Lingcod

STAR Panel Report

July 27-30, 2009
Deca Hotel
Seattle, WA

Panel Reviewers
Dr. Vidar Wespestad, STAR Chair and SSC representative
Dr. J.J. Maguire, Center for Independent Experts
Dr. Stephen Smith, Center for Independent Experts
Dr. Jim Ianelli, National Marine Fisheries Service Alaska Fisheries Science Center

STAR Panel Advisors Present:
Ms. Joanna Grebel, California Department of Fish and Game, GMT Representative
Mr. Dan Platt, GAP Representative
Mr. John DeVore, PFMC Representative

STAT:

Dr. Owen Hamel, National Marine Fisheries Service Northwest Fisheries Science Center
Ms.Suresh Sethi, School of Aquatic and Fisheries Sciences, University of Washington
Mr. Thomas Wadsworth, Moss Landing Marine Laboratories, Moss Landing, California
Dr. Hamel was present and presented for the STAT

Overview

A draft assessment of lingcod (*Ophiodon elongatus*) off the west coast of the United States, from the U.S.-Mexico border to the U.S. Canadian border was reviewed by the STAR panel during July 27-31, 2009. The assessment was conducted as two separate assessments of (1) Lingcod off of Washington and Oregon (the North stock), and lingcod off of California (the South stock).
For each stock, two fisheries are modeled: the commercial fishery and the recreational fishery (four fisheries). Landings are included from 1928-2008, with equilibrium landings estimated for the commercial fisheries prior to 1928. Since the fishery off of California developed earlier, the equilibrium catches there are an order of magnitude higher.
The previous assessment was conducted in 2005 in SS2. The current assessment utilizes SS3, extends the catch series, commercial discard rates from 2002-2007; Triennial survey indices for the years 1980-2004; NWFSC survey indices for the years 2003-2008; commercial logbook CPUE indices for the years 1976-1997 (North) or 1978-1997 (South); PSMFC Dockside (recreational) boat survey index 1980-1989, 1993-1997 (South); Commercial length composition data for 1965-2008 (North) or 1978-2008 (South); Commercial discard length composition data for 2003-2007 (North) and 2004-2007 (South); Recreational length composition data for 1993-2008 (North) or 1987-2008 (South); Triennial length composition data for 1986-2004 (North) or 1989-2004 (South); NWFSC length composition data for 2003-2008.

Age data was available and used in sensitivities but not in the base models due to issues with outliers and possible aging bias. Removing the age data significantly changed the recruitment time series- scaling it down and redefining recruitment strength in the early 1970s. The effect on the south model was clearly less significant, which was expected given the lack of age data in the south.

The current assessment indicated that the stock has recovered when assessed from a coastwide perspective as well as when assessed separately as substocks off of Washington and Oregon, and off of California. Overfishing last occurred in 2003, although there was some dispute about the magnitude of recreational fishery catch off of California for that year. The Base Model results for the depletion ratio of the spawning biomass at the start of 2009 were 61.9% for the North, 73.7% for the South, and 67.0% coastwide.

The STAR panel concluded that the lingcod assessment constitutes the best available scientific information on the status of lingcod off the U.S. west coast and recommends that it be used for status determination and management in the Council process. The STAR panel thanks the STAT members for their thorough preparation and willingness to respond to panel requests.

Analyses requested by the STAR Panel

1. The original base case models started estimation of recruitment in 1970 but the residual pattern for the commercial length compositions from the Northern stock indicated that there were strong signals for one or more year-classes moving through the fishery between 1966 and 1971 that were not being fit well by the model (Figures 70 and 71). The panel asked for a sensitivity run with the estimation of recruitment starting in 1950 for the Northern stock. Relatively large numbers of fish were sampled from a few trips in

the mid-1960s and the panel recommended that input N be calculated as 3.5 times the number trips in this early period — half the average conversion used for the more recent years.

The new model set 1950 as the initial year for estimating recruitment in the northern model and resulted in a better fit to the length compositions in the 1960s and hence reduced the associated residuals as well as picking up the large recruitment in 1964 which had not been so for the original base case. Depletion was estimated to be 47% compared to 62.1% for the original base case. These results suggest that the final base case should start estimating recruitment at least as early as 1950.

2. The stock assessment includes catches from 1928 but with recruitment only being estimated from 1970 in the original base case, error estimates for recruitment in the early period were obtained directly from the stock/recruitment curve and underestimated the true uncertainty for recruitment and other associated parameters from this early period. The panel requested a sensitivity run with recruitment estimated starting in 1928 to evaluate the uncertainty associated with SB_zero.

   The standard deviation for SB_zero changed by 1.4 times for the northern model and by 3.28 times for the southern model. This difference seemed reasonable given that there was more data for the northern model and the standard deviations were considered realistic enough to have the new base case begin estimating recruitment starting in 1928.

3. Include estimates of uncertainty estimated in request 2 as well as for many of the other parameters presented in the sensitivity tables.

   The standard deviations for SB_zero and SB_2009 were included the new sensitivity runs requested but there was some question as to whether all of the uncertainty was actually captured. The STAR panel and STAT deferred on how to better capture all the uncertainty given the structure of the assessment.

4. Spawning output is expressed in terms of female spawning stock and ignores the importance of the nest-guarding by the males for successful reproduction. The panel requested that the annual trend in sex ratio by numbers for ages five-plus from 1928 to 2009 be investigated to determine if fishing may have resulted in significant changes in this ratio leading to changes in spawning success.

   The proportion of females in the catch varied between 70 and 80% in the northern with little evidence of trend while the proportion of females in the south has declined since 1980, dropping to 65 to 70% in the 1980s to mid-1990s and again in 2003 to 2005.

   in The higher proportion of males in the southern area is not really indicative of any trend; but the proportion of males in the catch during the period of nest guarding may factor into reproductive success and perhaps be used as an indicator and incorporated into evaluations of reproductive output.

5. Growth curves for both sexes in the northern area estimated a length of 20 cm at age 0 (Figure 48) which seemed too large given the data. In addition, it was not clear whether SS3 assumes that T_0 equals 0 when estimating k and L_infinity. The panel requested that the data and growth model fit presented in Figure 48 be verified.

   This analysis discovered that lengths-at-age in SS3 were actually beginning of year and not mid-year as previously assumed. Changes to bin size, etc., were tried but results were still not satisfactory. Given that the model actually uses beginning of year length-at-age, the associated dispersions for the lengths-at-age will need to be lined up properly. Other options for setting the length at age 0 will be explored for the final base case run.

6. There appears to be a large number of outliers in the length-at-age relationships for the commercial data in the northern area (Figs 7 to 10) that may be due to incorrect determination of gender for the sampled fish. The panel requested a model run with combined sex conditional length-at-age compositions to evaluate this possibility.

   Combined sex conditional length-at-age compositions did not appear to resolve the outlier issue and made little difference to the model fit or parameter estimates.

7. The STAT presented a sensitivity model with no age data and the panel requested that the recruitment estimates from this sensitivity run be compared with the base case recruitment estimates to provide insight into how the age data and outliers identified in request 6 maybe affecting the model.

   The age data results in lower recruitments since 2000 than estimated without ages for the northern model. In the south there was less of a consistent pattern for the recruitment series estimated with and without ages. These results suggested that the no age option should be retained as a sensitivity run for the final base case.

8. The Washington tagging data was not used in the current assessment having been criticized in the previous assessment. The panel requested that the trends from the tagging data be plotted against recruitment estimates from base case to evaluate if there could be any reason to use the index.

   There was insufficient time to address this request.

9. The 2003 NWFSC survey estimate of lingcod biomass was much higher than either the 2004 estimate from the same survey or the 2004 estimate from the triennial survey. The panel requested that the frequency distribution of catches per tow be tabulated for the NWFSC by year for North and South areas. In addition, the catches making up the 2003 estimate from the NWFSC survey should be investigated to determine if there are reasons why the estimate may not be reflecting actual abundance.

   Three large tows of lingcod accounted for 63.5% of the total lingcod catch in the 2003 NWFSC survey. The first of these tows there was adequately sampled while the second and third tows contained large catches of dogfish and were subsampled. The second tow had only two lingcod in the subsample (one male and one female) that were scaled up to represent the overall catch. All three tows had large lingcod in them. There is really very little that can be done to develop a defensible estimate of the numbers caught after the fact when something like this happens and onboard procedures need to be in place to specify an adequate sample in these kinds of circumstances.

10. A dome-shaped selectivity pattern was estimated for the triennial survey in the north while the selectivity pattern was asymptotic for the southern area. Given that there was less data to estimate the selectivity pattern in the south and no reason to believe that selectivity patterns should differ between the two areas, the panel requested a model run for the south using the dome-shaped selectivity for the triennial survey.

    Use of the dome-shaped selectivity for the triennial survey from the northern model in the southern model resulted in a slight increase in biomass over the base case but stock status did not change appreciably. The panel recommended using the dome-shaped selectivity in the final base case for the southern model.

11. A number of extra abundance indices (e.g., PISCO scuba index, CENCAL index) were presented by the STAT for the southern area and evaluated in terms of improvement in fit for the abundance indices used in the base case. The panel requested that the fits of the south model to the abundance indices both with and without the extra indices be presented to fully evaluate the usefulness of these extra indices.

    The plots of the fits of the model to the abundance indices were updated as requested and showed that the extra abundance indices contributed little to improving the fit of the model.

12. Sensitivity runs presented by the STAT showed that removing the triennial survey from the southern model resulted in little change to stock status while removing the commercial and recreational CPUE data resulted in a much lower depletion level. The latter time series were only used up to 1997 to account for management changes in the more recent years and is was difficult to understand the reasons for the sensitivity results. The panel requested plots of the biomass trends from the sensitivity run for the southern model with either CPUE or the triennial survey indices removed.

    The biomass trends for the no triennial survey case were virtually identical to those of the base case while removal of the CPUE data resulted in lower overall biomass, especially in the most recent years. The possibility that the trends in the CPUE data relative to those in triennial survey prior to 1998 may compensate in the model for decline in the triennial survey after 1998 was discussed but it was not clear what the mechanism behind this behavior was.

13. The STAT presented sensitivity runs for the north model removing either the NWFSC survey, the triennial survey or the commercial CPUE. For any one of these runs, stock status changed little from the base case. The panel requested a sensitivity run with all of

the abundance indices and associated composition data removed from the Northern model to understand the influence of these indices on the northern model.

The removal of all of the abundances from the model resulted in little change in stock status from the base case model, probably reflecting the poor fit to the abundance indices, especially in the most recent years. Current trends appear to be a consequence of the trends in the length compositions.

14. The panel requested that the monthly distribution of catches be tabulated for both areas starting in 1981 to see if there have been seasonal changes in the monthly distribution of catches that might explain patterns observed in the length-at-age data.

    Catches appear to have increased in the May to July and August to October periods relative to the rest of the year since around 1997/98. Further investigation into the possible impact of this trend could be deferred to be a research recommendation.

15. The panel requested some preliminary runs on two new base case candidates:

    a. Estimate recruits starting in 1928, estimate L_1 and L_2 to be within a range of ages where adequate amounts of data were observed (e.g., ages 2 and 20, respectively) and use the selectivity estimated for the triennial survey in the north for the southern model.
    b. As above but remove all ages (checking to see if L_1 is still estimable).

    Initial results suggested that the outliers in the length-at-age data were affecting the models and the decision was made to go ahead with removing the age data for the base case. The new base run was compared to lower and higher assumed natural mortality rates in the north and south (M = 0.16 – 0.22, 0.18 base females; 0.285 – 0.39, 0.32 base males) and lower and higher values of assumed steepness (h = 0.7 – 0.9, 0.8 base). There was surprisingly little contrast in the results across this range of uncertainty.

Base Model Specification

The Panel agreed with the stock structure splits for north and south management units. For each region there are two fishing fleets. In the north three indices are used and in the south, there are four abundance indices. The model ranged from 1928 through 2008. In both models there was a single block for commercial selectivity and retention changes, occurring in 1998 (to present) reflecting the increased regulation and areal limitations which have come into place over that period. That same block is used to model changes in recreational selectivity, reflecting changes in minimum size limits. In the North, male and female selectivities are estimated separately for the recreational fishery, whereas data to do so is lacking in the South.

The modeled ages extended from 0 to the accumulator at age 20. The modeled length bins range from 10 to 128 at 2 cm intervals while the data extend from 28 to 110 cm. Growth is partially estimated, with max size estimated in N but not in S. The value of “L1” (length at age 1) is to be estimated.

The age data were omitted from both models since these data showed a poor residual pattern that was apparently due to data outliers. Also, at early ages there appears to be mis-aging that was not captured appropriately. Results using the length frequency data alone significantly changed the recruitment time series- scaling it down and redefining recruitment strength in the early 1970s. The effect on the south model was clearly less significant, which was expected given the lack of age data in the south. The Panel and author agreed that the results were an improvement and resolved a number of fit issues and residual patterns. In particular, the poor residual pattern noted in Figure 71 of the draft assessment was resolved.

The estimates of triennial survey selectivity for the northern stock are to be used for the southern stock since the original selectivity estimates were unreasonable.
The underlying model is dis-aggregated by gender in order to capture the sex-specific differences in natural mortality (set to 0.18 yr-1 for females and 0.32 yr-1 for males). Data on gender-specific composition data were available. Recruitment is to be estimated from 1928 (to better capture historical uncertainty in stock size) and the steepness parameter is fixed at 0.8. Other details for the base model were agreed and are as specified in the document (i.e., Tables 13-15).

Technical merits of the assessment

This was a very thorough assessment that explored a number of sources of uncertainty. The STAR Panel agrees with the STAT view that there was inherent uncertainty that was not included in the model that may be important such as the degree of connection between the two lingcod stocks and also between the northern stock and the stock off British Columbia; the effect of the PDO, ENSO and other climatic variables on recruitment, growth and survival of lingcod.

The STAR Panel found that the STAT base model is the best available results given the uncertainties regarding surveys and age and growth data addressed above. The sensitivity results showed high uncertainty in age data. A base model was selected based on extensive model testing and an attempt was made to balance the sources of uncertainty. In addition, an attempt was made to make the North and South models as equivalent in as possible.
The Panel recommends that the next lingcod assessment be an update rather than a full assessment. Given the problems event in the age and growth data and problems in survey availability the STAR Panel does not recommend another full assessment until the data issues are addressed.

Explanation of areas of disagreement regarding STAR panel recommendations

A. Among STAR panel members (including concerns raised by the GAP and GMT representatives

There were no areas of disagreement among STAR panel members.

B. Between the STAR panel and the STAT

There were no areas of disagreement between the STAR panel and the STAT.

Unresolved problems and major sources of uncertainty

Management, data, or fishery issues raised by the GAP and the GMT representatives

There were discussions regarding near shore surveys and the potential need to look at existing area closures that may improve access to lingcod by near shore fisheries. The GMT will be examining these issues as part of their management review.

Prioritized recommendations for future research and data collection

1. Investigate the effect of the year when recruitment is estimated on the estimates of B0 and of current status, since this may have an effect the estimated level of depletion.

2. Investigation of the large survey estimate for lingcod in the 2003 NWFSC survey showed that catches from only three tows made up 63.5% of the total lingcod catch in the survey. The second and third large tows also had large catches of dogfish and the catches were subsampled for counts and detailed sampling. As a result only 2 lingcod were actually measured in the second largest tow (one male and one female) but these measurements were expanded to the whole catch. It is difficult and inappropriate to try to correct such estimates after the fact during the assessments. Instead onboard sampling procedures need to be developed to ensure that a proper and informative subsample of fish be measured during the survey.

3. The sensitivity run with no abundance indices produced a similar fit to the base case suggesting that there was little trend information in the abundance indices used in the base case. Can it be determined if the NWFSC survey is fishing in the right places for lingcod? Are there other survey techniques that can be used (e.g., longline, combined lingcod/sablefish pot survey, trap surveys)?

4. Investigate the suitability of using catches of lingcod in the IPHC survey as an alternate abundance index.

5. Re-examine the usefulness of the Washington tagging data for next assessment.

6. There was confusion over whether SS3 was using mid-year or beginning of year length at age resulting in larger than expected mean length at age for age 0 and 1. The method for setting the correct mean length at age for the younger ages needs to be clarified before the next assessment.

7. Further investigation of the age and length data needs to be done to understand if seasonal or area differences or some other causes are behind the outliers observed in the length-at-age data.

8. Look at environmental covariates for recruitment and time-varying growth and availability inshore.

9. The fact that lingcod males (and cabezon) are nest-guarders was ignored when determining reproductive output. A cursory look at the proportion of sex ratio in the catch did not appear to indicate any serious changes for either species in recent years. However, we do not know what kind of change in sex ratio would indicate a serious change in reproductive success. The impact of nest-guarding on reproductive output should be investigated.

Acknowledgements

The Panel thanks Dr. Jim Hastie and staff at the NWFSC for their exceptional support and provisioning during the STAR meeting.

Executive Summary

Stock

This is the third full assessment of the population status of cabezon (*Scorpaenichthys marmoratus* [Ayres]) off the west coast of the United States. The first assessment was for a state-wide California cabezon stock in the year 2003 (Cope *et al.* 2004). The second assessment (Cope and Punt 2006) considered two sub-stocks (the northern California sub-stock (NCS) and the southern California sub-stock (SCS)), demarcated at Point Conception, CA. The current assessment retains the two California sub-stocks, also evaluating the population as a coast-wide California stock (CAS), and extends the assessment to a third sub-stock for cabezon in the waters off of Oregon (ORS). Separation of these spatial sub-stocks is based on distinguishing localized population dynamics, preliminary population genetics results, and is supported by spatial differences in the fishery (the NCS has been the primary area from which removals have occurred), the ecology of nearshore groundfish species, and is consistent with current state management needs.

Catches

Cabezon removals were assigned to six fleets in California (two commercial and four recreational) and four fleets in Oregon (two commercial and two recreational) for each sub-stock because each of these fleets targets a different component of the population (Figures E-1–E-3; Table E-1). The California time series begins in 1916, with the onset of commercial landings, while Oregon begins in 1973, with the start of the recreational fishery. Historical recreational removals for California were based on the reconstruction used in Cope and Punt (2006), while the staff of the Oregon Department of Fish and Wildlife supplied the historical Oregon recreational time series. Historically, vessel-based recreational catch (PBR (private) and CPFV (charter)) has been the primary reported source of biomass removals of cabezon. Commercial catch has become a major source of removals in the last 15 years because of the developing live-fish fishery in both California and southern Oregon. The sensitivity of the assessment results to the magnitude of historical recreational catch is explored as part of the assessment. Commercial discard mortality, assumed negligible in the last assessment, is included in this assessment. Because cabezon are caught primarily in the nearshore fishery and are believed to not suffer from barotrauma, discard mortality is assumed to be low. The sensitivity of model outputs to assumptions of discard mortality is explored.

Catch histories used in the current assessment differ slightly from the former assessment (Figure E-4). Whereas the commercial removals are very similar, the recreational sector is different from 1980 onward. These years are mostly dependent on RecFIN data extractions, which showed both changes in mean weights and numbers of catch, resulting in minor but noticeable differences. The largest difference is found in 1980, where the RecFIN PBR value in southern California (SCS) was determined to be unreasonably high and set instead to the average of values for years 1981-1989.

Data and assessment

Each sub-stock assessment uses data on size (mean weight and length compositions) and indices of abundance to inform the population dynamics, as was the case in the 2005 assessment. Additionally, these assessments incorporate conditional age-at-length data for the first time to estimate growth parameters internal to the model (previous assessments used growth parameters derived from externally fitted growth curves). All sub-stock assessments use Stock Synthesis 3.03A as the modeling environment.

Several potential indices of abundance are formally considered for the California sub-stocks: 1) Fishery-dependent CPFV logbook CPUE, a CDFG hook-and-line survey, and PSMFC dockside and onboard surveys, 2) Fishery-independent adult surveys (TENERA and PISCO), and 3) recruitment surveys (CalCOFI, Southern California Edison Impingement, PISCO SMURFS, SLO SMURFS). There is also one index of abundance for the Oregon sub-stock based on the Ocean Recreational Boat Survey (ORBS) sampling program. Changes in bag and size limits in California also necessitated the separation of the CPFV data into two series: 1960-99 and 2000-08. This approach differs from the previous assessment, which used a continuous index from 1960-2004. Sensitivity of model output to this assumption is investigated.

Each index of abundance is developed by fitting generalized linear models (GLMs) to the proportion of non-zero records and the catch-rate given that the catch was non-zero, and taking the product of the resultant year effects. Only the CPFV logbook index is used in the base model for the California sub-stocks, because of its area-wide coverage. Small-scale resolution, large uncertainty, short time series, and potential bias in SCUBA surveys for cryptic species like cabezon, as well as the low occurrence of cabezon in sampling protocols ruled out including the other indices in the base case. The Oregon sub-stock base case included the ORBS survey.

Additional modifications were made to the specification of this year's assessment models, relative to the previous assessment. Changes in regulations necessitated the implementation of time blocks on the selectivities of the commercial live-fish fishery and boat-based recreational fleets for all sub-stocks. Additional variance was applied to the perceived variability of the candidate abundance indices in order to address the underestimation of variability in the delta GLM-based models. The models were also tuned to balance the input of recruitment variability ($_R$) and sample sizes of length and age compositions with model output estimates of these same values. This resulted in $_R$ values less than those used in the last assessment.

Stock biomass

Cabezon were lightly exploited until the 1940s in California, particularly in northern California. Catches began to increase in southern California in the 1960s. This increase in catch caused a relatively large decline in spawning biomass. In Oregon, the take of cabezon did not begin until the 1970s, which in turn has also caused a decline in spawning biomass (Figures E-5 and E-6). The estimated depletion levels for NCS and SCS are 45% (± 7%) and 60% (± 14%), respectively. Estimated depletion for the CAS and ORS sub-stocks are 34% (± 6%) and 52% (± 10%), respectively. Greatest uncertainty is found in the smaller SCS and ORS sub-stocks.

The model-derived initial and terminal female spawning biomass estimates corresponding to the above depletion measures are 1036 (± 60) and 469 (± 97) mt for the NCS, 262 (± 23) and 158 (± 48) mt for the SCS, 1207 (±61) and 410 (± 85) mt for the CAS and 409 (±57) and 214 (±69) for the ORS. Overall, spawning biomass has increased in California in recent years but not in Oregon. Recent trends in spawning biomass and depletion for each sub-stock can be seen in Tables E-2 and E-9.

Total unfished cabezon spawning output, as a sum of the two California sub-stocks, is estimated at 1298 mt compared to 1361 mt for the 2005 assessment. The CA state-wide estimates of spawning output are 1207 mt for the 2009 assessment and 1268 mt for the 2005 assessment (Table E-3). Current total cabezon spawning output, summed from the two sub-stock models is 627 mt, compared with 410 mt for the one stock state-wide model. Median depletion in the 2005 assessment versus the 2005 depletion estimate from the current assessment is more similar to the results obtained from summing the two sub-stock models than for the one stock state-wide model.

Though much of the declines in cabezon populations correspond to removals by the recreational fishery sectors, the added impact of the live-fish fishery is also witnessed in declines through the mid- to late-1990s in all sub-stocks.

Recruitment

A Beverton-Holt equation with lognormal process error is used to characterize the spawner-recruitment relationship of all cabezon sub-populations. The steepness parameter is also set to 0.7 for all base models. Recruitment residuals are estimated for 1970–2006 for all California sub-stocks and 1980-2006 for the Oregon sub-stock. These series were defined by identifying the informative portion of recruitment deviations through declining asymptotic variances when the full time series of recruitment deviations are estimated. The last 10 years of recruitments for each sub-stock are found in Tables E-4 and E-9.

There are several notable recruitment events in and among the California stocks after 1980, but only one (in 2005) after 2000 (Figures E-7 and E-8). Distinct recruitment patterns are seen in both California sub-stocks. For the state-wide California model, all recruitments since 2000 are below the expectation of deterministic recruitments, contributing to the overall decline in recent years. The fact that depletion in the state-wide model is estimated to be lower than that of either individual sub-stock demonstrates how overall recruitment patterns can be altered by combining data from areas with different patterns. Such an approach can diminish or embellish recruitment deviations and result in emergent population dynamics unrepresentative of the individual areas (Figure E-9). The addition of more age-composition data would help resolve more fully the estimates of recruitment patterns in California.

Oregon recruitment is less dynamic than in California, but shows a similar trend of one large recruitment in the late 1990s (1999) and only one notable recruitment above expectation in the most recent years (2004). The relative uncertainty around recruitments in Oregon is also lower than in the California sub-stocks.

Recruitment deviations

Year

Figure E-9. Recruitment deviations for each of the California sub-stocks.

Reference points

The unfished spawning outputs of the northern and southern California cabezon sub-stocks are estimated to be 1036 (NCS) and 262 (SCS) mt, respectively, with estimated 2009 spawning outputs of 469 (NCS) and 158 (SCS) mt (Figure E-5). The unfished spawning outputs for the state-wide California and Oregon stocks are estimated at 1207 (CAS) and 409 (ORS) mt, respectively, with estimated 2009 spawning outputs of 410 (CAS) and 214 (ORS) mt (Figure E-6). Total unfished cabezon spawning output, as a sum of the two California sub-stocks, is estimated at 1298 mt. This compares to 1361 in the 2005 assessment and 1207 for the 2009 one CA sub-stock. Current total cabezon spawning output for the summed CA sub-stock models is 627 mt, compared with 410 mt for the one-stock model. Median depletion in 2005 versus the 2005 depletion estimate from the current assessment is more similar to the summed results of the two sub-stock models than the one-stock model.

The target reference point for cabezon is 40% of the spawning biomass ($SB_{40\%}$), with a limit reference point of 25% ($SB_{25\%}$). Allowable Biological Catch is set using an

F_{MSY}-proxy harvest rate of $SPR_{45\%}$ ($F_{45\%}$), with Optimum Yields reduced from that level, according to the 40-10 harvest policy, when the spawning biomass falls below the target level. An alternative set of reference points comes from the Nearshore Fishery Management Plan (NFMP) of California that suggests a 60-10 rule with $SPR_{50\%}$ ($F_{50\%}$). Under these scenarios, the reference points only changed when based on the SPR proxy for MSY. Due to the large number of reference points and associated yields relating to the four base case models in this assessment, refer to Table E-10 for each of the sub-stock-specific quantities. Population and fishing rates relative to target levels are given in Figures E-10 and E-11.

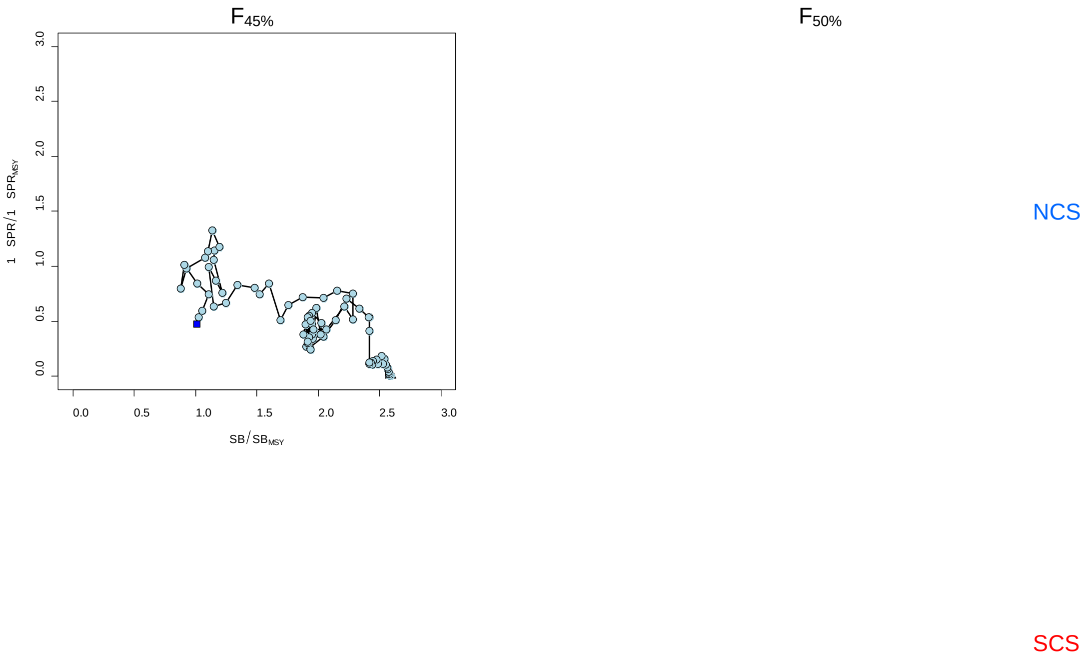

Figure E-10. Spawning biomass (x-axis) and exploitation rates (y-axis) relative to the target levels (at MSY) for each sub-stock (NCS top row; SCS bottom row) for each F_{MSY} proxy (columns). Solid triangles represent the start of the time period; solid squares represent the end of the time period.

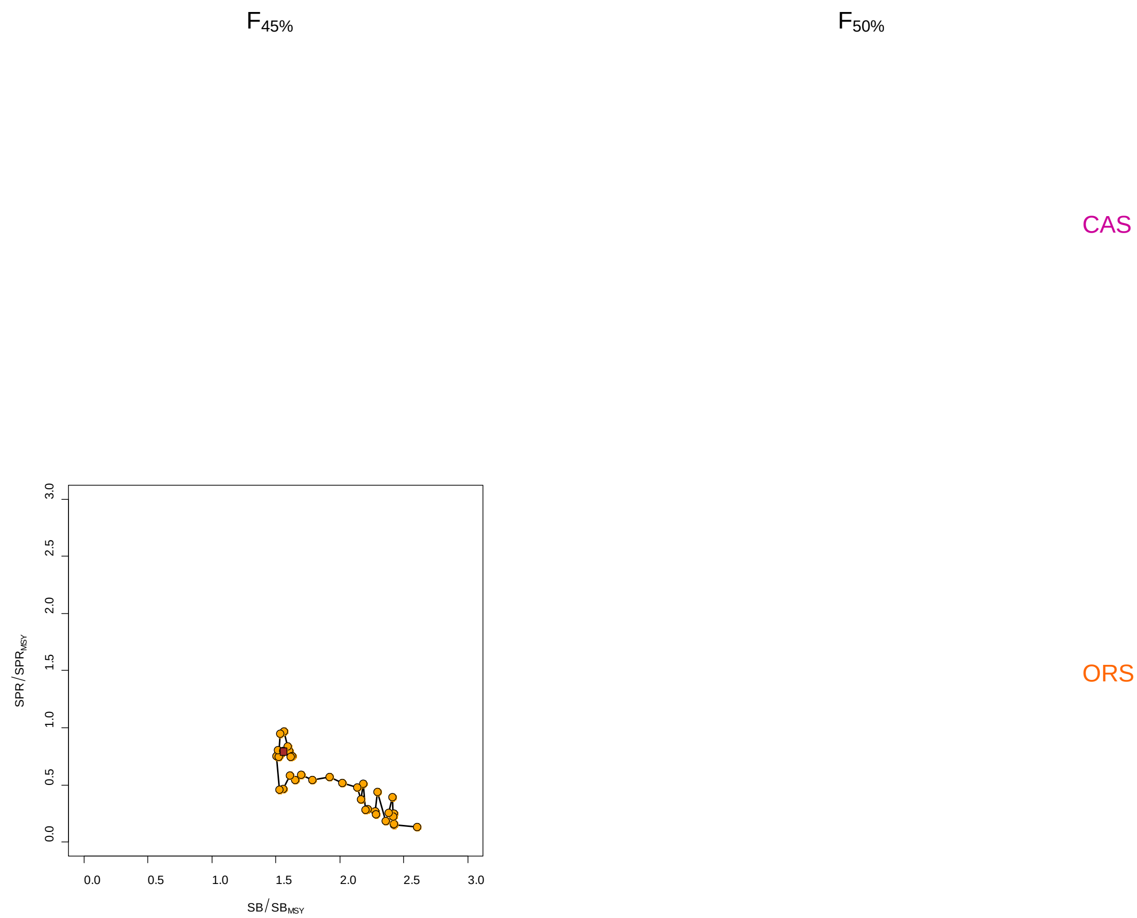

Figure E-11. Spawning biomass (x-axis) and exploitation rates (y-axis) relative to the target levels (at MSY) for each state sub-stock (CAS top row; ORS bottom row) for each F_{MSY} proxy (columns). Solid triangles represent the start of the time period; solid squares represent the end of the time period.

Exploitation status

The abundance of cabezon is estimated to have dropped below the $SB_{40\%}$ management target in 1998 (CAS), 1999 (NCS) and 1986 (SCS) in the California sub-stock base case models. Oregon has yet to fall below the target level. The state-wide California model approaches the overfished threshold ($SB_{25\%}$) in the year 2001 and the SCS falls below this threshold in the years 1991-1998 (Figure E-12). The current (2009) spawning output of the cabezon resource off California is estimated to be about 45% (NCS) and 60% (SCS) of the unfished level, both above the target level of 40% (Figure E-12). The state-wide California model is currently estimated at 34% of the unfished biomass, below the target but above the limit reference point. The Oregon base case estimate of depletion is at 52%, above the target level. The SCS model is the most dynamic, with large uncertainties in current biomass. While the uncertainty in the depletion level of the Oregon stock is generally low, uncertainty in the spawning biomass is high (Figure E-6).

Fishing mortality rates in excess of the current F-target for cabezon of $SPR_{45\%}$ are estimated to have begun in the 1980s in southern California and in the 1990s in northern California (Figure E-13), but have dropped in more recent years (Table E-5). Harvest rates for the Oregon stock have not exceeded this target level. In 2008, relative F (catch/biomass of age2+) is estimated at 0.04 (NCS), 0.03 (SCS), 0.06 (CAS) and 0.09 (ORS) for the sub-stocks.

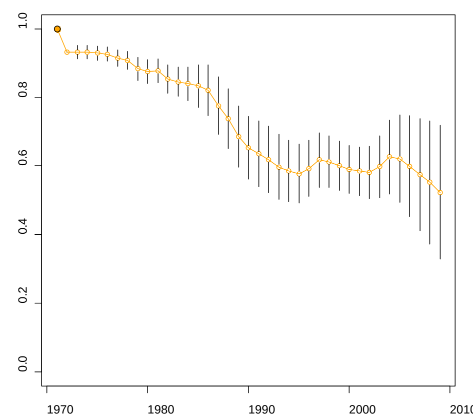

Figure E-12. Time trajectories of depletion and spawning output compared to the target and limit reference points for each cabezon sub-stock considered in this assessment.

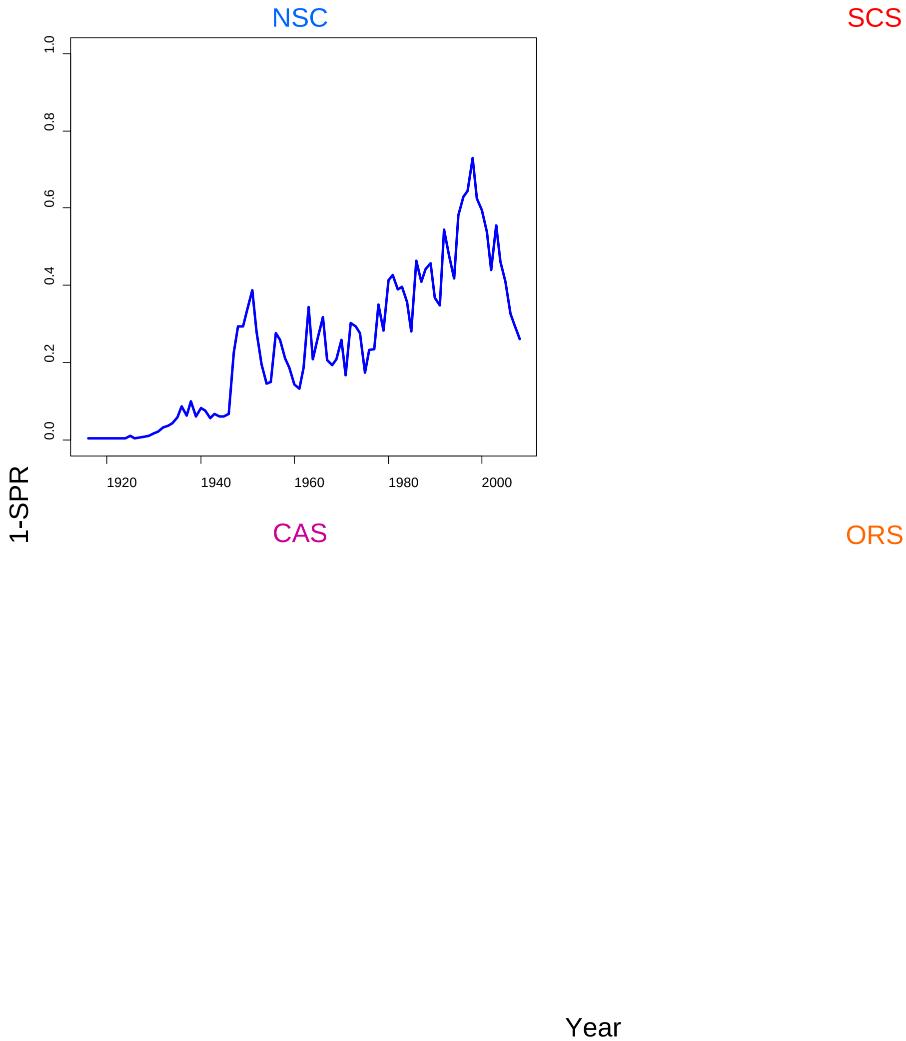

Figure E-13. Estimate of the spawning potential ratio (1-SPR) from each of the sub-stock base case models. Values above the red overfishing line indicate fishing above the MSY proxy harvest rate.

Table E-5. Recent trend in fishing rate as it relates to spawning potential ratio (1-SPR) and relative exploitation rate (catch/biomass of age-2+).

Management performance
Currently, cabezon has a 15 inch size limit in California for both the commercial and recreational fisheries. Since 2005, there has been a one fish bag limit for recreational anglers. Cabezon experienced emergency commercial closures for some portion of the year from 2001-2005 once the OY had been exceeded. Since then, cumulative trip limits have been reduced from 900 pounds to 200-300 pounds (inseason adjustment) so the commercial fishery could remain open year-round and not exceed the state-wide OY of 69 mt (Table E-6). Even though the 2005 assessment of cabezon was split into two sub-stocks, resulting in depletion levels of 40% (NCS) and 28% (SCS), the State of California continued to manage cabezon on a state-wide level.

Oregon established a 16 inch size limit for cabezon in 2004. Currently, there is a six fish bag limit for the “rockfish et al” complex combined that includes cabezon. From 2004-2008, inseason changes were made where cabezon were prohibited to be taken by boats during portions of the year. This is the first of assessment of cabezon in Oregon, so ABCs have not been previously set for cabezon to evaluate management performance.

Figures E-10 and E-11 indicate reference points based on the federal (the 40-10 control rule with a $F_{45\%}$ F_{MSY} proxy) and state (the 60-20 control rule with a $F_{50\%}$ F_{MSY} proxy) guidelines for each sub-stock. The SCS assessments demonstrates a sub-stock that was historically overfished and undergoing overfishing, based on the current harvest rate proxies. For the SCS, these thresholds were exceeded from the 1980s through the 1990s (Figure E-13). The NCS and CAS experienced potential overfishing during the late 1990s (attributable to the increase in live-fish landings), but never exceeded harvest to a level to be considered overfished (Figure E-13). The ORS base case infers that no level of overfishing has occurred, though exploitation rates have been at their highest historical levels in the most recent years (Figure E-13).

Table E-6. Recent trend in estimated total cabezon catch and commercial landings (mt) relative to management guidelines. [N/A because cabezon have been managed using state-wide OY (CAS) or first time assessment (ORS).] The NCS has recently landed around 80% of California's state-wide cabezon take, SCS around 20%.

* State-wide OYs in California (CAS) prior to 2005 were put into place by the Fish and Game Commission.

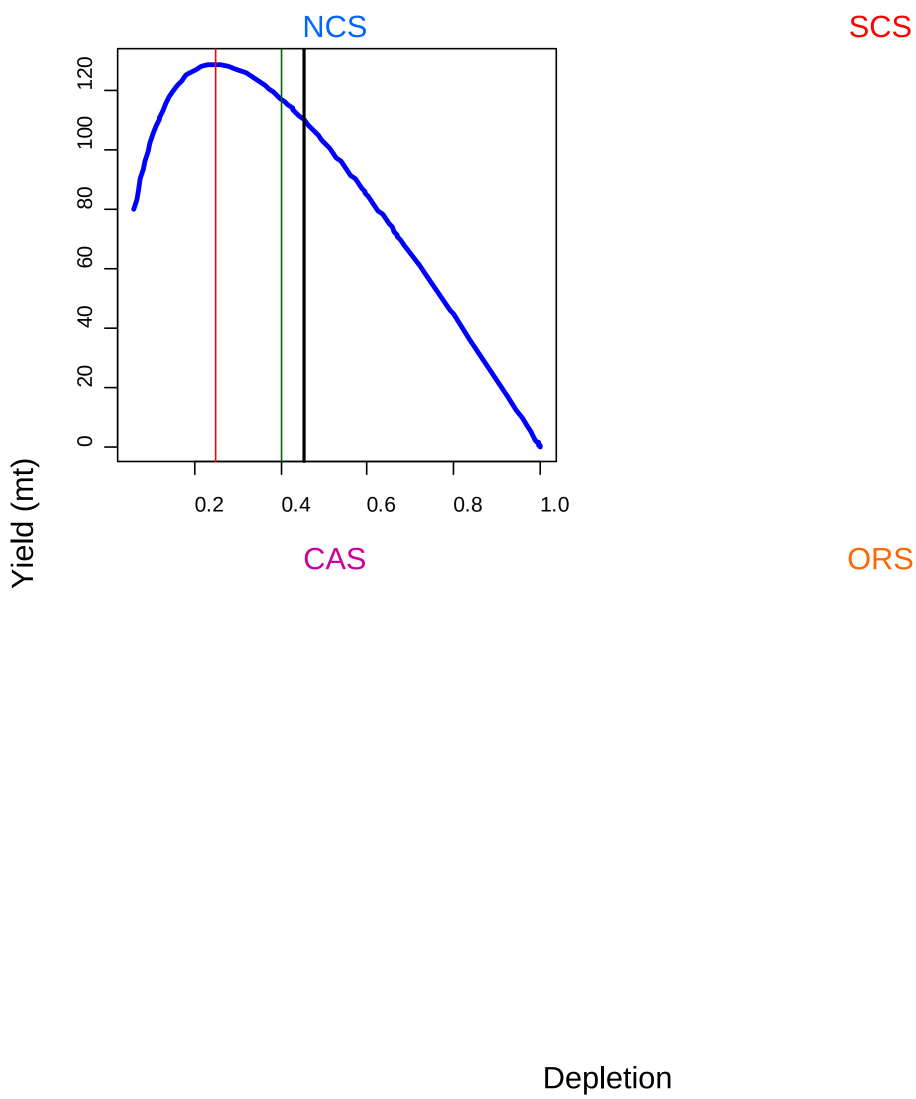

Figure E-14. Equilibrium yield curves for each sub-stock base case model. Reference points and current stock status are indicated by the vertical lines.

Regional Management

The results of these assessments provide the scientific basis for cabezon to be managed regionally using the California Department of Fish and Game northern/central and southern California management areas and/or across the entire states of California and Oregon. They also provide a basis by which state-wide management can still be informed by regional dynamics. Given important differences in population dynamics between the two California sub-stocks, summing the biomass across sub-stocks results in state-wide biomass estimates that incorporate regional differences in dynamics. This approach is not equivalent to the one stock state-wide model that ignores regional dynamics.

More work and sampling effort is needed to evaluate whether cabezon among these areas differ biologically (growth, maturity, etc.), but the results of this assessment indicate that the center of cabezon biomass resides within central/northern California. The possibility of additional cabezon sub-populations can not be ruled out. Regional management is an important consideration in relatively sedentary nearshore reef species such as cabezon and future assessments should continue to provide scientific analyses on increasingly finer spatial scales.

Unresolved problems and major uncertainties

Several sources of uncertainty were recognized and explored using sensitivity analyses. Results for all California sub-stock assessments are insensitive to the systematic inclusion or exclusion of each data source. In the previous assessment, the NCS was sensitive to the inclusion of the TENERA adult survey, causing the population to show a greater decline compared to the base case. Sensitivity to the TENERA adult survey is not a characteristic of the current assessment. The 2005 assessment of the SCS was highly sensitive to the inclusion of the 2000 man-made recreational fleet mean weight data. This behavior is also not seen in the current implementation of the assessment. The model was not sensitive the choice of breaking the CPFV time series into two series because of management changes affecting the interpretation of the continuous time series.

Other major uncertainties relate to the values assumed for natural mortality (*M*) for each sex, the assumption of male growth patterns, the choice of the stock-recruit relationship (Beverton-Holt vs. Ricker), and values assumed for recruitment compensation (steepness (*h*)). Most uncertainty was seen in the absolute biomass measures. Overall, all California models are less sensitive than in the previous assessments and population depletion in most sensitivity trials was either above or near the target depletion levels.

The Oregon model was robust to almost all data and parameter manipulation trials accept the removal of the ORBS survey. Removal of the only abundance index causes the population to drop sharply below the overfished level and absolute biomass to be much smaller than in the base case.

Forecasts

Twelve-year forward projections of yield are conducted for each sub-stock under two alternatives based on federal and state ABC control rule definitions (based on F_{MSY} proxies of $F_{45\%}$ and $F_{50\%}$, respectively) and federal and state OY threshold harvest control rules (40-10 or 60-20, respectively). The standard PFMC OY control rule for groundfish such as cabezon is based on $F_{45\%}$ with a 40-10 adjustment for stocks below the target level of 40% of the unfished reproductive output. The California Nearshore Fishery Management Plan proposes the use of a F_{MSY} proxy of $F_{50\%}$ and a 60-20 adjustment for stocks below 60% of the unfished reproductive output. The relative proportion of all fleets in future harvests is assumed to be the same as the last year (2008) in the model. Results of the projections are given in Table E-7. Overfishing limits (OFLs) are provided in this table because they will be used in the 2011-12 management cycle.

Decision table

Decision table projections based on alternative states of nature (columns in the decision tables) for 3 of the 4 sub-stocks were explored to capture uncertainty in population conditions (Table E-8) and control rules (40-10,$F_{45\%}$ and 60-20,$F_{50\%}$). The STAR panel agreed with the STAT that state-wide management was most appropriately determined from the combined NCS and SCS models, not the CAS model. A decision table for the CAS is therefore not presented. For the NCS, SCS, and ORS sub-stocks, the low and high *M* scenarios refer to different assumptions about sex-specific natural mortality (the greatest source of uncertainty in all sub-stock models) and were retained from the last assessment. The low scenario assumes M = 0.2/yr and 0.25/yr for females and males respectively, while the high scenario assumes 0.3/yr and 0.35/yr respectively. Catch histories (rows in the decision tables) were based on three proposed catch scenarios: 1) catch series based on the specified control rule (either 40-10 or 60-20) derived from the low *M* state of nature (low *M* catch scenario); 2) catch series based on the specified control rule (either 40-10 or 60-20) derived from the base case *M* state of nature (base case *M* scenario); and 3) catch series based on the specified control rule (either 40-10 or 60-20) derived from the high *M* state of nature (high *M* catch scenario).

All sub-stocks demonstrated spawning output depletion below limit reference points when the low *M* scenario was subjected to the base case and high catch scenarios. This also occurred when the base case *M* scenario was subjected to the high catch scenario. All other scenarios demonstrated depletion near or above the target reference points at the end of each projection period. Relative to biomass and depletion estimates, the 60-20 rule was much more conservative than the 40-10 rule.

Table E-8. Decision analysis of spawning output depletion based on different states of nature (columns) under different catch histories (rows) and control rules for each cabezon sub-stock. For the 40-10 rule, 0.40 and 0.25 are the target and limit reference points, respectively. For the 60-20 rule, 0.60 and 0.30 are the target and limit reference points, respectively. At or above the target reference point is indicated by green; between the target and limit reference points is indicated by yellow; below the limit reference point is indicated by red.

Research Recommendations

1. Improve estimates of natural mortality: All sub-stocks show significant sensitivity to natural mortality, a parameter not estimated in the model and assumed known. Estimates of natural mortality may be derived from tag-recapture studies or the comparison of length compositions inside and outside marine protected areas. There are two studies currently attempting to gather this information for future use in stock assessments. One is being conducted in the northern Channel Islands (J. Wilson, UCSB, pers. comm.) and the other is being conducted in the Morro Bay area (R. Nakamura and D. Wendt, CalPOLY, pers. comm.). These studies, and other like them, need to be encouraged.

2. Age and growth determination: The large discrepancy in estimated male growth parameters between Oregon and California deserve further attention to confirm this relationship. Further attention to ageing cabezon in California is needed to increase our spatial understanding of cabezon growth along the coast. Age samples from each fishery would also help to define growth and selectivity, while informing recruitment patterns and helping decrease the uncertainty in the scale (absolute abundance) of each sub-stock.

3. Fishery-independent surveys: Continued support and development of current fishery-independent nearshore surveys (like those initiated in Morro Bay and Monterey) is needed to extend the time series and increase spatial coverage. Both are required to increase the power of such indices in statistical catch-at-age models.

4. Defining the stock structure of cabezon: Current work on cabezon stock structure needs continued attention to better understand the connectivity between cabezon subpopulations. This would help focus or inform future sampling design to provide data for assessment purposes.

5. Alternative assessment procedures: The need for greater spatial resolution in the management of nearshore fisheries also increases the amount of data required to perform traditional stock assessments. Alternative assessment procedures that are less data-hungry, but still provide relevant management outputs should be encouraged. This assessment provides examples of some approaches as applied to cabezon. Such side-by-side comparisons of simplified assessment approaches to the statistical catch-at-age model outputs are useful in understanding the relationship of alternative to traditional assessment methods in hopes of developing the best available scientific advice for management under data-limited situations.

6. Re-defining “spawning biomass”: The nest-guarding behavior of cabezon males gives added reproductive importance to their abundance, relative to most other groundfish species. A metric other than female spawning biomass may be needed to incorporate the status of the male portion of the population into reference points. Further investigation is needed to identify appropriate ways in which the role of males in reproductive success can be incorporated into metrics for evaluating population status.

7. Changes in batch fecundity with age: Batch fecundity in cabezon is recognized, but it is not understood how and if batch fecundity changes with age. Understanding

whether the number of batches increases with age will help specify the fecundity relationship in the assessment model.

8. The effects of climate on cabezon population dynamics: The recruitment patterns of the California sub-stocks suggest a possible link between environmental forcing and population dynamics. Specifically, strong ENSOs conditions (especially in southern California) may be a pre-cursor to significant recruitment events. This link should be explored further to help increase the understanding of spatially-explicit recruitment responses and inform future recruitment events.

Purpose

This is the third assessment of the population status of cabezon (*Scorpaenichthys marmoratus* [Ayres]) off the California coast and the first to include Oregon waters (Figure 1). Available data sources remain insufficient to form the basis for a reliable assessment of cabezon in Washington. The current assessment is intended to provide information that will be of use by managers at both the state and federal levels. This document follows, to the extent possible given the available information, the Terms of Reference (TOR) for stock assessments established by the PFMC Scientific and Statistical Committee.

Three objectives are addressed in this document. First, the life history of cabezon is described and all the available data sources that were considered for use in the assessment models are explained. Second, the document describes the results of modeling cabezon populations at different spatial scales while attempting to incorporate and represent the uncertainty contained in both the model and its derived outputs. Including spatially-structure sub-stocks addresses the biological reality that cabezon populations are not continuously connect along the long California coastline. Outlining specific points wherein the model is both uncertain and sensitive should identify areas of future research needed to improve our understanding of cabezon population dynamics. Thirdly, although this model uses the traditional west coast approach of incorporating likelihood theory into statistical catch at age models (specifically, Stock Synthesis (Methot 2009), we also explore some alternative assessment methods useful for either rapidly assessing many species or assessing species with limited traditional stock assessment data.

This assessment is notable from many other west coast groundfish species because there is no fishery-independent index of abundance that covers the range of the assessed stocks. It consequently relies on indices of abundance based on recreational CPUE and spatially-restricted fishery-independent data, and information about larval and recruit abundance. Although no state- or federally-funded biomass indices are currently available for this species and private entities (e.g. SLOSEA in the Morro Bay area) are still developing an adequate time series of abundance, these alternative data sources can, in the meantime, inform estimation of the parameters of a population dynamics model. Much uncertainty remains in regard to the assumption that changes in recreational CPUE are linearly proportional to changes in population size. There is also no information on the age-structure of catches to inform selectivity, just aged samples for the purpose of estimating growth parameters. Therefore, although the model is age-structured, it is fit to mean weights and length-composition data by converting the model-predicted catch age-compositions to catch size-compositions using growth curves and weight-length relationships.

Introduction

The cabezon (*Scorpaenichthys marmoratus*) is the largest member (up to 99 cm) of the family Cottidae (commonly referred to as sculpins) found in the waters along the Northeast Pacific. Cabezon are desired by both commercial and recreational fishers because of their great size, physical attractiveness, and tasty flesh. Knowledge of cabezon life history has improved, but remains sparse relative too many other groundfishes. Current understanding is based on information collected from a limited extent of the ecological distribution and over limited time periods. The population status of cabezon in California waters was last assessed in 2005, and the spawning output was estimated to be near 40% of the unfished spawning output for the northern California sub-stock and near 28% for the southern California sub-stock, but there was considerable uncertainty, especially for the southern California sub-stock (Cope and Punt 2006). Cabezon are currently managed as part of a nearshore complex of fishes that include several species of rockfishes and greenlings.

This is the third quantitative assessment of the population status of cabezon. Spatial differences in biomass trends were included by recognizing two putative populations ("sub-stocks") of cabezon in California, demarcated at Point Conception, CA and one sub-stock in Oregon (Figure 1). Available data from coastal Washington waters remain insufficient to form the basis for a reliable stock assessment.

Stock Structure

The need for increased spatial resolution in the assessment of cabezon was recognized during the STAR panel review of the first cabezon assessment (STAR Panel 2004). This need was addressed in the second assessment by distinguishing two stocks in California waters, to the north and south of Point Conception (Figure 1): the northern (NCS) and southern (SCS) California sub-stocks. This designation was based on distinct fishing histories, the distribution of fishing effort, patchy and discrete habitat, and perceived low dispersal and movement of cabezon in all life stages. Specifically, the live-fish fishery for cabezon is active primarily north of Point Conception while, historically, the recreational take of cabezon has been greatest in central California, with the removals off southern Californian being fairly low. Cabezon are a cooler-water species, and are more abundant in the central and northern Californian nearshore areas. Additionally, cabezon and their habitat are often spatially discrete, increasing susceptibility to serial depletion (Oresanz *et al.* 1998, Perry *et al.* 1999)—the systematic depletion of small populations in discrete areas. Recognizing and avoiding serial depletion underscores the need to examine population trends at decreasing spatial scales. The extent to which assessments can be conducted at small spatial scales is, however, often limited by data availability, resources needed to develop and review additional assessments, and management's capacity for implementing finer-scale regulations and enforcement. It nevertheless is important to balance these trade offs to provide the most informed assessment for resource management (Cope 2008).

Two lines of evidence support maintaining at least two cabezon sub-stocks for assessment purposes in California and one sub-stock in Oregon. Villablanca and Nakamura (2008), investigating both mitochondria DNA and microsatellite genetic markers, distinguished 6 cabezon subpopulations in California (3 north and 3 south of Point Conception; Figure 2). They also found differences between these populations and those sampled in Oregon.

Additional insight into cabezon population structure in California comes from investigating spatial population dynamics. We applied the two-step clustering method of Cope and Punt (2009) to CPUE data from the Commercial Passenger Fishing Vessel fishery (see *CPFV CPUE indices* in the 'Indices of Abundance' section for data details) to detect areas with similar population dynamics. Twenty-one fishing locations along the California coast (Figure 3) were considered in the analysis. Only locations (18 of the 21) with common years were included in the analysis, so there is a trade-off between the numbers of years and locations used in the analysis (Figure 4A). Four different location/year combinations were considered (Figure 4B) to look for consistent location groupings. The average coefficient of variation (CV) of each location varied among locations and data sets (Figure 5). Large CVs (>1) can obscure the results of the cluster analysis and need to be interpreted with this in mind.

The cluster analysis supports the minimum designation of sub-stocks at Point Conception when all data sets and caveats are considered (Figure 6). This designation is consistent with the California Department of Fish and Game's central and northern management areas (Figure 1). Further investigation separating the NCS and SCS data sets and re-clustering each sub-stock data set separately indicates an additional subpopulation designation north and south of Monterey. Southern California locations did not demonstrate strong differentiation among locations. Though this additional structure in California is consistent with the genetic data, data and management limitations advise maintaining just two sub-stocks of cabezon in California at this time.

In addition to consider the cabezon resource as multiple sub-stocks in California, this assessment also explores the implications of assessing the entire cabezon resource off California (CAS) as a single homogeneous resource to compare some of the impacts of allowing for spatial resolution. In all scenarios, Oregon (ORS) remains separate from the California sub-stock(s). There was no available evidence of stock structure in Oregon waters, so all populations in Oregon are treated as one stock.

Life History

Distribution

Cabezon is distributed along the entire west coast of the continental United States. It ranges from central Baja California north to Sitka, Alaska (Quast 1968; Miller and Lea 1972; Love *et al*. 2005). Cabezon are primarily a nearshore species found intertidally, among jetty rocks, and in and around kelp forests and rocky reefs out to depths of greater than 110 m (Miller and Lea 1972; Love *et al*. 2005). The majority of the commercial and recreational catch is taken inside of 15–20fm (and approximately 99% within 30fm; Feder *et al.* 1974) and along the central California coast up through Oregon, with the Morro Bay area in California supporting a major cabezon fishery. The nearshore distribution of this species makes it accessible to a greater portion of coastal populations and users marine resources. This proximity to land also makes cabezon habitat susceptible to terrestrial land use outfalls.

Species Associations

Cabezon is a member of a nearshore assemblage of fishes that includes several *Sebastes* species (*e.g. S. atrovirens, S. auriculatus, S. carnarus, S. caurinus, S. chrysomelas, S. dallii, S. maliger, S. melanops, S. mystinus, S. nebulosus, S. rastrelliger, S. serranoides*, and *S. serriceps*), kelp (*Hexagrammos decagrammus*) and rock greenling (*H. lagocephlaus*), monkeyface prickleback (*Cebidichthys violaceus*), California scorpionfish (*Scorpaena guttata*), and California sheephead (*Semicossyphus pulcher*). These 19 fishes are included in California's Nearshore Fishery Management Plan (CDFG 2002), an FMP required by mandate of the 1999 Marine Life Management Act. Cabezon is also included in the Oregon interim nearshore fishery management plan (ODFW 2002). Though often considered data poor relative to many other assessed groundfishes, decades of recreational removals and the increase of the live-fish fishery has increased management attention on nearshore fishes and facilitated the allocation of state and federal resources to perform stock assessments for nearshore fishes. Presently, cabezon, California sheephead (Alonzo *et al*. 2004), black rockfish (Sampson 2008, Wallace *et al*. 2008), blue rockfish (Key *et al*. 2008), gopher rockfish (Key *et al.* 2006), kelp greenling (Cope and MacCall 2006), and California scorpionfish (Maunder 2006) have been assessed.

Spawning and Early Life History

Cabezon are known to spawn in recesses of natural and manmade objects, and males demonstrate nest-guarding behavior (Garrison and Miller 1982). Spawning is protracted, and there appears to be a seasonal progression of spawning that begins off California in winter and proceeds northward to Washington by spring. Spawning off California peaks in January and February (O'Connell 1953) while spawning in Puget Sound (Washington State) occurs for up to 10 months (November-August), peaking in March–April (Lauth 1987). Laid eggs are sticky and adhere to the surface where deposited. After hatching, the young of the year spend 3–4 months as pelagic larvae and juveniles. Settlement takes place after the young fish have attained 3–5 cm in length (O'Connell; 1953; Lauth 1987). It is apparent that females lay multiple batches in different nests (often of different colors), but whether these eggs are temporally distinct enough to qualify for separate spawning events is not understood (O'Connell 1953; Lauth 1987).

The number of eggs spawned appears to increase with fish size (weight or length) (O'Connell 1953; Lauth 1988). However, the actual relationship between age / size and number of eggs spawned is uncertain because of the possibility of multiple spawnings per year. For the purposes of this assessment, reproductive output is defined to be proportional to the product of maturity-at-age and body weight at the start of the year. Unless number of batches changes by age (of which we have no information or way of parameterizing the effects), this assumption seems robust.

Maturity ogives (Table 1; Figure 7) for all California sub-stocks were estimated using the California Department of Fish and Game (CDFG) visual inspection codes and the data used by Grebel (2003). Females with gonads that had early-yolk-stage eggs were assumed to be mature, although it is possible that some of these fish were maturing, but not yet mature. This will lead to a more optimistic interpretation of the rate at which cabezon mature (younger and at smaller size).

Oregon maturity curves (Table 1; Figure 7) were estimated using samples obtained from the ports of Newport, Depoe Bay, and Port Orford. Methods and details of the data collection and maturity determination are found in Hannah *et al.* 2009.

Age and Size relationships

Cabezon are among the largest of the cottids, attaining a length of nearly 1m and a weight in excess of 11 kg (Feder *et al.* 1974). Female cabezon are larger than males of the same age. O'Connell (1953) provided the first estimates of cabezon age and growth using whole otoliths from specimens from central and southern California. Lauth (1987) provided another estimate of cabezon growth from the Puget Sound (WA) using several ageing structures (whole otoliths, sectioned fin rays). Most recently, Grebel (2003) conducted a large study (almost 700 individuals collected over 6 years) on age and growth of cabezon from California using several age structures (sectioned otoliths, pectoral fin rays, dorsal fin rays, dorsal spines, and vertebrae). Her results using a thin-section of the saggital otolith form the basis for estimating growth for California cabezon in this assessment. Ages from Grebel (2003) were all standardized to a 1 January birthdate to avoid bias caused by rapid growth during the first years of life. Lastly, Oregon Department of Fish and Wildlife (J. Thompson, pers. comm.) provided age-at-length measurements from 2005-08 to provide data for the only estimates of cabezon growth in Oregon (Figure 8).

Growth curves based on the von Bertalanffy growth function incorporating multiple age reads via the random effects model developed by Cope and Punt (2007) were fit to the resulting age-length data for each state (Table 1; Figure 8). Incorporation of multiple age reads in the growth curve fitting better incorporates uncertainty in the age-length relationship via ageing error, which can be substantial. Individuals of both sexes obtained greater lengths at lower growth rates in Oregon (Figures 8 & 9).

Partial "validation" of growth curves is possible by comparing tag-recapture data from fish of known length and age. Tagging data from California (courtesy of J. Grebel) compare reasonably well with the externally fit growth curves (Figure 10). Because Grebel (2003) found no biologically significant differences between the age-at-length relationships among regions (northern, central, and southern) in California, her sex-specific results are used for both sub-stocks in this assessment. The growth curves obtained by Grebel (2003) differed statistically from that of O'Connell's (1953), who had much larger individuals in his samples. Whether these differences in estimated age-length relationships derive from an ageing disparity between whole (used by O'Connell) and sectioned (used by Grebel) otoliths, or they represent real differences caused by changes in the population structure (possibly due to fishing and/or the environment) is purely speculative at present. We consider model sensitivity to alternative growth assumptions by including a trial model run using the O'Connell estimates of growth (see *Sensitivity analysis* section).

Growth curves for Oregon age and growth data, for areas north and south of Cape Blanco (Figure 1), were also fit to investigate spatial trends in growth (Figure 11). No significant growth trends were apparent, so only one growth morph is considered for Oregon.

Weight-length relationships for cabezon are provided in O'Connell (1953; central California), Lauth (1987; Puget Sound, WA), and Lea *et al.* (1999; central California) for both sexes combined. Lea *et al*. (1999) also provide relationships for females and males separately, in central California only. Raw length-weight data used in Grebel (2003) provide sub-stock- and sex-specific length-weight information with larger sample sizes than the earlier studies, and these data are used for the present assessment (length in cm and weight in kg; Table 1). Sampling effort covered the years 1993–2002 for the NCS and 2002 for the SCS. Lacking data specific to Oregon, the California data were also used to define the weight-length relationship in Oregon waters.

Natural Mortality (*M*)
Little is known about the natural mortality rate of cabezon, so empirical methods using life history traits (growth rate (k), age-at-maturity (a_M), maximum age ( )) were used to estimate natural mortality for each sub-stock. Four general methods for estimating M (O. Hamel, NWFSC, pers. comm., which combines Hoenig 1983 and Pauly 1980; Chen and Watanabe 1989; Jensen 1996) were applied to data for each sex, and the results averaged to obtain sex-specific natural mortality rates (Table 2). The means of these approaches imply natural mortality rates of approximately 0.25/yr for females and 0.3/yr for males, but these methods may produce highly uncertain values of M (Pascual and Iribarne 1993). Therefore, sensitivity of the assessment model to the assumed values of M is explored and summarized.

Fisheries History

Historically, the recreational sector has been the main source of cabezon removals. Cabezon have been a very minor component of the catch in commercial fisheries for more than a century (Jordan and Everman 1898). The earliest modern commercial fishery information (O'Connell 1953) indicates that a small amount of cabezon was being sold in fish markets in the San Francisco area by the 1930s with incidental take recorded back to 1916. However, it was not until the 1990s that a truly directed commercial fishery for cabezon was established in the waters of California and Oregon.

The most significant change in the fishery for cabezon has been the development of the live-fish/premium commercial fishery that, in addition to cabezon, targets several other nearshore fishes (CDFG 2002). This fishery started in southern California in the late 1980s and spread northward during the late 1990s to Oregon (Starr *et al.* 2002). Fishermen routinely obtain much higher prices for fish brought back to markets alive. Cabezon are not subject to barotrauma because they lack a swim bladder and are usually found in shallow nearshore waters accessible to many fishers. These traits make cabezon an ideal target for both the live-fish and recreational fisheries. Gears that take cabezon include hook and line and pot/trap type gears, as they are successful at bringing up fish with relatively little damage. Cabezon continues to be an important component of the live-fish fishery, even with increased restrictions on the live-fish catch, especially as the allowable catches of other marketable groundfish species have been reduced.

Fisheries Management
The Pacific Fishery Management Council (PFMC) and NOAA Fisheries have management responsibility for the groundfish species included in the Groundfish

Fishery Management Plan (FMP) out to the boundary of the 200-mile Exclusive Economic Zone (EEZ). Many nearshore species, such as cabezon, that fall primarily within the 3-mile limit of states' waters are also included in state-specific Nearshore Fishery Management Plans (NFMP). NFMPs are currently being developed and implemented in California and Oregon in response to the increased commercial take of the live-fish fishery (CDFG 2002).

No management regulations existed for cabezon in California before 1982 when a size limit (12-inches) was set for recreationally and commercially caught cabezon (see Appendix A for a complete list of California regulations). This limit was raised to 14-inches in 1999 for the commercial fishery, and extended to include recreationally retained fish in 2000. It was increased further to 15-inches in 2001 for both the commercial and recreational fisheries. Recreational bag limits have been 10fish/day in California since 2002, however changed from 10 to 3 in different areas of the coast in 2004 and 2005, with one inseason change. In 2005, the bag limit was changed to 1 and is still today. Cabezon are currently included in the California recreational regulatory complex Rockfish, Cabezon, and Greenlings (the RCG complex) and subject to seasonal closures for recreational fishers.

Historically, commercial landings of cabezon were monitored as part of a mixed group called "Other Fish". This group of species includes sharks, skates, rays, grenadiers and other groundfish. This group has been defined historically as groundfish species that do not have directed or economically important fisheries. The coastwise ABC for this entire group of species was 14,700mt during 1999–2002 (5,200mt for the Eureka, Monterey and Conception INPFC areas and 9,500mt for the Columbia and Vancouver INPFC areas). In California, the cabezon fishery is currently independently monitored and regulated by analyzing two-month cumulative trip limits within the Cabezon, Greenlings and California sheephead (CGS) complex. From 2001-2005 there were emergency closures for cabezon, but more recently, the fishery has been open all year, with cumulative trip limits reduced from 900 pounds down to 200 or 300 pounds (see Appendix A).

In Oregon, some general regulations since 1983 pertaining to hook and line gears are as follows: 1) it is unlawful to use more than one rod or one line when angling for any fish in the nearshore environment and 2) no more than three hooks may be used while angling for species other than Pacific halibut (*Hippoglossus stenolepis*). Furthermore, there are three areas that are closed to the take of marine fish in certain times of the year, including Whale Cove habitat refuge (May 1-Aug. 31), Pyramid Rock (May 1-Aug. 31) and Three Arch Rocks (May 1- Sept. 15). Specific to cabezon, Oregon imposed a 15 inch size limit in 2003, which was increased to a 16 inch size limit in 2004 and is still today. Initially, bag limits for cabezon began in 1978 with a 15 fish limit for the rockfish, cabezon and greenling complex. Currently, Oregon has a 6 fish per day bag limit for the "rockfish et al" complex combined. In the years 2004-2008, inseason changes were made where cabezon were prohibited to be taken by boats. Regulations affecting cabezon in the waters off Oregon can be seen in Appendix B.

Assessment Data Sources

Data for species managed by NOAA Fisheries and the Pacific Fishery Management Council are collected by both federal (and/or quasi-federal) and state agencies. This can complicate analysis because several agencies may collect the same types of data. Where this occurs, the analyses below are based on those data that are most likely to be informative regarding changes in population size.

Removals

Whenever possible, removals are characterized as landed catch plus fish released and presumed dead. Historical catches (prior to 1980) are reconstructed from historical documents, and reported and inferred relationships among fishing sectors. Different estimation procedures are used for California and Oregon.

Recreational Fishing History in California

Recreational fishing in California became popular in the late 1890s, but was limited to mostly big game fishes (tuna, marlin, and swordfish) and wealthy participants (Holder 1914). Recreational fishing opportunities in California for most people were quite limited before 1920. Private boat access to nearshore fishes increased after 1920 (Croaker 1939), but it was not until Commercial Passenger Fishing Vessels (CPFVs) began operating in earnest off southern California in 1928 that the general public gained extensive access to many nearshore fishes (Scofield 1928; Young 1969). Both barges – large, flat, open-spaced ships – and more traditional CPFV boats comprised the fleet. There were 15 barges and 20–30 boats off southern California in 1928 (Scofield 1928). The period 1929–39 saw a rapid increase in the popularity of CPFVs (Croaker 1939), which also spread northward to central and northern California. By 1932, sportfishing in Monterey was very popular, with cabezon a major target species (Classic 1932). Pier and shore fishing modes also provided major recreational fishing outlets during this time of increased CPFV activity (Scofield 1928; Croaker 1938; Baxter & Young 1953; Young 1969). In all modes, most fishing occurred during the summer and autumn months, with some fishing extending into spring (Fry 1932; Baxter & Young 1953). CPFV captains have been required to submit logbooks detailing catches since 1936 (Croaker 1939; Baxter & Young 1953; Young 1969), although compliance rates were and are not 100%. In 1937, the sportfishing catch exceeded the commercial catch for many species (Conner 1937).

The popularity of CPFV fishing continued to increase until the war years of 1942–46 when CPFV activity was considerably reduced (Calhoun 1950). The CPFV fleet underwent a period of rapid re-establishment, reinvention, and growth after 1946 (Young 1969). Fleets, boat size, and passenger interest all increased throughout California. This expansion continued into the 1970s with the fleet peaking in 1973 (Baxter & Young 1953; Young 1969; Hill & Schneider 1999). A concomitant increase in private boat, shorefishing, and pier/jetty modes also occurred during this time, particularly in central California (especially in Monterey and Morro Bay), where cabezon are well represented, during the 1950s (Baxter & Young 1953).

Reconstructing Recreational Removals

This assessment uses the same methods as the 2005 assessment (Cope and Punt 2006) for reconstructing catch history back to 1916 for both cabezon sub-stocks. The catches for the state-wide California stock (CAS) is the sum of the NCS and SCS catches. The initial year was selected because of the availability of commercial catches back to 1916 (see *Reconstructing Commercial Removals* below). There was very little recreational catch, if any, before 1916 so the fishing mortalities before 1916 are set to zero when conducting the assessment.

Four recreational fishing modes are distinguished in California: 1) Man-made (piers/jetties), 2) beach/bank, 3) Private Boat and Rental (PBR), and 4) CPFV. These modes were distinguished for analysis and modeling purposes because of differences in selectivities and the length-frequency of the catch: the man-made and beach/bank modes generally catch smaller individuals than the PBR and CPFV modes. Most cabezon are taken from jetties in the man-made mode (Pinkas *et al.* 1967).

Information on the activities of recreational fishermen has been collected by both state (California Recreational Fisheries Survey (CRFS); CDFG) and federal (Marine Recreational Fisheries Statistic Survey (MRFSS); PSMFC) programs. From 1980-2003 (excluding the years 1990–92), the MRFSS program (available via the RecFIN database: **http://www.recfin.org/**) provides effort information from a random-digit dialing protocol and catch/trip information from intercept interviews. These data can be used to calculate total catches by mode. In 2004, the CDFG, in cooperation with the Pacific States Marine Fisheries Commission (PSMFC), started the California Recreational Fisheries Survey (CRFS) program to replace the MRFSS sampling program in California for all modes. This program aims to increase sampling effort for better catch and effort estimation, to increase spatial resolution of catches, and to identify targeted species. Before the CRFS was implemented, CDFG only collected logbook catches from the CPFV fishery. Very few estimates of the removals by the man-made, beach/bank, and PBR modes are available for the years before 1980. The CPFV fleet therefore provides the longest time-series of measured catches (1936-present) and is used to reconstruct the removals by the other three modes for the years prior to 1980.

Total recreational removals for each cabezon sub-stock for each recreational mode were reconstructed in three steps: 1) the historical CPFV removals (in numbers) were reconstructed, 2) the CPFV removals were used to estimate the removals (in numbers) by the other three modes, and 3) the average weights per mode were used to estimate total removals in kg., which were then converted to metric tons (mt).

<u>1. Historical CPFV removals</u>
The historical CPFV catch (1916–2008) was reconstructed as follows:

> **Years 2004-2008**: CRFS, extracted from RecFIN 13 March, 2009.
> **Years 1957–78; 1980–2008**: Hill and Schneider (1999) performed a data recovery exercise to extract catch, effort, block (CDFG designated 10 x 10 nautical mile statistical areas), and month information from the California CPFV logbooks. This information provides area-specific catches (in numbers) for each cabezon sub-stock for 1957–2008, excluding 1979 (the data for this year are lost). This data set was obtained March 2009.
> **Year 1979:** Oliphant *et al.* (1990) report the total catch of cabezon by the CPFV fleet for 1979. This total is allocated to sub-stock using the geometric mean of the ratio $Catch_{NCS}$:$Catch_{SCS}$ for 1976–78 and 1980–82.
> **Years 1936–40; 1947–56**: Hill and Schneider (1999) provide CPFV catches for the SCS only. The total California CPFV catches for these years are found

in Best (1963). The difference between total California catches and the catches from the SCS give the catches from the NCS.

Years 1941–46: O'Connell (1953) provides the catch by the CPFV fleet in 1946 for each sub-stock. No data are available for 1941–45; the catches during these years have been assumed equal to that for 1946.

Years 1928(SCS)/1929(NCS)–1935: No data on catches are available for these years. Scofield (1928) identified the major start of the CPFV fleet in southern California to be 1928, which then moved into central and northern California in 1929 (Young 1969). These start years reflect the beginning of the CPFV time-series for the SCS and NCS, respectively. A linear increase in catch from the start year through 1935 is assumed because the CPFV fleet is known to have increased rapidly during these years (Fry 1932; Young 1969),

Years 1916–27(SCS)/–1928(NCS): The catches by the CPFV fleet were assumed to be zero for these years.

Heimann & Carlisle (1970) reported that cabezon are rarely discarded in the CPFV fishery because of their large size and trophy status. Furthermore, discarded cabezon have a higher probability of survival because they are not affected by barotrauma. Even though a size limit has been imposed in recent years (see Appendix A), the analyses of this document assume that there is no discard mortality by the recreational sector.

It was recognized early in the CPFV reporting process (Croaker 1938; Baxter & Young 1953) that logbook records may be inaccurate for two main reasons: 1) mis-reporting of catches (either over- or under-reporting; Karpov *et al.* 1995), and 2) less than 100% reporting compliance rates (Hill & Barnes 1998). Baxter & Young (1953) investigated these inaccuracies in CPFV catch and concluded that cabezon catch rates reported by the CPFV fleet are accurate and reliable. Reported CPFV removals are therefore not adjusted for mis-reporting. Since 1936, compliance rates have always been less than 100% though, and necessitate the adjustment of raw CPFV removals. Compliance rates (as reported from several sources) are provided in Table 3 and were assumed to be the same for the NCS and the SCS fleets. The reported compliance rates were then used to interpolate compliance rates for the years for which rates were not available, and CPFV removals in numbers were expanded to correct for lack of reporting compliance. There are no compliance rates for the period 1962–1980. Values used for these years were semi-arbitrarily set to account for the expanding fleet during the 1960s and 1970s.

The assumption of compliance rates being the same in the north and south may not be valid; however, we have no data to make this adjustment. During the 1940s-60s, there was full time staff at the CDFG in southern California devoted to working on CPFV logbook compliance, and it is believed that these efforts increased compliance rates in this region during this time period (S. Crooke, CDFG, pers. comm.).

<u>2. Estimating removals for the man-made, beach/bank, and PBR modes via CPFV ratios</u>

Removals (in numbers) for the other three recreational modes (man-made, beach/bank, and PBR) were determined in two ways: 1) based on surveys of the modes, and 2) based on an estimate of the ratio of the catch by the mode to the catch by the CPFV mode multiplied by the catch by the CPFV mode. Surveys are available for only a small numbers of years:

a) The RecFIN database contains estimates of removals for the years 1980–89 and 1993–2008. This data was extracted 13 March, 2009.
b) Miller & Gotshall (1965) provide estimates of NCS removals for the period 1957–61.

The ratios of the CPFV catches to the catches by the other modes from RecFIN were used to estimate removals when data were missing for the years 1980–2008 (Tables 4 & 5). The work of Miller & Gotshall (1965) and Pinkas *et al.* (1968) provide ratios for the years of their study (Tables 4 & 5). These ratios were used to make inferences about the ratios for the years for which no data are available. The PBR fishery was assumed to start in the same year as the CPFV fishery. The man-made and beach/bank modes began before the CPFV fishery, so the estimated catch in these modes for the years before the CPFV fishery began were projected back to 1916.

<u>3. Calculating removals in kg</u>

The average annual weight of the removals (in kg) for each mode are given in Tables 4 and 5 for the NCS and SCS respectively, with shaded values indicating mean weights that were reported. The true reported weights (not converted from lengths) for 1980–2008 were downloaded from RecFIN. The reported weights for the NCS for the years before 1980 are: 1) 1947–51: Baxter & Young (1953) and 2) 1957–61: Miller and Gotshall (1965), while the reported values for the SCS for 1964–66 were taken from Pinkas *et al.* (1968). The weights for all remaining years are assumed values, based on these sources, averaged RecFIN weights, or a mid-point of the two (Tables 4 & 5). The weights for the PBR mode for the years prior to 1980 are set to those for the CPFV mode because these fisheries catch similar sized fish. The removals in the NCS by mode are heavier on average than those in the SCS. Removals (in kg) were calculated by multiplying numbers by average weights then converted to metric tons before being included in the assessment model. The total removals (in mt) of the recreational sector by mode are shown in Figure 12.

Removals are considered known without error in the assessment, so Cope and Punt (2006) provided two sensitivity tests to examine the implications of uncertainty in the pre-1980 catch reconstruction time period. Also, the original recreational removal in the SCS for 1980 (185 mt) was identified as extraordinarily high. This high value is attributed primarily to the catch by the PBR mode (157 mt). Further investigation revealed that RecFIN waves (*i.e.* bi-monthly totals) 1, 2, 3, and 5 had notably higher removals in 1980 than during 1981–89, but that average wave weights were not markedly different among years (Figure 13). Comparing the relative RecFIN removals of other species in the 1980s also shows that the year 1980 comprises an unusually high proportion of the total removals for the decade (Figure 14). This systematic result across species can be explained either by a massive, but correctly estimated, increase in recreational take from the PBR recreational mode in 1980 south of Point Conception or an overexpansion of catch estimates. Anecdotal evidence suggests that effort during 1980, the first of the MRFSS program, was likely misapplied. The STAR panel agreed with the STAT team that the 1980 value was too high, so the value for the PBR was taken to be the average of the RecFIN removals for that mode from 1981-1989. This value corresponded very closely to the value in

1981. This adjusted 1980 value is included in Figure 12. Sensitivity to using the RecFIN extracted 1980 SCS PBR recreational removal is explored.

Reconstructing Recreational Removals in Oregon

The Oregon recreational fishery was broken into shore-based (man-made and beach/bank) and boat-based (PBR and CPFVs) modes for the purposes of this assessment. Figure 12 illustrates the total recreational removals (in mt). The shore-based catches were downloaded from RecFIN for 1980-2008. The average value of 1989 and 1993 was used for 1990-1992 (MRFSS sampling hiatus). The 1980 value was used back to 1973, the starting year for the Oregon catch history series. The boat-based catch estimates were provided by ODFW. Estimates of the numbers of cabezon harvested for the years 1973-1992 were obtained from various data sources. The following outline explains the historical catch estimation procedure for cabezon landed by boat-based recreational anglers fishing in open ocean areas for differing time periods.

> **Years 1973-77**: Estimated numbers of landed miscellaneous fish (category including cabezon) were obtained from handwritten summaries, provided by Don Bodenmiller. They then applied the average of annual proportion cabezon in miscellaneous category from 1979-1983 (5 yr. average) from ODFW historical species catch estimate database (Table 6).
>
> **Year 1978**: Estimated numbers of miscellaneous fish were obtained from printouts of estimates in ODFW storage loft. The same proportion cabezon as above was applied (Table 6).
>
> **Years 1979-89**: Estimated number of cabezon landed were obtained from ODFW historical species catch estimate database. Expansion factors were applied to adjust for each port that was not sampled during sampling time frame based on geographic distribution of catch from the closest time period where that port was sampled. Additional expansion factors were applied for the unsampled portion of year based on the temporal distribution of catch from the 1999-2000 year-round-sampling study. The start and stop dates of sampling at each port was subjectively analyzed to approximate start and stop dates of coast-wide sampling for each year (Table 7).
>
> **Years 1990-92**: Annual estimates of number of cabezon landed were obtained from historical reconstruction of annual catches completed by D. Bodenmiller, L. Zumbrunnen and E. Schindler (ODFW) in 2001. This reconstruction also provided the basis for Oregon RecFIN estimates from 1993-2000 (Table 7).
>
> **1993-2008**: Estimates of landed cabezon (in mt) were provided from the Oregon Recreational Boat Survey (ORBS) program

The estimation of average weight for conversion of numbers to metric tons in Oregon is as follows. There were no data on size from 1973-79, so the average of the 1980-82 average weights (obtained from RecFIN) were used, which is not the same as simply averaging weights of all sampled fish. Year specific average weights (also obtained from RecFIN) were used from 1980-89. No data on size is available from RecFIN for 1990-92, so an average weight was interpolated from the 1989 point estimate to 1993 point estimate.

Commercial Catches

Several sources of California commercial landings are available to reconstruct commercial cabezon landings by sub-stock back to 1916 (the first year of required reporting in the commercial fishery):

> **Years 1931–2008**: The CALCOM database provides annual landings (in pounds) by gear. Methodology can be seen in Ralston *et al* (in review). Data was extracted on 9 June, 2009. Additional allocation of landings to the live-fish fishery was available using the price per pound filed in the CFIS-CMASTR database. This analysis was provided by Bob Leos (CDFG).
>
> **Years 1930**: The Pacific Fisheries Environmental Laboratory (PFEL) live access server (http://las.pfeg.noaa.gov:8080/las_fish1/servlets/dataset) provide electronic summaries of CDFG fish ticket receipts originally reported in the Fish Bulletin series (available electronically at: http://ceo.ucsd.edu/fishbull/).
>
> **Years 1916–29:** The publication *California Fish and Game* (vols 1–16) are the original source of landing reports before the Fish Bulletin series and are used for this time period. During 1916–29, cabezon was included in the category "sculpin" which included California scorpionfish. Given the limited northern range of the scorpionfish (Love *et al*. 1987), 100% of the "sculpin" catch from Monterey north was assumed to be cabezon. Fish Bulletins 74 (CDFG 1949) and 149 (Heimann and Carlisle 1970) provide summarized commercial cabezon landings for 1916–47 and 1916–69, respectively, and were used to cross-compare cabezon catches from the *California Fish and Game* volumes. Both sources provided the same estimates of total cabezon landings.
>
> **Years 1916–30 adjusted**: Due to the spatial resolution of landings during this time period, an adjustment was made. Landings for the port complex "Santa Barbara" (including Morro Bay of the NCS and Santa Barbara of the SCS) were allocated to the appropriate sub-stock using the geometric mean of the ratio of the Morro Bay to Santa Barbara landings for the years 1978–82 from CALCOM.

Commercial landings are reported in pounds and were converted to metric tons for this assessment. Two fleets are modeled within the assessment: 1) vessels landing dead fish (non-live fishery), and 2) vessels landing live fish (live-fish fishery). Cabezon are caught commercially using a variety of gears-types, but have been taken almost exclusively by hook-and-line and pots since the 1990s. All catches are assumed to be taken using a single gear-type for the purposes of this assessment

California landings of cabezon were low until the early- to mid-1990s when the live-fish/premium finfish fishery began targeting cabezon. Commercial cabezon landings reached a peak of over 150mt in 1998 and averaged more than 80mt since the mid-1990s, most of which came from the NCS. Figure 15 shows the commercial landings by the two fleets.

There have also been spatial and temporal patterns in cabezon commercial landings. Historically, much of the landings were reported in the late winter/early spring months, but much of the catch has been taken in the summer and fall months since the start of the live-fish fishery. All catch is assumed to be taken in the middle of the year for the purposes of the assessment.

Oregon commercial landings estimates were taken directly from PacFIN (23 June, 2009). Similar to California, the live-fish fishery began in the late 1990s with a peak of around 45 mt in 2001-2002 (Figure 15).

Commercial Discards in California and Oregon
Commercial discard mortality estimates are provided by the West Coast Groundfish Observer Program (WCGOP; E. Heery, pers. comm.) and rates of mortality for discarded cabezon are assumed to be 100% for all trawl-related gear and 7% for the live-fish fishery (Figures 16 & 17). Cabezon are not as susceptible to discard mortality as many other fish because they live in shallow habitat, do not have swim bladders, and do not appreciably suffer from barotrauma. Recent information (beginning in 2003) regarding discards in the nearshore live-fish fishery were provided by the WCGOP. Prior to this, the harmonic mean discard ratio was applied back to 1983 in California. Estimated commercial landings and discards for each sub-stock are given in Table 8. Sensitivities to model assumption of discard rates are also considered in the tests of sensitivity.

Total Removals
Figure 18 illustrates the historical pattern of total cabezon removals in California and Oregon. Due to updates and changes in some data sources since the last assessment, a comparison of the two assessments historical catch reconstruction is made (Figure 19). Where the commercial fishery estimates did not change, differences can be seen in the recreational fishery since the 1980s, mainly due to changes in the mean weights used to calculate removals (described below).

Size Compositions
Cabezon otoliths and other ageing structures have not been collected routinely during port sampling. Therefore, the only information on the biological structure of the catch is from length and weight measurements. Sex is not recorded when sampling for length or weight, so all of the catch length-compositions considered in this assessment are sex-aggregated. Catch length-compositions were developed for each sub-stock, fishery sector, and fleet (Table 9; Figures 20-27).

The catch length compositions for each state and year for the recreational fisheries were obtained from RecFIN (extracted on 16 March, 2009). RecFIN expands the sampled length proportions by port, fishing fleet (mode), and wave (bi-monthly period) to estimate the proportions-at-length for the entire year. In the 2005 assessment, not all lengths retrieved from RecFIN were used because they were not true lengths, they were either converted from weights or another measurement of length (i.e. RecFIN converts total lengths (TL) into fork lengths (FL) for user downloads). For this reason, we used the sample lengths (in TL) where no conversions from weight were made. This increased samples substantially, especially in the 1980s. Comparison between the sampled and expanded length compositions showed no significant differences; using the sample data increased the number of measured fish that were otherwise disregarded due to sample strata.

Additional sources of length composition from two northern California CPFV studies were evaluated for use in this assessment. The first was a CDFG CPFV onboard observer program from 1987-98 that monitored catch north of Point Conception. The second was a more recent study in the Morro Bay area (CalPOLY) from 2003-08.

Even though samples for cabezon were low in these studies, the composition data were still used to help support more recent evaluation of the CPFV fishery. In the past, the CPFV fishery has not been sampled as much as the other recreational fishing modes; however, the CRFS program has made efforts to increase this effort since 2004.

Regarding SCS, information from two CDFG CPFV studies in southern California was also included in that model, representing the time periods from 1975-78 and 1986-89. Lastly, information from the Groundfish Disaster Relief Program in southern California from 2002-05 was used. Fish from this study were caught by hook and line on chartered CPFVs. Table 10 includes sample sizes for all length compositions used in each sub-stock assessment.

Mean weights from RecFIN were extracted for all recreational modes of fishing. In a similar situation, many weights were converted from lengths so we used the actual sampled weights to determine mean weights (Table 11). Using the sample weights also provided a source to calculate a coefficient of variation so as to fit the mean weight data in the assessment model using a likelihood function.

The commercial length-compositions for California were extracted on 29 March, 2009 from the CALCOM database. Commercial length samples are expanded using the standard routine at the port-gear-month level and then aggregated for the state. Oregon length compositions came from PacFIN biological database (extracted by J. Wallace, NOAA/NWFSC on 3 June, 2009).. The ORS is the only assessment containing sex-specific length compositions. No body weights are available for any of the commercial fleet.

Other sources of size-composition data and tagging information were considered for this assessment, representing different areas within California. Because of the sparse representation of cabezon in the data, the investigators of the projects were unsure if the data would be useful at this time, but were excited about the potential uses of this information in the future. Most of these studies were designed to evaluate the impacts of Marine Protected Areas (MPAs). The following sources should be considered in future assessments:

- San Luis Obispo Science and Ecosystem Alliance (SLOSEA) in Morro Bay, 2004-08 (R. Nakamura, CalPOLY pers. comm.)
- California Collaborative Fisheries Research Program (CCFRP) in central California, 2007-08 (R. Starr, CA Sea Grant, pers. comm.)
- CDFG tagging project in Carmel Bay (2008; D. Haas, CDFG, pers. comm.)
- Northern Channel Islands tagging project (2008; J. Wilson, UCSB, pers. comm.)

In the 2005 assessment, the following sources of length-composition and mean weight data were investigated for the SCS but cabezon did not occur in any of these databases frequently enough to provide additional information for the assessment of the SCS and were not used.

- CDFG southern California commercial fishery sampling program (1993–2001)
- Los Angeles County Sanitation Department trawl survey (1972–present)

City of Los Angeles Sanitation Department trawl and rig surveys (1987–present)
Orange County Sanitation Department trawl survey (1970–present)
San Diego County Sanitation Department trawl survey (1991–present)
Southern California Coastal Water Research Program (1994,1998)

Indices of Abundance

There is no standardized survey designed to provide biomass indices for cabezon along the U.S. west coast. All surveys presently used to provide biomass indices for groundfish populations are conducted at depths that are largely outside the depth preference of cabezon. Cabezon are caught so infrequently in the standardized trawl surveys that those data sources are not considered further in this assessment. A nearshore trap survey, designed to monitor cabezon abundance in the Morro Bay area (D. Wendt, CalPOLY, pers. comm.), is still in its infancy, though it may prove to be valuable for future cabezon assessments (and possibly those for other nearshore fishes). In lieu of an index designed specifically for cabezon abundance estimation, this assessment considers a wide variety of potential abundance indices. These include fishery dependent recreational data, adult SCUBA surveys, and egg/larval/juvenile surveys.

Potential indices of abundance are developed for each sub-stock by fitting generalized linear models (GLMs) to the proportion of zero and non-zero records, and then to the non-zero catch rates (or whatever quantity was being measured, such as number of larvae impinged). This approach is known as the "delta method" and is described in detail elsewhere (Lo *et al.* 1992; Vignaux 1994; Maunder & Punt 2004). The product of the year effects from each GLM (which can conveniently be based on different error structures) yields the index of abundance. Table 12 lists the data sources considered in this assessment for each sub-stock, the years for which data are available, the number of data points, the number of non-zero records for each data source, and the percentage of the data points for which the catch rate is non-zero.

The proportion of non-zero records was modeled as a binomial random variable; both gamma and lognormal error structures were explored for the positive records. Only main-factor models were considered and, initially, no interaction terms were explored, though year-area interactions, if present, can seriously compromise the development of abundance indices (Maunder & Punt 2004). A variety of alternative fixed-effects models were explored, and the final fixed-effects model for each choice of error model was selected using AIC (Burnham & Anderson 1998). Table 13 lists the fixed-effects models considered and the associated AIC values, and Tables 14-16 list the index values for each data source. The results of the analyses for the CPFV indices of all California sub-stocks and the Oregon ORBS survey index are illustrated by plots of the results of the gamma and lognormal models along with non-GLM derived indices produced using the geometric mean of positive catch rates (Figure 28). The CVs in Tables 14-16 were calculated by bootstrapping or jackknifing the best fitting model. Given inadequacies in spatial or sampling coverage, all resultant CVs should be viewed as under-estimates of the true variation of the index about the trend in the population. Additional variance (equivalent to 3 times the average yearly CV of the time series) was added to each index in order to more adequately capture the inherent uncertainty of each index (Tables 14-16; Figure 29). Sensitivity of derived model outputs to assuming the original CVs was also considered.

California: CPFV CPUE indices

The CPFV logbooks contain information on effort from 1947 for the southern California fleet and from 1957 for the central/northern California fleet (Hill & Schneider 1999). Effort was recorded as angler days prior to 1959 and as angler hours from 1962. Effort was recorded in angler hours and angler days in 1960 and 1961. Young (1969) estimated a conversion factor to relate the two measures of effort and estimated angler hours for 1947–59, the assumption being made that conditions in the CPFV fleet did not change over this period. Unfortunately, this was one of the most dynamic periods during the history of the CPFV fleet (Young 1969; see also *Recreational Fishing History in California*), so this assumption may not be valid. The previous assessment (Cope and Punt 2006) showed little sensitivity to the starting year of the index, so we consider the CPFV index beginning in 1960 to consistently use angler hour as the measure of effort. Changes in recreational regulations (size limitd, Figure 30; bag limits, Figure 31) were recognized as sufficient to divide the CPFV into two time periods: 1) 1960-99 and 2) 2000-08, based on RecFIN length composition data and bag limit analysis. Further scrutiny of changing size and bag limits rendered the 2000-08 time series for the NCS inadequate to consider in a base case. Sensitivities to including this time series and using the full time series (1960-2008) were investigated.

Factors considered in the CPFV GLM were year, month, and location. Instead of using CDFG blocks to define location, blocks were collapsed into groups based on major fishing ports or areas. The final fixed-effects model chosen for each sub-stock included all factors (Table 13). Both lognormal and gamma error structures were considered, but the lognormal model was ultimately selected for each base case. Dick (2004) also found the lognormal error model appropriate for California CPFV indices. Sensitivity to the choice of error model when standardizing the catch and effort data was not explored because the lognormal and gamma indices were similar in trends (Figure 28). Diagnostic plots for the base case CPFV indices are provided in Figures 32-34.

The STAR panel emphasized the difference in index trends between the geometric average and the delta-GLM derived index values for the NCS. Such a difference underscores a significant effect of the included factors (year, month, or location) on the resultant index (Figure 35). Investigation of interaction terms revealed significant interactions between location and year (specifically, the Santa Cruz location) and month and year (mostly for years in the 1960s and 1970s that were ultimately not fit well in the base model). The year-location interaction is not inconsistent with the emerging stock structure seen in the index clustering and genetic investigations (Figures 2 and 6). Given data constraints to only two areas in California, the index data was not broken up any further. The STAR panel recognized the need for future research to better reconcile these spatial interactions, but agreed the current formulation of the NCS is the most appropriate.

Further description of the spatial nature of catch rates along the California coast was explored using the percent index of relative importance (%IRI; Pinkas *et al*. 1971; Cortes 1999). Defined using numbers of cabezon, weight of cabezon catch, and frequency of cabezon occurrence, the %IRI was used to summarize the contribution of each fishing location (Figure 36) to the CPFV fishery through time. For the NCS, Princeton/Halfmoon Bay and Morro Bay comprised a large percentage of the IRI in the early years, but more northerly ports have since increased in contribution (Figure 36). In the south, most of the IRI is contributed by the northern-most locations through the whole time period (Figure 36), though it is clear cabezon are most encountered in the central and northern CPFV fisheries.

In the future, evaluating the CDFG logbook database in CFIS (1980-present) and compared to the historical database is recommended. Using the data in this format allows for better spatial resolution and the opportunity to subset the data into nearshore targeted trips, though at the expense of a shorter time series. If comparisons between the two data sets show little difference, the historical database should be retained for further considerations.

An index from the central California CPFV onboard observer program (1987–98), operated by CDFG, was also considered during the first cabezon assessment. The CPFV logbook and CPFV observer series exhibit similar trends (Cope *et al*. 2004). The index developed from the observer data was not used in this assessment because the information is not independent from the information contained in the CPFV logbooks and the indices based on the logbook data represent the longer time series.

ORBS Survey

The Ocean Recreational Boat Survey began development in 1979 to sample the catch and effort of ocean-going anglers off the Oregon coast. The most reliable data for development of an abundance index for cabezon is taken strictly from bottom-fishing trips. The most reliable time series runs from 2001-08 and was not affected by recreational regulations (T. Buell, ODFW, pers. comm.), so the full index is retained (Figure 39). Diagnostic plots for this index are found in Figure 37. This is the only survey available for the Oregon sub-stock.

Adult SCUBA Surveys

Two fishery-independent SCUBA surveys were investigated for potential use (Table 12) in the California sub-stocks. The first is a nearshore benthic survey of adult fishes, conducted from 1977–2008 by TENERA Environmental (an environmental consulting firm in San Luis Obispo, CA) at one site just south of Point Buchon (Figure 1), and this is only relevant to the NCS. Transects were 50m in length in depths from 3–10 m along high to moderate relief rocky reefs and kelp forests. Abundance indices were developed using the factors year and month (Table 13). The second is the Partnership for Interdisciplinary Studies of Coastal Oceans (PISCO) adult survey (1999-2008), particularly for the Monterey region. Since 2007, they have extended their survey area monitoring inside and outside MPAs in central and southern California.

These two indices were not included in any of the California base case models for two reasons: 1) SCUBA surveys may not provide reliable abundance indices for cryptic species such as cabezon; and 2) the spatial coverage of these surveys, which is limited, is such that abundance indices based on them may not be representative of state-wide trends (Cope and Punt 2006). Despite not including either of these adult surveys in the base case, sensitivity of the results of the assessment to their inclusion is examined.

CDFG hook-and-line, PSMFC dockside, and PSMFC onboard surveys
Three additional surveys applicable to the NCS were provided by Tom Wadsworth (MLML, pers.comm) for the STAR panel. Details of the data available and development of each survey into an index can be found in Wadsworth (2009). The CDFG hook-and-line survey runs from years 1979-82 and 1995-98 and cover represent the Big Creek Ecological Reserve (BCER) only. The PSMFC dockside runs from years 1981-89 and 1993-07 and covers the whole NCS. The PSMFC observer time series is 1999-07 and represents the whole NCS. These data series were not retained in the final base model because they had little influence on the results (see Sensitivity section for results).

Recruitment surveys
CalCOFI
The Southwest Fisheries Science Center (SWFSC) has conducted larval tows off California since 1950. Tows are generally made at stations from the Mexican border to roughly 36°N, so these data relate primarily to southern California. Surface (manta) tows made south of 31°N during June-September and west of 122°W are also excluded from the analyses due to few positive tows. Additionally, data for the years 1977, 1979, 1982 and 1983 are excluded because of changes in survey methodology. The factors considered in the analyses were: day and night (day: between 6AM and 6PM), latitude (north and south of 34°N), longitude (east and west of 121°W), and month. Since surface tows are the focus of consideration and have low numbers of positive tows (Table 12), this data source is not considered further in this assessment.

Power-plant Impingement
An index of recruitment was created using impingement data obtained from the Edison power plants in California (Table 12). These data (catch in numbers per standardized flow volume) come from only the extreme southern California Bight (33-34°N) and are consequently reflecting only the SCS. The factors considered when developing this index were: station (some stations had multiple intake areas), and season (Dec-Feb, Mar-May, Jun-Aug, and Sept-Nov). This index is considered to pertain to recruitment rather than to reproductive output because the lengths of the fish impinged were primarily those of fish aged 0 and 1 years.

SMURFS
PISCO and CalPOLY (San Luis Obispo) have both collected recruitment information on nearshore fishes in California. The description of these standard monitoring units for the recruitment of temperate reef fishes (SMURFS) and the methodology can be found in Ammann (2004). This method may be a good index for some nearshore fish, however there was not much information available for cabezon (Table 12).

All indices considered either in the base case or in sensitivities are shown in Figures 38 and 39. Tables 14-16 provide all values and CVs of these indices.

Indices not considered
RecFIN

The catch and effort data for the man-made, beach/bank and PBR modes contain few records with cabezon. As was the case in the former (2005) assessment, an abundance index based on RecFIN was not considered further in this assessment. A portion of this data is included in the PSMFC dockside survey provided by T. Wadsworth (MLML, pers. comm.).

Monterey Adult Survey
The survey is a visual count of adult fish among nearshore rocky reefs in the Monterey area during 1993–98. As the former assessment found no influence of this index on assessment results, its limited representation of the assessment area, and lack of additional years, this survey was not considered in any model trials.

Additional dive surveys are being conducted in the waters off California, who seek volunteers to help with their surveys. Where these surveys are not particularly good indicators of abundance for cryptic species such as cabezon, they could be evaluated for other nearshore species. We are listing some of these programs here so divers are aware of these volunteer opportunities in the future.

>
> Reef Environmental Education Foundation (REEF) began in 1990. (http://www.reef.org/)

Ichthyoplankton Indices
Cabezon larvae are initially neustonic and available (and readily identifiable) to planktonic sampling gears. The SWFSC has conducted ichthyoplankton surveys off the west coast and developed databases with information on the abundance of cabezon larvae. Generally the size of fish collected during these studies is <15mm (pre-settlement) and therefore not thought to correlate well with recruitment to age-1. However, the abundance of this size group may relate (in a linearly proportional way) to the amount of reproductive output the year before the year of sampling. The possibility of developing an index using the Santa Cruz mid-water juvenile rockfish survey was investigated. However, cabezon are only a very small component of the catch in this survey (S. Ralston, SWFSC, pers. comm.) so no attempt was made to develop an index of pre-settlement of cabezon using these data.

Southern California Sanitation Districts Fish Surveys
The sanitation districts of Los Angeles, Orange, and San Diego Counties and the City of Los Angeles conduct fish surveys every year to monitor the effects of sewage outfall on nearshore communities. This data sources provided insufficient information to develop indices of abundance for cabezon.

Data Input Files
The SS3 input files for each sub-stock are provided in Appendices C-1 (NCS) and D-1 (SCS), E-1 (CAS) and F-1 (ORS).

Assessment

Assessment Model
This is the third assessment of the cabezon resource off the California coast. It differs in several key ways from the past assessment (Cope and Punt 2006). This assessment uses the newest version of stock synthesis (SS 3.03A; Methot 2009), a flexible length- and age-based population dynamics modeling environment. Previous work (not shown here) replicated the old assessment derived outputs in this new version of SS to make certain new model outputs were not sensitive to the use of the new SS version.

This assessment includes several differences in the data and thier treatment compared to the former assessment. Catch histories, mostly in the recreational fishery, differed due to changes in the weight and numbers of fish reported in each fishery mode (Figure 19). The treatment of discards also differed between the previous and current assessments. While discards were not considered in the last assessment (partially due to the lack of commercial information on discards and to the basic biology and fishery behavior causing low impact on cabezon when discarded), the new assessment was able to use multiple years of data from the WCGOP. The 2005 assessment did not use any RecFIN lengths prior to 1993 because the lengths were derived from weights. This assessment has recovered the measured lengths of those samples and now includes the full time series of RecFIN length compositions for all modes in each of the sub-stocks. Finally, age-at-length data were treated conditionally so as to allow the estimation of growth parameters internal to the model rather than being externally fit as before.

On a technical note, all tuning was based on average effective sample sizes by fleet rather than tuning each year of each fleet. Finally, the addition of an Oregon sub-stock is new to this assessment.

The population dynamics model
The base case assessment for each sub-stock is based on the following assumptions:

1. There are two fishery sectors (commercial and recreational). The commercial sector consists of two fleets and the recreational sector consists of four fleets.
   - Fleet 1: Commercial non-live-fish fishery
   - Fleet 2: Commercial live-fish fishery
   - Fleet 3: Recreational mode: Man-made (MM)
   - Fleet 4: Recreational mode: Beach/bank (BB)
   - Fleet 5: Recreational mode: Private boat and rentals (PBR)
   - Fleet 6: Recreational mode: Commercial Passenger Fishing Vessel (CPFV).

Fleet distinctions imply different length-specific selectivity patterns. The Oregon sub-stock did not have enough data or data resolution for all four recreational fleets, so fleets 3 and 4 were combined into a ‘shore’ mode and fleets 5 and 6 were combined into ‘boat’ mode.

2. Selectivity is assumed to be dome-shaped for the commercial live-fish fishery and the man-made and beach/bank fleets in the recreational fishery because each of these fleets tends not to land the larger sized fishes. Selectivity is assumed to be asymptotic for the remaining fleets (all fleets, though, use selectivity option 24 to allow for sensitivity testing of estimating a dome-shaped selectivity curve). Changes in management regulations have affected selectivities in each sub-stock, so time blocks were used to allow estimation of

separate selectivities per block (Tables 17 & 18). For the CAS and NCS, additional selectivity curves were estimated for blocks based on changes in size limits (1999-08) in the commercial live-fish fishery and size and bag limits (2000-04; 2005-08) for the PBR and CPFV recreational modes. In the SCS, blocked selectivities also correspond to the commercial live-fish fishery (1999-08) and the PBR and CPFV recreational modes (2000-08). Blocking in the Oregon sub-stock model differed, with two blocks in the commercial fishery due to size limit changes (2000-03; 2004-08) and one block for the recreational boat fishery (2003-08). All yearly selectivities within a block are assumed to be constant over time. The sensitivity of the results of the assessment to alternative specifications related to selectivity and time-blocking is examined in the tests of sensitivity. The selectivity patterns for the non-live commercial fleet in the assessment of the SCS are set to those for the non-live commercial fleet in the NCS owing to a lack of size composition data for the commercial fleets in the SCS.

3. There is one fishing season each year and the removals are taken instantaneously in the middle of the year after half of the natural mortality.
4. The estimates of removals-in-mass are known with negligible error.
5. Recruitment is related to reproductive output by means of a Beverton-Holt stock-recruitment relationship with log-normally distributed process error.
6. Length-at-age is normally distributed about its expected value.
7. There is no connection between any of the sub-stocks of cabezon, either through recruitment or migration. This assumption as it pertains to the NCS and SCS is explored through sensitivities.

Parameter estimation

The population dynamics model includes many parameters. The values for some of these parameters are based on auxiliary information, while others are estimated by fitting the model to the data (Tables 17 & 18). The base-case value for steepness (*h*) is assumed to be 0.7, based on a recommendation from the past assessment review (Cope and Punt 2006). The implications of this choice of steepness are evaluated using a likelihood profile. Recruitment variation, $_{R}$, is initially set equal to 1.0, then tuned to match the residual mean square error of recruitment deviations derived from the fitted model. The base-case values for the instantaneous rate of natural mortality are set to $0.25yr^{-1}$ for females and $0.3yr^{-1}$ for males (Table 2). Given the considerable uncertainty associated with the (assumed) base-case values for *M*, sensitivity tests examine the consequences of changing this parameter value for each sex.

For the purposes of this stock assessment, data were prepared as conditional ages by length bin so as to internally estimate the growth parameters and perpetuate uncertainty in those estimates through the model fitting process. This is an improvement upon the former assessment that used the externally fit growth parameters and assumption of CVs about length at age. Growth parameter values estimated external to the assessment model are compared with those derived from estimation within the assessment to diagnose whether the realization of growth differs in each approach (Figure 74).

No attempt is made to estimate recruitment deviations for the first year of the assessment period (1916), nor those for some of the subsequent years, because the data are completely uninformative regarding the values for some of the early (and most recent) recruitment deviations. Observing the behavior of the asymptotic standard error estimates of recruitment deviations can help to inform the choice of the first year for which recruitment deviations are estimated. The base-case models for each sub-stock were run estimating recruitment deviations for all years to determine the first year for which recruitment deviations could be estimated with reasonable precision (Figure 40). A decrease in these standard deviations may indicate when estimation of recruitment deviations should begin because the data provide some information about the recruitment deviations. For all California sub-stocks models, 1970 was chosen as the first year for which a recruitment deviation is estimated. For the Oregon sub-stock, 1980 was determined the best year to begin estimating recruitments. The final year of the estimated recruitment time series is set to 2006 for all sub-stocks to account for the lack of informative data for estimating recruitments in the final years of the model. Additionally, it is recommended that the bias correction carry through the most informative period of the recruitment time series. This period where recruitments are bias-corrected for lognormal error was defined as 1980-2004 for all sub-stocks. The sensitivity of each sub-stock assessment to the choice of years for estimating recruitment deviations is considered in tests of sensitivity.

Selectivity as a function of length was estimated for all fleets for which mean weight or length-composition data were available. Dome-shaped selectivity was modeled using a six parameter double normal curve for the commercial live-fish and recreational man-made and beach/bank fleets. All parameters were estimated except for selectivity at the first size bin (<6 cm), which was assumed to be near 0 (Tables 17 & 18). Length selectivities for the non-live commercial and recreational PBR and CPFV fleets were also described using the six parameter double normal function, with three of the parameters (the width of the descending limb, selectivity at the first size bin (<6 cm), and selectivity of the final length bin (>92 cm)) set to mimic logistic selectivity. There are no length-frequency data for the non-live commercial fleet or the first selectivity block of the live-fish fishery for the SCS, so the selectivity patterns for these fleet mirrors the estimate for the NCS. The selectivity pattern for the CPFV abundance index mirrors that of its corresponding CPFV fleet. Likewise, the ORBS survey mirrors the boat mode selectivity in the Oregon sub-stock. All recruitment surveys were set to estimate age 0 recruitment (selectivity option 33 in SS v. 3.03A).

Likelihood components

The following six components comprised the objective function that was minimized to estimate the free parameters of the model:

1. Abundance Index (assumed log-normally distributed).
2. Mean Weight (assumed normally distributed).
3. Length Composition (assumed multinomially distributed).
4. Conditional age at length (assumed multinomially distributed).
5. Recruitment Deviations.
6. Parameter Priors (penalties on deviations from the prior distribution; generally very small for these model parameterizations).

Coefficients of variation (CV) about the abundance indices derived from bootstrapping or jackknifing techniques may greatly underestimate the true uncertainty regarding the relationship between these indices and biomass. Additional variance (equivalent to 3 times the average yearly CV of the time series) was added to each index in order to more adequately capture the inherent uncertainty (Tables 14-16). The sensitivity of the results to setting the CVs to the values obtained from the bootstrap procedure (Tables 14-16) is explored in the tests of sensitivity.

The mean weight data (Table 11) were assumed to be normally distributed with CVs based on the raw data when these data were included in the objective function. The CVs for the estimates of mean weight for the CPFV fleet for 1947–51 for the NCS and CAS were set to 0.5 (larger than observed for RecFIN) to avoid over-weighting these early data.

The catch length-composition data were pooled into 44 length-classes (up to 92 cm), each of width 2cm, except the first, which includes 0–5.9cm. Although the length compositions can be based on hundreds or thousands of measurements, fits to length-frequency data usually exhibit substantial overdispersion relative to a multinomial distribution where the sample sizes are set to the number of animals measured. Therefore, for the purposes of the present analyses, the sample sizes are compared to the "effective" number of animals measured each year using the approach developed by McAllister and Ianelli (1997). Sample sizes are then iteratively changed by adjusting yearly sample sizes so that the mean inputted sample sizes by fleet approach the model-derived mean effective sample sizes by fleet. Such an approach is termed 'tuning'. Model sensitivity to using the originally assumed sample sizes (a 'non-tuned' model) was explored in the tests of sensitivity.

Recruitment deviation and parameter priors were calculated assuming lognormal and normal error structures, respectively. The variances for all of the estimated parameters were set very high to minimize the influence of the prior on the results.

Parameter (Control) Input Files
The SS3 files for the assessments of each sub-stock are provided in Appendices C-2 (NCS) and D-2 (SCS), E-2 (CAS) and F-2 (ORS).

Model diagnostics (base models)
Abundance surveys
Figures 41 and 42 show the fits to the base-case indices of abundance for all sub-stock models. As seen in the previous assessments, the California models tracks the changes in the CPFV indices qualitatively, but there are considerable differences between the model-estimates and the data for some years. These differences are, for the most part, consistent with the very wide confidence intervals assumed for the data. The fit of the CPFV index for the SCS (Figure 41) is particularly poor in the mid 1980s to the early 1990s, but fit the most recent years well. The former assessment had trouble fitting the most recent years. Blocking the time series for this assessment seems to have improved the fit. The NCS (Figure 41) and CAS (Figure 42) models not surprisingly fit similarly to their respective time series. The Oregon sub-stock model has trouble fitting the earliest and lowest index value, but does track the rest of the index values. Weaker fits to the index data in each of the sub-stocks is generally attributable to the fact that the age, length and weight data drive population dynamics rather than the abundance index information.

Mean weights

Figures 43-46 show the fits to the mean weight data for all sub-stocks. The confidence intervals for the mean weights are wide (as expected given the CVs in Table 11), which implies that the model is not constrained to a substantial extent by these data. Model fits to the data are generally good and do not indicate any notable divergence of these data from the conclusions of the overall maximum of the posterior density (MPD). Improved fits to the mean weight are seen in the current stock assessment versus the previous assessment, indicating more coherence of data sources. The past SCS assessment showed major sensitivity to the mean weight for the man-made fleet (fleet 3) in 2000, a sensitivity not seen in the current assessment (see trial when mean weights are removed, Table 21B and the trial when the low value in 2000 is removed, Table 23). This low mean weight is still visible in the data and is interpreted as a recruitment event, though it does not well fit (Figure 44). Despite the lack of fit to the 2000 data point, the population still demonstrates the large recruitment, indicating information in other data sources (e.g. later year mean weights and length compositions) contribute independent information supporting the 1999 recruitment event.

Length composition data
The base-case fits and diagnostics to the length-composition data for each sub-stock are given in Figures 47-52 (NSC), 53-57 (SCS), 58-63 (CAS), and 64-69 (ORS). When interpreting these figures, it should be noted that the observed and model-predicted lengths are “plussed” at low and high sizes. This has little impact on the results at high size, but can give a misleading impression at low size (e.g. the fit to the data for 1999 and 2000 for the non-live-fish fleets in the NCS and CAS base case models (Figures 47 and 58)).

Overall, fits to the length compositions for all sub-stocks across all fleets was good. The strongest fits in the NCS (Figures 47-52) were found in the live-fish fishery and PBR mode samples (Figures 48 and 51). No severe misfits, residual patterns, or unbalanced inputs were detected in any of the fleets for any of the sub-stocks. Low sample sizes in the commercial live-fish fleet and shore-based modes (MM, BB) of the SCS (Figures 53-55) rendered them the weakest contributor to the length composition likelihood for that sub-stock. Fits were best in the PBR recreational mode (Figure 56). The CAS was similarly driven by live-fish fishery (Figure 59) and PBR (Figure 62) compositions and samples, the beach/bank mode contributed earlier in the time series (Figure 61). Similar to the California sub-stocks, the Oregon sub-stock gained much of its length composition information from the live-fish commercial (Figure 66) and boat-based recreational fishing modes (Figure 69).

Conditional age-at-length data
Fits to the conditional age-at-length data are provided for each sub-stock in Figures 70-73. These fits to ages conditioned on length produced estimates of growth similar to those derived by externally fitting the same age and length data with ageing error (Figure 74; Cope and Punt 2007).

Results

Base case results: NCS
Figure 75 shows the MPD estimates of the time-trajectories of spawning output (in absolute terms) and recruitment, along with their asymptotic 95% confidence intervals. There is considerable inter-annual variation in recruitment. The time series

of spawning biomass and recruitment are found in Table 19. The estimates of recruitment are most precise before 1980 because no recruitment deviations are estimated for these years and the estimates of recruitment consequently reflect expectations based on the stock-recruitment relationship (Figure 75, bottom panel). In contrast, the estimates of reproductive output are most precise during the late 1980s and early 1990s (Figure 75, top panel). The NCS is estimated to have been at 45% of its virgin level (1036 mt) at the start of 2009 (469 mt; Figure 76). These current estimates are generally consistent with probable scales of biomass and trajectories found in the 2005 assessment (Figure 77). A large bump in the biomass is seen in the late 1970s due to a major recruitment event in the early 1970s. Sensitivity to the start of the recruitment time series is investigated to observe whether the derived outputs are sensitive to this recruitment event. Other major recruitment events are seen in the 1990s. Figure 78 shows the estimated spawner-recruit relationship along with the asymptotic standard deviations of estimated recruitments demonstrating when the data begin to inform estimated recruitments (seen as a drop in the asymptotic standard deviation below the specified recruitment variation) Appendix G lists the MPD estimates of the numbers-at-age matrix for each sex (also plotted in Figure 79).

Figure 80 shows the length-specific selectivity ogives for each fleet. The live-fish fishery (fleet 2) is greatly dome-shaped with respect to length in the most recent (1999-2008) selectivity block. Selectivity for the beach bank fleet (fleet 4) also declines with size. The selectivity ogives suggest that immature fish are not completely excluded from the current and historical catch, especially in the man-made and beach/bank recreational modes.

Harvest rates for each fleet are given in Figure 81. The onset of the live-fish fishery in the late 1990s shows a dramatic peak in harvest rate by this fleet. Only the PBR recreational fishery fleets show harvest rates of the same magnitude. Harvest rates since the 1980s for the PBR recreational modes represent a major source of cabezon removals from the NCS. The combination of the expanding live-fish fishery and high recreational removals caused harvest to exceed the MSY-proxy harvest rate currently calculated for this sub-stock in the late 1990s (Figure 82).

Despite the fact that catches in the late 1990s exceeded the currently estimated MSY-proxy harvest rate, the NCS depletion level has since increased from the precautionary zone to a level above the target spawing biomass (Figures 76 & 83).

Base case results: SCS

Figure 84 shows the MPD estimates of the time-trajectories of spawning output (in absolute terms) and recruitment, along with their asymptotic standard errors. The historical values of spawning biomass and recruitment can be seen in Table 19. The time-trajectory of reproductive output drops dramatically after 1980, stays low until the early 2000s, and then increases substantially. The increase in reproductive output occurs because of the 1999 year-class, the largest in the time-series. Additional large recruitments were seen in 1984 and 1994. All three of these large recruitments followed on the heels of notable El Niño Southern Oscillation events (ENSOs) of 1982/1983, 1991/1992, and 1997/1998. This correlation with environmental conditions along with smaller relative biomass compared to conspecifics of the NCS may indicate that the SCS is a more dynamic subpopulation. This is also consistent with the higher recruitment variation ($_R$) estimated for the SCS (0.7) versus all other cabezon sub-stocks (0.5). Major recruitment events for the SCS are also consistently lagged 1 year compared to the NCS. The SCS reproductive output is estimated very precisely during the 1990s and is estimated, with much greater uncertainty, to have been at 60% of its virgin level (263 mt) at the start of 2009 (158 mt) (Figure 85). Though the relative and absolute level of the population trajectory is similar to the last assessment (Figure 77). Despite the increase in biomass scale, the biomass of cabezon off southern California remains much smaller than that off central / northern California. Figure 86 shows the estimated spawner-recruit relationship, along with the asymptotic standard error estimates around each estimated recruitment. The model is moderately informed regarding recruitments. Appendix H and Figure 87 give the MPD estimates of the numbers-at-age matrix.

Figure 88 shows the length-specific selectivity ogives for each fleet. The selectivity patterns for the non-live-fish fishery are inestimable because of the lack of length compositions and are therefore assumed equal to the selectivity for the non-live-fish fleet in the NCS. The live-fish fishery shows a very strong dome-shaped pattern that changes as size-limits affected fishery retention. The selectivity patterns for the man-made and beach/bank fleets decline more rapidly with length for the SCS than is the case for the NCS. These selectivity patterns suggest that immature fish are not completely excluded from the current and historical catch, especially in the man-made recreational fishery.

Harvest rates for each fleet are given in Figure 89. There are two significant periods of removals: 1) the 1980s when harvest rates increased dramatically because of the increase in recreational fishing, particularly by the PBR (fleet 5) recreational mode; and 2) the late 1990s when the live-fish fishery (fleet 2) took large catches. The first of these periods of harvest, along with the lack of strong recruitment events, led to the large reduction in reproductive output during the early 1980s (Figure 84). Through much of the 1980s and up until recently, catch of the SCS exceeded the currently estimated MSY-proxy harvest rate for that sub-stock (Figure 82). Large reductions in removals coupled with a major recruitment in the late 1990s has allowed the moderately growing cabezon to increase from 25% of the unfished level in 1999 to more than 60% since 2007 (Figures 83 and 85).

Base case results: CAS

Figure 90 shows MPD estimates of the time-trajectories of spawning output (in absolute terms) and recruitment, along with their asymptotic standard errors for the state-wide (i.e. treated as a single homogenous population) California assessment of cabezon. The historical values of spawning biomass and recruitment can be seen in Table 19. The time-trajectory of spawning output for the combined assessment is qualitatively most similar to that for the NCS, although, as expected, biomass levels are higher. In this base case, all data for each fleet is combined so as to create the same six fleets combining the data from the SCS and NCS. Despite both of the area-specific sub-stocks being above the target reference points, the depletion of the combined model is 34%, below the 40% target (410 mt compared to an unfished spawning biomass of 1,207 mt; Figure 91). The terminal year estimate of biomass is also smaller than the NCS estimate. Figure 92 shows the estimated spawner-recruit relationship along with the asymptotic standard errors estimates around each estimated recruitment. The model is well informed regarding recruitments. Appendix I and Figure 93 give the MPD estimates of the numbers-at-age matrix.

Comparison of the current state-wide base case to alternative ways of estimating state-wide California estimates of cabezon spawning output and recruitment are provided in Table 20 and Figure 94. The summation of the SCS and NCS leads to the highest spawning output and retains consistency with the stock status estimated for each individual-area assessment. It is also most consistent with state-wide results from the 2005 assessment that used different fleet designations to distinguish spatial-explicit fisheries (Table 20; Figure 77). Thus one can alternatively specify the current state-wide model using area-specific fleets (1 for each fleet in each area = 12 total fleets), as was done for the state-wide assessment in 2005. Such an approach gives you a depletion value (35%) closer to the state-wide model without spatial fleet designations and still less than either of the area-specific assessments. These seemingly incongruent results (deriving a state-wide depletion value less than either of the sub-stock models) can be attributed to combining divergent area-specific population dynamics to explain one synthetic overall pattern. This is seen most clearly when comparing recruitment deviations (Figure 95). The NCS and SCS have distinctive recruitment patterns. These area-specific patterns get obscured when the data have to explain just one best-fit recruitment pattern, causing much weaker recruitment in the last 10 years and thus, in this particular case, reducing the ability for the population to compensate for the combined removals. Allowing selectivities to vary by area (via area-specific fleet specification) does little to reduce this effect (Figure 95).

A final consideration to a state-wide model specification was the two-area (north and south) model with connected recruitment via a constant recruitment distribution ratio (Figure 94). This allowed for the two sub-stocks to be modeled with connectivity in the early life stage (as opposed to the base case assumption of no connectivity), with total recruitment being redistributed via an estimated recruitment ratio. Such an approach results in the largest combine biomass and least depleted state-wide stock (Table 23C). This formulation is based on the assumption of a well-estimated constant recruitment distribution, which is unlikely given the varying dynamics in each sub-stock.

Figure 96 shows the length-specific selectivity ogives for each fleet in the state-wide base case. The state-wide selectivities are heavily influenced by the NCS data and appropriately reflect this relationship.

Harvest rates for each fleet modeled in the CAS are given in Figure 97. Similar to the NSC and SCS, the 1980s and early 2000s PBR removals and the late 1990s commercial live-fish fishery removals are the major periods of harvest. These relatively large removals are reflected in exploitation rates at or surpassing currently estimated MSY-proxy harvest rates for much of that period (Figure 82). Large reductions in removals coupled have occurred in recent years, but without the kind of major recruitment event observed in the sub-area models, depletion has not rebounded to exceed the target level (Figures 83 and 91).

Base case results: ORS

Figure 98 shows MPD estimates of the time-trajectories of spawning output (in absolute terms) and recruitment, along with the asymptotic standard errors for the Oregon sub-stock. The historical values of spawning biomass and recruitment can be seen in Table 19. There is much uncertainty about the absolute scale of the population, though less uncertainty about the recruitment. Uncertainty in the spawning output under initial conditions is similar to that of the terminal year spawning output. The depletion of the ORS is 52% (214 mt compared to an unfished spawning biomass of 409 mt; Figure 99). Given the high uncertainty in both the initial and terminal conditions, certainty in the depletion is unsurprisingly higher, with only a small portion of the 95% distribution around mean depletion below the target reference point. In general, the scale of biomass off Oregon is greater than the SCS, but lower than the NCS. Figure 100 shows the estimated spawner-recruit relationship along with the asymptotic standard error estimates around each estimated recruitment. The model is generally well informed regarding recruitments. Appendix J and Figure 101 give the MPD estimates of the numbers-at-age matrix.

Figure 102 shows the length-specific selectivity ogives for each fleet in the ORS base case. Distinct dome-shaped selectivities are found in the live-fish fishery, with changes in the shape due to size regulations. The affects of size regulations on the recreational boat-based modes is less apparent.

Harvest rates for each fleet modeled in the ORS are given in Figure 103. Removal levels are much below those seen in any of the California sub-stocks, with the live fish fishery (fleet 2) being the highest. Only under the highest removals from the live-fish fishery did the population approach the MSY-proxy harvest rate (Figure 82). The base case MPD for the ORS suggests the current stock status is well above the target reference points (Figures 83 and 99).

Sensitivity analyses

Sensitivity tests were conducted to evaluate how derived model outputs may change due to our uncertainty in the data sources or model specification. The first set of sensitivities considered the affect of removing data sources on the derived outputs of initial spawning output (SB_0), terminal year spawning output (SB_{2009}), depletion and MSY. The results of these sensitivity analyses are provided in Table 21.

The NCS (Table 21A) was most sensitive to the removal of the CPFV abundance index (Trial 11), which dropped the depletion estimate below the target level, but still well above the overfished limit. The model was also sensitive to the removal of all length composition data (Trial 19), a result seen with all sub-stocks, but that is as expected when the primary information informing selectivity and recruitment deviations are the length compositions. Both spawning output measures were the most and similarly sensitive, whereas depletion and MSY (which ranged between 125 mt and 140 mt for most trials) were the most robust.

The SCS (Table 21B) demonstrated low sensitivity to all practical trials (removing all the lengths (Trial 14) is not considered a practical trial as it removes the primary information to estimate selectivity, but included for completeness), none of which dropped the stock status below the target level. Removal of the abundance indices (Trial 7) resulted in a less depleted stock, opposite the affect found in the NCS. MSY was again very robust, ranging between 25 mt and 35 mt.

The CAS (Table 21C) was similarly insensitive to most data trials, again showing the most sensitivity to removal of the CPFV abundance index (Trial 10). All practical trials were above the limit reference point with several raising the stock status above the target reference point. These trials included using one continuous CPFV time series, removing the live-fish length compositions, removing the beach/bank length compositions, and removing the conditional age-at-length data. These results did not mimic the results in the NCS, thus showing emergent behavior in the state-wide approach. MSY generally ranged from 140 mt to 155 mt.

The ORS (Table 21D), though generally robust to removing data, was highly sensitive to the removal of the ORBS survey (Trial1). Removing this piece of information caused the population to drop below the limit reference point. MSY was the relatively least certain amongst all sub-stocks, generally ranging from 30 mt to 50 mt.

Natural mortality (*M*) and steepness (*h*) were unknown and treated as fixed parameters in each of the sub-stock assessments. To investigate the sensitivity of model derived outputs to the values assumed for these parameters and whether the current data are informative to the value of these parameters, likelihood profiles of *M* and *h* were conducted for each sub-stock.

Steepness estimates proved uninformative in each of the sub-stocks (Figure 104) as it tended to either approach the upper (in the SCS and ORS) or lower (in the NCS and CAS) bound. The biggest change in behavior in each case occurred when steepness was above or below 0.4. Current spawning output is more sensitive than initial spawning output in all California sub-stocks, causing both depletion and MSY (which is expected) to approach zero as steepness approaches the minimum (Figures 105 & 106). The overfished state is reached in the NCS and SCS if steepness is less than 0.4. In the CAS base case, the overfished state is reached with steepness less than 0.5. The ORS was less sensitive to the assumption of steepness with the current spawning output being the least sensitive derived output. In no trial did the base case ORS fall below the overfished threshold.

The models also lacked information as to the value of *M*, though very different behaviors are obtained among the sub-stocks (Table 22; Figure 107). Information contained in the sub-stock data sets were most consistent with different levels of natural mortality across areas. The NCS and CAS tended to find better fits at the lower bounds of M, especially for females, whereas the ORS tended to fit better at the higher bounds (Figure 107). All sub-stocks dropped below the overfished level at the lowest values of M. Generally, values less than 0.2 led to overfished status. The values of M explored gave widely varying values for all derived outputs for the SCS and ORS. The NCS and CAS, while showing relatively more stability, still demonstrated disperate derived outputs depending on natural mortality. As was the case in the previous assessment, natural mortality is the most sensitive assumption in all models.

Additional sensitivities were run using a variety of model specifications to better understand the behavior of each assessment model to changes in key assumptions. Such sensitivities included alternative treatments of variance in abundance indices, retrospective analyses of the marginal contribution of data from recent yeears, and assumptions regarding catch histories, the time series of recruitment deviations and spawner-recruit relationships, selectivity specifications, and age and growth. The latter assumed either no ageing error or that male growth in California is more like that of Oregon males (Figure 9) or past estimates in California (O'Connell 1953).

Results to these sensitivities are found in Table 23. Assuming a Ricker spawner-recruit relationship caused a major decline in all California sub-stocks, though no evidence exists to support this relationship. Estimating natural mortality also caused major declines in the NCS and CAS. The SCS showed particular sensitivity to the assumption of the male growth parameters, where slower growing males with larger terminal size led to greatly depressed stock status. Oregon showed little sensitivity to any of the trials. These trials emphasize the importance of gaining further understanding of the growth and mortality rates for all sub-stocks.

Retrospective patterns, identified through the progressive removal of data back to a certain year, give further insight into the replicability of the current spawning output trajectories and estimated stock status (Table 23 and Figure 108). The California sub-stocks show consistent patterns and scales of spawning output for most retrospective analyses. The greatest difference is produced when 10 years of data are removed. This is expected given most of the conditional ages used to estimate growth and the length samples from the live-fish fishery to estimate selectivity are removed. The ORS shows much more unstable behavior, demonstrating again how the depletion status is robust to model specification, but the uncertainty about scale is very large. Removing 10 years of data essentially takes most of the data out of the assessment, thus causing an unrealistic decline in the population.

Projection and decision analysis

Twelve-year forward yield projections are conducted for each sub-stock under two alternative ABC control rules (based on F_{MSY} proxies of $F_{45\%}$ and $F_{50\%}$) and two OY threshold control rules (40-10 or 60-20). The standard PFMC OY control rule for groundfish such as cabezon is based on $F_{45\%}$ with a 40-10 adjustment for stocks below the target level of 40% of the unfished reproductive output. The California NFMP proposes the use of a F_{MSY} proxy of $F_{50\%}$ and a 60-20 adjustment for stocks below 60% of the unfished reproductive output. The relative proportion of the six fleets in future harvests is assumed to be the same as the last year (2008) in the model.

The results in Table 24 suggest that sub-stocks (NCS, SCS, and ORS) above the target reference level of $SB_{40\%}$ would see a reduction in population size converging on the target reference point near the end of the projection period under the 40-10 control rule. The CAS would increase toward the target reference point during the same period. The extent of this increase is greatest for the most conservative OY control rule ($F_{50\%}$ with a 60-20 adjustment) and least for the less conservative control rule ($F_{45\%}$ with a 40-10 adjustment). Most increases under the 60-20 rule increased populations near the 50% virgin biomass level.

Decision table projections based on alternative states of nature (columns in the decision tables) for 3 of the 4 sub-stocks were explored to capture uncertainty in population conditions (Table 25) and control rules (40-10,$F_{45\%}$ and 60-20,$F_{50\%}$). The STAR panel agreed with the STAT that state-wide management was most appropriately determined from the combined NCS and SCS models, not the CAS model. A decision table for the CAS is therefore not presented. For the NCS, SCS, and ORS sub-stocks, the low and high M scenarios refer to different assumptions about sex-specific natural mortality (the greatest source of uncertainty in all sub-stock models) and were retained from the last assessment. The low scenario assumes M = 0.2/yr and 0.25/yr for females and males respectively, while the high scenario assumes 0.3/yr and 0.35/yr for females and males respectively. Catch histories (rows in the decision tables) were based on three proposed catch scenarios: 1) catch series based on the specified control rule (either 40-10 or 60-20) derived from the low *M* state of nature (low *M* catch scenario); 2) catch series based on the specified control rule (either 40-10 or 60-20) derived from the base case *M* state of nature (base case *M* scenario); and 3) catch series based on the specified control rule (either 40-10 or 60-20) derived from the high *M* state of nature (high *M* catch scenario).

All sub-stocks demonstrated spawning output depletion below limit reference points when the low *M* scenario was subjected to the base case and high catch scenarios. This also occurred when the base case *M* scenario was subjected to the high catch scenario. All other scenarios demonstrated depletion near or above the target reference points at the end of each projection period. Relative to biomass and depletion estimates, the 60-20 rule was much more conservative than the 40-10 rule.

Alternative Assessment Approaches

Given the large number of species needing stock assessments and the lack of resources (e.g. data, time, etc.), simplified metrics or rapid assessment approaches that relate to stock status are needed. Here we report on three approaches that use minimal data and simplifying assumptions and compare their outputs (as applicable) to those of the current assessment.

Productivity-Susceptibility Analysis

Measuring the vulnerability of a stock (defined as the combination of stock productivity and susceptibility to fishing) relates directly to the goals of the US National Standard 1 guideline to maintain optimal yield without overfishing. Specifically, vulnerability determination may help determine whether a species is “in the fishery”, identify species complexes for management, and create additional buffers for management consideration.

Productivity-Susceptibility Analysis was recently presented by Patrick *et al.* (*in press*) as a formal means by which to define vulnerability. It defines the two axis of vulnerability (x-axis = productivity and y-axis = susceptibility) based on multiple attributes describing the life histories and functional relationship to fishing practices, respectively (see Patrick *et al.* for details). The attributes scores are then combined to give an overall productivity and susceptibility score. Vulnerability is then defined as the Euclidean distance of the coordinate productivity and susceptibility scores. Composite scores of 1 indicate the lowest productivity or lowest susceptibility, whereas scores of 3 indicate the highest of each. Vulnerability scores, therefore, are lowest at 0 and highest at 2.83.

Cabezon scores (1 score provided for the whole species) are as follows: productivity = 1.9; susceptibility = 2.1; vulnerability = 1.42. These scores indicates cabezon are both moderately productive and susceptible, thus have moderate vulnerability. Comparing this score to other groundfish species, cabezon are relatively less vulnerable and score near other species that are either near or above target biomass levels (Figure 109; Field *et al. in press*). These results are not inconsistent with the results of this stock assessment for any of the sub-stocks.

Length-based reference points
Froese (2004) suggested a way to assess potential fishery impacts on population dynamics by measuring three simple metrics (generically referred to as P_x) from catch length compositions: 1) proportion of mature individuals (P_{mat}), 2) proportion of fish at the size which the highest yield from a cohort occurs (P_{opt}), and 3) proportion of large, mature individuals (P_{mega}). Cope and Punt (*in press*) extended this analysis by adding a fourth metric (P_{obj}; the sum of all Froese (2004) metrics) that identifies the general selectivity pattern of the fishery and thus allows the resultant P_x measures to be related to biomass without knowledge of historical conditions. The analysis also presented general guidelines for interpreting stock status from P_x values.

The approach of Cope and Punt (*in press*) was applied to each of the sub-stocks by considering the combined length compositions of all fisheries (Figures 110 & 111). For each sub-stock, the P_x measure relatable to the spawning biomass proxies of $SB_{40\%}$ and $SB_{25\%}$ are provided along with the relationship of depletion with P_{obj}. In the current presentation, the use of P_{mat} to inform stock status is consistent with the current assessment results from the SCS (Figure 110) and ORS (Figure 111). This approach is more precautionary than the stock assessment results in the NCS (Figure 110) and CAS (Figure 111), indicating below target biomass levels when the stock assessment indicates biomass levels above the target. Three of the four sub-stocks (all but the SCS) also indicate relationships between P_{obj} and biomass opposite to expectations (right columns in Figures 110 & 111). These discrepancies may be due to improper weighting of the length composition data (weighted only by sample, not by relative catch, in these examples) and need to be explored further. Overall, the terminal year values of P_{mat} are consistent with the stock status presented in each sub-stock assessment.

Preliminary work has shown that using P_{obj} as a predictor of biomass may be used as an effective control rule. Further exploration (via simulation testing) and application are needed to establish the broad applicability of this approach. Given the diversity in selectivity, fishery types, and spatial scales, cabezon seems a good candidate to explore further.

Depletion-corrected average catch
The depletion-corrected average catch (MacCall 2009) was also considered, but is not reported because the correction factors become very small when natural mortality is above 0.2. The DCAC approach thus produces essentially the same estimate of ‘pretty good yield’ of cabezon as taking the average catch of the total removal history for each sub-stock. These averages are 58 mt (NCS), 14 mt (SCS), and 29 mt (ORS) and are about half that derived from the base cases (129 mt for the NCS, 30 mt for the SCS, and 51 mt for the ORS).

Response To Past Research Recommendations

<u>1. Accurate accounting of removals, especially from the recreational and live-fish fisheries:</u> The commercial live-fish fishery and recreational modes (especially the shore-based (man-made, beach/bank) and private boat modes) remain challenges to record accurate removals. Since 2003 the West Coast Observer Program has provided at-sea observations in the live-fish fishery. Programs such as these should grow and

the challenge of obtaining accurate removals of recreationally taken fish should contain to receive attention.

2. A fishery-independent survey of cabezon population abundance: Since the 2005 assessment, cooperative fisheries investigations have started along the California coast and hold promise to provide fishery-independent surveys to nearshore fishes, as well as improving our understanding of critical biological parameters such as natural mortality. The small-scale (relative to the stock assessed areas) coverage of these surveys remains a challenge. Maintenance and expansion of such surveys will increase the usefulness of these data sources in future assessments.

3. A study of the stock structure of cabezon: This assessment provided further research in the stock structure of cabezon (Cope and Punt 2009; Villablanca and Nakamura 2008). Genetic investigations are ongoing for cabezon. With the addition of Oregon, further understanding of cabezon populations at small and large scales is encouraged.

4. Age validation/ age determination: Catch age-composition that represent fishery data remain unavailable to the assessments and no new ages were available for California outside the Grebel (2003) study. Recent age sample were available in Oregon, but only useful for age and growth estimation, not informative to selectivity or recruitment. The Oregon samples did provide ageing comparisons within lab, but given the large discrepancy in growth between male cabezon in California and Oregon, ongoing comparisons among readers would be useful. As suggested in the previous assessment, information on the age-structure of the catches for each fishery sector would substantially improve some aspects of the assessment.

5. A better understanding of the relationship between CPUE and population size: No new information was provided on the relationship between fishery-dependent CPUE indices and biomass. The results of the assessments in California were relatively insensitive to the inclusion of such abundance indices, but the Oregon assessment was highly sensitive, underscoring the need for increased understanding of the relationship of such CPUE-based abundance indices to biomass.

6. Alternative assessment procedures: Alternative assessment methods were presented in this assessment to demonstrate how such methods can be compared to traditional assessment approaches and the potential they may have in informing of stock status and/or future catch recommendations. Such methods may have great utility when attempting to rapidly assess many species of varying data and resource availability. This assessment does not address the issue of alternative metrics such as a spawning biomass measure that includes to nest-guarding males. Alternative model specifications could also address this issue, but were not explored here. This subject is still very relevant to interpreting derived assessment outputs and appropriate proxies for stock status.

7. Effect of climate on cabezon: No new studies were done relating cabezon abundance to climate, though the results of these assessments (especially in the SCS) indicate there may be very strong relationship of recruitment to climate.

8. Sex-specific data: The correlation of color to sex in cabezon (O'Connell 1953; Lauth 1987; Grebel 2003) remains uncertain, but the collection of sex-specific information remains important to enhance future assessments. No additional sex information was provided in the Caliornia sub-stocks for this assessment.

Research Recommendations

1. Improve estimates of natural mortality: All sub-stocks show significant sensitivity to natural mortality, a parameter not estimated in the model and assumed known. Estimates of natural mortality may be derived from tag-recapture studies or the comparison of length compositions inside and outside marine protected areas. There are two studies currently attempting to gather this information for future use in stock assessments. One is representing the northern Channel Islands (J. Wilson, UCSB, pers. comm.) and the other is representing the Morro Bay area (R. Nakamura and D. Wendt, CalPOLY, pers. comm.). These studies, and other like them, need to be encouraged.

2. Age and growth determination: The large discrepancy in estimated male growth parameters between Oregon and California deserve further attention to confirm this relationship. Further attention to ageing cabezon in California is needed to increase our spatial understanding of cabezon growth along the coast. Age samples from each fishery would also help to define growth and selectivity, while informing recruitment patterns and helping decrease the uncertainty in the scale (absolute abundance) of each sub-stock.

3. Fishery-independent surveys: Continued support and development of current fishery-independent nearshore surveys (like those initiated in Morro Bay and Monterey) is needed to extend the time series and increase spatial coverage. Both are required to increase the power of such indices in statistical catch-at-age models.

4. Defining the stock structure of cabezon: Current work on cabezon stock structure needs continued attention to better understand the connectivity between cabezon subpopulations. This would help focus or inform future sampling design to provide data for assessment purposes.

5. Alternative assessment procedures: The need for greater spatial resolution in the management of nearshore fisheries also increases the amount of data required to perform traditional stock assessments. Alternative assessment procedures that are less data-hungry, but still provide relevant management outputs should be encouraged. This assessment provides examples of some approaches as applied to cabezon. Such side-by-side comparisons of simplified assessment approaches to the statistical catch-at-age model outputs are useful in understanding the relationship of alternative to traditional assessment methods in hopes of developing the best available scientific advice for management under data-limited situations.

6. Re-defining "spawning biomass": The nest-guarding behavior of cabezon males gives added reproductive importance to their abundance, relative to most other groundfish species. A metric other than female spawning biomass may be needed to incorporate the status of the male portion of the population into reference points.

Further investigation is needed to identify appropriate ways in which the role of males in reproductive success can be incorporated into metrics for evaluating population status.

7. Changes in batch fecundity with age: Batch fecundity in cabezon is recognized, but it is not understood how and if batch fecundity changes with age. Understanding whether the number of batches increases with age will help specify the fecundity relationship in the assessment model.

8. The effects of climate on cabezon population dynamics: The recruitment patterns of the California sub-stocks suggest a possible link between environmental forcing and population dynamics. Specifically, strong ENSOs conditions (especially in southern California) may be a pre-cursor to significant recruitment events. This link should be explored further to help increase the understanding of spatially-explicit recruitment responses and inform future recruitment events.

Acknowledgements

We are very grateful to the following for contributing data sources to evaluate for this assessment or background information to inform the use of the data: D. Aseltine-Neilson, M. Bellman, W. Dunlap, D. Haas, E. Heery, K. Herbinson, K. Hill, B. Leos, D. Malone, R. Nakamura, S. Owen, R. Starr, B. Stenberg, A. Suntsov, F. Villablanca, T. Wadsworth, J. Wallace, and J. Wilson. We are particularly thankful to Troy Buell, Mark Freeman, and the staff of ODFW for organizing and providing Oregon data and management regulation histories. Joanna Grebel (CDFG) and Josie Thompson (ODFW) provided critical ageing information to this study. Joanna also compiled the management regulations for California. Thank you also to J. Hastie, S. Miller, J. DeVore, members of the STAR Panel (J. Grebel, J. Ianelli, J.J. McGuire, D. Platt, S. Smith, V. Wespestad), and all who have read through and provided comments and critiques of this work.

Table 5 (Continued). Numbers removed, average weights, removals in weight, CPFV ratios, and expanded removals (numbers) by year for each mode in the recreational fleet for the SCS 1962-2008. Shaded values indicate reported values; non-shaded are assumed. Gray cell indicates the modified 1980 PBR value (average of 1981-89).

Table 10. Sample sizes and number of fish measured for all sub-stocks and fisheries. N is the number of trips (recreational modes) or clusters (commercial fisheries) and FISH is the number of fish actually measured. *Indicates expanded compositions. Recreational compositions came from RecFIN if not indicated otherwise.

Table 20. Total cabezon spawning output and depletion rates in differing California models, compared to the 2005 assessment.

	Total California Cabezon Spawning Biomass (mt)				
Model	SB_{1916}	SB_{2005}	SB_{2005}/SB_{1916}	SB_{2009}	SB_{2005}/SB_{1916}
2009 Assessment					
NCS+SCS	1298	567	44%	627	48%
CAS	1207	360	30%	410	34%
2005 Assessment					
NCS+SCS	1361	516	37.9%		
CAS	1268	634	50.0%		

Table 21. Values for the likelihood components and summary statistics related to current status of cabezon sub-stocks for sensitivity tests by changing the data sources included in each assessment. Gray boxes indicate data source is ignored. Green indicates stock status above the target reference point ($SB_{2009/1916} \geq SB_{40\%}$). Yellow indicates stock status in the precautionary zone ($SB_{25\%} < SB_{2009/1916} < SB_{40\%}$). Red indicates stock status below the limit reference point (($SB_{2009/1916} \leq SB_{25\%}$).

Table 23. Results of sensitivity trials to model specification for each cabezon sub-stock. Green indicates stock status above the target reference point ($SB_{2009/1916} \geq SB_{40\%}$). Yellow indicates stock status in the precautionary zone ($SB_{25\%} < SB_{2009/1916} < SB_{40\%}$). Red indicates stock status below the limit reference point (($SB_{2009/1916} \leq SB_{25\%}$).

Table 25. Decision analysis of spawning output depletion based on different states of nature (columns) under different catch histories (rows) and control rules for each cabezon sub-stock. For the 40-10 rule ($F_{45\%}$), 0.40 and 0.25 are the target and limit reference points, respectively. For the 60-20 rule ($F_{50\%}$), 0.60 and 0.30 are the target and limit reference points, respectively. At or above the target reference point is indicated by green; between the target and limit reference points is indicated by yellow; below the limit reference point is indicated by red.

FIGURES

Figure 1. Map of the cabezon sub-stock assessment areas (represented by solid lines at Pt. Conception and the California/Oregon border). Two important headlands are distinguished by broken lines. The North/South management area is shown with the broken dotted line and is also the border between the California Department of Fish and Game's Northern and Central California Marine Management regions. Point Conception divides the Central and Southern Marine Management regions. The 70m isobath indicates nearshore waters. Map courtesy of Marlene Bellman (PSMFC/NOAA Fisheries).

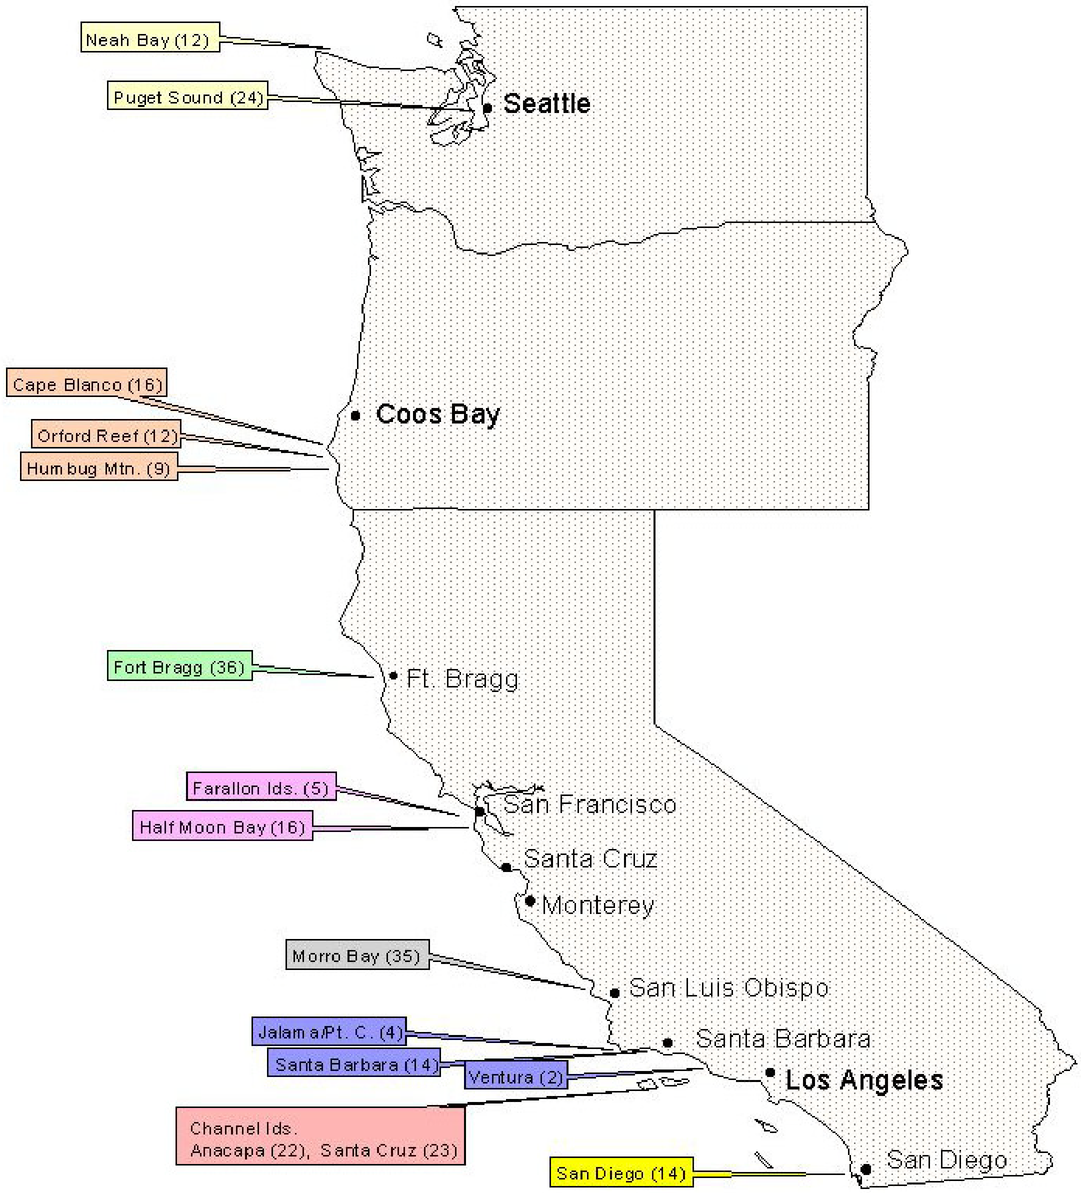

Figure 2. Map of distinct (distinguished by colored) cabezon subpopulations based on mtDNA markers (sample sizes in parentheses) from the work of Villablanca and Nakamura (2008). Map courtesy of F. Villablanca.

Figure 3. Map of California waters including the 18 fishing locations used in the cluster analysis of cabezon population dynamics based on CPFV CPUE. Map courtesy of Marlene Bellman (PSMFC/NOAA Fisheries).

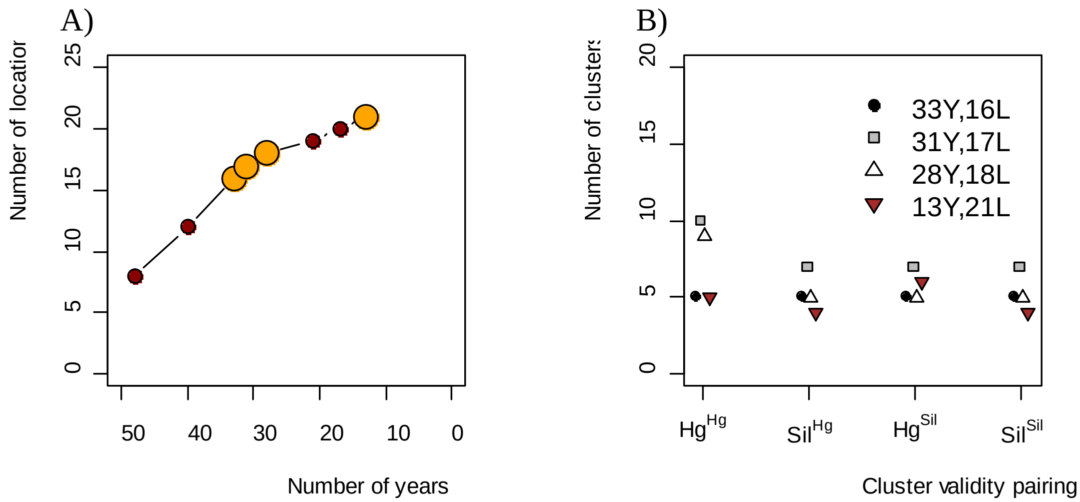

Figure 4. Determination of the CPFV data series used in the spatial clustering analyses of cabezon sub-stocks in California. A) Trade-off between number of years and number of landing locations in the California CPFV CPUE time series. Large circles indicate year/location pairing used in spatial cluster analysis. B) Number of spatial clusters based on cluster validity diagnostic pairings (see Cope and Punt i*n press* for details). Y = Years; L = Location; Hg = Hubert ; Sil= Silouette.

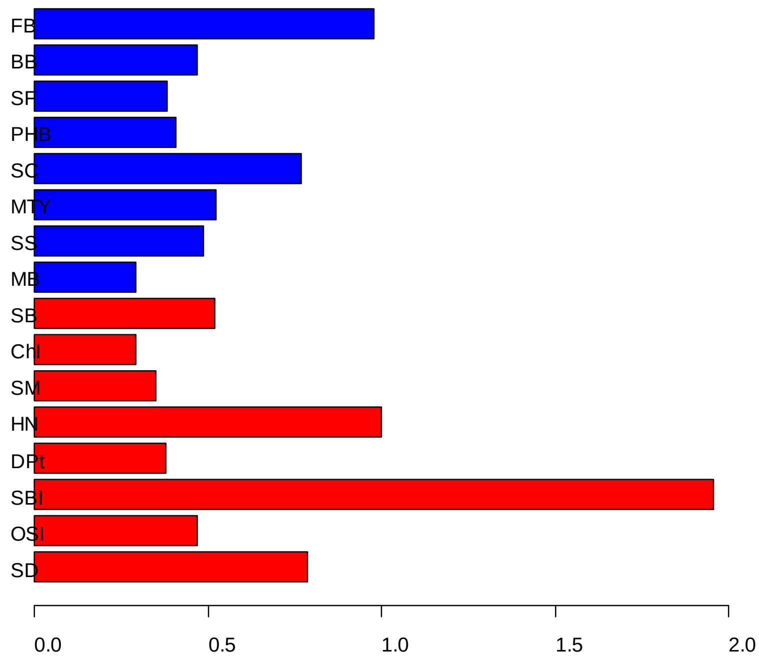

Figure 5. The coefficient of variation (CV) for each fishing location used in the spatial clustering analysis for the two extreme data series based on numbers of years and locations. Blue bars indicate the areas designated as the northern California sub-stock (NCS) while red bars indicate the southern California sub-stock (SCS).

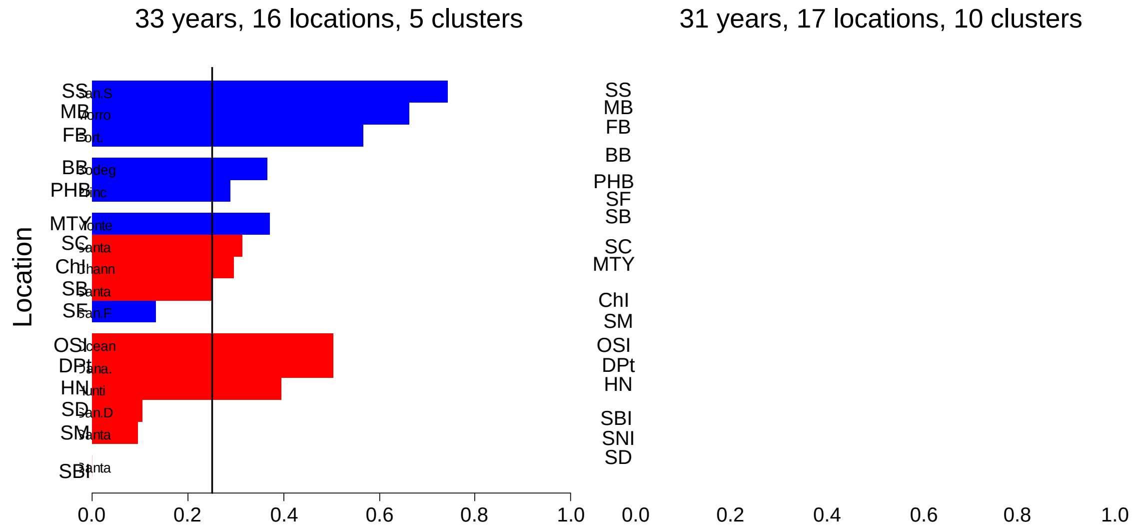

Figure 6. Resultant silhouette plots for the cluster analyses of cabezon fishing locations in California. Number of years, locations and cluster are noted above each plot. Blue bars indicate the areas designated as the northern California sub-stock (NCS) while red bars indicate the southern California sub-stock (SCS).

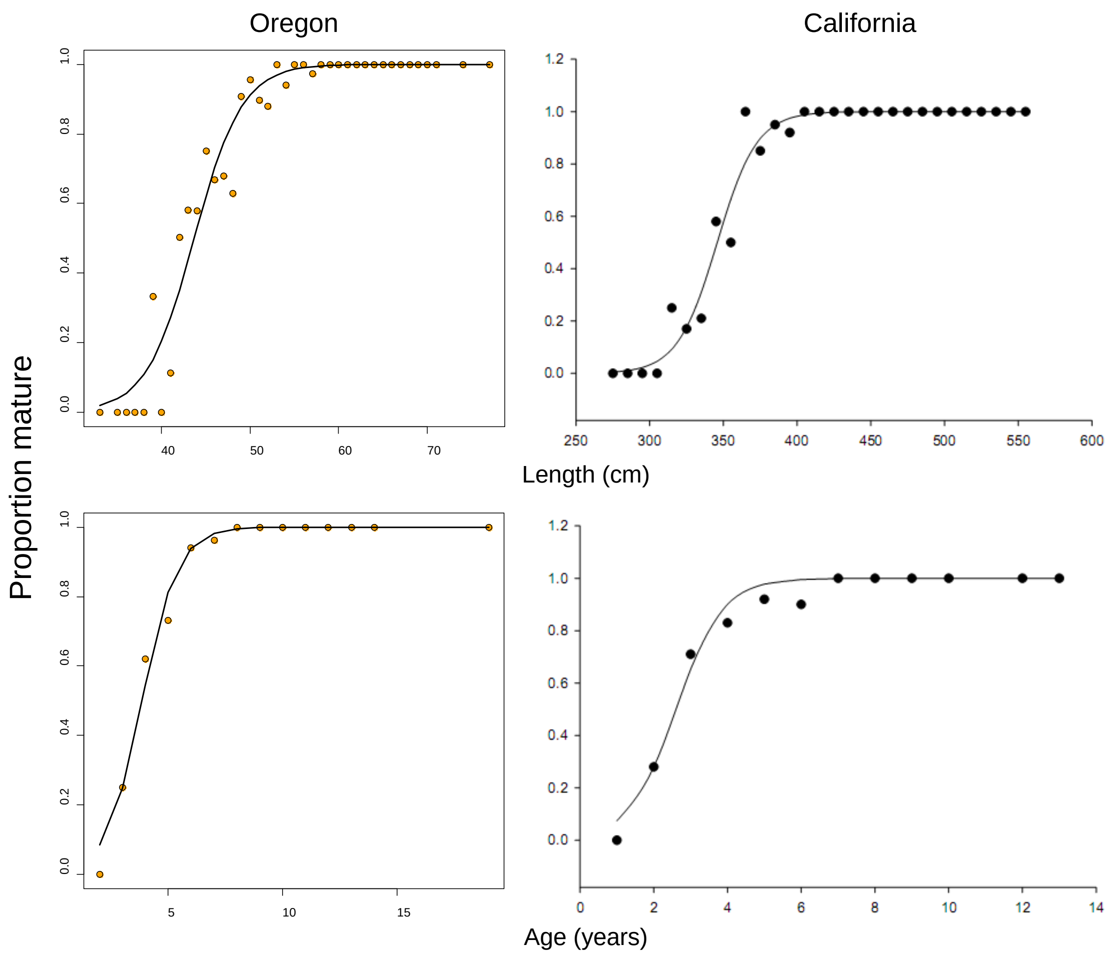

Figure 7. Length (top rows) and age (bottom rows) at maturity curves for Oregon (left panels) and California (right panels).

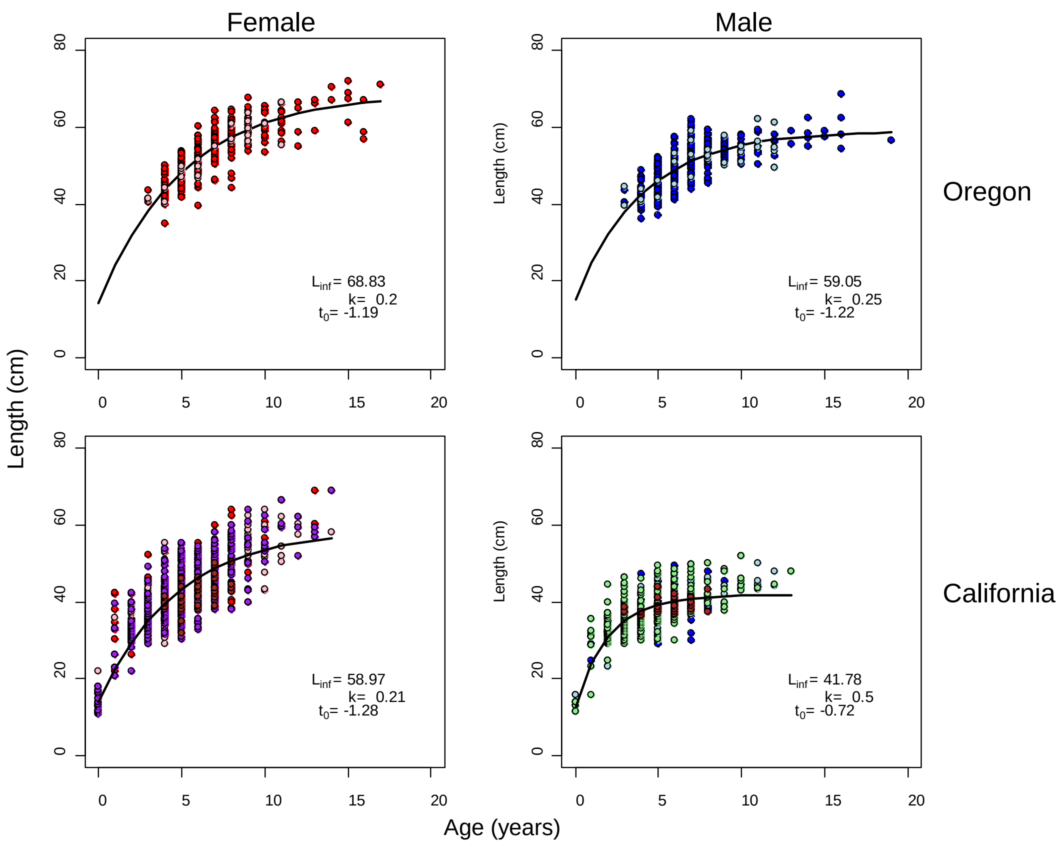

Figure 8. Age and growth fits and parameter estimates for the von Bertalanffy growth function incorporating multiple age reads (differing colored circles) for each sex (columns) and state (rows).

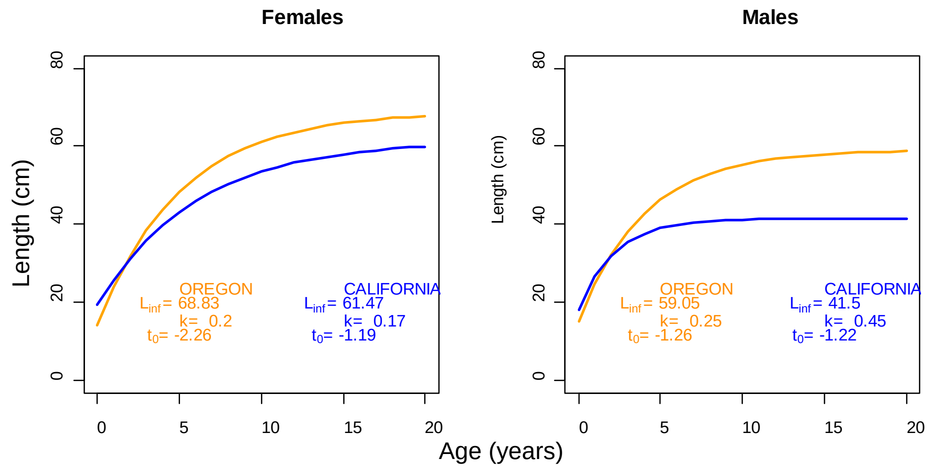

Figure 9. Comparison of estimated age at length of each sex by state. Growth fits in these comparisons are based on fits to the von Bertalanffy growth curve using primary age reads and does not incorporate the ageing error into estimation of the growth curve.

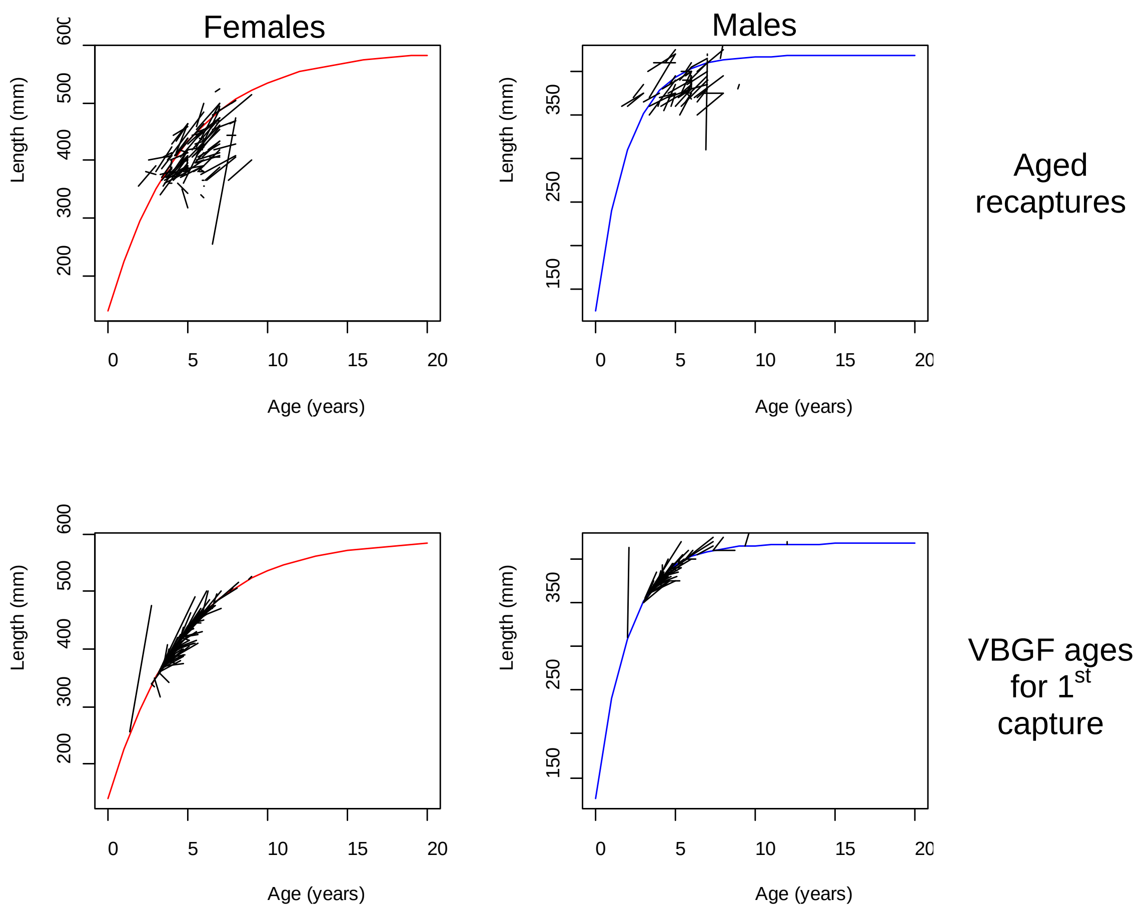

Figure 10. Stick plots of tagging data (black lines) compared to sex-specific (columns) growth curves in California. The tagging were compared to the growth curve in two ways: 1) The capture data was back-calculated from the age recapture (top row); 2) The capture age was estimated from the von Bertalanffy growth function (VBGF) and the recapture age was calculated by adding days at large to the capture age (bottom row).

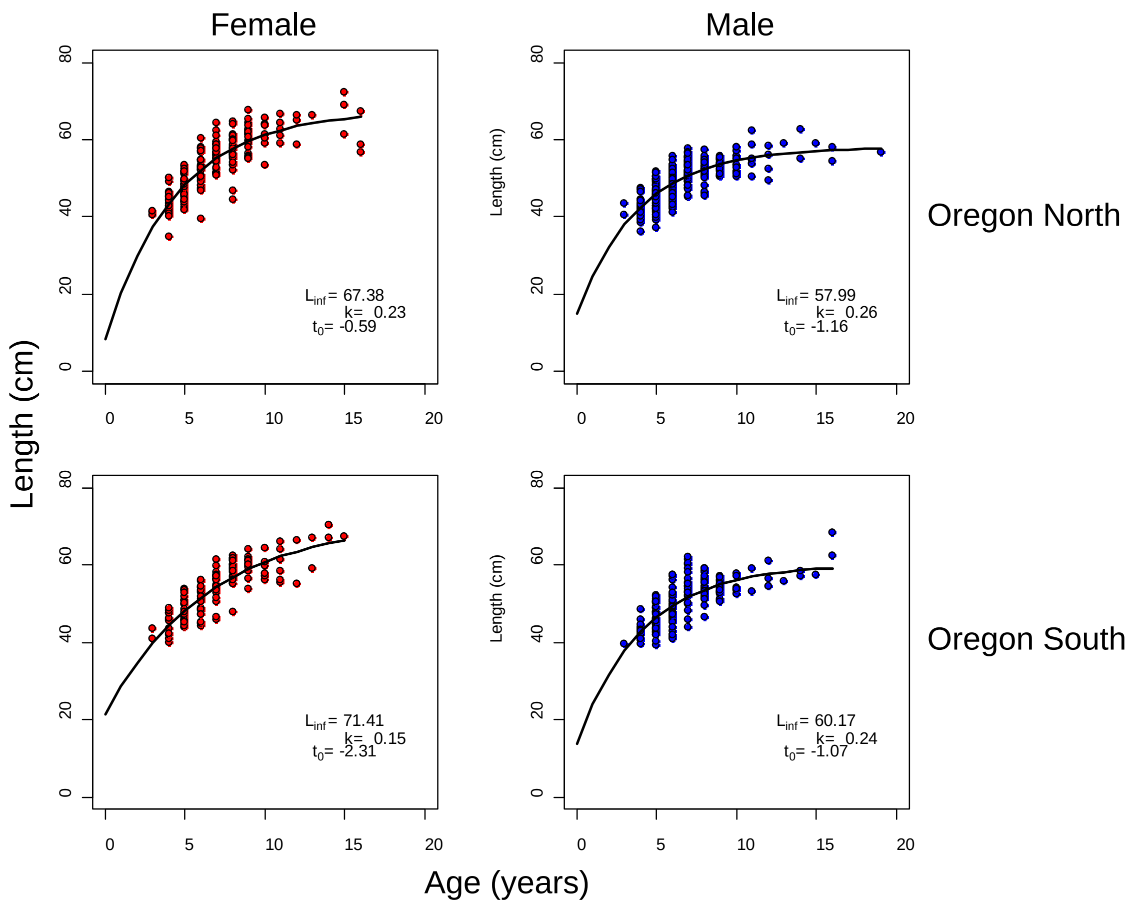

Figure 11. Plots and fits to the von Bertalanffy growth function of Oregon data above (North) and below (South) Cape Blanco.

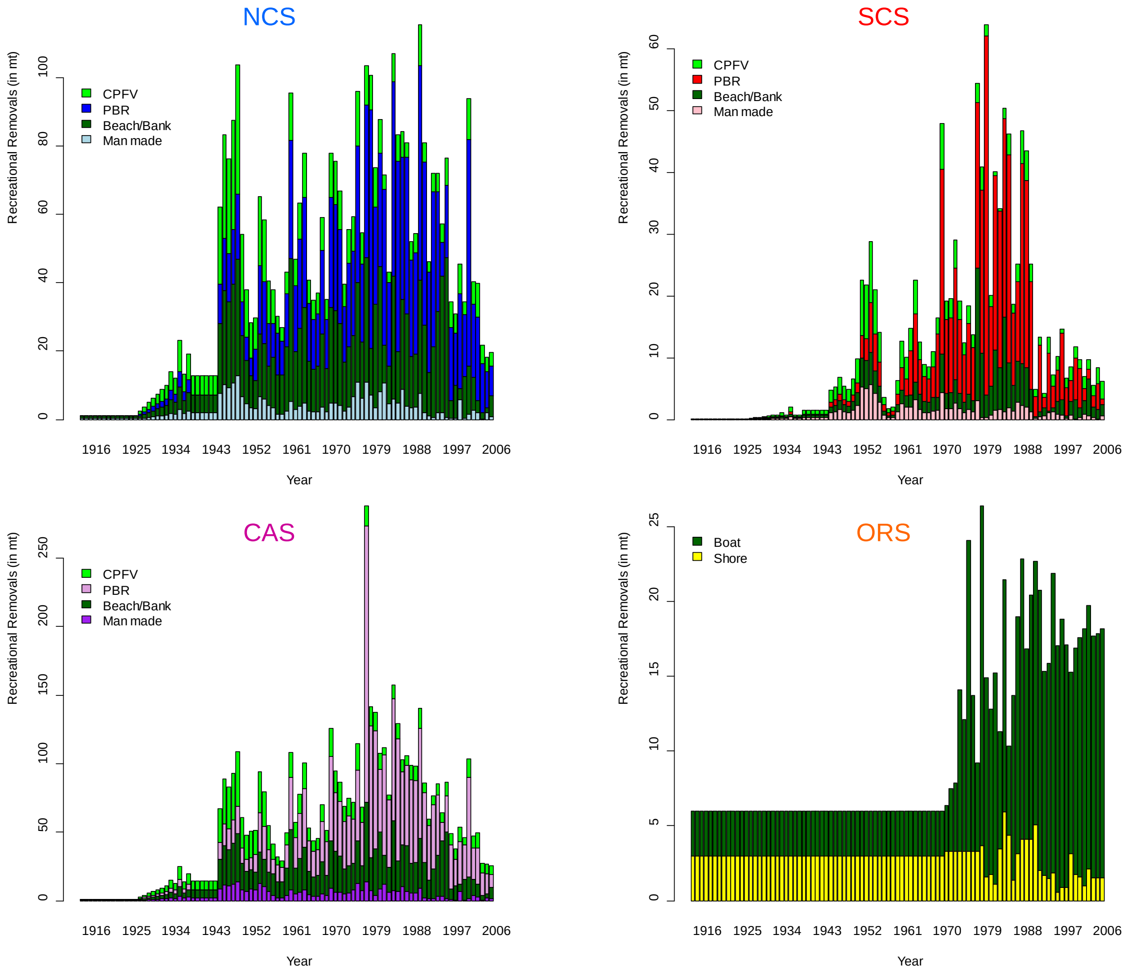

Figure 12. Recreational fishery cabezon removals (in mt) by fleet and sub-stock.

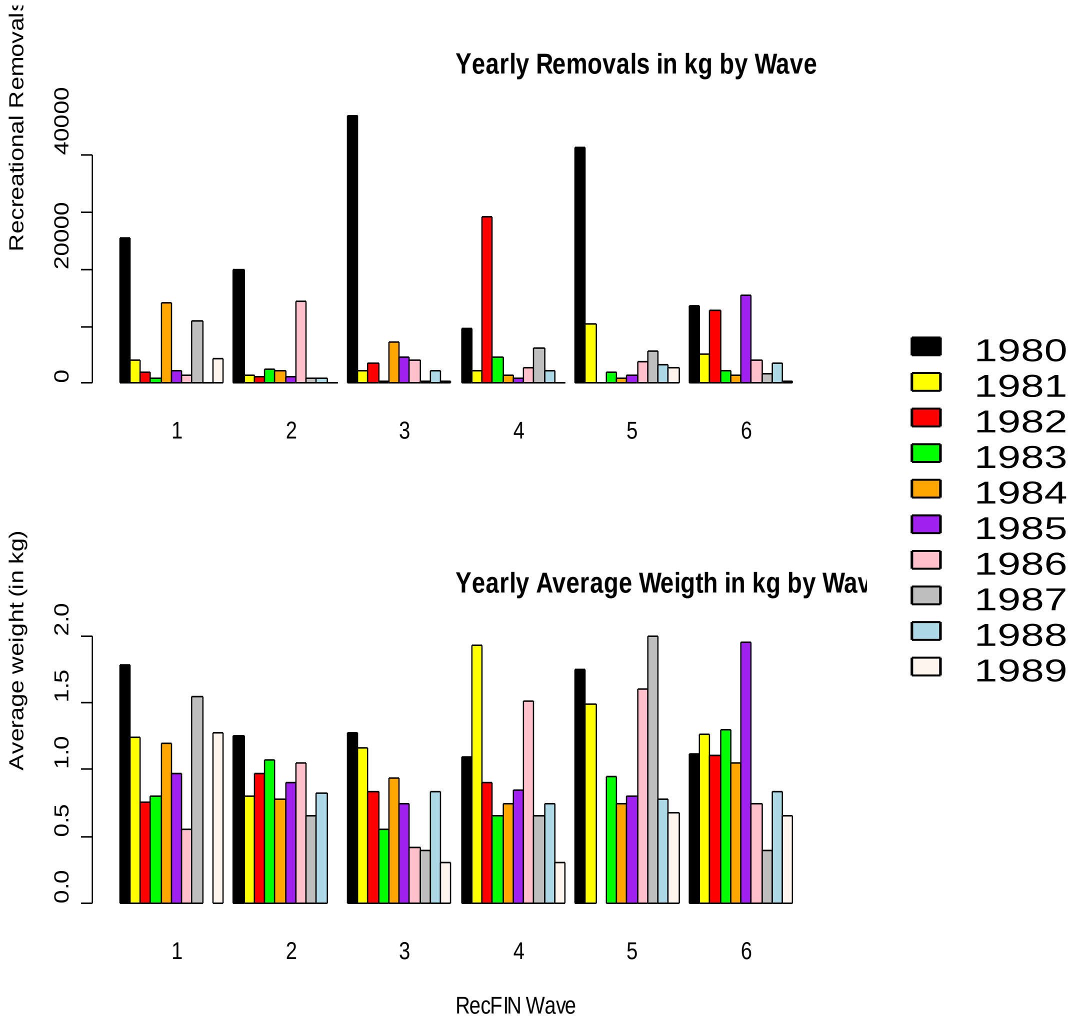

Figure 13. Yearly removals (top panel) and average weight (bottom panel) of cabezon by two-month sampling 'wave' taken in the PBR recreational mode for the SCS in years 1980-1989.

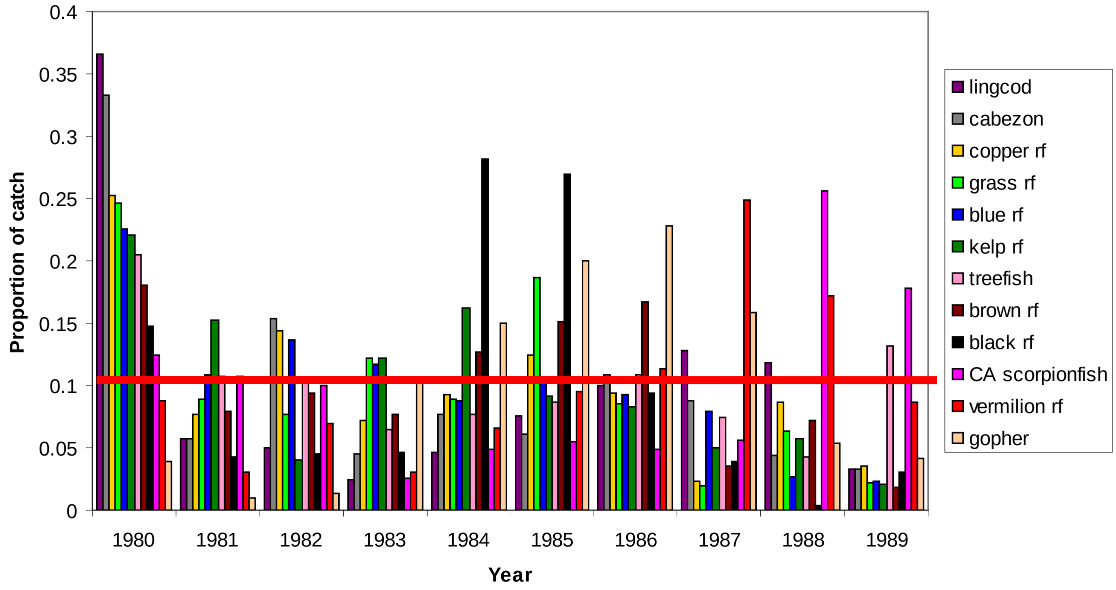

Figure 14. Proportion of yearly catch for several nearshore species associated with cabezon (gray bars) for years 1980-1989. Proportions are species-specific and defined as the proportion of the yearly species catch to the total species catch from 1980-1989. The red horizontal line is the expected value if all years were equivalent in proportionality.

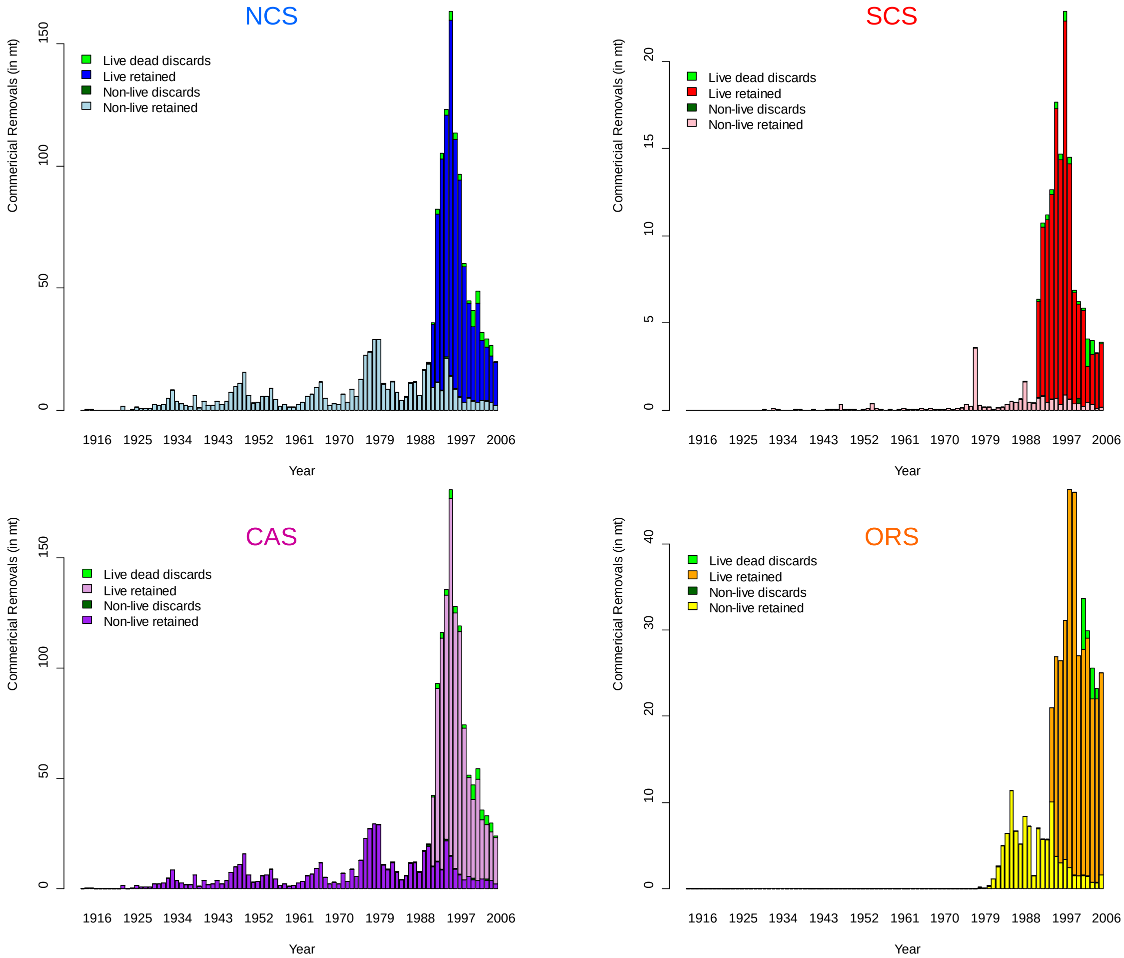

Figure 15. Commercial fishery cabezon removals (in mt) by fleet and sub-stock.

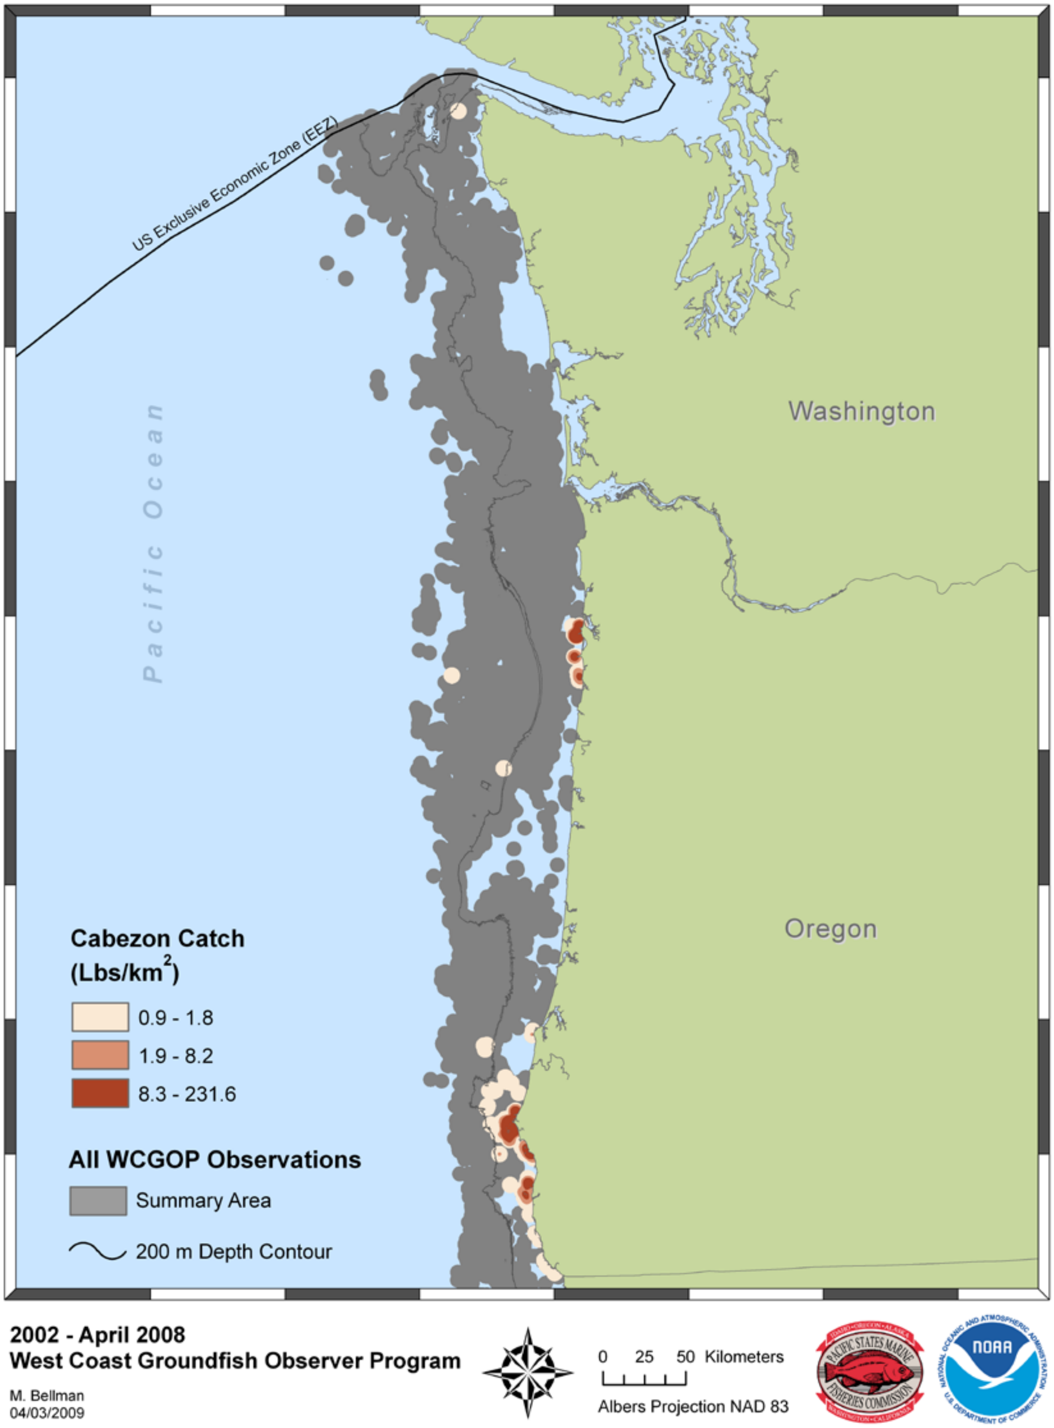

Figure 16. Spatial distribution of cabezon catch (lbs/km^2) observed by the West Coast Groundfish Observer Program from 2002 – April 2008 and the summary area of all observed fishing events off of Washington and Oregon. Map courtesy of M. Bellman.

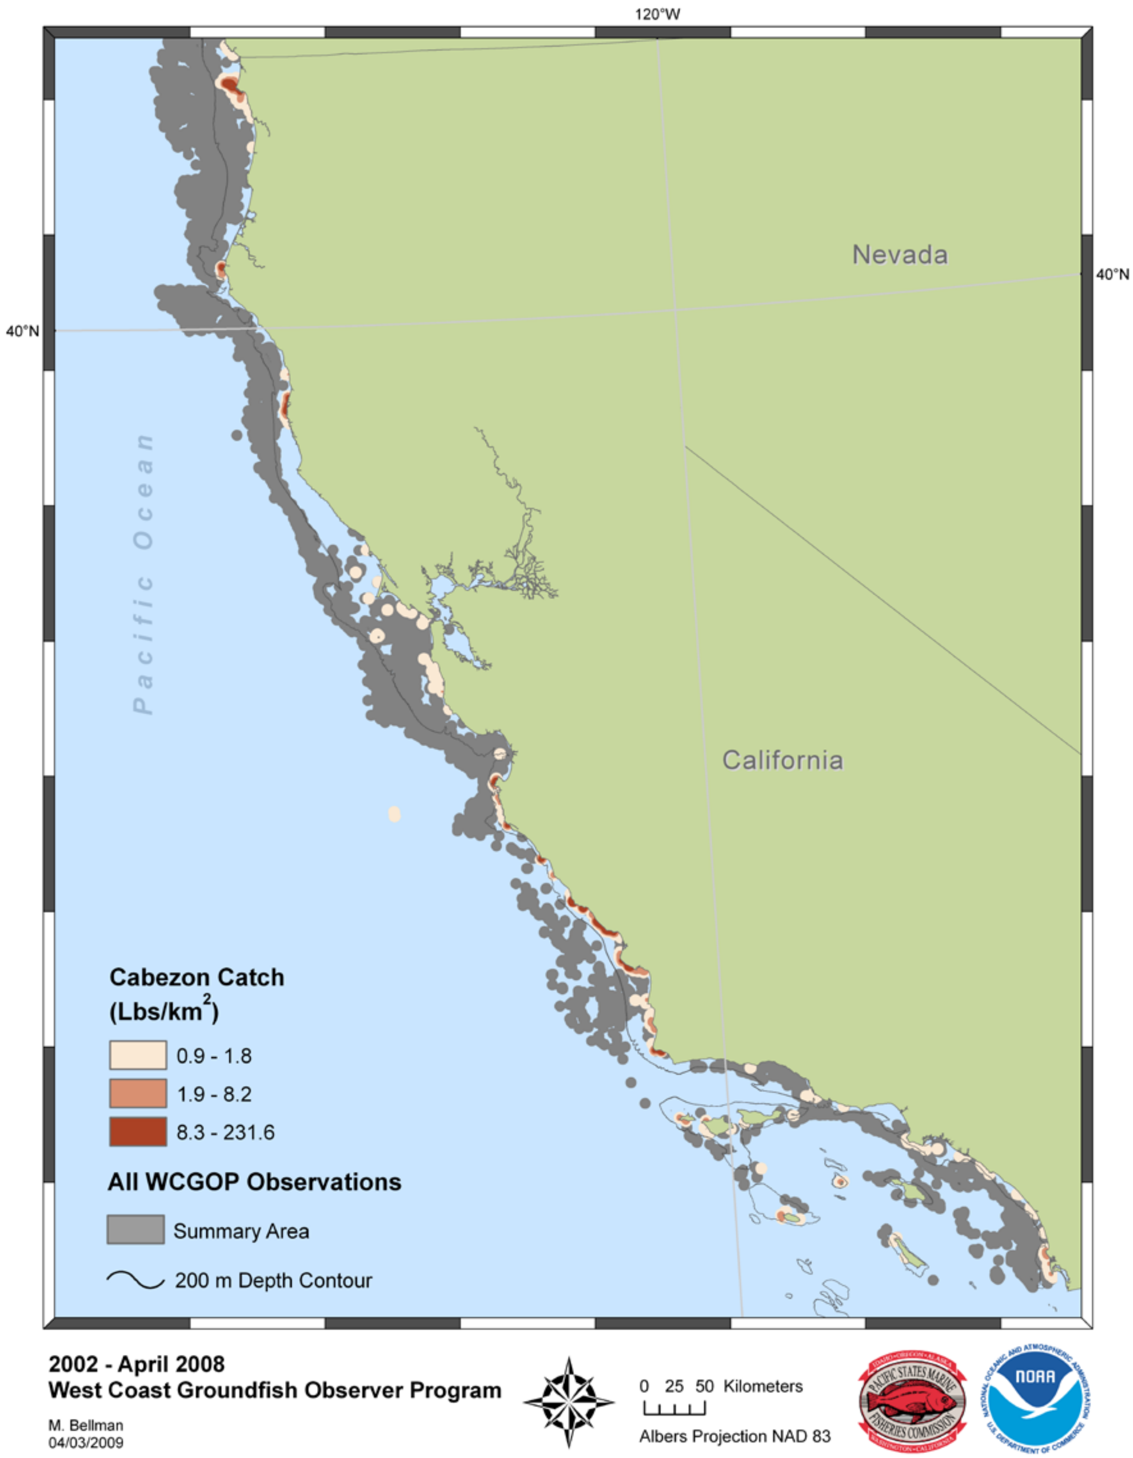

Figure 17. Spatial distribution of cabezon catch (lbs/km^2) observed by the West Coast Groundfish Observer Program from 2002 – April 2008 and the summary area of all observed fishing events off of California. Map courtesy of M. Bellman.

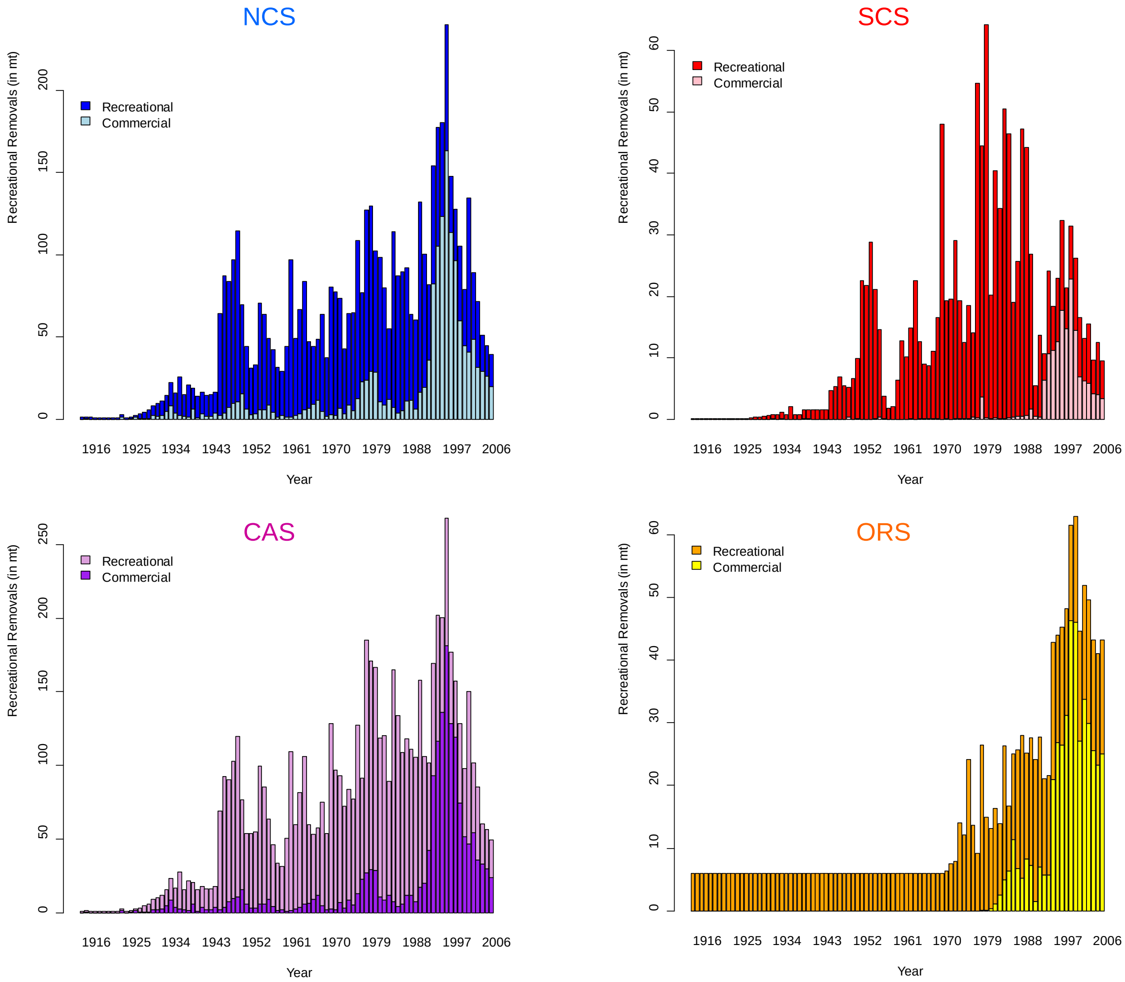

Figure 18. Total removals of cabezon (in mt) by major fishery and sub-stock.

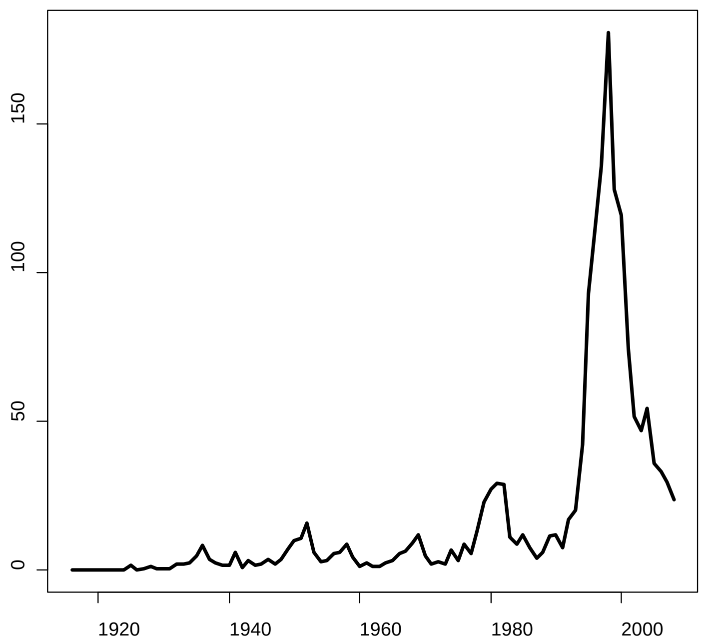

Figure 19. Comparison of total fishery removals between the 2009 and 2005 assessments for the commercial (top panel) and recreational (bottom panel) fishery sectors.

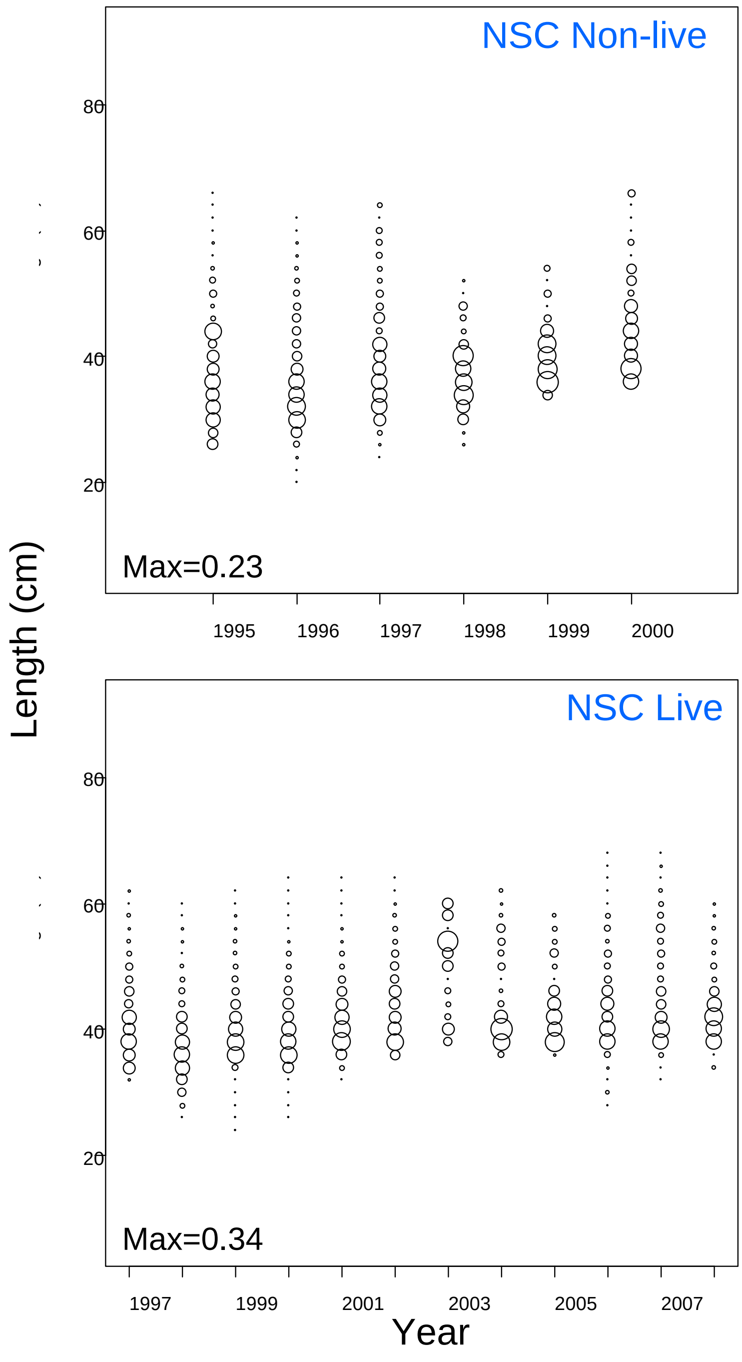

Figure 20. Length composition bubble plots for the NCS commercial fisheries. Values in the lower left of each panel refer to the proportion size of the biggest bubble.

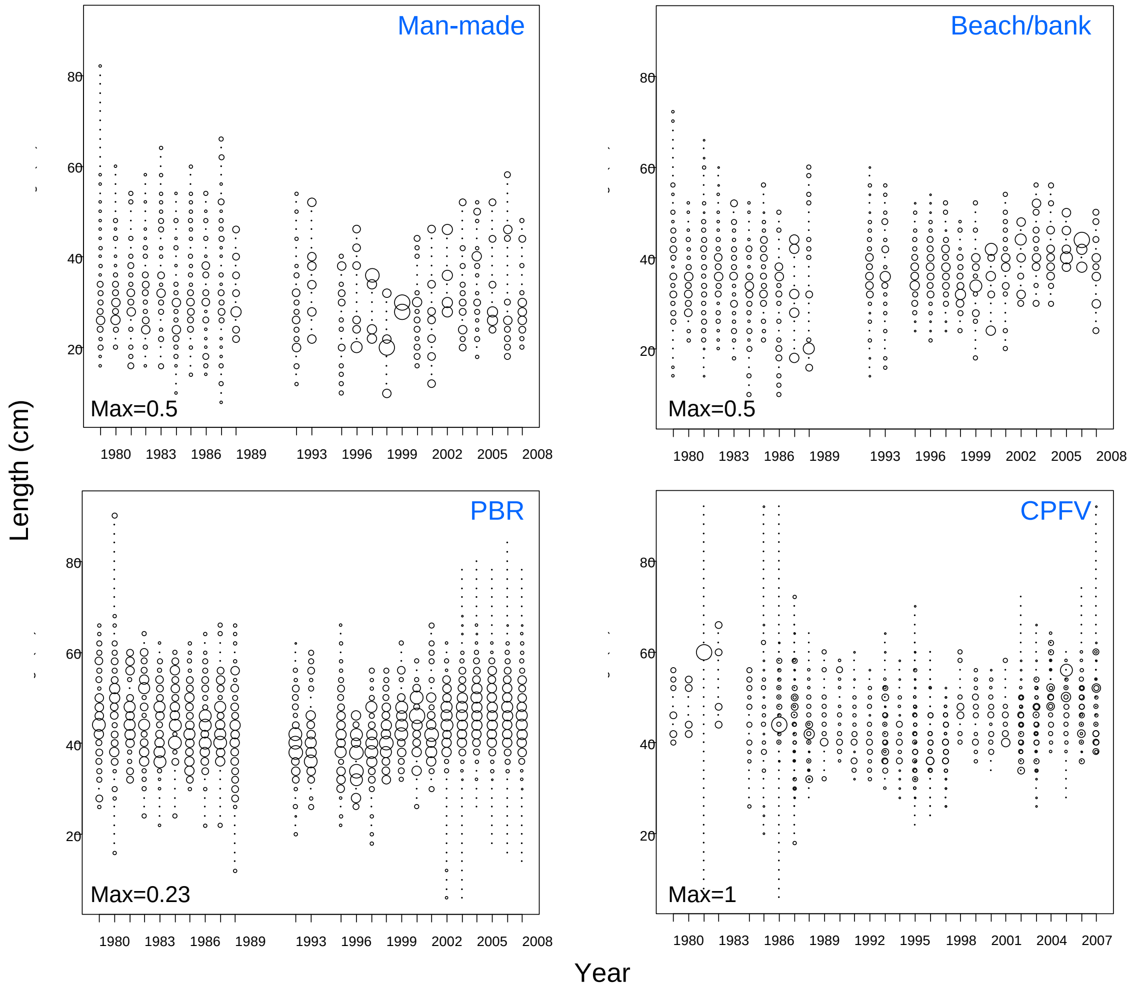

Figure 21. Length composition bubble plots for the NCS recreational fishery modes. Values in the lower left of each panel refer to the proportion size of the biggest bubble.

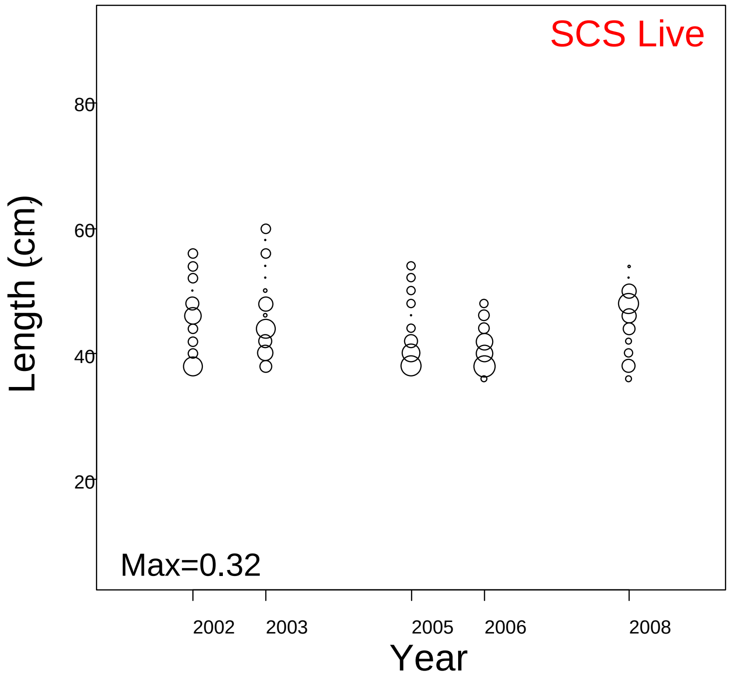

Figure 22. Length composition bubble plots for the SCS live-fish commercial fishery. Values in the lower left of each panel refer to the proportion size of the biggest bubble.

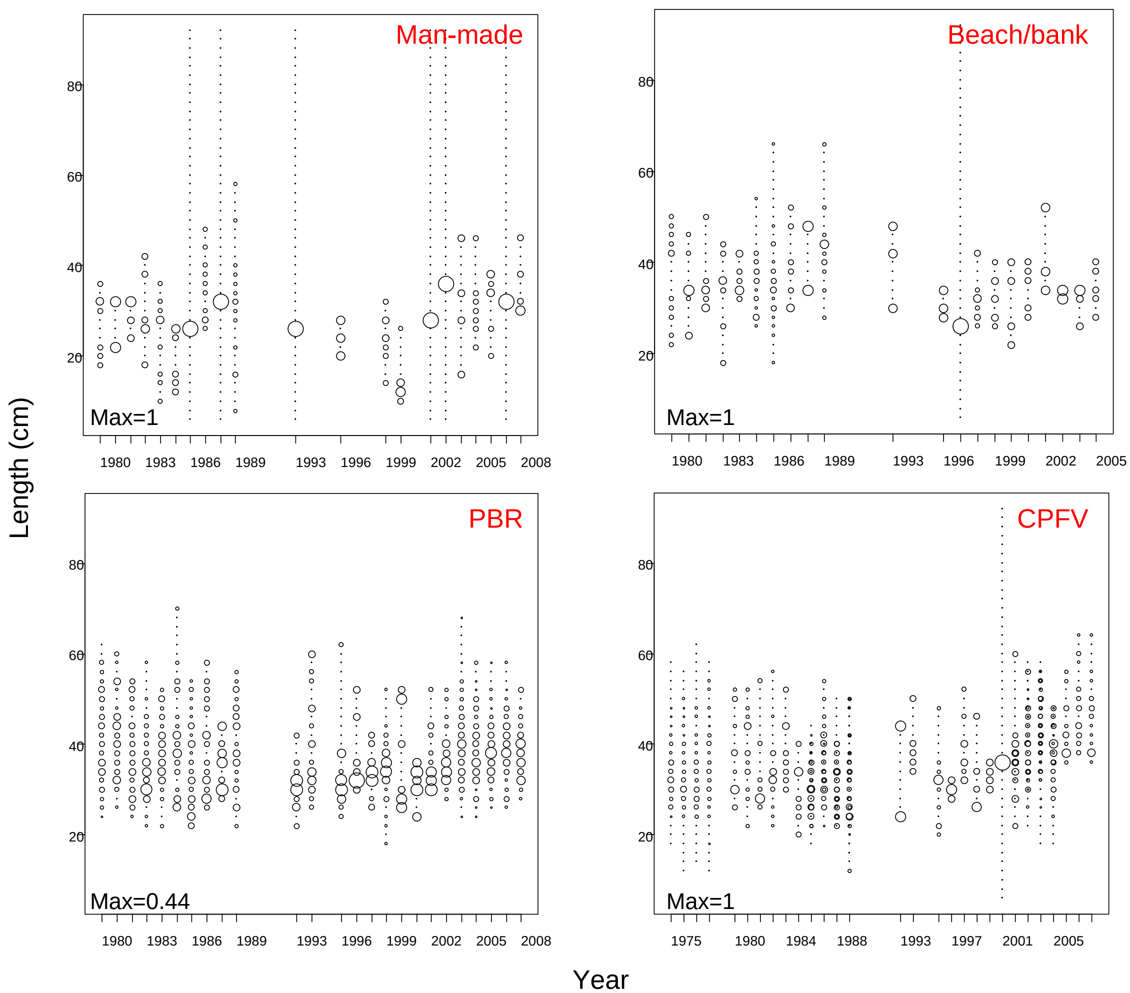

Figure 23. Length composition bubble plots for the SCS recreational fishery modes. Values in the lower left of each panel refer to the proportion size of the biggest bubble.

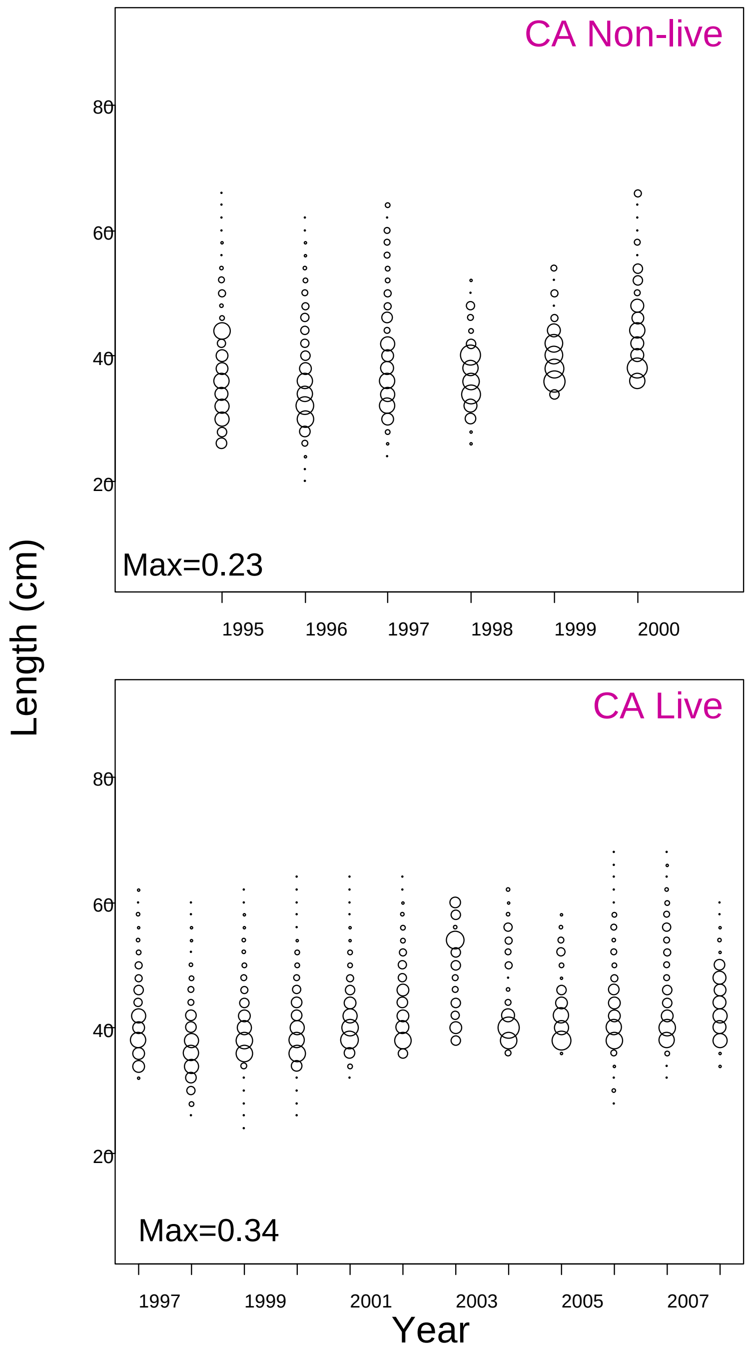

Figure 24. Length composition bubble plots for the CAS commercial fisheries. Values in the lower left of each panel refer to the proportion size of the biggest bubble.

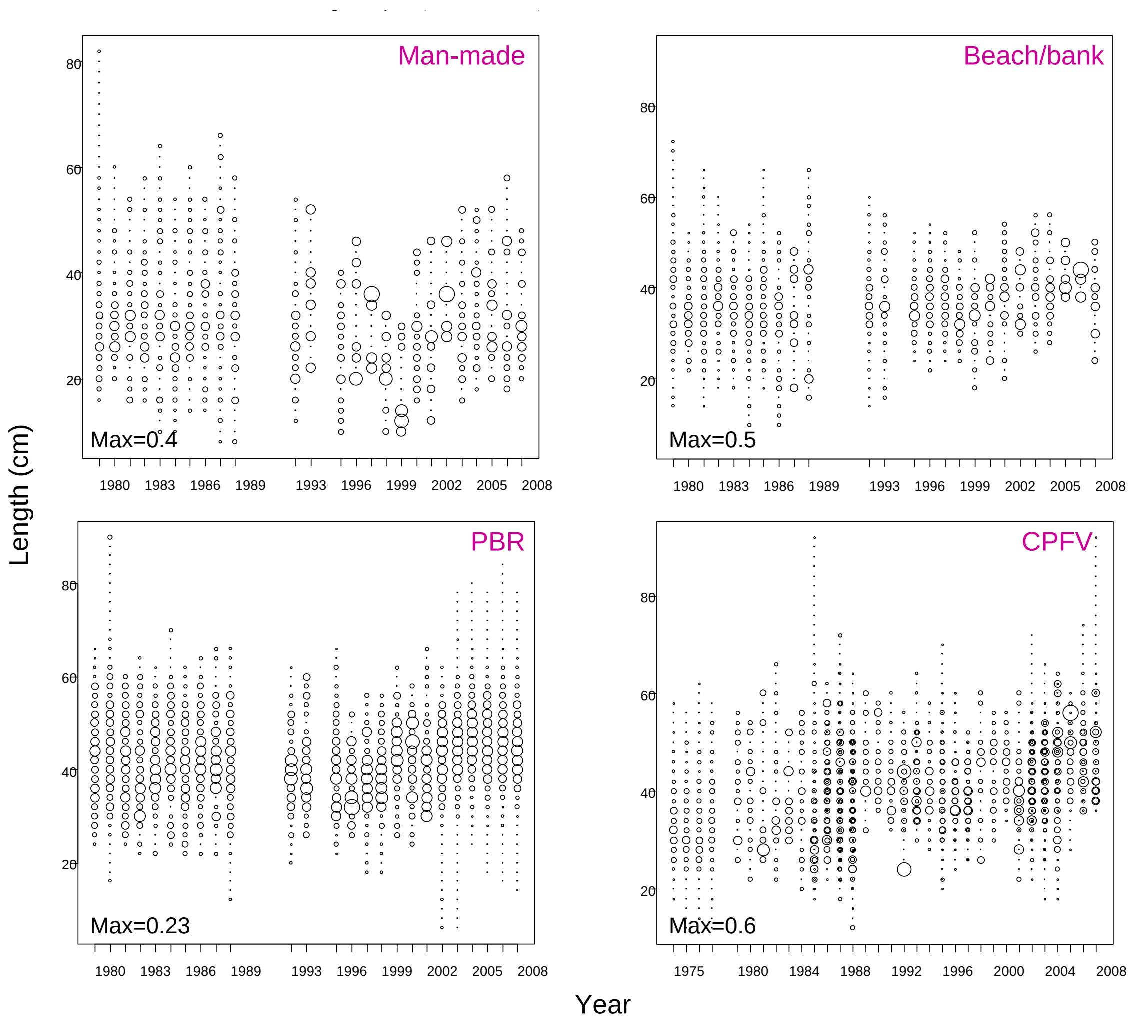

Figure 25. Length composition bubble plots for the CAS recreational fishery modes. Values in the lower left of each panel refer to the proportion size of the biggest bubble.

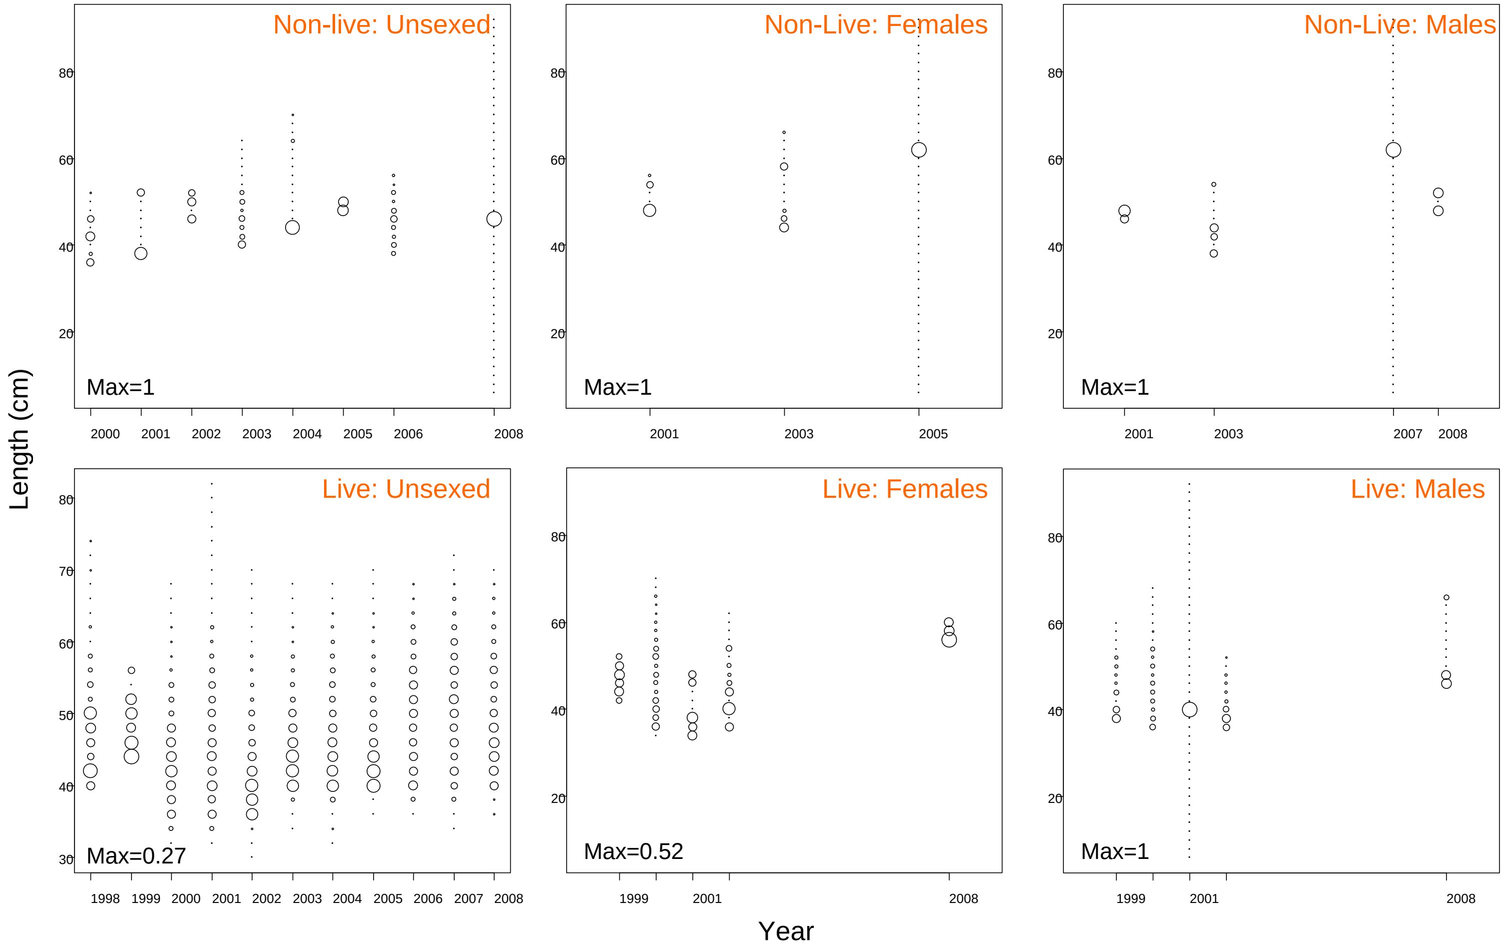

Figure 26. Length composition bubble plots for the ORS commercial fisheries. Values in the lower left of each panel refer to the proportion size of the biggest bubble.

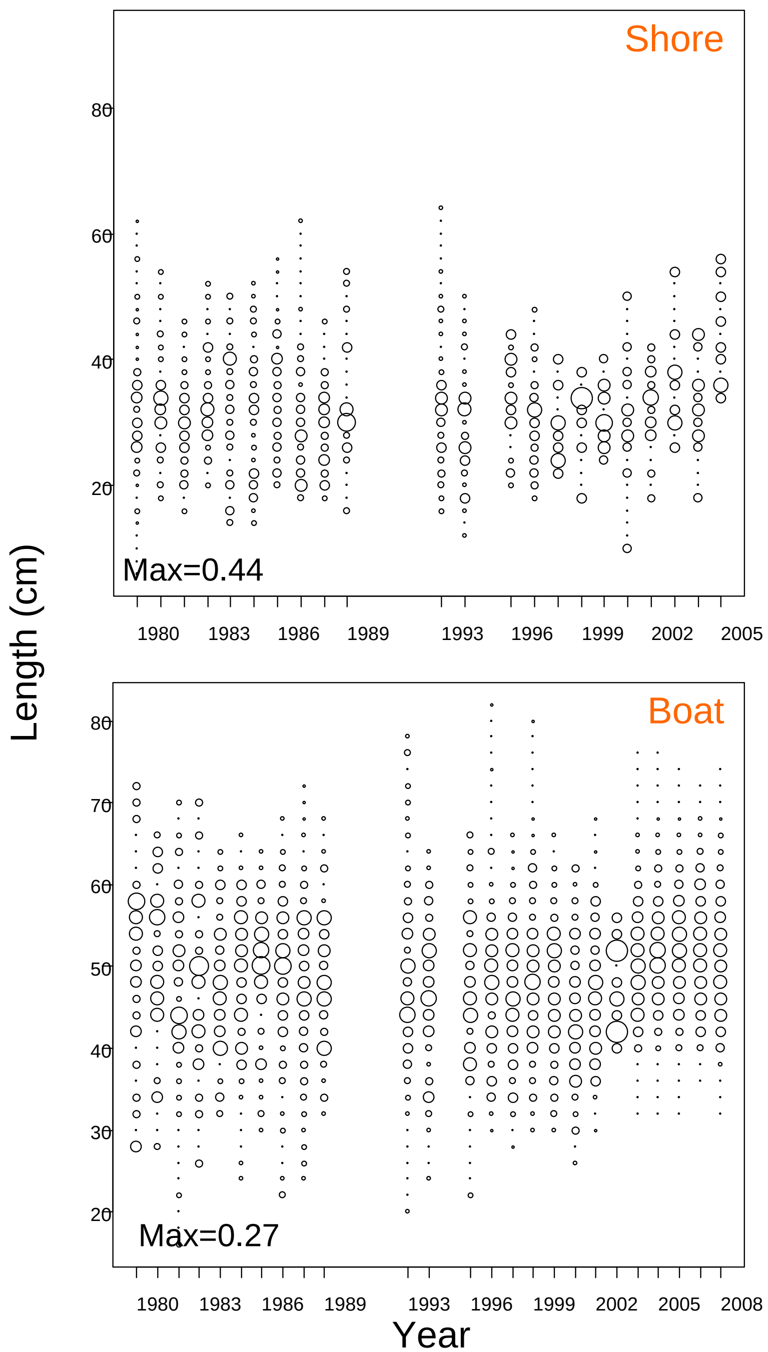

Figure 27. Length composition bubble plots for the ORS recreational fishery modes. Values in the lower left of each panel refer to the proportion size of the biggest bubble.

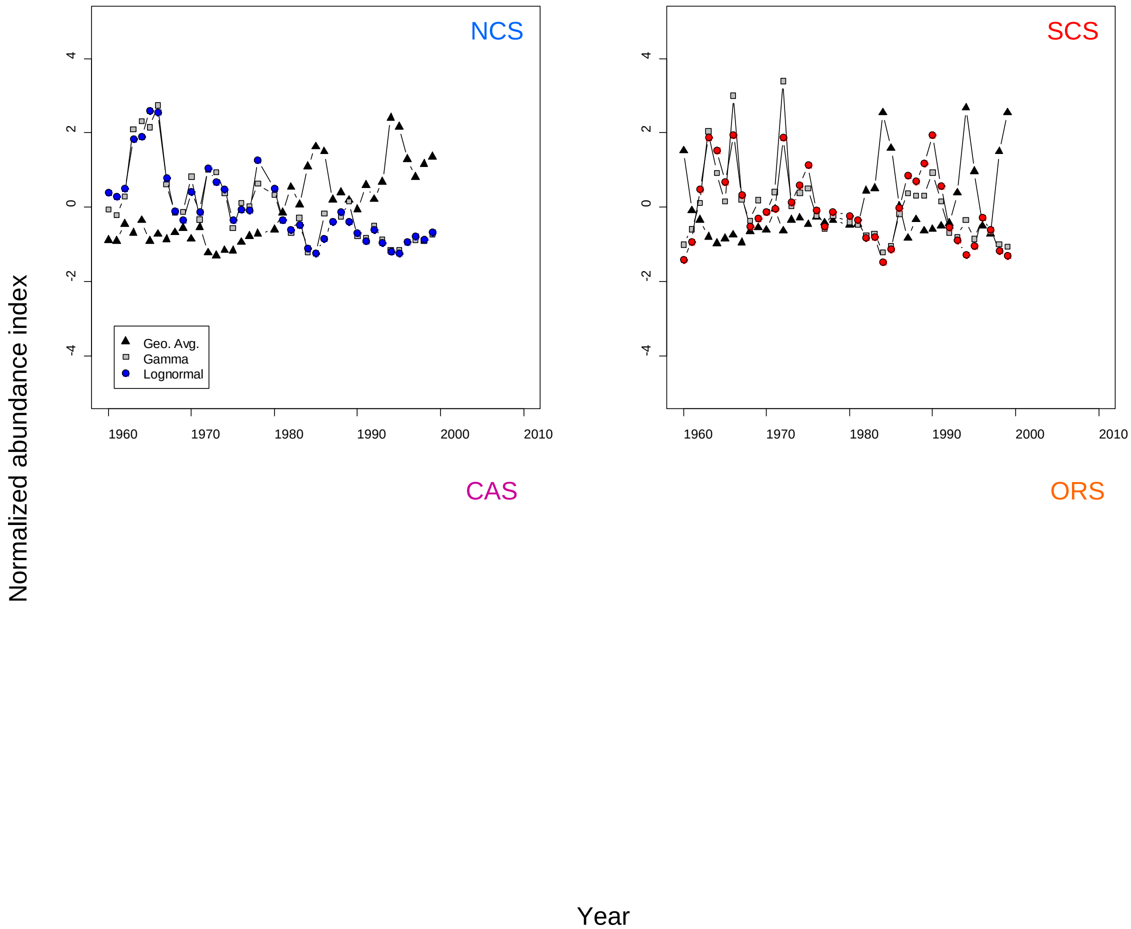

Figure 28. Geometric mean and delta GLM-based CPUE abundance indices for each sub-stock. Plotted values are the normalized (Z-score) index values. Vertical broken line shows the break in time series for the SCS CPFV indices.

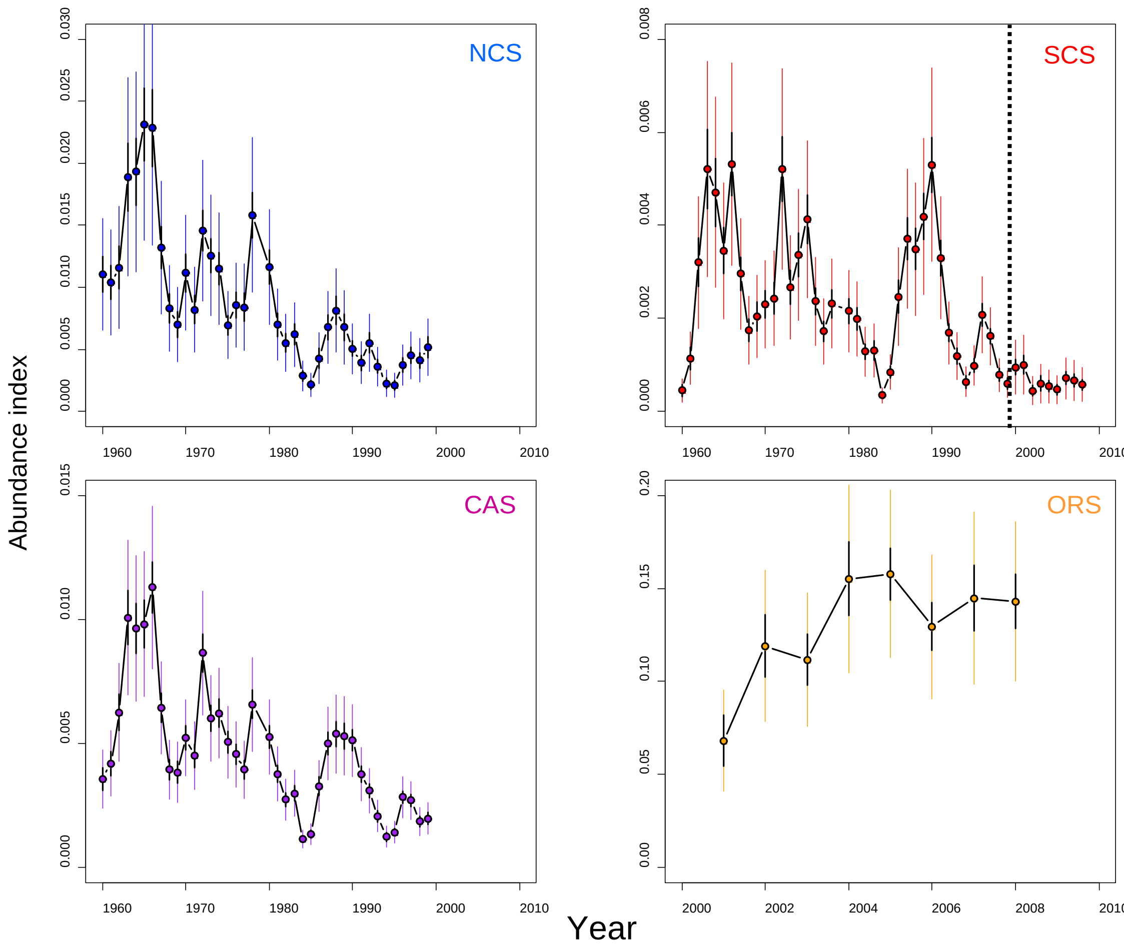

Figure 29. Time series of abundance series for the California CPFV indices and ORBS survey with 95% confidence intervals. Black line confidence intervals are based on the original estimates of CVs from the delta-GLM models; colored lines are based on the inflated CVs. Vertical broken line in the SCS panel distinguishes the two CPFV time series.

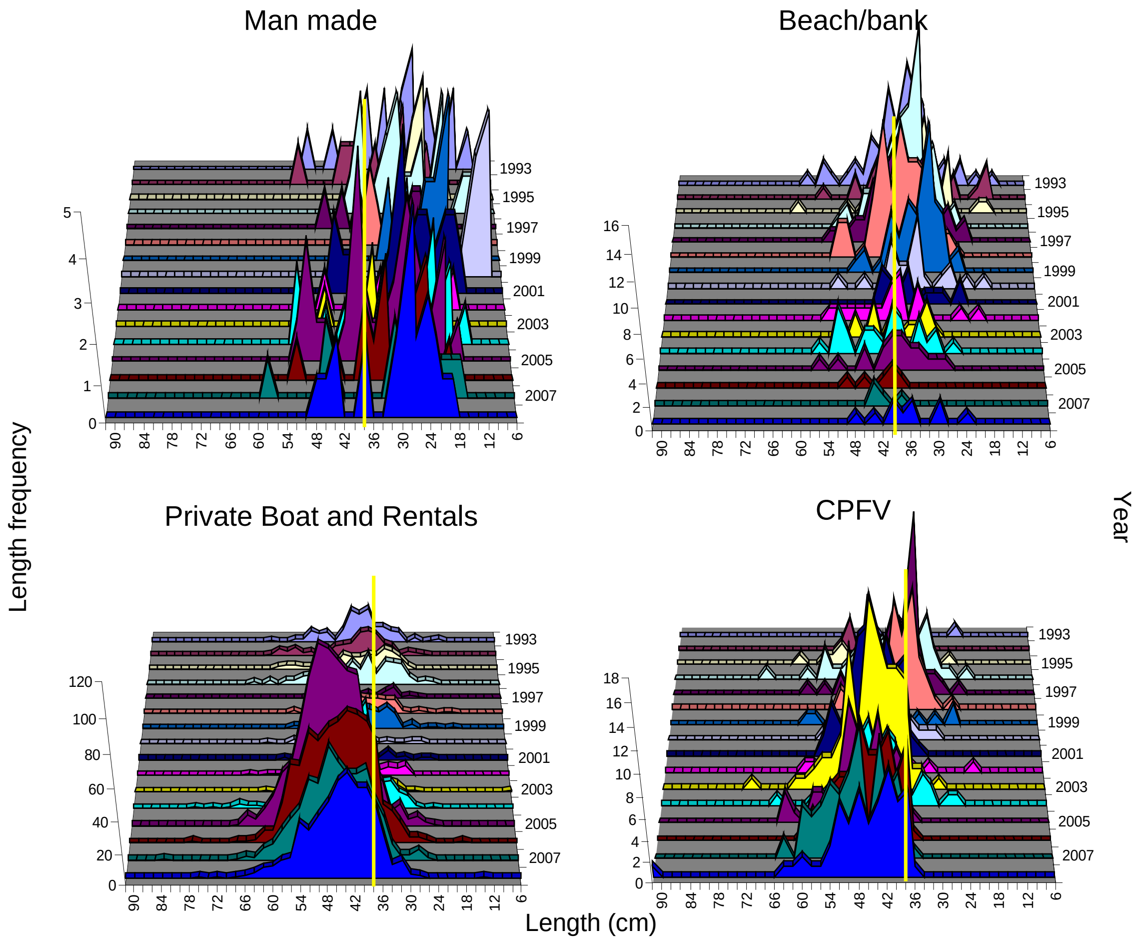

Figure 30. Length compositions for the four recreational modes in California. Yellow vertical line indicates the size limit (38 inches) implemented in 2000.

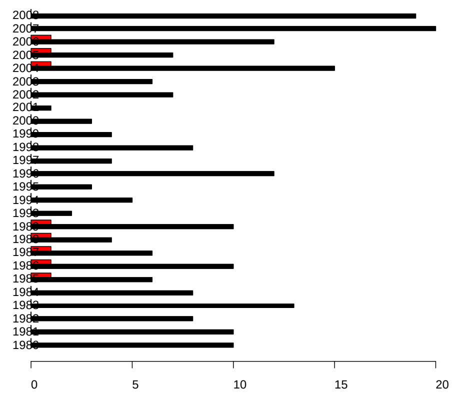

Figure 31. Frequency of cabezon in bags for the NCS and SCS sub-stocks from the PBR and CPFV recreational fishing modes. Horizontal blue and red lines indicate the transition to bag limits of 1.

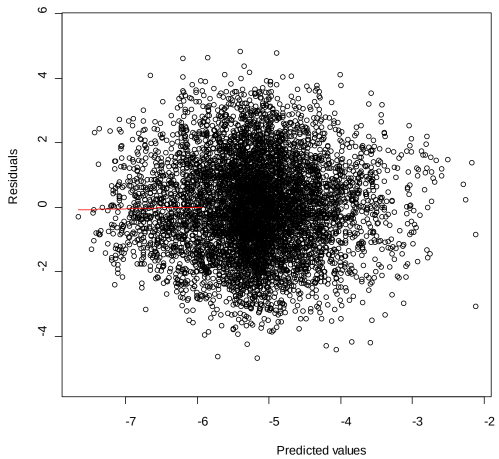

Figure 32. Diagnostic plots of the GLM-fit to the positive records for the CAS CPFV index.

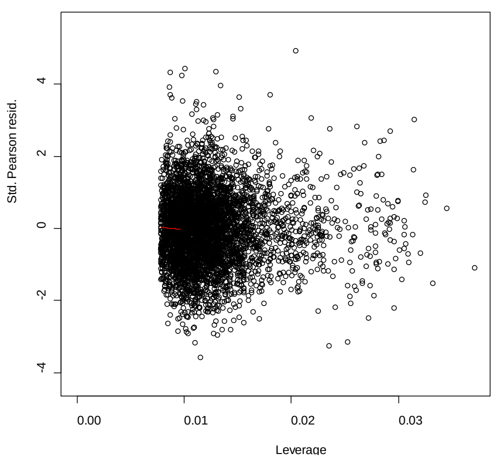

Figure 33. Diagnostic plots of the GLM-fit to the positive records for the NCS CPFV index.

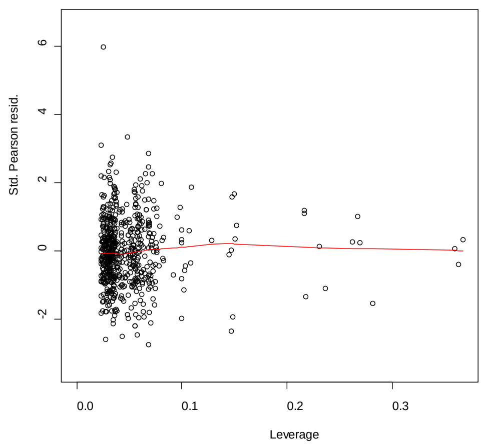

Figure 34. Diagnostic plots of the GLM-fit to the positive records for the SCS CPFV index (1960-2008).

Figure 35. Relationship between the natural log (ln) of catch versus year (top left panel), month (top right panel), and location (lower left panel) for the NCS CPFV index. The location of Santa Cruz (Sn.C) demonstrated significant location-year interactions.

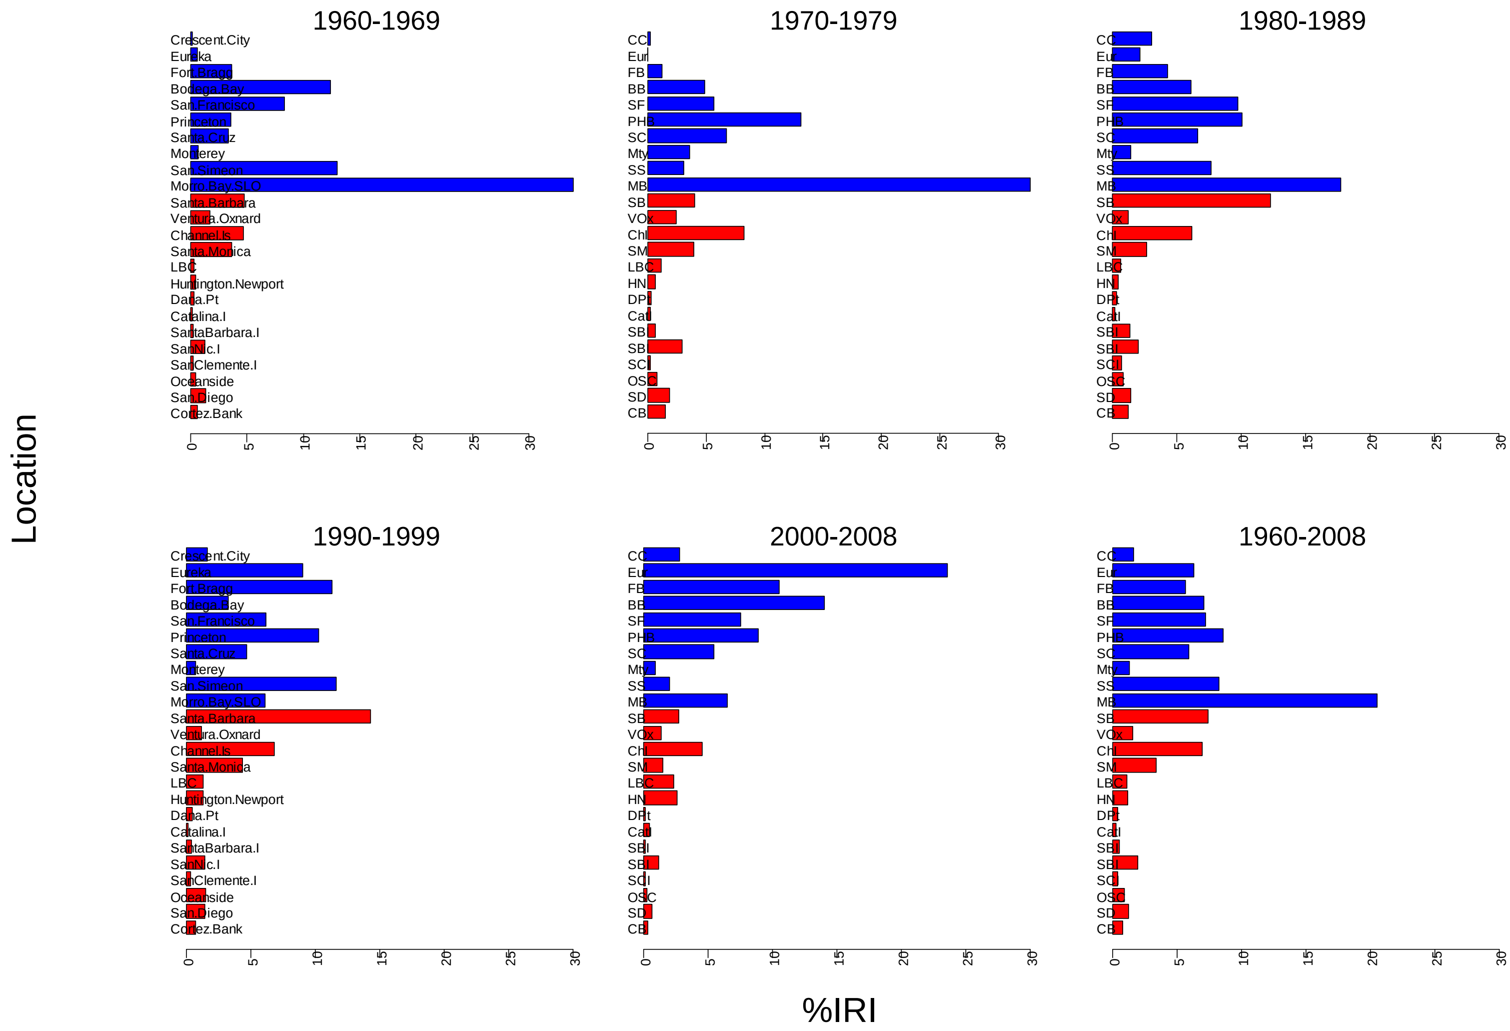

Figure 36. Percent Index of Relative Importance (%IRI) of cabezon catch in the CPFV fishery by fishing location through time.

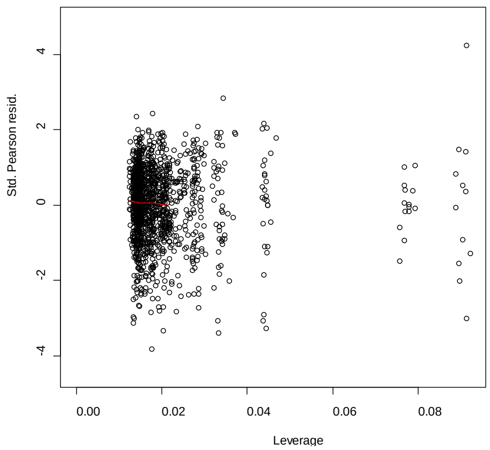

Figure 37. Diagnostic plots of the GLM-fit to the positive records for the ORS ORBS index.

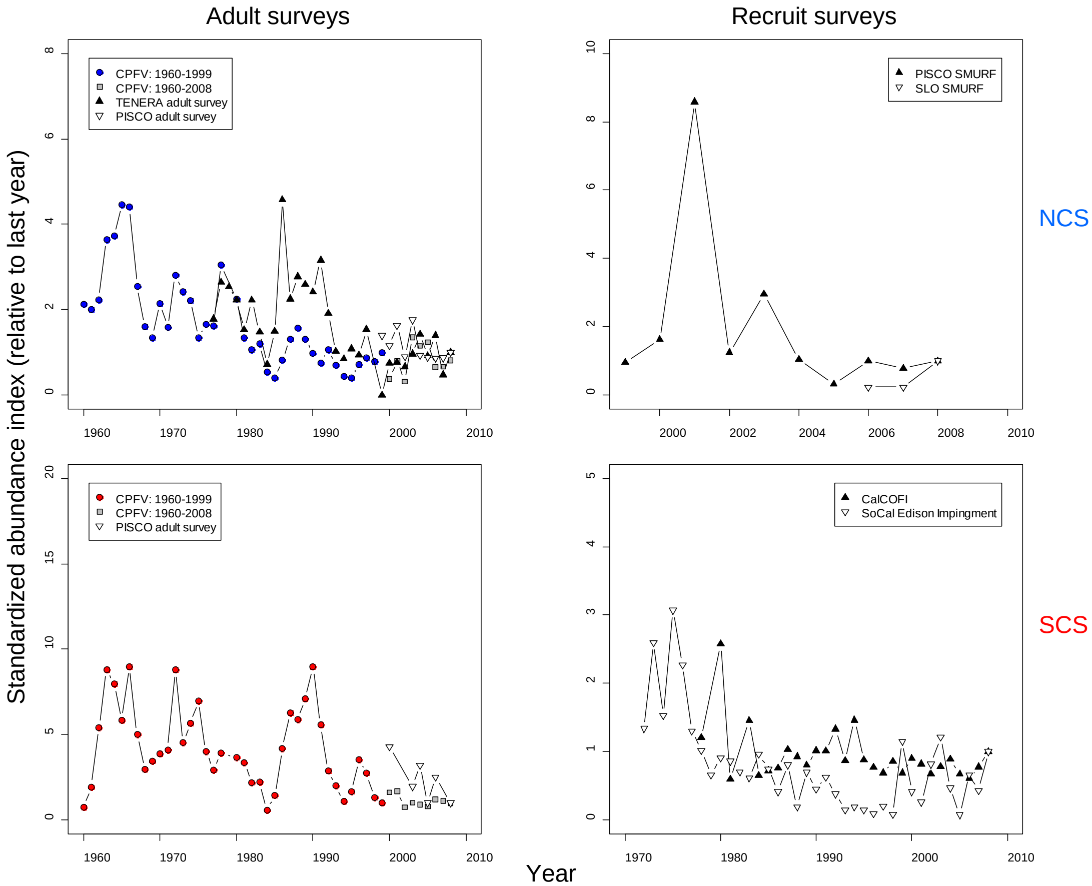

Figure 38. Indices of abundance (mean values) considered in either base case or sensitivity models for the NCS and SCS.

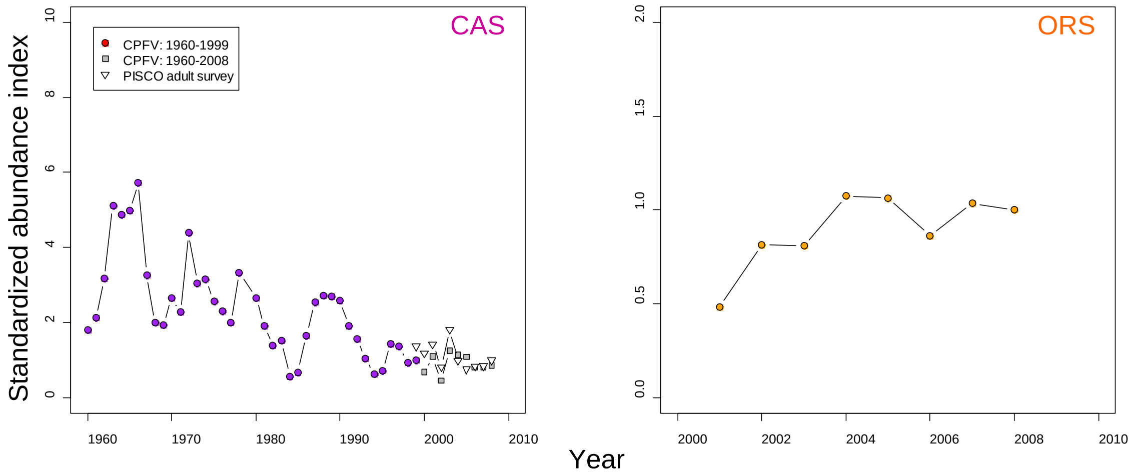

Figure 39. Indices of abundance (mean values) considered in either base case or sensitivity models for the CAS and ORS.

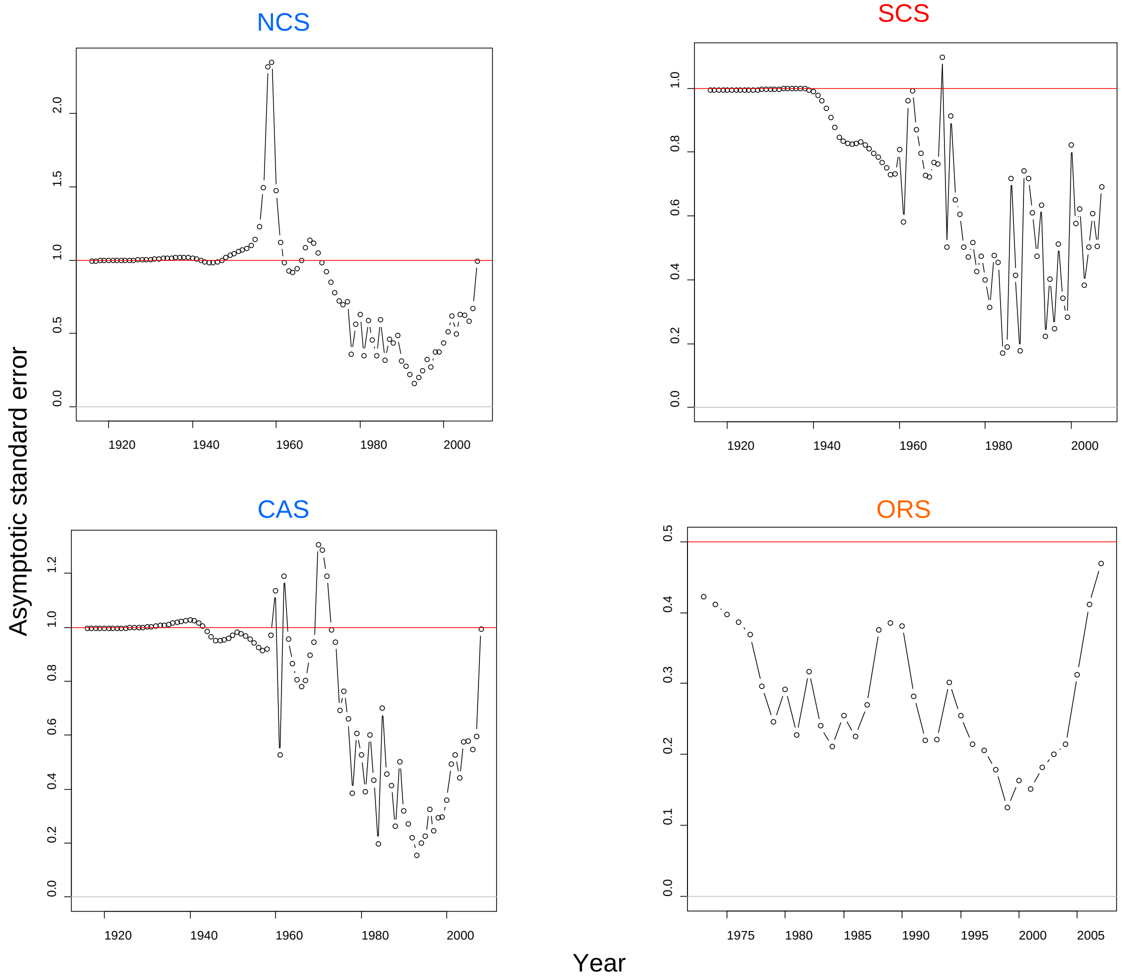

Figure 40. Asymptotic standard error of recruitment deviations when recruitment is estimated for the full time series in each sub-stock base case.

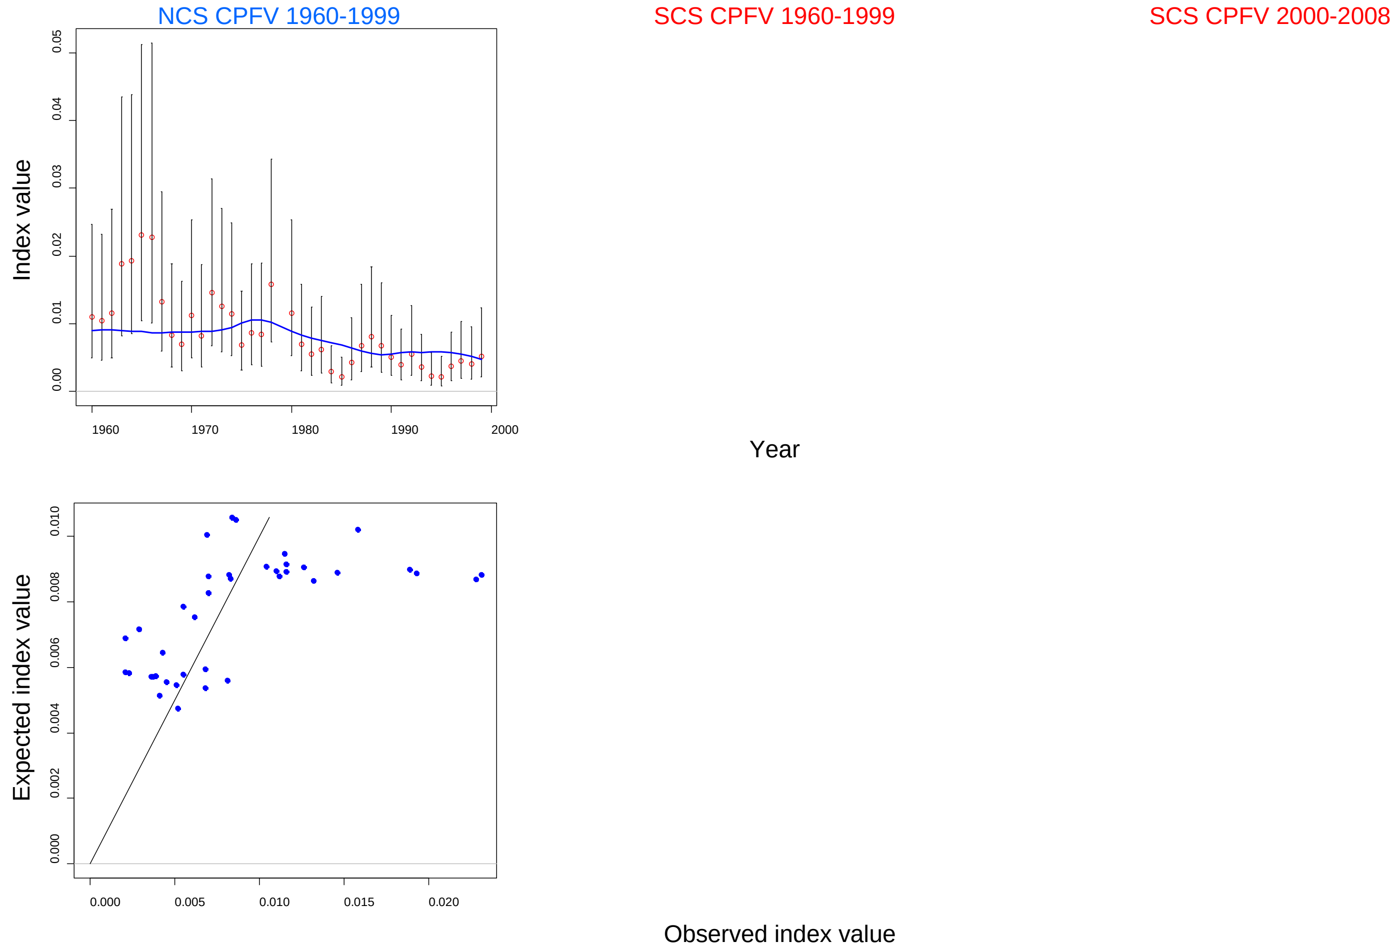

Figure 41. Fits to the CPFV relative abundance time series (top panels) and the 1:1 points to observed and expected index values (bottom panels) used in the NCS and SCS base cases.

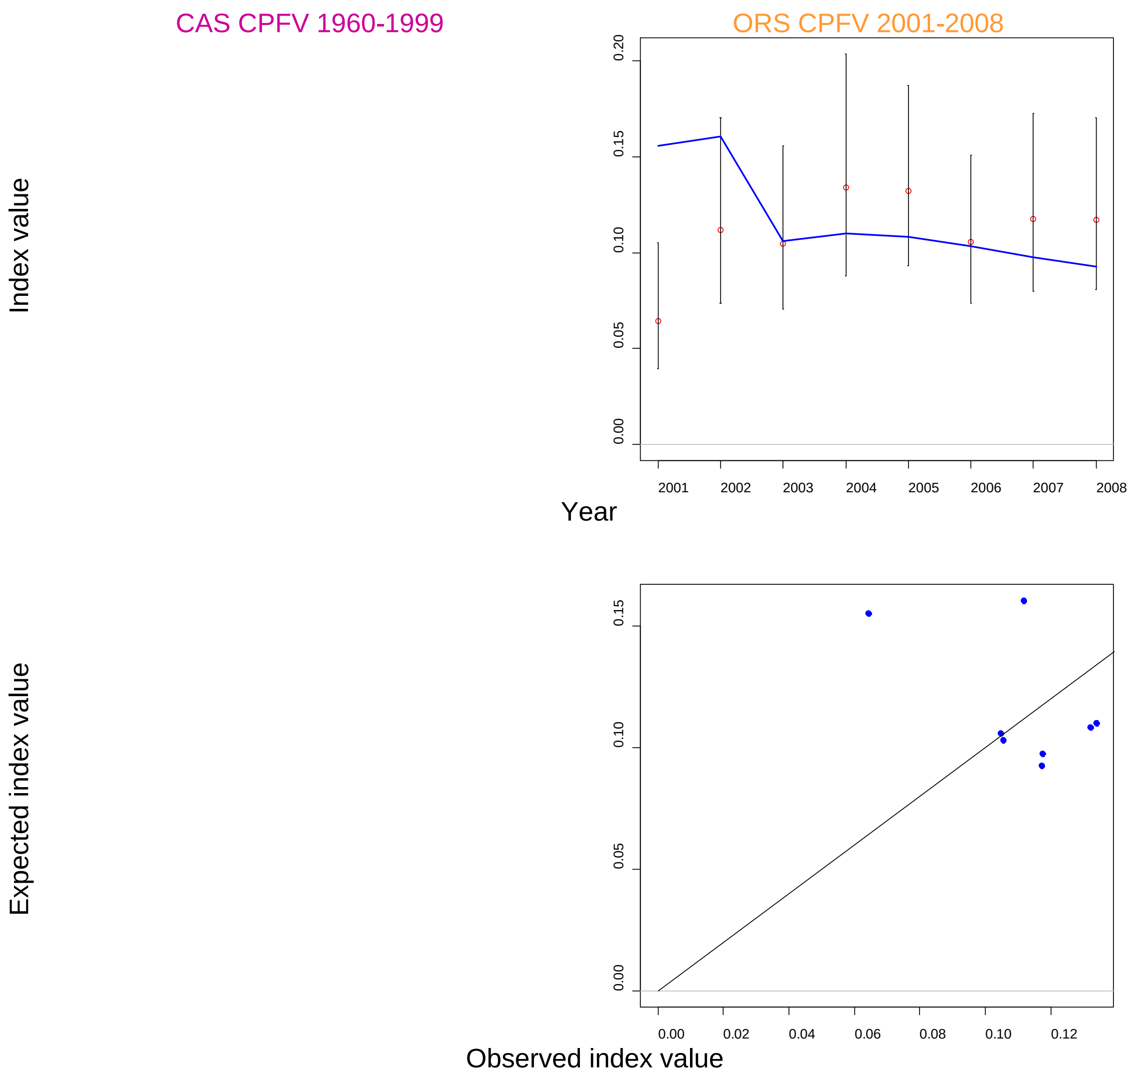

Figure 42. Fits to the CPFV relative abundance time series (top panels) and the 1:1 points to observed and expected index values (bottom panels) used in the CAS and ORS base cases.

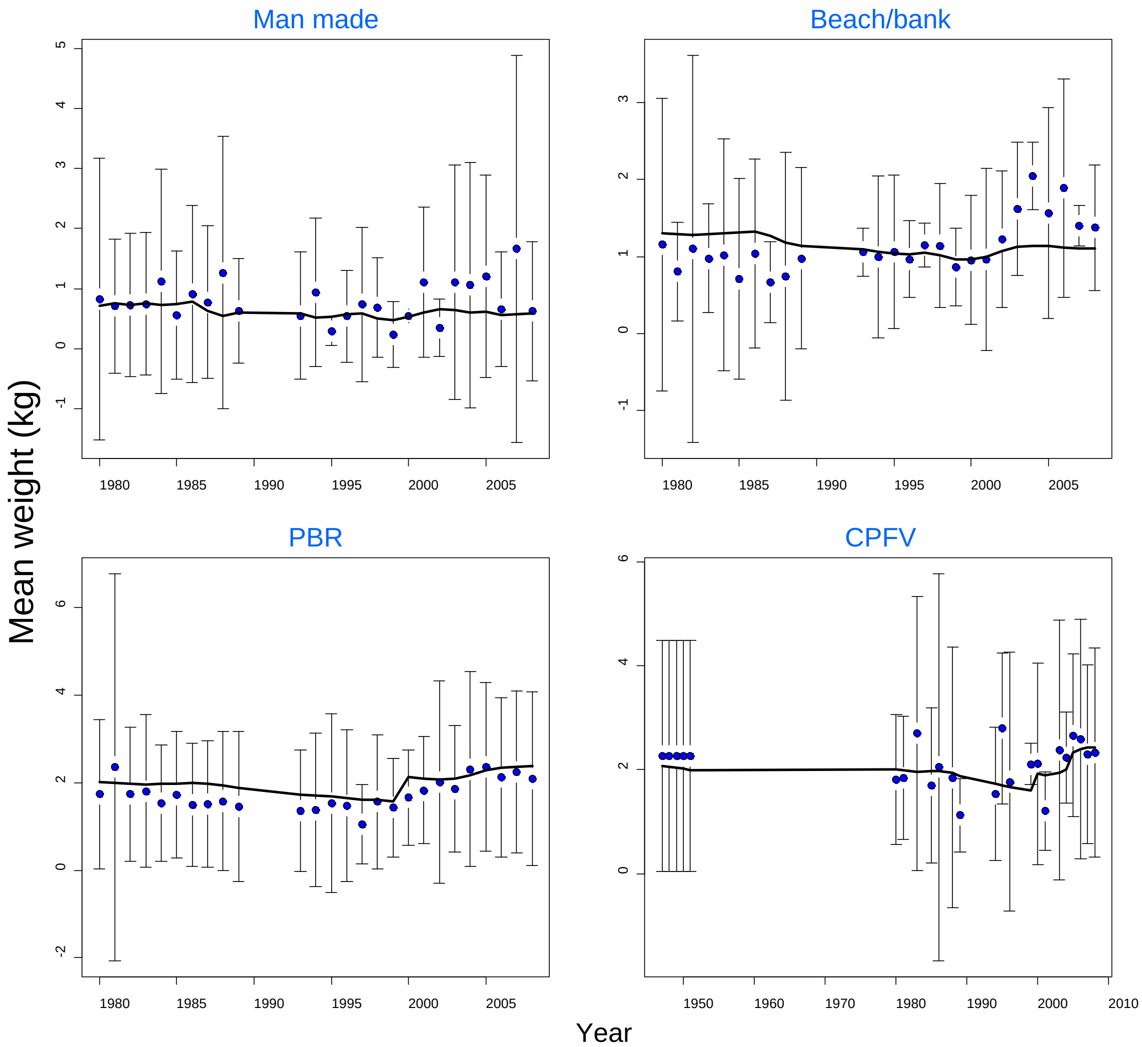

Figure 43. Plots to the observed (solid dots with 95% confidence intervals) and model-predicted (solid black lines) mean weights for each recreational fleet of the NCS.

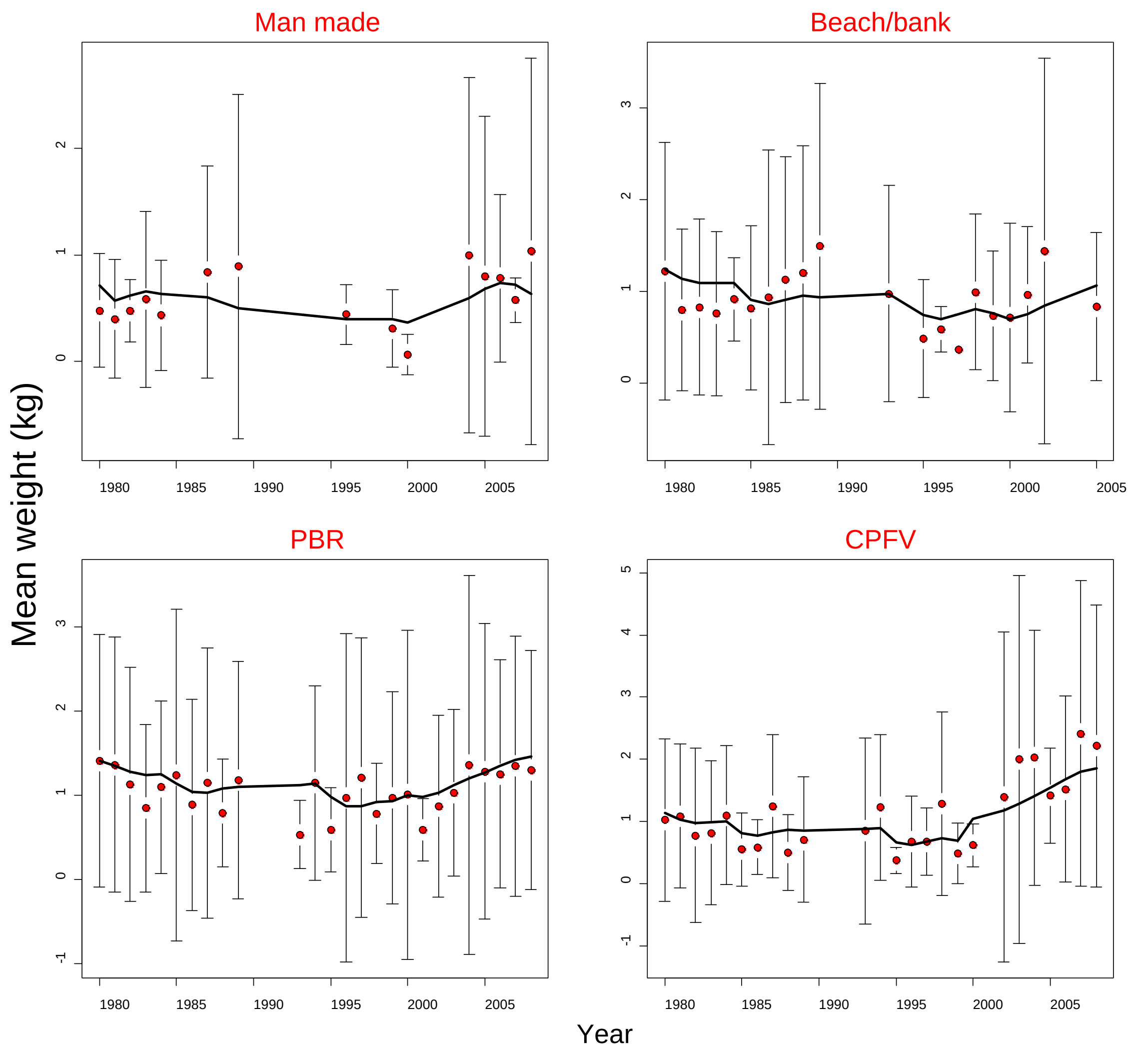

Figure 44. Plots to the observed (solid dots with 95% confidence intervals) and model-predicted (solid black lines) mean weights for each recreational fleet of the SCS.

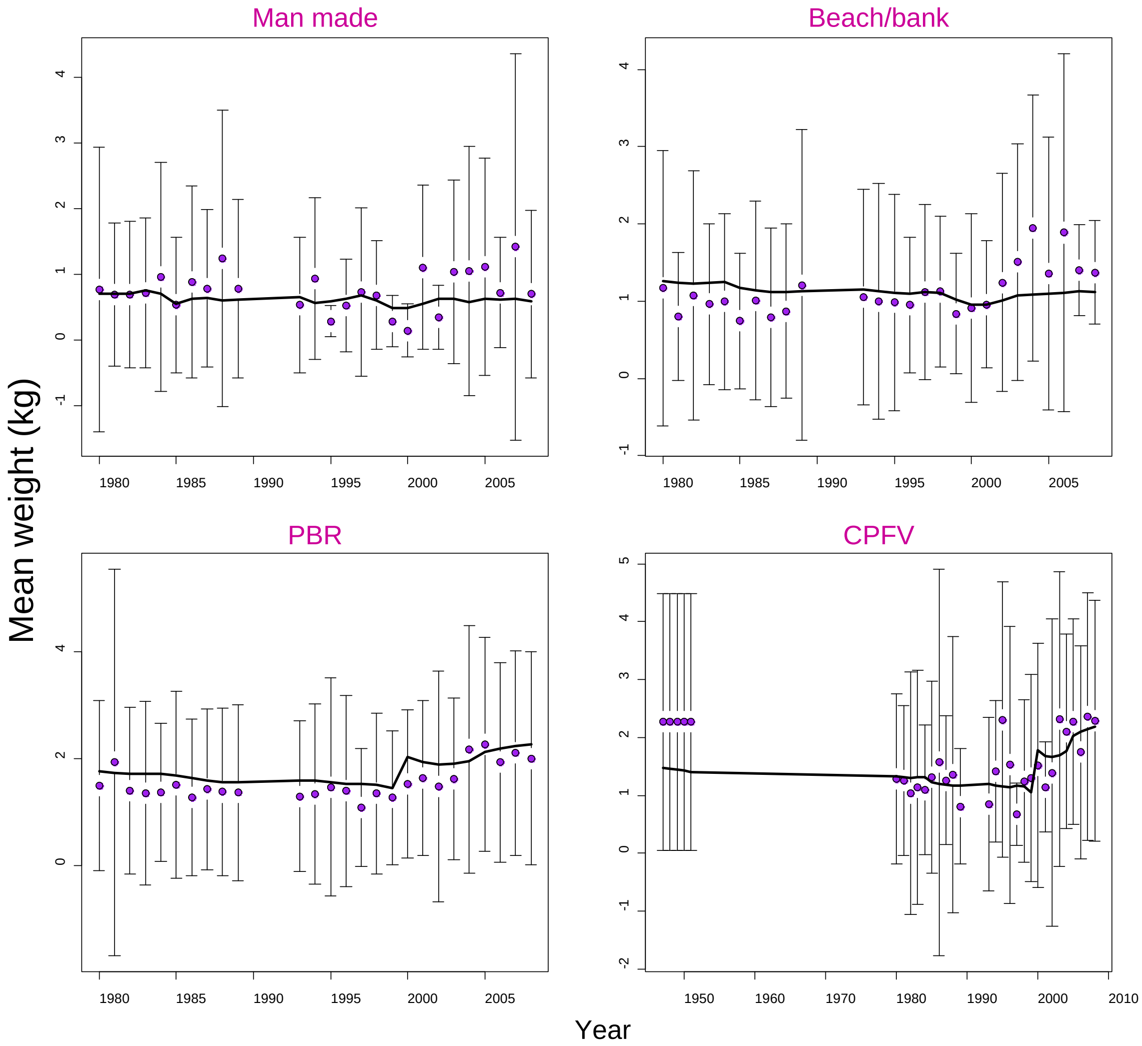

Figure 45. Plots to the observed (solid dots with 95% confidence intervals) and model-predicted (solid black lines) mean weights for each recreational fleet of the CAS.

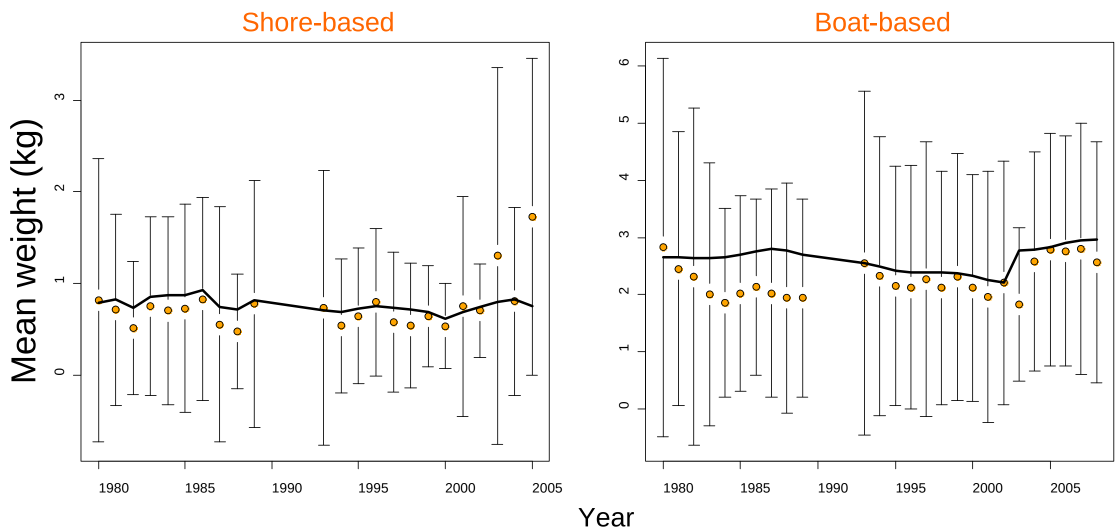

Figure 46. Plots to the observed (solid dots with 95% confidence intervals) and model-predicted (solid black lines) mean weights for each recreational fleet of the ORS.

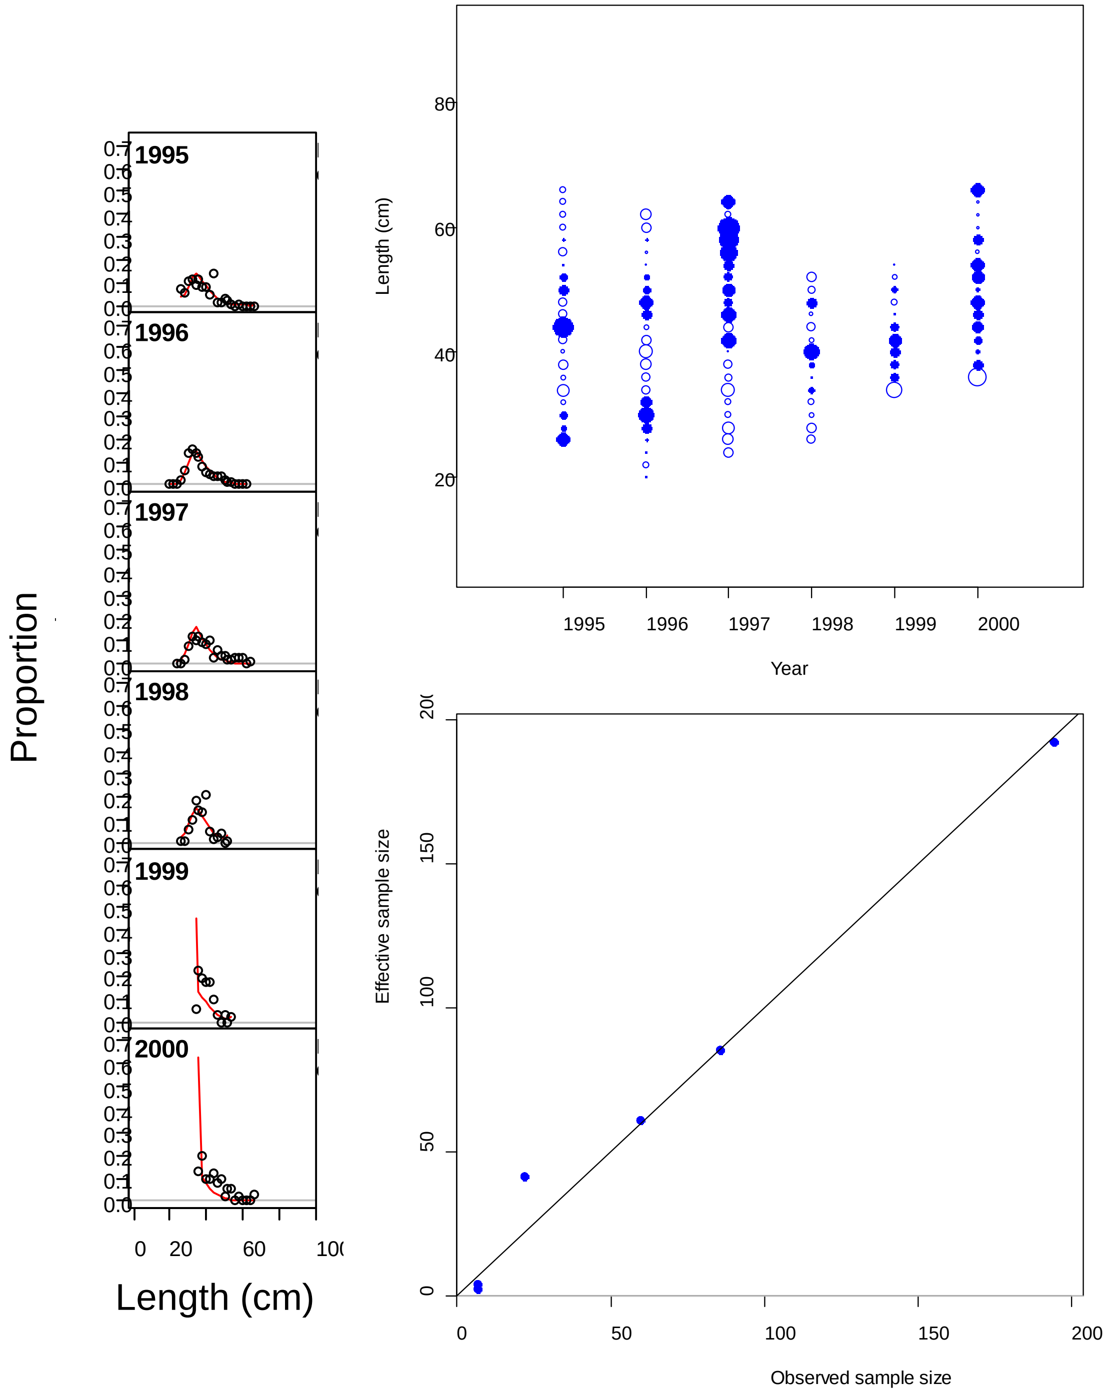

Figure 47. Fits to the Non-live (fleet 1) commercial fishery length compositions for the NCS. Left panel: Observed (circles) and model-predicted fits (red line) to length composition by year; top right panel: Pearson residuals to length composition fits; bottom right panel: comparison of inputted (observed) sample sizes vs. model-derived effective sample sizes for each year. Black solid line is the 1:1 line; red broken line is lowess fit.

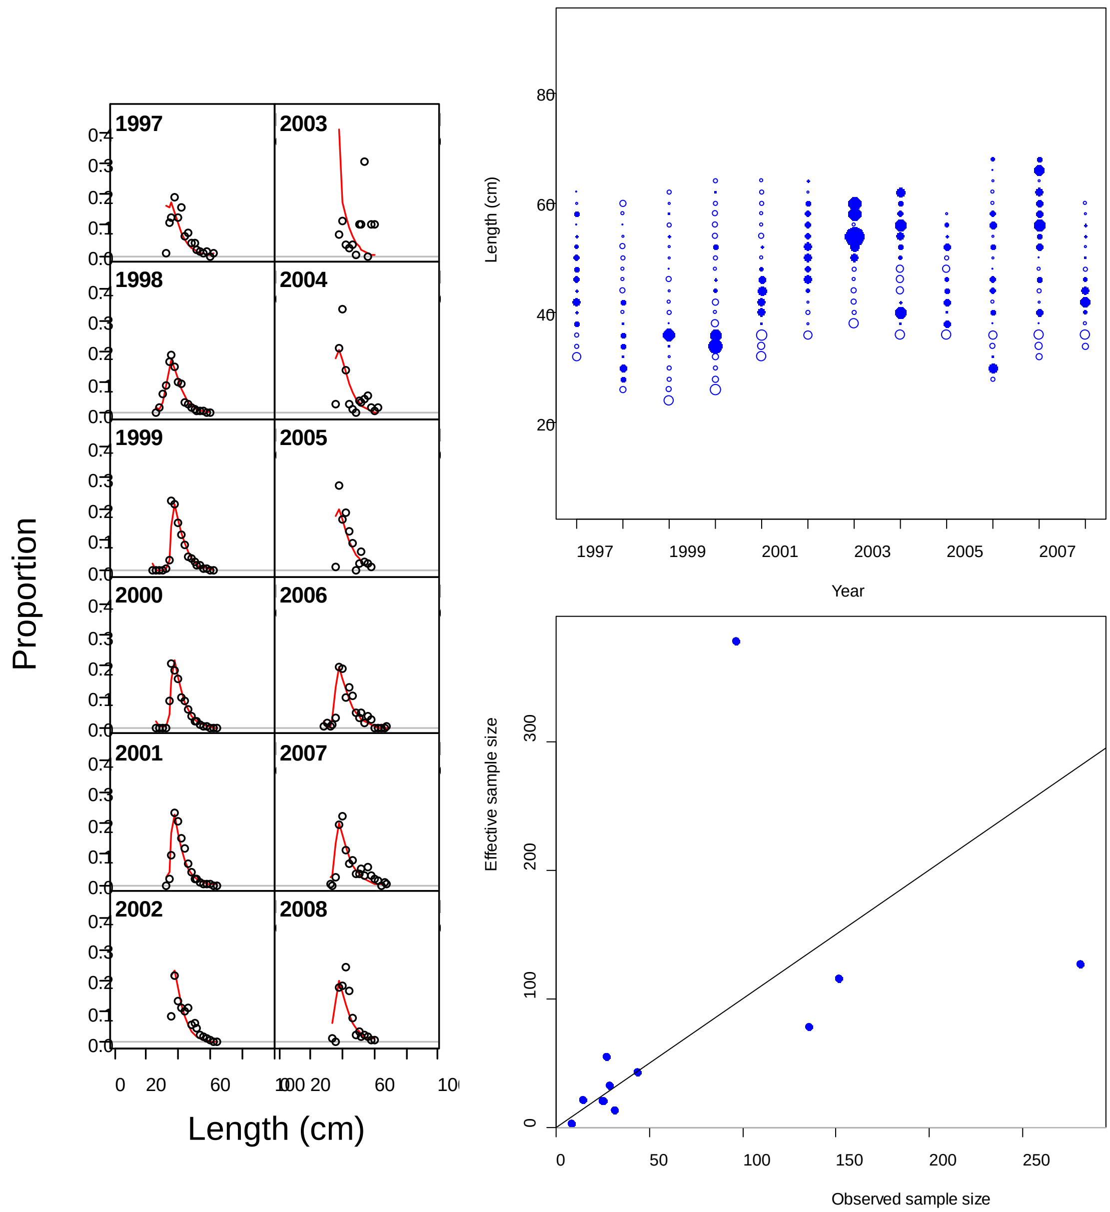

Figure 48. Fits to the live-fish (fleet 2) commercial fishery length compositions for the NCS. Left panel: Observed (circles) and model-predicted fits (red line) to length composition by year; top right panel: Pearson residuals to length composition fits; bottom right panel: comparison of inputted (observed) sample sizes vs. model-derived effective sample sizes for each year. Black solid line is the 1:1 line; red broken line is lowess fit.

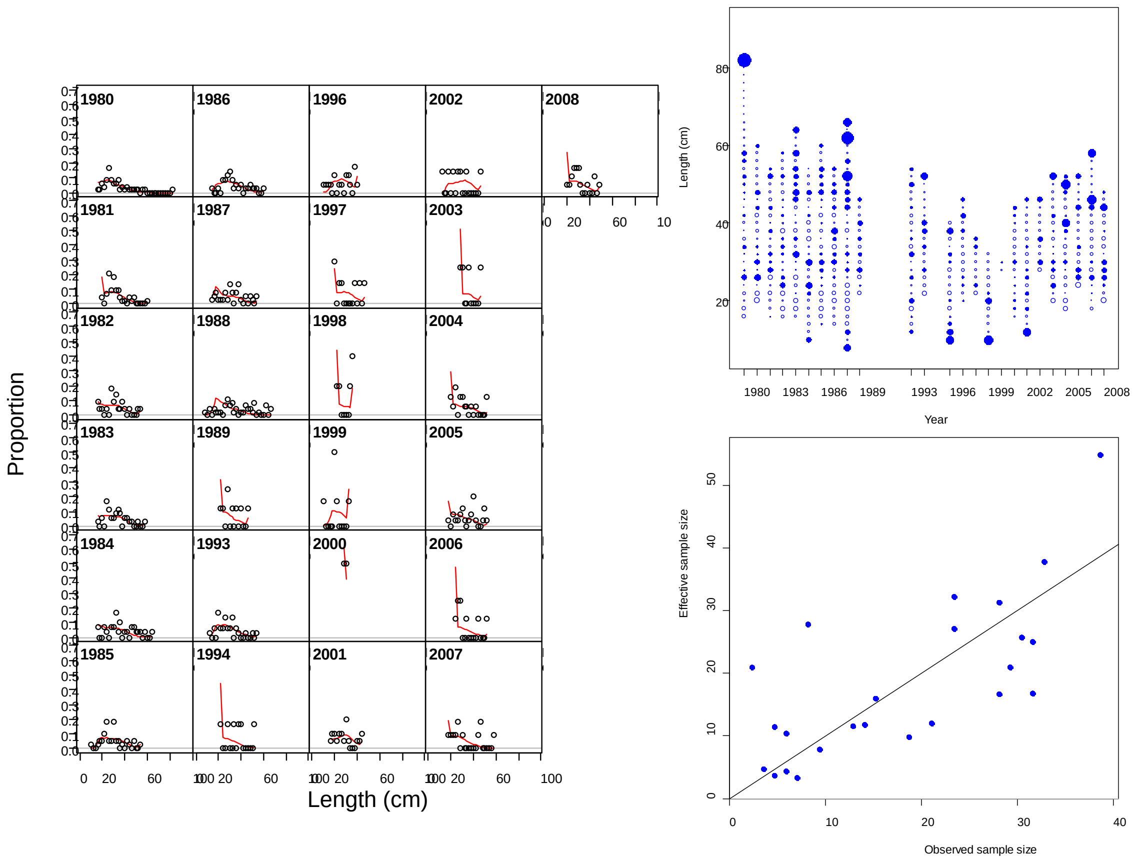

Figure 49. Fits to the man-made (fleet 3) recreational mode length compositions for the NCS. Left panel: Observed (circles) and model-predicted fits (red line) to length compositions by year; top right panel: Pearson residuals to length composition fits; bottom right panel: comparison of inputted (observed) sample sizes vs. model-derived effective sample sizes for each year. Black solid line is the 1:1 line; red broken line is lowess fit.

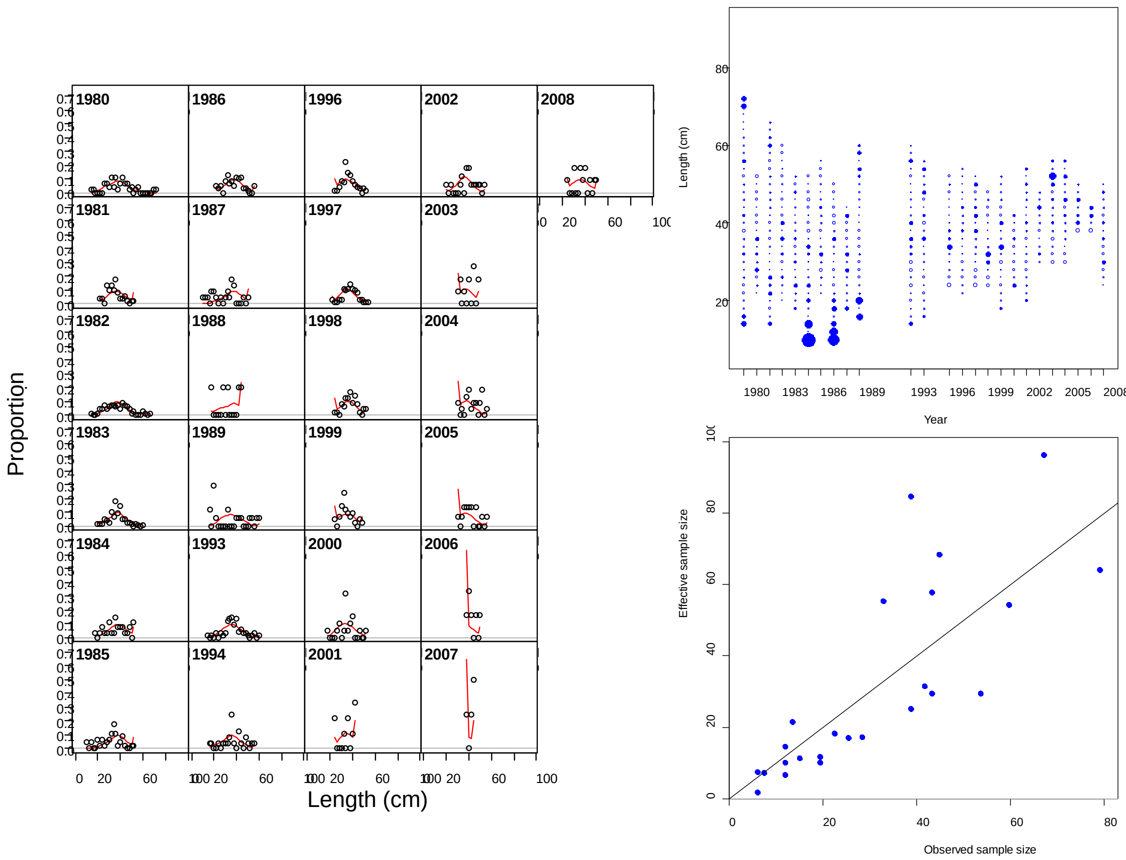

Figure 50. Fits to the beach/bank (fleet 4) recreational mode length compositions for the NCS. Left panel: Observed (circles) and model-predicted fits (red line) to length compositions by year; top right panel: Pearson residuals to length composition fits; bottom right panel: comparison of inputted (observed) sample sizes vs. model-derived effective sample sizes for each year. Black solid line is the 1:1 line; red broken line is lowess fit.

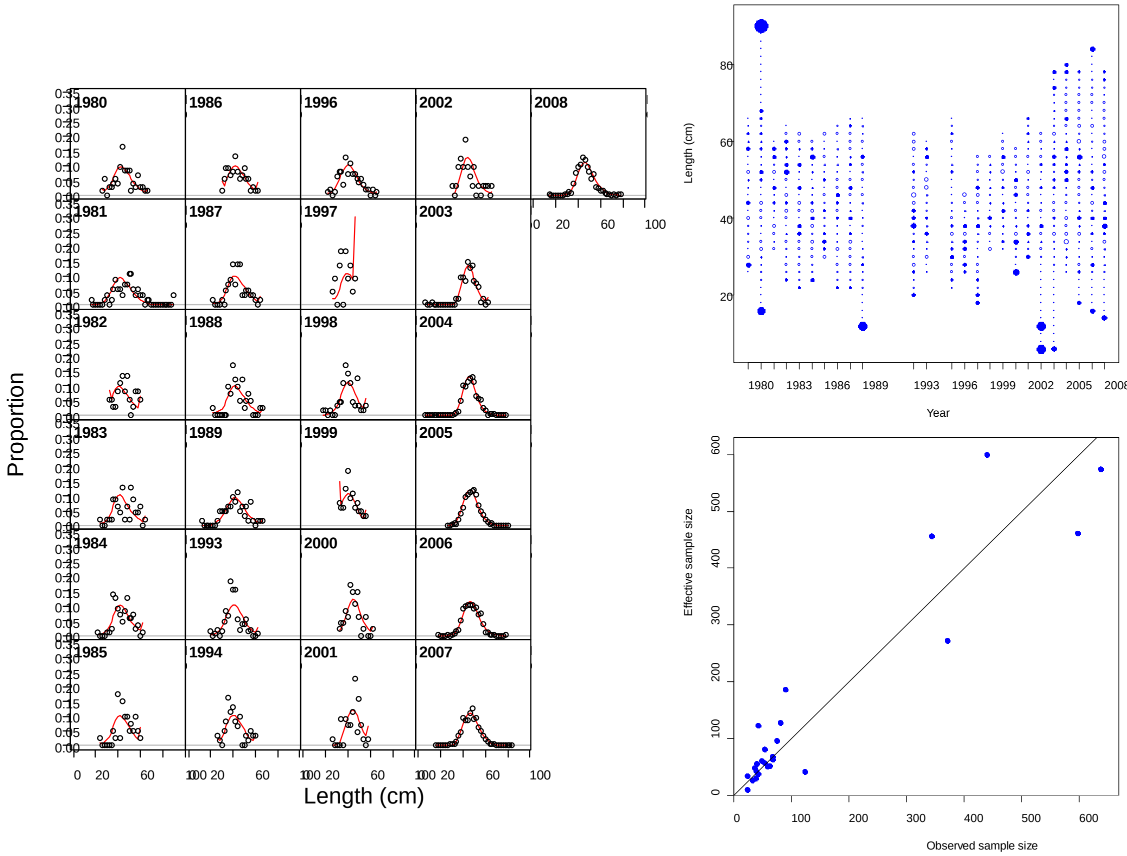

Figure 51. Fits to the PBR (fleet 5) recreational mode length compositions for the NCS. Left panel: Observed (circles) and model-predicted fits (red line) to length compositions by year; top right panel: Pearson residuals to length composition fits; bottom right panel: comparison of inputted (observed) sample sizes vs. model-derived effective sample sizes for each year. Black solid line is the 1:1 line; red broken line is lowess fit.

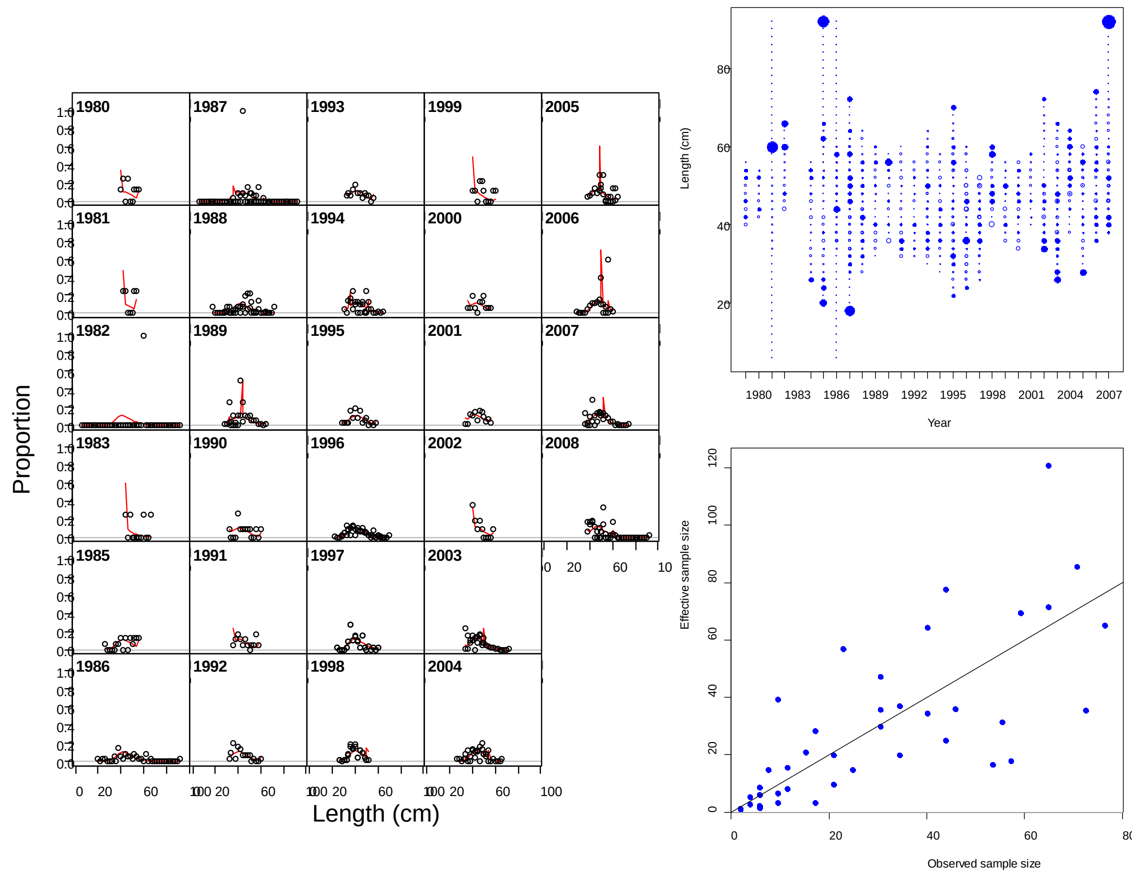

Figure 52. Fits to the CPFV (fleet 6) recreational mode length compositions for the NCS. Left panel: Observed (circles) and model-predicted fits (red line) to length compositions by year; top right panel: Pearson residuals to length composition fits; bottom right panel: comparison of inputted (observed) sample sizes vs. model-derived effective sample sizes for each year. Black solid line is the 1:1 line; red broken line is lowess fit.

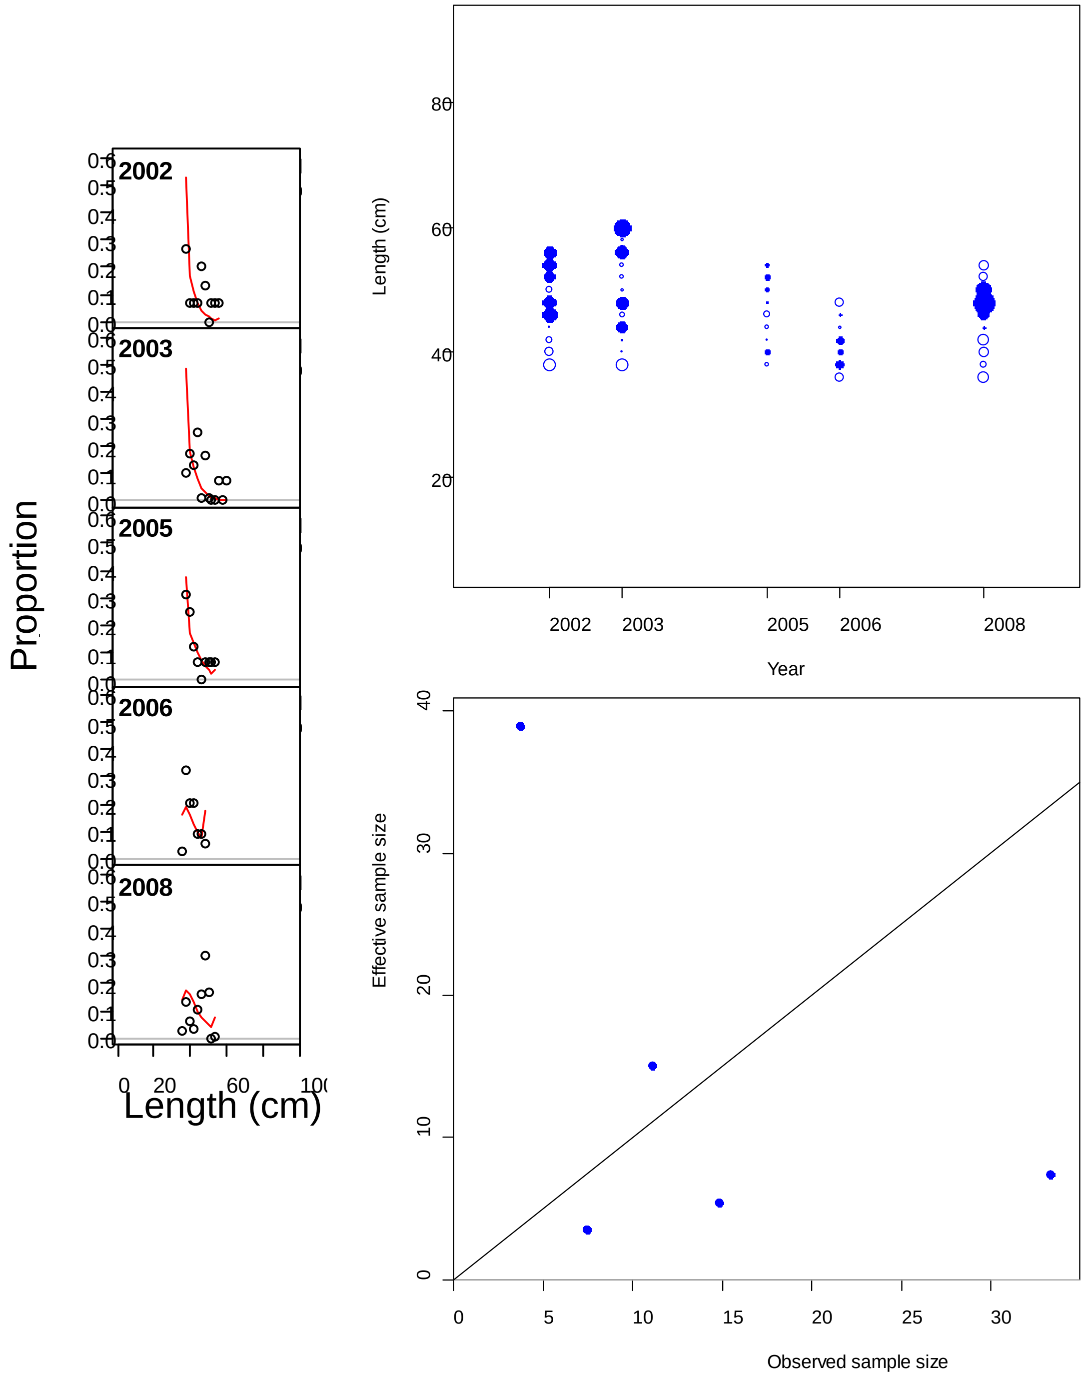

Figure 53. Fits to the live-fish (fleet 2) commercial fishery length compositions for the SCS. Left panel: Observed (circles) and model-predicted fits (red line) to length compositions by year; top right panel: Pearson residuals to length composition fits; bottom right panel: comparison of inputted (observed) sample sizes vs. model-derived effective sample sizes for each year. Black solid line is the 1:1 line; red broken line is lowess fit.

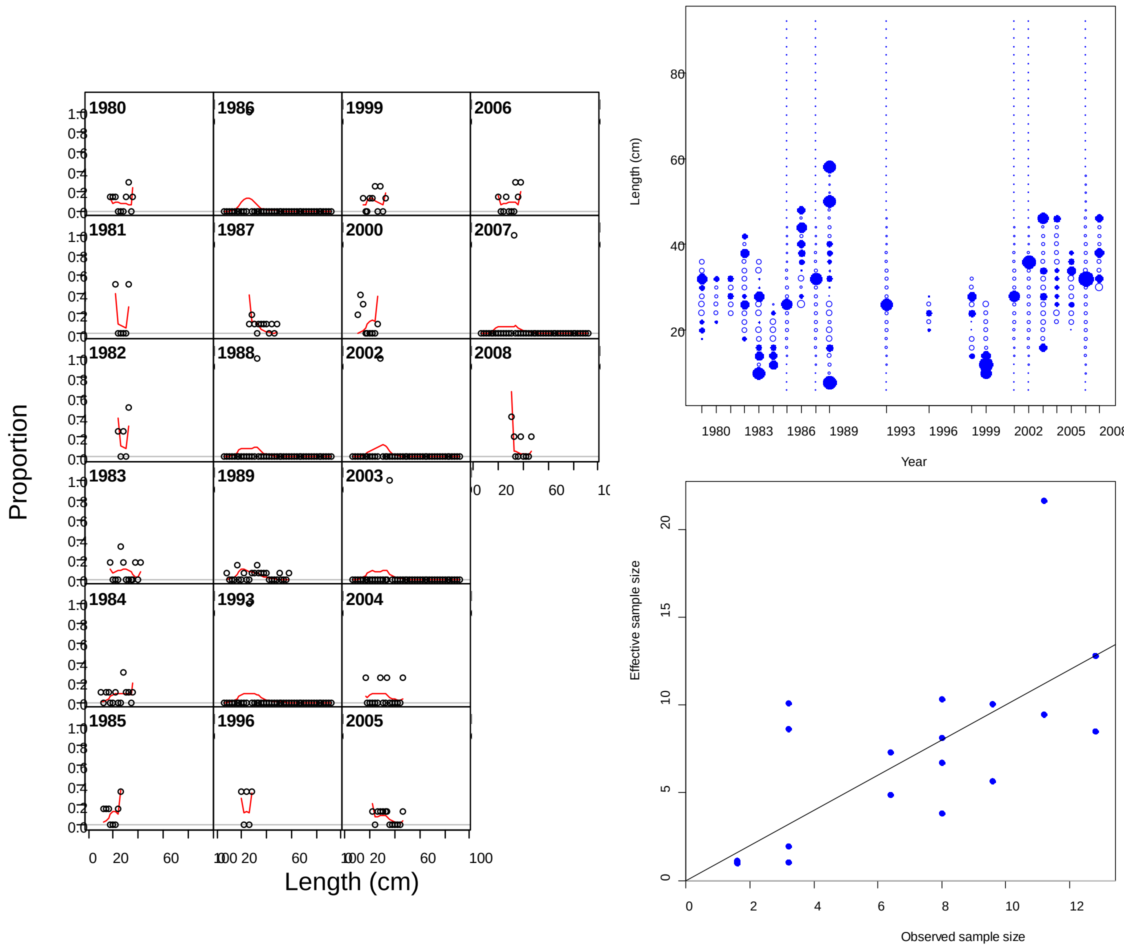

Figure 54. Fits to the man-made (fleet 3) recreational fishery length compositions for the SCS. Left panel: Observed (circles) and model-predicted fits (red line) to length compositions by year; top right panel: Pearson residuals to length composition fits; bottom right panel: comparison of inputted (observed) sample sizes vs. model-derived effective sample sizes for each year. Black solid line is the 1:1 line; red broken line is lowess fit.

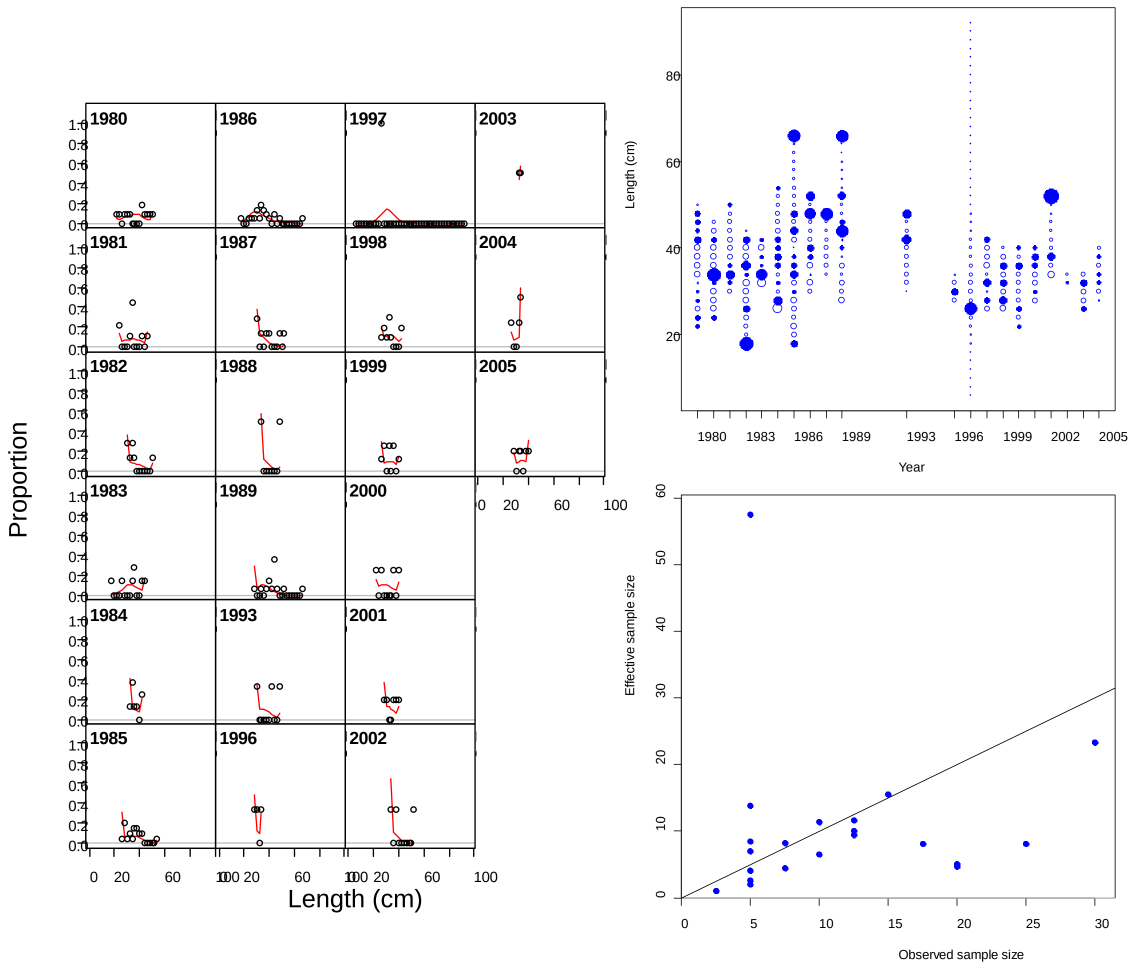

Figure 55. Fits to the beach/bank (fleet 4) recreational fishery length compositions for the SCS. Left panel: Observed (circles) and model-predicted fits (red line) to length compositions by year; top right panel: Pearson residuals to length composition fits; bottom right panel: comparison of inputted (observed) sample sizes vs. model-derived effective sample sizes for each year. Black solid line is the 1:1 line; red broken line is lowess fit.

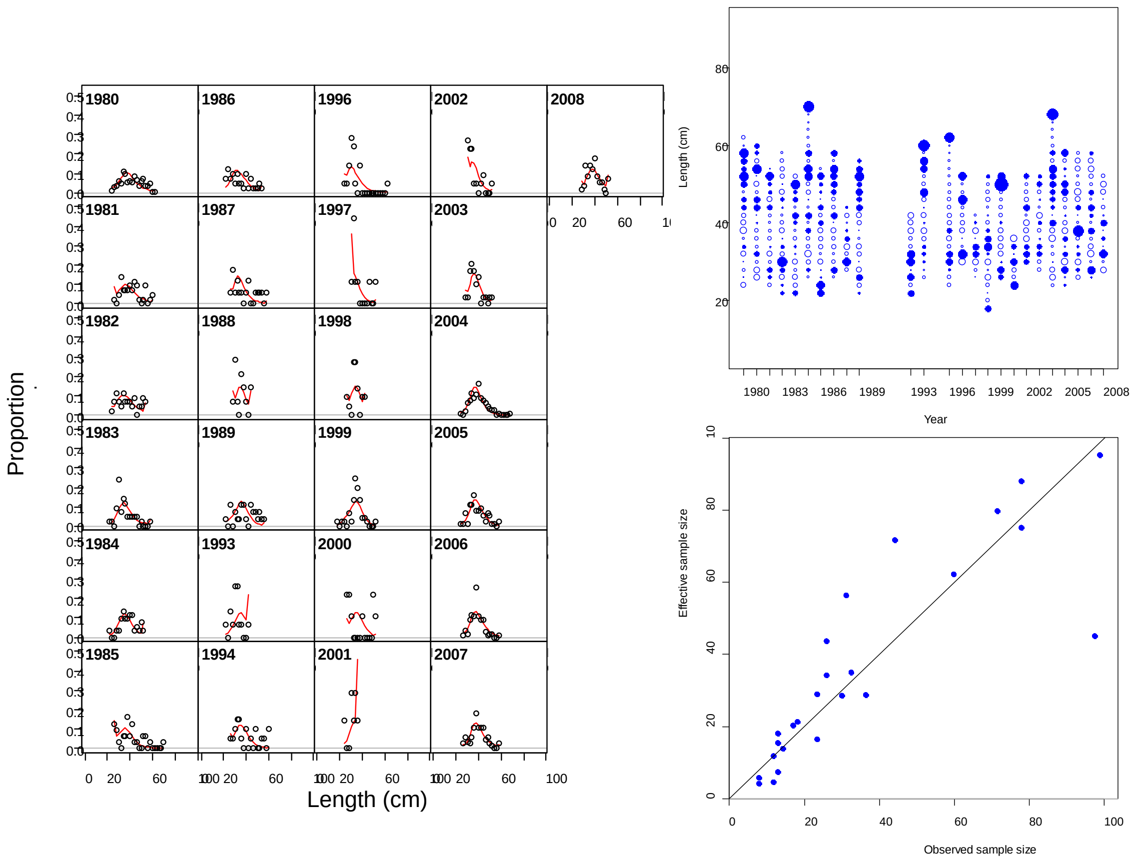

Figure 56. Fits to the PBR (fleet 5) recreational fishery length compositions for the SCS. Left panel: Observed (circles) and model-predicted fits (red line) to length compositions by year; top right panel: Pearson residuals to length composition fits; bottom right panel: comparison of inputted (observed) sample sizes vs. model-derived effective sample sizes for each year. Black solid line is the 1:1 line; red broken line is lowess fit.

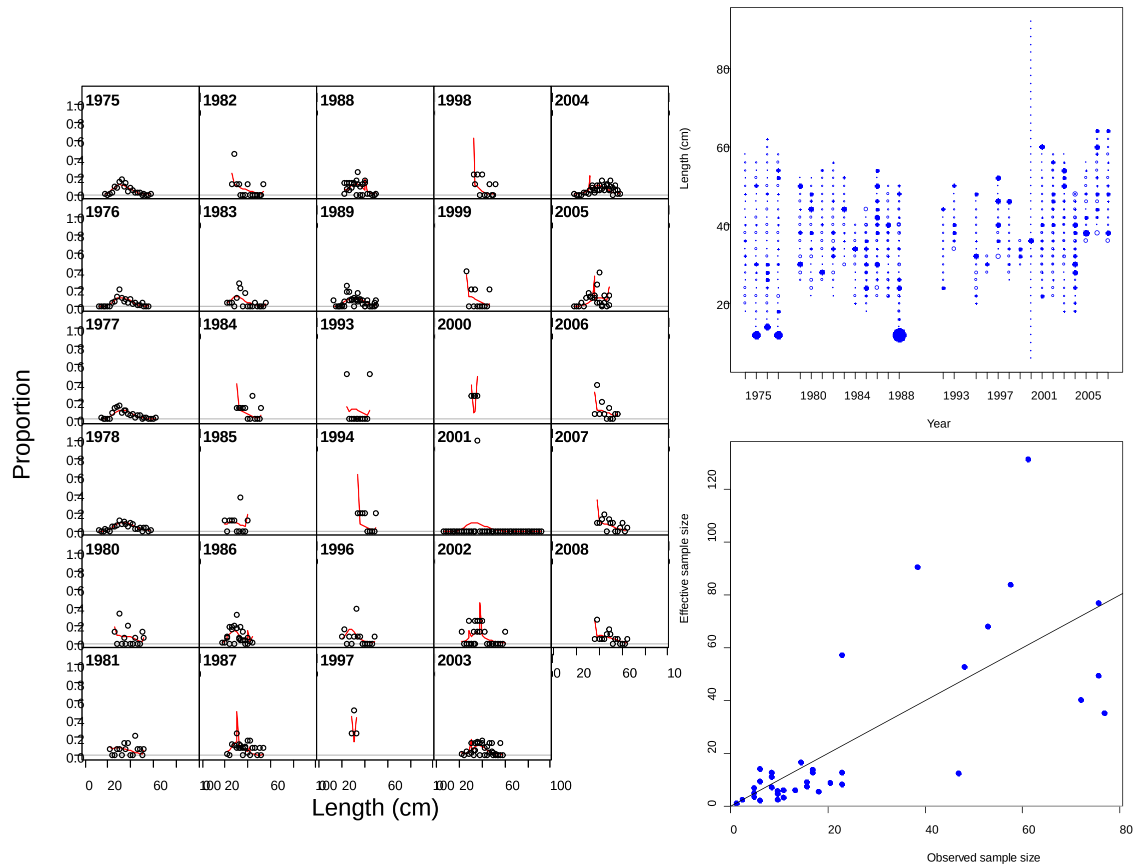

Figure 57. Fits to the CPFV (fleet 6) recreational fishery length compositions for the SCS. Left panel: Observed (circles) and model-predicted fits (red line) to length compositions by year; top right panel: Pearson residuals to length composition fits; bottom right panel: comparison of inputted (observed) sample sizes vs. model-derived effective sample sizes for each year. Black solid line is the 1:1 line; red broken line is lowess fit.

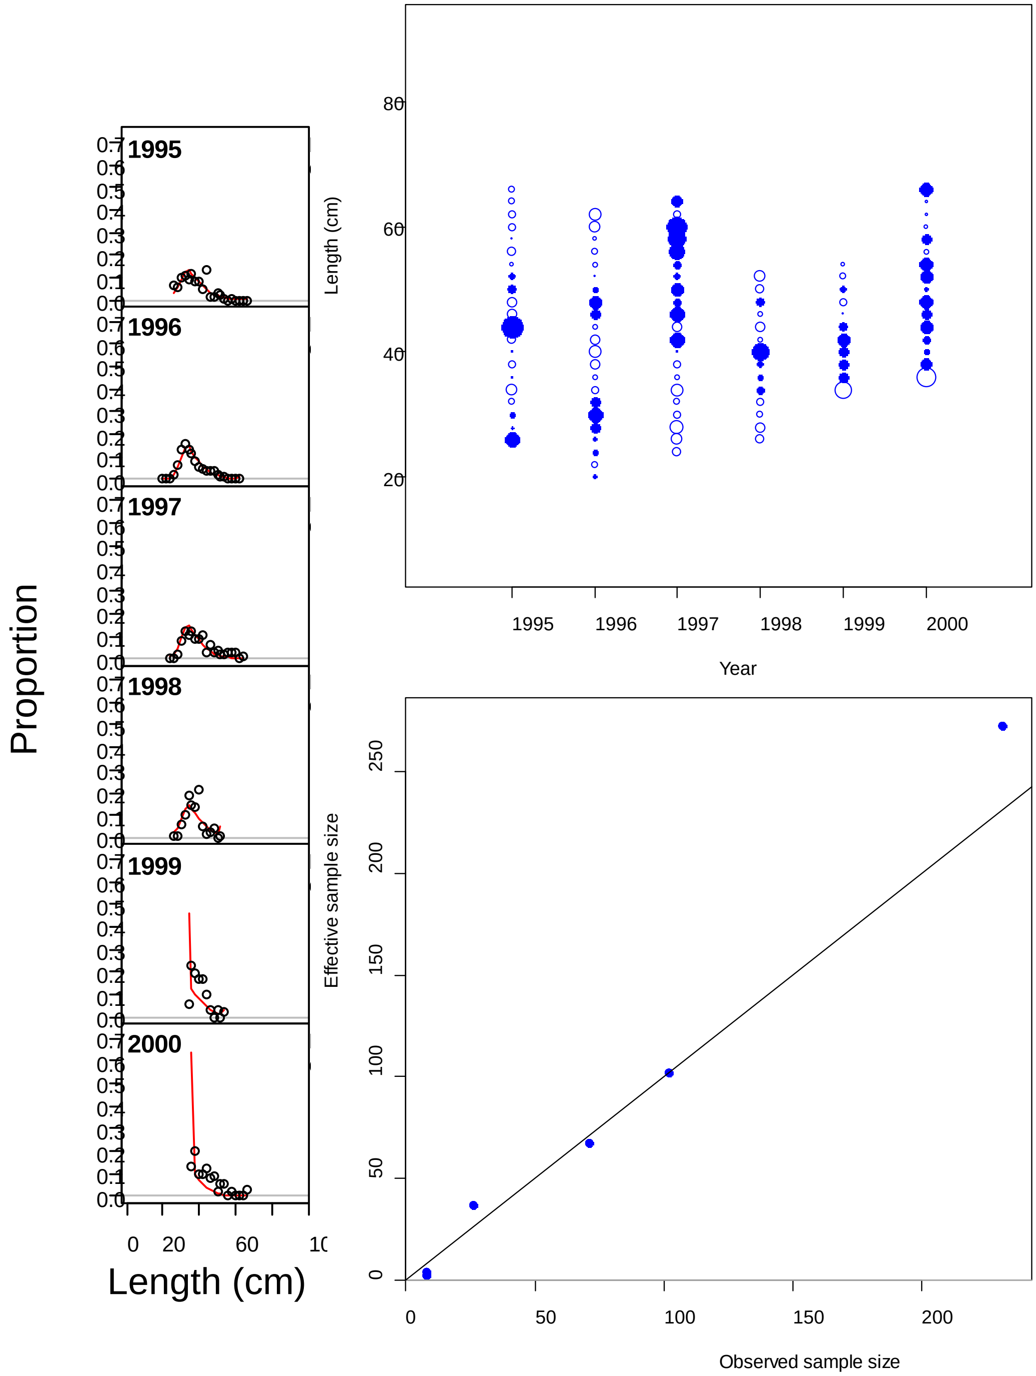

Figure 58. Fits to the non-live (fleet 1) commercial fishery length compositions for the CAS. Left panel: Observed (circles) and model-predicted fits (red line) to length compositions by year; top right panel: Pearson residuals to length composition fits; bottom right panel: comparison of inputted (observed) sample sizes vs. model-derived effective sample sizes for each year. Black solid line is the 1:1 line; red broken line is lowess fit.

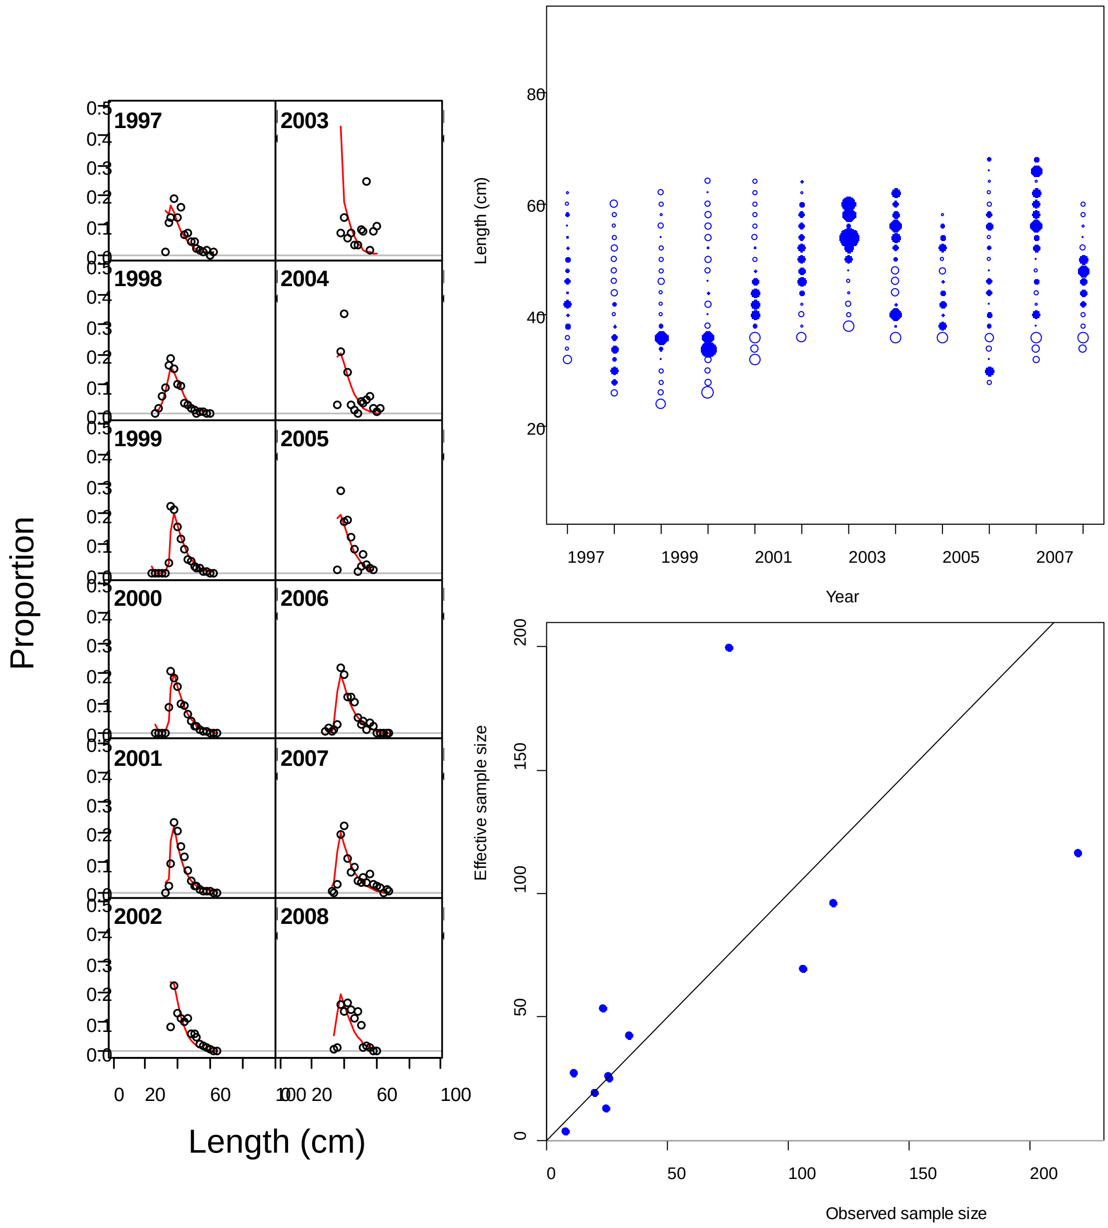

Figure 59. Fits to the live-fish (fleet 2) commercial fishery length compositions for the CAS. Left panel: Observed (circles) and model-predicted fits (red line) to length compositions by year; top right panel: Pearson residuals to length composition fits; bottom right panel: comparison of inputted (observed) sample sizes vs. model-derived effective sample sizes for each year. Black solid line is the 1:1 line; red broken line is lowess fit.

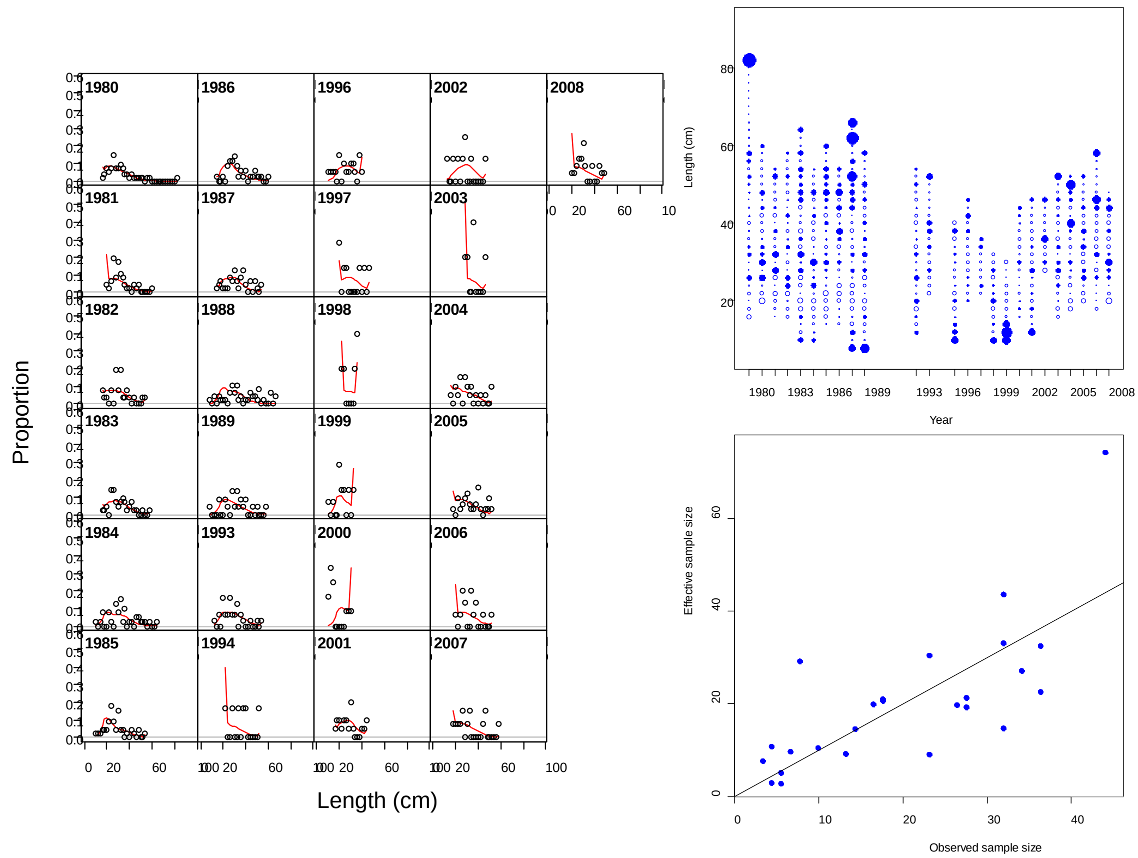

Figure 60. Fits to the man-made (fleet 3) recreational mode length compositions for the CAS. Left panel: Observed (circles) and model-predicted fits (red line) to length compositions by year; top right panel: Pearson residuals to length composition fits; bottom right panel: comparison of inputted (observed) sample sizes vs. model-derived effective sample sizes for each year. Black solid line is the 1:1 line; red broken line is lowess fit.

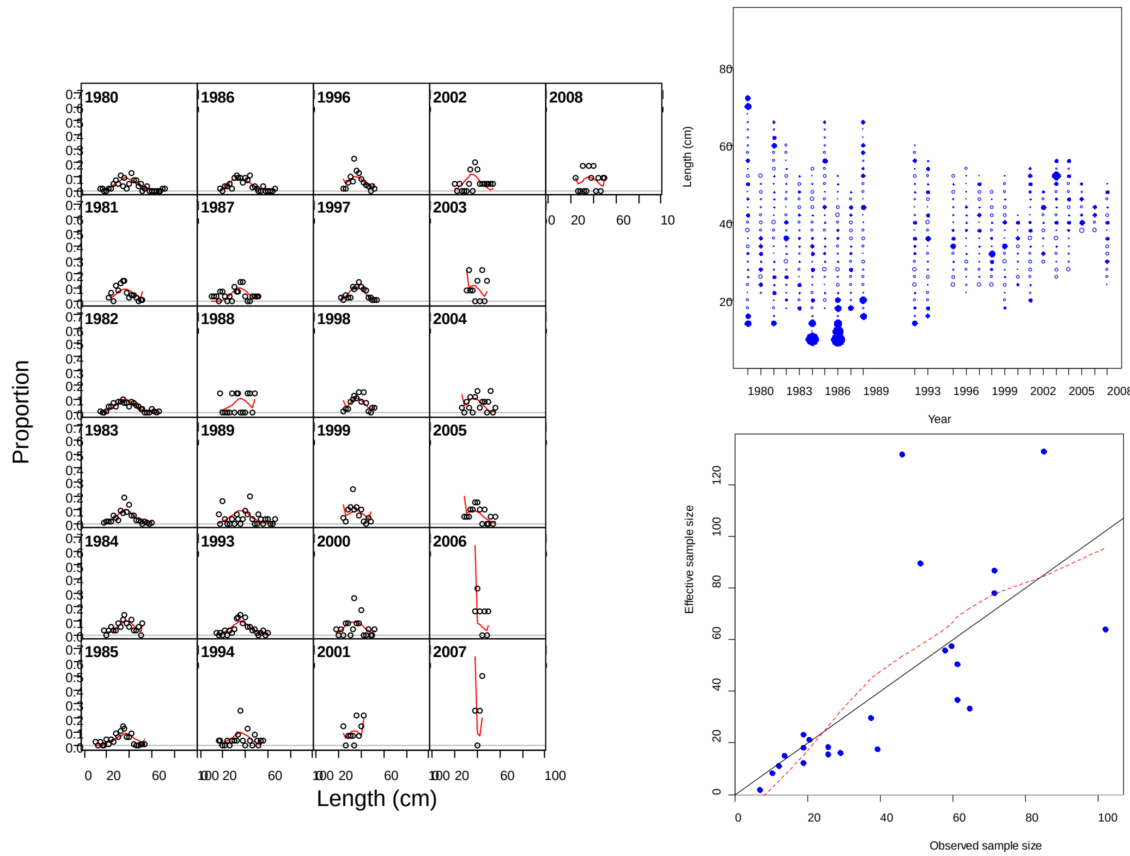

Figure 61. Fits to the beach/bank (fleet 4) recreational mode length compositions for the CAS. Left panel: Observed (circles) and model-predicted fits (red line) to length compositions by year; top right panel: Pearson residuals to length composition fits; bottom right panel: comparison of inputted (observed) sample sizes vs. model-derived effective sample sizes for each year. Black solid line is the 1:1 line; red broken line is lowess fit.

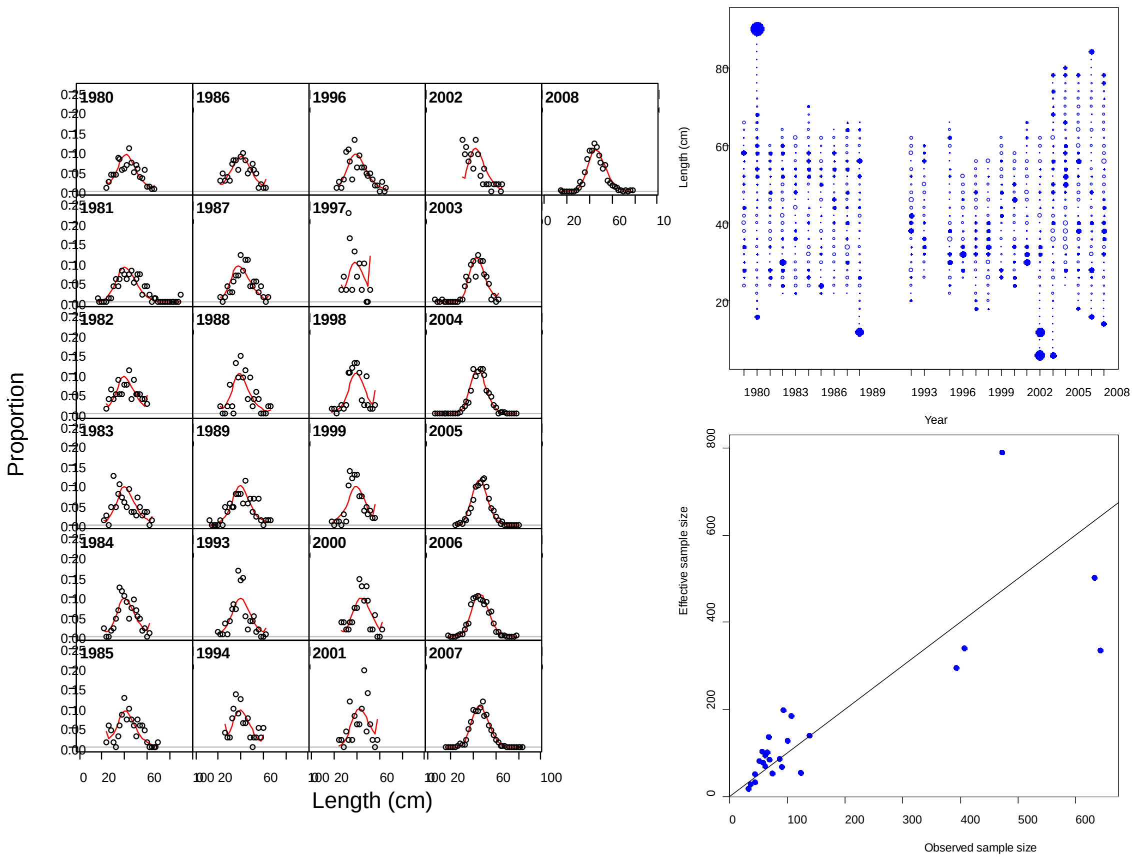

Figure 62. Fits to the PBR (fleet 5) recreational mode length compositions for the CAS. Left panel: Observed (circles) and model-predicted fits (red line) to length compositions by year; top right panel: Pearson residuals to length composition fits; bottom right panel: comparison of inputted (observed) sample sizes vs. model-derived effective sample sizes for each year. Black solid line is the 1:1 line; red broken line is lowess fit.

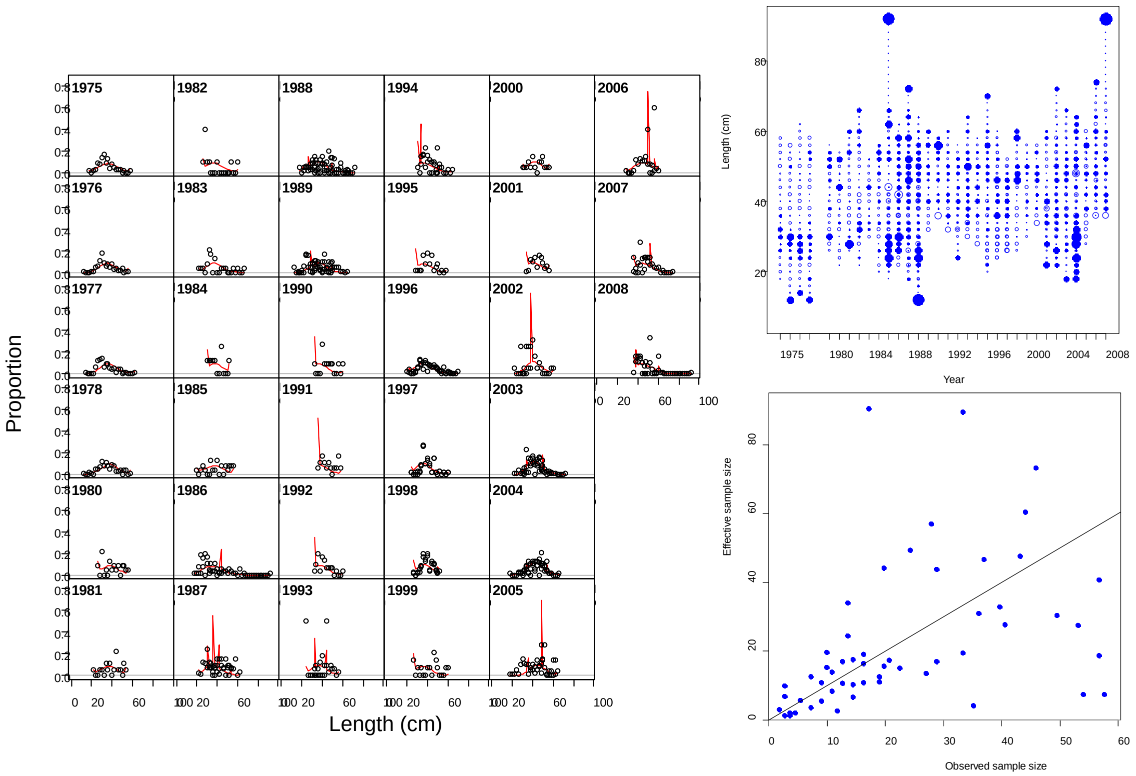

Figure 63. Fits to the CPFV (fleet 6) recreational mode length compositions for the CAS. Left panel: Observed (circles) and model-predicted fits (red line) to length compositions by year; top right panel: Pearson residuals to length composition fits; bottom right panel: comparison of inputted (observed) sample sizes vs. model-derived effective sample sizes for each year. Black solid line is the 1:1 line; red broken line is lowess fit.

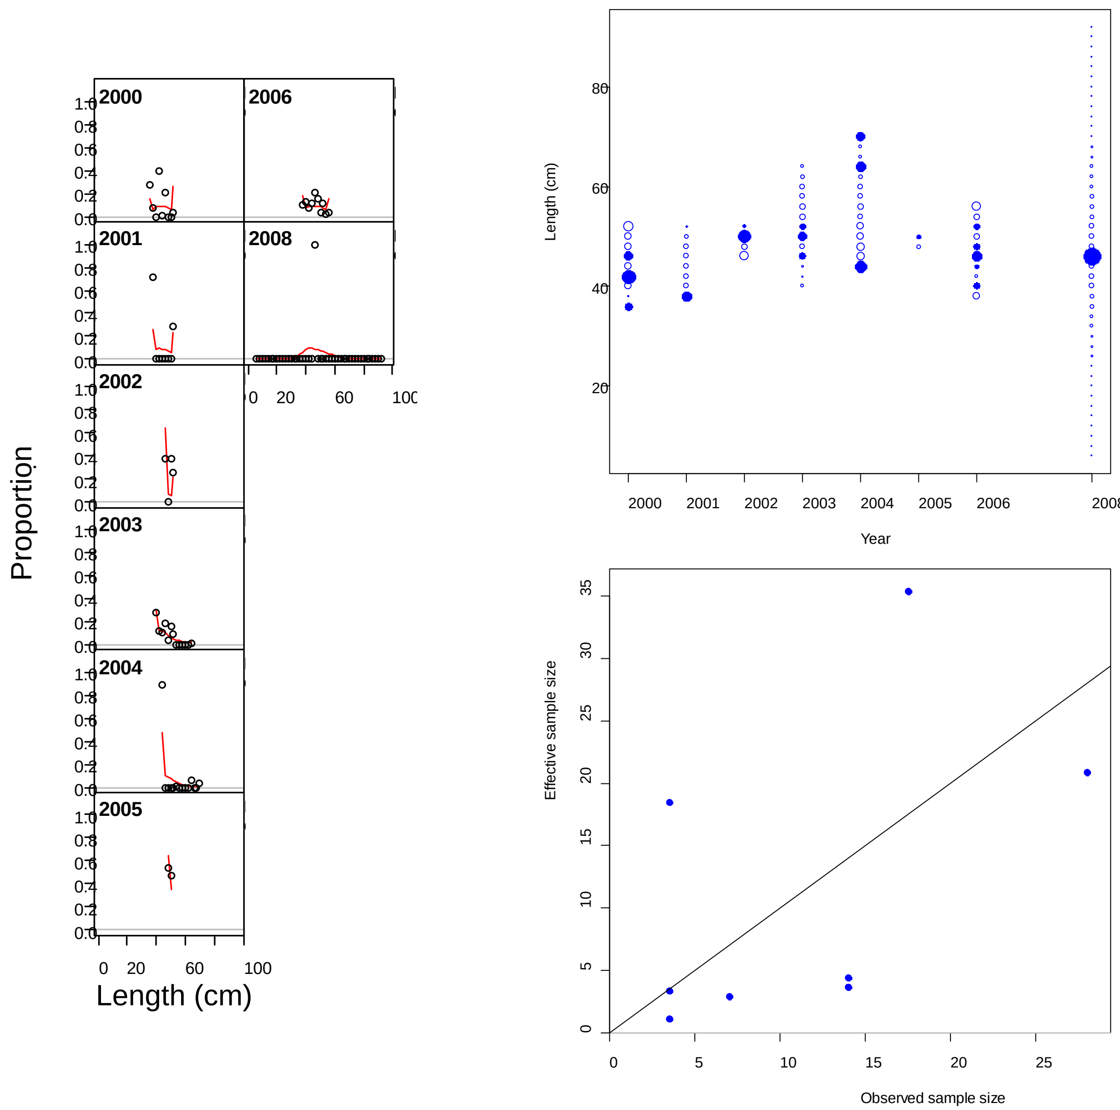

Figure 64. Fits to the unsexed non-live (fleet 1) commercial fishery length compositions for the ORS. Left panel: Observed (circles) and model-predicted fits (red line) to length compositions by year; top right panel: Pearson residuals to length composition fits; bottom right panel: comparison of inputted (observed) sample sizes vs. model-derived effective sample sizes for each year. Black solid line is the 1:1 line; red broken line is lowess fit.

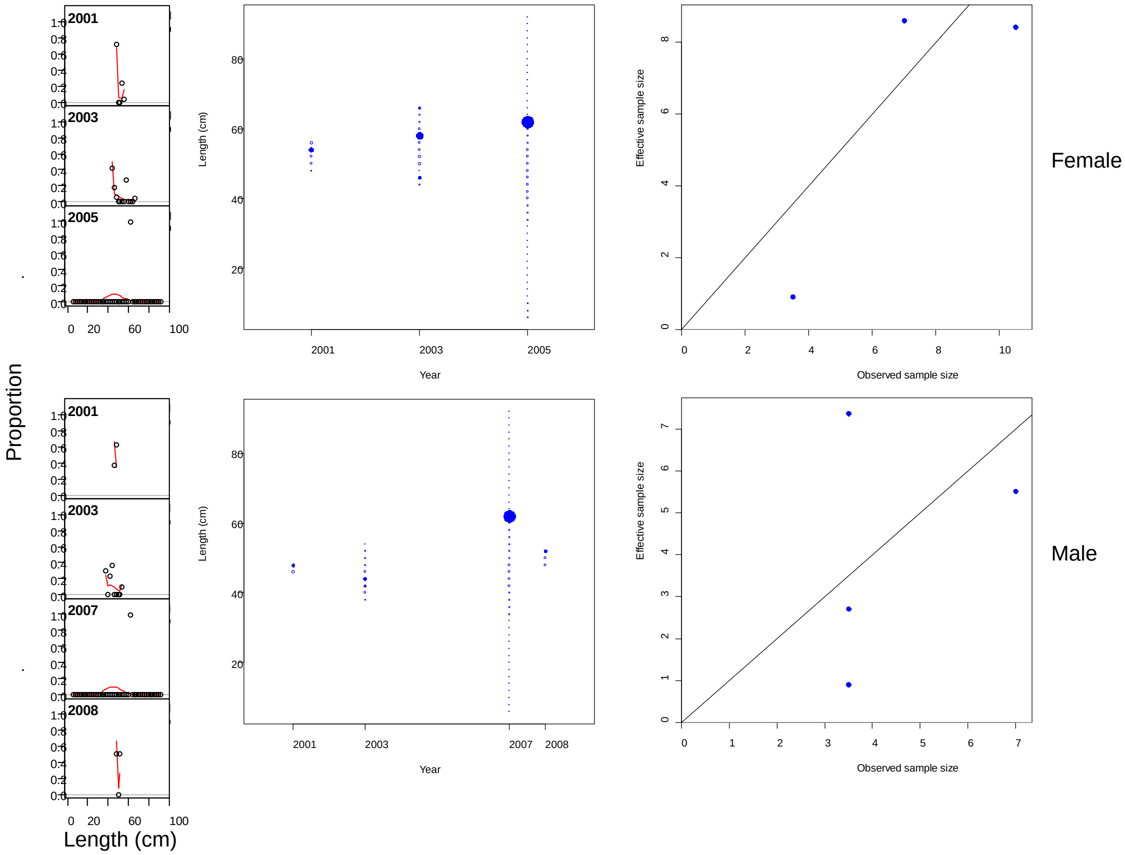

Figure 65. Fits to the sex-specific non-live (fleet 1) commercial fishery length compositions for the ORS. Left panel: Observed (circles) and model-predicted fits (red line) to length compositions by year; top right panel: Pearson residuals to length composition fits; bottom right panel: comparison of inputted (observed) sample sizes vs. model-derived effective sample sizes for each year. Black solid line is the 1:1 line; red broken line is lowess fit.

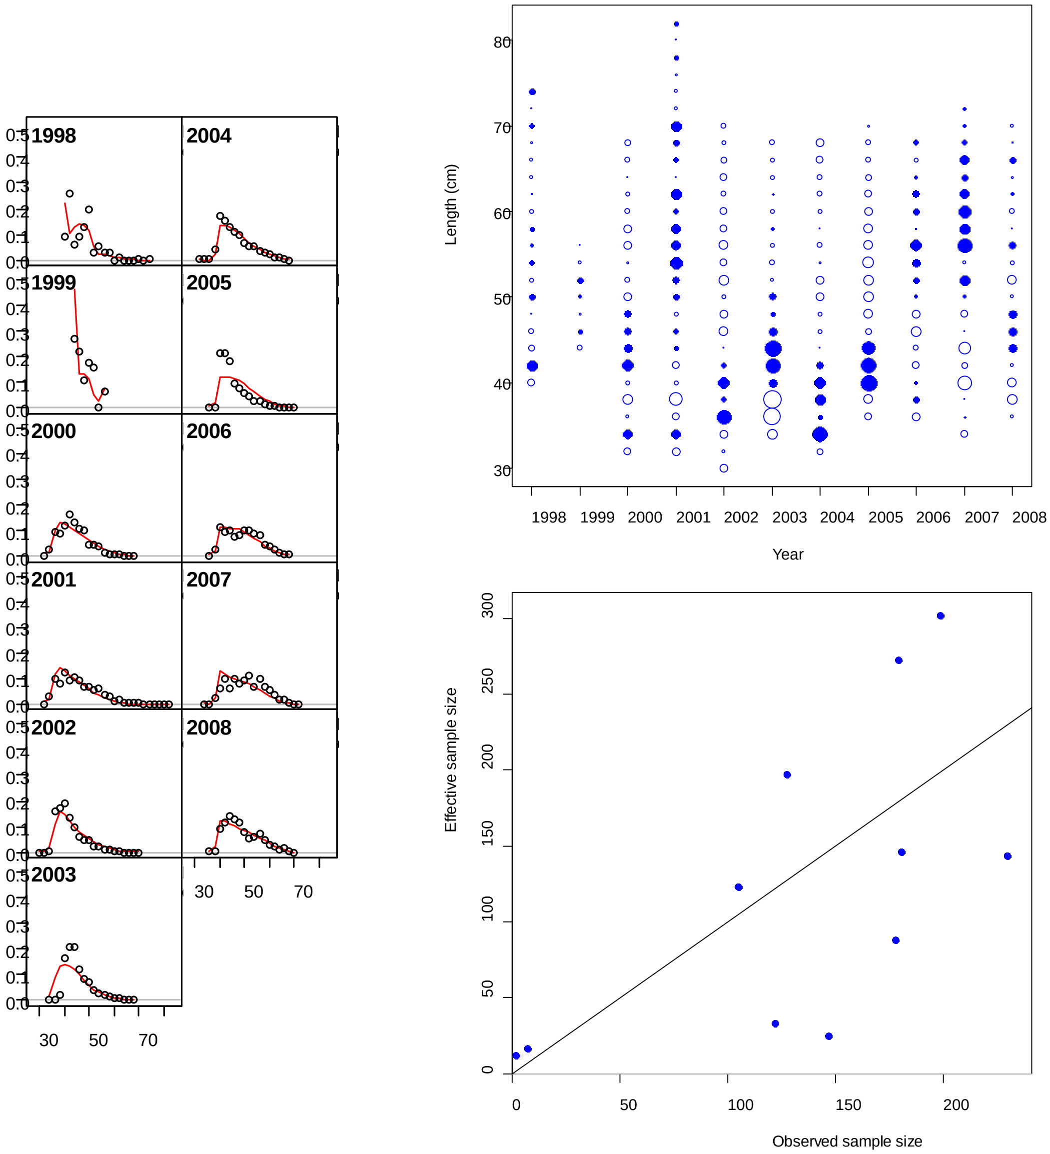

Figure 66. Fits to the unsexed live-fish (fleet 2) commercial fishery length compositions for the ORS. Left panel: Observed (circles) and model-predicted fits (red line) to length compositions by year; top right panel: Pearson residuals to length composition fits; bottom right panel: comparison of inputted (observed) sample sizes vs. model-derived effective sample sizes for each year. Black solid line is the 1:1 line; red broken line is lowess fit.

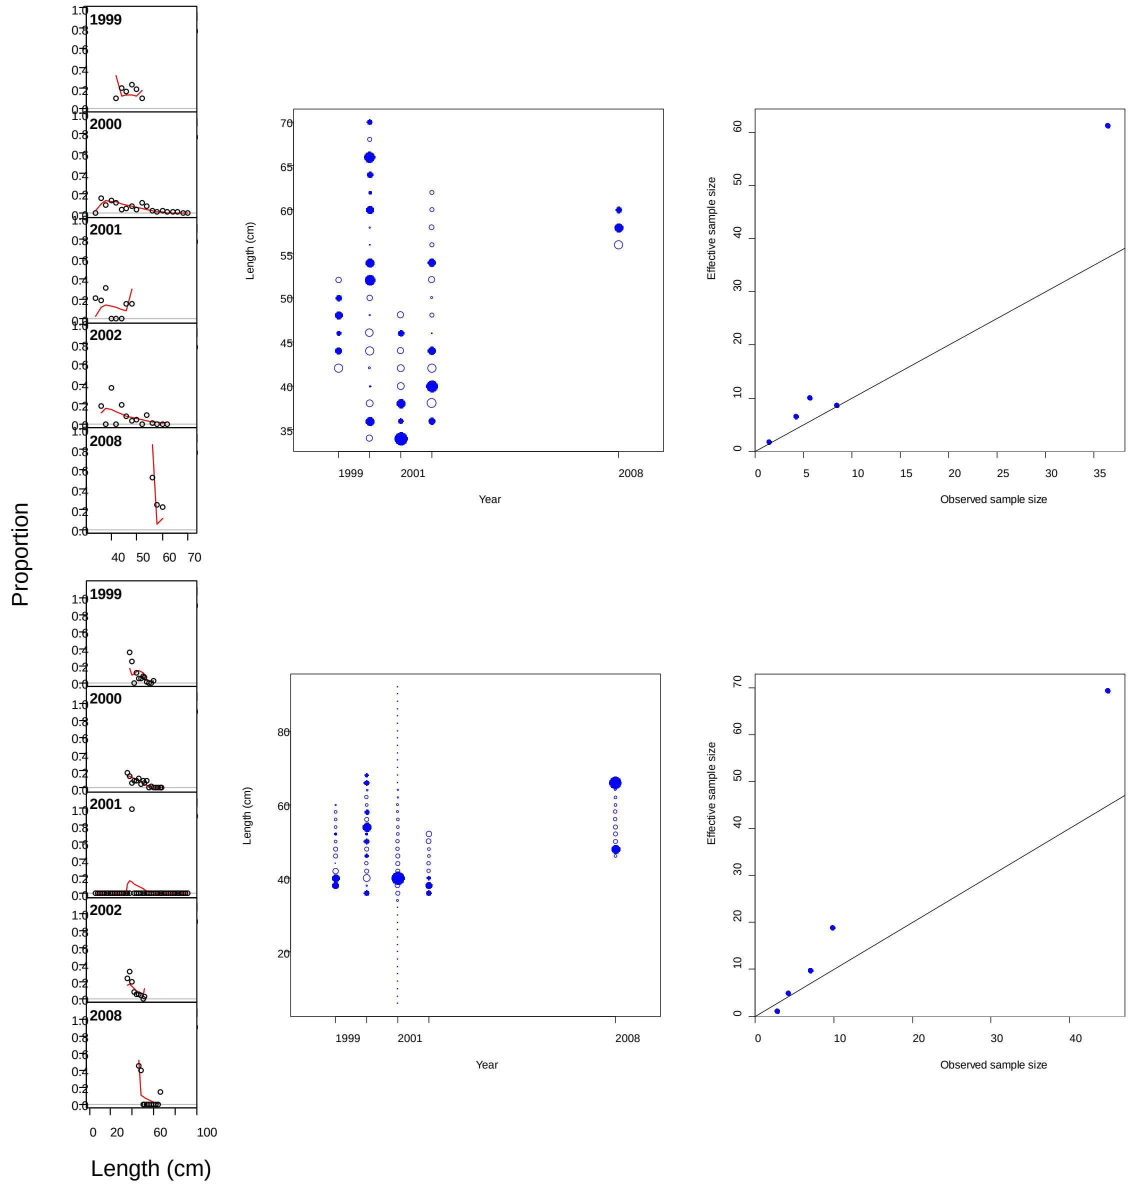

Figure 67. Fits to the sex-specific live-fish (fleet 2) commercial fishery length compositions for the ORS. Left panel: Observed (circles) and model-predicted fits (red line) to length compositions by year; top right panel: Pearson residuals to length composition fits; bottom right panel: comparison of inputted (observed) sample sizes vs. model-derived effective sample sizes for each year. Black solid line is the 1:1 line; red broken line is lowess fit.

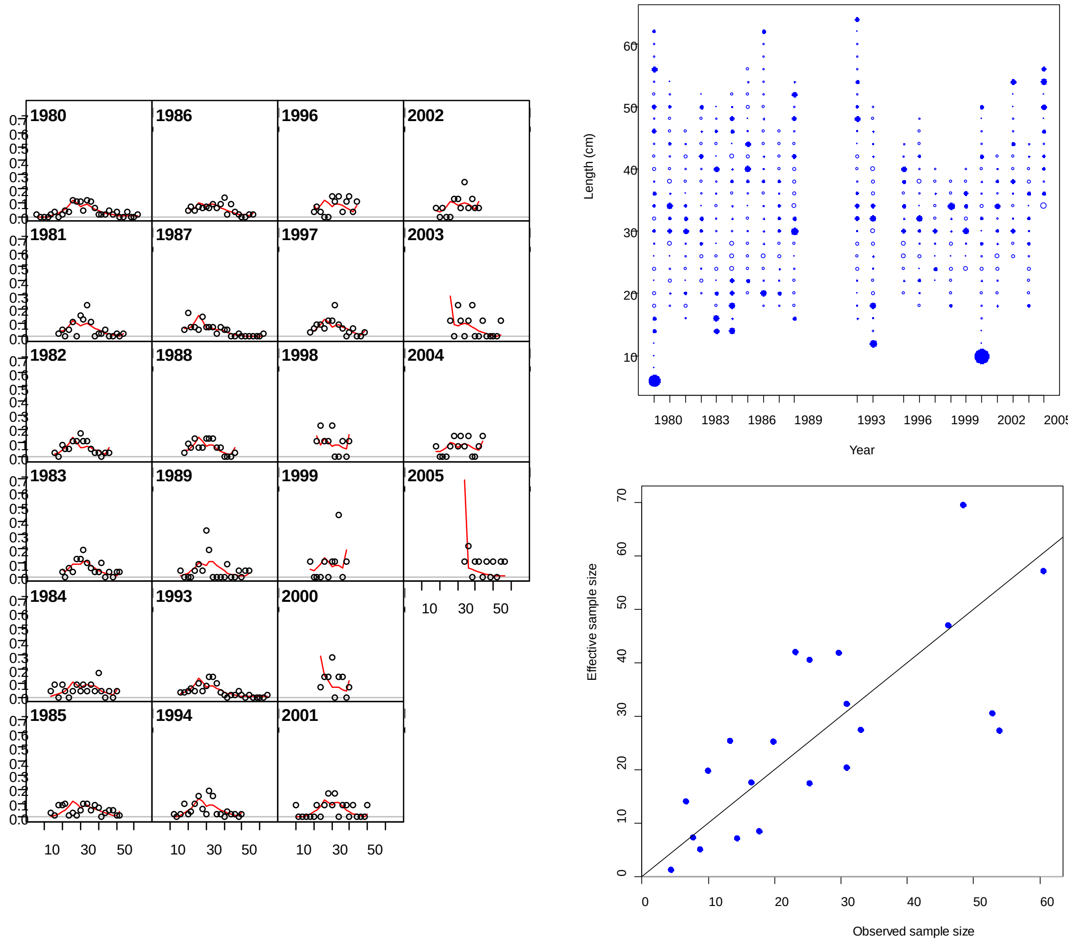

Figure 68. Fits to the shore-based (fleet 3) recreational mode length compositions for the ORS. Left panel: Observed (circles) and model-predicted fits (red line) to length compositions by year; top right panel: Pearson residuals to length composition fits; bottom right panel: comparison of inputted (observed) sample sizes vs. model-derived effective sample sizes for each year. Black solid line is the 1:1 line; red broken line is lowess fit.

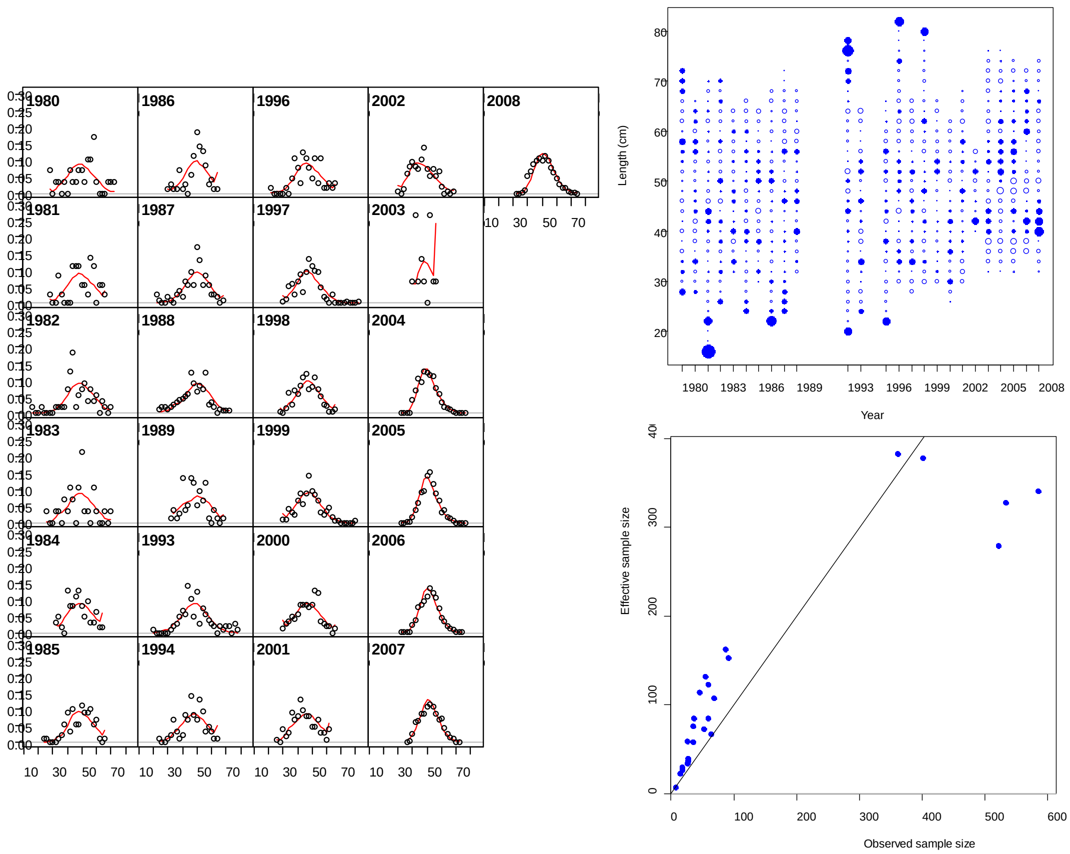

Figure 69. Fits to the boat-based (fleet 4) recreational mode length compositions for the ORS. Left panel: Observed (circles) and model-predicted fits (red line) to length compositions by year; top right panel: Pearson residuals to length composition fits; bottom right panel: comparison of inputted (observed) sample sizes vs. model-derived effective sample sizes for each year. Black solid line is the 1:1 line; red broken line is lowess fit.

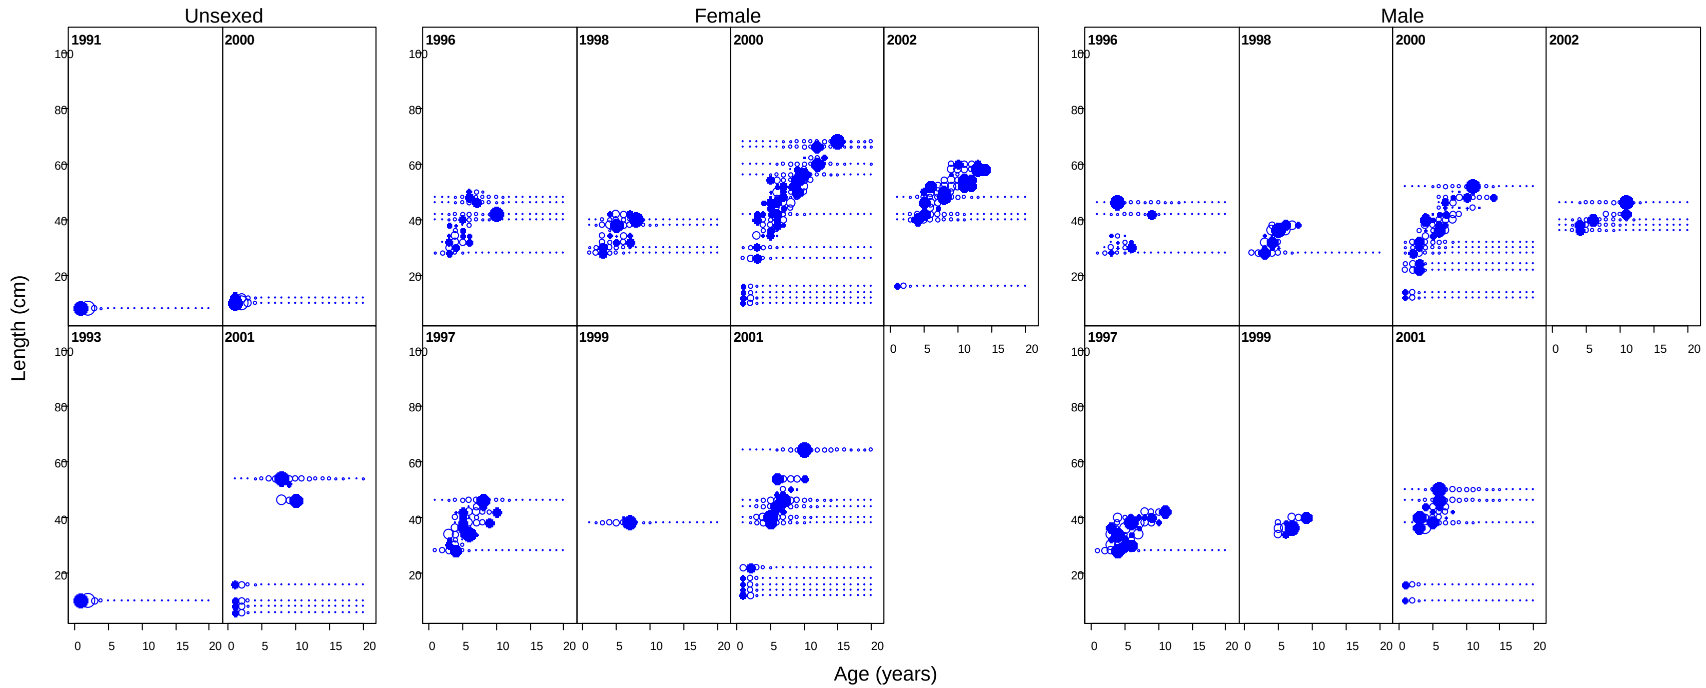

Figure 70. Pearson residual from fits to the unsexed and sexed conditional age at length data for the NCS.

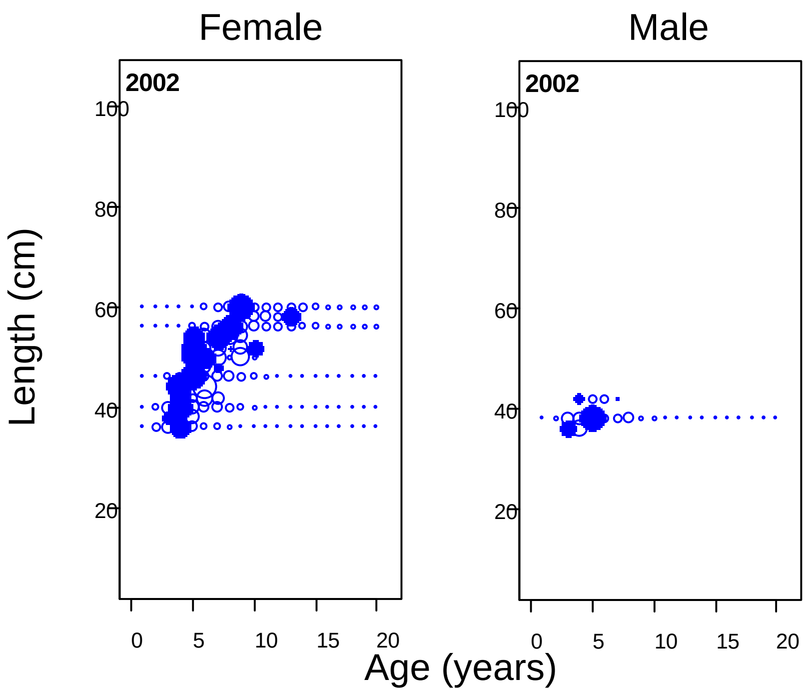

Figure 71. Pearson residual from fits to the sex-specific conditional age at length data for the SCS.

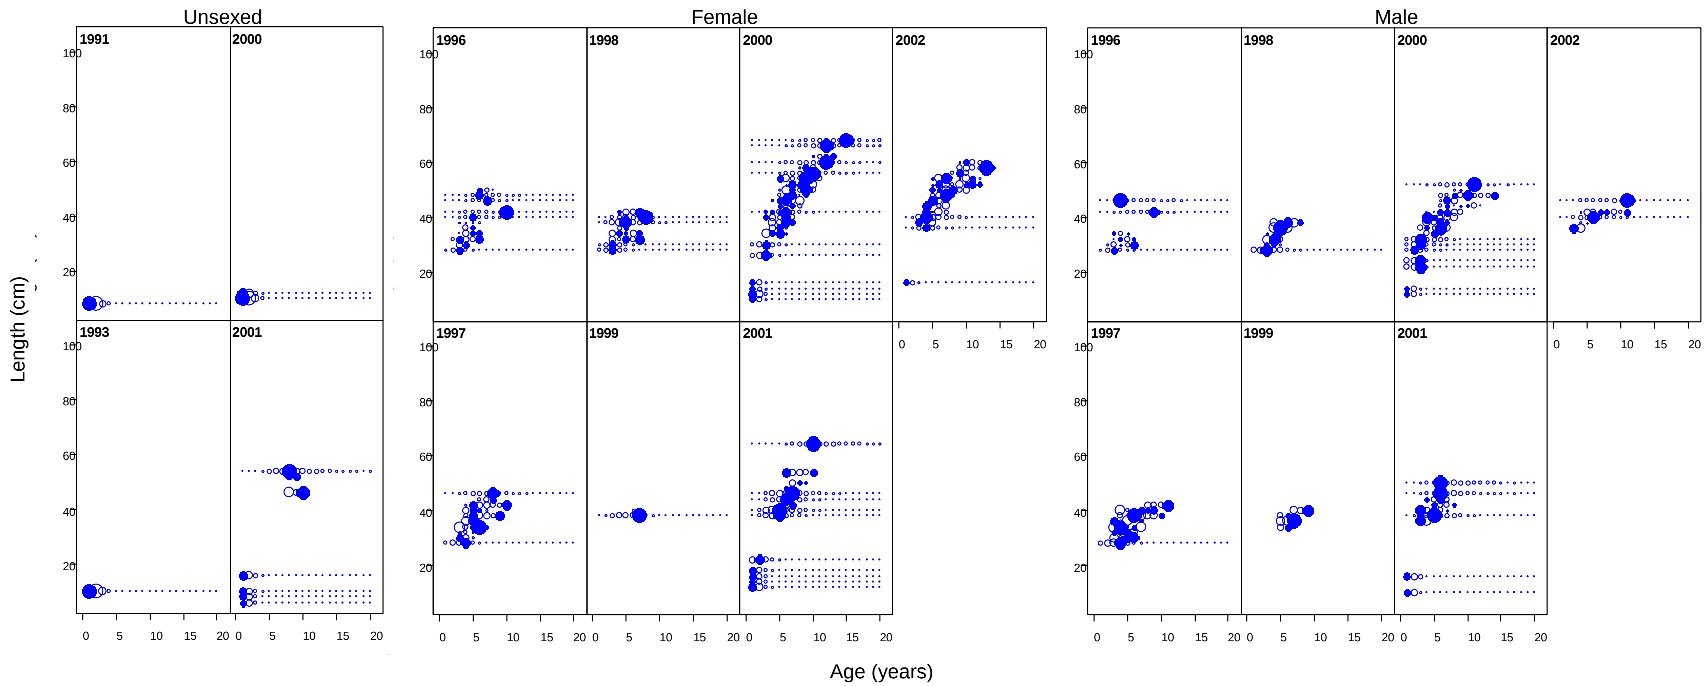

Figure 72. Pearson residual from fits to the unsexed and sexed conditional age at length data for the CAS.

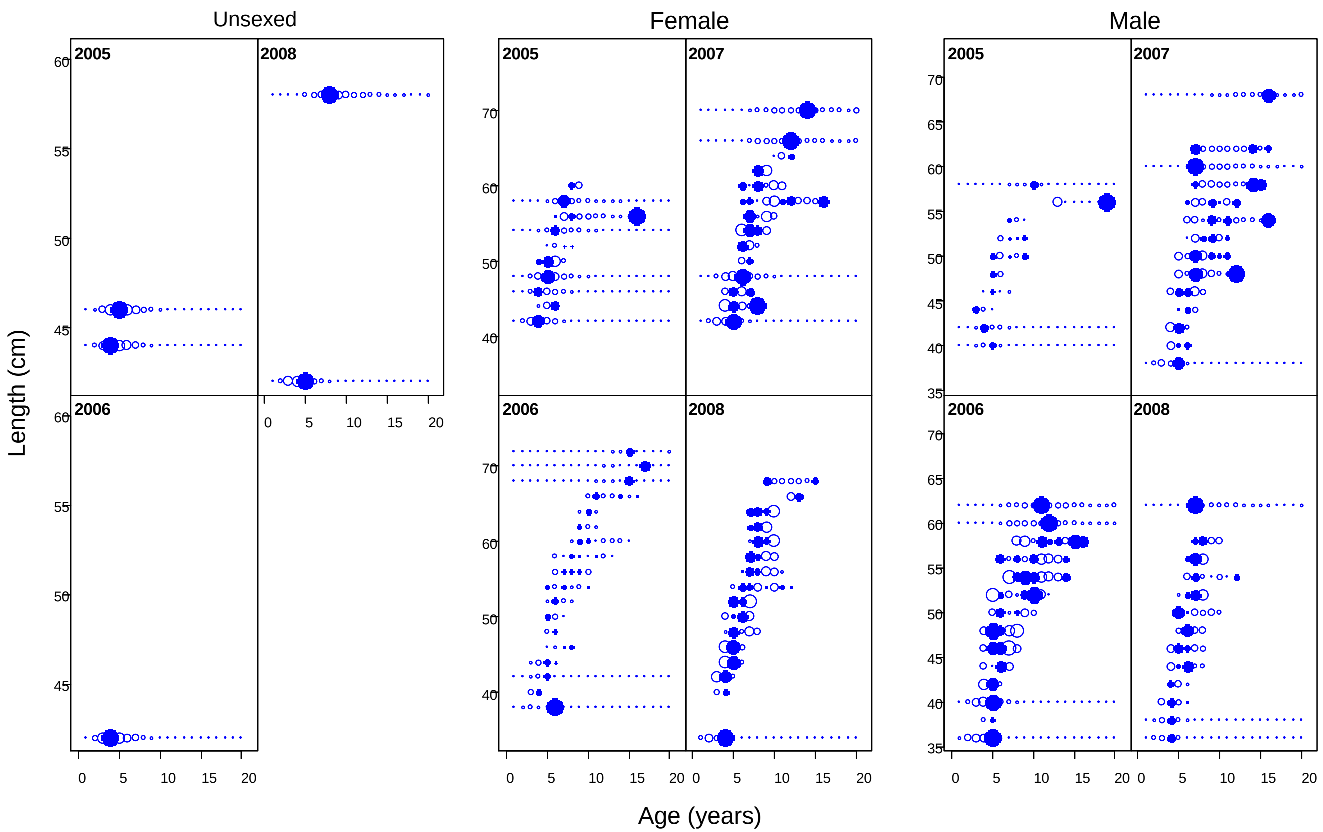

Figure 73. Pearson residual from fits to the unsexed and sexed conditional age at length data for the ORS.

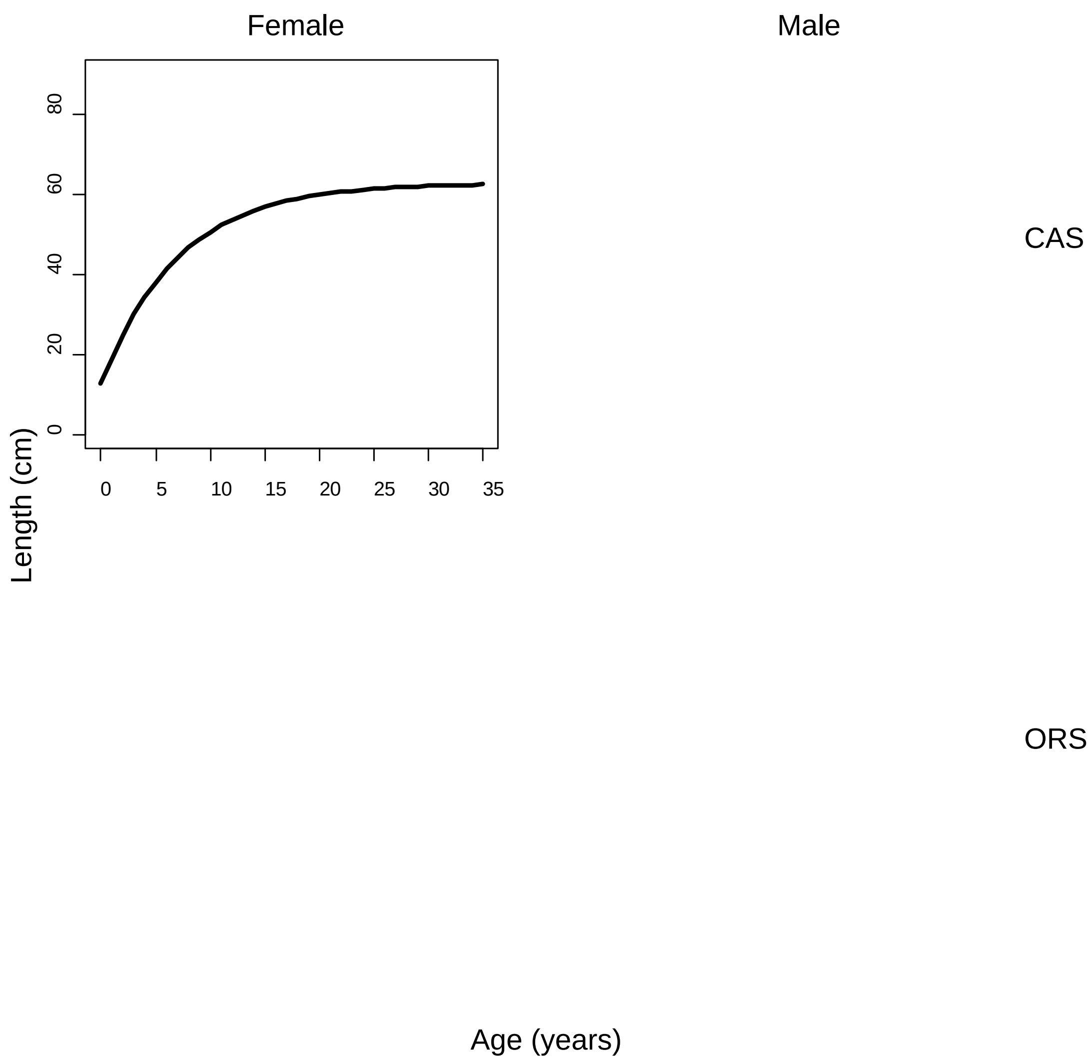

Figure 74. Comparison of growth curves from the assessment model estimates (black line) to externally fit growth curves (broken colored lines) for each sex (columns) and state sub-stock (rows).

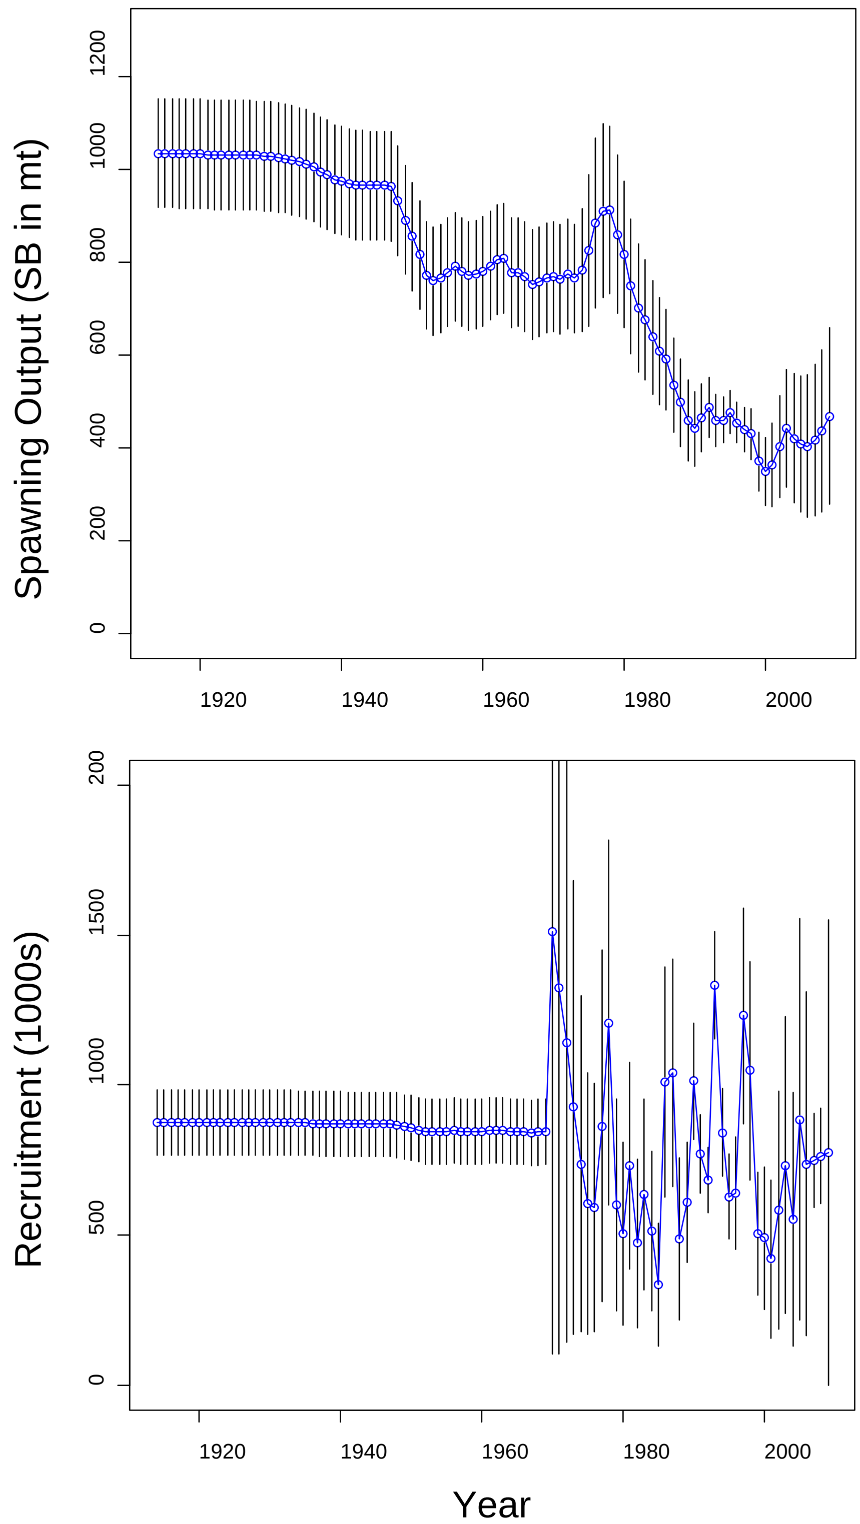

Figure 75. MPD time trajectories for spawning output (top panel) and recruitment trajectories (bottom panel) for the NCS. Vertical black lines are the asymptotic 95% confidence intervals.

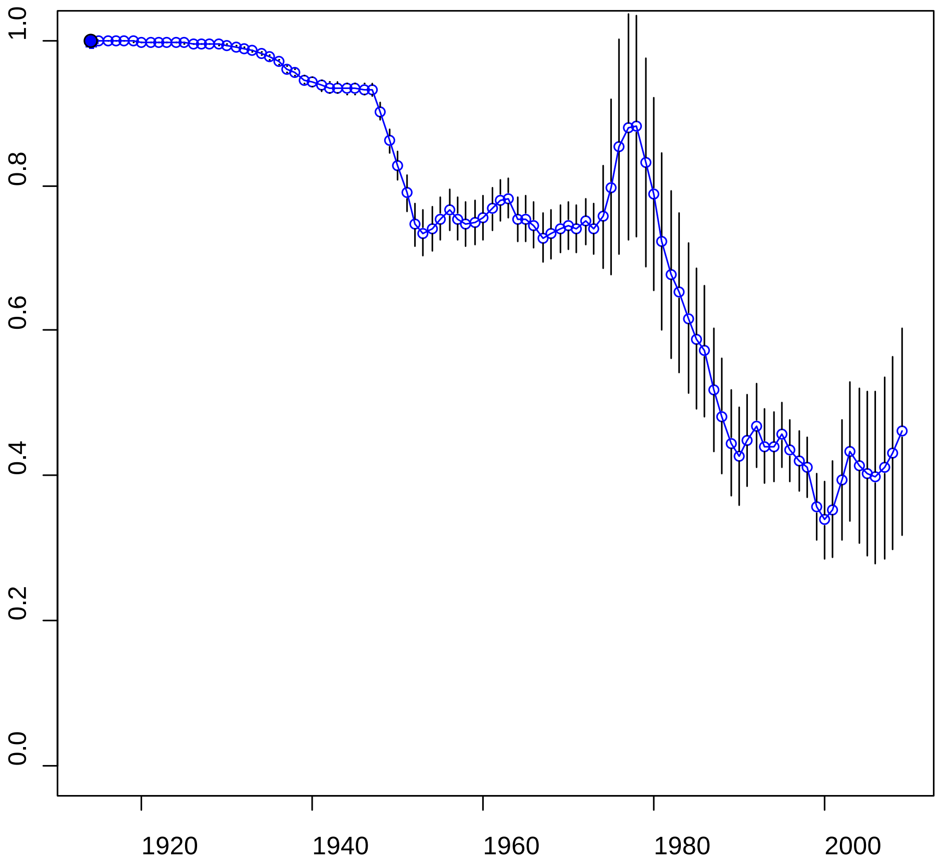

Figure 76. Time trajectories of depletion and spawning output compared to the target ($SB_{40\%}$) and limit reference ($SB_{25\%}$) points for the cabezon NCS.

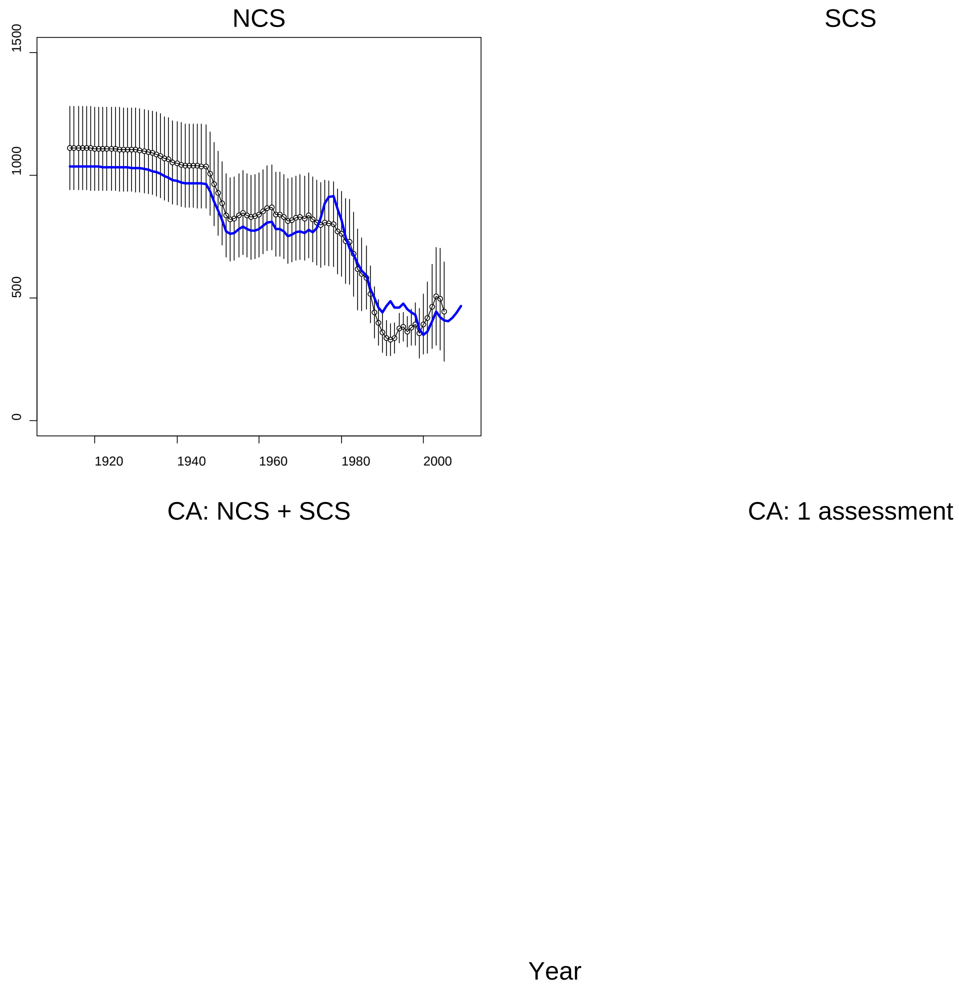

Figure 77. Time trajectories of spawning biomass of the 2005 assessment (black lines) compared to the current 2009 assessment (colored lines) for each sub-stock. Vertical lines are the 95% confidence intervals for the 2005 assessment.

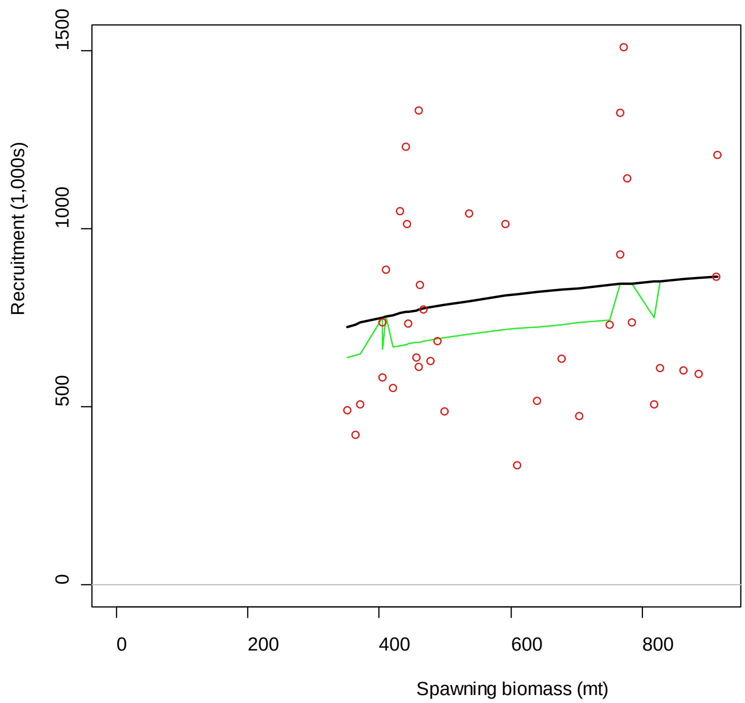

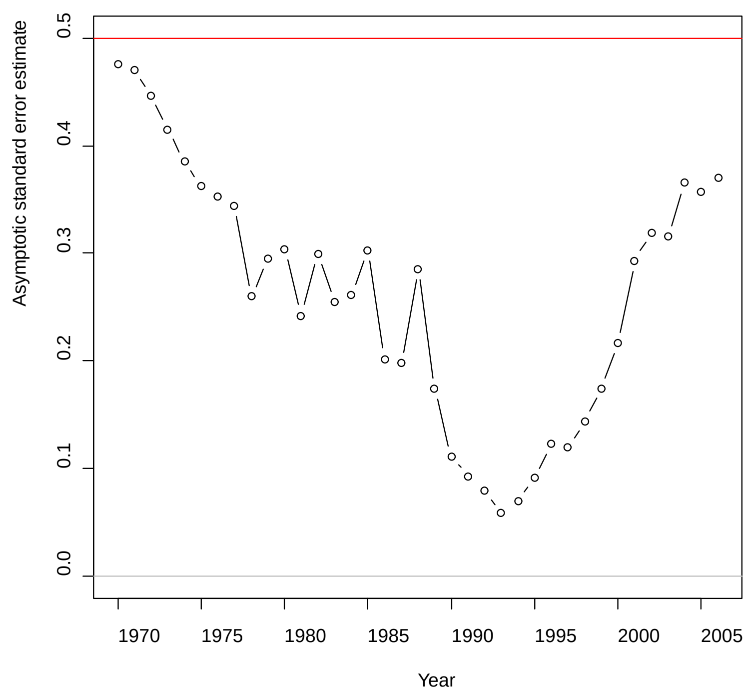

Figure 78. Spawner-recruit relationship (top panel) and the asymptotic standard deviations (bottom panel) for the NCS recruitment time series. Black line in top panel is the expected mean recruits; green line in same panel is the bias-adjusted expected recruits.

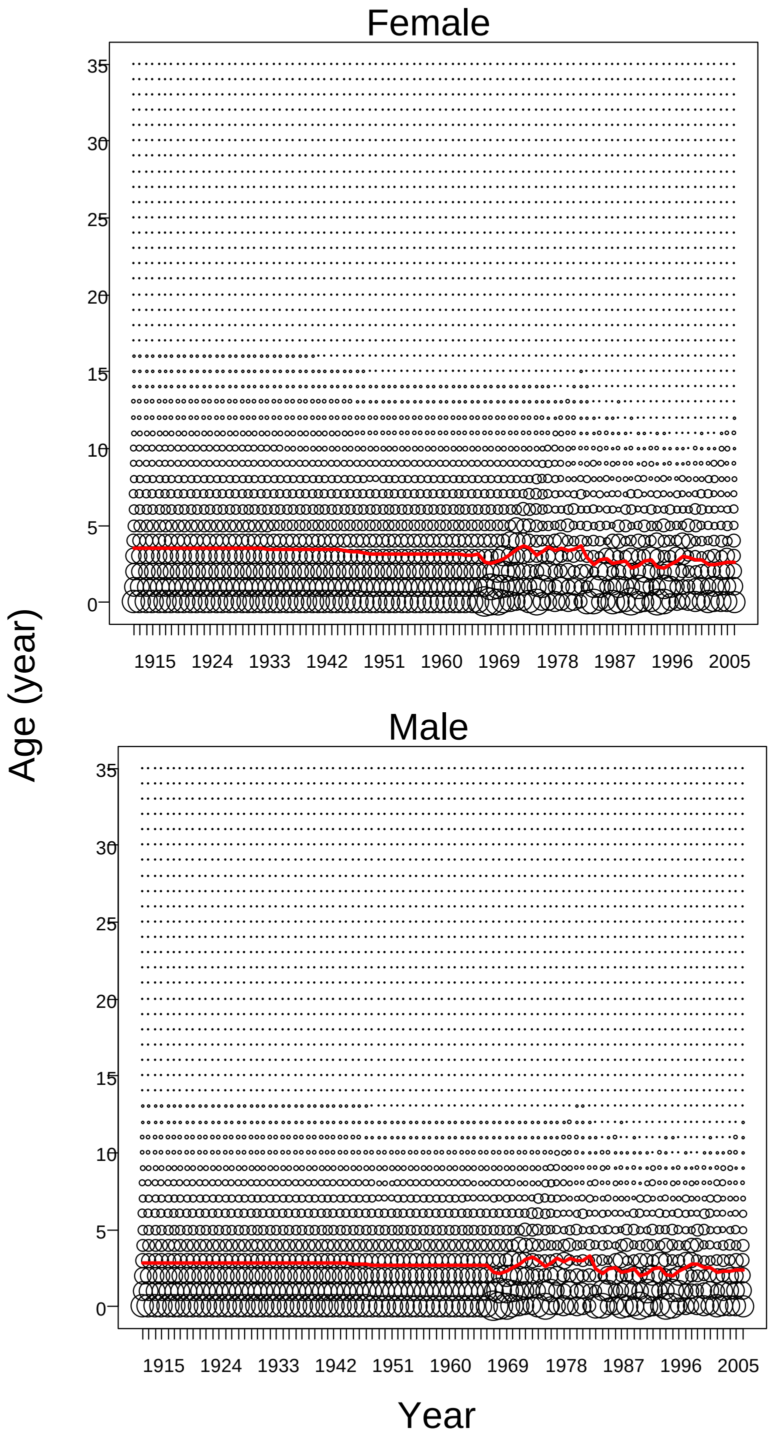

Figure 79. Numbers at age for females (top panel) and males (bottom panel) in the NCS. Red line shows the mean age by year.

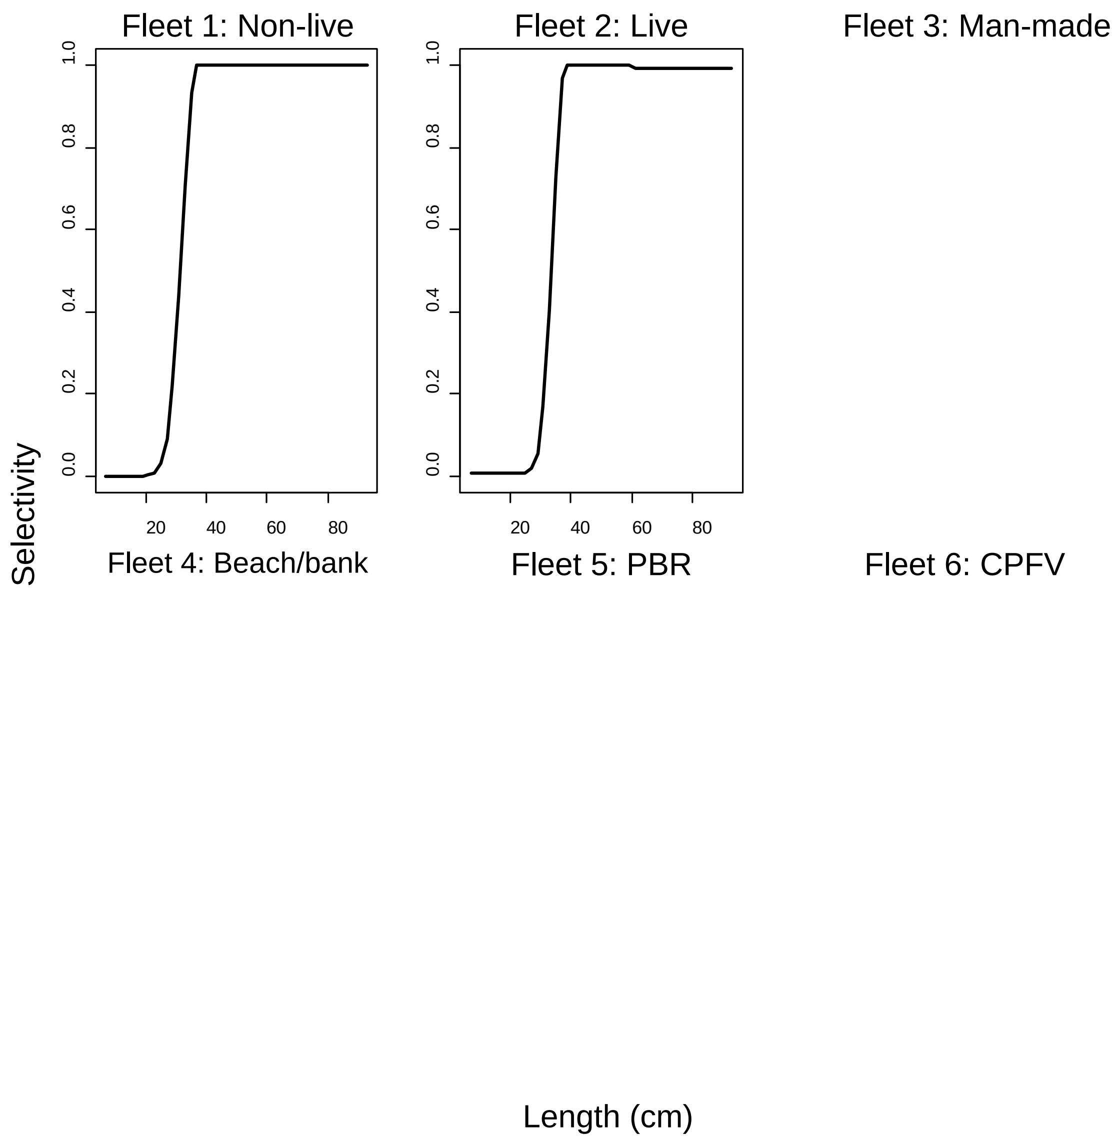

Figure 80. Selectivity at length for female and male cabezon by fishery fleet for the NCS. Black solid lines start selectivity in year 1916; blue broken lines start selectivity in year 1999 (fleet 2) and year 2000 (fleets 5 and 6); red dotted lines start selectivity in 2005.

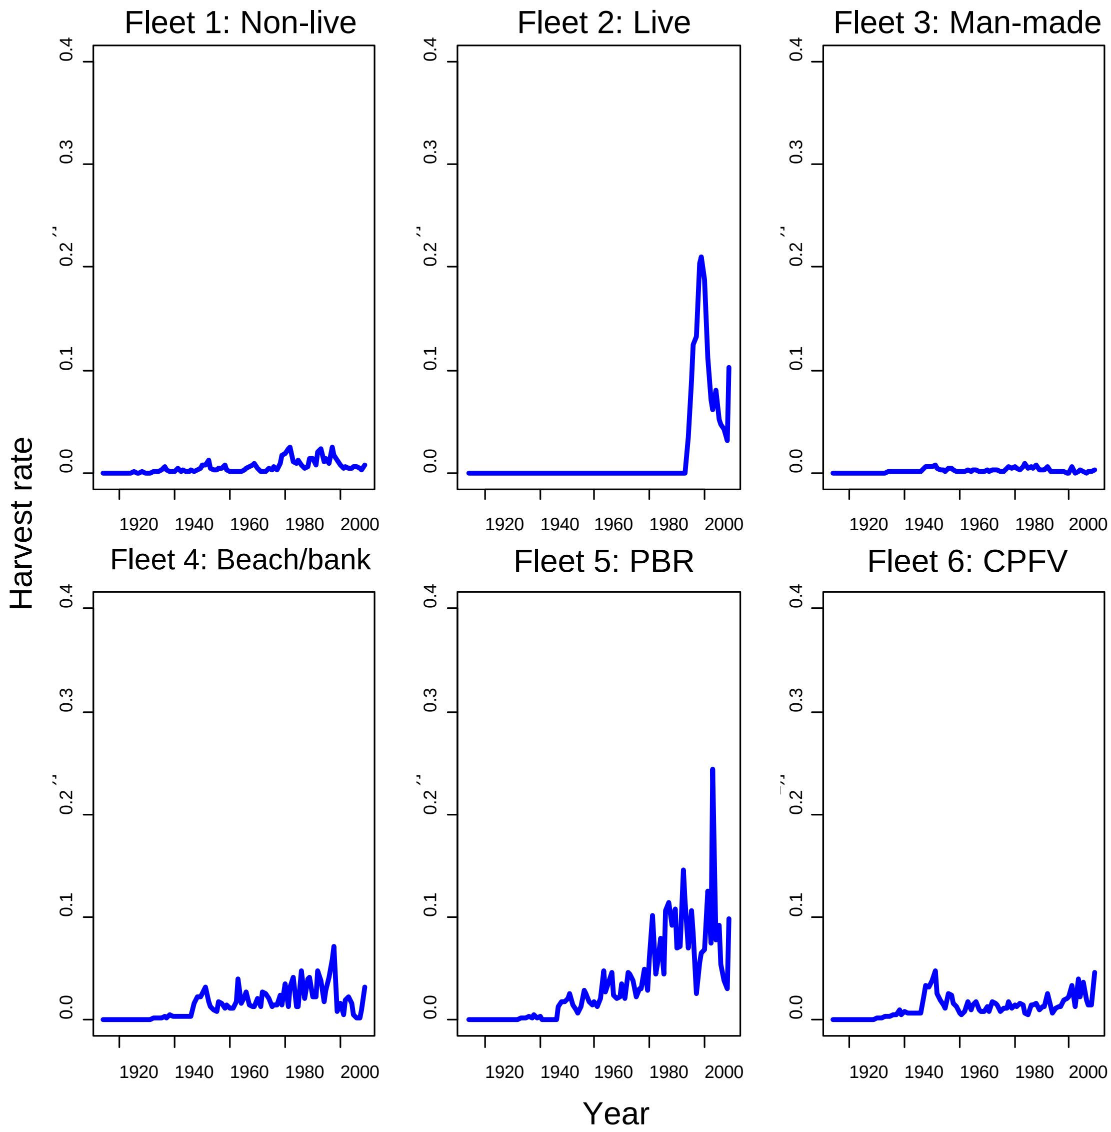

Figure 81. Time series of harvest rates by fishery fleet for the NCS.

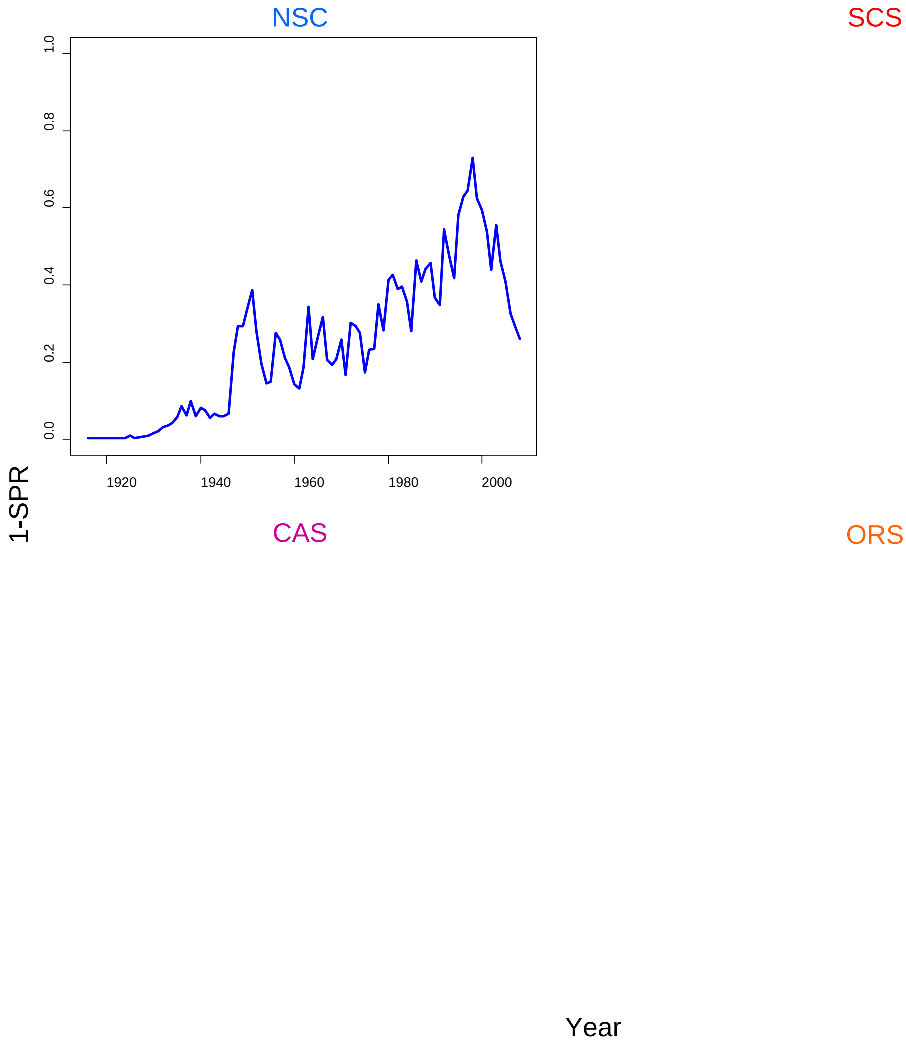

Figure 82. Estimate of the spawning potential ratio (1-SPR) from each of the sub-stock base case models. Values above the red overfishing line indicate fishing above the MSY proxy harvest rate.

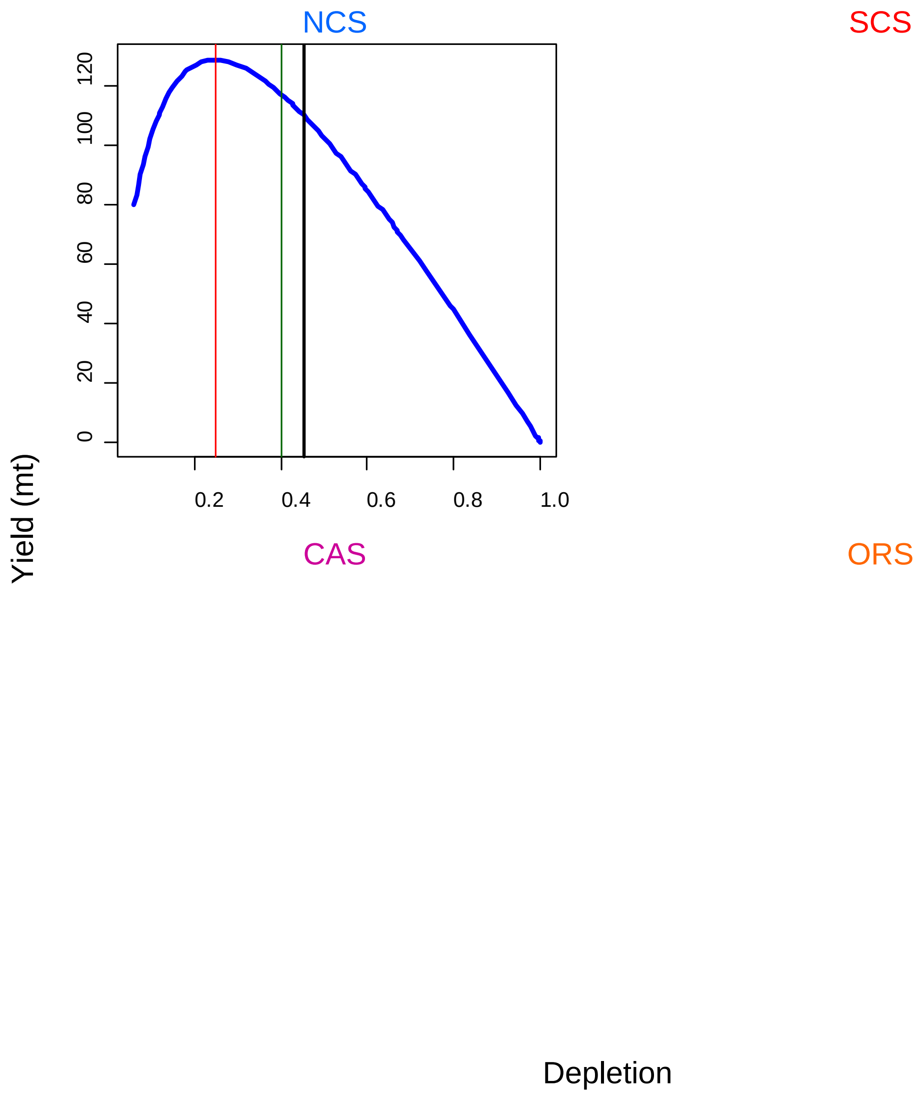

Figure 83. Equilibrium yield curves for each sub-stock base case model. Reference points and current stock status are indicated by the vertical lines.

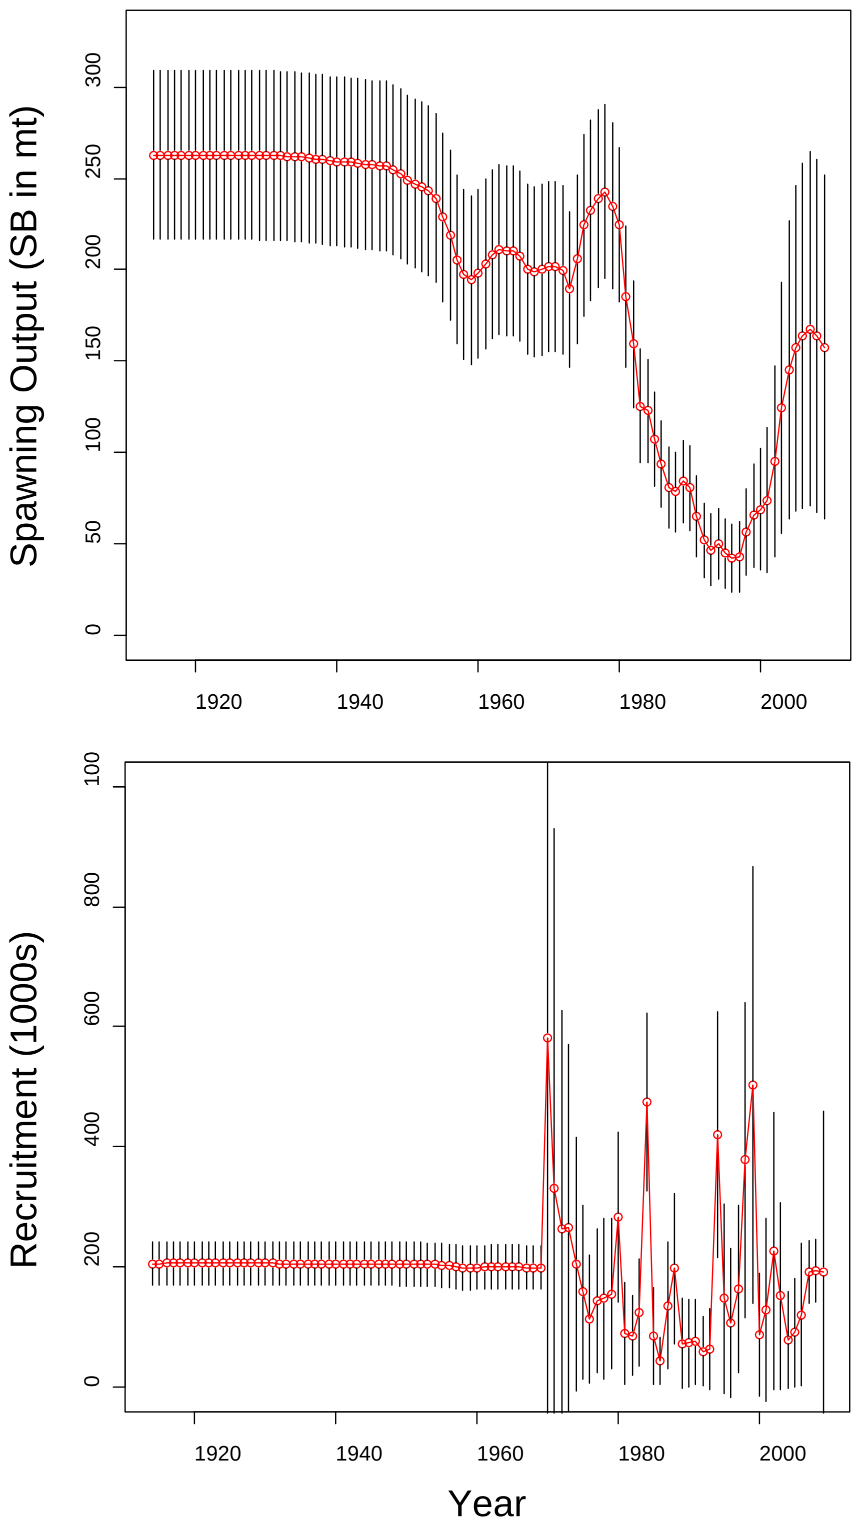

Figure 84. MPD time trajectories for spawning output (top panel) and recruitment trajectories (bottom panel) for the SCS. Vertical black lines are the asymptotic 95% confidence intervals.

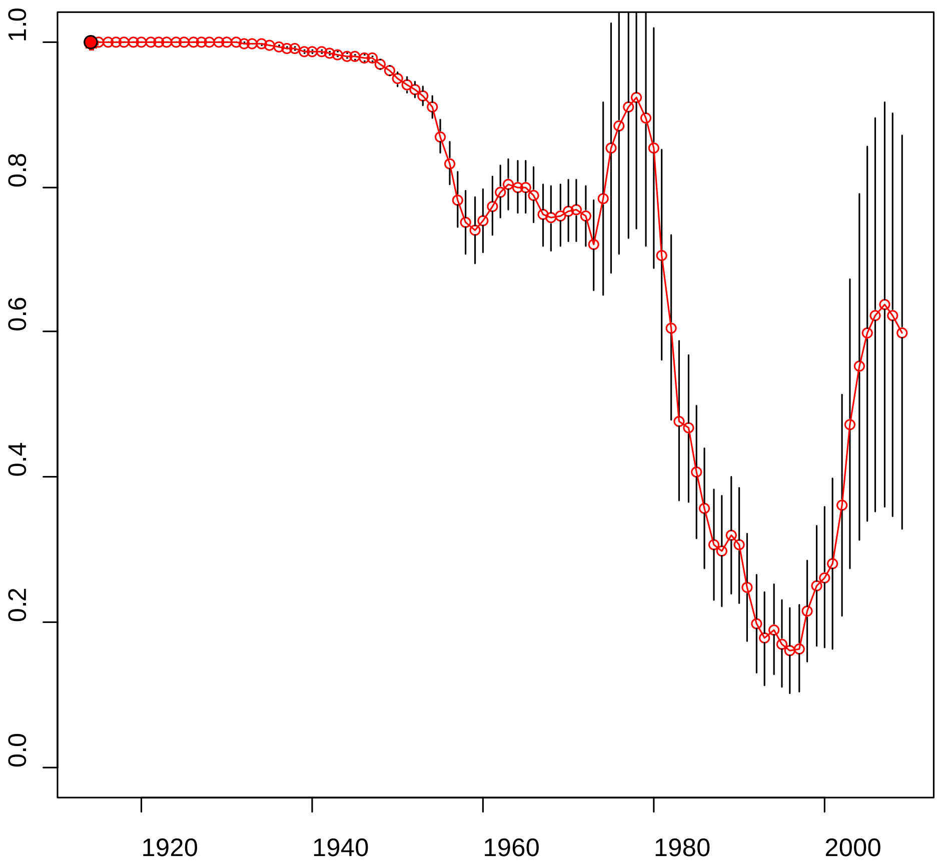

Figure 85. Time trajectories of depletion and spawning output compared to the target ($SB_{40\%}$) and limit reference ($SB_{25\%}$) points for the cabezon SCS.

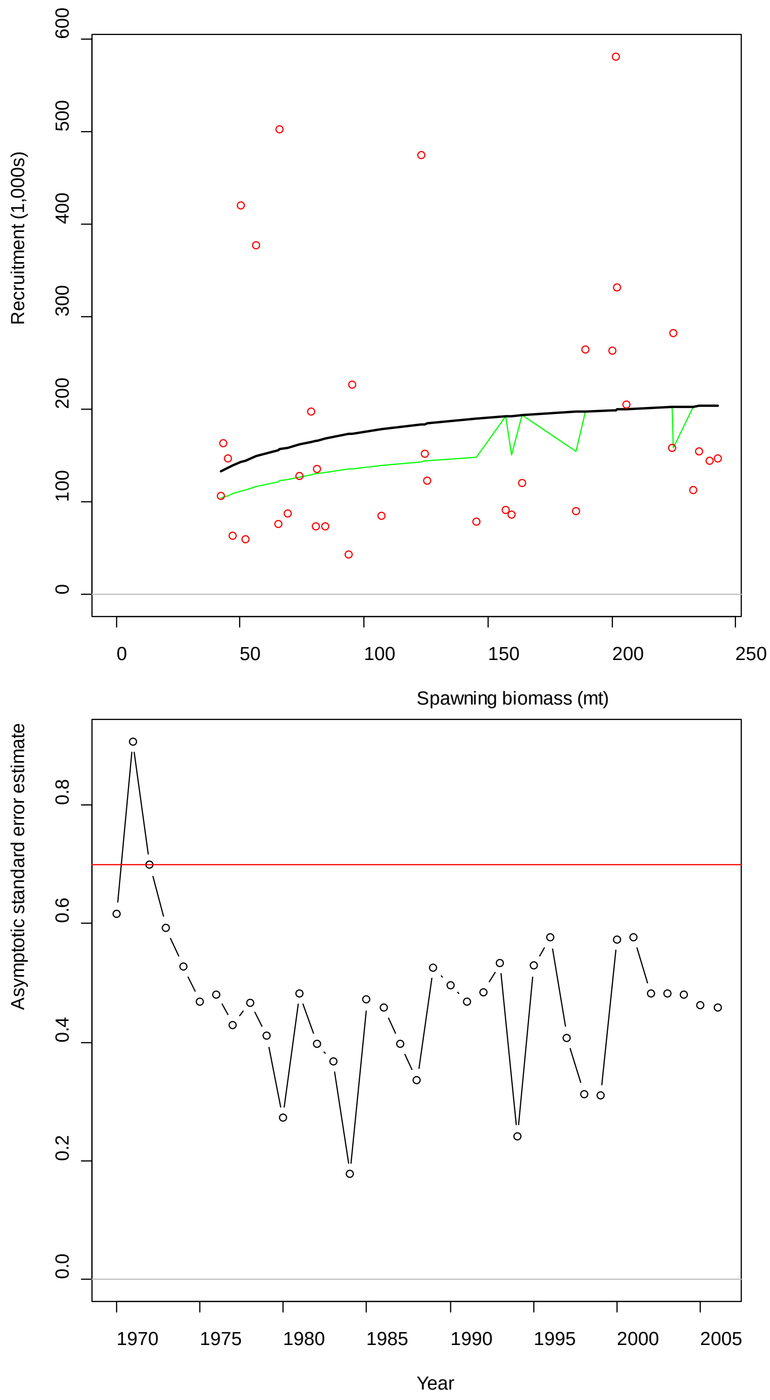

Figure 86. Spawner-recruit relationship (top panel) and the asymptotic standard deviations (bottom panel) for the SCS recruitment time series. Black line in top panel is the expected mean recruits; green line in same panel is the bias-adjusted expected recruits.

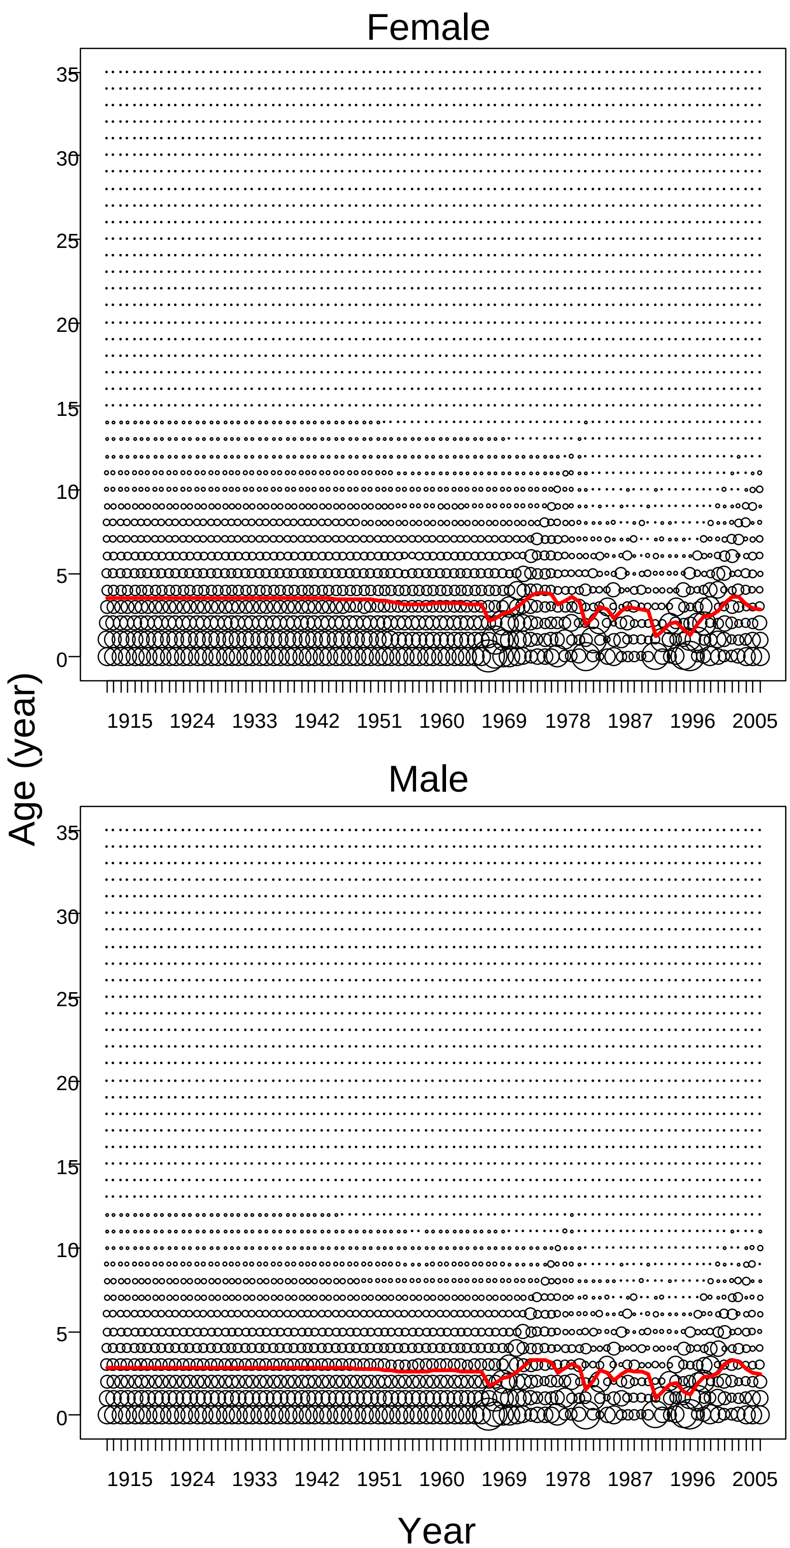

Figure 87. Numbers at age for females (top panel) and males (bottom panel) in the SCS. Red line shows the mean age by year.

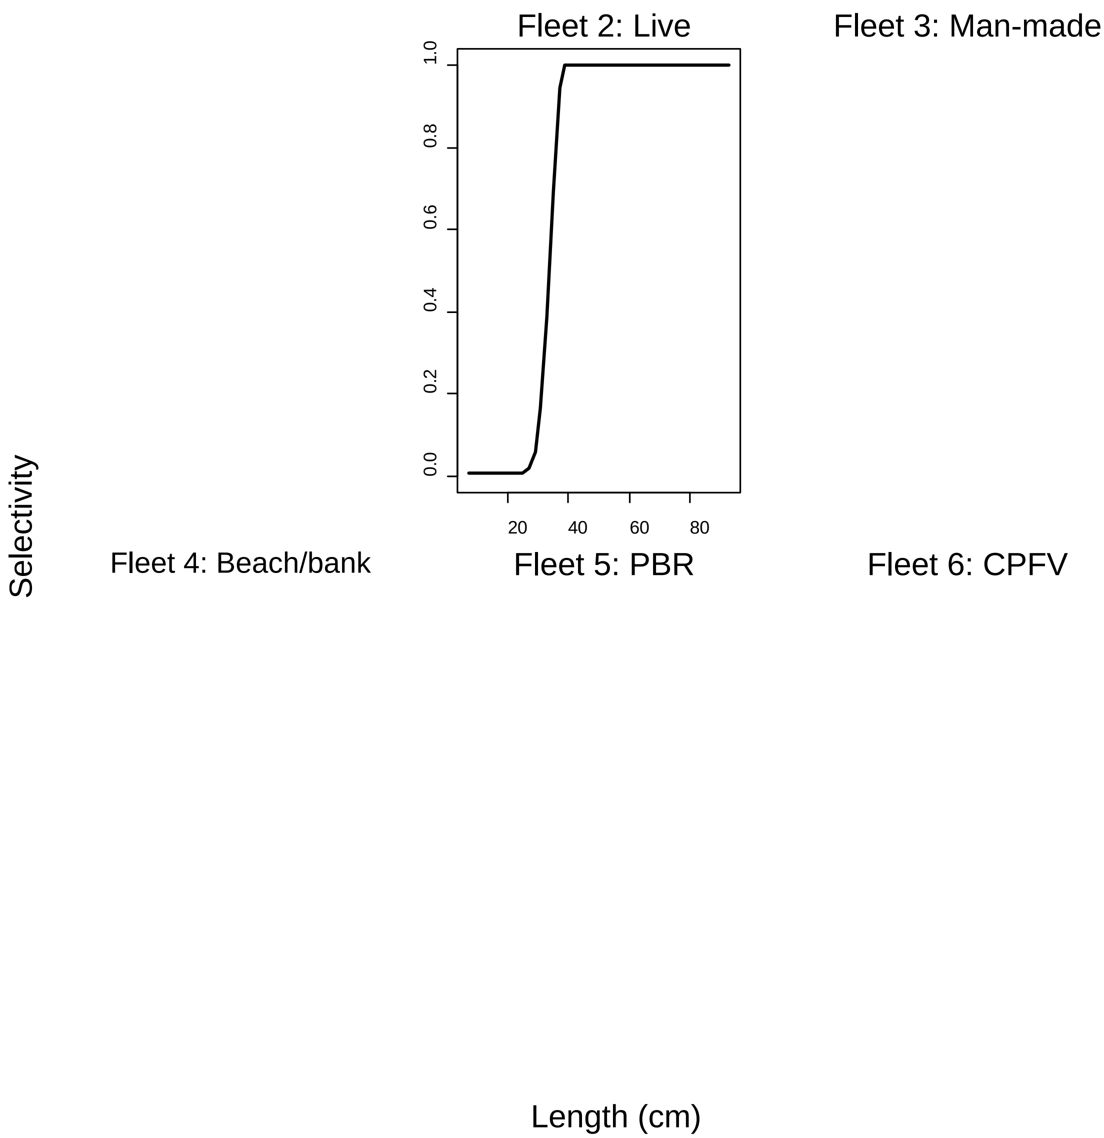

Figure 88. Selectivity at length for female and male cabezon by fishery fleet for the SCS. Black solid lines start selectivity in year 1916; blue broken lines start selectivity in year 1999 (fleet 2) and year 2000 (fleets 5 and 6). There is no length information for the non-live fishery in SCS (not included here).

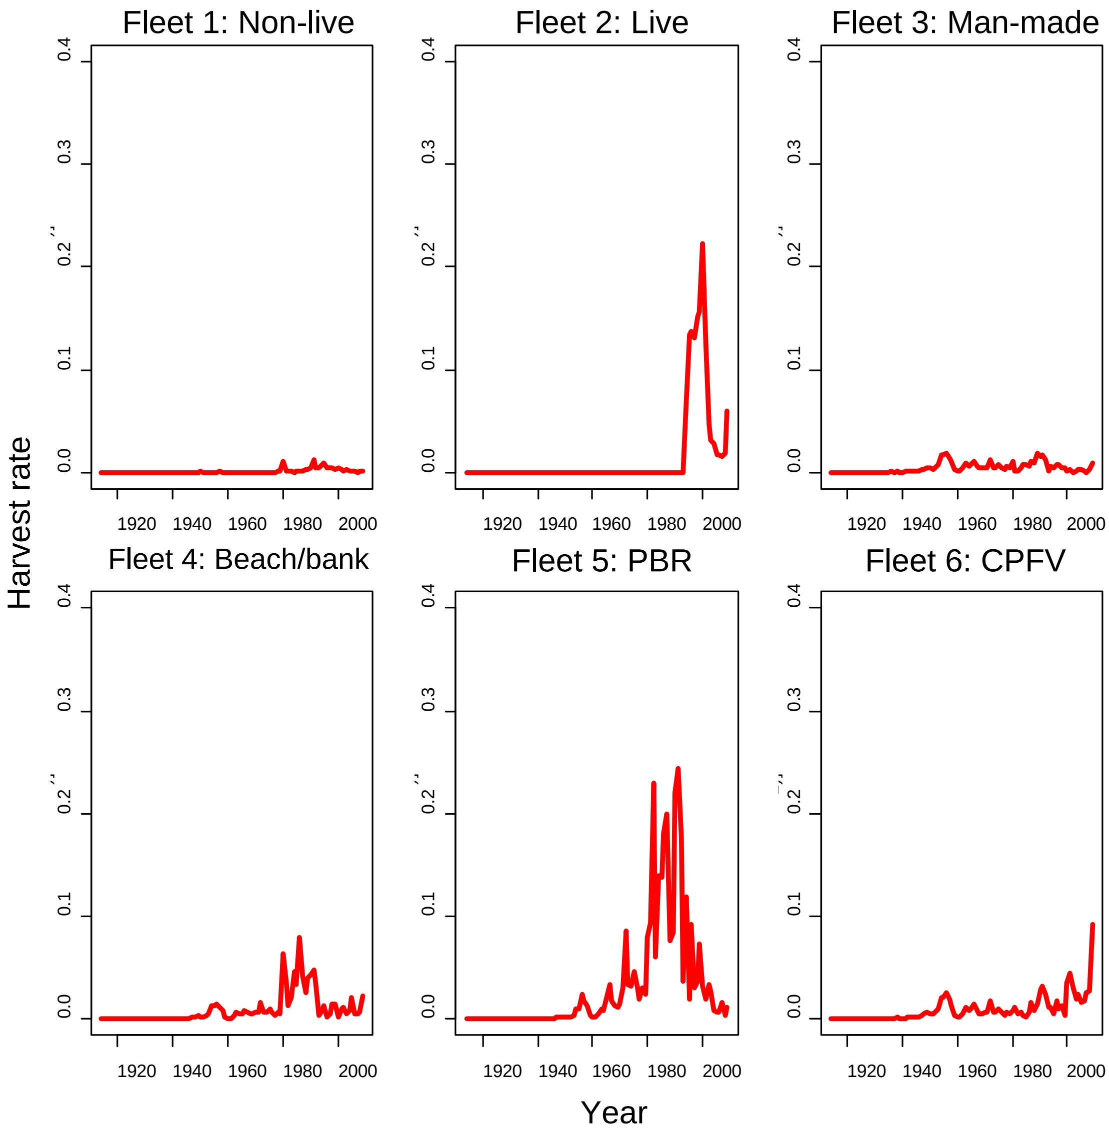

Figure 89. Time series of harvest rates by fishery fleet for the SCS.

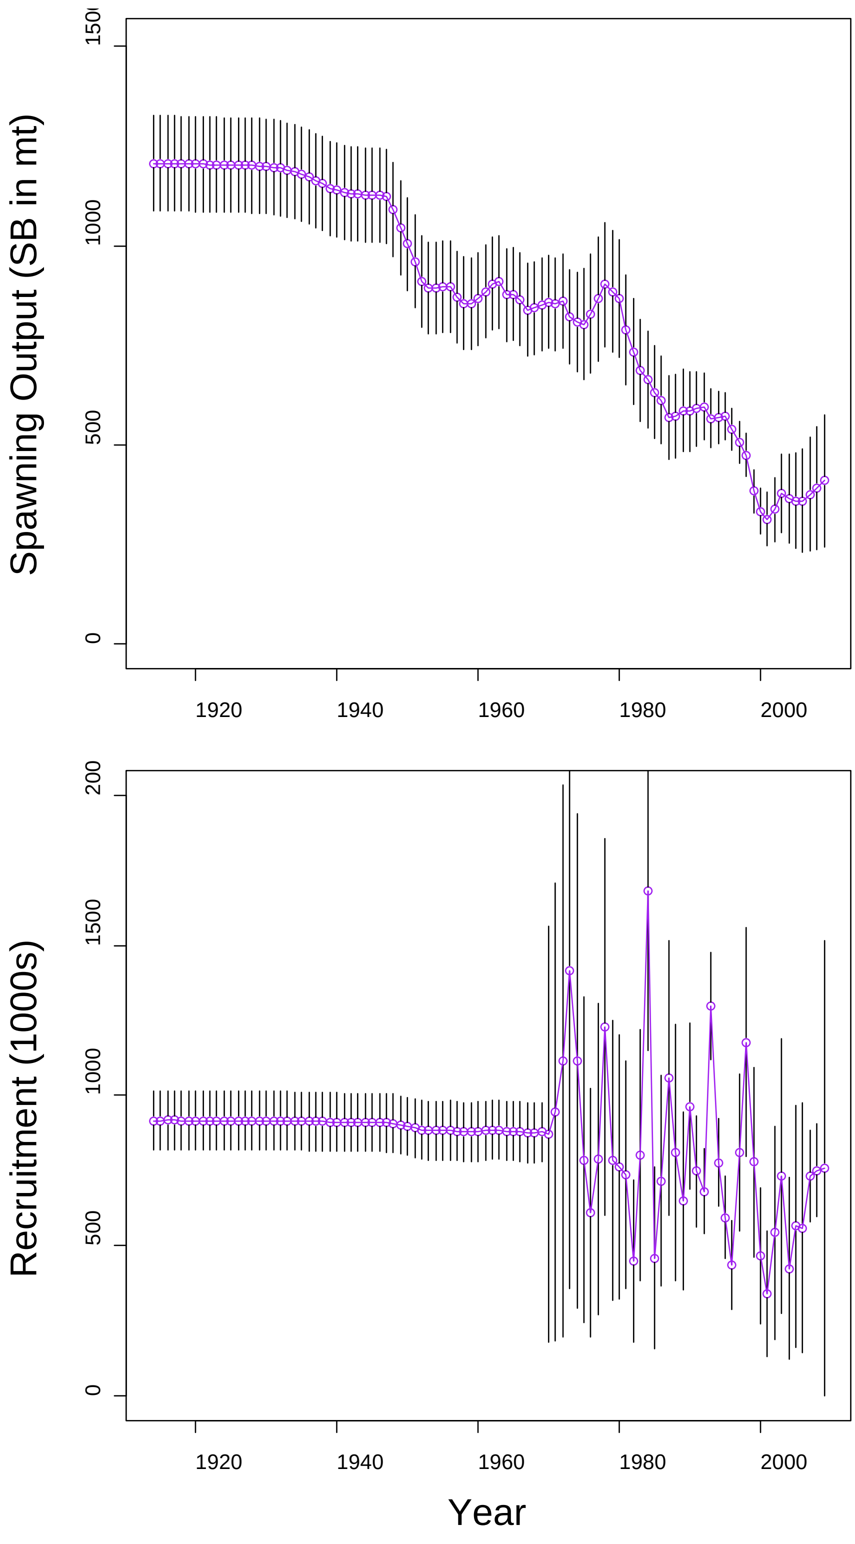

Figure 90. MPD time trajectories for spawning output (top panel) and recruitment trajectories (bottom panel) for the CAS. Vertical black lines are the asymptotic 95% confidence intervals.

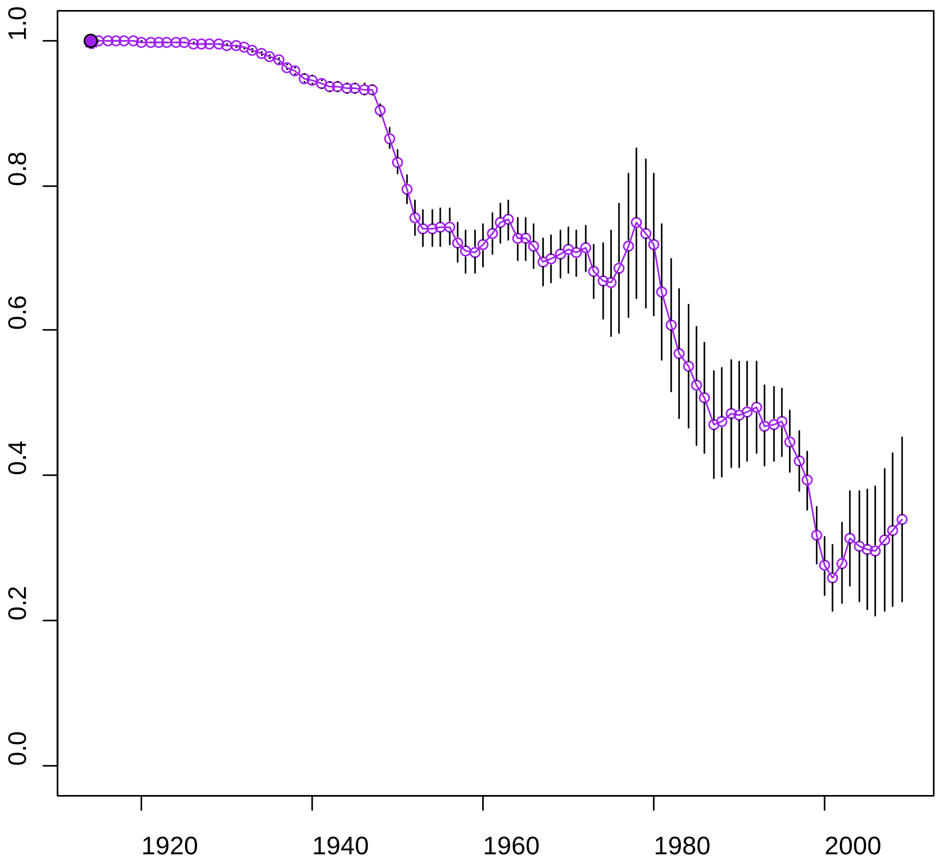

Figure 91. Time trajectories of depletion and spawning output compared to the target ($SB_{40\%}$) and limit reference ($SB_{25\%}$) points for the cabezon CAS.

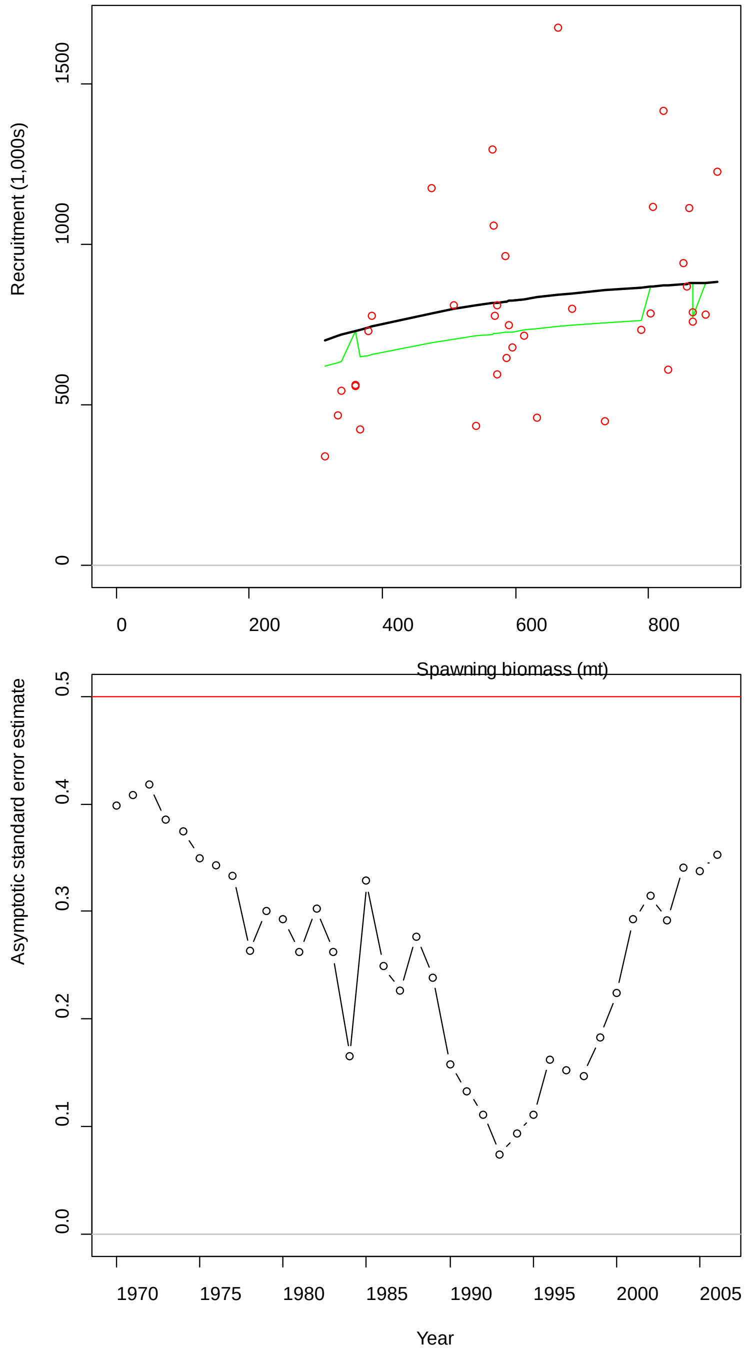

Figure 92. Spawner-recruit relationship (top panel) and the asymptotic standard deviations (bottom panel) for the CAS recruitment time series. Black line in top panel is the expected mean recruits; green line in same panel is the bias-adjusted expected recruits.

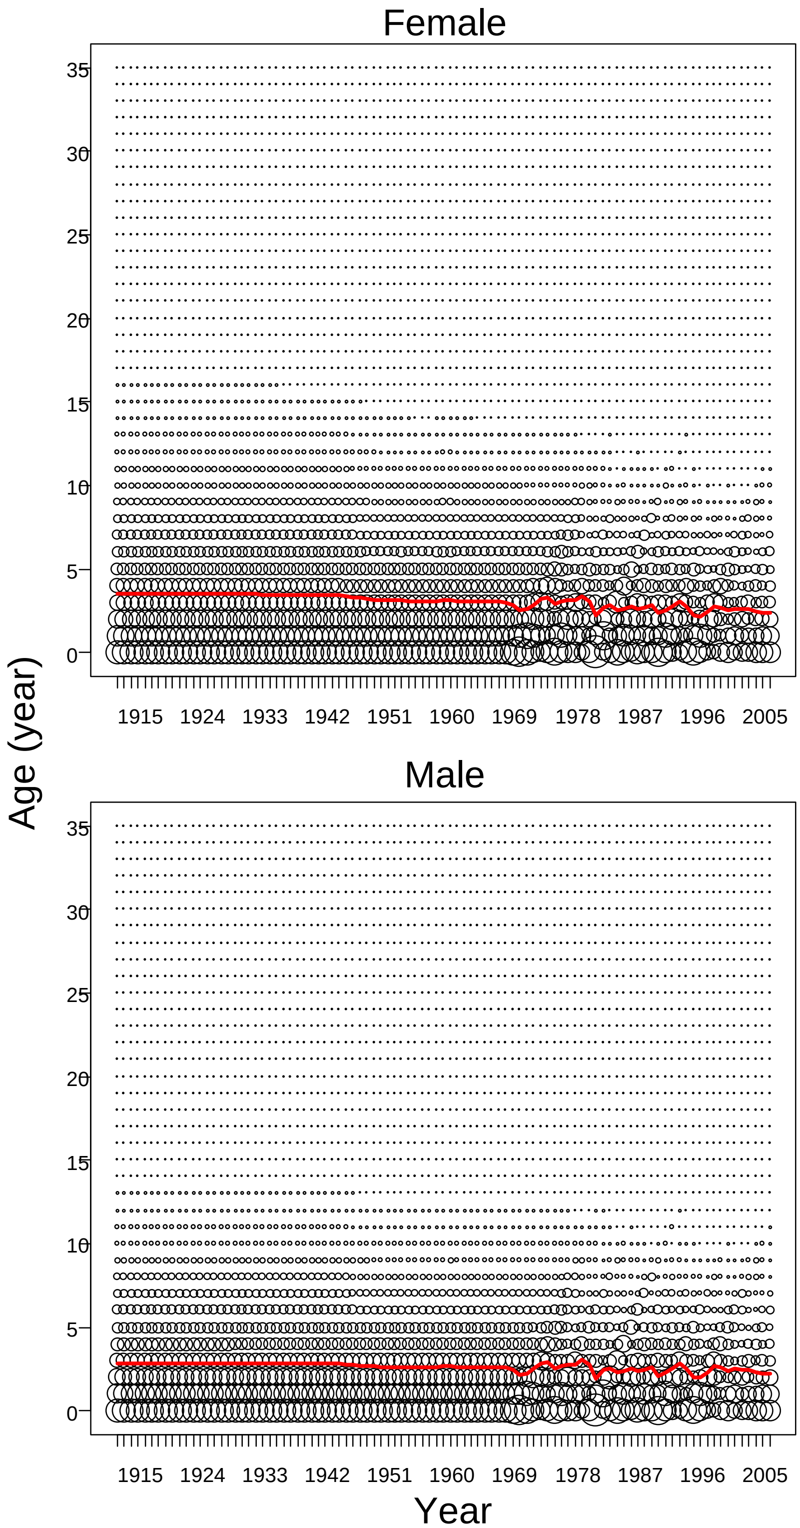

Figure 93. Numbers at age for females (top panel) and males (bottom panel) in the CAS. Red line shows the mean age by year.

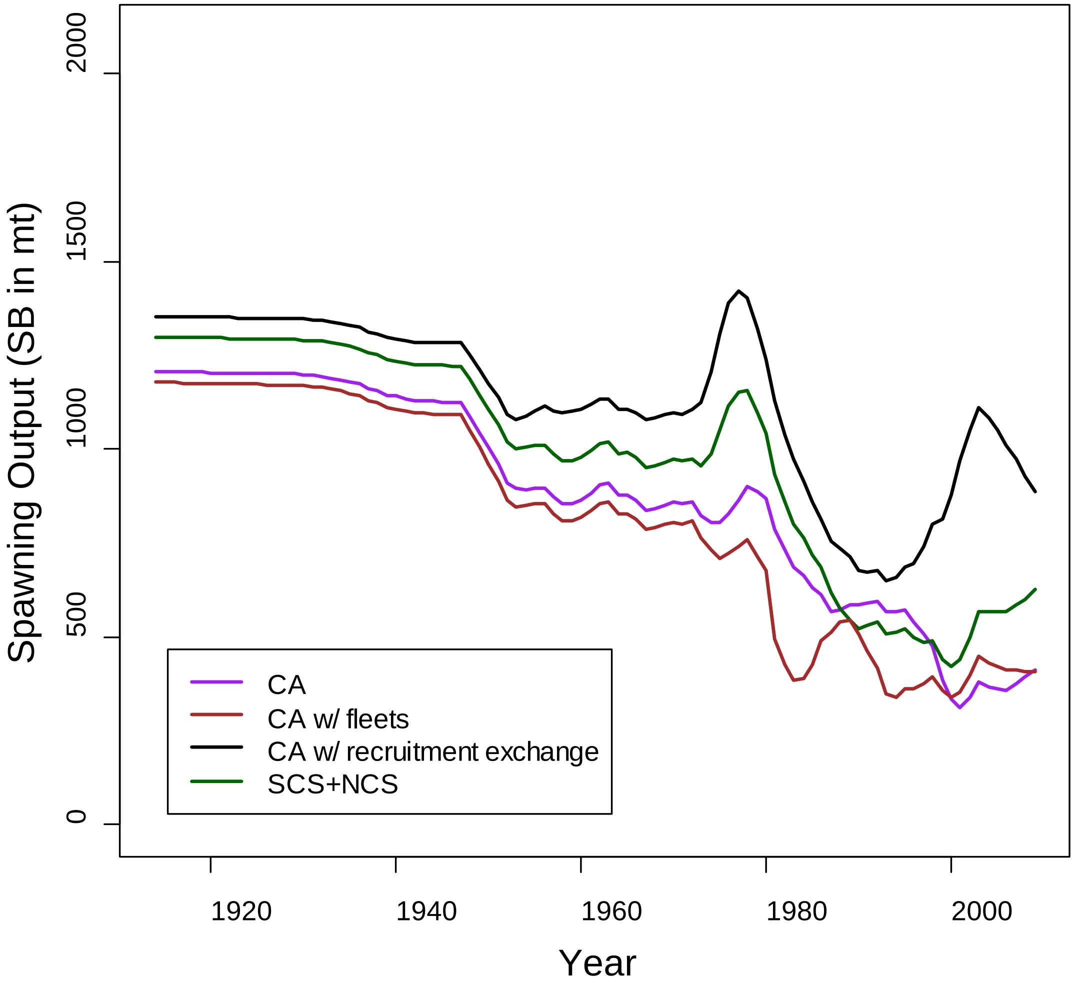

Figure 94. Comparison of spawning output trajectories for four realizations of a state-wide California cabezon sub-stock assessment.

Figure 95. Comparison of recruitment deviations between the NCS and SCS base cases (top left panel), all California sub-stock base cases (top right panel), and CAS and CAS ('+fleets') specified with separate NCS and SCS fleets.

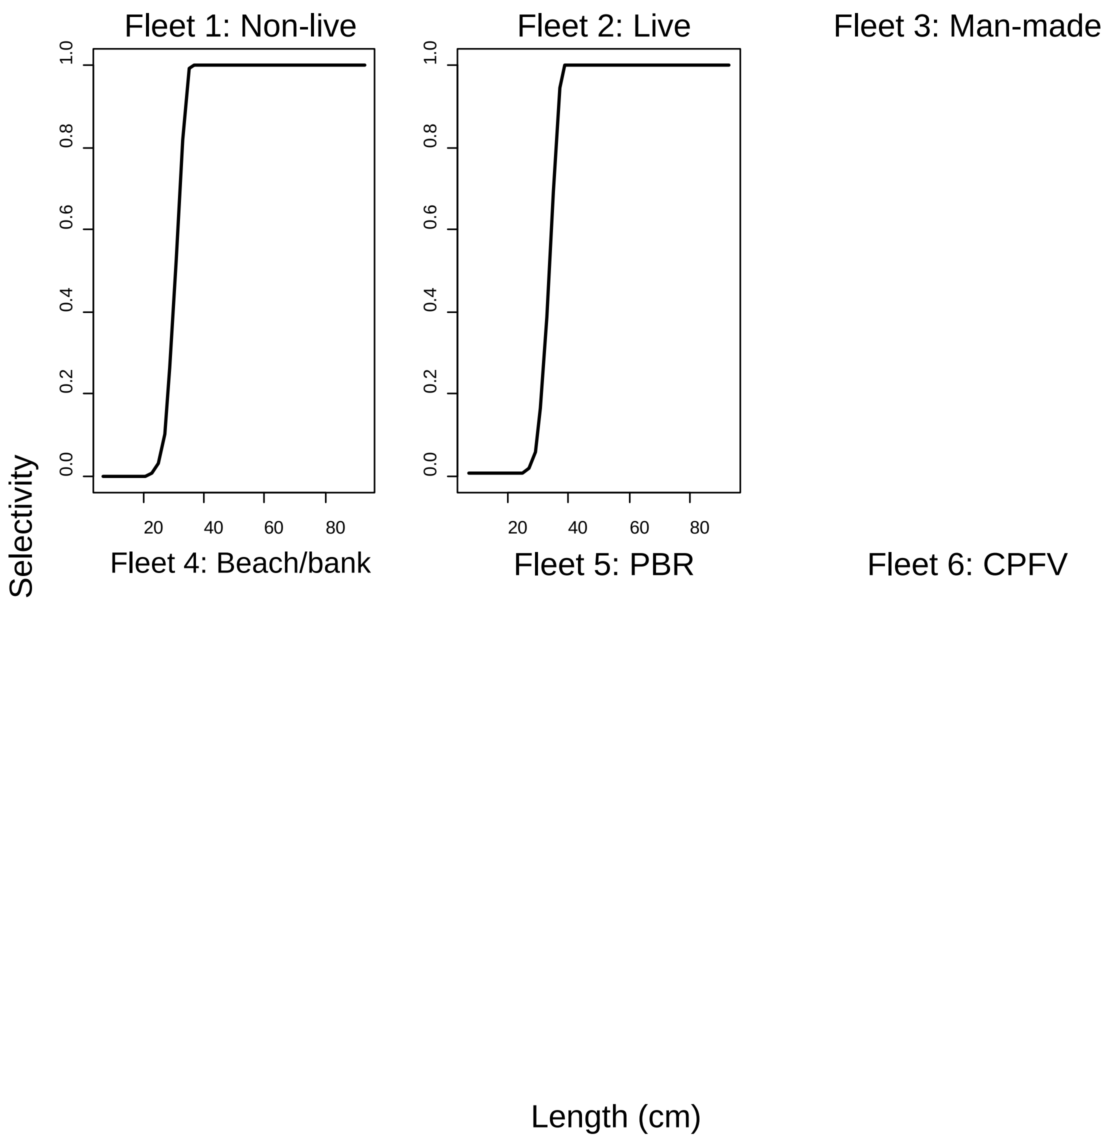

Figure 96. Selectivity at length for female and male cabezon by fishery fleet for the CAS. Black solid lines start selectivity in year 1916; blue broken lines start selectivity in year 1999 (fleet 2) and year 2000 (fleets 5 and 6); red dotted lines start selectivity in 2005.

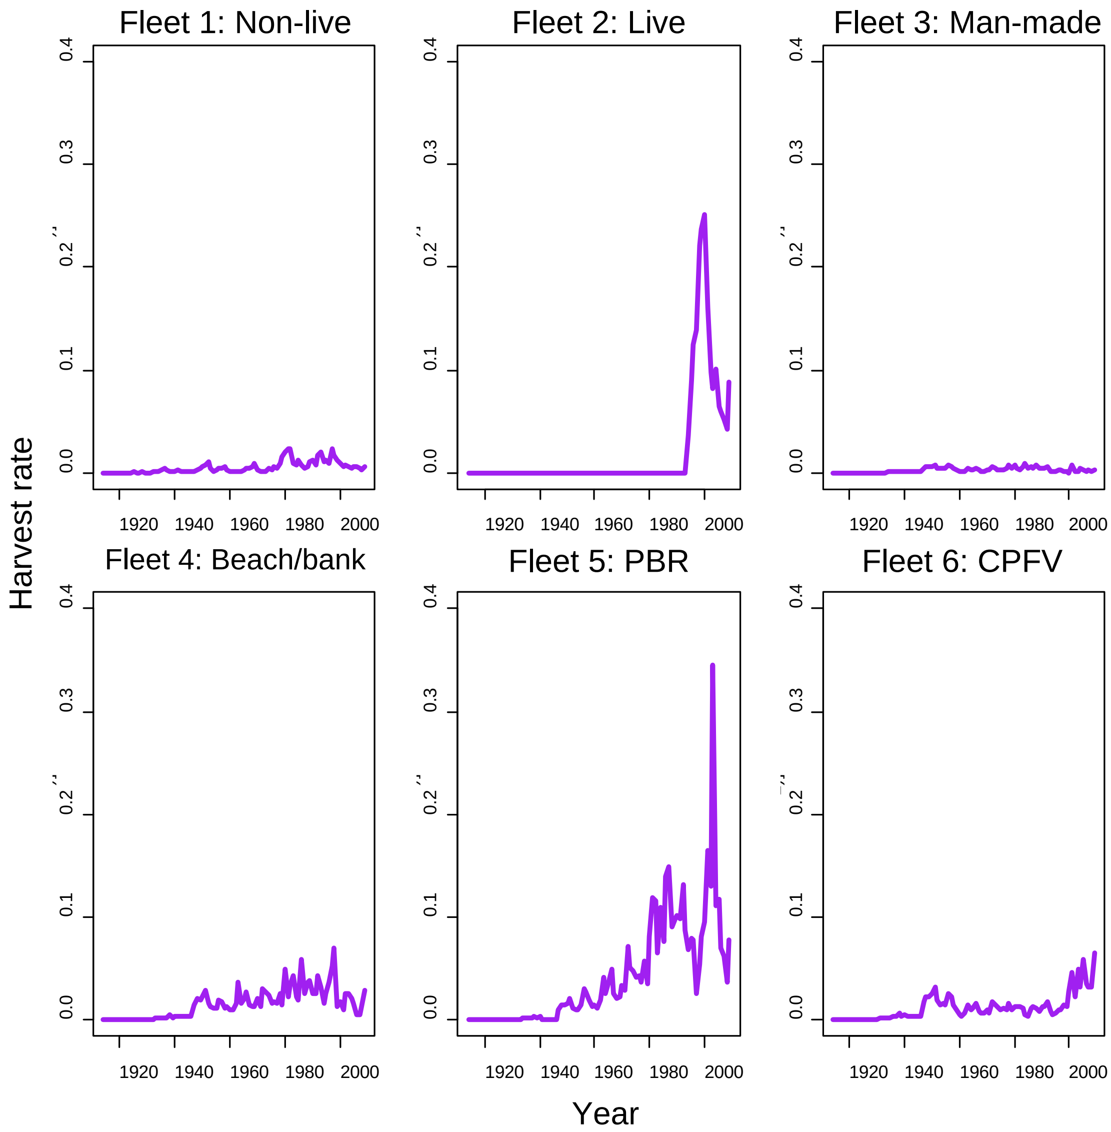

Figure 97. Time series of harvest rates by fishery fleet for the CAS.

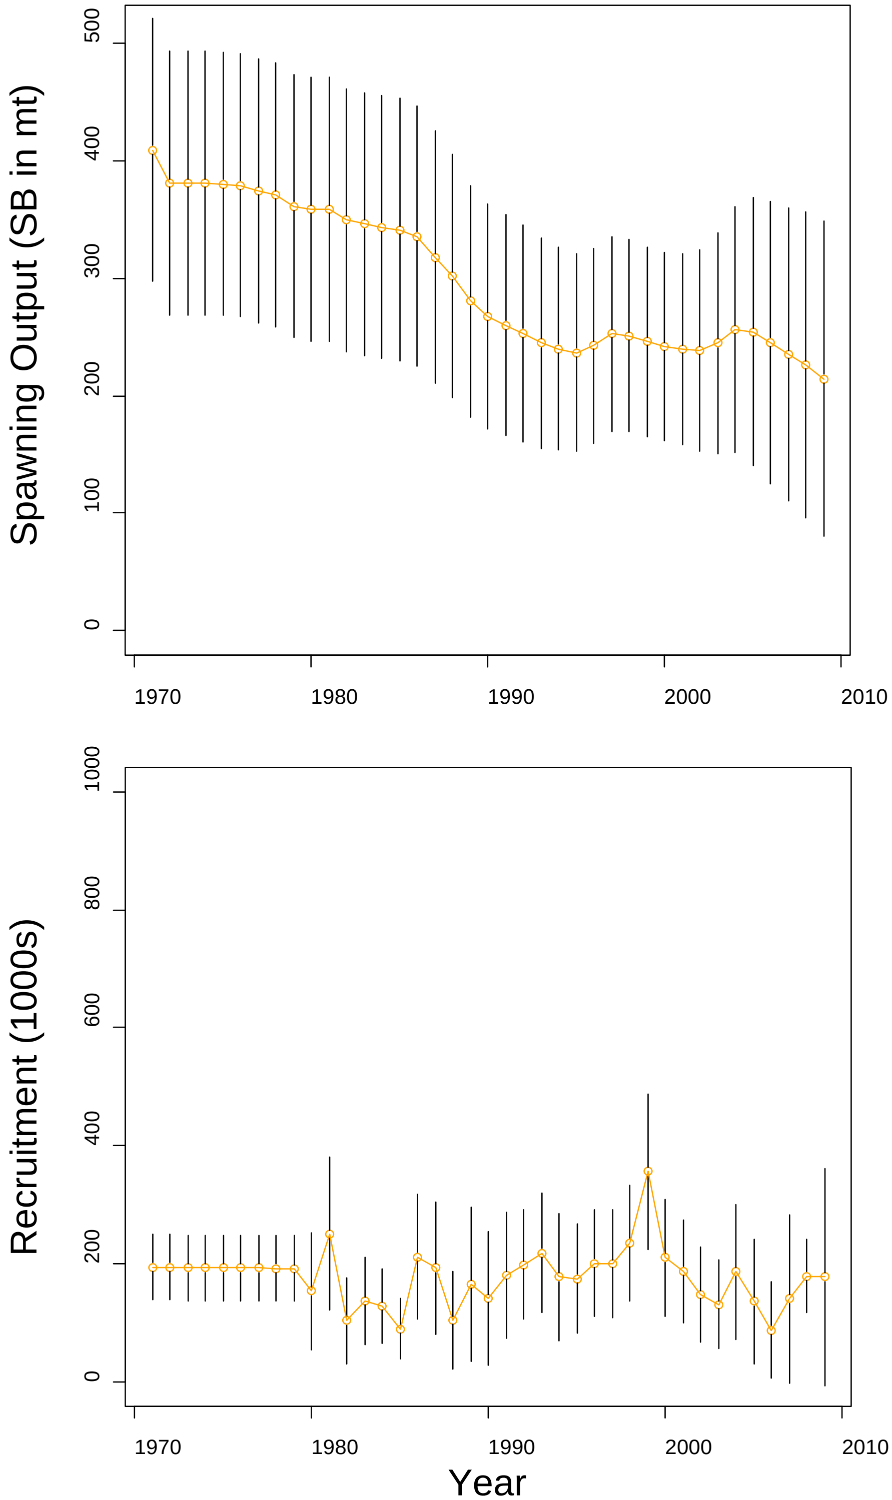

Figure 98. MPD time trajectories for spawning output (top panel) and recruitment trajectories (bottom panel) for the ORS. Vertical black lines are the asymptotic 95% confidence intervals.

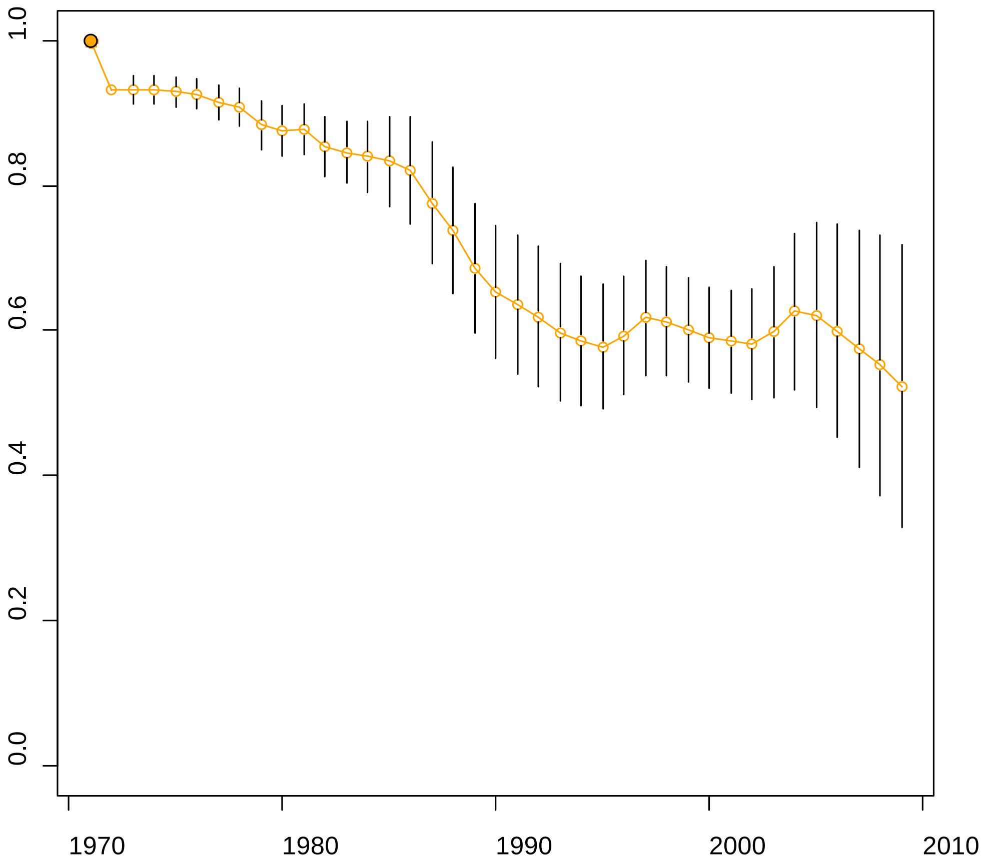

Figure 99. Time trajectories of depletion and spawning output compared to the target ($SB_{40\%}$) and limit reference ($SB_{25\%}$) points for the cabezon ORS.

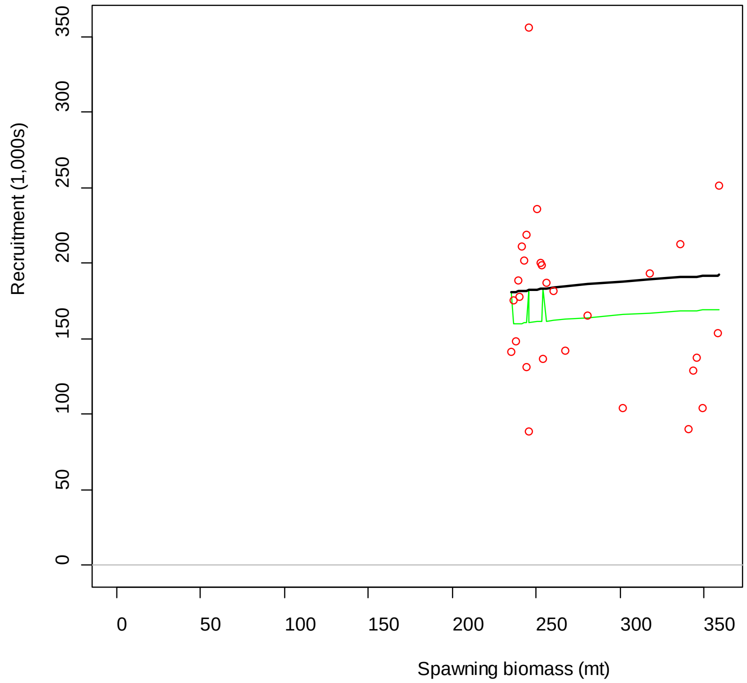

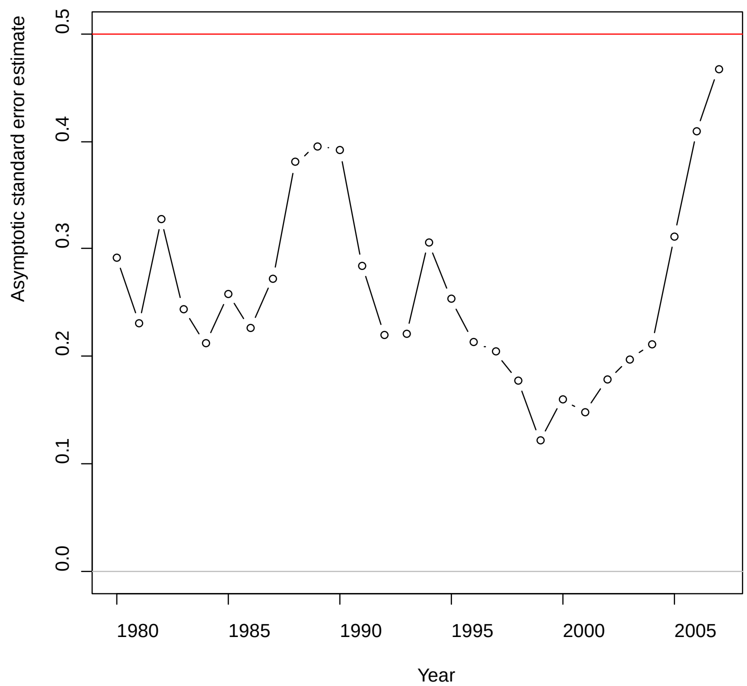

Figure 100. Spawner-recruit relationship (top panel) and the asymptotic standard deviations (bottom panel) for the ORS recruitment time series. Black line in top panel is the expected mean recruits; green line in same panel is the bias-adjusted expected recruits.

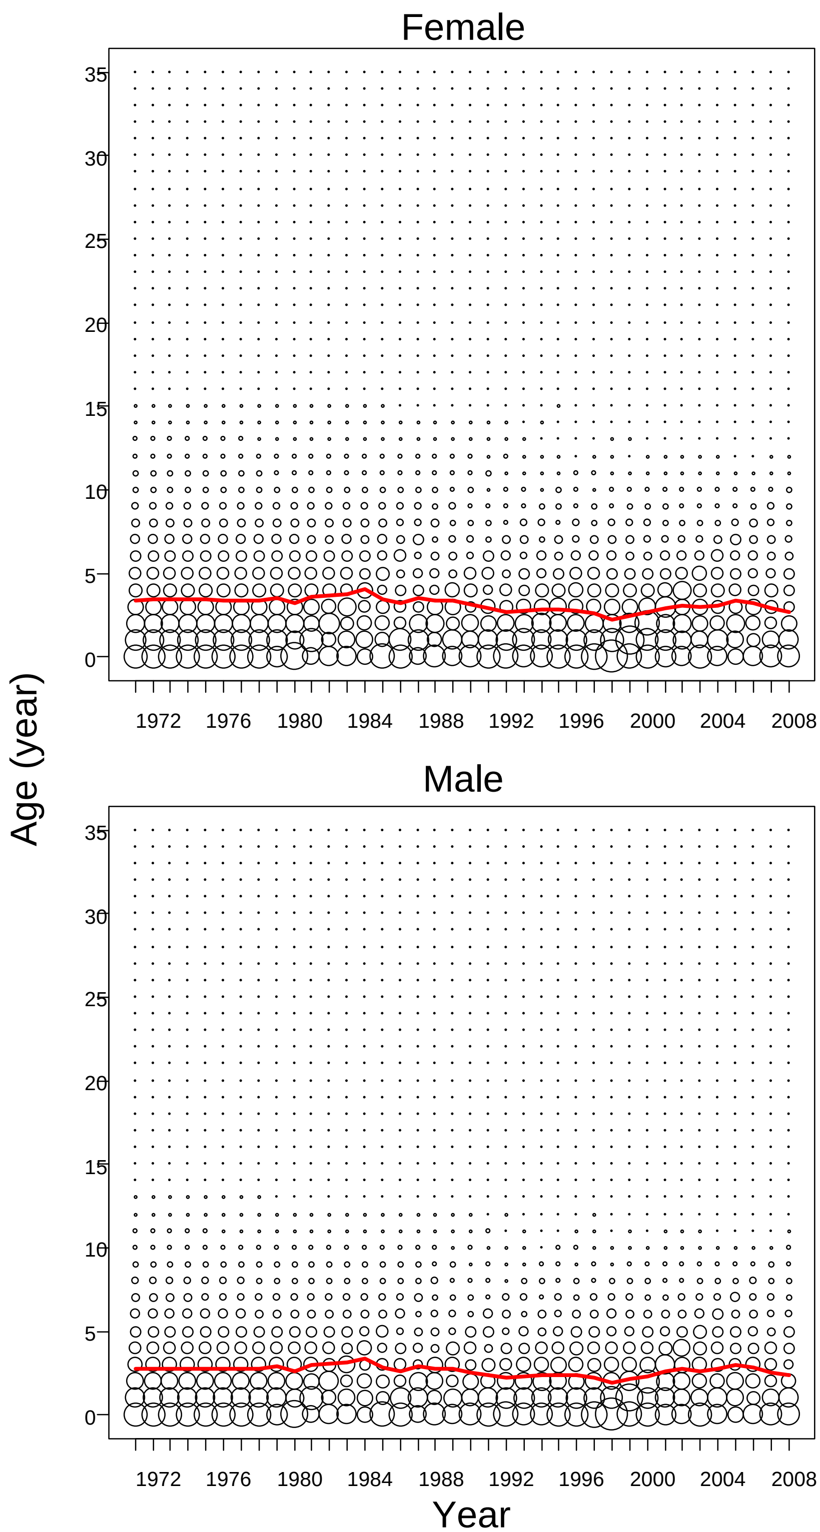

Figure 101. Numbers at age for females (top panel) and males (bottom panel) in the ORS. Red line shows the mean age by year.

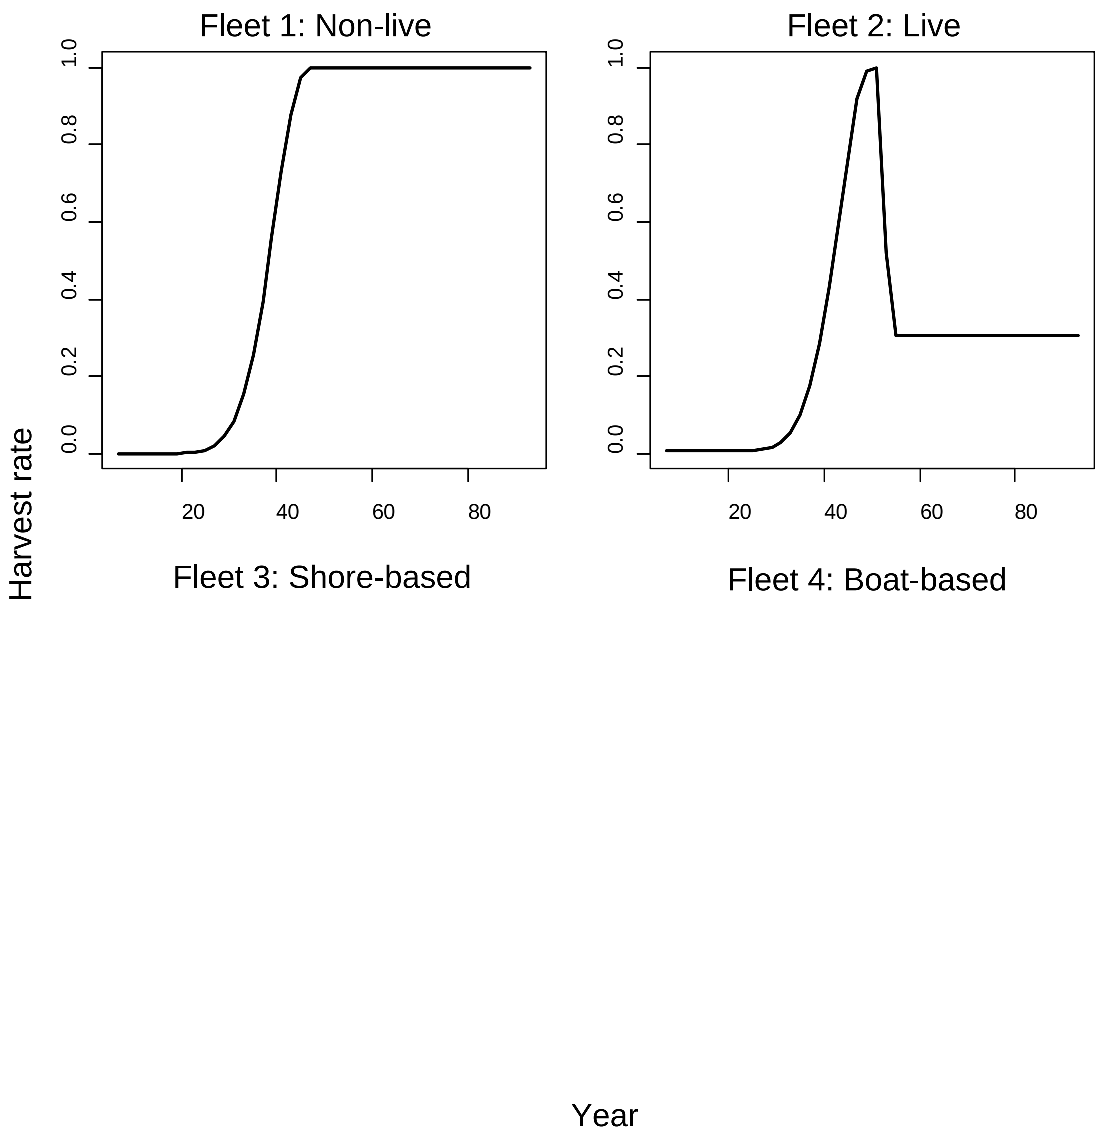

Figure 102. Selectivity at length for female and male cabezon by fishery fleet for the ORS. Black solid lines start selectivity in year 1916; blue broken lines start selectivity in year 2000 (fleet 2) and year 2003 (fleet 4); red dotted lines start selectivity in 2004.

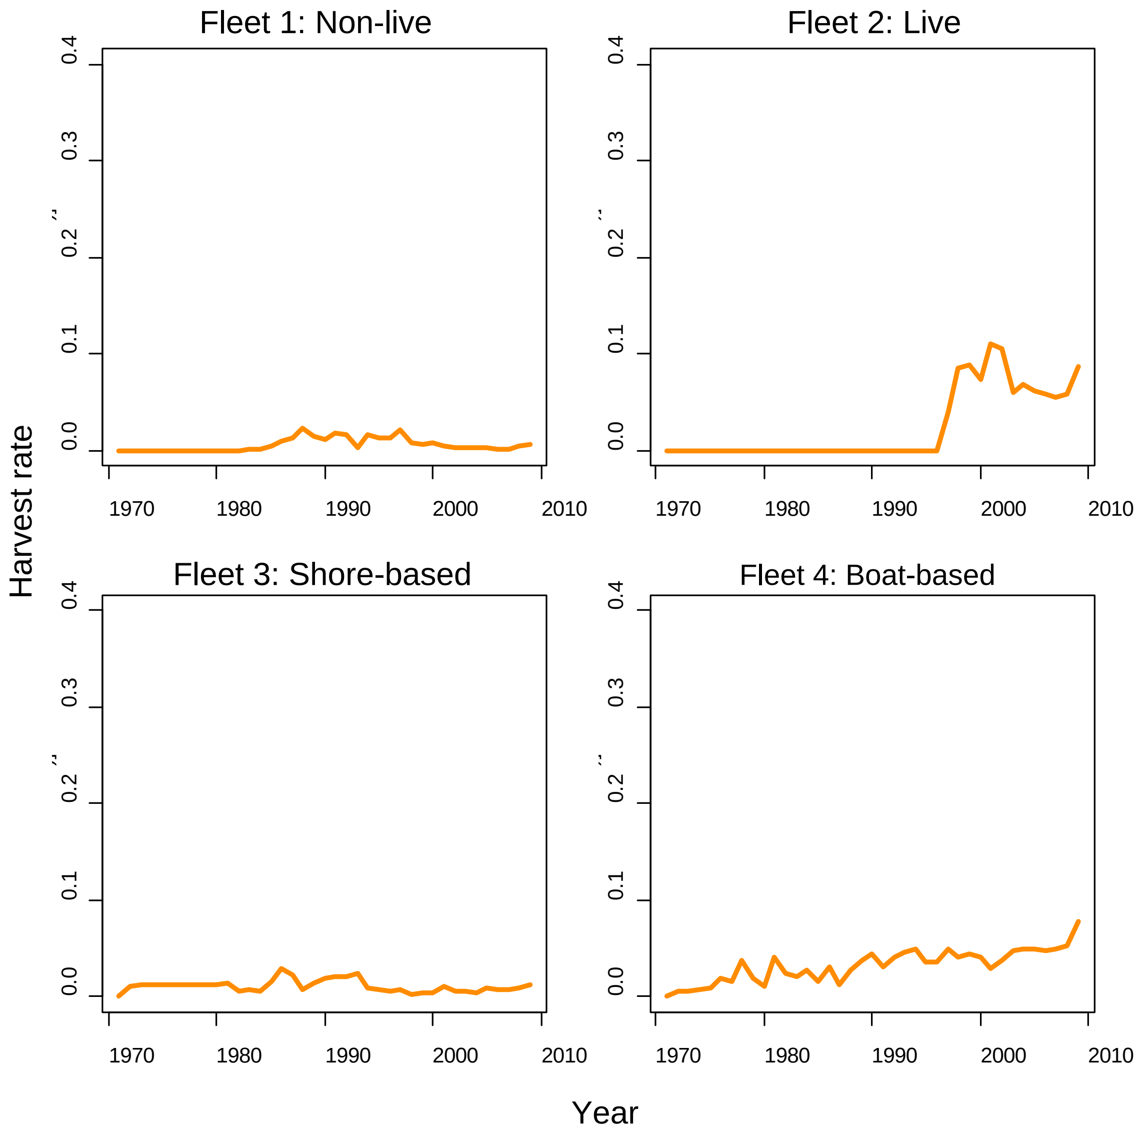

Figure 103. Time series of harvest rates by fishery fleet for the ORS.

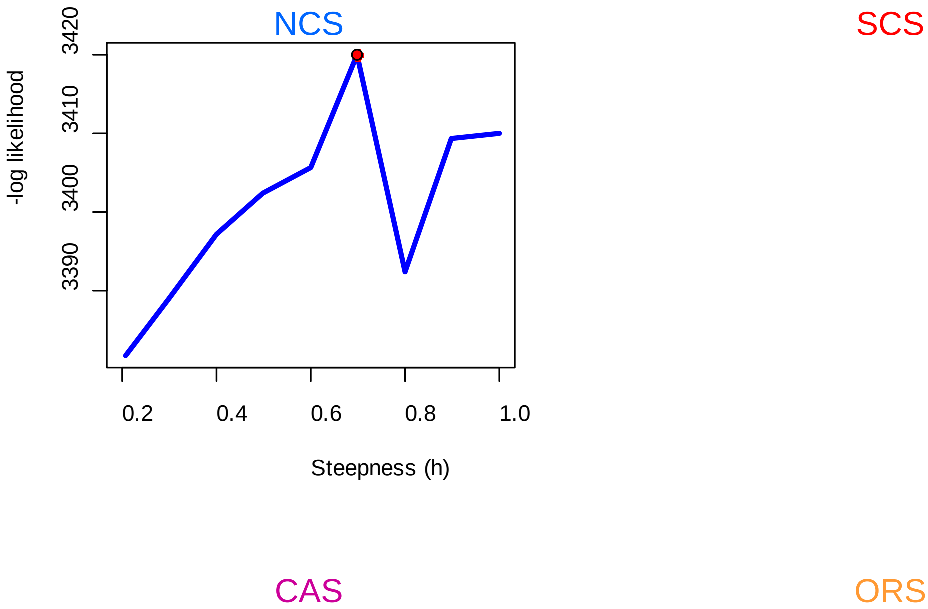

Figure 104. Recruitment compensation (steepness) likelihood profiles for each sub-stock. Red point show the assumed base case values. Broken black line indicates the likelihood value of significant difference.

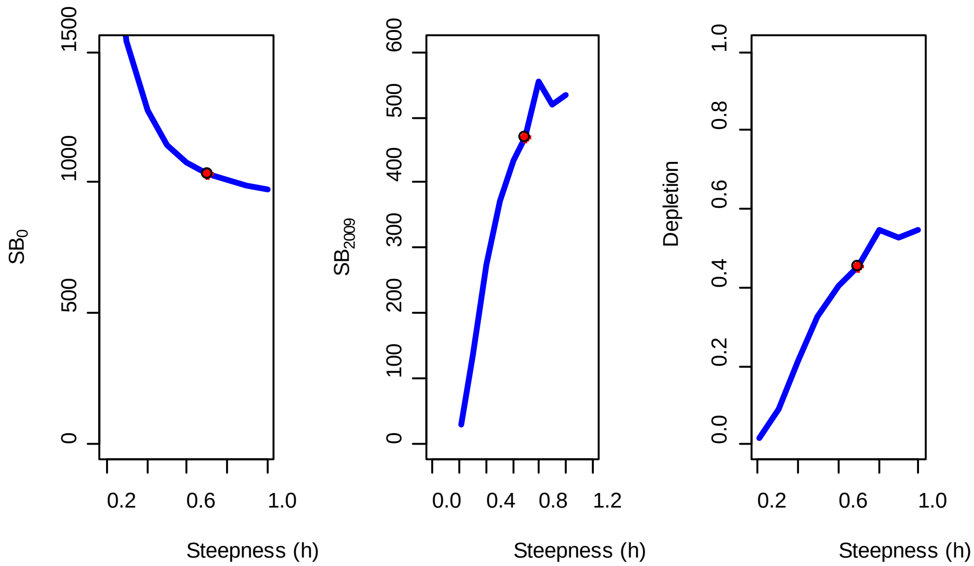

Figure 105. Values of initial spawning output (SB_0; left panels), current spawning output (SB_{2009}; middle left panels), depletion (middle right panels), and MSY (right panels) for the NCS (upper panels) and SCS (lower panels).

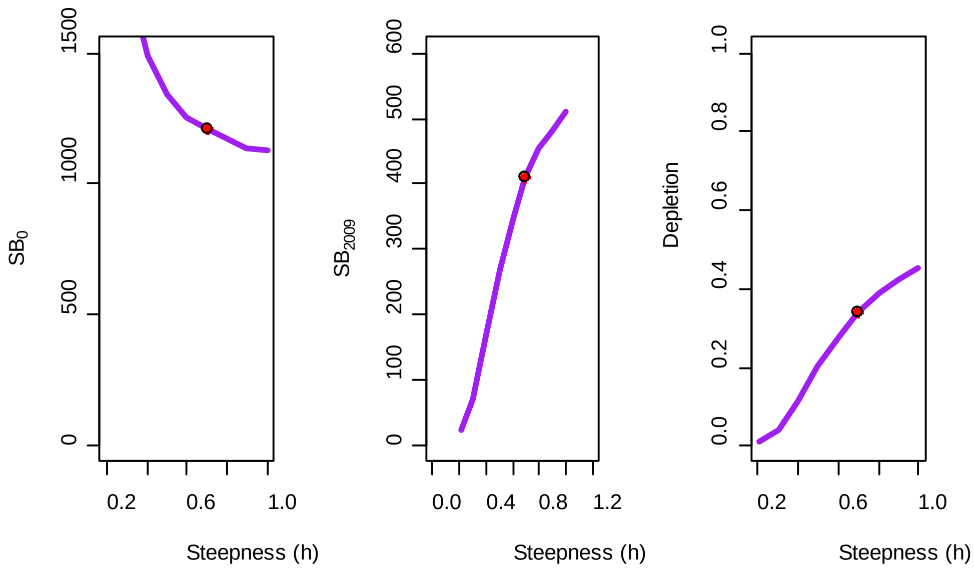

Figure 106. Values of initial spawning output (SB_0; left panels), current spawning output (SB_{2009}; middle left panels), depletion (middle right panels), and MSY (right panels) for the CAS (upper panels) and ORS (lower panels).

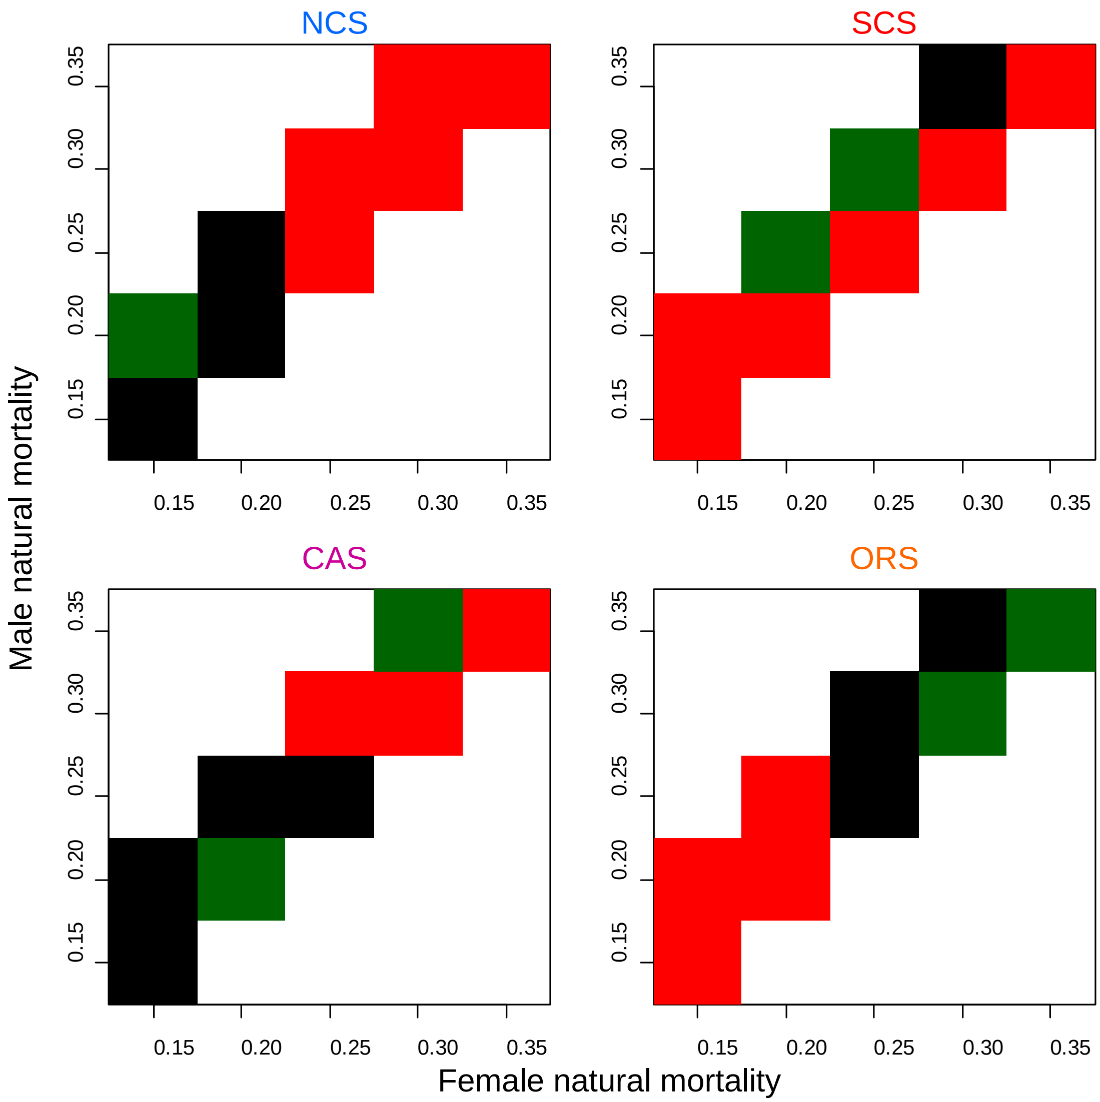

Figure 107. Likelihood profile for sex-specific natural mortality. Green values are within 1.92 likelihood units from the minimum. Black values are 1.92 to 10 likelihood units from the minimum. Red values are >10 likelihood units from the minimum.

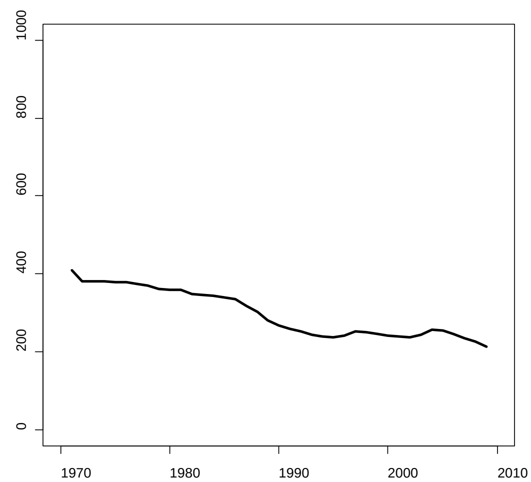

Figure 108. Spawning output trajectories estimated by the base case and retrospective analysis trials for each cabezon sub-stock.

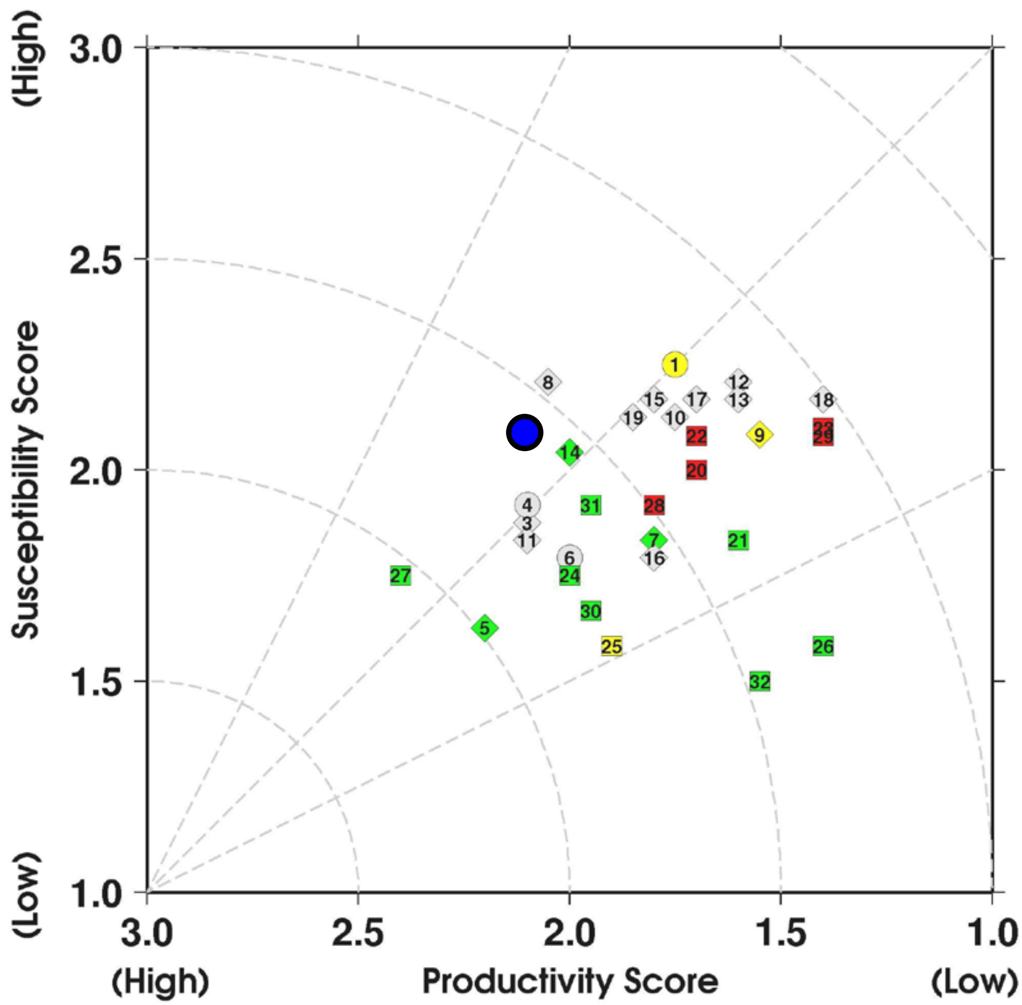

Figure 109. Productivity and susceptibility scores for cabezon (large blue point) compared with 31 other groundfish species. Grey points indicate species without assessment; red points indicate rebuilding stocks; yellow points indicate stocks that are in the precautionary zone ($0.25SSB_0 < \text{SSB} < 0.4SSB_0$); green points indicate assessed stocks above the target reference point. Figure provided by Field et al. (2009).

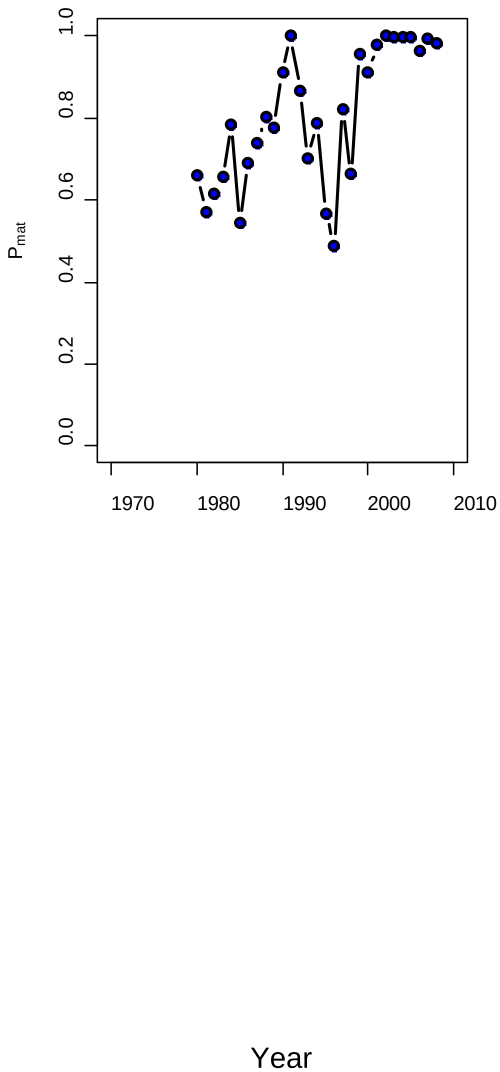

Figure 110. Relationship between P_x values and stock status for the NCS (top row) and SCS (bottom row). Left columns: Proportion of catch mature (P_{mat}) through time. Green broken line is the $SB_{40\%}$ proxy based on P_{mat}; red solid line is the $SB_{25\%}$ proxy based on P_{mat}. Shaded areas indicate years wherein the biomass falls below $SB_{40\%}$according to the sub-stock assessment. Left column: P_{obj} as it relates to depletion rate. Green line is the linear relationship. Blue lines are the linear relationship for different selectivity periods in the fishery.

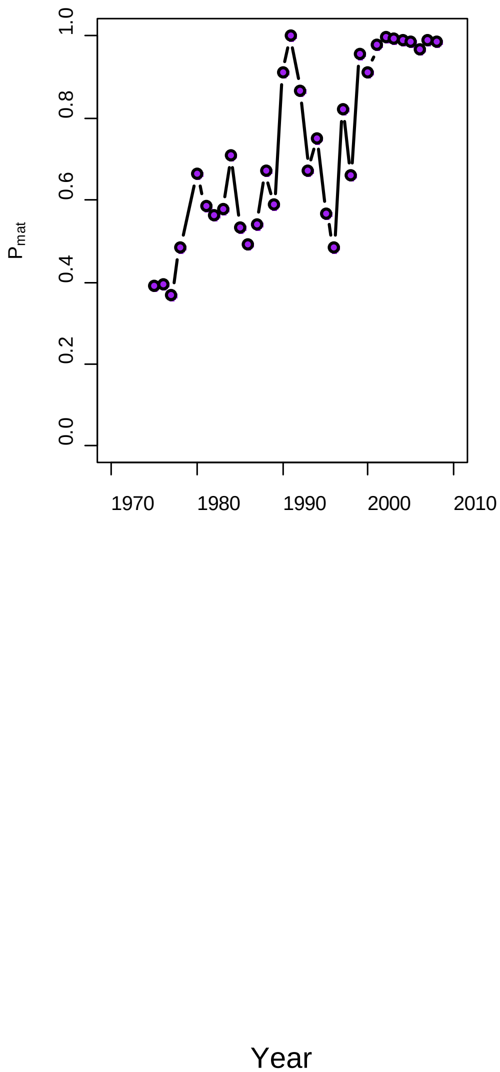

Figure 111. Relationship between P_x values and stock status for the CAS (top row) and ORS (bottom row). Left columns: Proportion of catch mature (P_{mat}) through time. Green broken line is the $SB_{40\%}$ proxy based on P_{mat}; red solid line is the $SB_{25\%}$ proxy based on P_{mat}. Shaded areas indicate years wherein the biomass falls below $SB_{40\%}$according to the sub-stock assessment. Left column: P_{obj} as it relates to depletion rate. Green line is the linear relationship.

Appendix A. Summary of California Management Measures Affecting Cabezon.

Year	Description	Effective Date
1982	Recreational & commercial size limit 12" (30.5 cm), TL	1/1/1982
Pre-1996	Recreational Regulations Recreational fillet length size limit of 12" (30.5 cm)	3/1/1996?
1999	Nearshore Fisheries Management Act gives Fish and Game Commission (FGC) additional authority to regulate fisheries (FG Code §8585.5)	1/1/1999
1999	After January 1, 1999 FGC may adopt regulations to regulate nearshore fish stock and fisheries (FG Code §8587.2)	1/1/1999
1999	Trawl caught dead nearshore (including cabezon) are exempt from size limits (FG Code §8588 (a))	1/1/1999
1999	Commercial size limit 14" (35.6 cm), TL (trawl caught dead nearshore fishes exempt)	1/1/1999
2000	Recreational size limit 14" (35.6 cm), TL	1/1/2000
2000	Recreational Regulations Shall not be filleted on a boat	3/1/2000
Pre-2003	Recreational Bag Limit of 10 fish w/in 20 fish aggregate	3/1/1984
1999	Nearshore fish stock defined with a nearshore fishery permit requirement to take cabezon	4/1/1999
2000	FGC fixes cabezon OY at 67,132 pounds (37.6%) recreational; 111,596 pounds (62.4%) commercial; Total = 178,728 pounds	10/2000
2001	Establishes a December 31, 1999 control date to qualify for the Restricted Access program (CCR Title 14 §150 (d))	10/13/2000
2000	FGC changes cabezon OY at 63,608 pounds (40.3%) recreational; 94,398 pounds (59.7%) commercial; Total = 158,006 pounds	12/2000
2001	Prohibit take from Thursday to Sunday, inclusive (except north of 40°10' – near Cape Mendocino)	01/2001
2001	Recreational Regulations Central and Southern Management Areas; Recreational Fishery open year round; no depth restrictions, except no take in Cowcod Closure area in southern management area in waters 20 fm or greater.	1/1/2001
2001	Size limit increased to 15" (38.1 cm), TL (recreational and commercial)	3/1/2001
2001	FGC fixes cabezon OY at 63,608 pounds recreational; 94,398 pounds commercial; Total OY = 158,006 pounds in emergency regulations	9/1/2001
2001	FGC enacts emergency action to close commercial fishery for the remainder of the calendar year	9/24/2001
2001	Limitation on the number of hooks (150) used to take nearshore stocks and the number of hooks per line (15)	3/5/2001

2001	Defines nearshore fish stocks (including cabezon), nearshore fisheries, nearshore waters, and shallow nearshore rockfish (CCR Title 14 §1.90 (a)(b))	3/5/2001
2001	Prohibits the take of cabezon in the northern rockfish and lingcod management area during March and April or in the southern rockfish and lingcod management area in January and February (CCR Title 14 §150.16 (a)	3/5/2001
2001	Commercial seasonal closures for cabezon shall apply that are consistent with federal seasonal closures for minor nearshore rockfishes, as noticed in the Federal Register by the National Marine Fisheries Service or defined in Title 50, Code of Federal Regulations (CFR), Parts 600 and 600, for ocean waters south of 40°10' (CCR Title 14 §150.06 (c)	3/5/2001
2002	Finfish traps required to have rigid 5” rings in entrance	1/8/2002
2002	FGC fixes cabezon OY at 84,330 pounds (47.2%) recreational; 94,398 (52.8%) pounds commercial; Total OY = 178,728 pounds reaffirming emergency action	2/4/2002
2002	FGC enacts emergency action to close commercial fishery for the remainder of the calendar year	7/01/2002
2002	Recreational Regulations Recreational Area Mgmt areas changed	1/10/2002
2002	Recreational Regulations Emergency Sportfishing Closure for cabezon in waters deeper than 20 fm for all boat-based anglers south of 40º10' N lat.	7/29/2002
2003	FGC fixes cabezon OY at 84,330 pounds (47.2%) recreational; 94,398 (52.8%) pounds commercial; Total OY = 178,728 pounds	1/1/2003
2003	Recreational Regulations Recreational rockfish, cabezon, and greenling (RCG) complex; 10 fish bag-limit regulation established in the Central and Southern Management Areas	1/1/2003
2003	Recreational Regulations Northern Management Area (CA/OR border to 40º10' N lat.): recreational bag limit remains at 10 fish (outside the rockfish bag limit); Open year round; No depth Restriction North-Central, South-Central and Southern Management Areas (40º10' N lat. to US/Mexico border): recreational bag limit 3 fish with in the RCG bag limit; Open July-Dec; 20 fm or less	1/3/2003
2003	Cumulative trip limits set for two-month periods, includes a two month closure from March to April.	
2003	FGC regulatory changes enacted as follows: Seasons: Jan-Feb – open Mar-Apr – closed May-Dec – open (or until the TAC allocation has been reached) Cumulative trip limits per nearshore permittee for January and February set at 200 pounds	1/1/2003

2003	Participants must have a valid 2003-2004 nearshore fishery permit for one regional management area (CCR Title 14 § 52.04)	2/8/2003
2003	CCR Title 14 §150 (c) defines nearshore fishes (including cabezon) used for landings qualifications and their respective market category codes	3/10/2003
2003	Commercial RCAs 42 N lat. to 40 10’ N lat. – closed 27 fm to 100 fm South of 40 10 N lat. January – June – closed 20 fm to 150 fm July-August – closed 20 fm to 150 fm, except between a line drawn due south from Point Fermin and a line drawn due west from Newport South Jerry, vessels fishing with hook and line and/or trap(or pot) gear may operate from shore to a boundary line approximating 50 fm September to December – 20 fm to 150 fm	5/7/2003
2003	Participants must have a valid 2003-2004 nearshore fishery permit for one management region.	4/1/2003
2003	FGC enacts emergency action to close commercial fishery for the remainder of the calendar year	7/10/2003
2003	Recreational Regulations Emergency sportfishing closure for cabezon statewide for all boat-based angers	12/8/2003
2003	Changes to Commercial RCAs 40 10’ N lat to 34 27’ N lat – closed 20 fm to 150 fm south of 34 27’ N lat July-August – closed 20 fm to 150 fm (special open area in Pt. Fermin/Newport South Jetty area) September to December – closed 30 fm to 150 fm	9/5/2003
2003	Weekday commercial closures repealed	12/3/2003
2003	Changes to Commercial RCAs South of 42 N lat.– November to December – closed shoreline to 150 fm	11/26/2003
2003	Additional cabezon cumulative trip limit regulations affecting the commercial take are defined. Cumulative two-month trip limits for the entire year are listed (CCR Title 14 § 150.16 (e)(6)(A))	12/7/2003
2004	FGC fixes cabezon OY at 118,300 pounds (61%) recreational; 75,600 pounds (39%) commercial; Total OY = 193,300 pounds	12/3/2003
2004	Seasonal closure periods in alignment with federal nearshore rockfish (north and south of 40 10’ N lat) (repealed and new subsection)	1/15/2004
2004	Recreational Regulations Northern Management Area (CA/OR border to 40º10' N lat.): recreational bag limit remains at 10 fish (outside the rockfish bag limit); Open year round; No depth Restriction	1/1/2004

	Central Management Area (40º10' N lat. to Point Conception): recreational bag limit 3 fish within the RCG bag limit; Open Jan-Feb (30 fm or less), May-Aug (20 fm or less), and Sep-Dec (30 fm or less) Southern Management Area (Point Conception to US/Mexico border): recreational bag limit 3 fish within the RCG bag limit; Open Mar-Dec; 60 fm or less	
2004	Recreational Regulations Northern Management Area (CA/OR border to 40º10' N lat.): recreational bag limit 3 fish within the RCG bag limit; Open Jun-Dec; 30 fm or less North-Central Management Area (40º10' N lat. to Point Lopez): recreational bag limit 3 fish within the RCG bag limit; Open Aug-Oct; 30 fm or less South-Central Management Area (40º10' N lat. to Point Lopez): recreational bag limit 3 fish within the RCG bag limit; Open Jun (30 fm or less), Aug (30 fm or less), Sep-Dec (20 fm or less) Southern Management Area (Point Conception to US/Mexico border): recreational bag limit 3 fish within the RCG bag limit; Open Jun-Aug (60 fm or less), Sep-Oct (30 fm or less), Nov-Dec (60 fm or less)	6/4/2004
2004	Commercial Regulations 42 N lat. to 40 10’ N lat - closed 30 fm to 100 fm 40 10’ N lat to 34 27’ N lat. January to April – closed 30 fm to 150 fm May to August – closed 20 fm to 150 fm September to December – closed 30 fm to 150 fm South of 34 27’ N lat. – closed 60 fm to 150 fm	1/8/2004
2004	FGC enacts emergency action to close commercial fishery for the remainder of the calendar year	9/4/2004
2005	FGC fixes cabezon OY at 92,800 pounds (61%) recreational; 59,300 pounds (39%) commercial; Total OY = 152,100 pounds	1/1/2005
2005	Commercial Regulations 42 N lat. to 40 10’ N lat - closed 30 fm to 100 fm 40 10’ N lat to 34 27’ N lat. January to April – closed 30 fm to 150 fm May to August – closed 20 fm to 150 fm September to December – closed 30 fm to 150 fm South of 34 27’ N lat. – closed 60 fm to 150 fm	1/1/2005
2005	Recreational Regulations 42 N lat to 40 10’ N lat - Open Jul1–Oct 31 40 fm restriction, 3 cabezon sub bag limit 40 10’ N lat. to 37 11’ N lat. - Open Jul 1–Nov 30 20 fm restriction, 3 cabezon sub bag limit 37 11’ N lat. to 36 N lat. - Open Jul 1–Nov 30	1/1/2005

	20 fm restriction, 3 cabezon sub bag limit 36 N lat. to 34 27’ N lat. - Open May 1–Sep 30 between 20-40 fm, 3 cabezon sub bag limit South of 34 27’ N lat. - Open Mar 1–Jun 30 between 30-60 fm; Jul 1-Sep 30, 40 fm restriction, 3 cabezon sub bag limit	
2005	Revised cumulative two month commercial trip limits established January – February – 300 lb/ 2 months March – April – closed May – June – 250 lb/2 months July – August – 150 lb/2 months September - October – 900 lb/2 months November - December – 100 lb/2 months	3/31/2005
2005	Recreational Regulations Recreational sub bag limit reduced from 3 fish to one fish	4/1/2005
2005	Recreational Regulations 42 N lat to 40 10’ N lat – extend season to May through Dec, 30 fm depth restriction 40 10 N lat. to 36 N lat. – extend season to July through Dec 36 N lat. to 34 27’ N lat – liberalize the RCA to 40 fm (instead of only open between 20 and 40) South of 34 27’ N lat. – extend season from March through December depth restrictions: March – status quo – open 30-60 fm April – August – 60 fm restriction Sept – Oct – 30 fm restriction Nov-Dec – 60 fm restriction	5/1/2005
2005	FGC enacts emergency action to close commercial fishery for the remainder of the calendar year	10/01/2005
2005	Recreational Regulations Emergency sportfishing closure – the Northern and North-Central Management Area closed Oct-Dec for all anglers	10/18/2005
2006	FGC fixes cabezon OY at 92,800 pounds (61%) recreational; 59,300 pounds (39%) commercial; Total OY = 152,100 pounds	1/1/2006
2006	Recreational Regulations 42 N lat to 40 10’ N lat - Open Jul 1–Oct 31 40 fm restriction, 1 cabezon sub bag limit 40 10’ N lat. to 37 11’ N lat. - Open Jul 1–Nov 30 20 fm restriction, 1 cabezon sub bag limit	1/1/2006

	37 11’ N lat. to 36 N lat. - Open Jul 1–Nov 30 20 fm restriction, 1 cabezon sub bag limit 36 N lat. to 34 27’ N lat. - Open May 1–Sep 30 between 20-40 fm, 1 cabezon sub bag limit South of 34 27’ N lat. - Open Mar 1–Jun 30 between 30-60 fm; Jul 1-Sep 30, 40 fm restriction, 1 cabezon sub bag limit	
2006	Commercial Sep-Oct cumulative trip limit reduced from 900 lb to 200 lb (inseason) to remain within TAC	9/1/2006
2007	FGC fixes cabezon OY at 92,800 pounds (61%) recreational; 59,300 pounds (39%) commercial; Total OY = 152,100 pounds	1/1/2007
2007	Commercial RCAs – 42 N lat. to 40 10’N lat. - closed 30 fm to 100 fm 40 10’N lat. to 34 27’ N lat – closed 30 fm to 150 fm South of 34 27’ N lat. - closed 60 fm to 150 fm	1/1/2007
2007	Recreational Regulations 42 N lat. to 40 -10’ N lat. – open May 1–Dec 31 30 fm restriction, 1 cabezon sub bag limit 40 10’ N lat. to 37 11’ N lat. – open Jun 1–Nov 30 30 fm restriction, 1 cabezon sub bag limit 37 11’ N lat. to 34 27’ N lat. – open May 1–Nov 30 40 fm restriction, 1 cabezon sub bag limit South of 34 27 N lat. – open Mar1–Dec 31 60 fm restriction, 1 cabezon sub bag limit	1/1/2007
2007	Commercial September-October cumulative trip limit reduced from 900 lb to 200 lb (inseason) to remain within TAC	9/1/2007
2007	Recreational Regulations Emergency sportfishing closure north of 37 11’ N lat (North and North-Central management Areas)	10/1/2007
2008	FGC fixes cabezon OY at 92,800 pounds (61%) recreational; 59,300 pounds (39%) commercial; Total OY = 152,100 pounds	1/1/2008
2008	Recreational Regulations Emergency sportfishing regulations – changed the maximum depth restriction north of 37 11’ N lat. to 20 fm (from 30 fm)	5/10/2008
2008	Commercial September-October cumulative trip limit reduced from 900 lb to 300 lb (inseason) to remain within TAC	9/1/2008
	Commercial RCA 42 N lat. to 40 10’ N lat – close 30 fm to 100fm	
2008	Recreational Regulations Emergency sportfishing closure north of Point Arena (38 57.5’ N lat.) and created a new management area (split the North-Central into two areas)	9/2/2008

2009	FGC fixes cabezon OY at 92,800 pounds (61%) recreational; 59,300 pounds (39%) commercial; Total OY = 152,100 pounds	3/1/2009
2009	Change to commercial RCA – 42 N lat. to 40 10' N lat. – close 20 fm -100 fm	3/1/2009
2009	Recreational Regulations 42 N lat. to 40 -10' N lat. – open May 15–Sep 15 20 fm restriction, 2 cabezon sub bag limit 40 10' N lat. to 38 57.5' N lat. – open May 15–Aug 15 20 fm restriction, 2 cabezon sub bag limit 38 57.5' N lat. to 37 11' N lat. – open Jun 13–Oct 31 30 fm restriction, 2 cabezon sub bag limit 37 11' N lat. to 34 27' N lat. – open May 1–Nov 15 40 fm restriction, 2 cabezon sub bag limit South of 34 27 N lat. – open Mar 1–Dec 31 60 fm restriction, 2 cabezon sub bag limit	3/1/2009
	Emergency closures enacted by the Fish and Game Commission for the commercial cabezon statewide fishery 2001 – closed from Sept. 21 to Dec. 31 2002 – closed from July 1 to Dec. 31 2003 – closed from July 10 to Dec. 31 2004 – closed from Sept. 4 to Dec. 31 2005 – closed from Oct. 1 to Dec. 31	

Appendix B. Summary of Oregon Management Measures Affecting Cabezon.

Year	Effective Jan. 1 (regulations set preseason)	Inseason Changes and Effective Dates
2008	Rockfish, cabezon (16" min.), greenling (10" min.): 6 Stonewall Bank YRCA: Closed for P. halibut and most marine species (open for salmon and offshore pelagic species). North of Humbug Mt.: Retention of any groundfish species other than sablefish is prohibited on all-depth P. halibut days when P. halibut is aboard vessel. North of Cape Falcon: Retention of any groundfish species other than sablefish and Pacific cod is prohibited on all-depth P. halibut days when P. halibut is aboard vessel.	7/7 Rockfish et al bag limit reduced from 6 to 5 and closed outside 20-fm line through Dec. 31; flatfish closed outside 40-fm line through Dec. 31 8/21 Cabezon prohib. for boats 9/7 Return to preseason regs., i.e., rockfish et al bag limit 6 and waters closed offshore of 40-fm line through Sept. 30
2007	Rockfish, cabezon (16" min.), greenling (10" min.): 6 Stonewall Bank YRCA: Closed for P. halibut and most marine species (open for salmon and offshore pelagic species). North of Humbug Mt.: Retention of any groundfish species other than sablefish is prohibited on all-depth P. halibut days when P. halibut is aboard vessel. North of Cape Falcon: Retention of any groundfish species other than sablefish and Pacific cod is prohibited on all-depth P. halibut days when P. halibut is aboard vessel.	8/11 Cabezon prohib. for boats
2006	Rockfish, cabezon (16" min.), greenling (10" min.), flounder, sole and other marine species not listed: 6 North of Humbug Mt.: Retention of any groundfish species other than sablefish is prohibited on all-depth P. halibut days when P. halibut is aboard vessel. North of Cape Falcon: Retention of any groundfish species other than sablefish and Pacific cod is prohibited on all-depth P. halibut days when P. halibut is aboard vessel.	9/23 Cabezon prohib. for boats

Year	Effective Jan. 1 (regulations set preseason)	Inseason Changes and Effective Dates
2005	Rockfish, cabezon (16" min.), greenling (10" min.), flounder, sole and other marine species not listed: 8 North of Humbug Mt.: Retention of any groundfish species other than sablefish is prohibited on all-depth P. halibut days when P. halibut is aboard vessel.	7/16 Rockfish *et al* bag limit reduced to 5 8/11 Cabezon prohib. for boats 10/18 P. halibut and groundfish closed <40 fm for boats
2004	Rockfish, cabezon (16" min.), greenling (10" min.): 10 40-fm curve: Seaward closed June 1-Sept. 30.	8/18 Cabezon prohib.
2003	Rockfish, cabezon (15" min.), greenling, flounder, sole and other marine species not listed: 10	11/21 ocean closed to GF outside 27-fm line
2002 through 2000	Rockfish: 10 Other fish: 25	
1999 through 1994	Rockfish: 15 Other fish: 25	
1993 through 1978	Rockfish, cabezon and greenling: 15 Other fish: 25	Effective 4/1/1978
1977	Other fish: 25, no more than 5 lingcod and 2 halibut	
1976	Other fish: 25, no more than 5 lingcod and 2 halibut	No bag limits prior 1976

CABEZON

STAR Panel Report

July 27-30, 2009

Deca Hotel
Seattle, WA

Panel Reviewers
Dr. Vidar Wespestad, STAR Chair and SSC representative
Dr. J.J. Maguire, Center for Independent Experts
Dr. Stephen Smith, Center for Independent Experts
Dr. Jim Ianelli, National Marine Fisheries Service Alaska Fisheries Science Center

STAR Panel Advisors Present:
Ms. Joanna Grebel, California Department of Fish and Game, GMT Representative
Mr. Dan Platt, GAP Representative
Mr. John DeVore, PFMC Representative

STAT Team:
Dr. Jason Cope, National Marine Fisheries Service Northwest Fisheries Science Center
Ms. Meisha Key, California Department of Fish and Game

Overview

The Star Panel met at the Hotel Deca in Seattle, WA to review the third full assessment of the population status of cabezon (*Scorpaenichthys marmoratus* [Ayres]) off the west coast of the United States. The first assessment was for a state-wide California cabezon stock in the year 2003, the second assessment in 2005, considered two sub-stocks (the northern California sub-stock (NCS) and the southern California sub-stock (SCS)), demarcated at Point Conception, CA.

The current draft assessment retains the two California sub-stocks, also evaluating the population as a State-wide California stock (CAS), and extends the assessment to a third sub-stock for cabezon in the waters off of Oregon (ORS). Separation of these spatial sub-stocks is based on distinguishing localized population dynamics, preliminary population genetics results, and is supported by spatial differences in the fishery (the NCS has been the primary area from which removals have occurred), the ecology of nearshore groundfish species, and is consistent with current state management needs.

The last full assessment of cabezon was done in 2006. Major changes made in this assessment, compared with the previous assessment include:

The assessment used the Stock Synthesis platform (version 3.03a) and incorporated a variety of data sources. Similar to the 2005 assessment each sub-stock assessment uses data on size (mean weight and length compositions) and indices of abundance. Primary catch data are from recreational databases and from commercial hook and line and trap fisheries in California. The low occurrence of cabezon in standard trawl surveys precludes their use.

Additional modifications made to the specification of this year's assessment models, relative to the previous assessment included:

- Implementation of time blocks on the selectivities of the commercial live-fish fishery and boat-based recreational fleets for all sub-stocks to account for regulatory changes.
- Additional variance was applied to the estimated variability of the candidate abundance indices in order to address the underestimation of variability in the delta GLM-based models.
- The models were tuned to balance the input of recruitment variability ($Sigma_R$) and sample sizes of length and age compositions with model output estimates of these same values. This resulted in $Sigma_R$ values less than those used in the last assessment.

- Incorporation of conditional age-at-length data for the first time to estimate growth parameters internal to the model (previous assessments used growth parameters derived from externally fitted growth curves).

Several potential indices of abundance were included for the California sub-stocks and one for the Oregon fishery:

- Fishery-dependent CPFV Logbook CPUE, a CDFG hook-and-line survey, and PSMFC dockside and onboard surveys,
- Fishery-independent adult surveys (TENERA and PISCO), and
- Recruitment surveys (CalCOFI, Southern California Edison Impingement, PISCO SMURFS, SLO SMURFS).
- Oregon Ocean Recreational Boat Survey (ORBS) sampling program.

Changes in bag and size limits in California also necessitated the separation of the CPFV data into two series: 1) 1960-1999 and 2000-2008. This approach differs from the previous assessment, which used a continuous index from 1960-2004.

The STAR panel concluded that the Cabezon assessment constitutes the best available scientific information on the status of Cabezon off the U.S. west coast and recommends that it be used for status determination and management in the Council process. The STAR panel thanks the STAT team members for their excellent preparation, presentation, and willingness to respond to panel requests.

Analyses requested by the STAR Panel

1. Clarify if larvae and juveniles are pelagic and for how long? This is related to stock structure and recruitment, whether spawners contribute locally or globally. This could also be a research recommendation for the next assessment.

   Rationale: The assessment assumes that there is little mixing at all life stages. Yet, after hatching the young of the year spend 3–4 months as pelagic larvae and juveniles which leaves considerable margin for mixing depending on where and when hatching occurs.

   Response: O'Connell 1953 states that "In all probability, the young carried offshore perish, unable to attain the bottom at the proper time. Assuming this to be true, extensive coastwise mixing would not occur." The chair consulted with Steve Ralston (NMFS/SWFSC) who considers that there is limited knowledge on cabezon larvae and juveniles and that there is no basis for O'Connell's probability statement. Further investigation of the abundance and distribution of cabezon larvae and juveniles in existing databases appears warranted for the next assessment.

2. Provide a model run using the pier catches as a recruit index for OR to compare with the ORBS index currently used in the assessment.

   Rationale: The catches of cabezon in the man-made fishery on piers and jetties are mostly of small cabezon and could possibly provide an early index of year class size.

   Response: The STAT was unable to complete this request because the data were not in an appropriate format and there appears to be several missing fields in the database. There were also questions on the appropriateness of estimated effort measures obtained from the RecFIN database. The next assessment should continue to explore additional indices of stock sizes for OR and CA as they become available.

3. Normalise, rather than standardize to a common year, the trends on Fig. 26 for a better comparison.

   Rationale: Figure 26 shows the geometric mean and delta GLM-based CPUE abundance indices for each sub-stock each on different scales which complicates their interpretation.

   Response: An updated graph was prepared with each series on similar scale. The trends for SCS, CAS and ORS showed greater consistency, but NCS still showed different trends.

4. Figure 26 in the draft assessment shows a big difference between the trends of the various treatment for NCS CPFV (table 13 of the draft assessment), in particular the geometric average. The Geometric average does not include any effect. Investigate what factor(s) accounts for the difference in trends.

   Rationale: Standardized catch per unit of effort is expected to be different than unstandardized CPUE, but the differences in trend in fig. 26 are more than normally expected and warrant further investigation.

   Response: The STAT found that location 6 had different CPUEs than the other locations and that December and January consistently had higher CPUEs than the other months. The standardization has no interactions term. The STAR Panel provided a general recommendation to address this issue in this and other assessments.

5. Provide a plot of the proportion of zeros for the NCS CPFV vs time.

Rationale: This was a further attempt at explaining the differences between the geometric mean average and the GLIM estimates in figure 26.

Response: The proportion of zeros seems to be increasing, particularly in the NCS where the problem is seen. The geometric mean does not include zeros, while the GLM does, so this may explain the differences.

6. Fit the growth model externally without t_0 to the data in fig. 8 assuming a zero intercept. Compare the fits and trends from this analysis to the case where growth was estimated in the model with t_0 estimated.

   Rationale: The von Bertalanffy growth equation was fitted in the model and resulted in relatively large negative t_0 estimates. The panel wanted to see how the L_{inf} and k parameters would change if a zero intercept was assumed.

   Response: Assuming a zero intercept made a relatively large difference in estimates of L_{inf} and K, but there is no basis to choose which one is better. For assessment purposes, the growth parameters were fit internal to the population model and resultant growth curves fit closely curves generated by the external fits when estimating t_0 (see Figure 74 of assessment document for the comparisons). The panel recommended that younger cabezon be aged to better inform the growth curves. The model estimate of spawning biomass is sensitive to estimates of k.

7. Provide a run with using the original CVs estimated for the NCS and the SCS CPFV 1960-1999. Show the fit to the NCS and the SCS CPFV 1960-1999 with the original CVs to see if fits better (figure 38).

   Rationale: The CVs derived when calculating surveys and CPUE indices are believed to underestimate the uncertainty in the indices. The draft assessment multiplied those CVs by 3 to better reflect the perceive uncertainty.

   Response: For NCS, using the original CVs did improve the fit noticeably, but it did not for SCS. Fitting the indices with the original CVs increased the absolute biomass outputs and resulted in higher depletion ratios (SB_{2009}/SB_{1916}) in the NCS, CAS and ORS. There was little change to either biomass or the depletion value in the SCS.

8. Label points as years in fig. 38 on the plots of expected vs. observed for NCS CPFV 1960 - 1999.

   Rationale: Figure 38 shows considerable lack of fit to the index and the panel wanted to evaluate if there was a temporal component to the lack of fit.

   Response: The largest outliers were at the beginning of the time series when there was little change in the expected values but relatively large changes in the observed values. There was no a priori reason to exclude those early years from the model. For more recent years there appears to be a better agreement between observed and expected values.

9. Verify that the confidence intervals on fig. 40 to 43 were correctly calculated. In the unlikely event that they were not, provide a run of the base case with the appropriate confidence intervals.

   Rationale: The panel found that the confidence intervals on those figures looked larger than expected.

   Response: The STAT confirmed that the confidence intervals were correctly calculated and that they were large.

10. Figure 105 (of the STAR assessment draft) showing the results of the retrospective analysis shows very different absolute stock size estimates for ORS depending on the number of years that are used in the assessment. Provide the confidence bounds of the retrospective analysis (base, -1 year and -5 years) to see if they overlap for OR.

    Rationale: Differences in absolute estimate of stock size of the magnitude showed in Fig. 105 for ORS are cause for concern. They imply very uncertain assessments.

    Response: The confidence intervals do overlap, confirming that the assessment is uncertain. The retrospective run with 5 years removed from the assessment shows a non-zero probability that the stock would go extinct. If asymmetric CI were calculated this problem would be eliminated.

11. Provide a table of the number of California commercial nearshore licenses for 2003 to 2008.

    Rationale: The panel wanted to have a better understanding of the potential changes in fishing effort.

    Response: In California the number of licenses decreased from 219 in 2003 to 171 in 2009.

12. Investigate why the plateau for fleet 4 ((beach/bank) in the California models) looks the same for all areas. This may be important for projection forward and for allocation calculations.

    Rationale: The panel wanted to be reassured that the selectivities were correctly estimated.

    Response: The STAT found that the model was not moving much from the starting value. The STAT used different starting values and parameter estimates but these modifications did not appreciably change the results from those obtained from the base model.

13. Provide a run where the selectivity for fleet 2 (live-fish fishery) for SCS comes from the coast wide estimates for the two periods.

    Rationale: Fleet 2 in SCS (figure 85) showed a highly peaked selectivity pattern that is unlikely to happen. The CAS selectivity (figure 93) shows a wider plateau and is more likely to have a biological basis.

    Response: The State wide (CAS) selectivity was used in the SCS base case and showed very similar results. The panel recommended using this State wide selectivity curve in the SCS base case.

14. On bubble plots for length compositions, remove years with only one sample (not necessarily for this meeting, but for final document).

    Rationale: Including those years with only one sample complicates the interpretation of the bubble plots.

Response: This was done in the final assessment.

15. Investigate interactions with years in the CPUE standardization for NCS CPFV (table 13 and figure 26 of the draft assessment).

Rationale: This was a continuation of the discussion covered in requests 3, 4 and 5 above. The panel has provided a general recommendation to address the issue of CPUE standardization for this and other assessments.

Response: The STAT team responded with runs examining alternative fits,

16. Multiply the geometric mean on slide 5 of the STAR request 1 for the NCS by 1 minus the proportion zero and plot against the GLIM.

Rationale: The panel wanted to see if the increasing proportion of zeros in the NCS CPUE caused the difference between the GLIM and the geometric mean time series.

Response: A continuation of request 15 that examined the effect of different treatments of zeros in the NCS CPUE (see request 19 and response for final resolution of issue)

17. For the base case, plot the gender ratio over time for ages 3+ in numbers from year 0.

Rationale: The panel wanted to see if there had been changes in gender ratio over time.

Response: The STAT plotted the gender ratio over time for the ORS, NCS and SCS. In all cases, the proportion of females was slightly higher than that for males, but there were no noticeable trends.

18. Provide a graph of main results with more informative confidence intervals.

Rationale: Sensitivity analysis focuses primarily on point estimates (the maximum posterity density) yet in some cases the results of the sensitivity runs relative to the base model should show the change (if any) of uncertainty for key parameters of interest (e.g., current stock size). For this reason, CVs or some other easy way to judge estimates of model uncertainty should be displayed.

Response: For the base case and each realization of the sensitivity trials, standard deviations were added to all tables reporting derived outputs (initial and terminal spawning output, depletion, and MSY) to provide a measure of the uncertainty around each point estimate. The STAT also presented to the STAR panel a figure comparing the CVs of the NCS base case versus the trial using the original (non-inflated) CPFV CPUE CVs. Much larger uncertainties were observed with the inflated CVs, except in most recent years (where it would count the most). The CPUE series stops in 1999, so it was not surprising that uncertainty increases afterwards. There was a strange period with stable CVs in the 1950s for base case which may have been due to the large catches in the late 1940s.

19. Plot the mean CPUE as shown in slide 22 of the STAR over the GLM values and the model results (expected and observed from base case over the slide 22 ln (cpue)).

    Rationale: This relates to requests 3 to 5 and 15 above to understand the differing trends between the GLM estimates and geometric mean estimates of CPUE.

    Response: The graphs provided by the STAT confirmed that the standardization was probably done correctly and that it was the geometric mean that was confusing the issue, having been calculated as the mean of the logs of the positive values and then exponentiated.

Description of base case model and alternative models to bracket uncertainty

The Panel agrees that the sub-stock configuration using Oregon (ORS), northern California (NCS), and southern California (SCS) model configuration is the most appropriate.

The NCS and SCS models include six fleets (two commercial and four recreational) and the ORS model includes four fleets (2 commercial and 2 recreational). The NCS and OCS (California) time series began in 1916, with the onset of commercial landings, while Oregon began in 1973. For the SCS, there were issues with the 1980 estimate of catch being nearly 4 times higher than 1979 and 1981. Because this estimate was derived from a new program, the Panel and authors agreed that a base model that uses the mean value for 1979 and 1981 for the 1980 estimate was preferred.

The base model includes the fishery-dependent CPFV Logbook CPUE (modeled through a GLM) for the California sub-stocks; the Oregon sub-stock model includes the Ocean Recreational Boat Survey (ORBS, 2001-2008). Note that changes in bag and size limits in California split the CPFV data into two series: 1) 1960-1999 and 2000-2008. The base model included the extra variance term added to the abundance indices (as specified in the document). Include available data on size (mean weight and length compositions) for each sub-stock assessment.

The underlying model is dis-aggregated by gender in order to capture the sex-specific differences in natural mortality (set to 0.25 yr^{-1} for females and 0.3 yr^{-1} for males). Data on gender-specific composition data were unavailable. The steepness parameter is also set to 0.7 for all base models. Recruitment residuals are estimated for 1970–2006 for all California sub-stocks and 1980-2006 for the Oregon sub-stock. The panel accepted the "tuned" recruitment variability (σ_R) and sample sizes of length and age compositions. Other details for the base model were agreed and are as specified in the document (i.e., Tables 17 and 18).

Technical merits of the assessment

This was a very thorough assessment, the team did a very complete analysis of all available fishery independent data and carried out many sensitivity runs to evaluate alternative model assumptions. The STAT team assembled all available data relating to both fishery and fishery independent time series data. The outstanding problem was that the traditional groundfish surveys provide very little information on cabezon trends since most of the biomass is concentrated in near-shore waters.

The STAT team proposed alternative assessment and management of nearshore fisheries to compensate for the lack of data required to perform traditional stock assessments. Alternative assessment procedures that require less data, but still provide relevant management outputs should be encouraged. This assessment provided examples of some approaches as applied to cabezon. Such side-by-side comparisons of simplified assessment approaches to the statistical catch-at-age model outputs are useful in understanding the relationship of alternative to traditional assessment methods in hopes of developing the best available scientific advice for management under data-limited situations.

The STAR panel encouraged the STAT team to explore less data intensive assessment methods and also to continue to improve spatial analysis to better define stock structure and distribution and geostatistical harvest control rules.

The STAR panel finds the assessment to be the best that can be produced with available data. The Panel recommends that future assessments be limited to updates until such time as the recommended research is accomplished, or new assessment methodology established. The STAR Panel doesn't recommend a new full assessment until there are improvements in the understanding of stock structure, mortality and growth parameters.

Explanation of areas of disagreement regarding STAR panel recommendations

A. Among STAR panel members (including concerns raised by the GAP and GMT representatives

There were no areas of disagreement among STAR panel members.

B. Between the STAR panel and the STAT team

There were no areas of disagreement between the STAR panel and the STAT team.

Unresolved problems and major sources of uncertainty

Stock structure is a major uncertainty that is being addressed with genetic studies and localized sampling. There is a need to increase sampling in near-shore waters so as to be able to determine the degree of stock separation. An absence of reliable fishery independent estimators complicates the assessment and makes it difficult to determine the absolute abundance of sub-stocks. The model results are sensitive to natural mortality estimates and there are considerable differences between males and females.

Management, data, or fishery issues raised by the GAP and the GMT representatives

GMT and GAP representatives commented that surveys in near shore areas are critical to better estimate abundance, and encourages the development of additional local monitoring surveys. There was discussion of working with commercial fishermen to develop potential cooperative indexing surveys to monitor population change.

Prioritized recommendations for future research and data collection

1. M seems high for both genders for a species of that size, shape and life habits. The current high estimates could be due to higher values at some ages or length. Tag – recapture studies currently being conducted are expected to be useful in that respect and should be used to estimate M. Information would be expected for the assessment cycle after the next.

2. Further tagging studies should be conducted to estimate growth, natural mortality, migration and to investigate stock structure, including for a larger portion of the distribution range.

3. Confirm/re-estimate the landings in 1980 in the RecFIN PBR which should include correcting the RecFIN database to avoid using unrealistic landings for that year in future assessments. Including the catch reconstruction from 1980 onwards, similar to what was done for lingcod.

4. Explore the shorter yet more detailed logbook data (digitized by license number) for CA from 1980 onwards (CPFV).

5. B_{MSY} is very close to the limit reference point. This suggests that further general investigation of target and limit reference point is warranted. Reference points need to be re-evaluated.

6. Develop at least one reliable fishery independent survey possibly using longline or trap (no rockfish bycatch) survey. This could be a combined cabezon and lingcod pot survey designed to adequately cover the inshore distribution area and the closed areas.

7. Continue to develop alternative management procedures that do not require traditional stock assessment.

8. Look at environmental covariates for recruitment and time-varying growth and availability inshore.

9. Investigate the implications of the male guarding behaviour (re-defining spawning output).

10. Investigate non-lethal methods to determine gender and collecting sex-specific data.

11. Investigate further the abundance and distribution of cabezon larvae and juveniles in existing databases to better understand stock structure and linkages.

12. Investigate the usefulness of catches of cabezon in the man-made fishery on piers and jetties as an index of recruitment.

Acknowledgements

The Panel thanks Dr. Jim Hastie and staff at the NWFSC for their exceptional support and provisioning during the STAR meeting.

Status of the U.S. yelloweye rockfish resource in 2009

Table of Contents

Executive Summary

Stock

This assessment reports the status of the yelloweye rockfish (*Sebastes ruberrimus*) resource off the coast of the United States from southern California to the U.S.-Canadian border using data through 2008. The resource is modeled as a single stock, but with three explicit spatial areas: Washington, Oregon and California. Each area is modeled simultaneously with its own unique catch history and fishing fleets (recreational and commercial) but the dynamics follow the current understanding of yelloweye stock structure: large stocks linked via a common stock-recruit relationship with negligible adult movement among areas.

Catches

Yelloweye rockfish catches were estimated from a variety of sources, but are very uncertain due to the relatively small contribution of yelloweye to rockfish market categories and the relatively large scale of recreational removals. Catches include estimates of discarding after 2001 when management restrictions resulted in nearly all yelloweye caught by recreational and commercial fishermen being discarded at sea. Recent catches were based on current total mortality estimates (2002-2007) and the GMT scorecard (2008). Estimated catches increased gradually throughout the first half of the 20th century, with the exception of a brief period of higher removals around World War II. Catches peaked in 1982 at 421 mt, with removals in excess of 200 mt estimated for all years between 1977 and 1997. Uncertainty in catches is treated explicitly throughout this analysis.

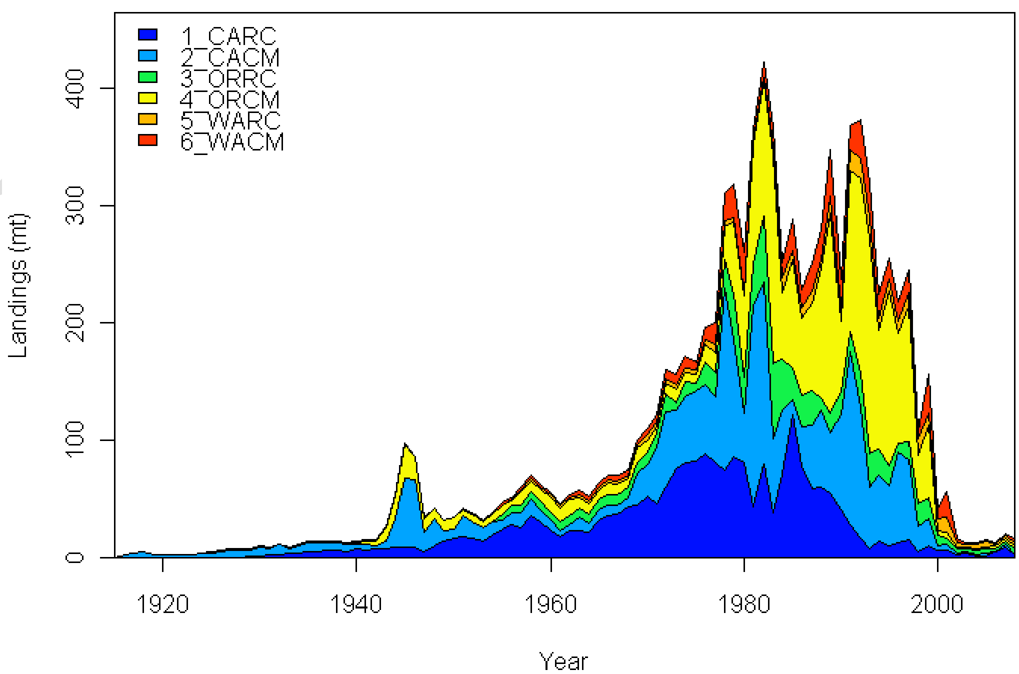

Figure a. Yelloweye rockfish estimated catch history, 1916-2008. Fleet names indicated by state (WA, OR or CA) and sector (recreational = RC, commercial = CM).

Table a. Recent yelloweye rockfish catches (mt) by fleet.

Year	California Recreational	California Commercial[1]	Oregon Recreational	Oregon Commercial[1]	Washington Recreational	Washington Commercial[1]
1999	9.4	23.5	18.1	61.3	10.6	32.9
2000	5.7	4.0	9.5	3.6	10.1	7.9
2001	6.4	4.3	4.8	6.2	12.5	21.8
2002	2.5	1.1	3.1	1.9	3.7	3.5
2003	3.7	0.7	3.0	1.0	2.6	1.3
2004	0.6	1.3	3.7	1.5	3.7	1.5
2005	0.9	1.9	4.3	1.4	5.2	1.4
2006	4.1	0.8	2.9	1.9	1.7	1.0
2007	8.0	2.9	3.1	2.0	2.5	1.1
2008	2.1	0.4	4.1	2.5	2.8	4.7

[1]Includes research catches.

Data and Assessment

This stock assessment used the newest version of Stock Synthesis available (3.03b, released 28 May 2009). The model data sources include catch, length- and age-frequency data from six state-specific recreational and commercial fishing fleets. Biological data is derived from both port and on-board observer sampling programs. Yelloweye catch in the IPHC long-line survey for Pacific halibut is also included via an index of relative abundance for Washington and for Oregon as well as length- and age-frequency data. Oregon recreational charter observer data from discarded yelloweye was used to construct a recent index of relative abundance (2004-2008) and length-frequency observations. The National Marine Fisheries Service (NMFS) Northwest Fisheries Science Center (NWFSC) trawl survey relative biomass indices and information from biological sampling, as well as the triennial trawl survey are included.

Externally estimated model parameters, including those defining weight-length, maturity, and fecundity relationships, are revised from values used in previous assessments. The assessment explicitly accounts for the small degree of dimorphic growth as well as markedly different exploitation histories among geographic areas (Washington, Oregon and California). Due to sparse and poorly informative age- and length-frequency data, recruitment is modeled as a deterministic process. Key parameters including natural mortality, stock-recruitment steepness and all growth parameters are estimated.

Although the base case assessment model captures some uncertainty via asymptotic intervals, uncertainty from two sources is reported through alternate states of nature bracketing the base case results and included explicitly in the decision table. The magnitude of the estimated catch time-series was found to have a large influence on the perception of current stock size and the estimate of steepness of the stock-recruit relationship was closely linked to the projected recovery rates. Alternate values of each were selected to bracket the best estimates with marginal probabilities one-half as likely. For historical catch these values, 75% and 150% of the estimated catch series prior to 2000, were subjective, but reflect both the lack of a comprehensive catch reconstruction in Washington and the change in likelihood of the fit to data sources over a reasonable range of catch levels. For steepness the 12.5th and 87.5th percentiles were calculated from the likelihood profile as a proxy for the probability distribution about this point estimate. The most optimistic and pessimistic of the nine combinations from these two axes (weighted 6.25% each relative to 25% for the best estimate on each dimension) are reported in this document and all combinations used to provide a more realistic degree of uncertainty for future projections, decision tables and rebuilding analyses.

Table b. Relative probabilities for combinations of the two alternate states of nature. Cells in bold denote those reported throughout this document.

		Historical catch		
		Low	Best estimate	High
Steepness	Low	**6.25%**	12.5%	6.25%
	Estimated value	12.5%	**<u>Base case</u>: 25%**	12.5%
	High	6.25%	12.5%	**6.25%**

Stock biomass

A fecundity relationship is used for yelloweye specifying that spawning output per unit weight increases with fish weight; therefore all reference to spawning output is in terms of eggs produced, instead of spawning biomass. Yelloweye rockfish are estimated to have been lightly exploited until the mid-1970's, when catches increased and a rapid decline in biomass and spawning output began. The relative spawning output reached a minimum of 15.8% of unexploited levels (slightly above the estimate of 12.1% from the 2007 assessment) in 2000. Yelloweye rockfish spawning output is estimated to have been gradually increasing since that time in response to large reductions in harvest. Although the relative trend in spawning output is quite robust to uncertainty in the estimated removals, the spawning output trajectory on an absolute scale is very sensitive. The estimated relative depletion level in 2007 is 19.2% (slightly above the estimate of 16.4% from the 2007 assessment) and 20.3% in 2009 (states of nature: 17.3-23.5%), corresponding to 201.5 million eggs. The range over states of nature reflects the very large uncertainty in the absolute scale of the estimated time-series for spawning output: 128.3-353.0 million eggs. The aggregate spawning output estimates mask the spatial heterogeneity included via the area-specific dynamics: relative spawning output has differed markedly among the three states, with California having the largest spawning output at unexploited equilibrium, followed by Oregon and then Washington. Currently, Oregon is estimated to have the largest spawning output, followed by California, then Washington. Relative depletion also varies dramatically by state, with California estimated to be at 16.4% of unexploited conditions, Oregon, 22.5%, and Washington, 27.3%.

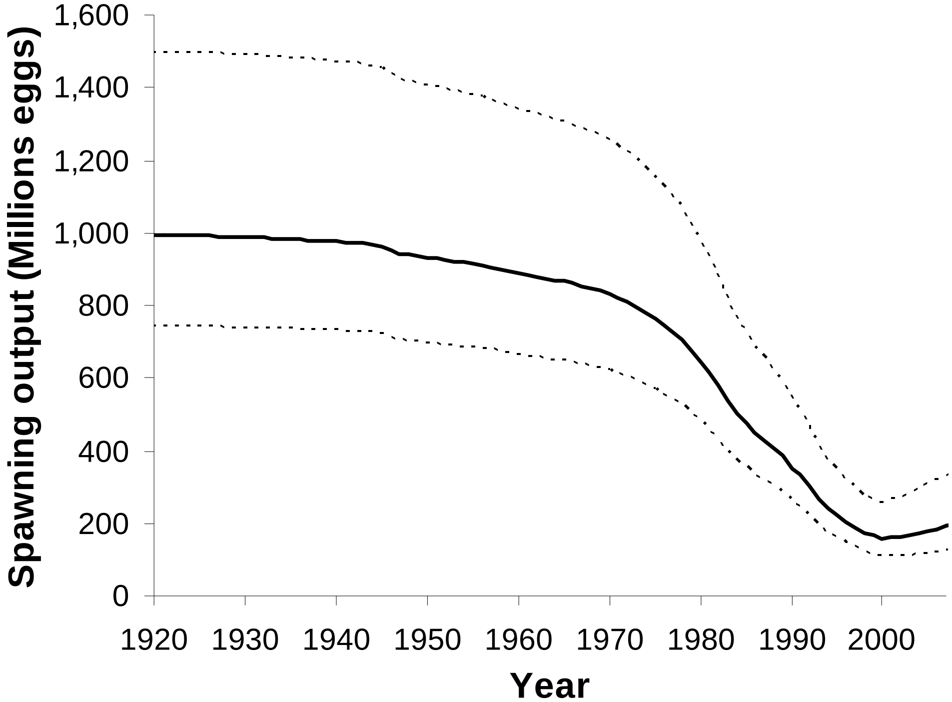

Figure b. Estimated spawning output time-series (1916-2009) for the base case model (solid line) with alternate states of nature (dashed lines).

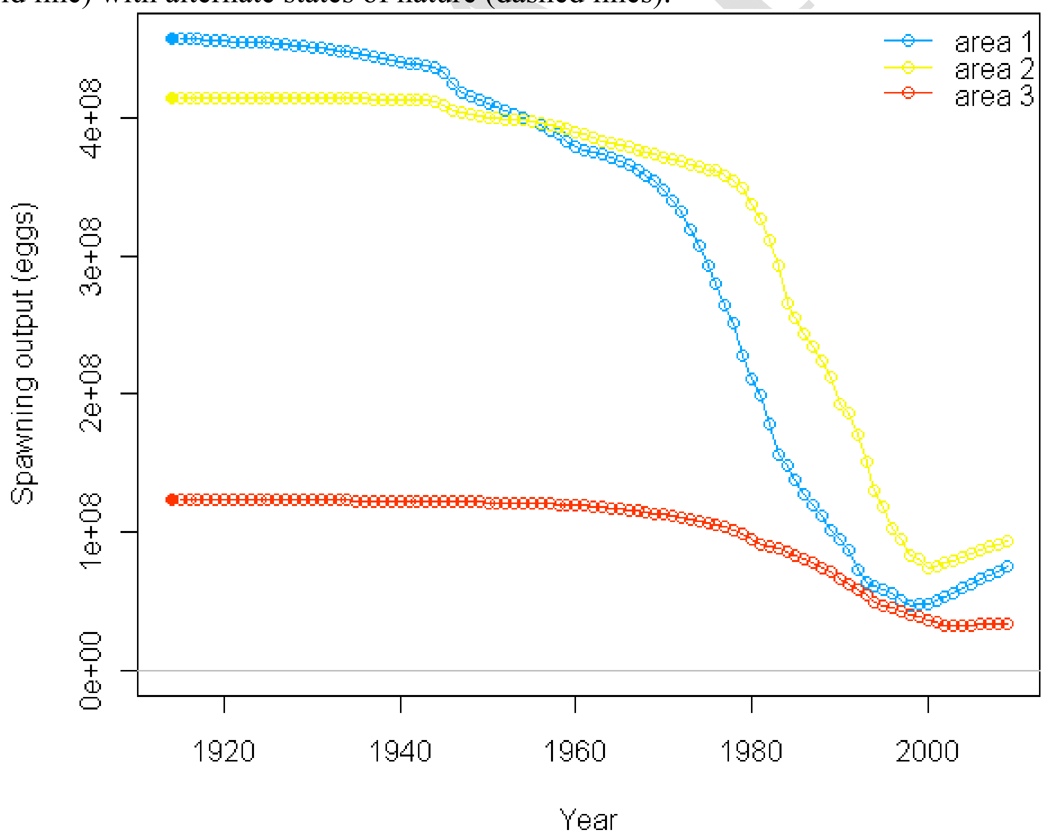

Figure c. Estimated spawning output time-series (1916-2009) by state for the base case model. Area 1, upper line (early years) = California; Area 2, middle line (early years) = Oregon; and Area 3, lower line (early years) = Washington.

Table c. Recent trend in estimated yelloweye rockfish spawning output, recruitment and relative depletion level.

Year	Spawning output (millions eggs)	Range of states of nature	Estimated recruitment (1000s)	Range of states of nature	Estimated depletion	Range of states of nature
2000	157.4	108.8-257.1	79.4	47.1-151.9	15.8%	14.6-17.2%
2001	160.3	109.2-265.1	80.5	47.2-154.9	16.1%	14.7-17.7%
2002	161.6	107.9-271.8	81.0	46.8-157.4	16.3%	14.5-18.1%
2003	167.3	110.9-283.1	83.2	47.9-161.5	16.8%	14.9-18.9%
2004	173.4	114.3-295.0	85.5	49.1-165.7	17.4%	15.4-19.7%
2005	179.5	117.6-307.0	87.7	50.3-169.8	18.1%	15.8-20.5%
2006	185.3	120.5-318.7	89.8	51.4-173.7	18.6%	16.2-21.3%
2007	191.3	123.7-330.7	92.0	52.5-177.6	19.2%	16.6-22.1%
2008	196.4	126.0-341.9	93.8	53.4-181.1	19.8%	16.9-22.8%
2009	201.5	128.3-353.0	95.5	54.2-184.5	20.3%	17.3-23.5%

Recruitment

Because year-class strength is modeled as a deterministic process in this assessment, the decline in estimated recruitment tracks closely that of the spawning output. The decline is especially pronounced given the low (and likely imprecise) estimate for steepness of the stock-recruit relationship in the base case model (0.417), and alternate models (0.344, 0.508). However, the considerable uncertainty in absolute recruitment levels is illustrated by the broad range over the states of nature.

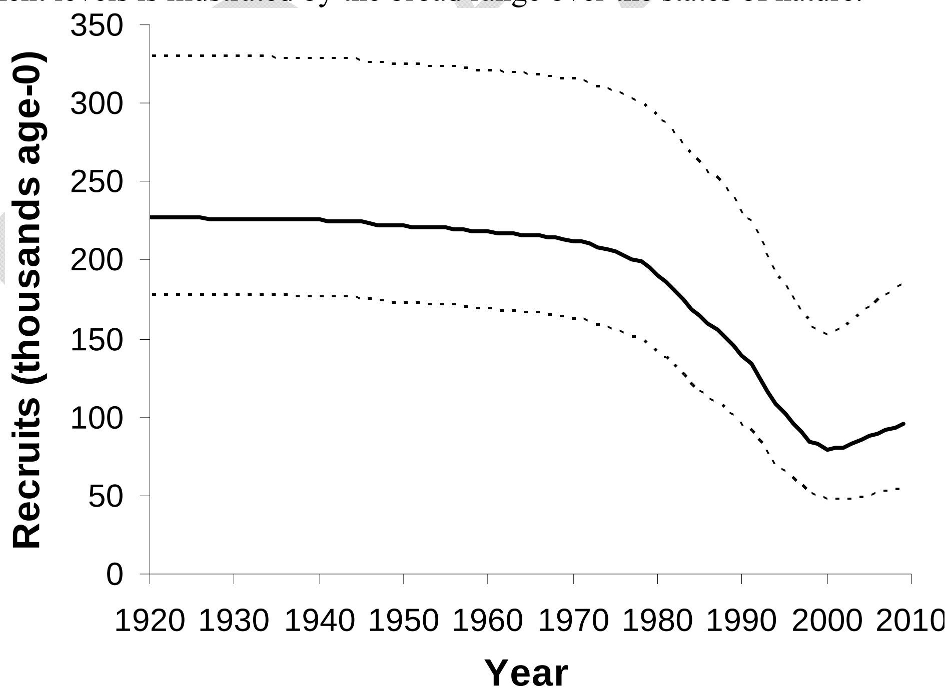

Figure d. Time series of estimated yelloweye rockfish recruitments for the base case model (solid line) and alternate states of nature (dashed lines).

Reference points

Unfished spawning output was estimated to be 994 million eggs. The target stock size ($SB_{40\%}$) is therefore 398 million eggs and the overfished threshold ($SB_{25\%}$) is 249 million eggs. Maximum sustained yield (MSY), conditioned on current fishery selectivity and allocations, was estimated in the assessment model to occur at a spawning stock biomass of 388 million eggs and produce an MSY catch of 56.4 mt (slightly above the estimate from the 2007 assessment of 43.7 mt). However, the yield at MSY is extremely sensitive to the states of nature resulting in a wide range for this value from 31.5 to 107.9 mt. Maximum sustainable yield is estimated to be achieved at an SPR of 60.4% (range of states of nature: 51.2-69.7%). This is nearly identical to the yield, 56.1 mt, generated by the SPR (61.0%) that stabilizes the stock at the $SB_{40\%}$ target. The fishing mortality target/overfishing level (SPR = 50.0%) results in a smaller equilibrium yield of 48.9 mt at a spawning output of 230 million eggs (23.1% of the unfished level).

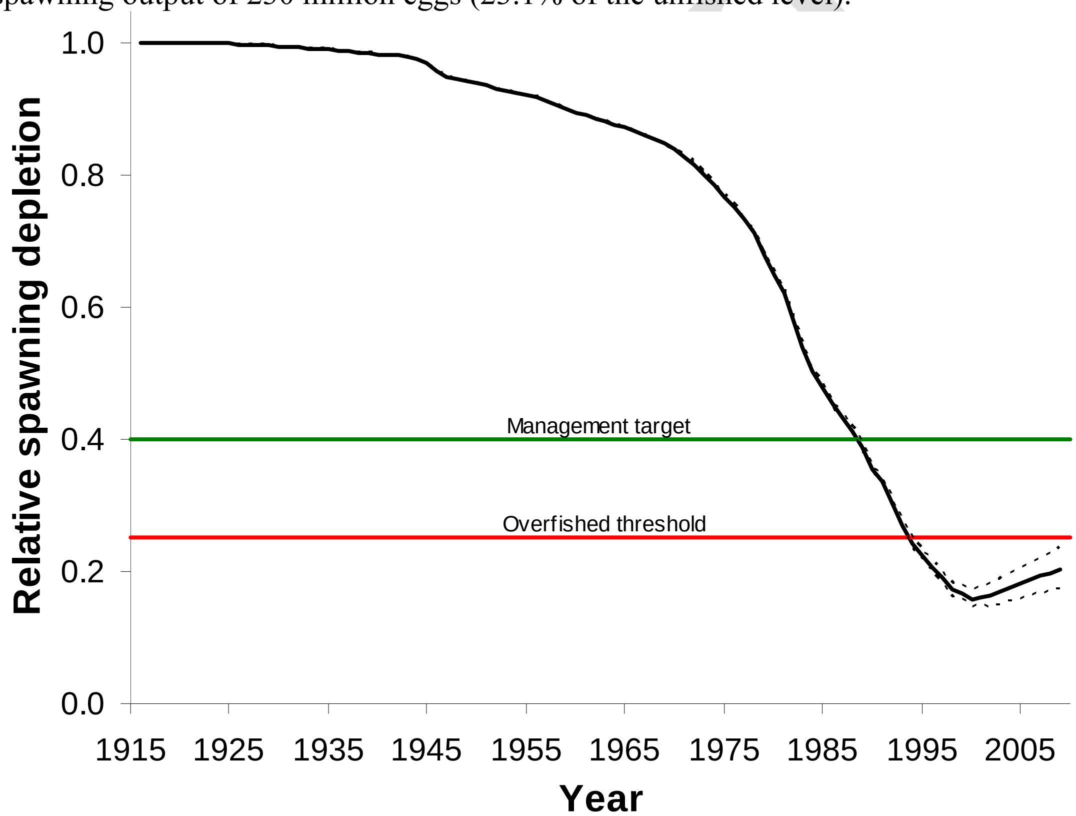

Figure e. Time series of relative spawning depletion as estimated in the base case model (solid line) and alternate states of nature (dashed lines).

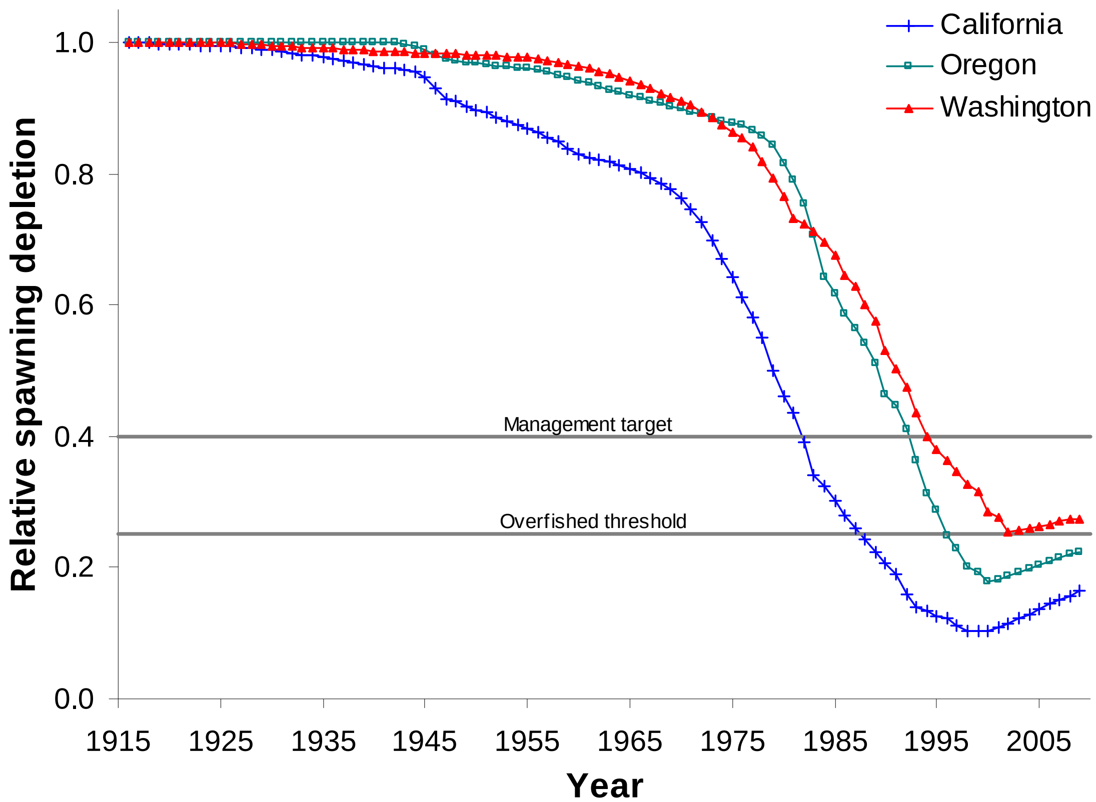

Figure f. Time series of relative spawning depletion by state for the base case model.

Exploitation status

The coast-wide abundance of yelloweye rockfish was estimated to have dropped below the $SB_{40\%}$ management target in 1989 and the overfished threshold in 1994. In hindsight, the spawning output passed through the target and threshold levels with annual catch averaging almost five times the current estimate of the *MSY*. The coast-wide stock remains below the overfished threshold, although the spawning output is estimated to have been increasing since 2000 in response to reductions in harvest. The degree of increase is largely insensitive to the magnitude of historical catch and only moderately sensitive to the value for steepness, but the absolute scale of the population reflects alternate removal series very closely. Fishing mortality rates are estimated to have been in excess of the current *F*-target for rockfish of $SPR_{50\%}$ from 1976 through 1999. Recent management actions have curtailed the rate such that recent SPR values are in excess of 60% over the last eight years. Relative exploitation rates (catch/biomass of age-8 and older fish) are estimated to have been at or less than 1% after 2001. The alternate states of nature result in estimated exploitation rates ranging from less than 1.6% to less than 0.6%.

Table d. Recent trend in spawning potential ratio (SPR) and relative exploitation rate (catch/biomass of age-8 and older fish).

Year	Estimated SPR (%)	Range of states of nature	Relative exploitation rate	Range of states of nature
1999	17.3%	15.9-19.0%	8.9%	8.2-9.6%
2000	53.0%	42.3-65.8%	2.4%	1.5-3.6%
2001	53.0%	42.4-65.3%	3.3%	2.0-4.9%
2002	76.6%	68.6-84.5%	0.9%	0.5-1.4%
2003	78.8%	70.8-86.4%	0.7%	0.4-1.1%
2004	82.0%	75.2-88.4%	0.7%	0.4-1.0%
2005	79.2%	71.5-86.5%	0.8%	0.5-1.2%
2006	79.6%	71.3-87.2%	0.6%	0.4-1.0%
2007	70.6%	60.4-80.9%	1.0%	0.6-1.6%
2008	79.3%	71.4-86.7%	0.8%	0.5-1.3%

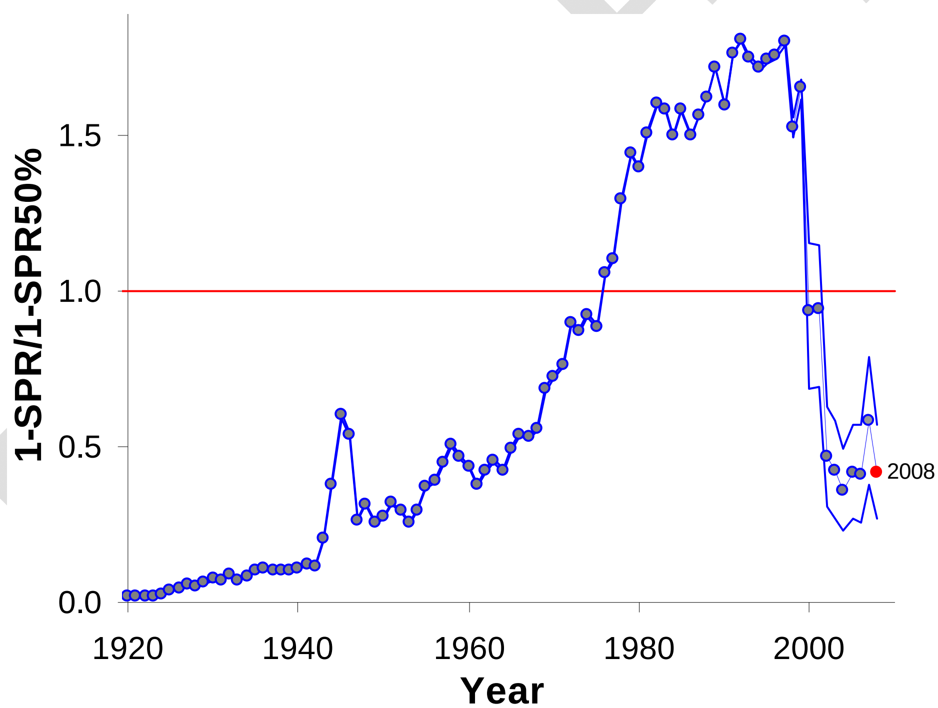

Figure g. Time series of relative spawning potential ratio (1-SPR/1-$SPR_{Target=0.5}$) for the base case model (round points) and alternate states of nature (light lines). Values of relative SPR above 1.0 reflect harvests in excess of the current overfishing proxy.

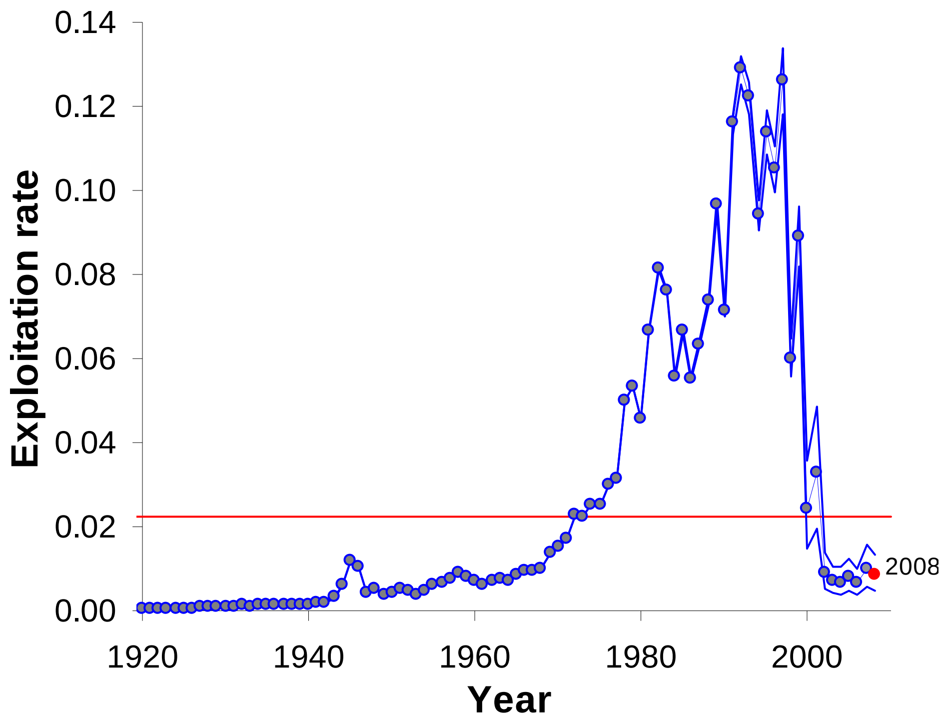

Figure h. Time series of estimated exploitation rate (catch/age 8 and older biomass) for the base case model (circles) and alternate states of nature (light lines). Horizontal line indicates the overfishing limit/target ($F_{50\%}$) from the base case.

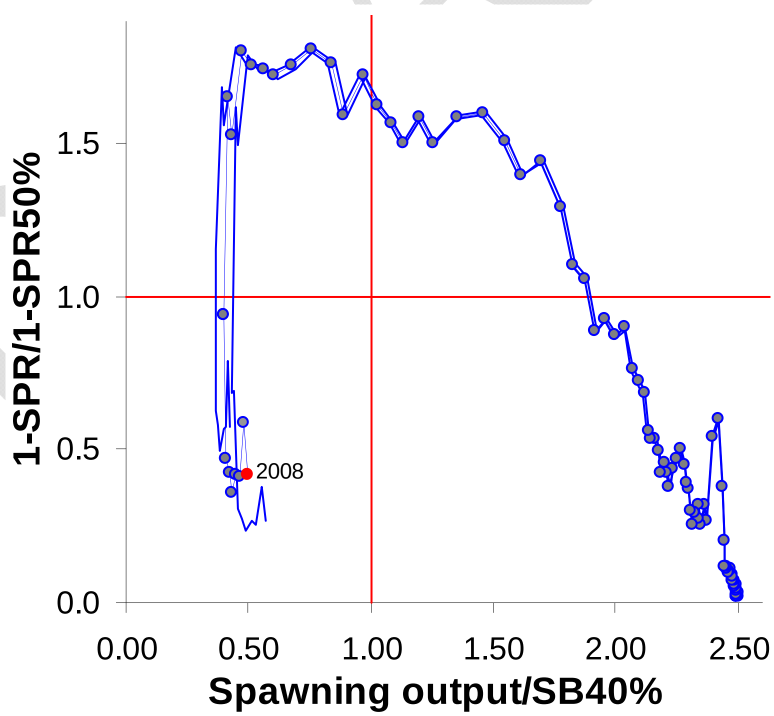

Figure i. Estimated relative spawning potential ratio relative to the proxy target/limit of 50% vs. estimated spawning output relative to the proxy 40% level from the base case model. Higher spawning output occurs on the right side of the x-axis, higher exploitation rates occur on the upper side of the y-axis.

Management performance

Before 2000, yelloweye rockfish were managed as part of the *Sebastes* Complex, which included all *Sebastes* species without individual assessments, ABCs and OYs. In 2000, the *Sebastes* Complex was divided into three depth-based groups (north and south of 40° 10’ N. latitude), and yelloweye rockfish were managed as part of the minor shelf rockfish group until 2002. Since then, there has been species-specific management, and total catch has been below both the ABC and OY for yelloweye each year. These catch levels represent a 95% reduction from average catches observed in the 1980s and 1990s. Managers have constrained catches by eliminating all retention of yelloweye rockfish in both commercial and recreational fisheries, instituting broad spatial closures (some specifically for moving fixed-gear fleets away from known areas of yelloweye abundance), and creating new gear restrictions intended to reduce trawling in rocky shelf habitats and the coincident catch of rockfish in shelf flatfish trawls. Since 2002, the total 6-year catch (88.5 mt) has been only 63% of the sum of the OYs for 2002-2008 and only 29% of the sum of the ABCs for that period. The total 2008 catch (16.7 mt) is estimated to be just 4% of the peak annual catch that occurred in the early 1980s.

Table e. Recent trend in yelloweye rockfish catch (mt) relative to management guidelines.

Year	ABC (mt)	OY (mt)	Commercial Catch (mt)[1]	Recreational Catch (mt)	Total Catch (mt)
1999	39[2]	NA	117.8	38.1	155.8
2000	39[2]	NA	15.5	25.3	40.9
2001	29[3]	NA	32.5	23.7	56.1
2002	27[3]	13.5[3]	6.4	9.3	15.8
2003	52	22	3.2	9.4	12.4
2004	53	22	4.4	8.0	12.3
2005	54	26	5.3	10.4	15.1
2006	55	27	3.8	8.7	12.4
2007	47	23	7.9	13.6	19.6
2008	47	20	7.8	9.0	16.7

[3]Includes the Columbia, Vancouver and Eureka INPFC areas only.

Unresolved problems and major uncertainties

Data for yelloweye rockfish are sparse and relatively uninformative, especially regarding current trend. Historical catches are very uncertain, as yelloweye comprise a small percentage of overall rockfish removals and actual species-composition samples are infrequently available for historical analyses. Further, the relative contribution of recreational removals was very large, and there is low certainty in the estimates of the exact magnitude of these removals. The management related quantities were found to be very sensitive to alternate catch time-series and this is presented as one of the primary axes of uncertainty.

The choice to model the yelloweye rockfish stock with explicit areas in the assessment model is based on the sedentary life-history of adult yelloweye, and the markedly different population trends as well as historical and current exploitation rates among the three states. The data do not clearly inform this choice, but it does have substantial ramifications for future projections and management decisions and should be considered a major uncertainty in the assessment.

Parameters that generally contribute significant uncertainty to stock assessments, including those defining steepness, natural mortality and growth are estimated, but may be poorly determined due to the short time-series of data, which are primarily available after the biggest period of removals from the stock. Steepness of the stock-recruitment relationship especially is often poorly estimated from a time series like that of yelloweye (a 'one-way trip'), but its value is very important in determining projected rebuilding. For this reason alternate values (from the likelihood profile) are included as a second axis of uncertainty in this assessment.

Process error in recruitment is not explicitly accounted for in this assessment. This choice is driven by several factors: the lack of substantial reduction in the estimates of uncertainty in recruitment deviations (when estimated) relative to the level of recruitment variability (σ_r), the need to integrate over long time-series of poorly informed recruitment deviations rather than use the maximum likelihood point-estimate in order to achieve unbiased estimates, the computation time required to minimize and integrate a much larger dimensioned model, and the fact that, even when accounted for, recruitment variability did not represent the dominant axis of uncertainty with regard to current management quantities. Previous assessments have struggled with the lack of signal in recruitment deviations; the 2006 and 2007 models estimated deviations over only a short period of the time series (1968-1992). Further research is needed to ensure unbiased estimation is achieved when integrating or estimating large numbers of poorly informed recruitment deviations in stock assessment models.

Currently available fishery-independent indices of abundance are imprecise and not highly informative. It is unclear whether increased rates of recovery (or lack thereof) will be detectable without more precise survey methods applied over broad portions of the coast. Fishery data are also unlikely to produce conclusive information about the stock for the foreseeable future, due to lack of retention and active avoidance of yelloweye among all fleets. For these reasons, it is unlikely that the major uncertainties in this assessment will soon be resolved.

Forecasts

The forecast reported here will be replaced by the rebuilding analysis to be completed in September-October 2009 following SSC review of the stock assessment. In the interim, the total catch in 2009 and 2010 is set equal to the OY (17 mt). The target exploitation rate for 2011 and beyond is based upon an SPR of 71.9%, which approximates the harvest level in the current (2007) rebuilding strategy (the 71.9% SPR rate represents the target after the 'ramp-down' portion of the strategy is completed in 2010). Uncertainty in the rebuilding forecast will be included via integrating over all combinations of the alternate states of nature for catch history and steepness.

Current medium-term forecasts predict increases in coast-wide abundance under the SPR=71.9% rebuilding strategy, however these increases are largely driven by the California and Oregon portions of the stock. In fact, the Washington portion is projected to remain at current levels under recent allocation of catch; however, this result is likely to be sensitive to future revision of the estimated Washington historical catch series. Catch allocation used for the forecast reflects the average distribution of *F*s in 2005-2007 among fleets (recreational, commercial) in: Washington (0.013, 0.005), Oregon (0.004, 0.002) and California (0.006, 0.003). The estimated OY values for 2011 and 2012 are larger (20.9, 21.2) than those predicted from the 2007 rebuilding analysis (13.9, 14.2). The following table shows the projection of expected yelloweye rockfish catch, spawning output (by area) and depletion. It may be desirable to evaluate specific alternative allocation scenarios, if relative removals based on future management actions will be substantially different than recent values by state.

Table f. Projection of potential yelloweye rockfish ABC, OY, spawning output and depletion for the base case model based on the SPR = 71.9% fishing mortality target used for the last rebuilding plan (OY) and $F_{50\%}$ overfishing limit/target (ABC). Assuming the OY of 17 mt is achieved exactly in 2009 and 2010. Catch allocation used for the forecast reflects the average distribution of *F*s in 2005-2007 among fleets (recreational, commercial) in: Washington (0.013, 0.005), Oregon (0.004, 0.002) and California (0.006, 0.003).

					Spawning output (million eggs)			
Year	ABC[1] (mt)	OY[1] (mt)	Coast-wide Age 8+ biomass (mt)	Coast-wide Depletion	Coast-wide	California	Oregon	Washington
2009	*31*	*17*	2,008	20.3%	202	75	93	34
2010	*32*	*17*	2,039	20.8%	206	78	95	34
2011	49.3	20.9	2,068	21.2%	211	80	97	34
2012	49.9	21.2	2,093	21.6%	215	82	98	34
2013	50.5	21.4	2,118	22.0%	219	85	100	34
2014	51.1	21.7	2,141	22.4%	222	87	101	34
2015	51.6	21.9	2,165	22.7%	226	89	103	34
2016	52.1	22.1	2,187	23.0%	229	91	104	34
2017	52.6	22.3	2,210	23.3%	232	93	105	34
2018	53.0	22.5	2,232	23.6%	235	94	107	34
2019	53.5	22.7	2,255	23.9%	237	96	108	34
2020	53.9	22.9	2,277	24.1%	240	98	109	34

[1]ABC/OY values for 2009 and 2010 have already been adopted, and are not based on the results of this assessment.

Decision table

Because yelloweye rockfish are currently managed under a rebuilding plan, this decision table is only intended to better evaluate the management implications of the considerable uncertainty in the base case assessment model. Various alternate management actions, including a range of SPR rates and fixed OYs, will be compared in the rebuilding analysis. Landings in 2009-2010 are 17 mt for all cases. Catch allocation used for the forecast reflects the average distribution of *F*s in 2005-2007 among fleets (recreational, commercial) in: Washington (0.013, 0.005), Oregon (0.004, 0.002) and California (0.006, 0.003).

Table g. Decision table of 12-year projections for alternate states of nature (columns) and management options (rows) beginning in 2011. Relative probabilities are based on the joint distribution of alternate historical catch levels and steepness values.

			State of nature					
			75% of catch < 2000 and steepness = 0.344		Base case 100% of catch < 2000 and steepness = 0.417		150% of catch < 2000 and steepness = 0.508	
Relative probability			0.0625		0.25		0.0625	
Management decision	Year	Catch (mt)	Depletion	Spawning output (millions eggs)	Depletion	Spawning output (millions eggs)	Depletion	Spawning output (millions eggs)
Rebuilding SPR 71.9% catches from low alternative	2011	13.2	17.8%	132	21.2%	211	25.0%	375
	2012	13.4	18.1%	134	21.7%	216	25.7%	385
	2013	13.5	18.3%	136	22.2%	220	26.4%	396

	2020	41.7	16.2%	121	22.4%	223	29.3%	439

Research and data needs

The available data for yelloweye rockfish are very sparse and generally weakly informative about current status. The following research topics could improve the ability of this assessment to reliably model the yelloweye rockfish population dynamics in the future and provide better monitoring of progress toward rebuilding:

1. Develop and implement a comprehensive visual survey.
2. Do a scientific review of current efforts to develop and improve stock size indices for yelloweye based on IPHC (including additional stations) and make recommendations on the best approaches to develop such indices.
3. Explore a recalculation of GLMM estimates in the IPHC survey that explores station effects which allows inclusion of stations that differ over time.
4. Continue to refine historical catch estimates using ex-vessel prices, etc., particularly in WA.
5. Investigate the development of a WA recreational yelloweye CPUE based on the recreational halibut fishery. Consider a full time series and one ending in 2002, since the yelloweye RCA in waters off northern WA was implemented in 2003.
6. Encourage the collection of samples to refine the estimate biological parameters, particularly maturity and fecundity.
7. Continue to evaluate the spatial aspects of the assessments, including growth, the number and placement of boundaries between areas, as well as the northern boundary with Canada.
8. More work is needed to better understand the performance of maximum likelihood and Bayesian estimators of stock size and trends when large numbers of poorly informed recruitment deviations are estimated. Although it is logically appealing to include such uncertainty, even when little coherent data informing cohort strengths is available, technical and computational issues need to be solved before this approach can be implemented in a case like yelloweye rockfish.
9. Investigate alternative ways of re-weighting. This issue is relevant for all west coast stock assessments.
10. Investigate how best to account for the variability in dates in trawl surveys through a meta-analysis. This issue is relevant for all west coast stock assessments.
11. Continue to refine coast-wide historical catch estimates. This issue is relevant for all west coast stock assessments.
12. Access and processing of recreational data (catch and biological sampling) currently entails differing locations and formats for data from each of the three states and RecFIN. A single database that holds all raw recreational data in a consistent format would reduce assessment time spent on processing these data and potential introduction of errors or alternate interpretations due to processing.
13. The IPHC data organization should be revisited. Currently biological samples cannot be linked to the station from which they were collected. Age data for 2003-2005 is disconnected from length and sex information and other unknown issues may persist in these data. A thorough evaluation of what data are reliable and a final determination of what information is lost, or can potentially be recovered, is needed.

Rebuilding projections

The rebuilding projections will be presented in a separate document after the assessment has been reviewed by the SSC in September 2009.

Table h. Summary of recent trends in estimated yelloweye rockfish exploitation and stock levels from the base case model; all values reported at the beginning of the year.

	2000	2001	2002	2003	2004	2005	2006	2007	2008	2009

[4] ABC/OY values for 2009 and 2010 have already been adopted, and are not based on the results of this assessment.

Table i. Summary of yelloweye rockfish reference points from the base case model.

Quantity	Estimate	Range of states of nature
Unfished spawning output (SB_0, millions eggs)	994	743-1,499
Unfished 8+ biomass (mt)	8,492	6,399-12,718
Unfished recruitment (R_0, thousands)	227	178-330
Reference points based on $SB_{40\%}$		
MSY Proxy Spawning output ($SB_{40\%}$, millions eggs)	392	297-600
Relative spawning depletion at $SB_{40\%}$	40.0%	NA
SPR resulting in $SB_{40\%}$ ($SPR_{SB40\%}$)	61.0%	54.6-68.6%
Exploitation rate resulting in $SB_{40\%}$	1.5%	1.2-1.9%
Yield with $SPR_{SB40\%}$ at $SB_{40\%}$ (mt)	56	31-107
Reference points based on SPR proxy for MSY		
Spawning output at $SPR_{MSY\text{-}proxy}$ (SB_{SPR}, millions eggs)	230	33-509
Relative spawning depletion at SB_{SPR}	23.1%	4.4-34.0%
$SPR_{MSY\text{-}proxy}$	50.0%	NA
Exploitation rate corresponding to SPR	2.2%	2.2-2.3%
Yield with $SPR_{MSY\text{-}proxy}$ at SB_{SPR} (mt)	49	7-108
Reference points based on estimated MSY values		
Spawning output at *MSY* (SB_{MSY}, millions eggs)	388	314-533
Relative spawning depletion at SB_{MSY}	39.1%	35.6-42.2%
SPR_{MSY}	60.4%	51.2-69.7%
Exploitation Rate corresponding to SPR_{MSY}	1.6%	1.1-2.1%
MSY (mt)	56	32-108

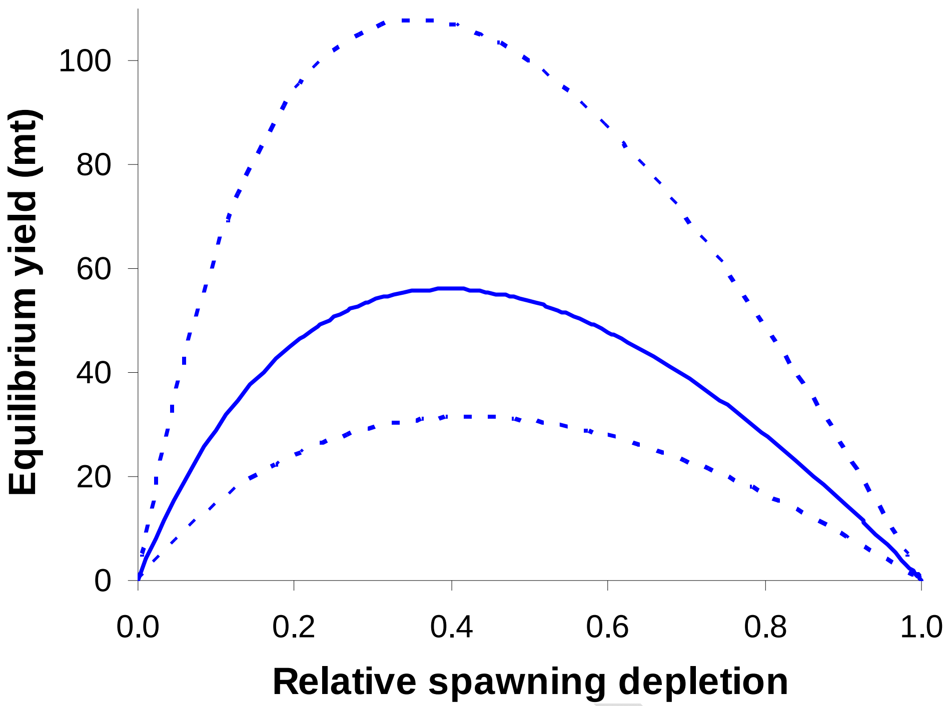

Figure j. Equilibrium yield curve for the base case model (solid line) and alternate states of nature (dashed lines), reflecting the higher and lower values for historical catch prior to 2000 and for steepness.

1. Introduction

1.1 Distribution and Stock Structure

Yelloweye rockfish (*Sebastes ruberrimus*) are distributed in the northeastern Pacific Ocean from the western Gulf of Alaska to northern Baja California (Hart 1973, Eschmeyer and Herald 1983, Love et al. 2002). The species is most abundant from southeast Alaska to central California (Love et al. 2002), with adults found along the continental shelf generally shallower than 400 m. Although smaller yelloweye tend to occur in shallower water, they do not show as pronounced an ontogenetic shift as do many eastern pacific rockfish species. Yelloweye are strongly associated with rocky bottom types, especially areas of high-relief such as caves and large boulders (Love et al. 2002). Mainly solitary, it is widely believed that yelloweye are very sedentary after settlement, with adults moving only short distances during their entire lifetime.

There is relatively little direct information regarding the stock structure of yelloweye rockfish off the U.S. and Canadian coasts. The pelagic larval phase exhibited by all rockfish promotes some mixing of reproductive output, dependent on ocean currents, the duration of the pelagic phase and the timing of annual spawning in relation to annually variable spring transition and upwelling events. However, the sedentary nature of yelloweye rockfish makes adult movement among major rocky habitat areas unlikely. An unpublished genetics study (Yamanaka et al. 2001) of yelloweye rockfish collected from northern Vancouver, B.C. and SE Alaskan waters found little variability among samples and suggested a panmictic stock in the study area. Preliminary results from an analysis of yelloweye collected off Oregon, Washington, Vancouver Island B.C., and the Strait of Georgia B.C. (Lynne Yamanaka, DFO, personal communication, cited in Wallace et al. 2006) suggest that there may be genetic separation between the Strait of Georgia (inside Vancouver Island) and the outer coast (Yamanaka et al. 2006). The yelloweye population residing in the waters of Puget Sound is also thought to be isolated from coastal waters. This Puget Sound stock was proposed for listing under the Endangered Species Act (Federal Register Vol. 73, No. 52, Monday, March 17, 2008, p. 14195-14200) with the result that the stock was considered distinct and proposed to have threatened status (Federal Register / Vol. 74, No. 77, Thursday, April 23, 2009, p. 18516-18542).

An unpublished study of otolith isotope levels (Gao et al. Draft Manuscript) examined ratios of C^{13}/C^{12} and O^{18}/O^{16} in 200 yelloweye rockfish otoliths from the Washington and Oregon coasts. The centroids from these otoliths showed no consistent differences, and suggest there might be a single spawning stock for this portion of the yelloweye rockfish population. Isotopic differences between otolith nuclei and the fifth annual zones may reflect changes in diet from age-1 to age-5. The fifth annual otolith zones differed between Washington and Oregon samples suggesting that the diet compositions of the two areas are slightly different, an unlikely result if appreciable numbers of age 5+ fish were moving between areas

This assessment attempts to mimic the general perception of stock structure for yelloweye rockfish: large stocks linked via a common (but annually variable) stock-recruit relationship with negligible adult movement among areas.

1.2 Life History and Ecosystem Interactions

Yelloweye rockfish spawn in late winter through the summer and possibly into the fall in SE Alaska (Love et al. 2002). Little is known about the pelagic juvenile phase, but recruiting juveniles settle in both shallow and deeper depths, often observed in the same areas as adults. These young juveniles are very conspicuous, and easy to identify, due to having markedly different coloration than adults.

Adult yelloweye rockfish are large-bodied, reaching lengths up to 91 cm (Eschmeyer and Herald 1983, Love et al. 2002). They are long-lived (the oldest observed age is 147 years, from Washington in 2005), late-maturing and slow growing. These life-history characteristics would suggest that yelloweye are relatively unproductive and very sensitive to exploitation. This is compounded by their status as an aggressive top-predator on rocky reefs, making hook-and-line gear highly effective, even gear designed for much larger species such as halibut and lingcod. Adult yelloweye are piscivorous predators eating most small pelagic and groundfish species as available.

The cohabitation of adult and juvenile yelloweye likely results in some cannibalism, and large changes in predator biomass (such as the rebuilding of lingcod, *Ophiodon elongatus,* in recent years) could have a strong feedback to juvenile survival and therefore stock productivity. Many rockfishes have shown decadal changes in productivity linked to ocean conditions, and it would not be surprising if yelloweye exhibited similar trends, although this is uncertain. There is evidence that changes in otolith ring width (and likely growth) is correlated with some of the leading environmental indicators of ocean conditions along the west coast (Black et al. 2008). It is very uncertain how future climate change may potentially influence west coast yelloweye growth, productivity or distribution.

1.3 Historical and Current Fishery

Yelloweye rockfish have historically been a prized catch for both commercial and recreational fleets. They have generally yielded a higher price than other rockfish and have therefore largely been retained when encountered, except in recent years when all retention has been prohibited. Throughout the exploitation history, yelloweye were targeted primarily with line-gear due to their affinity for rocky, and largely untrawlable, habitat.

Rockfish catches are recorded back to the beginning of the 20th century, primarily in California, but appreciable quantities were not landed until an early peak around World War II (Ralston et al. Draft Tech. Memo.). A small fraction of these catches have been yelloweye rockfish, gradually increasing in total removals until around 1970 and then increasing very rapidly as fishing technology, markets and total effort increased (Table 1, Figure 1). The late 1970s to the late 1990s saw the highest yelloweye catches of the time-series. After 2002, when yelloweye were declared overfished, total catches have been maintained at much lower levels. Yelloweye are currently caught only incidentally in commercial hook-and-line and sport fisheries targeting other species that are found in association with yelloweye. The recent fishery encounters a very patchy yelloweye rockfish distribution, and extensive effort is made to avoid all but a small amount of bycatch (Figure 2, Figure 3).

1.4 Management History and Performance

Modern rockfish management began in 1983 when the Pacific Fishery Management Council (PFMC) first imposed trip limits on landings of *Sebastes* species. Yelloweye were managed as part of the *Sebastes* complex until 2000, when the Council moved to species-specific management for overfished species of concern and a few others and minor rockfish groupings: nearshore, shelf or slope for the remaining species. Yelloweye rockfish were managed as part of the minor shelf rockfish group until 2002. In November 2001, the Council adopted a total catch optimum yield (OY) of 13.5 metric tons (mt) for yelloweye for all 2002 commercial, recreational, and tribal fisheries combined for Northern California (Eureka INPFC area), Oregon, and Washington. This was an interim level that allowed for fisheries to take place and potentially catch yelloweye along with other fish, but did not allow prosecution of fisheries that directly targeted yelloweye. Based on the 2002 assessment results (Methot et al. 2002), the Council adopted an OY of 22 mt for 2003. Since 2002, total catch has been below both the annual ABCs and OYs, which were based on rebuilding analyses showing very long time-periods required for stock recovery to target levels (Table 2). These catch levels represent a 95% reduction from average catches observed in the 1980s and 1990s. Managers have constrained catches by eliminating all retention of yelloweye rockfish in recreational fisheries, reducing commercial retention of yelloweye rockfish in the trawl fishery (to 200-300 lb per bimonthly period), instituting broad spatial closures, some specifically intended to move fixed-gear fleets away from known areas of yelloweye abundance, and creating new gear restrictions that have reduced trawling in rocky shelf habitats and the coincident catch of rockfish in shelf flatfish trawls. Since 2002, the total 6-year catch (88.5 mt) has been only 63% of the sum of the OYs for 2002-2008 and only 29% of the sum of the ABCs for that period. The total 2008 catch (16.7 mt) is estimated to be just 4% of the peak annual catch that occurred in the early 1980s.

1.5 Fisheries in Canada and Alaska

Yelloweye are caught by commercial line fisheries and recreational fleets in both British Columbia and Southeast Alaska. Current stock estimates and catches are much larger than those recently observed off the coasts of Washington, Oregon and California. In SE Alaska, total catches were 250 mt in 2007 and 261 mt in 2008 (Brylinsky et al. 2007). The overfishing level in SE Alaska has been 650 and 611 mt over the same period, more than twice the average estimated catches observed from the U.S. west coast over the period 1975-1999. Canadian yelloweye management also adopted conservation measures in 2002, reducing limits and closing 20% of the coastal waters to fishing. Prior to this time, peak catches had reached just over 1,000 mt in the early 1990s (Yamanaka et al. 2006). From 2002 to 2004, catches from Canadian outside waters have averaged 248 mt, but have trended downward from 313 to 200 mt. A large portion of this total (58%) comes from the halibut longline fishery.

2. Assessment

The following sources of data were used in building this assessment:

1) Fishery independent data: including relative abundance indices, length and age data from the International Pacific Halibut Commission's (IPHC) longline survey 1999-2008, and the NWFSC and Triennial bottom trawl surveys 2003-2008 (NWFSC survey) and 1980-2004 (Triennial survey).

2) Estimates of fecundity, maturity, length-weight relationships and ageing error from various sources.

3) Informative priors on natural mortality and stock recruit steepness derived from other fish and yelloweye stocks.

4) Commercial (targeted and bycatch) and recreational catch estimates from 1916-2008.

5) Commercial and recreational fishery biological data (age and length) from 1968-2008.

6) Fishery dependent catch-per-unit-effort series from recreational and charter observer programs from all three states.

Data availability by source and year is presented in Table 3. A description of each of the specific data sources is presented below.

2.1 Fishery Independent Data

2.1.1 International Pacific Halibut Commission Survey

The International Pacific Halibut Commission (IPHC) has conducted an annual longline survey for Pacific halibut off the coast of Oregon and Washington (IPHC area "2C") since 1997 (no surveys were performed in 1998 or 2000). Beginning in 1999, this has been a fixed station design, with roughly 1,800 hooks deployed at 84 locations each year (Figure 4); station locations differed in 1997 and are therefore not comparable with subsequent surveys. Rockfish bycatch, mainly yelloweye, has been recorded during this survey, although values for 1999 and 2001 are estimates based on subsampling the first 20 hooks of each 100-hook skate. The gear used to conduct this survey, while designed to efficiently sample Pacific halibut, is similar to that used in some targeted line fisheries for yelloweye and should be capable of sampling at least the adult population. Some variability in exact sampling location is practically unavoidable, and leeway is given in the IPHC methods to center the set on the target coordinates but to allow wind and currents to dictate the actual direction in which the gear is deployed. This can result in different habitats accessed at each fixed location among years.

Yelloweye catch has historically occurred at very few of the 84 stations in the design (Table 4). There are 27 stations in Washington waters, but yelloweye have been captured at only 10 of these, and 90% of the 341 yelloweye captured were encountered at just three stations. Further, 98% of the catch is accounted for by seven of the stations, with the most productive yelloweye stations occurring primarily in extreme northern Washington. There are 57 stations in Oregon, of which 12 have produced 1,338 yelloweye from 1999 to 2008. Of the twelve stations with yelloweye catches, five have produced 92% of the total catch and seven have accounted for 98%.

The IPHC longline survey catch data were standardized using a Generalized Linear Model (GLM) with binomial error structure. The choice of catch-per-hook, vs. catch per station was dictated by variability in the number of hooks deployed each year. The binomial error structure was logical, given the binary nature of capturing a yelloweye rockfish on each longline hook or not. The only two independent variables available to predict catch by the 495,600 hooks deployed were year (nine years) and station (84 fixed stations across both states). Treating station as a factor in the model was too computationally intensive to run, so only year was retained in the final analysis. Three models were run; two separate models for Oregon and Washington, as well as one with data from all stations fished for comparison of the method with previous analyses. The variability around the yearly index values was found using a Monte Carlo Markov Chain (MCMC) approach. Specifically, the function 'MCMClogit' that is part of the R package MCMCpack (Pemstein *et al*., 2007) was used. This approach dictated that the 'logit' link be used for the GLM model, because this is the only appropriate link available in MCMCpack (the MCMCprobit in MCMCpack is for ordinal data and is not suitable here). The final standardized index was the median of the posterior density for the back-transformed yearly effects (plus the grand mean). The annual estimates of the standard deviation of the logged MCMC values were used as the starting variance estimates for Stock Synthesis to correspond to the assumption of lognormal error.

The indices for both Oregon and Washington are highly variable and show conflicting if very little overall trend (Figure 5). This is to be expected given the small sample sizes, yet this survey may be the best index of relative abundance available for yelloweye rockfish, sampling the adult population in habitats where it is most abundant. The new method employed for this assessment was tested against the raw average catch per station (states combined) calculated for the 2007 assessment and the differences in point estimates were negligible (Figure 6), indicating that any change in information contribution of this series to the assessment model from 2007 to 2009 is primarily due to the choice to separate the series by state.

The fixed 84 IPHC station locations were supplemented in 2006, 2007 and 2008 by additional stations at the request of the states of Washington and Oregon. The addition of 'extra' stations in each state has followed divergent protocols, with Washington selecting new stations near existing stations that have captured yelloweye, and Oregon instituting a random station allocation to individual reefs based on habitat maps. Since this survey is analyzed as a relative index of abundance, there is no way to analyze these extra stations as part of the existing data set. Each of these data collection efforts could produce an improved time-series in the future, but are too short at present to be used as indices of relative abundance. Further, the divergent sampling designs will preclude analysis of pooled data for both states.

Biological samples were collected from yelloweye during the course of the IPHC survey. Length and sex information was recorded at sea, and age structures were retained for later ageing by Washington Department of Fish and Wildlife (WDFW) staff. Biological samples were augmented with the yelloweye captured at extra locations fished during 2006 to 2008 in Washington and in 2008 in Oregon. Both length and age data are available for IPHC survey yelloweye catches; however, station information for the biological samples has been lost (WDFW, personal communication, 2009). Further, due to a lab mishap, the age data for 2003-2005 cannot be connected with the rest of the biological sampling, and so must be treated as marginal age distributions with the sexes combined.

Thirty-seven length bins from 16 to 88 cm were used to summarize the length frequency of the IPHC survey catches in each year for Oregon and Washington, the first bin including all observations less than 16 cm and the last bin including all fish larger than 88 cm. This choice reflects the need to span the size range observed across all sources of data as well as retain as much information as possible about the growth trajectories (vs. aggregating to wider bins, such as 4 cm). Sampling for length and age was nearly complete for all yelloweye encountered, yet the sample sizes are still relatively small (Table 5), with a minimum of 17 and a maximum of 268 lengths recorded in each state annually, across all years. Broadly, the length frequency distributions for the IPHC survey from 1999-2008 in Washington show few fish smaller than 40 cm captured (Figure 7, Figure 8, Figure 9, Figure 10), consistent with the use of large hooks intended for halibut, the target species. Yelloweye captured in Oregon are slightly smaller, with a greater proportion of both sexes below 50 cm. Over this size range, it would be surprising if evidence of even the strongest cohorts was still visible, and none is in either state.

Age-frequency data from the recent (2006-2008) IPHC survey was compiled as conditional age-at-length distributions by state, sex and year. Individual length- and age-observations can be thought of as entries in an age-length key (matrix), with age across the columns and length down the rows. The approach consists of tabulating the sums within rows as the standard length-frequency distribution and, instead of also tabulating the sums to the age margin, the distribution of ages in each row of the age-length key is treated as a separate observation, conditioned on the row (length) from which it came. This approach has several benefits for analysis above and beyond the standard use of marginal age compositions. First, age structures are generally collected as a subset (or the same set) of the fish that have been measured. If the ages are to be used to create an external age-length key to transform the lengths to ages, then the uncertainty due to sampling and missing data in the key are not included in the resulting age-compositions used in the stock assessment. If the marginal age compositions are used with the length compositions in the assessment, the information content on sex-ratio and year class strength can be present twice in the likelihood, as the same fish are contributing to likelihood components that are assumed to be independent. Using conditional age-distributions for each length bin allows only the additional (and orthogonal) information provided by the limited age data (relative to the often far more numerous length observations) to be captured, without creating a 'double-counting' of the data in the total likelihood. The second major benefit to using conditional age-composition observations is that in addition to being able to estimate the basic growth parameters ($L_{age\text{-}1}$, $L_{age\text{-}70}$, K) inside the assessment model, the distribution of lengths at a given age, usually governed by two parameters -- the CV of length at some young age and the CV at a much older age -- are also able to be estimated. This information could only be derived from marginal age-composition observations where very strong and well-separated cohorts existed that were quite accurately aged and measured; rare conditions at best. By fully estimating the growth specifications within the stock assessment model, this major source of uncertainty is included in the assessment results, and bias due to size-based selectivity is avoided. Therefore, to retain objective weighting of the length and age data, and to fully include the uncertainty in growth parameters (and avoid potential bias due to external estimation where size-based selectivity is operating) conditional age at-length compositions were developed for the recent IPHC survey age data, and all other age-frequency series.

Age distributions included 64 bins from age 2 to age 65, with the last bin including all fish of greater age. The choice of these bins reflects the lack of any source for fish younger than age 2, and the need to reduce the computational time by limiting the total number of age bins for each entry. Most data series in the assessment model included very few fish greater than 65 years old; however they were most common in the IPHC survey. Nearly all fish sampled for length were also aged (Table 5). To aid in inspecting the full conditional age-at-length distributions, they are displayed graphically for each data set in this assessment via the entire matrix of age distribution-at-length, as well as summarized to marginal age-frequency distributions. It is often useful for data and model fit evaluation to compute these marginal age-compositions, and include them in the assessment model (with the likelihood contribution turned off, so they do not affect model fit in any way) for comparison of the 'implied' fit to the margin of the age-length key. The marginal age compositions allow for easier visual tracking of strong cohorts (although this information is still imparted to the model using conditional age-at-length observations, it is harder to visualize) and offer a view of the data more familiar for those accustomed to diagnosing model fit based on marginal age-composition data. This approach is used here.

The IPHC age data from 2006-2008 show many fish older than 65 years in both states, with somewhat more older and larger fish present in Washington than in Oregon (Figure 11, Figure 12, Figure 13). A similar pattern can be observed in the sex- and length-aggregated IPHC data available for the earlier period 2003-2005 (Figure 14, Figure 15). In aggregate, these age data appear relatively sparse, provide only a short time-series, show no coherent cohort structure and are unlikely to provide much more than estimates of the growth parameters and the diffuse information that there are more old fish remaining in Washington than in Oregon.

2.1.2 Triennial Bottom Trawl Survey

The longest time-series of fishery-independent data available for yelloweye rockfish is the triennial shelf trawl survey conducted by NMFS starting in 1977 (Dark and Wilkins 1994). The sampling methods used in the survey over the 21-year period are most recently described in Weinberg et al. (2002); the basic design was a series of equally spaced transects from which searches for tows in a specific depth range were initiated. In general, all of the surveys were conducted from mid-summer through early fall: the survey in 1977 was conducted from early July through late September; the surveys from 1980 through 1989 ran from mid-July to late September; the survey in 1992 spanned from mid-July through early October; the survey in 1995 was conducted from early June to late August; the 1998 survey ran from early June through early August; and the surveys in 2001 and 2004 were conducted in May-July (Figure 16). The abrupt shift in survey timing in 1995 led the 2007 canary rockfish (*Sebastes pinniger*) stock assessment to allow for a possibility that this change influenced catchability, and two separate catchability parameters were estimated for the two eras (Stewart 2007).

The initial year of the survey in 1977 was based on a sampling design that spanned depths from 50 to 260 fm (91 to 475 m), and did not come as far inshore (30 fm) as the subsequent surveys conducted on a triennial basis from 1980 to 2001. Because of the large number of 'water hauls' eliminated in 1977, especially in the US Vancouver INPFC area, and because the sampling depths were not the same as the other years, the 1977 survey year was not used in this assessment. A full description of the water haul issue can be found in Zimmerman et al. (2001).

The bottom trawl survey provides very sparse information on the spatial distribution of yelloweye rockfish, but identifies known areas of abundance off the northern Washington and central Oregon coasts corresponding to major rocky banks (Figure 17, Figure 18). Raw catch rates show a decline from 1980 to 1995, and then an increase in subsequent years, but are highly variable (Figure 19). There are no clear patterns in the catch rate by depth (Figure 20). The proportion of triennial tows that captured yelloweye rockfish shows an increasing trend over the entire early time-series, then an abrupt shift in 1995, coinciding with the shift to earlier sampling (Figure 21).

Triennial survey catch rates were standardized using the zero-inflated Generalized Linear Mixed Model (GLMM) based on the method described by Helser et al. (2004, 2007). The zero-inflated, or delta- approach explicitly models the proportion of positive observations via a binomial GLM (or GLMM) separately from the positive catch rates (e.g., Stefansson 1996). GLMMs were used because sampling vessels could be modeled as a random effect by assuming that vessels were chosen randomly each year from a larger distribution of vessels. Binomial GLMMs were used to predict the proportion of tows containing yelloweye rockfish in each year and gamma GLMMs with a log link were used to predict the catch-rates in each survey year for tows that included yelloweye. The product of the predicted values of the binomial and gamma GLMMs were back-transformed to calculate predicted density of yelloweye rockfish. This density was expanded to an area containing the range of depths within which positive tows were observed, and MCMC was used to estimate the variance about the estimated annual survey catch.

This method requires that all strata (year, area or depth-zone) contain enough positive catch observations to estimate the parameters of the Gamma GLMM. Preliminary exploration revealed that there were too few triennial tows to build a model for either the California or Oregon areas, or to separate the depth range into more than one stratum. Therefore a model was constructed for Washington waters only (46°N to 49°N, not including tows conducted north of the EEZ). The proportion of positive tows in Washington showed a similar pattern to those across the entire coast, with a distinct shift in 1995 (Figure 22). Positive tows ranged from three to 21 among survey years and number of fish from 13 to 114 making this survey index highly uncertain and subject to stochastic sampling variability (Table 6).

The GLMM fit the aggregate proportion positive observations very well (Figure 23). Evaluation of the deviance residuals (using a Gamma distribution with a log-link and ignoring the random effects) also reveals a reasonable fit to the sparse positive catches. The mean of the distribution of the estimated random effects is zero; hence the use of component deviances that ignore the random effects should produce plots that show the distribution of the residuals for each fitted value, but with somewhat more random variation than would be present if accounting for the random effects. However, the omission of random effects from the calculation of deviance components should not result in erroneous bias in the diagnostic figures. The deviance components should (and largely do) follow a gamma distribution with residuals concentrated about a small mean and a few observations with large residuals forming the long tail of the gamma distribution (Figure 24).

The estimated triennial survey time-series for Washington waters shows a relatively flat trend over both the early and later years of the survey, with the lowest values observed around 1995 (Figure 25).

Triennial survey length-frequency distributions are based on subsampling of survey-caught yelloweye rockfish from 1986 to 2004; biological samples of yelloweye were not collected in 1980 or 1983 (Table 7). These distributions are very noisy, and show no obvious trends in mean size or evidence of cohorts (Figure 26, Figure 27). Notably, nearly the entire size range of yelloweye observed from all sources is seen in the triennial data, fish occur across the 18 to 72 cm size categories. There were no age-structures collected for yelloweye during the triennial survey.

2.1.3 NWFSC Bottom Trawl Survey

The NWFSC shelf and slope trawl survey time series available for the depths in which yelloweye rockfish are found extends from 2003 to 2008. The survey identifies the same areas of increased abundance in northern Washington, the Heceta Bank area of Oregon and near Cape Mendocino in California (Figure 28, Figure 29). Positive catch rates show little trend over years or depth for all hauls conducted (Figure 30, Figure 31). The proportion of positive tows also does not show any clear trend over the relatively short time-span of the survey (Figure 32).

A GLMM-based approach identical to that used for the triennial survey was applied to the NWFSC data. Preliminary evaluation revealed that there were insufficient tows to populate models for either Washington or California waters. Even within Oregon, the NWFSC survey encounters yelloweye infrequently, in less than 10 tows for any year of the time series and has never observed more than 100 fish in a single year (although one of the tows conducted in 2003 captured 80 fish; Table 6). The proportion of non-zero tows in Oregon waters did not show a clear trend over time (Figure 33).

As for the triennial survey, the GLMM fit the aggregate proportion positive observations very well (Figure 34). The deviance residuals did not show a clear pattern against the linear-predictor (Figure 35; note again that random vessel effects are not included in this calculation). The biomass index shows a relatively flat trend over the period 2003-2008 with a very large value for 2003, a function of the single very large catch in that year (Figure 36).

The length-frequency distributions for the NWFSC survey from 2003-2008 were constructed using the same size bins as other data sources. These observations are based on very few fish, between 11 and 35 per year (Table 7). Most notably, the NWFSC length-frequency data show a very truncated size range; almost no fish larger than 58 cm were observed in any year of the survey (Figure 37, Figure 38). Fish less than 20 centimeters are rare, perhaps slightly more so than in the triennial survey. As is the case for the yelloweye length- and age-compositions from other fishery independent sources, neither clear trends, nor visible signs of cohorts appear in the biological data. Age structures were collected for nearly all yelloweye encountered by the NWFSC survey, but have not yet been read and are therefore unavailable for this assessment.

2.1.4 Visual Surveys

Yelloweye are a conspicuous member of the *Sebastes* genus, relatively easily identified during underwater visual surveys conducted by scuba-divers, manned or unmanned underwater vehicles. Density estimates for yelloweye rockfish have provided the basis for recent summaries of yelloweye rockfish population trends and abundance in both southeast Alaska and British Columbia waters (Yamanaka et al. 2006, Brylinsky et al. 2007, Brylinsky et al. 2008). An extensive effort was made specifically for this assessment to summarize existing density estimates from published and unpublished visual studies (W. Wakefield and J. Clemens, NWFSC, personal communication). These estimates, although not strictly comparable among all studies (in many cases the survey locations were non-random, or even selected based on predicted abundance of yelloweye and other species of interest), generally show lower but variable yelloweye density off the U.S. west coast compared to British Columbia or southeast Alaska (Table 8). Clear trends over time are not evident, but the observation that at least some locations in California may harbor relatively high densities suggests it is not outside the core range of the species.

2.1.5 Other Fishery Independent Data

A small number of yelloweye are encountered in the NWFSC's cooperative fishery independent hook-and-line survey targeting rockfish in the Southern California Bight (a total of five yelloweye, 2004-2008). These fish were included in the estimation of the weight-length relationship (see below), but no index can be developed from that survey. The authors are unaware of other small-scale projects that could currently provide data for this assessment, although some undoubtedly exist.

2.1.6 Research Removals

Research catches have historically been only a tiny fraction of the total removals from the yelloweye rockfish population. However, as total mortality has been substantially reduced in recent years, the relative contribution of research removals to the total has increased. This was particularly true in 2007, when research catches totaled 1.8 mt, or 9% of the total estimated removals from the stock. Research catches are included in estimates of total commercial catch, ensuring that all known sources of current mortality are accounted for in recent years.

2.2 Biological Data

A number of biological parameters were estimated outside the assessment model. These values are treated as fixed and therefore uncertainty reported for the stock assessment results does not include any uncertainty associated with these quantities. Input values for such parameters are provided in Table 9, and the methods are described below.

2.2.1 Weight-Length Relationship

The weight-length relationship used for this assessment is based on data from 2,012 fish sampled in California, Oregon and Washington between 1978 and 2008. Male and female curves were fit separately using a normal error assumption for the log-linear relationship $W = aL^b$. Parameter estimates derived from this analysis (Table 9) are consistent with other published studies and indicate that female yelloweye are slightly heavier for their length than males at sizes around and above that of maturity (Figure 39).

2.2.2 Maturity Schedule

The maturity-at-length relationship used in this assessment is based on a recent analysis conducted by researchers at ODFW (Hannah and Blume Draft Manuscript). They found that using histological methods produced a slightly lower size at 50% maturity than was previously estimated by visual inspection (Table 9). Their results indicate that 50% of female yelloweye are mature at a size of 38.8 cm; the logistic slope of -0.437 results in near complete maturity by 50 cm (Figure 39). These estimates are based on yelloweye from Oregon, and since no other maturity data are currently available, are used as the basis for the relationship for this stock assessment.

2.2.3 Fecundity

The disproportionate contribution of large female rockfish to reproductive output has been the topic of much research in recent years (e.g., Sogard et al. 2008). Increases in fecundity per unit female body weight have been identified and used in stock assessments for several rockfish species on the west coast. A recent analysis of fecundity data for 40 *Sebastes* species used a Bayesian hierarchical analysis to estimate fecundity per gram as a linear function of weight (Dick 2009). Yelloweye were found to have a relatively moderate increase in weight-specific fecundity with weight, with a posterior median intercept parameter of 137.9 eggs per gram and a slope of 0.0365. These values were quite uncertain, with the ~95% credibility interval ranging from -318.1 to 626.3 for the intercept and -0.0777 to 0.1418 for the slope. The relationship was converted to eggs per kg body weight for Stock Synthesis (Table 9, Figure 40) and results in predicted spawning output increasing slightly faster than the W-L relationship after maturity (Figure 39). Although uncertain, this analysis provides the best available estimates of fecundity for yelloweye rockfish and is used for this assessment.

2.2.4 Natural Mortality

The oldest observed yelloweye is a male, aged 147 years, captured in the Washington trawl fleet in 2005. Although this observation is subject to ageing imprecision, it, along with the large fraction of yelloweye aged 65+ in the IPHC surveys (Figure 11, Figure 12, Figure 13, Figure 14, Figure 15) indicate very low rates of natural mortality.

There are several sources of prior information for natural mortality for fish species and for yelloweye specifically. Two priors were developed based on a hybrid method including both Hoenig's (1983) method using maximum observed age, and Pauly's (1980) meta-analysis of natural mortality for a wide range of fish species. The method calculates prediction intervals based on the two methods, with the only required input information being the maximum observed age (O. Hamel, NWFSC, personal communication). Results for this analysis were relatively insensitive to the choice of maximum age: $\ln(M) = -2.953$, SD = 0.417 for a maximum age of 118 (the value assumed in previous assessments), and $\ln(M) = -3.05$, SD = 0.418 for a maximum age of 147 (Figure 41). Both values of maximum age generated priors with appreciable density over the entire plausible range from 0.02-0.10.

A second yelloweye-specific prior was constructed from age-distribution data collected at the Bowie seamount and at other locations in B.C., Canada. The Bowie seamount was thought to have been only very lightly exploited at the time these samples were collected and therefore the estimate of total mortality (Z) should be very close to that of natural mortality only (M) subject to the unknown effects of fluctuation in year-class strengths and sampling selectivity. The mean value for females based on Ricker's catch curve method was 0.0431 (Yamanaka et al. 2000) and it is this value that was used as the basis for fixing natural mortality (at 0.0431) in the 2007 assessment. Male yelloweye rockfish across five locations in B.C. showed a consistently higher estimate of Z (for the Bowie seamount, as well as other exploited locations) with offsets to female Z ranging from 0.04 to 0.12. To create a sex-specific prior for natural mortality, these offsets were bootstrapped and applied to a distribution for females with an arbitrary SD of 0.03 about the point estimate. The arbitrary SD was selected as the tightest value that still encompassed the range predicted from the Hoenig/Ricker prior developed above (i.e., it should be no more restrictive than that distribution). The prior was constructed for values for *M*, instead of ln(*M*), because this was the only form for the prior currently available in Stock Synthesis. The sex-specific priors derived from this method (Figure 41) were used for the pre-STAR base case model, however discussion during the review led to the mutual conclusion that Bowie Seamount data were not representative of the U.S. stock, largely due to the lack of evidence for highly divergent gender-specific mortality in the age-composition data. As a result, the prior derived from the Hoenig/Pauly method was approximated via a normal distribution (a log-normal prior was not available as an option in Stock Synthesis) and used for both males and females in the base case (Figure 42).

2.2.5 Ageing Bias and Imprecision

Observed yelloweye ages are derived from visually counting the rings on otoliths after they have been ‘broken-and-burned’. Because they are long-lived, these counts can be large, and the repeatability of individual age estimates is imperfect, especially for older fish. Treatment of ageing imprecision was a topic of specific concern in the 2006 assessment (see section on STAR panel recommendations below). Although not directly applicable for this assessment, an existing study using bomb-radiocarbon methods (Kerr et al. 2004) supports the premise that rings are formed annually on yelloweye otoliths and that enumeration of these rings is imprecise, but not likely to be systematically biased.

What is known about ageing imprecision for the U.S. west coast yelloweye stock is based on comparison of 556 otoliths read independently by two Washington Department of Fish and Wildlife (WDFW) age-readers (Figure 43). Individual reads ranged from 5 years to 123 years with most of the data consisting of reads between 15 and 60 years. Visual inspection reveals a wider degree of difference with increasing age, and generally precise double reads relative to other rockfish species on the U.S. west coast. For the 2009 assessment, these double reads were analyzed with software provided by A.E. Punt (University of Washington, personal communication), which is commonly used to estimate ageing imprecision and bias for west coast rockfish assessments (Punt et al. 2008). Briefly, the software estimates the underlying age distribution of a sample from up to three double- or cross-reads for each age structure, and can do this for multiple samples simultaneously. The most important assumption of the estimation technique is that at least one ageing method must be unbiased, so it is therefore not an age-validation. Functional forms can be explored for each method for both the bias (none, linear, type II) and the imprecision (constant or linear increase in CV, or type II increase in CV with age). Because the technique requires that the underlying age structure of each sample be estimated, a reasonably large quantity of data spread over the entire range of ages present in the sample is needed.

A step-wise procedure comparing the AIC values for ageing imprecision models fit to the double-read data was employed in order to select the most parsimonious functional form for the relationship. Because we have no external age-validation for comparison, ages are assumed to be unbiased. Estimates of the standard deviation of observed age at true age were very robust to choices of ‘minus’ and ‘plus’ groups (for accumulating the tails of the distribution) and a type II functional form improved the fit substantially (delta AIC > 20 units) over a simple linear relationship. The estimated relationship shows a non-linear increase in absolute imprecision with age, from a SD = 1.2 years at true age 10, to SD = 6.2

years at true age 100 (Figure 44), confirming the conclusions from purely visual inspection of raw double reads. This relationship was used in the base case model.

2.3 Fishery Dependent Data

2.3.1 Historical Commercial Catches

The historical commercial catch reconstruction used for this assessment represents an amalgamation of newly available data (unused in previous assessments), updates to 'standard' sources of information (PacFIN, CalCOM, and state databases), and portions of the reconstruction created for the 2006 (or possibly earlier) assessment retained as the best estimate where no additional improvements could be made. The results of this effort, by modeled fishing fleet, are provided in Table 1 and Figure 1. The sources and methods used for this reconstruction are summarized by state below.

For the state of California, commercial landings for the period 1916-1968 relied on estimates from the recent reconstruction efforts by SWFSC and California DFG scientists (Ralston et al. Draft Tech. Memo.). This effort utilized newly available spatial information regarding aggregate rockfish landings back to 1916 as well as intermittent species composition estimates by market category (and period over which that category was used) to apportion the aggregate catches to species, fishing gears and ports. This method is probably quite reliable for the most common species, but is likely much less accurate for species infrequently contributing to the total or making up a very small percentage. This reconstruction added substantial yelloweye catches to the early time period, especially around World War II. From 1969 to 2008, CalCOM (documentation: 2004) estimates of yelloweye catch were used. These estimates were updated in June, 2009 to reflect the changes made during that month. Changes in this database among recent assessments illustrate how sensitive the annual totals for individual species are to application of sparse species-composition sampling of time-varying market categories. A summary of the CalCOM catch estimation concluded that prior to 1992 "many of the landing estimates are not based on actual sampling, which could explain why they are highly erratic" (Pearson et al. 2008); they concluded those earlier landings were unreliable, but later years (from 1992 through 1996) were generally reliable.

In Oregon, there was no comprehensive historical reconstruction that could be used directly for this assessment, although data-entry and analysis efforts are underway. Instead, recently available (since the 2006 assessment) species composition estimates from the 1970s were used to estimate the fraction of aggregate rockfish catches that were likely yelloweye rockfish over the period 1916-1977. Alternate stratifications produced differing results, so simple summation over observed trips was used to derive an estimate of 0.0037%. This estimate reflects the rockfish fishery prior to the development of the mid-water (primarily widow rockfish) fishery in the late 1970s. Previously, in the 2006 and earlier assessments, estimates for this period were assumed to be 1% of aggregate rockfish catches and to have declined linearly before 1969. This fraction was applied to catch estimates from a variety of sources used in other reconstructions (Cleaver 1951, Fish and Wildlife Service, 1950-1955, 1957-1964, Anonymous 1957, Oregon Fish Commission, 1965-1967, and the Pacific Marine Fisheries Commission report 1977). The net result was a modest decrease, relative to the 2006 assessment, in the later portion of this period and an increase over 1925-1955, and 1916-1925, when flat estimates of 2 and 0 mt had been used. For the period 1978-1983 the values from the 2006 assessment were used. Beginning in

1984, best estimates of summary catch from the PacFIN system were extracted and values had changed only slightly from the estimates used in the 2007 update.

For the state of Washington there was also no comprehensive historical reconstruction that could be used directly for this assessment, although efforts are underway there, too. Due to difficulties in apportioning U.S., Canadian and Puget Sound catches, as well as a lack of new species composition estimates (although some hard-copy records exist that could be key-punched and used as a basis for future assessments), no effort was made to reanalyze the series created for the 2006 assessment by WDFW scientists (Wallace et al. 2006). Historical catch estimates from the 2006 assessment consisted of a linear ramp from 1 mt in 1955 to 4 mt in 1975. Catch estimates for the period 1976 to 1982 were referenced from Tagart and Kimura (1982). For 1983-1998 estimates from PacFIN supplemented with apportioned values from the state database for the line-fishery were retained. For the period since 1999, PacFIN summary catch estimates were extracted in late May, 2009.

The net result of the historical catch reconstruction in this yelloweye assessment was only a very small increase in total cumulative removals relative to the 2007 updated assessment, primarily occurring between 1940 and 1955 in California and Oregon (Figure 1,

Figure 45, Table 1). In aggregate, the estimated removals from commercial sources are based on sparse sampling of shifting market categories for a rare contributor to the total. Species compositions have been shared across years, areas and sectors, even in the recent (PacFIN) period since 1981. The degree of uncertainty in commercial catch should be an integral part of the conclusions drawn from this assessment.

2.3.2 Historical Recreational Catches

Estimates of recreational catch must be far more uncertain than those from commercial sources, due to a much less rigorous sampling program until very recently. For many west coast rockfish species, uncertainty in the recreational removals is relatively less important due to the small magnitude of these removals relative to commercial fisheries; however this is not the case for yelloweye rockfish. Yelloweye have been, until as recently at 2002, one of the most sought-after groundfish species captured by recreational fishermen. Release mortality for yelloweye is generally assumed to be very high, although sample sizes for existing studies are extremely small (e.g., 2 fish in Hannah and Matteson 2007). Recreational catch estimates from sources that can account for discarded fish have included all discard estimates for yelloweye as dead catch (e.g., “A+B1” estimates from RecFIN). For this yelloweye assessment some sources have been added or updated to reflect the current best estimates where new information has become available, and some of the values estimated for the 2006 assessment have been retained for lack of a better estimate. Sources and methods for each state are outlined below.

For the state of California, the historical recreational catch reconstruction provided by the SWFSC (Ralston et al. Draft Tech. Memo.) replaced the estimates included in the 2005 and 2007 assessments. This constituted a large increase in the total recreational removals over the period 1929-1980, and an extension of the estimates from 1955 (in the 2007 assessment) to 1929 (Table 1). Recreational catches were assumed to be negligible prior to 1929. Updated RecFIN estimates were extracted for the period 1981-2003 and converted to biomass via observed or extrapolated mean weights. An error was corrected in the recreational catch estimates prior to the STAR panel leading to a small change from the draft document provided for review. No attempt was made as part of this assessment to correct for the large numbers of recently discovered recreationally caught rockfish that have remained unapportioned to the species level in the state of California estimates. This should be revisited as part of the next assessment if species composition estimates become available.

A well-documented reconstruction was provided by the state of Oregon (T. Buell, ODFW, personal communication) for the period 1973-2002. Prior to 1973, recreational catch estimates were extrapolated for the 2006 assessment and those values were retained. The ODFW reconstruction apportioned the small number of unidentified recreationally caught rockfish to species, based on the ratio of species in the retained catch. This method makes several assumptions regarding angler behavior when interviewed, but no alternative approaches have been developed.

For the state of Washington, no revisions have been made to the estimates reported in the 2006 and 2007 assessments, as there have been no revisions to the sources upon which they were originally based (F. Wallace, WDFW, personal communication).

Some revisions were made to the California historical recreational catch reconstruction (1929-1980) after the data had been finalized for this assessment. These changes were small, but should be incorporated into future assessments.

The estimated removals from recreational sources are based on sparse sampling (or phone surveys) of only a very small fraction of anglers, trips and even ports where yelloweye have been caught. The degree of uncertainty in the recreational catch, perhaps even more so than the commercial catch, needs to be an integral part of the conclusions drawn from this assessment.

2.3.3 Foreign Catches

Foreign catches are included in the catch estimates for commercial fleets by state (Table 1), but are insignificant for yelloweye, totaling less than five mt in the peak year (1970) in Oregon.

2.3.4 Recent Removals (2002+)

Catches explicitly include discards beginning in 2002 when management restrictions have resulted in nearly all yelloweye caught by recreational and commercial fishermen being discarded at sea. Recent catches were based on current total mortality estimates (2002-2007) produced by the West Coast Groundfish Observer Program (WCGOP) and the GMT scorecard (2008). Although these sources are relatively comprehensive in covering all sources of mortality, incidental removals occurring in non-groundfish sectors, such as the fixed-gear halibut fishery are not routinely observed, nor included in these estimates.

In aggregate, all sources of removals have been below both the ABC and OY each year. These catch levels represent a 95% reduction from average catches observed in the 1980s and 1990s. Managers have constrained catches by eliminating all retention of yelloweye rockfish in both commercial and recreational fisheries, instituting broad spatial closures, some specifically for moving fixed-gear fleets away from known areas of yelloweye abundance, and new gear restrictions intended to reduce trawling in rocky shelf habitats and the coincident catch of rockfish in shelf flatfish trawls. Since 2002, the total 6-year catch (96 mt) has been only 63% of the sum of the OYs for 2002-2008 and only 29%

of the sum of the ABCs for that period. The total 2008 catch (16.7 mt) is just 4% of the peak annual catch that occurred in the early 1980s.

2.3.5 Fishery Catch-Per-Unit-Effort

There are four indices of recreational fishery catch per unit effort that were developed for previous assessments and are included again in this assessment. Methods used to calculate these time-series are described in the 2006 document. A number of concerns have been raised about these indices during the course of previous assessments, including changes in fishing behavior, target species, the types of trips included, and changes in management, as well as uncertainty in the underlying catch and effort estimates themselves. Upon further investigation of several of these indices, it was concluded that the issues could not be resolved with further analysis, or application of new methods for fitting the raw data, but that the actual data needed to confirm or reject such concerns was missing. For this reason, rather than provide many alternative formulations of the indices themselves, two steps were taken to reduce the potential for these factors to confound the current assessment: 1) years in which regulations had changed dramatically (bag limits, or limitation of co-occurring species) were removed, and 2) the relationship between observed indices and population abundance was allowed to be non-linear via the addition of a second catchability parameter for each index (Methot 2009). The individual indices are described below by state.

The California recreational CPUE series begins in 1980 and ends in 1999 with a gap between 1986 and 1993. The 2007 assessment included values for 2000 and 2001, but these years experienced large reductions in bag-limits and are therefore excluded in this assessment. This series is much higher, on average, in the 1980s than in the 1990s (Figure 46). Also in California, a recreational charter boat index was available for the years 1988 to 1998. This index shows little trend from 1988 to 1991 and then a consistent decline to the end of the series (Figure 47).

The Oregon recreational CPUE series is unchanged from the 2007 assessment. This series begins in 1979 and ends in 1999 with gaps in 1985 and 1997. There is an apparent upward trend from 1979 to 1983 and then a variable but generally declining trend until 1996, with 1998 and 1999 slightly higher than preceding years (Figure 48).

The Washington recreational CPUE series begins in 1990 and extends through 1999. The years 2000 and 2001 are again removed due to changes in bag limits (2001 was added in the 2006 assessment, but was not included in the original 2005 analysis). This series is uncertain and shows little coherent trend (Figure 49).

A new fishery dependent CPUE series was developed for this assessment based on the recreational charter observing program in Oregon. This program sends samplers on charter sport fishing trips where they record the catch rates and size distributions of yelloweye rockfish for as many anglers as they are capable of monitoring. Although this program has been in place since 2001, current non-retention regulations have been in place for yelloweye since 2004 making that the logical start year for a new time-series. Although a large number of drifts (a single-pass over rockfish habitat made by the charter vessel) have been observed in each year, the total number of yelloweye encountered has ranged from only 5 to 52 (Table 10).

A relative index of abundance from these data was fit using the statistical approach that was applied to the IPHC survey (described above). Binary data of whether a yelloweye rockfish was captured on each hook of each drift was analyzed with a binomial GLM. Auxiliary variables considered included: port (with sparse observations included in an aggregate port category), day of the calendar year, and depth at which fishing was conducted. In the final model, year and port group were used as factors with a fourth degree polynomial of depth and a second degree polynomial of the number of days into the calendar year (Figure 50). The final model's fourth degree polynomial of depth was identified via a preliminary fit using a GAM, and improved the model fit by 41.8 AIC units over fitting depth as a categorical variable. Fitting depth with a fourth degree polynomial was around 5 AIC units better than a third degree polynomial, and 10 and 59 units better than second degree and first degree (straight line) polynomials, respectively. The second degree day-of-year polynomial was one AIC unit better than a straight line fit and 0.7 AIC units better than a third degree polynomial. After using MCMClogit, the final back-transformed index was produced via MCMC with covariates standardized to median values of depth = 15 fathoms and the day-of-year = 191 days. This index shows a relatively uncertain increase in abundance from 2004-2008 (Figure 51).

2.3.6 Fishery Biological Data

Length-frequency distributions were developed for each fleet (recreational or commercial) for which observations were available. The same bin structure (2 cm) was used as for fishery independent observations. Due to the sparse sampling (mainly opportunistic, since yelloweye have been landed in very small proportions of mixed species market categories or recreational bag limits) length frequencies are raw, calculated as the count of fish among size bins. This has been the case in previous assessments, and preliminary investigation of alternate weighting procedures revealed little sensitivity to this choice. Sampling statistics (number of samples and number of individual fish) for each fleet and year (Table 11, Table 12) clearly show the different sampling targets employed over different time periods and between state agencies.

The California recreational fishery has yielded a small but relatively consistent number of samples since the early 1990s. Only measured lengths, not length converted from other measurements, are included in the length-frequency observations (this excludes many observations from the earlier years in California). The recreational charter boat sampling program produced over 1,800 lengths during the period 1987-1998. The Oregon has collected much of the length data (both sexed and unsexed) from the recreational fisheries, while Washington provides few samples beginning only in the late 1990s. California provides the majority of the commercial lengths from 1978 to 2007, with sampling in Oregon and Washington beginning only in the early 1990s.

Because most of the length data from California was not sex-specific, sexes-combined observations were summarized for recreational (Figure 52), charter (maintained separately in order to assess potential differences in selectivity; Figure 53) and commercial (Figure 54) fisheries. Although somewhat noisy, the recreational size-distributions contain fish from 16 to 68 cm during the 1990s and after. There are neither clear cohorts, nor obvious trends in average size. The charter vessel size-distributions show a similar range of size and perhaps a weak indication of a cohort moving through during the late 1980s and another in the mid 1990s. The commercial data, starting in 1978 do show a decreasing trend in size through the mid-1990s, after which they are relatively consistent with the recreational observations. As is expected, the commercial fishery observed fewer small (< ~26 cm) yelloweye than the recreational fishery.

Much of the length data from the Oregon recreational fishery was not sex-specific, and was therefore compiled as sexes-combined (Figure 55). Yelloweye from 20 to 82 cm are present in the data, and there is a slightly higher incidence of very large fish (> 66 cm) in the 1980s. The average size of yelloweye observed in the 1990s and thereafter was somewhat smaller, although a clear trend upward in average size is observed in this period. This trend may be due to changes in the population, particularly an above average 1983 year class, however comparison with yelloweye growth curves indicates that the increase is slightly more rapid than predicted via individual growth. It may represent faster growth rates, other factors, such as shifts in the fraction of private vs. charter boats and in target species (and therefore fishing areas and methods) that could be responsible for the trend, or a combination of both; the cause is unknown. Sex-specific observations from the Oregon recreational fishery show essentially the same range and lack of trend seen in the sexes-combined data for the earlier years (Figure 56). Beginning in 2004, length data from the Oregon recreational fishery have been collected by observers riding on charter boats from the major ports. Because these fish cannot be retained, they are measured quickly and released; fish are not routinely sexed. These data show a wide range in the size of yelloweye captured, with fish from 20 to 74 cm (Figure 57). The Oregon commercial fishery length data show fewer small yelloweye (< 30 cm) than observed in the recreational fishery, but generally the same size range (Figure 58). A noisy but slightly increasing trend in size may be present beginning around 2000.

From the Washington recreational fishery there are far fewer small yelloweye (< ~36 cm) than in California or Oregon fisheries (Figure 59). Among sexes-combined observations from the Washington commercial fishery, there are also few small yelloweye, and with perhaps a slight increasing trend in size appearing in the late 1990s (Figure 60). Recent samples from the Washington commercial fishery show no clear trends, but as many large yelloweye as seen in other sectors (Figure 61).

As for fishery independent data, fishery ages, recreational or commercial where available, are compiled as conditional age-at-length observations by two cm size bin. There are very few yelloweye ages available from the recreational fisheries (Table 13). All three states have collected a few ages, but there have been only a total of 83 samples collected from all recreational sources available for this assessment. Commercial age data are not much more numerous than those from recreational sources. Sparse sampling was conducted in the 1980s in California (resulting in only 52 useful ages), and only slightly better samples sizes have been collected in Oregon and Washington beginning in 2001 (Table 14). Age data from California was received late in the process, and although included not all lengths from the age samples were included in length frequency distributions. For the purposes of examination, the age data have been summed across length and plotted as marginal age compositions by fleet. Particularly sparse fleet-specific data (e.g., California recreational ages) have been omitted from plotting.

The Oregon recreational fishery captured yelloweye across a wide range of ages, including many fish of age 65 or greater in the 1980s (Figure 62). There seem to be slightly more females older than age 20, but there are no clear cohorts visible in the data. The Washington recreational fishery has also captured fish to age 65+, but the data is relatively sparse and presents no meaningful patterns (Figure 63). The California commercial fishery observed very few yelloweye older than age 30, despite the preponderance of the samples being collected in the 1980s (Figure 64). The Oregon commercial fishery age data is also very sparse, but does not contain many fish older than age 30 (Figure 65). The Washington commercial fishery ages clearly show many more old yelloweye than in Oregon or California, with many older than age 65 despite the samples primarily occurring after 2000 (Figure 66).

Some revisions were made to the Oregon recreational biological samples (additional ages now available) were made after the data for this assessment had been finalized. These should be included in the next assessment.

2.4 History of Modeling Approaches

2.4.1 Previous Assessments

Yelloweye stock abundance and trend were first analyzed as part of the "remaining rockfish" assessment completed in 1996 (Rogers et al. 1996). This assessment included a number of rockfish species managed as the "Sebastes complex". The estimated yelloweye rockfish Allowable Biological Catch (ABC) was 39 mt (included as a contribution to the 'other rockfish' ABC) for the Northern area (Columbia and Vancouver) based on biomass estimates from the triennial trawl survey and assumptions about natural mortality (*M*) and catchability (*Q*). No separate yelloweye ABC was estimated for the Southern area (Monterey and Conception), where yelloweye rockfish were also included in the ABC for the "other rockfish" assemblage.

The first yelloweye-specific stock assessment used the length-based version of Stock Synthesis (Methot 1989, 2000) to model the northern California and Oregon regions with separate models (Wallace 2001). Growth was estimated externally to the model. Recreational CPUE as well as recreational and commercial size-composition data were included in the model. The modeled time period extended from 1970 through 2000 and year-specific recruitments were estimated without constraint by a stock-recruit curve. The assessment examined both increasing natural mortality with age and dome-shaped selectivity with size as alternative factors to improve the fit to the data. Alternative model configurations found that increasing natural mortality with age provided a somewhat better fit to the data, but there were no age data included in the 2001 model.

The length-based version of Stock Synthesis was also employed in the 2002 stock assessment (Methot et al. 2002). There were a number of important differences in model configuration from Wallace (2001) that include: 1) inclusion of Washington catch, CPUE, size and age data, 2) inclusion of age-composition data from all three states, as available, and an update of size-composition data, 3) inclusion of mean length-at-age data from each data source, to aid in the simultaneous estimation of growth parameters and size selectivity, 4) allowing all fishery sectors to have dome-shaped selectivity 5) including a recruitment constraint to the stock-recruit relationship and estimating the curvature (steepness), 6) starting in 1955 rather than 1970, to better allow for potential long-term patterns in recruitment, and 7) use of a constant (and fixed) natural mortality rate of 0.045. The assessment explored area-specific model results including data from only subsets of the coast, and compared these results to a baseline coast-wide model. They concluded that the estimated differences between the areas (states) were neither sufficiently different nor sufficiently precisely estimated to recommend that management be based on area-specific population models. They suggested that area-specific modeling should remain in consideration as new data become available.

The 2005 assessment was a simple update of the 2002 model that included a revised catch time series and additional age- and length-composition information. The assessment used the newly revised version (1.19) of the Stock Synthesis modeling framework (Methot 2005, 2006).

In 2006, a full assessment for yelloweye rockfish was performed (Wallace et al. 2006). That assessment updated the 2005 analysis to the newest version (1.21) of Stock Synthesis available (Methot 2006). The 2006 yelloweye stock assessment included many model specifications carried over from the previous assessments. Separate area-specific models were again evaluated for Washington, Oregon and California, as well as a single coast-wide model assuming instantaneous mixing between areas. The area-specific models included only data from each area, except that the Oregon and Washington models both contained all IPHC length information. Results were presented for each of the area-specific models as well as the coast-wide model and also the aggregate of the area-specific models.

The 2007 assessment was an update, requiring no major changes to the basic model framework, approach and major structural assumptions. Several minor errors in data processing were corrected and the natural mortality rate borrowed from Canadian sources was corrected from the value used in 2006 (0.036) to the value reported by Yamanaka (2000) of 0.0431. The update also moved the assessment forward to the newest version of Stock Synthesis available at the time (Version 2.00c, March 2007).

In aggregate these assessments have largely drawn the same conclusions regarding population abundance and recent trends: that the yelloweye resource was heavily and unsustainably exploited from the early 1970s to around the year 2000 (Figure 67). There is clearly much retrospective uncertainty regarding the absolute scale of the yelloweye population, and there has also been a pattern of each subsequent assessment being slightly more pessimistic than those before since 2002. All of these assessments have estimated that the stock is relatively unproductive and will therefore require many years of low exploitation rates to rebuild to target levels and will never again produce catches as large as peak historical values.

2.4.2 Pre-Assessment Workshop, GAP and GMT Input

There were no 'pre-assessment' workshops held for the 2009 stock assessment and review cycle. However, the authors attempted to respond to all questions and concerns posed by interested parties via e-mail and phone conversations. GAP and GMT members were contacted early in the process and provided valuable background on the discussions regarding previous yelloweye assessments as well as industry points of contact. Discussion with commercial, charter and recreational fishermen were helpful in better understanding the current relationships among the fisheries, management and data collection programs. This has been a valuable part of the assessment process in recent years and should be continued in the future.

2.4.3 Response to STAR Panel Recommendations in 2006

The STAR panel report from the 2006 review (the 2007 assessment was an update, and did not go through the STAR process) identified a number of recommendations for future assessments. Although all these recommendations could not be addressed for 2009, progress on each is summarized below:

1) In the current assessment model, catches are assumed known without error. Because yelloweye rockfish are relatively rare in the fisheries, catches are estimated with considerable error. Ignoring this source of uncertainty will lead to an overestimation of model precision. Future assessments should allow catch to have some error to better propagate this key uncertainty to model estimates. SS2 should be modified to allow error in the catch data. This should not be difficult to code, although it may cause some problems with convergence that may require attention. Allowing for some autocorrelation in F might improve the estimation.

Preliminary investigation into the direct integration of uncertainty in catches via estimated parameters for annual *F*s indicated that it would not be feasible to integrate over the very broad distribution of possible catches in this manner. The method would probably be much more appropriate for assessments where only some portions of the catch has very great uncertainty associated with points estimates, however for yelloweye the entire time-series for all sectors is very uncertain. The choice of representing catch uncertainty via alternate states of nature represents an imperfect solution, but does attempt to provide those evaluating the results of this assessment with insight into the sensitivity of the model scale to historical catches.

2) Formal estimates of uncertainty in catch should be produced by modeling the species composition sampling process. This will require an extended analytical effort, but it should be doable. The analysis may lead to using model-based estimates for missing cells, rather than substitution, which may change the best estimates of catch somewhat. Estimates of uncertainties in the total unclassified rockfish landings and in the species fraction estimates in the earlier years may still have to be assumed.

This topic was not addressed specifically, but it should be noted that model-based catch estimators are an available tool for ongoing state-specific catch reconstructions. It is likely that all three states will have some level of comprehensive catch reconstruction completed for the 2011 assessment cycle; however, the authors are unaware of further exploration of model-based methods for these reconstructions.

3) Obtain data from Canada for a truly stockwide model.

This topic has been raised with Canadian scientists and may be more realistically possible after current (2009, L. Yamanaka, personal communication) assessment efforts for coastal waters of B.C. are completed.

4) Continue efforts on the fishery independent survey programs. The most promising should be expanded stockwide.

Although a number of projects are being evaluated in 'pilot' studies (e.g., open-ended trawls with cameras, AUV surveys, and others) it is likely to be several years (at a minimum) before any of these can produce results that might be directly useful as data in a stock assessment framework.

5) Consider an assessment model incorporating several rockfish species simultaneously.

The use of the meta-analysis for stock-recruit steepness is a step in this direction, but a formal process for developing (and reviewing) multiple-species assessments needs to be created before this will be a realistic option for stock assessment authors. The approach may be best tested in a 'research-mode' analysis before being applied to a 'production' assessment.

6) The panel recommends that aging error be explored again in future assessments. The panel was not completely comfortable with decreasing aging error as age increased as is currently in the base model. The panel discussed that it seemed counterintuitive that fish would become easier to age as they became older, and evidence for this pattern was sparse. However, removing the trend in aging error (to either a constant SD or CV) had small effects on model estimates.

This topic has been resolved using current double-read data and analysis software (see section 2.2.5 above).

7) Data are sparse in the most recent years of the model since the fisheries have been closed. Because of this, there is considerable uncertainty about current age and size structure of the population as well as uncertainty because most of the CPUE time series end in 2001. This uncertainty will become worse for future assessments if no new data streams are added. The best types of data to add would be surveys that estimate absolute abundance such as the submersible survey conducted in 2001. This survey would need to be expanded to include Oregon and California waters. Another option would be to continue and expand the IPHC survey.

As soon as actual data are produced by alternate survey methods it should be incorporated into the yelloweye stock assessment. It may be of little value to perform frequent full stock assessments if no new sources of (higher) quality data become available.

2.5 Model Description

2.5.1 Link from the 2007 to the 2009 Assessment Models

The results of this assessment (see below) provide a very close match to those from previous analyses, despite many changes in data, structural assumptions and modeling approaches. The 2007 depletion estimate is only slightly higher (14.5% in the 2007 assessment version vs. 19.2% in this assessment) despite all the changes made. The change from Stock Synthesis version 2.00c to version 3.0 was, in this author's experience, the easiest upgrade in recent assessment cycles; full back-compatibility of Stock Synthesis version 3 has made this possible when the model was configured in the same manner despite many new features.

Fully described below, a number of key parameters and modeling choices have been changed for this assessment. The most important of these are the use of fixed values in the 2007 assessment for natural mortality (0.043) and stock-recruitment steepness (0.45). Fecundity was previously assumed to be proportional to spawning biomass and recruitment deviations were estimated for the period 1968-1992. Further, there was no tuning of input sample sizes and variance estimates in the 2007 assessment.

2.5.2 Summary of Fleets

Fishery removals were divided among six fleets: 1) California recreational, 2) California commercial, 3) Oregon recreational, 4) Oregon commercial, 5) Washington recreational, and 6) Washington commercial. The California CPFV index of relative abundance and the length frequency distributions from this source are assigned the selectivity from the California recreational fishery. The Oregon charter observer index is treated separately (selectivity estimated independently) from the Oregon recreational fleet. The IPHC data is modeled by state, with each survey utilizing separate selectivity and catchability parameters. There were only sufficient data for a Washington triennial survey index and an Oregon NWFSC survey index, so each had its own fleet. The data available for each fleet are described in Table 3. The choice to structure fleets based on geographic areas allows direct comparison of the dynamics with and without explicit areas in the stock assessment model.

2.5.3 Modeling Software

This assessment used the Stock Synthesis modeling framework written by Dr. Richard Methot at the NWFSC. The most recent version (3.03b) was used, since it included many improvements in the output statistics for producing assessment results and several corrections to older versions used during the 2007 and earlier assessments.

2.5.4 Priors

Uniform (and intended to be noninformative) priors were applied to all estimated parameters in the base case model with only three exceptions where additional information was available (natural mortality, described in section 2.2.4, and steepness, described below). Parameter bounds were selected to be sufficiently wide to avoid truncating the searching procedure during maximum likelihood estimation. A list of all parameter bounds and priors are provided in this document (Table 15).

In addition to the priors for natural mortality, an informative prior for stock-recruitment steepness (h) is used for the base case model. The use of a prior on stock-recruitment steepness based on meta-analysis of rockfish (original basis: Dorn 2002) has become standard practice for U.S. west coast stock assessments. This prior has been updated to reflect current understanding in each of the 2007 and 2009 assessment cycles (M. Dorn, AFSC, personal communication). For 2009, this prior is relatively uninformative (less than two units of negative log-likelihood over most of the acceptable range for h, 0.2-1.0), but favors values approaching 1.0 (Figure 68). Sensitivity for the base case model to the use of these priors is reported below.

2.5.5 Sample Weighting

The approach to sample weighting used here attempts to achieve consistency between the degree of uncertainty in each data set and the model's ability to fit those data. Variances and sample sizes were first derived from the raw data sources. Variances and sample sizes were then iteratively re-weighted to ensure consistency between the input sample sizes (or standard errors) and the effective sample sizes (and root-mean-squared-errors) based on model fit. This approach attempts to reduce the potential for particular data sources to have a disproportionate effect of total model fit, while creating estimates of uncertainty that are commensurate with the uncertainty inherent in the input data. Iterative re-weighting was applied to the length data, starting from a compromise between the number of fish and the number of samples (a linear function of the number of samples and number of fish, not exceeding 44 fish per sample), and then multiplying the year-specific input sample sizes by a single constant for each data set that made the mean input sample size for compositional data roughly equal to the mean effective sample size based on model fit. The same method was applied to conditional age-at-length data, except that input sample sizes for age distributions, based on the number of fish observed in each sex-length bin combination were not further increased. These input samples sizes can be thought of as a maximum, where each fish is an independent sample from the true multinomial and therefore should not be increased. Similarly, variance estimates for index data were not reduced, even where the model was able to fit the data appreciably better than expected, because these estimates can be considered minimum estimates from the external analyses used to create them. These choices reflect the post-hoc nature of model tuning and the potential for increasing weight on those data sources that are consistent with model predictions, thereby reducing the perceived uncertainty in model results.

Table 16 shows the results of this re-weighting for compositional data in the base case model. The length data from a few fleets were up-weighted to reflect better than expected fit, except for the fleets where initial sample sizes reflected the number of fish, these were all down-weighted by a factor of 0.62-0.73. Age data fit better than expected (and so no tuning was applied), with the exception of the IPHC data which were down-weighted by a factor of 0.74 (Oregon) or 0.90 (Washington). An additional variance component was added to all of the fishery independent indices of abundance as part of the iterative reweighting process (Table 17). These values ranged from 0.36 to 0.54. Fishery dependent indices received an additional variance component of 0.0 to 0.16.

2.5.6 General Model Specifications

Stock synthesis has a broad suite of structural options available for each application. There are no true 'default' settings for most of these options; each application must be customized to best represent the life-history, dynamics, data-complexity and estimation approach (Bayesian or maximum likelihood) most appropriate.

This assessment is structured to be sex-specific, including separate growth curves for males and females, and therefore tracking the spawning output of only females for use in calculating management quantities. Growth parameters describing the von Bertalanffy growth equation, as well as the spread of lengths for a given age, were estimated for each sex, except that the length at age one year was forced to be identical for males and females. The parameterization used by Stock Synthesis allows the user to specify the age for the two growth parameters (rather than the length at age zero and the implied length at infinite age). Ages one and 70 were selected to be close to the range of observed data. Based on preliminary analyses, this choice had little effect on estimated growth curves. A list of the growth parameters, bounds and priors is given in Table 15. Natural mortality was freely estimated for each sex, based on the *a priori* evidence that it might differ for males and females.

For the internal population dynamics, ages 0-100 are individually tracked, with the accumulator age of 100 determining when the 'plus-group' calculations are applied. This is a relatively large age, and substantially increased the memory and computational requirements of the model, but was necessary to ensure that little growth would be predicted to occur (but not be modeled) at and beyond this age, since the model does not allow growth to continue in the plus-group.

Three explicit areas are included in the base case model, representing the three states: California, Oregon and Washington. Although these are political rather than strictly biological boundaries, the yelloweye population appears to be fragmented enough, and adult movement is likely small enough, that the exact placement of these lines is of little importance. What is known to be important (and related to states rather than biology) is the vastly different exploitation history among the three areas from the historical period to the current fishery. Growth is assumed to be identical among the three areas, largely due to the sparseness of the data. Recruitment dynamics are governed by a global stock-recruit function (using spawning output based on the fecundity relationship, rather than strictly spawning biomass as is common among assessments). This relationship is parameterized to include two estimated quantities: the log of unexploited equilibrium recruitment (R_0) and steepness (h). Recruitment is partitioned via estimation of one additional parameter for each area after the first, which are then renormalized to allocate the total recruits among the areas. The base case does not allow for process error in the stock recruitment relationships (either over time or areas) although this was investigated extensively during preliminary model building and via sensitivity analyses.

No seasons are used to structure removals or biological predictions, so data collection is assumed to be relatively continuous throughout the year. Fishery removals occur instantaneously at the mid-point of each year and recruitment on the 1st of January. Since the time-series is started in 1916, the stock is assumed to be in equilibrium at the beginning of the modeled period. The sex-ratio at birth is fixed at 1:1, although sex-specific natural mortality, size-based selectivity, and dimorphic growth can result in significant departure from equality due to differential mortality over age and sex.

2.5.7 Estimated and Fixed parameters

A full list of all estimated parameters and values of key parameters that are fixed is provided in Table 15.

A two-parameter logistic function was used to represent the selectivity for all fishing fleets and for the IPHC survey. Departure from simple logistic shapes via the use of double-normal selectivity was added for the two trawl surveys in the base case model. For all indices of abundance, catchability parameters were solved for analytically, except for the triennial survey, where allowing for a change (unrestricted) in catchability for the time-series including and after 1995 required the direct estimation of catchability for each period. For the historical fishery dependent time series, where the basic assumptions of CPUE analysis were likely violated, there were four additional parameters estimated to allow for a non-linear relationship between the index and modeled population abundance.

In total, there were nine estimated growth and mortality parameters, four parameters governing the stock recruitment relationship, six catchability related parameters (and seven analytic solutions which could have been treated as estimated parameters), and 23 parameters describing selectivity curves.

2.6 Model Selection and Evaluation

2.6.1 Key Assumptions and Structural Choices

All structural choices for stock assessment models are likely to be important under some circumstances. In this assessment these choices are generally made to 1) be as objective as possible, and 2) follow generally accepted methods of approaching similar models and data. The relative effect on assessment results of each of these choices is often unknown; however extensive effort was made to evaluate these choices during model building and the most important of these are presented through sensitivity analysis.

The use of a static (but sex-specific) value for natural mortality over time is also a very important assumption. In reality, natural mortality is likely to vary over time (and possibly space) and may be non-stationary where predation or environmental factors have directional instead of random patterns during the modeled period. However this degree of complexity is clearly beyond the information content of the available data. Growth is also assumed to be time- and space-invariant. This is a common assumption that has very important implications for estimation of selectivity and management quantities.

The three most important sources of uncertainty in this assessment are: the catch history, non-estimation of process-error in recruitment dynamics, both over space and time, and the choice to divide the assessment into explicit spatial areas.

Although the base case assessment model captures some uncertainty via asymptotic intervals, uncertainty from two sources is reported through alternate states of nature bracketing the base case results and included explicitly in the decision table. The magnitude of the estimated catch time-series was found to have a large influence on the perception of current stock size and the estimate of steepness of the stock-recruit relationship was closely linked to the projected recovery rates. Alternate values of each were selected to bracket the best estimates with marginal probabilities one-half as likely. For historical catch, these values, 75% and 150% of the estimated catch series prior to 2000, were subjective, but reflect the lack of a comprehensive catch reconstruction in Washington and the change in likelihood of the fit to data sources over a reasonable range of catch levels. For steepness the 12.5^{th} and 87.5^{th} percentiles were calculated from the likelihood profile as a proxy for the probability distribution about this point estimate. The most optimistic and pessimistic of the nine combinations from these two axes (weighted 6.25% each relative to 25% for the best estimate on each dimension) are reported in this document and all combinations used to provide a more realistic degree of uncertainty for future projections, decision tables and rebuilding analyses.

2.6.2 Alternate Models Explored

Hundreds of alternate assessment model formulations were evaluated prior to selecting the base case model. Because not all alternate formulations can be reported here, those that had the largest effects on parameter estimates or management quantities or are obviously of interest are retained and presented as sensitivity analyses (see below).

Prior to settling on the base case model, an extensive evaluation of dome-shaped vs. asymptotic selectivity curves for commercial, recreational and survey fleets was performed. Models very similar to the base case were fit while allowing each fleet to have dome-shaped selectivity. With only one exception, the NWFSC survey, all fleets produced asymptotic curves, requiring the application of informative priors on the descending limbs or fixed parameter values to ensure all parameters remained contributors to the objective function (i.e., when the final selectivity is estimated to be close to 1.0, then the descending width parameter is irrelevant to model fit and if not somehow informed can cause estimation instability). This exercise was repeated across fleets to determine whether additional flexibility was needed beyond a single parameter describing the ascending limb of the selectivity curve. This was found to be the case for the triennial survey, so an additional parameter was estimated, although little change was observed in model results.

This exercise was repeated as part of the STAR panel review, focusing on the IPHC selectivity for Oregon which was found to fit slightly better with dome-shaped selectivity. Although no change was made to the base case, the topic is addressed via sensitivity analyses below.

2.6.3 Convergence Status

To test for convergence prior to the STAR review, 100 trials were performed using a 'jitter' value (Methot 2009) of 0.1 for the base case model. This perturbs the initial values used for minimization with the intention of causing the search to traverse a broader region of the likelihood surface. Ninety-seven of these trials returned to exactly the same objective function value as in the base case, inverting the Hessian and producing small gradients. The remaining three got close to that minimum but failed to completely converge. Due to the high success rate, the exercise was repeated with a 'jitter' of 0.2. Of the second set of 100 trials, 69 returned to the base case minimum and 31 failed to converge. The spread of this search appears to indicate that the jitter was sufficient to search a large portion of the likelihood surface, and that the pre-STAR base case was not stuck in a local minimum. Results of runs that appeared to converge all showed identical levels of ending depletion and spawning biomass.

The exercise was repeated with the base case model after the STAR panel. A jitter value of 0.3 was applied for 100 trials, resulting in 43 models returning to the global minimum, and 57 failing to converge. This exercise appeared to traverse a wider region of the likelihood surface than earlier runs, but still did not discover any new minima. These tests cannot prove convergence of the model, but did not provide any evidence to the contrary. Robust behavior of this model over alternate phasing and initial values further indicated that there was little chance the results reported here are not the global maximum likelihood estimates.

2.7 Response to SSC Recommendations

If the SSC determines that additional analysis beyond completion of a rebuilding plan for the updated 2009 assessment is warranted, this work will be completed subsequent to the September 2009 review.

2.8 Base Case Model Results

The biological (growth and mortality) parameters estimated from the base case and alternate models appear to be quite reasonable (Table 18) and commensurate with inspection of the raw data. These parameters are relatively precisely estimated, both in terms of the asymptotic standard error estimates (Table 19) as well as the alternate states of nature (Table 18). Female and male yelloweye rockfish showed similar growth trajectories, beginning to diverge a approximately age 10; with males growing to a maximum size (66.4

cm) that was about 2.4 cm larger than females (Figure 70). Males are estimated to have a slightly wider spread of lengths at a given age, becoming more pronounced with age. The result that males are estimated to have a slightly larger size at the oldest ages (Figure 70) is somewhat unexpected for a *Sebastes* species. However, Canadian analyses (Yamanaka et al. 2006) also show males reaching a slightly larger (by 2 cm) maximum size, although those fish were slightly larger at 66 and 68 cm for females and males respectively.

The estimated natural mortality for males and females were nearly identical, with females slightly higher than males for both of the alternate states of nature. The estimated female value for the base case, 0.047, is slightly higher than that used in the 2007 assessment, but is still quite consistent with the very protracted age-structure observed in the population.

Estimated selectivity curves for the fishing fleets showed the expected pattern that the recreational sectors in all three states access somewhat smaller yelloweye than the commercial fisheries (Figure 71, Figure 72, Figure 73). This pattern was most pronounced in Oregon, and, also as expected, the recent charter fishing selectivity is shifted further toward smaller fish. Addition of the charter vessel length data did not appreciably change the estimate for the California recreational selectivity pattern and so the selectivity for the two series was not separated. Estimated selectivity curves for the IPHC surveys in both Oregon and Washington appear to access the largest yelloweye available, with Washington especially shifted slightly more than 10 cm larger than Oregon (Figure 74). The NWFSC trawl survey selected far more small yelloweye than did the triennial survey (Figure 75). That the estimated triennial survey selectivity was shifted toward the largest fish but also selecting some very small fish is likely an artifact of the very noisy compositional data. However, the pattern in selectivity makes direct interpretation of base case estimates for survey catchability (1980-1992: 1.43, and 1995-2004: 0.76) difficult, since very little of the population biomass occurs in the fully selected size range (> 85 cm). Forcing the triennial selectivity to conform to a more 'standard' parametric form had little effect on model results, but did degrade the fit to the survey data slightly. Similarly, catchability for the NWFSC survey was estimated to be 0.46 in the base case, however, with the highly dome-shaped selectivity, this does not imply that 46% of the biomass is actually observed.

The base case model predicted a relatively flat trend through both the Washington (Figure 76) and Oregon (Figure 77) IPHC survey indices. The poor residual pattern for the Oregon index (5 positive residuals followed by 4 negative residuals) seems unlikely to occur by chance, however, it also seems unlikely, given the life-history characteristics of yelloweye rockfish that any model could predict the negative offset seen between the 2004 and 2005 survey estimates. Although more investigation could be made, it would seem that there is likely still some unaccounted for process error in the survey methods.

The base case model was able to fit the NWFSC (Figure 78) and triennial (Figure 79) trawl survey indices as well as expected given the small number of positive hauls on which they are based, and the relatively small contribution to the total likelihood value. The fit to these indices, and the contribution of all indices to the objective function was largely unchanged among the three states of nature (Table 20).

Fits to the fishery CPUE series were generally quite good, and estimated power coefficients ranger from positive (0.55, California charter) to mildly negative (-0.27, Washington recreational; Table 18) indicating that observed values were often non-linear in relation to population trends. The predicted California recreational index tracked well the decline in observations through the 1990s (Figure 80), and the California charter series captured the difference between the 1980s observations and the reduced values in the 1990's, but none of the increasing trend in the early portion of the series (Figure 81). For the Oregon recreational index, the model again tracked the decline over the 20 year index, but none of the interannual variability (Figure 82). The Oregon recreational observer index showed a small and very uncertain increasing trend that was not captured by the predicted values but is not at all inconsistent with the results (Figure 83). With relatively large variances on many of the observations, the Washington recreational index provided a flat trend, which was largely matched by the slightly declining predictions (Figure 84).

The base case model fit the length distributions from the IPHC surveys in Oregon (Figure 85, Figure 86) and Washington (Figure 87, Figure 88) reasonably well, although there is some indication of negative residuals for the largest sizes in both series (especially Oregon, see sensitivity analyses below), indicating the model was predicting a greater proportion of the largest fish than was observed. Input sample sizes were tuned down slightly (Table 16), but this was expected, since the initial values were in numbers of fish rather than a compromise between numbers of fish and numbers of samples (it was not clear how correlated observations from a single long-line set would be). Both the NWFSC and triennial survey length-compositions were fit slightly better than expected (Figure 89, Figure 90, Figure 91, Figure 92; and were therefore tuned up, still resulting in relatively small average input sample sizes of 22 and 19). There appeared to be no pattern in the residuals for either series.

The sexes-combined length frequencies for the California recreational fleet fit somewhat better than expected (Figure 93), with no obvious patterns in the residuals (Figure 94). The sexes-combined length-frequency data for the California charter fleet was also fit slightly better than expected (Figure 95), and although there are no clear patterns in the residuals, there may be some indication of an above average cohort in the mid-1980s and another in the mid-1970s (Figure 96). The same was true for the California commercial length frequencies (Figure 97), although there were several large residuals apparent in 2001 (Figure 98). The unsexed Oregon recreational length data were tuned down (by a factor of 0.55, Table 16), however the number of samples was not available for all years, so it was expected that the number of fish would overestimate the appropriate input sample size for these data. Fits showed little residual pattern in the 1980s, but a strong diagonal pattern through the 1990s (Figure 99, Figure 100). This residual pattern from 1993-2003 could be due to a strong cohort (or cohorts) in the mid-1980s, although growth would have to be slightly above predicted rates to achieve the observed increase in mean size of this mode during the 10 year span over which it is observed. It is possible that other factors are also influencing this pattern, such as a shift in the targeting of the recreational fleet; however time-varying selectivity was not included for this fishery in the base case model. Little pattern is observed in the fits (Figure 101) or residuals (Figure 102) to the sex-specific Oregon recreational data from the 1980s. There are also no clear trends in the fit to the Oregon recreational charter observer data from 2004 to 2008 (Figure 103, Figure 104). Unlike the recreational length data from Oregon, the commercial lengths show no clear patterns in the fit or residuals through the 1990s (Figure 105, Figure 106), and fit the data slightly better than expected. In Washington, the recreational length data are quite sparse, but the fit and residuals appear reasonable (Figure 107, Figure 108). The sexes-combined length data for the Washington commercial fleet fit the data quite poorly, although still slightly better than expected (Figure 109). It is not clear whether patterns in the residuals should be investigated, or are just a result of the sparseness of the data (Figure 110). Sex-specific length frequencies from the Washington commercial fleet were also noisy, but showed no obvious patterns in the fits or residuals (Figure 111, Figure 112).

Fits to the age-frequency data are reported via the fit to the margin and residual plot where only marginal age data were available (early IPHC data) or via the full matrix of Pearson residuals for the conditional age-at-length data where these data were used. The early IPHC ages (not linked to length or sex information and so treated as marginal age distributions) fit the data slightly worse than expected, but showed little pattern in the residuals (Figure 113, Figure 114). For the more recent (2006 to 2008) sex-specific age data, the model appeared to underestimate the number of old fish present in the data (Figure 115, Figure 116); the cause of this pattern is unknown, but could perhaps be due to a mild misspecification of the selectivity curve, the growth curve if it tends to differ in Oregon, or some unknown degree of ageing bias in the samples. A similar, but slightly less pronounced pattern is also observed in the Washington IPHC age data (Figure 117, Figure 118). The California recreational fishery age data were very sparse, and little pattern can be discerned from the residuals (Figure 119, Figure 120), which fit about as well as expected. Oregon recreational age data fit slightly better than expected and showed no signs that the growth curve or lack of modeled annual recruitment strengths was inconsistent with the observations (Figure 121). The Oregon commercial age data are too sparse to draw much insight from residual patterns (Figure 122). Washington recreational (Figure 123) and commercial (Figure 124) age data also showed good residual patterns for the few years in which there were enough data to see them.

The estimated stock-recruitment relationship for the base case and alternate states of nature were very consistent in the prediction of little surplus production (steepness values 0.344, 0.417, 0.508; Table 20). These model runs reveal an almost linear relationship between the magnitude of historical removals and the scale of the estimated population size (Table 20, Figure 125). It is very appealing to try to integrate over the process error in recruitment variability via a longer time-series of deviations and more flexibility in the allocation of these deviations among areas, but this exercise is reserved for sensitivity analysis (see below) for this assessment. Because no process error in recruitment is modeled and steepness is relatively low among the states of nature, the time-series' of total recruitment (Figure 126) and spawning output (Figure 127) track one another very tightly. Both show that the aggregate yelloweye population was rapidly reduced from near unexploited conditions to low levels from about 1970 to 2000 (Table 20, Table 21), and this result is quite conserved among the alternate states of nature (Table 20, Table 22, Table 23). The coast-wide trend masks quite different levels of reduction among the three areas in the assessment. California is estimated to have had a much larger population historically, which has been reduced to much lower relative levels than in Oregon or Washington (Figure 128). The Washington stock is estimated to have been the smallest throughout the historical period, but to have been reduced the least. The same patterns are apparent in the estimated time-series of spawning output by area (Figure 129). Although there are not estimated to be extremely divergent values of growth and natural mortality for males and females, there are consistent trends in the predicted sex ratios for each of the three states with males becoming less numerous relative to females as exploitation rates increased (Figure 130). The matrix of predicted numbers at age by sex and area is provided in Appendix A.

A fundamental question that must be posed in light of these differences among areas is: Is the predicted density in the three areas reasonable in light of existing visual observations (and perhaps the common perception that there are more yelloweye rockfish in Washington than anywhere else on the coast)? To make this comparison, an estimate of the magnitude of available habitat, by area, was developed based on the assumption that only the hardest rocky lithology present in existing habitat maps (over depths in which yelloweye have been observed) would support appreciable yelloweye abundance (C. Whitmire, NWFSC, personal communication). This exercise revealed that the largest absolute quantity of yelloweye habitat in 55 to 450 m depths occurs in Oregon, where it comprises 10.5% of the total habitat in these depths and is more than four times as large as the suitable area in Washington (Table 24). California south of Point Conception represents the next largest habitat (although likely supporting a lower biomass of yelloweye given that this is the southernmost portion of their range) with 15.1% of the total habitat estimated to be rocky enough for yelloweye utilization. California north of Point Conception includes less than a third of the total area to the south (the continental shelf is much narrower throughout much of central and northern California than elsewhere on the coast) but still 48% more area than in Washington waters. Since most of the yelloweye observed via visual studies are at least three years old (although some juveniles are seen), the predicted numbers of age-3+ yelloweye in each area were divided by the suitable habitat area to generate a 'back-of-the-envelope' density estimate, assuming uniform distribution within areas, and, for lack of direct information, that one-third of the California stock occurs south of Point Conception. This calculation reveals that observed density estimates in the last 30 years should be in the range of 1-10 yelloweye per hectare (Figure 131), declining from 1980 through 2000, and that Washington should have the highest observed current density. This analysis appears consistent with density estimates for available visual studies (Table 8), given the assumption that these studies tended to focus on the rockiest regions and therefore perhaps the best yelloweye habitats.

Yelloweye rockfish are estimated to have been lightly exploited until the mid-1970's, when catches increased and a rapid decline in biomass and spawning output began. The relative spawning output reached a minimum of 15.8% of unexploited levels (slightly above the estimate of 12.1% from the 2007 assessment) in 2000 (Figure 132). Yelloweye rockfish spawning output is estimated to have been gradually increasing since that time, in response to large reductions in harvest. Although the relative trend in spawning output is quite robust to the uncertainty in the estimated removals and steepness captured in the alternate states of nature (Figure 132), the absolute scale of the spawning output trajectory is very sensitive (Figure 127). The estimated relative depletion level in 2007 is 19.2% (slightly above the estimate of 16.4% from the 2007 assessment) and 20.3% in 2009 (states of nature: 17.3-23.5%), corresponding to 201.5 million eggs. The range over states of nature reflects the very large uncertainty in the scale of the estimated time-series: 128.3-353.0 million eggs. The aggregate spawning output estimates do not convey the spatial heterogeneity included via the area-specific dynamics: relative spawning output has differed markedly among the three states, with California having the largest spawning output at unexploited equilibrium, followed by Oregon and then Washington. Currently, Oregon is estimated to have the largest spawning output, followed by California, then Washington. Relative depletion also varies dramatically by state, with California estimated to be at 16.4% of unexploited conditions, Oregon, 22.5%, and Washington, 27.3% (Figure 133).

2.9 Uncertainty and Sensitivity Analysis

Although the base case assessment model captures some uncertainty via asymptotic intervals, uncertainty from two sources is reported through alternate states of nature bracketing the base case results and included explicitly in the decision table. The magnitude of the estimated catch time-series was found to have a large influence on the perception of current stock size and the estimate of steepness of the stock-recruit relationship was closely linked to the projected recovery rates. Alternate values of each were selected to bracket the best estimates with marginal probabilities one-half as likely. For historical catch, these values, 75% and 150% of the estimated catch series prior to 2000, were subjective, but reflect the lack of a comprehensive catch reconstruction in Washington and the change in likelihood of the fit to data sources over a reasonable range of catch levels (Figure 134). For steepness the 12.5th and 87.5th percentiles were calculated from the likelihood profile using the X^2 critical value of 1.127 as a proxy for the probability distribution about this point estimate. This resulted in alternate values for steepness of 0.344 and 0.508 about the maximum likelihood estimate. The most optimistic and pessimistic of the nine combinations from these two axes (weighted 6.25% each relative to 25% for the best estimate on each dimension) are reported in this document and all combinations used to provide a more realistic degree of uncertainty for future projections, decision tables and rebuilding analyses.

2.9.1 Sensitivity Analysis

The results reported in this section are by no means meant to be a comprehensive comparison of all possible aspects of model uncertainty, nor do they reflect even the full range of models considered in developing the base case. These results are intended to provide more information about relatively obvious questions for any stock assessment such as sensitivity to priors, key structural choices and potential conflict in signal among data sources. The order in which they are presented is not intended to reflect their importance; each run included here provided important information for developing or evaluating the base model and alternate states of nature.

A series of sensitivity analyses were requested during the STAR panel review and are described here in the order in which they were requested. The STAT made the *a priori* decision to truncate all recreational CPUE series in 1999 to avoid the use of points in 2000 and 2001 that were potentially contaminated by changes in aggregate bag limits for rockfish and avoidance of certain species such as canary rockfish. When the CPUE estimates for 2000-2001 (California and Washington) were included in the base case model there was little change in the results for key parameters and derived quantities (Table 25). It is clear that the indices of abundance contribute very little to the overall objective function for this assessment, and that they appear to favor somewhat more pessimistic results. In order to better evaluate this pattern, a sensitivity run was performed where the likelihood contributions for all of the indices were increased by a factor of 10. This had the largest effect on the estimate for steepness, reducing the value to 0.30, but the estimate of depletion changed only to 15.4% and unexploited spawning output remained almost unchanged. Based on discussions with scientists at all three states while reviewing data sources for this assessment, the STAT decided to allow for recreational CPUE indices to be linear or non-linear via estimating an additional catchability exponent parameter for each series. This decision was largely driven by the inability to address major concerns over the behavior of these series via the standardization models (the data to do so not being extant). To test the influence of this decision on model results as sensitivity run was conducted forcing all recreational series to be strictly proportional to population abundance. This had very little effect on model results (Table 25).

During the STAR panel, a request was made to revisit the estimation of dome-shaped selectivity for the IPHC survey in Oregon. This was due to a mild pattern of over-predicting the largest fish for this series. When a very flat-topped dome was permitted (wide bounds on the width of the peak) the very largest fish were not estimated to be fully selected (Figure 135), however the ascending limb was nearly identical to the base case. Inspection of other selectivity curves in Oregon revealed no ‘cascade’ of dome-shaped estimates due to observations of at least a few large fish in each. Parameter estimates and management quantities were largely unchanged (Table 25). Inspection of recent growth data revealed evidence for a small size difference between yelloweye of both sexes in Oregon and Washington (Oregon fish slightly smaller) that could be an alternate explanation to dome-shaped selectivity (Figure 136). It was decided that further exploration of area-specific life-history characteristics (growth, maturity, fecundity) should be addressed before moving to dome-shaped selectivity for the IPHC survey in Oregon but not Washington.

Prior to the STAR panel review a range of sensitivity analyses were performed to investigate several aspects of the assessment. Because there was relatively little change between the pre- and post-STAR base case models (revised California recreational catches, addition of length-frequency data from the Northern California charter fleet, a processing error corrected in the Oregon recreational observer length-frequency data, and revision of the prior on natural mortality) these preliminary sensitivity analyses are retained here. Although the final base case may be slightly more or less sensitive to these factors than the pre-STAR model, they are still informative about the assessment.

The use of alternate states of nature for the level of historical yelloweye catches reflects the high degree of uncertainty in these estimates from both commercial and recreational sources. As is the case with any catch reconstruction, the plausible ‘envelope’ for actual catches probably widens for estimates farther back in time. In the case of catches this seems to be most relevant with the upper estimate rather than the lower as the likelihood of appreciable unaccounted for discarding goes up in the early time-periods. For this reason a series of pre-STAR models with 50% or 200% of the best estimates for historical catch were run using a different year to define the end of the ‘historical’ period. These pre-STAR models indicated a similar degree of sensitivity to alternate catch series for the period before 1996 and 1976 (Table 26).

The second set of pre-STAR sensitivity analyses presented here were intended to evaluate whether there is appreciably conflicting information among various data types and sources. Although this can also be evaluated via the likelihood profiles (see below), the implications for management related quantities are not always obvious without direct comparison of these estimates. To compare the influence of the length and age data (over all sources in the model) the emphasis was sequentially reduced by 50% for each. Very little change was observed from the pre-STAR base case results (Table 27). Given the high probability that the observed fishery dependent CPUE indices for yelloweye rockfish have been influenced by many factors other than population abundance, a model was run omitting these time-series. The results indicated these data were not having an undue influence on quantities of interest or key parameters (Table 27). Similarly, it is quite possible that the fishery independent sources of data have fundamental (and unknown) errors in our interpretation relative to this assessment (trawl surveys may not be adequately reflecting the population dynamics due to sparse sampling or more fundamental process errors like the biomass in trawlable areas not being proportional to the total). To investigate the effects of these data two pre-STAR models were run: 1) omitting all fishery independent data (index and biological) and 2) omitting all fishery independent data and forcing the catchability relationship between fishery dependent indices and population abundance to be linear (removing the *Q* power coefficients). Only the latter produced appreciable change in key quantities, increasing estimated steepness to 0.369, and therefore MSY to 53 mt, from 42.7 in the base case model (Table 27).

The third set of pre-STAR sensitivity models was intended to evaluate the effects of informative priors on steepness and natural mortality as well as the use of point estimates for the fecundity relationship, since this relationship is quite uncertain. Neither the steepness prior, the natural mortality priors or the fecundity relationship had much effect on the model results (Table 28).

The fourth set of pre-STAR sensitivity analyses was intended to address perhaps the most important choices made in building this assessment: structural choices regarding the explicit use of areas, sex-specific growth and mortality and estimation of recruitment deviations over the full time-series. Removing the explicit areas in the model increased the estimated steepness to 0.42 resulting in a slightly higher estimated MSY and current depletion (19.3%; Table 29). Removing sex-specific growth and mortality parameters (and therefore mimicking a single-sex model as has been used in previous assessments) resulted in very little change to model results, either with or without explicit areas included in the model structure (Table 29). When a full time-series of recruitment deviations was estimated, the modeled estimate of absolute biomass (historical and current) as well as current depletion went down (to 12.0%) but the perceived productivity of the stock went up (steepness to 0.393 and MSY to 49.7). However, in attempting to determine how reliable this model would be as a base case, a number of exploratory analyses were performed. Particularly, if many poorly informed deviations in recruitment strength and area apportionment are estimated in a maximum likelihood context it is important for these deviations to be zero-centered (such that reference point estimates are consistent with the observed time-series) and that the data are sufficiently informative to support their estimation. Given the lack of clear cohorts it is unclear whether there is appreciable evidence for recruitment variability; a reduction in the objective function of ~135 units was achieved, but with an additional 295 parameters. Shorter series of deviations resulted in frequent pathological behavior of the first or terminal deviations over areas, years or both. Perhaps more concerning for maximum likelihood estimation, was the result that although there were appreciable deviations in estimated annual recruitment strengths, the asymptotic variance estimates of these deviations were only slightly reduced below the input value for recruitment variability (σ_r, 0.5 for this sensitivity, but showing a similar pattern over a wide range of input values; Figure 137). In light of this behavior, it would be appealing to integrate over the deviation parameters, rather than trusting the maximum likelihood-based point estimates. Several attempts at summarizing the posterior density of model parameters and derived quantities resulted in poor performance of the jump function (likely due to parameter correlations and ambiguously determined recruitments: large in one of several years, but not in all, causing bimodal posterior distributions). Further, several issues regarding the application of the bias correction to get from the mean to the median during integration were identified, but could not be resolved in time for this assessment. These issues did not appear to have any effect on the base case model, where preliminary MCMC chains revealed little difference with MLE parameter estimates or confidence intervals.

In aggregate, these sensitivity analyses supported the use of historical catch as a primary axis of uncertainty, but suggest (not surprisingly) that this assessment is sensitive to many choices that cannot be clearly informed by the available data.

2.9.2 Retrospective Analysis

A 5-year retrospective analysis was conducted by running the model using data only through 2003 ("retrospective in 2004"), 2004, 2005, 2006 and 2007 (Figure 138). Little retrospective pattern is apparent as the terminal year of data is removed from the model.

The second type of retrospective analysis addresses assessment error, or at least the historical context of the current result given previous analyses. This comparison is framed in terms of relative depletion due to the use of a fecundity relationship this assessment. Because of this, some of the retrospective uncertainty in absolute scale of the yelloweye population is less pronounced. Since 2002, a pattern had emerged in which each new assessment was slightly more pessimistic about current status than those conducted previously, however the current results suggest a slight increase in relative spawning output (Figure 139).

2.9.3 Likelihood Profiles

Likelihood profiles (fully revised after the STAR panel) were completed for three key model parameters: steepness of the stock-recruit relationship (h), unexploited equilibrium recruitment (R_0), and male natural mortality (M_{males}). Likelihood profiles are commonly used to elucidate conflicting information among various data sources, to determine how asymmetric the likelihood surfaces surrounding point estimates may be, and to provide an additional evaluation of how precisely parameters are being estimated.

Steepness appears to be largely informed by the length data (Figure 140), but all likelihood components show a similar signal favoring steepness values below ~0.5. Although male natural mortality is correlated with steepness, it does not span a particularly wide range and is most correlated over the lowest steepness values (Figure 141).

Equilibrium recruitment is informed primarily by the length- and age-composition data (Figure 142); however, given a change of less than one unit of negative log-likelihood for the index data across a wide range of values, there appears (not surprisingly) to be no information in any of the abundance indices for this parameter. The choice to profile over male natural mortality was made easy, due to the nearly perfect correlation between estimated female natural mortality and the value used for males in the likelihood profile (Figure 143). For this reason, the profile can essentially be thought of as a profile over either male or female natural mortality. As was the case with R_0, the length and age data dominate the profile, showing a strong degradation to values much below 0.04 or above 0.052 (Figure 144). Again, the index data were largely uninformative and even the informative prior for female natural mortality was not having a substantial effect on the range of plausible parameter values.

2.9.4 Parametric Bootstrap Using Stock Synthesis

There is a built-in option to create bootstrapped data-sets using Stock Synthesis. This feature performs a parametric bootstrap using the error assumptions and sample sizes from the input data to generate new observations about the fitted model expectations. It is therefore not strictly a variance estimation exercise, but an exploration of the question: If the assessment was true, and the same relative quantity and quality of data were available, how reliably could the parameters and derived quantities be re-estimated?

There was insufficient time to use this powerful diagnostic tool for this assessment, but it should be considered a standard method for full assessments where time permits its application. Its use is particularly important for cases where the asymptotic (or posterior) intervals about model estimates are used as the primary representation of uncertainty.

3. Rebuilding Parameters

Revised rebuilding projections will be presented in a separate document after the assessment has been reviewed in September 2009. Although the base case assessment model captures some uncertainty via asymptotic intervals, uncertainty from two sources is reported through alternate states of nature bracketing the base case results and will be included explicitly in the decision table (Table 30).

4. Reference Points

The spawning output of yelloweye rockfish was estimated to have dropped below the $SB_{40\%}$ management target in 1989 and the overfished threshold in 1994. In hindsight, the spawning output passed through the target and threshold levels with annual catch averaging almost five times the current estimate of the MSY. The coast-wide stock remains below the overfished threshold, although the spawning output is estimated to have been increasing since 2000 in response to reductions in harvest. The degree of increase is largely insensitive to the magnitude of historical catch and only moderately sensitive to the value for steepness, but the absolute scale of the population reflects alternate removal series very closely. Fishing mortality rates are estimated to have been in excess of the current F-target for rockfish of $SPR_{50\%}$ from 1976 through 1999 (Figure 145, Figure 146, Figure 147). Recent management actions have curtailed the rate such that recent SPR values are in excess of 60% over the last eight years (Figure 148). Relative exploitation rates (catch/biomass of age-8 and older fish) are estimated to have been at or less than 1% after 2001. The alternate states of nature result in estimated exploitation rates ranging from less than 1.6% to less than 0.6%.

Unfished spawning output was estimated to be 994 million eggs. The target stock size ($SB_{40\%}$) is therefore 398 million eggs and the overfished threshold ($SB_{25\%}$) is 249 million eggs. Maximum sustained yield (MSY), conditioned on current fishery selectivity and allocations, was estimated in the assessment model to occur at a spawning stock biomass of 388 million eggs and produce an MSY catch of 56.4 mt (slightly above the estimate from the 2007 assessment of 43.7 mt). However, the yield at MSY is extremely sensitive to states of nature resulting in a wide range for this value from 31.5 to 107.9 mt. Maximum sustainable yield is estimated to be achieved at an SPR of 60.4% (range of states of nature: 51.2-69.7%). This is nearly identical to the yield, 56.1 mt, generated by the SPR (61.0%) that stabilizes the stock at the $SB_{40\%}$ target. The fishing mortality target/overfishing level (SPR = 50.0%) results in a much smaller equilibrium yield of 48.9 mt at a spawning output of 230 million eggs (23.1% of the unfished level). In sum, although the estimated MSY spawning output is very close to the proxy level, the harvest rate needed to achieve equilibrium at 40% of the unfished level in substantially lower than the MSY-proxy rate.

5. Harvest Projections and Decision Tables

The forecast reported here will be replaced by the rebuilding analysis to be completed in September-October 2009 following SSC review of the stock assessment. In the interim, the total catch in 2009 and 2010 is set equal to the OY (17 mt). The target exploitation rate for 2011 and beyond is based upon an SPR of 71.9%, which approximates the harvest level in the current (2007) rebuilding strategy (the 71.9% SPR rate represents the target after the 'ramp-down' portion of the strategy is completed in 2010). Uncertainty in the rebuilding forecast will be included via integrating over all combinations of the alternate states of nature for catch history and steepness. Current medium-term forecasts predict increases in coast-wide abundance under the SPR=71.9% rebuilding strategy, however these increases are largely driven by the California and Oregon portions of the stock. In fact, the Washington portion is projected to remain at current levels under recent allocation of catch. Catch allocation used for the forecast reflects the average distribution of Fs in 2005-2007 among fleets (recreational, commercial) in: Washington (0.013, 0.005), Oregon (0.004, 0.002) and California (0.006, 0.003). The estimated OY values for 2011 and 2012 are larger (20.9, 21.2) than those predicted from the 2007 rebuilding analysis (13.9, 14.2).The projection of expected yelloweye rockfish catch, spawning output (by area) and depletion shows very slow recovery (Table 31). It may be desirable to evaluate specific allocation scenarios, if relative removals based on future management actions will be substantially different than recent values by state.

Because yelloweye rockfish are currently managed under a rebuilding plan, the decision table included here (Table 32) is only intended to better evaluate the management implications of the considerable uncertainty in the base case assessment model. Various alternate management actions including SPR rates and fixed OYs will be evaluated in the rebuilding analysis. Landings in 2009-2010 are 17 mt for all cases. Catch allocation used for the forecast reflects the same relative *F*s used in the forecasts.

6. Regional Management Considerations

The choice to model the yelloweye rockfish stock with explicit areas in the assessment model is based on the sedentary life-history of adult yelloweye, and the markedly different population trends as well as historical and current exploitation rates among the three states. Current population status differs by state, with both near term forecasts as well as longer term the rates of recovery under OY catches predicted to be quite different for each area. This information may be valuable for making management and allocation decisions; alternate future projections can easily be added to this assessment, as needed, to better describe the implications of these choices.

The use of area-specific vs. coast-wide assessment models and management tools should be considered a major source of uncertainty. Future efforts, including links to

Canadian waters and alternate approaches to meta-population dynamics could produce differing results.

7. Research Needs

The available data for yelloweye rockfish are very sparse and generally weakly informative about current status. The following research topics could improve the ability of this assessment to reliably model the yelloweye rockfish population dynamics in the future and provide better monitoring of progress toward rebuilding:

1. Develop and implement a comprehensive visual survey.
2. Do a scientific review of current efforts to develop and improve stock size indices for yelloweye based on IPHC (including additional stations) and make recommendations on the best approaches to develop such indices.
3. Explore a recalculation of GLMM estimates in the IPHC survey that explores station effects which allows inclusion of stations that differ over time.
4. Continue to refine historical catch estimates using ex-vessel prices, etc., particularly in WA.
5. Investigate the development of a WA recreational yelloweye CPUE based on the recreational halibut fishery. Consider a full time series and one ending in 2002, since the yelloweye RCA in waters off northern WA was implemented in 2003.
6. Encourage the collection of samples to refine the estimate biological parameters, particularly maturity and fecundity.
7. Continue to evaluate the spatial aspects of the assessments, including growth, the number and placement of boundaries between areas, as well as the northern boundary with Canada.
8. More work is needed to better understand the performance of maximum likelihood and Bayesian estimators of stock size and trends when large numbers of poorly informed recruitment deviations are estimated. Although it is logically appealing to include such uncertainty, even when little coherent data informing cohort strengths is available, technical and computational issues need to be solved before this approach can be implemented in a case like yelloweye rockfish.
9. Investigate alternative ways of re-weighting. This issue is relevant for all west coast stock assessments.
10. Investigate how best to account for the variability in dates in trawl surveys through a meta-analysis. This issue is relevant for all west coast stock assessments.
11. Continue to refine coast-wide historical catch estimates. This issue is relevant for all west coast stock assessments.
12. Access and processing of recreational data (catch and biological sampling) currently entails differing locations and formats for data from each of the three states and RecFIN. A single database that holds all raw recreational data in a consistent format would reduce assessment time spent on processing these data and potential introduction of errors or alternate interpretations due to processing.
13. The IPHC data organization should be revisited. Currently biological samples cannot be linked to the station from which they were collected. Age data for 2003-2005 is disconnected from length and sex information and other unknown issues may persist in

these data. A thorough evaluation of what data are reliable and a final determination of what information is lost, or can potentially be recovered, is needed.

8. Acknowledgements

This assessment draws heavily on the text and analyses in the 2007 update, 2006 assessment and earlier documents, and has benefited greatly from the efforts of all authors contributing to those analyses. Many people at various state and federal agencies assisted with assembling the data sources included in this updated assessment. Stacey Miller and John Devore assisted in identifying points of contact and acquiring Pacific council and other documentation. Robert Alverson and Robert Jones (as GAP and GMT representatives) provided points of contact and insight into previous yelloweye assessments. Farron Wallace, Theresa Tsou, and Henry Cheng at WDFW provided extensive background material, data sets and continuity from previous assessments. Troy Buell organized and documented much of the data from Oregon and was invaluable in locating data sets and points of contact. Waldo Wakefield, Julia Clemons and Curt Whitmire generously contacted authors of published and unpublished visual studies and then summarized these habitat information and yelloweye density observations; their extensive help is much appreciated. We also thank the authors of these visual studies (Listed in Table 8) for sharing preliminary and unpublished results. Traci Larintino, Mathew Mitchie and Deborah Wilson-Vandenberg assisted with California biological data, and spotted an error in preliminary catch estimates. Don Pearson provided recent CalCOM landings and historical catch estimates from California. Eliza Heery provided total mortality estimates from recent years and summarized biological data from the West Coast Observer Program. Wade Van Buskirk assisted in extracting recreational data from RecFIN. Beth Horness provided summary statistics from the NWFSC trawl survey. We thank Mike Deach, Tim Klassen and Mike Hart for patiently answering (and posing) questions regarding the yelloweye assessment, management and data-collection in the commercial and recreational fisheries. Richard Methot has provided extensive guidance in the use of Stock Synthesis version 3 over the past five years. Ian Taylor has greatly improved and made much more accessible the R code for plotting and diagnostics of Stock Synthesis models (http://code.google.com/p/r4ss/) with which many of the figures in this document were created. Comments and suggestions from Jim Hastie substantially improved the quality of the document.

We thank the STAR panel reviewers: Steve Ralston, Richard Methot, Jean-Jacques Maguire, Vivian Haist, as well as Robert Jones and Robert Alverson (GMT and GAP representatives) and other participants for a critical and thoughtful review.

OR	2001	Heceta Bank	ROPOS ROV	Strip transect	58	7.5	(Wakefield et al. Unpublished data.)
CA	1992-93	Soquel Canyon	Delta sub	Strip transect	104	30.8[9]	(Yoklavich et al. 2000)

[4]Direct counts from "untrawlable habitat".
[5]Total of 160 yelloweye RF observed across all three years.
[6]Surveyed 1.0 hours.
[7]Surveyed 2.0 hours.
[8]Surveyed 12.8 hours.
[9]Density estimate based on total number observed relative to total area surveyed.

Table 9. Summary of fixed biological parameters estimated externally and used as input for this stock assessment

Quantity	Value	Source
Female weight-length coefficient (*a*)	0.00000977	All available data pooled from fishery and survey sources.
Female weight-length exponent (*b*)	3.17	
Male weight-length coefficient (*a*)	0.0000170	
Male weight-length exponent (*b*)	3.03	
Female length at 50% maturity	38.78	Hannah and Bloom, 2009
Female maturity logistic slope	-0.437	
Fecundity eggs/kilogram intercept	137,900	Dick, 2009
Fecundity slope	36,500	

Table 10. Summary of sampling used to generate the Oregon charter observer CPUE index.

Year	Number of observed drifts	Number of observed angler-drifts	Number of yelloweye encountered
2004	905	6,538	22
2004	949	6,510	21
2005	1,100	7,163	5
2006	1,396	8,746	37
2007	1,349	7,813	52
2008	905	6,538	22

Table 15. Description of model parameters in the base case assessment model.

Parameter	Number estimated	Bounds (low, high)	Prior (Mean, SD)
Natural mortality (*M*, female)	1	(0.01,0.15)	Normal (0.0517,0.0226)
Natural mortality (*M*, male)	1	(0.01,0.15)	Normal (0.0517,0.0226)
Stock and recruitment			
Ln(R_0)	1	(3,15)	Uniform
Ln(Mean recruitment offset Oregon, normalized)	1	(-5,5)	Uniform
Ln(Mean recruitment offset Washington, normalized)	1	(-5,5)	Uniform
Steepness (*h*)	1	(0.2,1.0)	Beta (0.73,0.189)
Catchability			
Surveys:			
Ln(*Q*) – IPHC Oregon	-		Analytic solution
Ln(*Q*) – IPHC Washington	-		Analytic solution
Ln(*Q*) – NWFSC survey (OR only)	-		Analytic solution
Ln(*Q*) – Triennial survey (1980-1992, WA only)	1	(-10,0)	Uniform
Ln(*Q*) – Triennial survey offset (1995-2004) to early	1	(-4,4)	Uniform
Fisheries:			
Ln(*Q*) – Fisheries	-		Analytic solution
Power coefficient for Ln(*Q*) relationship	4	(-6,6)	Uniform
Selectivity			
Fisheries (logistic):			
Length selectivity inflection	7	(10,70)	Uniform
95% width of selectivity logistic	7	(0.001,50)	Uniform
IPHC Surveys (logistic):			
Length selectivity inflection	2	(10,70)	Uniform
95% width of selectivity logistic	2	(0.001,50)	Uniform
Trawl Surveys (double-normal):			
Length at peak selectivity	1	(20,87)	Uniform
Width of top (as logistic)	-		Fixed at -4
Ascending width (as exp[width])	2	(0,8)	Uniform
Descending width (as exp[width])	1	(0,12)	Uniform
Initial selectivity (as logistic)	1	(-10,10)	
Final selectivity (as logistic)	-		Fixed at 10, or not used
Individual growth			
Females:			
Length at age 1	1	(10,35)	Uniform
Length at age 70	1	(40,120)	Uniform
von Bertalanffy *K*	1	(0.01,0.2)	Uniform
CV of length at age 1	1	(0.05,0.2)	Uniform
CV of length at age 70	1	(0.05,0.2)	Uniform
Males:			
Length at age 1 offset to females	-	NA	Fixed at 0.0
Length at age 70	1	(40,120)	Uniform
von Bertalanffy *K*	1	(0.01,0.2)	Uniform
CV of length at age 1	1	(0.05,0.2)	Uniform
CV of length at age 70	1	(0.05,0.2)	Uniform
Total: 44 estimated parameters			

Table 16. Input and effective sample sizes used for tuning the composition data in the base model.

Type of data	Fleet	Input adjustment	Average input after adjustment	Average effective N
Fishery independent:				
Length	IPHC (OR)	0.73[1]	103.9	104.5
	IPHC (WA)	0.62[1]	59.2	59.0
	Triennial (WA)	2.08	19.7	20.2

[1]Length data with initial input sample sizes (before tuning) based on number of fish instead of number of samples.

Table 17. Adjusted mean input standard errors and root-mean-squared error (RMSE) of fits to index data used to tune the base model. ~95% confidence interval intersection is reported as number of predictions inside the interval/number of data points.

Fleet	SD log(value) adjustment	Mean input SD log(value) after adjustment	RMSE	~95% CI intersection

	Estimated value	12.5%	25%	12.5%
	High	6.25%	12.5%	6.25%

Table 31. Projection of potential yelloweye rockfish ABC, OY, spawning output and depletion for the base case model based on the SPR = 71.9% fishing mortality target used for the last rebuilding plan (OY) and $F_{50\%}$ overfishing limit/target (ABC). Assuming the OY of 17 mt is achieved exactly in 2009 and 2010. Catch allocation used for the forecast reflects the average distribution of *F*s in 2005-2007 among fleets (recreational, commercial) in: Washington (0.013, 0.005), Oregon (0.004, 0.002) and California (0.006, 0.003).

Year	ABC[1] (mt)	OY[1] (mt)	Coast-wide Age 8+ biomass (mt)	Coast-wide Depletion	Spawning output (million eggs)			
					Coast-wide	California	Oregon	Washington
2009	*31*	*17*	2,008	20.3%	202	75	93	34
2010	*32*	*17*	2,039	20.8%	206	78	95	34
2011	49.3	20.9	2,068	21.2%	211	80	97	34
2012	49.9	21.2	2,093	21.6%	215	82	98	34
2013	50.5	21.4	2,118	22.0%	219	85	100	34
2014	51.1	21.7	2,141	22.4%	222	87	101	34
2015	51.6	21.9	2,165	22.7%	226	89	103	34

11. Figures

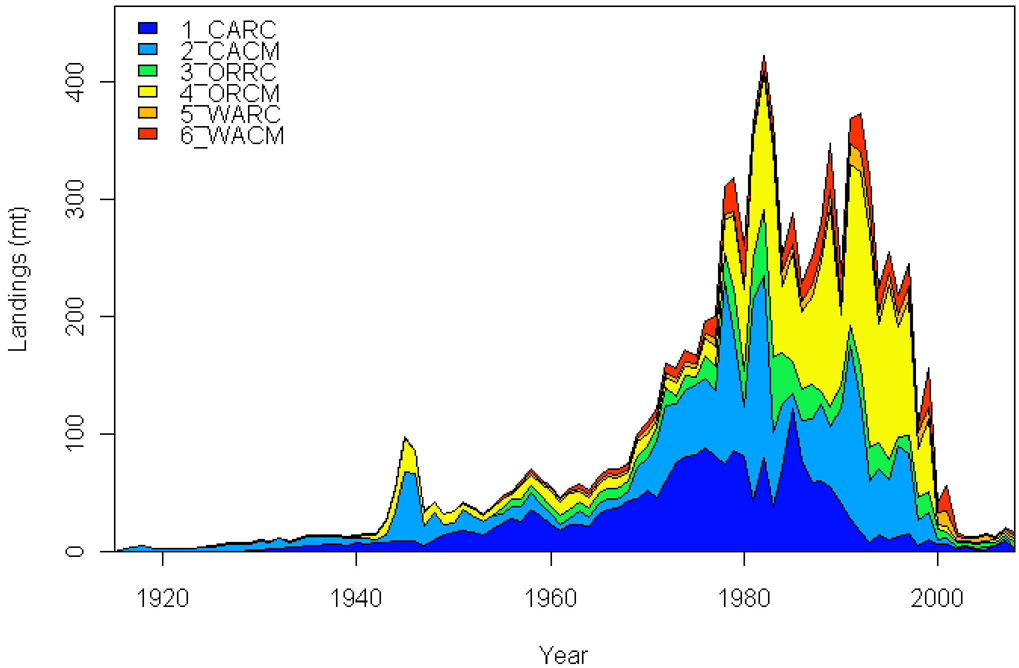

Figure 1. Yelloweye rockfish estimated catch history, 1916-2008. Fleet names indicated by state (WA, OR or CA) and sector (recreational = RC, commercial = CM).

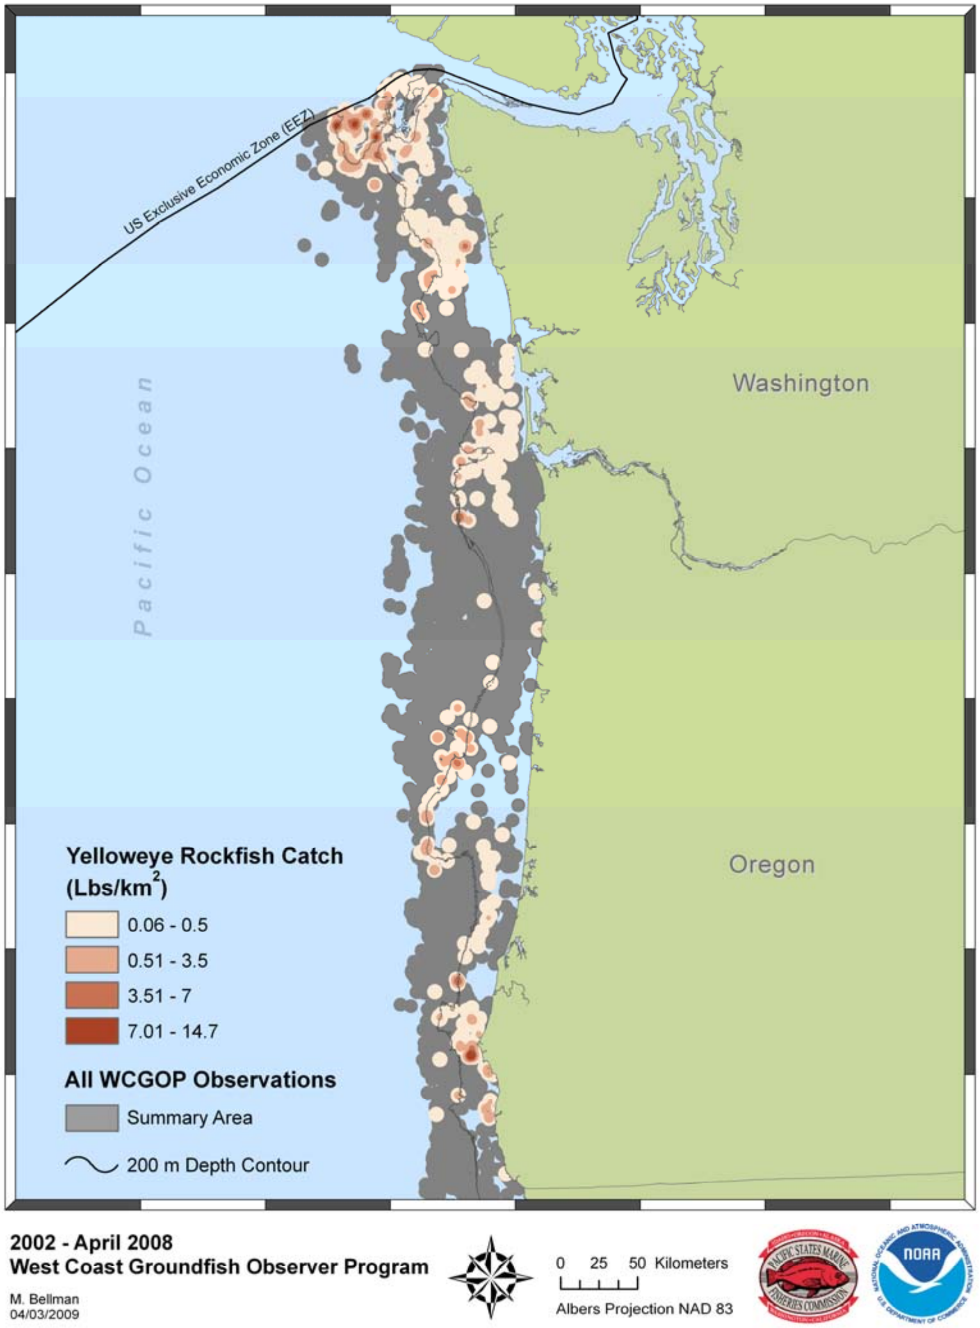

Figure 2. Spatial distribution of yelloweye rockfish catch (lbs/km^2) observed by the West Coast Groundfish Observer Program from 2002 – April 2008 in Oregon and Washington.

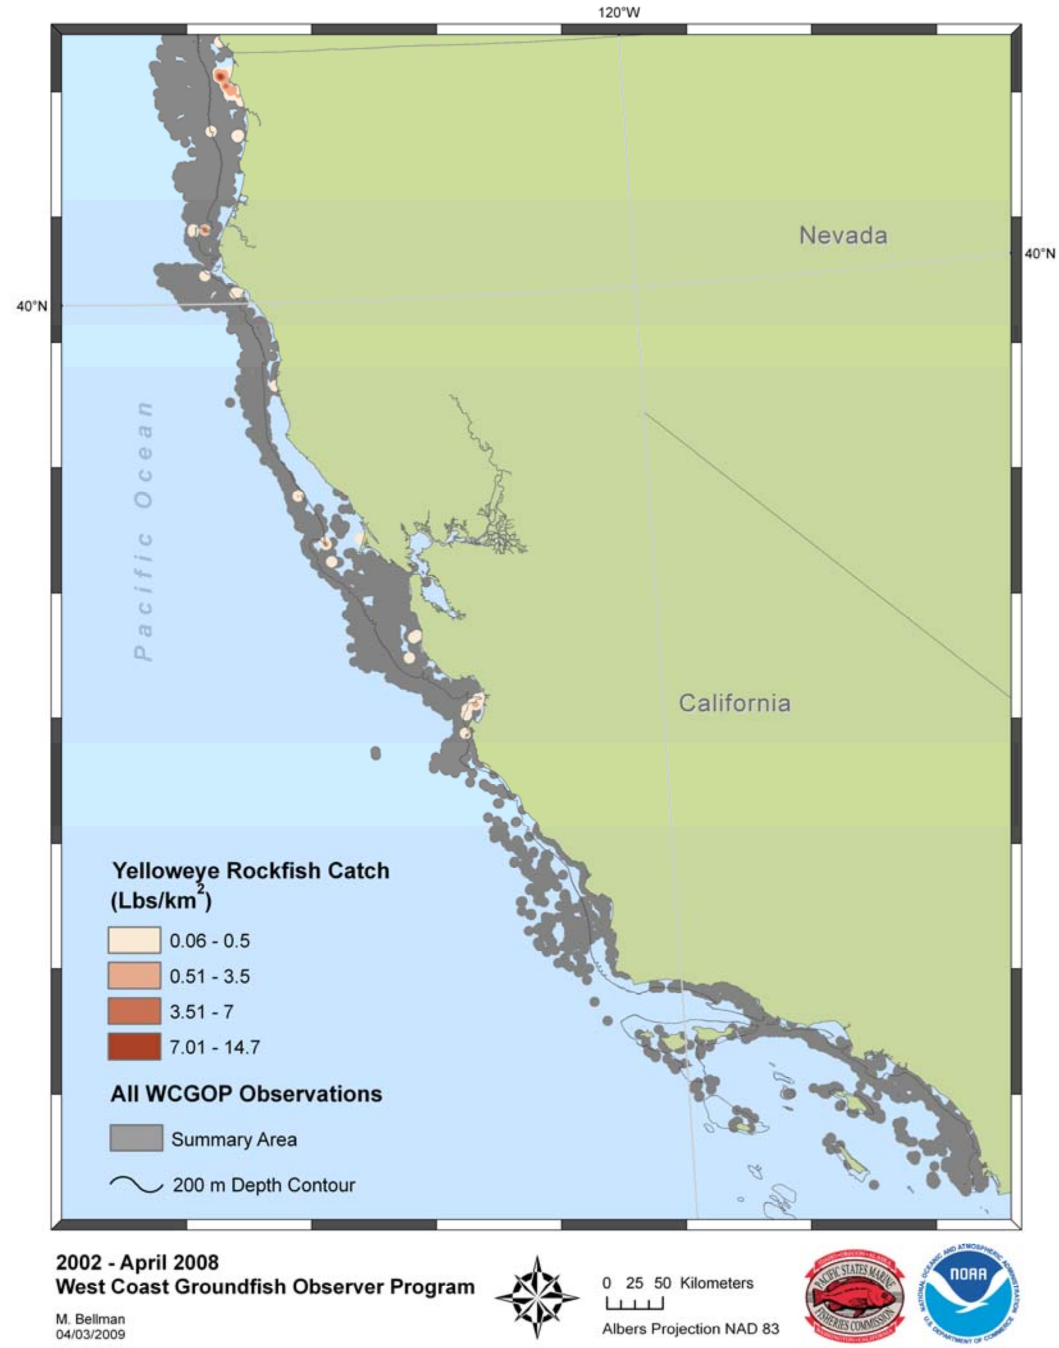

Figure 3. Spatial distribution of yelloweye rockfish catch (lbs/km^2) observed by the West Coast Groundfish Observer Program from 2002 – April 2008 in California.

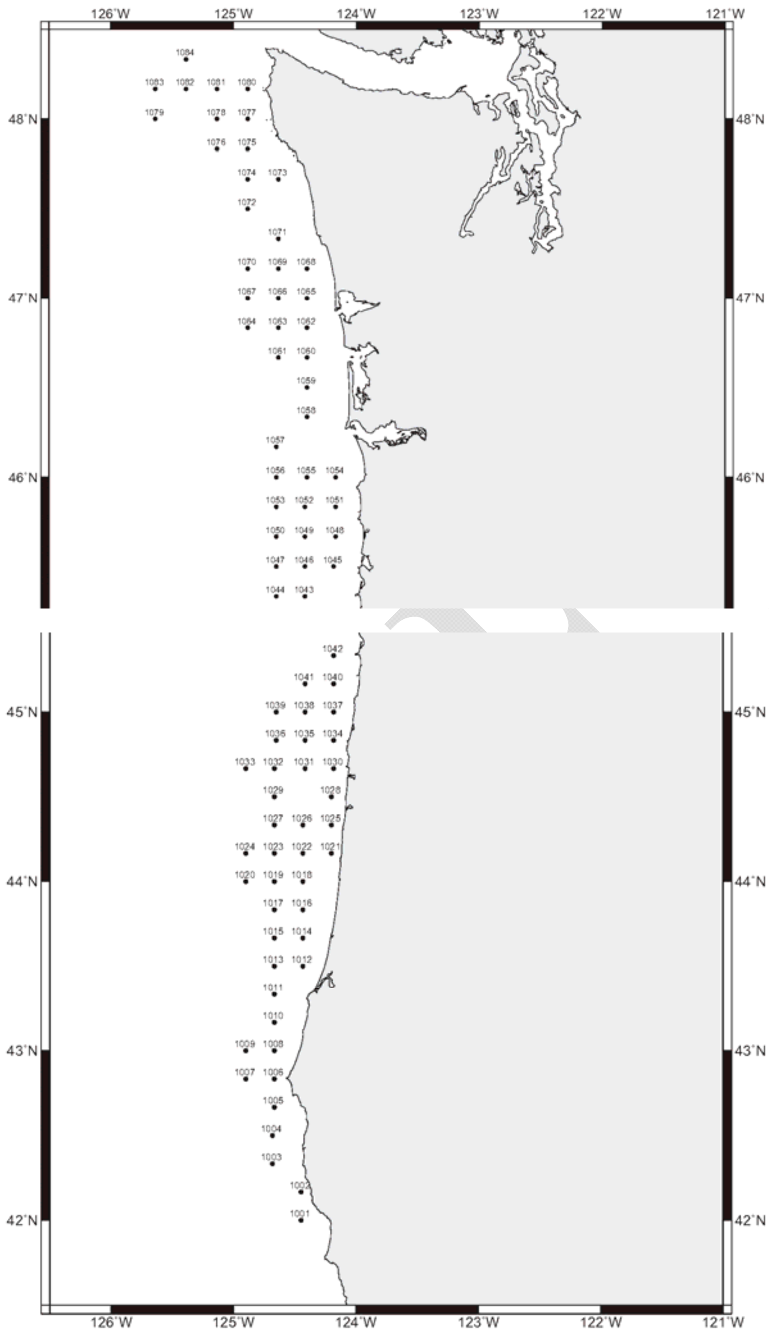

Figure 4. Stations fished by the IPHC long-line survey for Pacific halibut (From IPHC web-site: http://www.iphc.washington.edu/halcom/survey/ssadata/maps/ssa2amaps.pdf). Note that the two maps overlap slightly at the 1042-1044 station line.

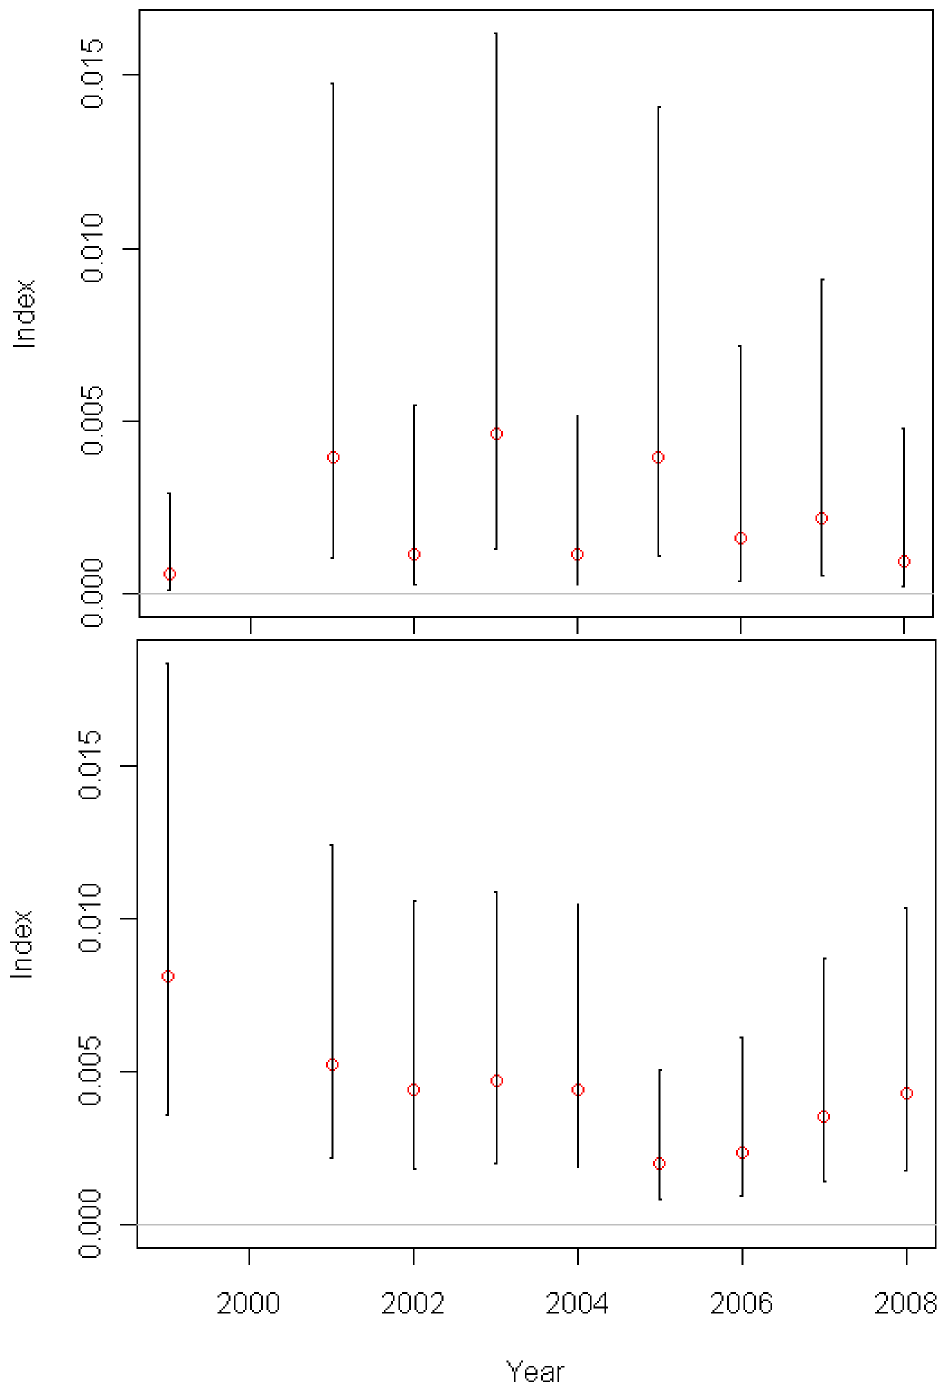

Figure 5. IPHC longline survey indices of relative abundance for Washington (upper panel) and Oregon (lower panel). Vertical lines indicate +/- 95% confidence intervals based on the assumption of lognormal error.

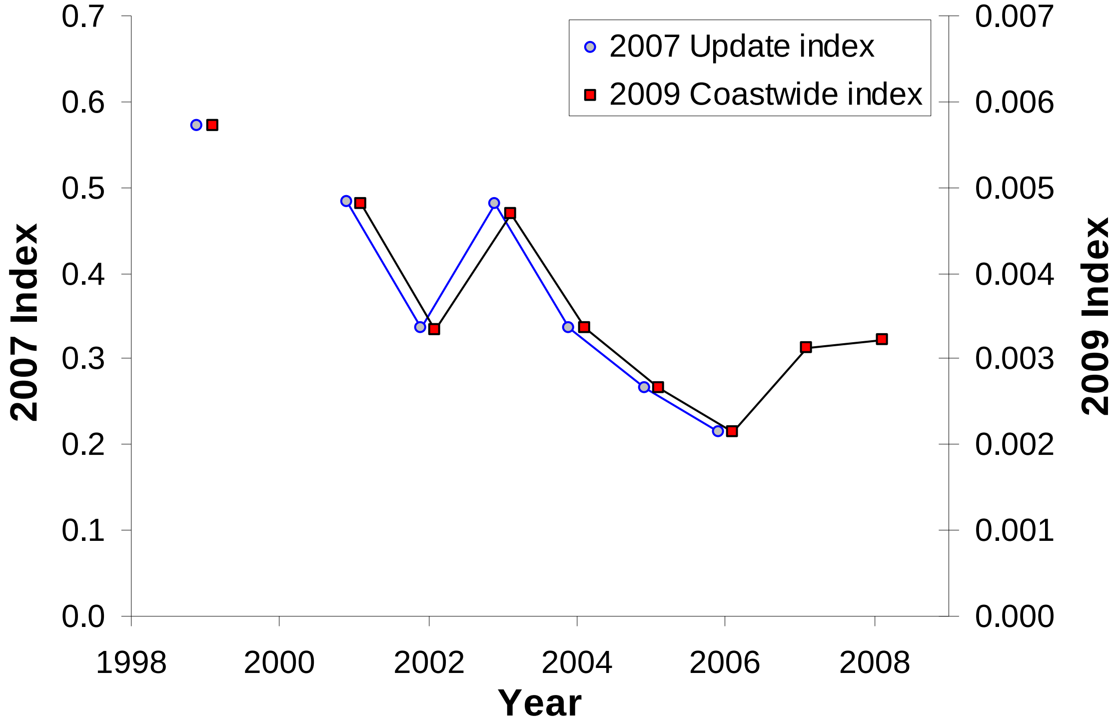

Figure 6. Comparison of a 2009 coast-wide index of abundance from the IPHC data with that calculated with the methods described in the 2007 assessment. Note that the years have been offset slightly to allow each point to be visible.

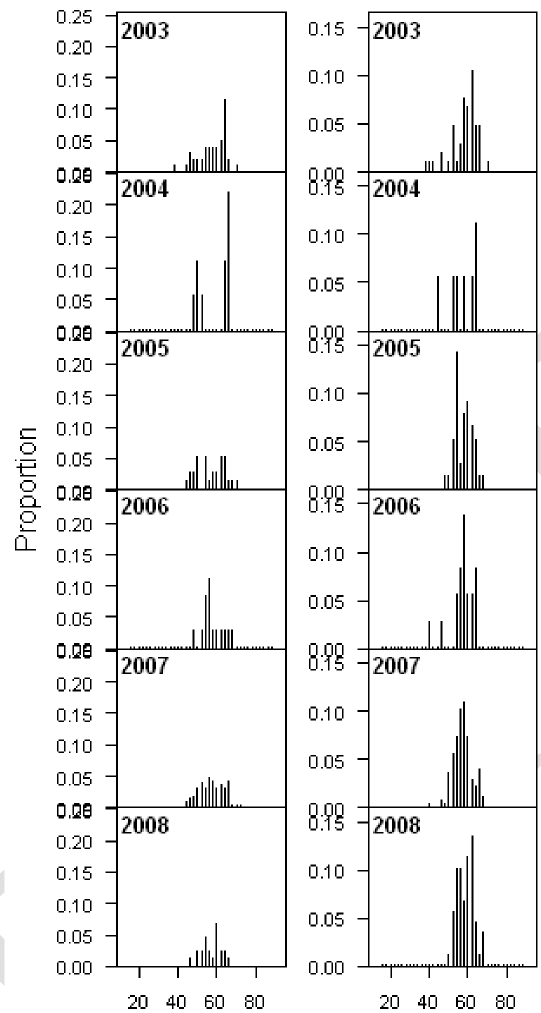

Figure 7. Length-frequency distributions for female (left panel) and male (right panel) yelloweye rockfish from the IPHC survey in Washington.

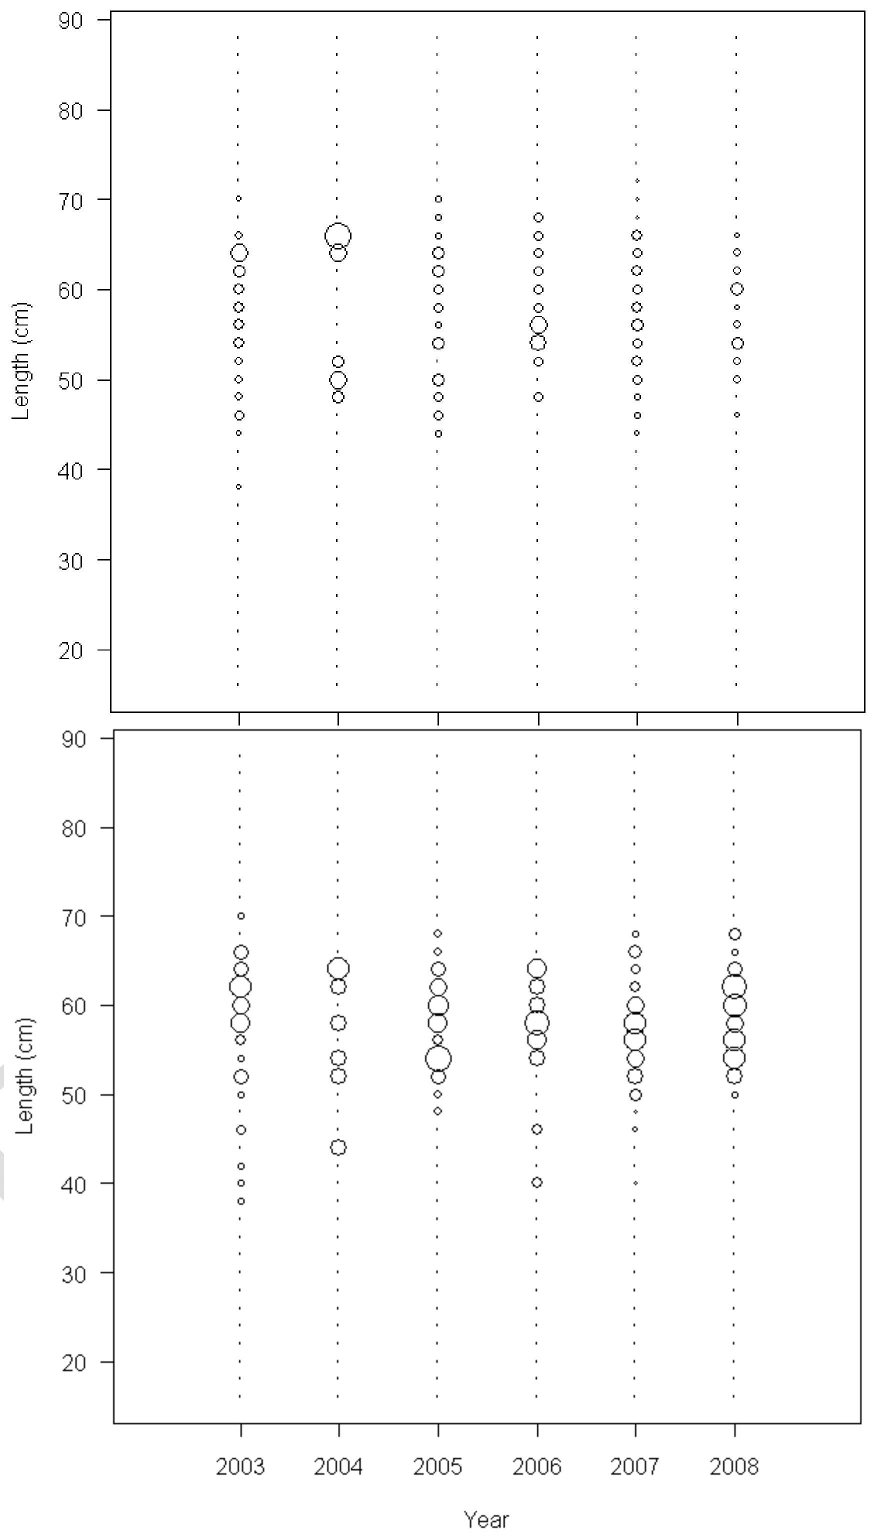

Figure 8. Length-frequency distributions for female (upper panel) and male (lower panel) yelloweye rockfish from the IPHC survey in Washington. Distributions sum to 1.0 in each year; the largest bubble sizes indicate proportions of 0.22 (females) and 0.14 (males).

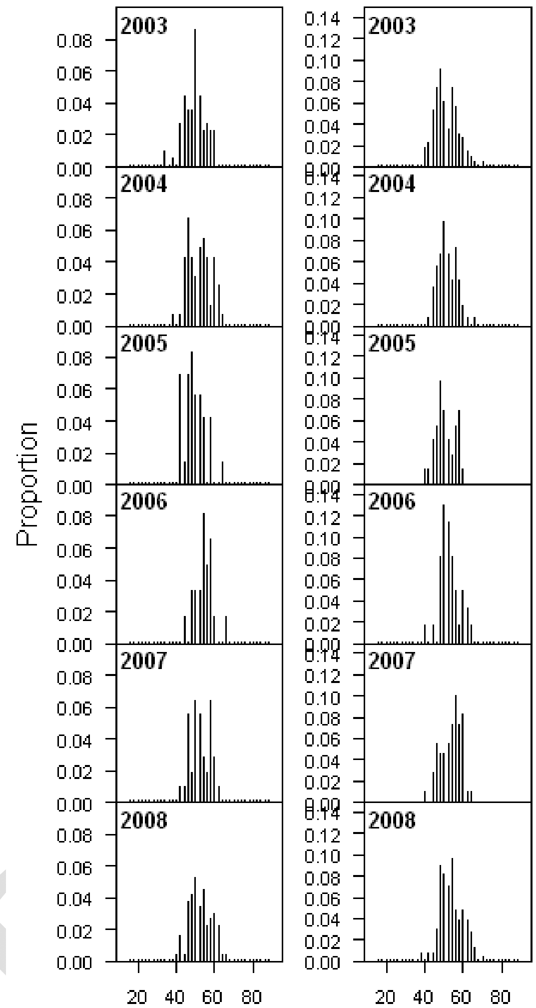

Figure 9. Length-frequency distributions for female (left panel) and male (right panel) yelloweye rockfish from the IPHC survey in Oregon.

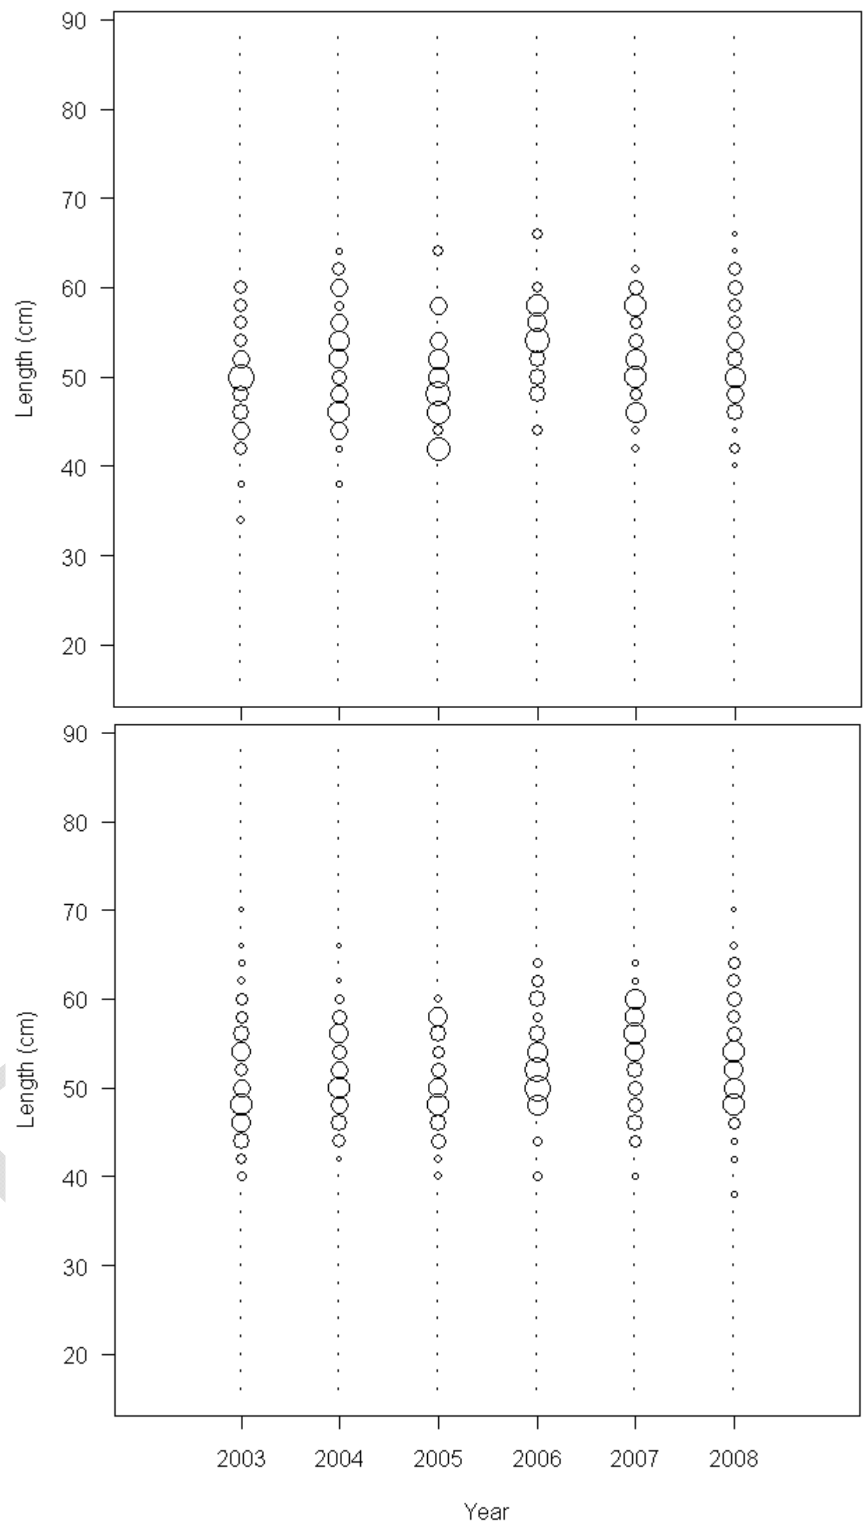

Figure 10. Length-frequency distributions for female (upper panel) and male (lower panel) yelloweye rockfish from the IPHC survey in Oregon. Distributions sum to 1.0 in each year; the largest bubble sizes indicate proportions of 0.09 (females) and 0.13 (males).

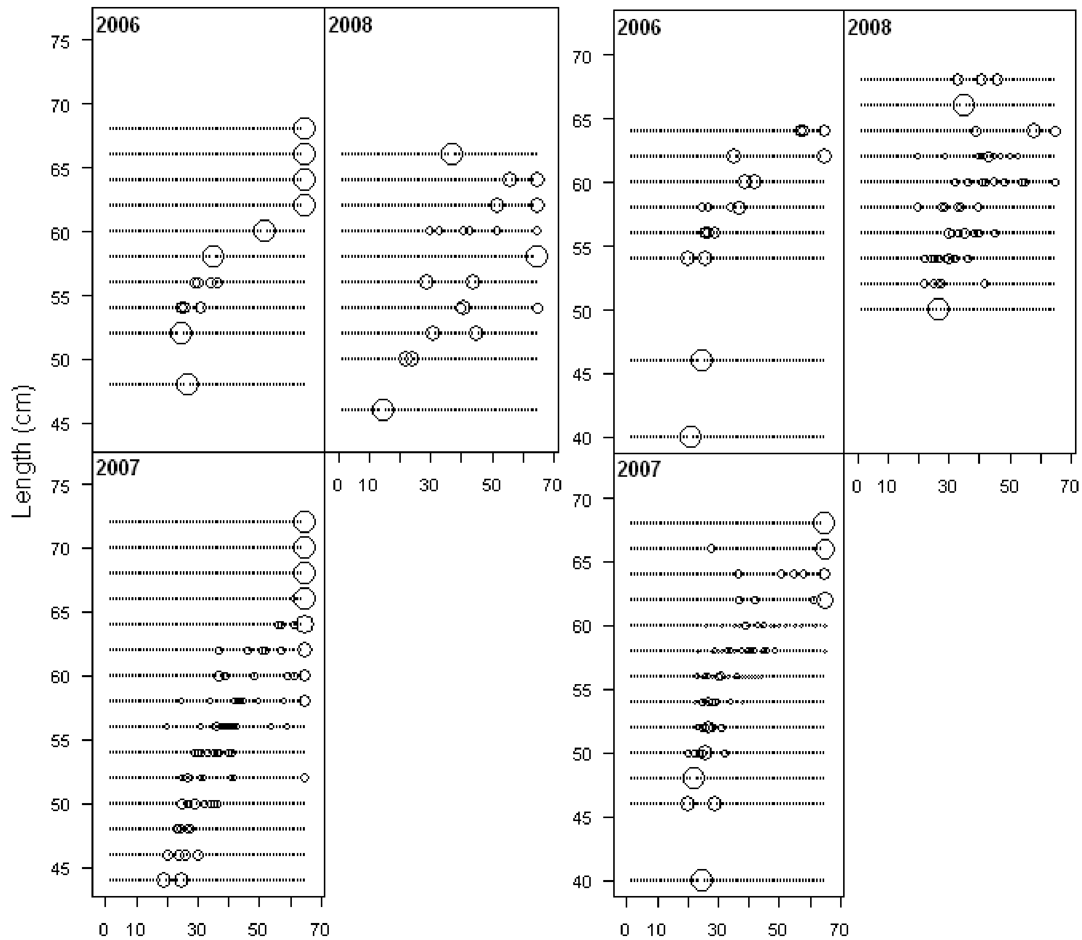

Figure 11. Conditional age-frequency distributions for female (left panels) and male (right panels) yelloweye rockfish from the recent IPHC surveys in Washington (2006-2008). Distributions sum to 1.0 in each age (row); the largest bubble sizes indicate proportions of 0.94 (one fish) for both females and males.

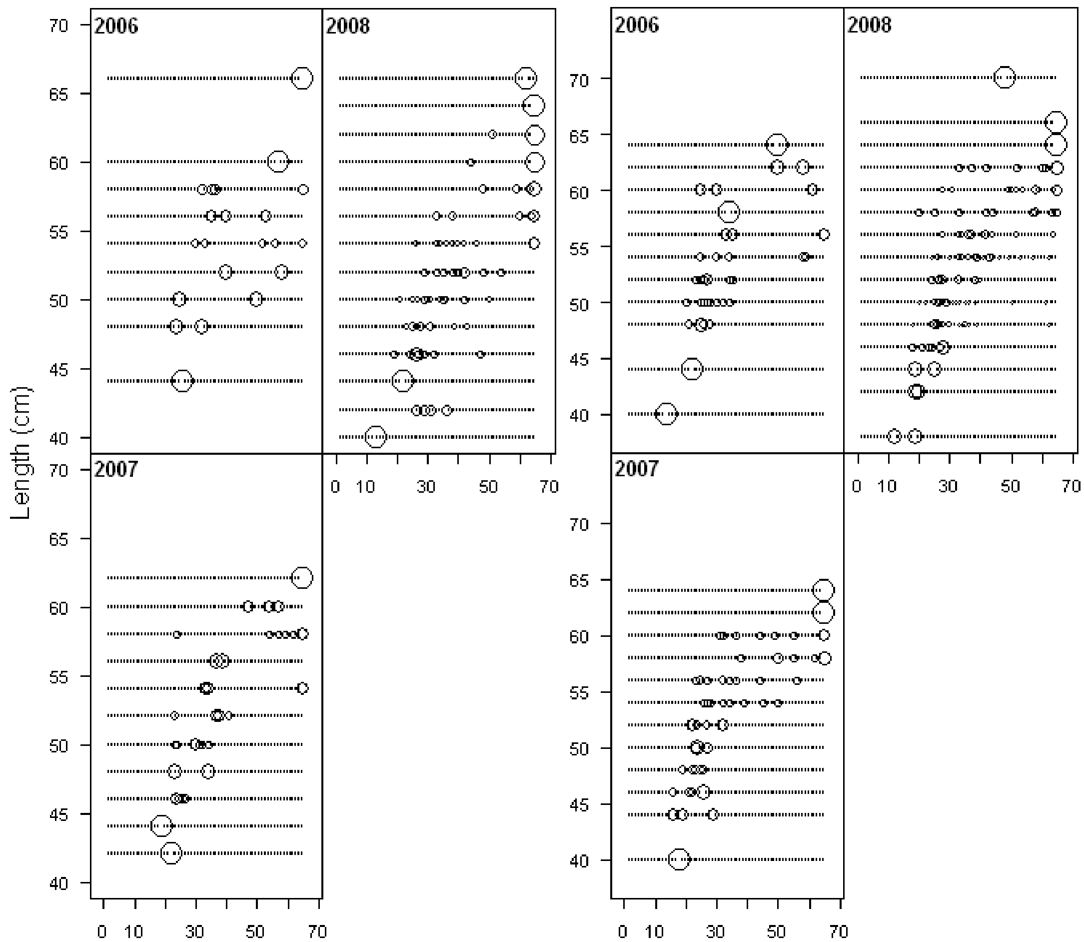

Figure 12. Conditional age-frequency distributions for female (left panels) and male (right panels) yelloweye rockfish from the recent IPHC surveys in Oregon (2006-2008). Distributions sum to 1.0 in each age (row); the largest bubble sizes indicate proportions of 0.94 (one fish) for both females and males.

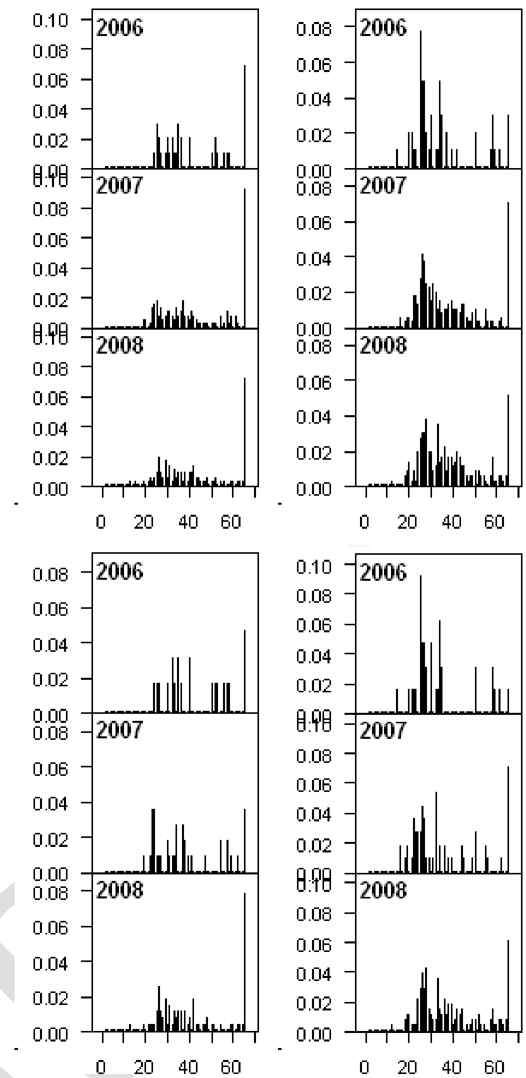

Figure 13. Marginal age-frequency distributions for female (left panels) and male (right panels) yelloweye rockfish from the recent IPHC surveys in Washington (upper panels) and Oregon (lower panels). These summaries are for inspection of the data only, they are not fit.

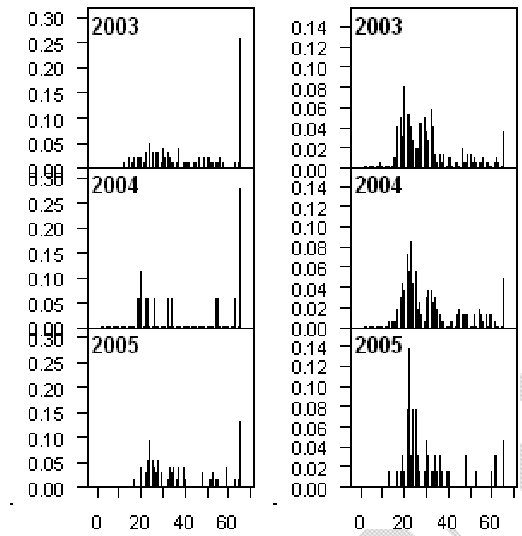

Figure 14. Marginal age-frequency distributions for Washington (left panels) and Oregon (right panels) yelloweye rockfish from the earlier IPHC surveys.

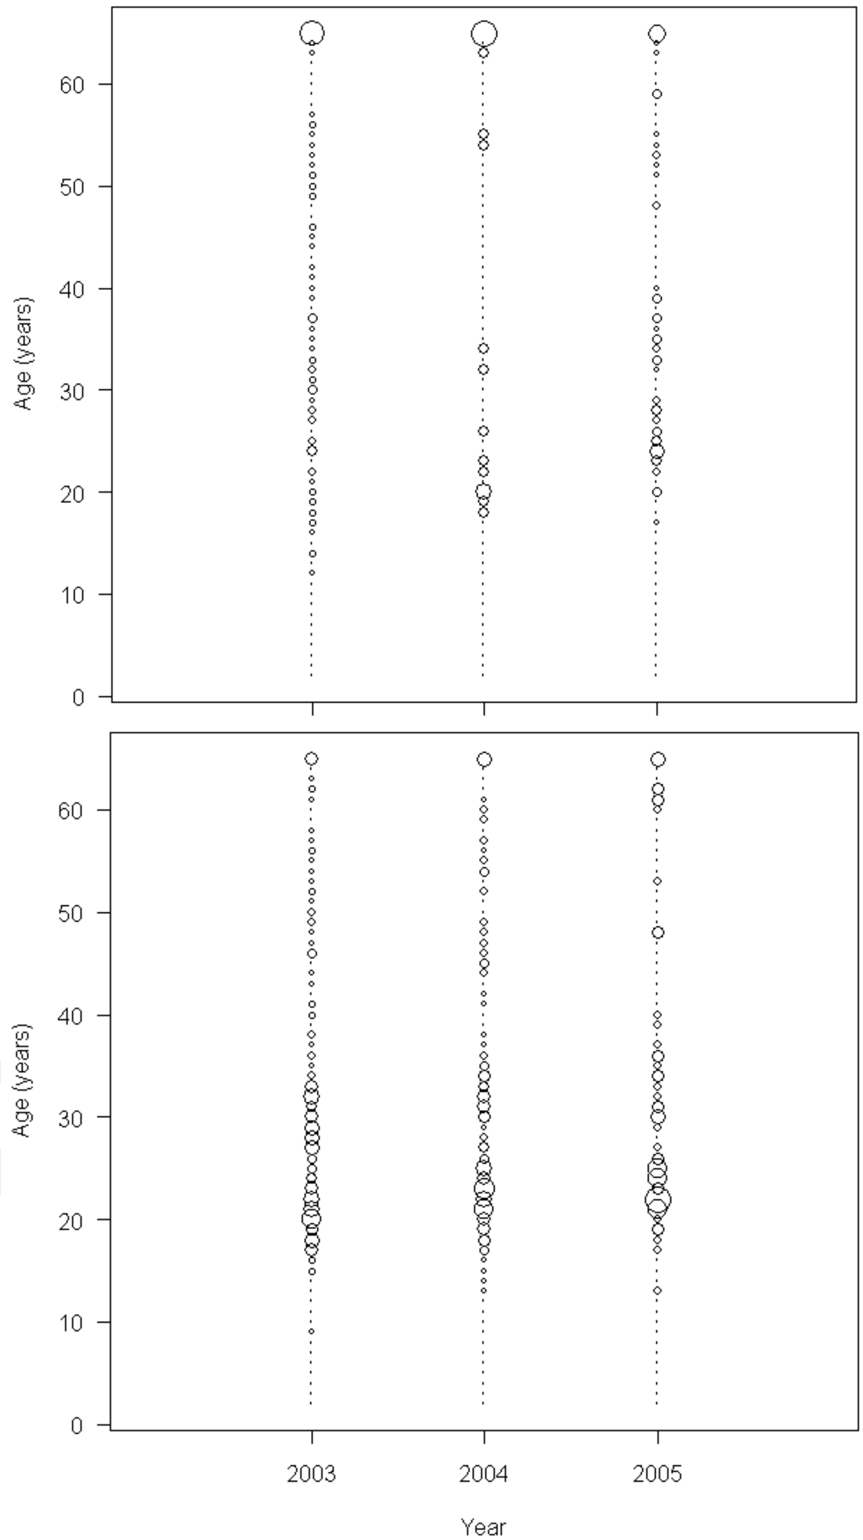

Figure 15. Marginal age-frequency distributions for Washington (upper panel) and Oregon (lower panel) yelloweye rockfish from the earlier IPHC surveys. Distributions sum to 1.0 in each year; the largest bubble sizes indicate proportions of 0.28 (Washington) and 0.14 (Oregon).

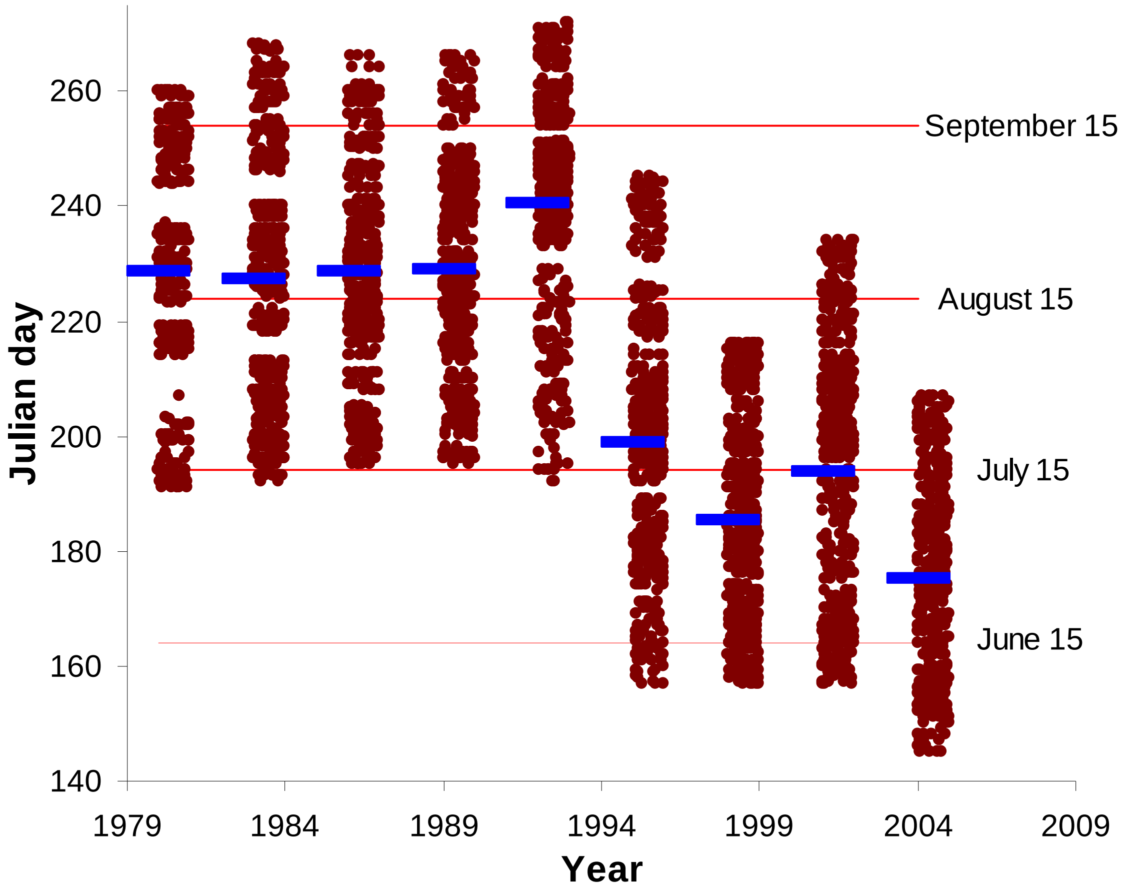

Figure 16. Distribution of dates of operation for the triennial survey (1980-2004). Solid bars show the mean date for each survey year, points represent individual hauls dates, but are jittered to allow better delineation of the distribution of individual points.

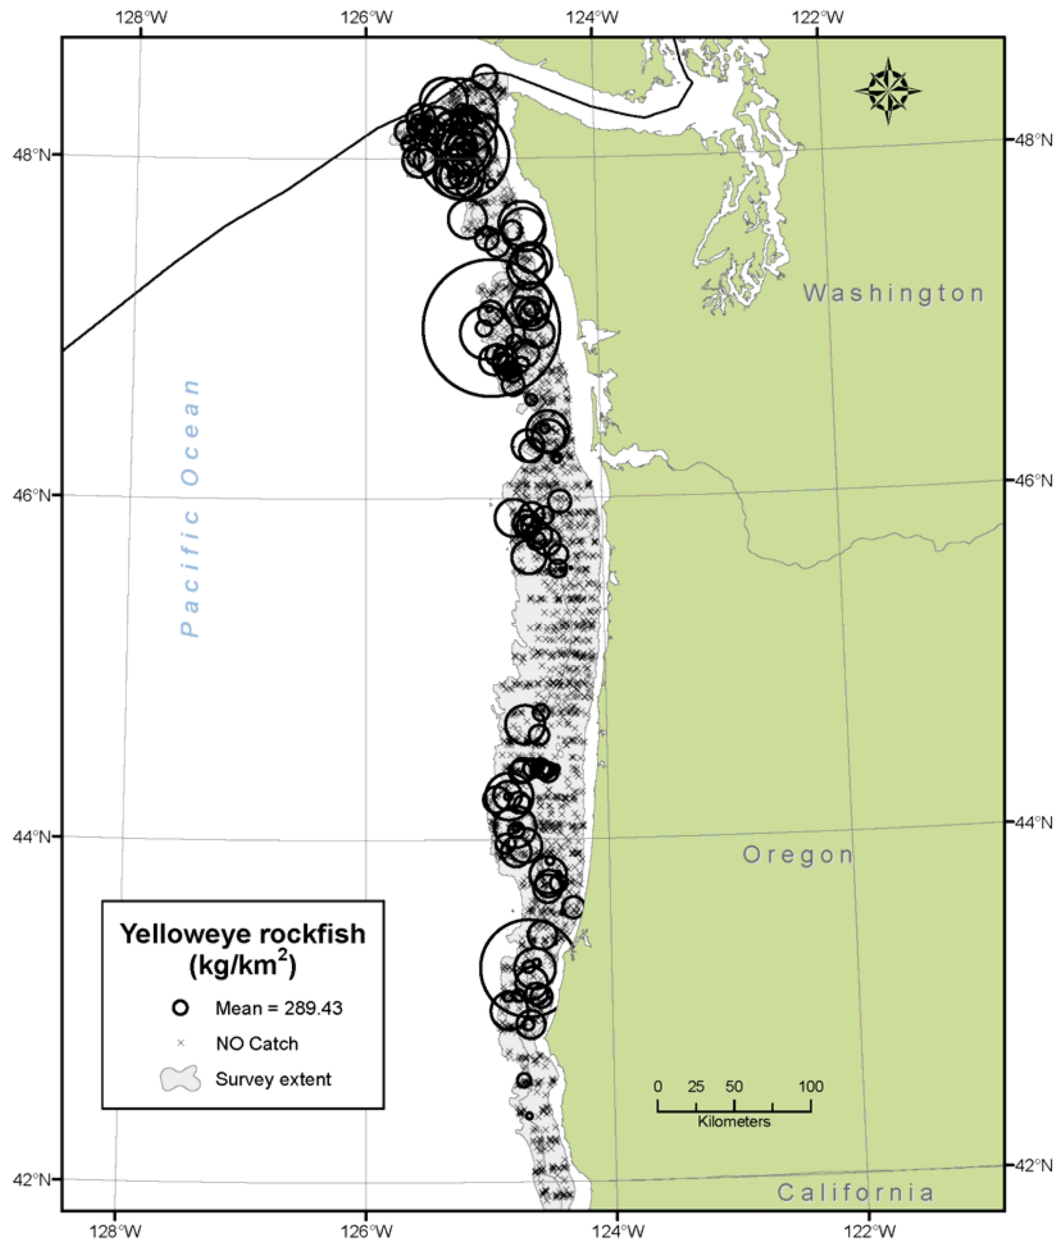

Figure 17. Distribution of yelloweye rockfish (*Sebastes ruberrimus*) catches for the Triennial trawl survey (1977-2004) in Washington and Oregon. Bubble area is proportional to CPUE (kg/km^2). Survey extent is 55-549 m (30-300 fm).

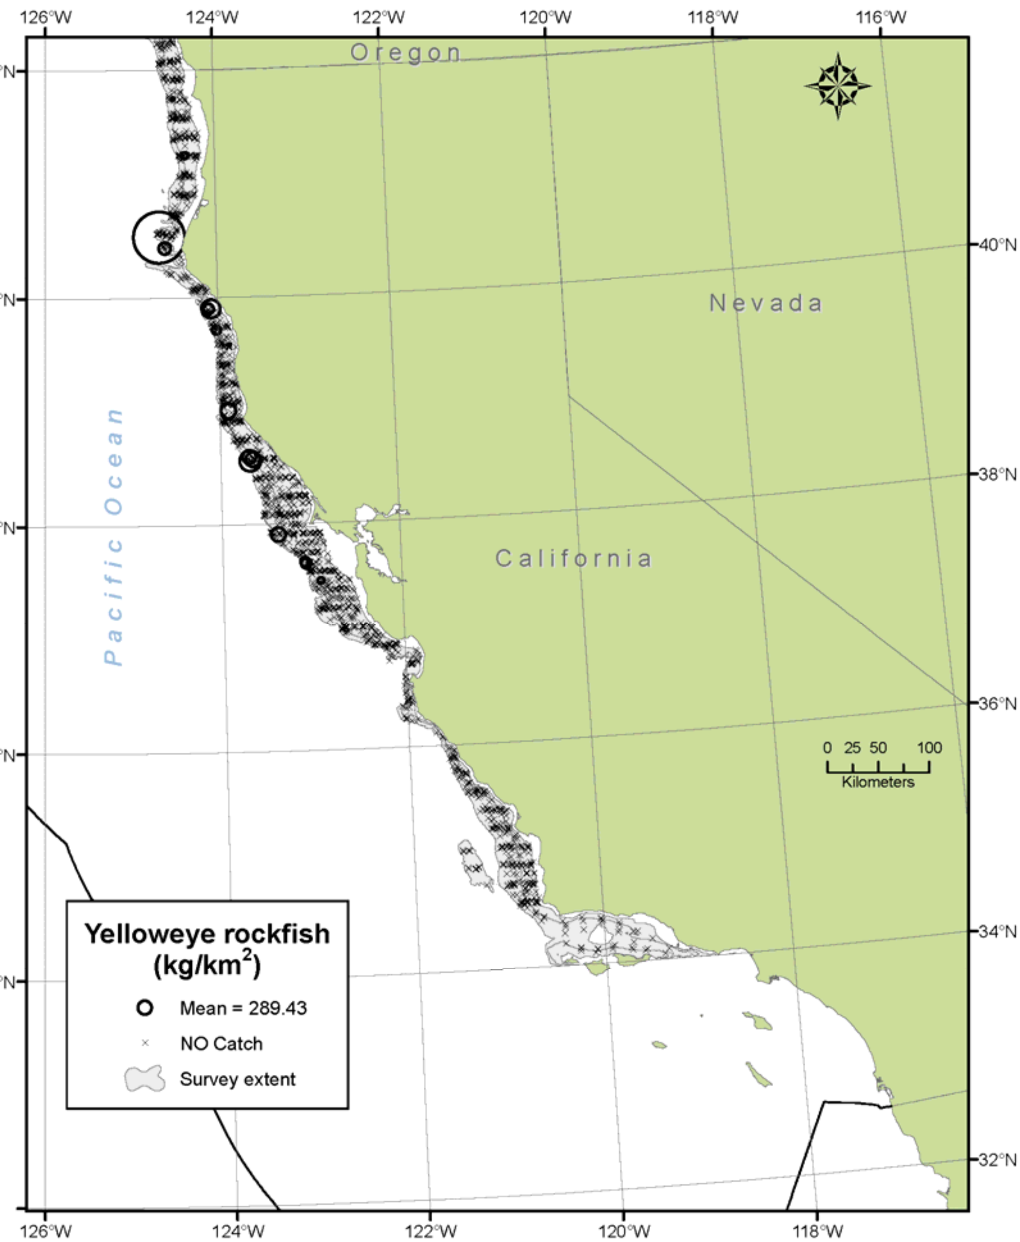

Figure 18. Distribution of yelloweye rockfish (*Sebastes ruberrimus*) catches for the Triennial trawl survey (1977-2004) in California. Bubble area is proportional to CPUE (kg/km^2). Survey extent is 55-549 m (30-300 fm).

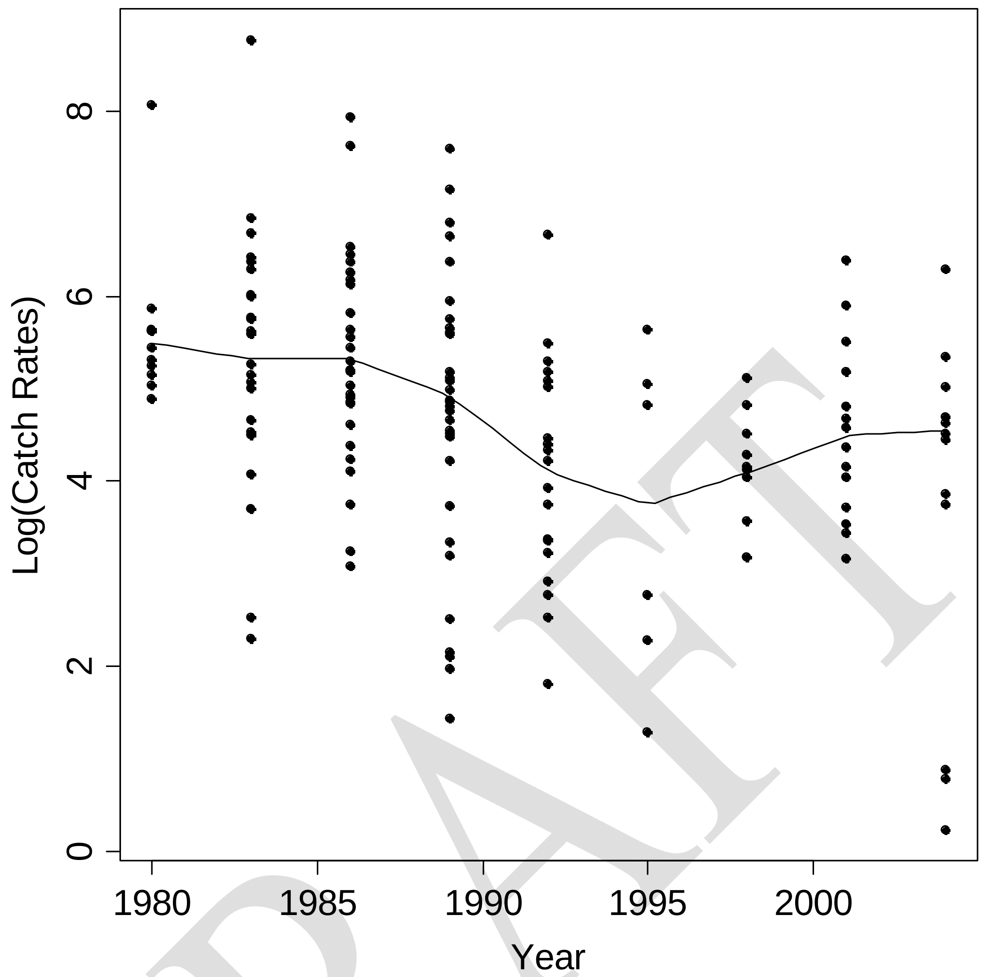

Figure 19. The log of the non-zero catch rates (in kg per km^2) by year for all positive hauls in the triennial survey, 1980-2004. The black line is a lowess smoother to aid evaluation only.

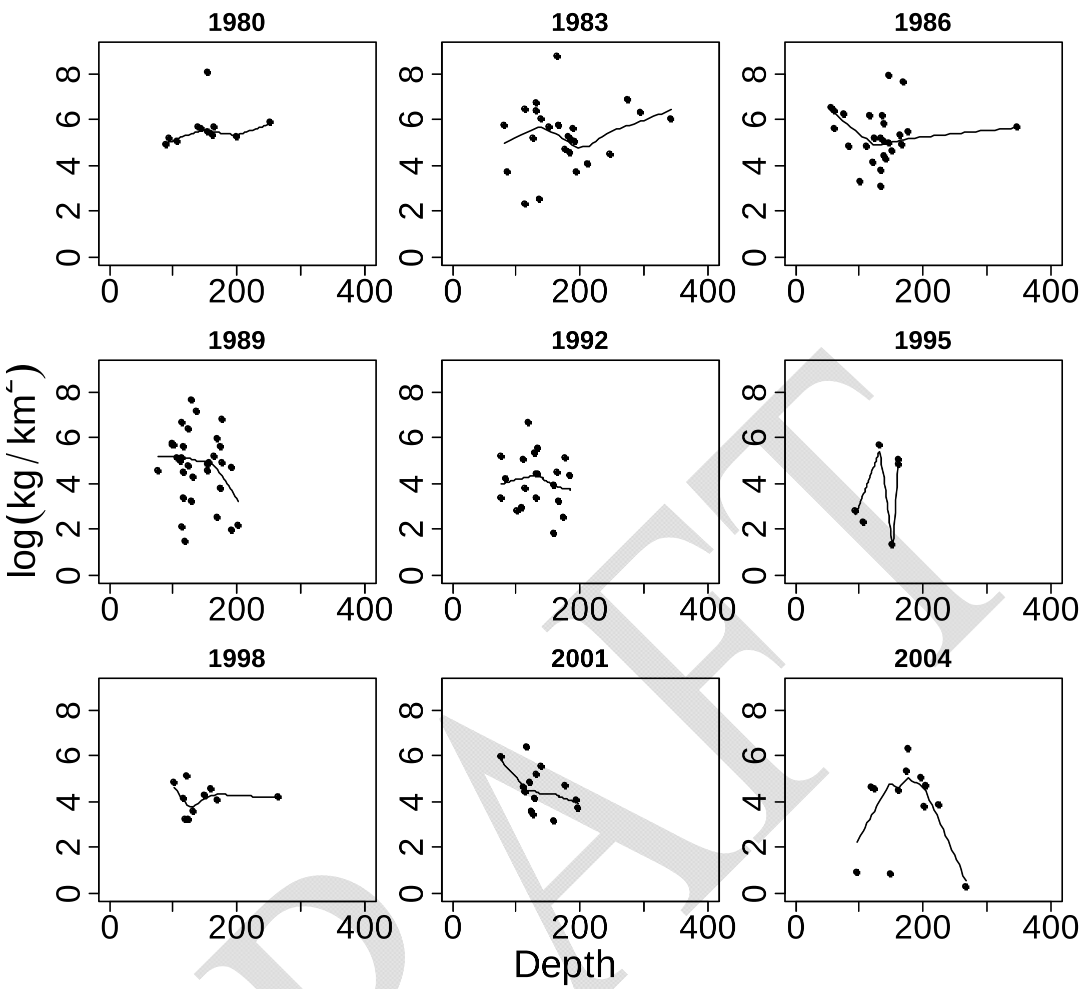

Figure 20. Non-zero catch rates, in log(kg/km^2), by depth and year for the triennial survey. The black line is a lowess smoother to aid evaluation only.

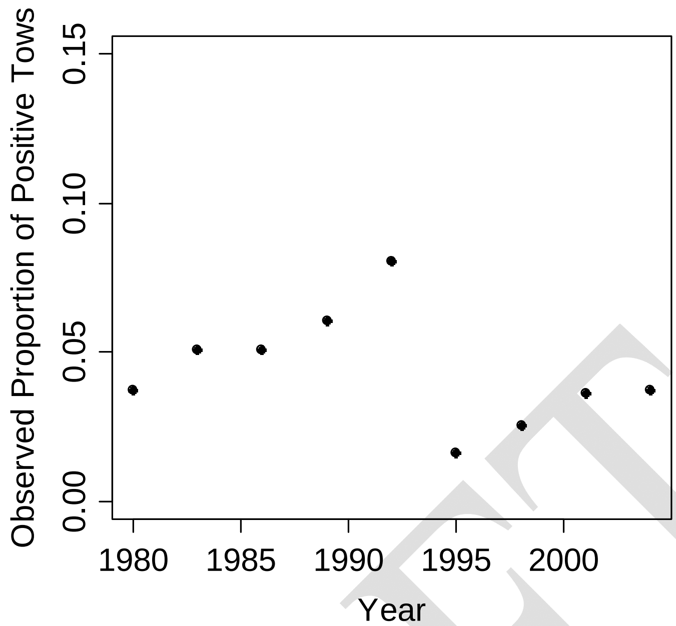

Figure 21. Observed proportion of non-zero tows by year in the triennial survey.

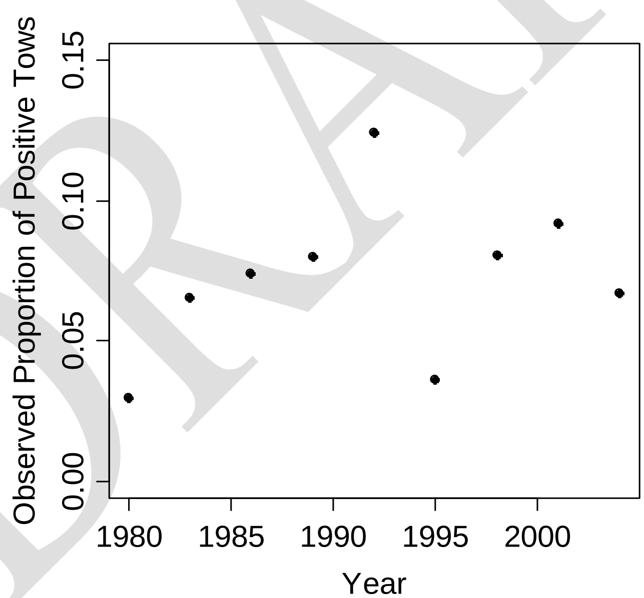

Figure 22. Observed proportion of non-zero tows by year in the triennial survey in Washington waters.

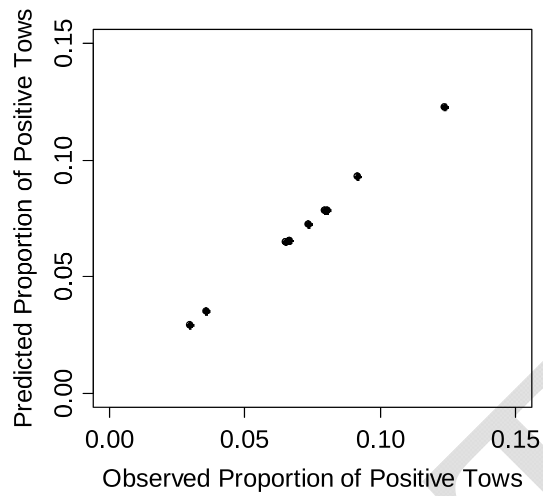

Figure 23. Observed vs. predicted proportion of positive tows for the triennial survey in Washington.

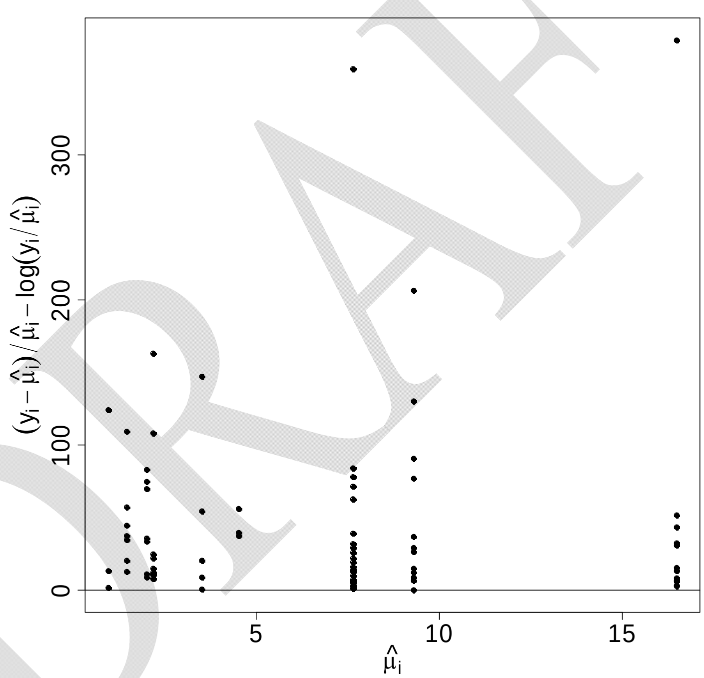

Figure 24. Deviance components (should be Gamma-distributed) vs. predicted values for all positive catch observations in the triennial GLMM for Washington. Note that variation from the random vessel-effects is not included.

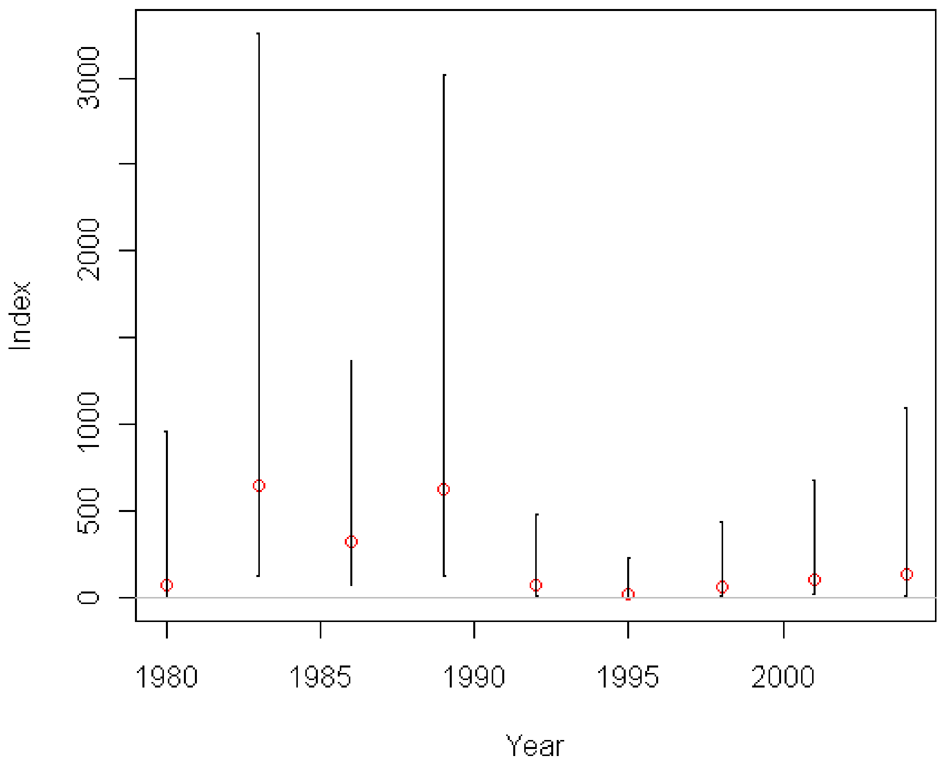

Figure 25. Index of relative abundance for the triennial survey in Washington.

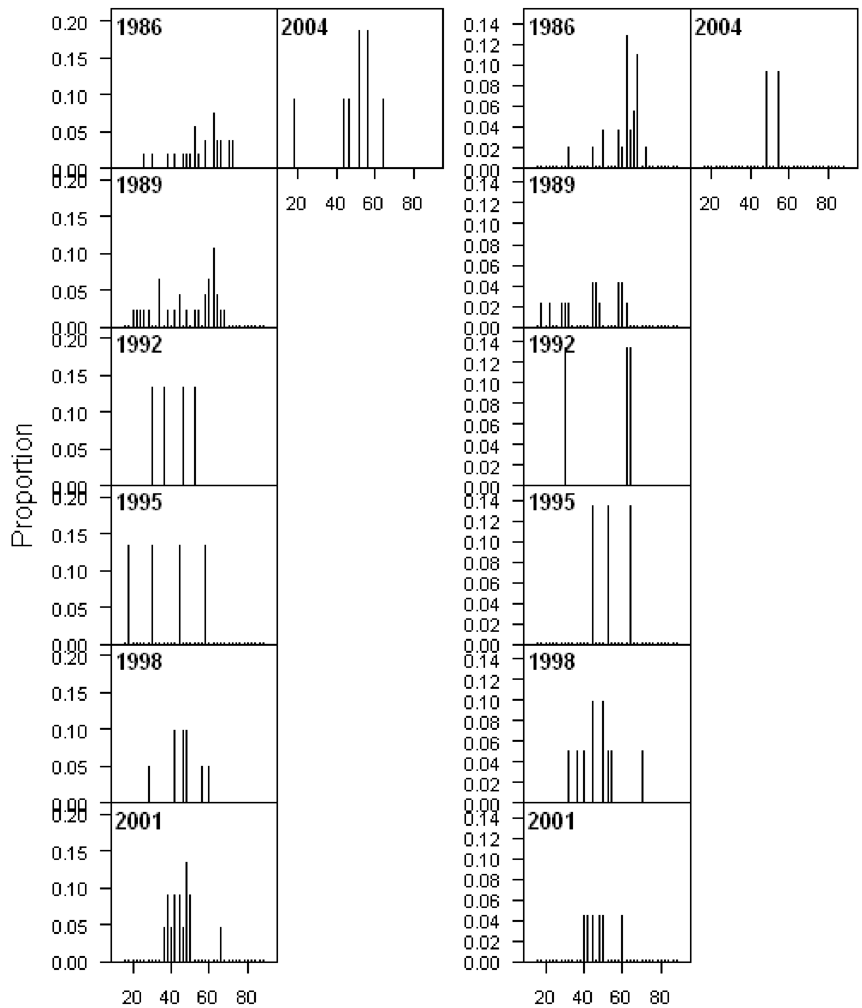

Figure 26. Length-frequency distributions for female (left panel) and male (right panel) yelloweye rockfish from the triennial bottom trawl survey in Washington. The x-axis represents the 2-cm size bin.

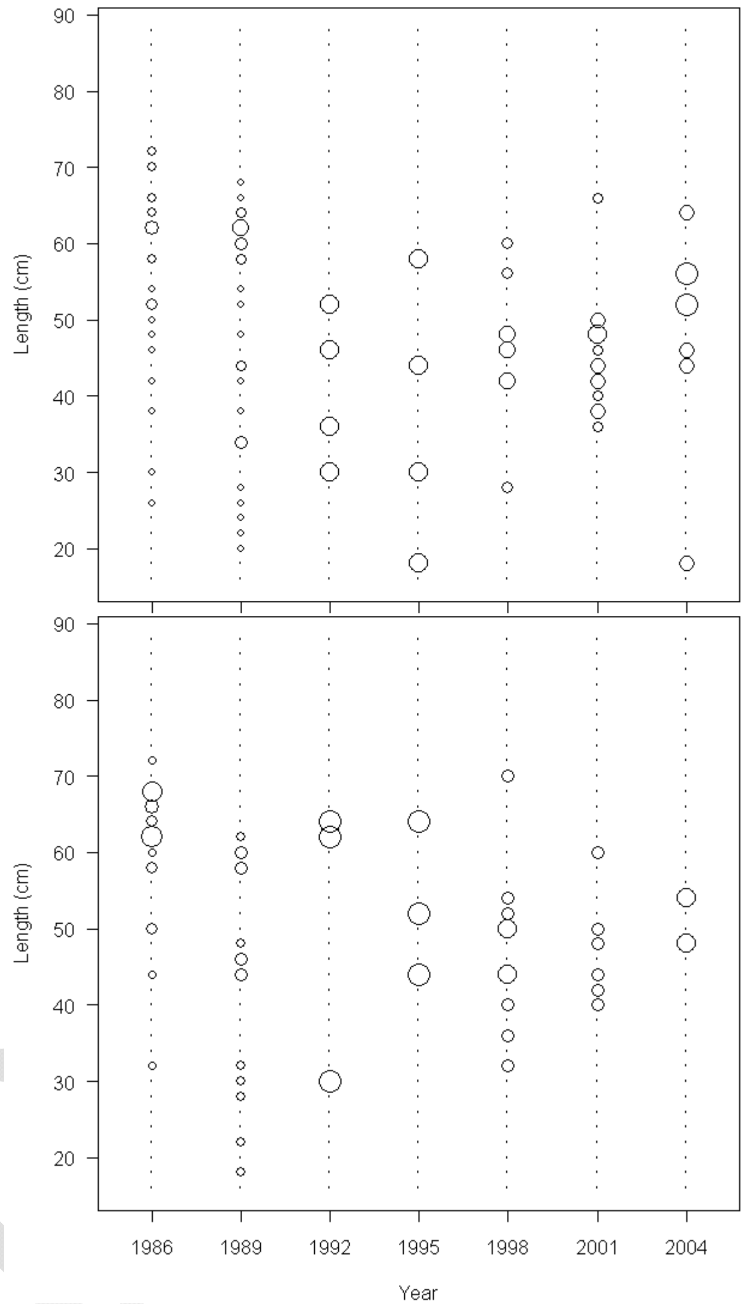

Figure 27. Length-frequency distributions for female (upper panel) and male (lower panel) yelloweye rockfish from the triennial bottom trawl survey in Washington. Distributions sum to 1.0 in each year; the largest bubble sizes indicate proportions of 0.19 (females) and 0.13 (males).

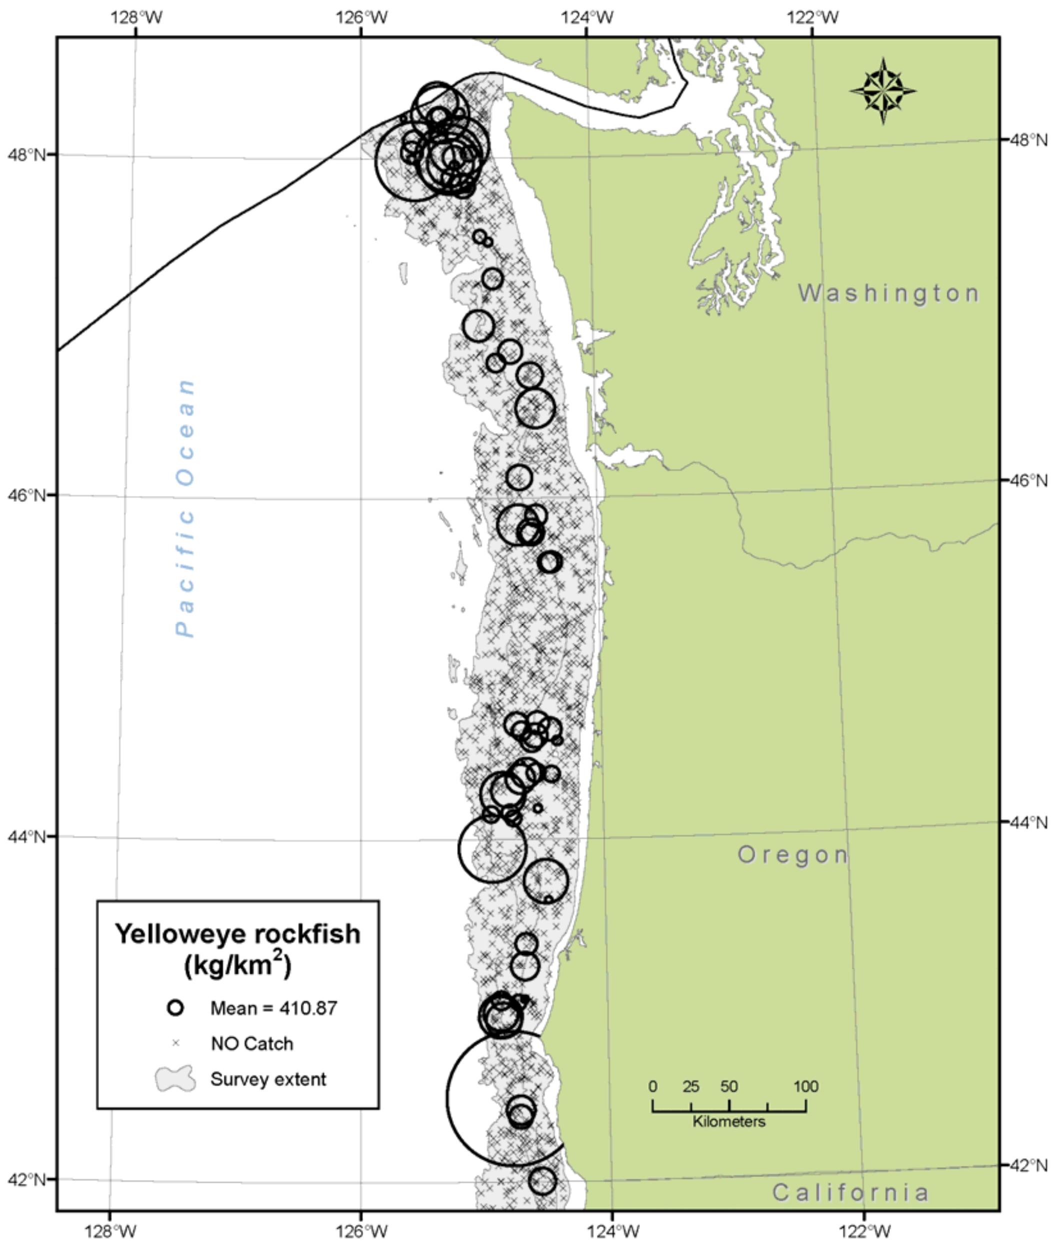

Figure 28. Distribution of yelloweye rockfish (*Sebastes ruberrimus*) catches for the NWFSC trawl survey (2003-2008) in Washington and Oregon. Bubble area is proportional to CPUE (kg/km^2). Survey extent is 55-1280 m (30-700 fm).

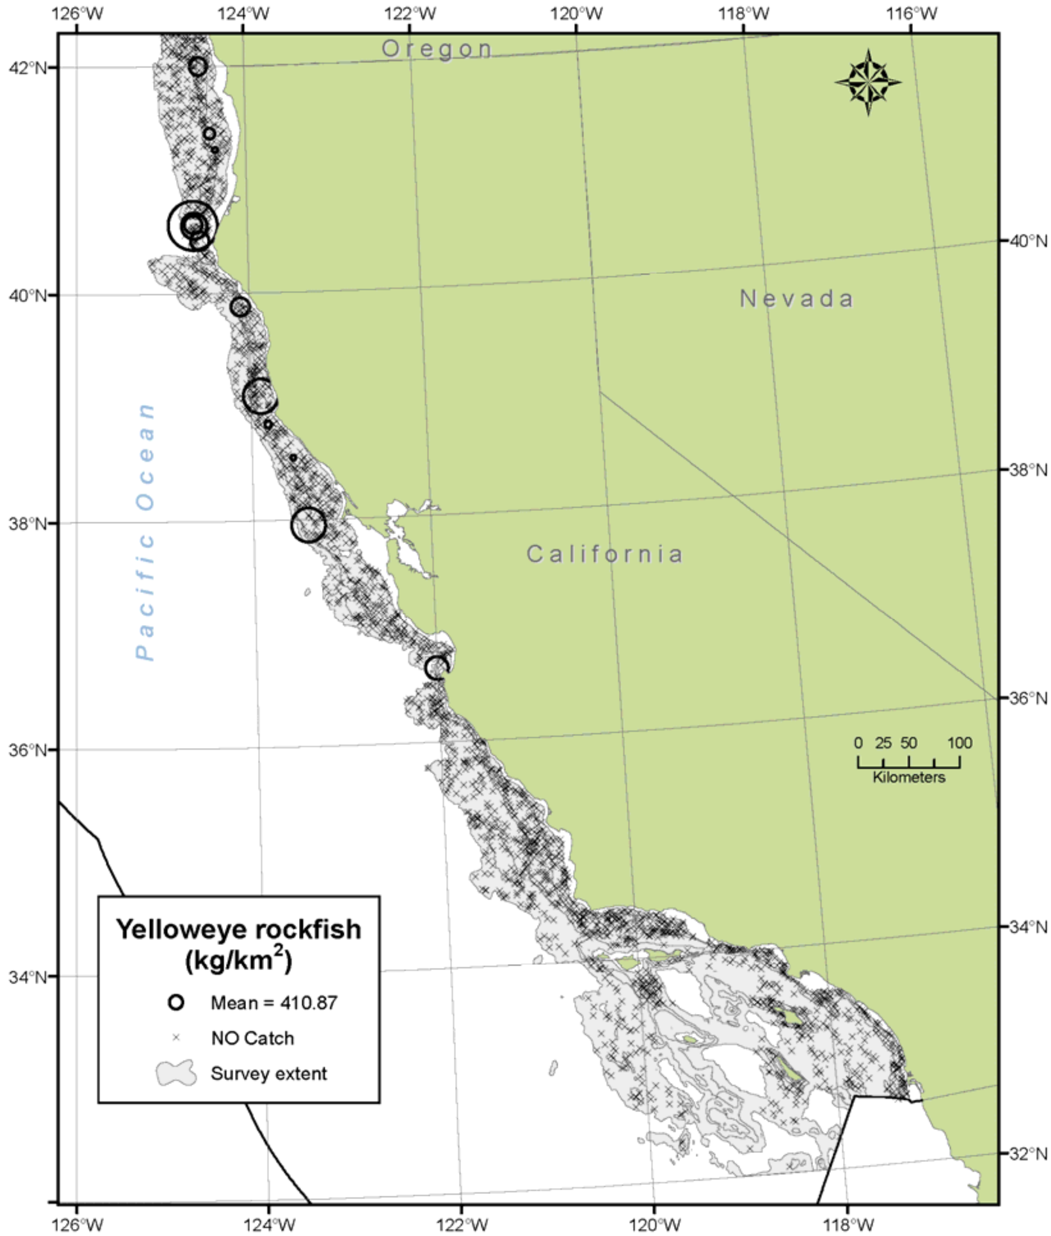

Figure 29. Distribution of yelloweye rockfish (*Sebastes ruberrimus*) catches for the NWFSC trawl survey (2003-2008) in California. Bubble area is proportional to CPUE (kg/km^2). Survey extent is 55-1280 m (30-700 fm).

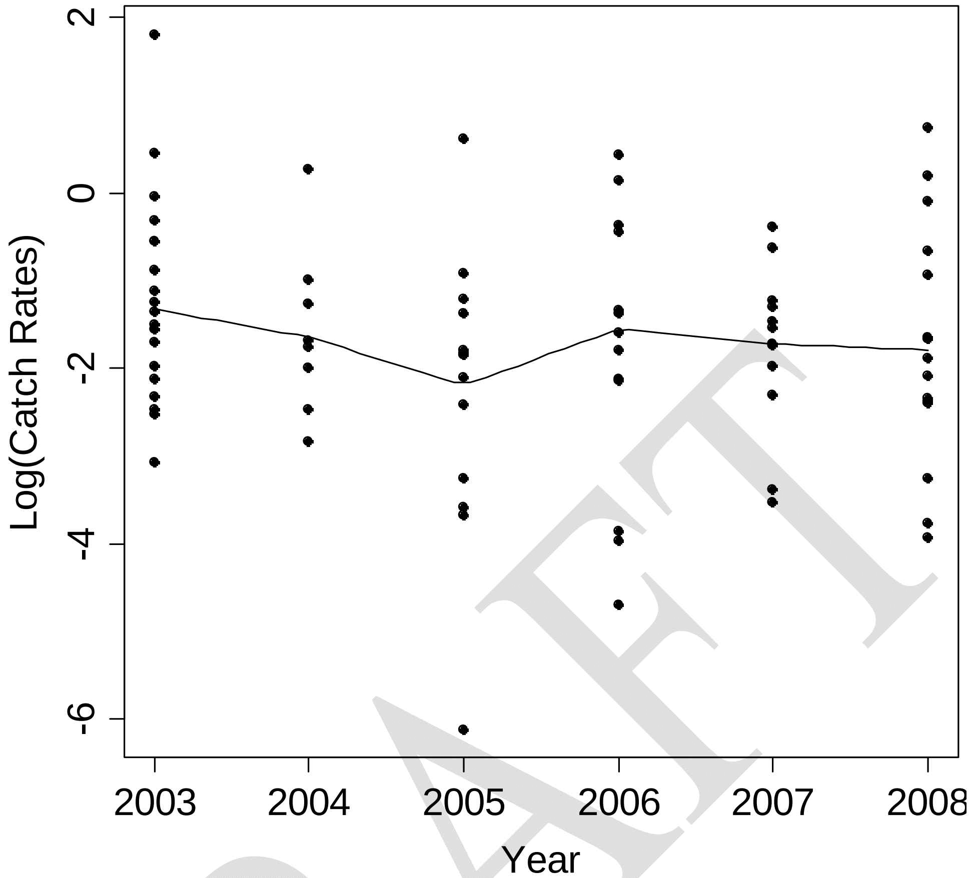

Figure 30. The log of the non-zero catch rates (in kg per km^2) by year for all positive hauls in the NWFSC survey 2003-2008. The black line is a lowess smoother to aid evaluation only.

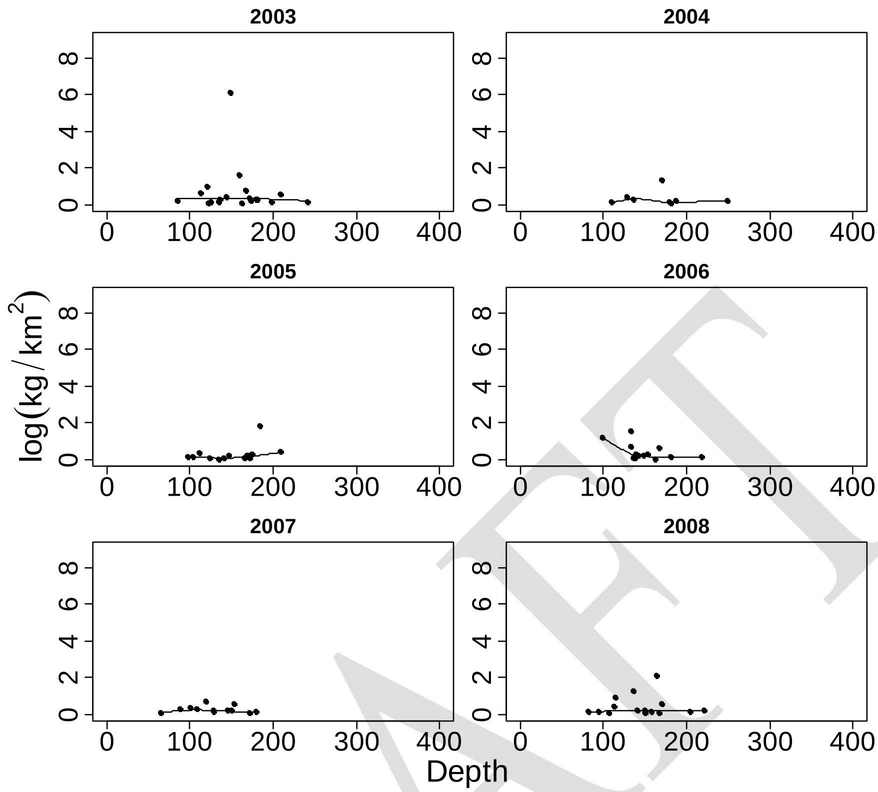

Figure 31. Coast-wide non-zero catch rates over depth for each year in log(kg/km^2); the black line is a lowess smoothing line (NWFSC survey).

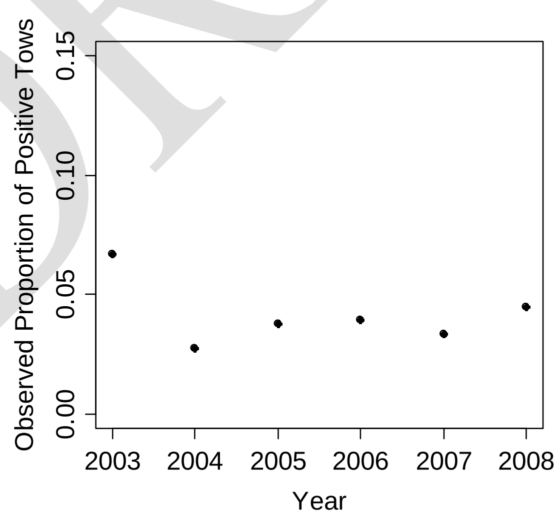

Figure 32. Observed proportion of non-zero tows by year in the NWFSC survey.

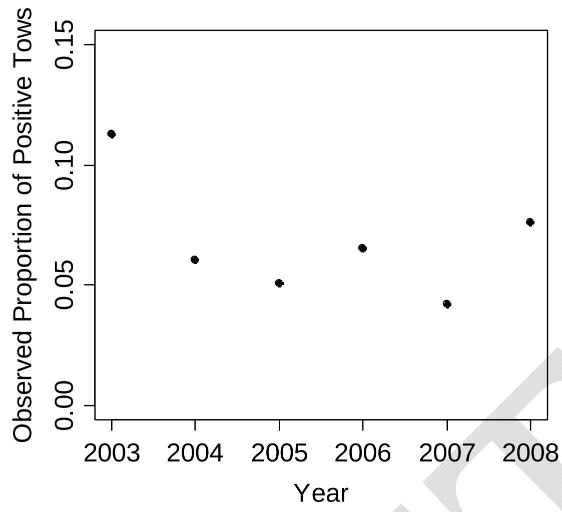

Figure 33. Proportion of non-zero tows in the NWFSC survey in Oregon.

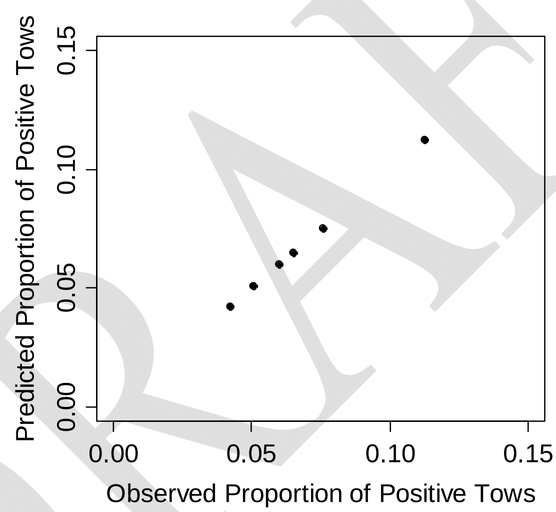

Figure 34. Observed vs. predicted proportion of positive tows for the NWFSC survey in Oregon.

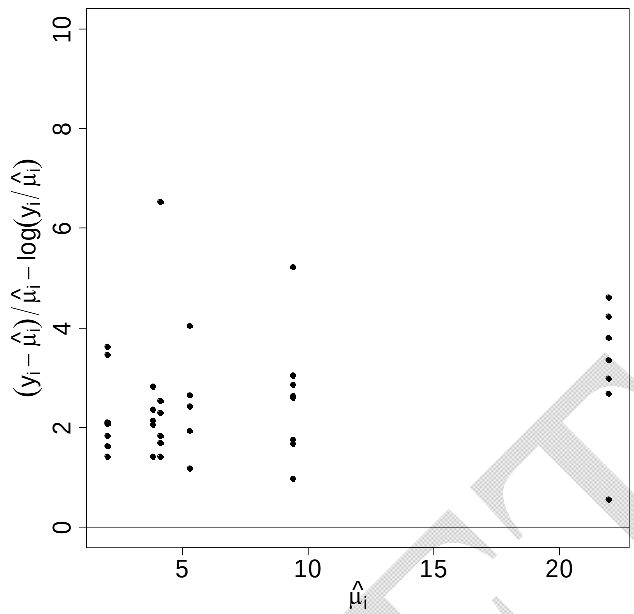

Figure 35. Deviance components (should be Gamma-distributed) vs. predicted values for all positive catch observations in the NWFSC GLMM for Oregon. Note that variation from the random vessel-effects is not included.

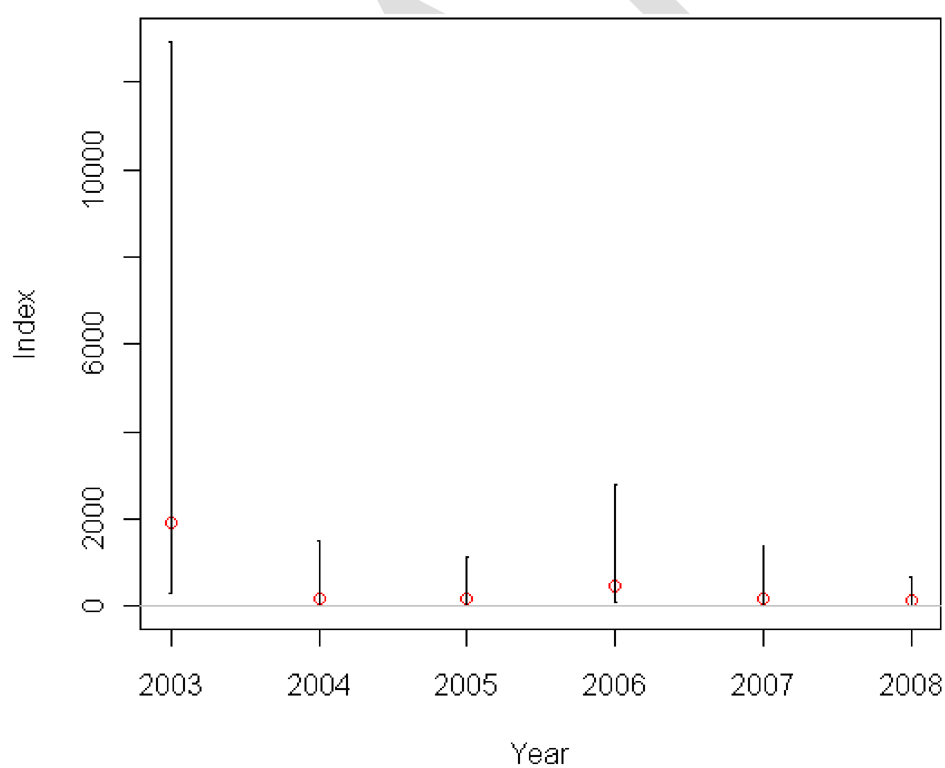

Figure 36. Index of relative abundance for the NWFSC survey in Oregon.

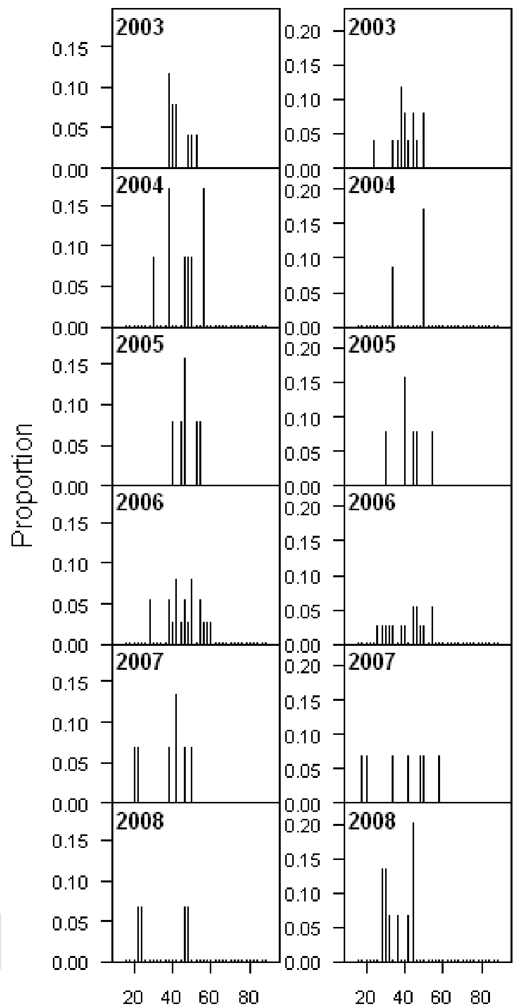

Figure 37. Length-frequency distributions for female (left panel) and male (right panel) yelloweye rockfish from the NWFSC bottom trawl survey in Oregon. The x-axis represents the 2-cm size bin.

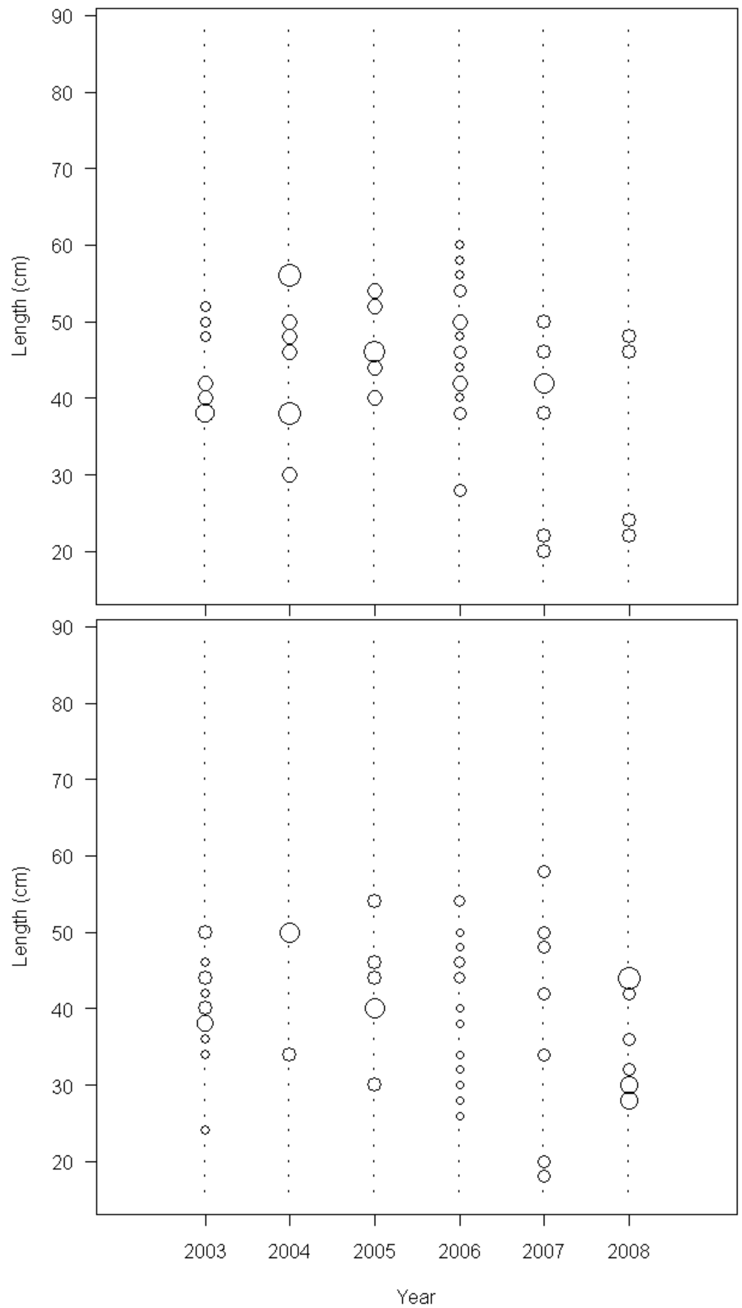

Figure 38. Length-frequency distributions for female (upper panel) and male (lower panel) yelloweye rockfish from the NWFSC bottom trawl survey in Washington. Distributions sum to 1.0 in each year; the largest bubble sizes indicate proportions of 0.17 (females) and 0.12 (males).

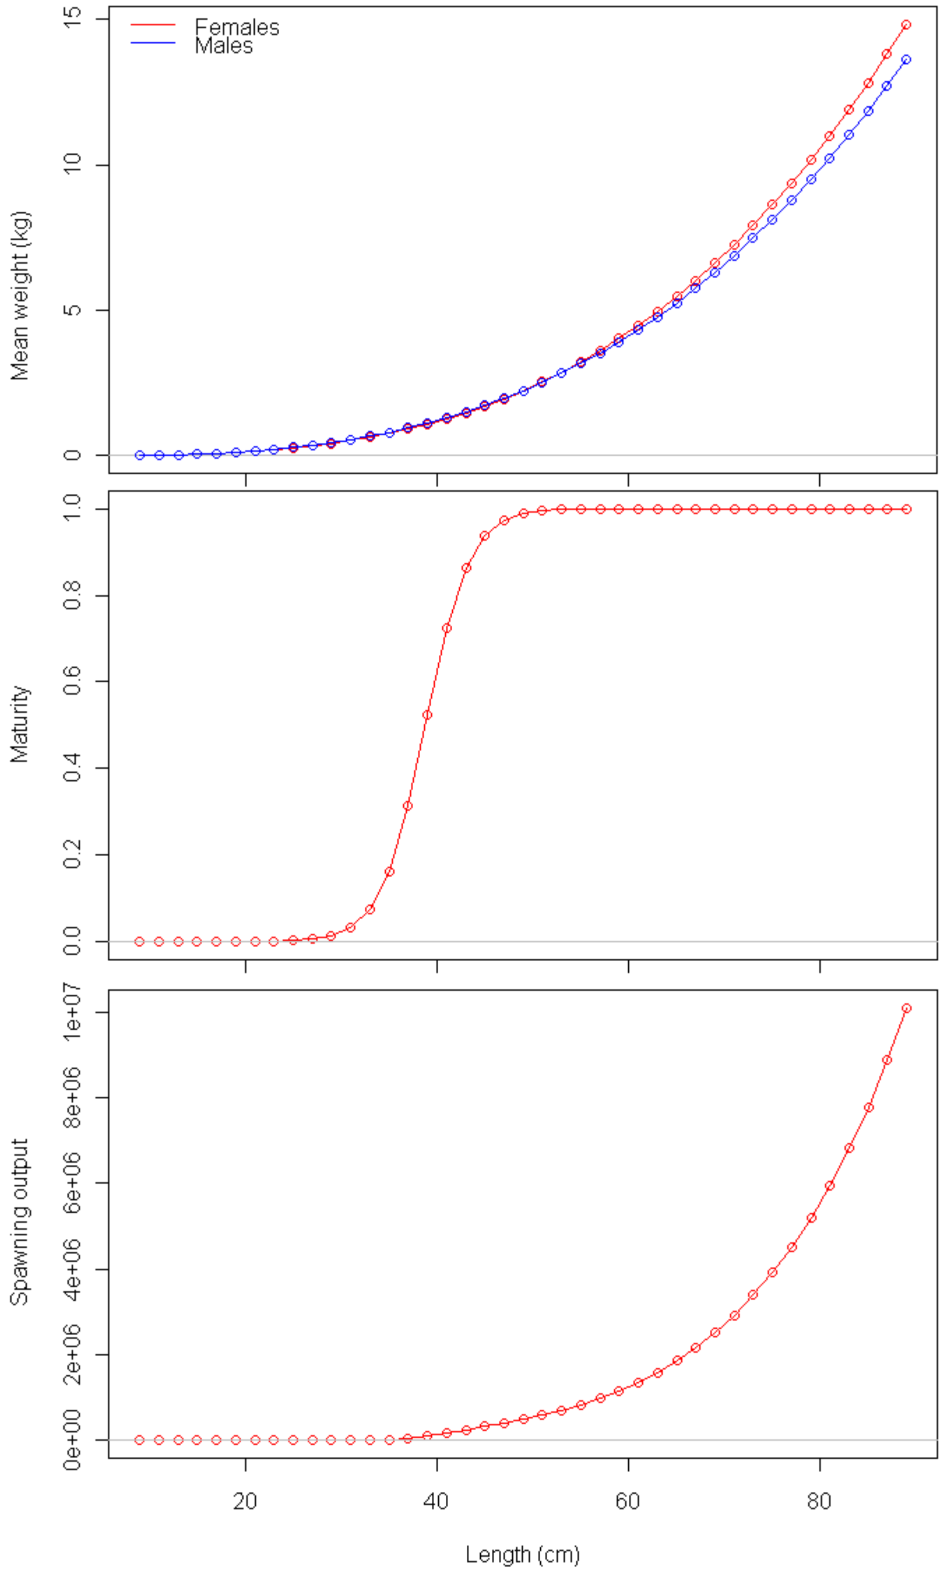

Figure 39. W-L relationship for male and female yelloweye (upper panel), female maturity curve (middle panel), and female spawning output at length (lower panel) illustrating the product of the female W-L, fecundity and maturity relationships.

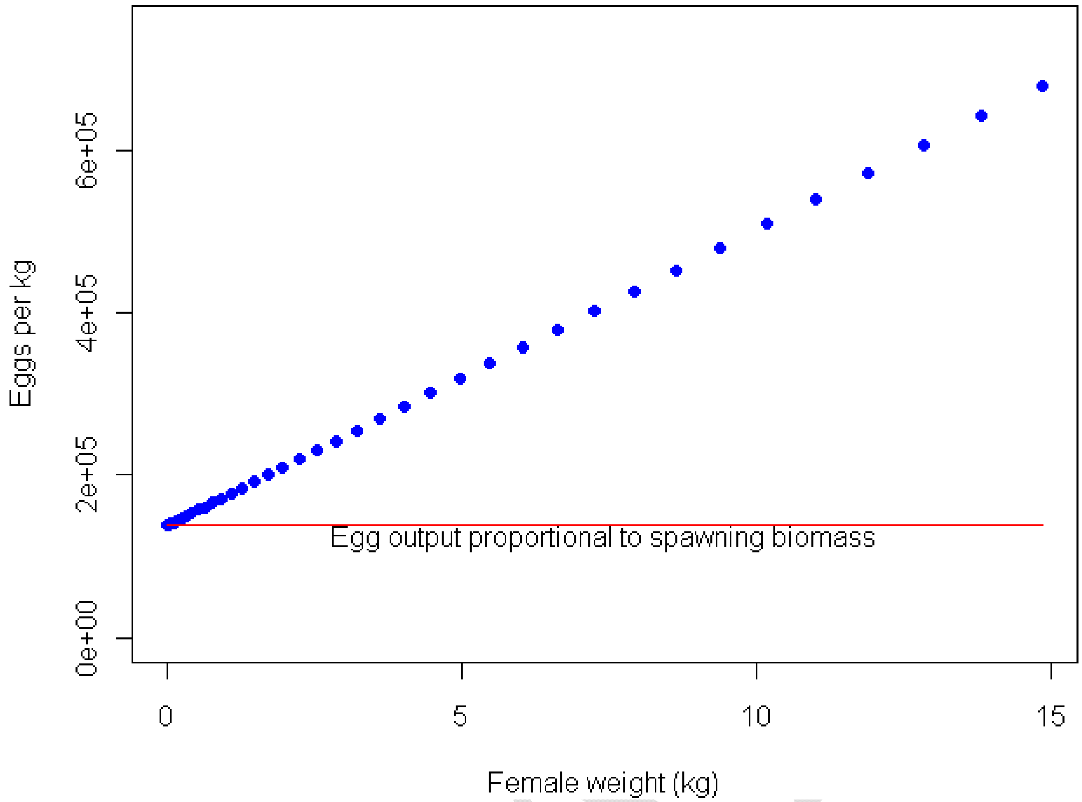

Figure 40. Female yelloweye fecundity relationship (Filled circles, From Dick, 2009). Horizontal line indicates no fecundity relationship (for comparison).

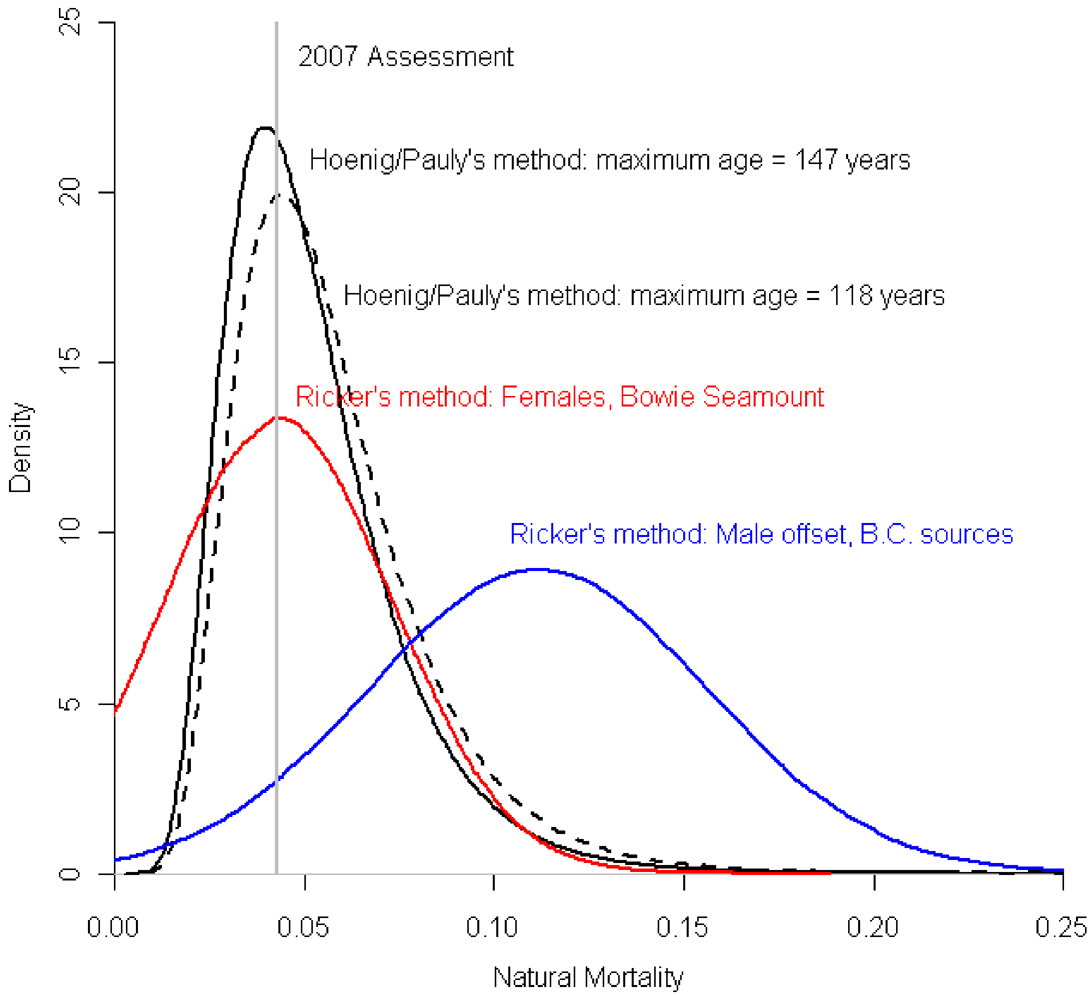

Figure 41. Priors for natural mortality from various sources.

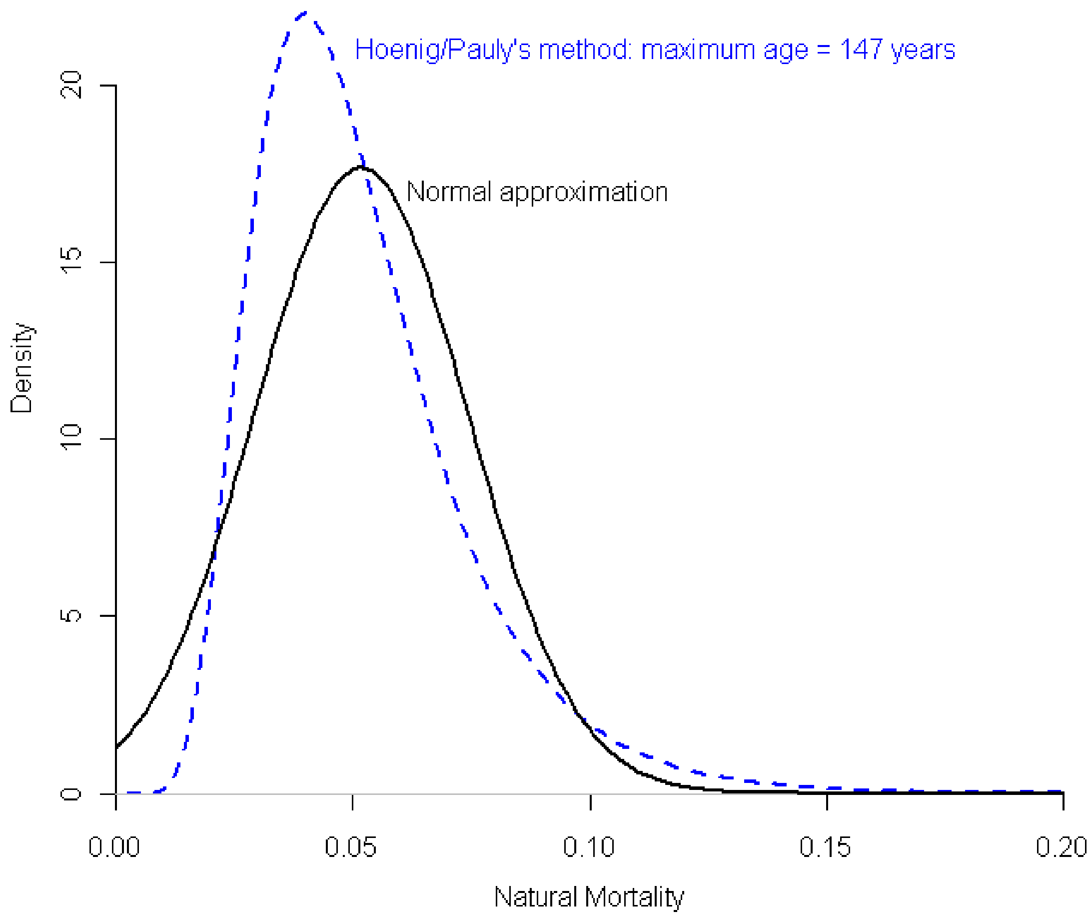

Figure 42. Prior for natural mortality (normal approximation) used in the base case model, with original log-normal distribution for comparison.

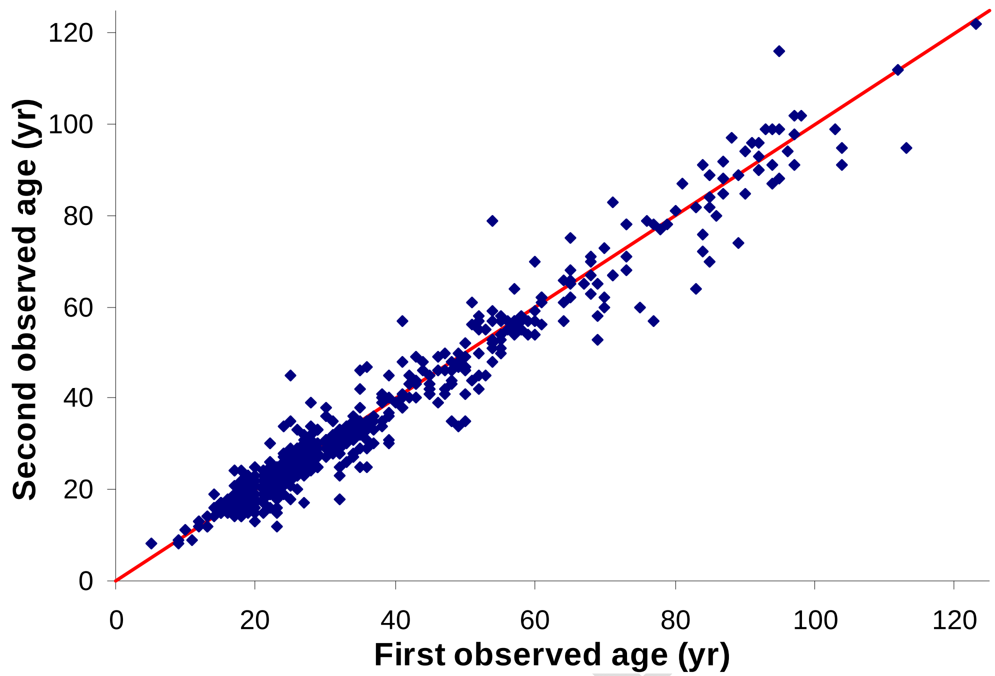

Figure 43. Comparison of first and second age reads (by WDFW age readers) for 556 yelloweye rockfish. Diagonal line indicates the 1:1 relationship.

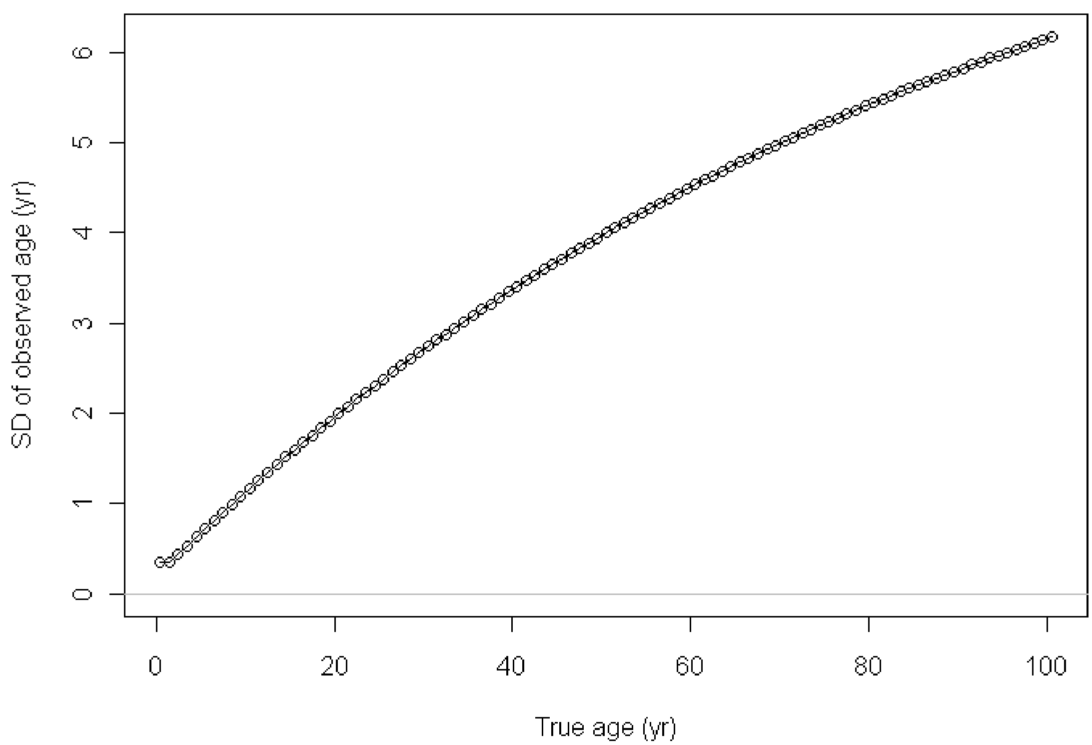

Figure 44. Externally estimated relationship between variability of observed age and true age in years.

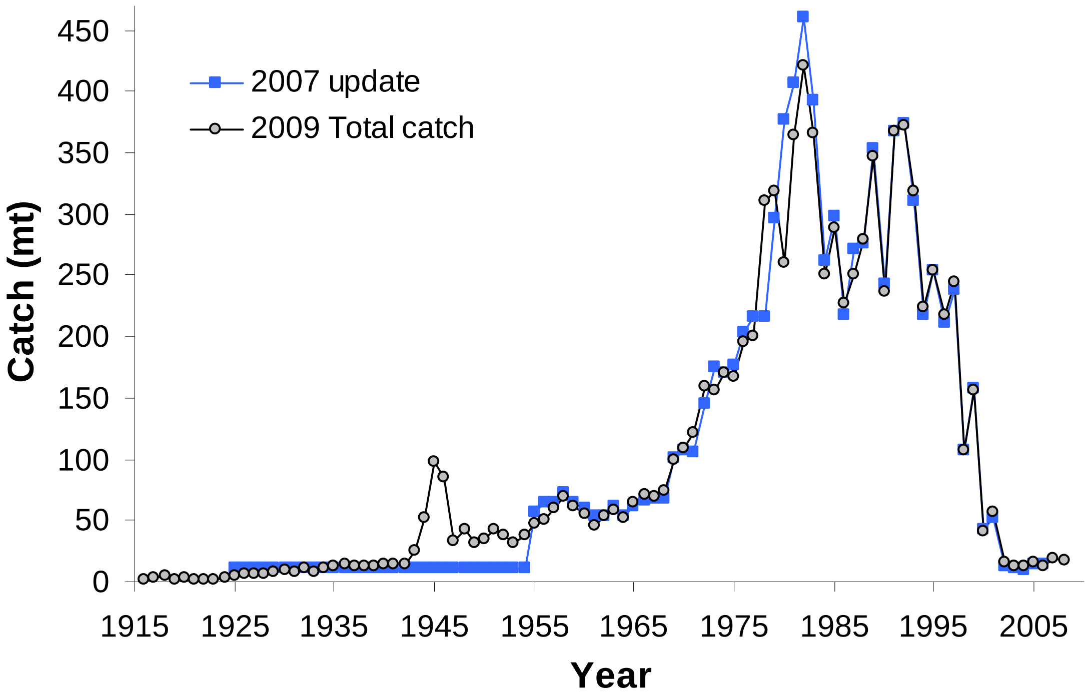

Figure 45. Comparison of the 2007 and recently revised yelloweye rockfish catch history, 1916-2008.

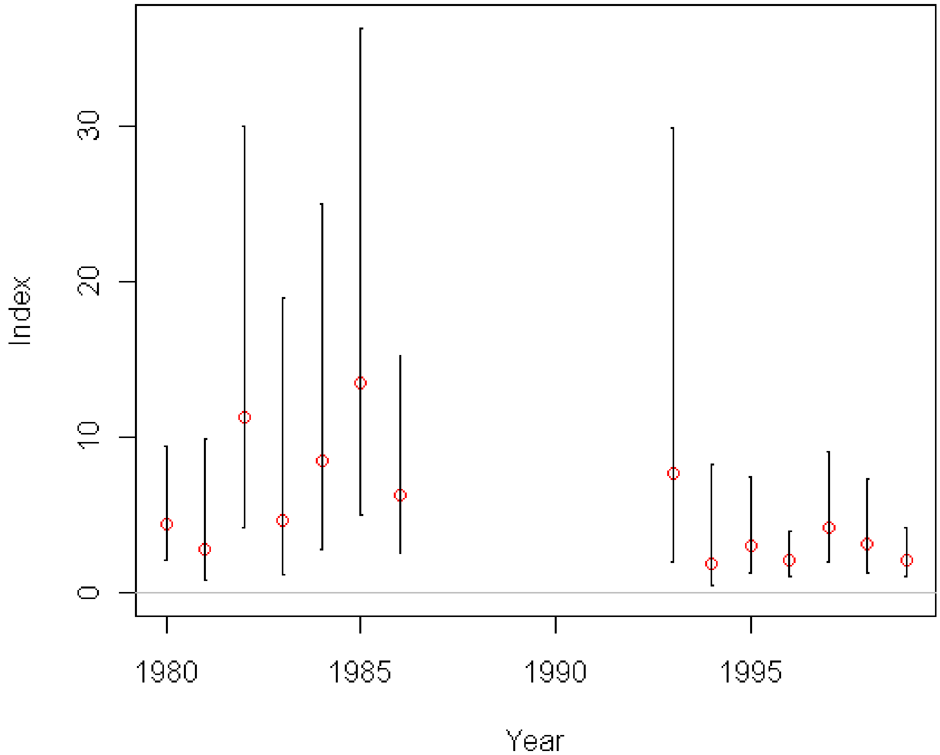

Figure 46. Index of relative abundance for the California recreational CPUE series.

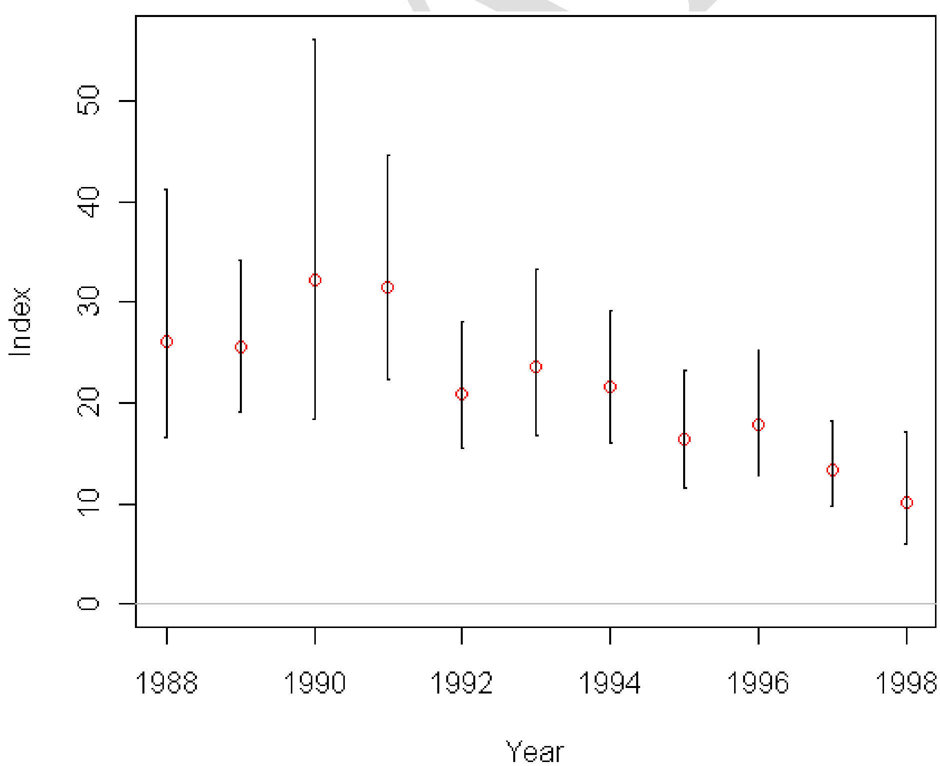

Figure 47. Index of relative abundance for the California recreational observer CPUE series.

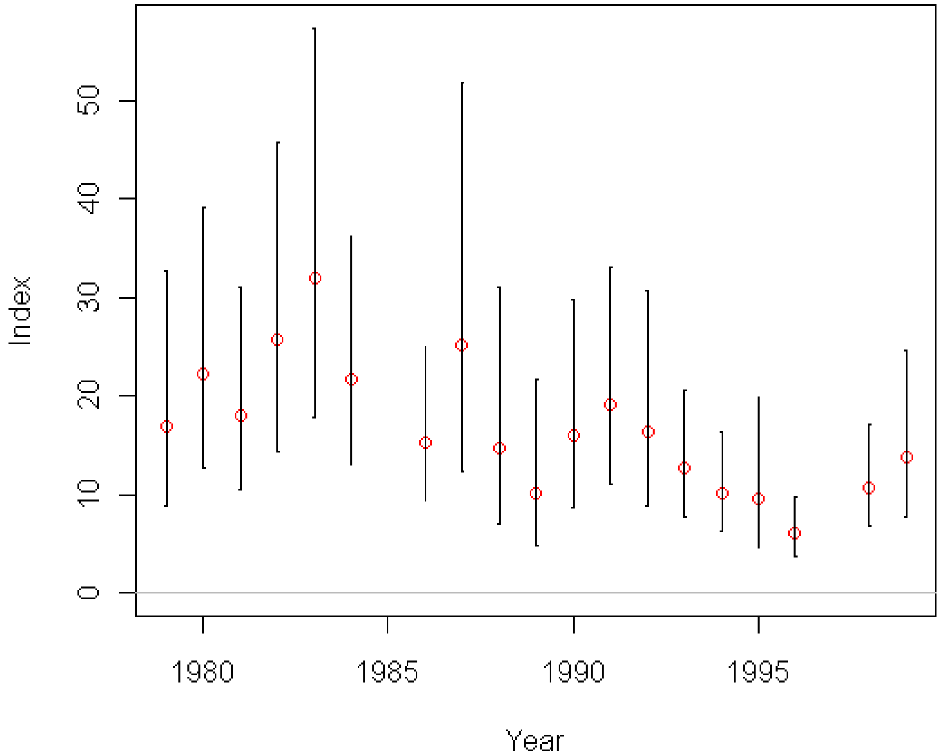

Figure 48. Index of relative abundance for the Oregon recreational CPUE series.

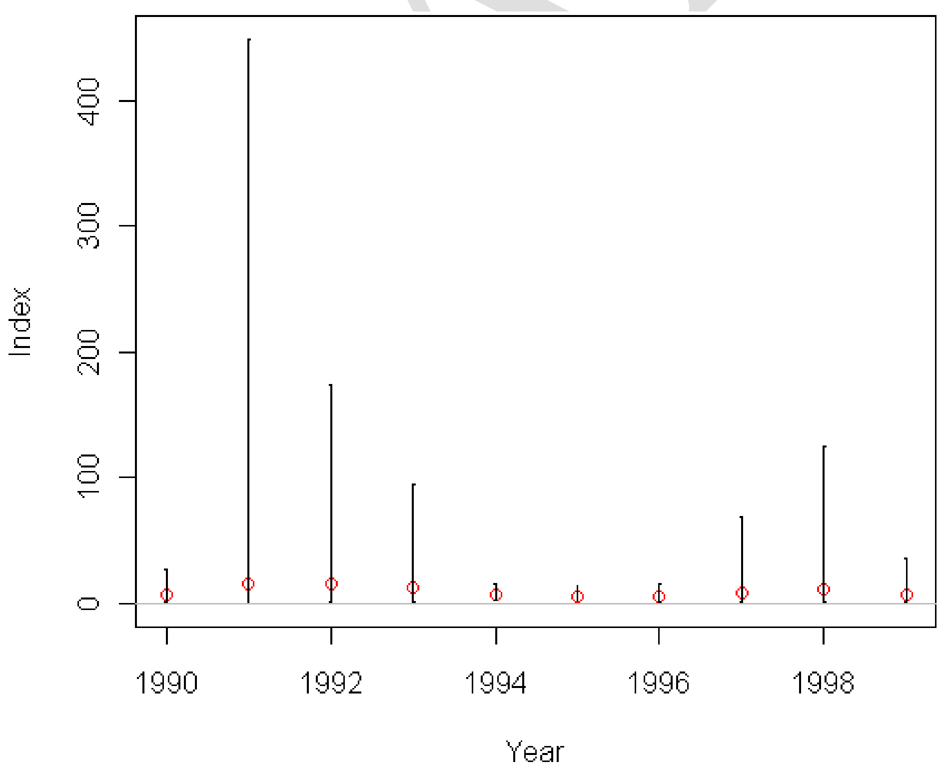

Figure 49.Index of relative abundance for the Washington recreational CPUE series.

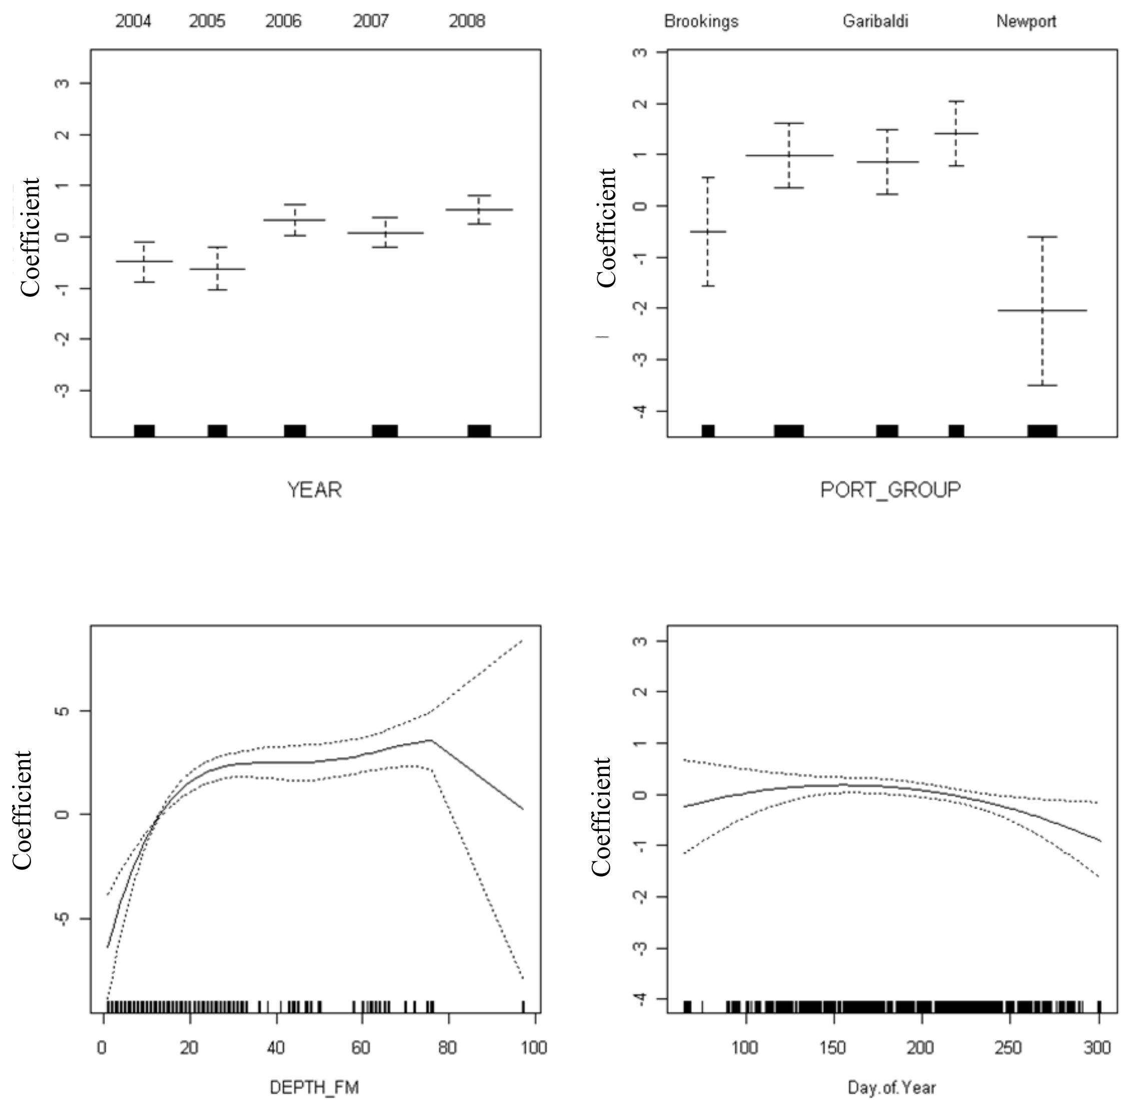

Figure 50.Estimated relationships of covariates included in the analysis of recreational charter observer CPUE data from Oregon. Error bars represent +/- 2 SEs about maximum likelihood estimates.

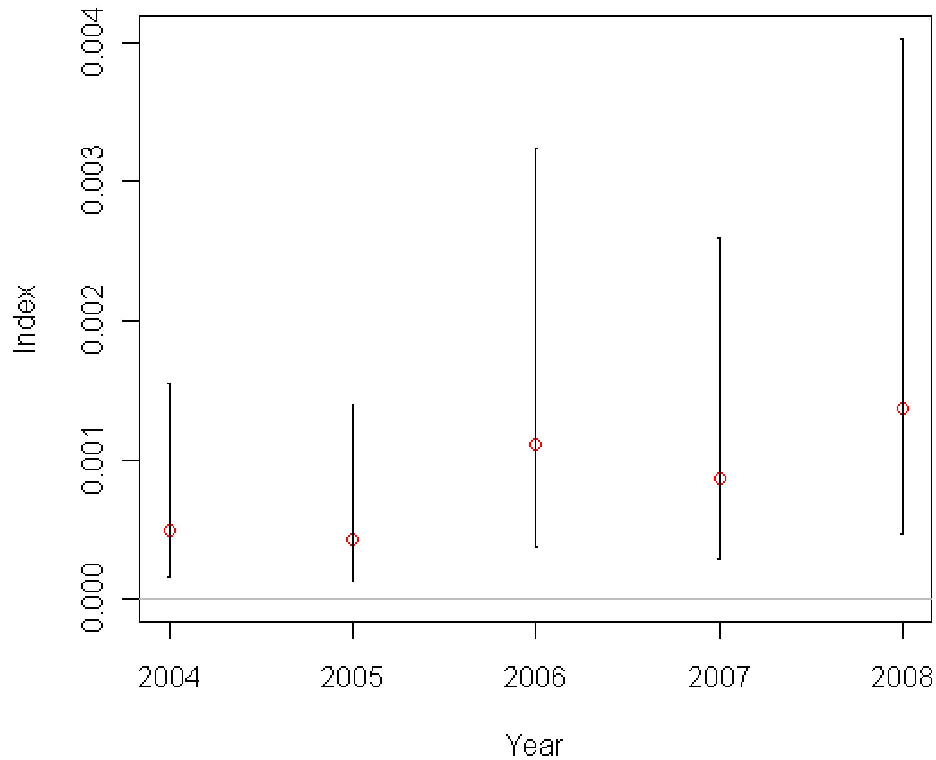

Figure 51. Index of relative abundance for the Oregon recreational observer CPUE series.

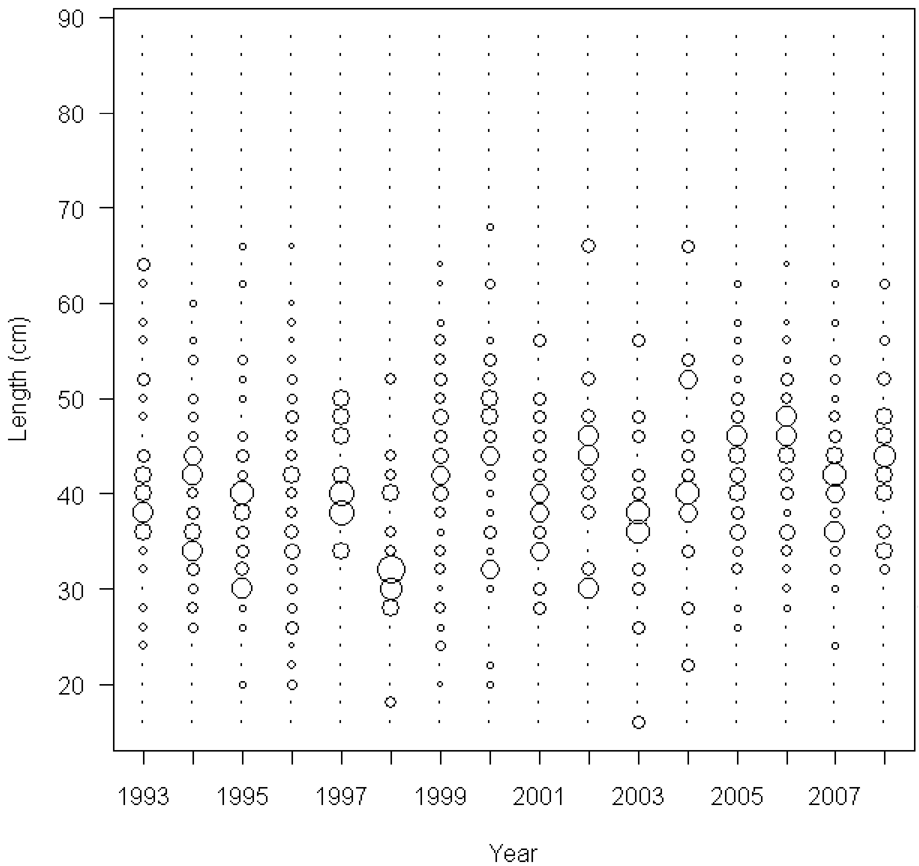

Figure 52. Length-frequency distributions for sexes-combined yelloweye rockfish from the California recreational fishery. Distributions sum to 1.0 in each year; the largest bubble sizes indicate a proportion of 0.27.

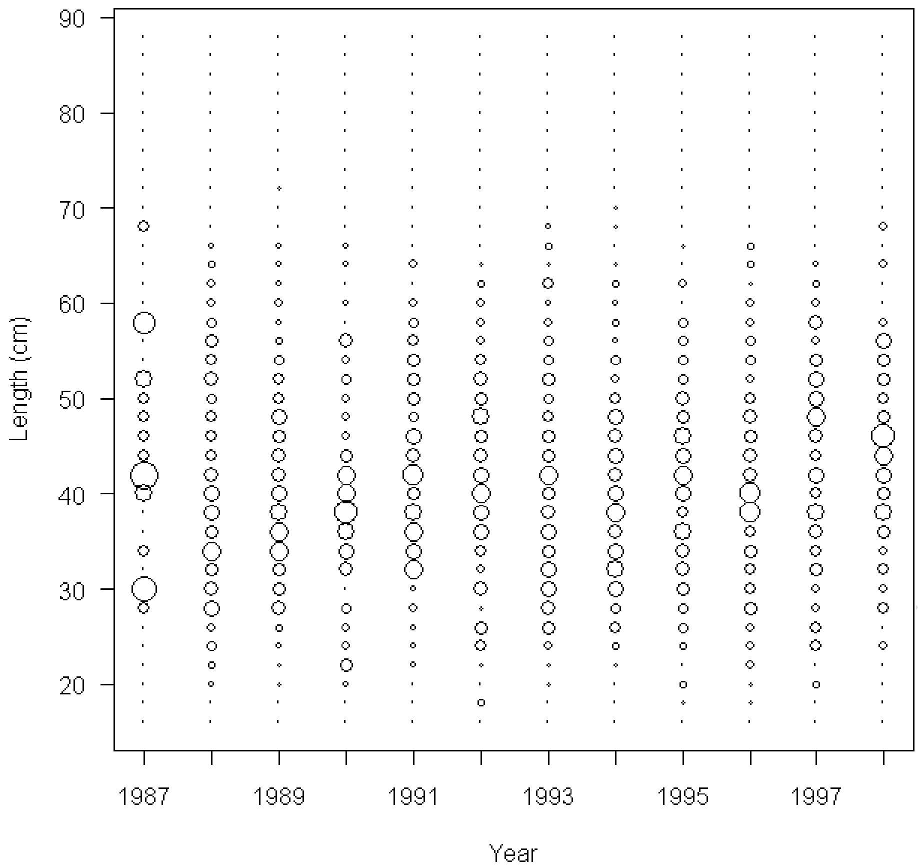

Figure 53. Length-frequency distributions for sexes-combined yelloweye rockfish from the California recreational charter fishery. Distributions sum to 1.0 in each year; the largest bubble sizes indicate a proportion of 0.21.

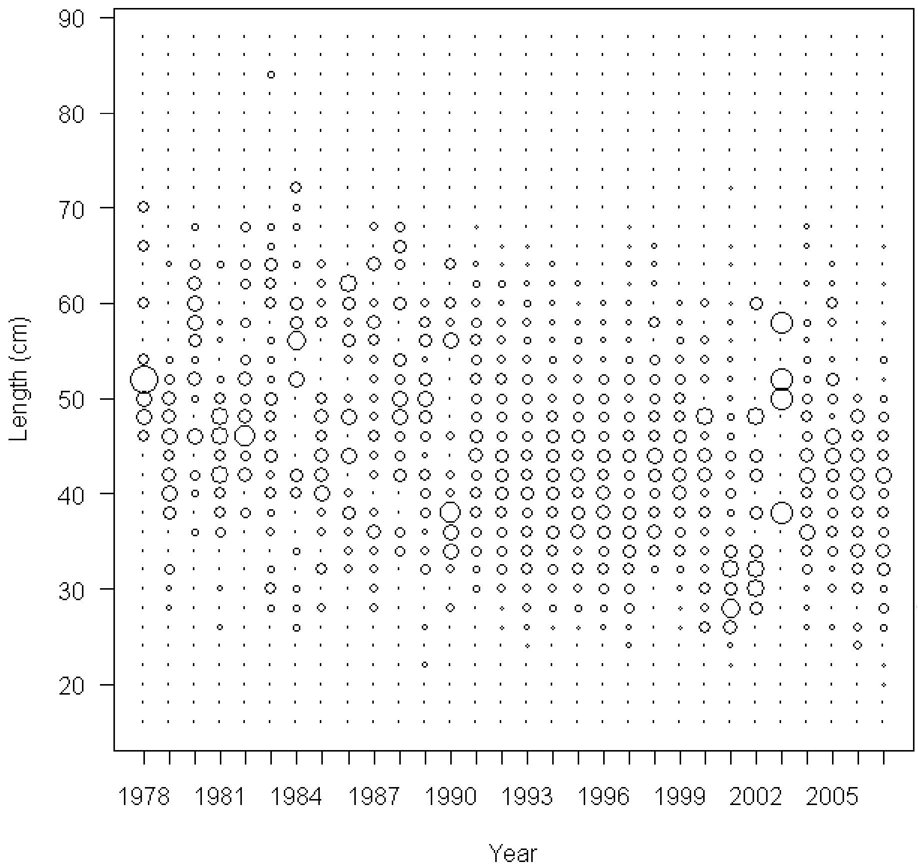

Figure 54. Length-frequency distributions for sexes-combined yelloweye rockfish from the California commercial fishery. Distributions sum to 1.0 in each year; the largest bubble sizes indicate a proportion of 0.39.

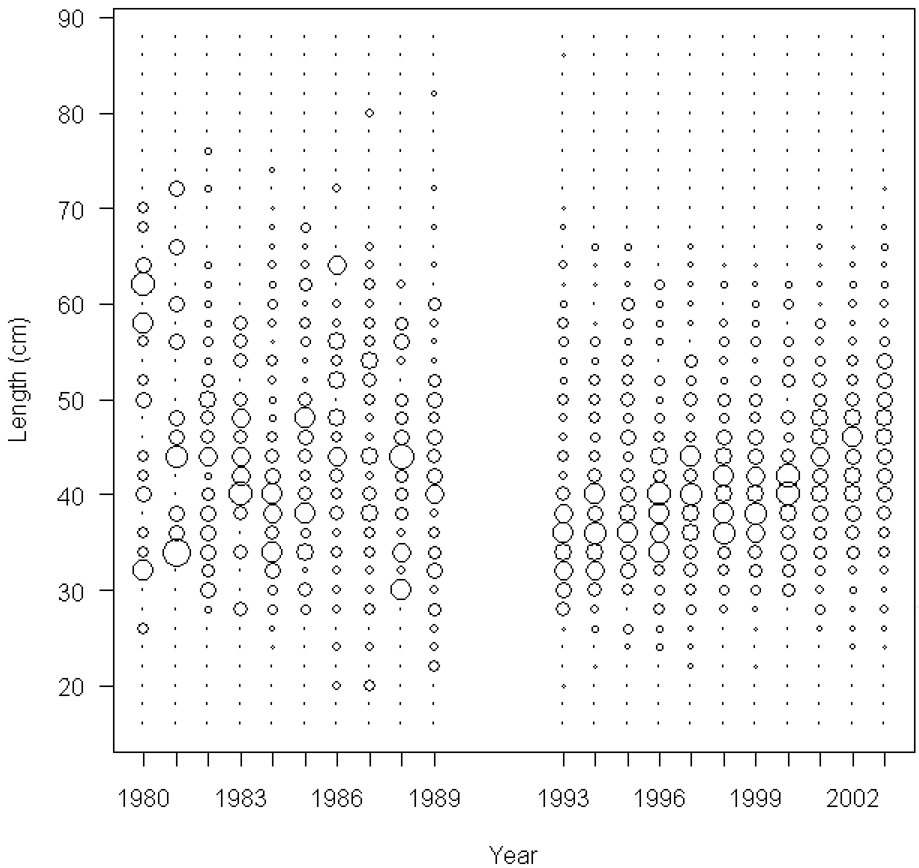

Figure 55.Length-frequency distributions for sexes-combined yelloweye rockfish from the Oregon recreational fishery. Distributions sum to 1.0 in each year; the largest bubble sizes indicate a proportion of 0.22.

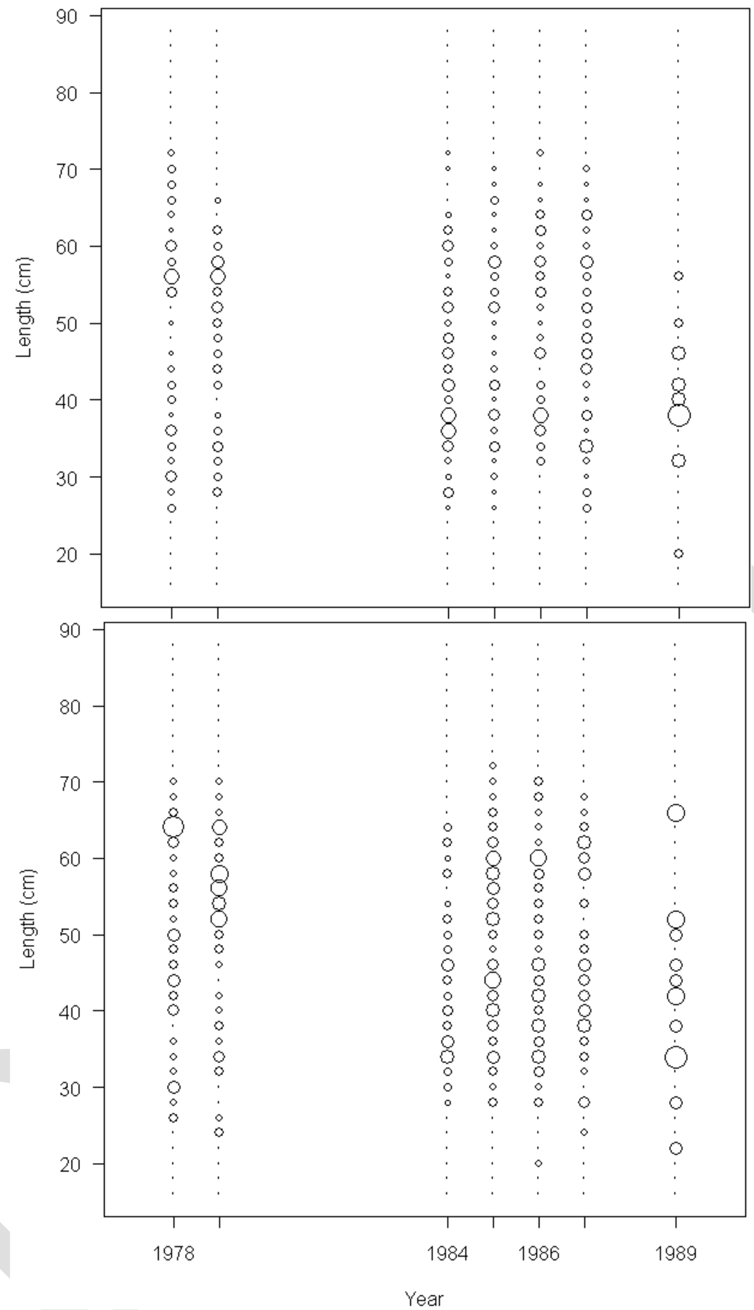

Figure 56. Length-frequency distributions for female (upper panel) and male (lower panel) yelloweye rockfish from the Oregon recreational fishery. Distributions sum to 1.0 in each year; the largest bubble sizes indicate proportions of 0.15 (females) and 0.09 (males).

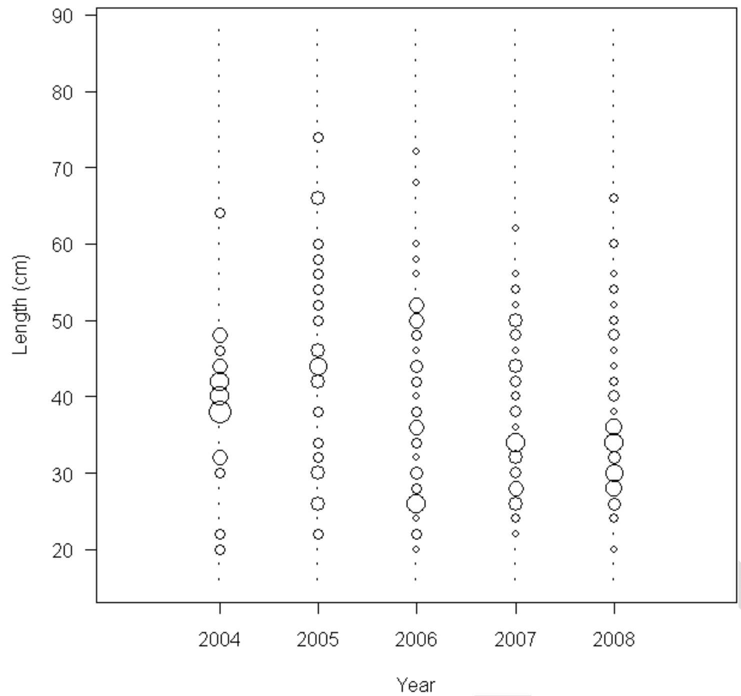

Figure 57. Length-frequency distributions for sexes-combined yelloweye rockfish from the Oregon recreational observer program. Distributions sum to 1.0 in each year; the largest bubble sizes indicate a proportion of 0.18.

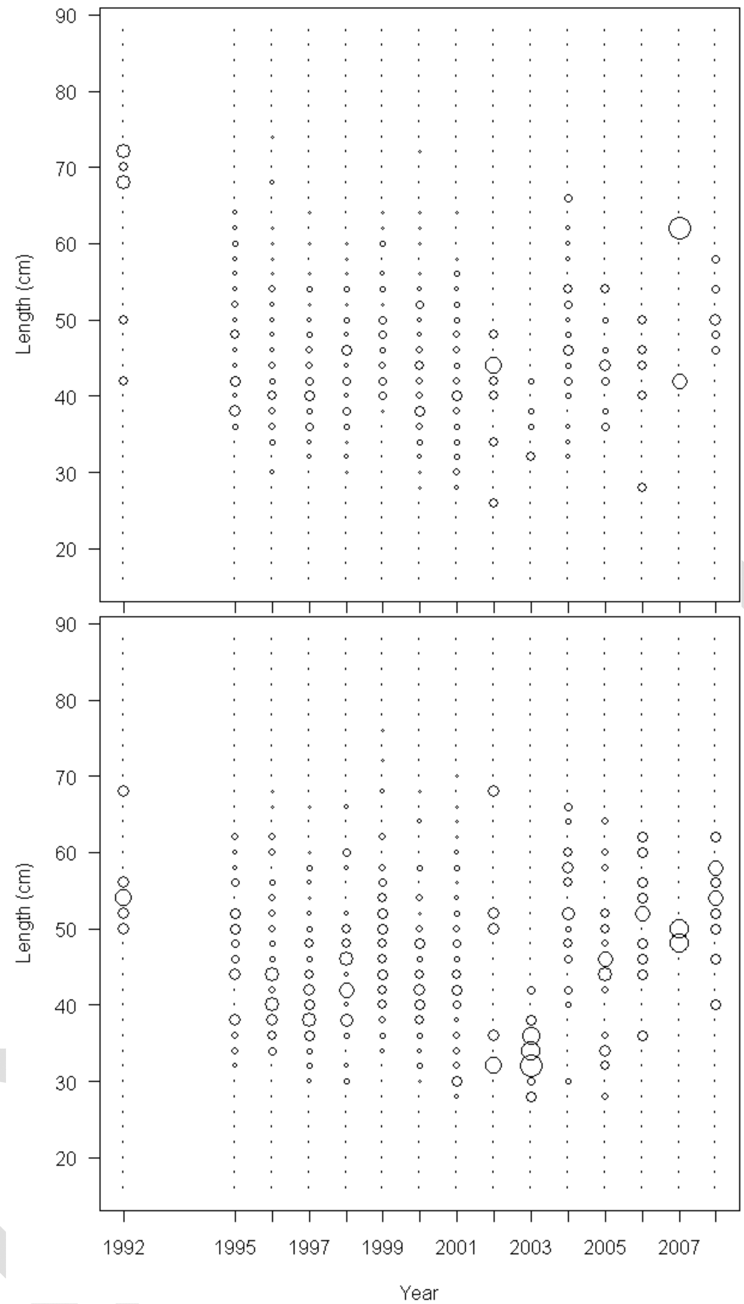

Figure 58. Length-frequency distributions for female (upper panel) and male (lower panel) yelloweye rockfish from the Oregon commercial fishery. Distributions sum to 1.0 in each year; the largest bubble sizes indicate proportions of 0.37 (females) and 0.25 (males).

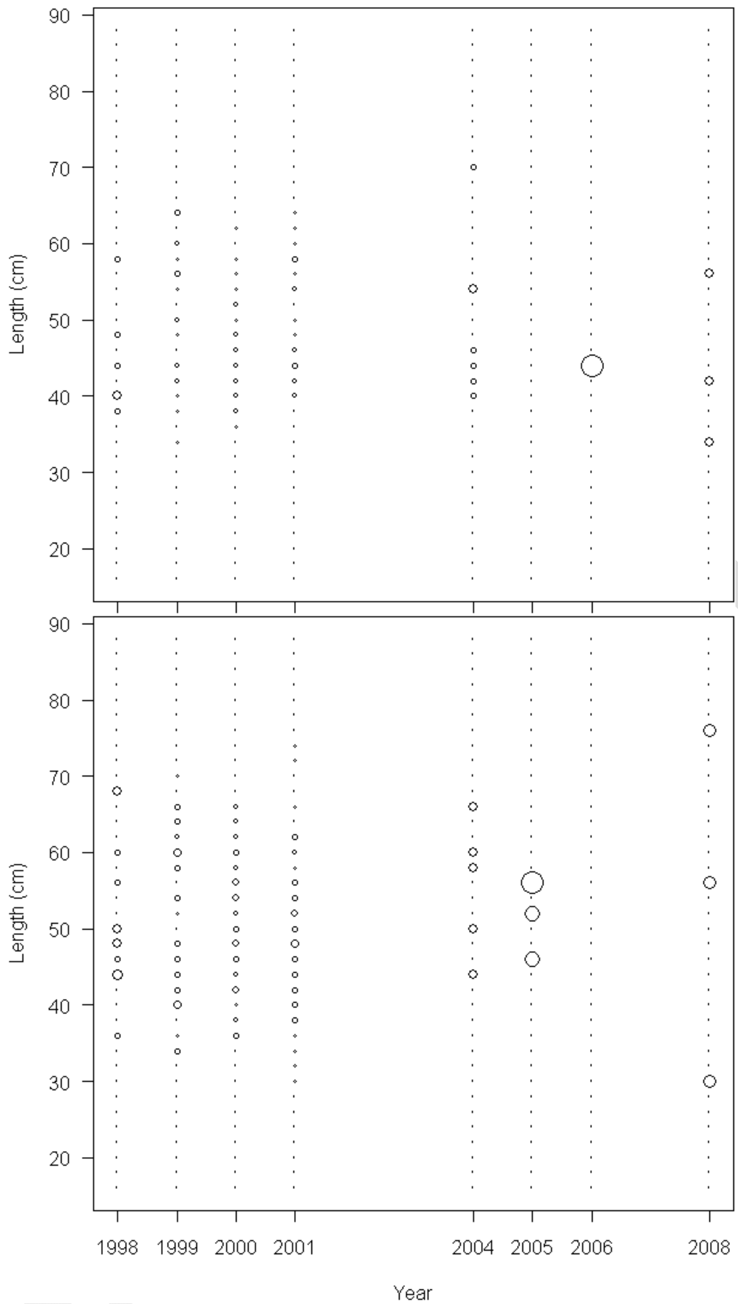

Figure 59. Length-frequency distributions for female (upper panel) and male (lower panel) yelloweye rockfish from the Washington recreational fishery. Distributions sum to 1.0 in each year; the largest bubble sizes indicate proportions of 0.93 (females) and 0.47 (males).

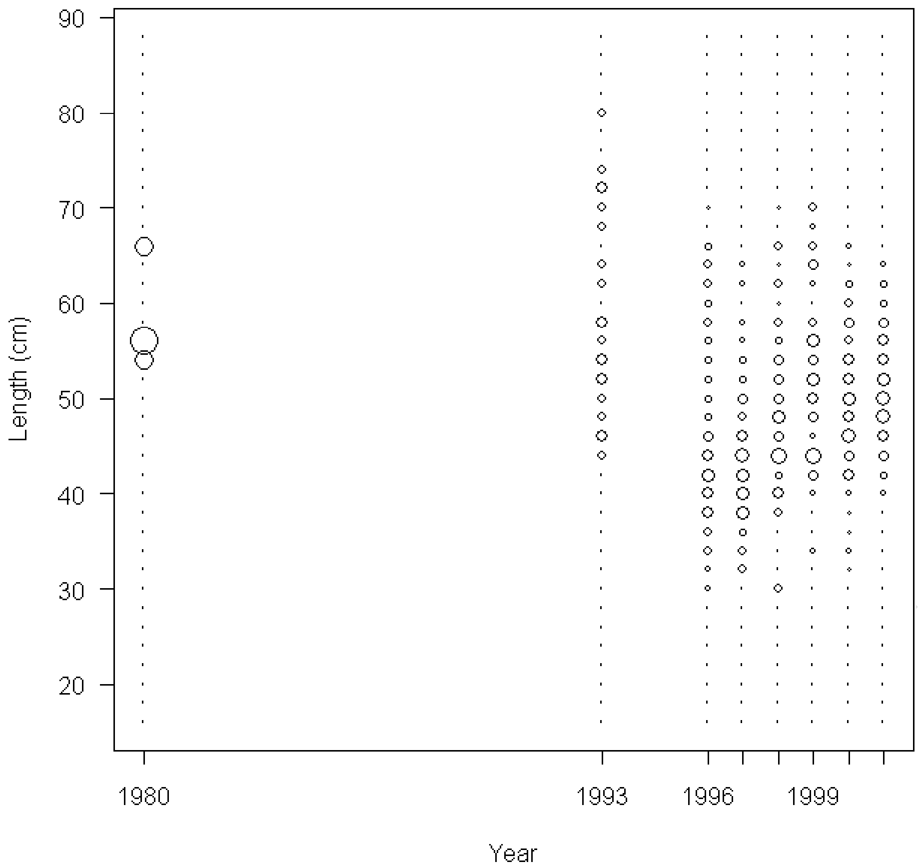

Figure 60. Length-frequency distributions for sexes-combined yelloweye rockfish from the Washington commercial fishery. Distributions sum to 1.0 in each year; the largest bubble sizes indicate a proportion of 0.48.

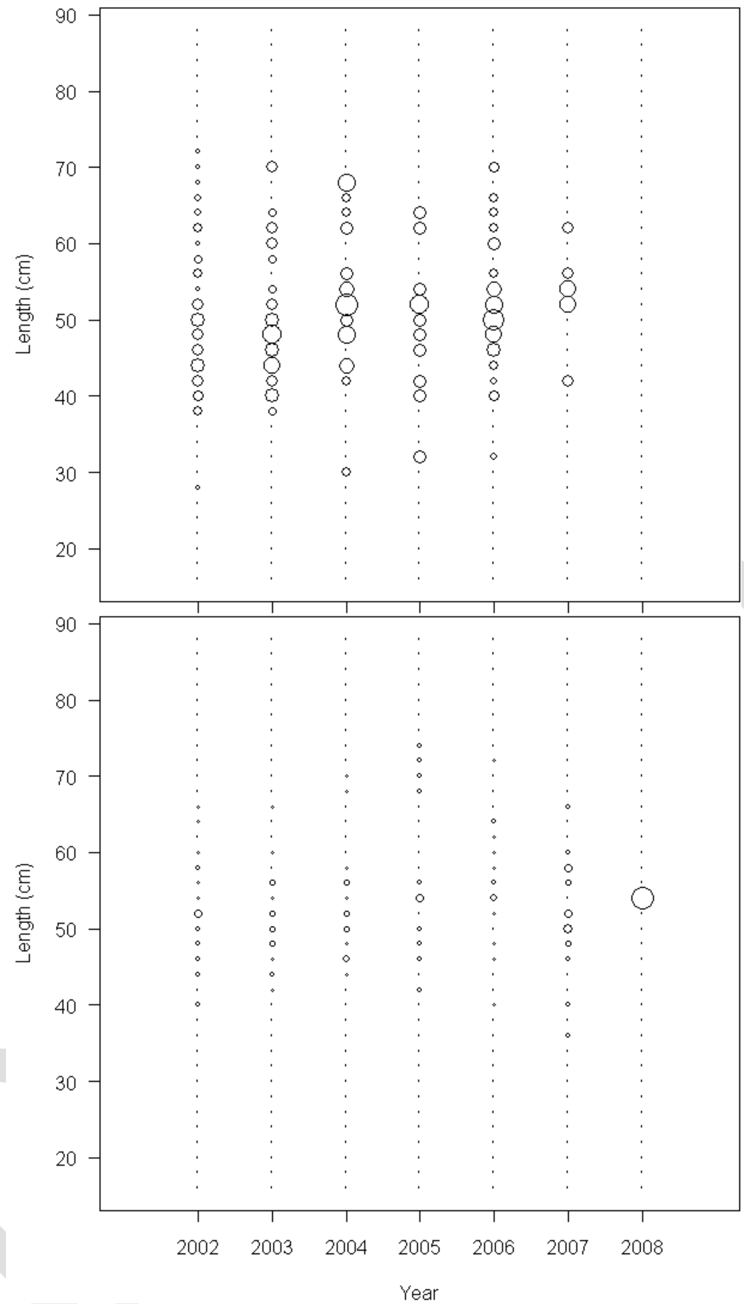

Figure 61. Length-frequency distributions for female (upper panel) and male (lower panel) yelloweye rockfish from the Washington commercial fishery. Distributions sum to 1.0 in each year; the largest bubble sizes indicate proportions of 0.11 (females) and 0.93 (males).

14. Appendix C: SS Control file

Control file for 2009 yelloweye assessment

Yelloweye 2009 control file

Morph setup
1 # Number of growth patterns
1 # N sub morphs within GPs

Area setup
3 # Number of recruitment assignments
0 # Recruitment interaction flag
For each recruitment assignment
GP seas area
 1 1 1
 1 1 2
 1 1 3
0 # Number of movement parameters

Time block setup
0 # Number of block designs

Mortality and growth specifications
0.5 # Fraction female at birth
1 # M setup: 0=single Par,1=N_breakpoints,2=Lorenzen,3=agespecific;_4=agespec_withseasinterpolate
1 # Number of M breakpoints
4 # Ages at M breakpoints
1 # Growth model: 1=VB with L1 and L2, 2=VB with A0 and Linf, 3=Richards, 4=Read vector of L@A
1 # Age for growth Lmin
70 # Age for growth Lmax or 999 = Linf
0 # SD constant added to LAA (0.1 mimics v1.xx for compatibility only)
0 # Variability about growth: 0=CV~f(LAA) [mimic v1.xx], 1=CV~f(A), 2=SD~f(LAA), 3=SD~f(A)
1 # Maturity option: 1=length logistic, 2=age logistic, 3=read age-maturity matrix by growth_pattern
2 # First age allowed to mature
1 # Fecundity option
0 # Hermaphroditic option
1 # mg parm offset option: 1=direct assignment, 2=each pat. x gender offset from pat. 1 gender 1, 3=offsets as SS2 V1.xx with M old and CV old offset from young values
1 # mg parm adjust method 1=do V1.23 approach, 2=use logistic transform between bounds

YELLOWEYE ROCKFISH

STAR Panel Report

August 3-6, 2009

Hotel Deca
4507 Brooklyn Ave NE
Seattle, WA 98105

Panel Reviewers

Stephen Ralston	Panel Chair, Scientific and Statistical Committee (SSC) Representative
Richard Methot	NMFS, Northwest Fisheries Science Center (NWFSC)
Vivian Haist	Center for Independent Experts (CIE)
J. J. Maguire	Center for Independent Experts (CIE)

Panel Advisors

John DeVore	Pacific Fishery Management Council
Robert Alverson	Groundfish Advisory Subpanel (GAP) Representative
Rob Jones	Groundfish Management Team (GMT) Representative

Stock Assessment (STAT) Team members present

Ian Stewart	NMFS, Northwest Fisheries Science Center (NWFSC)
John Wallace	NMFS, Northwest Fisheries Science Center (NWFSC)
Carey McGilliard	University of Washington, School of Aquatic & Fishery Resources

Overview

A draft assessment of yelloweye rockfish (*Sebastes ruberrimus*) stock status off the U. S. west coast (California, Oregon, and Washington) was reviewed by the STAR panel from August 3-6, 2009 in Seattle, WA. Within the model the population is treated as a single stock with separate sub-population structure within each of the three States, allowing for State-specific estimates of unexploited stock size and current depletion. The biological underpinnings of the model structure are that adults are site-attached and do not move appreciably among the three states whereas larval dispersal is widespread, assumptions that are well-supported in the scientific literature. In addition, because the age- and length-compositional data are not informative of the time series of recruitment and because it was infeasible to integrate across the range of uncertainty in these recruitments, stochasticity in the spawner-recruit relationship was not modeled.

The yelloweye stock assessment used the Stock Synthesis platform and incorporated a variety of data sources. Catch, length-frequency, and conditional age-at-length data from six fisheries were used in the assessment, i.e., commercial and recreational fisheries in each of the three states. The fishery-dependent relative abundance (CPUE) indices that were used in the model were developed from recreational fisheries data and were unchanged from the last assessment conducted in 2007. Separate fishery-independent time series of abundance were developed for Oregon and Washington using International Pacific Halibut Commission (IPHC) longline survey data. In addition, time series of yelloweye rockfish abundance in the triennial and NWFSC combined trawl surveys were estimated and incorporated into the base stock assessment model.

The last full assessment of yelloweye rockfish was completed in 2006 (an off-year) and that model was subsequently updated in 2007. Major changes made in this assessment, compared with the previous assessment include:

- Use of SS version 3.03b modeling framework instead of SS2;
- Incorporation of reconstructed landings that extended the modeled period to 1916 instead of 1925;
- Treatment of the population dynamics in an area-based model with recruitment apportioned to areas based on internal parameter estimation;
- Removal of stochasticity in recruitment;
- Addition of NWFSC shelf-slope trawl survey (referred to as NWFSC combined survey in the assessment report) and the triennial trawl survey;
- Incorporation of weight-specific fecundity based on a meta-analysis of rockfish reproduction;
- Revision of aging error estimates using software developed by Punt *et al*. (2008)
- Inclusion of age data as conditional age-at-length compositions;
- Estimation of gender-specific natural mortality and spawner-recruit steepness in the model using newly developed priors.

The STAR panel concluded that the yelloweye rockfish assessment constitutes the best available scientific information on the status of yelloweye rockfish off the U.S. west coast and recommends that it be used for status determination and management in the Council process.

The STAR panel thanks the STAT team members for their exceptional preparation, hard work, and willingness to respond to panel requests.

Panel Requests to the Yelloweye STAT

The following prioritized requests were made by the STAR panel to the yelloweye STAT:

Request 1: In figure 55, verify that observations in bin 70 are real and not the result of an aggregation at 70 – new base.

Rationale: Length-frequency distributions for gender-combined yelloweye rockfish from the Oregon recreational observer program show large observations in bin 70, suggesting that this bin could be an accumulator bin. Data verification request to verify that the data have been correctly used.

Response: Observations at 70 cm for Oregon recreational observer length frequencies were a formatting error. The error was corrected and all other bins remain unchanged.

Request 2: Provide a run with a normal approximation of Hamel's prior for natural mortality (M) on both males and females – new base.

Rationale: Runs where M was estimated with a higher M prior for the males resulted in estimated M for males very close to that estimated for female. Figure 41 in the draft assessment provides the rationale for higher M for males. Dr. Owen Hamel has completed a meta-analysis of M and his results were considered potentially more useful as prior information to be used in the model.

Response: Fixing the OR recreational observer length frequencies and using the Hamel prior for natural mortality resulted in minor changes in the model results. Correcting the error in the LF changed steepness by 0.01. Henceforth the base case is with OR recreational observer LF corrected and using new M priors.

Request 3: Provide a run keeping the observations after 1999 for the recreational CPUE series to estimate the effect of truncating the indices in 1999. Previous analyses had suggested that management measures after 1999 may not have substantially affected the indices until 2001 or so.

Rationale: This is essentially seen as a sensitivity run to document the effects (or not) of including those points in the assessment, inasmuch as they were included in some previous assessments.

Response: There is a difference of opinion between current and previous STAT teams on how to treat those points. The current STAT thinks that regulatory changes after 1999 were sufficient to potentially impact recreational CPUE and it considers that the burden of proof is to demonstrate that they did not. Including the 2000 and 2001 points made little change in the results and the Panel agreed that the base case would not include the recreational CPUE estimates for 2000 and 2001.

Request 4: Provide a run where stock size indices are up-weighted compared with the age / length compositions.

Rationale: This is also seen as a sensitivity run to understand the potential effect of giving more weight to the stock abundance indices compared with the length and age compositions.

Response: This request was addressed by increasing the lambdas on the stock size indices 10-fold. This resulted in lower stock size in 2009 and depletion equal to 15.4%, compared with 20.3% for the base case. Steepness decreased from 0.417 to 0.302. The likelihood of the age and length compositions did not change much suggesting that they were not strongly affected by the index data. This was not intended to change the base case.

Request 5: Provide sensitivity run with the exponential parameter on Q turned off for recreational CPUE time series.

Rationale: Another sensitivity run to understand the effect of allowing a non-linear relationship between abundance and CPUE in the fishery-dependent recreational data.

Response: Assuming that recreational CPUE series were linearly related to stock size had minimal effects on the results. The Panel agrees with the STAT that the potential for catchability to be nonlinearly related to stock size should be retained in the base case. The Panel noted that excluding 2000 and 2001 from the series and allowing for catchability to be nonlinearly related to stock size implied that the recreational CPUE were downweighted.

Request 6: In the GLM for the IPHC, drop the stations where yelloweye have never been caught and estimate a station effect. Plot the two time series versus time to investigate the difference.

Rationale: Given the association of yelloweye rockfish with rocky and other high relief habitats, a relatively strong station effect would be expected. However, because no yelloweye rockfish were caught at many stations it was not possible to estimate the station effect in the GLM when all stations were included in the analysis. Removing stations that had never caught yelloweye was suggested as a possible way of estimating station effects.

Response: Removing the stations where no yelloweye rockfish had ever been caught increased the absolute value of the stock size index, but did not change the trends over time for either the OR of WA indices. Including site effects makes it possible to include covariates in the CPUE modeling. Excluding stations where yelloweye rockfish have never been caught could be counterproductive in the future, however, if as the yelloweye population increases it expands its range and populates new areas. The Panel did not recommend that the base case should be changed to include CPUE standardized with site effects, but noted that this issue should be reviewed in the next update assessment. The Panel also noted that the IPHC longline survey could be a good survey for yelloweye if sampling intensity was higher, but higher sampling intensity could catch a considerable portion of the total OY.

Request 7: IPHC survey and Triennial surveys catch large yelloweye off WA, but neither the IPHC survey nor the NWFSC catch large yelloweye off OR. Does the NWFSC catch large yelloweye off WA?

Rationale: This is a first step in evaluating the selectivity curves for the different areas and gears versus the availability of large yelloweye in the various areas.

Response: There were a few larger yelloweye in the NWFSC survey off WA suggesting that the NWFSC can catch larger yelloweye rockfish if they are present. The Panel concluded that there was insufficient support to change the base case dome-shaped selectivity curve to asymptotic selectivity for the NWFSC trawl survey off OR.

Request 8: Is the IPHC survey off OR potentially dome shaped?

Rationale: This is related to request 7 where the IPHC survey seems not to be catching large yelloweye off OR. The question arose as to whether this is due to lack of large yelloweye in the area or because of dome-shaped selectivity.

Response: With the correction to the OR recreational observer length frequencies the selectivity for the IPHC survey in OR wanted to go dome shaped. The fit to the data with either domed or asymptotic selectivity are similar, although the residual pattern is somewhat improved with domed selectivity. Given that the selectivity for the IPHC in WA was asymptotic and because the absence of large fish in OR could be due to growth differences, the Panel recommended to keep the asymptotic selectivity for the IPHC survey in OR until there is a better understanding of growth and biological parameters. The selectivity pattern for both the trawl surveys and the IPHC longline surveys should be open for further investigation in subsequent assessments.

Request 9: Provide a plot of the gender ratio over time.

Rationale: This is to assess if there are temporal trends in the gender ratio over time.

Response: Expected gender ratio by State, age, and year were plotted. The difference in gender ratios was small, with the ratio of males to females between 0.90 and 1.1. While the difference in gender ratio by State, age, and year may not be sufficient to justify modeling genders separately, it is necessary to do so to accommodate variable female fecundity by size.

Request 10: Overlay length at age, color coded for WA, OR and CA, on the growth plot to estimate if there are differences by area.

Rationale: The intent is to investigate if there are differences in growth in the three areas.

Response: Yelloweye do get somewhat larger off WA, but the Panel did not recommend changing the base case. The Panel recommended that the next assessment evaluate the appropriateness of estimating biological parameters by area.

Request 11: Provide a plot of the profile of steepness as a function of M.

Rationale: The intent is to better understand the joint behavior of M and steepness and to evaluate if steepness should be used as an axis of uncertainty.

Response: The graph reinforced the impression that there is little information to estimate steepness from a one way trip. Steepness has a large effect on the rebuilding potential and the Panel and STAT agreed to use a combination of catch and steepness to provide nine states of nature to depict uncertainty scenarios.

Request 12: The stock assessment report should contain a reference to the proposed listing of yelloweye in Puget Sound as endangered (under the terms of the Endangered Species Act)).

Rationale: A proposed listing of a distinct population segment of yelloweye rockfish is important background information that managers may want to consider when developing management measures for yelloweye rockfish.

Response: Text will be incorporated in the final assessment, similar to what was included in the bocaccio assessment.

Description of base case model and alternative models to bracket uncertainty

- Start year of the model = 1916;
- Spatial structure has coastwide spawner-recruitment pool, with recruitment apportioned among three State areas according to estimated proportions;
- Each fishery and survey is specific to one State area;
- Discard incorporated into total catch;
- Sex-specific ***M*** estimated to be 0.047 yr^{-1} for females and 0.047 yr^{-1} males (with Hamel's normal approximation prior);
- ***h*** estimated to be 0.417 (with Dorn's prior);
- No recruitment deviations estimated in base model;
- von Bertalanffy growth parameters, including dispersion of individual growth, estimated for females and males;
- Fishery CPUE indices fit using density-dependent catchability.

Fisheries:

California commercial (all gears)
California recreational
Oregon commercial (all gears)
Oregon recreational
Washington commercial (all gears)
Washington recreational
Foreign and research catches included in commercial catch

Abundance indices:

IPHC longline survey – WA (1999-2008)
IPHC longline survey – OR (1999-2008)
Triennial trawl survey – WA (1980-2004); break in catchability in 1995
NWFSC shelf-slope trawl survey – OR (2003-2008)
Recreational (CPFV) CPUE – CA (1988-1998)
Recreational CPUE - CA (1980-1986, 1993-1999)
Recreational (CPFV) CPUE – OR (2004-2008)
Recreational CPUE - OR (1979-1999)
Recreational CPUE - WA (1990-1999)

Length compositions:

- Recreational (CPFV)– CA (1988-1998)
- Recreational - CA (1993-2008)
- Commercial - CA (1978-2007)
- Recreational (CPFV) - OR (2004-2008)
- Recreational - OR (1978-1989, 1993-2003)
- Commercial - OR (1992, 1995-2008)
- Recreational - WA (1998-2001, 2004-2008)
- Commercial - WA (1994-2008)
- IPHC – longline survey - OR (2003-2008)
- IPHC – longline survey - WA (2003-2008)
- Triennial trawl survey – WA (1980-2004)
- NWFSC shelf-slope trawl survey – OR (2003-2008)

Age compositions (as conditional age-at-length/sex):

- Recreational - CA (1983, 1996)
- Commercial - CA (1978-1983, 1985-1986, 1988, 2001, 2005)
- Recreational - OR (1979, 1984-1987, 1989, 2001)
- Commercial - OR (2001-2007)
- Recreational - WA (1998-2001, 2004-2008)
- Commercial - WA (1993, 2001-2008)
- IPHC – longline survey - OR (2003-2008)
- IPHC – longline survey - WA (2003-2008)

Uncertainty – The magnitude of historical landings of yelloweye rockfish is a substantial source of uncertainty in this assessment and strongly affects the absolute magnitude of estimated stock abundance, although not the long-term trend and depletion. The assessment was able to obtain reasonable estimates of natural mortality and spawner-recruitment steepness, but the magnitude of the steepness parameter is not precisely determined and is expected to have a substantial effect on projected rates of stock rebuilding. The magnitude of historical catch and spawner-recruitment steepness were selected as two axes of uncertainty for this assessment. The panel recommends that this uncertainty be carried forward into the rebuilding analysis.

Technical merits of the assessment

The yelloweye stock assessment team was exceptionally well prepared and had conducted a wide variety of analyses and sensitivity runs supporting their development of a proposed base-case model. The transition of the assessment to an area-specific model represents a substantial improvement in our understanding of regional variation in stock depletion. Likewise, incorporation of extensive historical catch reconstructions by the STAT provides greater insight into regional yelloweye productive capacity. Of significant concern to the STAR panel was that historical harvests from the State of Washington may be biased low, a concern likely to be addressed when the next assessment is completed.

Explanation of areas of disagreement regarding STAR panel recommendations

A. Among STAR panel members (including concerns raised by the GAP and GMT representatives

There were no areas of disagreement among STAR panel members.

B. Between the STAR panel and the STAT team

There were no areas of disagreement between the STAR panel and the STAT team.

Unresolved problems and major sources of uncertainty

Recently completed historical catch reconstructions had a marked influence on the yelloweye rockfish stock assessment, particularly on regional estimates of B_0. As a consequence, the STAT came to the meeting with a recommendation that uncertainty be bracketed by ranging historical catches ±50%. A particular problem identified by the STAR panel and the STAT is that Washington reconstructions were less well-developed than those from Oregon and California and estimates may be biased low. The panel therefore recommends that work continue on historical catch reconstructions and that updated catch time series from all three States be incorporated into the next stock assessment.

Another major unresolved problem facing the yelloweye stock assessment is the need to develop a good abundance statistic that can be used to track stock recovery. Two avenues worth pursuing were identified during the review: (1) development of *in situ* visual survey abundance measures in yelloweye habitat using ROVs, AUVs, submersibles, etc, and (2) improvement of the IPHC survey yelloweye rockfish bycatch index by increasing sample size and improving the statistical model (e.g., incorporating station effects). Given that Washington and Oregon have taken different approaches to supplementing IPHC survey sample size, the latter issue will be challenging to solve.

The STAR panel, in consultation with the STAT, ultimately identified two axes of uncertainty to carry forward into a decision table, i.e., historical catch reconstructions and statistical error in the estimate of stock productivity ($\boldsymbol{h} = 0.42$). The former was bracketed by 75% and 150% of the base-case reconstruction, whereas the latter was bracketed by assigning 25% of the probability mass to high and low values of steepness equal to 0.34 and 0.51 (based on likelihood profile). The two uncertainty axes were crossed, resulting in nine states of nature that should be carried forward into the rebuilding analysis, each with a specific probability of occurrence.

It is unlikely that the yelloweye rockfish stock assessment can be considerably improved in two years, other than by updating the historical catch reconstructions (especially for Washington) and the IPHC GLM indices to include supplemental sample sites that have been occupied in Oregon and Washington. Both issues, however, have the potential to alter the stock assessment and may exceed the requirements for stock assessment updates as specified in the PFMC's Groundfish Terms of Reference. The panel was therefore unsure whether to recommend that the next assessment should proceed as an update or as a full assessment. From a practical perspective it would be desirable if the Council's process could accommodate an "extended update" that could allow exploration of these two issues in 2011 without requiring a whole week of review.

Management, data, or fishery issues raised by the GAP and the GMT representatives

The yelloweye rockfish stock assessment is spatially explicit, with separate sub-population components modeled for Washington, Oregon, and California. Not surprisingly, given the constraining nature of the yelloweye rockfish resource on the array of groundfish management options available to the Council, there will be considerable interest in the allocative implications of the new assessment. For example, the accepted base model estimates that the stock is less depleted in the north but potential yields are greater in the south due to differences in unexploited stock size. Given the sensitivity of yelloweye rockfish OY allocations to the states, the GMT representative wanted some assurance that regional model scenarios could be run using the base model to better inform the Council as it works to develop yelloweye management measures for the 2011-12 biennial period. The STAT can therefore expect a number of requests from the GMT to model the effect of various state- and fishery-specific catch projections on population growth and recovery.

Prioritized recommendations for future research and data collection

1. Develop and implement an effective visual survey of yelloweye rockfish abundance.

2. Conduct a scientific review of current efforts to develop and improve stock size indices for yelloweye based on IPHC sampling (including the addition of new stations) and make recommendations on the best approach to develop such indices. In particular, divergent 'enhanced' sampling designs (stratified random vs. adaptive fixed stations) in Oregon and Washington makes it difficult to compare results. The next assessment should be able to make direct use of these additional stations, if sampling is continued in 2009 and 2010.

3. Recalculate GLMM estimates from the IPHC survey to explore inclusion of station effects and allow incorporation of sites that differ in occupancy over time.

4. Continue to refine historical catch estimates using ex-vessel prices, etc., particularly in the State of Washington.

5. Investigate the development of a Washington recreational yelloweye CPUE statistic based on trips from the recreational Pacific halibut fishery. Consider a full time series and one ending in 2002, since the yelloweye RCA in waters off northern WA was implemented in 2003.

6. Encourage the collection of specimen samples to refine estimates of biological parameters, particularly maturity and fecundity.

7. Continue to evaluate the spatial aspects of the assessment, including growth, the number and placement of boundaries between areas, as well as the northern boundary with Canada.

8. Sample organization and curation of specimen materials (e.g., otoliths) from the IPHC survey should be revisited. Currently biological samples cannot be linked to the station from which they were collected. Age data for 2003-2005 is disconnected from the

relevant length and sex information and other unknown problems may exist in the data. A thorough evaluation of what data are reliable and a final determination of what information is lost, or can potentially be recovered, is needed

General research recommendations

1. Investigate alternative methods of re-weighting the data series in Stock Synthesis.

2. More work is needed to better understand the performance of maximum likelihood and Bayesian estimators of stock size and trends when large numbers of poorly informed recruitment deviations are estimated. Although it is logically appealing to include such uncertainty, even when there are little coherent data informing cohort strengths, technical and computational issues need to be solved before this approach can be implemented in situations such as yelloweye rockfish.

3. Investigate how best to account for variability in calendar dates in trawl surveys, especially through a meta-analysis of multiple stocks.

4. Continue to refine coast-wide historical catch estimates.

5. Accessing and processing recreational intercept data from RECFIN and the three states is much too cumbersome for the STATs. A single database that holds all the raw recreational data in a consistent format would greatly expedite processing and interpretation of the data and would reduce the potential for introduction of errors.

Executive Summary

Stock

Greenstriped rockfish (*Sebastes elongatus*) are a small rockfish (maximum size near 45 cm) named after their slim shape and predominant green stripes. They have also been called strawberry rockfish, watermelons, poinsettas, serena, and reina. These rockfish can be found in abundance from British Columbia to Northern Baja California, but range from Chirikof Island in the Aleutian Islands (Gulf of Alaska) to central Baja California, and inhabit depths between 12 and 500 meters. Data show an increase in mean length with depth, suggesting that maturing fish move to deeper water. This species of rockfish is found with other congeners or alone in a wide range of habitats, including rocky outcroppings, but unlike most other species of rockfish they tend to prefer mud or sand bottoms.

This assessment is concerned with the stock of greenstriped rockfish on the outer west coast of the United States from the California/Mexico border to the Washington/Canada border, excluding Puget Sound, and is the first assessment of the greenstriped rockfish population in this area. A recent genetic study found very little genetic variation along the entire West Coast and the extent of migration is unknown. Therefore, this is a coast-wide, single-area assessment, but fishing fleets are separated geographically when possible in an attempt to capture varying geographic patterns in the fisheries data. Past studies have noted that greenstriped rockfish from Southern California exhibit different growth and maturity patterns when compared to greenstriped rockfish from Northern areas, but more recent survey data do not clearly support regional differences. In addition, data from Southern California that would be necessary to assess that area separately were limited, thus this assessment assumed one area. It is believed that this assessment has captured the overall trend in the greenstriped rockfish population and constitutes the best available science regarding the current status of greenstriped rockfish.

Catches

Greenstriped rockfish have not often been targeted by any fishery, thus discards as well as landings are an important component of the total fishing mortality on the stock. The majority of landings of greenstriped rockfish have occurred in the trawl fishery, but a small proportion has been observed in the hook and line, net, and recreational fisheries.

Landings for five different fleets were determined from species composition data. Landings increased in the mid 1940's, slumped in the early 1960's, then increased substantially in the late 1960's. Foreign trawl fisheries occurred between 1966 and 1976 and contributed to a large proportion of the catches during that time. Throughout the 1990's, landings were at high levels until a dramatic decline in recent years, which is likely due primarily to recent management actions aimed at reducing the bycatch of stocks on rebuilding plans.

Data and Assessment

Greenstriped rockfish off the west coast of the US was assessed here for the first time using the length- and age-structured model called Stock Synthesis (version 3.03a). Population parameters were estimated using fishery landings and length data from five fleets, abundance indices and length data from the National Marine Fisheries Service (NMFS) triennial survey, and abundance indices, length data, and age data from the Northwest Fisheries Science Center (NWFSC) survey. The Triennial survey was split into two series (1980–1992 and 1995–2004) based on changes in survey timing. The NWFSC survey added a considerable amount of information, including age data, which were fit in the model as conditional age-at-length vectors.

The base case model estimated parameters for male and female selectivities of all of the domestic fishing fleets, length-at-age relationships for males and females, and recruitment deviations for the last four decades. Natural mortality and steepness were not estimated and are sources of a considerable amount of uncertainty. Spawning biomass is usually the quantity used in evaluating stock status. However, greenstriped rockfish show an increase in fecundity per kg of body weight with increasing weight, which can lead spawning biomass to be a biased measure of stock productivity when older and larger fish have been removed through fishing. Therefore, the relationship between the number of eggs per kg of body weight and the fish weight was included in the model and the spawning stock quantity of interest that is reported is spawning output, which can be interpreted as the number of eggs which are produced annually by the mature females.

Uncertainty in the parameter estimates was determined in two ways. First, approximate asymptotic 95% confidence intervals were calculated using the base model. Second, fixed values of natural mortality and the fraction of greenstriped rockfish discarded were varied above and below the values assumed in the base model to define a range of the states of nature.

Stock biomass and spawning output

The estimated spawning output started to significantly decline in the 1960's, when the landings increased, and continued to decline until the late 1990's. The spawning output has increased quickly in the last decade from a low near 59% of unfished spawning output in 1999 to approximately 81% of unfished spawning output in 2009. Approximate confidence intervals based on the asymptotic variance estimates showed that the uncertainty in the estimated spawning output is high, but depletion is less uncertain. The various states of nature show that uncertainty in spawning output is much larger than the estimated uncertainty using only the base model.

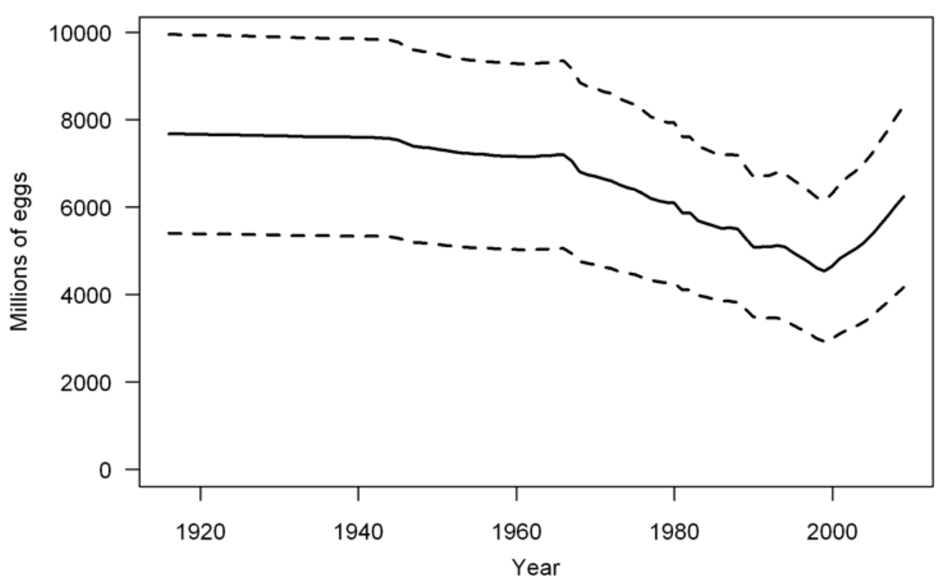

Figure b. Estimated spawning output (1916-2009) for the base case model (solid line) with an approximate asymptotic 95% confidence interval (thick dashed lines). The interval of spawning output over the states of nature is much larger as can be seen in Table b.

Table b. Recent trend in estimated female spawning output (millions of eggs) and relative depletion of spawning output. The range of the states of nature represent the largest amount of uncertainty which includes assumptions regarding the amount of natural mortality and the fraction of greenstriped rockfish discarded.

Output Year	Millions of eggs	~95% confidence interval	Range of states of nature	depletion (%)	~95% confidence interval	Range of states of nature
2000	4,663	3,001-6,324	912-47,435	60.7	51.9–69.5	38.8–92.0
2001	4,827	3,116-6,538	956-48,225	62.9	53.9–71.8	40.6–93.6
2002	4,953	3,206-6,700	993-48,605	64.5	55.5–73.5	42.2–94.3
2003	5,055	3,280-6,830	1,025-48,758	65.8	56.8–74.9	43.6–94.6
2004	5,193	3,383-7,003	1,067-49,115	67.6	58.6–76.6	45.5–95.2
2005	5,370	3,513-7,227	1,117-49,846	69.9	60.9–78.9	47.8–96.5
2006	5,582	3,669-7,495	1,172-50,893	72.7	63.7–81.6	50.3–98.3
2007	5,802	3,832-7,772	1,228-52,041	75.5	66.7–84.4	52.9–100.3
2008	6,029	4,002-8,056	1,287-53,185	78.5	69.8–87.2	55.7–102.2
2009	6,248	4,170-8,325	1,345-54,257	81.4	72.8–89.9	58.4–103.9

Recruitment

Recruitment deviations were estimated starting in 1970 and recruitment before then was assumed equal to mean recruitment as determined by the stock recruitment relationship. The estimates showed that recruitment is highly variable for greenstriped rockfish with high values in 1971, 1984, 1993, and 1998, and low estimates of recruitment in the 1990's, early 1970's, and 2006. The uncertainty in the estimated recruitment was high prior to 1985, but decreased in the 1990's and early 2000's when the age data were most informative. The age data from the NWFSC survey were very consistent with these estimates and precisely showed a very strong 1993 cohort.

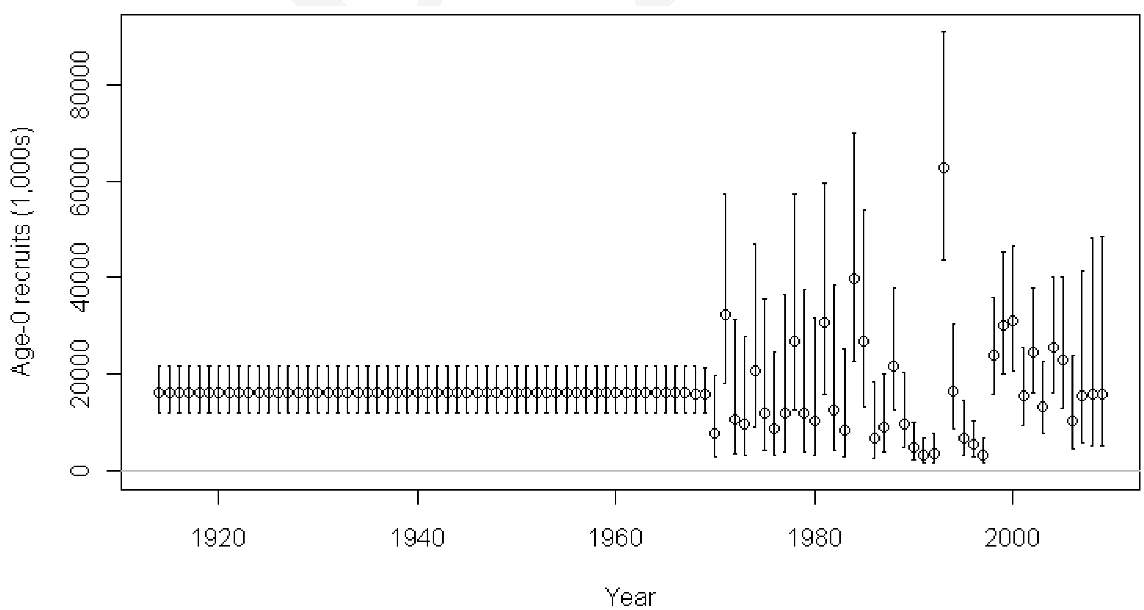

Figure c. Time series of estimated recruitments for the base case model (round points) with approximate asymptotic 95% confidence interval (vertical bars).

Table c. Recent estimated trend in greenstriped rockfish recruitment with approximate 95% confidence intervals determined from the base model and uncertainty in the estimated recruitment determined by varying the value of natural mortality and the fraction discarded.

Year	Estimated recruitment (1000s)	~95% confidence interval	Range of states of nature
2000	30,260	4,088–223,973	4,730–329,445
2001	31,187	4,212–230,944	4,932–333,433
2002	15,712	2,080–118,679	2,461–168,587
2003	24,734	3,327–183,866	3,907–262,380
2004	13,344	1,750–101,777	2,077–142,727
2005	25,531	3,409–191,198	3,942–275,722
2006	22,920	2,978–176,400	3,506–252,179
2007	10,362	1,212–88,576	1,618–114,327
2008	15,455	1,673–142,769	2,487–171,948
2009	15,800	1,575–158,450	2,562–172,960

Reference Points

Reference points were calculated using the estimated selectivities and a fleet distribution based on the proportions of the average landings from each fleet in the last two years. Sustainable total yields (landings plus discards) were 800 mt when using an $SPR_{50\%}$ reference harvest rate and ranged from 173 to 6,844 mt when varying the states of nature. The value for 40% of the unfished spawning output (analogous to $B_{40\%}$) was 3,072 million eggs.

The recent catches (landings plus discards) have been much less than the range of potential long-term yields calculated using an $SPR_{50\%}$ reference point. As a result, the spawning output and biomass of the stock has been steadily increasing over the last decade.

Exploitation status

The spawning output of greenstriped rockfish reached a low in the late 1990's before beginning to increase throughout the last decade. The estimated depletion has remained above the 40% of unfished spawning output target and it is unlikely that the stock has ever fallen below this threshold. Throughout the 1970's, 1980's, and 1990's the exploitation rate and *SPR* have generally increased and occasionally exceeded current estimates of the harvest rate limit ($SPR_{50\%}$). Recent exploitation rates on greenstriped rockfish have been very small, which is primarily due to management actions in the late 1990's and early 2000's to rebuild other species.

Table d. Summary of greenstriped rockfish reference points from the base case model. Values are calculated using a fishery distribution based the average of the landings from 2007 and 2008.

Quantity	**Estimate**	**~95% Confidence interval**	**Range of states of nature**
Unfished spawning output (millions of eggs)	7,680	5,402-9,958	2,179-52,580
Unfished age 2+ biomass (mt)	36,314	25,516-47,112	9,815-261,762
Unfished recruitment (R0, thousands)	16,281	2,242-118,211	2,760-172,741
Depletion (2009)	81.3%	72.8–89.9%	58.4–103.9%
Reference points based on $SB_{40\%}$			
Proxy spawning output ($B_{40\%}$)	3,072	2,161–3,983	872–21,032
SPR resulting in $B_{40\%}$ ($SPR_{B40\%}$)	46.7%	NA	NA
Exploitation rate resulting in $B_{40\%}$	0.0494	0.0483–0.0504	0.0407–0.0571
Yield with $SPR_{B40\%}$ at $B_{40\%}$ (mt)	828	581–1,075	179–7,091
Reference points based on $SPR_{50\%}$

MSY (mt)	870	611–1,129	188–7,471

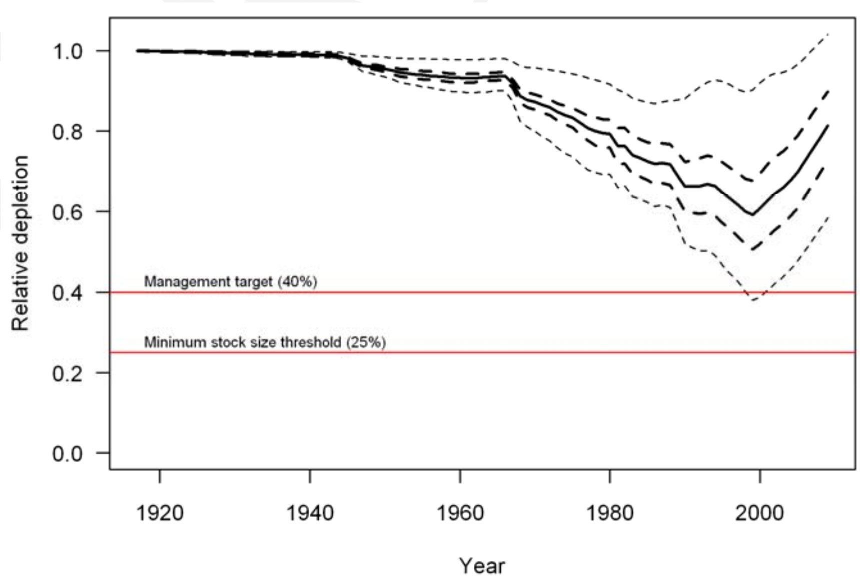

Figure d: Estimated relative depletion with approximate 95% asymptotic confidence intervals (thick dashed lines) for the base case assessment model and estimated depletion over the range of the states of nature (thin dashed lines).

Table e. Recent trend in spawning potential ratio (1-SPR) and summary exploitation rate (catch divided by biomass of age-2 and older fish).

Year	Estimated 1-SPR (%)	~95% confidence interval	Range of states of nature	Summary harvest rate (proportion)	~95% confidence interval	Range of states of nature
1999	75.1	80.1–70.1	94.7–49.7	1.66	1.25-2.07	0.35-3.81
2000	93.0	94.9–91.1	98.6–81.6	0.38	0.28-0.48	0.09-0.88
2001	93.2	94.9–91.6	98.6–82.7	0.37	0.28-0.46	0.09-0.82
2002	92.7	94.7–90.8	98.7–81.3	0.4	0.28-0.51	0.08-0.89
2003	98.9	99.3–98.6	99.8–97.0	0.06	0.04-0.07	0.01-0.12
2004	98.8	99.2–98.4	99.8–96.7	0.06	0.04-0.08	0.01-0.13
2005	98.8	99.2–98.5	99.8–96.7	0.06	0.04-0.08	0.02-0.13
2006	96.8	97.6–96.0	99.4–91.6	0.16	0.13-0.2	0.04-0.36
2007	99.5	99.6–99.4	99.9–98.6	0.02	0.02-0.03	0.01-0.06
2008	99.3	99.5–99.1	99.9–97.9	0.04	0.02-0.05	0.01-0.08

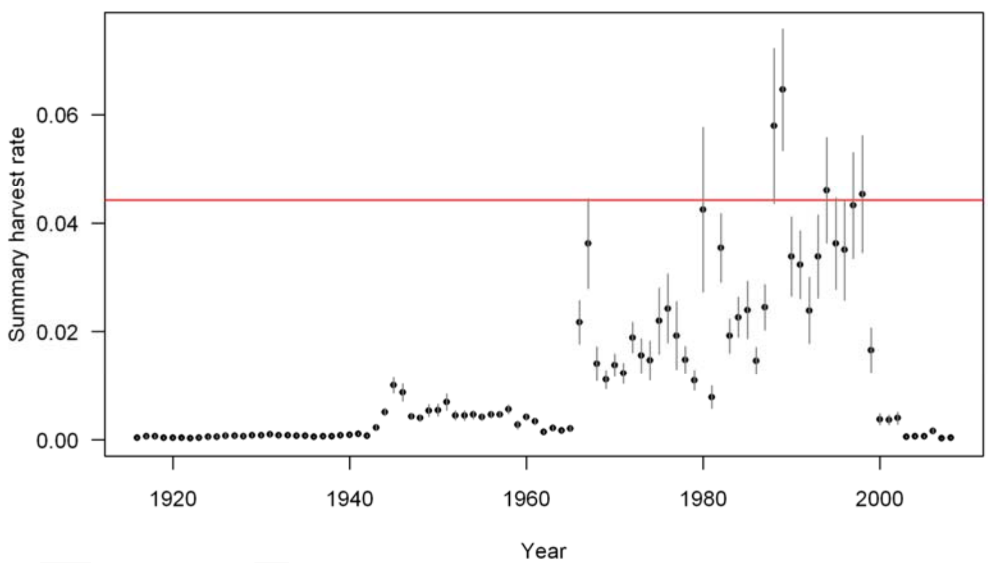

Figure e. Time series of estimated summary harvest rate (total catch divided by age 2 and older biomass) for the base case model (round points) with approximate 95% asymptotic confidence intervals (grey lines). The red line is the harvest rate at the overfishing proxy using $SPR_{50\%}$.

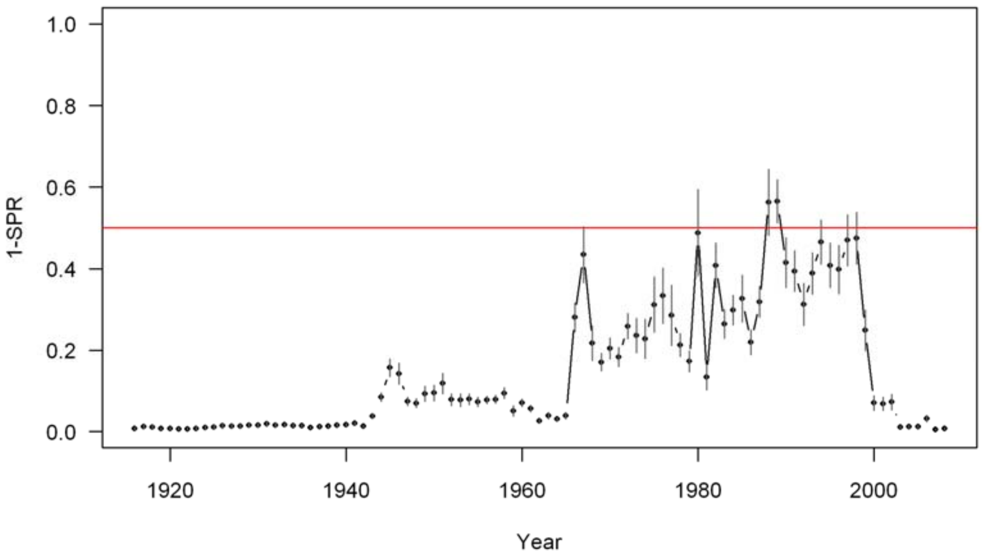

Figure f. Estimated spawning potential ratio (SPR) from the base case model with approximate 95% asymptotic confidence intervals. One minus SPR is plotted so that higher exploitation rates occur on the upper portion of the y-axis. The management target is plotted as a red horizontal line and values above this reflect harvests in excess of the overfishing proxy based on $SPR_{50\%}$.

Management performance

Greenstriped rockfish are currently managed as part of the minor shelf rockfish mixed-species group and have never been managed with a species-specific OY or ABC. Exploitation rates, on greenstriped rockfish in particular, have rarely exceeded the *MSY* proxy levels and the base case model did not predict that the stock has ever fallen below the target biomass defined as 40% of unfished spawning output. Recently, the exploitation rates have fallen drastically due to management measures implemented to reduce the impacts of fishing on other species of rockfish.

Table f. Recent trend in total catch and commercial landings (mt) relative to management guidelines.

Year	ABC (mt)	OY (mt)	Commercial Landings (mt)	Recreational Landings (mt)	Estimated[1] Total Catch (mt)
1999	—	—	59.0	11.0	393.1
2000	—	—	11.2	9.5	90.4
2001	—	—	13.6	6.6	90.7
2002	—	—	17.7	1.4	101.8
2003	—	—	2.7	0.3	14.6
2004	—	—	3.0	0.7	16.8
2005	—	—	2.9	1.6	16.7
2006	—	—	7.6	1.0	48.2
2007	—	—	1.0	1.3	7.3
2008	—	—	1.7	1.7	11.0

[1] Total annual catches reflect the commercial landings plus the model estimated discarded biomass, as well as recreational landings.

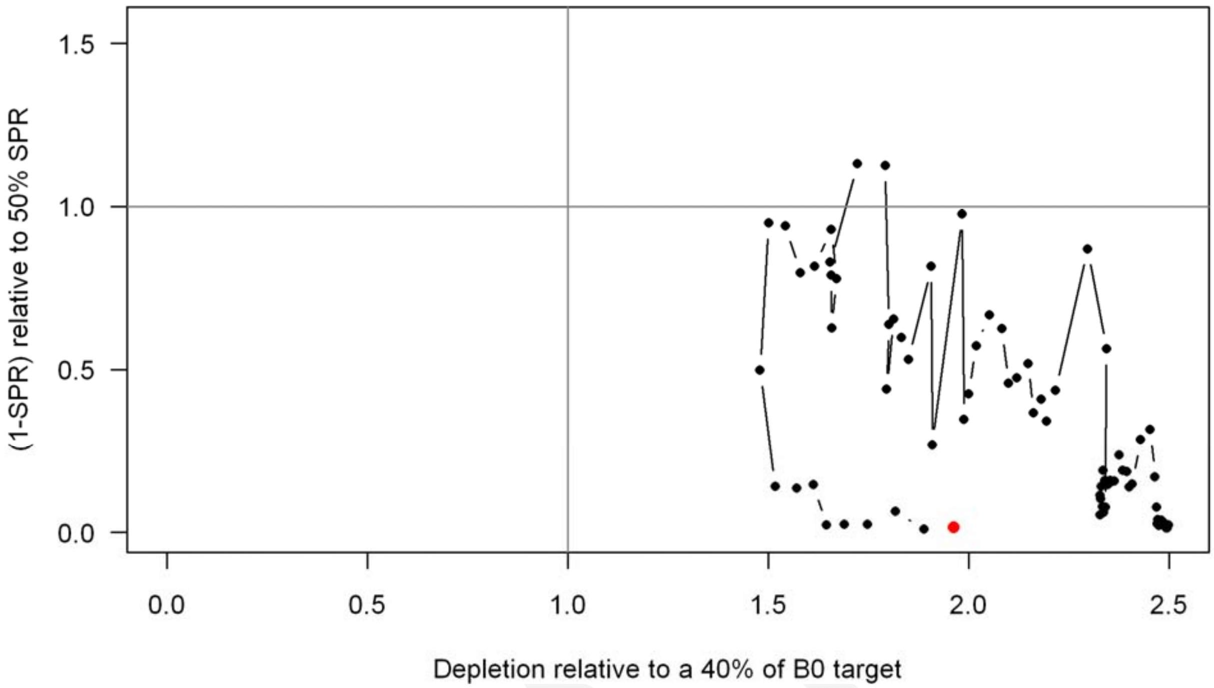

Figure g. Phase plot of estimated relative (1-*SPR*) vs. relative spawning biomass for the base case model. The relative (1-*SPR*) is (1-*SPR*) divided by 0.5 (the harvest rate limit). Relative depletion is the annual spawning output divided by the spawning output corresponding to 40% of the unfished spawning output. The red point indicates the current year (2008).

Unresolved problems and major uncertainties

The base case assessment model for greenstriped rockfish was developed to balance parsimony and realism with the goal of estimating a biomass trajectory for the population of greenstriped rockfish on the outer west coast of the United States. The model contained many assumptions to achieve parsimony and used many sources of data to estimate reality, but there will always be unresolved problems as well as uncertainty in the estimates.

The information in the model on discarding practices came from West Coast Groundfish Observer data collected since 2002 and the historical discarding practices are uncertain. Data are available from a discarding study in the mid-1980's, but due to a small number of samples and unexpected patterns, the data were not included in the model. However, the fraction of the catch that was discarded was included as an axis of uncertainty for the states of nature to provide an insight into the overall uncertainty.

An assumption that affected the estimated stock status was the value of natural mortality. This parameter was fixed in the base model at a value determined from otoliths collected in recent years during the NWFSC groundfish surveys. Changes to this parameter resulted in greater changes to the estimated depletion than any other factor for which model sensitivity was tested. The model with all of the data estimated natural mortality at a lower value than the fixed value of 0.08, and predicted a more depleted stock. As with the base model, though, recent exploitation rates were low and an increasing trend was predicted such that the stock status was forecasted to likely be above the target level within 2 years.

Natural mortality was also included as an axis of uncertainty in the states of nature to characterize this variability in the level of depletion.

One difficulty in the base case assessment was that the estimated length-based selectivity for some fleets showed an increasing selectivity up to the largest size modeled. There may be explanations for why a fleet would show this selectivity pattern for greenstriped rockfish, but the base case model forced the selectivity to reach its peak just before the largest length class modeled. Initial sensitivity analyses to this assumption showed that although the fit to the length frequency data changed, the consequences of bounding selectivity had little effect on the interpretation of current stock status.

An additional uncertainty in the base case model included the accuracy of the reconstructed landings time series. Sensitivity analyses to doubling and halving the landings scaled the population up and down, respectively, but did not change the estimates of stock depletion. However, increasing or decreasing the historical landings resulted in higher or lower predicted potential yields, respectively.

Approximate asymptotic confidence intervals were used to show uncertainty in the estimated parameters of the base model. Natural mortality and the fraction discarded were chosen to characterize states of nature to provide an indication of the overall uncertainty in the model. The base case model showed wide confidence intervals around spawning output throughout the time series, and estimated that depletion has been somewhat uncertain over the last decade. The range of the states of nature resulted in even wider confidence intervals around the estimated parameters, indicating that there is a considerable amount of uncertainty in model. In spite of these issues and uncertainties, it is apparent is that the recent trend in the population is likely increasing, some strong recruitment has occurred within the last 20 years, and the stock is unlikely to be at risk given the current catch levels.

Forecasts

Forecasts and projections of the greenstriped rockfish population up to the year 2020 were constructed under the assumption that future catches would never reach the calculated OY. The average catch from 2007 and 2008 was used for the catches in 2009 and 2010 and allocated to the fisheries based on the average proportion of these catches. The landings and distribution of catches among fleets for 2011 and beyond were assumed equal to the average of the fleet specific landings from 2000–2003. This forecast table is meant to be representative of the status quo, yet still be conservative since landings in 2000–2003 were higher than more recent landings, although not as high as landings observed in the 1980's and 1990's.

Forecasting with these status quo catches resulted in stock and ABC increases over time.

Table g: Projection of potential ABC, OY, landings and catch, summary biomass (age 2 and older), spawning biomass, and depletion for the base case model based on the status quo. Landings in 2009 and 2010 are a total of 9 mt, determined from the average of the 2007 and 2008 landings for each fleet and allocated to each fleet based on the proportion caught in 2007 and 2008. Forecasted landings after 2010 are 20 mt (the average of 2000–2003) and allocated to each fleet based on the average distribution in 2000–2003.

Year	ABC (mt)	OY (mt)	Total Catch (mt)	Landings (mt)	Age 2+ biomass (mt)	Spawning output (million eggs)	Depletion (%)
2009	1,466	1,466	9	3	31,806	6,248	81.4
2010	1,512	1,512	9	3	32,480	6,458	84.1
2011	1,554	1,554	94	20	33,064	6,652	86.6
2012	1,586	1,586	93	20	33,484	6,799	88.5
2013	1,612	1,612	92	20	33,830	6,918	90.1
2014	1,633	1,633	91	20	34,112	7,011	91.3
2015	1,650	1,650	90	20	34,338	7,086	92.3
2016	1,663	1,663	89	20	34,518	7,145	93.0
2017	1,673	1,673	89	20	34,659	7,193	93.7
2018	1,681	1,681	88	20	34,768	7,231	94.2
2019	1,688	1,688	87	20	34,851	7,261	94.5
2020	1,693	1,693	87	20	34,913	7,285	94.9

[1] The ABC here is the calculated total catch determined by F_{SPR}.

Decision table

Table h. Decision table of 12-year projections beginning in 2011 for alternate states of nature based on two axes of uncertainty. Columns range over natural mortality and rows range over the fraction discarded. There are no probabilities associated with these states of nature other than the base model (center square) is the most probable scenario.

				State of nature (natural mortality)					
				M=0.06		M=0.08		M=0.10	
		Year	Landed catch (mt)	Depletion (%)	Spawning output (million)	Depletion (%)	Spawning output (million)	Depletion (%)	Spawning output (million)
State of nature (fraction discarded)	Low fraction discarded	2011	20	66.7	1,453	89.1	3,129	107.0	10,496
		2012	20	68.5	1,493	90.8	3,186	108.0	10,591
		2013	20	70.1	1,528	92.0	3,231	108.6	10,646
		2014	20	71.5	1,559	93.0	3,266	108.8	10,671
		2015	20	72.8	1,586	93.8	3,293	108.8	10,673

Research and data needs

There are four topics for which additional research would greatly improve the assessment of greenstriped rockfish.

1. **Landings:** improving certainty of the commercial and recreational landings would result in a better estimate of the total yield as well as an improved understanding of the population dynamics of greenstriped rockfish. The landings have been determined in the best possible manner given the time constraints of this assessment, but there is still uncertainty in the catch reconstruction and in recent landings. The state of California has produced reconstructed and current landings for many species, which have been accepted as the best possible information. However, a similar reconstruction is not available for Oregon and Washington landings, although such a product is of interest to fisheries managers and stock assessors. Additionally, some errors were found in the PacFIN database of recent landings during the current catch reconstruction and are being reconciled. Further error checking may be worthwhile for greenstriped rockfish as well as other species.
2. **Discards:** discarding at sea is common practice for greenstriped rockfish and the levels of historical discards are poorly known due to a lack of data. The West Coast Groundfish Observer Program (WCGOP) has contributed greatly to the understanding of discard rates and size compositions. However, it would be useful to review what information is available from the past to understand discarding practices and to determine how reliable that information is.
3. **Natural mortality:** the value for natural mortality in the base case model was fixed at 0.08, which was determined from the maximum age observed in recent survey data. Other published estimates of natural mortality for greenstriped rockfish range from 0.09 to 0.149 and are based on maximum age, catch curve analyses, and gonadosomatic indices. The data used in the base model supported a natural mortality near 0.065. All of these estimates of natural mortality are uncertain and given the correlation between natural mortality and stock status, it would be useful to have a better understanding of the plausible range of values.
4. **Stock structure:** there is some evidence that the life history of greenstriped rockfish in Southern California may be different from greenstriped rockfish in Northern areas. Understanding and quantifying the differences in length, weight, ages, maturity, and fecundity (as well as the number of broods per year) would be helpful to determine if the model should incorporate these differences.

Table i. Summary of recent trends in estimated greenstriped rockfish exploitation and stock levels from the base case model.

	1999	2000	2001	2002	2003	2004	2005	2006	2007	2008	2009

1 Introduction

Greenstriped rockfish (*Sebastes elongatus*) are a small rockfish (maximum size near 45 cm) named after their slim shape and obvious green stripes. They have also been called strawberry rockfish, watermelons, poinsettas, serena, and reina, and have had the scientific names *Sebastodes elongatus* and *Pteropodus elongatus* (Love et al. 2002, Shaw & Gunderson 2006). This species is often observed in commercial and recreational fisheries, but due to its small size and reputed short shelf life, they are typically discarded (Love et al. 2002, Shaw & Gunderson 2006).

This assessment is focused on the population of greenstriped rockfish on the outer West Coast of the United States. This includes waters off of California, Oregon, and Washington, but does not include Puget Sound or Canadian waters.

1.1 Distribution and stock structure

Greenstriped rockfish can be found in abundance from British Columbia to Northern Baja California, but range from Chirikof Island in the Aleutian Islands (Gulf of Alaska) to central Baja California (Love et al 2002). Adults may inhabit depths between 12 and 500 meters, but are more commonly found between 100 and 250 m, and adults typically move to deeper water as they mature (Love et al 2002, Shaw & Gunderson 2006). This species of rockfish is found with other congeners or alone in a wide range of habitats, which include rocky outcroppings. However, unlike most other species of rockfish they seem to prefer mud or sand bottoms (Love et al 2002, Shaw & Gunderson 2006).

A genetic study of greenstriped rockfish was recently undertaken by Jon Hess (pers comm., NWFSC, NOAA) to study the stock structure of greenstriped rockfish. The genetic variability was remarkably low and showed less variability than most other rockfish species, even when including samples from Puget Sound. However, latitudinal differences in life-history traits have been observed, which are discussed in more detail below.

1.2 Life history and ecosystem interactions

Typical of other species of the genus *Sebastes*, greenstriped rockfish are long-lived with maximum observed ages greater than 50 years (Love et al 2002). Females grow larger than males, but typically mature at about the same length, between 18 and 24 cm, which corresponds to an age between 7 and 10 years. A latitudinal cline in maturity has been observed with fish maturing at a smaller size in the southern areas (Wyllie Echeverria 1987).

Greenstriped rockfish give birth to live young and the fecundity of a 0.5 kilogram female is on average around 200,000 eggs (Dick 2009), although a wide range of fecundity has been reported (Love et al 2002). The reproductive development of males and females is slightly offset with mating occurring in December through February, fertilization occurring in early spring, and parturition occurring about a month later in late spring (Shaw & Gunderson 2006). Females have the ability to store sperm during the time between copulation and fertilization to ensure the availability of spermatozoa when oocyte maturation has occurred (Shaw & Gunderson 2006). However, in southern latitudes, parturition may occur from January to July and females in Southern California may release two broods during this time (Love et al 2002). Juveniles settle to the bottom at about 3 cm in length in autumn and are commonly found along the interface of fine sand and clay. Maturing adults typically move to deeper water (Love et al 2002).

A wide range of prey items make up the diet of greenstriped rockfish. They will feed from the water column or the bottom on such things as fish, krill, shrimps, copepods, amphipods, and squid. Other fish species may prey on greenstriped rockfish. They have been found in the stomachs of king salmon (Love et al 2002) and reefs with small numbers of piscivorous rockfish had much higher numbers of small rockfish, such as greenstriped rockfish, than reefs with high numbers of piscivorous rockfish (PFMC and NMFS 2006).

1.3 Historical and current fishery

Greenstriped rockfish are a bycatch species with little market value mainly due to its small size, and it has been reported that fillets from this species have a short shelf life (Love et al 2002). As a result, there has not been a long-term directed fishery for this species. However, greenstriped rockfish are often observed in landings from various fisheries, although in small proportions. The most common occurrence of greenstriped rockfish is in trawl fisheries, but they are often caught in recreational fisheries, especially when fishing vessels drift off of the rocks.

After many attempts to start trawl fisheries off the west coast of the United States in the late 1800's, the availability of the otter trawl and the diesel engine in the mid-1920's helped the trawl fisheries expand (Douglas 1998). The trawl fisheries really became established during World War II when demand increased for shark livers and bottomfish. A mink food fishery also developed during World War II (Jones & Harry 1961). Foreign fleets began fishing for rockfish in the mid 1960's until the EEZ was implemented in 1977 (Rogers 2003). Since 1977, landings of rockfish were high until management restrictions were implemented in 2000.

Greenstriped rockfish are often caught in bottom trawls, but a long-term directed fishery has not occurred for this species and historical discarding rates are not well known. There have been many reports of greenstriped rockfish occurring in various fisheries, even as early as 1884 (Goode 1884). Fishermen report that greenstriped rockfish are ubiquitous, but are rarely if ever caught in great numbers. More detailed information of the fisheries by state is given in Section 2.1.1. when discussing the reconstructed landings.

1.4 Management history

Greenstriped rockfish outside of Puget Sound have not previously been assessed on the US west coast, and have not had individually specified ABC's or OY's. Beginning in 1983, the species was managed under ABC's and OY's for the Other Rockfish category, and per trip or cumulative limits for the *Sebastes* Complex. Since 2000, greenstriped rockfish have been included in the Minor Shelf Rockfish assemblage, with regard to OY's and cumulative limits. As late as 1998, cumulative limits for the *Sebastes* Complex were as high as 40,000 lb per two months. By 2000, landings of greenstriped rockfish were constrained by shelf rockfish limits of 300–1,000 lb per month.

1.5 Fisheries in Canada and Alaska

The exact details of fisheries in Canada and Alaska are unknown, but greenstriped rockfish is unlikely to have been targeted in either of these fisheries. Greenstriped rockfish are managed as part of a mixed-species category in Alaska, and details of Canada's fisheries for greenstriped rockfish are unknown at this time.

2 Data

The following sources of data were used in building this assessment:

1. Fishery dependent data:
   a. landings by state from various sources,
   b. lengths from port sampling,
   c. discard lengths from at-sea observations,
   d. discard mortality estimates from at-sea observations,
   e. discard mean weights from at-sea observations

2. Fishery independent data:
   a. relative abundance indices from the Triennial and NWFSC surveys,
   b. length frequencies from both surveys, and
   c. conditional age-at-length frequencies from the NWFSC survey.

The data sources and years of availability are summarized in Table 1 and Table 2. Estimates of biological relationships, such as fecundity, maturity, length-weight and length-at-age relationships, were either determined from the published literature or from the survey data.

2.1 Fishery dependent data

Greenstriped rockfish are not often targeted by any fishery, thus discards as well as landings are an important component of the total fishing mortality on the stock. Landings from the Pacific Fishery Information Network (PacFIN, Pacific States Marine Fisheries Commission) show that the majority of landings of greenstriped rockfish have occurred in the trawl fishery, but a small proportion has been seen in the hook and line, net, and recreational fisheries. An even smaller amount has been observed in the shrimp trawl fishery, but is not as substantial as the other fisheries. Table 3 shows the proportion of greenstriped rockfish landings from PacFIN reported for each gear type.

2.1.1 Historical catch reconstruction

Species composition sampling is used to determine the landings of greenstriped rockfish from the general market categories in which they were recorded. PacFIN serves as a clearinghouse for commercial landings data since the early 1980's, and before that, landings for each state were reconstructed using the assumptions described below.

2.1.1.1 Washington

Historical commercial landings of two gear types, trawl and longline, were reconstructed for greenstriped rockfish landed in Washington. No evidence of recreational landings was found and it was assumed that they constitute a negligible amount of the total mortality.

Washington's trawl fishery

Washington's coastal trawl fishery began in the early 1930's off of Cape Flattery and landings increased substantially by the 1940's (Tagart & Kimura 1982). In 1946, rockfish landings experienced a sharp decline, presumably in response to weakened market demand following World War II. After a period of steady landings of around 5,000 metric tons (mt) annually, landings rapidly increased in the 1960's, followed by a decline in the mid-1970's and a further increase in the late 1970's. Before the mid-1970's, most of the rockfish and POP catch came from Canadian waters. The implementation of the EEZ brought higher landings in WA from US waters and US landings rose to over 10,000 mt up until 1983. After that time, rockfish landings declined to around a 500 mt in the late 1990's.

Most of the rockfish landed in the Washington trawl fishery were historically categorized into two market categories: "Pacific Ocean Perch" (POP) or "other rockfish" (URCK). Additional market categories were added in the mid-1980's, but only POP and URCK were used to determine the landings of greenstriped rockfish. Figure 2 shows the amount landed in each category before proportioning out the species.

WDF began sampling rockfish landings for species composition in November 1966 and Tagart & Kimura (1982) reported the estimated landings of various rockfish species, including greenstriped rockfish when it was observed, for the years 1966–1979. Greenstriped rockfish were not often reported and the highest proportion of greenstriped observed in POP and other rockfish landings was 0.0012 in 1977.

Theresa Tsou (pers comm., WDFW) provided species composition data from landings for 1967–2009. From these data, the years 1968–1994 were used to calculate average proportions of greenstriped rockfish in the UPOP and URCK market categories from which greenstriped rockfish landings were calculated using historical landings. These years were chosen because landings in these two market categories were consistently sampled for species compositions. The average proportion of greenstriped in UPOP landings between 1968–1994 was 0.000840 and the average proportion of greenstriped in URCK landings between 1968–1994 was 0.000864. The average proportion of greenstriped in the sum of UPOP and URCK landings between 1968–1994 was 0.000860. The proportion of greenstriped rockfish in the URCK category substantially increased after 1994, when additional market categories were available (Figure 3).

A database of historical Washington landings (Greg Lippert, WDFW, pers comm.) contained landings from Puget Sound and was used to calculate a proportion of the US and Canadian rockfish landings (without POP) that were not from Puget Sound. POP was excluded because it was assumed all POP were caught outside of Puget Sound. From 1949 to 1969, the proportion of landings outside of Puget Sound were greater than 0.95 (Table 4). These estimates agreed closely with estimates calculated using data from research reports on the Washington trawl fishery (Holmberg et al. 1962, Holmberg et al. 1967). Prior to 1949, when POP and rockfish landings were not separated, it was assumed that 99% of the landings came from outside of Puget Sound.

Catches from US waters were derived from Forrester (1967) and Tagart & Kimura (1982). Forrester (1967) reports the separate US vessel and Canadian vessel catches of POP and rockfish for PSMFC areas near British Columbia in the years 1954–1965. Catches south of PSMFC area 3B were not reported, but it is likely that a large proportion of the catch south of 3B came from Oregon vessels. The proportion of Washington landings caught in US waters was calculated as the ratio between the US vessel catch in area 3B and the total catch by US vessels. It is unclear if area 3C as used by Forrester (1967) includes a portion of US waters. Tagart & Kimura (1982) report catches by PSMFC area for the years 1966–1979 and there was little catch in the areas south of 3B.

Historical landings of greenstriped rockfish were determined as follows for the periods shown.

< 1930: Assumed no catch of greenstriped rockfish.

1930–1934: The Pacific Fisherman Yearbook rockfish landings were used and it was assumed that all landings were caught in US waters. It was assumed that 1% of the total catch was from

Puget Sound, thus was removed (1% was used because POP could have been aggregated with rockfish). The proportion of greenstriped rockfish used was 0.00086.

1935–1941: Dept. of Fisheries WA reported landings (1955 Commercial Fishing Statistics, WA Dept Fisheries) were used instead of the Pacific Fisherman Yearbook. The sources are quite different, and the Pacific Fisherman Yearbook states it is reporting foodfish only (there was a substantial mink food fishery). I used 0.00086 as the proportion of greenstriped rockfish in the landings since POP landings were not separated. For US catches, I assumed a linear decrease from 100% of the catches in US waters in 1934 to 17.65% catches from US waters in 1946 (calculated from the average percentage of catch of rockfish+POP in US waters between 1954-1974, see Forrester 1967 and Tagart & Kimura 1982). However, it is likely that fishing vessels stayed closer to home during the war years. Puget Sound catches were assumed to comprise 1% of the total landings and were removed.

1942–1948: Fish & Wildlife Service reports (Pacific Coast Fisheries) were used to determine rockfish landings instead of the Pacific Fisherman Yearbook or Dept of Fisheries WA reported landings (1955 Commercial Fishing Statistics, WA Dept Fisheries). The Pacific Fisherman Yearbook was typically less than the other two sources, which were not much different. The value 0.00086 was used as the proportion of greenstriped rockfish in the landings. For US catches, the linear decrease to 17.65%, as above, was used and it was furthermore assumed that 17.65% of the catch came from US waters between 1946–1948. It was also assumed that 1% of the total catch came from Puget Sound.

1949–1951: A database of Washington landings provided by Greg Lippert (pers comm., WDFW) was used to determine landings of combined rockfish and POP for these years. The value 0.00086 was used as the proportion of greenstriped rockfish in the landings. For US catches, it was furthermore assumed that 17.65% of the catch came from US waters between 1946–1948. The proportion of landings that occurred outside of Puget Sound were determined from the database and ranged between 99.2% and 99.7% for these years.

1952–1965: The database of Washington landings was used for separated rockfish and POP landings. Values of 0.000864 and 0.00084 were used as the proportion of greenstriped rockfish in the other rockfish and POP categories, respectively. The proportion of landings from US waters were determined for the years 1954–1965 using data reported by Forrester (1967) and ranged from 3.1–40.2% for rockfish landings and 9.9–46.4% for POP landings. The proportions of rockfish and POP landings from US waters for the years 1952–1953 were 0.215 and 0.143, respectively, which were the averages of the proportions from US waters in the years 1954–1974 (before the proportion of landings caught in US waters began steadily increasing). Tagart & Kimura 1982 report that prior to 1968, POP landings were invariably 100% Pacific Ocean perch and species composition does not need to be applied. However, after discussions with Fish & Wildlife Biologists and noticing that greenstriped rockfish have been landed with POP catches after 1968, it was considered unreasonable given the large catch of POP prior to 1968 that no greenstriped rockfish would have been caught or landed in this category.

1966–1979: Landings of POP and rockfish were obtained from Tagart & Kimura (1982) for US waters only. Proportion of 0.00084 and 0.001097 were applied to the POP and rockfish landings, respectively, to obtain the landings of greenstriped rockfish. Tagart & Kimura report area specific landings, thus catches from US waters were calculated directly. The estimated landings of greenstriped rockfish increase rapidly near the end of this series, which is due to the domestic fleet taking more catch from US waters.

1980–1980: The estimate of greenstriped rockfish landings for this single year was obtained from a spreadsheet supplied to me by Vlada Gertsvena (pers comm., NWFSC, NOAA) which was supplied to her by Jack Tagart. This spreadsheet is called ROCKFI~2.xls and has the catch of greenstriped rockfish listed. Therefore, no proportions needed to be applied.

1980–2006: The estimates of greenstriped rockfish landings were obtained from PacFIN (extraction on May 11, 2009). These landings matched very closely with the spreadsheet called ROCKFI~2.xls supplied by Jack Tagart by way of Vladlena Gertseva (pers comm., NWFSC, NOAA).

The historical landings of greenstriped rockfish in the Washington trawl fishery were low until the late 1970's when the EEZ was implemented and US vessels fished more often in US waters. The various data sources are mostly in close agreement (Figure 4).

Washington longline fishery

The longline fishery contributes a small amount of greenstriped rockfish landings when compared to the trawl fishery. However, total rockfish landings were available from the Washington landings database for longline gear between 1949 and 1969, and from the Washington fish ticket data between 1970 and 1980 (pers comm., Theresa Tsou, WDFW).

Jack Tagart provided Vlada Gertsvena (NWFSC, NOAA Fisheries) with a spreadsheet containing species composition data for longline gear (called LLSPP~2.xls). Using these data from the period 1994–1998, the proportion of greenstriped rockfish observed in longline landings was 0.001863, and greenstriped rockfish were observed in three of the five years. This value is quite a bit higher than the proportion of greenstriped rockfish observed in Washington trawl landings, which may be due to the small number of years and the highest proportion of greenstriped rockfish observed in 1997 at 0.0073.

Longline landings of greenstriped rockfish have always been a small proportion of the total landings when compared to the trawl fishery (Figure 4).

Washington recreational landings

Historical recreational landings of greenstriped rockfish from Washington were not available. The mortality of recreational fisheries on greenstriped rockfish in Washington is uncertain, but it is likely to be a small proportion of the total mortality.

2.1.1.2 Oregon

Oregon's trawl fishery

Most of the rockfish landed from the Oregon trawl fishery were historically categorized into two market categories: "Pacific Ocean Perch" (POP) and "other rockfish" (UNRK). Both groups contained many species of *Sebastes* and *Sebastolobus* (Douglas 1998). In 1984, new market categories were created for widow rockfish (*Sebastes entomelas*), thornyhead rockfish (*Sebastolobus sp.*), and small rockfish. A yellowtail rockfish (*Sebastes flavidus*) category was added in 1985.

Landings have been sampled since 1962 to determine species composition in the market categories. Prior to about 1991, this consisted of taking random samples from the landings. Since then, cluster sampling has been employed to determine the species composition of the landings. Species compositions determined from Oregon trawl landings between 1963 and 1993 were used to determine the proportion of greenstriped rockfish in the various market categories. The historical reconstruction of the trawl fishery landings of greenstriped rockfish is given below. No reconstruction was attempted for other fisheries in Oregon.

< 1928: Landings of greenstriped rockfish were assumed to be minimal and set equal to zero for this time period.

1928–1949: Cleaver (1951) reported the landings of rockfish caught by trawl and longline gear. Trawl catches mainly consisted of black rockfish (*Sebastes melanops*), yellowtail rockfish (*S. flavidus*), canary rockfish (*S. pinniger*), and Pacific ocean perch (*S. alutus*), while the longline fishery primarily caught yelloweye rockfish (*S. ruberrimus*). Pacific ocean perch were first fished regularly in 1945 and recorded separately in mid-1949. The proportion of greenstriped applied to the total rockfish landings from 1928–1949 was calculated by dividing the total expanded sample weight of greenstriped rockfish by the total landed weight of the sampled landings for Pacific ocean perch and rockfish between 1963 and 1983 (see Douglas 1998). The estimated proportion was 0.003526. Scrapfish or landings for minkfood were first recorded in 1941 and increased greatly in the late 1940's. Cleaver (1951) reported that approximately 12% of these landings were rockfish. Therefore, the same proportion as above was applied to 12% of the scrapfish (minkfood) landings, which amounts to about 317 mt of greenstriped in 1948.

1950–1953: Smith (1956) reported Pacific ocean perch and other rockfish landings for this period as well as scrapfish landings. Separate proportions of greenstriped in the POP and UNRK categories were calculated using data from 1963–1983 (Douglas 1998) and applied to the landings. Scrapfish was assumed to be composed of 12% rockfish except for in 1953 when Jones & Harry reported scrapfish to be composed of 13% rockfish (scrapfish landings in 1953 also came from Jones & Harry 1961). The proportion of greenstriped rockfish in the UNRK category was applied to these percentages of the scrapfish landings to determine the weight of the greenstriped rockfish landed. The proportion of greenstriped rockfish in the POP and UNRK categories was estimated at 0.00136 and 0.004258, respectively.

1954–1955: Pacific ocean perch and rockfish landings were compiled from Pacific Coast States Fisheries reports (C.F.S. No. 1366 and C.F.S. No. 1580). The same proportions for greenstriped rockfish used in the POP and UNRK categories for the data from 1950–1953 were used here. Scrapfish landings came from Jones & Harry (1961) as well as the percentage of rockfish in the scrapfish landings (1954=23% and 1955=15%). The proportion of greenstriped rockfish in the rockfish category was applied to the estimated rockfish weight in the scrapfish landings.

1956–1962: The publication called "The Big Book" was used for landings of Pacific ocean perch and rockfish landings between 1956 and 1962. There were two categories for rockfish: one called "other rockfish" and the other called "rockfish". The "other rockfish" category listed commercial as its use while the use for the "rockfish" category was labeled as animal food. These categories were treated the same and summed before applying the rockfish proportion for greenstriped landings as was done for 1950–1953 landings. The proportion of greenstriped in the POP category was used as above. Scrapfish landings were reported by Jones & Harry (1961) for the years 1956-1957 and by Niska (1969) for the years 1958-1962. The proportion of rockfish in the scrapfish landings from 1956 was reported by Jones & Harry (1961) as 0.30, and the proportions for 1958–1962 were reported by Niska (1969).

The proportion for 1957 was unavailable, thus the average of the proportions of rockfish landed in scrapfish landings for the years 1958–1965 (Niska 1969) was used (0.094).

1963–1983: Douglas (1998) reported expanded weights of greenstriped rockfish in the POP and UNRK landings by PSMFC area. These weights were summed over all PSMFC areas to find the weight of greenstriped rockfish for each year. The proportion of greenstriped rockfish in each category was calculated by dividing the weight of sampled greenstriped rockfish by the total weight of the samples. The total landings of greenstriped in each year was calculated as the year specific proportion of greenstriped in the market category times the yearly total landings in the market category, summed over POP and UNRK market categories. Scrapfish landings as well as the proportion of rockfish in these landings for the years 1963–1965 were taken from Niska (1969). The scrapfish landings for the years 1966–1977 were calculated by adding the animal food category landings for PSMFC areas 2A, 2B, 2C, and 3A in the Big Book. The Big Book scrapfish landings for the years 1956–1962 were similar to those reported by Niska (1969). The average of the proportions of rockfish landed in scrapfish landings for the years 1958–1965 (Niska 1969) was used to estimate the weight of rockfish (0.094). It was assumed that there were no scrapfish landings after 1977.

1984–1986: In 1984 widow rockfish (*Sebastes entomelas*) and small rockfish market categories were introduced and the year specific proportions of greenstriped rockfish were calculated for these two market categories. The market categories for yellowtail rockfish (*Sebastes flavidus*) and thornyheads (*Sebastolobus sp.*) were not used in this reconstruction as they observed a very small proportion of greenstriped rockfish. The year specific proportions were multiplied by the yearly landings in each market category, and then summed over market categories to obtain the total landings of greenstriped rockfish.

Figure 5 shows the reconstructed landings series and how it is similar to the recent landings from PacFIN. Landings were generally small until the 1980's. Figure 6 shows the estimated landings for each market category used in the reconstruction. Most of the landings come from the general rockfish categories, but there is one year with a large amout of greenstriped rockfish estimated to have been landed in the widow category and may be the result of an error or limited sampling.

Oregon recreational landings

Oregon Department of Fish & Wildlife (ODFW) has collected recreational landings for the period 1973–1992, but has reported only numbers of total rockfish for the years 1973–1978 and numbers for each species between 1979–1992. Converting these numbers to weight would require an estimate of average weight and a species proportion for the years reporting only total numbers, resulting in extra uncertainty. Therefore, given the small number of recreational landings, a historical reconstruction of Oregon's recreational fisheries prior to 1979 was not done. The landings from 1979 to present are described in section 2.1.2.2.

2.1.1.3 California

California's commercial fisheries

Historical commercial fishery landings were obtained from the California Cooperative Groundfish Survey, also know as CALCOM (pers comm., Don Pearson, NMFS). Reconstructed landings for the gear categories trawl (TWL), other (OTH), and unknown (UNK) were provided for 1916–1968. All trawl landings were used to reconstruct the trawl fishery. The landings for the other (OTH) gear pertain to nets, diving, and spears (CalCOM documentation) and there were considerable landings in the early period (Figure 7). The gear type “OTH” showed an increase landings in later years. Because the total mortality of both of these gears appeared to be substantial, the landings were added together to create a non-trawl gear type.

California’s recreational fisheries

Reconstructed landings for recreational fisheries were provided by John Field (pers comm., SWFSC, NOAA; June 26, 2009) for the years 1928–1980. These landings were recently revised and are slightly less than the recreational landings downloaded from CalCOM (Figure 8).

2.1.2 Recent commercial and recreational landings

An extraction on May 11, 2009 from the PacFIN system, administered by the Pacific States Fishery Management Council, was used to determine the landings of greenstriped rockfish for the recent time period from 1981–2008. Recreational landings for 1980–2008 were downloaded from the RecFIN website (Pacific State Marine Fisheries Commission, 2009) and included estimated retained catch as well as estimated discarded dead catch. Historical and recent landings are reported in Table 5 and Table 6.

2.1.2.1 Washington

Washington’s commercial landings

All landings of greenstriped rockfish in the PacFIN database were listed under the species group GSRK and trawl gear (TWL). Landings reconstructed from Tagart & Kimura (1982) match closely with the PacFIN landings except for two years in the early 1990’s where the PacFIN landings were quite a bit lower (Figure 4). In general, Washington landings increased throughout the 1980’s, declined significantly in the late 1990’s, and since 2005, have been very small. The trawl landings of greenstriped rockfish in Washington have been a small proportion of the total coastwide landings (Figure 9).

Washington’s recreational landings

The only year for which recreational landings were available in ocean only areas of Washington was 1981, and were small compared to recreational landings from Oregon and California.

2.1.2.2 Oregon

Oregon’s recent commercial landings

Landings since 1987 were available for Oregon commercial fisheries from the PacFIN system. No landings from Oregon before 1987 were reported in this extraction. All catches landed at Oregon ports were reported specifically as greenstriped rockfish (code GSRK), which were determined by applying species compositions to the landings in the shelf rockfish category (pers. comm.., Mark Karnowski, ODFW). Landings were listed by the gear types HKL (hook and line), TWL (trawl), and TWS (shrimp trawl). TWL landings comprised 92% of the total landings reported for these three gear types. The TWS landings made up 7% of the landings, but the landings reported in 1996 were 86.9% of the landings reported for all years of TWS (87.4 mt in 1996 and the average of other years was 1.0 mt). It is likely that this large amount in 1996 reported for TWS is the result of a recording error where yellowtail rockfish were accidentally listed as greenstriped rockfish (pers comm., Mark Karnowski, ODFW). Without the TWS landings, HKL landings comprised 1.1% of the total TWL and HKL landings for all years from 1987 to 2008.

Recent trawl landings of greenstriped rockfish in Oregon were high in the late 1980's and throughout the 1990's. Landings greatly decreased in 2000 and have remained low (averaged 2,725 tons). As with Washington landings, PacFIN catches matched closely with overlapping historical reconstruction, except in the early 1990's when PacFIN landings were lower than the reconstructed landings (Figure 5). Oregon trawl landings of greenstriped rockfish have been a major component of the coastwide trawl landings (Figure 9).

Landings of greenstriped rockfish from gears other than trawl gear were a small proportion of the total coastwide other-gear landings and most landings in Oregon occurred in the 1990's (Figure 11).

Oregon's recent recreational landings and discards

RecFIN (Pacific State Marine Fisheries Commission, 2009) did not have recreational landings available for all years since 1979, but numbers of fish were available from ODFW (pers comm., Mark Karnowski, ODFW). Therefore, an average weight of all recreational landings was determined using the numbers of fish provided by ODFW and the weights provided by RecFIN. The numbers of fish provided by ODFW were then converted to weight by multiplying by this average weight, resulting in estimates of the recreational landings for years missing from the RecFIN data.

Oregon recreational landings of greenstriped rockfish have averaged around 500 kg per year over this period, and have been low compared to recreational landings from California (Figure 10).

2.1.2.3 California

California's recent commercial landings

Estimated landings from 1969–2008 were provided for California from CalCOM (pers comm., Don Pearson, NOAA) and were determined from actual landings and species compositions. Five gear types were reported in these data: FPT refers to pots and traps, HKL is troll, hook and line, and longline, MDT refers to midwater trawls, NET is gillnets, and TWL refers to all bottom type trawls including bottomfish and shrimp gear. These gear types were summarized in trawl and other-gear categories. Trawl gear included any landings labeled TWL or MDT. Midwater trawls were included because some greenstriped rockfish appeared in this gear category and Oregon samples from the widow market category showed greenstriped, which likely contained some midwater trawling. The other-gear category included NET and HKL gear types. The FPT gear category showed a very small amount of landings and was not included.

The trawl landings of greenstriped rockfish in California were large prior to 1980, reduced but substantial in the 1980's and 1990's, and minimal since 2001 (averaging less than 1 ton per year). Figure 9 shows these landings relative to the three states. Landings from other gears were substantial in the 1970's and 1980's, increased in the 1990's, and reduced to a very small amount in the recent decade (Figure 11).

California's recent recreational catches

Recreational catches in California were extracted from RecFIN (Pacific State Marine Fisheries Commission, 2009) since 1981 and included estimated landed weight and estimated discarded dead weight for ocean only areas. A large amount of greenstriped rockfish were landed in the recreational fishery in the early 1980's, and then decreased, but remained substantial, in the 1990's. Landings have been very small since 2003, which coincides both with numerous management restrictions as well as a change from the Marine Recreational Fisheries Statistic Survey (MRFSS) to the California Recreational Fisheries Survey (CRFS).

2.1.3 Discards

Greenstriped rockfish have not had any significant market in the past and have likely been discarded at sea. Two sources of data were available with discard information. These included three years of data collected from Oregon vessels in the mid-1980's (Pikitch et al 1988; data obtained from John Wallace, NWFSC, NOAA) and recent data since 2002 collected as part of the West Coast groundfish observer program (WCGOP data obtained from Eliza Heery, NWFSC, NOAA).

The data used in the study by Pikitch et al (1988) contained retained and discarded weights of the catch for trawl fisheries targeting bottomfish, deepwater dover, near shore mixed species, or shrimp in the years 1985–1987. Lengths were taken from a small number of tows in 1986 and 1987. The ratio of the observed discards to the total observed catch for each year and strategy is shown in Table 7 and ranged from 0.23 to 0.62. The length frequencies showed a strong size selection to retain greenstriped rockfish larger than 29 cmwith none discarded above 30 cm (Figure 12). This size selective discarding resulted in large average weights for the retained portion of the catch with discards averaging close to 0.25 kg and retained catch averaging more than 0.41 kg (Table 8).

Landed and discarded mortality estimates, mean weights of discards, and length frequencies of discarded greenstriped rockfish were available from WCGOP data for the trawl, limited entry fixed gear (longline and pot), and shrimp fisheries. The shrimp fishery did not show any landed greenstriped rockfish in the years 2004, 2005, and 2007, but the WCGOP reported 6.44, 2.74, and 2.76 metric tons of discarded greenstriped rockfish in these years, respectively. These data were not used in this assessment. The discard rates (discard weight divided by total catch weight) for the trawl and fixed gear fisheries are shown in Table 9 and ranged from 0.78 to 0.98 for trawl fisheries north of 40° 10' N and from 0.90 to 1.0 for trawl fisheries south of 40° 10' N. Fixed gear fisheries showed very high discard rates greater than 0.98. All of these discard rates are much larger than the discard rates from the Pikitch et al (1988) data.

Length frequencies were estimated for the trawl fishery in Oregon and Washington combined, the trawl fishery in California, and the coastwide fixed gear fishery. Table 10 shows the number of samples available for years and gears with length data. The discard length frequencies from the WCGOP showed a large proportion of fish greater than 20 cm, unlike the Pikitch et al (1988) data, suggesting that the recent fishery is not size selective (Figure 13). Furthermore, the fixed gear fishery appears to discard only large fish, which is possibly due to the selection of only large fish.

The mean weight of the discards from the WCGOP for the Oregon and Washington trawl fishery, the California trawl fishery, and the fixed gear fishery are shown in Table 11. The California trawl fishery had the smallest mean weights and the fixed gear fishery had the highest mean weights, which were more than twice the California trawl fishery.

2.1.4 Foreign catches

Foreign catches in US water were available by INPFC area from Rogers (2003) and occurred between 1966 and 1976. Reported catches of greenstriped rockfish from the Soviet Union, Japan, Poland, Bulgaria, and East Germany were summed and tabulated by INPFC area (Table 12). The Soviet Union caught the highest proportion of greenstriped rockfish in all years except in 1975 when Poland caught a slightly higher amount, and total foreign landings peaked in 1967 at 143 metric tons (Table 12).

Rogers (2003) reported that there were unlikely any discards of rockfish in the foreign catch (based on observations by United States fishermen and biologists). At the start of the series (1966–1970) the foreign catches comprise a very large proportion of the total domestic and foreign landings of greenstriped rockfish, which may be due to the lack of discarding by the foreign fleet (Figure 14).

2.1.5 Fishery logbooks

Logbook data for greenstriped rockfish were downloaded from PacFIN on May 11, 2009. There were 349 observations for the years 1993–2007 from different types of trawl gear, and all observations were reported by California. Table 13 shows the number of logbook observations by year and the small percentage of observed catch in most years (except 2003–2005). Due to the small sample sizes and changes in management over the period represented, it is unlikely that these data index the coastwide abundance of greenstriped rockfish. Therefore, no further analyses were done using these data.

2.1.6 Abundance indices

Due to the small sample sizes by year, the small proportion of the landings that were observed, the complication of discards, and changes in management over the period represented, it is unlikely that the logbook data adequately index the coastwide abundance of greenstriped rockfish. Therefore, a catch-per-unit-effort series was not calculated.

2.1.7 Fishery biological sampling

Biological data from commercial fisheries for greenstriped rockfish were extracted from PacFIN (PSMFC) on July 6, 2009. The only useful data available in this extraction were lengths taken during port sampling in California, Oregon, and Washington. The data were classified as groundfish trawl (TWL), shrimp trawl (TWS), hook and line (HKL), or net (NET), and 309 observations could not be classified as a particular gear. There were 60 observations removed that had a missing length, and 10 observations were removed that recorded a length of 55 cm or greater. There were no hauls outside of US waters in this extraction.

Table 14 shows the number of landings sampled as well as the number of lengths taken for each year since 1978 trawl and non-trawl gear, and the three states. California has regularly sampled a large number of landings during this time period. Oregon and Washington started regularly sampling trawl landings in 1996 and non-trawl (all hook and line) landings in 2000. Oregon, however, has sampled few landings compared to California and Washington. The number of lengths recorded by sex and gear are shown in Table 15 and Table 16.

Length frequencies for trawl and non-trawl gear were estimated using these data (Figure 15). Samples were weighted up to the total landing then combined into state specific length frequencies. Washington did not have the total weight of the landing recorded, thus was expanded to the total landing weight by a factor of 6.3, which is the median expansion for the Oregon landings. Oregon and Washington trawl length frequencies were combined by simply adding the expanded numbers at length and sex together for each year. They were not expanded to total state landings because the sparse samples from Oregon would swamp the length frequency and cause peaks at particular lengths. The expansion factors for the non-trawl gear length samples were much less than the trawl gear landing expansions and the Washington lengths were not arbitrarily expanded. The predicted numbers at length for each state were added to create a coast-wide length frequency. The majority of the samples came from California landings and it is uncertain whether or not this introduced any a bias to be concerned of (Table 16).

In some years, the gender of the sampled fish was not recorded. Therefore, length samples with an average number of males per tow less than 0.5 or a large percentage of unsexed samples were estimated for both sexes combined.

Shaw & Gunderson (2006) aged 123 greenstriped rockfish from Oregon landings in 1995. However, these data were unavailable at the time of this report. Also, there are length data available from commercial passenger fishing vessel (CPFV) surveys in California, but these data were made available after the model was finalized and could not be included.

A summary of the biological data available for greenstriped rockfish, reported by PacFIN on June 19, 2009, reports that there are maturity data available. The data available for this assessment did not contain maturity information (every observation was coded 'U'), but these data are typically macroscopic samples, when available, and can be subject to a large amount of error.

2.2 Fishery independent data

2.2.1 NWFSC trawl survey

The NWFSC fishery-independent shelf and slope trawl survey produces three sources of information: an index of relative abundance, length-frequency distributions, and age-frequency distributions. Only years in which the NWFSC survey included the continental shelf are considered (2003-2008).

The NWFSC survey is based on a random-grid design; covering the coastal waters from a depth of 55 m to 1,280 m (Keller et al. 2007). This design uses four industry chartered vessels per year, assigned to a roughly equal number of randomly selected grid cells and is divided into two 'passes' of the coast which are executed from north to south. Two vessels fish during each pass, which have been conducted from late-May to early-October each year. This design therefore incorporates both vessel-to-vessel differences in catchability as well as variance associated with selecting a relatively small number (~700) of possible cells from a very large population of possible cells spread from the Mexican to the Canadian border. Much effort has been expended on appropriate analysis methods for this type of data, culminating in the West Coast trawl survey workshop held in Seattle in November 2006 (see background materials).

The NWFSC survey commonly encounters greenstriped rockfish along the U.S. west coast (Table 17, Figure 16). The survey did not fish shallower than 54 meters and no greenstriped rockfish were caught deeper than 450 meters in any year. Figure 17 shows that the percentage of positive tows and the catch rate over depth peak around 180 meters and decline as depth increases. Figure 17 also shows that the prevalence and density of greenstriped are generally higher in the northern latitudes.

Figure 18 displays the mean fish length per tow of greenstriped rockfish against tow depth and shows large variation in length for both sexes in the shallow to middle depths with both the occurrence of small and large greenstriped rockfish. As depth increases, the range in lengths decreases with the majority of observations being composed of larger fish.

A Generalized Linear Mixed Model (GLMM) model based approach was used to estimate index of abundance for greenstriped, which was endorsed by the trawl survey workshop for use in West Coast stock assessments. The GLMM approach, which includes both fixed and random effects, explicitly captures vessel-specific differences in catchability (due to engine power, trawling experience of the skipper, etc.) via inclusion of random effects. The GLMM approach explicitly models both the zero catches as well as allows for skewness in the distribution of catch rates through the use of a Gamma or lognormal error structure. These factors result in the GLMM approach being robust to a few large tows and likely more reflective of actual trends in population abundance.

When implementing the GLMM approach, it is recommended that there are at least three positive tows in each stratum/year combination. Since the Conception, Monterey, and Eureka areas had fewer than three observations in some years by depth strata, the original stratification of five INPFC areas and three depth zones was collapsed. Because depth showed a strong trend in catch rates and with lower catch rates in the south, the five INPFC strata were collapsed into three areas by state: California (south of 42N), Oregon (42N – 46N), and Washington (north of 46N). Three splits by depth remained with breaks creating a shallow depth (54.864-125 m), a middle depth (125 m-182.88 m) and a deep depth (182.88 m – 500 m). The predicted values plotted against the residuals for the positive tow model are shown in Figure 19.

The biomass index from the GLMM showed a fluctuating trend with the highest biomass estimate peaking around 20,500 metric tons in 2008 (Table 18, Figure 20). The biomass by area, estimated by GLMM analysis, shows the highest biomass in the middle depth for each of the three areas with the largest contribution from the Oregon middle depth (Figure 21). Also, an increasing trend in biomass for each of the three depths within the Washington strata compared to the reference year of 2003 was estimated. The biomass trends in each of the other two areas by depth were relatively constant or slightly lower than the biomass estimated in the reference year.

Length bins from 10 to 40 cm in increments of 1 cm were used to summarize the length frequency of the survey catches in each year. Table 17 shows the number of lengths sampled during the survey. The first bin includes all observations less than 11 cm and the last bin includes all fish larger than 40 cm. The length frequency distributions for the NWFSC survey from 2003–2008 are plotted in Figure 22.

Age-frequency data from the NWFSC survey (Table 17, Figure 23) were included in the model as conditional age-at-length distributions by sex and year. Age-at-length observations can be thought of as entries in an age-length key (matrix), with age across the columns and length down the rows. The approach consists of tabulating the sums within rows as the standard length-frequency distribution and, instead of also tabulating the sums to the age margin, the distribution of ages in each row of the age-length key is treated as a separate observation conditioned on the row (length) from which it came. This approach has several benefits for analysis above the standard use of marginal age compositions. First, age structures are generally collected as a subset of the fish that have been measured. If the ages are to be used to create an external age-length key to transform the lengths to ages, then the uncertainty due to sampling and missing data in the key are not included in the resulting age-compositions used in the stock assessment. If the marginal age compositions are used with the length compositions in the assessment, the information content on sex-ratio and year class strength is largely double-counted as the same fish are contributing to likelihood components that are assumed to be independent. Using conditional age-distributions for each length bin allows only the additional information provided by the limited age data (relative to the generally far more numerous length observations) to be captured, without creating a 'double-counting' of the data in the total likelihood. The second major benefit of using conditional age-composition observations is that in addition to being able to estimate the basic growth parameters (L_{minAge}, L_{maxAge}, K) inside the assessment model, the distribution of lengths at a given age, governed by two parameters for the standard deviation of length at a young age and the standard deviation at an older age, are also quite reliably estimated. This information could only be reliably derived from marginal age-composition observations where very strong and well-separated cohorts exist and where they were quite accurately aged and measured. By fully estimating the growth specifications within the stock assessment model, this major source of uncertainty is included in the assessment results, and bias due to size-based selectivity is avoided. Therefore, to retain objective weighting of the length and age data, and to fully include the uncertainty in growth parameters (and avoid potential bias due to external estimation where size-based selectivity is operating) conditional age-at-length compositions were developed using the NWFSC trawl survey age data.

Age distributions included bins from age 1 to age 45, with the last bin including all fish aged 45 or greater (Figure 23). Approximately 3,472 fish were sampled for age, compared to 17,678 fish sampled for length (Table 17). These data show the growth trajectory of females reaching a maximum size near 34 cm and males reaching a maximum size of about 29 cm (Figure 24). It is often useful to compute the marginal age-compositions to allow for easier visual tracking of strong cohorts and offer a more familiar summary view of the data, although this information is still imparted to the model using conditional age-at-length observations. The NWFSC age distributions show a strong 1993 cohort through the years, starting at age ten in 2003 and ending at age 15 in 2008 (Figure 23). There is also indication of a strong cohort or a number of years of strong cohorts in the late 1990's (Figure 23).

2.2.2 Triennial trawl survey

The triennial shelf trawl survey conducted by NMFS starting in 1977 is the second source of fishery-independent data regarding the abundance of greenstriped rockfish (Dark and Wilkins 1994). The sampling methods used in the survey over the 24-year period are most recently described in Weinberg et al. (2002). The basic design was a series of equally spaced transects from which searches for tows in a specific depth range were initiated (Figure 25). The survey design has changed slightly over the period of time (Table 19, Figure 26). In general, all of the surveys were conducted in the mid-summer through early fall: the survey in 1977 was conducted from early July through late September; the surveys from 1980 through 1989 ran from mid-July to late September; the survey in 1992 spanned from mid-July through early October; the survey in 1995 was conducted from early June to late August; the 1998 survey ran from early June through early August; and the 2001, 2004 surveys were conducted in May-July (Figure 26). Haul depths ranged from 91–457 m during the 1977 survey with no hauls shallower than 91 m. The surveys in 1980, 1983, and 1986 covered the West Coast south to 36.8°N latitude and a depth range of 55–366 meters. The surveys in 1989 and 1992 covered the same depth range but extended the southern range to 34.5°N (near Point Conception). From 1995–2004, the surveys covered the depth range 55–500 meters and surveyed south to 34.5°N. In the final year of the triennial series (2004), the Fishery Resource and Monitoring division (FRAM) at the NWFSC undertook the survey from the AFSC and followed very similar protocols as the AFSC.

Given the different depths surveyed during 1977 the results from the 1977 survey were not included in this assessment. Water hauls (Zimmermann et al. 2003) and tows located in Canadian and Mexican waters were also excluded from the analysis of this survey and the Conception area (south of 36°N latitude) was removed from the analysis since it was not surveyed in the early years.

Similarly to the NWFSC trawl survey, greenstriped rockfish were encountered throughout the West Coast (Table 20, Figure 27). Larger catch rates were observed around depths of 180 m with an increase in positive tows and catch rates with increasing latitude (Figure 28). An analysis of the mean length by depth showed a similar pattern to the observations in the NWFSC trawl survey (Figure 29) and the same depth stratification was used for the triennial survey (54.864–125 m, 125–182.88 m and 182.88–500 m). The same latitudinal stratification was also used for the analysis of the triennial survey (36°N-42°N, 42°N-46°N, and 46°N-49°N).

A GLMM based estimator, similar to the GLMM used for the NWFSC survey, was used to estimate a triennial index of abundance for greenstriped rockfish over the years 1980–2004. The estimated total biomass by stratum for each survey index is given in Table 18 and Figure 30, and range from 1,575 metric tons in 1980 to 5,551 metric tons in 2004. A general trend of increasing biomass was observed over the triennial trawl survey time-series. These estimates of biomass were smaller than the swept area estimates of biomass from the NWFSC survey and showed larger standard errors (Table 18, Figure 30).

Size distributions (fork length in cm) were calculated following the same procedures as the NWFSC survey. The numbers of fish and number of hauls represented in each year of the survey are presented in Table 20. The length frequency distributions generally show evidence of larger fish in 1980, 1983, and 1986 compared to the latter years, some very small fish in 1998, and an increase in mean length from 1998 to 2004 (Figure 31). There may be information on strong cohorts in these data.

Age data for greenstriped rockfish from the Triennial survey were not available at this time, although Shaw & Gunderson (2006) reported having analyzed 342 ages.

2.2.3 Additional fishery independent data

There have been other surveys along the west coast of the United States, but these have typically covered the slope area whereas greenstriped rockfish are more commonly distributed along the continental shelf. Therefore, no additional fishery independent sources of data were considered.

2.2.4 Research removals

Research removals have historically been a very small proportion of the total removals by all fisheries. However, with greatly reduced fisheries landings, the research removals have been greater than fisheries landings for the last two years, although they have remained small relative to historical landings (Table 21).

2.3 Biological Data

Biological relationships were determined mostly from results published in the literature and data collected recently in the NWFSC survey.

2.3.1 Weight-at-length

Published relationships between weight and length were available from Shaw & Gunderson (2006) and Love et al (1990). Love et al (1990) used data collected between 1980 and 1987 from trawling (1 cm mesh in the cod end) and hook and line sampling in the Southern California Bight (south of Point Conception). It is unclear exactly which data Shaw and Gunderson (2006) used to determine weight at length, but they were definitely collected north of Point Conception. Data from the NWFSC survey for the years 2003–2008 were also available to predict weight-at-length relationships. One observation in 2003 was omitted as an obvious outlier (29 cm fish at 0.09 kg).

Weight-at-length relationships from Shaw & Gunderson (2006) predicted larger fish than the Love et al (1990) weight-at-length relationship for sexes combined (Figure 32). The NWFSC survey predicted weight-at-length was in between the Shaw & Gunderson (2006) and Love et al (1990) predictions. Shaw & Gunderson (2006) used nonlinear regression to estimate the parameters of the relationship whereas Love et al (1990) and the analysis of the NWFSC survey data used linear regression of the log transformed data. However, the differences seen are likely due to sampling error, area differences, year differences, or all of the above.

Sex-specific weight-at-length relationships were estimated using data from all years of the NWFSC survey south and north of the CA/OR border (Figure 33). Southern fish are on average smaller than northern fish, and a greater difference was observed between southern and northern females than for southern and northern males (Figure 34). Yearly weight-at-length relationships were predicted from the NWFSC survey data (Figure 35). The 2003 relationship predicted the smallest fish and the 2004 relationship predicted the largest fish, on average, although the difference between years was small (Figure 36).

2.3.2 Maturity and fecundity

Shaw & Gunderson (2006) reported the results of a microscopic maturity study using commercial samples from Oregon collected in 1995. The length at 50% mature ($L_{0.5}$) was 23.04 and 20.97 cm for males and females, respectively. They also reported that very few fish of either sex were mature by a length of 15 cm. Other sources have published information on maturity showing maturity at a smaller size in southern samples (Table 23). Love et al (1990) report maturity at a very small size in California, but these samples came from the California Bight. Wyllie Echeverria (1987) used samples taken mostly from central and northern California and reported maturity at size estimates similar to Shaw & Gunderson (2006). The estimates provided by Shaw & Gunderson (2006) are used in this assessment.

A meta-analysis on the relationship between fecundity (eggs per weight as a function of weight) was performed by Dick (2009) on many species of rockfish. The estimated intercept and slope in the linear relationship for greenstriped rockfish were 371,200 and 63,300, respectively.

2.3.3 Natural mortality

The only published estimates of natural mortality found were from Shaw & Gunderson (2006). They provided estimates of M based on three methods: maximum age using the method of Hoenig (1983) (M=0.092), a catch curve analysis (M=0.149 and 0.142 for females and males, respectively), and GSI methods (M=0.149 for females). A natural mortality rate of 0.145 would be synonymous with a maximum age of 29 using Hoenig's (1983) method, which is approximately the maximum age reported by Love et al (1990) for both males and females.

Based on the maximum ages observed for female and male fish from the NWFSC survey (51 and 49 years, respectively), the Hoenig (1983) method predicts natural mortality values of 0.08118 for females and 0.08452 for males (Table 25).

2.3.4 Length at age

Age data were only available from the NWFSC survey and were used to investigate length-at-age relationships. Shaw & Gunderson (2006) report ages from the 1995 triennial survey and Oregon landings sampled in 1995. However, these data were not available at the time of this assessment.

Length-at-age relationships for female and male greenstriped rockfish were estimated using the NWFSC survey data. Ages were determined by the Cooperative Ageing Project laboratory in Newport, OR and a discussion of the aging error is given below. The maximum ages for females and males were 51 and 49, respectively. Figure 24 shows the length at age for females and males as well as the predicted parameters of the von Bertalanffy growth curve. The maximum length is estimated at 33.64 and 28.48 for females and males, respectively. Figure 24 also show the standard deviation at age and the coefficient of variation (CV) at age. The CV at age shows a more linear trend over age than the standard deviation.

Splitting the survey data at the Oregon/California border into northern and southern areas shows a higher occurrence of older fish in the northern area (Figure 37). In addition, the northern fish are predicted to grow larger at a slower rate (Table 24). Estimated growth curves using data from each year of the survey showed very small differences.

2.3.5 Sex ratios

Greenstriped rockfish are small fish and show dimorphic growth. These qualities can result in skewed sex ratios observed in the commercial and survey landings if females and males are differentially selected. The commercial trawl data, based on sexed length data, show a higher percentage of females, but the survey data show a more equal ratio of males to females (Table 26).

2.3.6 Ageing precision and bias

The greenstriped rockfish age data are limited to the NWFSC survey ages recently completed by the Cooperative Ageing Project (CAP) laboratory in Newport, Oregon. Additionally, one limited study produced ages for greenstriped rockfish from commercial samples. However, the authors are not able to obtain those data at this time. All of the survey otoliths are aged using the break and burn method and one set of double reads are available from the CAP to estimate ageing bias and imprecision for this stock assessment. This analysis uses simultaneous estimation of bias and imprecision in a rigorous statistical framework programmed in AD Model Builder (Otter Research Ltd. 2005) by A. Punt, University of Washington (Punt et al. 2008). This program estimates the underlying age distribution of a sample from up to three double- or cross-reads for each age structure, and can do this for multiple samples simultaneously. The most important assumption of the estimation technique is that at least one ageing method must be unbiased, so it is therefore not an age-validation. Functional forms can be explored for each method for both the bias (none, linear, type 2) and the imprecision (constant CV, or type 2 increase in CV with age). Because the technique requires that the underlying age structure of each sample be estimated, a reasonably large quantity of data spread over the entire range of ages present in the sample is needed (Punt et al. 2008). A few very old ages do not contribute appreciable information but require many more parameters in the underlying model and create instability during estimation. For this reason, each analysis must be truncated at a maximum age that is reasonably well represented in all samples. The ageing error estimation also requires that one reader be specified as unbiased.

Ages of less than 40 years are well represented in the data and there are not strong differences between the ages from reader 1 and reader 2 (Figure 39 and Figure 40). Greenstriped rockfish ages have not been validated to determine reader biases and both readers were specified as unbiased in the ageing error models. Table 27 shows the different model fits to the data as well as the likelihoods, with the best model highlighted. The best model for the greenstriped break and burn ages included nonlinear standard deviation (Table 27). The observed number of ages plotted against the predicated number of ages show that the final model selected fits the data well (Figure 41). Generally, greenstriped rockfish ages from the CAP are accurate and have a low level of imprecision (Table 28, Figure 42). The standard deviation for the greenstriped rockfish ages increases from 0.134 to an asymptote of 0.974 at age 23.

3 History of Modeling Approaches

3.1.1 Previous assessments

Greenstriped rockfish are not a species targeted by any large fishery and have not been assessed as a single species in the past. However, an assessment on the species complex called “other slope rockfish” in the Gulf of Alaska, in which greenstriped rockfish is considered one of 17 different species, was done in 1999. This assessment basically consisted of determining the current exploitable biomass by calculating the average biomass of the complex from the three most recent surveys. In early 2007, a petition was submitted to list greenstriped rockfish in Puget Sound as an endangered or threatened species. However, it was determined that listing greenstriped was not warranted (Federal Register April 23, 2009).

3.1.2 GAP and GMT input

The Groundfish Advisory Subpanel (GAP) representative (Bob Alverson) and Groundfish Management Team (GMT) representative (Rob Jones) were contacted in the early stages of the assessment. Bob Alverson (Fishing Vessels Owner’s Association) noted that greenstriped rockfish are not often seen in the fisheries that he is familiar with. Rob Jones (Northwest Indian Fisheries Commission) noted that the PFMC has a policy of managing stock regionally to the extent possible and encouraged investigating an area specific model. He also provided advice on species compositions of the POP complex and thought that the catches were likely not 100% POP, although he made the suggestion to contact more knowledgeable people. Finally, Rob thought that it was worth trying to include as many fisheries as possible and remove them if evidence suggests they are incompatible.

3.1.3 Response to previous review panel recommendations in 2005

This is the first time that greenstriped rockfish have been assessed. Hence, there are no recommendations from previous assessments.

4 Model Description

An age-structured stock assessment model was used to predict the biomass trajectory of greenstriped rockfish. An approach of parsimony was attempted because this was a first assessment and data were limited for many of the fisheries. This allowed for the determination of general trends in the biomass over time instead of getting caught up in details that may not be relevant.

Stock Synthesis v3.03a was used to estimate the parameters of the model. R4SS, revision 259, along were R version 2.9.1 were used to investigate and plot model fits.

4.1 New modeling approaches

This is the first time that West Coast greenstriped rockfish have been assessed thus is a new modeling approach for this stock. The modeling approach used in this assessment is similar to recent assessments done at the NWFSC for other species of rockfish.

4.2 General model specifications and assumptions

Stock Synthesis has many options when setting up a model and the assessment model for greenstriped rockfish was set up in the following manner.

4.2.1 Definitions of fleets and areas

The availability of data was the main determination of fleets and areas. Greenstriped rockfish are frequently observed in West Coast fisheries and surveys, but have not always been sampled or have been recorded as part of another species complex. Therefore, accurate data are often limited.

Trawl fisheries had sufficient data to split the West Coast into two fleets: Oregon and Washington (WA/OR) and California (CA). Splitting at the California/Oregon border was chosen because landings were available by state and sampling programs differ between states. Oregon and Washington were combined because there were few length samples available from Oregon (Table 14). The foreign trawl fleet (1966–1976) was kept separate from the domestic trawl fleet because it was reported that no discarding had occurred. However, even though high catches came from all along the West Coast, this fleet was treated as a coast-wide fleet with the same selectivity as the California trawl fleet, which was chosen because there were earlier length frequencies from California which more closely matched the time period in which the foreign fleet was fishing.

The other-gear and recreational fisheries were treated as separate fleets covering the entire West Coast. These fleets were not split by states because there were limited data from Oregon and Washington for these fisheries. Therefore, California landings and length frequencies provided most of the information for these fleets. It is likely that more landings occurred in Oregon and Washington than are being accounted for, and it may be worthwhile to further investigate the impact of the Oregon and Washington fisheries on greenstriped rockfish.

4.2.2 Other specifications

The specifications of the assessment are listed in Table 29. Basically, the model is a two-sex, age-structured model starting in 1916 with ages pooled at 50 years. The Triennial survey was split into an early and a late series based mostly on timing of the survey (Figure 26), and the timing of the early series was specified to occur 60% of the way through the year instead of half way through, as with the late Triennial series, NWFSC survey, and all fleets.

The specification of when to estimate recruitment deviations is an assumption that may drive some of the model uncertainty. The earliest length-composition data occur in 1978 and it was decided to begin estimating recruitment deviations in 1970 after consideration of starting earlier. Furthermore, recruitment deviations in the 1970's were not precisely estimated, thus the bias correction was linearly ramped into the model between 1970 and 1986. The full bias correction occurred between 1986 and 2005, with no bias correction occurring for 2008 and onward into the forecasts.

The recommended selectivity type in Stock Synthesis is the double normal and was used in this assessment with separate selectivity-at-length relationships for females and males. Estimating a separate curve for males did not greatly improve the likelihood in initial runs, but keeping them separate helped control the variation in recruitment (σ_R). This is discussed more in section 4.8.2.

4.3 Data sources and weighting

The data are explained in detail in Section 2 and summarized in Table 1and Table 2. Briefly, there is one survey split into two series with length data for each year, a recent survey series with length and age data, length frequencies of retained and discarded catch from four fisheries, estimates of average weights of discards in recent years, and estimates of discarded catch from observer data. It is important to properly weight these data relative to each other so that each contributes to the likelihood appropriately. This was done in an iterative manner of mainly adjusting the effective sample size of the length frequency data. The data were weighted as follows.

The survey indices were standardized using a generalized linear mixed model and Markov chain Monte Carlo was used to estimate the variances of the estimates for each year. The effective sample sizes for the length frequencies were initially chosen based on an analysis performed by Ian Stewart (pers comm.)NWFSC, NOAA). He provided an estimate of the maximum effective sample size for each length frequency from the NWFSC survey data from which the effective number of samples per tow was calculated, which is typically much less than the total number of length samples taken. Figure 43 shows that the effective sample size is approximately a monotonic function of the number of greenstriped rockfish measured and that measuring more than 20 fish per tow does not offer much gain in effective sampling effort.

The Triennial survey sampled a minimum of 27 greenstriped rockfish per tow, when the species was measured. Because a large number of greenstriped rockfish were measured per tow, but a small percentage of tows were measured in some years, the starting effective sample sizes for the Triennial length compositions were determined by multiplying the number of tows by 4.5. This value is approximately the maximum expansion from the number of tows to the effective sample size seen in the analysis on NWFSC survey data done by Ian Stewart. The effective sample size for the Triennial survey length-composition data were then tuned from there. These initial values were not assumed to be the maximum effective sample sizes because of differences between the surveys and when they chose to measure greenstriped rockfish. Also, because few tows were measured, there is less possibility of observing rare size classes and biases could occur due to sampling tows with a larger catch of greenstriped rockfish. These concerns lead to omitting the 1980 length frequency data from this assessment.

4.4 Estimated and fixed parameters

There are 102 estimated parameters in the greenstriped rockfish base assessment model, of which 36 are recruitment deviates prior to 2006 and 15 are forecast recruitment deviates. The estimated parameters other than recruitment deviates represent initial recruitment, length-at-age, selectivity, and retention. Fixed parameters include natural mortality, steepness, and dome-shaped selectivity parameters. A listing of all parameters, whether or not they were fixed, initial values for these parameters, as well as bounds and priors are shown in Table 29, Table 30, and Table 31.

4.5 Model selection and evaluation

The base case assessment model for greenstriped rockfish was developed to balance parsimony and realism, and the goal was to estimate a biomass trajectory for the population of greenstriped rockfish on the outer west coast of the United States. The model contains many assumptions to achieve parsimony and uses many different sources of data to estimate reality. A series of investigative model runs were done to achieve the final base case model.

4.5.1 Models explored

Many models were explored before selecting the initial base case model. Despite some evidence of geographical differences in growth and maturity (Love et al 2002, NWFSC survey data), only coast-wide models were developed, due to the paucity of region-specific data and the observation that the greatest differences in growth and maturity originated from samples south of Point Conception, where the density of greenstriped rockfish is much lower than north of Point Conception. The trawl fishery was split into northern and southern fleets to capture some of the geographic differences in exploitation.

Other explorations included determining the significance of dome-shaped selectivity, separate female and male selectivity, the use of discard ratios vs. specifying discard amounts, and the year in which the estimation of recruitment deviations was initiated. Dome-shaped selectivity was not significant in any models that we tested. Separating female and male selectivity did not drastically improve the overall likelihood, but when there were not separate selectivities the estimated recruitment deviations were ill-behaved, thus sex specific selectivities were retained. Estimates of the total discard mortality were used because these are estimates that are not explicitly related to the landings of greenstriped rockfish (discard total mortality is expanded to the fleet using total landings of groundfish). Therefore, when the catch history is changed as a sensitivity, the estimate of total discards will remain the same instead of scaling it up or down by a ratio. Finally, it was determined to start estimating recruitment deviations in 1970 because patterns emerged in the deviations before that time. These patterns were not cleared up by changing the amount of bias correction applied.

4.5.2 Investigating key assumptions and structural choices

A number of sensitivities were done to investigate the major areas of concern and are reported later. During the model exploration phase, many of the key assumptions were explored and decisions were made that made the most sense when attempting to balance parsimony and reality.

4.5.3 Convergence status

Proper convergence was determined by starting the minimization process from dispersed values of the maximum likelihood estimates to determine if the model found a better minimum. This was repeated 50 times and a better minimum was not found. The model does not appear to have convergence issues, the final maximum gradient was low (Table 32), and the Hessian was always inverted. It was not expected that this model would have convergence issues, especially since natural mortality and steepness were fixed.

4.6 Response to STAR panel recommendations

The STAR panel made a number of recommendations that were adopted into the base case model. These recommendations were:

- remove the 1980 triennial survey length-frequency data (but not the 1980 survey index),
- re-run the ageing-precision and bias-estimation model assuming no bias in the ageing process,
- ramp in the recruitment bias correction from 1970 to 1986, and
- fix recruitment variability at 0.6,

There was considerable discussion regarding two areas that were incorporated into the states of nature. These were the use of early discard data that showed no discarding of large greenstriped rockfish, and whether or not natural mortality should be estimated. The early discard data covered a small period of time in the mid 1980's, a small area of the coast, and there were few length samples. However, this early data showed a very different pattern of discarding than recent data. It was decided to omit these data and to instead incorporate the fraction of discards into the model uncertainty.

The data supported values of natural mortality that were less than the fixed value of 0.08. Due to uncertainty whether or not the estimates of female and male natural mortality were realistic or were caused by model mis-specification, it was decided to keep natural mortality fixed at 0.08 and to incorporate it as an additional source of model uncertainty.

Overall, the STAR process went smoothly and there were no disagreements that could not be resolved.

4.7 Base case model results

The base case model parameter estimates along with approximate asymptotic standard errors are shown in Table 33 and the likelihood components are shown in Table 32. The peak selectivity parameters for the WA/OR trawl and other-gear fleets were estimated at the upper bound of 44 cm. This parameter defines at what length the fish are fully selected by the fleet and an estimate at the upper bound signifies that the selectivity continues to increase to the largest modeled size class. Estimates of key derived parameters and approximate 95% asymptotic confidence intervals are shown in Table 34. Many of the derived parameters related to productivity (such as unfished spawning output and *MSY*) were highly correlated with the estimated unfished recruitment (R_0).

4.7.1 Appropriateness of the parameter estimates

The parameter estimates seemed reasonable, based on previous publications describing the biology of greenstriped rockfish and previous assessments of other species of groundfish. The estimated initial recruitment parameter results in an unfished biomass of age 2+ individuals of 32,600 metric tons.

The estimates of survey catchability for the NWFSC survey catchability were 2.6 times the late Triennial survey series and over 4 times the catchability of the early Triennial survey. Much of the difference can be accounted for by differences between the survey designs, area covered, net configurations, and skipper experience. In addition, it is likely that there were improvements made in the Triennial survey implementation that may have improved catchability over time. It is believed that these estimates of catchability are reasonable for greenstriped rockfish, which are less associated with rocks than other species of rockfish. But, more importantly, the estimate of catchability is greatly influenced by the methods used to expand the catch rates up to a biomass estimate. The choices of strata areas, the total area of interest, and the effective swept area of the net can all cause large biases in the resulting estimate of biomass. This model analytically estimates the catchability parameter, treating it as a nuisance parameter, and is focused on fitting the trend in the survey rather than the absolute biomass. Catchability is a scaling parameter and accounts for any overall bias in the time series that may have occurred during the analysis.

It was anticipated that the retention curves would have a low asymptote due to expected high discard rates, and this was verified in the parameter estimates (Figure 45). Selectivity curves for the WA/OR trawl and other-gear fleets did not asymptote at 1, which is unintuitive, but is likely related to estimating the appropriate "kept fish" curve with a low propensity to keep fish of any size class. The "kept fish" curves are shown in Figure 46 and are more intuitive than looking at selectivity and retention. Stock Synthesis provided a warning when the upper bound on peak selectivity was set larger than the largest observed length bin, and due to fear that calculations may not be correct, the peak selectivity parameter was bounded at 44 cm. Sensitivity analyses showed that lowering the bound on the peak parameter had little effect on the overall conclusions.

Survey selectivity curves showed 50% selectivity around 15–20 cm (Figure 44). However, the early Triennial selectivity was shifted to the right of the other survey selectivity curves, which may be an artifact of the short time series and the split of the series at the years 1992 and 1995. A large year class was estimated in 1993 and the shift in selectivity may actually be related to the large influx of smaller fish seen in the later Triennial series.

If related to recruitment, the shift in the Triennial selectivity curves would cause a loss of information about recruitment in the early 1990's. Nonetheless, the recruitment estimate in 1993 was the second largest recruitment in the time series (Figure 47), and was strongly supported by age data from the NWFSC survey. Other strong years of recruitment were 1971, 1984, and 1998, which were all within a year or two of strong El Niño events (1973, 1983, 1992, 1998, from NOAA_CIRES CDC). Low recruitment occurred in a number of years in the late 1970's, throughout the 1990's, and in 2006 (Figure 47). The uncertainty in the estimates of recruitment was large except for during the 1990's, when recruitment was strongly informed by the NWFSC age data. It is of mild concern that there were higher than average recruitments in 1992 and 1993, but very small recruitments for 3 years before and 4 years after these strong events. This could be indicative of true recruitment variability, but there is a slight possibility that this could be a result of bias towards a single cohort in the ageing data (as was seen in the hake assessment; pers comm., Owen Hamel & Ian Stewart). The recruitment variability was fixed at 0.6 to account for the possibility that the data pertaining to the strongest cohorts were biased high, which would result in a upward biased estimate of recruitment variability.

There were no surprises in the estimated growth parameters (Figure 48). The model estimated length-at-age curve is steeper at young ages than the empirical growth curve, which is expected because of selectivity. The asymptote of the growth curve is clearly defined. The CV of the length-at-age is fit as a linear function with age in the model, and although the empirical CV is noisy, the fit is as good as expected.

4.7.2 Fits to the data

There are four types of data for which the fits are discussed: survey abundance indices, discard biomass and discard average weight estimates, length composition data (lfs), and conditional age-at-length observations.

Fits to the three series of survey abundances are shown in Figure 49. The increasing trend in the early Triennial survey is fit poorly with a slightly decreasing predicted population trajectory. The late Triennial series is fit well, and in spite of the variability in the NWFSC survey, the increasing trend is captured by the model.

The total discards showed a lot of variability between years and were not given a lot of weight in the model. They were included to guide the model and to provide comparisons of how the model was able to fit these data. The model was able to somewhat closely fit the discards in only some years (Figure 50). It appears that total discarded biomass may better be fit with a skewed probability distribution function. Fits to the mean weight of discards are relatively good for the trawl fisheries, but are mostly underestimated for the other-gear fleet (Figure 51).

Fits to the length-composition data are displayed in two different ways: the fitted line is drawn over the plotted proportions at length, and the Pearson residuals at length are shown for each year. Also shown is the estimated effective sample size plotted against the actual sample size used in the likelihood and input sample sizes are compared to the calculated effective sample sizes in Table 35.

The WA/OR trawl predicted length frequencies showed few serious departures from the observed length frequencies. The 2003 and 2008 fitted sex-specific length frequencies were shifted to the right of the observations (Figure 52), and the combined sex length frequencies showed opposite biases in the fits for the years 1996 and 1997 (Figure 53). The discard length frequencies were very noisy and it was difficult to tell where lack of fit may have occurred. The lack of fit to the 2003 and 2008 length frequencies may be due to a difference in discarding practices, but few 2003 discard length observations were available and 2008 discard length observations were not available at the time of this assessment. The input sample sizes were mostly similar to the calculated effective sample sizes (Figure 54).

There were many years of length frequency data for the CA Trawl fleet and the observed sizes of fish in the years 1993, 2003, and 2004 were much smaller fish than predicted (Figure 55 and Figure 56). The length frequencies for 2003 and 2004 contained few observations and are likely a poor representation of the actual landings. The discard length frequencies were noisy, but the general pattern seemed to be fit (Figure 55). The input sample sizes matched well with the calculated effective sample sizes (Figure 57).

Length frequencies for the other-gear fleet were estimated for combined sexes and were available for all but one year since 1979. The predicted length frequencies for years with the largest sample sizes (1985, 1989, 1994, 1996, and 1998) captured the overall trend very well (Figure 58 and Figure 59). Recent years (20052008) had fewer sample sizes than most of the other years (Table 35) and typically observed larger fish than were predicted, except in 2008 when a large number of small fish were observed (Figure 58 and Figure 59). The discard length frequency from 2007 underpredicted some of the larger length classes (Figure 58 and Figure 59). The input sample sizes were similar to the effective sample sizes and captured the same trend (Figure 60).

Recreational length frequencies were estimated for combined sexes and were comprised of landings and discards combined. The model captured the general trend in the length frequencies for years with the largest sample sizes (1993–2001), except in 1997 when a few specific lengths dominated the data (Figure 61 and Figure 62). No serious lack of fit was observed for other years. The input sample sizes mostly matched the effective sample sizes (Figure 63) except in 1997 when the effective sample is much smaller than the input, and 2001 and 2002 when small input sample sizes produce large effective sample sizes (Table 35).

The early Triennial survey took few lengths of greenstriped rockfish in the early years, but sampling increased over time. However, fewer than 50% of the tows with greenstriped rockfish in any year were sampled for lengths (Table 20). The fit was visually best to the length frequency in the last year (1992) of the series (Figure 64). A trend in the lack of fit was apparent for females, with a progression from under-predicting large fish early in the time series to the slight over-prediction of large fish in 1989 (Figure 65). The general trend in the effective sample size compared to the predicted sample size was captured although a rather large effective sample size was calculated for 1992 (Figure 66).

The proportion of tows with greenstriped rockfish sampled for lengths was much higher in the late Triennial survey series (Table 20). Fits to these length frequencies were decent and captured the observed bimodal distribution in later years due to the strong 1993 year class (Figure 67). However, the predicted length frequencies did not quite reach the high proportions in these peaks (Figure 68). The input sample sizes matched the effective sample sizes in all years except that the effective sample size for the 1995 length frequency (the unimodal length frequency) was double the input sample size (Figure 69).

Many length samples were used to estimate the length frequencies in recent years from the NWFSC survey. There were no strong patterns in the length frequencies, but some cohorts were apparent (Figure 70). The general patterns in the length frequencies were fit and no obvious biases were seen (Figure 71). The input sample sizes were determined by an analysis done by Ian Stewart (pers comm., NWFSC, NOAA) and were entered as the maximum sample size and were expected to only be tuned downward. The effective sample sizes were greater than the input sample sizes in all years except 2007 (Table 35, Figure 76).

Pearson residuals for the conditional age-at-length reveal no obvious biases in the fit to these data, although there are some large residuals for older ages-at-length (Figure 73). The conditional age-at-length data and fits are often difficult to visualize, thus the implied fits to the marginal age compositions were calculated and shown in Figure 74 and Figure 75. The trends of strong cohorts in the age data are captured by the predicted age composition, but the high frequencies of the 1993 and 1998 cohorts are often under-predicted. Input sample sizes were simply the number of fish observed at each length, and were similar to calculated effective sample sizes (Figure 76).

4.7.3 Population trajectory

The predicted spawning output in millions of eggs (a proxy for spawning biomass) is given in Table 36 and plotted in Figure 77 and shows a decline starting near 1960 and reaching a low in the late 1990's before dramatically increasing. The predicted summary biomass (age 2+) shows a similar pattern (Figure 77). Estimated depletion possibly dips below the 40% of unfished spawning output in the late 1990's with a very small probability (Figure 78).

Estimated recruits showed strong cohorts in 1971, 1981, 1984, 1993, and 1998–2000 (Table 36, Figure 47). Lower than average recruitment events occurred throughout the period for which recruits were estimated, with extremely low recruitment occurring throughout most of the 1990's. However, the strong recruitment events balance these low recruitment events and the population is predicted to increase in the last decade after rockfish landings decreased.

Approximate asymptotic standard deviations are given in Table 37.

4.8 Uncertainty and sensitivity analysis

Two types of uncertainty are presented for the assessment of greenstriped rockfish. First, uncertainty in the parameter estimates was determined using approximate asymptotic estimates of the standard error. These estimates were based on the likelihood theory that the inverse of the Hessian matrix (the second derivative of the parameter vector) approaches the true uncertainty of the parameter estimates as the sample size approaches infinity. This approach takes into account the uncertainty in the data and supplies correlation estimates between parameters, but does not capture possible skewness in the error distribution of the parameters and may not accurately estimate the standard error in some cases.

The second type of uncertainty that is presented is related to modeling error. This uncertainty cannot be captured in the base case model as it is related to errors in the assumptions used in the base case model. Therefore, sensitivity analyses were done where assumptions were modified to determine the effect they have on the model results.

4.8.1 Parameter uncertainty

Parameter estimates are shown in Table 33 along with approximate asymptotic standard errors. None of the parameters showed large uncertainty. Correlations between parameters were mostly below 0.9, except that correlations between the male offset selectivity parameters were around 0.95. Estimates of key derived parameters are given in Table 34 along with approximate 95% asymptotic confidence intervals. There is a considerable amount of uncertainty in the estimates of biomass and the coefficient of variation (CV) on the 2009 estimate of depletion was 5.3%. The confidence interval on current depletion is entirely above the management target of 40% of the unfished spawning output level.

4.8.2 Sensitivity analysis

Sensitivity analysis was performed to determine the model behavior under different assumptions than those of the base case model. Six sensitivities were conducted to explore the potential differences in model structure and assumptions such as uncertainty in reconstructed landings, the values assumed for steepness and natural mortality, and the amount of discarding. Likelihood values and estimates of key parameters are shown in Table 38 and predicted population trajectories are shown in Figure 79**Error! Reference source not found.**.

Most of the sensitivity analyses had little effect on the current status of the stock. Doubling or halving the landings did not significantly change the overall fit to the data and current depletion remained approximately the same, but the estimated biomass and potential yield from the stock significantly increased or decreased, respectively. The estimated steepness parameter was 1 (the upper bound) suggesting that there is not enough contrast in the data to estimate the reduction in recruitment at low population sizes. At this unrealistically high value, the overall likelihood improved slightly and estimated depletion increased by 0.03.

Using early (1980's) discard data and estimating natural mortality had the greatest effect on the model results. Using early discard data resulted in a lower discard fraction prior to 2000, along with lower spawning output and lower sustainable yields, but did not change the overall depletion much. The estimates of sex-specific natural mortality were lower than the fixed value of 0.08 in the base case model, and resulted in lower estimates of biomass, spawning output, potential yield, and depletion.

4.8.3 Retrospective analysis

A retrospective analysis was conducted by running the model using data only through 2003, 2004, 2005, 2006, and 2007 and estimating current values for the start of the year after data ends (Table 39, Figure 80). The unfished spawning output estimated in the 2009 assessment was intermediate when compared to retrospective model runs finishing in 2004-2008. The lowest estimated trajectory of unfished spawning output was in the 2004 retrospective run, but also showed the fastest rate of increase for the recent trajectory. In this run, the NWFSC survey had only one abundance estimate (2003), thus the data point was removed and no abundance estimates from the NWFSC survey were fitted. Overall, the retrospective analysis did not show any severe patterns and also indicated that the NWFSC survey data adds important information regarding the recent trend in the population.

4.8.4 Likelihood profiles

Likelihood profiles were developed for the steepness parameter and the female and male natural mortality parameters. The model estimated steepness at 1.0, but the likelihood profile (Figure 81) showed that the confidence interval of estimated steepness extends to a lower value near 0.4 and that depletion is not largely affected over the range of steepness. Figure 82 shows a joint likelihood profile over female natural mortality (x-axis) and the difference between male and female natural mortalities (y-axis). The data show that it is highly probable that male natural mortality is greater than female natural mortality and that it is likely that natural mortality is less than the assumed value of 0.08. Estimated depletion increases with the value of natural mortality, but does not change much with an increasing difference between male and female natural mortalities.

5 Reference points

Reference points were calculated using the estimated selectivities and a fleet distribution based on the proportions of the average landings from each fleet in the last two years. The last two years were used to determine the fleet distribution because landings of greenstriped rockfish were variable and the last two years better captures reality. Reference points were based on different scenarios: 1) a target spawning biomass of 40% ($B_{40\%}$), 2) a target SPR of 50% ($SPR_{50\%}$), and 3) a target of estimated *MSY*. Estimates of spawning output, exploitation rates, and long-term sustainable yield for each of these paradigms are shown in Table 34.

With a $B_{40\%}$ target, the MSY-proxy spawning output was 3,072 millions of eggs, producing a long-term yield of 828 mt (95% CI = 581–1,075 mt). This corresponds to an exploitation rate around 4.9% and an SPR of 46.7%. When using $SPR_{50\%}$ as a proxy for *MSY,* the target spawning output was greater (3,359 million eggs) and the long-term sustainable yield was less (800 mt with an approximate 95% confidence interval of 561–1,038). The corresponding exploitation rate was about 4.4%. The spawning output at maximum sustainable yield was lower than the other two paradigms, at about 29% of unfished spawning output (2,209 mt). *MSY* was therefore estimated at 870 mt (95% CI = 611–1,129), corresponding to an SPR_{MSY} of 36.7% and an exploitation rate near 6.8%.

Historically, exploitation rates have exceeded the overfishing threshold based on $SPR_{50\%}$ in six separate years, all occurring between 1980 and 2000 (Figure 83). Harvest rates, calculated by dividing the entire catch by the age 2+ biomass, exceed the threshold harvest rate based on $SPR_{50\%}$ more often (Figure 84). Also shown (Figure 85) is the phase plot of the trajectory for greenstriped rockfish relative to the threshold $SPR_{50\%}$ exploitation level and the $B_{40\%}$ biomass target. The trajectory has mostly been in the low exploitation rate and high biomass quadrant, although exploitation levels have exceeded the target in six separate years. More recently, exploitation on greenstriped rockfish has been low and the population size has been increasing, which is likely a result of management measures implemented to lower the exploitation of overfished rockfish stocks.

The estimated equilibrium curve is shown in Figure 86 with target thresholds based on $B_{40\%}$ and target thresholds based on *MSY* plotted. Current depletion is also plotted and is currently much greater than any target level.

6 Harvest projections and decision tables

Forecasts and projections of the greenstriped rockfish population up to the year 2020 were constructed under the assumption that future catches would never reach the calculated OY. The average catch from 2007 and 2008 was used for the catches in 2009 and 2010 and distributed among the fisheries based on the average proportion of these catches by fleet. The landings and fleet distribution for 2011 and beyond were assumed equal to the average of the fleet specific landings from 2000–2003. This forecast table is meant to be representative of the status quo, yet still be conservative since landings in 2000–2003 were higher than more recent landings, although not as high as landings observed in the 1980's and 1990's.

Forecasting with these status quo catches resulted in the stock and the ABC increasing over time (Table 40). Fleet catch distribution was determined from the years 2000–2003 and allocated more to the trawl fisheries than would have been the case if based on 2007 and 2008 landings. The resulting discard fraction is much higher, with almost 5 times the biomass being discarded as landed, illustrating the importance of the assumed distribution of catch in the projection process.

A decision table was constructed using two axes of uncertainty which are considered to be the areas of the assessment that are most uncertain. The first axis of uncertainty was the fraction of the catch that is discarded, with low and high levels of discarding when compared to the base case. The low level of discarding was set to be similar to the level of discarding determined from the sensitivity analysis using early discard data. These data indicated that all fish over about 30 cm were retained whereas the later discard data used in the base case model showed that a high proportion of fish over 30 cm were discarded. The high level of discarding was determined by increasing the fraction discarded from the base case model by an amount proportional to the low fraction case. The retention asymptote for the WA/OR trawl fishery was increased by a factor of 2.5 and the CA trawl retention asymptote was increased by a factor of 3. The second axis of uncertainty used low and high values of natural mortality. The low value of 0.06 was near the value of natural mortality that would be estimated if allowed to in the base case model. The high value of natural mortality (0.10) was the same distance from the base case value as the low value, except in the opposite direction, and meant to agree somewhat with values seen in published reports. No probabilities are associated with the states of nature other than that the base case model is the most probable.

As seen in the sensitivity runs, the fraction discarded influenced the spawning output and size of the stock, and the natural mortality influenced both the size of the stock as well as the level of depletion. Forecasts of spawning output and depletion are presented in Table 41 for all 9 possible combinations of the base model and the two axes of uncertainty. The worst-case scenario in terms of depletion was when the fraction of discarding is high and the natural mortality was low, but the stock is still forecasted to increase and maintain a status greater than the 40% of unfished spawning output. The best case scenarios are when natural mortality was high. The stock was predicted to exceed unfished spawning output because of recent large recruitments.

7 Regional management considerations

The outer West Coast population of greenstriped rockfish was modeled as a single stock and spatial aspects of this coast-wide population were addressed through the geographic separation of data sources where possible. There is little genetic evidence of biologically distinct stocks throughout the West Coast and although there is evidence that mature fish move into deeper water, there is no information on latitudinal movement. Studies of greenstriped rockfish in Southern California indicate that the life-history of these fish may differ from fish found north of Point Conception (see Love et al 1990). However, the greater proportion of biomass is found north of Point Conception and trying to account for these differences may prove to be futile. Additionally, the data showed that greenstriped rockfish in California did not commonly reach the older ages commonly seen in Oregon and Washington greenstriped rockfish, and it is uncertain whether or not this is due to a difference in natural mortality, fishing pressure, or both. With the continued collection of regional data on greenstriped rockfish, regional patterns may emerge and a spatially explicit model may be an option for future assessments.

8 Research needs

There are four topics for which additional research would greatly improve the assessment of greenstriped rockfish.

1. **Landings:** improving certainty of the commercial and recreational landings would result in a better estimate of the total yield as well as an improved understanding of the population dynamics of greenstriped rockfish. The landings have been determined in the best possible manner given the time constraints of this assessment, but there is still uncertainty in the catch reconstruction and in recent landings. The state of California has produced reconstructed and current landings for many species, which have been accepted as the best possible information. However, a similar reconstruction is not available for Oregon and Washington landings, although such a product is of interest to fisheries managers and stock assessors. Additionally, some errors were found in the PacFIN database of recent landings during the current catch reconstruction and are being reconciled. Further error checking may be worthwhile for greenstriped rockfish as well as other species.
2. **Discards:** discarding at sea is common practice for greenstriped rockfish and the levels of historical discards are poorly known due to a lack of data. The West Coast Groundfish Observer Program (WCGOP) has contributed greatly to the understanding of discard rates and size compositions. However, it would be useful to review what information is available from the past to understand discarding practices and to determine how reliable that information is.
3. **Natural mortality:** the value for natural mortality in the base case model was fixed at 0.08, which was determined from the maximum age observed in recent survey data. Other published estimates of natural mortality for greenstriped rockfish range from 0.09 to 0.149 and are based on maximum age, catch curve analyses, and gonadosomatic indices. The data used in the base model supported a natural mortality near 0.065. All of these estimates of natural mortality are uncertain and given the correlation between natural mortality and stock status, it would be useful to have a better understanding of the plausible range of values.
4. **Stock structure:** there is some evidence that the life history of greenstriped rockfish in Southern California may be different from greenstriped rockfish in Northern areas. Understanding and quantifying the differences in length, weight, ages, maturity, and fecundity (as well as the number of broods per year) would be helpful to determine if the model should incorporate these differences.

9 Acknowledgements

Many people were instrumental in the successful completion of this assessment and their contribution is greatly appreciated. Countless interruptions to Ian Stewart's work for questions regarding data and the Stock Synthesis framework, as well as discussions of model behavior were a great help. Ian Taylor contributed with further discussions and by updating the R4SS code when needed. Don Pearson guided me through the CalCOM data for Califronia, Mark Karnowski and Troy Buell (ODFW) supplied advice and data from Oregon, and Theresa Tsou, Greg Lippert, and Debbra Bacon (WDFW) put in countless hours of effort compiling data and references from Washington fisheries. Jayna Schaaf-da Silva thoroughly reviewed a draft of the assessment, kindly pointed out an error, and informed us of the CPFV data which may be of use in future assessments.

We are very grateful to Patrick McDonald and Lou Taylor for their hard work reading numerous otoliths and availability to answer questions when needed. Beth Horness was always eager to help, quick to supply survey extractions, and answered numerous questions we had. Eliza Heery patiently supplied data from the WCGOP. And, Jim Hastie supplied advice on the assessment and greatly improved an early draft.

Many industry representatives, including Brad Pettinger, Bob Alverson, and Pete Leipzig, were a great help in understanding the greenstriped rockfish fisheries. And finally, the reviewers of the STAR panel (J. J. Maguire, Vivian Haist, and Rick Methot), the STAR panel chair (Steve Ralston), and the GMT representative (Rob Jones) are greatly appreciated for their patience, advice, focus, understanding, and comments before, during, and after the STAR panel meeting.

2005	2004	7,635	4,786	62.7%	73.7%
2004	2003	4,662	2,266	48.6%	64.9%

Table 40: Projection of potential ABC, OY, landings and catch, summary biomass (age 2 and older), spawning biomass, and depletion for the base case model based on the status quo. Landings in 2009 and 2010 are a total of 9 mt, determined from the average of the 2007 and 2008 landings for each fleet and allocated to each fleet based on the proportion caught in 2007 and 2008. Forecasted landings after 2010 are 20 mt (the average of 2000–2003) and allocated to each fleet based on the average allocation in 2000–2003.

Year	ABC (mt)	OY (mt)	Total Catch (mt)	Landings (mt)	Age 2+ biomass (mt)	Spawning output (million eggs)	Depletion
2009	1,466	1,466	9	3	31,806	6,248	81.4
2010	1,512	1,512	9	3	32,480	6,458	84.1
2011	1,554	1,554	94	20	33,064	6,652	86.6
2012	1,586	1,586	93	20	33,484	6,799	88.5
2013	1,612	1,612	92	20	33,830	6,918	90.1
2014	1,633	1,633	91	20	34,112	7,011	91.3
2015	1,650	1,650	90	20	34,338	7,086	92.3
2016	1,663	1,663	89	20	34,518	7,145	93.0
2017	1,673	1,673	89	20	34,659	7,193	93.7
2018	1,681	1,681	88	20	34,768	7,231	94.2
2019	1,688	1,688	87	20	34,851	7,261	94.5
2020	1,693	1,693	87	20	34,913	7,285	94.9

[1] The ABC here is the calculated total catch determined by $F_{SPR50\%}$.

Table 41: Decision table of 12-year projections beginning in 2011 for alternate states of nature based on two axes of uncertainty. Columns range over natural mortality and rows range over the fraction discarded. There are no probabilities associated with these states of nature other than the base model (center square) is the most probable scenario.

State of nature (fraction discarded)		Year	Landed catch (mt)	M=0.06 Depletion (%)	M=0.06 Spawning output (million)	M=0.08 Depletion (%)	M=0.08 Spawning output (million)	M=0.10 Depletion (%)	M=0.10 Spawning output (million)
	Low fraction discarded	2011	20	66.7	1,453	89.1	3,129	107.0	10,496
		2012	20	68.5	1,493	90.8	3,186	108.0	10,591

State of nature (natural mortality)

12 Figures

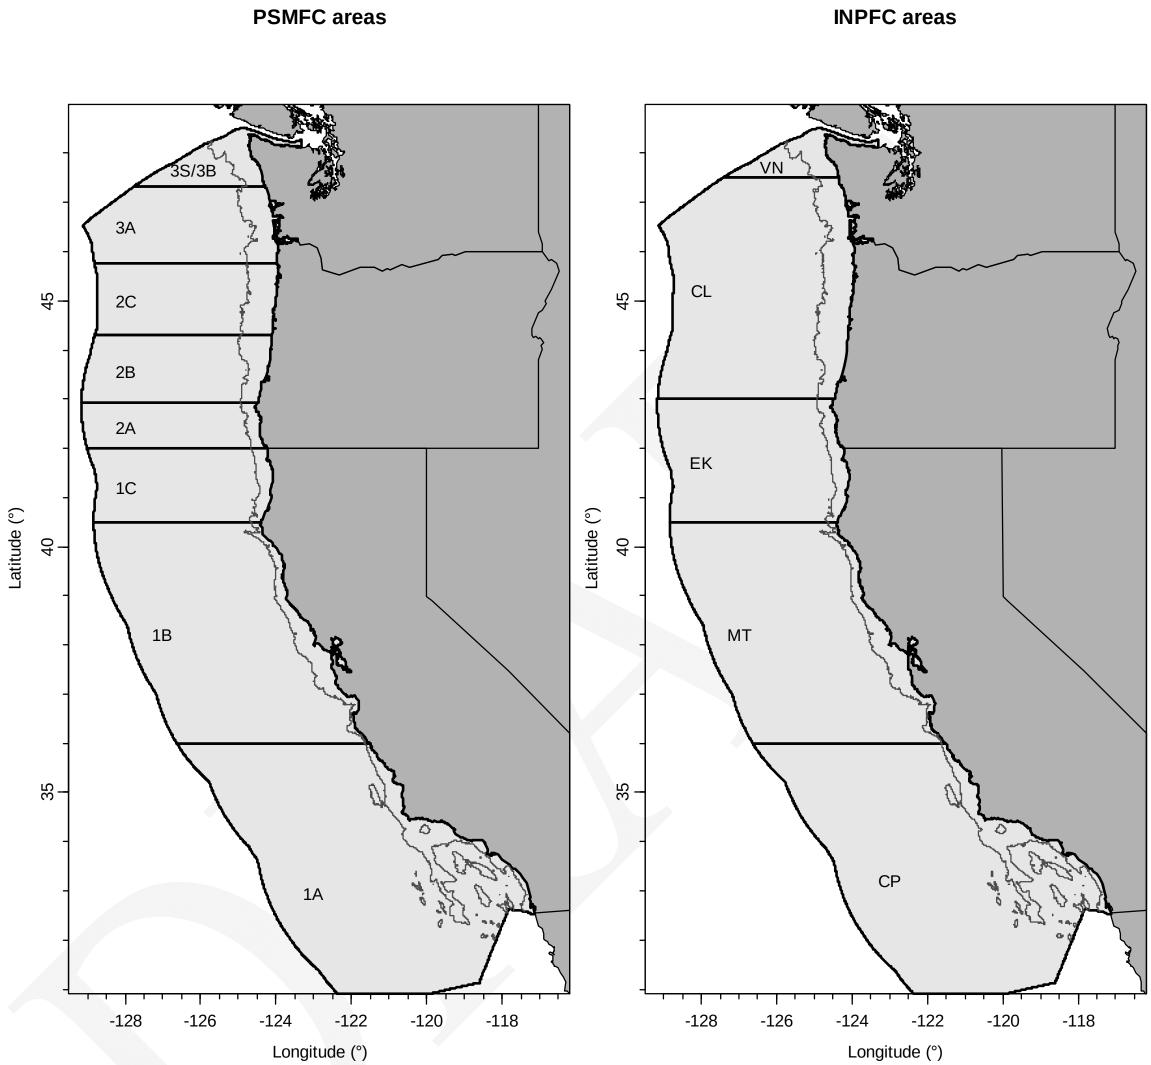

Figure 1: Map showing PSMFC and INPFC boundaries used in the 2009 assessment. The solid gray line off the coast is the 300 fathom depth contour.

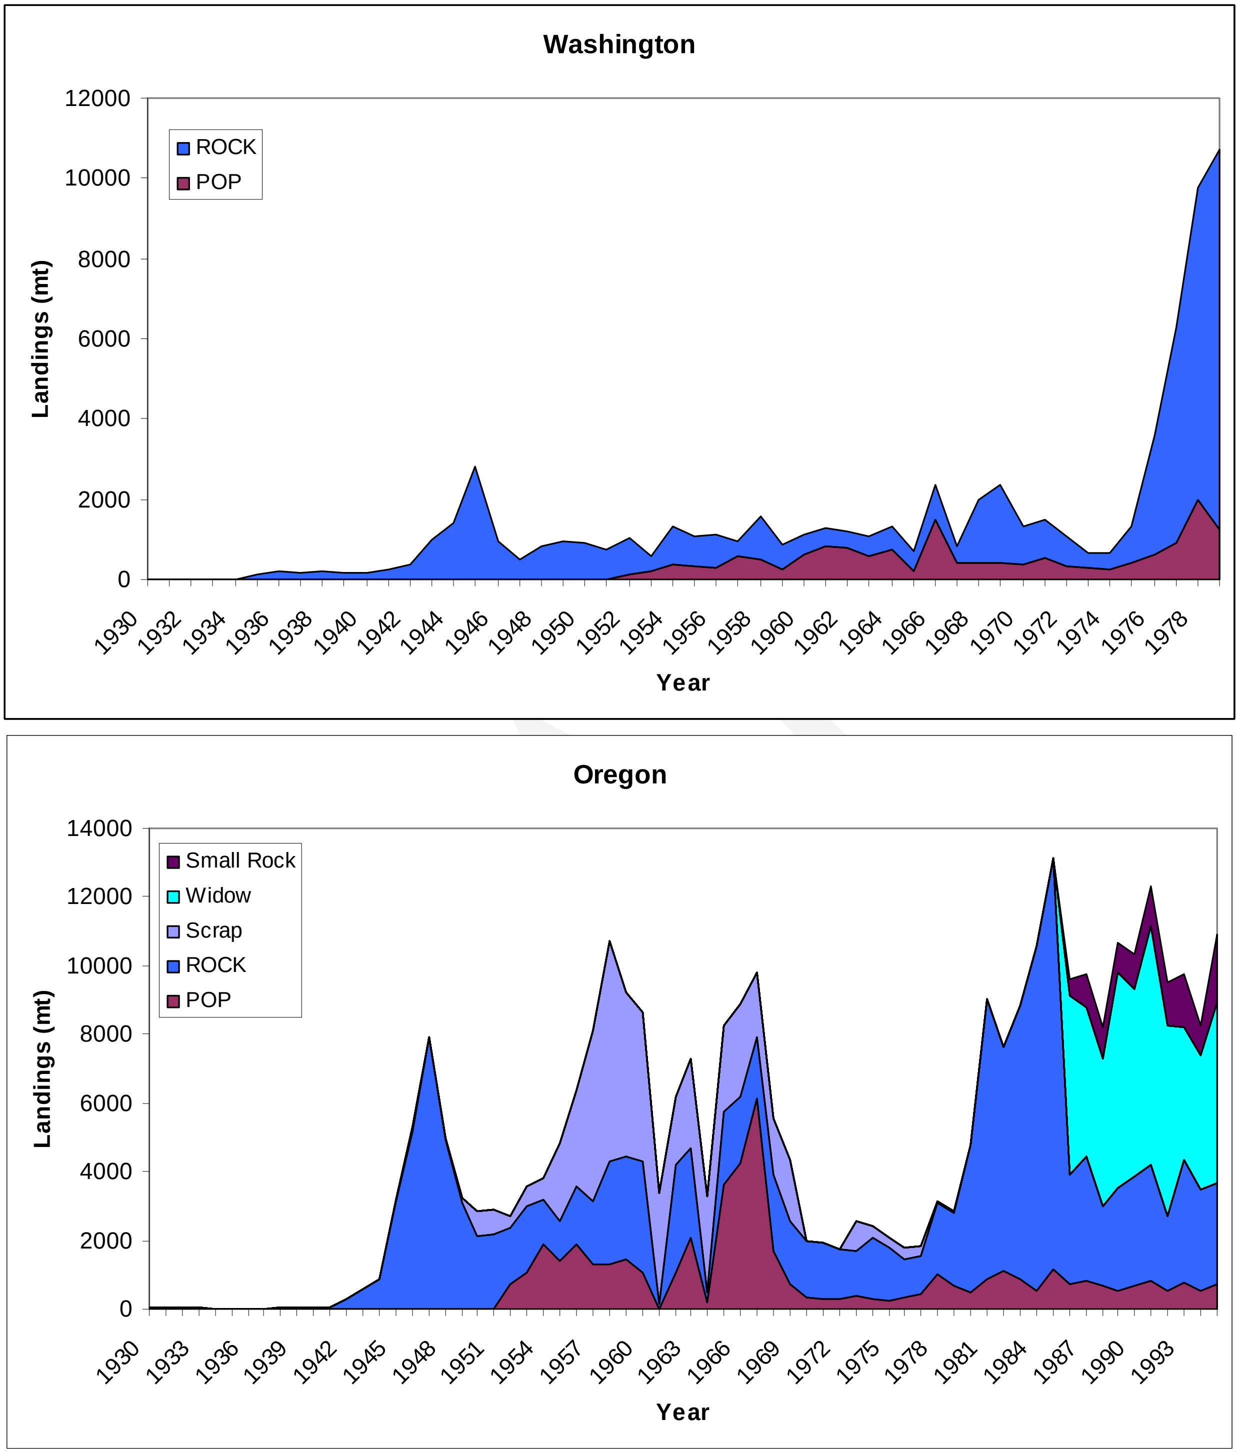

Figure 2: Landings for Washington and Oregon of each market category used in the historical catch reconstruction. Different proportions were applied to each market category to estimate the landings of greenstriped rockfish.

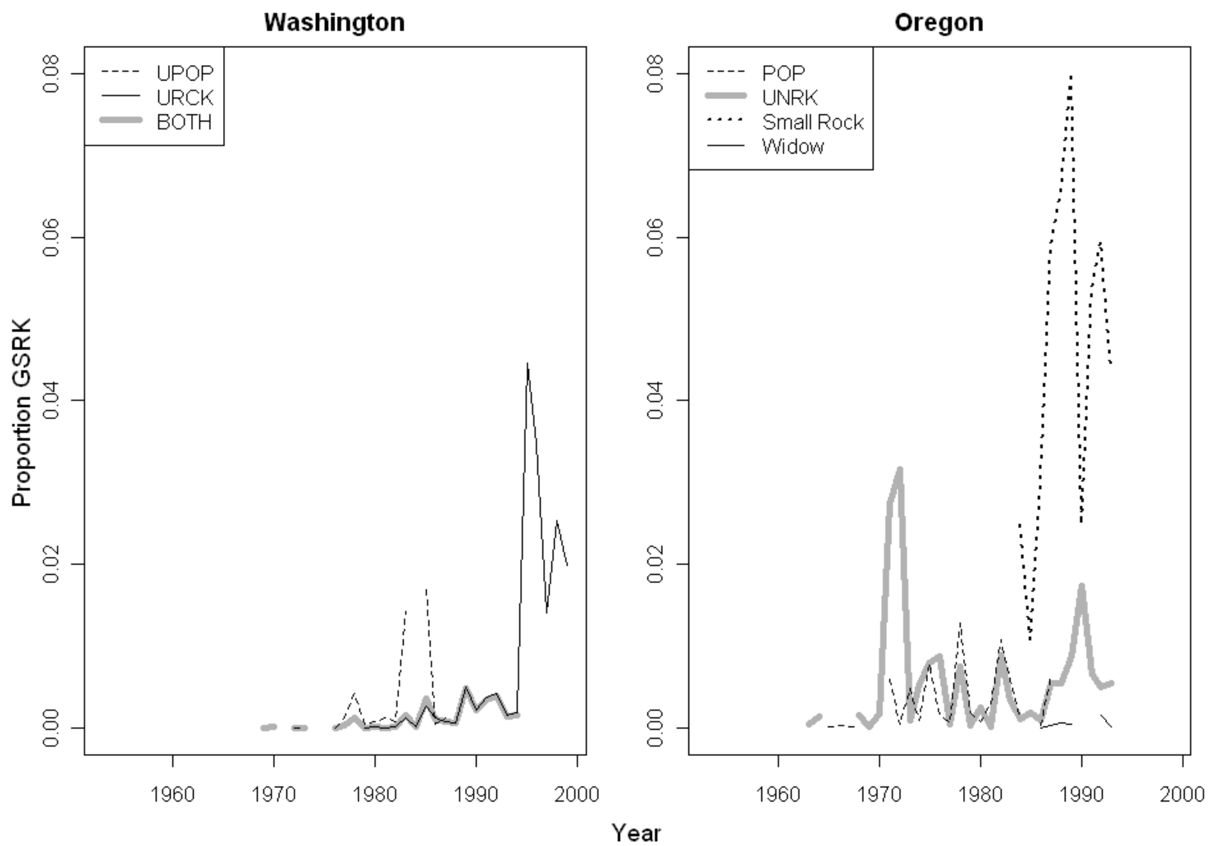

Figure 3: Proportion of greenstriped rockfish (GSRK) used to construct the historical landings as estimated from species composition sampling of different market categories for Oregon and Washington. See text for a full explanation of how these proportions were used.

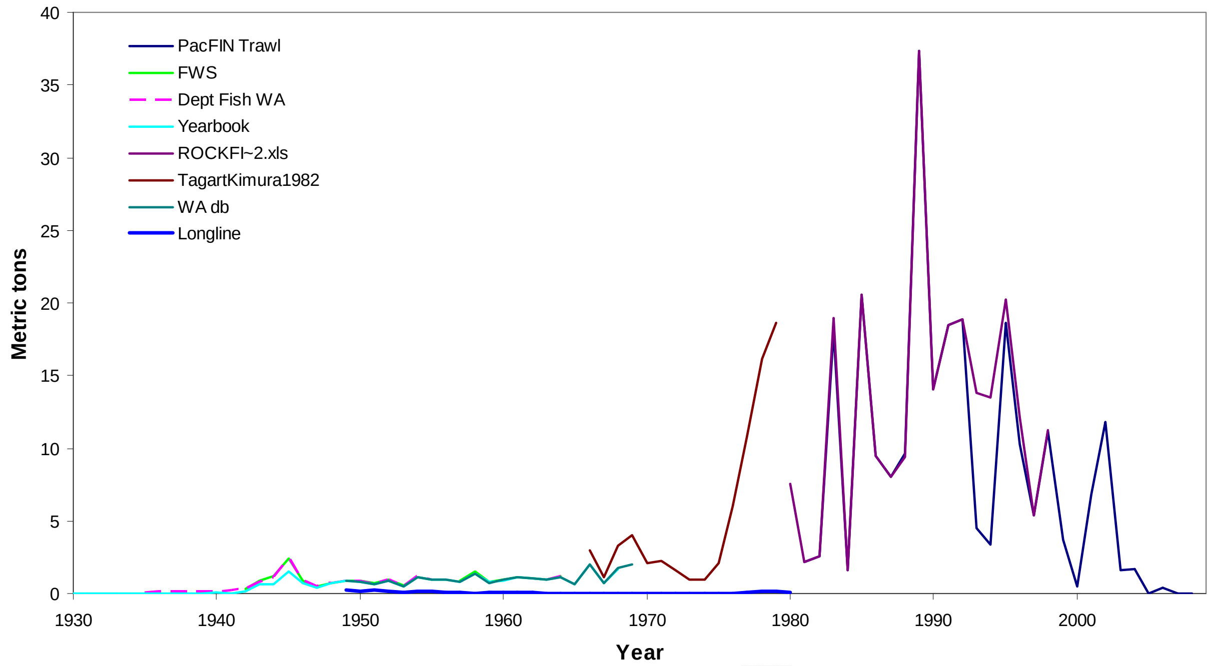

Figure 4: Landings of greenstriped rockfish from Washington trawl vessels as determined from different data sources.

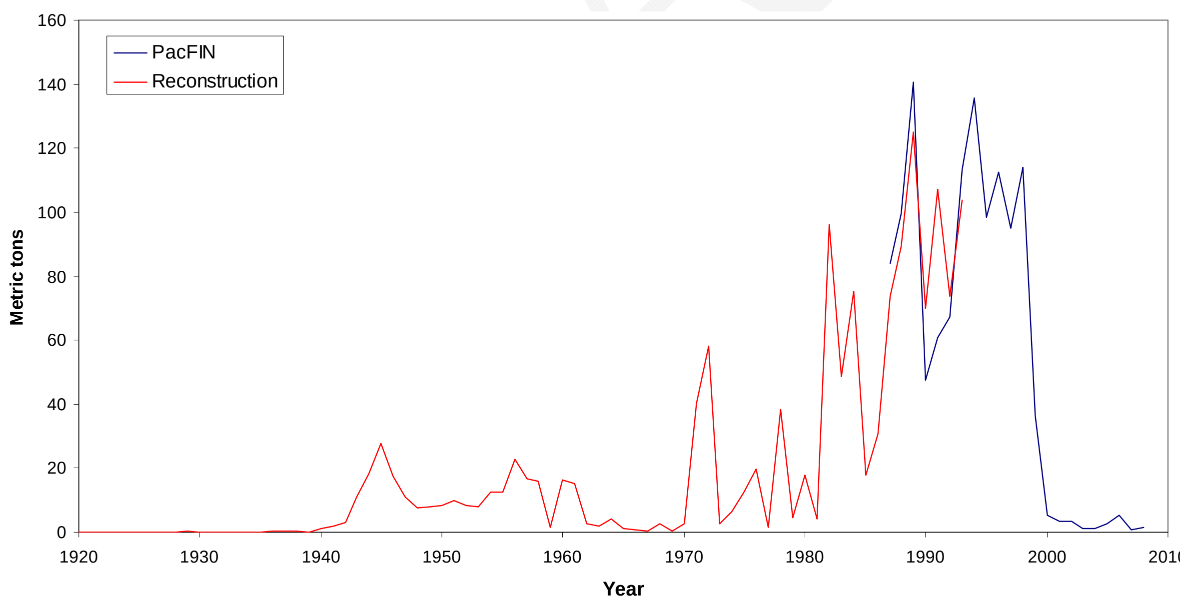

Figure 5: Landings of greenstriped rockfish from Oregon trawl vessels as determined from different data sources.

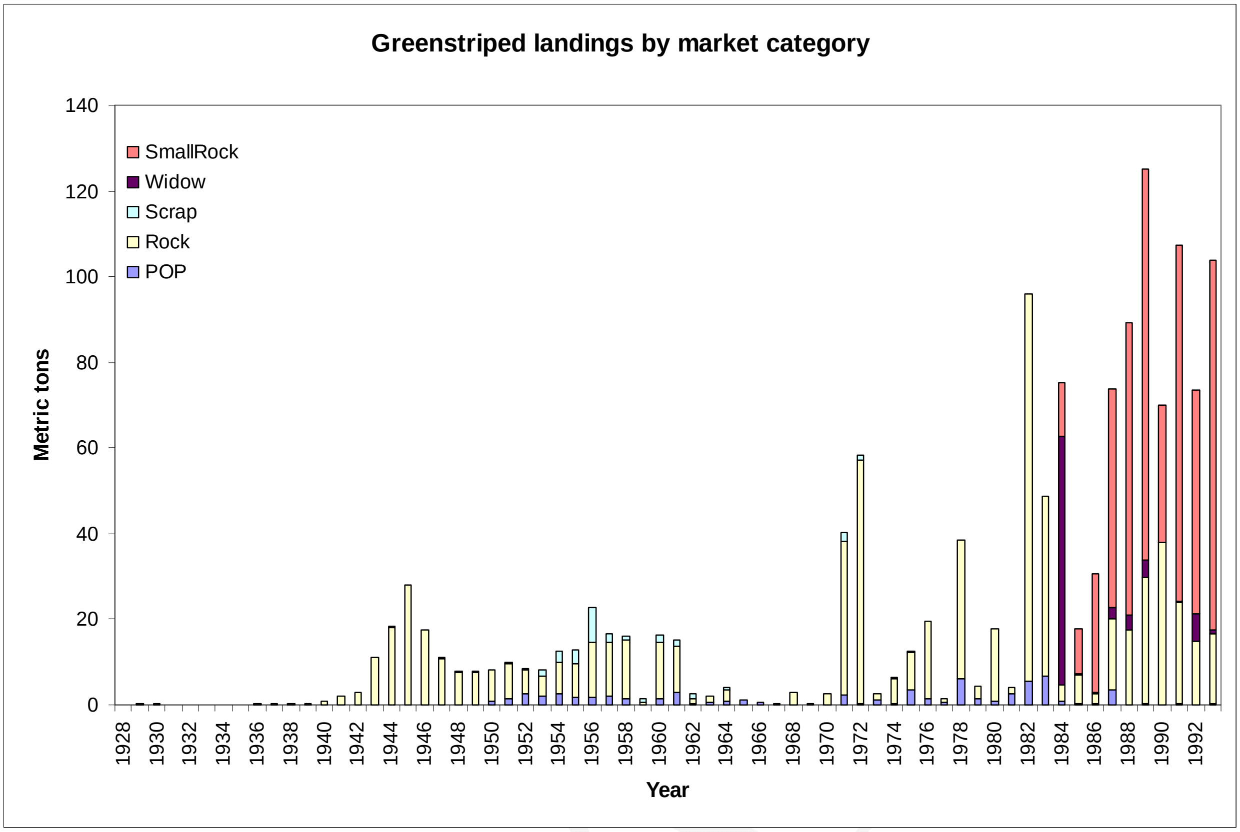

Figure 6: Landings of greenstriped rockfish in Oregon as determined from the different market categories.

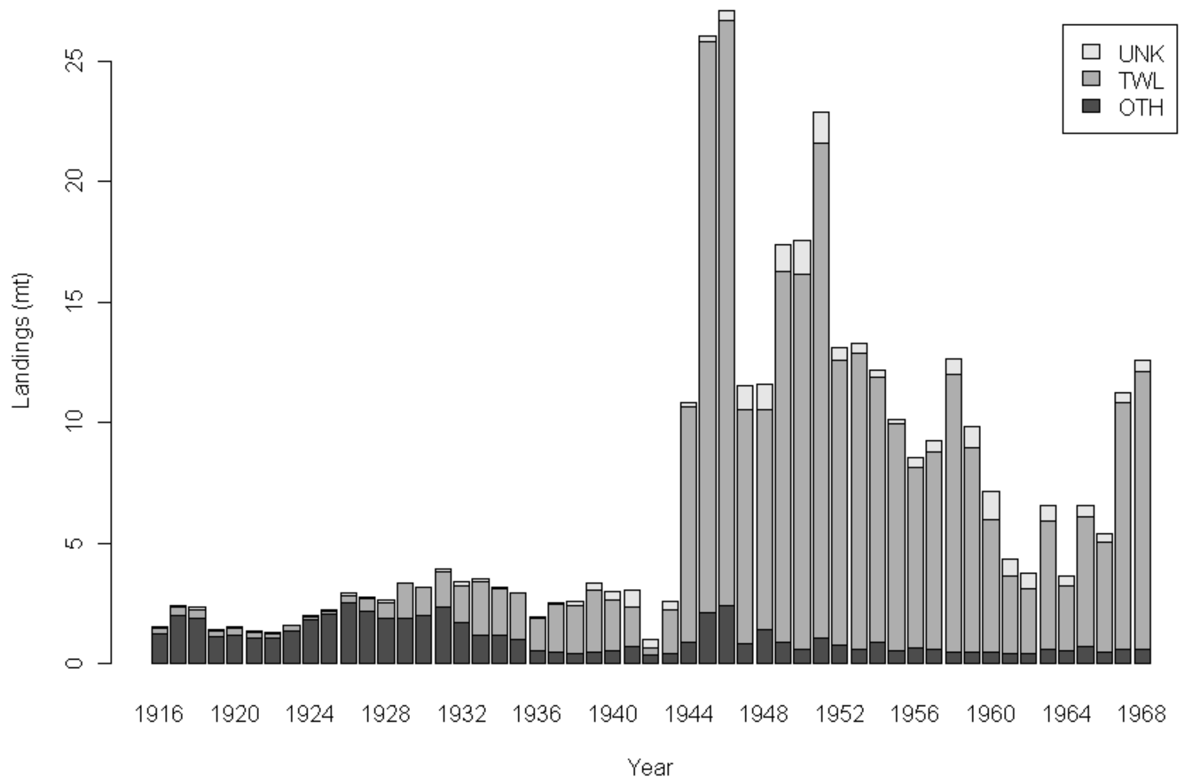

Figure 7: California reconstructed landings (tons) for the three gear categories unknown (UNK), trawl (TWL), and other (OTH).

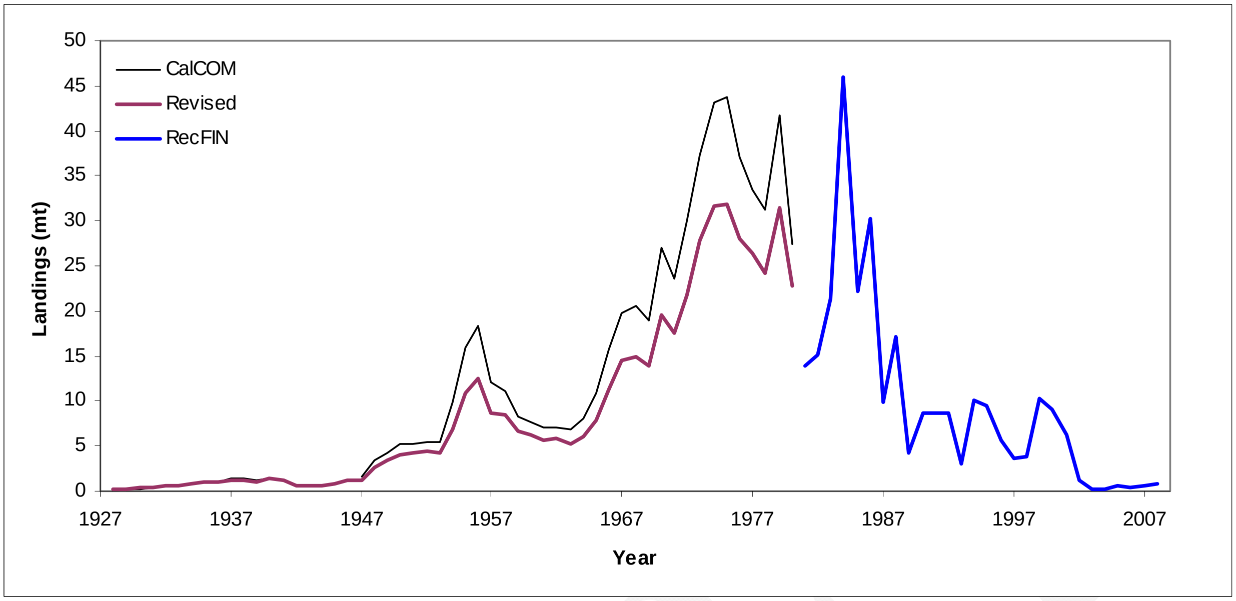

Figure 8: Reconstructed California recreational landings downloaded from CalCOM and revised by John Field (SWFSC, NOAA). Recent landings from RecFIN are also shown.

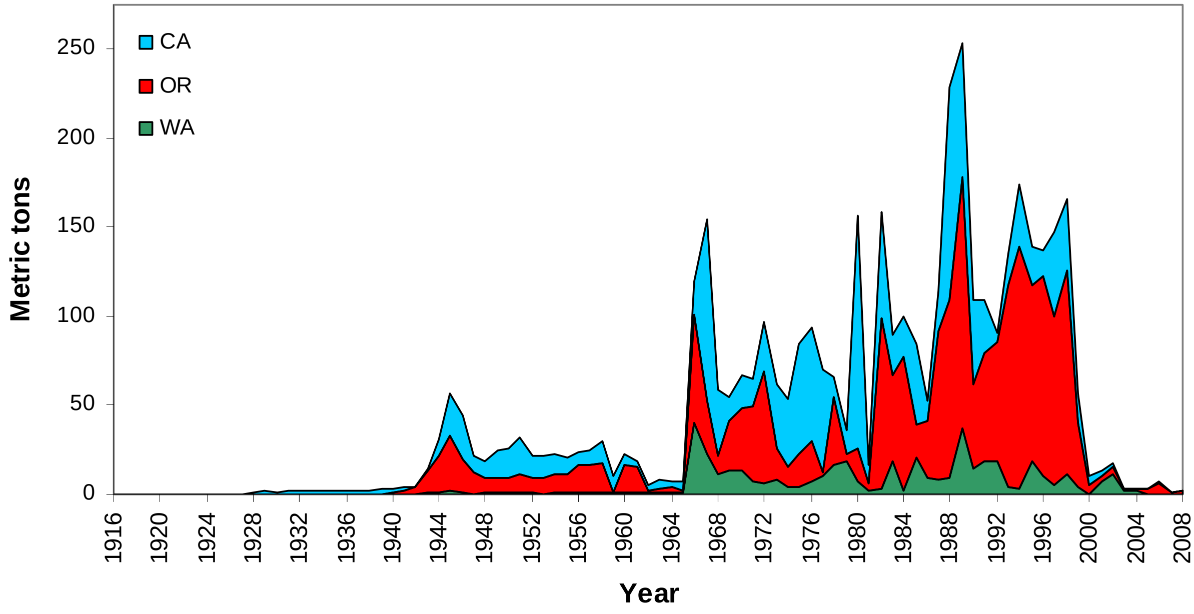

Figure 9: Full time series of trawl landings for each state.

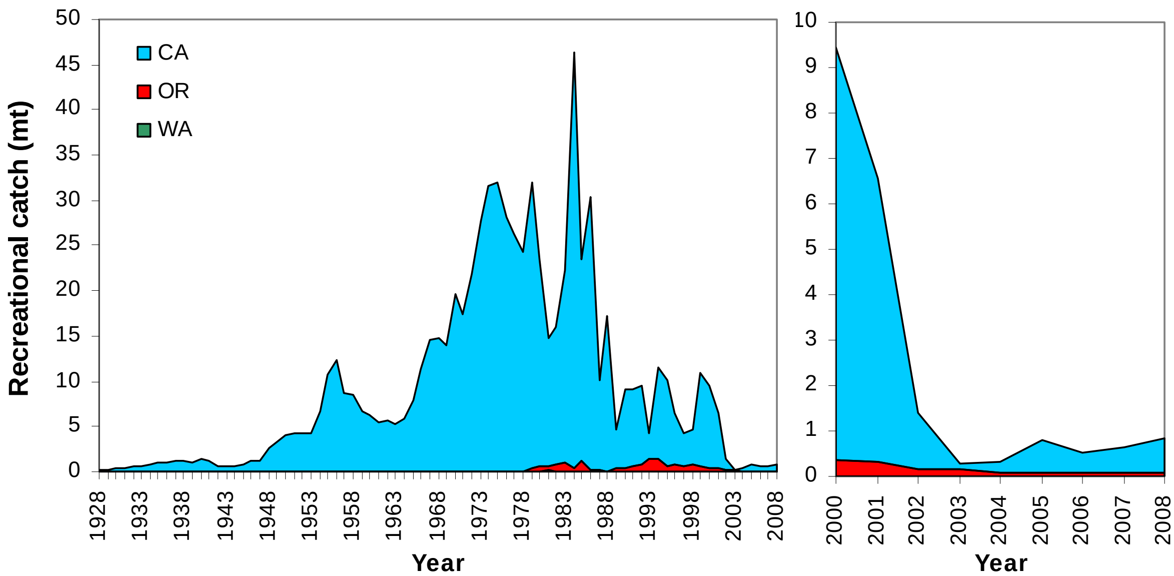

Figure 10: Recreational catches from California, Oregon, and Washington. The full time series is shown on the left and the current decade is shown on the right.

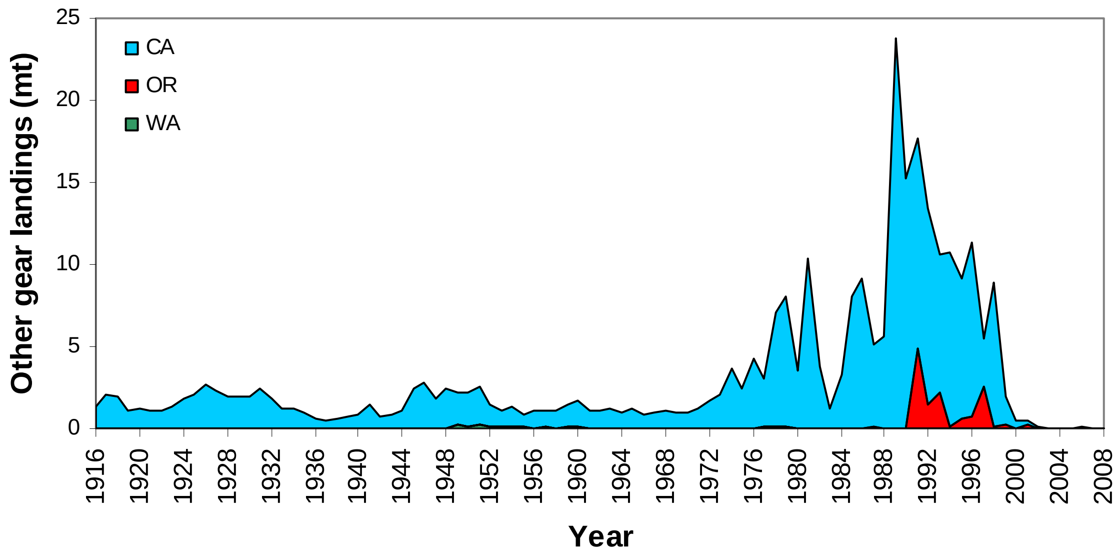

Figure 11: The full time series of landings from gears other than trawl for each state.

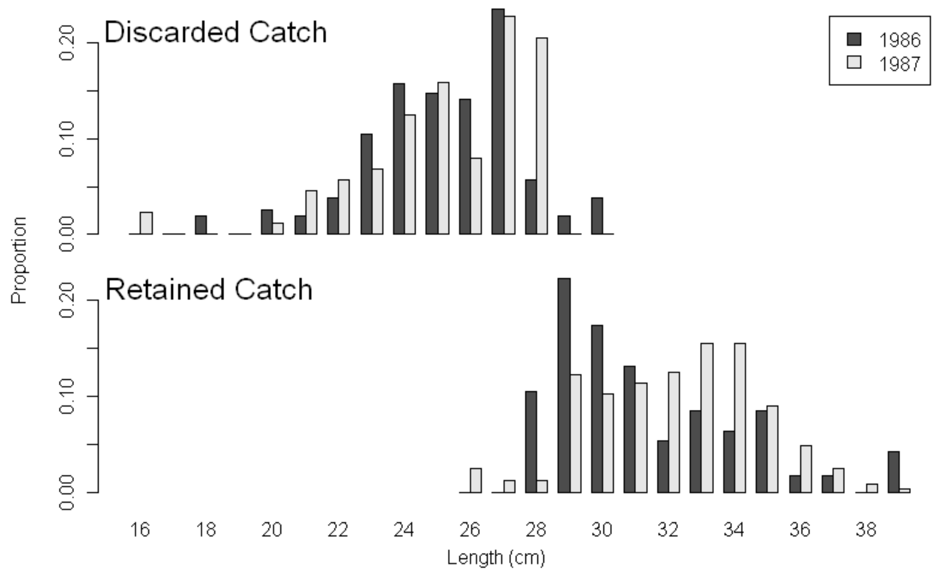

Figure 12: Length frequencies of discarded and retained catch from the Pikitch et al (1988) data.

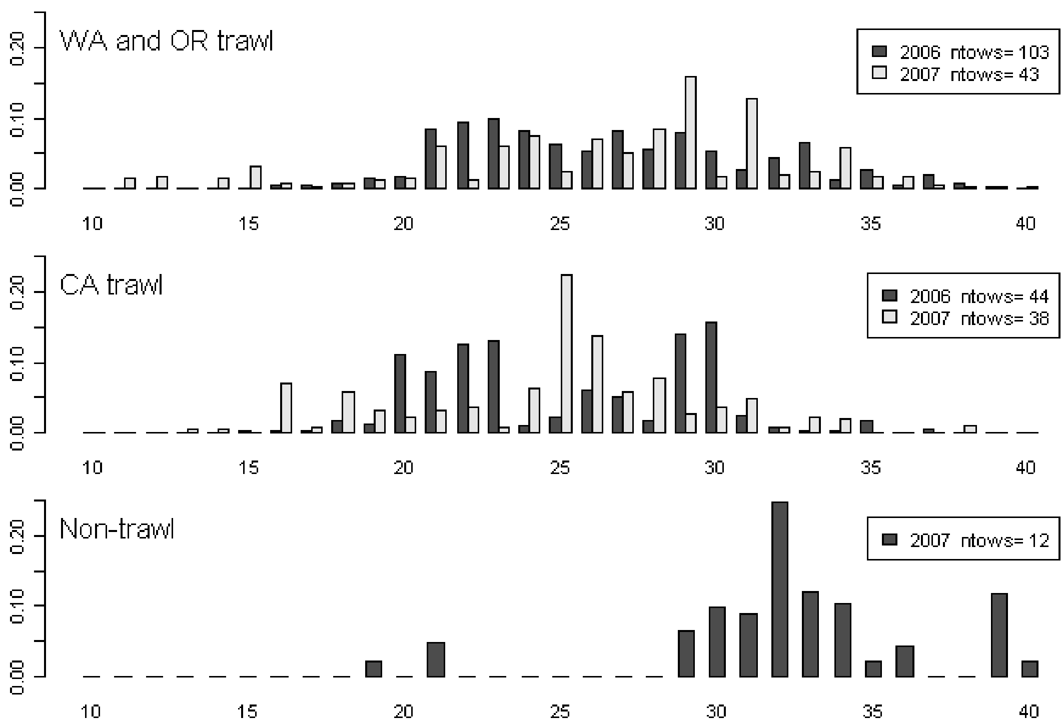

Figure 13: WCGOP length frequencies of discards from the Washington and Oregon trawl fisheries, California trawl fisheries, and coastwide non-trawl (fixed gear) fisheries. Only years with the largest number of sampled tows are shown.

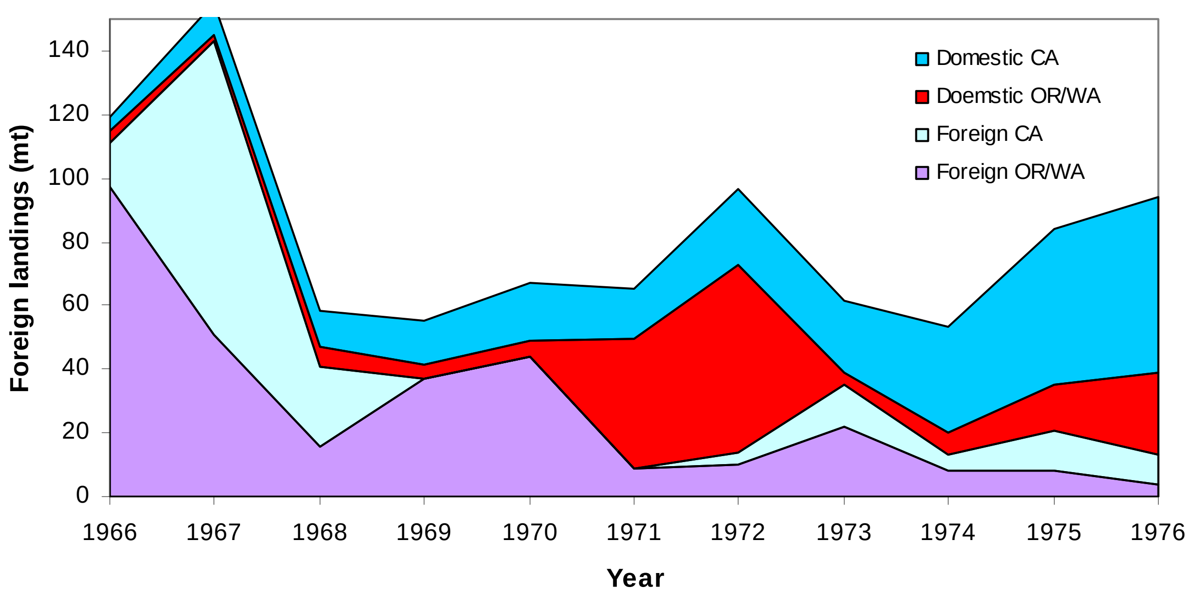

Figure 14: Foreign and domestic landings of greenstriped rockfish for the years 1966–1976.

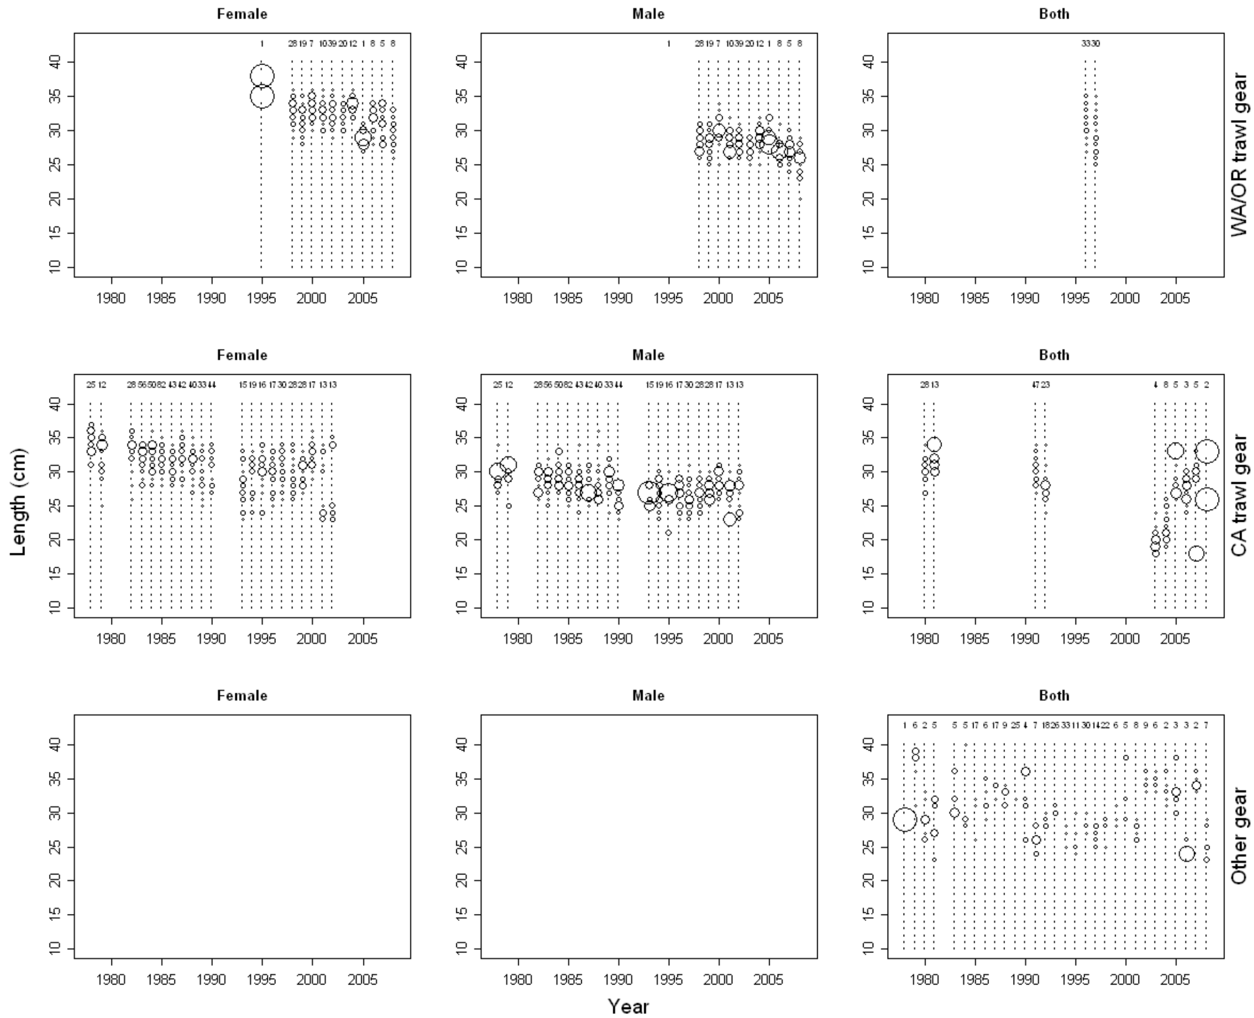

Figure 15: Estimated commercial length frequencies for three different gears and females, males, or both sexes combined, depending on how they were used in the model. The numbers of tows are listed above each length frequency (length frequencies with 1 tow were not fit by the model).

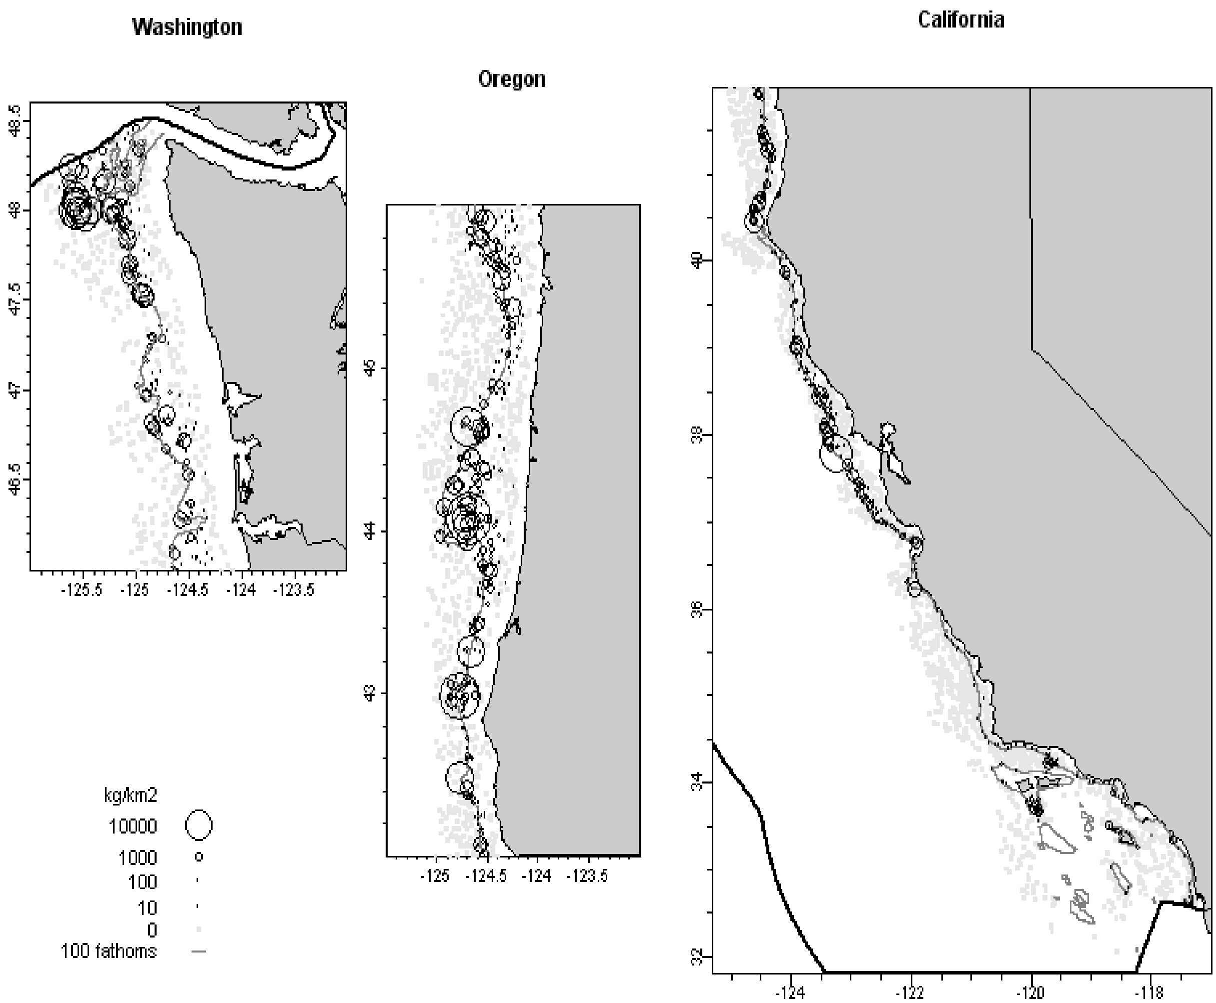

Figure 16: Catch rates over all years for the NWFSC survey.

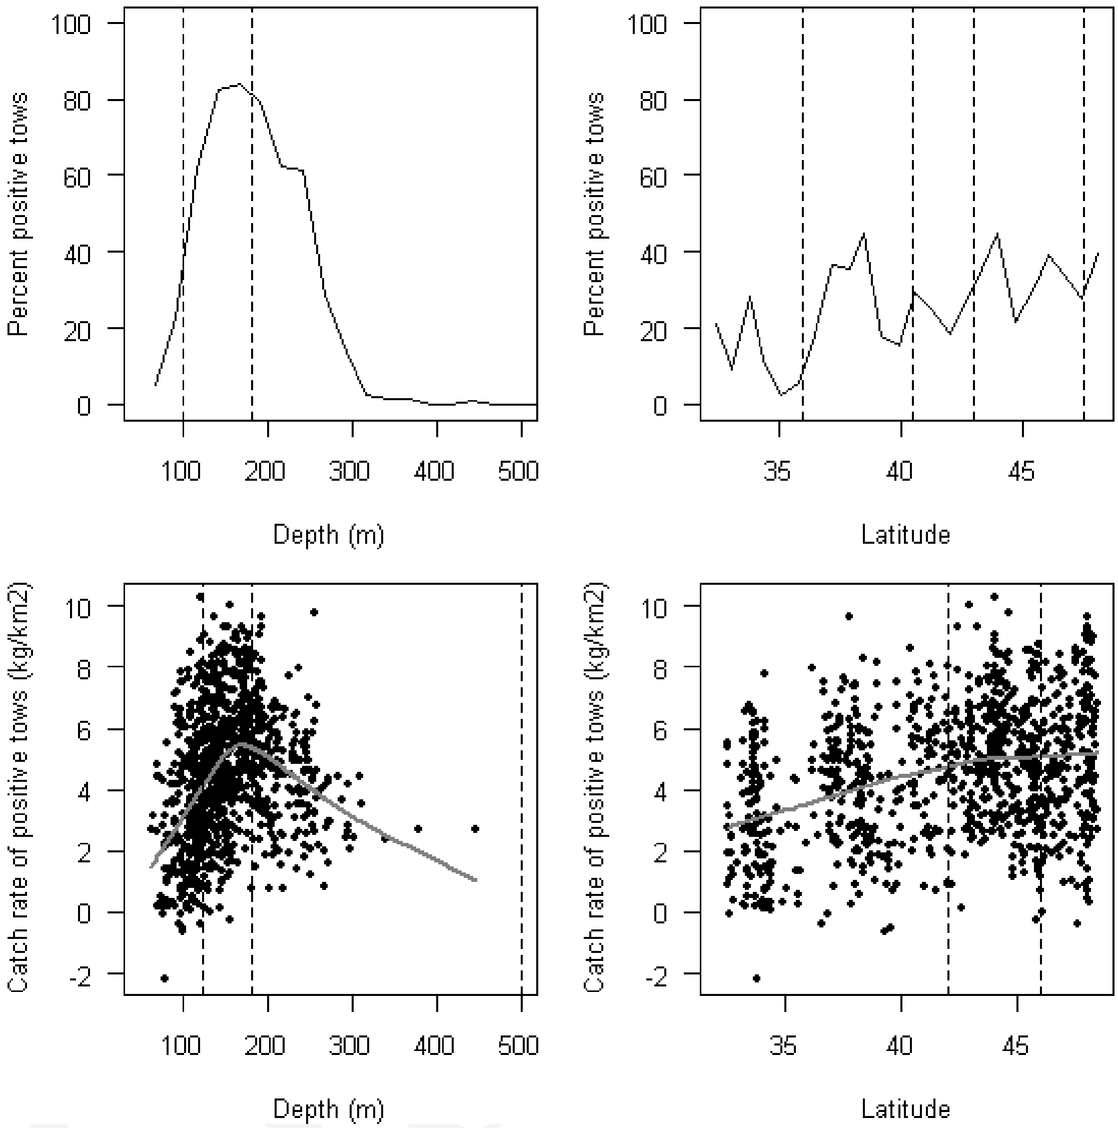

Figure 17: Plots of the percentage of positive tows and the catch rates for positive tows over depth and latitude.

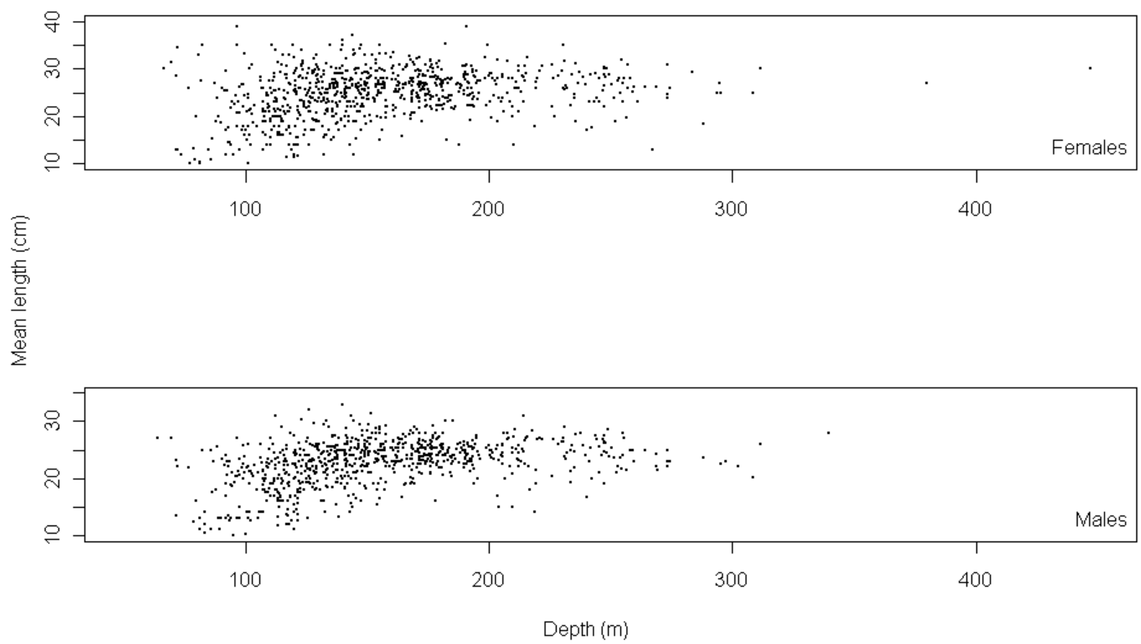

Figure 18: NWFSC survey mean length per tow by depth for females and males.

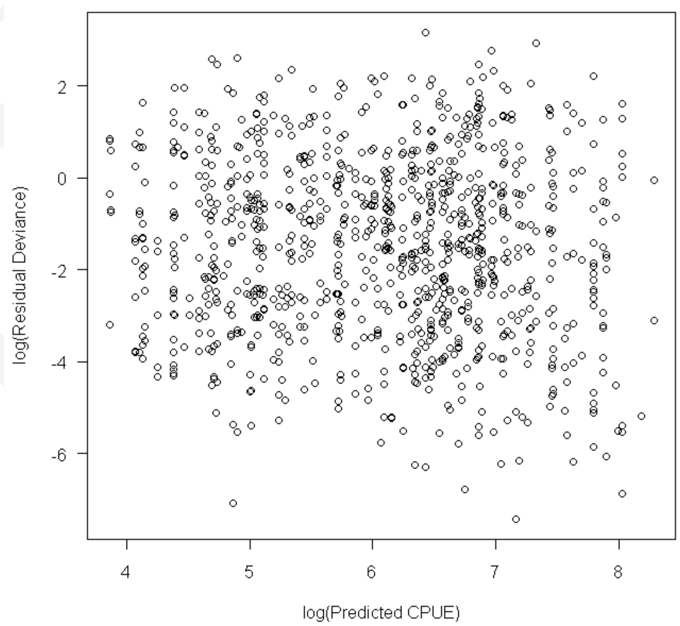

Figure 19: Plot of the predicted values against residuals for the positive tow model used in the GLMM.

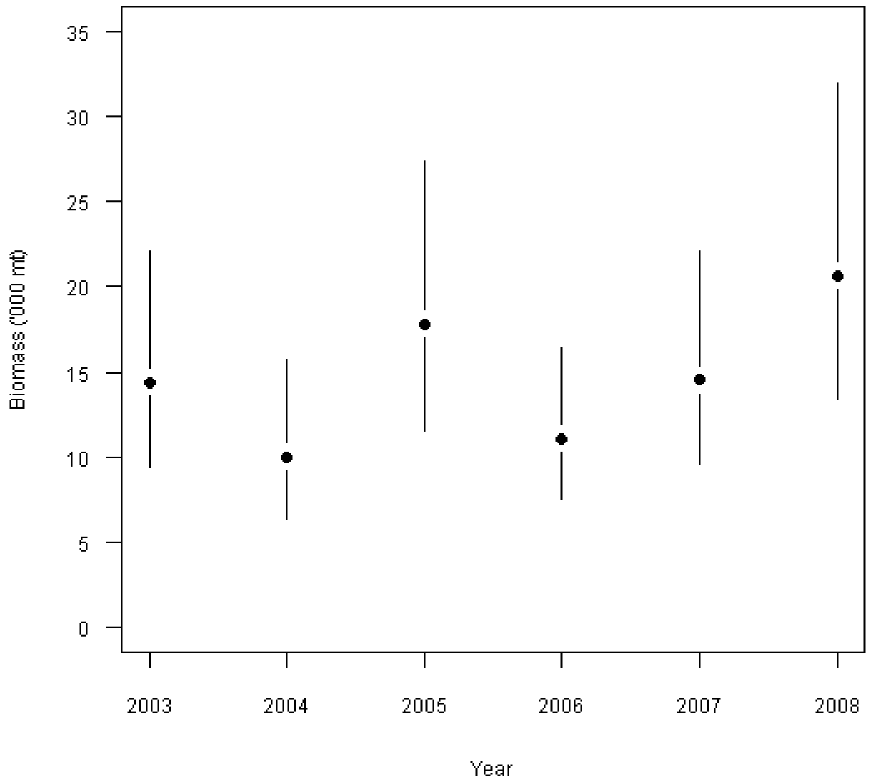

Figure 20: GLMM biomass estimates for the NWFSC survey.

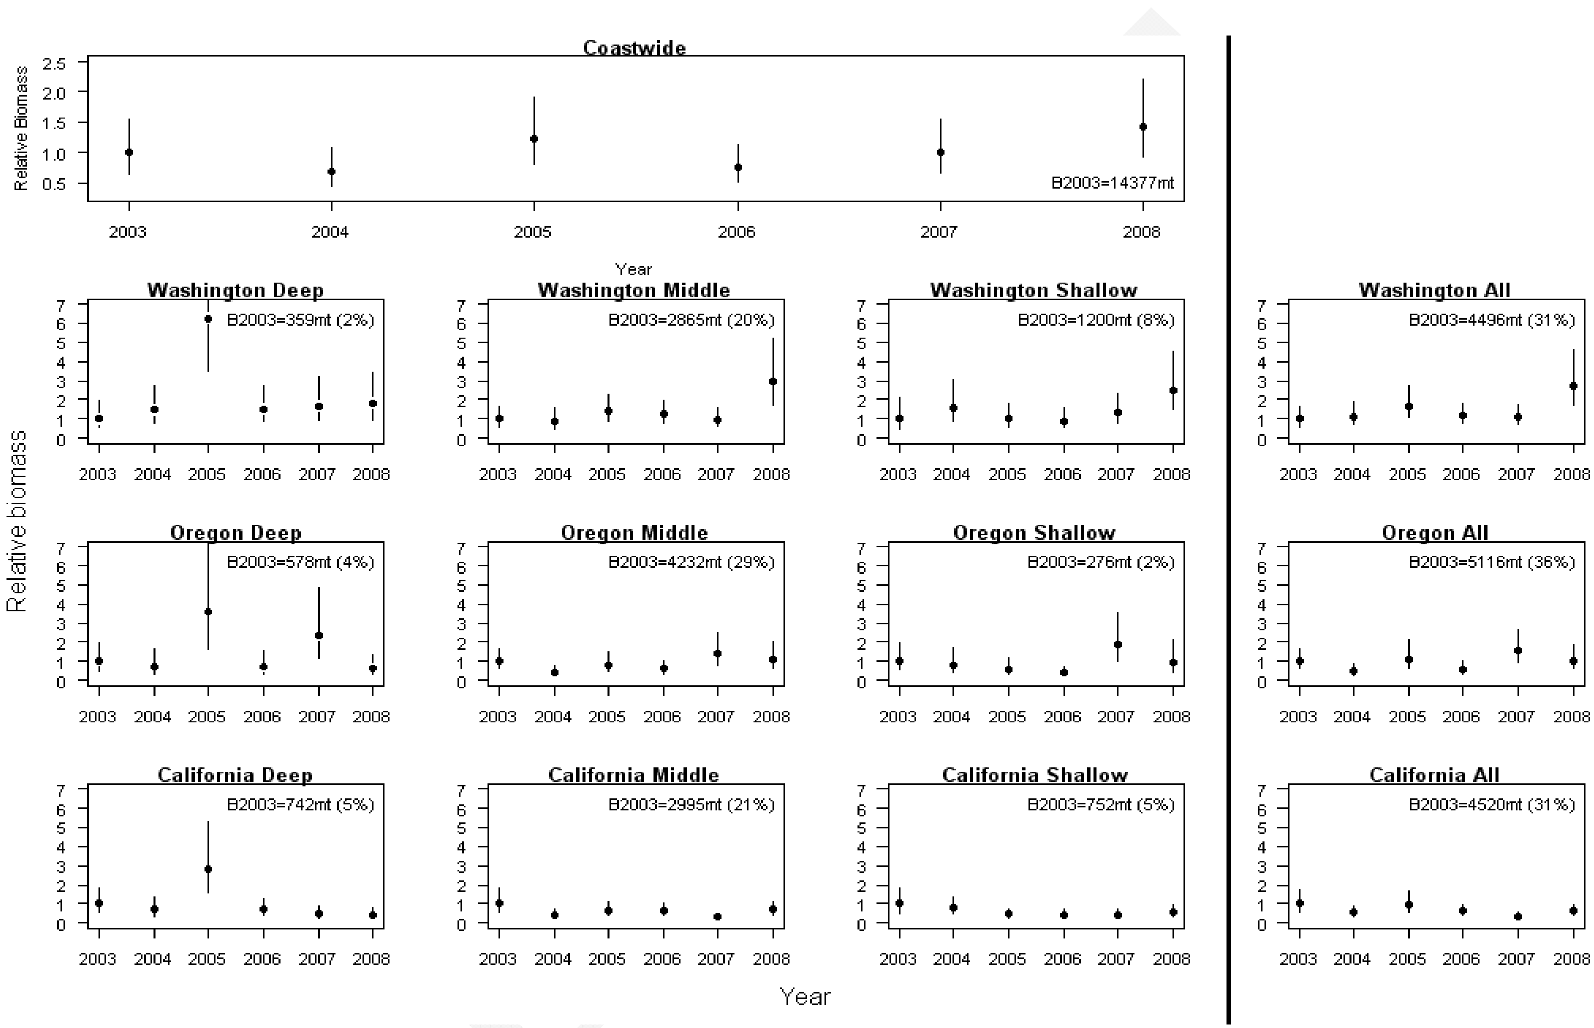

Figure 21: Plots of the estimated biomass relative to the year 2003 for each strata chosen for the GLMM using the NWFSC survey. The top wide plot is the entire coast and the plots to the right of the solid line are summer over depth.

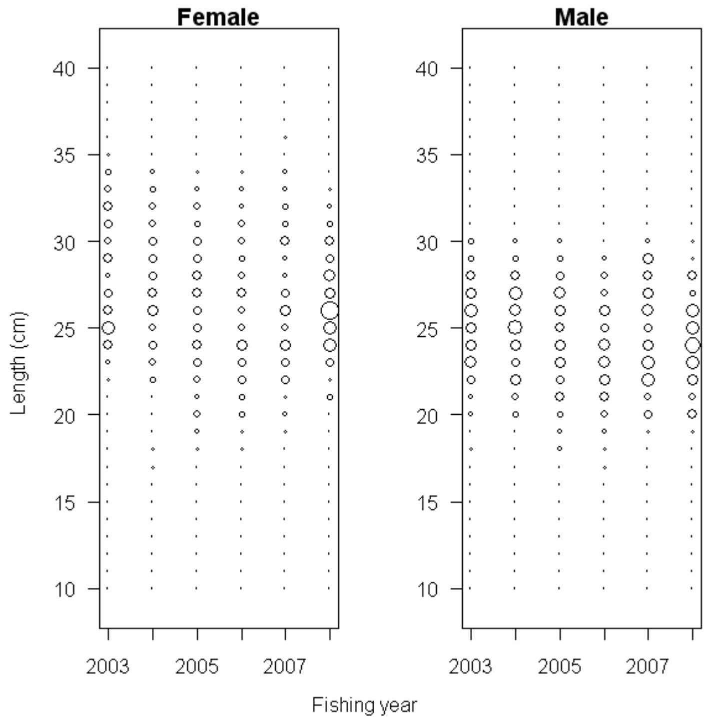

Figure 22: Length frequencies for the NWFSC survey.

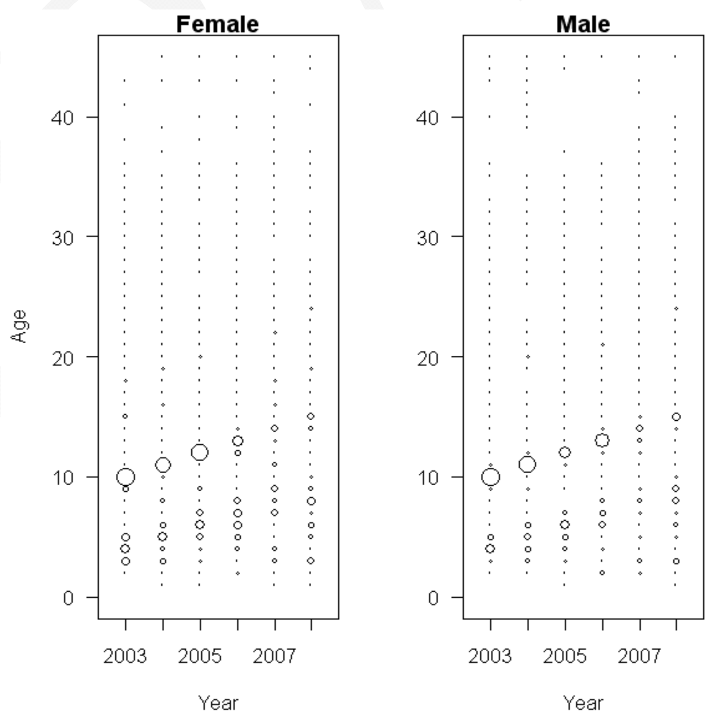

Figure 23: Age frequencies from the NWFSC survey. The omission of a circle indicates that no observation occurred at that age.

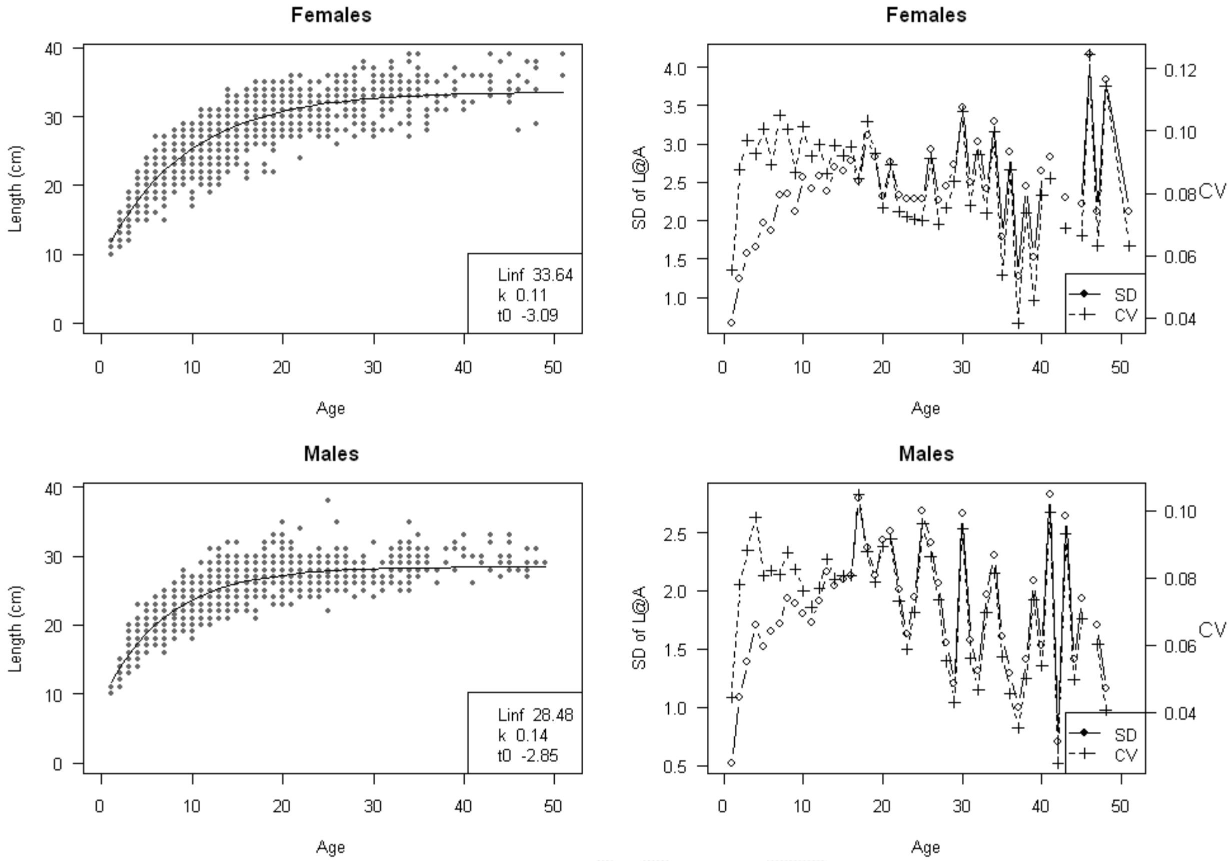

Figure 24: Length-at-age, standard deviation at age, and CV at age from all years of the NWFSC survey.

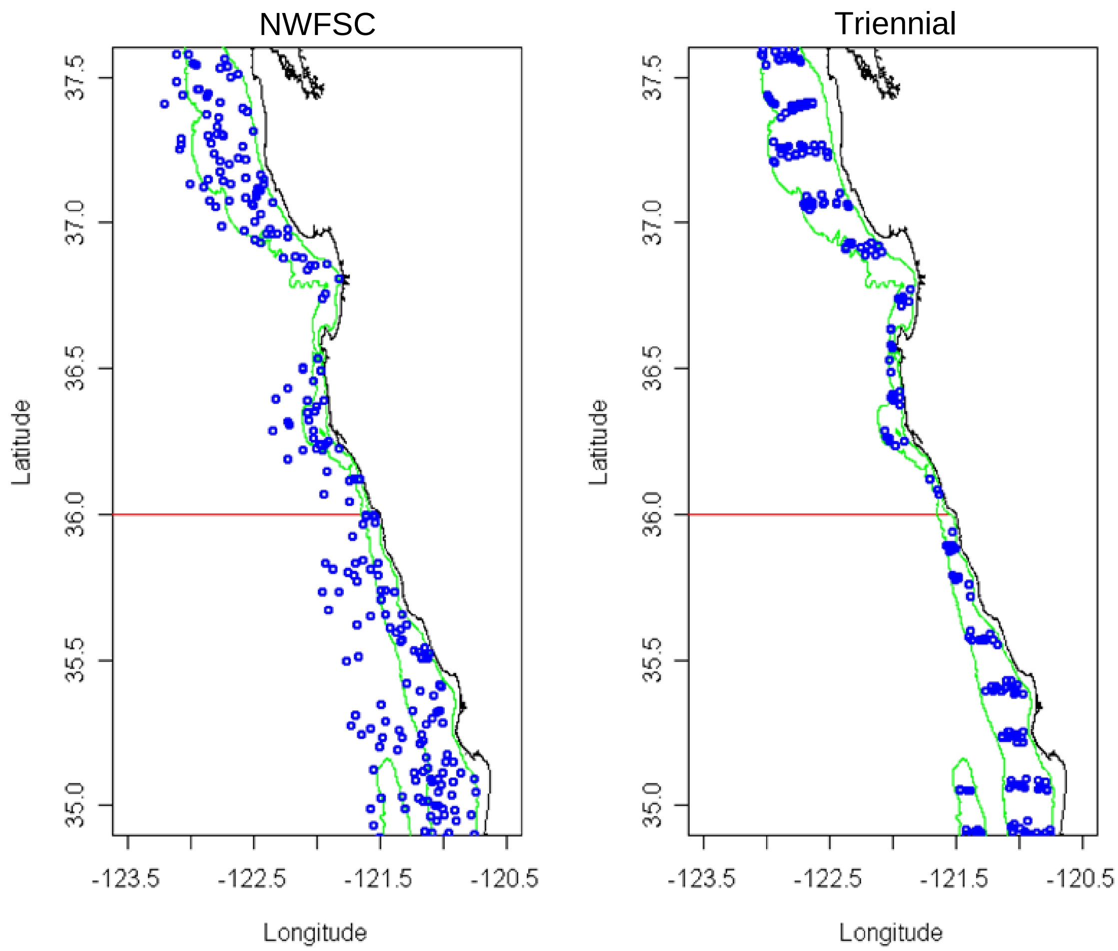

Figure 25: Survey tow locations in 2004, showing the difference in station design for the NWFSC survey relative to the Triennial trawl survey (Figure from Stewart (2007)).

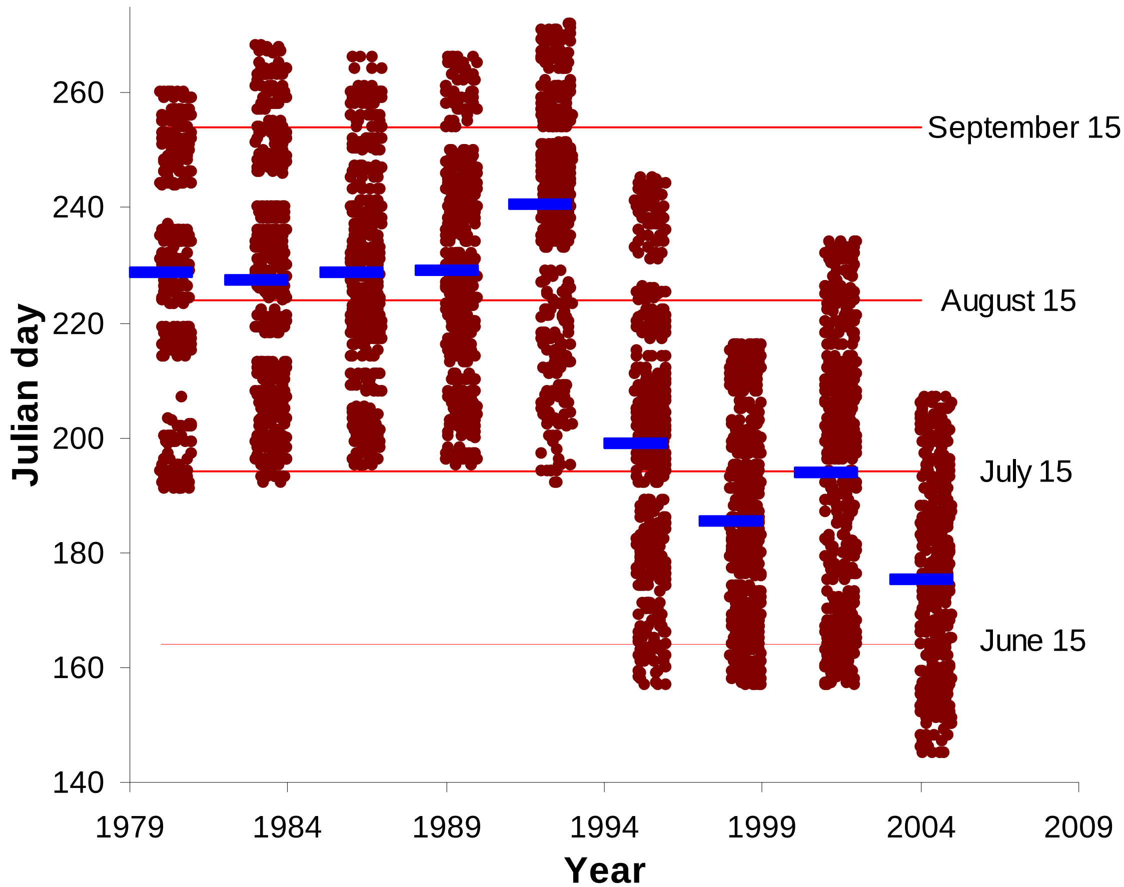

Figure 26: Distribution of dates of operation for the triennial survey (1980-2004). Solid bars show the mean date for each survey year, points represent individual hauls dates, but are jittered to allow better delineation of the distribution of individual points (Figure from Stewart (2007)).

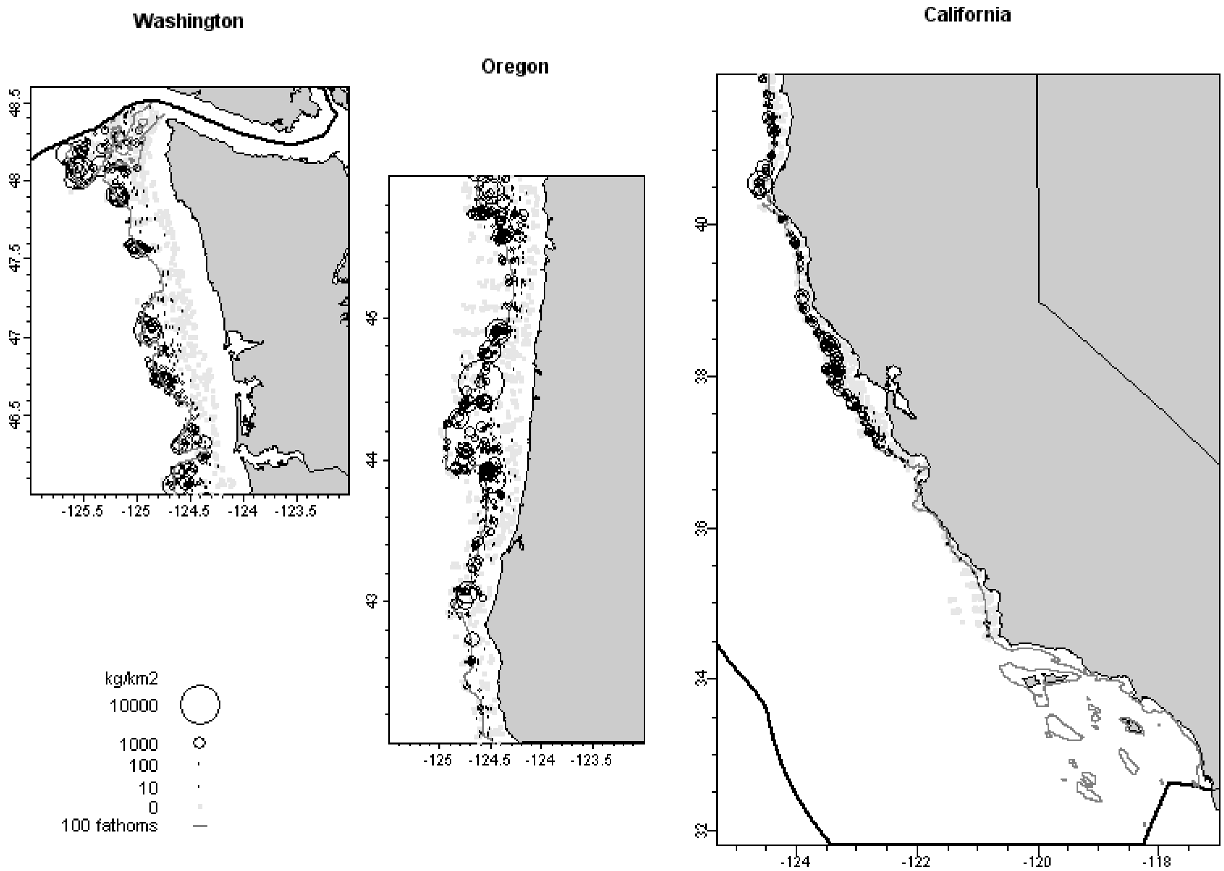

Figure 27: Catch rates over all years for the Triennial survey.

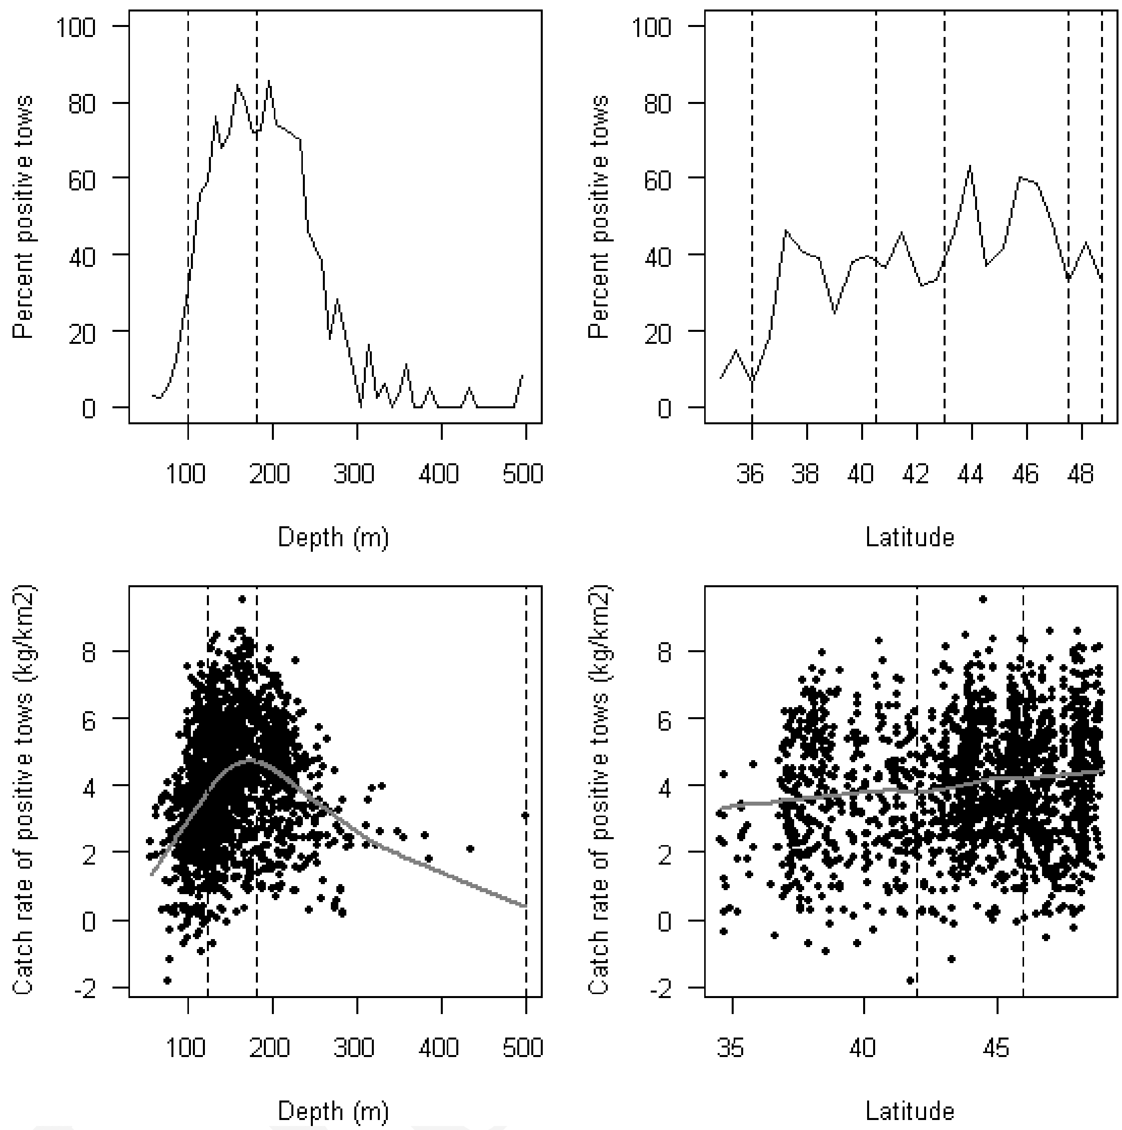

Figure 28: Plots of the percentage of positive tows and the catch rates for positive tows over depth and latitude.

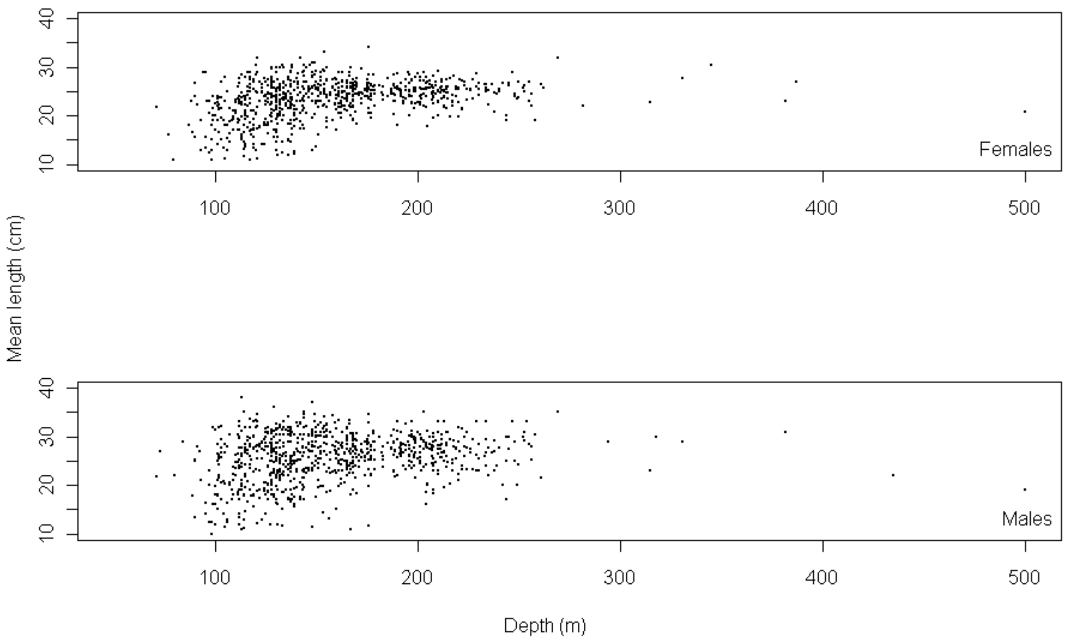

Figure 29: The mean length per tow from the Triennial survey data plotted over depth for females and males.

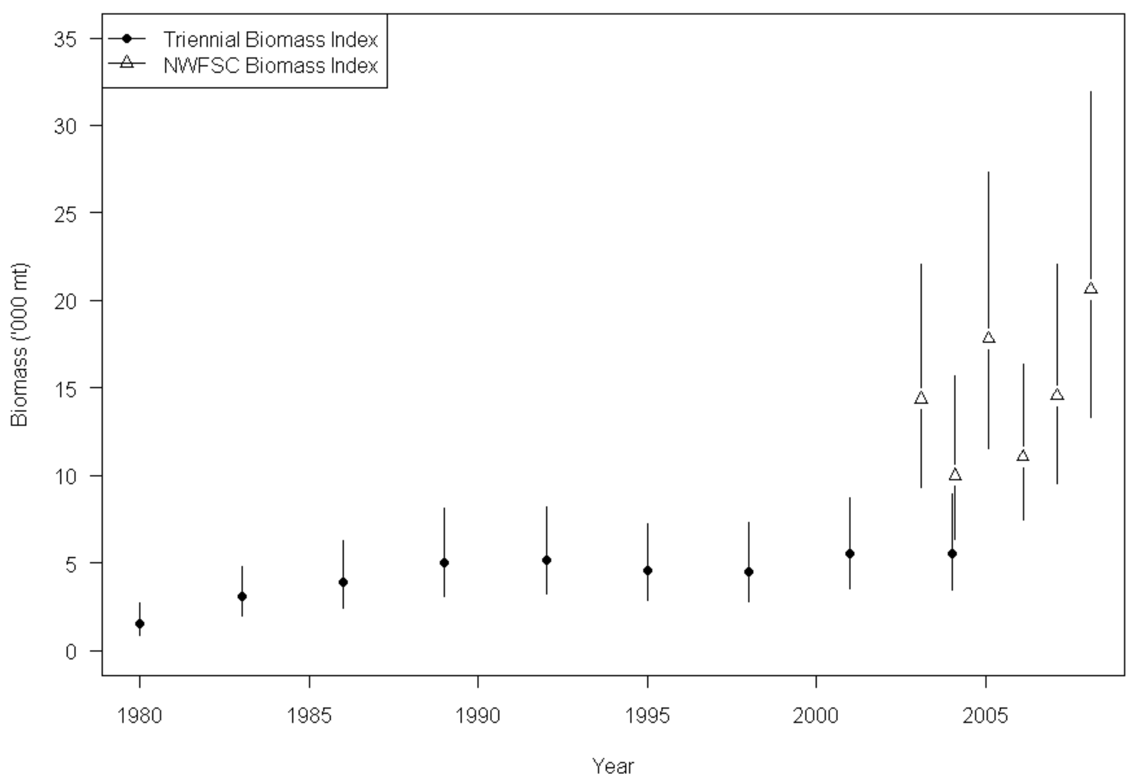

Figure 30: GLMM biomass estimates for the Triennial survey and the NWFSC survey.

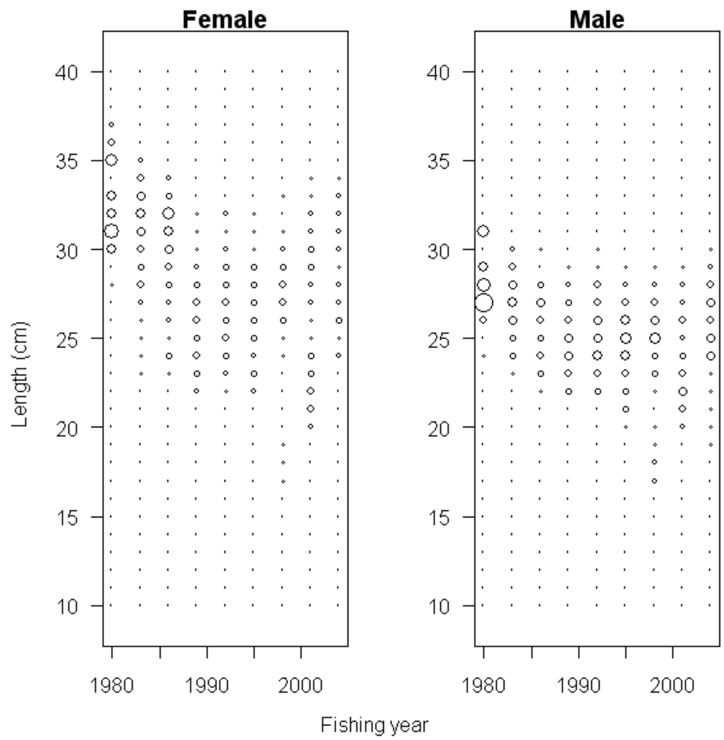

Figure 31: Plots of length frequencies from the Triennial survey.

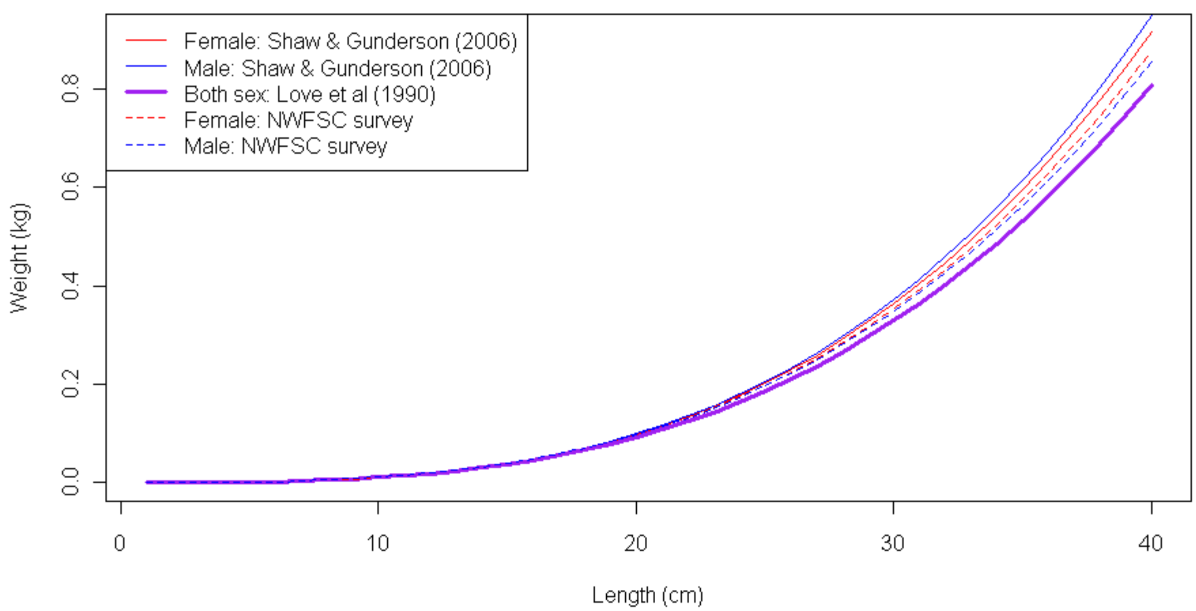

Figure 32: Weight- length relationships from Shaw and Gunderson (2006), Love et al (1990), and data collected during the NWFSC survey.

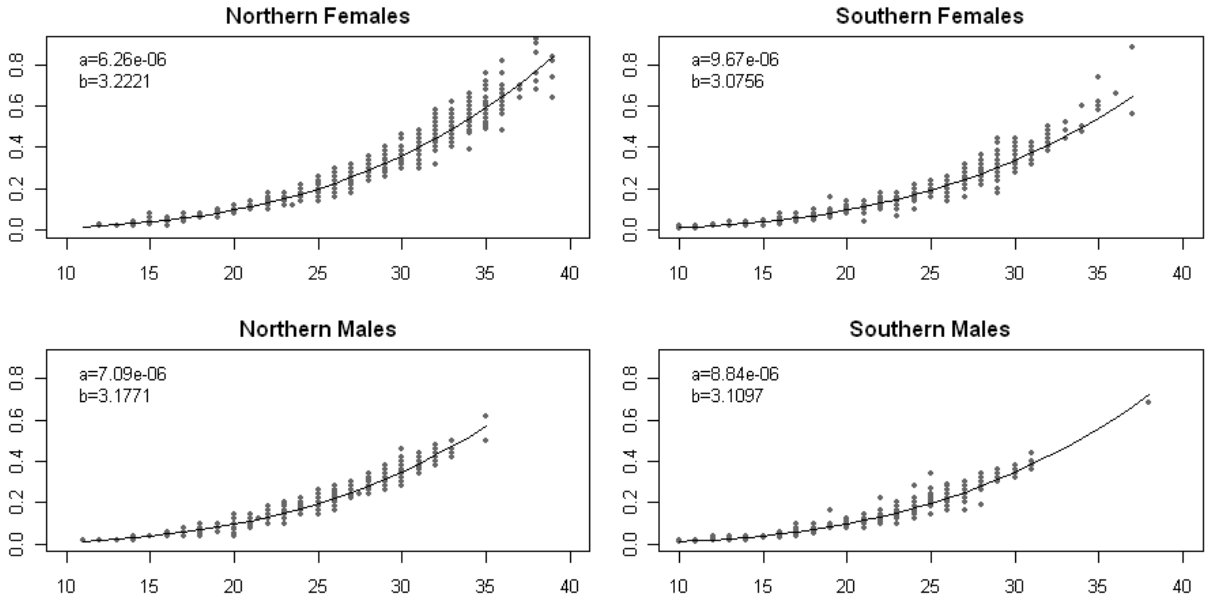

Figure 33: Weight-length relationships for females and males north and south of 42°N (CA/OR border).

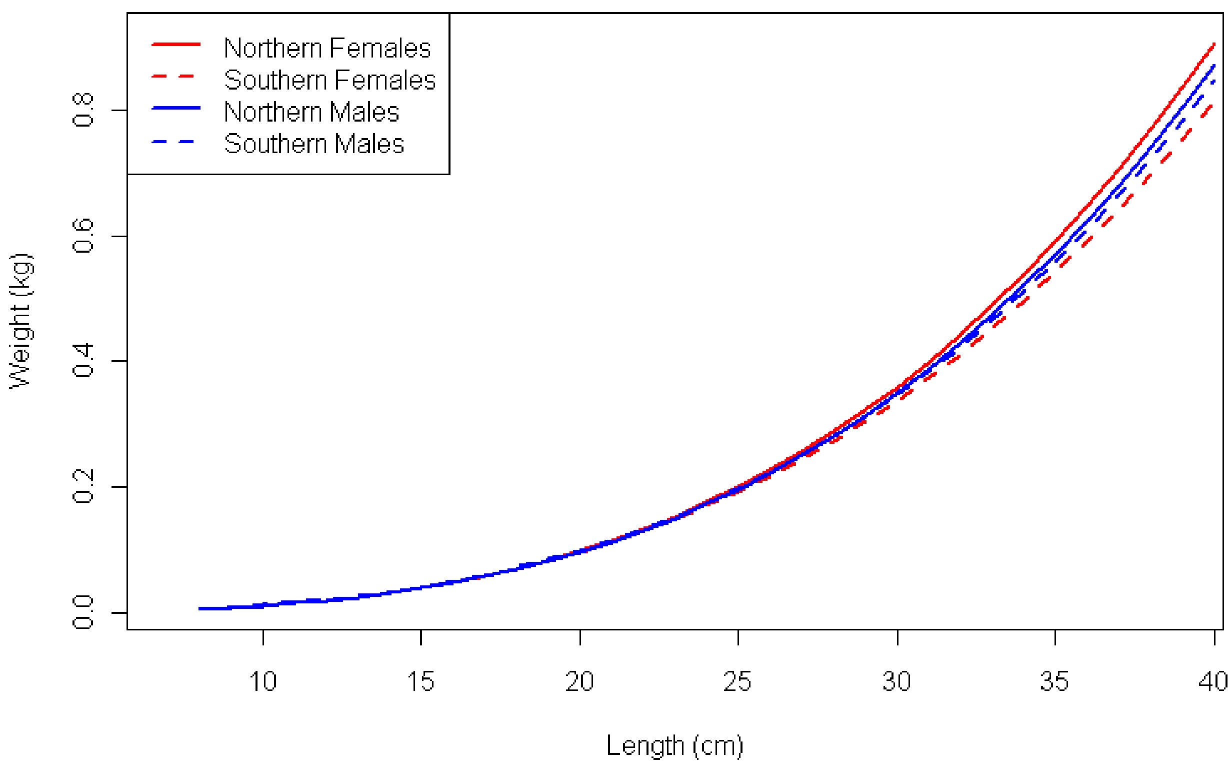

Figure 34: Weight length relationships north and south of 42°N by sex from the NWFSC survey data.

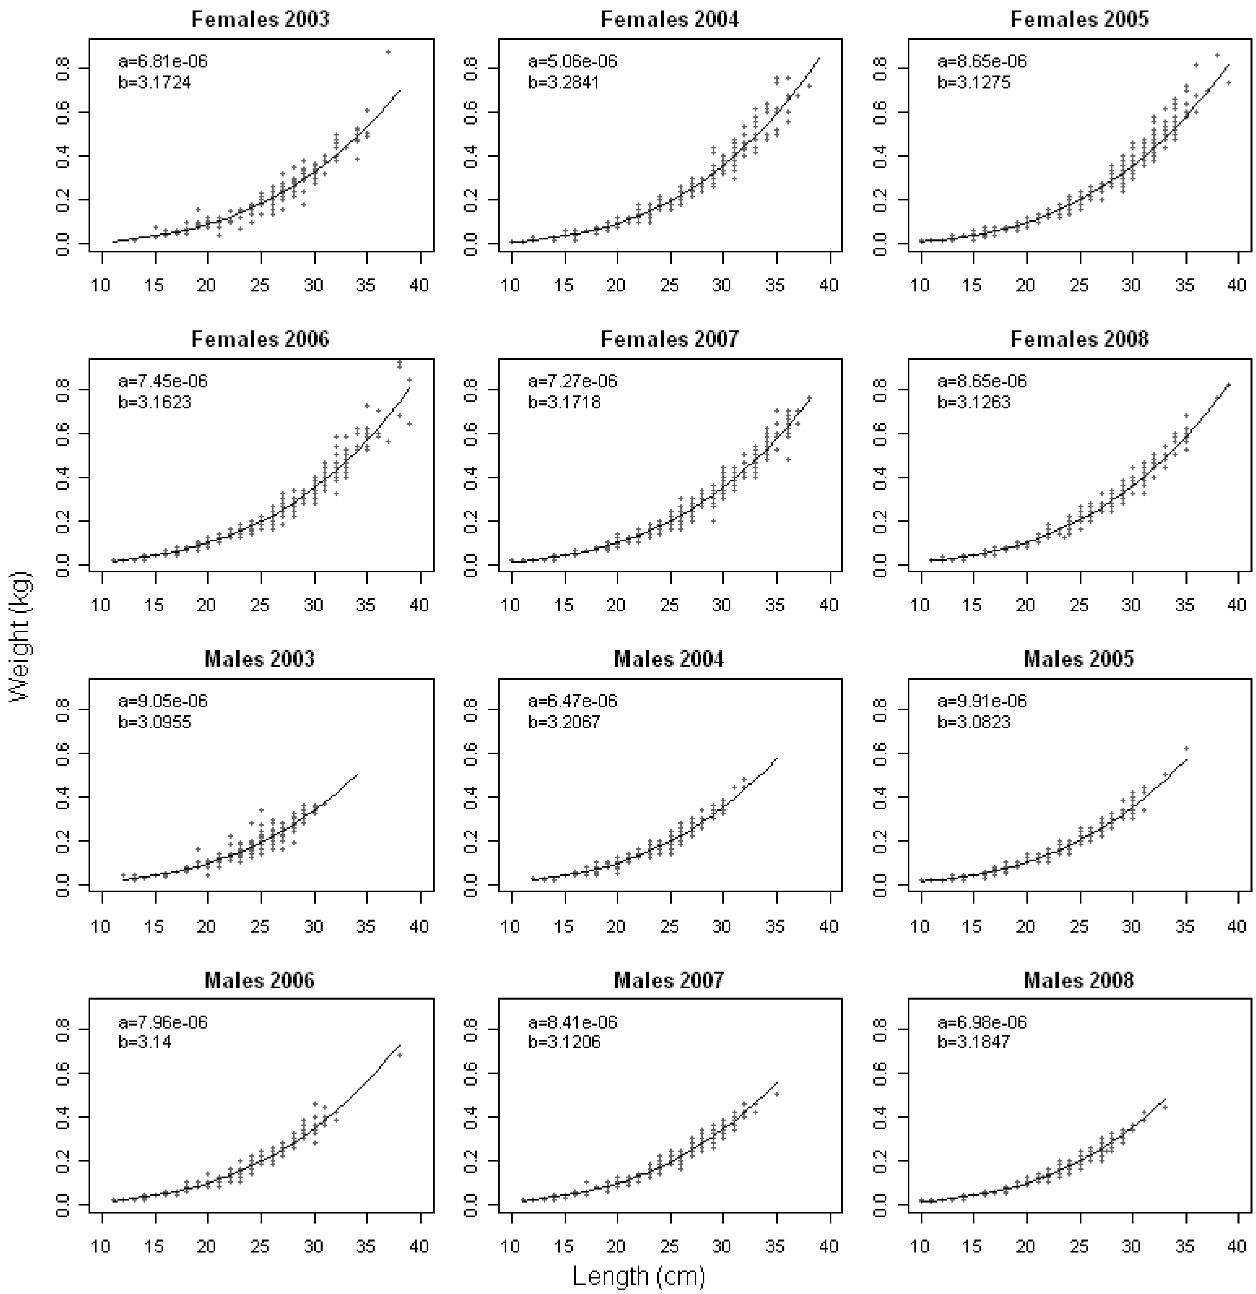

Figure 35: Yearly estimates of the weight-at-length relationship for greenstriped rockfish using NWFSC survey data.

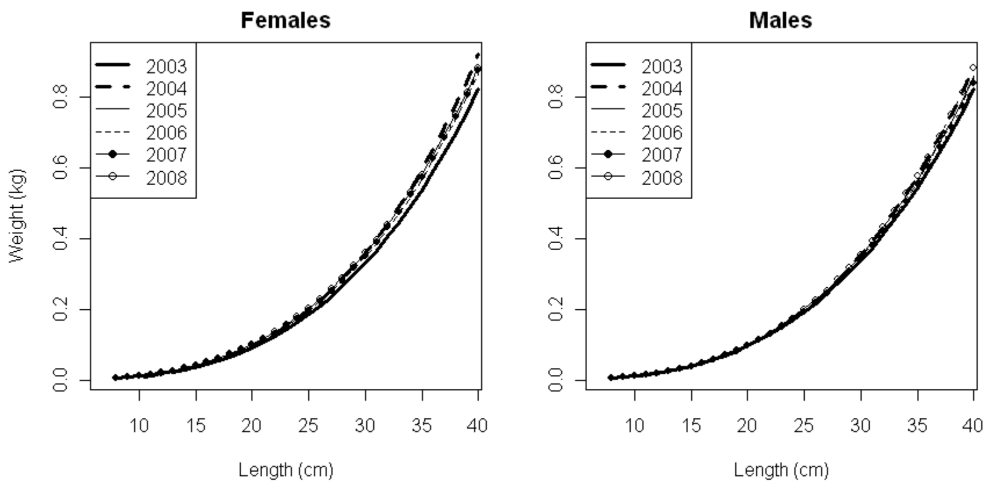

Figure 36: Comparison of yearly estimates, by sex, of the weight-at-length relationship for greenstriped rockfish using NWFSC survey data.

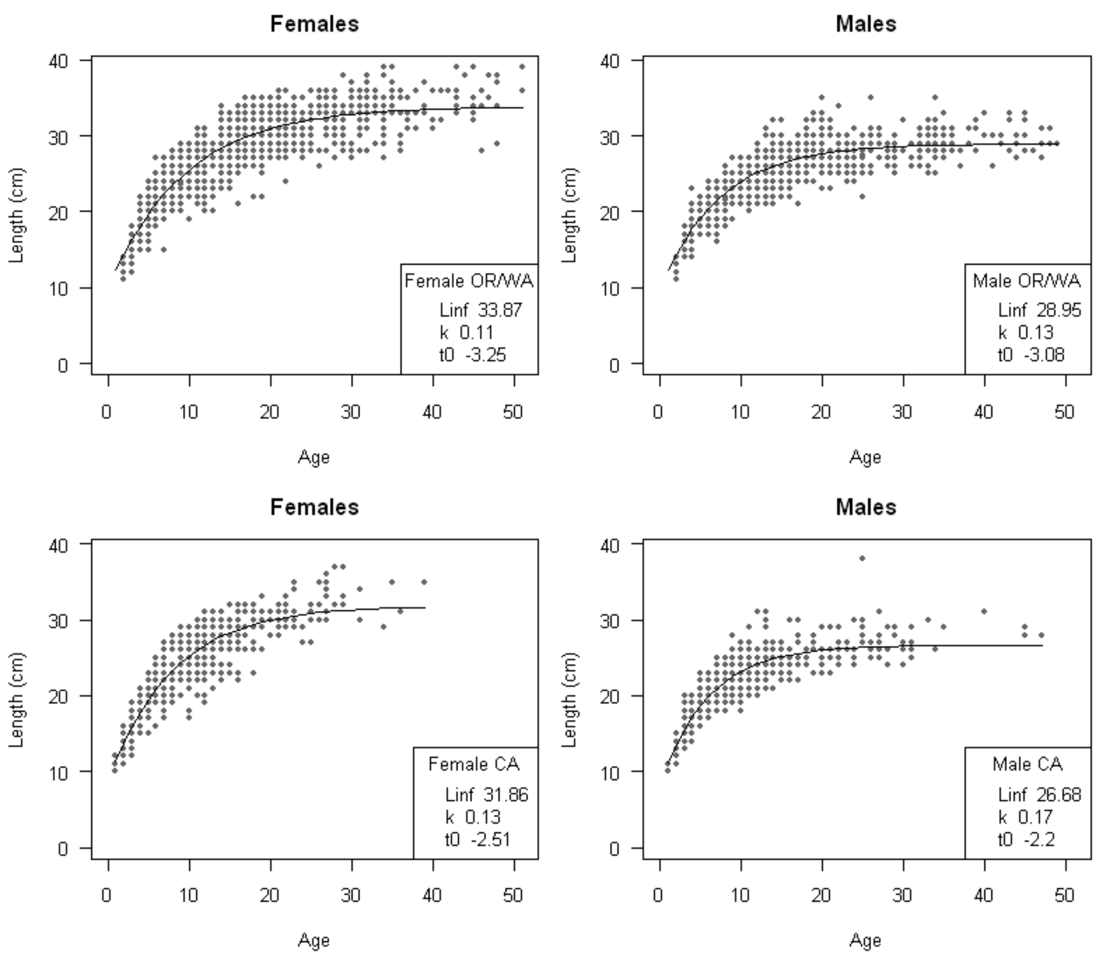

Figure 37: Length-at-age and predicted von Bertalanffy growth curves for female and male greenstriped rockfish sampled in the NWFSC survey from OR/WA (North) and CA (South).

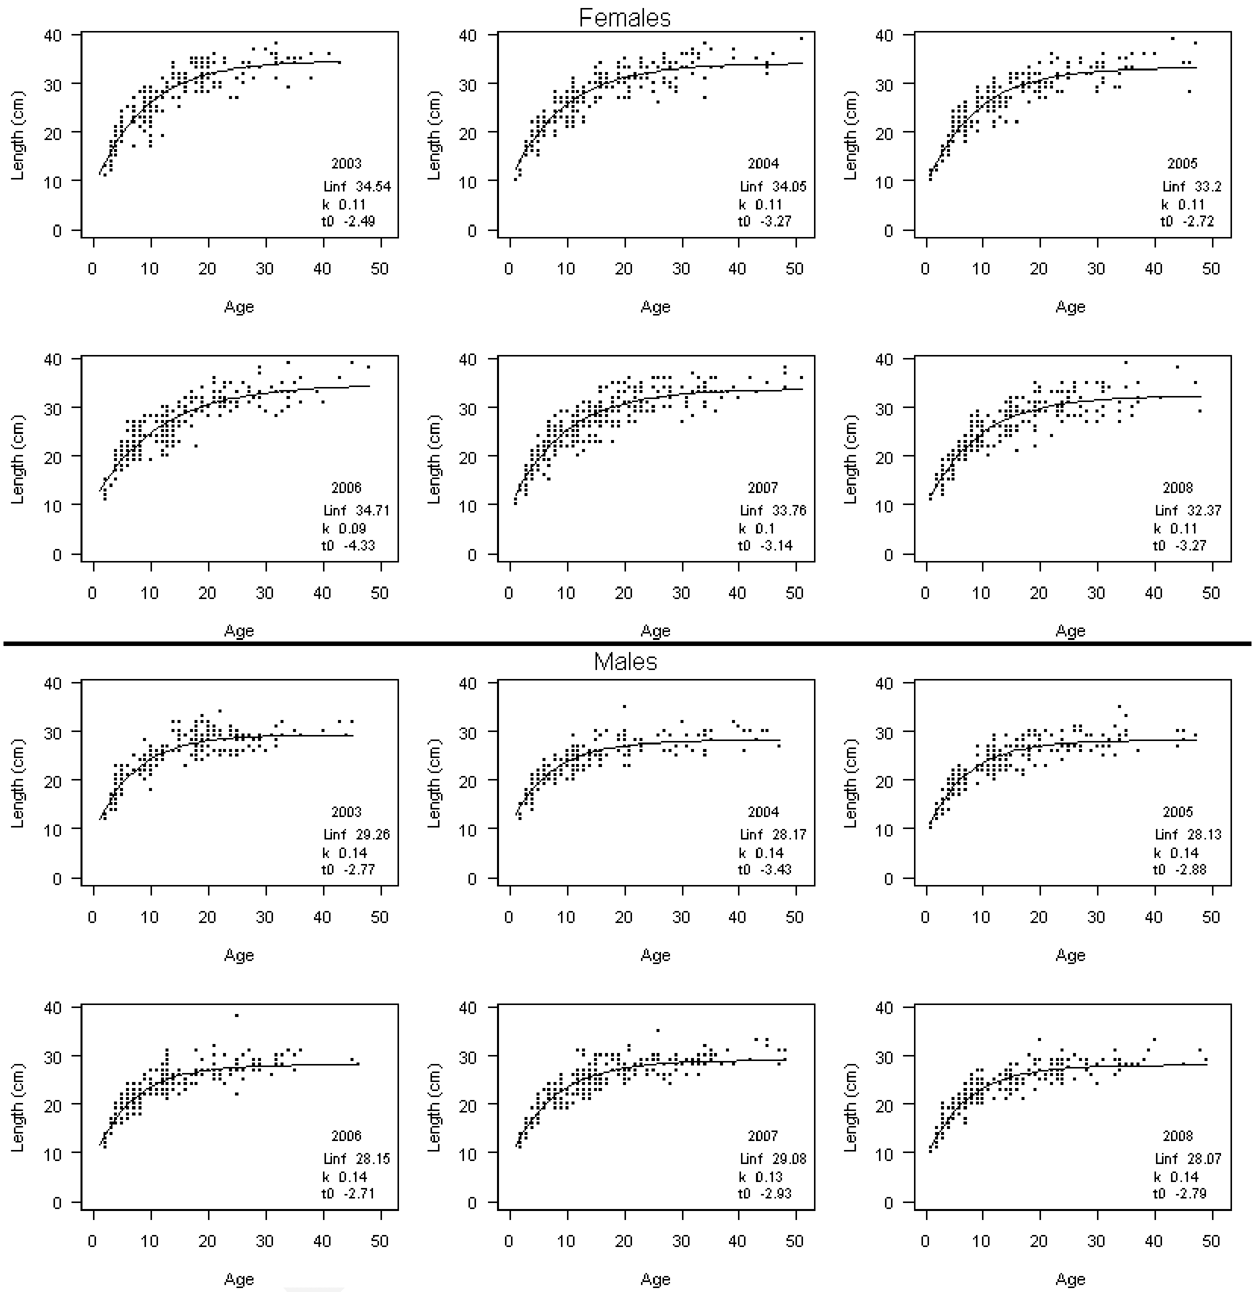

Figure 38: Estimated von Bertalanffy growth curves by year for females and males using the age data from the NWFSC survey.

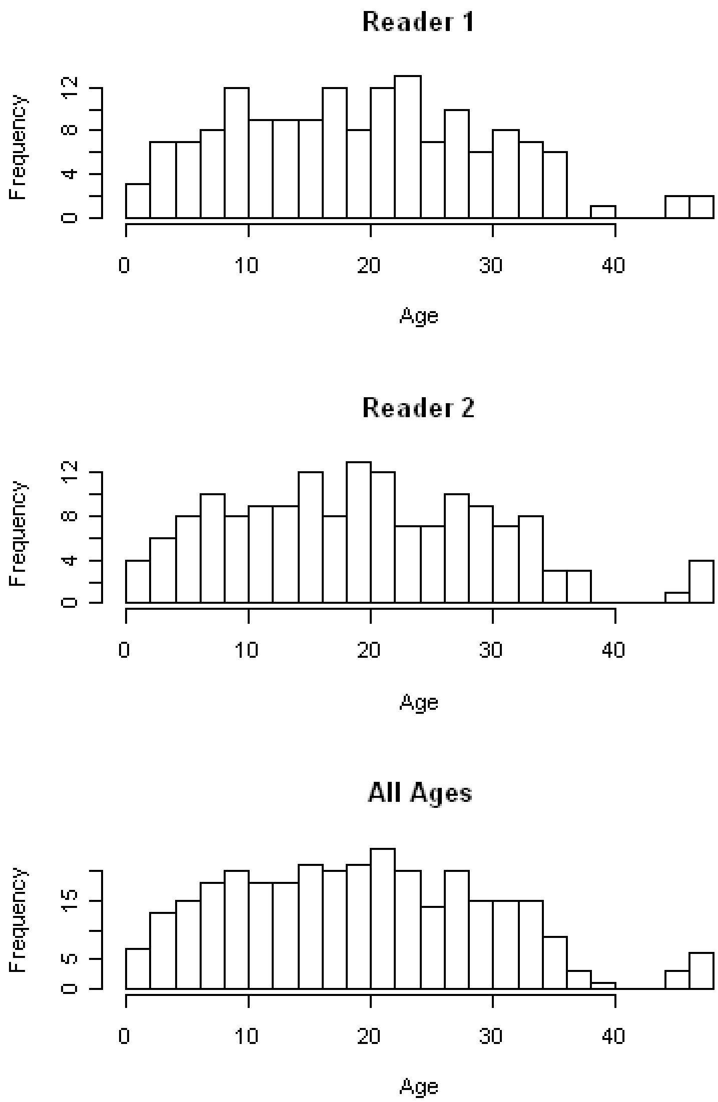

Figure 39: Histograms of greenstriped rockfish double reads for each age reader and all ages combined.

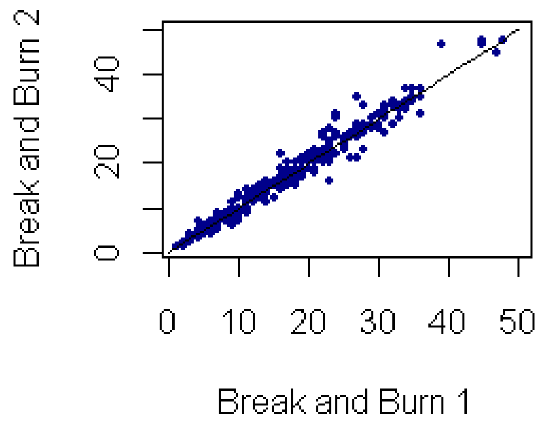

Figure 40: Scatter plot of the double read data from readers 1 and 2. The black line is the one-to-one line.

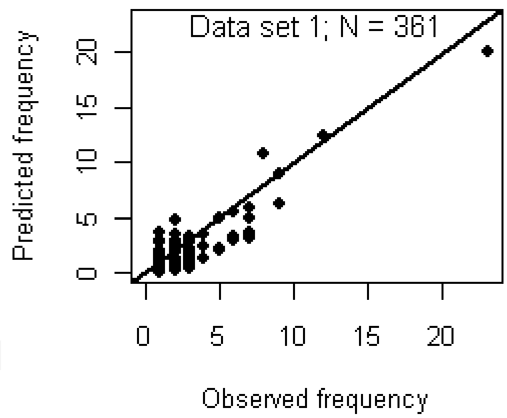

Figure 41: Points show the observed versus predicted number of ages. The black line is the one-to-one line and indicates a perfect fit.

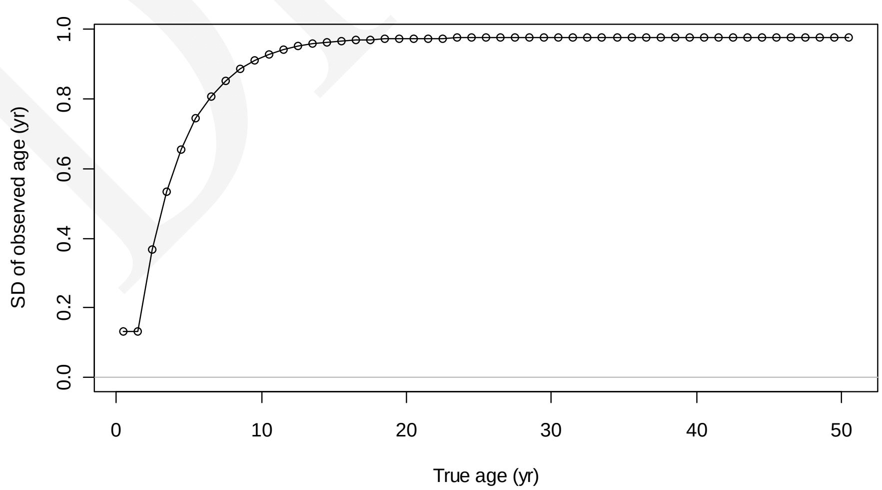

Figure 42: Model estimates of the standard deviation for the ageing error.

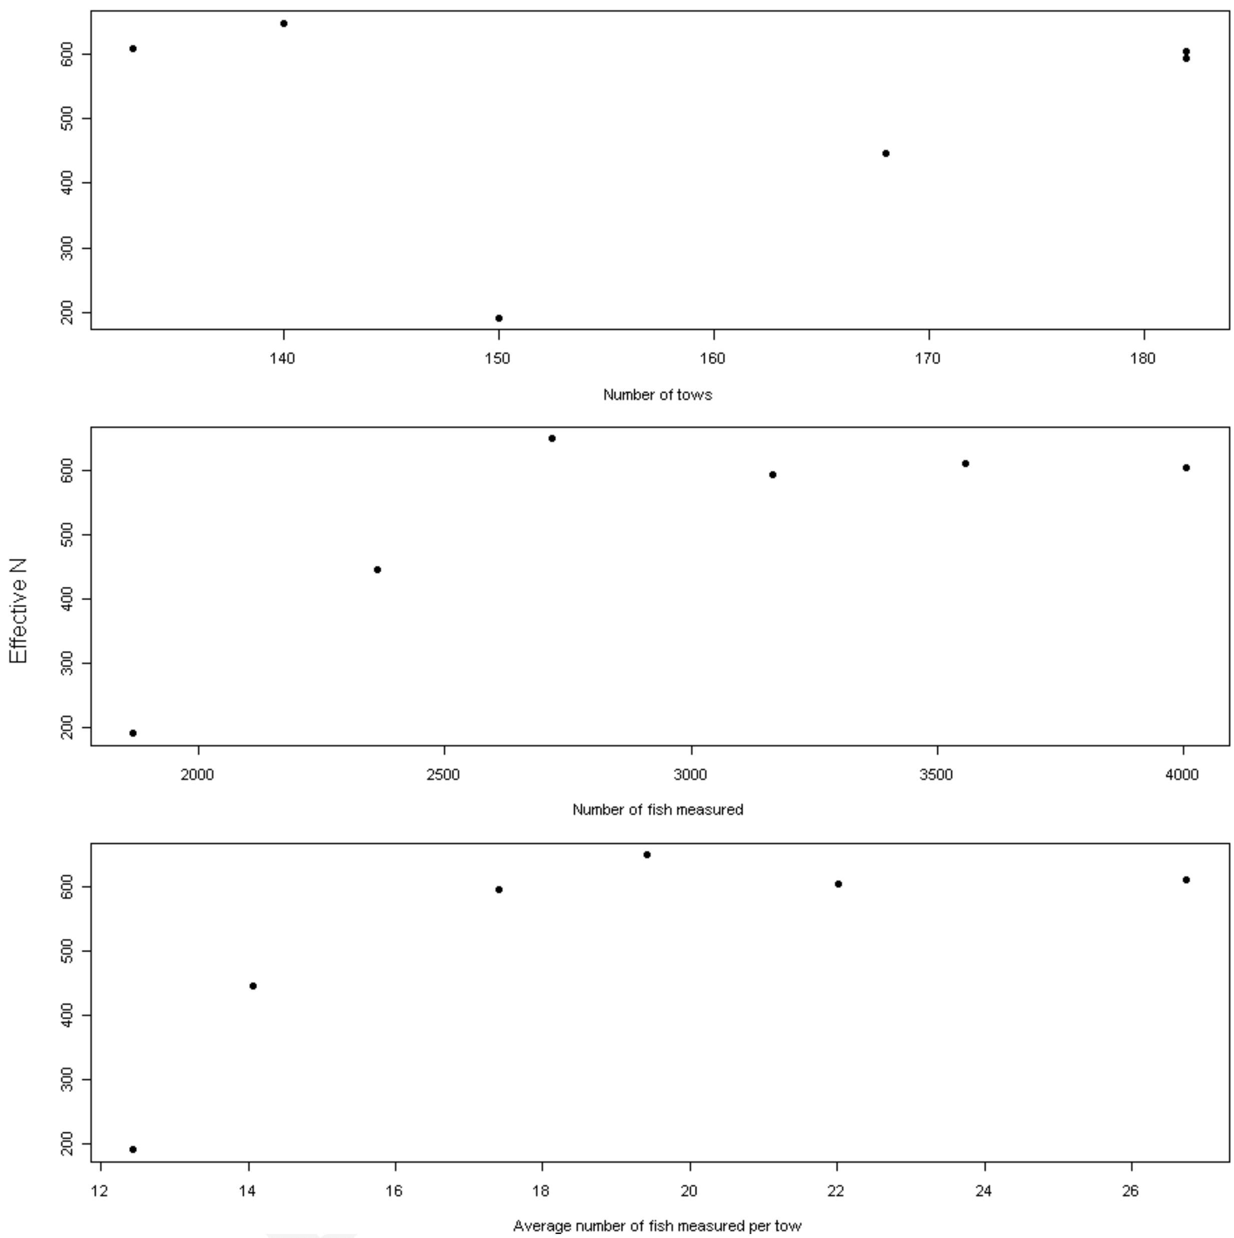

Figure 43: Effective N determined from the NWFSC survey plotted against the number of tows, the number of greenstriped rockfish measured, and the average number of greenstriped rockfish measured per tow.

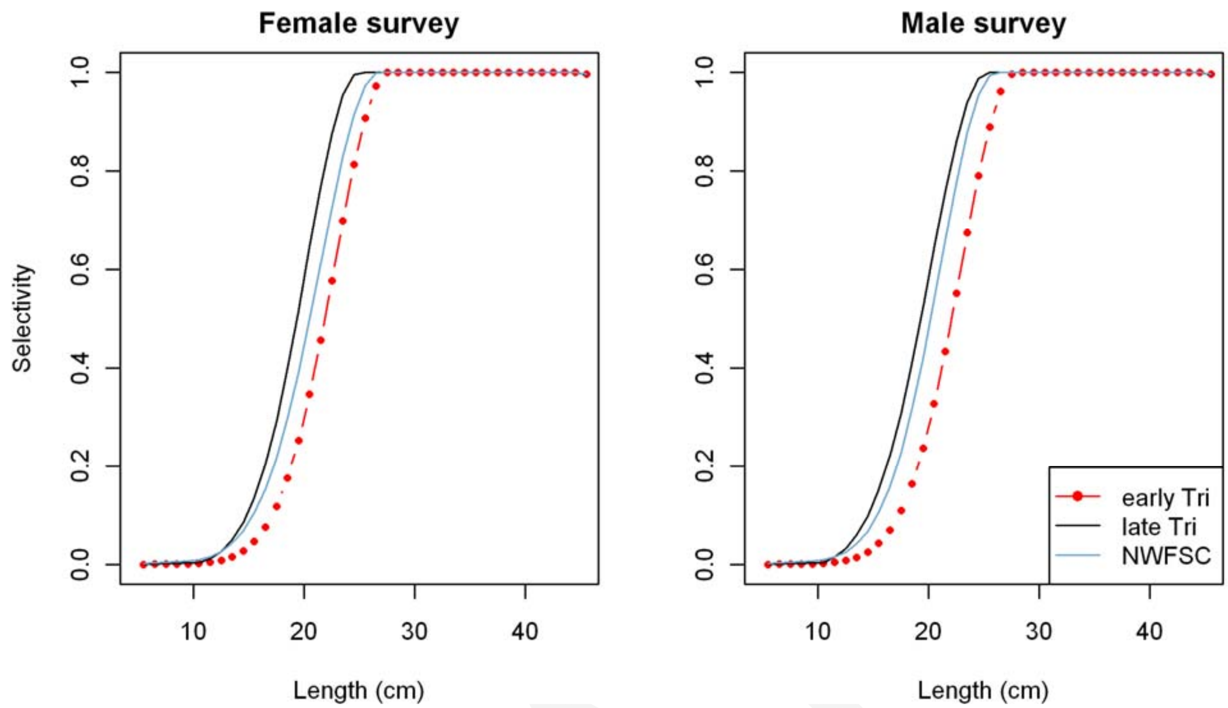

Figure 44: Estimated survey selectivity curves for females and males.

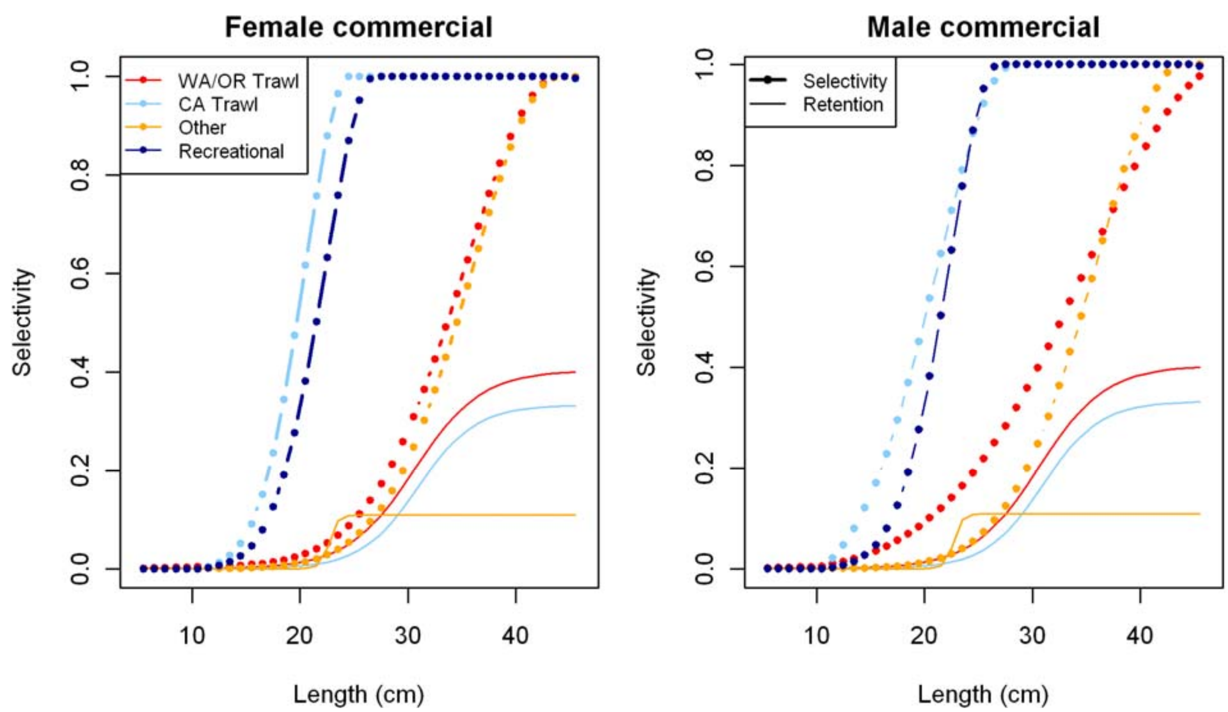

Figure 45: Estimated selectivity and retention curves for the domestic commercial fleets. The foreign fleet mirrors the CA Trawl selectivity without retention. The recreational fleet has discards included in the catch, thus does not model retention separate from selectivity. The fish at size kept by the fleet are determined from the product of selectivity and retention.

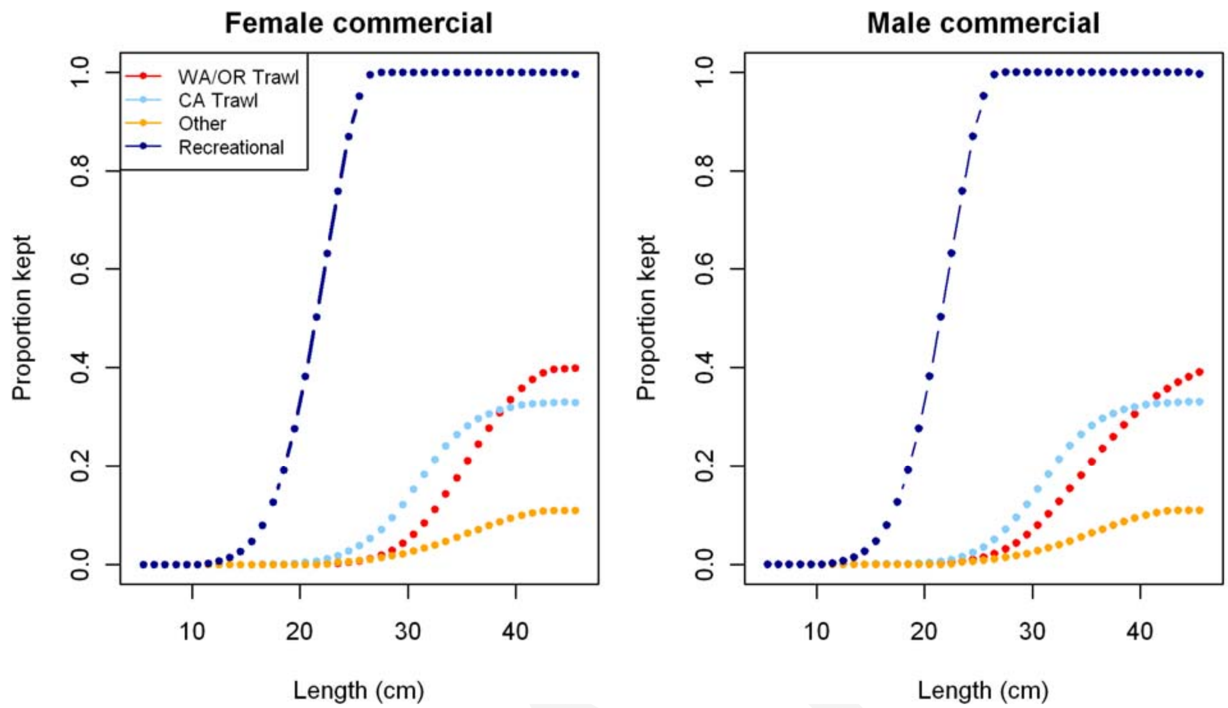

Figure 46: The kept fish selectivity curves determined from the product of selectivity and retention for each domestic fleet. Landings for recreational fisheries include discards thus are not explicitly modeled.

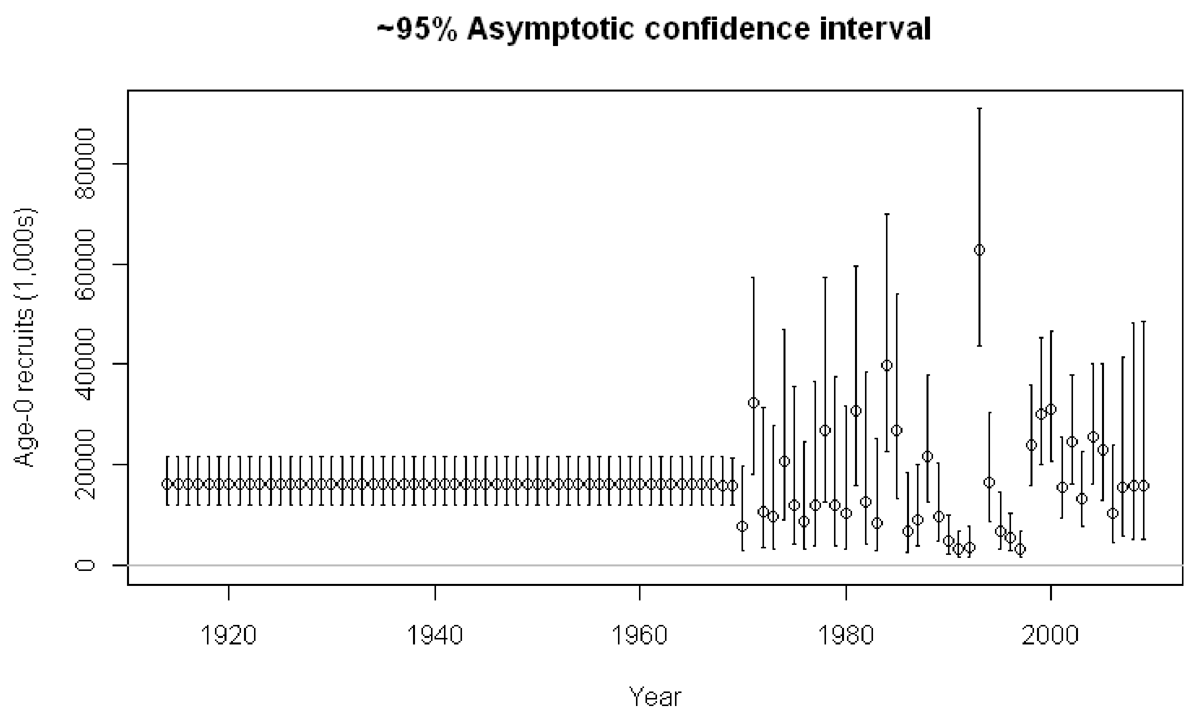

Figure 47: Estimated recruitment with approximate 95% asymptotic confidence intervals.

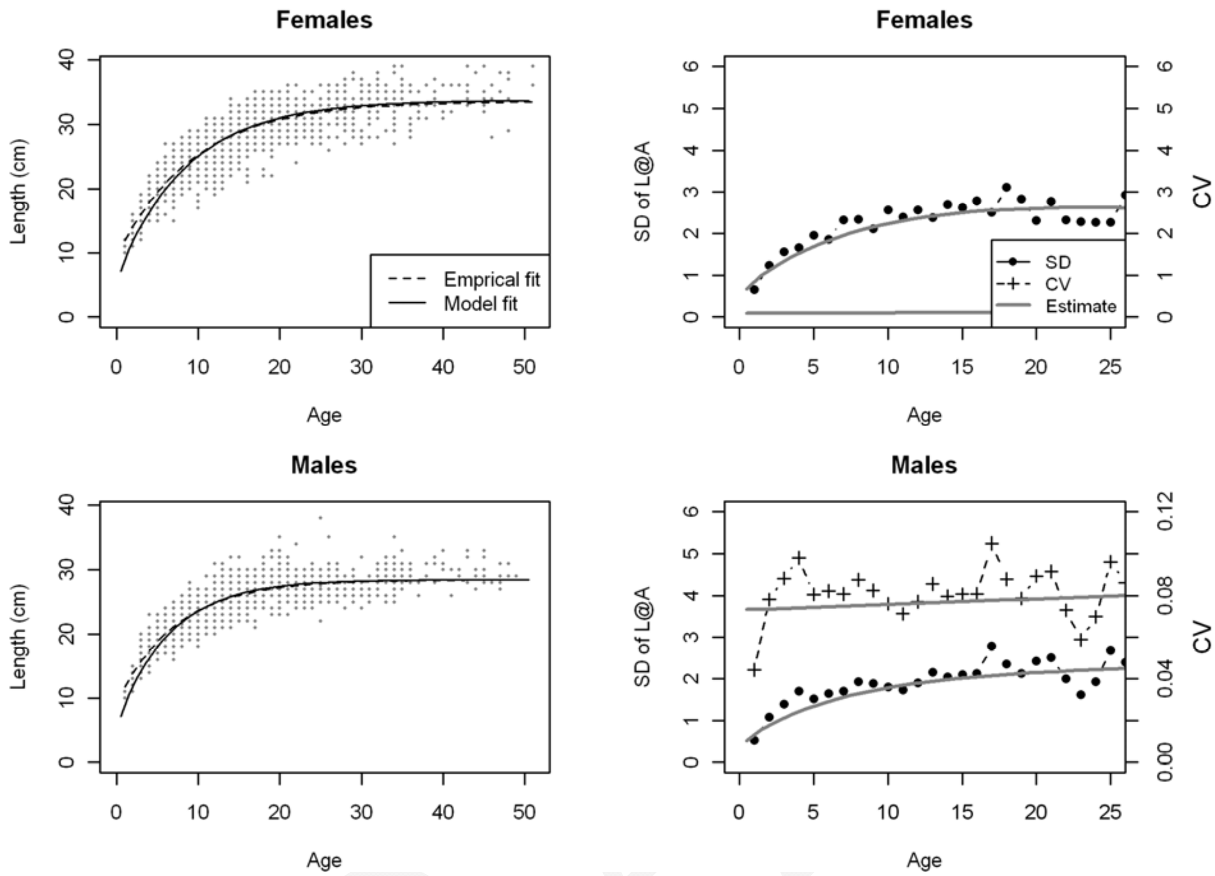

Figure 48: Fits to the length-at-age for females and males (left plots). Also shown are the fits to the CV of the growth curve as a function of age (fit directly in the model) and implied fits to the standard deviation (SD) of the growth curve at age.

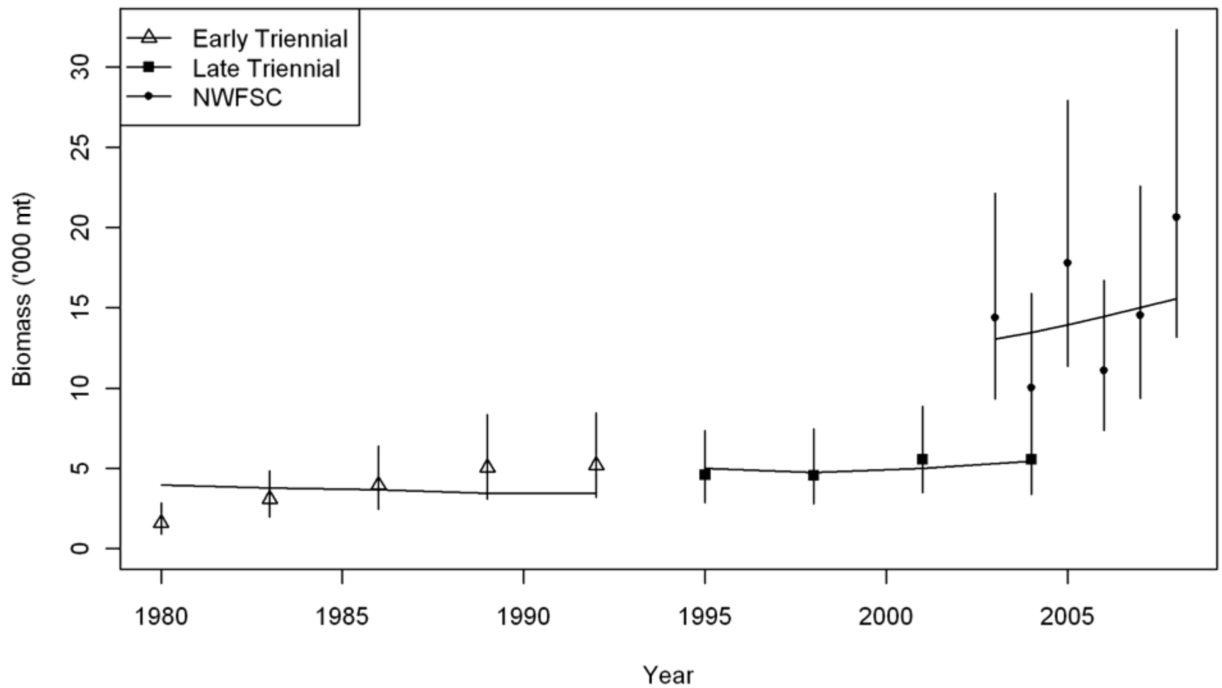

Figure 49: Fits from the base case model to the survey abundance indices with 95% confidence intervals on the observations.

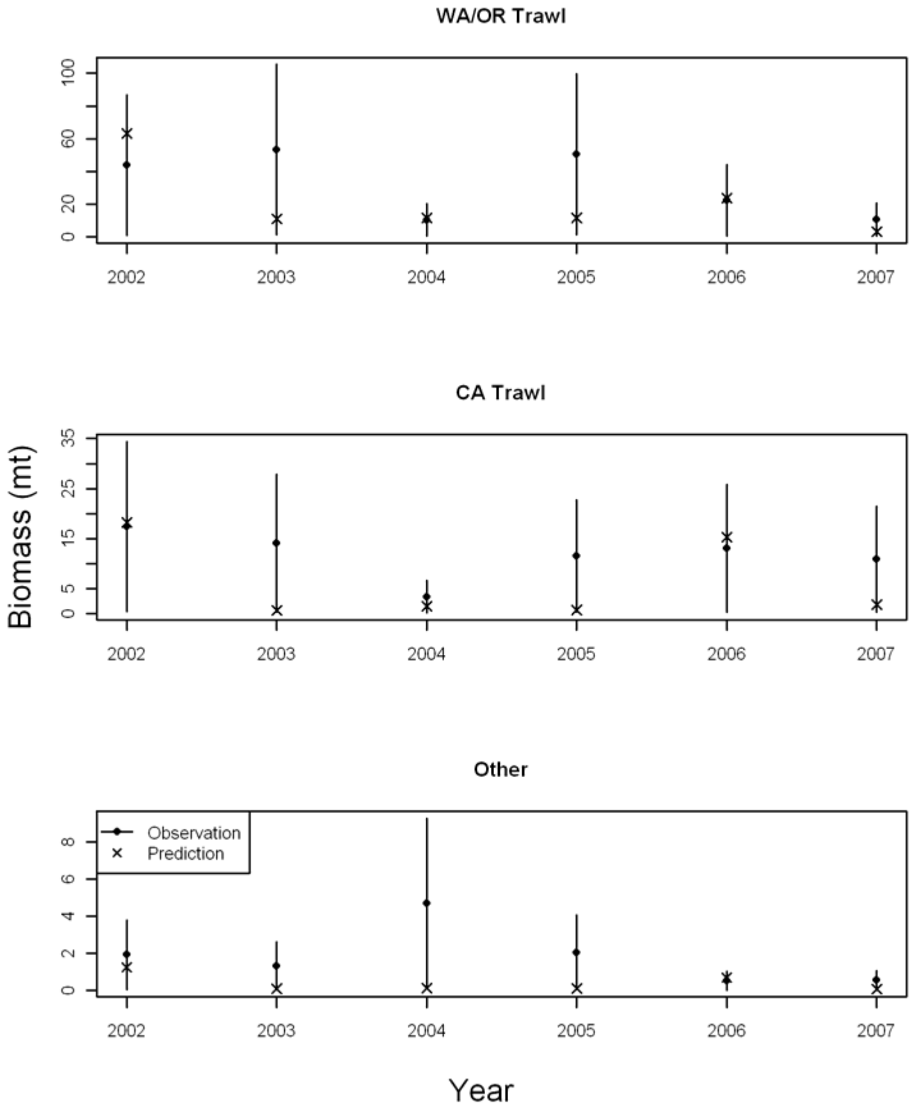

Figure 50: Fits to the total discards (mt) by fleet and year.

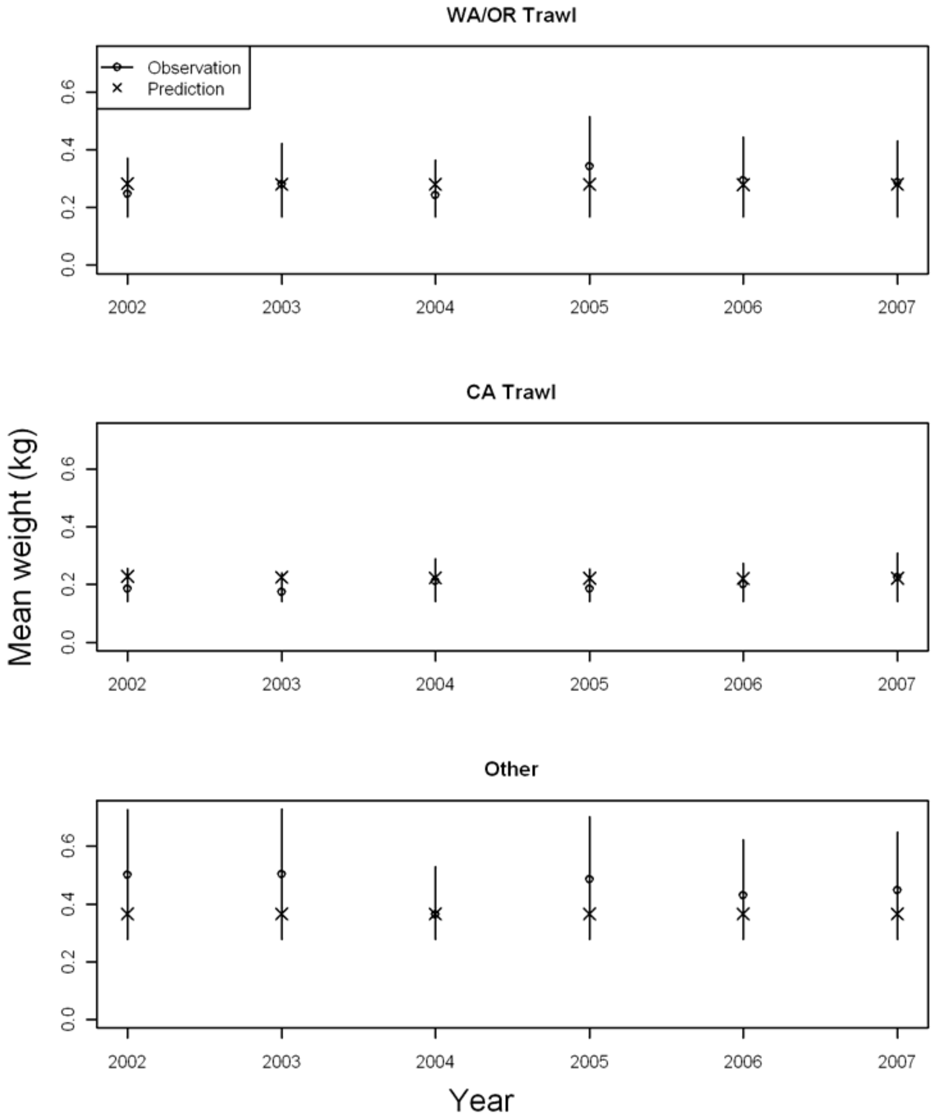

Figure 51: Fits to the mean weight of discards.

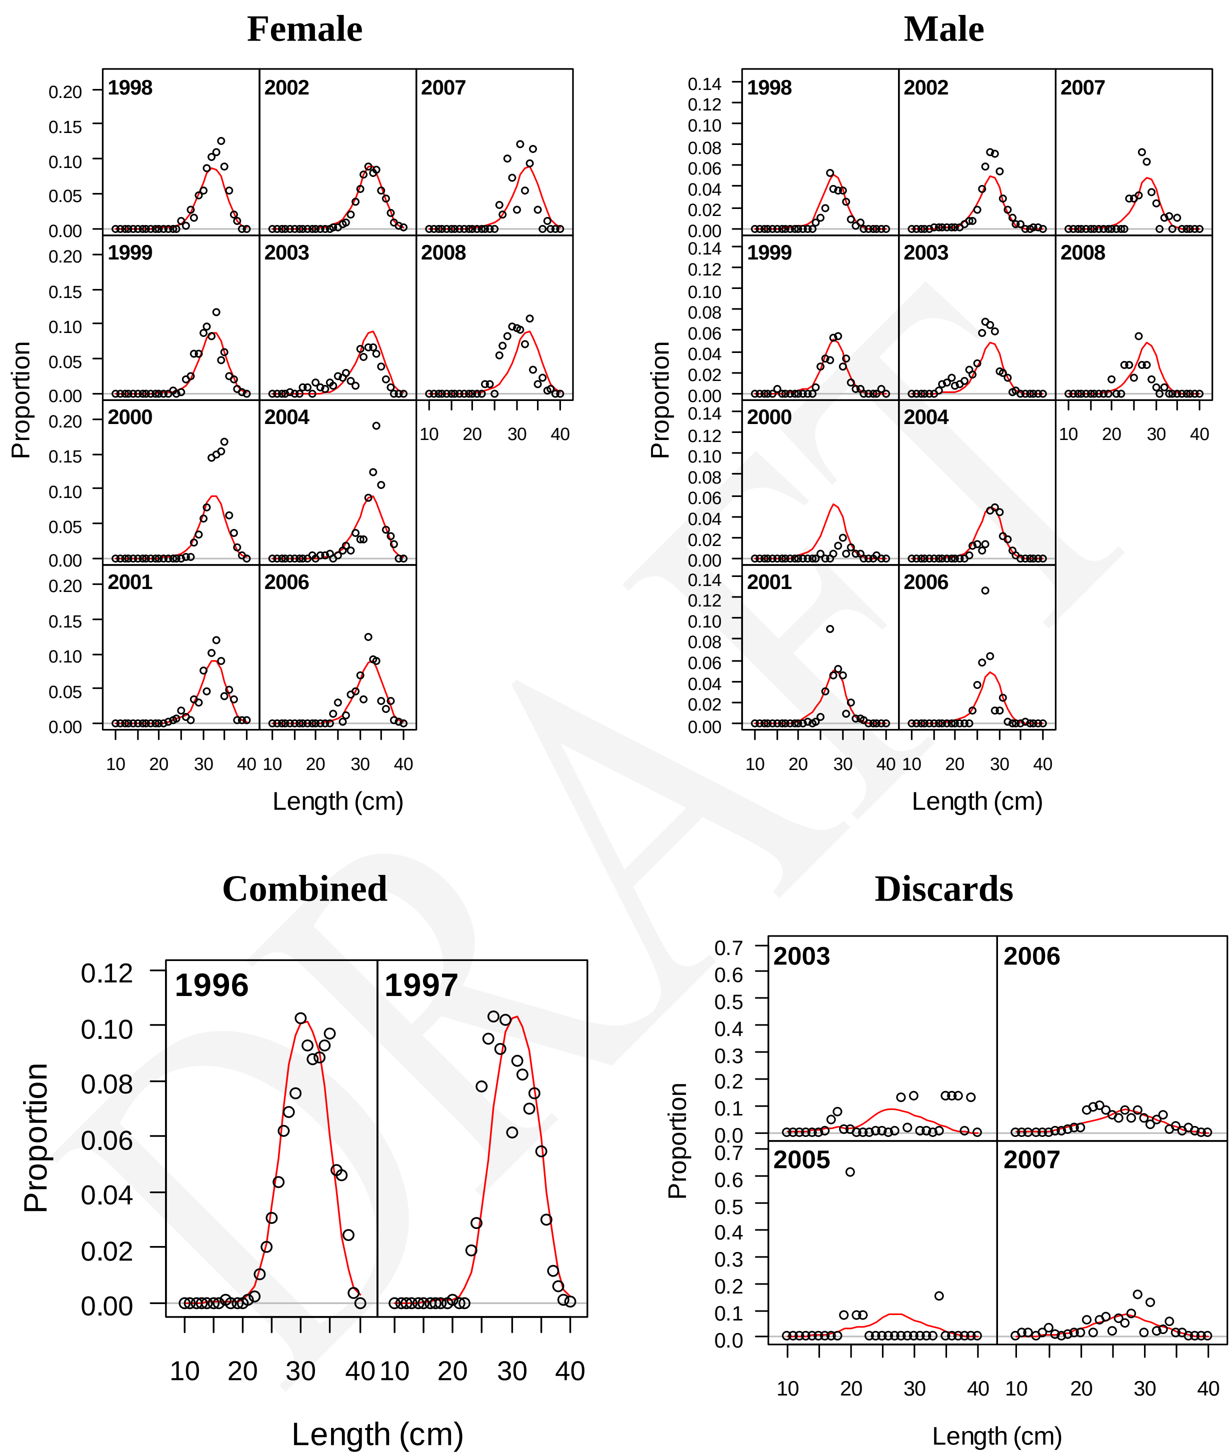

Figure 52: Fits to length compositions from the WA/OR trawl fleet.

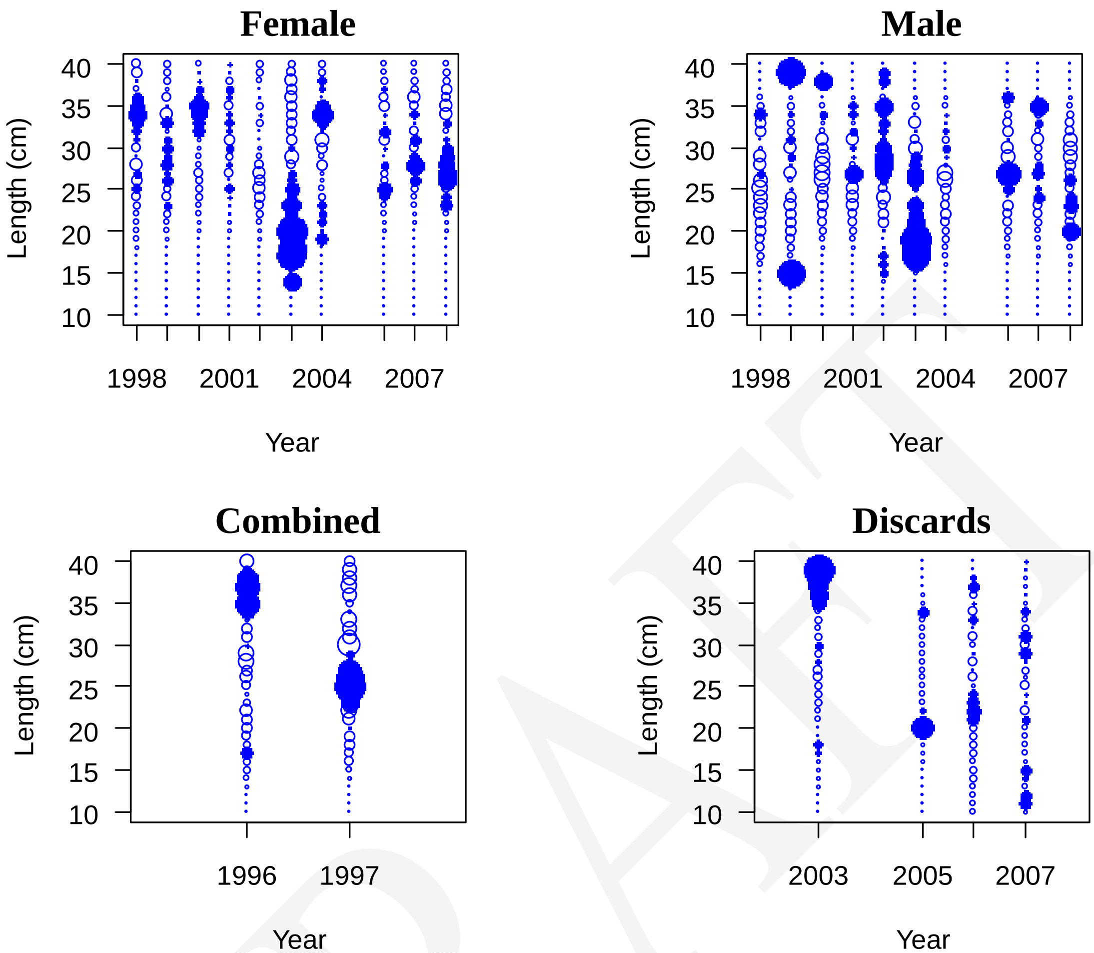

Figure 53: Pearson residuals for the retained and discarded length composition data from the WA/OR trawl fleet.

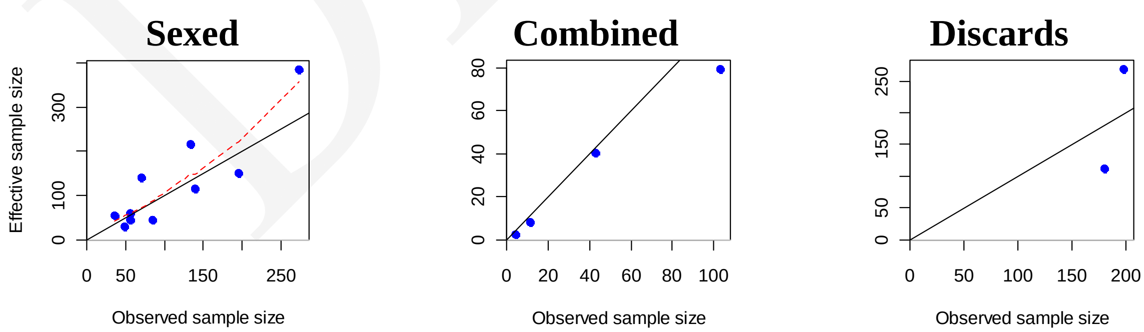

Figure 54: Effective sample size plotted against the entered sample size in the model for the WA/OR trawl fleet.

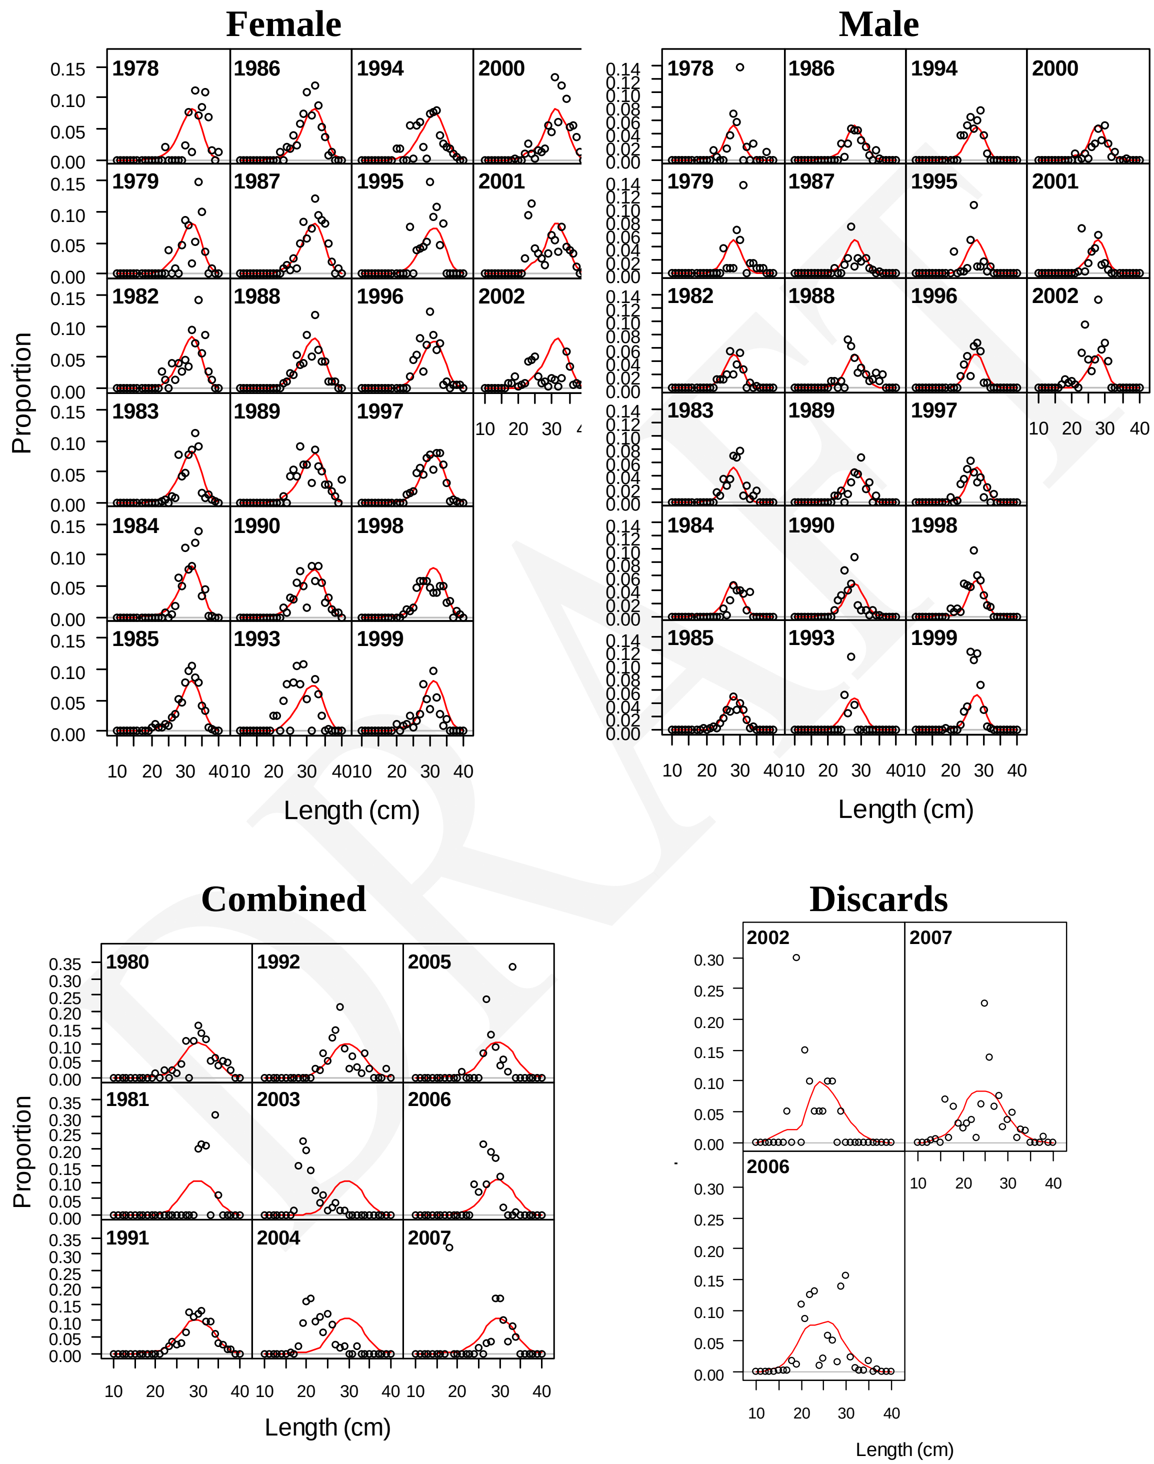

Figure 55: Fits to length compositions from the CA trawl fleet.

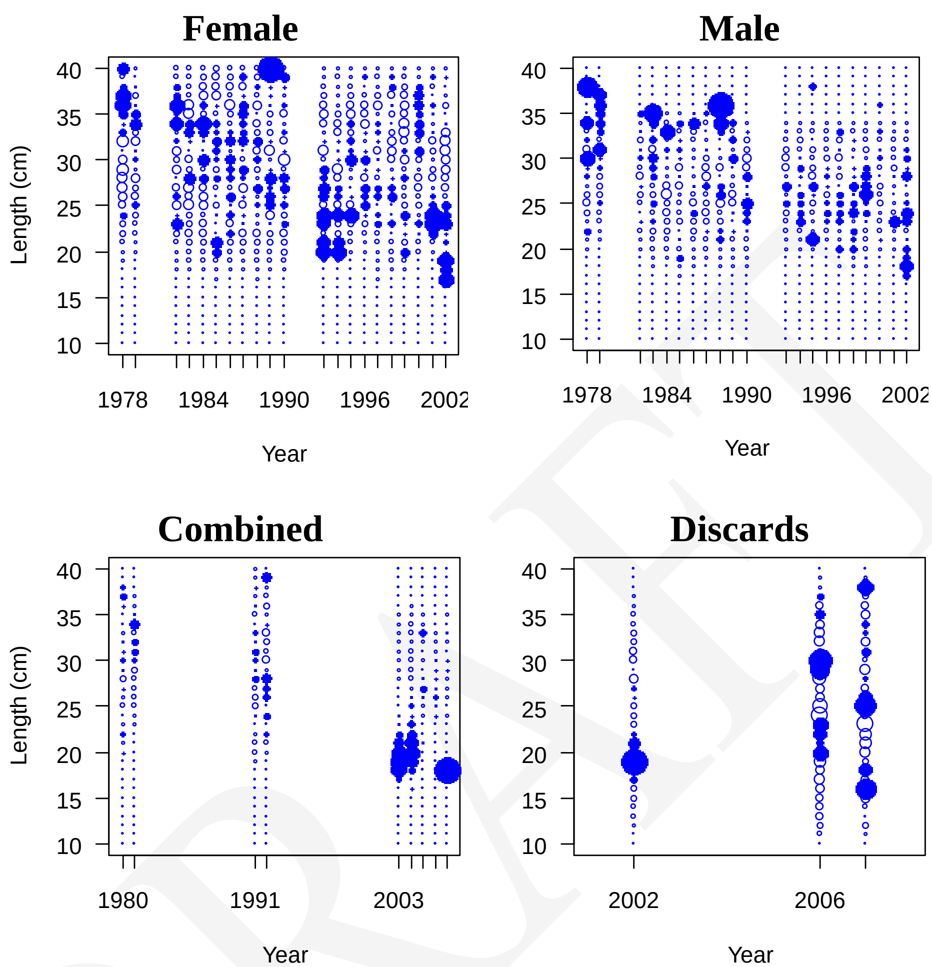

Figure 56: Pearson residuals for the retained and discarded length composition data from the CA trawl fleet.

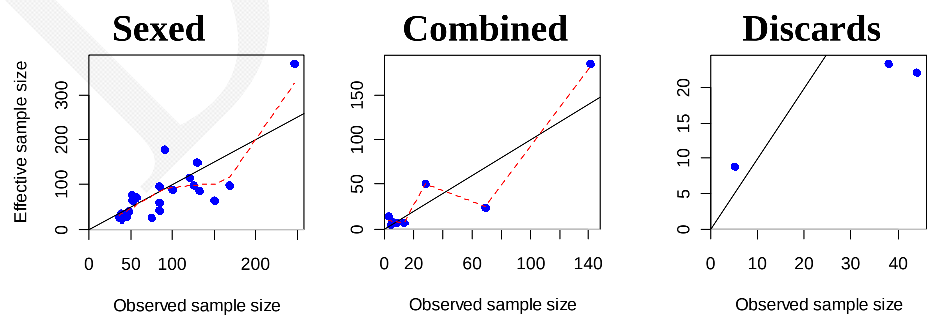

Figure 57: Effective sample size plotted against the entered sample size in the model for the CA trawl fleet.

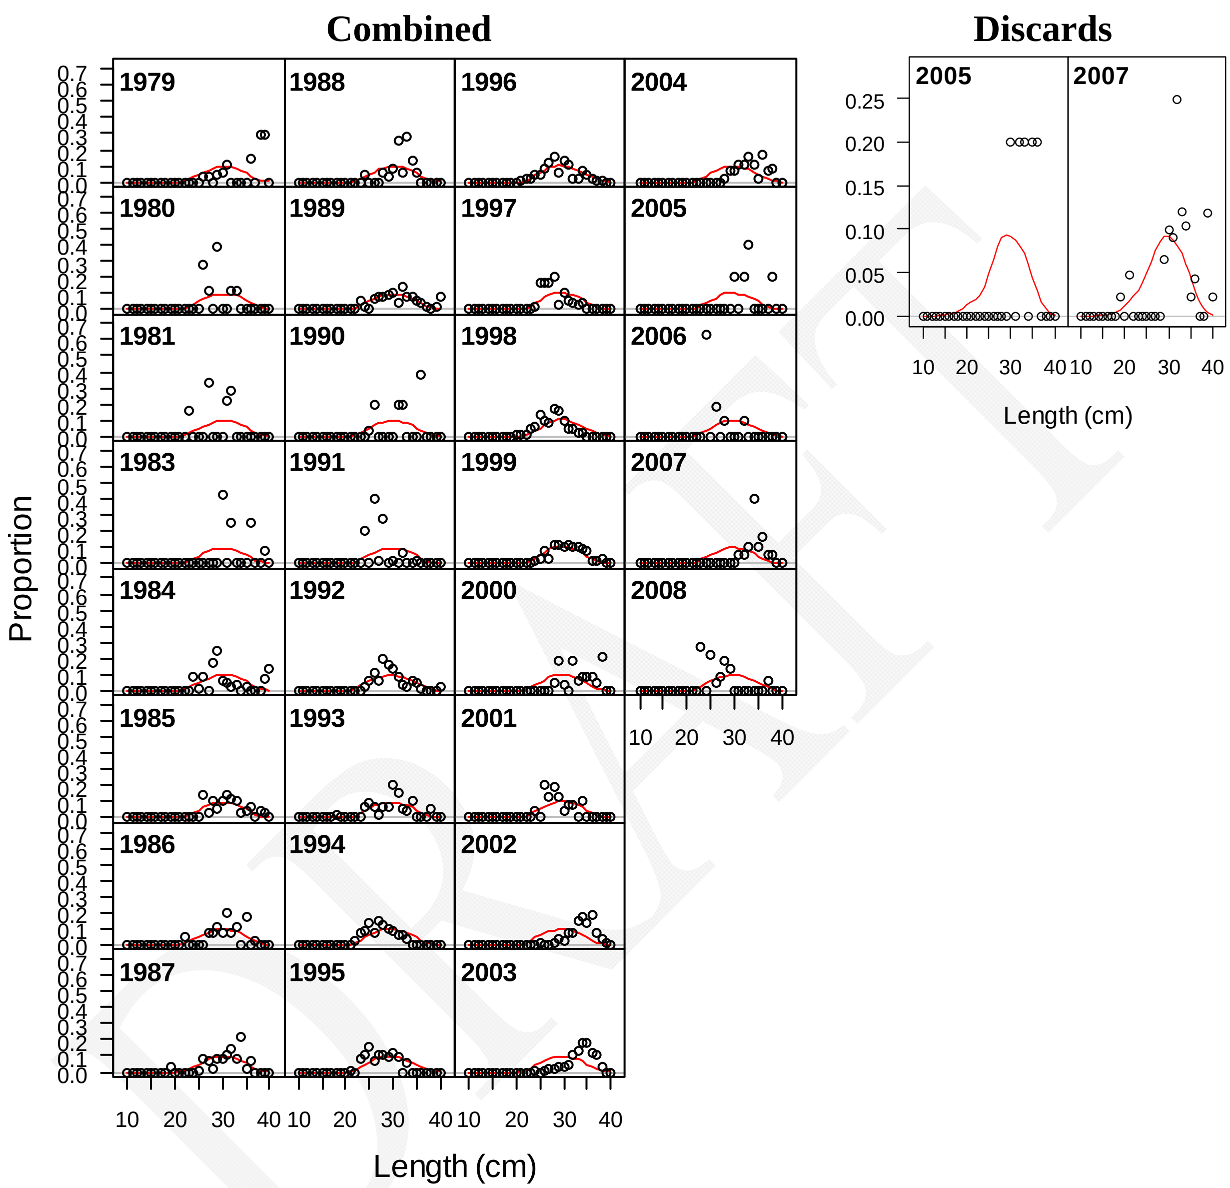

Figure 58: Fits to length compositions from the other-gear fleet.

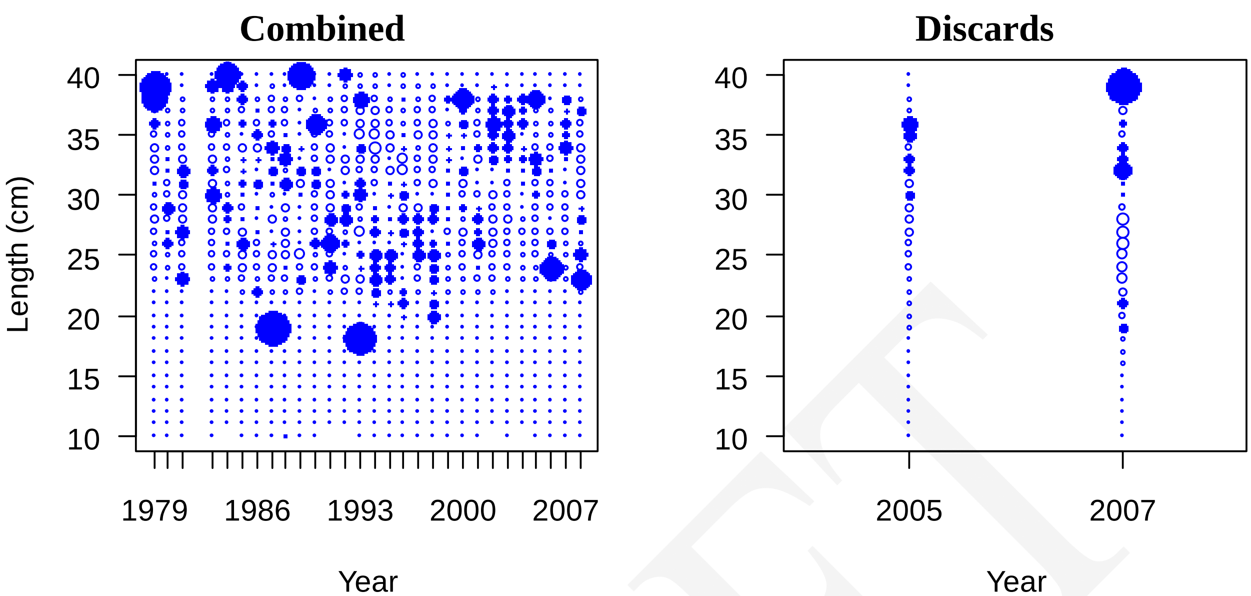

Figure 59: Pearson residuals for the retained and discarded length composition data from the other-gear fleet.

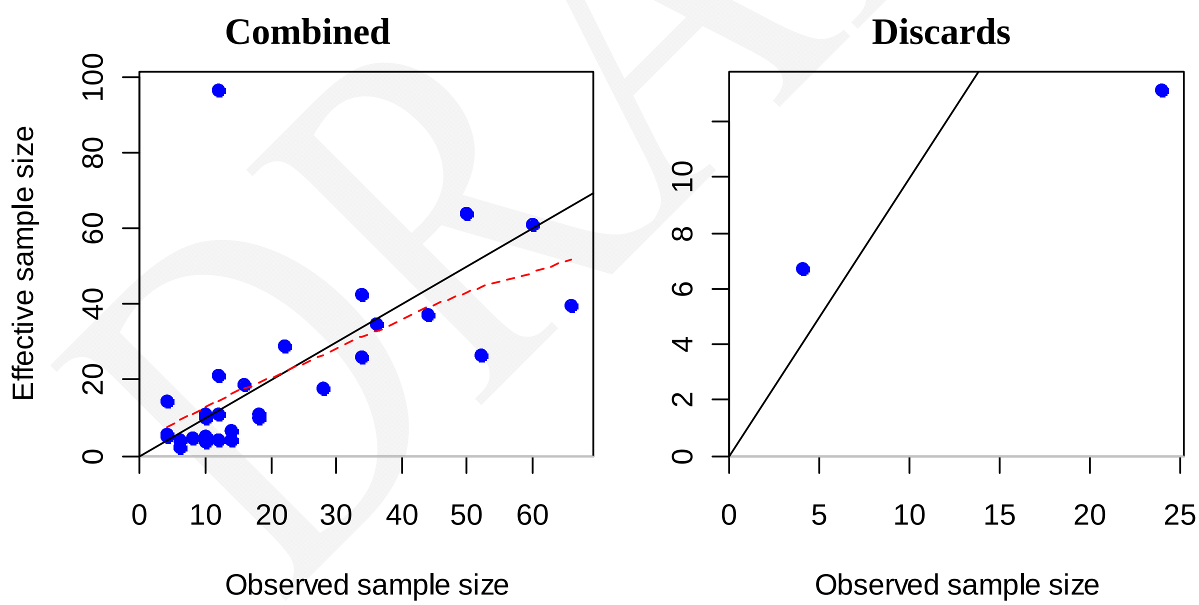

Figure 60: Effective sample size plotted against the entered sample size in the model for the other-gear fleet.

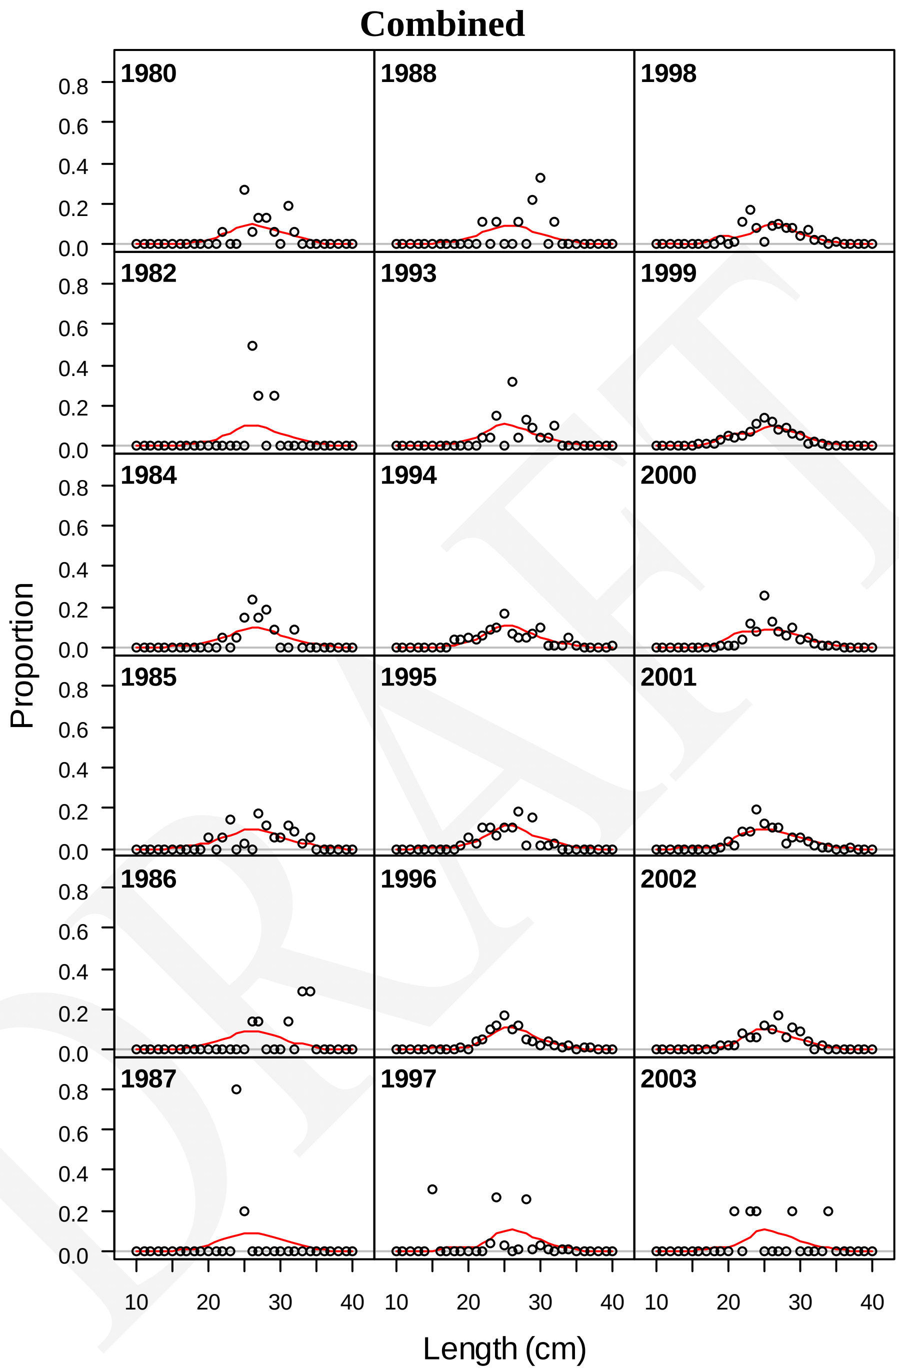

Figure 61: Fits to length compositions from the Recreational fleet.

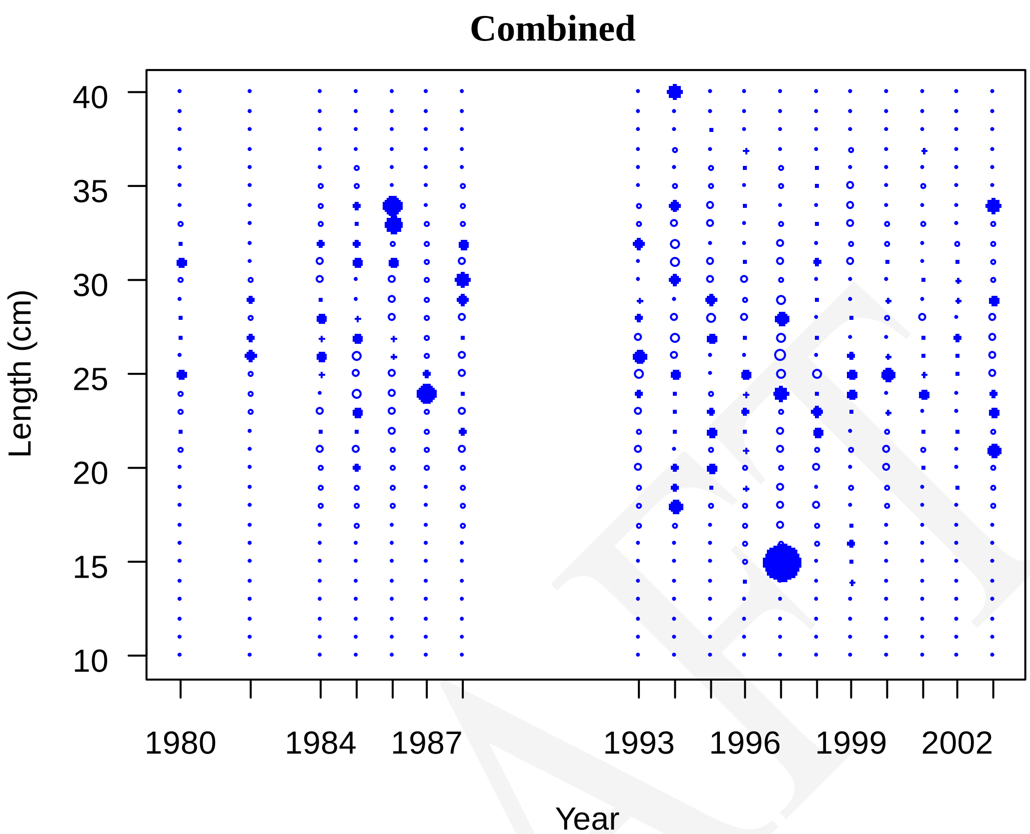

Figure 62: Pearson residuals for the combined sex length composition data from the Recreational fleet.

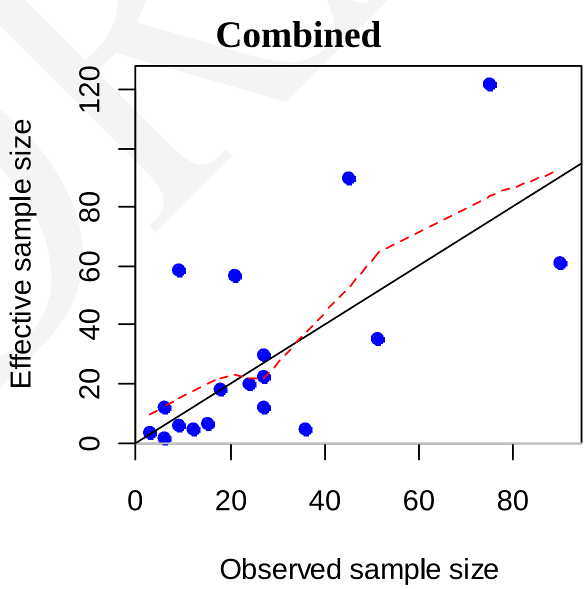

Figure 63: Effective sample size plotted against the entered sample size in the model for the ecreational fleet.

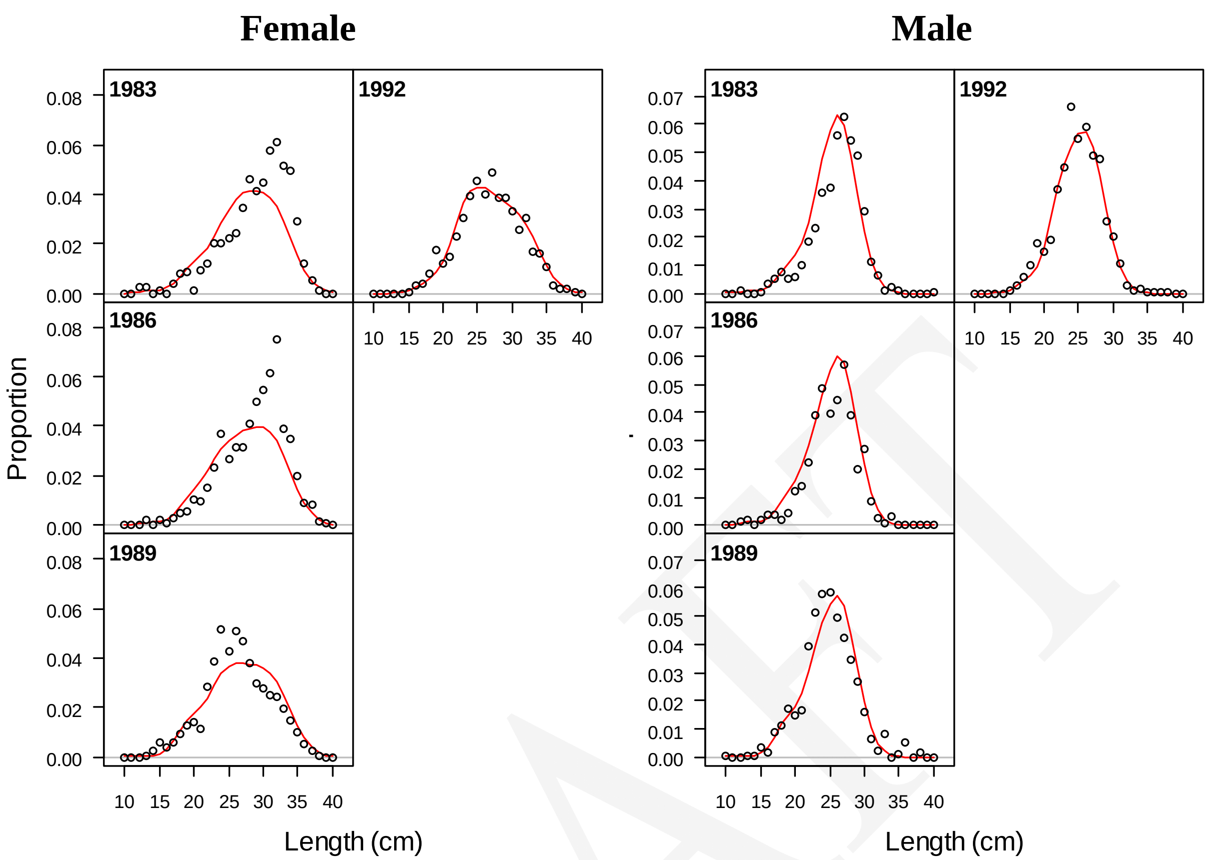

Figure 64: Fits to length compositions from the early Triennial survey.

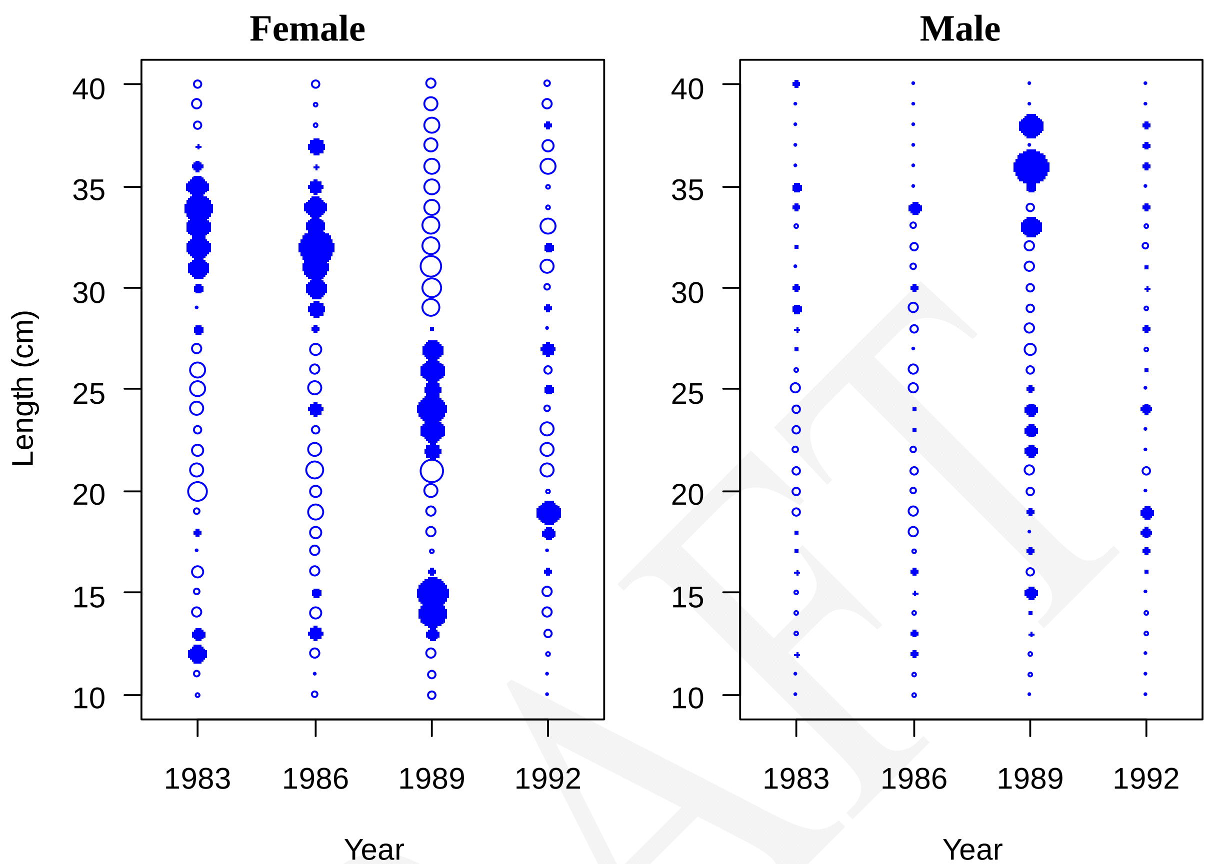

Figure 65: Pearson residuals for the length composition data from the early Triennial survey.

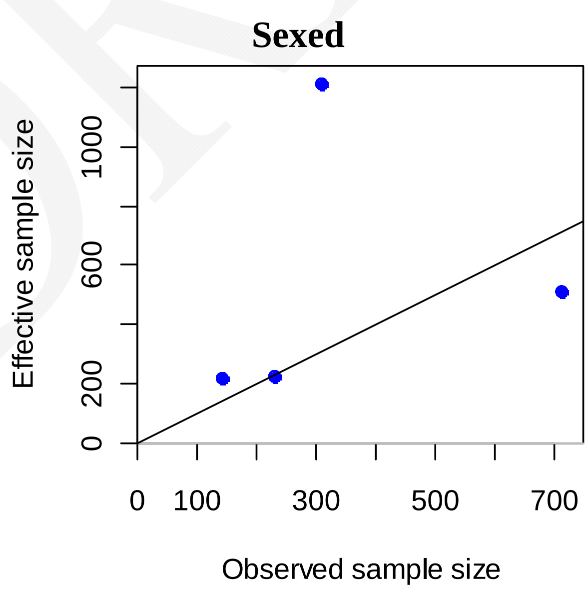

Figure 66: Effective sample size plotted against the entered sample size in the model for the early Triennial survey.

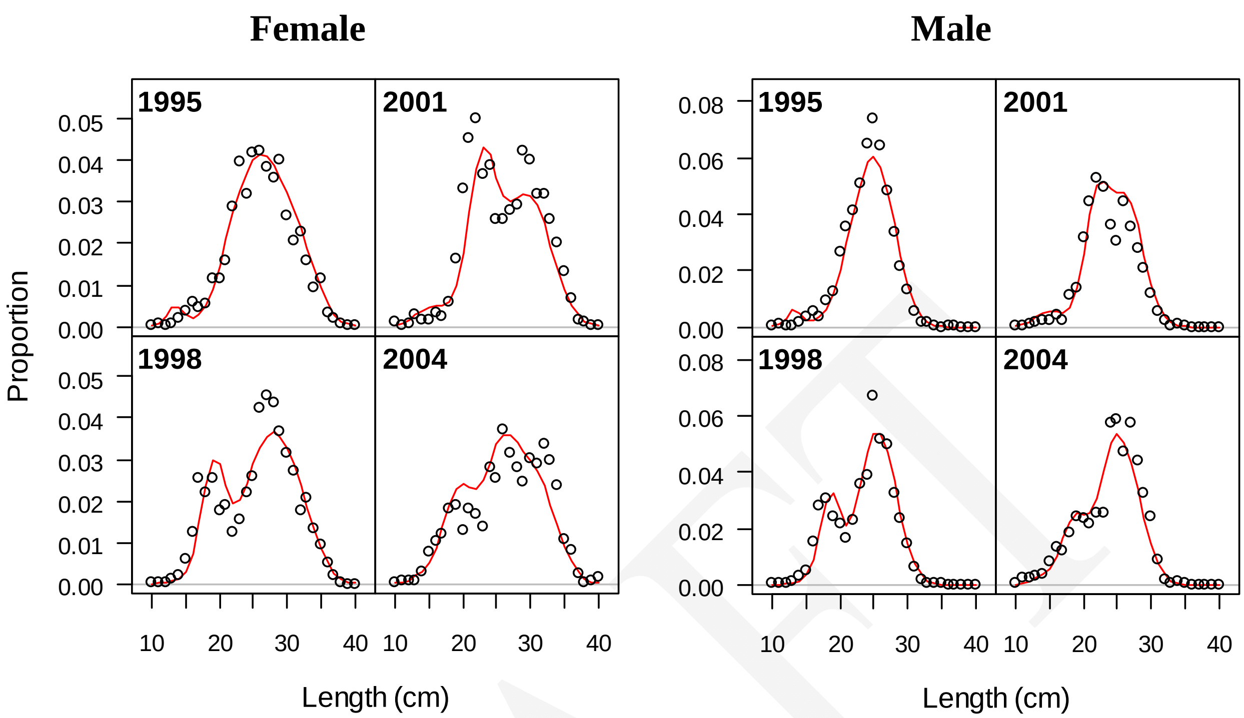

Figure 67: Fits to length compositions from the late Triennial survey.

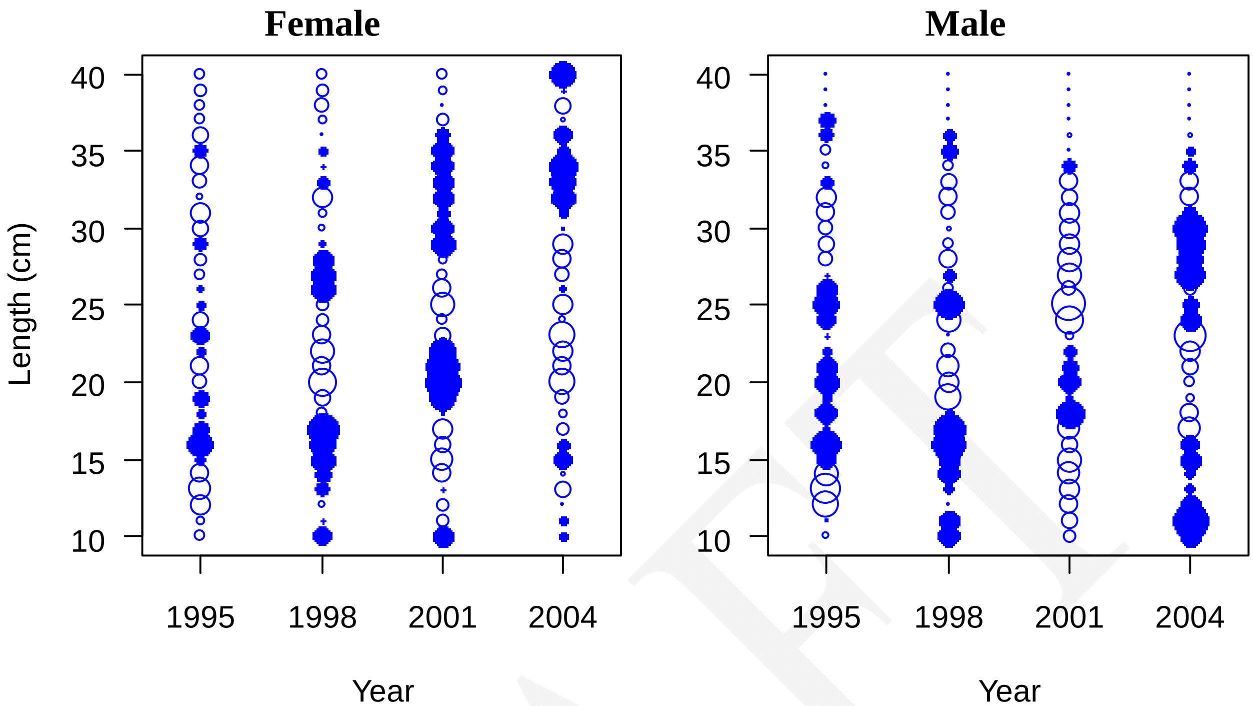

Figure 68: Pearson residuals for the length composition data from the late Triennial survey.

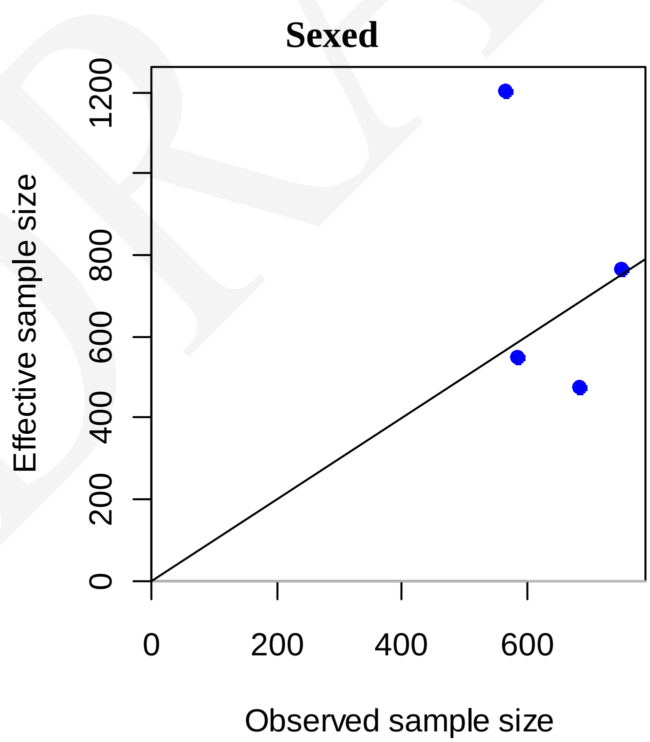

Figure 69: Effective sample size plotted against the entered sample size in the model for the late Triennial survey.

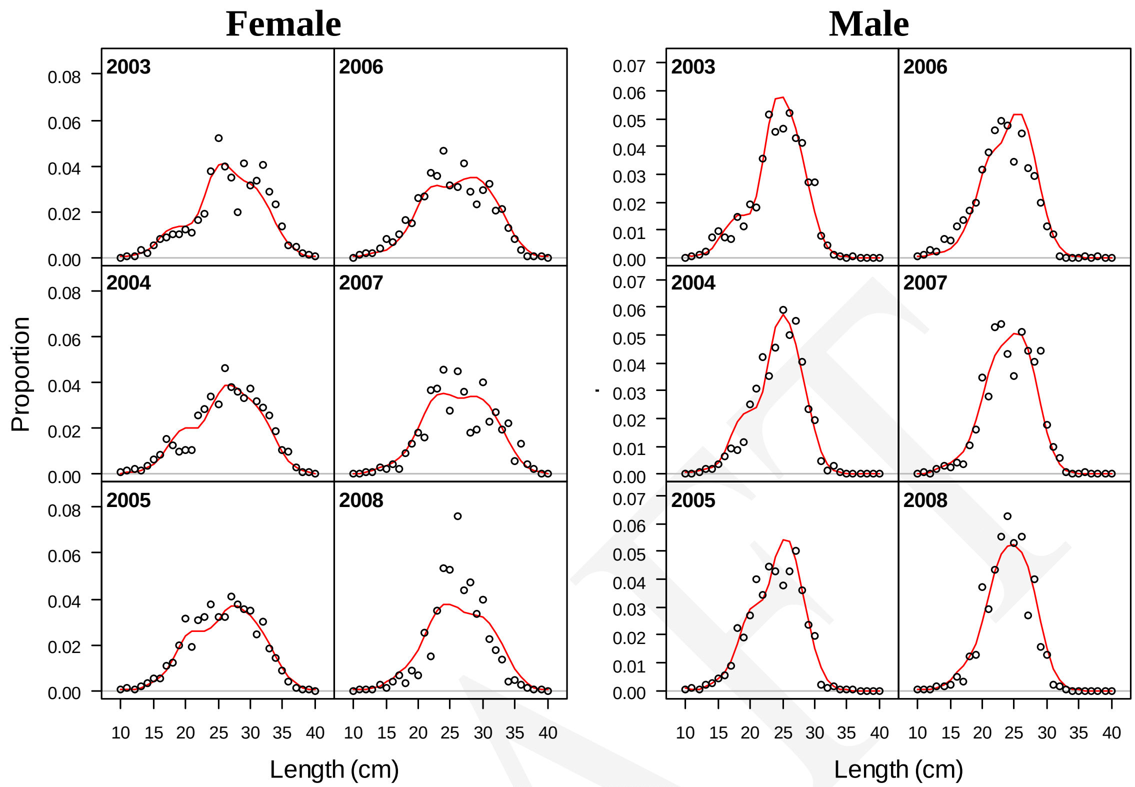

Figure 70: Fits to length compositions from the NWFSC survey.

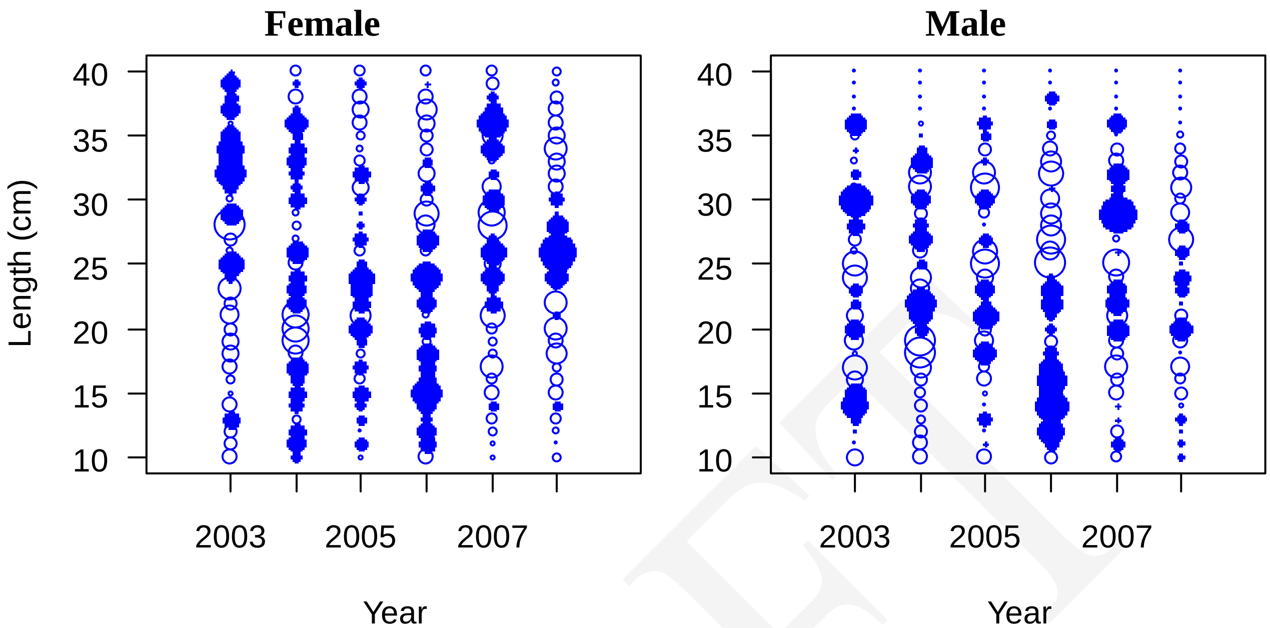

Figure 71: Pearson residuals for the length composition data from the NWFSC survey.

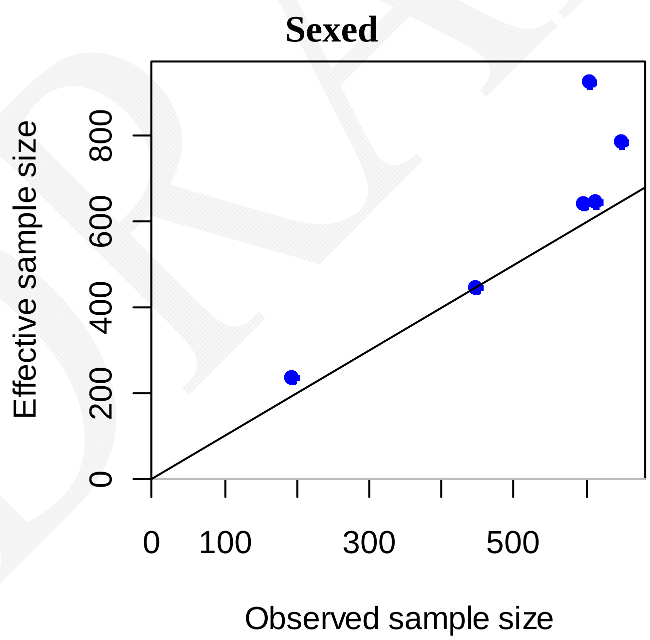

Figure 72: Effective sample size plotted against the entered sample size in the model for the NWFSC survey.

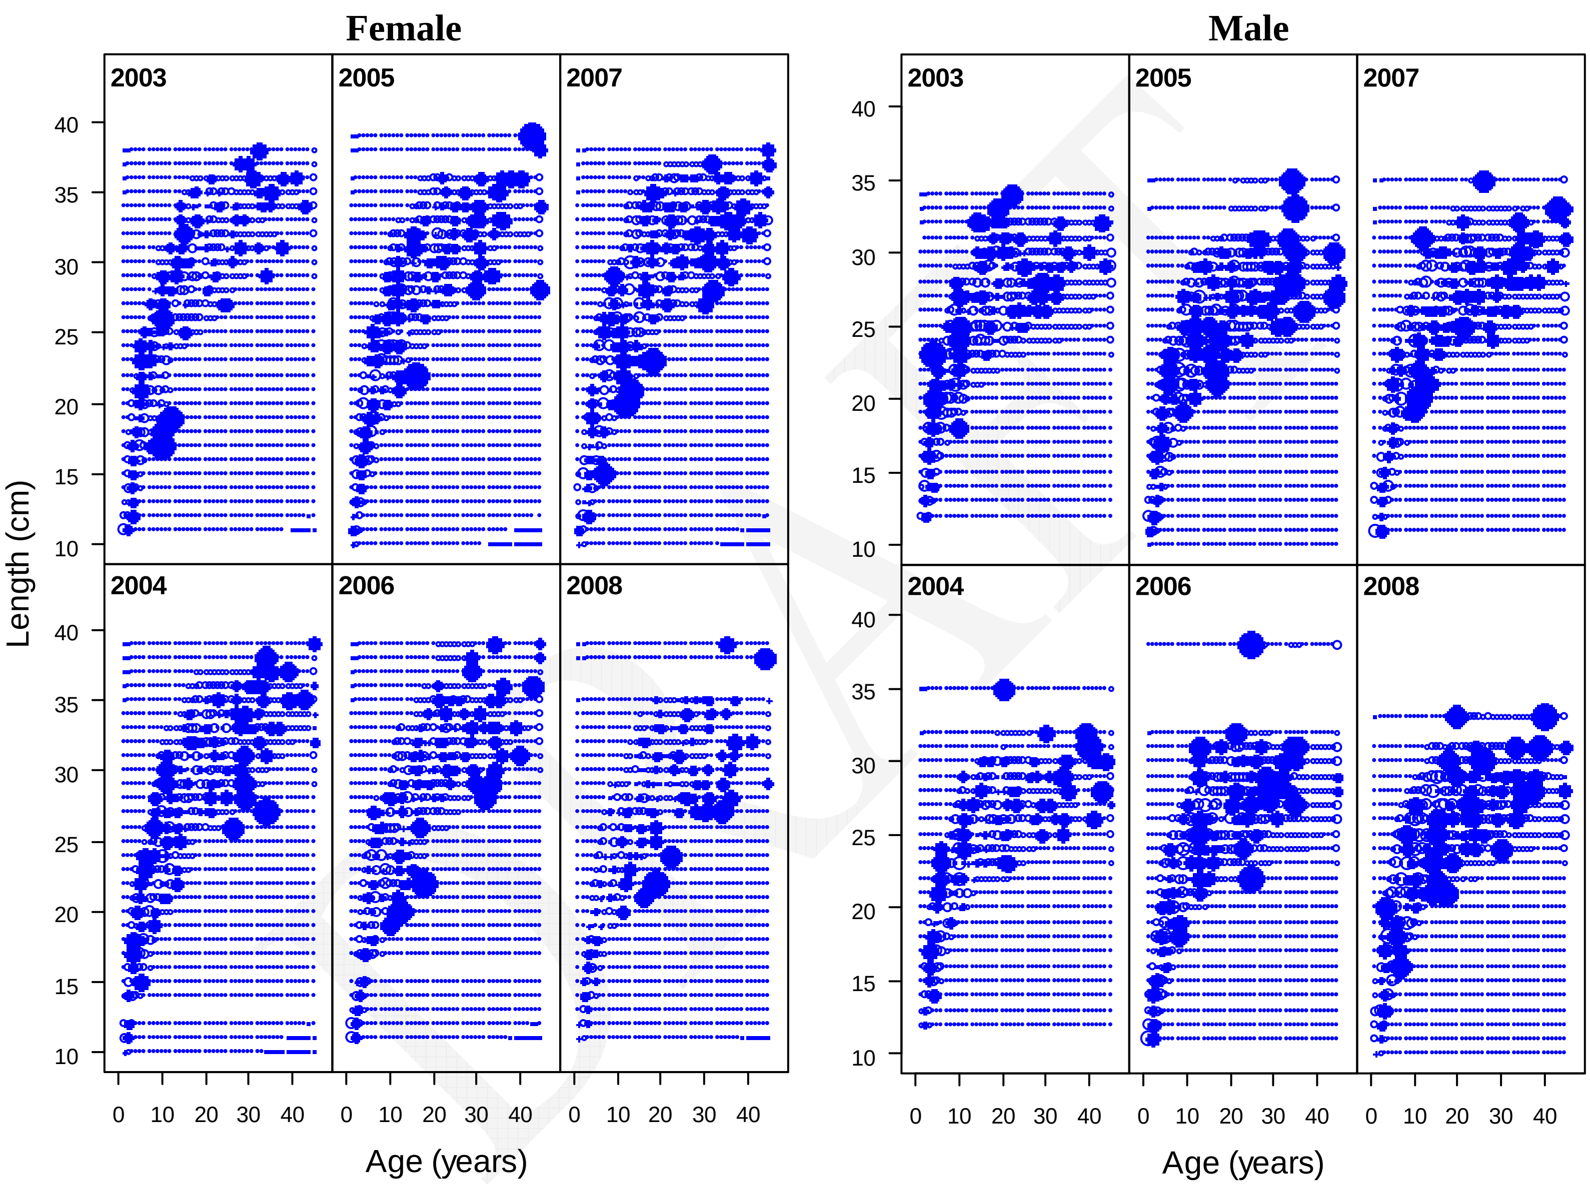

Figure 73: Pearson residuals for the fits to conditional age-at-length compositions from the NWFSC survey.

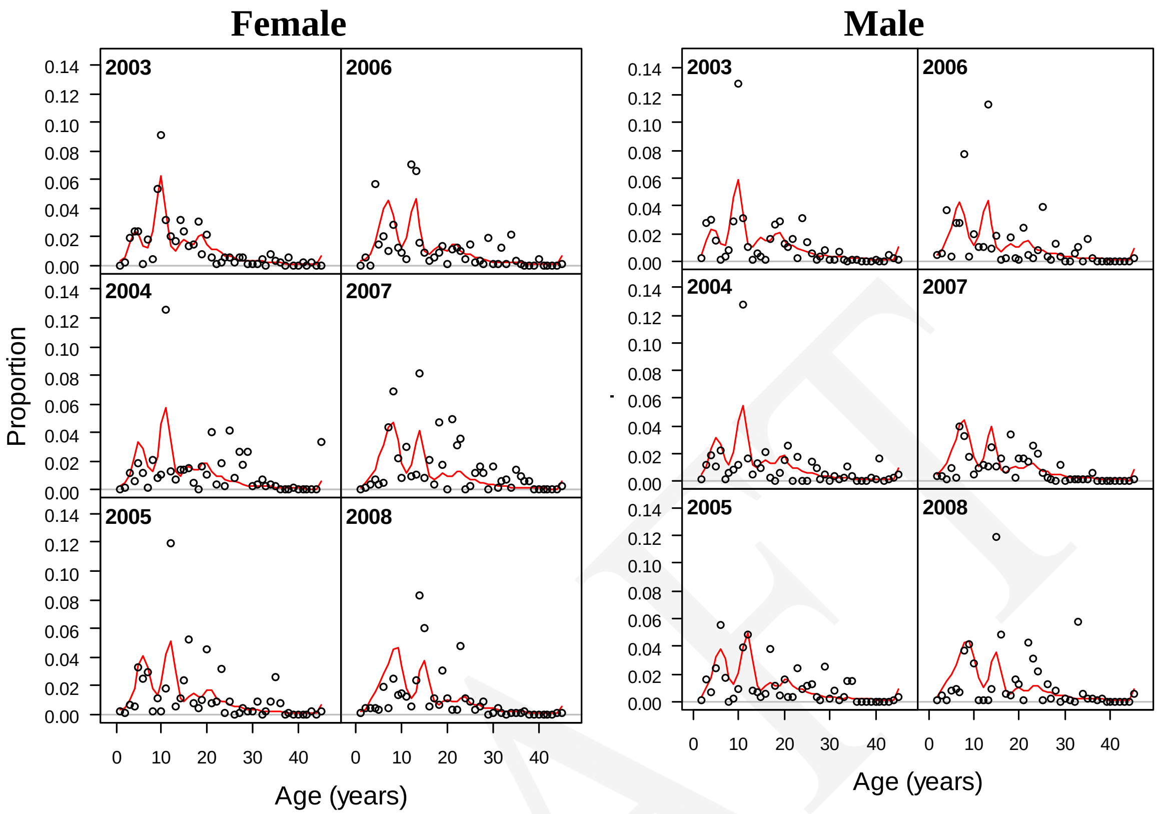

Figure 74: Implied fits to age compositions from the NWFSC survey. These are plotted for reference as the conditional age-at-length compositions are fit by the model.

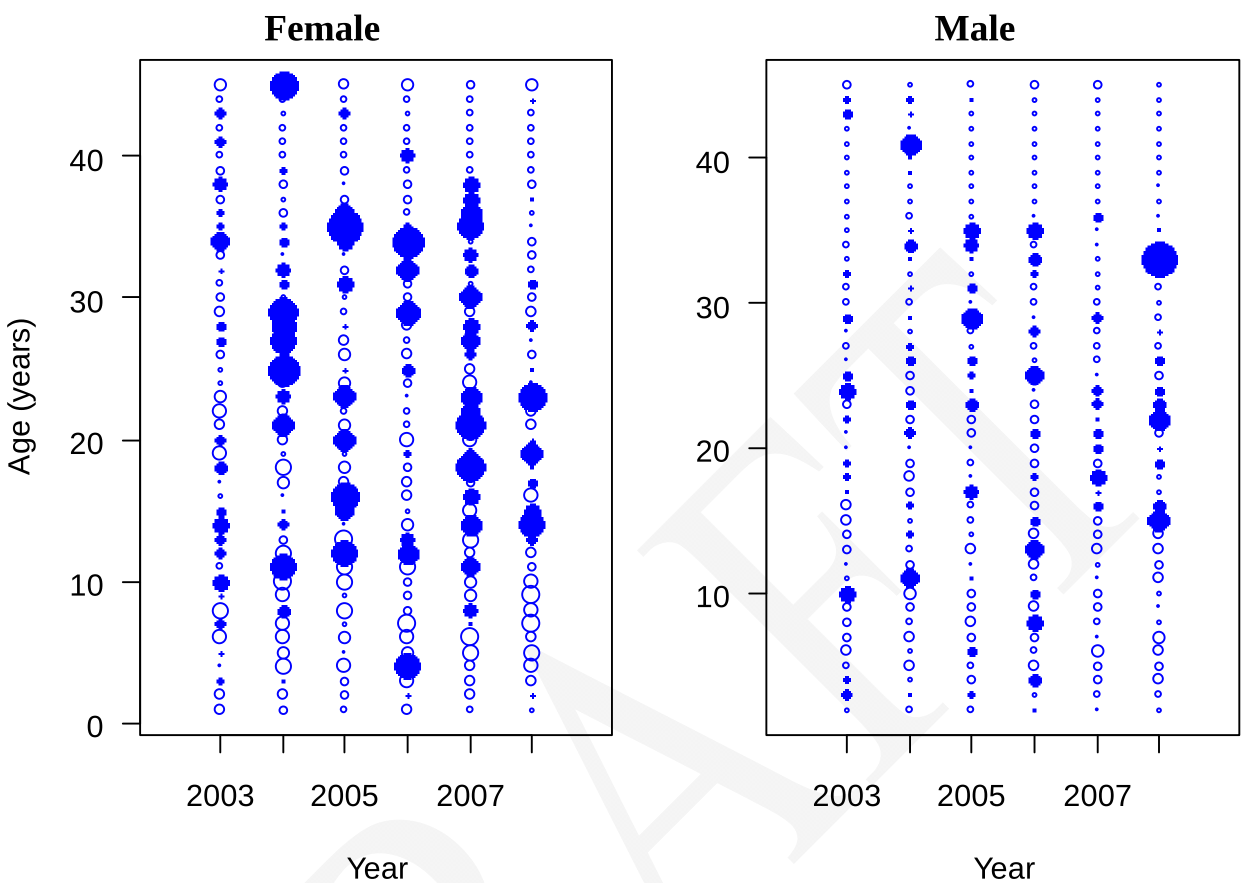

Figure 75: Pearson residuals for the implied fits to the age composition data from the NWFSC survey. These are presented for reference as the conditional age-at-length composition data are fitted by the model.

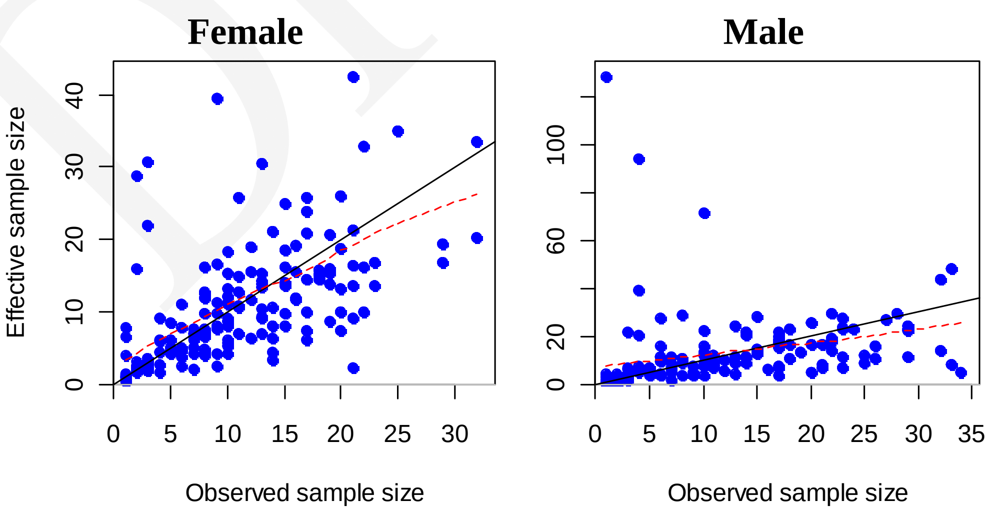

Figure 76: Effective sample size plotted against the entered sample size in the model for the NWFSC survey.

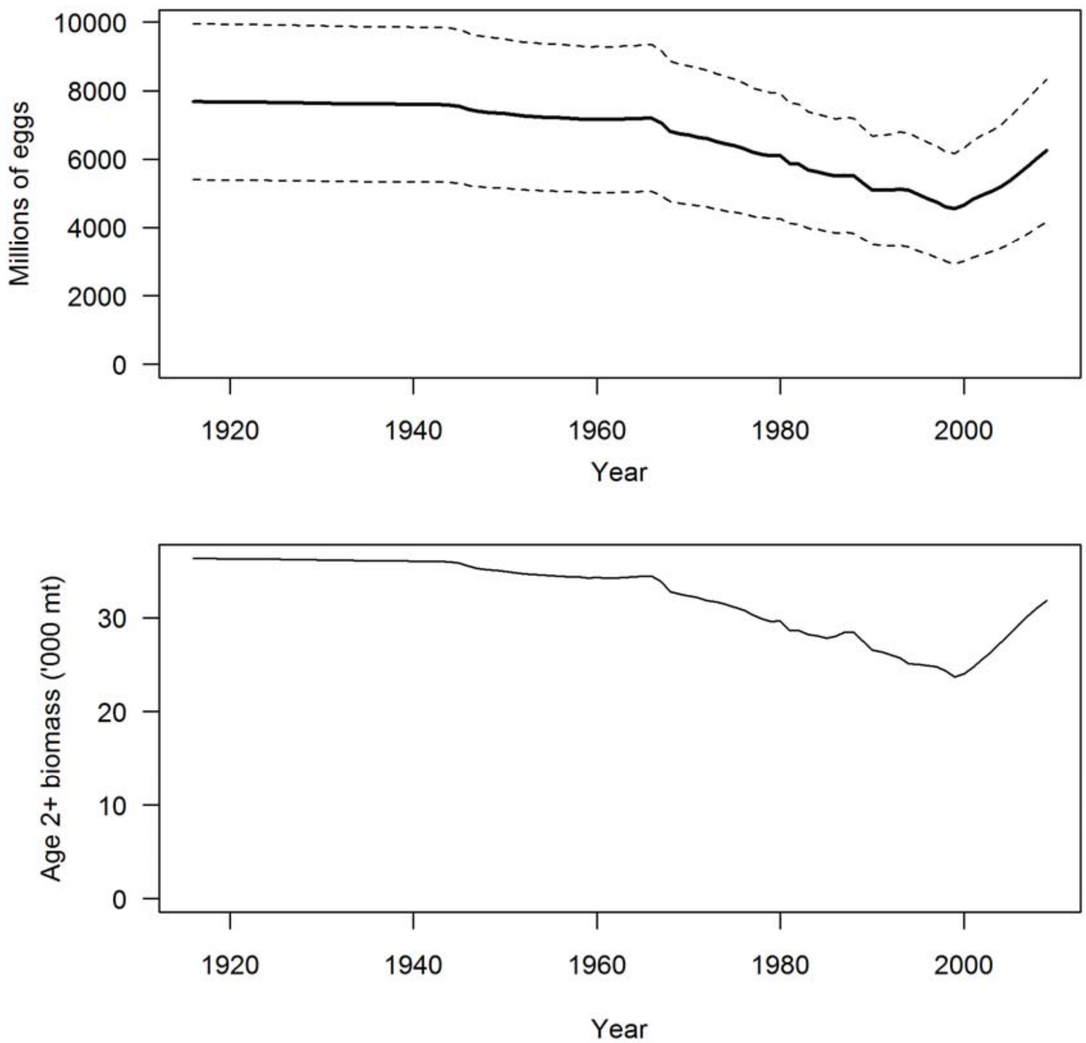

Figure 77: The predicted trajectory of spawning output in millions of eggs with approximate 95% asymptotic confidence intervals (top panel) and the predicted summary biomass (age 2+, bottom panel).

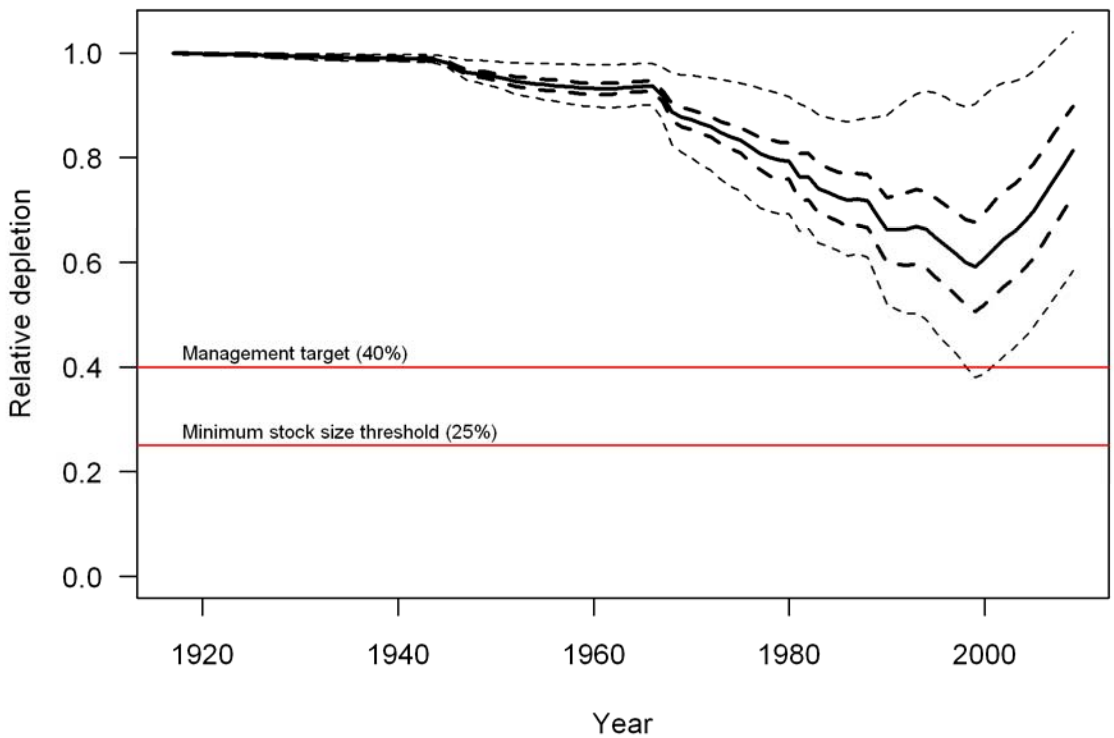

Figure 78: Estimated depletion as a function of unfished spawning output (solid line) with approximate 95% asymptotic confidence intervals (thick dashed lines) and the extreme range over the states of nature (thin dashed lines). Management thresholds are drawn as red horizontal lines.

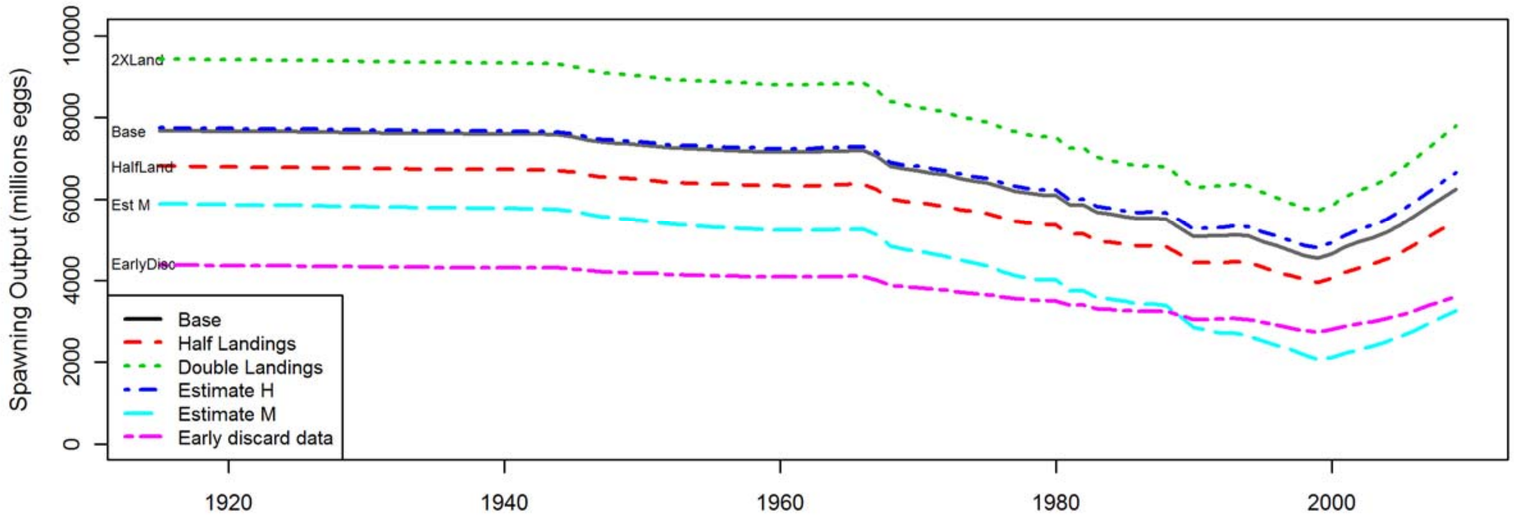

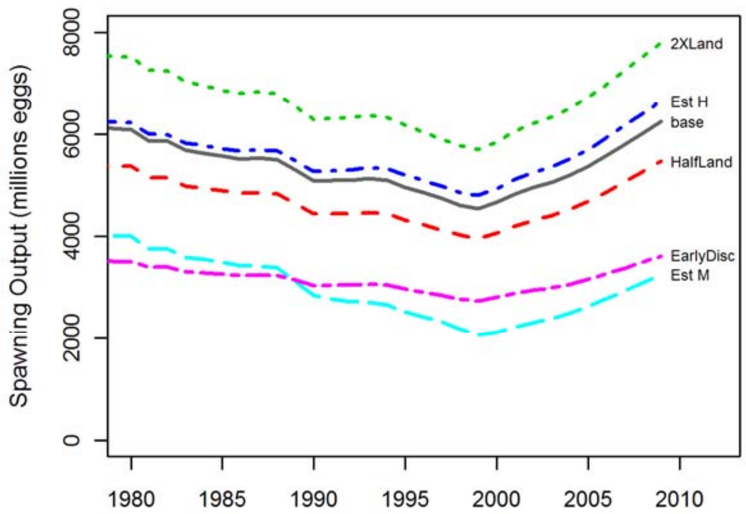

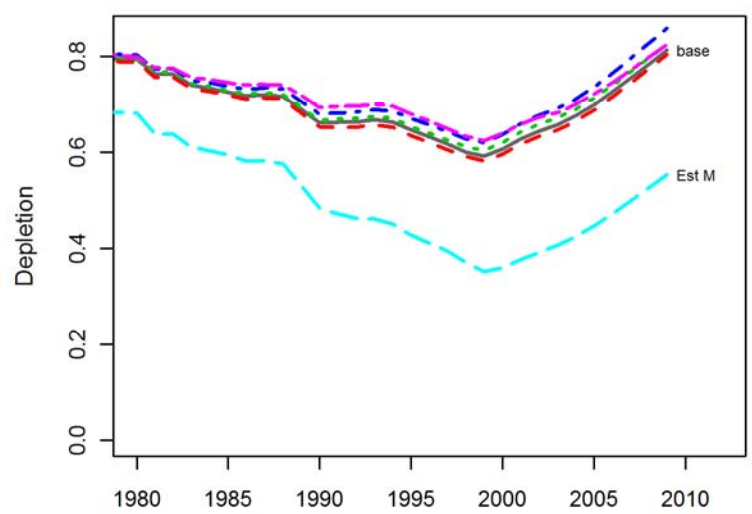

Figure 79: Sensitivity runs.

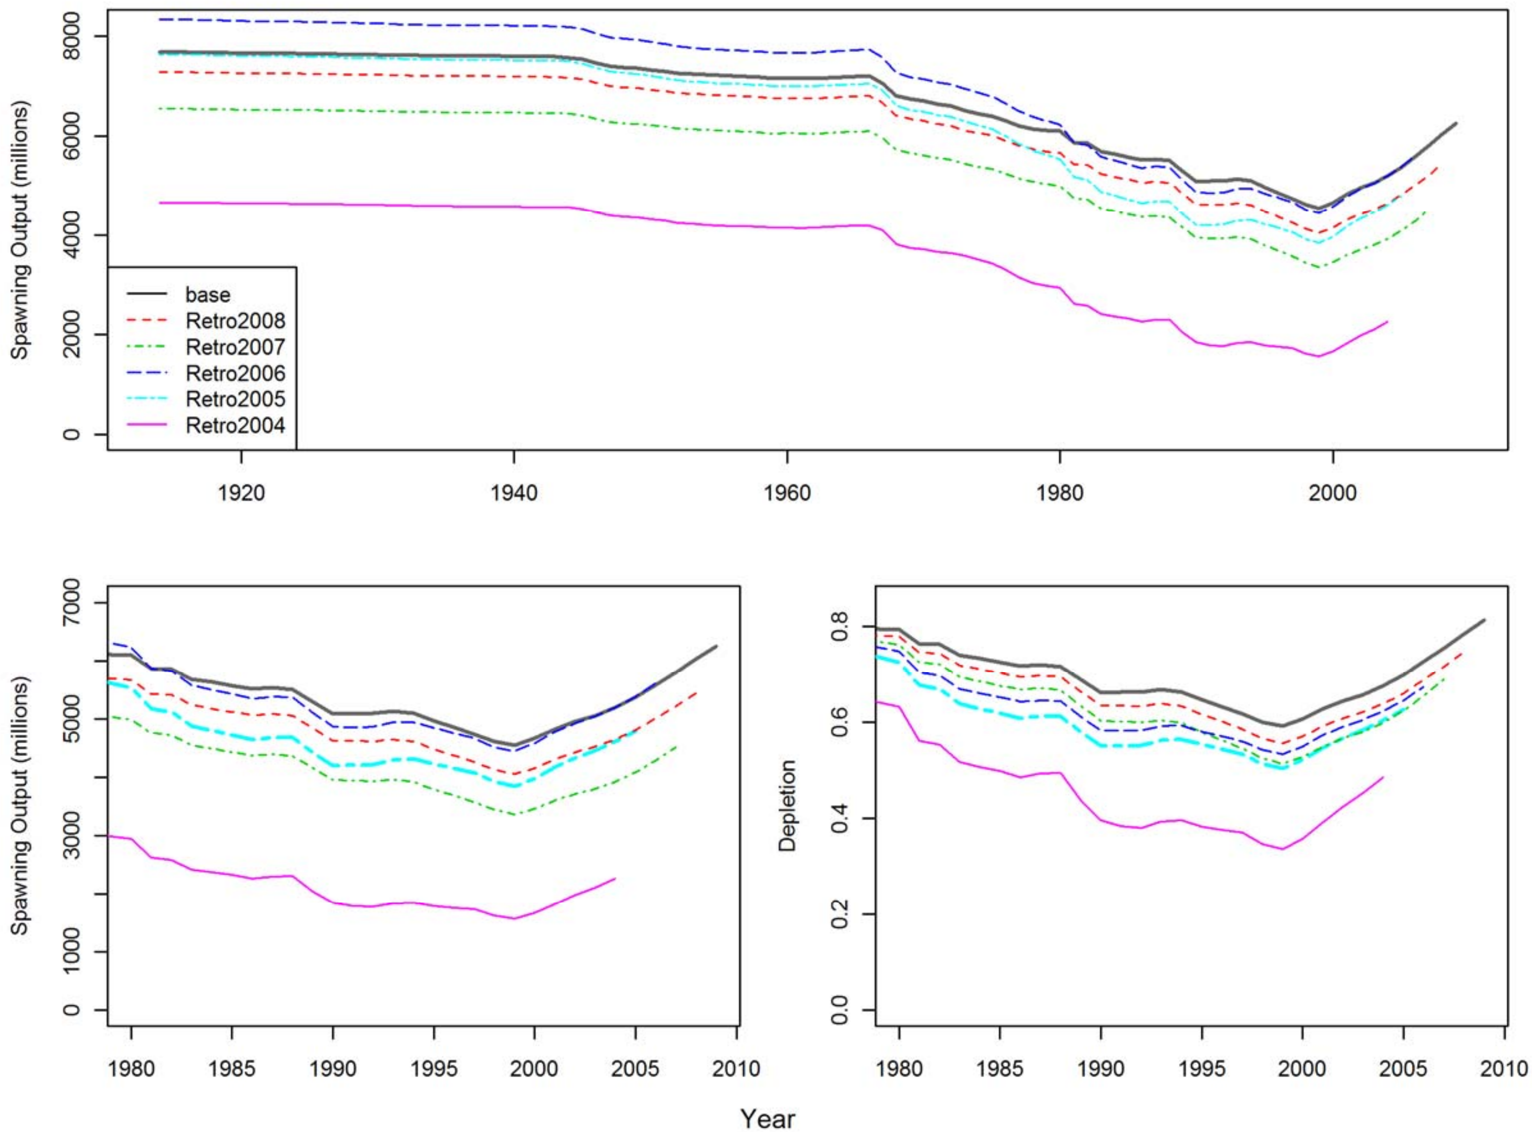

Figure 80. Results from a 5-year retrospective analysis. Each year of retrospective is performed as if the assessment were conducted in that year (i.e., retrospective in 2007 includes data through 2006).

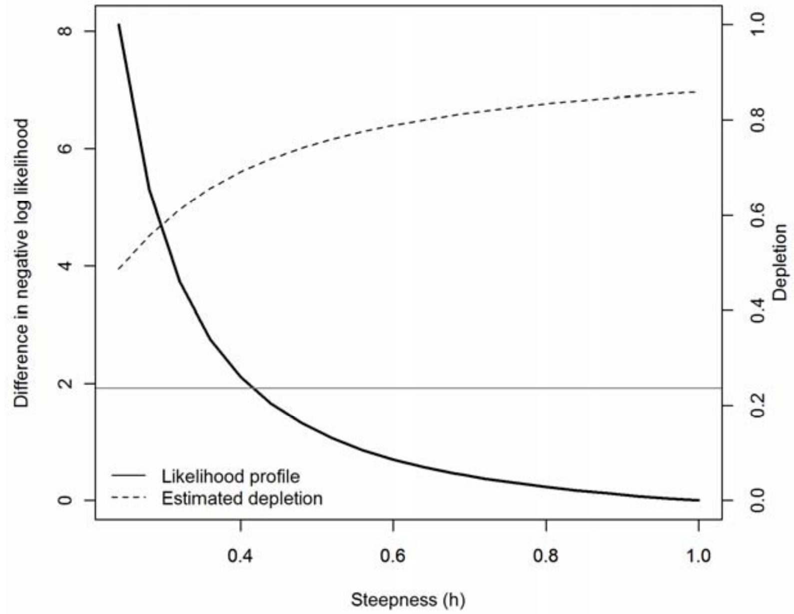

Figure 81: Likelihood profile on steepness (h). The horizontal line is the approximate 95% confidence interval and the dashed line show estimated depletion over steepness.

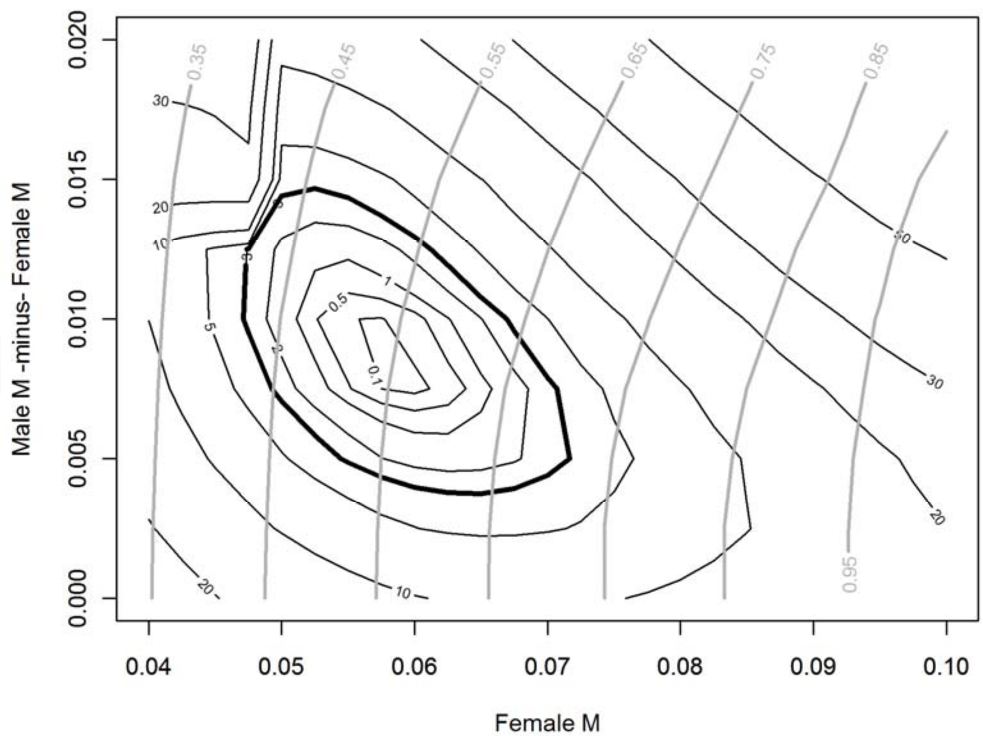

Figure 82: Likelihood profile on female natural mortality and the difference between male and female natural mortality. Black contour lines are the difference in negative log-likelihood and the bold line indicates an approximate 95% joint confidence interval. The gray, nearly vertical contour lines indicate the estimated level of depletion at that combination of male and female natural mortality.

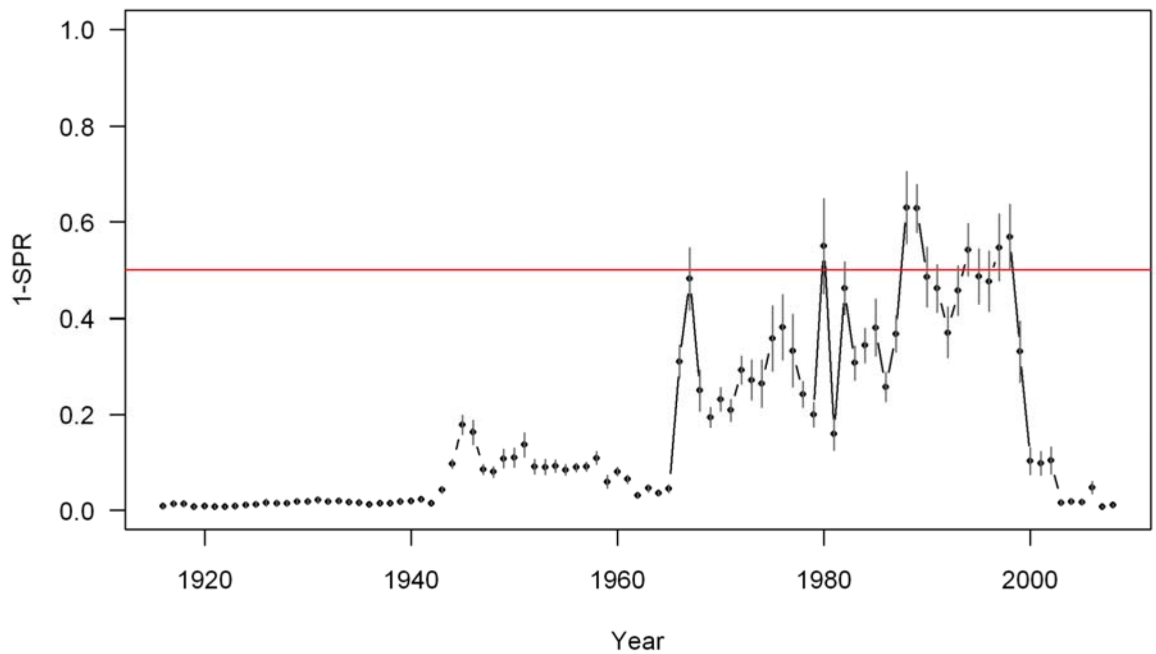

Figure 83: Estimated spawning potential ratio (shown as 1-SPR) from the base case model with approximate 95% asymptotic confidence intervals. One minus SPR is plotted so that higher exploitation rates occur on the upper portion of the y-axis. The management target is plotted as a red horizontal line and values above this reflect harvests in excess of the overfishing proxy based on $SPR_{50\%}$.

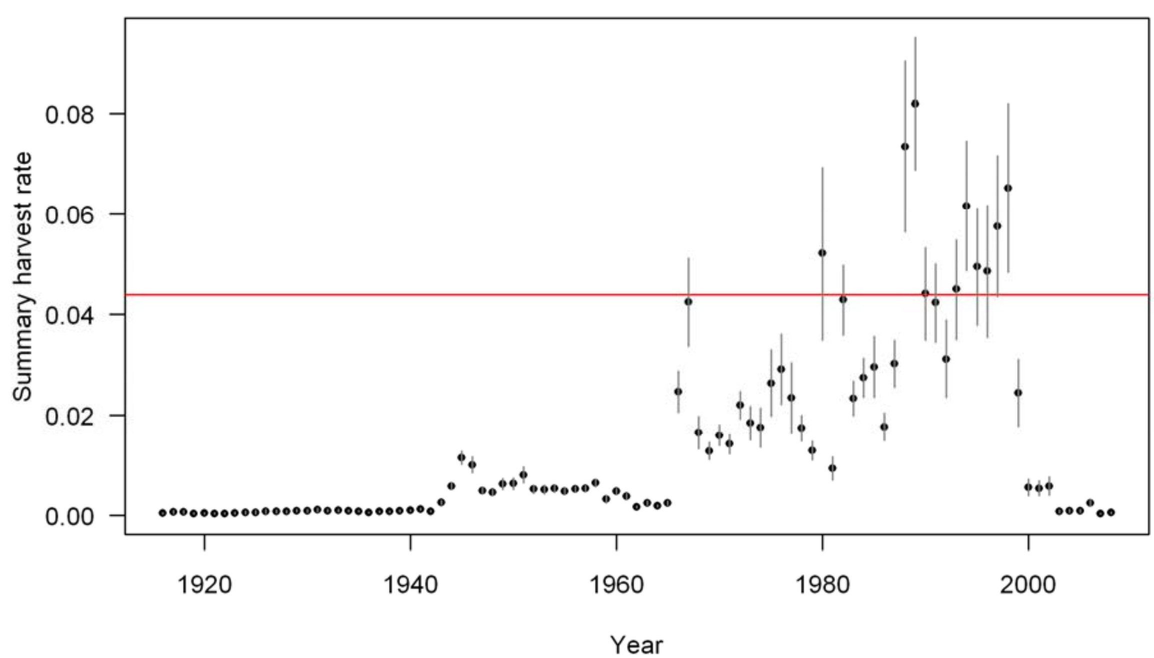

Figure 84: Time series of estimated summary harvest rate (total catch divided by age 2 and older biomass) for the base case model (round points) with approximate 95% asymptotic confidence intervals (grey lines). The red line is the harvest rate at the overfishing proxy using $SPR_{50\%}$.

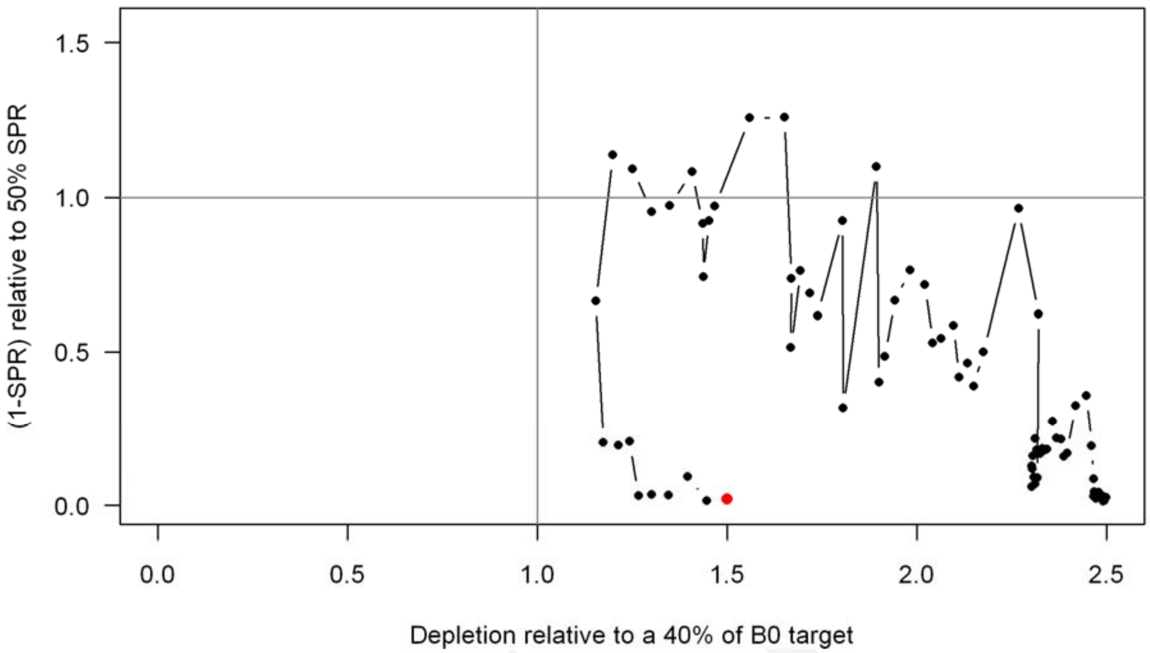

Figure 85: Phase plot of the predicted trajectory for greenstriped rockfish relative to the $SPR_{50\%}$ harvest rate and $B_{40\%}$ target. The red dot shows the current value (2008).

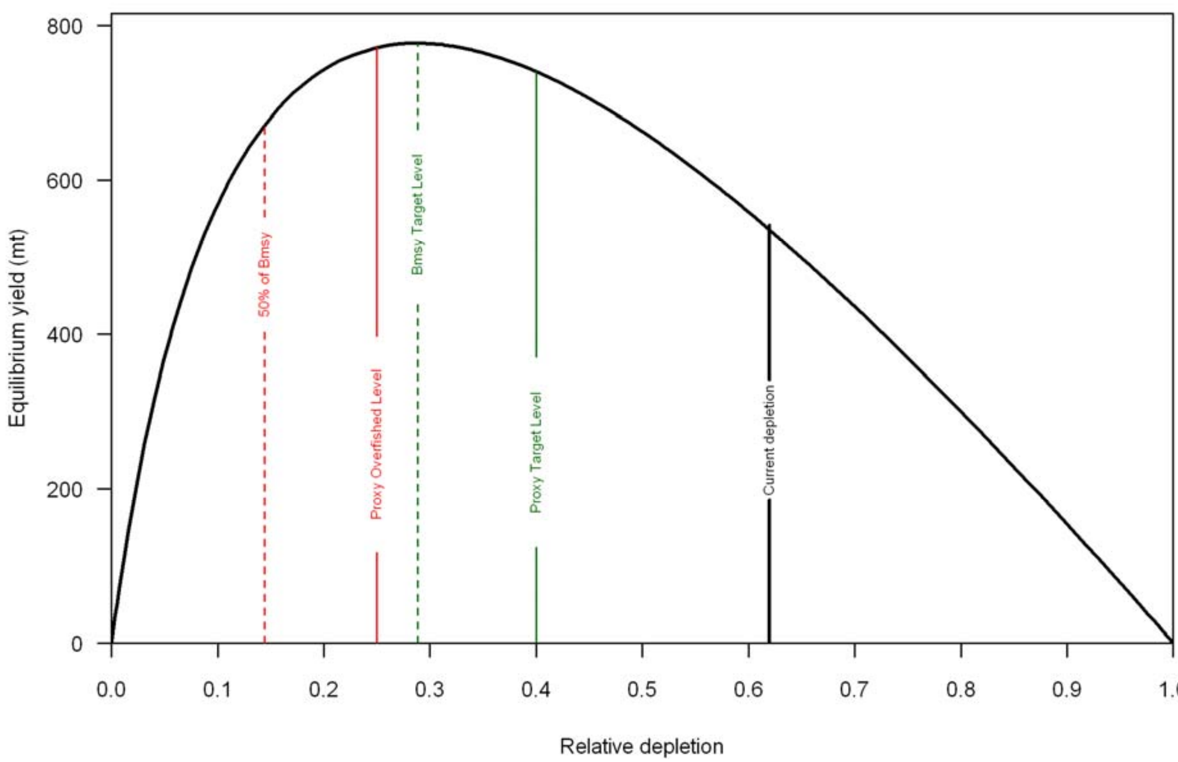

Figure 86: Estimated equilibrium yield with target levels based on 40% of unfished spawning output (solid lines) and target levels based on the spawning output at *MSY* (dashed lines).

GREENSTRIPED ROCKFISH

STAR Panel Report

August 3-6, 2009

Hotel Deca
4507 Brooklyn Ave NE
Seattle, WA 98105

Panel Reviewers

Stephen Ralston	Panel Chair, Scientific and Statistical Committee (SSC) Representative
Richard Methot	NMFS, Northwest Fisheries Science Center (NWFSC)
Vivian Haist	Center for Independent Experts (CIE)
J. J. Maguire	Center for Independent Experts (CIE)

Panel Advisors

John DeVore	Pacific Fishery Management Council
Robert Alverson	Groundfish Advisory Subpanel (GAP) Representative
Rob Jones	Groundfish Management Team (GMT) Representative

Stock Assessment (STAT) Team members present

Allan C. Hicks	NMFS, Northwest Fisheries Science Center (NWFSC)
Melissa A. Haltuch	NMFS, Northwest Fisheries Science Center (NWFSC)
Chantel Wetzel	University of Washington, School of Aquatic & Fishery Resources

Overview

A draft assessment of greenstriped rockfish (*Sebastes elongatus*) stock status off the U. S. west coast (California, Oregon, and Washington) was reviewed by the STAR panel from August 3-6, 2009 in Seattle, WA. Within the model the population is treated as a single homogeneous stock, but with fisheries that vary spatially. Greenstriped rockfish is a diminutive, low-value bycatch species and, as a consequence, there is great uncertainty about historical discarding practices. Recent data on discards collected by the West Coast Groundfish Observer Program from 2002-2007 were used in the assessment to model retention throughout the modeled period (1916-2008), although discard data collected during the 1980s were considered during the development of a base-model.

The assessment utilized the Stock Synthesis modeling platform and included a wide variety of data sets. Five fisheries were modeled, including: (1) Washington-Oregon (WA/OR) trawl, (2) California (CA) trawl, (3) foreign catches from 1966-1976, (4) "other" commercial gears, and (5) recreational harvests. Three fishery-independent time series of abundance were developed using Δ-GLMM analyses, i.e., early (1980-1992) and late (1995-2004) triennial trawl survey and the NWFSC combined trawl survey (2003-2008). Length compositional data were available to inform estimation of fishery and survey selectivities and conditional age-at-length data were obtained from the combined trawl survey.

This is the first assessment of greenstriped rockfish and a number of structural assumptions were evaluated and incorporated into the final model, including:

- Use of SS3 version 3.03a modeling framework;
- Inclusion of reconstructed landings with the modeled period beginning in 1916;
- Full bias-corrected stochastic recruitment from 1987-2005 with ramped bias corrections before (1970-1986) and after (2006-2020);
- Estimation of retention curves and discards for trawl and "other" commercial gears;
- Incorporation of weight-specific fecundity;
- Unbiased aging error estimates based on the method of Punt *et al*. (2008);
- Fixed $\boldsymbol{M}$ (0.08 yr^{-1}) based on longevity and Hoenig (1983);
- Fixed steepness ($\boldsymbol{h}$ = 0.69) based on Dorn's prior for an unobserved rockfish.

Results of the base assessment model indicate that depletion of the greenstriped rockfish stock (81%) is well above the Council's target for groundfish (40%) and that recent harvests (9-94 mt) are substantially below the potential yield. Uncertainty about the final base model was bracketed by jointly varying natural mortality and the discard retention curve. While decision table results vary widely over the range of possibilities considered, all indications are that the stock is in good condition. Given the robust conclusion that this stock is not currently in jeopardy, nor is it likely to be in the foreseeable future, the STAR panel recommends that this stock not be reassessed until such time that conditions within the fishery have changed substantially (e.g., targeting on greenstriped rockfish occurs) and/or fishery-independent survey statistics indicate a decline in stock abundance.

The STAR panel concluded that the greenstriped rockfish stock assessment developed by the STAT constitutes the best available scientific information on the status of this species off the U.S. west coast and recommends that it be used for status determination and management in the Council process. The STAR panel thanks the STAT team members for their exceptional preparation, hard work, and willingness to respond to panel requests.

Panel Requests to the Greenstriped Rockfish STAT

The following prioritized requests were made by the STAR panel to the greenstriped rockfish STAT:

1) Proposed new base case model. Beginning with the August 2nd version (which included minor updates to landings data, which the Panel endorsed), make the following changes:

   - Remove 1980 triennial survey length-frequency data (but not the 1980 survey index).
   - Re-run the ageing precision and bias estimation model assuming no bias in the ageing process; use the revised precision estimate in the new base case.
   - Use recruitment bias correction ramp (1970-1986).
   - All changes can be done in a single revised run.

Rationale: Sample sizes are small and there is potential bias in favor of mid-sized and more common fish in the early triennial survey length-frequency data. The calculation of both precision and bias in the ageing analysis was inappropriate. The difference between age readers was small and a better estimate of ageing imprecision is obtained by running the analysis with no bias between the readers. Research that is currently underway indicates the ramp-up bias correction method generates less biased estimates of recruitment.

Response: Tuning was done on the new base model for σ_R and resulted in a $\sigma_{R,in}$ of 1.05 and a $\sigma_{R,out}$ of 1.02. It is likely that σ_R increased because the main recruit deviation period from which $\sigma_{R,out}$ is calculated is shorter (1987–2005) and contains highly variable recruitments without the earlier recruitments dampening them. When $\sigma_{R,in}$ was 0.85 (prior to tuning), the estimated current depletion was 0.71, but when $\sigma_{R,in}$ was increased to 1.05, the estimated current depletion was 0.61, which is similar to the estimated depletion from the original base case model without the ramping in of the bias adjustment. So, even though originally it looked liked adjusting the bias adjustment may have an effect on current depletion, the model suggested tuning would bring it back to the same space. Other model parameter estimates were similar to those from the previous base case.

2) Two sensitivity runs that are modifications of the proposed base case model: The first, has a common selectivity for the WA/OR and CA trawl fisheries, but has different retention functions. The second run has a common WA/OR and CA trawl fishery retention function and different selectivity functions.

Rationale: It is difficult to disentangle the combined influence of the selectivity and retention functions on the residual pattern in the fits to the length-frequency data.

Response: The run with the mirrored retention function fit the data slightly worse, mostly in the length-frequency and mean-weight datasets. The overall results of the run were similar to the new base run. The asymptote of the retention curve was estimated at 0.4154 and selectivity curves were similar to the new base.

Somewhat different results were seen for the run with common selectivity for the WA/OR and CA trawl fisheries, but different retention functions. In comparison to the base model this model has poorer fits to the length and discards biomass data. The combined selectivity is most similar to the WA/OR trawl selectivity from the base model. The CA trawl fishery is now selecting fewer small fish in comparison to the base model but the WA/OR trawl selectivity is no longer having a problem with the peak parameter hitting the bound. The retention curve for the CA trawl suggests that the fishery is retaining more fish than the base model.

3) Two sensitivity runs to investigate uncertainty in historical retention rates. For both runs modify the proposed base case model to have a common WA/OR and CA trawl fishery retention function. These sensitivity runs have two time blocks with different retention functions: 1916-1999 and 2000-2008. The WCGOP discard data will apply to the 2000-2008 retention period.

   The first sensitivity run uses the Pikitch discard data for estimating retention parameters for the first time block. The second sensitivity run decreases the estimated asymptote of the retention curve (as estimated for the WCGOP data) by 50% for application to the first time period.

Rationale: The Pikitch data shows very different discard rates to the later WCGOP data, with much lower discarding rates. It seems unlikely that this Oregon data represents the full historical coastwide period, given the perception that historically greenstriped rockfish landings were a small fraction of the catch. These two sensitivity runs are constructed to bound the potential range of historical discards.

Response: The sample sizes for the Pikitch length-frequencies were set at 5 times the number of tows sampled, which resulted in 30 and 15 for 1986 and 1987, respectively. This was done as a tuning exercise as well as to increase the weight on the two length-frequencies which are the only information to inform a long time period. In addition, when just the number of tows was used for sample size, the retention asymptote was estimated at 0.05 and did not fit the length-frequencies at all. The results of the run with the Pikitch data resulted in a retention asymptote of 1.0 for the early time block and the fits to the Pikitch length-frequencies were reasonable. The unfished spawning output was 2,888 million eggs and the current depletion was estimated at 0.63. The retention asymptote for the later time block (WCGOP data) was 0.54. CA selectivity was still shifted to the left and WA/OR selectivity was shifted to the right. The discard fraction in the early time block was around 0.5-0.65 and in the later years was above 0.8.

The run with the retention asymptote fixed at 0.2077 estimated the discard fraction near 0.9 for the entire time period. The unfished spawning output was 10,700 million eggs and the estimated current depletion was 0.62.

4) Two sensitivity runs were requested to investigate the lack of fit to the 1993 year-class signal in the marginal age-composition data. For the first run, all research trawl length-

frequency data will be weighted lower. A maximum sample size of 200 will be used. For the second run, the marginal age-composition from the NWFS survey will be fitted and the length-frequency data removed.

Rationale: To investigate potential conflict between the length-frequency and marginal age-composition data.

Response: Decreasing the effective sample sizes of the survey length frequency data (maximum sample sizes of 200) produced better fits to the conditional age data in comparison to the base model, however visually the fit to the 1993 year class was not substantially improved. In this model run the $\sigma_{R,in}$ was 1.05 and $\sigma_{R,out}$ was 1.08. One run was completed to look at tuning σ_R up to 1.1 but the $\sigma_{R,out}$ was still higher than the input indicating that further tuning could be done.

The second model run removed the length-frequency from the NWFSC survey while retaining the marginal age composition data from that survey. With the length composition data removed the model was still unable to fit the high proportions in the age data from the 1993 cohort. The removal of the length-frequency data resulted in a new selectivity curve for the NWFSC that was shifted to the right with the peak parameter estimated at 43cm for females and 40cm for males which in turn result in a higher q for the NWFSC of 2.55. Due to this difficulty with the estimated selectivity, the length data were put back into the model with lambdas of 0.5 on the length frequencies and marginal age compositions from the NWFSC survey to improve the selectivity estimation. This resulted in a selectivity estimate similar to the base model and a q of 1 for the NWFSC survey. The model still failed to fit the large proportions of the 1993 year-class observed in multiple years. The final depletion estimated in this model was 0.58 compared to the base model estimate of 0.61.

During the meeting, an additional model run was conducted with ageing error turned off. This run resulted in substantially improved fits to the high proportions observed for the 1993 year class in the marginal age frequency data. With tuning, σ_R was estimated at 0.6 which is lower than the estimate of 0.85 for the base case model run. Because there certainly is error in ageing, and a potential for bias in the ageing data (from assigning more fish to a known strong year-class) the Panel decided that ageing error should be maintained in the base case model formulation. But, the lower σ_R (0.6) was considered more appropriate for this stock, and the base case model should fix σ_R at this value.

5) Check the discard ratio values presented in Table 9.

Rationale: Tabulated values appear suspicious because of similarity among the annual estimates for WA, OR, and CA.

Response: The formula used to calculate the discard ratios was incorrect (because data had been provided based on a North/South split, rather than a State-based split), and revised values for northern and southern regions were presented.

6) Provide model estimates of annual total catch and total retained catch from the base case and the two alternative retention scenarios.

Rationale: To determine how discard ratios vary between the base case and alternative retention scenario model runs.

Response: Results were presented in conjunction with the sensitivity runs discussed above.

7) Check data input for 2003 WA/OR trawl landings and discard length-frequency.

Rationale: Residuals for the landings and discard length-frequencies have opposite patterns.

Response: The data had been entered correctly and the suspicious residual pattern was the result of small sample sizes for the discard data.

8) Requested change to the assessment document: authors to document that the foreign fishery did not begin prior to 1966.

Rationale: Foreign fleet catches were high in 1966, suggesting the fishery could have begun earlier.

Response: The Rogers foreign catch reconstruction document states there was no foreign catch in US waters in 1965. The only catches reported in 1966 were from Soviet vessels, from the Monterey, Columbia, and US. Vancouver INPFC areas.

Description of base case model and alternative models to bracket uncertainty

- Start year of the model = 1916;
- Spatial structure: coastwide, single-area model;
- Discard for trawl and other-gear fisheries estimated within model from retention function;
- M set to 0.08 yr^{-1} for females and 0.08 yr^{-1} males following sensitivity analysis;
- h set to 0.692 on the basis of Dorn's prior;
- σ_R set to 0.6 following investigation of interaction with ageing imprecision;
- von Bertalanffy growth parameters, including dispersion of individual growth, estimated for females and males;

Fisheries:

Washington/Oregon trawl
California trawl
Foreign
Other commercial gears
Coastwide recreational

Abundance indices:

Early Triennial trawl survey (1980-1992)
Late Triennial trawl survey (1995-2004)
NWFSC shelf-slope trawl survey (2003-2008)

Discard data [mt discarded]:

Washington/Oregon trawl (2002-2007)
CA trawl (2002-2007)
Other commercial gears (2002-2007)

Discard data [mean body weight]:

Washington/Oregon trawl (2002-2007)
CA trawl (2002-2007)
Other commercial gears (2002-2007)

Length composition[1]:

Washington/Oregon trawl (1996-2008)
California trawl (1978-2007)
Other commercial gears (1979-2008)
Coastwide recreational (1980-2003)
Triennial trawl survey (1980-2004; triennial)
NWFSC shelf-slope trawl survey (2003-2008)
Washington/Oregon trawl discards (2003-2007)
CA trawl discards (2002-2007)
Other commercial gear discards (2005-2007)

Age composition (as conditional age-at-length by sex):

NWFSC shelf/slope trawl survey (2003-2008)

Uncertainty – Greenstriped rockfish are small bodied and have only sporadically been caught but never targeted by the fishery and fishery sampling programs; much of the catch is discarded (about 80% by weight in recent years). There is much uncertainty in both the reconstruction of historical landings and especially in historical levels of discard. The effect of this uncertainty is bracketed by setting the historical retention curve to higher and lower values than the base-case value estimated from recent (2002-2008) observer data. The higher historical retention curve is supported by the discard observations obtained by Pikitch for the Oregon trawl fishery in the mid 1980s. The lower retention curve is supported by the widespread occurrence of greenstriped rockfish in fishery-independent trawl surveys, yet their low landed catch in some areas. Higher retention, hence less discard and lower historical total catch, scales historical stock abundance lower and vice versa for the lower retention curve. In addition, the natural mortality is not precisely determined and the base model uses a value of 0.08. The high end of the range is set to 0.10 based on high values predicted from life history characteristics and the low end is set to 0.06 based upon values of natural mortality estimated from the data included in the assessment.

[1] Some years have no samples, see assessment document for details of sample availability.

The choice of natural mortality affects the estimated depletion, but even when M = 0.06, results still indicate that the stock is above the target stock size. The assessment finds that greenstriped rockfish have never been substantially reduced in abundance so the spawner-recruitment steepness cannot be estimated. Steepness is set equal to the mean of the prior derived from other rockfish species and the assessment result for greenstriped is not sensitive to this value.

Technical merits of the assessment

The greenstriped rockfish stock assessment team was very well prepared and had completed a thorough analysis, including a variety of sensitivity runs, in advance of the STAR panel meeting. Efforts to reconstruct landings for the States of Washington and Oregon were comprehensive and formed an essential component of the stock assessment, although additional work on landings reconstructions is expected to further improve our understanding of this species. Because greenstriped rockfish is essentially a non-targeted bycatch species, use of data from the West Coast Groundfish Observer Program (and the Pikitch study) to inform estimation of retention functions and total discards was a noteworthy technical accomplishment of the assessment.

Explanation of areas of disagreement regarding STAR panel recommendations

A. Among STAR panel members (including concerns raised by the GAP and GMT representatives

There were no areas of disagreement among STAR panel members.

B. Between the STAR panel and the STAT team

There were no areas of disagreement between the STAR panel and the STAT team.

Unresolved problems and major sources of uncertainty

It was the STAR panel's view that the principal source of uncertainty in the assessment relates to historical discarding practices. Recent data show significant discarding of all sizes of greenstriped rockfish, whereas data from Pikitch show both a lower overall discard rate and virtually no discarding of fish larger than 30cm. Given the ubiquity of this species in fishery-independent trawl surveys and relatively low reported landings over many years of observations, the Pikitch data were viewed with some skepticism and, as a consequence, were not included in the final assessment model. Nonetheless, the panel was concerned about application of discard data from the last decade, a time period of intense management, to the preceding historical period that started in 1916. While it is not clear how this issue can be resolved through further study, this remains a major source of uncertainty for greenstriped rockfish, for which discarding is generally acknowledged to be high.

Another source of uncertainty identified by the STAR panel is the estimate of greenstriped rockfish natural mortality (***M***), which in the base model was fixed at 0.08 yr^{-1}. Given observed longevities of male (49 yr) and female (51 yr) fish, which are relatively easy to age, the adopted value is reasonable. However, likelihood profiling indicates that a much better fit occurs at a lower value ($M \cong 0.06\ yr^{-1}$). Importantly, the difference between these two estimates has a considerable effect on estimates of stock size and potential production.

Management, data, or fishery issues raised by the GAP and the GMT representatives

No specific issues or concerns pertaining to the greenstriped rockfish stock assessment were raised by the GAP and/or GMT representatives during the meeting. It was acknowledged by industry participants at the meeting that on occasion catches were retained and landed during the course of normal fishing operations, but that targeting was unlikely to have occurred.

Prioritized recommendations for future research and data collection

Specific to greenstriped rockfish:

1. Develop alternative methods to deal with historical discards, where information is limited or non-existent. Co-occurrence of greenstriped rockfish with other species in fishery-independent trawl survey catches may provide a basis for estimating relative fishing effort trends.

2. Conduct a blind re-read of ageing structures from the strong 1993 year-class to ascertain if there is ageing bias resulting from an expectation of a strong year-class.

3. Explore stock structure and potential differences in northern/southern greenstriped rockfish life history characteristics.

General:

1. Continue to develop standardized landings reconstruction methodologies over all three west coast states.

2. Explore a GLMM approach with a calendar date covariate to estimate CPUE indices for the entire triennial survey time series. A species assemblage meta-analysis approach could be used to develop priors for the ratios of q among the early triennial, the late triennial and the NWFSC surveys.

3. Explore the relationship between ageing precision, recruitment variability, and bias adjustment (and effects on depletion estimates) using simulation methods, and develop recommended procedures for appropriate methods to follow.

Acknowledgements

The Panel thanks the Northwest Fisheries Science Center for organizational and logistical support during the meeting at the Hotel Deca, including especially Jim Hastie and Stacey Miller.

Agenda Item E.2.c
Supplemental SSC Report
September 2009

SCIENTIFIC AND STATISTICAL COMMITTEE REPORT ON PART II OF STOCK ASSESSMENTS FOR 2011-2012 GROUNDFISH FISHERIES

INTRODUCTION

The Scientific and Statistical Committee (SSC) completed a review of seven stock assessments and Stock Assessment Review (STAR) panel reports, including petrale sole, widow rockfish, yelloweye rockfish, greenstriped rockfish, bocaccio, cabezon, and lingcod. With the exception of petrale sole, these assessments were completed over the summer following the Council's June meeting. At that meeting the petrale sole assessment was referred to a SSC groundfish subcommittee meeting to be held later in the summer for further consideration and evaluation. Having now reviewed the entire set of full and updated stock assessments that were scheduled this year, the SSC is very pleased to inform the Council that the process performed very well this year. All the stock assessment teams submitted well-prepared documents in a timely manner and were responsive to all requests during the review process. As witness to that conclusion we note that no assessments were referred to the mop-up panel. For that reason the SSC would like to commend all the personnel and staff involved in this major effort for having performed at such a high level.

FULL STOCK ASSESSMENTS

Petrale Sole

At its June 2009 meeting, the SSC reviewed the new petrale sole assessment and, based on a number of concerns, was unable to endorse the assessment at that time. The STAR Panel report also recommended that the estimates of F_{MSY} and B_{MSY} produced by the assessment be investigated as alternatives to the currently used proxies of $F_{40\%}$ and $B_{40\%}$. The SSC developed a list of analytical requests for the petrale sole Stock Assessment Team (STAT) to address these issues, and the SSC's groundfish subcommittee met with the STAT on August 31st to review the response to these requests.

Dr. Melissa Haltuch provided the SSC with a brief overview of the petrale sole assessment, and presented the STAT's response to the SSC groundfish subcommittee requests. Dr. Stephen Ralston presented the report of the SSC groundfish subcommittee, which endorsed the petrale sole model that was approved by the STAR panel, and recommended that proxies of $B_{25\%}$ for B_{MSY} and $F_{30\%}$ for F_{MSY} be established for west coast flatfish.

The SSC revisited the issues that had already been considered in detail during the subcommittee meeting. The SSC agreed that the base petrale sole model represents the best available scientific information, and endorsed its use for status determination and management in the Council process.

The SSC concluded that there is no basis for rejecting the assessment based on the estimate of catchability coefficient (q) for Northwest Fisheries Science Center (NWFSC) trawl survey. However the SSC encourages further investigation of the catchability coefficient of the survey by experimental evaluation of trawl performance, quantification of trawlable and untrawlable habitat off the west coast, or by synthesis of available information and expert knowledge through development of an informative prior, as had been anticipated from the 2008 survey catchability workshop.

The raw catch per unit of effort (CPUE) presented in the petrale sole assessment suggests a potential discrepancy between the assessment results and the experience of the groundfish fleet. It is important to note that limited conclusions can be drawn from un-standardized CPUE data, and that standardization of these data will be difficult due to the many management changes in the groundfish fishery. Nevertheless, the SSC encourages further evaluation of fishery CPUE data in the next petrale sole assessment, if only to better understand and potentially reconcile these differences.

During its meeting, the SSC groundfish committee addressed the suggestion of the petrale sole STAR Panel to investigate the species-specific estimates of F_{MSY} and B_{MSY} as alternatives to the currently used proxies. The SSC endorses the groundfish subcommittee's recommendation to establish new proxies of $B_{25\%}$ for B_{MSY} and $F_{30\%}$ for F_{MSY} for west coast flatfish. These values are based on a number of considerations, including evaluation of information on flatfish productivity (steepness) for assessed west coast flatfish, published meta-analyses of other flatfish stocks, and recommendations on appropriate proxies for B_{MSY} and F_{MSY} in the scientific literature. The SSC does not at this time endorse the use of species-specific estimates of B_{MSY} and F_{MSY} for petrale sole because of high variability in these estimates between repeat assessments for other stocks and the sensitivity of these estimates to assumptions concerning stock structure. Instead, the SSC recommends that this issue be dealt with in a comprehensive way, perhaps through development of guidelines during an off-year harvest policy workshop.

Other aspects of the Council's harvest policy, such as the overfished threshold and the point at which the precautionary reduction for optimum yield (OY) becomes zero (40-10), are policy decisions that are at the discretion of the Council. A policy that mimics the Council's default proxies for groundfish would be to set the minimum stock size threshold (MSST) to $B_{15\%}$, which is 60 percent of the target stock size, and to implement a 25-6.25 precautionary adjustment for OY. Alternatively, the Council could set the MSST to 50 percent of $B_{25\%}$, which is the lowest value recommended by the National Standard 1 guidelines.

Finally, the SSC notes that the process of addressing a STAR panel recommendation with potentially broad ramifications has been less than ideal. Again, addressing harvest policy issues during an off-year science workshop would allow a more comprehensive approach to be developed. Such a workshop would also provide opportunity for outside review, which may be an important consideration given that SSC members are likely to be involved in technical analyses.

Widow Rockfish

Dr. Xi He presented the widow rockfish stock assessment to the Scientific and Statistical Committee (SSC). Dr. Martin Dorn summarized the report of the Stock Assessment Review (STAR) Panel of the widow rockfish assessment, held in Santa Cruz, California July 13-17, 2009.

The last full assessment of widow rockfish was conducted in 2005, with an update in 2007. The 2009 assessment differed from the previous assessment in several respects: a) the assessment used Stock Synthesis 3 (SS3) rather than a custom-designed model, b) the catch history was revised and extended back to 1916, c) catch, age, and survey data were updated with data from 2007 and 2008, and d) data from the NWFSC trawl survey were included in the assessment. Widow rockfish were modeled as a single stock with two areas and four fisheries. Additional work regarding how to model this species remains a priority given the sparseness of recent fishery data and the need to further explore spatial stock structure.

The STAR Panel considered the current assessment to be the best available scientific information and recommended its use in management. Much attention was given during the STAR Panel to refining the new data sets so that the base model is reasonably well developed. Less time was available to explore alternative model configurations and tuning. For example, the SSC observed that length selectivity patterns were not consistent among data sources and selectivity patterns for the triennial and NWFSC trawl surveys were unexpected. The SSC recommends that the next assessment should be a full assessment because several key problems remain unresolved.

The 2007 assessment identified a large partially-recruited 2002 year class that led to predictions of rapid rebuilding by 2009. This year class was less evident in the recent data and is not now estimated to be a strong year class. Nonetheless, there has been a gradual rise in the modeled depletion rate to 38.5 percent, just short of the 40 percent rebuilding threshold. The SSC endorses the use of the 2009 widow rockfish stock assessment for status determination and management in the Council process.

In general the SSC notes that estimates of recruitment for the most recent years of an assessment are often the most uncertain, yet can have a considerable impact on the outcomes of rebuilding projections. The SSC recommends that the STAT and STAR Panels consider imposing constraints on the estimates of recent year-classes to the extent we have lower confidence in these estimates.

The SSC is also generally concerned about the lack of data to inform the rate of stock rebuilding in recent years for several assessments of overfished rockfish. Specifically, fundamental assumptions about stock productivity are made in these models that will lead to a conclusion of stock recovery if catches are reduced markedly. The SSC notes that in a number of instances, recent predicted increases in abundance of overfished stocks are largely due to properties of the models and not to robust observational data.

Yelloweye Rockfish

Dr. Ian Stewart presented the yelloweye rockfish assessment to the Scientific and Statistical Committee (SSC). Dr. Stephen Ralston summarized the report of the Stock Assessment and Review (STAR) Panel of the yelloweye rockfish assessment, held in Seattle, Washington, August 3-6, 2009.

The last full assessment of yelloweye rockfish was conducted in 2006 with an assessment update in 2007. The 2009 assessment differed from these previous assessments in terms of assumed population structure and the data used to fit the model. The 2009 assessment was based on three regions (California, Oregon and Washington) under the assumptions that adults are sedentary, density-dependence is a function of coastwide egg production, and the proportion of recruits settling in each area is constant over time. This spatial structure is consistent with our understanding of the behavior of yelloweye rockfish, and reflects a compromise between a coastwide assessment and separate assessments for each state. This compromise allows for some regional differences to be captured within the model without requiring large numbers of additional parameters.

Even with a large number of changes to data inputs, the results from the 2009 yelloweye rockfish assessment are consistent with those from the 2006 and 2007 assessments. All of these assessments suggest that yelloweye rockfish experienced a substantial decline in abundance between 1980 and 2000, with a best estimate of stock depletion in 2009 from the current assessment of 20.3 percent.

In contrast to the 2006 and 2007 assessments, the 2009 assessment makes use of data from the NWFSC and Triennial trawl surveys as well as data on discarded yelloweye rockfish collected by observers in the Oregon recreational charter fishery. However, the International Pacific Halibut Commission (IPHC) survey data remain the most important index in the assessment, although IPHC survey data are only available for Washington and Oregon and not California where the largest potential biomass of yelloweye rockfish is estimated to occur. Unlike previous assessments, the relationship between fishery-dependent catch-rates and abundance is allowed to be non-linear. The assessment authors also reviewed and updated assumptions regarding growth, maturity and fecundity.

The catch history was revised as part of the 2009 assessment. However, the revised time-series of catches was not markedly different from that on which the 2006 and 2007 assessments were based. Considerable uncertainty regarding the time-series of historical catches remains, and this was identified as a key source of uncertainty in the assessment.

The assessment estimates trends in abundance by region. The SSC cautions against making use of these trends as the sole basis for the spatial allocation of harvest guidelines because the trend in abundance at the coastwide level is much more robust than those at the regional level. Reasons for this include that the time-series of historical catches by region are more uncertain than the coastwide totals and that the catch reconstructions for Washington are still somewhat incomplete. Given that the trends in abundance by region are driven to a considerable extent by the time-series of historical catches, uncertainty in the split of total catches to region will be reflected more in uncertainty in regional depletion than in total depletion.

The SSC endorses the research recommendations of the assessment authors and the STAR Panel, and identified two data sources which, if investigated, could provide additional indices of abundance: (a) the catch and effort data from the Oregon live-fish fishery, and (b) yelloweye rockfish catch rates from the recreational fishery for Pacific halibut. The SSC also highlights the continuing need for an index of abundance that can be used to reliably detect changes in yelloweye rockfish abundance. It also notes that visual survey techniques have the potential to index yelloweye rockfish abundance without inducing mortality which might hinder recovery.

The SSC recommends that the following be considered as potential items for workshops during the 2010 “off-year”: (a) review of efforts to develop stock size indices based on the IPHC surveys, including how to add stations to augment the survey and, (b) analyses to construct indices of abundance for yelloweye rockfish and other groundfish. Given the potential importance of the IPHC index to the assessment of yelloweye rockfish, the SSC also recommends participation by IPHC scientists at any workshops to review the use of the IPHC data in yelloweye rockfish assessments and at future STAR Panels. Finally, the SSC highlights the value of collecting biological data, such as age-length and maturation information, for yelloweye rockfish during the IPHC surveys.

The SSC recommends that the yelloweye rockfish assessment be an update during the 2011 assessment cycle unless off-year research leads to a marked change to how the IPHC survey data are analyzed or the development of a new index of abundance based on the discards in Oregon recreational charter fishery. The SSC notes that the assessment author plans to refine how the IPHC survey data are analyzed. In principle, changing the analytical method used to summarize survey data falls outside of the terms of reference for an assessment update. However, given that this is a stable assessment, this change can be accommodated within the scope of an assessment update, but this will require extra time for review.

The SSC endorses the use of the 2009 yelloweye rockfish assessment for status determination and management in the Council process. The SSC also endorses the approach used to quantify uncertainty, which will form the basis for the rebuilding analysis for this species.

Greenstriped Rockfish

Mr. Allan Hicks and Dr. Melissa Haltuch presented the greenstriped rockfish assessment to the Scientific Statistical Committee (SSC). Dr. Stephen Ralston summarized the report of the Stock Assessment and Review (STAR) Panel of the greenstriped rockfish assessment, held in Seattle, Washington, August 3-6, 2009.

This is the first assessment of the greenstriped rockfish off the US West Coast from US/Canada border to US/Mexico border. Greenstriped rockfish is a small, low-value bycatch species found in a wide range of habitats with a preference of mud or sand bottoms. The population is treated as one single stock in the assessment. There have been no fisheries targeting this species, thus discards constitute the main component of total fishing mortality on the stock. There is great uncertainty about historical discarding practices. Five fisheries and three fishery-independent surveys were modeled using Stock Synthesis 3.03a modeling framework.

An error in domestic catches was discovered and corrected after the STAR Panel. Revised results were presented to the SSC. In general, the revised results were very similar to those in the previous version. The estimated 2009 depletion remained the same at 81 percent, which is well above the Council's management target for groundfish (40 percent). Estimated total catches (landings plus estimated discards) in the past five years ranged between 3-78 mt and were substantially lower than the potential catch.

Uncertainty in states of nature was bracketed jointly by natural mortality and fraction discarded. There is only one harvest scenario in the decision table. The SSC noted that discards were not handled appropriately in two of the sensitivity runs (double and half of the landings) due to the fixed fraction of discards in model configuration. However, this does not affect the information provided in the decision table. It was also noted that the within assessment uncertainty is relatively high compared to other west coast groundfish assessments.

In this assessment, historical WA/OR catches were estimated by applying a fixed proportion to the documented landings of other rockfishes. However, due to the weighed-back issue of greenstriped catches, the historical removal requires further investigation.

The SSC noted that, in contrast to other rockfishes, trawl surveys provide reliable abundance indices for greenstriped rockfish. Given the high uncertainty in landings and discards in the assessment, establishing a tier system that allows a simpler approach for setting harvest control rules for greenstriped rockfish and other data-poor species is desired.

The SSC endorses the use of the 2009 greenstriped rockfish assessment for status determination and management in the Council process.

Bocaccio

Dr. John Field presented the bocaccio assessment and Dr. Martin Dorn summarized the report of the July 13-17, 2009 STAR Panel. The last full assessment of bocaccio was conducted in 2003, and it was subsequently updated in 2005 and 2007. The 2009 assessment: (a) used the SS3 modeling framework instead of SS1, (b) extended the northern boundary from Cape Mendocino to Cape Blanco, and (c) extended the period modeled from one beginning in 1951 to one beginning in 1892. There is evidence of two demographic clusters off the west coast centered off southern/central California and British Columbia. Although the bocaccio range extends considerably further north of Cape Blanco, abundance is low between Cape Mendocino and the Columbia River. Evidence also exists for a diffusion of young bocaccio from southern California northward as they age.

Major data changes for the 2009 assessment compared to previous assessments included a revised catch history and modeling of the trawl fishery as northern and southern components rather than as a single fishery. The 2009 assessment incorporated the NWFSC shelf-slope trawl survey for the first time, and also revised triennial trawl survey estimates. The 2009 assessment also used the NWFSC Southern California Bight hook and line survey and revised juvenile indices from the recreational pier index and juvenile trawl survey index.

The best estimate of current stock depletion in the 2009 assessment is 28 percent. The results of the 2009 assessment are consistent with those of the 2007 update, except for a smaller estimated starting biomass. The change in the estimated starting biomass resulted primarily from extension of the assessment period back to 1892 when spawning output was estimated to be close to unfished levels.

The SSC endorses the research and data collection recommendations of the assessment authors and the STAR Panel. While there are unresolved issues with the assessment, progress on these problems is likely to be difficult and incremental without additional biological data and information on stock structure. The SSC concurs with the STAR Panel recommendation that the next bocaccio assessment be an update rather than a full assessment.

The SSC endorses the use of the 2009 bocaccio assessment for status determination and management in the Council process.

The SSC supports extension of the assessment north of Cape Mendocino as biologically appropriate given our current understanding of stock structure, but also recognizes that this boundary extension raises issues with respect to area management. Approximately 6 percent of the coastwide bocaccio catch has occurred historically between Cape Mendocino and Cape Blanco while only 1 percent has been taken from the California/Oregon border to Cape Blanco. There is not a conservation issue at this time north of the $40^0$10' management boundary based on these low bocaccio catches in this area. Therefore, the SSC does not recommend changing the area where bocaccio are designated as overfished. Management should be based on a pro-rata allocation using the historical catch distribution north and south of $40^0$10'.

Cabezon

Dr. Jason Cope presented the cabezon stock assessment to the SSC. Dr. Vidar Wespestad presented the report of the Cabezon STAR Panel, held in Seattle, Washington on July 27-31, 2009.

The last full assessment of cabezon was conducted in 2005. The 2009 assessment extends the spatial range of the assessment to include Oregon as a third sub-stock, while retaining the two sub-stocks within California, north and south of Point Conception. Each of these sub-stocks was modeled separately, and a fourth scenario considered California as a single sub-stock. Several stock definition techniques support there being two or more stocks in California.

Notable changes in data from the 2005 assessment include a longer time series of catches and additional RecFIN length composition data prior to 1990. Conditional age-at-length data was used for the first time allowing for growth estimation internal to each model.

The stock assessment team (STAT) considered all available potential indices of abundance, but few were useful for assessment purposes due to a lack of appropriate spatial and temporal coverage. Consequently, only one index of abundance was used for each sub-stock (CPFV for California and the Oregon Recreational Boat Survey (ORBS) for Oregon). The SSC discussed the need for further review of local indices of abundance and their incorporation into stock assessment models.

The results of the 2009 assessment are consistent with the 2005 assessment for the Northern California sub-stock (NCS), but somewhat different for the Southern California sub-stock (SCS) mainly due to additional length composition data from the 1980s for the latter. A California coast-wide model estimated current depletion to be below either of the sub-area estimates. The SSC agrees with the STAT and STAR Panel that the NCS and SCS models best reflect the dynamics in each area, and that the results of the two sub-stock models should be combined in providing management advice for California.

The SSC endorses the use of the 2009 cabezon assessment for status determination and management in the Council process. A full assessment is not recommended in the next few assessment cycles in the absence of additional appropriate survey indices or better estimates of the natural mortality rate and/or growth parameters.

Lingcod

Dr. Owen Hamel presented the lingcod stock assessment to the SSC. Dr. Vidar Wespestad presented the report of the Lingcod STAR Panel, held in Seattle, Washington during July 27-31, 2009.

The assessment utilized data from the entire west coast of the contiguous United States (waters off Washington, Oregon and California). The lingcod population in these areas was modeled as two stocks in two separate assessment models covering [1] waters off Oregon and Washington (northern stock) and [2] waters off California (southern stock). This spatial delineation differed slightly from that used in the last stock assessment (2005) in which the stocks were separated at Cape Blanco (43° N vs. 42° N). The spatial change was necessary to facilitate access to existing databases for an analysis of candidate stock structures that was carried out prior to the assessment modeling.

Notable data differences from the 2005 assessment were (i) inclusion of four additional years of fisheries data (2005-08), (ii) extension of the catch time series back to 1928 (vs. 1956), and (iii) use of two new indices of abundance (NWFSC trawl survey and recreational dockside CPUE). Modeling changes included use of the SS3 software and other model structure refinements.

Key results of the 2009 assessment of the northern stock (B_0=33,000mt and depletion=62 percent) are generally consistent with the 2005 assessment. Further, sensitivity analysis demonstrated that these results are quite robust to the inclusion/exclusion of the various indices of abundance and other data sources. In contrast, results of the 2009 assessment of the southern stock (B_0=25,000mt and depletion=74 percent) are considerably more optimistic than the 2005 assessment; but are not nearly as robust as results from the northern stock. For example, exclusion of the recreational CPUE index from the southern base case reduced the depletion ratio estimate to 38 percent – a level more comparable to that estimated in the 2005 assessment, while inclusion of the age sampling data increased the depletion ratio estimate to 90 percent. Given these differences in uncertainty of the northern and southern stock results, the SSC concurs with the STAT that the respective decision tables should be structured differently. While natural mortality may serve as a reasonable major axis of uncertainty for the northern stock, the inclusion/exclusion of indices and data sources better characterizes the major uncertainty axis for the southern stock.

The NWFSC trawl survey index is highly variable and could not be well fit in either the northern or southern assessment model. The northern survey index is highly variable and without trend. However, while equally imprecise, the southern index exhibits a consistently declining trend over its six year history. As this trend is inconsistent with the assessment results, future work should investigate whether alternative model structures and/or assumptions can reproduce this trend; or whether re-analysis of the survey data may be warranted.

The considerable set of age sampling data was not incorporated in the base case for either the northern or southern lingcod assessment. The results for the southern stock were sensitive to the inclusion/exclusion of these data. Age validation and possible biases in age reading should be investigated. However, age sampling should continue until these issues can be resolved.

The SSC endorses the use of the 2009 lingcod assessment for status determination and management in the Council process. An updated assessment should be sufficient for the next lingcod assessment unless substantial progress can be made on ageing validation. Finally, the SSC endorses the research recommendations of the STAT and STAR Panel.

SSC Groundfish Subcommittee Report on Petrale Sole
AFSC, Seattle WA – August 31, 2009

Background

This year an assessment of the petrale sole (*Eopsetta jordani*) stock off the U.S. west coast was conducted and a scientific review was held at a Stock Assessment Review (STAR) panel meeting May 4-8th in Newport, OR. The assessment concluded that since 1943 the stock has experienced chronic annual overfishing, defined as fishing mortality rates in excess of $F_{40\%}$, which is the rate that would reduce the expected lifetime egg production of a new recruit to 40% of that expected to occur in the absence of fishing. Moreover, the assessment concluded that the abundance of the stock has been below the minimum stock size threshold (MSST) since 1953, which would require the development of a stock rebuilding plan. For all Council groundfish stocks, the MSST is defined to be 25% of the biomass if there were no fishing ($B_{25\%}$). In contrast to these conclusions, the assessment also showed that the stock has supported very steady annual catches in excess of 2,000 mt for the last half century. Moreover, the stock assessment team (STAT) argued that the Council's proxy flatfish reference points ($F_{40\%}$ and $B_{25\%}$) were inappropriate, given the estimated productivity of the stock. The STAR panel review concurred with the STAT's evaluation and recommended that the reference points (B_{msy} and F_{msy}) developed specifically for petrale sole be used by the Council in developing ABC and OY recommendations for the 2011-2012 biennial management cycle.

The SSC reviewed the stock assessment and the STAR panel report at the Council's June 2009 meeting in Spokane, WA and, based on a number of concerns that were identified at that time, was unable to endorse a re-definition of reference points specific to petrale sole. Instead, the SSC developed a list of analytical requests and asked that the STAT conduct further analysis and report its findings to a meeting of the SSC's groundfish subcommittee to be held sometime later in the summer. This report summarizes the deliberations of the subcommittee meeting, which was held August 31st at the Alaska Fisheries Science Center in Seattle, WA and provides several recommendations regarding the petrale sole stock.

The Problem

The Council has used a harvest control rule for its assessed groundfish stocks since passage of Amendment 11 to the FMP in 1998. The control rule specifies proxy F_{msy} harvest rates for flatfish and Pacific whiting ($F_{40\%}$), roundfish ($F_{45\%}$), and rockfish ($F_{50\%}$)[1]. The Council adopted these three taxon-specific proxy fishing mortality rates, due to perceived differences in the productivity among these groups. However, at the same time the Council has used a single "target" stock biomass as its nominal B_{msy} proxy ($B_{40\%}$), as well as a single MSST ($B_{25\%}$). The use of proxy estimates of F_{msy} and B_{msy} was adopted by the Council due to inherent statistical difficulties in estimating these quantities in any single stock assessment and because of a well-developed scientific

[1] Note that an $F_{40\%}$ harvest rate is greater than an $F_{45\%}$ harvest rate, which in turn is greater than an $F_{50\%}$ harvest rate, i.e., flatfish are expected to achieve MSY at greater fishing pressure than rockfish.

literature supporting the use of proxies. Nonetheless, the Council has previously been confronted with peculiarities associated with the use of its proxies. For example, in the case of Pacific whiting where, if fished at the proxy harvest rate, the spawning biomass would be expected to drop below the MSST with some regularity. Fundamentally, as the productivity of a stock increases, the fishing mortality rate that produces MSY increases and, concomitantly, the relative biomass of the stock when fished at that rate decreases. Hence, flatfishes would be expected to have a lower relative B_{msy} value than rockfishes and logically might have a lower MSST than rockfishes as well. However, all Council groundfish stocks are currently judged identically with respect to being overfished.

Requests to the Petrale Sole Analytical Team

In June the SSC developed a list of analyses for the petrale sole STAT that were divided into two major areas. The first set of analyses was designed to explore the extent of parameter confounding and the influence of Canadian catches on the stock assessment model, including: (1) generating MCMC outputs for key model parameters, (2) evaluating the effect of Canadian removals on stock status, (3) incorporating a new "prior" on spawner-recruit productivity, also termed steepness (h), and (4) altering the prior on the natural mortality rate (M) to make it more informative. The second set of requests dealt specifically with the use of generalized proxies versus petrale-specific management quantities, including: (1) characterization of uncertainty in estimates of B_0, B_{msy}, $B_{40\%}$, and F_{msy}, (2) evaluating the effect of time-blocked selectivities on the estimate of B_{msy}, and (3) providing a clear argument to support the use stock-specific estimates.

Response to the SSC Groundfish Subcommittee

The petrale sole STAT attempted to complete all the requested analyses but was unable to generate a converged MCMC chain from the base model due to a technical difficulty with the Stock Synthesis modeling platform. This precluded a detailed evaluation of parameter confounding and prevented a thorough description of uncertainty in some of the key assessment outputs, including the stock-specific estimates of B_{msy} and F_{msy}. The STAT reported that the technical difficulty has now been solved but that there was insufficient time available to conduct an MCMC analysis before the subcommittee meeting. The team did succeed in developing a Canadian petrale sole catch history, but was unsuccessful in its attempt to incorporate those data into the base model, primarily because the Canadian compositional data were unavailable until just before the subcommittee meeting and when reviewed they differed markedly from the lengths and ages from Washington. The subcommittee agreed with the STAT that incorporation of the Canadian data in the assessment would require considerable additional work and should be done in collaboration with Canadian scientists. With respect to incorporating priors on h and M, the STAT was successful, but the effect of those analyses on the assessment was minimal, as was the effect of time-varying selectivity blocks on the model's estimate of B_{msy}.

Given the information and analyses that were presented, the subcommittee found no fault with the base petrale sole model that was approved by the STAR panel and recommends that it be used as the basis for setting an ABC and OY. However, in light of the base model's stock-specific estimates of B_{msy} (19% of B_0) and F_{msy} (equivalent to $F_{20\%}$) the subcommittee discussed at some length the wisdom of using the Council's flatfish harvest control rule proxies for petrale sole.

In addition, with respect to survey catchability, during the SSC review of the assessment in June, the catchability coefficient for the NWFSC combined trawl survey was considered. In particular, the parameter estimate was considered high (q = 3.07) and reasons for this were discussed. During the groundfish subcommittee meeting the STAT team presented additional information to help the subcommittee interpret the estimate, including video showing the Aberdeen trawl footrope and the response of flatfish and rockfish to the approaching net. Although the subcommittee concluded that there was no basis for rejecting the assessment based on the estimate of q, the development of a prior for survey catchability, as had been anticipated from the 2008 survey catchability workshop, may have been useful.

The subcommittee also received comment from industry representatives present at the meeting regarding petrale sole fishery-dependent logbook CPUE data that evidently have increased substantially. When petrale sole is next assessed, it would be helpful to document and reconcile this increase in CPUE with the trends estimated by the model.

SSC Groundfish Subcommittee Recommendations

The SSC groundfish subcommittee still endorses the use of proxies as a general practice for two important reasons. First, as noted previously, it is usually quite difficult to obtain reliable stock-specific estimates of B_{msy} and F_{msy} in any particular assessment (Haltuch *et al*. 2008). From a meta-analytical perspective there is no doubt that useful inference about stock productivity can be drawn by comparative analysis of information drawn from studies of related species in comparable habitats. Second, the use of proxies has a stabilizing influence on stock reference points, which is beneficial to the management process. However, given the marked discrepancies between the Council's existing flatfish proxies and the stock-specific reference points derived from the approved base model ($F_{20\%}$ and 19% depletion), the subcommittee recommends that new flatfish proxies be developed for Council management. To that end, the subcommittee reviewed an analysis of productivity parameters for west coast flatfish (Dover sole, petrale sole, English sole, arrowtooth flounder, and starry flounder) developed by Dr. Martin Dorn and concluded that steepness was at least h = 0.80. Moreover, recent results presented in Punt *et al*. (2008) show that for a diverse set of west coast groundfish stocks (Pacific whiting, sablefish, petrale sole, and canary rockfish), a steepness value of 0.80 is associated with an F_{msy} value that is roughly equivalent to $F_{30\%}$ when the stock-recruit relationship has a Beverton-Holt form (see Figure 1). Moreover, the level of stock depletion associated with fishing at F_{msy} is approximately $B_{25\%}$ (see Figure 2). The subcommittee noted that use of the Beverton-Holt stock-recruitment relationship is appropriate in this case because: (a) all stock assessments for west coast groundfish are based on this relationship and (b) the data for petrale sole support the Beverton-Holt curve over the Ricker relationship.

Based on these considerations the SSC's groundfish subcommittee recommends that the Council tentatively adopt those values as new west coast flatfish MSY proxies. In addition, given that the current MSST ($B_{25\%}$) for groundfish is 62.5% of the target biomass ($B_{40\%}$), the subcommittee recommends that for west coast flatfish under Council management, the MSST be set at $B_{15\%}$, which is 60% of the target stock size. Because the estimate of petrale sole stock depletion in 2009 from the STAT's base model is 11.6%, if this MSST is adopted the stock would be declared overfished.

The subcommittee also recommends that a more comprehensive analysis of the PFMC's harvest control rule proxies be undertaken as soon as practicable, which may influence and/or supersede these recommendations. In particular, biomass targets and thresholds should be established that are consistent with expected stock productivities and in accordance with expected levels of intrinsic stock variability. The subcommittee recognizes that this will be a major undertaking, which logically should be conducted as a full management strategy evaluation, but these issues and concerns are fundamental to proper utilization, conservation, and stewardship of groundfish resources.

NOAA Technical Memorandum NMFS-F/SPO-31. 54 p.

Proxies for B_{MSY}

The equilibrium biomasses corresponding to the above-mentioned fishing mortality reference points can be used as proxies for B_{MSY}. In addition, B_{MSY} has been approximated by various percentages of the unfished biomass, B_0, usually in the range 30-60% B_0 (higher percentages being used for less resilient species, and lower percentages for more resilient species). Referring (in the preamble) to estimates based on two shapes of production models, the NSGs recommend $0.4B_0$ as a reasonable proxy for B_{MSY}. However, this value may be too low for species with low fecundity such as many species of sharks.

Another class of reference points that has gained prominence are those based on $F_{\%SPR}$. In particular, values in the range $F_{20\%}$ to $F_{30\%}$ have frequently been used to characterize recruitment overfishing thresholds (Rosenberg *et. al.* 1994), while values in the range $F_{30\%}$ to $F_{40\%}$ have been used as proxies for F_{MSY}. These uses are supported by Goodyear (1993); by Mace and Sissenwine (1993), who advocated $F_{20\%}$ as a recruitment overfishing threshold for well-known stocks with at least average resilience and $F_{30\%}$ as a recruitment overfishing threshold for less well-known stocks or those believed to have low resilience; and by Clark (1991; 1993), who advocated $F_{35\%}$ as a robust estimator of F_{MSY} applicable over a wide range of life histories, or $F_{40\%}$ if there is strong serial correlation in recruitment. Note, however, that much of the work on $F_{\%SPR}$ has presupposed a moderate amount of resilience to fishing pressure. Moderate resilience may not be a viable assumption for long-lived species and those with low reproductive output. For example, recent analyses of west coast rockfish (*Sebastes* spp.) stocks are showing the high SPR levels in the range of 50% to 60% are needed to sustain these fisheries (A. MacCall, personal communication). Similar high SPR levels may be necessary to protect many species of sharks and other species that have low productivity.

Agenda Item E.2.d
Supplemental GAP Report
September 2009

GROUNDFFISH ADVISORY SUBPANEL REPORT ON
PART II OF STOCK ASSESSMENTS FOR 2011-2012 GROUNDFISH FISHERIES

The Groundfish Advisory Subpanel (GAP) reviewed the new petrale assessment and received an overview from Mr. John DeVore on the Scientific and Statistical Committee (SSC) recommendations regarding new reference points for managing the stock. The GAP offers the following comments and recommendations.

The GAP does not believe the new petrale assessment result, especially the very high virgin biomass estimate driven by implausibly high historical catch estimates. The biomass trend in the assessment indicates that extremely high harvest in the 1930s and 1940s reduced biomass to an overfished level by 1951 according to the proxy $B_{25\%}$ threshold. This result suspends belief since the petrale fishery was not fully developed then. The deepwater winter petrale fishery did not even begin on the west coast until the mid to late 1950s leading the GAP to conclude the uncertain catch levels prior to this period to be implausibly high.

The GAP also recommends a lower biomass target than the $B_{40\%}$ proxy for petrale sole. The stock is clearly more productive as evidenced by the stock's continued high productivity under a 60-year harvest regime where the annual harvest has averaged the estimated maximum sustainable yield (MSY) in the new petrale assessment (see attached figure). If MSY was much lower, which is implied with biomass targets as high as $B_{40\%}$, the stock would have been driven to extinction in the 60 years of harvest at the estimated MSY. Specifically, the GAP recommends the estimated B_{MSY} of $B_{19\%}$ from the new petrale assessment as a management target. The petrale STAR Panel recommended the estimated B_{MSY} is a viable target given that the estimate is statistically robust to the assumed stock-recruitment relationship. That is, the B_{MSY} estimates are similar regardless of whether a Beverton-Holt or a Ricker relationship are assumed despite the fact that the current relative biomass or depletion estimates are dramatically different under these two assumptions.

Further, the GAP recommends the overfished level be set at 50 percent of the estimated B_{MSY} level (i.e., $B_{9.5\%}$) for petrale sole, a reference point allowed in the fishery management plan. The GAP is trying to avoid an overfished declaration for petrale sole- first because the GAP does not believe the stock is overfished for the reasons stated above, and second because of the severe negative socioeconomic consequences of a petrale rebuilding plan to west coast fishing communities. Petrale sole is the single most important target stock for the current west coast trawl fishery. An unnecessary overfished declaration and rebuilding plan is likely to eliminate the trawl industry by forcing the fleet into bankruptcy. This is an especially egregious outcome on the eve of implementing trawl rationalization. The threat of losing the entire fleet due to an ill-advised petrale rebuilding plan and the consequent impacts to shoreside processors will ripple through all west coast fishing communities as the groundfish trawl fishery is the foundation for shoreside processing. Losing a petrale target will make the trawl fishery unprofitable, imposing dramatically negative economic impacts to fishing communities that threaten the continued existence of the west coast groundfish fishery and perhaps non-groundfish fisheries as well.

The GAP is aware of the SSC's recommendations for new proxy biomass reference points for flatfish including petrale sole. Beyond underscoring the rationale for using the biomass targets estimated in the new assessment, the GAP is troubled that the SSC's recommendations are based on the lowest estimated values of steepness for flatfish assessed on the west coast. The new recommended flatfish biomass proxies are based on a steepness of 0.8 while the estimated steepness for petrale sole is 0.95. The higher petrale steepness means the stock is more productive and a lower biomass target than the recommended proxy is biologically responsible. The GAP believes the SSC recommendation for a new flatfish proxy biomass target is overly precautionary for petrale and strongly recommends the estimated biomass target from the assessment and an overfished level of half that amount for managing the stock. This recommendation is based on the best available science and avoids the dire socioeconomic consequences of an overfished declaration.

The Attachment will be added as soon as I receive an electronic copy.
Thanks for your patience, Sandra.

Agenda Item E.2.d
Supplemental GMT Report
September 2009

THE GROUNDFISH MANAGEMENT TEAM (GMT) REPORT ON PART II OF STOCK ASSESSMENTS FOR 2011-2012 GROUNDFISH FISHERIES

The Groundfish Management Team (GMT) discussed the stock assessments conducted for petrale sole, lingcod, and cabezon; and bocaccio, widow, yelloweye, and greenstriped rockfish for the 2011-2012 specification and management measures cycle. While several of these new assessments may have considerable implications for management in the next biennial cycle, the GMT thought it more appropriate to focus more on those issues when harvest specifications are discussed in November.

We did note, however, that with regard to bocaccio, extension of the range for the southern stock from a northern boundary at 40°10’ North latitude to 43° North latitude could have numerous management implications (i.e. potentially involving interstate catch agreements, individual quotas, etc.) with little change in our understanding of the status of the stock. In other words, the trend in abundance was not affected by exclusion of the area north of Cape Mendocino, and there was only a one percent decrease in depletion from limiting the spatial coverage of the assessment to 40°10’.

As such, the GMT requests that alternative rebuilding analyses extending to Cape Mendocino and Cape Blanco be presented to the Council for consideration in determining the geographic region managed using the bocaccio assessment results when setting harvest specifications for 2011-2012.

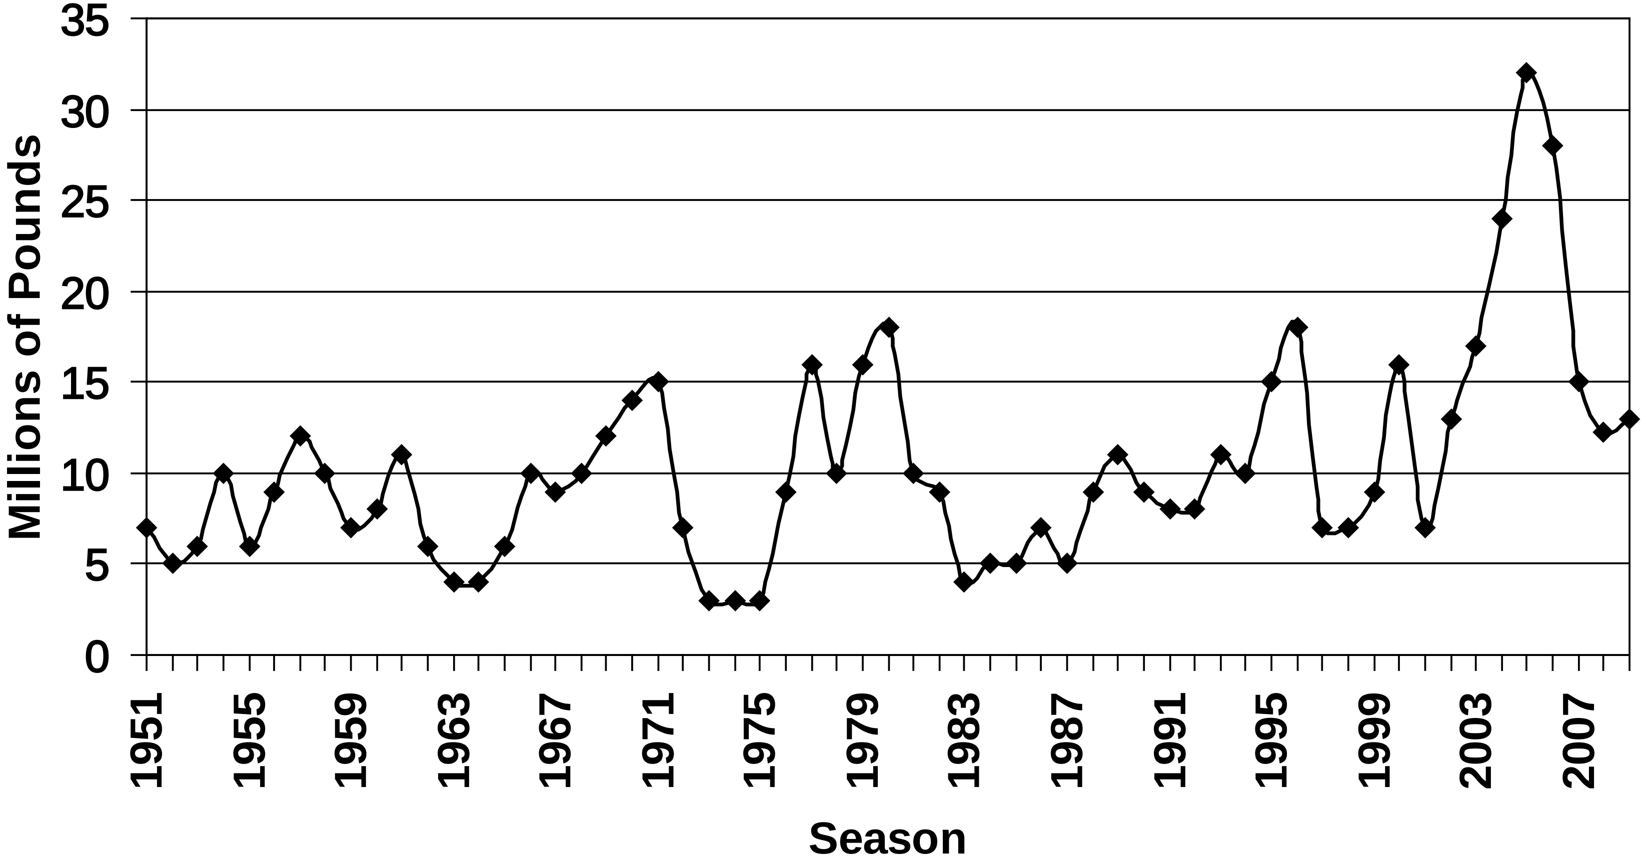
Annual Landings of Dungeness Crab in Oregon



OFF-YEAR SCIENCE IMPROVEMENTS

This year is considered the "on-year" for intensive science activities as new groundfish stock assessments and rebuilding analyses are formally approved for fishery management decision-making for 2011 and 2012 groundfish fisheries. While it is not entirely accurate to characterize the biennial management cycle in terms of an "on-year" and "off-year" for science, it is correct to distinguish the year in which stock assessments are conducted (the "on year") and the year other science activities are planned to prepare for the following assessment cycle and to resolve scientific issues that play a significant role in groundfish decision-making.

There are many activities that should be considered for "off-year" science improvements. Some of these activities may be planned and sponsored by the National Marine Fisheries Service fishery science centers; some activities may be planned and sponsored by the Council or the Council's Scientific and Statistical Committee (SSC) (e.g., a post-assessment review workshop to review how well the assessment process worked this year and a second harvest policy evaluation workshop); and some activities have been recommended by Stock Assessment Review Panels this year (Agenda Item E.3.a, Attachment 1).

The Council should consider the proposals and advice of the Northwest Fisheries Science Center, Council advisory bodies, other agencies, and the general public regarding off-year science improvements, and plan and prioritize science activities for 2010.

Council Action:

Prioritize and Plan Science Activities for 2010.

RECOMMENDATIONS FOR OFF-YEAR SCIENCE IMPROVEMENTS

Council Staff Recommendations

- Conduct a stock assessment review (i.e., "post-mortem") workshop to review the 2009 stock assessment review (STAR) process and discuss improvements for the 2011 STAR process.
- Conduct the second harvest policy evaluation workshop to review the current groundfish management framework and seek refinements.

NMFS Science Center Recommendations

- Continue efforts to develop, evaluate, and apply data-poor assessment methodologies to groundfish stocks that have yet to be assessed.
- Investigate, evaluate, and verify the appropriateness of various methods of "tuning" stock assessment models and, in particular, procedures for: (1) estimating input sample sizes of compositional information, (2) adjusting input sample sizes of compositional information to an "effective" sample size, (3) increasing the input variance of trend statistics to match model expectation, and (4) altering input estimates of recruitment process error (σ_r).
- Conduct a comprehensive investigation of the effect of calendar date on groundfish catch rates in the triennial trawl survey. The study should include a wide variety of stocks and should evaluate various statistical standardization procedures that would allow the survey to be maintained as a single time series from 1980-2004.
- Review the contents and recommendations of the NOAA Fisheries Habitat Assessment Improvement Plan (HAIP) and develop a process that would facilitate incorporation of habitat information into groundfish stock assessments.
- Consolidation, analysis, and evaluation of any habitat data, maps, and research relevant to west coast groundfish stocks that have become available since the 2005 Pacific Groundfish essential fish habitat (EFH) process. Such an evaluation is necessary and critical prior to the Council's first 5-year EFH Review, which is scheduled for 2011.

General Recommendations of STAR Panels

- A Management Strategy Evaluation (MSE) approach is needed to evaluate the 40-10 harvest control rule when applied to a stock with dramatically episodic recruitment, such as Pacific hake stock. An MSE is recommended for petrale sole because the estimates of B_0 and $B_{CURRENT}$ are sensitive to the assumed stock-recruitment relationship, making these reference points more uncertain, while B_{MSY} estimates are consistent among all the model run results. (MSE efforts are related to the harvest policy evaluation workshop)
- SS3 implements new options for bias adjustment of stock recruit relationships that have been used with little or no peer review. Simulation testing is needed to confirm that bias adjustment is justified in all cases. Guidelines should be developed on how to configure bias adjustment settings to reflect the biological characteristics of the stock and the available assessment information.

- Develop methods to incorporate uncertainty in natural mortality and/or steepness in model configurations in which these parameters are fixed. The delta method for propagating uncertainty (McCall in prep.) is a promising approach that warrants further evaluation.
- The comprehensive catch reconstructions currently underway in Washington and Oregon need to be completed (as well as the effort to reconstruct California catches). The mixing of U.S. and Canadian catches is of particular concern for the Washington fleets.
- The current assessment platform (SS3) is structurally complex, making it difficult to understand how individual data elements are affecting outcomes. The panel recommends investigating simpler, less structured models, including statistical catch/length models, to compare and contrast results as data and assumptions are changed.
- Explore a Generalized Linear Mixed Method (GLMM) approach with a calendar date covariate to estimate catch per unit of effort (CPUE) indices for the entire triennial survey time series. A species assemblage meta-analysis approach could be used to develop priors for the ratios of *q* among the early triennial, the late triennial and the Northwest Fisheries Science Center (NWFSC) surveys.
- Explore the relationship between ageing precision, recruitment variability, and bias adjustment (and effects on depletion estimates) using simulation methods, and develop recommended procedures for appropriate methods to follow.
- Investigate alternative methods of re-weighting the data series in Stock Synthesis.
- More work is needed to better understand the performance of maximum likelihood and Bayesian estimators of stock size and trends when large numbers of poorly informed recruitment deviations are estimated. Although it is logically appealing to include such uncertainty, even when there are little coherent data informing cohort strengths, technical and computational issues need to be solved before this approach can be implemented in situations such as yelloweye rockfish.
- Accessing and processing recreational intercept data from Recreational Fishery Information Network (RECFIN) and the three states is much too cumbersome for the stock assessment teams (STATs). A single database that holds all the raw recreational data in a consistent format would greatly expedite processing and interpretation of the data and would reduce the potential for introduction of errors.

Agenda Item E.3.c
Supplemental GAP Report
September 2009

GROUNDFISH ADVISORY SUBPANEL REPORT ON OFF-YEAR SCIENCE IMPROVEMENTS

The Groundfish Advisory Subpanel (GAP) received a presentation from Mr. John DeVore on off-year science improvements and offers the following recommendations and considerations for improving groundfish science.

The GAP believes convening a second harvest policy evaluation workshop is a high priority off-year science activity and is needed to seek improved harvest control rules that are more responsive to the life history characteristics of our groundfish stocks. In particular, the GAP believes it would be helpful to complete management strategy evaluations (MSEs) for a number of species in advance of a harvest policy workshop to facilitate progress. The GAP notes that recent Stock Assessment Review (STAR) panels, including the one that reviewed the new petrale sole assessment, have recommended MSEs to better understand the sensitivity of stocks to different management reference points and harvest control rules. A suite of MSEs prepared for the recommended workshop should also help to critically evaluate current harvest policies and decide refinements tailored to the diverse stocks managed under the groundfish FMP. While the first workshop held in December 2006 was an interesting investigation of current harvest policies, the GAP strongly encourages the objective of the next workshop to be to derive new policies that can be implemented as soon as possible.

Pacific whiting is another stock recommended for an MSE by STAR panels, stock assessment teams, and the SSC. The stock's dependence on dramatically episodic recruitments make the current harvest control rules particularly ineffective strategies for managing the stock. Given the stock's extreme life history patterns, it may be a challenge to develop effective harvest control rules. Therefore, the GAP recommends a separate harvest policy evaluation workshop for Pacific whiting.

Finally the GAP recommends reinstituting data modeling workshops in advance of the next round of assessments. The quality of assessments is often limited by the exclusion of available data and data treatments that could be solicited, discussed, and vetted more thoroughly prior to assembling data and developing the assessment model. As thorough and conscientious as many stock assessment teams are in preparing their assessments, data modeling workshops could only benefit data explorations that would improve assessment quality.

PFMC
09/14/09

THE GROUNDFISH MANAGEMENT TEAM (GMT) REPORT ON OFF-YEAR SCIENCE IMPROVEMENTS

The Groundfish Management Team (GMT) discussed science activities necessary to prepare for the next stock assessment cycle and possible projects to resolve scientific issues that play a significant role in groundfish decision-making. The GMT identified management strategy evaluation (MSE) of current target reference points and harvest control rules, completion of catch reconstruction efforts, development of alternative assessment methods, and improved access to and documentation of raw recreational data and derived quantities as key issues.

The GMT supports the Scientific and Statistical Committee’s (SSC) recommendation for an evaluation of proxy reference points and harvest control rules. This effort should look at taxon-specific life history traits and include examination of alternative stock-recruitment relationships, recruitment compensation, natural mortality, growth, and other factors affecting stock productivity. As has been recognized for a number of years, current proxy reference points may still be appropriate to rockfishes, while other reference points may better capture the relationship between yield and stock productivity for flatfishes, Pacific whiting, or other non-rockfish taxa.

The historical catch reconstruction for California was completed during the previous off-year period, and results from that study were incorporated into multiple stock assessments this cycle. The GMT supports the reconstruction efforts currently underway in Washington and Oregon, and continued refinement of the California reconstruction.

The GMT supports the ongoing development of alternative assessment methods useful in data-limited situations to inform Council decisions regarding the setting of annual catch limits.

The GMT recognizes the need for improved access to raw recreational data and documentation of the methods (metadata) and parameters used for derived quantities. Access and interpretation of RecFIN data was an issue for multiple Stock Assessment Teams during this stock assessment cycle. Specifically, a single database providing tables of all raw (i.e., not summarized) recreational data would help analysts identify potential outliers and other factors that may lead to questionable estimated quantities. Clearer documentation and availability of parameters used in the development of summary statistics is needed by stock assessors and the GMT. These steps would facilitate investigation of quantities used for inseason management, such as outlier catch estimates resulting from inflated effort, average weight or cost per unit of effort estimates.

In addition to historical catch reconstruction efforts, the GMT would also support organization of a workshop focusing on the identification and utilization of historical databases (e.g. discard studies) not already commonly provided for use in stock assessments. Discard and catch were major sources of uncertainty in the assessment of greenstriped rockfish and will likely be so for many rockfish that have yet to be assessed. The workshop could produce a guide to the use and availability of these alternative databases.

SCIENTIFIC AND STATISTICAL COMMITTEE REPORT ON OFF-YEAR SCIENCE IMPROVEMENTS

The Scientific and Statistical Committee (SSC) reviewed a number of off-year research proposals submitted by Council Staff, National Marine Fisheries Service (NMFS) Fisheries Science Centers, and Stock Assessment Review (STAR) Panels. The SSC found a significant degree of overlap between proposals and grouped them into categories for analysis and response.

The SSC did not find it necessary to conduct a review of the STAR process as proposed by Council Staff. The 2009 Panels worked well with a high degree of consistency and the overall quality of stock assessments was much improved, followed the Terms of Reference and promptly produced the analyses and information needed by the SSC.

The second Council Staff proposal suggests a harvest policy evaluation workshop to review the current groundfish management framework. The SSC supports this proposal and notes that the idea is repeated in the STAR Panel recommendations contained in Item E.3.a, Attachment 1. The SSC places a high priority on a harvest policy workshop to evaluate a range of harvest control rules and to develop a management strategy evaluation (MSE). One area of interest is establishment of a tiered system of control rules based on data quantity and quality.

There are several recommendations related to the use and potential modification of the Stock Synthesis model. The recommended research relates to instituting changes and additions to the SS3 model. The SSC supports this as a high to medium priority and suggests that the proposed work be brought forward through a series of mini workshops of assessment scientists actively engaged in the topics.

The SSC places a high priority on the establishment of a working group to assess alternative assessment methods for data poor stocks. The SSC is seeking simpler, robust assessment methods to track data poor stocks.

The SSC endorses the NMFS Science Center proposal for standardization of the triennial trawl survey calendar date effect, and the STAR Panel proposal for the same work and an examination of q priors as high priority items. The SSC hopes this may reduce some of the uncertainty in trawl survey estimates.

The recommendation for catch reconstruction in Washington and Oregon is a high priority for the SSC. Catch reconstruction worked well for California and the SSC encourages Oregon and Washington to complete their reconstructions. High quality catch data is a critical element for stock assessment.

The SSC places medium priority on STAR Panel recommendations related to model development, but encourages further evaluation. A STAR Panel recommendation to explore model parameters and data treatment via simulations methods is an item that ought to provide insights into model performance.

The SSC in its review of the recommendations determined that there is a need for additional high priority items:

A workshop or working group to evaluate the use of the International Pacific Halibut Commission (IHPC) survey in the yelloweye rockfish assessment and to develop recommendations on how to incorporate supplemental samples being collected by the States of Oregon and Washington.

A working group to explore the development of spatial modeling methods. The SSC notes that spatial modeling and data handling was handled in several different ways in the assessments completed this year. More guidance is needed on establishing criteria for developing spatially explicit models.

The SSC notes that both the cabezon and lingcod assessments reported results of indices of local abundance produced by small-scale monitoring programs distributed along the coast. While these monitoring programs have potential utility for stock assessment, at present it unclear how this information can be used in stock assessments, which typically are conducted at a larger scale than these local monitoring programs. A workshop to consider methods of incorporating this information in stock assessments, and promoting greater coordination of these monitoring programs would be valuable.

The SSC concurs with the STAR Panel recommendation regarding the need for a standardized repository of recreational data required for use by stock assessment analysts. These include catch per unit of effort (CPUE), age and length data, and total catch data. This is a long standing problem that once again should be brought to the attention of RecFIN and the contributing agencies

PFMC
09/15/09

INSEASON ADJUSTMENTS TO 2009 AND 2010 GROUNDFISH FISHERIES – PART I

Management measures for the 2009 and 2010 groundfish season were set by the Council with the understanding these measures would likely need to be adjusted throughout the biennial period to attain, but not exceed, the optimum yields (OYs). This agenda item will consider inseason adjustments to ongoing 2009 fisheries, and preliminary adjustments to 2010 fisheries.

As part of this agenda item, the Council will discuss more precautionary approaches to managing petrale sole and canary rockfish within the current biennium. At the June Council meeting the Council considered recent information on the status of both petrale sole and canary rockfish. During this meeting the Council adopted preliminary measures for reducing the mortality of petrale sole in 2009 and 2010 pending further analysis, and also indicated the intention to reduce the canary rockfish OY in 2010. The most recent stock assessments for petrale sole and canary rockfish are relatively more pessimistic than the previous assessments used in the 2009 and 2010 harvest specifications process, raising the possibility of needing to take a mid-course action to protect the status of these stocks and to remain on target to meet rebuilding plan goals. Included within this agenda item is a draft Environmental Assessment (EA) outlining the biological and socioeconomic effects of reducing the petrale sole OY. Also included within this EA is an analysis showing the type of impacts that may be expected to occur from possible reductions in the 2010 canary rockfish OY.

The Groundfish Management Team (GMT) and the Groundfish Advisory Subpanel (GAP) will meet prior to this agenda item to discuss and recommend inseason adjustments to 2009 groundfish fisheries. After hearing this advisory body advice and public comments, the Council will consider preliminary or final inseason adjustments. Agenda Item E.7 is scheduled for Thursday, September 17, should further analysis or clarification be needed.

Council Task:

1. **Adopt initial or final inseason adjustments.**
2. **Consider revised management measures for petrale sole and canary rockfish, if appropriate.**

Table of Contents

List of Tables

List of Figures

1 Chapter 1 Introduction

This document provides background information and analyses of revisions to 2009 management measures and 2010 harvest specifications and management measures for petrale sole (*Eopsetta jordani*) and canary rockfish (*Sebastes pinniger*) in fisheries covered by the Pacific Coast Groundfish Fishery Management Plan (FMP). The groundfish harvest specifications are set every two years. Harvest specifications for all groundfish species for the 2009 and 2010 biennium, including petrale sole and canary rockfish, were analyzed in a previous Environmental Impact Statement (PFMC and NMFS 2009) and were based on the best scientific information available at that time.

Petrale sole has been a relatively healthy stock off the West Coast, harvested primarily by the limited entry trawl fleet during winter months when the stock is aggregated on the slope. Petrale sole is not currently subject to overfishing, nor is it overfished. In recent stock assessments the status of the stock has fluctuated from 42 percent of its unfished biomass (1999 Assessment), 29 percent of its unfished biomass (2001 Assessment), and 32 percent of its unfished biomass (2004 Assessment). A new full assessment for petrale sole was prepared during 2009 to inform the process for establishing 2011-2012 Pacific Coast groundfish harvest specifications and management measures.

Canary rockfish are incidentally caught coastwide in all sectors of the West Coast groundfish fishery. Canary rockfish is an overfished shelf rockfish species that is currently subject to a rebuilding plan. A stock assessment update for canary rockfish was prepared during 2009 to inform the process for establishing 2011-2012 Pacific Coast groundfish harvest specifications and management measures.

In response to the new stock assessments NMFS has determined the need to reevaluate the 2009-2010 groundfish harvest specifications and management measures for petrale sole and canary rockfish. The Council reviewed a new stock assessment for petrale sole in June 2009, considered questions raised by the Stock Assessment and Review Panel (STAR Panel) and the Scientific and Statistical Committee (SSC), and asked the SSC to review the open issues and report back to the Council in September 2009. While there is uncertainty regarding the results of the final stock assessment, it is likely that, under any outcome, the stock will be overfished at the beginning of 2011 if the entire current petrale optimum yields (OYs) are taken in 2009 and 2010. The canary rockfish assessment was an update of the prior assessment, incorporating revised historic catch data. This assessment concluded that the stock is more depleted than the previous assessment had indicated. The Council approved the new stock assessment, and the assessment authors will develop a rebuilding analysis for consideration by the Council in November. The Council will use the results of the rebuilding analysis to consider likely revisions to the rebuilding plan for 2011 and to consider OY and harvest revisions in 2010.

This EA tiers from the Proposed Acceptable Biological Catch and Optimum Yield Specifications and Management Measures for the 2009-2010 Pacific Coast Groundfish Fishery EIS (January 2009 EIS) (PFMC and NMFS 2009) and provides new analysis and alternatives for managing petrale sole and canary rockfish in 2009 and 2010. Unless otherwise noted, all of the information used in this EA is from the January 2009 EIS (PFMC and NMFS 2009).

1.1 Purpose and Need for the Proposed Action

The proposed action includes: reducing total fishing mortality of petrale sole for the remainder of 2009; specifying 2010 optimum yield (OY) values for petrale sole and canary rockfish and establishing management measures to constrain total fishing mortality consistent with these specifications. These specifications and management measures are proposed in response to the stock status estimates in the 2009 assessments for these two species.

The need for the proposed action is to ensure that petrale sole and canary rockfish are maintained at, or restored to, sizes and structures that will produce the highest net benefit to the nation, while taking into account environmental and social values. New stock assessments for canary rockfish and petrale sole were conducted in 2009 that changed the understanding of stock status. The new stock assessments are more pessimistic than the stock assessments used to determine the 2009 and 2010 harvest specifications (OYs) and management measures. Action is needed to respond to the most recently available stock status information during the remainder of 2009 and in 2010, while NMFS and the Council complete the stock assessments, rebuilding analyses, EIS, and rulemaking for the 2011 and 2012 specifications and management measures.

The purpose of the proposed action is to prevent petrale sole from being in an overfished status in 2011, or to speed the rebuilding of petrale if it is found to be overfished. The purpose of the proposed action is also to facilitate rebuilding of canary rockfish and easing the negative impact on industry from the reduced canary rockfish harvest specifications that will likely result in 2011-2012 from the new stock assessment and rebuilding analysis.

2 Chapter 2 Alternatives Including the Proposed Action

There are two sets of alternatives analyzed in this EA. The first set of alternatives provides a range of harvest specifications and management measures that reduce total mortality of petrale sole in the limited entry trawl fishery in order to prevent this species' stock status from falling below the overfished threshold in 2011, or to speed rebuilding if it does fall below the threshold. The second set of alternatives is a range of harvest specifications and management measures that reduce total mortality of canary rockfish to facilitate rebuilding and to ease negative impacts on industry from lower 2011-2012 harvest specifications, and more restrictive management measures.

2.1 Harvest Specifications and Management Measures for Petrale Sole

2.1.1 Alternative P1/No Action:

Alternative P1 is the no action alternative, which would leave the current specifications and management measures in place for petrale sole in 2009 and 2010. Harvest specifications and projected impacts to the petrale sole stock for Alternative P1 are outlined below in Table 2-1.

Management measures that pertain specifically to controlling catch of petrale sole in the limited entry trawl fishery include modified trawl rockfish conservation area (RCA) boundary lines and bi-monthly cumulative limits and/or sub-limits for petrale sole. The modified trawl RCA lines keep areas of petrale aggregation on the slope open to the trawl fishery in winter months (January-March and November-December). Depending on the type of trawl gear used and the time of year, petrale sole trip limits are either species specific, for example "25,000 lb [of petrale sole] per 2 months", or are a sublimit of the other flatfish trip limit, for example "110,000 lb [of other flatfish, English sole, and starry flounder], per 2 months, no more than 25,000 lb per 2 months of which may be petrale sole". Management measures associated with the no action alternative are listed in the trip limit tables from the July 6, 2009 inseason action rule (74 FR 31874), and are shown in Appendix A for reference. Projected impacts to petrale sole under current management measures, as of July 1, 2009, are listed in Table 2-1.

If no action is taken to reduce catches of petrale sole in 2009-2010, it is likely that petrale sole will be overfished at the start of 2011.

Table 2-1. Alternative P1: No action alternative for petrale sole

	Coastwide ABC (mt)	Coastwide OY (mt)	Projected Impacts (mt)[/a]		
			LE Non-Whiting Trawl Fishery	Other Groundfish Fisheries	Total
2009	2,811	2,433	2,393	0	2,393
2010	2,751	2,393	2,393	0	2,393

/a Projected impacts for 2009 are the projected impacts after inseason adjustments to fishery management measures on July 1, 2009 (74 FR 31874). Projected impacts for 2010 assume that the same management measures that are currently in place for the 2009 calendar year are repeated in 2010.

2.1.2 Alternative P2/Preferred Alternative

Alternative P2 is an action alternative to implement management measures that would reduce projected catch of petrale sole in 2009, and decrease the 2010 petrale sole OY and implement management measures to keep projected impacts below the new 2010 OY.

In June, 2009 the Council's Groundfish Management Team (GMT) coordinated with 2009 petrale sole stock assessment authors to model how a range of reductions in petrale catch during 2009 and 2010 would affect the projected stock abundance levels at the beginning of 2011, using the base case model. As a means of avoiding an overfished status at the beginning of 2011, or to speed the rebuilding of petrale if it is found to be overfished, the Council considered measures that would: reduce the catch of petrale sole to a level of approximately 2,000 mt in 2009, or roughly 400 mt below the 2009 OY; and reduce the catch to approximately 1,200 mt in 2010, or approximately 1,200 mt below the current 2010 OY of 2,393. It is estimated that by making these reductions in catch during 2009 and 2010, the stock status in 2011 would be improved by 4 percent of $B_{unfished}$ and by 20 percent of the directly-estimated B_{MSY}. See Table 2-5 for a comparison of the effects of different catch scenarios on 2011 petrale sole stock abundance.

Therefore, the Council and NMFS developed Alternative P2 to: reduce projected catches by 400 mt during the remainder of 2009; reduce the 2010 petrale sole OY by 1,200 mt; and implement management measures to keep projected impacts below the new 2010 OY of 1,193 mt. Alternative P2 harvest specifications are outlined below in Table 2-2.

NMFS and the Council considered options for revisions to management measures that reduce projected impacts to petrale sole in 2009 and 2010 in order to reduce the likelihood of petrale sole being considered overfished at the start of 2011, or to speed the rebuilding if it is found to be overfished, based on the new 2009 petrale sole stock assessment. Management measure revisions include removal of the open areas for fishing petrale aggregations on the slope in winter months. This will be done by using the un-modified 200 fm RCA boundary line that does not include cut-outs that open known areas of petrale sole abundance North of 40°10' N. lat. Revisions will also include reductions to cumulative limits and sub-limits for petrale sole coastwide, for all limited entry trawl gear types. Revisions to management measures are proposed for November-December (Period 6) of 2009 and for all of 2010. Figure 2-1 presents proposed management measures for Period 6 of 2009 to reduce projected mortality of petrale sole by approximately 400 mt. Figure 2-2 presents proposed management measures for 2010 to reduce projected mortality of petrale sole by approximately 1,200 mt. Projected impacts to petrale sole under these Alternative P2 management measures are listed in Table 2-2.

Table 2-2. Alternative P2: Reduced harvest specifications for petrale sole

	Coastwide ABC (mt)	Coastwide OY (mt)	**Projected Impacts (mt)** [a]		
			LE Non-Whiting Trawl Fishery	Other Groundfish Fisheries	Total
2009	2,811	2,433	1,995	0	1,995
2010	2,751	1,193	1,178	0	1,178

/a Projected impacts are calculated based on the preliminary preferred Council alternative management measures for petrale sole. Projected impacts listed here include changes to projected impacts to petrale sole that resulted from management measures implemented in the July 6, 2009 inseason action final rule (74 FR 31874).

Figure 2-1. Alternative P2 management measures for Period 6 of 2009 to reduce projected mortality of petrale sole by 400 mt. BOLD text is what is different from Alternative P1.

2.2 Harvest Specifications and Management Measures for Canary Rockfish

2.2.1 Alternative C1

Alternative C1 is the no action alternative, which would leave the current specifications and management measures in place for canary rockfish in 2009 and 2010.

The 2010 canary rockfish OY of 105 mt is based in the base case model in the 2007 stock assessment and the associated rebuilding plan. The rebuilding plan maintained the 2007-2008 SPR harvest rate of F88.7%, and specified a target rebuilding year of 2021, which is earlier than the year in the prior rebuilding plan. The 105 mt OY comes from a more conservative SPR rate of 92.2 percent. For additional information on the rationale for the 2010 canary rockfish OY of 105 mt and the associated revisions made to the canary rockfish rebuilding plan, see the January 2009 EIS (PFMC and NMFS 2009), particularly Sections 2.1.1.2, and 4.3.1.1.

Harvest specifications and projected impacts to canary rockfish under Alternative C1 are outlined below in Table 2-3.

Table 2-3. Projected impacts to canary rockfish under Alternative C1, or the no action alternative

	Coastwide ABC (mt)	Coastwide OY (mt)	Projected Impacts (mt) [a]							
			LE Non-Whiting Trawl Fishery	Non-Tribal Whiting Trawl Fishery [b]	LE Fixed Gear and Open Access Fisheries	Other (Tribal fisheries, Non-whiting EFPs, Research, etc.)	Recreational [c]			Total
							WA	OR	CA	
2009	937	105	22.1	18.0	7.0	17.3	19.3		21.3	105.0
2010	940	105	22.1	18.0	7.0	17.3	19.3		21.3	105.0

/a Projected impacts for 2009 are the projected impacts after inseason adjustments to fishery management measures on July 1, 2009 (74 FR 31874). Projected impacts for 2010 assume that the same management measures that are currently in place for the 2009 calendar year are repeated in 2010.

/b Values for the non-tribal whiting trawl fishery reflect the total of sector-specific bycatch limits adopted in regulations, not projected impacts.

/c Values listed for recreational fisheries are the state-specific harvest guidelines (WA/OR=20.9 and CA=22.9), minus 1.6 mt that were not projected to be harvested, consistent with final council action at their June 2009 meeting.

Status quo management measures for commercial fisheries that catch canary rockfish were published in the trip limit tables from the July 6, 2009 inseason action rule (74 FR31874) and are provided in Appendix A for reference. Status quo management measures for recreational fisheries that catch canary rockfish are listed in Federal Regulations at 50 CFR 660.384 and are provided in Appendix B for reference. Projected impacts to canary rockfish under status quo management measures, as of July 1, 2009, are listed in Table 2-3.

Canary rockfish rebuilding parameters based on the 2007 stock assessment, catch sharing, and analysis of how the stock would be rebuilding as quickly as possible taking into account the appropriate factors, are described in the January 2009 EIS (PFMC and NMFS 2009). If catches in 2009 and 2010 are equivalent to the 2009 and 2010 OYs (105 mt), then, according to the 2009 stock assessment, the status of the stock at the beginning of 2011 will be at 25.2 percent depletion. The stock assessment update presented at the June 2009 Council meeting also predicted that using an SPR of 92.2%, which approximates the SPR for the harvest level in the 2009 and 2010 specifications, results in a 2011 coastwide canary rockfish OY of approximately 69 mt. A rebuilding analysis will be completed in September/October 2009, which will provide a range of potential OYs and rebuilding time periods for the Council to consider as it develops the 2011-2012 specifications. Based on the new, more pessimistic stock assessment, more restrictive management measures will most likely be needed in 2011 to rebuild canary rockfish as quickly as possible, taking into account the appropriate factors.

Table 2-4. Yield amounts (mt) of canary rockfish available to groundfish sectors in 2010 (after deducting projected set-asides) for each canary rockfish OY alternative.

Groundfish Sector	Catch Share (%)	Yield Amounts (mt)		
		C1 = 105 mt	C2 = 85 mt	C3 = 44 mt
LE Non-Whiting Trawl	22.9	19.7	15.1	5.7
LE Whiting Trawl	20.9	18	13.8	5.2
LE Fixed Gear	2.6	2.2	1.7	0.6
Directed OA	2.9	2.5	1.9	0.7
WA Rec	5.7	4.9	3.8	1.4
OR Rec	18.6	16	12.3	4.7
CA Rec	26.6	22.9	17.6	6.7

Excerpted from Tables 2-8 and 2-9 of the 2009-2010 FEIS (PFMC and NMFS 2009)

2.2.2 Canary Rockfish Action Alternatives

The OY values associated with Alternatives C2 and C3 are a subset of the OY values analyzed in the January 2009 EIS (PFMC and NMFS 2009). Supplemental description of these alternatives in this EA is necessary to reflect the new information on stock status, and therefore the same OY alternatives are now presented in the context of the updated 2009 stock assessment.

2.2.3 Alternative C2:

Alternative C2 proposes to reduce the 2010 canary rockfish OY to 85 mt. Alternative C2 also considers a range of potential modifications to management measure that may be necessary to keep total mortality of canary rockfish below 85 mt.

Preliminary information prior to the rebuilding analysis indicates that constraining catches of canary rockfish to 85 mt in 2010 has the following effects on canary rockfish stock abundance at the start of 2011, according to the 2009 stock assessment model: the depletion level will be unchanged, at 25.2 percent depletion, with a 2011 OY of approximately 69 mt (Stewart, pers. comm.).

Both canary rockfish action alternatives (C2 and C3) assume that the catch sharing of canary rockfish that was described in the January 2009 EIS (PFMC and NMFS 2009) will be unchanged. Therefore, for each alternative, the coastwide OY is apportioned among sectors and states in the same manner as in the no action alternative (Table 2-4).

Potential management measures that reduce canary rockfish total mortality to 85 mt may include: expansion of the trawl RCA to close areas with high canary bycatch for parts of the year; expansion of the non-trawl RCA; reductions in trip limits for co-occurring shelf species in both the LE trawl fishery and in the LE fixed gear fishery and open access commercial fishery; reductions in trip limits for vessels using selective flatfish trawl gear; reductions in recreational fishery season length; closures of recreational fisheries in some areas of the coast for a portion of the year; reduction in recreational bag limits for rockfish or other co-occurring species; and a reduction in the bycatch limit for canary rockfish in the LE non-tribal whiting fishery.

The Council will consider the range of management measure alternatives presented in Alternatives C2 and C3 for reducing canary rockfish impacts at the November 2009 Council meeting, following review of the new canary rockfish rebuilding analysis. Projected OYs for 2011 and 2012 and estimates of spawning stock abundance in a new rebuilding analysis will allow the Council to recommend interim measures that would reduce canary rockfish impacts in 2010, resulting in less disruption to 2011 and 2012 fisheries. A description of the final preferred alternative for canary rockfish harvest specifications and management measures in 2010 will be provided as a supplement to the EA after the November 2009 Council meeting.

2.2.4 Alternative C3:

Alternative C3 proposes to reduce the 2010 canary rockfish OY to 44 mt. Alternative C3 also considers a range of potential management measure modifications that may be necessary to keep total mortality of canary rockfish below 44 mt.

Preliminary information prior to the rebuilding analysis indicates that constraining catches of canary rockfish to 44 mt in 2010 has the following effects on canary rockfish stock abundance at the start of 2011, according to the 2009 stock assessment model: the depletion level will improve from 25.2 percent to 25.3 percent and the 2011 OY will increase to approximately 70 mt.

Potential management measures to reduce canary rockfish total mortality to 44 mt would include the same types of changes as outlined above in Alternative C2. However, the duration of commercial area restrictions and trip limit reductions may increase and the reductions in trip limits would likely be more severe. The canary rockfish bycatch limit in the LE non-tribal whiting trawl fishery may be severely reduced. The non-whiting Exempted Fishing Permits (EFPs) may also be restricted or terminated in 2010 to reduce their projected catch of canary rockfish (approximately 2.7 mt). Recreational fisheries seasons may be shortened further, or closed entirely, for some portions of the coast.

The Council will consider the range of management measure alternatives presented in Alternatives C2 and C3 for reducing canary rockfish impacts at the November 2009 Council meeting, following review of the new canary rockfish rebuilding analysis. Projected OYs for 2011 and 2012 and estimates of spawning stock abundance in a new rebuilding analysis will allow the Council to recommend interim measures that would reduce canary rockfish impacts in 2010 and result in less disruption to 2011 and 2012 fisheries that will be operating under OYs set using a revised rebuilding plan. A description of the final preferred alternative for canary rockfish harvest specifications and management measures in 2010 will be provided as a supplemental to the EA after the November 2009 Council meeting.

2.3 Alternatives Considered but Rejected from Further Analysis

NMFS and the Council considered reducing the 2009 petrale sole OY. However, this is an ongoing fishery, and 10 out of 12 months of the 2009 fishery will have concluded before this action takes effect, so this option was removed from further consideration. Changing the trip limits, as proposed in alternative P2 would have the same effect on the harvest levels.

NMFS and the Council considered reducing impacts to petrale sole by varying amounts for 2009. Specifically, they considered what the overfished status of petrale sole would be if no changes were made to reduce catches in 2009. Comparing "Rejected 1" abundance levels with "Alternative 2" abundance levels in Table 2-5 shows that there is a slight increase in abundance when catches are reduced in 2009. However, if catches in 2009 were only reduced by approximately 200 mt, there was no appreciable improvement in stock status relative to the percent of $B_{unfished}$, and only a minor improvement relative to the directly-estimated B_{MSY}. Therefore, since neither of these scenarios had an appreciable difference from Alternative P2 in improving the petrale sole stock status for 2011, they did not meet the purpose and need, and therefore were rejected from further consideration.

Table 2-5. Base case model projections of 2011 petrale stock abundance under four 2009-2010 catch scenarios.

	2009/2010 Catch Scenarios (mt)			
2011 abundance	Alt. P1 (No Action) (2,433/2,393)	Rejected 1 (2,433/1,200)	Rejected 2 (2,200/1,200)	Alt. P2 (2,000/1,200)
% of $B_{unfished}$	9%	12%	12%	13%
% of directly-estimated B_{MSY}	48%	63%	66%	68%

The GMT, an advisory body to the Council, considered implications of setting cumulative trip limits for petrale sole to zero in winter months (or "CLOSED"), as this could potentially be an option for reducing projected impacts to petrale sole. A complete closure would induce regulatory discarding of co-occurring petrale sole, and the associated mortality of those discards. Therefore, we want to allow some retention, though reduce trip limits enough to discourage targeting of petrale sole. Keeping winter trip limits at 1,000-2,000 lb is designed to allow retention of some incidental take of petrale sole when vessels are targeting co-occurring flatfish and slope species. Since a complete closure of the winter petrale fishery would not result in appreciable difference in projected impacts, due to discard mortality of incidentally caught petrale sole, this alternative did not meet the purpose and need, and therefore was not recommended for Council consideration by the GMT.

NMFS and the Council considered analyzing interim canary rockfish OYs lower than 44 mt. The last time the canary rockfish stock status was more pessimistic was in the 2006 assessment. During the 2007-2008 harvest specifications and management measures process, considerable analysis was conducted. That analysis revealed that setting the canary rockfish OY below 44 mt would have required a variety of fisheries to be either severely constrained or closed (71 FR 57764), and made a modest difference in the rebuilding parameters. The updated 2009 stock assessment is similar in that it is more pessimistic than the 2009 assessment. To date, the final rebuilding analysis based on the 2009 stock assessment is not complete, so it is uncertain how the alternative interim harvest specifications and management measures would affect rebuilding parameters for canary rockfish. However, the situation is similar to what occurred in 2007. Therefore, interim alternative OYs lower than 44 mt were not considered for 2010. For more information on the economic impacts of setting the canary rockfish OY below 44 mt, see the 2007-2008 Harvest Specifications and Management Measures EIS (PFMC and NMFS 2006) and the preamble to the Proposed Rule (71 FR 577764).

3 Chapter 3 Affected Environment

A description of west coast marine ecosystems and the affected essential fish habitat are available in volume 1 of the Council's 2008 Stock Assessment and Fishery Evaluation (SAFE) document. Volume 1 of the 2008 SAFE document is available by request to the Council office or online at www.pcouncil.org/groundfish/gfsafe.html.

The affected environment for proposed action is the same as the affected environment considered in the January 2009 EIS (PFMC and NMFS 2009). The affected environment chapter (Chapter 3), of that EIS is incorporated by reference and not repeated in this EA. That analysis considered the ecosystem in terms of physical and biological oceanography, climate, biogeography, essential fish habitat (EFH), marine protected areas, and the role of depleted species' rebuilding in the marine ecosystem.

It should be noted that the scale of the proposed action in this EA is smaller than the action in the January 2009 EIS due to the change in focus from setting specifications and management measures for all species in the FMP to setting specifications and management measures as they pertain particularly to canary rockfish and petrale sole.

Petrale sole is one of the main target species for the non-whiting trawl fishery. Arguably, the two species most important to the trawl fishery are petrale sole and sablefish. Markets are readily available for these two species and nearly every trawl vessel along the west coast relies upon petrale sole and sablefish as a source of revenue. These two species have relatively high prices per pound. Petrale sole fetches approximately $0.95 to $0.99 per pound at the dock depending upon the year. This compares to a less desirable flatfish species that may fetch on the order of $0.30 per pound.

Petrale sole is important both to harvesters and to processors. Anecdotal information indicates that the economic margin for petrale sole is greater in the consumer and wholesale market place than for other species. Since petrale sole is sought after in the market, petrale has both a higher profit margin than other species, and there is relatively more certainty regarding the ability to sell petrale into the market place. This fact is evidenced in other types of industry practices. Anecdotal information indicates that, while harvesters deliver a wide array of species, the purchase of many species by the processor is conditional on the fact that harvesters deliver petrale sole and sablefish with those other species. This can be explained by the concept that the processor knows he/she will generate a given amount of revenue from petrale. Since the expected amount of revenue from other species is less certain and comes at a lower profit margin, the processor often cannot afford to rely on species other than sablefish and petrale alone. Reliance on species other than petrale and sablefish is therefore relatively "risky" as the processor will likely realize lower margins on those other species and there is relative uncertainty regarding the ability to sell those species at all. In some ways, having petrale sole and sablefish available allows harvesters and processors to take on the risk of harvesting and processing these other, less desirable species.

All of the rebuilding strategies used to reduce mortality of depleted species on the west coast are used to help rebuild canary rockfish. Management of this stock has tended to constrain more west coast fisheries than any other groundfish stock since canary rockfish are distributed coastwide, are found in a variety of habitats, and are caught by a variety of different fishing gears. Canary rockfish are distributed from nearshore areas as juveniles out to about 150 fm as adults and are found at times suspended off the bottom or in atypical soft-bottom habitats for rockfish. Canary rockfish are not allowed to be retained in commercial and recreational hook and line or fixed gear fisheries and a small, incidental landing limit is allowed in the limited entry trawl fishery to account for unavoidable incidental bycatch. Mandating the use of the selective flatfish trawl shoreward of the RCA north of 40°10' N latitude has helped reduce bycatch in the trawl fishery. The midwater trawl fishery for whiting, which is not currently restricted in the trawl RCA, also catches canary rockfish. Implementation of a canary rockfish bycatch cap, where, if attained, the non-tribal fishery would close inseason even if whiting quotas have not been attained, has successfully reduced canary rockfish mortality. Canary is also taken in recreational fisheries. Table 4-4 below illustrates the various commercial and recreational fisheries that take canary as bycatch.

4 Chapter 4 Environmental Consequences

The impacts described in the January 2009 EIS (PFMC and NMFS 2009) remain the same except for the changes related to the alternatives presented in this EA which are described below.

4.1 Discussion of Direct and Indirect Impacts

4.1.1 Petrale sole Alternatives

Petrale sole is primarily caught in the limited entry trawl fishery. Therefore, analysis of alternatives for changes to harvest specifications and management measures for petrale sole are considered in the context of the coastwide limited entry non-whiting trawl fishery for Pacific Coast groundfish and the effects of changes to management measures in that sector of the fishery.

4.1.1.1 Alternative P1/No Action

4.1.1.1.1 Impacts to the petrale sole resource

If no action is taken to reduce fishery impacts to petrale sole in 2009 or 2010, then the fishing mortality on the stock through 2010 will be the same as described in the January 2009 EIS (PFMC and NMFS 2009). However, if no action is taken to reduce catches of petrale sole in 2009-2010, it is likely that petrale sole will be overfished at the start of 2011, according to the new 2009 stock assessment. Projected impacts to petrale sole under Alternative P1 are listed in Table 2-1.

Under Alternative P1, no action is taken to change fishery impacts to petrale sole in 2009 and 2010. Under this alternative, the results of the new petrale sole stock assessment will be used to develop the 2011 and 2012 harvest specifications only, and will not be used to take interim measures in 2009 and 2010.

4.1.1.1.2 Socioeconomic Impacts

If no action is taken to reduce fishery impacts to petrale sole in 2009 or 2010, then the short term socioeconomic impacts would be very similar to those described in the January 2009 EIS (PFMC and NMFS 2009). As the purpose of the proposed action is to prevent petrale sole from being in an overfished status in 2011, or to speed the rebuilding of petrale if it is found to be overfished, the long term impacts of maintaining the status quo will be reduced OYs and potentially more severe rebuilding plans if petrale sole is found to be overfished. As a result, management of the fishery will become more complex, revenues from the fishery will decline and costs will increase as a result of more restrictive management measures, and less income will be generated in the associated fishing communities.

The January 2009 EIS used the best available information available at that time. Since the publication of that document, routine updates of fishery information have been made to catch projection models. The catch projection models are used to project fishery impacts under current management measures, and to see how projected fishery impacts may change if routine management measures are adjusted inseason. The relatively minor changes to fishery information have an indirect effect on the socioeconomic environment, and results in slightly different economic impacts (particularly projected ex-vessel revenue) than those predicted in the January 2009 EIS. Updated projections of ex-vessel revenue in limited entry non-whiting trawl fishery under Alternative P1 are shown in Table 4-2. The indirect effects of these changes in fishery information raised projected ex-vessel revenue in the non-whiting trawl fishery by 1.8 million dollars, or approximately 4 percent. Comparison of the action alternatives are made to the updated projected ex-vessel revenue in the non-whiting trawl fishery under the No Action alternative.

Fishery information that is routinely updated includes West Coast Groundfish Observer Program data and logbook and fish ticket information from the three west coast states.

4.1.1.1.3 Impacts to Other Groundfish Species

If no action is taken to reduce fishery impacts to petrale sole in 2009 or 2010, then the impacts to other groundfish species would be very similar to those described in the January 2009 EIS (PFMC and NMFS 2009). However, impacts to overfished groundfish species are slightly different than those listed in the January 2009 EIS.

The January 2009 EIS used the best available information available at that time. Since the publication of that document, routine updates of fishery information (listed in section 4.1.1.1.2 of this EA) have been made to catch projection models that result in slightly different projected impacts to some overfished and target groundfish species than what were predicted in the January 2009 EIS. These updated projected impacts are listed in Table 4-1.

Table 4-1: Projected Impacts to Rebuilding and Target Species in the Limited Entry Non-Whiting Trawl Fishery, Coastwide, Under Alternative P2

		Projected Impacts for Alt. P1 – No Action (mt)
		2009/2010
Rebuilding Species:	Canary Rockfish	22.3
	POP	106.8
	Darkblotched Rockfish	239.0
	Widow Rockfish	20.8
	Bocaccio	12.7
	Yelloweye Rockfish	0.6
	Cowcod	1.3
Target Species:	Sablefish	3,253.0
	Longspine Thornyheads	1,006.4
	Shortspine Thornyheads	1,308.5
	Dover Sole	13,752.4
	Arrowtooth Flounder	4,000.7
	Petrale Sole	2,393.4
	Other Flatfish	2,370.7
	Slope Rockfish	278.6

4.1.1.2 Alternative P2/Preferred Alternative

4.1.1.2.1 Impacts to the petrale sole resource

The petrale sole OY alternative and the 2009-2010 management measure alternative (Alternative P2) that the Council chose for analysis is based on the need to prevent the petrale sole stock status from falling below the overfishing threshold at the beginning of 2011. It is based on the immediate need to reduce catches, and how those reductions in projected catches in 2009-2010 affect the stock status in 2011, based on the new 2009 stock assessment.

A new full assessment for petrale sole was presented to the Council in June 2009. The draft assessment indicates the stock is depleted to 11.6% of its unfished biomass. The Groundfish FMP defines the overfished level at 25% of the unfished biomass when the proxy B_{MSY} .is used. This means that the stock may be overfished under this standard. However, the stock assessment review panel recommended using the biomass that would support maximum sustainable yield (B_{MSY}), as determined from the assessment (the directly-estimated Bmsy), as a management target because B_{MSY} is believed to be well estimated (Cook et. al 2009). The Groundfish FMP allows use of the directly-estimated Bmsy (also referred to as a deterministic B_{MSY}) target and defines the overfished level as no less than 50% of the directly-estimated B_{MSY}. The draft 2009 assessment estimates the stock spawning biomass is at 61% of the directly-estimated B_{MSY} and therefore may not be overfished under a directly-estimated B_{MSY} target. The Council's Scientific and Statistical Committee (SSC) did not recommend the petrale sole assessment for management decision-making pending further review of the assessment this summer. The SSC will also further explore the use of a directly-estimated B_{MSY} target for the stock when they meet this summer. While the petrale sole assessment is not yet adopted for use in making management decisions, projections from the draft assessment indicate that stock spawning biomass will be driven to a lower level of depletion if the entire 2009 and 2010 OYs are taken in this management cycle. Spawning biomass is projected to decline to less than 50% of the directly-estimated B_{MSY} by 2011 if the entire 2009 and 2010 OYs are taken, which is an overfished state even under a directly-estimated B_{MSY} target.

The Council's choice of catch reductions of approximately 400 mt in 2009 and the lower coastwide OY for 2010 of 1,193 mt is based on the need to prevent the stock status from falling below the overfished threshold at the beginning of 2011, or to speed the rebuilding of petrale if it is found to be overfished. Using the base model from the 2009 assessment, model runs were made assuming different catches of petrale in 2009 and 2010. It was estimated by the GMT that catches could be reduced by approximately 1,200 mt in 2010 if the winter target fishery for petrale sole was severely restricted. Therefore, the remainder of the current 2010 OY, 1,193 mt, was treated as the preferred OY for 2010 in this action.

The Council also considered making no changes to 2009 management measures, and therefore not reducing petrale sole projected impacts in 2009. If no reduction were made for 2009, model runs indicated that an increase of between a 0-1 percent of $B_{unfished}$ and between a 3-5 percent of the directly-estimated B_{MSY} would be sacrificed (Table 2-5). The Council felt that the potential for a small increase in abundance, in an attempt to prevent the stock from falling below the overfished status in 2011, or to speed the rebuilding of petrale if it is found to be overfished was a better alternative than taking no reduction in 2009 (See Section 2.3 for more detail).

4.1.1.2.2 Socioeconomic Impacts

This section describes the economic implications of reducing the allowable catch of petrale sole in the 2009 and 2010 biennium. Both qualitative and quantitative information is used to show the overall effect to the industry, and the distributional effect of that reduction to west coast communities. Below is a description of the importance of petrale sole to the west coast harvesting and processing industry as a whole and how petrale sole affects the industry relative to other species. Quantitative information is used to illustrate the effects of petrale sole reductions to west coast communities (Table 4-2).

4.1.1.2.2.1 Effects of Petrale Sole Reductions to West Coast Trawl Harvesters

As indicated above, petrale sole is important to nearly every trawler along the west coast. In this section we simulate the effects of reducing petrale sole opportunities on trawl harvesters. This is done by using the GMT trawl model to estimate the effects (in revenue terms) upon west coast trawl harvesters under status quo conditions and under the Council's preliminary 2009 and 2010 measures to reduce petrale sole impacts. We illustrate this information in a histogram showing the effect these impacts will have to west coast trawl vessels in percentage terms.

The Council's preliminary option for reducing petrale sole impacts in 2009 and 2010 restricts the fishery during period 1 and period 6 (the period 1 reduction is limited to 2010). Reducing the petrale sole fishing opportunities during this period maintains the summer petrale sole fishery. During the summer months, petrale sole fetches a higher price per pound than during the winter fishery. Furthermore, restricting petrale sole fishing opportunities in the winter months affects fewer trawlers than if the fishing opportunities were restricted during the summer. This is because several trawlers cannot fish in the deeper areas where petrale are found during the winter, so their catches of petrale are limited to periods when petrale are on the shelf. In other cases, trawlers that are able to prosecute winter activities engage in the Dungeness crab fishery rather than the winter trawl fishery. In any event, the number of trawl vessels relying on winter petrale sole opportunities is smaller than the number of trawl vessels relying on summer petrale opportunities. However, for those vessels that rely on winter opportunities, the effect of the winter restriction is fairly large. Figure 4-1 is based on the current GMT model that estimates that there are about 139 trawlers participating in the non-whiting trawl fishery, and describes the number of limited entry non-whiting trawl vessels that may have a reduction in ex-vessel revenue. As shown in the figure below, a large number of vessels may have a relatively small decrease in revenue. However, a few vessels may have a relatively large decrease in revenue. For example: around 20 vessels may see their revenues decline by 5 to 9 percent, 5 to 19 vessels may see their revenues decline by 10 to 14 percent (depending on the year), and some vessels may see their revenues decline by over 20 percent.

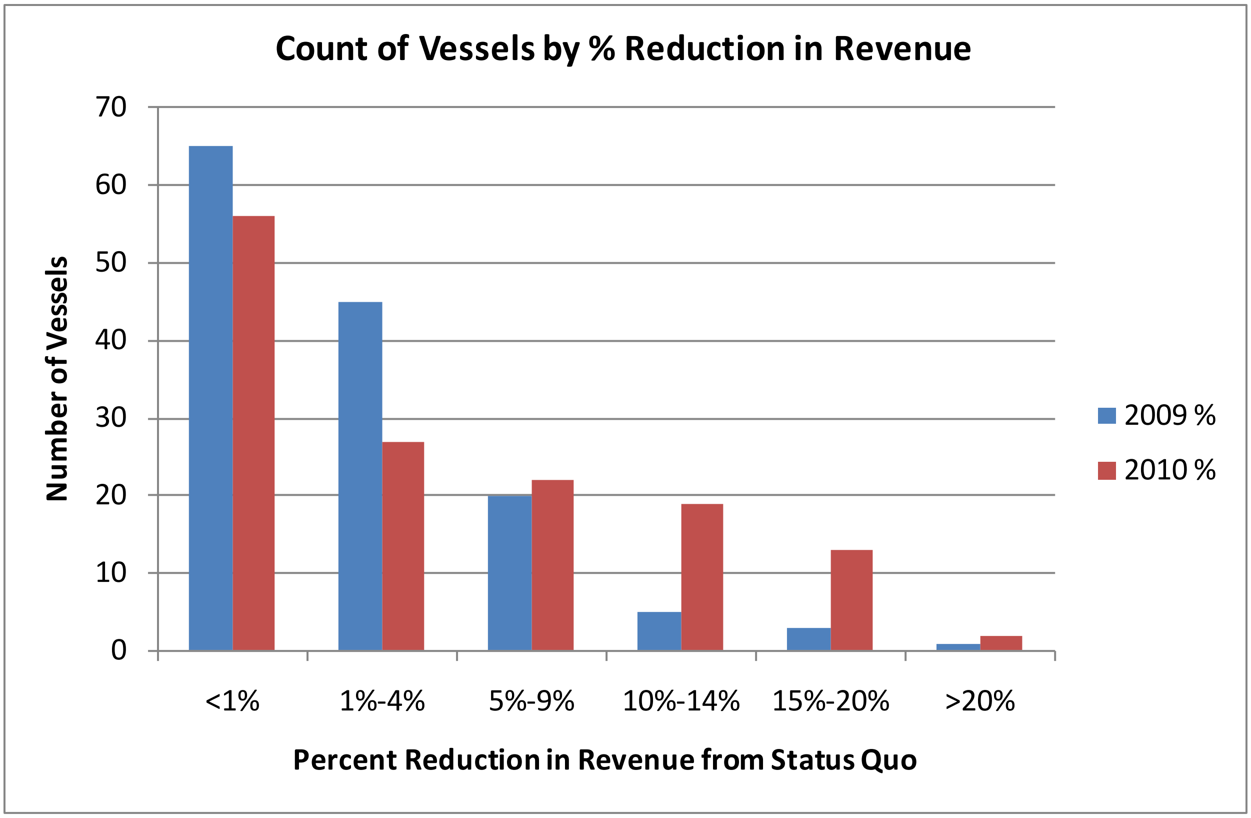

Figure 4-1: Count of Limited Entry Trawl Vessels by Percent Reduction in Ex-vessel Revenue Under Alternative P2

4.1.1.2.2.2 Effects of Petrale Sole Reductions to West Coast Communities

The effect of these petrale sole reductions on west coast communities is estimated by simulating the Council's preliminary options for reducing petrale catches on individual vessels, and by tying those impacts to each vessels principal port. Principal port is defined as the port which a vessel makes the majority of its landings to in a given year. Based on this approach, Figure 4-2 and Table 4-2 were developed. From this information it is apparent that some communities may be affected to a greater degree than others. The ports of Astoria, Bellingham, Coos Bay, Eureka, Moss Landing, Newport, Princeton/Half Moon Bay, and San Francisco all see reductions that are greater than or equal to 6 percent.

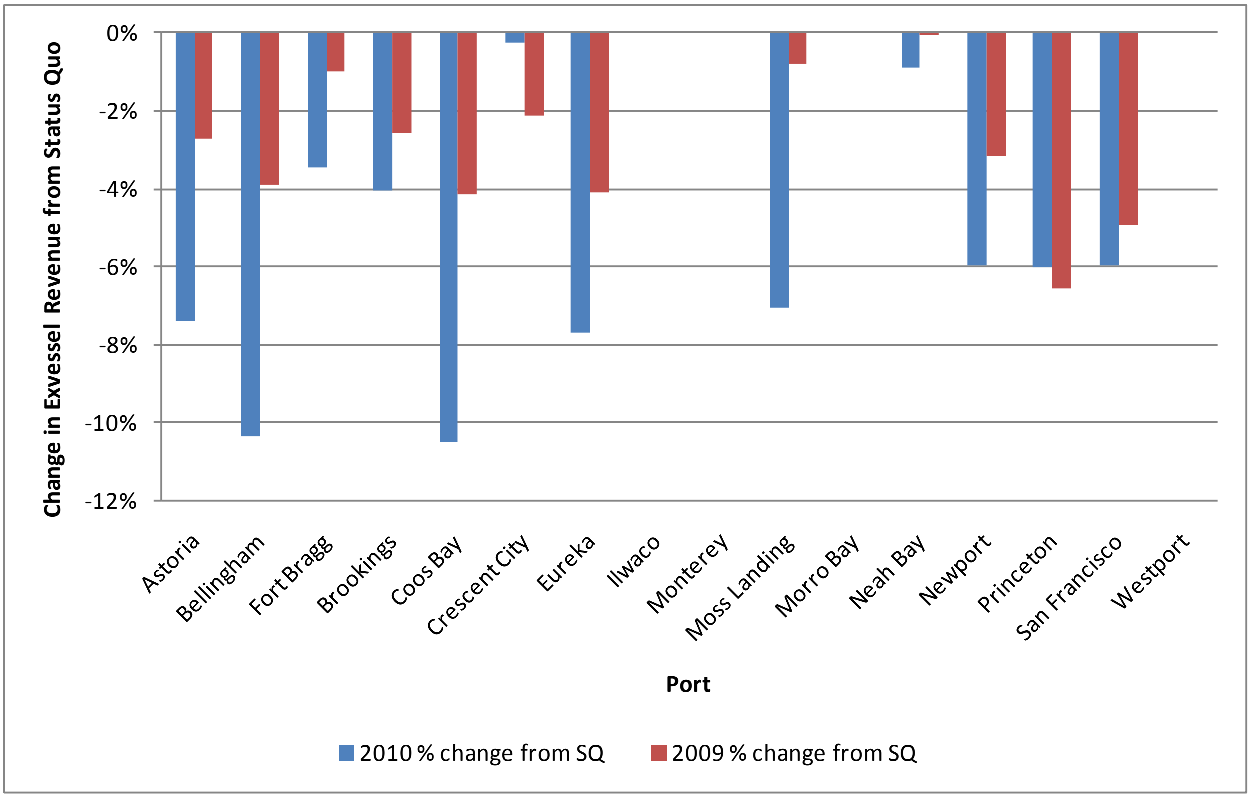

Figure 4-2: Change in Ex-vessel Revenue by Port

Table 4-2: Estimated Ex-vessel Revenue in the Limited Entry Non-Whiting Trawl Fishery by Port and Petrale Reductions for 2009 and 2010

	Alternative P1 – No Action[1/]	Alternative P2		2010 % change from SQ	2009 % change from SQ
	2009 Status Quo value	2009 Reduction	2010 Reduction

Total	28,190,988	27,249,505	26,109,063	-7%	-3%

Note: "C" indicates data is withheld due to confidentiality. The results included in the "Total" row includes these data.

1/ The projected ex-vessel revenue under Alternative P1 – No Action shows slightly different impacts that those described in Table 7-52 in the January 2009 EIS (PFMC and NMFS 2009). These are due to the indirect effects of the updates in fishery information and catch projection models. See discussion in section 4.1.1.2.2.

4.1.1.2.3 Impacts to Other Groundfish Species

In addition to the routine addition of new fishery information, described in sections 4.1.1.1.2 and 4.1.1.1.3, alternative P2 further changes projected impacts to overfished species because of the associated reduction in fishing effort as a result of more restrictive management measures for petrale sole. Because the level of proposed catch reductions in 2009 and 2010 are different, associated impacts for each year are also different. The projected impacts to overfished species from the fishery under Alternative P2 for 2009 and for 2010 are listed below in Table 4-3.

Table 4-3: Projected Impacts to Rebuilding and Target Species in the Limited Entry Non-Whiting Trawl Fishery, Coastwide, Under Alternative P2

		Projected Impacts of Alternative P2 (mt)	
		2009	2010
	Canary Rockfish	22.2	22.1
	POP	95.0	77.3
Rebuilding Species	Darkblotched Rockfish	202.8	146.5

	Widow Rockfish	19.4	17.3
	Bocaccio	12.7	12.7
	Yelloweye Rockfish	0.6	0.6
	Cowcod	1.4	1.4
Target Species	Sablefish	3,246.1	3,237.2
	Longspine Thornyheads	1,006.5	1,005.6
	Shortspine Thornyheads	1,301.2	1,287.9
	Dover Sole	13,716.7	13,688.0
	Arrowtooth Flounder	3,976.0	3,818.5
	Petrale Sole	1,995.0	1,178.3
	Other Flatfish	2,353.6	2,312.9
	Slope Rockfish	273.7	263.5

4.1.2 Canary rockfish Alternatives

The Council expressed concerns that the new 2009 stock assessment update, that was adopted for use in management at their June 2009 meeting, is more pessimistic than the 2007 stock assessment. The 2007 stock assessment was the basis of the rebuilding analysis and rebuilding plan and establishment of the 2009-2010 harvest specifications. In June 2009 the Council preliminarily recommended that actions in 2010, to restrict fisheries that catch canary rockfish incidentally, should be considered. Stock status information in the 2009 canary rockfish stock assessment update will be used to generate a rebuilding analysis in August and September 2009. The results of the rebuilding analysis will be considered by the Council at their November 2009 meeting. The results of the rebuilding analysis will provide the Council more information on the effects of Alternatives C1, C2, and C3 on rebuilding parameters, including time to rebuild. Because the results of the rebuilding analysis are not known at this time, much of the analysis in this section is qualitative in nature, or uses only the existing rebuilding parameters run through the new 2009 stock assessment as a baseline for estimating impacts of each alternative.

During the 2009-2010 harvest specifications and management measure process, various OY alternatives were considered for canary rockfish, including 85 mt and 44 mt (PFMC and NMFS 2009). Unless otherwise noted, all of the information used in this EA is from the January 2009 EIS (PFMC and NMFS 2009).

4.1.2.1 Alternative C1/No Action

4.1.2.1.1 Impacts to canary rockfish

The 2010 canary rockfish OY of 105 mt is based in the base case model in the 2007 stock assessment and the associated rebuilding analysis. If catches in 2009 and 2010 are equivalent to the 2009 and 2010 OYs (105 mt), then, according to the 2009 stock assessment, the status of the stock at the beginning of 2011 will be at 25.2 percent depletion.

If no action is taken to respond to the new 2009 stock assessment update, and to reduce harvest specifications and management measures for canary rockfish in 2010, then the fishing mortality on the stock in 2010 will be similar to that described in the January 2009 EIS (PFMC and NMFS 2009) under the Council's final preferred alternative. However, in 2011 and beyond, once the 2009 stock assessment update is incorporated for use in management, retrospective impacts to canary rockfish from the 2010 fishery would be higher, because the new stock assessment estimates a smaller biomass. In addition to the impacts described in the January 2009 EIS, the routine addition of new fishery information slightly changed the projected impacts to canary rockfish under the no action alternative. These projected impacts are listed in Table 2-3. Even with the incorporation of new fishery information, routine management measures are available to keep projected impacts within the 2009-2010 rebuilding OY of 105 mt.

Under Alternative C1, no action is taken to change the 2010 canary rockfish OY. Under this alternative, the results of the canary rockfish stock assessment update will be used to develop the 2011 and 2012 harvest specifications only, and will not be used to take interim measures in 2010.

4.1.2.1.2 Socioeconomic Impacts

Socioeconomic impacts of the 2010 management measures that keep projected impacts of canary rockfish below the 2010 OY of 105 mt are described in Section 7.2.8 the January 2009 EIS (PFMC and NMFS 2009). In that EIS, the impacts of a canary rockfish OY of 105 mt are considered as part of rebuilding alternative 5b and as the Council Preferred Alternative.

The quantitative analysis of socioeconomic impacts for the Pacific coast groundfish fishery is done on the management measures that keep projected impacts below harvest specifications. In this EA, the discussion of socioeconomic impacts for the canary rockfish alternatives is solely qualitative. This is because this draft EA does not propose a specific suite of management measures associated with the canary rockfish action alternative OYs in C2 and C3. Therefore, the socioeconomic impacts of the action alternatives cannot be accurately quantified at this time, as the specific management measures have not been identified.

While we describe the types of management measures that could be used, and in which sectors of the groundfish fishery they could be implemented (Section 2.2.2) the Council will provide guidance on which management measures to implement, depending on the available harvest (or OY), at the November 2009 Council meeting. The Council will use the socioeconomic analysis presented in the January 2009 EIS to generate a preferred suite of management measures for each OY alternative. Once the management measures that would be associated with each of the alternatives has been outlined, the quantitative socioeconomic analysis will be presented as a supplement to this EA.

The action alternatives are evaluated qualitatively in this draft EA; therefore, the No Action alternative must also be characterized in a qualitative manner, to allow direct comparison between the No Action alternative and the action alternatives (C2 and C3). In order to be able to directly compare the two action alternatives to the No Action alternative, no changes to fishery information that indirectly affect the socioeconomic environment are incorporated in the socioeconomic analysis at this time.

We refer the readers to the economic analysis in Section 7.2.8 of the January 2009 EIS (PFMC and NMFS 2009). The January 2009 EIS analyzed how the estimates of ex-vessel revenue change under alternative 2009-2010 harvest specifications and management measures. The EIS also analyzed impacts on the recreational fishery. In that EIS, alternative 5a looks at the socioeconomic impacts of a rebuilding alternative that includes a canary rockfish OY of 85 mt and the associated management measures. This alternative in the EIS can provide us with an initial starting place for a qualitative comparison between the No Action alternative in this EA and alternatives C2 and C3. This will be the source for the qualitative discussion of the economic effects of the action alternatives.

4.1.2.1.3 Impacts to Other Groundfish Species

If no action is taken to reduce fishery impacts to canary in 2010, then the impacts to other resources would be very similar to those described in the January 2009 EIS (PFMC and NMFS 2009). However, impacts to overfished groundfish species are slightly different than those listed in the January 2009 EIS.

The January 2009 EIS used the best available information available at that time. Since the publication of that document, several updates have been made to bycatch projection models that result in slightly different biological impacts to overfished species than what were predicted in the January 2009 EIS. For more information on these updates, see section 4.1.1.1.3 of this EA. As a result of these updates, projected impacts to overfished species are slightly different under the No Action alternative than those described in the January 2009 EIS. These updated projected impacts for canary rockfish are listed in Table 2-3. Updated projected impacts for all other overfished species are listed below in Table 4-4.

Table 4-4: Projected mortality impacts (mt) of overfished groundfish species updated with most recent research estimates and fishery projections through June and Council Final Action from June 2009 Inseason Under Agenda Item E.9.

Fishery	Bocaccio b/	Canary	Cowcod	Dkbl	POP	Widow	Yelloweye

	2.0	8.0	0.2	2.0	2.0	5.7	1.9
TOTAL	103.1	105.0	1.9	244.3	103.0	336.6	15.5
2009 OY f/	288	105	4.0	285	189	522	17
Difference	184.9	0.0	2.1	40.7	86.0	185.4	1.5

Percent of OY	35.8%	100.0%	47.5%	85.7%	54.5%	64.5%	91.2%
Key		= either not applicable; trace amount (<0.01 mt); or not reported in available data sources.					

a/ Non-tribal whiting values for canary, darkblotched, and widow reflect bycatch limits for the non-tribal whiting sectors. The widow bycatch limit is the difference between the OY and the projected impacts in all non-whiting fisheries. All other species' impacts are projected from the GMT's whiting impact projection model. The Council may elect to change these bycatch limits when setting final whiting management measures in March of 2009 or 2010 or under any inseason action at any of their future meetings.

b/ South of 40°10' N. lat.

c/ Mortality estimates are not hard numbers; based on the GMT's best professional judgment.

d/ Bycatch amounts by species unavailable, but bocaccio occurred in 0.1% of all port samples and other rockfish in another 0.1% of all port samples (and squid fisheries usually land their whole catch).

e/ Values in scorecard represent projected impacts for all species except canary and yelloweye rockfish, which are the prescribed harvest guidelines. For canary rockfish, the projected impacts from the WA/OR and CA recreational fisheries are the harvest guidelines minus 1.6 mt that were not projected to be harvested.

f/ 2009 and 2010 OYs are the same except for darkblotched (291 mt in 2010), POP (200 mt in 2010), and widow (509 mt in 2010).

4.1.2.2 Alternative C2

4.1.2.2.1 Impacts to Canary Rockfish

The Alternative C2 OY (2010 canary rockfish OY of 85 mt) is the same canary rockfish OY that was analyzed as a part of rebuilding alternative 5a in the January 2009 EIS (PFMC and NMFS 2009). The analysis in the January 2009 EIS was based on the 2007 canary rockfish stock assessment and rebuilding analysis, and the OY alternative of 85 mt was based on an SPR harvest rate of F96.2%. For additional information on the rationale for the canary rockfish OY of 85 mt based on the 2007 assessment, see the January 2009 EIS (PFMC and NMFS 2009), particularly Section 2.1.1.2.

In order to get a sense of the magnitude of the effects on the canary rockfish stock from a reduction in the 2010 OY from 105 to 85 mt, this reduction in the 2010 catch was run through the 2009 canary rockfish assessment model to see how the projection of potential 2011 OYs and depletion level might change if Alternative C2 is adopted. The stock assessment update presented at the June Council meeting predicted that using an SPR of 92.2% in 2011, which approximates the SPR for the harvest level in the 2009 and 2010 specifications, results in a 2011 coastwide canary rockfish OY of approximately 69 mt and a depletion level of 25.2% when 105 mt and 85 mt of canary rockfish are taken in 2009 and 2010, respectively (Stewart Pers. Comm.). It should be noted that the OY and depletion values generated by the base case stock assessment model do not account for uncertainty in the stock assessment like the rebuilding analysis will. Therefore, these point estimates are uncertain, with an unknown confidence interval, and are presented to facilitate comparison of alternatives in a qualitative manner.

4.1.2.2.2 Socioeconomic Impacts

As stated in section 4.1.2.1.2, the socioeconomic impacts of Alternative C2 will depend on the final suite of associated management measures that the Council will recommend in November 2009. Therefore the following discussion is qualitative in nature, and refers to the analysis in Section 7.2.8 of the January 2009 EIS (PFMC and NMFS 2009). In that EIS, alternative 5a looks at the socioeconomic impacts of a rebuilding alternative that includes a canary rockfish OY of 85 mt and the associated management measures, which may differ from what the Council selects in November. However, this alternative in the

EIS can provide us with an initial starting place for a qualitative comparison between alternatives C1 and C2 in this draft EA.

Table 4-5 shows how the change in the canary rockfish OY from 105 mt to 85 mt in 2010 could impact the overall level of ex-vessel revenue in the Pacific Coast groundfish fishery, coastwide. The reduction in revenue of approximately 8.54 percent would likely impact all of the sectors described in section 2.2.2. However, the suite of management measures that the Council recommends may change the distribution of the economic effects from status quo. Once the Council has adopted their preferred suite of management measures for each action alternative, the quantitative socioeconomic analysis will be completed. This analysis will describe the impact of the action alternatives on the ex-vessel revenue of each affected fishery sector.

Table 4-5 Percent Change in Total Ex-vessel Revenue of the Coastwide Groundfish Fishery Alternative Canary Rockfish OYs

	No Action	Action Alternatives		
Alternative in this EA:	Alternative C1 - 105 mt	Alternative C2 – 85 mt	Alternative C3 – 44 mt	
Alternative in the January 2009 EIS[1/]:	Final Council-Preferred Alternative	Rebuilding Alternative 5a	Rebuilding Alternative 2	Rebuilding Alternative 3
Total ex-vessel revenue ($ million)[2/]	105.42	96.42	94.32	81.32
Change in ex-vessel revenue from "No Action" (%)	**0**	**-08.54%**	**-10.53%**	**-22.86%**

1/ The EIS had two alternatives that included a canary rockfish OY of 44 mt: Rebuilding Alternatives 2 and 3. The differences between rebuilding alternatives 2 and 3 occur in the other overfished species OYs that were considered, and in the associated management measures. The ex-vessel revenue under each of these EIS alternatives is incorporated for informational purposes.

2/ The dollar amounts of ex-vessel revenue listed in this table are incorporated from Tables 7-50a and b in the January 2009 EIS (PFMC and NMFS 2009). The actual dollar amounts associated with the alternatives in this EA may be different than those from the EIS due to the indirect effects of incorporating routine fishery information to catch projection models since publication of the EIS. A quantitative analysis and description of changes to dollar amounts associated with these alternatives will occur in a supplemental to this EA, once the preliminary management measures are determined.

4.1.2.2.3 Impacts to Other Groundfish Species

Canary rockfish are a shelf species that co-occur with many healthy target species and are encountered in almost every sector of the groundfish fishery, coastwide. If the coastwide OY is reduced to 85 mt in

2010, it would reduce access to healthy stocks to a level lower than those considered in this EA under the No Action Alternative (C1).

As canary rockfish are distributed most heavily in the north (north being north of 38 degrees north latitude), we assume that measures taken to reduce canary impacts will be principally targeted toward portions of each fishery that operates in this northern area. In general we expect that achieving reductions in canary rockfish catch will be achieved by restricting the following fisheries: LE non-whiting trawl; LE whiting trawl; Northern California, Oregon, and Washington recreational groundfish; and nearshore commercial groundfish.

While the actual impacts of the action alternatives for canary rockfish (Alternatives C2 and C3) cannot be quantified without further Council specificity on how to keep projected impacts below those OYs, we can discuss the effect of the types of management measures that will be necessary to arrive at these numbers and the subsequent effect these management measures will have on other affected species.

As management measures affecting shelf opportunities become more restrictive, fishing effort may shift offshore, where fishing opportunities are unchanged via this action, due to lower canary rockfish abundance offshore. Effort shifts from the shelf to the slope could increase impacts of fisheries on all slope species, including overfished slope species such as darkblotched and Pacific Ocean perch (POP). Effort shifts will increase as the canary rockfish OY decreases, due to the restrictive management measures that will be associated with keeping projected impacts within lower OYs.

4.1.2.3 Alternative C3

4.1.2.3.1 Impacts to Canary Rockfish

The Alternative C3 OY (2010 canary rockfish OY of 44 mt) is the same canary rockfish OY that was analyzed as a part of rebuilding alternatives 2 and 3 in the January 2009 EIS (PFMC and NMFS 2009). The 44 mt OY was the No Action alternative OY for canary rockfish and had an associated SPR harvest rate of F93.6% in the rebuilding analysis that was based on the 2007 stock assessment. For additional information on the rationale for the canary rockfish OY of 44 mt, based on the 2007 assessment, see the January 2009 EIS (PFMC and NMFS 2009), particularly Section 2.1.1.2.

In order to get a sense of the magnitude of the effects on the canary rockfish stock from a reduction in the 2010 OY from 105 to 44 mt, this reduction in the 2010 catch was run through the 2009 canary rockfish assessment model to see how the projection of potential 2011 OYs and stock depletion might change if Alternative C3 is adopted. The stock assessment update presented at the June Council meeting predicted that using an SPR of 92.2% in 2011, which approximates the SPR for the harvest level in the 2009 and 2010 specifications, results in a 2011 coastwide canary rockfish OY of approximately 70 mt and a depletion level of 25.3% when 105 mt and 44 mt of canary rockfish are taken in 2009 and 2010, respectively (Stewart Pers. Comm.). It should be noted that the OY and depletion values generated by the base case stock assessment model do not account for uncertainty in the stock assessment like the rebuilding analysis will. Therefore, these point estimates are uncertain, with an unknown confidence interval, and are presented to facilitate comparison of alternatives in a qualitative manner.

4.1.2.3.2 Socioeconomic Impacts

As stated in section 4.1.2.1.2, the socioeconomic impacts of Alternative C3 will depend on the final suite of associated management measures that the Council will recommend in November 2009. Therefore the following discussion is qualitative in nature, and refers to the analysis in Section 7.2.8 of the January 2009 EIS (PFMC and NMFS 2009). In that EIS, rebuilding alternatives 2 and 3 look at the socioeconomic impacts of rebuilding alternatives that includes a canary rockfish OY of 44 mt and associated management measures. These alternatives in the EIS can provide us with an initial starting place for a qualitative comparison between alternatives C1 and C3 in this draft EA.

Table 4-5 shows how the change in the canary rockfish OY from 105 mt to 44 mt in 2010 could impact the overall level of ex-vessel revenue in the Pacific Coast groundfish fishery, coastwide. The reduction in revenue described in Table 4-5 range from 11 percent to 23 percent pending on the rebuilding alternative. This alternative would likely impact all of the sectors described in section 2.2.2, but to a larger degree than under alternative C2. The suite of management measures that the Council recommends may change the distribution of the economic effects from what occurs under status quo. Once the Council has adopted their preferred suite of management measures for each action alternative, the quantitative socioeconomic analysis will be completed. This analysis will describe the impact of the action alternatives on the ex-vessel revenue of each affected fishery sector.

4.1.2.3.3 Impacts to Other Groundfish Species

Canary rockfish are a shelf species that co-occur with many healthy target species and are encountered in almost every sector of the groundfish fishery, coastwide. If the coastwide OY is reduced to 44 mt in 2010, it would reduce access to healthy stocks to a level lower than those considered in this EA under both the No Action Alternative (C1) and Alternative C2. See section 4.1.2.2.3 for more information.

5 Chapter 5 Cumulative Effects

Generally speaking, the proposed action alternatives would restrict fishing activities that take petrale sole and canary rockfish, and therefore may reduce fishing effort in some areas of the coast.

Alternative P2 would reduce fishing opportunities for petrale sole. With the reduction in fishing opportunities, a corresponding reduction in fishing effort is expected. This is because it is unlikely that effort previously targeting on petrale sole will be displaced from the area seaward of the trawl rockfish conservation area (RCA) to the area shoreward of the trawl RCA because target opportunities in the area shoreward of the RCA are very limited in winter months. Reduced trawl fishing effort could have positive impacts on habitat, and would reduce the likelihood of impacts to ESA-listed species or marine mammals that could be encountered in the limited entry trawl fishery off Washington, Oregon, and California.

Alternatives C2 and C3 would likely reduce fishing opportunities in several sectors of the groundfish fishery. Depending on how the management measures are designed, there may be a reduction in overall fishing effort in these sectors, or there may be effort shifts to areas of the coast or to depths where canary rockfish are less abundant. A decrease in fishing effort may reduce negative impacts to EFH from both commercial and recreational groundfish fishing activities off West Coast states. Shifts in fishing effort to different areas in order to reduce incidental catch of canary rockfish could have a differing effect on the ecosystem from the no action alternative; however, those differences are not quantifiable.

If the Council chooses an action alternative for both petrale sole and for canary rockfish, these actions are not completely independent of each other. This is because petrale sole is caught primarily in the limited entry non-whiting trawl fishery, and this sector of the fishery also has impacts on canary rockfish. If Alternative P2 is adopted, projected impacts to canary rockfish in the limited entry non-whiting trawl fishery are reduced by 0.1 mt from the No Action Alternatives (P1 and C1). Qualitatively, if the canary rockfish OY is reduced in 2010 from 105 mt, effort could shift to the area seaward of the trawl RCA. Petrale sole are primarily caught seaward of the RCA. If, in combination with one of the canary rockfish action alternatives, Alternative P2 is adopted, then there will be less petrale sole available for harvest for those vessels displaced by restrictive management measures in the area seaward of the trawl RCA.

It should be noted that the scale of the proposed action in this EA is smaller than the January 2009 EIS (PFMC and NMFS 2009) due to the change in focus from setting specifications and management measures for all species in the FMP to setting specifications and management measures as they pertain particularly to canary rockfish and petrale sole. This, combined with the fact that the action alternatives all reduce available harvest from the No Action alternative, means that the cumulative effects of this action are within or below those estimated in the January 2009 EIS (PFMC and NMFS 2009)

6 Chapter 6 List of Preparers

Name	Affiliation	Participation
Ms. Gretchen Arentzen	NMFS, Northwest Region	Principal author
Mr. Merrick Burden	PFMC Staff	Contributing author, Chapter 4
Ms. Eileen Cooney	NOAA General Counsel	Principal reviewer
Mr. Kevin Duffy	NMFS, Northwest Region	Principal reviewer
Ms. Shelby L. Mendez	NOAA NEPA Coordinator	Principal reviewer
Dr. Ian Stewart	NMFS Northwest Fisheries Science Center	Principal author of the canary rockfish stock assessment and rebuilding analysis

7 Chapter 7 Acronyms and Glossary

Acronym	Definition
ABC	Acceptable biological catch. The ABC is a scientific calculation of the sustainable harvest level of a fishery and is used to set the upper limit of the annual total allowable catch. It is calculated by applying the directly-estimated (or proxy) harvest rate that produces maximum sustainable yield to the estimated exploitable stock biomass (the portion of the fish population that can be harvested).
B_{MSY}	The biomass that allows maximum sustainable yield to be taken.
$B_{unfished}$	Estimated unfished biomass
EA	Environmental Assessment
EFH	Essential Fish Habitat
EFP	Exempted Fishing Permit
EIS	Environmental Impact Statement
FMP	Fishery Management Plan
FR	*Federal Register*
GMT	Groundfish Management Team
IPHC	International Pacific Halibut Commission
lb	Pounds
LE	Limited entry fishery
PFMC	Pacific Fishery Management Council
mt	metric tons
NMFS	National Marine Fisheries Service
NOAA	National Oceanic & Atmospheric Administration; The parent agency of National Marine Fisheries Service
OA	Open access fishery

OY	Optimum Yield
POP	Pacific Ocean perch
RCA	Rockfish Conservation Area
SAFE	Stock Assessment and Fishery Evaluation
SPR	Spawning biomass per recruit
STAR Panel	Stock Assessment Review Panel. A panel set up to review stock assessments for particular fisheries. In the past there have been STAR panels for sablefish, rockfish, squid, and other species
Status quo	Same as the “No Action” alternative
SSC	Scientific and Statistical Committee

9 Appendix A - No Action Trip Limit Tables

Trip limit tables (Tables 3 (North), 3 (South), 4 (North), 4 (South), 5 (North), and 5 (South), as updated in the July 6, 2009 inseason action rule (74 FR31874), are provided here for reference.

Table 3 (North) to Part 660, Subpart G -- 2009-2010 Trip Limits for Limited Entry Trawl Gear North of 40°10' N. Lat.

Other Limits and Requirements Apply -- Read § 660.301 - § 660.399 before using this table

061509

TABLE 3 (North)

		JAN-FEB	MAR-APR	MAY-JUN	JUL-AUG	SEP-OCT	NOV-DEC
	Rockfish Conservation Area (RCA)[6/]:						
1	North of 48°10' N. lat.	shore - modified[7/] 200 fm line[6/]	shore - 200 fm line[6/]	shore - 150 fm line[6/]		shore - 200 fm line[6/]	shore - modified[7/] 200 fm line[6/]
2	48°10' N. lat. - 45°46' N. lat.	75 fm line[6/] - modified[7/] 200 fm line[6/]	75 fm line[6/] - 200 fm line[6/]	75 fm line[6/] - 150 fm line[6/]	100 fm line[6/] - 150 fm line[6/]	75 fm line[6/] - 200 fm line[6/]	75 fm line[6/] - modified[7/] 200 fm line[6/]
3	45°46' N. lat. - 40°10' N. lat.			75 fm line[6/] - 200 fm line[6/]	100 fm line[6/] - 200 fm line[6/]		

Selective flatfish trawl gear is required shoreward of the RCA; all trawl gear (large footrope, selective flatfish trawl, and small footrope trawl gear) is permitted seaward of the RCA. Large footrope and small footrope trawl gears (except for selective flatfish trawl gear) are prohibited shoreward of the RCA. Midwater trawl gear is permitted only for vessels participating in the primary whiting season.

See § 660.370 and § 660.381 for Additional Gear, Trip Limit, and Conservation Area Requirements and Restrictions. See §§ 660.390-660.394 and §§ 660.396-660.399 for Conservation Area Descriptions and Coordinates (including RCAs, YRCA, CCAs, Farallon Islands, Cordell Banks, and EFHCAs).

State trip limits and seasons may be more restrictive than federal trip limits, particularly in waters off Oregon and California.

61	**Other Fish** 5/	Not limited					

TABLE 3 (North) con't

1/ Bocaccio, chilipepper and cowcod are included in the trip limits for minor shelf rockfish.
2/ Splitnose rockfish is included in the trip limits for minor slope rockfish.
3/ "Other flatfish" are defined at § 660.302 and include butter sole, curlfin sole, flathead sole, Pacific sanddab, rex sole, rock sole, and sand sole.
4/ The minimum size limit for lingcod is 22 inches (56 cm) total length North of 42^{o} N. lat.
5/ "Other fish" are defined at § 660.302 and include sharks, skates (including longnose skate), ratfish, morids, grenadiers, and kelp greenling. Cabezon is included in the trip limits for "other fish."
6/ The Rockfish Conservation Area is an area closed to fishing by particulary gear types, bounded by lines specifically defined by latitude and longitude coordinates set out at §§ 660.391-660.394. This RCA is not defined by depth contours, and the boundary lines that define the RCA may close areas that are deeper or shallower than the depth contour. Vessels that are subject to the RCA restrictions may not fish in the RCA, or operate in the RCA for any purpose other than transiting.
7/ The "modified" fathom lines are modified to exclude certain petrale sole areas from the RCA.
8/ If a vessel has both selective flatfish gear and large or small footrope gear on board during a cumulative limit period (either simultaneously or successively), the most restrictive cumulative limit for any gear on board during the cumulative limit period applies for the entire cumulative limit period.

To convert pounds to kilograms, divide by 2.20462, the number of pounds in one kilogram.

TABLE 4 (North)

1/ "Other flatfish" are defined at § 660.302 and include butter sole, curlfin sole, flathead sole, Pacific sanddab, rex sole, rock sole, and sand sole.
2/ Bocaccio, chilipepper and cowcod are included in the trip limits for minor shelf rockfish and splitnose rockfish is included in the trip limits for minor slope rockfish.
3/ For black rockfish north of Cape Alava (48°09.50' N. lat.), and between Destruction Is. (47°40' N. lat.) and Leadbetter Pnt. (46°38.17' N. lat.), there is an additional limit of 100 lb or 30 percent by weight of all fish on board, whichever is greater, per vessel, per fishing trip.
4/ The minimum size limit for lingcod is 22 inches (56 cm) total length North of 42° N. lat. and 24 inches (61 cm) total length South of 42° N. lat.
5/ "Other fish" are defined at § 660.302 and include sharks, skates (including longnose skates), ratfish, morids, grenadiers, and kelp greenling. Cabezon is included in the trip limits for "other fish."
6/ The Rockfish Conservation Area is an area closed to fishing by particular gear types, bounded by lines specifically defined by latitude and longitude coordinates set out at §§ 660.391-660.394. This RCA is not defined by depth contours (with the exception of the 20-fm depth contour boundary south of 42° N. lat.), and the boundary lines that define the RCA may close areas that are deeper or shallower than the depth contour. Vessels that are subject to RCA restrictions may not fish in the RCA, or operate in the RCA for any purpose other than transiting.
7/ The 125 fm line restriction is in place all year, except on days when the directed halibut fishery is open. On those days the 100 fm line restriction is in effect.
To convert pounds to kilograms, divide by 2.20462, the number of pounds in one kilogram.

17	**Minor shelf rockfish[1/], Shortbelly, Widow, & Yellowtail rockfish**	200 lb/ month					
18	**Canary rockfish**	CLOSED					
19	**Yelloweye rockfish**	CLOSED					
20	**Minor nearshore rockfish & Black rockfish**						
21	North of 42° N. lat.	5,000 lb/ 2 months, no more than 1,200 lb of which may be species other than black or blue rockfish [3/]					
22	42° - 40°10' N. lat.	6,000 lb/ 2 months, no more than 1,200 lb of which may be species other than black or blue rockfish [3/]			7,000 lb/ 2 months, no more than 1,200 lb of which may be species other than black rockfish [3/]		
23	**Lingcod[4/]**	CLOSED		400 lb/ month			CLOSED
24	**Pacific cod**	1,000 lb/ 2 months					
25	**Spiny dogfish**	200,000 lb/ 2 months		150,000 lb/ 2 months	100,000 lb/ 2 months		
26	**Other Fish[5/]**	Not limited					

TABLE 5 (North)

Table 5 (North). Continued

27	**PINK SHRIMP NON-GROUNDFISH TRAWL** *(not subject to RCAs)*		TABLE 5 (North) con't
28	North	**Effective April 1 - October 31:** Groundfish: 500 lb/day, multiplied by the number of days of the trip, not to exceed 1,500 lb/trip. The following sublimits also apply and are counted toward the overall 500 lb/day and 1,500 lb/trip groundfish limits: lingcod 300 lb/month (minimum 24 inch size limit); sablefish 2,000 lb/month; canary, thornyheads and yelloweye rockfish are PROHIBITED. All other groundfish species taken are managed under the overall 500 lb/day and 1,500 lb/trip groundfish limits. Landings of these species count toward the per day and per trip groundfish limits and do not have species-specific limits. The amount of groundfish landed may not exceed the amount of pink shrimp landed.	
29	**SALMON TROLL**		
30	North	Salmon trollers may retain and land up to 1 lb of yellowtail rockfish for every 2 lbs of salmon landed, with a cumulative limit of 200 lb/month, both within and outside of the RCA. This limit is within the 200 lb per month combined limit for minor shelf rockfish, widow rockfish and yellowtail rockfish, and not in addition to that limit. Salmon trollers may retain and land up to 1 lingcod per 15 Chinook, plus 1 lingcod up to a trip limit of 10 lingcod, both within and outside of the RCA. This limit is within the 400 lb per month limit for lingcod, and not in addition to that limit. All groundfish species are subject to the open access limits, seasons, size limits and RCA restrictions listed in the table above.	

1/ Bocaccio, chilipepper and cowcod rockfishes are included in the trip limits for minor shelf rockfish. Splitnose rockfish is included in the trip limits for minor slope rockfish.

2/ "Other flatfish" are defined at § 660.302 and include butter sole, curlfin sole, flathead sole, Pacific sanddab, rex sole, rock sole, and sand sole.

3/ For black rockfish north of Cape Alava (48°09.50' N. lat.), and between Destruction Is. (47°40' N. lat.) and Leadbetter Pnt. (46°38.17' N. lat.), there is an additional limit of 100 lbs or 30 percent by weight of all fish on board, whichever is greater, per vessel, per fishing trip.

4/ The minimum size limit for lingcod is 22 inches (56 cm) total length North of 42^{o} N. lat. and 24 inches (61 cm) total length South of 42^{o} N. lat.

5/ "Other fish" are defined at § 660.302 and include sharks, skates (including longnose skates), ratfish, morids, grenadiers, and kelp greenling. Cabezon is included in the trip limits for "other fish."

6/ The Rockfish Conservation Area is an area closed to fishing by particular gear types, bounded by lines specifically defined by latitude and longitude coordinates set out at §§ 660.391-660.394. This RCA is not defined by depth contours (with the exception of the 20-fm depth contour boundary south of 42^{o} N. lat.), and the boundary lines that define the RCA may close areas that are deeper or shallower than the depth contour. Vessels that are subject to RCA restrictions may not fish in the RCA, or operate in the RCA for any purpose other than transiting.

7/ The 125 fm line restriction is in place all year, except on days when the directed halibut fishery is open. On those days the 100 fm line restriction is in effect.

To convert pounds to kilograms, divide by 2.20462, the number of pounds in one kilogram.

Table 5 (South) to Part 660, Subpart G -- 2009-2010 Trip Limits for Open Access Gears South of 40°10' N. Lat.

Table 5 (South). Continued

30	**Minor nearshore rockfish & Black rockfish**						
31	Shallow nearshore	600 lb/ 2 months	CLOSED	800 lb/ 2 months	900 lb/ 2 months	800 lb/ 2 months	600 lb/ 2 months
32	Deeper nearshore						
33	40°10' - 34°27' N. lat.	700 lb/ 2 months	CLOSED	700 lb/ 2 months		600 lb/ 2 months	700 lb/ 2 months
34	South of 34°27' N. lat.	500 lb/ 2 months		600 lb/ 2 months			
35	California scorpionfish	600 lb/ 2 months	CLOSED	600 lb/ 2 months	1,200 lb/ 2 months		
36	**Lingcod**[3/]	CLOSED		400 lb/ month			CLOSED
37	**Pacific cod**	1,000 lb/ 2 months					
38	**Spiny dogfish**	200,000 lb/ 2 months		150,000 lb/ 2 months	100,000 lb/ 2 months		
39	**Other Fish**[4/] **& Cabezon**	Not limited					
40	**RIDGEBACK PRAWN AND, SOUTH OF 38°57.50' N. LAT., CA HALIBUT AND SEA CUCUMBER NON-GROUNDFISH TRAWL**						
41	**NON-GROUNDFISH TRAWL Rockfish Conservation Area (RCA) for CA Halibut, Sea Cucumber & Ridgeback Prawn:**						
42	40°10' - 38° N. lat.	100 fm - modified 200 fm [6/]	100 fm - 150 fm				100 fm - modified 200 fm [6/]
43	38° - 34°27' N. lat.	100 fm - 150 fm					
44	South of 34°27' N. lat.	100 fm - 150 fm along the mainland coast; shoreline - 150 fm around islands					
45		Groundfish: 300 lb/trip. Trip limits in this table also apply and are counted toward the 300 lb groundfish per trip limit. The amount of groundfish landed may not exceed the amount of the target species landed, except that the amount of spiny dogfish landed may exceed the amount of target species landed. Spiny dogfish are limited by the 300 lb/trip overall groundfish limit. The daily trip limits for sablefish coastwide and thornyheads south of Pt. Conception and the overall groundfish "per trip" limit may not be multiplied by the number of days of the trip. Vessels participating in the California halibut fishery south of 38°57.50' N. lat. are allowed to (1) land up to 100 lb/day of groundfish without the ratio requirement, provided that at least one California halibut is landed and (2) land up to 3,000 lb/month of flatfish, no more than 300 lb of which may be species other than Pacific sanddabs, sand sole, starry flounder, rock sole, curlfin sole, or California scorpionfish (California scorpionfish is also subject to the trip limits and closures in line 31).					
46	**PINK SHRIMP NON-GROUNDFISH TRAWL GEAR** *(not subject to RCAs)*						
47	South	**Effective April 1 - October 31:** Groundfish: 500 lb/day, multiplied by the number of days of the trip, not to exceed 1,500 lb/trip. The following sublimits also apply and are counted toward the overall 500 lb/day and 1,500 lb/trip groundfish limits: lingcod 300 lb/ month (minimum 24 inch size limit); sablefish 2,000 lb/ month; canary, thornyheads and yelloweye rockfish are PROHIBITED. All other groundfish species taken are managed under the overall 500 lb/day and 1,500 lb/trip groundfish limits. Landings of these species count toward the per day and per trip groundfish limits and do not have species-specific limits. The amount of groundfish landed may not exceed the amount of pink shrimp landed.					

TABLE 5 (South) con't

1/ Yellowtail rockfish is included in the trip limits for minor shelf rockfish. POP is included in the trip limits for minor slope rockfish. Bronzespotted rockfish have a species specific trip limit.

2/ "Other flatfish" are defined at § 660.302 and include butter sole, curlfin sole, flathead sole, Pacific sanddab, rex sole, rock sole, and sand sole.

3/ The size limit for lingcod is 24 inches (61 cm) total length South of 42° N. lat.

4/ "Other fish" are defined at § 660.302 and include sharks, skates (including longnose skates), ratfish, morids, grenadiers, and kelp greenling.

5/ The Rockfish Conservation Area is an area closed to fishing by particular gear types, bounded by lines specifically defined by latitude and longitude coordinates set out at §§ 660.391-660.394. This RCA is not defined by depth contours (with the exception of the 20-fm depth contour boundary south of 42° N. lat.), and the boundary lines that define the RCA may close areas that are deeper or shallower than the depth contour. Vessels that are subject to RCA restrictions may not fish in the RCA, or operate in the RCA for any purpose other than transiting.

6/ The "modified 200 fm" line is modified to exclude certain petrale sole areas from the RCA.

To convert pounds to kilograms, divide by 2.20462, the number of pounds in one kilogram.

10 Appendix B - No Action Recreational Management Measures

Management measures for recreational fisheries under the No Action alternative are listed in Federal Regulations at 50 CFR 660.384 and are provided here.

*****

50 CFR § 660.384 Recreational fishery management measures.

(a) General. Federal recreational groundfish regulations are not intended to supersede any more restrictive state recreational groundfish regulations relating to federally-managed groundfish. The bag limits include fish taken in both state and Federal waters.

(b) Gear restrictions. The only types of fishing gear authorized for recreational fishing are hook-and-line and spear. Spears may be propelled by hand or by mechanical means. More fishery-specific gear restrictions may be required by state as noted in paragraph (c) of this section (e.g. California's recreational "other flatfish" fishery).

(c) State-specific recreational fishery management measures. Federal recreational groundfish regulations are not intended to supersede any more restrictive State recreational groundfish regulations relating to federally-managed groundfish. Off the coast of Washington, Oregon, and California, boat limits apply, whereby each fisher aboard a vessel may continue to use angling gear until the combined daily limits of groundfish for all licensed and juvenile anglers aboard has been attained (additional state restrictions on boat limits may apply).

(1) Washington. For each person engaged in recreational fishing off the coast of Washington, the groundfish bag limit is 15 groundfish per day, including rockfish and lingcod, and is open year-round (except for lingcod). In the Pacific halibut fisheries, retention of groundfish is governed in part by annual management measures for Pacific halibut fisheries, which are published in the Federal Register. South of Leadbetter Point, WA to the Washington/Oregon border, when Pacific halibut are onboard the vessel, no groundfish may be taken and retained, possessed or landed, except sablefish and Pacific cod. The following sub-limits and closed areas apply:

(i) Recreational Groundfish Conservation Areas off Washington.

(A) North Coast Recreational Yelloweye Rockfish Conservation Area. Recreational fishing for groundfish and halibut is prohibited within the North Coast Recreational Yelloweye Rockfish Conservation Area (YRCA).It is unlawful for recreational fishing vessels to take and retain, possess, or land groundfish taken with recreational gear within the North Coast Recreational YRCA.A vessel fishing in the North Coast Recreational YRCA may not be in possession of any groundfish. Recreational vessels may transit through the North Coast Recreational YRCA with or without groundfish on board. The North Coast Recreational YRCA is defined by latitude and longitude coordinates specified at §660.390.

(B) South Coast Recreational Yelloweye Rockfish Conservation Area. Recreational fishing for groundfish and halibut is prohibited within the South Coast Recreational YRCA .It is unlawful for recreational fishing

vessels to take and retain, possess, or land groundfish taken with recreational gear within the South Coast Recreational YRCA.A vessel fishing in the South Coast Recreational YRCA may not be in possession of any groundfish. Recreational vessels may transit through the South Coast Recreational YRCA with or without groundfish on board. The South Coast Recreational YRCA is defined by latitude and longitude coordinates specified at §660.390.

(C) Westport Offshore Recreational Yelloweye Rockfish Conservation Area. Recreational fishing for groundfish and halibut is prohibited within the Westport Offshore Recreational YRCA. It is unlawful for recreational fishing vessels to take and retain, possess, or land groundfish taken with recreational gear within the Westport Offshore Recreational YRCA. A vessel fishing in the Westport Offshore Recreational YRCA may not be in possession of any groundfish. Recreational vessels may transit through the Westport Offshore Recreational YRCA with or without groundfish on board. The Westport Offshore Recreational YRCA is defined by latitude and longitude coordinates specified at §660.390.

(D) Recreational Rockfish Conservation Area. Fishing for groundfish with recreational gear is prohibited within the recreational RCA. It is unlawful to take and retain, possess, or land groundfish taken with recreational gear within the recreational RCA.A vessel fishing in the recreational RCA may not be in possession of any groundfish. [For example, if a vessel participates in the recreational salmon fishery within the RCA, the vessel cannot be in possession of groundfish while in the RCA. The vessel may, however, on the same trip fish for and retain groundfish shoreward of the RCA on the return trip to port.]

(1) Between the U.S. border with Canada and the Queets River, recreational fishing for groundfish is prohibited seaward of a boundary line approximating the 20-fm (37-m) depth contour from May 21 through September 30, except on days when the Pacific halibut fishery is open in this area. Days open to Pacific halibut recreational fishing off Washington are announced on the NMFS hotline at (206) 526–6667 or (800) 662–9825. Coordinates for the boundary line approximating the 20-fm (37-m) depth contour are listed in §660.391.

(2) Between the Queets River and Leadbetter Point, recreational fishing for groundfish is prohibited seaward of a boundary line approximating the 30-fm (55-m) depth contour from March 15 through June 15, except that recreational fishing for sablefish and Pacific cod is permitted within the recreational RCA from May 1 through June 15. Retention of lingcod seaward of the boundary line approximating the 30-fm (55-m) depth contour south of 46°58' N. lat. is prohibited on Fridays and Saturdays from July 1 through August 31. For additional regulations regarding the Washington recreational lingcod fishery, see paragraph (c)(1)(iii) of this section. Coordinates for the boundary line approximating the 30-fm (55-m) depth contour are listed in §660.391.

(ii) Rockfish. In areas of the EEZ seaward of Washington that are open to recreational groundfish fishing, there is a 10 rockfish per day bag limit. Taking and retaining canary rockfish and yelloweye rockfish is prohibited.

(iii) Lingcod. In areas of the EEZ seaward of Washington that are open to recreational groundfish fishing and when the recreational season for lingcod is open, there is a bag limit of 2 lingcod per day, which may

be no smaller than 22 in (56 cm) total length. The recreational fishing season for lingcod is open as follows:

(A) Between the U.S./Canada border to 48°10' N. lat. (Cape Alava) (Washington Marine Area 4), recreational fishing for lingcod is open, for 2009, from April 16 through October 15, and for 2010, from April 16 through October 15.

(B) Between 48°10' N. lat. (Cape Alava) and 46°16' N. lat. (Washington/Oregon border) (Washington Marine Areas 1–3), recreational fishing for lingcod is open for 2009, from March 14 through October 17, and for 2010, from March 13 through October 16.

(2) Oregon —(i) Recreational Groundfish Conservation Areas off Oregon. (A) Stonewall Bank Yelloweye Rockfish Conservation Area. Recreational fishing for groundfish and halibut is prohibited within the Stonewall Bank YRCA. It is unlawful for recreational fishing vessels to take and retain, possess, or land groundfish taken with recreational gear within the Stonewall Bank YRCA.A vessel fishing in the Stonewall Bank YRCA may not be in possession of any groundfish. Recreational vessels may transit through the Stonewall Bank YRCA with or without groundfish on board. The Stonewall Bank YRCA is defined by latitude and longitude coordinates specified at §660.390.

(B) Recreational Rockfish Conservation Area. Fishing for groundfish with recreational gear is prohibited within the recreational RCA, a type of closed area or GCA. It is unlawful to take and retain, possess, or land groundfish taken with recreational gear within the recreational RCA. A vessel fishing in the recreational RCA may not be in possession of any groundfish. [For example, if a vessel participates in the recreational salmon fishery within the RCA, the vessel cannot be in possession of groundfish while in the RCA. The vessel may, however, on the same trip fish for and retain groundfish shoreward of the RCA on the return trip to port.] Off Oregon, from April 1 through September 30, recreational fishing for groundfish is prohibited seaward of a recreational RCA boundary line approximating the 40 fm (73 m) depth contour. Coordinates for the boundary line approximating the 40 fm (73 m) depth contour are listed at §660.391.

(C) Essential Fish Habitat Conservation Areas. The Essential Fish Habitat Conservation Areas (EFHCAs) are closed areas, defined by specific latitude and longitude coordinates at §§660.396 through 660.399, where specified types of fishing are prohibited. Prohibitions applying to specific EFHCAs are found at §660.306.

(ii) Seasons. Recreational fishing for groundfish is open from January 1 through December 31, subject to the closed areas described in paragraph (c)(2) of this section.

(iii) Bag limits, size limits. The bag limits for each person engaged in recreational fishing in the EEZ seaward of Oregon are three lingcod per day, which may be no smaller than 22 in (56 cm) total length; and 10 marine fish per day, which excludes Pacific halibut, salmonids, tuna, perch species, sturgeon, sanddabs, flatfish, lingcod, striped bass, hybrid bass, offshore pelagic species and baitfish (herring, smelt, anchovies and sardines), but which includes rockfish, greenling, cabezon and other groundfish species. The bag limit for all flatfish is 25 fish per day, which excludes Pacific halibut, but which includes all soles,

flounders and Pacific sanddabs. In the Pacific halibut fisheries, retention of groundfish is governed in part by annual management measures for Pacific halibut fisheries, which are published in the Federal Register. Between the Oregon border with Washington and Cape Falcon, when Pacific halibut are onboard the vessel, groundfish may not be taken and retained, possessed or landed, except sablefish and Pacific cod. Between Cape Falcon and Humbug Mountain, during days open to the Oregon Central Coast "all-depth" sport halibut fishery, when Pacific halibut are onboard the vessel, no groundfish may be taken and retained, possessed or landed, except sablefish and Pacific cod. "All-depth" season days are established in the annual management measures for Pacific halibut fisheries, which are published in the Federal Register and are announced on the NMFS halibut hotline, 1–800–662–9825. The minimum size limit for cabezon retained in the recreational fishery is 16-in (41-cm), and for greenling is 10-in (26-cm). Taking and retaining canary rockfish and yelloweye rockfish is prohibited at all times and in all areas.

(3) California. Seaward of California, California law provides that, in times and areas when the recreational fishery is open, there is a 20 fish bag limit for all species of finfish, within which no more than 10 fish of any one species may be taken or possessed by any one person.[Note: There are some exceptions to this rule. The following groundfish species are not subject to a bag limit: petrale sole, Pacific sanddab and starry flounder.]For groundfish species not specifically mentioned in this paragraph, fishers are subject to the overall 20–fish bag limit for all species of finfish and the depth restrictions at paragraph (c)(3)(i) of this section. Recreational spearfishing for all federally-managed groundfish, except lingcod during January, February, March, and December, is exempt from closed areas and seasons, consistent with Title 14 of the California Code of Regulations. This exemption applies only to recreational vessels and divers provided no other fishing gear, except spearfishing gear, is on board the vessel. California state law may provide regulations similar to Federal regulations for the following state-managed species: ocean whitefish, California sheephead, and all greenlings of the genus Hexagrammos. Kelp greenling is the only federally-managed greenling .Retention of cowcod, yelloweye rockfish, and canary rockfish is prohibited in the recreational fishery seaward of California all year in all areas. For each person engaged in recreational fishing in the EEZ seaward of California, the following closed areas, seasons, bag limits, and size limits apply:

(i) Recreational Groundfish Conservation Areas off California. A Groundfish Conservation Area (GCA), a type of closed area, is a geographic area defined by coordinates expressed in degrees latitude and longitude. The following GCAs apply to participants in California's recreational fishery.

(A) Recreational Rockfish Conservation Areas. The recreational RCAs are areas that are closed to recreational fishing for groundfish. Fishing for groundfish with recreational gear is prohibited within the recreational RCA, except that recreational fishing for "other flatfish" is permitted within the recreational RCA as specified in paragraph (c)(3)(iv) of this section. It is unlawful to take and retain, possess, or land groundfish taken with recreational gear within the recreational RCA, unless otherwise authorized in this section. A vessel fishing in the recreational RCA may not be in possession of any species prohibited by the restrictions that apply within the recreational RCA. [For example, if a vessel participates in the recreational salmon fishery within the RCA, the vessel cannot be in possession of rockfish while in the RCA. The vessel may, however, on the same trip fish for and retain rockfish shoreward of the RCA on the return trip to port.]

(1) Between 42° N. lat. (California/Oregon border) and 40°10.00' N. lat. (North Region), recreational fishing for all groundfish (except "other flatfish" as specified in paragraph (c)(3)(iv) of this section) is prohibited seaward of the 20-fm (37-m) depth contour along the mainland coast and along islands and offshore seamounts from May 15 through September 15; and is closed entirely from January 1 through May 14 and from September 16 through December 31 (i.e., prohibited seaward of the shoreline).

(2) Between 40°10' N. lat. and 38°57.50' N. lat. (North-Central North of Point Arena Region), recreational fishing for all groundfish (except "other flatfish" as specified in paragraph (c)(3)(iv) of this section) is prohibited seaward of the 20-fm (37-m) depth contour along the mainland coast and along islands and offshore seamounts from May 15 through August 15; and is closed entirely from January 1 through May 14 and from August 16 through December 31 (i.e. , prohibited seaward of the shoreline).

(3) Between 38°57.50' N. lat. and 37°11' N. lat. (North-Central South of Point Arena Region), recreational fishing for all groundfish (except "other flatfish" as specified in paragraph (c)(3)(iv) of this section) is prohibited seaward of the boundary line approximating the 30-fm (55-m) depth contour along the mainland coast and along islands and offshore seamounts from June 13 through October 31; and is closed entirely from January 1 through June 12 and from November 1 through December 31 (i.e. , prohibited seaward of the shoreline). Closures around the Farallon Islands (see paragraph (c)(3)(i)(C) of this section) and Cordell Banks (see paragraph (c)(3)(i)(D) of this section) also apply in this area. Coordinates for the boundary line approximating the 30-fm (55-m) depth contour are listed in §660.391.

(4) Between 37°11' N. lat. and 36° N. lat. (Monterey South-Central Region), recreational fishing for all groundfish (except "other flatfish" as specified in paragraph (c)(3)(iv) of this section) is prohibited seaward of a boundary line approximating the 40-fm (73-m) depth contour along the mainland coast and along islands and offshore seamounts from May 1 through November 15; and is closed entirely from January 1 through April 30 and from November 16 through December 31 (i.e. , prohibited seaward of the shoreline). Coordinates for the boundary line approximating the 40-fm (73-m) depth contour are specified in §660.391.

(5) Between 36° N. lat. and 34°27' N. lat. (Morro Bay South-Central Region), recreational fishing for all groundfish (except "other flatfish" as specified in paragraph (c)(3)(iv) of this section) is prohibited seaward of a boundary line approximating the 40-fm (73-m) depth contour along the mainland coast and along islands and offshore seamounts from May 1 through November 15; and is closed entirely from January 1 through April 30 and from November 16 through December 31 (i.e., prohibited seaward of the shoreline). Coordinates for the boundary line approximating the 40-fm (73-m) depth contour are specified in §660.391.

(6) South of 34°27' N. latitude (South Region), recreational fishing for all groundfish (except California scorpionfish as specified below in this paragraph and in paragraph (v) of this section and "other flatfish" as specified in paragraph (c)(3)(iv) of this section) is prohibited seaward of a boundary line approximating the 60-fm (110-m) depth contour from March 1 through December 31 along the mainland coast and along islands and offshore seamounts, except in the CCAs where fishing is prohibited seaward of the 20-fm (37-m) depth contour when the fishing season is open (see paragraph (c)(3)(i)(B) of this

section). Recreational fishing for all groundfish (except California scorpionfish and "other flatfish") is closed entirely from January 1 through February 28 (i.e., prohibited seaward of the shoreline). Recreational fishing for California scorpionfish south of 34°27' N. lat. is prohibited seaward of a boundary line approximating the 40-fm (73-m) depth contour from January 1 through February 28, and seaward of the 60-fm (110-m) depth contour from March 1 through December 31, except in the CCAs where fishing is prohibited seaward of the 20-fm (37-m) depth contour when the fishing season is open. Coordinates for the boundary line approximating the 40-fm (73-m) and 60-fm (110-m) depth contours are specified in §§660.391 and 660.392.

(B) Cowcod Conservation Areas. The latitude and longitude coordinates of the Cowcod Conservation Areas (CCAs) boundaries are specified at §660.390. In general, recreational fishing for all groundfish is prohibited within the CCAs, except that fishing for "other flatfish" is permitted within the CCAs as specified in paragraph (c)(3)(iv) of this section. However, recreational fishing for the following species is permitted shoreward of the 20 fm (37 m) depth contour when the season for those species is open south of 34°27' N. lat.: Minor nearshore rockfish, cabezon, kelp greenling, lingcod, California scorpionfish, and "other flatfish" (subject to gear requirements at paragraph (c)(3)(iv) of this section during January–February). [NOTE:California state regulations also permit recreational fishing for California sheephead, ocean whitefish, and all greenlings of the genus Hexagrammos shoreward of the 20 fm (37 m) depth contour in the CCAs when the season for the RCG complex is open south of 34°27' N. lat.] It is unlawful to take and retain, possess, or land groundfish within the CCAs, except for species authorized in this section.

(C) Farallon Islands. Under California state law, recreational fishing for groundfish is prohibited between the shoreline and the 10–fm (18–m) depth contour around the Farallon Islands, except that recreational fishing for "other flatfish" is permitted around the Farallon Islands as specified in paragraph (c)(3)(iv) of this section. (Note: California state regulations also prohibit the retention of other greenlings of the genus Hexagrammos, California sheephead and ocean whitefish.) For a definition of the Farallon Islands, see §660.390.

(D) Cordell Banks. Recreational fishing for groundfish is prohibited in waters less than 100 fm (183 m) around Cordell Banks as defined by specific latitude and longitude coordinates at §660.390, except that recreational fishing for "other flatfish" is permitted around Cordell Banks as specified in paragraph (c)(3)(iv) of this section. [Note: California state regulations also prohibit fishing for all greenlings of the genus Hexagrammos , California sheephead and ocean whitefish.]

(E) Point St. George Yelloweye Rockfish Conservation Area (YRCA). Recreational fishing for groundfish is prohibited within the Point St. George YRCA, as defined by latitude and longitude coordinates at §660.390, on dates when the closure is in effect. The closure is not in effect at this time, and recreational fishing for groundfish is open within the Point St. George YRCA from January 1 through December 31. This closure may be imposed through inseason adjustment.

(F) South Reef YRCA. Recreational fishing for groundfish is prohibited within the South Reef YRCA, as defined by latitude and longitude coordinates at §660.390, on dates when the closure is in effect. The

closure is not in effect at this time, and recreational fishing for groundfish is open within the South Reef YRCA from January 1 through December 31. This closure may be imposed through inseason adjustment.

(G) Reading Rock YRCA. Recreational fishing for groundfish is prohibited within the Reading Rock YRCA, as defined by latitude and longitude coordinates at §660.390, on dates when the closure is in effect. The closure is not in effect at this time, and recreational fishing for groundfish is open within the Reading Rock YRCA from January 1 through December 31. This closure may be imposed through inseason adjustment.

(H) Point Delgada (North) YRCA. Recreational fishing for groundfish is prohibited within the Point Delgada (North) YRCA, as defined by latitude and longitude coordinates at §660.390, on dates when the closure is in effect. The closure is not in effect at this time, and recreational fishing for groundfish is open within the Point Delgada (North) YRCA from January 1 through December 31. This closure may be imposed through inseason adjustment.

(I) Point Delgada (South) YRCA. Recreational fishing for groundfish is prohibited within the Point Delgada (South) YRCA, as defined by latitude and longitude coordinates at §660.390, on dates when the closure is in effect. The closure is not in effect at this time, and recreational fishing for groundfish is open within the Point Delgada (South) YRCA from January 1 through December 31. This closure may be imposed through inseason adjustment.

(J) Essential Fish Habitat Conservation Areas. The Essential Fish Habitat Conservation Areas (EFHCAs) are closed areas, defined by specific latitude and longitude coordinates at §§660.396 through 660.399, where specified types of fishing are prohibited. Prohibitions applying to specific EFHCAs are found at §660.306.

(ii) RCG Complex. The California rockfish, cabezon, greenling complex (RCG Complex), as defined in state regulations (Section 1.91, Title 14, California Code of Regulations), includes all rockfish, kelp greenling, rock greenling, and cabezon. This category does not include California scorpionfish, also known as "sculpin.

(A) Seasons. When recreational fishing for the RCG Complex is open, it is permitted only outside of the recreational RCAs described in paragraph (c)(3)(i) of this section.

(1) Between 42° N. lat. (California/Oregon border) and 40°10' N. lat. (North Region), recreational fishing for the RCG complex is open from May 15 through September 15 (i.e. it's closed from January 1 through May 14 and from September 16 through December 31).

(2) Between 40°10' N. lat. and 38°57.50' N. lat. (North Central North of Point Arena Region), recreational fishing for the RCG Complex is open from May 15 through August 15 (i.e. it's closed from January 1 through May 14 and May 16 through December 31).

(3) Between 38°57.50' N. lat. and 37°11' N. lat. (North Central South of Point Arena Region), recreational fishing for the RCG Complex is open from June 13 through October 31 (i.e. it's closed from January 1 through June 12 and November 1 through December 31.

(4) Between 37°11' N. lat. and 36° N. lat. (Monterey South-Central Region), recreational fishing for the RCG Complex is open from May 1 through November 15 (i.e. it's closed from January 1 through April 30 and from November 16 through December 31).

(5) Between 36' N. lat. and 34°27' N. lat. (Morro Bay South-Central Region), recreational fishing for the RCG Complex is open from May 1 through November 15 (i.e. it's closed from January 1 through April 30 and from November 16 through December 31).

(6) South of 34°27' N. latitude (South Region), recreational fishing for the RCG Complex is open from March 1 through December 31 (i.e. it's closed from January 1 through February 28.

(B) Bag limits, hook limits. In times and areas when the recreational season for the RCG Complex is open, there is a limit of 2 hooks and 1 line when fishing for rockfish. The bag limit is 10 RCG Complex fish per day coastwide. Retention of canary rockfish, yelloweye rockfish, bronzespotted and cowcod is prohibited. Within the 10 RCG Complex fish per day limit, no more than 2 may be bocaccio, no more than 2 may be greenling (kelp and/or other greenlings) and no more than 2 may be cabezon. Multi-day limits are authorized by a valid permit issued by California and must not exceed the daily limit multiplied by the number of days in the fishing trip.

(C) Size limits. The following size limits apply: bocaccio may be no smaller than 10 in (25 cm) total length; cabezon may be no smaller than 15 in (38 cm) total length; and kelp and other greenling may be no smaller than 12 in (30 cm) total length.

(D) Dressing/Fileting. Cabezon, kelp greenling, and rock greenling taken in the recreational fishery may not be fileted at sea. Rockfish skin may not be removed when fileting or otherwise dressing rockfish taken in the recreational fishery. The following rockfish filet size limits apply: bocaccio filets may be no smaller than 5 in (12.8 cm) and brown-skinned rockfish fillets may be no smaller than 6.5 in (16.6 cm). "Brown-skinned" rockfish include the following species: brown, calico, copper, gopher, kelp, olive, speckled, squarespot, and yellowtail.

(iii) Lingcod —(A) Seasons. When recreational fishing for lingcod is open, it is permitted only outside of the recreational RCAs described in paragraph (c)(3)(i) of this section.

(1) Between 42° N. lat. (California/Oregon border) and 40°10.00' N. lat. (North Region), recreational fishing for lingcod is open from May 15 through September 15 (i.e. it's closed from January 1 through May 14 and from September 16 through December 31).

(2) Between 40°10' N. lat. and 38°57.50' N. lat. (North Central North of Point Arena Region), recreational fishing for lingcod is open from May 15 through August 15 (i.e. it's closed from January 1 through May 14 and May 16 through December 31).

(3) Between 38°57.50' N. lat. and 37°11' N. lat. (North Central South of Point Arena Region), recreational fishing for lingcod is open from June 13 through October 31 (i.e. it's closed from January 1 through June 12 and November 1 through December 31.

(4) Between 37°11' N. lat. and 36° N. lat. (Monterey South-Central Region), recreational fishing for lingcod is open from May 1 through November 15 (i.e. it's closed from January 1 through April 30 and from November 16 through December 31).

(5) Between 36' N. lat. and 34°27' N. lat. (Morro Bay South-Central Region), recreational fishing for lingcod is open from May 1 through November 15 (i.e. it's closed from January 1 through April 30 and from November 16 through December 31).

(6) South of 34°27' N. latitude (South Region), recreational fishing for lingcod is open from April 1 through November 30 (i.e. it's closed from January 1 through March 31 and from December 1 through 31).

(B) Bag limits, hook limits. In times and areas when the recreational season for lingcod is open, there is a limit of 2 hooks and 1 line when fishing for lingcod. The bag limit is 2 lingcod per day. Multi-day limits are authorized by a valid permit issued by California and must not exceed the daily limit multiplied by the number of days in the fishing trip.

(C) Size limits. Lingcod may be no smaller than 24 in (61 cm) total length.

(D) Dressing/Filleting. Lingcod filets may be no smaller than 16 in (41 cm) in length.

(iv) "Other flatfish". Coastwide off California, recreational fishing for "other flatfish" is permitted both shoreward of and within the closed areas described in paragraph (c)(3)(i) of this section. "Other flatfish" are defined at §660.302 and include butter sole, curlfin sole, flathead sole, Pacific sanddab, rex sole, rock sole, and sand sole. Recreational fishing for "other flatfish" is permitted within the closed areas. "Other flatfish," except Pacific sanddab, are subject to the overall 20-fish bag limit for all species of finfish, of which there may be no more than 10 fish of any one species. There is no season restriction or size limit for "other flatfish;" however, it is prohibited to filet "other flatfish" at sea.

(v) California scorpionfish. California scorpionfish predominately occur south of 40°10' N. lat.

(A) Seasons. When recreational fishing for California scorpionfish is open, it is permitted only outside of the recreational RCAs described in paragraph (c)(3)(i) of this section.

(1) Between 40°10' N. lat. and 37°11' N. lat. (North Central Region), recreational fishing for California scorpionfish is open from June 1 through November 30 (i.e., it's closed from January 1 through May 31 and from December 1 through December 31).

(2) Between 37°11' N. lat. and 36° N. lat. (Monterey South Central Region), recreational fishing for California scorpionfish is open from May 1 through November 30 (i.e., it's closed from January 1 through April 30 and from December 1 through December 31).

(3) Between 36° N. lat. and 34°27' N. lat. (Morro Bay South Central Region), recreational fishing for California scorpionfish is open from May 1 through November 30 (i.e., it's closed from January 1 through April 30 and from December 1 through December 31).

(4) South of 34°27' N. lat. (South Region), recreational fishing for California scorpionfish is open from January 1 through December 31.

(B) Bag limits, hook limits. South of 40°10.00' N. lat., in times and areas where the recreational season for California scorpionfish is open, the bag limit is 5 California scorpionfish per day. California scorpionfish do not count against the 10 RCG Complex fish per day limit. Multi-day limits are authorized by a valid permit issued by California and must not exceed the daily limit multiplied by the number of days in the fishing trip.

(C) Size limits. California scorpionfish may be no smaller than 10 in (25 cm) total length.

(D) Dressing/Fileting. California scorpionfish filets may be no smaller than 5 in (12.8 cm) and must bear an intact 1 in (2.6 cm) square patch of skin.

GROUNDFISH ADVISORY SUBPANEL REPORT ON INSEASON ADJUSTMENTS TO 2009 AND 2010 GROUNDFISH FISHERIES – PART I

The Groundfish Advisory Subpanel (GAP) received a presentation on inseason adjustments from Mr. Rob Jones and the Groundfish Management Team (GMT) and has the following recommendations:

1) Eliminate the daily-trip-limit in the limited entry fixed gear (LEFG) sablefish fishery North of 36° N latitude for the remainder of the year. The daily-trip-limit leads to increased regulatory discards and limited trip viability.
2) Increase the weekly limit in the LEFG sablefish fishery north of 36° from 1500 lbs. / week to 2000 lbs. / week. The rationale is that under the current weekly limit the optimum yield (OY) will not be attained and fish will be left on the table. Under the proposed limit there is a greater likelihood that the full OY or something close to it might be achieved.
3) Increase the bimonthly limit in the LEFG sablefish fishery north of 36° from 6000 lbs. / 2 months to 8000 lbs. / 2 months. This change would provide greater opportunity to the fleet without the risk of exceeding the OY because there is only one period left in the year and many of the participants in the fishery are likely to begin fishing for crab, thereby reducing overall sablefish effort.
4) Do away with the daily-trip-limit for LEFG sablefish south of 36° and increase the weekly limit to a cumulative limit of 3000 lbs. / week. This change will reduce regulatory discards and provide more economic opportunity for a fishery that is currently unlikely to reach the OY. The GMT's preliminary proposal suggested changing the weekly limit to one landing of 3000 lbs. / week which might disadvantage small boats that are unable to carry that much fish.
5) Increase the open access trip limits for sablefish south of 36° to 2500 lbs. / week with no daily or bimonthly limit for the remainder of the year. The current limits are 400 lbs. / day 1500 lbs. / week and 8000 lbs. / 2 months.
6) Subject to the availability of canary rockfish in the scorecard, increase the limited entry and open access rockfish trip limits south of 40°10' north to 800 lbs. / 2 months for the remainder of the year. The current limit is 600 lbs. / 2 months.
7) Adopt option 1 of the proposed specifications for sablefish and petrale sole for the remainder of the year. The GAP also believes that closing the petrale cutouts will free up Pacific ocean perch and darkblotched in the scorecard which could provide additional opportunity for lingcod, arrowtooth, and slope rockfish. Those opportunities should be analyzed.

PFMC
09/15/09

requirements of Executive Order 13175, entitled *Consultation and Coordination with Indian Tribal Governments* (65 FR 67249, November 6, 2000), do not apply to this proposed rule.

G. Executive Order 13045: Protection of Children from Environmental Health Risks and Safety Risks

This action is not subject to Executive Order 13045, entitled *Protection of Children from Environmental Health Risks and Safety Risks* (62 FR 19885, April 23, 1997), because this is not an economically significant regulatory action as defined by Executive Order 12866, and this action does not address environmental health or safety risks disproportionately affecting children.

H. Executive Order 13211: Actions that Significantly Affect Energy Supply, Distribution, or Use

This proposed rule is not subject to Executive Order 13211, entitled *Actions Concerning Regulations That Significantly Affect Energy Supply, Distribution, or Use* (66 FR 28355, May 22, 2001), because this action is not expected to affect energy supply, distribution, or use.

I. National Technology Transfer Advancement Act

Since this action does not involve any technical standards; section 12(d) of the National Technology Transfer and Advancement Act of 1995 (NTTAA), Public Law 104–113, section 12(d) (15 U.S.C. 272 note), does not apply to this action.

J. Executive Order 12898: Federal Actions to Address Environmental Justice in Minority Populations and Low-Income Populations

This action does not entail special considerations of environmental justice related issues as delineated by Executive Order 12898, entitled *Federal Actions to Address Environmental Justice in Minority Populations and Low-Income Populations* (59 FR 7629, February 16, 1994).

List of Subjects in 40 CFR Part 721

Environmental protection, Chemicals, Hazardous substances, Reporting and recordkeeping requirements

Dated: August 25, 2009.

Wendy C. Hamnett,

Acting Director, Office of Pollution Prevention and Toxics.

Therefore, it is proposed that 40 CFR chapter I be amended as follows:

PART 721—[AMENDED]

■ 1. The authority citation for part 721 continues to read as follows:

Authority: 15 U.S.C. 2604, 2607, 2625(c).

■ 2. Section 721.10068 is amended by revising paragraph (a) and adding a new paragraph (b)(2)(vii) to read as follows:

§ 721.10068 Elemental mercury.

(a) *Definitions.* The definitions in §721.3 apply to this section. In addition, the following definition applies:

(1) *Motor vehicle* has the meaning found at 40 CFR 85.1703.

(2) *Flow meter* means an instrument used in various applications to measure the flow rate of liquids or gases.

(3) *Natural gas manometer* means an instrument used in the natural gas industry to measure gas pressure.

(4) *Pyrometer* means an instrument used in various applications to measure extremely high temperatures.

(b)* * *

(2)* * *

(vii) Manufacturing or processing of elemental mercury for use in flow meters, natural gas manometers, and pyrometers except for use in these articles when they are in service as of September 11, 2009.

* * * * *

DEPARTMENT OF COMMERCE

National Oceanic and Atmospheric Administration

50 CFR Part 660

[Docket No. 0907301200–91202–01]

RIN 0648–AY07

Magnuson-Stevens Act Provisions; Fisheries off West Coast States; Pacific Coast Groundfish Fishery; 2009–2010 Biennial Specifications and Management Measures for Canary Rockfish and Petrale Sole

AGENCY: National Marine Fisheries Service (NMFS), National Oceanic and Atmospheric Administration (NOAA), Commerce.

ACTION: Proposed rule; request for comments.

SUMMARY: NMFS proposes a rule to revise the 2009 management measures for petrale sole and to revise the 2010 harvest specifications and management measures for petrale sole and canary rockfish taken in the U.S. exclusive economic zone (EEZ) off the coasts of Washington, Oregon, and California.

DATES: Comments on this proposed rule must be received no later than 5 p.m., local time on October 13, 2009.

ADDRESSES: You may submit comments, identified by RIN 0648–AY07 by any one of the following methods:

- Electronic Submissions: Submit all electronic public comments via the Federal eRulemaking Portal *http://www.regulations.gov*.
- Fax: 206–526–6736, Attn: Gretchen Arentzen
- Mail: Barry A. Thom, Acting Regional Administrator, Northwest Region, NMFS, 7600 Sand Point Way NE, Seattle, WA 98115–0070, Attn: Gretchen Arentzen.

Instructions: All comments received are a part of the public record and will generally be posted to *http://www.regulations.gov* without change. All Personal Identifying Information (for example, name, address, etc.) voluntarily submitted by the commenter may be publicly accessible. Do not submit Confidential Business Information or otherwise sensitive or protected information.

NMFS will accept anonymous comments (enter N/A in the required fields if you wish to remain anonymous). Attachments to electronic comments will be accepted in Microsoft Word, Excel, WordPerfect, or Adobe PDF file formats only.

Copies of the Draft Environmental Assessment (DEA) prepared for this action is available from the NMFS Northwest Region website at *http://www.nwr.noaa.gov* or from the mailing and street addresses listed above.

FOR FURTHER INFORMATION CONTACT: Gretchen Arentzen (Northwest Region, NMFS), phone: 206–526–6147, fax: 206–526–6736 and e-mail *gretchen.arentzen@noaa.gov*.

SUPPLEMENTARY INFORMATION:

Electronic Access

This proposed rule is accessible via the Internet at the Office of the Federal Register's Website at *http://www.gpoaccess.gov/fr/index.html*. Background information and documents are available at the Pacific Fishery Management Council's website at *http://www.pcouncil.org/*.

Background

The 2009 and 2010 ABCs, OYs and HGs for Pacific coast groundfish species were established in the final rule for the 2009–2010 groundfish harvest specifications and management measures (74 FR 9874, March 6, 2009). This rule proposes interim measures for two species. For petrale sole this action would reduce catches in 2009 by implementing more restrictive management measures, lower the 2010 OY for petrale sole, and implement more restrictive management measures in 2010 to keep projected impacts below the new 2010 OY. For canary rockfish this action would lower the 2010 OY and implement more restrictive 2010 management measures to keep projected impacts below the new 2010 OY. These changes are being proposed because the PFMC received new stock assessments that indicate the stocks are in worse shape than we had thought at the beginning of 2009.

The Council reviewed a new stock assessment for petrale sole in June, considered questions raised by the Stock Assessment and Review Panel (STAR Panel) and the Scientific and Statistical Committee (SSC), and asked the SSC to review the open issues and report back to the Council in September. While there is uncertainty regarding the results of the final stock assessment, it is likely that, under any outcome, the stock will be overfished at the beginning of 2011 if the entire current petrale OYs are taken in 2009 and 2010. In September the Council will consider the updated information and make a final recommendation for the petrale changes in 2009 and 2010, and make its initial recommendations for management for 2011 and beyond. NMFS anticipates implementing a final rule for 2009 and 2010 in October. The canary rockfish assessment was an update of the prior assessment, incorporating revised historic catch data. This assessment concluded that the stock is more depleted than the previous assessment had indicated. The Council approved the new stock assessment, and the assessment authors will develop a rebuilding analysis. The Council will use the results of the rebuilding analysis in November to consider likely revisions to the rebuilding plan for 2011 and beyond and to recommend OY and harvest revisions in 2010. NMFS anticipates implementing the final rule for 2010 in December 2009.

This action is needed to respond to the most recently available stock status information during the remainder of 2009 and in 2010, while NMFS and the Council complete the stock assessments, revised rebuilding plans, EIS, and full rulemaking for the 2011 and 2012 specifications and management measures for the entire groundfish fishery.

The interim measures being proposed in this rule in combination with the existing regulations are designed to prevent the stock status of petrale sole from falling below the overfished threshold at the beginning of 2011, or to speed the rebuilding of petrale sole if it is found to be overfished. These interim measures are also intended to facilitate rebuilding and to ease negative impacts on industry from the anticipated lower 2011–2012 canary rockfish harvest specifications, and more restrictive management measures.

The Council's policies on setting ABCs, OYs, other harvest specifications, and management measures are discussed in the preamble to the December 31, 2008, proposed rule (73 FR 80516) for 2009–2010 harvest specifications and management measures.

Routine management measures, as described in the preamble to the 2009–2010 harvest specifications and management measure proposed rule (73 FR 80516, December 31, 2008), will continue to be adjusted to modify fishing behavior during the fishing year to allow a harvest specification to be achieved, or to prevent a harvest specification from being exceeded.

The following preamble discussion is divided into two parts: harvest specifications and management measures for petrale sole in 2009 and 2010; and harvest specifications and management measures for canary rockfish in 2010.

Harvest Specifications and Management Measures for Petrale Sole in 2009–2010

2004 Petrale Sole Stock Assessment

Petrale sole was last assessed in 2004. The result of that stock assessment was the best available science at the time that the 2007–2008 and the 2009–2010 harvest specifications were developed. For additional discussion of the results of the 2004 petrale sole stock assessment, see the September 29, 2006 proposed rule (71 FR 57764). The 2009–2010 ABCs are based on the 2004 stock assessment which used the default F 40 percent FMSY proxy and the 2009–2010 OYs are derived using the 40–10 harvest policy applied to the ABC for both the northern and southern assessment areas. Also an additional 25 percent reduction was made in the OY contribution for the southern area due to assessment uncertainty, as a precautionary measure. The March 6, 2009 final rule (74 FR 9874) established the 2009 and 2010 coastwide petrale sole harvest specifications, including the OYs of 2,433 mt in 2009 and 2,393 mt in 2010.

2009 Petrale Sole Stock Assessment

A new, full stock assessment for petrale sole was presented to the Council at their June 2009 meeting. The draft assessment indicated the stock is depleted to 11.6 percent of its unfished biomass. If the Bmsy management target remained the same as in the 2004 assessment, at 40 percent of the unfished biomass using the proxy for BMSY, the 2009 stock assessment indicates that petrale sole would be overfished in 2011. However, the stock assessment review panel recommended establishing a management target using the biomass that would support maximum sustainable yield (BMSY) as determined from the assessment (referred to as a directly-estimated Bmsy, as opposed to proxy BMSY). This management target was recommended, rather than the standard proxy BMSY, given that BMSY is well estimated. The Groundfish FMP allows use of a directly-estimated BMSY target and defines the overfished level as no less than 50 percent of the directly-estimated BMSY. The draft assessment estimates the stock spawning biomass is at 61 percent of the directly-estimated BMSY and therefore may not be overfished under a directly-estimated BMSY target.

The Council's Scientific and Statistical Committee (SSC) did not recommend the petrale sole assessment for management decision-making at their June 2009 meeting, but will review it further during summer 2009, and it will be presented for final adoption at the Council's September 2009 meeting. The SSC will also further explore the use of a deterministic BMSY target for the stock when they meet this summer. While the petrale sole assessment is not yet adopted for use in making management decisions, projections from the draft assessment indicate that stock spawning biomass will be driven to a lower level of depletion if the entire 2009 and 2010 OYs are taken. If the entire current 2009 and 2010 OYs are taken, by 2011 the spawning biomass is projected to decline to less than 50 percent of directy-estimated BMSY in this case, which is an overfished state even under a deterministic BMSY target.

Changes to Petrale Sole Harvest Specifications

At their June 2009 meeting, the Council identified a point of concern under FMP section 6.2.2 and recommended that NMFS take action to reduce harvest of petrale sole in 2009 and 2010 in response to the preliminary results of the new 2009 stock assessment. The primary purpose of this recommendation is to prevent the status of the petrale sole stock from falling below the overfished threshold at the start of 2011.

In June 2009, the Groundfish Management Team (GMT), an advisory body to the Council, prepared a preliminary analysis of a range of petrale sole harvest levels for Council consideration. This analysis examined how different levels of petrale sole harvest in 2009 and 2010 affected the petrale sole stock status at the beginning of 2011, under the base case model in the preliminary 2009 petrale sole stock assessment. Based on the results of the GMTs preliminary analysis, the Council chose a preliminary preferred alternative to reduce the existing 2010 petrale sole coastwide OY by 1,200 mt. This action proposes to establish a new 2010 petrale sole coastwide OY of 1,193 mt (Table 2a).

Though this action does not propose a change in harvest specifications for petrale sole in 2009, it does propose changes to management measures in order to reduce projected mortality of petrale sole in 2009 by approximately 400 mt. Implementing management measures that reduce petrale sole catch in 2009, when combined with reductions in the petrale sole OY for 2010 (and concurrent changes to management measures), results in an increase from 9 percent unfished biomass to 13 percent unfished biomass and from 48 percent to 68 percent of the directy-estimated BMSY under the base case model in the preliminary 2009 stock assessment.

Based on the analysis presented above, the Council recommended and NMFS is proposing the following changes to petrale sole harvest specifications: reducing the 2010 petrale sole coastwide OY of 2,393 mt by 1,200 mt, resulting in a new 2010 coastwide petrale sole OY of 1,193 mt. This proposed change is listed in Table 2a to 50 CFR 660, Subpart G.

Changes to Management Measures Affecting Petrale Sole

Petrale sole is almost exclusively caught in the limited entry non-whiting commercial trawl fishery. Therefore, proposed changes to management measures are only considered in the limited entry non-whiting trawl fishery. The Council recommended preliminary preferred alternative management measures for November-December 2009 and for January-December 2010 to reduce projected catch of petrale sole by approximately 400 mt in 2009 and to prevent projected mortality of petrale sole from exceeding the preliminary preferred 2010 petrale sole OY. In order to reduce projected catches of petrale sole in 2009 and 2010 this proposed rule adjusts management measures that are routinely adjusted during the year to respond to updated fishery information, as described at § 660.370, and does not impose any new management measures. The Council's preliminary preferred alternative management measures result in approximately 1,995 mt projected catch of petrale sole in 2009 and approximately 1,178 mt projected catch of petrale sole in 2010. Changes to management measures include adjusting the seaward boundary of the trawl RCA coastwide and reducing petrale sole cumulative trip limits and/or sub-limits for all trawl gears coastwide.

Based on the need to reduce catches in 2009 and 2010 to prevent petrale sole stock status from falling below the overfished threshold at the beginning of 2011, the Council recommended and NMFS is proposing changes to management measures in November-December 2009 and for all of 2010. For November-December (Period 6) 2009, the Council recommended and NMFS is proposing the following: shifting the seaward boundary of the trawl RCA to a boundary line approximating the 200–fm (366–m) depth contour North of 40 10' N. lat.; and reducing petrale sole cumulative trip limits and/or sub-limits to 2,000 lb (907 kg) per two months for vessels using all limited entry trawl gear types, coastwide. These proposed 2009 changes are shown in 2009 tables 3 (North) and 3 (South). For 2010, the Council recommended and NMFS is proposing the following: shifting the seaward boundary of the trawl RCA to a boundary line approximating the 200–fm (366–m) depth contour from January-April (Periods 1 and 2) and September-December (Periods 5 and 6) North of 40 10' N. lat.; shifting the seaward boundary of the trawl RCA to a boundary line approximating the 200–fm (366–m) depth contour from January-December South of 40 10' N. lat.; reducing petrale sole cumulative trip limits and/or sub-limits to 1,000 lb (454 kg) per two months for vessels using all limited entry trawl gear types, coastwide, during January-February (Period 1) and November-December (Period 6); reducing petrale sole sub-limits to 18,000 lb (8,165 kg) per two months for vessels using all limited entry trawl gear types, coastwide, from March-October (Periods 2 through 5). These proposed changes to 2010 trip limits are shown in 2010 Tables 3 (North) and 3 (South).

Harvest Specifications and Management Measures for Canary Rockfish in 2010

2007 Canary Rockfish Stock Assessment

Canary rockfish was last assessed in 2007. The results of that stock assessment and rebuilding analysis were the basis for the 2009–2010 harvest specifications, and represented the best available science at that time. For additional discussion of the results of the 2007 canary rockfish stock assessment, see the December 31, 2008 proposed rule, 73 FR 80516. The 2009–2010 harvest specifications and revisions to the rebuilding plan for canary rockfish were established on March 1, 2009. The approach used for setting the 2009–2010 harvest specifications for canary rockfish was the same as that used for setting the 2007–2008 harvest specifications under FMP Amendment 16–4. The 2007 stock assessment fundamentally changed the understanding of stock productivity. The SSC, therefore, recommended changing the Am. 16–4 rebuilding plan. In the rebuilding plan, the Council revised the target rebuilding year from 2063 to 2021 (which was two years longer than F0), but maintained the existing SPR of 88.7%. Nonetheless, the adopted OY for 2009 and 2010 of 105 mt was based on a more conservative SPR of 92.2%. The March 6, 2009 final rule (74 FR 9874) established the 2009 and 2010 coastwide canary rockfish harvest specifications, including the OYs of 105 mt in 2009 and 2010.

2009 Canary Rockfish Stock Assessment

An updated stock assessment for canary rockfish was presented to the Council at their June 2009 meeting. The stock assessment indicated the canary rockfish stock is depleted to 23.7 percent of its unfished biomass, compared with a 32.4 percent depletion in 2007. The stock is increasing, but based on the new information in the new stock assessment, the rebuilding plan will need to be revised, and it is anticipated that lower OYs will be required. The Council's SSC recommended the canary rockfish assessment for management decision-making at their June 2009 meeting. At the November Council meeting the PFMC will receive the rebuilding analysis for canary rockfish based on the 2009 stock assessment, for use in the 2011–2012 specifications process. At that time the Council will also decide whether to recommend a revision to the 2010 canary rockfish OY in order to smooth the transition to the revised rebuilding plan and to facilitate rebuilding.

Changes to 2010 Canary Rockfish OY

At their June 2009 meeting, the Council recommended that NMFS take action to reduce catches of canary rockfish in 2010 in response to the results of the new 2009 stock assessment update. The primary purpose of taking precautionary measures is to facilitate rebuilding of canary rockfish, and to reduce the socioeconomic impacts of a sudden reduction in harvest specifications that will likely be implemented in 2011. Under the FMP, harvest specifications for species subject to rebuilding requirements may be modified during the biennium if the Council determines they are not adequately conservative to meet rebuilding plan goals. FMP Section 5.5.1

Canary rockfish is currently overfished and subject to a rebuilding plan. The results of the new rebuilding analysis, that will be based on the new stock assessment update, are scheduled to be presented to the Council at their October 31–November 5, 2009, meeting. At that time, while the Council is considering revisions to the rebuilding plan for 2011 and beyond, they will also consider whether changes should be made in 2010 for the reasons explained above.

Based on the need to first consider the new rebuilding analysis for 2011–2012 OYs, the Council has not chosen a preferred canary rockfish OY alternative for 2010. Therefore, a range of OYs between 44 mt and 105 mt is proposed in Table 2a of this proposed rule. No changes to catch apportionment of the new 2010 OY are proposed at this time; however, the Council may consider changes to canary rockfish catch apportionment at their September or November 2009 meetings. A final preferred alternative for canary rockfish OY in 2010 will be considered in a supplement to the EA. Changes to 2010 canary rockfish harvest specifications would be implemented in a separate final rule, after the November 2009 Council meeting. Any revisions are anticipated to be in effect on January 1, 2010.

Changes to Management Measures Affecting Canary Rockfish

Canary rockfish are caught incidentally in almost every sector of the Pacific Coast groundfish fishery, North of 34° 27' N. lat. To reduce projected catch of canary rockfish below a lower 2010 OY would likely require that additional restrictions be placed on the following fisheries: limited entry non-whiting trawl; limited entry non-tribal whiting trawl; Washington, Oregon, and northern California recreational groundfish; and nearshore commercial non-trawl. The types of potential management changes include, but are not limited to: expansion of the trawl RCA to close areas with high canary bycatch for all or part of the year; expansion of the non-trawl RCA to close areas with high canary bycatch for all or part of the year; reductions in trip limits for co-occurring shelf species in both the LE trawl fishery and in the LE fixed gear fishery and open access commercial fishery; reductions in trip limits for vessels using selective flatfish trawl gear; reductions in recreational fishery season length; closures of recreational fisheries in some areas of the coast for a portion of the year; reduction in recreational bag limits for rockfish or other co-occurring species; a reduction in the bycatch limit for canary rockfish in the LE non-tribal whiting fishery; and the non-whiting Exempted Fishing Permits (EFPs) may also be restricted or terminated in 2010 to reduce their projected catch of canary rockfish (approximately 2.7 mt).

At their November 2009 meeting where the Council will consider potential changes to the 2010 OY, the Council will consider a wide range of routine management measure alternatives for reducing projected catches of canary rockfish to stay within the new OY. Consideration of new rebuilding information and potential changes to routine management measures will allow the Council to recommend interim measures that would reduce canary rockfish impacts in 2010. A final preferred alternative for canary rockfish management measures in 2010 will be considered in a supplement to the EA. Changes to management measures to reduce projected catch of canary rockfish will be implemented in a separate final rule, after the November 2009 Council meeting. These management measures are anticipated to be in effect on January 1, 2010.

Classification

At this time, NMFS has preliminarily determined that the revisions to 2009–2010 harvest specifications and management measures for canary rockfish and petrale sole proposed in this rule are consistent with the national standards of the Magnuson-Stevens Act and other applicable laws. NMFS, in making the final determination, will take into account the data, views, and comments received during the comment period.

A DEA was prepared for the revisions to the 2009–2010 harvest specifications and management measures for petrale sole and canary rockfish. A copy of the DEA is available online at *http://www.nwr.noaa.gov/*.

The Council considered two sets of alternatives for revising the 2009–2010 harvest specifications and management measures for petrale sole and canary rockfish. The first set of alternatives considered more restrictive management measures to reduce catch of petrale sole in 2009 and new harvest specifications for petrale sole in 2010 and management measures necessary to keep projected impacts to petrale sole below the new 2010 OY. The second set of alternatives considered new harvest specifications for canary rockfish in 2010 and a range of management measures necessary to keep projected impacts to canary rockfish below the alternative 2010 OYs.

The range of management measure alternatives intended to keep total catch of canary at the low end of the ABC/OY alternatives are considered here, since these were the alternatives the Council evaluated in the 2009 and 2010 rulemaking for their effects on small entities.

NMFS has initially determined that this proposed rule is not significant for purposes of Executive Order 12866.

An IRFA was prepared, as required by section 603 of the Regulatory Flexibility Act (RFA). The IRFA describes the economic impact this proposed rule, if adopted, would have on small entities. A summary of the analysis follows. A copy of this analysis is available from NMFS (see ADDRESSES).

The Small Business Administration has established size criteria for all major industry sectors in the US including fish harvesting and fish processing businesses. The RFA recognizes and defines three kinds of small entities: small businesses, small organizations, and small governmental jurisdictions.

Most permit owners and vessel owners are independent fishermen who are owner/operators of their vessel or members of family owned businesses or members of small partnerships. As such, they are considered to be a small business. Because canary rockfish is taken as bycatch in most groundfish fisheries the description of small entities associated with the 2009 EIS (73 FR 80516) is applicable. The Council estimates that nearly 2,600 small entities harvest groundfish. These entities include those that either target groundfish or harvest groundfish as bycatch and include limited entry trawlers and fixed gear, open access participants, the west coast charterboat fleet, and the tribal fleets. Included in this estimate are businesses, probably fewer than 30, that should be classified as ''large'' businesses as they are affiliates or components of large processing companies. Following past practice, the Council classifies the four catcher-processors that fish and process in the whiting fishery ''large'' entities as they are components of large international seafood companies. Noting the exceptions above, the Council has classified all harvesters in the groundfish fishery as ''small businesses.''

In summary, using Small Business Administration standards, most of the estimated 2,600 entities that harvest groundfish are small businesses. The exceptions are the catcher vessels who also fish off Alaska, some shoreside processors, and all catcher-processors and motherships (less than 30) that are affiliated with larger processing companies or large international seafood companies.

Under the no action petrale sole alternative, groundfish revenues by the non-whiting trawl fleet would be about $28 million in 2009 and in 2010. Under the Council's preferred alternative (P2), the 139 vessels in this fishery would collectively earn $27 million in 2009 and $26 million in 2010. Between 30 and 35 of these vessels would see their revenues fall by more than 5 percent.

By reducing the 2009 petrale sole harvest and the 2010 petrale sole OY, we may prevent petrale sole from being in an overfished status in 2011, or speed the rebuilding of petrale if it is found to be overfished. By reducing the 2010 canary OY we may facilitate rebuilding of canary rockfish and ease the negative impact on industry from the reduced canary rockfish harvest specifications that will likely result in 2011–2012 from the new stock assessment and rebuilding analysis.

There are no reporting, recordkeeping or other compliance requirements in the proposed rule.

No Federal rules have been identified that duplicate, overlap, or conflict with this action.

NMFS issued Biological Opinions under the ESA on August 10,1990, November 26,1991, August 28,1992, September 27,1993, May 14, 1996, and December 15, 1999 pertaining to the effects of the Pacific Coast groundfish FMP fisheries on Chinook salmon (Puget Sound, Snake River spring/summer, Snake River fall, upper Columbia River spring, lower Columbia River, upper Willamette River, Sacramento River winter, Central Valley spring, California coastal), coho salmon (Central California coastal, southern Oregon/northern California coastal), chum salmon (Hood Canal summer, Columbia River), sockeye salmon (Snake River, Ozette Lake), and steelhead (upper, middle and lower Columbia River, Snake River Basin, upper Willamette River, central California coast, California Central Valley, south/central California, northern California, southern California). These biological opinions have concluded that implementation of the FMP for the Pacific Coast groundfish fishery was not expected to jeopardize the continued existence of any endangered or threatened species under the jurisdiction of NMFS, or result in the destruction or adverse modification of critical habitat.

NMFS reinitiated a formal section 7 consultation under the ESA in 2005 for both the Pacific whiting midwater trawl fishery and the groundfish bottom trawl fishery. The December 19, 1999, Biological Opinion had defined an 11,000 Chinook incidental take threshold for the Pacific whiting fishery. During the 2005 Pacific whiting season, the 11,000 fish Chinook incidental take threshold was exceeded, triggering reinitiation. Also in 2005, new data from the West Coast Groundfish Observer Program became available, allowing NMFS to complete an analysis of salmon take in the bottom trawl fishery.

NMFS prepared a Supplemental Biological Opinion dated March 11, 2006, which addressed salmon take in both the Pacific whiting midwater trawl and groundfish bottom trawl fisheries. In its 2006 Supplemental Biological Opinion, NMFS concluded that catch rates of salmon in the 2005 whiting fishery were consistent with expectations considered during prior consultations. Chinook bycatch has averaged about 7,300 fish over the last 15 years and has only occasionally exceeded the reinitiation trigger of 11,000 fish.

Since 1999, annual Chinook bycatch has averaged about 8,450 fish. The Chinook ESUs most likely affected by the whiting fishery has generally improved in status since the 1999 section 7 consultation. Although these species remain at risk, as indicated by their ESA listing, NMFS concluded that the higher observed bycatch in 2005 does not require a reconsideration of its prior ''no jeopardy'' conclusion with respect to the fishery. For the groundfish bottom trawl fishery, NMFS concluded that incidental take in the groundfish fisheries is within the overall limits articulated in the Incidental Take Statement of the 1999 Biological Opinion. The groundfish bottom trawl limit from that opinion was 9,000 fish annually. NMFS will continue to monitor and collect data to analyze take levels. NMFS also reaffirmed its prior determination that implementation of the Groundfish FMP is not likely to jeopardize the continued existence of any of the affected ESUs.

Lower Columbia River coho (70 FR 37160, June 28, 2005) were recently listed and Oregon Coastal coho (73 FR 7816, February 11, 2008) were recently relisted as threatened under the ESA. The 1999 biological opinion concluded that the bycatch of salmonids in the Pacific whiting fishery were almost entirely Chinook salmon, with little or no bycatch of coho, chum, sockeye, and steelhead. The Southern Distinct Population Segment (DPS) of green sturgeon (71 FR 17757, April 7, 2006) were also recently listed as threatened under the ESA. As a consequence, NMFS has reinitiated its Section 7 consultation on the PFMC's Groundfish FMP.

After reviewing the available information, NMFS concluded that, in keeping with Sections 7(a) (2) and 7(d) of the ESA, the proposed action would not result in any irreversible or irretrievable commitment of resources that would have the effect of foreclosing the formulation or implementation of any reasonable and prudent alternative measures.

With regards to marine mammals, sea turtles, and seabirds, we are reviewing the available data on fishery interactions and have entered into pre-consultation with the United States Fish and Wildlife Service, NMFS and other Federal agencies. In additions, we have begun discussions with Council staff on the process to address the concerns, if any, that arise from our review of the data.

Pursuant to Executive Order 13175, this proposed rule was developed after meaningful consultation and collaboration with tribal officials from the area covered by the FMP. Under the Magnuson-Stevens Act at 16 U.S.C. 1852(b)(5), one of the voting members of the Pacific Council must be a representative of an Indian tribe with federally recognized fishing rights from the area of the Council's jurisdiction.

List of Subjects in 50 CFR Part 660

Fisheries, Fishing, Indian Fisheries.

Dated: September 8, 2009.

Samuel D. Rauch III,

Deputy Assistant Administrator for Regulatory Programs, National Marine Fisheries Service.

For the reasons set out in the preamble, 50 CFR part 660 is proposed to be amended as follows:

PART 660—FISHERIES OFF WEST COAST STATES

1. The authority citation for part 660 continues to read as follows:

Authority: 16 U.S.C. 1801 *et seq.* and 16 U.S.C. 773 *et seq.*

2. Tables 2a and 2c to part 660, subpart G, and footnotes ''/k'' and ''/r'' are revised to read as follows:

BILLING CODE 3510–22–S

BILLING CODE 3510–22–C

* * * * *

/k A petrale sole stock assessment was prepared for 2005. In 2005 the petrale sole stock was estimated to be at 32 percent of its unfished biomass coastwide (34 percent in the northern assessment area and 29 percent in the southern assessment area). The 2010 ABC of 2,751 mt is based on the 2005 assessment with a F40% FMSY proxy. To derive the 2010 OY, the 40 10 harvest policy was applied to the ABC for both the northern and southern assessment areas. As a precautionary measure, an additional 25 percent reduction was made in the OY contribution for the southern area due to assessment uncertainty. As another precautionary measure, an additional 1,200 mt reduction was made in the coastwide OY due to preliminary results of the more pessimistic 2009 stock assessment. The coastwide OY is 1,193 mt in 2010.

* * * * *

/r A canary rockfish stock assessment was completed in 2007 and the stock was estimated to be at 32.7 percent of its unfished biomass coastwide in 2007. The coastwide ABC of 940 mt is based on a FMSY proxy of F50%. The OY of 105 mt is based on a rebuilding plan with a target year to rebuild of 2021 and a SPR harvest rate of 88.7 percent. An OY of 44 mt or 85 mt would be based on a new rebuilding analysis to be considered in November 2009.

* * * * *

3. Beginning November 1, 2009, Tables 3 (North) and 3 (South) to part 660, subpart G are revised to read as follows:

BILLING CODE 3510–22–S

Table 3 (North) to Part 660, Subpart G -- 2009 Trip Limits for Limited Entry Trawl Gear North of 40°10' N. Lat.

Other Limits and Requirements Apply -- Read § 660.301 - § 660.399 before using this table

110109

		JAN-FEB	MAR-APR	MAY-JUN	JUL-AUG	SEP-OCT	NOV-DEC
	Rockfish Conservation Area (RCA)[6/]:						
1	North of 48°10' N. lat.	shore - modified[7/] 200 fm line[6/]	shore - 200 fm line[6/]	shore - 150 fm line[6/]		shore - 200 fm line[6/]	shore - 200 fm line[6/]
2	48°10' N. lat. - 45°46' N. lat.	75 fm line[6/] - modified[7/] 200 fm line[6/]	75 fm line[6/] - 200 fm line[6/]	75 fm line[6/] - 150 fm line[6/]	100 fm line[6/] - 150 fm line[6/]	75 fm line[6/] - 200 fm line[6/]	75 fm line[6/] - 200 fm line[6/]
3	45°46' N. lat. - 40°10' N. lat.			75 fm line[6/] - 200 fm line[6/]	100 fm line[6/] - 200 fm line[6/]		

Selective flatfish trawl gear is required shoreward of the RCA; all trawl gear (large footrope, selective flatfish trawl, and small footrope trawl gear) is permitted seaward of the RCA. Large footrope and small footrope trawl gears (except for selective flatfish trawl gear) are prohibited shoreward of the RCA. Midwater trawl gear is permitted only for vessels participating in the primary whiting season.

See § 660.370 and § 660.381 for Additional Gear, Trip Limit, and Conservation Area Requirements and Restrictions. See §§ 660.390-660.394 and §§ 660.396-660.399 for Conservation Area Descriptions and Coordinates (including RCAs, YRCA, CCAs, Farallon Islands, Cordell Banks, and EFHCAs).

State trip limits and seasons may be more restrictive than federal trip limits, particularly in waters off Oregon and California.

55	**Lingcod** 4/					
56	large & small footrope gear	1,200 lb/ 2 months	4,000 lb/ 2 months			
57	selective flatfish trawl gear		1,200 lb/2 months			
58	multiple bottom trawl gear 8/					
59	**Pacific cod**	30,000 lb/ 2 months	70,000 lb/ 2 months			30,000 lb/ 2 months
60	**Spiny dogfish**	200,000 lb/ 2 months	150,000 lb/ 2 months	100,000 lb/ 2 months		
61	**Other Fish** 5/	Not limited				

1/ Bocaccio, chilipepper and cowcod are included in the trip limits for minor shelf rockfish.
2/ Splitnose rockfish is included in the trip limits for minor slope rockfish.
3/ "Other flatfish" are defined at § 660.302 and include butter sole, curlfin sole, flathead sole, Pacific sanddab, rex sole, rock sole, and sand sole.
4/ The minimum size limit for lingcod is 22 inches (56 cm) total length North of 42° N. lat.
5/ "Other fish" are defined at § 660.302 and include sharks, skates (including longnose skate), ratfish, morids, grenadiers, and kelp greenling. Cabezon is included in the trip limits for "other fish."
6/ The Rockfish Conservation Area is an area closed to fishing by particular gear types, bounded by lines specifically defined by latitude and longitude coordinates set out at §§ 660.391-660.394. This RCA is not defined by depth contours, and the boundary lines that define the RCA may close areas that are deeper or shallower than the depth contour. Vessels that are subject to the RCA restrictions may not fish in the RCA, or operate in the RCA for any purpose other than transiting.
7/ The "modified" fathom lines are modified to exclude certain petrale sole areas from the RCA.
8/ If a vessel has both selective flatfish gear and large or small footrope gear on board during a cumulative limit period (either simultaneously or successively), the most restrictive cumulative limit for any gear on board during the cumulative limit period applies for the entire cumulative limit period.

To convert pounds to kilograms, divide by 2.20462, the number of pounds in one kilogram.

42	**Other Fish[5/] & Cabezon**	Not limited					

1/ Yellowtail is included in the trip limits for minor shelf rockfish. Bronzespotted rockfish have a species specific trip limit.
2/ POP is included in the trip limits for minor slope rockfish
3/ "Other flatfish" are defined at § 660.302 and include butter sole, curlfin sole, flathead sole, Pacific sanddab, rex sole, rock sole, and sand sole.
4/ The minimum size limit for lingcod is 24 inches (61 cm) total length South of 42° N. lat.
5/ Other fish are defined at § 660.302 and include sharks, skates (including longnose skate), ratfish, morids, grenadiers, and kelp greenling.
6/ The Rockfish Conservation Area is an area closed to fishing by particulary gear types, bounded by lines specifically defined by latitude and longitude coordinates set out at §§ 660.391-660.394. This RCA is not defined by depth contours, and the boundary lines that define the RCA may close areas that are deeper or shallower than the depth contour. Vessels that are subject to the RCA restrictions may not fish in the RCA, or operate in the RCA for any purpose other than transiting.
7/ South of 34°27' N. lat., the RCA is 100 fm line - 150 fm line along the mainland coast; shoreline - 150 fm line around islands.

4. Beginning January 1, 2010, Tables 3 (North) and 3 (South) to part 660, subpart G are revised to read as follows:

* * * * *

Table 3 (North) to Part 660, Subpart G -- 2010 Trip Limits for Limited Entry Trawl Gear North of 40°10' N. Lat.

Other Limits and Requirements Apply -- Read § 660.301 - § 660.399 before using this table

010110

		JAN-FEB	MAR-APR	MAY-JUN	JUL-AUG	SEP-OCT	NOV-DEC
	Rockfish Conservation Area (RCA)[6/]:						
1	North of 48°10' N. lat.	shore - 200 fm line[6/]		shore - 150 fm line[6/]		shore - 200 fm line[6/]	shore - 200 fm line[6/]
2	48°10' N. lat. - 45°46' N. lat.	75 fm line[6/] - 200 fm line[6/]		75 fm line[6/] - 150 fm line[6/]	100 fm line[6/] - 150 fm line[6/]	75 fm line[6/] - 200 fm line[6/]	75 fm line[6/] - 200 fm line[6/]
3	45°46' N. lat. - 40°10' N. lat.			75 fm line[6/] - 200 fm line[6/]	100 fm line[6/] - 200 fm line[6/]		

Selective flatfish trawl gear is required shoreward of the RCA; all trawl gear (large footrope, selective flatfish trawl, and small footrope trawl gear) is permitted seaward of the RCA. Large footrope and small footrope trawl gears (except for selective flatfish trawl gear) are prohibited shoreward of the RCA. Midwater trawl gear is permitted only for vessels participating in the primary whiting season.

See § 660.370 and § 660.381 for Additional Gear, Trip Limit, and Conservation Area Requirements and Restrictions. See §§ 660.390-660.394 and §§ 660.396-660.399 for Conservation Area Descriptions and Coordinates (including RCAs, YRCA, CCAs, Farallon Islands, Cordell Banks, and EFHCAs).

State trip limits and seasons may be more restrictive than federal trip limits, particularly in waters off Oregon and California.

TABLE 3 (North) con't

1/ Bocaccio, chilipepper and cowcod are included in the trip limits for minor shelf rockfish.
2/ Splitnose rockfish is included in the trip limits for minor slope rockfish.
3/ "Other flatfish" are defined at § 660.302 and include butter sole, curlfin sole, flathead sole, Pacific sanddab, rex sole, rock sole, and sand sole.
4/ The minimum size limit for lingcod is 22 inches (56 cm) total length North of 42° N. lat.
5/ "Other fish" are defined at § 660.302 and include sharks, skates (including longnose skate), ratfish, morids, grenadiers, and kelp greenling. Cabezon is included in the trip limits for "other fish."
6/ The Rockfish Conservation Area is an area closed to fishing by particular gear types, bounded by lines specifically defined by latitude and longitude coordinates set out at §§ 660.391-660.394. This RCA is not defined by depth contours, and the boundary lines that define the RCA may close areas that are deeper or shallower than the depth contour. Vessels that are subject to the RCA restrictions may not fish in the RCA, or operate in the RCA for any purpose other than transiting.
7/ The "modified" fathom lines are modified to exclude certain petrale sole areas from the RCA.
8/ If a vessel has both selective flatfish gear and large or small footrope gear on board during a cumulative limit period (either simultaneously or successively), the most restrictive cumulative limit for any gear on board during the cumulative limit period applies for the entire cumulative limit period.

To convert pounds to kilograms, divide by 2.20462, the number of pounds in one kilogram.

GROUNDFISH MANAGEMENT TEAM (GMT) REPORT ON CONSIDERATION OF INSEASON ADJUSTMENTS

The Groundfish Management Team (GMT) considered requests from industry representatives, the most recent information from the West Coast Groundfish Observer Program and the status of ongoing fisheries. The following considerations and recommendations are offered.

SCIENTIFIC RESEARCH UPDATES

The greatest amount of research catch of canary rockfish is from the Northwest Fisheries Science Center Annual Bottom Trawl Survey. The survey is currently 70 percent complete, and catch through September 2, 2009 of canary rockfish totals less than 0.1 mt. In 2008 the bottom trawl survey took 1.7 mt of canary rockfish. As a precautionary approach, and to leave an adequate buffer in the scorecard in the case of unexpected canary catch during the remainder of the survey, the GMT assumes that up to double this amount could be caught in the bottom trawl survey (total of 3.4 mt). This assumption leads to a total catch estimate of canary rockfish for all research of approximately 4.5 mt. This is a decrease from the 8.0 mt that was in the scorecard at the start of the year which assumed the highest canary catch that was seen in the bottom trawl survey in recent years (7.2 mt in 2006).

The International Pacific Halibut Commission (IPHC) survey has been completed for this year. The total take of yelloweye rockfish in that survey was 0.5 mt. That brings the total projected research catch of yelloweye to 0.7 mt.

RECREATIONAL UPDATES

The Oregon recreational fishery is estimated to come in below preseason estimates for canary rockfish. This results in a 9 mt savings. Likewise, the California recreational fishery is projected not to exceed 15 mt, down from 21.3 mt. The Washington recreational fishery is currently tracking as projected.

Routine Adjustments to Management Measures

Limited Entry Fixed Gear Sablefish North of 36° N. lat.

The GMT received a request to increase the weekly and monthly limits in the limited entry fixed gear sablefish daily-trip-limit (DTL) fishery north of 36° N. lat. The GMT also received a request to eliminate the daily trip limit for this northern fishery. Available information indicates that catches in the limited entry DTL portion of the sablefish fishery have been substantially less than the allocations in recent years (Table 8). The GMT notes that even though modest inseason increases to daily, weekly, and bimonthly limits were made effective May 1 and July 1, 2009 (Table 9), trends in catch data suggest that unless additional increases are made, the 2009 harvest will be much lower than the 2009 allocation (Figure 1).

Table 8. Limited Entry Fixed Gear Sablefish DTL allocation, catch, and proportion of allocation for 2006 – 2008 north of 36° N. lat.

Year	Allocation (mt)	Catch (mt)	Proportion of Allocation
2006	356	106	0.30
2007	276	116	0.42
2008	276	159	0.54
2009	351		

Table 9. Daily, weekly, and cumulative trip limits for the Limited Entry Fixed Gear Sablefish DTL north of 36° N. lat.

Date	2008	2009
1 January	300 lbs / day, or 1 landing / week to 1000 lbs; 5000 lbs / 2 months	300 lbs / day, or 1 landing / week to 1000 lbs; 5000 lbs / 2 months
1 May		500 lbs / day, or 1 landing / week to 1500 lbs; 5500 lbs / 2 months
1 July	500 lbs / day, or 1 landing / week to 1000 lbs; 6500 lbs / 2 months	500 lbs / day, or 1 landing / week to 1500 lbs; 6000 lbs / 2 months
1 November	500 lbs / day, or 1 landing / week to 1500 lbs; 6500 lbs / 2 months	

Monthly catches shown in Figure 1 were taken from the quota species monitoring (QSM) system catch reports. This figure illustrates total catch north of 36° N lat. for 2008 and catches through August 31, 2009. Data from previous months and previous years were used to estimate September catches for all three states (Figure 1). This estimation procedure is conservative because bimonthly limits were more restrictive during these months of 2009 than during 2008 (Table 2) and because effort is restricted and does not widely fluctuate as fishing opportunities are adjusted for this limited entry sector. In addition, RCAs were larger during 2009 than during 2008, resulting in even more restrictive management during 2009. Nonetheless, catch was higher during winter and spring 2009 than during 2008; these higher rates were accounted for in the September 2009 estimate.

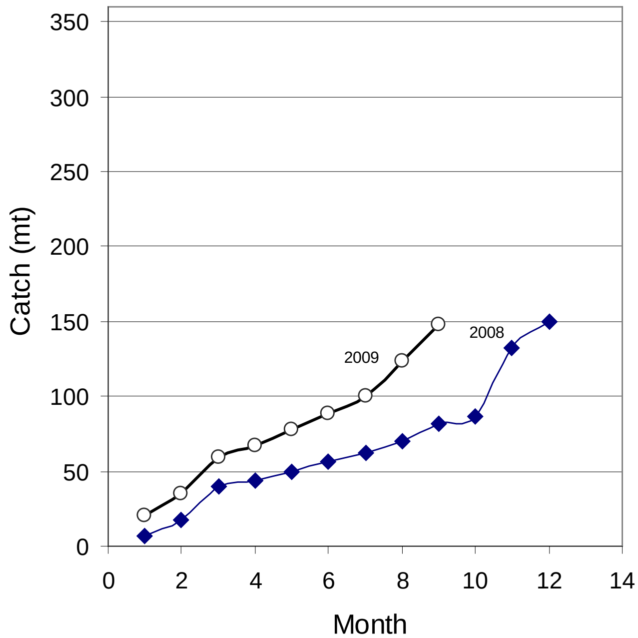

Figure 1. Monthly sablefish catch (mt) by the Limited Entry Fixed Gear sablefish DTL fleet for 2008 and 2009. Catches reported through the last day of each month are shown. Allocations were 276 mt and 351 mt for 2008 and 2009, respectively.

PacFIN data indicate that the total number of limited entry vessels participating in the DTL fishery in the past several years has ranged from 37 to 43 vessels north of the Conception area (36° N. lat.). Using this historic participation and catch information, the GMT evaluated a potential increase in the weekly and bimonthly limit for October 1 through December 31, 2009. Assuming all 43 vessels participate in the fishery and attain their bimonthly limit, the GMT estimated that the bimonthly limit could be raised from 6,000 lbs to 7,000 lbs and catches would remain within the limited entry DTL allocation. Elimination of the daily trip limit is not predicted to exceed the allocation. The daily limit was put in place when regulations were the same for LEFG and open access (OA) and the OA fishery relied on the daily limit to control effort. That same concern does not exist for a limited entry fishery. Changing the weekly limit to 2,000 pounds per week is not predicted to exceed the allocation because these specified parameters are for a short period of time (approximately 10 weeks).

Based on the projections described above, the GMT recommends the Council consider increasing the bimonthly cumulative limit from 6,000 lbs to 7,000 lbs, increasing the weekly limit from 1,500 lbs to 2,000 lbs, and eliminating the daily limit through the end of the year.

Limited Entry Sablefish Fishery South of 36° N. lat.

The GMT received a request to examine an increase in limits for sablefish in the DTL south of 36° N. lat. from 400 lb/day or 1,500 lb/week to 3,000 lb/week with no daily limit for the remainder of the year. In 2009, the optimum yield (OY) increased significantly in the Conception area due to a more optimistic stock assessment. The latest QSM indicates that 313 mt have been caught out of a 1371 mt OY. Without any inseason adjustment, the limited entry and/or open access fisheries are expected to fall short of their allocation.

Elimination of the daily trip limit is not predicted to exceed the allocation. The daily limit was put in place when regulations were the same for LEFG and OA and the OA fishery relied on the daily limit to control effort. That same concern does not exist for a limited entry fishery. The GMT estimates that these increases to sablefish trip limits will not increase impacts to overfished species because the model assumes that the entire Conception area OY is taken. Impacts to co-occurring target species are not expected to exceed OYs.

The GMT recommends consideration of increasing trip limits from "400 lb / day, one landing per week up to 1,500 lb" to a "weekly limit of 3,000 lb", with no daily limit.

Open Access Sablefish South of 36° N. lat

The GMT received a request to examine an increase in limits for sablefish in the DTL fishery south of 36° N. lat. from 400 lb/day, 1,500 lb/week, and 8,000 lb per/ 2 months to 400 lb/day, 2,500 lb/week and no bi-monthly limit.

Although the open access fishery is more dynamic and significant changes to trip limits can induce shifts and increases in effort, discussions with industry indicate that this is not likely to materialize because many of the open access fishermen in this area would have left to participate in other fisheries. Consultation with NMFS staff indicate that the soonest a trip limit increase could be in place is mid-October 2009, resulting in approximately 10 weeks of available fishing.

The GMT recommends the Council consider increasing the trip limits from "400 lb/day, 1,500 lb/week, and 8,000 lb per/ 2 months" to "400 lb/day, 2,500 lb/week" and no bi-monthly limit for the remainder of the year.

Limited Entry and Open Access Deeper Nearshore Rockfish South of 40° 10' N. lat.

The GMT received a request to increase the deeper nearshore rockfish trip limits in the limited entry and open access fishery in California south of 40°10' N. lat for the remainder of the year to allow conversion of discarded catch into landed catch.

Current trip limits for deeper nearshore rockfish south of 40°10' N lat. are as follows:

		SEP-OCT		NOV-DEC	
Minor nearshore rockfish & Black rockfish					
	Deeper nearshore				
	40°10' - 34°27' N. lat.	600 lb/ 2 months		700 lb/ 2 months	
	South of 34°27' N. lat.	600 lb/ 2 months			

Industry request to increase deeper nearshore rockfish trip limits for the entire area south of 40°10’ N lat. to 800 lb/2 months for the remainder of the year are depicted here:

		SEP-OCT		NOV-DEC	
Minor nearshore rockfish & Black rockfish					
	Deeper nearshore				
	South of 40°10' N. lat.	800 lb/ 2 months			

The deeper nearshore rockfish trip limit is comprised of black, blue and deeper nearshore rockfish species, so any increase in this trip limit can result in an increase in landings in any one or all of those species. Black rockfish is a healthy stock and has been under harvested over the last few years. If the trip limit is increased, black rockfish is projected to attain only 17 percent of its harvest guideline south of 40°10’ N lat. Blue rockfish are less common south of 40°10’ N. lat. and any potential increase in their landings as a result of increasing the deeper nearshore trip limits are not expected to exceed the statewide harvest guideline of 220 mt. The deeper nearshore rockfish and shallow nearshore rockfish are managed as part of the minor nearshore rockfish, with a combined HG of 138 mt. This increase in deeper nearshore rockfish trip limits is expected to result in attainment of 76 percent of the harvest guideline.

Previous discussions of increasing nearshore opportunities have raised concerns over the potential impact on overfished species – canary in particular south of 40°10’ N lat. The nearshore model, unlike other models, is a landings-based model which estimates overfished species impacts based on the previous year’s landings, not on attainment of a harvest guideline. Projected impacts, prior to changes to the nearshore fishery, in the scorecard is 3.3 mt of canary. Increasing the trip limits as requested by industry is expected to increase canary impacts to 3.6 mt.

The GMT recommends the Council consider increasing the deeper nearshore rockfish trip limits for the entire area south of 40°10’ N lat. to 800 lb/2 months for the remainder of the year.

Limited Entry Non-Whiting Trawl Fishery

Inseason opportunities in the limited entry trawl fishery are influenced by the Council’s decision on petrale opportunities in 2009. Leaving the petrale areas open affects the catch of several groundfish stocks, specifically, it increases the impacts on darkblotched rockfish and Pacific Ocean perch, reducing the ability to increase opportunities on other target species. As a result, the GMT developed two options for Council consideration that respond to whether the Council elects to finalize the preliminary measures for 2009 petrale opportunities adopted in June. One inseason option assumes the Council restricts the period 6 petrale fishery, while the other inseason option assumes that the period 6 petrale areas remain open and cumulative limits are less restrictive in period 5 and 6. In addition to the petrale matter, the GMT received a request to examine increasing opportunities for sablefish, arrowtooth, and slope rockfish in the non-whiting portion of the limited entry trawl fishery. Since many target species become less available to vessels using selective flatfish gear in the north late in the year, the focus was on opportunities for vessels using large footrope gear in the north and for vessels using all types of bottom trawl gear in the south.

The most recent fish ticket data indicates that catch of sablefish in the trawl fishery is roughly 1,300 metric tons below the trawl sector allocation and is projected to be approximately 300 metric tons below the allocation without any inseason adjustments, which is well below the expected catch level for the fishery at the time when management measures were initially developed. Therefore, there appear to be substantial opportunities to increase sablefish cumulative limits in this fishery, provided doing so would keep the fishery within acceptable overfished species impacts.

The catch of arrowtooth flounder is expected to reach approximately half of the OY without inseason adjustments. The GMT received a request to examine an increase in arrowtooth, principally as a means of reducing regulatory discard in the fishery. Option 1 increases arrowtooth in the north from 150,000 lbs to 180,000 lbs per two months in period 5 and 6 in order to reduce discard. This trip limit increase is not expected to increase arrowtooth impacts.

Recent fish ticket information also indicates that catch of petrale sole in the trawl fishery is below what was projected in June 2009. Therefore, if the Council does not elect to reduce catches of petrale sole at the end of 2009 in response to the point of concern, then the Council could consider increasing cumulative limits for petrale sole through the remainder of 2009 while keeping projected impacts below the 2009 petrale sole OY.

Table 3. Status Quo Cumulative limits and RCA boundaries (assumes Council finalizes preliminary action on petrale in period 6).

The GMT developed cumulative limits for the trawl fishery that attempt to increase opportunities on target species while staying within acceptable impacts to overfished stocks. Option 1 assumes the period 6 petrale fishery is restricted, while Option 2 leaves the period 6 petrale fishery open. Option 1 increases sablefish cumulative limits to 27,000 lbs in period 5 and 6 for vessels in the north using large and small footrope trawl gear, and in the south for all bottom trawl gear. Option 1 also increases arrowtooth in the north (for vessels using large and small footrope) to 180,000 lbs per two months starting in period 5, increases slope rockfish in the north to 4,000 lbs per two months beginning period 5, increases slope rockfish between 38 degrees N lat and 40 degrees 10 minutes N lat to 15,000 lbs in period 5 and to 18,000 lbs in period 6. Option 2 increases petrale cumulative limits to 30,000 lbs and 50,000 lbs in periods 5 and 6 respectively (except for vessels using SFFT in the north), while increasing sablefish limits to 26,000 lbs in periods 5 and 6 (except for vessels using SFFT in the north).

Petrale Sole and Canary Rockfish Interim Measures

In June, 2009 the Council identified a point of concern under FMP section 6.2.2 and recommended that NMFS take action to reduce harvest of petrale sole in 2009 and 2010 in response to the preliminary results of the new 2009 stock assessment. The Council also recommended that NMFS take action to reduce catches of canary rockfish in 2010 in response to the results of the new 2009 stock assessment update. Under the FMP Section 5.5.1, harvest specifications for species subject to rebuilding requirements may be modified during the biennium if the Council determines they are not adequately conservative to meet rebuilding plan goals.

Based on the Council recommendations in June 2009, NMFS developed and analyzed the potential impacts of two petrale sole alternatives, and three canary rockfish alternatives (including status quo/no action). NMFS published a Draft EA (Agenda Item E.4.b NMFS Report) and a proposed rule (Agenda Item E.4.b Supplemental NMFS Report 2) for changes to harvest specifications and management measures for these two species on September 11, 2009.

As a means of avoiding an overfished status at the beginning of 2011, or to speed the rebuilding of petrale if it is found to be overfished, the Council considered measures that would: reduce the catch of petrale sole to a level of approximately 2,000 mt in 2009, or roughly 400 mt below the 2009 OY of 2,433 mt; and reduce the catch to approximately 1,200 mt in 2010, or approximately 1,200 mt below the current 2010 OY of 2,393. Alternative P2 from the Draft EA results in impacts of 1,995 mt in 2009 and 1,178 mt in 2010 with a commensurate estimated depletion of 13 percent in 2011 (compared to 9 percent for P1, the no action alternative). In June, the Council preliminarily recommended modifications to petrale sole trip limits and sub-limits, and closure of petrale areas by modifying the trawl RCA as described in Table 13 below. These are reflected in the options put forward by the GMT for the LE non-whiting trawl earlier in this document.

Table 13. Proposed management measures to reduce petrale sole projected impacts by approximately 400 mt at the end of 2009. (Figure 2-1 in the Draft EA)

	NOV-DEC
Rockfish Conservation Area (RCA):	
North of 48°10' N. lat.	shore - **200 fm line**
48°10' N. lat. - 45°46' N. lat.	75 fm line - **200 fm line**
45°46' N. lat. - 40°10' N. lat.	
South of 40°10' N. lat.	100 fm line - 150 fm line
Flatfish North of 40°10' N. Lat. (except Dover sole and Arrowtooth flounder)	
Other flatfish, English sole, starry flounder, & Petrale sole	
large & small footrope gear for Other flatfish, English sole, & starry flounder	110,000 lb/ 2 months
large & small footrope gear for Petrale sole	**2,000 lb/ 2 months**
selective flatfish trawl gear for Other flatfish, English sole, & starry flounder	90,000 lb/ 2 months, **no more than 2,000 lb/ 2 months of which may be petrale sole.**
selective flatfish trawl gear for Petrale sole	
multiple bottom trawl gear	90,000 lb/ 2 months, **no more than 2,000 lb/ 2 months of which may be petrale sole.**
Flatfish South of 40°10' N. Lat. (except Dover sole and Arrowtooth flounder)	
Other flatfish[3/], English sole, & starry flounder	110,000 lb/ 2 months
Petrale sole	**2,000 lb/ 2 months**

Several alternative canary OYs are considered in the Draft EA. Preliminary estimates of changes in depletion from reducing the canary OY in 2010 are presented in Table 14.

Table 14. Canary Rockfish 2010 OY Alternatives – excerpted from Draft EA

Alternative	2010 OY	Estimated 2011 % Depletion [a/]
C1 – No Action	105 mt	25.2
C2	85 mt	25.2
C3	44 mt	25.3

a/ NOTE: These point estimates are presented to facilitate comparison of the alternative 2010 OYs. The depletion values are generated in the base case stock assessment (assuming the same harvest rate adopted under Amendment 16-4) and do not account for uncertainty in the assessment like the rebuilding analysis will. These point estimates are uncertain, with an unknown confidence interval.

The Council is scheduled to take final action at this meeting on management measures for the end of 2009 relative to petrale sole. The Council may choose to finalize their preliminary recommendation, as described in Table 13 and the LE trawl Option 1 presented in this report.

In November the Council is scheduled to consider the rebuilding analysis for canary rockfish, which will illustrate the rebuilding trade-offs of the three alternative 2010 OYs and make a final recommendation on a 2010 canary rockfish OY, and associated management measures. The Council will also make a final recommendation on a 2010 petrale sole OY, and associated management measures. This may include considering the rebuilding analysis for petrale sole (assuming the stock is overfished), which will illustrate the rebuilding trade-offs of the two alternative 2010 OYs.

GMT Recommendations:

1. Consider increasing the LEFG sablefish DTL limits north of 36° N.lat. from “1,500 lbs per week, and 6,000 lbs per 2 months” to “2,000 lbs per week, and 7,000 lbs per 2 months” and eliminating the daily limit for the remainder of the year.
2. Consider increasing LEFG sablefish DTL weekly limit South of 36° N. lat from “400 lb / day, one landing per week up to 1,500 lb” to a “weekly limit of 3,000 lb”, with no daily limit.
3. Consider increasing the OA sablefish DTL trip limits South of 36° N. lat from “400 lb per day, one landing per week of up to 1,500 lb, and 8,000 lb per/ 2 months” to “400 lb/day, one landing per week of up to 2,500 lb” and eliminating the bi-monthly limit for the remainder of the year.
4. Consider increasing the LE and OA deeper nearshore rockfish trip limits south of 40°10’ N lat. to “800 lb/2 months” for the remainder of the year.
5. Consider changes to petrale sole, sablefish, arrowtooth, and slope rockfish cumulative limits and RCA boundaries for the LE non-whiting trawl fishery.
6. Provide notice of the intention to implement measures for 2010 groundfish fisheries that impact petrale sole and canary rockfish at the November meeting.

Projected mortality impacts (mt) of overfished groundfish species updated with most recent research estimates and fishery projections through June 2009.

a/ Non-tribal whiting values for canary, darkblotched, and widow reflect bycatch limits for the non-tribal whiting sectors. The widow bycatch limit is the difference between the OY and the projected impacts in all non-whiting fisheries. All other species' impacts are projected from the GMT's whiting impact projection model. The Council may elect to change these bycatch limits when setting final whiting management measures in March of 2009 or 2010 or under any inseason action at any of their future meetings.

b/ South of 40°10' N. lat.

c/ Mortality estimates are not hard numbers; based on the GMT's best professional judgment.

d/ Bycatch amounts by species unavailable, but bocaccio occurred in 0.1% of all port samples and other rockfish in another 0.1% of all port samples (and squid fisheries usually land their whole catch).

e/ Values in scorecard represent projected impacts for all species except canary and yelloweye rockfish, which are the prescribed harvest guidelines.

f/ 2009 and 2010 OYs are the same except for darkblotched (291 mt in 2010), POP (200 mt in 2010), and widow (509 mt in 2010).

FISHERY MANAGEMENT PLAN AMENDMENT 23 – ANNUAL CATCH LIMITS AND ACCOUNTABILITY MEASURES

The Magnuson-Stevens Fishery Conservation and Management Reauthorization Act of 2006 (MSRA) established several new fishery management provisions pertaining to National Standard 1 (NS1) of the Magnuson-Stevens Fishery Conservation and Management Act (MSA), which states, "Conservation and management measures shall prevent overfishing while achieving, on a continuing basis, the optimum yield (OY) from each fishery for the United States fishing industry." On January 16, 2009, the National Marine Fisheries Service (NMFS) published a final rule in the Federal Register to implement the new MSRA requirements and amend the guidelines for NS1.

The MSRA and amended NMFS guidelines introduce new fishery management concepts including overfishing levels (OFLs), annual catch limits (ACLs), annual catch targets (ACTs), and accountability measures (AMs) that are designed to better account for scientific and management uncertainty and to prevent overfishing. One important change in the final guidelines is that ACTs are no longer mandatory, rather they are included as an optional accountability tool intended for the management of fisheries without inseason monitoring and harvest controls. These important aspects of the MSRA are required to be implemented by 2011 for most species and by 2010 for those species designated as being subject to overfishing. There are no groundfish species currently subject to overfishing, so 2011 is the implementation goal.

Precautionary harvest control rules exist for the actively managed species in the fishery management plan (FMP), control rules which provide a solid foundation for the implementation of new fishery management provisions such as the OFL and the ACL, which are analogous to the current definition of acceptable biological catch (ABC) and OY, respectively in the FMP. However, a new definition and control rules for specifying an ABC which, under the new NS1 guidelines, factors scientific uncertainty into the specification, will likely take considerably more thought.

The Council decided in April to proceed with Amendment 23 to incorporate these new NS1 guidelines in the FMP. The Council decided to pursue frameworking these guidelines in the FMP under an ambitious amendment schedule so as to reach finality at the November, 2009 Council meeting in order to synchronize with the biennial specifications process which starts at that meeting. The Scientific and Statistical Committee (SSC) provided a conceptual framework in April for factoring scientific uncertainty in the ABC rule for stocks with a history of multiple assessments. They recommended quantifying assessment variability as a basis for evaluating the size of a scientific uncertainty buffer (i.e., the difference in yield between the OFL and the ABC) and the risk of overfishing the stock. Further Council guidance in June for advancing Amendment 23 included tasking the GMT and Council staff to document the performance of the inseason groundfish catch monitoring and adjustment mechanism to evaluate the efficacy of these accountability measures. The SSC and Council staff will also coordinate development of alternative ABC control rules to synchronize with the 2011-12 biennial specifications process. Development of ABC control rules and ACL considerations for target and overfished species will be prioritized, with unassessed species as the next priority. The Council asked for ABC control rules that are based on relatively simple and understandable metrics.

The Groundfish Subcommittee of the SSC met on September 1 and 2 to further develop the conceptual framework for an ABC control rule. Their recommendations will be brought forward at this meeting to the full SSC and the Council.

Council staff and the GMT are also evaluating the efficacy of current catch monitoring tools to decide if these are adequate AMs to prevent overfishing. This evaluation and the GMT recommendations will be forthcoming in a supplemental GMT report under this agenda item.

Finally, there may be consideration for classifying some FMP species as Ecosystem Component species. According to the new NS1 guidelines, Ecosystem Component species do not require specification of reference points (i.e., OFLs, ABCs, and ACLs) but should be monitored to the extent that any new pertinent scientific information becomes available (e.g., catch trends, vulnerability, etc.) to determine changes in their status or their vulnerability to the fishery. For this classification, such species should: 1) be a non-target species or stock; 2) not be determined to be subject to overfishing, approaching overfished, or overfished; 3) not be likely to become subject to overfishing or overfished, according to the best available information, in the absence of conservation and management measures; and 4) not generally be retained for sale or personal use. There are a number of dwarf rockfish species that are largely unexploited and appear to meet the criteria for an Ecosystem Component classification (Agenda Item E.5.a, Attachment 1).

The Council should consider the new NS1 guidelines and consider the comments of Council advisory bodies and the public before providing guidance for further development of Amendment 23. Further, the Council should discuss and give guidance on a realistic schedule for reaching a final decision on this amendment package.

Council Action:

Provide guidance on further development of Amendment 23.

Supplemental GMT Report
September 2009

GROUNDFISH MANAGEMENT TEAM (GMT) REPORT ON
FISHERY MANAGEMENT PLAN AMENDMENT 23 – ANNUAL CATCH LIMITS
AND ACCOUNTABILITY MEASURES

Council staff presented the Groundfish Management Team (GMT) with an overview of a proposed schedule for incorporation of the annual catch limits (ACL) requirements and revised national standard 1 (NS1) guidelines into the groundfish fishery management plan (FMP) and implementation of the ACL framework during the 2011-2012 harvest specifications and management measures process. The new ACL framework largely matches with the Council's acceptable biological catch (ABC) and optimum yield (OY) reference points; however, the addition of a new reference point could create some timing issues.

As it has been presented to the Council at previous meetings, the major difference between the new ACL framework and the Council's current groundfish FMP relates to the overfishing threshold. Currently, the Council's best estimate of that overfishing threshold is identified as the ABC. The NS1 guidelines, however, now designate the overfishing threshold as the overfishing limit (OFL), with the ABC reduced from the OFL to reduce the probability of overfishing by taking into account scientific uncertainty around the estimate of a stock's biomass and its maximum fishing mortality threshold.

To facilitate the Council's preferred schedule of finalizing biennial harvest specifications at the April 2010 meeting, Council staff has recommended completion of the ACL framework (Amendment 23) and finalization of ABCs at the March 2010 meeting. The ABC is the upper limit for the ACL. The ACL can be no higher than the ABC yet can be set lower based on considerations beyond scientific uncertainty (e.g., 40-10 adjustment).

The Scientific and Statistical Committee (SSC) is currently evaluating alternative methods for deriving ABC control rules that create a scientific uncertainty buffer from the OFL. The GMT understands that the SSC may use these alternative methods to recommend a range of ABCs in November. In past cycles, the Council has identified a single ABC for each stock and a range of OYs derived from that ABC. This cycle will involve consideration of a range of ACLs from a range of ABCs, which could create challenges if the Council chooses to set ACLs below the ABC.[1] The GMT therefore agrees that the identification of final preferred ABCs in March 2010 would likely aid the Council's identification of final preferred ACLs in April 2010. At the same

[1] The GMT does not expect the ACL framework to further complicate the Council's considerations of ACLs for rebuilding species. As occurs under status quo, rebuilding ACLs will continue to be based on estimates of uncertainty in the time to rebuild estimated from the rebuilding analysis and not on the method for factoring in scientific uncertainty between the OFL and the ABC.

time, the GMT understands that the March meeting is traditionally full and focused primarily on non-groundfish items.

In June, the Council asked Council staff and a subgroup of the GMT to evaluate the team's role in Amendment 23, specifically regarding the evaluation of management uncertainty and use of annual catch targets (ACTs). We have had preliminary discussions on this topic and will begin the analysis at our October 5-9 meeting in Portland, Oregon. At that meeting, we also plan to begin an evaluation of the 90+ species in the groundfish FMP, as well as species encountered in the groundfish fisheries but not currently managed by the FMP, against the new NS1 criteria for determining whether a stock should be included "in the fishery" and managed with an ACL. The GMT has reviewed and plans to evaluate the FMP species using an assessment method developed by the NMFS Vulnerability Evaluation Work Group (VEWG) that looks at the susceptibility and resilience (i.e., productivity) of each stock to fishing mortality.[2] This vulnerability analysis will also help inform an evaluation of the FMP's current stock complexes against the standards in the revised NS1 guidelines and will help guide the Council in deciding whether to incorporate ecosystem component species into the FMP. We have had initial discussion with the NWFSC and West Coast Groundfish Observer Program about data to use in the analysis and will be asking Council staff to make formal requests for data at our October meeting. Lastly, we will also analyze the use of sector-specific ACLs and ACTs and evaluate current accountability measures in the FMP. We will present the results of our preliminary analyses and evaluation to the Council for consideration in November.

SCIENTIFIC AND STATISTICAL COMMITTEE REPORT ON FISHERY MANAGEMENT PLAN AMENDMENT 23 – ANNUAL CATCH LIMITS

The Magnuson-Stevens Fishery Conservation and Management Reauthorization Act of 2006 (MSRA) established several new fishery management provisions pertaining to National Standard 1 (NS1) of the Magnuson-Stevens Fishery Conservation and Management Act. On January 16, 2009, the National Marine Fisheries Service (NMFS) published a final rule in the Federal Register to amend the guidelines for NS1 that provide guidance to the Councils in revising their Fisheries Management Plans (FMPs) to conform to the new MSRA requirements. Specifically, there is now a need to implement overfishing levels (OFLs), annual catch limits (ACLs), annual catch targets (ACTs), and accountability measures (AMs) by 2011 for most species, and by 2010 for those species designated as being subject to overfishing. The major task for the Scientific and Statistical Committee (SSC), however, is to satisfy provisions of the MSRA to redefine the Acceptable Biological Catch (ABC) to account for scientific uncertainty.

The Council has decided to framework how ABCs will be calculated in its groundfish and coastal pelagic species (CPS) fishery management plans (FMPs). The SSC provided a conceptual framework in April 2009 to account for scientific uncertainty when calculating ABCs for "data-rich" stocks with a history of multiple assessments. They recommended quantifying the variability in biomass estimates from stock assessments as a basis for evaluating the size of a scientific uncertainty buffer (i.e., the difference between the OFL and the ABC) and the risk of overfishing the stock.

The groundfish and coastal pelagic species subcommittees of the SSC met in Seattle, Washington September 1-2, 2009 to discuss implementation of the NMFS guidelines and, in particular, how to calculate the scientific uncertainty buffer that defines the difference between the OFL and the ABC. That meeting considered three general approaches to defining scientific buffers for groundfish and CPS species, and agreed that defining these buffers based on a value of P^* (the probability of exceeding the OFL) was most appropriate. This scientific buffer would be based on a tier system, with different tiers for species with different levels of information. The size of the buffer for data-rich stocks would be determined using information on "between" and "within" assessment variation in biomass estimates, and with buffers for data-poor species being set larger than data-rich species. While this is only a first step in quantifying scientific uncertainty, the SSC endorses this approach.

The SSC recommends that the method of translating a value of P^* into a scientific buffer should be frameworked in the environmental assessment (EA) because methods for doing this translation are still evolving and because no methods currently exist that can capture all sources of scientific uncertainty. The SSC intends to use the approach it outlined in April as the basis for providing ABC recommendations at the March 2010 meeting. While not perfect, in particular because it does not address assessment bias, this approach captures many key sources of scientific uncertainty to the extent currently possible. Specifically, two sources of scientific uncertainty will be computed: (a) the statistical uncertainty that is captured within each stock assessment and (b) a measure of the remaining scientific uncertainty which cannot be captured within a stock assessment, but can be inferred from changes over time in estimates of biomass from stock assessments. Dr Stephen Ralston and assessment authors will be working to collate the information needed to compute the between-assessment variation in biomass estimates for data-rich species, and hence the magnitude of this second source of uncertainty, with a view to providing an example at the November meeting of how the approach can be applied to calculate scientific buffers.

The SSC concurs with the need to revisit the OFL and ABC values for: (a) species with ABCs computed by multiplying survey swept-area biomass estimates by $0.75*M$, (b) Restrepo's method of computing 50% of the average catch over a period of years when catches are stable, and (c) species complexes that are aggregates of single species. This task will need to be completed at the March 2010 meeting and may involve a special meeting of the SSC groundfish subcommittee in early 2010.

The SSC notes that it has focused its attention on approaches for determining scientific uncertainty and calculating scientific buffers, given a measure of scientific uncertainty and a choice for $P*$. The SSC expects that the Council will choose values of $P*$ for each tier level; the SSC is willing to work with Council staff to develop tools to illustrate the trade-offs between the probability of overfishing and the size of scientific buffers.

Finally, the SSC notes that it is in the somewhat unusual role of developing methods and also reviewing them. However, methods development has occurred primarily by members of the groundfish and CPS subcommittee and additional review can be provided by SSC members who are not on these subcommittees. The methodology will likely be presented at the National SSC meeting in November, and further review of the methods will also occur as part of the review of the EA.

SSC Groundfish and CPS Subcommittee Report on Implementation of National Standard 1 for West Coast Groundfish and Coastal Pelagic Species.

September 1-2, 2009 Seattle, WA

Background:

The Magnuson-Stevens Fishery Conservation and Management Reauthorization Act of 2006 (MSRA) established several new fishery management provisions pertaining to National Standard 1 (NS1) of the Magnuson-Stevens Fishery Conservation and Management Act (MSA), which states, "Conservation and management measures shall prevent overfishing while achieving, on a continuing basis, the optimum yield (OY) from each fishery for the United States fishing industry." On January 16, 2009, the National Marine Fisheries Service (NMFS) published a final rule in the Federal Register to amend the guidelines for NS1 that provide guidance to the Councils in revising their Fisheries Management Plans (FMPs) to conform to the new MSRA requirements.

The MSRA and amended NMFS guidelines introduce new fishery management concepts including overfishing levels (OFLs), annual catch limits (ACLs), annual catch targets (ACTs), and accountability measures (AMs) that are designed to better account for scientific and management uncertainty and to prevent overfishing. These important aspects of the MSRA are required to be implemented by 2011 for most species and by 2010 for those species designated as being subject to overfishing. A new definition and control rules for specifying an Acceptable Biological Catch (ABC) which, under the new NS1 guidelines, factors scientific uncertainty into the specification, will likely take considerably more thought.

The Council decided to framework these guidelines in its groundfish and coastal pelagic FMPs under an ambitious amendment schedule targeting the November, 2009 Council meeting to synchronize with the groundfish biennial specifications process which starts at that meeting. The Scientific and Statistical Committee (SSC) provided a conceptual framework in April for factoring scientific uncertainty in the ABC rule for stocks with a history of multiple assessments. They recommended quantifying variability in assessment outcomes as a basis for evaluating the size of a scientific uncertainty buffer (i.e., the difference in yield between the OFL and the ABC) and the risk of overfishing the stock. The SSC and Council staff will also coordinate development of ABC control rules to synchronize with the 2011-12 biennial specifications process. Development of ABC control rules and ACL considerations for target and overfished species will be prioritized, with unassessed species as the next priority. The Council asked for ABC control rules that are based on relatively simple and understandable metrics.

Considerations:

The Groundfish and Coastal Pelagic Species (CPS) subcommittees of the Pacific Fisheries Management Council's (PFMC's) Scientific and Statistical Committee (SSC) met in Seattle Washington on September 1-2, 2009 to discuss implementation of the NMFS guidelines under the Council process, and particularly how to implement the scientific uncertainty buffer which defines the difference between OFL and ABC.

Dr. Richard Methot presented the NOAA Fisheries Office of Science and Technology view on how ABC, ACL and ACTs will relate to OFLs under the new NS1 guidelines. All of these are expressed in terms of total catch (i.e. landings and discards combined), whether in biomass or numbers. The talk focused on incorporating scientific uncertainty to define the difference between the OFL and the ABC. Dr. Andre Punt presented methods considered for the Bering Sea and Aleutian Islands crab stock given uncertainty estimates.

The three general approaches to defining buffers for groundfish and CPS species considered were:

1. Create a Tier system whether the size of the buffer between the OFL and the ABC will the same for all species in each tier but differ among tiers; the size of the buffer would increase with increasing tier number (from well-assessed Tier 1 species up through increasingly data poor species).
2. Use P* (a probability of exceeding "true" OFL (the OFL level which would be defined given perfect information about the stock and the proxy SPR fishing rate)). This can include a tier system as above. The relationship between P* and the size of the buffer would be calculated using the Tier 1 (well assessed) species.
3. Use a decision-theoretic approach.

The meeting agreed that the decision-theoretic approach required too much information and was too complex to implement in the limited timeframe. It was also not clear that the example presented for crab was defining its objective in a way that reflects avoidance of overfishing. The meeting also noted that adopting approach 1 (fixed buffers by tier) would mean that species would differ a tier in terms of the probability of exceeding "true" OFL which adopting approach 2 (fixed P* by tier) would mean that species within a tier would differ in terms of the buffer applied.

The P* approach associated with a tier system appears the most appropriate approach at this time. One additional difficulty is that currently projections can only correctly estimate buffer for a single year forecast. While methods to approximate the correct buffer in multi-year forecasts were discussed, the subcommittees concluded that forecasting while using the buffer for the single year forecast for multiple years would be acceptable until appropriate multi-year forecasting software is developed.

Dr. Stephen Ralston presented a method for estimating historical between-assessment variability as one component of uncertainty to consider. The subcommittees agreed that this was a reasonable way to estimate uncertainty external to individual assessments. However, a number of improvements to the method were suggested, and further discussion of the method is needed prior to it being used. These suggestions include:

1. using only full assessments (or the most recent update of a full assessment in lieu of the full assessment itself);
2. limiting the time frame for comparison between assessments (certainly not considering the earliest periods which may generally reflect B_0, and perhaps more limited than that); and
3. not including early assessments that used considerably less sophisticated assessment methods, or which were severely data limited.

Dr. Ralston agreed to work on the method and to produce results for a larger suite of species using several approaches, while assessment authors and others would be tasked with producing the retrospective time series as well as the measures of uncertainty from the most recent assessments.

General Conclusions:
The SSC subcommittees propose the following method for determining the scientific uncertainty in OFL values: for species with successful assessments develop estimates of between (external) assessment uncertainty (using retrospective multi-species meta-analyses) and within (internal) assessment uncertainty (using asymptotic estimates of uncertainty)

within individual assessments. For CPS stocks, consider grouping with groundfish or analyzing separately (the latter less likely to be successful due to the few assessed species within CPS).

The SSC subcommittees suggest providing the council with graphs of isopleths for the relationship of P* to buffer (proportion of catch) given internal and external variance estimates, using log-normal approximation (see figures 1 and 2 for examples) to aid in Council decision making. These figures could be annotated with lines denoting the internal assessment uncertainty.

While the P* values chosen by the Council will determine buffers for future assessments, there should be some flexibility for specific decisions about ABC within this framework to account for perceived unaccounted for of uncertainties. Given greater uncertainty with a greater number of forecast years, there is more incentive to do new assessments for species important to the fishery.

The SSC subcommittees suggest revisiting OFL and ABC values for species with ABCs defined via Roger's method of considering survey area swept biomass estimates and applying $F = 0.75*M$ or Restrepo's method of half of average catch over a period of years, and for species complexes which are made up largely of such species. Revisiting, updating and improving these methods, as well as examining uncertainty associated with them would be a key off-year science project. The results of the uncertainty examination will provide a stronger basis for developing buffers which are at least as risk-averse as those developed based on assessment uncertainty. Since OFL and ABC values for many data-poor species are based on analyses that have not been updated for some time, consideration should be given to establishing an additional buffer that reflects the timeliness of the information used to establish the OFL and ABC values.

There are species for which only one full assessment has been conducted. The buffer for these species will also be computed using the outcome of the further application of Ralston's method.

For many species within complexes, discard, often from fisheries without observers, is the largest component of catch which may therefore be poorly known. For those species with low vulnerability due to closures and other fishery management actions, this may be of little concern in the near term.

The SSC subcommittees note that vulnerability scores would affect ACLs rather than ABCs, and factors such as in-season tracking issues would affect ACTs. Since being in the precautionary zone of relative spawning output is in a sense an indication of increased vulnerability, the 40-10 rule and similar catch-reduction rules could be applied to ABCs as part of the determination of the ACLs.

Finally, the SSC subcommittees note that any system for defining scientific uncertainty is necessarily approximate. Specifically, although the method outlines attempt to capture all quantifiable scientific uncertainty, there are sources of uncertainty (e.g. caused by climate change, stock structure uncertainty, the validity of F_{MSY} proxies, etc.) which cannot be addressed at present (and probably not in the foreseeable future). Many of these sources of uncertainty should be more important on a longer time-scale.

Near-term Approach:
The following stock assessment authors and Council Staff will be asked to provide retrospective assessment time series as well as biomass CV's from the most recent assessments and a description of parameters estimated or fixed within those assessments to Steve Ralston by October 2, 2009:

- Jason Cope: Cabezon
- Paul Crone: Pacific mackerel
- John DeVore: Sablefish and Dover sole
- John Field: Chilipepper rockfish and Bocaccio
- Melissa Haltuch: Petrale sole
- Owen Hamel: Darkblotched rockfish, Pacific ocean perch, shortspine thornyhead and lingcod
- Xi He: Widow rockfish
- Kevin Hill: Pacific sardine
- Ian Stewart: Pacific hake and canary rockfish
- John Wallace: Yellowtail rockfish

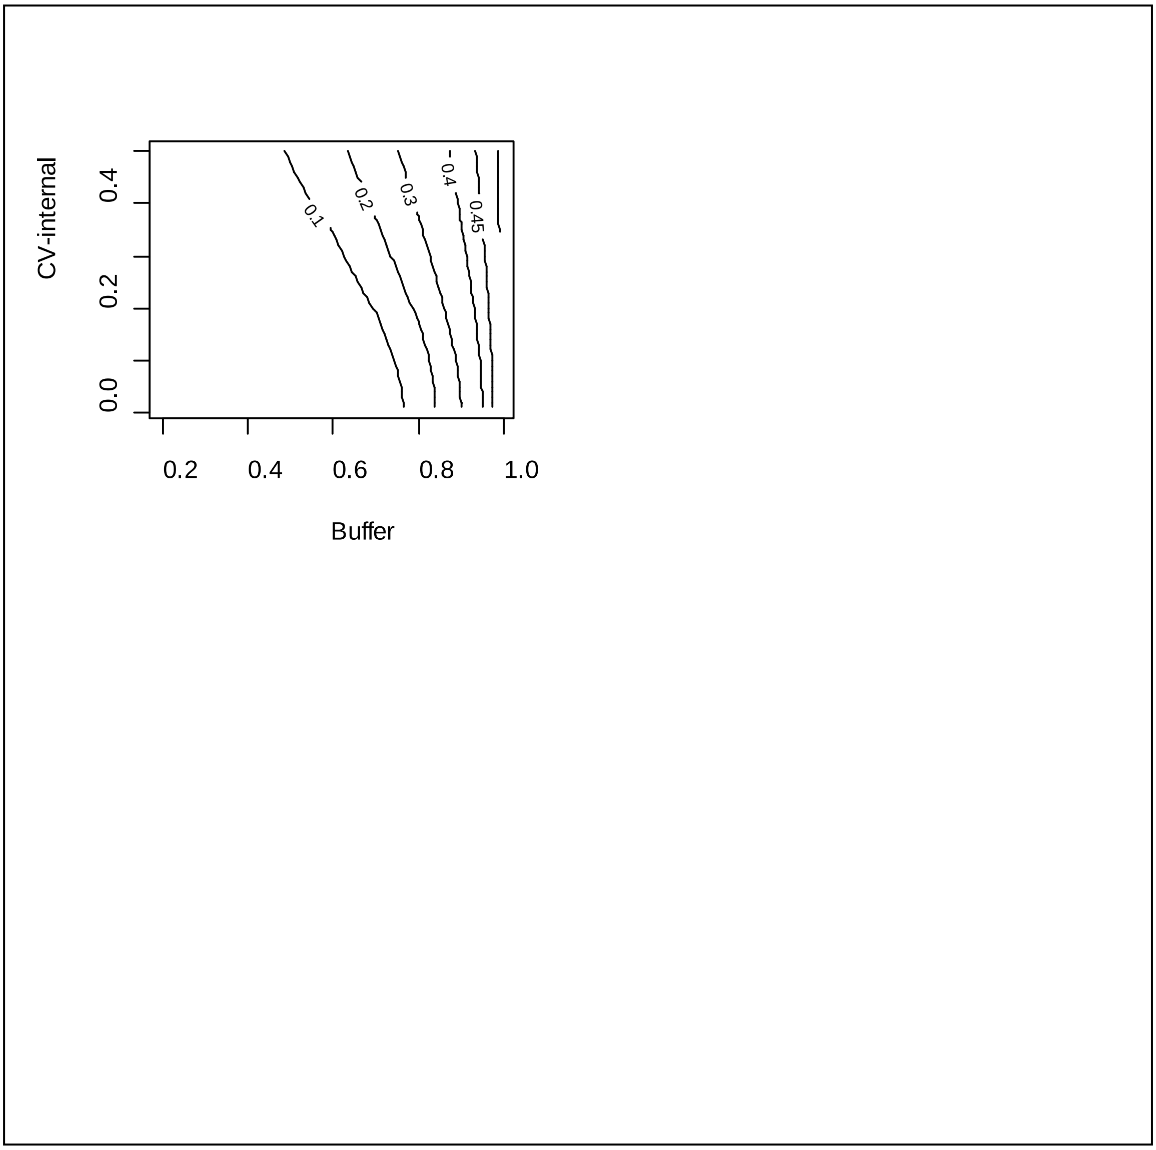

Figure 1. Isopleths of P* values associated with a buffer (Proportion that ABC is of OFL) and the internal (to the assessment) CV and the external CV (to be provided by Ralston's analysis). The value of P* is computed as the cumulative probability below the buffer for a lognormal distribution with median 1 and CV^2 given by the sum of the internal and extra variances.

Expressing Scientific Uncertainty in PFMC Groundfish Stock Assessments

Two Key Assertions

- Data-poor assessments cannot be more certain than data-rich assessments
- Variation “among” stock assessments captures a wide variety of sources of uncertainty, including:
  - Data used (e.g., NWFSC combined trawl survey)
  - Model software (e.g., SS1 vs. SS3)
  - Model specification (dome-shaped or asymptotic)
  - Parameter priors (e.g., Dorn prior on ***h***)
  - STAT team composition
  - STAR panel composition

FISHERY MANAGEMENT PLAN AMENDMENT 20 – TRAWL RATIONALIZATION REGULATION LANGUAGE REVIEW AND MISCELLANEOUS IMPLEMENTATION MATTERS

The Council adopted its final recommendations on trawl rationalization at its June 2009 meeting (E.6.a, Attachment 1). Over the summer, the Council staff has been working to update the preliminary draft environmental impact statement (EIS) to reflect the Council's final action and National Marine Fisheries Service (NMFS) Northwest Region (NWR) has been reviewing the Council action and the updated draft EIS.

At this meeting, NMFS is scheduled to present the Council with an update on the implementation process, including any regulatory language it has developed and any initial questions that may have arisen regarding Council intent (Agenda Item E.6.b, NMFS Report).

Following this meeting, the approval process calls for the following to occur this fall: continued review of and revisions to the draft EIS, transmittal of the draft EIS to the Environmental Protection Agency (EPA), and the start of the public comment period on the draft EIS (to commence upon EPA publication of the notice of availability of the document). The Council's Amendment 20 recommendations are tentatively scheduled for official transmittal in the spring of 2010. Assuming the Council recommendations are approved, it is anticipated that the program will be implemented at the start of the 2011.

Directly following the June Council meeting, the Council staff released to permit holders the analysis estimates of quota share (QS) allocations for each permit and an example conversion of those QS to quota pounds based on application of trawl allocations to the 2010 OYs. After release of the QS estimates used in the analysis, many permit owners expressed substantial concern about the initial QS allocation. In response to these concerns an "airing" session is scheduled to occur Saturday morning (September 12) at the Groundfish Advisory Subpanel meeting. There has been some talk among industry representatives about asking that the Council reconsider the initial allocation formula. Public testimony to the Council on this issue may also come up under the open public comment period just prior to this agenda item. If the Council decides to reopen this issue, it could not do so at this meeting but would have to take the matter up under Agenda Item J.4, Future Council Meeting Agenda and Workload Planning, and schedule the question of reconsideration on Amendment 20 for a subsequent meeting.

Council Task:

1. Review NMFS submissions and respond to questions.

OCTOBER 2008

Revised and printed on September 1, 2009

1. Overview of Recommendations by Sector

The Pacific Fishery Management Council's (Council) sector specific recommendations for rationalizing the trawl fishery are provided here and will be finalized and forwarded to the National Marine Fisheries (NMFS) for approval later in 2009. The recommendations were adopted at the Council's November 2008 meeting. In general, the Council recommends the following:

Shoreside Trawl Sector (nonwhiting groundfish species and whiting):

Manage with IFQs.

Provide 90% of the initial allocation of nonwhiting IFQ to holders of vessel permits; and set aside 10% of the initial allocation for an adaptive management program that may benefit processors and communities, among others.

Provide 80% of the initial allocation of whiting IFQ to holders of vessel permits; and provide 20% of the initial allocation of whiting to processors.

Mothership Trawl Sector (whiting and groundfish bycatch species):

Manage with a harvester co-op system and limited entry for mothership processors.

Require that vessels declare preseason the mothership processor for which they will fish in a coming year.

Catcher Processor Sector (whiting and groundfish bycatch species):

Create a permit endorsement to prevent expansion of the number of participants.

Allocate whiting and bycatch to the existing voluntary co-op.[1]

Provide an IFQ program if the voluntary co-op fails (initially allocate IFQ equally among all permit holders).

[1] When the Council took final action, NMFS indicated its preliminary intent to license the voluntary co-op. However, this was not part of the Council's final action.

The amount of allocation available for these sectors will be determined through the intersector allocation process. IFQ for the shoreside fishery may not be delivered to at-sea processors, nor may quota allocated to the mothership or catcher-processor sectors be delivered shoreside.

The following sections provide a general summary of the program for each sector, followed by a complete description that also identifies trailing actions the Council has been working on in 2009. These actions will be completed prior the time it submits the package to NMFS for approval.[2] *The trailing actions pertain to eligibility to own IFQ, accumulation limits, and adaptive management. Implementation is not expected earlier than 2011.*

2. Shoreside Trawl Sector: IFQ Program (Appendix A of the EIS)

This section details the IFQ program that the Council is recommending for the shoreside sector of the groundfish fishery. The first part of the section describes major components of the program. Table 1, which starts on page 6, presents complete details on elements of the recommended IFQ program.

2.1. Overview of the IFQ Program Elements

Under this program, most status quo management tools would remain in place. The main exceptions are cumulative landing limits for nonwhiting groundfish species and a closure period to control whiting harvest at the start of the year.[3] Other measures, such as RCA boundaries, may be adjusted as experience is gained with the IFQ program.

An IFQ will grant an entity the privilege to catch a specified portion of the trawl sector's allocation. Within the IFQ program, vessels will be allowed to use a variety of directed groundfish commercial gear (including nontrawl gear) to take the shoreside trawl sector allocation, which will thus allow for "gear switching." IFQs will be created for most species of groundfish under the Groundfish FMP (although some will still be managed collectively at the stock complex level, e.g. remaining minor slope rockfish). Some groundfish species rarely caught by trawl gear and dogfish will be excluded from the IFQ program. To ensure that optimum yields (OY) for species not covered by IFQ are not exceeded, catch of those species will be monitored and deductions made from the OY in anticipation of the expected level of shoreside trawl sector catch. For trips targeted on whiting, IFQ will be required only for whiting and the main bycatch species.

Halibut individual bycatch quota (IBQ) will be required to cover the incidental catch[4] of Pacific halibut in the groundfish trawl shoreside fishery. Under an IBQ program, retention would not be allowed.

The following sections describe the major provisions of the IFQ program.

2.1.1. Initial Allocation

The program will initially allocate IFQ as quota share (QS) to fishery participants based mainly on their historic involvement in the fishery. Following the initial allocation, transfers (described below) will

[2] During its March and April 2009 meetings the Council also clarified a number of its recommendations. These clarifications are reflected in the version of the trawl rationalization recommendation provided here.
[3] This closure period is necessary because of Endangered Species Act concerns related to salmon.
[4] At its June meeting the Council will consider a recommendation by the GAC to interpret previous Council action under Amendment 21 as creating an IBQ program to cover incidental mortality rather than catch.

allow for others to also participate in the fishery as quota holders. The initial allocation can be viewed in two segments:

First, in developing its recommendation the Council considered the groups that should be included in the initial allocation, and the proportional split among the groups. The Council recommended that harvesters (those holding limited entry permits for trawl vessels) be given an initial allocation of 90% of the nonwhiting QS and 80% of the whiting QS. Ten percent of the QS for nonwhiting species would be made available for an adaptive management program and processors would receive 20% of the whiting QS.

Second, the Council considered specific allocation formulas that will determine the amount of QS each eligible entity will receive. These calculations are based primarily on the delivery history associated with a vessel permit or processing company over a set number of years. For the allocation to permits, the QS associated with the history of permits retired in the buyback program will be distributed equally among the remaining qualified permits (just less than 45% of the QS will be allocated in this fashion). A special calculation is provided for incidentally caught overfished species. For these species the allocation will be based on the QS recipient's need to cover incidental catch under current fishing practices (as measured by bycatch rates, individual permit logbooks for recent years, and the amount of target species QS that an entity receives). None of the QS for these species will be allocated equally among harvesters. A similar approach would be used for the allocation of halibut IBQ.

2.1.2. Stock Management Units for IFQs

QS will be issued for the species groups and areas for which there are OYs (management units). However, QS will not be required for some rarely-caught species. Catch of these species would be monitored to ensure they don't exceed any established allocations. There may be further area subdivisions for species for which there is an area specific precautionary harvest policy. There are also provisions that provide for both species group and area subdivision of QS after initial allocation.

2.1.3. Annual Issuance, Holding Requirements and Transfer Rules

In designing the management regime for the IFQ program, the Council is balancing the benefits of flexibility and individual accountability with program costs and the constraints of the very low allowable catch levels of overfished species. Prior to the start of each fishing year, NMFS will issue quota pounds (QP) to entities based on the amount of QS they hold and the shoreside trawl sector allocation. The QP would have to be transferred to a vessel account in order to be used. When a vessel goes fishing under the IFQ program, all catch must be recorded (including discards) and must be matched by an equal amount of QP from the vessel's QP account. If there is not enough QP to cover the catch from a trip, there is a 30-day grace period during which adequate QP must be transferred into the vessel's account. A vessel's fishing will be limited, and its permit cannot be sold, until the overage is covered. A carryover provision will allow for an overage in one year to be covered by up to 10 percent of the following year's QP; likewise, the provision also will allow QP that were not used in one year to be carried over into the following year, up to 10 percent.

Bycatch reduction and greater efficiency are expected to occur in the groundfish fishery under the IFQ program because of the transferability of QS and QP. Through the transfer of QS/QP (bought and sold or "leased" through private contract), it is anticipated that those best able to avoid catching overfished species, and those who are most efficient, will increase the amount of QS/QP registered to them, while those who consistently have high bycatch rates or operate less efficiently might choose to sell their QS and leave the fishery. Generally, anyone eligible to own a U.S.-documented fishing vessel could also acquire QS and QP, and the QS and QP could be acquired in very small increments.[5] These provisions will allow for new entrants into the fishery; for example, a crew member could slowly purchase amounts of quota. The also allow for ownership of QS by entities that do not otherwise participate in the fishery. *In early 2009,during its trailing actions the Council considered but rejected substantially modifying provisions pertaining to who is eligible to own the QS.*

While transferability is an important component, in order to protect against unintended consequences some provisions limit transferability. For example, there will be accumulation limits on the amount of QS or QP that can be controlled by an entity, and accumulation limits on the amount of QP registered to a vessel. The intent of these limits is to prevent excessive control of quota by a participant. *The exact percentages which will be used in these limits will be determined through a trailing action.*

An adaptive management provision will allow the Council to use 10 percent of the trawl allocation to provide incentives, support, or other compensation to offset adverse impacts of the program. This program may benefit communities and processors, among others. *Details will be the subject of a trailing action.*

2.1.4. Tracking and Monitoring

A tracking and monitoring program is necessary to assure that all catch (including discards) is documented and matched against QP. At-sea observers would be required on all vessels and shoreside monitoring during all off-loading (100 percent coverage). Cameras may be used to augment the observers and assure compliance. Compared to status quo monitoring, this will be a significant increase for a large portion of the trawl fleet, particularly non-whiting shoreside vessels. More accurate estimates of total mortality will benefit stock conservation goals. Discarding will be allowed, though all fish discarded will also have to be covered by QP. There would be 100 percent shoreside monitoring; and there may be limited landing hours to control costs. Additionally, a program for the mandatory submission of economic data is included to facilitate monitoring program performance.

2.1.5. Costs and Fee Structure

Program costs are of concern and ongoing Federal administrative costs are estimated in the EIS at $2.4 to $2.9 million per year for the entire trawl rationalization program, including the co-ops for the at-sea segment of the fishery (see Section 3). Program benefits are expected to significantly exceed costs. The costs listed here do not include initial implementation costs or the costs that industry will bear for observers. Fee structures will be proposed to recover program costs from industry, up to the limit of 3% of exvessel value.

2.1.6. Program Monitoring, Review and Future Auction

The Council will conduct a formal review of program performance no later than 5 years after implementation and every four years thereafter. The result of the evaluation could include dissolution of the program, revocation of all or part of quota shares, or other fundamental changes to the program. At the time of its first review, the Council will consider also the use of an auction or other non-history based method when distributing quota share that may become available after the initial allocation.

2.2. Detailed Specification of IFQ Program Elements and Options

Table 1 provides a complete description of the IFQ program.

[5] To be eligible to own QS the person need not actually own a U.S. documented fishing vessel.

Table 1. Full description of the IFQ Program for shoreside trawl deliveries.

	Element	SubElement	
A. *Trawl Sector Management*			
A-1.1	Scope for IFQ Management, Including Gear Switching		For trips delivered shoreside, QP will be required to cover catch of all groundfish (including all discards) by LE trawl vessels with certain gear and species exceptions. Gear Exception: Vessels with an LE trawl permit using the following gears would not be required to cover their groundfish catch with QP: exempted trawl, [a] gear types defined in the coastal pelagic species FMP, gear types defined in the highly migratory species FMP, salmon troll, crab pot, and LE fixed gear when the vessel also has a LE permit endorsed for fixed-gear (longline or fishpot) AND has declared that they are fishing in the LE fixed-gear fishery. Species Exception: The following would be excepted from the QP requirement longspine thornyheads south of 34º27' N latitude, minor nearshore rockfish (north and south), black rockfish (WOC), California scorpionfish, cabezon, kelp greenling, shortbelly rockfish, and the "Other Fish" category of groundish. *This definition of the scope allows an LE trawl vessel to switch between trawl and nontrawl groundfish gears, including fixed-gear, for the purpose of catching their QP ("gear switching"). It also allows a nontrawl vessel to acquire a trawl permit, and thereby use trawl QP to catch the LE trawl allocation using nontrawl gear.*[b]

Table 1. Full description of the IFQ program (continued).

	Element	SubElement	
A-1.2	IFQ Management Units, Including Latitudinal Area Management		QS will carry designations for the species/species group, area, and trawl sector to which it applies (see A-1.3 for the list of trawl sectors). The QP will have the same species/species group, area, and sector designations as the QS on the basis of which the QP was issued. QP will not be used in a trawl sector other than that for which it was issued,[c] and will not be used in a nontrawl sector (i.e. by vessels without trawl permits).[d] QP will not be used in a catch area or for a species/species group other than that for which it is designated. For those species within the scope of the program, the QS/QP species groupings and area subdivisions will be those for which OYs are specified in the ABC/OY table that is generated through the groundfish biennial specifications process and those for which there is an area-specific precautionary harvest policy[e] QS for remaining minor rockfish will be aggregated for the shelf and slope depth strata (nearshore are excluded from the scope, see Section A-1.1). Changing the management units. After initial QS allocation the Council may alter the management units by changing the management areas or subdividing species groups. Section A-2.1.6 provides methods for reallocating QS when such changes are made after initial implementation of the program.[f] *Hereafter, all references to species include species and species group, unless otherwise indicated.*
A-1.3	General Management and Trawl Sectors		Unless otherwise specified, status quo regulations, other than trip limits for species within the scope of the IFQ program, will remain in place. If individual vessel overages (catch not covered by QP) make it necessary, area restrictions, season closures, or other measures will be used to prevent the trawl sector (in aggregate or the individual trawl sectors listed here) from going over allocations.[g] The IFQ fishery may also be restricted or closed as a result of overages in other sectors. There will be three trawl sectors: shoreside, mothership, and catcher-processors. However, as per Section A-1.1, IFQ will be required only for the shoreside trawl sector. The mothership and catcher-processor sectors will be managed using co-ops, as specified in the co-op section of the trawl rationalization program. If the industry organized voluntary co-op program for the catcher-processor sector collapses, IFQ will be required for the catcher-processor sector, as specified in the co-op program described for that sector. *Allocation among trawl sectors has been determined in FMP Amendment 21. Those allocations not covered by Amendment 21 will be addressed in the biannual specifications process.* *Trawl vessels fishing IFQ with nontrawl gear will be required to comply with the RCA lines applicable for that gear. Such restrictions, as necessary, will be determined in a separate process.*
A-1.4	Management of NonWhiting Trips		Nonwhiting trips are those with less than 50% whiting. No changes to management measures, other than those identified in Section A-1.3, have been identified at this time.
A-1.5	Management of Whiting Trips[h]		Whiting seasons will not be changed under the IFQ program, and so the current spring openings will be maintained to control impacts on ESA-listed salmon.[i] When the primary whiting season is closed for shoreside deliveries, cumulative whiting catch limits will apply and shoreside QP will be required to cover whiting incidental catch.

Table 1. Full description of the IFQ program (continued).

	Element	SubElement	
A-1.6	Groundfish Permit Length Endorsements		Length endorsement restrictions on LE permits endorsed for groundfish gear will be retained; however, the provision that requires that the size endorsements on trawl permits transferred to smaller vessels be reduced to the size of that smaller vessel will be eliminated (i.e., length endorsements will not change when a trawl-endorsed permit is transferred to a smaller vessel).
A-2. ***<u>IFQ System Details</u>***			
A-2.1	**Initial Allocation and Direct Reallocation**		
A-2.1.1	Eligible Groups	a Groups and Initial Split of QS	***Eligible Groups*** The initial allocation of QS will be made either only to permit owners and processors, as follows. Whiting QS: 80% to permits, 20% to processors and 0% for adaptive management. Nonwhiting QS: 90% to permits, 0% to processors, and 10% for adaptive management. *After initial allocation, trading will likely result in changes in the distribution of shares among permit owners and processors. Additionally, entities that are neither permit owners nor processors may acquire QS (see below: "IFQ/Permit Holding Requirements and IFQ Acquisition").*
		b Permits	Landing history will accrue to the permit under which the landing was made. The owner of a groundfish LE permit at the time of initial allocation will receive the QS issued based on the permit. (Also, see Section A-2.1.4 on permit combinations and other exceptional situations.)
		c Processors and Processing Definition	A special definition of "processor" and "processing" will be used for initial QS allocation. A main intent of the definition is to specify that only the first processor of the fish be credited for the history of that delivery when the initial allocation formula is applied (see footnote for definition).[j]
		d Attributing and Accruing Processing History	For an allocation for **shoreside processors (applies only to whiting):** attribute history to the receiver reported on the landing receipt (i.e. the entity responsible for filling out the state fish ticket), except history may be reassigned to an entity not on the landings receipt, if parties agree or through an agency appeals process. *The intent of this option is to provide an opportunity for catch history to be assigned to the entity that actually processed the fish.* For shoreside processors, allocations go to the processing business and successor-in-interest will be recognized. NMFS will develop criteria for use in determining the successor in interest with respect to the entities listed on the landings receipts or otherwise eligible for an initial QS allocation based on being the first processor of the fish.[k]
A-2.1.2	Recent Participation	a Permits (including CP permits)	Recent participation is not required in order for a permit to qualify for an initial allocation of QS.
		b Processors (motherships)	Not applicable because a co-op program was provided for this sector rather than IFQs. *(This header is being left in the document so that paragraph numbering will correspond to numbering in the analysis.)*

Table 1. Full description of the IFQ program (continued).

	Element	SubElement	
		c Processors (shoreside)	Recent participation is required to qualify for an initial allocation of whiting QS: 1 mt or more of deliveries from whiting trips in each of any two years from 1998-2004.
A-2.1.3	Allocation Formula	a Permits with catcher vessel history	QS will be issued for all fish management units within the scope of the program (see Section A-1.2) based on equal division and permit history, as follows:[l] **Equal Division:** There will be an equal division of the buy-back permits' pool of QS among all qualifying permits *(except the incidentally caught overfished species)*. Qualifying permits include all catcher vessel permits, including those that have been used only in the mothership sector. (The QS pool associated with the buyback permits will be the buyback permit history as a percent of the total fleet history for the allocation period. The calculation will be based on total absolute pounds with no other adjustments and no dropped years.) **Permit History:** The remaining QS *(including all QS for overfished species)* will be allocated based on each permit's history (see following formulas). **For the portion of the allocation based on each permit's history .** For **non-whiting** trips, permit history used for QS allocation will be calculated: **For non-overfished species**: using an allocation period of 1994-2003. Within that period use relative history and drop the three worst years.[m] **For overfished species taken incidentally:[n]** use target species QS as a proxy based on the following approach: Apply fleet average bycatch rates to each permit's depth and latitude distributions and target species QS allocations. Fleet average bycatch rates for latitudinal areas[o] divided shoreward and seaward of the RCA will be developed from West Coast Observer Program data for 2003-06. For the purposes of the allocation, a permit's QS for each target species will be distributed shoreward and seaward of the RCA and latitudinally based on the permit's logbook information for 2003-06. If a permit does not have any logbooks for 2003-06, fleetwide averages will be used.[p] For **whiting** trips, permit history used for QS allocation will be calculated as follows: **For whiting**, use an allocation period of 1994-2003. Within that period, use relative history and drop the two worst years. [q] **For bycatch species** (if IFQ is used for bycatch species): use the whiting history as a proxy (i.e., allocation will be pro rata based on the whiting allocation). **Area Assignments:** Landings history will be assigned to catch areas based on port of landing.[r] **Relative history (%).** For each sector, the permit history for each year is measured as a percent of the sector's total for the year. **In some situations the Initial allocations may be constrained by accumulation limits.** See Section A-2.2.3.e for a discussion of the limits and divestiture requirements.

Table 1. Full description of the IFQ program (continued).

	Element	SubElement	
.		b Permits with catcher-processor history	Not applicable because a co-op program was provided for this sector rather than IFQs. *(This header is being left in the document so that paragraph numbering will correspond to numbering in the analysis).*
		c Processors (motherships)	Not applicable because a co-op program was provided for this sector rather than IFQs *(This header is being left in the document so that paragraph numbering will correspond to numbering in the analysis).*
		d Processors (shoreside)	For whiting: • Allocate whiting QS based on the entity's history for the allocation period of 1994-2004 (drop two worst years) and use relative history. **Initial allocations will be cosntrained by accumulation limits.** See Section A-2.2.3.e for a discussion of the limits and divestiture requirements.
A-2.1.4	History for Combined Permits and Other Exceptional Situations		Permit history for combined permits will include the history for all the permits that have been combined. For history occurring when two or more trawl permits were stacked, split the history evenly between the stacked permits. History for illegal landings will not count toward an allocation of QS. Landings made under nonwhiting Experimental Fishing Permits (EFPs) that are in excess of the cumulative limits in place for the non-EFP fishery will not count toward an allocation of QS. Compensation fish will not count toward an allocation of QS.
A-2.1.5	Initial Issuance Appeals		There will be no Council appeals process on the initial issuance of IFQ. NMFS will develop a proposal for an internal appeals process and bring it to the Council for consideration. Any revisions to an entity's fish tickets must be approved by the state in order to be accepted. Any proposed revisions to fish tickets should undergo review by state enforcement personnel prior to finalization of the revisions.

Table 1. Full description of the IFQ program (continued).

	Element	SubElement	
A-2.1.6	Direct Reallocation and Future Allocations After Initial Issuance		**Reallocation With Change in Overfished Status**: When an overfished species is rebuilt or a species becomes overfished there may be a change in the QS allocation within a sector (allocation between sectors is addressed in the intersector allocation process). When a stock becomes rebuilt, the reallocation will be to facilitate the re-establishment of historic target fishing opportunities. When a stock becomes overfished, QS may be reallocated to maintain target fisheries to the degree possible. That change may be based on a person's holding of QS for target species associated with the rebuilt species or other approaches deemed appropriate by the Council. **Reallocation With Changes in Area Management** (Changes in management lines are expected to be rare; however, when they occur the following provides for the reallocation of QS in a manner that will give individual QS holders with the same amounts of total QP before and after the line changes.) **Area Subdivision**: If at any time after the initial allocation an IFQ management unit is geographically subdivided, those holding QS for the unit being subdivided will receive an amount of QS for each newly created area that is equivalent to the amount they held for the area before it was subdivided. **Area Recombination**: When two areas are combined, the QS held by individuals in each area will be adjusted proportionally such that (1) the total QS for the area sums to 100%, and (2) a person holding QS in the newly created area will receive the same amount of total QP as they would if the areas had not been combined. **Area Line Movement**: When a management boundary line is moved, the QS held by individuals in each area will be adjusted proportionally such that they each maintain their same share of the trawl allocation on a coastwide basis (a fishing area may expand or decrease, but the individual's QP for both areas combined wouldn't change because of the change in areas). In order to achieve this end, the holders of QS in the area being reduced will receive QS for the area being expanded, such that the total QP they would be issued will not be reduced as a result of the area reduction.[s] Those holding QS in the area being expanded will have their QS reduced such that the total QP they receive in the year of the line movement will not increase as a result of the expansion (nor will it be reduced). **Reallocation With Subdivision of a Species Group**: If at any time after the initial allocation an IFQ management unit for a species group is subdivided, those holding QS for the unit being subdivided will receive an amount of QS for each newly created IFQ management units that is equivalent to the amount they held for the species group before it was subdivided. For example, if a person holds 1% of a species group before the subdivision, that person will hold 1% of the QS for each of the groups resulting from the subdivision. **Future Allocation of Groundfish Outside the Scope of the IFQ Program:** For the "Other Fish," category of groundfish, if at some time in the future the Council adds it to the IFQ system, the initial allocation would be determined using the same history criteria as was used for other IFQ species (i.e. 1994-2003 history), unless otherwise specified by a future Council action.

Table 1. Full description of the IFQ program (continued).

	Element	SubElement	
A-2.2	**Permit/IFQ Holding Requirements and Acquisition** **(after initial allocation)**		
A-2.2.1	Permit/IFQ Holding Requirement		1. Only vessels with LE trawl permits are allowed to fish in the trawl IFQ fishery. 2. For a vessel to use QP, the QP must be in the vessel's QP account. 3. All catch a vessel takes on a trip must be covered with QP within 30 days of the landing for that trip unless the overage is within the limits of the carryover provision (Section A-2.2.2.b), in which case the vessel has 30 days or a reasonable time (to be determined) after the QP for the following year are issued, whichever is greater.[t] 4. For any vessel with an overage (catch not covered by QP), fishing that is within the scope of the IFQ program (Section A-1.1) will be prohibited until the overage is covered, regardless of the amount of the overage. Vessels which have not adequately covered their overage within the time limits specified in paragraph 3, must still cover the overage before resuming fishing, using QP from the following year(s), if necessary. If a vessel covers its overage, but coverage occurs outside the specified time limit (paragraph 3), the vessel may still be cited for a program violation. 5. For vessels with an overage, the LE permit may not be sold or transferred until the deficit is cleared.
A-2.2.2	IFQ Annual Issuance	a Annual Quota Pound Issuance	QP will be issued annually to QS holders based on the amount of QS held.[u] *As specified above, QS holders will have to transfer their QP to a vessel account in order for those QP to be used.*

Table 1. Full description of the IFQ program (continued).

	Element	SubElement	
		b Carryover (Surplus or Deficit)	To the extent allowed by the conservation requirements of the MSA, a carryover allowance will allow surplus QP in a vessel's QP account to be carried over from one year to the next or allow a deficit in a vessel's QP account for one year to be carried over and covered with QP from a subsequent year. Surplus QP may not be carried over for more than one year. A vessel with a QP **surplus** at the end of the current year will be able to use that QP in the immediately following year, up to the limit of the carryover allowance (see below). However, if there is a decline in the OY, the amount of QP carried over as a surplus will be reduced in proportion to the reduction in the OY. A vessel with a QP **deficit** in the current year will be able to cover that deficit with QP from the following year without incurring a violation if (1) the amount of QP it needs from the following year is within the carryover allowance (see below), and (2) the QP are acquired within the time limits specified in A-2.2.1.[v] **Carryover Allowance**: Limit of up to 10 percent carryover for each species. This applies to both non-overfished species and overfished species. The percentage is calculated based on the total pounds (used and unused) in a vessel's QP account for the current year. The percentage used for the carryover provision may be changed during the biennial specifications process.
		c QS Use-or-Lose Provisions (Deleted)	*This section has been deleted but the numbering is being maintained as a placeholder so as not to change section numbering and corresponding references in the analysis.*[w]
		d Entry Level Opportunities	Under the MSA, the Council is required to consider entry level fishermen, small vessel owners, and crew members, and in particular the possible allocation of a portion of the annual harvest to individuals falling in those categories. No special provisions have been identified for analysis. New entry is addressed indirectly by allowing crew, captains and others to acquire QS in small increments.
A-2.2.3	IFQ Transfer Rules	a Eligible to Own or Hold	No person can acquire quota shares or quota pounds other than 1) a United States citizen, 2) a permanent resident alien, or 3) a corporation, partnership, or other entity established under the laws of the United States or any State, that is eligible to own and control a US fishing vessel with a fishery endorsement pursuant to 46 USC 12113 (general fishery endorsement requirements and 75% citizenship requirement for entities). However, there is an exception for any entity that owns a mothership that participated in the West Coast groundfish fishery during the allocation period and is eligible to own or control that US fishing vessel with a fishery endorsement pursuant to sections 203(g) and 213(g) of the AFA.

Table 1. Full description of the IFQ program (continued).

	Element	SubElement	
		b Transfers and Leasing	QS/QP will be transferable and transfers must be registered with NMFS. NMFS will not differentiate between a transfer for a lease and a permanent transfer.[x] Each year, all QP must be transferred to a vessel account. A penalty for not meeting this transfer requirement has not been recommended; however, this requirement is intended to encourage its availability for use by the fleet. QP can only be transferred into vessel accounts. Once in a vessel account QP can be transferred from one vessel account to another.
		c Temporary Transfer Prohibition	NMFS may establish temporary prohibitions on the transfer of QS, as necessary to facilitate program administration. QS will not be transferred in the first two years of the program (QP will be transferable).
		d Divisibility	QS will be highly divisible and the QP will be transferred in whole pound units (i.e. fractions of a pound may not be transferred).

Table 1. Full description of the IFQ program (continued).

	Element	SubElement	
		e Accumulation Limits (Vessel and Control)	Limits[y] may vary by species/species group, areas, and sector. The values for the limits are provided in Table 2. The vessel unused QP limits may be revisited in the first biennial specifications process after implementation of the program. **Vessel Use Limit (Vessel Limit)**: A limit on the total QP that may be registered for a single vessel during the year. This element will mean that a vessel could not have more used and unused quota pounds registered for the vessel than a predetermined percentage of the QP pool. **Vessel Unused QP Limit**: A limit on the amount of unused QP that may be registered to the vessel at any time. This limit applies only for overfished species and Pacific halibut. **QS Control Limit:** A person, individually or collectively, may not control QS in excess of the specified limit (because there is no the grandfather clause). QS controlled by a person shall include those registered to that person, plus those controlled by other entities in which the person has a direct or indirect ownership interest, as well as shares that the person controls through other means.[z] The calculation of QS controlled by a person will follow the “individual and collective” rule. Individual and Collective Rule: The QS that counts toward a person's accumulation limit will include 1) the QS or QP owned by them, and 2) a portion of the QS owned by any entity in which that person has an interest. The person's share of interest in that entity will determine the portion of that entity's QS that counts toward the person's limit.[aa] **Grandfather Clause and Divestiture:** There will not be a grandfather clause for the QS control limits, however, an adjustment period is provided through the following divestiture rules. QS will be issued for amounts in excess of aggregate and species control limits only for holders of permits transferred by November 8, 2008, if such transfers have been registered with NMFS by November 30, 2008. The holder of any permit transferred after that time will be eligible to receive an initial allocation for that permit of only those QS that are within the aggregate and individual species control limits. Anyone who qualifies for an initial allocation of QS in excess of the control limits will be allowed to receive that allocation but required to divest themselves of that excess QS sometime during years 3 and 4 of the IFQ program (the two years after the QS transfer moratorium specified in Section A-2.2.3.c). Holders of QS in excess of the limits may receive and use the QP associated with that excess, up to the time their divestiture is completed. However, QP for year 5 of the program will not be issued for QS held in excess of the limits. At the end of year 4, any QS still held in excess of the species or aggregate limits in place at the time of the initial QS allocation will be revoked and redistributed to the remainder of the QS holders in proportion to their QS holdings. No compensation will be due for any revoked shares. Divestiture transfers will be allowed in accordance with the provisions established here and the transfer rules and processes implemented by NMFS. Permit transfers will not be limited or required by the divestiture provision. **Calculation of Aggregate Nonwhiting QS Holdings:** To determining how much aggregate nonwhiting QS an entity holds, an entity’s QS for each species will be converted to pounds. This conversion will always be conducted using the trawl allocations applied to the 2010 OYs, until such time as the Council recommends otherwise. Specifically, each entity’s QS for each species will be multiplied by the shoreside trawl allocation for that species. The entity’s pounds for all nonwhiting species will then be summed and divided by the shoreside trawl allocation of all nonwhiting species to get the entity’s share of the aggregate nonwhiting trawl quota. *Note: QS that is not allocated because of the accumulation limits and absence of the grandfather clause will be distributed to other eligible recipients in a manner that maintains the distribution among groups specified in A-2.1.1 and based on the allocation formulas specified in A-2.1.3.*

Table 1. Full description of the IFQ program (continued).

	Element	SubElement	
A-2.3	**Program Administration**		
A-2.3.1	Tracking, Monitoring and Enforcement		It is the Council intent to provide NMFS flexibility sufficient to design and implementation a tracking and monitoring program that will achieve the goals and objectives of the trawl rationalization program. **Discarding by Shoreside Sector** Non-whiting – Discarding of IFQ species allowed, discarding of IBQ species required, discarding of non-groundfish species allowed. Whiting Maximized retention vessels: Discarding of fish covered by IFQ or IBQ, and non-groundfish species prohibited. Vessels sorting at-sea: Same as for non-whiting. **At-Sea Catch Monitoring for Shoreside Sector** Nonwhiting – The sorting of catch, the weighing and discarding of any IBQ and IFQ species, and the retention of IFQ species must be monitored by the observer. Whiting For maximized retention vessels: video monitoring as proposed under Amendment 10. Observers would be required in addition to or as a replacement for video monitoring. For vessels that sort at-sea: The sorting, weighing and discarding of any IFQ or IBQ species must be monitored by an observer with supplemental video monitoring. Shoreside Landings Monitoring The sorting, weighing and reporting of any IFQ species must be monitored by a shoreside landings monitor (IBQ will have been discarded at sea). (Description continued on next page.)

Table 1. Full description of the IFQ program (continued).

	Element	SubElement	
			(...continued from previous page) **Catch Tracking Mechanisms for Shoreside Sector** **Electronic vessel logbook report** VMS-based electronic logbook required to be transmitted from vessel. At-sea entry by vessel personnel required including catch weight by species and if retained or discarded. **Vessel landing declaration report** Mandatory declaration reports. **Electronic ITQ landing report** Mandatory reports completed by processors and similar to electronic fish ticket report. **Processor production report** Mandatory reports (possible inclusion of proprietary data included to be recommended as option is fleshed out). **Cost Control Mechanisms for Shoreside Sector** **Shoreside landing hour restrictions** Landing hours may be restricted. **Shoreside site Licenses** Mandatory license for shoreside deliveries. License can be issued to any site that meets the monitoring requirements. **Vessel Certification** Mandatory certification. Certificate can be issued to any vessel that meets the monitoring requirements. **Program Performance Measures for Shoreside Sector** Integrate into the tracking and monitoring program the collection of data on cost, earnings and profitability; economic efficiency and stability; capacity measures; net benefits to society; distribution of net benefits; product quality; functioning of quota market; incentives to reduce bycatch; market power; spillover effects into other fisheries; contribution to regional economies (income and employment); distributional effects/community impacts; employment in seafood catching and processing; safety; bycatch and discards; administrative, enforcement, and management costs. (See A-2.3.2)
A-2.3.2	Socio-Economic Data Collection		The data collection program will be expanded and submission of economic data by harvesters and processors will be mandatory. Random and targeted audits may be used to validate mandatory data submissions. See footnote for a full description[bb] Information on QS transaction prices, will be included in a central QS ownership registry. *NOTE: Data collection started before the first year of implementation would be beneficial, in order to have a baseline for comparison.*
A-2.3.3	Program Costs	a Cost Recovery	Fees up to 3% of exvessel value, consistent with 303A(e) of the MSA may be assessed. Cost recovery shall be for costs of management, data collection, analysis, and enforcement activities.
		b Fee Structure	To be determined. The TIQC recommended a fee structure that reflects usage. A fee structure that allows for equitable sharing of observer costs for smaller vessels may be developed.

Table 1. Full description of the IFQ program (continued).

	Element	SubElement	
A-2.3.4	Program Duration and Modification		The Council shall begin a review of the IFQ program no later than 5 years after implementation of the program. The review will evaluate the progress the IFQ program has made in achieving the goal and objectives of Amendment 20. The result of this evaluation could include dissolution of the program, revocation of all or part of quota shares, or other fundamental changes to the program. Holders of quota shares should remain cognizant of this fact when making decisions regarding their quota shares, including buying selling, and leasing of these shares. The Council shall consider the use of an auction or other non-history based methods when distributing quota share that may become available after initial allocation. This may include quota created when a stock transitions from overfished to non-overfished status, quota not used by the adaptive management program, quota forfeited to “use it or lose it” provisions, and any quota that becomes available as a result of the initial or subsequent reviews of the program. The specific form of the auction or other method of distribution shall be designed to achieve the goals of Amendment 20, specifically including minimizing the adverse effects from an IFQ program on fishing communities to the extent practical. After the initial review, there will be a review process every four years. A community advisory committee will take part in the review of IFQ program performance.

Table 1. Full description of the IFQ program (continued).

	Element	SubElement	
A-3	***Adaptive Management** (also see Section A-9)*		Ten percent of the non-whiting QS will be reserved to facilitate adaptive management in the shoreside non-whiting sector. Therefore, each year 10% of the shoreside trawl sector nonwhiting quota pounds will be available for use in adaptive management (adaptive management QP). The set aside will be used to address the following objectives. o Community stability o Processor stability o Conservation o Unintended/Unforeseen consequences of IFQ management. o Facilitating new entrants. **Years 1 and 2.** During the first 2 years in which the IFQ program is in place, the method to be used in distributing QP in years 3 through 5 will be determined, including. o The decision making and organization structure to be used in distributing the QP set aside[cc] o The formula for determining community and processor eligibility, as well as methods for allocation, consistent with additional goals. o The division of QP among the states. o Whether to allow the multi-year commitment of QP to a particular project. **Years 3 through 5.** QP will be distributed through the organizational structure, decision process, formulas and criteria developed in years 1 and 2 and implemented through subsequent Council recommendation and NMFS rule making processes. Consideration will be given to the multiyear commitment of QP to particular projects (3 year commitments). **Review and Duration.** The set aside of QP for the identified objectives will be reviewed as part of the year 5 comprehensive review and a range of sunset dates will be considered, including 10, 15, 20 year and no sunset date options.
A-4	***Pacific Halibut IBQ—non-retention***		IBQ for Pacific halibut bycatch in the trawl fishery will be established. The IBQ will be required to cover legal and sublegal sized Pacific halibut bycatch mortality in the area north of 40°10 N latitude. It is the intent of the Council that halibut IBQ mortality be estimated on an individual vessel basis. Such IBQ will be issued on the basis of a bycatch rate applied to the target species QS an entity receives in a manner similar to that described in Section A-2.1.3.a, for overfished species caught incidentally. Area-specific bycatch rates may be used for allocation but halibut IBQ will not be geographically subdivided.

[a] California halibut gear of 7.5" or greater used in state waters would be exempted.

[b] Mandatory gear conversion (the permanent switching from trawl to some other gear) was considered but not included at this time.

Table 1. Full description of the IFQ program (continued).

[c] Since the shoreside trawl sector covers all shoreside deliveries, this implies that IFQ issued for the shoreside trawl sector may not be used for at-sea deliveries (i.e. may not be used to cover deliveries made to motherships or catch by catcher-processors).

[d] Not withstanding this provision, a vessel with a LE trawl permit may catch the trawl QP with a nontrawl gear, as per Section A-1.1.

[e] At present there are no groundfish species for which the harvest in the trawl fishery is managed differently by geographic area. An example of an area specific precautionary policy from outside trawl fishery management is the geographic differential recommended by the SSC for lingcod. Lingcod is monitored and managed differently in different geographic areas though there is a single coastwide ABC and OY for lingcod. Since there are no geographic subdivisions in the trawl management measures for lingcod, it is assumed that lingcod trawl IFQ will not be geographically subdivided.

[f] Such changes in latitudinal area management may occur as a result of changes in the management areas for species/species complexes in the ABC/OY table or as a result of separate Council action to change the trawl QS by area. In either case, specific Council action will be required to change the management areas and such action will be accompanied by appropriate supporting analysis and public comment opportunity.

[g] The Council authority to establish or modify RCAs will not be changed by this program.

[h] A whiting QP rollover provision was considered but rejected from further analysis. This provision would have allowed unused QP to be reclassified so that they could be used in any whiting sector.

[i] The current process for changing the whiting fishery opening dates involves a regulatory amendment developed under the FMP through a framework process. Implementation of an IFQ program should not change this process.

[j] "**Processors**" are defined as follows:

An at-sea processor is a vessel that operates as a mothership in the at-sea whiting fishery or a permitted vessel operating as a catcher-processor in the at-sea whiting fishery.

A shoreside processor is an operation, working on US soil, that takes delivery of trawl-caught groundfish that has not been "processed at-sea" and that has not been "processed shoreside"; and that thereafter engages that particular fish in "shoreside processing." Entities that received fish that have not undergone "at-sea processing" or "shoreside processing" (as defined in this paragraph) and sell that fish directly to consumers shall not be considered a "processor" for purposes of QS allocations.

"Shoreside Processing" is defined as either of the following:

1. Any activity that takes place shoreside; and that involves: cutting groundfish into smaller portions; OR freezing, cooking, smoking, drying groundfish; OR packaging that groundfish for resale into 100 pound units or smaller for sale or distribution into a wholesale or retail market.

OR

2. The purchase and redistribution into a wholesale or retail market of live groundfish from a harvesting vessel.

[k] Transfer of physical assets alone should not be considered a basis for successor in interest. Business relationships such as transfer of the company name and customer base might be reasonable evidence of successor in interest.

Table 1. Full description of the IFQ program (continued).

[l] Due to the divestiture provision of Section A-2.3.2.e, it is relatively unlikely that accumulation limits will constrain the amount of QS an entity recieves in the initial allocaiton. However, if an entity qualifies for QS in excess of accumulation limits and it does not qualify to receive that QS under the divestiture provision, the initial allocation will be constrained by first applying the aggregate limits and then, if necessary, the individual species limits. In using this approach, the entity's QS allocation should not be scaled back more than necessary to stay within limits and any QS not allocated will be reallocated to other QS recipients.

[m] State landings receipts (fish tickets) will be used to assess landings history for shoreside deliveries. In some cases, fish ticket records do not identify species to the same level of detail used for the IFQ management units (e.g. reports "unspecified rockfish"). Standard species composition routines usually used at the port level have been applied to vessel level data to estimate the species composition of such landings. In some instances, even after applying species composition information there may be some fish ticket records with a species groundfish categorization that does not match with one of the IFQ management units (primarily "unspecified rockfish"). Under such circumstances, when the initial allocations are made other information on the landings records and in logbooks might be used to assign the landing to its most probable species category.

[n] The intent is to provide an allocation method for QS for overfished species which addresses the vessel's need to have the QS to cover incidental catch in fisheries that target healthy stocks. The method would attempt to allocate the species to those who will be receiving QS for related target species. By allocating overfished species QS to those most in need of it, such an allocation would be expected to reduce disruption and transition costs. Currently, the list of overfished species that fall into this category is as follows: bocaccio, canary rockfish, cowcod, darkblotched rockfish, Pacific Ocean perch, widow rockfish, and yelloweye rockfish. This list may change by the time the program is ready to be implemented. If a major target species became overfished, it would not be intended that such a species would be allocated this alternative method (for example species such as Dover sole, sablefish, or Pacific whiting).

[o] The four areas are as follows: (1) north of 47°40 N Lat; (2) between 47°40 N Lat and 43°55 N Lat; (3) between 43°55 N Lat and 40°10 N Lat; and (4) south of 40°10 N Lat

[p] In order to determine an amount of aggregate target species to which bycatch rates will be applied, each vessel's QS will be multiplied by the trawl allocation at the time of implementation.

[q] State landings receipts (fish tickets) will be used to assess landings history for shoreside deliveries.

[r] Catch area data on fish tickets are not considered appropriate for this purpose. The catch area field is often filled out by fish receivers that do not know the area in which the vessel fished. Additionally catch area is often left unspecified. Therefore it will be assumed that all catch comes from ocean areas near the port of landing.

[s] Unless there is a change in the total OY or other factors affecting trawl allocation for the areas involved, in which case their change in QP would be proportional to the change in the trawl allocation.

[t] QP from a subsequent year may not be accessed until such QP have been issued by NMFS.

[u] Including QS that an entity received in excess of accumulation limits in place at the time of initial allocaiton (see Section A-2.2.3.e).

[v] Carryover of deficits provides some flexibility to use pounds from a year to cover a deficit from a previous year. Without a carryover provision, a vessel would still need to use pounds in a subsequent year to cover an overage but would incur a violation.

Table 1. Full description of the IFQ program (continued).

[w] The following is the text deleted from this section: "No QS use-or-lose provision has been specified.. The need for this provision will be evaluated as part of program review process, and the provision could be added later, if necessary. *Section A-2.2.3.b contains a provision mandating the transfer of QP to vessels each year. This is intended to encourage QP use."*

[x] QS may be transferred on a temporary basis through private contract (leased) but NMFS will not track lease transfers differently than any other transfer.

[y] The "vessel" accumulation limit was originally termed a "permit" limit. The term "permit" was changed to "vessel" to be consistent with Section A-2.1.3, which indicates that QP go into vessel accounts, not permit accounts. The term "own or control" was shortened to "control" for simplicity. "Control" includes ownership and therefore is inclusive of "ownership."

[z] It is the Council intent that control limits should not constrain the formation of risk pools to help the fishermen deal with overfished species constraints, so long as the pools do not undermine the effectiveness of the accumulation limits. A risk pool is one in which two or more people enter into an agreement whereby if one person does not have the QP it needs the others would agree to provide the QP, if they have them. Whether these kinds of agreements are informal or formal, as other considerations and conditions are added to the agreements they may begin to constitute control. It is the Council intent to allow for these pooling agreements, so long as they do not become control.

[aa] For example, if a person has a 50 percent ownership interest in that entity, then 50 percent of the QS owned by that entity will count against the individual's accumulation limit unless it is otherwise determined that the have effective control of a greater or lesser amount.

[bb]**Expanded data collection** would include:

mandatory submission of economic data for LE trawl industry (harvesters and processors),

voluntary submission of economic data for other sectors of the fishing industry,

transaction value information in a centralized registry of ownership, and

formal monitoring of government costs.

Mandatory Provisions: The Pacific Fishery Management Council and NMFS shall have the authority to implement a data collection program for cost, revenue, ownership, and employment data, compliance with which will be mandatory for members of the West Coast groundfish industry harvesting or processing fish under the Council's authority. Data collected under this authority will be treated as confidential in accordance with Section 402 of the MSA.

A mandatory data collection program shall be developed and implemented as part of the groundfish trawl rationalization program and continued through the life of the program. Cost, revenue, ownership, employment and other information will be collected on a periodic basis (based on scientific requirements) to provide the information necessary to study the impacts of the program, including achievement of goals and objectives associated with the rationalization program. These data may also be used to analyze the economic and social impacts of future FMP amendments on industry, regions, and localities. The program will include targeted and random audits as necessary to verify and validate data submissions. Additional funding (as compared to status quo) will be needed to support the collection of these data. The data collected would include data needed to meet MSA requirements (including antirust).

Table 1. Full description of the IFQ program (continued).

The development of the program shall include: a comprehensive discussion of the enforcement of such a program, including discussion of the type of enforcement actions that will be taken if inaccuracies are found in mandatory data submissions. The intent of this action will be to ensure that accurate data are collected without being overly burdensome on industry in the event of unintended errors.

Voluntary Provisions: A voluntary data collection program will be used to collect information needed to assess spillover impacts on non-trawl fisheries.

Central Registry: Information on transaction prices will be included in a central registry of QS owners. Such information will also be included for LE permit owners/lessees.

Government Costs: Data will be collected and maintained on the monitoring, administration, and enforcement costs related to governance of the trawl rationalization program.

[cc] The following are three options for the sequences of agency involvement in decision making for the distribution of adaptive management QP after year 2..

1. NMFS
2. State → Council →NMFS
3. Council →NMFS

Page left intentionally blank

Table 2. Control and vessel limit options: Council preferred alternative.

Species Category	Vessel Limit (Applies to all QP in a Vessel Account, Used and Unused)	Vessel Unused QP Limit	QS Control Lim
Nonwhiting Groundfish Species	3.2%		2.7%
Lingcod - coastwide	3.2%		2.5%
Pacific Cod	20.0%		12.0%
Pacific whiting (shoreside)	15.0%		10.0%

3. Whiting At-sea Trawl Sector: Cooperative Program (Appendix B of the EIS)

The at-sea whiting sector co-op program is described generally below. Table 3 provides an outline of the sections of the program. A full description of the co-op programs follows Table 3, beginning with a section on management of the whiting fishery and followed by sections on the mothership and catcher-processor sectors of the whiting fishery (the "at-sea" sectors).

The Council considered but did not adopt a co-op program for the shoreside whiting fishery. Instead, the shoreside whiting sector was merged with the nonwhiting sector, both to be managed with IFQs. However, section place holders for the shoreside whiting co-op program are maintained in this document to maintain a numbering system that will correspond to the numbering of the alternatives and sections of the analysis as they are laid out in the EIS.

3.1. Overview of Co-op Program Elements

3.1.1. At-sea Whiting Sector Management under Co-ops

While co-ops will be used to control the harvest within the at-sea whiting sectors, a number of management measures will still be required to control competition between the whiting sectors. This section covers those measures along with other measures which will apply to all sectors managed under co-ops, such as observer requirements and mandatory submission of economic data. The description of the co-op management program for each at-sea whiting sector starts in Section 3.1.2.

The existing allocation of whiting between the shoreside, mothership, and catcher-processor (CP) sectors will not change under the rationalization program (42, 24, and 34 percent, respectively).

Provisions also address bycatch in the at-sea whiting fishery (particularly that of certain overfished species). The Council is recommending incidental groundfish species caps for each of the whiting sectors, for the co-op and non-co-op fisheries within the mothership sector, and for the co-ops within the mothership sector. Within sectors, bycatch allocations would be pro rata, based on the amount of whiting allocated to that sector.

Area closures may be used to control the pace of the fishery. For the mothership sector, the fishery will be divided into a co-op fishery and a non-co-op fishery (for those who do not desire to take part in a co-op). Participants in the non-co-op fishery will not have a claim to a particular amount of the fish allocated to that fishery; therefore the vessels will likely race to harvest the available allocation.

NMFS will close the whiting fishery, a particular sector, the co-op or non-co-op fishery within a sector, or individual co-ops, as appropriate, when it is projected that a whiting catch or bycatch limit will be reached. With respect to co-ops, inseason monitoring and closure will be needed only at the highest level of aggregation of the co-ops. For example, if individual co-ops join together to form an inter-co-op that covers the entirety of one of the whiting sectors, then NMFS will track and close at the sector level. Nevertheless, vessel level monitoring will still be required to ensure that catch is accurately recorded.

Given the high level of monitoring already in place in the whiting fishery, only moderate changes in monitoring are needed to implement this program for the at-sea whiting fishery. For the at-sea segment of the fishery, 100 percent coverage aboard mothership and catcher processors will continue. A program for the mandatory submission of economic data is also included, to facilitate monitoring program performance.

3.1.2. Co-ops for Catcher Vessels Delivering to Motherships

Under this program, those who hold whiting-endorsed permits for catcher vessels in the mothership sector will choose each year whether to be part of a co-op or to register to fish in the non-co-op portion of the fishery. The holders of catcher vessel permits with mothership whiting endorsements will form the co-ops. Based on its catch history, each permit that qualifies for a mothership whiting endorsement will be capped at a portion of the history (endorsement share) of the mothership sector allocation of whiting and bycatch species. Each year, NMFS will distribute a catch allocation to each catcher vessel co-op based on the sum of the endorsement shares for the permits registered to that co-op. NMFS will also distribute a catch allocation each year to the non-co-op portion of the fishery, based on the collective endorsement shares of the permits opting to participate in the non-co-op fishery.

The co-op organization will coordinate harvest by its members. Although co-op agreements will include a mandatory clause that the catch allocation made to a member must equal the amount that the member brings into the co-op, co-op members may transfer catch allocations among themselves. Similarly, if multiple co-ops join together in an inter-co-op, one co-op will be allowed to transfer catch allocation to another co-op within that inter-co-op. NMFS will not necessarily need to track transfers among co-op members or within an inter-co-op.

The class of motherships will be closed by creating a LE permit for mothership vessels. There will be restrictions limiting a vessels ability to both catch and operate as a mothership in the whiting fishery in the same year. This will limit the ability of processing vessels to move between the catcher processor and mothership sectors.

Prior to the start of each season, each catcher vessel permit desiring to participate in the co-op fishery will obligate itself to deliver its catch to a particular mothership. The obligation to a particular co-op or mothership will not carry-over from one year to the next, it may be changed at the catcher vessel permit owners discretion based on its preseason declaration. While catch may be transferred among participants in a co-op or inter-co-op, such transfers would not change the mothership to which the catch is obligated, unless a mutual agreement is reached.

As in the IFQ program, accumulation limits will be imposed to prevent excessive concentration of catch allocations. They will cap the proportion of whiting that an individual or entity can process, cap the proportion of whiting an individual or entity could accumulate via ownership of catcher vessel permit(s), and cap the amount that can be landed by any one catcher vessel.

3.1.3. Co-ops for Catcher-Processors

Under the catcher-processor (CP) co-op program, as under status quo, a voluntary CP co-op may continue to be formed by CP permit holders. This system will continue as long the existing co-op system continues to operate successfully or until the FMP is otherwise amended. If the voluntary co-op system fails, it will be replaced with an IFQ system. Currently the co-op operates under a private contract that includes division of the harvest among participants according to an agreed schedule. In the event the co-op system fails, IFQ will be allocated equally to each CP permit (equally divided among all CP endorsed permits).

Under the catcher-processor (CP) co-op program, the main Council recommendations are the creation of a CP endorsement to close the CP fishery to new entrants and the assignment of an allocation to the voluntary CP co-op. The endorsement will be granted to LE permits registered to CP vessels if the vessels meet specified qualification criteria. Only vessels with a CP LE permit will be allowed to harvest fish from the CP sector's allocation. LE permits with CP endorsements will continue to be transferable. NMFS will not establish an allocation of catch or catch history among CP permits unless the co-op fails. NMFS will specify in regulation the assignment of the CP sector allocation to the CP sector co-op. If necessary, a closure will be used to keep the CP sector from exceeding its allocation of whiting and bycatch species.

3.2. Detailed Specification of Co-op Program Elements

B-4.2	Co-op Formation and Operation Rules
B-4.3	NMFS Role

B-1 Whiting Sector Management Under Co-ops

B-1.1 Whiting Management

Under the co-op program, catcher vessel permits for the mothership sector will be endorsed for deliveries to motherships and amounts of history assigned to each catcher vessel permit based on past harvest in the fishery. Catcher-processor permits will be endorsed for participation in the catcher-processor sector.

The whiting catch history calculation for each mothership-endorsed catcher vessel permit [CV(MS)] will be assigned to a pool for the co-op in which the permit will participate or a pool for the mothership non-co-op fishery. NMFS will make an allocation assignment to the catcher-processor sector co-op based on the allocation to the CP sector. Co-ops are responsible for monitoring and enforcing the catch limits of co-op members.

NMFS will monitor the catch in the mothership non-co-op fishery, the mothership co-op fishery, the CP fishery, and the overall whiting catch of all at-sea sectors. NMFS will close each segment of the fishery based on projected attainment of whiting catch. Additionally, all at-sea sectors will be subject to closure based on attainment of the overall trawl whiting allocation.

B-1.2 Annual Whiting Rollovers

There will not be a rollover of unused whiting from one sector to another.

B-1.3 Bycatch Species Management

For the foreseeable future, the whiting fishery will be managed under bycatch limits (hard caps) for widow, canary, darkblotched rockfish, and Pacific Ocean perch. The catch of all groundfish will be accounted for and tracked against the OY.

The ESA-listed salmon bycatch management measures—that is, the 11,000 Chinook threshold, 0.05 rate threshold, and triggered 100 fathom closure—will also continue to be in place.

The goal of bycatch management is to control the rate and amounts of rockfish and salmon bycatch to ensure each sector is provided an opportunity to harvest its whiting allocation.

There will be a set aside of Pacific halibut for the at-sea whiting fishery, as specified in the intersector allocation process (Amendment 21).

B-1.3.1 Bycatch Allocation Subdivision

Subdivide bycatch species managed with hard caps (widow, canary, darkblotched rockfish, and Pacific Ocean perch) among each of the whiting sectors; within the sectors subdivide between the co-op fishery and non-co-op fishery (subdivision for the non-co-op fishery does not apply to the catcher-processor co-op program); and subdivide among co-ops.

Only those species with hard caps will be subdivided for bycatch management and bycatch will be allocated to each permit and co-op pro rata in proportion to its whiting allocation. The mothership sector's bycatch allocation will be divided between its co-op and non-co-op fishery, based on the allocations made to the permits participating in each portion of the fishery.

B-1.3.2 Bycatch Management

All sectors and co-ops will close based on projected attainment of the at-sea whiting fishery bycatch cap for any one species. The mothership co-op fishery, non-co-op fishery, and catcher-processor fishery will each be closed based on projected attainment of their individual allocation. Additionally, each co-op will cease fishing when its bycatch allocation is reached.

The Council may also use area closures (seasonal or year-round) to manage overfished stocks in the co-op and non-co-op fisheries. The area closures may be the same or different for different species. Area closures may be year-round, seasonal, or triggered automatically by the attainment of certain levels of catch.

Unused bycatch may be rolled over from one sector to another if the sector's full allocation of whiting has been harvested or participants in the sector do not intend to harvest the remaining sector allocation.

.

B-1.4 At-sea Observers/ Monitoring

At-sea Whiting Fishery: 100 percent observer coverage aboard mothership and catcher-processors will continue.

For some coverage, cameras may be used in place of observers (feasibility to be determined). It is the Council intent to provide NMFS flexibility sufficient to design and implementation a tracking and monitoring program that will achieve the goals and objectives of the trawl rationalization program.

B-1.5 Mandatory Data Collection

The following are the central elements of the data collection program that will be implemented as part of the co-op program.

- Mandatory submission of economic data for LE trawl industry (harvesters and processors).
- Voluntary submission of economic data for other sectors of the fishing industry.
- Include transaction value information in a centralized registry of ownership.
- Formal monitoring of government costs.

Mandatory Provisions. The Pacific Fishery Management Council and NMFS shall have the authority to implement a data collection program for cost, revenue, ownership, and employment data, compliance with which will be mandatory for members of the west coast groundfish industry harvesting or processing fish under the Council's authority. Data collected under this authority will be treated as confidential in accordance with Section 402 of the MSA.

A mandatory data collection program shall be developed and implemented as part of the groundfish trawl rationalization program and continued through the life of the program. Cost, revenue, ownership, employment and other information will be collected on a periodic basis (based on scientific requirements) to provide the information necessary to study the impacts of the program, including achievement of goals and objectives associated with the rationalization program. These data may also be used to analyze the economic and social impacts of future FMP amendments on industry, regions, and localities. The program will include targeted and random audits as necessary to verify and validate data submissions. *Data collected under this authority will be treated as confidential in accordance with Section 402 of the MSA.* Additional funding (as compared to status quo) will be needed to support the collection of these data. The data collected would include data needed to meet MSA requirements (including antirust).
The development of the program shall include a comprehensive discussion of the enforcement of such a program, including discussion of the type of enforcement actions that will be taken if inaccuracies are found in mandatory data submissions. The intent of this action will be to ensure that accurate data are collected without being overly burdensome to industry in the event of unintended errors. Annual reports will be provided to the Council.

Voluntary Provisions: A voluntary data collection program will be used to collect information needed to assess spillover impacts on non-trawl fisheries.

Central Registry: Information on transaction prices will be included in a central registry of whiting endorsed permit and mothership permit owners. Such information will also be included for sales and lessees.

Government Costs: Data will be collected and maintained on the monitoring, administration, and enforcement costs related to governance of the rationalization program.

B-1.6 Adaptive Management

There will not be an adaptive management set aside for the at-sea whiting fisheries. *(This section is being maintained as a place holder so that numbering will correspond to that in the alternatives and analysis of the EIS.)*

B-1.7 Length Endorsement

Length endorsement restrictions on LE permits endorsed for groundfish gear will be retained, however, the provision that requires that the size endorsements on trawl permits transferred to smaller vessels be reduced to the size of that smaller vessel will be eliminated (i.e. length endorsements will not change when a trawl endorsed permit is transferred to a smaller vessel).

B-2 Whiting Mothership Sector Co-Op Program

Overview. Qualified permits will be endorsed for mothership (MS) co-op participation. Each year the holders of those permits will choose whether their vessels will fish in the co-op fishery, in which individual co-ops will direct harvest, or fish in a non-co-op fishery that will be managed by NMFS as an Olympic style fishery. The co-op will be obligated to deliver its fish to specific mothership processors based on the obligations of each permit in the co-op determined based on preseason declarations. LE permits will be issued for motherships and required for a mothership to receive whiting from catcher vessels.

B-2.1 Participation in the Mothership Sector

a. Catcher Vessels

Vessels with CV(MS)-endorsed permits may participate in either the co-op or non-co-op portion of the mothership fishery. They will choose annually which fishery they will participate in for the coming year. Additionally, any groundfish LE trawl permitted vessels may participate in the co-op portion of the fishery if they join a co-op (as described in Section B-2.3.3).[6] No other catcher vessels may participate in the mothership fishery.

A vessel may not engage in the processing of whiting during any year in which a catcher vessel (mothership) (CV(MS)) endorsed permit is registered for use with the vessel.

b. Processors

Only motherships with a mothership LE permit may receive deliveries from catcher vessels participating in the co-op or non-co-op portions of the mothership sector whiting fishery. (Note: motherships may acquire such permits by transfer; see Section B-2.2.2.)

c. Vessels Excluded[7]

Motherships also operating as a catcher-processor may not operate as a mothership: during a year in which it also participates as a catcher-processor.

[6] When such permits participate in a co-op the co-op will not be allocated any additional fish based on participation by such a vessel.

[7] A vessel that has been under foreign registry after the date of the AFA and that has participated in fisheries in the territorial waters or exclusive economic zones of other countries will not be eligible to participate as a mothership in the mothership sector of the Pacific whiting fishery, as per Section 12102(c)(6) of the AFA.

B-2.2 Permits/Endorsement Qualification and Characteristics

B-2.2.1 Catcher Vessel Mothership Whiting Endorsement (CV(MS) Whiting Endorsement)

a. Endorsement Qualification and History Assignment

Permits with a qualifying history will be designated as CV(MS) permits through the addition of an endorsement to their LE groundfish permit. At the time of endorsement qualification, each permit will also be assigned a catch history that will determine the share of the mothership whiting allocation associated with that permit.

Qualifying for a CV(MS) Whiting Endorsement. A LE permit will qualify for a CV(MS) whiting endorsement if it has a total of more than 500 mt of whiting deliveries to motherships from 1994 through 2003

Catch History Assignment (Identification of Endorsement Related Catch History). The initial catch history calculation for CV(MS) whiting endorsements will be based on whiting history of the permit for 1994 through 2003, dropping 2 worst years. A permit's history for each year will be measured as a share of the fleet history for that year (i.e. "relative pounds" will be used This catch history will be used by NMFS to assign both whiting and bycatch species allocations to the co-ops and non-co-op fishery pools, as per section B.1.3.2.

For the purpose of the endorsement and initial calculation, catch history associated with the permit includes that of permits that were combined to generate the current permit.

b. Whiting Permit and Endorsement Transferability and Endorsement Severability

The CV(MS) whiting endorsement (together with the associated catch history) *may not be* severed from the groundfish LE trawl permit. Catch history associated with the whiting endorsement may not be subdivided. CV (MS) permits may be transferred two times during the fishing year, provided that the second transfer is back to the original catcher vessel (i.e. only one transfer per year to a different catcher vessel

c. Accumulation Limit

CV(MS) Permit Ownership: No individual or entity may own CV(MS) permits for which the allocation total is greater than 20%.
Catcher Vessel Usage Limit: No vessel may catch more than 30% of the mothership sector's whiting allocation.

d. Combination

CV(MS) Permit Combination to Achieve a Larger Size Endorsement. When a CV(MS)-endorsed permit is combined with another permit (including unendorsed permits), the resulting permit will be CV(MS) endorsed[8]

B-2.2.2 Mothership Processor Permit

a. Qualifying Entities

The owners of qualifying motherships will be issued MS permits. In the case of bareboat charters, the charterer of the bareboat will be issued the permit.

b. Qualification Requirements

A qualifying mothership is one which processed at least 1,000 mt of whiting in each of any two years from 1997 through 2003.

c. Transferability

1. MS permits will be transferable
2. MS permits may be transferred to a vessel of any size (there will be no size endorsements associated with the permit) MS permits **may not** be transferred to a vessel engaged in the *harvest* of whiting in the year of the transfer.
3. Limit on the Frequency of Transfers: MS permits may be transferred two times during the fishing year provided that the second transfer is back to the original mothership (i.e. only one transfer per year to a different mothership).

d. Usage Limit

No individual or entity owning a MS permit(s) may process more than 45 percent of the total MS sector whiting allocation.

[8] Specifically, a CV(MS)-endorsed permit that is combined with a LE trawl permit that is not CV(MS) endorsed or one that is CV(Shoreside) [CV(SS)] endorsed will be reissued with the CV(MS) endorsement. If the other permit is CV(SS) endorsed, the CV(SS) endorsement will also be maintained on the resulting permit. However, CV(MS) and CV(SS) catch histories will be maintained separately on the resulting permit and be specific to participation in the sectors for which the catch histories were originally determined. If a CV(MS) permit is combined with a CP permit, the CV(MS) endorsement and history will not be reissued on the combined permit. The size endorsement resulting from permit combinations will be determined based on the existing permit combination formula.

B-2.3 Co-op Formation and Operation Rules.

B-2.3.1 Who and Number of Co-ops

Co-ops are not required but may be voluntarily formed among CV(MS) permit owners. The number of co-ops will be indirectly limited by the limit on the minimum number of vessels able to form a co-op (see Section 2.3.3-b).

B-2.3.2 When

Each year at a date certain prior to the start of the fishery, MS and CV(MS) permit holders planning to participate in the mothership sector must register with NMFS. At that time CV(MS) permit holders must identify which co-op they will participate in or if they plan to participate in the non-co-op fishery.

B-2.3.3 Co-op Agreement Standards

a. Submissions to NMFS and the Council

Co-op agreement. Co-op agreements will be submitted to NMFS for approval. Signed copies of the cooperative contracts must be filed with the Council and NMFS and available for public review before the co-op is authorized to engage in fishing activities.[9] Any material changes or amendments to the contract must be filed annually with the Council and NMFS by a date certain.

Letter to Department of Justice. Co-ops must also file with the Council and NMFS a copy of a letter from the co-op requesting a business review letter on the fishery cooperative from the Department of Justice and any response to such request.

b. Number of Participants in Each Co-op (Including Inter-co-ops)

CV permits may join together in separate harvester co-ops. A minimum of 20% of the CV(MS) permit holders are required to form a co-op.[10] Co-ops may form co-ops with other co-ops. Within one of the whiting sectors, these co-ops may be formed to manage directed catch and/or bycatch. Whiting and bycatch allocations may be transferred among co-ops through inter-co-op agreements.

c. Catch History Distributions Among Permits

Co-op agreements must stipulate that catch allocations to members of the co-op be based on their catch history calculation by NMFS used for distribution to the co-op.

[9] During council discussion this was flagged by NOAA GC as a potential legal problem.

[10] The minimum threshold number of participants required to form a co-op balances the potential advantages for multiple co-ops while limiting implementation and management costs and administrative requirements for managing this sector.

d. Participation by Non-CV (MS) Endorsed Permits

Through temporary arrangements a co-op allocation may be harvested by any catcher vessel holding a valid LE trawl permit which has joined the co-op (including one that does not have a CV(MS) endorsement).[11]

e. Other Required Co-op Agreement Provisions

The Council's intent is to have mothership sector participants work with NMFS to develop and describe a process and co-op agreement requirements to include in implementing regulations for this action.

A co-op agreement must include:

1. A list of all vessels, and which must match the amount distributed to individual permit holders by NMFS
2. Signature of all permit holders participating in the co-op
3. A plan to adequately monitor catch and bycatch
4. Adequate enforcement and penalty provisions to ensure that catch and bycatch overages do not occur
5. Measures designed to reduce bycatch of overfished species
6. An obligation to manage inseason transfers of catch history
7. A requirement that agreement by at least a majority of the members is required to dissolve a co-op (**During council discussion this was flagged by NOAA GC as a potential legal problem**)
8. An obligation to produce an annual report to the Council and NMFS by a date certain documenting the co-op's catch and bycatch data and inseason transfers (the report is to be available for review by the public)
9. Identification of a co-op manager who will:
   a. serve as the contact person with NMFS, the Council and other co-ops,
   b. be responsible for the annual distribution of catch and bycatch,
   c. oversee transfers,
   d. prepare annual reports, and
   e. be authorized to receive or respond to any legal process against the co-op.
10. Provisions that prohibit co-op membership by permit holders that have incurred legal sanctions that prevent them from fishing groundfish in the Council region
11. A provision that requires new owners to comply with membership restrictions in the co-op agreements

f. Additional Provisions for Inter-co-op Agreements

1. In the case of two or more cooperatives entering into an inter-cooperative agreement, the inter-co-op agreement must incorporate and honor the provisions of the individual co-op agreements unless all such agreements (or modifications thereof) are resubmitted for approval.
2. The requirements of Sections 2.3.3.a-2.3.3.e apply to the inter-co-op agreement, except that for the purpose of Section 2.3.3.e., subparagraph 7, the members of the inter-co-ops are the co-ops and not the participants in each co-op.

[11] As a member of the co-op, such a vessel would be subject to Section B-2.4 and the indicated processor obligations.

B-2.3.4 Annual Allocation Transferability

a. The annual allocations received by a co-op based on catch history of the whiting endorsements held by its members may be transferred among co-op members and from one co-op to another so long as obligations to processors are met (as per Section B-2.4). Additionally, in order to transfer annual allocation from one co-op to another there must be a NMFS approved inter-co-op agreement.
b. Allocations may not be transferred from the mothership sector to another sector.

B-2.4 Obligations to Processors (Processor TIes)

Each year, a permit will obligate to a processor all of its catch for a coming year.

B-2.4.1 Formation and Modification of Processor Tie Obligations

There will not be processor tie that caries from one year to the next. CV(MS) permits will be obligated to a single MS permit for an entire year but may change to a different MS permit through a preseason declaration of intent.

By September 1 of the year prior to implementation and every year thereafter, each CV(MS) permit is required to contact NMFS and indicate whether CV(MS) permit will be participating in the co-op or non-co-op fishery in the following year. If participating in the co-op fishery, then CV(MS) permit must also provide the name of the MS permit that CV(MS) permit will be linked to in the following year (i.e., annual catcher vessel, mothership linkage that may be changed each year without requirement to go into the "non-co-op" fishery). Once established, the catcher vessel, mothership linkage shall remain in place until changed by CV(MS) permit.

Mothership Permit Transfer. If a mothership transfers its MS permit to a different mothership or different owner, the CV(MS) permit obligation for that year remains in place and transfers with the MS permit to the replacement mothership unless the obligation is changed by mutual agreement. The obligation does not extend beyond the fishing year.

B-2.4.2 Flexibility in Meeting Obligations to Processors

a. Temporary Transfer of the Annual Allocation Within the Co-op or from One Co-op to Another

When CV(MS) permit owners transfer co-op allocations from one co-op member to another within the co-op or from one co-op to another within an inter-co-op such allocations must be delivered to the mothership to which the allocation is obligated through the preseason declaration, unless released by mutual agreement.

b. Mutual Agreement Exception

By mutual agreement of the CV(MS) permit owner and mothership to which the permit is obligated, a permit may deliver to a licensed mothership other than that to which it is obligated.

B-2.4.3 Mothership Processor Withdrawal

If a mothership withdraws subsequent to quota assignment, then the CV(MS) permit that it is obligated to it is free to participate in the co-op or non-co-op fishery. The MS permit shall notify NMFS and linked CV(MS) permits of its withdrawal, and CV(MS) permits shall notify NMFS of their intent to participate in the co-op or non-co-op fishery thereafter. If continuing in co-op fishery, then CV(MS) permit shall provide NMFS with the name of the new MS permit to which it will be obligated for that season.

B-2.5 NMFS Role

B-2.5.1 Permit and Endorsement Issuance

NMFS will issue all necessary permits and endorsements under the rules specified under this program. Appeals processes will be provided as appropriate and necessary.

B-2.5.2 Fishery Registration and Co-op Approval

NMFS will announce a deadline before which all co-op agreements must be received for the coming year. NMFS will review and approve or reject co-op agreements based on standards provided here and other standards that it deems necessary to achieve the policy intent of the Council's actions.

B-2.5.3 Annual Allocation to Co-ops and the Non-co-op Fishery

a. Co-op Allocation

Each year NMFS will determine the percent of the mothership sector's harvest allocation to be given to each co-op based on the catch history calculation of CV(MS) permits registered to participate in the co-op that year. NMFS does not allocate to the individual permit holder; rather, NMFS allocates an aggregate amount of harvest tonnage annually to the co-op based on the catch histories associated with the members of the co-ops.

b. Non-co-op Allocation

Each year NMFS will determine the distribution to be given to the non-co-op fishery based on the catch history calculation of permit holders registered to participate in that fishery.

B-2.5.4 Fishery Management and Co-op Monitoring

1. NMFS will track all permit transfers and the invocation of mutual agreement exceptions. Permit transfers will not be valid until registered and acknowledged by NMFS.

2. NMFS will monitor catch and close segments of the fishery as necessary to ensure catch limits are not exceeded for:
   a. the whiting mothership co-op fishery

   b. the whiting mothership non-co-op fishery
   c. the mothership whiting sector as a whole
3. NMFS will not necessarily monitor, but will investigate and enforce as it deems necessary, the permit and co-op obligations to motherships.
4. NMFS will not necessarily monitor or enforce (except as it deems necessary):
   a. an individual permit's progress towards its catch allocations (permit level catch control will be at the co-op level and enforced through execution of the private contract)
   b. a co-op's progress toward its catch allocation[12]
   c. actual performance of the co-op agreement (the parties to the contract will resolve through private contract and remedies any deviation from provisions such as that requiring that a vessel have the opportunity to harvest the catch allocated to the co-op based on that vessel's permit, Section B-2.3.3.c)
5. NMFS will monitor other program provisions as needed. In some situations, there may need to be a declaration procedure to determine where a permit is delivering its obligated catch, for example, if a mothership withdraws without transferring its permit or reaching a mutual agreement for the transfer of obligated deliveries to a different mothership.

B-3 Whiting Shoreside Sector Co-Op Program (placeholder, not recommended)

The shoreside whiting sector will be managed with an IFQ program. This section header is being maintained so that section numbering here will correspond to section numbering in the alternatives and analysis in the EIS.

[12] This assumes that there is an inter-co-op agreement in place that covers the entire co-op fishery. If such an agreement is not in place covering both catch and bycatch, NMFS may need to monitor catch by each individual co-op (but not by the individual vessels in the co-op).

B-4 Catcher-Processors Co-op Program

Catch by the catcher-processor sector will be controlled primarily by closing the fishery when a constraining allocation is reached.[13] As under status quo, vessels may form co-ops to achieve benefits that result from a slower-paced, more controlled harvest. The main recommendations are the creation of a limited number of catcher-processor endorsements and the specification in regulation of the amounts that will be available for harvest by the voluntary co-op. A new entrant will have to acquire a permit with a catcher-processor endorsement in order to enter the fishery. If the co-op system fails it will be replaced by an IFQ program and the initial issuance of IFQ will be allocated equally among the permits (equally divided among all CP endorsed permits).

B-4.1 Participation in the Catcher-Processor Sector , Endorsement Qualification and Permit Transferability.

Catcher-processor (CP) Endorsement. The class of CP endorsed permits (CP permits) will be limited by an endorsement placed on a LE permit. LE permits registered to qualified catcher-processor vessels will be endorsed as CP permits. A qualified permit is one that harvested and processed in the catcher-processor sector of the Pacific whiting fishery at any time from 1997 through 2003. Only vessels catcher-processor vessels with a CP endorsed LE permit will be allowed to process whiting at-sea as part of the CP sector. LE permits with CP endorsements will continue to be transferable.

Participation as Mothership. A catcher-processor cannot operate as a mothership during the same year it participates in the CP fishery.

CP Permit Combination to Achieve a Larger Size Endorsement. A CP permit that is combined with a LE trawl permit that is not CP endorsed will result in a single CP permit with a larger size endorsement. (A CV(MS) endorsement on one of the permits being combined will not be reissued on the resulting permit.) The resulting size endorsement will be determined based on the existing permit combination formula.

CP Permit Transfers to Smaller Vessels. Length endorsement restrictions on LE permits endorsed for groundfish gear will be retained, however, the provision that requires that the size endorsements on trawl permits transferred to smaller vessels be reduced to the size of that smaller vessel will be eliminated (i.e. length endorsements will not change when a trawl endorsed permit is transferred to a smaller vessel).

Number of Transfers Per Year. CP permits may be transferred two times during the fishing year, provided that the second transfer was back to the original CP (I.e., only one transfer per year to a different CP).

[13] All references to catcher-processors in this section references to vessels operating in the catcher-processor sector. Vessels under 75' which catch and process at-sea as part of the shoreside sector are not covered here.

B-4.2 Co-op Formation and Operation Rules

No annual registrations or declarations are required. As under status quo, co-op(s) will be formed among holders of permits for catcher-processors. Participation in the co-op will be at the discretion of those permit holders. If eligible participants choose to form a co-op, the catcher-processor sector will be managed as a private voluntary cooperative and governed by a private contract that specifies, among other things, allocation of whiting among CP permits, catch/bycatch management, and enforcement and compliance provisions. Under the co-op program, if more than one co-op is formed, a race for fish could ensue absent an inter co-op agreement. NMFS will not establish an allocation of catch or catch history among permits unless the co-op fails to form. If the co-op system fails it will be replaced by an IFQ program and the initial issuance of IFQ will be divided equally among all CP endorsed permits.

Annual Reporting Requirements. The CP cooperative will submit an annual report to the Pacific Fishery Management Council at their November meeting. The report will contain information about the current year's CP fishery, including the CP sector's annual allocation of Pacific whiting; the CP cooperative's actual retained and discarded catch of Pacific whiting, salmon, rockfish, groundfish, and other species on a vessel-by-vessel basis; a description of the method used by the CP cooperative to monitor performance of cooperative vessels that participated in the CP sector of the fishery; and a description of any actions taken by the CP cooperative in response to any vessels that exceed their allowed catch and bycatch. The report will also identify plans for the next year's CP fishery, including the companies participating in the cooperative, the harvest agreement, and catch monitoring and reporting requirements.

B-4.3 NMFS Role

B-4.3.1 Permit and Endorsement Issuance

NMFS will issue all necessary endorsements under the rules specified under this program. Appeals processes will be provided as appropriate and necessary.

B-4.3.2 Annual Allocation

Harvest amounts for the co-op will be specified in regulation. If the co-op breaks up, IFQ will issued and divided equally among the 10 permits.

The catcher-processor sector allocation may be divided among eligible catcher-processor vessels (i.e., those catcher-processor vessels for which a CP permit is held) according to an agreed catcher-processor cooperative harvest schedule as specified by private contract.

B-4.3.3 Fishery and Co-op Monitoring

1. NMFS will track all permit transfers. Permit transfers will not be valid until registered and acknowledged by NMFS.
2. NMFS will monitor catch and close the catcher-processor sector fishery as necessary to ensure catch limits are not exceeded.

Agenda Item E.6.b
NMFS Report
September 2009

AMENDMENT 20 & 21 (Trawl Rationalization and ISA) –DEEMING round 1

NMFS is developing regulations to implement the groundfish trawl rationalization program (program) based on our ongoing review of recommendations from the Council. The Council has developed the trawl rationalization program through two amendments to the Pacific Coast Groundfish Fishery Management Plan (FMP): (1) Amendment 20, the trawl rationalization program, and (2) Amendment 21, intersector allocation. Amendment 20 would create the structure and management details of the trawl rationalization program while Amendment 21 would allocate the groundfish stocks between trawl and non-trawl fisheries. The Council took initial action on Amendment 20 at its November 2008 meeting, with subsequent actions at its March and April 2009 meetings, culminating in a final recommendation to NMFS at the June 2009 meeting. The Council took final action on Amendment 21 at its April 2009 meeting but revised its recommendation on Pacific halibut at its June 2009 meeting. These amendments have not yet been formally transmitted from the Council to NMFS, but are scheduled for transmission in the spring of 2010.

To prepare for transmission of these amendments, NMFS is working on the following:

- A schedule of actions
- A rulemaking to collection ownership information for the program
- An outline of the regulatory structure for the program
- The initial issuance and appeals process

For the November Council meeting, NMFS plans to continue working on elements of the trawl rationalization program and bring further detail concerning the regulations forward for deeming by the Council. NMFS also plans to bring forward any issues which may need further clarification.

Draft Schedule

NMFS announced a draft schedule for implementation at the June PFMC meeting under Agenda item E.10. This schedule reiterates that announcement.

- NMFS intends to combine review and, pending approval, implementation of AM 20 & 21. NMFS and Council staff will work together to set a transmittal day for both FMP Amendments, likely spring 2010.

- Subject to review and approval, NMFS intends to implement the trawl rationalization program through three or more rulemakings beginning in the fall of 2009.
    1. Ownership data rule
    2. AM 20 & 21 FMP and “grand framework” rule
    3. Follow-up rule

- The ownership data rule is explained below and will allow NMFS to begin collecting ownership information for the trawl rationalization program. It will also announce the databases NMFS intends to use to determine initial QS (PacFIN & NorPac).
  - proposed rule to be published in September 2009
  - ownership information collected from industry beginning in early 2010

- If the AM 20 & 21 DEISs are published in November 2009, review of AM 20 & 21 and rulemaking for the main program components is scheduled for the summer/fall of 2010. The initial issuance and appeals process is scheduled to begin in late 2010.

- NMFS expects that there will be a need to do beta testing of tracking and monitoring components over the summer of 2010.

- NMFS believes there will be a need for a follow-up rule that will implement further program details possibly including additional tracking and monitoring requirements and cost recovery.

Ownership Data Proposed Rule

In September 2009, NMFS plans to publish a proposed rule to collect ownership interest information from potential participants in the trawl rationalization program (a draft of the proposed rule is provided under this agenda item). In order to prepare for implementation of the accumulation limits, this rule would allow NMFS to begin collecting ownership information from potential participants in the program, including the at-sea fleet (whiting motherships, whiting mothership catcher vessels, and whiting catcher/processors), the shore-based fleet (whiting and non-whiting permit owners and vessel owners) and the whiting shore-based processors. Similar to current requirements to collect ownership information from the limited entry fixed gear sablefish fleet, the primary purpose of collecting ownership interest information from the trawl fleet is to allow NMFS to monitor control of the groundfish resource in the trawl fishery to ensure participants remain within the accumulation limits recommended by the Council in Amendment 20 to the FMP. Initially, NMFS would use the ownership information collected as the first step in the application process to determine which potential quota share holders might be over their accumulation limits as an individual or as a member of a business entity. By collecting ownership information from potential participants in advance of the FMP amendment approval process, NMFS would expedite the quota share initial issuance process which is expected to take place in the fall of 2010. After ownership interest forms from this rulemaking are completed early in 2010, NMFS could provide partially pre-completed ownership interest forms with the initial issuance package in the fall of 2010, reducing the burden on potential participants and shortening the application process. If the ownership information requested as part of this rulemaking is not completed, it may delay implementation of the trawl rationalization program or issuance of an eligible participant’s quota share.

NMFS would collect ownership information through a Trawl Identification of Ownership Interest Form (a draft form is provided under this agenda item) mailed out to potential participants in the program. This rule would establish a onetime mailing requesting this information. Failure to return the completed form and any required supplemental documentation may result in the entity not receiving an initial allocation of QS, should the future trawl rationalization program be implemented. In the future and if the trawl program is implemented under Amendment 20, the form would likely be required during the permit or QS renewal process and during any permit or QS transfers.

This action would also announce that NMFS intends to use landings data from the Pacific States Marine Fisheries Commission's PacFIN and the NMFS, Northwest Fisheries Science Center's Pacific whiting observer (NORPAC) databases to determine initial allocations of quota share for the program. This action urges potential quota share owners to go directly to the source where fisheries data is entered in to these databases to get it corrected before NMFS extracts the data for initial issuance of quota share.

The public comment period is expected to be sometime between September and October 2009.

Draft Regulatory Structure

In reviewing the existing groundfish regulatory structure to plan for the trawl rationalization program, NMFS sees the opportunity to reorganize the entire groundfish regulations to make them easier to follow on a program by program basis. The trawl rationalization program will add regulatory complexity to the existing groundfish regulations. In an effort to make Federal regulations easier to follow and to prevent program-specific regulations, like the trawl rationalization program, from becoming too compartmentalized in the existing regulations, NMFS is reorganizing the groundfish regulations in to multiple subparts within the Code of Federal Regulation (CFR). Current groundfish regulations are found at 50 CFR part 660, subpart G. The reorganized groundfish regulations would be found at 50 CFR part 660, subparts C through G. An outline of the current and draft regulatory structure follows.

CURRENT

50 CFR CHAPTER VI
PART 660–FISHERIES OFF WEST COAST AND WESTERN PACIFIC STATES

Subpart A–General
660.1 Purpose and scope.
660.2 Relation to other laws.
660.3 Reporting and recordkeeping.

Subpart B-F [Reserved]

Subpart G–West Coast Groundfish Fisheries
660.301 Purpose and scope.
660.302 Definitions.
660.303 Reporting and recordkeeping.
660.305 Vessel identification.
660.306 Prohibitions.

monitoring
660.312 Vessel Monitoring Program (VMS) requirements.
660.314 Groundfish observer program.

allocations
660.320 Allocations.
660.321 Black rockfish harvest guideline.
660.322 Sablefish allocations.
660.323 Pacific whiting allocations, allocation attainment, and inseason allocation reapportionment.
660.324 Pacific Coast treaty Indian fisheries.

LE program
660.331 Limited entry and open access fisheries--general.
660.333 Limited entry fishery–eligibility and registration.
660.334 Limited entry permits–endorsements.
660.335 Limited entry permits–renewal, combination, stacking, change of permit ownership or permit holdership, and transfer.
660.336 Pacific whiting vessel licenses.
660.337 [Reserved]
660.338 Limited entry permits–small fleet.
660.339 Limited entry permit and Pacific whiting vessel license fees.
660.340 Limited entry permit appeals.
660.341 Limited entry permit sanctions.

660.350 Compensation with fish for collecting resource information–exempted fishing permits.
660.365 Overfished species rebuilding plans.

special programs
660.370 Specifications and management measures.
660.371 Black rockfish fishery management.
660.372 Fixed gear sablefish fishery management.
660.373 Pacific whiting (whiting) fishery management.

spex & mgmt measures
660.380 Groundfish harvest specifications.
660.381 Limited entry trawl fishery management measures.
660.382 Limited entry fixed gear fishery management measures.
660.383 Open access fishery management measures.
660.384 Recreational fishery management measures.
660.385 Washington coastal tribal fisheries management measures.

closed areas
660.390 Groundfish conservation areas.
660.391 Latitude/longitude coordinates defining the 27 fm (49 m) through 40 fm (73 m) depth contours.
660.392 Latitude/longitude coordinates defining the 50 fm (91 m) through 75 fm (137 m) depth contours.
660.393 Latitude/longitude coordinates defining the 100 fm (183 m) through 150 fm (274 m) depth contours.
660.394 Latitude/longitude coordinates defining the 180 fm (329 m) through 250 fm (457 m) depth contours.
660.395 Essential Fish Habitat (EFH).
660.396 EFH Conservation Areas.
660.397 EFH Conservation Areas off the Coast of Washington.
660.398 EFH Conservation Areas off the Coast of Oregon.
660.399 EFH Conservation Areas off the Coast of California.

TABLES: Tables (1a), OY tables (1b), Allocation tables (1c), Tables 2a, 2b, and 2c, Tables 3-5 North and South (Trip Limit Tables), and Figure 1, and Table 2 to Part 660 (Vessel Capacity Ratings)

REORGANIZED

Subpart A–General (stays same)

Subpart B [Reserved]

Subpart C – West Coast Groundfish Fisheries – General (660.10-660.99)
Purpose and Scope
Definitions
Prohibitions
Recordkeeping and reporting
Vessel Monitoring System (VMS) Program requirements.
Groundfish observer program.
Vessel and Gear Identification
Permits and Fees – limited entry permits
Compensation with fish for collecting resource information - EFPs
Overfished species rebuilding plans
Pacific Coast Treaty Indian fisheries
Allocations (include sablefish, whiting, black rockfish)
Specifications and management measures.
Groundfish harvest specifications.
Closed Area - GCA's and EFH
* ABC/OY Tables - Tables 1a-c & 2a-c
* Vessel Capacity Rating Table - Table 2 to Part 660

Subpart D – West Coast Groundfish – Trawl Fisheries (660.100-660.199)
IFQ Program – Shore-based Trawl Fishery
- IFQ Species and Allocations
- QS permits and accounts
- Vessel QP accounts
- Processor Permit
- Observers/Compliance monitors/cameras (?)
- Retention requirements (whiting and non-whiting vessels)
- Gear Switching (?)
- Adaptive Management Program

Mothership (MS) Co-op Program – Whiting At-sea Trawl Fishery
- MS Co-op Program Species and Allocations
- Co-op Permit (Agreement)
- Mothership Permit
- Catcher Vessel Mothership (CV/MS) endorsement
- Inter-Co-op Agreements
- Co-op accounts
- Non-Co-op Fishery
- Observers/cameras (?)
- Retention requirements

Catcher-Processor (C/P) Co-op Program - Whiting At-sea Trawl Fishery
- C/P Co-op Program Species and Allocations
- Co-op Permit (Agreement)
- C/P endorsement
- Observers
- Retention requirements

Crossover provisions – Areas, Gears (?), Trawl Fisheries
Limited entry trawl fishery management measures.
* Figure 1 & Trip Limit Tables - Table 3 North and South

Subpart E – West Coast Groundfish - Fixed Gear Fisheries (660.200-660.299)
Fixed gear sablefish fishery management.
Limited entry fixed gear fishery management measures.
* Trip Limit Tables - Table 4 North and South

Subpart F – West Coast Groundfish - Open Access Fisheries (660.300-.349)
Open access fishery management measures.
* Trip Limit Tables - Table 5 North and South

Subpart G – West Coast Groundfish – Recreational Fisheries (660.350-.399)

Initial Issuance and Appeals

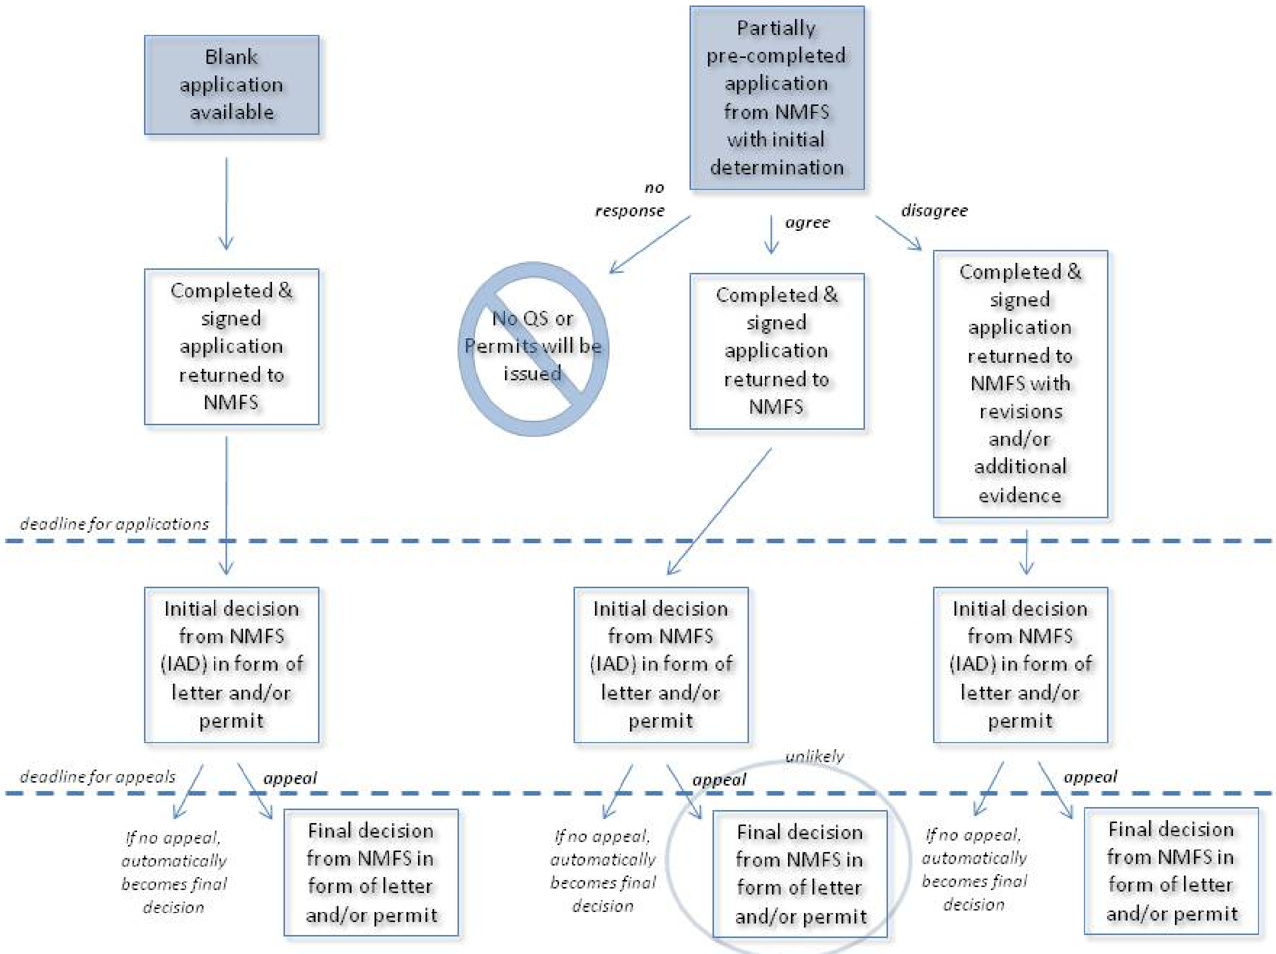
NMFS is still developing an initial issuance and appeals process. The draft implementation schedule provides NMFS only four months to go through the initial issuance and appeals process. Therefore, NMFS is making an effort to streamline that process via the ownership data rulemaking and providing partially pre-completed applications. Currently, NMFS intends to mail out partially pre-completed applications to participants NMFS determines are eligible to qualify for the following: IFQ QS, co-op mothership permits, co-op mothership/catcher vessel endorsements with catch history assignments, co-op catcher/processor endorsements. (Additional permits may be required for the IFQ and co-op fisheries, but would be handled on an ongoing basis, through a separate process (e.g., IFQ processor/first receiver permits, co-op permits)). NMFS would also provide blank applications on our website and by request for people that did not receive a pre-completed application and who can provide credible evidence that they should qualify. For the IFQ fishery, pre-completed applications would include NMFS determination of QS for each species and landings or data used to figure QS.

Potential QS, permit, or endorsement owners would return signed applications either agreeing with NMFS' initial determinations and requesting the QS, permit, or endorsement or disputing NMFS determination and providing additional credible evidence. This is a "pre-appeal" opportunity intended to speed up the initial issuance process, while still allowing fishermen an opportunity to correct their QS, mothership/catcher vessel catch history assignment, or initial determination. ALL applications would have a deadline by which they must be completed and returned to NMFS. QS, permits, or endorsements would not be issued to late applications.

NMFS would then make an initial administrative decision (IAD) that would be sent to the applicant in writing. If the applicant qualifies, the initial administrative decision would include QS, a permit, or an endorsement on a limited entry groundfish trawl permit, as appropriate. There would be one chance to appeal the initial administrative decision within a given deadline. Appeals would be reviewed by an appeals officer who makes a recommendation to the NMFS, Northwest Region, Regional Administrator. The final decision would be in writing from the Regional Administrator. If the applicant then qualifies, the final decision would include QS, a permit, or an endorsement on a limited entry groundfish trawl permit, as appropriate. Or, for QS or mothership/catch vessel catch history assignments, if the amount is different than the initial administrative decision, the final decision would include revised QS or catch history assignments, respectively.

The following is a diagram of the preliminary draft initial issuance and appeals process:

Preliminary draft initial issuance and appeals process -



BILLING CODE 3510-22-S

DEPARTMENT OF COMMERCE

National Oceanic and Atmospheric Administration

50 CFR Part 660

[Docket No.   ]

RIN 0648-AX98-X

Fisheries off West Coast States; Pacific Coast Groundfish Fishery; Data Collection for the Trawl Rationalization Program

AGENCY: National Marine Fisheries Service (NMFS), National Oceanic and Atmospheric Administration (NOAA), Commerce.

ACTION: Proposed rule; request for comments.

SUMMARY: NMFS proposes to collect data to support implementation of a future trawl rationalization program under the Pacific Coast Groundfish Fishery Management Plan (FMP). NMFS proposes to collect ownership information from all potential participants in the trawl rationalization program. In addition, NMFS is notifying potential participants that the agency intends to use the Pacific States Marine Fisheries Commission's Pacific Fisheries Information Network (PacFIN) database and the NMFS, Northwest Fisheries Science Center's Pacific whiting observer data from NORPAC (a database of North Pacific fisheries and Pacific whiting information) to determine initial allocation of quota share (QS) for the trawl rationalization program, if approved and implemented.

DATES: Comments on this proposed rule must be received no later than 5 p.m., local time on [Insert date 30 days after date of publication in the FEDERAL REGISTER].

ADDRESSES: You may submit comments, identified by RIN 0648-AX98 by any one of the following methods:

Electronic Submissions: Submit all electronic public comments via the Federal eRulemaking Portal http://www.regulations.gov.

Fax: 206-526-6736, Attn: Jamie Goen.

Mail: Barry Thom, Acting Administrator, Northwest Region, NMFS, 7600 Sand Point Way NE, Seattle, WA 98115-0070, Attn: Jamie Goen.

Instructions: All comments received are a part of the public record and will generally be posted to http://www.regulations.gov without change. All Personal Identifying Information (for example, name, address, etc.) voluntarily submitted by the commenter may be publicly accessible. Do not submit Confidential Business Information or otherwise sensitive or protected information.

NMFS will accept anonymous comments (enter N/A in the required fields if you wish to remain anonymous). Attachments to electronic comments will be accepted in Microsoft Word, Excel, WordPerfect, or Adobe PDF file formats only. Written comments regarding the burden-hour estimates or other aspects of the collection-of-information requirements contained in this proposed rule may be submitted to NMFS, Northwest Region and by e-mail to David_Rostker@omb.eop.gov or fax to (202) 395-7285.

FOR FURTHER INFORMATION CONTACT: Jamie Goen, phone: 206-526-4656, fax: 206-526-6736, and e-mail jamie.goen@noaa.gov.

SUPPLEMENTARY INFORMATION:

Electronic Access

This proposed rule is accessible via the Internet at the Office of the Federal Register's Website at http://www.gpoaccess.gov/fr/index.html. Background information and documents are available at the Pacific Fishery Management Council's website at http://www.pcouncil.org/.

Background

Since 2003, the Pacific Fishery Management Council (Council) has been developing a trawl rationalization program for the Pacific Coast groundfish fishery, which would affect the limited entry trawl fishery. The trawl rationalization program is intended to increase net economic benefits, create individual economic stability, provide full utilization of the trawl sector allocation, consider environmental impacts, and achieve individual accountability of catch and bycatch.

The Council has developed the trawl rationalization program through two amendments to the Groundfish FMP: (1) Amendment 20, the trawl rationalization program, and (2) Amendment 21, intersector allocation. Amendment 20 would create the structure and management details of the trawl rationalization program while Amendment 21 would allocate the groundfish stocks between trawl and non-trawl fisheries. The Council took final action on Amendment 20 at their November 2008 meeting, with trailing actions at its March 2009, April 2009, and June 2009 meetings. The Council took final action on Amendment 21 at its April 2009 meeting. When the Council formally transmits those amendments to NMFS, the agency will publish a notice of availability (NOA) of an FMP amendment and a proposed rule in the Federal Register to announce a public comment period. Following the public comment period on the NOA and proposed rule, NMFS will announce its decision on whether or not to approve the amendments in a final rule published in the Federal Register. The FMP approval process and implementation, if appropriate, are expected to occur in 2010.

The trawl rationalization program would be a limited access privilege program (LAPP) under the Magnuson-Stevens Fishery Conservation and Management Act, as reauthorized in 2007 (MSA). A LAPP is considered a grant of permission to the holder of the limited access privilege or quota share to participate in the program and may be revoked, limited, or modified at any time. In other words, it is a conditional privilege, conveyed through quota shares or catch shares, to harvest a specified amount of fish. The MSA requires the Council or the Secretary of Commerce to ensure that limited access privilege holders do not acquire an excessive share of the total limited access privileges in the program and to establish a maximum share, expressed as a percentage that each limited access privilege holder may hold, acquire, or use. For the trawl rationalization program, the Council has adopted limits on the amount of pounds a vessel can hold, acquire, or use (i.e., vessel limits) and limits on the amount of quota share that can be held, acquired, or used (i.e., control limits).

Trawl Rationalization Program Structure

The trawl rationalization program would consist of: (1) an individual fishing quota (IFQ) program for the shore-based trawl fleet and (2) cooperative (co-op) programs for the at-sea trawl fleet. The shore-based trawl fleet would include IFQ participants who land groundfish to shore-based processors or first receivers. The at-sea trawl fleet would include fishery participants harvesting whiting with midwater trawl gear (i.e., whiting catcher/processor vessels, whiting motherships, and whiting catcher vessels associated with motherships). The co-op programs for the at-sea trawl fleet are further divided as follows: (1) the whiting catcher/processor co-op; and

(2) the whiting mothership co-ops. The mothership co-ops may consist of a single or multiple co-ops where vessels pool their harvest together or may consist of vessels not associated with a particular mothership (i.e., “non-co-op” segment of the mothership fishery).

The IFQ program for the shore-based fleet would require an initial allocation of harvest quota share to individual participants based on historic participation in the fishery, specifically to limited entry trawl permit owners and shore-based whiting processors who meet the eligibility requirements. In order to comply with the MSA, NMFS would be required to determine and track ownership interest in quota shares to determine if individuals are within set limits, both at the initial allocation stage and during the operation of the program. In Amendment 20, the Council has adopted limits (by species group and area) on the amount of quota share an individual can control (i.e. control limits).

The Council has adopted different whiting catcher/processor co-op and whiting mothership co-ops based on how the co-ops have operated in the past. The structure of the co-ops will be described in more detail in the proposed rule to implement Amendment 20, expected in 2010. The catcher/processor co-op would not require an initial allocation to individual vessels, provided a co-op is established, while the mothership co-op would. Quota shares for the at-sea fleet (called catch history assignments in Council documents) would initially be allocated to the individual whiting catcher vessels associated with the mothership fishery and would be non-transferable amounts associated with the vessel. They would show how much an individual vessel contributes to the total amount of fish their mothership co-op can harvest. However, the individual vessel in the co-op could harvest more than their at-sea quota, within the restrictions on individual vessel harvest and mothership co-op limits. Similar to the shore-based IFQ program, NMFS would be required to track ownership interest in quota shares to determine if individuals are within set limits. In addition, ownership interest in the co-op programs (catcher/processor and mothership) and IFQ program would be tracked to the individual level to monitor crossover of participants and ownership interest among the programs.

Collection of Ownership Information

Pursuant to section 402(a)(2) of the MSA, if the Secretary of Commerce determines that additional information is necessary for developing or implementing an FMP, the Secretary may, by regulation, implement an information collection program requiring submission of such additional information for the fishery. In this proposed rule, ownership information would be collected from the potential participants in the trawl rationalization program, including the at-sea fleet (whiting motherships, whiting mothership catcher vessels, and whiting catcher/processors), the shore-based fleet (whiting and non-whiting permit owners and holders) and the whiting shore-based processors. Ownership information would be collected to support and facilitate timely implementation of the potential future trawl rationalization program under the Groundfish FMP. Similar to current requirements to collect ownership information from the limited entry fixed gear sablefish fleet, the primary purpose of collecting ownership interest information from the trawl fleet is to allow NMFS to monitor control of the groundfish resource in the trawl fishery to ensure participants remain within the accumulation limits, or control limits on quota share, recommended by the Council in Amendment 20 to the FMP. Initially, NMFS would use the ownership information collected under this rule as the first step in the application process to determine which potential quota share holders might be over their accumulation limits as an individual or as a member of a business entity. By collecting ownership information from potential participants in advance of the FMP amendment approval process, NMFS would expedite the quota share initial issuance process which is expected to take place in the fall of 2010. After ownership interest forms from this rulemaking are completed early in 2010, NMFS intends to provide pre-filled out ownership interest forms with the initial issuance application package in the fall of 2010, reducing the burden on potential participants and shortening the application process. If the collection of the ownership information requested as part of this rulemaking is not completed at the time NMFS provides these forms, it may delay implementation of the trawl rationalization program or issuance of an eligible participant's quota share due to the additional time needed to gather the ownership information and to determine if an eligible participant is within the accumulation limits.

In addition, the ownership information collected would create a baseline of ownership information to evaluate the trawl rationalization program during periodic reviews of the program, as required by the MSA. It would allow NMFS to better understand the relationship between processors, permit owners, and the entities owning the vessel registered to the permit (i.e., permit holders). In other words, it would allow NMFS to better understand who will control QS and which individuals will potentially use QP. Further, it would allow NMFS to better understand potential vessel accounts for QP and to better understand the ownership of vessels that crossover between different sectors in the trawl fishery. For example, it would allow NMFS to better understand the ownership of vessels that participate in both the whiting shore-based and the mothership fisheries.

NMFS would send a Trawl Identification of Ownership Interest Form to potential participants in the trawl rationalization program requiring the following information to be filled out: type of entity; qualifying permit number; name of company or name of individuals owning the limited entry permit, vessel or processing plant; tax identification number (TIN) for each entity; date of birth (DOB) for each individual; state registered in for each business entity; business mailing address; physical address for processing plants, business phone number, fax number and email; authorized representative's name; name of each individual having ownership interest in the limited entry permit, vessel or processing plant; the individual's business addresses; percentage of ownership by each entity (if there are multiple entities given as an owner of the permit, vessel, or processing plant) and each individual shareholder in each entity; printed name of authorized representative, signature, and date. The percentage of ownership of all shareholders must equal 100 percent. The form would also allow owners to certify whether or not they are a small business according to Small Business Administration (SBA) and the Regulatory Flexibility Act standards.

For permits, the legal owner of the permit or authorized representative would be required to complete the form and provide all necessary information on the individual or entity owning each groundfish limited entry trawl permit. For vessels, the vessel owner would be required to complete the form and provide all necessary information on the individual or entity owning each vessel that is registered to a groundfish limited entry trawl permit (i.e., permit holder). For shore-based whiting processors or first receivers, the legal owner or authorized representative would be required to complete the form and provide all necessary information on the individual or entity owning each shore-based whiting processing or first receiver company. The individual signing the form would certify under penalty of perjury that the information provided is true and correct and the form would be required to be notarized by a notary public.

The form would be required even if the owner of the permit or potential participant in the trawl rationalization program is an individual person. This form does NOT prequalify these persons for quota share nor guarantee that they will qualify for quota share under the future trawl rationalization program.

In addition to filling out the mandatory ownership interest form, potential trawl rationalization program participants may be required to submit additional documentation. If the ownership interest in the permit, vessel, or potential quota share involves a business entity, then additional documentation will be required. If there is an authorized representative for a business entity, then a corporate resolution would be required authorizing the person signing to do so on behalf of the entity. Business entities established under the laws of the United States or any State would be required to provide proof that they had done so and to verify that they are an active corporation. If an entity was not established under the laws of the United States or any other State, they would not be required to do so by this proposed rule. However, this will be a requirement to qualify for an initial allocation of quota share, pursuant to section 304(c)(1)(D) of the MSA. Providing the information at this stage will expedite the initial issuance process.

Additional documentation that NMFS may request after review of the completed Trawl Identification of Ownership Interest Form include articles of incorporation, a contract, or any other credible documentation that substantiates those with ownership interest in the entity and the their percent ownership. NMFS may require a certified copy of the current vessel document (USCG or state) as evidence of vessel ownership. NMFS may also request or consider any other relevant, credible evidence.

NMFS would send out the Trawl Identification of Ownership Interest Form with instructions to the current address in NMFS records for potential participants in the trawl rationalization program. Completion of this form would be required only once in preparation for implementation of the trawl rationalization program. This form would be sent to the at-sea fleet (whiting motherships, whiting mothership catcher vessels, and whiting catcher/processors), the shore-based fleet (whiting and non-whiting permit owners and holders) and the whiting shore-based processors. Potential participants would have at least 60 days from the effective date of the Federal Register final rule for this action to return the completed form. The completed form must be returned to NMFS no later than May 1, 2010. If the completed form is not returned by the deadline date of May 1, 2010, NMFS will send a second written notice to delinquent applicants requesting the completed form by a revised deadline date of June 1, 2010. In the future and if the trawl program is implemented under Amendment 20, the ownership interest form would likely be required during the permit or QS renewal process and during any permit or QS transfers.

Databases to be Used for Initial Allocation of Quota Share

Potential participants of the trawl rationalization program should be aware that the agency intends to use landings data from the Pacific States Marine Fisheries Commission's PacFIN database and the NMFS, Northwest Fisheries Science Center's Pacific whiting observer data from NORPAC to determine initial allocations of QS for the trawl rationalization program. Landings data from state fish tickets, as provided by the states to the PacFIN database, would be used to determine initial allocation of IFQ QS for the shore-based whiting and nonwhiting harvesters and for the shore-based whiting processors. Landings data from the NORPAC database would be used to determine initial allocation of at-sea QS for the whiting mothership catcher vessels.

NMFS intends to "freeze" the databases for the purposes of initial allocation on the date the proposed rule proposing to implement Amendment 20 to the FMP is published in the Federal Register. This should allow time for NMFS to compile the dataset and cross check the data for any errors. "Freezing" the databases means that NMFS will extract a snapshot of the databases as of the proposed rule publication date and will use those for initial allocation of QS. "Freezing" the databases is necessary to hold them constant for use during qualification and initial issuance of the trawl rationalization program and to form an administrative record of the database at a given point in time. Following the "freezing" of the databases, any corrections to the "frozen" database would be made with NMFS through the processes set forth in future trawl rationalization rules. The PacFIN and NORPAC databases will continue to exist and be updated through their normal processes, but such updates may not be used for initial allocations of quota share.

If potential participants in the trawl rationalization program have concerns over the accuracy of their data that has been entered in the PacFIN database, they should contact the state in which they landed those fish to get it corrected. Any revisions to an entity's fish tickets would have to be approved by the state in order to be accepted. Contacts at the states are as follows: (1) Washington – Carol Turcotte (360-902-2253, Carole.Turcotte@dfw.wa.gov); (2) Oregon – Michelle Grooms (503-947-6247, Michelle.L.Grooms@state.or.us); and (3) California – Gerry Kobylinski (916-323-1456, Gkobylin@dfg.ca.gov). For concerns over the accuracy of NORPAC data, contact Janell Majewski (206-860-3293, janell.majewski@noaa.gov). NMFS urges potential QS owners to go directly to the source where fisheries data is entered in the database to get it corrected before NMFS extracts the data for initial issuance of QS.

Classification

Pursuant to section 402(a)(2) of the Magnuson-Stevens Act, the NMFS Assistant Administrator, acting on behalf of the Secretary of Commerce, has determined that information collected under this proposed rule is necessary for developing and implementing the trawl rationalization program. The NMFS Assistant Administrator has also determined that this proposed rule is consistent with other applicable law, subject to further consideration after public comment.

This proposed rule has been determined to be not significant for purposes of Executive Order 12866.

An initial regulatory flexibility analysis (IRFA) was prepared, as required by section 603 of the RFA (RFA). The IRFA describes the economic impact this proposed rule, if adopted, would have on small entities. A description of the action, why it is being considered, and the legal basis for this action are contained at the beginning of this section in the preamble and in the SUMMARY section of the preamble. A copy of this analysis is available from the NMFS (see ADDRESSES). A summary of the analysis follows:

The proposed rule would allow NMFS to collect data to support implementation of a future trawl rationalization program (program), Amendment 20, to the Groundfish FMP. A separate RIR/IRFA will be prepared for the full trawl rationalization program as part of the rulemaking for Amendment 20. This proposed rule would also announce that NMFS intends to use landings data from the Pacific States Marine Fisheries Commission's PacFIN and the NMFS, Northwest Fisheries Science Center's Pacific whiting observer (NORPAC) databases to determine initial allocations of quota share for the program. Section 402(a)(2) of the MSA gives the legal authority for the action. If the Secretary determines that additional information is necessary for developing or implementing an FMP, the Secretary may, by regulation, implement an information collection requiring submission of such additional information for the fishery.

The Council has recommended accumulation limits to comply with the MSA requirement to ensure that participants do not acquire an excessive share of the total limited access privileges in the program. Initially, NMFS would use the ownership information collected as the first step in the application process to determine which potential quota share holders might be over their accumulation limits as an individual or as a member of a business entity. By collecting ownership information from potential participants in advance of the FMP amendment approval process, NMFS would expedite the initial issuance of quota share which is expected to take place in the fall of 2010. NMFS could use the completed forms to troubleshoot any unforeseen data collection issues and to provide pre-filled ownership interest forms with the initial issuance package in the fall of 2010. Pre-filled forms would reduce the burden on potential participants and shorten the initial issuance and appeals process.

The IRFA considers three alternatives: (1) no action, (2) a blank form to collect ownership interest information, and (3) a partially pre-filled form to collect ownership information. The no action alternative would delay collecting any ownership interest information until the initial issuance and appeals process expected to take place in the fall of 2010. Under the second alternative, NMFS would mail a blank Trawl Identification of Ownership Interest Form to potential participants in the trawl rationalization program. Under the third and selected alternative, NMFS would mail out a partially pre-filled Trawl Identification of Ownership Interest Form to potential participants in the trawl rationalization program. NMFS would use its Permit's Office database to pre-fill the permit and/or vessel owner's name of record and address. NMFS would also use this information to begin to fill out the names of participants with ownership interest.

Compared to the no action alternative, both alternatives would facilitate a more timely implementation of the trawl rationalization program. And the preferred alternative, partially pre-filled forms, would expedite the process even more and would be the most helpful to the person completing the form. This should aid the person completing the form with what information is needed and how NMFS database currently views the permit and/or vessel owner or owner of the whiting processor. While a timely implementation of the program benefits program participants, NMFS must also be aware that doing so is not too burdensome and costly to the potential program participants. This proposed rule would establish a onetime mailing requesting this information. Filling out a Trawl Ownership Interest Form is expected to take approximately 30 minutes per response. There is an incentive to respond as this is the initial step by any business to gain ownership rights in the fishery that can, at a future time, be harvested, sold, leased, or combined with other businesses in fishing operations. The financial benefits of participating in the trawl rationalization program should far outweigh the minimal cost of time and effort to fill out a form. (Very preliminary Pacific Council estimates indicate that for the harvesting vessels, after taking into account the costs of having observer coverage, over time the fishery may increase annual profits (revenue minus costs) to $10 to $20 million.)

This proposed rule would collect ownership information from approximately 250 potential participants who may receive initial allocation of quota share, including the at-sea fleet (whiting motherships, whiting mothership catcher vessels, and whiting catcher/processors), the shore-based fleet (whiting and non-whiting permit owners and holders) and the whiting shore-based processors. Using Small Business Administration standards, most of the estimated 250 entities are considered small businesses, except for some catcher vessels who also fish off Alaska, some shoreside processors and all catcher-processors and motherships (less than 30) that are affiliated with larger processing companies or large international seafood companies. One of the purposes of this data collection is to have these entities certify that they are "small" or "large" entities based on SBA size and affiliation criteria.

This information collection would be requested of all potential participants in the program, regardless of size, and would not have a disproportionate effect on small versus large entities. Nor would this information collection have any effect on profitability for small entities.

These changes will not duplicate, overlap or conflict with other laws or regulations. This proposed action is not expected to meet any of the RFA tests of having a "significant" economic impact on a "substantial number" of small entities. Nonetheless, NMFS has prepared an IRFA for this action. NMFS is requesting comments on this conclusion.

This proposed rule contains a collection-of-information requirement subject to review and approval by OMB under the Paperwork Reduction Act (PRA). This requirement has been submitted to OMB for approval. The public reporting burden for the Trawl Identification of Ownership Interest Form is estimated to average 30 minutes per response, including the time for reviewing instructions, searching existing data sources, gathering and maintaining the data needed, and completing and reviewing the collection information.

Public comment is sought regarding: whether this proposed collection of information is necessary for the proper performance of the functions of the agency, including whether the information shall have practical utility; the accuracy of the burden estimate; ways to enhance the quality, utility, and clarity of the information to be collected; and ways to minimize the burden of the collection of information, including through the use of automated collection techniques or other forms of information technology. Send comments on these or any other aspects of the collection of information to NMFS, Northwest Region (see ADDRESSES section), and by e-mail to David_Rostker@omb.eop.gov or fax to (202) 395-7285.

Notwithstanding any other provision of the law, no person is required to respond to, and no person shall be subject to penalty for failure to comply with, a collection of information subject to the requirements of the PRA, unless that collection of information displays a currently valid OMB control number.

List of Subjects in 50 CFR Part 660

Fishing, Fisheries, and Indian Fisheries.

Dated:

____

For the reasons set out in the preamble, 50 CFR Part 660 is proposed to be amended as follows:

PART 660–-FISHERIES OFF WEST COAST STATES

1. The authority citation for part 660 continues to read as follows:

Authority: 16 U.S.C. 1801 et seq.

2. A new § 660.337 is added to read as follows:

§ 660.337 Trawl rationalization program - data collection requirements.

(a) Ownership reporting requirements — (1) In 2010, NMFS will send a Trawl Identification of Ownership Interest Form to the current address on record requesting information from participants in the trawl fishery. Receipt of this form does NOT prequalify these persons for quota share nor guarantee that they will qualify for quota share under a future trawl rationalization program. The following participants in the trawl fishery must complete and return the form to NMFS:

(i) Owners of each limited entry permit endorsed for trawl gear;

(ii) Owners of each vessel registered to a limited entry permit endorsed for trawl gear (i.e., permit holder) if not identical to the permit owner covered by paragraph (a)(1)(i) of this section;

(iii) Owners of each vessel registered to a Pacific whiting vessel license that are not covered by paragraphs (a)(1)(i) and (ii) above; and

(iv) First receivers issued current Pacific whiting first receiver exempted fishing permits.

(2) Supporting documentation.

(i) Business entities completing the Trawl Identification of Ownership Interest Form are required to submit the following:

(A) A corporate resolution or any other credible documentation as proof of the authorized representative selected to act on behalf of the entity; and

(B) Proof that the business entity was established and is currently recognized as active under the laws of the United States or any State, if indeed they were.

(ii) After review of the Trawl Identification of Ownership Interest Form, NMFS may require the following additional documentation:

(A) Articles of incorporation, a notarized contract, or any other credible documentation that identifies each person who owns an interest in the entity and their percentage of ownership;

(B) A certified copy of the current vessel document (USCG or state) as evidence of vessel ownership; or

(C) Such other relevant, credible evidence as the applicant may submit, or the SFD or the Regional Administrator request or acquire.

(3) Deadline. Applicants will be provided at least 60 calendar days to submit completed forms. If the persons listed in paragraph (a)(1) fail to return the completed form by the deadline date of May 1, 2010, NMFS will send a second written notice to delinquent applicants requesting the completed form by a revised deadline date of June 1, 2010.

(b) [Reserved]

TRAWL IDENTIFICATION OF OWNERSHIP INTEREST

PACIFIC COAST GROUNDFISH

National Marine Fisheries Service, Northwest Region
Fisheries Permits Office
7600 Sand Point Way NE, Bldg. 1
Seattle, WA 98115-0070

Phone (206) 526-4353 *Fax* (206) 526-4461 www.nwr.noaa.gov

INSTRUCTIONS

The purpose of this form is to provide NOAA Fisheries with baseline information on participants in the trawl groundfish fishery to prepare for implementation of a future trawl rationalization program. Receipt of this form does not guarantee that you will qualify for an initial allocation of quota share.

IMPORTANT! This form should be submitted by the following:

1) Current owners of each limited entry permit endorsed for trawl gear;
2) Current owners of each vessel registered to a limited entry permit endorsed for trawl gear if not identical to the permit owner in number 1 above;
3) Current owners of Pacific whiting vessel licenses (if the vessel is not also associated with a permit listed in numbers 1 or 2 above); and
4) First receivers issued Pacific whiting first receiver exempted fishing permits (EFPs) during the 2009 Pacific whiting shoreside fishery.
   Pacific whiting shoreside first receivers means persons who receive, purchase, or take custody, control, or possession of Pacific whiting onshore directly from a Pacific whiting shoreside vessel.

A form should be filled out for each permit, vessel, EFP, or whiting license for which you have an ownership interest. Failure to complete this form may result in you not receiving an initial allocation of quota share. Please type or print legibly in ink. Attach additional sheets as necessary. Sign in ink, have your signature notarized, keep a copy for your records and mail the completed form to the address listed above.

SECTION A - PERMIT/VESSEL/PROCESSOR OWNER IDENTIFICATION
This section is pre-filled using information from NOAA Fisheries records. Please verify that the information included is correct and make any necessary corrections by crossing out and filling in correct data on the form.

- **Field 1. Check all boxes that apply**: If the permit owner and vessel owner are identical, check both boxes. If there are any differences among the permit or vessel owners, then a new form needs to be completed for each. If you are a Pacific whiting shoreside first receiver, check that box.

- **Fields 2-4. Permit Number/Vessel Name/Vessel Registration Number**: As applicable, list the Federal groundfish limited entry permit number, the name of the vessel registered to the permit and the U.S. Coast Guard documentation or state vessel registration number.

- **Fields 5-6. Name/TIN/DOB**: Enter the name of the business entity or individual that owns the permit, vessel, or first receiver. If a business entity, list their tax identification number (TIN). If an individual, list their date of birth (DOB) using the format of mm/dd/yyyy.

- **Field 7. State Registered**: If a business entity is listed in Field 5, list the state where that entity was established and is currently recognized as active.

- **Field 8. Business Mailing Address**: Enter the business mailing address, including street or PO Box number, state, and zip code, where the item(s) should be sent. Also list a physical address for first receivers, if different from mailing address.

- **Fields 9-11. Business Phone, Fax and Email**: List the business telephone and fax numbers including the area codes; the fax number and email are optional.

SECTION B - IDENTIFICATION OF SHAREHOLDERS AND PARTNERS

This section is partially pre-filled using the business entity name(s) from Section A. The intent of Section B (Parts 1 and 2) is to identify all of the individuals who control the business and their percent of ownership interest.

Part 1 – first level

Part 1 will be pre-filled with the business entities or individuals listed in Section A. List the TIN for business entities and the DOB for individuals. List the mailing address (if different than Section A), and the % ownership interest in the permit, vessel, or processor as listed in Section A. If there is only one individual listed, then the percent ownership interest held should equal 100%. If one business entity is listed, then the percent ownership interest held should equal 100%. If an individual and a business entity are listed, then list the percent of the individual and the percent of the business entity. (see examples below)

Part 2 – second level

If the information from Part 1 hasn't gotten down to the individual level and still includes business entities, then Part 2 should be completed. Part 2 will be pre-filled with any business entity names from Part 1. List the individual names of all shareholders/partners of the business entity. The DOB is required for each individual as an additional means of identification. List each individual's business mailing address and the percent ownership interest they hold in the business entity. The individual(s) listed under each business should equal 100%. Information should be provided down to the individual level. If necessary, attach an additional sheet of paper. (see examples below).

<u>Business entities established under the laws of the United States or any State must submit proof that they have done so and to verify that they are an active corporation.</u> NOAA Fisheries may request further documentation as proof of ownership, including percentage of ownership. Note the Privacy Act Statement at the end of the form.

Example A: jointly named owners on permit , two individuals

Part 1

NAME	TIN/DOB	BUSINESS MAILING ADDRESS	% HELD
Ahab, Captain R	05/15/1959	1234 Petrale St, Astoria, OR 54321	75
Starbuck, Jim T	10/23/1963	PO Box 555, Newport, OR 54123	25
		TOTAL OWNERSHIP =	**100%**

Part 2

NAME	DOB	BUSINESS MAILING ADDRESS	% HELD
business name from Part 1			
List individual names			
		TOTAL OWNERSHIP =	**100%**

Not Required

Example B: jointly named owners on permit , an individual and a business

Part 1

NAME	TIN/DOB	BUSINESS MAILING ADDRESS	% HELD
Dragger, Joe A	05/15/1959	3 Dover Lane Astoria, OR 54321	50%
Trawlers, Inc.	91-1234567	PO Box 70, Newport, OR 54123	50%
		TOTAL OWNERSHIP =	**100%**

Part 2

	NAME	DOB	BUSINESS MAILING ADDRESS	% HELD
business name from Part 1	Trawlers, Inc.			
List individual names	Ahab, Captain R	05/15/1959	1234 Petrale St, Astoria, OR 54321	55%
	Starbuck, Jim T	10/23/1963	PO Box 555, Newport, OR 54123	30%
	Ishmael, Mark S	03/07/1965	8 White Whale Dr. Newport, OR 54123	10%
	Queequeg, Warren G	07/23/1968	13 Wildside Blvd. Astoria, OR 54321	5%
			TOTAL OWNERSHIP of Business 1 =	**100%**

Example C: jointly named owners on permit , two businesses

Part 1

NAME	TIN/DOB	BUSINESS MAILING ADDRESS	% HELD
Trawlers, Inc.	91-1234567	PO Box 70, Newport, OR 54123	30%
Big Boat, LLC	71-7654321	4 Ever Whiting Astoria, OR 54321	70%
		TOTAL OWNERSHIP =	**100%**

Part 2

	NAME	DOB	BUSINESS MAILING ADDRESS	% HELD
business name from Part 1	Trawlers, Inc.			
List individual names	Ahab, Captain R	05/15/1959	1234 Petrale St, Astoria, OR 54321	55%
	Starbuck, Jim T	10/23/1963	PO Box 555, Newport, OR 54123	30%
	Ishmael, Mark S	03/07/1965	8 White Whale Dr. Newport, OR 54123	10%
	Queequeg, Warren G	07/23/1968	13 Wildside Blvd. Astoria, OR 54321	5%
			TOTAL OWNERSHIP of Business 1 =	**100%**
business name from Part 1	Big Boat, LLC			
List individual names	Hake, Fred C	06/03/1950	4 Ever Whiting Astoria, OR 54321	$33^{1/3}$%
	Hake, Brenda K	08/30/1954	4 Ever Whiting Astoria, OR 54321	$33^{1/3}$%
	Hake, Jr., Fred J	11/23/1975	12 Ever Whiting Astoria, OR 54321	$33^{1/3}$%
			TOTAL OWNERSHIP of Business 2 =	**100%**

SECTION C – SMALL BUSINESS CERTIFICATION

Read the criteria to determine if you are a small business according to the criteria listed. Check the appropriate box, yes or no.

SECTION D - CERTIFICATION OF APPLICANT AND NOTARY

The authorized agent must sign and date the form in the presence of a notary to certify that the individual(s) signing the form have satisfactorily identified themselves. By signing and dating the form, the authorized agent certifies that all information set forth in the form is true, correct, and complete to the best of the applicant's knowledge and belief. The form will not be considered without the authorized agent's signature. If a single individual is listed in Field 5 above, then that individual must sign. If two individuals are listed in Field 5 above with an "and" between their names, then both individuals must sign. If two individuals are listed in Field 5 above with an "or" between their names, then one of the individuals must sign. If an individual and a business entity are listed in Field 5 above, then the individual and the authorized agent for the business entity must both sign.

The notary must sign and date this section, and affix notary stamp or seal.

The authorized agent must include a copy of the corporate resolution or other authorizing document allowing the authorized agent to sign and certify on behalf of the business entity.

SECTION A – PERMIT/VESSEL/FIRST RECEIVER OWNER IDENTIFICATION

1. Are you a: ❑ Permit Owner ❑ Vessel Owner ❑ Pacific Whiting First Receiver

2. Permit Number GF	3. Vessel Name		4. USCG Doc or State Registration Number
5. Name			6. TIN or DOB
			7. State Registered, if business entity
8. Business Mailing Address (also list physical address for first receiver, if different) *Street* ***or*** *PO Box*			9. Business Phone ( )
			10. Business Fax (*optional*) ( )
City	*State*	*Zip Code*	11. Business Email (*optional*)

SECTION B - IDENTIFICATION OF SHAREHOLDERS AND PARTNERS
PART 1 – first level

NAME ***(Last, First, Middle Initial)***	**TIN or DOB**	**BUSINESS MAILING ADDRESS (*Street or PO Box, City, State, Zip Code*)**	**% INTEREST HELD**
		TOTAL OWNERSHIP =	**100%**

SECTION B - IDENTIFICATION OF SHAREHOLDERS AND PARTNERS
PART 2 – second level

NOTE: Owners of a business entity from Part 1 above must be listed down to the level of individual persons that make up that business. If more than one business is listed, be clear which individuals belong to which business.

If necessary, attach an additional sheet of paper with the information required below.

	NAME *(Last, First, Middle Initial)*	**DOB** (*mm/dd/yyyy*)	**BUSINESS MAILING ADDRESS** (*Street or PO Box, City, State, Zip Code*)	**% INTEREST HELD (IN BUSINESS)**
business name from Part 1				
list individual names				
			TOTAL OWNERSHIP of Business 1 =	**100%**
business name from Part 1				
list individual names				
			TOTAL OWNERSHIP of Business 2 =	**100%**
business name from Part 1				
list individual names				
			TOTAL OWNERSHIP of Business 3 =	**100%**

SECTION C – SMALL BUSINESS CERTIFICATION

Are you a small business according to the standards outlined below? ❑ YES ❑ NO

Small businesses. The Small Business Administration has established size criteria for all major industry sectors in the US, including fish harvesting and fish processing businesses. A business involved in fish harvesting is a small business if it is independently owned and operated and not dominant in its field of operation (including its affiliates) and if it has combined annual receipts not in excess of $4.0 million for all its affiliated operations worldwide. A seafood processor is a small business if it is independently owned and operated, not dominant in its field of operation, and employs 500 or fewer persons on a full time, part time, temporary, or other basis, at all its affiliated operations worldwide. A business involved in both the harvesting and processing of seafood products is a small business if it meets the $4.0 million criterion for fish harvesting operations. A wholesale business servicing the fishing industry is a small business if it employs 100 or fewer persons on a full time, part time, temporary, or other basis, at all its affiliated operations worldwide. For marinas and charter/party boats, a small business is one with annual receipts not in excess of $7.0 million.

Small organizations. The Regulatory Flexibility Act defines “small organizations” as any nonprofit enterprise that is independently owned and operated and is not dominant in its field.

Small governmental jurisdictions. The Regulatory Flexibility Act defines small governmental jurisdictions as governments of cities, counties, towns, townships, villages, school districts, or special districts with populations of less than 50,000.

SECTION D - CERTIFICATION OF APPLICANT AND NOTARY

This section must be completed by a notary to certify that the individual(s) have satisfactorily identified themselves.

Under penalties of perjury, I hereby declare that I, the undersigned, completed this form, and the information contained herein is true, correct, and complete to the best of my knowledge and belief.

Signature of Authorized Representative	Date
Printed Name of Authorized Representative (*NOTE: attach authorization, if needed*)	
Notary Public Signature ❑ ATTEST	Affix Notary Stamp or Seal Here
Date Commission Expires	

WARNING STATEMENT: A false statement on this form is punishable by permit sanctions (revocation, suspension, or modification) under 15 CFR 904, a civil penalty of up to $140,000 under 16 USC 1858, and as a federal crime under 18 USC 1001.

PRIVACY ACT STATEMENT: Your DOB and/or TIN are confidential and protected under the Privacy Act. Provision of your DOB or TIN is mandatory as part of this collection. The primary purpose for requiring the DOB and/or TIN is to verify the identity of individuals/entities doing business with the government to provide a unique identification for assistance to comply with the Debt Collection Improvement Act of 1996 (Public Law 104-134) and for enforcement activities. The information collected is part of a Privacy Act System of Records, COMMERCE/NOAA #19, Permits and Registration for United States Federally Regulated Fisheries. A notice was published in the Federal Register on April 17, 2008 (73 FR 20914) and became effective on June 11, 2008 (73 FR 33065).

PRA STATEMENT: Public reporting burden for this collection of information is estimated to average 0.5 hours per response, including the time for reviewing the instructions, searching existing data sources, gathering and maintaining the data needed, and completing and reviewing the collection of information. Send comments regarding this burden estimate or any other aspect of this collection of information, including suggestions for reducing the burden, to NOAA/National Marine Fisheries Service, Northwest Region, Attn: Assistant Regional Administrator, Sustainable Fisheries Division, 7600 Sand Point Way NE, Seattle, WA 98115. Some of the information collection described above is confidential under section 402(b) of the Magnuson-Stevens Act and under NOAA Administrative Order 216-100, Protection of Confidential Fisheries Statistics. Phone number, fax, email, TIN, and DOB are not released to the public. The names of individuals who have an ownership interest in an entity that owns a permit, vessel or processing plant and the actual percentage of ownership are considered business confidential and are not released to the public.

Agenda Item E.6.b
Supplemental NMFS PowerPoint
September 2009

Amendment 20 & 21 (TIQ & ISA)

Deeming - Round 1
NMFS Report

Overview

- Draft Schedule & Rulemaking Plans
- Ownership Data Proposed Rule
- Draft Regulatory Structure
- Initial Issuance of Quota Share & Appeals Process
- Thoughts on Tracking & Monitoring

Draft Schedule & Rulemaking plans

- Combined Review of Amendments 20 & 21
- NEPA: DEIS in November 2009
- If Approved, 3 Rulemakings to Implement
  - Ownership Data Rule (now)
  - "Grand Framework" Rule (summer 2010)
  - Follow-Up Rule (Fall 2010)

Ownership Data Rule

- Published Today -- Comments until Oct 16
- Primary Purpose: Collect Ownership Interest Information
  - Accumulation Limits
  - Expedite Initial Issuance of Quota Shares
- Secondary Purposes:
  - Use of NORPAC & PacFIN; Freeze Date

Draft Regulatory Structure

- Completely Reorganized
  - Make Our Jobs Easier
  - Make it Easier on Fishermen & Public

Initial Issuance & Appeals process

- Scheduled: September 2010
- Facilitated by Ownership Data Rule
- “Pre-Appeal” Process
- Initial Administrative Decision
- Deadline for Appeal

Tracking & Monitoring

- State Fish Ticket System as the Foundation

  → Electronic Submission

- NOAA
  - QS/QP Tracking
  - Onshore Compliance Monitors
  - 100% Observers (NWC)
- Discussions with States
- Cameras on Whiting Catcher Vessels??

Federal Register / Vol. 74, No. 178 / Wednesday, September 16, 2009 / Proposed Rules **47545**

value of the portion and how frequently the portion is used by the species. In addition, the portion may contribute to resiliency for other reasons—for instance, it may contain an important concentration of certain types of habitat that are necessary for the species to carry out its life history functions, such as breeding, feeding, migration, dispersal, or wintering.

Redundancy of populations may be needed to provide a margin of safety for the species to withstand catastrophic events. This does not mean that any portion that provides redundancy is a significant portion of the range of a species. The idea is to conserve enough areas of the range such that random perturbations in the system act on only a few populations. Therefore, each area must be examined based on whether that area provides an increment of redundancy that is important to the conservation of the species.

Adequate representation insures that the species' adaptive capabilities are conserved. Specifically, the portion should be evaluated to see how it contributes to the genetic diversity of the species. The loss of genetic diversity may substantially reduce the ability of the species to respond and adapt to future environmental changes. A peripheral population may contribute meaningfully to representation if there is evidence that it provides genetic diversity due to its location on the margin of the species' habitat requirements.

Based upon factors that contribute to our analysis of whether a species or subspecies is in danger of extinction throughout all or a significant portion of its range, and in consideration of the status of, and threats to, the Bliss Rapids snail discussed previously, we find that the primary threats to the continued existence of the Bliss Rapids snail occur throughout all of its range. Therefore, it is not necessary to conduct further analysis with respect to the significance of any portion of its range.

Finding

On the basis of the best available scientific and commercial information, as discussed above, we find that the Bliss Rapids snail is likely to become endangered within the foreseeable future (*i.e.,* it is threatened, as defined by the Act). Therefore, removing the Bliss Rapids snail from the List is not warranted.

50 CFR Part 660

[Docket No. 0907281183–91184–01]

RIN 0648–AX98

Fisheries off West Coast States; Pacific Coast Groundfish Fishery; Data Collection for the Trawl Rationalization Program

AGENCY: National Marine Fisheries Service (NMFS), National Oceanic and Atmospheric Administration (NOAA), Commerce.

ACTION: Proposed rule; request for comments.

SUMMARY: NMFS proposes to collect data to support implementation of a future trawl rationalization program under the Pacific Coast Groundfish Fishery Management Plan (FMP). NMFS proposes to collect ownership information from all potential participants in the trawl rationalization program. In addition, NMFS is notifying potential participants that the agency intends to use the Pacific States Marine Fisheries Commission's Pacific Fisheries Information Network (PacFIN) database and NMFS' Northwest Fisheries Science Center's Pacific whiting observer data from NORPAC (a database of North Pacific fisheries and Pacific whiting information) to determine initial allocation of quota share (QS) for the trawl rationalization program, if it is approved and implemented.

DATES: Comments on this proposed rule must be received no later than 5 p.m., local time on October 16, 2009.

ADDRESSES: You may submit comments, identified by RIN 0648–AX98 by any one of the following methods:

Electronic Submissions: Submit all electronic public comments via the Federal eRulemaking Portal *http://www.regulations.gov*.

Fax: 206–526–6736, Attn: Jamie Goen.

Mail: Barry Thom, Acting Administrator, Northwest Region, NMFS, 7600 Sand Point Way NE, Seattle, WA 98115–0070, Attn: Jamie Goen.

Instructions: All comments received are a part of the public record and will generally be posted to *http://www.regulations.gov* without change. All Personal Identifying Information (for example, name, address, etc.) voluntarily submitted by the commenter may be publicly accessible. Do not submit Confidential Business Information or otherwise sensitive or protected information.

NMFS will accept anonymous comments (enter N/A in the required fields if you wish to remain anonymous). Attachments to electronic comments will be accepted in Microsoft Word, Excel, WordPerfect, or Adobe PDF file formats only. Written comments regarding the burden-hour estimates or other aspects of the collection-of-information requirements contained in this proposed rule may be submitted to NMFS, Northwest Region and by e-mail to David__Rostker@omb.eop.gov or fax to (202) 395–7285.

FOR FURTHER INFORMATION CONTACT: Jamie Goen, phone: 206–526–4656, fax: 206–526–6736, and e-mail *jamie.goen@noaa.gov*.

SUPPLEMENTARY INFORMATION:

Electronic Access

This proposed rule is accessible via the Internet at the Office of the **Federal Register's** Web site at *http://www.gpoaccess.gov/fr/index.html*. Background information and documents are available at the Pacific Fishery Management Council's website at *http://www.pcouncil.org/*.

Background

Since 2003, the Pacific Fishery Management Council (Council) has been developing a trawl rationalization program, which would affect the limited entry trawl fishery of the Pacific Coast groundfish fishery. The trawl rationalization program is intended to increase net economic benefits, create individual economic stability, provide full utilization of the trawl sector allocation, consider environmental impacts, and achieve individual accountability of catch and bycatch.

The Council has developed the trawl rationalization program through two amendments to the Groundfish FMP: (1) Amendment 20, the trawl rationalization program; and (2) Amendment 21, intersector allocation. Amendment 20 would create the structure and management details of the trawl rationalization program, while Amendment 21 would allocate the groundfish stocks between trawl and non-trawl fisheries. The Council took final action on Amendment 20 at their November 2008 meeting, with trailing actions at its March 2009, April 2009, and June 2009 meetings. The Council took final action on Amendment 21 at its April 2009 meeting. When the Council formally transmits those amendments to NMFS, the agency will publish a notice of availability (NOA) of an FMP amendment and a proposed rule in the **Federal Register** to announce a public comment period. Following the public comment period on the NOA and proposed rule, NMFS will announce its decision on whether or not to approve the amendments in a final rule published in the **Federal Register**. The FMP approval process and implementation, if appropriate, are expected to occur in 2010.

The trawl rationalization program would be a limited access privilege program (LAPP) under the Magnuson-Stevens Fishery Conservation and Management Act (MSA), 16 U.S.C.1851–1891d, as reauthorized in 2007. A LAPP is considered a grant of permission to the holder of the limited access privilege or QS to participate in the program and may be revoked, limited, or modified at any time. In other words, it is a conditional privilege, conveyed through QS or catch shares, to harvest a specified amount of fish. The MSA requires the Council or the Secretary of Commerce to ensure that limited access privilege holders do not acquire an excessive share of the total limited access privileges in the program and to establish a maximum share, expressed as a percentage that each limited access privilege holder may hold, acquire, or use. For the trawl rationalization program, the Council has adopted limits on the amount of pounds a vessel can hold, acquire, or use (i.e., vessel limits) and limits on the amount of QS that can be held, acquired, or used (i.e., control limits).

Trawl Rationalization Program Structure

The trawl rationalization program would consist of: (1) An individual fishing quota (IFQ) program for the shore-based trawl fleet; and (2) cooperative (co-op) programs for the at-sea trawl fleet. Under trawl rationalization, the shore-based trawl fleet would consist of IFQ participants who land groundfish to shore-based processors or first receivers. The at-sea trawl fleet would consist of fishery participants harvesting whiting with midwater trawl gear (i.e., whiting catcher/processor vessels, whiting motherships, and whiting catcher vessels associated with motherships). The co-op programs for the at-sea trawl fleet would be further divided as follows: (1) The whiting catcher/processor co-op; and (2) the whiting mothership co-ops. The mothership co-ops may consist of a single co-op or multiple co-ops where vessels pool their harvest together, or it may consist of vessels not associated with a particular mothership (i.e., ‘‘non-co-op’’ segment of the mothership fishery).

The IFQ program for the shore-based fleet would require an initial allocation of harvest QS to individual participants based on historic participation in the fishery, specifically to limited entry trawl permit owners and shore-based whiting processors who meet the eligibility requirements. In order to comply with the MSA, NMFS would be required to determine and track ownership interest in QS to determine if individuals are within set limits, both at the initial allocation stage and during the operation of the program. In Amendment 20, the Council has adopted limits (by species group and area) on the amount of QS an individual can control (control limits).

The Council has adopted different program structures for the whiting catcher/processor co-ops and whiting mothership co-ops, based on how these co-ops have operated in the past. The structure of the co-ops will be described in more detail in the proposed rule to implement Amendment 20, which is expected in 2010. The catcher/processor co-op would not require an initial allocation of QS to individual vessels, provided a co-op is established.

QS for the at-sea mothership fleet (called ‘‘catch history assignments’’ in Council documents) would initially be allocated to the individual whiting catcher vessels associated with the mothership fishery, and would be non-transferable amounts associated with the vessel. The QS allocated to individual vessels would reflect that individual vessel's contribution to the total amount of fish its mothership co-op can harvest. However, an individual vessel in the co-op could harvest more than its at-sea quota, within the restrictions on individual vessel harvest and mothership co-op limits. Similar to the shore-based IFQ program, NMFS would be required to track ownership interest in QSs to determine if individuals are within set limits. In addition, ownership interest in the co-op programs (both the catcher/processor and mothership) and IFQ program would be tracked at the individual level to monitor crossover of participants and ownership interest among the programs.

Collection of Ownership Information

Pursuant to section 402(a)(2) of the MSA, if the Secretary of Commerce determines that additional information is necessary for developing or implementing an FMP, the Secretary may, by regulation, implement an information collection program requiring submission of additional information for the fishery. In this proposed rule, ownership information would be collected from the potential participants in the trawl rationalization program, including the at-sea fleet (whiting motherships, whiting mothership catcher vessels, and whiting catcher/processors), the shore-based fleet (whiting and non-whiting permit owners and holders) and the shore-based whiting processors. Ownership information would be collected to support and facilitate the timely implementation of the potential future trawl rationalization program under the Groundfish FMP.

Similar to current NMFS requirements to collect ownership information from the limited entry fixed gear sablefish fleet, the primary purpose of collecting ownership interest information from the trawl fleet is to allow NMFS to monitor control of the groundfish resource in the trawl fishery to ensure participants remain within the accumulation limits, or control limits on QS, recommended by the Council in Amendment 20 to the FMP. Initially, NMFS would use the ownership information collected under this rule as the first step in the application process to determine which potential QS holders might be over their accumulation limits as individuals or as members of a business entity. By collecting ownership information from potential participants in advance of the FMP amendment approval process, NMFS would expedite the QS initial issuance process, which is expected to take place in the fall of 2010. After ownership interest forms from this rulemaking are completed early in 2010, NMFS intends to provide pre-filled ownership interest forms with the initial issuance application package in the fall of 2010, thereby reducing the burden on potential participants and shortening the application process. If the collection of the ownership information requested as part of this rulemaking is not completed at the time NMFS provides these forms, NMFS may delay implementation of the trawl rationalization program or the issuance of an eligible participant's QS due to the additional time needed to gather the ownership information and determine if an eligible participant is within the accumulation limits.

In addition, the ownership information collected would create a baseline of ownership information to evaluate the trawl rationalization program during periodic reviews of the program, as required by the MSA. It would allow NMFS to better understand the relationship between processors, permit owners, and the entities owning the vessel registered to the permit (i.e., permit holders). In other words, it would allow NMFS to better understand who will control QS and which individuals will potentially use quota pounds (QP). Moreover, the ownership information would allow NMFS to better understand potential vessel accounts for QP and to better understand the ownership of vessels that crossover between different sectors in the trawl fishery. For example, it would allow NMFS to better understand the ownership of vessels that participate in both the whiting shore-based and the mothership fisheries.

NMFS would send a Trawl Identification of Ownership Interest Form to potential participants in the trawl rationalization program requiring the following information to be filled out: Type of entity; qualifying permit number; name of company or name of individuals owning the limited entry permit, vessel or processing plant; tax identification number (TIN) for each entity; date of birth (DOB) for each individual; state in which each business entity is registered; business mailing address; physical address for processing plants; business phone number, fax number and email; authorized representative's name; name of each individual having ownership interest in the limited entry permit, vessel or processing plant; the individual's business addresses; percentage of ownership by each entity (if there are multiple entities given as an owner of the permit, vessel, or processing plant) and each individual shareholder in each entity; printed name of authorized representative, their signature, and the date. The percentage of ownership of all shareholders must equal 100 percent. The form would also allow owners to certify whether or not they are a small business according to Small Business Administration (SBA) and the Regulatory Flexibility Act (RFA) standards.

For permits, the legal owner of the permit or authorized representative would be required to complete the form and provide all necessary information on the individual or entity owning each groundfish limited entry trawl permit. For vessels, the vessel owner would be required to complete the form and provide all necessary information on the individual or entity owning each vessel that is registered to a groundfish limited entry trawl permit (i.e., permit holder). For shore-based whiting processors or first receivers, the legal owner or authorized representative would be required to complete the form and provide all necessary information on the individual or entity owning each shore-based whiting processing or first receiver company. The individual signing the form would certify under penalty of perjury that the information provided is true and correct and the form would be required to be notarized by a notary public.

The form would be required even if the owner of the permit or potential participant in the trawl rationalization program is a person and not an entity. This form does NOT prequalify these persons for QS nor guarantee that they will qualify for QS under the future trawl rationalization program.

In addition to filling out the mandatory ownership interest form, potential trawl rationalization program participants may be required to submit additional documentation to NMFS. If the ownership interest in the permit, vessel, or potential QS includes a business entity, then additional documentation will be required. If there is an authorized representative for a business entity, then a corporate resolution would be required authorizing the person signing to do so on behalf of the entity. Business entities established under the laws of the United States or of any State would be required to provide proof of the establishment of their business and to verify that they are an active corporation. If an entity was not established under the laws of the United States or of any other State, this rule would not require the entity to become so established. However, an entity must be established under the laws of the United States or of any State in order to qualify for an initial allocation of QS, pursuant to section 303A(c)(1)(D) of the MSA. Providing the information at this stage will expedite the initial issuance process.

Additional documentation that NMFS may request after review of the completed Trawl Identification of Ownership Interest Form includes articles of incorporation, a contract, or any other credible documentation that substantiates those with ownership interests in the entity and their percent ownership. NMFS may require a certified copy of the current vessel document (United States Coast Guard or state) as evidence of vessel ownership. NMFS may also request or consider any other relevant, credible evidence.

NMFS would send out the Trawl Identification of Ownership Interest Form with instructions to the current address in NMFS records for potential participants in the trawl rationalization program. Completion of this form would be required only once in preparation for implementation of the trawl rationalization program. This form would be sent to the at-sea fleet (whiting motherships, whiting mothership catcher vessels, and whiting catcher/processors), the shore-based fleet (whiting and non-whiting permit owners and holders) and the shore-based whiting processors. Potential participants would have at least 60 days from the effective date of the **Federal Register** final rule for this action to return the completed form. The completed form must be returned to NMFS no later than May 1, 2010. In the future and if the trawl program is implemented under Amendment 20, the ownership interest form would likely be required during the permit or QS renewal process and during any permit or QS transfers.

Databases to be Used for Initial Allocation of Quota Share

Potential participants of the trawl rationalization program should be aware that the agency intends to use landings data from the Pacific States Marine Fisheries Commission's PacFIN database and NMFS' Northwest Fisheries Science Center's Pacific whiting observer data from NORPAC to determine initial allocations of QS for the trawl rationalization program. Landings data from state fish tickets, as provided by the states to the PacFIN database, would be used to determine initial allocation of IFQ QS for the shore-based whiting and nonwhiting harvesters and for the shore-based whiting processors. Landings data from the NORPAC database would be used to determine initial allocation of at-sea QS for the whiting mothership catcher vessels.

NMFS intends to ''freeze'' the databases for the purposes of initial allocation on the date the proposed rule proposing to implement Amendment 20 to the FMP is published in the **Federal Register**. This should allow time for NMFS to compile the dataset and cross check the data for any errors. ''Freezing'' the databases means that NMFS will extract a snapshot of the databases as of the proposed rule publication date and will use those for initial allocation of

QS. ''Freezing'' the databases is necessary to hold them constant for use during qualification and initial issuance of the trawl rationalization program and to form an administrative record of the database at a given point in time. Following the ''freezing'' of the databases, any corrections to the ''frozen'' database would be made with NMFS through the processes set forth in future trawl rationalization rules. After NMFS extracts a copy of the databases, the PacFIN and NORPAC databases will continue to exist and be updated through their normal processes, but such updates may not be used for initial allocations of QS.

If potential participants in the trawl rationalization program have concerns over the accuracy of their data in the PacFIN database, they should contact the state in which they landed those fish to correct any errors. Any revisions to an entity's fish tickets would have to be approved by the state in order to be accepted. State contacts are as follows: (1) Washington - Carol Turcotte (360–902–2253, *Carol.Turcotte@dfw.wa.gov*); (2) Oregon - Michelle Grooms (503–947–6247, *Michelle.L.Grooms@state.or.us*); and (3) California - Gerry Kobylinski (916–323–1456, *Gkobylin@dfg.ca.gov*). For concerns over the accuracy of NORPAC data, contact Janell Majewski (206–860–3293, *janell.majewski@noaa.gov*). NMFS urges potential QS owners to go directly to the source where fisheries data is entered in the database to get it corrected before NMFS extracts the data for initial issuance of QS.

Classification

Pursuant to section 402(a)(2) of the MSA, the NMFS Assistant Administrator, acting on behalf of the Secretary of Commerce, has determined that information collected under this proposed rule is necessary for developing and implementing the trawl rationalization program. The NMFS Assistant Administrator has also determined that this proposed rule is consistent with other applicable law, subject to further consideration after public comment.

This proposed rule has been determined to be not significant for purposes of Executive Order 12866.

An initial regulatory flexibility analysis (IRFA) was prepared, as required by section 603 of the RFA. The IRFA describes the economic impact this proposed rule, if adopted, would have on small entities. A description of the action, why it is being considered, and the legal basis for this action are contained at the beginning of this section in the preamble and in the SUMMARY section of the preamble. A copy of the IRFA is available from the NMFS (see ADDRESSES). A summary of the analysis follows:

The proposed rule would allow NMFS to collect data to support implementation of a future trawl rationalization program, Amendment 20, to the Groundfish FMP. A separate Regulatory Impact Review/IRFA will be prepared for the full trawl rationalization program as part of the rulemaking for Amendment 20. This proposed rule would also announce that NMFS intends to use landings data from the PacFIN and NORPAC databases to determine initial allocations of QS for the trawl rationalization program. Section 402(a)(2) of the MSA gives the legal authority for the action. If the Secretary determines that additional information is necessary for developing or implementing an FMP, the Secretary may, by regulation, implement an information collection requiring submission of such additional information for the fishery.

The Council has recommended accumulation limits to comply with the MSA requirement to ensure that participants do not acquire an excessive share of the total limited access privileges in the trawl rationalization program. Initially, NMFS would use the ownership information collected as the first step in the application process to determine which potential QS holders might be over their accumulation limits as individuals or as members of a business entity. By collecting ownership information from potential participants in advance of the FMP amendment approval process, NMFS would expedite the initial issuance of QS, which is expected to take place in the fall of 2010. Also, NMFS could use the completed forms to troubleshoot any unforeseen data collection issues and to provide pre-filled ownership interest forms with the initial issuance package in the fall of 2010. Pre-filled forms would reduce the burden on potential participants and shorten the initial issuance and appeals process.

The IRFA considers three alternatives: (1) No action; (2) a blank form to collect ownership interest information; and (3) a partially pre-filled form to collect ownership information. The no action alternative would delay collecting any ownership interest information until the initial issuance and appeals process for the trawl rationalization program, which is expected to take place in the fall of 2010. Under the second alternative, NMFS would mail a blank Trawl Identification of Ownership Interest Form to potential participants in the trawl rationalization program. Under the third and selected alternative, NMFS would mail out a partially pre-filled Trawl Identification of Ownership Interest Form to potential participants in the trawl rationalization program. NMFS would use its Permit Office's database to pre-fill the permit and/or vessel owner's name of record and address. NMFS would also use this information to begin to fill out the names of participants with ownership interest.

Compared to the no action alternative, both alternatives would facilitate a timelier implementation of the trawl rationalization program. Additionally, the preferred alternative, partially pre-filled forms, would further expedite the trawl rationalization program implementation process and would be the most helpful to the person completing the form. This should aid the person completing the form by providing details on what information is needed and how NMFS database currently views the permit and/or vessel owner or owner of the whiting processor. While timely implementation of the trawl rationalization program benefits its participants, NMFS must also be aware that doing so is not too burdensome and costly to the potential trawl rationalization program participants. This proposed rule would establish a onetime mailing requesting ownership information. Filling out a Trawl Ownership Interest Form is expected to take approximately 30 minutes per response and cost approximately $19.15 per response (which includes the respondent's time ($8.51), mailing, photocopying, and notary fee). There is no fee for this form. There is an incentive to respond because this is the initial step by any business to gain ownership rights in the fishery that can, at a future time, be harvested, sold, leased, or combined with other businesses in fishing operations. The financial benefits of participating in the trawl rationalization program should far outweigh the minimal cost of time and effort to fill out a form. (Very preliminary Pacific Council estimates indicate that for the harvesting vessels, after taking into account the costs of having observer coverage, over time the fishery may increase annual profits (revenue minus costs) by $10 to $20 million.)

This proposed rule would collect ownership information from approximately 250 potential participants who may receive initial allocation of QS, including the at-sea fleet (whiting motherships, whiting mothership catcher vessels, and whiting catcher/processors), the shore-based fleet (whiting and non-whiting permit owners and holders) and the shore-based whiting processors. Using SBA standards, most of the estimated 250 entities are considered small businesses, except for some catcher vessels that also fish off Alaska, some shoreside processors and all catcher-processors and motherships (fewer than 30) that are affiliated with larger processing companies or large international seafood companies. One of the purposes of this data collection is to have these entities certify that they are ''small'' or ''large'' entities based on SBA size and affiliation criteria.

This information collection would be requested of all potential participants in the trawl rationalization program, regardless of size, and would not have a disproportionate effect on small versus large entities. Nor would this information collection have any effect on profitability for small entities.

These changes will not duplicate, overlap or conflict with other laws or regulations. This proposed action is not expected to meet any of the RFA tests of having a ''significant'' economic impact on a ''substantial number'' of small entities. Nonetheless, NMFS has prepared an IRFA for this action. NMFS is requesting comments on this conclusion.

This proposed rule contains a collection-of-information requirement subject to review and approval by OMB under the Paperwork Reduction Act (PRA). This requirement has been submitted to OMB for approval. The public reporting burden for the Trawl Identification of Ownership Interest Form is estimated to average 30 minutes per response, including the time for reviewing instructions, searching existing data sources, gathering and maintaining the data needed, and completing and reviewing the collection information. This form is estimated to cost approximately $19.15 per response (which includes the respondent's time ($8.51), mailing, photocopying, and notary fee). There is no fee for this form.

Public comment is sought regarding: Whether this proposed collection of information is necessary for the proper performance of the functions of the agency, including whether the information shall have practical utility; the accuracy of the burden estimate; ways to enhance the quality, utility, and clarity of the information to be collected; and ways to minimize the burden of the collection of information, including through the use of automated collection techniques or other forms of information technology. Send comments on these or any other aspects of the collection of information to NMFS, Northwest Region (see **ADDRESSES** section), and by e-mail to *David__Rostker@omb.eop.gov* or fax to (202) 395–7285.

Notwithstanding any other provision of the law, no person is required to respond to, and no person shall be subject to penalty for failure to comply with, a collection of information subject to the requirements of the PRA, unless that collection of information displays a currently valid OMB control number.

List of Subjects in 50 CFR Part 660

Fishing, Fisheries, and Indian Fisheries.

Dated: September 11, 2009.

Samuel D. Rauch III,

Deputy Assistant Administrator For Regulatory Programs, National Marine Fisheries Service.

For the reasons set out in the preamble, 50 CFR Part 660 is proposed to be amended as follows:

PART 660—FISHERIES OFF WEST COAST STATES

1. The authority citation for part 660 continues to read as follows:

Authority: 16 U.S.C. 1801 *et seq.*

2. A new § 660.337 is added to read as follows:

§ 660.337 Trawl rationalization program - data collection requirements.

(a) Ownership reporting requirements - (1) In 2010, NMFS will send a Trawl Identification of Ownership Interest Form to the current address on record requesting information from participants in the trawl fishery. Receipt of this form does NOT prequalify these persons for quota share nor does it guarantee that they will qualify for quota share under a future trawl rationalization program. The following participants in the trawl fishery must complete and return the form to NMFS:

(i) Owners of each limited entry permit endorsed for trawl gear;

(ii) Owners of each vessel registered to a limited entry permit endorsed for trawl gear (i.e., permit holder) if not identical to the permit owner covered by paragraph (a)(1)(i) of this section;

(iii) Owners of each vessel registered to a Pacific whiting vessel license that are not covered by paragraphs (a)(1)(i) and (ii) above; and

(iv) First receivers issued current Pacific whiting first receiver exempted fishing permits.

(2) Supporting documentation.

(i) Business entities completing the Trawl Identification of Ownership Interest Form are required to submit the following:

(A) A corporate resolution or any other credible documentation as proof of the authorized representative selected to act on behalf of the entity; and

(B) Proof that the business entity was established and is currently recognized as active under the laws of the United States or any State, if indeed they were.

(ii) After review of the Trawl Identification of Ownership Interest Form, NMFS may require the following additional documentation:

(A) Articles of incorporation, a notarized contract, or any other credible documentation that identifies each person who owns an interest in the entity and their percentage of ownership;

(B) A certified copy of the current vessel document (United States Coast Guard or state) as evidence of vessel ownership; or

(C) Such other relevant, credible evidence as the applicant may submit, or as the SFD or the Regional Administrator request or acquire.

(3) Deadline. Persons listed in paragraph (a)(1) will be provided at least 60 calendar days to submit completed forms. All forms must be completed and returned to NMFS with a postmark no later than the deadline date of May 1, 2010.

(b) [Reserved]

Thoughts on Costs

- Costs will be dependent on industry decisions

Sea Days vs. Monthly Stipend

Observer Paid by Sea Day

Sea Days/ Month	Approximate Daily Rate	Vessel Monthly Cost	Vessel cost/year
5	$500 per day	$2,500	$30,000
10	$500 per day	$5,000	$60,000
15	$500 per day	$7,500	$90,000
20	$500 per day	$10,000	$120,000
25	$500 per day	$12,500	$150,000

Observer Paid by Monthly Stipend

Month Stipend	Daily cost if observers available 30 days	Daily cost if observers available 20 days	Vessel Monthly Cost	Vessel cost/year (100% observer availability)
$5000	$167.00	$250	$5000	$60,000

Formation of Observer Groups

Monthly Cost for observer*	Number of Vessels	Vessel cost per 3 months	Vessel cost per year
$5,000.00	1	$15,000.00	$60,000.00
	2	$7,500.00	$30,000.00
	3	$5,000.00	$20,000.00
	4	$3,750.00	$15,000.00
	5	$3,000.00	$12,000.00
	6	$2,500.00	$10,000.00
	7	$2,142.86	$8,571.43
	8	$1,875.00	$7,500.00
	9	$1,666.67	$6,666.67
	10	$1,500.00	$6,000.00
	11	$1,363.64	$5,454.55
	12	$1,250.00	$5,000.00
	13	$1,153.85	$4,615.38
	14	$1,071.43	$4,285.71
	15	$1,000.00	$4,000.00
	16	$937.50	$3,750.00
	17	$882.35	$3,529.41
	18	$833.33	$3,333.33
	19	$789.47	$3,157.89
	20	$750.00	$3,000.00
	21	$714.29	$2,857.14
	22	$681.82	$2,727.27
	23	$652.17	$2,608.70
	24	$625.00	$2,500.00
	25	$600.00	$2,400.00
	26	$576.92	$2,307.69
	27	$555.56	$2,222.22
	28	$535.71	$2,142.86
	29	$517.24	$2,068.97
	30	$500.00	$2,000.00

*Monthly cost was estimated at $5000 which is equal to the monthly stipend or 10 days if observers are paid by sea day.

Timeline for TIQ Observer Planning

ID	Task Name	Start	Finish	Duration
1	Vessels notify observer provider	10/1/2010	11/1/2010	4.4w
2	Observer provider recruits observers	10/1/2010	11/30/2010	8.6w
3	Observer Training	12/6/2010	12/22/2010	2.6w
4	Observer deployment	1/3/2011	3/31/2011	12.8w

Knowns:

1. Observer program plans quarterly TIQ trainings: Dec 2010
2. Observer providers will need at minimum one-month to recruit and hire observers.

   Therefore, fleet will need to plan observer coverage in 3 -month blocks.

INSEASON ADJUSTMENTS TO 2009 AND 2010 GROUNDFISH FISHERIES – PART II

Consideration of inseason adjustments to 2009 and 2010 groundfish fisheries may be a two-step process at this meeting. The Council will meet on Tuesday, September 15, 2009, and consider advisory body advice and public comment on inseason adjustments under Agenda Item E.4. If the Council elects to make final inseason adjustments under Agenda Item E.4, then this agenda item may be cancelled. If finalization is not canceled under Agenda Item E.4, it will be completed at this time.

Council Action:

Consider information on the status of ongoing 2009 fisheries and adopt inseason adjustments as necessary for 2009 and 2010.

Reference Materials: None.

Agenda Order:

a. Agenda Item Overview — Merrick Burden
b. Reports and Comments of Management Entities and Advisory Bodies
c. Public Comment
d. **Council Action:** Adopt or Confirm Final Adjustments to 2009 and 2010 Groundfish Fisheries

Agenda Item E.8
Situation Summary
September 2009

REPORT ON CATCH OF UNDENTIFIED ROCKFISH SPECIES
IN THE RECREATIONAL FISHERY

In October of 2008, Recreational Fishery Information Network (RecFIN) staff reported occurrences of unidentified rockfish in the recreational fishery that have not been accounted for in historical estimates of recreational impacts. This catch appears to be comprised of recreational discards or retained catch that cannot be identified by a sampler. The Council considered this matter at the March 2009 Council meeting. During this meeting, the Council directed RecFIN committees, appropriate state staff, and National Marine Fisheries Service (NMFS) and Council staff to meet and discuss the risks associated with the unidentified rockfish issue. The Council requested that a report be brought back at the September meeting where the Council would provide further guidance on working to resolve the issue.

In June of 2009, state, NMFS, PSMFC, and Council staff held a teleconference to discuss the unidentified rockfish issue and how to respond to the Council guidance received in June. Participants concluded that staff at each of the state agencies should provide a report to the Council for the September meeting. These reports would address the Council's request by identifying the magnitude of the issue in each state, the conservation risks posed by having unidentified rockfish, the reasons for the presence of unidentified rockfish, potential ways of resolving the issue, and a stated preference on how to move forward. These reports are included under Agenda Item E.8.b.

The Council task under this agenda item is to consider the information provided by each of the three west coast states and to provide direction on how to continue moving forward. Such direction may include a time line for resolution and implementation, an identification of resources to be devoted toward that task, and guidance on alternative means for identifying any unidentified rockfish.

Council Action:

1. Consider recommendations for resolving this issue.

Agenda Item E.8.b
ODFW Report
September 2009

OREGON DEPARTMENT OF FISH AND WILDLIFE REPORT ON UNIDENTIFIED ROCKFISH FROM THE RECREATIONAL FISHERY

The Recreational Fisheries Information Network (RecFIN) provides estimates of recreational catches separately for three 'types' of recreational catch. Type A catch estimates are based on "sampler examined catch" and represent landed fish. Type B1 catch estimates are based on "angler reported harvested dead catch" and may represent fish that were landed but not observed by the sampler, fish that were released dead at sea, or a combination of these depending on the year and region. For Oregon, type B1 estimates currently represent only fish that were released dead at sea. Type B2 catch estimates are based on "angler reported released alive catch". Catch is estimated in units of numbers of fish, which may be converted to weight of catch via multiplication by stratified estimates of average weight. All three RecFIN catch types contain estimates of unidentified rockfish in at least some years for Oregon, but because the primary interest here is accounting for fishery mortality by species, this report focuses on addressing type A and B1 estimates.

1. Magnitude of the Issue

ODFW examined recreational catch data from 1980 through 2008 to determine the magnitude of unidentified rockfish ("rockfish genus" in RecFIN) catch (Figure 1). In the early 1980s, there were large numbers (415,000 in 1982) of unidentified rockfish, primarily released fish and likely artificially high due to a small sample size and high expansion factors. Since the early 90's, with the exception of 2000, the number of unidentified rockfish has been much lower. Similar to the early 1980s, 2000 may be due to a change in sample design, as this was the beginning of the transition from Marine Recreational Fishery Statistical Survey (MRFSS) to the Ocean Recreational Boat Survey (ORBS) in Oregon.

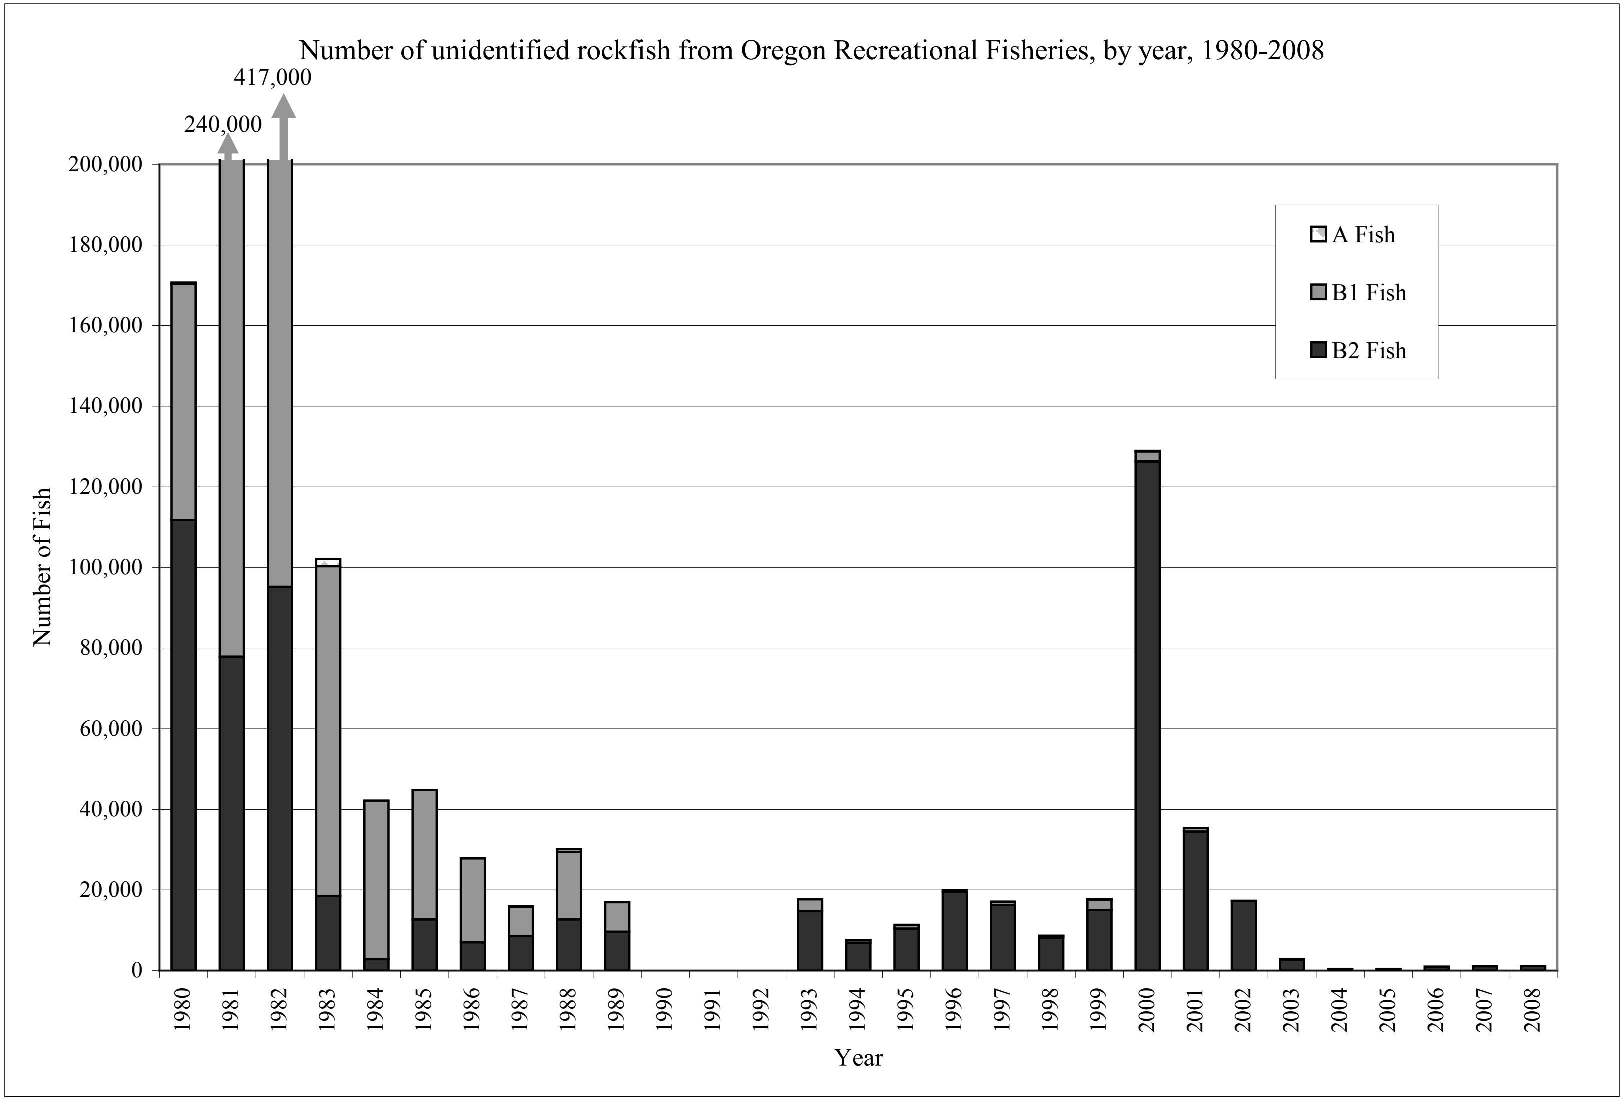

Figure 1. Total number of unidentified rockfish (A, B1 and B2) from Oregon recreational fisheries 1980-2008 from the RecFIN database.

Looking more closely at recent (2004-2008) data, there has been an average of seven unidentified A fish, zero B1 fish and 872 B2 fish per year (Table 1).

Table 1. Total number of unidentified rockfish (A, B1 and B2) from Oregon recreational fisheries, 2004-2008, from the RecFIN database.

Year	A	B1	B2	Total
2004	9	0	793	802
2005	8	0	393	401
2006	7	0	982	989
2007	8	0	1,075	1,083
2008	4	0	1,117	1,121
Average	7	0	872	879

Between 2004 and 2008, 52% of unidentified rockfish came from anglers targeting halibut (Figure 2). Anglers on bottomfish trips reported 36%, 11% on combination trips, and salmon and tuna trips combined account for less than 1% of the unidentified rockfish.

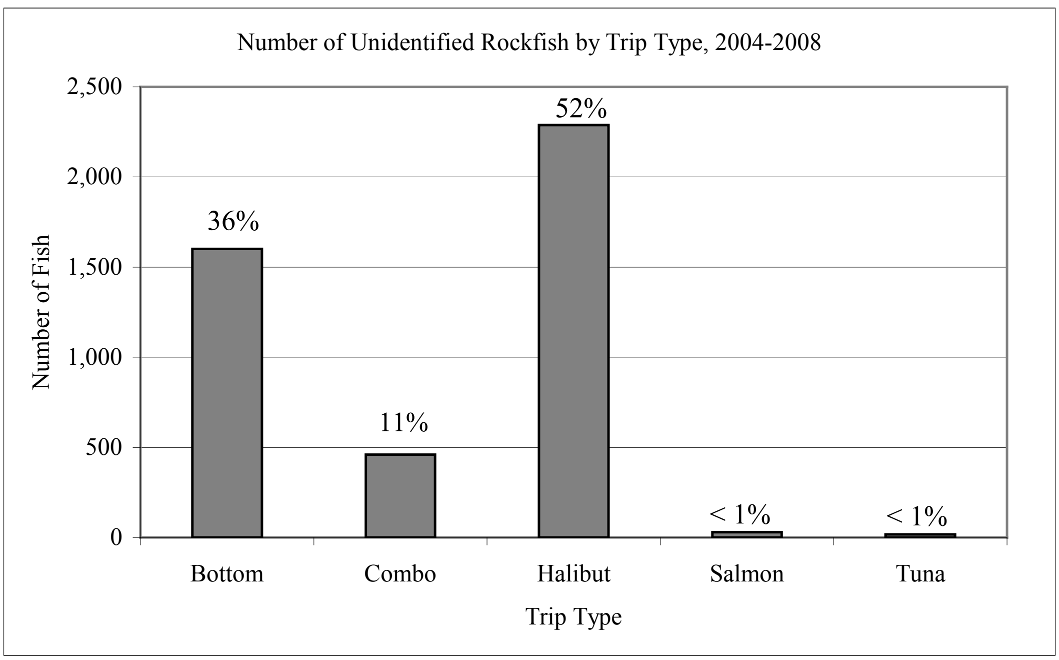

Figure 2. Total number of unidentified rockfish (A, B1 and B2) from Oregon recreational fisheries by trip type, 2004-2008.

The methodology used to produce historical estimates of unidentified fish, whether landed or discarded, has changed through time. There are three periods of estimates based on differing methodologies. The earliest spans the period from the early 1980's through 1989 and is based on MRFSS. In this survey anglers were asked if they discarded any fish and about the disposition of the fish (live or dead). Unless the sampler was confident the angler knew the rockfish species discarded, the fish were recorded as unidentified rockfish. During the period from 1990 through 2001 the landed statistics reported to RecFIN were from ODFW's ORBS. During that period discards, except for salmon and lingcod in the later years, were not recorded. The MRFSS program was also conducted during that period, but the landed estimates from the ORBS program were considered more accurate, and thus used in RecFIN. The sources of discards reported during that period on RecFIN are unknown and may be a product of the MRFSS sampling. The third period started in 2001 when ORBS began recording all fish landed by species and inquiring about all discards at the species level. Anglers were not asked about the disposition of fish discarded (i.e., dead or alive) yet they are reported on RecFIN as B1 and B2. This distinction could not be due to MRFSS sampling starting in July 2003 as the program was discontinued in Oregon. How RecFIN assigns discarded fish to B1 versus B2 will be examined and taken into account when the partitioning methodology is finalized. The estimates are not available by trip type in many years. Since 1999 they have been available by trip type and boat type.

The sampling programs described above represent sampling of ocean, shore and estuary fisheries. From July 2003 through June 2005 MRFSS was replaced by the Shore and Estuary Boat Sampling (SEBS) program. Shore and estuary sampling was discontinued in July 2005 due to lack of funding.

Several factors influence the accuracy of the catch estimates including regulations. Prior to the late 1990s with the advent of a sub-bag limit for canary rockfish there was little reason not to report releases. Most fish were either sub-legal (lingcod) or smaller fish. This changed with the adoption of a canary rockfish sub-limit in 1999 and intensified when retention of both canary rockfish and yelloweye rockfish were prohibited. Anglers did not always report releases of these species as they would count toward an annual limit on impacts, which included release mortality. In fact, these restrictions resulted in an increase in the release of “red” rockfish due to uncertainty in identification. Other examples of the influence of regulations are offshore closures and non-retention of groundfish in the directed halibut fishery. The advent of these regulations either promoted discards (prohibition) or influenced species composition (offshore closures), therefore careful attention must be given to the effects of regulation when developing methodologies for partitioning unidentified rockfish.

2. Conservation Risks

The conservation risks associated with the unidentified rockfish are that the actual impacts in a year may have exceeded a species’ Optimum Yield (OY or Acceptable Biological Catch (ABC). Based on preliminary calculations, none of the additional impacts from Oregon recreational fisheries caused the total species’ OY or ABC to be exceeded. However, this may not be the case when all three states include their additional impacts. Preliminary calculations (based on RecFIN data 2004-2008) of additional impact from partitioning all unidentified catch (A, B1 and B2) into species (the worst case scenario), shows that the additional impacts from Oregon recreational fisheries would have caused the Oregon portion of the yelloweye harvest guideline, but not the ABC or OY, to be exceeded by less than 0.1 mt in 2008 and 0.2 mt in 2005. The black rockfish recreational harvest guideline, but not the ABC or OY, was exceeded in 2004 by approximately 5 mt; however, partitioning of unidentified rockfish contributed less than 0.1 mt to that exceedence. No other rockfish species federal harvest guideline, OY, or ABC’s would have been approached in the time period 2004-2008, even with the additional impacts. Just examining A and B1 fish, there are currently less than ten A and B1 unidentified rockfish per year (Table1). Even if all ten unidentified rockfish were yelloweye rockfish, there would be less than 0.03 mt of additional impacts per year, not enough to cause an exceedence of the ABC or OY in any given year. However, it is unknown (to ODFW) how released fish are currently partitioned into B1 and B2 estimates, but it is assumed that some type of mortality rate calculation is used. If species specific mortality rates are greater than that applied to unidentified rockfish, the conservation risks may increase substantially.

3. Reasons for Unidentified Rockfish

ORBS relies on a combination of sampler examination of landed catch and angler reported discards to estimate total catch data. Over the last five years, 99% of the unidentified rockfish were reported by anglers as discarded, and are estimated as B2 (released alive) fish in RecFIN. The reasons for the angler reports of unidentified rockfish could be due to anglers' inexperience with rockfish identification. A second possibility is that the anglers can identify rockfish by species but don't want to report their discarded catch for fear that the information may close an area or the entire fishery. A more likely scenario is that anglers correctly identify and report the common rockfish species, and the species of concern (yelloweye and canary rockfish), but are unfamiliar with rare or unusual rockfish. Finally, ORBS protocol does not request that the samplers investigate/ask further questions about species ID. They simply ask "what did you discard" and are not instructed to try to dig in and investigate if unknown.

ODFW has been working to educate anglers on rockfish identification. ODFW produced a Red Rockfish Guide to assist with rockfish identification for common species such as vermillion, canary, and yelloweye rockfish. In the ports of Brookings and Newport, traditionally the two highest angler effort ports for marine recreational fishing in Oregon, ODFW built informational kiosks. These kiosks include regulations, the Red Rockfish Guides, and other information related to fish identification. During the summer of 2009, ODFW held two open house angler education events, in Brookings and Newport that focused on fish identification, collaborative research projects, navigating the management process, and regulations. The two events were attended by approximately 300 people. Most participants were interested in how to identify fish that they were allowed to retain from those they could not. Future angler education events will be scheduled in other ports in future years, dependent upon funding.

4. Methodology for Partitioning Unidentified Catch into Species

Since there are no direct data on the species composition of unidentified rockfish, partitioning to species will require the application of species composition estimates derived from other data sources. Development of alternative methodologies for partitioning will consist of at least three steps. First, appropriate datasets for deriving species composition estimates must be identified for each type of RecFIN catch estimate. Second, a method for deriving estimates of species composition and applying these to estimates of unidentified rockfish must be chosen. Third, a method for converting estimated numbers of fish (by species) to weight must be chosen because weight is the quantity of interest to managers. This report does not seek to develop or recommend a particular methodology, but rather to outline the data and methods available.

Species composition data for Oregon recreational fisheries is available from three independent sources; ORBS, MRFSS/SEBS, and ODFW's charter vessel observer program (Observer) (Table 2). ORBS has collected rockfish species composition samples for fish landed by boat-based anglers fishing in ocean waters from a subset of dockside interviews since 1979. Through 1998 samples were recorded as weekly tallies, with the consequence that the number of fishing trips sampled for rockfish species composition is unknown. Starting May 1999, species composition samples were linked to individual fishing trips, and in 2000 rockfish species composition samples became mandatory for all dockside interviews. ORBS began collecting data on the species composition of rockfish discarded at sea (as reported by anglers) in May 2001. MRFSS has collected data on landed and discarded rockfish species composition from both boat-based and shore-based anglers fishing in ocean and estuary waters for 1980-1988 and 1993-2003. ODFW's observer program has collected species composition data for both landed and discarded fish for 2001 and 2003-present. These samples are restricted to charter vessels targeting bottomfish, with the majority of the samples from fishing activity taking place shallower than 40 fathoms. In addition, observers did not begin recording the condition (live or dead) of released fish until 2005. All three data sources are applicable to the partitioning of type A unidentified rockfish and to the partitioning of type B1 unidentified rockfish for those years that type B1 estimates represent released dead fish only. For those years that include angler reported landings in the estimates, only MRFSS data is applicable to partitioning type B1 unidentified rockfish. For all three catch types, only MRFSS/SEBS data is applicable to partitioning shore and estuary catch prior to 2001. After 2001, ORBS data may be applicable to partitioning catches made by boat-based anglers fishing in estuary waters. However, estuaries are not the focus of ORBS, and it does not sample all estuaries or estuary fisheries.

Table 2. Summary of data sources available for partitioning unidentified rockfish to species.

Survey	Years	Modes	Waters	Available data from species composition sampling: Number landed	Number discarded	Disposition (alive or dead)	Trip type or target species	Boat type
MRFSS	1980-1989	Shore and Boat	Ocean and Estuary	Y	Y	Y	N	Y
	1993-2003	Shore and Boat	Ocean and Estuary	Y	Y	Y	Y	Y
SEBS	2003-2005	Shore and Boat	Estuary	Y	Y	Y	Y	Y
ORBS	1979-1987	Boat	Ocean	Y	N	N	N	Y
	1987-2000	Boat	Ocean	Y	N	N	Y	N
	2001-present	Boat	Ocean and Estuary	Y	Y	N	Y	Y
Observer	2001, 2003-2004	Charter boat	Ocean	Y	Y	N	Y	Y
	2005-present	Charter boat	Ocean	Y	Y	Y	Y	Y

Given an appropriate source of species composition data, the method of partitioning that is the simplest, most straightforward, and consistent with current methods is to stratify the data by factors thought to affect species composition, calculate the average proportion of each species within each unique strata combination, then multiply the average proportion by the estimated number of unidentified rockfish in the corresponding strata combination. The stratification used will be a major decision point when applying this methodology and to a degree will be dictated by the available data. For 1979-May 1999, ORBS data may be stratified by year, month, port, and boat type (1979-1987 only) or trip type (1988-May 1999 only). For May 1999 to present, ORBS data may be stratified by both trip type and boat type, and at higher temporal (calendar date) and spatial (reef area) resolutions. MRFSS data may be stratified by time period (e.g. week, month, year), interview site (finer spatial resolution than port), primary target species (1993-2003), and waters fished (inland, state, or federal). Observer data may be stratified by time period, port, and location. For all data sources this method will likely require some aggregation of strata levels due to small sample sizes for some unique strata combinations. Alternatively, a statistical model similar to that developed by Sampson and Lee (2008) may be used to describe the relationship of species composition to factors such as year, port, boat type, etc. These relationships may then be used to predict the expected proportion of each species for any combination of factor levels. However, such an approach will likely be difficult to incorporate into the estimation and reporting process currently used by RecFIN. A hybrid approach may be to use a statistical model to inform decisions regarding stratification and aggregation of strata levels used in calculating average proportions.

Average weight for each species may be estimated for each combination of strata where estimates of unidentified rockfish occur. However, it is likely that a simplified stratification (compared to that used for calculating average species proportions) will be necessary due to the very small sample sizes for fish weights (e.g. one fish) that occur in some individual strata.

5. Resources Necessary to Partition Catch

Key in determining how much staff time to dedicate for the multiple agencies involved will be the level of priority given this item by the Council, along with the budget and staffing status of the respective agencies. ODFW would need to commit staff time to (1) finalize the methodology for portioning catch, (2) back calculate estimates by species both in numbers of fish and in weight, and (3) make the appropriate updates to databases, reports, calculations, etc. For the Council processes, time will be needed for both the SSC and GMT to review the proposed methodologies, as well as Council staff time working on this issue. The RecFIN Technical Team and/or Statistical Team will need to spend some time determining how unidentified rockfish should be dealt with in RecFIN. Finally, staff time for Pacific States Marine Fisheries Commission staff will also be necessary to make updates and/or corrections to the RecFIN database.

6. Pros and Cons of Partitioning

Will the species specific estimates be accurate? If so, they could provide better information for stock assessments. If not, they could detract from stock assessments and possibly overestimate or underestimate impacts for depleted species. Either way the revised estimates may result in increasing or decreasing previous estimates of depleted species and either put the estimate over or under the state harvest guidelines.

It is important to note that all of the methods of partitioning discussed will likely result in catch estimates that are biased high for common species and biased low for rare species because both samplers and anglers are more likely to be able to identify common species than rare species. The extent of this bias is unknown and it is likely not resolvable given our current knowledge. Research on the ability of anglers to identify rockfish to species may help resolve this issue, but to the best of our knowledge no such research is currently being undertaken.

7. Implementation Preference

ODFW believes that the most logical time to implement accounting for unidentified rockfish would be at the beginning of a biennial specification (SPEX) cycle. However, if there are conservation concerns for any species, action should be taken as soon as possible to mitigate those effects. All three states should begin accounting for the unidentified rockfish at the same time to prevent any one state from being held to a higher or lesser standard than the others.

ODFW will also continue with its angler education activities to promote accurate identification of rockfish, proper release techniques including use of recompression devices, and fishing strategies to avoid overfished species.

California Department of Fish and Game Report on Unidentified Rockfish in the California Recreational Fishery

At its March 2009 meeting, the Pacific Fishery Management Council (Council) requested that the Groundfish Management Team (GMT), RecFIN committees, and others identify the conservation risks associated with the unidentified rockfish category and recommend a process to apportion the catch[1] by species. The California Department of Fish and Game (CDFG) offers these comments after reviewing the unidentified rockfish category in California Recreational Fisheries Survey (CRFS), considering issues of data quality, and evaluating possible conservation risks and workload priorities.

Amount and Source of Unidentified Rockfish Catch

Less than 10 percent of the total estimated recreational rockfish catch in California was classified as unidentified rockfish in 2008 (Table 1). The two primary sources of unidentified rockfish are fish reported by anglers and fillets that could not be identified to species. About 69 percent of the unidentified rockfish were angler-reported released fish, and 31 percent were angler-reported landed fish or fillets.

Table 1. 2008 CRFS estimates (mt) of total rockfish catch and unidentified rockfish catch, and percent of unidentified rockfish catch by CRFS District.

CRFS District	Management Area	CRFS Estimated Total Rockfish Catch (mt)	CRFS Estimated Unidentified Rockfish Catch (mt)	Percent Unidentified Rockfish Catch by District
Redwood (6)	Northern	110	0.2	0.2%
Wine (5)	North-Central North of Point Arena	45.7	0.6	1.3%
Bay (4)	North-Central South of Point Arena	158.7	17.6	11.1%
Central (3)	South -Central	245.3	15.2	6.2%
Channel (2)	Southern	119.7	16.5	13.7%
Southern (1)	Southern	109.7	24.7	22.5%
Total	*Statewide*	*789.1*	*74.7*	*9.5%*

A number of factors make it difficult for anglers to report catch to the species level:

- The sheer number of rockfish species encountered by California's anglers. In 2008, CRFS samplers observed 37 of the 60 or more rockfish species found off California.
- Many species of rockfish are very similar in appearance and difficult to identify.

[1] In this report, "Catch" is defined as total fishing mortality: landed fish plus mortality due to discards (all angler-reported released fish, alive or dead, with a mortality rate applied).

- Anglers are being asked to recall fish at the end of their trip when they may be rushed for time or fatigued. Either situation may adversely affect their ability to recall their released catch by species.

CDFG believes that some species are less likely to comprise the unidentified rockfish category than others. This is because anglers are better able to identify and more likely to recall easily recognizable species, prohibited species, and/or species with individual bag limits. Since 2000, the CDFG increased outreach and education efforts promoting protection of overfished rockfishes and improving groundfish identification materials. CDFG believes that these ongoing efforts help reduce illegal take, and increase the ability of anglers to identify prohibited or managed species, and contributed to the decline in unidentified rockfish catch in the California recreational fishery.

Management Issues

Beginning to account for unidentified rockfish in species specific catches would be a step toward full catch accounting. Accomplishing this task in a meaningful manner would require a commitment of staff resources that would be diverted from other Council priorities. **The potential error that can be introduced into catch estimates as a result of accounting for unidentified rockfish must be weighed against the potential for conservation risks when deciding when or whether the Council should account for this additional catch.**

If the Council decides to go forward with decomposing the unidentified rockfish catch, this catch needs to be accounted for in all processes in the management cycle before incorporating unidentified rockfish catch into inseason catch tracking. Five processes requiring action or analysis by the Council or GMT are typically undertaken in a management cycle, each of which would be affected by accounting for unidentified rockfish: 1) stock assessments, 2) allocation between sectors, 3) interstate catch sharing agreements, 4) regulatory development, and 5) inseason catch tracking relative to management targets (e.g. harvest guideline, HGs). The potential implications of accounting for unidentified rockfish catch in each process are described in the March 2009 Final Inseason Supplemental GMT report (Agenda Item G.7.b) http://www.pcouncil.org/bb/2009/0309/G7b_SUP_GMT_0309.pdf. To date, with few exceptions, unidentified rockfish have not been accounted for in any of these steps. To forego accounting in any one process in the management cycle while accounting for the catch in another, results in potential inequities. For example, accounting for unidentified rockfish catch inseason before accounting for them in the historical catch previously used for stock assessments and allocation, could unduly constrain the recreational fishery.

Potential Conservation Risks

Conservation risks could ensue if the total magnitude of the additional apportioned catch of any species caused its annual optimum yield (OY) or allowable biological catch (ABC) to be exceeded. Conservation risks were evaluated for black, blue, bocaccio, canary, cowcod, widow and yelloweye rockfish and Minor Nearshore Rockfish South using CRFS catch data from the 2008 season. **The addition of apportioned**

unidentified rockfish catch did not result in exceeding any annual HG, OY or ABC of the species or management groups evaluated.

A simple approach was used to estimate species composition of the unidentified rockfish category for the risk evaluation: the estimated number of unidentified rockfish was partitioned into individual species based on the proportion of each species in the "identified catch". Estimates were made for each CRFS district and catch type (sampler-observed landed fish, angler-reported landed fish, and angler-reported released fish). Mortality rates were applied to released fish. The total weight of the catch was then estimated by multiplying the number of fish by that species average weight. Data from 2008 were used, because the magnitude of the 2008 unidentified rockfish catch is assumed to be the most representative of the 2009 catch given the recent changes in the economy, current groundfish depth restrictions, ongoing outreach efforts, and salmon restrictions.

For angler-reported released fish, this methodology is expected to overestimate species that anglers are better able to identify or more likely to recall (i.e., easily recognizable species, prohibited species, and species with size or bag limits). Thus, the method most likely overestimated the catch of black, blue, bocaccio, canary, cowcod, widow and yelloweye rockfishes as well as most members of Minor Nearshore Rockfish South. More refined methods would be desirable if the Council decides to decompose the unidentified rockfish category in catch histories and in inseason estimates.

The estimated 2008 unidentified rockfish catch apportioned by species and CRFS district is presented in Table 2, and the estimated total catch in Table 3. **The HGs for Minor Nearshore Rockfish South and black, blue, bocaccio, canary and widow rockfishes would not have been exceeded as a result of accounting for unidentified rockfish in 2008 (Table 3). Cowcod would have exceeded its projected recreational impact by 0.7 mt. However, the overage would not have resulted in exceeding the OY or ABC.**

Table 2. Results of the apportionment of the 2008 unidentified rockfish catch by CRFS District for overfished and managed species groups.

Species/Group	Estimated Unidentified Rockfish Catch by CRFS District (mt)						
	South (1)	Channel (2)	Central (3)	Bay (4)	Wine (5)	Redwood (6)	*Statewide**
Black Rockfish	0.00	0.00	0.69	0.80	0.10	0.14	*1.7*
Blue Rockfish	0.01	0.35	2.44	2.65	0.17	0.01	5.6
Bocaccio	8.00	1.22	0.17	0.00	0.00	0.00	*9.4*
Canary Rockfish	0.06	0.72	0.19	0.96	0.04	0.02	*2.0*
Cowcod	0.05	0.66	0.00	0.00	0.00	0.00	*0.7*
Minor Nearshore Rockfish South**	4.18	3.49	6.59	8.96	0.31	NA	*23.5*
Widow Rockfish	0.00	0.02	0.21	0.00	0.00	0.00	*0.2*
Yelloweye Rockfish	0.00	0.00	0.01	0.16	0.04	0.01	*0.2*

***** Rounded to the nearest tenth.

** Includes blue rockfish

Table 3. Comparison of 2008 harvest guidelines with total estimated catch (unidentified rockfish estimated catch apportioned to species plus CRFS estimates by species).

Species/Group	Estimate of Unidentified Rockfish Catch (mt)	2008 CRFS Estimates (mt)	Total Estimated Catch (mt)	2008 Harvest Guideline* (mt)	Total Estimated Catch as a Percent of 2008 Harvest Guideline
Black Rockfish	1.7	154.3	156.0	168.0	**92.9%**
Blue Rockfish	5.6	85.0	90.6	NA	**NA**
Bocaccio	9.4	34.8	44.2	66.3	**66.7%**
Canary Rockfish	2.0	5.6	7.6	9.0	**84.3%**
Cowcod	0.7	0.3	1.0	0.3*	**320.0%**
Minor Nearshore Rockfish South**	23.5	303.0	326.5	426.0	**76.7%**
Widow Rockfish	0.2	4.7	4.9	8.0	**61.6%**
Yelloweye Rockfish	0.2	1.7	1.9	2.1	**91.0%**

*****Not a harvest guideline for cowcod; this is a projected impact and an overage does not require mandatory action if exceeded.
** Includes blue rockfish

Potential Apportionment Methods

Decomposing the unidentified rockfish category to its component species will produce results of questionable reliability in the absence of a deliberative and methodical approach. Should the Council decide to use decomposed unidentified rockfish catch estimates in management processes, considerable resources may be needed to undertake a coordinated effort among the three states to develop plausible methods for the west coast recreational fishery. Moreover, the reconstruction of historic catch will likely require different methods than for estimating inseason catch, because less data are available for decomposing historic catch than for current catch.

Adding species estimates from the unidentified rockfish category to the individual species catch estimates will increase uncertainty. Any approach that is chosen should be thoroughly evaluated and potential biases identified. Species composition of the unidentified rockfish category and average weight of individual species are typically influenced by:

- Catch category (i.e., landed or released)
- Fishing mode
- Geographic area
- Fishing depth
- Regulations
- Time period (seasons or years)
- Long-term trends in relative abundance of species

The Council's ongoing California catch reconstruction project (Ralston et al, 2009) has not yet attempted to estimate species composition of released fish. However, many of the factors that lead to uncertainties in that project's estimates of species composition of landed fish would apply to estimates of the species composition of the unidentified rockfish category.

A major limitation is the availability of suitable data sets and the potential biases introduced by their use, including:

- Most of the data sets are relatively recent and may not reflect historic trends in species composition.
- The data available will vary depending on the time period and location.
- It may be necessary to average across time periods due to uncertainty resulting from a lack of data prior to the Marine Recreational Fisheries Statistical Survey sampling or gaps in the sampling program.
- Most sampler-observed data is for retained catch. Species composition of retained catch is not representative of released catch.
- All sampler-observed data on released fish is from Commercial Passenger Fishing Vessels (CPFVs). Species composition in the private/rental boat mode and shore mode tend to differ from the CPFV mode. By weight, 46 percent of the unidentified released rockfish in 2008 was from the private/rental and shore modes. The lack of direct observations of released fish in the private/rental and shore modes will increase the uncertainty in any estimates of species composition.
- Angler-reported catch data are dependent on the angler's ability to identify and recall their catch. Species that are easily identified tend to be more prevalent in the reported catch.

Recommendations

Given that no conservation risks were apparent from unidentified rockfish catch, the biases resulting from estimation methods that rely on limited data, and the resources that would be diverted from other Council duties to fully address the issue, CDFG does not believe accounting for unidentified rockfish catch in the Council process is imperative. **Therefore, CDFG recommends no further action.**

If the Council decides to proceed:

CDFG recommends that species specific accounting should begin with the adoption of a stock assessment that includes SSC and RECFIN approved apportionment methodologies and that the process should begin during the same management cycle for all three states. As much as possible, consistent methodologies should be applied among the states.

CDFG recommends that any apportionment of historic catches proceed as part of the currently ongoing historic catch reconstruction efforts.

The following are considerations that contribute to these recommendations:

- State agency staff indicated that addition of an entire catch stream is a time and labor-intensive undertaking that would divert many hours of time from existing duties and assignments. With current furloughs and overtime restrictions on many state staff due to budget issues, the time devoted to this item will need to be taken from other Council priorities.

- The CRFS staff indicated that current work priorities, including integrating depth dependent mortality rates, revising catch type categories, and updating average weight estimates, are expected to have a more substantial impact on CRFS catch estimates and believes these improvements need to be completed before any work on apportioning unidentified rockfish begins.
- Given the implications of incorporating estimates of unidentified rockfish into the historical and inseason catch estimates, the GMT noted at the March 2009 Council meeting that the Council may wish to have any new methodology reviewed by the RecFIN Technical Committee. The CDFG agrees with this suggestion, however, the time commitments of the RecFIN Technical Committee are unknown and may present delays.

GROUNDFISH MANAGEMENT TEAM REPORT ON CATCH OF UNIDENTIFIED ROCKFISH SPECIES IN THE RECREATIONAL FISHERY

Introduction

The Groundfish Management Team (GMT) reviewed the reports provided by California, Oregon, and Washington regarding accounting for unidentified rockfish catch in Recreational Fishery Information Network (RecFIN). Each report included the magnitude of unidentified rockfish catch, assessment of the conservation risks presented by unidentified rockfish catch, and the associated management implications.

Catch accounting is central to the GMT's role in the Council's management of the Pacific Coast groundfish fisheries. As reflected in the revised National Standard 1 guidelines, an accounting of total fishing removals, including uncertainty in our ability to account for catch, is essential to sustainable fisheries management. For recreational fisheries, the challenges and complexities involved with surveying catch are well known. These challenges and complexities have been an issue of national focus, stemming from a 2006 National Research Council report and new mandates and programs included in the Magnuson-Stevens Reauthorization Act of 2006.[1] NMFS has begun implementation of new projects and regulatory programs through the Marine Recreational Information Program (MRIP). The recreational survey programs in the three west coast states are currently on par or ahead of those in other regions of the country. Although the GMT would always prefer better catch information, we fully recognized that recreational monitoring involves prioritization amidst limited resources.

The magnitude of the 2008 unidentified rockfish catch varies between regions within states. Estimates of unidentified rockfish catch in 2008 varied from less than 1 percent of total rockfish catch in Washington, Oregon, and Northern California to 13.8 percent in Southern California (CRFS District 1) (Table 1). The statewide unidentified rockfish catch represented less than 7 percent of the total rockfish catch in each state.

[1] National Research Council, Review of Recreational Fisheries Survey Methods (2006).

Table 1. Total rockfish catch, unidentified rockfish catch, and unidentified rockfish catch as a percentage of total rockfish catch, by region in 2008 reported numbers of fish.

State/Region	Total Rockfish Catch (# of Fish)	Unidentified Rockfish Catch (# of Fish)	Unidentified Rockfish as a % of Total Rockfish Catch
Washington	225,139	454	0.2%
Oregon	304,319	1,121	0.4%
CA, District 1	189,201	26,199	13.8%
CA, District 2	201,988	17,168	8.5%
CA, District 3	381,194	16,773	4.4%
CA, District 4	253,978	17,937	7.1%
CA, District 5	52,233	591	1.1%
CA, District 6	99,260	213	0.2%
CA Total	1,177,854	78,880	6.7%

None of the states reported an overage in any species optimum yield (OY) in 2008 based on their preliminary estimates of unidentified rockfish impacts. However, we do not have information to inform ongoing conservation risk inseason at this time. As mentioned in our report under Agenda Item E.5.b, the GMT will evaluate the management uncertainty associated with all fisheries in analyzing control rules under Amendment 23.

The GMT could not reach consensus on whether the Council should move forward with accounting for unidentified rockfish catch. Concerns expressed include the results of the quantification of conservation risk, work load associated with accounting for unidentified rockfish catch, the amount of unidentified rockfish catch, the magnitude of error in existing catch estimates, other priorities of the state programs in improving the existing catch estimates, and the potential biases to be introduced in the apportionment of unidentified rockfish catch given limited data.

Methodology Review Steps

The states' evaluation of conservation risks involved use of preliminary estimation methods, which need refinement and review prior to final implementation. The following sequence represents an outline for developing and implementing catch apportionment methods:

- State and Science Center personnel develop and submit proposed methodology for historical apportionment of unidentified rockfish to species-specific catch estimates to the RecFIN Technical Committee.
- State representatives develop and submit proposed methodology for inseason apportionments to the RecFIN Technical Committee.
- RecFIN Technical Committee provides comments and refinement.
- SSC review and approval of inseason apportionment methodology.

The GMT recommends implementation of the apportionment of the historical unidentified rockfish catch be conducted as part of each state's historical catch reconstruction effort. Assessments informing the 2013-2014 management cycle will be conducted in early 2011. The proposed historical apportionment methodology should be provided to the RecFIN Technical Committee early enough to allow for review during their October 2010 meeting.

In addition to historical catch reconstruction, each state needs to develop inseason unidentified rockfish catch apportionment methods. The GMT, the RecFIN Technical Committee and the SSC should review this methodology prior to approval by the Council for final implementation. Partitioning unidentified rockfish into species would also inform catch projection models preseason and may affect catch sharing agreements or allocations.

Considerations for the Timing of Implementation

The time needed for methodology development and review would preclude implementation in the 2010 season for all three states. Stock assessments have been adopted for the 2011 and 2012 biennial specification process. Likewise, there is not sufficient time for development and review of methods before the estimates are needed for implementation in other aspects of the management process for 2011-2012. In other words, historical catch estimates cannot be used in assessments until 2011 at the earliest. Likewise, development of methodologies by state personnel for inseason accounting and review of those methodologies cannot happen prior to development of preliminary management alternatives for the 2011-2012 cycle.

The unidentified rockfish catch could be accounted for in the 2013-2014 biennial specification process with sufficient time for methodological review and would be the first opportunity to incorporate it in all aspects of the management cycle. Development and review of the unidentified rockfish catch apportionment methodology may proceed in the interim in 2010 and the results integrated into the management processes for the 2013-2014 regulatory specification development.

Lastly, as mentioned above, the NMFS MRIP is focused on improving recreational survey methodologies. The Highly Migratory Species Management Team was able to initiate and coordinate with RecFIN and the states on two recreation survey project proposals that were funded by the NMFS Marine Recreational Information Program in Fiscal Year 2009. The GMT recommends that this unidentified rockfish issue be submitted for MRIP funding in Fiscal Year 2010. Funding from MRIP could help address some of the budgetary and staffing concerns of the states and bring in outside experts to help examine the issue. If the Council concurs, members of the GMT have expressed their willingness to assist the RecFIN Technical Committee in developing the proposal.

Agenda Item E.8.b
Supplemental SSC Report
September 2009

SCIENTIFIC AND STATISTICAL COMMITTEE REPORT ON UNIDENTIFIED ROCKFISH SPECIES IN THE RECREATIONAL FISHERY

Mr. Russell Porter of the Pacific States Marine Fisheries Commission briefed the Scientific and Statistical Committee (SSC) on the treatment of unidentified rockfish within the Recreational Fisheries Information Network (RecFIN), including a historical perspective and differences among States in the way that this catch category is tracked and recorded. Mr. John Budrick (California Department of Fish and Game [CDFG]) and Ms. Lynn Mattes (Oregon Department of Fish and Wildlife [ODFW]) of the Groundfish Management Team (GMT) were present to answer questions regarding written materials that were provided by ODFW and CDFG. The SSC also received a written report from Washington Department of Fish and Wildlife on this subject.

Unidentified rockfish catches from recreational fisheries are currently not taken into account in stock assessments, the setting of optimum yields (OY), or the tracking of catches against limits. The amount of unidentified rockfish in each state is small, but not insignificant, compared to identified catches, and the proportion of unidentified catch has been trending down in recent years, apparently due to angler education efforts and public awareness that overfished species may not be retained. Preliminary analyses presented in the State reports indicate that this unaccounted catch is probably not of sufficient magnitude to have caused the OY for any overfished rockfish to have been exceeded in recent years.

It is consistent with the goal of total catch accounting for this source of additional impacts to be included in rockfish management. However, there does not appear to be an immediate conservation concern related to this issue, and development of a solution represents a significant additional workload. There is a range of possible ways to apportion this catch by species, and differences exist in the data collected among States that complicate potential solutions. Therefore, the SSC recommends that the RecFIN staff be asked to work with state representatives to partition the unidentified rockfish catch to species so that the results can be incorporated into management as soon as is practical. The SSC suggests that any proposed analytical protocols should be reviewed by the RecFIN Statistical Committee before they are considered for use in stock assessments or management decisions.

WASHINGTON DEPARTMENT OF FISH AND WILDLIFE REPORT ON UNIDENTIFIED ROCKFISH IN THE RECREATIONAL FISHERY

In March, it was brought to the Council's attention that unidentified rockfish catches in the recreational fishery have not been accounted for in historical annual catch estimates. This could be a concern to the extent that a portion of the unidentified rockfish could be overfished species. In response, the Council requested that each state provide a report at the September meeting that describes the magnitude of the unidentified catch, the reasons why all fish are not identified, the potential amount of unidentified rockfish that could be overfished species, and a recommendation for how to move forward. This is the Washington Department of Fish and Wildlife's (WDFW's) initial response to that request.

Magnitude of Unidentified Catch

Unidentified rockfish in Washington is comprised of both retained and released catches. When interviewing anglers, WDFW samplers will attempt to collect complete species information for all fish caught, at times using rockfish identification cards to assist anglers in accurately determining the species. For a rockfish to be recorded in the "unidentified" category, it means that the fish were not available to the sampler (for retained catch) or were released by the angler who could not identify the species.

In RecFIN, estimates of recreational catches are reported as landed or retained catch (A), and released catch (B). Released catch is further separated into catch that is reported by the angler to be released dead (B1) or released alive (B2). WDFW's Ocean Sampling Program records all released rockfish in the B1 category, and does not ask anglers whether or not a fish was released live (B2). The mortality of released fish is then estimated using the Groundfish Management Team's discard mortality by depth matrix.

The number of identified rockfish caught by Washington anglers, on average, is about 281,500 per year. Of that amount, about 10% are released (Table 1).

Table 1. Number of identified rockfish caught in Washington recreational fishery, 2005-2008.

Identified Rockfish	2005	2006	2007	2008
Total Rockfish Landed (A)	288,072	268,293	248,716	205,597
Total Rockfish Released (B1)	43,479	29,332	24,021	19,088

The number of unidentified rockfish recorded by WDFW samplers, on average, is about 355 per year, or about 0.4 mt using an average weight across all rockfish species. Of that amount, approximately 58% are retained catch. In general, unidentified rockfish represents less than 0.1% of the total rockfish landed and 0.5% of the total rockfish released (Table 2).

Table 2. Estimated catch of unidentified rockfish in Washington recreational fishery, 2005-2008.

Unidentified Rockfish		2005	2006	2007	2008
Numbers of Fish	Landed (A)	295	122	145	278
	Released (B1)	165	127	113	175
	Total	***460***	***249***	***259***	***454***
Weight (mt)	Landed (A)	0.4	0.1	0.2	0.3
	Released (B1)	0.2	0.2	0.1	0.2
	Total	***0.6***	***0.3***	***0.3***	***0.5***
Percent Total Rockfish Landed		0.1%	0.05%	0.06%	0.14%
Percent Total Rockfish Released		0.4%	0.4%	0.5%	0.9%

Unidentified Rockfish by Washington Subarea

Higher amounts of unidentified rockfish are encountered off Washington's north coast (WDFW Marine Catch Areas 3 and 4) with decreasing amounts as you move further south. On average, about 66% of the unidentified rockfish were from the north coast and less than 10% from the Columbia area (Marine Catch Area 1) (Figure 1).

The diversity of rockfish species encountered in the north coast is also considerably greater than what occurs in the south coast (Marine Catch Area 2) and Columbia areas, which may contribute to the higher amounts of unidentified rockfish in the area. Black rockfish make up 92% of the rockfish landed in the south coast and 97% in the Columbia area with yellowtail rockfish comprising most of the balance in both areas. In the north, about 85% are black rockfish, with the balance being blue, china, copper, quillback, and yellowtail rockfish.

Another factor that may contribute to the higher amount of unidentified rockfish in the north could be the larger number of private boats that fish the area. In general, having more boats to sample means that a sampler is not always present when the boat reaches the dock, giving anglers time to fillet their catch before the sampler arrives.

Unidentified Rockfish by Trip Type

On average, most of the unidentified rockfish are encountered on fishing trips targeting bottomfish (47%), followed by salmon (26%) trips and halibut trips (22%) (Figure 2). Salmon and halibut trips are defined by species on board even though combination trips could occur (e.g., halibut and bottomfish). Although rare, we have seen a few salmon/halibut combination trips in recent years (noted as sal/hal in the figure).

The amount of unidentified rockfish attributed to the different types of fishing trips varied between years, which could be the result of changes in regulations, such as depth restrictions, or fluctuations in salmon and halibut seasons.

Figure 1. Distribution of unidentified rockfish by Washington recreational subarea.

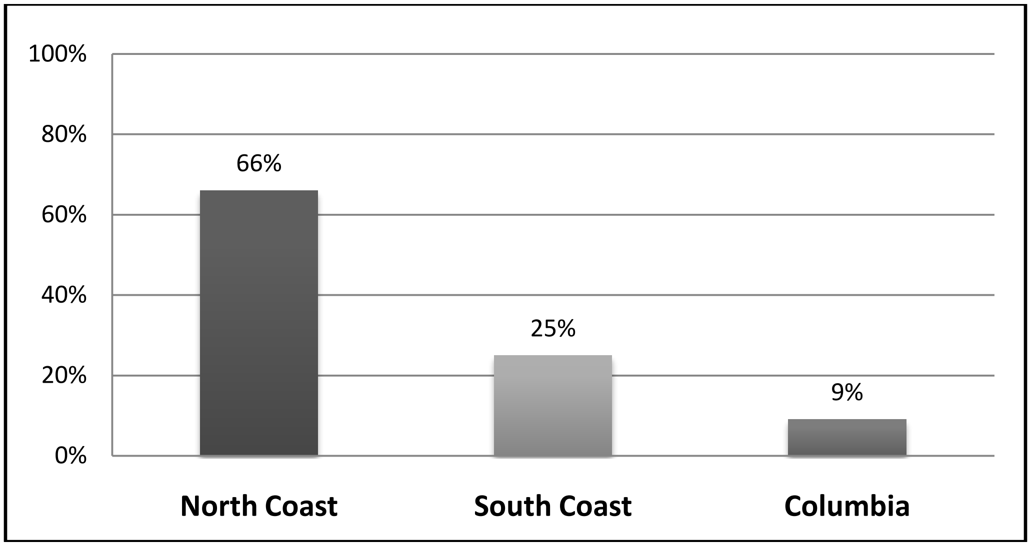

Figure 2. Distribution of unidentifed rockfish by trip type.

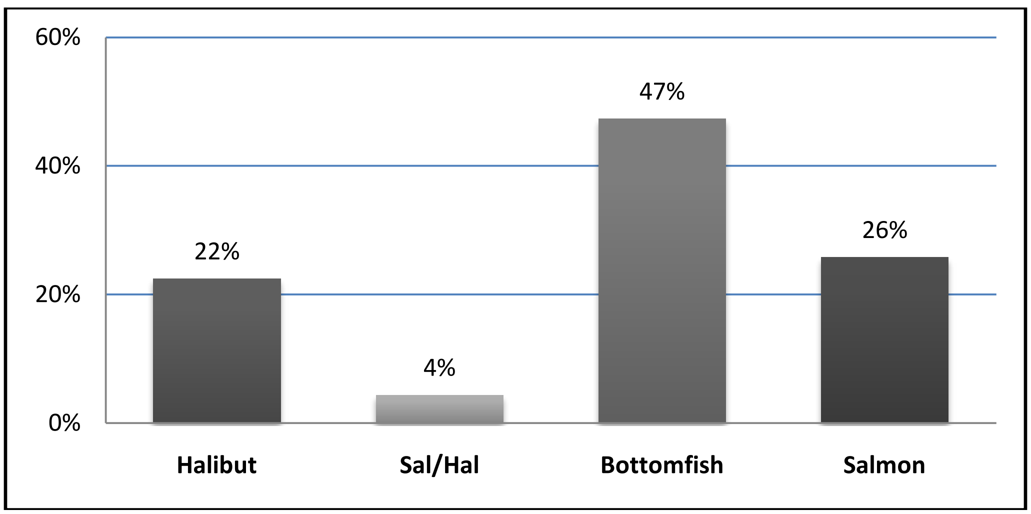

<u>Estimating Proportion of Overfished Species</u>

From a conservation perspective, it is essential that we have as accurate catch reporting as possible in all groundfish fisheries, including recreational. Incorporating unidentified rockfish catches into historical and future catch estimates could affect achievement of optimum yields for overfished species, such as canary and yelloweye rockfish. Given that these species are managed under rebuilding plans with recreational-specific harvest guidelines, we want to be certain that our estimates are based on sound data collection and expansion methods.

Apportioning the unidentified rockfish to the species level requires a process for estimating the species composition of both the landed (A) and released (B1) unidentified rockfish. It is also important to take into consideration the variability in landed and released catch by coastal area, month, trip type and boat type when deciding on the best apportionment method.

WDFW examined summarized data, which were provided by the Oregon Department of Fish and Wildlife (ODFW), from observations on Oregon charter vessel trips. After careful consideration, we determined that the ODFW data would not be representative of the Washington unidentified rockfish catches. There are considerable differences in the fishing regulations between the two states, including depth restrictions by area and bag limits, and target species, all of which affect where boats fish and the composition of their retained and discarded catch In addition, as noted above, there is quite a bit of difference among Washington subareas relative to rockfish catch composition, so applying one species composition across all Washington subareas does not seem appropriate.

Ideally, WDFW would have at-sea observations for Washington trips across trip types and subareas. However, absent this data the best source of information we have is the Ocean Sampling Program data. Apportioning the unidentified rockfish to the species level using these data statified by port, month, trip type and boat type will provide our best estimate of overfished rockfish species catches, and will ensure that consideration for the variablity in management measures by Washington subarea are accounted for in the estimates.

Results

By applying the WDFW Ocean Sampling Program annual expanded estimates to the unidentified rockfish catch data, we calculated preliminary estimates of yelloweye and canary rockfish (Table 3). These catches have not been stratified by depth; therefore, we have not yet applied the depth-based mortality rates to estimate the mortality of canary and yelloweye rockfish in the unidentified rockfish category.

Table 3. Preliminary WDFW catch estimates of yelloweye and canary rockfish in the unidentified rockfish category.

Yelloweye Rockfish		**2005**	**2006**	**2007**	**2008**

Recommendation

In general, WDFW recommends that the unidentified rockfish catch be accounted for through the annual catch reporting by state and the biennial management and specifications process, beginning with the 2011-12 process. Given the variability among the three states relative to the magnitude and catch composition of unidentified rockfish, we believe that a coordinated approach by the Groundfish Management Team and RecFIN staff would be appropriate. Provided that potential unidentified rockfish catches can be accounted for preseason, and management measures adopted accordingly through the biennial management process, we would not see a need to address unidentified rockfish catches through inseason management.

Specific to Washington, WDFW plans to stratify our preliminary estimates of unidentified rockfish by depth and apply the depth-based mortality rates to estimate the mortality of rockfish, by species, within the unidentified rockfish category. We will then provide that information to the GMT and Scientific and Statistical Committee in November for consideration.
