## **Summary**

Based on the 2009 stock assessment, this rebuilding analysis compares the results of applying a suite of potential future management actions to the U.S. yelloweye rockfish stock. The base case model for the 2009 assessment estimated that the yelloweye rockfish resource is at 20.3% of the unexploited equilibrium spawning output at the beginning of 2009. This represents an increase from the 2007 updated assessment, which estimated depletion in 2007 to be 16.4%. Uncertainty about the base case results is included through the integration over eight alternate (and less likely) states of nature along two axes of uncertainty: steepness ( $h$ ), and the magnitude of historical catch prior to 2000. In the yelloweye assessment, steepness is the primary parameter governing productivity and the rebuilding trajectory, while the magnitude of catch determines the absolute scale of the population estimate. The 2009-2010 OYs were set at 17 mt by the Pacific Council. In the context of the 2009 assessment, the 17 mt OYs represented an SPR rate of 75.2%, or somewhat less fishing mortality than the existing rebuilding SPR target of 71.9%. These levels of harvest are estimated to be far below that which would result in overfishing.

Assuming the 2010 OY of 17 mt is removed, various management options for 2011 and subsequent years are considered ranging from zero fishing mortality to the largest removal that could occur without overfishing (ABC catches). In the absence of any future fishing mortality (beginning in 2011 and assuming a 2010 OY of 17 mt) the yelloweye rockfish stock is projected to have a 50% probability of recovery to the rebuilding target ( $SB_{40\%}$ ) by 2047, slightly sooner than the estimate of 2049 from the 2007 rebuilding analysis. In contrast, the stock is not projected to reach this level within the next 500 years if the full ABC catches are removed. The current rebuilding harvest rate (SPR = 71.9%) would produce an OY of 20.4 mt in 2011 (20.7 mt in 2012) and has a 50% probability of rebuilding by 2087 (this is consistent with the preliminary forecasts reported in the 2009 updated stock assessment for the base case). A range of additional management approaches to recovery based on historical and recalculated reference points are presented.

## **Introduction**

The yelloweye rockfish (*Sebastodes ruberrimus*) stock was determined to be “overfished” in 2002, based on the 2001 stock assessment (Wallace 2001) which included only the California and Oregon portions of the stock. The next assessment included the entire U.S. coastal population (Methot et al. 2002) and estimated that the stock was at 24% of unexploited spawning biomass in 2002. An updated rebuilding analysis was conducted (Methot and Piner 2002) and the estimated rebuilding parameters were adopted by the Pacific Fishery Management Council (PFMC 2004). Subsequent rebuilding analyses were conducted on the basis of the 2005 (Wallace et al. 2005), 2006 (Wallace et al. 2006) and 2007 (Wallace 2008) stock assessments.

The 2002 rebuilding analysis estimated that the mean generation time for yelloweye rockfish was 44 years, and that if no fishing occurred beginning in 2003 there would be a 50% chance of rebuilding by 2027. The estimated value for steepness ( $h$ ) from the 2002 assessment was 0.437, and the degree of recruitment variability ( $\sigma_r$ ) was assumed to be 0.4. Management alternatives with OYs for 2003 between 22 and 27 mt were presented.

The 2005 rebuilding analysis (Tsou and Wallace 2005) was based on the updated stock assessment and estimates of steepness, and recruitment variability that were unchanged from 2002. Mean generation time was again estimated to be 44 years, but the year in which a 50% chance of rebuilding was projected to be achieved was increased to 2036. The maximum allowable rebuilding time ( $T_{MAX}$ ) was estimated to be 2071, and the probability of achieving this target under the target  $F$  of 0.0153 was 80%.

A full stock assessment and subsequent rebuilding analysis (Tsou and Wallace 2006) was conducted in 2006. The 2006 assessment included area-specific models and revised the assumed values for natural mortality (from 0.045 to 0.036), steepness (from 0.437 to 0.45) and the degree of recruitment variability (from 0.4 to 0.5). The 2006 assessment estimated the 2006 depletion level to be 17.7%, somewhat lower than previous analyses. As a result of these changes, the rebuilding plan estimated that the mean generation time was 50 years and that in the absence of fishing beginning in 2007 the coastwide yelloweye stock would not rebuild to target levels with a 50% probability until 2046. The selected target SPR rate was 71.9%, with further reductions in the 2007 and 2008 OY levels to 14.0 and 14.3 mt respectively if this rate were to be maintained. The results of this rebuilding analysis were included in Amendment 16-4 of the 2006 Pacific Coast Groundfish Fishery Management Plan (PFMC 2006) re-evaluating and revising the yelloweye rockfish rebuilding plan so that the rebuilding periods are as short as possible, taking into account the status and biology of the species, the socioeconomic needs of West Coast fishing communities, and the interaction of the depleted species within the marine ecosystem. The council ultimately adopted a ‘ramp-down’ from then *status quo* catch levels to those consistent with the SPR target of 71.9%, which led to OYs in 2007 and 2008 of 23 and 20 mt.

The 2007 updated yelloweye assessment included several key changes: (1) correction of a technical error in the definition of age and length classes, (2) deletion of incorrectly classified trawl-caught fish from hook-and-line age compositions, and (3) revision of the fixed natural mortality rate from 0.036 to 0.043. The combination of these corrections led to an overall downward revision in the estimate of current spawning

biomass and the level of relative depletion, compared to the 2006 assessment. The 2007 rebuilding plan was consistent with previous analyses in predicting an extremely long period need to achieve target stock levels, and did not require a revision of the target reference points or strategy from the previous analysis. The median year to rebuild with no fishing mortality beginning in 2009 was estimated to be 2049, and it was estimated that recovery would not be achieved at an SPR rate consistent with ABC harvest levels (50.0%). The median year to rebuild under the SPR target (71.9%) was estimated to be 2082. An SPR of 71.2% (slightly more fishing mortality) was estimated to be possible and still achieve a 50% probability of recovery by the target year in Amendment 16-4, 2084. Management alternatives were presented that included the ‘ramp-down’ from *status quo* OY levels to those consistent with the SPR target of 71.9% by 2011, as well as immediate (2009) implementation of this level. The ‘ramp-down’ alternative provided in the 2007 rebuilding analysis consisted of 2009 and 2010 harvest of 17 and 14 mt respectively. Subsequent analysis indicated no change in the estimated year for rebuilding with a 50% probability for the option ultimately accepted by the council of 17 mt harvest in both years.

### **2009 Assessment summary**

In the 2009 assessment (Stewart et al. 2009), all major structural and parameter assumptions from previous stock assessments were revisited. Revised inputs included: weight-length relationships, the maturity schedule, and addition of a fecundity relationship. Instead of fixed parameter values, natural mortality and steepness were estimated, as well as all growth parameters. Structural changes included use of a two-sex model, with explicit treatment of areas (California, Oregon and Washington) linked via a common stock-recruitment relationship and the removal of stochastic recruitment variability over the limited period for which it had been estimated in previous assessments (1968-1992). Because a fecundity relationship was used for yelloweye specifying that spawning output per unit weight increases with fish weight, all reference to spawning output was in terms of eggs produced, instead of spawning biomass.

In the 2009 assessment, the estimated relative depletion level in 2007 was 19.2% (slightly above the estimate of 16.4% from the 2007 assessment) and 20.3% in 2009, corresponding to 201.5 million eggs. Although the base case assessment model captured some uncertainty via asymptotic intervals, uncertainty from two sources is reported through alternate states of nature bracketing the base case results and included explicitly in the decision table. The magnitude of the estimated catch time-series was found to have a large influence on the perception of current stock size and the estimate of steepness of the stock-recruit relationship was closely linked to the projected recovery rates. Alternate values of each were selected to bracket the best estimates with marginal probabilities one-half as likely. For historical catch these values, 75% and 150% of the estimated catch series prior to 2000, were subjective, but reflect both the lack of a comprehensive catch reconstruction in Washington and the change in likelihood of the fit to data sources over a reasonable range of catch levels. For steepness the 12.5<sup>th</sup> and 87.5<sup>th</sup> percentiles were calculated from the likelihood profile as a proxy for the probability distribution about this point estimate. These two axes of uncertainty were both assigned a marginal probability such that the base case model was twice as likely as either the low or higher alternative

(Table 1). All nine combinations from these two axes are used to provide a more realistic degree of uncertainty in this rebuilding analysis.

### **Management performance under rebuilding**

Following the 2002 declaration that the yelloweye rockfish stock was overfished the catch of yelloweye was reduced to 28% of the 2001 level and maintained between 12.3 and 19.6 mt since then (Table 2). These catch levels represent a 95% reduction from average catches observed in the 1980s and 1990s. Managers have constrained catches by eliminating all retention of yelloweye rockfish in both commercial and recreational fisheries, instituting broad spatial closures (some specifically for moving fixed-gear fleets away from known areas of yelloweye abundance), and creating new gear restrictions intended to reduce trawling in rocky shelf habitats and the coincident catch of rockfish in shelf flatfish trawls. Since 2002, the total 6-year catch (88.5 mt) has been only 63% of the sum of the OYs for 2002-2008 and only 29% of the sum of the ABCs for that period. The total 2008 catch (16.7 mt) is estimated to be just 4% of the peak annual catch that occurred in the early 1980s.

### **Rebuilding calculations**

This rebuilding analysis was conducted using software developed by A. Punt (version 3.12a, September 2009). Because the rebuilding software does not have the capability for modeling area-based dynamics consistent with those in Stock Synthesis, there may be some differences in the rebuilding trajectory estimated here and that from the stock assessment. The steps followed were:

1. Define how virgin biomass ( $SB_0$ ) will be calculated.
2. Define how future recruitment will be generated.
3. Define the fishery selectivity and allocation to be applied during rebuilding.
4. Decide how to include uncertainty in input parameters from the stock assessment in the rebuilding analysis.
5. Recalculate rebuilding reference points from the most current assessment results
  - a) Calculate the projected year in which the stock would rebuild with a 50% probability if all future fishing mortality was eliminated ( $T_{F=0}$ ).
  - b) Calculate the projected year for a 50% probability of rebuilding from the year in which the stock was first declared overfished ( $T_{MIN}$ ).
  - c) Calculate the mean generation time.
  - d) Calculate the maximum allowable rebuilding time ( $T_{MAX}$ ).
6. Identification and analysis of alternative harvest strategies for rebuilding.

#### *1. Definition of $SB_0$*

The equilibrium spawning output level ( $SB_0$ ) used in this rebuilding analysis is calculated via the stock-recruitment, growth, maturity and fecundity relationships in order to be consistent with assessment model results. This level is estimated to be 994 million eggs in the base case assessment model, which dictates that the rebuilding target ( $SB_{40\%}$ ) is 398 million eggs. This result is highly uncertain, based on the range of values among the nine states of nature (Table 3), and this uncertainty is included in rebuilding projections.

## *2. Generation of future recruitment*

The estimated parameters of the stock recruitment relationship (unexploited equilibrium recruitment [natural log of  $R_0$ ], and steepness [ $h$ ]) for each of the nine states of nature, are used to generate future recruitments in the rebuilding analysis. Because the degree of recruitment variability ( $\sigma_r$ ) was not a component or result of the 2009 stock assessment, a value of 0.5 is used to be consistent with the last two rebuilding analyses, however sensitivity to this assumption is evaluated via analyses conducted with alternate values. The values for equilibrium recruitment and steepness for each combination of the two states of nature are provided in Table 4.

## *3. Fishery selectivity and allocation*

In order to project the effect of fishing on the yelloweye rockfish rebuilding trajectory, it is necessary to specify the fishery selectivity and relative allocation among fleets. This rebuilding analysis projects forward using selectivity and allocation averaged over recent years (2005-2007), not including the terminal year with catch, 2008, since these catches are projected based on the GMT scorecard and may not well reflect the final fleet-specific values in that year. This choice also provides some consistency between assessment model results and short term-forecasts from the rebuilding analysis, although the two still may differ. The resulting selectivity and weight at age are included in the basic input data files (Appendices A and B).

## *4. Inclusion of uncertainty*

Uncertainty is included in this rebuilding analysis via 1,600 random simulations of stochastic future recruitment strengths and integration over the nine combinations of the two states of nature. Because these states of nature represent discrete levels, it is expected that there will be some degree of ‘stair-stepping’ in reported probabilities.

## *5. Recalculate reference points*

The median year of recovery in the absence of fishing ( $T_{F=0}$ ) was calculated by setting fishing mortality to zero in 2011, and is equal to 2047. The value for  $T_{MIN}$ , the median year for rebuilding to the target level in the absence of fishing since the year of declaration (2000) is 2044 (revised downward slightly from 2046 in the 2007 analysis). That  $T_{MIN}$  is only three years shorter than  $T_{F=0}$  in 2011, indicates that harvest rates during this eight-year period have been low enough to have had little effect on the stock trajectory.

The estimated generation time has increased by one year to 45 years compared to the 2007 analysis. In conjunction with  $T_{MIN}$ , the mean generation time dictates the revised estimate of  $T_{MAX}$ , 2089 (increased slightly from 2090 in the 2007 analysis). Applying the same harvest rate ( $SPR_{TARGET} = 71.9\%$ ) retained in 2007 (from Amendment 16-4) leads to a revised  $T_{TARGET}$  of 2087, three years longer than the current target. This harvest rate generates a  $P_{MAX}$  (probability of recovery by  $T_{MAX}$ ) of 52.3%, slightly lower than the 2007 estimate of 68.9%.

All reference points from Amendment 16-4, the 2007 rebuilding analysis, and those recalculated here are summarized in Table 5.

## *6. Alternate rebuilding strategies*

Assuming that a constant rate of harvest will be applied throughout a rebuilding period, the basis for rebuilding alternatives can be divided into two approaches: 1) strategies based on selection of a harvest rate, and 2) strategies based selection of a  $T_{TARGET}$  (year for 50% probability of recovery). The result of each of these strategies is contingent on the actual OY removed in 2010, which is assumed to be 17 mt. This rebuilding analysis therefore presents 14 alternate strategies:

- 1) Eliminate all harvest beginning in 2011 ( $F=0$ ).
- 2) Apply the harvest rate that would currently generate a 14 mt 2010 OY  
( $SPR=78.9\%$ )
- 3) Apply the harvest rate that would currently generate the 17 mt 2010 OY  
( $SPR=75.2\%$ )
- 4) Apply the harvest rate that is estimated to generate a 50% probability of recovery by the  $T_{TARGET}$  from 2007 and Amendment 16-4 (2084,  $SPR=72.8\%$ )
- 5) Apply the current rebuilding harvest rate target ( $SPR_{TARGET}=71.9\%$ ).
- 6) Apply the harvest rate that estimated to generate a 50% probability of recovery by the  $T_{MAX}$  from 2007 (2090,  $SPR=71.0\%$ )
- 7) Apply the harvest rate that estimated to generate a 50% probability of recovery by the  $T_{MAX}$  from Amendment 16-4 (2096,  $SPR=69.9\%$ )
- 8) Apply a 40:10 harvest policy.
- 9) Apply the ABC harvest rate ( $SPR_{50\%}$ ).

Apply the harvest rate that achieves a 50% probability of recovery for years distributed between  $T_{F=0}$  (2047) and the current  $T_{MAX}$  of 2089 (in increasing SPR order for easier interpretation and with 2092 included to provide additional comparability to previous analyses):

- 10) 2056
- 11) 2065
- 12) 2074
- 13) 2083
- 14) 2092

## **Results**

Summary results from alternatives 1-9, are presented in Table 6. Detailed results are presented in Tables 8-10 and Figures 1-3. In the absence of any future fishing mortality, the yelloweye rockfish stock is projected to have a 50% probability of recovery to the rebuilding target ( $SB_{40\%}$ ) by 2047 (alternative 1). In contrast, the stock is not projected to reach this level during the 500 years over which this projection was performed if the ABC catches are removed (alternative 9). The SPR proxy target used to generate ABC catches is 50%, which represents substantially more fishing mortality than that estimated to produce MSY for the base case assessment model (60.4%) occurring at an estimated 39.1% relative depletion. Even the most optimistic state of nature predicts MSY harvest to be achieved with less fishing mortality (51.2%) than the MSY proxy. These two scenarios (alternatives 1 and 9) bound the range of fishing mortality between none and the overfishing level. All other scenarios lie within this range.

Fishing at the current SPR target (alternative 5) results in an increase from the 17 mt OY in 2010 to 20.4 mt in 2011. This harvest rate target results in a reduced probability of median recovery by the recalculated  $T_{MAX}$  (2089) of 52.3%, even though the estimated  $T_{F=0}$  has been reduced from 2049 to 2047. The current rebuilding harvest rate (SPR = 71.9%, alternative 4) results in a median year to rebuild (recalculated  $T_{TARGET}$ ) of 2087, and a probability of recovery in the  $T_{TARGET}$  from amendment 16-4 (2084) of 46.4%. If the SPR target is reduced to 72.8% (alternative 3), the 2011 OY is reduced to 19.6 mt (2012 to 19.9 mt), and the probability of rebuilding by the amendment 16-4  $T_{TARGET}$  is estimated to be 50.0% (alternative 3). The harvest rate calculated from the 2009 assessment that is consistent with the 2010 OY (17 mt) is SPR = 75.2% (alternate 3), and if continued, results in a 50% probability of recovery achieved by 2077.

Figures 4-6 and Table 7 show the results of alternate management actions 10-14, fishing at SPR rates that result in a 50% probability of recovery by an arbitrary range of years between  $T_{F=0}$  in 2011 (2047) and slightly above the recalculated  $T_{MAX}$  (2089). Except for alternative 14, these runs correspond to harvest rates lower than that of the SPR = 71.9% value used to design the current approach (post ‘ramp-down’ target). Detailed results of these management alternatives are presented in tables 11-13.

Sensitivity analyses for the degree of recruitment variability ( $\sigma_r$ ) used in rebuilding simulations were performed to evaluate the use of 0.5. The choice of 0.5 was intended to both provide consistency with previous analyses, as well as reflect a ‘reasonable’ level for west coast rockfish. Future assessments may be able to better inform this quantity. The year in which there is a 50% probability of recovery for the SPR target strategy (71.9%) is largely insensitive to the choice of  $\sigma_r$  between 0.01 and 1.0 (Figure 7). However, as the degree of recruitment variability increases, the ‘smoothness’ of the trajectory improves, indicating that year-to-year variability in recruitment strength is reducing the contrast between the nine states of nature (dominated by the steepness axis in this plot). It may therefore be useful to consider, when comparing the full suite of management alternatives, that probabilities differing substantially from the median may be more heavily influenced by the choice of  $\sigma_r$ . Inclusion of parameter uncertainty for all estimated quantities would generally cause the same type of smoothing behavior for any rebuilding analysis, although this is not currently possible for maximum likelihood based estimates.

## **Acknowledgements**

Andre Punt, Ian Taylor and Richard Methot provided assistance in using the rebuilding software and Stock Synthesis. This document draws on the work of many previous yelloweye assessment and rebuilding plan authors. Andre Punt and the review panel members at the SSC Groundfish Subcommittee Meeting and Rebuilding Analysis Review provided several comments improving the quality and clarity of the results presented here.
