent or appear to have been discarded without proper analysis. We ask that the analysis be revised to address the following concerns.

1. **Legal properties of quota.** We recommend that the Council adopt explicit language as part of any IFQ program clarifying that quota shares are privileges that can be revoked by NMFS or the Council. We suggest the following language, from S. 2012, stating that IFQs under this program:
   - shall be considered a permit for purposes of sections 307, 308, and 309 of the Magnuson-Stevens Fishery Conservation and Management Act;
   - may be revoked, limited, or modified at any time in accordance with the Act, including revocation for failure to comply with the terms of the plan or if the system is found to have jeopardized the sustainability of fish populations or safety of fishermen;
   - shall not confer any right of compensation to the holder if the privilege is revoked, limited or modified;
   - shall not create, or be construed to create, any right, title, or interest in or to any fish before the fish is harvested by the holder; and
   - shall be considered a grant of permission to the holder to engage in activities permitted by such limited access privilege.

San Francisco, CA 94104
TEL 415 875-6100 FAX 415 875-6161

NEW YORK · WASHINGTON, DC · LOS ANGELES

2. **Gear switching.** If the only way to get, use, and hold quota is to trawl then trawl gear will continue to be a major part of the groundfish fishery. The bycatch and habitat impacts of a permanent trawl fishery—even with the Councils' EFH provisions—are likely to be much greater than that of a fishery that includes a higher ratio of fixed gear to trawl effort. The Council should include a program allowing quota holders to convert from trawl gear to other gears without losing their quota or landings history. Analysis of such an option could help identify measures that might be needed to avoid potential adverse impacts on other gear groups. For example, conversions could be limited to a certain amount of quota or vessels each year and linked to an analysis demonstrating the possible impacts of increased effort in areas open to fixed gear. We understand that Chris Kubiak and Rod Fujita have submitted a gear-switching proposal to the Allocation Committee, and we believe gear-switching should be explicitly addressed in the IFQ process.

3. **Initial allocation.** The analysis focuses primarily on using catch history and recent participation to award initial shares. NRDC strongly disagrees with this approach. One of the premises of an IFQ system is that they are a market-based approach to allocating fish, and yet Section 1.2.1 of the analysis indicates that market-based approaches to initial allocation, such as auctions, will not be considered. An allocation system based solely on past performance places the Council in the extremely difficult position of picking winners and losers, and invariably leads to extensive analyses of multiple allocation schemes as everyone strives to be in the winners circle. We believe it could be much more effective to structure a tiered auction, including categories for different size vessels and a cap on consolidation. This also has the benefit of returning more of the real value of the public resource to the public trust and providing start-up management funds. Tiered lotteries can provide many of the same benefits without forcing the Council to reward or punish individual fishermen. We ask the Council to reconsider auctions and lotteries in initial allocation.

   At a minimum, catch history and recent participation should be part of a multi-factor allocation system that also includes conservation criteria, such as a vessel's history of low bycatch rates.

4. **Hard bycatch caps**. Because of the multi-species nature of the groundfish fishery, it includes several overfished species as well as species whose market value has changed dramatically over time. NRDC supports hard bycatch caps for overfished species, as well as measures designed to keep the total mortality of every managed species within its OY, and measures that will systematically reduce the bycatch of species without OYs over time (e.g. a bycatch cap with annual reduction targets until a minimum level is reached). NRDC does not support rollover of quota for overfished species.

5. **Processor quotas.** NRDC is opposed to a separate system of processor shares and we support the Council's current decision to forgo such a system and only focus on quotas for catching fish.

Designing and implementing an IFQ program is a complex process and we appreciate the Council's work in keeping its process accessible and open to the public. We look forward to continuing to work with the Council and staff on groundfish management.

Sincerely,

Karen Garrison

Kate Wing

CONSIDERATION OF INSEASON ADJUSTMENTS

The Council set optimum yield (OY) levels and various management measures for the 2006 groundfish management season with the understanding these management measures will likely need to be adjusted periodically through the biennial management period with the goal of attaining, but not exceeding, the OYs. The Groundfish Management Team (GMT) will begin meeting on Sunday, June 11, 2006 and the Groundfish Advisory Subpanel (GAP) will begin meeting on Monday June 12, 2006 (see Ancillary A and C agendas) to discuss and recommend inseason adjustments to ongoing 2006 groundfish fisheries.

Under this agenda item, the Council is to consider advisory body advice and public comment on the status of ongoing fisheries and recommended inseason adjustments prior to adopting final changes as necessary.

Council Action:

1. **Consider information on the status of ongoing fisheries.**
2. **Consider and adopt inseason adjustments as necessary.**

DRAFT CALIFORNIA DEPARTMENT OF FISH AND GAME REPORT ON INSEASON MANAGEMENT PROPOSALS FOR THE 2006 CALIFORNIA RECREATIONAL FISHING SEASON

BACKGROUND AND PROPOSED ACTION

The Pacific Fisheries Management Council (Council) approved inseason changes to California's recreational 2005 season and depth structure at its March 2005 meeting. The Council, in adopting these changes, took into account a number of factors including: 1) the 2004 annual California Recreational Fisheries Survey (CRFS) estimates of recreational take which showed that harvest of overfished species was below their respective California recreational harvest targets in 2004; and 2) the improved ability for real-time inseason catch monitoring through the new CRFS program. The March 2005 inseason changes provided more recreational fishing opportunity while keeping projected impacts (derived from California's recreational catch model) within recreational harvest guidelines or allocations for overfished and constraining species.

In March 2006, complete CRFS estimates of recreational take for 2005 (through December) became available. These estimates indicated that even under this modified management structure adopted at the March 2005 meeting, the California recreational harvest guidelines or allocations for overfished species were not exceeded and, in some cases, catch was well below the projected impacts. However, due to the shallow water restriction of 20 fm in some areas, fishing pressure was increased on nearshore groundfish species resulting in take that met or exceeded these species OYs or harvest targets. These results suggest that the current 2006 management structure could be further modified to allow for additional fishing opportunities for shelf species such as vermilion rockfish (thereby reducing fishing pressure on nearshore groundfish species such as the nearshore rockfish and cabezon), while still remaining within recreational harvest targets for overfished and constraining species.

A proposed season and depth structure for the California recreational fishery is provided in Attachment 1. We request that the Council consider adopting at the June 2006 PFMC meeting these inseason management measures in federal waters for 2006.

A table with the impacts of this proposed inseason change is provided below. These impacts were projected using a modeling approach that has been reviewed and approved by the Groundfish Management Team for use in crafting 2007-2008 recreational fishery management options.

Prepared by: Debbie Aseltine-Neilson, Susan Ashcraft, Deb Wilson-Vandenberg, and Kirk Lynn

ESTIMATED IMPACTS RESULTING FROM ACTION:

Species		2005 CRFS Catch Estimates	Projected 2006 Catch Estimates Under Current Regulations	Projected 2006 Catch Estimates Under Proposed Changes	HG[1], updated impact estimate[2], or HT[3]
Rebuilding Species	Bocaccio	38	52	66	66[2]
	Canary	2.3	6.2	7.9	9.3[1]
	Cowcod	0.1	0.2	0.3	0.4[3]
	Darkblotched	0	0	0	0[2]
	Lingcod	300	256	228	422[1]
	POP	0	0	0	0[2]
	Widow	1.7	5.7	17.6	17.6[2]
	Yelloweye	1.7	1.5	1.3	3.7[1]
Other Target Species	Black RF	180	176	142	171[3]
	Minor NS RF North (40˚10' – CA/OR)	19.9	17.3	15.3	15.3[2]
	Minor NS RF South (40˚10' – US/Mexico)	430	447[5]	436[5,6]	383[3]
	Cabezon	41.8	43.0	33.5[6]	42.1[4]
	Greenlings	4.8	6.7	5.5	15.5[4]

1 – Harvest Guideline (HG) established in Federal Regulations
2 – Best estimate of recreational impact in 2006
3 – Harvest Target (HT): For black rockfish, this is the state-derived recreational harvest target within the Federal HG for CA recreational and commercial catch, combined. The black rockfish recreational target is derived from CA Fish and Game Commission allocation guidance between recreational and commercial sectors.
4 – Total Allowable Catch (TAC) established in State Regulations.
5 – Includes increased take of California scorpionfish projected under California regulations which now couples fishing for California scorpionfish with fishing for nearshore rockfish, resulting in the same seasons and depths for both.
6 – These species show a reduction in projected take under the proposed inseason change primarily because the projection model does not include an increase in catch due to an inshore shift in effort when fishing is at or greater than 40 fm.

Attachment 1. Proposed California Recreational Inseason Action for June 2006 PFMC Meeting.

Agenda Item F.4.e
Public Comment
June 2006

Dear Don,

I have fished for over 35 years and own a part in a crab processing cannery. This is the oldest continuously operating cannery on the Col. River. In the last year we began purchasing black cod, I have been out on the open access part with one of my sons. We have a $1500 electronic scale on the boat — we weigh one garbage can at a time — as the boat rolls — 99 — 102 — 101 — 99 — 100 — and so on — looks like a 100 ~~lbs~~ — dump them into the slush ice — do it again — 10 times = 1000 lbs — everyone usually has some extra to throw over — hopefully theyre alive. Any way we get to the cannery — up the hoist — And the weight is 1011 ~~lbs~~ — now what — was it slush ice theyre suspended in — taking on a little water — or the almost impossible chance to hit 100 each time?

Some guys draw a line around the garbage can, also one around the tote — but again a guess — if they are smaller they pack more and your over a little.

Believe me were trying to be honest — we're facing this delima at our cannery right now.

How can we improve this program?

I know you guys are on the enforcement review at your next meeting — so let me try some thoughts from the fishermen and cannery

(2)

point of view — What if you created a realitively small range of overages – lets say 5% – 6% — or 50 Lbs. – something not very large – just enough to help make it possible to be close. There shouldn't be any incentive for the fisher to go over, — so buyer would make out a state ticket and send the overage check to the state or Nat. Mar. fish –

Then the next part for no incentive is the obvious fact that what ever the overages add up to would come off the final bio mass that is allocated to the open access. You would get a pretty good picture of how the small overages add up — by mid season you would have a pretty good scientific picture of what the final adjustment would be — As you put a couple of years into this method I believe you would have a good picture how it works –

It is very hard to "hit" the number – and most fishermen don't want to throw them back — esp. at the cost of fuel — I would hope you wouldn't just drop the weekely level by 50 Lbs. for every delivery, because I believe in most cases guys will get pretty close either just below or a little above. With negative incentives – Pay the state (no wants to do that) and the adjusted loss from the total! Please think about this – only trying to keep us legal —

Sincerely – Steve Gray – 360 642-2408 —

Agenda Item F.4.b
Supplemental GMT Report
June 2006

THE GROUNDFISH MANAGEMENT TEAM (GMT) REPORT ON CONSIDERATION OF INSEASON ADJUSTMENTS

The GMT reviewed several inseason management issues and have the following recommendations for consideration by the Council.

COMMERCIAL

Darkblotched Rockfish Bycatch Limits For The Whiting Fishery

In the non-tribal sectors of the whiting fishery, overfished species bycatch limits are currently in place for canary (4.7 mt) and widow rockfish (200 mt). Prior to the start of the 2006 whiting season, the projected catch of darkblotched rockfish by the non-tribal sectors was 16.2 mt. Although the Council considered a bycatch limit for darkblotched rockfish at its March and April meetings, a limit was not adopted.

At the Council's April meeting, in response to the Council request to examine a darkblotched rockfish bycatch limit, the GMT identified the need for whiting vessels to have flexibility to change fishing locations to avoid Chinook salmon, canary and widow rockfish; recognized that darkblotched rockfish encounters could increase if the fishery chose to operate in deeper waters to avoid Chinook salmon or overfished shelf species; recognized that the increased abundance of darkblotched rockfish as it nears the rebuilt stock level could also result in an increased bycatch rate for darkblotched rockfish; and, highlighted the past success of the whiting fishery to modify their fishing behavior to avoid all species of concern. Therefore, the GMT did not recommend a specific darkblotched rockfish bycatch limit to the Council.

Since the start of the 2006 primary whiting season, higher than anticipated darkblotched rockfish catch has occurred in the shore-based and at-sea fisheries. In addition, higher than anticipated darkblotched bycatch has occurred in the bottom trawl fishery. Data available on June 9, 2006, indicates that 30 mt of darkblotched rockfish could be taken by the non-tribal whiting sectors if the current catch rates continue throughout the season. The GMT believes that a 25 mt darkblotched rockfish bycatch limit for the non-tribal commercial sectors would reduce the likelihood of the darkblotched rockfish OY being exceeded, and reduce the risk of the whiting fishery affecting the continuance of other groundfish fisheries that encounter darkblotched rockfish. If the Council imposes substantial restrictions to the bottom trawl fishery to reduce darkblotched rockfish catch, there is still a substantial risk that the darkblotched rockfish OY may still be exceeded if the current darkblotched bycatch rate in the whiting fishery continues without a bycatch limit. It is important to recognize that proposing 25 mt cap for darkblotched rockfish in the whiting fishery is not equivalent to a bycatch allocation. There would be no guarantee that the whiting fishery would have the full 25 mt available to achieve the whiting OY. However, the GMT recognized that there is limited ability to detect and respond inseason to darkblotched rockfish harvest targets being exceeded in the non-whiting fisheries this summer, such that the whiting fishery could be restricted to prevent the darkblotched rockfish OY from being exceeded.

Darkblotched Rockfish Catch In The Limited Entry Bottom Trawl Fishery

Higher than expected darkblotched rockfish catch early in the year is projected to result in the darkblotched rockfish OY being exceeded by late summer unless the bottom trawl fishery north of 38° N. lat. is constrained. Darkblotched rockfish catch is approximately 40-50% higher than what was projected at the start of the fishing year. Preseason projections in January 2006 had indicated that 80-90 mt of darkblotched rockfish would be taken by the end of June. However, current data indicates that 122 mt will be taken by the end of June 2006. If measures are not taken to constrain the bottom trawl fishery, the groundfish fishery as a whole (including the whiting fishery) is projected to take 284.1 mt of darkblotched rockfish through the end of the year, exceeding the 200 mt OY. Approximately 20 to 30 mt are needed for the period 6 petrale fishery to occur. With an OY of 200 mt and a projected catch of 122 mt through the end of June, the catch of darkblotched rockfish needs to be minimized from July 1 through the end of October for the period 6 petrale fishery to occur.

To slow the catch of darkblotched rockfish in the bottom trawl fishery, the GMT considered options for increasing the size of the RCA north of 38° N. lat. for July through December, reducing cumulative limits for slope rockfish and species that co-occur with darkblotched rockfish, and reducing limits in areas where fishing effort shifts could result in high catch of other overfished species. The GMT considered changes to RCA boundaries and cumulative limits and would like to forward three options to the Council for consideration

OPTION B.1: Beginning on July 1, move the seaward boundary of the RCA north of 38° N. lat. out to 250 fm from July through the end of the fishing year (with petrale sole modifications for the November-December period); and move the shoreward boundary of the RCA north of 40° 10' N. lat from 100 fm to 75 fm for the July–August cumulative period.

OPTION B.2: Beginning on July 1, move the seaward boundary of the RCA north of 40° 10' N. lat. out to 250 fm from July through the end of the fishing year (with petrale sole modifications for the November-December period); and move the shoreward boundary of the RCA north of 40° 10' N. lat from 100 fm to 75 fm for the July–August cumulative period. Beginning July 1, move the seaward boundary of the RCA between 38° N. lat and 40° 10' N. lat to 200 fm until the end of August, and move the seaward boundary of the RCA between 38° N. lat and 40° 10' N. lat to 250 fm from September 1 to the end of the year (with petrale sole modifications for the November-December period).

OPTION B.3: Beginning on July 1, move the seaward boundary of the RCA north of 40° 10' N. lat. out to 250 fm from July through the end of the fishing year (with petrale sole modifications for the November-December period); Beginning July 1, move the seaward boundary of the RCA between 38° N. lat and 40° 10' N. lat to 200 fm until the end of August, and move the seaward boundary of the RCA between 38° N. lat and 40° 10' N. to 250 fm from September 1 to the end of the year (with petrale sole modifications for the November-December period).

In addition to RCA changes under either Option B.1 and B.2 the following trip limit changes would be made:

- reduce the “minor slope & darkblotched rockfish” trawl limits (large footrope, small footrope, and selective flatfish trawl) north of 40° 10’ N. lat. to 1,000 lb per 2 months.

- reduce the “minor slope & darkblotched rockfish” trawl limit between of 40° 10’ N. lat and 38° N. lat. to 1,000 lb per 2 months.

- reduce the splitnose rockfish trawl limit between of 40° 10’ N. lat and 38° N. lat. to 1,000 lb per 2 months.

- reduce selective flatfish trawl limits north of 40° 10’ N. lat. for Dover sole to 20,000 lb per 2 months, Other Flatfish to 40,000 lb per 2 months, petrale sole to 18,000 lb per 2 months, and arrowtooth flounder to 40,000 lb per 2 months.

- increase the shortspine thornyhead limit for large and small footrope gear north of 40° 10’ N. lat and between of 40° 10’ N. lat and 38° N. lat to 7,500 lb per 2 months.

- reduce sablefish limts for selective flatfish trawl north of 40° 10’ N. lat for the July-August period to 7,000 lb per 2 months.

Under option B.3, trip limit adjustments would be the same as option B.2, but shoreward limits north of 40 degrees 10 minutes N latitude would remain as currently scheduled in federal regulations.

Each option can be differentiated by the amount of risk they pose to the darkblotched rockfish stock and the probability that a period 6 petrale fishery can be accommodated. Option B.1 reduces darkblotched rockfish catch more than Option B.2, but Option B.1 eliminates much of the period 4 fishing opportunity for trawl vessels that home port in Fort Bragg. Option B.3 is the same as B.2 for slope opportunities.

Measures proposed under Option B.1. are expected to result in 162.0 mt of darkblotched rockfish being caught through the end of the year for the non-whiting portions of the groundfish fishery, as compared to 165.6 mt of darkblotched rockfish that are projected to be taken under Option B.2 and Option B.3.

In addition to increasing the size of the RCAs, the GMT recommends reducing trip limits for slope rockfish. Reducing the slope rockfish limits is intended to eliminate any incentive to target slope rockfish species and to make reductions in darkblotched rockfish a bit more certain. The “shoulder” of slope rockfish distribution is about 250 fm, with fishable concentrations at these depths. Even though we assume slope species are sparse seaward of the 250 fm contour, some boats are currently targeting the slope limits now and may continue to do so even with a 250 fm line. Reducing the slope limit to 1,000 lb per 2 months is expected to eliminate the incentive to target slope rockfish and ensure an opportunity for a period 6 petrale sole fishery.

Generally, the GMT supports transitional slope rockfish management measures in the area between of 40° 10’ N. lat and 38° N. lat. (darkblotched rockfish abundance rapidly declines in the area yet are frequently encountered.) Inseason data for 2006 shows that darkblotched rockfish landings off California are approximately 6.7 mt south of 40° 10’ N. lat and approximately 8 mt north of 40° 10’ N. lat to the CA/OR border. Data provided by CDFG for the area between 40° 10’ N. lat and 38° N. lat indicate that in 2005, 79% of darkblotched rockfish came from shallower than 200 fm, while the remaining amount came from 200-250 fm (none deeper than 250 fm). However, over a longer period of time data indicated that 9% of the darkblotched rockfish catch was from waters deeper than 250 fm, approximately 20% was from 200-250 fm and approximately 70% was from waters shallower than 200 fm. Because of the clear need to reduce darkblotched rockfish catch to as low as possible the GMT recommends that the slope rockfish limit reductions also be applied to the area between 40° 10’ N. lat and 38° N. lat.

Moving the seaward line of the RCA to deeper depths is predicted to result in an increase in trawl fishing effort in the areas shoreward of the RCA. Canary impacts decline as the shoreward boundary of the RCA is shifted from 100 to 75 to 60 fathoms respectively. Because of concerns that the catch of canary rockfish could increase over current projections, Options B.1 and B.2 include cumulative limit reductions for Dover sole, Other Flatfish, petrale sole, and arrowtooth flounder. These reductions are projected to keep the projected impacts within the 8.0 mt canary level specified by the Council for the limited entry non-whiting trawl fisheries. Sablefish reductions during period 4 are proposed to minimize the effort shift into the shoreward areas.

The Council’s previous consideration of a shoreward trawl RCA boundary of either 60 or 50 fm generated a number of concerns from state management agencies, the coastal tribes and coastal fishers. Among these concerns are Dungeness crab impacts, particularly during the summer molting period when trawl mortality of soft-shelled molting crab is likely high. Additionally, the nearshore area is a nursery ground for juvenile flatfish and other groundfish species; concentrating trawl effort in this area could increase mortalities on juvenile and unmarketable fish, or even increase the risk of localized depletions. Additionally, fishers have repeatedly stated that the viability of the trawl fishery is markedly reduced as it is increasingly constrained to shallower areas. These factors should be considered in evaluating placement of the nearshore trawl RCA line.

Because the DTS fishery is projected to shift into deeper waters to protect darkblotched rockfish, raising the shortspine thornyhead limit is expected to reduce regulatory discards while keeping the total catch of shortspine thornyhead within the 1,011 mt commercial shortspine HG.

The GMT understands that the GAP preferred option is option B.3. for the bottom trawl fishery. This option keeps selective flatfish trawl limits and shoreward RCA boundaries north of 40 degrees 10 minutes N latitude as planned, pushes the seaward boundary of the RCA to 250 fm, and closes the shelf portion of the bottom trawl fishery when the fleet reaches 8.0 mt of canary rockfish. Under this scenario, the GMT estimates that 8.0 mt of canary is projected to be caught by September 30, which is after the September Council meeting and would allow the Council to take action in time to close the shelf portion of the fishery by October 1.

Trawl representatives have indicated that the limits proposed in option B.1 and B.2 are too low to justify fishing and would create substantial discard. However, processors have indicated that the risk of closing the shelf fishery in October poses an economic risk to markets for flatfish species. This has the potential to interrupt market flow, and if this occurs, this creates a scenario where existing markets may be lost.

The GMT recommends that, if the Council elects to continue with currently scheduled regulations for shoreward trawl opportunities north of 40 degrees 10 minutes N lat, that this be accommodated with an inseason trigger for NMFS to take action outside of the Council meeting, and that this action would be implemented on September 1.

Limits Currently in Regulation

Widow Rockfish Bycatch Limits For The Whiting Fishery

At the March 2006 Council meeting, the GMT examined the 2006 whiting OY alternatives in relation to the impacts on overfished species. With a whiting OY of 269,069 mt and in the absence of any further restrictions, the widow rockfish catch was estimated to be approximately 122 mt. After considering the projected catch of overfished species in all other fishing and research activities, the Council recommended that the bycatch limit for widow rockfish be set at 200 mt.

Bycatch of widow rockfish in the whiting fishery was estimated to be at 95.65 mt through June 8, 2006. The GMT discussed the use of sector specific bycatch limits; however, such limits are not currently available as a routine management measure. The GMT concluded that sector specific bycatch limits should be considered as part of the biennial specifications process rather than an inseason management measure.

Widow rockfish catch in all groundfish fisheries is 111 mt through June 8, 2006. Estimates based on inseason data through June 8, 2006 indicates that 174 mt of widow rockfish are projected to be taken in the whiting fishery by the end of the primary whiting season. For all groundfish fisheries, the projected catch of widow rockfish is 233 mt. At this time (prior to June inseason actions), 31.1 mt of widow rockfish is unassigned to any fishery or research.

Whiting Fishery Catch Through June 8, 2006

Sector	Whiting Allocation (mt)	Whiting Catch (mt)	Widow Rockfish Catch (mt)	Fishery Status	Percent Of Whiting Allocation Taken
Shore-based	97,469	5,241	3.38	CA fishery 4/1-5/25; Coastwide fishery starts 6/15	.3%
Mothership	55,696	35,896	64.47	Started 5/15	64.4%
Catcher/processor	78,903	23,207	27.80	Started 5/15	29.4%
Total Commercial	232,069	64,344	95.65		27.7%
Tribal	35,000	175	0.00		0.5%

Widow Catch in the whiting fishery by year, 2001-2005

Sector	2001	2002	2003	2004	2005
Motherships	27.68	20.43	0.69	11.42	35.5
Catcher/Processors	139.71	114.79	11.56	8.21	43.14
Tribal	3.28	19.49	2.15	1.50	1.91
Shore-based	44.27	5.11	12.54	28.26	77.15

Lingcod Harvest Guideline

The 2006 commercial harvest guideline for lingcod of 214.7 mt is projected to be exceeded before the end of the year. However, the anticipated total catch is not expected to exceed either the lingcod OYs (1,801 mt north of 42° N. lat. and 612 mt south of 42° N. lat) or the ABC (2,716 mt). Allowing the commercial lingcod harvest guideline to be exceeded will prevent the commercial fishery from being unnecessarily constrained.

Allowance For NMFS Inseason Action Between Council Meetings (Triggers)

In recent years there has been limited ability to respond to unexpected changes in undesirable harvest trends between the June and September Council meetings. By September, there is often very little that can be done to reverse "bad trends." However, the Council could choose to specify a routine management measure that it would like NMFS to take if a specific undesirable harvest trend occurs in the fishery between Council meetings. For example, if higher than projected catch rates of key species reaches a pre-specified threshold, NMFS could respond by reducing trip limits or shifting RCA boundaries as specified by the Council at its previous meeting. A GMT and/or Council level conference call could be incorporated into this process, if necessary.

In meeting with the GAP, the GMT found that there was support for this idea as a mechanism for addressing concern for the potential loss of the period 6 fishery, and concern that factors influencing other fisheries (low shrimp catches, etc) could result in greater bottom-trawl effort. The GMT considered the following triggers and inseason actions:

- Canary rockfish
    - A) If the catch of canary in the LE bottom trawl sector is projected to reach 7.25 mt of the by August 31, NMFS will move the shoreward boundary of the RCA in to 60 fathoms north of 40° 10' N. lat. for period 5. The GMT will re-evaluate management measures relative to canary rockfish at the Council's September meeting.
    - B) If the catch of canary in the LE bottom trawl sector is projected to reach 7.75 mt of the end of a month, NMFS will move the shoreward boundary of the RCA in to the shore north of 40° 10' N. lat. at the end of that month. The GMT will re-evaluate management measures relative to canary rockfish at the Council's September meeting.

- Petrale Sole – If the catch of petrale sole in the LE bottom trawl sector is projected to reach 2,000 mt (72% of the OY) by August 31, NMFS will reduce cumulative limits for petrale sole for period 5. Petrale sole limits for each type of bottom trawl and each area will be reduced by 8,000 lbs per 2 months coastwide, and limits of Other Flatfish and arrowtooth will also be reduced to 4 times the petrale sole limit if those limits are more than 4 times the petrale sole limit. The GMT will re-evaluate management measures at the September meeting.

Open Access DTL Sablefish Limits

Current Open Access Sablefish Limits	
North of 40°10'	300 lb/ day, or 1 landing per week of up to 1,000 lb, not to exceed 3,000 lb/ 2 months
40°10' - 36° N. lat.	

On May 1, 2006, per the Council's recommendation, NMFS reduced the OA DTL sablefish cumulative limit north of 36° N. lat. from 5,000 lb per 2 months to 3,000 lb per 2 months. The Council recommended this reduction in anticipation of a large influx of fishing effort into the DTL fishery as a result of salmon fishery closures. The minimal fishing gear needed to participate in the DTL fishery and numerous calls to fishery managers by new participants interested in entering in the fishery resulted in this concern. The amount of effort that could shift into the fishery could not be well estimated in April.

To date, the catch of OA sablefish appears to be higher in 2006 than catch projected from historical data. This supports the assumptions that restrictions in the salmon fishery may have resulted in increased effort in the OA DTL fishery, above what was expected for periods 1-3. Traditionally, most catches have occurred in the second half of the year, with period 4 (July-August) typically being the highest. If 2006 catches continue at a higher rate, then the OA sablefish allocation for the year would be taken under the current catch limits. Reducing the cumulative limit was intended to provide for a longer season, which was thought to most benefit fishers who have historically participated in the year-round fishery.

The GMT discussed the OA DTL limits with the GAP. At the GAP's request, the GMT considered when the fishery would reach the sablefish allocation under 2 month cumulative limits of 4,000 lbs and 5,000 lbs. With a 2-month cumulative limit of 4,000 lbs, the fishery is projected to reach the OA sablefish allocation in mid-November. With a 2 month cumulative limit of 5,000 lbs, the fishery is projected to reach the OA sablefish allocation in mid-October. With the current QSM system, it is not possible to look at the number of new entrants relative to last year.

The general consensus of the GMT was that effort-shift concerns are still high and would be more appropriately dealt with in September. Waiting to liberalize these limits until September, when effort shifts are better understood, would be unlikely to result in foregone yield, as measures taken in September could result in achieving targets by the end of the year.

RECREATIONAL

There are no inseason recreational proposals for Oregon or Washington, but both states report that their recreational fisheries are tracking behind expected catches at this point in time.

California Recreational Fishery

The GMT reviewed CDFG's proposed inseason changes to the current season structure for the recreational fishery provided in Agenda Item F.4.c CDFG Report and a revised set of tables provided during the GMT meeting (see Agenda Item F.4.c, CDFG Revised Supplemental Report). California's initial proposal increased the maximum fishing depth to 40 fm along the central and northern California coast. After review of available information on canary depth distributions, CDFG revised this proposal to extend fishing out to only 30 fm. The background for these proposed changes was discussed in the context of past "overages" by the recreational fishery prior to the implementation of the new recreational monitoring program (California Recreational Fisheries Survey – CRFS), and the rationale for expanding depth opportunities. Depth constraints have been imposed on the California recreational fishery since 2002. These constraints initially were imposed on only a part of the season, but in recent years fisheries in, areas such as central California have been constrained to approximately 20 fm throughout the season, raising concern about heavy fishing pressure on mostly unassessed nearshore rockfish stocks. Since CRFS estimates indicate bycatch of rebuilding species has been staying well below current targets, CDFG would like to move some of the fishing effort offshore, thereby relieving this fishing pressure.

The GMT acknowledged the benefit of moving anglers to deeper water to reduce pressure on nearshore rockfish stocks, but felt that these benefits needed to be weighed against the uncertainty of increased encounters with canary or widow rockfish. In particular, the GMT expressed concern over the increased impact on widow rockfish if fishing were allowed in depths to 40 fm. As part of the GMT discussion, CDFG shared information based on recreational sample data that indicated a higher probability of canary rockfish encounters between 30 and 40 fm, particularly at Deep Reef (San Mateo County) and some other spots in the North Central Rockfish and Lingcod Management Area.

The GMT also discussed the need for a rapid response if catches were projected to exceed California's recreational harvest guideline, as well as the inherent uncertainty in catch projections. There was some general discussion among the states that inseason tracking capabilities have improved to the extent that action can be taken in a timely fashion if expectations in the proposal are not met. The separate California harvest guideline and the capability of the new CRFS program to generate more timely catch estimates were identified as existing measures that help to minimize the resulting uncertainty.

Under the revised proposal, CDFG recreational model projection impacts on rebuilding species are expected to be: bocaccio 65 mt, canary rockfish 7.7 mt, widow rockfish 7.7 mt, cowcod 0.3 mt, lingcod 262 mt, and yelloweye rockfish 1.5 mt. All projected catch estimates continue to remain within harvest targets, allocations and/or California harvest guidelines. Impacts on target species are provided in Agenda Item F.4.c, CDFG Revised Supplemental Report.

The GMT supports the more moderate proposal provided in the CDFG Revised Supplemental Report. This will provide some relief to nearshore rockfish stocks while reducing the risks associated with moving to deeper waters. It also includes impacts to canary and widow rockfish that are more fully supported by the GMT. The 30 fm line in the CDFG Revised Supplemental Report is defined by waypoints, and may be more enforceable. In recognition of California's ability to track the fishery in a timely and accurate manner using CRFS, the ability to take prompt inseason action later in the year to close the fishery if expected harvests exceed projections should minimize the risk to overfished species associated with liberalizing the fishery.

A December lingcod opening was considered, but is not being recommended by the GMT. This is because the 2005-2006 EIS did not consider a year round lingcod fishery or fishing in December. Lingcod fishing was closed in December because of the need to protect them during spawning. In addition, the Council motion for California recreational management specifically included a December closure of the lingcod fishery. Benefits to overfished species that co-occur with lingcod as a result of the closures were also considered by the Council at that time. In addition, the groundfish Allocation Committee guidance to the GMT was to manage lingcod in 2006 under status quo management.

TRIBAL

The GMT discussed the Makah Tribe proposal to examine the effectiveness of different trawl gear configurations combined with area management to reduce impacts to overfished rockfish and Pacific halibut. To complete this work the Makah trawl fleet would create combined harvest targets for Dover sole and arrowtooth flounder that are equivalent to the limited entry cumulative limits specified for periods 4, 5, and 6 and which have been in place at the beginning of the year. When multiplied by the number of vessels (10) in the fleet, this represents a total fleet harvest target of 476.3 mt (1,050,000 lbs) for Dover sole and 1360.8 mt (3,000,000 lbs) for arrowtooth flounder. The GMT considered the tribal proposal and determined that the impact of the change is not expected to result in the OYs being exceed.

GMT RECOMMENDATIONS

- Adopt a 25 mt bycatch limit for darkblotched rockfish for the primary whiting fishery.

- Adopt Option B.1, B.2, or B.3. RCA modifications and trip limits for reducing darkblotched and canary rockfish catch in the non-whiting trawl fisheries north of 38° N. lat

- Allow the commercial lingcod harvest guideline to be exceeded.

- Recommend the adoption of triggers that allow NMFS to take action to restrict the non-whiting trawl fishery to reduce canary rockfish and petrale sole catch between the June and September Council meetings.

- Maintain the cumulative limits for sablefish in the OA DTL fishery at 3,000 lb/ 2 months and task the GMT with evaluating effort shifts into this fishery for potential inseason adjustments at the September meeting when further data become available.

- Consider inseason adjustments as proposed in the CDFG report under agenda item F.4.c.

- Consider tribal proposal to evaluate trawl gear effectiveness and area management.

DRAFT CALIFORNIA DEPARTMENT OF FISH AND GAME REPORT ON INSEASON MANAGEMENT PROPOSALS FOR THE 2006 CALIFORNIA RECREATIONAL FISHING SEASON

BACKGROUND AND PROPOSED ACTION

The Pacific Fisheries Management Council (Council) approved inseason changes to California's recreational 2005 season and depth structure at its March 2005 meeting. The Council, in adopting these changes, took into account a number of factors including: 1) the 2004 annual California Recreational Fisheries Survey (CRFS) estimates of recreational take which showed that harvest of overfished species was below their respective California recreational harvest targets in 2004; and 2) the improved ability for real-time inseason catch monitoring through the new CRFS program. The March 2005 inseason changes provided more recreational fishing opportunity while keeping projected impacts (derived from California's recreational catch model) within recreational harvest guidelines or allocations for overfished and constraining species.

In March 2006, complete CRFS estimates of recreational take for 2005 (through December) became available. These estimates indicated that even under this modified management structure adopted at the March 2005 meeting, the California recreational harvest guidelines or allocations for overfished species were not exceeded and, in some cases, catch was well below the projected impacts. However, due to the shallow water restriction of 20 fm in some areas, fishing pressure was increased on nearshore groundfish species resulting in take that met or exceeded these species OYs or harvest targets. These results suggest that the current 2006 management structure could be further modified to allow for additional fishing opportunities for shelf species such as vermilion rockfish (thereby reducing fishing pressure on nearshore groundfish species such as the nearshore rockfish and cabezon), while still remaining within recreational harvest targets for overfished and constraining species.

A proposed season and depth structure for the California recreational fishery is provided in Attachment 1. We request that the Council consider adopting at the June 2006 PFMC meeting these inseason management measures in federal waters for 2006.

A table with the impacts of this proposed inseason change is provided below. These impacts were projected using a modeling approach that has been reviewed and approved by the Groundfish Management Team for use in crafting 2007-2008 recreational fishery management options.

Prepared by: Debbie Aseltine-Neilson, Susan Ashcraft, Deb Wilson-Vandenberg, and Kirk Lynn

ESTIMATED IMPACTS RESULTING FROM ACTION:

Species		2005 CRFS Catch Estimates	Projected 2006 Catch Estimates Under Current Regulations	Projected 2006 Catch Estimates Under Proposed Changes	HG[1], updated impact estimate[2], or HT[3]
Rebuilding Species	Bocaccio	38	52	66	66[2]
	Canary	2.3	6.2	7.9	9.3[1]
	Cowcod	0.1	0.2	0.3	0.4[3]
	Darkblotched	0	0	0	0[2]
	Lingcod	300	256	228	422[1]
	POP	0	0	0	0[2]
	Widow	1.7	5.7	17.6	17.6[2]
	Yelloweye	1.7	1.5	1.3	3.7[1]
Other Target Species	Black RF	180	176	142	171[3]
	Minor NS RF North (40˚10' – CA/OR)	19.9	17.3	15.3	15.3[2]
	Minor NS RF South (40˚10' – US/Mexico)	430	447[5]	436[5,6]	383[3]
	Cabezon	41.8	43.0	33.5[6]	42.1[4]
	Greenlings	4.8	6.7	5.5	15.5[4]

1 – Harvest Guideline (HG) established in Federal Regulations

2 – Best estimate of recreational impact in 2006

3 – Harvest Target (HT): For black rockfish, this is the state-derived recreational harvest target within the Federal HG for CA recreational and commercial catch, combined. The black rockfish recreational target is derived from CA Fish and Game Commission allocation guidance between recreational and commercial sectors.

4 – Total Allowable Catch (TAC) established in State Regulations.

5 – Includes increased take of California scorpionfish projected under California regulations which now couples fishing for California scorpionfish with fishing for nearshore rockfish, resulting in the same seasons and depths for both.

6 – These species show a reduction in projected take under the proposed inseason change primarily because the projection model does not include an increase in catch due to an inshore shift in effort when fishing is at or greater than 40 fm.

Attachment 1. Proposed California Recreational Inseason Action for June 2006 PFMC Meeting.

CALIFORNIA DEPARTMENT OF FISH AND GAME REPORT ON REVISED INSEASON MANAGEMENT PROPOSALS FOR THE 2006 CALIFORNIA RECREATIONAL FISHING SEASON

In the Agenda Item F.4.c, CDFG Report, the California Department of Fish and Game provides an inseason proposal for the recreational 2006 groundfish fishery that includes changing the open recreational fishing depths from the Oregon/California border (42° N. lat.) to Lopez Point (46° N. lat) to 0-40 fm.. Under that proposal, the projected impact for widow rockfish in the bycatch scorecard increased to 17.6 although this additional impact was not expected to result in an increase above the OY. The projected increased impact on canary rockfish in the bycatch scorecard (6.2 mt) increased to 7.9 mt -- well under the harvest guideline.

After further review of the risks associated with moving anglers into deeper waters and a review of additional canary depth distribution information, concerns arose over the uncertainty of increased encounters with canary rockfish and widow rockfish above model estimates. Higher than projected canary or widow take could result in later inseason action to decrease the RCA boundary or close the fishery. Given that CDFG would like to prevent such an action, and given the unknown risks associated with the initial proposal, CDFG determined that a more prudent approach was warranted.

This revised supplemental report presents an alternative preferred proposal that provides for increasing the open recreational fishing depths to 30 fm from Cape Mendocino (42° 10' N. lat.) to Lopez Point as well as providing an additional month of fishing in the area between Lopez Point and Point Conception (34° 27' N. lat.). Similar to the previous proposal, this proposal includes increasing the depth in the Southern RLMA to 60 fms in September and October.

The rationale for relaxing the current depth restrictions is the same as that provided in the Agenda Item F.4.c CDFG Report. To summarize, the 2005 season and depth structure had been conservatively crafted using MRFSS data to minimize the possibility that recreational catches of some groundfish species of interest exceeded their harvest guidelines, or OYs. The 2005 California Recreational Fisheries Survey (CRFS) estimates of total recreational take showed that harvest of overfished species was well below their respective California recreational harvest targets, particularly for canary rockfish. CDFG wants to simplify regulations and relieve, where possible, economic burdens that resulted from overly restricted seasons and depths. In addition, CDFG has concerns about the pressure on "data poor" nearshore stocks that have received heavy fishing pressure since 2003 as fishing has been concentrated within 20 fms.

Under the revised proposal, recreational model projection results estimate canary rockfish impacts to be 7.7 mt when the North Central and South Central RLMAs are open to 30 fms. The projected impact for widow rockfish under this revised proposal would be 7.7 mt. All projected catch estimates continue to remain within harvest targets, allocations and harvest guidelines. CDFG continues to track catches on a monthly basis through the CRFS program.

The proposed season and depth structure for this revised alternative, and a table showing its projected impacts are provided below.

California Recreational Inseason Action Revised Alternative Proposal

Changes to Current 2006 Management (SQ):
DEPTHS: North Central and South Central Monterey areas - open 0-30 fm; South area Sep.- Oct. open 0-60 fm
MONTHS: Add October for South-Central Morro Bay

RCG SEASON BY REGION

<table>
<tr><th>Region</th><th>Jan</th><th>Feb</th><th>Mar</th><th>Apr</th><th>May</th><th>Jun</th><th>July</th><th>Aug</th><th>Sep</th><th>Oct</th><th>Nov</th><th>Dec</th></tr>
<tr><td>North Region</td><td>---</td><td>---</td><td>---</td><td>---</td><td colspan="8">> 30fm Closed</td></tr>

</table>

NOTES AND KEY:

Shore fishing allowed in all waters in all months

RCG = Rockfish, cabezon, greenlings

--- = Closed to boat-based fishing for RCG

Lingcod season is open only when RCG is open, except closed Dec, Jan, Feb & Mar for spawning.

*In all regions including the South Region, the CA scorpionfish season matches the nearshore RF season.

ESTIMATED IMPACTS RESULTING FROM ACTION:

Species		2005 CRFS Catch Estimates (Actual)	Projected 2006 Catch Estimates Under Current Regulations[7]	Projected 2006 Catch Estimates Under Proposed Changes	HG[1], updated impact estimate[2], or HT[3]
Rebuilding Species	Bocaccio	38	52	65	65[2]
	Canary	2.3	6.1	7.7	9.3[1]
	Cowcod	0.1	0.2	0.3	0.4[3]
	Darkblotched	0	0	0	0[2]
	Lingcod	300	254	262[6]	422[1]
	POP	0	0	0	0[2]
	Widow	1.7	5.6	7.7	7.7[2]
	Yelloweye	1.7	1.5	1.5	3.7[1]
Other Target Species	Black RF	180	176	172	171[3]
	Minor NS RF North (40˚10' – CA/OR)	19.9	17.3	17.3	17.3[2]
	Minor NS RF South (40˚10' – US/Mexico)	430	447[5]	480[5]	383[3]
	Cabezon	41.8	37.0	40.3	42.1[4]
	Greenlings	4.8	6.7	6.8	15.5[4]

1 – Harvest Guideline (HG) established in Federal Regulations
2 – Best estimate of recreational impact in 2006
3 – Harvest Target (HT): For black rockfish, this is the state-derived recreational harvest target within the Federal HG for CA recreational and commercial catch, combined. The black rockfish recreational target is derived from CA Fish and Game Commission allocation guidance between recreational and commercial sectors.
4 – Total Allowable Catch (TAC) established in State Regulations.
5 – Includes increased take of California scorpionfish projected under California regulations which now couples fishing for California scorpionfish with fishing for nearshore rockfish, resulting in the same seasons and depths for both.
6 – This is the projected impact for lingcod with December closed.
7 – The estimates for 2006 have been updated since the first inseason proposal for the June 2006 Council meeting was submitted.

In summary, the specific actions proposed related to recreational fishing for rockfish and associated species are:

- Increase recreational fishing depths from Cape Mendocino (42° 10’ N. lat.) to Lopez Point to 0-30 fm during open months
- Allow fishing out to 40 fms in October in the area between Lopez Point and Point Conception (34° 27’ N. lat.)
- Allow recreational fishing out to 60 fms in the Southern RLMA in September and October consistent with other months

- The season and depths for scorpionfish would be the same as the Southern RLMA season for rockfish, and associates species.

A suboption considered under this proposal would open lingcod fishing in December for all areas but South Central Morro Bay. However, this suboption is not possible as it was not considered in the 2005-2006 EIS.

Agenda Item F.4.c
Supplemental Tribal Comments
June 2006

MAKAH TRIBAL TESTIMONY ON IN-SEASON ADJUSTMENT IN GROUNDFISH FISHERY

Good morning Mr. Chairman, members of the Council. For the record my name is Russell Svec, Fisheries Manager for the Makah Tribe and with me this morning is Steve Joner, fishery biologist, and Brandon Bryant, groundfish biologist for the Makah Tribe.

The Makah Tribe proposes an in-season adjustment for groundfish for the remainder of 2006. We need the ability to redistribute the bi-monthly trip limits for Dover sole and arrowtooth flounder. We want to combine the bi-monthly cumulative limits for July and August, for September and October, and for November and December to give more flexibility to harvest these abundant species, while keeping bycatch rates low on Pacific Ocean perch (POP), canary rockfish, widow rockfish, and darkblotched rockfish.

We have two purposes for this in-season adjustment:

- The first purpose is to take our harvest guideline of Dover sole (476.3 mt) arrowtooth flounder (1360.8 mt) and blackcod without exceeding the caps on Pacific Ocean Perch and other depleted rockfish species, or on blackcod. We also want to minimize the bycatch of Pacific halibut during this period.

- In addition, we want to test different gear configurations in combination with area management to reduce impacts on these bycatch species.

Our fisheries for Dover sole and arrowtooth flounder currently have high catch rates and are relatively clean in terms of bycatch. The fishery targeting on Dover sole and arrowtooth flounder has a bycatch rate of 8.8 percent blackcod, and only 0.3 percent Pacific Ocean perch. Applying these bycatch rates to the remaining harvest targets for Dover sole and arrowtooth flounder, we could expect a bycatch of 6 metric tons of Pacific Ocean perch; however, our bycatch caps on blackcod would reduce the catch of Dover sole and arrowtooth flounder, so it is more likely that the POP bycatch would be even lower – perhaps by as much as half.

These bycatch numbers are well within the guideline for these species.

To achieve the second objective, we want to compare the difference in bycatch rates between standard bottom trawl gear with small footrope, and pineapple – cutback headrope gear. When we have the results from this commercial evaluation fishery, we will prepare a report to the Council summarizing our findings. We hope to have this report ready by the November 2006 Council meeting.

Thank you for your consideration of our proposal. We'd be glad to answer any questions you might have about this fishery.

GROUNDFISH ADVISORY SUBPANEL REPORT ON CONSIDERATION OF INSEASON ADJUSTMENTS

The Groundfish Advisory Panel (GAP) heard a presentation from the Groundfish Management Team on the need to consider inseason adjustments for the Daily Trip Limit (DTL) fishery, the California Recreational Fishery, the LE Trawl fishery and Whiting fishery with regards to Dark Blotched Rockfish. The GAP also heard a discussion from the whiting industry regarding the widow bycatch in the early part of At-Sea whiting fishery.

For Open Access the GAP recommends:

Deeper Nearshore Rockfish: Increase the deeper nearshore rockfish limits during period 5 from 400 lbs to 500 lbs from 34º27' N. lat. to 40°10' N. lat.

DTL: At the current rate, sablefish in the open access DTL fishery will come in short of full attainment. The GAP recommends increasing the DTL to 4,000 lbs, 1000 lbs per week or 300 lbs per day for the 2-month cumulative limit beginning on July 1. The GAP also recommends that we revisit this issue in September.

For the California Recreational Fishery the GAP is supportive of the CDFG proposal.
That is :

North Region:	Open inside of 30 fm from May to December
North Central:	Open inside of 30 fm from July to December
South Central, Monterey	Open inside of 30 fm from July to December
South Central, Morro Bay	Open inside of 40 fm from May to October
South Region	Open inside of 60 fm from March to December

LE Trawl Fishery with respect to darkblotched rockfish:

Beginning July1, move the seaward boundary of the RCA between 38º N. lat. and 40º10' N. lat. to 200 fm until the end of August, and then at the beginning of the period 5 move the seaward boundary of the RCA between 38º N. lat. and 40º10' N. lat. to 250 fm until the end of the year [with petrale sole modifications for period 6]. Moving out the line out to 250 fm in period 4 would preclude summer access to the DTS opportunity due to the limited bottom contours.

For the area north of 40º10' N. lat., the GAP recommends moving the line out to 250 fm until the end of the year with the petrale areas open in period 6.

Whiting Industry With Regards To Darkblotched Rockfish:

The whiting industry has been resisting yet another hard cap on the whiting industry. However, the industry does understand the difficult position that has been created by the high catches of dark blotched rockfish. The GAP did not have a consensus regarding the size of the hard cap in the whiting industry, oscillating between 25 to 30 mt. The LE Trawl Industry would like to see 25 mt hard cap on the whiting industry. The Whiting industry would like a 30 mt hard cap of dark blotched rockfish for 2006. The whiting industry would like the council to consider this as a hard cap for 2006 only.

LE Trawl: The GAP agrees with the GMT and recommends an increase for shortspines to 7500 lbs beginning July 1 north of 36º N. lat.

The GAP notes lingcod harvest is lagging far behind projected landings. Through June 6, 2006, QSM reports trawl landings to be on track under the harvest guideline allotted them. QSM reports coastwide catch through June 6th of 102 mt out of a 2006 OY of 2414 mt. 50% of this catch represents discard.

The GAP notes the very high discard rate and believes we should attempt to reduce discard by turning it into landed catch.

During the summer months, in particular during period 4, lingcod are intercepted as incidental catch in all shelf fisheries. Targeting by the trawl fishery is near non-existent. It is truly 100% incidental catch. Any increase in cumulative limits will be caught in directed fishing for other shelf species. Therefore, the GAP believes increasing lingcod landings by the trawl fishery will not increase or result in canary or yelloweye mortality.

The GMT reports that we have lingcod to burn north of 40º10' N. lat. The GAP recommends increasing the lingcod trip limits to 2000 lbs in the north to turn projected discards into landed catch. This action may require the Council revisiting and adjusting the scorecard harvest guideline as a result of this proposed action. This action is warranted. It will help relieve the economic cost imposed by high fuel cost. Any opportunity, which is justified, is needed to maintain viability in the trawl fleet. This measure will help!

The GAP strongly urges the Council to manage for maximum allowed harvest under OY limits to ensure lingcod, the most voracious predator feeding on juvenile overfished species such as canary and yelloweye. To do otherwise is irresponsible as we attempt to rebuild these stocks.

The GAP recommends that north of 40º10' N. lat. for period 4, that we leave the shoreward RCA line at status quo and utilize the August 31st trigger of 7.25 mt for canary rockfish impacts to move the line into 60 fm if that level of catch is reached. The canary rockfish impacts can then be re-evaluated at the September Council meeting.

Widow in the Whiting Industry:

The GAP heard a report from the whiting industry regarding the unusually high numbers of widow rockfish taken early in the season by the catcher-processor and mothership sectors. During the first ten days of the season, several tows with high widow rockfish occurred.

In response, the entire whiting industry began talks to determine what and if anything could be done to avoid encounters with widow rockfish for the rest of the season. These talks were productive and avoidance behaviors were adjusted.

Since May 26th, the encounters of widows in the at-sea whiting sectors have declined. In addition, effort in the at-sea whiting sectors has been greatly reduced. Therefore, the GAP is not recommending any sector split of widows for the 2006 whiting season.

Dear Don,

I have fished for over 35 years and own a part in a crab processing cannery. This is the oldest continuously operating cannery on the Col. River. In the last year we began purchasing black cod, I have been out on the open access part with one of my sons. We have a $1500 electronic scale on the boat — we weigh one garbage can at a time — as the boat rolls — 99 — 102 — 101 — 99 — 100 — and so on — looks like a 100 ~~lbs~~ — dump them into the slush ice — do it again — 10 times = 1000 lbs — everyone usually has some extra to throw over — hopefully theyre alive. Any way we get to the cannery — up the hoist — And the weight is 1011 ~~lbs~~ — now what — was it slush ice theyre suspended in — taking on a little water — or the almost impossible chance to hit 100 each time?

Some guys draw a line around the garbage can, also one around the tote — but again a guess — if they are smaller they pack more and your over a little.

Believe me were trying to be honest — we're facing this dilema at our cannery right now.

How can we improve this program?

I know you guys are on the enforcement review at your next meeting — so let me try some thoughts from the fishermen and cannery

(2)

point of view — What if you created a relatively small range of overages – lets say 5% – 6% — or 50 Lbs. — something not very large — just enough to help make it possible to be close. There shouldn't be any incentive for the fisher to go over — so buyer would make out a state ticket and send the overage check to the state or Nat. Mar. fish –

Then the next part for no incentive is the obvious fact that what ever the overages add up to would come off the final bio mass that is allocated to the open access. You would get a pretty good picture of how the small overages add up — by mid season you would have a pretty good scientific picture of what the final adjustment would be — As you put a couple of years into this method I believe you would have a good picture how it works –

It is very hard to "hit" the number – and most fishermen don't want to throw them back — esp. at the cost of fuel — I would hope you wouldn't just drop the weekly level by 50 Lbs. for every delivery, because I believe in most cases guys will get pretty close either just below or a little above. With negative incentives – Pay the state (no wants to do that) and the adjusted loss from the total! Please think about this – only trying to keep us legal —

Sincerely – Steve Gray – 360 642-2408 –

MOTION IN WRITING ON CONSIDERATION OF INSEASON ADJUSTMENTS

The Makah Tribe is proposing commercial evaluation fisheries for the remainder of 2006 to test different gear configurations in combination with area management to reduce impacts to depleted rockfish as well as Pacific halibut.

I move that for both Dover sole and arrowtooth flounder, the Makah trawl fleet would have a combined harvest target equivalent to the limited entry cumulative limits for periods 4, 5, and 6 in place at the beginning of the year multiplied by the number of vessels (10) in the fleet. This represents a total fleet target of 1,050,000 lbs (476.3 mt) for Dover sole and 3,000,000 lbs (1360.8 mt) for arrowtooth flounder. These combined limits would allow them the flexibility to conduct these fisheries.

COUNCIL CLARIFICATION OF TENTATIVELY ADOPTED 2007-2008 GROUNDFISH FISHERY SPECIFICATIONS/MANAGEMENT MEASURES AND AMENDMENT 16-4 (IF NECESSARY)

This agenda item provides the chance for the Groundfish Advisory Subpanel (GAP) and the Groundfish Management Team (GMT) to present initial analysis of the 2007 and 2008 management measures tentatively adopted under Agenda Item F.2 and receive further clarification, guidance and direction from the Council. This guidance will be used to refine recommendations and analyses the Council may need to make final decisions on 2007 and 2008 management measures under Agenda Item F.6.

Council Action:

1. Provide Guidance to the GMT and GAP for Further Analysis of Management Measure Alternatives, if Necessary.

Reference Materials:

None.

Agenda Order:

a. Agenda Item Overview — John DeVore
b. State, Tribal, and Federal Agency Recommendations
c. Reports and Comments of Advisory Bodies
d. Public Comments
e. Council Discussion and Guidance on Final Adoption Necessities

PFMC
05/23/06

FINAL ADOPTION OF 2007-2008 GROUNDFISH FISHERY SPECIFICATIONS/MANAGEMENT MEASURES AND AMENDMENT 16-4

This is the final step of three at this meeting (Agenda Items F.2 and F.5 being the other two) in the process to adopt final 2007-2008 groundfish fishery management measures that will be recommended to the U.S. Secretary of Commerce.

Council Action:

1. **Adopt Final Groundfish Harvest Specifications for 2007-2008 Fisheries.**
2. **Adopt Final 2007-2008 Groundfish Fishery Management Measures.**
3. **Adopt Amendment 16-4: Final Rebuilding Plans for Seven Depleted Groundfish Species.**

Reference Materials:

None.

Agenda Order:

a. Agenda Item Overview — John DeVore
b. State, Tribal, and Federal Agency Recommendations
c. Reports and Comments of Advisory Bodies
d. Public Comments
e. **Council Action**: Adopt Final Fishery Specifications, Management Measures, and Rebuilding Plan Revisions

Re: 2007-08 Groundfish Management Measures and the Cowcod Conservation Area

---

Regarding the Cowcod Conservation Area, I note with some disquiet yet another attempt to peel away some of the protections afforded by these closures.

Truly, this is the typical "Death By A Thousand Cuts" that is the traditional pattern of most fishery management around the world, where decent regulations are, over time, abraded by sheer dint of effort on the part of user groups and apparent fatigue by fishery managers. While both of these processes are understandable, and I even have a certain sympathy for all of the participants, one might ask, after all of the disastrous fishery management decisions that have occurred for several centuries, haven't we have evolved past this?

Here are some of the reasons that rolling back the size of the Cowcod Conservation Area footprint makes no sense.

1. **We don't know what lives in the rocky areas to be opened**. No one has conducted any surveys examining the densities of fishes and habitat-forming invertebrates (such as deep-water corals) in the areas suggested for opening. At the very least, it is not clear that cowcod do not live in the area to be opened to fishing. In this day and age, why would anyone allow the start of fishing operations of any sort in an area that has not been assessed?
2. **Fishing operations cannot be accurately monitored**. Having conducted surveys in much of the CCA, it is clear that there are numerous steep-sided areas where bottom depth drops off abruptly. In some areas, bottom depth may change hundreds of feet over a very short lateral distance. Given the limitations of the ship tracking devices, it is not credible that ship positions will be able to be assessed sufficiently accurately to detect either inadvertent or intentional poaching.
3. **The CCA protects more than cowcod**. The CCA protects all of the benthic organisms within its boundaries. Fishes and invertebrates of all types enjoy these benefits. Given that the stocks of most benthic fish species (let alone deepwater corals and other habitat-forming invertebrates) have not been properly assessed, why would it be prudent to allow greater take of these animals? For instance, in the depths that are proposed to be opened, blackgill rockfish (Sebastes melanostomus) are found. It is debatable whether the stock of this animal is in good shape, why then allow greater take?

I really like both the commercial and recreational fishing industries. I hope they become a lot healthier and more self-sustaining than they are today. But really, prudence should be the watchword here. Worldwide, prudence has not been in the vocabulary of much fishery management for a long time. Perhaps it can start here

CALIFORNIA DEPARTMENT OF FISH AND GAME (CDFG) REPORT ON FINAL 2007-2008 MANAGEMENT MEASURES

Under the suite of ABCs/OYs adopted by the Council for all species, including those for species under rebuilding plans, the California Department of Fish and Game (CDFG) recommends the following commercial management measures for adoption:

Nearshore Commercial Fisheries Management

The suite of OYs adopted by the Council under Agenda Item F.2 provides for near-status quo management of California's nearshore commercial fisheries north of 40°10' N latitude, and some adjustments to the management measures for the area south of 40°10' N latitude consistent with Action Alternative 3b as described in Table 2-12a of the DEIS. The trip limits contained in the tables below reflect the CDFG's recommendation for trip limits for 2007-08.

North of 40°10' N latitude to 42° N latitude

- Adopt Action Alternative 3b: Status quo federal trip limits and a year-round RCA boundary of 30 fm. This alternative keeps impacts to canary and yelloweye rockfish within targets.

South of 40°10' N latitude:

- Adopt Action Alternative 3b, which provides for a 10 month season at 30 fm, modified to provide for increases in trip limits as detailed below.
- Trip limit options are based on the Department's intent to use a precautionary harvest guideline in drafting management measures. The Federal harvest goal is 564 metric tons (mt), while the Department's management goal is 515 mt for minor nearshore rockfish south of 40°10' N latitude. This translates into a commercial allocation of 120 mt, which represents a 23 mt increase over the status quo HG of 97 mt. Of the proposed 120 mt HG, 78 mt are proposed for the shallow nearshore rockfish group and 42 mt for the deeper nearshore rockfish group.
- During the March – April annual closure, shelf rockfish need to be closed to prevent discard of nearshore species when targeting shelf rockfish.
- Trip limit increases: In light of an increase to the minor nearshore rockfish OY and an associated increase in commercial harvest guideline from 97 mt to 120 mt, increases in trip limits can be provided for, with little increased impact to overfished species.
- Catch levels will be closely tracked inseason to evaluate appropriate inseason adjustments to RCA boundaries and trip limits if needed.

Shallow Nearshore Rockfish Trip Limits:

Status quo and CDFG-preferred trip limits (in pounds per 2 months)		
Period	STATUS QUO	CDFG-Preferred
1	300	500
2	closed	closed
3	500	700
4	600	800
5	500	700
6	300	500

Deeper Nearshore Rockfish Trip Limits:

Status quo and CDFG-preferred trip limits (in pounds per 2 months)						
Between 40°10' and 34°27'				Between 34°27' and US/Mexico		
Period	STATUS QUO	CDFG-Preferred		Period	STATUS QUO	CDFG-Preferred
1	500	700		1	500	500
2	closed	closed		2	closed	closed
3	500	700		3	600	600
4	500	700		4	600	600
5	400	600		5	600	600
6	500	700		6	400	400

Limited Entry Trawl

Darkblotched Rockfish Conservation Area

The CDFG proposed two polygon areas between 40°10' N latitude and 38° N latitude for designation as Darkblotched Rockfish Conservation Areas (DRCAs) (Agenda Item F.2.b CDFG Report). Staff consulted with industry representatives and revised the coordinates relative to their input. The industry's input focused on 1) revisions to the southern portion of the Pt. Arena DRCA to allow continued harvest of bank rockfish that occur there; 2) explanation of the importance of the proposed areas as winter petrale fishing grounds and concern that any adopted DRCAs be restricted to periods outside of the winter petrale season; and 3) willingness to support the two polygon closures provided that they would result in higher slope rockfish target limits during periods when the DRCAs are in place. CDFG believes that there are data that may assist in evaluating these areas for potential catch savings, however, CDFG is willing to work with the GMT relative to whether DRCAs and higher slope rockfish trip limits can be implemented together, and is willing to work further with industry representatives to finalize coordinates that are agreeable to all parties. Analysis to date will be included in the DEIS, and it is our understanding that DRCAs may be implemented during 2007 or 2008 through a Tiered EA with our assistance.

OREGON DEPARTMENT OF FISH AND WILDLIFE REPORT DETAILING THE PREFERRED ALTERNATIVE FOR MANAGEMENT OF THE OREGON RECREATIONAL GROUNDFISH AND COMMERCIAL GROUNDFISH FISHERIES IN 2007 AND 2008

This report details Oregon Department of Fish and Wildlife's (ODFW) preferred management measures for the 2007 and 2008 recreational and commercial groundfish fisheries. ODFW recommends the Council adopt the following management measures:

RECREATIONAL

The Oregon Department of Fish and Wildlife (ODFW) recommends adoption of Alternative 3b (described in Chapter 2 of the preliminary Draft EIS, p. 90), as modified in this report, for the Oregon recreational groundfish fisheries in 2007 and 2008. This preferred season structure (Table 1) produces a fishery that is open offshore year round, except from April 1 to September 30 when fishing is only allowed shoreward of 40 fathoms. Estimated impacts for yelloweye rockfish and canary rockfish associated with this preferred alternative are 3.2 mt and 4.3 mt respectively. We recommend a marine fish[a/] daily bag limit of eight fish in aggregate and a flatfish daily bag limit of 25 fish in aggregate, consisting of all soles and flounders except Pacific halibut. The lingcod daily bag limit is two with a 22-inch minimum length limit.

Table 1**:** ODFW preferred 2007-2008 Oregon recreational groundfish fishery management measures.

<table>
<tr><th colspan="12">Season Structure</th><th colspan="4">Bag/Length Limits</th><th colspan="2">Impacts</th></tr>
<tr><th colspan="12">Month</th><th rowspan="2">Marine Species Daily Bag[a/]</th><th rowspan="2">Flatfish Daily Bag[b/]</th><th rowspan="2">Ling Daily Bag</th><th rowspan="2">Lingcod Length Limit</th><th rowspan="2">Yelloweye Impact (mt)</th><th rowspan="2">Canary Impact (mt)</th></tr>
<tr><th>J</th><th>F</th><th>M</th><th>A</th><th>M</th><th>J</th><th>J</th><th>A</th><th>S</th><th>O</th><th>N</th><th>D</th></tr>
<tr><td colspan="3">All depth</td><td colspan="6"><40 fm</td><td colspan="3">All depth</td><td>8</td><td>25</td><td>2</td><td>22</td><td>3.2</td><td>4.3</td></tr>
</table>

[a/] Marine bag includes all species other than lingcod, salmon, steelhead, Pacific halibut, flatfish, surfperch, sturgeon, striped bass, pelagic tuna and mackerel species, and bait fish such as herring, anchovy, sardine and smelt
[b/] Flatfish bag consists of all soles and flounders except Pacific halibut

Marine Fish Daily Bag Limit: ODFW recommends adoption of a marine fish daily bag limit of 8 fish in aggregate (as defined above). This will provide management flexibility to make necessary adjustments to the marine fish daily bag limit through the yearly state process, reflecting the progression of the current year's fishery. The species most affected by adjustments in the marine fish daily bag limit is black rockfish. The fishery will be managed within the black rockfish harvest guideline.

Flatfish Daily Bag Limit: ODFW recommends adoption of a flatfish daily bag limit of 25 fish in aggregate (excluding Pacific halibut), removing flatfish from the status quo definition of "marine fish".

Lingcod Daily Bag Limit: ODFW recommends adoption a lingcod daily bag limit of 2 fish, carrying forward the current bag limit.

Minimum Length Limits: ODFW recommends adoption of a minimum length limit of 22-inches for lingcod. This adjustment should reduce time on the water by allowing anglers to achieve the lingcod bag limit quicker, and thus reduce impacts to depleted rockfish species (primarily canary rockfish and yelloweye rockfish) as well as constraining target species (i.e. black rockfish). This will also provide more access to the increased amount of harvestable lingcod available. Analysis shows that more lingcod are expected to be harvested due to decreasing the minimum length limit than increasing the daily bag limit. ODFW also recommends continuation of the minimum length limits for cabezon and kelp greenling of 16-inches and 10-inches respectively.

Stonewall Bank YRCA: ODFW recommends prohibiting groundfish retention within a defined area (Table 2), encompassing the high relief rocky habitat of Stonewall Bank, residing approximately 15 miles offshore from Newport, Oregon. There currently exists a Stonewall Bank Yelloweye Rockfish Conservation Area, adopted in Pacific halibut rules, which is closed to the retention of Pacific halibut only. Implementation of this same area (p. 55, Chapter 2, DEIS) in the groundfish fishery would aid in the conservation of depleted rockfish species. Targeting and retention of Pacific halibut and groundfish would be prohibited in the area year-round. Data is currently being collected to determine if anglers targeting Pacific halibut in the open areas of Stonewall Bank are also encountering yelloweye rockfish. This data will be used to determine if expansion of the adopted area is warranted for both the 2007 Pacific halibut fishery and the 2007-2008 groundfish fishery.

Table 2: Coordinates of the ODFW recommended Stonewall Bank YRCA.

ID#	Degrees	Minutes	Degrees	Minutes
1	44	37.46	124	24.92
2	44	37.46	124	23.63
3	44	28.71	124	21.80
4	44	28.71	124	24.10
5	44	31.42	124	25.47

Groundfish retention in the all-depth Pacific halibut fishery: Currently only sablefish may be retained in the Pacific halibut fishery at any depth in the area from Cape Falcon to Humbug Mountain, Oregon. North of Cape Falcon both sablefish and Pacific cod may be retained at any depth during the Pacific halibut fishery. It is expected that groundfish retention in the all-depth Pacific halibut fishery will be similarly constrained in 2007 and 2008.

Inseason Management: The inseason actions that may be implemented if the 2007 or 2008 Oregon recreational groundfish fishery does not proceed as expected include: length limit adjustments, bag limit adjustments (including non retention), and season, depth, and area closures.

Depth management will be the main inseason tool for controlling canary rockfish and yelloweye rockfish harvest, as retention is prohibited. Offshore closures may be implemented inseason at

30, 25, or 20 fathoms as the presence of these two species is reduced nearshore and release survival increases. ODFW will monitor inseason progress toward recreational harvest targets for canary rockfish and yelloweye rockfish. If inseason catch projections indicate that one or both of the state harvest targets may be exceeded, ODFW and WDFW will consult to share catch information. If the states determine that a management response is necessary to avoid exceeding the Oregon-Washington harvest guideline of canary or yelloweye rockfish, then the appropriate agency(ies) will implement inseason management actions to reduce catches, as necessary. Regulations will depend upon the timing of the determination for their need.

Adjustments to the daily marine fish bag limit may be implemented to achieve season duration goals in the event of accelerated or decelerated black rockfish or other nearshore rockfish harvest. Season and/or area closures may also be considered if harvest targets are projected to be attained. Non-retention and length restrictions are the likely inseason tools to use for cabezon and greenling as release survival is very high. They may also be used to reduce impacts on nearshore species, such as black rockfish.

Gear restrictions and/or release technique requirements may be implemented to reduce the impact of overfished rockfish species if successful techniques are developed, researched, reviewed, and accepted. Research in this area is currently being conducted, testing the effectiveness and selectivity of various gears and the survivability of rockfish released at depth.

Directed yellowtail rockfish and/or flatfish fisheries may be implemented inseason, as were implemented in 2004, in the event of a closure of the recreational groundfish fishery due to attainment of target species harvest guidelines or state harvest caps. Specific gear restrictions may be implemented in the event that flatfish remains open during a groundfish closure. Fisheries will be monitored to ensure that impacts to yelloweye and canary rockfish are not in excess of the harvest targets.

In the event that the duration of total season is reduced from 12 months, or the nearshore waters are closed to groundfish fishing due to management of nearshore species, the fishery may be expanded to waters seaward of the RCA that is in effect at the time, promoting directed yellowtail rockfish and offshore lingcod opportunity. Fisheries will be monitored to ensure that impacts to yelloweye and canary rockfish are not in excess of the harvest targets.

COMMERCIAL

Commercial Limited Entry Fixed Gear and Open Access Fisheries

ODFW recommends adoption of a 22-inch minimum length requirement for lingcod in the limited entry fixed gear and open access fisheries off Oregon and Washington. This will provide consistency with lingcod minimum length requirements in the recreational fisheries in Oregon and Washington. Industry representatives have asserted that there is a viable market for smaller lingcod, primarily in the live-fish fishery off Oregon. This action would allow fishers to retain previously discarded fish, and access the increased allowable harvest of lingcod in 2007 and 2008.

Commercial Limited Entry Bottom Trawl Fishery

ODFW recommends the required analysis (DEIS) be conducted to provide the ability to implement a “one-gear-on-board” per cumulative period regulation in the bottom trawl fishery as a routine management measure in 2007-2008 for the purpose of partitioning the trawl fleet and improving catch projection modeling.

Commercial Nearshore Fishery

ODFW recommends adoption of Action Alternative 3b as described on p. 88 in Chapter 2 of the preliminary draft EIS. This alternative provides for a near status quo fishery shoreward of 30 fathoms, and results in updated expected impacts for canary rockfish, widow rockfish, and yelloweye rockfish of 1.7, 0.1, and 2.1 mt, respectively. The fishery would operate for 12 months under federal and state harvest guidelines and federal trip limits (northern California) and state harvest caps and state trip limits (Oregon). The fishery will be closely monitored inseason and trip limits will be adjusted via federal or state inseason action to avoid exceeding federal harvest guidelines or state harvest caps for target species. In the event that new information indicates that the projected impacts to depleted species would be exceeded, the fishery may be adjusted using depth based management tools. A 20-fathom open access RCA line is being added to the list of available inseason tools.

ENFORCEMENT CONSULTANTS REPORT ON FINAL ADOPTION OF 2007-2008 GROUNDFISH FISHERY SPECIFICATIONS/MANAGEMENT MEASURES AND AMENDMENT 16-4

The Enforcement Consultants (EC) has the following comments regarding agenda item F.6 Final Adoption of 2007-2008 Groundfish Fishery Specifications/Management Measures and Amendment 16-4.

Cowcod Conservation Area

During this discussion, I will be referring to Figure 2-12 Cowcod West, Alternative 2, 175 fm Contour, found on page 79 of Agenda Item F.2.a, Attachment 1, June 2006.

Regarding the Cowcod Conservation Area (CCA) Alternative 2, 175 fm Contour, the EC understands that industry would like to have the opportunity to fish for blackgill and other species outside the 175 fm contour in areas currently closed within the CCA. The industry proposes allowing fishing outside this fathom contour by vessels equipped with vessel monitoring systems (VMS). Our understanding is that up to 9 limited entry fixed gear vessels may participate in this fishery with an unknown number potentially entering the fishery after January 1, 2007 when open access is required to have VMS.

We understand the vessels participating in this fishery participate in the fixed gear observation pool. But within this fixed gear pool, vessels who participate in overnight trips and some which are deemed un-seaworthy are exempt. We find this troublesome and believe the Council may want to consider increased observer coverage if this fishery proposal goes forward. Given the proposed 07-08 four ton cowcod optimum yield (OY), and the fact that one tenth of a ton has been projected for this proposed fishery in the bycatch scorecard, the EC views this fishery as a “zero tolerance” bycatch fishery.

I refer you to Figure 2.12, where the 150 and 175 fm contour are replicated. To maximize fishing opportunity, the industry would like see the 175fm contour replicated to the greatest resolution practicable using a series of lat/long way points. The NMFS Office of Law Enforcement and California Fish and Game Enforcement are prepared to undertake this mapping exercise as a first measure in redefining open fishing area within the status quo CCA. Once this mapping exercise is completed, enforcement will be faced with the tasked of enforcing open/closed areas with extremely close tolerances, some as small as 100 yards or up to a quarter mile.

Vessels operating in this fishery travel at a speed of 6 to 8 knots on average, and may deploy vertical longline gear in as short of time as 20 minutes. The current VMS pinging standard for the West Coast Rockfish Conservation Area is once every 60 minutes. This rate was established after considering the Council’s long standing request to keep VMS costs as a minimum. The pinging rate in every other region of the country is once every 30 minutes. Considering the operational times and vessel speed employed in this fishery, and the extremely small distances between 150 fm (identified as cowcod habitat) and 175 fm (identified as black gill habitat), the EC recommends increasing the pinging rate for this proposal to four times an hour or every 15 minutes. We hope this increased pinging rate will provide the fishing track resolution necessary to insure the integrity of the closed areas given these very close distance tolerances.

The current transmitting costs to fishermen at once an hour is on average approximately $30 a month. This proposal will increase that transmittal costs to approximately $100 or more a month, a $70 or more per month increase in operating costs.

If this fishing opportunity is approved, the EC recommends the current CCA geographic definition be maintained, and that new regulatory language be crafted requiring vessels carrying groundfish fixed gear, hook-and-line, pot, or trawl gear, and entering the status quo CCA, be equipped with VMS units which are operational and pinging at 15 minute intervals.

Regarding transiting the closed fishing areas within the CCA, the EC has considered the industries desire to transit these closed fishing area. Given the zero tolerance for fishing bycatch of cowcod in these areas, the EC cannot recommend allowing transiting of the closed fishing areas. The EC recommends that the closed areas identified on page 79 be closed to all fishing and all transiting of vessels carrying groundfish fixed gear, hook-and-line, pot, or trawl gear.

Finally, the EC would like to remind the Council that VMS is a spatial monitoring tool and as such does not ensure compliance of unlawful possession or nonretention regulations. Given the distant location of this fishery and its close proximity to prohibited species habitat, the EC has great reservations regarding this fishery's ability to demonstrate zero cowcod bycatch.

Trawl Gear

The EC supports the GMT recommendation that trawl vessels be limited to one trawl net type in a two month period.

PFMC
06/16/06

GROUNDFISH ADVISORY SUBPANEL (GAP) REPORT ON FINAL ADOPTION OF 2007-2008 GROUNDFISH FISHERY SPECIFICATIONS/MANAGEMENT MEASURES AND AMENDMENT 16-4

The Groundfish Advisory Subpanel (GAP) recommendations on commercial fishery seasons, trip limits and rockfish conservation area (RCA) boundaries are as follows.

Limited Entry Trawl

The GAP agrees with the GMT's recommendations on limited entry trawl RCA and cumulative trip limits coastwide.

GAP members became aware of a proposal to limit the fleet to one gear on board per cumulative limits for the 2007-2008 fisheries. GAP members voiced concern over receiving the proposal on the Friday morning of the final action agenda item. The GAP understands that this proposal results from the GMT's hope they could better estimate effort shifts.

A subcommittee of the GAP explored the option briefly and has the following comments:

1. **Cost.** The costs associated with this proposal are large. The proposal would require fishermen to return to port between cumulative periods and switch their gear. Currently the vessels are allowed to have both gears on board. The costs associated with switching the gear can be significant.
2. **Flexibility**. The proposal limits the fleet's flexibility to access fish when and where they become available.
3. **Effectiveness**. Given the uncertainty of availability of target fish and the variability of bycatch species the GAP does not believe that this restriction will increase the accuracy of bycatch or target species actual catch.

The GAP realizes that this option was initially proposed prior to consideration of a trigger mechanism that allows for management action between Council meetings. The GAP believes that the trigger mechanism will be sufficient to adjust management measures as necessary. The trigger mechanism is the GAP's preferred alternative for dealing with this issue. Other options include some type of declaration system or an information sharing meeting where the GMT meets with members of the fleet to discuss their expected "game plans" for the upcoming season.

The GMT is also proposing that selective trawl gear be required south of 40˚10 in order to avoid bocaccio rockfish capture. The GAP notes that there is little or no data on the effectiveness of this gear south of 40˚10 with respect to bocaccio. Furthermore, the GAP is confident that the next bocaccio stock assessment will reflect a significantly higher, if not rebuilt, population of bocaccio. With this in mind the GAP believes that the costs associated with requiring this gear south of 40˚10 poses an unnecessary economic hardship on the fleet when the gear may become irrelevant within the next management cycle.

Limited Entry Fixed Gear

The GAP recommends status quo management measures for limited entry fixed gear north of 40º10' N. lat.

The GAP also recommends status quo management measures for limited entry fixed gear south of 40º10' N. lat. with the following exceptions:

- The 34º27' N. lat. management line is recommended for stratifying management measures for thornyheads.
- Increase the California scorpionfish cumulative trip limit to 600 lbs/2 months during periods 1, 3, and 6; increase to 800 lbs/2 months during periods 4 and 5.
- Increase the shallow nearshore rockfish cumulative trip limit to 600 lbs/2 months during periods 1 and 6; increase to 800 lbs/2 months during periods 3 and 5; and increase to 900 lbs/2 months during period 4.
- Increase the deeper nearshore rockfish cumulative trip limit north of 34º27' N. lat. to 600 lbs/2 months during period 5; increase the deeper nearshore rockfish cumulative trip limit south of 34º27' N. lat. to 600 lbs/2 months during period 6.
- Increase the lingcod cumulative trip limit to 100 lbs/ month during periods 1 and 6.

Open Access

The GAP recommends Alternative 3b management measures for open access gears north of 40º10' N. lat. with the following exceptions:

- Increase the lingcod cumulative trip limit to 400 lbs/month from May through November.

The GAP also recommends status quo management measures for open access gears south of 40º10' N. lat. with the following exceptions:

- The 34º27' N. lat. management line is recommended for stratifying management measures for thornyheads.
- Increase the California scorpionfish cumulative trip limit to 600 lbs/2 months during periods 1, 3, and 6; increase to 800 lbs/2 months during periods 4 and 5.
- Increase the shallow nearshore rockfish cumulative trip limit to 600 lbs/2 months during periods 1 and 6; increase to 800 lbs/2 months during periods 3 and 5; and increase to 900 lbs/2 months during period 4.
- Increase the deeper nearshore rockfish cumulative trip limit north of 34º27' N. lat. to 600 lbs/2 months during period 5; increase the deeper nearshore rockfish cumulative trip limit south of 34º27' N. lat. to 600 lbs/2 months during period 6.
- Increase the lingcod cumulative trip limit to 300 lbs/ month during November; increase to 100 lbs/ month during December.

The GAP recommends recreational management measures as follows.

California Recreational Management Measures

The GAP recommends option 5b California recreational seasons and open depths as follows:

RCG SEASON BY REGION

Region	Jan	Feb	Mar	Apr	May	Jun	July	Aug	Sep	Oct	Nov	Dec
North Region	---	---	---	---	> 30 fm Closed							
North Central	---	---	---	---	---	> 30 fm Closed						---
South Central - Monterey	---	---	---	---	> 40 fm Closed							---
South Central - Morro Bay	---	---	---	---	> 40 fm Closed							---
South Region	---	---	> 60 fm Closed									

NOTES AND KEY:

RCG = Rockfish, cabezon, greenlings

--- = Closed to boat-based fishing for RCG

The estimated impacts under option 5b are:

	Estimated Impacts (mt)								
Region	**Yelloweye**	**Canary**	**Cowcod**	**Bocaccio**	**Widow**	**Minor NS RF North**	**Minor NS RF South**	**CA Scorpionfish**	**Lingcod**
North region	0.9	0.7	N/A	N/A	0	17.3	N/A	0	51
North Central	0.6	5.5	0	0.2	2.2	N/A	165	0	152
South Central - Monterey	0	0.5	0	7.4	0.9	N/A	104	0	29
South Central - Morro Bay	0	1.3	0	2.5	0.1	N/A	92	0	24
South Region	0	0.3	0.3	57.4	5.2	N/A	61	75	26
TOTAL CALIFORNIA	1.7	8.3	0.3	67.5	8.4	17.3	422	75	282

Oregon Recreational Management Measures

Yelloweye: The GAP recommends a no-action management measure as described in agenda item F.2.b, ODFW Report June 2006. Also recommended is an ability to change to alternative more restrictive depth based management measures should the yelloweye impacts exceed a rate compatible with preseason projections. This in-season constraint ability would allow for a lowering of the impact rate.

Lingcod: The GAP recommends a change of the lingcod minimum length from 24” to 22”.

Bag limit: The GAP recommends that the bag limit be limited to no less than 5 fish with all management measures as indicated through Oregon public comment. A depth constraint or season closure is preferred to a bag of less that 5. Flat fish 25 bag limit in aggregate not to include Pacific Halibut.

Washington Recreational Fisheries

Statewide Measures:

- Maintain status quo bag limits as described in the No Action Alternative (Chapter 2, p. 52), which include a recreational groundfish bag limit of 15 fish per day, including rockfish and lingcod, with a sublimit of 10 rockfish, and 2 lingcod. Retention of canary and yelloweye rockfish is prohibited.

- Maintain status quo lingcod season as described in the No Action Alternative (Chapter 2, p. 52); in 2007 and 2008, the following lingcod seasons would apply:

    - Marine Areas 1-3: Open the Saturday closest to March 15 (which is March 17 in 2007 and March 15 in 2008) through the Saturday closest to October 15 (which is October 13 in 2007 and October 18 in 2008).

    - Marine Area 4: Open April 15 through October 13 in 2007 and open April 15 through October 15 in 2008.

- Reduce the minimum size for lingcod from 24 inches to 22 inches.

Area-Specific Measures:

Management Measures for Marine Areas 3 and 4 (Queets River to U.S./Canada border)

Action Alternative 3 (Chapter 2, p. 89), with two revisions: Prohibit fishing for, retention, and possession of **groundfish** seaward of a line approximating 20 fm from May 1 through **September 30**, except on days that halibut fishing is open.

Revisions:
1. Change "rockfish and lingcod" to more broadly cover "all groundfish" for ease of regulatory understanding and enforcement of the regulations
2. Move the depth restriction in July from 10 fm seaward to 20 fm

Management Measures for Marine Area 2 (Leadbetter Pt. to the Queets River)

Action Alternative 3 (Chapter 2, p. 89), with one revision: Prohibit fishing for, retention, and possession of **groundfish** seaward of a line approximating 30 fm from the lingcod opening day in March through April 30, and from June 16 through July 31. From May 1 through June 15 (i.e., during the average period of the South Coast halibut fishery), allow the retention of sablefish and Pacific cod seaward of the 30-fm depth restriction.

Revision:

1. Change “rockfish and lingcod” to more broadly cover “all groundfish” for ease of regulatory understanding and enforcement of the regulations, while still allowing the retention of sablefish and Pacific cod, which may be caught incidentally while targeting halibut offshore.

Management Measures for Marine Area 1 (Oregon/Washington border to Leadbetter Pt.)

No Action Alternative (Chapter 2, p. 54), which would prohibit fishing for, retention, and possession of groundfish, except sablefish and Pacific cod, when Pacific halibut are onboard the vessel.

<u>Cowcod Conservation Area Boundary Changes</u>

The GAP supports the Alternative 2 Cowcod Conservation Area West boundary change to allow vessels equipped with VMS to fish within the bounds of the current CCA in depths greater than 175 fm. These new open areas are important for accessing healthy slope species, such as blackgill rockfish, and will not impact cowcod, which are not found in these areas. The GAP believes only about 9 vessels will actively fish in this area. Enforcement Consultants notified GAP members that there may be increased costs to vessels fishing in this area associated with increased VMS “ping” rates. The GAP and affected industry members are willing to bear these increased costs to provide increased slope fishing opportunities.

PFMC
06/16/06

GROUNDFISH MANAGEMENT TEAM (GMT) REPORT ON 2007-08 GROUNDFISH MANAGEMENT MEASURES

Under Agenda Item F.2., the Council adopted a series of tentative overfished species OYs and provided the GMT and GAP with direction on developing management measures to keep the fishery within the OYs. Tribal fishery management measures were tentatively adopted under agenda item F.2. The Council also provided guidance on management measures for non-tribal fisheries under that agenda item. Each of the three states has developed a supplemental report on recreational fisheries management in 2007-2008 for this agenda item, F.6. The GMT reviewed these reports in draft and supports the management measures proposed therein as appropriate for keeping the recreational fisheries within Council-recommended harvest levels. Therefore, the remainder of this report focuses on catch-sharing issues and management measures for the non-tribal commercial fisheries. Any management measures not specifically adopted by the Council for revision in 2007-2008 would remain in place, as implemented via Federal regulation.

The tentative 2007-2008 overfished species OYs adopted under F.2. were:

	2007 OY	2008 OY
Bocaccio	218 mt	218 mt
Canary rockfish	44 mt	44 mt
Cowcod	4 mt	4 mt
Darkblotched rockfish	290 mt	290 mt
Pacific ocean perch	150 mt	150 mt
Widow rockfish	368 mt	368 mt
Yelloweye rockfish	23 mt	20 mt

The Council also adopted tentative recreational harvest guidelines for canary and yelloweye rockfish:

	2007 Recreational HGs	2008 Recreational HGs
Canary rockfish	8.2 mt – Washington/Oregon 9.0 mt – California	8.2 mt – Washington/Oregon 9.0 mt – California
Yelloweye rockfish	6.8 mt – Washington/Oregon 2.1 mt – California 1.5 mt – Sport residual	6.8 mt – Washington/Oregon 2.1 mt – California

These recreational harvest guidelines will be adopted in Federal regulations via the footnotes to the ABC/OY tables published in 50 CFR 660. As in past years, NMFS will also publish any estimated research catch, tribal allocations, recreational set-asides, open access allocations, and limited entry trawl and non-trawl allocations, as appropriate, in the footnotes to those tables. Unless otherwise previously designated by regulation, allocation scheme, or specified by the Council at this meeting, NMFS will use the values provided in Table 1, the bycatch scorecard for the Council's preferred alternative.

Black Rockfish Sharing Between Oregon and California

At its April meeting, the Council adopted a tentative black rockfish sharing framework for 2007-2008, which would need to be adopted under this agenda item to implement in 2007-2008. As in 2005-2006, carry forward the black rockfish catch sharing recommendation of 58% to Oregon and 42% to California within the southern OY, and specify those values as harvest guidelines in the federal regulations for the respective states. These percentages result in an Oregon harvest guideline of 419 mt (recreational and commercial harvest guidelines of 286.6-350.2 mt and 90.5-110.7 mt respectively) and a California harvest guideline of 303 mt. The states of California and Oregon have factored in precautionary approaches in managing to these black rockfish targets.

State Nearshore Management

Nearshore fisheries in Oregon and California are based on conservative management measures. Catches will be closely monitored inseason and trip limits will be adjusted via federal or state inseason action to avoid exceeding federal harvest guidelines or state harvest caps. In the event that new information indicates that the projected impacts to depleted species would be exceeded, the fishery may be adjusted using depth-based management tools where possible.

Oregon and Northern California

The GMT supports the ODFW and CDFG recommendation of Action Alternative 3b, described on p. 88 in Chapter 2 of the preliminary DEIS. This alternative provides for a near status quo fishery shoreward of 30 fathoms, and results in updated expected impacts for canary rockfish, widow rockfish, and yelloweye rockfish of 1.7, 0.1, and 2.1 mt, respectively. The fishery would operate for 12 months under federal and state harvest guidelines and federal trip limits (northern California) and state harvest caps and state trip limits (Oregon).

A 20-fathom open access RCA line is being added to the list of available inseason tools.

Central and Southern California

The GMT supports CDFG recommendation of Action Alternative 3b, described on p. 88 in Chapter 2 of the preliminary DEIS, along with increases to trip limits as provided in the Supplemental CDFG Report under this agenda item. The updated expected impacts to overfished species are 0.33 mt for canary rockfish and 0.0 mt for all other overfished species.

Depth- and area-based management

The GMT recommends adopting the following new RCA boundary lines for use in 2007-2008:

- Boundary lines off Washington approximating the 10, 20 and 25 fm depth contours.

- Boundary lines off Oregon approximating the 20 and 25 fm depth contours. The 25 fm depth contour boundary line would replace the line currently in Federal regulations for 27 fm.
- A boundary line off California approximating the 250 fm depth contour south of 38° N. lat., a 250 fm line modified to provide for petrale fishing areas south of 38° N. lat., and a 180 fm line modified to provide for petrale fishing areas.

In addition to adopting these particular new lines, the States and NMFS are working together to make corrections to existing RCA lines to ensure that: the lines better approximate the depth contours they are intended to represent; the petrale open areas are more consistent between the petrale-modified depth contour lines; and the lines that intersect with EFH conservation areas are compatible with the boundaries of those areas.

Limited Entry Trawl

The Council directed the GMT to draft management measures for the limited entry trawl fishery consistent with those provided in Table 2-22 (page 87) in the Preliminary DEIS, working under the tentative overfished species OYs and the OYs already adopted for non-overfished species. Draft trip limit tables for 2007-2008, including RCA boundaries, are provided as Table 3 for this report. The GMT also herein recommends additional new management measures for the whiting trawl fishery and for the non-whiting limited entry bottom trawl fishery.

Whiting fishery bycatch limits. The GMT discussed sector specific bycatch limits for the non-tribal whiting fishery and concluded that further analysis is needed before a recommendation can be made to the Council. Specifically, the GMT believes that an analysis needs to examine:

- Adequacy of using at-sea observer sample data to monitor sector bycatch limits for infrequently or rare occurring species
- Adequacy of a shore-based monitoring program for monitoring bycatch limits
- Timeliness of data for monitoring limits
- Appropriate bycatch limits for each non-tribal sector

The GMT does not believe that there is time to prepare an adequate analysis for the 2007-2008 management measures. However, the GMT does believe that an analysis could be completed in conjunction with the regulatory package that is being proposed for a monitoring program in the shore-based fishery. This package is proposed to be available to the Council in September, with an intended implementation in early 2007. At this time, the shore-based whiting fishery is operating under an EFP that provides for at-sea monitoring, but the future of a monitoring program for the shore-based whiting fishery is unknown. If the fishery reverts to sorting at sea, neither fleetwide nor sector bycatch limits could be adequately monitored.

The GMT recommends implementing placeholder fleet-wide annual overfished species bycatch limits for the non-tribal whiting fisheries in 2007 and 2008. The GMT plans to review these limits in early 2007 for their compatibility with the 2007 whiting OY:

- Canary rockfish, 4.7 mt
- Darkblotched rockfish, 25 mt
- Widow rockfish, 200 mt

Whiting fishery salmon bycatch prevention. During the 2005 fishery, when it became apparent that the 11,000 Chinook level specified in the Biological Opinion was going to be exceeded, NMFS defined an Ocean Salmon Conservation Zone (OSCZ) for all waters shoreward of a boundary line approximating the 100-fm (183-m) depth contour. Fishing for whiting during the remaining portion of the 2005 primary season was prohibited within the Ocean Salmon Conservation Zone.

For 2007 and beyond, automatic action authority could be established to implement an OSCZ for the whiting fishery if inseason response is needed to prevent high salmon take. When NMFS projects the catch of Chinook salmon in the Pacific whiting fishery will exceed the 11,000 fish threshold, the OSCZ could be put in place for all non-tribal sectors of the whiting fishery though a single Federal Register notice. Similarly, NMFS would consult with the Makah Tribe to enact area management to reduce Chinook salmon interactions. The GMT does not recommend beginning the whiting season with the OSCZ already in place, since an automatic closure in the nearshore area would move the whiting fleet offshore and closer to waters where darkblotched rockfish may be encountered. By allowing flexibility early in the season, whiting fleet participants may continue their past practice of sharing bycatch information with each other during the season to balance the various bycatch species that they must avoid in both nearshore and offshore waters.

Bottom trawl fishery salmon bycatch prevention. Estimates of Chinook salmon bycatch for the (non-whiting) limited entry bottom trawl fishery have only recently become available. WCGOP has estimated that 18,120 salmon caught in 2002, 13,862 fish in 2003, and 1,978 fish in 2004. Virtually all of the salmon caught were Chinook salmon. The 2006 supplemental biological opinion notes that “more bycatch, in the bottom trawl fishery in particular, was shifted south into northern California than was previously thought”. As a result, Sacramento winter-run Chinook, California coastal Chinook, and Central Valley spring-run Chinook may be disproportionately affected by the bottom trawl fishery. However, component ESUs for these stocks have increased or remained stable over the past 10 years.

There is considerable uncertainty about bycatch of salmon in the bottom trawl fishery. The magnitude and distribution of bycatch in the trawl fishery since 2002 has been affected by significant changes in management measures to protect overfished groundfish stocks and changes in fishing effort as a result of the trawl buyback program. The uncertainty will remain until more years of observer data are available and changes in groundfish fishery management and effort distribution are analyzed in relation to the incidental take of salmon. Once new data from the WCGOP becomes available, the GMT plans to look at ways of reducing salmon bycatch in the bottom trawl fishery to meet the concerns specified in the biological opinion.

Selective Flatfish Trawl Gear South of 40°10’ N. lat.

Selective flatfish trawl gear was implemented as a mandatory gear when fishing shoreward of the RCA in the area north of 40°10’ N. Lat in 2005. Implementation was delayed for areas further south in light of an ongoing EFP to measure bycatch rates of overfished species in that area. The GMT supported the potential implementation of the gear depending on the results from the EFP.

Participation in the EFP was low, and bycatch rate estimates for bocaccio and other overfished species in that area remain uncertain. However, bycatch reductions associated with this gear have been proven in the north, and it is expected that bycatch for canary rockfish will decrease in the south through the implementation of this gear. While bycatch rate reductions for bocaccio are also likely through the implementation of this gear, the GMT believes that expected canary rockfish bycatch reductions alone are sufficient to justify the implementation of this gear in order to reduce the bycatch of canary rockfish and to reduce the risk of early closure of the bottom trawl fishery. Therefore, the GMT recommends that selective flatfish gear be implemented as a requirement to fish shoreward of the RCA south of 40°10’ N. lat. Projected impacts for proposed trip limits contained in this report reflect the lower expected bycatch rate for canary rockfish. The projected canary mortality for the area south of 40°10’ N. Lat is 2.0 mt with selective gear, which represents a catch savings of approximately 0.5 mt over non-selective gear. The GMT notes that the bycatch scorecard (attached) reflects a residual amount of 0.8 mt after EFP set-asides are removed; this residual would be reduced to 0.3 mt under status quo gear.

Scottish Seine Gear Between 38° N. lat. and 36° N. lat.

Based on results from a three-year EFP study conducted by CDFG, the GMT considered a Scottish seine gear exemption from trawl RCA closures. This particular type of small footrope trawl gear was demonstrated to have lower bycatch rates of overfished species than more conventional trawl gear. This gear requires VMS and must adhere to declaration requirements to provide for enforcement of this exemption. The GMT continues to support the use of gears that reduce the bycatch rate of non-target species; however, the Team recommends that this exemption apply only to the area south of 38° N latitude and north of 36° N. lat., where low bycatch rates of overfished species were demonstrated. The GMT further recommends that this exemption be limited to depths less than 100 fm. This encompasses the primary flatfish target areas but reduces risk associated with the exemption. This gear will remain within the WCGOP pool, enabling the GMT to monitor bycatch rates into the future. If the Council chooses to adopt a Scottish seine exemption from RCA closures, the GMT recommends that enforcement be consulted in order to develop regulations that clearly define Scottish seine gear.

Darkblotched Rockfish Conservation Areas.

The GMT reviewed the CDFG proposal to establish two new Darkblotched Rockfish Conservation Areas in the area between 40°10’ N. lat and 38° N. Lat and recommends that two DRCAs be considered for use in 2007-08. These polygons are located where survey and logbook data analysis indicated higher catches of darkblotched rockfish than the surrounding area. However, the proposed DRCAs overlap important fishing grounds for the winter petrale fishery, and therefore the GMT recommends that, if adopted, they only apply in periods 2-5.

Slope rockfish target opportunities have been reduced substantially in recent years due to concerns over potential catches of darkblotched rockfish in this area. There is interest in restoring slope rockfish opportunities, however these opportunities are limited by the amount of darkblotched associated with slope rockfish. It is the GMT’s understanding that industry members were willing to support the proposed closures with the expectation that they would receive more slope rockfish opportunity as a result. Unfortunately, a full analysis of potential catch savings of darkblotched rockfish that might be assumed from these closures has not been completed at this time, although analysis to date will be provided in the DEIS. The GMT cautions against creating closed areas with the expectation of increasing limits until a thorough analysis can be conducted and reviewed to ensure that increased trip limits can be accommodated. It is our understanding that a supplemental NEPA analysis may be required to implement final DRCAs during 2007-08. The GMT requests that the Council direct the Team to evaluate possible bycatch reductions associated with the DRCAs.

Limited Entry Fixed Gear and Open Access

The Council directed the GMT to draft management measures for the limited entry fixed gear fishery consistent with those provided in Tables 2-8a and 2-8b (pages 40-42,) and for the open access fishery consistent with those provided in Tables 2-9a and 2-9b (pages 43-46) in the Preliminary DEIS, working under the tentative overfished species OYs and the OYs already adopted for non-overfished species. Draft trip limit tables for 2007-2008, including RCA boundaries, are provided in Tables 4 and 5 in this report.

The limited entry fixed gear primary sablefish fishery's tier limits for both 2007 and 2008 under the sablefish OYs adopted by the Council in April are: Tier 1, 48,500 lb; Tier 2, 22,000 lb; and Tier 3, 12,500 lb.

Lingcod in the Salmon Troll Fishery. At their March meeting, the GMT reviewed an analysis of an observer program conducted by WDFW in the Washington salmon troll fishery for the past 3 years. The analysis showed a strong increasing trend of incidental catch of lingcod, consistent with the recovery of the stock, over the period of the study. The catch rate in 2005 was one lingcod for every seven Chinook. Since lingcod retention was prohibited during this time, this catch is assumed to be entirely incidental. The Council included for analysis in the draft EIS a measure to allow an incidental allowance of lingcod in the salmon troll fishery north of 40°10' N. lat. of one lingcod for every 10 Chinook landed, not to exceed the open access lingcod cumulative limit. The team did express concern that, although the fleet-wide incidental catch ratio of lingcod in the northern troll fleet appears to be well within this ratio, some increased lingcod targeting could occur and potentially increase overfished rockfish bycatch. It was also noted that most lingcod released in the troll fishery survive.

Yelloweye Rockfish Conservation Areas. To constrain yelloweye rockfish incidental catch in the commercial hook-and-line fisheries, the GMT recommends adopting a new yelloweye rockfish conservation area that would apply to the limited entry and open access fixed gear fisheries. Within the Washington North Coast area, the area labeled North Coast Area B in the Preliminary DEIS (Chapter 2, Figure 2-8, p. 65) is bounded by the following coordinates:

> Beginning at 48°11.77' N lat., 125°13.03' W long.;
> Then to 48° 16.43' N lat., 125°07.55' W long.;
> Then to 48° 14.72' N lat., 125°01.84' W long.;
> Then to 48°13.36' N lat., 125°03.20' W long.;
> Then to 48°12.74' N lat., 125°05.83' W long.;
> Then to 48°11.55' N lat., 125°04.99' W long.;
> Then to 48°09.96' N lat., 125°06.63' W long.;
> Then to 48°09.68' N lat., 125°08.75' W long.;
> And back to the point of origin.

This area would be closed to commercial limited entry fixed gear and open access groundfish fishing. This area is already closed to trawl gear with the implementation of the trawl rockfish conservation area and the essential fish habitat trawl closure. Under salmon conservation measures in support of the Salmon FMP, most of this area is already closed to salmon troll as a salmon conservation measure.

To constrain yelloweye rockfish incidental catch in the salmon troll fishery, the GMT recommends adopting a new yelloweye rockfish conservation area. Within the Washington North Coast area in the Preliminary DEIS (Chapter 2, Figure 2-11, p. 69) bounded by the following coordinates:

> Beginning at 48°00.00’ N lat., 125°14.00’ W long.;
> Then to 48°02.00’ N lat., 125°14.00’ W long.;
> Then to 48°00.00’ N lat., 125°16.50’ W long.;
> Then to 48°02.00’ N lat., 125°16.50’ W long.;
> And back to the point of origin.

This area would be closed to the commercial salmon troll fishery. WDFW would like to point out that this area overlaps a portion of the “C-shaped” YRCA, and is already closed to recreational groundfish and halibut fishing.

<u>Cowcod Conservation Areas.</u> The most significant risk of altering the perimeters of the CCA is the possibility that incidental catches of cowcod and bocaccio would increase, either as a result of incidental catches at the boundary of the fathom lines, where cowcod tend to be rare, or from incidental catches resulting from inadvertent incursions of vessels or gear into shallower depth in the boundary lines. Although this risk is difficult to evaluate, observer data has shown no cowcod in fixed gear landings south of 40˚10’ N. lat. since the inception of the observer program. However, the steep and complex topography of the continental slope in these regions, the inference from the stock assessment that nearly two-thirds of the assessed (Conception area) cowcod biomass is found within the CCAs, and the corresponding complexity of the 175 fm line alternative considered here, would suggest some potential for increased bycatch.

The draft EIS suggested that changing the boundaries of the CCA could undermine the ability to replicate resource surveys within those boundaries, such as the submersible survey. The SSC has questioned whether this is true, based on their conclusion that the methodology used to expand the biomass estimate within the CCAs to the entire range of the stock would not be appropriate for future surveys. Consequently, this language will be removed from the Draft EIS. However, the GMT notes that there is limited observer coverage in this area, and is concerned about the ability to adequately monitor the consequences of changing the CCA boundaries. The GMT did not arrive at a consensus recommendation regarding this proposal, but recommends that the challenges associated with adequately monitoring the consequences of this decision be considered in making management decisions regarding this issue.

<u>Open Access Non-Groundfish Trawl</u>
The GMT recommends RCA boundaries for open access trawl fisheries be the same as limited entry trawl RCA lines, except that ridgeback prawn trawl is exempted to 100 fm when the inner boundary of the RCA is moved shallower than 100 fm.

Other Regulations

The GMT reviewed federal gear regulations and requirements at its May meeting to ensure that they are consistent with the intent of 2007-2008 management measures.

Chafing Gear Regulations The GMT recommends that NMFS revise chafing gear requirements in federal regulation. In 2003, when new chafing gear requirements were added for small footrope trawl gear, reference language regarding the chafing gear requirements for midwater trawl were inadvertently changed in the regulation. The GMT believes that the regulatory language should be revised such that the chafing gear requirements are reinstated for midwater trawl gear and maintained for small footrope trawl.

Lingcod size limit The GMT recommends setting lingcod size limits at 22 inches for Washington and Oregon recreational fisheries and limited entry fixed gear and open access commercial fisheries north of 42˚ N. lat., and remain at the status quo size limit of 24 inches for California recreational and commercial fisheries.

GMT Recommendations:

1. Adopt recreational fisheries management measures specified in ODFW and CDFG supplemental reports under this agenda item and the WDFW supplemental report under Agenda Item F.2
2. Adopt nearshore management measures for Oregon and California as recommended in ODFW and CDFG supplemental reports under this agenda item
3. Adopt proposed new RCA lines and revised RCA lines for use in 2007-08
4. Adopt limited entry trawl RCA boundaries and cumulative limits as shown in table 3
5. Adopt whiting bycatch limits (to be reconsidered inseason in March 2007)
6. Adopt the requirement to use selective flatfish trawl gear in the limited entry trawl fishery south of 40 degrees 10 minutes latitude when fishing groundfish bottom trawl gear in areas shoreward of the trawl RCA
7. Adopt open access and limited entry fixed gear RCA boundaries and cumulative limits as specified in tables 4 and 5
8. Adopt changes to open access non-groundfish trawl RCA boundaries as specified in GMT report
9. Consider changes to the Cowcod Conservation Area boundaries
10. Consider exempting Scottish seine gear from trawl RCA requirements in areas between 38 degrees North latitude and 36 degrees North latitude to a depth of 100 fm and task the GMT and EC to work on establishing a clear definition of Scottish seine gear
11. Adopt lingcod size limit change for commercial limited entry fixed gear and open access fisheries and recreational fisheries in Washington and Oregon
12. Adopt YRCAs

Table 1. Council Preferred Alternative: 2007-2008 Estimated Total Mortality (mt) a/

Key	(shaded) = either not applicable; trace amount (<0.01 mt); or not reported in available data sources.							

a/ The mortality in Incidental groundfish and tribal fisheries were held constant at 2006 scorecard values, with the exception of an increase in mortality of canary and yelloweye in the salmon troll fishery. Research take was adjusted based on April 2006.

b/ South of 40°10' N. lat.

c/ Mortality estimates are not hard numbers; based on the GMT's best professional judgment.

d/ Bycatch amounts by species unavailable, but bocaccio occurred in 0.1% of all port samples and other rockfish in another 0.1% of all port samples (and squid fisheries usually land their whole catch). In 2001, out of 84,000 mt total landings 1 mt was groundfish. This suggests that total bocaccio was caught in trace amounts.

e/ Values for canary rockfish and yelloweye rockfish represent specified harvest guidelines.

f/ Values are proposed EFP bycatch caps, not estimates of total mortality. The EFP is terminated inseason if the cap is projected to be attained early. There is no EFP set-aside for yelloweye rockfish in 2008.

Table 3 (North) to Part 660, Subpart G -- 2006 Trip Limits for Limited Entry Trawl Gear North of 40°10' N. Lat.

Other Limits and Requirements Apply -- Read § 660.301 - § 660.390 before using this table

62006

		JAN-FEB	MAR-APR	MAY-JUN	JUL-AUG	SEP-OCT	NOV-DEC
	Rockfish Conservation Area (RCA)[6/]: North of 40°10' N. lat.	75 fm - modified 250 fm [7/]	75 fm - 250 fm	75 fm - 200 fm	100 fm - 200 fm	75 fm - 200 fm	75 fm - modified 250 fm [7/]

Selective flatfish trawl gear is required shoreward of the RCA; all trawl gear (large footrope, selective flatfish trawl, and small footrope trawl gear) is permitted seaward of the RCA. Midwater trawl gear is permitted only for vessels participating in the primary whiting season.

See § 660.370 and § 660.381 for Additional Gear, Trip Limit, and Conservation Area Requirements and Restrictions. See §§ 660.390-660.394 for Conservation Area Descriptions and Coordinates (including RCAs, YRCA, CCAs, Farallon Islands, and Cordell Banks).

State trip limits may be more restrictive than federal trip limits, particularly in waters off Oregon and California.

TABLE 3 (North) con't

1/ Bocaccio, chilipepper and cowcod are included in the trip limits for minor shelf rockfish.
2/ Splitnose rockfish is included in the trip limits for minor slope rockfish.
3/ "Other flatfish" are defined at § 660.302 and include butter sole, curlfin sole, flathead sole, Pacific sanddab, rex sole, rock sole, sand sole, and starry flounder.
4/ The minimum size limit for lingcod is 24 inches (61 cm) total length.
5/ "Other fish" are defined at § 660.302 and include sharks, skates, ratfish, morids, grenadiers, and kelp greenling. Cabezon is included in the trip limits for "other fish."
6/ The Rockfish Conservation Area is a gear and/or sector specific closed area generally described by depth contours but specifically defined by lat/long coordinates set out at § 660.390.
7/ The "modified 250 fm" line is modified to exclude certain petrale sole areas from the RCA.
8/ If a vessel has both selective flatfish gear and large or small footrope gear on board during a cumulative limit period (either simultaneously or successively), the most restrictive cumulative limit for any gear on board during the cumulative limit period applies for the entire cumulative limit period.

To convert pounds to kilograms, divide by 2.20462, the number of pounds in one kilogram.

DRAFT

Table 3 (South) to Part 660, Subpart G -- 2006 Trip Limits for Limited Entry Trawl Gear South of 40°10' N. Lat.

Other Limits and Requirements Apply -- Read § 660.301 - § 660.390 before using this table

62006

		JAN-FEB	MAR-APR	MAY-JUN	JUL-AUG	SEP-OCT	NOV-DEC
	Rockfish Conservation Area (RCA)[6/]:						
	40°10' - 38° N. lat.	100 fm - modified 200 fm [7/]	100 fm - 150 fm				100 fm - modified 200 fm [7/]
	38° - 34°27' N. lat.	100 fm - 150 fm					
	South of 34°27' N. lat.	100 fm - 150 fm along the mainland coast; shoreline - 150 fm around islands					

Selective flatfish trawl gear is required shoreward of the RCA; all trawl gear (large footrope, selective flatfish trawl, and small footrope trawl gear) is permitted seaward of the RCA.

See § 660.370 and § 660.381 for Additional Gear, Trip Limit, and Conservation Area Requirements and Restrictions. See §§ 660.390-660.394 for Conservation Area Descriptions and Coordinates (including RCAs, YRCA, CCAs, Farallon Islands, and Cordell Banks).

State trip limits may be more restrictive than federal trip limits, particularly in waters off Oregon and California.

DRAFT

Table 4 (South). Continued

30	**Lingcod**[3/]	CLOSED	800 lb/ 2 months		CLOSED	
31	**Pacific cod**	1,000 lb/ 2 months				
32	**Spiny dogfish**	200,000 lb/ 2 months	150,000 lb/ 2 months	100,000 lb/ 2 months		
33	**Other fish**[4/] **& Cabezon**	Not limited				

1/ "Other flatfish" are defined at § 660.302 and include butter sole, curlfin sole, flathead sole, Pacific sanddab, rex sole, rock sole, sand sole, and starry flounder.
2/ POP is included in the trip limits for minor slope rockfish. Yellowtail is included in the trip limits for minor shelf rockfish.
3/ The minimum size limit for lingcod is 24 inches (61 cm) total length.
4/ "Other fish" are defined at § 660.302 and include sharks, skates, ratfish, morids, grenadiers, and kelp greenling.
5/ The Rockfish Conservation Area is a gear and/or sector specific closed area generally described by depth contours but specifically defined by lat/long coordinates set out at § 660.390.
To convert pounds to kilograms, divide by 2.20462, the number of pounds in one kilogram.

Table 5 (North) to Part 660, Subpart G -- 2006 Trip Limits for Open Access Gears North of 40°10' N. Lat.

Other Limits and Requirements Apply -- Read § 660.301 - § 660.390 before using this table

62006

		JAN-FEB	MAR-APR	MAY-JUN	JUL-AUG	SEP-OCT	NOV-DEC
	Rockfish Conservation Area (RCA)[6/]:						
	North of 46°16' N. lat.	shoreline - 100 fm					
	46°16' N. lat. - 40°10' N. lat.	30 fm - 100 fm					
	See § 660.370 and § 660.383 for Additional Gear, Trip Limit, and Conservation Area Requirements and Restrictions. See §§ 660.390-660.394 for Conservation Area Descriptions and Coordinates (including RCAs, YRCA, CCAs, Farallon Islands, and Cordell Banks).						
	State trip limits may be more restrictive than federal trip limits, particularly in waters off Oregon and California.						
1	**Minor slope rockfish[1/] & Darkblotched rockfish**	Per trip, no more than 25% of weight of the sablefish landed					
2	**Pacific ocean perch**	100 lb/ month					
3	**Sablefish**	300 lb/ day, or 1 landing per week of up to 1,000 lb, not to exceed 3,000 lb/ 2 months					
4	**Thornyheads**	CLOSED					
5	**Dover sole**	3,000 lb/month, no more than 300 lb of which may be species other than Pacific sanddabs. South of 42o N. lat., when fishing for "other flatfish," vessels using hook-and-line gear with no more than 12 hooks per line, using hooks no larger than "Number 2" hooks, which measure 11 mm (0.44 inches) point to shank, and up to two 1 lb (0.45 kg) weights per line are not subject to the RCAs.					
6	**Arrowtooth flounder**						
7	**Petrale sole**						
8	**English sole**						
9	**Other flatfish[2/]**						
10	**Whiting**	300 lb/ month					
11	**Minor shelf rockfish[1/], Shortbelly, Widow, & Yellowtail rockfish**	200 lb/ month					
12	**Canary rockfish**	CLOSED					
13	**Yelloweye rockfish**	CLOSED					
14	**Minor nearshore rockfish & Black rockfish**						
15	North of 42° N. lat.	5,000 lb/ 2 months, no more than 1,200 lb of which may be species other than black or blue rockfish [3/]					
16	42° - 40°10' N. lat.	6,000 lb/ 2 months, no more than 1,200 lb of which may be species other than black or blue rockfish [3/]					
17	**Lingcod[4/]**	CLOSED		400 lb/ month			CLOSED
18	**Pacific cod**	1,000 lb/ 2 months					
19	**Spiny dogfish**	200,000 lb/ 2 months		150,000 lb/ 2 months	100,000 lb/ 2 months		
20	**Other Fish[5/]**	Not limited					

TABLE 5 (North)

DRAFT

21	**PINK SHRIMP NON-GROUNDFISH TRAWL** *(not subject to RCAs)*	
22	North	**Effective April 1 - October 31:** groundfish 500 lb/day, multiplied by the number of days of the trip, not to exceed 1,500 lb/trip. The following sublimits also apply and are counted toward the overall 500 lb/day and 1,500 lb/trip groundfish limits: lingcod 300 lb/month (minimum 24 inch size limit); sablefish 2,000 lb/month; canary, thornyheads and yelloweye rockfish are PROHIBITED. All other groundfish species taken are managed under the overall 500 lb/day and 1,500 lb/trip groundfish limits. Landings of these species count toward the per day and per trip groundfish limits and do not have species-specific limits. The amount of groundfish landed may not exceed the amount of pink shrimp landed.
23	**SALMON TROLL**	
24	North	Salmon trollers may retain and land up to 1 lb of yellowtail rockfish for every 2 lbs of salmon landed, with a cumulative limit of 200 lb/month, both within and outside of the RCA. This limit is within the 200 lb per month combined limit for minor shelf rockfish, widow rockfish and yellowtail rockfish, and not in addition to that limit. All groundfish species are subject to the open access limits, seasons and RCA restrictions listed in the table above.

1/ Bocaccio, chilipepper and cowcod rockfishes are included in the trip limits for minor shelf rockfish. Splitnose rockfish is included in the trip limits for minor slope rockfish.
2/ "Other flatfish" are defined at § 660.302 and include butter sole, curlfin sole, flathead sole, Pacific sanddab, rex sole, rock sole, sand sole, and starry flounder.
3/ For black rockfish north of Cape Alava (48°09.50' N. lat.), and between Destruction Is. (47°40' N. lat.) and Leadbetter Pnt. (46°38.17' N. lat.), there is an additional limit of 100 lbs or 30 percent by weight of all fish on board, whichever is greater, per vessel, per fishing trip.
4/ The size limit for lingcod is 24 inches (61 cm) total length.
5/ "Other fish" are defined at § 660.302 and include sharks, skates, ratfish, morids, grenadiers, and kelp greenling. Cabezon is included in the trip limits for "other fish."
6/ The Rockfish Conservation Area is a gear and/or sector specific closed area generally described by depth contours but specifically defined by lat/long coordinates set out at § 660.390.

To convert pounds to kilograms, divide by 2.20462, the number of pounds in one kilogram.

36	**RIDGEBACK PRAWN AND, SOUTH OF 38°57.50' N. LAT., CA HALIBUT AND SEA CUCUMBER NON-GROUNDFISH TRAWL**						
37	**NON-GROUNDFISH TRAWL Rockfish Conservation Area (RCA) for CA Halibut, Sea Cucumber & Ridgeback Prawn:**						
38	40°10' - 38° N. lat.	100 fm - modified 200 fm [7/]	100 fm - 150 fm				100 fm - modified 200 fm [7/]
39	38° - 34°27' N. lat.	100 fm - 150 fm					
40	South of 34°27' N. lat.	100 fm - 150 fm along the mainland coast; shoreline - 150 fm around islands					
41		Groundfish 300 lb/trip. Trip limits in this table also apply and are counted toward the 300 lb groundfish per trip limit. The amount of groundfish landed may not exceed the amount of the target species landed, except that the amount of spiny dogfish landed may exceed the amount of target species landed. Spiny dogfish are limited by the 300 lb/trip overall groundfish limit. The daily trip limits for sablefish coastwide and thornyheads south of Pt. Conception and the overall groundfish "per trip" limit may not be multiplied by the number of days of the trip. Vessels participating in the California halibut fishery south of 38°57'30" N. lat. are allowed to (1) land up to 100 lb/day of groundfish without the ratio requirement, provided that at least one California halibut is landed and (2) land up to 3,000 lb/month of flatfish, no more than 300 lb of which may be species other than Pacific sanddabs, sand sole, starry flounder, rock sole, curlfin sole, or California scorpionfish (California scorpionfish is also subject to the trip limits and closures in line 31).					
42	**PINK SHRIMP NON-GROUNDFISH TRAWL GEAR** *(not subject to RCAs)*						
43	South	**Effective April 1 - October 31:** Groundfish 500 lb/day, multiplied by the number of days of the trip, not to exceed 1,500 lb/trip. The following sublimits also apply and are counted toward the overall 500 lb/day and 1,500 lb/trip groundfish limits: lingcod 300 lb/ month (minimum 24 inch size limit); sablefish 2,000 lb/ month; canary, thornyheads and yelloweye rockfish are PROHIBITED. All other groundfish species taken are managed under the overall 500 lb/day and 1,500 lb/trip groundfish limits. Landings of these species count toward the per day and per trip groundfish limits and do not have species-specific limits. The amount of groundfish landed may not exceed the amount of pink shrimp landed.					

TABLE 5 (South) con't

1/ Yellowtail rockfish is included in the trip limits for minor shelf rockfish and POP is included in the trip limits for minor slope rockfish.
2/ "Other flatfish" are defined at § 660.302 and include butter sole, curlfin sole, flathead sole, Pacific sanddab, rex sole, rock sole, sand sole, and starry flounder.
3/ The size limit for lingcod is 24 inches (61 cm) total length.
4/ "Other fish" are defined at § 660.302 and include sharks, skates, ratfish, morids, grenadiers, and kelp greenling.
5/ The Rockfish Conservation Area is a gear and/or sector specific closed area generally described by depth contours but specifically defined by lat/long coordinates set out at § 660.390.
6/ The "modified 200 fm" line is modified to exclude certain petrale sole areas from the RCA.
To convert pounds to kilograms, divide by 2.20462, the number of pounds in one kilogram.

CALIFORNIA DEPARTMENT OF FISH AND GAME MOTION ON THE ADOPTION OF THE 2007-2008 GROUNDFISH FISHERY SPECIFICATIONS/ MANAGEMENT MEASURES

For the 2007-2008, CDFG recommends that the Council adopt the following management measures for 2007-2008 that will keep harvests within recreational harvest targets for rebuilding and target species. California proposes maintaining the five regions described under the No Action Alternative to manage California recreational groundfish fisheries provided in Agenda Item F.6.b Supplemental CDFG Report on "Corrections to California Recreational Alternatives in Chapter 2.0 of the 2007-2008 Groundfish Management Specifications Draft EIS".

The status quo (No Action) California recreational management measures that continue to apply include the following:

- Regulations apply to groundfish (with sanddab fishery exception) and associated state-managed species (rock greenling, California sheephead, and ocean whitefish).
- The sport fishery for sanddabs, using gear specified in federal and state regulations (size #2 hooks or smaller), is exempt from the season closures and depth restrictions placed on other federally-managed groundfish.
- Retention of species in the Other Flatfish complex is allowed when fishing with size #2 hooks or smaller (≤ 11 mm from point to shank) for Pacific sanddabs.
- A two-fish bag limit for bocaccio in the northern RLMA (north of 40°10' N latitude to the Oregon/California border at 42° N latitude) and a one-fish bag limit south of 40°10' N latitude to the U.S./Mexico border within the 10-fish RCG daily bag limit.
- No retention of cowcod, canary, or yelloweye rockfish.
- Lingcod size limit of 24 inches with a daily bag limit of two fish.
- Notwithstanding other fishing opportunities for groundfish, lingcod may not be retained during January, February, March, and December.
- Waters of Cordell Bank less than 100 fm in depth are closed to fishing at all times.
- Recreational fishing for groundfish prohibited between the shoreline and the 10 fm (18 m) depth contour around the Farallon Islands and Noonday Rock.
- All divers (boats permitted while diving for rockfish or other closed species during closed periods provided no hook and line gear on board or in possession while diving to catch rockfish) and shore-based anglers would be exempt from the seasonal closures and depth restrictions for rockfish, greenlings, California scorpionfish, California sheephead, and ocean whitefish.
- Fishing is allowed within the Cowcod Conservation Areas shoreward of the 20 fm line when fishing is open for groundfish other than California scorpionfish, but including select non-groundfish species (California sheephead and ocean whitefish).

California recreational groundfish management measures that differ from status quo include the following:

- Combined rockfish + cabezon + greenling (RCG) complex daily bag limit of 10 fish, of which one can be a cabezon and two can be a greenling of the genus *Hexagrammos*.
- In the South Region, CA scorpionfish is open 12 months: 0-40 fm January-February, 0-60 fm in March-December.

The CDFG recommended recreational seasons and depth restrictions by region are summarized below.

2007-2008 CA Option H11=3

RCG SEASON BY REGION

Region	Jan	Feb	Mar	Apr	May	Jun	July	Aug	Sep	Oct	Nov	Dec
North region	---	---	---	---	> 30 fm Closed							
North Central	---	---	---	---	---	> 30 fm Closed						---
South Central - Monterey	---	---	---	---	---	> 40 fm Closed						---
South Central - Morro Bay	---	---	---	---	---	> 40 fm Closed						---
South Region	---	---	> 60 fm Closed									

NOTES AND KEY:
RCG = Rockfish, cabezon, greenlings
--- = Closed to boat-based fishing for RCG

Adopt nearshore commercial recommendations and trip limits contained in Agenda Item F.6.c Supplemental CDFG Report 2.

Agenda Item F.6.e
Supplemental Motion in Writing
June 2006

OREGON DEPARTMENT OF FISH AND WILDLIFE MOTION ON FINAL ADOPTION OF 2007-2008 GROUNDFISH FISHERY SPECIFICATIONS/MANAGEMENT MEASURES AND AMENDMENT 16-4

I move that the Council approve the following management measures for the 2007 and 2008 recreational and commercial nearshore groundfish fisheries as described in the Action Alternatives in the draft Environmental Impact Statement (DEIS) for final adoption.

RECREATIONAL

Action Alternative 3b (Chapter 2, DEIS, p. 90) with the following revisions (Table 1):

- Allow fishing in all-depth waters during the following time periods: January through March, and October through December.
- A Marine Fish Daily Bag Limit of 8 fish in aggregate.
- Stonewall Bank YRCA under the No Action Alternative (Chapter 2, DEIS, p. 55), as described by the following coordinates:

ID#	Degrees	Minutes	Degrees	Minutes
1	44	37.46	124	24.92
2	44	37.46	124	23.63
3	44	28.71	124	21.80
4	44	28.71	124	24.10
5	44	31.42	124	25.47

Table 1**:** ODFW preferred 2007-2008 Oregon recreational groundfish fishery management measures.

<table>
<tr><th colspan="12">Season Structure</th><th colspan="6">Bag/Length Limits</th></tr>
<tr><th colspan="12">Month</th><th rowspan="2">Marine Fish Daily Bag[a/]</th><th rowspan="2">Flatfish Daily Bag[b/]</th><th rowspan="2">Lingcod Daily Bag</th><th rowspan="2">Lingcod Length Limit</th><th rowspan="2">Cabezon Length Limit</th><th rowspan="2">Kelp Greenling Length Limit</th></tr>
<tr><th>J</th><th>F</th><th>M</th><th>A</th><th>M</th><th>J</th><th>J</th><th>A</th><th>S</th><th>O</th><th>N</th><th>D</th></tr>
<tr><td colspan="3">All depth</td><td colspan="6"><40 fm</td><td colspan="3">All depth</td><td>8</td><td>25</td><td>2</td><td>22</td><td>16</td><td>10</td></tr>
</table>

a/ Marine bag includes all species other than lingcod, salmon, steelhead, Pacific halibut, flatfish, surfperch, sturgeon, striped bass, pelagic tuna and mackerel species, and bait fish such as herring, anchovy, sardine and smelt

b/ Flatfish bag consists of all soles and flounders except Pacific halibut

Estimated impacts (mt) to overfished rockfish species under this suite of recreational management measures are:

Bocaccio[a/]	Canary	Cowcod[a/]	Darkblotched	POP	Widow	Yelloweye
	4.3		0	0	1.1	3.2

[a/] Bocaccio and Cowcod have not been declare overfished off Oregon.

COMMERCIAL

Commercial Limited Entry Fixed Gear and Open Access Fisheries

Adopt a 22-inch length limit for lingcod off Oregon and Washington (north of 42°00’ N. latitude) for the limited entry fixed gear and open access fisheries.

Commercial Limited Entry Bottom Trawl Fishery

Provide the ability to implement a “one-gear-on-board” per cumulative period regulation in the bottom trawl fishery as a routine management measure.

Commercial Nearshore Fisheries North of 40°10’ N. Latitude.

Action Alternative 3b as described in Chapter 2 of the DEIS (p. 88), absent any modifications.

Estimated impacts (mt) to overfished rockfish species under this suite of commercial nearshore management measures are:

Bocaccio	Canary	Cowcod[a/]	Darkblotched	POP	Widow [a/]	Yelloweye
0	1.7	0.1	0	0	0.1	2.1

[a/] This amount is combine for commercial nearshore fisheries north and south of 40°10’ N. latitude

TRIBAL MOTION ON FINAL ADOPTION OF 2007-2008 GROUNDFISH FISHERY SPECIFICATIONS/MANAGEMENT MEASURES AND AMENDMENT 16-4

Mr. Chairman,
I move that, for the 2007-2008 management cycle, the Council adopt as final the Proposed Treaty Indian Management Measures presented under Agenda Item F.2.b.
