Agenda Item F.1
Situation Summary
June 2014

NATIONAL MARINE FISHERIES SERVICE REPORT

National Marine Fisheries Service (NMFS) West Coast Region (WCR) will briefly report on recent regulatory developments relevant to groundfish fisheries and issues of interest to the Council.

NMFS Northwest Fisheries Science Center (NWFSC) will also briefly report on groundfish-related science and research activities.

Council Task:

Discussion.

Reference Materials:

1. Agenda Item F.1.b, FR Notices: *Federal Register* Notices Published Since the Last Council Meeting.
2. Agenda Item F.1.b, NMFS Report: Draft Rulemaking Plan for 2014: Groundfish and Halibut.
3. Agenda Item F.1.c, FSC Report: National Marine Fisheries Service Report – Groundfish Science.

Agenda Order:

a. Agenda Item Overview — Kelly Ames
b. Regulatory Activities — Frank Lockhart
c. Fisheries Science Center Activities — Michelle McClure, John Stein
d. Reports and Comments of Advisory Bodies and Management Entities
e. Public Comment
f. Council Discussion

Draft Rulemaking Plan for 2014

Groundfish and Halibut

In addition to a list of groundfish and halibut rules that have already been proposed and/or completed over 2014, NMFS is providing a list of rulemakings that are in progress over the remainder of 2014.

Completed rules:

1. Trawl Cost Recovery, Final Rule (12/11/2013, effective 1/10/2014)
2. Pacific Halibut Catch Sharing Plan, Proposed Rule (2/6/2014)
3. Observer/Catch Monitor, Proposed Rule (2/19/2014)
4. Whiting Fishery Allocations, Proposed Rule (2/28/2014)
5. Trawl Program Improvement and Enhancement (PIE 2) Rule, Correction (3/5/2014)
6. Trawl Chafing Gear, Proposed Rule (3/19/2014)
7. Pacific Halibut Catch Sharing Plan, Final Rule (4/4/2014)
8. Trawl Chafing Gear, Proposed Rule Correction (4/4/2014)
9. Inseason Action (4/9/2013)
10. Trawl Rockfish Conservation Area (RCA), Final Rule (4/17/2014)
11. Whiting Fishery Allocations, Final Rule (5/13/2014)
12. Trawl Rockfish Conservation Area (RCA), Correction (5/13/2014)
13. 13-14 Specifications, Trawl Allocations, Correction (5/16/2014)

In Progress:

1. Chafing Gear Rule Timing: Final rule – summer 2014 Effective – summer 2014 Includes: changes to chafing gear requirements Sectors affected: limited entry (LE) trawl (IFQ/MS/C/P)	**6. Whiting Clean-up Rule** Timing: Proposed Rule – fall 2014 Final rule – December 2014 Effective – January 1, 2015 Includes: whiting IFQ must have 50% whiting by weight, disposition of maximized retention catch, only midwater in RCA north of 40°10' N. lat. Sectors affected: LE trawl (IFQ/MS/C/P)
2. Observer/Catch Monitor Rule Timing: Final rule – summer 2014 Effective – summer 2014 Includes: permitting for new observer providers, observer safety, minor revisions Sectors affected: LE trawl (IFQ/MS/C/P)	**7. Whiting Season Date Rule** Timing: Proposed Rule – winter 2014/2015 Final rule – spring 2015 Effective – ~ May 2015 Includes: IFQ whiting season date starts May 15 Sectors affected: LE trawl (IFQ, MS, C/P)
3. Seabird Rule Timing: Proposed Rule – summer 2014 Final rule – 2014 Effective – 2014 Includes: mandatory streamer lines Sectors affected: LE and open access (OA) fixed gear	**8. AMP pass-thru Rule** Timing: Proposed Rule – fall 2014 Final rule – December 2014 Effective – January 1, 2015 Includes: pass through of the AMP QP to QS owners Sectors affected: LE trawl (IFQ)
4. 2015/2016 Harvest Specifications and Management Measures, Amendment 24 Timing: Proposed Rule – fall 2014 Final rule – December 2014 Effective – January 1, 2015 Includes: groundfish harvest levels, allocations, commercial trip limits, bag limits, etc. Sectors affected: Tribal, LE trawl, LE fixed gear, OA, and recreational	**9. Pacific Halibut Catch Sharing Plan, 2015** Timing: Proposed Rule – December 2014 Final rule – March 2015 Effective – March 2015 Includes: changes to commercial and recreational halibut fisheries for Area 2A Sectors affected: LE and OA fixed gear
5. Sablefish Rule Timing: Proposed Rule – fall 2014 Final rule – winter 2014/2015 Effective – April 1, 2015 Includes: Registering a LE trawl and fixed gear permit to a vessel at same time (joint registration), sablefish-endorsed LE fixed gear ownership issues, electronic fish tickets Sectors affected: LE trawl (IFQ), LE fixed gear, OA	

Agenda Item F.1.c
FSC Report
June 2014

NATIONAL MARINE FISHERIES SERVICE REPORT -- GROUNDFISH SCIENCE

Topics for presentation during the NMFS Science Center Report for Groundfish include:

- **2014 Groundfish Bottom Trawl Survey.** The first pass of the groundfish survey began sampling at sunrise on May 24, with the expectation of completing 752 tows before the survey concludes in October. During the initial leg of the survey, fishing will occur from Newport, OR to the U.S.-Canada border aboard two chartered fishing vessels, the Last Straw and Noah's Ark. Each vessel will be staffed with a 3-person crew and a 3-person scientific party. The entire first pass is scheduled to end July 29 with demobilization in Newport.

- **Likely Mechanisms of the Humboldt Squid Range Expansion in the California Current.** With two separate modeling approaches using unique, long-term data based on in situ observations of predator, prey, and environmental variables, our analyses suggest that Humboldt squid are indirectly affected by OMZ shoaling through effects on a primary food source, myctophid fishes. Our results suggest that this indirect linkage between hypoxia and foraging is an important driver of the ongoing range expansion of Humboldt squid in the northeastern Pacific Ocean.

- **Programmatic Review of Stock Assessment Process.** As part of a national, 5-year series of programmatic reviews, the NW Fisheries Science Center will host an independent review of the California Current groundfish stock assessment process on June 10-13, 2014. Each of the Panel members will submit comments, along with an overview prepared by the Chair. As in past reviews, the NWFSC will prepare formal responses to the major recommendations of Panel members and develop a set of action items in each area as appropriate. Future Science Report to the Council will include an overview of the major themes in the review comments and the Center's response.

- **Economic Data Collection – 2013 Submissions.** In response to Council's request, participants now have the option to complete the EDC forms through a web form. As the use of web forms is optional, paper forms were mailed to participants in May along with instructions for online submission.The forms continue to ask about the number of crew/workers positions on a vessel or in a plant. In addition, a new question was added in order to obtain the number of employees (crew and workers) directly engaged in fishing and processing. The additional question asks for the total number of individuals employed during the year. This information will provide important information about total employment.

- **CIE Review of the Joint Hake-Sardine survey.** We will discuss findings and responses to the 2014 review of the joint hake-sardine survey by the Center for Independent Experts.

Groundfish EFH Tasking for September Council Meeting

NOAA FISHERIES SERVICE

NOAA FISHERIES SERVICE

NWFSC/SWFSC Groundfish EFH Tasking for September Council Meeting

- Specific tasks listed in briefing book, referenced by Council member
- Prioritizing tasks based on available resources for completion by the Council's Sept. action (scoping)

  For example:
  - Analyses of the effects of existing management measures on groundfish EFH
  - Preliminary analyses of proposals (e.g., mapping and cataloging impacts of proposals on fishing effort)

NOAA
FISHERIES
SERVICE

Theme 1: How do current EFH proposals relate to other factors?

- In relation to
  - Current trawling effort and availability
  - Catch
  - Each other
  - RCAs
- Conclusion: Straightforward GIS analysis, intended to be complete by September Council meeting.

NOAA FISHERIES SERVICE

Theme 2: What do we already know?

- What have been the effects of
  - Gear switches
  - RCA
  - Catch shares
- Conclusion: part 1
  - We will summarize existing studies addressing these issues
  - Complete analysis is mult-dissertation worthy
- Conclusion: part 2
  - Preliminary analysis of Amend. 20 as part of BiOp

NOAA FISHERIES SERVICE

Theme 3: Do mid-water trawls really hit the bottom?

- Concern that the true effect of mid-water trawling on bottom habitats is not accurately characterized

- Conclusion: Tabulation of bottom-dwelling organisms (as proxy for hitting bottom) in hauls from catch data
  - For September Council meeting

NOAA FISHERIES SERVICE

Theme 4: Did you guys use those EFH boundaries anyway?

- Issues
  - Any mistakes?
  - Did EFH factor into decision-making?

- Conclusion:
  - List of wrongly/poorly placed boundaries (e.g. Potato Bank)
  - Table of decisions/etc. using EFH
  - Policy side to deal with these

NOAA FISHERIES

NWFSC

SWFSC

Center for Independent Experts (CIE) Panel Review of the Joint Pacific Sardine and Hake (SaKe) acoustic--trawl surveys

January 21-24, 2014

Seattle WA

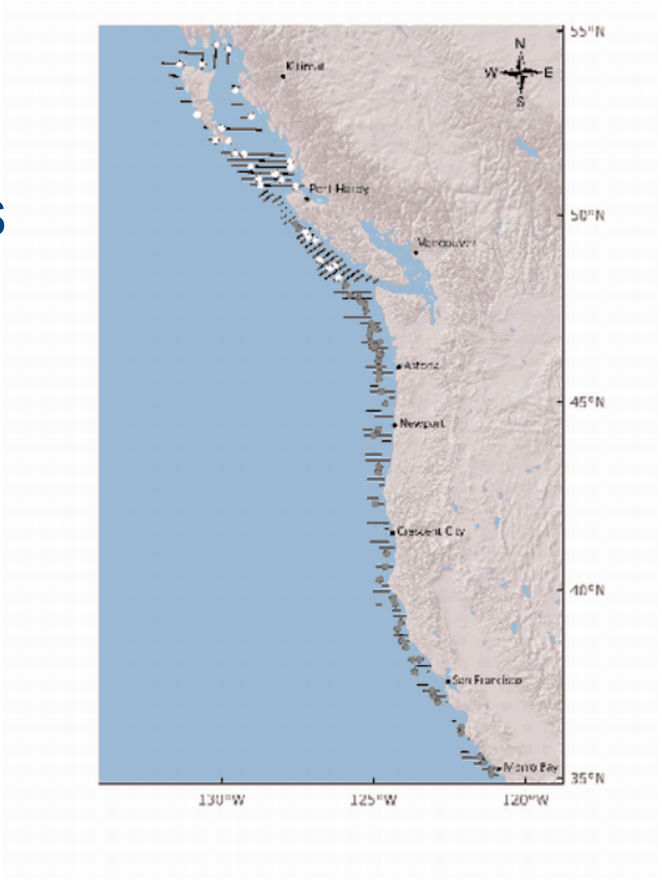

Figure 2. Acoustic transect lines and locations of midwater and bottom trawls during the 2011 integrated acoustic and trawl (IAT) survey of Pacific hake in U.S. and Canadian waters off the Pacific coast. Gray circles represent trawls conducted by the NOAA Ship *Bell M. Shimada*; white circles

Michelle McClure, Fishery Resource Analysis and Monitoring Division, NWFSC
Dale Sweetnam, Fisheries Resources Division, SWFSC
June 20, 2014

CIE Review of the Joint Hake-Sardine survey Terms of Reference:

1. Evaluate the historic, independent sardine and hake surveys
2. Evaluate the current joint SaKe survey
3. Evaluate the tradeoffs of transitioning from independent surveys to a joint sardine-hake survey.
4. Evaluate the potential of the SaKe survey to provide status and trend info for hake and CPS
5. Evaluate the costs and benefits of :
    - Separate and joint hake and sardine surveys
    - Biennial v. Annual
    - Ecosystem v. no ecosystem information.

- Provide recommendations to increase the efficacies and efficiencies (e.g., through advanced technologies) the survey

NOAA FISHERIES

NWFSC

SWFSC

SaKe Methodology Review Panel

Leader, Fishery Dynamics Research Group, Principal Research Scientist
Institute of Marine Research, Norway

NOAA FISHERIES

NWFSC
SWFSC

- Conclusion 1: Joint survey is strongly supported
  - Hake and CPS assessment support
  - Basis for ecosystem studies
  - Climate response
- Response: All right, then
  - Centers continue to develop and implement joint efforts

NOAA FISHERIES

NWFSC
SWFSC

- Conclusion 2: A development phase is needed before “annual production”
  - 5 years
  - Techniques/methodologies
  - Resource development
- Response: yes!
  - 2014 – survey and development year
    - Net testing – interchangeability
    - Acoustic development
  - Integrate experiments with surveys

NWFSC
SWFSC

- Conclusion 3: Improve coordination
  - Between Centers
  - With Canada and Mexico
- Response: Long-term and ongoing efforts
  - Working group for planning and design
  - Better coordination on data storage and processing
  - Work to expand international (i.e. biologically-appropriate) coverage

NOAA FISHERIES

NWFSC
SWFSC

- Conclusion 4: Research Areas
  - Transect spacing, direction of survey, simultaneous use of 2 vessels
  - Development and validation of geostatistical techniques
  - Migration behavior and rates
  - Target strengths and species id
- Response: Prioritizing and Pursuing
  - Multiple review efforts (SRG, Program Review, CIE)

NOAA FISHERIES

NWFSC
SWFSC

- General Issues Raised
  - Possibly oversampling (transect density)
  - Length of time of survey
  - Understanding ecosystem dynamics is as important as biomass estimates
  - Juvenile indices
  - 2nd vessel (Lasker) to provide additional opportunities
  - Climate change

NOAA FISHERIES

NWFSC
SWFSC

- A joint survey with oceanographic sampling provides "a grand opportunity to work towards a true ecosystem-based survey that provides advice for stock assessment of the main commercial species plus the ecosystem information needed to fully understand productivity changes… that are currently occurring or coming at us soon."

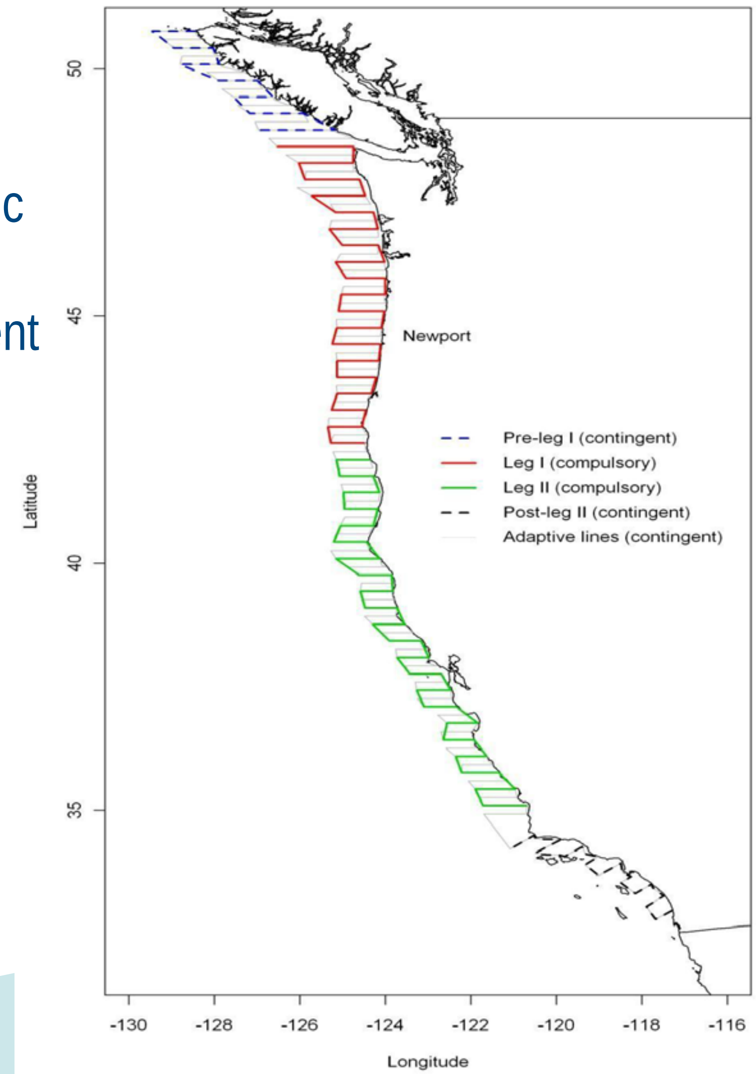
-George Rose

2014 Summer SaKe Survey and beyond

NOAA FISHERIES

SWFSC

- Survey Dates June 24-September 14, 2014
- First two legs are a Synoptic Acoustic-Trawl survey of CPS in the California Current Ecosystem
- Last two legs are hake specific research investigating survey methods, life history, and associated ecosystem



Moving Forward / Moving Parts

NOAA FISHERIES
SWFSC

- This year
  - Survey + research
  - Planning meeting aimed at addressing issues
- Moving Parts
  - Results of methodological tests
  - Ship time
  - Other resources
  - Standardization of data
  - Interoperability of data and equipment

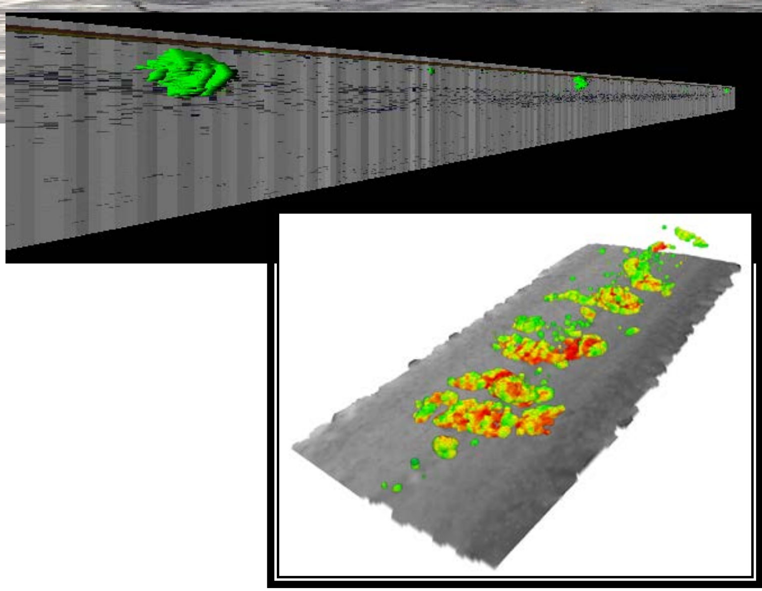
New FSV to address
California Current ecosystem questions

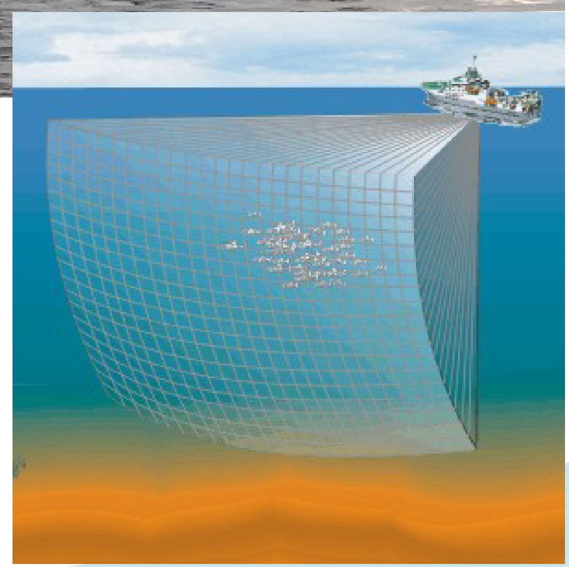
The Lasker is the fifth in a series of Oscar Dyson-class ships (208 ft; 63m) home ported in San Diego

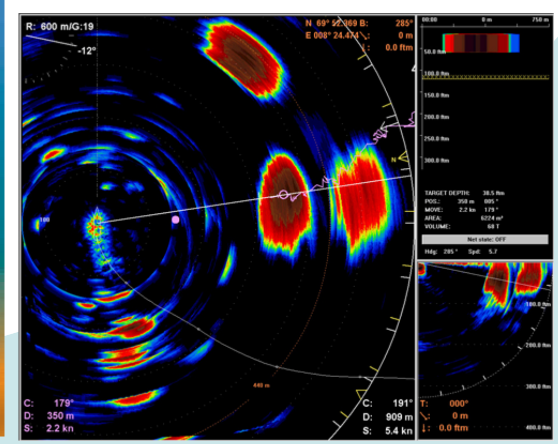
Equipped with technologies for fisheries and oceanographic research, including advanced navigation systems, acoustic sensors.

- Five-frequency split-beam echosounders
- Scanning, Multi-beam and Imaging Sonars

The ship is engineered to produce less noise than other survey vessels.







Agenda Item F.2
Situation Summary
June 2014

ELECTRONIC MONITORING REGULATORY PROCESS

The Council adopted a range of alternatives and options for an electronic monitoring (EM) program in November 2013, and at the April 2014 Council meeting the Council provided guidance on further development of an EM program. On May 7 and 8, the Groundfish Electronic Monitoring Policy Advisory Committee (GEMPAC) and Technical Committee (GEM Committees) met in Seattle, Washington to discuss potential revisions and additional options for Council consideration (Agenda Item F.2.b, GEMPAC Report). Council staff presented a framework for developing a cost analysis for an EM program. In addition, the GEM Committees heard from the only two west coast observer providers about how they may be affected by the development of an EM program to assist the GEM Committees and Council staff in the development of EM options and the impact analysis.

The GEMPAC report provides recommended definitions, revisions, and additional options to the Council's adopted alternatives, and a summary of observer provider comments. A new detailed listing of alternatives that includes the GEMPAC's recommendations is provided in the Council's draft analytical document titled "Draft Analysis of an Electronic Monitoring Program for the Pacific Coast Limited Entry Trawl Groundfish Fishery Catch Shares Program" (Agenda Item F.2.a, Attachment 1). The draft Council decision document, which will ultimately evolve into a National Environmental Policy Act-compliant document, provides background on the development of the EM program, alternatives and options, and initial draft impact and cost analyses. In addition, Pacific States Marine Fisheries Commission submitted its final 2013 field study report for Council consideration (Agenda Item F.2.b, PSMFC Report). The NMFS Fisheries Science Center provided a net revenue analysis on the topic of EM (Agenda Item F.2.b, NMFS Report).

Under this agenda item, the Council is scheduled to refine alternatives, assign focused analysis, and select any preliminary preferred alternatives that may be appropriate for the different fishery sectors. The Council is currently scheduled for final decision making on a regulatory program recommendation to the NMFS at the September, 2014 Council meeting. At that time, the Council may make final decisions on individual fishery sectors, as opposed to needing to make a final decision for all sectors simultaneously.

Under a separate agenda item (F5, Final Exempted Fishing Permit (EFP) Approval for 2015-2016), the Council is scheduled to consider for final approval electronic monitoring EFP applications. The Council may want to consider the implications of the applications and how the projects could assist the Council in their development of EM program policies.

<u>Council Action</u>:

Consider Refining Alternatives and Adopting Preliminary Preferred Alternatives, as Appropriate, for Public Review

Agenda Item F.2.a
Attachment 1
June 2014

Draft Analysis of an Electronic Monitoring Program for the Pacific Coast Limited Entry Trawl Groundfish Fishery Catch Shares Program

Abstract: Participants with a Pacific Coast groundfish limited entry trawl permit that have a quota share (QS) permit and operate using individual fishing quota under the catch share program (Shorebased IFQ program) are subject to 100 percent observer coverage. Some participants have experienced difficulties in securing observers in a timely or consistent manner. In addition, program participants will be responsible for the full cost of observer coverage in the near future. Therefore, Electronic Monitoring (EM) (i.e., video monitoring) is being explored as flexible and economical substitute for human observers.

This draft decision document analyzes the effects of establishing an EM program for catcher vessels using bottom trawl, midwater trawl, and fixed gear (i.e., longline and pots) in the Shorebased IFQ program. The proposed EM program would be established to monitor vessels for compliance with individual fishing quotas (IFQ), individual bycatch quotas (IBQ), or groundfish allocations assigned to QS permit holders. The program would be voluntary and includes eligibility requirements to use EM, individual vessel monitoring plans, equipment and installation requirements of a video monitoring system, video data processing protocols, and compliance measures. Under the proposed action, the regulatory requirement of 100 percent human observer coverage on all IFQ fishing trips would be maintained. The proposed EM program is not intended to meet the needs for biological data or monitoring of other scientific information; however, human observers would continue to collect this information at an appropriate level to support scientific needs. Therefore, on EM trip, the vessel could be randomly chosen by NMFS to carry an observer for the purpose of collecting scientific information. However, if a vessel qualifies and chooses to fish using an EM system on an IFQ trip, the vessel would be exempted from the requirement for a human observer on the trip form compliance monitoring but would still be subject to random observer placement for scientific data collection.

The alternatives considered would maintain the full accountability of IFQs, IBQs, and groundfish allocations managed under the Shorebased IFQ program. This document analyzes the effects that an EM program would have on the socioeconomic, biological, and physical environments. No additional allocations of fish resources would be required, and fishing operations (area fished, effort, or gear used) are not expected to change under the proposed action. Impacts to the biological and physical environment are expected to be similar to those realized under the current Shorebased IFQ program.

TABLE OF CONTENTS

List of Tables

List of Figures

GLOSSARY

Electronic Technology(ies) **–** Any electronic tool used to support catch monitoring efforts both on shore and at sea, including electronic reporting (e.g., e-logbooks, tablets, and other input devices) and electronic monitoring (Vessel Monitoring Systems, electronic cameras, and sensors on-board fishing vessels).

Electronic Monitoring (EM) **–** The use of technologies – such as vessel monitoring systems or video cameras – to passively monitor fishing operations through observing or tracking. Video monitoring is often referred to as EM.

Electronic Reporting (ER) **–** The use of technologies – such as smart phones, computers and tablets – to record, transmit, receive, and store fishery data.

Fishery-dependent Data Collection Program **-** Data collected in association with commercial, recreational or subsistence/customary fish harvesting or subsequent processing activities or operations, as opposed to data collected via means independent of fishing operations, such as from research vessel survey cruises or remote sensing devices.

Full Retention **–** A type of fishery where total catch is retained and brought to shore, without discards. This is a generic definition, used in the Policy Directive for illustrative purposes only. There are multiple stages in the fishing process where intentional and unintentional discards can occur. Such variations (e.g., maximum retention, operational discards, prohibited species catch, etc.) require specific definition in each fishery for regulatory compliance and/or enforcement purposes.

Maximized Retention **–** A type of fishery where total catch is retained and brought to shore, except for minor operational amounts of catch lost by a catcher vessel. A vessel is generally required to retain all catch share species, non-catch share groundfish species, non-groundfish species (Non-FMP and not prohibited species).

Optimized Retention **-** A vessel is generally required to retain all catch share species and may be allowed to discard certain species.

CHAPTER 1 INTRODUCTION

The groundfish fishery in the Exclusive Economic Zone (EEZ), offshore waters between 3 and 200 nautical miles (nm), off the coasts of Washington, Oregon, and California (WOC) is managed under the Pacific Coast Groundfish Fishery Management Plan (FMP), while the nearshore areas are managed by the states and tribes. The Pacific Coast Groundfish FMP was prepared by the Pacific Fishery Management Council (Council) under the authority of the Magnuson Fishery Conservation and Management Act (subsequently amended and renamed the Magnuson-Stevens Fishery Conservation and Management Act). The FMP has been in effect since 1982.

Actions taken to amend FMPs or to implement regulations to govern the groundfish fishery must meet the requirements of several Federal laws, regulations, and executive orders. In addition to the Magnuson-Stevens Fishery Conservation and Management Act (Magnuson-Stevens Act), these Federal laws, regulations, and executive orders include: National Environmental Policy Act (NEPA), Regulatory Flexibility Act (RFA), Endangered Species Act (ESA), Marine Mammal Protection Act (MMPA), Coastal Zone Management Act (CZMA), Paperwork Reduction Act (PRA), Executive Orders (E.O.) 12866, 12898, 13132, and 13175, and the Migratory Bird Treaty Act.

NEPA regulations require that NEPA analysis documents be combined with other agency documents to reduce duplication and paperwork (40 CFR§§1506.4). Therefore, this EA will ultimately become a combined regulatory document to be used for compliance with not only NEPA, but also E.O. 12866, RFA, and other applicable laws. NEPA, E.O. 12866, and the RFA require a description of the purpose and need for the proposed action as well as a description of alternative actions that may address the problem.

- Chapter One describes the purpose and need of the proposed action.
- Chapter Two describes a reasonable range of alternative management actions that may be taken to meet the proposed need.

- Chapter Three contains a description of the socioeconomic, biological, and physical characteristics of the affected environment.
- Chapter Four examines changes in the socioeconomic, biological, and physical environments resulting from the alternative management actions.
- Chapter Five addresses consistency with the FMP and other applicable laws.
- Chapter Six is the regulatory impact review and regulatory flexibility analysis.
- Chapter Seven is a list of individuals who help prepare this document.
- Chapter Eight provides a list of references for this document.

1.1 Summary of the Proposed Action

The proposed action is to create the regulatory framework for an electronic monitoring program, to monitor the fisheries for compliance with IFQ and groundfish allocations under the Shorebased IFQ program (See Appendix E of the Pacific Coast Groundfish FMP). The EM program would include a video monitoring system for catch accounting that is adequate to maintain the integrity of the IFQ program and ensure that resource management objectives are being met. The proposed EM program would monitor vessels for compliance with individual fishing quotas (IFQ), individual bycatch quotas (IBQ), or groundfish allocations assigned to QS permit holders. The program would be voluntary and includes eligibility requirements to use EM, individual vessel monitoring plans, equipment and installation requirements of a video monitoring system, video data processing protocols, and compliance measures. The requirement for 100 percent observation of trips would be maintained; therefore, vessels will be required to have either a human observer or an EM system to operate in the Shorebased IFQ program.

This action is intended to implement a voluntary program that would allow participants under the IFQ program to use EM rather than human observers via long-term Federal regulations. If approved, the action is intended to be implemented in 2016.

1.2 Purpose and Need for the Proposed Action

There is a need to adequately monitor the IFQ program for compliance in an economical and flexible manner yet meet the goals and objectives of national policies and standards, the Pacific Coast Groundfish FMP, the trawl rationalization program, and all applicable laws and acts including the Magnuson-Stevens Act (MSA) and Endangered Species Act (ESA). NMFS and the Council identified that electronic monitoring (EM) may be a viable option to monitor IFQ fisheries for compliance.

The purpose of the proposed action is to meet the following regulatory objectives:

1. Reduce total fleet monitoring costs to levels sustainable for the fleet and agency;
2. Reduce observer costs for vessels that have a relatively lower total revenue;
3. Maintain monitoring capabilities in small ports;
4. Increase national net economic value generated by the fishery;
5. Decrease incentives for fishing in unsafe conditions;
6. Use the technology most suitable and cost effective for any particular function in the monitoring system; and
7. Reduce the physical intrusiveness of the monitoring system by reducing observer presence.

1.3 Decision to be Made

From the information in this document, the Council may refine alternatives, assign focused analysis, and select any preliminary preferred alternatives that may be appropriate for the different fishery sectors. The Council is currently scheduled for final decision making on a regulatory program recommendation to the NMFS at the September, 2014 Council meeting. At that time, the Council may make final decisions on individual fishery sectors, as opposed to needing to make a final decision for all sectors simultaneously.

1.4 Management of the Pacific Coast Groundfish Fishery and the Trawl Rationalization Program

1.4.1 History of Management

The west coast groundfish trawl fishery is jointly managed by state and Federal authorities under the MSA, which was passed in 1976 to "Americanize" U.S. fisheries. In addition to establishing eight regional fishery management councils, the MSA extended U.S. fishery management authority in territorial waters from 12 miles out to 200 miles from the shore. This created the EEZ, which, including U.S. Federal territorial waters, extends from 3 to 200 miles off shore. For the west coast (California, Oregon, and Washington), the Council coordinates Federal management of fisheries in the Federal EEZ with state management of fisheries occurring in state waters (i.e., between the shoreline and 3 miles offshore).

The groundfish fishery as a whole comprises several different sectors, defined by fishing gear, species targeted, and regulatory context. The list of current trawl target species includes flatfish, roundfish, thornyheads, and a few species of rockfish. Primary flatfish target species include petrale sole and Dover sole. Roundfish target species include Pacific whiting, Pacific cod, and sablefish. Some rockfish species, especially Pacific ocean perch and widow rockfish, were important trawl targets until the mid 1990s. However, seven rockfish species are currently declared overfished pursuant to the MSA. The need to rebuild these stocks to a healthy size has led to a variety of harvest constraints on groundfish fisheries, and rockfish are generally no longer a target of these fisheries.

The groundfish trawl fishery is subject to a Federal license limitation program (referred to as LE), implemented in 1992; currently there are 178 extant groundfish LE trawl permits. For purposes of analysis in this document, the LE trawl fishery is divided into the shoreside and at-sea midwater trawl fishery (catcher vessels only and does not include at-sea motherships or catcher/processors), mid-water non-whiting trawl fishery, fixed gear fishery (includes longline with hook-and-lines and longline with pots), and bottom trawl.

At its November 2008 meeting, the Council recommended trawl rationalization through an IFQ program for the shoreside fishery and co-ops for the whiting mothership and catcher-processor sectors (hereafter referred to as Shoreside IFQ program). Following the November 2008 meeting, the Council worked on critical trailing actions needed to complete Amendment 20. These actions covered topics such as eligibility to own IFQs, accumulation limits, a set-aside for adaptive management, and miscellaneous clarifications. The Council completed the critical trailing actions at its June 2009 meeting and adopted the related FMP amendment language. The initial allocation of canary quota shares was modified at the November 2009 Council meeting. The Council's final recommendations on Amendments 20 and 21 were submitted to the Secretary of Commerce for approval on May 7, 2010. On August 9, 2010, NMFS issued a letter approving the bulk of both Amendments 20 and 21. The final regulations to initiate implementation of Amendments 20 and 21 were published in the *Federal Register* on October 1, 2010 (the initial allocation rule). A proposed rule for a separate set of regulations required for implementation (the components rule) was published on August 31, 2010. The components rule was finalized December 2010 and implemented January 11, 2011. Since implementation, the Council has recommended a number of adjustments to the trawl catch share program (see Trailing Amendments and Actions on Trawl Rationalization [Catch Shares]).

The Shoreside IFQ program for the limited entry bottom trawl fleet and two distinct cooperative programs for the at-sea hake mothership and catcher-processor trawl fleets. The bottom trawl fleets traditionally operates from the U.S./Canadian border to Morro Bay, California. The at-sea hake fleet operates off the coasts of Oregon and Washington. Observer data is used to account for any IFQ discarded catch, including the mandatory discarding of Pacific halibut. Observer data, in combination with landings data, enable fishermen to track their individual fishing quotas and allow managers to monitor the progress of the fishery. The program requires that each vessel acquire quota pounds (QP) to cover its catch (including discards) of nearly all groundfish species.[1] Proper functioning of the program requires some form of at-sea monitoring to ensure that discards are enumerated for each vessel. The catch share program specified that this monitoring function be achieved through 100% at-sea observer coverage (compliance monitoring).

1.4.2 Applicable Federal Permits, Licenses, or Authorizations Needed in Conjunction with Implementing this Proposal

The Shorebased IFQ Program applies to qualified participants in the Pacific Coast Groundfish limited entry fishery and includes a system of transferable quota shares (QS) for most groundfish species or species groups, individual bycatch quota (IBQ) for Pacific halibut, and trip limits or set-asides for the remaining groundfish species or species groups. A QS permit would be required to participate in the proposed EM program. NMFS will issue a QS permit to eligible participants and will establish a QS account for each QS permit owner to track the amount of QS or IBQ and quota pounds (QP) or IBQ pounds owned by that owner. NMFS will establish a vessel account for each eligible vessel owner participating in the Shorebased IFQ Program, which is independent of the QS permit and QS account. In order to use QP or IBQ pounds, a QS permit owner must transfer the QP or IBQ pounds from the QS account into the vessel account for the vessel to which the QP or IBQ pounds is to be assigned. Harvests of IFQ species may only be delivered to an IFQ first receiver with a first receiver site license. A Pacific Coast groundfish limited entry permit is required to establish a vessel account and, amongst other requirements, a limited entry permit would be required to participate in the EM program.

1 Exceptions were made for some species rarely caught in the trawl groundfish fishery.

1.4.3 Background on Decisions to Consider EM

1.4.3.1 Why is 100% Monitoring Needed for this Fishery?

Prior to the trawl rationalization program, the West Coast groundfish observer program monitored approximately 20 percent of the trips taken on groundfish trawl vessels. The trawl rationalization program relies on the monitoring of all trips. One hundred percent monitoring is required to provide for the individual accountability on which the program relies, to fully achieve the potential program benefits, and to prevent the complexity and challenging enforcement circumstances which would arise if some vessels were monitored and others were not.

The trawl fishery is a multispecies fishery in which the allowable harvest levels for some stocks (potentially including overfished species) constrain total harvest. If a vessel were not monitored on a particular trip, the elimination of individual accountability would generate an incentive to alter fishing behavior and target stocks that are more difficult to catch without encountering high levels of constraining species. The trawl rationalization program has helped the fleet make tremendous gains in bycatch avoidance. During an unmonitored trip the incentive to avoid bycatch would be minimal. Alternative regulations would have to be developed for unmonitored trips, adding to regulatory complexity. Those regulations would have to assume high bycatch rates for constraining species in order to ensure that the trawl allocations not be exceeded. The assumption of such high bycatch rates would increase vessel operation costs (require the vessel to use more quota) and diminish quota potentially available for the remainder of the fleet. To provide more opportunity, different bycatch rates could be created for different harvest areas. However, this would increase regulatory complexity with a greater number of management lines and assumed bycatch rates, make the calculation of trip catch more complex and time consuming, and potentially burden enforcement with determination of whether any tows on the trip crossed into the high bycatch area. This example assumes that area of catch is the only parameter affecting high bycatch rates of constraining species. Other parameters such as the sonar signal on which fishermen set their gear and the configuration and manner in which the gear is fished may also affect bycatch rates. For example, halibut excluders might be disabled on unmonitored trips in order to increase CPUE.

Finally, the Council is in the process of considering how to more fully achieve the potential benefits of the individual incentives provided by the trawl rationalization program by liberalizing a number of regulations governing trawl vessels (e.g. gear regulations). If some vessels were unmonitored, two sets of regulations might need to be maintained, one for monitored vessels the other for unmonitored vessels, further increasing regulatory complexity. For these reasons, 100 percent monitoring is required for effective function of the program.

1.4.3.2 Why Monitor With Observers?

Currently 100% monitoring is achieved through the use of observers on the vessels. The Council's final action on trawl rationalization included a provision allowing vessel observes to be supplemented with cameras (one of the most common forms of electronic monitoring), but not allowing the use of cameras to completely fulfill the monitoring function. At the time the Council took final action, the program had already been in development for over five years and consideration of camera monitoring may have further delayed implementation. The trawl rationalization program entailed a tremendous change to the fishery and, while the change was expected to be positive, there was concern about the potential for unexpected consequences. Even though cameras had been successfully used to monitor the whiting fleet on an experimental basis, the incentives provided by individual accountability also create an incentive to avoid detection, which was not present during the development of the camera monitoring program for the whiting fishery. The West Coast Groundfish Observer Program was successfully monitoring about 20 percent of the trips and, thus providing a familiar tool. While the incentives to avoid detection could also lead to behaviors frustrating the observer's role, a human observer has more ability than a camera system to detect and respond to contingencies and collect information useful to modifying the monitoring program. Thus, the decision to not include cameras as an alternative to observes was made in the context of uncertainties about the performance of the overall program and cameras and potential delays in program implementation that may have resulted from a more careful considering of the camera options.

1.4.3.3 Why Monitor With EM?

The circumstances, under which electronic monitoring was originally rejected, have changed. Fishery managers have now had two years of experience under the program, which has provided a better understanding of how the fishery performs and how fishermen operate under the program. This has reduced some of the uncertainty about potential unintended consequences. Now, increasing information is becoming available on the performance of electronic monitoring and there is time to more carefully consider the utility of electronic monitoring relative to human observers. There are a number of needs that an alternative to monitoring with observers may address. First, for vessels, the need to pay for vessel observers is one of the most expensive compliance costs associated with participation in the trawl rationalization program. For the first years of the program, NMFS has subsidized observer costs to help the fleet though the period of adjusting to the new management system. Overall fleet profits, and consequently the price of quota, will be below what they might otherwise be if less expensive monitoring is available. Second, small vessels may be disproportionately affected by observer costs. Vessels are billed for observers on a per day basis, and because smaller vessels may have a lower total revenue per day at sea observer costs reduce vessel net revenue disproportionately more than for larger vessels. On this basis, over time it might be expected that quota will migrate to larger vessels and there will be fewer smaller vessels in the fleet—assuming small vessels do not have other countervailing advantages. Third, because of the overhead involved with maintain observer availability in small, somewhat isolated ports with relatively low demand for observers, at least one observer company has indicated that it may pull out of at least one of the small ports on the West Coast. In addition some observer companies may not be willing to provide observers for safety reasons. Thus, over time, smaller ports may be disadvantaged by the observer requirement, relative to larger ports. Fourth, if overall monitoring costs can be reduced (those borne by both private parties and the public), national net economic benefits may be increased. And finally, the observer fee system puts pressure on vessels to fish in unsafe conditions. Because vessels are billed on per day both for at-sea and for standby time, vessels may incur higher costs for standing down due to marginal weather conditions.

1.5 ESA Opinions and Thresholds for the Pacific Coast Groundfish Fishery

Six marine mammal species are known to have interacted with groundfish trawl gear: California sea lion, harbor seal, harbor porpoise, pacific white-sided dolphin, northern elephant seal, and Stellar sea lion (unidentified sea lions are also recorded, which could be either California or Stellar). Various seabird species have been observed taken in the groundfish trawl fishery; none is ESA-listed.

On December 7, 2012, NMFS issued a Biological Opinion (Opinion) under the ESA on the continuing operation of the Pacific Coast groundfish fishery. NMFS concluded that the fishery is not likely to jeopardize the continued existence of green sturgeon *(Acipenser medirostris),* eulachon *(Thaleichthyspacificus),* humpback whales *(Megaptera novaeangliae),* Steller sea lions *(Eumetopiasjubatus),*and leatherback sea turtles *(Dermochelys coriacea).* We also conclude that the proposed action is not likely to destroy or adversely modify designated critical habitat of green sturgeon or leatherback sea turtles. Furthermore, NFMS concluded that the proposed action may affect, but is not likely to adversely affect the following species and designated critical habitat:

Sei whales *(Balaenoptera borealis),*
North Pacific Right whales *(Eubalaena japonica),*
Blue whales *(Balaenoptera musculus),*
Fin whales *(Balaenoptera physalus),*
Sperm whales *(Physter macrocephalus),*
Southern Resident killer whales *(Orcinus orca),*
Guadalupe fur seals *(Arctocephalus townsendi),*
Green sea turtles *(Chelonia mydas),*
Olive ridley sea turtles *(Lepidochelys olivacea),*
Loggerhead sea turtles *(Carretta carretta),*
Critical habitat of Southern Resident killer whales, and Critical habitat of Steller sea lions

On November 21, 2012, the US Fish and Wildlife Service (USFWS) issued an Opinion under the ESA on the continuing operation of the Pacific Coast groundfish fishery. USFWS concluded the fishery would not jeopardize the continued existence of short-tailed albatross *(Phoebastria albatrus),*and concurred that the fishery is not likely to adversely affect the marbled murrelet
(Brachyramphus marmoratus), California least tern (*Sterna antillarum browni),* southern sea otter *(Enhydra lutris nereis),* and the federally threatened bull trout *(Salvelinus confluentus)* and its designated critical habitat. The USFWS anticipates a yearly average of one short-tailed albatross could be taken as a result of the fishery. The incidental take is expected to be in the form of short-tailed albatross killed from longline hooks or trawl cables.

The most recent Biological Opinion covering the incidental take of ESA-listed salmon in groundfish fisheries was published in 2006 (NMFS 2006c). That document includes a detailed history of section 7 consultations on the groundfish fishery.

Salmon are caught incidentally in both the at-sea and shore-based segments of the whiting fishery and bottom trawl. This bycatch is closely monitored through an at-sea observer program and dockside sorting of shore deliveries. A salmon bycatch reduction plan has also been implemented in this fishery. NMFS issued a Supplemental Biological Opinion on March 11, 2006 concluding that neither the higher observed bycatch of Chinook in the 2005 whiting fishery nor new data regarding salmon bycatch in the groundfish bottom trawl fishery required a reconsideration of its prior "no jeopardy" conclusion. NMFS also reaffirmed its prior determination that implementation of the Groundfish PCGFMP is not likely to jeopardize the continued existence of any of the affected ESUs. The 1999 biological opinion concluded that the bycatch of salmonids in the Pacific whiting fishery were almost entirely Chinook salmon, with little or no bycatch of coho, chum, sockeye, and steelhead.

NMFS will continue to monitor and collect data to analyze take levels for all protected species.

1.6 Environmental Review Process and Public Scoping

The purpose of the environmental review process is to determine the range of issues that the NEPA document needs to address. The environmental review process is intended to ensure that problems are identified early and properly reviewed; issues of little significance do not consume time and effort; and that the draft NEPA document is thorough and balanced. The environmental review process should: identify the public and agency concerns; clearly define the environmental issues and alternatives to be examined in the NEPA document; eliminate non-significant issues; identify related issues; and identify state and local agency requirements that must be addressed. The following public review and scoping presented in this document is in reference to the development of an EM program for the Shoreside IFQ program.

In 2011, NMFS implemented a Council developed catch share program for the West Coast limited entry groundfish trawl fishery. The program requires that each vessel acquire quota pounds (QP) to cover its catch (including discards) of nearly all groundfish species.[2] Proper functioning of the program requires some form of at-sea monitoring to ensure that discards are enumerated for each vessel. The catch share program specified that this monitoring function be achieved through 100% at-sea observer coverage. Electronic monitoring (EM) is being explored as a potential technically and economically viable substitute for the use of human observers in the function of compliance monitoring for the catch share program.

At the November 2012 Council meeting, the Council directed that an EM workshop be held. The workshop was held February, 2013. The purpose of the workshop was to begin developing the policy context and identify necessary elements for a thorough Magnuson-Stevens Act (MSA) process to use EM in the West Coast groundfish trawl catch share program.

The Council decided at the April, 2013 Council meeting to move forward with consideration of the possible use of EM for the trawl catch share program. At that time, the Council decided that

2 Exceptions were made for some species rarely caught in the trawl groundfish fishery.

the primary focus of integrating EM into the trawl catch share program would be to achieve the compliance monitoring required for individual accountability of catch and bycatch, as opposed to using EM to meet needs for biological data or other scientific information monitoring. A set of regulatory objectives and calendar from the February EM workshop report were adopted. Also, at the April meeting a set of recommendations on the 2013 EM field study was approved for forwarding to Pacific States Marine Fisheries Commission. A similar field study was conducted in 2012. Both studies focus on comparison of video and observer data.

At the June 2013 Council meeting, the Council established two EM committees to focus on the development of options for EM use in the trawl catch share program. In August 2013 both the Groundfish Electronic Monitoring (GEM) Policy Advisory Committee (GEMPAC) and the GEM Technical Advisory Committee met to further the Council scoping process. The GEMPAC report for their August meeting provides a draft set of EM program alternatives for Council consideration and were presented at the September 2013 Council meeting. The Council provided guidance to the GEMPAC for continued development of EM program alternatives.

The GEM Committees met again in October, 2013 to discuss the guidance provided by the Council. The GEMPAC refined the draft alternatives and developed a GEMPAC report with recommendations for Council consideration at their November, 2013 meeting. The Council decided to revise the alternatives with the modifications recommended in the Enforcement Consultants report and to move forward with an impact analysis of the draft alternatives. The Council is scheduled to hear an update on the analysis in April, 2014 and in June will review the full analysis to pick preliminary preferred alternatives. The Council is scheduled to pick its final preferred alternatives for an EM program at its September 2014, meeting with the expectation of implementing an EM program by January 2016.

Trawl Catch Share Program Electronic Monitoring (EM) Workshop Report
The Pacific Fishery Management Council held a workshop on the potential use of electronic monitoring (EM) in the trawl fishery catch share program, February 25-27, 2013. The full report is available at: http://www.pcouncil.org/wp-content/uploads/D7b_EM_WKSHOP_RPT_APR2013BB.pdf)

During the EM workshop there was a discussion of the potential regulatory requirements for an EM system and the need for regulatory flexibility, both with respect to technologies employed and processes. The needed flexibility would allow private industry to develop efficient and effective monitoring system and to continue to innovate as new technologies become available over time. It was suggested that rather than being prescriptive, regulations should specify performance standards which must be met. This recommendation is in line with Executive Order 12899, which requires that each agency "identify and assess alternative forms of regulation and shall, to the extent feasible, specify performance objectives, rather than specifying the behavior or manner of compliance that regulated entities must adopt."

1.6.1 Trawl Catch Share Program Electronic Monitoring (EM) Workshop Report

The Pacific Fishery Management Council held a workshop on the potential use of electronic monitoring (EM) in the trawl fishery catch share program, February 25-27, 2013. The full report is available at: http://www.pcouncil.org/wp-content/uploads/D7b_EM_WKSHOP_RPT_APR2013BB.pdf)

During the EM workshop there was a discussion of the potential regulatory requirements for an EM system and the need for regulatory flexibility, both with respect to technologies employed and processes. The needed flexibility would allow private industry to develop efficient and effective monitoring system and to continue to innovate as new technologies become available over time. It was suggested that rather than being prescriptive, regulations should specify performance standards which must be met. This recommendation is in line with Executive Order 12899, which requires that each agency "identify and assess alternative forms of regulation and shall, to the extent feasible, specify performance objectives, rather than specifying the behavior or manner of compliance that regulated entities must adopt."

1.6.2 NMFS Policy Directive

On May 3, 2013, NMFS released its Policy on Electronic Technologies and Fishery Dependent Data Collection to " adoption of electronic technology solutions in fishery-dependent data collection programs" (NMFS, 2013). A complete copy of this policy has been posted on the EM page of the Council web site (http://www.pcouncil.org/groundfish/trawl-catch-share-program-em/). The objective for this policy is stated as follows:

> It is the policy of the National Oceanic & Atmospheric Administration's (NOAA's) National Marine Fisheries Service (NOAA Fisheries) to encourage the consideration of electronic technologies to complement and/or improve existing fishery-dependent data collection programs to achieve the most cost-effective and sustainable approach that ensures alignment of management goals, data needs, funding sources and regulations.

Appendix A contains NMFS policy directive, and the goals and objectives of the MSA, the trawl rationalization program, and the Pacific Coast Groundfish FMP.

1.6.3 Issues and Concerns Raised Through Scoping

In addition to the goals and objectives of the Pacific Coast Groundfish FMP and trawl rationalization program, several objectives were adopted by the Council at the June 2013 meeting during the public scoping process to develop an EM program for trawl catch share program compliance monitoring:

1. reduce total fleet monitoring costs to levels sustainable for the fleet and agency;
2. reduce observer costs for vessels that have a relatively lower total revenue;
3. maintain monitoring capabilities in small ports;
4. increase national net economic value generated by the fishery;

5. decrease incentives for fishing in unsafe conditions;
6. use the technology most suitable and cost effective for any particular function in the monitoring system; and
7. reduce the physical intrusiveness of the monitoring system by reducing observer presence; while,
8. maintaining current individual accountability for catch and preserving equitable distribution of monitoring coverage among members of the fleet,
9. supporting the collection of biological information necessary for managing the fishery, for stock assessments, and to meet other needs for scientific data, with no degradation relative to pre-trawl catch share program standards
10. taking into account agency budgets and abilities to support any new policy,
11. maintaining capabilities for ACL management (e.g. for non-quota species), and
12. following an implementation path most optimal for the fishery.

The first seven items in the above list are direct regulatory objectives, i.e. reasons for considering EM. Items eight through twelve in this list are considerations, i.e. the Council would not be undertaking this action in order to achieve items eight through twelve but rather in pursuing the first seven objectives will be bounded by items eight through twelve.

CHAPTER 2 **ALTERNATIVES**

2.1 Introduction

This chapter describes the alternative management actions that could be taken to establish an EM program.

Several approaches to monitoring participants for compliance in the shoreside IFQ program are defined and analyzed in this document. Components and options are listed in summary Table 2-1 and described in detail in this chapter. Table 2-1 provides the most current set of alternatives and options developed by the Council with revisions and additional options developed by the GEMPAC in May 2014. Preliminary preferred alternatives identified by some representatives of the GEMPAC are identified in the “Component” categories in the left-hand column.
In addition, fishery specific options are listed in Table 2-2 through Table 2-4.

Under the National Environmental Policy Act, a reasonable range of alternatives must be identified for a federal action, and includes the “no-action” alternative or status quo. The alternatives were developed to examine potential components and options for an EM program and are compared to the no-action alternative.

The EM program would need to account for discard events at sea, and provide sufficient information to identify fish species and enumerate the weight of fish discarded so that IFQ accounts and catch allocations can be debited. Under the proposed options for an EM program, vessels would need to apply for an exemption to use EM rather than a human observer and qualify for the exemption. It’s expected that participants would need to secure an EM provider, purchase or lease an approved EM system, and incur the cost for its maintenance and the video review. This information is analyzed in Section 4.3, under subsections on costs and impacts to different segments of the fishery and communities. Even if an exemption from required observer coverage is provided by NMFS for vessels that choose to use EM, observers would still need to be randomly deployed to collect scientific information such as biological data, bycatch estimates, and protected species interactions.

An EM program could be developed that is specific to each fishery that operates in the Shorebased IFQ program. Currently these fisheries are identified as shoreside and at-sea midwater trawl fishery (catcher vessels only and does not include at-sea motherships or catcher/processors), mid-water non-whiting trawl fishery, fixed gear fishery (includes longline with hook-and-lines and longline with pots), and bottom trawl.

Two major decision points must be made prior to selecting each component of an EM program: 1) what is the data source for the discard information - logbooks or video; and 2) which species may be discarded that would preserve the integrity of individual accounting in the IFQ system.

The choice may vary based on fishery, vessel operations, and the ability to accurately account for catch.

For example, it may be optimal to require the midwater trawl whiting fishery to continue fishing under a maximize retention regulatory environment, use logbooks as documentation for discards, then review a fixed percentage of the video to verify the discard documented in the logbooks (i.e., maximized retention with self-reporting and audit). For fixed gear (i.e., longline and pot), it may be optimal to allow discard of certain species because each fish is handled by the crew and video cameras could be used to document the species, length, and weight before it is discarded. Then, a review of all video images could be conducted to enumerate discards (i.e., optimized retention with video census). For bottom trawl, discard may be limited to certain species that can be identified on video, then audit the logbooks to verify events recorded in the logbooks are accurate and complete (i.e., optimized retention with self-reporting and audit). These potential combinations are described in more detail in Section 4.3, under subsections on costs and impacts to different segments of the fishery and communities.

Table 2-1. Summary of EM program components and alternatives with options for all fisheries. NOTE: Section references in the table coincide with descriptions following the table. Key: Yellow highlights are new components with new options; Red, bold italicized text are original components with some new text or options.

		DETAILED COMPONENTS FOR All FISHERIES		
		1	2	3
Section Reference	Component	**Status Quo: Human Observers Estimate Discard**	**Camera Recordings Used to Estimate Discard**	**Logbooks Used to Estimate Discard, with Camera Audits**
2.2	**Compliance Monitoring Basic Provisions**			
2.2.1	Discard Documentation Technology	Observers	***Individual*** vessel Option to Use Cameras ***in lieu of human observer***	
2.2.1	Documentation Coverage	100%	100% of all IFQ trips must either have observer or cameras	
2.2.2	Video Reading Protocols	None	**Option A**: 100% (census). **Option B**: Subsample Video (% to review must be developed) GEMPAC recommended preliminary Preferred Alts: MDWT whiting representatives like Alternative 3, audit logbook at 10% review level but would like to see analysis for Alternative 2, Option B before final recommendation.	Audit logbook (intensity varies based on vessel's compliance history) GEMPAC recommended preliminary Preferred Alts: Fixed gear representatives like Alternative 3, logbook audit.

2.3	Discard Accounting - Individual or Fleet-wide	Observers/IFQ	**Accounting of discards are either accounted against IFQ, accounted against sector-wide, annual catch limit (ACL), or not accounted. Estimation of discard may be done through EM, WCGOP observer program, or not estimated.** **Option A**: One discard category and all discards are estimated using EM and counted against IFQ: • Dumped off deck (e.g., shoveled, picked out of net) • Dumped/washed out of net for safety reasons (bleeding, pull zipper, etc.). • Dropped off gear • Floating fish • Lost gear (not captured by EM ,estimate using WCGOP protocol) • Consumed/used as bait (not captured by EM) • Unobserved sets/hauls (not captured by EM, maybe apply discard rate using EM estimates from previous sets/hauls) **Option B**: Split into two discard categories; Category 1 count against IFQ, Category 2 count against sector or ACL; for some discard the estimate is based on trips with observer coverage: Discard 1 IFQ Accounting: • Dumped off deck (e.g., shoveled, picked out of net) • Dumped/washed out of net for safety reasons (bleeding, pull zipper, etc.). • Unobserved sets/hauls (not captured by EM, apply discard rate using WCGOP Discard 2 Sector or ACL accounting: • Dropped off gear (use WCGOP estimates) • Floating fish (use WCGOP estimates) • Estimated from lost gear (estimate using WCGOP protocol) • Consumed/used as bait (not captured by EM, use WCGOP estimates) **Option C:** Split into two discard categories; Category 1 count against IFQ, no accounting for discard 2 category: Discard 1 IFQ Accounting: • Dumped off deck (e.g., shoveled, picked out of net) • Dumped/washed out of net for safety reasons (bleeding, pull zipper, etc.). • Unobserved sets/hauls (not captured by EM, apply discard rate using WCGOP Discard 2 No accounting: • Dropped off gear • Floating fish • Lost gear • Consumed/used as bait

Table 2-1. Summary of EM program components and alternatives with options for all fisheries. NOTE: Section references in the table coincide with descriptions following the table. Key: Yellow highlights are new components with new options; Red, bold italicized text are original components with some new text or options.

		DETAILED COMPONENTS FOR All FISHERIES		
		1	2	3
Section Reference	Component	**Status Quo: Human Observers Estimate Discard**	**Camera Recordings Used to Estimate Discard**	**Logbooks Used to Estimate Discard, with Camera Audits**
			Council staff note: In order for option 3 to be valid it would have to comply with MSA national standards. All catch and discard must be accounted to estimate total mortality estimates and ensure annual catch limits are not exceeded.	
2.4	Definitions for Total Catch Accounting - Total Catch, Discard, Retained	Use WCGOP definitions	**NOTE: Under the IFQ and catch allocation system all catch must be accounted for to debit individual QS accounts and fishery allocations, regardless if it categorized as retained catch or discard.** **Total catch for trawl:** Total catch is defined as the sum, or estimated weight, of all organic and inorganic material caught by the gear, to include any organic or inorganic material confined within a trawl net as the net is being landed, lost gear, as well as any visually discernible catch lost during the retrieval process that can be reasonably attributed to the vessel. **Total catch for fixed gear:** Total catch is defined as the sum, or estimated weight, of all organic and inorganic material caught by the gear to include any fish hooked or in a pot as the gear is being landed, lost gear, as well as any visually discernible catch lost during the retrieval process that can be reasonably attributed to the vessel. **Discard for fixed and trawl gear:** Discard is any portion of the total catch that is not delivered to a buyer. Fish caught for bait or onboard consumption are considered discard. For gear that is lost, or sets and hauls that are unobserved, discard rates will be applied based on similar sets and hauls. **Retained catch for fixed gear and trawl:** Retained catch is any portion of the total catch that is delivered to a buyer or processor.	

2.5	Discard Requirements	Discard at will unless required to retain. • May discard any species unless regulations require you to retain them. • May discard catch share species, non-catch share species. • May discard non-groundfish • Allow discard of trash, mud coral, etc. • Require discards of prohibited species. • Require discards of ESA and MMPA species (protected species).	**Option A**: **Maximized Retention** - A vessel is generally required to retain all catch share species, non-catch share groundfish species, non-groundfish species (Non-FMP and not prohibited species) • No selective discard for catch share species, non-catch share groundfish species • No selective discard for non-groundfish species • Allow selective discard of trash, mud coral, etc. • Require selective discards of prohibited species (except whiting trips); • Require selective discards of ESA and MMPA species (i.e., protected species). • Non-selective discard for e.g., safety, "bleeding net", zipper accidentally opened, fish came off hook, gilled in net **Option B**: **Optimize Retention of Catch Share Species with Limited discards** - A vessel is generally required to retain all catch share species. • Allow selective discard of trash, mud coral, etc. • Require selective discards of prohibited species (except whiting trips); • Require selective discards of ESA and MMPA species (i.e., protected species). • Non-selective discard for e.g., safety, "bleeding net", zipper accidentally opened, fish came off hook, gilled in net **Potential Gear Specific Sub-options under Optimized Retention (must be verifiable under EM)**: Allowable Discards Midwater trawl non-whiting trips, bottomtrawl, and fixed gear trips may discard the following species if verifiable under the EM program: a) For catch share species Option a – Allow discard of flatfish Option b – Allow discard of lingcod and sablefish Option c – Allow discard of all non-rockfish groundfish (full retention of rockfish only) Option d – Allow discard if species that are verifiable with EM b) For non-catch share groundfish species Option c – Allow discard of all non-rockfish groundfish (full retention of rockfish only) Option d – Allow discard if species that are verifiable with EM c) For non-groundfish (Non-FMP and not prohibited species) Option e – Allow discard of all non-groundfish species Option d – Allow discard if species that are verifiable with EM **Option C** - **Discard At Will** (Status Quo) • May discard any species unless regulations require you to retain them • May discard catch share species, non-catch share species • May discard non-groundfish • Allow selective discard of trash, mud coral, etc. • Require selective discards of prohibited species (except whiting trips); • Require discards of ESA and MMPA species (i.e., protected species). **GEMPAC recommended preliminary Preferred Alts:** • Fixed gear and bottom trawl representatives prefer Optimized retention (option B) • Midwater trawl whiting representatives prefer Maximize retention (Option A)

Table 2-1. Summary of EM program components and alternatives with options for all fisheries. NOTE: Section references in the table coincide with descriptions following the table. Key: Yellow highlights are new components with new options; Red, bold italicized text are original components with some new text or options.

		DETAILED COMPONENTS FOR All FISHERIES		
		1	2	3
Section Reference	Component	**Status Quo: Human Observers Estimate Discard**	**Camera Recordings Used to Estimate Discard**	**Logbooks Used to Estimate Discard, with Camera Audits**
2.6	Halibut Retention/Discard with Fishery Specific Options	Use WCGOP and IPHC protocols	**Option A**: Apply IPHC mortality rate for specific gear type: MDWT Whiting 100% mortality; MDWT non-whiting and BTW 90% mortality if discarded; Fixed gear longline 16% mortality if discarded; Fixed gear pot 18% mortality if discarded. **Option B**: WCGOP scientific observations (assumed 20-30% coverage) is applied to fleet **Option C**: IPHC exemption to allow full retention (need to examine the feasibility of this option for fisheries other than MDWT whiting) **Option D**: Captain and crew provide assessment (training would be required) **Option E**: Use EM viability assessment (currently conducting study, need IPHC approval) **Option F**: Use vessel specific mortality rate (update rates periodically)	
2.7	Discard Species List Adjustments	None	**Options for a process to expand or change the species lists:** **Option 1**: NMFS to make determination and provide list to fishers through the NMFS EM Observer Exemption Process. **Option 2**: Use Council process for changing species list using routine management measures if initial list is fully analyzed for environmental impacts (e.g., use groundfish specification process, or some other routine management measure). **Option 3**: Set initial lists in regulation and change at some future point through Council process with proposed/final rule making.	
2.8	**Vessel Operation Provisions**			
2.8.1	Observer Exemption Process	None	NMFS to Develop Application and Approval Process	

Table 2-1. Summary of EM program components and alternatives with options for all fisheries. NOTE: Section references in the table coincide with descriptions following the table. <tr><td>2.8.2</td><td>Eligibility For Camera Use</td><td>N/A</td><td colspan="2">Vessel in good standing and has approved equipment and operational plan certifications.

<u>Initial eligibility criteria</u>:
1. Limited entry groundfish trawl permit
2. Quota share permit
3. No IFQ deficits
4. No civil penalties related to fishing activity exceeding a certain amount and timeframe
5. Schematic and Description of NMFS approved Individual Vessel Monitoring Plan (IVMP)
a. IVMP unique for each vessel
b. Multiple IVMPs included if submitted by group of vessels
6. Self-Governing Plan (if applicable, not required)
a. Data Delivery and Analysis (DDA) specifications
b. submitted by either a group of vessels or an individual vessel

<u>Continued eligibility</u>:
1. Participants must be in compliance with their IVMP
2. Demonstrate proper documentation of the discards in logbooks or on video
3. No civil penalties related to fishing activity exceeding a certain amount within the time period of EM use</td></tr>
</table>

2.8.3	Application Approval and Required Information	N/A	Requires application to NMFS to use EM, could include: 1. Operational Informational information. a. Installation by certified EMS Provider b. EMS service provider responsibilities c. Data Confidentiality Standards d. Data Storage and Delivery Standards e. EMS Coverage Requirements f. Monitoring Requirements g. Vessel Responsibilities 2. Data Sources a. Digital Camera(s) b. Winch Sensors c. Hydraulic Sensors d. Log Book e. VMS f. GPS 3. EM Data Standards a. Secure Watertight Control Box Data Storage b. Encrypted Data c. Storage Standards d. Date and Time Stamp and Counter e. Digital File Format f. Minimum Frame Rate g. Minimum Resolution h. Accepted Delivery Methods i. Time Frames j. Color Optics k. Lighting Standards l. Power Supply Standards

Table 2-1. Summary of EM program components and alternatives with options for all fisheries. NOTE: Section references in the table coincide with descriptions following the table. Key: Yellow highlights are new components with new options; Red, bold italicized text are original components with some new text or options.

2.9.4	Video and Data Processing and Analysis	N/A	Video reviewers (not mutually exclusive): **Option A** -NMFS **Option B** -PSMFC **Option C** - EM Provider ***Option D - Third Party***	
2.10	**WCGOP Scientific Observations**			
2.10.1	Payment for Scientific data collection/observations	Status quo however in near future industry will need to pay for all observer costs	**Option A**: Government funded, same as pre IFQ **Option B**: Industry Funded **Option C**: Combination of both Government and Industry [Need to discuss allocating costs] **GEMPAC Recommended Preliminary Preferred Alts**: Most industry representatives would like Option A	
2.11	**NMFS Processes**	N/A	Identify items for NMFS to work out and then conduct a formal deeming process with the Council (i.e., Observer Exemption Application, Application and Approval Process, EM Equipment Type-Approval, IVMP Review)	
2.12	**Spatial Variation for High Bycatch Areas**	Status quo for current are restrictions (e.g., Rockfish Conservation Areas)	**Option A** - No special provisions ~~**Option B** - fishing activity in areas that are likely to have lower bycatch could be monitored with EM rather than using observers; no EM in high bycatch areas~~ ~~**Option C** - Under this option, if you chose to fish in a high bycatch area, a higher level of EM review may be required~~	

Table 2-1. Summary of EM program components and alternatives with options for all fisheries. NOTE: Section references in the table coincide with descriptions following the table. Key: Yellow highlights are new components with new options; Red, bold italicized text are original components with some new text or options.

		DETAILED COMPONENTS FOR All FISHERIES		
		1	2	3
Section Reference	Component	**Status Quo: Human Observers Estimate Discard**	**Camera Recordings Used to Estimate Discard**	**Logbooks Used to Estimate Discard, with Camera Audits**
2.13	**Adaptive or Phased Implementation**	N/A	**Option A**. None, implement all fisheries at one time through regulatory implementation **Option B**. Use EFPs to test final Council policy, prior to full regulatory implementation. **Option C**. Phase in by sector/gear. **Option D**. Phase in retention options over time. **Options B-D are not mutually exclusive.**	

Fishery Specific Alternatives and Options

Several components in Table 2-1 are applicable to all fisheries and do not have options; therefore they are not presented in the fishery specific Tables 2-2 through 2-4. Fishery specific decision Tables 2-2 through 2-4 provide the alternatives and options that are germane to each fishery. Only components of the EM program that contain options are provide in the tables. These are the decision points for the Council for each fishery.

Table 2-2. Decision table for alternatives and options specific to midwater trawl whiting. NOTE: Section references in the table coincide with section descriptions in document.

		MIDWATER TRAWL WHITING ALTERNATIVES		
Section Reference	Component	1 **Status Quo: Human Observers Estimate Discard**	2 **Camera Recordings Used to Estimate Discard**	3 **Logbooks Used to Estimate Discard, with Camera Audits**
2.2.2	Video Reading Protocols	None	**Option A**: 100% (census). **Option B**: Subsample Video (must develop) GEMPAC recommended preliminary Preferred Alts: MDWT whiting representatives like Alternative 3, audit logbook at 10% review level but would like to see analysis for Alternative 2, Option B.	Audit logbook (intensity varies based on vessel's compliance history) GEMPAC recommended preliminary Preferred Alts: Fixed gear representatives like Alternative 3, logbook audit.
2.3	Discard Accounting - Individual or Fleet-wide	Observers/IFQ	**Accounting of discards are either accounted against IFQ, accounted against sector-wide, annual catch limit (ACL), or not accounted. Estimation of discard may be done through EM, WCGOP observer program, or not estimated.** (See Table 2-1, Section 2.3 for option details) **Option A**: One discard category and all discards are estimated using EM and counted against IFQ. **Option B:** Split into two discard categories; Category 1 count against IFQ, Category 2 count against sector or ACL; for some discard the estimate is based on trips with observer coverage: **Option C**: Split into two discard categories; Category 1 count against IFQ, no accounting for discard 2 category. **Council staff note: In order for option 3 to be valid it would have to comply with MSA national standards. All catch and discard must be accounted to estimate total mortality estimates and ensure annual catch limits are not exceeded.**	

Table 2-2. Decision table for alternatives and options specific to midwater trawl whiting. NOTE: Section references in the table coincide with section descriptions in document.

		MIDWATER TRAWL WHITING ALTERNATIVES		
Section Reference	Component	1 **Status Quo: Human Observers Estimate Discard**	2 **Camera Recordings Used to Estimate Discard**	3 **Logbooks Used to Estimate Discard, with Camera Audits**
2.4	Definitions for Total Catch Accounting - Total Catch, Discard, Retained	Use WCGOP definitions	**NOTE: Under the IFQ and catch allocation system all catch must be accounted for to debit individual QS accounts and fishery allocations, regardless if it categorized as retained catch or discard.** **Total catch for trawl:** Total catch is defined as the sum, or estimated weight, of all organic and inorganic material caught by the gear, to include any organic or inorganic material confined within a trawl net as the net is being landed, lost gear, as well as any visually discernible catch lost during the retrieval process that can be reasonably attributed to the vessel. **Discard for fixed and trawl gear:** Discard is any portion of the total catch that is not delivered to a buyer. Fish caught for bait or onboard consumption are considered discard. For gear that is lost, or sets and hauls that are unobserved, discard rates will be applied based on similar sets and hauls. **Retained catch for fixed gear and trawl:** Retained catch is any portion of the total catch that is delivered to a buyer or processor.	
2.5	Discard Requirements	Maximized Retention	**Option A**: **Maximized Retention** - A vessel is generally required to retain all catch share species, non-catch share groundfish species, non-groundfish species (Non-FMP and not prohibited species). Sorting whiting at-sea requires discard of prohibited and protected species however this is generally not practiced. **GEMPAC Recommended Preliminary Preferred Alts:** • Midwater trawl whiting representatives prefer Maximize retention (Option A)	
2.6	Halibut Retention/Discard	Observers/100% mortality	**Option A**: Apply mortality rate for specific gear type: MDWT Whiting 100% mortality	

Table 2-2. Decision table for alternatives and options specific to midwater trawl whiting. NOTE: Section references in the table coincide with section descriptions in document.

Section Reference	Component	MIDWATER TRAWL WHITING ALTERNATIVES 1 **Status Quo: Human Observers Estimate Discard**	2 **Camera Recordings Used to Estimate Discard**	3 **Logbooks Used to Estimate Discard, with Camera Audits**
2.7	Discard Species List Adjustments	Use current regulatory requirements for discard	**Options for a process to expand or change the species lists:** **Option A:** NMFS to make determination and provide list to fishers through the NMFS EM Observer Exemption Process. **Option B:** Use Council process for changing species list using routine management measures if initial list is fully analyzed for environmental impacts (e.g., use groundfish specification process, or some other routine management measure). **Option C:** Set initial lists in regulation and change at some future point through Council process with proposed/final rule making.	
2.8.5	EM Vessel Operational Plan - IVMP Expiration	No plan required	**Option A –** No Expiration unless modifications are made **Option B –** Annual Expiration or if modifications are made **Option C** - Indefinite (example 2 or 3 year duration)	
2.8.6	Declaration of EM Use	No declaration except for VMS requirments	**Option A** - Annual Declaration Use EM all year **Option B** - Declaration for Intermittent Use For the coming year, participants must indicate in which months, if any, it will use EM and in which months, if any, it will use an observer. (e.g. quarterly) **Option C** -Trip by Trip Basis Vessel and the observer provider would need to work out when observers may be available on a per trip basis. **Exception for Emergency Situation for Option A and B** For example, camera broke so need an observer tomorrow, vice versa

2.10.1	Payment for Scientific data collection/observations	Status quo however in near future industry will need to pay for all observer costs	**Option A: Government funded, same as pre IFQ** **Option B: Industry Funded** **Option C: Combination of both Government and Industry [Need to discuss allocating costs]** **GEMPAC Recommended Preliminary Preferred Alts:** Most industry representatives would like Option A	
2.12	**Spatial Variation for High Bycatch Areas**	Status quo for current are restrictions (e.g., Rockfish Conservation Areas)	**Option A** - No special provisions **Option B** - fishing activity in areas that are likely to have lower bycatch could be monitored with EM rather than using observers; no EM in high bycatch areas **Option C** - Under this option, if you chose to fish in a high bycatch area, a higher level of EM review may be required	
2.13	**Adaptive or Phased Implementation**	N/A	**Option A**. None, implement all fisheries at one time through regulatory implementation **Option B**. Use EFPs to test final Council policy, prior to full regulatory implementation. **Option C**. Phase in by sector/gear. **Option D**. Phase in retention options over time. **Options B-D are not mutually exclusive.**	

2.2 Compliance Monitoring - Overview

All IFQ trips must be monitored in an adequate manner to provide the necessary data to debit QP accounts. In order to monitor the fisheries for compliance with the IFQ program, discard must either be monitored by a human observer or be captured on video for a video reviewer to verify the discard events.

2.2.1 Discard Documentation Technology and Documentation Coverage

Currently, all discard on IFQ trips must be monitored by a human observer in order to monitor the fisheries for compliance with the IFQ program. Observers participating in the IFQ program are referred to as IFQ program observers and are employed by private third-party companies. Vessels make arrangements with the third-party observer provider to secure an observer for a trip and pay the provider directly. The Northwest Fisheries Science Center trains, certifies, and equips IFQ program observers; ensures data quality; and stores, maintains, and analyzes data collected by observers. Under all alternatives, vessels would continue to have the option to use human observers for compliance monitoring and it’s expected that “third-party” observer providers would continue to provide this service to the vessels in the IFQ program.

Under the proposed action, discard must either be monitored by a human observer (Alternative1) or be captured on video for a video reviewer to verify the discard events. A voluntary EM program provides the industry an opportunity to choose either a human observer or EM to monitor their compliance with IFQs, IBQs, and catch allocations. Both catch and discard is debited from the QP or catch allocation. Catch that is landed would continue to be monitored shoreside with catch monitors that are employed as a “third-party” observer. At sea, discarded catch would be monitored by either a human observer or EM. The EM program would need to account for discard events and provide sufficient information to identify fish species and enumerate the weight of fish discarded so that QP accounts and catch allocations can be debited in a timely manner. Under these alternatives, and in support of the current requirement of the IFQ program, 100% observations of all IFQ trips must be observed through either EM or human observers.

2.2.2 Video Reading Protocols

A discard monitoring method that would adequately account for discard in each fishery is necessary and likely the most critical component of an EM program. The data source to accurately account for discard is either a human observer, logbook, or video data.

2.2.2.1 Alternative 1 - No Action

The No Action Alternative or status quo (Alternative 1) defines the default management structure if no Federal action was taken. Under Alternative 1, the current mandatory 100% human observer coverage would continue in order to monitor fishery participants for compliance with IFQs, IBQs, and allocated groundfish. Existing requirements and regulations to participate in the Shorebased IFQ program would be maintained. This information is described in subparts C through E of Part 50 of the Code of Federal Regulations (CFR). These subparts include, but are not limited to, requirements for a limited entry and QS permit, use of a vessel monitoring system (VMS), at sea observer requirements, human catch monitors at shoreside first receiver locations, and reporting requirements (i.e., logbook, fish ticket, economic data collection program, and prohibitions). Under Alternative 1, the cost for observer coverage in the near future will no longer be federally subsidized. It's expected that the industry will pay the full amount for compliance monitoring by human observers. The 2014 subsidy rate by the Federal government is 48% of the cost for an observer per day of fishing activity.

2.2.2.2 Alternative 2 - Camera Recordings Used to Estimate Discard

Under Alternative 2, the video images are the sole data source for estimating discards. The video is review for fish discarded by fishermen, the species are identified, assign an estimated weight, and the QS account is debited. Two options are identified under Alternative 2 to conduct the review and estimate the catch:

Option A: 100% (census)
Option B: Subsample Video

Option A is to conduct a census of all video images i.e., review all video segments and estimate the total discard for each set or haul that occurred in a trip. Option B is to subsample the video images at some predetermined percent of video review (e.g., 25%), speciate the discard, estimate the weight of the discard, then expand the discard rate to the entire set, haul, or trip to provide a total estimated discard for the trip.

2.2.2.3 Alternative 3 - Logbooks Use to Estimate Discard, with Camera Audits

Alternative 3 provides the opportunity for the fishermen to speciate and estimate the total discarded weight of the fish for each set or haul and provide this information in a logbook. Then, the video images would be reviewed to verify discard events and the species/weight estimates for the trip. The video images of documented discard events would be reviewed at some predetermined level (e.g., 25%) to verify the discard. In addition, all video segments would be subject to random review, at some predetermined level, (e.g., 10%) to look for undocumented discard events. This would ensure the vessel is in compliance with the EM program and documentation of all discard events.

2.3 Discard Accounting – Individual or Fleetwide

Under the catch shares program, total catch must be accounted for to debit individual quota share accounts and fishery allocations. Retained and discarded catch is combined to get total catch. Shoreside monitors are used to verify retained catch when it is landed on motherships or shoreside processors and the West Coast Groundfish Observer Program (WCGOP) uses at-sea monitors to estimate and report discards by species.

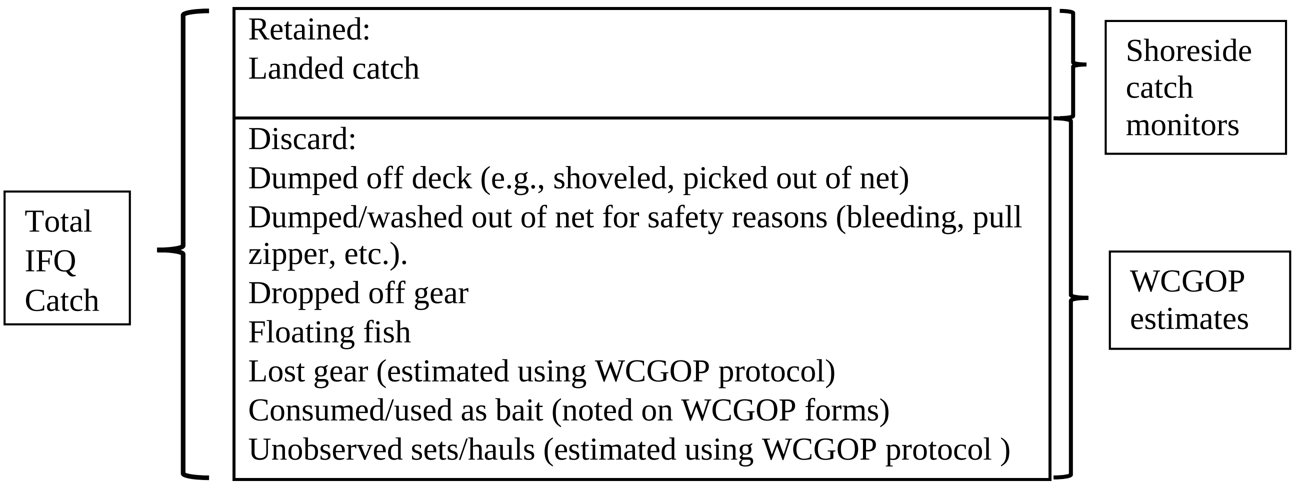

Figure 2-1. General depiction of total catch accounting in the Shorebased IFQ program.

Under an EM program, the estimation (speciation and weight) for these discard events would be conducted using EM rather than the WCGOP. However some of the discard events and scenarios noted in Figure 2-1 may not be captured by EM, such as lost gear, crew consuming fish onboard the vessel, using fish caught as bait, and unobserved hauls/sets that had discard (i.e., EM failed to record the discard), therefore; some other source of data may need to be used to account for the discard activity. In addition, some events may be capture by EM but are difficult to quantify or are rare, such as floating fish on the surface of the water or a fish dropped from the gear.

If these events cannot be estimated using EM, then they could be estimated either annually by the WCGOP or not at all. The discard could be estimated using historical observations by the WCGOP for the time period of 2010 to 2014 to get an average number per year or through the annual observations made by WCGOP that are on vessels that do not use EM in combination with vessels that are randomly selected to have a scientific observer while the vessel uses EM.

In addition, rather than accounting for this discard at the individual level (IFQ) it's possible to account for it during the specification process for Annual Catch Limits (ACL), at the sector level or not at all. Assuming that the total mortality estimated at the sector level from this activity is minor amounts and would not affect individual vessels quota share accounts or other fishery participants, the estimated mortality could be deducted from the ACL prior to allocation to each sector or at the sector level to be taken “off-the-top” prior to IFQ distribution and catch allocation distributions.

Potential changes were developed in the flowing way:
1) Discard events were grouped into discard categories 1 and 2;
2) Accountability was established (i.e., IFQ, Fleetwide, or not accounted);
3) Data source were identified as either EM or the WCGOP.

Three possible options were developed for discard accounting:

Option A: **Estimate Discard with EM and Count against IFQ**
One discard category and all discards are estimated using EM and counted against IFQ:
• Dumped off deck (e.g., shoveled, picked out of net)
• Dumped/washed out of net for safety reasons (bleeding, pull zipper, etc.).
• Dropped off gear
• Floating fish
• Lost gear (not captured by EM, estimate using WCGOP protocol)
• Consumed/used as bait (not captured by EM)
• Unobserved sets/hauls (not captured by EM, maybe apply discard rate using EM estimates from previous sets/hauls)

Option B: **Split into two discard categories; Category 1 count against IFQ, Category 2 count against sector or ACL; for some discard the estimate is based on trips with observer coverage**

Discard 1 IFQ Accounting:
• Dumped off deck (e.g., shoveled, picked out of net)
• Dumped/washed out of net for safety reasons (bleeding, pull zipper, etc.).
• Unobserved sets/hauls (not captured by EM, apply discard rate using WCGOP

Discard 2 Sector or ACL accounting:
• Dropped off gear (use WCGOP estimates)
• Floating fish (use WCGOP estimates)
• Estimated from lost gear (estimate using WCGOP protocol)
• Consumed/used as bait (not captured by EM, use WCGOP estimates)

Option C: Split into two discard categories; no accounting for discard 2 category:

Discard 1 IFQ Accounting:
• Dumped off deck (e.g., shoveled, picked out of net)
• Dumped/washed out of net for safety reasons (bleeding, pull zipper, etc.).
• Unobserved sets/hauls (not captured by EM, apply discard rate using WCGOP

Discard 2 No accounting:

• Dropped off gear
• Floating fish
• Lost gear
• Consumed/used as bait

Council staff note: In order for option 3 to be valid it would have to comply with MSA national standards. All catch and discard must be accounted to estimate total mortality estimates and ensure annual catch limits are not exceeded.

2.4 Definitions for Total Catch Accounting - Total Catch, Discard, Retained

For analysis purpose the GEMPAC has developed draft definitions for the total, retained, discarded catch under an EM program. WCGOP provided the GEMPAC draft definitions of total catch and discard that are specific to trawl and fixed gear. The GEMPAC consolidate the individual gear definitions for total catch and discard into the following draft definitions:

Total catch for trawl: Total catch is defined as the sum, or estimated weight, of all organic and inorganic material caught by the gear, to include any organic or inorganic material confined within a trawl net as the net is being landed, lost gear, as well as any visually discernible catch lost during the retrieval process that can be reasonably attributed to the vessel.

Total catch for fixed gear: Total catch is defined as the sum, or estimated weight, of all organic and inorganic material caught by the gear to include any fish hooked or in a pot as the gear is being landed, lost gear, as well as any visually discernible catch lost during the retrieval process that can be reasonably attributed to the vessel.

Retained catch for fixed gear and trawl: Retained catch is any portion of the total catch that is delivered to a buyer or processor.

Discard for fixed and trawl gear: Discard is any portion of the total catch that is not delivered to a buyer. Fish caught for bait or onboard consumption are considered discard. For gear that is lost or sets and hauls that are unobserved, discard rates will be applied based on similar sets and hauls.

2.5 Discard Requirements

Currently, under the trawl rationalization program each fishery may discard, or is required to discard, certain species. Under an EM program, discard events will be documented with video; however, it may be difficult to identify some species or differentiate between species on video. Therefore, each fishery is examined for potential discard options and retention requirements under an EM program (see Section 4.3.). For example, when longline fishing, video cameras may be able to capture each individual species as it is hauled above the surface of the water and boarded. However, it still may be difficult to see which species of fish incidentally fell off the hook or was discarded prior to being boarded. In addition, when retrieving a midwater trawl net, fish may "bleed" out of the net as it surfaces so it may be difficult to capture the weight and identification of species when they are unintentionally discarded as a mixed group.

Some statutory management measures such as the Endangered Species Act (ESA) or the Marine Mammal Protection Act (MMPA) may restrict the consideration of some retention rules. Currently, there is an exception for the midwater trawl fishery that targets whiting which allows retention of salmon and halibut if the fish are not sorted at sea. Therefore, exceptions are provided as part of the description of alternatives.

There are three Options identified that allow for discard (Table 2-1, Section 2.5) maximized retention (minimal discard allowed), B) optimized retention (some allowable discard of IFQ species), and C) discard at will (discard any species). The retention and discard requirements are described under each alternative. Exceptions for allowable discard are also described and includes the species groups that may potentially be discarded under each alternative. The discard species are grouped by catch share groundfish species, non-catch share groundfish species, non-groundfish species, prohibited species (halibut, salmon and Dungeness crab), and ESA/MMPA protected species (turtles, marine mammals, seabirds, etc.). Table 2-5, Table 2-6 and Table 2-7 contain species lists.

For analysis purpose the GEMPAC has developed draft definitions for the retention of species under an EM program. The draft definitions were developed based on existing descriptions for maximized and optimized retention options developed in previous GEMPAC reports and adopted by the Council in November 2013. Both definitions contain the same existing regulatory requirements and discard exceptions.

2.5.1 Option A: Maximize Retention

Definition: A vessel is generally required to retain all catch share species, non-catch share groundfish species, non-groundfish species (Non-FMP and not prohibited species).

- No selective discard for catch share species, non-catch share groundfish species
- No selective discard for non-groundfish species
- Allow selective discard of trash, mud coral, etc.
- Require selective discards of prohibited species (except whiting trips);
- Require selective discards of ESA and MMPA species (i.e., protected species).
- Non-selective discard for e.g., safety, "bleeding net", zipper accidentally opened, fish came off hook, gilled in net

The following regulatory requirements or discard exceptions apply:

Existing Regulatory Requirements
Vessels must discard prohibited, ESA-listed, and marine mammal species unless otherwise allowed to retain them by regulation or under federal exemption for scientific purposes. The following regulatory requirements apply:

- Mid-water trawl IFQ trips for whiting that deliver to shoreside processors must retain prohibited species (halibut, salmon, and Dungeness crab) unless sorting at sea.
- Mid-water trawl catcher vessels delivering to motherships must retain prohibited species

(halibut, salmon, and Dungeness crab).

- Midwater trawl whiting trips that are unsorted may discard minor amounts of catch not delivered to shoreside or mothership processors. (current regulation**: "**Maximized retention vessels participating in the Pacific whiting IFQ fishery may discard minor operational amounts of catch at sea if the observer has accounted for the discard (i.e., a maximized retention fishery).")
- For LE fixed gear 22 or 24 inch lingcod must be discarded or if the vessel exceeds their non-IFQ trip limit; i.e Regulatory discards. (The minimum size limit for lingcod is 22 inches (56 cm) total length North of 42^{o} N. lat. and 24 inches (61 cm) total length South of 42^{o} N. lat.) **This information would need to be verifiable under an EM system.**

Discard exceptions when fishing under maximized retention - All discards must be enumerated and reported

- The vessel may discard for safety reasons.
- The trawl net is ripped or zipper accidentally opened, or fish fell off hook.
- Fish washed out of the trawl net or is overflowing.
- Vessels may discard mud, sponges, coral, inverts, and inorganic material not generally retained for sale or use.

2.5.2 Option B: Optimize Retention Retain Catch Share Species with Limited Discard Options

The GEMPAC discussed fishery specific discard options under an optimized retention regulatory environment. The definition for optimized retention contains some fishery specific discard options, however it is difficult for the GEMPAC to select which species are appropriate for allowable discard since species identification issues while using EM limit the options. PSMFC has begun to identify species that may be identifiable for discard and further analysis of these options will need be conducted to assist the Council in choosing an initial species list that is specific to each fishery.

Definition: A vessel is generally required to retain all catch share species but may be allowed fishery specific selective discard options of some catch share, non-catch share, and groundfish species if verifiable with EM.

The following regulatory requirements and discard exceptions:

*Existing Regulatory Requirements (**Same as Maximized Retention**)*
Vessels must discard prohibited, ESA-listed, and marine mammal species unless otherwise allowed by regulation or under federal exemption for scientific purposes. The following regulatory requirements apply:

- Mid-water trawl IFQ trips for whiting that deliver to shoreside processors must retain prohibited species (halibut, salmon, and Dungeness crab) unless sorting at sea.
- Mid-water trawl catcher vessels delivering to motherships must retain prohibited species (halibut, salmon, and Dungeness crab).
- Midwater trawl whiting trips that are unsorted may discard minor amounts (**define?**) of

catch not delivered to shoreside processors.

- For LE fixed gear 22 or 24 inch lingcod must be discarded or if the vessel exceeds their non-IFQ trip limit; i.e Regulatory discards. (The minimum size limit for lingcod is 22 inches (56 cm) total length North of 42° N. lat. and 24 inches (61 cm) total length South of 42° N. lat.) T**his information would need to be verifiable under an EM system.**

*Discard exceptions when fishing under maximized retention - All discards must be enumerated and reported (**Same as Maximized Retention**)*

- The vessel may discard for safety reasons (**define?**)
- The trawl net is ripped or zipper accidentally opened, or fish fell off hook.
- Fish washed out of the trawl net or is overflowing
- Vessels may discard mud, sponges, coral, inverts, and inorganic material not generally retained for sale or use.

***Potential Gear Specific Sub-options under Optimized Retention**:*
This information would need to be verifiable under an EM system. Options here are not mutually exclusive; however, there must be adequate images for species identification and weight estimates of catch share species discards.

Midwater trawl non-whiting trips, bottomtrawl, and fixed gear trips may discard the following species if verifiable under the EM program and approved by NMFS:

a) For catch share species
   Option a – Allow discard of flatfish
   Option b – Allow discard of lingcod and sablefish
   Option c – Allow discard of all non-rockfish groundfish (full retention of rockfish only)
   Option d – Allow discard if species that are verifiable with EM

b) For non-catch share groundfish species
   Option c – Allow discard of all non-rockfish groundfish (full retention of rockfish only)
   Option d – Allow discard if species that are verifiable with EM

c) For non-groundfish (Non-FMP and not prohibited species)
   Option e – Allow discard of all non-groundfish species
   Option d – Allow discard if species that are verifiable with EM

2.5.3 Option C: Discard At Will (Status Quo)

Vessels would be allowed to fish in the same manner as they currently do and may discard any species or be required to retain species according to current regulations.

- May discard any species unless regulations require you to retain them
- May discard catch share species, non-catch share species
- May discard non-groundfish
- Allow selective discard of trash, mud coral, etc.
- Require selective discards of prohibited species (except whiting trips);
- Require discards of ESA and MMPA species (i.e., protected species).

Table 2-5. IFQ program and Non-IFQ groundfish species groups that are noted in section 2.5 as potential discards. Source regulations are noted in each list.

Catch share species (IFQ program groundfish species, From: 660.140(c)(1))	**Non-catch share species** **(Non-IFQ Groundfish Species From: Table 1 and 2 to Part 660, Subpart D -- Limited Entry Trawl Rockfish Conservation Areas and Landing Allowances for non-IFQ Species and Pacific Whiting North and South of 40°10' N. Lat.)**
ROUNDFISH	Minor nearshore rockfish & Black rockfish

Table 2-7. ESA-listed species that may be found in the area of operation for groundfish fisheries.

ESA Species	
Green sturgeon *(Acipenser medirostris)*	Southern Resident killer whales *(Orcinus orca)*
Eulachon *(Thaleichthys pacificus)*	Guadalupe fur seals *(Arctocephalus townsendi)*
Humpback whales (*Megaptera novaeangliae*)	Green sea turtles *(Chelonia mydas)*
Steller sea lions *(Eumetopiasjubatus)*	Olive ridley sea turtles *(Lepidochelys olivacea)*
Leatherback sea turtles (*Dermochelys coriacea*)	Loggerhead sea turtles (Carretta carretta)
Sei whales *(Balaenoptera borealis)*	Short-tailed albatross *(Phoebastria albatnfs)*

North Pacific Right whales *(Eubalaenajaponica)* Blue whales *(Balaenoptera musculus)* Fin whales *(Balaenoptera physalus)* Sperm whales *(Physter macrocephalus)*	Marbled murrelet *(Brachyramphus marmoratus)* Southern sea otter *(Enhydra lutris nereis)* California least tern (*Sterna antil/arum browni*)

2.6 Halibut Retention/Discard with Fishery Specific Options

Pacific Halibut Data Collection in the Shore-delivery IFQ Fishery
The WCGOP designed sampling methodologies that help ensure P. halibut mortality can be estimated, regardless of the limitations imposed by the vessel, catch composition, or catch quantity. Three pieces of information are necessary to estimate Pacific halibut mortality (also see Table 2-1, Section 2.6):
1. A count of individual P. halibut in the haul or sample
2. Actual or visual length measurements (cm)
3. A viability obtained by physical assessment of individual P. halibut using IPHC designed dichotomous keys that relate the physical condition of the fish to a viability code (NWFSC 2013). A unique key is used for each gear type (trawl, longline, pot).

Observers could sample all or a subset of P. halibut caught in a haul/set. The proportion of P. halibut sampled is based on the number of P. halibut caught in the haul/set, the level of assistance provided by the crew, as well as other variables (e.g., physical space, time of day, weather). Sampling and assessment of P. halibut is dependent on crew assistance and cooperation. Regulations prohibit vessel crew from discarding any P. halibut without first notifying the observer. The vessel crew must comply with any and all requests by the observer to ensure proper P. halibut sampling, including but not limited to: modifying P. halibut sorting procedures, assisting the observer by delivering the P. halibut to the observer, and modifying operations to ensure P. halibut sampling is completed. Table 2-8 describes the P. halibut data obtained on IFQ-permitted vessels fishing different gear types.

Table 2-8. Data collected from Pacific halibut caught on IFQ vessels using different types of gear. Viability is assessed at the point of fish release when returned to sea.

Gear	Count	Length Measurement	Viability
Bottom trawl	all in the haul	actual, all or subset	yes
Midwater trawl	all in the haul	actual, all or subset	yes
Pot	all in sampled portion	actual, all or subset	yes
Hook -and- line	all in sampled portion	visual, all or subset	no

The Council had specific questions regarding the options for the retention or discard of halibut in each fishery. The GEMPAC developed fishery specific options and took into account the existing regulatory requirements, the current process for viability assessments that are normally conducted by observers, and discard mortality estimations that are applied to each type of gear. IPHC provides the mortality "keys" by fishing gear type that observers use to determine mortality of pacific halibut. The IPHC also determines what mortality rates apply to the different viabilities (Excellent, Poor, Dead for trawl and pot or Minor, Moderate, Severe, Dead for hook and line). The IPHC also has sector specific average mortality rates (i.e., longline and pot). Vessel or sector specific mortality rates based on data from the catch share program could be developed by the WCGOP.

The following gear specific options need to be examined for feasibility and IPHC may need to approve certain options. Council staff and NMFS will work with the IPHC to examine potential changes to halibut mortality assessment methods and the use of sector or vessel specific mortality rates.

For midwater trawl whiting:
Since the fishery is already a maximized retention fishery and all catch is allowed to be retained and landed, all halibut would be considered dead (100% mortality). Current regulations allow fishermen to sort whiting at sea, and if a fishermen chose to do so, would be required to discard halibut. The GEMPAC and GEMTAC believe that sorting at-sea does not occur so only one option was developed for the EM program. If the impact analysis reveals that another option is needed, Council staff will consult the GEMPAC.

For bottom trawl and non-whiting midwater trawl gear:
Option A: Use IPHC mortality rate for specific gear type: 90% mortality if discarded.
Option B: WCGOP scientific observations (assumed 20-30% coverage) is applied to fleet
Option C: IPHC exemption to allow full retention (need to examine the feasibility of this option)
Option D: Captain and crew provide assessment (training would be required)
Option E: Use an appropriate EM viability assessment (currently conducting study, need IPHC approval)
Option F: Use vessel specific mortality rate (update rates periodically)

For Fixed gear:
Option A: Use WCGOP mortality rate for specific gear type: 16% mortality if discarded from longline; 18% mortality rate if discarded from pots.
Option B - Option F: same as bottom trawl and non-whiting midwater trawl gear

2.7 Discard Species List Adjustments

In the future, it's expected that recognition software programs may assist in further refinement or expansion of a species discard list under an optimized retention regulatory environment. During the GEMPAC discussions the group identified that a process to update the species discard list to accommodate advances in fish identification technology or an increase in the ability to identify more species using video review. The development of a species discard list for each fishery is a difficult task and changing technology may allow expansion of these lists after their initial creation. Each fishery will likely have a specific species discard lists. In the future, recognition software may be further developed or regulatory actions could provide the option to expand or change the species lists, therefore; a process that is efficient and flexible to change the list should be developed. Therefore a new component was added to the EM program options.

The GEMPAC identified three options to account for technological changes and to streamline the revision of species discard lists for an EM program:

Option 1: NMFS to make determination and provide list to fishers through the NMFS EM Observer Exemption Process.
Option 2: Use Council process for changing species list using routine management measures if initial list is fully analyzed for environmental impacts (e.g., use groundfish specification process, or some other routine management measure).
Option 3: Set initial lists in regulation and change at some future point through Council process with proposed/final rule making.

2.8 Vessel Operation Provisions

The following sections discuss provisions that relate to vessel operations and include approval and application processes, and EM system requirements.

2.8.1 Observer Exemption Process

Since observer coverage is mandatory under the IFQ program, participants would need to initially apply for an exemption from NMFS to use EM and then demonstrate they are complying with the standards and practices of its use to continue using EM. Therefore, both initial eligibility criteria and continued eligibility criteria are needed. Since EM use would be a privilege, participants must show they are diligently and effectively using the system to monitor their activity. If vessels do not comply, then the privilege may be revoked and the vessel would be required to use a human observer to monitor their activity. The requirement to be in compliance would provide an administrative incentive for proper use of EM.

The following sections describe potential observer exemption process, eligibility for using EM, IVMP requirements, duration of effectiveness of the IVMP, and participant's requirements to declare when a vessel will use EM. As appropriate, regulations will be specific or performance based for the proposed criteria

2.8.2 **Eligibility for Camera Use**

Under the proposed EM program, participants would need to eligible to use EM. Participants would need to apply for an exemption from the existing observer requirement for all IFQ trips. Participants would need to meet certain "eligibility requirements" and NMFS would review the application for approval. The application would also include a NMFS approved individual vessel monitoring plan (IVMP, See Section 2.8.3).

2.8.2.1 Initial eligibility criteria:

1. Limited entry groundfish trawl permit
2. Quota share permit
3. No IFQ deficits
4. No civil penalties related to fishing activity exceeding a certain amount and timeframe
5. Schematic and Description of NMFS approved Individual Vessel Monitoring Plan (IVMP)
   a. IVMP unique for each vessel
   b. Multiple IVMPs included if submitted by group of vessels
6. Self-Governing Plan
   a. Data Delivery and Analysis (DDA) specifications
   b. submitted by either a group of vessels or an individual vessel

2.8.2.2 Continued eligibility:

1. Participants must be in compliance with their IVMP
2. Demonstrate proper documentation of the discards in logbooks or on video
3. No civil penalties related to fishing activity exceeding a certain amount within the time period of EM use

2.8.2.3 Self-Governing Plan Elements

If applicable, the following information would also be necessary.

Group Self-Governing Agreement (not inclusive of all elements)

a. Comply with all Federal and State Regulations
b. Retention / Discard Requirements
c. Time and Area Restrictions
d. Data Collection Equipment Criteria
e. Data Collection Requirements
f. Data Analysis Agreement Clause
g. Discard Assessment Protocols and Procedures
h. Vessel / Operator Performance Standards
i. Vessel / Operator Responsibility
j. Compliance Criteria
   i. By Example: escalation of consequences (to be defined by group)

   ii. No Further use of Camera Use Alternative Criteria
k. Escape Clause

Individual Self-Governing Agreement (not inclusive of all elements)

a. Comply with all Federal and State Regulations
b. Retention / Discard Requirements
c. Time and Area Restrictions
d. Data Collection Equipment Criteria
e. Data Collection Requirements
f. Data Analysis Agreement Clause
g. Discard Assessment Protocols and Procedures
h. Vessel / Operator Performance Standards
i. Vessel / Operator Responsibility
j. Compliance Criteria
   i. By Example: fail to demonstrate compliance, vessel must use observer for rest of the year.
k. Escape Clause

2.8.3 Application Approval and Required Information

Applicants would need to follow specific regulations and provide adequate information for NMFS to evaluate the Observer Exemption application. If NMFS deems the application incomplete, it would provide the applicant an opportunity to revise it appropriately. Specifics regarding denial of an exemption would be provided on a case by case basis but the decision would likely be based on set standards that would be developed. This process is identified as a NMFS process; therefore, the standards would likely involve a Council deeming process (see Section 2.11).

1. Operational Information
   a. Installation by certified EMS Provider
   b. EMS service provider responsibilities
   c. Data Confidentiality Standards
   d. Data Storage and Delivery Standards
   e. EMS Coverage Requirements
   f. Monitoring Requirements
   g. Vessel Responsibilities

2. Data Sources
   a. Digital Camera(s)
   b. Winch Sensors
   c. Hydraulic Sensors
   d. Log Book
   e. VMS
   f. GPS

3. EM Data Standards
    a. Secure Watertight Control Box Data Storage
    b. Encrypted Data
    c. Storage Standards
    d. Date and Time Stamp and Counter
    e. Digital File Format
    f. Minimum Frame Rate
    g. Minimum Resolution
    h. Accepted Delivery Methods
    i. Time Frames
    j. Color Optics
    k. Lighting Standards
    l. Power Supply Standards

2.8.4 EM Vessel Operational Plan - Individual Vessel Monitoring Plans (IVMP)

IVMPs would play a major role as part of the EM program. These plans would help facilitate an effective program and serve as a clear plan for discard documentation, installation and maintenance of an EM system, protocols for data storage and transfer, among other things.

2.8.4.1 IVMP requirements

Each vessel operator/owner would be responsible for developing an IVMP for the vessel and acquiring the needed approval from NMFS. An IVMP that is approved by NMFS would be part of the Observer Exemption Criteria. NMFS would specify IVMP requirements in regulation. This process is identified as a NMFS process; therefore, the standards would likely involve a Council deeming process (see Section 2.11). A general list of categories of information that would be included in the IVMP is provided here.

Potential categories of information in an IVMP:
a) Type of system
b) Hardware
c) Software
d) Emergency protocols
e) Back-up equipment use protocols
f) Catch handling protocols
g) Layout of vessel
h) Screen shots of all camera views
i) Number of cameras needed with placement specifications
j) Care and maintenance of the EM system
k) Types of sensors and data for sensors to capture
l) Download/maintenance schedule
m) Logbook format (electronic or paper)
n) Tamper Resistant/Taper Evident

o) Lighting Locations (Stern, Deck, Discard Shoot, etc.)
p) Bridge Mounted Computer Interface/Monitors
q) GPS Receiver
r) Winch Sensors
s) Hydraulic Pressure Transducers
t) Power Supply / Backup
u) Wire Runs
v) Geo Fencing (NMFS supplied)
w) System's Check Certification
x) Data logger

2.8.5 EM Vessel Operational Plan - IVMP Expiration

The duration of the IVMP effectiveness must be determined; however, modifications may be necessary. For example, to accommodate changes in fishing practices, changes in fish handing protocols to obtain better information, or protocols for data handling. If modifications to the IVMP are necessary, changes must be made in agreement between the vessel representative and the EM provider. Such changes may require re-approval by NMFS; therefore, criteria that trigger re-approval will need to be developed.

Three options have been identified:
Option A – No Expiration unless modifications are made

- Approval of plans by NMFS
- Plan modification provisions: (NMFS to decide how this is done)
    1. EM Provider and vessel operator provisions – changes that do not need re-approval by NMFS (e.g. camera position changes)
    2. NMFS provisions - changes that trigger the need for re-approval by NMFS (e.g. operator will use a different vessel)

Option B – Annual Expiration or if modifications are made
Same as Option A but with annual expiration

Option C – Indefinite or if modifications are made (example 2 or 3 year duration)
Same as Option A but with indefinite expiration

2.8.6 Declaration of EM Use

Agencies and contractors (i.e., NMFS, PSMFC, EM providers, enforcement, states, and observer providers) will need to know the level of participation for EM use. This will help determine employee workload needs (e.g., how many observers, video reviewers, or catch monitors are needed month to month or annually), scheduling data transfers, EM system maintenance needs, etc. In order to process the fisheries in an orderly way, IVMP must provide a "Declaration of EM Use" and specify when an EM system will be used and when the vessel would, if at all, need an observer for a specified period of time within fishing year.

Option A - Annual Declaration of Intent to Use EM (year around).

Option B - For the coming year, participants must indicate in which months, if any, it will use EM and in which months, if any, it will use an observer (e.g. quarterly). The IVMP would provide a description of the responsibility for vessel operator to notify NMFS, EM provider, and NMFS observer program when EM will be used and when observer will be used.

Option C - Trip by trip basis. Under this option, the vessel and the observer provider would need to schedule when observers are needed or available on a per trip basis. The IVMP would provide a description of the responsibility for vessel operator to notify NMFS, EM provider, and NMFS observer program when EM will be used and when observer will be used.

Exception for Emergency situations (e.g., camera broke so need an observer tomorrow, vice versa)

2.9 Equipment and Protocol Provisions

The success of an EM program relies on the ability to capture the data and process it in a timely manner. EM equipment that provides the necessary data for efficient processing and accurate review is critical. A type approval process will need to be developed by NMFS with the aid of current experience and technology. However, technology will change in the future so a process that incorporates the ability to change the standards for equipment use, data formats, and protocols for data transfer will need to be flexible.

2.9.1 EM Equipment Requirements

Although NMFS policy requests the use of open source software so that common platforms can use the data generated or multiple users can access data, the GEMPAC suggest allowing both open source and proprietary equipment and software be allowed if they meet the performance criteria. The following topics would need to be worked out with technical advisors and input from the industry.

2.9.1.1 Data formats:

Create a standardized data output that can be used by multiple users such as PSMFC and NMFS to analyze data or video without a cumbersome conversion process to access the data. This will need to be specified in the future with the advice of PSMFC, States, NMFS, and other technical advisors such as EM providers.

2.9.1.2 Video Hardware:

Image quality must be sufficient to allow clear identification of species or species categories being discarded. Performance standards need to be developed during implementation between NMFS, PSMFC, states, and contractors.

2.9.1.3 Logbook Data Source:

Allow either paper or electronic logbooks; however, electronic logbooks may increase efficiencies in the EM analysis.

2.9.1.4 On Vessel Data Storage:

Integrated and in a secure format (video hardware, sensor data, vessel location data, logbook data)

2.9.1.5 Onboard operations:

Topic examples:

a) Self check system to ensure proper functioning of EM system ("functionality test" within the EM system with a record that the test was performed)
b) EM system is powered on during entire trip, however cameras could be triggered to turn on at first hydraulic event and remain on for the duration of the trip.
c) Back-up equipment use protocols if EM unit or portions of it fail
d) Performance standards need to be developed during implementation between NMFS, PSMFC, states, and contractors.

2.9.2 Data Transfer Process

Protocols need to be established for data transfer. This is a critical component of the EM program since it involves the physical transfer of the data from the vessel to the video reviewer. The process of transferring the data could be electronically via a WiFi network or email or physically pulling a hard drive out of a computer modual and sending it in the mail or driving it from the port to the reviewer. Protocols may also vary based on the type of data being transferred (video, electronic log, or data logger). The method of transfer would be dependent on the amount and type of data being transferred. For example, electronic logbooks can be emailed but a hard drive with a terabyte of data would likely need to be pulled out of the EM system and physically transferred to the reviewer. The method of transfer that would be allowed under the EM program will be developed during implementation however some methods have been identified for use such as Wi-Fi, satellite signal, email, and thumb drives.

Data transfer protocols and frequency may vary by fishing sector. For example, mothership catcher vessels may seldom return to port. This would increase the volume of data to store and affect the frequency of data transfer. If the data transfer processes are to be included in the Council recommended policy then both generic provisions that apply to all vessels or all vessels of a sector, and individual provisions may need to be specified.

The choice of transfer method may drive costs of the program up or down. For example, email would incur minimal costs but hiring personnel to drive port to port to pull hardrives may incur significant costs and is dependent on the frequency of this activity.

Since the data could potentially be used in enforcement actions, data transfer protocols would have to address chain of custody and ensure the integrity of the data is not compromised. Typically the video data is encrypted by the EM provider and cannot be accessed or altered.

Several personnel options have been identified to provide the transfer data from the vessels to the reviewer.

(1) Vessel Operator
(2) Crew
(3) Shoreside catch monitor
(4) PSMFC
(5) EM Provider
(6) Contractor (hired by processor, port, or fisher)

2.9.3 Data Confidentiality/Accessibility/Ownership

All data collected in the EM system (e.g., video, logbooks, and applications) would be considered confidential according to the Magnus-Stevens Fishery Conservation and Management Act, NMFS internal confidentiality rules, and any new or revised rules that are proposed at this time (NMFS confidentiality Final Rule will be released in 2014). This includes access, ownership, and public dissemination of the information.

2.9.4 Video and Data Processing and Analysis

EM data processing would likely involve analysis of EM sensor, video data, and logbooks. The following is an outline of some of the considerations. Video review is a critical component of the EM program; therefore, entities that can perform this function must be identified and clearly defined methods for review and validation must be developed.

2.9.4.1 Video Review Process

The basic review process would include matching video segments with logbook discard events then verifying the discarded species and an estimated weight. Standard review protocols would need to be developed for each fishery and if compliance issues arise that require further review. It's possible that the protocol would need to include defining "audit units" that match fishing logs units (i.e., fishing events, transiting time periods to and from fishing grounds). For some fisheries fishing events are not clearly defined to facilitate an audit and may need to be developed during implementation between NMFS, PSMFC, and contractors.

Once a fishing trip is reviewed and the total discard is estimated, this information would need to be transferred to NMFS to debit a QP account. This information currently flows through PSMFC then to NMFS for final accounting. Since PSFMC manages the Pacific Fisheries Information Network this data flow protocol is expected to remain. However there may be efficiencies to consider if data is reviewed by an EM provider or a third party and transferred to PSMFC versus directly to NMFS.

The amount of video to review depends on the method chosen to monitor discards. For example, if a census of all video for a fishery is chosen then all video of discard events would be captured. If logbooks with audit is chosen, then a determination must be made as to how much video should be reviewed that would reduce the risk of missing discard activity to a level that is appropriate for IFQ accounting. What level of sampling is appropriate if sub-sampling the video for discard events and expanding the rate to the entire trip is used?

An analysis of this information can be found in Section 4, Impact Analysis of the Alternatives (analysis needs further development).

2.9.4.2 Video reviewers

Potential reviewers for discard events (not mutually exclusive):

Option A: NMFS
Option B: Pacific States Marine Fisheries Commission
Option C: EM Provider
Option D: Third Party

2.10 WCGOP Scientific Observations

The NMFS Northwest Fishery Science Center Fisheries Observation Science Program collects and analyzes critical fisheries data from U.S. West Coast fishing vessels. Independent field biologists known as observers are deployed aboard working fishing boats to collect this scientific data. While at sea, observers collect a variety of data on fishing operations, catch composition, and protected resources. They also collect biological samples from the catch. Staff provide logistical and scientific support, ensure data quality, and train observers. Our scientists also produce a variety of data products and reports to support fisheries management and the NOAA mission. Fishery scientists and managers depend on observer data and analysis for stock assessments, management decisions, in-season quota tracking, and scientific research.

2.10.1 Observer Programs

There are currently two Federal observer programs being operated by the NMFS Northwest Fishery Science Center in the Pacific coast groundfish fishery: Shorebased IFQ Program and the WCGOP.

These two programs are very different from each other particularly in how they are funded, the type of sampling and fishery data that are used to derive total catch, and availability of data for inseason management. Two types of funding mechanisms are currently used to fund observers: federally funded observers and third-party or “pay-as-you-go” observers. The WCGOP is federally funded and currently provides observer coverage in the LE and open access nonwhiting fisheries. Federal funds are used to run the program infrastructure (training, debriefing, and data management) and to hire, equip, insure, and transport observers. Third party providers are used to observe fishing activity under the Shorebased IFQ program and are funded by the fishery participant directly to the third party provider.

2.10.1.1 West Coast Groundfish Observer Program

The WCGOP is a year-round program that provides observers for all of the commercial groundfish fisheries . Because monitoring of the Pacific whiting shoreside sector has been carried out under EFPs, WCGOP observers have not been used to provide coverage for that sector. All WCGOP sampling protocols and coverage strategies are defined by NMFS. Because there are few observers relative to the number of vessels in the groundfish fishery, observer sampling coverage has focused on obtaining bycatch data at sea that can be combined with state fish ticket data to derive bycatch ratios for different fishing areas and target fishing strategies. Vessel logbook data are used to estimate fleetwide fishing effort. Using observer, fish ticket, and logbook data, the fishery is modeled to derive an estimate of total catch by species. Due to the delayed availability of fish ticket and logbook data, and the time needed to process observer data, the final analysis of estimated total catch by species is typically not finalized until well over one year after the fishing year has ended.

Observer coverage goals for the WCGOP are detailed in a coverage plan (NMFS 2006a). Observers initially covered about 10 percent of the west coast LE trawl fleet effort, selected via a stratified random sample. Trawl fleet coverage has since increased to about 25 percent and has also been expanded to include the LE fixed-gear and open access vessels.

2.10.1.2 IFQ Fisheries Observer Program

Third party providers are used to secure observers for IFQ fishing trips. These observers are trained in the same manner as those observers in the WCOP. The NMFS-permitted observer providers collect the fees directly from the vessels, recruit qualified individuals, provide insurance and benefits to the observers, deploy the observers, and ensure that the observer data are delivered to NMFS.

The IFQ Program requires 100% at-sea observer coverage, as all catch of IFQ species/species groups must be accounted for. The observer data is used to account for any IFQ discard, including the mandatory discarding of Pacific halibut. The observer data, in combination with landings data, will enable the fishermen to track their individual quotas and allow managers to monitor the progress of the fishery. Because both the discarded and the retained weights are estimates; the observed estimates of total catch contain some uncertainty.

Vessels that require observer coverage are:

- All whiting and non-whiting groundfish trawl and non-trawl vessels.

- All motherships participating in the at-sea whiting fishery.
- All mothership catcher-vessels participating in the at-sea whiting fishery.
- All catcher processors participating in the at-sea whiting fishery.

Under the IFQ program both observers (at sea) and catch monitors (at shoreside facilities) are used to monitor total catch. Observers are highly trained biologists that work independently aboard vessels to quantify total catch. They estimate bycatch, collect biological samples, and monitor for fishery interactions with marine mammals, sea turtles, and seabirds. A catch monitor is someone who is land-based at first receiver facilities and confirms that total landings are accurately sorted, weighed, and recorded on fish tickets (landing receipts).

Observers focus on scientific data collection at sea, while catch monitors ensure compliance with IFQ landed fish sorting requirements, and together they give NMFS a very accurate and complete picture of the fishing mortality in the IFQ program. First receivers must use an approved electronic fish ticket reporting software to and submit the data to Pacific States Marine Fisheries Commission.

Observers collect the following information:

- Fishing activity, including areas and depths fished, gear set, and retrieval times.
- Catch, such as how much of each species was discarded.
- Individual fish, including length, weight, and sex.
- Bycatch of protected species like marine mammals.

All IFQ catch is delivered to licensed first receivers. This can be a person or company that receives, purchases, or takes custody, control, or possession of catch onshore from a vessel that harvested fish under the IFQ Program (e.g., fish buyer station or processing plants). All buyers must hold a first receiver site license for each physical landing site. Site licenses are effective for one year from the date of issuance. First receivers currently holding a site license, must register prior to the ending date to continue to receive landings from the IFQ program. New first receivers must contact the Pacific States Marine Fisheries Commission to install electronic fish ticket software.

Each first receiver taking delivery of IFQ species is required to have a certified catch monitor present for the entire duration of the landing. Catch monitors are certified by NMFS and must meet responsibilities specified in the regulations at § 660.17. Once verified, catch monitors independently report catch data to the Pacific States Marine Fisheries Commission and NOAA Fisheries catch accounting databases. Catch monitors are available from approved observer providers. Catch monitors perform more of a compliance role than that of a biologist and are required to report any observations of suspected violations of regulations.
There are two types of duties for observers in the IFQ fishery, compliance observations and scientific observations. Compliance observations are needed to support catch and discard monitoring in the IFQ fishery to estimate total catch by a fishermen. Scientific observations are conducted to collect data to support stock assessments and estimate protected species interactions, amongst other things. If EM is used on IFQ trips and the observer is removed from the vessel without making other program adjustments, significant scientific information would be lost. A

continuous need exists for at least some level of scientific observer coverage to collect biological samples and other scientific data on EM trips.

2.10.2 Payment for Scientific data collection/observations

Previous to the IFQ program NMFS provided scientific data collection on roughly 20 percent of the limited entry trawl fleet. This cost was covered by the Government. Under an EM program scientific data collection will be needed from vessels without an observer. It's estimated that the WCGOP will sample roughly 20-30 percent of the EM fleet; however, these rates will need to be examined and a sampling scheme developed by NMFS in the future.

A funding source to continue this task under an EM program must be identified to support the WCGOP efforts. Three options were developed:

Option A: Government funded, same as pre IFQ
Option B: Industry Funded
Option C: Combination of both Government and Industry

2.11 NMFS Processes

While working through the development of the alternatives and options certain components or portions of the EM program were identified for NMFS to develop. For example, NMFS will need to set up an internal process to conduct a "type-approval" process that authorizes vessels to use certain EM equipment on a vessel, and set up a process for applicants to submit an "Observer Exemption Application" to request use of EM in lieu of an observer.

A list of processes are identified here; however it's expected that some of the development will be done in consultation with the GEMPAC or other technical advisors. In addition, regulations will need to be developed to provide specific guidance to fishermen and EM providers, or observer providers (e.g., fill out applications, make changes to individual vessel monitoring plans, or for compliance with program rules). The development of these processes and associated regulations would likely involve a Council deeming process for the Council to review the draft regulations before they go into the proposed rule stage. Approval from the Office of Management and Budget for the collection of information under the Paperwork Reduction Act (PRA) will be needed when appropriate and are preliminarily identified in the list below. The list may be updated as the decision document is developed and the impact analysis expanded.

- Observer Exemption Process (including an application for fishermen, PRA)
- Individual Vessel Monitoring Plan Approval (including a form for submission to NMFS for review, PRA)
- Equipment Type Approval (including a list of specifications for EM providers to accommodate, PRA)

- Approved EM Provider List (including a list of specific criteria for providers to demonstrate their capability and standards, PRA)
- Eligibility Criteria (Initial and Continued)
- Declaration Process to Use EM (possibly including port hail in/out process, PRA)
- Confidentiality Rules (if different from status quo)
- WCGOP Scientific Observation Sampling Scheme

2.12 Spatial Variation for High Bycatch Areas

This option could be applied to allow the use of EM based on ocean areas that are known for high or low bycatch. Under these options, the areas need to be identified and designed for explicit use of EM or would use preexisting areas such as the Rockfish Conservation Area or Essential Fish Habitats.

Option A - No special provisions

Option B - Under this option, fishing activity in areas that are likely to have lower bycatch could be monitored with EM rather than using observers. Vessels would declare their fishing area prior to departure and be required to follow the appropriate fishing protocols for that area.

Option C - Under this option, if you chose to fish in a high bycatch area, a higher level of EM review may be required. The level of review would need to be determined.

The GEMPAC understand the possible utility of this type of management, however; this type of spatial management may add too much complexity to the management of the IFQ fishery and would require identifying additional management areas which in turn may be difficult and costly to manage.

Therefore, the GEMPAC recommends removal of Option B and C for spatial management options.

2.13 Adaptive or Phased Implementation

Implementation of an EM program could be done for all fisheries at one time through regulation (Option 1). However, there may be other options. Implementation of an EM program could be done through a pilot program using an Exempted Fishing Permit (ESP.) (Option 2). For example, an EM program may be developed for a fishery, and then implemented on a temporary basis through an EFP to identify issues and improve the program before it is implemented full scale for a particular fishery or all fisheries. It could also be done through a "phased-in" approach. For example, if development of an EM monitoring program (i.e., regulations, camera system, EM providers, review process, accounting protocols, enforcement, etc.) is ready for use in the mid- water trawl fishery then NMFS could implement the program by regulation before other EM programs are fully developed for use in other fisheries such at the bottom trawl (Option 3).

Another approach would be to implement an EM program based on retention rules (Option 4), starting with any gear types that are willing to fish under a maximized retention type fishery (See Alternative 2 in Section 2.5 for a description of a maximize retention fishery). For example, bottom trawl and non-whiting mid-water trawl vessels that are willing to retain and land all fish (excluding prohibited species and ESA/MMPA species) would be allowed to use EM. Then, as EM capabilities improve to provide verifiable species identification (for example distinguishing aurora rockfish from rough eye rockfish), the EM program could be expanded to include other discard options. A list of species that are shown to be verifiable with EM would need to be developed over time.

Implementation could be organized in a number of ways.
Option A. None, implement all fisheries at one time through regulatory implementation
Option B. Use EFPs to test final Council policy, prior to full regulatory implementation.
Option C. Phase in by sector/gear.
Option D. Phase in retention options over time, start with maximize retention fisheries and move to other retention rules as reliable technologies for speciation are developed.
Options B-D are not mutually exclusive.

2.14 Alternatives Considered but Eliminated from the Detailed Analysis

The following topics were discussed during the public scoping process; however the Council eliminated them from further consideration and not analyzed in this document. An explanation is provided under each topic.

2.14.1 Mandatory Use of an EM program

Under this option, all participants in the Shoreside IFQ program would be required to use EM. No human observers would be used to monitor for compliance with IFQs, IBQs, or catch allocations. Making the EM program mandatory was considered during the public scoping; however, it was not further analyzed in this EA because some participants may not want to use EM and only want a human observer. If the system breaks down vessel would not be able to fish until the system is working. This could delay fishing activity until a technician can repair the system. This limits vessels options and can monetarily impact a vessel significantly depending on the amount of time the vessel is tied up, the target species, and the price of fish.

2.14.2 Full retention of All Catch

Under this option, vessels would be required to retain all retain all catch share species and non-catch share groundfish species for the IFQ and co-op fisheries (see **Table 2-5** and **Table 2-6**, respectively), non-groundfish species, prohibited species; ESA species (Table 2-7); and MMPA species. Vessels would not be allowed to discard species for safety reasons, bleeding nets or any other reason.

This option was considered impractical and potentially dangerous. Vessels would not be able to retain marine mammals or ESA listed species unless instructed to do so through a Federal exemption. Although exemptions can be made, it's typically done for special cases and research purposes. In addition, retaining large marine organisms is not possible or safe in some cases. Also, trying to capture fish they may have accidentally been released would be impractical and by not allowing vessels to discard fish for safety reasons could endanger vessel crew.

2.14.3 No declaration of EM use

Under this option, vessels would not be require to declare to appropriate agencies and contractors their intention to use EM. This option was not further analyzed because federal and non-federal agencies, EM providers, observer providers and enforcement need this information for budgetary and labor planning purposes.

CHAPTER 3 AFFECTED ENVIRONMENT

This chapter describes the Pacific Coast groundfish fishery and the resources that would be affected by the alternative action. Physical resources are discussed in Chapter 3.2, biological resources are described in Chapter 3.3, and socio-economic resources are described in Chapter 3.3. Rather than repeat information detailed in the other NEPA documents, the information has been summarized in this document and the reader is referred to the appropriate sections in the other NEPA documents for further detail.

3.1 Action Area and Physical Characteristics of the Affected Environment

The action area is the state and federal waters of the U.S. and includes the shoreline out to the 200 nautical mile line of the U.S. Exclusive Economic Zone. The area of operation of the Pacific Coast groundfish fishery is within this area (Figure 3-1).

Figure 3-1. Fishery management lines on the U.S. west coast. Source: PFMC 2014, SAFE.

3.2 Biological Characteristics of the Affected Environment

3.3 Socio-Economic Characteristics of the Affected Environment

3.3.1 Landings, Revenue, and Participation

Section 3.2 in the 2015-16 Groundfish Harvest Specifications FEIS (as well as EISs for earlier biennial periods) describes commercial fisheries targeting groundfish and characterizes west coast fishing communities with respect to groundfish fisheries. Section 3.2.1 of the FEIS describes revenue trends for commercially important groundfish. That information is incorporated by reference here. The 2014 Groundfish SAFE document contains a series of tables summarizing landings and ex-vessel revenue in groundfish fisheries, landings and revenue by port, and indicators of fishery participation. These data may be summarized here to highlight current fishery trends. Both long-term historical landings, revenue, and price data (the full PacFIN database time series) and a recent a 10-year baseline period of 2003-2012 are used to characterize fisheries and communities.

Table 3-1 shows the share of landings and inflation-adjusted ex-vessel revenue by groundfish fishery sector (IFQ, whiting catcher processor, and whiting mothership) for the 2012 baseline period.

Table 3-1. Exvessel revenue and total pounds landed in 2012 by month and fishery sector.

Key IFQ = Individual Fishing Quota, CP = Catcher processor or CP, and Mothership or MS.

Year	Month	IFQ lbs.	IFQ rev.	CP lbs.	CP value	MS lbs.	MS value
2012	Jan	1,491,862	1,141,585	0	0	0	0
2012	Feb	2,395,897	1,639,885	0	0	0	0
2012	Mar	3,329,906	2,110,348	0	0	0	0
2012	Apr	4,954,879	2,844,151	0	0	0	0
2012	May	4,265,175	2,236,024	44,844,730	6,329,660	9,390,741	1,325,467
2012	Jun	13,934,687	3,411,107	0	0	6,049,386	922,719
2012	Jul	26,469,461	5,863,888	0	0	1,097,743	167,691
2012	Aug	36,519,674	7,520,641	8,223,969	1,251,804	4,642,409	744,548

Pacific whiting fisheries dominate in terms of landings, accounting for 88% of the total. However, because whiting fetches a low price per pound, those sectors accounted for only 39% of inflation-adjusted ex-vessel revenue. Non-whiting trawl/shoreside IFQ accounts for the next largest share of landings and revenue, 10% and 34% respectively. Fixed gear landings fetch a relatively higher price so while those sectors accounted for only a little more than 2% of landings, they garnered a quarter of groundfish revenue, primarily in the non nearshore sector that targets sablefish.

Figure 3-2 shows revenue trends for groundfish sectors over the baseline period. Revenues have been more stable for nonwhiting sectors compared to whiting. One way of assessing variability is the coefficient of variation (the standard deviation divided by the mean). The values for the sectors (over the baseline period) shown in the figure are as follows: nonwhiting trawl (including non-trawl IFQ in 2011-2012): 0.131; shoreside whiting trawl: 0.584; non nearshore fixed gear: 0.269; nearshore fixed gear 0.074; at-sea catcher-processors: 0.503; at-sea mothership catcher vessels: 0.551.

CHAPTER 4 IMPACT ANALYSIS OF THE ALTERNATIVES

The terms "effect" and "impact" are used synonymously under NEPA. Impacts include effects on the environment that are ecological, aesthetic, historic, cultural, economic, social, or health, whether direct, indirect, or cumulative. Direct effects are caused by the action itself and occur at the same time and place. Indirect effects are caused by the action and are later in time or farther removed in distance, but are still reasonably foreseeable. Indirect effects may include growth-inducing effects and other effects related to induced changes in the pattern of land use, population density or growth rate, and related effects on air and water and other natural systems, including ecosystems. Cumulative impacts are those impacts on the environment that result from the incremental impact of the action when added to other past, present, and reasonably foreseeable future actions, regardless of what agency (Federal or non-federal) or person undertakes such other actions. Cumulative impacts can result from individually minor but collectively significant actions taking place over a period of time.

Sections 4.1 through 4.3 of this document discuss the direct and indirect impacts on the physical, biological, and socio-economic environment that are likely to occur under each of the proposed alternatives, including the Status Quo alternative. Section 4.4 presents the reasonably foreseeable cumulative effects of the environment from the proposed alternatives.

4.1 Effects on the Physical Environment

Alternatives 2 and 3 would implement an EM program that is a general framework for each fishery. There are several options to choose from within the alternatives that can be specific for each IFQ gear sector and may be appropriate for one sector and not the other. However, each alternative and options selected with those alternatives are unlikely to have a significant direct impact on fishing activities. Although the range of options include maximized retention to discarding fish species at will, all fish (except halibut, lingcod, and sablefish) are considered dead.

Landing more fish that are undesirable by the fish processors (under maximized retention) may have an impact on processing plants financially through additional handling and trucking of fish. Additional costs to dispose of fish may be passed on to fishermen or born by the processing facility. It’s possible that fish meal may be utilized in other ways to help off-set the cost of trucking and handling the surplus of fish that are generally unmarketable.

Impacts to essential fish habitat (EFH) or marine habitats are not expected to change as a result of the proposed actions since fishing practices and areas fished are not expected to change significantly. Fishing practices (number of hooks, pots, trips, set/hauls) are not expected to significantly change under all options using EM. Fish handling on deck may take more time under all retention options to accurately identify and estimate species weights before they are discarded. Under the option to allow EM in low bycatch areas (Spatial Management Sub-option 1) or higher review of EM video in areas with high bycatch (Spatial Management Sub-option 2) could change areas fished by the fleets if they chose to fish in areas with low bycatch or chose to avoid high by catch areas. Generally fishermen already try to fish in low bycatch areas or avoid high bycatch areas. A significant amount of analysis would be needed to identify these management areas as well as monitoring activity within them. These sub-options could create more complexity in management. None of the remaining alternatives or options are expected to alter areas currently fished by all fisheries.

4.2 Effects on the Biological Environment

Effects on the biological environment resulting from fishery management actions primarily include changes in species mortality levels resulting from implementation of the alternatives. Implementation of an alternative that changes fish retention and discard requirements could have a direct biological effects; however, the fisheries would continue to operate under current ACLs and IFQ limits. Additional mortality of some species could be realized if maximum retention was required in all fisheries, although most of the species currently discarded under the status quo would not result in exceeding current ACls or IFQ limits. All other options that are available to build an EM program are mostly administrative and do not affect the bioloigical environment. Indirect effects from fishery management actions include changes in fishing practices that affect the biological environment, but are further away in time or location than those occurring as a direct impact. Indirect biological impacts could result if catch data were inaccurate or delayed such that fishery specifications (bycatch limits, species allocations, OYs, and biological opinion thresholds) could not be adequately monitored or the fishing stopped before one of the specifications were exceeded. If a fishery specification were exceeded, the magnitude of the impact would depend of the status of the stock (healthy, precautionary zone, or overfished), the proportion of allowable fishing mortality represented by fishery specification that was exceeded, and the stock's sensitivity to changes in fishing mortality. If other fisheries could not be effectively managed to stay within the same fishery specification, cumulative indirect impacts could result.

4.2.1 Overview of Effects

Under the No Action Alternative (Alternative 1), vessel's would still be required to have a limited entry permit with a QS permit and must have quota pounds in their account to continue fishing under the IFQ Program. Participants in the IFQ Program must continue using human observers on 100% of all IFQ trips. Observers would continue to estimate catch and discard to provide full accounting of all IFQ catch and submit this information to PSMFC, and NMFS would debit IFQ QS accounts. Catch monitors would still be required to monitor offloading and verify catch accounting by observers. Fishermen would still be allowed to discard any species, regardless if it is an IFQ or non-IFQ species, and continue to discard species they are required to discard under the current groundfish regulations. Fishermen would continue to use existing procedures regarding logbook reporting requirements for permit holders/vessel operators, to submit this information along with economic data, and be required to use VMS. Observer coverage is currently subsidized by NMFS; however, in the near future full payment will be required by the industry.

The one major difference between all action alternatives is how discard is documented and enumerated to debit a vessels QP account.

Under Alternative 2, a vessel captain “self reports” the discard by species and provides a weight in a logbook. Video documentation of those discards are then reviewed at some predetermined level (See section x.x for a discussion of review rates) to verify the discarded species and weight. The reviewer would also look for discard events that are not recorded in the logbooks. If there are no discrepancies between the two data sources then the logbook data is used to debit the QP account. Protocols for resolving discrepancies would be used.

Under Alternative 2, video documentation of the discard events would be reviewed to identify and enumerate the discard either through a census of all video (or through a sampling and expansion of the discard that is documented in the video. Under Alternative 3, the fishermen self-report the discard by recording the species and their weights in a logbook; the video is then reviewed to verify the information submitted. Discrepancies between both data sources are resolved before debiting the fishermen’s QP account.

Beyond these major differences, there are many options to choose from within each alternative to build a EM program, such as which species can be discarded, declaration process for vessels to announce when they will use EM, how fish should be handled so the video can capture adequate images of them before they are discarded, how and what data is captured on video, how will data be transferred from the vessel, how will analyze the data, and how will the program be implemented.

The most important decision is which species will be retained and which will be allowed for discard in each fishery (i.e., midwater trawl whiting, midwater trawl non-whiting, bottom trawl and longline). Allowing discard will hinge on whether video can appropriately capture the discard in a clear image so a video reviewer can identify the species and estimate the weight of the discard. Three options are provided: 1) maximize retention; 2) optimum retention (some selective discard of certain species), and 3) discard at will (currently allowed).

Overall, impacts to fish resources are not expected to change significantly under any alternative or option since most fish discarded (except halibut, lingcod and sablefish) are considered dead after release. Since the fishery is under an IFQ system, exceeding ACLs is unlikely. Most of the IFQ species are not being caught and there is room for increase. If fish are discarded and not reported or captured by EM then impacts could increase but it will be difficult to enumerate this.

Each fishery will be examined for impacts to fish resources under these three basic options (not yet analyzed). Under optimized retention, further analysis is provided regarding the impact of choosing several species or species groups for discard in each fishery. In general impacts to fish resources may be greater under Option 1 (maximize retention requirements) since vessels would be required to retain nearly all catch and bring it to shore or deliver it to motherships, as is the case with the current midwater trawl whiting fishery. Impacts to fish resources may be less under Option 2 (optimize retention) if certain species are allowed to be selectively discarded by fishermen, assuming fish mortality rate estimates do not change. Option 3, fishermen in the non-whiting midwater trawl, whiting vessels that sort at sea, bottom trawl, and fixed gear (pot and longline) would still be allowed to discard any species unless required to retain them by regulation. Therefore Option 3 would have the least impact on fish resources and discard rates would be similar to what is estimated under the current program. However, fish identification is most difficult with EM under Option 3 and least under Option 1. At this time multiple efforts are being pursued to help identify fish through different fish handling protocols (such as with chutes, fish length boards and discard stations, and fish recognition software). At this time a specific EM species discard list for each fishery has not been developed.

Of critical importance, and yet to be analyzed, is the level of risk that managers are willing to take to capture rare events such as yelloweye rockfish discard if a fisher was allowed to discard them, log it, and then use video review to not only review the logbook discard event but also to randomly sample the video to see if discard events are not logged. Fishery managers will need to examine what level of risk is appropriate and the cost implications for trying to capture all events to balance management of overfished species and the economics of fishing activity. Cost for video review can increase dramatically for a fishermen if all video is reviewed (census) versus only 10 or 25 percent.

4.2.1.1 Overfished Species and Affect on Rebuilding Plans

Harvest specifications, and the science used as the basis for management decision-making are derived from the most recent assessments and/or rebuilding analyses prepared for those stocks informed by an assessment. Please see the 2015-2016 SAFE document for an explanation of the process that sets the harvest limits for the managed groundfish stocks (PFMC 2014).

There are six overfished west coast rockfish stocks (i.e., bocaccio south of 40º10' N lat., canary rockfish, cowcod south of 40º10' N lat., darkblotched rockfish, Pacific ocean perch, and yelloweye rockfish) and one overfished flatfish stock (i.e., petrale sole) at the start of 2013. All seven of these stocks are rebuilding and three (i.e., bocaccio south of 40º10' N lat., darkblotched rockfish, and petrale sole) are predicted to rebuild by the start of 2015.

Rebuilding plans are in place for six overfished rockfish species, as well as petrale sole, where assessments have indicated spawning biomass has declined to below the MSST. New full and updated assessments and rebuilding analyses were done in 2013 inform the 2015 and 2016 harvest specifications for many of the overfished species. New full assessments were conducted for cowcod, darkblotched rockfish, and petrale sole in 2013; however, a new rebuilding analysis was only prepared for cowcod. The results of the new assessments for darkblotched rockfish and petrale sole indicated those stocks would be rebuilt by 2015 and 2014, respectively. The SSC did not recommend new rebuilding analyses for these two stocks given their imminent rebuilding expectation. An update assessment for bocaccio was prepared in 2013. Like darkblotched, the stock is predicted to rebuild by 2015 and the SSC therefore recommended no new rebuilding analysis be prepared. Catch reports for canary rockfish, Pacific ocean perch, and yelloweye rockfish were prepared in 2013. These catch reports indicated total catches were within limits prescribed in these stocks' respective rebuilding plans.

Stock rebuilding parameters estimated from the most recent rebuilding analyses and current rebuilding parameters specified at the start of 2013 are provided in Table 4-1.

Table 4-1. Rebuilding parameters estimated in the most recent rebuilding analyses and specified in rebuilding plans for overfished groundfish stocks at the start of the 2013-2014 management cycle.

Stock	T_{MIN}	$T_{F=0}$	T_{MAX}	T_{TARGET}	**Harvest Control Rule Specification**
Bocaccio	2018	2018	2031	2022	SPR 77.7%
Canary	2027	2028	2050	2030	SPR 88.7%
Cowcod	2059	2060	2097	2068	SPR 82.7%
Darkblotched	2012	2016	2037	2025	SPR 64.9%
POP	2040	2043	2071	2051	SPR 86.4%
Petrale sole	2014	2014	2021	2016	25-5 Rule
Yelloweye	2044	2047	2089	2074	SPR 76%

4.2.1.2 Bycatch Limits

Under the IFQ system there are individual by catch limits for halibut. In addition, there are bycatch limits for certain groundfish species that are either pooled by groups of fishermen or traded amongst individuals. The at-sea whiting sectors are managed under bycatch limits for selected overfished species. Mandatory co-ops in the mothership sector are allocated a portion of these sector bycatch limits and are accountable for keeping catch of these species within their allocation. Bycatch limits are not expected to change under any of the proposed alternatives.

4.2.1.3 Tracking and Monitoring Under the Proposed Action

All vessels would be required to carry at-sea observers at their own expense to monitor sorting and discarding of the catch and shoreside landings. There would also have to be an electronic system to report bycatch and landings, which may be integrated with the current state fish ticket (landings reporting) system. NMFS would also continue to administer a system to track QS/QP holdings. A comprehensive EM program is expected to require minimal increases in enforcement effort. Since the EM program would be voluntary, vessels may immediately lose privileges for certain violations. In addition, it's possible that existing coops and new coops could assist in "self-policing" to increase accountability between members and lessen the need for enforcement actions. To resolve ongoing EM monitoring issues or in response to violations, observers may be required in place of EM.

Under Alternative 1 (No Action), at-sea observers would be required on all vessels (100 percent coverage). Observers would be required to monitor the sorting, weighing, and discarding of catch.

Under Alternative 2 or 3, to assure accuracy when QPs are discarded at sea, vessels may be required to meet specified monitoring and weighing provisions, including adequate space for catch sorting, an adequate location for video monitoring, and the equipment necessary for accurately weighing and documenting QP species at sea.

Under all alternatives, biological data collected by shoreside samplers would include age structure data (lengths, otoliths, scales, snouts, etc .) and would continue to provide much needed fishery dependent length and age data use in stock assessments. Providing quality fishery dependent length and age data is expected to have a beneficial effect, as it helps stock assessment scientists better understand a stock's population status and changes in the stock. Stock assessments are important to the management process because they are generally used as the basis for setting future harvest levels.

Under alternative 1, catch composition data would continue to be collected by at-sea observers; however, under alternative 2 and 3, sampling would need to be conducted on EM vessels to collect biological data and possibly verify EM data that is seen by reviewers and logged by vessel operators. The level of sampling and the cost to support these efforts has not yet been evaluated or decided upon.

A catch monitor is present during the entire delivery to ensure that all incidental catch makes it to the point of weighing. This includes monitoring the primary sorting stations and confirming the weight of the catch includes species that may have been missed in the initial sorting, and confirming that all catch is recorded accurately. Depending on a processor's capacity and efficiency, and the size of vessel deliveries, a full offload could take a few hours to the majority of the day. Although this monitoring program would remain in regulation, it's possible that some efficiencies may be lost since many observers depart the vessel and become the shoreside catch monitor. Under Alternative 2 and3 a shoreside monitor will need to be present for vessels that deliver and do not have an observer aboard the vessel. Vessels and processors will need to work together to ensure a catch monitor is available.

Fish ticket data must be submitted within 24 hours of the time the catch was landed rather than daily, electronic fish ticket data for some deliveries may not be submitted until almost two days after the catch was landed and would be available to managers shortly thereafter.

One major consideration for debiting a QP account is the timeframe to get the data into the system. Under Alternative 3 (logbook audit) it's possible to get the data from the logbook into the system within a week; however, it may take up to a month or more depending on the review software and the number of discard events to review, or corrections to be made to get the data into the system and reconcile a QP account. The physical transfer of the video data (via electronic or car) to the reviewer and the length of time it takes for the reviewer to conduct the audit are the limiting factors for the process. Review all the video (Alternative 2, Option A: census), would take the most time and be the most costly to fishermen.

4.2.1.4 Indirect Biological Effects

Valid and timely data are needed to monitor total catch of all IFQ species, IBQ species, and catch allocations. Positive indirect biological effects could occur if the quality of catch data were improved such that more timely and accurate data were available for managing the fishery inseason and keeping total catch within the fishery specifications, including: bycatch limits, species allocations, OYs, and biological opinion thresholds. Negative indirect biological effects could result if catch data used to manage the fisheries inseason were inaccurate or delayed such that fishery specifications could not be adequately monitored or the fishing stopped before one of the fishery specifications were exceeded.

If a fishery specification for precautionary zone and healthy groundfish species or species groups is exceeded, the risk to the stock is generally lower than it is for overfished species. If a fishery specification of a constraining overfished species was greatly exceeded due to unreported discarding at sea, inaccurate catch accounting, or delayed catch reporting, the risk of exceeding rebuilding-based OYs is increased. There are many variables that affect the time it takes a stock to rebuild, fishing mortality is only one of those variables. However, exceeding the rebuilding based OY could result in an extended rebuilding period for an overfished species.

4.2.2 Effects on prohibited species and protected species

Salmonids: None of the alternatives would cause additional impact to salmonids since fishing behavior is unlikely to change and fishers would be required to discard them (except shoreside and at-sea whiting catcher vessels). If other fisheries are required to retain them under Option A Maximized retention then some additional impacts may occur; however, current impacts are minimal in groundfish fisheries. The shoreside and at-sea whiting fishery operates under a limit and an EM program would not increase the limit nor cause an increase in catch rates.

Halibut: Halibut impacts are not expected to increase unless vessels are required to retain them under maximized retention, as is the current practice in the shoreside and at-sea whiting fishery. IF all catch is considered dead then impacts may reach a maximum but would not exceed current IBQs and catch allocations for each sector. If vessel continue to discard them and current IPHC halibut mortality rates are applied then impacts would likely be similar to the status quo. Several options for discard mortality and retention are identified but are not yet analyzed yet: Using WCGOP scientific observations (assumed 20-30% coverage) is applied to fleet (Option B**),** captain and crew provide assessment (Option D), an appropriate EM viability assessment (Option E), or vessel specific viability assessment (Option F).

Marine Mammals: The alternative actions are not likely to affect the incidental mortality levels of marine mammals over what has been considered in previous NEPA analyses.

Seabirds: The alternative actions are not likely to affect the incidental mortality levels of seabirds over what has been considered in previous NEPA analyses.

Sea Turtles: The alternative actions are not likely to affect the incidental mortality levels of sea turtles over what has been considered in previous NEPA analyses.

Endangered Species: The alternative actions are not likely to affect the incidental mortality levels of endangered species over what has been considered in previous NEPA analyses.

4.3 Effects on the Socioeconomic Environment

This section of the EA looks at direct and indirect impacts, positive and negative, on the socio-economic environment. Basic information regarding the people and the fisheries that are projected to be affected by the management alternatives will be presented in Chapter 3. The following section differs from Chapter 3 in that it discusses what is projected to happen to the affected people and fisheries as well as what social changes are expected to occur, and, how changes are expected to affect fishing communities.

In this section, the primary impact mechanisms that will be traced through to their socioeconomic effects are:

- Increased retention of unwanted fish
- Replacement of human compliance observers with electronic monitoring, on a voluntary basis
- New onboard catch handling restrictions (e.g. ensuring adequate quality camera capture of any discards)
- Other new data collection activities (e.g. discard logbooks)
- New data processing related tasks (e.g. data retrieval and video review)
- Changes in the configuration of the shoreside monitoring task (e.g. use of catch monitors present in the port rather than relying on observers)
- New and changing distribution of responsibility for paying for various tasks (e.g. payment for at-sea biological observations, payment for video review)

One of the main impacts of the alternatives that runs through all sectors, including the government sector, is the impacts on the direct costs of the compliance and biological monitoring programs. For that reason, this section will start with an assessment of the direct compliance and biological monitoring costs of the alternatives followed by a full evaluation of the impacts to each sector.

4.3.1 Analysis of Program Costs for Compliance and Biological Monitoring

A complete assessment of costs is underway and is expected to be completed in the summer of 2014. Contributions to the cost assessment have been requested from NMFS WCR and NWFSC as well as PSMFC. There will be some significant uncertainties in that assessment including uncertainties about

1. EM program participation rates in aggregate and by port
2. Additional fleet consolidation
3. Organization of the shoreside monitoring function

4. Changes to fees charged by providers for compliance observers and shoreside catch monitors

The outcome for some of these uncertainties will depend on how fishery participants respond to the program. To deal with these some of these uncertainties, ranges of estimates will be developed and some results may be presented qualitatively, or quantitatively but with out dollar values assigned.

Others uncertainties depend on the eventual design of the program. There are also a number of decision points that will affect the cost estimates and distribution of costs. A few of the more significant ones may be

1. Who will retrieve data from vessels
2. Whether all video must be reviewed (Alternative 1) or only a percentage of it (Alternative 2).
3. What amount of discarding will be allowed (and hence the video that must be reviewed more carefully reviewed)
4. Who will carry out the video review function
5. Who will pay for the video review function

Note: The following analysis has not yet been fully reviewed by the Groundfish Electronic Monitoring Technical Advisory Committee.

4.3.1.1 Assumptions

Participation Rates

On one of the most important factors – EM participation rates – a range of working assumptions is being considered on a preliminarily basis. **Comment on this range is sought at the June Council meeting.**

Table 4-2. Preliminary working assumptions on rates of vessel participation in the EM program.

Low Rate	Medium Rate	Higher Rate
20	50	80

Fleet Consolidation

Under the No Action Alternative, there may be further fleet consolidation as a continuation of the rationalization process started with the implementation of Amendment 20 in 2011. While there has already been some consolidation, additional consolidation might be expected with the start of QS trading and as subsidies for observer fees end. It would be expected that if the action alternatives have a substantial effect on vessel operating costs there might be an effect on fleet consolidation. The amount of consolidation expected is extremely difficult to predict and it is possible that there would be no additional consolidation under No Action. On this basis, no attempt will be made to model additional fleet consolidation but the possibility or such consolidation will be covered in the discussion of results and discussion of the impact on fishery participants.

Other Assumptions

Other assumptions will be identified and specified as the analysis is further developed.

4.3.1.2 Cost Categories

For purposes of developing the analysis, costs have been broken out into the categories provided in Table 4-3. It may be necessary to develop cost estimates in two fashions: one for implementing a program for all sectors at one time and another for implementing the program for one or two sectors, with an assessment of the incremental costs for adding sectors at a later time. Costs may vary in important ways depending on how many sectors are covered at one time.

Table 4-3. Cost estimation template.

a/ PSMFC trains the catch monitors and processes the reports they generate. These costs are covered by a government contract.

b/ Values provided here are based on PSMFC's study and include time identifying retained species, which may not be necessary if cameras are only being used for discard monitoring. Additionally, these cost estimates do not take into account other operational modifications that vessels may be able to make to reduce video review time.

c/ Catch monitoring costs are implicated since observers will no longer be available to move shoreside and handle catch monitoring responsibilities.

d/ The video review costs do not go down by 80 percent in moving from the 100% video review of Alternative 2 to the 20% video review of Alternative 3, because 20% is the minimum level of review permitted (1 of 5 hauls, or 2 of 10). A minimum of one haul must be reviewed from each trip. If the trip has less than 5 hauls, one haul will always be algebraically more that 20% of the trip. E.g., a trip that has a total of three hauls will always have 1 haul reviewed. 1 haul of a total of 3 is 33%, not 20%. Similarly, if a vessel fishes 12 hauls on a trip, 3 hauls will be reviewed. 3 of 12 is 25%. Additionally, a fixed cost of one half hour per trip was added to the review time to cover the time it takes to handle the drives and identify trips and hauls from the sensor data. An additional one half hour added to the time would further increase the cost from a directly proportional time per haul calculation.

Government Policy Development, Implementation and Administrative Costs (Across Categories)

Government costs have been broken out into a number of categories for purposes of completeness. However, the categories may be rolled up and a single estimate provided for the program as a whole. Under the action alternatives, program planning and administrative costs will be required for tasks such as developing criteria for and then approving individual vessel monitoring plans and electronic monitoring equipment; organizing the retrieval, transmission, and storage of data from the field; coordinating the video review function (whether carried out as a government or contractor activity); summarizing and responding to data requests; developing and implementing observer deployment and sampling plans to collect biological data given only partial at-sea coverage by compliance monitors. Depending on the amount of participation in the EM program, there may be a need to develop a new system for vessels to provide advance notification of trip. There may also be an addition to the costs for data summary and analysis as a result of the need to develop statistical estimates (there is currently a census) and to incorporate information from the EM system as a way of improving those estimates. Total observer training, debriefing, gear and equipment costs may decline with fewer observers but average costs could increase.

Under the action alternatives, government costs will likely vary depending on the sectors and gears covered by the alternative adopted. With respect to program development and planning costs, it may be that once a program is developed for one sector, the additional costs for adding other sectors will be lower. Some of the ongoing costs of administering the program are likely to vary by the number of participants, which will be a partial function of the sectors and gears covered. The government costs associated with the EM program might be considered costs associated with a LAPP in which case those costs would be recoverable through fees of up to three percent of total exvessel value (maximum on total cost recovery for the trawl rationalization program as a whole). The shorebased IFQ sector is already being charged the maximum 3 percent fee, therefore any increases in government costs will have to be covered from other sources. The mothership sector is being charged less than the three percent maximum, therefore it might be that some of the government costs associated with the program can be passed through to the industry. It should be noted that for the WCGOP there may be some administrative savings as a result of managing fewer observers. An assessment will be required to determine whether these savings are greater than the expected cost increases associated with the EM program.

Electronic Monitoring

Video Review Costs

Under the action alternatives there would be a new cost for video review that is not present under the No Action Alternative. It has not been determined who would bear the video review costs. Estimates have been developed for the cost of video review time during initial catch retrieval and sorting. These are displayed in Table 4-3. These estimates currently include time required to identify catch being retained. Time required for video review may be less than these estimates if only discard events have to be evaluated for species identification. Additionally, other innovations could be developed which speed video review time.

Vessels need to be monitored for discard events for the entire time fish are onboard the vessel until they are offloaded. This costs is not included in the current video review time estimate. It may be possible that video review between catch sorting activities and arrival in port may be assisted through programming software that identifies video segments where back deck activity is occurring, thus reducing the amount of transit video that needs to be reviewed. Other technologies such has hatch sensors may be useful in increasing the efficiency of reviewing video.

Logbooks (Alternative 2 Only) and Fish Tickets

Logbook reporting requirements would not change under Alternative 1. Under Alternative 2 fishermen would be required to report discards by species and provide an accurate estimate of the weight. This will require the creation of logbooks for certain fisheries. The current state trawl logbook for midwater and bottom trawl activity would need to be modified to include species discard categories with instructions. This would require additional fields in the Pacific Fisheries Information Network (PACFIN) reporting system and may require additional changes to state computer reporting systems. Potential changes to existing logbook system are described in the Table 4-4.

Table 4-4. Potential changes to logbooks or additional logbooks for each fishery under Alternative 3.

Key: MDTW = midwater trawl, LL = longline, BTW = bottom trawl

Fishery/Gear	Additional data fields	Changes to state system	Changes to PACFIN
Whiting/MDTW	Estimated Pounds Discarded Each Tow	Yes if state wants/required to track	Yes if discard info is provided to NMFS via PSMFC, may need to apply species comp to estimated total discard to get individual species discards
Non-whiting/ MDTW; BTW	Estimated Pounds Discarded Each Tow	Yes if state wants/required to track	Yes if discard info is provided to NMFS via PSMFC, may need to apply species comp to estimated total discard to get individual species discards
Fixed gear/LL and Pot	May not need changes for Oregon fixed gear logbook; California trap log – add discard field; Need to develop a logbook for Washington.	Yes if state wants/required to track	Yes if discard info is provided to NMFS via PSMFC; changes to accommodate California and Washington data.

Under each of the alternatives, first receivers in the states of Washington and California would continue to complete and submit the required paper fish tickets on forms as required by the state of landing. In the State of Oregon, first receivers would either complete paper fish ticket forms provided by the state, or computer generated tickets providing they contain all data fields specified in state law. State requirements for fish ticket submissions would not be changed under any of the proposed alternatives.

Additional Sections to be Developed

Biological and Compliance Observers

Prior to the trawl rationalization program approximately 20 to 25 percent of the trips were covered with government paid biological observers. Under the trawl rationalization program industry paid compliance observers have also filled the biological observer function. Under the No Action Alternative this would be expected to continue with no change. Under either of the Action Alternatives, biological observer coverage would be required to sample the catch and collect other data at-sea on a randomly distributed sample of trips by vessels participating in the EM program. A determination will be needed on who pays for the observers used in the new biological sampling regime under EM: Would the vessels pay or would government payment for observers resume? Depending on that determination, there may be a new government cost for the biological observers replacing the compliance observers paid for by industry or the industry might pay some costs for the biological observers, in addition to the EM costs.

In the past, biological observers for the trawl fishery were provided by largely the same companies that currently provide the compliance observers; and the training for both types of observers is quite similar. Under the action alternatives, the total demand for observers will likely be reduced; the demand for compliance observers will go down, mitigated to some degree by an increase in demand for biological observers. The reduction in overall demand is likely to result in an increase in the per-day-at-sea price for observers. There may also be a reorganization of the shoreside monitoring tasks such that it is no longer carried by observers once they reach port. Such a reorganization, by reducing the revenue an observer provider generates with an observer already in place in the field, could cause providers to have to increase prices to maintain a reasonable profit margin.

Shoreside Catch Monitors

It is expected that the organization and total costs associated with the shoreside catch monitoring program would change with the implementation of any of the action alternatives. Currently the catch monitoring function is generally carried out by the at-sea observers who, upon arriving in port, go to shore and fulfill the monitoring function at first receiver site. The shoreside catch monitoring task might take an hour or two or a half-day or more to complete, depending on the type of delivery. This would be expected to continue under the No Action Alternative. Under the action alternatives, to the degree that vessels opt into the EM Program, observers would not be available to fulfill this function and other arrangements will have to be made. This reorganization of the shoreside monitoring task is expected to impact provider fees for catch monitors and observers as well as catch monitoring program administrative costs, and gear and equipment costs.

Effect on Catch Monitoring and Observer Costs

The impact on catch monitoring and observer costs will depend on the EM program participation rates, how industry decides to organize itself to fulfill this function, and how government functions are organized. Observer time fulfilling the shoreside monitoring function is paid by the first receiver, rather than the vessel. The fees providers currently charge for catch monitoring services are influenced by the efficiencies related to having an observer fulfill the shoreside catch monitoring function and might be higher if the catch monitoring function were fulfilled by shorebased personnel, particularly in ports where this is not enough demand to support a full time catch monitor.[3] If some vessels are not carrying observers, a shoreside monitor will need to be in the port to cover a task which may only be a few hours in duration. Depending on the number of landings in the port or port region and the number of those landings without observers to cover the shoreside monitoring function, the task might need to be handled by a part time monitor or a monitor travelling in from another region. Anecdotally it has been reported that for remote ports with a small number of landings that the costs of servicing the ports with observers has been problematic. This challenge might be even greater when a catch monitor is needed in a port for only part of a day. Variable EM participation will create logistical challenges in organizing this task and add to the need for advance planning, particularly if there are only one or two catch monitors covering a region. First receiver cooperation in timing of offloads and sharing of catch monitors would also affect the number of monitors that need to be available and related costs. First receivers and providers might decide to organize the shoreside function by largely ignoring opportunities for utilization of the at-sea observers in this capacity and relying only on "dedicated shoreside monitors". Unless there are a large number of landings in a particular port or port area, or catch monitors are able to fulfill some other program functions when not observing offloads, it seems likely that the average catch monitoring field costs (labor, transportation, etc.) are likely to be higher than under the current system where the at-sea observer fulfills the shoreside monitoring function. First receivers in ports in which there are a large number of landings, may gain some additional measure of advantage over first receivers in smaller more isolated ports, if their volume of landings allows them to achieve lower average catch monitoring fees. While the current practice is that first receivers pay the shoreside monitoring fees, increased fees could affect the exvessel prices first receivers are willing to pay for deliveries. Current rates that providers charge for the catch monitoring tasks are provided in Table 4-5.

Table 4-5. Current provider fees for catch monitoring services.

Reorganization of the catch monitoring task could also exert an upward influences on the prices vessels pay for observers, since providers will no longer be able to cover some of the logistics

[3] Analyst's conclusion based on personal communications with Alaska Observers Inc and Saltwater Inc on May 27, 2014.

related costs of placing observers in the field with revenue from fees charged when observers fulfill the catch monitoring function.

By Port Demand for Catch Monitoring Services

Catch monitoring costs will be influenced by the demand for services in a port or port region. The by-port demand for catch monitoring services will be a function of the number of vessels in a port participating and not participating in the EM program; the number of first receivers in a port and their ability to coordinate landings with vessels and with one another; and the total number and seasonality of landings. Additionally, geographic proximity to other ports and related travel time and costs will determine the opportunity first receivers have to pool together with other ports to generate greater demand and potentially lower prices.

This section provides information on the distribution trawl IFQ program of landings, vessels, and first receivers across ports from 2011 through 2013 (Figure 4-1 through Figure 4-3 provide annual data and Figure 4-4 though Figure 4-19 provide monthly data). Annual values are also broken out by IFQ gear sector: nonwhiting trawl (may include some vessels using midwater trawl to catch whiting, whiting trawl (vessels using midwater trawl used to target whiting) and nontrawl (vessels using non-trawl gears to participate in the trawl IFQ program). Monthly figures do not provide IFQ gear sector break outs. The reader should be aware that the scale of the axis for landing counts for Oregon ports is larger (going to a maximum of 250) than for Washinton and California (going to a maximum of 50). Other than that, the same scales are maintained between graphs to facilitate comparisons between ports. In Westport, in one month the number of landings exceeded the scale provide (a total of 51 landings were made, as noted on the graph). Table 4-6 provides a key to the port abbreviations used in the annual tables.

The following summary is based on the 2011 to 2013 annual and monthly landings by port in Figure 4-1 through Figure 4-19. Bellingham is geographically isolated from other ports and has very low levels of landings spread through most of the year. Westport has high levels of landings but they are seasonal and dominated by whiting. Covering off–season landings might be problematic and it could become much more difficult to cover Westport with catch monitors if vessels in the whiting fishery were able to participate in EM but not vessels in other IFQ gear sectors. Ilwaco has a lower level of demand for catch monitors but may benefit by its proximity to the high demand port of Astoria. Astoria has the highest demand for catch monitoring along the coast and has high demand for coverage of both whiting and nonwhiting landings. Newport also has high demand for coverage of whiting landings but much lower for nonwhiting landings (comparable to Ilwaco and Brookings). Other than Astoria, Coos Bay, Eureka, and Fort Bragg have the highest annual demands for coverage of nonwhiting landings. If the 2011 to 2013 trend in Crescent City continues, it will likely fade out as an IFQ port. As mentioned above, the landings showing for Bodega Bay and Berkeley appear to be coding errors and will be removed from the next draft of this document. The other active ports from San Francisco south (San Francisco, Half Moon Bay, Monterey, Moss Landing, and Morro Bay) have generally lower numbers of nonwhiting landings than ports to the north with the exceptions of Crescent City, Westport, and Bellingham. Landings for 2011 in Half Moon Bay and 2012 in Morro Bay might be the exceptions. Avila appears to have faced out as an IFQ port.

There is some degree of seasonal variations in the landings of most every port. In six of the fifteen ports in which there were landings in 2013,[4] there were at least some months in which there were no landings (Bellingham, Westport, Brookings, Crescent City, Half Moon Bay, and Monterey, Table 4-7). For months in which fishing occurred, there were fewer than an average of five landings a month in 2013 in Bellingham, Crescent City, San Francisco, Monterey, and Moss Landing. There was an average of between six and ten landings a month for months fished in 2013 in Ilwaco, Brookings, Eureka, Fort Bragg, Half Moon Bay and Morro Bay. There were an average of 16 per month in Westport and Coos Bay, but seasonality was much heavier in Westport than Coos Bay. The greatest averages were in Astoria (56 per month) and Newport (50 per month). Demand and seasonality in Westport and Newport are heavily influenced by the whiting fishery. Footnotes in Table 4-7 provide information on the travel time between ports.

Table 4-6. Key to port abbreviations.

Port Abbreviation	Port
BLL	Bellingham, Washington
WPT	Westport, Washington
ILW	Ilwaco, Washington
AST	Astoria, Oregon
NWPT	Newport, Oregon
COS	Coos Bay, Oregon
BRK	Brookings, Oregon
CC	Crescent City, California
ERK	Eureka, California
FB	Fort Bragg, California
BDG	Bodega Bay, California
SF	San Francisco, California
B	Berkeley, California
HLF MN	Half Moon Bay, California
MNT	Monterey, California
MOS	Moss Landing, California
MOR	Morro Bay, California
AVL	Avila, California

[4] Of the 16 ports in Table 4-7 only Avila had no 2013 landings.

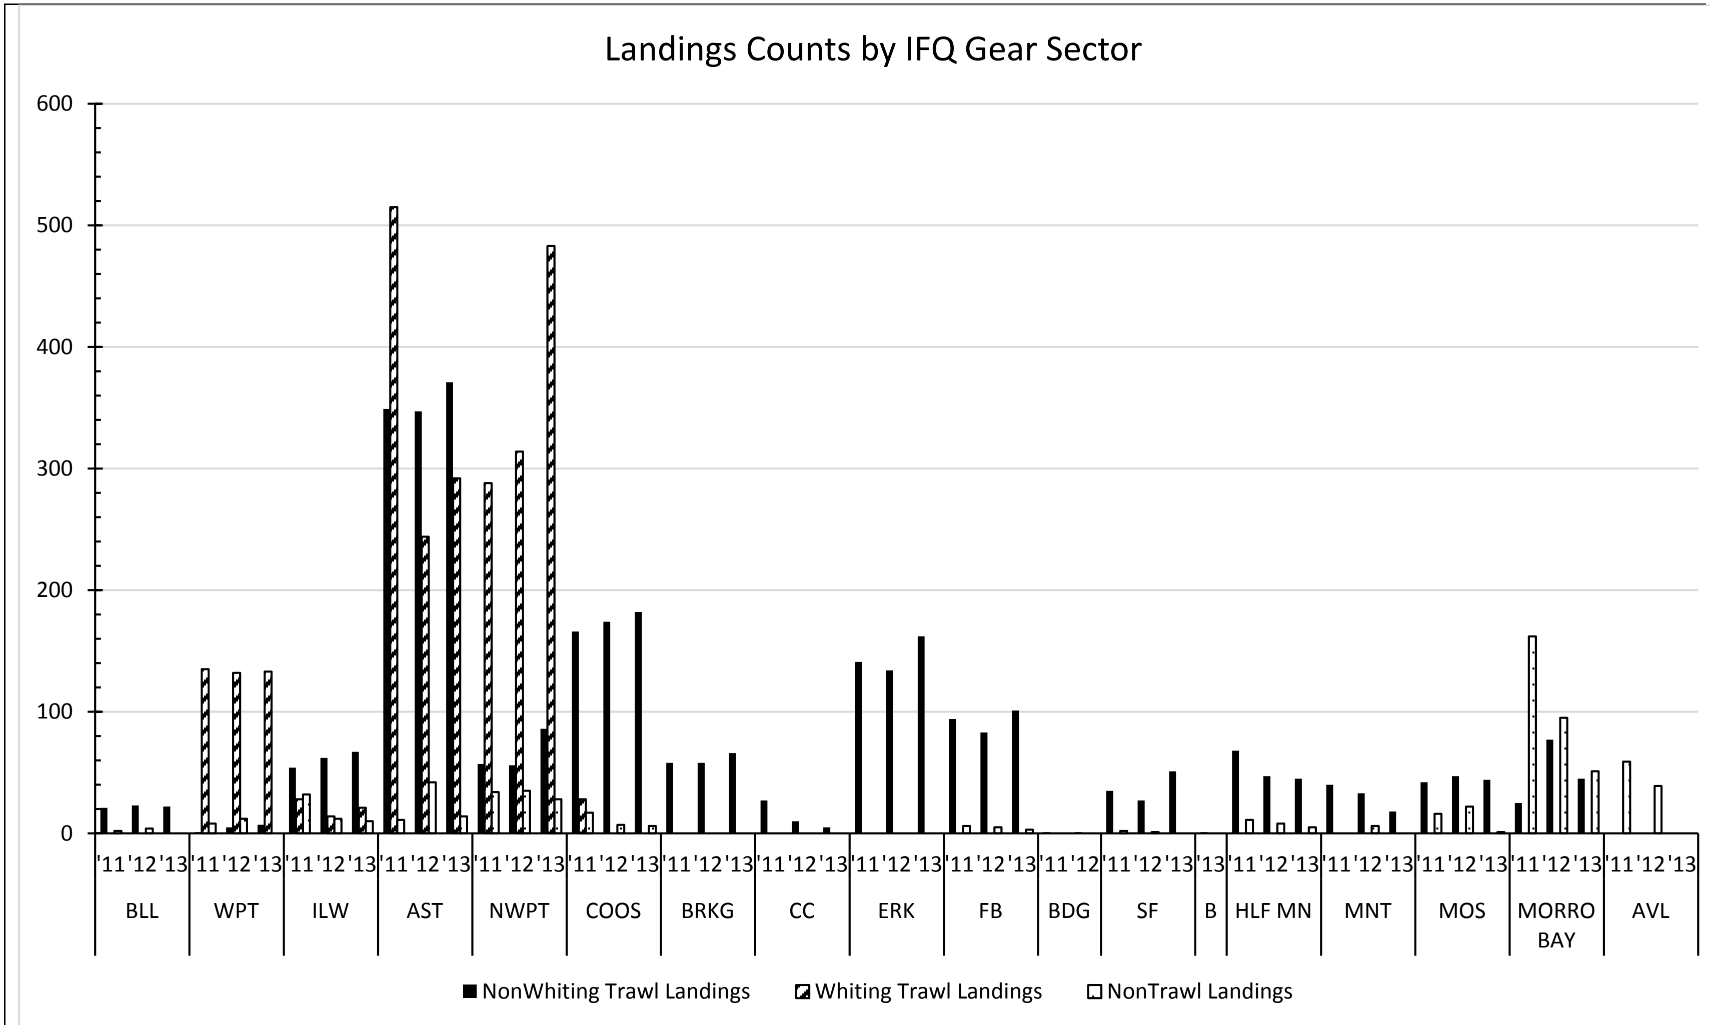

Figure 4-1. Number of nonwhiting trawl, whiting trawl, and nontrawl IFQ landings by port for 2011, 2012, and 2013 (see Table 4-6 for key to port names)) – there are no first receives in Bodega Bay (BDG) or Berkeley (B) therefore the landings reported for these ports are likely miscodings.

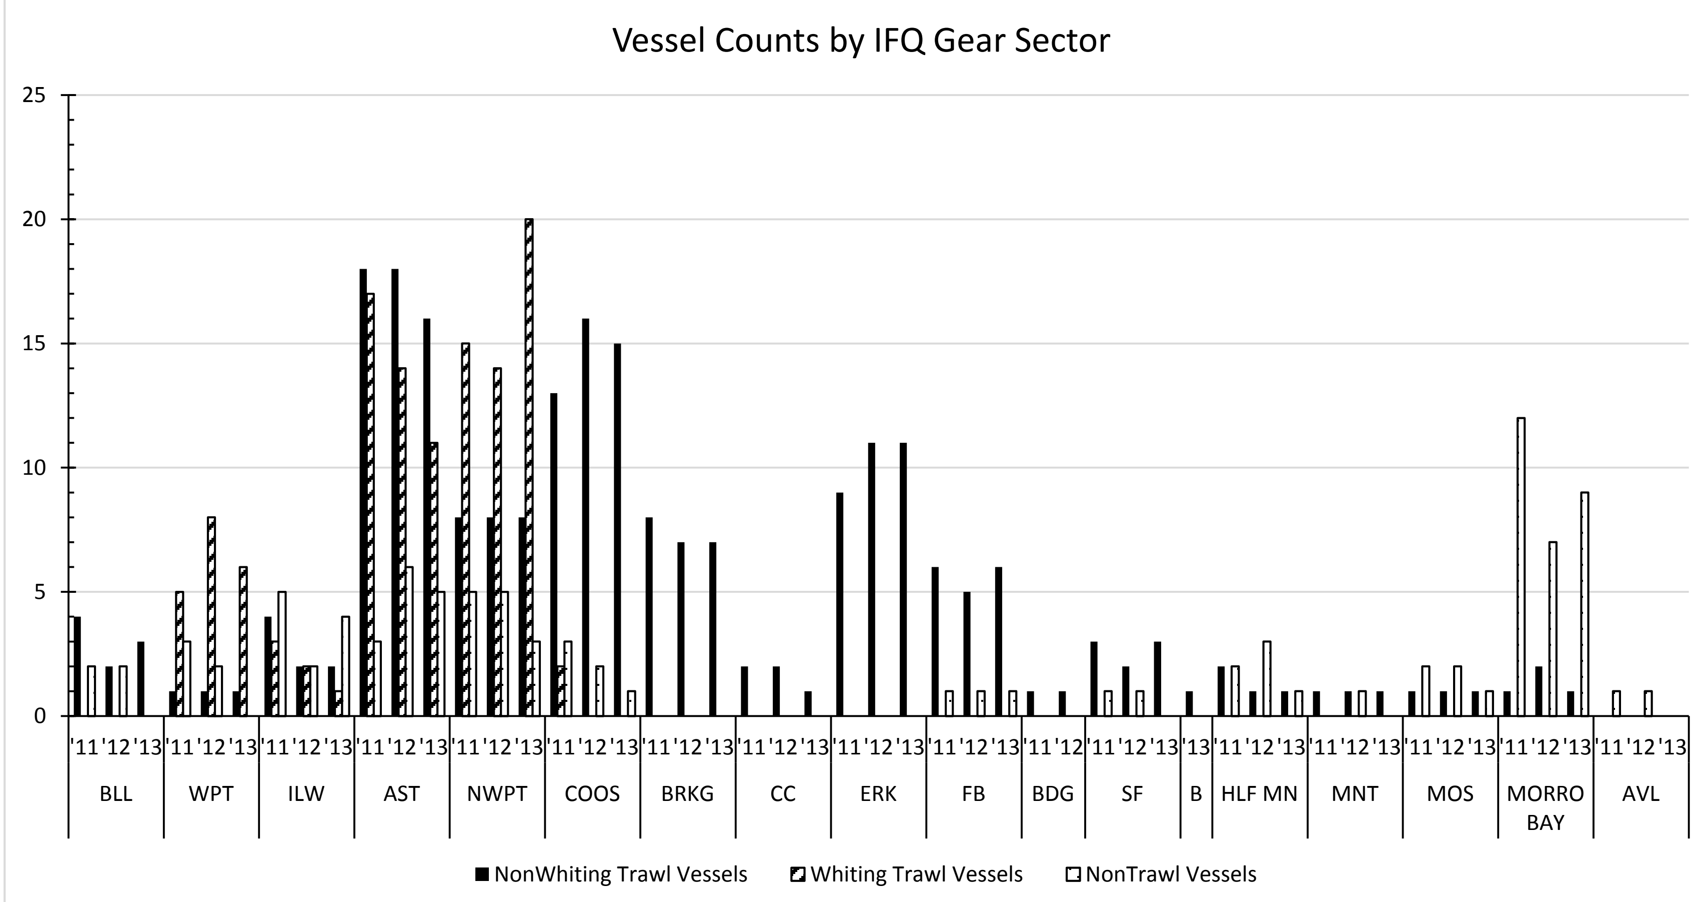

Figure 4-2 Number of nonwhiting trawl, whiting trawl, and nontrawl IFQ vessels by port for 2011, 2012, and 2013 (vessels participating in more than one IFQ gear sector or landing in more than one port are counted more than once, see Table 4-6 for key to port names)) – there are no first receives in Bodega Bay (BDG) or Berkeley (B) therefore the landings reported for these ports are likely miscodings.

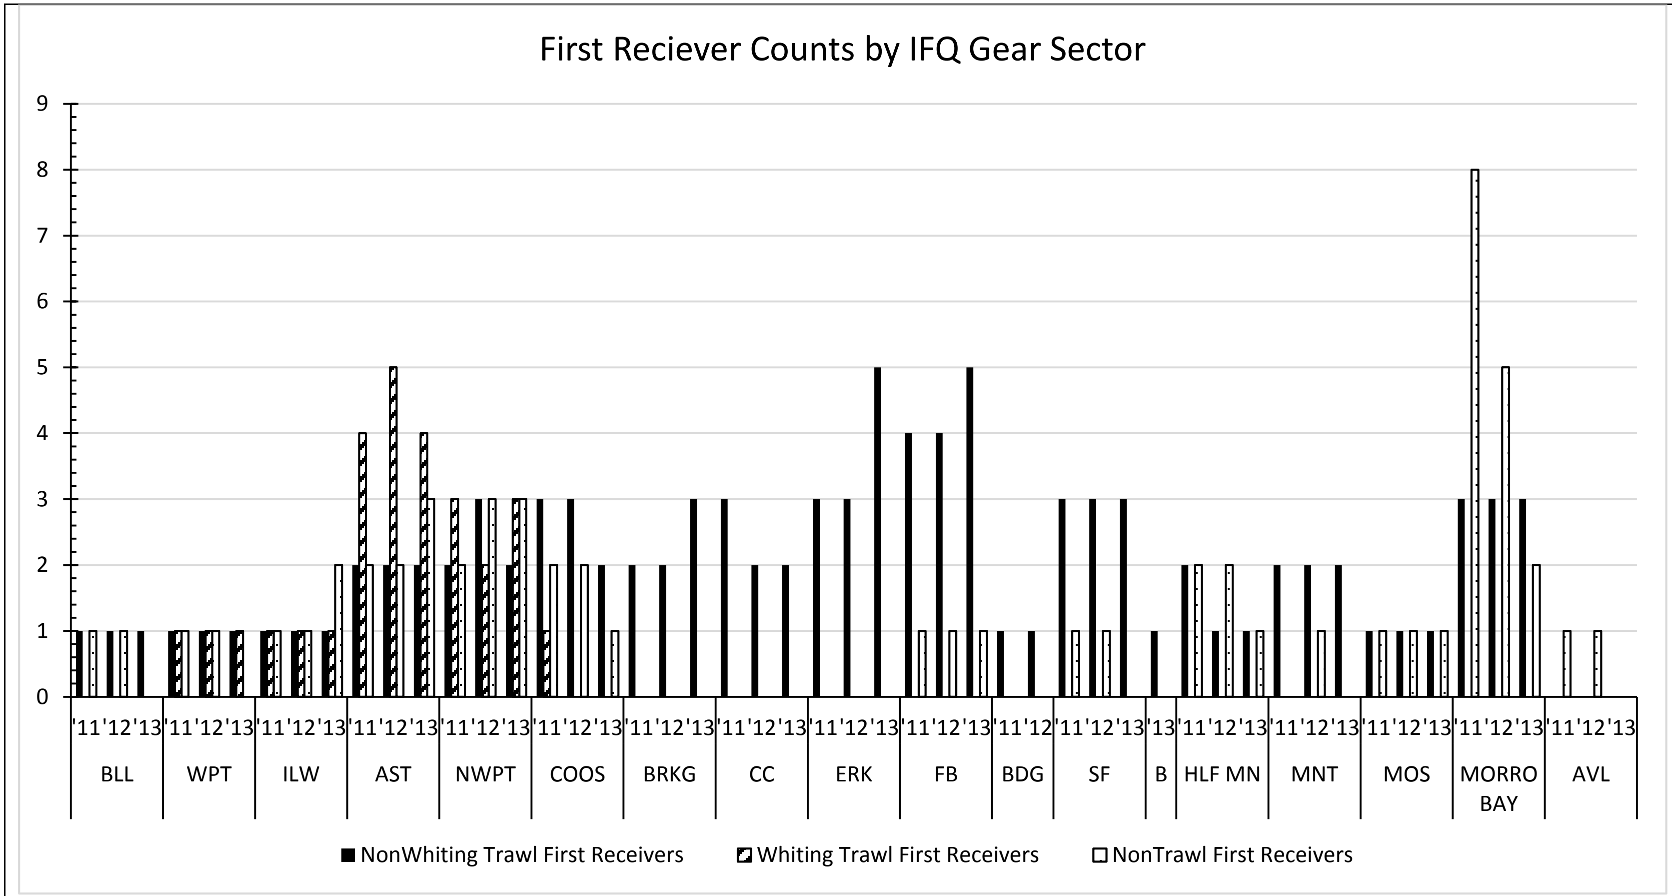

Figure 4-3 Number of nonwhiting trawl, whiting trawl, and nontrawl IFQ first receivers by port for 2011, 2012, and 2013 (first receivers receiving from more than one gear group are counted more than once, see Table 4-6 for key to port names) – there are no first receives in Bodega Bay (BDG) or Berkeley (B) therefore the landings reported for these ports are likely miscodings.

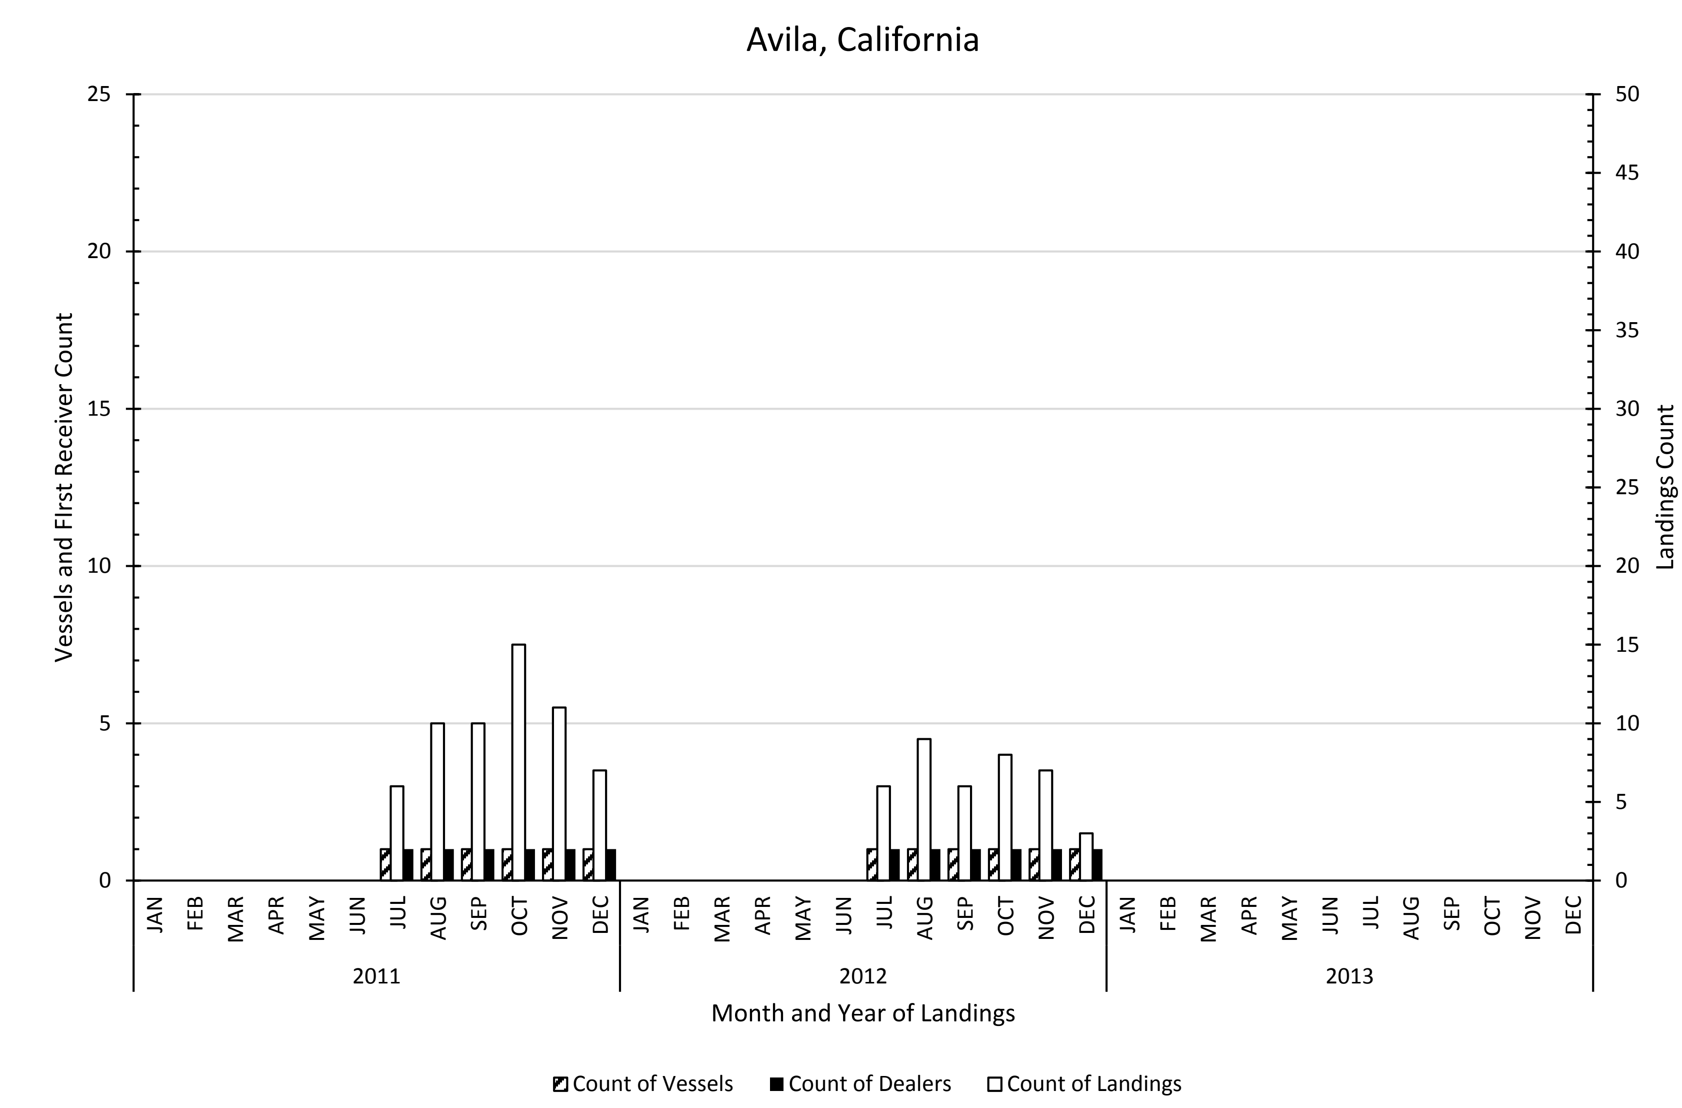

Figure 4-19 Avila, California, counts of vessels, dealers and landings by month for 2011 through 2013 (includes nonwhiting landings only – no whiting landings were made to this port).

Government Costs for Catch Monitors

Currently, in addition to observer training with the NWFSC, most every observer goes to a separate training with PSFMC to learn how to fulfill the shoreside catch monitoring function. Catch monitors are able to use the equipment provided by the NWFSC to fulfill their shoreside monitoring tasks. The PSMFC checks data quality of the reports submitted by catch monitors on a bimonthly basis and debriefs catch monitors annually. The costs of training and debriefing are covered through a government contract. This would likely continue to be the case under the No Action Alternative.

Under the action alternatives, if the shoreside catch monitoring task is reorganized to use monitors dedicated to only shoreside activities fewer shoreside monitors would be needed to fulfill this function. This could result in a reduction in the total number of shoreside monitors that need to be trained on an annual basis and possibly a reduction in debriefing time. The administrative effort for the bimonthly quality checks would be relatively unaffected, assuming that there is no change in the total number of landings. There is no reason to believe there would be substantial differences between the action and no action alternatives.

Table 4-7. PREIMINARY assessment of challenges with providing catch monitoring in each port based on seasonal landing patterns (summary of data in Figure 4-4 through Figure 4-19).

Port	Assessment of CM Needs Based on Number of Landings (averages are for months with landings – zero months excluded)	PRELIMINARY Assessment of Feasibility of Dedicated Shoreside Monitoring With Current Practices
Bellingham, Washington	Occasional seasonal (Oct-May). In 2013, an average of 2 per month, max of 4 and minimum of 1 (3 zero months).	[i]
Westport, Washington	Regular seasonal (June through November). In 2013, an average of 16 per month, max of 39 and minimum of 2 (3 zero months).. The whiting fishery is the source of the vast majority of the landings see Figure X-X.	[ii]
Ilwaco, Washington	Year round part time with seasonal peaks. In 2013, an average of 8 per month, max of 16 and minimum of 1 (no zero months).	[iii]
Astoria, Oregon	Year round full time (possibly), with season peaks. In 2013, an average of 56 per month, max of 136 and minimum of 19 (no zero months).	
Newport, Oregon	Seasonal full time and year round part time. In 2013, an average of 50 per month, max of 153 and minimum of 4 (no zero months).	[iv]
Coos Bay, Oregon	Consistent, year round part time. In 2013, an average of 16 per month, max of 27 and minimum of 3 (no zero months).	[v]
Brookings, Oregon	Consistent, year round part time – very low. In 2013, an average of 6 per month, max of 12 and minimum of 3 (1 zero months).	[vi]
Crescent City, California	Very low brief seasonal. In 2013, an average of 2 per month, max of 3 and minimum of 1 (9 zero months).	[vii]
Eureka, California	Consistent, year round part time with seasonal peak. In 2013, an average of 9 per month, max of 26 and minimum of 14 (no zero months).	[viii]

Port	Assessment of CM Needs Based on Number of Landings (averages are for months with landings – zero months excluded)	PRELIMINARY Assessment of Feasibility of Dedicated Shoreside Monitoring With Current Practices
Fort Bragg, California	Year round but very low demand in winter months. In 2013, an average of 9 per month, max of 18 and minimum of 2 (no zero months).	[ix]
San Francisco, California	Year round low level, small seasonal increase in the summer In 2013, an average of 4 per month, max of 9 and minimum of 1 (no zero months).	[x]
Half Moon Bay, California	Low level seasonal demand May through October In 2013, an average of 6 per month, max of 11 and minimum of 2 (4 zero months).	[xi]
Monterey, California	Relatively consistent low level demand, ending June 2013. In 2013, an average of 4 per month, max of 6 and minimum of 2 (6 zero months).	[xii]
Moss Landing, California	Relatively consistent low level demand. In 2013, an average of 4 per month, max of 6 and minimum of 3 (no zero months).	[xiii]
Morro Bay, California	Year round variable demand. In 2013, an average of 8 per month, max of 20 and minimum of 3 (no zero months).	[xiv]
Avila, California	July thru Dec low level landings in 2011 and 2012. No landings in 2013.	[xv]

[i] Problematic because of seasonality, low demand and isolated relative to other fishing ports.
[ii] Some low demand in shoulder seasons, might be met with catch monitors from the Columbia River area. There might be enough demand from June through October to support a catch monitor and requirements for a second person during peak months, particularly if offloading is continuing for more than 8 to 12 hours a day.
[iii] Proximity to Astoria might make fulfilling the catch monitoring function more feasiable.
[iv] During seasonal peaks there would not appear to be a problem, assuming vessels and first recievers are able to coordinate the timing of deliveries. Off season would require part time only.
[v] Might be possible with a year round part time catch monitor.
[vi] Might be possible with a year round part time catch monitor.
[vii] Possible with coverage travelling in from Eureka. Travel time 1 hr 34 minutes. Appears to be disappearing as a trawl port.
[viii] Would require part time coverage year round. Seasonal peak might be covered with only part time coverage.
[ix] Very part time work in the winter.
[x] Possible if same part-time catch monitor could cover other bay area ports, including Half Moon Bay.
[xi] Possible if same part-time catch monitor could cover other bay area ports.
[xii] Possibly a part time individual might cover both Monterey and Half Moon Bay – driving time 27 minutes.
[xiii] Twenty minute driving time from Moss Landing to Monterey.
xiv Two hour 20 minute driving time from Moss Landing to Morro Bay.
[xv] 27 min driving time from Moss Landing to Avila.

4.3.2 Trawl IFQ Program Fishing Operations (Harvesters)

This section considers the impact of no action and the action alternatives on fishing operations/harvesting businesses. These entities are defined by their operation of a vessel, whether access to the vessel is acquired through vessel ownership or lease. Separate discussion is provided with respect to potential impacts on other types of fishery participation: quota share ownership, vessel ownership for purposes of leasing, crew and vessel operators, etc.

With respect to fishing operations, the main impacts that will be considered are as follows:

1 Change in Operating Costs
2 Change in Operational Flexibility

3 Change in Privacy

4.3.2.1 No Action Alternative

Under the no action alternative, the current Federal subsidy for observers is likely to run out in the next year or two. With the end of this subsidy, the increased financial costs may lead to an increase in consolidation within the fleet, resulting in fewer fishing vessels. Additionally, the impacts of the cost increases may be greater for vessels which have lower net revenue per day of fishing than vessels with higher net revenue per day. Observer costs which are a fixed cost for each day of fishing will erode a greater proportion of the profits of lower net revenue per day vessels than higher net revenue per day vessels. Depending on cost structures this could change the nature of the fleet. For example if smaller vessels also tend to have lower net revenue per day then the number of smaller vessels in the fleet may diminish. Or if vessels operating along a particular area of the coast have lower net revenue per day then those vessels may sell their quota to vessels operating on other regions of the coast.

4.3.2.2 Action Alternative

For both those who participate and do not participate in the EM program, costs are likely to be higher if some sectors of the fleet are covered by EM while others are not (as compared to a system where all sectors are covered at the same time). Also, the lower the participation rate in the EM program the higher the likely per fishing day costs of the program; and similarly the lower the participation rate in the at-sea compliance monitoring program, the higher the likely per day fishing costs for those carrying compliance observers.

Effects on Participants in the EM Program

- Elimination of observer costs
- New costs for electronic equipment (acquisition and maintenance)
- New costs for servicing (retrieving and transmitting/transferring data) (responsible party still to be determined)
- New costs for video review (responsible party still to be determined)
- New costs for disposal of unwanted retained fish
- Increased operational flexibility with respect to departure and duration of fishing trip
- Decreased operational flexibility with respect to discards (until camera technologies improve)
- More constraints on fish handling on the vessel, potentially reducing efficiency (to ensure good camera images, including a possible requirement for the use of discard chutes).
- More privacy with respect to potential observer presence throughout the ship and privacy related to factors other than visual images
- Less privacy with respect to constant video surveillance within camera range
- Reduction in available hold space for a maximized retention fishery
- Problematic mixing of species (e.g. retained dogfish may have adverse impact on product quality if kept in the same hold with other fish).

- Time required to fill out logbooks (Alternative 2 only
- To the degree that discards are allowed, crew members may need to become more proficient in species identification, including juveniles and flatfish species for which species identification can be more problematic.
- There may be application fees associated with the individual vessel monitoring plans that vessels would be required to acquire.

In addition to these factors, the consistency of EM programs between fisheries (especially between the West Coast and Alaska) will have an impact on costs (e.g. if each fishery has different camera and logbook requirements then costs would be higher than they might otherwise be).

Federal permits and endorsements*:* Under all of the alternatives, vessels participating in the IFQ fishery must be registered to a limited entry permit with a trawl endorsement. In 2013, the cost to renew a limited entry permit with a trawl endorsement was $152.00. Under Alternatives 2 and 3, the costs for limited entry trawl permits with trawl endorsements are expected to remain relatively unchanged, with only minor upward adjustments being made if administrative costs increase.

Effects on Those Not Participating in the EM Program

- Potential increase in per day observer costs
- The current pool of funds for observer cost subsidies may last longer if there are fewer vessels drawing on it and that money is not reprogrammed to other types of reimbursements.

4.3.3 Quota Share Owners

Under an IFQ program, on average over the long-term, the fishing operations are expected to make zero economic profit, which is a technical way of saying that the industry is achieving normal profit levels. Under a normal profit situation, QS owners will capture any unexpected economic profits (above normal profits) which occur from changing conditions in the fishery, e.g. unexpected increases in exvessel prices would increase QS value and unexpected increases in fuel costs would decrease QS value. If the EM program reduces operational costs a portion of that reduction will be capitalized in the value of the QS, increasing the costs to subsequent entrants such that their costs are more likely to be at normal profit levels. Absent other changes in the market place, those holding the QS at the time of the change will experience increased revenue up until they sell the QS and then a higher revenue from the sale of the QS. Under the action alternatives it is expected that the fishery will operate at normal profit levels on average over the long term with higher quota share prices than would otherwise be present. Under the no action alternative, it is expected that the fishery will operate at normal profit levels on average over the long term with lower quota share prices than would occur under EM (assuming the analysis shows that EM is less than expensive than observer coverage).

4.3.4 Vessel Owners

Vessel owners will be differentially affected depending on the vessel efficiency (net profits) on a per day basis. Those who have invested in vessels only able to generate a lower net profit per day (e.g. because of hold size) may find the value of the asset diminishes as the fixed per-day at-sea compliance monitoring costs increase, and may benefit as those costs decrease. Under No Action, per day costs are expected to increase as a result of a reduction in subsidies under. Under the action alternatives, per day costs are expected to decrease for vessels participating in the EM program (analysis has yet to determine this for certain). Also, whether the decrease will be enough to compensate for the loss of subsidies is also yet to be determined. Costs for vessels continuing to use observers are likely to increase. While some smaller vessels may have been challenged in providing space to accommodate an observer, there is no reason to expect that a vessel, because of its physical configuration, would be unable to participate in the EM program if its operator so desired.

4.3.5 Crew Members

Crew members may be directly affected by

- Changes in fish handling task
- Changes in privacy and social circumstances (cameras compared to observers)
- Changes in vessel profits that could lead to changes in crew revenue (depending on the structuring of crew payments and negotiating leverage)

Crew members may also be affected by consolidation in the fleet or a geographic redistribution of job opportunities. If EM reduces per day monitoring costs it could enhance the viability of vessels which have lower revenue per day, allowing those vessels to survive longer reducing total fleet consolidation. With respect to geographic distribution, on the one hand, EM might make it more viable to achieve at-sea monitoring out of isolated low demand ports. On the other hand, the shoreside catch monitoring function may become more difficult to fulfill in those ports, as discussed in Section 4.3.1.2.

4.3.6 Other Fisheries

Inconsistency in requirements for EM monitoring among different fisheries could make it more expensive for vessels moving between fisheries. Creating a greater cost barrier for movement between fisheries could change the competition within fisheries.

If maximized retention requirements increase the mortality of non-groundfish taken in the groundfish fishery, fishing opportunities in other fisheries could be reduced (an assessment of current bycatch information is needed to evaluate this as a possible outcome).

4.3.7 Processors

The most likely direct effect on first receivers will relate to possible changes in the costs of shoreside catch monitoring services (see discussion in Section 4.3.1.2). In that regard, first receivers in high landing ports (higher number of landings) may experience either no change or a lesser increase in catch monitoring costs than first receivers in low landing ports. This could advantage processors in high landings ports. While first receivers in low landing ports could try to pass costs on by reducing exvessel prices, the expected long-term result of such a practice would be the transfer of QS out of those ports to the higher landing ports. The need to control catch monitoring costs could encourage first receivers to coordinate with one another in

How significant is the shoreside catch monitoring cost to processors? To be developed: catch monitoring costs relative to exvessel revenue for a range of typical sized landings.

Processors may also be impacted depending on how the disposal of unwanted retained catch is handled. Whiting deliveries are already made under maximum retention rules so under either action alternative there would be no expected change in retention with respect to the whiting fishery, relative to the no action alternative.

4.3.8 EM Providers

Under status quo, EM providers have been participating in research and development work. That would likely draw to a close under either of the action alternatives if all sectors are covered by EM. Under the action alternatives, new business opportunities would be created for EM providers. Depending on businesses' strategies, the EM provider companies could be the same as the catch monitor provider companies. There are a number of different tasks that could be handled by either EM providers or Observer/Catch Monitor providers

- EM equipment, installation, and maintenance
- EM software
- Data retrieval (hard drive retrieval)
- Video review

Some of these functions, such as hard drive retrieval, might also be handled by catch monitors, state personnel, or crew members. More policy development is needed in this area.

4.3.9 Video Reviewers

The new task of reviewing video will be created. Video review might be conducted by:

- PSMFCa
- NMFS
- 3rd Party (EM Provider or Observer/Catch Monitor Provider)

Costs of review and who pays for the review may vary depending on the entity providing the services. If NMFS handles the video review task it would be difficult to create a funding mechanism by which industry would pay for the task. The maximum 3 percent of exvessel revenue fee is already being collected for the shorebased IFQ program. However, the mothership co-op program is at about 2 percent, which might leave some room for charging video for review (if the additional one percent is not taken up by other expenses related to the electronic monitoring program). If industry pays for the review there will be more private incentive for innovation to develop technologies and software to increase efficiency of the review process.

4.3.10 **Observer Providers**

A transition to EM would likely inject considerable uncertainty during the adjustment period. The demand for observer and catch monitor services will depend both on the amount of participation in the program and the at-sea biological observations contracted for by the WCGOP. The provision of shoreside catch monitoring services might present some particular logistical challenges (see Section 4.3.1.2). For ports with relatively low levels of demand for catch monitoring it may be difficult for more than one provider to service the port, affecting competition and fees. Fees for observers and catch monitors might have to increase in order to maintain a reasonable profit level.

4.3.11 **Communities**

Communities will be effected depending on the industries ability to coordinate and supply shoreside catch monitors to ports with low level and season demand. Other factors which may affect the flow of QS trading among geographic areas may impact communities. Further discussion will be developed.

Communities may also be impacted depending on how the disposal of unwanted retained catch is handled. Impacts might include odor, water usage, and truck noise. If a meal plant is installed, the retained catch may benefit the community.

4.3.12 **Government**

4.3.12.1 Federal

In addition to the direct costs of the EM program and adjustments to the program for biological observers (see Section 4.3.1.2), some of the additional costs and savings to be considered include

- Costs for increased shoreside biological sampling of retained fish (could be a state task)
- *List to be developed*

4.3.12.2 States

States might be called on for biological sampling in the ports (to replace the retained catch sampling currently conducted by at sea observers). There is a question as to whether the states could become providers for shoreside catch monitoring services. There may also be a need to modify trawl logbooks to allow the recording of discards. The logbooks used in the fishery are currently state logbooks. If the Federal requirement for recording discards is met with state logbooks there may be some additional changes required for the computer reporting system. See Section 4.3.1.2 for further discussion.

4.3.12.3 Pacific States Marine Fisheries Commission

PSMFC currently receives Federal money for training, debriefing and data quality checks for shoreside catch monitors. This contract could decrease if there are fewer catch monitors in the field. PSMFC could take on other roles in the EM system, including the role of video reviewer.

PSMFC may need to make changes to the PacFIN data system to incorporate a new discard logbook (Alternative 3).

4.4. Cumulative effects

CHAPTER 6 REFERENCES

APPENDIX A

MSA Management Standards

Table 6-1. National Standards from the Section 301 of the MSA.

NS-1	Conservation and management measures shall prevent overfishing while achieving,on a continuing basis, the optimum yield from each fishery for the United States fishing industry.
NS-2	Conservation and management measures shall be based upon the best scientific information available.
NS-3	To the extent practicable, an individual stock of fish shall be managed as a unit throughout its range, and interrelated stocks of fish shall be managed as a unit or in close coordination.
NS-4	Conservation and management measures shall not discriminate between residents of different States. If it becomes necessary to allocate or assign fishing privileges among various United States fishermen, such allocation shall be (A) fair and equitable to all such fishermen; (B) reasonably calculated to promote conservation; and (C) carried out in such manner that no particular individual, corporation, or other entity acquires an excessive share of such privileges.
NS-5	Conservation and management measures shall, where practicable, consider efficiency in the utilization of fishery resources; except that no such measure shall have economic allocation as its sole purpose.
NS-6	Conservation and management measures shall take into account and allow for variations among, and contingencies in, fisheries, fishery resources, and catches.
NS-7	Conservation and management measures shall, where practicable, minimize costs and avoid unnecessary duplication.
NS-8	Conservation and management measures shall, consistent with the conservation requirements of this Act (including the prevention of overfishing and rebuilding of overfished stocks), take into account the importance of fishery resources to fishing communities by utilizing economic and social data that meet the requirements of paragraph (2), in order to (A) provide for the sustained participation of such communities, and (B) to the extent practicable, minimize adverse economic impacts on such communities.
NS-9	Conservation and management measures shall, to the extent practicable, (A) minimize bycatch and (B) to the extent bycatch cannot be avoided, minimize the mortality of such bycatch.
NS-10	Conservation and management measures shall, to the extent practicable, promote the safety of human life at sea.

Trawl Rationalization Goals and Objectives (Amendment 20)

Table 6-2. Trawl Rationalization goals and objectives from Amendment 20.

Goal *Create and implement a capacity rationalization plan that increases net economic benefits, creates individual economic stability, provides for full utilization of the trawl sector allocation, considers environmental impacts, and achieves individual accountability of catch and bycatch.*
Objectives The above goal is supported by the following objectives:
1. Provide a mechanism for total catch accounting.
2. Provide for a viable, profitable, and efficient groundfish fishery.
3. Promote practices that reduce bycatch and discard mortality and minimize ecological impacts.
4. Increase operational flexibility.
5. Minimize adverse effects from an IFQ program on fishing communities and other fisheries to the extent practical.
6. Promote measurable economic and employment benefits through the seafood catching, processing, distribution elements, and support sectors of the industry.
7. Provide quality product for the consumer.
8. Increase safety in the fishery.
Constraints and Guiding Principles The above goals and objectives should be achieved while the following occurs:
1. Take into account the biological structure of the stocks including, but not limited to, populations and genetics.
2. Take into account the need to ensure that the total OYs and allowable biological catch (ABC) are not exceeded.
3. Minimize negative impacts resulting from localized concentrations of fishing effort.
4. Account for total groundfish mortality.
5. Avoid provisions where the primary intent is a change in marketing power balance between harvesting and processing sectors.
6. Avoid excessive quota concentration.
7. Provide efficient and effective monitoring and enforcement.
8. Design a responsive mechanism for program review, evaluation, and modification.
9. Take into account the management and administrative costs of implementing and oversee the IFQ or co-op program and complementary catch monitoring programs, as well as the limited state and Federal resources available.

Pacific Groundfish FMP Goals and Objectives

General FMP

Table 6-3. Pacific Groundfish FMP Goals and Objectives

Goal 1 - Conservation. Prevent overfishing and rebuild overfished stocks by managing for appropriate harvest levels and prevent, to the extent practicable, any net loss of the habitat of living marine resources.
Goal 2 - Economics. Maximize the value of the groundfish resource as a whole.
Goal 3 - Utilization. Within the constraints of overfished species rebuilding requirements, achieve the maximum biological yield of the overall groundfish fishery, promote year-round availability of quality seafood to the consumer, and promote recreational fishing opportunities.
Objectives. To accomplish these management goals, a number of objectives will be considered and followed as closely as practicable:
Conservation Objective 1. Maintain an information flow on the status of the fishery and the fishery resource which allows for informed management decisions as the fishery occurs.
Objective 2. Adopt harvest specifications and management measures consistent with resource stewardship responsibilities for each groundfish species or species group. Achieve a level of harvest capacity in the fishery that is appropriate for a sustainable harvest and low discard rates, and which results in a fishery that is diverse, stable, and profitable. This reduced capacity should lead to more effective management for many other fishery problems.
Objective 3. For species or species groups that are overfished, develop a plan to rebuild the stock as soon as possible, taking into account the status and biology of the stock, the needs of fishing communities, recommendations by international organizations in which the United States participates, and the interaction of the overfished stock within the marine ecosystem.
Objective 4. Where conservation problems have been identified for non-groundfish species and the best scientific information shows that the groundfish fishery has a direct impact on the ability of that species to maintain its long-term reproductive health, the Council may consider establishing management measures to control the impacts of groundfish fishing on those species. Management measures may be imposed on the groundfish fishery to reduce fishing mortality of a non-groundfish species for documented conservation reasons. The action will be designed to minimize disruption of the groundfish fishery, in so far as consistent with the goal to minimize the bycatch of non-groundfish species, and will not preclude achievement of a quota, harvest guideline, or allocation of groundfish, if any, unless such action is required by other applicable law.
Objective 5. Describe and identify EFH, adverse impacts on EFH, and other actions to conserve and enhance EFH, and adopt management measures that minimize, to the extent practicable, adverse impacts from fishing on EFH.
Economics Objective 6. Within the constraints of the conservation goals and objectives of the FMP, attempt to achieve the greatest possible net economic benefit to the nation from the managed fisheries.
Objective 7. Identify those sectors of the groundfish fishery for which it is beneficial to promote year-round marketing opportunities and establish management policies that extend those sectors fishing and marketing opportunities as long as practicable during the fishing year.
Objective 8. Gear restrictions to minimize the necessity for other management measures will be used whenever practicable. Encourage development of practicable gear restrictions intended to reduce regulatory and/or economic discards through gear research regulated by EFP.

Utilization Objective 9. Develop management measures and policies that foster and encourage full utilization (harvesting and processing), in accordance with conservation goals, of the Pacific Coast groundfish resources by domestic fisheries.
Objective 10. Recognize the multispecies nature of the fishery and establish a concept of managing by species and gear or by groups of interrelated species.
Objective 11. Develop management programs that reduce regulations-induced discard and/or which reduce economic incentives to discard fish. Develop management measures that minimize bycatch to the extent practicable and, to the extent that bycatch cannot be avoided, minimize the mortality of such bycatch. Promote and support monitoring programs to improve estimates of total fishing-related mortality and bycatch, as well as those to improve other information necessary to determine the extent to which it is practicable to reduce bycatch and bycatch mortality.
Social Factors. Objective 12. When conservation actions are necessary to protect a stock or stock assemblage, attempt to develop management measures that will affect users equitably.
Objective 13. Minimize gear conflicts among resource users.
Objective 14. When considering alternative management measures to resolve an issue, choose the measure that best accomplishes the change with the least disruption of current domestic fishing practices, marketing procedures, and the environment.
Objective 15. Avoid unnecessary adverse impacts on small entities.
Objective 16. Consider the importance of groundfish resources to fishing communities, provide for the sustained participation of fishing communities, and minimize adverse economic impacts on fishing communities to the extent practicable.
Objective 17. Promote the safety of human life at sea.

APPENDIX A. ANALYSIS OF EM PROGRAM PROVISIONS

1.1. Retention options

1 Max retention - this would be status quo for midwater whiting; however for other gears there would likely be additional cost to sort, market, and distribute fish, additonal costs to send to landfill. ay flood markets if too much fish is landed accross region. Optimum retention cos would be less than max retention but uncertain based on marketability of certain species. Discrad of know unmarketable fish is positive benefit cus it reduces the costs of sorting, marketing and distribution of fish. May flood markets if too much fish is landed accross region. Discard at will allows fishermen to meet loacl and regional/national demands, similar to staus quo so future landings would be similar to current state of fisheries.

direct impact if changes are needed, definitons of catch/discard could affect handling protocols; max retention may be inefficient, take up hold space; installation of equipment and a change in fish handling may reduce efficiencies for vessel (reduce profit?)

direct impact-need to identify EM provider and create plan; costs to contract with EM provider and purchase system and modify vessel if necessary.

Agenda Item F.2.a
Supplemental Electronic Monitoring
Regulatory Process Overview
June 2014

Agenda Item F2

Electronic Monitoring Regulatory Process

Agenda Item F2 - Reference Materials

- F2a Att1: Draft Analysis of an Electronic Monitoring Program for the Pacific Coast Limited Entry Trawl Groundfish Fishery Catch Shares Program.
- F2a Supplemental Att 2: Letter from Honorable DeFazio
- F2b GEMPAC Report: GEMPAC Report to Council.
- F2b PSMFC Report: PSMFC Final 2013 Report.
- F2b NMFS Report: Net Revenue Analysis for Electronic Monitoring on the West Coast.
- F2c Supplemental Pub Comment: Report on the 2004 to 2010 US Shore-based Whiting EM Program

Council Action

Consider Refining Alternatives and Adopting Preliminary Preferred Alternatives, as Appropriate, for Public Review

Overview

- GEMPAC report
- Draft Analysis of Alternatives
- Net Revenue Highlights
- Advisory body statements
- Public Comment
- Council Action

Agenda Item F.2.b,
GEMPAC Report to Council

GEMPAC Recommendations

1) Adopt the definitions for total catch, retained catch, discard, maximized, and optimized retention for trawl and fixed gear as noted in Appendix C for the purpose of development and analysis of an EM program.

2) Revise the alternatives and options as detailed in Appendix D, "Recommended Revisions and Additions to Adopted Alternatives and Options."

GEMPAC Recommendations in the Draft EM Program Analysis Attachment 1, Table 2-1

Video Reading Protocols

		DETAILED COMPONENTS FOR All FISHERIES		
Section Ref.	**Component**	**Alternative 1 Status Quo: Human Observers Estimate Discard**	**Alternative 2 Camera Recordings Used to Estimate Discard**	**Alternative 3 Logbooks Used to Estimate Discard, with Camera Audits**
2.2.2	Video Reading Protocols	None	**Option A**: 100% (census). **Option B**: Subsample Video (% to review must be developed)	Audit logbook (intensity varies based on vessel's compliance history)

GEMPAC recommended preliminary Preferred Alts:
Fixed gear representatives like Alternative 3. MDWT whiting like Alt 3 but want further analysis of Alt 2 prior to final recommendation.

Current IFQ Retained/Discard Accounting

Total IFQ catch

Retained:

Landed catch

Shoreside catch monitors

Discard:

Dumped off deck (e.g., shoveled, picked out of net)
Dumped/washed out of net for safety reasons (bleeding, pull zipper, etc.).
Dropped off gear
Floating fish
Lost gear (estimated using WCGOP protocol)
Consumed/used as bait (noted on WCGOP forms)
Unobserved sets/hauls (estimated using WCGOP protocol)

WCGOP estimates

Discard Accounting

		DETAILED COMPONENTS FOR All FISHERIES		
Section Reference	**Component**	**Alternative 1 Status Quo: Human Observers Estimate Discard**	**Alternative 2 Camera Recordings Used to Estimate Discard**	**Alternative 3 Logbooks Used to Estimate Discard, with Camera Audits**
2.3	Discard Accounting - Individual or Fleet-wide	Observers/IFQ	**Option A**: One discard category and all discards are estimated using EM and counted against IFQ. **Option B:** Split into two discard categories; Category 1 count against IFQ, Category 2 count against sector or ACL; for some discard in Category 1, the estimate is based on trips with observer coverage. **Option C**: Split into two discard categories; Category 1 count against IFQ, no accounting for discard 2 category.	

Discard Accounting - Option A

Option A - Estimate Discard with EM and Count against IFQ

One discard category with IFQ accounting:

- Dumped off deck (e.g., shoveled, picked out of net)
- Dumped/washed out of net for safety reasons (bleeding, pull zipper, etc.).
- Dropped off gear
- Floating fish
- Lost gear (not captured by EM, estimate using WCGOP protocol)
- Consumed/used as bait (not captured by EM)
- Unobserved sets/hauls (not captured by EM, maybe apply discard rate using EM estimates from previous sets/hauls)

Discard Accounting - Option B

Option B - Split into two discard categories; Category 1 count against IFQ, Category 2 count against sector or ACL

Discard 1 IFQ Accounting:

- Dumped off deck (e.g., shoveled, picked out of net)
- Dumped/washed out of net for safety reasons (bleeding, pull zipper, etc.).
- Unobserved sets/hauls (not captured by EM, apply discard rate using WCGOP

Discard 2 Sector or ACL accounting (use WCGOP estimates and protocols):

- Dropped off gear
- Floating fish
- Estimated from lost gear
- Consumed/used as bait

Discard Accounting - Option C

Option C- Split into two discard categories; no accounting for discard 2 category

Discard 1 IFQ Accounting:

- Dumped off deck (e.g., shoveled, picked out of net)
- Dumped/washed out of net for safety reasons (bleeding, pull zipper, etc.).
- Unobserved sets/hauls (not captured by EM, apply discard rate using WCGOP

Discard 2 No accounting:

- Dropped off gear
- Floating fish
- Estimated from lost gear
- Consumed/used as bait

Discard Requirements

		DETAILED COMPONENTS FOR All FISHERIES		
Section Reference	**Component**	**Alternative 1 Status Quo: Human Observers Estimate Discard**	**Alternative 2 Camera Recordings Used to Estimate Discard**	**Alternative 3 Logbooks Used to Estimate Discard, with Camera Audits**
2.5	Discard Requirements	Discard at will unless required to retain.	**Option A**: **Maximized Retention** **Option B**: **Optimize Retention of Catch Share Species with Limited - Potential Gear Specific Sub-options under Optimized Retention (must be verifiable under EM)** **Option C - Discard At Will** (Status Quo)	

GEMPAC Recommended Preliminary Preferred Alts:

- Fixed gear and bottom trawl representatives prefer Optimized retention (Option B)
- Midwater trawl whiting representatives prefer Maximize retention (Option A)

Halibut Retention/Discard

		DETAILED COMPONENTS FOR All FISHERIES		
Section Ref.	**Component**	**Alternative 1 Status Quo: Human Observers Estimate Discard**	**Alternative 2 Camera Recordings Used to Estimate Discard**	**Alternative 3 Logbooks Used to Estimate Discard, with Camera Audits**
2.6	Halibut Retention/ Discard with Fishery Specific Options	Use WCGOP and IPHC protocols	**Option A**: Apply mortality rate for specific gear type: • MDWT Whiting 100% mortality; • MDWT non-whiting and BTW IPHC 90% mortality if discarded; • Fixed gear longline IPHC 16% mortality if discarded; • Fixed gear pot IPHC 18% mortality if discarded.	

Halibut continued

		DETAILED COMPONENTS FOR All FISHERIES		
Section Ref.	**Component**	**Alternative 1 Status Quo: Human Observers Estimate Discard**	**Alternative 2 Camera Recordings Used to Estimate Discard**	**Alternative 3 Logbooks Used to Estimate Discard, with Camera Audits**
2.6	Halibut Retention/ Discard with Fishery Specific Options	Use WCGOP and IPHC protocols	**Option B:** WCGOP scientific observations (assumed 20-30% coverage) is applied to fleet **Option C:** IPHC exemption to allow full retention (need to examine the feasibility of this option) **Option D:** Captain and crew provide assessment (training would be required) **Option E**: Use an appropriate EM viability assessment (currently conducting study, need IPHC approval) **Option F**: Use vessel specific mortality rate (update rates periodically)	

Discard Species List

		DETAILED COMPONENTS FOR All FISHERIES		
Section Reference	**Component**	**Alternative 1 Status Quo: Human Observers Estimate Discard**	**Alternative 2 Camera Recordings Used to Estimate Discard**	**Alternative 3 Logbooks Used to Estimate Discard, with Camera Audits**
2.7	Discard Species List Adjustment	None	**Options for a process to expand or change the species lists:** **Option A**: NMFS make determination and provide list to fishers through the NMFS EM Observer Exemption Process. **Option B**: Use Council process routine management measures (e.g., use groundfish specification process, or some other routine management measure). **Option C**: Set initial lists in regulation and change through Council process with proposed/final rule making.	

Payment for Scientific Collection

		DETAILED COMPONENTS FOR All FISHERIES		
Section Reference	**Component**	**Alternative 1 Status Quo: Human Observers Estimate Discard**	**Alternative 2 Camera Recordings Used to Estimate Discard**	**Alternative 3 Logbooks Used to Estimate Discard, with Camera Audits**
2.10.1	Payment for Scientific data collection/observations	Status quo however in near future industry will need to pay for all observer costs	**Option A**: Government funded, same as pre IFQ **Option B**: Industry Funded **Option C**: Combination of both Government and Industry [Need to discuss allocating costs] **GEMPAC Recommended Preliminary Preferred:** Most industry representatives would like Option A	

NMFS Processes

		DETAILED COMPONENTS FOR All FISHERIES		
Section Reference	**Component**	**Alternative 1 Status Quo: Human Observers Estimate Discard**	**Alternative 2 Camera Recordings Used to Estimate Discard**	**Alternative 3 Logbooks Used to Estimate Discard, with Camera Audits**
2.11	NMFS Processes	N/A	Identify items for NMFS to work out and then conduct a formal deeming process with the Council. • Observer Exemption Process • Individual Vessel Monitoring Plan Approval • Equipment Type Approval • Approved EM Provider List • Eligibility Criteria • Declaration Process to Use EM • Confidentiality Rules • WCGOP Scientific Observation Sampling Scheme	

Spatial Management

		DETAILED COMPONENTS FOR All FISHERIES		
Section Reference	**Component**	**Alternative 1 Status Quo: Human Observers Estimate Discard**	**Alternative 2 Camera Recordings Used to Estimate Discard**	**Alternative 3 Logbooks Used to Estimate Discard, with Camera Audits**
2.12	Spatial Variation for High Bycatch Areas	Status quo for current are restrictions (e.g., Rockfish Conservation Areas)	**Option A** - No special provisions ~~**Option B** - fishing activity in areas that are likely to have lower bycatch could be monitored with EM rather than using observers; no EM in high bycatch areas~~ ~~**Option C** - Under this option, if you chose to fish in a high bycatch area, a higher level of EM review may be required~~	

GEMPAC recommends removal of Option B and C.

EM Fishery Specific Alts and Options

Fishery specific decision Tables 2-2 through 2-4 provide the alternatives and options for:

- Midwater trawl whiting
- Fixed gear (longline & pot)
- Midwater non-whiting and bottom trawl

Only components of the EM program that contain options are provide in the tables.

These are the decision points for the Council for each fishery.

QUEST-
IONS?

Draft EM Program Analysis
Attachment 1

Purpose & Need (pp. 11):

"…monitor the IFQ program for compliance in an economical and flexible manner…"

Objectives (pp. 19-20):

1. Reduce total fleet monitoring costs to levels sustainable for the fleet and agency;
2. Reduce observer costs for vessels that have a relatively lower total revenue;
3. Maintain monitoring capabilities in small ports;

and others…

Chapter 4: Impact Analysis

Physical and Biological Environment

- Potential gear switching
- Potential changes in geographic distribution
- Increased retention and related mortality
- Changes in certainty around groundfish mortality estimates
- Changes in certainty around compliance
- Changes in quality of data on interactions with protected species

Socio Economic Impacts

- Continuing to develop the socioeconomic impact assessment
- Today covering
  - Cost estimation
  - Participation rate assumption
  - Logistical challenges
  - Net revenue analysis
- Information not available at May GEMPAC Mtg

Cost Estimation

- Working with NMFS and PSMFC to develop
  - Template – Table 4-3, pp. 91-92
    - Cost centers
    - Columns on who pays
    - Includes PSMFC video review cost estimates
    - Much to be developed
- Average Costs Will Vary Depending on Fisheries Included and Participation
  - Both government and private (provider fees)
  - With more fisheries, fixed costs spread over more vessels.
  - Likely inverse correlation
    - More EM participation,
      lower average EM costs, **higher** average observer costs
    - Less EM participation,
      higher average EM costs, **lower** average observer costs

Participation Rate Assumption

Costs will be affected by participation rates

Analysis range:

- High - 80%
- Medium - 50%
- Low - 20%

Looking for comments on this range

Logistical Challenges

- Monitoring capability in small ports
  - Resolve at-sea compliance observers
  - New challenge - shoreside catch monitors?
    - Currently observers cover shoreside monitoring
    - How will cost of shoreside coverage be affected?

- Seasonal by port - Figures 4-4 through 4-19
  - Seasonal summary for 2013 – Table 4-7.

Excerpts from Table 4-7.

Port	2013 Seasonal Summary (averages are for months with landings – zero months excluded)
Bellingham, Washington	Average of 2 per month, max of 4 and minimum of 1 (3 zero months).

Excerpts from Table 4-7.

Port	2013 Seasonal Summary (averages are for months with landings – zero months excluded)
Bellingham, Washington	Average of 2 per month, max of 4 and minimum of 1 (3 zero months).
Astoria, Oregon	Average of 56 per month, max of 136 and minimum of 19 (no zero months).

Excerpts from Table 4-7.

Port	2013 Seasonal Summary (averages are for months with landings – zero months excluded)
Bellingham, Washington	Average of 2 per month, max of 4 and minimum of 1 (3 zero months).
Astoria, Oregon	Average of 56 per month, max of 136 and minimum of 19 (no zero months).
Fort Bragg, California	Average of 9 per month, max of 18 and minimum of 2 (no zero months).

Excerpts from Table 4-7.

Port	2013 Seasonal Summary (averages are for months with landings – zero months excluded)
Bellingham, Washington	Average of 2 per month, max of 4 and minimum of 1 (3 zero months).
Astoria, Oregon	Average of 56 per month, max of 136 and minimum of 19 (no zero months).
Fort Bragg, California	Average of 9 per month, max of 18 and minimum of 2 (no zero months).
Monterey, California	An average of 4 per month, max of 6 and minimum of 2 (6 zero months).
Moss Landing, California	Average of 4 per month, max of 6 and minimum of 3 (no zero months).

Excerpts from Table 4-7.

Port	2013 Seasonal Summary (averages are for months with landings – zero months excluded)
Bellingham, Washington	Average of 2 per month, max of 4 and minimum of 1 (3 zero months).
Astoria, Oregon	Average of 56 per month, max of 136 and minimum of 19 (no zero months).
Fort Bragg, California	Average of 9 per month, max of 18 and minimum of 2 (no zero months).
Monterey, California	An average of 4 per month, max of 6 and minimum of 2 (6 zero months).
Moss Landing, California	Average of 4 per month, max of 6 and minimum of 3 (no zero months).
Morro Bay, California	Average of 8 per month, max of 20 and minimum of 3 (no zero months).

Shoreside Logistical Challenges

- A smaller local core of observers/monitors
- Some vessels carrying EM
- Some observers at-sea
- Need to cover a few hour task.

- Responses to situation: uncertain
- Depending on the response - might expect
  - Some decrease in efficiency
  - Increased need for coordination
  - Reduced flexibility regarding landings

NMFS Report - Net Revenue Analysis (Agenda Item F.2.b, NMFS Report)

Economic health of fleet & at-sea monitoring costs

Table 2. Trawl endorsed vessels (page 5)	Variable Net Revenue Per Day	Per Vessel Annual Total Cost Net Revenue
At-sea Pacific Whiting	$11,500	$220,000

Ms. Dorothy Lowman
Chair, Pacific Fisheries Management Council
7700 NE Ambassador Place, Suite 101
Portland, Oregon 97220-1384

Dear Ms. Lowman,

As the Chair of the Pacific Fisheries Management Council (Council), I urge you to prioritize the adoption of a regulatory framework for the use of electronic monitoring (EM) as an economically viable substitute for human observers in the West Coast Groundfish Trawl Catch Share Program at this week's Council meeting.

Since the catch share program was implemented in 2011, stocks have increased and bycatch has largely been eliminated thanks to improved personal accountability, a cornerstone of the catch share program currently achieved through 100% human observer coverage. Unfortunately, the cost of human observers is substantial and continues to grow each year. The National Marine Fisheries Service (NMFS) initially capped observer salaries at $350 per day, but today the average daily cost of an onboard observer has risen to roughly $450—36% above the national average[1]. Observer salaries exceed most crew member salaries and may constitute up to 10% of the gross earnings of small vessel operators. If the catch share program is to remain economically viable, the Council must work with NMFS to expedite the implementation of an EM program to reduce the cost of compliance monitoring.

The Council is clearly aware that the growing financial burden of human observers is unsustainable and has taken a number of steps towards developing an EM program to alleviate that burden, but final implementation of the program is not expected until January 2016. It is unclear why such a delay is necessary since NMFS has already endorsed the use of video cameras to meet monitoring and compliance needs in maximized retention fisheries[2] and the two committees (GEMPAC and GEMTAC [3]) tasked with evaluating the Council's preferred alternatives submitted their final recommendations over six months ago.

I am aware that the committees' recommendations are scheduled for review at this week's meeting, and I urge the Council to take whatever steps necessary to adopt final recommendations for NMFS as soon as possible. It is critical that the Council expedite the implementation of EM in the Groundfish Trawl Catch

Share Program to reduce the cost of compliance monitoring and increase profitability, particularly for our small boat operators.

Sincerely,

Peter A. DeFazio
Ranking Member
Committee on Natural Resources

GROUNDFISH ELECTRONIC MONITORING POLICY ADVISORY COMMITTEE REPORT

Report to Council

On May 7 and 8, 2014 the Groundfish Electronic Monitoring (GEM) Policy Advisory and Technical Advisory Committees (GEM Committees) met to discuss initial alternatives adopted by the Council for analysis for an electronic monitoring (EM) program. Council staff presented draft definitions, additional draft EM components and options, and a framework for the development of a cost analysis of the potential EM program. The GEM Committees recommended definitions for total catch, discard, maximized and optimized retention, and made some modifications and additions to the Council's adopted alternatives and options for an EM program. The GEM Committees also heard from the only two west coast observer providers (Saltwalter Inc. and Alaskan Observers Inc.) regarding their current program activities, their involvement in EM pilot projects, and potential impacts of an EM program on their companies. Their general comments are provided in the Report Summary. Finally, representatives of the industry on the GEMPAC then attempted to pick preliminary preferred alternatives and options; these selections are noted in the Report Summary.

Appendix A of this report contains the GEM Committees' Proposed Agenda. Appendix B contains draft definitions from the West Coast Groundfish Observer Program (WCGOP) and Appendix C contains draft definitions developed by the GEMPAC based on the WCGOP definitions. Appendix D provides an overview of GEMPAC's recommended revisions and additions to the Council's adopted alternatives and options.

Report Summary

In November 2013, the Council adopted for analysis alternatives and options for an EM program. At the Council's April 2014 meeting the Council provided guidance for further development of the alternatives and options. Prior to the GEMPAC meeting, Council staff split these alternatives and options into fishery-specific options to begin the development of an impact analysis to provide guidance to the Council for selecting preliminary preferred alternatives in June 2014. During this process, additional components to the draft EM program for policy decision-making were identified and presented to the GEMPAC for discussion in May. Appendix D, Section 1 provides a description of the recommended revisions made to the Council's adopted alternatives and options, and Section 2 includes new EM components and options developed by the GEMPAC.

These revisions and new options can also be found in the Council's draft decision document titled "Draft Analysis of an Electronic Monitoring Program for the Pacific Coast Limited Entry Trawl Groundfish Fishery Catch Shares Program" (Agenda Item F.2.a, Attachment 1). The draft decision document provides background on the development of the EM program, alternatives and options, and an initial draft impact and cost analysis.

GEMPAC Recommendations
The GEMPAC provides the following recommendations for further development of an EM program and Council consideration:

Recommendation 1: The GEMPAC recommends adopting the definitions for total catch, retained catch, discard, maximized, and optimized retention for trawl and fixed gear as noted in Appendix C for the purpose of development and analysis of an EM program.

Recommendation 2: The GEMPAC recommends revising the alternatives and options as detailed in Appendix D "Recommended Revisions and Additions to Adopted Alternatives and Options."

Potential Preliminary Preferred Alternatives (PPA)
The following alternatives and options were preliminarily recommended by representatives of the industry that participate on the GEMPAC. At the time of the GEMPAC meeting, much of the data and cost analysis was not available to make a decision on all alternatives and options, however; representatives provided a "best guess" at the time based on their knowledge of the issues, their constituents' needs, and forthcoming impact and cost analysis. The GEMPAC will review a more thorough analysis prior to the September Council meeting to provide further guidance.

Monitoring for Discards
Two action alternatives have been identified to account for fish under an EM program:

Alternative 2: Camera Recordings Used to Estimate Discard
Option A: 100% (census).
Option B: Subsample Video (% to review must be developed)

Alternative 3: Logbooks Used to Estimate Discard, with Camera Audits.

PPA: Fixed gear representatives prefer self-reporting and logbook audit (Alternative 3)
PPA: Midwater trawl whiting representatives prefer self-reporting and audit logbook (Alternative 3) at 10% review level but wants to see analysis for video subsampling/expansion option before choosing (Alternative 2, Option B)

Retention Options and Allowable Discard
For analysis purpose the GEMPAC has developed draft definitions for the retention of species under an EM program (Maximized Retention and Optimized Retention) and are described in Appendix C. The definitions include the regulatory requirements for retention and discard and some discard exceptions that may be allowed based on fishery operations. In addition, some fisheries could be allowed to discard if a species or species group can be clearly identified using video images.

At this time there are three options for retention to choose from that would govern fishery operations:

Option A: Maximize retention; generally retain all retain all catch share species, non-catch share groundfish species, non-groundfish species

Option B: Optimize retention; generally retain all retain all catch share species.

Option C: Discard at will; may discard species according to current regulations

PPA: Fixed gear and bottom trawl representatives prefer Optimized retention (Option B)
PPA: Midwater trawl whiting representatives prefer Maximize retention (Option A)

<u>Payment for Scientific Data Collection/Observations</u>
Previous to the IFQ program NMFS provided scientific data collection on roughly 20 percent of the limited entry trawl fleet. This cost was covered by the Government. Under an EM program scientific data collection will be needed from vessels without an observer. It's estimated that the WCGOP will sample roughly 20-30 percent of the EM fleet however these rates will need to be examined and a sampling scheme developed by NMFS in the future. In addition, a funding source must be identified to support the WCGOP efforts. The GEMPAC developed three options:

Option A: Government funded, same as pre-IFQ
Option B: Industry Funded
Option C: Combination of both Government and Industry

PPA: Most industry representatives would like the government to fund scientific observations on EM trips (Option A)

Summary of Observer Provider Comments
Council staff invited the only two observer providers to talk about how their company may be affected by the development of an EM program (both positive and negative) to assist the GEMPAC and Council staff in the development options and the impact analysis. For example, what are the critical policy decision points or topics of the draft EM program that may affect the provider, would they continue to provide observer coverage, what might be the thresholds for making that decision, and would you expand your program to include EM? Following the providers statements on these topics, the GEMPAC held a Q&A session with the providers.

Much of the discussions and issues that surround EM is the anticipated level of participation in an EM program and the level of need for at-sea observations in the IFQ. Overall up to 7,445 sea-days were observed in the 2013 IFQ fishery.

Sea days for 2013 were as follows:
Shoreside non-whiting (trawl and fixed gear) – 4975
Shoreside whiting – 1934
Mothership catcher vessels – 536
Total WCGOP Catch Shares – 7445
(Data Source: WCGOP)

Summary

The midwater trawl whiting fishery provides significant revenue or the only revenue to observer provider companies. A reduction in the level of observer coverage in the whiting fishery due to implementation of EM may affect observer providers ability to cover additional costs (e.g., overhead for travel and housing) in other fishery sectors. Providing services to other fishery sectors in California, in remote ports that do not require a high level of coverage, or in ports that are sporadic in the number of observers needed is costly to observer providers. Some vessels only need 2 to 5 sea days per month or only one observer is needed in a port part time. At times a full time observer is not needed in a port; however, a vessel will need one at some point in the month. It is difficult to provide fleet support at these low levels for a profit (in California there is no profit margin) and especially difficult to plan the future if the level of EM participation is unknown. Providers are planning their efforts up to 3 years in advance and it's difficult to plan for observer coverage if exempted fishing permits are provided in 2015 in large numbers. One provider suggested limiting the number of EFPs to lessen the impact on all participants in the IFQ program.

Observer providers want to provide the coverage but may need to increase their billable costs if revenue is lost from ports that drastically reduce their demand for observers. They are sensitive to daily costs that may cause hardship to the industry and do not want to drive cost so high that it causes a vessel to tie up and not fish. One provider commented that funding from the cost recovery program of the IFQ program could alleviate increasing costs to vessels and may stabilize the situation.

One provider said it would continue to support the observer needs and does not intend to become an EM provider but looking to create efficiencies in the potential EM program. One observer provider is working on a business model to accommodate an increase in the use of EM and are working on development of open source software to support EM. If there is a reduction in the need for at-sea observations it's possible that both companies may use some observers in another capacity such as to provide review of EM data or system installation/maintenance.

Currently, many at-sea observers play the role of a shoreside catch monitor for the vessel when it offloads. However if the observer is no longer needed then someone will need to fill that catch monitor role. One provider estimated that each processors would need two full time catch monitors in each plant for 100 to 120 days for the whiting fishery, which is 15 to 18 full time positions. The same observer provider commented that when people are living in ports and only working 100 days, it's impossible to keep them there.

The dual role of observer/catch monitor creates efficiencies in the IFQ program; however, this is removed when the observer is removed from the vessel under EM. Observers are trained for at-sea observations and catch monitoring by NMFS WCGOP and PSMFC. If a person does not intend to do at-sea observations, there may be a need to develop a separate training for shoreside catch monitoring that is comprehensive enough and does not rely on the fish identification portion of the at-sea observer training.

APPENDIX B
Draft Definitions for Total Catch, Retained and Discard
Northwest Fisheries Science Center Observer Program (WCGOP)

NOTE: Information regarding the At-Sea Hake Observation Program definitions were removed from the WCGOP draft document since they do not apply to the EM program.

WCGOP Fixed Gear

Total Catch:

Observer total catch (OTC) is defined as the total sum, or extrapolated weight, of all organic and inorganic material caught by the gear.

How is it estimated?

All organic and inorganic material which breaks the surface of the water and can be reasonably attributed to the vessel is counted and identified by the observer to species, species group, or type, for all - or a subsample - of the set. Weight estimates, taken using multiple weight methods allowed under WCGOP protocol, are applied to everything counted. These weights are summed, or extrapolated to unsampled segments, to calculate the Observer Total Catch.

Retained:

Retained is any portion of the total catch that is delivered to a buyer, consumed aboard, or is used for bait or other purposes.

How is it estimated?

All retained catch or a subsample of, is counted and identified to species, species group, or type. Observer weight estimates for all retained are taken using multiple weight methods allowed under WCGOP protocol. These weight estimates are applied to the counts to determine the weight of retained catch.

Discard:

Discard is any portion of the total catch that is not delivered to a buyer or utilized for any other purposes.

How is it estimated?

All discarded catch, or a subset of, is counted and identified to species, species group, or type. Observer weight estimates for all discards are taken using multiple weight methods allowed under WCGOP protocol. These weight estimates are applied to the counts to determine the weight of discarded catch.

WCGOP Trawl Gear

Total Catch:

Total catch is defined as any organic or inorganic material confined within a trawl net as the net is being landed, as well as any visually discernible catch lost during the retrieval process that can be reasonably attributed to the vessel.

How is it estimated?

Total catch estimates are estimated by an observer as the net is being landed or after the catch is dumped on deck.

Retained:

Retained is any portion of the total catch that is delivered to a buyer, consumed aboard, or is used for bait or other purposes.

How is it estimated?

Retained is estimated using a combination of vessel estimates from the vessel logbook and observer estimates (e.g. overfished species). Observer estimates are taken using multiple weight methods allowed under WCGOP protocol.

Discard:

Discard is any portion of the total catch that is not delivered to a buyer or utilized for any other purposes.

How is it estimated?

Discard estimates are taken by observers using multiple weight methods allowed under WCGOP protocol.

WCGOP Additional Information:

Observers are not able to estimate discard that they cannot see, are not aware of, or has been discarded without their knowledge. Observers do their best to communicate with vessel crew to let them know what portions of the catch they need access to.

Another challenge in estimating discarded catch are any organisms that remain trapped in the mesh of the net after the bag has been dumped and are not removed by the crew. These are commonly known as “gillers”. Their weight is not accounted for in either retained or discard since there is a potential for double-counting and the inability to associate gillers to a particular haul after multiple hauls have been made. These fish make up a very small percentage of the catch.

Catch consumed on board or used for bait is another tricky situation for catch accounting. In 2014 the WCGOP will begin recording this as discard with a unique “reason for discard” of “utilized on board” in order to track this discard from other types of discard. The reason for this is so that this catch will be reported to the vessel account system and debited from quota accounts. Currently the observer program only reports discard to the vessel account system. In previous years, this type of catch was considered retained as it was used by the vessel.

There may be discrepancies between definitions of catch (listed above and followed by observers for data collection purposes) and what is used to calculate fleet wide mortality estimates or reported to the vessel account system for catch accounting purposes (following sections in this document). For example, the fixed gear definition of catch is "..material which breaks the surface of the water…", however for catch accounting purposes catch estimates are reported for lost gear that does not break the surface of the water. The observer program recognizes these discrepancies and determines that they are necessary in order to effectively train observers to capture data at sea while adequately reporting discards for accurate quota management.

<u>WCGOP Fixed Gear</u>

Lost Gear

Partial Set Lost

Scientific Analysis/Reporting protocols- Effort (i.e., fish tickets) from these sets result in discard accounting for these sets within the fleet-wide discard estimates.

Catch Accounting Protocols (Catch share quota pounds reported to the Vessel Account system for debiting) - Retained and discard observer estimates from the haul are expanded to the total set, as it is assumed the observer data for the sampled portion of the gear (retained and discard) adequately represents the composition of the lost portion of gear. Both retained and discarded catch estimates for IFQ species occurring on the lost portion of the gear are reported as discard. Additionally, PHLB has an assumed mortality rate of "dead" when occurring in lost gear.

Full Set Lost

Scientific Analysis/Reporting protocols - Effort (i.e., fish tickets) from these sets result in discard accounting for these sets within the fleet-wide discard estimates.

Catch Accounting Protocols (Catch share quota pounds reported to the Vessel Account system for debiting) – A catch per unit of effort is determined for all retained and discarded IFQ species from other sets observed during the trip and applied to the number of units of effort (hooks, pots, etc) for the lost set. These estimates for the lost gear are summed and reported as discard. Additionally, all PHLB estimated to have occurred in the lost gear are assigned a mortality rate of "dead". In the event that no other sets were sampled within the trip, like sets from other trips made by the vessel are used. Like sets are those sets observed on the same vessel with the same gear type and target strategy occurring in a similar area, depth and time period.

Unobserved Sets

Scientific Analysis/Reporting – For fisheries outside of the trawl IFQ fishery effort (i.e., fish tickets) from these sets result in discard accounting for these sets within the fleet-wide discard estimates. For the trawl catch share fishery ratio estimators are used to apportion unsampled weight to specific species.

Catch Accounting Protocols (Catch share quota pounds reported to the Vessel Account system for debiting) – A catch per unit of effort is determined for discarded IFQ species from other sets observed during the trip and applied to the number of units of effort (hooks, pots, etc) for the unobserved set. Only discarded catch is estimated and reported as discard as the retained catch is and landed by the vessel and reported through landings/catch monitors. In the event that no sets were sampled within the trip, like sets from other trips are used. Like sets are those sets observed on the same vessel with the same gear type and target strategy occurring in a similar area, depth and time period.

Reclaimed (previously lost) Gear

Sets lost, but later found, are handled on a case by case basis taking into consideration factors such as how long the gear was lost and if any viable fish were retrieved. Generally these are handled using the partially or fully lost set protocols listed above.

WCGOP Trawl Gear

Lost Gear

Scientific Analysis/Reporting protocols- Effort (i.e., fish tickets) from these sets result in discard accounting for these sets within the fleet-wide discard estimates.

Catch Accounting Protocols (Catch share quota pounds reported to the Vessel Account system for debiting) - – A catch per unit of effort is determined for all retained and discarded IFQ species from other sets observed during the trip and applied to the number of units of effort (tow minutes) for the lost set. These estimates for the lost gear are summed and reported as discard. Additionally, all PHLB estimated to have occurred in the lost gear are assigned a mortality rate of "dead". In the event that no other sets were sampled within the trip, like sets from other trips made by the vessel are used. Like sets are those sets observed on the same vessel with the same gear type and target strategy occurring in a similar area, depth and time period.

Unobserved Hauls and Unsampled or Partially Sampled Catch

Scientific Analysis/Reporting protocols- – For fisheries outside of the trawl IFQ fishery effort (i.e., fish tickets) from these sets result in discard accounting for these sets within the fleet-wide discard estimates. For the trawl catch share fishery ratio estimators are used to apportion unsampled weight to specific species.

Catch Accounting Protocols (Catch share quota pounds reported to the Vessel Account system for debiting) – Observers are trained to at a minimum make visual estimates of the amount of IFQ and non-IFQ species in hauls that they are unable to sample (broken scales, sickness, etc.). If able, they will make estimates of each discarded species or species group and this is reported as discard to the vessel account system. When a weight estimate of total IFQ species in the haul is all that the observer was able to obtain, the ratios of all discarded IFQ species found in the other sampled hauls in the trip is applied to the IFQ weight estimate. For hauls where the observer is not able to sample or make any estimates of IFQ catch, a catch per unit of effort (tow minutes) is determined for discarded IFQ species from other sets observed during the trip and applied to the number of units of effort (tow minutes) for the unobserved set.

Only discarded catch is estimated and reported as discard as the retained catch is landed by the vessel and reported through landings/catch monitors. In the event that no sets were sampled within the trip, like sets from other trips are used. Like sets are those sets observed on the same vessel with the same gear type and target strategy occurring in a similar area, depth and time period.

APPENDIX C
Draft Definitions for Development and Analysis of an EM Program

Section 1 - Retention Definitions, Requirements, and Exceptions

For analysis purpose the GEMPAC has developed draft definitions for the retention of species under an EM program. The draft definitions were developed based on existing descriptions for maximized and optimized retention options developed in previous GEMPAC reports and adopted by the Council in November 2013. Both definitions contain the same existing regulatory requirements and discard exceptions.

The GEMPAC discussed fishery specific discard options under an optimized retention regulatory environment. The definition for optimized retention contains some fishery specific discard options, however it is difficult for the GEMPAC to select which species are appropriate for allowable discard since species identification issues while using EM limit the options. PSMFC has begun to identify species that may be identifiable for discard and further analysis of these options will need be conducted to assist the Council in choosing an initial species list that is specific to each fishery.

In the future, it's expected that recognition software programs may assist in further refinement or expansion of a species discard list under an optimized retention regulatory environment. During the GEMPAC discussions the group identified that a process to update the species discard list to accommodate advances in fish identification technology or an increase in the ability to identify more species using video review. Therefore a new component was added to the EM program options (see Appendix D Section 1.8)

Maximize Retention:
A vessel is generally required to retain all catch share species, non-catch share groundfish species, non-groundfish species (Non-FMP and not prohibited species). The following regulatory requirements or discard exceptions apply:

Existing Regulatory Requirements
Vessels must discard prohibited, ESA-listed, and marine mammal species unless otherwise allowed to retain them by regulation or under federal exemption for scientific purposes. The following regulatory requirements apply:

- Mid-water trawl IFQ trips for whiting that deliver to shoreside processors must retain prohibited species (halibut, salmon, and Dungeness crab) unless sorting at sea.
- Mid-water trawl catcher vessels delivering to motherships must retain prohibited species (halibut, salmon, and Dungeness crab).
- Midwater trawl whiting trips that are unsorted may discard minor amounts of catch not delivered to shoreside or mothership processors. (current regulation**: "**Maximized retention vessels participating in the Pacific whiting IFQ fishery may discard minor operational amounts of catch at sea if the observer has accounted for the discard (i.e., a maximized retention fishery).")

- For LE fixed gear 22 or 24 inch lingcod must be discarded or if the vessel exceeds their non-IFQ trip limit; i.e Regulatory discards. (The minimum size limit for lingcod is 22 inches (56 cm) total length North of 42º N. lat. and 24 inches (61 cm) total length South of 42º N. lat.) **This information would need to be verifiable under an EM system.**

Discard exceptions when fishing under maximized retention - All discards must be enumerated and reported

- The vessel may discard for safety reasons (**define?**),
- The trawl net is ripped or zipper accidentally opened, or fish fell off hook.
- Fish washed out of the trawl net or is overflowing
- Vessels may discard mud, sponges, coral, inverts, and inorganic material not generally retained for sale or use.

Optimize Retention (Retain Catch Share Species with Discard Options):
A vessel is generally required to retain all catch share species. The following regulatory requirements, discard exceptions, or allowable gear specific discards apply:

*Existing Regulatory Requirements (**Same as Maximized Retention**)*
Vessels must discard prohibited, ESA-listed, and marine mammal species unless otherwise allowed by regulation or under federal exemption for scientific purposes. The following regulatory requirements apply:

- Mid-water trawl IFQ trips for whiting that deliver to shoreside processors must retain prohibited species (halibut, salmon, and Dungeness crab) unless sorting at sea.
- Mid-water trawl catcher vessels delivering to motherships must retain prohibited species (halibut, salmon, and Dungeness crab).
- Midwater trawl whiting trips that are unsorted may discard minor amounts (**define?**) of catch not delivered to shoreside processors.
- For LE fixed gear 22 or 24 inch lingcod must be discarded or if the vessel exceeds their non-IFQ trip limit; i.e Regulatory discards. (The minimum size limit for lingcod is 22 inches (56 cm) total length North of 42º N. lat. and 24 inches (61 cm) total length South of 42º N. lat.) T**his information would need to be verifiable under an EM system.**

*Discard exceptions when fishing under maximized retention - All discards must be enumerated and reported (**Same as Maximized Retention**)*

- The vessel may discard for safety reasons (**define?**)
- The trawl net is ripped or zipper accidentally opened, or fish fell off hook.
- Fish washed out of the trawl net or is overflowing
- Vessels may discard mud, sponges, coral, inverts, and inorganic material not generally retained for sale or use.

***Potential Gear Specific Sub-options under Optimized Retention**:*
This information would need to be verifiable under an EM system. Options here are not mutually exclusive; however, there must be adequate images for species identification and weight estimates of catch share species discards.

Midwater trawl non-whiting trips, bottomtrawl, and fixed gear trips may discard the following species if verifiable under the EM program and approved by NMFS:

a) For catch share species
   Option a – Allow discard of flatfish
   Option b – Allow discard of lingcod and sablefish
   Option c – Allow discard of all non-rockfish groundfish (full retention of rockfish only)
   Option d – Allow discard if species that are verifiable with EM
b) For non-catch share groundfish species
   Option c – Allow discard of all non-rockfish groundfish (full retention of rockfish only)
   Option d – Allow discard if species that are verifiable with EM
c) For non-groundfish (Non-FMP and not prohibited species)
   Option e – Allow discard of all non-groundfish species
   Option d – Allow discard if species that are verifiable with EM

Section 2 - Definitions for Total Catch, Retained Catch, and Discard

Under the catch shares program, total catch must be accounted for to debit individual quota share accounts and fishery allocations (Figure 1). Retained and discarded catch is combined to get total catch. Shoreside monitors are used to verify retained catch and the West Coast Groundfish Observer Program uses at-sea monitors to account for and estimate discards.

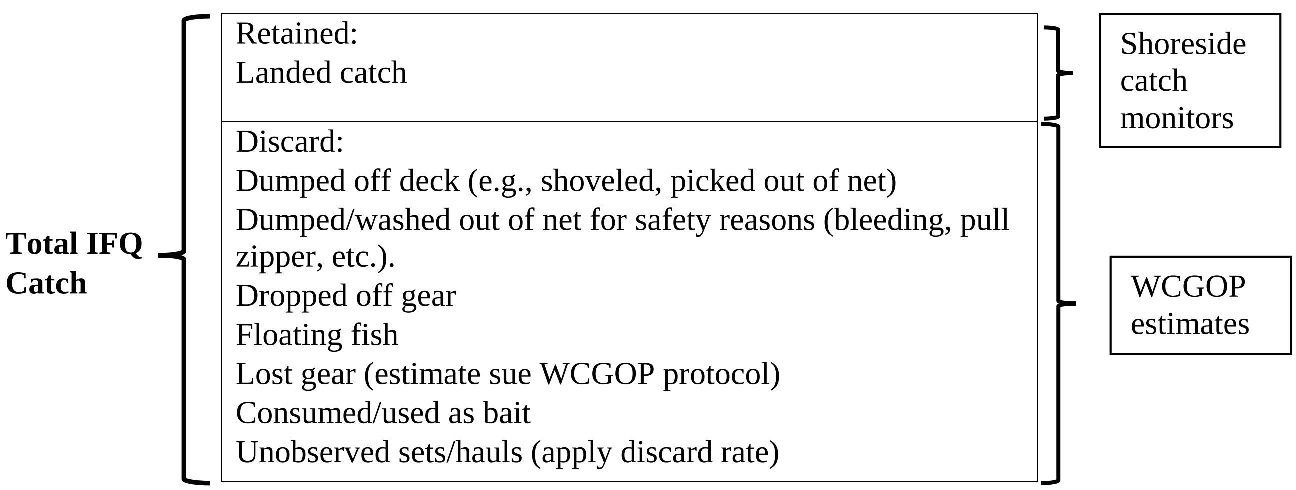

Figure 1. General depiction of total catch accounting in the Shorebased IFQ program.

WCGOP provided the GEMPAC draft definitions of total catch and discard that are specific to trawl and fixed gear. The GEMPAC consolidate the individual gear definitions for total catch and discard into the following draft definitions:

<u>Total catch for trawl: </u>Total catch is defined as the sum, or estimated weight, of all organic and inorganic material caught by the gear, to include any organic or inorganic material confined within a trawl net as the net is being landed, lost gear, as well as any visually discernible catch lost during the retrieval process that can be reasonably attributed to the vessel.

Total catch for fixed gear: Total catch is defined as the sum, or estimated weight, of all organic and inorganic material caught by the gear to include any fish hooked or in a pot as the gear is being landed, lost gear, as well as any visually discernible catch lost during the retrieval process that can be reasonably attributed to the vessel.

Retained catch for fixed gear and trawl: Retained catch is any portion of the total catch that is delivered to a buyer or processor.

Discard for fixed and trawl gear: Discard is any portion of the total catch that is not delivered to a buyer. Fish caught for bait or onboard consumption are considered discard. For gear that is lost or sets and hauls that are unobserved, discard rates will be applied based on similar sets and hauls.

APPENDIX D
Recommended Revisions and Additions to Adopted Alternatives and Options

The GEMPAC provide the following recommended revisions and additions to the Council's adopted alternatives for an EM program. For a complete table of alternatives with the recommended revisions please see the Table 1 of the Council's decision document "Draft Analysis of an Electronic Monitoring Program for the Pacific Coast Limited Entry Trawl Groundfish Fishery Catch Shares Program" (June Council meeting Agenda Item F2a, Attachment 2).

2.2.1 - Discard Documentation Technology

The GEMPAC clarified that the discard documentation option is to either use a human observer (No Action, Alternative 1) or a vessel may have the option to use cameras in lieu of human observer in both alternative 2 and 3. The following was added to the table of alternatives: "Individual Vessel Option to Use Cameras in Lieu of Human Observer"

2.3 - Discard Accounting - Individual or Fleet-wide

Under the catch shares program, total catch must be accounted for to debit individual quota share accounts and fishery allocations. Retained and discarded catch is combined to get total catch. Shoreside monitors are used to verify retained catch and the West Coast Groundfish Observer Program uses at-sea monitors to account for and estimate discards.

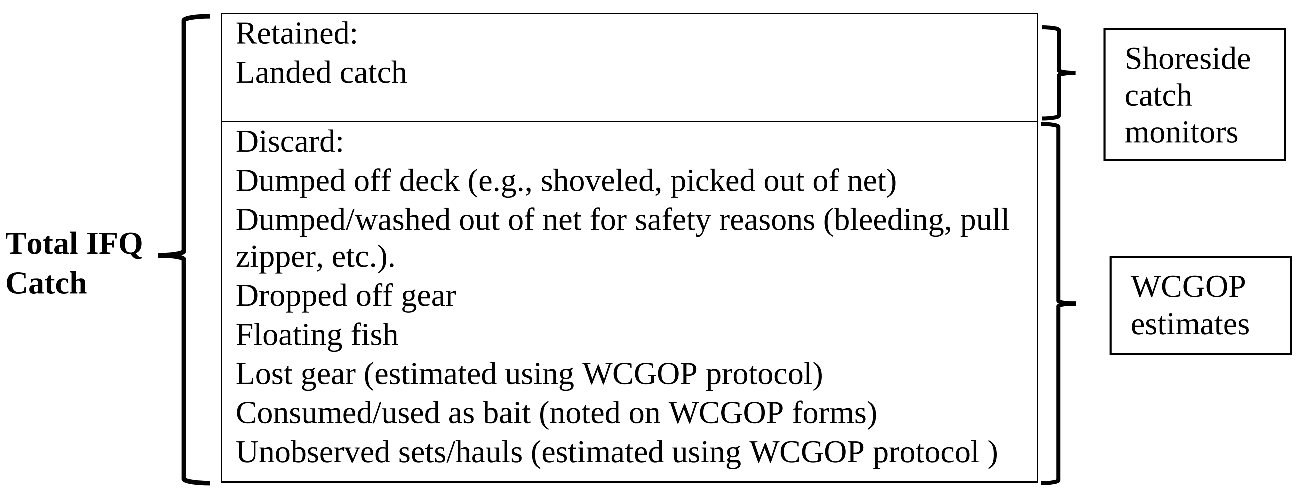

Figure 2. General depiction of total catch accounting in the Shorebased IFQ program.

Under an EM program, the estimation (speciation and weight) for these discard events would be conducted using EM rather than the WCGOP (Figure 2). However some of the discard events and scenarios noted in Figure 1 may not be captured by EM, such as lost gear, crew consuming fish onboard the vessel, using fish caught as bait, and unobserved hauls/sets that had discard (i.e., EM failed to record the discard), therefore; some other source of data may need to be used to account for the discard activity. In addition, some events may be capture by EM but are difficult to quantify or are rare, such as floating fish on the surface of the water or a fish dropped from the gear. An analysis of these events and the total discard mortality will be conducted to quantify frequency of occurrence, weight, and species conducted to examine the viability of these options for Council consideration.

If these discard events cannot be estimated using EM, then they could be estimated either annually by the WCGOP or not at all. The discard could be estimated using historical observations by the WCGOP for the time period of 2010 to 2014 to get an average number per year or through the annual observations made by WCGOP that are on vessels that do not use EM in combination with vessels that are randomly selected to have a scientific observer while the vessel uses EM.

In addition, rather than accounting for this discard at the individual level (IFQ) it's possible to account for it during the specification process for Annual Catch Limits (ACL), at the sector level or not at all. However this would remove the individual accountability of the IFQ program or not comply with MSA national standards. Assuming that the total mortality estimated at the sector level from this activity is minor amounts and would not affect individual vessels quota share accounts or other fishery participants, the estimated mortality could be deducted from the ACL prior to allocation to each sector or at the sector level to be taken "off-the-top" prior to IFQ distribution and catch allocation distributions.

Potential changes were developed in the flowing way:
1) Discard events were grouped into discard categories 1 and 2;
2) Accountability was established (i.e., IFQ, Fleetwide, or not accounted);
3) Data source were identified as either EM or the WCGOP.

Three possible options were developed for discard accounting:

Option 1: **One discard category and all discards are estimated using EM and counted against IFQ:**

- Dumped off deck (e.g., shoveled, picked out of net)
- Dumped/washed out of net for safety reasons (bleeding, pull zipper, etc.).
- Dropped off gear
- Floating fish
- Lost gear (not captured by EM, estimate using WCGOP protocol)
- Consumed/used as bait (not captured by EM)
- Unobserved sets/hauls (not captured by EM, maybe apply discard rate using EM estimates from previous sets/hauls)

Option 2: **Split into two discard categories; Category 1 count against IFQ, Category 2 count against sector or ACL; for some discard the estimate is based on trips with observer coverage**:

Discard 1 IFQ Accounting:

• Dumped off deck (e.g., shoveled, picked out of net)
• Dumped/washed out of net for safety reasons (bleeding, pull zipper, etc.).
• Unobserved sets/hauls (not captured by EM, apply discard rate using WCGOP

Discard 2 Sector or ACL accounting:
• Dropped off gear (use WCGOP estimates)
• Floating fish (use WCGOP estimates)
• Estimated from lost gear (estimate using WCGOP protocol)
• Consumed/used as bait (not captured by EM, use WCGOP estimates)

Option 3: Split into two discard categories; Category 1 count against IFQ, no accounting for discard 2 category:

Discard 1 IFQ Accounting:
• Dumped off deck (e.g., shoveled, picked out of net)
• Dumped/washed out of net for safety reasons (bleeding, pull zipper, etc.).
• Unobserved sets/hauls (not captured by EM, apply discard rate using WCGOP)

Discard 2 No accounting:
• Dropped off gear
• Floating fish
• Lost gear
• Consumed/used as bait

Council staff note: In order for option 3 to be valid it would have to comply with the MSA and National Standards. All catch and discard must be accounted to estimate total mortality estimates and ensure annual catch limits are not exceeded.

2.4 - Definitions for Total Catch Accounting - *Total Catch, Discard, Retained*
See Section 2 of Appendix C of this document.

2.6 - Halibut Retention/Discard with Fishery Specific Options

The Council had specific questions regarding the options for the retention or discard of halibut in each fishery. The GEMPAC developed fishery specific options and took into account the existing regulatory requirements, the current process for viability assessments that are normally conducted by observers, and discard mortality estimations that are applied to each type of gear. IPHC provides the mortality "keys" by fishing gear type that observers use to determine mortality of pacific halibut. The IPHC also determines what mortality rates apply to the different viabilities (Excellent, Poor, Dead for trawl and pot or Minor, Moderate, Severe, Dead for hook and line). The IPHC also has sector specific average mortality rates (i.e., longline and pot). Vessel or sector specific mortality rates based on data from the catch share program could be developed by the WCGOP.

The following gear specific options need to be examined for feasibility and IPHC may need to approve certain options. Council staff and NMFS will work with the IPHC to examine potential changes to halibut mortality assessment methods and the use of sector or vessel specific mortality rates.

For midwater trawl whiting:
Since the fishery is already a maximized retention fishery and all catch is allowed to be retained and landed, all halibut would be considered dead (100% mortality). Current regulations allow fishermen to sort whiting at sea, and if a fishermen chose to do so, would be required to discard halibut. The GEMPAC and GEMTAC believe that sorting at-sea does not occur so only one option was developed for the EM program. If the impact analysis reveals that another option is needed, Council staff will consult the GEMPAC.

For bottom trawl and non-whiting midwater trawl gear:
Option A: Use IPHC mortality rate for specific gear type: 90% mortality if discarded.
Option B: WCGOP scientific observations (assumed 20-30% coverage) is applied to fleet
Option C: IPHC exemption to allow full retention (need to examine the feasibility of this option)
Option D: Captain and crew provide assessment (training would be required)
Option E: Use an appropriate EM viability assessment (currently conducting study, need IPHC approval)
Option F: Use vessel specific viability assessment (update rates periodically)

For Fixed gear:
Option A: Use WCGOP mortality rate for specific gear type: 16% mortality if discarded from longline; 18% mortality rate if discarded from pots.
Option B - **Option F**: same as bottom trawl and non-whiting midwater trawl gear

2.7 - Discard Species Lists Adjustments

The development of a species discard list for each fishery is a difficult task and changing technology may allow expansion of these lists after their initial creation. Each fishery will likely have a specific species discard lists. In the future, recognition software may be further developed or regulatory actions could provide the option to expand or change the species lists, therefore; a process that is efficient and flexible to change the list should be developed. The GEMPAC identified three options to account for technological changes and to streamline the revision of species discard lists for an EM program:

Option 1: NMFS to make determination and provide list to fishers through the NMFS EM Observer Exemption Process.
Option 2: Use Council process for changing species list using routine management measures if initial list is fully analyzed for environmental impacts (e.g., use groundfish specification process, or some other routine management measure).

Option 3: Set initial lists in regulation and change at some future point through Council process with proposed/final rule making.

2.8.2 - Eligibility for Camera Use

Eligibilty criteria would be established in order to use EM. Item 4 in the list was clarified so that civil penalties must not exceed a certain dollar amount *and* timeframe. The phrase now reads as: "Initial eligibility criteria: 4. No civil penalties related to fishing activity exceeding a certain amount and timeframe**."**

2.8.5 - EM Vessel Operational Plan - IVMP Expiration

Regarding the expiration of vessel monitoring plans and at the advice of the GEMTAC, the GEMPAC added an option for an expiration date of vessel monitoring plans that is indefinite. For example the monitoring plan could be approved by NMFS for a period of 2 or 3 years rather than no expiration or an annual expiration. The following is now the current list of options:

Option A – No Expiration unless modifications are made
Option B – Annual Expiration or if modifications are made
Option C – Indefinite (ex. 2 or 3 year duration)

2.9.1 - Equipment Requirements

NMFS policy regarding electronic technologies and fishery-dependent data collection "encourages the use of electronic technologies that utilize open source code or standards that facilitate data integration and offer long-term cost savings rather than becoming dependent on proprietary software." However, the GEMPAC would like to revise the table of alternatives under the category of *EM Equipment Requirements* to clarify that both open source or proprietary software/hardware be allowed if they meet a performance criteria that provides the necessary information to document the discard and transmit the information in a manner that can be used by NMFS to accurately debit quota share accounts.

2.9.2 - Data Transfer Process

The GEMPAC, through advice of the GEMTAC removed enforcement from the potential list of entities that could remove data from a vessel and transfer it to the video reviewer. The GEMTAC thought it would be impractical since it's unlikely that enforcement officers (state or federal) would be available in a timely manner to collect the information from a vessel or too costly (monetarily and time consuming). Two options were added to the list; vessel operator and third-party contractor (possibly hired by a processor, port, or vessel). Both options seemed viable at this time. The draft list in the table of alternatives is:

(Options are not mutually exclusive)
• Crew
• Catch monitor
• PSMFC
• EM Provider
• Contractor (hired by processor, port, or fisher)
• Vessel operator

2.9.3 - Data Confidentiality (all data collected in the EM system)

The GEMPAC added that all data collected, including access to and authorization for public release of the data, is confidential according to the Magnuson-Stevens Act, NMFS internal confidentiality rules, and any new or revised rules that are proposed at this time (NMFS confidentiality Final Rule will be released in 2014).

2.9.4 - Video and Data Processing/Analysis

The GEMPAC added "Third Party" to the list of potential video reviewers. It's possible that some other entity may want to provide just video review and analysis of discard events to NMFS. The list of options is now as follows, (not mutually exclusive):

Option A: NMFS
Option B: PSMFC
Option C: EM Provider
Option D: Third Party

2.10.1 - Payment for Scientific Data Collection/Observations

Previous to the IFQ program NMFS provided scientific data collection on roughly 20 percent of the limited entry trawl fleet. This cost was covered by the Government. Under an EM program scientific data collection will be needed from vessels without an observer. It's estimated that the WCGOP will sample roughly 20-30 percent of the EM fleet however these rates will need to be examined and a sampling scheme developed by NMFS in the future. In addition, a funding source must be identified to support the WCGOP efforts. The GEMPAC developed three options:

Option A: Government funded, same as pre IFQ
Option B: Industry Funded
Option C: Combination of both Government and Industry [Need to consider allocating costs]

2.11 - NMFS Processes

While working through the development of the alternatives and options certain components or portions of the EM program were identified for NMFS to develop. For example, NMFS will need to set up an internal process to conduct a “type-approval” process that authorizes vessels to use certain EM equipment on a vessel, and set up a process for applicants to submit an “Observer Exemption Application” to request use of EM in lieu of an observer.

A list of NMFS processes are identified here; however it’s expected that some of the development will be done in consultation with the GEMPAC or other technical advisors. In addition, regulations will need to be developed to provide specific guidance to fishermen and EM providers, or observer providers (e.g., fill out applications, make changes to individual vessel monitoring plans, or for compliance with program rules). The development of these processes and associated regulations would likely involve a Council deeming process for the Council to review the draft regulations before they go into the proposed rule stage. Approval from the Office of Management and Budget for the collection of information under the Paperwork Reduction Act (PRA) will be needed when appropriate and are preliminarily identified in the list below. The list may be updated as the decision document is developed and the impact analysis expanded.

- Observer Exemption Process (including an application for fishermen, PRA)
- Individual Vessel Monitoring Plan Approval (including a form for submission to NMFS for review, PRA)
- Equipment Type Approval (including a list of specifications for EM providers to accommodate, PRA)
- Approved EM Provider List (including a list of specific criteria for providers to demonstrate their capability and standards, PRA)
- Eligibility Criteria (Initial and Continued)
- Declaration Process to Use EM (possibly including port hail in/out process, PRA)
- Confidentiality Rules (if different from status quo)
- WCGOP Scientific Observation Sampling Scheme

2.12 - Spatial Variation for High Bycatch Areas

The initial set of alternatives provided three options for spatial management while using EM:

Option A - No special provisions
Option B - Fishing activity in areas that are likely to have lower bycatch could be monitored with EM rather than using observers; no EM in high bycatch areas
Option C - Under this option, if you chose to fish in a high bycatch area, a higher level of EM review may be required

The GEMPAC understand the possible utility of this type of management, however; this type of spatial management may add too much complexity to the management of the IFQ fishery and would require identifying additional management areas which in turn may be difficult and costly to manage.

Therefore, the GEMPAC recommends removal of Option B and C for spatial management options.

June 2014

Net Revenue Analysis for Electronic Monitoring on the West Coast

Erin Steiner
Economics and Social Science Research Program
Northwest Fisheries Science Center

June 2, 2014

Contents

1 Introduction

The vessels that participate on the West Coast Groundfish Trawl Catch Share Program are very diverse. Target species in the fishery range from $0.10 per pound to upwards of $3.00 per pound, different species are targeted by different vessels, participation ranges from Southern California to Northern Washington, and vessel length ranges from less than 60 feet to more than 100 feet. These characteristics and others result in different profit margins. It therefore follows that changing the cost structure for monitoring fisheries could have varying effects on different sectors of the fisheries.

We have divided the catch share program into five fisheries: At-sea Pacific whiting, Shoreside Pacific whiting, DTS trawl with trawl endorsement, Non-whiting, non-DTS trawl with trawl endorsement, and Groundfish fixed gear with trawl endorsement. The first section provides summaries for all fisheries, then there is a separate fishery specific section. In the fishery specific sections, we first summarize the data by home port, vessel length, and whether the vessel fished in Alaska. In many cases, some of these "breakouts" are not shown in order to prevent displaying confidential information.

After the summaries, we then calculate the variable cost net revenue and total cost net revenue at various levels of daily electronic monitoring costs and annual electronic monitoring costs. For our purposes, we consider the daily monitoring costs to include the cost of maintaining the equipment and reviewing the data collection by the equipment on-board. The annual cost would include either the cost of renting the equipment or purchasing the equipment, depending on how the final program is implemented. For all statistics shown, observer costs are not included, however, the variable cost net revenue and total cost net revenue with observer coverage can be found by looking at the variable EM costs where the fixed EM costs are zero.

1.1 Data

Estimating the net revenue earned by operating a commercial fishing vessel requires data on vessel revenues and costs. Since the same entity that owns a commercial fishing vessel may also be engaged in any number of other fishing related or non-related activities, it is important to define which revenues and costs are included in the measurement of net revenue.

The NWFSC Economic Data Collection (EDC) program focuses on collecting revenue and cost information directly related to the operation of a commercial fishing vessel. There are a variety of costs that are associated with running a catcher vessel that are not requested on the form because it is difficult to determine the share of the cost associated with the vessel. These costs include items that can be used for activities other than fishing, or are too difficult to allocate to a particular vessel in a multi-vessel company. These expenses include office space, pickup trucks, storage of equipment, professional fees, and marketing. In general, the data collection forms attempt to capture costs that are directly related to vessel maintenance and fishing operations, and not costs that are related to activities or equipment off the vessel. For these reasons, the aggregated measures of costs (variable costs, fixed costs, and total costs) underestimate the true costs of operating a business. Therefore, the measures of net revenye overstate actual net revenue.

Net revenue is calculated two ways: using only variable costs, and using variable costs plus fixed costs (total costs). The first calculation is called *variable cost net revenue*, while the second is called *total cost net revenue*. Variable cost net revenue is useful to examine changes in fishery operations that are not so great as to affect fixed costs. For example, the cost of fishing an additional day, or catching an additional metric ton of fish, is better represented by only considering variable costs. Total cost net revenue is usually a better summary measure of financial gain or loss for an entire year, season, or fishery. For these analyses, we focus on total cost net revenue.

Since most vessels operate in multiple fisheries, much of the available cost data pertain to multiple fisheries. While some of the costs, such as vessel repairs and maintenance, are joint costs, other costs, such as fuel, are not necessarily joint costs but are not reported separately by fishery in the survey. While it is not necessary to disaggregate costs in order to analyze net revenue for all vessel operations, it is necessary in order to analyze net revenue associated with operations in the West Coast groundfish fishery (or any other individual fishery). The methods used for disaggregation can be found in the Economic Data Collection Program Catcher Vessel Report 2009-11.[1]

1.2 Data Sources

For the shoreside sector, landings and ex-vessel revenue were obtained from state fish tickets. The at-sea sector deliveries to motherships were obtained from the NORPAC database and the ex-vessel revenues were obtained from the NWFSC Economic Data Collection (EDC) Program. All cost data were obtained from the EDC Program.

The costs were categorized into variable costs and fixed costs. Note that costs related to obtaining a limited entry trawl permit and quota are not included.

Variable Costs

- Bait
- Captain
- Communications
- Crew
- Fishing association dues
- Food
- Freight
- Fuel and lubrication
- Ice
- License fees
- Observer costs
- Offloading
- Supplies
- Travel
- Trucking

Fixed Costs

- Fishing gear
- Processing equipment
- Vessel and on-board equipment
- Insurance premium payments
- Moorage

[1]Steiner, E., A. Harley, and T.Lee. 2014. Economic Data Collection Program Catcher Vessel Report 2009-11, Northwest Fisheries Science Center. Available at www.nwfsc.noaa.gov/research/divisions/fram/economic/economic_data.cfm.

1.3 Simulating Costs for Electronic Monitoring

In order to analyze the potential effects of the costs of electronic monitoring on the annual profitability of vessels by fishery, we first calculate the total cost net revenue including all fishing revenue and all fishing costs as described above. **Each statistic reported represents the average vessel while participating in that fishery.** The costs and earnings associated with that vessel will be apportioned to each of the fisheries in which it participates. The average total cost net revenue is first reported in the fishery summary tables, and includes the cost of observers. In the electronic monitoring cost tables, the cost of observer coverage was not included and therefore the first row in each of these tables where EM variable costs per day and EM fixed costs per year shows the total cost net revenue assuming that the vessel paid $0 for monitoring, whether the monitoring was observer coverage or electronic monitoring. We chose a set of variable costs per day, $0, $200, $400, $600, $800, $1,000, and annual fixed costs $0, $5,000, $10,000, $15,000, $20,000. This assumes that the fixed costs paid are only for the vessels' operation in that fishery.

2 West Coast Groundfish Catch Share fisheries

We use data from PacFIN and the Economic Data Collection (EDC) program to calculate 2011 revenue and 2011 variable costs. Due to the patchiness of fixed costs, an average of 2009-2011 was used.

2.1 West Coast Groundfish Catch Share fisheries summary

Table 1: Number of vessels per fishery in 2011. A vessel will be counted in all fisheries in which they participated.

	N
At-sea Pacific whiting	18
Shoreside Pacific whiting	26
DTS trawl with trawl endorsement	64
Non-whiting, non-DTS trawl with trawl endorsement	48
Groundfish fixed gear with trawl endorsement	24

Table 2: Average revenue, variable costs, fixed costs, variable cost net revenue, and total cost net revenue ($). Revenues and variable costs are 2011 values, fixed costs are the average of 2009-2011 fixed costs.

	Revenue	Variable costs	Fixed costs	Variable cost net revenue	Total cost net revenue
At-sea Pacific whiting	624,685	257,634	145,517	365,813	220,297
Shoreside Pacific whiting	837,866	407,470	231,491	426,624	195,133
DTS trawl with trawl endorsement	315,167	184,363	69,556	128,802	59,245
Non-whiting, non-DTS trawl with trawl endorsement	104,676	61,762	20,664	42,178	21,514
Groundfish fixed gear with trawl endorsement	288,449	141,997	64,536	144,907	80,371

Table 3: Average variable cost and variable net revenue per day and per pound.

	Variable cost per day	Variable cost per pound	Variable net revenue per day	Variable net revenue per 1,000 lbs
At-sea Pacific whiting	8,498	43	11,456	58
Shoreside Pacific whiting	8,375	55	8,144	52
DTS trawl with trawl endorsement	4,422	451	2,884	239
Non-whiting, non-DTS trawl with trawl endorsement	4,136	414	2,958	265
Groundfish fixed gear with trawl endorsement	4,172	1,637	3,934	1,288

2.2 West Coast Groundfish Catch Share fisheries EM costs

Table 4: Average total cost net revenue for all vessels in the 5 groundfish fisheries, the EM variable costs represent the per day cost to the vessel, the EM fixed costs represent an annual cost for leasing or purchasing the EM equipment. Vessels are grouped in vessel length classes and also by whether the vessel also fished in Alaska. The costs related to observer coverage were not included, however, the daily EM variable costs can be used as a proxy for observer coverage.

EM variable costs per day	EM fixed costs per year	Small vessel (< 60 ft)	Medium vessel (> 60 ft, <= 80 ft)	Large vessel (> 80 ft)	Fished in AK	Only West Coast
0.00	0	58,385	62,623	144,969	199,797	54,903
0.00	5,000	53,385	57,623	139,969	194,797	49,903
0.00	10,000	48,385	52,623	134,969	189,797	44,903
0.00	15,000	43,385	47,623	129,969	184,797	39,903
0.00	20,000	38,385	42,623	124,969	179,797	34,903
200.00	0	51,913	54,812	137,785	192,433	47,651
200.00	5,000	46,913	49,812	132,785	187,433	42,651
200.00	10,000	41,913	44,812	127,785	182,433	37,651
200.00	15,000	36,913	39,812	122,785	177,433	32,651
200.00	20,000	31,913	34,812	117,785	172,433	27,651

3 At-sea whiting

In 2011, there were 18 vessels that participated in the At-sea Pacific whiting fishery. Most of those vessels also fished in Alaska and had home ports in either Newport or Seattle, other ports cannot be shown to protect confidential information.

3.1 At-sea whiting summary

Table 6: Number of vessels per length category in the At-sea Pacific whiting fishery

	N
Small vessel ($<$ 90 ft)	5
Medium vessel ($>$ 90 ft, $<=$ 110 ft)	6
Large vessel ($>$ 110 ft)	7

5 DTS trawl with trawl endorsement

In 2011, there were 64 vessels that participated in the DTS trawl with trawl endorsement fishery. Of those, only three fished in Alaska. Home ports were located throughout the entire West Coast. Using 2011 revenues, costs, and days at sea, the vessels that also fished in Alaska had negative total cost net revenue in 2011, and in our simulations of electronic monitoring costs, small vessels (<65 feet) started generating negative total cost net revenue when variable costs reached $600/day. The average vessel in Newport, Charleston and Fort Bragg experience negative net revenue at relatively low levels of electronic monitoring costs. The average vessel in Washington, Astoria, Brookings, and Crescent City/Eureka never generated negative total cost net revenue in our simulations.

5.1 DTS trawl with trawl endorsement summary

Table 17: Number of vessels per length category in the DTS trawl with trawl endorsement and whether the vessels also fished in Alaska

	Fished in AK	Only West Coast
Large vessel (> 75 ft)	3	21
Medium vessel (> 65 ft, <= 75 ft)	0	21
Small vessel (< 65 ft)	0	19

6 Non-whiting, non-DTS trawl with trawl endorsement

In 2011, there were 48 vessels that participated in the Non-whiting, non-DTS trawl with trawl endorsement fishery. Of those, only four fished in Alaska. Home ports were located throughout the entire West Coast. The vessels that also fished in Alaska had negative total cost net revenue in 2011, and in our simulations of electronic monitoring costs, small vessels (¡65 feet) started generating negative total cost net revenue when variable costs reached $600/day. The average vessel in Newport, Charleston and Fort Bragg experience negative net revenue at relatively low levels of electronic monitoring costs. The average vessel in Washington, Astoria, Brookings, and Crescent City/Eureka never generated negative total cost net revenue in our simulations.

6.1 Non-whiting, non-DTS trawl with trawl endorsement summary

7 Groundfish fixed gear with trawl endorsement

In 2011, there were 24 vessels that participated in the Groundfish fixed gear with trawl endorsement fishery. Of those, only four fished in Alaska. Home ports were located throughout the entire West Coast. Using 2011 revenues, costs, and days at sea, the average vessel fishing in Northern Oregon had negative net revenue, all other vessels had positive total cost net revenue, ranging, on average, from $33 thousand to $75 thousand. Taking into account the potential costs of electronic monitoring, small and medium sized vessels ($\leq$ 60 feet) maintained positive total cost net revenue, while, large vessels when electronic monitoring costs reached $800/day and annual fixed costs were at least $15 thousand. Aside from Northern Oregon vessels which had negative total cost net revenue before electronic monitoring costs were taken into account, Southern California was the only other group by vessels that experienced negative total cost net revenue once electronic monitoring costs were taken into account.

7.1 Groundfish fixed gear with trawl endorsement summary

Table 30: Number of vessels per length category in the Groundfish fixed gear with trawl endorsement.

	N
Small vessel (< 50 ft)	8
Medium vessel (> 50 ft, <= 60 ft)	8
Large vessel (> 60 ft)	8

Table 31: Number of Groundfish fixed gear with trawl endorsement vessels that fished in Alaska or only on the West Coast.

	N
Fished in AK	4
Only West Coast	20

Table 32: Number of vessels by port/state in the DTS trawl with trawl endorsement fishery.

	N
Washington	5
Northern Oregon	5
Southern Oregon	6
Northern California	4
Southern California	4

Fixed Gear

Comparing on-board compliance monitor haul level retained and discarded catch estimates with video reviewer estimates of IFQ species aggregated to the haul level. No weight estimates were made in 2012.

Bottom Trawl

Comparing on-board compliance monitor haul level retained and discarded catch estimates with video reviewer estimates of IFQ species aggregated to the haul level. No weight estimates were made in 2012.

Overview/History

The objective of the Electronic Monitoring (EM) program is to test the viability of Electronic Monitoring as a source of data to document individual accountability of catch and bycatch in the Pacific Trawl Rationalization Program.

Pacific States Marine Fisheries Commission (PSMFC) launched the Electronic Monitoring program in 2012 in anticipation of the Pacific Fishery Management Council (PFMC) considering EM as a compliance monitoring tool in the newly implemented Pacific Trawl Rationalization Program.

In order to effectively and accurately debit discarded catch from individual fishing quota (IFQ) holder accounts, the PFMC instituted 100% human observer coverage on all trips for all vessels participating in the IFQ fishery. The cost of this program was regulated to transition from federally subsidized to industry funded over the course of the first 3 years of the program. The industry is interested in finding a less costly and more flexible method to monitor catch and discards at sea.

During the April 2013 PFMC meeting, "the Council indicated their desire to move ahead with consideration of electronic monitoring (EM) by stating that **compliance monitoring, rather than the collection of biological data, would be the primary focus for EM in the trawl catch share program**[...]"

The electronic monitoring program is meant to address some key questions, including: can video monitoring be used effectively to track an individual's catch to be debited from a quota account; and how much would such a program cost the industry as compared to the human compliance monitor program?

The expectation is that the West Coast Groundfish Observer Program (WCGOP) will continue to administer a level of scientific observer coverage to provide stock assessors and other scientists the necessary scientific data for effective management of the various West Coast fisheries. The EM program is not meant to replace scientific observers. This program is solely meant to explore the ability of electronic monitoring systems to estimate the at-sea discards of vessels for the purposes of effectively debiting quota accounts throughout the fishing season, therefore replacing the need for 100% at-sea human compliance monitor coverage. For this reason, throughout this document we will use the term observer when we are referring to the tasks performed by a WCGOP observer for the purposes of science data collection and refer to at-sea Compliance Monitors (CMs) when reporting data related to the compliance monitoring role.

Finalized 2012 and 2013 at-sea compliance monitoring data were received from the WCGOP for comparison to the video data. Since retained catch is weighed and accounted for by fish dealers at the dock, discards were the main concern for at-sea catch accounting of IFQ species on this project. While analysis of both retained and discarded data are presented in this report, the discard analysis should be more closely scrutinized for this reason.

Providers

PSMFC contracted with Archipelago Marine Research (AMR) in 2012 and both AMR and Saltwater, Inc. in 2013 to provide and install electronic monitoring (EM) systems on volunteer fishing vessels in the midwater trawl, bottom trawl, and fixed gear fisheries, collect data drives from the vessels, train PSMFC video reviewers, and provide logistical support. AMR also provided Electronic Monitoring Interpret™ Pro (EMI) software for converting the raw data into usable catch information.

Archipelago Marine Research

The on-board AMR system includes sensors for drum movement, hydraulic pressure, and GPS locations from which the speed of the vessel is calculated, and 1-4 cameras. To aid in review and interpretation of the video data, the sensor, GPS and video output are integrated within the EMI software mentioned above. A GPS location along with any sensor data was recorded every ten seconds during a trip. Sensor data was recorded at all times that the vessel's power was on. Gaps therefore occurred when in port and the vessel was powered down or the system was turned off manually to prevent the system from draining the vessel's battery when in port. On midwater and bottom trawl vessels, the system was configured to trigger recording video when the vessel moved outside of a "port area" geo-fence designated by AMR and continue recording imagery until they returned to port. On fixed gear vessels, systems were configured to trigger recording video when the hydraulic pressure exceeded a threshold that was set by the technician that installed the equipment and was specific to each vessel. Imagery recording would then continue for 20 minutes in 2012 and 30 minutes in 2013 past the last use of those hydraulics to allow for all catch handling to be captured for each haul.

When the raw sensor and video data were received by PSMFC, annotations were made using the AMR software EMI. Start and end dates, times, and locations, for trips and hauls as well as gear and catch information were captured using EMI. The annotation data were imported into a Microsoft Access Database for analysis.

Saltwater, Inc.

The on-board Saltwater system includes a sensor for hydraulic pressure, a GPS for location data which is stamped on the video of one camera, and 2 cameras. One camera is situated high above to capture the entire deck in a single view, while the second camera is positioned closer to the fishing activity to get a better view for the identification of retained and discarded fish. The cameras are capable of initializing and recording either 100% of the time or only when the hydraulic sensor achieves a pressure level preset by the technician and for 15 minutes after the pressure drops below that set level. The sensor and video data are not integrated.

When the raw sensor and video data were received by PSMFC, Mobotix software was used to identify trips and hauls. Since no data capturing tool was provided, video reviewers recorded all information on sheets of paper that will be data entered into a database by PSMFC. Start and end dates, times, and locations, for trips and hauls as well as gear and catch information were captured.

Saltwater, Inc. data are not presented in this report.

Definition of Catch

For the purposes of EM review, catch is anything that we see that breaks the surface, excluding sea birds and marine mammals that are swimming freely alongside the vessel. If it is kept on the vessel, it is recorded as retained. If it is not kept on the vessel, it is recorded as discard. Discard includes marine organisms that wash out of the net before the net comes onboard the vessel, that fall off or out of fishing gear before it makes it on the vessel, or are free floating on the surface.

Hake

Methods

EM systems were installed on 6 volunteer hake trawl vessels fishing IFQ quota out of Newport and Astoria, Oregon in 2012 and 4 in 2013. All fishing vessels carried the EM system for most of the fishing seasons. In 2012, all 6 made both shoreside and mothership deliveries. In 2013, less than three made mothership deliveries, barring our ability to report results for that fishery. Results for 2013 shoreside hake delivery trips are reported.

Retained catch, or catch transferred to the mothership, was calculated by video reviewers by counting the number of straps of the codend that contained fish. This number was then multiplied by an estimated weight per strap in 2012, and a known weight per strap supplied by the skipper in 2013, to get the total weight of retained fish in the codend.

While compliance monitors make independent estimates of total catch and discards, they are advised to use skipper hailed weights recorded in the vessel's logbook for retained catch when they are available and to make individual estimates of retained catch only when a vessel logbook is not available (Ryan Shama, personal communication, March 19, 2013).

While specific protocols are in place to try to accurately estimate the weight of discards, general methods can be described here. One method is visualizing how many round baskets the discarded fish may fill. With the conversion of 80 lbs of hake per basket, the video reviewer is able to calculate an estimate of total weight. A second method is using the codend and the supplied weight per strap values to visually estimate the weight of fish lost. If the video show approximately one strap worth of fish spilling out of the net and the known weight per strap for that codend is 2,000 pounds then the video reviewer will record 2,000 pounds of discard. Estimating weight of discards that are floating on the surface of the water with no real reference is more subjective. Video reviewers will use a variety of methods to try estimating the weight as closely as possible, including visualizing how many round baskets the fish would fill and taking into account how densely packed the fish are on the surface.

Compliance monitor and video hauls were matched using vessel ID, set date, and order of haul on that fishing date. For example, haul 3 of a fishing day in the compliance monitor data was matched to haul 3 of the same fishing day for the same vessel in the video data. This was necessary since there could be multiple hauls in a day and the haul times did not match exactly. The quality of the match was then confirmed manually in excel and adjustments were made where necessary. Adjustments were only necessary if a time gap occurred in the electronic data that led to the EM system missing a haul, a haul occurred near the midnight time mark causing a different date in each of the datasets, if the EM data recorded an individual haul with very little catch (~5000lbs) that was put in the hold when the observer data did not, or if the EM data recorded a net cleaning where the observer data did not.

Most hauls in the EM data had corresponding hauls in the compliance monitor data. It was therefore possible to compare catch at the haul level.

Of all the hake trips reviewed by EM to date, 15 were mothership catcher-vessel trips in 2012 and 236 were shoreside delivery hake trips with 154 from 2012 and 82 from 2013. One trip in the 2012 dataset included one mothership delivery haul and the catch from the remaining hauls of the trip was stored onboard and delivered shoreside (Table 1).

In 2012 and 2013 a total of 75 hake trips were missing electronic data entirely, 65 of which were due to skippers not turning the system on when they went fishing. This was a concentrated occurrence with a small number of vessels. Three were due to improper activation of the system by a technician. Seven were from a single vessel that had a technical problem with the EM system interfering with the VMS system. Since VMS is mandatory, the EM system was kept turned off until the issue was resolved.

Official haul level catch amounts delivered to motherships were available from NORPAC data in PacFIN. Since fish tickets are not available for this fishery, the NORPAC dataset is the best estimate for total catch amounts delivered from the catcher vessels to the motherships. The NORPAC official total catch weight of a haul is the aggregated total weight of retained and discarded fish of that haul. To extract the weight of the codend that was delivered to the mothership from the official total catch weight, the WCGOP recorded discards were subtracted from the official total catch weight of the haul.

Official trip level landed weights were available for the shoreside deliveries from the state landing receipts in PacFIN. These were matched based on vessel ID and return date. All hauls or trips had corresponding official retained catch amounts.

To address concerns voiced in the PFMC Electronic Monitoring Workshop about quality of EM discard estimation with night light versus day light, hauls brought on board in day light and night light were differentiated in the figures where possible. Hauls brought onboard between 6 AM and 6 PM were labeled day hauls, and hauls brought onboard between 6 PM and 6 AM the next day were labeled night hauls.

Results and Discussion

Shoreside Hake
(2012 and 2013)

Results
Retained

Retained catch estimated by the video compared to the compliance monitor data and the official catch data on fish tickets from PacFIN had very similar patterns (Figures 2, 4, 6 and 7). In both 2012 and 2013, the trend line qualitatively tracked the video = compliance monitor reference line closely. In 2012, the trend line hovered just above the reference line.

Discard

In 2012, the compliance monitor data contained a larger number of discard events than the video data. Despite this, the total amount of discarded weight captured by the video was estimated to be almost double the discarded weight captured by the compliance monitor (Table 2). Most discard events were very small (Figures 3 and 5). In 2012, only six observations of discards occurred during the night and all were from the compliance monitor dataset. There were only 4 hauls where discards were recorded in both datasets.

In 2013, the video data contained a larger number of discard events than the compliance monitor data. Again, the total amount of discarded weight captured by the video was estimated to be almost double the discarded weight captured by the compliance monitor (Table 2). Most discard events were very small (Figures 3 and 5). In 2013, both datasets observed discard events during the night. There were only 15 hauls where discards were recorded in both datasets

Discussion
The shoreside hake haul level retained weights were on average (using the trend line as a gauge) accurate but had variability when assessing at the trip level (Figures 6 and 7). In 2012 the variability was higher with the EM estimates larger on average. This was likely due to vessel to vessel variability of nets and codend capacity and the lack of information about each vessel that the video reviewers had available to them when estimating catch. In 2013, with skipper provided net capacities, variability was lower with the trend lines tracking the reference line very closely.

The discarded catch estimates were more variable than in the at-sea catcher vessel fishery with only 4 of the 30 total discard observations in 2012 and 15 of the 100 total discard observations in 2013 overlapping in both datasets (Table 2). Most of the discard observations were only detected in one of the two datasets. The magnitude of most of these discard events were generally small at less than 2,000 pounds (Figures 3 and 5).

In 2012, there were four discard events that were larger than 2,000 pounds that were recorded by the video but not the compliance monitor. Two of these were blowout panel discards prior to the net boarding the vessel. The other two were due to deck washing of fish. The one discard event recorded in the compliance monitor data but not in the video data that was larger than 2,000 pounds was also a deck washing event.

In 2013, there were four discard events that were larger than 2,000 pounds that were recorded by the video but not the compliance monitor. All four were blowout panel discards prior to the net boarding the vessel. This means that the discard occurred as the codend was approaching the stern of the vessel. The one discard event recorded in the compliance monitor data but not in the video data that was larger than 2,000 pounds was not evident upon a second review of the video data.

Discussion with WCGOP suggested that while additional training is in order to ensure discards are not missed, some of these discard events not being recorded is due to safety concerns, and the difficulty to see and quantify discards that are in the water from the low angle of standing on the deck of the boat. It is important to note that the EM system has cameras mounted on the aft gantry that provide a long field of view behind the vessel that the CM cannot get. Also, the EM system has multiple views of the vessel and the water at once and can be reviewed multiple times if needed to get an accurate estimate of total discards.

Mothership Catcher Vessels
(*2012 Only, 2013 is Confidential)*

Results
Retained

Retained catch estimated by the video compared to the compliance monitor data and the official catch data from NORPAC had very similar patterns (Figure 8). Again, the relationship of video to compliance monitor retained estimates was consistent regardless of whether the haul was retrieved in night-time or day-time lighting. The relationship between video and compliance monitor retained estimates fell across the video = compliance monitor/NORPAC reference line. Video retained catch estimates tended to be higher than compliance monitor estimates on loads smaller than 50,000 pounds, and tended to be lower than compliance monitor estimates on loads larger than 50,000 pounds (Figure 8).

Discard

The video data contained a larger number of discard events than the compliance monitor data, and those discard events were estimated by the video to be larger than the compliance monitor estimate (Figure 9). Most discard events were very small. The relationship of video to compliance monitor discard estimates was consistent regardless of whether the haul was retrieved in night-time or day-time lighting.

Discussion
No information was obtained from the vessels in 2012 about the capacity of their nets or the dimensions of their vessel to aid in catch estimation from the camera view prior to video reviewing. Obtaining this information in 2013 helped with the accuracy of estimation of retained catch weight in codends.

Discard events were much more abundant in the video data than in the compliance monitor data for this fishery (Table 2). The majority of the discard events recorded in the video data were of a magnitude smaller than 2,000 pounds. This suggests that compliance monitors were not recording discards in most instances when the magnitude was considered small. In 2012, compliance monitors were instructed to only record discard events that were larger than 2-3 baskets or more than 100 pounds. Protocols were revised just prior to the 2013 season so that all discard events, regardless of their size, were recorded.

In 2012, there were five large discard events above 2,000 pounds, ranging from 3,000 to 16,000 pounds not reported in the compliance monitor data. All five of these events were net bleeds due to the codend being overcapacity, making it impossible to tie the codend off prior to transfer to the mothership. When WCGOP reviewed video of such events they agreed that there was a large discard. Compliance monitors reported that they were instructed by the Captain to stand amidships rather than near the stern due to safety concerns. This might have prevented them from seeing some discard events which happened very close to the stern ramp, causing there to be no record of a discard in the WCGOP data.

Fixed Gear

(*2012 and 2013)*

Methods

The electronic monitoring system was installed on volunteer fixed gear vessels (5 in 2012 and 5 in 2013) fishing IFQ quota out of Morro Bay, CA, Half Moon Bay, CA, Coos Bay, OR and Newport, OR. All but two of the vessels fished pot gear solely. Two vessels fished both pot and longline gear.

Two definitions for fixed gear hauls are presented in the WCGOP manual for the IFQ fishery:

> "A set begins at a buoy and ends at a buoy. The set includes all of the hooks or pots in between the two buoys." (NWFSC 2012, Section 5-8)
>
> "Small pieces of gear with individual buoys are often set haphazardly in a general area or fishing spot. The gear is frequently set and retrieved over and over again, with individual pieces of gear soaking for as little as 5 minutes between retrievals. If each retrieval was considered a set, one day of fishing could have over fifty sets, with each set only having one or two fish caught. Obviously, this would create an unreasonable quantity of paperwork for the amount of data collected. Therefore, individual pieces of gear can be grouped to form a single set using a standard set of criteria." (NWFSC 2012, Section 6-10)

Since strings of gear were distinguishable by the EM system, the former definition was used. The compliance monitor used the second method to define a haul on some of the corresponding trips.

On many trips, the haul count in the compliance monitor data was much lower than the count from the video data (Table 1). This difference in haul definition at the data level led to an inability to assess catch at the EM haul level and thus catch data were compared to compliance monitor data at the compliance monitor haul level. EM hauls were aggregated to correspond to the compliance monitor haul designation and were matched manually in excel. All trips monitored electronically had corresponding trips in the compliance monitor data.

In the two years of fixed gear participation in the EM project four trips did not have any EM data recorded. Three trips were due to the skipper failing to turn the system on and one was due to a system failure (Table 1).

In-season feedback

In 2012, fishermen and technicians were not given in-season feedback on how to maximize data quality for the video project. Thus, there were instances where the fishermen or the compliance monitors stood with their backs to the camera while sorting, or sorting of catch was conducted out of camera view, or cameras were poorly placed, which made counting and classifying catch into species groupings impossible.

In 2013, fishermen and technicians were given in-season feedback on how to maximize data quality for the video project. Increased communication greatly reduced technical and behavioral issues that would hinder catch identification and quantification.

Weights or counts

In 2012, weights were not directly estimated by the video reviewer. Instead, counts of individual pieces for each species or grouping were recorded. All fish seen on the video were counted by the reviewer including fish that dropped off of the line before being pulled onto the fishing vessel and fish that were damaged or partially eaten. Fish whose fate could not be determined due to being taken or thrown out of camera view or the video ending before fish were put into the hold or discarded were recorded as disposition 'unknown'.

In 2013, in addition to counts, weights were also estimated. Weight estimation was done by either obtaining information from the skippers on the hold capacity of discrete areas on their vessel where they tended to sort fish, or by obtaining information on how much a standard round basket weighed when filled with specific species. This information aided in converting visual estimates of volumes of fish to weights.

Weights recorded by the compliance monitor were based on actual or average weights collected during each trip.

Compliance monitor data contained more species specific information than was possible to collect from the video data. Data were therefore aggregated to different levels of groupings to aid in comparisons of catch quantities.

Excluded data

Some compliance monitor hauls were subsampled, and then the counts and weights were expanded to the full haul. Since these numbers were not true counts and weights, hauls that were expanded were excluded from the catch comparison.

Other reasons for exclusion include gear problems, if a clean haul merge was not possible between the CM and video data, or if the condition of the video data was not usable.

Filtering left 952 (620 from 2012 and 332 from 2013) of the total 1,256 EM recorded hauls to be included in the analysis.

Retained and discarded counts and weights of fish were compared to compliance monitor data at the haul and IFQ complex and species group level. Results for the IFQ groupings sablefish, rockfish, thornyheads, and flatfish are reported in this document.

Since only two vessels used longline gear, results could not be reported by fixed gear types (pot vs. longline) due to confidentiality rules. Both pot and longline gears were therefore reported on the same figures.

Results

Three general patterns emerge for all results. The first is that video reviewers had higher species identification success in 2013 than they did in 2012. The second is that in 2013, the relationship between CM and video reviewer weight estimates showed more variability than the relationship between counts. Finally, discarded catch had lower speciation and quantification success than the retained catch.

For the target species of this fishery, sablefish, compliance monitor and video reviewer estimates of retained and discarded catch tracked the reference line closely in both 2012 and 2013 (Figure 10).

For Pacific hake, no retained hake were recorded in either datasets. The CM record shows 30 fish discarded on observed hauls in 2013 while the video reviewer only recorded 10 (Table 3). There were four instances of CM recorded hake where the video review recorded none.

For flatfish, quantification of retained counts improved from 2012 to 2013. Fewer discards were recorded in 2013 than in 2012 (Table 3, Figure 11a).

Dover sole were the most frequently seen flatfish in the fixed gear fishery. In 2012, CM recorded more dover sole retained than the video reviewer. This aggregate trend reversed in 2013 (Table 3). Video recorded fewer discards in both years (Table 3, Figure 11a). Records of 11 discarded and retained petrale sole recorded in 2013 by the CM were not recorded by the video reviewer (Table 3). Similarly, records of 8 arrowtooth flounder in the EM dataset in 2012 had no corresponding record in the CM dataset. Record of one discarded arrowtooth in the

CM dataset was recorded as retained in the EM dataset. Number of unidentified flatfish decreased from 2012 to 2013 (Table 3, Figure 11c).

For rockfish, fewer rockfish were recorded as unidentified in the EM data in 2013 (Table 3, Figure 12). In 2012, all of the rockfish recorded by the CM were from the minor slope rockfish complex; most of these were recorded as unidentified rockfish by the video reviewer. In the 2013 CM dataset, all except one of the rockfish seen in this fishery were from the Minor Slope Rockfish complex (Table 3, Figure 12). A single Pacific ocean perch rockfish was recorded in the CM dataset. This fish was recorded as unidentified in the EM dataset. There were 5 fish identified as darkblotched rockfish in the EM dataset but recorded as minor slope rockfish in the CM dataset (blackgill or rougheye rockfish). At the haul level, the trend line for retained minor slope rockfish in 2013 tracked the reference line closely for counts and was slightly above for weights (Figure 12).

For thornyheads, longspine thornyheads were consistently recorded as mixed thornyheads in the EM dataset (Table 3, Figure 13b). Retained haul level shortspine thornyhead and total thornyhead counts in both 2012 and 2013 tracked the reference line very closely (Figures 13a). There were few discards of thornyheads yet the EM data recorded fewer individuals than the CM dataset. Some of these thornyheads were identified as “Red rockfish” in the EM data.

Discussion

Video reviewers’ higher species identification success in 2013 than in 2012 could be due to multiple factors. First, AMR cameras were upgraded from analog to digital at the beginning of the 2013 season. This means that the video reviewers were working with higher resolution video and an ability to zoom into the camera views. Second, the video reviewers had moved up the learning curve, improving their species identification by camera. Third, feedback to fishers and technicians was a focus during the 2013 season, improving camera angles, video coverage of the deck, and fisher or compliance monitor behavior.

The higher variability in the relationship between CM and video reviewer weight estimates than between count estimates is simple. Compliance monitors weigh fish on scales while video reviewers are making educated estimates of the weight of fish that they see. Using onboard measuring boards to assist in converting length to weight for some species is being tested along with testing accuracy of volume estimates and establishing tested volumetric weight conversions. Results are not available.

Video reviewers have noted that speciation of discards was more difficult than retained catch due to the nature of where the CM work station was on the deck of the vessel. The CM was often in a corner of the deck further from the camera than where retained catch was being sorted. Although efforts were made to place a camera focused on the part of the deck where the CM typically worked, this location was not always constant between trips or even hauls on a trip.

Fish can generally be identified to the species group level (flatfish or rockfish) successfully (Figures 11a and 12), but this is not sufficient for the IFQ fishery. Since quota is tracked at the IFQ complex level, including a number of individual flatfish and rockfish species, discards must be tracked at the IFQ grouping level. In the fixed gear fishery, identification to the IFQ complex greatly improved between 2012 and 2013, especially for the larger volume IFQ species seen in the fishery, such as sablefish, dover sole, and minor slope rockfish.

Bottom Trawl

(2013 Only, no volunteers in 2012)

Methods

The AMR electronic monitoring system was installed on 6 volunteer bottom trawl vessels fishing IFQ quota out of Morro Bay, CA, Coos Bay, OR and Newport, OR. Some were not installed until after the shrimping season in November of 2013.

EM hauls were matched to the compliance monitor hauls manually based on vessel, haul date and time.

Nine trips did not have any EM data recorded. All 9 were due to interference with the VMS system onboard two of the vessels (Table 1). The skippers intentionally kept the systems turned off until the problem could be resolved.

In-season feedback

In 2013, fishermen and technicians were given in-season feedback on how to maximize data quality for the video project. Increased communication greatly reduced technical and behavioral issues that would hinder catch identification and quantification. Despite this, the bottom trawl fishery is a high volume mixed species fishery. In this fishery, catch is sorted onboard and there can be large amounts of selective discarding at sea. This means that larger changes in fisher behavior are required to accurately speciate and quantify catch.

Weights or counts

Counts were not estimated by the video reviewer for all catch due to the nature of this fishery. Instead, weights and species of catch were estimated.

All fish seen on the video were estimated by the reviewer including fish that spilled from the net before being pulled onto the fishing vessel. Fish whose fate could not be determined due to being taken or thrown out of camera view or the video ending before fish were put into the hold or discarded were recorded as fate 'unknown'. Weight estimation was done by either obtaining information from the skippers about how much areas on their vessel that they tended to sort fish into could hold, or by obtaining information on how much a standard round basket weighed when filled with specific species. This information aided in converting visual estimates of volumes of fish to weights.

Compliance monitor data contained more species specific information than was possible to collect from the video data. Data were therefore aggregated to different levels of groupings to aid in comparisons of catch quantities.

Excluded data

Some hauls were excluded from the catch comparisons. Reasons for exclusion include gear problems, if a clean haul merge was not possible between the CM and video data, or if the condition of the video data was not usable. Filtering left 247 of the total 274 EM recorded hauls to be included in the analysis.

Retained and discarded weights of fish were compared to compliance monitor data at the haul and IFQ complex and species group level. Results for the IFQ groupings sablefish, rockfish, thornyheads, and flatfish are reported in this document.

Results

Reminder: Weight estimates were made in the bottom trawl fishery from video data. As seen in the fixed gear fishery, weight estimates can have more variability than counts since there is no direct way to measure the weight of the fish. Therefore, all of the results will show noise around the trend lines. Counts were not recorded in all instances due to the high volume nature of the fishery. Counts are therefore not used in this report.

Also, in most cases, discarded IFQ fish were being sorted by the on board catch monitor prior to discarding. If subsampling occurred, the remainder of the discarded catch was pushed overboard unsorted. These data therefore represent accuracy of speciation and quantification of sorted discarded catch.

For sablefish, lingcod and Pacific halibut (Figure 14), compliance monitor and video reviewer estimates of retained and discarded catch tracked the reference line closely on average. There was one halibut that was recorded by the CM as discard that was recorded as retained in the EM dataset (Table 3, Figure 14). According to the observer, this PHLB was discarded via a scupper that was off camera. There was a different halibut that was recorded by the CM as a discard but was missed by the video reviewer.

For Pacific hake, the discard estimates tracked the reference line but the retained estimates were far off (Table 3, Figure 14). The EM data estimated 3,565 pounds of retained weight for the bottom trawl fishery where the CM data recorded only 480 pounds. Fish tickets recorded 3,603 lbs of Pacific hake.

For flatfish, in aggregate at the flatfish group level, both retained and discard estimates from the video data were lower than measurements in the CM data (Table 3, Figure 15). There are a number of clustered points in the retained figure on the X- axis giving the appearance that there are a number of hauls where the EM data did not see more than 2000 pounds of catch. These fish were recorded by the video reviewer but were categorized as unidentified groundfish (or mixed groundfish). These were cases where the crew did not sort their retained catch on board but pushed mixed catch into the hold. This behavior makes it impossible for the video reviewer to identify and quantify the retained catch. When sorting is done prior to retained catch being stowed in the hold, identification and quantification is more successful.

For the larger magnitude species, arrowtooth flounder and petrale sole, the retained and discard trend line falls on or slightly below the reference line for retained catch and below the reference line for discarded catch (Figure 15). For dover sole, retained catch is quantified effectively with the trend line falling on the reference line whereas discarded catch is not captured by the video reviewer, with the CM data reporting 793 pounds of discards and the EM data reporting only 245 pounds (Table 3).

For rockfish, in aggregate at the haul level, quantification of both discards and retained catch tracked the reference line (Table 3, Figure 16a). There are a number of data points clustered on the Y-axis with the EM data having record of 200-500 pounds of retained rockfish that were not recorded by the CM. Many of these data points were instances where the video reviewer categorized the catch as unidentified rockfish but could not see the species, and the CM recorded them as longspine thornyheads. The trend line for discarded rockfish fell slightly below the reference line due to a number of hauls where the CM data reported rockfish but the EM data did not. All of these were due to lack of sorting of discarded catch, with large volumes of catch that were subsampled by the observer being shoveled off of the deck and pushed out the scuppers.

Splitnose rockfish was consistently recorded as unidentified rockfish (Table 3, Figure 16a).

Retained chilipepper rockfish were accurately identified and quantified (Table 3, Figure 16a).

Retained minor slope rockfish were accurately categorized for most hauls with only three hauls of large magnitude being categorized as unidentified rockfish causing the trend line to fall below the reference line (Figure 16b).

Discarded minor slope and minor shelf rockfish were consistently recorded as unidentified rockfish by the video reviewer (Table 3).

For thornyheads, longspine thornyheads were consistently recorded as mixed thornyheads or unidentified rockfish in the EM dataset (Table 3, Figure 17). Retained haul level total thornyhead weights tracked the reference line very closely (Figure 17). The trend line for retained shortspine thornyhead was slightly low. Discards of thornyheads were all recorded as 70 pounds or less on any given haul.

Discussion

As in the fixed gear fishery, fish can generally be identified to the species group level (rockfish, thornyheads or flatfish) successfully with bottom trawl gear (Figures 11a, 12, and 13a). Since quota is tracked at the IFQ complex level, including a number of individual flatfish and rockfish species, discards must be recorded at the IFQ complex level. With the exception of minor slope, minor shelf, splitnose rockfish and longspine thornyheads, other IFQ complexes were successfully identified by video reviewers with the current technology available. Weight estimation could be improved using other methods that will be tested in the coming months.

When complete sorting of discards and retained fish occurred on deck, most of the flatfish species were identified effectively to the IFQ complex. For rockfish, identification was less successful with most of the rockfish being categorized as unidentified rockfish by the video reviewer. Video reviewers have noted that if they cannot identify a rockfish to the species level, it is not possible with the current camera views to categorize them into broader categories such as minor slope, minor shelf, or neither. Speciation was even more difficult for discarded catch due to the nature of where the CM work station was on the deck of the vessel. The CM was often in a corner or at the end of the trawl alley further from the camera than where retained catch was being sorted. Although efforts were made to place a camera focused on the part of the deck where the CM typically worked, this location was not always constant between trips or even hauls within a trip.

Sorting discards in a specific location of the deck may improve the video reviewer’s ability to consistently identify discarded IFQ rockfish. Video reviewers, however, still could not identify almost all of the splitnose rockfish that were retained or discarded when the catch was sorted. Preliminary results of a discard chute study indicate that identification of splitnose is possible using a discard chute where it is not possible on the same haul using other camera views. Whether identification is accurate is yet to be determined. Results from that study will be published at a later date.

Finally, longspine thornyheads were impossible to identify to the species level. When in hand, a longspine thornyhead often requires careful examination to confirm its identity. Shortspine thornyheads are easier to identify due to the larger size that they can achieve. This means that if the video reviewers see what looks like a thornyhead and the specimen is larger than a longspine could be, they are able to use the size of the fish to categorize it as a shortspine thornyhead, explaining the higher success of identification for shortspine thornyheads. Despite this, thornyheads are red, spiny fish and sometimes cannot be differentiated from a red rockfish on the deck.

Acknowledgements

We would like to thank the owners, skippers, and crew of the volunteer fishing vessels for volunteering and helping this project. We would like to thank the West Coast Groundfish Observer Program for providing data for this report.

Figures

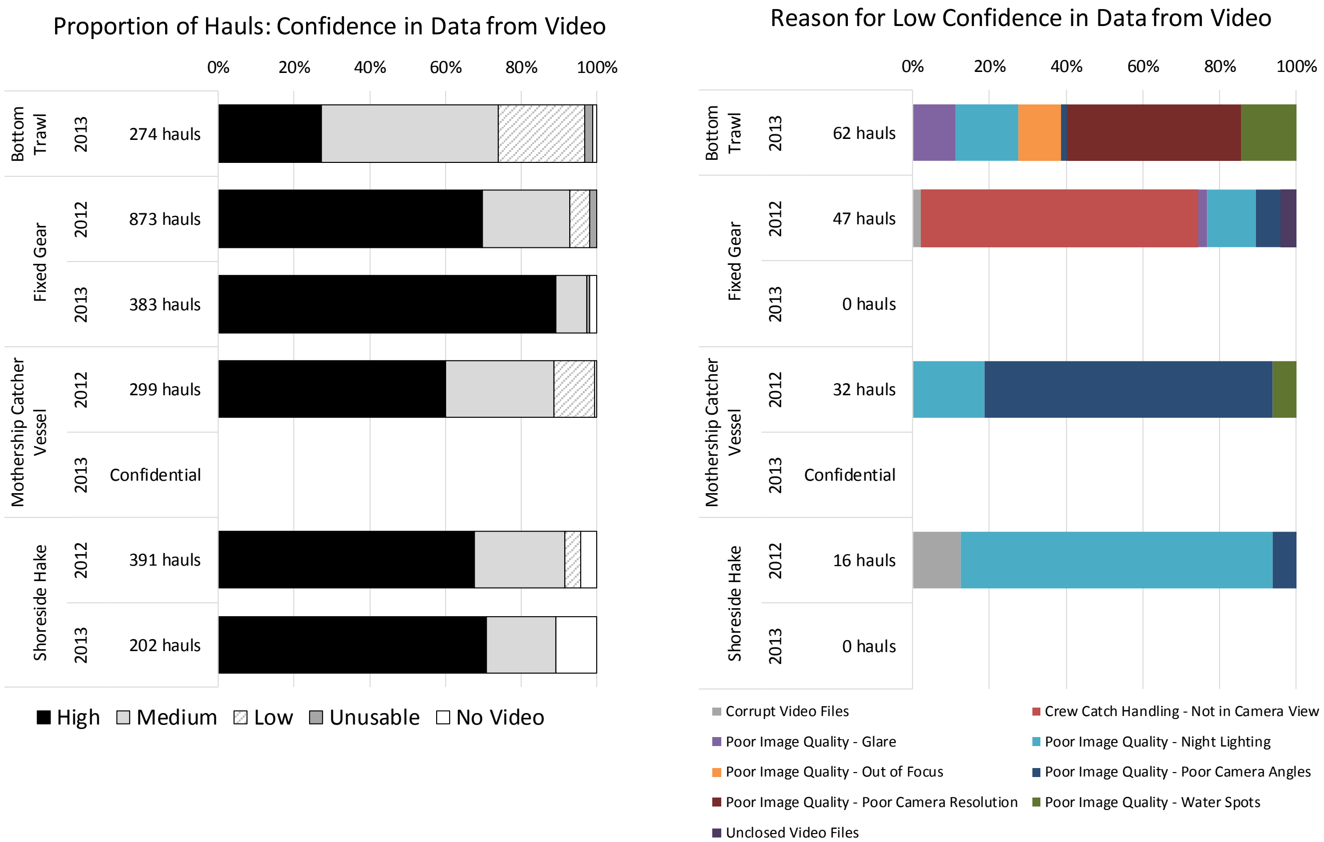

Figure 1. Distribution of confidence in data from video in all fisheries in all years (left). For hauls labeled low confidence, distribution of reason for low confidence in video (right).

<u>Note for the following figures (figures 2 through 17):</u>

For all catch comparison figures (figures 2 through 17), the dashed grey line is the video = compliance monitor (or official catch) line. If video and compliance monitor counts agreed, the point would fall on the dashed line. The solid line is a fitted trend line to give a snapshot of the relationship between the two datasets. If the trend line falls below the video = compliance monitor line, compliance monitor estimates tend to be larger than video estimates. If the trend line falls above the video = compliance monitor line, compliance monitor estimates tend to be smaller than video estimates.

For fixed gear and bottom trawl catch comparison figures (figures 10 through 17), points are partially transparent, with the lightest shade of grey indicating one point and black indicating 4 or more points.

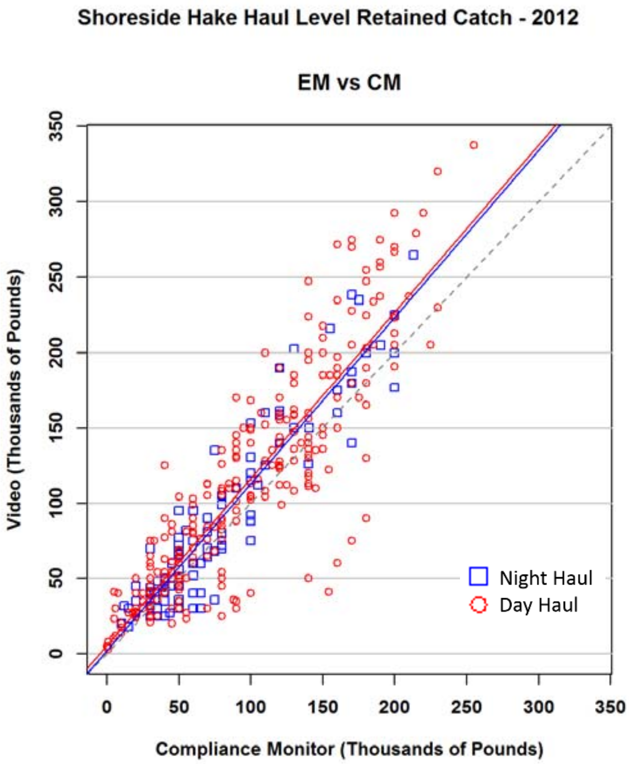

Figure 2. Shoreside Hake 2012. Comparing on-board compliance monitor haul level retained catch estimates with video reviewer estimates of all species aggregated to the haul level.

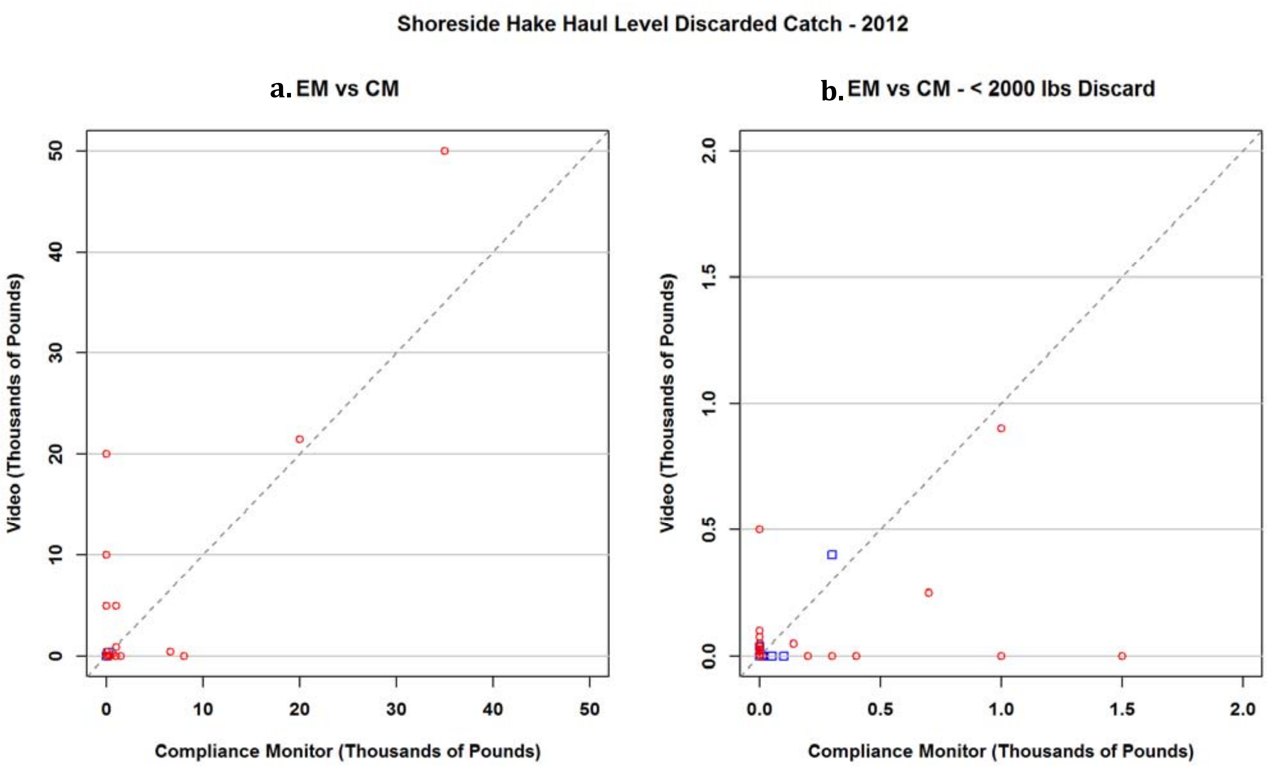

Figure 3. Shoreside Hake 2012. Comparing on-board compliance monitor haul level discarded catch estimates with video reviewer estimates of all species aggregated to the haul level. Figure b. is the same data as figure a. with different axis scales to show the data clustered in the bottom left corner of figure a.

ENFORCEMENT CONSULTANTS REPORT ON ELECTRONIC MONITORING REGULATORY PROCESS

The Enforcement Consultants (EC) has reviewed the documents associated with Agenda Item F.2. In general, the EC had difficulty making recommendations for refining or adopting numerous Preliminary Preferred Alternatives. Primarily because we feel there is a need for additional information, information we hope to obtain through the electronic monitoring (EM) Exempted Fishing Permit (EFP) process, which the Council will take up later this week. The EC has been consistent in its position that EFPs will better inform all parties for making decisions regarding the use of EM in lieu of, or in conjunction with observers in the Trawl Rationalization Fishery. Our review of this agenda item has done nothing to change our opinion in that regard. With that understanding, the EC makes the following comments pertaining to the alternatives listed under Chapter 2 of the document *Draft Analysis of an Electronic Monitoring Program for the Pacific Coast Limited Entry Trawl Groundfish Fishery Catch Shares Program*. As an alternative to listing our recommendation as a summary at the end of our analysis, we offer our recommendations/endorsements as presented in bold text throughout the document.

2.2 Compliance Monitoring Basic Provisions

2.2.1 We **endorse the draft analysis position,** that it is the individual vessel's option to use cameras in lieu of human observers and that 100% of all individual fishing quota (IFQ) trips must either have an observer or camera.

2.2.2 Video Reading Protocols: At this point in the process, the EC has no position on this option and awaits additional information gleaned through the EFP process and/or analysis from the Northwest Fisheries Science Center (NWFSC), Scientific and Statistical Committee (SSC), and Pacific States Marine Fisheries Commission (PSMFC).

2.3 Discard Accounting: The EC believes individual catch accounting should be maximized, which is one of the hallmark objectives of the Trawl Rationalization Program and which is achieved in the current program using 100% observer coverage. **We endorse Option A in that it appears to be the best "fit" for maintaining this management objective.**

2.4 Definitions for Total Catch Accounting: **The EC endorses these definitions as presented**. These definitions are consistent with the definitions used by the WCGOP in evaluating discards reported by observers and therefore seem appropriate.

2.5 Discard Requirements: Regarding Option A: Maximize Retention and Option B: Optimize Retention Retain Catch Share Species with Limited Discard Options, both Options A and B have been proposed for testing in the EFP applications currently under Council consideration. As with the Video Reading Protocols, the EC prefers to wait for additional information gleaned through the EFP process and/or analysis from the NWFSC, SSC, and PSMFC prior to endorsing or recommending either or both Options A and B.

Option B provides flexibility regarding discard proposals as well as requiring purposeful definition of the discard. Option C appears to be unduly broad, especially in light of the fact that speciation through camera technology has proven, thus far, to have limited application. For these reasons, **the EC recommends Option C: Discard at Will, be rejected from further consideration.**

2.6 Halibut Retention/Discard with Fishery Specific Options: The EC has no position other than to note any option adopted must be compliant with International Pacific Halibut Commission rules and regulations.

2.7 Discard Species List Adjustments: The EC has no position on this matter.

2.8 Vessel Operations Provisions

- 2.8.1 Observer Exemption Process
- 2.8.2 Eligibility for Camera Use:
  - 2.8.2.1 Initial eligibility criteria
  - 2.8.2.2 Continued eligibility
  - 2.8.2.3 Self-Governing Plan Elements

- 2.8.3 Application Approval and Required Information

- 2.8.4 EM Vessel Operational Plan – Individual Vessel Monitoring Plans (IVMP)
  - 2.8.4.1 IVMP requirements

With respect to Sections 2.8.1-2.8.4, the EC endorses these options as presented but also notes that if EM EFPs are approved by the Council later this week, that the information gleaned from those EFPs may alter, change, and/or enhance these options as currently presented.

2.8.5 EM Vessel Operational Plan – IVMP Expiration: **The EC endorses Option B Annual Expiration or if modifications are made.** This option is consistent with general West Coast federal or state permitting processes. Although not a permit, the IVMP supports a request for a regulatory exemption. As such the exemption should be viewed as a privilege. We believe the status of that privilege, at least initially, should expire, be reviewed, and potentially renewed on an annual basis. Our position demonstrates a conservative approach to the initial implementation of the EM Program. As the program matures and all participating effected parties become familiar with the program components and requirement, we believe this annual requirement may become a candidate for modification. This has been our experience in the First Receiver Site License Program which has similar elements.

2.8.6 Declaration of EM Use

At present, the EC is not prepared to recommend or endorse any of the options and awaits additional information regarding industry needs, such as, what is considered feasible by observer providers, and analysis from the NWFSC, SSC, and PSMFC.

2.9 Equipment and Protocol Provisions

The EC is not prepared to make a recommendation on this issue, but notes that currently, there are only two EM systems available for deployment in the trawl fishery, either by EFP or regulation.

2.9.1 EM Equipment Requirements

2.9.1.1 Data formats

2.9.1.2 Video Hardware

2.9.1.3 Logbook Data Source

2.9.1.4 On vessel Data Storage

2.9.1.5 Onboard operations

With respect to Section 2.9.1, the EC has no objection to these options as presented but notes these options, as listed, are incomplete in their detail and application description since the details will be developed during implementation. As with other operational components, we anticipate our understanding of needed equipment requirements will improve through the EFP process if EM EFPs are approved by the Council later this week.

2.9.2 Data Transfer Process

The EC is actively engaged in this issue. Chain of custody is a topic that is often raised in this discussion. The EC is confident that chain of custody requirements can be developed that create reasonable requirements on industry participants while meeting the evidentiary requirements of enforcement.

Regarding the personnel options listed for transfer of the data from the vessels to the reviewer, the EC believes all listed options are viable as long as proper training and accountability elements are in place.

Speaking specifically to the "crew" option, while a crew member may in fact, be the person who does the change out of the hard drive, the EC believes the ultimate responsibility for ensuring the transfer of the data from the vessel to the reviewer is completed, lies with the vessel operator/captain.

The EC recommends the shoreside catch monitor option as the option with the lowest probability of compromise of the data in the transfer process.

2.9.3 Data Confidentiality/Accessibility Ownership

2.9.4.1 Video Review Process

2.9.4.2 Video reviewers

The EC concurs with the options as stated with a caveat and an exception.

Video Reviewers, Option C: EM Provider. The EC is concerned there may be a conflict of interest with an EM provider reviewing their own data or some other EM provider's data. EM providers want to promote the capabilities and reliability of their product as a basic element of their business plan, which may influence their review of the data generated by their systems, i.e. their analysis may be biased because of their interest in demonstrating the advertised capability or reliability of their system, which in turn may be exaggerated or overstated. Conversely, this bias may manifest doubt on the capabilities or reliability of their competition's system.

The EC is also concerned about the consistence of the data analysis fleet wide. Even with one reviewing entity doing all data analysis coast wide, there will be some level of subjectivity in that analysis. The inconsistency of that subjectivity could expand exponentially if, for example, there are three or four system providers all doing their own data analysis, or possibly even more so if there is an additional third party analysis option.

The EC believes strongly that taking a conservative approach in the initial implementation phases of this program is a prudent course of action. One such step is to have one provider doing the data analysis for the entire coast, at least in the beginning of this program.

We also believe that it is reasonable to assume the video review will be deemed an inherently government function. **The EC recommends NMFS or its agent assume the video analysis responsibility, with one reviewer doing the data analysis for the entire coast.**

2.10 WCGOP Scientific Observations

The EC defers to the WCGOP for this entire section.

2.11 NMFS Processes

The EC has no deletions or changes to offer at this time, but as with other options, we await additional information gleaned through the EFP process and/or analysis from the NWFSC, SSC, and PSMFC.

2.12 Spatial Variation for High Bycatch Areas

The EC supports the GEMPAC recommendation to remove Options B and C for spatial management options. We agree the spatial management will add complexity to the management of the IFQ fishery and will require identifying additional management areas which in turn will be more difficult and more costly to manage.

2.13 Adaptive or Phased Implementation

The EC looks forward to agenda item F.5, later this week, where the merits of the four EM EFPs will be discussed and evaluated.

Agenda Item F.2.b
Supplemental GAP Report
June 2014

GROUNDFISH ADVISORY SUBPANEL REPORT ON THE ELECTRONIC MONITORING REGULATORY PROCESS

The Groundfish Advisory Subpanel (GAP) was briefed by Mr. Brett Wiedoff on the Electronic Monitoring (EM) regulatory process, draft analysis, and Groundfish Electronic Monitoring Policy Advisory Committee (GEMPAC) report. The GAP would like to thank Mr. Wiedoff and Mr. Seger for their work on the analytical document, as well as the GEMPAC for its report.

Overall, the GAP would like to see regulations for EM move forward as expeditiously as possible. The rationale for moving forward quickly is described in detail in previous GAP statements and is encapsulated on page 15 of the Draft Analysis of an Electronic Monitoring Program for the Pacific Coast Limited Entry Trawl Groundfish Fishery Catch Shares Program (Agenda Item F.2.b, Attachment 1, June 2014). High costs, measured both in direct payments to observer providers as well as in lost opportunity when observers are not available, a heavier burden for small boats and more remote ports with less activity, and the indication that observer companies may pull out of "unprofitable" ports are some of the primary reasons for needing to implement an EM system. Additionally, many in the fleet feel that having an observer is intrusive, takes up critical space on vessels, and limits operational flexibility.

The GAP endorses the entire GEMPAC report, but does not offer any recommendations on specific preliminary preferred alternatives (PPA) at this time other than those contained in the report. The GAP hasn't yet seen the necessary cost analysis and believes that more analysis is needed before selecting PPAs for many items. The GAP firmly believes the Council should take final action in September, and we expect the necessary analysis will be complete in time for us to take final action at that time.

The GAP offers the following specific comments on the documents.

First, the GAP agrees with the GEMPAC recommendation to strike the "Spatial Variation for High Bycatch Areas" option from the draft analytical document. The GAP believes that it would add unnecessary complexity, and would likely constrain opportunities for use of EM when no such constraint is required in a program that holds each individual accountable.

Second, the GAP believes that while potential impacts to observer provider companies should be given consideration, primary consideration in the decision to move forward or refrain from moving forward with EM should be focused on the fleet. Furthermore, if observer providers are so tenuous that transition to EM for a portion of the fleet may seriously threaten their business models, then that illustrates that alternatives to human compliance monitors are indeed desperately needed. Finally, there was some discussion about whether the removal of human compliance monitors from vessels would disrupt the shoreside catch monitor component of the program. The GAP believes that there are a variety of alternatives that could serve this purpose if the removal of human compliance monitors did in fact require changes to the current structure of the shoreside catch monitor system.

GROUNDFISH MANAGEMENT TEAM REPORT ON THE ELECTRONIC MONITORING REGULATORY PROCESS

The Groundfish Management Team (GMT) held a publicly noticed webinar to discuss Electronic Monitoring (EM) Program regulatory issues (on Tuesday, June 10, 2014). Council staff and the committees have done a considerable amount of work in a relatively short amount of time. However, we do not see how the Council could choose preliminary preferred alternatives at this point, at least for the core program design elements like those in Section 2.2. At the same time, preparing for this last meeting of the 2015-16 harvest specifications and management measures cycle has involved a lot of work for members of the GMT. We therefore may be behind the Council and other advisory bodies as to comfort and understanding of how EM might work.

We begin with some general thoughts on how the team has reviewed or would continue reviewing the EM alternatives and options. In following the team's analytical role, we attempt to focus on the risks and incentives that affect catch accounting. The overall thrust of our statement involves suggestions on where the analysis might focus next. If we had more time for writing and discussion, we would have had more detailed comments including on specific alternatives. And with more time over the coming months, we believe we could provide valuable input on the design of the EM programs.

Purpose of Observers and Electronic Monitoring

We have noted some confusion in discussions at this meeting and before about the purposes observers and EM serve. Discussions around EM often make a distinction between "science" and "compliance" with the point being made that EM is mainly for compliance and not for science. We understand "science" to refer to measurements like taking the lengths and sex of fish as part of stock assessments (i.e., biological data collection). Yet the GMT finds this distinction to be of limited helpfulness. EM may be designed mainly around compliance yet that compliance is meant to serve accurate catch accounting. Likewise, the core purpose of the West Coast Groundfish Observer Program (WCGOP) observers has been to account for discards and to take other measurements that cannot be made onshore (e.g., collecting sablefish otoliths). In other words, their main role has been to perform total catch accounting.

Our point here is that it would be helpful to list the specific observations/measurements/tasks that observers conduct and to consider, one by one, how they can or cannot be made under EM in conjunction with state port sampling programs, etc. There are likely to be trade-offs and information lost (e.g., of interest to the GMT is that we might lose tow by tow catch information under EM), yet it may be that many observations can still be made onshore under EM programs where most fish are retained. Furthermore, it is possible that EM might improve some types of observations.

We would recommend that the Council consider these issues in the full context of sampling design, the accuracy and precision of estimates made from sampling, and the various purposes for which fishery-dependent observations are made (i.e., catch accounting, stock assessment, protected species management, etc.) We understand that WCGOP may be working on such an analysis but it will not be ready until later this year or next year. The specifics of such an analysis would be very helpful for understanding how EM and observers would fit together.

The Different Levels of Catch Accounting

Again, we see the primary purpose of EM as accounting for catch. In our discussions, we found it useful to keep in mind that there are two different levels of catch accounting involved: (1) estimates of total annual catch, and (2) accounting to create individual accountability in the individual fishing quota (IFQ) and co-op fisheries. Individual accountability requires a higher level of monitoring, but ultimately it is meant to keep total annual catch to the Council's preferred sector allocations and annual catch limits. There is some concern about how EM might reduce individual accountability. However, for some species we would argue that individual accountability may not be needed to adequately control catch. When considering risk, we attempt to be specific about whether we are referring to individual accountability or to the more general matter of accounting for total fishery removals.

Of note, Pacific halibut presents another layer to individual accountability. The halibut Individual Bycatch Quota (IBQ) system is meant to improve the survivability of the fish by giving fishery participants individualized estimates of discard mortality.

Thinking About Risks and Incentives Generally

Some GMT members were able to attend the National EM Workshop this past January in Seattle. Many of the discussions were very informative. One that stood out was a talk given by Rick Stanley on his experience with the design of EM systems in British Columbia.[1] He indicated that they spent considerable time, including holding meetings over several years (perhaps before and after EM had already been implemented), considering how people might "game the system" and figuring out how to plug the holes that were identified. He referred to it as "means, motives, and opportunity" for evading the EM system. He also emphasized the importance of having these conversations with the fishery participants because they best know which behaviors to be realistically concerned about.

We would recommend conducting a similar exercise here to best understand and compare and contrast the risks of optional program designs. The "means, motives, and opportunities" would be different by vessel type and sector and even species and possibly area. We would like to emphasize that the GMT does not mean to take an overly cynical view of how fishery participants would behave under an EM system. Most participants would likely act responsibly. Nonetheless, knowing how a system might realistically be exploited is valuable to understanding risks. We believe that there is widespread interest in ensuring the integrity and fairness of the monitoring system.

Retention Definitions

As a small matter, some on the team question the use of the term "optimum." The plain and technical meanings of that word are different than what is meant by the proposal. The proposal is

[1] The talk may be viewed here: http://www.eminformation.com/presentation/plenary-session-3. The remarks referred to can be heard at approximately the 7:20 mark on the video.

in essence to simply allow more species to be discarded. We think the focus would best be turned toward the factors that make discards acceptable or not, which is a species by species determination based on some of the risks we lay out here (e.g., the precision and accuracy of discard estimates, the effect on individual accountability, and at the higher level, how the error in discard estimates affect the risk of exceeding an Annual Catch Limit (ACL) and ability to estimate stock status with assessments). As discussed below, this would involve species by species consideration along the lines of the "Discard Species List" option.

Coverage Levels

The EM alternatives are focused on retention-based programs where discards are limited. These programs basically work by either: (1) disallowing discard with compliance measures focused on detecting illegal discards, (2) incentivizing accurate reporting, or (3) some combination of these. In short, there are various ways of designing programs but the problem of proof is focused on the question of how well fish tickets will reflect what was caught in total.

We had some confusion about matters of coverage level and video review. In other words, what would a 10 percent coverage or review level be a percentage of? We have heard coverage spoken about in terms of the number of tows or sets made on a trip. We can see how that would be appropriate in a system where it is possible to see which fish came aboard and then confirm with reasonable confidence that it was recorded on a fish ticket or in a logbook. The sampling logic would be that the accuracy of logbooks or fish tickets could be incentivized by the prospects of getting caught intentionally or unintentionally making inaccurate entries. Such systems depend on being able to determine how accurately logbooks or fish tickets record total catch.

When discards are of concern, the sampling problem becomes a bit different. Using the concepts of sampling theory, the ideal is to use a "sampling frame" that when sampled from, gives every unit in the total "population/universe" of possible events an equal chance of being sampled. If EM is meant to ensure compliance with retention requirements, then the "universe" of possible events to sample from is the total time in which there are means and opportunity to discard, or from the time the fish is caught to the time the catch is confirmed reported on a fish ticket.

The main point we emphasize here is that we are unsure how to think about risks and coverage levels without more specifics on how the EM programs would function.

Comparative Risks of Observers and EM

We have heard arguments, both within team discussions and elsewhere, that EM should not be held to a higher standard than observers. Observers can certainly be fooled, may make errors in their estimates, be forced to basket sample and provide expanded estimates, or may not be able to sample all hauls during a trip. We would recommend giving attention to the holes in monitoring, whatever the program design, in a risk-based manner. No program will be perfect, but it would be preferable to be aware of what the holes in the monitoring might be, and how they might affect the accuracy of catch estimates, individual accountability, etc.

We do not mean to prompt discussion of whether observers or EM are superior to one another. There are trade-offs involved with each. However, the comparison is being made in the analysis given the standard protocol of comparing action alternatives against status quo/no action. Where comparisons are made, we would again point to the concepts of sampling theory. For instance, an observer might be thought of as a mobile “sampling frame”, that while not looking all the time, may be looking when not expected. In other words, 100 percent observer coverage does not mean the observer will detect every event of interest. A camera based system may be more fixed, but again, it depends on the design. Likewise, observers have protocols for knowing when fish come onboard that make it more likely the fish would be missed if discarded surreptitiously. These are just examples of what the analysis might look to when comparing and contrasting alternatives.

Lastly, we would like to express concern about statements that there are consistent ways of fooling observers. These statements are usually made, again, to argue that EM should not be expected to be perfect either, and we have not seen direct evidence of consistent cheating in the IFQ and co-op programs. Nonetheless, those of us that are concerned are concerned enough to recommend that the Council also look at observer protocols and how they may or may not be changed so as to reduce the chances of bias in catch accounting and holes in individual accountability.

The fish “in the water” problem - Controllability

A lot of attention seems focused on the problem of estimating the species and weight of fish that are caught but not seen onboard, for instance, when fish are “bled” from the net intentionally or come loose unintentionally when bringing gear aboard. Arguments are made about how significant the amount of fish might be, and in many cases, it seems that the amounts are relatively low. Yet taking a risk-based view, we would recommend focusing on how controllable certain behaviors are, or in other words, focus on the means and opportunity for “gaming the system.” If the activity is not controllable, then it is unlikely to affect the incentives of individual accountability. If individual accountability might be affected, then the Council may wish to address them with the program design.

Species and Areas

The level of precision and accuracy needed for catch accounting and compliance may depend on the species, who the interested end-user of the information is (i.e., fisherman, stock assessor, manager, or enforcement), and by the question that we are trying to answer (see above). Questions regarding the necessary level of precision/accuracy may be considered by fishermen for their individual catch accounting needs, by management for ensuring individual accountability and catch remains below the ACL, and by stock assessors for their assessments. If discarding certain species is of importance to a sector (e.g., undersized English sole), then the risk of using EM to estimate those discards would ideally be evaluated by each end-user group of the information.

One question we discussed was along the lines of “how significant would the impact be if the discard estimate provided by EM was wrong (i.e., different from the “true” value)?” For example, the impact of being wrong, whether for compliance or for discard weight estimates, may be much lower for species that are typically caught in quantities far below the trawl allocation and the ACL (e.g., English sole) and are easily identified and discernible from all other species. On the other hand, there are species for which attainment is high, annual fishing mortality is near the ACL, and/or identification may be difficult (e.g., rougheye rockfish, petrale sole, and overfished species). For these types of species, fishermen, management, stock assessors, and enforcement may require a much higher level of precision and accuracy, because the impacts of being wrong may be much greater than for species such as English sole.

The risks and incentives at play with EM are likely to be by area as well. Using the extreme example of yelloweye rockfish, some areas will have higher probability of encountering yelloweye than others. These matters could be looked at with existing observer data. We understand that WCGOP is preparing analysis that would help understand these probabilities better.

An example of individual accountability and ACL management

We provide the following example for perspective on team discussions about EM and concerns of individual accountability. Evaluating the risk of potential impacts of allowing discard can be made on a species-by-species basis. The example uses English sole because one EFP proposes allowing two bottom trawl vessels to discard English sole (Agenda Item F.5.a, Attachment 2, June 2014).

The 2015 ACL for English sole is 11,040 mt; (see Agenda Item F.7.a, Attachment 2). The 2014 IFQ allocation is approximately 5,260.9 mt. The average attainment of English sole for the IFQ fishery 2011-2013 was 2 percent of the IFQ fishery allocation (see Agenda Item F.4.b, Supplemental NMFS Report, June 2014). If the assumption is made that 10 trawl vessels may participate in EM, then approximately 15 percent of the trawl IFQ fleet would be monitored using EM whereas the remaining portion of the fleet (85 percent) would opt for status quo observations (i.e., 68 vessels fished IFQ trawl during 2013; see Agenda Item F.4.b, Supplemental NMFS Report, June 2014). In this case, we might project that the "true" discard of English sole by vessels using EM may be approximately: (5,261 mt trawl allocation) x (2 percent attainment) x (17.8 percent discard) x (15 percent of vessels) = 2.8 mt, or 0.28 mt per vessel. The "true" discard of English sole in this example would represent 0.025 percent of the ACL (= 2.8 mt / 11,040 mt). If for some reason, estimated discard from EM was one-half the true value, then the error would be 0.0125 percent of the ACL, or 1.4 mt for the 10 vessels combined (= 0.14 mt per vessel).

These types of calculations could be helpful for considering the potential cost of being wrong if EM is not as precise or accurate as human observers.

Economic Connections Between Observers and EM

We have heard about the concerns an EM program might have for the economics of observer providers, catch monitors in small ports, and more. We see these as very important questions that should be looked at in as much detail as possible to avoid unintended consequences to fishing communities and to the monitoring capabilities across all sectors.

Dear Dr. McIsaac,

Re: Report on the 2004 to 2010 US Shore-based Whiting EM Program

The attached paper summarizes the results from 2004 to 2010 EM program carried out with the US shore-based whiting fishery. While the results were previously reported in the individual annual reports, the purpose of this paper was to compile the results of the seven-year EM program in order to review the operation of the monitoring program and how it evolved over time. The paper was also intended to document the operational aspects to demonstrate that effective EM programs are a lot more than the underlying technology. As well, the intent of the paper was also to summarize what we learned, with the aim of evaluating the merits of the program and providing insights that would assist in other fisheries where EM is being considered.

The EM program evolved over time with operational efficiencies and improvements in technology. EM data collection success across these years exceeded 98% sensor data for all but one year, image data over 95% for five of seven years, and sensor and image data 99% for the last two program years. The EM program provided increased transparency which was a contributing factor to the marked decline in at sea discards over the seven year period. In particular, vessel specific information showed that the majority of the discard problem could be attributed to a small minority of the fleet, and that many vessels could successfully participate in the fishery with little or no discards. In 2005, nearly all vessels discarded, with most discarding 1.5% or more of their catch. Over time, the discard levels declined with increasing numbers of vessels showing very low levels of discard. By 2010, a third of the fleet had no observed discards, and among those vessels with discards, all but three discarded less than 0.6% of their total catch.

The program was co-funded by industry and NMFS, and the 2007-2010 average annual cost was $6.03 per mT, $254 per sea day, or 3.6% of the landed catch value. The EM cost per sea day was about 30% less than the rate for an at-sea observer, yet the latter does not reflect the total cost of the observer program. The cost comparison between EM and observers from an industry perspective would likely center on the portions of the program they would fund, rather than the total program cost. Cost effectiveness of EM as compared to observers comes down to an assessment of the resource risk associated with potentially less granularity of EM data versus more detailed observer data at greater cost. Given that EM was lower in cost and that the incidence of discarding was reduced to a low level, EM is considered to be the most cost-effective monitoring solution for this fishery.

The report summarized a number of lessons learned that would be applicable to the application of EM in any fishery:

- EM based monitoring should not be considered a "plug-and-play" alternative to observer programs as each has their own opportunities and challenges.
- The utility of EM for collecting fisheries data relies on a careful design process that integrates the EM technology, the vessel specifications, and specific on board catch handling and EM system duty of care requirements.
- EM programs are much more than the underlying technology. The majority of cost is with the service components and thus, a structured program design approach is needed.
- Successful use of EM often depends upon integration with other data collection processes and information sources. Data integration opportunities should be considered in the design process.
- Stakeholder engagement is an essential ingredient to EM program success. This should occur at a variety of levels in order to improve the program, optimize operations, and effect change.
- A key risk to EM is the hidden bias that can result from strategic intentional data loss (i.e., turning the system off to avoid recording). While some data loss is to be expected in any monitoring program, effective measures are needed to control, monitor and manage the level of missing data.
- EM technology will change over time and the program design needs to be flexible to include change, where appropriate.
- Effective EM programs require control measures through governance, regulations, incentives or disincentives. Instruments such as an EFP are particularly effective as they can be easily modified during the early stages of program implementation.
- EM programs take time to implement and a multi-year time horizon is needed to establish operations and infrastructure, and offset start up costs. Uncertainty of program tenure will slow the process and reduce cost efficiencies that can be achieved with EM approaches.

The EM program for the shore-based fishery was discontinued in 2010 with the onset of the 100% at-sea monitoring and the IFQ program. I believe this was more the result of an effort to bring the entire west coast groundfish fishery under a single monitoring framework than from a shortcoming of the EM program.

As the potential for EM is being considered by the Pacific Fishery Management Council it is hoped that this paper will aid in these discussions. Please feel free to distribute this report. I would be happy to address any comments or questions at the email address provided below.

Sincerely,

Howard McElderry, M. Sc.,

This report summarizes the results of 2004 to 2010 Shore-based Whiting EM program carried out for the National Fisheries Marine Service of NOAA, funded jointly by NMFS and the shore-based whiting fishery participants. Funding for this report was provided by the Pacific States Marine Fisheries Commission and Archipelago Marine Research Ltd. We would like to thank the authors of the original reports, in particular Janet Cowan, Andrea Crumpacker, Morgan Dyas, and Dale McCullough. Several individuals within NMFS contributed to the project design included: Jonathan Cusick, Becky Renko, Janell Majewski, and Elizabeth Clark. Steve Parker, of the Oregon Department of Fish and Game, provided helpful advice during early phases of the program design. The authors would also like to thank the following reviewers for their useful advice on the manuscript: Dave Colpo, Mark Holliday, George Lapointe, Dayna Matthews and Michelle McClure. Lastly, and importantly, we would like to thank the shore-based whiting fishery participants for their support and ongoing advice during the seven year program.

Summary

This paper provides an overview of a seven-year program involving the use of electronic monitoring (EM) on the US shore-based Pacific whiting (*Merluccius productus*) midwater trawl fishery. The paper describes the fishery and the EM program, and how these have changed over this time period. We also examine the operational aspects of the EM program to better inform an assessment of cost effectiveness of this monitoring method.

The whiting fishery is a high volume spring/summer fishery operating off the coasts of Washington, Oregon and northern California, consisting of ~35 vessels making day fishing trips. Total removals are estimated from landed catch and no discards are permitted. Full retention regulations were monitored from 2004 to 2010 using EM, whereby each vessel was equipped with closed circuit television cameras, GPS, winch and hydraulic sensors, operating continuously while the vessel was at sea.

Over the seven-year monitoring program, the fishery ranged from 24 to 180 days duration, 500 to 1,300 vessel sea days, and 40,294 mT to 972,677 mT total catch. EM data collection success across these years exceeded 98% sensor data for all but one year, image data over 95% for five of seven years, and sensor and image data 99% for the last two program years. Early monitoring results yielded a clearer understanding of fishing practices, providing a framework for more practical regulations on permissible levels of ‘operational discarding’. The EM program provided increased transparency which was a contributing factor to the marked decline in at sea discards over the seven year period. In particular, vessel specific information showed that the majority of the discard problem could be attributed to a small minority of the fleet, and that many vessels could successfully participate in the fishery with little or no discards. In 2005, nearly all vessels discarded, with most discarding 1.5% or more of their catch. Over time, the discard levels declined with increasing numbers of vessels showing very low levels of discard. By 2010, a third of the fleet had no observed discards, and among those vessels with discards, all but three discarded less than 0.6% of their total catch.

EM data reviewers estimated discard quantities using volume-density estimation methods. A small study comparing EM estimates with direct weights from a research vessel suggested EM estimates were correlated but highly variable. We believe estimation methods improved over time; however, the 90% decline in discard quantity over the seven-year period reduced discards to a level where the lower precision of the EM estimate became less important.

EM results were compared closely with vessel log data. Estimates of discard quantity were correlated but highly variable and it was not possible to attribute error as both were estimates. Most challenging to estimate were events where

discarding occurs directly from the net without coming aboard. The level of alignment between EM and vessel logs with respect to recorded discard events improved over time and we suggest using EM to audit vessel logs as a possible future program design.

EM data loss was closely monitored, particularly after a 2007 incident involving large discard quantity of widow rockfish. Data loss occurring during catch stowage operations was a particular concern because of the potential opportunity to discard unwanted sensitive species. In 2010, data loss during these critical periods was estimated at 0.5% of the total fishing events for the year. We examined monitored landings data to estimate the potential missed catch from EM data loss and determined the level to be less than 1% of the Annual Catch Limit for all sensitive species except widow rockfish and POP (5% and 3%, respectively). Hence, the data loss occurring in most program years would not pose a resource risk caused by unaccounted for catch but the results underscore the need to ensure that EM data loss is monitored and actively managed.

The program was co-funded by industry and NMFS, and the 2007-2010 average annual cost was $6.03 per mT, $254 per sea day, or 3.6% of the landed catch value. These figures reflect the total cost of the monitoring program, including program planning, field data collection and all the steps required to produce a finished data set. The costs are also reflective of a mature program where startup costs such as data-base development, program design, and infrastructure development have already taken place. EM equipment provision and field service were the largest cost component, over twice the data analysis and reporting component. The uncertain tenure led to higher EM equipment costs as most participants chose to lease rather than purchase.

The EM cost per sea day was about 30% less than the rate for an at-sea observer, yet the latter does not reflect the total cost of the observer program. The cost comparison between EM and observers from an industry perspective would likely center on the portions of the program they would fund, rather than the total program cost. Cost effectiveness of EM as compared to observers comes down to an assessment of the resource risk associated with potentially less granularity of EM data versus more detailed observer data at considerably greater cost. Given that EM was lower in cost and that the incidence of discarding was reduced to a low level, EM was considered a more cost-effective method for this fishery.

Although the EM program likely drove the significant improvement in the full retention compliance and the quality of catch data, it was discontinued in 2011 when the groundfish trawl fleet implemented a catch share quota system with 100% observer coverage, funded by NMFS.

1.0 Introduction

The non-tribal commercial Pacific whiting (also known as Pacific hake) (*Merluccius productus*) fishery is a seasonally intense spring/summer fishery that operates off the coasts of Washington, Oregon and northern California. This fishery consists of an at-sea processor fleet and a shore-based fleet. The shore-based fleet consists of approximately 30 vessels that make day fishing trips and deliver their catch to six ports. During the fishery, most of the vessels operate out of three Oregon ports: Charleston (Coos Bay), Newport and Astoria. The remaining four to six vessels deliver their catch to Westport (WA), Eureka, (CA) and Crescent City, (CA). The dates for the shore-based hake season coincide with the movement of hake along the coast: an early season in northern California, a main season fishery, usually opening mid-June off the Oregon and Washington coasts, and a late season fishery starting in the fall in the same areas.

At-sea information for the shore-based whiting fishery is important because of several factors unique to this fishery. During the fishery, vessels transit for several hours from the fishing grounds to deliver their catch to shore-based processing plants. Unsorted catch must be rapidly transferred from the net to refrigerated seawater holds to retard a parasitic degradation process common to this whiting population (Alderstein and Francis 1991). The immediate transfer of catch to preserve product freshness makes it impractical to sort the catch at sea. Therefore, by-catch monitoring takes place at dockside when the unsorted catch is delivered to the processing plants. In support of this shore-based method of catch monitoring all fishing vessels participating in the fishery are required to maximize retention of catch. At sea monitoring has been a requirement since 2004 to ensure compliance with maximized retention.

Traditionally, trained fisheries observers are used to provide onboard monitoring of fishing vessels. This past approach may not be practical or cost effective in certain circumstances, particularly when the scientific data collection needs are low. A variety of studies have shown that some types of monitoring can be more effectively carried out using electronic monitoring (EM) technologies (MRAG 2004, Ames et al. 2005, Sommerville 2004, McElderry 2008, Stanley et al. 2009, Stanley et al. 2011). In 2002, a pilot study was carried out with a single shore-based whiting fishing vessel (McElderry et al. 2002), and on the basis of these successful results, EM-based at-sea monitoring was extended to the entire shore-based component of the fishery from 2004 to 2010. The EM program for this fishery was established under an annual exempted fishing permit (EFP), which was renewed each year until 2011 when the fishery transitioned to an IFQ program, and 100% monitoring by at-sea observers became compulsory.

The transition from EM to observers in the shore-based whiting fishery in 2011 came about more as a desire to establish a consistent monitoring program for the entire groundfish fishery rather than any documented shortcomings with the EM program. Prior to 2011, the EM program for the shore-based whiting fishery was mostly industry funded (about 70%), whereas the 2011 observer program was mostly funded by the National Marine Fisheries Service (NMFS). The federal funding of at-sea monitoring was planned as a transition measure with monitoring costs being increasingly borne by the fishing industry over time. With monitoring costs rising for industry, there is increased interest in exploring a technology-based monitoring alternative, which could be more cost effective. While an EM program was carried out over a seven-year period prior to 2011 when it was replaced with human observers there has been no formal assessment of the EM program and its efficacy in addressing the monitoring requirements for this fishery.

The EM program for the shore-based whiting fishery was carried out under an annual contract by Archipelago Marine Research Ltd. (Archipelago) with NMFS. The program was delivered in a generally consistent fashion across all program years, beginning as a program under the science branch, then transitioning to a compliance program in 2007. Over the seven years, the program evolved with improved technology and minor changes to methodology. The results from each program year were summarized in technical reports for NMFS, as referenced in Table 1-1.

The purpose of this paper is to compile the results of the seven-year EM program in order to review the operation of the monitoring program and how it evolved over time, as well as, to describe how the fishery changed over this period as a result of the monitoring program. We also examine the operational aspects of the EM program to better inform an assessment of the cost effectiveness of this monitoring method.

2.0 Materials and Methods

2.1 EM Technology

EM System Specifications

The EM systems used for this project were manufactured by Archipelago in Victoria, BC, Canada and are designed for the automated collection of sensor and image data which can be used to produce fisheries information. While different equipment models were used over the seven-year period, the basic configuration was the same, as schematically shown in Figure 2-1. This equipment has been used on a variety of fishing gear types and boats around the world, and have been in use as a key source of fishery data in the British Columbia Groundfish Fishery since 2006 (McElderry 2008, Stanley et al. 2011). The EM system is comprised of a system control centre, up to four closed circuit television cameras, a GPS receiver, a hydraulic pressure sensor, and a winch rotation sensor. The sensor configuration was the same for the entire program period, as were the analog CCTV cameras. The control central computer software manages the collection and storage of high-frequency sensor data and CCTV image data at specified settings throughout the fishing trip. Image and sensor data are stored digitally on a removable hard drive that can be exchanged at intervals during the fishery.

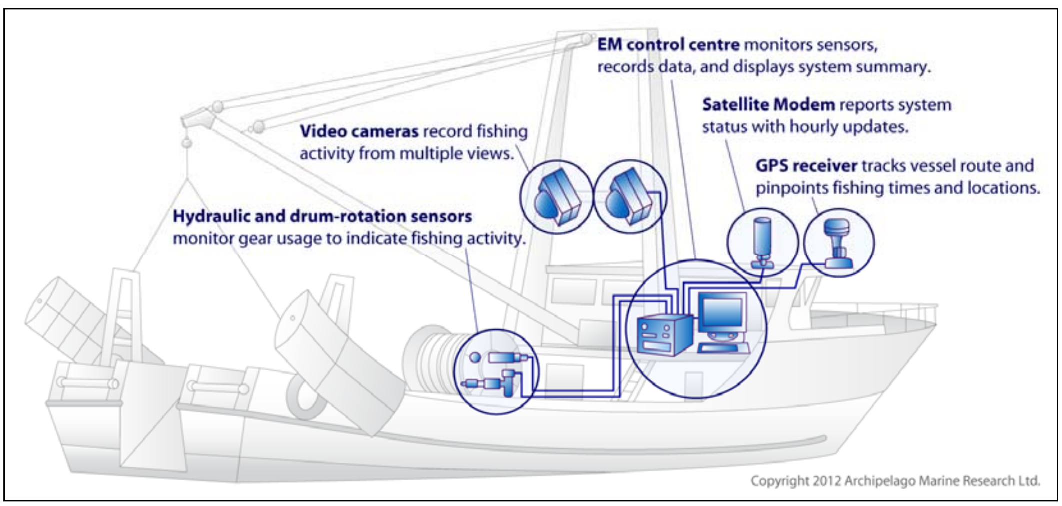

Figure 2-1. Schematic diagram of the electronic monitoring system used for 2004 to 2010 program years.

The control centre software was set to collect and store sensor data (GPS, hydraulic pressure and drum rotation) every ten seconds. This recording frequency delivered an accurate account of vessel activity that could be used to develop a distinctive digital "signature" of vessel activities including transit, gear setting, net towing, net retrieval, and catch stowage. Image data was generally recorded at a rate of one frame per second and the control centre was set up to record imagery from all cameras when the first fishing activities occurred on the trip, and continue image recording until the vessel returned to port. Detection of fishing activity was evidenced by either or both hydraulic pressure and winch sensors. A geo-fence of port locations and vessel GPS data was used to determine vessel location in relation to port.

EM Technology Evolution

Over the seven-year EM monitoring program period, EM systems evolved with improvements in technology. Table 2-1 provides a summary of the key improvements to the EM equipment over the duration of the program. From 2004 to 2006, a V3.0 control centre was used. This system consisted of a small industrial computer, paired with a CCTV system, commercially available from the security industry. The industrial computer managed the sensor data while the CCTV system managed and recorded the image data. Starting in 2007, a V4.0 platform was introduced, which consisted of a single computer platform that recorded sensor and image data in a more integrated fashion. This newer equipment was fully adopted for 2008 to 2010 program years.

Table 2-1. EM system components used for the 2004 to 2010 program years.

Components	2004	2005	2006	2007	2008	2009	2010
EM Hardware	V3.0	V3.0	V3.0	V3.0 & V4.0	V4.2	V4.2	V4.2
EM Software	VDL 1.0	VDL 1.0	VDL 1.0	VDL 1.0	VS 2.0	VS 2.0	VS 2.0
Image Data Player	Proprietary player	Proprietary player	Proprietary player	WMP	WMP	Video Analyzer	Video Analyzer

The earlier V3.0 system recorded image data in a proprietary non-PC format, which limited the ability to view and manage image data files. The later V4.0 system recorded in the standard PC file formats (MP3 and WMP) which provided greater flexibility for viewing, storing and managing image files. A standardized sensor data format occurred throughout the program but starting in 2008, the method of sensor polling changed to improve the ability to detect gaps in the data set. Prior to 2008, a sensor record could be delayed if the GPS signal was poor, whereas afterwards this was forced to provide precise 10 second recording intervals. Thus, time intervals greater than 10 seconds between adjacent records represented a ‘data gap’ which could easily be detected for investigation.

There were also changes with the software tools used to process EM data sets. As mentioned, the image data format of the V3.0 system was proprietary and could only be viewed using the CCTV platform provided by the vendor. The change to the more common MP3 and WMP formats provided more options for handling image data, starting with simple commercially available viewing software (e.g., Window Media Player), then moving a custom built viewing software that allowed for viewing of multiple camera images simultaneously. The sensor data was initially displayed in graphical format, but later was integrated with the viewing software to enable direct referencing between sensor signatures and image data. Interpretations from raw EM data sets such as set time and location, catch events, etc. were initially recorded in a separate spreadsheet. Later, these data entry functions were integrated using the custom viewing software, providing a single platform for loading a raw EM data set, navigating through different parts of a fishing trip to review pertinent monitoring activities, then directly record observations into a database (Figure 2-2). This evolution to a single analysis platform greatly improved the quality and reliability of EM data, as well as significantly improved the efficiency of data processing activities.

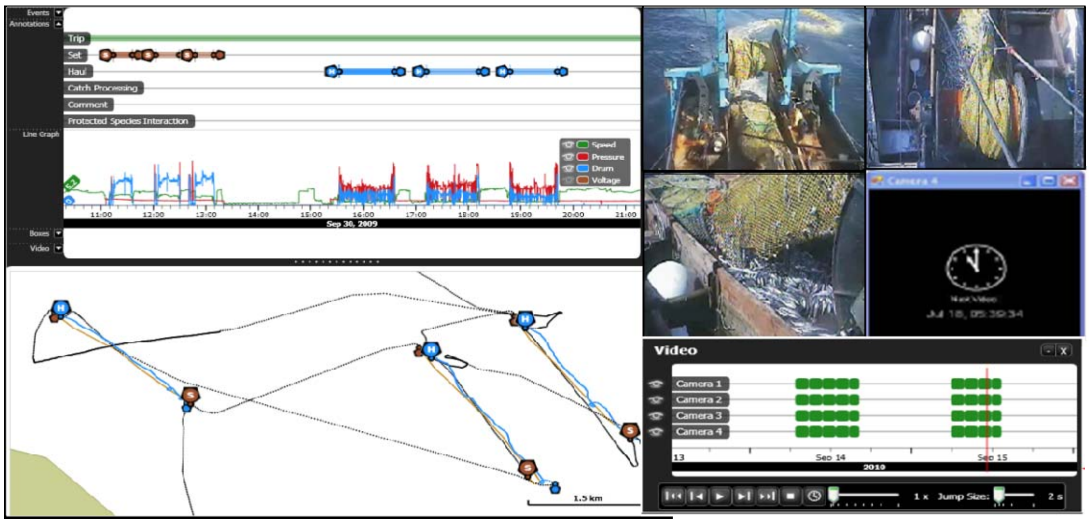

Figure 2-2. EM analysis software display of whiting fishing trip. Upper left shows time series graph of vessel speed, hydraulic pressure, winch (drum) and voltage. Lower left shows vessel cruise track and right panels show CCTV camera imagery.

2.2 EM Program Operations

An EM program is more than the underlying technology itself and includes a variety of service elements, as summarized in Figure 2-3. The diagram outlines the service elements associated with a typical seasonal cycle for the shore-based whiting fishery. The EM program service elements occurred before, during and after the fishery took place and related to the effort needed to: ensure that the technology was in place to achieve its stated objective; ensure that there was the appropriate level of feedback and coordination between all the program participants (e.g., industry, agency, service provider); and to ensure there was appropriate and timely effort to interpret and report on fishery data derived from the EM data set. Each of the operational program elements are described in the following sections.

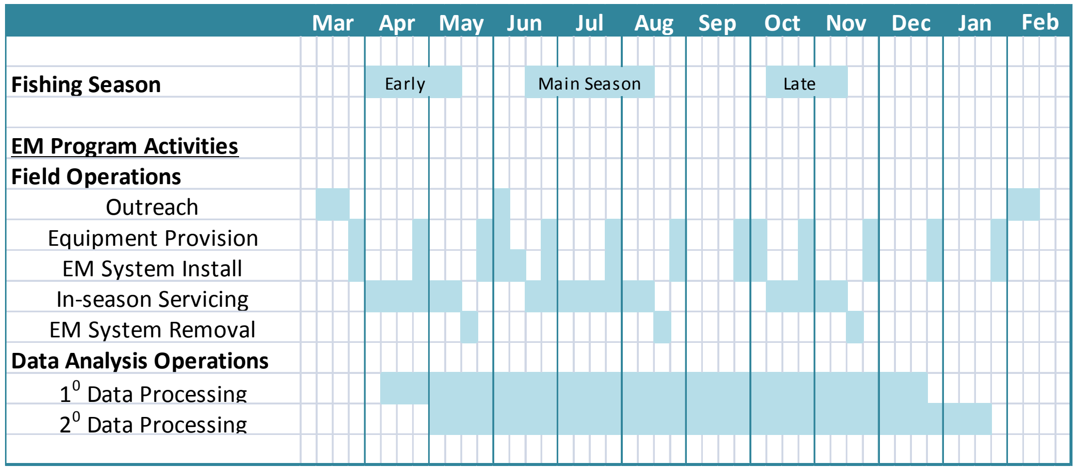

Figure 2-3. Schematic timeline of key program operational components for the 2004 to 2010 program years.

2.2.1 Field Operations

Outreach

The EM program was integrated with NMFS staff and industry through several outreach processes. Program planning took place between Archipelago and NMFS in advance of scheduled outreach meetings with industry, and usually in conjunction with finalization of the EFP and operational planning for the season. In later years of the program, there was a higher level of interaction with NMFS Office of Law Enforcement (OLE) staff that included training with the operation of EM systems and analysis software.

The main instrument for launching the program and creating alignment among the different program participants were outreach meetings scheduled in advance of the early and main season fishery. The meetings involved representatives from the active fishing vessels, agency staff and service delivery staff and served to provide information about the program for the coming season, provide an overview of the EFP, provide summary information from previous program years and gather specific input to improve program coordination. Participation in the outreach meetings was a mandatory condition of the EFP. In addition to the pre season meetings, program staff also conducted outreach by phone and during regular service visits to the vessel. Upon completion of the fishery in 2004 and 2005, a questionnaire was administered to participating vessels in order to solicit feedback on the EM program and issues in the fishery.

EM Equipment Provision

The EM systems were provided by Archipelago (described in Section 2.1), available on a sale or lease basis. The year-to-year tenure of the EM program for the fishery resulted in most participants choosing to lease EM equipment. In advance of each season program staff prepared and tested all the EM systems expected for the upcoming season. This equipment was transported to the various ports for deployment on participating vessels. EM system provision included ensuring an inventory of spare parts was available to ensure continuous operation of EM systems during the fishery.

Installation and Removal of EM Systems

Each year of the program usually involved a significant field effort to install equipment prior to the start of the fishery. The mobilization efforts included deploying a mobile crew of service technicians traveling with EM systems to the ports, working under tight timelines of vessel availability prior to the start of the fishery. The process was repeated at the conclusion of the fishery, or when vessels exited the fishery. The 2008 and 2010 fishing season length was extended (148 and 180 days, respectively) with closure periods to avoid by-catch. In these cases, EM systems were often left in place until the vessel completed fishing for the season. As mentioned, there were a few vessels with purchased EM systems, but numbers were not significant to alleviate the hectic pre-season equipment mobilization effort.

The installation procedure on each fishing vessel began with consultations with vessel personnel regarding the layout of the vessel, fishing deck configuration, onboard electrical system, hydraulic systems and wire access routes. Vessels were typically fitted with two to three CCTV cameras. The GPS sensor was mounted at a high point away from other electronics, with a clear sky view. Hydraulic pressure sensors were usually mounted on a winch hydraulic supply line or in the engine room. Winch rotation sensors were mounted on either a warp winch or the stern net drum. Beginning in 2005, the EM system was fitted with an uninterrupted power supply unit (UPS), which was intended to stabilize power interruptions and reduce data loss caused by brief power interruptions. Upon completion of installation and testing, technicians briefed vessel personnel on the operation of the EM system and their duty of care responsibilities (see Section 2.2.4). Installation crews also photographed and measured fish holding areas on the deck (e.g., trawl alley, fish checkers) to enable density-volume catch estimations by image analysis staff.

Shortly after the close of the fishery, service technicians removed EM systems from the vessels. Often, participating vessels departed the area for other fisheries, causing an intense busy period to demobilize many vessels over a short time period. EM sensor and camera wiring was often left in place (with permission by vessel operators) to simplify future installations of EM equipment.

In-season Servicing

During the first week of the fishery, technical staff attempted to visit each vessel to confirm the functionality of the EM system. Thereafter, service visits occurred every two to four weeks as either a scheduled visit, or if the technician was in port for another vessel they would try to service as many available vessels as possible. EM service events were typically done while the boat was offloading or while the vessel was waiting to offload. EM servicing involved removing sensor and image data from the EM system and refreshing data storage capacity by installing a new hard drive. Servicing also involved an evaluation of system performance to ensure that all systems were functioning correctly. This included an examination of recorded data and a visual inspection of all components for wear and damage. Technicians also obtained photograph copies of the vessel logs during the service trips.

The program goal was to ensure vessels participating in the fishery had EM systems operational for 100% of their fishing operations. Vessel operators had several 'duty of care' responsibilities toward the EM system, which included:

- Keeping the system continuously powered while the vessel was at sea;
- Regularly cleaning camera dome surfaces to ensure sharp image resolution;
- Conducting periodic inspections of system components and conducting regular system checks to ensure the EM system was performing properly;
- Ensuring that camera view areas were adequately lit during night operations;
- Immediately contacting program staff and NMFS if the EM system stopped operating; and
- Maintaining regular contact with service provider for data retrieval and service scheduling.

Program staff was available to address service issues during the fishery. As well, information from EM data analysis alerted staff of any changes to the EM configuration or special duty of care needs aboard the vessel. This information was directed to vessel personnel and technical service staff in order to improve data quality.

2.2.2 Data Analysis Operations

The volume of data for a four week period of active fishing was approximately 120 GB from a typical vessel, large image data files accounting for most. This resulted in data from the fishery being stored on several hard drives, each drive representing a period of fishing operations for a single vessel.

Figure 2-4 illustrates the data processing operations that are described in the following sections. EM program data were assembled and managed in a relational database, linking operational elements of the program with specific service, trip and fishing event level data. Data summaries were designed to examine operational performance issues, as well as to examine compliance with the specific fishery monitoring objectives.

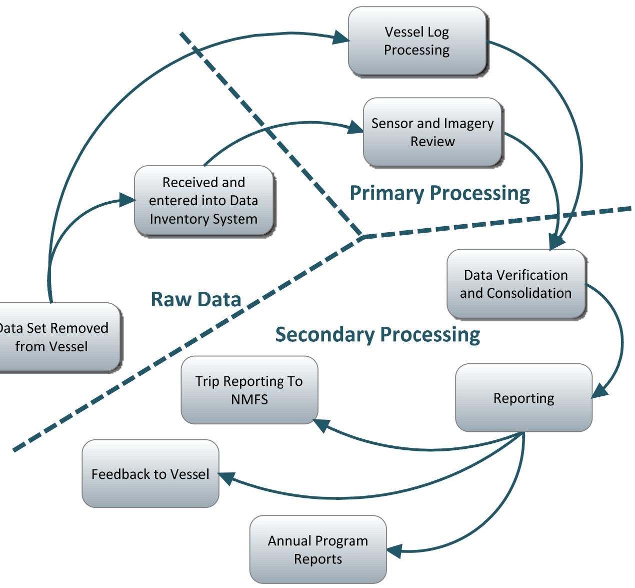

Figure 2-4. Schematic of data flow from the vessel retrieval to data reporting for the EM program.

EM data processing consisted of examining all the data products collected from a service event and compiling summary reports. The analysis objectives were as follows:

- Sensor data:
  - Evaluating data set completeness,
  - Identifying fishing events, and
  - Compile detailed fishing tow tracks.
- Image data:
  - Confirm fishing events,
  - Examine catch stowage operations to assess compliance with maximized retention requirements, and
  - Document the characteristics of discard events.
- Vessel logs:
  - Verify that trips and fishing events aligned with that recorded from the sensor data, and
  - Compare skipper records of discard information as compared with EM data.

Service Coordination

Data service coordination ensured that hard drives and data sets created by active fishing vessels were tracked throughout the operational cycle. Hard drive management involved the use of an inventory management system to track hard drives throughout their use cycle. During 2004, hard drives were deleted once analyzed and returned for use in the fishery. From 2005 to 2010, hard drives were kept for the entire duration of the fishery, enabling archiving of compliance events, and re-analysis as needed. From 2007 to 2010, hard drives were kept for a year following the fishery, and drives showing compliance could be kept longer, if desired by OLE. During these years, the entire hard drive was delivered to OLE when compliance events were identified. Other drives were kept in the project office and turned over to OLE at the end of the fishing season.

Data tracking was also carried out to monitor data set progress through the processing cycle. This included tracking the transit of the hard drive from the vessel to the office, through sensor and data processing, data consolidation and data reporting.

2.2.2.1 Primary Data Processing

Sensor Data

A preliminary analysis of sensor data occurred during each vessel servicing event to verify quality and identify possible service needs. Later, the data set was examined in greater detail to further examine data quality and identify vessel activities. Sensor data (GPS, hydraulic, winch rotation) for fishing episodes were simplified to one-minute intervals (versus 10-second intervals) to enable compilation of fishing event spatial data. Fishing trips were defined as the time from when a vessel left port until the time the vessel returned to port. Port location and vessel speed were used to define trip start and end. The start and end of fishing events was discernible from sensor data although fish stowage also required referencing the image data.

Image Data

Technicians reviewed all recorded image data (i.e., from the first set of a trip until the vessel returned to port). The following definitions were used to describe fishing operations:

- ***Set Interval*** **-** the period from when the trawl doors entered the water until they were returned and stowed.
- ***Catch Stowage Interval*** **-** the period from when the codend was winched on deck until when the all fish were stowed in the hold, or (rarely) when the vessel holds were full and the remaining catch stowed as a deck load.

EM Data Completeness

Data collection performance of EM systems was assessed in several ways. On a trip by trip basis, the quantity of sensor data expected (i.e., the duration between beginning and end) was compared with what was actually recorded by the EM system. EM data sets from each fishing trip were categorized as follows:

- ***Complete*** – Complete data record for the entire trip;
- ***Incomplete*** – Data record for trip has intermittent breaks;
- ***No data*** – No data recorded from the trip; and
- ***Post-collection data loss*** – Data was recorded successfully by the EM system but could not be accessed later. This problem was specific to the V3.0 CCTV system used until 2007.

EM data sets from each fishing trip were also assessed for sensor performance. The GPS, hydraulic and winch sensor data were examined and performance for a trip was considered complete if all data were present with intelligible (uncorrupted) results. CCTV camera image data quality was assessed as an average for the entire trip, using the following scale:

- ***High*** – the imagery was properly focused, the viewing area was clearly visible and net retrieval and catch stowage operations were easily assessed;
- ***Medium*** - there was a loss of image clarity, poor camera positioning or minor obstructions, but the analyst was able to confidently assess net retrieval and catch stowage operations;
- ***Low*** – there was low image quality due to reduced light, water droplets, poor focus or major obstruction of view and fishing operations were difficult to monitor; and
- ***No Data*** – image data were missing or when the quality was obstructed or insufficient to reliably assess fishing operations.

The data sets for each fishing trip were also evaluated for data gaps, or breaks in the data record. The data gap threshold was one minute, allowing consistency across all program years. Data gaps, often related to power interruptions, provided a measure of overall data success rate. Starting in 2008, time gaps were further categorized according risk as follows:

- ***Minor*** - Time gap occurred during the trip, but fishing activity had not yet begun;
- ***Moderate*** - At least one set had been completed when the time gap occurred, but the gap did not overlap with catch stowage operations;
- ***Critical*** - Time gaps occurred while catch stowage operations were underway; and
- ***Major System Failure*** - Any time gaps lasting more than half the duration of a fishing trip.

Discard Estimation

All catch stowage operations were examined to assess vessel compliance with the maximized retention requirements. It is normal that some fish will be discarded on nearly all catch stowage operations, owing to the high catch volumes and some fish being damaged or gilled in the net. A threshold of 0.045 mT (100 lbs) was used as a standard to distinguish normal operations from discarding events. In 2004, confidence in discard quantification was uncertain and hence discard quantities were categorized only by relative magnitude (<0.045 mT, 0.045-0.45 mT, 0.45-4.5 mT, and >4.5 mT). In 2005, discard quantities were estimated and recorded using finer intervals (<0.045, 0.045-0.450 mT, 0.450-2.2 mT, then ~2.0 mT intervals to 18.1 mT, >18.1 mT), and from 2008-2010, discards were recorded as the estimated quantity, rather than as interval data.

Two methods were used for estimating discard quantities. The preferred and most common method was using a standard volume-density approach, based on deck measurements, codend straps, or other references. Both trawl alley and codend volumes were estimated directly from image data, based on deck dimensions obtained by technicians at the start of the season. Height estimates were determined based on the height of comparable objects, such as bin boards or people. The volume-density formula (0.7854 x length x width x height) was applied to fish holding areas on deck and a standard ellipsoidal cylinder density volume formula (0.7854 x π x diameter (min) x diameter (max) x length / 4) was applied for net codends. In some cases, such as for incidents of bleeding, the only estimation method possible was visual, estimating the change in net volume before and after discarding using net dimensions and codend straps for reference.

The following terminology was used in 2004 to describe the catch retention activities:

- ***Maximized Retention*** – All catch was brought aboard and transferred to the fish holds. Any discards were less than a 0.045 mT threshold;
- ***Discarding*** – Some (or all) of the catch was released back into the sea in one of the following ways:
  - ***High Grading*** – species that were selectively discarded from the entire catch on deck. Criteria for selectively discarding fish were size, quality and species.
  - ***Bleeding*** –catch that was non-selectively discarded from the net via a "zipper" that the crew opened to release excess fish before the net was brought aboard (bleeding is also referred to as slipping).
  - ***Dumping*** –catch that was non-selectively discarded from the deck after the net was brought aboard. Dumping occurred in two ways: from the deck, or by towing the codend to flush fish from a full or partially full net.

From 2005 to 2010 discarding was categorized as follows:

- ***Selective*** – As above.
- ***Non-Selective*** – Non-selective discarding occurred when fish were discarded and no selection was apparent, usually connected with a vessel being full to capacity and excess fish are released. Four non-selective discarding categories were used:

- ***Bleeding*** – catch that was non-selectively discarded from the net via a "zipper" that the crew opened to release excess fish before the net was brought aboard. * Bleeding is also referred to as slipping.
- ***Codend flushing*** –when a partially filled codend is opened, lowered into the water and flushed by the forward motion of the vessel.
- ***Deck disposal*** –when catch is discarded directly from the deck, usually by using a water hose to flush fish overboard.
- ***Net Cleaning*** –discards of fish that were entangled in the net. Crew would usually pick the net to removed fish gilled in the mesh.

Vessel Log Data

Data processing also included processing vessel logbook data. Trips recorded in vessel logs were assigned a unique identifier and entered into an MS Access database. Data entry included trip and set information, as well as catch and discard quantities. Discard events were not always recorded at the set level, cases where discards were only recorded at the trip level were flagged as such and discards assigned to the last set. Vessel log data were primarily used to compare with fishery data as determined from information analysis of the EM data set.

2.2.2.2 Secondary Data Processing

Secondary data processing involved a series of steps to produce finished data sets from the interpreted EM data. Data consolidation involved making comparisons of data from EM sources with vessel logs to verify completeness of the EM data set and assess quality of self-reported data. Inconsistencies identified from this comparison could result in further review of original EM data. These comparisons could then be used for program feedback.

2.2.2.3 Reporting

Reporting evolved over the seven program years. In-season reporting was intended to provide timely analysis information to assist with in-season management of the fishery. From 2004 to 2006, in-season reporting occurred weekly (or bi-weekly in 2004) and consisted of a summary of vessel discarding activity for processed data sets, delivered to NMFS. No in-season reporting occurred in 2007 as efforts were focused toward development of a more standardized post season report which included more comprehensive vessel specific information. From 2008 onwards in-season reports followed each batch of completed data analysis, and a post season report was delivered to NMFS. Vessel specific in-season reports were delivered to participating vessels. In addition to data reports, NMFS received copies of EM data and summary data, provided in database format.

In addition to structured reporting, feedback among program participants often resulted from analysis of a data set in order to improve the quality and effectiveness of the EM deployment on the fishing vessel. Common feedback would be adjustments to system settings, changes to camera positions, advice to vessel personnel on duty of care responsibilities, or catch handling practices.

2.2.2.4 Discard Accuracy Study

In an effort to assess the accuracy of estimating discard quantities, comparisons between EM volumetric estimates and vessel weight estimates were conducted. An EM system was installed aboard NOAA's R/V Miller Freeman and the scientific crew weighed and sorted all whiting catch during the 2005 research cruise. This made it possible to compare direct weights with density volume estimates determined from EM image data. EM and vessel comparisons were made only for sets with catch large enough to fill the 1.8 m by 2.6 m sorting table, allowing the viewer to estimate only one parameter of volumetric estimation: height.

3.0 Results

3.1 Fishery Overview

The following three sections provide an overview of the 2004 to 2010 fishery in terms of key characteristics, the spatial footprint of the fishery and the management regime. This information provides an overall context to the monitoring program.

Key Characteristics

Key elements of the shore-based whiting fishery from 2004 to 2010 are presented in Table 3-1. Except for the first two years, fishery participation included about 35 vessels and fleet activity (days at sea, fishing trips and fishing events) was generally aligned with the total catch allocation, with the total catch ranging from 40,294 mT to over 972,677 mT. The season length varied by program year; partially in relation to catch allocation but also bycatch avoidance. In particular, the season in 2008 and 2010 was extended to over 140 days with voluntary closures in order to reduce the risk of exceeding bycatch limits. This was in contrast to season lengths of 24 to 60 days for other years.

As mentioned previously, the fishery typically consists of an early, main and late season component; the former involving 5-8 vessels fishing off the northern California coast, taking about 5% of the catch allocation. The EM program captured all phases of the shore-based fishery except for 2004 and 2005 where program initiation was delayed and the early season was missed.

Table 3-1. Summary of the shore-based whiting fishery during the 2004 to 2010 program years. Fishery characteristics were derived from program data except that denoted as '*' (source PFMC, 2011). Sea days are calendar days vessels are at sea as per Northern Economics (2011).

Fishery Characteristics	2004	2005	2006	2007	2008	2009	2010
Seasons Monitored	M	M	E/M	E/M/L	E/M/L	E/M	E/M
Vessels Participating	24	28	35	36	36	33	35
Season Length (days)	60	60	48	41	148	24	180
Sea Days	1,489	1,834	1,513	1,449	1,281	887	1,984
Total Trips	1,019	1,105	1,113	902	609	478	728
Total Sets	1,762	2,013	2,197	1,968	1,248	940	1,843
Whiting Catch (mT)*	89,251	97,378	972,677	73,277	50,760	40,294	62,655
Catch Value ($000's)*	n/a	n/a	13,617	12,078	11,914	5,536	10,038

Spatial Footprint

The spatial footprint of the fishery is shown in Figure 3-1, showing fishery location based on EM tow track data. Fishing locations ranged from Northern California to Northern Washington, with the bulk of the activity occurring off the coast of Oregon. During 2004 to 2007, vessel-fishing tracks were located closer to shore as compared with 2008 to 2010 where vessels were required to fish further offshore. Fishing activity inshore also appeared to be more dispersed as compared to years prior to 2008. In 2010 fishing activity was the furthest offshore and most dispersed as compared to previous years.

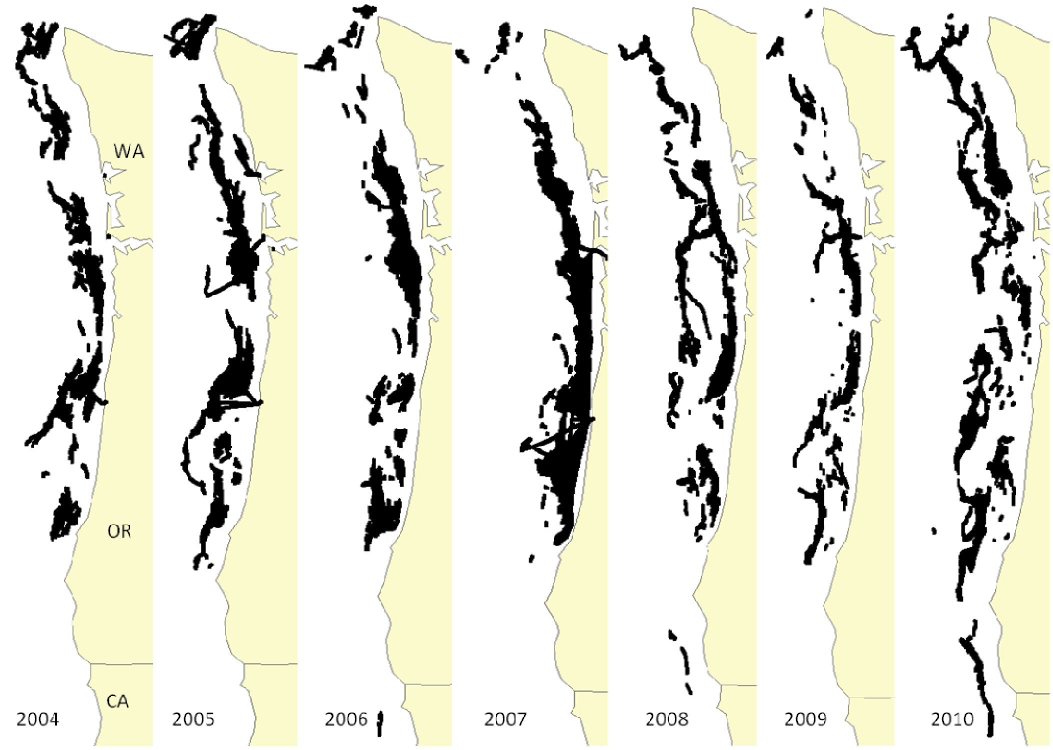

Figure 3-1. Spatial plots showing fishing locations during the main season for the shore-based whiting fishery for each of the program years (2004-2010). Fishing location data were taken from EM data when fishing gear was deployed.

Management Regime

As mentioned earlier, the fishery was managed under recurring Exempted Fishing Permits (EFP) for the 2004 to 2010 seasons. This annual permit process is generally used for experimental research or special cases that fall outside the normal regulatory process. The EFP process was not intended for ongoing fishery management and was instituted primarily to exempt vessels from the on-board catch sorting required under regulation. The EFP was a convenient tool for implementing EM-specific requirements because of the ease in which EFP wording could be updated to accommodate program specific needs. Over the 2004 to 2010 period, the specific language in the EFP changed in response to a growing understanding of the fishery and building more specific regulations aimed at addressing key fishery issues.

Changes in the EFP wording over time included more specific language concerning EM program requirements. Mostly, this related to increasing vessel responsibility toward monitoring the functionality of the EM system. Vessel operators were required to ensure the EM system was functioning properly, following specific 'duty of care' requirements (see Section 2.2.1), and immediately contact a service technician and OLE if problems were identified.

Most EFP changes related to catch and discard issues. In 2004, the requirements were to retain and land all catch caught during fishing operations. Discards due to emergency or safety situations were the only exceptions permitted. In 2005, the language changed to “maximized retention”. Discarded amounts for each species and reason for discarding were to be recorded in the logbook as required by the State of landing. In 2006, the language describing discards remained the same, but cumulative limits were listed for Pacific cod, lingcod and various rockfish.

In 2007 area restrictions were put in place limiting retention of more than 4.5 mT (10,000 lbs) of Pacific whiting per trip shoreward of the 100-fathom contour in the Eureka area (43°00' N. lat. - 40°30' N. lat.). Increased emphasis toward compliance resulted in the following revisions concerning discard events.

- ***Large marine organisms (2008–2010) -*** Large individual marine organisms, such as marine mammals or fish species longer than 6 ft (1.8 m) in length, may be discarded. If a large marine organism is discarded, the species and the reason for discarding must be recorded and labeled as “discard” in the required logbook.
- ***Avoidable discards (added in 2006, removed in 2008)*** - Discards that resulted from malfunctioning net sensors and catching more than the vessel hold capacity were considered avoidable and must be minimized to the extent practicable. Vessels were encouraged to modify gear and fishing practices to limit occurrences of avoidable discards.
- ***Unavoidable discard (2004-2007)*** - Discard events that resulted from hazardous weather conditions, unusual codend condition (i.e., over full codend), school density, and net cleaning, must be minimized to the extent practicable. If unavoidable discarding occurred, the discard event must be clearly recorded in the vessel logbook, detailing total discard amount by species, location and reason for discarding.
- ***Unavoidable discards (2008-2010)*** - Same as above, plus: Immediately following an unavoidable discard event, the vessel must stop fishing and immediately return to port, with notification to NMFS, OLE being made prior to arrival in port.
- ***Operational discards (added in 2008)*** - Pacific whiting removed from the deck and fishing gear during cleaning may be discarded, provided that the total operational discards must not exceed one basket from any single haul, with the maximum dimensions of the basket being 24 inches by 16 inches by 16 inches. If net cleaning resulted in a greater amount, all catch in excess of the one basket must be placed into the fish hold. Discarding operational discards of more than one basket of Pacific whiting per haul is prohibited. Discarding any quantity of groundfish species other than Pacific whiting is prohibited.

3.2 EM Data Collection Success

It is useful to evaluate overall data collection success prior to examining monitoring results, as gaps and poor quality source data can potentially bias the results. As mentioned previously, the goal of the program for each year was to monitor 100% of all participating vessels for the entire time they were at sea. Data collection success is summarized in two tables (Table 3-2 and Table 3-3), for sensor and image data collection, respectively.

The total expected sensor data for most program years exceeded 20,000 hours (Table 3-2). Based on EM data, the annual totals for fishing time (time gear in the water) was over 5,000 hours for most years, while catch stowage time was usually greater than 1,500 hours per season. This equates to approximately 20% and 6%, respectively, of the total vessel time at sea (the balance of time spent in transit and searching).

The sensor data success rate (i.e., percentage of hours recorded versus the total fishery hours) exceeded 98% for all but one year. The sensor data collection success rate was lowest in 2006 at 94.6%, or 1,347 hours of missing sensor data from a total expected of 25,030 hours. The causes were primarily (57%) source power related (interruptions to power, UPS compatibility issues), with the balance mostly attributed to a removable hard drive seating problem (poor electrical connection). While UPS devices were present on many vessels, compatibility issues with generated AC electrical power resulted in them not being effective on certain vessels.

Sensor component performance was evaluated differently, as the percentage of fishing trips in which the specific sensor was fully functioning. The GPS receiver showed the highest performance level, ranging from 91% to 100% across program years. The winch sensor had the most variable performance level, ranging from 82% to 100%. The winch sensor was usually located on the fish deck and more easily fouled, making it more prone to failure than other sensors.

Table 3-2. Summary of EM sensor data collection performance across the 2004 to 2010 program years. Sensor performance includes both complete and incomplete trips.

	2004	2005	2006	2007	2008	2009	2010
Total Trips	1,019	1,105	1,113	902	609	478	728
Complete Trips (%)	98.4%	99.0%	88.5%	87.5%	91.6%	93.3%	93.3%
Incomplete Trips (%)	0.7%	1.0%	7.0%	11.6%	7.9%	6.7%	6.7%
Trips No Data (%)	0.9%	0.0%	4.5%	0.9%	0.5%	0.0%	0.0%
Sensor Performance (by % of total trips)							
GPS	98.0%	100.0%	91.0%	99.0%	99.0%	97.0%	98.0%
Hydraulics	81.0%	100.0%	89.0%	98.0%	96.0%	100.0%	98.0%
Winch	97.0%	100.0%	82.0%	87.0%	94.0%	98.0%	89.0%
Sensor Data Success (by % of total hours)							
Total Hrs Expected	19,755	23,576	25,030	24,578	17,900	11,665	30,193
Total Hrs Recorded	19,377	23,524	23,683	24,182	17,645	11,593	29,974
Fishing Time (hrs)	4,499	5,241	5,564	7,534	3,562	2,115	6,563
Catch Stowage (hrs)	1,547	1,591	1,953	1,858	1,319	1,146	1,838
Success Rate (%)	98.1%	99.8%	94.6%	98.4%	98.6%	99.4%	99.3%

The success rate of recorded image data, expressed as hours recorded versus hours expected, exceeded 95% for five of the seven program years (range 87.1% to 99.0%,Table 3-3). As with sensor data, image data recording success rates were lowest in 2006 at 87.1%, or 2,752 hours of missing data. The lower image recording success for 2006 was due to power loss (10%), drive seating failure (41%), 'post collection data loss' (12%) and technician error (15%). The V3.0 equipment was phased out in 2007, which resulted in marked improvements to sensor and image success rates in the latter years of the program. A single incident in 2008 represented over half the total annual data loss. With this removed, the rate was over 98%. Success rates (as hours recorded versus hours expected) were highest in the final two years of the program at 99.0% and 99.6%.

In terms of the proportion of the fishing trips with complete data, the values for 2008 to 2010 were 93% to 96%, while years prior were 83% to 91%. In terms of image quality, over 80% of the total trips were rated as either high or medium for five of the seven program years. The higher rate of medium quality image data in 2007 was likely associated with differences between EM reviewers in making quality assessments. Across all seven years of the program low quality image data made up 10% or less of the total trips.

Table 3-3. Summary of image data collection performance across the 2004 to 2010 program years.

	2004	2005	2006	2007	2008	2009	2010
Total Trips	1,019	1,105	1,113	902	609	478	728
Complete Trips (%)	87.9%	91.1%	82.6%	84.0%	92.9%	95.8%	94.8%
Incomplete Trips (%)	2.5%	1.1%	2.6%	7.2%	5.1%	4.2%	5.2%
Trips No Data (%)	9.6%	2.5%	10.6%	8.8%	2.0%	0.0%	0.0%
Post Collection Loss (%)	0.0%	5.2%	4.2%	0.0%	0.0%	0.0%	0.0%
Image Data Quality (by % of total trips)							
High	82.6%	87.7%	69.1%	44.6%	94.6%	87.4%	82.4%
Medium	7.8%	4.2%	14.1%	37.5%	2.5%	11.5%	8.1%
Low	0.0%	0.4%	2.0%	9.2%	0.3%	1.0%	2.7%

Image Data Success (by % of total hours)							
Total Hrs Expected	12,896	20,471	21,250	21,578	15,577	9,734	26,763
Total Hrs Recorded	12,347	19,967	18,498	19,463	15,026	9,633	26,643
Success Rate (%)	95.7%	97.5%	87.0%	90.2%	96.5%	99.0%	99.6%

EM sensor and image data gaps are further summarized in Table 3-4, showing missing data by both hours and events by program year. In the most common instance where the entire EM system was down, there were gaps in the sensor data record and, if image recording was activated, gaps in the image data set as well. Sensor data gap events were nearly twice as common as image data gaps, reflecting time breaks at the start of fishing trips where image recording had not yet been triggered. In some cases, as in 2009, there were more gaps in the image data set because the EM system was operating but image recording had failed to activate, as would occur with a faulty hydraulic sensor. The very high amount of image data loss in 2006 and 2007 related to post collection data loss, mentioned previously. The lowest levels of missing sensor and image data, in terms of both number of events and hours, were in 2009 and 2010. Data gaps were not a fleet-wide phenomenon, but concentrated to a portion of the fleet. For example, during 2008 to 2010 program years, about 60% of the fleet showed 100% sensor data capture success and the five vessels with the most sensor data loss accounted for over 80% of the total.

Table 3-4. Summary of sensor and image data gap events across 2004 to 2010 program years.

	2004	2005	2006	2007	2008	2009	2010
Total Events	1,762	2,013	2,197	1,968	1,248	940	1,843
Total Sensor Hours Recorded	19,377	23,524	23,683	24,182	17,645	11,593	29,974
Total Video Hours Recorded	12,347	19,967	18,498	19,463	15,026	9,633	26,643
Sensor Data Gaps							
Total Hours	386	52	1,347	396	231	72	219
Total Events	565	368	250	239	146	59	83
Image Data Gaps							
Total Hours	549	504	2,752	2,115	551	100	119
Total Events	N/A	N/A	243	113	89	37	71

Table 3-5 provides a risk-based view of missing image data from the 2008 to 2010 program years, in terms of hours, number of events and vessels involved. In 2008 and 2009, over three-quarters of the image data loss was from 'major system failure' events and these represented less than 14% of the total events and a small number of vessels (4 and 2, respectively). In 2010, about half the missing time was classified as critical, most of which (80%) was from two events by one vessel on a single trip. There were five events by four vessels, ranging in length from six minutes to six hours, and a further seven events by five vessels, ranging from 1 to 3 minutes in length. The latter events correspond to the reboot cycle time of the EM control center, caused by a brief power interruption or the error detection (watchdog) software. In our view, it is unlikely that unreported discarding could occur with these events.

Table 3-5. Summary of image data gaps for the 2008 to 2010 program years by hours, events and vessels involved. See text for risk category definitions.

	2008	2009	2010
Total Image Hours Recorded	15,026	9,633	26,643
Critical	60	17.9	58.5
Moderate	54.2	6.5	23.2
Minor	18.9	0	37.6
Major System Failure	418	75.6	0
Total Missing Hours	**550.8**	**100**	**119**

Major System Failure	4	2	0
Total Vessels With Data Gaps	**32**	**15**	**30**

3.3 Maximized Retention Compliance

The primary monitoring goal of the EM program was to monitor vessel compliance with the requirement to retain all catch aboard during the fishing trip. Recognizing that there are periodic needs for operational discards, the program goal was not only to detect discard events but also to characterize these in terms of estimated quantity and discard type. Finally, the program goal was to ensure that instances of discarding were properly recorded in the vessel logbooks. In the following sections, these issues are examined collectively for the fleet across program years, then in terms of individual vessel performance across program years.

Fleet-wide Performance

In terms of absolute quantities of fish, discards of fish declined markedly across the seven program years, starting at an estimated 1,400 mT in 2004 to under 180 mT in 2010 (Figure 3-2). The decline in discard quantity was most pronounced after 2007 when the EM program became more compliance focused. In 2009 there was a two-fold increase in discarding activity from the 2008 levels (288 mT versus 125 mT) and the percentage of sets with discards rose to 15%, as compared with 4% in 2008. This was mostly due to an increase in high volume discards (>4.5 mT) which accounted for 84% of the total discard volume in 2009. It should be noted that discarding accounted for a very low overall percentage of the total catch in all program years, declining over time from 1.7% to below 0.3%, the most marked decline occurring in 2008.

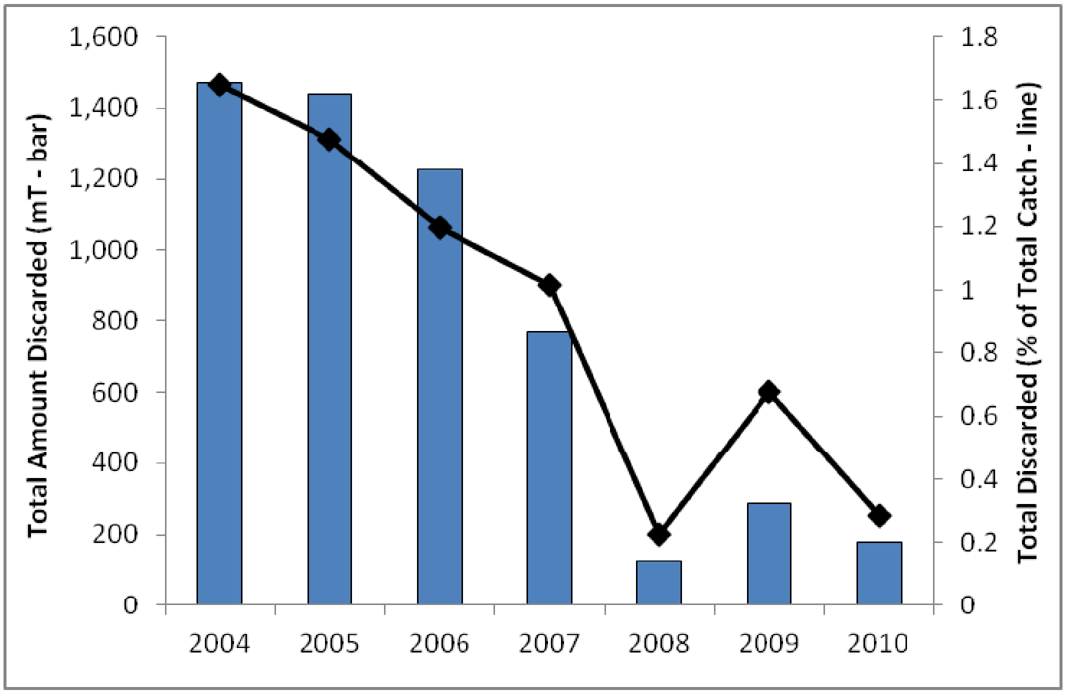

Figure 3-2. Summary by total amount (mT) discarded (primary y-axis) and the total amount discarded as a percent of the total catch (secondary y-axis) for the fishery by year across the entire duration of the program (2004-2010). *The total volume discarded for 2004 is only a general estimate following ranked quantities (see Section 2.2.2).

In a pattern similar to discard quantities, there was also a decline in the number of discard events: 250 to 350 events per annum between 2004 and 2007 versus 50-125 events per annum for 2008 to 2010 (Figure 3-3). In 2004 and 2005, discard events were almost exclusively on the last fishing event of the trip, indicative of the vessel being full to capacity and excess fish being discarded. Discarding during fishing events other than the last event of the trip became increasingly common in later years, indicative of unavoidable discard situations.

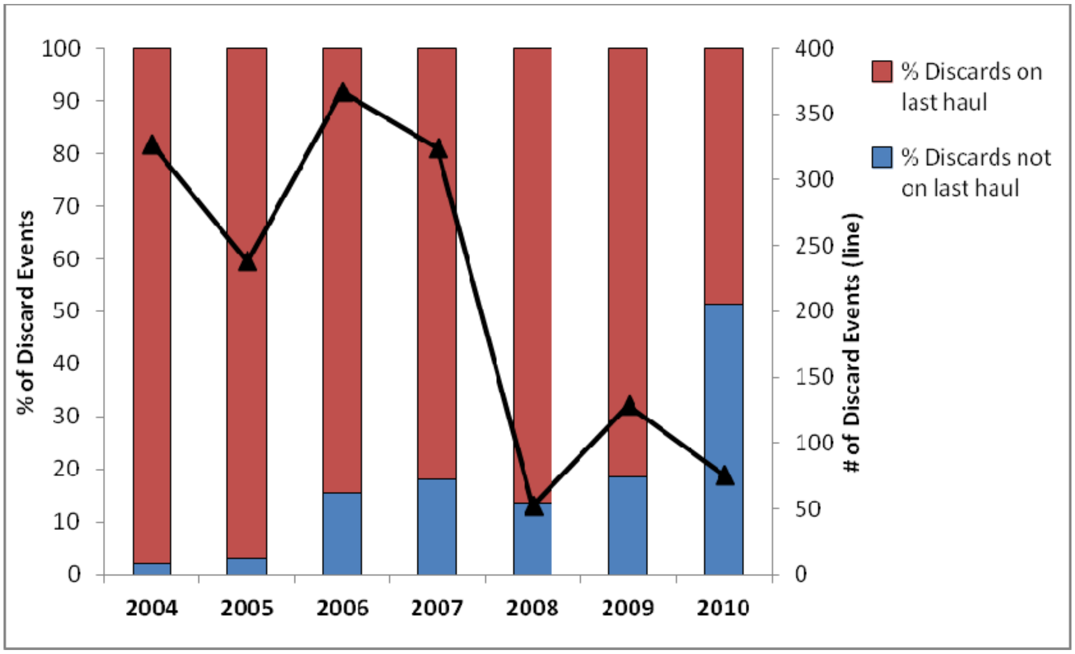

Figure 3-3. Summary of the percent of discard events (primary y-axis) not occurring on the last haul, and the total number of discard events (secondary y-axis) across the entire duration of the program (2004-2010).

In terms of the quantity of fish discarded per event, there was a marked change across program years (Figure 3-4). In 2005 and 2007, over a third of the total discard events were more than 4.5 mT, whereas these events were much less common after 2007. Discard events less than 0.45 mT varied by year in no obvious trend, however these events made up almost two thirds of the total discard events in 2010, much higher than any other year. The pattern is likely due to variability in viewers between years, more structured vessel catch accounting in later years (using a fish basket) and annual differences in whiting size, affecting amounts gilled in the net. Looking only at discard events greater than 0.45 mT, the decline in discard events across program years becomes much more marked, declining by nearly an order of magnitude between 2005 and 2010. One notable change in discarding activity in 2009 was the increase in discards greater than 4.5 mT. However, over 50% of the total discard volume in that year came from four vessels, indicating this was a localized issue.

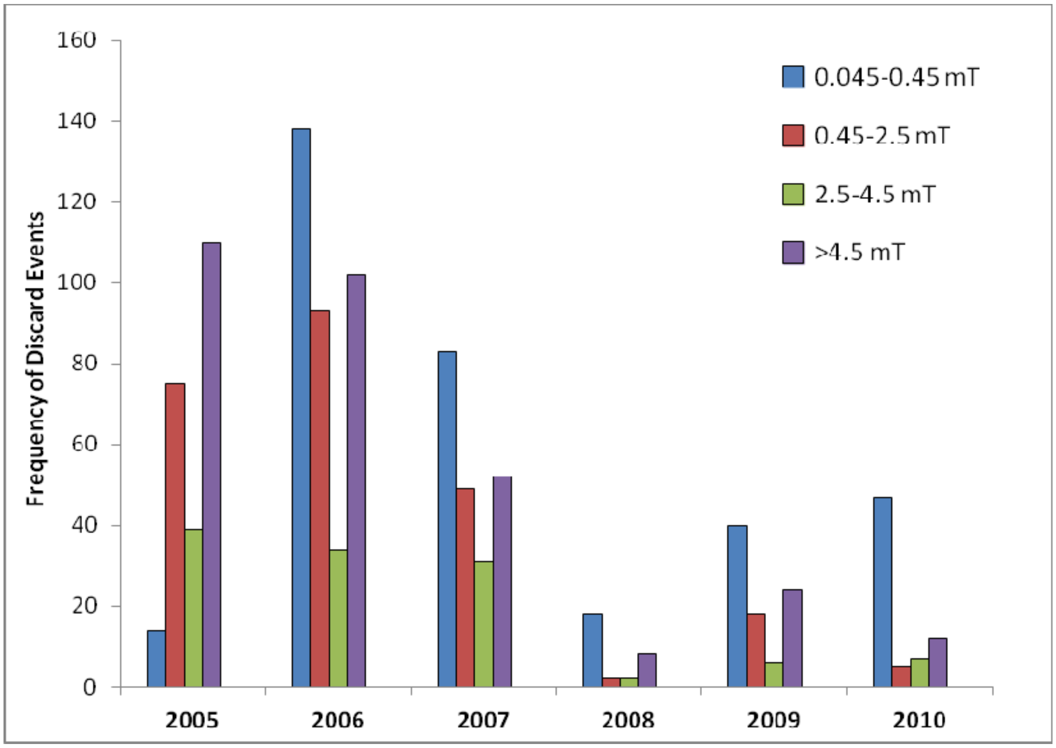

Figure 3-4. Frequency of the various size categories (mT) of discarding events for 2005 to 2010. * Data was not available for 2004, as discard amounts were not estimated for that year.

The frequency and type of discard events are shown by program year in Figure 3-5. Selective discarding consistently made up less than 1 % of the total discards from 2005-2010. Likewise, discards resulting from net cleaning made a small contribution to the total discard quantity. Net flushing, bleeding, and deck discards were the main discard methods, all three of which declined between 2005 and 2010. Deck discarding declined most markedly of the three (475 mT to 1.1 mT), followed by net flushing. Discard quantities from net bleeding were higher before 2008, as compared with after, and the proportion of discards from net bleeding increased from 10% to 60% as a consequence of declines in the other methods.

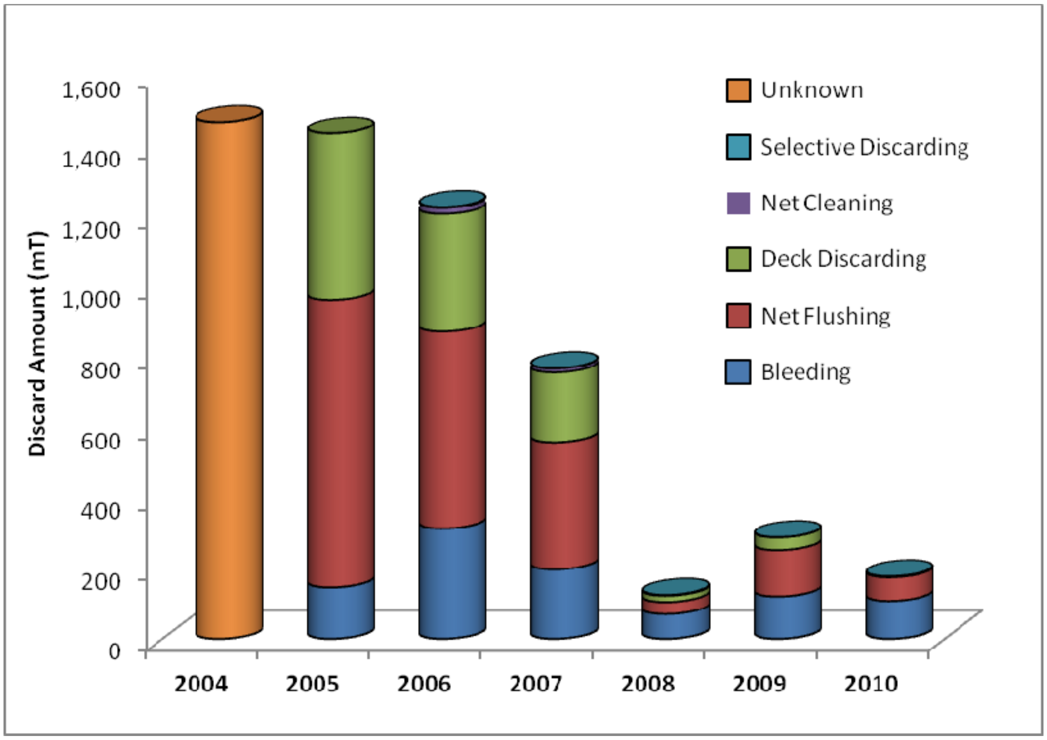

Figure 3-5. Summary of the total discard amount (mT) by discard type for the entire duration of the program (2004-2010). Data for 2004 were not available by discard type.

Vessel Specific Performance

Compliance with the maximized retention requirement by individual vessels was examined in a few different ways. Quantities discarded by individual vessels are shown in Figure 3-6 and Figure 3-7. Interestingly, across program years there was a marked decline in both the number of vessels discarding catch and in the proportion of catch discarded. In 2005, nearly all vessels discarded and most discarded 1.5% or more of their catch (Figure 3-6a). In 2010, a third of the fleet had no observed discards, and all but three vessels discarded less than 0.6% of their total catch (Figure 3-6f). Vessel reference numbers were unchanged between program years and vessels showed no consistent discard patterns. Vessels high in discards in one year were more often low in others. This is possibly the result of different skippers on the same vessel over time, but more likely the common challenge by all skippers of avoiding occasional instances of high catch. As was evident with the fleet-wide results, there was a marked difference in vessel discard patterns for the years prior to 2008 as compared to the three years from 2008 to 2010.

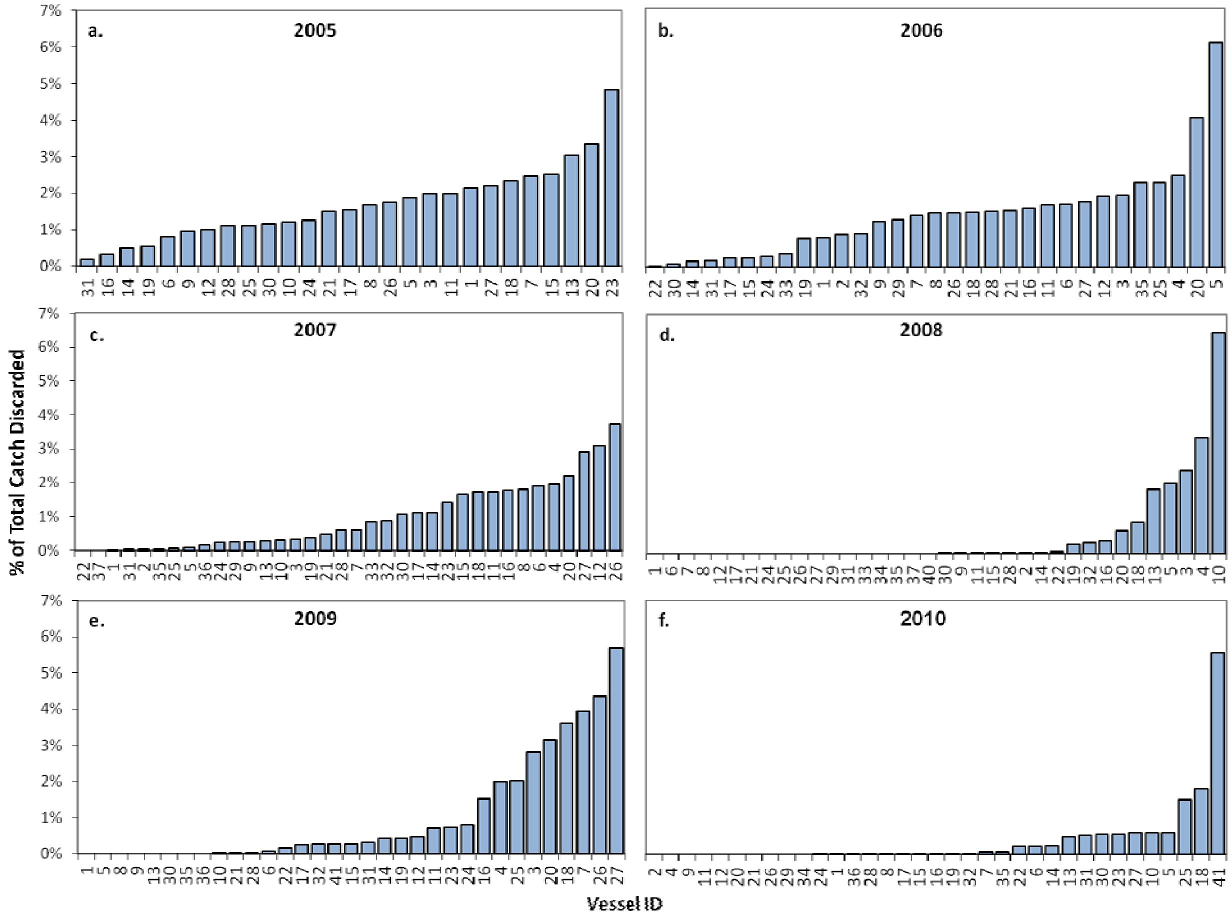

Figure 3-6. Quantities discarded as a percentage of total landed weight by vessel ID across six years of the program (2005-2010), with the vessels ordered (identified by ID numbers) from lowest to highest discard rates.

Table 3-7 examines the relationship between discard quantity (total for season and average for fishing events) and the level of vessel activity. The plots suggest that discard quantity was unrelated to the level of fishing activity for all program years. For example, in 2005 Vessel 8 that fished for ~ 60 trips discarded around the same percent of total catch (~2%) as Vessel 5 that fished for ~ 5 trips (Figure 3-7a). The plots also show that the average discard quantity per set (bubble size) did not vary with total catch or level of activity. As observed in Figure 3.6 there were no consistent vessel specific patterns; vessels showing high discard levels observed in one year were often lower in other years.

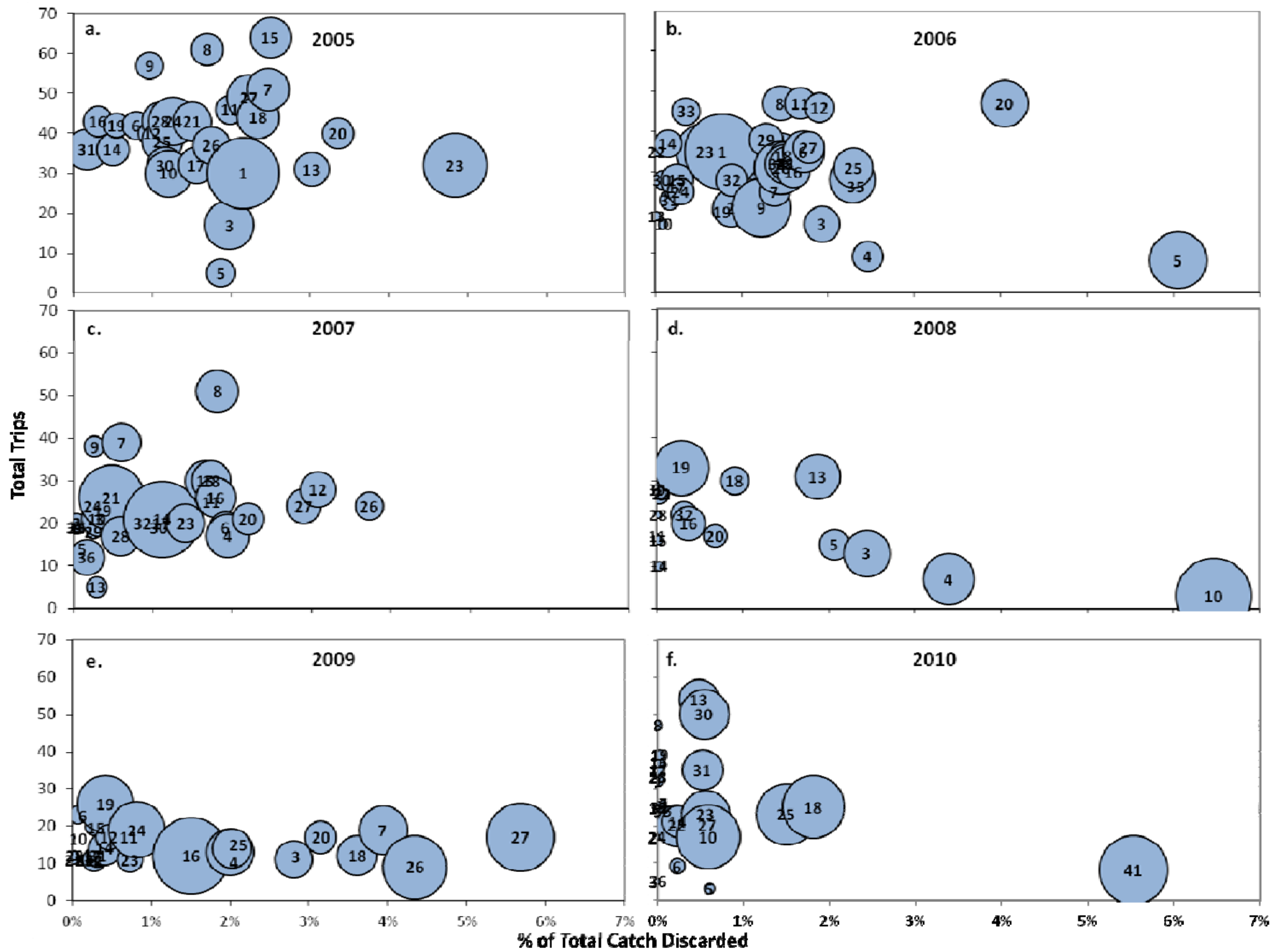

Figure 3-7. Vessel discard patterns expressed as the average discard quantity per set (bubble size) in relation to total quantity landed and the total number of trips by vessel across 2005 to 2010 program years. Reference numbers identify specific vessels.

Discard Estimation Accuracy

During the 2005 Miller Freeman research cruise, crewmembers weighed and sorted all catch, making it possible to directly compare estimates of volume as determined from EM imagery to actual weights from the Miller Freeman. Among the 65 hauls taken, most were either too small or too large, leaving 10 hauls where the quantity was suited to volumetric estimation on the sorting table (Table 3-6). On average, volumetric estimation by EM resulted in a 8.5% lower amount than the actual weight taken aboard the vessel. The average catch estimates did not differ significantly between EM and the Miller Freeman (paired one-way t-test P=0.238). However, variability on individual hauls was considerable (range 1.2% to 62.6%), with only 4 of 10 estimates within 5%. The largest difference was unrelated to the volume estimation but came from the EM viewer not detecting that the sorting table was filled twice instead of the usual practice of filling once. The comparison showed that the EM estimate made from these tests was not very precise, but unbiased in estimating the vessel catch volume across the full data set.

Table 3-6. Summary of EM weight estimates by volumetric method and Miller Freeman actual weight (kg). A negative difference indicated that the EM estimate was greater than the actual weight, and vice versa.

Haul #	EM Weight Estimate (kg)	Actual Weight (kg) (Miller Freeman)	Difference (kg)	Difference %
13	1,012	1,199	187	15.6%
14	1,012	972	-40	-4.1%
22	1,012	1,103	91	8.3%
23	1,380	1,183	-197	-16.7%
24	1,503	1,358	-145	-10.7%
25	767	737	-30	-4.1%
32	1,135	1,167	32	2.7%
47	1,012	623	-389	-62.4%
58	1,135	1,121	-14	-1.2%
63	1,258	1,115	-143	-12.8%
Total	**11,226**	**10,578**	**-648**	**-**
Average	**-**	**-**	**-65**	**-8.5%**

3.4 EM and Vessel Logbook Data Comparison

Starting in 2005, vessel log data were compared with the EM data for discarding activity (Table 3-7). The proportion of comparable events (i.e., where the data sets could be aligned) varied across the program years from 73% to 94%, showing a clear improvement over time. The data sets were considered in agreement if both EM and log data recorded a discard event (EM+Log+) or if neither recorded a discard event (EM-Log-). The level of agreement (% match) ranged from 86% to 96%, the majority (74% to 95%) of which were from fishing events that did not involve discarding. Cases where both EM and vessel logs recorded discards (EM+Log+) ranged between 1% and 15%, while the percentage of discard events that did not match (EM-Log+ or EM+Log-) varied between 1% and 8%. Discard events that were recorded in the vessel log and not by EM (EM-Log+) in 2006 and 2007 likely related to small volume discards (<450 kg) such as net cleaning that were more commonly reported in the vessel logs than by EM reviewers.

Table 3-7. Comparison of Vessel logbook (Log) and EM data (EM) sets across the 2005 to 2010 program years. The proportion of matched and unmatched sets is from comparable sets. See text for description of EM/Log detection categories.

Year	Total Sets	% Comparable Sets*	% Match	EM- Log-	EM+Log+	% Not Matched	EM-Log+	EM+Log-
2005	2,013	89%	96%	85%	11%	4%	3%	1%
2006	2,197	73%	89%	74%	15%	11%	7%	4%
2007	1,968	89%	86%	77%	9%	14%	8%	6%
2008	1,248	83%	96%	95%	1%	4%	2%	2%
2009	940	93%	89%	86%	3%	11%	3%	8%
2010	1,843	94%	95%	93%	2%	5%	2%	3%

**The percent of comparable sets are sets where either one or both of EM and vessel log record a discard event*

In order to further examine discard events missed by the EM viewer (EM-Log+), events logged by vessels with discards >0.45 mT were re-examined. For the 2010 data set, this resulted in five events where EM did not record a discard (EM-Log+) out of a total of 34 events with discards >0.45mT. In three instances, no discarding was observed but the reviewer noted image quality issues (sun glare, poor image, and poor lighting conditions). In one instance the image quality was very good and no discarding was evident, likely a vessel log recording error, while in another discarding was evident, indicating a viewer error.

The reverse situation where events missed by the vessel log were also re-examined (EM+Log-), taking events logged by EM viewer with discards >0.45 mT. This resulted in a total of eight events of 53 in the 2010 data set. In four instances, the vessel log notes that discarding occurred but no quantity was recorded. Among the remaining four events, three recorded catch but no discards and one recorded the event but no catch or discard quantity.

Table 3-8 provides a summary of regression tests between EM and vessel log estimates of discard events, according to different discard types. The data used for this comparison was drawn from 2005 to 2010 program years, from cases where discards were recorded by both EM and vessel logs. While the correlation was significant (Pearson's Correlation test, $p<0.05$) for all three discard types, the correlation coefficients were low ($R^2<0.43$) in all cases, indicating there is a high level of variability between the two data sources. Interestingly, the deck discard estimates showed the strongest correlation, yet the EM estimate was 33% below the vessel log estimate. Keeping in mind that both EM and vessel logs are estimates, the results do not attribute error to one source over the other.

Table 3-8. Summary statistics for comparisons between EM and vessel log discard estimates by type of discard. * Denotes a statistically significant Pearson Correlation value (P<0.05).

Discard Type	Sample Size (n)	EM Discards (mT)	Log Discards (mT)	% Difference (EM:Log)	R^2	Y-Int.	Slope	Pearson's Correlation
Deck Discards	270	531.2	797.1	-33.4%	0.43	1.15	0.92	0.657*
Bleeding	71	361.1	374.1	-3.4%	0.32	1.94	0.66	0.568*
Net Flushing	108	698.9	566.6	18.9%	0.35	1.11	0.64	0.593*
Total	**449**	**1,591.2**	**1,737.8**	**-8.4%**	**0.35**	**1.22**	**0.64**	**0.65**

3.5 EM Program Operational Considerations

In addition to the fishery specific program results, there was a progression in the operational aspects of the program, which affected the quality of data, operational efficiencies and program cost. The salient aspects of this program evolution are summarized in the following sections.

Industry Outreach

Results from the 2004 and 2005 questionnaire surveys to industry demonstrated support for the EM program and its effectiveness as a monitoring tool. Among the responses received (about half the fleet), there was consensus that EM was an effective monitoring tool (86% and 100% for the two years, respectively), the majority supported the use of EM (73% and 75%) and the majority did not experience technical difficulties with EM technology (80% and 75%). Interestingly, the majority of respondents also felt that EM did not cause changes to their fishing practices (73% and 58%), but it is suspected that this result would be very different during the period from 2008 to 2010.

Industry outreach was also useful in communicating program specific results. At the annual pre-season meeting, skippers received copies of prior year fleet performance graphs (Figure 3-6). The vessel names associated with reference numbers were confidential, except on an individual basis. Vessel owners or skippers were provided with the reference number of their vessel in order to determine their performance in relation to the rest of the fleet. This information served to create an understanding of general discard patterns in the fishery and helped fishery participants compare their vessel performance in relation to the rest of the fleet. The feedback focused discussion on problem areas and helped shape opinions of acceptable discard practices in the fishery. Starting in 2008, participating vessels received in-season reports showing EM analysis results including EM data collection success, compliance with maximized retention, vessel logbook recording practices, and comments regarding corrections needed. This feedback process was considered useful but not very timely, given the time delays in collecting EM data sets and completing data processing. Other feedback, showing vessel specific bycatch information was published on shore-based fishery website, hosted by the Oregon Department of Fish and Game. This information, while not part of the EM program, served to keep attention focussed on bycatch issues and compliance with full retention requirements.

Field Services

A consistent issue across the program years was the large mobilization and demobilization effort required to deploy EM systems. Timelines were short because access to the whole fleet was usually limited to a narrow time window at the start and end of the fishery. This component of field services required a large service staff, and was logistically complex and costly. In-season field service efforts were also challenging because the fleet activity was distributed across several ports and access to vessels was often limited to the brief time when they were in port to offload. With offloads scheduled to provide a steady supply of fish to plants, only a portion of the fleet was accessible at any point in time during a port service visits. There was no single best way to cover the fleet; technicians could either stay in a single port waiting for vessels to land, or travel from port to port, meeting vessels opportunistically. Vessels requiring technical support were usually given service priority and collection of hard drives was opportunistic, based on vessel accessibility. This resulted in a variable supply of hard drives for data analysis.

The seasonal nature of the fishery, the fact that no single location had sufficient activity to justify establishing dedicated port-based services, and the challenge to provide responsive field services with qualified technicians across a broad geographic area created ongoing logistical challenges across the seven program years. From 2004 to 2006, technicians were based in Newport, Oregon, which is more central to many of the active ports. This staffing effort satisfied in-season field service requirements but was insufficient at the start and end of the fishery when a larger number of technicians were needed. This Newport-based approach was abandoned in 2007 in recognition that gains in efficiency did not justify the expense and complexity of establishing a program-dedicated EM technician for the short fishery duration. Field services were then based from Archipelago's head office in Victoria, BC, where there was a larger pool of qualified EM technicians who could more easily be tasked to the fishery as required.

EM Data Processing

EM data processing followed the same general method but there were differences across program years. The most significant change came from the evolution of the EM technology, mentioned previously, that affected both operational efficiency and accuracy. The integrated data analysis software (used from 2008 to 2010) enabled technicians to easily work through EM data sets, distinguishing trips and sets, viewing multiple camera images simultaneously, and recording their observations into a database directly from the analysis software. These efficiencies significantly improved the data analysis processes.

Data processing efficiency is often expressed with analysis ratios, defined as the amount of time required to review imagery divided by actual time of the event. Analysis ratios from the 2010 project year (Table 3-9) showed an average ratio for catch stowage time of 0.249 (i.e., one hour of catch stowage operation takes 15 minutes to review). The analysis ratio for transit and fishing was much lower at 0.048, reflecting the higher speed that imagery can be reviewed when no fish handling activities are occurring. The higher rate for catch stowage operations related to the more careful examination required from different cameras to monitor for discard events. When discarding was evident, more time was needed to examine the event and data enter observations, hence the wide range in analysis ratios.

Sensor data processing time on average took 15 minutes per trip, and was not affected by the duration of the trip. In contrast image data review time was dependant on the duration of the trip, number of cameras, image quality, complexity of deck operations, and other factors. The data review time for a fishing trip varied considerably but in general, less than an hour was required to process an average trip of 41 hours in duration.

Table 3-9. Summary of analysis ratios (viewing time/actual elapsed time) for imagery review during catch stowage operations versus transit and fishing time for the 2010 project year.

	Catch Stowage (fish on deck)	Transit and Fishing (no fish on deck)
Total Events Reviewed (n)	128	73
Average	0.249	0.048
Min	0.001	0.013
Max	0.643	0.087

While improvements in analysis tools streamlined the data services components of the program, it was difficult to provide timely monitoring results throughout the seven program years. In 2005, there was approximately a five-week delay from initial data collection to finished results which, given bi-weekly hard drive collection, translated to a delay of as much as seven weeks from when an event occurred. In 2010 the delay averaged 3.5 weeks (range of 0.5 to 7.4 weeks) following collection, or about 5.5 weeks from when an event occurred. With usually less than 60 day fishery duration and 30 or more active vessels, there are significant challenges with the field and data services operational components if the goal were to produce EM monitoring results for in-season management.

Program Cost Analysis

The EM program was co-funded by industry and NMFS throughout the 2004 to 2010 period and, owing to a number of circumstances, the proportional contribution varied from year to year. A cost summary for the 2007 to 2010 program years is presented in Table 3-10, showing total program cost, the contribution by industry, and program cost in relation to catch and vessel days. The program costs represent the total fees paid to the contractor for the delivery of the EM program and represent the true total cost of an ongoing EM program. It should be noted however, that program start up costs are not included and these would vary considerably depending upon program design and the service delivery approach used. Table 3-10 shows that program costs varied from year to year, the fluctuation driven by season length, catch quantity, the number of participating vessels and the number of vessel days at sea. Season length was the most significant cost driver: 2008 and 2010 program years were over 140 days, while 2009 and 2007 were 24 and 40 days, respectively. The four year average program cost was $6.03 per mT, or $254 per sea day. The number of sea days per season is equivalent to the total number of calendar days that fishing vessels are at sea (i.e., partial days count as a full day), in line with how the term is generally defined by observer programs.

Table 3-10. Summary of total EM program costs for the 2007 to 2010 program years. See text for definition of sea days.

Year	Total Program Cost (000's)	% Industry Funded	Cost per mT	% Catch Value	Cost per Sea Day
2007	$346.3	64.0%	$4.58	2.9%	$239.0
2008	$434.8	76.0%	$7.87	3.6%	$339.0
2009	$228.4	66.0%	$5.37	4.1%	$258.0
2010	$412.2	79.0%	$6.61	4.1%	$208.0
4yr Average	**$355.4**	**72.0%**	**$6.03**	**3.6%**	**$254.0**

Figure 3-8 provides a breakout of program costs for 2009 and 2010, according to the program components defined in Section 2.2. The largest single cost factor (40-42%) was the service effort relating to installation, in-season servicing and post season removal of EM equipment for the fishery. In 2010, EM system provision cost was the second largest cost factor (36%), where as this was only 15% in 2009, owing to season length differences. As mentioned previously, most vessels leased EM systems as opposed to purchasing them. Had purchased systems been used, savings would occur with both EM system provision and mobilization and demobilisation costs, resulting in about a 15% program cost savings. Analysis and reporting was proportionately higher in 2009, as a significant portion of the fishery analysis and reporting effort was independent of season length.

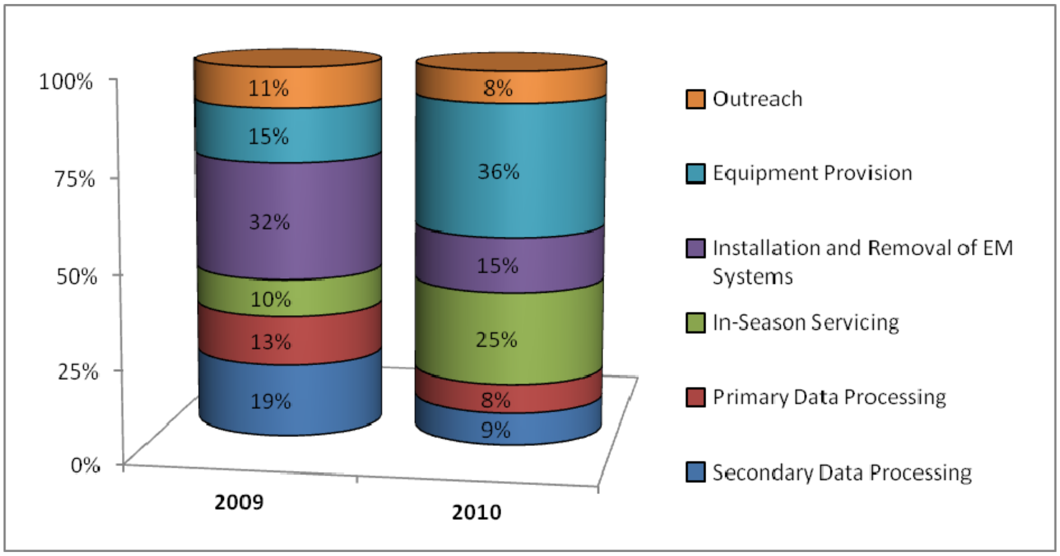

Figure 3-8. Distribution of 2009 and 2010 EM program costs by component.

4.0 Discussion

The purpose of this paper was to compile the results of the seven-year EM program in order to review the operation of the monitoring program and how it evolved over time. The paper was also intended to document the operational aspects to demonstrate that effective EM programs are a lot more than the underlying technology. As well, the intent of the paper was also to summarize what we learned, with the aim of evaluating the merits of the program and providing insights that would assist in other fisheries where EM is being considered. The following key questions are relevant for this purpose:

- Was EM effective?
- Was EM cost-effective?
- What were the ingredients to success?
- What are the lessons learned?

4.1 Was EM Effective?

One of the challenges when evaluating the role of EM in contributing to the change in fleet-wide discarding activity is the lack of other monitoring methods that can be directly compared to EM, or understanding the discarding practices occurring in the fishery when no monitoring was in place. As well, the EM program was just one of a few initiatives that increased the level of attention toward discarding practices and the relative role of EM would be difficult to isolate. Clearly, EM had a role in building a level of awareness and other factors such as stakeholder engagement, feedback, more stringent EFP regulations and OLE involvement all played a role in creating change in the fishery.

4.1.1 EM Data Collection Success

The effectiveness of EM as a fishery monitoring tool can be evaluated from both a fishery management and operational perspective. The seven-year program consistently demonstrated that it was possible to cover nearly all, of the fishery using EM technology, without any significant loss of fleet monitoring coverage. Over the seven-year program period, technology and program efficiencies improved to a level where over 99% of the fishery was monitored, creating confidence that results from the EM program were a true reflection of the fishery. The technology was well suited for this application and, for the most part, provided consistently high reliability. The sensor data success rate exceeded 98% for all but one year and the success rate for image data exceeded 95% for five of the seven program years. EM sensor data provided a very precise time and area footprint of the fishery.

Some data loss occurred in all program years which raises the question of the risk posed by missing key events in the fishery. While missing data is a component of any monitoring program, EM should probably be held to a different standard than observers because of the potential hidden bias with potentially purposeful data gaps. Put another way, fishery participants can alter the fishery results by 'accidentally' shutting the system off when undesirable events occur. In July 2007, an enforcement incident, reported by Matthews (Pers. Comm.), highlighted the potential harm of minor breaks in the data record. A large quantity of groundfish, consisting of whiting and widow rockfish (*Sebastes entomelas*), was reported washed ashore in Southern Washington. Using VMS data, OLE officials were able to narrow the potential suspects to a vessel whose skipper admitted to turning the EM system off in order to discard approximately 17 mT of fish, including about 3 mT of widow rockfish. The EM data record for this incident showed a data gap thereby preventing the discarding incident from being detected. In a fishery with limited bycatch allowances, a capture event such as this could put the fishery at risk and would therefore motivate participants to conceal the event. This potential area of resource risk became even more relevant with the 2011 implementation of the groundfish IFQ program, where bycatch was individualized to single quota holders or groups of quota holders.

The above incident prompted a change in EM data analysis methodology where greater attention was given to data record gaps. In 2008, changes to wording in the EFP, greater emphasis by OLE, and more detailed analysis of data gaps resulted in a sharp decline in missing data. In the 2008 to 2010 program years, success rates were greater than 99% and the vast majority of data gaps were attributed to moderate or low risk events (i.e., data gaps were not during fish stowage operations), where an event such as described above could not have taken place. In 2010, 13 data gap events occurred during fish stowage operations and eight were considered as potential candidates for unrecorded discarding. As there were over 1,800 fishing events in 2010, the EM program was effective at reducing the likelihood of such discard events to less than 0.5% of the total.

Despite these low levels of EM data loss, the question remains of the potential risk to sensitive species. In order to assess this risk, we examined landings data from the 2011-2013 whiting fishery (Colpo, Pers. Comm.) to construct a worst case scenario of the amount of unrecorded catch that would be associated with various levels of missing EM data. The 2011-2013 years correspond to a period of 100% catch accounting using 100% at-sea observers and 100% shore-based landings monitoring. We examined catch quantities of sensitive species from the landings data to identify the highest bycatch incidents and selected the year of highest bycatch for each sensitive species. We then estimated a 'worst case' catch quantity associated with EM data loss rates of 0.5% by summing 0.5% of the highest catch events from the highest of the three years for each sensitive species. This was repeated for EM data loss rates of 1% and 5% and the results are shown in Table 4-1. Other than widow rockfish, bycatch levels of most sensitive species is low, both in terms of the percentage of fishing when present (percent occurrence) and catch quantity. Taking the highest catch rates from the three years and using a 0.5% EM data loss rate, the worst case amount of missing catch would be less than 1% of the ACL for all species but widow rockfish and POP. The missing catch for these species would still be below 2% of the ACL with a 5% EM data loss. As compared with other species widow rockfish has a much higher occurrence rate and therefore, missing EM data is more critical for this species. As much as 5% of the ACL could be missed at a 0.5% EM data loss and 14% at a 5% EM data loss. POP, with much lower fishery occurrence pattern and lower ACL, would have as much as 3% of the ACL missing at a 0.5% EM data loss. This analysis was a 'worst case' assessment where missing catch data would result if only the highest bycatch events were excluded from the EM data record. Also, the species results are mutually exclusive; that is, selecting the worst case for one species would not likely result in the worst case catch rates for other species. In our view, these results suggest that, at the data loss rates experienced for most program years, the hidden bias from missing EM data is more likely to impact management of individual IFQ holdings than pose a risk to the resource caused by large amounts of unaccounted catch. However, these results underscore the need to ensure that EM data loss is monitored and actively managed in an EM program.

Table 4-1. Risk assessment of worst cast missing catch data for sensitive species associated with different levels of EM data loss based on 2011 to 2013 landings data (Colpo, Pers. Comm.).

Sensitive Species	2012 ACL (mt)	Highest Catch Year	Percent Occurrence (%)	Max Catch Event (mT)	0.5% Data Loss		1% Data Loss		5% Data Loss	
					Missed Catch (mT)	Percent of ACL	Missed Catch (mT)	Percent of ACL	Missed Catch (mT)	Percent of ACL
Widow	600	2012	75.0%	14.04	28.23	4.7%	39.19	6.5%	86.96	14.5%
Darkblotched	296	2012	28.5%	0.78	1.44	0.5%	1.95	0.7%	4.41	1.5%
POP	183	2012	25.8%	3.28	5.76	3.1%	7.71	4.2%	12.58	6.9%
Canary	107	2013	13.7%	0.12	0.34	0.3%	0.52	0.5%	1.754	1.6%
Bocaccio	274	2011	0.9%	0.03	0.03	0.0%	0.05	0.0%	0.1679	0.1%

Sockeye	-	2011	0.1%	0.00	0.00	-	0.00	-	0.0032	-

4.1.2 Maximized Retention Compliance

Importantly, the EM program provided individualized results of vessel compliance with maximized retention. In 2005, nearly all vessels discarded and most discarded 1.5% or more of their catch. Over time, the discard levels declined with increasing numbers of vessels showing very low levels of discards. By 2010, a third of the fleet had no observed discards, and among those vessels with discards, all but three discarded less than 0.6% of their total catch. Vessel-specific discard information showed that the majority of the discarding activity was caused by a minority of the fleet, and that many vessels could successfully participate in the fishery with little or no discards. In our view, the data rich vessel-specific information system provided by the EM program was instrumental in helping drive this change in the fishery.

While not contributing directly to catch data, the EM program strengthened the veracity of the offload monitoring data collection system. Without at-sea monitoring, the landings data only report offloaded catch, leaving uncertainty for what was discarded at sea. The EM program provided estimates of discarded catch, and also corroborated information provided in vessel log data. Events of selective discarding were of particular concern, given the potential to bias overall species composition from landed catch. Very few selective discarding incidents were observed and the vast majority (>99%) were considered non-selective discarding events. These two categories were distinguishable more by crew behavior than by species recognition. Selective discarding could be damaged whiting, sharks or sensitive species and likewise, non-selective discarding could be mixed species or all whiting. Given the decline in large volume discard events and the shift to predominantly net bleeding and flushing methods over the seven year period, discarding seemed to be more related to an over-full or the vessel being full to capacity rather than discarding for species avoidance purposes. Hence, the level of at-sea discarding in this fishery (<0.03% in 2010) would likely contribute very little bias to the species composition obtained from landings data.

The results from the EM program identified the difficulties in quantifying discarded catch. The CCTV cameras provided an overall view of the fishing deck from various angles in order to monitor fish stowage operations and estimate discard quantities volumetrically. Using a similar set up on the R/V Miller Freeman, we observed no significant difference between weighed catch and estimates from EM imagery. However, these results must be interpreted with caution given the very small sample size (n=10 hauls) and different quantities between the fishery (.045 mT to >15.0 mT) and research vessel (~1 mT). As well, the discard accuracy study was conducted in the second year of the program and would not be representative of the seven-year program, particularly as technology and methods improved.

4.1.3 EM and Vessel Logbook Data Comparison

The comparisons of estimated discards by EM and vessel logs showed significant correlation across three discard types (deck discards, net flushing and bleeding), yet there was a high level of variability between the two data sets (R^2 <0.4). As both are estimates, it was not possible to attribute the error to vessel logs or EM estimation method but it is reasonable to conclude that density volume estimates from EM imagery were imprecise. Quantification of net bleeding events (no catch comes aboard) is difficult for EM reviewers, but also for observers and skippers. Without bringing fish aboard, it would be difficult to improve on estimates of fish discarded by net bleeding. The majority of catch was discarded in this manner in 2010. Discard events from the fishing deck were more easily estimated from referencing dimensions of deck features (e.g., checkers, trawl alley, etc.), yet this was still an imprecise process for skippers, observers and EM reviewers without more careful controls. Estimates of discard quantities could be improved with the use of more structured on board catch handling methods to facilitate more accurate volume estimation. This would entail placing fish intended to be discarded in containers such as baskets, totes or designated checker areas, the size being appropriate to the quantity desired. Other approaches including weigh scales, stereoscopic volume estimation (Ruff et al. 1995), and piece to weight conversion (Pria et al. 2012) should be considered in respect to cost benefit. Given the discard quantities declined to below 0.3% of total catch in this fishery (the majority by net bleeding), it is questionable whether more sophisticated catch quantification techniques would be justified. The importance of more precision is probably less important than ensuring that the species composition of discarded is unbiased.

One of the limitations of the EM system was with providing suitable imagery to identify individual species. The camera technology used in this program was analog, providing lower resolution (smaller file size) images that provide little detail when enlarged from the full deck perspective. Generally, fish that were distinctively different from whiting (i.e., different size, shape or color) could be distinguished but often could not be specifically identified. Close up cameras were not used in this study as was done by Bonney and McGauley (2008), which would have enabled species identification at a discard control point. This does limit the ability to use EM data for species specific enforcement and to collect biological data at the species level (i.e., species distribution information). However, species identification was not one of the monitoring objectives, instead, monitoring efforts were primarily directed at monitoring crew activities during catch stowage operations. Incidents of selective discarding could easily be detected, but were rarely observed. Generally, activities were non-selective with quantities of fish being transferred *en masse* from the net to the hold. More problematic were incidents where catch was discarded directly from the net to the water either as a bleeding event, or net flushing event. We examined such cases carefully, reasoning that such events occurring when the vessel was not full to capacity were considered suspect for having a higher bycatch composition than those of the last fishing event on a trip where the vessel was full to capacity. The EFP regulation in 2008 requiring vessels to end their trip and come to port if discarding occurred was intended to address this potential risk.

Program improvements to enable species identification would be beneficial. Recent technology provides much higher resolution digital imagery and much larger data storage devices, enabling much higher image quality than was previously possible. This would allow much greater image resolution during catch stowage operations. Designated discard control points and measures to control the rate of fish flow would still be necessary to distinguish among discards of predominantly whiting. The best application for EM for this high volume fishery would be to verify maximized retention, and if limited discarding were permissible (e.g., halibut, large sharks, etc), they be released singly through a discard chute.

4.1.4 EM Program Operational Considerations

An ongoing challenge for the EM program related to the timeliness of data reporting. These processes were improved over the program years, but with a fleet size of ~35 vessels, seasonally intense fishing effort, sporadic access to vessels for data collection, and a short season, it was very difficult to provide data reports within 4-5 weeks of the fishery activity. We recognized that timelier reporting of EM data would result in better overall program coordination, improved compliance, and greater responsiveness, yet this was countered by managing program costs and logistics. More timely collection of hard drives is possible but the analysis bottleneck still presents a challenge given the high but seasonal data volume. Options for timely data collection and reporting could be explored to determine if the additional cost and complexity could be justified.

In terms of meeting the fisheries management objectives of the EM program, there are a number of aspects to consider. The EM program contributed to the improvement of the fishery in several ways. The EM program addressed a critical need to measure compliance with full retention; the estimates of discard event frequency and quantity improved over time and showed significant declines. The EM program reported discard events by type and apparent reason, providing a better understanding of situations where discards occur. Program results showed the estimated quantity of discards declined by nearly an order of magnitude and there was a shift away from 'top off' discarding to less frequent, apparently unavoidable overfull net circumstances when a portion of catch needs to be discarded prior to bringing the codend aboard.

4.2 Was EM Cost-Effective?

4.2.1 EM Program Costs

An evaluation of EM cost effectiveness must take into consideration the value for expenditure in relation to other available alternatives, which in this case is an observer program. Based on the results of this study, we have a clear understanding of the total cost of an EM program. Financial information presented for the 2007 to 2010 program years showed the average EM program costs to be about $6.00 per mT or 3.6% of the landed value of the catch. These figures reflect the total cost of the monitoring program, including program planning, field data collection and all the steps required to produce a finished data set. The costs are also reflective of a mature program where startup costs such as data base development, program design, and infrastructure development have already taken place. As mentioned previously, the lease choice over the purchase of EM caused by the lack of program tenure resulted in program costs being elevated by as much as 20%. Including this, costs of an EM program could have been below $5 per mT, or less than 3% of the catch value.

4.2.2 EM vs. Observer Program Costs

It is very difficult to develop a like-for-like comparison with an observer program for cost comparison purposes. The sea day rate used in the 2011 groundfish IFQ observer program was $365, however the rate was not reflective of the true cost of observer deployments but derived by examining the average costs across several US observer programs (Colpo, Pers. Comm.). Furthermore, the sea day rate only includes the field portion of an observer program, not the overhead elements such as observer training, deployment management, briefing/debriefing, and data processing and reporting. We know from experience delivering the at sea observer program for the BC groundfish trawl fishery from 1995 to 2014 that overhead costs can easily contribute 30% or more of the total program cost. While this component can vary widely from one program and another, there is no reason to believe it to be less for the groundfish IFQ observer program. While the EM cost per sea day was about 30% less than the $365 rate, taking these other factors into consideration, we believe the cost of an EM program to be less than half the cost of an observer program.

In the case of the whiting fishery, it is reasonable to conclude that the cost of an EM program would be much less than an observer program, but was it more cost effective? The data available from an observer program is potentially much more comprehensive and likely more timely than that of an EM program, but is this level of detail necessary? Unlike an observer program, the EM program reduces the overall monitoring opportunity to a single purpose: monitoring compliance with full retention. Results from the seven-year program suggest that EM was very effective at monitoring full retention compliance and contributed to a significant decline in the level of discarding. Yet discarding still occurs in the fishery and EM will likely never capture 100% of all discard events. The data granularity provided by observers for these limited discard events is likely to be richer than what EM can provide and the choice of monitoring method comes down to a decision of whether the additional cost of an observer program is justified for the additional data collection opportunity. In our view, EM had a significant role reducing discarding to a level where the lower precision of the EM-based estimate becomes unimportant.

4.2.3 Future EM Program Cost

The issue of program cost effectiveness must also be considered in the context of other pertinent issues. We drew a comparison between the estimated total costs between EM and observer programs, yet there is no indication that the observer program overhead costs, currently funded by NMFS, would transfer to industry. As well, the EM program was co-funded by NMFS and industry and it is not known if future EM programs would also be partially funded by NMFS. Hence, the cost comparison between EM and observers from an industry perspective would center on the portions of the program they would fund, rather than the total program cost.

Also factoring into future cost consideration with EM is the issue of the service delivery model. Service delivery refers to how the EM monitoring services within a program are organized and delivered, including options such as segregated roles for field and data services as well as single versus multiple service providers. The 2004-2010 EM programs were delivered as a single integrated program with all participants using the same technology and all service functions being carried out by a single service provider. Changes to the service delivery model will affect program efficiencies and resulting costs. The EM program costs shown for the 2007 to 2010 program period reflected a mature program, three years after implementation. A new program can expect to have implementation inefficiencies with higher costs during the start up years. With both EM and observer methods, there are ancillary issues that affect the total cost. For example, observer program costs also need to consider insurance, food, and logistical considerations associated with carrying an additional person aboard. EM programs need to consider additional power and other needs to host EM equipment, additional duty of care responsibilities, and changes to fish stowage operations if special catch handling methods are required.

One of the key factors that affected the overall equipment costs was that the majority of the fleet leased EM systems instead of purchasing. This decision resulted in increased mobilization and demobilization costs as the leased EM systems required installation and removal after each fishing season (and in some cases within the season during extended periods of non-fishing). It is important to consider how infrastructure costs would change under a long-term purchase amortization schedule in an operational program. Vessels are more likely to purchase EM systems in a long-term operational program, which leads to decreased servicing and equipment costs. In addition, as long-term programs mature, the local infrastructure develops to support the day-to-day program management needs, and subsequently further reduces the overall program costs. In long-term programs, it is also important to factor in the costs associated with replacing EM systems and parts over longer periods of time.

In conclusion, the results from this program showed that EM was lower in cost than an observer program, and given that monitoring reduced the incidence of discarding to a low level, EM was a more cost-effective method for this fishery. Future considerations of cost-effectiveness by EM will need to also consider the service delivery framework, the timeline to achieve results, and the ancillary impacts of the EM approach.

4.3 What Were the Ingredients to Success?

The 2004 to 2010 shore-side whiting EM program was essentially a fully implemented operational EM program. As opposed to the more than 30 EM pilot studies conducted on various US fisheries over the past decade the program was an integral part of the management of the fishery. The program was in place to ensure compliance with full retention and to provide comprehensive information for better understanding of the fishery. Other than the seven-year program tenure as compared with the short duration pilot studies, there were many features of the program design that ensured its success.

4.3.1 EM Technology Evolution

Firstly, the technology itself was appropriately suited to the working environment and the monitoring objectives of the fishery. As mentioned, the EM technology became more effective and reliable over the program period, yet was consistently able to provide the level of data collection required to address monitoring issues in the fishery. There were no significant technology issues that compromised the monitoring objectives. Moreover, fishery participants were satisfied with the technology and felt that it was effective in achieving its purpose. Their confidence made it easier for the program to achieve industry acceptance. As shown by the questionnaire results, industry participants did not necessarily want EM-based monitoring but they felt it was effective.

4.3.2 Management Regime

Secondly, the EM program was a mandatory requirement for participation in the fishery. This requirement was enforced through the EFP and vessel operators risked expulsion from the fishery, future access, or fines if they failed to comply with the EFP. As a result, industry participants were directly compelled to cooperate, as compared to the voluntary nature of most pilot programs. Furthermore, the annual term of the EFP provided flexibility in wording, such that the program requirements could evolve. This resulted in improvements to the EM program over time, becoming more directly focused on the information needs in the fishery. From 2008 onward, the level of involvement by OLE and State Fisheries Officers increased, and staff received more training on the use of the EM system and became more directly involved in potential compliance events. The increased enforcement involvement in the program resulted in the most dramatic declines in discarding over the seven-year period.

As mentioned, the EFP provided annual flexibility and allowed for modifications to enforcement as the program evolved, which was integral to the success of the EM program. However, the EFP was not the only element of the program that evolved over the years. Improvements to the EM technology led to very high data collection success rates and consistent discard monitoring over the program years that was independent of the EFP. The increased flexibility was a very important aspect of the EFP which allowed for the evolution and success of the EM program. However, for fisheries that are not managed under an EFP, the key aspect of flexibility can be achieved by implementing a long-term EM program using a scaled approach. This can be achieved by starting the EM program on a small number of vessels in order to identify the primary monitoring objectives and the appropriate EM system configurations and data analysis procedures.

Once the program elements have been identified during the field trials then it can then be scaled up to a full operational program. Alternatively, EM operational programs can be implemented right away however the fishery will likely go through an initial learning curve that will require some modifications to EM system configurations and data analysis procedures.

4.3.3 Industry Outreach

Also important to the success was the level of information sharing established between agency, industry and the service provider. Information from the monitoring program provided for dialog on a variety of issues. Incorporation of vessel log data into the EM program was adopted early, recognizing that this information expedited EM data analysis as well as providing a way to audit vessel logs and potentially further streamline the monitoring process. Feedback to skippers on comparisons between EM and vessel log data resulted in improvements to data quality. In our view, vessel log data, corroborated by EM, could provide the most cost-effective, data rich information system for this fishery, as opposed to 'mining' the EM data set for the same information. Outreach processes also a high level of operational communication among the groups, providing responsive service for technical issues, providing feedback on monitoring information, leading to corrective action, and, to the extent possible by analysis timelines, directing OLE officials to potential problem areas in the fishery.

4.4 What Were the Lessons Learned?

With the aim of providing advice to those considering the use of EM in other fisheries, the following are a number of salient lessons with broad applicability:

- EM based monitoring should not be considered a "plug-and-play" alternative to observer programs as each has their own opportunities and challenges.
- The utility of EM for collecting fisheries data relies on a careful design process that integrates the EM technology, the vessel specifications, and specific on board catch handling and EM system duty of care requirements.
- EM programs are much more than the underlying technology. The majority of cost is with the service components and thus, a structured program design approach is needed.
- Successful use of EM often depends upon integration with other data collection processes and information sources. Data integration opportunities should be considered in the design process.
- Stakeholder engagement is an essential ingredient to EM program success. This should occur at a variety of levels in order to improve the program, optimize operations, and effect change.

- A key risk to EM is the hidden bias that can result from strategic intentional data loss (i.e., turning the system off to avoid recording). While some data loss is to be expected in any monitoring program, effective measures are needed to control, monitor and manage the level of missing data.
- EM technology will change over time and the program design needs to be flexible to include change, where appropriate.
- Effective EM programs require control measures through governance, regulations, incentives or disincentives. Instruments such as an EFP are particularly effective as they can be easily modified during the early stages of program implementation.
- EM programs take time to implement and a multi-year time horizon is needed to establish operations and infrastructure, and offset start up costs. Uncertainty of program tenure will slow the process and reduce cost efficiencies that can be achieved with EM approaches.

4.5 Conclusions

In our view, the EM program was successful for the shore-based whiting fishery. Comparing discard patterns in 2004 with those in 2010, they appear as though there were two different fisheries. EM contributed to change the fishery by providing vessel specific information on discarding practices, and showing that many vessels could successfully participate in the fishery with little or no discards. The cost of the EM program was lower than an observer alternative and in consideration of the monitoring objectives, EM is considered to be the most cost effective approach for this fishery.

In consideration of the applicability for other fisheries, it is important to recognize that EM based monitoring is more than the capabilities of the technology. A holistic perspective is needed, linking the fishery characteristics and monitoring needs with technology capabilities, monitoring options, regulatory framework, incentive systems, and program operational requirements (i.e., field service infrastructure, data analysis specifications, and other program components) to ensure the program is efficient, effective, cost effective, and integrated with management needs. Often overlooked is the importance of incentive systems to appropriately distribute responsibility toward the monitoring program within industry participants. This is reinforced through individualized vessel-specific performance reporting, feedback and engagement with industry. As well, missing data in an EM program requires active management to minimize hidden bias in the program results. Finally, timelines are important for success of an EM program as, compared to an observer program, it will take longer to achieve performance objectives and cost efficiencies as a result of the increased complexity of this type of fishery monitoring.

OMNIBUS REGULATION CHANGES PART 1

Under this agenda item, the Council is slated to

- make a final recommendation on continuation of the trawl rationalization adaptive management program (AMP) pass-through,
- address any other issues identified by National Marine Fisheries Service (NMFS) with respect to development of rules to implement the Council's past recommendations on trawl trailing actions, and
- begin to develop a list of potential new groundfish management measures to be considered outside the biennial process, including trawl rationalization trailing actions and limited entry fixed gear-related actions.

Adaptive Management Program

At this meeting, the Council is scheduled to finalize a recommendation on continuation of the AMP pass-through. Ten percent of the annual distributions of the quota pounds (QP) issued for nonwhiting quota shares (QS) and halibut individual bycatch quota (IBQ) are reserved for the AMP. Currently the QP issued for the AMP QS/IBQ are distributed annually to QS/IBQ holders, in proportion to their QS/IBQ holdings, i.e. "passed through" based on QS/IBQ percentages. This "pass-through" has been in place as a temporary measure because the Council has yet to develop alternative criteria for their distribution (criteria that would address the objectives for the AMP program (see Agenda Item F.3.a, Attachment 1). The "pass-through" regulations are scheduled to sunset prior to the distribution for the 2015 fishing year and some Council action is required to provide direction on how the QP will be distributed for 2015. At its March 2014 meeting, the Council adopted the following alternatives for consideration:

- No Action Alternative: Beginning in 2015, the QP associated with the QS set-aside for AMP purposes will be distributed in accordance with procedures developed under the AMP provisions adopted under Amendment 20.
- Action Alternative 1: The AMP QP allocation procedures will be considered as part of the five-year review and the pass-through procedure used since 2011 will be continued
  - Suboption A: through 2017.
  - Suboption B: until the implementation of regulations resulting from the five-year review.
- Action Alternative 2. The pass-through procedures used since 2011 will be continued until procedures are developed as specified in the AMP provisions of Amendment 20.

If no action is taken, since other procedures have not been developed and the pass-through would sunset, the AMP QP would go undistributed. In these alternatives, all references to QS include halibut IBQ QS and all references to QP include the related halibut IBQ QP. A discussion of these alternatives is provided in Agenda Item F.3.a, Attachment 1.

New Rule Clarifications for Trawl Trailing Actions

At this time there are a number of issues on which the Council has taken action for which implementation is in progress. For two of these, the chafing gear rule and the observer/catch monitoring rule, proposed rules have been published and the comment periods completed, but the final rules had not been published as of the briefing book deadline. For two others, fixed gear trawl permit stacking (joint registration) and shorebased whiting season date changes, the proposed rules have yet to publish. This agenda item provides the Council an opportunity to respond to implementation questions which NMFS might identify, if any.

New Groundfish Management Measures

In March 2013, the Council adopted a process whereby only adjustments to routine management measures[1] would be considered during the process to establish biennial harvest specifications and management measures (see http://tinyurl.com/nh9soch, Motion 11, Item 4). New management measures[2] would be considered outside of the biennial process, and specifically, a call for new management measure proposals would be conducted at the June Council meeting in even-numbered years (e.g., 2014). At that June meeting, the Council would adopt a draft calendar and a prioritized list of new management measures to be analyzed outside of the harvest specifications and management measures process. The recommendation for narrowing the types of management measures considered during the biennial process, along with the development of default harvest control rules under Amendment 24 and the long-term impact analysis, was intended to reduce workload during the biennial process and increase the probability that harvest specifications would be implemented January 1. Also, at the March 2014 meeting, the Council aggregated consideration and prioritization of trawl trailing actions, delayed from last September to this June's Council meeting, to allow for a more holistic evaluation of groundfish priorities and workload.

In April 2014, the Council decided to postpone the adoption of a draft calendar and a prioritized list of new management measures to be analyzed outside of the harvest specifications and management measures process until the September 2014 Council meeting, given the anticipated workload and Council floor time necessary to accomplish the biennial specifications agenda items. However, the Council wanted to establish a list of candidate new management measures at the June Council meeting. To meet this objective, an initial unprioritized list of potential management measure topics, ordered by category and sector, has been provided in Agenda Item F.3.a, Attachment 2, derived from previous Council discussions. In order to assist in comprehensive workload planning, this attachment also includes a list of other groundfish-related matters with workload implications for Council, state, and Federal staff. Under Agenda Item F.3, the Council is scheduled to establish a tentative list of topics and, under Agenda Item F.9, the Council is scheduled to add to the list any additional candidates that may have arisen during the week.

Over the summer, staff will develop some preliminary background material on each issue of interest to the Council. In order to optimize the information available for the September prioritization, the Council may wish to identify those issues which should receive the most focus

[1] Routine management measures are defined in regulation and a range of alternatives have been previously analyzed.
[2] New management measures are those for which the environmental impacts have not been previously analyzed and/or have not been previously implemented in regulations.

between the June and September Council meetings under Agenda Item F.9, such as identifing three levels of background detail expected for the September Council meeting (e.g., high, medium, or low). Staff will distribute their available time among the topics based on these rankings. Since the Council removed prioritization from the June Council meeting task, the level of detail requested by the Council in June should not necessarily reflect the priorities assigned at the September Council meeting.

In September, the Council is scheduled to prioritize the list it develops at this meeting, determine the groups in which issues will be packaged for moving through the Council process, and identify a calendar for those packages. At that time, it is expected that a workload analysis of West Coast Region staff capabilities will be available for alignment with Council staff and Advisory Bodies, workload capabilities. For actions to be implemented by the start of 2016, alternatives for analysis will have to be finalized at the November Council meeting and final action taken by April 2015. Some of the criteria the Council may want to have in mind are provided as Agenda Item F.3.a, Attachment 3, which includes the Groundfish Strategic Plan executive summary, groundfish Fishery Management Plan goals and objectives, and a list of National Standards.

Council Task:

1. **Adopt final preferred alternative for Adaptive Management Pass-through.**
2. **Consider new rule clarifications, if any.**
3. **Identify initial list of candidate new management measures for further consideration under Agenda Item F.9.**

Reference Materials:

1. Agenda Item F.3.a, Attachment 1: Trawl Rationalization Issue: Adaptive Management Program QP Pass-Through, Council Decision Document.
2. Agenda Item F.3.a, Attachment 2: Initial Compilation of Possible Groundfish Management Measures for Council Consideration.
3. Agenda Item F.3.a, Attachment 3: Considerations for Prioritizing the List of Groundfish Management Measures.
4. Agenda Item F.3.c, Public Comment.

Agenda Order:

a. Agenda Item Overview — Jim Seger and Kelly Ames
b. Reports and Comments of Advisory Bodies and Management Entities
c. Public Comment
d. **Council Action:** Adopt Final Preferred Alternative for Adaptive Management Program Pass-Through; Consider New Rule Clarifications, if Any; and Identify Initial List of Candidate Management Measures Including Trawl Catch Share Trailing Actions and Off-cycle Groundfish Management Measures, for Further Consideration Under Agenda Item F.9

TRAWL RATIONALIZATION

ISSUE: ADAPTIVE MANAGEMENT PROGRAM QP PASS-THROUGH

Council Decision Document

PREPARED BY
THE PACIFIC FISHERY MANAGEMENT COUNCIL
7700 NE AMBASSADOR PLACE, SUITE 101
PORTLAND, OR 97220
503-820-2280
WWW.PCOUNCIL.ORG

Table of Contents

CHAPTER 1 PURPOSE AND NEED FOR THE PROPOSED ACTION

1.1 Introduction

This document provides background information and analyses for

> a provision that would extend the current method for annual distribution of quota pounds (QP)—a pass-through to quota share (QS) holders in proportion to their QS holdings—issued for the QS set aside for the Adaptive Management Program (AMP)—10% of the nonwhiting QS.[1]

The AMP was adopted by the Council as part of its trawl rationalization program, Amendment 20 to the Pacific Coast Groundfish Fishery Management Plan (FMP). The proposed actions would require an amendment to the regulations implementing the groundfish FMP. If the regulatory amendments are implemented, the description of the trawl rationalization program contained in Appendix E to the groundfish FMP would automatically be revised to reflect the regulatory modification. The proposed action must conform to the Magnuson-Stevens Fishery Conservation and Management Act (MSA), the principal legal basis for fishery management within the Exclusive Economic Zone (EEZ), which extends from the outer boundary of the territorial sea to a distance of 200 nautical miles from shore.

1.2 Description of the Proposed Action

The proposed action is to amend the regulations implementing the groundfish FMP to change provisions related to the distribution of QP issued for the QS set aside for the AMP.

1.3 Purpose and Need for the Proposed Action

Under the Amendment 20 trawl rationalization program, an IFQ system was adopted for the shoreside trawl fishery. That catch share system includes a set aside of 10 percent of the nonwhiting QS for an AMP. The AMP QP, issued each year for those QS, are to be distributed to address the following objectives.

- Community stability
- Processor stability
- Conservation
- Unintended/Unforeseen consequences of IFQ management.
- Facilitating new entrants.

For the first four years of the program, the annually issued AMP QP have been passed through to the QS holders in proportion to their holdings of QS. The catch share program originally specified that the Council would develop alternative criteria for distribution of the AMP QP beginning in year 3 of the program. In 2011, the Council recommended an extension of the pass-through until the end of 2014 due to concern that given the other high priority trailing actions that the Council was working on alternative criteria might not be developed and implemented by 2013, in which case there would be no procedure in place for distribution of the AMP QP. Subsequent to that time, the Council has not prioritized the development of a pass-through formula due to the absence of an adequately pressing need. With the pass-through due to expire at the end of this year and no alternative criteria yet developed, the Council

[1] In this document, all references to QS include halibut individual bycatch quota (IBQ) quota shares and all references to QP include the related halibut IBQ quota pounds.

is once again considering options to extend the pro rata pass-through so that the fish authorized for harvest through the biennial specifications process will be continue to available to benefit the fishing industry, dependent communities, and consumers.

CHAPTER 2 DESCRIPTION OF THE ALTERNATIVES AND COUNCIL ACTION

2.1 Alternatives

At its March 2014 meeting, the Council adopted a range of alternatives for final consideration at its June 2014 meeting.

No Action Alternative: Beginning in 2015, the QP associated with the QS set-aside for AMP purposes will be distributed in accordance with procedures developed under the AMP provisions adopted under Amendment 20.

Action Alternative 1: The AMP QP allocation procedures will be considered as part of the five year review and the pass-through procedure used since 2011 will be continued

Suboption A: through 2017.

Suboption B: until the implementation of regulations resulting from the 5-year review.

Action Alternative 2. The pass-through procedures used since 2011 will be continued until procedures are developed as specified in the AMP provisions of Amendment 20.

2.2 Rationale for Council Final Action

To be developed.

CHAPTER 3 IMPACTS

3.1 Direct and Indirect Impacts to the Physical and Biological Environment

Under the No Action Alternative, there may be a reduction of trawl IFQ sector impacts starting in 2015, if no alternative means are developed for distribution of the AMP QP and assuming that resolution of the situation would not qualify for emergency action. Under the action alternatives, there would be no impacts relative to a 2013-2014 baseline and the trawl allocation authorized under the 2015-2016 groundfish specifications. The alternatives provide the trawlers an opportunity to fully harvest the allocations authorized and analyzed under other fishery management actions. The action alternatives would allow full harvest of the authorized allocations; and there would be no difference among any of the action alternatives with respect to impacts on the physical and biological environments. Under any of the alternatives, at any time the Council would be free to recommend either another extension of the pass-through or an earlier than specified end to the pass-through. All alternatives leave the adaptive management program in place in its current form.

3.2 Direct and Indirect Impacts to the Socioeconomic Environment

The main socio-economic impacts of the No Action Alternative are the possibility of a 10 percent reduction in the shoreside nonwhiting trawl harvest starting in 2015 and the attendant adverse social and economic impacts that would be experienced by the fishing industry, fishing communities, and consumers.

Under any of the action alternatives, at any time the Council would be free to recommend either another extension of the pass-through or an earlier than specified end to the pass-through. Therefore, the primary impacts of action alternatives relate to administrative burden of making changes to the pass-through provisions and QS holder expectations regarding whether the pass-through will be continued.

A regulatory amendment would be required for all action alternatives; and to implement alternative criteria all action alternatives would require a future regulatory amendment; but the action alternatives vary with respect to the time at which, or whether, the Council would either have to recommend alternative criteria or recommend another extension. Under Alternative 1, Suboption A, which continues the pass-through through 2017, another Council final action would be required sometime in 2016 or no later than June of 2017. The deadline for action would depend on the complexity of the criteria to be implemented (including the possibility that there would be another continuation of the pass-through). Alternative 1, Suboption B terminates the pass-through as of the date of regulatory actions coming out of the five year review of the trawl rationalization program, and presumes that review will be conducted in 2016, after data from year five of the program is available. It also presumes that the review would lead to some additional regulatory modifications. For Suboption B, it is not clear whether the end of the pass-through would be triggered if the review process did not generate any regulatory actions. Depending on the time required for the review and the time required to generate and act on alternatives in response to information developed during the review, the continuation of the pass-through would likely be to a date comparable to or later than what would occur under Supoption A. Suboption B would continue the pass-through to a time (after the five year review) when the Council might have more information on the utility of implementing alternative criteria for the distribution of the AMP QP. However, this is not to say that adequate information might not be available before that time. Under Alternative 2, the pass-through would be extended indefinitely but the QS set aside for the AMP would remain in place, facilitating implementation of alternative criteria at any time the Council and NMFS decided they were needed. If the ultimate outcome is that the AMP pass-through continues and alternative distribution criteria are never developed, then Alternative 2 will have been the lowest administrative cost alternative.

All of the alternatives, including No Action, entail some uncertainty, which may affect QS pricing. QS prices are likely to vary depending on whether traders anticipate a long-term continuation of the pass-through. If expectation of a long-term continuation of the pass-through is built into QS prices, this would likely generate resistance to future proposals for alternative distributions. If the Council is relatively ceratin it will eventually recommend implementation of alternative criteria for distribution of AMP QP, then a continuation of the pass-through for a specified amount of time might increase the probability that QS transactions are priced properly with respect to the reasonably expected value of the annually issued QP, relative to an open ended continuation of the pass-through.

Agenda Item F.3.a
Attachment 2
June 2014

INITIAL COMPILATION OF POSSIBLE GROUNDFISH MANAGEMENT MEASURES FOR COUNCIL CONSIDERATION

This document provides an initial unprioritized list of potential management measure topics, ordered by category and sector, derived from previous Council discussions. In order to assist in comprehensive workload planning, a list of other groundfish related matters with workload implications for Council, state and Federal staff are included. Public comment received by the deadline is included in the reference materials for Agenda Item F.9 but is not summarized here. Council actions under Agenda Item F.3 and F.9 can modify the list, based on public and advisory body comment, if desired.

The list is broken into three categories:

A. Items on Which Council Action Has Been Completed Which Still Entail Some Workload
B. Immediate and Long-Term Commitments
C. Candidate Items for Prioritization in September

Items are categorized based on their expected status as of the September 2014 Council meeting. For any action to be implemented by the start of 2016, alternatives for analysis will have to be specified by the November 2014 Council meeting and a final preferred alternative chosen by the April 2015 Council meeting.

Note that trawl trailing actions and Phase II of the limited entry fixed gear sablefish program review are not listed here as such. In September, when actions are prioritized and packaged, the Council may want to assign items to these two, as well as other, categories.

A list of the short titles is provided in the following table, followed by more detailed descriptions for some items. A blank column is provided to the right in order to allow this table to serve as a decision template.

Acronyms and abbreviations used in the following table:

COP – Council Operating Procedure
CP – Catcher Processor
IFQ – Individual Fishing Quota
LEFG – Limited Entry Fixed Gear
MS – Mothership
OA – Open Access
QP – Quota Pounds
QS – Quota Shares
Rec – Recreational
TOR – Terms of Reference
VMS – Vessel Monitoring System

Table 1. Unprioritized list of groundfish related workload items and initial candidate groundfish management measures grouped by category and sector.

	Sector	Short Title	
A. Items on Which Council Action Has Been Completed Which Still Entail Some Workload[1]			
1.	Trawl, Non-Trawl, Rec	2015-2016 Harvest Specifications and Management Measures and Amendment 24 (June 2014)	
2.	Trawl and Non-Trawl	Seabird Rule - Mandatory Streamers for vessels ≥ 55’	
3.	Trawl and Non-Trawl	Clarify Catch Accounting Rules for Amendment 21	
4.	Trawl and Non-Trawl	Fishery Declaration Enhancements	
5.	Trawl IFQ, MS, & CP	Cost Recovery Corrections	
6.	Trawl IFQ & MS	Electronic Monitoring Exempted Fishing Permits (if final in June 2014)	
7.	Trawl IFQ & MS	Pacific Dawn Lawsuit Appeal to District Court (Whiting Allocation)	
8.	Trawl IFQ & MS	Whiting Cleanup Rule, Including Maximized Retention Regulations	
9.	Trawl CP	Glacier Fish Co Lawsuit (Cost Recovery)

12.	Trawl IFQ	Continue Adaptive Management Program Pass-Through	
13.	Trawl IFQ	Update eTicket for Web-based Submissions	
14.	Trawl IFQ	Rule for Forfeitures for Exceeding Aggregate NonWhiting Control Limit	
15.	LEFG	Revise Limited Entry Fixed Gear Permit Control Rule (If Recommended)	
16.	LEFG and OA	Require E-Tickets for Sablefish Landings (If Recommended)	
17.	LEFG and OA	Sablefish North of 36 Degrees - Allocation Correction	
18.	LEFG and OA	Logbooks for Fixed Gear	
19.	OA	Amendment 22 - Open Access License Limitation	
B. Immediate and Long-Term Commitments			
Currently on the Year at a Glance Schedule (See Agenda Item C.6.a, Attachment 1)			
20.	Trawl, Non-Trawl, Rec	Inseason Management (Sept 2014 and beyond, excluding March 2015)	
21.	Trawl, Non-Trawl, Rec	Adopt Final Stock Assessment Plan and TOR for 2015 (Sept 2014)	
22.	Trawl, Non-Trawl, Rec	Develop a COP for Groundfish Methodology Review Process (Sept and Nov 2014)	
23.	Trawl, Non-Trawl, Rec	Omnibus Regulations Changes (Sept and Nov 2014, Mar-June 2015)	
24.	Trawl, Non-Trawl, Rec	Essential Fish Habitat: Phase 3 of the 5 Year Review (Sept 2014)	
25.	Trawl, Non-Trawl, Rec	Amendment 25: Comprehensive Ecosystem-Based Amendment (Sept 2014 and Mar 2015)[2]	
26.	Trawl, Non-Trawl, Rec	2015 Pacific Halibut Catch Sharing Plan (Sept and Nov 2014)[3]	

[1] This list includes actions anticipated at the June 2014 meeting. Workload primarily involves NMFS and Council staff, however GMT and state staffs may be involved. Several items in this category are also covered under Agenda Item F.1.b, NMFS Report.
[2] Scheduled to occur under an Ecosystem agenda item but involves amending the groundfish Fishery Management Plan and groundfish staff.
[3] Scheduled to occur under a Pacific halibut agenda item but may involve groundfish considerations and/or staff that also work on groundfish.

	Sector	Short Title	
27.	Trawl, Non-Trawl, Rec	2015 Incidental Regulations for Pacific Halibut (Mar and Apr 2015)3	
28.	Trawl, Non-trawl, Rec	Stock Assessments for 2017-2018 Biennium (June 2015)	
29.	Trawl, Non-Trawl, Rec	Start of the Process to Establish 2017-2018 Specifications and Regulations (June 2015)	
30.	Trawl IFQ & MS	Electronic Monitoring Regulations (Sept 2014, June 2015)	
Items on the Horizon			
31.	Trawl IFQ, MS, & CP	Five Year Review (Starts in 2016)	
32.	Trawl IFQ	QS/QP Control Rule - Safe Harbor for Risk Pools - post 5-year review	
33.	Trawl IFQ	Resolve Long-term Whiting Surplus Carryover Provision - post 5-year review	
C. Candidate Items for Prioritization in September			
34.	Trawl, Non-Trawl, Rec	Rebuilding Revision Rules (signal vs. noise)	
35.	Trawl, Non-Trawl, Rec	Further Consideration for Reorganizing Stock Complexes	
36.	Trawl and Non-Trawl	Groundfish Conservation Areas for Rougheye Rockfish	
37.	Trawl and Non-Trawl	New Dressed to Round Conversion Factors for Sablefish	
38.	Trawl and Non-Trawl	Increase VMS Ping Rates	
39.	Trawl and Non-Trawl (LE)	Eliminate Permit Size Endorsements	
40.	Trawl and Non-Trawl	Seabird Avoidance Devices for Vessels less than 55 feet	
41.	Trawl IFQ, MS & CP	Revise Length of Time Required for the Trawl Fleet to Retain Records	
42.	Trawl IFQ (& MS &CP?)	Fishery Declaration Enhancements (With Gear Stowed and Testing Gear)	
43.	Trawl IFQ, MS & CP	Year Round Whiting Season and Other Modifications	
44.	Trawl IFQ, MS & CP	Revise Regulations on At-Sea and Shoreside Flow Scales	
45.	Trawl IFQ	Gear Use - Multiple Gears Onboard and Use	
46.	Trawl IFQ and LE Pot	Remove Certain Area-Management Restrictions	
47.	Trawl IFQ	Remove Certain Restrictions on Trawl Gear Configuration	
48.	Trawl IFQ	Resolve Long-term Non-Whiting Surplus Carryover Provision	
49.	Trawl IFQ	Carryover when Management Units Change	
50.	Trawl IFQ	Allow Trading of Previous Year Quota Pounds in Current Year	
51.	Trawl IFQ	Widow Rockfish QS Reallocation	
52.	Trawl IFQ	Discard Survival Credit for Lingcod and Sablefish	
53.	Trawl IFQ	Require Posting of First Receiver Site Licenses	
54.	Trawl IFQ	Develop Criteria for Distributing Adaptive Management Program QP	
55.	LEFG	Cost Recovery for the Permit Stacking Program	
56.	LEFG and OA	Commercial Gear Restriction for Targeting Flatfish in CA	
57.	LEFG and OA	Retain Halibut in the Sablefish Fishery (South of Pt. Chehalis)	
58.	Recreational	50 fm Depth Restriction (WA and OR)	
59.	Recreational	Mid-water Sport Fishery (OR and CA)	

Discussion

A. Items on Which Council Action Has Been Completed Which Still Entail Some Workload

1. **Trawl, Non-Trawl, and Rec – 2015-2016 Harvest Specifications and Management Measures and Amendment 24 (June 2014)**

The process to adopt the 2015-2016 harvest specifications and management measures, including non-electronic monitoring EFPs, and Amendment 24 culminates at this meeting with final action scheduled under Agenda Item F.7. Over the summer and fall, Council, NMFS, and state staffs will be responding to comments on the draft Environmental Impact Statement (EIS), preparing the final EIS, and preparing the regulations necessary to implement Council action. The anticipated rulemaking schedule is outlined in Agenda Item F.1.b, NMFS Report.

2. **Trawl and Non-Trawl - Seabird Rule - Mandatory Streamers ≥ 55'**

At the November 2013 meeting, the Council recommended that streamer lines be required during setting operations on commercial fixed gear vessels 55 feet or greater in length with a safety exception in the event of rough weather, which would be triggered by a National Weather Service forecast of a gale force wind warning. In January 2014, Council staff transmitted regulations necessary to implement the Council action. NMFS advises that rulemaking is in progress and the proposed rule is anticipated this summer (see Agenda Item F.1.b, NMFS Report).

3. **Trawl and Non-Trawl - Clarify Catch Accounting Rules for Amendment 21**

At its June 2012 meeting, as part of the preferred alternative for the 2013-2014 harvest specification and management measures, the Council recommended reinstating catch accounting language in the FMP that was inadvertently deleted when Amendment 21 was implemented. Changes to the FMP language were also recommended to further clarify the decision rules for determining the allocation against which a vessel's catch would count (i.e., whether it would count against the limited entry allocation or the open access allocation). The Council and NMFS staff has made progress on some draft FMP language; however, due to competing workload, language for Council consideration has not yet been fully developed.

4. **Trawl and Non-Trawl - Fishery Declaration Enhancements**

At its June 2013 meeting, the Council took action to require that vessels activating VMS units make a fishery declaration at the time of activation, even if they are not entering a groundfish fishery at that time. Additionally, the Council recommended that, for clarity purposes, category 24 in the current list of declarations (660.13(d)(5)(iv)) be modified from "other gear" to "other," to encompass declarations to participate in fisheries not specifically named in the declaration list and for research activities.

5. **Trawl IFQ, MS, & CP - Cost Recovery Corrections**

After cost recovery was implemented for the trawl rationalization program in January 2014, NMFS announced clarifications to the regulations through a public notice (see NMFS public notice, NMFS-SEA-14-12, March 20, 2014). The clarifications were on (1) fish buyer's use of principal from a deposit account in cases of credit card payment to Pay.gov (IFQ & MS), and (2) in the CP sector, only retained groundfish are subject to the cost recovery fee. In the future, NMFS intends to revise the associated regulatory language for these issues and, if further issues arise, may have additional cost recovery corrections or clarifications.

6. **Trawl IFQ & MS - Electronic Monitoring Exempted Fishing Permits (if final in June 2014)**

The Council is also in the middle of considering exempted fishing permits (EFPs) to allow some vessels to use electronic monitoring in lieu of at-sea compliance observers. Council action might be completed at this meeting (see Agenda Item F.5 for additional background), however, substantial ongoing effort by NMFS staff would be required to have the EFPs in place during the 2015 fishery.

7. **Trawl IFQ & MS - Pacific Dawn Lawsuit Appeal to District Court (Whiting Allocation)**

On May 13, 2014, an appeal to the Ninth Circuit Court was filed in the Pacific Dawn lawsuit challenging the allocation of whiting IFQ and mothership sector catch history allocations. Responding to this appeal will require the time of NOAA GC attorneys, as well as other NMFS staff, who are also integral to making progress on the development and implementation of groundfish actions.

8. **Trawl IFQ & MS - Whiting Cleanup Rule, Including Maximized Retention Regulations**

The proposed whiting cleanup rule would establish criteria for a whiting trip (at least 50% of the landing by weight must be whiting), re-establish regulations needed to cover the disposition of catch in the maximized retention fishery, and clarify the ability of midwater gear to be used to target all groundfish species in the RCAs north of 40°10′ north latitude after the whiting opening. This rule is expected to be finalized by December 2014 (see Agenda Item F.1.b, NMFS Report).

9. **Trawl CP - Glacier Fish Co Lawsuit (Cost Recovery)**

On January 9, 2014, Glacier Fish Company LLC filed a suit in relation to the cost recovery regulations challenging the categorization of the catcher-processor co-op program as a limited access privilege program, challenging the status of co-op members as limited access privilege holders, claiming that the cost recovery regulations were not properly promulgated, and claiming adequate documentation of the basis of the cost figure has not been provided. Responding to this suit will require the time of NOAA GC attorneys, as well as other NMFS staff, who are also integral to making progress on the development and implementation of groundfish actions.

10. Trawl IFQ - Joint Registration and Prohibition of Processing IFQ Sablefish

At its April 2012 meeting, the Council recommended allowing a fixed gear permit and a trawl permit to be registered to the same vessel at the same time. Implementation is expected by the winter of 2014/2015, as part of the upcoming Sablefish Rule (see Agenda Item F.1.b, NMFS Report).

11. Trawl IFQ - Move Shorebased Whiting Season Opening Dates

At its November 2012 meeting, the Council recommended moving the shoreside sector primary whiting season opening date to May 15, starting in 2013 to the extent that such a change could be made without requiring a plan amendment. It is expected that the season date change can be made for all areas north of 40°30′ north latitude. The current April 15 opening will remain in place south of that line. Implementation is expected by May 2015 (see Agenda Item F.1.b, NMFS Report).

12. Trawl IFQ - Continue Adaptive Management Program Pass-Through

Under this agenda item, the Council will likely extend the current AMP pass-through for a number of additional years (see Agenda Item F.3.a, Attachment 1). A regulatory action, completed by the end of the year, will be required to implement that extension (see Agenda Item F.1.b, NMFS Report).

13. Trawl IFQ - Update eTicket for Web-based Submissions

Pacific States Marine Fisheries Commission is improving the trawl IFQ e-Ticket system by moving to a web-based platform. This will require some regulatory changes and may be implemented over the winter of 2014/2015, as part of the upcoming Sablefish Rule (see Agenda Item F.1.b, NMFS Report), if the Council recommends e-tickets for the sablefish fishery (see Item 16).

14. Trawl IFQ - Rule for Forfeitures for Exceeding Aggregate NonWhiting Control Limit

Current regulations require forfeiture of QS held in excess of control limits as of November 30, 2015. There is no guidance in the regulations for which QS would be revoked if a QS permit owner does not get their individual and collective QS amounts under the aggregate nonwhiting QS control limit. This issue may not require Council action and may only be a clarification of policy if the situation arises. In the interim, QS permit owners are encouraged to get their own QS permits/accounts under the QS control limits listed at 660.140(d)(4)(i) by November 30, 2015, so that NMFS does not have to take an administrative action. NMFS notified QS permit owners that were over QS control limits of the amounts they were over when NMFS issued initial QS permits. Later in 2014, NMFS will again notify QS permit owners that are over QS control limits. NMFS has several tools available on the QS Permit and Accounts website at: http://www.westcoast.fisheries.noaa.gov/fisheries/groundfish_catch_shares/quota_share_permits_accounts.html. The website includes the table of IFQ accumulation limits (i.e., QS control limits), and tools for QS permit owners to calculate their non-whiting groundfish aggregate QS to determine if they are over the limit.

15. LEFG - Revise Limited Entry Fixed Gear Permit Control Rule (If Recommended in June 2014)

At this meeting, the Council will decide whether or not to recommend a revision to the limited entry fixed gear permit control rule (Agenda Item F.6). If the Council recommends such revisions, the recommendation will be in the NMFS approval and implementation phase by the time of the September Council meeting, with the attendant workload for NMFS and Council staff, including regulatory deeming. Implementation would be expected by the winter of 2014/2015, as part of the upcoming Sablefish Rule (see Agenda Item F.1.b, NMFS Report).

16. LEFG and OA - Require E-Tickets for Sablefish Landings (If Recommended in June 2014)

At this meeting, the Council will decide whether or not to recommend that electronic fish tickets be required for limited entry fixed gear and open access sablefish landings (Agenda Item F.6). If the Council recommends such regulations, the recommendation will be in the NMFS approval and implementation phase by the time of the September Council meeting, with the attendant workload for NMFS and Council staff, including regulatory deeming. Implementation would be expected by the winter of 2014/2015, as part of the upcoming Sablefish Rule (see Agenda Item F.1.b, NMFS Report).

17. LEFG and OA - Sablefish North of 36 Degrees - Allocation Correction

The May 2014 version of the groundfish FMP accurately represents the Council intent for sablefish catch accounting and allocations. That is, consistent with the Amendment 6 catch accounting rules, sablefish landed north of 36 deg. N. lat. by vessels registered to a LE fixed gear permit, regardless of their intended target (i.e., groundfish or non-groundfish species), will be debited against the LE fixed gear daily trip limit allocation (LE DTL). Sablefish landings by vessels not registered to a LE permit, regardless of their intended target (e.g. groundfish or non-groundfish species), will be debited against the OA fixed gear daily trip limit allocation (OA DTL). Action is needed to revise the groundfish regulations to be consistent with the FMP.

18. LEFG and OA - Logbooks for Fixed Gear

At its June 2008 meeting, as part of the preferred alternative for the 2009-2010 harvest specification and management measures, the Council recommended that NMFS develop and implement a mandatory Federal logbook for limited entry and open access fixed gear vessels. The Council's Groundfish Management Team, the West Coast Groundfish Observer Program, NMFS, and state staffs worked with Pacific States Marine Fisheries Commission to prepare a draft fixed gear logbook. The logbook has not been finalized and implemented due to concerns raised by NMFS, including lack of funding.

19. OA - Amendment 22 - Open Access License Limitation

In June 2009, the Council recommended a registration program for fishermen intending to land groundfish in the open access fishery, whether targeting those species or taking them incidentally while fishing for non-groundfish species (e.g., salmon, pink shrimp, California halibut) or nearshore species (e.g., cabezon, black rockfish). The Council has taken final action on Amendment 22 yet the registration program has not been implemented. More recently, some OA vessels are required to have an authorization on board under the Marine Mammal Protection Act (i.e., sablefish pot vessels) and NMFS is having difficulty getting addresses for those vessels. An OA registration system would address this issue.

B. Immediate and Long-Term Commitments

20. Trawl, Non-Trawl, and Rec - Inseason Management (Sept 2014 and beyond, excluding March 2015)

Management measures for groundfish are set by the Council with the general understanding that these measures will likely need to be adjusted within the biennium to attain, but not exceed, the ACLs. On the Year at a Glance, inseason adjustments are scheduled to be discussed at the Sept-Nov 2014 meetings as well as in 2015 (except March).

21. Trawl, Non-Trawl, and Rec - Adopt Final Stock Assessment Plan and TOR for 2015

In September and November of the even numbered years (e.g., 2014), the Council develops a stock assessment plan for the upcoming biennium and a Terms of Reference (TOR) for conducting the assessments.

22. Trawl, Non-Trawl, and Rec - Develop a COP for Groundfish Methodology Review Process (Sept and Nov 2014)

The Council recommended developing a Council Operating Procedure (COP) for conducting groundfish methodology reviews, similar to COP 15 for salmon. The Council is scheduled to adopt the COP at the September and November 2014 meetings.

23. Trawl, Non-Trawl, Rec – Omnibus Regulation Changes (Sept and Nov 2014, Mar-June 2015)

On the Year at a Glance, Omnibus Regulation changes are scheduled to be discussed at the Sept-Nov 2014 meetings as well as in 2015. Any prioritized management measures (e.g., those included under Category C: Candidate Items for Prioritization) could be considered under the Omnibus Regulation Changes agenda item.

24. **Trawl, Non-Trawl, and Rec - Essential Fish Habitat – Phase 3 of the 5 Year Review (Sept 2014 and Mar 2015)**

As the first step in the Phase 3 process, the Council requested that the Northwest and Southwest Fisheries Science Centers investigate the question of Essential Fish Habitat (EFH) effectiveness, accuracy, and completeness and to present their findings in the advance Briefing Book for consideration at the September 2014 Council meeting. At the September 2014 meeting, the Council is tentatively scheduled to initiate a fishery management plan amendment, including alternatives for refining elements of groundfish EFH as warranted by new information, the Science Center evaluation, and proposals received.

25. **Trawl, Non-Trawl, and Rec - Amendment 25: Comprehensive Ecosystem-Based Amendment (Sept 2014 and Mar 2015)**

In April 2014, The Council approved a range of alternatives for protecting unfished and unmanaged forage fish species and identified the Ecosystem Trophic Role pathway as a preliminary preferred alternative. Under this pathway, protective measures for forage species would be added to each of the Council's four FMPs, perhaps under an omnibus process aggregating the four actions into one process. The Council is scheduled to review the alternatives and proposed amendatory language for the groundfish FMP at the September 2014 Council meeting.

26. **Trawl, Non-Trawl, Rec – 2015 Pacific Halibut Catch Sharing Plan (Sept and Nov 2014)**

Each September and November meeting, the Council considers proposed changes to the Pacific halibut regulations and Catch Sharing Plan (CSP) for Area 2A. Starting in 2014, in response to recent unusually high harvests of Pacific halibut off Southern Oregon and Northern California, the Council established a new management line at the Oregon/California border, creating separate Oregon and California subareas with area-specific CSP allocations and management measures. The Council is scheduled to consider, at the September and November 2014 meetings, whether additional changes to the 2A CSP allocations are necessary and whether additional adjustments to management measures are necessary to comply with allocation provisions of the CSP. The anticipated rulemaking schedule is outlined in Agenda Item F.1.b, NMFS Report.

27. **Trawl, Non-Trawl, Rec – 2015 Incidental Regulations for Pacific Halibut (Mar and Apr 2015)**

Regulations governing incidental harvest of halibut in the salmon troll fishery and primary fixed gear fishery for sablefish north of Point Chehalis require the Council to adopt halibut landing restrictions to allow incidental harvest while assuring quotas are not exceeded. The Council is scheduled to recommend incidental halibut regulations at the March and April 2015 meetings.

28. Trawl, Non-Trawl, Rec - Stock Assessments for 2017-2018 Biennium (June 2015)

At this meeting, under Agenda Item F.8, the Council is scheduled to adopt for public review the list of stocks to be assessed in 2015 for use in 2017 and beyond and a stock assessment review schedule. The first stock assessment is scheduled for Council adoption in June 2015.

29. Trawl, Non-Trawl, Rec - Start of the Process to Establish 2017-2018 Specifications and Management Measures (June 2015)

In most cycles, the start of the process to establish the biennial regulations begins in June of the odd numbered years (e.g., June 2015).

30. Trawl IFQ & MS - Electronic Monitoring Regulations (Sept 2014, June 2015)

The Council has received funding and is in the middle of a process for the consideration of electronic monitoring as a replacement for the monitoring function of at-sea observers. This action is currently scheduled for completion by the September Council meeting though it appears likely that further deliberations will be required for at least some sectors. See Agenda Item F.2 for additional background.

31. Trawl - Five Year Review (Starts in 2016)

The trawl rationalization program will complete its fifth year at the end of 2015. Planning for the review might begin during 2015 but the compilation of data sets for the review will not occur until sometime during 2016 – when the final data becomes available.

32. Trawl - QS/QP Control Rule - Safe Harbor for Risk Pools - post 5-year review

At its September 2011 meeting, the Council recommended providing risk pools a safe harbor from the QS control rules. At its September 2013 meeting, the Council agreed that risk pools appeared to be functioning adequately under current regulations and that implementation of this recommendation could wait until the five year program review.

33. Trawl - Resolve Long-term Whiting Surplus Carryover Provision - post 5-year review

A workshop was held on November 2, 2012 to explore possibilities for fully implementing whiting surplus carryover in 2013 and a report was presented to the Council at its November 2012 meeting. The Council decided that it will review this issue again during the 5 year program review, scheduled for 2016.

C. Candidate Items for Prioritization in September

34. Trawl, Non-Trawl, and Rec - Rebuilding Revision Rules (signal vs. noise)

The Council recommended consideration of rebuilding revision rules during Amendment 24 and the 2015-2016 harvest specifications and management measures process. Such rules involve assessing adequacy of progress toward rebuilding and altering rebuilding plans, given a change in stock status. Some have referred to the rebuilding revision rules as separating the signal (true rebuilding) from the noise (variability in the estimates). The management strategy evaluation necessary to inform potential rebuilding revision rules is ongoing and will not be completed in time to be implemented with Amendment 24.

35. Trawl, Non-Trawl, and Rec - Further Consideration for Reorganizing Stock Complexes

During the past few cycles, the Council has made progress evaluating the performance of the existing stock complexes relative to the revised National Standard 1 Guidelines. In the event the Council wishes to further consider reorganizing the stock complexes, such work should be completed prior to the start of the biennial analysis (e.g., June 2015 prior to the 2017-2018 cycle).

36. Trawl and Non-Trawl - Groundfish Conservation Areas for Rougheye Rockfish

During the development of the 2015-2016 harvest specifications and management measures, the Council recommended an analysis be conducted to explore the impacts of implementing a Groundfish Conservation Area to reduce the catch of rougheye and blackspotted rockfish. Due to complexities in the analysis and competing workload in the 2015-2016 process, the Council recommended that this measure be discussed and prioritized accordingly during the omnibus regulation changes process.

37. Trawl and Non-Trawl - New Dressed to Round Conversion Factors for Sablefish

New information may be coming available on dressed to round conversion factors for sablefish, including conversion factors for product forms that are currently not covered with existing factors.

38. Trawl and Non-Trawl - Increase VMS Ping Rates

An Administrative Law Judge ruling on the F/V RISA LYNN case has raised question as to whether or not the current hourly locational pings used in the VMS system are sufficient to enforce area closures. This possible need to increase ping rates was first brought to the Council's attention at its November 2013 meeting and discussed in more detail at its March 2014 meeting, at which NMFS Office of Law Enforcement (Agenda Item H.1.b, NMFS OLE Report, March 2014) and the Enforcement Consultants (Agenda Item H.1.c, EC Report, March 2014) each provided reports. Additionally, the Groundfish Advisory Subpanel identified alternative tools for addressing the concern: "data loggers in conjunction with electronic logbooks, specific polygons in the RCA, automatic identification systems, and more." (Agenda Item H.1.c, GAP Report, March 2014). At that time, the Council deferred further action until this meeting in order to determine the relative priority for this issue among other potential groundfish actions.

39. Trawl and Non-Trawl (LE) – Eliminate Permit Size Endorsements

Gear Workshop Report from the November 2012 Council meeting (Agenda Item I.5.a, Attachment 4 – Gear Workshop Report) stated: "The trawl permit length endorsement and associated permit transfer provisions are no longer needed as vessel capacity is no longer an issue under the IFQ program. However, there may be impacts to non-target species and to target species taken with fixed gear under gear switching that will need to be taken into account." It has also been suggested that the size endorsements are no longer needed for the fixed gear sablefish endorsed permits." This issue was also been identified in The Trawl Rationalization Regulatory Evaluation Committee (TRREC) Report from the November 2011 Council meeting (Agenda Item E.7.b, Supplemental TRREC Report).

40. Trawl and Non-Trawl – Seabird Avoidance Devices for Vessels less than 55 feet

In 2012, the U.S. Fish and Wildlife Service (USFWS) published a biological opinion considering the effects of West Coast groundfish fisheries to Endangered Species Act (ESA) listed marine species, including seabirds. The opinion includes reasonable and prudent measures (RPMs), terms and conditions, and conservation recommendations to minimize take of seabirds, particularly the endangered short-tailed albatross. The RPMs stipulate that NMFS shall 1) minimize the risk of short-tailed albatross interactions with commercial hook and line gear, 2) establish a work group as an advisory body to NMFS and USFWS for the purposes of reducing risk to short-tailed albatross (and other ESA-listed species), 3) monitor and report all observed, reported, and estimated short-tailed albatross take as well as report on the efficacy of avoidance and minimization measures, and 4) facilitate the salvage of short-tailed albatross carcasses taken by longline gear. In 2013, the Council recommended streamer line regulations for vessels 55 feet and greater (see item #39); however regulations are also needed for vessels less than 55 feet. SeaGrant research results are expected in 2015 and should inform the development of these regulations.

41. Trawl IFQ, MS & CP - Revise Length of Time Required for the Trawl Fleet to Retain Records

As described in September 2013 (Agenda Item G.9.a, Attachment 1), consider revising regulations that require the trawl fleet to retain records for three years and make them available upon request (660.113(a)(2)) to clarify how that works with regulations that require retention of records on board for 15 days into the next cumulative limit period (660.13(c)).

42. Trawl IFQ (& MS &CP?) - Fishery Declaration Enhancements (With Gear Stowed and Testing Gear)

It has been suggested that declarations for transiting with gear stowed and for testing trawl gear (with no retention) be implemented and that on trips with these declarations no observer coverage would be required.

43. Trawl IFQ, MS & CP - Year Round Whiting Season and Other Modifications

The November 2011 TRREC Report recommended as a first priority the movement of all shorebased whiting season start dates to May 15 and elimination of the 5 percent cap on the early season California fishery. Council action to move the shoreside season openings for the area north of 40°30′ north latitude (see Item 15) has been completed but the April 15 start date for the area south of that line remains, along with the 5 percent cap have not been implemented (due to the need for a FMP amendment to modify these provisions). The TRREC recommended as a secondary priority the consideration of a year round whiting season.

44. Trawl IFQ, MS & CP - Revise Regulations on At-Sea and Shoreside Flow Scales

As described in September 2013 (Agenda Item G.9.a, Attachment 1), NMFS Alaska Region is currently revising at-sea flow scale regulations for the North Pacific because incidences of manipulation were discovered. West coast trawl rationalization program regulations at 660.15 may need to be revised in coordination with revisions to North Pacific regulations which are expected for 2015. New regulations are required to address the need for daily scale testing criteria for the new shoreside flow scales.

45. Trawl IFQ - Gear Use - Multiple Gears Onboard and Use

TRREC Report from the November 2011 Council meeting and the Gear Workshop Report from the November 2012 Council meeting (see item #39) both contained recommendations for the carrying and use of multiple gear types on a single trip, including both trawl and fixed gears.

46. Trawl IFQ - Remove Certain Area-Management Restrictions

Both the TRREC and Gear Workshop Reports (see item #39) included recommendations relative to area management restrictions. The TRREC report identified this issue as a general topic for consideration, plus the need to consider allowing vessels to fish in more than one area. The Gear Workshop report recommended allowing year-round use of midwater gear in the RCA be considered and elimination of the selective flatfish gear requirement in place shoreward of the RCA. It also recommended that the use of midwater gear be allowed in in all groundfish essential fish habitat conservation areas coastwide and year round (except that targeting on whiting would be subject to whiting regulations); and that vessels be allowed to move fixed gear across management lines without going to shore (currently that movement is considered to be fishing in two areas on the same trip).

47. Trawl IFQ - Remove Certain Restrictions on Trawl Gear Configuration

The TRREC (see item #39) suggested that with the individual incentives provided by the trawl rationalization program it would be possible to "Eliminate codend, chafing gear, mesh size and selective flatfish trawl gear requirements and restrictions" but that large and small footrope distinctions would have to remain due to EFH considerations—though they might be modified. For similar reasons, the Gear Workshop (see item #39) recommended reducing the minimum mesh size for bottom trawl by ½ inch, to 4 inches and also recommended eliminating the selective flatfish trawl requirement. One particular obstacle presented by the selective flatfish requirement is that the nets are two seamed nets and it is not possible to put rockfish excluders in two seamed nets.

48. Trawl IFQ - Resolve Long-term Non-Whiting Surplus Carryover Provision

The trawl IFQ program allows up to 10 percent of a vessel's QP to be carried from one year to the next, either as a deficit covered with following year QP or an unused surplus which can be fished in the following year. Concern that the surplus carryover provision might be interpreted as violating allowable catch limits has led NMFS to not issue surplus carryover for some species in some years. A consultative process between NMFS and the Council was developed as part of the 2013-2014 biennial specifications, to inform the NMFS decision process about whether or not to issue the surplus carryover. However, there continues to be uncertainty each year as to whether or not surplus quota pounds from the previous year will be reissued. The uncertainty may be encouraging vessels to fish into deficit to avoid the loss of QP which would occur if surplus QP are not reissued. The Council has requested further analysis and development of options to ensure that, in the long term, the surplus carryover provisions can be implemented with greater certainty.

49. Trawl IFQ - Carryover When Management Units Change

As described in September 2013 (Agenda Item G.9.a, Attachment 1), the regulations do not cover how carryover should be handled when there is a reallocation as a result of changes in management areas (area subdivision, combination, or line movement) or subdivision of a species group that cause shifts in the distribution of QS. This issue was identified with the recent geographic subdivision of lingcod and relates to 660.140(c)(3)(vii).

50. Trawl IFQ - Allow Trading of Previous Year Quota Pounds in Current Year

At the April 2013 Council meeting, it was proposed that the trading of QP issued for a previous year be allowed to occur in the current year up until the last landings data for the previous year is in the catch and QP accounting system. This would allow greater flexibility for the fleet as a whole to use unused QP from a previous year to cover catch in that year. For example, in situations where a vessel was in deficit at the end of the year, during the subsequent calendar year it might acquire QP from a vessel that had a surplus at the end of that same year, rather than having to use QP from the subsequent year to cover previous year catch. Further action on this issue was deferred, to be take up as part of the next trawl rationalization trailing action package.

51. Trawl IFQ - Widow Rockfish QS Reallocation

At its April 2012 meeting, the Council decided to consider reallocation of the widow rockfish QS, now that widow rockfish is rebuilt. At its June 2012 meeting, the Council decided that for widow rockfish QS, the moratorium on QS trading should be continued until December 31, 2014, or until the widow rockfish reallocation process is complete, whichever comes first. Consequently, the Council recommended and NMFS implemented an indefinite extension on the widow rockfish QS moratorium through the reconsideration of the allocation of whiting (78 FR 18879, March 28, 2013). Therefore, while QS trading started for all other species in January 2014, the moratorium continues for widow rockfish QS. Some implementation issues have resulted due to the moratorium on transfer of widow rockfish QS affecting QS owners wanting to leave the fishery or change business arrangements. QS permit owners who are trying to retire or otherwise sell their QS are stuck with their widow QS until such time as the Council makes a decision on reallocation. Even though they will just be carrying one IFQ species in their QS account, they still will have the same renewal, paperwork, and QP transfer burden as all other QS owners and could result in stranded widow QP. Similarly, situations have occurred where a corporation is dissolved, wants to change ownership, or wants to change their structure by registering in a new state, perhaps with a new tax ID number. With the moratorium on widow QS transfer, the corporation will have to decide if it is in their best interest to dissolve and risk losing widow QS or remain a corporation to keep their widow QS until it is transferrable.

52. Trawl IFQ - Discard Survival Credit for Lingcod and Sablefish

The annual estimates of groundfish mortality, prepared by the West Coast Groundfish Observer Program, include discard survival credits for sablefish (50 percent for trawl, 20 percent for fixed gear) and lingcod (50 percent mortality for trawl). However, within the shorebased IFQ program, total catch, regardless of survival, is debited from vessel QP accounts and tracked inseason against the trawl allocation and annual catch limits. Industry has requested the consideration of an IFQ survival credit for discarded lingcod and sablefish, and particularly for the discard of small sized lingcod—for which discard is currently required.

53. Trawl IFQ - Require Posting of First Receiver Site Licenses

As described in September 2013 (Agenda Item G.9.a, Attachment 1), add a requirement that first receivers possess and display a valid first receiver site license at each processing site. This would be similar to existing requirements at 660.12(d)(1) and 660.25(b)(1)(iii) that require vessels registered to limited entry permits to carry valid permit onboard the vessel.

54. Trawl IFQ - Develop Criteria for Distributing Adaptive Management Program QP

Under the Amendment 20 trawl rationalization program, the shoreside IFQ program includes a set aside of 10 percent of the nonwhiting QS (including halibut individual bycatch quota, IBQ) for an Adaptive Management Program (AMP). The AMP QP, issued each year for those QS, are to be distributed to address the following objectives: community stability; processor stability; conservation; unintended/unforeseen consequences of IFQ management; and facilitating new entrants. However, to date, the QP associated with this program have been passed through to QS holders on a pro rata basis in proportion to their QS holdings. Under this agenda item, the Council will be considering whether and for how long to continue that pass-through (see Agenda Item F.3.a, Attachment 3). Regardless of that decision, it will take some time to develop and analyze alternative criteria for distribution of the AMP QP. The Council may wish to prioritize beginning work on these criteria in anticipation of having that work completed on time for the expiration of the next pass-through period (if there is one).

55. Non-Trawl - Cost Recovery for the Permit Stacking Program

The limited entry fixed gear sablefish stacking program is considered a limited access privilege program (a LAPP). The MSA requires LAPPs to develop a methodology and means to identify and assess cost of management, data collection and analysis, and enforcement programs that are directly related to and in support of the LAPP. Further, the Secretary of Commerce is authorized to establish and collect fees paid by holders of limited access privileges that will cover the costs of management, data collection and analysis, and enforcement activities; not to exceed 3 percent of the ex-vessel value of the fish harvested under the program. The LEFG sablefish program was established prior to the addition of these requirements in the MSA and, to this point, a means to identify costs or policy to establish a cost recovery program have not been developed. This issue is discussed further in the fixed gear sablefish program sablefish review (Agenda Item, F.6.a, Attachment 1).

56. LEFG and OA - Commercial Gear Restriction for Targeting Flatfish in CA

In California, commercial vessels using a specific gear configuration designed to target flatfish species are authorized to fish in several Groundfish Conservation Areas, including the non-trawl RCA, Cowcod Conservation Area, Farallon Islands, and Cordell Banks. During the development of the 2015-2016 harvest specifications and management measures, the Council recommended an analysis be conducted to explore the impacts of either removing or modifying restrictions on the gear and where those vessels can fish. Due to complexities surrounding the analysis and competing workload in the 2015-2016 process, the Council recommended that this measure be discussed and prioritized accordingly during the omnibus regulation changes process.

57. LEFG and OA - Retain Pacific Halibut in the Sablefish Fishery (South of Pt. Chehalis, WA)

At the September 2010 meeting, the Council recommended an analysis be conducted to explore the impacts of allowing incidental Pacific halibut retention in the sablefish fixed gear fishery south of Point Chehalis, Washington; which could include both limited entry and open access sectors. The analysis was intended to be completed in time to inform the development of the 2012 Pacific Halibut Catch Sharing Plan, though there was some discussion such a timeline was ambitious. Initial queries indicate that no analysis of the measure has been completed to date.

58. Recreational - 50 fm Depth Restriction (WA and OR)

Federal regulations provide coordinates for a 50 fm recreational Rockfish Conservation Area. During the development of the 2015-2016 harvest specifications and management measures, Washington and Oregon recommended analyzing the impacts of implementing the 50 fm line, if recommended. Due to the complexities surrounding the analysis and competing workload in the 2015-2016 process, the Council recommended that this measure be discussed and prioritized accordingly during the omnibus regulation changes process.

59. Recreational - Mid-water Sport Fishery (OR and CA)

In June 2013, the Council voted to move forward with evaluation of a midwater sport fishery in Oregon and California, as proposed in Agenda Item F.3.c, June, 2013, Holloway Proposal, with a potential implementation of January 1, 2015. This topic was originally scheduled for Council action in November 2013 and March 2014; however, the analysis was delayed due to competing workload.

CONSIDERATIONS FOR PRIORITIZING THE LIST OF GROUNDFISH MANAGEMENT MEASURES

The following are some of the factors the Council may wish have in mind for determining what it will include on the omnibus list and for its September prioritization exercise.

Magnuson Stevens Act National Standards

Section 301(a) of the MSA states: "Any fishery management plan prepared, and any regulation promulgated to implement any such plan, pursuant to this title shall be consistent with the following national standards for fishery conservation and management" The following are those national standards (NS):

NS-1 Conservation and management measures shall prevent overfishing while achieving,on a continuing basis, the optimum yield from each fishery for the United States fishing industry.

NS-2 Conservation and management measures shall be based upon the best scientific information available.

NS-3 To the extent practicable, an individual stock of fish shall be managed as a unit throughout its range, and interrelated stocks of fish shall be managed as a unit or in close coordination.

NS-4 Conservation and management measures shall not discriminate between residents of different States. If it becomes necessary to allocate or assign fishing privileges among various United States fishermen, such allocation shall be (A) fair and equitable to all such fishermen; (B) reasonably calculated to promote conservation; and (C) carried out in such manner that no particular individual, corporation, or other entity acquires an excessive share of such privileges.

NS-5 Conservation and management measures shall, where practicable, consider efficiency in the utilization of fishery resources; except that no such measure shall have economic allocation as its sole purpose.

NS-6 Conservation and management measures shall take into account and allow for variations among, and contingencies in, fisheries, fishery resources, and catches.

NS-7 Conservation and management measures shall, where practicable, minimize costs and avoid unnecessary duplication.

NS-8 Conservation and management measures shall, consistent with the conservation requirements of this Act (including the prevention of overfishing and rebuilding of overfished stocks), take into account the importance of fishery resources to fishing communities by utilizing economic and social data that meet the requirements of paragraph (2), in order to (A) provide for the sustained participation of such communities, and (B) to the extent practicable, minimize adverse economic impacts on such communities.

NS-9 Conservation and management measures shall, to the extent practicable, (A) minimize bycatch and (B) to the extent bycatch cannot be avoided, minimize the mortality of such bycatch.

NS-10 Conservation and management measures shall, to the extent practicable, promote the safety of human life at sea.

The Council FMP Goals and Objectives

With respect to goals and objectives, the Council's FMP reads as follows

> Section 2.1 Goals and Objectives for Managing the Pacific Coast Groundfish Fishery
>
> The Council is committed to developing long-range plans for managing the Washington, Oregon, and California groundfish fisheries that will promote a stable planning environment for the seafood industry, including marine recreation interests, and will maintain the health of the resource and environment. In developing allocation and harvesting systems, the Council will give consideration to maximizing economic benefits to the United States, consistent with resource stewardship responsibilities for the continuing welfare of the living marine resources. Thus, management must be flexible enough to meet changing social and economic needs of the fishery as well as to address fluctuations in the marine resources supporting the fishery. The following goals have been established in order of priority for managing the west coast groundfish fisheries, to be considered in conjunction with the national standards of the Magnuson-Stevens Act.
>
> **Management Goals**
>
> Goal 1 - Conservation. Prevent overfishing and rebuild overfished stocks by managing for appropriate harvest levels and prevent, to the extent practicable, any net loss of the habitat of living marine resources.
>
> Goal 2 - Economics. Maximize the value of the groundfish resource as a whole.
>
> Goal 3 - Utilization. Within the constraints of overfished species rebuilding requirements, achieve the maximum biological yield of the overall groundfish fishery, promote year-round availability of quality seafood to the consumer, and promote recreational fishing opportunities.

Objectives. To accomplish these management goals, a number of objectives will be considered and followed as closely as practicable:

Conservation

Objective 1. Maintain an information flow on the status of the fishery and the fishery resource which allows for informed management decisions as the fishery occurs.

Objective 2. Adopt harvest specifications and management measures consistent with resource stewardship responsibilities for each groundfish species or species group. Achieve a level of harvest capacity in the fishery that is appropriate for a sustainable harvest and low discard rates, and which results in a fishery that is diverse, stable, and profitable. This reduced capacity should lead to more effective management for many other fishery problems.

Objective 3. For species or species groups that are overfished, develop a plan to rebuild the stock as soon as possible, taking into account the status and biology of the stock, the needs of fishing communities, recommendations by international organizations in which the United States participates, and the interaction of the overfished stock within the marine ecosystem.

Objective 4. Where conservation problems have been identified for non-groundfish species and the best scientific information shows that the groundfish fishery has a direct impact on the ability of that species to maintain its long-term reproductive health, the Council may consider establishing management measures to control the impacts of groundfish fishing on those species. Management measures may be imposed on the groundfish fishery to reduce fishing mortality of a non-groundfish species for documented conservation reasons. The action will be designed to minimize disruption of the groundfish fishery, in so far as consistent with the goal to minimize the bycatch of non-groundfish species, and will not preclude achievement of a quota, harvest guideline, or allocation of groundfish, if any, unless such action is required by other applicable law.

Objective 5. Describe and identify EFH, adverse impacts on EFH, and other actions to conserve and enhance EFH, and adopt management measures that minimize, to the extent practicable, adverse impacts from fishing on EFH.

Economics

Objective 6. Within the constraints of the conservation goals and objectives of the FMP, attempt to achieve the greatest possible net economic benefit to the nation from the managed fisheries.

Objective 7. Identify those sectors of the groundfish fishery for which it is beneficial to promote year-round marketing opportunities and establish management policies that extend those sectors fishing and marketing opportunities as long as practicable during the fishing year.

Objective 8. Gear restrictions to minimize the necessity for other management measures will be used whenever practicable. Encourage development of practicable gear restrictions intended to reduce regulatory and/or economic discards through gear research regulated by EFP.

Utilization

Objective 9. Develop management measures and policies that foster and encourage full utilization (harvesting and processing), in accordance with conservation goals, of the Pacific Coast groundfish resources by domestic fisheries.

Objective 10. Recognize the multispecies nature of the fishery and establish a concept of managing by species and gear or by groups of interrelated species.

Objective 11. Develop management programs that reduce regulations-induced discard and/or which reduce economic incentives to discard fish. Develop management measures that minimize bycatch to the extent practicable and, to the extent that bycatch cannot be avoided, minimize the mortality of such bycatch. Promote and support monitoring programs to improve estimates of total fishing-related mortality and bycatch, as well as those to improve other information necessary to determine the extent to which it is practicable to reduce bycatch and bycatch mortality.

Social Factors.

Objective 12. When conservation actions are necessary to protect a stock or stock assemblage, attempt to develop management measures that will affect users equitably.

Objective 13. Minimize gear conflicts among resource users.

Objective 14. When considering alternative management measures to resolve an issue, choose the measure that best accomplishes the change with the least disruption of current domestic fishing practices, marketing procedures, and the environment.

Objective 15. Avoid unnecessary adverse impacts on small entities.

Objective 16. Consider the importance of groundfish resources to fishing communities, provide for the sustained participation of fishing communities, and minimize adverse economic impacts on fishing communities to the extent practicable.

Objective 17. Promote the safety of human life at sea.

[Amended; 7, 11, 13, 16-1, 18, 16-4]

Trawl Rationalization Goals and Objectives (Amendment 20)

Trawl Rationalization goals and objectives from Amendment 20 are as follows.

Goal

Create and implement a capacity rationalization plan that increases net economic benefits, creates individual economic stability, provides for full utilization of the trawl sector allocation, considers environmental impacts, and achieves individual accountability of catch and bycatch.

Objectives

The above goal is supported by the following objectives:
1. Provide a mechanism for total catch accounting.
2. Provide for a viable, profitable, and efficient groundfish fishery.
3. Promote practices that reduce bycatch and discard mortality and minimize ecological impacts.
4. Increase operational flexibility.
5. Minimize adverse effects from an IFQ program on fishing communities and other fisheries to the extent practical.
6. Promote measurable economic and employment benefits through the seafood catching, processing, distribution elements, and support sectors of the industry.
7. Provide quality product for the consumer.
8. Increase safety in the fishery.

Constraints and Guiding Principles

The above goals and objectives should be achieved while the following occurs:
1. Take into account the biological structure of the stocks including, but not limited to, populations and genetics.
2. Take into account the need to ensure that the total OYs and allowable biological catch (ABC) are not exceeded.
3. Minimize negative impacts resulting from localized concentrations of fishing effort.
4. Account for total groundfish mortality.
5. Avoid provisions where the primary intent is a change in marketing power balance between harvesting and processing sectors.
6. Avoid excessive quota concentration.
7. Provide efficient and effective monitoring and enforcement.
8. Design a responsive mechanism for program review, evaluation, and modification.
9. Take into account the management and administrative costs of implementing and oversee the IFQ or co-op program and complementary catch monitoring programs, as well as the limited state and Federal resources available.

Sablefish Permit Stacking Program (Amendment 14)

Key objectives of Amendment 14 and the permit stacking program were further defined as follows.

Key Objective	Consistency with Management Objectives of the FMP and MSA
1. Rationalize the fleet and promote efficiency	Capacity reduction is one of the key elements of the Council's strategic plan. The strategic plan generally approaches capacity reduction by reducing the number of fishing vessels. This reduction does not of itself imply the rationalization of the fleet or increased efficiency. It is possible that the most efficient fixed gear sablefish harvest could involve a greater number of vessels taking sablefish as bycatch in other fisheries. However, given the high degree of overcapitalization in the fishery, it is believed that a reduction in capacity will generally move the fishery toward greater efficiency, addressing National Standard (NS) 5 and FMP Objective 6 on net national benefits.
2. Maintain or direct benefits toward fishing communities	This objective relates to NS 8 on fishing communities and FMP Objective 16 on fishing communities.
3. Prevent excessive concentration of harvest privileges	This objective relates to NS 4 on allocation, NS 8 on fishing communities, and FMP Objective 15 on avoiding adverse impacts to small entities.
4. Mitigate the reallocational effects of recent policies (3-tier system and equal limits)	This objective relates to NS 4 on allocation and FMP Objectives 12 on equitable allocation and 14 on minimizing disruption.
5. Promote equity	This objective relates to NS 4 on allocation and FMP Objective 12 on equitable sharing.
6. Resolve or prevent new allocation issues from arising	This objective relates to NS 4 on allocation and FMP Objectives 12 on equitable sharing and 14 on minimizing disruption.
7. Promote safety	This objective relates to NS 10 and FMP Objective 17 on safety.
8. Improve product quality and value	This objective relates to NS 5 on efficiency and FMP Objective 6 on net national benefits.
9. Take action without creating substantial new disruptive effects.	This objective relates to FMP Objective 14 on minimizing disruption.
10. Create a program that will readily transition to a multi-month IQ program.	This objective relates to capacity reduction recommendations in the strategic plan. Where individual quotas are transferable and divisible, they address NS 6 by providing the fleet with substantial flexibility to respond to changing conditions in the fishery and NS 5 by taking efficiency into account. FMP Objective 6 is also addressed.

Groundfish Strategic Plan From 2000

The following pages contain the groundfish strategic plan from the year 2000.

Pacific Fishery Management Council

Strategic Plan

“Transition to Sustainability”

Executive Summary

Prepared by
The Ad-Hoc Pacific Groundfish Fishery
Strategic Plan Development Committee

For
The Pacific Fishery Management Council

October 2000

Statement of Purpose and Acknowledgments

The Ad-Hoc Pacific Groundfish Fishery Strategic Plan Development Committee was formed by the Pacific Fishery Management Council and tasked with the development of a Draft Groundfish Strategic Plan for review and comment by the Council, its Advisory Entities, and the Public.

The members of the Ad-Hoc Committee were selected from the Council membership or as a Council member's designee.

This draft document was prepared through a consensus decision-making process and is the work-product of all members of the Committee.

The Groundfish Strategic Plan Document is *not* proposed as a Fishery Management Plan amendment. Rather, the purpose of the Groundfish Strategic Plan is to guide the future management of the Groundfish Fishery, including development of Plan amendments, regulations, and other implementation actions as needed.

Ad-Hoc Groundfish Strategic Plan Committee Members

Robert Alverson, Fishing Vessel Owners Association
Phil Anderson, Washington Department of Fish & Wildlife
Ralph Brown, Commercial Fisherman
Neal Coenen, Oregon Department of Fish & Wildlife
Bob Fletcher, Sportfishing Association of California
Dave Hanson, Committee Chair, Pacific States Marine Fisheries Commission
Bill Robinson, National Marine Fisheries Service
Patty Wolf, California Department of Fish & Game

Council Staff, NOAA Legal Counsel and Facilitator

Don McIsaac/Jim Glock, Pacific Fishery Management Council
Eileen Cooney, NOAA General Counsel's Office
Debra Nudelman, Committee Facilitator, RESOLVE, Inc.

The Pacific Fishery Management Council
Pacific Groundfish Fishery
Strategic Plan

<u>Executive Summary</u>

I. The Strategic Plan Overview – "Where Do We Want To Go?"

<u>A. Context and Need for Strategic Planning in the Groundfish Fishery</u>

The Pacific Fishery Management Council (Council) formed the Groundfish Strategic Planning Committee because it needed an advisory group that could work outside of the hectic Council meetings to craft a long-term vision for the future of groundfish fisheries and groundfish management. Several groundfish stocks are severely depleted and need strong protective management to rebuild. Commercial and recreational discards are not monitored, and those discards have unknown effects on the health of groundfish stocks. There is little information about the effects of fishing and non-fishing activities on groundfish habitat. Scientific efforts to assess the status of groundfish stocks, life histories, and habitat needs have been grossly underfunded.

The groundfish resource is cannot support the number of vessels now catching and landing groundfish. There are over 2,000 licensed West Coast commercial fishers, and many thousands of sport fishers. To bring harvest capacity in line with resource productivity, the number of vessels in most fishery sectors will have to be reduced by at least 50%. Coastal ports have significant shoreside infrastructures to support this once-prosperous industry, such as processing plants, boat yards, machine shops, marine supply stores, motels, and restaurants. Fishing fleet overcapitalization has been a major factor in fish stock depletion, and the industry and coastal communities are facing an economic and social crisis.

This strategic plan is intended to provide guidance for groundfish management in 2001 and beyond. It is intended to be a resource for Council efforts to rebuild depleted stocks and maintain healthy stocks. And, it is intended to guide Council efforts to reduce the size of the fishing fleet to a level that is both biologically sustainable for the resource and economically sustainable for the fishing fleet.

The Committee expects that, to be effective, this strategic plan will have to address the difficult issues of: reducing fishing capacity, setting more responsible harvest rates, making allocation decisions, meeting scientific needs, protecting habitat, and improving the Council management processes. This planning work will take place during a time when fishery restrictions will be used to rebuild overfished stocks. These conditions provide the clearest evidence of the need for a longer-term vision and road map for the future of groundfish management.

The Committee designed a process and schedule to get key information, identify specific problems and develop a range of solutions. The Committee has developed a draft strategic plan document for Council and public review that:

$ Recommends new management goals and objectives;
$ Initiates new groundfish plan amendments for the 2001 management cycle;
$ Outlines detailed actions for Council work plans and a schedule of priorities for the next 3-5 years; and
$ Develops specific recommendations for other entities to address that will complement the Council's needed management changes; such recommendations may propose changes in law, calls for budget support, and expectations for improving coordination between industry, government and educational institutions.

B. Vision For The Future Of The Groundfish Fishery

The Strategic Plan's vision for the future of the groundfish fishery assumes that the Plan's recommended actions are fully implemented with passage of sufficient time for the anticipated benefits to have been fully realized. The Plan's drafters recognize that the transition to this future will require major changes in the structure and operation of the fishery, which will certainly have short-term adverse effects on current participants. The plan envisions that fishery management decisions are based on sound scientific data and analysis and an open and fair Council process.

1. The Fishery

We envision a future where Pacific groundfish stocks will be healthy, resilient, and where substantial progress has been made rebuilding overfished stocks. Harvest policies will result in total fishery removals that are consistent with the long-term sustainability of the resource. The fishing industry will be substantially reduced in numbers and harvest capacity will be reduced to a level that is in balance with the economic value of the available resource. Those remaining in the fishery will operate in an environment that is diverse, stable, market-driven, profitable, and adaptive over a range of ocean conditions and stock sizes.

Unlimited or open access to the groundfish fishery will no longer exist because current open access participants will be brought into the limited entry program and the number of participants reduced to those who are most dependent on and committed to the fishery.

Whenever possible, management approaches will create incentives for fishers to operate in ways that are consistent with management goals and objectives.

Allocation disputes will be resolved and all harvest sectors will believe they were treated fairly, including those non-groundfish fisheries where groundfish is an unavoidable incidental catch. Discarded bycatch by all gear groups will be minimal and quantified.

Fishery regulations will be less complex and more easily enforced. Council management may be simplified by removing some species from the FMP through delegation or deferral to state management.

Essential groundfish habitat will be adequately protected and adverse effects from all groundfish fishing gears will be reduced to minimal levels. Marine reserves, or no take zones, will provide a base level of protection as an insurance policy to reduce the risks of uncertain science and long stock rebuilding periods.

The improved operating conditions and profitability for those remaining in the fishery will allow participants to accept responsibility for a portion of the cost of effective science and management, including an at-sea observer program, that is commensurate with the level of benefits associated with exclusive access to the fishery.

Finally, the Council will have full access to all fishery management tools and will use them to provide protection for and reasonable access to groundfish stocks.

2. The Science

The basis for future management of the groundfish fishery relies to a very large degree on the availability of good science. West Coast groundfish science will meet national and international standards, be accepted as credible and will be understood by the all stakeholders. Scientific data collection will be a collaborative process involving partnerships between federal, state, and tribal agencies, the fishing industry, and academia, and may include contributions from private foundations.

Data collection and monitoring programs will provide stock assessments with acceptable levels of uncertainty for use by the Council's scientific, management, and advisory committees. Scientific data collected from the fishery will provide the capability to accurately assess the effects of current and potential fishery management measures on groundfish stocks and fishery participants. Finally, scientific tools will have been developed to provide stock assessments throughout the distribution of the various groundfish stocks geographic ranges incorporating the variability and effects of ocean regime shifts.

3. The Council

Future Council activities will be characterized as open to all stakeholders, inclusive of all views, credible and interactive. Council actions will be documented and easily understood and developed with meaningful involvement by the public, including environmental, commercial and recreational representatives. Council decisions will be documented with readily available explanation and analysis of the underlying biological and socio-economic considerations. Council advisory entities will work together to contribute advice and expertise that results in recommendations that are accepted by stakeholders. Regulations development will be simplified and streamlined. Regulations will be generally stable over multi-year periods, but there will be flexibility to respond quickly when changes are needed.

C. Consequences of Inaction

There is another vision from that presented above. The Council could continue attempting to manage an overcapitalized fleet in the face of declining resource abundance and the necessity to meet stock rebuilding requirements. This will most certainly result in shorter fishing seasons, smaller trip limits, higher discard rates, and the continuous inability to accurately account for fishery-related mortalities. Many fishers will not be able to meet their basic financial responsibilities and will be forced from the fishery by a feeling of futility or bankruptcy. The Council and participating agencies will be overwhelmed by the need to implement short term fixes to long term problems with little or no chance to focus on the underlying problems of the fishery or to develop a long term management strategy.

To avoid this other vision of the future, the Council will have to act swiftly and soon. The Council has a choice in charting the future of the groundfish fishery. Decisions that the Council makes now will have profound effects for years to come.

II. The Strategic Plan "What Will We Do To Get There?"

A. Groundfish Fishery Management

1. Overall Fishery Management Concerns

Strategic Plan Goal For Management Policies

To adopt understandable, enforceable, and stable regulations that, to the greatest extent possible, meet the FMP's goals and objectives and the requirements of the Magnuson-Stevens Act.

Management Policies Recommendations

These recommendations assume that the objective of maintaining year-round harvesting and processing opportunity remains the Council's highest social and economic priority. In that case, it is imperative that Recommendation 1 for capacity reduction be implemented as rapidly as possible. If substantial harvest capacity reductions are not possible or are delayed, the Council must consider several of the alternative strategies for restructuring the fishery to restrict access by some portion of the fishing fleet for major periods.

In the event that none of the recommended measures or alternatives are viable or effective, the Council may have to shorten the annual fishing season. The Strategic Planning Committee cannot emphasize strongly enough the need for some level of observer coverage to evaluate the effectiveness of different management strategies.

1. Develop an implementation plan to reduce capacity initially by at least 50% in each sector. However, the capacity reduction goal will not be fully realized until capacity has been reduced to a level that is in balance with the economic value of the resource and those remaining in the fishery are able to operate profitably and flexibly. The implementation plan should take into account the need to implement other Plan recommendations (i.e., allocations, nearshore rockfish delegation) prior to or at the same time as capacity reduction. Reducing capacity will relieve the need to adopt management policies that are both inefficient and ineffective at achieving the FMP's goals and objectives. By better matching fleet capacity to resource availability, the regulatory structure will become more stable, resulting in regulations that are more enforceable.

2. Explore the use of higher landing limits or other incentives to encourage fisherman to fish with bycatch friendly fishing gear or to fish in areas where bycatch is less likely.

3. Make the necessary allocation decisions so that fishery participants in each sector can plan on a specific share of future OY's. Allocations may be outright percentages or a framework with criteria that specify how the allocation changes as resource availability changes.

4. Consider delegating or deferring nearshore rockfish and other groundfish species, such as scorpionfish, greenling, and cabezon, to the States.

5. All commercial fisheries should be limited through state and/or federal license or permit programs.

2. Harvest Policies

Strategic Plan Goal for Harvest Policies

To establish an allowable level of catch that prevents overfishing while achieving optimum yield based on best available science.

Harvest Policies Recommendations

1. In consideration of the uncertainties in the estimation of ABCs, set optimum yields (OYs) lower than the ABC, manage the fishery to a fixed OY(s), and close the fisheries when the OY is reached.

2. Harvest levels must be increasingly precautionary when less biological information is available, and particularly if monitoring programs fail to provide reliable estimates of total fishery-related mortality. Consider a hierarchal approach, where increased levels of conservatism would be required based on the specific quantity and quality of biological and fisheries information that is available.

3. For unassessed stocks, set precautionary harvest levels based on simple parameters such as a fixed proportion of the mean catch or survey abundance, or as a function of the lowest rate allowed for an assessed stock.

4. To protect weak stocks harvested in multi-species fisheries, adopt a policy requiring closure of the fishery when the ABC or OY of the weak stock has been taken. In setting the OYs, determine whether benefit/cost considerations might justify overfishing a particular weak stock under the mixed-stock exception in the National Standard Guidelines. Do not knowingly allow harvest rates that drive the stock below the level defined in the FMP as "overfished" or to a condition warranting listing under the ESA.

5. Without an international agreement on setting and sharing the total allowable catch for trans-boundary stocks, the Council should conserve that portion of the stock within the geographic range of its authority.

3. Capacity Reduction

Strategic Plan Goal for Capacity Reduction

To have a level of harvest capacity in the fishery that is appropriate for a sustainable harvest and low discard rates, and which results in a fishery that is diverse, stable, and profitable. This reduced capacity should lead to more effective management for many other fishery problems. For the short term, adjust harvest capacity to a level consistent with the allowable harvest levels for the 2000 fishing year, under the assumption that stock rebuilding will require reduced harvests for at least the next two decades. Maintaining a year-round fishery may not be a short-term priority.

Capacity Reduction Recommendations

The highest priority for reducing capacity is Recommendation #1 from the Management Policy section. That recommendation is to develop an implementation plan to reduce capacity initially by at least 50% in each sector. As noted earlier, the capacity reduction goal will not be fully realized until capacity has been reduced to a level that is in balance with the economic value of the resource and those remaining in the fishery are able to operate profitably and flexibly. In designing capacity reduction, the Council should consider fleet structure, profile, and diversity, with a goal of maintaining a mix of small and large vessels.

The capacity reduction plan should take into account the need to implement other strategic plan recommendations (i.e., allocations, nearshore rockfish delegation) prior to or at the same time as capacity reduction. Reducing capacity will relieve the need to adopt management policies that are both inefficient and ineffective at achieving the FMP's goals and objectives. By better matching fleet capacity to resource availability, the regulatory structure will become more stable, resulting in regulations that are more enforceable.

These capacity reduction recommendations include both the short and long-term and transitional elements discussed below, such as license-limitation (for the targeted open access fishery), permit stacking, and IFQs either individually or in combination with a vessel buyback program.

Short to Intermediate Term

1. Separate the current open access fishery into a sector that directly targets groundfish and a sector that lands groundfish as bycatch in non-groundfish fisheries. Require current open access vessels that directly target groundfish to obtain a federal limited entry permit (B permit) based on historical landings and current participation. Minimum landing requirements for a federal permit should reflect significant dependence on the fishery. Consider developing and implementing a voluntary permit stacking program for the B permit. Require a federal permit ("C" permit) to land groundfish taken incidentally in non-groundfish fisheries.

2. Divide the current open access allocation into separate allocations for the “B” and “C” permit holders and manage each sector to stay within its allocation each year.

3. Consider using historical landings only from 1994-1999 and recent participation from either 1998 or 1999 for initially qualifying B permit holders.

4. For the limited entry fixed gear fishery, immediately develop and implement a voluntary permit stacking program with the intent of transitioning to an IFQ program to provide for a multiple month season. The Permit Stacking allowance should be implemented prior to the 2001 regular sablefish season. Stacked permits should **NOT** allow increased access to the daily sablefish trip limit. Simultaneously, develop an IFQ system for fixed-gear sablefish for implementation in 2002. If Congress continues to prohibit IFQ programs, consider making the permit-stacking program mandatory.

5. For the limited entry trawl fleet, immediately develop and implement a voluntary permit-stacking program that links each permit with a cumulative period landing limit with the intent to transition to an IFQ program. The first, or base permit should be entitled to a full period landing limit, while each stacked permit should entitle the vessel to additional landing limits on a discounted basis as one alternative. Another alternative is to have the full period landing limit the same for all permits. If Congress continues to prohibit IFQ programs, consider making the permit-stacking program mandatory.

6. To prevent future overcapacity in the whiting fishery, consider developing and implementing a whiting species endorsement that restricts future participation in the whiting fishery to vessels registered to a permit with a whiting endorsement. Qualification for a whiting endorsement should be based on a permit’s whiting landings since 1994 when the current limited entry program began. Consider setting a threshold quantity of whiting above which a whiting endorsement is required for a landing. Individual landings below the threshold would not require an endorsement.

7. Pursue a buyback program to remove latent capacity.

Intermediate to Long Term

8. Develop of a comprehensive IFQ program for the limited entry trawl fishery, or in the alternative, a mandatory permit-stacking program.

9. Consider establishing a rockfish endorsement for the limited entry fixed gear fleet and open access (B permit) fleet. Qualifying criteria would be based on historical landings and recent participation.

10. Consider access limitation for commercial passenger fishing vessels. (This program may be better managed by the states.)

4. Allocation of Groundfish Resources

Strategic Plan Goal for Allocation

To distribute the harvestable surplus among competing interests in a way that resolves allocation issues on a long-term basis.

Allocation Recommendations

General Allocation Principles

1. All fishing sectors and gear types will contribute to achieving conservation goals (no sector will be held harmless). The fair and equitable standard will be applied to all allocation decisions but is not interpreted to mean exactly proportional impacts or benefits.

2. Non-groundfish fisheries that take groundfish incidentally should receive only the minimal groundfish allocations needed to efficiently harvest their target (non-groundfish) species. To determine the amount of allocation required, identify the economic values and benefits associated with the non-groundfish species. Directed fishery harvest of some groundfish may need to be restricted to incidental levels to maintain the non-groundfish fishery. Consider gear modification in the non-groundfish fishery to minimize its incidental harvest.

3. Modify directed rockfish gears, as needed, to improve their ability to target healthy groundfish species and avoid or reduce mortality of weak groundfish species.

4. When information on total removals by gear type becomes available, consider discards in all allocations between sectors and/or gear types. Each sector will then receive adjustments for discard before allocation shares are distributed.

5. Fairly distribute community economic impacts and the benefits and costs of allocation coast-wide. Allocations should attempt to avoid concentration and assure reasonable

access to nearby resources. Consider the diversity of local and regional fisheries, community dependency on marine resources and processing capacity, and infrastructure in allocation decisions.

6. Consider impacts to habitat and recovery of overfished stocks or endangered species (dependent on affected habitats) when making allocation changes.

7. Allocation decisions should consider and attempt to minimize transfer of effort into other fishery sectors, particularly for state managed fisheries (crab and shrimp).

8. Allocation decisions will: (a) consider ability to meet increased administrative or management costs; and (b) be made if reasonably accurate in-season quota monitoring or annual catch accounting has been established or can be assured to be established and be effective.

9. As the tribe(s) expand their participation in groundfish fisheries, allocations of certain groundfish species may have to be specified for tribal use. In such cases, the Council should ask the affected parties to U.S. v. Washington to convene and develop an allocation recommendation.

Area Management as Related to Allocation

10. Structure allocations considering both the north-south geographic *and* nearshore, shelf and slope distributions of species and their accessibility by various sectors and gears.

11. In addressing recreational/commercial rockfish allocation issues, use the following fishery priorities by species group: for nearshore rockfish, states may recommend a recreational preference, with any excess to be made available for commercial use; for shelf rockfish, the Council may set a recreational preference only on a species-by-species basis; and for slope rockfish, commercial allocation.

12. Licenses, endorsements or quotas established through management or capacity reduction measures may be limited to specific areas through exclusive area registrations and consider port landing requirements.

5. Observer Program for Quantifying Bycatch, Total Catch, and Total Fishery-Related Mortality

Strategic Plan Goal for an Observer Program

To quantify the amount and species of fish caught by the various gears in the groundfish fishery and account for total fishery-related removals.

Observer Program Recommendations

1. Immediately implement an at-sea groundfish observer program, with determination of total groundfish catch and mortality as the first priority, consistent with established Council priorities.

2. Consider the following options to fund an observer program:

a) Seek federal/state funding;

b) Continue to support legislative change to provide authority to collect fees from the fishing fleet to support the observer program;

c) If federal/state or industry funding is not available, make individual vessels responsible for providing some level of observer coverage as a condition of participation in the fishery.

3. Even with limited funding, both trawl and non-trawl fleets should have some meaningful, but not necessarily the same, level of observer coverage. Determine which harvesting sector(s) will receive the initial observers.

4. Consider alternative monitoring approaches that augment an observer program, including logbooks and video.

5. When an effective observer program has been established, a full retention strategy may be considered to reduce discard and improve biological information collection.

6. As a secondary priority, an observer program should collect additional data for stock assessments. For example, the North Pacific Council requires its observers to dedicate a small portion of the working day to taking otoliths and length measurements, in order to supplement information on the age and size distribution of particular species.

6. Marine Reserves as a Groundfish Management Tool

Strategic Plan Goal for Marine Reserves

To use marine reserves as a fishery management tool that contributes to groundfish conservation and management goals, has measurable effects, and is integrated with other fishery management approaches.

Marine Reserves Recommendations

1. Adopt marine reserves as a fishery management tool for Pacific groundfish and proceed with implementation, as appropriate.

2. Identify the specific objectives that marine reserves are expected to meet.

3. Develop siting and design criteria, including the size of the reserve, that will meet specified marine reserve objectives. Analyze options for establishing reserves that include nearshore, shelf, and slope habitat.

4. Adopt final siting criteria, including reserve size and location, and proceed with implementation and evaluation as quickly as possible, to ensure compatibility with other management changes.

5. Direct the Scientific and Statistical Committee to recommend new methodologies for continued stock assessments and for establishing harvest levels outside the reserves following the implementation of reserves.

7. Groundfish Habitat

Strategic Plan Goal for Pacific Groundfish Habitat

To protect, maintain, and/or recover those habitats necessary for healthy fish populations and the productivity of those habitats.

Pacific Groundfish Habitat Recommendations

1. Consider regulatory changes (including incentive systems) that result in modification or elimination of fishing gears or fishing practices that are determined to adversely affect EFH areas of concern such as nearshore and shelf rock-reef habitats.

2. Develop and implement gear performance standards for hook and line, pot, set gillnet, and trawl to increase gear selectivity, protect habitat, and/or decrease ghost fishing by lost gear.

3. Promote scientific research on the effects of fishing gear on various habitats.

4. Promote research to modify existing gear and practices to provide practical, economically viable alternatives to fishing gear that adversely affects habitats.

5. Identify habitats necessary for healthy fish populations and identify locations of those habitats.

B. Science, Data Collection, Monitoring, and Analysis

Strategic Plan Goal for Science, Data Collection, Monitoring, and Analysis

To provide comprehensive, objective, reproducible, and credible information in an understandable and timely manner to meet our conservation and management objectives.

Science Recommendations

1. Prioritize stock assessments for suspected "weak stocks" in mixed-stock fisheries.

2. Create cooperative partnerships between state, federal, private foundations, and other private entities to collect and analyze the scientific data needed to manage groundfish.

3. Promote improved mutual understanding, communication and credibility between the fishing industry and scientists through increased communication and collaboration, including at-sea ride-alongs.

4. Develop methods for incorporating fisher observations into stock assessment and monitoring programs, including employing commercial fishing vessels to conduct cooperative resource surveys and to collect other scientific data.

5. Implement the Council's draft West Coast Fisheries Economic Data Plan.

6. Ensure that economists and social scientists are adequately included on Council plan teams and ad hoc committees where appropriate, to ensure that all dimensions of management issues, options, and solutions are well reflected in their input to the Council.

7. Hold an annual or bi-annual meeting of U.S./Canada and/or U.S./Mexico stock assessment scientists to plan upcoming (preferably joint) assessments of transboundary stocks. The U.S./Canada portion of this recommendation could be conducted under the umbrella of the existing U.S./Canada Groundfish Technical Subcommittee.

8. Meet annually with National Marine Fisheries Service's Northwest and Southwest Regions and Science Centers and the Pacific States Marine Fisheries Commission to integrate the Council's data and research needs into NOAA's budget process.

9. Meet with the states and NMFS to develop a joint multi-year research and data collection/analysis plan for west coast groundfish.

10. Direct scientific efforts to measure the changes in groundfish productivity due to ocean environmental changes.

11. Obtain a dedicated research vessel(s) to perform annual surveys and collect other data needed to manage the coastwide groundfish under Council jurisdiction.

C. Council Process and Effective Public Involvement During and Beyond the Transition

Strategic Plan Goals for Council Process

$ *To establish and maintain a management process that is transparent, participatory, understandable, accessible, consistent, effective, credible, and adaptable;*

$ *To provide a public forum that can respond in a timely way to the needs of the resource and to the communities and individuals who depend on them; and*

$ *To establish a long-term view with clear, measurable goals and objectives.*

Council Process Recommendations

1. Encourage long term thinking so the Council can suggest creative solutions to Congress and NMFS during the Magnuson-Stevens Act reauthorization process.

2. Establish a performance evaluation committee to periodically and critically review progress made towards Council goals and objectives. The committee should also analyze improvements needed in Council procedures to maintain efficiency.

3. Update goals and objectives in the FMP to incorporate the strategic plan's vision and goals. These updated goals and objectives should: (a) be measurable, (b) have minimal conflicts, and (c) be clearly prioritized wherever possible.

4. Continue to routinely update its mailing lists and ensure that they contain commercial and recreational fishing associations, conservation and environmental groups, commercial licensed fishers for groundfish and other fishery species, local port offices, media contacts, and community-based organizations.

5. More effectively use newsletters, web page displays, public forums, news releases, and public service announcements to improve public participation in Council activities and decisions.

6. Make draft agendas available earlier to the local media from fishing communities, highlighting key issues.

7. Sponsor workshops to explain the Council process, its role and responsibility relative to fishery management, the roles of its committees and advisory entities, and the various opportunities for public involvement. Workshops should be held by the Council and state agencies in local port communities.

III. "How Will We Measure Success?" Implementing and Updating the Strategic Plan

<u>A. Proposed Implementation Process</u>

Implementing the Strategic Plan Recommendations

1. At the September 2000 Council meeting, the Council adopts the Final Groundfish Strategic Plan document (per revisions incorporated after the summer public comment phase).

2. The Council directs the formation of a "Groundfish Strategic Plan Implementation Oversight Committee" which should be composed of Council members, some of which will have been members of the Strategic Plan Development Committee, to ensure continuity and an effective transition to implementation.

3. At its discretion, the Implementation Oversight Committee may establish small implementation development teams to develop specific alternative(s) for implementing elements of the Strategic Plan. Implementation development teams will be comprised of Council subpanel, management team, and committee members from the GMT, GAP, SSC, EC, and members of the public as deemed necessary by the Implementation Oversight Committee.

4. The Implementation Oversight Committee works at direction of the Council and is tasked with making recommendations regarding implementation of the strategic plan.

5. The Implementation Oversight Committee **goals** should include: (a) effective transition to the implementation phase, (b) ensuring the plan is implemented in a timely fashion, and (c) whenever possible, doing so in a fashion that provides for constituent acceptance and buy-in.

6. At the direction of the Council, the Implementation Oversight Committee will develop recommended schedules for carrying out all components of the strategic plan.

7. The Implementation Oversight Committee will develop recommendations for all components of the strategic plan that can be developed further: (a) directly by the Council, (b) via advisory entity assignments, or (c) through formation and use of a implementation development team approach, e.g., capacity reduction implementation development team(s), which would handle all of the complexities of addressing the implementation of capacity reduction. For example, there might be four teams – with industry representatives from trawl, fixed gear, open access with groundfish target, and open access with non-groundfish target. Each of these teams will also have a representative from the Implementation Oversight Committee, with a charge to develop a plan and product by “x” date. The Implementation Oversight Committee considers the work of the implementation development teams and develops the final recommendations for the Council. Clarification, input, and technical support will be available to all teams with “on-call” availability from Council staff, states, NMFS staff and General Counsel, etc.

8. It will be important to consider current conditions in the groundfish fishery, including the effects of recent changes in resource status, fishery management, and the environment, as part of the strategic plan implementation process.

B. Measuring Success

Options for Updating the Groundfish Strategic Plan Document

A good strategic plan is rigid enough to have clearly-stated, expected results but also flexible enough to modify when evaluation indicates change is necessary. The Council wishes to maximize the value of the time, energy, and money invested in its strategic plan by regularly evaluating the plan's effectiveness and initiating changes as deemed necessary to enhance success. The Council also recognizes that periodic review provides plan continuity for Council members and staff, and promotes public awareness.

Updating The Strategic Plan Recommendations

The Council should schedule a routine review every five years. If a Council member determines that a review should occur more frequently, the member could seek to have the review placed on the Council agenda in the same manner that other actions are placed on the agenda. When the review takes place, the Council should follow the standard Council meeting process and take written and oral public comment, and involve the appropriate advisory entities.

Agenda Item F.3.b
Supplemental EC Report
June 2014

ENFORCEMENT CONSULTANTS REPORT ON
OMNIBUS REGULATION CHANGES, PART I

The Enforcement Consultants (EC) has reviewed the documents pertaining to Agenda Item F.3.a, June 2014 and has the following comments. Referencing Attachment 2, *Initial Compilation of Possible Groundfish Management Measures for Council Considerations,* the EC recommends the following be moved forward for final rule making.

Table 1 (A):

- Seabird Rule-Mandatory Streamers for vessels fifty five feet or greater
- Fishery Declaration Enhancements
- Update E-Ticket for Web-based Submissions
- Require E-Tickets for Sablefish Landings

Seabird Rule-Mandatory Streamers: Council action has been completed. Considering the Endangered Species Act (ESA) implications for this fishery, completion of this rule should be considered a high priority.

Fishery Declaration Enhancement: Council action has been completed. The United States Coast Guard (USCG) notification problem identified under Council consideration of this action has been addressed by increasing NOAA Fisheries Office of Law Enforcement (OLE) and USCG daily/weekly communications. The EC suggests this action be rolled into the next Groundfish rule making opportunity.

Update E-Ticket for Web-based Submission: Moving E-Ticket to a web-based platform represents a significant enhancement for E-Ticket reporting on the West Coast and should be supported by federal rule making at the earliest opportunity.

Require E-Tickets for Sablefish Landings: A recently completed Department of Commerce (DOC) Office of Inspector General (OIG) report found that NMFS was not adequately tracking sablefish tier status' in-season and subsequently was not pursuing enforcement of tier overage violations. E-Ticket reporting of all West Coast sablefish landings will give enforcement the necessary tool to track individual limited entry permit (LEP) tier status and cumulative bi-monthly, weekly, and daily trip limits, in both the daily-trip-limit (DTL) and open access (OA) fisheries.

Table 1(C):

- Increase Vessel Monitoring System (VMS) Ping Rate.

Increase VMS Ping Rate: The EC places this issue among its highest priorities and asks the Council to schedule it for action at the earliest opportunity. In discussions with Council staff, if given a high priority for the September meeting, alternatives could be developed for the November Council meeting for Council action on a preliminary preferred alternative (PPA) in

March, with final action in April. This schedule establishes a realistic expectation that regulations could be in place by January 2016. In light of the significant need to maintain a vigorous Rockfish Conservation Area and essential fish habitat monitoring capability, any further delay of this action would be highly detrimental to enforcement's ability to ensure closed/conservation area integrity. The EC requests that this item be identified for focus in development of background information for September.

In conclusion the EC recommends:

1. The following be moved forward for final rule making.
   Table 1 (A):
   - Seabird Rule-Mandatory Streamers for Vessels greater than fifty five feet
   - Fishery Declaration Enhancements
   - Update E-Ticket for Web-based Submissions
   - Require E-Tickets for Sablefish Landings

2. Increasing the VMS ping rate be given a high September scheduling priority with follow-on expedited action.

PFMC
06/21/14

Agenda Item F.3.b
Supplemental GAP Report
June 2014

GROUNDFISH ADVISORY SUBPANEL REPORT ON GROUNDFISH OMNIBUS REGULATION CHANGES PART I/INITIAL COMPILATION OF MANAGEMENT MEASURES

The Groundfish Advisory Subpanel (GAP) heard a report by Ms. Kelly Ames and Mr. Jim Seger and offers the following comments on the Omnibus Regulation Changes.

Adaptive Management Program

As noted in No. 54 and (and No. 12) on the list, the GAP supports Alternative 2 for continued pass-through of Adaptive Management Program (AMP) quota pounds. Most recently, the GAP commented on this in March and in several statements before that. The GAP continues to believe that the AMP is a solution looking for a problem and that no valid problems have been brought forward that would be solved by initiating the AMP. There are many more pressing matters that could create efficiencies in the trawl rationalization program that should be considered before this issue. We suggest No. 54 simply be removed.

Sections A, B and C of the Omnibus list

First, we referred to and copied the template found in Agenda Item F.3.a, Initial Compilation of Possible Groundfish Management Measures for Council Consideration, so the discussion is easier to follow.

Second, we've added some columns to the right of each numbered item that we hope provides the Council guidance for prioritization of these issues in September. The columns are as follows:

- In sections A and B: GAP comments: We realize most of the issues in these sections are already in the works and that the Council is not prioritizing anything at this meeting. However, we request National Marine Fisheries Service (NMFS) provide the Council and advisory bodies with a clearer idea of which items *the agency* sees as a priority due to workload, budgets, staff, etc.

  The GAP recognizes that anything with a hard timeline imposed by courts or biological opinions or the like should be met.

- In section C: GAP "on or off" the list and comments: These boxes makes it clear which of the items we view as ones the Council should prioritize in September and which could be delayed. We expect further refinement of these items under F.9, Omnibus II and/or at the September Council meeting.

Third, we have listed eight issues at the end that we'd like to see added to the list. Any Council guidance related to these issues can be addressed in F.9, Omnibus II, or in September.

GAP discussion

As a prelude to consideration of individual items on the list, GAP members spent a bit of time expressing frustration at the laundry list of items, many of which should have been implemented years ago. On one hand, we – and the Council – have spent a several meetings shuffling some items from one list to another before they were put on this omnibus list; on the other hand, perhaps *this* omnibus list finally will allow for a consistent follow-through for completion. In short, let's stop spending our time making lists and instead get things done.

Many GAP members also expressed frustration at what seems to be a bottleneck at NMFS and are skeptical that few items in the omnibus will actually move forward. This points to the greater problem of damaging the successful working relationship industry has had with NMFS for years.

In addition to the greater level of analysis being required for action, multiple layers of review and bureaucracy is destroying a fishery and creating a dysfunctional system.

While the GAP recognizes these problems, we also request both NMFS and the Council consider what additional actions members of the GAP, as individuals and as an advisory panel, can take to assist in implementation of backlogged issues. The GAP would like to remind the Council that the trawl catch share program participants are now paying cost recovery fees to offset management costs and it is still unclear what tasks are actually being completed with these dollars. Continuing delays threaten the success of the quota share program.

Relative to the task at hand, the GAP recognizes the most important items deal with moving the annual harvest specifications and management measures through the process. Any efficiencies we can gain here are paramount as they will affect the entire industry. Items specific to individual sectors are secondary, but barely. While it may appear the omnibus list is overloaded with items related to the trawl rationalization program, many of these issues are not new and were in fact identified prior to implementation of the program. Without inferring any additional priority at this time, all sectors should have items that move forward for prioritization in September.

	Sector	Short Title	
A. Items on Which Council Action Has Been Completed Which Still Entail Some Workload			**GAP comments**
1.	Trawl, Non-Trawl, Rec	2015-2016 Harvest Specifications and Management Measures and Amendment 24 (June 2014)	This is of utmost importance to get accomplished so the new harvest specifications are available for harvest on Jan. 1, 2015 (e.g., higher petrale and sablefish ACLs).
2.	Trawl and Non-Trawl	Seabird Rule - Mandatory Streamers for vessels ≥ 55'	It's important for NMFS to meet the timeline dictated in the BiOp
3.	Trawl and Non-Trawl	Clarify Catch Accounting Rules for Amendment 21	--
4.	Trawl and Non-Trawl	Fishery Declaration Enhancements	--
5.	Trawl IFQ, MS, & CP	Cost Recovery Corrections	--
6.	Trawl IFQ & MS	Electronic Monitoring Exempted Fishing Permits (if final in June 2014)	This is important to the GAP, as we have stated in Agenda Items F.2 and F.5.
7.	Trawl IFQ & MS	Pacific Dawn Lawsuit Appeal to District Court	--
8.	Trawl IFQ & MS	Whiting Cleanup Rule, Including Maximized Retention Regulations	This should be simple to do, but why is this holding up the whiting season start date (No. 11)? It's important to finish so the shorebased whiting season date change goes into effect in 2015.
9.	Trawl CP	Glacier Fish Co Lawsuit (Cost Recovery)	--
10.	Trawl IFQ	Joint Registration and Prohibition of Processing IFQ Sablefish	Yes, move this forward. We understand the workload is not huge.
11.	Trawl IFQ	Move Shorebased Whiting Season Opening Dates	Yes, this is a priority for the GAP. See also No. 8.
12.	Trawl IFQ	Continue Adaptive Management Program Pass-Through	As the GAP has said in past statements, this should move forward indefinitely: Alternative 2, from F.3.a, Attachment 1, "AMP Quota Pound Pass-through."
13.	Trawl IFQ	Update eTicket for Web-based Submissions	Low priority; web-based submissions already are in use, but not required by regulation. As such, the timing of this measure isn't critical.
14.	Trawl IFQ	Rule for Forfeitures for Exceeding Aggregate NonWhiting Control Limit	The GAP suggests this move forward to be done by the transfer date deadline but any proposed date change is up to the Council.
15.	LEFG	Revise Limited Entry Fixed Gear Permit Control Rule (If Recommended)	These items were or will be addressed under agenda item F.6, Sablefish Catch Share Program Review.
16.	LEFG and OA	Require E-Tickets for Sablefish Landings (If Recommended)	
17.	LEFG and OA	Sablefish North of 36 Degrees - Allocation Correction	
18.	LEFG and OA	Logbooks for Fixed Gear	This is stale, not needed. Revisit the original purpose to see if the needs still apply.
19.	OA	Amendment 22 - Open Access License Limitation	This should move forward for situations such as the rougheye situation – it's important to reach the people involved. There are management benefits, such as more precise inseason trip limits for sablefish.

B. Immediate and Long-Term Commitments			
Currently on the Year at a Glance Schedule (See also Agenda Item C.6.a, Attachment 1)			**GAP comments**
20.	Trawl, Non-Trawl, Rec	Inseason Management (Sept 2014 and beyond, excluding March 2015)	No comment
21.	Trawl, Non-Trawl, Rec	Adopt Final Stock Assessment Plan and TOR for 2015 (Sept 2014)	No comment
22.	Trawl, Non-Trawl, Rec	Develop a COP for Groundfish Methodology Review Process (Sept and Nov 2014)	No comment
23.	Trawl, Non-Trawl, Rec	Omnibus Regulations Changes (Sept and Nov 2014, Mar-June 2015)	No comment
24.	Trawl, Non-Trawl, Rec	Essential Fish Habitat: Phase 3 of the 5 Year Review (Sept 2014)	Low priority
25.	Trawl, Non-Trawl, Rec	Amendment 25: Comprehensive Ecosystem-Based Amendment (Sept 2014 and Mar 2015)	Low priority
26.	Trawl, Non-Trawl, Rec	2015 Pacific Halibut Catch Sharing Plan (Sept and Nov 2014)	No comment
27.	Trawl, Non-Trawl, Rec	2015 Incidental Regulations for Pacific Halibut (Mar and Apr 2015)	No comment
28.	Trawl, Non-trawl, Rec	Stock Assessments for 2017-2018 Biennium (June 2015)	No comment
29.	Trawl, Non-Trawl, Rec	Start of the Process to Establish 2017-2018 Specifications and Regulations (June 2015)	High priority
30.	Trawl IFQ & MS	Electronic Monitoring Regulations (Sept 2014, June 2015)	High priority
Items on the Horizon			
31.	Trawl IFQ, MS, & CP	Five Year Review (Starts in 2016)	No comment
32.	Trawl IFQ	QS/QP Control Rule - Safe Harbor for Risk Pools - post 5-year review	Low priority
33.	Trawl IFQ	Resolve Long-term Whiting Surplus Carryover Provision - post 5- year review	Should be removed from prioritization, since this will be dealt with under the 5-year program review.

C. Candidate Items for Prioritization in September			Council notes	GAP on or off the list	GAP comments
34.	Trawl, Non-Trawl, Rec	Rebuilding Revision Rules (signal vs. noise)		ON	--
35.	Trawl, Non-Trawl, Rec	Further Consideration for Reorganizing Stock Complexes		OFF	--
36.	Trawl and Non-Trawl	Groundfish Conservation Areas for Rougheye Rockfish		OFF	--
37.	Trawl and Non-Trawl	New Dressed to Round Conversion Factors for Sablefish		ON	--
38.	Trawl and Non-Trawl	Increase VMS Ping Rates		OFF	--
39.	Trawl and Non-Trawl (LE)	Eliminate Permit Size Endorsements		n/a	Not applicable at this time. The GAP may discuss this further at a later date.
40.	Trawl and Non-Trawl	Seabird Avoidance Devices for Vessels less than 55 feet		ON	--
41.	Trawl IFQ, MS & CP	Revise Length of Time Required for the Trawl Fleet to Retain Records		OFF	--
42.	Trawl IFQ (& MS &CP?)	Fishery Declaration Enhancements (With Gear Stowed and Testing Gear)		ON	We would like to change the declaration requirements that would allow a catcher vessel that delivers its last delivery to a mothership to be able to make a declaration, then start a new fishing trip on the way to shore and deliver to a shoreside processor.
43.	Trawl IFQ, MS & CP	Year Round Whiting Season and Other Modifications		ON	As part of this package, the GAP requests other modifications include the ability for MS and CPs to process whiting below 42° N. lat.
44.	Trawl IFQ, MS & CP	Revise Regulations on At-Sea and Shoreside Flow Scales		ON	--
45.	Trawl IFQ	Gear Use - Multiple Gears Onboard and Use		ON	--
46.	Trawl IFQ and LE Pot	Remove Certain Area-Management Restrictions		ON	The GAP requests the Council/NMFS continue to refine non-trawl/rec RCA lines as well.
47.	Trawl IFQ	Remove Certain Restrictions on Trawl Gear Configuration		ON	--
48.	Trawl IFQ	Resolve Long-term Non-Whiting Surplus Carryover Provision		ON	--
49.	Trawl IFQ	Carryover when Management Units Change		ON	The GAP recognizes this also is likely dependent on keeping No. 48 on the priority list.
50.	Trawl IFQ	Allow Trading of Previous Year Quota Pounds in Current Year		ON	--
51.	Trawl IFQ	Widow Rockfish QS Reallocation		ON	--

C. Candidate Items for Prioritization in September			Council notes	GAP on or off the list	GAP comments
52.	Trawl IFQ	Discard Survival Credit for Lingcod and Sablefish		ON	--
53.	Trawl IFQ	Require Posting of First Receiver Site Licenses		OFF	--
54.	Trawl IFQ	Develop Criteria for Distributing Adaptive Management Program QP		OFF	See also comments under No. 12
55.	LEFG	Cost Recovery for the Permit Stacking Program		ON	--
56.	LEFG and OA	Commercial Gear Restriction for Targeting Flatfish in CA		OFF	--
57.	LEFG and OA	Retain Halibut in the Sablefish Fishery (South of Pt. Chehalis)		ON	--
58.	Recreational	50 fm Depth Restriction (WA and OR)		ON	--
59.	Recreational	Mid-water Sport Fishery (OR and CA)		ON	--

Items to be added to the prioritization list

The GAP requests the following five items be added to the prioritization list. Brief descriptions are provided here but we expect details of these issues to be made available in September.

1. Equal share rockfish transfer between sectors: Allow MS sector participants voluntary access to their quota pounds in their shoreside IFQ accounts of four rockfish species (canary, darkblotched, widow and POP) that are based on the "equal share" of the catch history of the permits retired through the buyback loan program. Allow transfer of these rockfish quota pounds to the at-sea mothership fishery cooperative on an annual basis and only up to the equal share allocation amount if constraining species bycatch limits are constraining the at-sea fishery operations and threatening participants' ability to obtain their whiting allocation.

2. The 60-mile bank RCA lines: An area known as the 60-mile bank is a cowcod-rich area along the U.S./Mexico border. This area is not marked with RCA lines, leaving it unenforceable by California Department of Fish and Wildlife (CDFW). This creates a huge area deeper than 60 fathoms that is fished without enforcement. The 60 mile bank needs to be clearly defined so both vessels and enforcement are on the same page and cowcod limits are not exceeded.

3. Blackgill allocation: The trawl/non-trawl allocations currently in place for blackgill rockfish management are currently incorrect, leading to complications between the traditional non-trawl fixed-gear fleet and the IFQ fixed-gear fleet in the Conception management area.

There has been an increase in the targeting of blackgill by the IFQ fleet, so fixing the allocation is necessary.

4. Oregon and Washington nearshore management: The GAP understands both the Oregon and Washington Departments of Fish and Wildlife are requesting state management of nearshore fisheries. The GAP understands this may cause some workload issues but supports adding these items to the Omnibus list.

5. Combine the LE DTL fishery and the tier fishery: The GAP would like to propose the addition of analysis to combine the daily trip limit fishery with the permitted tier fishery. The analysis would include selection of a window period and conversion of the pounds caught during that period to specific permits. This would also encompass the unendorsed sablefish permits. If the Council requests, we can make more information available about this option under F.9, Omnibus II.

6. Retrieve derelict crab gear in the RCA: At the request of some members of the public and the states, the GAP suggests exploring the ability to retrieve derelict Dungeness crab gear while transiting the RCA. Currently, derelict gear is a safety issue and also leads to gear conflicts. This may be avoided by being able to pick up stray crab pots while returning from a sablefish trip, for example.

7. Exploration of flexible regulations that allow transfer of overfished species between sectors to prevent stranding target fish.

8. The use of descending devices in the rod-and-reel nearshore commercial fisheries. The GAP requests consideration of allowing the same depth-based mortality rates for cowcod, canary and yelloweye in the commercial fisheries as allowed in the recreational fisheries.

GROUNDFISH MANAGEMENT TEAM REPORT ON OMNIBUS REGULATION CHANGES - PART I

The Groundfish Management Team (GMT) reviewed and discussed the materials provided under this Agenda Item and provides the following comments.

Trawl Individual Fishing Quota Program Adaptive Management Program (AMP) Pass-Through

The GMT only spent a small amount of time discussing the alternatives for AMP in the trawl individual fishing quota (IFQ) program, but sees value in Action Alternative 1, Sub-Option B (Agenda Item F.3.a Attachment 1) that would consider AMP quota pound (QP) allocation procedures as part of the five-year review and specifically, after the implementation of regulations resulting from the five-year review. Issues may rise to the surface during the review that will provide further direction on how best to handle the distribution of non-whiting quota shares and Pacific halibut individual bycatch quota pounds currently reserved for the AMP. The GMT notes that additional work will be needed on AMP if the Council selects Alternative 1B, which could be added to Section B, Immediate and Long-Term Commitments, on the list of management measures identified as "on the horizon" (Agenda Item F.3.a Attachment 2).

New Rule Clarifications for Trawl Trailing Actions

At the time of the GMT discussion, we understand that the National Marine Fisheries Service (NMFS) had not identified any issues with implementation of the chafing gear rule and the observer/catch monitoring rule.

Omnibus Regulation Changes

The GMT reviewed and discussed the initial compilation of management measures for Council consideration (Agenda Item F.3.a, Attachment 2) and the summary of documents intended to help the Council in the prioritization exercise (Agenda Item F.3.a, Attachment 3). While the list of near complete, near and long-term commitments, along with new management measures provided in Attachment 2 may seem overwhelming, the GMT appreciates that listing them all in one place presents the opportunity to evaluate groundfish management measures in a holistic manner that provides a process for establishing Council priorities and addressing workload issues.

The GMT often provides comments during the Future Council Meeting Agenda and Workload Planning agenda items to highlight the expected workload associated with analyzing groundfish issues under Council consideration. This has become more important as the level of analysis and documentation has changed and now requires much more time and effort. In addition, the GMT's role in stock assessment review (STAR) panels (item B-21) has increased with members of the GMT often responsible for providing detailed summaries of regulations and working with stock assessment authors in advance to ensure that correct data are used; all of this requires additional time, not just for the GMT but for all advisory bodies (e.g., the GAP and Scientific andn Statistical Committee, SSC). As science advancements provide the opportunity for a greater number of assessments (e.g., increase in data moderate assessments), it has become clear that sufficient time is necessary to develop corresponding management measures (items B-28 and B-29). It has become increasingly difficult to have the necessary discussions, conduct analysis, and complete reports within the time frames we have traditionally used. Therefore, we see this prioritization exercise as an opportunity to be more strategic and consider new ways for packaging multiple management measures in ways that provide the biggest efficiencies.

The GMT discussed that the current list of management measures is dominated by those focused on the trawl sector; however, we recognize that a lot of the trawl items address issues that arose following the implementation of the trawl IFQ program and are needed for regulatory streamlining. While there was some discussion about whether future measures should be more evenly distributed by sector, the GMT acknowledged that items should be considered based on need rather than an attempt to set an arbitrary standard of even representation. Alternatively, we do not want to see items being repeatedly delayed or postponed, such as the recreational midwater fishery item which first appeared on a "year-at-a-glance" calendar in November of 2012 (Agenda Item F.4.a, Supplemental Attachment 3, November 2012), for discussion in June 2013, but has yet to occur.

Next, the GMT discussed alternative ways of creating packages of regulatory bundles that might be easier to analyze and more efficient to implement. These regulatory packages could be bundled in a variety of ways, we provide a couple of examples below:

- Items that would be relatively easy versus those that would be more complicated, in terms of both the analysis needed and implementation
- Enforcement issues
- Groundfish management areas for all groundfish (commercial and recreational) sectors

The GMT provides some initial thoughts on the items within the sections (A, B, and C of Attachment 2) with the understanding that more information will be available from NMFS and Council staff in September to further inform prioritization.

Section A: Items Which Action Has Been Completed Which Still Entail Some Workload

At this time, the GMT has no additions to the items in Section A.

Section B: Immediate and Long-Term Commitments

The GMT recommends that discard mortality rates currently used in the nearshore bycatch model and by the West Coast Groundfish Observer Program (WCGOP) in the annual groundfish mortality reports be added to the list in Section B, Immediate and Long-Term Commitments. There is little documentation for applying the discard mortality rates (100 percent) for some rockfish in the deeper depth strata (e.g., deeper than 20 fathoms). This rate is higher than that used in the recreational fisheries and the GMT would like to ensure it's accurate. This would require GMT time as well as the appropriate review by the SSC, if changes to the rates are needed.

Section C: Candidate Items for Prioritization in September

The GMT also identified management measures that we recommend be included in Section C, Candidate Items for Prioritization in September (the order below is not prioritized).

- Further consideration for ecosystem component (EC) species, for example developing management measures for EC species that would prevent future fisheries from starting up.
- Evaluate groundfish management performance and the need to adjustment management measures by comparing the multi-year average catch against an average annual catch limit (ACL). National Standard 1 Guidelines (see 74 FR 3178) references such an approach which could provide stability for industry and reduce workload for the Council and NMFS.
- Consider mortality rates reflecting the use of descending devices in the rod-and-reel component of the commercial nearshore fishery.
- Continuation of model reviews and refinement

If the Council provides guidance on the criteria for prioritization the GMT could further evaluate the management measures as well as the Public Comment submitted under this agenda item. To further assist the Council in prioritizing these items, the GMT could provide information on what work has been done, how complex the discussions about the items may be, as well as the anticipated workload, for each management measure in Section C of the list in Attachment 2 under Agenda Item F.9 at this meeting.

GMT Recommendations:

1. The GMT recommends that discard mortality rates currently used in the nearshore bycatch model and by the West Coast Groundfish Observer Program (WCGOP) in the annual groundfish mortality reports be added to the list in Section B, Immediate and Long-Term Commitments.
2. The GMT recommends including the items listed above under Section C, Candidate Items for Prioritization in September be added to the list.

06/21/14

OREGON DEPARTMENT OF FISH AND WILDLIFE REPORT ON DEFFERING NEARSHORE GROUNDFISH MANAGEMENT AUTHORITY TO THE STATE OF OREGON

We, the Oregon Department of Fish and Wildlife (ODFW), request exploration of deferral of nearshore species (i.e., nearshore rockfish, cabezon, and kelp greenling) management to state oversight, specifically, by adding this issue to the 'Omnibus' list.

Since these species principally occur entirely within our state waters, full deferral to the state for the entire stock ranges is most efficient and logical. Per federal law, the Submerged Lands Act (43 USC 1301-1315) and the Magnuson-Stevens Act (16 USC 1801-1882) provide jurisdiction of marine resources, including fisheries stocks, to the states. Accordingly, to officially transfer management authority of the stocks to the states, the Pacific Fishery Management Council (PFMC) and National Marine Fisheries Service (NMFS) will have to amend the federal Groundfish Fishery Management Plan (FMP) to exclude each state's respective component stocks. In doing so, the onus will shift to our state management process, which already includes a strategic management framework for these species, with goals synonymous to those of the National Standards, but with greater emphasis on local conservation, communities, and economies.

Additionally, the Council recognized the appropriateness of deferral of nearshore management to the states during the development of the Groundfish Fishery Strategic Plan (plan), adopted in 2000. When answering the question "What are some strategies for increasing enforcement effectiveness and reducing complexity", the need for deferring nearshore species is detailed: "Review the scope of the management unit, particularly with respect to nearshore rockfish management. Consider delegating or deferring to the states management of nearshore rockfish species that reside in and are harvested primarily within state waters." This review would equally apply to cabezon and kelp greenling.

Overview:

The nearshore groundfish stocks occurring within our state waters (i.e., 0-3 nautical miles) support some of the most diverse and complex fisheries within our nation, including the kayak fleet of Depoe Bay, the dory fleets of Pacific City, the live-fish fishery of Port Orford, the spear fishermen of Cape Arago, the charter operators of Garibaldi, the cliff anglers of Cape Foulweather, and many more.

Understanding and meeting the localized needs of these diverse interest groups and communities is a time consuming and resource intensive task that would further constrain the already limited capacity of PFMC and NMFS. While we applaud the larger, regional scale efforts undertaken in the federal process, we have concerns about the ability to address our local stakeholder needs. Accordingly, we seek management oversight of our nearshore groundfish fisheries and stocks, specifically to provide more localized support to the diversity of communities and interest groups that occur in Oregon.

We are fully capable of managing these stocks sustainably, while also better addressing the immensely diverse needs of our local communities. There is no greater exemplification of our abilities than the recent Marine Stewardship Council certifications of our state managed commercial Dungeness crab and pink shrimp fisheries. More directly related to state oversight of nearshore groundfish, we have a long and dedicated track record of managing these stocks more conservatively at the state level for both our commercial nearshore and sport fisheries.

Specifically, we developed more conservative state landing caps for both the sport and commercial fisheries, and implemented a limited-entry permit system to control the growth and prevent overcapitalization of our commercial nearshore fishery. We currently have in place more conservative bag limits, spatial and temporal closures, and size limits in our sport fisheries and trip limits, size limits, spatial management, and reporting requirements (e.g., mandatory logbooks) in our commercial fishery.

While many of our more conservative state actions have caused huge upheavals among our fleets, it is important to document that we have the backbone to close or restrict our fisheries amid conservation concerns. Most notable was our decision to close our sport groundfish fisheries prior to Labor Day in 2004, due to attainment of the black rockfish sport landing cap. This closure, known as "Black Friday" to the sport fleet, still resonates to date.

Our request for state oversight only pertains to species in the Groundfish FMP that principally occur within our state waters and are non-migratory (i.e., nearshore rockfish, cabezon, and kelp greenling). As such, our state oversight would have minimal or no bearing to the fisheries and stocks occurring in the other states.

The remainder of this document describes in greater detail how we, given state oversight of nearshore groundfish stocks, could ensure sustainable management practices, while also more fully meeting the needs of our immensely diverse stakeholder groups.

Population (stock) Assessments:

We have the expertise and data to comprehensively assess nearshore groundfish stocks to ensure sustainable fisheries under state management

To prevent overfishing and ensure long-term viability of fisheries, timely and accurate population assessments are needed to establish sustainable catch limits. We employ multiple staff (including contractors), with extensive backgrounds in population modeling, who can be entrusted to provide robust assessments of the nearshore groundfish stocks. Most notable, pertaining to nearshore groundfish, our staff conducted the most recent federal assessment of black rockfish, the most important nearshore groundfish stock to both our commercial nearshore (in terms of value) and sport groundfish fisheries (in terms of effort and catch).

In addition to modeling expertise, we also collect and provide the bulk of the data that has been used in "full", "data-poor", and "data-moderate" federal stock assessments of nearshore groundfish, including: sport and commercial catch histories (e.g., sport and commercial CPUEs and sport total morality estimates) and biological data (e.g., age, size, sex, maturity, and fecundity).

And finally, we are proactively taking actions to improve the quality of nearshore groundfish stock assessments. While not to say that the outputs of the recent "data-moderate" and "data-poor" federal assessments are erroneous, we do, however, want to acknowledge that the results are highly uncertain, and possibly inaccurate, because limited fishery-dependent data was used (additional available fishery-dependent data was not used in the assessments due to model methodology structure). Fishery-independent survey data was not included because it does not exist; nearshore groundfish live in habitats too shallow and rocky to be sampled by the NMFS bottom trawl survey. Accordingly, our researchers have begun using video-landers, capable of surveying shallow and rocky reef habitats, to better our understanding of nearshore groundfish stock dynamics.

Research:

Our research team is dedicated to resolving key management issues and uncertainties, such as reducing bycatch and protecting critical habitats to improve our state management of nearshore groundfish.

To further our understanding of nearshore groundfish stock dynamics and thus better manage them, we are seeking to determine the influences of ecological drivers on fish stocks, as trophic or environmental shifts greatly affect abundances (especially for short-lived species). By doing so, our researchers can resolve some of the key uncertainties associated with setting long-term sustainable harvest levels. For instance, we are currently researching the influence of hypoxic events on fishery catch rates, which is a primary driver of nearshore assessments.

In addition to enhancing our understanding of nearshore groundfish stock dynamics, our researchers are also working together with industry to reduce bycatch. Notable examples of bycatch reduction efforts include: 1) identification of protected species hotspots (e.g., Stonewall Bank Yelloweye Rockfish Conservation Area), 2) developing clean-gear innovations (e.g., excluder panels in shrimp trawls), and 3) evaluating methods to reduce mortality of bycatch (e.g., rockfish descending devices).

Management:

We best understand the diverse needs of our local stakeholder groups, which is essential for ensuring that divisions of available catch are equitable and economically optimal

After sustainable catch limits have been determined via stocks assessments, fisheries managers have to divide the available catch among stakeholders in an equitable, yet economically optimal manner, while also ensuring the safety of the fleet. In order to accomplish this, managers must have an innate knowledge of the degree of fishery dependence for each individual stakeholder group or community. Determination of stakeholder fishery dependence at such a localized level is an extremely time and resource consuming task, beyond what PFMC and NMFS can provide due to their commitments with larger, regional issues.

In fact, the Groundfish Strategic Plan states: “Increasingly, the Council has been asked to adopt complex regulations designed to respond to the particular needs of communities in specific geographic locations. Most of these requests relate to very small vessels accessing local rockfish stocks and marketing them within the area. The Council is not well equipped to evaluate these requests and accommodating them increases the complexity of the regulations. In addition, the Council and NMFS are not well suited to assess the biological requirements of many of these local populations, to assess the social and economic issues associated with them, or to monitor localized fisheries". We assert that these issues are still relevant today and that the state is best able to address these needs.

In order to acquire this stakeholder or community information, we have had to invest heavily into our communication networks: 1) sport and commercial advisory bodies; 2) public meetings throughout the entire coast; 3) e-mail and mailing lists (containing ~5,000 contacts); 4) online surveys and 5) one-on-one communications via phone or e-mail. Since the user groups and their needs change continuously, we have to maintain our communication network in order to learn of these changes as they arise.

Without these communication networks, we would have no other way of knowing, for example, that there is a kayak fleet from Depoe Bay or whether the needs for commercial fishermen who target black rockfish differ than those who target minor nearshore rockfish. Extensive knowledge of user groups, such as this, is critically vital to ensuring that divisions of catch are fair and equitable.

Our state management processes have the capabilities to address stakeholder needs in a timely, responsive, and comprehensive manner. First, we already have the strategic management frameworks in place to address fisheries, conservation, and ocean policy issues (i.e., Oregon's Nearshore Strategy), with goals similar to those of the National Standards, but with more emphasis on local stocks, economies, and communities. Second, our policy makers (i.e., Oregon Fish and Wildlife Commission) are already proficient in state fisheries management, and they are able to address issues more responsively because they meet frequently throughout the year. The timeframe for permanent rulemaking is approximately two months. Oregon has an efficient quick response system to address inseason management needs and action can be taken in as short a time as a single day.

Monitoring:

Our sampling programs are well-recognized for providing timely and accurate estimates, thus we would continue to manage the nearshore groundfish resource responsively in order to ensure catches stay within limits

In order to prevent overfishing, fisheries managers have to monitor catches to ensure that they stay within sustainable limits. Our state sampling programs, currently responsible for providing landings of sport and commercial nearshore groundfish, are well recognized by external reviewers (such as the National Resource Council and NOAA's Marine Recreational Information Program) for providing robust and timely catch estimates. Landings of commercially harvested fish are recorded on state fish tickets. Spatial information is collected through a state-mandated logbook program, as is information on discards. Biological information, including length, weight, sex, age and maturity structures, etc., is collected by our commercial port sampling program. On the sport side, precise and accurate estimates are ensured via relatively high sample rates for all spatial and temporal stratums. Our dock-side sampling program also collects biological information such as length, weight, and sex. The state-funded sport observer program collects information on fish discarded at-sea, as well as biological information such as age structures. The state has a staff person devoted to aging structures collected from nearshore species to determine ages of catch and maturity curves, when paired with gonad analysis.

Enforcement:

Law officers ensure that fishers comply with the conservation-based regulations set forth by fisheries managers

As for catch monitoring, the onus of enforcement for the commercial nearshore and sport fisheries already falls upon the state. Our enforcement unit, the Oregon State Police, is responsible for both dock-side and at-sea operations. Accordingly, we have the enforcement capabilities to ensure that regulations set forth by state fisheries managers would be abided by.

Conclusion:

We have been entrusted by the citizens of Oregon to protect their resources and to hear their voices, and we have delivered upon those promises with our state managed fisheries for many years. We have the track record, the infrastructure, the capability and the desire to ensure the same level of success for nearshore groundfish under state oversight. The state of Oregon already assumes responsibility for the management of these stocks through more conservative state regulations. The 2000 Groundfish Strategic Plan recommends exploration of deferral of nearshore rockfish, cabezon, and kelp greenling to the states in effort to reduce regulation and process complexity and increasing enforcement effectiveness. We request to add this issue to the list of evaluations through the omnibus process.

RE: CORRECTING BLACKGILL ROCKFISH TRAWL/NON-TRAWL ALLOCATION

Madame Chair and Council,

Gerry Richter (GAP fixed gear rep) here again to remind the Council that the trawl/non-trawl allocations currently in place for management of Blackgill rockfish are incorrect and need to be fixed. The non-IFQ fixed gear fleet in the Conception management area is becoming increasingly concerned about the IFQ fixed gear targeting of Blackgill rockfish in our area. You'll recall that current stock status stands at around 30% depletion which is barely above the overfishing level of 25% B/o. It appears there is little that can be done management wise to prevent IFQ targeting of this important species so it becomes even more critical that we correct the allocations. My hope is this could be done within the "Omnibus Regulation Changes" agenda item of the upcoming June Council meeting.

I have included my letter and public testimony from the March 2012 Council meeting for background information.

Thank you,
Gerry Richter
GAP fixed gear

March 12, 2012

Pacific Fishery Management Council
7700 NE Ambassador Place, Suite 101
Portland, Oregon 97220-1384

RE: TENTATIVE ADOPTION OF 2013/2014 BIENNIAL SPECS/BLACKGILL ROCKFISH ALLOCATION

Mr. Chairman and Council Members,

For the record, my name is Gerry Richter and I represent fixed gear fishermen as a member of the Groundfish Advisory Subpanel (GAP). You'll recall my public comment during the Emerging Issues portion of the March meeting where I informed the Council of a developing problem dealing with allocation of Blackgill rockfish for the 2013/2014 season.

Blackgill was assessed this past August, and the results of that assessment were much more pessimistic than the prior 2005 review. Current stock status stands at about 30% depletion and there are indications the species may have been overfished from the 1990's up until around 2008. We are looking at drastically reduced 2013/2014 ABC's, OFL's and ACL's with trip limits reduced accordingly as well.
Blackgill is a component of the Minor Slope rockfish complex in the south. The species has been a very important contributor to fixed gear fisheries catches from Morro Bay all the way south to the Mexican border. Catches in southern California alone averaged over 400 tons per year from the late 1970's thru the mid 1990's. Gear types were vertical longline, horizontal longline, rod & reel and set gill nets.

The emerging issue with Blackgill is the way it will be allocated for the 2013/2014 season. Per Amendment 21, Slope rockfish were allocated at 63% to the trawl sector while 37% went to fixed gear. While as a total Slope complex component this allocation is likely accurate, it is not accurate for the individual Blackgill species itself. Historical catches favor fixed gear in any time frame one wishes to choose. The entire 2000 to 2010 catch period produces a 52% fixed gear to 48% trawl result. Going back 20 years the landings from 1990 to 2010 favor fixed gear 63% to 37% (Interestingly exact opposite of what Amend. 21 produced). If one were to go back to the late 70's the percentages increase to 4 to 1 fixed gear over trawl.

I'm not commenting here to rip trawl or the IFQ program, I'm not about that and never have been. This is about what is right and fair and believe me the fixed gear sector is going to need every last pound of Blackgill it can get! Trip limits of 10,000 to 40,000 pounds of Slope rockfish, of which could have been all Blackgill, could well be dropping down to as low as 250 to 700 pounds or so. Those very low numbers may affect the directed Sablefish fishery just as a bycatch species. It is critically important to this fixed gear representative that we correct the allocation error per Amend. 21 for Blackgill rockfish and correct it in time for the start of the 2013 fishing season.

Thank you for your consideration of this very important emerging issue,
Gerry Richter
GAP fixed gear

Date: Fri, May 23, 2014 at 12:13 AM
Subject: F.9 Omnibus Regulation Change
To: "pfmc." <pfmc.comments@noaa.gov>
Cc: Bill James <Halibutbill@live.com>

Madame Chair members of the Council: My name is Bill James . I am the fishery consultant for PSLCFA out of Avila Beach California.

Our Open Access and Fixed gear commercial fishermen fishing Blackcod and Blackgill Rockfish are experiencing problems from large IQ out of state vessels fishing the ocean waters front Point Lopez to Point Conception. They are saturating the fishing grounds with 200 to 500 pots per vessel. These boats occupy the area for 3 to 4 weeks at a time and then leave trucking their fish back north. For at least a month after their visit our vessels cannot catch enough fish to make it worthwhile.

What is happening I believe is in violation of quite a few National Standards of the Magnuson Stevens Fishery Conservation and Management Act. and many of the objectives in the Pacific Coast Groundfish Management Plan.

Please develop some regulations that makes it a more level playing field. Thank you, Bill James

Subject: PFMC June 2014 meeting comments
To: "pfmc.comments@noaa.gov" <pfmc.comments@noaa.gov>

Dear Madam Chair and Council members,

It has been brought to our attention that there has been concern about the status of Conception area sablefish. We are part of about 40 longline permit holders who call this area home, and southern sablefish are a very important component of our livelihoods as groundfish fishermen in California. We are concerned about the new concentrations of intense single species fishing effort by large, out of town, trap vessels, fishing trawl IFQ close to our home ports that now threatens an existing stable LEP sector. Most of us fish in boats less than 40 feet in length with hand baited artisanal longline gear. We are proud, providing fresh sablefish and other groundfish to California residents for over three decades. Large vessels are now targeting Conception area sablefish in traditional fishing areas of our small longline operations. We are concerned about the extremely high rate of harvest, significant amounts of abandoned trap gear, and nearly exclusive targeting of the spawning female biomass by these large vessels fishing under the trawl IFQ program. We feel that these new operations are in stark contrast to the historic nature of the trawl fishery of Conception area sablefish, and changes should be considered to protect the livelihoods of our small town fishing fleets and the associated fishing infrastructure in our homeport communities.

Beginning in 2011, large trap vessels from as far as Alaska began flocking to central and southern California to take advantage of the gear switching provision of the new trawl IFQ program and excellent markets for frozen sablefish exported to Asia emerging in 2011. These vessels, each with hundreds of sablefish traps, began inundating our traditional fishing areas with massive amounts of trap gear, harvesting Conception area sablefish at staggering rates. Markets for exported frozen sablefish have fluctuated over the past few years, but they are again becoming stronger and we are concerned about massive effort by these large IFQ vessels displacing our small vessels that are limited to areas close to port. As recently as this year, landings close to 100,000 pounds in a single month have been relatively common by IFQ boats. These vessels far exceed historic levels of take by the trawl fleet in central California, which had catch limits exceeding 15,000 pounds in a single two month period. This fast extraction has had devastating effects on some of our local fishing grounds. Each line of traps set by these large vessels is one to three miles long and each vessel sets four to eight of these sets. These traps are often kept in the same areas, often close to our harbors, for several weeks or even months, forcing those of us in small vessels to venture farther from port to avoid losing our longlines by tangling with traps, putting us in more danger from inclement weather. This practice has effectively closed off many miles of prime fishing areas close to port for weeks or even months at a time. This fast rate of harvest also devastates the fishing in these areas, leading to declines in CPUE for many months after.

Each two mile set of trap gear lost off our coast results in another area small scale longliners cannot fish due to risk of snagged and lost lines. Traps are normally left unattended at sea while returning to port to unload fish, often in areas of high ship traffic. Miles of heavy rope with traps have been lost in Conception area sablefish habitat off our coasts every year since 2011, leaving more and more area littered with derelict traps, which make it impossible for us to return to fish these spots with our lighter longlines without losing them on the traps and rope. Although these big boats have considerable range and ability to withstand rough weather conditions, they have fished close to Morro Bay and Santa Barbara with very few exceptions, leaving lost gear in traditional fishing areas close to these ports. Requiring all traps to be retrieved before returning to port and considering trap limits for each vessel could help to reduce gear loss by the new IFQ trap fishery.

We are also deeply concerned about the nearly exclusive targeting of the large mature females by these vessels, which fetch a much higher price than averaged sized male sablefish. Traps are fished in deep water with large escape rings, which allow all but the large female fish to escape. The importance of the spawning females to the future of the sablefish fishery is made very clear in the 2011 stock assessment. We think it would be prudent to limit the maximum size of escape rings used in sablefish traps, and special consideration given to the change in sizes of sablefish harvested by the trawl fleet since the beginning of the IFQ program began, to prevent over harvest of the spawning female biomass by new trap boats.

Rates of sablefish harvest by the fixed gear trawl sector should reflect the historic nature of that fishery. Trap limits and requiring sablefish gear to be more closely attended to can help protect our local waters from derelict fishing gear, and the local fishing communities that rely on these fishing areas. These steps are being considered as limitations for considering allowing sablefish traps in Alaska by the North Pacific Fisheries Management Council, and we believe they deserve consideration for Conception area sablefish as well. In light of the 2011 stock assessment, the importance of the spawning female biomass for west coast sablefish cannot be overstated, and we believe the use of large escape rings to exclusively target large female sablefish is not acceptable for the long-term future of the fishery.

Many of us have grown up fishing these waters and we all feel a strong sense of stewardship for our local resources, as they allow us to provide for our families and at the same time provide an economic benefit to our local homeport fishing communities and associated infrastructure. Please consider our concerns for our fishery and the jobs and high quality seafood it provides for thousands of Californians.

Sincerely,

Owen Hackleman

Coastal Trollers Association

RECEIVED

APR 23 2014

PFMC

Created to enhance and protect an economically viable Washington salmon troll fishery.

April 18, 2014

Dr. Donald McIsaac
PFMC Executive Director
7700 NE Ambassador Place, Suite 101
Portland, Oregon 97220-1384

Dear Dr. McIsaac:

The Coastal Trollers Association welcomes the opportunity to speak on behalf of its members who have VMS units and take incidental ling cod and yellowtail rockfish while trolling for salmon. The CTA is against NOAA's request to change the ping rate from once per hour to four times per hour for salmon trollers for several reasons.

First, trollers have been against the VMS requirement since it was first required. At an Ad Hoc VMS Committee (VMSC) meeting in Portland chaired by Mark Cedergreen, two of our members spoke out that there were no rockfish conservation areas to stay out of. However, later, with the assistance of WDFW's Ms. Michelle Culver, trollers volunteered to refrain from fishing in a known yelloweye rockfish habitat. This Yelloweye RCA has been on the books for several years now.

Second, an email with WDFW's Enforcement Officer Mike Cenci confirmed that there have been no citations issued to trollers for trespassing into the RCA. Apparently, the VMS requirement and once per hour ping rate is working. In fact, the PFMC Enforcement Consultants wrote in their Supplemental EC Report for Agenda Item H.1.c dated March 2014, "the EC supports the list (of 8 gear types) , but recommends removing salmon troll gear from the 15 minute ping rate requirement." They concluded, "We do not believe this gear type requires any ping rate modification."

Given this history of cooperation by our troll fleet, we see this ping rate change to be an unnecessary financial burden. According to an April 12, 2013 mailing to All Licensed Washington Troll Fishers from the WDFW, "Salmon troll vessels with VMS may retain up to one pound of yellowtail rockfish for every two pounds of salmon landed, with a cumulative limit of 200 pounds per month... In addition to rockfish, salmon trollers may retain and land up to 1 lingcod per 15 Chinook per trip, plus 1 lingcod per trip, up to a limit of 10 lingcod..." With these severe restrictions on ling cod and yellowtail rockfish and given the prices paid to fishermen at the dock, it may be difficult for trollers to maintain a profit given the ping rate hike. That rate hike is estimated to be as little as $25 more per month to as much as $129. per month, depending on the service provider (as described in the NMFS OLE Report for Agenda Item H.1.b, dated March 2014). This ping rate action may force those with VMS on board to unplug them.

Finally, others support our request to be excluded besides the PFMC **Enforcement Consultants**. The **Salmon Advisory Subpanel** wrote in their Supplemental SAS Report for Agenda Item H.1.c dated March 2014, "The SAS requests that the Council exempt open access salmon troll vessels from the requirement to increase the ping rate from one hour intervals to a 15 minute ping rate. Regarding all 8 gear types, the **Groundfish Advisory Subpanel** Supplemental GAP Report for Agenda Item H.1.c dated March 2014 concludes, "This matter is strictly an issue of an increased financial burden for what is perceived as a retaliatory action. Further, other options are available that have not fully been considered for an environment in which the goal should be compliance, not conviction." And, leaders of the **Coastal Trollers Association** and the **Washington Trollers Association** gave public testimony at the Westport meeting held March 24th asking for trollers to be exempted. Even the conservative organization **Oceana**, represented by Ben Enticknap, recommended an exemption for trollers in a Tuesday, March 11th public comment before the Council.

If NOAA is truly interested in reducing bycatch in our fisheries, we would hope to see regulations that aid us in that goal, not make it more economically restrictive. We join with others and ask that NOAA's ping rate request be amended to exempt salmon troll from their list of eight gear types.

Ms. Dorothy: Lowman: Council Chair:
Mr. Frank Lockhart
Groundfish Program Manager:
Sustainable Fisheries Division:

RE: WHITING FAIR START WITH OTHER SECTORS

Dear Dorothy and Frank,

I feel the need to express my great disappointment in the bureaucratic nonsense of the National Marine Fisheries Service (NMFS) and Pacific Fishery Management Council (PFMC) that allows two sectors, Catcher Processors(CP) and Mother ships(MS), to get an early start on the Pacific Whiting season, while making the third sector, Shore side(SS) Processors, wait.

Ocean Gold Seafood's, Inc., and her vessels, are being denied access due to the fact that the CP and MS are allowed to scoop up "their" allocations and have what appears to be an entitlement to early markets which, in turn, gives them an economic advantage. SS Processors are penalized by being forced to sit and wait on the sidelines an additional month.

What is the fairness in this? Why does this process feel the need to punish and/or jeopardize our jobs and families? The Pacific Whiting season is just as important to us, our employees, and the community that we support. Does your agency believe that SS jobs and production are less important than that of CP and MS? How can you just sit there and allow the CP and MS to camp right on our doorstep, just off of Westport, WA and Newport, OR, and let them fish, while we are forced to wait for permission from "The Man" to make a living? Either your agency is blind, or have not given any thought to the lives and communities it places in jeopardy.

The agency always keeps coming back to the same old line, "We don't have funding to do that…", and continues to allow other trailing amendments to take priority. Seriously? How hard can it be to write a letter, put it in for public comment, and make it official? The agency seems more concerned about chafing gear than coastal jobs. What is clear to us is that the SS Processors are being stifled, and that this is economic exclusion.

Our jobs have to wait until the CP and the MS fill their bellies, and then run off to Alaska. Meanwhile, while we are waiting, the Pacific Whiting move further up the edge and into the higher by-catch zones. This is unfair.

In the Bering Sea, all sectors of the Pollock fisheries start both the “A” and “B” seasons at the same time. It seems to work well for them. All sectors are treated equally, and have equal access to the same markets. This is all we are asking for.

This one month delay excludes us in the early Pacific Whiting marketplace, and is a relic of the pre IQ fishery. The old regime was driven by the offshore sector that clearly receive an economic advantage, and you continue to let it happen, even though we are in a IQ fishery. It is very upsetting to watch this, year after year.

The bureaucratic circus puts the SS Fisheries on a lower rung of the economic ladder. With AIS now available on the net, our crews pays attention to vessel movement. Our employees come in, having seen that the Whiting season has started and ask when work begins, we have to explain to them that the government gave the offshore sector a month head start again this year, and we will have to wait.

Do you have any idea how it feels to tell someone you can’t work, strictly because some official agency feels that you’re not important enough? That other participants in this common fishery get favorable treatment because they are more astute in the council process?

We at Ocean Gold Seafood’s, Inc., want our employees to work. To do that, we need product for our employees to process. During the typical month of Pacific Whiting production, Ocean Gold Seafood’s, Inc., will have a payroll of $1,300,000 to $1,500,000, which goes directly back into our communities. The agency must understand that we need a fair start date in common with the other sectors to be competitive.

We are asking for a fair start.

We need a fair and even playing field.

Sincerely,

Greg Shaughnessy
General Manager
Ocean Gold Seafood’s, Inc.

Pacific Fishery Management Council
7700 NE Ambassador Pl., Suite 101
Portland, Oregon 97220-1384

Madame Chair and Council,

This is a letter requesting an amendment to Table 2 in the Federal Registry. Specifically, to amend the trip limits for shallow and deeper near shore species to allow more than one State issued Near Shore or Deeper Near Shore permit holder to make landings on the same vessel. I propose NMFS add to Table 2 a section that states that vessels with more than one State issued Near-Shore Permit aboard may retain twice the limit set by NMFS.

I want to clarify that in California the Near Shore and Deeper Near Shore species are retained only through State issued permits that are issued to individual licensees and that trip landings are allocated to these individual permit numbers, not to the fishing vessels. This is different from the Federal Limited Entry permits, which are registered to the fishing vessel with the associated vessel based cumulative trip limits. Federal LE permits do not allow retention of the Near Shore and Deeper Near shore species of rockfish in California but because these species are managed by the NMFS they are subject to the vessel based cumulative trip limits detailed in Table 2. Because Table 2 refers only to vessels, it doesn't account for fishermen who share a vessel but possess individual and separate Near Shore or Deeper Near shore permits. This is the issue that we are seeking to address with an amendment to Table 2.

My brother and I, along with many other partnered fishermen in California, are being greatly affected by this aspect of Table 2. We are partners in our fishing business and co-owners of our vessel, and we both possess State issued Near Shore permits. Currently we cannot land our individual Sebaste quotas on our boat because of the vessel based cumulative trip limit specification in Table 2. The only way for each of us to retain our Sebaste quota would be to buy another vessel. A new vessel along with the slip fees, VMS, and added maintenance and fuel costs is not financially feasible or ecologically responsible. The Sebaste allotment is only 600 to 1,000 pounds of fish over a two-month period, this is not worth the costs of obtaining another vessel but does impact our ability to make a living as commercial fishermen in the Near Shore and Deeper Near Shore fishery. We have invested in these permits and should be able to fully utilize them as they are intended.

I respectfully propose that NMFS add a section to Table 2 that states that vessels with more than one State issued Near Shore or Deeper Near Shore permit holder aboard may retain twice the limit set by NMFS and listed in Table 2.

Thank you,
Jason Robinson

Pacific Fisheries Management Council
7700 NE Ambassador Pl., Suite 101
Portland, Oregon 97220-1384

Madame Chair and Council,

This letter is regarding the "VMS enhancement" proposal by the Office of Law Enforcement to increase the VMS "ping rate" from once hourly four times an hour. This proposal is unacceptable because it fails to achieve the enforcement goals of the OLE and negatively impacts west coast commercial fishermen.

This action will not achieve the OLE's goal of better monitoring GCAs. I agree that it is important that the OLE has all the tools necessary to monitor and enforce restricted fishing areas and I assert that they have more than adequate resources to do so. The OLE has NOAA research vessels, coast guard cutters, coast guard helicopters, CFW patrol boats, CFW spotter planes, drone aircrafts, and a real time GPS monitoring system (VMS) on every boat with the ability to transmit every couple minutes. The OLE already has the ability to increase the ping rate of any vessel at any time they choose.

I am knowledgeable about the details of the VMS situation because I was recently engaged in a court case with the OLE where VMS data was the entirety of the OLE's case. The ALJ court ruled in my favor and stated that VMS data alone did not prove incursion and that additional investigation and documentation was required. It is apparent that this proposal is a retaliatory action for the loss they suffered in the ALJ court as well as an effort to continue using VMS as sole evidence instead of following the ruling of the Justice to employ additional verification procedures.

This proposal will negatively impact the west coast fishing fleet because the cost of the increased rate will be charged to the commercial fishermen, who will gain nothing and have done nothing to incur an additional expense. The notion that the price increase is small is a bogus justification when there are hundreds of "small costs" that add up to a very high overhead in the commercial fishing industry. An increased ping rate on the VMS will also increase a vessels battery usage, decreasing the life of the batteries and costing the fisherman even more.

It is important to recognize that even though the OLE claims that an increased ping rate is crucial for enforcement of the GCAs, they do not suggest extending the program to the recreational fishing sector. Recreational fishermen, who go about unmonitored with no tracking or catch data, land 80% of the rockfish in Southern California. This selective law enforcement criminalizes commercial fishermen, who have zero incentive to break fishing laws. It shows that GCAs are directed primarily toward commercial fishermen, who are the vast minority; this is either a huge oversight in fisheries management or clear discrimination. Either way, this proposed increase in the VMS ping rate for commercial fishing vessels is absurd. This proposal will not help the OLE protect closed areas and it hurts commercial fishermen. The only winner will be the VMS service provider who stands to increase profit by 400%. I respectfully suggest that this proposal be dismissed.

Sincerely,
Jason Robinson

Agenda Item F.3 Omnibus and F.6 Fixed GearPublic Comment

Dear Chair Lowman and Council Members:

My husband , Bob Eder and I are owner/operators of the F/V Timmy Boy , based in Newport Oregon. We fish for sablefish under the LE Fixed Gear program, and also participate in the trawl IQ program, using fixed gear.

We are submitting this letter as public comment under two agenda items, as I have received varying guidance from NMFS and Council staff as to where this would best fit.

We would like to propose a rule change to 50 CFR 660, Subpart C, Section 660.12 (a) (11). This rule currently provides that it is a violation to fail to remove all fish from the vessel at landing (as defined in § 660.11) and prior to beginning a new fishing trip. "Land or Landing" is defined in the regulations as: "To begin transfer of fish, offloading fish, or to offload fish from any vessel. Once transfer of fish begins, all fish aboard the vessel are counted as part of the landing. "

Recently, we've received various interpretations as to how this rule is applied, depending on whether it is Fixed Gear Limited Entry Sablefish, or Trawl IQ Sablefish. It appears that if it is our trawl sablefish, it can be unloaded at 2 different locations, as long as they are both licensed first receivers. Conversely, it appears that if it is fixed gear sablefish, the rule is being interpreted to require we offload all our fish at one time, which, practically speaking, means at one location.

We'd like a rule change so that when we come in with a load of fixed gear sablefish, we can unload some to a buyer at a public hoist, for example, and then deliver the remainder to our main processor. Fish tickets , paper or in the future, electronic, would be written at both places for the amount sold, and the LE fixed gear permit numbers would be on the tickets so the fish is accounted for.

One of the reasons we'd like to do this is so we can potentially add value to our fish. We'd like to sell to an emerging live sablefish market, which does pay premium prices. We may also want to deliver fish across the dock and sell some of our fish to our own fish company for custom processing. In either event, the rule currently prohibits our ability to develop markets for our fixed gear fish, other than selling the entire load at one place for one set of prices.

A change in the rule as described above would provide for additional economic opportunity and development, to benefit the entire coast wide fixed gear fleet, and the public it serves.

Thank you for your consideration.

Sincerely,

Michele Longo Eder and Bob Eder

CONSIDERATION OF INSEASON ADJUSTMENTS

Management measures for groundfish are set by the Council with the general understanding that these measures will likely need to be adjusted within the biennium to attain, but not exceed, the annual catch limits (ACL). This agenda item will consider inseason adjustments to ongoing 2014 fisheries. Potential inseason adjustments include adjustments to Rockfish Conservation Area (RCA) boundaries and adjustments to commercial and recreational fishery catch limits. Adjustments are, in part, based on recent landings and the latest information from the West Coast Groundfish Observer Program. Public comment received by the public comment deadline is included in the reference materials.

At its April 2013 meeting, the Council considered the performance of the shorebased individual fishing quota fishery in 2011 and 2012 and the progress to date in 2013, and recommended a 100 fm shoreward boundary and 150 fm seaward boundary for Period 6 in 2013 throughout 2014 in the area 40°10' to 48°10' N. latitude. The RCA boundary adjustments were intended to provide greater access to target species while allowing the individual accountability afforded by the rationalized fishery to minimize bycatch of overfished species. At its September 2013 meeting, the Council reaffirmed action taken in April after reviewing the draft Environmental Assessment prepared by the National Marine Fisheries Service (NMFS) (Agenda Item G.6.b, Draft EA, September 2013), Advisory Body reports (Agenda Item G.6.b, Supplemental GMT Report, September 2013, Agenda Item G.6.b, Supplemental GAP Report, September 2013, and Agenda Item G.6.b, Supplemental EC Report, September 2013), and public comment.

On April 17, 2014, NMFS partially approved the Council-recommended RCA boundary adjustments (Agenda Item F.4.a, Attachment 1; Agenda Item F.4.a, Attachment 2; and Agenda Item F.4.a, Attachment 3). NMFS disapproved the Council recommendations in the area 40°10' N. latitude to 45°46' N. latitude, and, as such, the seaward boundary of the RCA is scheduled to remain 200 fm in Periods 2 through 5 and 200 fm modified in Periods 1 and 6. Under Agenda Item F.4, the Council should consider and discuss the NMFS letter and implementing regulations.

At the March 2014 meeting, the Council recommended that NMFS issue the maximum eligible 2013 surplus carryover (up to 10 percent) for all non-whiting species into 2014 shorebased individual fishing quota (IFQ) program. In light of a recent D.C. District court decision, NMFS decided not to issue surplus carryover for those species where the ACL is equal to the acceptable biological catch (ABC) (Agenda Item F.4.a, Attachment 4). Surplus carryover was issued for the 19 IFQ species/area categories for which the ABC is greater than the corresponding ACL. Under Agenda Item F.4, the Council should consider and discuss the NMFS letter regarding surplus carryover issuance.

Council Action:

1. **Consider information on the status of 2014 fisheries and adopt inseason adjustments, as necessary.**
2. **Consider and discuss the NMFS letter and implementing regulations for the trawl RCA boundaries.**
3. **Consider and discuss the NMFS letter regarding issuance of surplus carryover in 2014.**

Dorothy Lowman, Chair
Pacific Fisheries Management Council
7700 NE Ambassador Place, Suite 101
Portland, Oregon 97220-1384

RE: Council Recommendations for the Trawl Rockfish Conservation Area Configuration for 2013-2014 Groundfish Fisheries

Dear Chair Lowman:

This letter responds to the Pacific Fisheries Management Council's (Council) inseason transmittal letters dated on April 30, 2013, and September 30, 2013, recommending the shoreward boundary of the trawl rockfish conservation area (RCA) be moved from 75 to 100 fathoms year-round, and the seaward boundary of the trawl RCA be moved from 200 fathoms to 150 fathoms year-round, from the area 40° 10' to 48° 10' N. latitude.

The final rule associated with this action (79 FR 21639) adopts all Council recommendations with the exception of the seaward boundary area (between 40° 10' N. latitude and 45° 46' N. latitude), which will remain as status quo (i.e., closed). The final rule will allow fishermen significantly more access to the current trawl RCA than under existing regulations, and will increase year-round groundfish bottom trawl access to over 2,300 square miles of fishing grounds. Furthermore, additional refinements to the trawl RCA boundaries can still be made in the future. Our rationale for this decision follows.

The Council did not include any analysis of the seaward upper slope area between 40° 10' N. latitude and 45° 46' N. latitude (herein referred to as the identified area) in making their recommendations. Fishery management plans are required to describe and identify Essential Fish Habitat (EFH) and take measures to minimize adverse effects on EFH caused by fishing to the extent practicable (16 U.S.C. § 1853(7)). Logbook data analyzed in the Environmental Assessment (EA) associated with this rule demonstrate an absence of bottom trawling activities, both pink shrimp bottom trawling and groundfish bottom trawling since September 2004, providing a decade in which habitat has had a greater chance to recover from potentially adverse impacts. NMFS analysis included in the EA demonstrated that the identified area is in a more recovered state than the adjacent core RCA area that was not recommended for opening. In NMFS's view, the Council did not sufficiently acknowledge or contribute additional analysis to minimize the potential for adverse impacts on the identified area as compared to the other recommended areas, and did not provide sufficient rationale when they made their initial recommendation at the

2013 April Council meeting, nor when they reaffirmed their recommendation at the 2013 September Council meeting. At this time, NMFS concludes that allowing trawling in the identified area is likely to have adverse impacts on some of the bottom substrate.

Further, to address the "practicable" elements of section 303(a)(7) of the Magnuson Stevens Act, there is not sufficient information at this time to conclude that opening the identified area would have a substantial enough beneficial economic impact for the groundfish bottom trawl fleet to outweigh the potential adverse impacts on EFH. At the September 2013 Council meeting, industry representatives expressed a desire to use bottom trawl gear in the identified area, but did not demonstrate a sufficient need to fish in the identified area using groundfish bottom trawl gear. Furthermore, during public comment industry representatives stated that access to the identified area is desirable, but not crucial to the industry in light of the other areas that would be opened. NMFS also received comments from environmental organizations on the proposed rule and draft EA, who asserted that an Environmental Impact Statement (EIS) would be required before NMFS could open this area and that the rule as proposed called into question whether the Council and NMFS were meeting their duty to minimize adverse effects on EFH caused by fishing to the extent practicable.

As noted above, the Council and NMFS must minimize adverse effects of fishing to the extent practicable on EFH. NMFS believes opening the identified area could affect EFH in a manner that is more than minimal and not temporary in nature. Therefore, we conclude that keeping the identified area closed, at this time, minimizes to the extent practicable adverse effects on this habitat caused by bottom trawl fishing.

The Council continues to have the ability to refine the RCA boundaries, including the identified area, provided the record concerns reflected above are considered and adequately addressed.

Should your staff have any questions regarding NMFS's decision on this matter, please contact me at your convenience.

Sincerely,

Robert Turner for

William W. Stelle, Jr.
Regional Administrator

cc: Dr. D.O. McIsaac

Federal Register / Vol. 79, No. 74 / Thursday, April 17, 2014 / Rules and Regulations 21639

PART 622—FISHERIES OF THE CARIBBEAN, GULF, AND SOUTH ATLANTIC

■ 1. The authority citation for part 622 continues to read as follows:

Authority: 16 U.S.C. 1801 *et seq.*

■ 2. In § 622.193, paragraph (h) is suspended and paragraphs (z) and (aa) are added to read as follows:

§ 622.193 Annual catch limits (ACLs), annual catch targets (ACTs), and accountability measures (AMs).

* * * * *

(z) *Deep-water complex (including yellowedge grouper, silk snapper, misty grouper, queen snapper, sand tilefish, black snapper, and blackfin snapper)*—(1) *Commercial sector*—(i) If commercial landings for the deep-water complex, as estimated by the SRD, reach or are projected to reach the commercial ACL of 60,371 lb (27,384 kg), round weight, the AA will file a notification with the Office of the Federal Register to close the commercial sector for this complex for the remainder of the fishing year. On and after the effective date of such a notification, all sale or purchase of deep-water complex species is prohibited and harvest or possession of these species in or from the South Atlantic EEZ is limited to the bag and possession limit. This bag and possession limit applies in the South Atlantic on board a vessel for which a valid Federal commercial or charter vessel/headboat permit for South Atlantic snapper-grouper has been issued, without regard to where such species were harvested, *i.e.*, in state or Federal waters.

(ii) If commercial landings exceed the ACL, and at least one of the species in the deep-water complex is overfished, based on the most recent Status of U.S. Fisheries Report to Congress, the AA will file a notification with the Office of the Federal Register, at or near the beginning of the following fishing year to reduce the ACL for that following year by the amount of the overage in the prior fishing year.

(2) *Recreational sector.* If recreational landings for the deep-water complex, as estimated by the SRD, exceed the recreational ACL of 19,313 lb (8,760 kg), round weight, then during the following fishing year, recreational landings will be monitored for a persistence in increased landings and, if necessary, the AA will file a notification with the Office of the Federal Register, to reduce the length of the following recreational fishing season by the amount necessary to ensure recreational landings do not exceed the recreational ACL in the following fishing year. However, the length of the recreational season will also not be reduced during the following fishing year if the RA determines, using the best scientific information available, that a reduction in the length of the following fishing season is unnecessary.

(aa) *Blueline tilefish*—(1) *Commercial sector.* If commercial landings for the blueline tilefish, as estimated by the SRD, reach or are projected to reach the commercial ACL of 112,207 lb (50,896 kg), round weight, the AA will file a notification with the Office of the Federal Register to close the commercial sector for the remainder of the fishing year. On and after the effective date of such a notification, all sale or purchase of blueline tilefish is prohibited and harvest or possession of blueline tilefish in or from the South Atlantic EEZ is limited to the bag and possession limit. This bag and possession limit applies in the South Atlantic on board a vessel for which a valid Federal commercial or charter vessel/headboat permit for South Atlantic snapper-grouper has been issued, without regard to where such species were harvested, *i.e.*, in state or Federal waters.

(2) *Recreational sector.* If recreational landings of blueline tilefish, as estimated by the SRD, reach or are projected to reach the recreational ACL of 111,893 lb (50,754 kg), round weight, then the AA will file a notification with the Office of the Federal Register to close the recreational sector for blueline tilefish for the remainder of the fishing year. On and after the effective date of such notification, the bag and possession limit of blueline tilefish in or from the South Atlantic EEZ is zero. This bag and possession limit also applies in the South Atlantic on board a vessel for which a valid Federal commercial or charter vessel/headboat permit for South Atlantic snapper-grouper has been issued, without regard to where such species were harvested, *i.e.*, in state or Federal waters.

Fisheries off West Coast States; Pacific Coast Groundfish Fishery Management Plan; Commercial Groundfish Fishery Management Measures; Rockfish Conservation Area Boundaries for Vessels Using Bottom Trawl Gear

AGENCY: National Marine Fisheries Service (NMFS), National Oceanic and Atmospheric Administration (NOAA), Commerce.

ACTION: Final rule.

SUMMARY: This final rule will implement revisions to the boundaries of the Rockfish Conservation Area (RCA) that is currently closed to vessels fishing groundfish with bottom trawl gear. This rule will affect the limited entry bottom trawl sector managed under the Pacific Coast Groundfish Fishery Management Plan (FMP) by liberalizing RCA boundaries to improve access to target species.

DATES: Effective on April 17, 2014.

ADDRESSES: NMFS prepared a Final Regulatory Flexibility Analysis (FRFA), which is summarized in the Classification section of this final rule. NMFS also prepared an Initial Regulatory Flexibility Analysis (IRFA) for the proposed rule. Copies of the IRFA, FRFA the Small Entity Compliance Guide, and the Environmental Assessment (EA) NMFS prepared for this action are available from the NMFS West Coast Regional Office: William W. Stelle, Jr., Regional Administrator, West Coast Region, NMFS, 7600 Sand Point Way NE., Seattle, WA 98115–0070; Attn: Colby Brady. This final rule also is accessible via the Internet at the Federal eRulemaking portal at *http://www.regulations.gov*, identified by NOAA–NMFS–2013–0134, or at the Office of the Federal Register Web site at *http://www.access.gpo.gov.* Background information and documents, including electronic copies of the Final Regulatory Flexibility Analysis (FRFA) prepared for this action may are available at the NMFS West Coast Region Web site at *http://www.westcoast.fisheries.noaa.gov/fisheries/management.html* and at the Council's Web site at *http://www.pcouncil.org.*

SUPPLEMENTARY INFORMATION:

Background

Since 2002 NMFS has used large-scale, depth-based closures to reduce catch of overfished groundfish, while still allowing the harvest of healthy stocks to the extent possible. RCAs are gear specific closures, and apply to vessels that take and retain groundfish species. Through this final rule, NMFS is changing portions of the boundaries defining the RCA that is closed to vessels fishing for groundfish with bottom trawl gear, or the "trawl RCA." This rule will not change how the trawl RCA applies to vessels fishing for groundfish using bottom trawl gear; rather, it will only change the boundaries of the trawl RCA.

This final rule implements the RCA boundary modifications as recommend by the Pacific Fishery Management Council (Council), and as proposed at 78 FR 56641 (September 13, 2013), with the exception of the seaward boundary change between 45°46′ N. lat. and 40°10′ N. lat. NMFS originally proposed moving the seaward boundary line between 45°46′ N. lat. and 40°10′ N. lat. from a line approximating 200 fathoms (fm) (366-m) to a line approximating 150 fm (274-m), during periods 1–6 (note that the "modified 200 fm (366-m)" line, which is a version of the 200 fm (366-m) line modified to increase access to stocks such as petrale sole, is currently in place in periods 1 and 6). However, after considering comments received on the proposed rule and the record as a whole, NMFS has determined that there is an insufficient basis to proceed with the seaward boundary change between 45°46′ N. lat. and 40°10′ N. lat. prior to the conclusion of the Council's groundfish Essential Fish Habitat (EFH) review. Therefore, as explained more fully below, this rule maintains the seaward trawl RCA boundary between 45°46′ N. lat. and 40°10′ N. lat. as currently established through the 2013–2014 harvest specifications and management measures. 78 FR 580 (January 3, 2013). The remaining boundary changes are implemented as proposed.

A detailed description of the trawl RCA boundaries that NMFS proposed, and the alternative boundaries that NMFS considered in the EA, can be found in the proposed rule 78 FR 56641 (September 13, 2013), and in the tables below. The changes from the proposed rule are discussed more fully in the section titled "Changes from Proposed Rule."

Table 1: Status Quo Trawl RCA Boundaries (48°10' N. latitude to 40°10' N. latitude).

Changes From the Proposed Rule

As mentioned above, the only change from the proposed rule is maintaining the status quo seaward boundary line between 40°10′ N. latitude to 45°46′ N. latitude. This final rule implements trawl RCA boundaries as follows, and as reflected in table 4:

- Shoreward 100 fm (183-m)(year-round) between 40°10′ N. latitude to 48°10′ N. latitude, and;
- Seaward 150 fm (274-m)(year-round) north of 45°46′ N. latitude to 48°10′ N. latitude, and;
- Seaward 200 fm (366-m) between 40°10′ N. latitude to 45°46′ N. latitude during periods 2–5, and modified 200 fm (366-m) in periods 1 and 6 (i.e., status quo).

Table 4: RCA boundaries implemented through this final rule.

	JAN-FEB	MAR-APR	MAY-JUN	JUL-AUG	SEP-OCT	NOV-DEC
48°10' N. lat. - 45°46' N. lat.	100 fm line- 150 fm line					
45°46' N. lat. - 40°10' N. lat.	Shoreward 100 fm line (Seaward line below)					
45°46' N. lat. - 40°10' N. lat.	Seaward modified 200 fm line	Seaward 200 fm line				Seaward modified 200 fm line

As described in the proposed rule, in addition to the Council recommended boundaries, NMFS considered and requested comments on alternative boundaries that were somewhat different from what the Council recommended in April 2013. The alternative trawl RCA boundaries would have been the same as the Council's recommended trawl RCA boundaries, except that they would have kept closed the area between the boundary line approximating the 150 fm (274-m) depth contour and the boundary line approximating the modified 200 fm (366-m) depth contour off Southern Oregon and Northern California (between 40°10′ N. latitude to 45°46′ N. latitude); this area has been largely closed to groundfish bottom trawling since 2004 and would have been opened under the initial recommendations of the Council from its April 2013 meeting.

At the Council's September 12–17, 2013 meeting in Boise, Idaho, NMFS consulted with the Council and provided additional information from the draft EA regarding the alternative boundaries. After considering the information NMFS presented, reports from the Council's advisory bodies, and public comment, the Council reaffirmed its recommendation to modify the trawl RCA boundaries as originally proposed.

After reviewing public comment on the proposed rule, information being developed through the Council's groundfish EFH review, the Council's recommendations, and the EA for this action, NMFS has determined that there is an insufficient record to conclude that the seaward boundary modification between 45°46′ N. lat. and 40°10′ N. lat., as originally proposed, minimizes adverse effects on groundfish EFH caused by fishing to the extent practicable. Therefore, NMFS is not implementing that seaward boundary change at this time.

NMFS and the Council initially established trawl RCAs to minimize catch of overfished species while still allowing the harvest of target stocks to the extent possible. Despite the fact that the trawl RCAs were not established to serve as habitat protection, the seaward areas between 45°46′ N. lat. and 40°10′ N. lat.. between the 150 fm (274-m) and modified 200 fm (366-m) lines have largely been closed since 2004. The EA for this action indicates that this is the only large-scale area that would be opened under the originally proposed boundaries where benthic habitats may have, to some extent, recovered from previous groundfish bottom trawling impacts.

The Council's ongoing groundfish EFH review will likely address whether any changes to EFH designations or measures to minimize adverse effects to the extent practicable are warranted. This includes consideration of whether areas currently closed year-round to groundfish bottom trawling by the RCAs should receive additional protection through management measures designed to minimize to the extent practicable adverse effects on groundfish EFH caused by fishing. During the public comment period for the proposed rule, it became evident that some of the groundfish EFH proposals that may be considered by the Council during its review include proposals for new EFH conservation areas within the portion of the RCA that has essentially been closed to groundfish bottom trawling year-round since 2004. In light of that information, opening year-round closed areas to groundfish bottom trawling now, before the merits of those proposals have been considered and additional progress has been made on the groundfish EFH review, is premature. This final rule will only increase year-round access to areas that are already open to bottom trawling at some times during the year. NMFS and the Council have yet to determine whether groundfish EFH changes are warranted or practicable, but at its November 2013 and March 2014 meetings, the Council indicated its intent to continue with the EFH review process.

This final rule will increase year-round groundfish bottom trawl access to approximately 2,389 square miles of fishing grounds in a fishery where participants are motivated by Individual Fishing Quota (IFQ) to keep bycatch of overfished species low, irrespective of trawl RCA boundaries. The increased access may enable higher attainment of available quota pounds for several valuable species that are currently not fully harvested, while still protecting overfished rockfish species.

The trawl RCA boundaries being implemented are expected to have a favorable economic impact on groundfish fishing vessels and for businesses and ports where groundfish are landed. The benefits of not opening the upper slope area between 45°46′ N. lat. and 40°10′ N. lat., compared to the majority of areas that will be opened are unknown at this time. Accordingly, the potential cost and safety benefits and the increased access to target stocks on the slope would be somewhat reduced as compared to the proposed boundaries. However, it would still be an overall improvement compared to not making any changes.

Finally, NMFS notes that at the Council's September 2013 meeting several industry groups and environmental nongovernmental organizations submitted a joint letter indicating their intent to collaborate on long term RCA proposals (Agenda Item G.9.d, Supplemental Public Comment 2). That effort, coordinated with the ongoing EFH review, could provide one option for considering the catch control aspects of RCAs along with the habitat aspects, potentially yielding increased access to fishing grounds while continuing to protect areas with extremely sensitive habitat or unacceptably high bycatch risks.

Comments and Responses

NMFS solicited public comment on the trawl RCA proposed rule (78 FR 56641, September 13, 2013). The comment period ended October 15, 2013. NMFS received five letters of comments on the proposed rule submitted by individuals or organizations.

Comment 1: Bottom trawl gear should be declared illegal. Trawl gear exacerbates the problem of whales and other large ocean fish becoming entangled in lines. Instead of opening the trawl RCAs, NMFS should consider expanding them.

Response: This rule does not affect the types bottom trawl gear allowed in the Pacific coast groundfish fishery, it only affects where vessels may fish with that gear. NMFS disagrees with the commenter that bottom trawl gear should be declared illegal. Bottom trawl gear is particularly efficient at targeting high volumes of species such as various flatfish (e.g., dover sole, English sole), roundfish such as Pacific cod, and other healthy bottom dwelling species such as thornyhead species; all of which are more inefficiently harvested with other groundfish gears. Therefore, groundfish bottom trawl gear can offer substantial benefits to the Nation in terms of providing consistent healthy protein supply and economic benefits when carefully managed. In addition, entanglements with marine mammals or other large ocean fish are comparatively rare in the groundfish bottom trawl fishery. For example, the groundfish bottom trawl fishery is considered a Category III fishery under the Marine Mammal Protection Act, indicating a remote likelihood of or no known serious injuries or mortalities to marine mammals. *See* 78 FR 73477 (December 6, 2013), which may have been updated prior to publication of this final rule.

With respect to expanding RCAs, NMFS notes that expansion of trawl RCAs continues to be an option available to the Council and NMFS through inseason modifications to the Code of Federal Regulations if needed. However, the purpose of this rule includes increasing access to target stocks, not reducing access.

Comment 2: The rule as proposed (Alternative 1) provides increased access to target stocks and better achieves optimum yield, consistent with National Standard 1 of the Magnuson Stevens Fishery Conservation and Management Act (MSA). The rule as proposed will provide vessels opportunities seaward of the RCAs to catch target species, primarily Dover Sole.

Response: NMFS agrees that the Council's recommendation as contained in the proposed rule would provide IFQ vessels fishing with bottom trawl gear increased access to target species catch, including Dover sole. However, even in the most uninhibited regulatory scenarios, attainment of all groundfish ACLs is affected by natural inter-annual ecosystem changes, market priorities, and other business realities. This final rule will still allow some increased opportunities seaward of the RCA North of 45°46′ N. latitude, will liberalize all of the shoreward RCA boundaries as recommended by the Council, and is consistent with National Standard 1. The trawl RCA boundaries being implemented are expected to have a favorable economic impact on groundfish fishing vessels and for businesses and ports where groundfish are landed. Moreover, additional refinements of RCA boundaries can still occur once habitat and other aspects associated with opening long-term RCA closures have been addressed.

Comment 3: Under the IFQ program, the Pacific groundfish trawl fishery operates with enhanced monitoring and individual accountability. Bycatch of overfished species and discard of target species has decreased dramatically from pre-IFQ years, as noted by NMFS own scientists. Therefore the boundaries as proposed in the rule will not create problems with increased catch of overfished species. The risk of exceeding bycatch of overfished species is minimal given the draft EA results and the IFQ program. The chances of an overfished species "lightning strike" are slim to none, as evidenced by NMFS' trawl surveys, which fish in these areas and presumably do not try to avoid overfished species. If NMFS believes the IFQ system has not been responsible for reducing bycatch, then NMFS must immediately direct the Council to end the IFQ program.

Response: NMFS agrees with the commenter that the IFQ program has been very effective at reducing bycatch of some overfished species. NMFS also agrees that increased bycatch of overfished species as a result of this rule, either as proposed or as implemented, is unlikely to result in exceeding annual catch limits. However, NMFS notes that at some point a large unanticipated tow of overfished species may occur, and management measures are in place for action should the Council and NMFS need to respond. Regarding NMFS' trawl surveys, although those vessels are not actively trying to avoid certain rockfish species, and survey activities have not resulted in high overfished species catch events that would threaten continued commercial activities, the scientific surveys have dramatically different aims than that of commercial vessels. Trawl surveys typically use 15 minute tows, while commercial bottom trawl gear deployments of 3–6 hours are common, and may even exceed that, in which case undesired bycatch events of overfished species may be more likely to occur.

Comment 4: There is no reason to keep RCA areas closed until habitat areas of particular concern (HAPC) are modified. When the Council established its first groundfish HAPC designations, it included areas that had been subjected to extensive trawling. If the Council determines through the groundfish EFH review that all or a portion of the RCA that will be opened under this rule deserves additional protection, the Council can still do that later through the existing process. In addition, the RCA being considered in the proposed rule has been subject to trawling prior to the establishment of the RCA and restrictions on trawl gear use. The area has also been subject to fishing by other bottom contact gears and research surveys. This is not virgin wilderness that has been and should remain untouched. NMFS should implement the rule as proposed. Furthermore, EFH concerns are not the intent of RCAs, which were implemented to reduce catch of rebuilding rockfish stocks, and EFH should not be considered when deciding whether to liberalize RCAs.

Response: NMFS agrees that benthic habitat that would be exposed to groundfish bottom trawling by opening the seaward areas between 45°46′ N. lat. and 40°10′ N. lat. has likely been impacted to some degree in the past. NMFS further acknowledges that prior to the closure of these areas, substantially less restrictive trawl gear regulations were in place. Historical bottom trawl gear types were more destructive to sensitive habitat than current bottom trawl gear restrictions. Current restrictions have reduced incentives to deploy bottom trawl gear in hard and mixed substrate areas, particularly high-relief hard pinnacle areas where the greatest abundance of sensitive biogenic habitat (corals and sponges) are found. NMFS also agrees that the seaward areas between 45°46′ N. lat. and 40°10′ N. lat. have been subject to fishing by other gear types and some limited trawling activity by NMFS' scientific surveys.

Nevertheless, the seaward areas between 45°46′ N. lat. and 40°10′ N. lat., between the 150 fm (274-m) and modified 200 fm (366-m) line have largely been closed to groundfish bottom trawling since 2004, and the other gear types and survey activities have relatively lower impacts to benthic habitats. The EA indicates that this area is more likely than others to have recovered from the impacts of groundfish bottom trawling. In fact, this area may currently have greater conservation value than portions of the actual "core" RCA (between the 100 fm and 150 fm lines, 183-m and 274-m). That core RCA has been closed to groundfish bottom trawling since at least 2003, but some of the areas are currently impacted by pink shrimp bottom trawl gear, whereas the seaward areas between 45°46′ N. lat. and 40°10′ N. lat., between the 150 fm (274-m) and modified 200 fm (366-m) are not. The recovery estimates provided in the 2005 EFH Environmental Impact Statement and subsequent 2012 and 2013 EFH review reports (excluding coral and sponge regeneration/recovery time) support NMFS' conclusion that this area has had some opportunity to recover from trawling impacts.

NMFS agrees that the trawl RCAs were implemented primarily to reduce the catch of rebuilding rockfish stocks by closing off areas to bottom trawl activity where those species of concern were found in higher densities or where larger bycatch events had previously occurred. However, when long term closures such as the seaward area at issue have allowed for some level of habitat recovery, NMFS must take that into account.

While it is true that the Council and NMFS adopted EFH conservation areas through Amendment 19 encompassing habitat that had been previously been trawled, opening the seaward area between 45°46′ N. lat. and 40°10′ N. lat., between the 150 fm (274-m) and modified 200 fm (366-m) line now has the potential to adversely impact habitat that has partially recovered, prior to the Council considering whether additional protections are warranted. Doing so could negate some of the recovery that has occurred. At its November 2013 meeting, the Council decided to move forward with phase III of its groundfish EFH review after determining that there was sufficient new information to warrant continuing evaluation of its existing groundfish EFH designations. Liberalizing the seaward RCA boundary between 40°10′ N. latitude and 45°46′ N. latitude, between the 150 fm (274-m) and modified 200 fm (366-m), may ultimately be consistent with the Council's EFH responsibilities. This rulemaking did not address the question of whether any of the seaward areas between 45°46′ N. lat. and 40°10′ N. lat. and the 150 fm (274-m) and modified 200 fm (366-m) lines, should ultimately receive additional protection through management measures designed to minimize, to the extent practicable, adverse effects on EFH from fishing. It did, however, highlight that additional analysis of this area is needed. Prior to the completion of the phase III review of EFH proposals, or additional consideration of whether practicable measures exist that could minimize impacts of bottom trawling between 40°10′ N. latitude and 45°46′ N. latitude and the 150fm (274-m) and modified 200fm (366-m) RCA lines, NMFS believes there is an insufficient basis to open this year-round closed area to bottom trawling.

Comment 5: The proposed rule provides increased harvest opportunities consistent with National Standards 5, 7, and 8 by considering efficiency in the utilization of fishery resources, minimizing costs, and taking into account the importance of fishery resources to fishing communities. The costs for participating in the west coast groundfish fishery continue to increase with the pending 3 percent cost recovery fee, the annual 5 percent buyback loan payments, state landing taxes, observer costs, and the possible implementation of the adaptive management program that could reduce 10 percent of the available quota pounds. Harvesters need the access to fishing grounds allowed by the rule as proposed.

Response: NMFS is aware that fishermen have costs associated with the buyback repayment, state landing taxes, observer coverage, and cost recovery. However, participants in the IFQ program have already started realizing the benefits of the program even with these costs. Preliminary data from the mandatory economic data collection program compares data from 2009 and 2010 (pre-trawl rationalization) versus 2011 (post-trawl rationalization) (see Agenda Item F.2 from the Council's June 2013 meeting), and shows that when looking at net revenue, the fleet is still profitable even with increased costs (e.g., high fuel prices, observer costs). However, with only one year of data post-trawl rationalization, it is too early to make conclusions on the economic benefits of the program.

While buyback loan repayment is a cost to industry, the harvesters that remained and are now in the Shorebased IFQ program have benefitted from the buyback program. NMFS also understands that fishermen are petitioning Congress to approve legislation that would refinance the buyback loan, extending the term of the loan and capping the fee rate at three percent of ex-vessel value, down from five percent.

NMFS is evaluating whether electronic monitoring could reduce the cost of monitoring the fishery. With respect to the adaptive management program, it is unclear at this time how it will be structured or affect the fleet. Ultimately, this final rule will increase access to fishing grounds and is consistent with the National Standards.

Comment 6: The potential for gear conflicts resulting from liberalized RCAs was an issue raised at the Council's September 2013 meeting. However, fishing gears of various types are already in use throughout the area currently open to fishing with no indication that extensive gear conflicts are occurring. Allowing trawling in deeper water on the continental shelf out to 100 fathoms instead of the current 75 fathoms could actually reduce gear conflicts because there would be more area for vessels to operate.

Response: The Groundfish Advisory Subpanel and Groundfish Management Team considered the possibility of gear conflicts at the September 2013 Council meeting. By increasing the areas available to trawlers, including the deeper water on the continental shelf out to 100 fathoms, this final rule could potentially reduce concentration of gear between the trawl and fixed gear sectors in the areas where they currently overlap. Additionally, the shoreward boundary change could potentially reduce gear conflicts between crab and groundfish bottom trawl vessels. During public comment under this agenda item at the September Council meeting, trawl and fixed gear industry representatives commented and agreed with the above-mentioned assumptions. Any ancillary gear conflict consequences that might result from implementation of RCA boundary changes through this rule could likely be avoided through increased communications among vessels.

Comment 7: Alternative 2 in the EA falls short of providing meaningful access to healthy target species while the risks associated with both alternatives are virtually the same. The rule as proposed provides increased access to currently closed trawl RCA areas in a manner that allows trawl IFQ fishermen to continue to demonstrate the benefits of 100 percent accountability of catch and discards. Trawl RCAs are a relic of pre-IFQ management.

Response: NMFS agrees that trawl RCAs are to some extent a relic of pre-IFQ trawl fishery management, which depended largely on trip limits and area closures to control catch in the groundfish trawl fishery. On the other hand, RCAs can still serve as an additional tool for controlling catch in areas with unacceptably high bycatch risks. NMFS also agrees that increased access to currently closed trawl RCA areas allows trawl IFQ fishermen to continue to demonstrate the benefits of the program, including individual accountability of catch and discards.

However, NMFS disagrees that the trawl RCA boundaries implemented through this final rule fall short of providing meaningful access to healthy target species. This final rule provides approximately 2,389 square miles of additional year-round access to groundfish compared to taking no action (similar to Alternative 2 considered in the EA, which provide increased year-round access to approximately 2,600 square miles). This is still a meaningful increase in access to fishing grounds. Both the rule as proposed and the boundaries as implemented would provide more benefit than the no-action alternative. This increased access should provide greater access to healthy groundfish stocks, which could improve efforts to more fully attain harvest levels. The Council and NMFS can still consider additional modifications to trawl RCA boundaries in the future in manner that addresses the catch control aspects of RCAs along with the habitat aspects.

With respect to the risks associated with the different trawl RCA boundary configurations, NMFS notes that while the EA determined that the boundaries as proposed presented relatively little risk of greatly increased overfished species catch, the trawl RCA boundaries implemented through this final rule would not increase access beyond the seaward line of the current RCA between 45°46′ N. lat. and 40°10′ N. lat. Therefore, to the extent there are any increased impacts to overfished species by opening new fishing areas, they are expected to be lower in frequency and magnitude under this final rule, particularly for slope species, than under the proposed action.

Comment 8: NMFS should not implement the rule as proposed. The draft EA makes several erroneous assertions about past impacts to benthic habitat, arguing that the degraded baseline state of the benthic environment means that the impacts from opening the RCA to groundfish bottom trawling will be relatively lower. Illegal incursions into the RCA, fishing by other gears and fisheries, NMFS' trawl surveys, and pre-RCA trawling do not mean that the rule as proposed will have insignificant impacts. Most of these activities are relatively less harmful to benthic habitat, but trawl nets still bring up sponges and corals even in areas frequently trawled, as evidenced by NMFS West Coast Groundfish Observer Program (WCGOP) bycatch data.

Response: NMFS disagrees that prior impacts to benthic habitat in the RCAs are irrelevant to assessing the state of the affected environment and the types of impacts that could be anticipated from opening up areas to groundfish bottom trawling. The EA demonstrates that various activities have impacted benthic habitat in the past, including those activities mentioned by the commenter. NMFS agrees that fixed gear is generally ranked lower with respect to overall benthic habitat impacts when compared to bottom trawl gear. However, fixed gear is particularly adept at accessing some rocky areas such as hard/mixed rocky pinnacles with substantially less risk of damage to fishing gear, as compared to bottom trawl gear. Fixed gear impacts, in practice, can be greater in areas that bottom trawl vessels actively avoid or are considered untrawlable. NMFS also notes that although coral and sponges are present in trawlable habitat of all substrate types (soft, medium, hard), the magnitude of coral and sponges generally increases in hard areas that are untrawlable, and in which other fixed gear types are actively engaged in fishing activities.

Ultimately, recognizing the degree of previous and ongoing impacts to benthic habitat within the RCA boundaries under consideration contributed to NMFS' conclusion that the upper slope area should remain closed, at least until additional groundfish EFH consideration has occurred. The area between 40°10′ N. latitude and 45°46′ N. latitude and the 150fm (274-m) and modified 200fm (366-m) RCA lines has not been trawled in almost a decade by groundfish bottom trawl gear, and in practice is not trawled by pink shrimp trawl gear. As such, this area has at least partially recovered from the relatively more substantial trawl impacts, despite still being subjected to fixed gear effort and occasional research trawls or inadvertent incursions.

In addition, while intensive trawling from the 1970s through early 2000s likely did destroy a significant amount of biogenic habitat, NMFS agrees that any assumption that none remains would be unwarranted and that NMFS bottom trawl survey and WCGOP data show coral and sponge bycatch, even in areas of high fishing effort. Trawling effort is heterogeneously distributed, with some areas trawled repeatedly and others less often or in some cases not at all. Ultimately, NMFS concluded that the RCA boundaries implemented through this final rule will not significantly affect the quality of the human environment. All of the additional areas opened through this rule are currently subjected to groundfish bottom trawling at some point during the year. This rule would only change the boundaries to allow year-round access.

Comment 9: The proposed rule could have significant impacts on corals, sponges, and other marine life. Removal by bottom trawling of slow growing corals could cause long-term changes in associated megafauna, which provide shelter and food sources for juvenile fish and shellfish. Corals, sponges, and Pennantulacea (sea whips and sea pens) also create three-dimensional structures that form habitat for bottomfish, shellfish, invertebrates, and other marine life, and impacts by bottom trawling may impact fish stocks. Some corals may live in excess of 2,000 years, some sponges may be over 220 years old, and some mounds formed by sponges appear have been estimated to be between 9,000 to 125,000 years old. NMFS needs to consider impacts to biogenic habitat in conjunction with impacts to substrate. The impacts to ocean floor substrate and impacts to biogenic habitat such as corals and sponges may be different.

Response: NMFS agrees that corals, sponges, and Pennantulacea (sea whips and sea pens) have the potential to create three-dimensional structures that form habitat for marine life, and impacts by bottom trawling may have an impact on fish stocks. This was considered in the EFH synthesis review documents that informed the EA associated with this final rule. As the EA points out, recolonization and recovery rates and recovery times may be greater than 100 years for deep-sea corals. NMFS agrees that some corals may live in excess of 2,000 years, some sponges may be over 220 years old, and that some mounds formed by sponges appear to have been estimated to be between 9,000 to 125,000 years old. However, many of these habitats and mounds are particularly inaccessible to bottom trawl gear given current gear restrictions. In addition, all of the areas opened through this rule are currently subjected to groundfish bottom trawling at some point during the year.

NMFS agrees that impacts to ocean floor substrate and impacts to biogenic habitat, such as corals and sponges, may be different and that the physical environment of the seafloor is formed by the combination of invertebrates with sediment structures. NMFS fully considered the physical environment of the seafloor formed by the combination of invertebrates with sediment structures in the EA for this action. The recovery tables and other information provided by the EFH habitat synthesis review products are utilized in the EA, which considers impacts to biogenic habitat in conjunction with impacts to substrate types. Citing recovery times from those reviews, the EA specifically excludes structure-forming invertebrates in the recovery table, and qualifies the limitations of biogenic habitat recovery estimates regarding the available analysis. Although the recovery tables in the EA are mostly relevant to seafloor areas lacking biogenic habitat, impacts to biogenic habitat such as corals, sponges, and sea whips/pens are explained elsewhere in detail in the EA (as well as in the 2005 EFH EIS and recent EFH synthesis analysis review documents). NMFS notes that the majority of scientific peer-reviewed literature on biogenic habitat abundance suggests that the abundance of slow growing epibenthic coral and sponge fauna tends to be greater in mixed/hard and hard substrates, as opposed to soft sand and mud habitat. Soft sandy/mud habitat is estimated to comprise over 90 percent of groundfish habitat substrate within all RCA areas, including those that will remain closed after this final action. This rule would only change the boundaries to allow year-round access. NMFS disagrees that this rule will have significant impacts.

Comment 10: Trawl vessels do not avoid hard and mixed substrate sufficiently to mitigate impacts to areas with coral or sponge. The rule as proposed will allow trawling in areas with mixed and hard substrate and adversely impact corals and sponges.

Response: NMFS agrees that not all areas of hard and mixed substrate are untrawlable or actively avoided by vessels, and that trawling has the potential to impact corals and sponges when encountered. However, as the commenter acknowledged, at least some areas may be avoided due to potential negative impacts on trawl gear. Despite the fact that trawl vessels do tow over some trawlable smooth hard and mixed substrates, some high relief areas are considered untrawlable because of the potential for severe damage to trawl gear. These areas provide a financial and safety disincentive for vessels to engage in trawling, regardless of RCA configuration.

Comment 11: The proposed rule raises doubts about the adequacy of the existing measures to protect groundfish EFH habitat from the adverse effects caused by fishing to the extent practicable, as required by the MSA.

Response: As described earlier in the preamble to this final rule, after reviewing public comment on the proposed rule, information developed through the Council's groundfish EFH review, the Council's recommendations, and the EA for this action, NMFS has determined that additional consideration regarding the impacts of the seaward boundary modification on groundfish EFH between 45°46′ N. lat. and 40°10′ N. lat., between the 150 fm (274-m) and modified 200 fm (366-m) is warranted. Therefore, NMFS is not implementing that seaward boundary change at this time.

Comment 12: Changes to the RCA should be made through a comprehensive coastwide process in coordination with revisions to EFH.

Response: NMFS agrees that addressing changes to RCAs and revisions to EFH in a more coordinated and comprehensive manner could have some benefits. However, there are numerous procedural avenues available to the Council and NMFS that could accomplish these goals. As mentioned previously, at the Council's September 2013 meeting several industry groups and environmental nongovernmental organizations submitted a joint letter indicating their intent to collaborate on long term RCA proposals (Agenda Item G.9.d, Supplemental Public Comment 2). That effort, coordinated with the ongoing EFH review, could provide one option for considering the catch control aspects of RCAs along with the habitat aspects.

Classification

The NMFS Assistant Administrator has determined that this final rule is consistent with the Pacific Coast Groundfish FMP, other provisions of the MSA, and other applicable law. To the extent that the regulations in this final rule differ from what was deemed by the Council, NMFS invokes its independent authority under 16 U.S.C. 1855(d).

An Environmental Assessment (EA) was prepared for this action. The EA includes socio-economic information that was used to prepare the RIR and FRFA. A copy of the final EA is available online at *www.westcoast.fisheries.noaa.gov.*

NMFS finds good cause to waive the 30-day delay in effectiveness pursuant to 5 U.S.C. 553(d), so that this final rule may become effective April 17, 2014. This rule reduces regulatory restrictions by allowing trawl vessels access to areas previously closed to fishing at certain times during the year. Failure to waive the 30-day delayed effectiveness would result in missed opportunities for trawl vessels to increase profits by attempting to increase their catch of healthy fish stocks that are under harvested. Implementing this rule quickly will allow these additional fishing opportunities during the months of March and April that would otherwise be forgone. Moreover, this rule adds no requirements, duties, or obligations on the affected entities, and therefore they do not need time to modify their behavior to come into compliance with the rule. Accordingly, NMFS finds good cause to waive the delay in effectiveness.

A Regulatory Impact Review (RIR) was prepared on the action and is included as part of the final regulatory flexibility analysis (FRFA) on the regulatory changes. The FRFA and RIR describe the impact this rule will have on small entities. A description of the action, why it is being considered, and the legal basis for this action are contained at the beginning of this section in the preamble and in the **SUMMARY** section of the preamble. A copy of the FRFA is available from NMFS (see **ADDRESSES**) and a summary of the FRFA, per the requirements of 5 U.S.C. 603(a), follows:

The trawl RCA is an area is closed to vessels fishing groundfish with bottom trawl gear. This action would revises the bimonthly boundaries of the RCA that is closed to vessels fishing groundfish with bottom trawl gear. This rule affects the limited entry bottom trawl sector managed under the Pacific Coast Groundfish FMP. This RCA was designed to prevent the fleet from exceeding harvest quotas when fishing under trip limits. Since the implementation of the IFQ program, the industry has shown a remarkable ability to avoid bycatch. Therefore, the industry is seeking a reduction in the RCA area so that it can have a greater chance to fish more of their individual quotas.

NMFS considered three alternative RCA boundary configurations, as described above, and the RCA boundaries of Alternative 1 as modified in this final rule. The alternative considered were: The current trawl RCA boundaries for 2014 (no action), the Council recommended proposed trawl RCA boundaries between 48°10′ N. lat. and 40°10′ N. lat., (Alternative 1, Table 1), alternative trawl RCA boundaries between 48°10′ N. lat. and 40°10′ N. lat. added by NMFS (Alternative 2, Table 2), and the proposed trawl RCA boundaries between 48°10′ N. lat. and 40°10′ N. lat., as recommended by the Council in April 2013 with no seaward action between 45°46′ N. lat. and 40°10′ N. lat.

The amount of increased catch and reduced costs resulting from the proposed alternatives is not known due to limitations of the available data and models. However, the regulatory changes associated with Alternative 1, Alternative 2, and Alternative 1 as modified will have positive economic effects including reduced fuel, improved safety, and increased access to important target species. Overall, the most likely potential impacts are higher attainments of the trawl allocations than would be expected under the No-Action alternative. Alternative 1 as implemented in this final rule is slightly more restrictive than Alternative 2; Alternative 2 is more restrictive compared to the non-implemented Alternative 1; Alternative 2 opens some areas that have been intermittently closed, but not as much new areas as Alternative 1 as proposed would have done.

This rulemaking directly affects bottom trawlers participating in the IFQ fishery. To fish in the IFQ fishery, a vessel must have a vessel account. As part of this year's permit application processes for the non-tribal fisheries, applicants indicate if they are "small" business based on a review of the Small Business Administration (SBA) size criteria. These criteria have recently changed. On June 20, 2013, the SBA issued a final rule revising the small business size standards for several industries effective July 22, 2013 (78 FR 37398, June 20, 2013). The rule increased the size standard for Finfish Fishing from $ 4.0 to 19.0 million, Shellfish Fishing from $ 4.0 to 5.0 million, and Other Marine Fishing from $4.0 to 7.0 million (Id. at 37400-Table 1). Based on the new size standard ($19 million), NMFS reassessed those businesses considered large under the old size standard ($4 million) based on information provided by these companies under the NMFS Northwest Fisheries Science Center's (NWFSC) Economic Data Collection Program. After taking into account NWFSC economic data, NMFS permit and ownership information, PacFIN landings data for 2012, and affiliation between entities, NMFS estimates that there are 66 entities affected by these proposed regulations, of which 56 are "small" businesses. As noted below, these small entities are not negatively impacted by this rule.

There were no significant issues raised by the public comments in response to the IRFA. Several comments to the proposed rule had economic content (see especially Comments 2, 3, and 5 and associated responses of the Final Rule.) Based upon comments explained above in the preamble, NMFS is implementing Alternative 1 with the exception of the seaward boundary change between 45°46′ N. lat. and 40°10′ N. lat., to provide IFQ participants with the increased flexibility to attain underutilized target species.

This final rule will increase access to fishing grounds in a fishery where the individual accountability of the IFQ program has a three-year track record of providing strong incentives to keep bycatch of overfished species low, irrespective of trawl RCA boundaries. The changes to the trawl RCA boundaries would continue to refine groundfish fishery management measures to enable higher attainment of available quota pounds for several valuable species, while still protecting overfished species. The EA demonstrates that the upper slope area benthic habitat between 45°46′ N. latitude to 40°10′ N. latitude, 150 to 200 fm, which would be opened under the Council-preferred Alternative 1, may have experienced some recovery from the effects of bottom trawling. This area has been closed to bottom-trawl gear impacts for almost a decade. NMFS has determined that the area between 45°46′ N. latitude to 40°10′ N. latitude, from the 150 fm to modified 200 fm lines should remain closed pending completion of the groundfish EFH review or additional consideration of whether opening that area is consistent with minimizing the adverse effects on groundfish EFH caused by fishing to the extent practicable. However, this final rule will still increase year-round access to areas that are already open to bottom trawling at some times during the year. This rule opens up approximately 2,389 square miles of additional year-round access to the bottom trawl fleet compared to taking no action.

Accordingly, NMFS believes that this rule will have a positive impact on small entities and will not have significant adverse economic impacts on a substantial number of small entities.

This final rule was developed after meaningful collaboration, through the Council process, with the tribal representative on the Council.

No Federal rules have been identified that duplicate, overlap, or conflict with the final action. Public comment is hereby solicited, identifying such rules.

This rule has been determined to be not significant for purposes of Executive Order 12866.

List of Subjects in 50 CFR Part 660

Fisheries, Fishing, and Indian fisheries.

Dated: April 11, 2014.

Samuel D. Rauch III,

Deputy Assistant Administrator for Regulatory Programs, National Marine Fisheries Service.

For the reasons stated in the preamble, 50 CFR part 660 is amended as follows:

PART 660—FISHERIES OFF WEST COAST STATES

■ 1. The authority citation for part 660 continues to read as follows:

Authority: 16 U.S.C. 1801 *et seq.* and 16 U.S.C. 773 *et seq.*

■ 2. Table 1 (North) to part 660, subpart D, is revised to read as follows:

Table 1 (North) to Part 660, Subpart D – Limited Entry Trawl Rockfish Conservation Areas and Landing Allowances for non-IFQ Species and Pacific Whiting North of 40°10' N. Lat.

This table describes Rockfish Conservation Areas for vessels using groundfish trawl gear. This table describes incidental landing allowances for vessels registered to a Federal limited entry trawl permit and using groundfish trawl or groundfish non-trawl gears to harvest individual fishing quota (IFQ) species.

Other Limits and Requirements Apply – Read § 660.10 - § 660.399 before using this table 02012014

TABLE 1 (North)

		JAN-FEB	MAR-APR	MAY-JUN	JUL-AUG	SEP-OCT	NOV-DEC
	Rockfish Conservation Area (RCA)[1/]:						
1	North of 48°10' N. lat.	shore - modified[2/] 200 fm line[1/]	shore - 200 fm line[1/]	shore - 150 fm line[1/]		shore - 200 fm line[1/]	shore - modified[2/] 200 fm line[1/]
2	48°10' N. lat. - 45°16' N. lat.	100 fm line[1/] - 150 fm line[1/]					
3	45° 10' N. lat. - 40°10' N. lat.	Shoreward 100 fm line (Seaward line below)[1/]					
4	45° 10' N. lat. - 40°10' N. lat.	Seaward modified[2/] 200 fm line[1/]	Seaward 200 fm line[1/]				Seaward modified[2/] 200 fm line[1/]

Selective flatfish trawl gear is required shoreward of the RCA; all bottom trawl gear (large footrope, selective flatfish trawl, and small footrope trawl gear) is permitted seaward of the RCA. Large footrope and small footrope trawl gears (except for selective flatfish trawl gear) are prohibited shoreward of the RCA. Midwater trawl gear is permitted only for vessels participating in the primary whiting season. **Vessels fishing groundfish trawl quota pounds with groundfish non-trawl gears, under gear switching provisions at § 660.140, are subject to the limited entry groundfish trawl fishery landing allowances in this table, regardless of the type of fishing gear used. Vessels fishing groundfish trawl quota pounds with groundfish non-trawl gears, under gear switching provisions at § 660.140, are subject to the limited entry fixed gear non-trawl RCA, as described in Tables 1 (North) and 1 (South) to Part 660, Subpart E.**

See § 660.60, § 660.130, and § 660.140 for Additional Gear, Trip Limit, and Conservation Area Requirements and Restrictions. See §§ 660.70-660.74 and §§ 660.76-660.79 for Conservation Area Descriptions and Coordinates (including RCAs, YRCA, CCAs, Farallon Islands, Cordell Banks, and EFHCAs).

State trip limits and seasons may be more restrictive than federal trip limits, particularly in waters off Oregon and California.

		JAN-FEB	MAR-APR	MAY-JUN	JUL-AUG	SEP-OCT	NOV-DEC
3	**Minor nearshore rockfish & Black rockfish**	300 lb/ month					
4	**Whiting**						
5	midwater trawl	Before the primary whiting season: CLOSED. – During the primary season: mid-water trawl permitted in the RCA. See §660.131 for season and trip limit details. – After the primary whiting season: CLOSED.					
6	large & small footrope gear	Before the primary whiting season: 20,000 lb/trip. – During the primary season: 10,000 lb/trip. -- After the primary whiting season: 10,000 lb/trip.					
7	**Cabezon**						
8	North of 46°16' N. lat.	Unlimited					
9	46°16' N. lat. - 40°10' N. lat.	50 lb/ month					
10	**Shortbelly**	Unlimited					
11	**Spiny dogfish**	60,000 lb/ month					
12	**Longnose skate**	Unlimited					
13	**Other Fish[3/]**	Unlimited					

1/ The Rockfish Conservation Area is an area closed to fishing by particular gear types, bounded by lines specifically defined by latitude and longitude coordinates set out at §§ 660.71-660.74. This RCA is not defined by depth contours, and the boundary lines that define the RCA may close areas that are deeper or shallower than the depth contour. Vessels that are subject to the RCA restrictions may not fish in the RCA, or operate in the RCA for any purpose other than transiting.

2/ The "modified" fathom lines are modified to exclude certain petrale sole areas from the RCA.

3/ "Other fish" are defined at § 660.11 and include sharks (except spiny dogfish), skates (except longnose skate), ratfish, morids, grenadiers, and kelp greenling.

To convert pounds to kilograms, divide by 2.20462, the number of pounds in one kilogram.

FEDERAL COMMUNICATIONS COMMISSION

47 CFR Part 73

[MB Docket No. 05–263; RM–11269; DA 14–458]

Radio Broadcasting Services; Grants and Church Rock, New Mexico

AGENCY: Federal Communications Commission.

ACTION: Final rule; dismissal of petition for partial reconsideration.

SUMMARY: This document dismisses the Petition for Partial Reconsideration filed by Reynolds Technical Associates in response to the "Request to Dismiss." Reynolds Technical Associates states that it is no longer interested in pursuing the Petition for Partial Reconsideration, and it certifies that there is no agreement and no consideration received or promised in exchange for such withdrawal.

DATES: Effective May 13, 2014.

ADDRESSES: Federal Communications Commission, 445 12th Street SW., Washington, DC. 20554.

FOR FURTHER INFORMATION CONTACT: Rolanda F. Smith, Media Bureau, (202) 418–2700.

SUPPLEMENTARY INFORMATION: This is a summary of the Commission's *Memorandum Opinion and Order,* MB Docket No. 05–263, adopted April 3, 2014, and released April 4, 2014. The full text of this Commission decision is available for inspection and copying during normal business hours in the Commission's Reference Center 445 12th Street SW., Washington, DC 20554. The complete text of this decision may also be purchased from the Commission's duplicating contractor, Best Copy and Printing, Inc., 445 12th Street SW., Room CY–B402, Washington, DC 20554, telephone 1–800–378–3160 or *www.BCPIWEB.com.* This document is not subject to the Congressional Review Act. (The Commission is, therefore, not required to submit a copy of this *Memorandum Opinion and Order* to the General Accounting Office pursuant to the Congressional Review Act, *see* 5 U.S.C. 801(a)(1)(A), because the Petition for Partial Reconsideration was dismissed.

Federal Communications Commission.

Peter H. Doyle,

Chief, Audio Division, Media Bureau.

BILLING CODE 6712–01–P

DEPARTMENT OF COMMERCE

National Oceanic and Atmospheric Administration

50 CFR Part 660

[Docket No. 130808694–4378–03]

RIN 0648–BD37

Magnuson-Stevens Act Provisions; Fisheries off West Coast States; Pacific Coast Groundfish Fishery; Commercial Groundfish Fishery Management Measures; Rockfish Conservation Area Boundaries for Vessels Using Bottom Trawl Gear; Correction

AGENCY: National Marine Fisheries Service (NMFS), National Oceanic and Atmospheric Administration (NOAA), Commerce.

ACTION: Final rule; correcting amendment.

SUMMARY: This action contains coordinate corrections to the Rockfish

Conservation Area (RCA) boundary regulations that published in the **Federal Register** on April 17, 2014. This document corrects 2014 groundfish bottom trawl Rockfish Conservation Area boundary coordinates described in table 1 (North) that were inadvertently misreported in Rockfish Conservation Area Boundaries for Vessels Using Bottom Trawl Gear final rule.

DATES: This correcting amendment is effective May 13, 2014.

FOR FURTHER INFORMATION CONTACT: Colby Brady, 206–526–6117; *Colby.brady@noaa.gov.*

SUPPLEMENTARY INFORMATION:

Background

The 2013–2014 Biennial Specifications and Management Measures rule established the 2013–2014 harvest specifications and management measures for groundfish taken in the U.S. exclusive economic zone off the coasts of Washington, Oregon, and California consistent with the Magnuson-Stevens Fishery Conservation and Management Act (MSA) and the Pacific Coast Groundfish Fishery Management Plan (PCGFMP) (78 FR 580, January 3, 2013). Since 2002 NMFS has used large-scale, depth-based closures to reduce catch of overfished groundfish, while still allowing the harvest of healthy stocks to the extent possible. RCAs are gear specific closures, and apply to vessels that take and retain groundfish species. Regarding RCA coordinates, there was an error in the 2014 Limited Entry Trawl Rockfish Conservation Areas and Landing Allowances table 1 (North) coordinates published in the **Federal Register** (79 FR 21639). Three intended references to 45°46′ N. lat. as published in lines 2, 3, and 4 of table 1 (North) were not correctly specified. As published, Line 2 incorrectly specified 45°16′ N. lat., instead of the correct reference, 45°46′ N. lat.; and lines 3 and 4 incorrectly specified 45°10′ N. lat., instead of the correct reference, 45°46′ N. lat. As published, line 3 described the shoreward line, and line 4 described the seaward lines. This rule will delete line 4 and describe the range of shoreward and seaward boundary lines within line 3, consistent with the format of the rest of the table. This action is to correct the 2014 Limited Entry Trawl Rockfish Conservation Areas and Landing Allowances Table 1 (North) to part 660, subpart D as published, in order to properly reflect the trip limit table coordinates as intended by the Agency in the Trawl RCA final rule (79 FR 21639).

Classification

The Assistant Administrator (AA) for Fisheries, NOAA, finds that pursuant to 5 U.S.C.553(b)(B), there is good cause to waive prior notice and an opportunity for public comment on this action, as notice and comment would be impracticable and contrary to the public interest. This notice corrects coordinates in the 2014 Limited Entry Trawl Rockfish Conservation Areas and Landing Allowances Table 1 (North) to part 660, subpart D that were inadvertently misreported in the Rockfish Conservation Area Boundaries for Vessels Using Bottom Trawl Gear final rule. This correction must be implemented in a timely manner to avoid confusion to the public likely to be caused by the errors in the table and avoid the potential for fishing in an area that was intended to be closed for conservation purposes. It would be contrary to the public interest to delay implementation of these changes until after public notice and comment, because making this regulatory change by May 13, 2014, corrects the errors and avoids confusion created by the above-referenced table and the potential for fishing in an area intended to be closed for conservation purposes. For the reasons above, the AA finds good cause under 5 U.S.C. 553(d)(3) to waive the 30-day delay in effectiveness and makes this rule effective immediately upon publication.

List of Subjects in 50 CFR Part 660

Fisheries, Fishing, and Indian fisheries.

Dated: May 7, 2014.

Samuel D. Rauch III,

Deputy Assistant Administrator for Regulatory Programs, National Marine Fisheries Service.

For the reasons set out in the preamble, 50 CFR part 660 is corrected by making the following correcting amendments:

PART 660—FISHERIES OFF WEST COAST STATES

■ 1. The authority citation for part 660 continues to read as follows:

Authority: 16 U.S.C. 1801 *et seq.* and 16 U.S.C. 773 *et seq.*

■ 2. Table 1 (North) to part 660, subpart D, is revised to read as follows:

BILLING CODE 3510–22–P

Table 1 (North) to Part 660, Subpart D -- Limited Entry Trawl Rockfish Conservation Areas and Landing Allowances for non-IFQ Species and Pacific Whiting North of 40°10' N. Lat.

This table describes Rockfish Conservation Areas for vessels using groundfish trawl gear. This table describes incidental landing allowances for vessels registered to a Federal limited entry trawl permit and using groundfish trawl or groundfish non-trawl gears to harvest individual fishing quota (IFQ) species.

Other Limits and Requirements Apply -- Read § 660.10 - § 660.399 before using this table 04012014

TABLE 1 (North)

		JAN-FEB	MAR-APR	MAY-JUN	JUL-AUG	SEP-OCT	NOV-DEC
	Rockfish Conservation Area (RCA)[1/]:

RIN 0648–BD75

Magnuson-Stevens Act Provisions; Fisheries off West Coast States; Pacific Coast Groundfish Fishery; Annual Specifications and Management Measures for the 2014 Tribal and Non-Tribal Fisheries for Pacific Whiting

AGENCY: National Marine Fisheries Service (NMFS), National Oceanic and Atmospheric Administration (NOAA), Commerce.

ACTION: Final rule.

SUMMARY: NMFS issues this final rule for the 2014 Pacific whiting fishery under the authority of the Pacific Coast Groundfish Fishery Management Plan (FMP), the Magnuson Stevens Fishery Conservation and Management Act (Magnuson-Stevens Act), and the Pacific Whiting Act of 2006. This final rule announces the 2014 U.S. TAC, establishes the tribal allocation of 55,336 metric tons of Pacific whiting for 2014, establishes a set-aside for research and bycatch of 1,500 metric tons, and announces the final allocations of Pacific whiting to the non-tribal fishery for 2014.

DATES: Effective May 13, 2014.

FOR FURTHER INFORMATION CONTACT: Kevin C. Duffy (Northwest Region, NMFS), phone: 206–526–4743, and email: *kevin.duffy@noaa.gov.*

SUPPLEMENTARY INFORMATION:

Electronic Access

This final rule is accessible via the Internet at the Office of the Federal Register Web site at *https://www.federalregister.gov.* Background information and documents are available at the NMFS West Coast Region Web site at *http://www.westcoast.fisheries.noaa.gov/fisheries/management/whiting/pacific_whiting.html* and at the Pacific Fishery Management Council's Web site at *http://www.pcouncil.org/.*

Copies of the final environmental impact statement (FEIS) for the 2013–2014 Groundfish Specifications and Management Measures are available from Donald McIsaac, Executive Director, Pacific Fishery Management

May 20, 2014

Dorothy Lowman
Chair
Pacific Fishery Management Council
7700 Ambassador Place, Suite 101
Portland, OR 97220-1384

Dear Chair Lowman:

This letter is to inform the Council of the list of species for which surplus carryover will be issued from 2013 into the 2014 season of the Shorebased Individual Fishing Quota (IFQ) Program. NMFS has decided to issue surplus carryover for 19 IFQ species that have 2014 Annual Catch Limits (ACLs) established at a level lower than their corresponding 2014 Acceptable Biological Catches (ABCs). NMFS will not issue surplus carryover for the remaining IFQ species that have 2014 ACLs established equal to their 2014 ABCs. This decision is the result of a recent court decision discussed below.

Court decision

On April 4, 2014, the D.C. District Court issued its decision in Conservation Law Foundation's (CLF's) challenge to Framework 50 to the New England Groundfish Fishery Management Plan (FMP), *Conservation Law Foundation v. Pritzker*, No. 13-00821 (D.D.C. Apr. 4, 2014). The primary issue in that case was a challenge to NMFS's authority to allow carryover of unused catch in fishing year 2013 that resulted in a total allocation of catch higher than the ABC recommended by the Scientific and Statistical Committee (SSC). The court held that carryover is inconsistent with the Magnuson-Stevens Act if it results in a total potential catch level that exceeds the ABCs recommended by the SSC.

In light of the court's holding, NMFS West Coast Region has decided that 2014 ACLs, including carryover from 2013, should not exceed the ABCs recommended by the SSC. Thus we will not be issuing carryover for any IFQ species where adding 2013 carryover onto the 2014 ACL would result in exceeding an IFQ species' ABC.

There are 19 IFQ species/area categories for which the ABC is greater than the corresponding ACL, and NMFS will issue surplus carryover in 2014 for all of them: Bocaccio Rockfish South of 40°10' N., Canary Rockfish, Cowcod South of 40°10' N., Darkblotched Rockfish, Dover Sole, Longspine Thornyheads North of 34°27' N., Minor Shelf Rockfish North of 40°10' N., Minor Shelf Rockfish South Of 40°10' N., Minor Slope Rockfish North of 40°10' N., Other Flatfish, Pacific Cod, Pacific Halibut (IBQ) North Of 40°10' N., Pacific Ocean Perch North of 40°10' N., Sablefish North of 36° N., Sablefish South of 36° N., Shortspine Thornyheads North of 34°27' N., Shortspine Thornyheads South of 34°27' N., Widow Rockfish, and Yelloweye Rockfish. These species will receive full eligible surplus carryover pounds, after application of any necessary reductions according to regulation.

Consistent with the PFMC recommendation, NMFS will not issue surplus carryover for Pacific whiting due to the need for adherence to the international whiting agreement, where a method for addressing carryover of unused Pacific whiting already exists. Since the Pacific halibut Total Constant Exploitation Yield for area 2A (Washington, Oregon and California) is set by international agreement, and there is no ACL, the court's holding is not applicable to this species, and NMFS will continue with its past practice.

As listed above, NMFS is issuing surplus carryover for Sablefish North of 36° N. In the first 3 years of the catch shares program, NMFS had established a policy that we would not issue surplus carryover for IFQ species with overall attainment at or above 100 percent of the Shorebased IFQ Program allocation in the prior year. This policy would have precluded issuance of carryover for Sablefish North of 36° N. into the 2014 season. However, now that the program is in its fourth year, we have available three years of catch data that show: 1) The fleet has not gone into deficit in aggregate for any species, and 2) When NMFS issues carryover for high attainment species the fleet tends to catch more, but stays within the total amount issued. Given the performance of the fishery during the first three years, NMFS revisited the initial policy regarding high attainment of the allocation.

NMFS will make the decision of whether or not to issue carryover for species with very high attainment of the previous year's shorebased trawl allocation on a case-by-case basis, rather than automatically dismissing this possibility. The case-by-case analysis will at the minimum include a review of fleet behavior in the prior year, as well the potential for impacts of carryover on non-trawl sector allocations. NMFS may still deny issuance of carryover, especially if we determine that the risk of exceeding the ACL is unacceptably high, and we will continue to maintain a higher level of precaution for overfished species.

NMFS conducted additional analyses of Sablefish North of 36° N. based on the new policy. After considering our additional analyses, NMFS has decided to issue full eligible surplus carryover of sablefish north of 36 degrees N. latitude. We will carefully monitor catch throughout the year, and we are prepared to initiate AMs, should catch exceed expectations. Catch in 2014 is projected to remain within the coastwide OFL and ABC as well as the northern ACL, and the risk of exceeding the ACL is acceptably low.

NMFS also recommends that the Council explore measures to make the annual surplus carryover process in the Shorebased IFQ Program more efficient and predictable, while adhering to Magnuson-Stevens Act requirements and the recent court decision. Creating a solution will likely require a non-trivial amount of effort, and NMFS is prepared to participate in developing constructive solutions. We suggest that it may be most appropriate to include this issue as part of the 5-year review of the catch share program, but we are open to other schedule suggestions.

If you have any questions or comments regarding this letter, please contact me directly.

GROUNDFISH ADVISORY SUBPANEL REPORT ON CONSIDERATION OF INSEASON ADJUSTMENTS

The Groundfish Advisory Subpanel (GAP) met with the Groundfish Management Team (GMT) to discuss progress of this year's fishery and possible inseason adjustments. The GMT discussion was led by Mr. Bob Leos. The GAP offers the following recommendations and comments on proposed inseason adjustments to ongoing groundfish fisheries.

Limited Entry Fixed Gear Sablefish Fishery North of 36° N. Latitude

Current trip limit (950 weekly/2,850 bimonthly)

Industry has requested an increase in trip limits for sablefish for the balance of the year (periods 4 through 6). The GMT analyzed 2 alternatives for the Council to consider. The GAP supports **GMT Alternative 1, (1 landing per week of up to 1,000 lb., not to exceed 3,000 lb. per 2 months).** The model suggests a sufficient buffer (est. between 88 percent to 93 percent take) depending on which price assumption is used.

Open Access Fixed Gear Sablefish Fishery North of 36° N. Latitude

Current trip limit (300 daily/800 weekly/1,600 bimonthly)

Open Access representatives on the GAP have requested exploring the possibility of an increase in trip limits for sablefish for the remainder of the year (periods 4 through 6). Open access fishermen are currently working with a very narrow profit margin due to high fuel prices combined with very low trip limits. The GAP supports **GMT Alternative 1, (350 lb. per day, or 1 landing per week of up to 1,600 lb., not to exceed 3,200 lb. per 2 months).**

Limited Entry/Open Access Fixed Gear Shallow/Deeper Nearshore Rockfish South of 40° 10' N. Latitude

Current trip limit (900 lb. per 2 month period)

The Port San Luis Commercial Fishermen's Association requested an increase in the trip limits for both shallow nearshore and deeper nearshore rockfish for the balance of the year (periods 4 through 6). The GMT analyzed this request and has noted that this fishery has already been projected to exceed its allocation of Canary rockfish by .1 MT (GMT Table 4 Scorecard Projected Impacts). Therefore the GAP does not support this request as any increase in nearshore trip limits would likely increase this overage of Canary rockfish.

Open Access Fixed Gear Lingcod South of 42° N. Latitude

The Port San Luis Commercial Fishermen's Association requested opening Lingcod in December of this year with a 400 pound monthly limit. The GAP notes this fishery has been closed to Lingcod fishing for decades during this time of year to protect nesting spawning females. The GAP believes bycatch impacts to Canary and/or Yelloweye rockfish would increase with this request. We note that a similar request has been brought forward for the 2015/2016 fishing seasons and is currently being analyzed under the Biennial Specifications package. The GAP does not support this request as an inseason action and prefers holding off until the final Specs analysis has been completed before considering again in the future.

Summary of GAP recommendations

1) Limited Entry Fixed Gear Sablefish Fishery North of 36° N. Latitude

GMT Alternative 1, (1 landing per week of up to 1,000 lb., not to exceed 3,000 lb. per 2 months)

2) Open Access Fixed Gear Sablefish Fishery North of 36° N. Latitude

GMT Alternative 1, (350 lb. per day or 1 landing per week of up to 1,600 lb., not to exceed 3,200 lb. per 2 months)

PFMC
06/21/14

GROUNDFISH MANAGEMENT TEAM REPORT ON CONSIDERATION OF INSEASON ADJUSTMENTS

Action items:

- Proposed trip limit increases for the limited entry and open access fixed-gear sablefish DTL sectors north of 36° N. latitude for 2014.
- Request for increased bimonthly trip limits for shallow and deeper nearshore species in the LE fixed gear and OA, south of 40°10' N. latitude.
- Proposed trip limit for the limited entry and open access lingcod fishery for December 2014, south of 42° N. latitude.

Informational items:

- Research catch update
- Overfished Species Scorecard update

Appendix A: Fixed Gear Sablefish Daily Trip Limit (DTL) Forecast Assumptions and Uncertainty

The Groundfish Management Team (GMT) considered the most recent information on the status of ongoing fisheries, research, and requests from industry and provides the following recommendations for 2014 inseason adjustments.

The GMT also received guidance from the National Marine Fisheries Service (NMFS) West Coast Region (WCR) regarding timing of implementation of inseason recommendations from this meeting. NMFS anticipates implementing routine inseason adjustments to fishery management measures by August 1, 2014.

1. ACTION ITEMS

1.1. Fixed gear sablefish, daily trip limit fisheries in 2014

Here we describe inseason considerations for 2014 in the four fixed gear daily trip limit (DTL) fisheries, including both limited entry (LE) and open access (OA), north and south of 36° N. latitude. We refer to them as follows: LE North, LE South, OA North, and OA South.

Projection models have been updated with a year of new data (2013), re-specified accordingly, and new catch information about progress through the first part of 2014 is available from the Quota Species Monitoring (QSM) Best Estimate Report (BER), from the Pacific Fisheries Information Network (PacFIN).

1.1.1. Current status and alternatives

Current projections under status quo and action alternatives are shown in Table 1. Alternative trip limits are shown in Table 2.

Under the action alternatives, we maintained the same ratio of weekly to bimonthly trip limits as status quo for each fishery, since there were no industry requests to diverge from them. The exception is for Alternative 3 in the OA North, where the bimonthly limit is much higher than status quo and it may require up to three trips to attain the bimonthly trip limit.

Table 1. Forecasted landings (mt) and attainment (percent) under the alternatives, for the fixed gear sablefish DTL fisheries in 2014. Landings projections are bracketed by a range of three levels of assumed ex-vessel price curves in the LE North fishery (see Appendix A. for description).

	LE N, by price assumption						
2014 No Action	**Low**	**Med**	**High**	**OA N**	**LE S**	**OA S**	**South sum**
Landing target	**214**	**214**	**214**	352	483	392	875.0

Table 2. Trip limits (pounds/vessel/unit time) under the alternatives for the fixed gear sablefish DTL fisheries in 2014. Potential action alternative trip limits are in bold font. For the OA North, the No Action Alternative, Alternative 1, and Alternative 2 are structured so that it is possible to achieve the bimonthly limit in two weeks. For Alternative 3, it would take three weeks.

Fleet/ area	period	2014 No action trip limits			2014 Alt. 1 trip limits			2014 Alt. 2 trip limits			2014 Alt. 3 trip limits		
		bimo	week	day	bimo	week	day	bimo	week	day	bimo	week	day
LE N	1-3	2,850	950	-	2,850	950	-	2,850	950	-	2,850	950	NA
	4-6				**3,000**	**1,000**	-	**3,200**	**1,075**	-	-	-	-
OA N	1-3	1,600	800	300	1,600	800	300	1,600	800	300	1,600	800	300
	4-6				**3,200**	**1,600**	**350**	**4,400**	**2,200**	**375**	**5,400**	**1,800**	**400**
LE S	1-6	-	2,000	-	-	-	-	-	-	-	-	-	-
OA S	1-6	3,200	1,600	320	-	-	-	-	-	-	-	-	-

<u>LE North</u>

Projected attainment in the LE North fishery under No Action during 2014 ranges between 85 and 90 percent of the target, depending upon assumptions of ex-vessel price (Table 1 and Table 2). Projected attainment under Alternative 1 ranges between 88 and 93 percent, and for Alternative 2, it ranges between 93 and 98 percent.

<u>OA North</u>

Projected attainment under No Action in the OA North fishery during 2014 is for 45 percent of the target. Projected attainment under the action alternatives ranges between 66 percent for Alternative 1, 82 percent for Alternative 2, and 96 percent for Alternative 3 (Table 1 and Table 2).

<u>LE South</u>

The status quo LE South projection using the best currently available information is for 107 percent attainment (Table 1), thus no alternatives trip limits are presented. This would be similar to the attainment level during 2013 of 104 percent. However, industry reports of low effort during Period 2 (March and April) due to bad weather suggest that actual attainment may turn out to be somewhat lower than projected. Accurate QSM estimates of sablefish landings in the Conception International North Pacific Fisheries Commission (INPFC) area during Period 2 are not currently available, so it is difficult to check these reports. The OA South fishery is currently projected to have low attainment, and would allow ample room for the small predicted overage in the LE South fishery, should it occur.

<u>OA South</u>

Projected attainment in the OA South fishery in 2014 is low (27 percent, Table 1), and attainment has been low in 2012 and 2013 (Appendix A.). The GMT believes there is sufficient opportunity under the current OA South trip limits (320 pounds daily, 1,600 pounds weekly, and 3,200 pounds bimonthly, Table 2), judging by comparison over the historical time series, and no requests have been made by industry for this fishery. Thus, we are not proposing action alternatives for the OA South at this time.

Appendix A. gives information on the current annual changes to model specifications, coinciding with the addition of new input data each Spring, as soon as they become final in PacFIN. Details about trending fishery behavior in the OA North fishery, and our measures to compensate for it in forecasts is also described in the appendix.

1.2. Limited entry and open access fixed gear - shallow and deeper nearshore rockfish trip limits and a December trip limit for lingcod

The GMT reviewed a request from industry asking for increased bimonthly trip limits for shallow and deeper nearshore species in the limited entry fixed gear and open access fisheries south of 40°10' N. latitude for the remainder of this year (Agenda Item F.4.c, Public Comment)). The request is to increase the current trip limit amounts from 900 pounds per two months (July-August) and 800 pounds per two months (Sept-Oct) to 1,000 pounds per two months. There was also a request for a 400 pound trip limit for the lingcod limited entry fixed gear and open access fisheries to be implemented for December for south of 42° N. latitude. Lingcod retention is currently prohibited from December – April. For the 2015-2016 cycle, the GMT provided an analysis which could provide for lingcod retention, beginning in 2015 (See Agenda Item F.7.a, Supplemental Attachment 10, June 2014).

The Council has supported trip limit increases for the nearshore fishery in the past. For example, the most recent increase took place last year when the trip limit for period 6 trip limit was increased to 1,000 pounds.

In considering these requests, the GMT evaluated the possible mortality increases to overfished species (OFS), specifically canary and yelloweye rockfish, even though no formal analysis was completed due to the lack of time. If the Council chooses, the GMT could conduct an analysis in time for the September Council meeting for the nearshore species trip limit request. However, we provide the following information to assist with this decision. The 2014 directed open access commercial nearshore fishery canary rockfish allocation is 6.4 mt with a projected mortality of 6.5 mt (Table 3). Any trip limit increase in the nearshore fishery south of 40°10' N. latitude would likely add to the existing projected mortality amount. For yelloweye rockfish, the directed open access allocation (coastwide) is 1.2 mt with a projected mortality of 1.1 mt. While the projected mortality is 0.1 mt less than the allocation amount, if one considers the additional opportunity to take lingcod in December (plus any additional take of nearshore rockfishes), it is possible that the 1.2 mt allocation may be exceeded (Table 3). This is because lingcod landings made with nearshore rockfish landings are closely associated with the constraining canary and yelloweye rockfish mortality estimates and are factored into the nearshore bycatch model that estimates OFS mortality in the nearshore fishery. Regarding the request to open the lingcod closed season in December, it is the GMT's understanding that this action is not yet considered routine and cannot be done as an inseason action after a single meeting and without a notice and comment rulemaking.

2. INFORMATIONAL ITEMS

2.1. Research

The International Pacific Halibut Commission (IPHC) is just beginning their annual set-line survey for Pacific halibut. Therefore, there are no updates to the IPHC research catches of yelloweye rockfish at this time. The GMT was informed that the NMFS trawl survey has encountered one tow of approximately 1.5 mt of canary rockfish. Through one out of five legs in the May-July period, the survey has captured a total of 2.2 mt of canary rockfish. The scorecard currently has 4.5 mt of canary rockfish set-aside for research, which was based on recent average catches. There is also currently a residual of 21.3 mt of canary rockfish in the scorecard (Table **3**). The GMT anticipates receiving further updates on these research projects at the September meeting.

2.2. Scorecard Update

The scorecard has been updated to reflect changes to the Tribal set-asides, based on the 2014 Pacific whiting total allowable catch (TAC; Table 3). Canary and darkblotched rockfish, and POP estimates are based on a 5-year weighted averaged bycatch rate applied to the whiting allocation which was recently codified in the Final Rule (79FR27198). Bycatch projections for canary rockfish went from 10.1 mt to 9.2 mt, darkblotched rockfish went from 0.4 mt to 0.2 mt, and POP went from 14.8 mt to 7.4 mt. There are no other updates to the scorecard at this time.

GMT Recommendations:

1. **Increase fixed gear sablefish DTL trip limits for limited entry north of 36° N lat. in 2014 in periods 4 through 6, according to the Council's risk tolerance.**

2. **Increase fixed gear sablefish trip limits for open access north of 36° N lat. in 2014 in periods 4 through 6, according to the Council's risk tolerance.**

Table 3 Scorecard for the beginning of 2014. Allocations[a] and projected mortality impacts (mt) of overfished groundfish species for 2014.

a/ Formal allocations are represented in the black shaded cells and are specified in regulation in Tables 1b and 1e. The other values in the allocation columns are 1) off the top deductions, 2) set asides from the trawl allocation (at-sea petrale only) 3) ad-hoc allocations recommended in the 2013-14 EIS process, 4) HG for the recreational fisheries for canary and YE.

b/ South of 40°10' N. lat.

c/ EFPs are amounts set aside to accommodate anticipated applications. Values in this table represent the estimates from the 13-14 biennial cycle, which are currently specified in regulation.

d/ Includes NMFS trawl shelf-slope surveys, the IPHC halibut survey, and expected impacts from SRPs and LOAs.

e/ The GMT's best estimate of impacts as analyzed in the 2013-2014 Environmental Impact Statement (Appendix B), which are currently specified in regulation.

f/ Tribal values in the allocation column represent the the values in regulation. Projected impacts are the tribes best estimate of catch.

APPENDIX A. FIXED GEAR SABLEFISH DAILY TRIP LIMIT (DTL) FORECAST ASSUMPTIONS AND UNCERTAINTY

A.1. LE North

Ex-vessel price is one predictor in the current model (adjusted for inflation) and uncertainty in the landings forecasts are expressed using a range of imputed price curves during 2014 (**Figure A.1**). The current 2014 projections for the LE North fishery assume a seasonal ex-vessel price curve of the same shape as 2013, but is inflated by 7 percent throughout 2014 (the "mid" line in **Figure A.1**). This assumption is based on differences in price between 2013 and 2014 over the first four months of available data. The high curve represents double the average increase in price seen so far in 2014, compared to 2013 (seven percent higher than the "mid" curve, and 14 percent higher than 2013, the "low" curve), while the low curve represents prices instead falling by the same amount that they have risen (7 percent lower than the "mid" curve for periods 3 through 6 of 2014, and equal to 2013 levels).

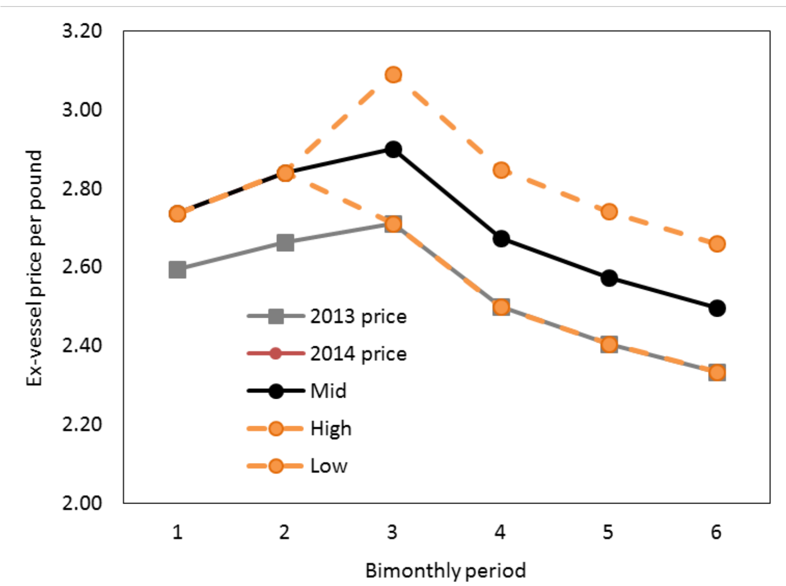

Figure A.1. Ex-vessel price structure assumed for the LE North DTL fishery inseason forecasts in 2014. The solid black line represents the middle assumed price curve for 2014. Period 1 and 2 (January-April) 2014 estimates were queried from PacFIN; estimates for periods 3 through 6 of 2014 (May through December) were derived in relation to 2013 prices and early differences between those from 2014. See text for details. Dashed orange lines are high and low assumptions. The solid grey line (square markers) represents 2013 prices, and is equal to the low price assumption for 2014.

Current fit of predicted to actual landings in the LE North fishery can be expressed as the percent of variation in actual landings explained by predicted landings, with an R^2 value of 0.94 (Figure A.2). Attainment of the landing target in the LE North over the past three years since intersector allocation has ranged from 159 percent in 2011, to 91 percent in 2012, and 97 percent in 2013 (Table A1). The overage in 2011 was due to erroneous input data in PacFIN, which has since been corrected (see Agenda Item E.5.b, Supplemental GMT Report, June 2011 PFMC meeting for description).

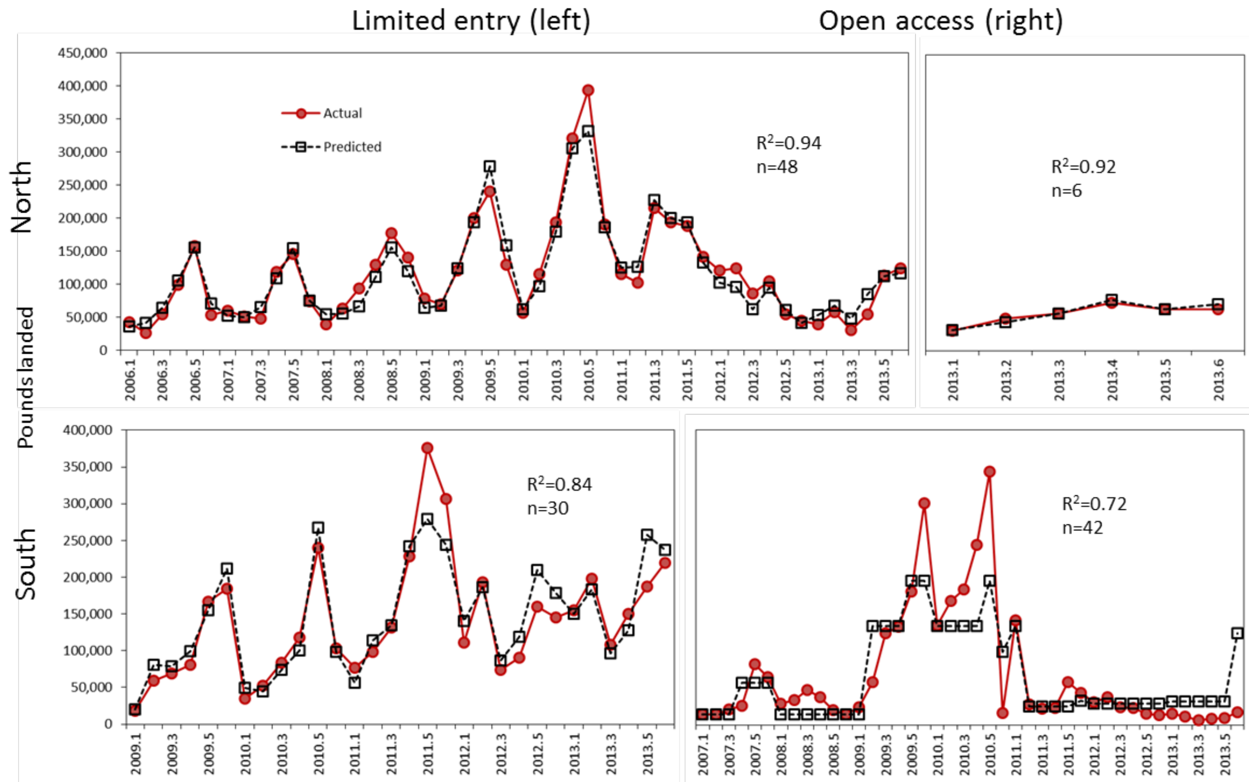

Figure A.2. Paneled time series charts showing current fits of predicted to actual landings in the four fixed gear, sablefish DTL fisheries, north and south of 36 degrees N. latitude, over the time series of model input data. The red solid line shows actual landings, and the black dashed line shows predicted landings. The R^2 value in each panel quantifies fit as the percent of variation in actual landings that is explained by predicted landings; "n" is the number of bimonthly periods used in each case. Note that including more than only the most recent year in the OA North model led to substantial landings overpredictions.

A.2. OA North

Attainment has been low in this fishery over the past two years (Table A.1., Figure A.3). With the addition of 2013 data, it appears that participation has been falling during 2012 and 2013, and a trend of upwardly biased predicted landings has emerged as a result. According to the current data, the average number of vessels landing declined to 48 percent of historical levels through 2013 (Table A.2).

Since the linear model fits to an average relationship over the time series, this model is not particularly adept at predicting participation and thus fleet catch when they are far from the average over the input time series, as in 2012 and 2013.

In order to increase accuracy of 2014 forecasts we've elected to use only the most recent year's data (2013) for the current model run (Figure A.2). Using additional years produced substantial over-predictions for the most recent year, 2013 as well as 2012 (Figure 4A). Fishery behavior in the current year tends to most closely resemble that of the previous year, so we assigned priority to fit 2013 data. Down-weighting older data was tried before removing them, but the degree of down-weighting necessary to stop over-prediction for the most recent year (2013) was enough that older data were finally removed from the model, resulting in better fit (Figure A.2).

The current version of the model predicts landings more accurately and without apparent bias, both for 2013 (R^2=0.92, predicted vs actual) and so far in 2014; within 5 percent of the QSM estimate for periods 1 and 2. Since the short range of the data in the model (six bimonthly periods from 2013) does not include the higher trip limits presented in the alternatives; we are extrapolating to produce alternative trip limits and caution should be exercised in choosing among them. Trip limits could be revisited as early as September if necessary.

Table A.1. Fishery catch and attainment in 2011, 2012 and 2013 in the four sablefish DTL fisheries, sorted by area, fleet and then year, according to current estimates in PacFIN. These data show continuing high attainment in the limited entry, and a trend of decreasing attainment in the open access DTL fisheries. Also see Figure A.3.

Year	Fleet	Area	Pounds	mt	Target	Attainment
2011	LE	North	956,547	433.9	273	159%
2012	LE	North	533,226	241.9	265	91%
2013	LE	North	422,762	191.8	198	97%

2013	Sum	South	1,097,033	498	808	62%

Under the action alternatives, trip limits would need to be higher in the OA North than the LE North, to enable sufficient effort and high attainment for the rest of the year. The harvest guideline is substantially (more than 50 percent) higher in the OA North than the LE North. Substantially higher trip limits for open access may encourage some migration of effort, but since both fisheries fall under the northern annual catch limit (ACL), this does not appear to be a critical issue. The OA North fishery also has a daily limit, while the LE does not. The OA North limits have been higher than the LE North during four different bimonthly periods since 2004; two during 2005 and two during 2012. We have used similar limits to those presented in the alternatives before, at the end of the year in 2005 and 2010 to boost attainment at the end of the year.

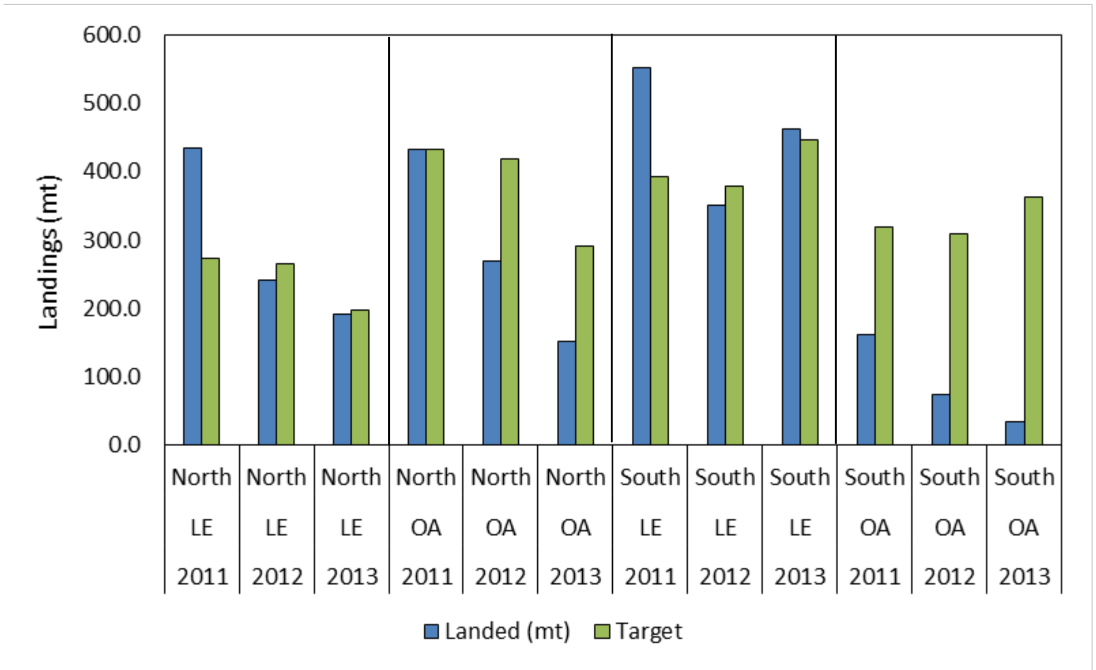

Figure A.3. Fishery landings and attainment in 2011, 2012 and 2013 in the four sablefish DTL fisheries, sorted by area, fleet and then year, according to current estimates in PacFIN. The plot illustrates continuing high attainment in the limited entry, and a trend of decreasing attainment in the open access DTL fisheries (values in Table 3).

Note that starting in 2014, sablefish catch north of 36° N. latitude in non-groundfish fisheries (e.g. the incidental open access fisheries) is no longer removed from the OA allocation pre-season. Removing this amount preseason was an error which resulted in double counting since the appropriate catch accounting rules for non-groundfish fisheries are applied inseason. That is, the inseason process debits catch by LE vessel against LE DTL allocation and catch by OA vessel against OA DTL allocation, consistent with Amendment 6 to the Groundfish Fishery Management Plan (FMP). There's no need for a preseason adjustment. We have accounted for projected incidental open access catch of sablefish within the projection for the OA North DTL values in Table 1.

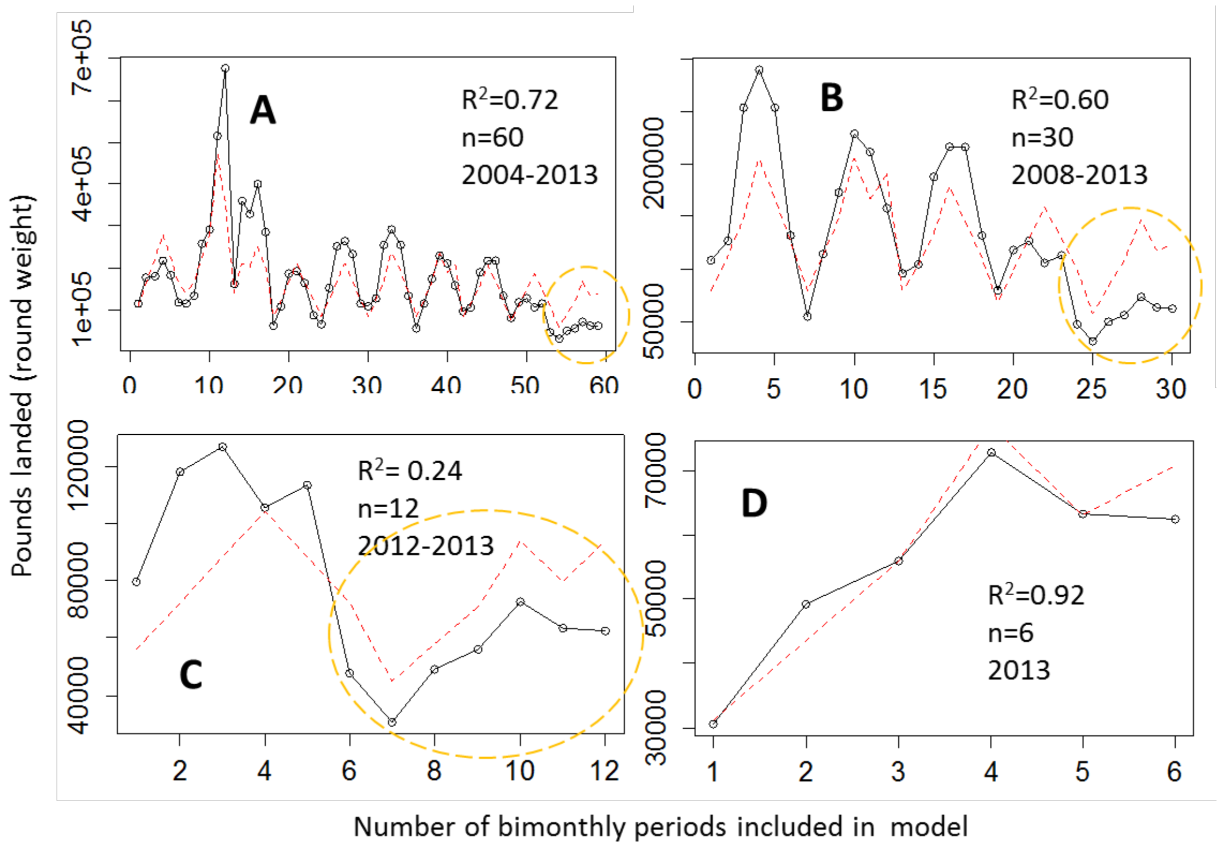

Figure A.4. Paneled fit plots for retrospective analysis of the OA North fishery showing model sensitivity to variation in number of vessels participating, and its inflating effect on predicted landings in 2012 and 2013 (enclosed by yellow dashed line circles). The red dashed line shows predicted landings, and the black solid line shows actual landings by bimonthly period (reverse color scheme from Figure A.2). In each panel, the time series progresses from the oldest year included in the model on the left, to 2013 on the right. Each point represents one bimonthly period (six per year).

Table A.2. Bimonthly counts of participating vessels in the OA North fishery from 2004 through 2014.

Bimonthly period	2004	2005	2006	2007	2008	2009	2010	2011	2012	2013
1 (Jan-Feb)	59	56	80	61	60	80	57	68	69	34
2 (Mar-Apr)	78	69	151	88	100	103	80	87	88	47
3 (May-Jun)	131	140	201	162	170	169	125	138	119	74
4 (Jul-Aug)	134	146	223	142	175	166	143	151	95	70
5 (Sep-Oct)	91	141	181	109	150	143	125	147	95	55
6 (Nov-Dec)	62	166	2	60	91	77	79	94	47	42
Average	93	120	140	104	124	123	102	114	86	54

A.3. LE South

We made forecasts for the LE South using two model configurations. The one with the best fit (R^2 = 0.84, **Figure A.**1.), and produced the projections in Table 1 included ex-vessel price and weekly trip limits as predictors. We used the same method to construct the predicted price curve for 2014 used in the model as described earlier for the LE North model. An alternate LE South model configuration containing only weekly trip limit as a predictor (used in previous years) was also run, and resulted in slightly lower predicted attainment of 100 percent. The fit for this configuration was much lower at R^2 = 0.58.

A.4. OA South

An adjustment factor was applied to predicted landings for this fishery as a correction since model projections have been substantially higher than actual in 2012 and 2013, and the input data for this fishery model have low information content. Like the OA North fishery, recent participation has been lower than expected based on historical time series. Industry accounts suggest that many previous participants may be leasing and fishing under LE permits. The permits branch in the West Coast Region of NMFS confirms that there has been some new permit leasing activity which may support these accounts.

A. Figures

B. Tables

1. Summary

This report describes progress during 2014 in the Shorebased IFQ Program, for catch and related metrics, as well as select topics for 2011 through 2013. Non-whiting midwater landings, revenue, and deliveries have been increasing rapidly since 2011 through 2013, targeting yellowtail and widow rockfish. In contrast, non-trawl landings and revenue have been consistently dropping from 2011 through 2013, likely related to declining sablefish prices over those years. Bottom trawl metrics varied little over this period by comparison. Current attainment during 2014 as of June 3 is shown compared to average annual attainment for 2011-2013. Retention rates remain high, and vary little compared with average annual rates, except minor shelf rockfish which is currently lower than average in the North, and higher in the South. Monthly non-whiting effort and catch per unit effort (CPUE) are also tracking close to historical averages, except that January values were unusually high this year, coinciding with unusually high Dover sole and longspine thornyhead catch in January.

2. Narrative

2.1. Data used in this report

Data from the Pacific Fisheries Information Network (PacFIN) and the National Marine Fisheries Service Shorebased IFQ Vessel Accounts Database (VA) were used for this report. PacFIN was used to inform landings, revenue, gear type, and corresponding counts of trips, deliveries and vessels. PacFIN data were queried from the VDRFD table on June 6, 2014 (data originate from paper fish tickets). Data completeness at that time was estimated as greater than 90 percent complete through March for Washington, April for Oregon, and February for California. Only data from groundfish landings on IFQ trips are presented. Trip type is designated based on vessel-day, while deliveries are defined as landing receipts. Non-trawl landings from PacFIN cannot be divided further at this time (e.g. to longline, pot, etc.) due to confidentiality criteria based on number of vessels per stratum; 2014 data do not yet include enough vessels to show catch by gear type at finer resolution. NMFS VA data were used to show total catch, landings, discard and derived metrics by IFQ species category. VA data were queried on June 10; landings are complete through June 9, although discard may lag slightly behind.

2.2. Landings, revenue, price, deliveries, trips and participation (source = PacFIN)

Shorebased IFQ landings, revenue, ex-vessel price, deliveries trips and participation for 2011 through the present are shown divided by gear type (mid-water trawl, bottom trawl and non-trawl) and trip type (whiting or non-whiting) in Figures 1 and 2, and Table 1. Distribution of non-whiting IFQ landings by gear type is shown in Table 2. These data are from paper fish tickets, and lag behind the NMFS VA data (based on e-tickets) as described in section 2.1.

Non-whiting midwater landings, revenue, and deliveries have been increasing rapidly since 2011 through 2013, although the number of vessels has varied little (Figures 1 and 2, Table 1). Average ex-vessel prices for these landings increased from 2011 to 2012, and dropped slightly in 2013. Yellowtail rockfish has been the most obvious target species from non-whiting mid-water trips, with substantial catch of widow rockfish as well.

Non-trawl landings and revenue have been consistently dropping 2011 through 2013. Sablefish is overwhelmingly the main species caught with IFQ fixed gear, and primarily north of 36 degrees N. latitude. Ex-vessel price has also been dropping from 2011 through 2013, but has increased during the spring of 2014. The extent of the apparent 2014 price increase may reflect low sampling density in incomplete April data, particularly from California. There have been spring price increases in fixed gear IFQ sablefish prices the past three years, followed by a mid-year drop and flattening out for the rest of the year.

Bottom trawl landings, revenue, ex-vessel price, deliveries, trips and participation have all been very consistent from 2011 through 2013, in comparison with other gear types. Bottom trawl revenue, as a proportion of the sector has been increasing over 2011 to the present, mostly as a result of the decreasing proportion of IFQ sector revenue for non-trawl gear.

2.3. Total catch, attainment and retention rates (source = NMFS VA)

Current total catch and attainment rates for each IFQ species/area category in 2014 (as of June 3) are shown in Table 3 and Figure 3. Average annual attainment for 2011 through 2013 and standard deviation are also provided for reference. There were only non-whiting trips as of June 3.

Current non-whiting landed and discarded catch amounts, as well as retention rates for 2014 as of June 3 are shown in Table 4 and Figure 4. Average annual attainment for 2011 through 2013 and standard deviation are also provided for reference. Current retention rates are tracking close to their annual average rates, except shelf rockfish North, which is running below average, and shelf rockfish South, which is running above average. Retention rates are above 80 percent for all categories on non-whiting trips except shelf rockfish, Pacific whiting, and splitnose rockfish (retention of Pacific halibut IBQ is not allowed). Two thirds of the categories are consistently retained at a rate of higher than 90 percent. Aggregate non-whiting retention is currently 95 percent.

2.4. Effort and catch per unit effort (source = NMFS VA)

Monthly effort (number of trips) and catch per unit effort (total catch per trip) for 2014 compared with average values for 2011 through 2013 are shown in Figure 5, in the left and right panels respectively. January effort and CPUE were unusually high; 71 percent and 26 percent higher than average respectively, coinciding with unusually high Dover sole and longspine thornyhead catch in January. Monthly values for other species are very similar to average.

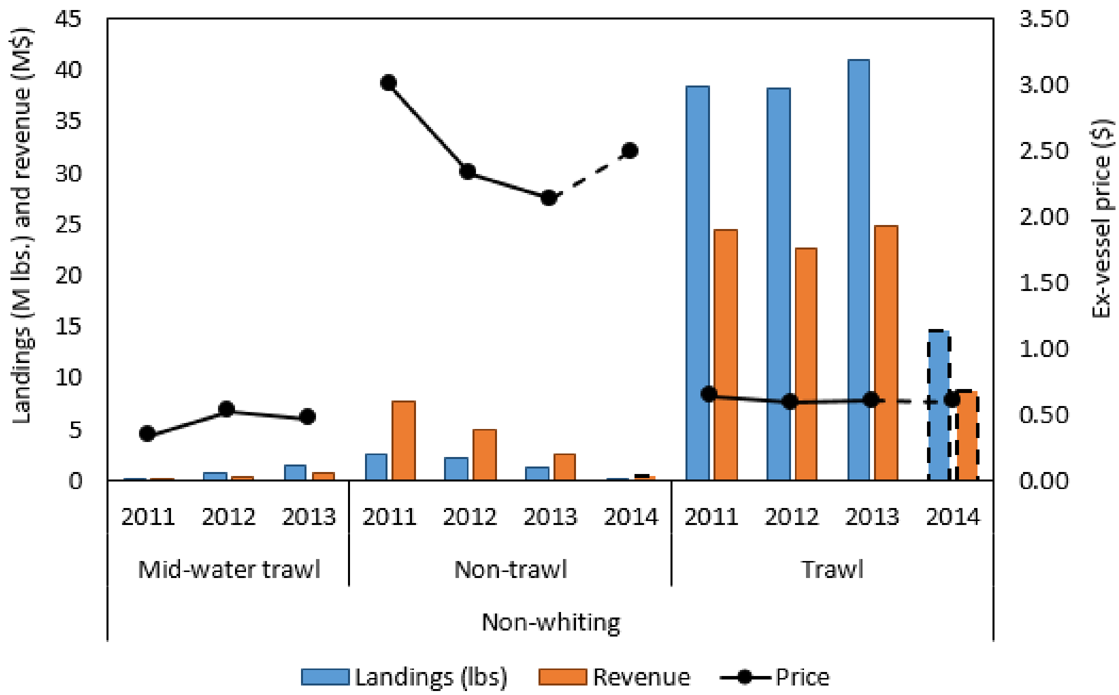

Figure 1. IFQ landings of groundfish species, ex-vessel revenue and price by gear type, trip type and year, from non-whiting trips. Trips were designated as vessel-days. See Table 1 for values. Dashed lines represent 2014 data (year in progress). See text for PacFIN 2014 data completeness as of the date of this query.

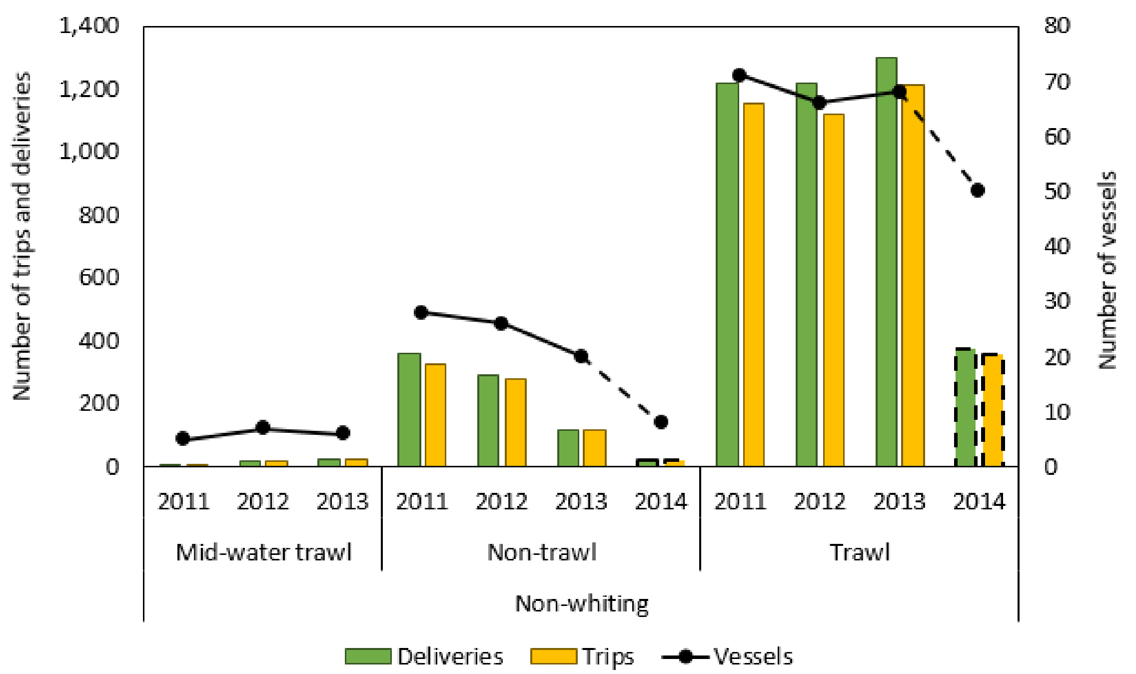

Figure 2. Counts of IFQ deliveries (landing receipts), trips (vessel days), and vessels making landings groundfish species by gear type, trip type and year. Data shown here are all from non-whiting trips. Trips were designated as vessel-days. See Table 1 for values. Dashed lines represent 2014 data (year in progress). See text for PacFIN 2014 data completeness as of the date of this query.

Table 1. IFQ landings of groundfish species, corresponding ex-vessel revenue, counts of deliveries, trips and vessels participating by trip type (whiting or non-whiting), for 2011-present. Trips were defined as vessel-days. *See text for 2014 data completeness in PacFIN as of the date of this query.

---------- Forwarded message ----------
From: **Bill James** <Halibutbill@live.com>
Date: Thu, May 22, 2014 at 11:20 PM
Subject: F.4 Inseason Adjustments
To: "pfmc." <pfmc.comments@noaa.gov>
Cc: Bill James <Halibutbill@live.com>

Madame Chair members of the Council: My name is Bill James and I am here today representing Port San Luis Commercial Fishermen's Association.

Today I am requesting both Shallow Nearshore Species and Deeper nearshore Species bi-monthly trip limits be raised to 1000 pounds per 2 months south of 40:10 for the remainder of the year. In the last couple of years commercial nearshore landings have approached only 50 percent of the ACL for both Shallow and Deeper Nearshore species.

Please open Lingcod in December of this year with a 400 pound monthly limit for December 2014 for open access south of 42 degrees.

Sincerely, Bill James

FINAL EXEMPTED FISHING PERMIT (EFP) APPROVAL FOR 2015-2016

At the November 2013 Council meeting the Council considered three exempted fishing permit (EFP) applications and preliminarily adopted one EFP for public review, sponsored by the San Francisco Community Fishing Association. The Council recommended the same set-asides for this EFP for 2015-2016 as for the one approved for 2013-2014, with the exception of 1.0 metric tons (mt) of canary rockfish and 0.03 mt of yelloweye rockfish.

At the November 2013 meeting, the Council also scheduled consideration of special, out-of-cycle EFP proposals for electronic monitoring (EM EFPs) with maximized retention requirements, with preliminary approval at the April 2014 Council meeting and final approval at the June 2014 Council meeting. After the meeting, a letter regarding this special EFP process was provided to the fishing industry participants, including the Council Operating Procedures that describe the EFP application process.

At the April 2014 Council meeting, the Council preliminarily approved four out of five EM EFP applications for further consideration and final approval at the June 2014 Council meeting (i.e., the Leipzig, CA Risk Pool, Mann/Paine, and Eder et al. EFPs). At the meeting, the Council provided guidance to each applicant on further development of the EM EFPs and asked that applicants consider resubmitting revised applications for Council consideration at the June meeting. The following additions to the applications were requested by the Council: 1) Leipzig EFP application: limit the number of vessels and require up to 100 percent observer coverage; 2) CA Risk Pool application: limit the number of vessels and require up to 100 percent observer coverage on bottom trawl vessels; 3) Eder et al. application: limit the number of vessels. The Council also requested that the EFPs address how the halibut viability assessments could be conducted without the presence of a human observer, with the intention that halibut retention not be permitted. In addition, the Council recommended that EFP applications include a feature that requires applicants to provide the National Marine Fisheries Service (NMFS) and the States a list of vessels and processors that will be participating in the EFP a minimum of 30 days before they commence their EFP.

The NMFS West Coast Region volunteered to work with EM EFP applicants on an ad hoc basis to improve EFP applications, and since the April Council meeting has conducted conference calls with each applicant to provide guidance.

The Council received five revised EFP applications (Agenda Item F.5.a, Attachments 1 through 5). A summary of the EM EFP applications, including responses to the Council's requests is provided in Agenda Item F.5.a, Attachment 6.

Under this agenda item, the Council is to consider final approval of all EFP applications provided by the fishing industry. Those EFPs recommended at this Council meeting are forwarded to NMFS for implementation in the next biennial management cycle.

<u>Council Action</u>:

1. **Recommendations for final approval of EFPs.**
2. **Provide other guidance as necessary.**

<u>Reference Materials</u>:

1. Agenda Item F.5.a, Attachment 1: Leipzig Fishermen's Marketing Association EFP Application.
2. Agenda Item F.5.a, Attachment 2: California Risk Pool EFP Application.
3. Agenda Item F.5.a, Attachment 3: Mann/Paine Whiting EFP Application.
4. Agenda Item F.5.a, Attachment 4: Eder et al. Fixed Gear EFP Application.
5. Agenda Item F.5.a, Attachment 5: San Francisco Community Fishing Association EFP Application: Yellowtail Rockfish Jig Fishing off California.
6. Agenda Item F.5.a, Attachment 6: Table 1. Summary of EM EFP applications.

<u>Agenda Order</u>:

a. Agenda Item Overview — Brett Wiedoff and John DeVore
b. Reports and Comments of Advisory Bodies and Management Entities
c. Public Comment
d. **Council Action**: Adopt Final Recommendations for EFPs, Including Electronic Monitoring EFPs

Purpose and Need for Exempted Fishing Permit

Purpose

Issuance of the EFPs would allow fishery participants to fish in the Pacific Groundfish IFQ fishery using Electronic Monitoring Equipment in lieu of an observer and to allow the National Marine Fisheries Service (NMFS) to evaluate components of an overall monitoring program before implementation of a comprehensive regulatory program.

Need

On January 1, 2011, west coast groundfish trawl fishermen began fishing under an individual fishing quota program. Under the new program, all vessels are required to have 100% at-sea observer coverage in addition to 100% shoreside monitoring of all offloads. While full accountability is critical to the success of the program, the fleet is concerned that monitoring costs will be untenable, and may cause individual fishermen or even whole ports to stop fishing.

Observer contracts vary somewhat, but most observer providers are charging between $450-500 per day. This expense disproportionately impacts smaller trawl vessels. Based on these projected costs, the observer issue has become one of the fundamental hurdles to the success of the IFQ program. It is essential to find a way for fishermen to meet NMFS' and PFMC's accountability requirements without imposing such prohibitive costs on the fleet.

At the implementation of the program, NMFS announced that they had funding to subsidies the cost of observers, but would need to reduce this subsidy over several years, until 100% of the cost was being paid by the industry. During 2014 this subsidy will be $216, so fishermen are currently paying a little more than one half of the cost of observers. It is anticipated that in the future this cost to fishermen will increase as the subsidy declines and the cost of placing observers increases.

It is important to remember that the cost of observers although significant it is not the only cost which trawl fishermen are paying to participate in this fishery. Trawlers are now paying 5% of gross revenue for the buy-back loan repayment, 3% of gross revenue for cost recovery in the IFQ program, State landing taxes, and industry organization dues. The cost of observers is a fixed cost per day, rather than a percentage of gross revenue, so the calculation of percentage of gross is dependent upon the gross revenue. For higher grossing boats the percent is lower, for lower grossing boats the percentage is higher. A fair estimate of the cost of observers is between 10% and 15% of gross revenue, with a combined total cost to participate in the fishery of 18% to 23% of gross revenue.

Lastly, a compelling argument can be made for the use of cameras when examining the availability of observers. Not all ports have a large fleet of boats which are making back to back fishing trips. Most ports have a few vessels, which out of need will also participate in the Pink shrimp fishery and the Dungeness crab fishery during those seasons. The work as an observer is not steady in those ports and therefore the ability to provide observer coverage in a number of locations has proved to be difficult. The use of cameras is a logical alternative in these situations.

Species to be harvested and their disposition:

This EFP is not requesting any additional allocation of groundfish species for participants. The participant will cover all species harvested under this EFP with Quota Pounds or Bycatch Quota in the same manner that all participants in the groundfish IFQ fishery cover their landings. All species caught will be retained and unloaded at the completion of each fishing trip at a first receiver site and monitored by a shoreside monitor, with the exception of Pacific halibut which will be discarded at sea. All Pacific halibut caught will be measured for length and recorded in a discard log.

Mortality estimates for Pacific halibut may be determined either by using each vessel’s past average halibut mortality rate, the fleet average mortality rate, or an estimate based upon tow duration, time on deck, and ambient air temperature.

Broader Significance:

It is hoped that this EFP will allow participants to lower their cost of observation. But additionally, the issuance of this EFP will provide experience to better develop procedures involving the installation of cameras, the retrieval of video data, and the analysis of that data. Overall this EFP will provide the NMFS greater insights into how best to structure and write regulations which will allow the use of cameras on a broader basis.

Looking more into the future, this EFP will provide researchers a great deal of additional data which can then be used to improve the development of image recognition software. This type of software has enormous potential to greatly reduce the cost of video review.

Lastly, the lessons learned from this EFP will benefit other sectors of the groundfish fishery, as well as other fisheries both regionally as well as nationally that are wrestling with the cost of observers.

Duration:

It is requested that this be an annual permit and to be continually renewed until comprehensive permanent regulations can be implemented.

Number of Vessels Covered:

The total number of vessels involved with this EFP will be limited to six. The selection of the six boats will be made so that all of the boats are based out of ports with close proximity to each other. For example, all of the boats could be from Astoria, or all of the boats could be from Brooking, Crescent City, and Eureka. The need to have the boats in close proximity is to reduce travel cost associated with the service provider.

Thirty days prior to any fishing under this permit and list of each participating vessel, their home port, and fish companies to which they will be selling their catch will be provided to NMFS and each of the three States.

Scope:

This EFP would apply to all fishing activities by the permitted vessel while fishing with trawl gear in the Pacific Groundfish IFQ program.

This EFP authorizes, for limited purposes as described in this permit, the following activities which would otherwise be prohibited by federal regulation:

1. Under 50 CFR § 660.12 (a)(1) it is unlawful for any person to retain any prohibited species, which must be returned to the sea as soon as practicable with a minimum of injury when caught and brought on board. This EFP allows the permitted vessel to retain prohibited species until offloading and requires the vessel to deliver all catch, with the exception of Pacific halibut.

2. Under 50 CFR 660.140 (h)(1)(i)(A) any vessel participating in the Pacific Groundfish IFQ fishery is required to carry an observer. This EFP allows participants to utilize EM in lieu of the requirement to carry observers, beginning on the third fishing trip following the installation and testing of the camera system.

All other provisions of 50 CFR Part 660 would apply to fishing conducted under this EFP.

Reporting Requirements

Trawl logbooks must be maintained as required by the applicable state law. Additionally, a discard logbook will be maintained, in which the discarding of all Pacific halibut will be recorded.

Fishing Restrictions

A vessel fishing under this EFP must bring all catch on board the vessel and retain that catch (including prohibited species) until offloading, with the following exceptions:

1. Operational discards. For the purposes of this permit, any fish that pass through the webbing of the net while the net is being retrieved or any fish that cannot be completely removed from the net prior to the net being reset or at the termination of fishing, shall be considered operational discards and need not be estimated or recorded.

2. Pacific halibut. All Pacific halibut must be discarded at sea. The vessel operator will be required to measure and record in a discard logbook all halibut discarded.

3. Large marine organisms. Large individual marine organisms, such as marine mammals or fish species longer than 6 ft (1.8 m) in length, may be discarded. If a large marine organism is discarded, the species and the reason for discarding must be recorded and labeled as "discard" in the required logbook.

4. Debris. It is perfectly acceptable for the crew of a permitted vessel to discard any and all debris items which may be encountered while fishing.

Monitoring Requirements

Each vessel must have properly installed and functioning Electronic Monitoring System (EMS) equipment. Owners of vessels must arrange for EMS services from a (NMFS approved) EMS service provider.

The EMS must be installed, tested, the system initialized and the EMS computer box sealed with tamper evident seals before the vessel leaves port on the first EFP fishing trip. Fishing without installing and testing the EMS equipment is a violation of this EFP.

Each vessel will carry an observer during the first two fishing trips. This will ensure monitoring during the period with the greatest chance for malfunctioning of the EM equipment.

As specified by the EMS provider, the vessel operator must schedule maintenance of EMS equipment and data removal by the NMFS-specified EMS provider by scheduling periodic appointments during the term of this EFP.

On each trip prior to leaving port, the vessel operator must conduct an EMS system status check as specified by the EMS provider to confirm that all components of the EMS are functioning properly. The EMS will record the results of this check. If the EMS check identifies a malfunction, the vessel must contact the NMFS-specified EMS provider immediately. When requested by the EMS service provider, the vessel would be required to carry EMS units that transmit system performance data while a vessel is at sea. Any such requirement would be in addition to the operator initiated system check which is to occur on each trip.

Each vessel operating under this EFP must provide continuous lighting to the following vessel areas such that the manipulation of trawl nets and fish handling can be clearly recorded by the EMS cameras: fish hold openings, deck spaces, and the trawl ramp.

The vessel is obligated to monitor the EMS performance. When aware that the EMS is not functioning properly or that the power has been interrupted, the vessel must contact the EMS service provider immediately. The EMS provider is required to provide technical service within 24 hours of notification at the vessels expense.

Other Restrictions

It is unlawful and in violation of this EFP for any person to tamper with, disconnect, damage, destroy, alter, or in any way distort, render useless, inoperative, ineffective, or inaccurate any component of the EMS unit required by this EFP.

EXEMPTED FISHING PERMIT APPLICATION

ELECTRONIC MONITORING FOR GROUNDFISH IFQ VESSELS IN 2015 AND 2016

1. Date of Application: 5/23/14

2. Applicant

California Risk Pool
Fort Bragg Groundfish Association: Michelle Norvell
Half Moon Bay Groundfish Marketing Association: Lisa Damrosch
Central California Seafood Marketing Association: Bill Blue

3. Project Partners

Environmental Defense Fund: Shems Jud, Sarah McTee, Alexa Fredston-Hermann, Huff McGonigal
The Nature Conservancy: Melissa Stevens, Michael Bell, Kate Labrum

4. Summary

This EFP application seeks exemption from the requirements at 50 CFR 660.140 (h)(1)(i)(A), requiring observers on board trawl and fixed gear IFQ fishing trips during the 2015 and 2016 fishing seasons. In place of observers, we propose to use the electronic accountability and reporting mechanisms described below as well as any additional measures the Council may require. The EFP includes approaches for both trawl and fixed gear vessels under one application. However, if for any reason the provisions applying to one of these sectors are not approved, it is our hope that the Council may view the trawl and fixed gear components as severable.

Details are provided in Sections 10 and 11, but the primary components of this application are as follows:

- EFP participants will provide all quota needed to conduct the EFP.
- All fixed gear vessels in this EFP will operate under maximized retention.
- Two shoreside bottom trawl vessels will also operate under a maximized retention plan, while two others will operate under optimized retention. Testing both approaches to retention requirements will allow for a comparison of respective costs and operational feasibility. The bottom trawl vessels operating under optimized retention may discard arrowtooth flounder, Dover sole, and English sole. Individual vessel monitoring plans will be used to outline appropriate catch handling and discard methods for those species.
- Field testing will begin with 100% observer coverage, *before* the permit that exempts EFP vessels from the 100% observer coverage requirement is issued. This initial phase will use both observers and electronic monitoring (EM) to establish a baseline for comparison once observers are removed, and will allow more fishing trips and sea-days overall to be included in the project. Observers are proposed to be retained on 20% of all trips even after the permit

is issued, to ensure that biological information is collected as needed for the West Coast Observer Program, and for other reasons discussed in Section 11.

- All Pacific halibut will be measured on a length board in view of an EM camera, and then discarded. Quota will be deducted from the vessel's quota account by calculating the weight of the halibut from its length, and then applying a vessel-specific average halibut mortality rate from 2011-2014 using Observer Program data (providing the vessel caught halibut after 2011). For vessels using hook and line gear, the mortality rate established by the Groundfish Observer Program will be applied, consistent with existing Observer Program protocol. If the Council concludes that it cannot authorize exemptions to rules relating to halibut discard and mortality estimates, this EFP can be conducted with the conservative assumption of 100% mortality of discarded halibut. We are also interested in collaborating with PSMFC on their research evaluating proxy factors to estimate halibut mortality.
- An electronic logbook will serve as the primary source of data for documenting and accounting for discards. To confirm that discard data in the e-logbook is correct, 100% of video from the discard control point on bottom trawl vessels will be reviewed. In addition, video from 10% of fishing events (i.e. hauls) on all vessels will be reviewed. Retained catch data from the e-logbook will be confirmed using shoreside catch monitor data.

5. Statement of Purpose and Goals

Purpose

The purpose of this EFP is to help identify a pathway towards a viable and more cost effective means of ensuring accountability in the Pacific groundfish catch share grogram by testing the operational and cost implications of using EM to monitor compliance with retention requirements.

Goals

1. Identify individual and overall cost components of implementing EM on fixed gear and bottom trawl vessels.
2. Establish best practices for discard control points on bottom trawl vessels using optimized retention.
3. Compare the relative benefits and drawbacks of optimized and maximized retention fishing plans.
4. Determine whether human observers and EM have different effects on fishing behavior.
5. Identify improvements to EM systems and protocols that can be made to inform a broader regulatory approach that encompasses all segments of the groundfish fleet.
6. Build comfort with EM within the industry, law enforcement, and management communities
7. Operationalize the lessons learned through national EM pilot studies.
8. Determine how to implement electronic monitoring and accountability in a way that will provide economic relief and operational flexibility to the groundfish IFQ program while maintaining individual accountability and the integrity of the catch share program.

Definition of Terms

This EFP will use a definition of "retained catch" and "discarded catch" (i.e. will describe what fish are to be counted against the vessel's quota) based on the pending GEM Committee recommended definitions and subsequent NMFS guidance on this topic. We ask for NMFS/GEM Committee guidance on definitions to be consistently applied to all EFP applicants.

6. Justification and Broader Significance

The transition of the Pacific groundfish fishery to catch share management has brought considerable conservation and management benefits including significantly reduced discards and bycatch of overfished species. Fleetwide revenues under the program have also increased. A critical component of the catch share's success is 100% accountability through at-sea observers; however, the costs associated with these monitoring requirements also pose the greatest risk to the program. As the fleet begins to bear more of the financial burden of monitoring, smaller businesses that are already at the margin of profitability may no longer be viable, resulting in socioeconomic impacts to the fishermen and their port communities. Beyond direct costs, the deployment of human observers also poses logistical and operational challenges to the fleet that prevent the program from reaching its full potential. These types of impacts will have serious negative consequences for the durability and scalability of this catch share program. This is therefore not only an economic issue, but a significant conservation and management issue as well.

While the EFP would be limited in scope and number of participating vessels (approx. 7), it has much broader significance through its potential to inform an eventual regulatory package that applies across the fleet. Beyond West Coast groundfish, national EM programs are struggling to operationalize. This EFP represents an important opportunity to move EM forward in a vital fishery and in a manner that is well controlled.

This EFP will provide a detailed cost breakdown for monitoring vessels in this fishery using EM, and the contribution of individual EM components to the overall cost will be identified. This project will provide detail on the optimal design of discard areas and demonstrate the ability of EM trained analysts to accurately speciate and estimate weights for certain flatfish (see Section 9). By providing a cost and logistics comparison of optimized and maximized retention for trawl, this EFP may also help to guide the Council's decision-making process with regards to EM for these sectors. The authors of this EFP plan to work closely with the SSC and the GMT to ensure data collection and analysis is done in a thoughtful and predetermined fashion so that it contributes the most value to EM research in general.

7. Duration

Given the amount of resources required to approve and issue an EFP, we request the permit be issued for 2 years (2015, and 2016). However, if the Council wishes to limit the EFP to a single year we request that it be for 2015.

8. Number of Vessels

We anticipate that approximately 7 vessels will participate in this EFP: 3 from the fixed gear fleet and 4 trawlers.

9. Description and Amount of Harvested Species

Target Species: Sablefish, Dover Sole, Chilipepper rockfish, Lingcod, minor shelf rockfish, minor slope rockfish, Splitnose rockfish, Yellowtail rockfish, English sole, Petrale sole, other flatfish

Rebuilding Species: Cowcod, Canary rockfish, Yelloweye rockfish, Darkblotched rockfish, Bocaccio

The amount of these species that will be taken is difficult to estimate, however, the participating vessels will be providing all quota required and no request for quota pounds is being made.

10. Accountability Mechanism

In an effort to mitigate accountability concerns, the vessels participating in this EFP will be required to sign a collective contractual agreement. The EFP manager will hold all fishermen accountable to the terms of the contract. This structure will help ensure that compliance incentives are in place and that minor issues are dealt with by the EFP applicant.

This contract will be developed in partnership with, and to the satisfaction of, NOAA OLE, and will include the following features:

- i. An acknowledgement by signatories that violations by one vessel may result in penalties for all participants, and that potential violations will be reviewed by an EFP manager (selected by the participants) and notified to NMFS OLE.
- ii. An acceptance by participants of the possibility of the EFP being revoked in the case of a serious violation by a single fishing vessel.
- iii. Incentives to report accurately and to cooperate with EM protocols.
- iv. This contract will *not* involve any quota pooling or mandatory spatial fishing plans.
- v. A description of possible violations and the associated monetary, quota, and participation penalties. This penalty schedule will be developed in partnership with, and to the satisfaction of, NOAA OLE.

Finding electronic means of maintaining the accountability that human observers provide is a challenge, particularly for the trawl segment of the fleet. Adoption of EM creates genuine accountability and enforcement risks. However, there are ways to mitigate these risks, and they need to be compared to the broader programmatic and policy risks associated with failing to address the issue of observer costs, particularly for the non-whiting fleet. Any risk also needs to be evaluated in the context of those risks inherent in the management of other sectors of the groundfish fleet, including the recreational and open access sectors. The insurance of accountability, in terms of identifying instances of non-compliance and determining penalties, is described in Section 11. On balance, we believe that given the measures proposed in this application, the benefits of moving forward with this EFP far outweigh any perceived risks.

The following retention plans were drawn from the range of Alternatives for Groundfish Electronic Monitoring Policy adopted by the Council in November 2013.

<u>Maximized Retention Plan</u>

This plan will apply to *all fixed gear vessels* and *two bottom trawl vessels.* Vessels fishing under maximized retention will retain *all groundfish species*, both IFQ species and non-IFQ species. This retention plan reflects Alternative 2: Maximize Retention of the discard alternatives from the November 2013 PFMC meeting, with provisions intended for other gear types (i.e. midwater trawl) removed:

- i. Discards **required** for:
  - a. ESA species, MMPA species, and other protected species.
  - b. Prohibited species, when applicable.
  - c. Halibut, after a length measurement is obtained; see below for details.

ii. Discards **permitted** for:
   a. Non-IFQ, non-groundfish species that can be clearly recognized as such and will not be confused with IFQ groundfish in EM video review (e.g. elasmobranchs or finfish not listed in groundfish FMP).
   b. Trash, mud, wood, and other inorganic debris.
   c. Crabs, starfish, coral, sponges and other invertebrates.
   d. Situations where human life or safety is threatened.

iii. Discards **prohibited** for:
   a. IFQ groundfish species.
   b. Non-IFQ groundfish species.
   c. Prohibited species, when applicable.

<u>Optimized Retention Plan</u>

After consulting with fishery participants, we concluded that a maximized retention plan may not be economically viable for some shoreside bottom trawl vessels (Alternative 2). Shoreside bottom trawl vessels often discard low-value fish at-sea, typically flatfish. Retaining these species could significantly impact the profitability of a vessel's fishing trip by filling the hold with low-value or unmarketable catch. Additionally, even if vessels were to land these fish (which are typically undersized, unmarketable, or both), processors and/or buyers likely may accept them. Ultimately, these undesirable fish could need to be discarded on land or at sea, resulting in additional disposal costs to the fishing vessel.

Industry members identified three low-risk species that represent much of the discards in this fishery. These high-quota, low-attainment species are Dover sole, English sole and arrowtooth flounder. It is worth noting here that some of the trawl vessels that will participate in this EFP are also experimenting with modified trawl gear that significantly reduces their bycatch of small flatfish, often from thousands of pounds down to hundreds of pounds. We anticipate that the catch accounting system proposed for bottom trawl discards will be used for no more than several hundred pounds of discarded fish per trip. In 2012, California Risk Pool vessels discarded an average of 50 pounds or less each of Dover sole, English sole, and arrowtooth flounder per trawl tow. More detail on how discards will be identified is given under Section 11.

Consequently, we propose to explore under this EFP a limited discard or "optimized retention" option that better reflects fishing operations and needs, thereby providing a realistic model for how EM could operate in this fishery in the future. We anticipate that two bottom trawl vessels in this EFP will operate under optimized retention and two under maximized retention (using the retention plan described above), allowing a comparison of both retention plans.

This proposal is a modified version of Alternative 3, Retention of Catch Share Species with Options:

i. Discards **required** for:
   a. ESA species, MMPA species, and other protected species.
   b. Prohibited species, when applicable.
   c. Halibut, after a length measurement is obtained; see below for details.

ii. Discards **permitted** for:
   a. Non-IFQ, non-groundfish species that can be clearly recognized as such and will not be confused with IFQ groundfish in EM video review (e.g. elasmobranchs or finfish not listed in groundfish FMP).

b. Dover sole, provided they can be identified and assigned weight estimates using EM.
c. English sole, provided they can be identified and assigned weight estimates using EM.
d. Arrowtooth flounder, provided they can be identified and assigned weight estimates using EM.
e. Trash, mud, wood, and other inorganic debris.
f. Crabs, starfish, coral, sponges and other invertebrates.
g. Situations where human life or safety is threatened.

iii. Discards **prohibited** for:
a. All IFQ groundfish, excluding Dover sole, English sole, and arrowtooth flounder.
b. IFQ groundfish that cannot be adequately identified by the skipper or crew and/or assigned weight estimates using EM.
c. Non-IFQ groundfish species.
d. Prohibited species, when applicable.

<u>Halibut</u>

This EFP is intended to test an operational model of EM that could be scaled to the entire fleet; consequently some estimate of halibut mortality is necessary. Understanding that this application is open to vessels that are not part of the California Risk Pool (whose members have not caught Pacific halibut since implementation of the IFQ), we propose the following method for assessing halibut mortality for any vessels in this EFP *with halibut history since 2011, except* those using hook and line gear:

> A quota deduction will be generated by obtaining a length measurement visible to the camera using a measuring board, which will then be used to calculate weight. A mortality estimate will be applied based on the vessel's individual 2011-2014 average halibut mortality rate, as determined by the Observer Program.

For hook and line gear, the mortality rate established by the Observer Program will be applied instead of the vessel-specific average. The halibut handling protocol on-board will be the same as other gear types. This is consistent with current Observer Program protocols for this gear type.

California Risk Pool vessels, and many other vessels in California, have not caught Pacific halibut since the implementation of the catch share program in 2011. However, if halibut are encountered, we propose the following method for assessing halibut mortality for all vessels in this EFP *without halibut history since 2011, except* those using hook and line gear:

> A quota deduction will be generated by obtaining a length measurement visible to the camera using a measuring board, which will then be used to calculate weight. A mortality estimate will be applied based on the fleet-wide 2011-2014 average halibut mortality rate, as determined by the West Coast Observer Program.

If the Council concludes that it cannot authorize exemptions to the rules relating to halibut discard and mortality estimates, we request that the EFP be approved with the conservative assumption of 100% halibut mortality.

If 2014 Observer Program data is not available when this project begins, halibut mortality estimates will be derived from 2011-2013 data until and unless 2014 data becomes available during the project.

11. Proposed Data Collection

EM Services

Three components exist in the data collection process for EM: the technical system (the EMS itself), the field services (hard drive retrieval and maintenance), and the video review. This EFP intends to use hardware (camera systems, sensors, hard drives, etc.) and video analysis software from Archipelago Marine Research Ltd. We are currently exploring options for video review, including Pacific States Marine Fisheries Commission (PSMFC) and Tenera Environmental. PSMFC has been conducting EM research since 2012 and has experience reviewing EM footage from the Archipelago systems. Tenera Environmental is currently contracted to conduct field services for PSMFC's Pacific groundfish EM study, and was certified to review Archipelago EM footage under the 2010 EM EFP conducted by The Nature Conservancy. Regardless of which agency performs video review services, it is expected that Tenera Environmental or another private vendor will be contracted to perform field service responsibilities under this EFP.

The EMS will include the following:

i. Secure, watertight control box for data storage.
ii. Digital cameras that include or are connected to a date and time stamp and counter.
iii. A minimum camera resolution and frame capture rate (to be determined).
iv. A minimum amount of on-board data storage (to be determined).
v. Tamper-evident hardware.
vi. A monitor showing a live feed from all EMS cameras, so that the skipper can ensure the EMS is functioning correctly.
vii. An electronic reporting system consisting of a device (smartphone, tablet, or computer) and software that, at a minimum, contains data entry fields and units that conform to the existing state logbooks.

The installation and operation of the EMS will be governed by the Individual Vessel Monitoring Plan (IVMP) drafted by the EMS provider in collaboration with the vessel skipper. The IVMP will address the following:

i. Hardware, including but not limited to the control box, removable hard drive, camera specifications, GPS receiver, and pressure and motion sensors.
ii. Software for data collection.
iii. Protocols for EMS malfunction.
iv. Back-up equipment use protocols.
v. Catch handling protocols.
vi. Vessel layout and camera coverage, including screen shots of camera views.
vii. Number and placement of cameras.
viii. Lighting requirements.
ix. Required/necessary power supply for EMS.
x. Instructions for care and maintenance of the EMS.
xi. Schedule for EMS maintenance and data transfer.
xii. Instructions for filling out and submitting electronic logbooks.

EM data capture and analysis

For the purpose of assessing compliance with individual quotas, EM data analysis will draw on a variety of data sources, including pressure and motion sensors, electronic logbooks, VMS, and GPS devices, shoreside catch monitors, as well as the camera footage itself.

The EMS service provider and any 3rd party contractors selected by the EFP participants will:

i. Describe and adhere to a clear chain of custody for hard drives with EM data.
ii. Ensure the timely retrieval of hard drives from EFP vessels.
iii. Maintain confidentiality of EM data at all times.

In this EFP, quota accounting will be accomplished by cross-checking the electronic logbook against two main data sources: EM, which provides data on discards, and shoreside catch monitors, which provide data on landings. In other words, the total catch and discards of a vessel will be determined using the shoreside monitor data plus any discard events witnessed using EM to verify the e-logbook.

A designated discard control point will be established and all discards are required to occur at that location on the vessel. A camera will be focused on the discard control point and 100% of discard events will be reviewed. Some examples of discard control points include discard chutes, or specific areas on deck where fish are passed individually through a camera view and then discarded. For each of the discard events, the EM reviewer will identify each IFQ fish to species and record a weight estimate, likely based on length-weight relationships for the species or known volumes of storage containers on deck. This discard data will be compared to the vessel e-logbook.

Based on PSMFC research presented at the April Council meeting and conversations with service providers, discard control points with designated cameras greatly improve the quality of EM video and the accuracy of quantifying discards. Using high-quality video where fish are viewed individually, and attempting to differentiate only three IFQ groundfish species, video reviewers should be able to confidently speciate all IFQ fish discarded under the optimized retention plan. In addition, as described in Section 10, the volume of small flatfish discarded by participating vessels is likely to be relatively small.

As an additional layer of accountability, 10% of the fishing events identified in the vessel's EM video data (at least one per trip) will be randomly selected for review. This review will ensure that no discards occurred outside of the discard area. Sensor data will be used to confirm all fishing events and trips were recorded in the electronic logbook.

<u>Concurrent observer coverage</u>

This EFP is requesting an exemption from regulations mandating 100% observer coverage. However, we anticipate deploying EM before NMFS issues the EFP and while observers are present on every trip. This initial 100% observer coverage with EM will serve multiple purposes. It will ensure that no lapses in full accountability occur while the skipper and crew are adjusting to EM. It will also allow the project to determine if an observer effect is occurring.

Once each vessel operator has stated their readiness in operating with EM, and the EFP has been issued, we intend to reduce observer coverage to 20% – representing the approximate level necessary for the Groundfish Observer Program to collect biological data. The design of this component will be developed with input from the GMT and SSC, and in collaboration with the Observer Program, to ensure that the resulting data is informative. It is imperative to conduct a substantial number of fishing trips during this EFP *without* an observer present, for a number of reasons:

- Maintaining both 100% observer coverage and full EM deployment represents redundant expenditures, undermines the incentive to participate, and fails to achieve the goal of cost-effective monitoring for this fishery.
- The percentage of fish discarded vs. retained, and the overall catch composition, may be compared from vessels fishing with and without an observer to determine if fishing behavior

changes. This analysis will help determine whether an “EM effect” exists similar to the “observer effect”.

- This approach will allow the Groundfish Observer Program to test out protocols for biological data collection as well as catch sampling under partial observer coverage.
- Members of the Pacific Council have expressed concern during the EM regulatory process about abruptly transitioning from 100% observer coverage to a much lower percentage in the fixed gear and bottom trawl fleets. This EFP will provide proof-of-concept that full accountability can be maintained using only EM in those sectors.
- Valuable lessons will be learned from the deployment of EM and subsequent data collection and analysis that will inform the EM regulatory alternatives currently being developed by the Council and NMFS.
- Recent reports by Pacific States Marine Fisheries Commission commented that the presence of an observer during their EM study may have had a deleterious effect on their results, because the observer may have prevented crew members from utilizing all available deck space or handling catch clearly.

Quota accounting

Catch accounting will use three sources of data: e-logbooks, shoreside catch monitor landing data, and data from the EM video review. This accounting system relies on the assumption that all discards are reported in logbooks and captured by the EMS (and any behavior violating this assumption would be treated as a violation, as described below).

For discarded fish, the vessel’s quota account will be debited whichever is greater: the estimated weight by species from the EM video reviewer, or the recorded weight by species from the e-logbook. For retained fish, the vessel’s quota account will be debited the weight by species from the shoreside catch monitor, consistent with the status quo under 100% observer coverage.

Discrepancies identified during video review may include, but are not limited to, the following:

i. Unauthorized discards: discarding species required to be retained (e.g. rockfish).
ii. Discard events occurring outside of the predetermined discard area.
iii. Crew behavior or fish handling preventing accurate fish identification or weight estimation.
iv. Discard event was not recorded in e-logbook.
v. Fishing trip or event not recorded in e-logbook
vi. The e-logbook underestimates discards by more than 10% for any species.

If the discrepancy between the e-logbooks and the EM video reviewer is greater than 10%, then a video reviewer will watch 100% of the video from all fishing events in the trip. The vessel will be responsible for the cost of additional video review.

Compliance and penalty structure

We define an EMS failure as one or more cameras malfunctioning, and/or any loss of sufficient quality video footage during a fishing event. In every case of EM malfunction, the camera provider will examine the EMS for signs of tampering. In the event of EMS malfunction, vessels may return to traditional monitoring using on-board observers in order to begin another fishing trip if desired.
The consequences of an EMS failure hinge on the tamper-evident nature of the EM equipment, the crew adhering to the care and maintenance protocols, as well as any disruption in video feeds to the monitor available to the skipper and crew:

i. If the EMS fails and the skipper's EM video feed shows some malfunction, the skipper must alert the service provider and immediately suspend fishing activities and return to port. The skipper may not begin another fishing trip without carrying an observer or ensuring the EMS is repaired.
ii. If an EMS failure is noted during data retrieval and analysis, but the EM video feed had not been affected (i.e. the skipper was unaware), the vessel's quota account will be settled using the e-logbook as confirmed with fish ticket data. The quota account will also be debited an additional 5% of the fishing trip's landed pounds (of each species) to compensate for the EMS failure. The skipper may not begin another fishing trip without carrying an observer or ensuring the EMS is repaired.
iii. *In any EMS failure*, if the service provider determines the system has been tampered with, the vessel will be penalized according to NMFS and OLE determination.

These measures and others will be codified in the collective contract among EFP participants, described in Section 10.

12. Vessel Selection Process

Up to 7 vessels will be selected to participate in the EFP that meet the following criteria.

The *vessel* must:
i. Have sufficient space and ventilation for EMS hard drive.
ii. Have sufficient power to run EMS uninterrupted.
iii. Have or establish a designated discard area that can be monitored with an unobstructed view.
iv. Create an Individual Vessel Monitoring Plan (IVMP).
v. If possible, have participated in a previous EM pilot project or EFP.

The *skipper/owner* must:
i. Be engaged in and responsible for EMS deployment, troubleshooting, and implementation on their vessel.
ii. Be willing to retrofit the vessel and catch handling operations necessary for EM deployment.
iii. Participate in or designate a representative to participate in PFMC meetings and related workshops, representing this EFP.
iv. Be able to re-train crew in appropriate behavior for EM.
v. Sign a collective contract indicating acceptance of appropriate protocols in the case of EM malfunctions and penalties in the case of violations.
vi. Fill out and submit electronic logbooks, in addition to the currently required State logbooks.
vii. Must be in "good standing" with NMFS and Risk Pool (i.e. no outstanding violations).
viii. Share vessel-specific 2011-2014 halibut mortality estimates as determined by the Observer Program (if any halibut were caught), as well as all discard and catch data from fishing that occurs under this EFP.

The table below includes all 10 vessels currently participating in the California Risk Pool, up to 7 of which may participate in this EFP. Inclusion in this list does not imply any commitment at this stage on the part of these fishermen to participate in the EFP. Other vessels that are not members of the California Risk Pool may also participate in this EFP; the total number of vessels will not exceed 7.

The first receivers that may receive landings from EFP fish include, but are not limited to, the following:

- Caito Fisheries, Ft. Bragg, CA

- Deyerle Brothers Seafood Inc., Monterey, CA
- Alber Seafoods Inc., San Francisco, CA
- North Coast Fisheries Inc., Santa Rosa, CA
- Bettencourt and Son, Half Moon Bay, CA
- Central Coast Seafood, Atascadero, CA
- Mr. Morgan Fisheries Inc., Moss Beach, CA

Owner/Skipper	Vessel	Gear
Geoff Bettencourt	Moriah Lee	Traps
Steve Fitz	Mr. Morgan	Scottish seine
Bernie Norvell	Donna J	Trawl
Brian Jourdain	Blue Pacific	Traps
Tom Estes	Tara Dawn	Trawl
Vince Doyle	Verna Jean	Trawl
Bill Blue, John Blue	Brita Michele	Traps
David Rose	Nikki J	Longline
Rob Seitz	South Bay	Trawl
Keith Marshall	Captain John	Trawl

13. Times and Places of Fishing, Type of Gear

Exact fishing locations and times will depend on the vessels that are selected, their home ports and fishing plans. The gears used will be groundfish bottom trawl gear and groundfish fixed gear. For trawl vessels, it is anticipated that fishing will occur both seaward and shoreward of the trawl Rockfish Conservation Area and with both large and small footropes. All fishing will be conducted south of Cape Mendocino.

bpaine@ucb.org

Purpose and Need for Exempted Fishing Permit:

Purpose
Ballooning monitoring costs and operational considerations form a well-defined need and justification to move forward with issuing an Exempted Fishing Permit (EF) for the at-sea and shoreside whiting fisheries. The purpose of the EFP is to determine whether utilizing cameras in lieu of human observers proves both cost effective and operationally effective while still providing 100% monitoring of catch and discards that adequately comply with the personal accountability requirements of Amendment 20.

Need
Amendment 20 was implemented in January 2011. The Trawl rationalization program includes individual transferable quotas for the shoreside whiting fleet and a cooperative system for the at-sea whiting fleet. A majority of west coast whiting fishermen participates in both sectors. Both programs require 100% monitoring of catch and discards as a fundamental component of the catch accounting system. Currently the monitoring mandate is accomplished using human observers provided by two National Marine Fisheries Service (NMFS) approved providers with the majority of the cost borne by the industry and a subset of the cost covered by a government reimbursement. While NMFS recently published a rule detailing a certification process for additional observer providers, it is our understanding that there are no observer providers immediately wanting to become providers for the west coast groundfish trawl fishery.

For 2014 the government reimbursement is $216 of the total $450-$500 per day cost of a human observer. The cost of monitoring is only one piece of a larger financial burden that fishermen participating in the trawl groundfish fishery are facing. In addition to the normal operating costs associated with running a fishing vessel, there are several other government-imposed fees including state landings taxes (set to increase in Oregon), a 5% annual Buyback Loan payment and an annual Cost Recovery fee totaling 3% for the shoreside whiting fishery participants and 2.4% for mothership fishery participants. All of these costs are based on ex-vessel value – so they come out of a business's gross earnings, which can equate to upwards of 15-18% of a vessel's gross *before* paying out all the other costs associated with running the business. Human observer costs are expected to continue to increase in the coming years. Cost relief is the primary reason we are seeking to experiment with using electronic monitoring versus human observers in the whiting fishery. It is expected that monitoring costs will decrease with the use of cameras versus human observers. This expectation is based on previous experience and information gathered from a pilot program utilizing cameras in the west coast shoreside whiting fishery from 2004-2010. This expectation is further bolstered by data provided by the Pacific States Marine Fisheries Commission resulting from their most recent study.

Another primary reason we are seeking to utilize electronic monitoring in lieu of human observers is related to logistical and operational considerations. Human observers are just that – human. There are times when observers are unable to conduct their required sampling duties or they are unavailable to deploy when a vessel is ready to depart to go fishing. Comparatively, cameras are always on, they do not eat, sleep or get sea sick and once installed they are always ready to head out on a fishing trip, regardless of time or location.

Species Disposition:
All species harvested under this EFP must be covered by quota share or cooperative species allocation as currently detailed in the existing Amendment 20 regulations. This EFP mirrors fishing strategies that are currently employed in the whiting fisheries and the only difference is the use of a camera for monitoring versus a human observer. This EFP does not request a special allowance to harvest any additional species (species of concern or otherwise) and the disposition of all species should mirror current fishing operations and strategies. There is no set aside of any species – target or otherwise – with this EFP and impacts on rebuilding species are already considered and included in annual scorecard accounting and monitoring based on Amendment 21 allocations.

Broader Significance:
The proposed activity under this EFP will have broader significance than simply achieving certain goals for the applicants. There are other sectors and fisheries on the west coast that are interested in utilizing EM – the bottom trawl and fixed gear sectors of the trawl ITQ fishery as well as other Pacific fisheries in need of monitoring but unable to carry observers due to small vessel size or even safety

concerns. In addition, there is a national push to explore and implement electronic monitoring in a variety of fisheries utilizing an assortment of gears. The information garnered through this EFP will be very informative in helping to design and implement EM systems both on the west coast and around the country in other regions as well.

Duration:
The EFP would be issued for two years and cover two entire whiting seasons, which begins in May and continue through the remainder of any given year. We are seeking a 2-year EFP for the shoreside and whiting fisheries covering 2015 and 2016 fisheries.

Number of Vessels Covered:
Any catcher vessel which participates in the primary mothership or shoreside whiting fishery would be eligible to participate under this EFP as long as they meet all criteria and requirements as outlined in this application – this could be as many as 37 vessels. Midwater Trawlers Cooperative represents 23 catcher-vessels of which 18 participate in the at-sea and/or shoreside whiting fishery. Out of these 18 vessels, 16 have indicated a desire to utilize electronic monitoring if the opportunity is available and if the technology is cost-effective. United Catcher Boats represents 72 catcher-vessels of which 16 participate in the at-sea and/or shoreside whiting fishery. Out of these 16 vessels, we estimate 10 to 14 would utilize electronic monitoring beginning in 2015.

Whiting Fishery Description:
The West Coast whiting fishery is divided up into three distinct sectors: the shoreside fishery where vessels deliver to seafood processors onshore; the mothership sector where vessels catch and deliver the fish to at-sea seafood processors; and the catcher processor sector where vessels catch and process whiting on the same vessel. This EFP applies to the shoreside and mothership sectors. Currently the at-sea season begins May 15 and the full shoreside sector begins June 15 (there is a small shoreside fishery in California which begins in May). In 2015 both sectors are expected to begin May 15 following the implementation of an amendment to the program that changes the shoreside start date to effectively match the start date of the at-sea fishery.

Fishermen target Pacific whiting (also known as hake) with midwater trawl gear. There is no sorting of the catch at-sea and the crew works to get the catch into the fish holds and refrigerated seawater systems (RSW) as quickly as possible to ensure the high quality fish required by the market. Pacific whiting contain an enzyme that causes the flesh to deteriorate and break down rapidly unless the fish is significantly chilled down immediately after capture. All sorting of pacific Whiting is done at the processing level. For the shoreside fishery the catch is sorted at the shoreside seafood processor during the offload. In the at-sea fishery the catch is delivered directly to the mothership processor (the fish is never brought onboard the catcher vessel) and it is sorted during the offload period. Bycatch species typically associated with both the at-sea and shoreside whiting fisheries includes rockfish and sometimes salmon.

Fishing activity is not expected to change under this EFP. There may be more flexibility for fishermen who are not bound by the scheduling restraints of human observers – but once on the water the strategies and fishing behavior should be consistent with recent years since implementation of the rationalization program.

History:
From 2004 through 2010 the shoreside whiting fishery operated under an EFP and cameras were required to monitor maximized retention on the catcher-vessels. The EFP was granted in order to exempt vessels from the onboard catch shorting required under the regulations. As noted above, the need to get the catch into the RSW systems as quickly as possible necessitated the exemption to sorting out prohibited or other species at-sea. The program was discontinued in 2011 when Amendment 20 was implemented, not because of shortcomings with the EM program, but rather to have a consistent monitoring program across all trawl groundfish vessels that provides 100% monitoring to support the personal accountability component of the program.

Scope:
This EFP application is to use an EM system in the whiting fishery for compliance with monitoring requirements only. Biological information collection is not part of this EFP but it is assumed that biological sampling will continue at the processing level for both the at-sea and shoreside fisheries similar to current practices. Currently human observers are not actively doing biological or other sampling on whiting vessels since the vessels are not sorting their catch at-sea. Observers do log any operational discards and under this EFP the vessel's captain will log any operational discards in the required logbook.

Eligible Vessels
Midwater vessels that are targeting non-whiting are not eligible for this particular EFP. Any whiting vessel that wants to take advantage of this opportunity must be a member of either MTC or UCB. MTC and/or UCB will be the applicant(s) for the EFP and the EFP will be administered through these organizations which will act as umbrellas for their member vessels that participate.

Maximized Retention
The participants will fish under a maximized retention scenario like the one that is used in the fishery now and described above. Participants in the shoreside fishery are required to dump unsorted catch directly below deck and would be allowed to land unsorted catch providing an electronic monitoring system is used on all fishing trips to verify retention of catch at-sea. Catcher vessels participating in the at-sea mothership fishery will continue to deliver full, unsorted cod-ends to a mothership processor. The mothership catcher vessels will not bring any filled cod-ends

onboard the catcher vessel but will deliver it directly to the mothership, as is the current practice.

Disposition of Prohibited Species
Disposition of prohibited species such as salmon or halibut will be the same as the procedures that are in place currently. In the shoreside fishery any prohibited species are sorted out at the plant, enumerated by the catch monitor, and turned over to the state of landing for donations to food banks. In the mothership fishery any prohibited species are sorted out by the mothership processor, recorded (enumerated) by the mothership's observer, and discarded at sea.

Video Review
We would like to test two approaches to the video review and see which one meets the requirements for 100% accountability and is most cost-effective. In the first approach, the vessel captain will self-report their catch and any operational discards in their logbook. The video from the cameras will be used as an "audit" to ensure correct reporting of discard events. After the reviewers watch the video for any reported discards (noted from logbook) the reviewers will then follow-up with a 10% random review of the remaining video seeking any unreported discard events. The additional 10% random review is patterned after the system that is currently utilized in the British Columbia groundfish fishery. The second approach is patterned after the recent Pacific States Marine Fisheries Commission study and involves 100% review of the video to ensure no discards are taking place.

This EFP seeks to have the EM provider also complete the logbook audit and video review – not NMFS personnel.

EFP Compliance
Any blatant unreported discard events that are discovered during the review will result in the immediate loss of EFP privileges for the remainder of the EFP. Any vessel that loses its EFP privileges will be required to carry a human observer for the remainder of the EFP. We are exploring whether or not the whiting at-sea and shoreside cooperatives would be appropriate for management of the EFPs or whether the applicant organizations would be more appropriate. We do not, however, envision individual EFPs for every participating vessel but rather an umbrella organization that will manage the EFPs.

Required Data Collection and Vessel Monitoring Plans
Fishermen will be required to complete a logbook that includes the following information:

- Date
- Set time
- Depth
- Time of net retrieval
- Latitude & Longitude

- Depth of head rope
- Estimated amount of catch
- Estimated amount of any operational discard

Applicants will work with a 3rd party provider to develop an electronic logbook – if an electronic logbook cannot be developed in time for when the EFP is implemented, than a paper logbook that captures the same information will be utilized (as is currently done in both the at-sea and shoreside whiting fisheries).

The vessel will work together with the EM provider to develop a Vessel Monitoring Plan (VMP) that will be approved by NMFS. The VMP will layout the placement of all cameras on the vessel and detail the criteria that the camera system must meet. It is assumed that the set-up that will be utilized will be similar or the same as that system used in the 2004-2010 pilot program. This system is comprised of a system control center, up to 4 cameras, a GPS receiver, a hydraulic pressure sensor, and a winch rotation sensor. Image and sensor data are stored digitally on a removable hard drive that can be exchanged at intervals (to be determined) during the fishery.

It is the responsibility of the vessel captain to ensure that all systems are operational before leaving port. Consultation between the EM service provider and the vessel is expected to be thorough and the captain is responsible for several aspects of the system including: keeping the system continuously powered while the vessel is at-sea, regularly cleaning camera dome surfaces to ensure sharp image resolution; conducting periodic inspections of system components and conducting regular system checks to ensure the EM system is performing properly; ensuring that camera view areas are adequately lit during night operations; immediately contacting program staff and NMFS if the EM system stops performing; and maintaining regular contact with service provider for data retrieval and service scheduling.

For the shoreside fishery the camera will be turned on once the first set is made and remain on until the vessel returns to port to offload. A shoreside trip averages 1-3 hauls and can last 1-2 days. The camera will not be required to be on while the vessel is initially transiting to the fishing grounds and a geofence will be established around the ports the vessel is utilizing. For the at-sea fishery a trip is defined differently – vessels stay on the fishing grounds delivering to the mothership over a period of several weeks. The camera will be on during the entire trip or less if the EM provider determines the camera can be turned off without impacting the integrity of the program.

For the shoreside fishery video and logbook information will be transmitted once the vessel returns to shore via the already existing shoreside catch monitor. During the at-sea fishery video and logbook information will be stored on board the vessel until it returns to port after finishing the at-sea portion of the fishery. Alternatively, the video and logbook information could be transmitted to one of the observers stationed on the mothership.

A 3rd party organization (approved by NMFS) will be responsible for review of the logbook and associated video. We propose the EM provider will provide this service, not NMFS personnel.

Specific Regulations from Which an Exemption is Being Requested:

a. Under 50 CFR § 660.12 (a)(1) it is unlawful for any person to retain any prohibited species, which must be returned to the sea as soon as practicable with a minimum of injury when caught and brought on board. This EFP allows the permitted vessel to retain prohibited species until offloading and requires the vessel to deliver all catch.

b. Under 50 CFR 660.140 (h)(1)(i)(A) any vessel participating in the Pacific Groundfish IFQ fishery is required to carry an observer. This EFP allows participants to utilize EM in lieu of the requirement to carry observers

Reporting Requirements

- Trawl logbooks must be maintained as required by the applicable state law and include the information detailed above

Maximized Retention Requirements

- All catch must be brought on board the vessel and retained until offloading, with some exceptions:
  - Pacific whiting removed from the deck and fishing gear during cleaning may be discarded, provided that the total does not exceed one based from any single haul, with the maximum dimensions of the basket being 24 inches by 16 inches by 16 inches. All catch in excess of the one basket would need to be placed into the fish hold. Discarding species other than pacific whiting would be prohibited.
  - Large individual marine organisms, such as marine mammals or fish species longer than 6 feet in length, could be discarded provided the species and the reason for discarding were properly recorded in the required logbook
  - All incidentally caught marine mammals would need to be documented in the vessel logbook and reported to the NMFS Office of Protected Resources by submitting a completed Marine Mammal Authorization Program mortality/injury report form.
  - Unavoidable discard of catch would be the result of an event that is beyond the control of the vessel operator or crew. The quantity and all species discarded as a result of an unavoidable discard event would need to be estimated, and the location of the tow, and reason for discarding recorded in the logbook.

    - Discard that results when more catch is taken than is necessary to fill the hold is within the control of the vessel operator and would continue to be prohibited.
- All prohibited species incidentally caught in a midwater trawl, and required to be retained under this section, would be abandoned to the State of landing immediately upon offloading.

EMS Requirements

- Owners of participating vessel would be required to arrange from EMS services from a NMFS-approved provider and pay all associated costs
- Vessels required to procure EMS services may also be required to carry an NMFS West Coast Groundfish Observer Program observer (for the purposes of capturing biological information)
- The vessel operator would be required to schedule maintenance of EMS equipment
- Before each haul is retrieved, the vessel operator would be required to check status of EMS control box to confirm that the EMS is functioning properly
- From 30 minutes before official sunset until 30 minutes after official dawn, each vessel covered under this EFP would be required to provide adequate lighting to areas where the trawl nets and fish are handled and fish hold openings, deck spaces, and the trawl ramp so the activities could be clearly recorded by the EMS cameras.

Application for Exempted Fisheries Permit

Use of Electronic Monitoring in West Coast Trawl Fishery on Vessels Utilizing Fixed Gear.

Date: May 25, 2014

Background:

In 2011, NMFS implemented a Council-developed catch share program for the West Coast limited entry groundfish trawl fishery. The program requires that each vessel acquire quota pounds (QP) to cover its catch (including discards) of nearly all groundfish species. Proper functioning of the program requires some form of at-sea monitoring to ensure that discards are enumerated for each vessel. The catch share program specified that this monitoring function be achieved through 100% at-sea observer coverage. In conjunction with vessel logbooks, electronic monitoring (EM) is being explored as a potential technically and economically viable substitute for the use of human observers in the function of compliance monitoring for the catch share program.

In 2012 and 2013, Pacific States Marine Fisheries Commission (PSMFC) expanded its initial pilot project to test the feasibility of using electronic monitoring for catch accounting in the trawl catch share program in the west coast groundfish fishery. Included in expansion of the project were trawl-permitted vessels utilizing both pot and longline gear. Vessels were outfitted by EM service providers. In addition to the installation of EM systems, permitted vessel owners were also required to continue to contract for and carry a federal fisheries observer. This pilot project is continuing in 2014.

On May 3, 2013, National Marine Fisheries Services issued policy directive 30-133, setting forth the following objective:

It is the policy of the National Oceanic & Atmospheric Administration's (NOAA's) National Marine Fisheries Service (NOAA Fisheries) to encourage the consideration of electronic technologies to complement and/or improve existing fishery-dependent data collection programs to achieve the most cost-effective and sustainable approach that ensures alignment of management goals, data needs, funding sources and regulations.

Purpose and Goals:

For this exempted fishery permit (EFP), applicants propose to monitor catch and discard aboard a trawl-permitted vessel, utilizing fixed gear, via an electronic monitoring system, without 100% observer coverage as currently required by regulation. Comparison of the logbook recording of discard events by the skipper and the subsequent review of the video of the fishing activity for accuracy and compliance is the primary focus of this application. The use of fisheries observers onboard the vessel as an adjunct to the project is included in this application and further described below.

While industry is interested in finding less costly and more flexible methods to monitor catch and discards at sea, this application is also meant to begin to address some key management issues:

1) Can video monitoring be used on board a trawl-permitted vessel using fixed gear to accurately track and correctly identify a vessel's fish catch, including discards, to be debited from a quota account?

2) Can this be done without the presence of a federal fisheries observer?

3) Are fishermen able to accurately identify and record in logbooks the species caught, including both retained catch and discard?

4) What percentage of monitoring of the video from EM is required to verify catch and discard recorded in the logbooks?

Applicants seek the issuance of an EFP to show whether a sufficiently high confidence level in the accounting of catch and discard aboard a vessel can be demonstrated through the use of logbooks, verified by random monitoring of video from EM, and without the presence of a human observer.

Broader Significance of EFP:

In the event that there is a very high correlation of EM video review and logbook data of the catch and discard of species aboard the vessel pursuant to this EFP, it is anticipated that the requirement for 100% human observer coverage on trawl-permitted vessels using fixed gear for compliance-monitoring purposes may be significantly reduced, if not entirely eliminated, across the fleet. In fact, it may be demonstrated that observers on board trawl-permitted vessels using fixed gear may only be needed for the purpose of scientific data gathering.

A. Duration of EFP and Number of Vessels Participating:

Applicants request that this EFP be for a duration of two years, beginning January 1, 2015 and ending December 31, 2016. Four (4) vessels will participate in the first year, using pot gear, and two of these same vessels may also use longline gear.

Applicants envision the successful outcome of this EFP will be demonstrated within the first year, and anticipate Council action and NMFS future approval of a regulatory amendment to allow the use of EM without 100% observer coverage on board a vessel.

Past experience with the regulatory process leads applicants to believe that the amendment process for a fleet-wide EM program may be quite lengthy, possibly exceeding two years. With the implementation of a two year EFP on January 1, 2015: 1) additional vessels might be able to join for the second year, providing additional data; 2) the EFP can continue without interruption, pending the full regulatory amendment; and 3) the EFP may be modified.

If the EFP is issued for two years as requested, applicants propose that NMFS review the applicant's performance under the EFP before the end of the first year. NMFS would have the option to approve the EFP for a second year "as is", require or allow modifications to any aspect of the permit, and/or any vessel's operational plan, allow additional vessels to participate in this EFP, and/ or terminate the EFP in its entirety at any time.

B. Qualifications of Applicants:

John Corbin has longlined for sablefish off the West Coast and Alaska for more than 30 years. The F/V Buck and Ann is 56 ft. long and the F/V Southeast is 66 ft. long. Both vessels have trawl permits with sablefish and other groundfish quota in their respective vessel accounts, and have fished the trawl permits with pot gear for the last 3 years. During 2013, the F/V Buck and Ann participated in the PSFMC project, deploying an EM system while also carrying a federal fishery observer, and will continue to do so in 2014.

For purposes of this application, the F/V Buck and Ann will be using pot gear as will the F/V Southeast. The F/V Buck and Ann and the F/V Southeast may also utilize longline gear.

Bob Eder has fished for sablefish with pots off the coasts of Oregon and Washington for 35 years. The F/V Timmy Boy is a 60 ft. vessel, and has a trawl permit, sablefish and other groundfish quota in its vessel account, and fished its trawl permit with pot gear in 2011 and 2013. During 2013, the F/V Timmy Boy also participated in the PSFMC project, deploying an EM system while also carrying a federal fisheries observer. The vessel will continue to participate in this program in 2014.

Burton Parker has fished numerous pot and trawl fisheries and owned commercial vessels off the West Coast and Alaska for 40 years. He has previous experience with the installation and operation of EM in the whiting fishery. Alyssa Ann LLC is the owner of the F/V Alyssa Ann, a 44 ft. vessel that fishes for sablefish out of Newport and Astoria OR. Burton Parker is the sole member of the LLC. The vessel has a trawl permit, quota in the account, and uses pots to fish for sablefish. The vessel's skipper is Jake Erickson, who has commercially fished for 10 years, and has 3 years' experience operating the F/V Alyssa Ann, fishing for sablefish with pots.

All of the applicants have successfully participated in at least one, if not multiple years, in an EM program aboard vessels they own. All have experience working with EM contractors, having vessels outfitted with gear and cameras, making system modifications suited to the individual vessel to ensure operational success, using customized logbooks, and facilitating data storage, retrieval, and delivery to EM contractors.

C. Target Species, Areas Fished, Gear Used, Time Frame, Declaration:

Applicants will target sablefish, both North and South of 36 degrees, off the coast of WA, OR, CA. The F/V Alyssa Ann and the F/V Timmy Boy will be fishing pot gear North of 36 degrees; the F/V Buck and Ann and the F/V Southeast may use both longline and/or pot gear, and fish both North and South of 36 degrees. Vessels will make an annual declaration of their intent to participate in the EM EFP, but will also be required each year to notify NMFS 30 days in advance of the start of their fishing for the year which months they will be operating in the fishery and utilizing EM.

D. Electronic Monitoring Plan

1. The EM Plan will include the following:

   a. Secure, watertight control box for data storage.
   b. Digital cameras that include or are connected to a date and time stamp and counter.
   c. A minimum camera resolution and frame capture rate (to be determined).
   d. A minimum amount of on-board data storage (to be determined).
   e. Tamper-evident hardware.
   f. A monitor showing a live feed from all EMS cameras, so that the skipper can ensure the EMS is functioning correctly.

2. Individual Vessel Monitoring Plan:

The installation and operation of the EMS will be governed by an Individual Vessel Monitoring Plan (IVMP) drafted by the service provider with collaboration from the vessel skipper/owner. The IVMP will also include a schematic of the operational system for each vessel, to be approved by NMFS.

The IVMP will address the following:

a. Hardware, including but not limited to the control box, removable hard drive, camera specifications, GPS receiver, pressure and motion sensors, and power supply.
b. Software for data collection.
c. Protocols for EMS malfunction.
d. Back-up equipment use protocols.
e. Retained catch and discard handling protocols.
f. Vessel layout and camera coverage.
g. Number and placement of cameras.
h. Lighting requirements.
i Design of measuring board
j. Instructions for care and maintenance of the EMS.
k. Schedule for EMS maintenance and data transfer.

3. Agreements by Applicants:

Generally, for purposes of this EFP, the skipper/owner must:

a. Be engaged in and responsible for EMS deployment, troubleshooting, and implementation on their vessel.

b. Be willing to retrofit the vessel and catch handling operations necessary for EM deployment.

c. Participate in or designate a representative to participate in PFMC meetings and related workshops, representing this EFP.

d. Be able to train crew in appropriate procedures for EM.

e. Fill out and submit logbooks timely to state and federal agencies as required and to EM video reviewer.

f. Not have outstanding civil violations relating to fishing activity of the vessel exceeding $5000.00 in the last three years, or have any criminal matters pending, as per COP 19.

g. Enter into a "Self-Governing Plan" with each other vessel in this application that will include procedures in the event of an EM system breakdown, a fisheries violation or intentional EM system breach. The "Plan" is to be approved by NMFS. Part of the "Plan" will include a provision that the applicants agree that in the event of a wilful violation of the EFP by an individual applicant, the EFP for that individual applicant may, without due process, be summarily revoked by NMFS.

h. To be eligible for a second year under this EFP, the vessel must be in compliance with its IVMP, demonstrate proper documentation of their discards in logbooks as verified by video; and not have civil or criminal penalties referenced above.

4. Logbooks:

For purposes of this EFP, vessel captains will utilize what is known as an "Oregon Fixed Gear Logbook," as modified per instructions from PSMFC and utilized in 2013 in the EM protocols. Vessels shall also maintain any other logbooks as required by state and federal agencies. At the end of each trip, Captains may photograph and email photos of logbook pages to PSMFC for their review. If an option is available to use electronic logbooks, applicants may utilize these instead.

E. Fishing Requirements:

1. Gear.

   Only legal pot or longline gear may be used for fishing under this EFP.

2. Permits.

   Each participating vessel must have a limited entry trawl permit registered to the vessel, and have a vessel account with quota pounds registered to the account before beginning fishing. A copy of this EFP must be carried on board the vessel while EFP fishing and when fish caught while fishing under the EFP are on board the vessel.

3. Total Catch, Retention Requirements and Discards:

Total catch is defined as any fish hooked or in a pot as the gear is being landed, as well as any visually discernable catch lost during the retrieval process that can be reasonably attributed to the vessel.

Discard is any portion of the total catch that is not delivered to a buyer. Fish caught for bait on onboard consumption are considered discard. For gear that is lost, discard rates will be applied based on similar sets and or hauls.

All catch of IQ species must be accounted for, to be debited against quota accounts, regardless of whether it is categorized as retained catch or discard.

A vessel fishing trawl quota share with fixed gear under this EFP shall comply with the policy of "Maximized Retention" defined as follows:

All IFQ species, non-IFQ groundfish and non–IFQ species must be retained until offloading, with the following exceptions:

a) Discards required for:

1) ESA species, MMPA species, and other protected species
2) Prohibited species
3) Large marine organisms
4) Halibut
5) Regulatory discards, i.e. Ling cod smaller than 22 inches N of 42 degrees

b) Except as enumerated and defined below, discards are prohibited for:

1) IFQ groundfish species
2) Non-IFQ groundfish species
3) Non-groundfish finfish species

c) Discards permitted for:

1) Trash, mud, wood, and other debris
2) Deepwater crab, coral, starfish, grenadier, urchins, sponges and other invertebrates
3) Predated fish:

Predated fish are defined as any of the above IFQ, Non-IFQ and non-groundfish finfish species that are:

a) otherwise required to be retained, but
b) have been eaten or destroyed by another species or event,
c) while in or on the gear, and
d) subsequently brought on board the vessel.

Current practice on observed and EM monitored vessels is to measure the fish on camera, estimate its weight by length, count the number of predated fish and use the average weight of the fish in that string or pot, times the number of fish, to determine the discard weight. The discard weight and numbers of fish are recorded in the logbook. The fish are discarded. The weights are counted against the vessel's quota for that species.

4. Halibut Accounting:

Discussions are ongoing with NMFS regarding accounting for halibut discard and rate to be applied for mortality. Applicants will continue to work with NMFS and others to finalize an acceptable option. Options include but are not limited to:

a) A mortality estimate will be applied based on the individual's vessel's 2011-2013 average halibut mortality rate, as determined by the West Coast Groundfish Observer Program.(WCGOP).

b) A mortality rate established by the WCGOP or the IPHC for the gear type will be applied.

c) IPHC exemption to allow full retention.

d) Captain and crew trained to provide actual mortality assessment on camera.

F. Observers: Extent and Type of Coverage and Costs:

Discussions are ongoing with NMFS regarding presence of WCGOP observers aboard vessels utilizing EM under an EFP. It appears there may be several functions for observers that are currently being examined:

1) to serve as an observer pursuant to the current regulatory requirements, i.e. compliance; and/or

2) to serve as an observer solely for the gathering of scientific data.

3) Some combination of the two functions

In either event, there remain issues of extent of coverage on board the vessel and the percentage of trips on which an observer may be required. Applicants propose that, similar to the observer coverage in the fixed gear limited entry fleet, which deploys observers for the purposes of gathering scientific data, that coverage by observers not exceed 30% of the trips fished under the EM EFP.

In addition, the question of who pays for the observers under an EFP is still to be determined by NMFS. Applicants propose (also similar to the fixed gear limited entry program) that NMFS pay for the observer coverage under this EFP.

G. Delivery/Offloading of Catch:

No less than 30 days prior to the start of fishing, Applicants will provide to NMFS a list of all fish processors to whom Applicants may unload fish to during their fishing activity each season. All catch must be offloaded at a designated processing plant and the offloading of catch from one trip cannot be split between two or more processing plants. Once offloading has begun at a designated processing plant, all fish on board the vessel must be continuously offloaded at that plant. The processing plant must be one qualified to receive trawl quota fish under the limited entry trawl IFQ program.

H. Catch Accounting of Species

Catch accounting will be accomplished through three sources of data: fish tickets documenting retained catch, logbook data of discard events and species weights, and data verifying the discard events and weights of species discarded by EM video review.

1) For retained IFQ fish, the vessel's quota account will be debited the weight by species by the dockside monitor/fish ticket.

2) For discarded fish, the vessel's quota account will be debited the recorded weight by species from the logbook.

3) In the event there are video events of discards and the reviewer's estimate of pounds of fish discarded is greater than that recorded in the logbook, the reviewer's larger weight estimates will be used against the vessel's quota.

I. Compliance:

1) Each applicant will enter into an IVMP as described above, as well as a contractual agreement regarding participation in this EFP. Conditions of the agreement are to include NMFS right to remove any individual vessel from participation in this EFP for any intentional violation of any agreement pertaining to the EFP, including, but not limited to: violation of federal fishery regulations, intentional damage or tampering with EM equipment, and/or intentional failure to accurately report catch or discard.

2) In the event of an EM malfunction, (i.e. equipment fails to operate such that all sensors are inoperable and/or video recordings do not start upon fishing events and record and store data), if the vessel is dockside, the applicant with notify NMFS, PSMFC and the EM provider and make arrangements for repairs.

3) The vessel will not be allowed to fish without a fully operational EM system, defined as capable of recording and storing the data relating to all fishing and discard events on board the vessel. In the event the vessel intends to fish without a fully operational EM system, vessel owner must make arrangements to carry a federal fisheries observer for 100% of its fishing, until the EM system is again operable.

4) In the event that the EM system fails while vessel is at sea, (generally defined as failure of EM system to record and store viewable video of all fishing activities of the vessel), the vessel must terminate its fishing, return to port for EM repairs, unless, during that same trip, the vessel is carrying a fisheries observer trained in species identification and accounting of retained catch and discard. The vessel may not again leave port without either a) an operable EM system or b) a federal fisheries observer.

J. <u>Data Retrieval and Analysis:</u>

Applicants will work in partnership with NMFS, PSMFC and EM service providers to insure the integrity of and timely delivery of data from the vessel to the service provider for analysis. Options discussed include:

1) Removal of the hard drive from the computer and delivery by the Captain to the monitoring site (PSMFC) by secure delivery

2) Removal of the hard drive from the computer by the Catch Monitor at the processing plant, who will then send it via secure delivery to the monitoring site (PSMFC).

3) Once the data is obtained from the vessel, the following is a general description of the options for analysis that may be undertaken by the service provider.

    a) Evaluate data set completeness and identify fishing events.

    b) Confirm fishing events, and examine catch stowage operations to examine compliance with "maximized retention" of species as defined above, with the enumerated exceptions

    c) Document discard events.

    d) Examine vessel logbooks to verify trips and fishing events align with sensor data.

    e) Compare vessel operator logbook records of landed catch and discard as compared with EM data and with fish tickets.

4) Discussions are ongoing with NMFS and PSMFC as to the extent of the video to be reviewed for comparison to the vessel's logbook. Options include, but are not limited to :

    a) up to 100% review of the hauls recorded on the video

    b) up to 50% review of the hauls recorded on the video

    c) up to 25% review of the hauls recorded on the video

    d) % of video reviewed to be determined, and made specific to the individual vessel, as determined by NMFS/PSMFC

    e) % of video to be reviewed to be determined and made specific to the gear type, as determined by NMFS/PSMFC

K. <u>Final Reporting Requirements:</u>

1. Preliminary: Pursuant to Council Operating Procedures, applicants, in conjunction with the EM service provider, will present a preliminary report on the results of the EFP at the November Council meeting in 2015. The report will indicate the applicants' intent to continue the EFP activity for the second year of the management cycle.
2. Final: A final written report of the results of the EFP will be presented by the applicants to the GMT, GAP, SSC and the Council at the September Council meeting of the year following the management cycle for which the EFP activity is conducted. The final report will include a summary of the work completed, an analysis of the data collected, a conclusion and recommendations.

On Behalf of Applicants

Agenda Item F.5.a
Attachment 5
June 2014

William W. Stelle, Jr.

Regional Administrator

Attn: Gretchen Hanshew

7600 Sand Point Way NE

Seattle WA 98115-0070

This is intended to inform you of our request that the enclosed EFP be issued and that the desired start date is January 1, 2015. This application is the same as the one that was recommended by the Council in June.

Thank you very much for your work on this permit.

Sincerely,

Barbara Emley

Dan Platt

Groundfish EFP Proposal:
Yellowtail Rockfish Jig Fishing off California

Date of Application: May 23, 2014

Applicants	Mailing address	Telephone #	Email
San Francisco Community Fishing Association Contact: Barbara Emley	535 Ramsell St. San Francisco, CA 94132	(415) 585-5711	barbaraemley@gmail.com

Changes from 2013-2014

Change allocation to 0.03mt of Yelloweye
Change Other fish to Spiny Dogfish
Revise Lingcod from S of 42° to N and S of 40.10°
Change the limit of lines allowed to be fished at one time from 2 to 4. (hook number remains 100 total)
Change the depth limit to 150 fm, instead of 100 fm to allow for the possibility to target chilipepper as well as yellowtail rockfish.

Purpose and Goals

Purpose

To continue the 2013-2014 EFP for two more years (2015-2016)

West Coast fisheries have been increasingly restricted in state and federal waters over the last decade to reduce impacts from fishing. Yet, demand remains for fresh, local seafood. To harvest healthy and abundant fish stocks with less impact, conservation engineering and gear experimentation is needed. The purpose of this EFP is to test the potential for a new commercial jig gear configuration to harvest currently underutilized rockfish species (yellowtail) while avoiding overfished stocks to enhance optimum yield in the mixed stock West Coast groundfish fishery.

Goals

This EFP seeks to fulfill and comply with national mandates and goals of the Magnuson-Stevens Act (MSA) for fisheries, fisheries resources, and fishing communities by addressing specific conservation and management issues in the mixed stock groundfish fishery off of California.

1. Consistent with MSA National Standard 1 (optimum yield) and National Standard 9 (minimize bycatch), harvest abundant stocks while minimizing bycatch and providing for rebuilding of overfished stocks.
2. Consistent with the purpose of MSA to conserve and manage U.S. fishery resources to realize their full potential (i.e., by providing employment, food, and revenue to the nation) and consistent with MSA National Standard 8 (fishing communities), seek to develop and utilize gear technology that contributes to sustained participation of fishing communities while also preventing overfishing and ensuring rebuilding of overfished stocks.
3. Provide additional opportunity in the groundfish fishery off California that has been greatly constrained since rockfish conservation areas (RCAs) and lowered quotas were implemented to rebuild overfished species.
4. Test the success of this experimental commercial jig gear configuration at: 1) avoiding deep dwelling overfished rockfish stocks (canary and yelloweye) while selectively harvesting an abundant mid-water rockfish stock (yellowtail), and 2) providing enough harvest of abundant rockfish species to support, or at least contribute to, a commercial fishery off the West Coast in the long-term.

Disposition of Catch

Target species (yellowtail rockfish) and legal incidental catch, such as chilipepper rockfish, will be retained for sale. Fish not authorized for sale would be released alive if possible. If desired, incidental catch of certain species (e.g., canary and yelloweye) that cannot be released alive could be retained by the observer and provided to NMFS, CDFG, or other researchers.

Justification

The fishing grounds which have been historically accessible to portfolio fishermen in California's coastal communities are geographically identified as "shelf", and because of this, the gear used by these fishermen isn't useful for catching fish on the "slope" (depths greater than 100 fathoms-see Figure 5). The creation of the non-trawl rockfish conservation area (RCA) over the shelf (between 30 and 150 fathoms) has pushed fishermen outside their historical fishing grounds into deeper waters where fishing is no longer feasible with their current gear (see Appendix E).

In order to protect and rebuild overfished yelloweye and canary rockfish off California, depth and area closures were implemented off of California. Unfortunately, these closures have also prevented harvest of more abundant yellowtail rockfish that live higher in the water column. Combined with lower quotas, these measures caused many fishermen in California's coastal communities to switch fisheries and/or supplement their incomes in non-fishery jobs because they could no longer harvest the abundant groundfish stocks. If a gear could be developed capable of harvesting the more abundant mid-water species while avoiding catch of the overfished bottom dwellers, then the optimum yield of the fishery could be enhanced. There are currently no conservation concerns with yellowtail rockfish which is an under-utilized species.

In 2009, the Oregon Recreational Yellowtail Rockfish EFP, approved by the Council, was permitted to the Southern Oregon Sport Fishermen and Recreational Fishing Alliance (Oregon Chapter) for fishing in 2010 and 2011. Although not identical, this OR EFP is based on the same concept (i.e., placing hooks near the target species in mid-water and away from non-targets on the bottom). Therefore, it offers interesting insights of some relevance to this EFP application, particularly its catch composition and success at avoiding the non-target species. Under this EFP, 29 trips were made with an average of 11 anglers and 33 hooks per vessel (3 per line) were deployed on average. Reported catch of 4.3 mt (as of Aug. 1, 2011) was composed of roughly 62% Yellowtail, 23% Widow, 12% Canary and 3% other rockfish and 4kg of Yelloweye (2 fish) (see Appendix B). This catch is well below the 1 mt of Canary and 100 kg Yelloweye authorized for year two alone.

A similar design will be tested under this EFP with some modifications for use in a commercial fishery (e.g., number of hooks, size of weight). An EFP is necessary to test this gear because it is not currently authorized under the Groundfish FMP regulations and because fishing conducted under this EFP is proposed for areas that are currently closed to fishing. If the proposed modified vertical hook and line fishing technique is successful, this exempted fishing permit (EFP) would allow commercial fishermen to access historical fishing grounds targeting healthy rockfish stocks and would promote ecologically and economically sustainable fisheries in Central and Northern California.

Broader Significance

The long-term goal, if experiments prove successful, is to allow commercial jig fishing with this gear off the entire West Coast, including in the RCAs, by the Open Access and Limited Entry participants. If successful, this gear could also be used by the Nearshore fleet to avoid species of concern and could create a fishery that would fill out the portfolios of those who make up the bulk of the fishermen in the West Coast's coastal communities. The recreational fleet might also benefit from using a similar gear with fewer hooks, similar to the Oregon Yellowtail EFP previously mentioned. Thus, the benefits of this EFP would extend beyond the initial EFP participants.

Despite the generally depressed condition of many west coast groundfish stocks, there are some stocks that remain healthy. These healthier stocks could safely sustain increased harvest levels if they could be fished more cleanly and without bycatch of more depleted stocks. If stronger stocks could be targeted without increasing fishing mortality on depressed stocks, the West Coast commercial fishing fleet would have alternative fishing opportunities that would provide some economic relief to the industry while providing the public with highly desirable sustainably harvested local seafood.

Details

In determining the proposed specifications for this experiment, several factors have been considered.

- **Creating a statistically valid sample size –** allowing for a sufficient number of hooks, lines, days, vessels, and locations that can provide valid conclusions as to the success of this gear at avoiding overfished non-target species and harvesting the target yellowtail in sufficient quantity to allow for potential expansion of this gear to support future commercial fishing.
- **Feasibility and efficiency –** whether participants can at least cover the costs involved to perform these experiments (including observer costs, fuel, gear, and bait), even if no profit is made under the EFP.
- **Safety-at-sea –** ensuring participants can fish on days with safe weather conditions.

- **Precaution and minimizing risk –** Knowing that overfished rockfish could be encountered and because at least some of the fishing would take place in the RCA, several precautionary measures are proposed.

With consideration of these factors, applicants are open to discussing modifications to this proposal with the GMT and GAP (e.g., # hooks, depth range, etc.).

Total Duration of the EFP

This EFP proposal is for a total of 2 years (2014-2015)

Location of Fishing under the EFP

The fishing will occur between Point San Pedro and the Oregon/California border (37°35'N and 42°N), between 35 and 150 fathoms. Fishing will take place deeper than 35 fms to avoid hydrocorals (primarily *Stylaster spp.*) found mainly shallower than 30 fathoms. Locations for the EFP fishing have been chosen based on known yellowtail habitat, rather than lines of latitude or fathom lines and it is known that there is appropriate yellow-tail habitat in this area, i.e., high relief rocky reef deeper than 30 fathoms (see Appendix D).

Yellowtail rockfish is the target in this experiment because they are underutilized and because they are a mid-water species, whereas the overfished rockfish species of greatest concern tend to be more bottom associated. (i.e., canary and yelloweye). The hooks would be located only in the mid-water column based on the hypothesis that this will be in the range of yellowtail but out of range for canary and yelloweye rockfish, making it less likely that they would encounter the hooks.

Fishing under this EFP is proposed to occur within the RCAs making this a sensitive and delicate experiment that would be undertaken with precautionary steps, such as having 100% observer coverage and daily limits (see section on **Precautionary Measures**). Unfortunately, it is thought that yellowtail rock fish live primarily inside the RCAs and it would be useful to verify this assertion by reviewing fish ticket information from years prior to implementation of the RCAs. Recently, the Superintendent of the Cordell Bank National Marine Sanctuary reports seeing very large numbers ("clouds") of yellowtail rockfish on the "high spots" while in a submersible and saw no adult yelloweye and very few canary rockfish in this same area.

If the project proves successful in avoiding stocks of concern, then fishermen in other West Coast harbors may want to explore other appropriate habitat in their area. Much of the area proposed for this EFP is within the boundaries of the Gulf of the Farallones and Cordell Bank National Marine Sanctuaries. These sanctuaries are in support of this experiment. It has been 10 years since any fishing has taken place in this area, and the Sanctuaries' superintendents are very interested in learning the results of this experiment.

Description of the Gear to be Used

Specifications

- A vessel will fish up to four lines.
- Each line will consist of all of the following:
    1. a tuna cord mainline
    2. a float at least 3.5 inches in diameter, above the top hook to keep the gear from contacting the bottom, as suggested by the GMT in 2009; a monofilament ganion with 25 to 50 hooks (shrimp flies) each for a total of no more than 100 hooks, spaced 1-3 feet apart
    3. a weight of no more than 15 lbs
    4. a breakaway (lower test line) that is a minimum of 30 feet (5 fathoms) located between the lowest hook and the weight
    5. When two or more lines are used they may be deployed with different lengths of breakaway line.
- Still to be determined: weight, , and strength of the breakaway line.

Storage and Deployment

- The mainline can be coiled in a basket, wound on the reel of a fishing pole, or spooled on the boat's gurdies.
- The hooks can be placed on a "pinning rail" (usually a long piece of rubber with slots for the hooks) followed by the breakaway and the weight.
- After the weight is thrown overboard followed by the breakaway, the hooks will peel off the pinning rail.
- The float will be attached above the hooks as the gear is deployed.
- Once the fisherman feels the weight hit bottom, he immediately pulls the line up so that it does not drag on the bottom and to avoid tangling in the rocks.

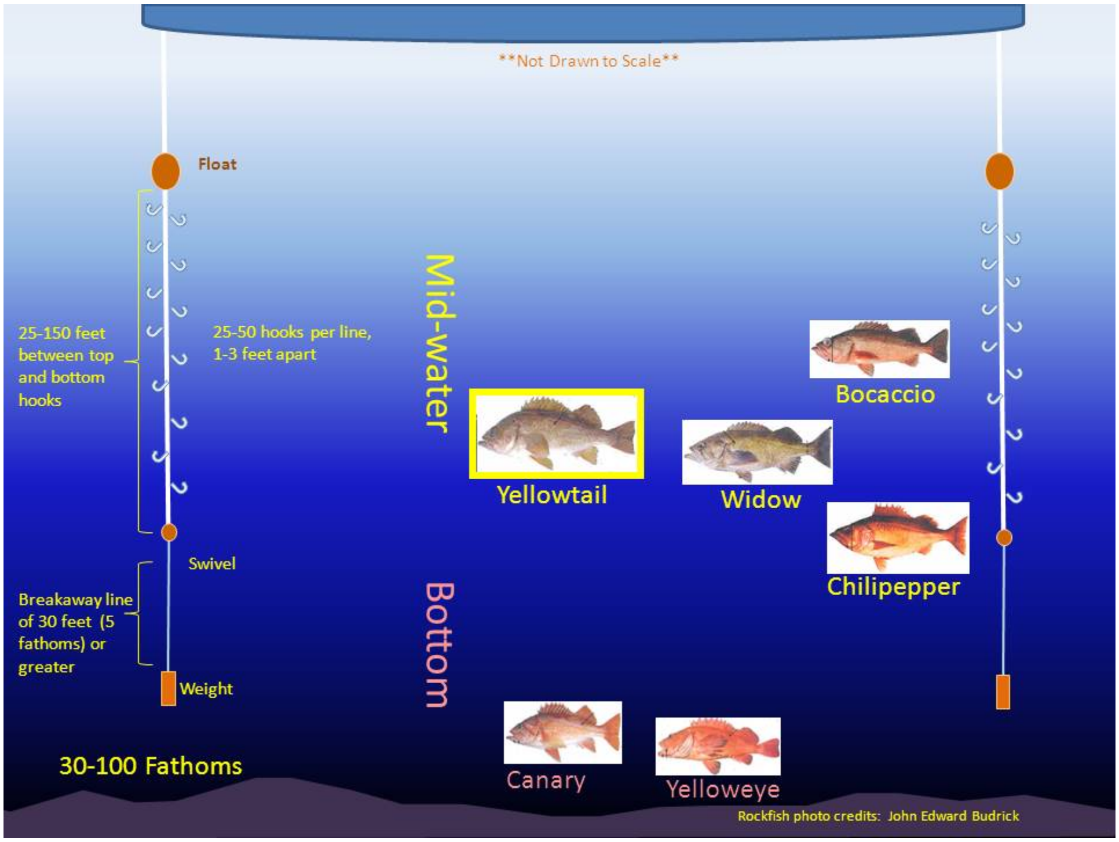

Figure 6. Conceptual drawing of the proposed gear

Effort

- *Trip length*:
  - Vessels out of Ft. Bragg and south – 4 to 5 days (2 day travel time, 2-3 fishing days);
  - Vessels out of Crescent City – 1 day
- *Drops per day*: TBD (depends on conditions), possibly 5 hours total drop time
- *Length of drop*: possibly 5 min to 30 minutes

Number of vessels covered under the EFP

A total of 4 vessels would participate in the study the first year (potential vessels: 2 out of San Francisco, 1 out of Ft. Bragg, 1 out of Crescent City). While the area is very large for 4 vessels to cover, we want the first year simply to explore whether the gear will be able to catch Yellowtail and successfully avoid overfished bottom-dwelling species. If successful and with PFMC approval, in the second year, the experiment could expand with more vessels to cover more area and locate additional suitable habitat (applicants are open to GMT/GAP feedback to determine an appropriate level of expansion if a specific proposal is necessary at this time or leaving it at 4 for both years). Applying for a second two-year EFP for the 2015-2016 cycle might be appropriate to discover more suitable habitat in a larger West Coast area and add more vessels.

Species to be Harvested (target and incidental)

Table 1 provides an overview of the species that will be caught under the EFP, their status, and estimated catch amounts.

Table 1. Overview of Target and Incidental Species Caught under the EFP

Species	Target or Incidental?	Overfished? Y/N	Depth Range	Requested Amount of EFP Harvest (mt)
Bocaccio *Sebastes paucispinis*	Incidental	Yes	0-1050 ft (0-175 fms)	3
Canary Rockfish *Sebastes pinniger*	Incidental	Yes	0-900 ft (0-150 fms)	1
Cowcod *Sebastes levis*	Incidental	Yes	132-1620ft (22-270fms)	0.015
Darkblotched Rockfish *Sebastes crameri*	Incidental	Yes	240-1200ft (40-200fms)	0.1
Widow Rockfish *Sebastes entomales*	Incidental	No	0-1050 ft (0-175 fms)	9
Yelloweye Rockfish *Sebastes ruberrimus*	Incidental	Yes	150-1200 ft (25-200 fms)	0.03
Lingcod N of 40.10°	Incidental	No		0.5
Lingcod S of 40.10°	Incidental	No		1.0
Sablefish N of 36°	Incidental	No		1
Chilipepper S of 40.10° *Sebastes goodei*	Incidental	No	0-1080 ft (0-180 fms)	10
Splitnose Rockfish S of 40.10°	Incidental	No		1.5
Yellowtail Rockfish *Sebastes flavidus* N. of 40.10°	Target	Yes		10
Minor Slope N of 40.10°	Incidental	Yes		1
Minor Slope S of 40.10°	Incidental	No		1
Minor Shelf N of 40.10°	Incidental	No		3
Minor Shelf S of 40.10° (includes Yellowtail rockfish)	Target	No		30
Black Rockfish S of 46.16°	Incidental	No		1
Pacific Whiting	Incidental	No		1
Spiny Dogfish	Incidental	No		1

a. Species Descriptions

Descriptions of the **species life histories** can be found in Appendix B2 of the Pacific Coast Groundfish Fishery Management Plan.
http://www.nwr.noaa.gov/Groundfish-Halibut/Groundfish-Fishery-Management/NEPA-Documents/upload/FMP-Appendix-B2.pdf

Updated information on **species abundance** can be found in Chapter 3 of the Proposed Harvest Specifications and Management Measures for the 2011-2012 Pacific Coast Groundfish Fishery and Amendment 16-5 to the Pacific Coast Groundfish Fishery Management Plan to Update Existing Rebuilding Plans and Adopt a Rebuilding Plan for Petrale Sole; Final Environmental Impact Statement. http://www.nwr.noaa.gov/Groundfish-Halibut/Groundfish-Fishery-Management/NEPA-Documents/upload/1112GF_SpexFEIS_100806-FINAL_feb21_.pdf

b. Estimated Harvest Amounts
Requested allocation is found in Table 1.. To assist in determining potential harvest amounts, provided for consideration is an estimated range of CPUE and potential catch composition. Appendix A includes CPUE estimates, which was derived in order to consider the landings likely needed to cover costs of fishing under this EFP.

No prior data exists from which to pull an exact catch composition estimate from this gear. However, some data may be informative and could possibly be considered as the best available proxies. A possible proxy may potentially be derived from the mix of species caught during the first two years of the Oregon Recreational Yellowtail Rockfish EFP. If considered appropriate and desirable to use, an attempt to analyze this data can be found in Appendix C. Under that EFP, the reported catch of 4.3 mt (as of Aug. 1, 2011) was composed of roughly 62% Yellowtail, 23% Widow, 12% Canary and 3% other rockfish and 4kg of Yelloweye (2 fish) (see Appendix B). Also, analysis of PacFIN data to look at block data from groundfish landings from relevant ports could be another potential source. However, limitations with this data include: the landings would encompass trawl and hook & line gear together, past landings data could reflect abundance issues (i.e., lower abundance because of overfished stocks), and concerns with the accuracy of block reporting. Landing data from 1992-1998 for all California Ports North of 37° were summed by DFG Block. The data show that most blocks within the proposed area have some yellowtail catch during the years prior to the RCA (See Appendix F).

Catch Accounting and Compliance

This EFP will incorporate a standardized data collection and reporting format. Under the terms of this EFP there will be 100% observer coverage. Fisheries Observers will collect data on fishing gear, location, catch, and disposition of catch.

Precautionary Measures

Given the potential to catch overfished species and by fishing in the RCA, the utmost caution will be taken with this experiment. The following measures are proposed and applicants are open to working with the PFMC, NMFS, and CDFG to implement others deemed necessary.

1. **Observers –** 100% observer coverage (a standard measure for EFPs, but worth noting here).
2. **Caps –** Based on input from the PFMC and NMFS, each boat will have either a ***daily*** or ***trip*** limit/cap of canary and yelloweye. If this cap is reached, based on catch accounting reports verified by the observer, fishing will cease for that day or trip.
3. **Trip reports and catch accounting –** On a timeline agreeable to NMFS and CDFG, trip and cumulative catch reports will be provided after each trip (e.g., within 48 hours).
4. **Status and evaluation call before each trip –** Before each vessel departs on a trip, a cumulative catch accounting report (i.e., running total for the season) and evaluation of the

trips taken thus far will be reviewed to determine if another trip can be made and to discuss lessons learned (e.g., float sizes, bait, etc.). If it is likely that the allocated harvest cap would be exceeded in the upcoming trip, then all fishing under the EFP will cease for the season. Participants on each call would include the EFP participants and could include NMFS (SF & OLE), CDFG (Marine Region & Enforcement) and National Marine Sanctuaries Service.

5. **VMS and Vessel Marking –** Before each trip a vessel will call the West Coast Groundfish Declaration Line to report the trip. (This procedure should work for both the EFP and for future use of this gear type). Vessels participating in this EFP will also display a banner with "EFP Fishing" written in 2 foot high letters.

Data Collection and Analysis Methodology

Data Collection

The following data will be collected by observer for all fishing under this EFP:

Gear Configuration

- Number of hooks and type
- Weight size
- Float size
- Breakaway line length
- Distance between hooks

Set and Haul Data:

- Position (GPS coordinates)
- Time
- Bottom Depth

Catch

- Species
- Disposition (landings and discards)
- Total weight
- Count
- Length
- Biological Sampling (if applicable)
- Species
- position on line (e.g., hook #)

Attachment of depth recorders may be used, as available.

If desired, incidental catch of certain species (e.g., canary and yelloweye) that cannot be released alive could be retained by the observer and provided to NMFS, CDFG, or other researchers for biological sampling.

Data Analysis

Catch per unit effort will be calculated based on hooks per hour fished. This will allow comparison between short and long drops and different gear configurations. The data will be reported on a trip by trip level. The catch data will be analyzed for CPUE of all species and each species individually.

We have received a grant to engage an undergraduate student to provide data analysis and to ensure statistically valid data. We have begun to make arrangements with Cal Poly for that student and his/her supervisor,

Participation

Choosing Participants

Vessels participating in this EFP will be chosen on their ability to accommodate an observer, which means having bunk space for overnight trips; a life raft for enough people and a coast guard decal and their willingness to maintain detailed catch data. Vessels will also be required to have VMS as required by the open access and limited entry groundfish regulations.

Planned EFP Fishing by Participants

Fishing will take place in appropriate habitats within the latitudes and fathom curves mentioned earlier. Finding these habitats is important to the success of the EFP. Weather conditions are critical for this type of fishing, which involves drifting (not too much wind or current), so times will be left to the discretion of the captains. It is likely that October will be the best time of year, but fishing would not be limited to October. The gear is as described earlier except that a vessel may choose to use less gear than authorized to check species composition prior to setting all gear.

Appendix A- CPUE Estimates

Catch per unit effort is calculated below using 1 hook per hour as a unit of effort. The assumed effort per day is 5 hours of actual fishing time (gear in the water). Therefore, total catch is calculated for various numbers of hooks and CPUE of either 1 fish (2kg) or 2 fish (4kg) per hook per hour five hours a day. These numbers are expanded for 30 and 45 fishing days (3 vessels) and 40 and 60 fishing days(4 vessels). The green highlighted fields represent the estimated catch required to meet expenses of $800/day.

Estimated effort for 3-6 vessels

One day of effort is approximately 5 hours of wet gear time

# of vessels	Days per vessel		Total Days	
	4 trips / vessel	6 trips / vessel	10 days/ vessel	15 days/ vessel
3	10	15	30	45
4	10	15	40	60
5	10	15	50	75
6	10	15	60	90

Assessment of estimated harvest for Year 1 of the EFP

Preferred Gear Configuration | $800 a day needed to cover expenses (Including Observer Coverage, Fuel, Bait, and Gear) | fish = all fish caught, not species specific | Amount that would cover expenses

Comparision of gear configuration by day and CPUE

			Possible CPUE Values in # of fish / hour		Possible CPUE Values in kg of fish / hour	
# of hooks/line (2 lines / boat)	Total # of hooks per boat	spacing between top hook and bottom hook (1-3 ft btwn hooks)	CPUE = 1 fish per hook per hour x 5 hours	CPUE = 2 fish per hook per hour x 5 hours	CPUE =l kg per hook per hour x 5 hours	CPUE = 2 kg per hook per hour x 5 hours
10	20	9-27ft	100	200	100	200
20	40	19-57ft	200	400	200	400
25	50	24-72ft	250	500	250	500
30	60	29-87ft	300	600	300	600
40	80	39-117ft	400	800	400	800
45	90	44-132ft	450	900	450	900
50	100	49-147ft	500	1000	500	1000
100	200	99-297ft	1000	2000	1000	2000

Conclusion: At least 50 hooks would be needed to meet expenses if CPUE was between 1 and 2 fish per hook per hour with 5 hours of wet gear time.

Comparision of number of hooks for 30 days of fishing

			Possible CPUE Values in # of fish / hour		Possible CPUE Values in kg of fish / hour	
# of hooks/line (2 lines / boat)	Total # of hooks per boat	total days	CPUE = 1 fish per hook per hour x 5 hours	CPUE = 2 fish per hook per hour x 5 hours	CPUE =l kg per hook per hour x 5 hours	CPUE = 2 kg per hook per hour x 5 hours

Conclusion: With 60 days of fishing, between 24 and 48 MT of fish would be harvested

Appendix B- Oregon EFP Catch

In 2009, the Oregon Recreational Yellowtail Rockfish EFP, approved by the Council, was permitted by NMFS to the Southern Oregon Sport Fishermen and Recreational Fishing Alliance (Oregon Chapter) for fishing in 2010 and 2011. Although not identical, this OR EFP is based on the same concept (i.e., placing hooks near the target species in mid-water and away from non-targets on the bottom), and, therefore, offers interesting insights of relevance to this EFP application, particularly the catch composition and success at avoiding non-target species. Under this EFP, 29 trips were made with an average of 11 anglers and 33 hooks per vessel (3 per line) were deployed on average.

Oregon Recreational Yellowtail Rockfish EFP Catch

Year 1	kg	% of total	anglers	catch per angler day

Table 1. Summary of proposed electronic monitoring exempted fishing permit applications. Table continues on page 2.

EFP Applicant (Name, Attachment)	Maximized or Optimized Retention	Number of Vessels and Gear	Proposed Observer Coverage	Halibut Retention	Duration
Leipzig Fisherman's Marketing Assoc., Attachment 1	Maximized retention; bring all catch on board the vessel and retain that catch (including prohibited species) until offloading, with some discard exceptions (i.e., operational discard[1], halibut, 6 ft or larger organisms, debris).	6 trawl vessels; based out of one port or ports in close proximity	carry an observer only during the first two fishing trips	Length measurement then discarded at sea; mortality estimation: use vessel's past average halibut mortality rate, the fleet average mortality rate, or an estimate based upon tow duration, time on deck, and ambient air temperature	"…annual permit and to be continually renewed until comprehensive permanent regulations can be implemented."
California Risk Pool Attachment 2	**Maximized retention** for all (3) fixed gear vessels and 2 bottom trawl vessels; retain all IFQ and non-IFQ groundfish species with some discard exceptions (i.e., prohibited, ESA, marine mammals, and other protected species, halibut, Non-IFQ/non-groundfish species that can be clearly recognized as such and will not be confused with IFQ groundfish in EM video review (e.g. elasmobranchs or finfish not listed in groundfish FMP), trash, mud, wood, and other inorganic debris, crabs, starfish, coral, sponges and other invertebrates, and in situations where human life or safety is threatened). **Optimized retention** for 2 bottom trawl vessels; retain all IFQ and non-IFQ groundfish species with discard exceptions (i.e., allow discard of prohibited, ESA, marine mammals, and other protected species, halibut, Non-IFQ/non-groundfish species that can be clearly recognized as such and will not be confused with IFQ groundfish in EM video review, Dover sole, English sole, and arrowtooth flounder).	3 fixed gear hook and line; 4 bottom trawl	100% prior to issuance of EFP then 20% of all trips after EFP is issued.	All vessels measure fish on a length board in view of an EM camera, and then discard. For vessels using longline and pot gear, the mortality rate established by the NMFS Observer Program will be applied: 16% mort rate for longline, 18% mort rate for pot. For vessels that caught halibut after 2011 (excluding longline and pot gear vessels), calculate weight of halibut from length, and then apply a vessel-specific average halibut mortality rate from 2011-2014 using NMFS Observer Program data. For vessels without halibut catch history after 2011use fleet-wide 2011-2014 average halibut mortality rate. If no exemptions can be made for discard mortality estimates, this EFP can be conducted using 100% mortality rate for discarded halibut.	2015 – 2016 (2 yrs)

[1] For the purposes of this permit, any fish that pass through the webbing of the net while the net is being retrieved or any fish that cannot be completely removed from the net prior to the net being reset or at the termination of fishing, shall be considered operational discards and need not be estimated or recorded.

EFP Applicant (Name, Attachment)	Maximized or Optimized Retention	Number of Vessels and Gear	Proposed Observer Coverage	Halibut Retention	Duration
Mann/Paine, At-sea and Shoreside West Coast Whiting Fishery, Attachment 4	Maximized retention; retain all fish caught with some discard exceptions (i.e., operational discard[2], 6 ft or larger organisms, unavoidable discard beyond the control of the crew or captain).	16 from Midwater Trawlers Assoc. and 10 to 14 from United Catcher Boats, total up to 37 midwater trawlers targeting whiting	None	Retain all halibut according to current regulations; 100% mortality.	2015 – 2016 (2 yrs)
Eder et al. Fixed Gear, Attachment 3	Maximized retention; retain all IFQ and Non-IFQ groundfish and Non-groundfish finfish species with some discard exceptions (i.e., prohibited species, debris, deepwater crab, coral, starfish, grenadier, urchins, sponges and other invertebrates, predated fish).	4 vessels will participate in the first year, using pot gear, and two of these same vessels may also use longline gear.	not to exceed 30% of the trips	Applicants will continue to work with NMFS and others to finalize an acceptable option. Options include but are not limited to: a) A mortality estimate will be applied based on the individual's vessel's 2011-2013 average halibut mortality rate, as determined by the West Coast Groundfish Observer Program.(WCGOP). b) A mortality rate established by the WCGOP or the IPHC for the gear type will be applied. c) IPHC exemption to allow full retention. d) Captain and crew trained to provide actual mortality assessment on camera.	2015 – 2016 (2 yrs)

[2] No definition provided.

ENFORCEMENT CONSULTANTS REPORT ON FINAL EXEMPTED FISHING PERMIT (EFP) APPROVAL FOR 2015-2016

The Enforcement Consultants (EC) has reviewed the documents and attachments pertaining to Agenda Item F.5 and has the following comments.

Leipzig/Fisherman's Marketing Association, Attachment 1:
This maximized retention exempted fishing permit (EFP) proposal has been significantly modified since it was first presented to the Council at their April meeting, and appears to incorporate much of the guidance received by the Council at that time to include:

- Limiting the number of participants to six vessels.
- Giving 30 days' notice of participants' home port and fish companies to which the participants will deliver their catch.
- Inclusion of a discard trawl logbook for recording the discard of all halibut.
- A definition of operational discards and clarification for discarding Pacific halibut, large marine organisms, and debris.
- Carrying an observer on the first two trips made with electronic monitoring (EM) equipment.
- Vessel will provide continuous lighting for clarity in video.

The applicant does not intend to serve as an EFP sponsor.

The EFP proposal lacks the detail found in a number of other EFP proposals being considered by the Council, including:

- Accountability Mechanisms
    - Self-Regulating /Self-Governing Plan
    - Compliance and Penalty Structure
- EM Services/ EM Systems
    - Provider Not Identified
    - Reviewer Not Identified
    - Individual Vessel Monitoring Plans
    - EM Data Capture and Analysis
- Actual List of Participating Vessels
- Log Book
    - Not clear if the discard log will be used for all discards, not just halibut

Due to the lack of detail in this application and because the applicant does not intend to serve as the EFP sponsor, this EFP, in comparison to the other EFPs under consideration by the Council, represents the greatest amount of workload for National Marine Fisheries Service (NMFS) and its partners in terms of issuance, monitoring, and enforcement.

California Risk Pool, Attachment 2:
This EFP application is sponsored by the California Risk Pool which includes the Fort Bragg Groundfish Association, the Half Moon Bay Groundfish Marketing Association, and the Central

California Seafood Marketing Association. The EFP applicant seeks approval for up to seven vessels including both trawl and fixed gear. The fixed gear vessels will be operating under a maximized retention fishing regime, and the trawl vessels will be operating under a modified optimized retention plan, with discards of arrowtooth flounder, English sole, and Dover sole allowed.

Provisions for halibut accounting and discard and use of an electronic logbook are also detailed in the allocation summary. All elements of the application seem to be adequately described and addressed.

The EC especially appreciates the accountability mechanism described under Item 10, the proposed data collection explanations under Item 11, and the vessel selection process described under Item 12. We believe any EM EFP application could benefit from inclusion of this level of detail and suggest the Council may want to provide direction regarding inclusion of detail before considering EFPs for final approval at this meeting.

Eder et al. Fixed Gear, Attachment 3:
This application is for four fixed gear vessels using an EM maximized retention strategy. The EFP application has no sponsor, but rather presents a description of the three vessel owners and their vessels.

Like the California Risk Pool application, this application discusses in detail a number of important design elements including:

- EM Planning
- Individual Vessel Monitoring Plans
- Agreement by Applicants inclusive of a Self-Governing Plan
- Second Year Eligibility
- Logbooks
- Total Catch, Retention Requirements and Discards
- Halibut Accounting
- Delivery and Offload of Catch
- Catch Accounting of Species
- Compliance Requirements
- Data Retrieval and Analysis
- Final Reporting

The applicant is open to using observers in conjunction with EM, not to exceed 30 percent of the trips fished under the EM EFP.

As we found with the California Risk Pool application, we believe any EM EFP application could benefit from inclusion of this level of detail in their application and suggest the Council may want to provide direction in this regard before considering EFPs for final approval.

Mann/Paine, At-sea and Shoreside West Coast Whiting Fishery, Attachment 4:
This EFP application is sponsored by the Midwater Trawlers Association and the United Catcher Boats, for the purpose of using EM under a maximum retention scenario. The applicant has

indicated that all vessels belonging to the Mid-water Trawlers Cooperative (18) and all eligible vessels represented by United Catcher Boast (16) would be eligible to participate under this EFP, for a total of 34 vessels. They further estimate that, of these 34 vessels, 26 to 30 may participate, making this application the largest participant pool by far.

Although yet to be determined, the applicant indicates that an umbrella organization will manage one EFP listing the participating vessels. The application contains an in-depth discussion regarding EFP compliance, required data collection, and vessel monitoring plans. Although some specific consequences for violations of the EFP provisions are discussed, the EC believes more detail of specific behavior expectations and consequences for failure to meet the expectations would be beneficial.

In describing the EM system, the applicant indicates up to four cameras will be included in the system. The EC notes that this may not be adequate for some vessels and that the number of cameras and their placement should be determined through development of the Individual Vessel Monitoring Plan (IVMP). Unlike the other applications before the Council, there is no discussion of using observers during EM deployment as a means of conducting a blind comparison.

Unique to this application is the proposal to test two types of video review, both 100 percent review of the video, and an audit approach where the logbook is the self-reported data, with video review of reported discard events and a 10 percent random review of the video.

All in all, the application appears to be adequate for analysis, and generally provides the Council with a good overview proposal for consideration.

Conclusion:
In summary, the EC believes it is in the applicants' best interest to provide as much detail as they can pertaining to their EM proposals. We recognize that following the Council's final EFP approval decision, NMFS will continue working with the applicants to further develop the details contained within their applications.

Agenda Item F.5.b
Supplemental GAP Report
June 2014

GROUNDFISH ADVISORY SUBPANEL REPORT ON FINAL EXEMPTED FISHING PERMIT (EFP) APPROVAL FOR 2015-2016

The Groundfish Advisory Subpanel (GAP) was briefed by Mr. Brett Wiedoff on four Exempted Fishing Permits (EFP) for electronic monitoring (EM), as well as an additional EFP for yellowtail rockfish jig fishing off California. The GAP supports final approval for all five EFPs. Specific comments and recommendations are provided below.

As we mentioned in our F.2 statement on the electronic monitoring regulatory process, and in previous statements on EM EFPs, the GAP believes EM is a major priority and could prove critical to the long-term success and durability of the groundfish trawl catch share program. To reiterate our previous statements, costs of participating in the individual fishing quota program are high and growing, access to target stocks remains low, and many trailing amendments that could reduce cost or increase profitability have yet to be implemented. Moving forward with EM EFPs could provide relief for a small subset of the fleet, and should provide valuable information for the EM regulatory process, which we believe will ultimately reduce some of the cost burden and provide additional operational flexibility.

The GAP discussed several overarching issues that pertain to all of the EM EFPs. The first was compliance monitoring and what level of coverage should be required in addition to EM. The GAP believes that there is a great deal of confusion around this topic. While some level of observer coverage will always be required for biological sampling purposes, that should be a National Marine Fisheries Service (NMFS) West Coast Groundfish Observers Program decision and should not be part of this discussion.

Generally speaking, the GAP believes that ongoing observer coverage for compliance monitoring purposes in addition to whatever level is needed for biological sampling will be detrimental to the utility and viability of the EFPs. It will add significant cost, and may serve to confuse the results. Further, it’s not clear what purpose additional observer coverage would serve. If there is going to be additional observer coverage for compliance monitoring, the GAP believes everyone would benefit from a much clearer explanation of the rationale.

Similarly the GAP does not support any arbitrary limits on the number of participants for each EFP. Reducing the number of participants potentially increases the costs to each participant (less people to spread costs over) and this is contrary to the objectives for moving forward with EM.

Concerns about shoreside catch monitors have also been raised and discussed. As we explained in our statement on F.2, we believe there are several different options that should be explored, including models that utilize community members who can become certified by NMFS to act as catch monitors.

NMFS has been clear that they believe the EFPs are an important tool to help inform the regulatory process for EM. The GAP agrees and believes that the EFPs should all move forward and be implemented as soon as possible.

Finally, the GAP believes the yellowtail rockfish EFP is promising and should also move forward.

PFMC

GMT Supplemental Report

Category	Leipzig	Cal. Risk Pool (Fixed Gear)	Cal. Risk Pool (Bottom Trawl)	Mann & Paine	Eder et. al.
Maximized retention or optimized?	Max	Max	Both	Max	Max
Observer coverage during EM [a]	2 trips	20%	20%	No [b]	< 30%
Risk of exceeding ACLs	Low	Low	Low	Low	Low
Individual accountability	Yes	Yes	Yes	Yes	Yes
Use chute/choke point for discards	only halibut, can be prescribed	Yes	Yes	yes, designated spot on deck	yes, choke point
Broad application (depth)	Shoreward and seaward of RCA	shoreward & seaward of RCA	shoreward & seaward of RCA	depends on concentration of whiting	seaward of the RCA
Broad application (latitude)	OR/WA	likely S of 40-10 only	likely S of 40-10 only	depends on concentration of whiting	Coastwide
Multiple strategies?	bottom trawl	longline and pot	bottom trawl, possibility of Scottish seine	shoreside and catcher vessel/mothership mid-water trawl	longline and pot
Possible to compare observer to electronic monitoring?	Yes (2 trips)	Yes	Yes	No, done in previous PFMC study	Yes
Possible to compare electronic monitoring and discard log?	Yes	Yes	Yes	Yes	Yes
Possible for direct halibut viability?	Yes, 2 trips in beginning	Yes	Yes	Yes, 100% mortality	Yes
Incentives for compliance, amongst the EFP participants?	if individual hinders use of cameras, permit gets revoked	collective contract (joint liability)	collective contract (joint liability)	individual violators will be removed from EFP	individual violators will be removed from EFP

GROUNDFISH MANAGEMENT TEAM REPORT ON REVIEW OF EXEMPTED FISHING PERMITS FOR 2015-2016 GROUNDFISH FISHERIES AND ELECTRONIC MONITORING

The Groundfish Management Team (GMT) reviewed the yellowtail rockfish exempted fishing permit (EFP) application for 2015-2016 that was forwarded for review at the November 2013 Council meeting and submitted for approval at this meeting. Additionally, the GMT reviewed the four electronic monitoring (EM) EFP applications that were forwarded for review at the April 2014 Council meeting. The GMT's review was based on the evaluation criteria in the Council Operating Procedure (COP) 19 on EFPs.

The GMT reviewed the EFPs based on their technical merits and points out that the Council will likely need to make their final decision on the San Francisco Community Fishing Association (SFCFA) EFP based partially on the availability of overfished species, relative to the 2015-2016 harvest specifications. At this meeting, the Council will be considering and adopting final preferred set aside amounts to be deducted from the annual catch limits (ACLs) or annual catch targets (ACTs) under Agenda Items F.7. The total set aside amount will include those reserved for EFPs under this agenda item. Table 1 summarizes the set asides by species and EFP requested by the applicants and the Council's preliminary preferred alternative set asides for 2015-2016 adopted in November for use in the analysis in the draft Environmental Impact Statement. The four EFP applications for the use of EM are not requesting set-asides; all EFP activities will occur under normal fishing activities, trip limits, individual fishing quota (IFQ) limits, etc.

COP 19 outlines several questions for the GMT to consider when reviewing EFP applications. A primary requirement of EFPs is the evaluation of fishing gear or management measures that can be transferred into regulation and eventually applied fleet-wide. EFPs that rely upon operator experience, skill, or abilities that cannot be harnessed through a regulation or readily replicated by other fishermen, fail to meet this requirement because the resulting bycatch rates may differ from those estimated in the EFP. In addition, the groundfish Fishery Management Plan (FMP) also states that the purpose for EFPs is "to promote increased utilization of underutilized species, realize the expansion potential of the domestic groundfish fishery, and increase the harvest efficiency of the fishery consistent with the Magnuson-Stevens Act and the management goals of the FMP."

Renewal EFP

Yellowtail rockfish jig fishing off California – San Francisco Community Fishing Association / Emley and Platt

This EFP (Agenda Item F.5.a., Attachment 5) is intended to test commercial jig gear that is configured to selectively target yellowtail rockfish in mid-water (30-100 fathom) areas of the rockfish conservation area (RCA) in northern California while avoiding harvest of overfished species. In November 2013, the Council preliminarily approved the set-asides for this EFP contained in Table 1 of the GMT Report (Agenda Item H.2.b. Supplemental GMT Report) with a reduction in the set-aside amount for canary rockfish to 1.0 mt and increase in the set-aside for yelloweye rockfish to 0.03 mt (Table 1). The GMT notes that the requested set-aside table included in the November 2013 application (Agenda Item H.2.a., Attachment 4, November 2013), had incorrect values most notably for chilipepper and yellowtail rockfish. Those values have been corrected in the current version. The table of requested set-asides (Table 1) in this report reflects the corrected values.

For 2013-2014, and again for 2015-2016, the applicants requested 1.0 mt of black rockfish to cover any catches that may occur while fishing in the shallower depths. The GMT noted that black rockfish are covered under a state issued deeper nearshore permit and cannot be landed without this permit. At that time it was uncertain whether all the participants in this EFP had the appropriate state permit necessary to land black rockfish (note: deeper nearshore species permits are issued to individuals, not vessels and are non-transferrable). As such, the GMT again recommends removing black rockfish from the list of species to be retained, as was done in the 2013-2014 terms and conditions of the EFP. It should also be noted that the take, retention, and landing of any nearshore species requires the appropriate state issued permit.

The GMT continues to see the value of the data that could be gathered from this EFP and based on its technical merits, supports Council approval for 2015-2016.

New Electronic Monitoring EFPs

Overarching Considerations

The GMT would like to note that typically EFPs are done to inform a regulatory process. It is difficult to consider rule development for the electronic monitoring program at the same time as the EFPs, and vice versa. The EFPs to test electronic monitoring could be used to explore and solve issues that are identified through the regulatory process. These EFPs may also provide unanticipated results that will help in refining and improving the regulatory framework for the EM program.

All four of the new EFP applications are requesting the use of electronic monitoring systems in place of human fisheries observers to test cost savings, catch accounting, safety factors, and compliance monitoring. None of these applications are requesting additional set-asides of overfished or non-overfished species to pursue their project. All catch will come from their normal individual fishing quota (IFQ) operations and quota pounds.

The GMT held a publicly noticed webinar on Tuesday, June 10 to discuss the overall electronic monitoring program and the electronic monitoring EFP applications. The GMT would like to thank the applicants that participated in the webinar for being available to answer questions, provide clarification, and feedback.

The GMT evaluated each of the applications in relation to the requirements of COP-19 and appreciates the clarifications by the applicants. Additionally, all of the applications appear to have addressed the issues that the Council brought up for them in April.

The GMT then focused discussions on some "bigger picture" questions about the electronic monitoring EFPs. Some of these questions/topics were covered in more detail in Agenda Item F.2.b, Supplemental GMT Report, and are summarized as:

- What question(s) need to be answered (i.e. compliance monitoring vs. catch accounting)?
- Will there be a broad application of results (e.g., by latitude and depth)
- What precision and accuracy of discard quantification and catch accounting is necessary?
- What sampling rates are necessary?
- What is the risk of exceeding annual catch limits (ACL)?

In thinking about those questions, the GMT, with help from the applicants, developed Table 2. Categories shown in the table provide an additional tool for comparing and considering the EFPs. Some clarification of table categories and responses follow.

- Maximized Retention: All EFPs plan to implement maximized retention for all vessels and all trips, with one exception. The California Risk Pool EFP intends to use maximized retention for all vessels and trips except for two trawl vessels, which will implement optimized retention (i.e., discard select groundfish species).
- Observer Coverage: The observer coverage rates proposed by the applicants are shown.
- Risk of Exceeding ACLs: Is there an increased risk of exceeding the ACL if these EFPs move forward? Because most are maximized retention, and only 2 vessels plan optimized retention for species that show low attainment rate (see Agenda Item F.2.b, Supplemental GMT Report), the GMT concluded the additional risk of exceeding ACLs is low from these EFPs
- Individual Accountability: Is the EFP designed to ensure individual accountability?
- Provide comparison with and without observers. The GMT is uncertain whether the applicants will be making that comparison. Regardless, the EFPs have been designed in a way that the data should be available, at least for later analysis.
- Use of Chute or Choke Point: Do the applicants plan to use either a chute for all discards, or a choke point (focal point) where all discards will be clearly seen and recorded by the camera?
- Broad Application (depth): What is the intended depth ranges for fishing by applicants, and is it broad enough to draw inference for the fleet?
- Broad Application (latitude): What is the intended latitudinal distribution by the applicant and is it broad enough to draw inference for the fleet?
- Multiple Strategies: Will multiple fishing strategies be implemented? For trawl, fishing gear and catch varies shoreward and seaward of the rockfish conservation area (RCA). Fixed gear EFPs intend to use pots and longline.
- Direct Comparison of EM and Observers: Will the design be such that direct comparisons can be made between EM and Observers (or EM with and without observers present)?
- Direct Comparison of EM and Logbook Discard Estimates: Will the design be such that direct comparisons can be made between EM and logbooks?
- Incentives for Compliance: Is the EFP designed to ensure or incentivize compliance with the specifications of the EFP?

The GMT do not consider whiting vessels not carrying observers under EFPs as a negative to what can be learned from EFPs. The shoreside whiting fishery operated without observers 2004-2010, and participated extensively with the Pacific States Marine Fisheries Commission (PSFMC) EM studies. In addition, whiting fisheries by design are much different than the other sectors, in that catch is dumped directly under the deck (unsorted) or the catch is transferred directly to the mothership without reaching the deck of the catcher vessel. Ultimately, the West Coast Observer Program (WCGOP) makes the determination of necessary observer coverage, not the GMT.

EFP Reports

The GMT recommends the Council consider reporting requirements by the EFPs, needed to track catch and manage the fisheries. The timing, frequency and content of the reports should be coordinated with the managing entity. The frequency of these reports could be quarterly, and some elements that should be included in the reports are: total landed pounds by species/complex and total discard estimates by species/complex.

Pacific Halibut and Individual Bycatch Quotas (IBQ)

The GMT recommends continued communication and coordination with the International Pacific Halibut Commission (IPHC) in regards to the discard mortality estimation of Pacific halibut. IPHC may be able to provide additional insight on what works and what doesn't, based on their experiences working with fisheries in British Columbia and Alaska. In their supplemental letter (Agenda Item F.3.b, Supplemental IPHC Report), IPHC expressed willingness to work with the applicants and Council on this process. The GMT suggests the Council not exclude any of the current halibut discard alternatives from consideration and analysis until IPHC has provided their input. This will hopefully prevent the situation where the only alternatives forwarded by the Council and analyzed are ones that IPHC does not see as viable.

The GMT reminds the Council of the Amendment 20 goals and objectives for Pacific halibut IBQ: *The trawl rationalization program is expected to provide individual fishery participants more flexibility and more individual accountability for their impact on overfished species, other groundfish species, and possibly Pacific halibut* (Groundfish FMP Amendment 20 Environmental Impact Statement). These EFPs, and the overall regulatory process, should achieve those same goals, unless the Council intends to treat halibut bycatch in the rationalized fishery differently

Applicability

The GMT discussed the importance of the applicability of results. In other words, how applicable are the results to the broader fishery? If the purpose of EFPs is to evaluate potential regulatory structure, as well as precision and accuracy of discard estimates and regulatory compliance, then EFPs should be conducted across a range of depths, latitudes, sectors, and fishing strategies. This will ensure that lessons learned may be applicable (or not applicable) for a broad range of vessel types and strategies. Although the breadth of coastal coverage or gear coverage may not be complete for each individual EFP, collectively, these EFPs extend across the entire coast, across most fishing depths, and include all gear types and strategies.

Therefore, the GMT sees merit in the EM EFPs and recommends they move forward with the request to work with NMFS and IPHC to further refine the methodology and details.

GMT Recommendations

1. **approve the SFCFA mid-water yellowtail rockfish EFP for 2015-2016, with the set-asides in Table 1**
2. **forward the four EM EFP applications**
    a. **requesting the applicants continue to work with NMFS to refine the projects prior to issuance of the EFP**
    b. **work with IPHC to develop and refine the methods for estimating Pacific halibut discard mortality prior to issuance of the EFP**
    c. **the Council consider inseason reporting requirements by the EFPs needed to track and manage the fisheries**

Table 1. Request EFP set-asides for 2015-2016.

	Species	SFCFA	Leipzig	CA Risk Pool	Mann/ Paine	Eder et al.	Total EFP Requests	PPA 2015-2016 set-asides a/
Overfished Species	Bocaccio	3	Covered with IFQ				3	6

RE: Agenda Item F.5. Final Exempted Fishing Permit Approval for 2015-2016

Dear Chair Lowman:

The staff of International Pacific Halibut Commission (IPHC or Commission) has reviewed the submission of proposed electronic monitoring experimental fishing permit (EFP) applications. We have the following comments for your consideration.

1. For all of the proposals, any provision involving retention of halibut by non-hook gear requires permission from the IPHC. Authority to define legal gear for halibut retention rests solely with the Halibut Convention between Canada and the United States. As you know, the Commission has previously granted this permission as part of the EFP for the hake fishery, largely because of the small quantities involved.

2. The staff welcomes the initiative to integrate multiple tools (EM, observers, historical data) to estimate halibut mortality rates. We note that multiple methods to determine those rates are presented in the proposals, some with more detail and potential applicability than others. There is precedent for using assumed discard mortality rates (DMR), in some Alaskan fisheries. These DMRs are calculated annually from observer data and a three-year average used in bycatch management (see attached paper). However, the data are continually updated via annual observer coverage at 100% for most fisheries in the Bering Sea. This continuous and comprehensive data collection is a fundamental difference between the proposed EFP (to be based on combinations of EM, partial observer coverage, and past average DMRs), and procedures used for fisheries in the Bering Sea.

   The potential to use observer data and EM, in conjunction with characteristics of hauls and treatment of halibut on deck, holds some promise to streamline mortality accounting and estimation. However, a procedure using the mortality rates associated with various haul characteristics (tow duration, weight and species composition of the catch, sea and air temperature, etc.) and treatment of halibut (time on deck, handling procedures) needs to be based on an adequate data set of such observations, and the associated condition factors of the halibut, in order to estimate those rates. We do not have such a data set and available observations indicate that mortality rates are quite sensitive to these elements, particularly for some fisheries and gears. This variability underscores the need for a comprehensive data set with which to estimate average DMRs. We would welcome the opportunity to work with the proponents to begin the construction and potential use of such a data set. The Commission staff recognizes the Council's desire to move toward a new model for bycatch mortality estimation and we look forward to cooperating in this effort.

Sincerely,

Bruce M. Leaman, Ph.D.
Executive Director

cc: IPHC Commissioners

Recommendations for Pacific halibut discard mortality rates in the 2013-2015 groundfish fisheries off Alaska

Gregg H. Williams

Abstract

Analysis of 2009-2011 observer data on the release condition of halibut from trawl, longline, and pot vessels fishing groundfish off Alaska has resulted in new estimates of discard mortality rates for discarded halibut in each target fishery for those years. The new rates are similar to those determined in previous analyses. The rates were added to the accumulated time series, which serve as the basis for recommendations to the North Pacific Fishery Management Council and the National Marine Fisheries Service for assumed rates to be used in the in-season estimation of halibut bycatch mortality for the 2013-2015 groundfish fisheries off Alaska.

Introduction

Pacific halibut discard mortality rates (DMRs) in the Alaskan groundfish fisheries are estimated from viability (injury and condition) data collected by fishery observers. These data are analyzed each year by staff of the International Pacific Halibut Commission (IPHC). This paper reports on an analysis of viability data collected during the 2009-2011 Community Development Quota (CDQ) and non-CDQ groundfish fisheries off Alaska. The results from these three years are combined with previous years' data to form the basis for recommended DMRs to be used for in-season estimation and management of halibut bycatch mortality in the 2013-2015 CDQ and non-CDQ groundfish fisheries.

Data description and methods

The analysis followed the same approach that has been employed since 1996, which was originally described by Williams (1997). Observer haul data from the NMFS groundfish observer database formed the basis of the analysis. The data records included the catch of groundfish by species or species group, estimates of the number and weight (kg) of halibut, and the number and length of halibut assessed for release viability by category (excellent/poor/dead for trawl and pot gear; minor/moderate/severe/dead for longline gear). Records for all hauls sampled by observers in 2009-2011 were obtained; hauls not sampled for species composition were excluded.

The hauls were assigned to target fishery categories based on the species composition of the catch within the haul, relative to the overall total and retained catches (Table 1). For example, hauls were coded as midwater pollock if pollock comprised 95% or more of the summed total catch for the reporting week (Sunday-Saturday). Flatfish targets in the Bering Sea/Aleutians (BSA) were determined in a succession of comparisons of individual flatfish species compositions in the catch. The determination for the flatfish targets was based on the greatest percentage of the non-arrowtooth flounder catch. Table 1 shows the target codes and definitions used.

Fishery observers examined halibut for release condition or injury immediately before being returned to the sea. Each fish was judged according to a set of criteria (Williams and Chen 2004), which were used to determine the presence and extent of internal and external injuries and body damage from predators (e.g., amphipods and marine mammals). A dichotomous key, first introduced in 2000, was supplied to observers to reduce subjectivity in the determination of condition and injury. Observers recorded the number of halibut in excellent, poor, and dead condition (trawls and pots) or with minor, moderate, or severe injuries, or dead (longlines) on each haul or set sampled, respectively. Samples were only collected on hauls that were sampled for species composition. The species composition sampling provides an estimate of the total number of halibut caught in the haul, as well as the catch of groundfish necessary for determining the target. Observers were instructed to limit the number of fish examined to a maximum of 20, although this was occasionally exceeded by enthusiastic observers.

Next, the viability distribution for a target fishery was calculated. First, for each haul, the proportion of halibut in each category was extrapolated to the total number of halibut caught. The extrapolated numbers of halibut for each vessel by viability category were then summed within each region/gear/target strata.

The general model for calculating the DMR for halibut caught by gear g was of the form:

$$DMR_g = \sum_{i=1}^{4} \left(m_{i,g} \times P_i \right)$$

where ***m*** is the mortality rate for gear ***g***, and ***P*** is the proportion of halibut in condition ***i***, where 1 is excellent/minor, 2 is poor/moderate, 3 is dead (trawl or pot)/severe, and 4 is dead (longline).

There are several factors that contribute to release viability, which vary by gear type. With trawl-caught halibut, condition is related to the size of the catch, tow duration, and halibut size. For longline bycatch, injuries are most frequently caused by improper release methods used by vessel crews. Another significant factor is the length of the soak time, which can exacerbate the mortality caused by hooking injuries and also increase the potential for amphipod predation. The condition of halibut caught in pots is affected by soak time and the presence of other animals in the pot, especially crabs, whose spiny carapaces have been observed to scratch and abrade the skin of the captive halibut.

The mortality rate ***m*** varies among gear types and represents the aggregate effects of external and internal injuries to the fish and the presence of predation by amphipods or marine mammals. The mortality rates have been determined through long-term tagging studies conducted by IPHC. See Clark et al. (1992) for trawls, Williams (1997) for pots, and Kaimmer and Trumble (1998) for longlines. Estimated halibut mortality rates by gear and condition/injury were as follows:

Gear (*g*)	m_{exc}	m_{poor}	m_{dead}	
Trawl	0.20	0.55	0.90	
Pot	0.00	1.00	1.00	
	m_{minor}	$m_{moderate}$	m_{severe}	m_{dead}
Longline	0.035	0.363	0.662	1.00

Mean fishery DMRs and associated standard errors were estimated by assuming that each vessel acts as a separate sampling unit, so that a DMR was calculated for each individual vessel in a target fishery. The DMR for a target fishery was then estimated as the mean of vessel DMRs, where the vessel's proportion of the total number of bycaught halibut was used as a weighting factor, as follows:

Let DMR_v = observed DMR on vessel ***v***

p_v = proportion of total number of halibut caught on vessel ***v*** in a fishery

Then $$\overline{DMR} = \sum_{v=1}^{n}\left(p_v \times DMR_v\right)$$

Standard errors of the weighted mean DMR were estimated as:

$$V\left(\overline{DMR}\right) = \sum_{v=1}^{n}\left(p_v^2 \times V\left(DMR_v\right)\right)$$

and $$SE\left(\overline{DMR}\right) = \sqrt{V\left(\overline{DMR}\right)}$$

where $V\left(DMR_v\right)$ is the sample variance of all the $DMRs_v$, and $V\left(\overline{DMR}\right)$ and $SE\left(\overline{DMR}\right)$ are the variance and standard error of $\overline{DMR}$, respectively.

Results

Non-CDQ fisheries

A summary of observer coverage, sampling, and halibut size composition data is shown in Table 2. Coverage and sampling in the major targets produced a large number of sampled hauls, and a substantial number of halibut sampled. For example, observers sampled over 5,000 hauls and 4,200 halibut in the BSA midwater pollock fishery in 2009. Two flatfish targets, yellowfin and rock soles, often had some of the largest halibut sample sizes than any other target. Sample sizes were generally very high (>1,000 hauls and/or >1,000 halibut measured) in most BSA trawl fisheries. The longline fishery for cod was the only BSA longline fishery to receive significant sampling in 2009-2011. In past years, sampling has also occurred on rockfish and turbot vessels but only minimally, and 2009-2011 was no exception, as only turbot fishing had any sampling. Pot fishing was focused on cod, as in past years.

Most of the sampling in GOA trawl fisheries occurred in the cod, rockfish, and flatfish targets. The rockfish fishery tallied the largest number of observed tows; this probably reflects the higher observer coverage requirements of the Central Gulf Rockfish Program. Sampling of the cod and the two pollock fisheries occurred at similar levels (31-39 vessels; roughly 200-400 hauls). Sampling of flatfish fishing occurred in the shallow water flatfish, arrowtooth, and rex sole targets. Only minimal vessel effort was noted in the deepwater flatfish target, which in past years was primarily directed at Dover sole. The number of sampled longline and pot vessels targeting cod was similar to past years.

Sampling and fishery totals of release viability (condition or injury) data by region and fishery are summarized in Table 3. The sample totals represent the summed observations recorded by observers. In most cases, these raw data total less than those shown in Table 2, as the latter include some halibut which were not examined for condition/injury. The observations on each haul were extrapolated upwards to the total number of halibut caught on the haul, and then summed across vessel and target fishery strata. For most fisheries, the distribution of the extrapolated viability data is very similar to the raw data. The complete time series of fishery DMRs, expressed as percentages, is provided in Tables 4 and 5 for the BSA and GOA, respectively.

CDQ fisheries

In 2009-2011, CDQ fishing was conducted using pots, trawls, and longlines. The primary species targeted by trawl operations included pollock, and rock sole and yellowfin sole during 2010-2011. Pacific cod were targeted by longline, and sablefish by pots. Sampling levels and injury/viability data for CDQ operations are summarized in Table 6; the time series of mean annual DMRs is shown in Table 7.

Almost all halibut caught in the trawl operations were dead when examined. Typically this is caused by a larger haul size and/or longer haul duration.

Of the 13 DMRs calculated for the 2009-2011 CDQ trawl targets, all but two were either 0.89 or 0.90. These results are generally higher than what is seen in non-CDQ fishing for the same target, which suggests there are other variables which are negatively affecting the condition of the released halibut. For example, different catch processing or handling methods for CDQ hauls may contribute to poorer release viability.

Longline CDQ fishing consisted of 14-17 vessels targeting cod. In previous analyses, the distribution of release injuries to halibut in the CDQ longline cod fishery has been similar to that observed in the non-CDQ cod fishery. However, the results for 2010 were much higher than the non-CDQ results (0.18 in CDQ vs. 0.09 in non-CDQ).

The pot fishery targeted sablefish, with either two or three vessels observed. Very few halibut were examined by observers, but not many halibut were caught. The fishery DMR (0.50) was unchanged during 2009-2010, but dropped quite a bit (0.31) in 2011, more in line with the long term mean. Halibut mortality is positively correlated with longer pot soak time; long soaks increase the potential for amphipod predation of captured fish in the pot.

Recommendations for 2013-15

The North Pacific Fishery Management Council is using a plan in which the DMRs used to monitor halibut bycatch are an average of data from the most recent 10-year period. These 10-year mean DMRs for each fishery are used for a 3-year period, with the justification being two-fold: 1) interannual variability of fishery DMRs is relatively small, and 2) to provide stability for the industry to better plan their operations. The following table outlines the range of data used for the specific years of application:

10-Year Basis Period	Years of application
1990-1999	2001 - 2003
1993-2002	2004 – 2006
1996-2005	2007 - 2009
1999-2008	2010 - 2012
2002-2011	2013 - 2015

As shown, information from 2002-2011 is the basis for the DMR recommendations for 2013-2015. The 10-year mean DMRs for 2013-2015 are shown in Table 8. For some targets, a full ten years of data are not available, so the recommended DMR is based on as much data as is available from the 2002-2011 basis period.

For CDQ targets with no past observations or data, such as longline turbot, and pot cod, DMRs derived from non-CDQ fisheries data are recommended. For the 'other species' and any other target not explicitly noted here in the non-CDQ fisheries, the DMR for the cod fishery in that region/gear stratum is recommended.

Table 1. Groundfish target definitions and target determination criteria for observer sampled hauls.

BSA		GOA	
Target	**Definition**	**Target**	**Definition**
A	Atka mackerel	A	Atka mackerel
B	Bottom pollock	B	Bottom pollock
C	Pacific cod	C	Pacific cod
F	Other flatfish	D	Deep water flatfish
K	Rockfish	H	Shallow water flatfish
L	Flathead sole	K	Rockfish
O	Other spp.	L	Flathead sole
P	Midwater pollock	O	Other spp.
R	Rock sole	P	Midwater pollock
S	Sablefish	S	Sablefish
T	Greenland turbot	W	Arrowtooth flounder
W	Arrowtooth flounder	X	Rex sole
Y	Yellowfin sole		

CDQ and Non-CDQ TARGET FISHERY DETERMINATION

Bering Sea/Aleutians

P if pollock ≥ 95% of total catch, or
W if arrowtooth flounder ≥ 65% of total catch.
Y/R/L/F if (rock sole + other flatfish + yellowfin sole + flathead) is the largest component of the retained catch using this rule:
Y if yellowfin sole is ≥ 70% of (rock sole + other flatfish + yellowfin sole + flathead sole), or
R if rock sole > other flatfish and rock sole > flathead sole, or
L if flathead sole > other flatfish and flathead sole > rock sole, or
F if none of the three conditions above are met.

Note: If target is not P, W, Y, R, L or F, then target is whichever species or species group (A, B, C, K, O, S, or T) forms the largest part of the total catch.

Gulf of Alaska

P if pollock ≥ 95% of total catch, or
W if arrowtooth flounder ≥ 65% of total catch.

Note: If target is not P or W, then target is whichever species or species group (A, B, C, D, H, K, L, O, S, or X) forms the largest part of the total catch.

Agenda Item F.5.b
Supplemental SSC Report
June 2014

SCIENTIFIC AND STATISTICAL COMMITTEE REPORT ON FINAL EXEMPTED FISHING PERMIT (EFP) APPROVAL FOR 2015–2016

Mr. Brett Wiedoff briefed the Scientific and Statistical Committee (SSC) on the revised exempted fishing permit (EFP) applications for electronic monitoring (EM) (Agenda Item F.5.a Attachments 1 – 4). The applicants were present to answer questions. The utility of the data obtained through these EFPs can be enhanced if there is consistency in data collection and reporting procedures. If the information is not collected and compiled in a consistent manner, it may result in a lost opportunity to compare results among EFPs and to compare results between EFP and non-EFP fleets. For example, economic data are valuable in evaluating cost effectiveness of EM. Collection of common data components, such as cost of equipment purchase, maintenance, and video review, should be considered by all EFP participants. The SSC encourages the EFP applicants, the Council staff, and National Marine Fisheries Service regional staff to collaborate on identifying common data components, standardizing reporting procedures, and planning for future data analyses.

The SSC found insufficient information to evaluate whether the level of observer coverage in the applications is adequate. Observer responsibilities include compliance monitoring and collecting scientific data and discard samples at sea. Since most of the EFPs are premised on maximized retention, the role of the observer on an EFP vessel will be different than on non-EFP vessels. It is not clear to the SSC how changes in observer coverage with EFPs might affect the quantity and quality of data needed for science, management, and compliance monitoring. The SSC requests that the observer program provide information regarding the data currently being collected, how they are used, and how they might be affected by reduced observer coverage.

ALASKAN OBSERVERS

Agenda Item F.5.c
Supplemental Public Comment
June 2014

27 May 2014

Dorothy Lowman
Chair
Pacific Fishery Management Council
7700 NE Ambassador Place, Suite 101
Portland, OR 97220-1384

Dear Dorothy,

As the Council continues to consider approval of the various Electronic Monitoring (EM) EFP's currently under consideration, we would like to point out a number of questions that need to be answered and impacts that need to be addressed before Observer Providers and the Observer and Monitoring programs are in a position to maintain required coverages on the West Coast in 2015.

1) What level of observer coverage will vessels participating in the various EM EFP's be required to take? Observer coverage in the EM EFP's is currently set at a level somewhere between zero and 100%. This leaves providers able to wonder but unable to plan, and we imagine it leaves the Agency in much the same place. Since each EFP might end up with different coverage requirements, the sooner the Council can get this question sorted out the better.

2) How many vessels will be permitted to participate in each EFP? At one time a limit of six boats per permit was being discussed, but that's apparently gone away. Again, not knowing how extensive participation may be makes any planning impossible.

3) It is remarkable that the EFP proposals fail to mention Catch Monitoring, since all deliveries made by EFP participants--whether or not a given trip is observed--will have to be monitored.

   The Catch Monitoring requirement could turn out to be particularly onerous in California. Fishing effort in California is light enough so that it has been a challenge to maintain the employment of observers who both ride boats and monitor offloads. If a number of vessels in Central and Southern CA are part of the EM EFP in that area and are subject to something less than 100% observer coverage, then the number of employed days available will be reduced from where it stands now. This will make it more difficult than ever to provide observer and monitor services in that area.

   Will the Council make EFP participants responsible for ensuring monitors are in place before offloads begin? Or will this responsibility rest with First Receivers?

4) In determining observer coverage levels for the various EFP's, the Council should consider that any coverage requirement of less than 100% will result in the loss of scientific data that the Agency needs in order to evaluate the effectiveness of EM. To gather this information from

130 NICKERSON, SUITE 206 • SEATTLE, WA 98109 • 206•283-6604 • 206•283-7310 • FAX 206•283-6519

unobserved trips, the Observer Program will have to design an approach to gather this data during offloads. Catch Monitors, as they are currently trained, do not gather this kind of data. If additional personnel are required to gather the data, the Council will need to determine who will be responsible for ensuring they are present and how they will be paid for.

In the rush to put EM into place, it seems a number of important details have gone unaddressed. Taking for granted that providers will figure out how to handle whatever observing and monitoring needs arise from implementation of the various EM projects before the Council is a mistake—instead, the effects should be acknowledged and addressed as part of the EFP approval process.

Sincerely,

ALASKAN OBSERVERS, INC.

Michael Lake
President

FIXED GEAR SABLEFISH CATCH SHARE PROGRAM REVIEW, INCLUDING FEDERAL ELECTRONIC FISH TICKETS FOR OPEN ACCESS SABLEFISH DELIVERIES

The Council began a review of its sablefish permit stacking program at its September 2013 meeting. Phase I of the program review includes:

1) an assessment of the program as it has performed against its original objectives;
2) early consideration of two issues for action—
   a) rules for assessing permit control, and
   b) electronic fish tickets; and
3) identification of additional issues for potential action.

The Council is scheduled to approve the final program assessment document and final preferred alternatives for the two action items at this meeting. If, during the review, additional issues for action are identified, a second phase of the review may be conducted for the purpose of considering action on these issues. These other issues would be added to the omnibus action under F.9 and prioritized along with other groundfish items at the September 2014 Council meeting.

The first phase of this review process will produce two separate documents: a program assessment and a document that presents and analyzes impacts for the two action issues.

The first of these two documents is the program assessment document (Agenda Item F.6.a, Attachment 1). Based on guidance provided at the April Council meeting, additional information on the following topics was added to the review: development of the permit system; post-implementation changes in the groundfish management regime; permit and vessel length distributions; Northwest Fishery Science Center safety study; tier utilization; community dependence on fisheries; regional economic benefits; and net revenue estimates. A pre-briefing book draft was made available to the public on May 12 (http://www.pcouncil.org/2014/05/30362/pre-pub-rvw-draft-fgsps-0514/), which included everything except the sections on permit and vessel length and Section 3.3 "Prevent Excessive Concentration of Harvest Privileges," both of which are included in the final draft provided here.

The latter of these two documents (Agenda Item F.6.a, Attachment 2) is the Council decision analysis document, which is also the environmental analysis (EA) required under the National Environmental Policy Act and will fulfill the analytical requirements of the Magnuson-Stevens Act and other applicable law. On the issue of the rules for assessing the thee-permit control limit, the Council selected Alternative 2a as its preliminary preferred alternative, which provides a limited exception to the rule—for 20 percent vessel ownership. Additionally, since the April Council meeting, Council staff has identified two additional areas in which the Council may wish to add provisions to the alternative: rules for assessing individual and collective control (ownership pass through), and rules on coordinated ownership. Strawman suboptions for Council consideration have been added to the action alternatives. Further, NMFS has identified a different approach for addressing the purpose and need for the action on the control limit and has provided that approach as Agenda Item F.6.a, NMFS Report 2. On the electronic fish ticket issue, in April the Council did not select a preferred alternative but did remove suboptions that would have maintained paper fish tickets and removed some language that contained unnecessary implementation details. Additionally, NMFS has identified a number of implementing issues for Council consideration on this topic (Agenda Item F.6.b, NMFS Report 1).

In April of 2012, under its trawl trailing actions, the Council took final action on a decision to allow joint registration of trawl and fixed gear (longline and fishpot) permits to the same vessel at the same time. National Marine Fisheries Service (NMFS) is developing a Secretarial review and implementation package on this issue, which will be combined with the two action items being considered as part of this review. In June, after the Council takes final action on the fixed gear catch sharing program review and issues for action, a draft EA will be published and proposed regulations promulgated on all three issues. If NMFS identifies any questions regarding Council intent with respect to the joint registration issue (none have been identified as of the time of the advance briefing book), it may bring those questions to the Council under the omnibus considerations (Agenda Item F.3).

Council Action:

1. **Provide guidance on finalization of the Phase I review document, as appropriate, including recommendations, if any.**
2. **Select final preferred alternatives for the rules for assessing permit control and electronic fish ticket requirements.**
3. **Identify Phase II issues for inclusion in the omnibus process, if any (Agenda Item F.9).**

DOCUMENT PREPARATION AND ACKNOWLEDGEMENTS

Preparation of this draft review of the limited entry fixed gear (LEFG) sablefish permit stacking program was performed by a work group composed of the following members:

Mr. Jim Seger and Dr. John Coon	Pacific Fishery Management Council
Dr. Edward Waters	Economics Consultant
Ms. Ariel Jacobs, Dr. Steve Freese, and Mr. Kevin Ford	National Marine Fisheries Service, West Coast Region

Additional assistance and consultation was provided by personnel of the National Marine Fisheries Service, Northwest Fisheries Science Center, especially Mr. John Bishop, Dr. Carl Lian, Ms. Alia Al-Humaidhi, and Ms. Lisa Pfeiffer.

A draft report of the Pacific Fishery Management Council pursuant to National Oceanic and Atmospheric Administration Award Number FNA10NMF4410014. This public review draft is not citable.

1.0 INTRODUCTION

This review document concerns implementation of Amendment 14 to the Pacific Coast Groundfish Fishery Management Plan (FMP). Amendment 14 (PFMC, 2001) was approved by the Pacific Fishery Management Council (Council) at its November 2000 meeting and partially implemented by National Marine Fisheries Service (NMFS) on August 2, 2001(Federal Register, 2001), in time to provide for a limited entry fixed gear (LEFG) sablefish season (longline and pot gear) from August 15 through October 31, 2001. The amendment, which covers the LEFG sablefish fishery north of 36° N. latitude, was fully implemented for the 2002 fishery. This amendment created a permit stacking program for permits with sablefish endorsements (i.e., the sablefish permit stacking program or simply the sablefish program). The program was expected to lengthen the duration of the LEFG primary sablefish fishery, increase safety and flexibility for fishery participants, and reduce capacity in the LEFG fleet.

1.1 Purpose and Need for a Program Review

The purpose of this document is to provide an overall review of the sablefish program to determine how well it has met the Council's stated objectives, and to help identify any potential modifications or improvements to the program which would then be considered through the Council's standard notice and review process. The goals and objectives of the program are based on, and are consistent with, the goals and objectives of the Magnuson-Stevens Fishery Conservation and Management Act (MSA), which is the ultimate authority for regional council fishery management.

While the sablefish program seems to have been generally successful at achieving its main objectives, a few limited requests for program modifications have emerged in the more than 12 years that have elapsed since its implementation (see Section 1.2). During that time there have been several changes in the fishery and groundfish management. In consideration of the changes and time elapsed, the Council and NMFS have agreed upon the need to review the program with a more in-depth look to determine how well it has met its original objectives and how well it continues to serve Pacific Coast groundfish management and its stakeholders. In addition, the sablefish permit stacking program is of a type of fishery management program that was categorized in the 2006 reauthorization of the MSA as a limited access privilege program (LAPP). After 2006, any programs initiated as LAPPs had to meet certain requirements listed in Section 303A(c) of the MSA, including the need to be reviewed on a periodic basis. While it was initiated as a LAPP prior to the MSA requirements for new LAPPs, a periodic review of any program to determine how well it is working and achieving its original objectives is a prudent management process and is consistent with the requirements in §303A of the MSA.

1.2 Concurrent Considerations of the Sablefish Program

Separate from this review, the Council is currently considering two potential modifications to the regulations implementing the sablefish program: 1) liberalizing the own-and-hold threshold which currently specifies that no matter how small, any partial ownership of a permit or a vessel registered to a permit, results in those permits counting toward the individual's three-permit maximum control limit, and 2) requiring the use of electronic reporting to aid in the tracking of landings. A final Council decision on these two potential changes to the sablefish program is scheduled for the June 2014 Council meeting. Additionally, in trailing actions for the trawl individual fishing quotas (IFQ) program (trawl rationalization) the Council has previously approved a regulatory change to allow fixed gear and trawl permits to be jointly registered to the same vessel at the same time. NMFS is in the process of considering the Council's recommendation on joint registration and may incorporate that proposed action into the same regulatory package with the own-and-hold threshold and electronic reporting issues.

2.0 BACKGROUND

2.1 Pre-Permit Stacking Management History

Sablefish (*Anoplopoma fimbria*), also known as "black cod," is one of the most valuable species in the groundfish fishery off Washington, Oregon, and California. Because of its high exvessel value per pound, sablefish is a desirable target species for many West Coast fisheries and gear groups. Management of sablefish was, and continues to be, divided at 36° N. latitude (approximately 20 miles south of Point Sur, California) with separate annual catch limits (ACLs) for the northern and southern fisheries divided by this line. The ACLs in the north are substantially higher than those in the south (the northern ACL was three times that set for the southern area). The Council made several sablefish allocation decisions over the 15 years prior to implementation of Amendment 14 in an attempt to divide this desirable resource among different sectors of the fishery in an equitable and beneficial way.

Intersector Allocation and Seasonal Management. In 1987, an allocation of northern area sablefish was established that provided 52 percent to the trawl fishery and 48 percent to the non-trawl gear groups. This allocation was later adjusted to 58 percent and 42 percent for trawl and non-trawl, respectively. Industry representatives for participants in the non-trawl sablefish fisheries expressed their desire that the fishery be managed on a seasonal basis (as opposed to the year-round policy the Council pursued for most sectors of the groundfish fishery). The pursuit of seasonal management for the non-trawl segment of the sablefish fishery was a key decision that, when combined with a decline in sablefish abundance and increasing effort, ultimately impacted safety, efficiency, and allocation issues that the permit stacking program was meant to address.

License Limitation. The vast majority of the trawl and non-trawl sablefish harvest (as well as that of other groundfish species) was placed under a license limitation program through Amendment 6 to the groundfish FMP, recommended by the Council in 1991 (PFMC, 1992) and implemented in 1994. Of the non-tribal commercial optimum yield of sablefish, 90.6 percent was allocated to the limited entry (LE) fishery and 9.4 percent was allocated to the open access fishery. The LE sablefish allocation was then allocated 58 percent to the LE trawl sector and 42 percent to the LE non-trawl (fixed gear) sector. The license limitation system provided the underlying structure for the LEFG sablefish catch share program that was finally implemented in 2001 under Amendment 14. Under Amendment 6, the owners of vessels which met a July 11, 1984 through August 1, 1988 (qualifying period) minimum landing requirement were given LE permits endorsed for the gear that was used to meet the requirement and endorsed for the size of the vessel. Permits were provided for trawl, longline, and fishpot vessels which were allowed to qualify for more than one gear endorsement (but only one permit was issued for each vessel). Minimum landing requirements were set with the intent of establishing LE fleets that were the size of the active fleet in 1987. The requirement for a longline permit was 6 days of landings over 500 pounds or 37.5 metric tons of total landings in the qualifying period. The requirement for a fishpot permit was 5 days of landings over 500 pounds or 150 mt of total landings in the qualifying period. The 1987 “active fleet” objective was met for the longline and fishpot vessels. Vessels using all gear types other than trawl, longline, and fishpot were left in the open access groundfish fishery, and a small open access opportunity was also provided for fishpot and longline vessels that did not qualify for permits. The opportunity for use of longline and fishpot gear in the open access fishery was provided because landings less than 500 pounds were not counted toward the landing requirement.[1]

Deliberations on a Fixed Gear Sablefish IFQ Program. After the Council finished its 1991 deliberation on Amendment 6, recognizing that a license limitation program would only slow the growth in capacity, the Council moved immediately to consideration of an IFQ program for the fixed gear sablefish fishery. Work on this program continued from 1991 through 1994. In the fall of 1994, the Council set its deliberations aside in response to a request from the West Coast Congressional delegation to defer action until the MSA reauthorization was completed. In its 1996 re-authorization of the MSA, Congress included a moratorium on implementing new, individual quota (IQ) programs through October 1, 2000, bringing deliberations on a sablefish IFQ Program to a complete halt.

Subdivision and Management of the Fixed Gear Allocation and Derby Management. Until implementation of IFQs as part of the trawl rationalization program in 2011, the coastwide trawl

---

[1] A similar opportunity was not provided for trawl vessels because the 500 pound minimum had no effect on the number of vessels qualifying.

fishery took sablefish as part of its year-round cumulative trip limit fisheries. During this same time, the northern area fixed gear fleet landed 85 percent of its allocation in a directed sablefish season, and 15 percent of its allocation in daily trip limit (DTL) sablefish fisheries. In the north, DTL regulations were in place before and after the directed sablefish season. The southern fixed gear fleet landed all of its allowed harvest in a DTL fishery. The directed season north of 36º N. latitude had become increasingly tense over the years as vessel capacity and competition for landings increased and amounts of fish available for harvest decreased. Through 1996, the directed (or “primary”) season was managed as an open competition derby in which vessels raced with each other to catch fish before the quota was gone and the fishery closed. Derby duration shortened each year, until the fishery was just five days long in 1996.

The Sablefish Endorsement and Equal Cumulative Limits. Concern for the safety of participants in the sablefish derby led the Council to develop Amendment 9 to the FMP (PFMC, 1996). NMFS implemented Amendment 9, the sablefish endorsement program, in 1997. Under this program, the LE permit holders were eligible for sablefish endorsements based on their permit history. A fixed gear sablefish endorsement was added to permits that had a history of landing more than 16,000 pounds of sablefish in any one year from 1984 to 1994. Permits without sufficient sablefish landings history were not endorsed for future participation in the primary season, but could still be used in the DTL fisheries. When this endorsement was adopted, it was recognized that it was only the first in a series of stop gap measures to control increasing capacity and deteriorating seasons in the fishery.

Even with the sablefish endorsement to prevent LE vessels from shifting into the sablefish fishery, the fishing season was expected to remain short. In order to lengthen the season, equal limits on the harvest of all qualified participants (sablefish endorsement holders) were imposed in 1997. However, the season still had to be limited to keep the fishery from being classified as an IQ program, prohibited under the MSA moratorium on such programs. A fishery with a limited class of participants, each with an amount of fish they are allowed to harvest, is an IQ. The moratorium was interpreted to cover any program that would allow a vessel ample time and opportunity to catch a limit allocated specifically to that vessel. The moratorium forced the Council to manage the primary season for a short duration that prevented many participants from fully taking their vessel-specific limits (a “modified derby”). To further assure that the cumulative limits would not be categorized as an IQ program, regulations were established to set a maximum season length of 10 days. After the modified derby, any of the primary fishery allocation remaining was taken in a two-week mop-up fishery in which each vessel had the same cumulative limit. Equal cumulative limits for the primary fishery were viewed by the Council as being extraordinarily reallocative in nature, but for 1997, equal limits were the only option available to lengthen the season and to begin to address safety issues.

Three Tiers of Cumulative Limits. The inequitable allocation system created by the equal cumulative limits was partially resolved with a “three-tier” system, which was established by regulatory amendment for 1998 and beyond. Under this “three-tier” system, the primary fishery continued to be managed by providing each vessel with a single cumulative limit; however, sablefish endorsement holders were ranked into three different tiers based on their permit histories, with the lowest tier (Tier 3) having the lowest qualification requirements and receiving the lowest cumulative limits. This system is described in greater detail in Section 2.3. Annual management of the three-tier cumulative limit system required that the allocation for this fishery be divided such that there were three different cumulative limits for the different tiers. While somewhat more equitable than the cumulative limit program, the three-tier system still required some fishermen to make large cutbacks in their harvest levels while allowing others to expand. The system provided little flexibility to operators to determine the manner in which their sablefish catch was harvested or to scale their harvest upward to match their pre-existing levels of capital investment. This lack of flexibility undoubtedly reduced efficiency, resulting in a lower net value for harvest.

Continuation of Short Seasons. Even under the three-tier system, the fishery still had to be managed as a modified derby, and the seasons were still too short (between 6-9 days) to allow fishermen to operate with care and safety. Short derby seasons are believed to result in accidents due to fatigue and financial pressure to fish and transit under unsafe conditions.

Fixed Gear Sablefish Catch Shares. The MSA moratorium on new IQ programs expired on October 1, 2000. On December 21, 2000, Public Law 106-553, an appropriations bill for the National Oceanic and Atmospheric Administration (NOAA), contained a continuation of the IQ moratorium through October 1, 2002 and an exception to that moratorium for the West Coast fixed gear sablefish fishery. On August 2, 2001, Amendment 14 implemented a permit stacking program, in which up to three sablefish-endorsed permits could be registered for use with a single vessel and that vessel could then have access to the primary season sablefish cumulative limits associated with each of those permits. Most importantly, the exception to the IQ moratorium for the fixed gear sablefish fishery allowed longer seasons (April through October, as implemented through Amendment 14) so that each vessel could fish against its limits at its own speed.

Phased Implementation of Catch Shares. Portions of Amendment 14 were implemented for the 2001 primary sablefish season. The extended sablefish season (April 1 through October 31) was fully implemented in 2002. In 2006, NMFS implemented additional regulations for Amendment 14. In the future, NMFS will consider implementing a permit stacking program fee system as required by the MSA (see Section 3.11). Table 2-1 recounts the implementation history.

Table 2-1. Implementation of Amendment 14.

Date	Action	Reference
08/02/2001	NMFS final rule implementing initial permit stacking provisions as follows: 1) up to 3 sablefish-endorsed permits per vessel; 2) limited entry, primary sablefish season of August 15 - October 31; 3) a vessel may fish for sablefish in the primary season with any of the gears specified on at least one of the limited entry sablefish-endorsed permits registered for use with that vessel; 4) no person may own or hold more than 3 sablefish-endorsed limited entry permits unless that person owned more than 3 permits as of November 1, 2000; 5) no partnership or corporation may own a sablefish-endorsed limited entry permit unless that partnership or corporation owned a permit as of November 1, 2000; 6) cumulative limits for species other than sablefish and for the sablefish daily trip limit (DTL) fishery remain per vessel limits and are not affected by permit stacking; and 7) the limited entry DTL fishery for sablefish is open during the primary season for vessels not participating in the primary season.	66 FR 41152, August 7, 2001
03/01/2002	As part of the final rule implementing the 2002 groundfish regulations, the primary limited entry sablefish season was extended to April 1 – October 31.	67 FR 10490, March 7, 2002
04/03/2006	Final rule including additional permit stacking regulations as follows: 1) permit owners and permit holders required to document their permit ownership interests to ensure that no person holds or has ownership interest in more than 3 permits; 2) owner-on-board requirement for permit owners who did not own sablefish-endorsed permits as of November 1, 2000; 3) an opportunity for permit owners to add a spouse as co-owner; 4) vessels not meeting minimum frozen sablefish historic landing requirements are not allowed to process sablefish at sea; 5) permit transferors required to certify sablefish landings during mid-season transfers; and 6) a definition of the term “base permit.”	71 FR 10614, March 2, 2006

2.2 Permit Stacking Program Goals and Objectives

The legal basis for Amendment 14 is the Groundfish FMP approved by the Secretary of Commerce under the authority provided by the MSA.

Permit stacking and its accompanying regulatory provisions were expected to help the Council address objectives related to National Standards 4 (fair and equitable allocation), 5 (consider efficiency), 6 (take into account variations and contingencies), 8 (take communities into account), 9 (minimize bycatch and bycatch mortality), and 10 (promote safety). Specifically, it was expected to affect achievement of Groundfish FMP Goals 2 (maximize the value of the resource as a whole) and 3 (achieve maximum biological yield) through impacts related to Objectives 6 (achieve greatest net benefit), 9 (reduce wastage), 11 (minimize bycatch), 12 (equitable sharing of the conservation burden), 13 (minimize gear conflicts), and 14 (accomplish changes with minimum disruption).

Key objectives of Amendment 14 and the permit stacking program were further defined as provided in Table 2-2.

The stacking program was intended to modify the economic and social impacts of the fishery management system in order to attain a more favorable result with respect to the entire suite of standards, goals, and objectives for management of the groundfish fishery.

Table 2-2. Key objectives of the permit stacking program and consistency with management objectives.

Key Objective	Consistency with Management Objectives of the FMP and MSA
1. Rationalize the fleet and promote efficiency	Capacity reduction is one of the key elements of the Council's strategic plan. The strategic plan generally approaches capacity reduction by reducing the number of fishing vessels. This reduction does not of itself imply the rationalization of the fleet or increased efficiency. It is possible that the most efficient fixed gear sablefish harvest could involve a greater number of vessels taking sablefish as bycatch in other fisheries. However, given the high degree of overcapitalization in the fishery, it is believed that a reduction in capacity will generally move the fishery toward greater efficiency, addressing National Standard (NS) 5 and FMP Objective 6 on net national benefits.
2. Maintain or direct benefits toward fishing communities	This objective relates to NS 8 on fishing communities and FMP Objective 16 on fishing communities.
3. Prevent excessive concentration of harvest privileges	This objective relates to NS 4 on allocation, NS 8 on fishing communities, and FMP Objective 15 on avoiding adverse impacts to small entities.
4. Mitigate the reallocational effects of recent policies (3-tier system and equal limits)	This objective relates to NS 4 on allocation and FMP Objectives 12 on equitable allocation and 14 on minimizing disruption.

Key Objective	Consistency with Management Objectives of the FMP and MSA
5. Promote equity	This objective relates to NS 4 on allocation and FMP Objective 12 on equitable sharing.
6. Resolve or prevent new allocation issues from arising	This objective relates to NS 4 on allocation and FMP Objectives 12 on equitable sharing and 14 on minimizing disruption.
7. Promote safety	This objective relates to NS 10 and FMP Objective 17 on safety.
8. Improve product quality and value	This objective relates to NS 5 on efficiency and FMP Objective 6 on net national benefits.
9. Take action without creating substantial new disruptive effects.	This objective relates to FMP Objective 14 on minimizing disruption.
10. Create a program that will readily transition to a multi-month IQ program.	This objective relates to capacity reduction recommendations in the strategic plan. Where individual quotas are transferable and divisible, they address NS 6 by providing the fleet with substantial flexibility to respond to changing conditions in the fishery and NS 5 by taking efficiency into account. FMP Objective 6 is also addressed.

2.3 Description of the Current Permit Stacking Program

The sablefish fishery primary season managed under the permit stacking program occurs north of 36º N. latitude. Vessels in this fishery registered to at least one LE permit with a gear endorsement for either longline or trap (or pot) gear and an endorsement for sablefish, fish a specified tier limit. Such vessels are eligible to fish in the DTL fishery before the primary season (i.e., January through March) and after their aggregate tier limit on the vessels have been harvested, or the season has ended, whichever comes first. This transition between fisheries often occurs during the sablefish primary season. Under the permit stacking program, each fixed gear sablefish endorsed LE permit is assigned to one of three tiers. The permit's tier level determines the poundage of sablefish which can be landed by that permit each season while participating in the primary sablefish fishery. Sablefish endorsements and their tiers may not be transferred separately from the LE permits. For sablefish endorsed, LE permits, the Regional Administrator biennially or annually announces the size of the cumulative trip limit for each of the three tiers associated with the sablefish endorsement such that the ratio of limits between the tiers is approximately 1:1.75:3.85 for Tier 3, Tier 2, and Tier 1, respectively. Up to three permits can be stacked onto a single vessel, allowing that vessel to land up to the sum of the three tier limits in aggregate.

The program also includes other provisions, including a prohibition on the ownership of permits by corporations or other business entities, a permit owner-on-board requirement, a limit on the number of permits any individual or entity (individually and collectively) can own or hold, and a prohibition on at-sea processing. A grandfather clause was provided for each of these provisions, allowing the continuation of situations in place prior to Council action. For non-grandfathered permits, the owner of the permit must be on-board the vessel during the primary season when that permit's tier amount is being fished. If landings from a trip will be attributed to multiple permits, then the owners of those permits being fished must be onboard during fishing operations. However, there are medical and death exemptions from this requirement.

Currently there are 164 sablefish endorsed permits of which 131 are endorsed for longline only; 27 are fishpot endorsed only, and six have two gear endorsements (i.e., four are endorsed for both longline and fishpot gear, one is endorsed for both fishpot and trawl gear, and one is endorsed for both longline and trawl gear). The number of permits by tier level is as follows: Tier 1 – 28 permits; Tier 2 – 42 permits, and Tier 3 – 94 permits. As of August 2013, approximately 40 vessels have stacked permits.

2.4 Relevant Groundfish Policy and Regulatory Changes since Program Implementation

Since the implementation of the fixed gear sablefish permit stacking program, numerous regulatory changes have taken place within the Pacific Coast groundfish fishery. Chief among these changes was implementation of groundfish conservation areas (i.e., ecologically important habitat closed areas and rockfish conservation areas) and the rationalization of the trawl fishery. Vessel movement between the LEFG sablefish fishery and the rationalized trawl fishery make the development of the rationalized trawl fishery especially important in reviewing the sablefish program.

Fishery Disaster and Rockfish Conservation Areas. Just as the Council policies for the LEFG catch share program were being finalized in 2000, a number of stocks were being identified as overfished, primarily rockfishes, and severe harvest reductions were imposed on the groundfish fishery. The first stock assessments identifying the overfished status of some rockfish species were published in 1999. In 2000, the West Coast groundfish fishery was declared a disaster and new management measures were sought to reduce impacts. In the fall of 2002, vast swaths of the continental shelf were closed in order to reduce bycatch of overfished darkblotched rockfish. In 2003, Rockfish Conservation Area (RCA) closures were imposed for both fixed gear and trawl vessels to protect a number of overfished rockfish species.

Vessel Monitoring System. The need to enforce the RCAs led to a requirement that, starting in 2003, all LE vessels carry equipment and subscribe to services to allow satellite tracking of vessels, a vessel monitoring system (VMS).

Trawl Rationalization. Deliberations over rationalization of the trawl fishery began in 2003 and the program was implemented for the 2011 fishery. Trawl rationalization involved two closely related and interlinked decisions. The first was the specification of the management system used to rationalize the trawl fishery—Amendment 20 to the groundfish FMP (PFMC and

NMFS, 2010). Amendment 20 involved the consideration of harvest control tools such as IFQs and harvester co-ops. The second decision involved determining the proportion of the available catch that would be allocated to the trawl versus the non-trawl fishery. This decision was addressed as Amendment 21 to the Groundfish FMP (PFMC, 2010).

The trawl rationalization program allows gear switching (the use of nontrawl gear to catch fish under the trawl IFQ program). Gear switching not only allows trawl vessels to use fixed gear to catch sablefish, it also allows fixed gear vessels to acquire a trawl permit and trawl IFQ to increase their harvest of sablefish while using fixed gear. Whether by trawl or fixed gear vessels, the result has been an increase in the harvest of sablefish with fixed gear, increasing competition and potential conflict on the fixed gear sablefish fishing grounds.

3.0 PROGRAM PERFORMANCE AND REVIEW

This review of the LEFG sablefish LAPP will concentrate on assessing achievement of the 10 key objectives of the sablefish program (Sections 3.1 through 3.10) as provided in Groundfish Amendment 14 and summarized in Table 2-2 of this document. These objectives are all socio-economic objectives. While the biological impacts of the sablefish permit stacking program have not been quantified, they are believed to be insignificant. The impacts, if any, would result from a potential increase in unreported discards of smaller sablefish and changes in retention of other groundfish species. An increase in discard of small-sized sablefish (high-grading) might be expected because the permit tier limits are landing limits rather than catch limits, which would limit both catch and discards. The degree of high-grading will be a function of the price differential between large and small fish, catch composition by size class, and fishing costs. The degree of high-grading cannot be assessed based on fish tickets as there is no reliable data on size composition of landings because different buyers use different size categories. The ending of the derby fishery constraint may have allowed vessels to increase their retention of other groundfish or may have had no effect. Under current management, the conservation of sablefish and other groundfish is protected by ACLs which are independent of the permit stacking program.

This is the first official review of the impacts and outcome of this program by the Council. In 2013, NOAA published a technical memorandum on the performance of U.S. catch share programs (Brinson, Ayeisha A. and Thunberg, Eric A., 2013) which included a review of the Pacific Coast sablefish fishery. The authors of that report found evidence for capacity reduction in the fishery as well as better achievement of the catch quota. Total revenue (adjusted for inflation) also increased, however, they were not able to determine what part of the change might be due to the program versus other market forces.

This review will utilize primarily available Pacific Fishery Information Network (PacFIN) landings data, Alaska Fishery Information Network (AKFIN) vessel participation indicators ("yes/no" flags), and U.S. Coast Guard records on safety incidents to look at how the program has met its objectives.

The assessment of each objective of the program, as identified above, follows in sections 3.1 through 3.10 below.

3.1 Rationalize the Fleet and Promote Efficiency

3.1.1 Background

Rationalizing the fleet and promoting efficiency, primarily through reducing the number of participating vessels (capacity reduction) and lengthening the season, was a key objective of Amendment 14. In considering how to reduce the fleet, the Council also had to balance that reduction with its other objective of preventing excessive concentration of harvest privileges (see also Section 3.3). At the time Amendment 14 was adopted, the Council had just completed the Groundfish Strategic Plan (PFMC, 2000) for which capacity reduction is one of the goals. In support of the Council's Strategic Plan development process, the Scientific and Statistical Committee (SSC) assessed the capital utilization rates in year 2000 groundfish fisheries. The SSC characterized the capital utilization rate for a fishery as "the percentage of boats in the [year 2000] fleet needed to harvest the groundfish available in 2000." For the LEFG sablefish fishery, the SSC calculated that just 9 percent of the vessels in that fleet in 2000 were capable of harvesting that fleet's sablefish allocation for that year. While the Council was not interested in reducing the number of vessels participating in the LEFG sablefish fleet to 9 percent of the year 2000 levels, capacity reduction was a significant objective for Amendment 14 and the permit stacking program.

Amendment 14 was designed to allow the fleet to achieve some balance between too little and too much capacity reduction, without specific criteria for what constituted "too little" or "too much." Too little capacity reduction could mean that commercial fishermen intending to make a career of fishing would have to rely on sablefish landings providing a smaller proportion of their incomes and require more reliance on other fisheries. Too much capacity reduction could mean that the fleet could be reduced and concentrated to such a small number of vessels that harvest benefits from the fishery would be channeled to relatively few individuals, coastal communities, and processors.

Amendment 14 was explicitly *not* designed to reduce the fleet numbers to as few vessels as possible. The Council's judgment on whether the fleet's capacity has been reduced by too much or by too little, and whether excessive concentration of harvest privileges has occurred, will be necessarily qualitative, since the Council did not set an explicit capacity reduction goal with Amendment 14.

Information and data for considering whether the fleet has been rationalized and made more efficient include assessing the following changes:

- season length and average fishing days by year;
- number of participating vessels, attainment of allocations, and the concentration of harvest, including combinations of stacked permits, landings, and revenue by vessels in the fishery, both before and after program implementation;
- vessel capacities; and
- permit prices for available years.

While we do not have an assessment of pre-program net revenues per vessel to compare with similar post-program data, there is information available on the LEFG sablefish fishery for 2010 which has been compiled by Dr. Carl Lian of the Northwest Fisheries Science Center. Dr. Lian's paper, which is attached at the end of our review, provides estimates of total cost net revenue earned by commercial catcher vessels in the West Coast LEFG groundfish fishery, West Coast LEFG sablefish fishery, and the West Coast LEFG primary sablefish fishery. These estimates have been developed based on cost information collected through the NMFS periodic voluntary economic data collection program. An explanation of the estimates and how they were derived is provided in the attached document.[2] Based on the most recent year of data available (2010), estimated average per vessel total cost net revenue estimates were as follows:

- All LEFG vessels: $14,530
- Only those LE vessels participating in the fixed gear sablefish fishery: $13,042
- Only those LE vessels participating in the fixed gear sablefish primary fishery: $18,159

Total cost net revenue estimates for the fleet as a whole in 2010 were as follows:

- All 142 LEFG vessels: $2,063,260
- The 139 LE vessels participating in the fixed gear sablefish fishery: $1,812,838
- The 90 LE vessels participating in the fixed gear sablefish primary fishery: $1,634,310

Additional breakdowns of these estimates are provided in the attached document.

3.1.2 Assessment

Season Length and Average Fishing Days per Year. The sablefish program provided an immediate and significant lengthening of the primary sablefish fishery and average duration of the time over which a vessel might fish. Table 3-1 provides a succinct display of the season length and management history, including the mop-up fishery. In 1996, the primary fishery lasted only 5 days (noon to noon, September 1-6) in the derby mode. Beginning with 2002, the

[2] The explanation in Dr. Lian's paper includes the caution that net revenue is an upwardly biased indicator of profitability since the cost-earnings surveys used do not capture 100 percent of the costs associated with operating a commercial fishing vessel.

annual primary sablefish season was increased to 7 months in length (April 1 through October 31), giving fishermen and processors far more flexibility in how and when they fished and made landings. It also eliminated the need for a mop-up fishery.

Table 3-1. Season length and management summary for the primary LEFG sablefish season north of 36° N. latitude, 1992 through the present.

Year	Primary Season Length	Management
1992-1994	2 to 3 weeks	Derby
1995	7 days	Derby with Mop-up Fishery (Mop-up Season Sep. 1-30; Cumulative Trip Limit 5,500 lb per Vessel)
1996	5 days	Derby with Mop-up Fishery (Mop-up Season Oct. 1-15; Cumulative Trip Limit 3,400 lb per Vessel)
1997	9 days	Equal Limits/Modified Derby with Mop-up Fishery (Mop-up Season Oct. 1-22; Cumulative Trip Limt 8,500 lb per Vessel)
1998	6 days	Tiered Limits/Modified Derby with Mop-up Fishery (Mop-up Season Aug. 28-Sep. 12; Cumulative Trip Limit 3,200 lb per Vessel)
1999	9 days	Tiered Limits/Modified Derby with Mop-up Fishery (Mop-up Season Sep. 20-25; Cumulative Trip Limit 1,100 lb per Vessel)
2000	9 days	Tiered Limits/Modified Derby with Mop-up Fishery (Mop-up Season Sep. 5-19; Cumulative Trip Limit 3,000 lb per Vessel)
2001	Aug. 15 - Oct. 31	Aug. 2 implementation of Permit Stacking
2002-present	Apr. 1 - Oct. 31	Permit Stacking

Figure 3-1 displays the average duration in days over which a vessel was fished per year in the primary sablefish fishery (calendar days from a vessel's first until its last landing made as part of the primary sablefish fishery). Looked upon in that way, within the 7 months of fishing opportunity each year from 2002 to 2013, individual vessels tailored seasons for themselves that ranged on average from 51 to 75 days. If the duration is weighted by the landings per vessel[3], the average duration ranged from 52 to 81 days.

Number of Vessels, Attainment of Allocations, and Concentration of Harvest. With regard to reducing the capacity of the fishery, Figure 3-2 displays the number of vessels participating in the sablefish fishery prior to and following implementation of the sablefish tier program. Primary season participation from 1996 through 2000 (prior to the program) averaged 146

[3] Weighting each vessel's season duration by its total primary sablefish landings adjusts for vessels that may have had relatively low total landings or that may have fished only sporadically during the season.

vessels compared to an average of 90 vessels after program implementation (2002 through 2013), a 38 percent decrease. The number of vessels and landings in the primary season fishery prior to 1998 were not recorded separately from the total fishery, and are estimates based on counts of vessels in the LE fishery that landed at least 1 mt of sablefish north of Santa Barbara County within the appropriate season periods.

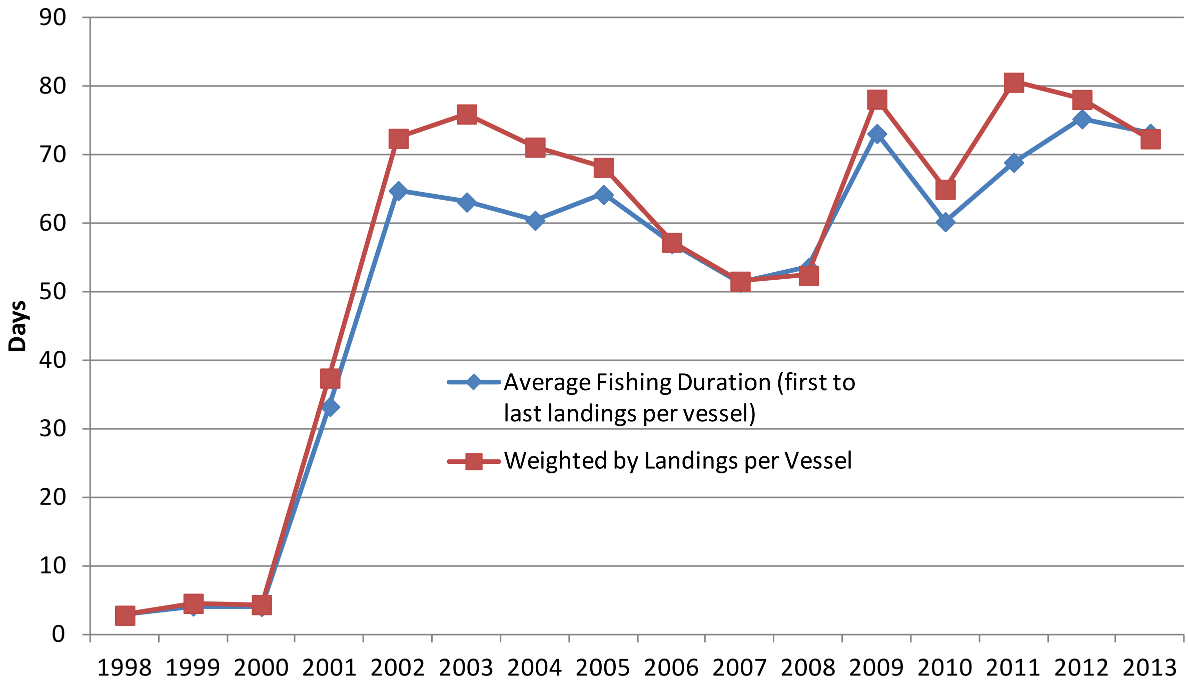

Figure 3-1. Average duration in days from first to last day of landings for vessels participating in the primary sablefish fishery (1998-2013).

Figure 3-3 displays the historical sablefish fishery allocations from 1996 through 2013 by total, primary, and DTL fisheries. Note that the allocations reported for years prior to 2002 in this and the following two figures include the total LEFG sablefish fishery, as there were no explicit allocations to primary and nonprimary fisheries. Figure 3-4 displays the LEFG sablefish fishery allocation and landings from 1996 through 2013. Note that from 1998 through 2001 the reported landings include the DTL and mop-up fisheries. Figure 3-5 displays the annual percent of the LEFG sablefish allocation landed each year of the period 1996 through 2013. Comparing pre-program (1996 through 2001) and post-implementation (2002 through 2013) periods, it can be seen that since implementation of the program the percentage landed appears within a more consistent range and has not exceeded the allocation. This appearance may be a factor of the short timeframe over which the pre-program landings are graphed, but seems more likely the result of the longer, less derby-like fisheries which are more efficiently prosecuted and managed to meet individual (permit tiers) and aggregate (sector allocation) targets.

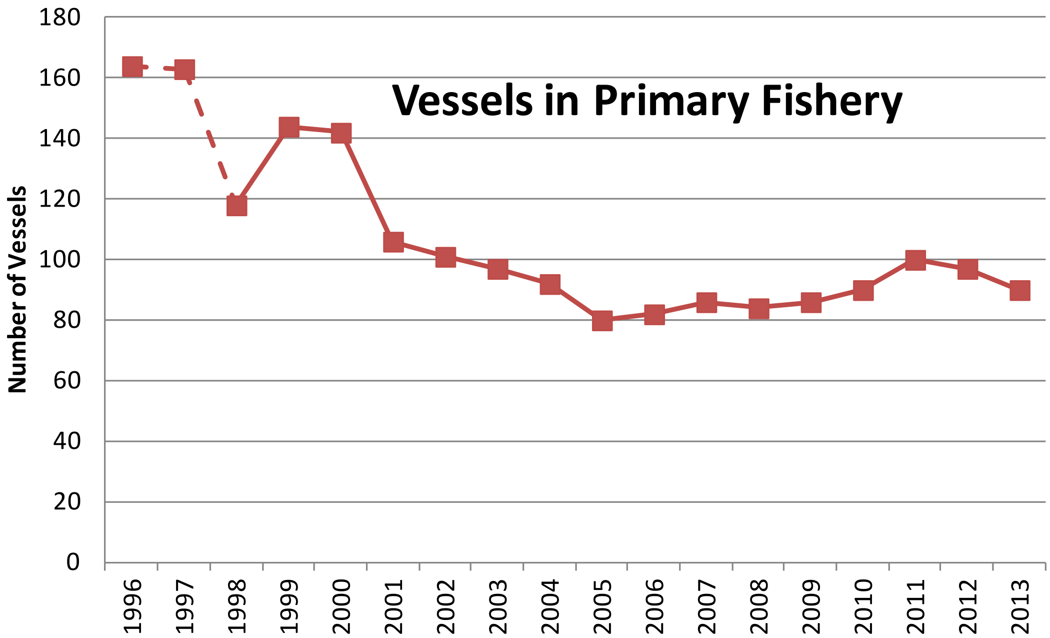

Figure 3-2. Number of vessels participating in the LEFG primary sablefish fishery from 1998 to 2013. Vessel counts for years prior to 1998 are estimated based on vessels in the LE fishery that landed at least 1 mt of sablefish north of Santa Barbara County within the appropriate season periods.

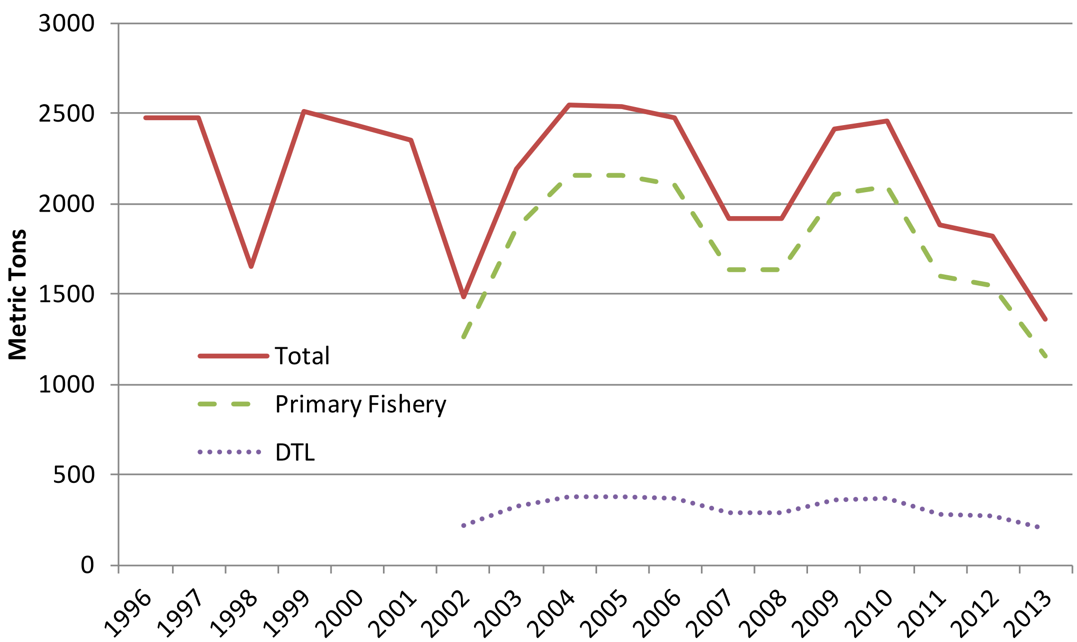

Figure 3-3. LEFG Sablefish fishery allocations by total, primary, and DTL fisheries, 1996-2013. Prior to 2002 there were no explicit allocations to the primary and DTL fisheries.

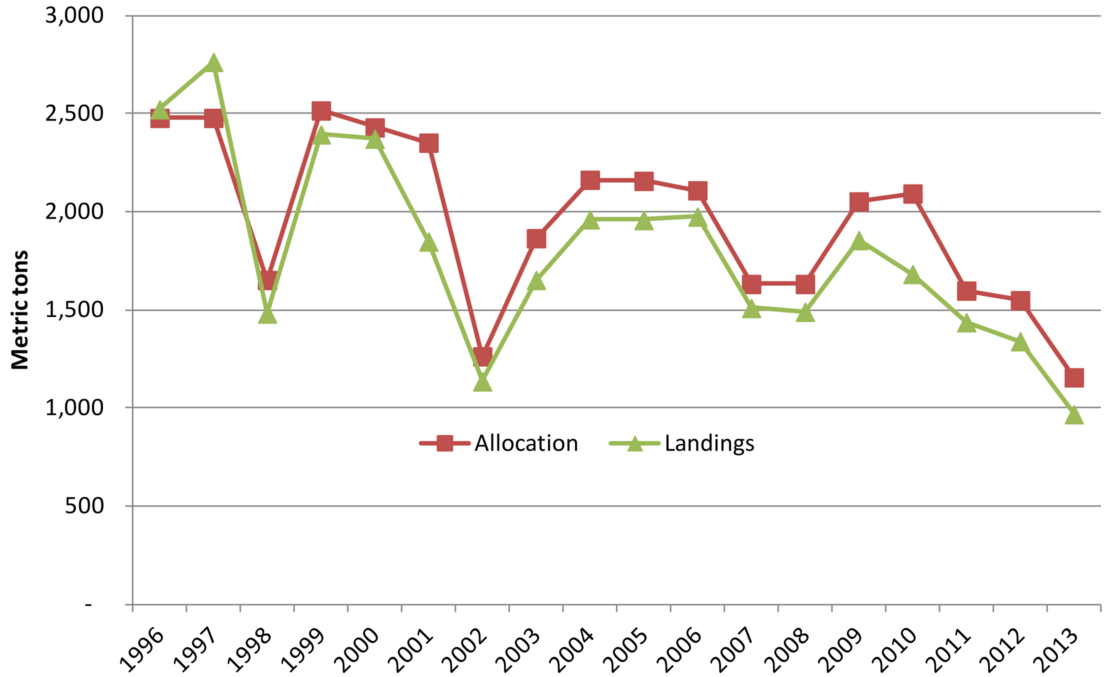

Figure 3-4. LEFG sablefish allocations and landings, 1996 through 2013. Years prior to 2002 include the mop-up and DTL fisheries, while years from 2002 to 2013 are for the primary season only.

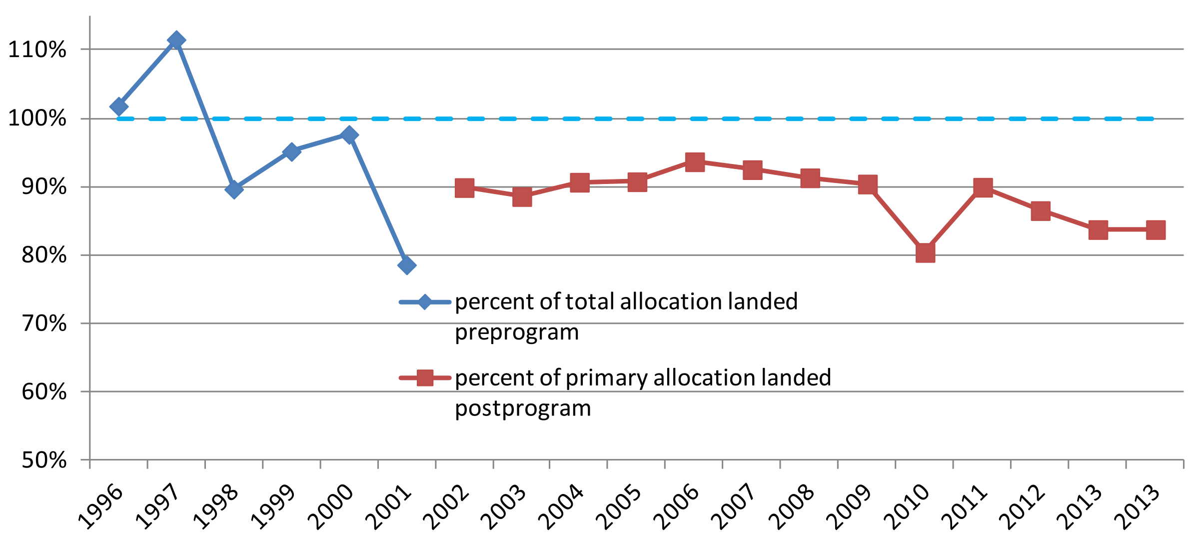

Figure 3-5. Pre- and post-program LEFG sablefish allocations and landings as a percent of the allocations, 1996 through 2013.

Over the period of program implementation, Tables 3-2 and 3-3 compare the number of vessels, their relative allocations, and landings by the various possible permit and permit stacking combinations for the years 2002, 2004, 2008, and 2012. Table 3-3 also displays the percent of the sablefish trawl IFQ harvested by vessels with tier permits during the years 2011 through 2013 (17.2 percent).

From the snapshots within the first 12 years of the program provided by Tables 3-2 and 3-3, it is hard to pick out any consistent direction of change that would indicate significant consolidation or disaggregation of permits and landings at the fleet level or on a per-vessel basis. The number of vessels with combinations other than a single Tier 3 permit varied only slightly between 58 and 61 vessels. The main differences between years are due to the number of vessels with only a single Tier 3 permit (last row before the total in Table 3-2).

Table 3-4 is somewhat more informative as to how the different permit tiers have or have not been stacked. The higher tier permits (Tier 1 and Tier 2) appear more likely to be stacked (consolidated) to the maximum of three. The stacking of three Tier 1 or three Tier 2 permits on a single vessel showed a fairly consistent increase (consolidation) from 2002 to 2012, increasing by over 46 percent in each case. At the same time, as would be expected, the frequency of vessels with only one or two permits declined. For all tiers, permits that are not triple-stacked are fairly evenly split between being double-stacked and unstacked. For Tier 3 permits there is an interesting anomaly which has not yet been explained. There appears to have been a consistent increase in the number of Tier 3 permits stacked until a change occurred between 2008 and 2012, during which the occurrence of triple-stacked permits dropped from 43 down to 22, almost as low as in the first full year of the program. ***The drafting team for this document solicits information that may explain this apparent anomaly.***

Figure 3-6 displays how the participating vessels and concentration of landings in the LEFG primary sablefish fishery changed during selected years between 1996 and 2012. The number of participating vessels decreased fairly consistently from a high of 164 in 1996 to a low of 82 in 2006. After 2006, the number of vessels participating in the primary fishery increased to 84 in 2008, 90 in 2010, and 97 in 2012. The number of vessels participating in 2012 was the highest since 92 participated in 2004. The concentration of landings among vessels generally increased over this period as well, which is more apparent in Figure 3-7 which normalizes the curves by comparing share of harvest to percent of fleet rather than to the number of vessels (Figure 3-6).

Table 3-2. Comparison of the number of vessels and allocations for various combinations of stacked permits in 2002, 2004, 2008, and 2012. (Note that this snapshot in time may not capture changes in permit combinations during the season.)

a/ Analysis based on registrations as of July 1 each year plus post-July 1 registrations for permits not registered on July 1st.

In Figure 3-7, an equal distribution line has been added which indicates the shape of the curve in the event that each vessel had landed exactly the same amount in a given year. Greater deviations from the equal distribution line indicate relatively greater concentration of landings among fewer vessels. The graph shows the distribution changing over the years since program implementation. The dark line for 1996 shows the distribution during the final year of the derby fishery. The 1997 line shows the degree to which management under equal cumulative limits equalized the distribution of harvest among vessels. The lines for 1998 and 2000 show movement toward the 1996 distribution. After the permit stacking provisions went to effect in 2001, the lines move even closer to the 1996 line. The similarity of the curves for the earliest year, 1996, to the most recent year, 2012, is striking (see Section 3.4 for additional discussion of this graph). Although many fewer vessels participated in the fishery in 2012 than in 1996, they delivered a similar cumulative distribution of landings in both years.

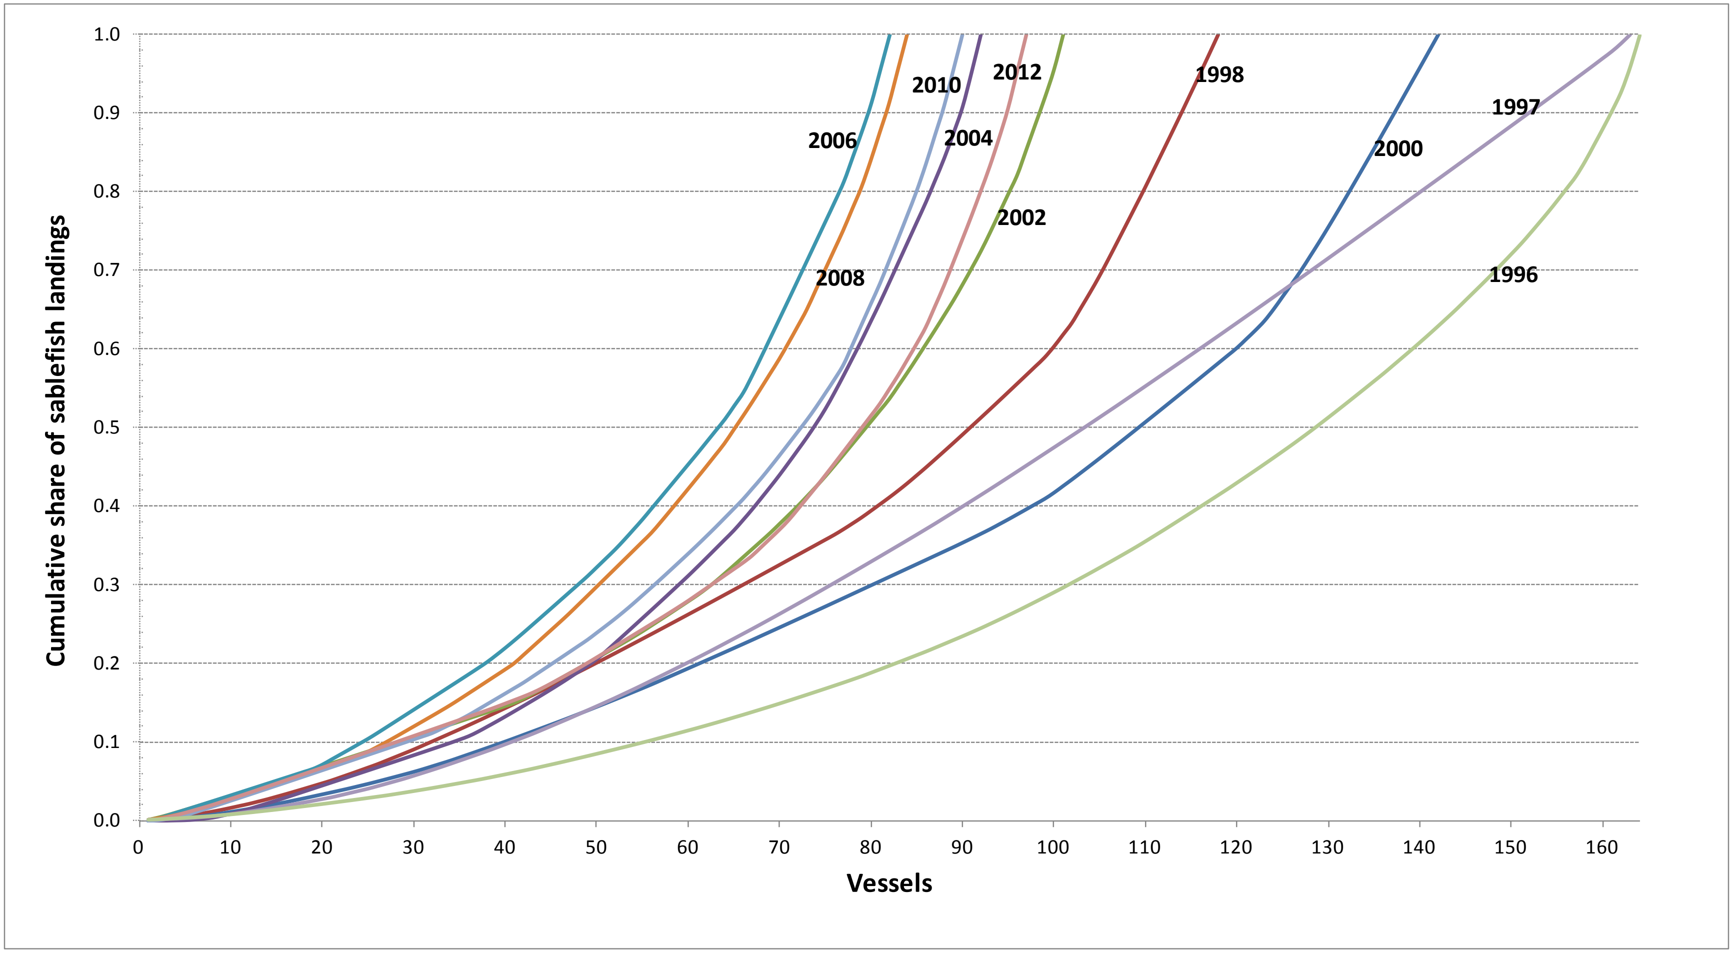

Figure 3-6. Cumulative share of landings by the number of vessels participating in the LEFG primary sablefish fishery during selected years from 1996-2012.

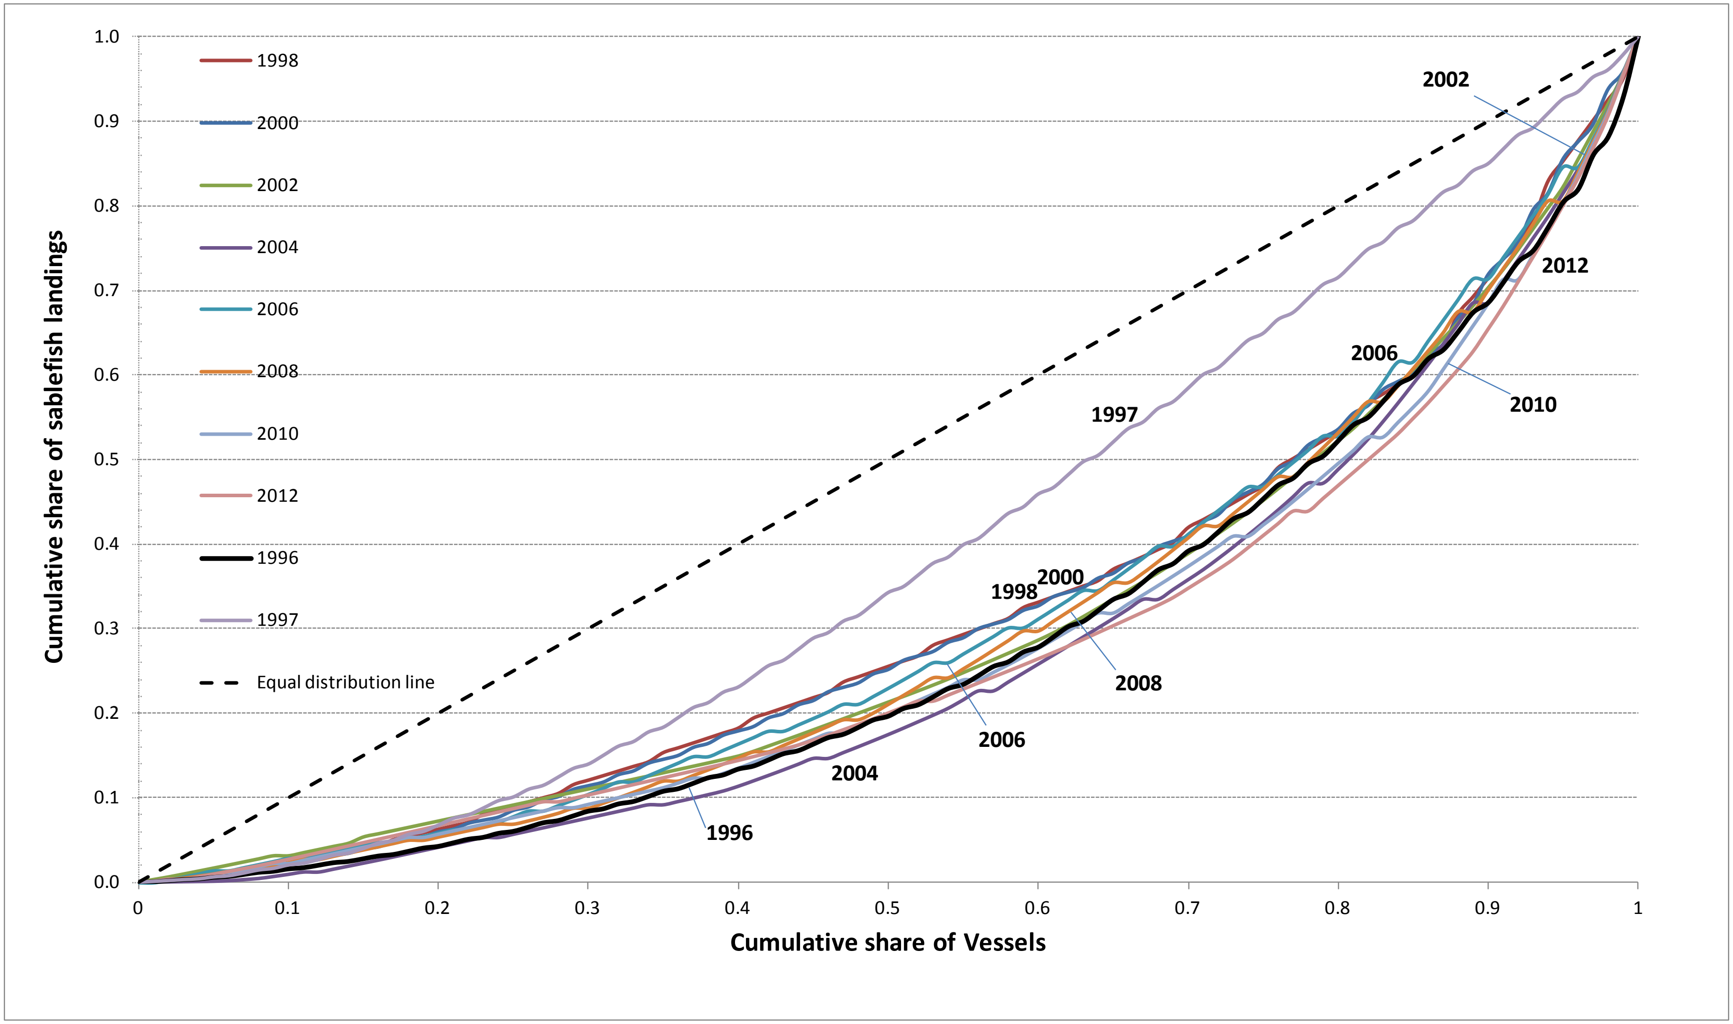

Figure 3-7. Concentration of landings by the cumulative share of vessels participating in the LEFG primary sablefish fishery for selected years from 1996-2012.

The similarity in the concentration of primary sablefish landings for 2012 and 1996 is reinforced by comparing the Gini coefficient values for concentration of landings by vessels in those years shown in Figure 3-8 (derived from the data displayed in Figure 3-7). Gini coefficients are an indicator of the deviation from the equal distribution line shown in Figure 3-7. A Gini coefficient of zero indicates an equal distribution of landings, while a value of 1 indicates that a single vessel made all the landings (i.e., the most concentrated distribution). Gini coefficient values greater than zero and less than one indicate increasingly concentrated landings distributions. The figure shows that since the imposition of the equal cumulative limits fishery in 1997, the distribution of landings has generally trended toward recreating the concentration exhibited by the 1996 fishery. The 2013 Gini coefficient value of 0.47 is about 7 percent higher than the value for the fishery of 0.44 in 1996.

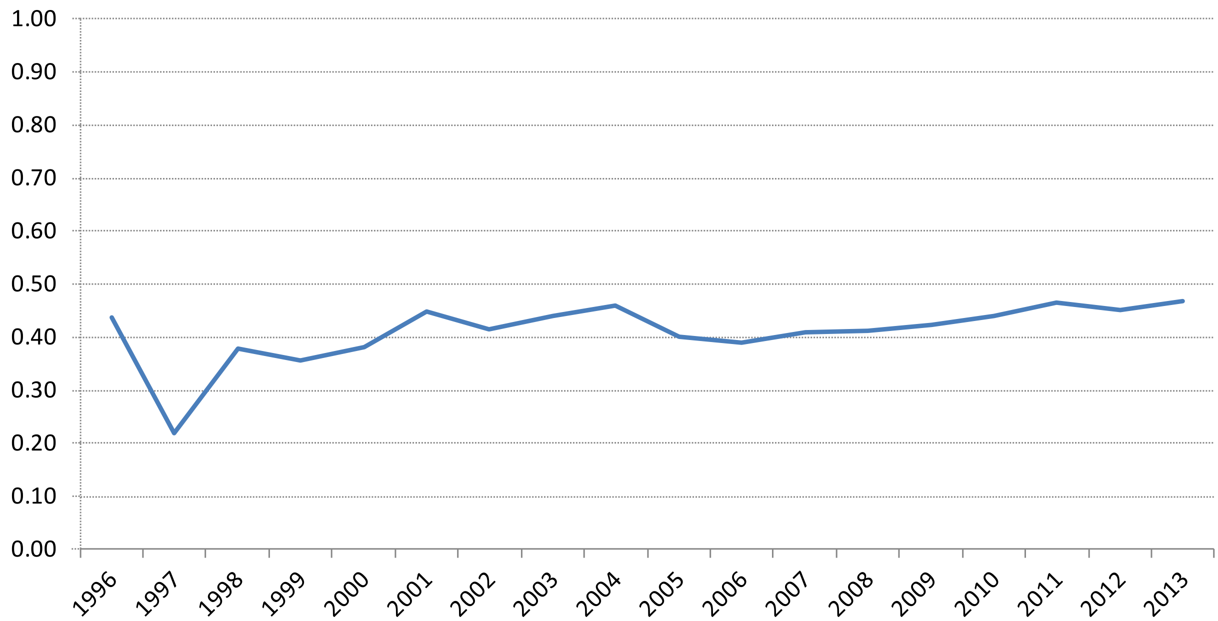

Figure 3-8. Gini coefficients for the concentration of landings by vessels in the LEFG primary sablefish fishery for years before and after full implementation of the permit stacking program in 2002.

[Note: A Gini coefficient of 0 implies a perfectly even distribution among all participants, while a coefficient of 1 indicates one vessel landed all of the fish.]

Vessel Capacity. Table 3-5 and Figures 3-9 and 3-10 display information about the distribution of vessel lengths and permit length endorsements in the LEFG sablefish fishery in 2012. Table 3-5 shows the distribution of length endorsements for sablefish permits by tier and also by gear endorsement. The table shows the average length endorsement for Tier 1 permits (66.6 feet) is longer than the average for both Tier 2 permits (53.1 feet) and Tier 3 permits (47 feet). The minimum length endorsements follow the same pattern, with the minimum Tier 1 permit length endorsement (40 feet) exceeding those for both Tier 2 (32 feet) and Tier 3 permits (18 feet).

However the same is not true for the maximum length endorsements. While the longest Tier 3 permit (97.3 feet) is shorter than the longest Tier 1 permit (138 feet), it is longer than the longest Tier 2 permit (88 feet). From Table 3-5 it is difficult to discern any meaningful patterns regarding permit length and gear endorsements.

Table 3-5. Distribution of permit length endorsements for LEFG sablefish permits in 2012.

Permit Category	Number of Permits	Permit Length Endorsements in Feet			Permits Within One Standard Deviation	
		Average	Range of: Minimum to Maximum	Range of: One Standard Deviation	Number	Percent
Tier 1	28	66.6	40 to 138	44.4 to 88.9	20	71.4%
Tier 2	42	53.1	32 to 88	39.8 to 66.3	28	66.7%
Tier 3	94	47.0	18 to 97.3	35.1 to 59.0	67	71.3%
Longline	132	50.2	18 to 97.3	36.9 to 63.5	90	68.2%
Pot	28	60.4	32 to 138	35.6 to 85.3	19	67.9%
Both Longline and Pot	4	49.2	40 to 55.3	43.5 to 54.9	2	50.0%

Figure 3-9 shows the number of vessels carrying stacked (two or three) and unstacked (one) permits by vessel length class on July 1, 2012. Vessel length classes were constructed so that an approximately equal number of vessels fell into each class. From the figure it is evident that permit stacking is more prevalent on longer vessels than on shorter ones. Seventy five percent of the 20 vessels involved in the fishery that are at least 60 feet in length carried stacked permits, while only 50 percent of the 18 vessels between 50 and 60 feet in length and the 22 vessels between 43 and 50 feet in length carried stacked permits. Only one of the 17 vessels less than 35 feet in length carried stacked permits.

Figure 3-10 shows the distribution of stacked and unstacked permits by permit length endorsement class. The permit length endorsement categories were chosen to mirror the vessel length classes in Figure 3-9. In Figure 3-10, stacked permits are further bifurcated into base and non-base categories (for administrative purposes, NMFS normally designates one of the permits in a stack as the "base permit"). The figure shows that among permit length endorsement categories, the greatest number of stacked base permits is in the greater-than-or-equal-to 60 feet category, while the greatest number of stacked non-base permits is in the 35-to-43 feet category (as is the greatest number of unstacked permits).

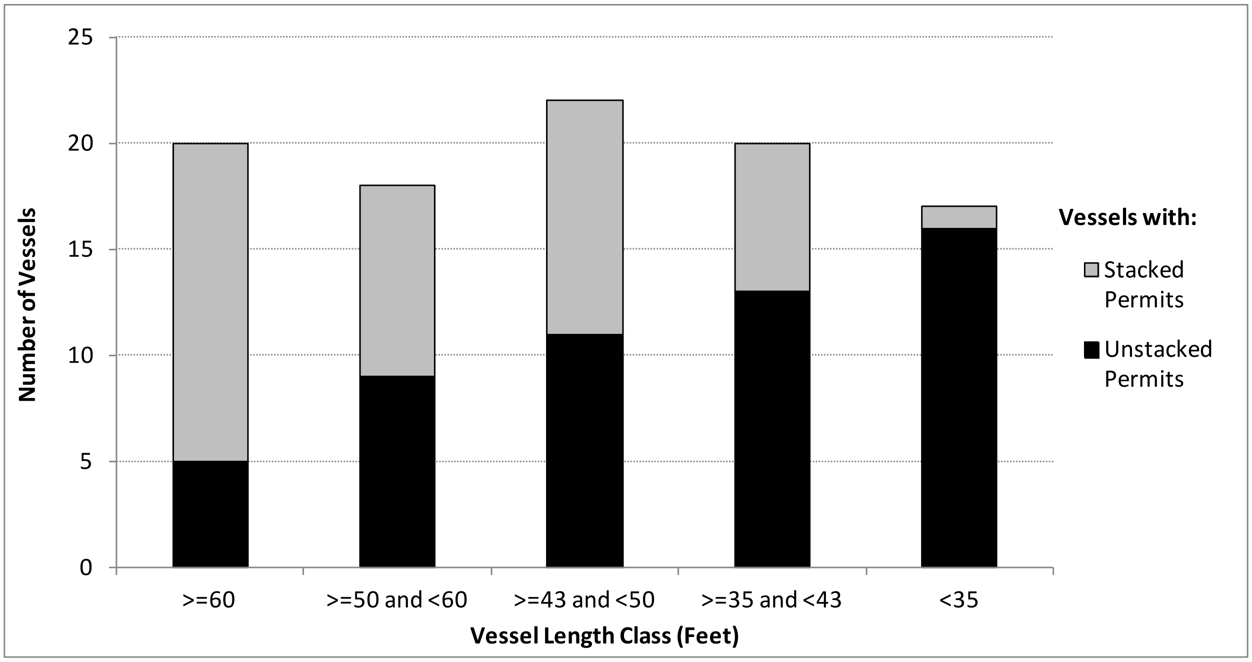

Figure 3-9. Number of LEFG sablefish vessels in 2012 with unstacked and stacked permits by vessel length class.

[Note: There were three permits with length endorsements of 64.1, 45.0 and 34.2 that were not associated with vessels on the reference date, 07-01-2012.]

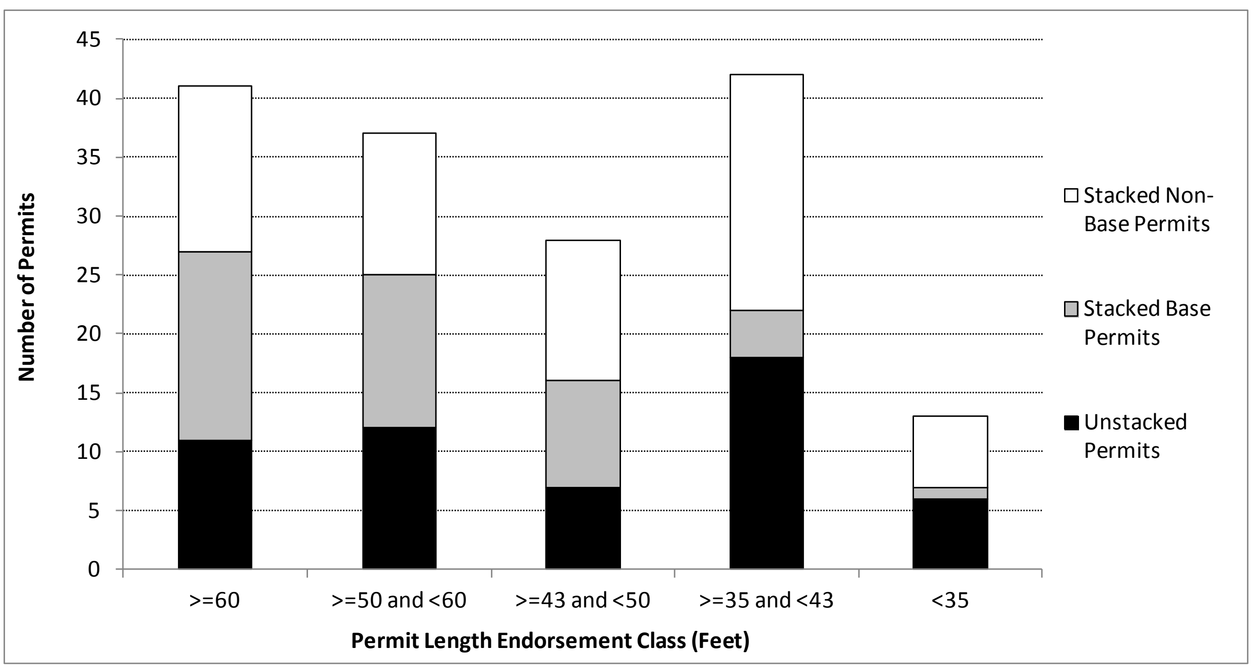

Figure 3-10. Number of LEFG sablefish permits in 2012 by permit length endorsement class and status (unstacked, stacked base, and stacked-non-base). See Note for Figure 3-9.

Comparing Figure 3-9 to Figure 3-10 shows permits are being used on vessels smaller than what is authorized by the length endorsements of the permits, indicating that the average size of vessels being used in the fleet has declined since the derby fishery, a possible source of increased efficiency. For example Figure 3-9 shows there are 20 vessels greater than 60 feet in length in the fishery while Figure 3-10 shows that permits with length endorsements greater than 60 feet are being used as the "primary" permit (i.e., the sum of the unstacked permits and the stacked base permits) on 27 vessels. When permits are stacked one permit is identified as the base permit ("Stacked base permits") and the vessel length must be of a size authorized by that permit's length endorsement. Similarly, there are 18 vessels between 50 and 60 feet in length (Figure 3-9) but there are 25 permits in that length endorsement class being used as primary permits (Figure 3-10), indicating that smaller vessels are being used than would be allowable based on the length endorsements of the associated permits authorizing those vessels' participation (i.e., the length endorsements on the unstacked or base permits). Continuing, there are 20 vessels between 35 and 43 feet in length but there are 22 permits in that length endorsement class being used as primary permits. Vessels in the 43-to-50 foot and less-than-35-foot categories appear to be absorbing the larger permits. For example, there are 22 vessels in the 43-to-50 foot size category, but only 16 such permits active as either unstacked or base permits, indicating there are vessels in this category that are using permits that authorize larger vessels. Similarly, there are 17 vessels in the less-than-35 foot size category, but only 7 such permits active as either unstacked or base permits.

Permit Prices. Information on sablefish permit prices proved to be too limited for use in determining any trends in the permit values over time. Table 3-6 shows recent offerings of tier permit prices from Dock Street Brokers website. This snapshot appears to show a preponderance of trading for Tier 3 permits (the lowest quota share level).

Table 3-6. Recent listings of West Coast longline sablefish-endorsed permits offered for sale on Dock Street Brokers (info@dockstreetbrokers.com).

Type of Permit	Asking Price	Updated	Notes
Tier 1	$825,000	11/26/2012	- pot endorsed
Tier 2		05/17/2013	- Call for Pricing
Tier 2		03/05/2014	- Will trade for northern sablefish trawl quota
Tier 3	$165,000	08/23/2013	- make offer
Tier 3	$197,000	10/15/2013	- Good to ~70' LOA
Tier 3	$155,000	03/10/2014	- SOLD
Tier 3	$140,000	02/21/2014	- Price Reduced** good to 51 feet
Tier 3	$208,000	01/25/2013	
Tier 3	$145,000	02/25/2014	- SOLD 3/10/2014
Tier 3	$170,000	04/02/2013	
Tier 3		05/17/2013	- Pot Endorsed Call for pricing
Tier 3	$13,000	04/14/2014	- Lease available for 2014 season

3.2 Maintain or Direct Benefits toward Fishing Communities

3.2.1 Background

This objective relates most directly to National Standard (NS) 8 and FMP Objective 16 (take socio-economic needs of fishing communities into account) [4]. Did the program provide for the sustained participation of fishing communities and, to the extent practicable, minimize adverse economic impacts on such communities?

To consider how well the sablefish program maintained or directed benefits toward fishing communities requires data on changes in the sablefish landings by West Coast port over the life of the program. Additionally, an owner-on-board requirement, intended, in part, to direct benefits toward local fishing communities, can be assessed by evaluating changes in the number of entities subject to the provision. The following information was considered or analyzed for this objective:

- Identification of the primary ports where sablefish landings (both primary season landings and landings made in the DTL fishery) are occurring;
- Calculation of a port involvement and dependence ratio; and
- Percent of landings by owner on board versus non-owner on board vessels.

3.2.2 Assessment

Port Involvement. Figure 3-11 displays the involvement of individual port groups in the LEFG sablefish fishery for even years from 1996 through 2012. Involvement is measured as the exvessel value of fixed gear sablefish landings in a port as a share of the total exvessel value of the entire West Coast fixed gear sablefish fishery. Figure 3-12 removes some of the complexity in viewing the pre- and post-program changes by using three-year averages to display the same data. The most significant shifts in involvement appear to be at the northern and southern extremities of the region, with Puget Sound becoming less involved in the fishery in more recent years (in terms of landings to the area) and Morro Bay having increasing involvement. The Brookings area also appears to show a trend toward increased involvement since implementation of the program in 2002. Port Orford is part of the Brookings area and has an active non-profit organization (Port Orford Ocean Resources Team) which seeks to enhance the small fixed gear fishery operating out of that port. The existence of the permit stacking program may have enhanced the ability of the community to influence the development of the fishery in the port and the community's economic future. However, for most ports, no consistent trend is obvious from these figures, and it is not possible to separate the effects of the program from the many other causes of variation in involvement by the port groups.

[4] Objective 17 at the time Amendment 14 was adopted.

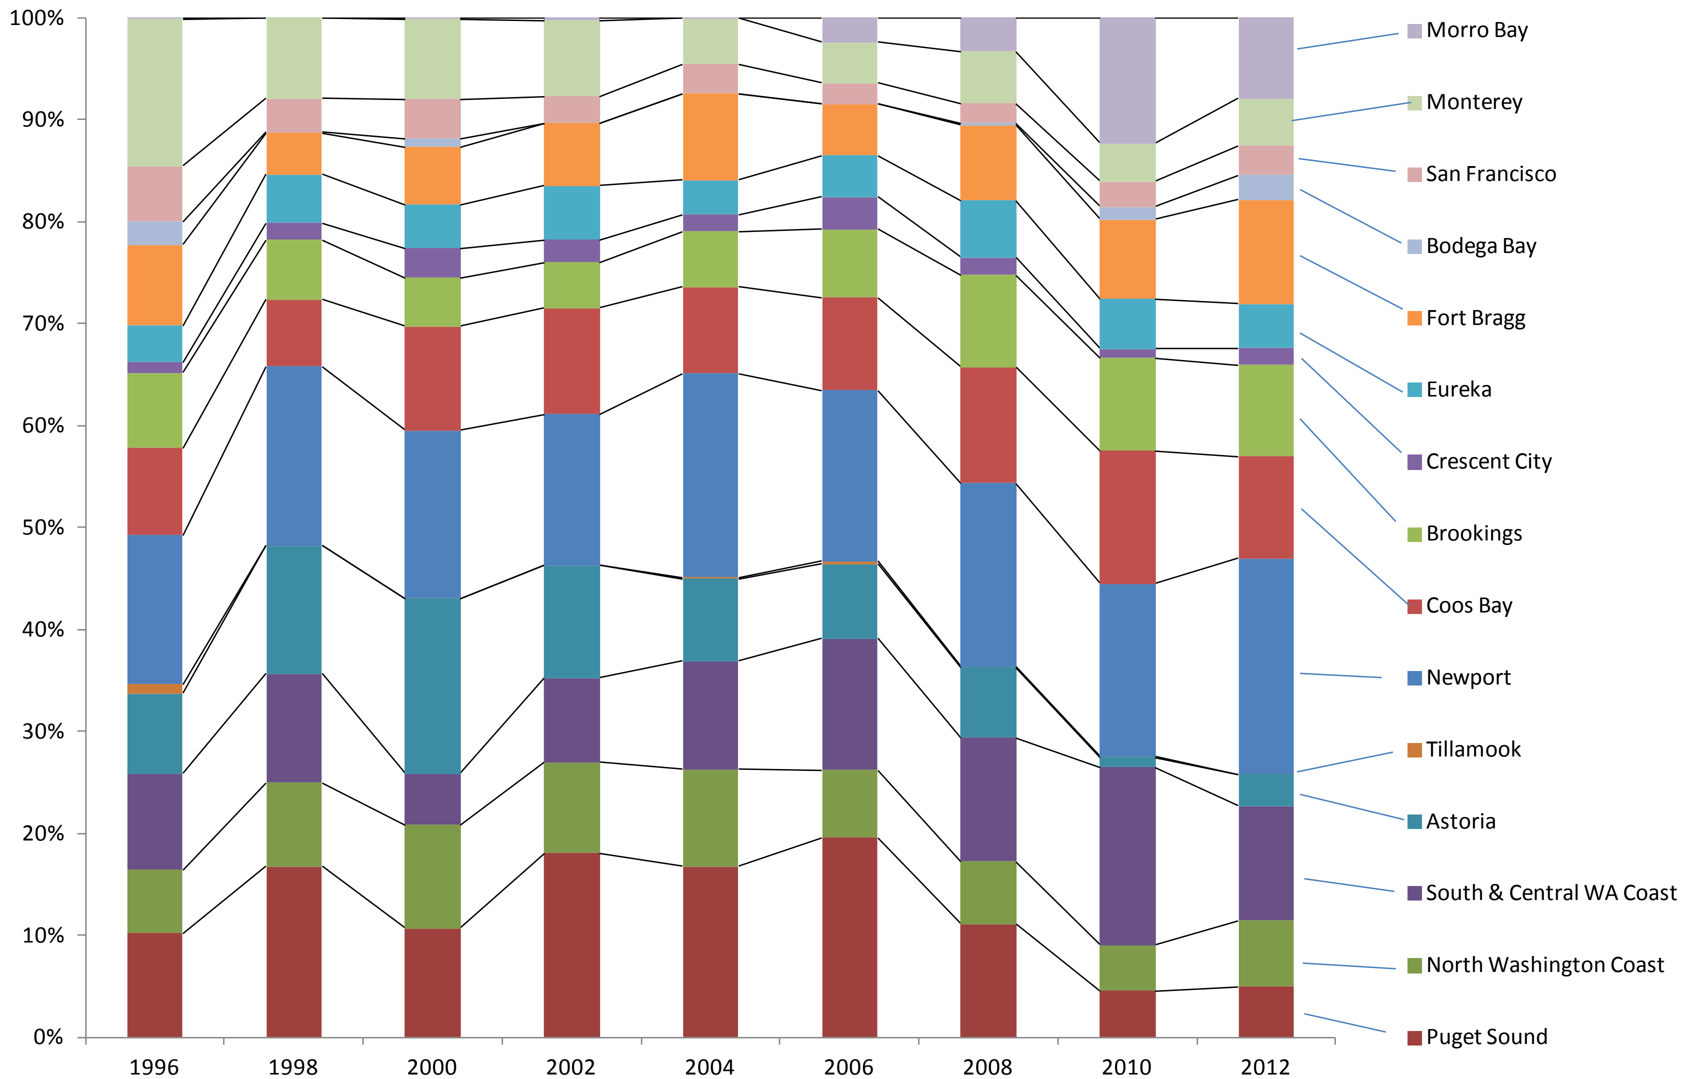

Figure 3-11. Involvement (percent of West Coast exvessel revenue) in the LEFG sablefish fishery by port group (data for even years 1996-2012).

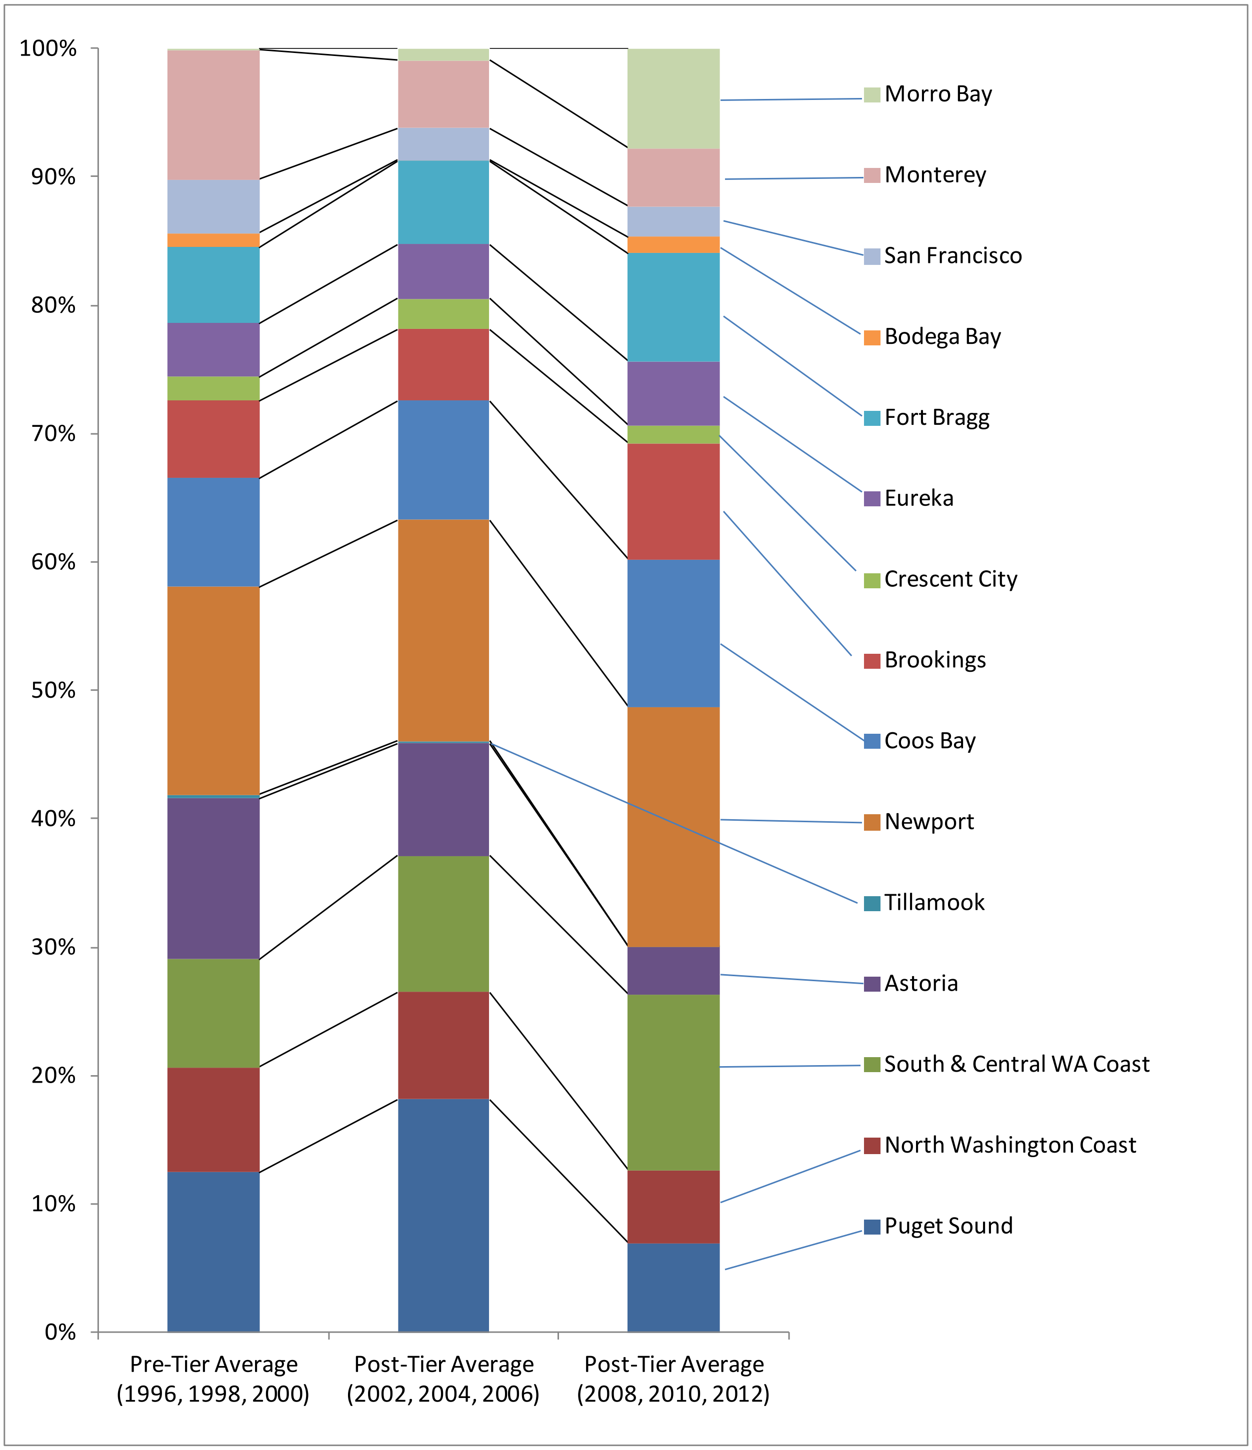

Figure 3-12. Involvement (percent of West Coast exvessel revenue) in the LEFG sablefish fishery by port group in terms of 3-year averages (data for even years 1996-2012).

Port Dependence. Figures 3-13 and 3-14 display the dependence of port groups on revenue from the LEFG sablefish fishery measured as a percent of each port's total landings revenue from all non-tribal fisheries. The pattern for most ports shows annual variation within a range that might be expected given changes in species availability, weather, market forces, and varying allocations. However, a huge spike in revenue dependence for Morro Bay in 2010 (Figure 3-13) may reflect the beginning of The Nature Conservancy exempted fishing permit program under which vessels with trawl permits were authorized to use fixed gear. Trawl landings in Morro Bay dropped to zero in that year, but reappeared in 2011 and 2012.

Another apparent deviation involves ports in Puget Sound which exhibited a significant drop in fixed gear sablefish landings and dependence since 2008 for reasons that are unclear (Figure 3-14). Perhaps there were changes in buying station operations, or vessels changing their main port of landing. ***The drafting team for this document solicits information on the reasons for this deviation*.**

Figure 3-15 displays port dependence in terms of employment (number of jobs). The figure compares the number of jobs provided by the LEFG sablefish fishery with employment generated by the total non-tribal groundfish fishery and the total port area labor force (based on the estimated number of jobs in 2014 (from IO-PAC analysis of the 2015-2016 groundfish management specifications process) and the total work force in 2012 (taken from U.S. Bureau of Labor Statistics county-level data). While the data displayed in Figure 3-15 indicate the sablefish fishery provides a relatively small number of jobs in comparison to the total non-tribal groundfish fishery and coastwide labor force, for a few ports it constitutes a significant proportion of the groundfish labor force, providing 20 percent or more of non-tribal groundfish fishery employment for the port areas of Puget Sound, North Washington Coast, Crescent City, Fort Bragg, Bodega Bay, Santa Barbara, and Los Angeles.

Figure 3-16 displays port dependence in terms of income (total salary and wages). Again these estimates are from IO-PAC analysis of the 2015-2016 groundfish management specifications and data from the U.S. Bureau of Labor Statistics. As would be expected, this data fairly closely mirrors the employment dependence results in Figure 3-15.

Landings Under the Owner-on-board (OOB) Exemption. Table 3-7 shows the distribution of vessels and landings (at 4-year intervals from 2000 to 2012) for vessels controlled by entities that were exempt from the OOB permit requirement. The table shows the number of vessels that participated in the primary fishery with OOB exemptions declined from 2000 to 2008 and remained relatively unchanged from 2008 to 2012. However, the share of total vessels with owners exempt from the OOB provision declined over the entire period and in each of the years displayed. The share of total primary fishery landings accounted for by these vessels also declined during that time, although not as precipitously as the share of total vessels.

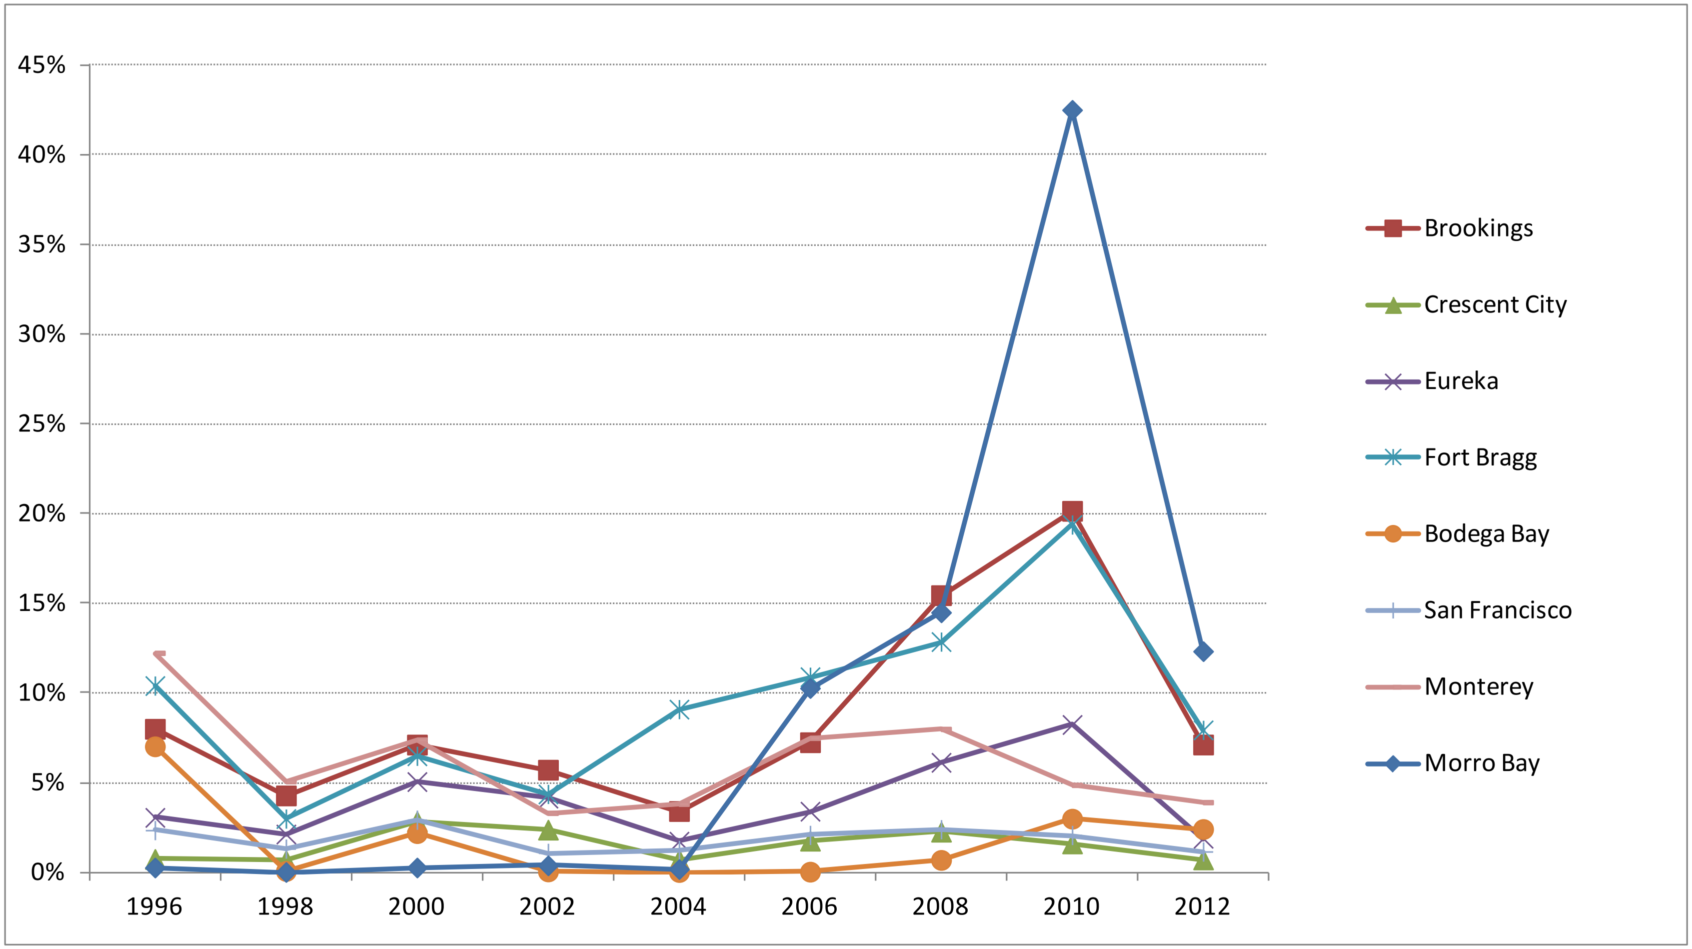

Figure 3-13. Dependence (percent of port total exvessel revenue) on LEFG sablefish landings by port group from Brookings, Oregon to Morro Bay, California (data for even years 1996-2012).

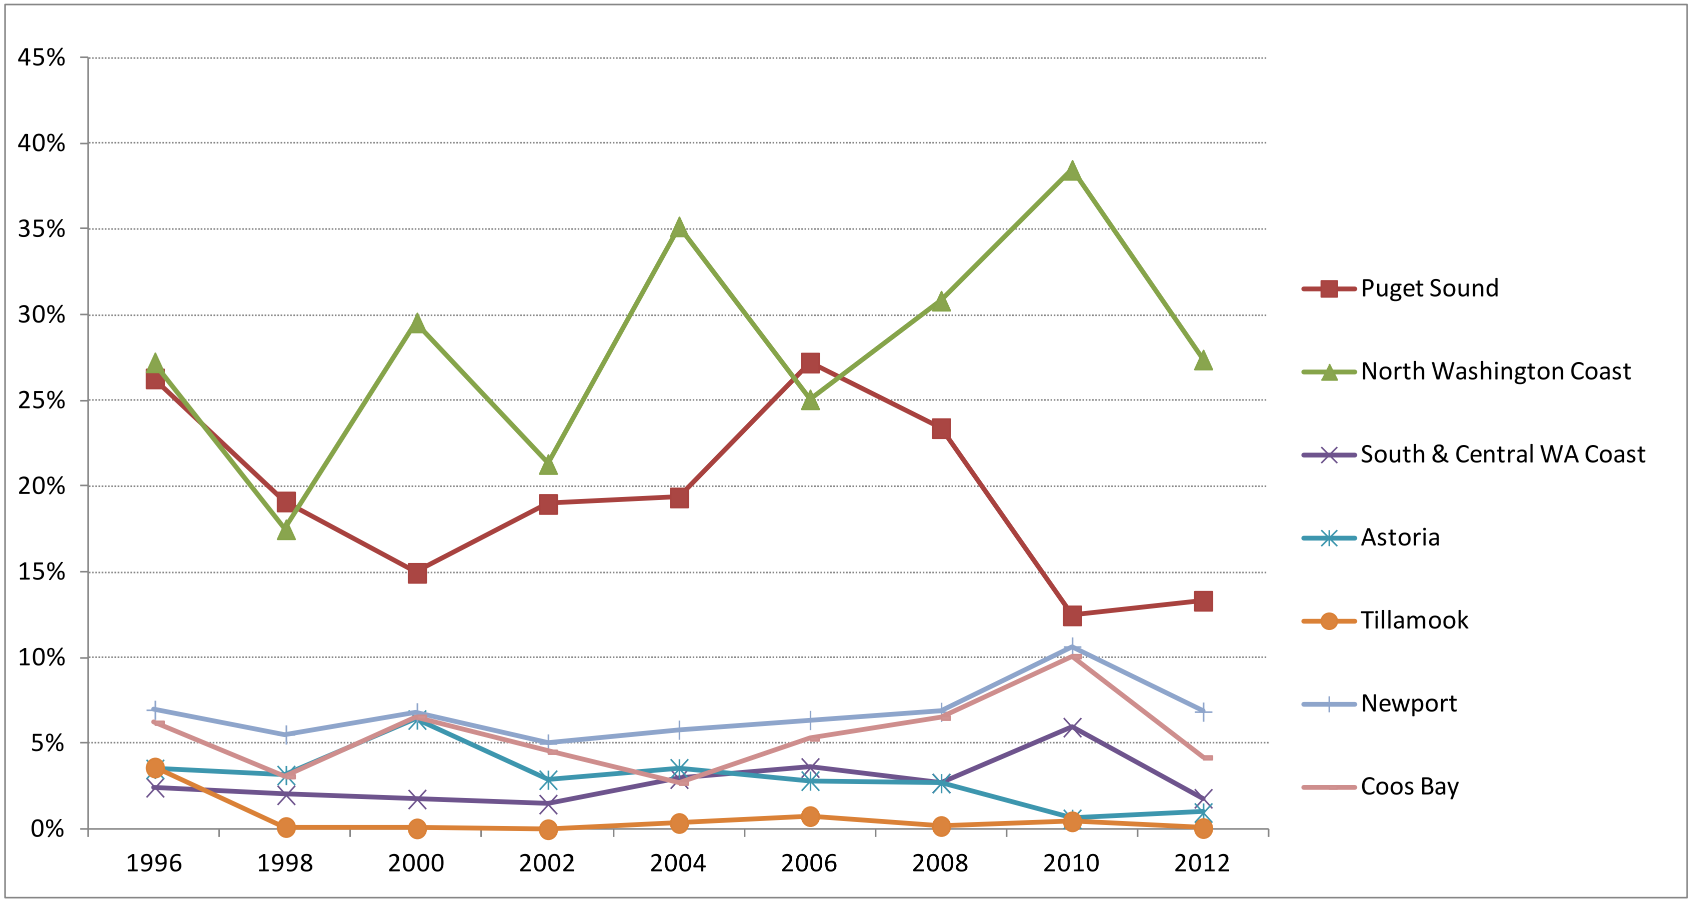

Figure 3-14. Dependence (percent or port total exvessel revenue) on LEFG sablefish landings by port group from the North Washington Coast to Coos Bay, Oregon (data for even years (1996-2012).

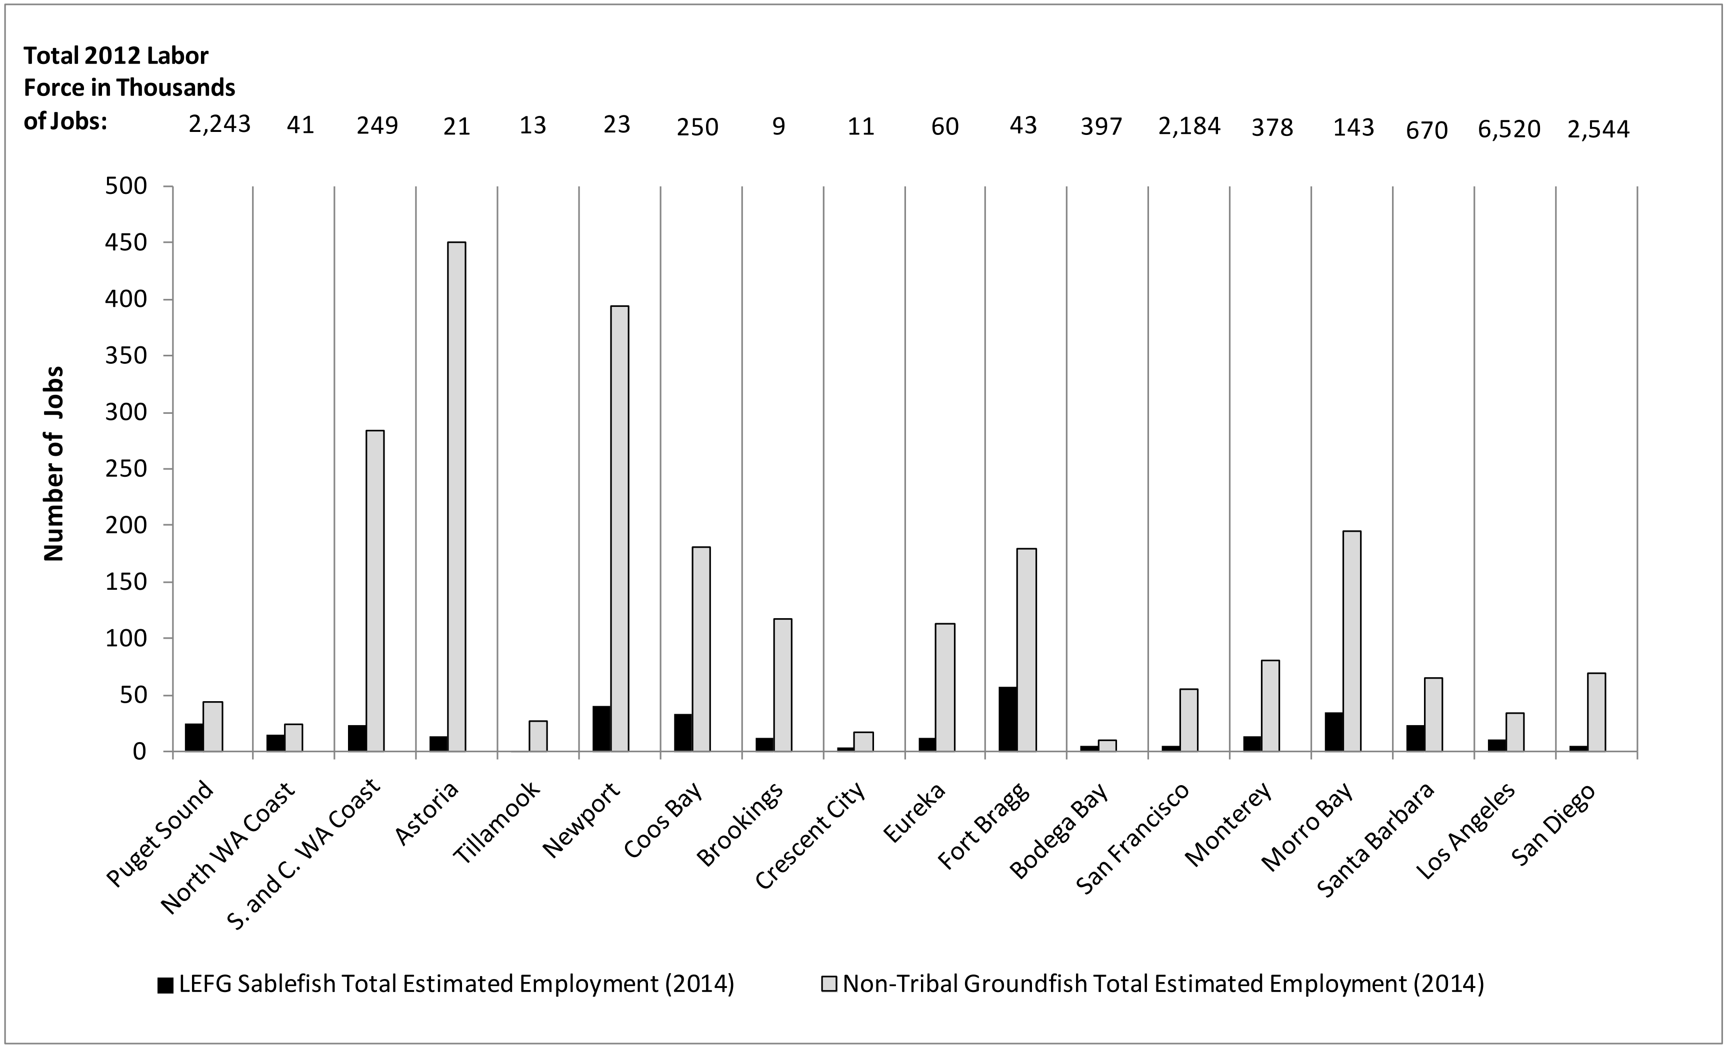

Figure 3-15. West Coast port dependence on the LEFG sablefish fishery in terms of employment (estimated number of jobs using 2014 data) in comparison to employment by the total non-tribal groundfish fishery (2014 data) and the total port-area labor force (2012 data).

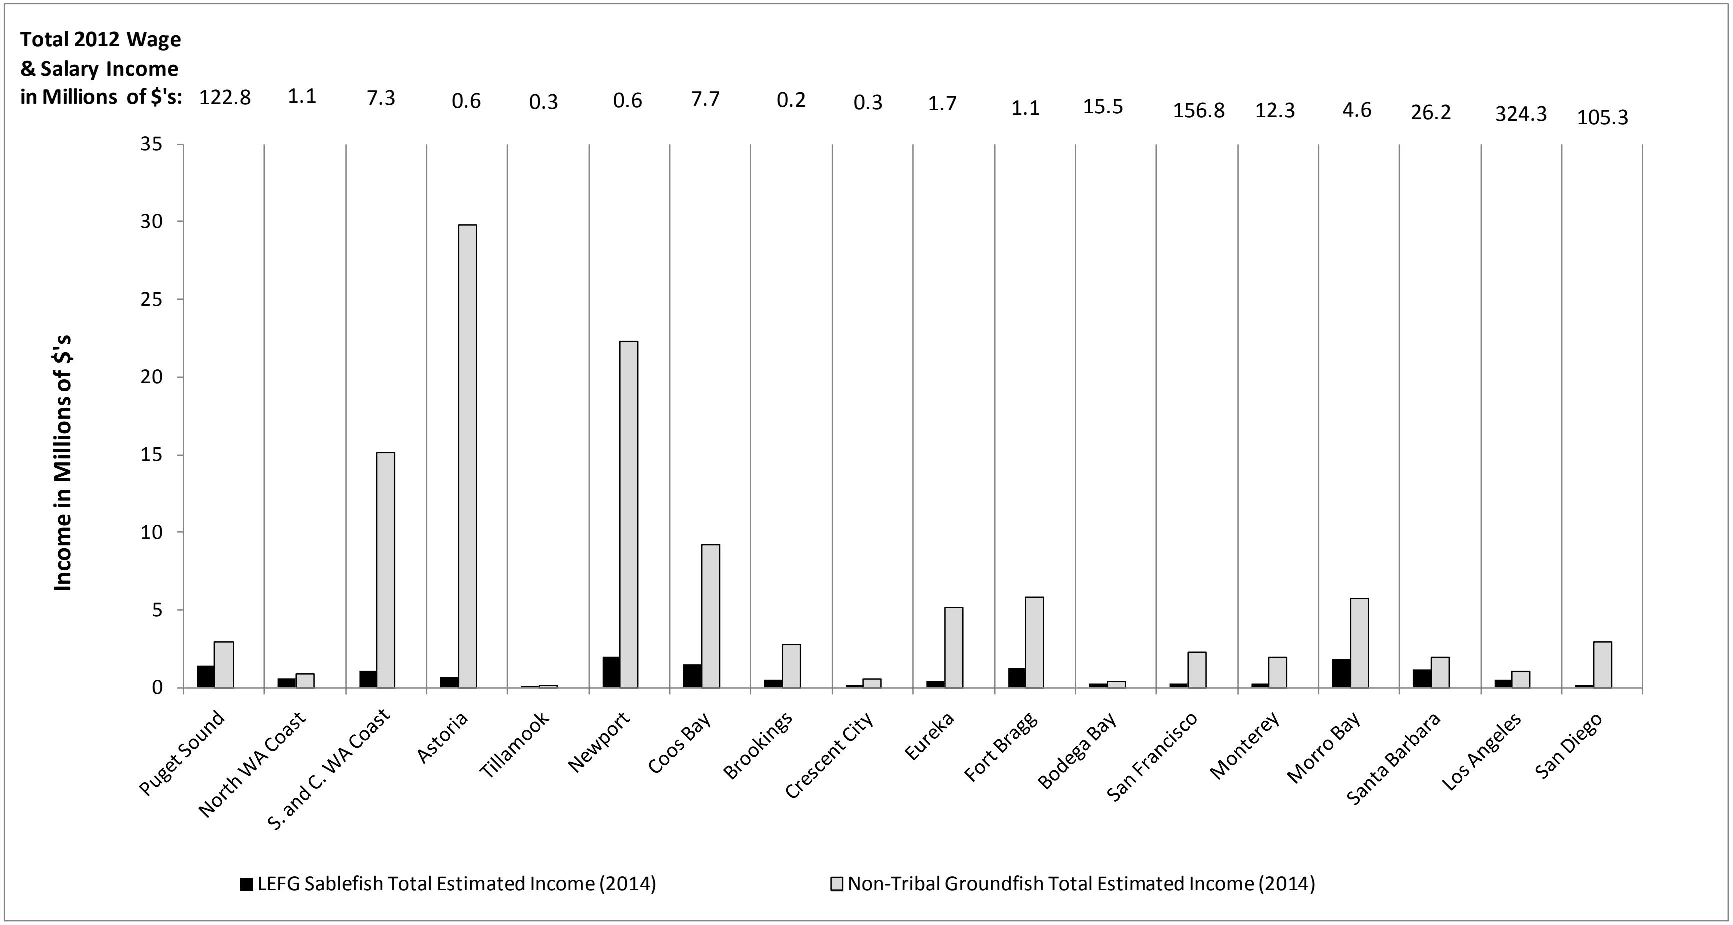

Figure 3-16. West Coast port dependence on the LEFG sablefish fishery in terms of income (wage and salary data for 2014) in comparison to income for the total non-tribal groundfish fishery (2014) and the total port area income (2012 data).

Table 3-7. Summary of landings in selected years by vessels participating in the primary sablefish fishery and operating under permits that were exempt from the owner-on-board requirements.

Year	Vessel Count	Share of Total Vessels	Landings (mt)	Share of Total Landings
2000	131	92.3%	1,160	65.7%
2004	72	78.3%	1,223	62.4%
2008	43	51.2%	687	46.1%
2012	44	45.4%	579	43.2%

3.3 Prevent Excessive Concentration of Harvest Privileges

3.3.1 Background

This objective relates to NS 4 on allocation and NS 8 and FMP Objective 16 on fishing communities. In the Council's effort to reduce capacity in the fishery, did they provide an environment for excessive concentration of the remaining harvest privileges among a few individuals or entities? Such concentration could lead to significant changes in the distribution of fishery benefits among participating communities.

3.3.2 Assessment

One source of insight into whether the sablefish program has prevented excessive concentration of harvest privileges is to examine if there is any apparent pattern to the changes in the ownership or control of permits and vessels in the fishery.

Figure 3-17 displays the Gini coefficients for permit and vessel ownership in the LEFG sablefish fishery for selected years prior to (1998 and 2000) and following (2002-2012) implementation of the permit stacking program. Gini coefficients are indicators of the deviation from an equal distribution. In this case, a Gini coefficient of zero would imply an equal distribution of the ownership of permits and vessels, while a value of 1 indicates that a single participant owns all of the permits or vessels. The range of Gini coefficient values in this case indicates very little change in the concentration of ownership and control of the LEFG sablefish vessels and permits following implementation of the permit stacking program. Comparing the averages of Gini coefficient values for the 2 years prior to the program with the averages of the 4 years post-program indicates increases of less than 5 percent and 10 percent in permit ownership and vessel ownership concentrations, respectively.

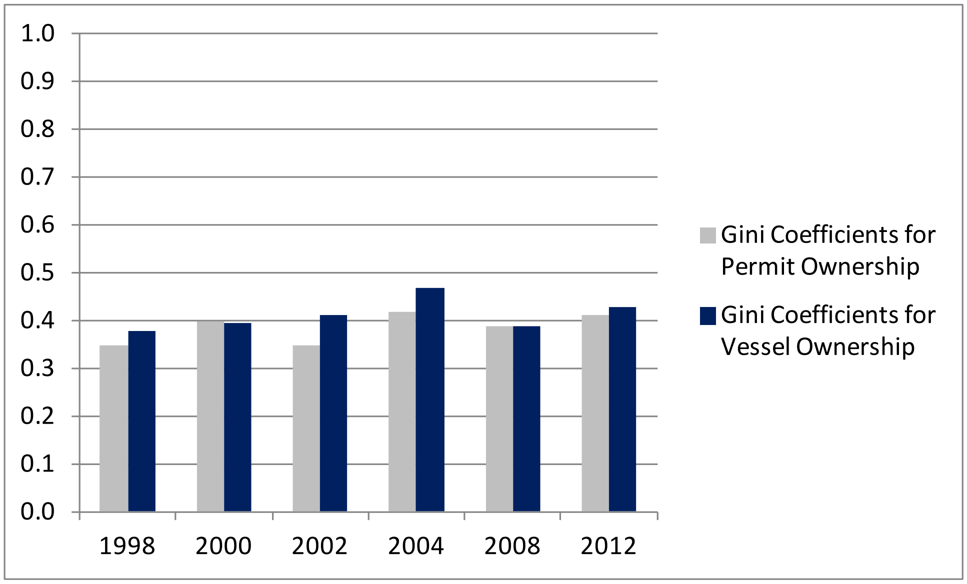

Figure 3-17. Gini coefficients for the concentration of landings in the LEFG primary sablefish fishery by permit and vessel owning entities for selected years before and after implementation of the permit stacking program in 2002.

[Note: A Gini coefficient of 0 implies a perfectly even distribution among all participants, while a coefficient of 1 indicates one owner landed all of the fish.]

3.4 Mitigate the Reallocational Effects of Policies just prior to this Program (e.g., the Three Tier System and Equal Limits)

3.4.1 Background

This very specific objective can really be categorized as a subset of the broader objective of promoting overall equity which is covered in Section 3.5. Both objectives relate to National Standard 4 on allocation, FMP Objective 12 on equitable allocation, and FMP Objective 14 on minimizing disruption.

The regulatory regime prior to Amendment 14 had included a series of partial and short-term policies and actions in an attempt to end the derby fishery during a time when new IQ programs were prohibited by Congress (Table 3-1). In 1997, the regulations substantially flattened the distribution of harvest among vessels in the fleet by giving equal cumulative limits to fishery participants who qualified for LEFG sablefish endorsements. These limits were substantially higher than the maximum landings ever made by many of the lower-level participants and substantially lower than historic landings of the high-liners. The flattening effect of the equal limits in 1997 can be seen by comparing the shapes of the annual lines in Figure 3-7.

3.4.2 Assessment

To assess how well the sablefish program mitigated the effects of the temporary policies used to modify the derby fishery requires comparing the vessel harvests prior to the 1997 equal cumulative limit management regime with harvests following full implementation of the stacking program. The first step toward restoring the prior distribution was the implementation of tiered cumulative limits in 1998. Each sablefish-endorsed permit was assigned to one of three tiers based on its landing history. Tier 1 permits received cumulative limits 3.85 times that of Tier 3 permits, and Tier 2 permits received cumulative limits 1.75 times that of Tier 3 permits. The lines for 1998 and 2000 shown in Figure 3-7 are fairly close together and illustrate some movement away from the 1997 equal cumulative limits line and convergence toward the harvest distributions that occurred during the 1996 derby fishery. Landings during the derby year reflect a typical distribution that occurs when all vessels are on an equal footing with respect to speed of harvest. The final step in mitigating the reallocation effects was implementation of the permit stacking program in August 2001 with its allowance for up to three tier-endorsed permits and their associated tier limits to be stacked on a single vessel. The effectiveness of this policy is illustrated in Figure 3-7 by the trend of the annual vessel harvest distribution lines for the years following program implementation to converge ever closer to the 1996 line. In general, under the derby system, vessels competed on the basis of how quickly and effectively they could fish. The tier system replaced speed of harvest with other economic factors in determining the competitive outcome, resulting in a somewhat similar distribution of harvest concentration.

3.5 Promote Equity

3.5.1 Background

Promoting equity is an overarching objective that includes the objective of the previous section (3.4). Both objectives relate to NS 4 on allocation, FMP Objective 12 on equitable allocation, and FMP Objective 14 on minimizing disruption. The issue of compliance (with the regulations) also bears heavily on this objective. If some fishermen are not complying with the program, they are often viewed as gaining an unfair advantage over other fishermen.

3.5.2 Assessment

Much of this objective was addressed through the re-establishment under permit stacking of the opportunity to achieve a distribution of harvest among vessels similar to the distributions prior to imposition of equal cumulative limits in 1997, and similar to what is seen in many other fisheries (Figure 3-7).

Regarding compliance with regulations, data on the number of permits that were estimated to have had sablefish landings exceeding the permit limit from 2008 through 2013 are shown in Table 3-8. For all tiers taken together, the number of permits fished between 2008 and 2012 ranged from a high of 162 in 2011 down to a low of 158 in 2012[5]. During that time, the number of permits estimated to have landings exceeding their permit limits ranged from a low of 25 in 2012 to a high of 41 in 2009; or a range of 16 percent to 25 percent of total permits in the fishery. A cursory review of data for individual permits did not indicate that it was the same permits that were consistently over (or under) their limits. Also, the amount (percentage) of the overage has generally been quite small over that range of years, as shown in Figure 3-18. These data would tend to support the conclusion that noncompliance is not a significant equity issue for the fishery, and has also not been a significant target of industry comments to the Council. Table 3-8 also shows the percent of pounds landed short of the permit quotas (i.e., the underage) . It is noteworthy that in each year shown in the table the total underage is significantly larger than the total overage, thus resulting in consistent under-harvest of the total allowable quotas in each year of the period (Figures 3-4 and 3-5).

3.6 Resolve or Prevent New Allocation Issues from Arising

3.6.1 Background

This objective relates to NS 4 on allocation and FMP Objectives 12 on equitable sharing and 14 on minimizing disruption.

3.6.2 Assessment

Since implementation of the permit stacking program in 2002, there have been few calls for any changes to the allocations within the fixed gear sector. Most discussion and concern has been with intersector allocations. However, while there was some brief discussion of the intersector sablefish allocation during the Council's formal consideration of its groundfish allocations for Amendment 21, it was decided that, relative to other workload concerns at that time, there was not a sufficient need to reconsider intersector allocations of sablefish.

Within the LEFG sector, 15 percent of the sablefish is set aside for a DTL fishery. There has been some suggestion that this allocation and its management might be revisited, but up until the time this program review was initiated, the interest in modifications has not been sufficient to bring the topic onto the Council agenda.

---

[5] The year 2013 was excluded from this comparison since the fishery in that year was not complete at the time of the data query and consequently may be artificially low.

Table 3-8. Comparison of tier quotas to landings in the LEFG primary sablefish fishery, 2008-2013.

				Overage				Underage			
Tier	Number of Permits Fished	Total Tier Quota (lbs)	Tier Limits (lbs)	Percent of Pounds Landed over the Tier Quota	Number of Permits Over	Maximum Overage (lbs)	Avgerage Overage (lbs)	Percent of Pounds Landed under the Tier Quota	Number of Permits Under	Maximum Underage (lbs)	Avgerage Underage (lbs)

a/ On the query date (11/04/2013), data were 90 percent complete in PacFIN--through: August for Washington Department of Fish and Wildlife, September for Oregon Department of Fish and Wildlife, and July for California Department of Fish and Wildlife data.

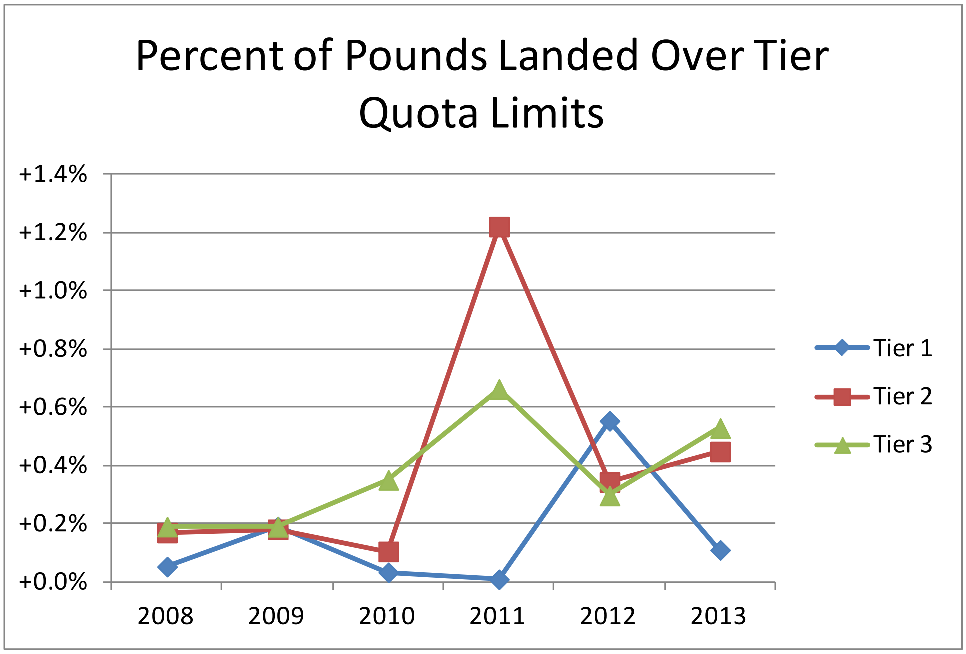

Figure 3-18. Total overage for all vessels with overages as a percent of pounds allocated by tier limit category for 2008-2013. Data for 2013 is incomplete.

3.7 Promote Safety

3.7.1 Background

This objective relates to NS 10 and FMP Objective 17 on safety. Before Amendment 14 was implemented, the LEFG sablefish fishery had become a classic derby fishery, lasting only 5 days in 1996. Such classic derby fisheries are well-known for creating safety hazards. The short seasons provide a strong incentive to fish regardless of the weather in order to get an adequate share of the catch and also encourage taking risks with overloading the capacity of the vessel or to skip important maintenance at inopportune times (National Resarch Council, Marine Board, Committee on Fishing Vessel Safety, 1991).

3.7.2 Assessment

The elimination of the derby fishery through the extension of the season to seven months could be expected to have a positive effect on reducing the pressure to fish under unsafe conditions. Support for this assumption could be inferred from the fact that following implementation of Amendment 14, there has been an absence of anecdotal reports on safety problems associated with the primary fishery, particularly in comparison to the volume of concerns expressed during the derby fisheries of the mid-1990s. However, explicit information on significant safety incidents that might be useful in evaluating the safety record of the fleet before and after implementation of the fixed gear permit stacking program is not readily available.

While the United States Coast Guard (USCG) keeps safety incident statistics, it is only possible to isolate those statistics by date, geographic area, and broad fishery categories (e.g., groundfish, salmon, etc.). Available data bases of past incidents do not provide direct information on the fishery in which a vessel involved in an incident was participating (particularly when events prevented a vessel from making a landing). However, the incident report required (of the vessel operator and any insurance company) in current Federal law (Title 46 Part 28.80) now includes information on the specific fishery, intended catch, and length of fishery opening. This may help to make more fishery-specific data available in the future.

Table A.3 in the Council's Fishery Ecosystem Initiatives Appendix to the Pacific Coast Ecosystem Fishery Plan (PFMC, 2013) uses USCG vessel incident data to display recorded vessel incidents by FMP (e.g., groundfish, salmon, etc). However, the data do not identify the specific season or fishery in which the incidents occurred. The available data primarily cover a time period after implementation of the permit stacking program.

The Northwest Fisheries Science Center is currently conducting an assessment that examines fishery and permit data, available incident report data from the USCG, and certain weather information in an attempt to provide more specific insights into the safety effects of the LEFG sablefish permit stacking program within the primary sablefish fishery. The preliminary results of the assessment have been made available as a working paper (Pfeiffer & Gratz, 2014) with the intent of issuing the final report as a NMFS technical publication. The authors used USCG incident databases filtered by location, timing, and vessel and permit information to try to isolate reported incidents which are likely to have occurred during the primary sablefish fishery from 1994 through 2012 (Figure 3-19). While the number of incidents appears to have generally declined after the permit stacking program, the number of reported incidents is small (four or fewer per year) and, as such, random events may appear significant. Figure 3-20, also from the working paper, shows that the proportion of trip starts under high wind advisories appears to have declined and remained consistently smaller than during the pre-program period.

Figure 3-20 also shows that the proportion of trip starts under high wind advisories in the mop-up fishery was lower than it was for the initial short (derby) seasons in years prior to the program.[6] The results of the assessment would seem to help confirm an improvement in safety following initiation of the permit stacking program. The report authors hope to continue working to discern the safety effects from various other factors that would influence these statistics, such as vessel size, expected costs and revenues, and alternative fishery opportunities.

[6] Mop-up fisheries provided IQ to the permit holders and thus were similar to the current permit stacking program.

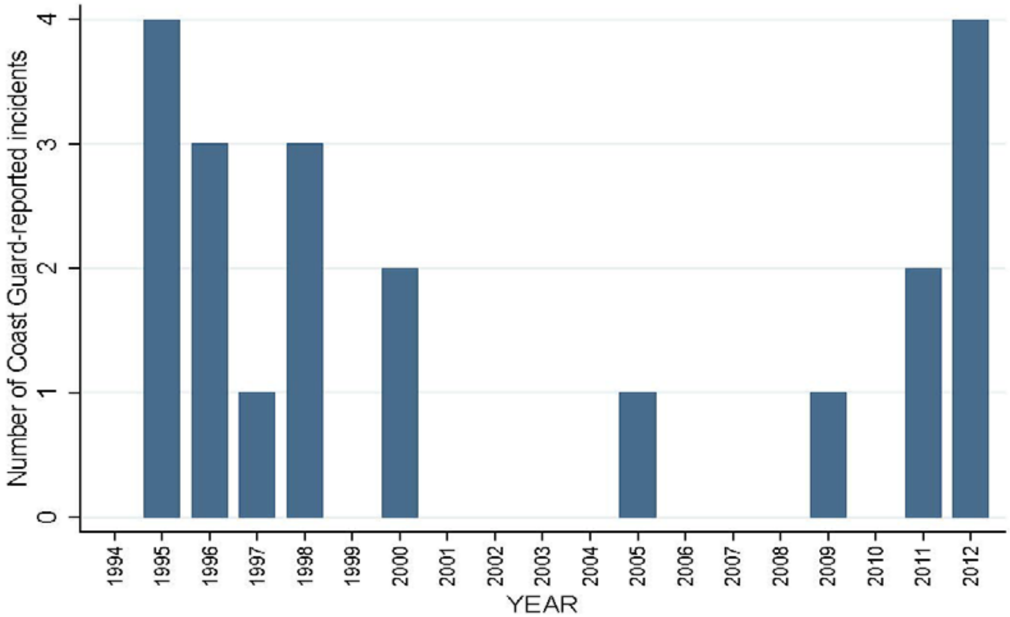

Figure 3-19. Number of USCG-reported incidents in the LEFG primary sablefish fishery (from Pfeiffer and Gratz, 2014).

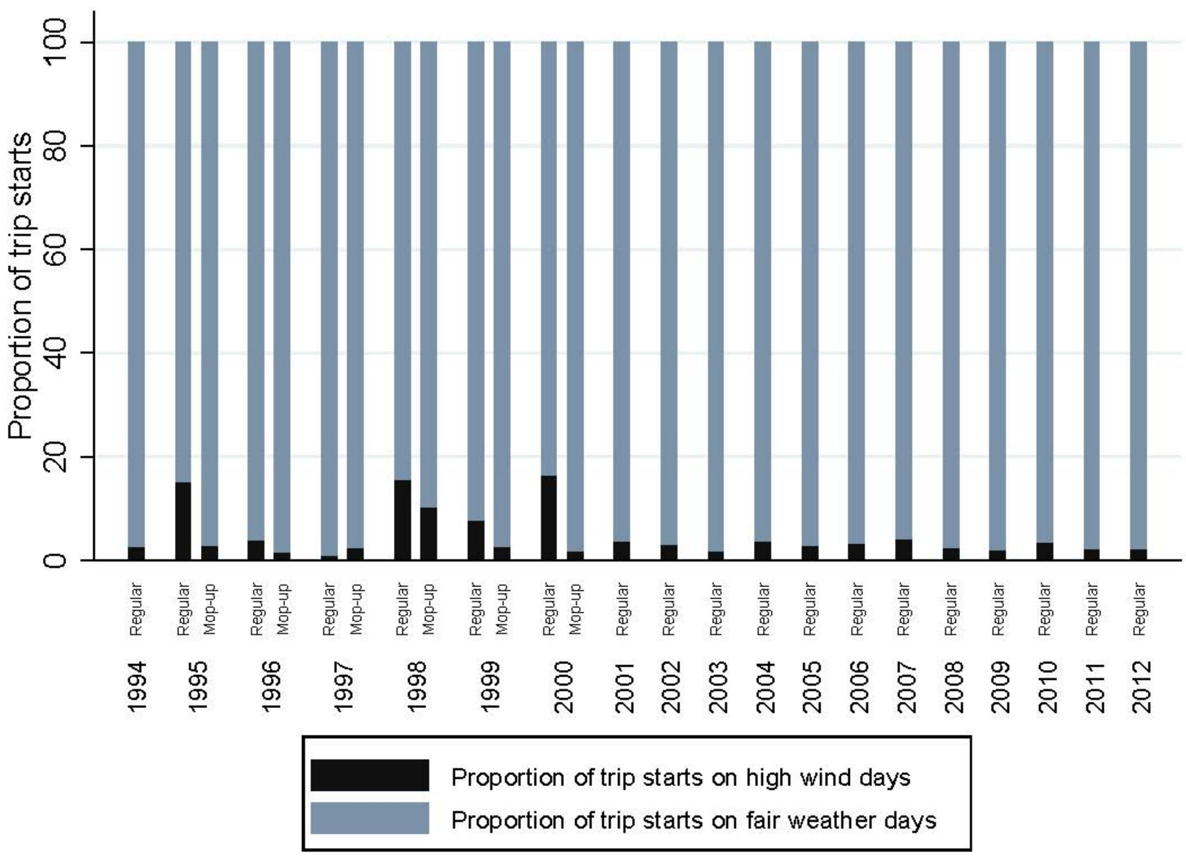

Figure 3-20. Proportion of trip starts on high wind days and fair weather days (from Pfeiffer and Gratz, 2014).

3.8 Improve Product Quality and Value

3.8.1 Background

This objective relates to NS 5 on efficiency and FMP Objective 6 on net national benefits. Determining achievement of this objective could be reflected by changes in the sales price and volume of sablefish after implementation of Amendment 14. However, changes in exvessel price (the most readily-available data) are strongly driven by market conditions which might overshadow any effects resulting from a change in product quality. For example, sales volumes and prices for some species have been influenced by shifts in fuel prices which affect transportation costs, and also by the recent worldwide recession because species like sablefish are essentially luxury goods. An analysis of the difference between exvessel prices for fixed-gear-caught and trawl-caught sablefish during the derby years, compared with the price differential between these gears after implementation of the permit stacking program could provide some limited insight. A widening gap might indicate an improvement in the quality of fixed gear-caught sablefish. Larger fish generally bring higher prices and might be considered a higher quality. Size of fish landed may also be increased by gear selectivity or high-grading, which the longer season may facilitate. However, unfortunately, there is no consistent and reliable fish ticket information on the size of fish landed.

3.8.2 Assessment

Figure 3-21 displays average annual exvessel sablefish prices (revenue per round weight pound) by gear type in inflation-adjusted 2013 dollars. The longline and pot gear prices are heavily weighted by, but not exclusive to, landings in the LEFG primary sablefish fishery. Relative to trawl landings, the size of the price differential for longline and pot gear landings does not seem to show any significant change after the permit stacking program was initiated and, as stated above, is likely to be influenced by market conditions and other factors to a greater extent than by events in the West Coast sablefish fishery. There may be some stabilization of the price differential between gear types following the implementation of the permit stacking program in 2002 through 2010 (Figure 3-22). This stabilization may reflect harvesters' increased ability to tailor deliveries to meet market demand and thereby garner better prices, rather than being solely at the mercy of whatever prices prevailing market conditions happened to present during the relatively short seasons prior to 2002. Between 2009 and 2011, exvessel prices for all three gear types showed a rapid upward trend to reach their highest levels in inflation-adjusted terms since the beginning of the time series, before falling in 2012 (Figure 3-21). Figure 3-22 also shows a dramatic departure since 2010 in the price differential for longline gear-caught sablefish compared to the price differential earned for pot-gear landings. ***At this time the drafting team does not have an explanation of the reasons for the recent price trends.***

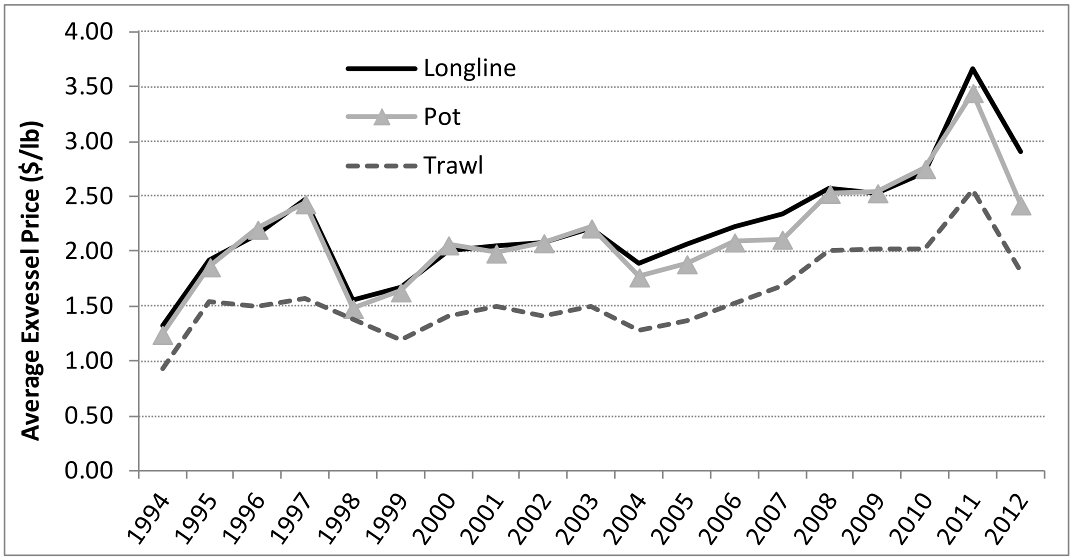

Figure 3-21. Average annual exvessel sablefish prices by gear type in inflation-adjusted 2013 dollars per pound (1994-2012).

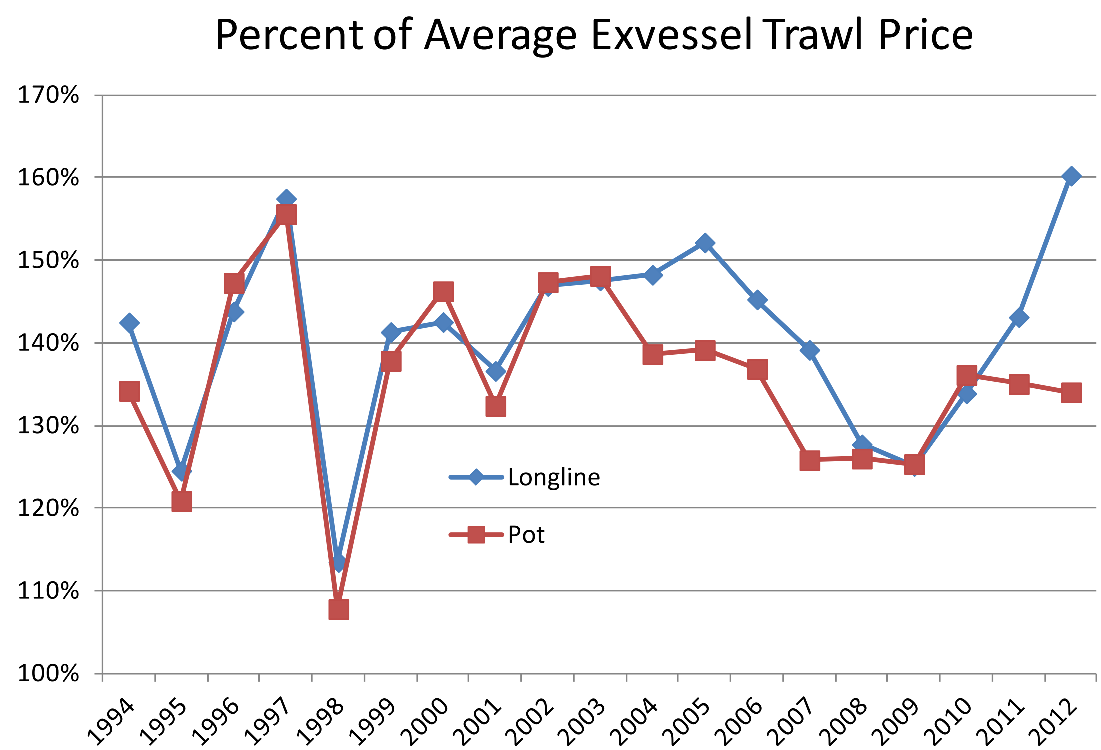

Figure 3-22. Average annual exvessel prices received for sablefish caught by longline and pot gear expressed as a percent of prices received for trawl-caught sablefish: 1994-2012 (inflation-adjusted 2013 dollars per pound).

3.9 Avoid Creating Substantial New Disruptive Effects

3.9.1 Background

This objective relates to FMP Objective 15 that directs the Council when considering alternative management measures to choose the measure that best accomplishes the change with the least disruption of current domestic fishing practices, marketing procedures, and environment. The Council moved toward the permit stacking program because the existing derby fishery and initial limited steps available to deal with it were a significant cause of disruption to the historical fishery.

3.9.2 Assessment

The derby fishery and equal cumulative limit management system that the permit stacking program replaced were extremely disruptive. The Council and industry were mostly in accord with moving to the permit stacking program. When the new program was proposed for implementation, only seven entities provided formal comments on the proposed rule (two state agencies, one commercial organization, and four individuals). Public comment generally included overall positive comments about the program. Dissent generally concerned specific issues relating to a few individuals (e.g., permit allocation, ownership or control, and owner-on-board requirements). The comments were generally split between support or opposition to the owner-on-board requirement, the limit on the number of permits that could be stacked, and the restrictions on processing at sea.

Not only did the permit stacking program avoid new disruption, it replaced the ongoing disruption of a derby fishery and equal cumulative limits with a much more efficient program that was more compatible with the existing fishing industry stakeholders. The objective was achieved with program implementation that allowed for a longer, more reasonable fishing season, and by allowing fishermen to acquire and stack permits rather than directly changing the allocation among permits. Given that permit caps (tier limits) were already in place, the creation of a longer season allowed participants to have more flexibility in when they went fishing. At the same time, the allowance for tiers based on fishing history and the capability to stack permits limited disruption of former practices and provided sufficient flexibility to meet the different and changing needs among the fishermen. In the 12 years the program has operated, the Council has received little, if any, complaint about disruption caused by the program.

3.10 Create a Program that Will Readily Transition to a Multi-month IQ Program

3.10.1 Background

The type of program created for the sablefish fishery assists in attaining capacity reduction recommendations in the Groundfish Strategic Plan and responds to NS 6 (take into account variations and contingencies). Individual harvest quotas that are transferable provide the fleet with substantial flexibility to respond to changing conditions in the fishery or to changes faced by individual fishermen. The properties of transferability and divisibility also address NS 5 (efficiency) and FMP Objective 6 (achieving the best possible net economic benefit).

3.10.2 Assessment

At the time it was implemented, the permit stacking program transitioned to a multi-month catch share program with a season that is seven months long. To date, there have been no moves to consider allowing the sablefish tiers to be separated from permits or divided into smaller units, such that the permit stacking program would resemble a more typical IFQ program. While such divisibility could be added to the program, this might diminish achievement of other standards and objectives. Net effects would have to be assessed during consideration of such a change.

While there have been no Council actions or discussions regarding a transition to a more typical IFQ program, the objective of Amendment 14 was to create a program that could readily make such a transition, not necessarily to make the transition. The existence of an already-implemented allocation among permits addresses one of the major challenges for new catch share programs (the initial allocation). On that basis, this objective might be considered to have been met.

3.11 Management Costs and Cost Recovery

The MSA requires LAPPs to develop a methodology and means to identify and assess cost of management, data collection and analysis, and enforcement programs that are directly related to and in support of the LAPP. Further, the Secretary of Commerce is authorized to establish and collect fees paid by holders of limited access privileges that will cover the costs of management, data collection and analysis, and enforcement activities; not to exceed 3 percent of the ex-vessel value of the fish harvested under the program. The LEFG sablefish program was established prior to the addition of these requirements in the MSA and, to this point, a means to identify costs or policies to establish a cost recovery program have not been developed.

Prior to the program review, incremental costs associated with this LAPP were likely minimal, although at this time no quantitative assessment of incremental costs has been done. However, certain actions being considered during this review process would implement an electronic fish ticket and modify the control rules. Also, the Council has taken action to allow trawl and LEFG-endorsed permits to be registered to the same vessel at the same time. These actions may introduce additional incremental administrative costs. For example, implementation of modified control rules could require collection of additional information on the vessel ownership interest form (or a new form), as well as new database programming requirements that would take time and would require additional funding to implement. These are examples of additional incremental costs that could be tracked and partially recovered through implementation of a cost recovery program for the LAPP.

4.0 RESEARCH NEEDS

At the Council's April 2014 meeting, the SSC recommended the following future research to add further insight into the LEFG sablefish tier permit fishery.

1. Routine collection of permit sale prices to indicate the market value of the fishery.

2. Collect information about crew, captains, and owners of vessels. Information about the county of residence and participation in the fishery is necessary to understand the regional economic impacts of the fishery (for models such as IO-PAC), and to estimate the number of people who directly work in the fishery. This information will also assist in an evaluation of the community effect of the owner-on-board requirement.

5.0 PRELIMINARY CONCLUSIONS AND QUESTIONS

5.1 Preliminary Conclusions

Overall, this review supports the conclusion that the LEFG sablefish permit stacking program, adopted under Groundfish FMP Amendment 14, has been mostly successful in achieving a significant majority of the goals and objectives intended by the Council. The work group drafting this review believes that sufficient information and data are available to classify eight of the Council's ten objectives as significantly achieved. Two objectives could not be adequately assessed to sufficiently indicate a probable result. However, existing data and anecdotal information suggests that the Council's actions were at least neutral in regard to these two objectives. Table 5-1 summarizes the work group's conclusions.

Table 5-1. Preliminary conclusions of the work group on the success of the Council's LEFG sablefish permit stacking program.

Objective	Assessment Summary and Preliminary Conclusions
1. Rationalize Fleet and Promote Efficiency (Significantly Achieved)	• Significantly lengthened seasons and ended derby fishery (Table 3-1 and Figure 3-1). • Reduced number of participating vessels (Figure 3-2) while: ◦ Improving the ability of the fleet to achieve, without exceeding, the overall harvest allocation (Figures 3-4 and 3-5); ◦ Allowing appropriate flexibility in how permits are stacked and fished (Tables 3-2 through 3-4); and ◦ Allowing a similar concentration of landings as the original fishery (Figures 3-6, 3-7, and 3-8).
2. Maintain or Direct Benefits toward Fishing Communities (Limited Assessment; Likely Neutral Effect)	• Appears to be a possible decrease in involvement of Puget Sound in recent years and an increase in Brookings and Morro Bay. Landings data are extremely variable and program effects cannot be clearly separated from other sources of variation (Figures 3-11 through 3-14).

Objective	Assessment Summary and Preliminary Conclusions
3. Prevent Excessive Concentration of Harvest Privileges (Significantly Achieved)	• Gini coefficients indicate little change in the concentration of permit and vessel ownership after implementation of the permit stacking program. Comparing the averages of the years prior to the program with the averages of the years post-program indicates increases of less than 5 percent and 10 percent in permit and vessel ownership concentrations, respectively (Figure 3-17).
4. Mitigate the Reallocational Effects of Policies just prior to this Program (Significantly Achieved)	• Maintained a similar concentration of landings as the original fishery (Figures 3-7 and 3-8).
5. Promote Equity (Significantly Achieved)	•Maintained a similar concentration of landings as the original fishery (Figures 3-7 and 3-8). • Estimates of landings exceeding tier quota limits are very small and there does not appear to be a consistent pattern of offending permits over time (Figure 3-18 and Table 3-8).
6. Resolve or Prevent New Allocation Issues from Arising (Significantly Achieved)	• Few calls for any changes to the allocations within the fixed gear sector. • During formal consideration of groundfish allocations for Amendment 21, Council decided that there was not a sufficient need to examine reallocations of sablefish among sectors.
7. Promote Safety (Significantly Achieved)	• Significantly lengthened season and eliminated the derby fishery (Table 3-1 and Figure 3-1). • USCG incident data and estimates of trip starts under high wind conditions indicate generally safer vessel operations (Figures 3-19 and 3-20).
8. Improve Product Quality and Value (Limited Assessment)	• Changes in exvessel prices do not indicate a significant change in product value and are driven by numerous variables outside the scope of this study. However, since the inception of the program there may have been stabilization in the relative price differential between fixed gear and trawl-caught sablefish (Figures 3-21 and 3-22).
9. Avoid Creating New Disruptive Effects (Significantly Achieved)	• Created season of reasonable length without changing allocations, by allowing flexibility with permit stacking.
10. Capability to Readily Transition to a Multi-Month IQ Program (Significantly Achieved)	• Allocations are already established (a difficult first step in an IQ program) and could be transitioned to a more typical IQ program (with divisible quota freely transferable separate from the limited entry permits) if the need arises. Thus far the program is working well enough that there has been no call for a transition.

5.2 Questions for Constituent Comment

The data examined in this review raised some questions that were not readily explainable. The drafting team encourages fishermen, stakeholder, and industry input on any of the following questions that they may be able to answer or share some insights on.

1. The number of Tier 3 permits stacked with two other permits increased consistently from the initiation of the program through 2008, but declined thereafter. What may have caused the significant decrease that occurred from 2008 to 2012? During that time the occurrence of Tier 3 permits that were triple stacked dropped from 43 down to 22, almost as low as in the first full year of the program (Table 3-4).

2. What may have caused the apparently significant drop in fixed gear sablefish landings and dependence for Puget Sound ports since 2008 (Figure 3-14)?

3. Is other fishery or processor information available concerning improvement in product quality or size of fish under the stacking program (e.g., targeting by location or depth, different product forms, etc.)?

4. What might be the cause of the rapid increase in longline-to-trawl exvessel price differential for sablefish since 2010 that is not shared by the pot gear landings (Figure 3-22)?

6.0 COUNCIL RECOMMENDATIONS

[To be developed at the Council's June 2014 meeting and included in the final review document released following Council consideration.]

Some examples of potential recommendations would be:

1. Consider the possibility of making the following program changes for Phase 2 of the review (beyond the two already under consideration in Phase 1, i.e., ownership and control limits and electronic reporting):
    a. ?
    b. ?

2. Schedule another review within the next 7 years required for LAPPs.

3. Other

Net Revenue Earned in the West Coast Limited Entry Fixed Gear Groundfish Fishery and Primary Sablefish Fishery During 2010

Carl Lian
Economic and Social Science Research
Northwest Fisheries Science Center
Seattle, WA 98112
May 2014

I. Introduction

This paper provides estimates of total cost net revenue earned by commercial catcher vessels in the West Coast limited entry fixed gear groundfish fishery, West Coast limited entry fixed gear sablefish fishery, and the West Coast primary sablefish fishery. Estimates of total cost net revenue are based on 2010 cost earnings data collected by the Northwest Fisheries Science Center (NWFSC) in cooperation with the Pacific States Marine Fisheries Commission (PSMFC).

Since the cost earnings survey collected cost data at the vessel level and most of the vessels considered in this paper participate in multiple fisheries, producing estimates of total cost net revenue at the fishery level requires allocating joint costs to individual fisheries. This paper allocates the costs incurred by catcher vessels responding to the cost earnings survey to individual fisheries. After cost data has been allocated to individual fisheries, it is used to calculate the total cost net revenue derived from operations in individual fisheries.

II. Data Requirements and Cost Earnings Survey Data

A. Defining Revenues and Costs Directly Related to Commercial Fishing Vessel Operation

Estimating total cost net revenues earned by operating a commercial fishing vessel requires data on vessel revenues and costs. Since the same entity that owns a commercial fishing vessel may also be engaged in any number of other fishing related or non-related activities, it is important to define which revenues and costs are included in the measurement of net revenue.

The NWFSC economic data collection program focuses on collecting revenue and cost information directly related to the operation of a commercial fishing vessel. There are a variety of costs that are associated with running a catcher vessel that are not requested on the form because it is difficult to determine the share of the cost associated with the vessel. These costs include items that can be used for activities other than fishing, or are too difficult to allocate to a particular vessel in a multi-vessel company. These expenses include office space, pickup trucks, storage of equipment, professional fees, and marketing. In general, the data collection forms attempt to capture costs that are directly related to vessel maintenance and fishing operations, and not costs that are related to activities or equipment off the vessel. For these reasons, the aggregated measures of costs (variable costs, fixed costs, and total costs) underestimate the true costs of operating a business.

Since most vessels considered in this paper operate in multiple fisheries, much of the available cost data pertain to multiple fisheries. While some of the costs, such as vessel repairs and maintenance, are joint costs, other costs, such as fuel, are not necessarily joint costs but are not reported separately by fishery in the survey[7] While it is not necessary to disaggregate costs in order to analyze net revenue for all vessel operations, it is necessary in order to analyze net revenue associated with operations in the West Coast limited entry fixed gear groundfish fishery, the West Coast limited entry fixed gear sablefish fishery, and the West Coast primary sablefish fishery.

B. Data Sources

Data on ex-vessel revenue, landings, and number of active vessels in each fishery considered in this analysis was obtained from the Pacific Fisheries Information Network (PacFIN). Cost information for catcher vessels was obtained from a voluntary cost earnings survey conducted by the NWFSC in cooperation with the PSMFC. Survey responses were obtained from 67 of the 142 (47%) vessels participating in the limited entry fixed gear groundfish fishery during 2010 and 53 of the 90 vessels (59%) participating in the primary sablefish fishery during 2010. Table 1 provides a list of the cost categories collected from catcher vessels by this survey.

C. Testing and Correcting for Non-response Bias

A two sample t-test was used to determine whether the differences observed between survey respondents and non-respondents were statistically significant. The two sample t-test is based on a null hypothesis that the mean value of the variable being tested is the same for respondents and non-respondents. Variables considered when testing for non-response bias were vessel length, engine horsepower, West Coast sablefish revenue, and West Coast landings revenue from all species.

Tests for non-response bias indicated that non-response bias was statistically significant at the 91% confidence level for the limited entry fixed gear fleet. Therefore, the responses to the limited entry fixed gear survey were weighted in order to reduce non-response bias. Survey weights were based on the species that accounted for the most vessel landings and the dollar value of West Coast landings. Non-response bias for the limited entry fixed gear fleet resulted from higher response rates for vessels that participate in the primary sablefish fishery (and have a higher level of landings) than vessels that participate in other groundfish fisheries (such as the live thornyhead fishery).

---

[7] Joint costs are production costs incurred by the firm when two or more outputs are jointly produced. Joint costs can occur when the cost of an input is a fixed cost and when that input is used to produce multiple outputs either concurrently or consecutively. In the case of concurrent outputs, a variable cost can be a joint cost. Repair and maintenance costs that prepare the vessel for use in all fisheries are joint costs. If a single trawl tow harvests both sablefish and Dover sole, the fuel used to harvest the sablefish and Dover sole from the same tow is a joint cost. However, fuel costs incurred to harvest sablefish in July and crab in December would not be a joint cost even if fuel expense is reported on an annual basis.

III. Calculating Fishery Costs

This section presents the methodology used to allocate costs reported on the 2010 cost earnings survey for vessel operations to individual fisheries. Because cost data collected from the limited entry groundfish fixed gear fleet covers vessel operations in all fisheries, it is necessary to allocate reported cost data to individual fisheries for vessels participating in multiple fisheries in order to obtain cost data for individual fisheries. Allocating costs to individual groundfish fishery is necessary to calculate the total cost net revenue earned by participants in the fishery.

Terry et al. (1996) identify three properties any cost allocation method should satisfy. First, a cost allocation method should be the same for all fisheries in which a commercial fishing vessel participates. Second, the cost allocation method should be simple and easy to understand (in order to promote trust in the analysis). Third, the cost allocation method should be equitable. They recommend the use of facilities method (UFM) of cost allocation, which allocates costs to fisheries in proportion to the use of common facilities by each fishery. Three methods of implementing the UFM method of cost allocation are (i) by days at sea in each fishery, (ii) by revenue earned in each fishery, and (iii) by pounds harvested in each fishery. For information on the method used to allocate each cost category to individual fisheries, see Appendix A of Steiner, Harley, and Lee (2014).

IV. Net Revenue

Table 2 presents estimates of total revenue, total costs, and total cost net revenue derived from survey respondents participating in the limited entry fixed gear groundfish fishery, the West Coast limited entry fixed gear sablefish fishery, and the West Coast primary sablefish fishery. The 67 survey respondents participating in the West Coast limited entry fixed gear groundfish fishery earned revenue of $109,801 per vessel, incurred $95,271 in costs, and earned $14,530 in total cost net revenue. When the per vessel total cost net revenue of $14,530 for survey respondents is multiplied by the population of 142 vessels in the fishery, an estimate of $2,063,260 total cost net revenue earned in the West Coast limited entry fixed gear groundfish fishery is obtained.

The average survey respondent earned $94,380 revenue in the West Coast limited entry fixed gear sablefish fishery (which includes both the primary sablefish fishery and the daily fishery). The average vessel incurred $81,338 in costs from operations in this fishery, and earned $13,042 in total cost net revenue from these operations. When the per vessel total cost net revenue of $13,042 is multiplied by the 139 vessels participating in this fishery, an estimate of $1,812,838 is obtained for total cost net revenue earned by all fishery participants.

Among the 53 survey respondents who participated in the primary sablefish fishery, the average revenue earned in the primary sablefish fishery was $123,362. The average vessel incurred costs of $105.203 from operations in the primary sablefish fishery and earned total cost net revenue of $18,159. When the per vessel total cost net revenue of $18,159 is multiplied by the 90 vessels participating in the fishery, an estimate of $1,634,310 in total cost net revenue is obtained for the primary sablefish fishery during 2010. During 2010 the primary sablefish fishery earned 90% of the total cost net revenue earned in the limited entry fixed gear sablefish fishery and 79% of the total cost net revenue earned in the limited entry fixed gear groundfish fishery.

V. Variations by Vessel Size and Geography

The data reported in Table 2 provides an estimate of total cost net revenue across all vessels operating in each fishery. This section examines how total cost net revenue earned by survey respondents varied by length of vessel and state in which the vessel made the most West Coast landings. This comparison is provided for the limited entry fixed gear groundfish fishery and the primary sablefish fishery.

Table 3 classifies each survey respondent as having a vessel less than 35 feet in length, 35 to 50 feet in length, or over 50 feet in length. Within the limited entry fixed gear groundfish fishery, total cost net revenue per vessel rises from $4,811 for vessels under 35 feet to $14,881 for vessels between 35 and 50 feet in length and $18,715 for vessels over 50 feet in length. For vessels under 35 feet in length, total cost net revenue is a smaller share of revenue than for vessels over 35 feet in length. Within the limited entry fixed gear groundfish fishery, survey respondents in Oregon had the highest revenue and total cost net revenue while survey respondents in California had the lowest revenue and total cost net revenue. Total cost net revenue as a share of revenue was slightly higher in Oregon than Washington, and slightly higher in Washington than California.

Within the primary sablefish fishery, results are not reported for vessels under 35 feet in length because the number of survey respondents was not sufficient to protect data confidentiality. Total cost net revenue as a percentage of revenue increases as vessel length increases --- from 14% for vessels between 35 and 50 feet in length to 16% for vessels over 50 feet in length. Vessels in Oregon and Washington earned higher total cost net revenue as a percentage of revenue (15%) than vessels in California (12%). . .

Table 1
Cost Categories Collected by Limited Entry
Fixed Gear Catcher Vessel Survey

Cost Category

Variable Cost Categories
- Bait
- Captain
- Communications
- Crew
- Fishing association dues
- Food
- Freight
- Fuel and lubrication
- Ice
- License fees
- Observers
- Offloading
- Supplies
- Travel
- Trucking

Fixed Cost Categories (Capitalized and Expensed Collected Separately)
- Fishing gear
- Processing equipment
- Vessel and on-board equipment

Other Fixed Cost Categories (Expensed)
- Insurance premium payments
- Lease of vessel
- Moorage

Data for 2010 was collected in 2010 dollars. All cost, revenue, and total cost net revenue figures reported in this document are reported in 2010 dollars.

Table 2
Total Cost Net Revenue Earned in Three Limited Entry Fixed Gear Fisheries

Fishery	Revenue Per Vessel	Total Cost Per Vessel	Total Cost Net Revenue Per Vessel	Total Cost Net Revenue Fishery
Limited Entry Fixed Gear Groundfish	$109,801	$95,271	$14,530	$2,063,260
Limited Entry Fixed Gear Sablefish	$94,380	$81,338	$13,042	$1,812,838
Primary Sablefish	$123,362	$105,203	$18,159	$1,634,310

Table 3
Variation in Total Cost Net Revenue with Vessel Length and State

Fishery	Revenue Per Vessel	Cost Per Vessel	Total Cost Net Revenue Per Vessel
Limited Entry Fixed Gear Groundfish	$109,801	$95,271	$14,530
< 35 feet	$58,212	$53,401	$4,811
35 to 50 feet	$107,627	$92,746	$14,881
➢ 50 feet	$144,229	$125,514	$18,715
California	$83,123	$73,823	$9,300
Oregon	$121,199	$103,766	$17,433
Washington	$107,168	$93,940	$13,228
Primary Sablefish	$123,362	$105,203	$18,159
< 35 feet	---	---	---
35 to 50 feet	$108,274	$93,127	$15,147
➢ 50 feet	$152,139	$128,317	$23,822
California	$81,222	$71,100	$10,122
Oregon	$150,470	$127,261	$23,209
Washington	$118,298	$100,777	$17,521

Revenue, Costs, and Total Cost Net Revenue not reported for vessels < 35 feet in the primary sablefish fishery because the number of observations was not sufficient to protect respondent confidentiality

Table of Contents

Chapter 1 Background, Proposed Action, Purpose and Need for the Action

1.1 Proposed Action

The proposed action is to: (a) implement an electronic fish ticket requirement for the sablefish fishery, (b) modify the control rules for the Limited Entry Fixed Gear Sablefish Permit Stacking Program (program), and (c) implement joint registration (allow limited entry fixed gear and trawl permits to be registered to the same vessel at the same time).

1.2 Purpose and Need

The purpose of the electronic fish ticket measure is to consider the implementation of a Federal requirement for an electronic fish ticket to capture essential fishery catch data for non-trawl groundfish fisheries. This measure is needed to improve catch accounting and to enforce sablefish tier limits in the primary fishery such that the integrity of the catch share program is maintained. In addition, there is a need to improve the timeliness of the data for management and enforcement of the fixed gear fisheries.

The purpose of the own/control limit measure is to modify the vessel ownership threshold used to evaluate the control limit on the number of limited entry fixed gear permits owned or held by a single entity. The need for this measure is to accommodate fishing enterprises that participate in both the Alaskan fixed gear sablefish and halibut IFQ program (Alaska IFQ program) and the West Coast primary sablefish fishery, as well as West Coast fishing enterprises in which a person's minor financial interests in a vessel may disrupt its business unnecessarily by preventing full attainment of the tiers.

The purpose of the joint registration measure is to allow limited entry trawl permits and limited entry fixed gear permits to be registered to the same vessel at the same time. While joint registration is prohibited under existing regulations it may no longer be necessary given improved catch accounting and monitoring under the Pacific coast groundfish trawl rationalization program and considering the proposed improvements to catch accounting under the electronic fish ticket measure analyzed in this document. The need for this measure is to provide for increased flexibility for fishermen that participate in both the trawl and fixed gear fisheries.

1.3 Background

1.3.1 Summary of Past Management Actions

Sablefish (*Anoplopoma fimbria*) is one of the most valuable species in the groundfish fishery off Washington, Oregon, and California, and is managed under the Pacific Coast Groundfish Fishery Management Plan (FMP). Because of its high ex-vessel value per pound, sablefish is a desirable target species for many West Coast fisheries and gear groups. The Pacific Fishery Management Council (Council) made several sablefish allocation decisions over the 15 years prior to implementation of Amendment 14 in 2001 establishing the limited entry fixed gear sablefish permit stacking program, which is a type of individual fishing quota (IFQ). The limited entry fixed gear sablefish permit stacking program was structured to increase safety and efficiency, while maintaining the small, owner-operator character of the fleet.

In 1987, an allocation of sablefish was established between trawl and non-trawl gear groups. Industry representatives of vessels participating in the non-trawl sablefish fisheries expressed their desire that the fishery be managed on a seasonal basis (as opposed to the year-round policy the Council pursued for most sectors of the groundfish fishery). The pursuit of seasonal management for the non-trawl segment of the sablefish fishery was a key decision that, when combined with a decline in sablefish abundance, ultimately impacted safety, efficiency, and allocational issues that the permit stacking program was meant to address.

The vast majority of the trawl and non-trawl sablefish harvest was placed under a license limitation program in 1994 (Amendment 6). Of the non-tribal commercial optimum yield of sablefish, 90.6% was allocated to the limited entry fishery and 9.4% was allocated to the open access (OA) fishery. The limited entry sablefish allocation was then allocated 58% to the limited entry trawl sector and 42% to the limited entry non-trawl (fixed gear) sector.

Management for the fixed gear fleet was, and continues to be, divided at the 36º N. lat. line with separate annual catch limits (ACLs) for the northern and southern fisheries. While the coastwide trawl fishery took sablefish as part of its year-round cumulative trip limit fisheries, the northern fixed gear fleet landed 85% of its allocation in a directed sablefish season, and 15% of its allocation in daily trip limit fisheries. The southern fixed gear fleet landed all of its allowed harvest in daily trip limit fisheries. The directed season north of 36ºN. lat. became increasingly tense over the years, as vessel capacity and competition for landings increased and amounts of fish available for harvest decreased. Through 1996, the directed (or "primary") season for the limited entry fixed gear fleet was managed as an open competition derby ("derby"). Derby duration shortened each year, until the fishery was just five days long in 1996.

Concern for the safety of participants in the sablefish derby led the Council to develop Amendment 9 to the FMP. In 1997, NMFS implemented Amendment 9, the sablefish endorsement program. Limited entry permit holders were eligible for sablefish endorsements based on their permit history. Permits without sufficient sablefish landings history were not endorsed for future participation in the primary season, but they could still be used in the daily trip limit fisheries.

Even with the sablefish endorsement, the fishery season remained short (nine days in 1997). To lengthen the season and improve safety, equal limits were imposed on all qualified participants (sablefish endorsement holders). However, the season still had to be limited to keep the fishery from being classified as an IFQ program. A fishery with a limited class of participants each with an amount of fish they are allowed to harvest is an IQ. In its 1996 re-authorization of the Magnuson-Stevens Fishery Management and Conservation Act (MSA), Congress had included a moratorium on implementing new IFQ programs through October 1, 2000. The moratorium was interpreted to cover any program that would allow a vessel ample time and opportunity to catch a limit allocated specifically to that vessel. The moratorium forced the Council to manage the primary season to a short duration that prevented many participants from fully taking their vessel-specific limits (a "modified derby"). To further assure that the cumulative limits would not be categorized as an IFQ program, regulations were established to set a maximum season length of 10 days. Equal cumulative limits were viewed by the Council as being extraordinarily reallocative in nature, but for 1997, equal limits were the only option available to lengthen the season and to begin to address safety issues.

The inequitable allocation system created by the equal cumulative limits was partially resolved with a “three-tier” system, which was established by regulatory amendment for 1998 and beyond. Under this “three-tier” system, sablefish endorsement holders were ranked into three different tiers based on their permit histories, with the lowest tier (Tier 3) having the lowest qualification requirements. Annual management of the three-tier cumulative limit system required that the allocation for this fishery be divided such that there were three different cumulative limits for the different tiers. While somewhat more equitable than the equal cumulative limit system, the three-tier system still required some fishermen to make large cutbacks in their harvest levels while allowing others to expand. The system provided little flexibility to operators to determine the manner in which their sablefish catch is harvested or to scale their harvest upward to match their pre-existing levels of capital investment. This lack of flexibility undoubtedly reduced efficiency, resulting in a lower net value for harvest.

Even under the three-tier system, the fishery still had to be managed as a modified derby to keep from being considered an IFQ, and the seasons were still too short (between 6-9 days) to allow fishermen to operate with care and safety. Short derby seasons are believed to result in accidents due to fatigue and financial pressure to fish and transit under unsafe conditions.

The MSA moratorium on new IFQ programs expired on October 1, 2000. On December 21, 2000, Public Law 106-553, an appropriations bill for NOAA, contained a continuation of the IFQ moratorium through October 1, 2002 and an exception to that moratorium for a permit stacking program in the West Coast fixed gear sablefish fishery. On August 2, 2001, Amendment 14 implemented a permit stacking program, in which up to three sablefish-endorsed permits could be registered for use with a single vessel and that vessel could then have access to the primary season sablefish cumulative limits associated with each of those permits. Most importantly, the exception to the IFQ moratorium for the fixed gear sablefish fishery as implemented through Amendment 14 allowed longer seasons (April through October), so that each vessel could fish against its limits at its own speed.

Portions of Amendment 14 were implemented for the 2001 primary sablefish season. The extended sablefish season was fully implemented in 2002. In 2006, NMFS implemented additional regulations for Amendment 14, many of which were intended to keep the fishery a small, owner-operator fleet. It was decided that, in the future, NMFS would implement a permit stacking program fee system (cost recovery program) as required by the MSA.

Beginning in 2001, NMFS implemented the initial permit stacking provisions (66 FR 41152, August 7, 2001). The following provisions were put in place in 2001:

(1) up to 3 sablefish-endorsed permits may be registered for use with a single vessel;
(2) the limited entry, primary sablefish season is from August 15 - October 31, 2001;
(3) a vessel may fish for sablefish during the primary season with any of the gears specified on at least one of the limited entry sablefish-endorsed permits registered for use with that vessel;

(4) no person may own or hold more than 3 sablefish-endorsed limited entry permits unless that person owned more than 3 permits as of November 1, 2000;
(5) no partnership or corporation may own a sablefish-endorsed limited entry permit unless that partnership or corporation owned a permit as of November 1, 2000;
(6) cumulative limits for species other than sablefish and for the sablefish daily trip limit fishery remain per vessel limits and are not affected by permit stacking; and
(7) the limited entry daily trip limit fishery for sablefish is open during the primary season for vessels not participating in the primary season.

Beginning in 2002, NMFS extended the fishing season to April 1 - October 31 as part of the Pacific Coast groundfish final specifications and management measures (67 FR 10490; March 7, 2002).

Beginning in 2006, NMFS implemented further permit stacking regulations that include the following provisions (71 FR 10614, March 2, 2006):
(1) permit owners and permit holders are required to document their ownership interests in their permits to ensure that no person holds or has ownership interest in more than 3 permits;
(2) an owner-on-board requirement for permit owners who did not own sablefish-endorsed permits as of November 1, 2000;
(3) an opportunity for permit owners to add a spouse as co-owner;
(4) vessels that do not meet minimum frozen sablefish historic landing requirements are not allowed to process sablefish at sea;
(5) permit transferors are required to certify sablefish landings during mid-season transfers; and
(6) a definition of the term "base permit."

1.3.2 Current State of the Program

The current permit stacking program applies to the sablefish primary fishery, which occurs north of 36º N. lat. Under this program, vessels registered to at least one limited entry permit, with either a gear endorsement for longline or trap (or pot) gear, and an endorsement for sablefish, fish a specified tier limit during a seven-month primary fishery season (April through October).

Under the permit stacking program, each fixed gear sablefish-endorsed, limited entry permit is assigned to one of three tiers. Tiers are permanently affixed to the sablefish endorsed permit and cannot be transferred separately from the permit. The permit's tier level determines the poundage of sablefish which can be landed by that permit each season while participating in the primary sablefish fishery. For sablefish-endorsed, limited entry permits, the NMFS Regional Administrator biennially or annually announces the size of the cumulative trip limit for each of the three tiers associated with the sablefish endorsement such that the ratio of limits among the tiers is approximately 1:1.75:3.85 for Tier 3:Tier 2:Tier 1, respectively. Up to three permits can be stacked onto (registered to) a single vessel, allowing that vessel to land up to the sum of the three tier limits in aggregate. Because each vessel is assigned a proportion of catch based on its tier limit, the stacking program is considered an IFQ, or catch share program.

Vessels with sablefish-endorsed permits are also eligible to fish in the daily-trip limit (DTL) fishery before the primary season (i.e., January through March) and after their aggregate tier limit on the vessel has been harvested, or the primary season has ended, whichever comes first. All landings made starting on April 1 by a vessel registered to a sablefish-endorsed permit(s) are debited against the tier amount until the tier amount remaining is below the daily trip limit amount. Because each vessel has its own primary fishery limit, vessels often transition from the primary to DTL fisheries sometime during the sablefish primary season.

The program also includes other provisions, including a prohibition on the ownership of permits by corporations or other business entities, a permit owner-on-board requirement, a limit on the number of permits any individual or entity (individually and collectively) can own or hold, and a prohibition on at-sea processing. A grandfather clause was provided for each of these provisions, allowing the continuation of situations in place prior to Council action. For non-grandfathered permits, the permit owner must be on board the vessel during the primary season when that permit's tier amount is being fished. If landings from a trip will be attributed to multiple tiers, then all permit owners of those tiered permits being fished must be onboard. However, there are limited[1] medical and death exemptions from this requirement.

Currently, there are 164 sablefish-endorsed permits of which 131 are endorsed for longline only; 27 are trap/pot endorsed only, and 6 have two gear endorsements. The number of permits by tier levels is as follows: Tier 1 -28 permits; Tier 2 – 42 permits, and Tier 3 – 94 permits. As of August 2013, approximately 40 vessels have stacked (multiple) permits (either 2 or 3 permits).

Electronic Fish Tickets

The first measure covered by this EA considers changing landing reporting requirements to implement a Federal requirement for an electronic fish ticket. Background on landing reporting requirements and reasons for considering modifications are provided in this section.

When a sablefish fixed gear tier delivery is made, the delivery is recorded on a state fish ticket. Landings recorded on this one fish ticket may count against multiple permits with varying tier endorsements. If the vessel operator does not specify which permit/tier the catch should be counted against, the delivery is apportioned to the individual tiers (up to 3) by an even split until the tiers are reduced to a point where they are equal to or less than the daily-trip limits (DTL). All of this tabulation is done by the state agency(s) and then sent to the Pacific States Marine Fisheries Commission (PSMFC) for entry into the Pacific Fishery Information Network (PacFIN).

At the September 2013 meeting of the Council, the Enforcement Consultants (EC) report outlined several concerns with the existing reporting requirements. Their primary concern was that the opportunity for underreporting is extremely great under the current regulations, which defer to the states to report catch data and permit numbers on State fish tickets (which are recorded on paper), and enforcement agents often have little access to data that is often times

[1] These exemptions can only be given for three years maximum (consecutive or cumulative) to a permit owner or to the surviving spouse of a permit owner.

outdated. This creates a situation where at-sea boarding or dockside inspection can do little besides checking the permit status, because no real-time information on the actual status of the tier(s) being fished is available. In addition, with current landing reports, enforcement of the owner-on-board requirement is difficult without having real-time permit and landing information. During an at-sea boarding or dockside inspection, enforcement must determine which owner, if any, is supposed to be onboard the vessel during that trip.

Since inception of the tier program, NMFS has requested that the state agencies list the Federal permit number on the state ticket (see 71 FR 10614, March 2, 2006, response to comment 1). Washington requires the tier permit number be listed on the State fish ticket, and Washington enforcement and management personnel have ready access to the Washington State landing data. In 2013, Oregon enacted state regulations that require documentation of the permit number on the state fish ticket. Unlike Washington and Oregon, in California there are no state regulatory requirements for the tier permit number to be listed on the state fish ticket.

Although Federal or state enforcement personnel may request information from their individual states or from PacFIN, the information process is laborious, time consuming, dated, and most importantly, does not lend itself to making information available to an agent or officer working in the field performing patrol-related activities.

The Department of Commerce, Office of the Inspector General recently released a report highlighting these issues and finding, in part, that the sablefish permit stacking program does not have adequate data and that NOAA is not monitoring to determine whether individual permits are exceeding their allowed landings (Final Report No. OIG-14-019-I, May 1, 2014). The OIG report recommends, in part, that NMFS (1) develop a process to ensure that accurate landings information is obtained by individual permit in a timely manner, and (2) develop controls to monitor landings on an individual permit basis to ensure overage violations are adequately addressed. This action seeks to address these catch accounting issues.

Own/Control Limits

The second measure covered by this EA considers changing the criteria used to determine the number of permits an entity controls, for purpose of assessing compliance with the three-permit own/control limit. Background on the control rule and criteria, and reasons for considering a modification, are provided in this section.

Control occurs when a person owns or holds a permit. Thus, a person can control a permit by directly owning the permit or by owning a vessel to which a permit is registered (i.e., “holding” a permit). In this latter situation, the permit registered to the vessel may be owned by someone else. The current own/control regulations limit participants (permit owners and/ or vessel owners) in this program to owning or holding no more than three permits (a three-permit control limit). This limit was intended to prevent concentration of harvest privileges. For the purpose of determining the number of permits a person controls, ownership of any percentage of a permit counts as 1 permit. Additionally, persons who have any percentage ownership interest in a vessel are considered to hold any permit associated with that vessel, i.e. to control the permits associated with the vessel (see regulations at 660.25(b)(3)(iv)(C)(2)). The regulations were implemented in this way, under Amendment 14, with the intention of moving the program towards an owner-operator fleet.

While the own/control limit has been in place since 2001 without any issues being raised by the majority of the fleet, two examples have come forward highlighting barriers the own/hold limit causes. The two examples brought to the Council's attention pertain to (1) sablefish permit stacking participants that also harvest Alaska fixed gear halibut and sablefish IFQ program[2] (Alaska IFQ) and (2) vessel/permit purchase transactions. These situations are described briefly here and in detail in the impacts section of Chapter 4.

The first example is for participants in the sablefish permit stacking program that also harvest Alaska IFQ. The way the West Coast sablefish permit stacking program counts permits registered to a vessel (for purposes of the three-permit control limit) constrains Alaska IFQ participants that are grandfathered. Grandfathered participants are exempt from Alaska owner-on-board requirements and Alaska limitations on individuals owning IFQ[3]. Unlike the West Coast sablefish permit stacking program, the Alaska IFQ program requires that, under certain circumstances, an entity acquire at least 20 percent ownership interest in the vessel that will fish its Alaska IFQ. If the vessel which is hired also participates in the West Coast sablefish permit stacking program (is a West Coast and Alaska vessel), there may be West Coast limited entry fixed gear (LEFG), sablefish-endorsed permits (i.e., LEFG permits) registered to the vessel. When an entity acquires an ownership interest to hire the vessel to participate in the Alaska IFQ program, any LEFG permits that happen to be registered to the vessel would also count against that entity's West Coast LEFG 3-permit limit. If that entity already controls some LEFG permits (e.g. owns a different vessel which participates in the West Coast fishery) then its ability to hire another West Coast vessel to fish its permits may be limited.

There are two circumstances under which an entity is required to acquire a 20-percent ownership interest in the vessel which will be hired to fish its IFQ. Both involved grandfathered participants. The first involves those individuals grandfathered in with an exemption from the IFQ owner-on-board requirement. Regulations for the Alaska sablefish IFQ program require that individual owners of catcher vessel quota shares (QS) (Alaska QS, vessel categories B, C, or D) be onboard the vessel during all IFQ fishing. An exemption to the owner-on-board requirement allows an initial recipient of catcher vessel Alaska QS to employ a hired master to fish his or her IFQ, but only if the initial recipient owns a minimum of 20 percent interest of the vessel on which they hire a master to fish their IFQ. The second involves those entities (corporations, partnerships, etc.) grandfathered in with an exemption to provisions which limits IFQ ownership to individuals. To operationalize the owner-on-board provision, acquisition of Alaska IFQ by entities was prohibited, except for those entities that already existed and were eligible for an initial allocation. Over time and similar to the West Coast fishery, individuals and entities eligible for these two exemptions will leave the fishery, and there will no longer be any remaining grandfathered entities. Like the West Coast sablefish fishery, the regulations were

[2] The North Pacific Fishery Management Council (NPFMC) managed IFQ Program for fixed-gear Pacific halibut and sablefish fisheries in and off of Alaska.
[3] The West Coast sablefish permit stacking program also has owner-on-board requirements and a requirement that only individuals own LEFG, sablefish-endorsed permits, unless grandfathered. However, these West Coast provisions are not constraining participation in Alaska IFQ.

structured in this way to maintain a predominantly owner-operator fishery. Alaska regulations have recently been modified to further encourage more rapid movement toward a solely owner-operated fishery in Alaska.

The second example is for vessel or permit purchase transactions. The other barrier to fishermen cooperation created by the criteria used to determine ownership of West Coast LEFG permits comes into play as part of sale transactions. A typical business practice in West Coast fisheries is for the seller of a vessel to finance the buyer's purchase of the vessel. When this is done, the seller will often retain at least partial ownership interest in the vessel until all payments have been made, at which time the seller will sign over entire interest in the vessel. If, for example, the seller of a West Coast fixed gear vessel is upgrading to a different fixed gear vessel and the buyer of the vessel wants to continue to use the vessel in the LEFG fishery, then by retaining partial ownership, the seller would be counted as controlling all the LEFG permits on the vessel he or she sells, plus any permits on the new vessel. Thus, the criteria for counting permit control may be interfering with this method of financing vessel transactions among West Coast fishermen.

Chapter 2 Description of Alternatives

2.1 Electronic Fish Ticket Alternatives

For the electronic fish ticket measure, there are the No Action alternative and three action alternatives, which are summarized here and described in more detail in the following sections.

> Alternative 1: (No Action) There are currently no Federal regulations requiring electronic fish ticket documentation for sablefish landings in the primary (tier) sablefish fishery, within the larger limited entry fixed gear (LEFG) fishery or within the OA fishery, which are managed under daily, weekly, and bimonthly trip limits.
>
> Alternative 2: A Federal requirement that **all tier** deliveries be recorded on an electronic fish ticket that documents the associated Federal groundfish permit number.
>
> Alternative 3: A Federal requirement that **all limited entry permit sablefish deliveries (primary/tier and DTL)** be recorded on an electronic fish ticket that documents the associated Federal groundfish permit number.
>
> Alternative 4: A Federal requirement that **all sablefish deliveries (primary/tier, DTL, and OA)** be recorded on an electronic fish ticket that documents the associated Federal groundfish permit number.

2.1.1 No Action Alternative

> Alternative 1: (No Action) There are currently no Federal regulations requiring electronic fish ticket documentation for sablefish landings in the primary (tier) sablefish fishery, within the larger limited entry fixed gear (LEFG) fishery or within the OA fishery, which are managed under daily, weekly, and bimonthly trip limits.

Catch accounting in the LE and OA fisheries is based on landed catch derived from state landing receipts. Total catch is derived by combining landed catch values from state landing receipts with discard ratios derived from observer sample data. Current regulations at 50 CFR 660.3[4] and 50 CFR 660.13 require vessels to adhere to applicable state laws for recordkeeping and reporting. However, State landing receipts do not consistently include the Federal groundfish permit number associated with the landing, which can be problematic, particularly when multiple permits are registered to a single vessel. Electronic fish ticket regulations at 50 CFR 660.15 apply only to first receivers in the Shorebased Trawl IFQ program and not to the LE and OA fisheries first receivers. Landings data are available in the PacFIN database for management and enforcement purposes several months after the date of landing.

At the time of implementation of Amendment 14, no Federal regulations requiring fish ticket documentation of the groundfish permit number associated with sablefish landings in the primary (tier) sablefish fishery were enacted. Documentation of catch against tier limits and

[4] § 660.3 Reporting and recordkeeping. Any person who is required to do so by applicable state law or regulation must make and/or file all reports of management unit species landings containing all data and in the exact manner required by applicable state law or regulation.

documentation of permit numbers was left to the states to implement. In the Amendment 14b final rule (71 FR 10614, March 2, 2006), comment and response section, Washington Department of Fish and Wildlife (WDFW) and Oregon Department of Fish and Wildlife (ODFW) committed to requiring Federal permit numbers to be recorded on state fish tickets by 2007. At that time California Department of Fish and Game, now California Department of Fish and Wildlife (CDFW), had already added a line for a Federal permit number on their state ticket and entered that information into PacFIN. Washington requires the tier permit number be listed on the state fish ticket, and Washington enforcement and management personnel have ready access to the Washington State landing data. The State of Oregon has recently changed their regulations to require that the permit number be documented on the state landing receipt. As of 2014, Federal permit numbers are not being recorded consistently on state landing receipts associated with sablefish landings.

Under the current system, when a sablefish fixed gear tier delivery is made, the delivery is recorded on a state paper fish ticket in accordance with state law. One to three tiers may be delivered and recorded on this one trip ticket. If not specified by the operator, the delivery is apportioned to the individual tiers (up to three) by an even split until the tiers are reduced to a point where they are equal to or less than the DTL. All of this tabulation is done by the state agency(s) and then sent to PSMFC for entry into PacFIN. Under the No Action Alternative, the requirements for sending in paper landing receipts varies among states with Washington requiring the paper landing receipts to be received within six working days, Oregon requiring the landing receipts to be received within five working days, and California requiring the landing receipts to be received by the first and sixteenth of the month. It is a considerable time after the tickets are prepared and submitted that the data are entered into a state database, edited, and forwarded to the PacFIN database; depending on the state, it may take several months.

2.1.2 Action Alternatives

Each of the Alternatives 2-4 would implement a Federal requirement that nontrawl commercial sablefish landings to U.S. West Coast ports be recorded on an electronic fish ticket. The action alternatives differ from each other in the fleets that they address: Alternative 2 would affect participants in the primary, tiered limited entry fixed gear (LEFG) sablefish fishery; Alternative 3 would expand upon Alternative 2 to add participants in the LEFG DTL fishery; and Alternative 4 would expand upon Alternative 3 to add participants in the OA DTL sablefish fishery. Under each of the action alternatives, the electronic tickets already in use by the Shorebased IFQ Program would be used to record sablefish landings. The electronic ticket could easily accommodate nontrawl sablefish landings with little to no revision to the existing electronic ticket. Any dealer required to fill out an electronic ticket would need to request a free PSMFC dealer account, then fill out an electronic ticket online, and submit that electronic ticket to PSMFC within 24 hours of landing. The catch data recorded on the electronic ticket is then made available to state and Federal management and enforcement agencies, and later entered into PacFIN along with other catch data. Table 1 of this document, below, summarizes some of the potential differences between the No Action Alternative and Alternatives 2-4.

Electronic fish ticket means a software program or data files meeting data export specifications approved by NMFS that is used to send landing data to PSMFC. Electronic fish tickets are used to collect information similar to the information required in state fish receiving tickets or landing receipts, but they do not replace or change any state requirements. However, the State may use the electronic fish ticket to satisfy their State requirements. The electronic fish ticket system was designed and is managed by the PSMFC, with funding from NMFS. The electronic fish ticket system has been used for the Pacific whiting shoreside fishery since 2007 (see 72 FR 50906, September 5, 2007). In 2011, the electronic fish ticket system was expanded to include not only the Pacific whiting shoreside fishery but all groundfish delivered shoreside by vessels participating in the Shorebased IFQ Program under Amendment 20 (the Trawl Rationalization Program). The current electronic fish ticket system is software-based; however, PSMFC is in the process of moving to a web-based electronic fish ticket system. This change would affect the requirements associated with using the electronic ticket. Electronic fish ticket regulations at 50 CFR 660.15 explain the current software and hardware requirements associated with using the electronic ticket. These regulations currently apply only to first receivers[5] in the Shorebased Trawl IFQ program and not to the LEFG and OA fisheries. The existing electronic fish ticket varies slightly by state such that each form records the information necessary for compliance with state landings regulations. Although the form is currently used for the Shorebased IFQ Program, it could easily accommodate landings in the commercial nontrawl groundfish fleet, and also provides unique reporting functions, such as preparation of tax information, that may be beneficial to first receivers.

> Alternative 2: A Federal requirement that **all tier** deliveries be recorded on an electronic fish ticket that documents the associated Federal groundfish permit number.

Sablefish landings made against sablefish endorsed (tier) permits during the primary season for the limited entry fixed gear fishery north of 36ºN (April 1 through October 31, or until the permit holder's tier limit has been reached, whichever occurs first), would be required to be recorded on a Federal electronic fish ticket that documents the associated federal groundfish permit number. The existing electronic ticket already has the appropriate fields and drop down boxes necessary to accommodate this fishery and would be expanded to include sablefish landings. State landings receipts would still be required per state landings regulations; the electronic ticket would be separate from and in addition to state landing requirements. After a landing was made to a first receiver, all necessary landing and catch information would be recorded on the electronic ticket provided by the first receiver. This electronic ticket would then be uploaded to PSMFC within 24 hours of the landing, made available to all interested parties (i.e. the state agencies, enforcement, NMFS, and permit owners), and the data would be processed and entered into PacFIN.

> Alternative 3: A Federal requirement that **all limited entry permit sablefish deliveries (primary/tier and DTL)** be recorded on an electronic fish ticket that documents the associated Federal groundfish permit number.

Sablefish landings made against sablefish-endorsed (tier) permits during the primary season and sablefish landings made by vessels registered to limited entry fixed gear permits, before and after the primary season, and subject to the restrictions and limits of the limited entry daily and/or weekly trip limit (DTL) fishery for sablefish, would be required to be recorded on a Federal electronic fish ticket that documents the associated Federal groundfish permit number. The existing PSMFC electronic ticket already has the appropriate fields and drop down boxes

[5] First Receiver means a person who receives, purchases, or takes custody, control, or possession of catch onshore directly from a vessel.

necessary to accommodate this fishery and would be expanded to include sablefish landings. State landings receipts would still be required per state landings regulations; the electronic ticket would be separate from and in addition to state landing requirements. After a landing was made to a first receiver, all necessary landing and catch information would be recorded on the electronic ticket provided by the first receiver. This electronic ticket would then be uploaded to PSMFC within 24 hours of the landing, made available to all interested parties (i.e. the state agencies, enforcement, NMFS, and permit owners), and the data would be processed and entered into PacFIN.

> Alternative 4: A Federal requirement that **all sablefish deliveries (primary/tier, DTL, and OA)** be recorded on an electronic fish ticket that documents the associated Federal groundfish permit number.

Sablefish landings in the primary/tier and LEFG, and OA DTL fisheries that exceed a poundage threshold, would be required to be recorded on a Federal electronic fish ticket that documents the associated Federal groundfish permit number. The existing PSMFC electronic ticket already has the appropriate fields and drop down boxes necessary to accommodate this fishery and would be expanded to include sablefish landings. State landings receipts would still be required per state landings regulations; the electronic ticket would be separate from and in addition to state landing requirements. After a landing was made to a first receiver, all necessary landing and catch information would be recorded on the electronic ticket provided by the first receiver. This electronic ticket would then be uploaded to PSMFC within 24 hours of the landing, made available to all interested parties (i.e. the state agencies, enforcement, NMFS, and permit owners), and the data would be processed and entered into PacFIN.

Table 2.1 Benefits of the electronic fish ticket action alternatives over the no action alternative.

Issues	No Action Alternative	Electronic Ticket Alternatives
Timely reporting of catch	• Electronic ticket not required. • Paper reports required by state of landing. • May take 2-4 months for NMFS to have access to landings by permit	• Federal requirement for electronic fish tickets. • Submission of electronic fish tickets within 24 hours of the date of landing. • Paper reports required by state of landing.
Accurate reporting of catch	• In-season data available for monitoring is a combination of paper ticket data and estimates • NMFS unable to obtain real-time, accurate landings data (permit number not consistently recorded on ticket) • Paper tickets are subject to compromise and error	• Data electronically entered into the system can be verified and validated at the time of entry by buyer personnel • Provides a tool for processors and buyers to capture and track fish tickets, generate tax reports, and summary data
Enforce landing overage violations	• In-season estimates are not sufficient for enforcement purposes • Data delays prevent real-time, in-season enforcement of tier overages and the owner on board requirement	• Accurate, real-time tracking of landings against cumulative limits will allow enforcement to monitor and enforce tier limits and DTLs

2.1.3 Alternatives Considered But Rejected From Further Analysis

Action Alternatives 2-4 each included a suboption to require sablefish deliveries be recorded on state paper fish tickets, rather than on Federal electronic fish tickets. Under these suboptions, NMFS would implement a Federal requirement that sablefish landings and the Federal groundfish permit number associated with the landing(s) be recorded on the state paper fish tickets.

Although the paper fish ticket suboptions would cause the least disruption to the existing landings process, adding new requirements to the state paper fish ticket system would fail to address the Purpose and Need for this action because doing so would not improve the timeliness of catch accounting and enforcement capabilities in the fishery. Adding new requirements to the state paper fish ticket system would also cause several logistical challenges in managing the sablefish fishery: sablefish landings data would not be uploaded into the Pacific Fisheries Information Network (PacFIN) database at a faster than current rate, there would continue to be a lag time of several months between when the landings occur and when the data are available, and further augmenting paper fish ticket recording requirements would be disruptive to state data collection and management practices. Therefore, this suboption has been considered but rejected from further analysis.

The action alternatives originally included language that spoke to how the catch data recorded on the electronic tickets would be used on the back end ("That Tier Permits be loaded into the IFQ Vessel Account System with deductions made as appropriate when a tier delivery is made and recorded on the E Fish Ticket"). This language was premature and overly restrictive; how the data are processed and made available to end users is largely an implementation issue and it may be premature to discuss such implementation issues this early in the process. Therefore, this portion of the action alternatives has been considered but rejected from further analysis.

2.2 Own/ Control Limit Alternatives

For the permit counting criteria for the own/control limit, the alternatives are No Action and two action alternatives, which are summarized here and described in more detail in the following sections. For all alternatives, the own/control limit is 3 permits. The criteria for counting a permit toward that limit varies among the alternatives.

<u>Alternative </u>1: (No Action) The control limit to own and hold is 3 permits. Any level of permit ownership would count as 1 permit towards the limit of 3 permits. Additionally, any permits registered to a vessel, wholly- or partially-owned by the entity, would count toward the three permit limit. Select permit owners are grandfathered in with more than 3 permits based on what they owned as of November 1, 2000. Any group ownership interest in the permit results in a permit count of 1 being attributed to each group member. Permits acquired after November 1, 2000, can only be owned by an individual.

<u>Alternative 2a (Preliminary Preferred Alternative)</u>: No Action for permit ownership (any percentage ownership in a permit is a count of 1); however, holding a permit is counted only if the vessel owner has a greater than 20% share. Partial vessel ownership is capped at two vessels, i.e. the 20% or less ownership in a vessel exemption could only be used twice. **After this two-permit exception is reached, then any permits registered to a vessel, wholly- or partially-owned by the entity, would count toward the three permit limit, as described under No Action**.[6]

Bolded text is a staff recommended addition to clarify the alternative and requires Council approval before becoming part of the formal option.

<u>Alternative 2b</u>: No Action for permit ownership (any percentage ownership in a permit is a count of 1); however, holding a permit is only counted if the vessel owner has a greater than <u>30%</u> share. Partial vessel ownership is capped at two vessels, i.e. the 30% or less ownership in a vessel exemption could only be used twice. **After this two-permit exception is reached, then any permits registered to a vessel, wholly- or partially-owned by the entity, would count toward the three permit limit, as described under No Action**.6

Bolded text is a staff recommended addition to clarify the alternative, requiring Council approval before becoming part of the formal option.

Under the action alternatives, the 20 and 30 percent vessel ownership is a threshold for determining whether the permits registered to that vessel should count against the vessel owner's

[6] Unless modified by the action alternative, all other provisions of No Action would continue, including the three-permit limit, grandfather provisions for permit owners with more than 3 permits as of November 1, 2000, and rules for attributing permit control to individuals who participate in group ownership of a permit.

own/control limit. The 20 percent threshold was chosen because this would allow vessels that also participate in the Alaska sablefish fishery to maintain 20 percent ownership in vessels that also participate in the West Coast primary fishery without triggering the control limit. The thirty percent threshold was chosen for comparison purposes. A percentage threshold above thirty percent was not added to the range of alternatives because the advisory bodies and Council felt that a higher threshold went beyond addressing the scope of the issue and could potentially result in unwanted consolidation within the West Coast fishery. A percent threshold lower than 20 percent was not considered because a lower threshold would not adequately address the need for this measure (to accommodate overlap between the Alaska sablefish fishery and the West Coast primary fishery). For Alternatives 2a and 2b, staff has provided some new strawman suboptions for Council consideration; a more detailed description of the alternatives follows.

2.2.1 No Action Alternative

Alternative 1: (No Action) The control limit to own and hold is 3 permits. Any level of permit ownership would count as 1 permit towards the limit of 3 permits. Additionally, any permits registered to a vessel, wholly- or partially-owned by the entity, would count toward the three permit limit. Select permit owners are grandfathered in with more than 3 permits based on what they owned as of November 1, 2000. Any group ownership interest in the permit results in a permit count of 1 being attributed to each group member.

Under No Action, the criteria for determining permit control are: (1) any share in the ownership of a permit and (2) any share in the ownership of a vessel to which a permit is registered. Any shares of ownership in these two situations cause the involved permits to count against an individual's permit limit. Unless grandfathered, a permit must be owned by an individual. In contrast to permit ownership requirements, vessel ownership (i.e., permit holder) was not grandfathered and may be owned by an individual, partnership, or corporation. As an example: the partnership of Mary and Mike Smith own a tier permit (Permit 1 in Figure 2-1) and have registered it to the fishing vessel Fairweather which they also own. As a result, each of them would be considered to have individually incurred a count of one permit towards the 3 permit limit, and the partnership also has a count of one towards the limit. Similarly, Group Z (owned by John Doe and his partners) has 20% ownership of the fishing vessel Fairweather registered to the permit owned by Mary and Mike Smith. Group Z accrues a count of one permit held towards the three-permit limit AND John Doe and each of his partners accrue a count of one permit held towards the three permit limit. Note that if Group Z owned another permit and vessel (Permit 2 and the vessel Foulweather in Figure 2-2), that permit would not count against the Smith's since the Smiths do not have an ownership interest in Group Z, Permit 2, or the vessel Foulweather.

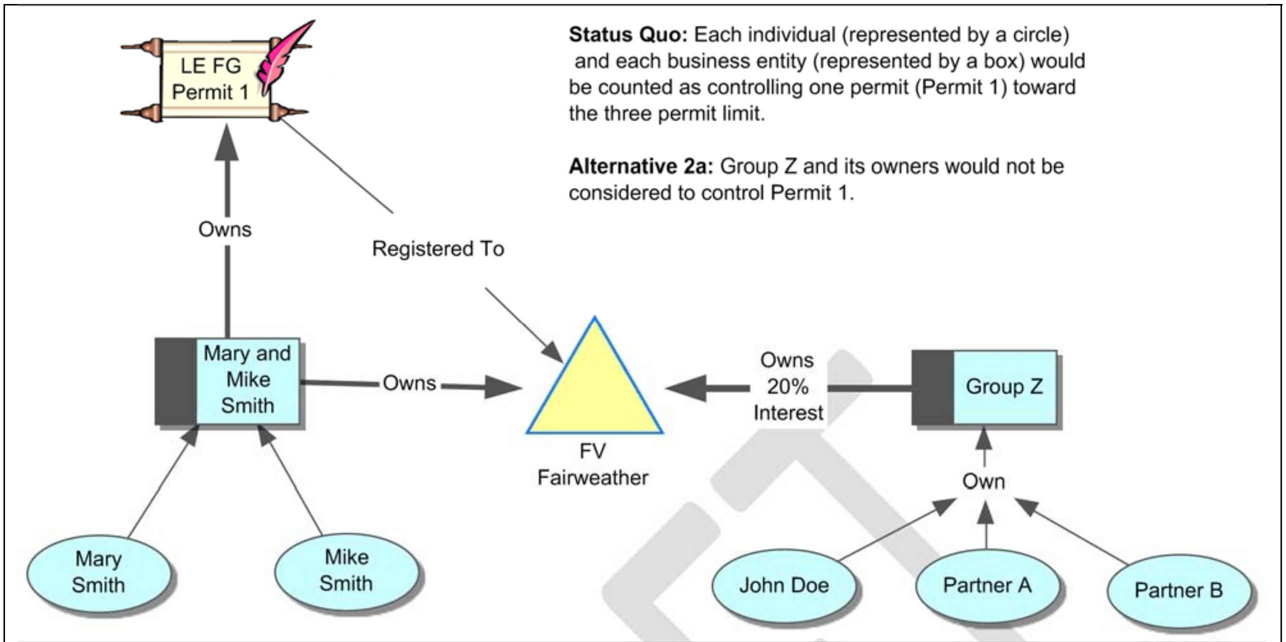

Figure 2-1. Permit counting under No Action and Alternative 2a with two business entities, one vessel, and one permit.

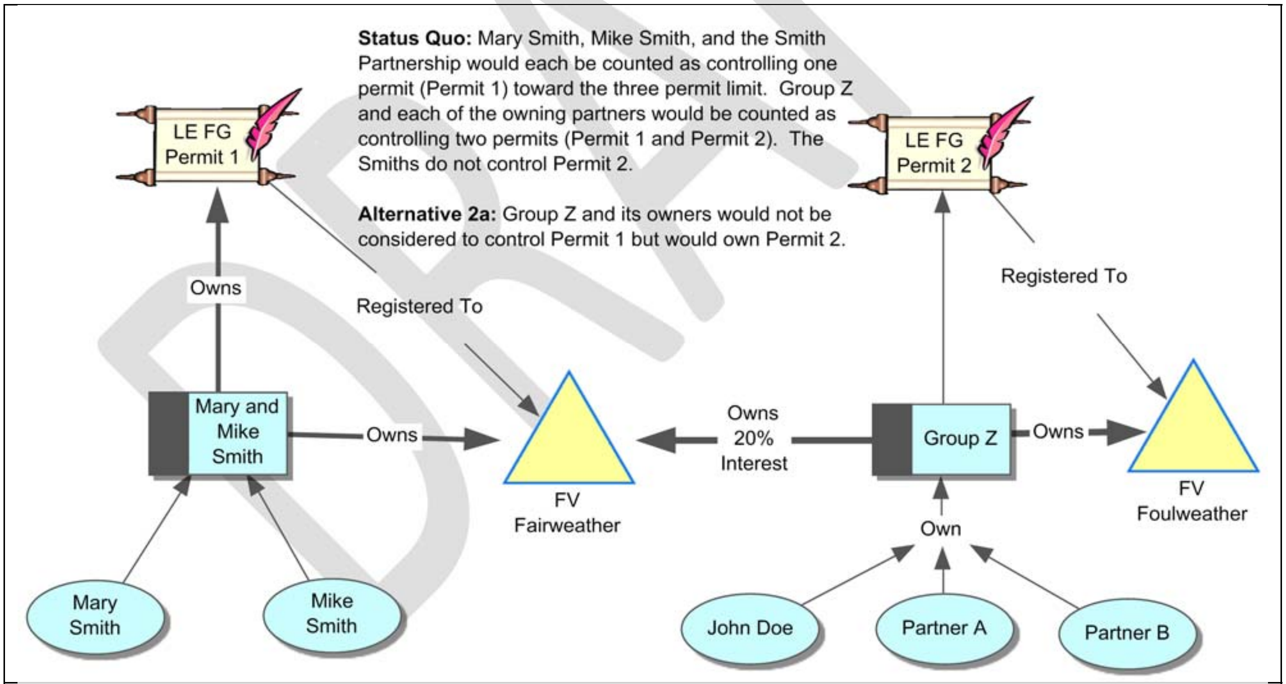

Figure 2-2. Permit counting under No Action and Alternative 2a with two business entities, two vessels, and two permits.

2.2.2 Action Alternatives

Alternative 2a (Preliminary Preferred Alternative): No Action for permit ownership (any percentage ownership in a permit is a count of 1); however, holding a permit is counted only if the vessel owner has a greater than 20% share. Partial vessel ownership is capped at two vessels, i.e. the 20% or less ownership in a vessel exemption could only be used twice. **After this two-permit exception is reached, then any permits registered to a vessel, wholly- or partially-owned by the entity, would count toward the three permit limit, as described under No Action**. 6

Bolded text is a staff recommended addition to clarify the alternative, requiring Council approval before becoming part of the formal option.

At its April 2014 meeting, the Council selected Alternative 2a as its preliminary preferred alternative (PPA). The staff recommended addition was not provided at that time, nor were the suboptions provided below.

Under Action Alternative 2a, the criteria for determining permit control are: (1) any share in the ownership of a permit (i.e. same as No Action), and (2) more than a twenty percent share in the ownership of a vessel to which a permit is registered. Whereas under the No Action example in Figure 2-1, Group Z and all of the owners of Group Z would each accrue a count of one permit held toward the 3 permit limit, under Alternative 2a neither Group Z nor any of its owners would incur a count for Permit 1 because their ownership of the vessel Fairweather is only 20% (i.e. is less than the vessel ownership threshold at which the associated permit would count). If Group Z owned 21% of Fairweather, then the Group would incur a count of one. The count incurred by each individual would depend on the method for assessing individual and collective counts, i.e. the method used to count percent interest which accrues to an individual when that interest accrues through a legal entity such as a corporation. For example, if Group Z is a corporation in which three individuals equally share in ownership, would the interest that Group Z has in a vessel pass through in whole to the individuals, or would a *pro rata* rule apply under which the individuals' share in ownership of the vessel would be determined by their share in ownership of Group Z. If it passes through in whole, then if Group Z owns 20 percent of a vessel, each individual would be considered to own 20 percent of the vessel If the *pro rata* rule applies, then each individual would be considered to own 6.66 percent of the vessel (one third of 20 percent).[7]

Individual and Collective Suboptions

As just described, there are at least two approaches for determining how the ownership interest held by an entity such as a corporation or partnership accrues to the individual owners of that entity. Strawman suboptions for Council consideration are as follows:

Strawman Suboption (1) Entire Ownership Interest Passes Through – If an entity owns a vessel, any individuals with a share in the ownership of that entity are counted as having the same share in ownership of the vessel as the entity has (e.g., if an entity owns 50 percent of a vessel, then for purposes of evaluating the three permit control limit all

[7] As with No Action, no permits owned by Group Z would be counted against the Smith partnership, collectively or individually, because Group Z has no ownership in the Smith partnership.

individuals who own that entity are counted as having 50 percent ownership in that vessel).

Strawman Suboption (2) Pro-Rata Ownership Interest Passes Through – If an entity owns a vessel, any individuals with a share in the ownership of that entity are counted as having a share in ownership of the vessel proportional to their actual share in ownership of the entity (e.g., if a corporation owns 50 percent of a vessel, and two individuals each own 50 percent of the corporation then for purpose of evaluating the three permit control limit those two individuals are each counted as having 25 percent ownership in that vessel). [This approach is the same as that used in the Trawl Rationalization Program.]

Coordinated Ownership

Under Action Alternative 2a, the three owners of Group Z could each individually own up to 20% of the Fairweather (60% in total) without incurring a count for controlling Permit 1, so long as Group Z itself did not have any ownership. This situation is illustrated in Figure 2-3. The Council may wish to consider a suboption to limit this means of control.

Strawman Suboption on Coordinated Ownership: If individuals participating in the ownership of an LEFG entity (an entity which controls an LEFG permit) collectively own more than 40% of a particular vessel (i.e. their individual shares of ownership in a vessel sum to more than 40%), then any LEFG permits registered to that vessel will count against their three-permit control limits, regardless of the provision that exempts from the permit count ownership amounts of less than 20 percent for up to two vessels.

Other versions of this suboption could replace the 40% limit with some other limit.

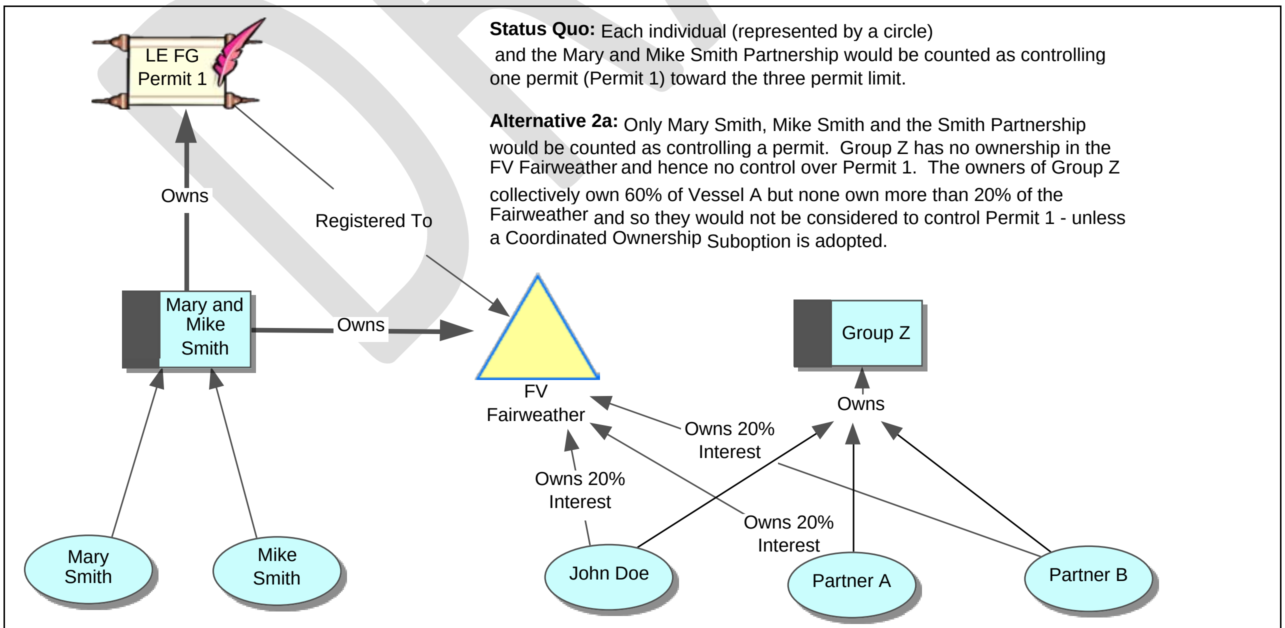

Figure 2-3 Permit counting under No Action and Alternative 2a when vessel owners participate in ownership of a business entity but hold vessel ownership outside that business entity.

Alternative 2b: No Action for permit ownership (any percentage ownership in a permit is a count of 1); however, holding a permit is only counted if the vessel owner has a greater than 30% share. Partial vessel ownership is capped at two vessels, i.e. the 30% or less ownership in a vessel exemption could only be used twice. **After this two-permit exception is reached then any permits registered to a vessel, wholly- or partially-owned by the entity, would count toward the three permit limit, as described under No Action**.[6]

Bolded text is a staff recommended addition to clarify the alternative, requiring Council approval before becoming part of the formal option.

Alternative 2b would perform the same as Alternative 2a but with a 30% threshold. Similar suboptions could be considered.

2.2.3 Alternatives Considered But Rejected From Further Analysis

The following alternatives were considered but have been rejected from further analysis because they are administratively burdensome to implement and track (Alternative 3), or because they weaken the control limits beyond what is needed to address the purpose and need for this action (Alternatives 4, 5, and 6). If the control limits were revised to the extent that Alternatives 4 through 6 would allow, this could undermine the purpose of having control limits in place, namely to maintain the owner-operator nature of the fleet.

Alternative 3: Maintain a three permit limit but calculate control based on percentage ownership of permits and vessels. Total ownership (permit ownership and holdership) is capped at 300%. 1st and 2nd generation owners would be limited to a total of 300 percent. (The intent being to limit total ownership to 3 permits which is status quo.)

For example, John Doe wholly owns GF0001 and 20% of the vessel Fairweather. Fairweather is registered to GF0001 and GF0002. John Doe has a count of 120%. Another possible example: The partnership of Mike and Mary Smith own 3 permits. As such, Mike and Mary Smith, as a partnership, have 300% of total ownership, which is the limit. However, Mike as an individual has 150%, as does Mary.

Alternative 4: Increase the own and hold limit to 6 permits. Partial or any percent ownership or holdership is a count of 1 towards the limit of 6. (Permit counts are determined as under No Action.)

For example, John Doe owns GF0001, GF0003, and 20% of the vessel Fairweather. Fairweather is registered to GF0001, GF0002, and GF0004. John Doe owns 2 permits and holds 2 additional permits due to partial ownership of Fairweather for a total count of 4.

Alternative 5: No Action on permit owner (no one may own more than 3 permits unless grandfathered in). Cap the number of tier permits an entity may register to a vessel at 3 permits. Cap the number of limited entry fixed gear tier vessels an entity can own at three. The maximum own and hold limit is effectively increased to 12 permits (an entity could own 3 permits and have partial or total ownership of three vessels each of which are registered to three different permits owned by others).

For example, John Doe owns GF0001, GF0002, and GF0003. Mr. Doe also owns 20% of the vessel Alpha, 10% of the vessel Beta, and 30% of the vessel Gamma. Alpha is registered to GF0004, GF0005, and GF0006; Beta is registered to GF0007, GF0008, and GF0009; and Gamma is registered to GF00010, GF00011, and GF00012. John Doe owns 3 permits and has partial ownership of 3 vessels that each hold 3 permits; his total count is 12. In this example, Doe could not register his own permits to any other vessels he owns beyond Alpha, Beta, and Gamma, but he could lease the additional permits out to other vessels. He has maxed out on the number of vessels he has an ownership interest in and they are in the primary fishery. Also, Alpha, Beta, and Gamma are at the limit of 3 permits registered to them during the primary season; they cannot remove a permit mid-season and add a 4th permit.

Alternative 6: No Action on 3-permit limit, but the calculation is based only on ownership of permits; holding or leasing a permit/ ownership in the vessel would not count towards the 3 permit limit. A person could own 3 permits and hold any number of additional permits by registering the vessel(s) they own to permits owned or leased by other persons.

For example, John Doe owns GF0001, GF0002, and GF0003, and 20% of the vessel Fairweather. Fairweather is registered to GF0004, GF0005, and GF0006. John Doe owns 3 permits and his partial ownership of a vessel registered to other permits does not affect his own and hold limit; his total count is 3.

Chapter 3 Affected Environment

3.1 Physical Environment

This section describes the current condition of the physical environment that may be affected by this action. The effects of implementation of the action alternatives on the physical environment are presented in Chapter 4.

Sablefish (*Anoplopoma fimbria*) is a component of the groundfish fishery managed under the FMP that occurs in the United States Exclusive Economic Zone (US EEZ) from three to 200 nautical miles off the coasts of Washington, Oregon, and California. The offshore ocean is comprised of many diverse habitats, including rocky and non-rocky shelf regions, deep submarine canyons, and continental slopes and basins. Sablefish are primarily caught in commercial fisheries with trawl, longline, and pot gear. Longline gear in the groundfish fisheries has been shown to have little impact on habitat, and the primary sablefish fishery is shorter in duration and in geographic scope than the groundfish fishery. The longline and pot gear used by this fishery may come in contact with the bottom habitat.

Physical topography off the U.S. West Coast is characterized by a relatively narrow continental shelf. The 200 m depth contour shows a shelf break closest to the shoreline off Cape Mendocino, Point Sur, and in the Southern California Bight, and widest from central Oregon north to the Canadian border as well as off Monterey Bay. Deep submarine canyons pocket the EEZ, with depths greater than 4,000 m common south of Cape Mendocino.

Sablefish are abundant in the North Pacific, from Honshu Island, Japan, north to the Bering Sea, and southeast to Cedros Island, Baja California. Large adults are uncommon south of Point Conception. In the North Pacific, sablefish is considered an inner-continental shelf-bathybenthal species. Adults are found as deep as 1,900 m, but are most abundant between 200 and 1,000 m. Survey data for the North Pacific indicate that almost all sablefish were taken at depths <700 m. However, off southern California, sablefish were abundant to depths of 1,500 m.

3.2 Biological Environment

This section describes the current condition of biological resources that may be affected by these actions. The effects of implementation of the action alternatives on the biological resources are presented in Chapter 4.

3.2.1 Groundfish Stocks

The current status of the groundfish stocks managed under the FMP was most recently analyzed in the Proposed Harvest Specifications and Management Measures for the 2013-2014 Pacific Coast Groundfish Fishery (2013-14 Specifications EIS); that document is incorporated by reference here. For the purposes of this document, this section will be limited to information regarding sablefish and co-occurring groundfish species.

Sablefish was last assessed in 2011 and is described as a precautionary zone stock in the 2013-14 Specifications. The estimated spawning biomass in 2011 is 60,957 mt (95 percent interval ranges broadly from 16,418 mt to 105,495 mt). The relative spawning biomass is estimated to be at 33 percent of unfished biomass levels in 2011 (~95 percent intervals range from 18-49 percent). It seems that large 1999 and 2000 year classes briefly slowed the rate of stock decline between 2002 and 2005. An above-average 2008 cohort is currently moving through the population; however, it has yet to mature, and therefore is not currently contributing to the trend in spawning biomass.

The available data for sablefish are largely uninformative about the absolute size and productivity of the stock. Uncertainty in the properties of current ageing methods (both potential bias and imprecision), as well as relatively sparse fishery sampling, affect the reliability of age data. Because sablefish grow very rapidly and reach near asymptotic length in their first decade of life, length-frequency data are not particularly informative about historical patterns in recruitment. The patterns observed in historical sablefish recruitment suggest that stock trajectory (via shifts in recruitment strength) is closely linked to productivity regimes in the California Current. Uncertainty in future environmental conditions should be considered a large source of uncertainty in all projections of stock status. More detailed information on the stock status can be found in the stock assessment document (Stewart, *et al.* 2011b).

Based on the 2012 groundfish mortality reports, darkblotched rockfish was the most frequently discarded bycatch (that is also an overfished stock/ rebuilding species) in the coastwide limited entry fishery at 8.23 mt of bycatch. In the limited entry trawl fishery, sablefish are targeted as part of a deepwater complex with Dover sole and thornyheads (also called DTS for Dover-

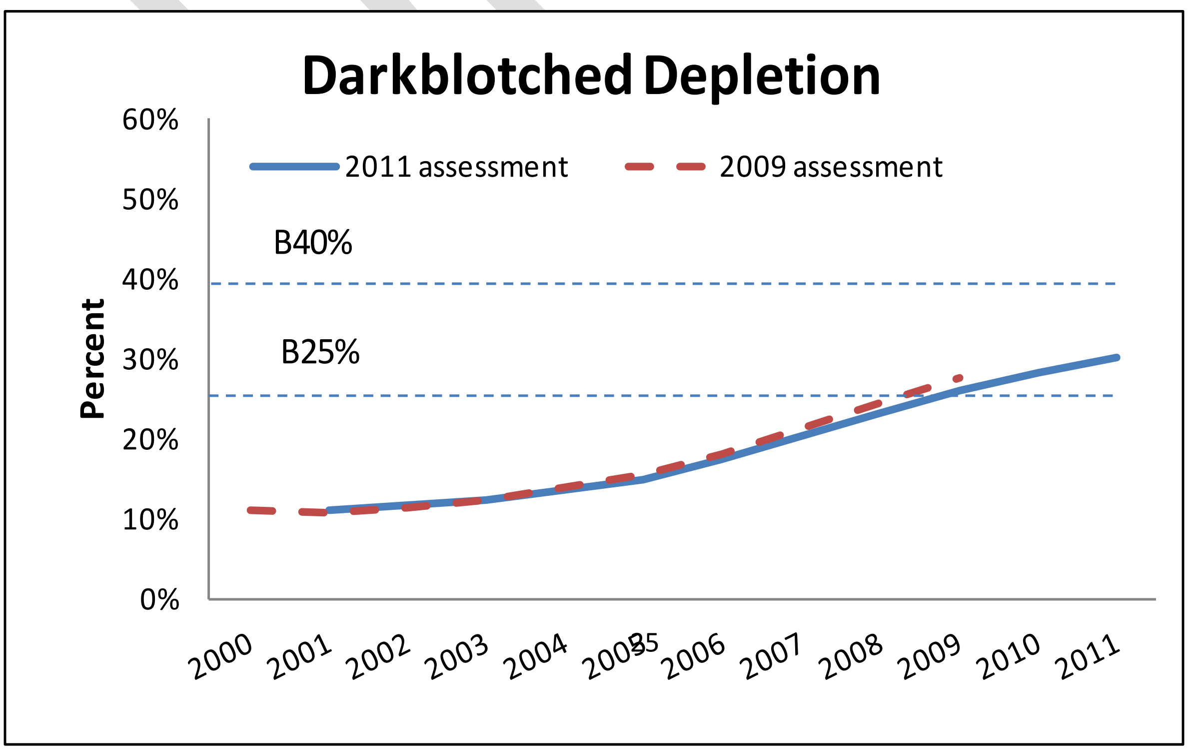
Thornyheads-Sablefish).The following description of the status of the stock is taken from the 2013-14 Specifications.

Darkblotched Rockfish, Dover Sole, and Thornyheads
Stephens et al. (2011) prepared a stock assessment update for darkblotched rockfish in the U.S., Vancouver, Columbia, Eureka, and Monterey areas using the Stock Synthesis model version 3.21d. The darkblotched rockfish population in these areas was modeled as a single stock. The information presented in this section was summarized from the 2011 stock assessment update.

The biomass (1+ age fish) in 2011 was estimated to be 13,926 mt. The recruitment pattern for darkblotched rockfish is highly variable among years. With the exception of the 1999, 2000, and 2008 year classes, recruitment levels (age-0 recruits) between the 1980s and 1990s were generally poor when compared with historical average recruitment levels. Darkblotched rockfish continues to show an increasing trend with the point estimate for the depletion of the spawning output at the start of 2011 at 30.2 percent of its unfished biomass. The assessment suggests that the west coast darkblotched stock is above the overfished threshold, but below the management target of $B_{40\%}$. The spawning output seems to have increased steadily over the past 10 years. Since 2003, overfishing is estimated to have occurred once, with estimated catch exceeding the acceptable biological catch (ABC) (now referred to as the overfishing limit (OFL)) by 1 mt in 2004.

The major sources of uncertainty in the updated darkblotched assessment are the estimated natural mortality and the assumed steepness of the stock-recruitment relationship. Sources of uncertainty not addressed in the model include the degree of connection between the populations of darkblotched rockfish off British Columbia and the U.S. West Coast; the effect of climatic variables on recruitment, growth, and survival of darkblotched rockfish; and gender-based differences in survival. More detailed information on the stock status can be found in the stock assessment update (Stephens, *et al.* 2011).

Figure 3-1 Darkblotched Depletion.



Dover sole, as well as longspine and shortspine thornyhead, were listed as healthy stocks in the 2013-14 Specifications EIS.

3.2.2 Non-groundfish Species

A thorough description of non-groundfish species including Pacific and California halibut, coastal pelagic species, Dungeness crab, highly migratory species, pink shrimp, and other species may be found in the 2013-14 Specifications EIS.

3.2.3 Protected Species

Protected species are species listed under the ESA, the Marine Mammal Protection Act (MMPA), the Migratory Bird Treaty Act (MBTA), and EO 13186. A thorough description of protected species including ESA-listed salmon and steelhead, green sturgeon, eulachon, marine mammals, seabirds, and other species may be found in the 2013-14 Specifications EIS.

3.2.4 The Marine Ecosystem and Essential Fish Habitat

In the North Pacific Ocean, the large, clockwise-moving North Pacific Gyre circulates cold, sub-arctic surface water eastward across the North Pacific, splitting at the North American continent into the northward-moving Alaska Current and the southward-moving California Current. Along the U.S. West Coast, the surface California Current flows southward through the U.S. West Coast EEZ. The California Current is known as an eastern boundary current, meaning that it draws ocean water along the eastern edge of an oceanic current gyre. Along the continental margin and beneath the California Current flows the northward-moving California Undercurrent. Influenced by the California Current system and coastal winds, waters off the U.S. West Coast are subject to major nutrient upwelling, particularly off Cape Mendocino (Bakun, 1996). Shoreline topographic features such as Cape Blanco, Point Conception and bathymetric features such as banks, canyons, and other submerged features, often create large-scale current patterns like eddies, jets, and squirts. Currents off Cape Blanco, for example, are known for a current "jet" that drives surface water offshore to be replaced by upwelling sub-surface water (Barth, et al, 2000). One of the better-known current eddies off the West Coast occurs in the Southern California Bight, between Point Conception and Baja California (Longhurst, 1998), wherein the current circles back on itself by moving in a northward and counterclockwise direction just within the Bight. The influence of these lesser current patterns and of the California Current on the physical and biological environment varies seasonally (Lynn and Simpson, 1987) and through larger-scale climate variation, such as El Nino-La Nina or Pacific Decadal Oscillation (Longhurst, 1998).

The effects of climate on the biota of the California Current ecosystem have been recognized for some time. Climate change and ocean acidification pose major additional stresses to managed fisheries on top of fishing mortality (IPCC 2007; IPPC 1995; WBGU 2006). Heat stress from warming waters and changes in the timing and magnitude of upwelling and associated nutrients and prey are just two examples. As climate change proceeds, there will likely be greater departure from historic population trends and increased uncertainty and risk in fisheries management. In addition, the effects of fishing pressure may unexpectedly magnify the effects of climate change and vice-versa (Harley and Rogers-Bennett 2004; Hsieh, *et al.* 2008; IPCC 2001).

EFH has been described within the project area for highly migratory species, CPS, salmon, and groundfish. The MSA defines EFH to mean "those waters and substrate necessary to fish for spawning, breeding, feeding or growth to maturity" (16 U.S.C. 1802 sec. 3(10)). Regulatory guidelines elaborate that the words "essential" and "necessary" mean EFH should be sufficient to "support a population adequate to maintain a sustainable fishery and the managed species' contributions to a healthy ecosystem." The regulatory guidelines also establish authority for Councils to designate Habitat Areas of Particular Concern (HAPC) based on the vulnerability and ecological value of specific habitat types. Councils are required to minimize, to the extent practicable, the adverse effects of fishing on EFH, when information indicates that fishing activities may adversely affect EFH. NMFS works through a consultation process to minimize adverse effects of nonfishing activities (50 CFR 600 subpart J). Refer to Volume 1 of the Council's 2008 groundfish SAFE document for more information. Groundfish EFH is currently undergoing an EFH review.

3.3 Socio-economic Environment

This section describes the current socio-economic environment that may be affected by these measures. The effects of implementation of the action alternatives on the socio-economic environment are presented in Chapter 4.

3.3.1 Participants in the Fixed Gear Sablefish Fishery

Participants in the fixed gear sablefish fishery (LE or OA) that are likely to be affected by these measures fall into one of several groups:

- Owners of LEFG permits, a subset of which would be owners of LEFG permits that have a sablefish endorsement for pot or longline gear (i.e. participants in the primary sablefish fishery north of 36ºN latitude);
- Owners of vessels registered for use with LEFG permits that participate in the LEFG sablefish fishery;
- Participants in the DTL OA fishery;
- Buyers, processors, and first receivers of sablefish landings in the primary and DTL sablefish fishery; and
- Crew that work on vessels that fish in the sablefish fishery.

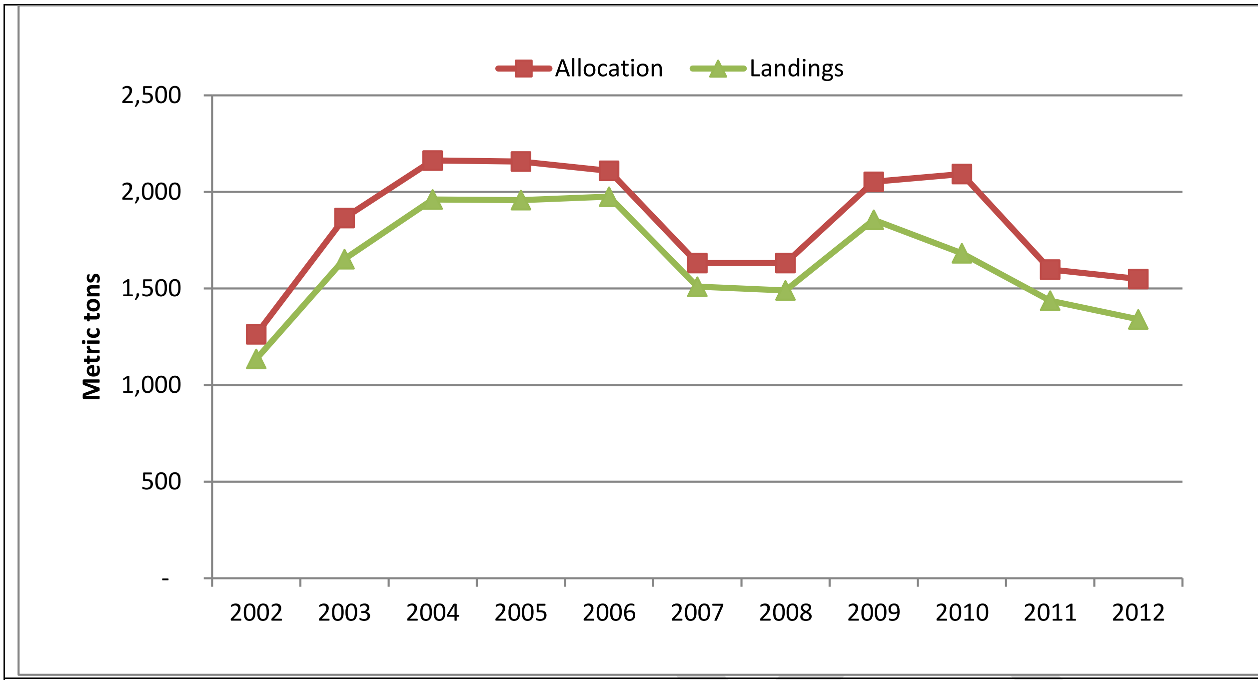


Figure 3-2. The LEFG sablefish primary season allocation and landings (2002 through 2012).

3.3.2 Participants in Other Fisheries (Shorebased Trawl IFQ and Alaska Program)

As mentioned previously, the other two fisheries whose participants may be affected by these actions are the Shorebased Trawl IFQ fishery and the Alaskan fixed gear sablefish and halibut IFQ program (Alaska program). Participants in these fisheries fall into one of several groups:

- Owners of trawl endorsed limited entry permits that participate in the shorebased IFQ program (not mothership or catcher/ processor endorsed trawl permit owners);
- Owners of vessels registered to limited entry trawl permits that harvest IFQ species with trawl or fixed gear for delivery to shorebased first receivers;
- Owners of quota share (QS) permits;
- Shorebased IFQ first receivers with a first receiver site license eligible to receive IFQ landings;
- Initial recipients of Alaska sablefish IFQ that qualify for the owner on board exemption by owning partial interest in a vessel that is also used to fish LEFG permits on the West Coast; and
- Owners of vessels that harvest both sablefish in the Alaska program, as well as sablefish in the West Coast LEFG sablefish fishery.

3.3.3 Communities

The groundfish fishing communities of Washington, Oregon, and California are described in detail in the 2013-14 Specifications EIS at 3.2.2. Fishing communities specific to the LEFG sablefish fishery are described in the Pacific Coast Groundfish Limited Entry Fixed Gear Sablefish Permit Stacking Program Review document which will be incorporated by reference here following final adoption by the Council.

3.3.4 State and Federal Management and Enforcement Agencies

The state agencies in Washington, Oregon, and California are currently responsible for tracking sablefish landings through collection of paper landing tickets. State and Federal enforcement agencies are responsible for ensuring compliance with existing and future regulations. NMFS is responsible for tracking allocations and for implementing any administrative requirements associated with these fisheries and as such will incur any costs associated with implementation.

Chapter 4 Environmental Consequences - Impacts of the Proposed Action Alternatives on the Affected Environment

4.1 Impact Mechanisms

In Section 4.1 impact mechanisms are discussed, and in following sections the effects of the impact mechanisms on each resource of concern are identified, including physical, biological, and socio-economic. Impact mechanisms are the first level expected instrumental effects of the action with only such interpretation of meaning as is necessary to explain the mechanism. The instrumental impacts mechanisms are given their full policy meaning as the effects on each resource area are described in each subsequent section. As a simple example, consider as an impact mechanism an event in which a vessel strikes a reef, a crewman nearly loses his life, oil is spilled and coral damaged. These are the instrumental impact mechanisms. Having described the event in a single comprehensive fashion, the meaningful impacts of concern can then be discussed such as the loss to the economy and a business of the capital asset of a fishing vessel; the physical and emotional trauma to the crew member, his family, and rescue personnel; the effect of the mechanical damage to the reef and oil spill on stock productivity, future harvests, and ecosystem services. The boundary between impact mechanism and impact to the resources can be fuzzy, particularly where the impact mechanisms primarily operates through the human system as in the case of the actions considered in this EA. However, particularly where issues are complex, it is useful to provide the reader with a single concise starting point and initial understanding of the expected dynamics associated with the events to be evaluated, from which the reader can then evaluate the conclusions drawn with respect to the impact on each resource. This approach reduces the need for partial repetitive and piecemeal explanations which sometimes result when discussion of the impact mechanisms is more dispersed through the document, leaving the reader without really ever having achieved a comprehensive understanding of the dynamics being evaluated. The impact mechanism section provides a clear opportunity for the reader to evaluate for him or herself the premises which underlie the entire analysis before proceeding with consideration of the evaluation of the impacts on each individual resource.

4.1.1 Electronic Fish Ticket

The action alternatives would implement a Federal requirement that an electronic fish ticket be used to document sablefish landings in either the primary LEFG sablefish fishery, the primary and LEFG DTL fisheries, or in the primary and LEFG and OA DTL fisheries. This would be in addition to the existing state reporting requirements. The impacts from this action may be divided into two types of categories: the physical and biological, and the socio-economic. These are discussed further in 4.2.1, Effects on the Physical and Biological Environment, and in 4.3.1, Effects on the Socio-economic Environment.

4.1.2 Own/Control Limits

The action alternatives would change the criteria by which it is determined whether an entity controls a limited entry fixed gear (LEFG) permit. Currently, entities are considered to control any permit with which they have some share in the direct ownership plus any permit registered with a vessel in which they have at least a partial ownership interest. For example, if a fisherman owns one vessel and owns two LEFG permits (Fisherman 2 in Figure 4-1), but also holds a partial ownership interest in another vessel (perhaps as security for a loan), then all the permits of the other vessel also count toward that fisherman’s total (in Figure 4-1, for Fisherman 2 a total of four permits, i.e. one in excess of the three-permit limit). Such a situation might also arise for a lender or any other person who takes part ownership in a vessel to secure a loan or other debt, rather than establishing a maritime lien (Figure 4-2). The current accounting rule might be conceptualized as an "all-or-nothing" rule: if an entity has any ownership interest in a vessel then all LEFG permits associated with the vessel count as being under that entity's control.[8] The action alternative would allow entities to have a small percent ownership interest in a vessel without being considered to also be in control of the permits attached to the vessel.

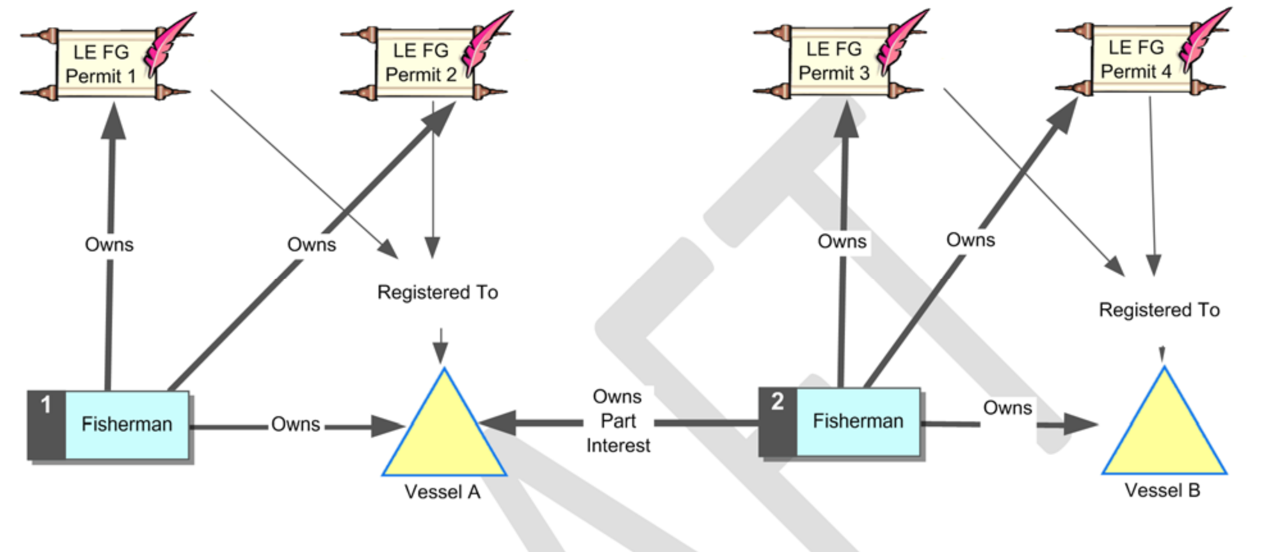

Figure 4-1. Fisherman example--full or partial ownership of a vessel implies control over the limited entry fixed gear (LEFG) permits associated with that vessel, potentially resulting in violation of the three-permit control limit (in this example, four permits for Fisherman 2).

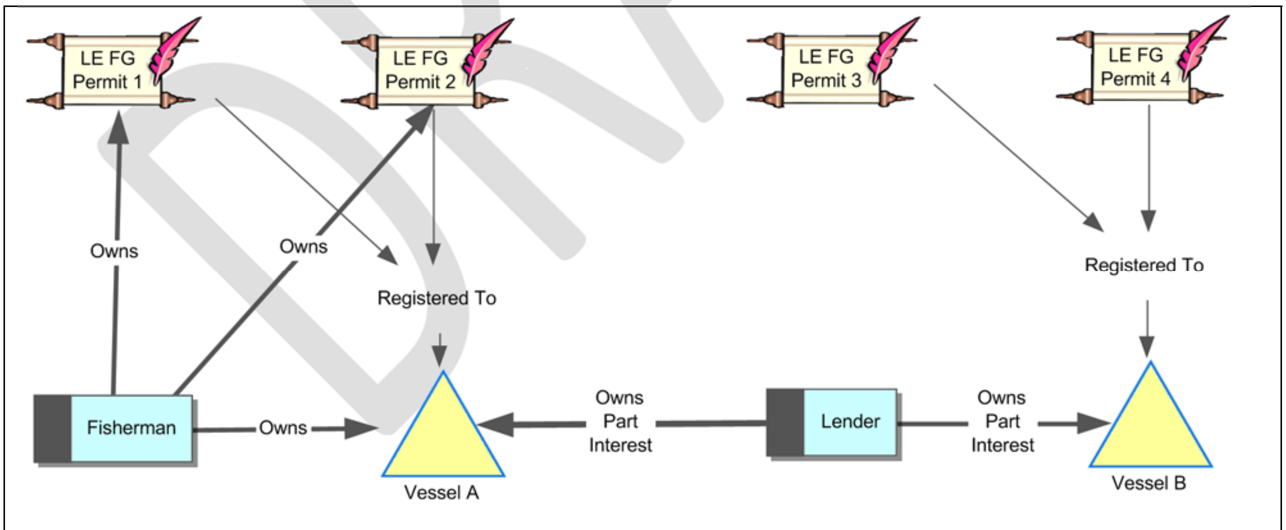

Figure 4-2. Lender example--full or partial ownership of a vessel implies control over the limited entry fixed gear (LEFG) permits associated with that vessel, potentially resulting in violation of the three-permit control limit (in this example, four permits for a lender that secures interest through vessel ownership rather than through a maritime lien).

[8] Direct ownership of a permit is counted in a similar fashion, i.e. any fraction of ownership counts as ownership of the entire permit.

While there are a number of imaginable situations constrained by the current “all-or-nothing” rule, there are primarily two types of situations that have been brought to managers’ attention. Because these are the situations which are currently bumping up against the all-or-nothing rule, they are the most likely indicators of how human activity would change with a change in the constraint. The first situation had to do with a family wanting to bring other members into the fishery by helping them purchase a vessel, essentially by acquiring the vessel and selling it to them. Whether within a family or among fishermen, a frequent practice is that a seller financing a vessel allows the buyer to operate the vessel (to virtually act as owner), but the seller retains an ownership interest until the vessel is fully paid for (at which time the transaction is completed and full vessel ownership transferred to the buyer). However, by maintaining that ownership interest in the vessel for security (regardless of how small), any LEFG permits the vessel buyer attaches to the vessel will also count against the control total for the seller, and potentially put the seller over the cap, if the seller owns another vessel with LEFG permit(s).

In the second situation, rather than to secure financing, the incentive for maintaining ownership in a limited entry fixed gear vessel relates to that vessel’s participation in the Alaskan fixed gear sablefish and halibut IFQ program (Alaska program). In the Alaska program, as in the West Coast sablefish program, there is an IFQ owner-on-board requirement with a grandfather clause exception. In Alaska, most partnerships, corporations, and other non-individual Alaska IFQ owners are required to hire skippers to fish their IFQ and individuals grandfathered in are allowed to hire skippers to fish in their stead. However, to hire a skipper an Alaska IFQ owner must have at least a 20% ownership interest in the vessel on which the IFQ will be fished (50 CFR 679.42). This creates a situation in which vessel ownership established to take advantage of the exception to the owner-on-board requirements of the Alaska program may push an entity over the West Coast LEFG permit control limits if that vessel also fishes in the West Coast sablefish fishery. For example, if an individual that owns a vessel that participates only in the West Coast fixed gear sablefish fishery also has ownership of Alaskan IFQ, then that person may desire to acquire part ownership in a vessel participating in the Alaskan IFQ fishery to take advantage of the Alaskan owner-on-board exception provision. Under such circumstances, any West Coast permits which are attached to the vessel that fishes in the West Coast limited entry fixed gear fishery and also fishes Alaskan IFQ would also count against the individual’s control limit for West Coast LEFG permits, as illustrated in Figure 4-3. In Figure 4-3, Fisherman 2 has a 20% ownership of Vessel A (owned by Fisherman 1) and as a result all permits registered to Vessel A count against Fisherman 2’s three-permit cap, even though Fisherman 2 has no ownership over Fisherman 1’s permits. Also note that while Fisherman 1’s permits registered to Vessel A count against Fisherman 2, Fisherman 2’s permits, registered to Vessel B, do not count against Fisherman 1 because Fisherman 1 has no ownership in Vessel B of Fisherman 2’s permits. A similar situation would pertain to corporations, partnerships, etc. In the Alaska program, these entities are required to hire a skipper to fish their initial allocations of Alaska IFQ.[9]

[9] The Alaska program grandfathered in corporations, partnerships, and other non-individual entities. Their grandfather status will expire with the addition of new owners or the sale of their IFQ. Similarly, the West Coast sablefish tier program grandfathered these entities in a similar fashion and has similar rules for the expiration of those grandfather exceptions.

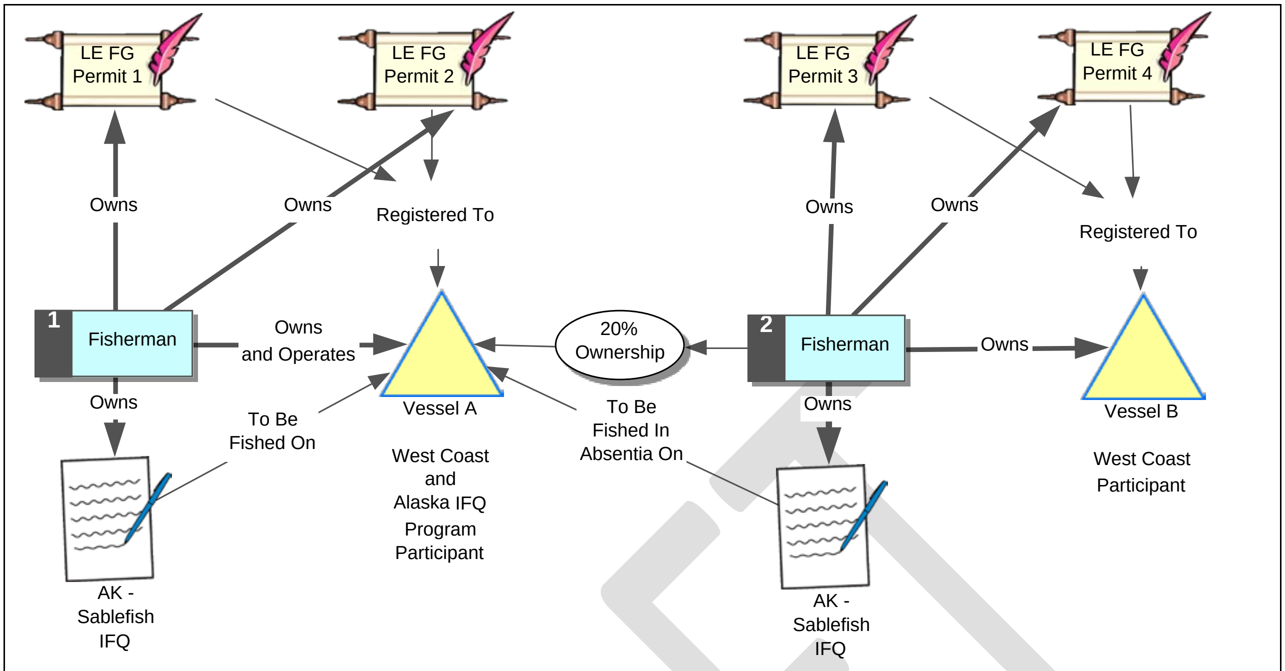

Figure 4-3. Alaska cross participation example--full or partial ownership of a vessel implies control over the limited entry fixed gear (LEFG) permits associated with that vessel, potentially resulting in violation of the three-permit control limit (in this example, four permits for Fisherman 2).

Thus, there seem to be two potential impact mechanisms of particular concern with the all-or-nothing criteria for counting permits toward the control limit:

1. an effect on arrangements that involve financial interests secured through vessel ownership, and
2. an effect on the distribution of limited entry privileges (both Alaska IFQ and LEFG permits) among fishing operations.

The latter of these two situations seem to be of most concern at this time, based on the content of public testimony to the Council.

In addition to these two mechanisms which operate through a change in participant behavior, a third mechanism operates on the administrative side of the program:

3. a change in effort required to comply with and administer the program (submission, collection, and tracking of additional information).

Impact Mechanisms Related to Lending

To date, institutional lenders have not expressed any concerns about financing and the all-or-nothing rule for assessing the three-permit control limit. An action alternative would only affect assessing the three-permit limit with respect to vessel ownership (i.e., it does not change how the control limit would be assessed with respect to direct permit ownership). Institutional lenders likely secure loans against vessels through a *preferred mortgage* and associated maritime lien.

> A preferred mortgage is a mortgage which is given status as a maritime lien. As such it enjoys a certain priority in the event of default. In addition, the Coast Guard is prohibited from making certain changes in documentation including, but not limited to, change of vessel ownership, name, and hailing port without consent of the mortgagee. For this reason, many financial institutions require vessels which are eligible for documentation to be documented and to have preferred mortgages recorded against them.
>
> USCG National Documentation Center (http://www.uscg.mil/nvdc/nvdcfaq.asp#18)

As discussed above, the main lending practice likely to be affected by an action alternative would be that which is reported to occur among industry members (as fishing operations and families secure loans they make to other fishermen by maintaining possession of the vessel being sold until such time as all payments have been made, as described above).

If such within industry arrangements are advantageous over working with an institutional lender, it is likely because it generates some economic advantages that would not be available through an institutional lender. For a vessel seller, providing a buyer direct financing may allow the seller to negotiate a better price. The buyer may gain either through access to financing that would otherwise not be available or through access at a lower cost. A seller's personal knowledge and social connections with the buyer may mean that the transaction is a lower risk than would be perceived by an institutional lender or the seller may have a social interest in the buyer's entry into the fleet. At the same time, the fleet has been operating for over 12 years under the current all-or-nothing control rule and in the interim may have found other ways to achieve similar private financing outcomes.

Thus, with respect to lending, the impact mechanism of an action alternative might be

- **a redistribution of risks, financing transaction costs, and related profits from institutional lenders toward the private parties involved in a transaction, and**
- **more social connections between buyers and sellers than might be the case if borrowers were qualified by institutional lenders.**

Impact Mechanism Related to Distribution of Fishing Privileges

To consider the impact mechanisms with distribution of fishing privileges we will look at three groups of participants:

1. West Coast and Alaska (WC&AK) participants,
2. Alaska only participants (AKO), and
3. West Coast only participants (WCO).

For purposes here: West Coast participation is participation involving control of a West Coast LEFG permit; and Alaska participation involves owning or fishing Alaska IFQ. An AKO participant is one that participates in the Alaska IFQ program and may own a vessel that is partially owned by a West Coast participant but the AKO participant does not have an ownership interest in a West Coast operation, i.e. fishing enterprise active in the West Coast limited entry sablefish fishery.

The WC&AK group can be further divided into

1. those who directly participate only on the West Coast (either with a permit or a vessel registered to permits), fishing their Alaska sablefish IFQ on an AKO vessel without traveling to Alaska (i.e. hiring a skipper to fish their Alaska IFQ for them), and
2. those who individually or with their vessel travel to Alaska to participate in the Alaska fishery in addition to fishing on the West Coast.

For the second subgroup to participate in the Alaska IFQ program, there is no requirement that they have ownership in the vessel that fishes in Alaska. Therefore, with respect to the WC&AK group, the impact mechanism operates directly through the first subgroup of WC&AK participants, those fishing under a grandfather exception to the Alaska owner-on-board provision, which allows them to participate without being present during fishing operations. As a result of the impact on the first subgroup members of the second WC&AK subgroup and AKO participants may subsequently be affected. The owners of approximately 87 percent (Table 4-1) of the West Coast limited entry fixed gear sablefish vessels (84 of 97) might fall in the first subgroup (their vessels do not go to Alaska) but would fall in the second category if they travel there individually or would not be affected if they do not own Alaska IFQ. The owners of the remaining 13 percent of vessels (13 of 97) fall in the second category (their vessels fish on the West Coast and in Alaska, Tables 4-1) and are impacted by a constraint on their ability to fish Alaska IFQ for members of the first group. The WC&AK vessels which travel to Alaska to fish Alaska IFQ could not be hired to fish Alaska IFQ by an entity that has an LEFG permit if the permits registered to that WC&AK vessel would put the hiring entity over its limit.

Tables 4-1. Number of vessels with LEFG permits that participate in Alaska fisheries in 2012.

	Number of Permits Stacked on a Vessel				
	3 Permits	2 Permits	1 Permit	Total	Percent
	Number of Vessels				
Number of Vessels Without Alaska Participation (owners might have Alaska IFQ) [a/]	18	16	50	84	86.6%
Number of Vessels With Known Alaska Participation	3	6	4	13	13.4%
Total	21	22	54	97	

a/ These data provide only a general indication of the magnitude of the number of entities potentially affected by the all-or-none accounting method and Alaska participation requirement. On the one hand, the number of entities affected may be greater than these numbers indicate because there may be more than one owner per vessel affected (if for a single vessel there are multiple owners that each individually own Alaska IFQ). On the other hand, the number may be smaller because: some of these owners may still travel to Alaska on their own, and therefore not need to take advantage of the grandfather clause; some may not qualify under the grandfather clause; and some (many) may not have Alaska IFQ.

The following discussion shows the impact mechanisms of the action alternative is likely to be some degree of increase in consolidation of harvest privileges both in West Coast and Alaska, including:

- **consolidation of Alaskan IFQ on vessels that also participate in the West Coast LEFG fishery (WC&AK participants),**
- **consolidation of West Coast LEFG permits on vessels that fish in both fisheries (WC&AK participants), and**
- **acquisition of West Coast LEFG permits by vessels that previously fished only in the Alaskan IFQ fishery (AKO participants).**

To simplify the discussion, we will first examine the effects with respect to WC&AK operations, starting with operations that have three permits. Then we will examine effects with respect to AKO participants.

Currently, a WC&AK vessel with three LEFG permits cannot hire another WC&AK vessel to fish its Alaska IFQ for it, but could hire an AKO vessel. For a WC&AK operation to participate in the Alaska IFQ fisheries, while taking advantage of the Alaska grandfather exception for the owner-on-board provision, it must acquire ownership in a vessel participating in the Alaska fishery (as indicated in Figure 4-3). If the WC&AK operation has three LEFG permits, it cannot fish its AK IFQ as an absent owner on another WC&AK vessel because acquiring an ownership interest in that vessel would put it over the three permit limit. Therefore, the Alaska IFQ owner with ownership in a WC&AK operation that has three permits would either have to fish its Alaska IFQ from an AKO vessel or participate in the fishery in person (forego use of the grandfather clause). This situation is illustrated on the left hand side of Figure 4-4 and characterized as a constraint on the opportunity of a WC&AK participant to hire a vessel to fish in its Alaska IFQ. .

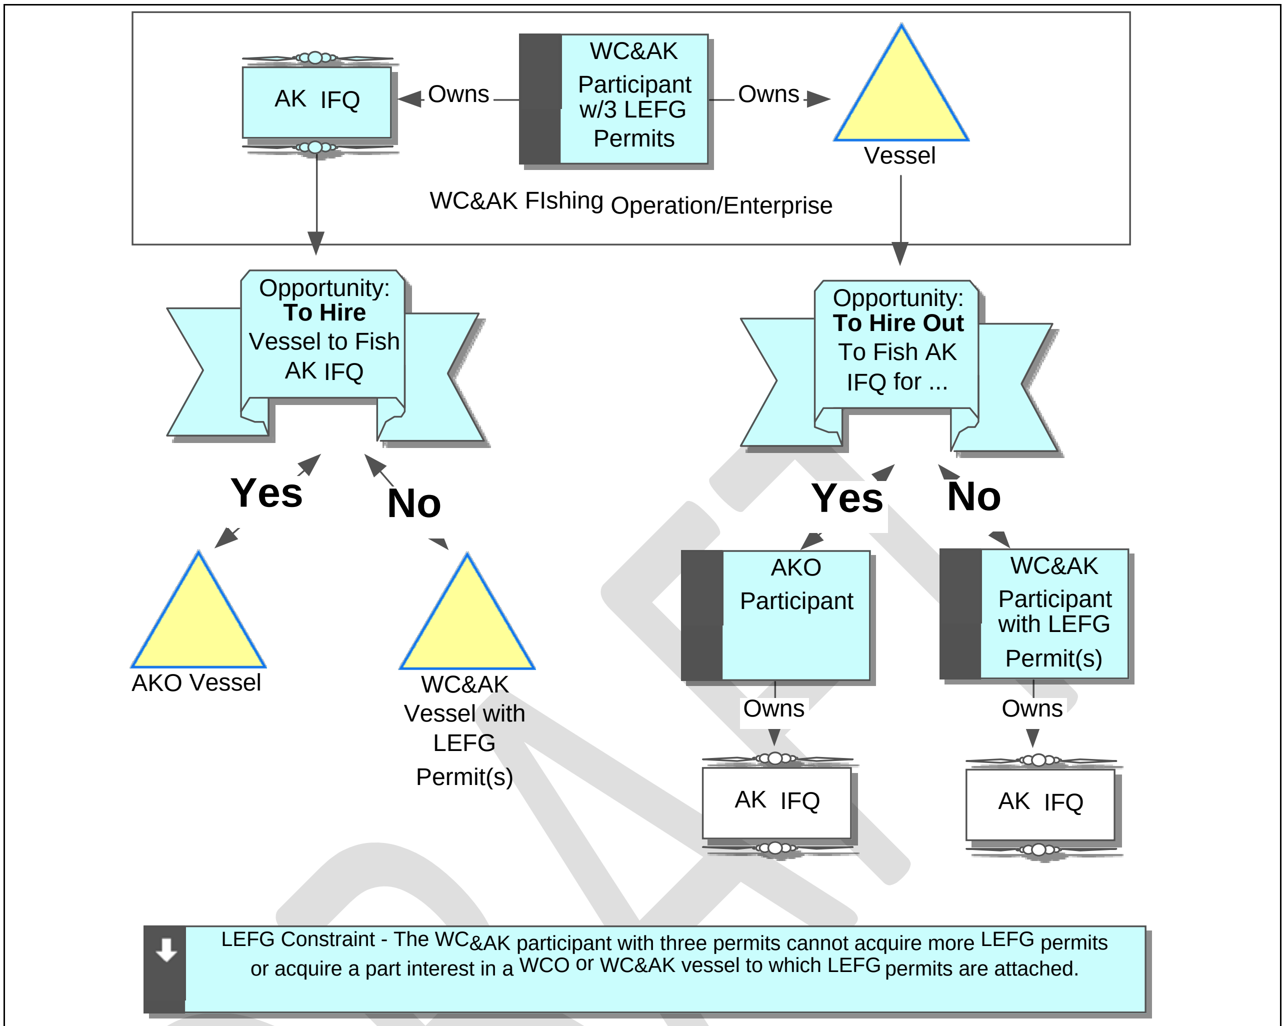

Figure 4-4. Ability of a West Coast and Alaska fishing operation to hire others to fish Alaska IFQ for it or hire out to fish Alaska IFQ for others.

Additionally, under current rules, a WC&AK vessel with three LEFG permits cannot hire out to fish IFQ for another WC&AK vessel. Vessels also have an opportunity to operate as a "hired skipper" in the Alaska IFQ fisheries, fishing the Alaska IFQ for other absent IFQ owners taking advantage of the Alaska grandfather exception to the owner-on-board provisions. A WC&AK vessel with three LEFG permits would not be able to hire out to fish Alaska IFQ for another WC&AK operation because that other operation would have to acquire an ownership in the WC&AK vessel with three permits, which would put it over the three permit limit. This is illustrated on the right hand side of Figure 4-4.

WC&AK participants with fewer than three LEFG permits would have more flexibility to hire, or hire out to other WC&AK vessels to fish Alaska IFQ, with the number of other vessels with which they could work depending on the number of permits owned by each party. Table 4-2 illustrates the combinations of WC&AK participants and AKO participants that would be allowed to operate and not operate together under No Action.

Tables 4-2. No Action: ability of WC&AK and AKO vessels to fish Alaska sablefish IFQ for the potential participant listed in the first column (to “hire out” to the participant listed in the first column) and number of additional LEFG permits that the owners of each entity listed in the columns might acquire.

	WC&AK Vessels			AKO Vessels
	Number of Permits Registered to the Vessel			
	3 Permits	2 Permits	1 Permit	
Participants Seeking to Hire Out Their AK IFQ (Hire a Skipper)	Able to Fish IFQ For Entity Listed to Left – Yes or No (Maximum Number of Additional Permits That Could Be Acquired, If Vessel is Able to Fish for Entity Listed to Left)			
WC&AK w/3 LEFG Permits	N (-)	N (-)	N (-)	Y (0)
WC&AK w/2 LEFG Permits	N (-)	N (-)	Y (0)	Y (1)
WC&AK w/1 LEFG Permits	N (-)	Y (0)	Y (1)	Y (2)
AKO (i.e. no LEFG Permits)	Y (0)	Y (1)	Y (2)	Y (3)

“N” means vessel in the column could not hire out to the participant listed in the row.
Numbers in parenthesis show the number of additional LEFG permits the vessel in the column could acquire without violating the three permit limit (a “-“ is displayed where the combination is impermissible).

This impact mechanism involves the creation of a new opportunity which participants may or may not take advantage of. While we cannot predict the degree to which participants will avail themselves of that opportunity we can describe the change in the opportunity. Under an action alternative, WC&AK operations would have more opportunity to both hire out to other WC&AK operations or to hire other WC&AK vessels to fish their Alaska IFQ, because the 20 percent ownership in a hired vessel needed to meet the requirements of the Alaska IFQ program would not be enough to cause associated LEFG permits to count against the three-permit cap. This increased opportunity to hire and hire out is reflected in the increased number of permissible combinations in Table 4-3 as compared to Table 4-2 (number of cells with a “Y”). All of the new opportunities are for WC&AK vessels with LEFG permits, **indicating that the action alternative would provide more opportunities for consolidation of AK IFQ on WC&AK vessels.**

Tables 4-3. Action alternative: ability of WC&AK and AKO vessels to fish Alaska sablefish IFQ for the potential participant listed in the first column (to “hire out” to the participant listed in the first column) and number of additional LEFG permits that the owners of each entity listed in the columns might acquire.

	WC&AK Vessels			AKO Vessels
	Number of Permits Registered to the Vessel			
	3 Permits	2 Permits	1 Permit	
Participants Seeking to Hire Out Their AK IFQ (Hire a Skipper)	Able to Fish IFQ For Entity Listed to Left – Y/N (Maximum Number of Additional Permits That Could Be Acquired, If Vessel is Able to Fish for Entity Listed to Left)			
WC&AK w/3 LEFG Permits	Y (0)	Y (1)	Y (2)	Y (3)
WC&AK w/2 LEFG Permits	Y (0)	Y (1)	Y (2)	Y (3)
WC&AK w/1 LEFG Permits	Y (0)	Y (1)	Y (2)	Y (3)
AKO (i.e. no LEFG Permits)	Y (0)	Y (1)	Y (2)	Y (3)

Numbers in parenthesis show the number of additional LEFG permits the vessel in the column could acquire without violating the three permit limit.

In addition to an increase in the opportunity for WC&AK participants to fish Alaska IFQ for each other (either hiring out or being hired), additional flexibility would be created for these vessels to acquire more LEFG permits without diminishing their opportunities in the Alaska IFQ fishery. In Table 4-2, values shown in parentheses are the number of additional permits the vessel represented in the column would be able to acquire without interfering with its ability to hire out to the types of vessels listed for each row. For example, the owner of a vessel with 1 permit (represented in the third column of numbers) could work with a WC&AK vessel with 1 permit and would still have the flexibility to acquire one additional permit without exceeding the 3-permit control limit. Under an action alternative, there are not only more permissible combinations of WC&AK vessels with other fishing operations, but the number of additional permits which could be acquired by vessels operating in those combinations increases in every column except for the vessels which already have three permits (first column of numbers). **Thus, an action alternative could lead to increased consolidation of West Coast LEFG permits on fewer West Coast vessels.**

Vessels that participate in Alaska but not the West Coast currently have flexibility to fish for multiple WC&AK operations. If an AKO participant is fishing Alaska IFQ for an absent WC&AK participant (i.e. the WC&AK participant has part ownership in the AKO vessel), each WC&AK participant must have some ownership interest in the AKO vessel but the AKO operation does not have to have an ownership interest in the WC&AK operations. Moreover, under the action alternatives, an AKO vessel might fish for several separately owned WC&AK operations, each with three LEFG permits, without violating the three-permit control limit. This situation is illustrated in Figure 4-5.

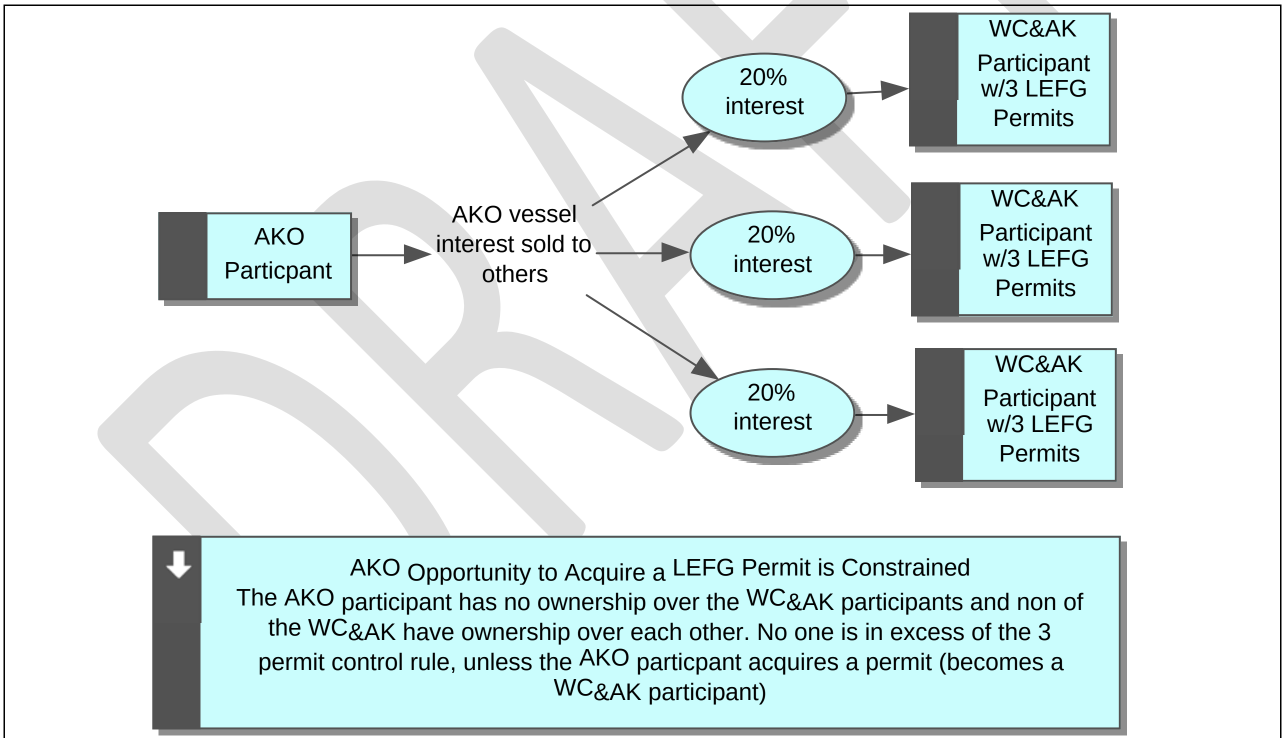

Figure 4-5. Opportunity for AKO participant to hire out to multiple WC&AK participants, each of which might be at the three-permit limit for control of FG Groundfish permts.

While AKO vessels can fish for multiple WC&AK operations (each with up to three permits), the AKO vessels may be constrained in their ability to acquire West Coast LEFG permits (i.e. to become a WC&AK vessel). The LEFG permits held by the WC&AK operations that an AKO vessel fishes Alaska IFQ for do not prevent an AKO vessel from acquiring its own LEFG permit but may provide a disincentive for such acquisitions. Since the WC&AK operations that the AKO vessel fish for are required to have an ownership interest in the AKO vessel, any permits the AKO participant acquires would count against the permit totals for the WC&AK entities. Thus, if the AKO participant acquires a LEFG permit(s) it could force the WC&AK operations it fishes for to find another vessel to hire, if that acquisition pushes one of the WC&AK operations over its three-permit limit. Figure 4-6 diagrams the opportunities present for the AKO operation, and the boxes at the bottom discuss the constraint on acquiring an LEFG permit. Comparison of the AKO vessel column in Table 3-2 to the AKO vessel column in Table 3-3 shows that under an action alternative there would be more situations in which AKO vessels could acquire up to the three-permit limit (i.e. become WC&AK vessels with three LEFG permits without sacrificing their ability to hire out to fish AK IFQ for other WC&AK vessels). **This could lead to some increased consolidation of LEFG permits on AKO vessels (movement of AKO vessels into the LEFG fishery).**

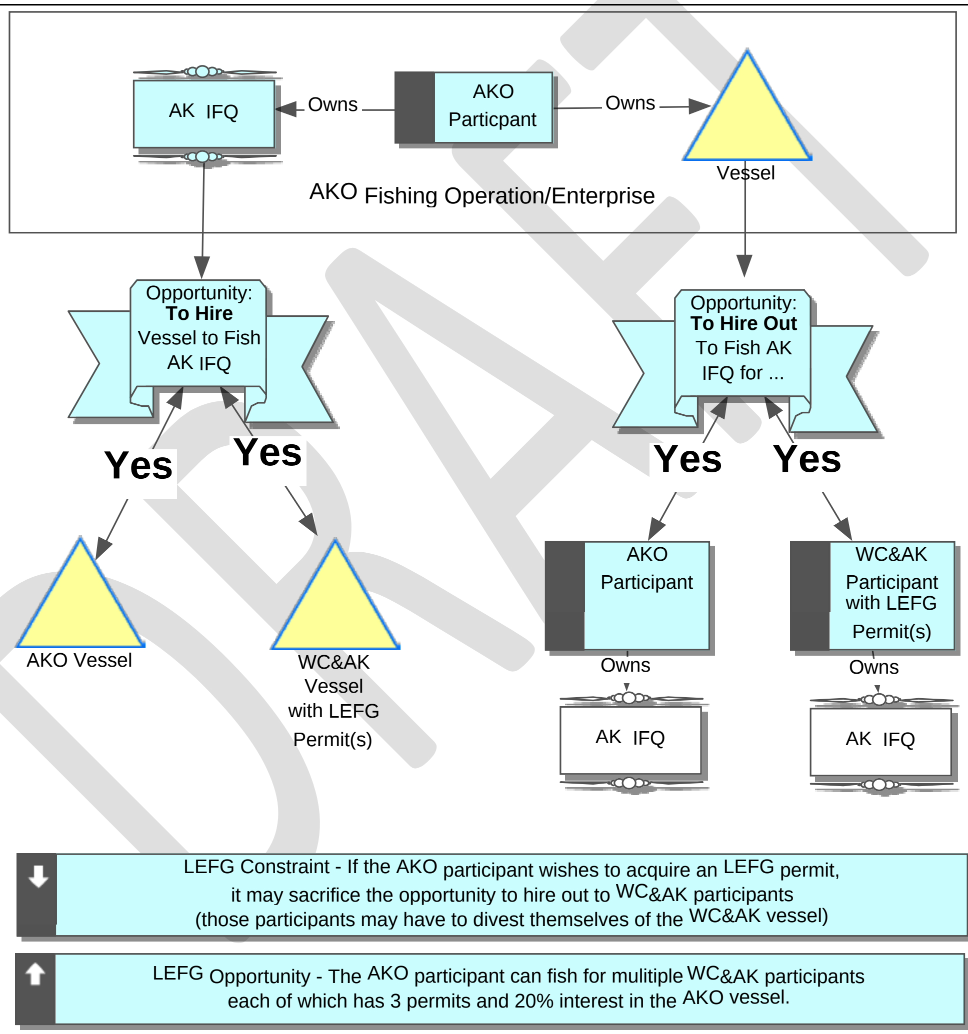

Figure 4-6. Ability of an Alaska only fishing operation to hire out to fish Alaska IFQ or to hire others to fish Alaska IFQ for it and constraints on acquiring a West Coast LEFG permit.

With respect to the new opportunities for consolidation, the situations affected may be somewhat limited. The impact mechanisms pertain only to those situations in which a WC&AK participant both qualifies for a grandfather exception to the Alaska owner-on-board provision and chooses (or would prefer to choose) to exercise that exception by hiring a vessel and skipper rather than travelling to Alaska to participate in the fishing activities. In those situations, both those entities that would hire a vessel to fish Alaska IFQ and the entities that would be hired are involved in the impact mechanism.

With respect to those entities that would hire a vessel to fish their Alaska IFQ, any of the owners of the 97 LEFG vessels (in 2012) and the 164 LEFG permits may be affected in their ability to hire but, in 2012, of 97 vessels (164 permits), 13 vessels (25 permits) participated in the Alaska fishery (Table 4-1). Of the vessels that did not participate in Alaska in 2012, the 18 owners of vessels with three permits could not hire any of the WC&AK vessels that travel to Alaska; the 16 owners of vessels with two permits could hire any one of the 4 of the WC&AK vessels that travel to Alaska; the owners of the 50 vessels with one permit could hire any one of the 10 of the WC&AK vessels that travel to Alaska (Table 4-4).[10] Under the action alternative, these owners could hire any of the 13 WC&AK vessels that travel to Alaska. The numbers provided here are only indicators since they are only for one year and do not take into account the possibility that for a single West Coast permit or vessel there may be multiple owners which each, independently of one another, own Alaska IFQ. Additionally, there are individuals that own multiple permits and vessels such that they may be at higher levels of consolidation (closer to the three-permit limit) than indicated here. The 164 LEFG permits are owned by only 112 unique owners. Therefore, the numbers provided here only indicate a rough order of magnitude of the potential impacts.

Table 4-4. Vessels that go to Alaska and are available for hire, as constrained by the number of permits held by the vessels that might hire them.

West Coast Vessels that Did not Go to Alaska (Owners might have Alaska IFQ to hire out)		WC&AK Vessels that Went To Alaska (Number of LEFG Permits)			
Number of Permits	Number of Vessels	3 Permits	2 Permits	1 Permit	Total
		Number of Vessels			
3 permits	18	-	-	-	0
2 permits	16	-	-	4	4
1 permit	50	-	6	4	10

Statistics on rate at which Alaska IFQ owners hire vessels in the Alaska IFQ fishery may provide some indication of the degree to which the hiring practice occurs and therefore, the degree to which West Coast entities with Alaska IFQ might be constrained by the current permit counting rule. In 2012, 39 percent (201) of all Alaska sablefish IFQ owners (511) hire out their IFQ to a vessel ("hire a skipper") (Table 4-5). This was 64 percent of those eligible or required to do so (315). Because of the geographic distances involved, it seems likely that the proportion of participants in the LEFG fishery that are Alaska IFQ owners and hire a vessel would likely be higher than the averages reported here.

[10] These values assume that the owners of the vessels do not also own other vessels or permits. If for example, one of the owners of a vessel with two permits also owned a vessel with one permit (or owned a permit and leased it to another vessel), then the number of entities at the three-permit limit would be higher than indicated by the count of vessels at the three-permit limit.

Tables 4-5. Participation in Alaska sablefish IFQ fishery (NOAA Fisheries Service, 2012 and 2014)

	1995	2012
Total number of vessels fishing.	616	362
Total Entities with sablefish quota	688	511
Individuals with sablefish quota	528	445
Individuals eligible to hire a skipper	496	239
Non-individuals with quota (corporations, partnerships etc.) - must hire a skipper [a/]	160	76
Total individuals or non-individuals who are eligible to or must hire skippers	656	315
Number (individuals and non-individuals) that do hire a skipper	82	201
Number of skippers hired by individuals	30	N/A
Number of skippers hired by non-individuals	51	N/A
Total number hired	N/A	193

a/ The requirement that non-individuals must hire skippers did not go into place until 1998.

On the other side of the transaction are owners of the vessels which would hire out to West Coast LEFG participants that own Alaska IFQ. Most directly impacted are those who have West Coast LEFG permits and take their vessels to Alaska. These are the entities which would have the opportunity to hire out their vessels but have LEFG permits which would add to the permit count of any entity that hires them. In 2012, there were 13 vessels with a cumulative total of 25 permits that are constrained under No Action and could potentially benefit under one of the action alternatives (Table 3-1). Vessels with three permits going to Alaska can only hire out to entities which have Alaska IFQ but do not participate in the West Coast LEFG fishery (presumed for purpose of this analysis to be Alaska only (AKO) participants. In 2012, there were three such vessels. Vessels with two LEFG permits can fish for AKO participants or the owners of one of the 50 vessels that only have a single permit (or the owners of single permits). In 2012, there were six such vessels. Vessels with one LEFG permit can fish for AKO participants or the owners of one of the 66 vessels that have one or two LEFG permits (or owners of one or two permits). In 2012 there were four such vessels. These vessel counts assume that the owners of the vessels do not also own other vessels or permits. To the degree that there is cross ownership, the constraints may be greater than indicated here for either the number of the 13 vessels at the three-permit limit or the number of vessels owners with which those vessels could work. Under the action alternatives, all 13 of the West Coast LEFG vessels that participate in Alaska would be able to hire out to the owner of any other West Coast LEFG vessel or permit.

The West Coast rule constrains AKO participants from acquiring a LEFG permit only if they hire out to an owner of one of the 18 vessels with three permits or some other three-permit owner. Not all of these, and potentially none, may own Alaska IFQ. Thus, the number of AKO-only entities that the three- permit limit inhibits from entering the West Coast fishery under No Action is probably small (particularly in the context of the total number of Alaska IFQ vessels and owners, Table 4-5). Therefore, the action alternatives would not be expected to result in a substantial increase in Alaska vessel participation in the West Coast LEFG fishery.

Impact Mechanism Related to Administrative Effort and Compliance Requirements

Currently, NMFS collects only a listing of the individuals with an ownership interest in LEFG permits and the vessels to which they are registered. Under the action alternatives, NMFS would have to collect information on percent of ownership interest in vessels, and those ownership interests would have to be updated with any change in the portions of ownership and with any permit transfer where the permit is registered to another vessel.[11] Additionally, depending on the policy guidance, ownership interests may have to be tracked through several levels of ownership – for example, if one partnership is part owner of a second partnership that owns a vessel. For any vessel that is owned by more than one individual or owned by a corporation or some other legal entity, the owners would have to submit a detailed vessel ownership interest form.

Changing Conditions

With respect to the impact mechanisms related to the Alaska IFQ program, the function of the mechanism and need for this action is expected to diminish over time as those who are grandfathered in with an exception to the owner-on-board requirement leave the fishery. Recent final and proposed rules for the Alaska halibut and sablefish IFQ fisheries are expected to expedite the shift of the fishery toward an all owner-on-board fishery in Alaska. NMFS, Alaska Region, recently published a final rule (79 FR 9995, February 24, 2014) that imposes a 12-month vessel ownership requirement on initial individual recipients of QS who wish to use an exemption from the owner-on-board requirement and use a hired master to harvest their IFQ. NMFS has also proposed a regulation that would prevent an initial recipient from using a hired master to harvest QS that an initial recipient acquired by transfer after February 12, 2010, with a limited exception for small amounts of QS (78 FR 24707, April 26, 2013).

Summary of Impact Mechanisms and Differences Between Alternatives 1 and 2

On the basis of the situations that regulations currently constrain, it is expected that the direct impact mechanisms of the action alternatives would be some increased flexibility in financing within the fishery (including an increase in personal connections between lenders and borrowers) and at most, some modest consolidation of both LEFG permits and Alaska sablefish and halibut IFQ on fewer vessels. Additionally, there may be some impact on program administrative costs. The effects of these changes on each of the resources is discussed in the following sections. In summary, the primary direct impact mechanisms for the action alternatives are expected to be as follows.

[11] This entails ownership interests of shareholders in a corporation and the relative ownership in partnerships. Example

Acme Inc. and Fish Inc. own a vessel
Acme Inc. and Fish Inc. each 50% ownership in the vessel
Acme Inc. is made up of John Doe and Mary Doe and each owns 50% of Acme
Fish Inc. is made up of Mark and Sarah Smith and each have a 50% interest in Fish.

1. A potential effect on arrangements that involve financial interests secured through ownership in vessels:
    a. a redistribution of risks, financing transaction costs, and related profits from institutional lenders toward the private parties involved in a transaction, and
    b. more social connections between buyers and sellers than would be the case if borrowers were qualified by institutional lenders
2. An uncertain but at most modest effect on the distribution of limited entry privileges among fishing operations:
    a. Some degree of increased opportunity for consolidation of Alaskan IFQ on vessels that also participate in the West Coast LEFG fishery,
    b. Some degree of increased opportunity for consolidation of LEFG permits on vessels that fish in both fisheries, and
    c. Some degree of increased opportunity for acquisition of LEFG permits by vessels that previously fished only in the Alaskan IFQ fishery.
3. An increase in the administrative effort required to track and enforce the control limits and an increase in compliance requirements for all participants.

Alternative 2a compared to Alternative 2b

Alternatives 2a and 2b vary from one another in terms of the threshold amount of vessel ownership which counts as ownership of the associated LEFG permits. Under Alternative 2a the amount (20 percent) is the minimum ownership required to take advantage of the grandfather exception provision to the owner-on-board clause for the Alaska IFQ program. The Alternative 2b threshold (30 percent) provides some additional leeway for agreements that may have been established to take advantage of the exception that, for one reason or another, provided somewhat more than the minimum ownership required. These percentages are well below the 50 percent threshold at which majority interest and control would be established. Both action alternatives represent a compromise compared to the No Action, under which any one holding even a fraction of a percent ownership of a vessel would meet the control threshold and be credited with complete control over all of the permits associated with the LEFG vessel. The primary impact mechanism at work in these alternatives is the LEFG permit owner and vessel owner response to the change in the rule for determining permit control through vessel ownership. The difference in the amplitude of the impact mechanism between the alternatives will depend on how those who own (or would like to own) between 20 percent and 30 percent of a vessel respond.

With respect to the lending situation, one might expect some difference in private individual's willingness to lend depending on whether they could maintain an ongoing 20 percent or 30 percent interest, with a greater willingness at 30 percent. However, as mentioned earlier, while a standard industry practice is to maintain ownership to secure a private loan financing the sale of a vessel there are alternatives ways to secure such an interest. Based on the absence of recent complaints about how the control rule restricts private lending it may be that industry has found a work-around with respect to the 3-permit control limit. Because of the alternative means of securing loans, industry's apparent adjustment and the relatively small difference between the two alternatives with respect to amount of security provided, it may be that there is little difference between these to alternatives with respect to the response in lending activities.

With respect to the situations of WC&AK participants, again the amplitude of the impact mechanism will depend on how those with (or who would like to acquire) between 20 percent and 30 percent ownership interest in a WC&AK vessel respond to a 20 percent limit. If they divest themselves down to 20% in order to take advantage of the exception created by Alternative 2a (or acquire only 20 percent rather than some greater amount to take advantage of that exception), then the degree of consolidation of LEFG permits and Alaska IFQ on WC&AK vessels would not vary between the action alternatives but there would be lower percent ownerships under Alternative 2a. If instead, they opted not to divest (or went ahead and acquire more than 20 percent), then they would not benefit from the exception and for these individuals there would be no difference between No Action and Alternative 2a. With respect to those who would choose not divest down (not acquire a smaller percent interest) Alternative 2b would provide opportunity for that higher percent ownership and would increase LEFG permits and Alaska IFQ on WC&AK vessels. Information is not available which would allow a prediction of the difference in response between these two alternatives. However, given only a 10 percent difference between the alternatives, given that the difference is well below that needed to establish majority interest control (50%), and given the relatively small number of operations that this provision is expected to impact, it appears unlikely that there will be a substantial difference in the size of the response to Alternative 2a or 2b.

4.2 Effects on the Physical and Biological Environment

4.2.1 Electronic Fish Ticket

Alternatives 2-4 consider implementing a Federal catch accounting requirement, an electronic fish ticket for nontrawl vessels landing sablefish into U.S. West Coast ports. None of the catch accounting action alternatives are expected to change where fishing vessels operate at sea or where they land their catch, because none of the action alternatives would constrain how much or how little gear fishery participants use, where they use the gear, or whether and how they interact with the ocean floor or essential fish habitat. Therefore, NMFS does not anticipate that any of the alternatives would have any effect on the physical environment, nor would the action alternatives result in the monitored fisheries having different effects on the physical environment from those experienced under the No Action alternative.

Effects on the biological environment resulting from fishery management actions primarily include changes in fishing mortality levels resulting from implementation of the alternatives. This particular action considers changes to a catch accounting system and record keeping and reporting requirements for fishery participants. No direct biological effects are expected to result from any of the action alternatives because none of the alternatives would change the allowable directed harvest or incidental catch levels allowed in the fishery. The Council considers allowable groundfish harvest levels under its specifications and management measures process and this action would not alter harvest levels set through that process, nor would it alter the fishing practices of vessels pursuing the allowable harvest. Indirect impacts from fishery management actions include changes in fishing practices that affect the biological environment, but are further away in time or location than those occurring as a direct impact. Indirect biological impacts could result if catch data were inaccurate or delayed such that fishery specifications could not be adequately monitored or the fishing was not stopped before a specification was exceeded. Exceeding a specification increases the risk of overfishing, may affect rebuilding times for overfished species, or result in a stock becoming overfished.

Accurate and timely data are needed to monitor total catch of all groundfish, including sablefish (a precautionary zone stock), to prevent overfishing and to maintain rebuilding schedules for overfished stocks. Since implementation of the permit stacking program in 2002, inseason management of the primary and DTL sablefish fixed gear fisheries has been based on two types of information: (1) paper landing receipts that typically have a two month time lag between the date of landing and when the landing data are available in PacFIN, and (2) the Quota Species Monitoring (QSM) Best Estimate Report, which fills in the three-month time lag based on estimates from the previous years' landings. Both of these data sources estimate which landings are attributed to the primary (tier) fishery and which are attributed to the DTL fishery. Thus, the current catch accounting system is subject to inaccuracy and time delays under the No Action Alternative and will continue to be if this alternative is selected.

Under the No Action Alternative, the requirements for sending in paper landing receipts varies among states with Washington requiring the paper landing receipts to be received within six working days, Oregon requiring the landing receipts to be received within five working days, and California requiring the landing receipts to be received by the first and sixteenth of the month. It is a considerable time after the tickets are prepared and submitted that the data are entered into a state database, edited, and forwarded to the PacFIN database; depending on the state, it may take several months. Extending the electronic fish ticket requirements to the non-trawl fisheries would result in fish tickets being submitted within 24 hours of landing. The requirement for daily submissions of electronic fish tickets, under Alternatives 2-4 provides for timely and efficient reporting of landing data such that species allocations and ACL can be effectively monitored and inseason adjustments for conservation purposes can be made as necessary. Electronic fish tickets would allow managers to use timely, accurate data to manage the fisheries inseason rather than having to rely on estimates and data from the previous year to supplement data from paper landing receipts as is currently the case under No Action. The electronic fish tickets would also provide daily landings estimates for all species landed, not just sablefish, providing improved inseason data for other species, including overfished species. Electronic fish ticket reporting is expected to expedite the receipt of catch data which are combined with observer data for total catch estimates. Timely reporting reduces the risk of indirect impacts on the biological resource.

The quality and accuracy of data could also be expected to improve with the use of electronic fish tickets. Paper landing receipts introduce two areas where data entry errors could occur, when the first receiver enters the data on the paper form and when the data are entered into the database weeks to months later by the state. The electronic fish ticket allows users to pre-load landings data into their account. For example, a first receiver that generally receives sablefish landings from five different vessels could enter each of the vessels identifying information into their user account. Then, at the time of landing, the first receiver would simply select information such as vessel I.D. and permit number from drop down menus in each field. The first receiver also has the ability to fill out an electronic fish ticket and save it and submit it at a future date, should any corrections need to be made. There are also numerous, built-in data checks that prevent entry errors and improve the quality of landings data for all species. These built-in data checks include pre-loaded lists of allowed gear types, current species, and area restrictions. Also, an electronic ticket would allow NMFS to specify the reporting groups consistent with Federal regulation. This could improve the quality of species-specific reporting (for example, when a stock is left in a complex, but NMFS requires reporting for conservation concerns). By reducing data entry errors, issues can be resolved in a timely manner by the first receivers and fishers, such that the resolution is likely to be more accurate and timely than errors found weeks to months after the landing occurred.

If catch accounting difficulties continue, delays in catch reporting may or may not have an effect on the biological condition of groundfish stocks. The severity of the impact caused by inaccurate or untimely landings data depends on how sensitive the groundfish stock is to changes in catch levels. For precautionary zone and healthy groundfish species or species groups, the risk to the stock is lower than it is for overfished species. If catch allocations of the most constraining overfished species are greatly exceeded due to delayed or inaccurate catch reporting, the risk of exceeding rebuilding based OYs is increased. Although there are many variables that affect the time it takes a stock to rebuild, exceeding the rebuilding-based OY could result in an extended rebuilding period for an overfished species. Additionally, since sablefish is a precautionary zone species that is usually fished to a high level of attainment, inseason monitoring and management is especially important when managers are trying to make decisions that may be impacted by exceeding or attaining sector ACLs, such as the annual issuance of carry over quota in the shorebased IFQ fishery.

In terms of improved catch accounting, Alternative 4 has the greatest beneficial indirect impacts in that it would require all sablefish and DTL landings in the LEFG and OA fisheries to be reported via electronic fish tickets. The scope of Alternative 3 is narrower than Alternative 4 in that it would not require DTL OA landings to be recorded on electronic tickets. Alternative 2 has the narrowest scope in that it would require only sablefish landings in the primary (tier) fishery to be recorded on electronic fish tickets and the least beneficial indirect impacts among the action alternatives.

4.2.2 Own/Control Limits

Summary: Under the no action and action alternative no substantial impact to the physical or biological environment would be expected relative to baseline conditions. The primary potential effect would result from a possible geographic shift in the area of harvest under an action alternative. Any such shift is expected to be modest (as described in Section 4.1.2). If that shift were to occur, the data collection and reporting system would alert managers to any substantial impacts and management tools authorized under the MSA and groundfish FMP (see Chapter 6 of the Groundfish FMP) are available for an appropriate response.

Section 3.1 and 3.2 describe the potentially affected physical and biological environment including:

- Groundfish stocks
- Nongroundfish Species

- Protected Species
- Essential Fish Habitat
- California Current Marine Ecosystem

Impacts on the physical and biological environment would depend on whether the changes in the control rule changed fishing behavior. Impacts to the physical and biological environment might change if there were:

- changes in total harvest,
- changes in the types of gear used,
- changes in the way gear is fished,
- changes in the amount of fishing effort required to take a given amount of harvest (CPUE), or
- changes in the distribution of harvest.

The limited entry fixed gear allocations are fully distributed among participants and nearly fully harvested under the limited entry fixed gear permit stacking program by vessels using longline and/or fishpot gear (Figure 3-X). There is no opportunity to increase total removals and no reason to expect that changing the control rule provision would result in a decrease of harvest. Any increase in attainment would be within the impact levels anticipated and analyzed in the NEPA document for the groundfish biennial harvest specifications.

Under the No Action alternative, the current regulatory environment would be maintained and there is no reason to believe that situations would worsen with respect to the conditions leading to the need for this action. In fact, as the number of those with a grandfather exception in the Alaska program diminishes, the situations in which individuals are constrained from either benefiting from Alaska IFQ or acquiring more limited entry permit, as described in Section 4.1.2, would diminish. The impacts of a control rule change under either action alternative would occur through the mechanism of changes in financing or consolidation (see Section 4.1.2). There is no reason to expect that consolidation of harvest on fewer vessels or increased financing opportunities (the two identified impact mechanisms identified in Section 4.1.2) would cause a substantial change in the type of gear used, the way the gear is fished, or the catch per unit effort (CPUE) in either the West Coast LEFG sablefish or Alaska sablefish and halibut IFQ fisheries.

If the changes result in some modest degree of consolidation on vessels that fish in both the West Coast and Alaska (see discussion in Section 4.1.2) and those vessels tend to fish in a different geographic distribution along the West Coast than the vessels from which the permits are acquired, then there could be a spatial shift in the distribution of effort and catch. The current program does not restrain redistribution of sablefish harvest and landings within the management area for the stock. Such redistributions may occur in response to local area CPUE, local fish marketing opportunities, and shifts of the permits between ports (through transfer or changing locations of fishing operations). To a certain extent, a natural rebalancing of effort would be expected from any substantial shifts. For example, if effort shifted enough to cause a CPUE decline in a particular area then, as a result of the increased fishing cost, effort would be expected to reshift to some other area. Biologists and managers have determined that the northern sablefish stock to which this program applies (roughly north of 36 degrees north latitude) is a unit that can be effectively managed as such, i.e. there are not issues of localized depletion that would require further subdivisions to ensure the productivity of the target species. All catch in the fishery (including sablefish and nontarget species) is assessed through an observer program, and landings are recorded on state fish tickets. Thus, if there is a geographic shift and if that shift leads to changes that are of management concern, a data collection and reporting system is in place to alert managers to the situation, and coordinated Federal, state, and tribal regulatory authority is available to mitigate such impacts.

Habitat impacts are limited to the possibility that there may be a redistribution of effort, redistributing gear impacts along the coast. The amount of any such redistribution would be expected to be small (see section on impacts on communities in Section 4.3.2). Amendment 19 to the groundfish FMP set aside essential fish habitat conservation areas and provided a process for five-year reviews which includes assessment of changes in the intensity and distribution of fishing effort (see NMFS, 2013 for an example of the type of information produced). This review process provides an opportunity for adaptive management in response to any substantial shifts in fishing effort that adversely impacts habitat.

4.3 Effects on the Socio-economic Environment

4.3.1 Electronic Fish Ticket

The action alternatives primarily affect fishermen, first receivers where non-trawl sablefish are landed (LE and OA), and state and federal enforcement and management agencies. This document deals with three inter-related measures: (1) implementation of a federal electronic fish ticket, (2) modification of the own/hold control rules, and (3) implementation of joint registration (allow a LEFG and trawl permit to be registered to the same vessel at the same time). The first measure would affect either only the sablefish permit stacking program (the primary sablefish fishery north of 36ºN latitude) or both the primary fishery and the daily trip limit (DTL) fishery north and south of 36ºN latitude. In the LEFG fishery (primary and DTL), sablefish is taken as directed catch and the only gear types allowed are longline or trap (or pot). Longline vessels harvest some other groundfish species, but for pot vessels, sablefish comprises the vessels' only significant commercial groundfish species harvest.
The second measure only affects the primary sablefish fishery north of 36ºN latitude.
The third measure affects both the LEFG fishery and the shorebased trawl individual fishing quota (IFQ) program. Participants in the shorebased trawl IFQ program typically use trawl gear to target sablefish as part of the DTS groundfish complex (Dover Sole/ Thornyhead/ Sablefish complex), in a near shore mixed groundfish species strategy, or when targeting slope rockfish.

Impacts to Sablefish Fishermen

It is likely that under the action alternatives regulations will require that sablefish landings be made to first receivers that have electronic fish ticket capabilities. To the extent that this limits the number of first receivers that may receive sablefish landings, fishermen may find a reduced number of first receivers capable of recording sablefish landings on electronic fish tickets. In order to be able to fill out and submit an electronic ticket, first receivers would need a computer with an internet connection and browser. The catch accounting issues previously discussed in this document (i.e. the time lag associated with landing data from state landing receipts and subsequent use of estimates for inseason management) affect the ability of state and Federal enforcement to accurately track sablefish landings on an individual permit basis. Overages in the primary fishery may impact sector specific allocations and introduce potential issues of intersector inequity. By implementing an electronic fish ticket, NMFS will be able to better track instances of tier overages and ensure that neither the tier limits nor the DTL limits are exceeded inseason, and will be better able to track compliance with the owner on board requirement.

Impacts to Sablefish First Receivers

The main burden of implementation of an electronic fish ticket would fall on sablefish first receivers that receive: (1) primary (tier) sablefish landings, (2) primary and LEFG DTL sablefish landings, or (3) primary (tier) and DTL (LEFG and OA) sablefish landings, and are not already licensed IFQ first receivers. This socio-economic group is estimated to be approximately 33 unique first receivers in the primary sablefish fishery and 53 first receivers in the primary and LEFG DTL fisheries, and 77 first receivers across the primary, DTL, and OA fisheries. These 77 additional first receivers account for approximately 34% of sablefish landings in these fisheries. Twenty-three sablefish first receivers are also IFQ first receivers and already use electronic fish tickets to record shorebased-IFQ trawl landings. The approximately 77 first receivers across the primary and DTL fisheries who do not already use electronic fish tickets would be most affected by the action alternatives (see Table 4-6 below).

Table 4-6: The number of additional first receivers required to use electronic tickets under each alternative, by state.

	Alternative 1	Alternative 2	Alternative 3	Alternative 4
Washington	0	9	9	13
Oregon	0	4	4	11
California	0	20	40	53
Coastwide	0	33	53	77

	Net Addition	13	331,142	854,860

Table 4-10. Coastwide first receivers affected by each action alternative.

		Number of First Receivers	Sablefish Landed (lbs)	Net Revenue (U.S. dollars)
Alternative 2	Total	56	3,192,949	7,820,273
	IFQ FRSL	23	2,358,375	5,661,791
	Net Addition	33	677,813	1,785,743
Alternative 3	Total	76	3,556,080	8,791,639
	IFQ FRSL	23	2,358,375	5,661,791
	Net Addition	53	1,197,705	3,129,848
Alternative 4	Total	100	3,983,236	9,805,662
	IFQ FRSL	23	2,632,014	6,204,586
	Net Addition	77	1,351,222	3,601,076

The action alternatives would increase the amount of time first receivers spend recording sablefish landings. Action Alternatives 2-4 do not require that additional data be gathered, but do require additional time in the States of Washington and California, because the data would need to be recorded on both the paper forms provided by the state and entered into the electronic fish

[12] For the states of Washington and Oregon, Alternatives 2 and 3 affect the same number of first receivers because all first receivers that process primary sablefish landings also process LEFG DTL sablefish landings.

ticket forms. Entering the fish ticket information is expected to take eight minutes per ticket, including the time necessary to check for transcription errors. For first receivers in all three states, two minutes per response would be required to access the internet and send the data files.

There are approximately 639 primary (tier) landings each year, with approximately 373 of the deliveries occurring in Washington and California and the remaining 266 occurring in Oregon. The burden on first receivers in Washington to submit electronic fish tickets under Alternative 2 is estimated to be approximately 29 hours annually over the No Action Alternative. The burden on first receivers in California to submit electronic fish tickets under Alternative 2 is estimated to be approximately 34 hours annually over the No Action Alternative. For first receivers in Oregon, the additional burden is only the time it takes to send the electronic fish ticket, since state law already requires that the information be gathered and allows the submission of a printed and signed electronic ticket in lieu of a paper landing receipt. For processors in Oregon, it is expected to take a total of approximately 9 hours annually to submit electronic fish tickets. In total for all three states, 72 hours annually are estimated for preparing and submitting electronic fish tickets under Alternative 2.

Under Alternative 3, the number of landings in Washington and California would be expanded to 264 and 1,838 respectively, while the number of landings in Oregon would be expanded to 579. Therefore, under Alternative 3 the burden to first receivers in Washington and California would be expected to be 44 hours and 306 hours, respectively, over the No Action Alternative, while the burden to first receivers in Oregon would be 19 hours. In total for all three states, 369 hours annually are estimated for preparing and submitting electronic fish tickets under Alternative 3. Similarly, under Alternative 4, the number of landings in Washington and California would be expanded to 520 and 3,258, respectively, while the number of landings in Oregon would be expanded to 1,072. Therefore, under Alternative 4 the burden to first receivers in Washington and California would be expected to be 87 hours and 543 hours, respectively, over the No Action Alternative, while the burden to first receivers in Oregon would be 36 hours. In total for all three states, 666 hours annually are estimated for preparing and submitting electronic fish tickets under Alternative 4.

Table 4-11. Burden hour estimates for California first receivers.

	Number of sablefish landings[13] per year	Time to fill out and submit e-ticket (minutes per landing)	Burden hour estimate (hours)	Burden hour estimate using a 50 pound sablefish threshold (hours)

Alternative 3	2,682	369	297	76
Alternative 4	4,851	666	578	100

[14] The number of sablefish landings is an average of unique landings from 2008 through 2013 that contain greater than zero pounds of sablefish.
[15] The number of sablefish landings is an average of unique landings from 2008 through 2013 that contain greater than zero pounds of sablefish.
[16] The number of sablefish landings is an average of unique landings from 2008 through 2013 that contain greater than zero pounds of sablefish.

It is assumed that all first receivers have access to a personal computer and internet access adequate to access the electronic fish ticket website developed by PSMFC. The electronic fish ticket requirements would require that the first receiver's personal computer be properly operating when accepting landings requiring electronic fish ticket reporting. Therefore, some first receivers may choose to have an additional personal computer or laptop computer as a back-up. To reduce the potential impacts on first receivers should there be a system failure, a waiver could be granted by NMFS that would temporarily exempt a processor from the reporting requirements and allow reasonable time to resolve the electronic fish ticket system problem. The duration of the waiver would be determined on a case-by-case basis. First receivers that are granted a temporary waiver from the requirement to submit electronic fish tickets must submit on paper the same data as are required on electronic fish tickets within 24 hours of the date received during the period that the waiver is in effect.

Table 4-14 above provides a comparison of coastwide burden hour estimates against the total number of first receivers required to fill out electronic tickets by alternative. The second column in Table 4-14 provides the estimated additional amount of time required to fill out an electronic ticket for landings that include any amount of sablefish. Since this is based on the time estimated to fill out and submit an electronic ticket multiplied by the number of unique sablefish landings in a given year, the resulting burden hour estimate is the additional time spent in a year for all first receivers. To put this in perspective, under Alternative 2, the 72 burden hours could be split out among the 56 first receivers. Divided up evenly, this results in approximately 1 hour and 20 minutes per first receiver over the course of a year, or roughly 7 additional minutes per month per first receiver spent filling out and submitting electronic tickets.

After Alternative 1 (the no action alternative), Alternative 2 places the least amount of burden hours on first receivers for all states, individually and coastwide (see Tables 4-11 through 4-14). For first receivers accepting both DTL LE and OA, Alternative 3 would introduce complexity by splitting the DTL fishery and only requiring electronic tickets for LE DTL sablefish landings. Alternatives 2 and 4 would not introduce this added regulatory complexity because Alternative 2 limits the electronic ticket requirement to the primary fishery and Alternative 4 includes the primary and LE and OA DTL sablefish fisheries. Additionally, Tables 4-11 through 4-14 include a column titled, "Burden hour estimate using a 50 pound sablefish threshold". The purpose of this column is to aid in the discussion of an implementation issue described in Agenda Item F.6.b NMFS Report 1, Issue 1, whether a poundage threshold or some other distinction should be made for OA DTL sablefish landings such that, for example, only OA DTL sablefish landings of 50 pounds or greater would be trigger the electronic ticket requirement. Omitting smaller sablefish landings from the electronic ticket requirement would have the most noticeable impact on burden hour estimates for California under Alternatives 3 and 4.

Impacts to State Agencies

As mentioned previously, implementation of a Federal requirement for an electronic fish ticket would be separate from, and in addition to, existing state reporting requirements. Under Alternatives 2-4, each sablefish buyer would be responsible for recording sablefish landings on an electronic fish ticket in addition to state (landing receipt) landing requirements. States may decide the extent to which they would like their landing receipt system to overlap with the electronic ticket. In the state of Oregon, a printed copy of the electronic ticket may be submitted in lieu of a paper landing receipt; however, in Washington and California, a hand-written landing receipt would likely be required in addition to the federally-required electronic ticket. Each state would have access to their state's electronic fish ticket landings data through the electronic ticket system. Currently, Oregon and Washington receive their state's PacFIN landings data every night, enabling them to check their state landing receipts for quality assurance and quality control. Because the electronic ticket is separate from, and in addition to, the state required landing receipts, it is unlikely that any burden due to implementation of a electronic ticket would be placed on state management and enforcement agencies.

Impacts to Federal Agencies

Section 6.10.1 of the Pacific Coast Groundfish Fishery Management Plan identifies some of the issues involved in managing enforcement risks. The primary goals of enforcement are to ensure a cost-effective way that all fishing is conducted in accordance with fishery regulations, while reducing management complexity, and ensuring that the monitoring methods used are sufficient to enforce existing regulations. As mentioned previously, there are several problems with the current system. The paper-based landing receipts are subject to compromise and typographical error, inconsistently record the Federal permit number, and are subject to a time lag of several months. Additionally, the use of inseason estimates for catch accounting purposes does not provide NMFS with sufficient evidence to enforce tier landing overage violations or the owner on board provision, either inseason or post-season.

Tier Catch against Tier Quotas by Permit

The *Review of NOAA Catch Share Programs* Final Report No. OIG-14-019-1 (published May 1, 2014) found that NOAA does not have adequate data and does not track or enforce landings overage violations in the Pacific Sablefish Permit Stacking Individual Fishing Quota (IFQ). Additionally, NOAA currently does not monitor Pacific Sablefish landings on an individual permit basis during a fishing season. Instead, it only monitors landings for the entire fishery as a whole, using a paper-based system that is subject to compromise and the multiple possibilities of error associated with any manual process. In addition, the report identified 189 instances where actual landings exceeded the allowed landings for individual permits from 2008 through 2013, as summarized in Table 4-15 below.

Table 4-15. Sablefish Tier Overages 2008-2013.

Amount of Overage (lbs)	Number of Permits	Total Overage (lbs)	Average Overage (lbs)
0–100	110	3,279	30
100–500	52	11,734	226
500–1,000	15	10,215	681
> 1,000	12	32,607	2,717
Total	**189**	**57,835**	

Source: Final Report NO. OIG-14-019-1, OIG from NOAA data. The total annual overages ranged from 0.13 to 0.56 percent of the total tier fishery, or 0.28% of the total tier fishery, from 2008 through 2013.

Implementation of an electronic fish ticket would improve the accuracy and timeliness of landings data and would provide managers with the real time data necessary to do inseason management of the primary and DTL fisheries. It would also provide enforcement with the permit specific landings data necessary to monitor landings overages in the primary (tier) and DTL sablefish fisheries and could also help aid enforcement of the owner on board requirement.

4.3.2 Own/Control Limits

Under the No Action alternative, the current regulatory environment would be maintained and there is no reason to believe that situations would worsen with respect to the conditions leading to the need for this action. In fact, as the number of those with a grandfather exception in the Alaska program diminishes, the situations in which individuals are constrained from either benefiting from Alaska IFQ or acquiring more limited entry permits, as described in Section 4.1.2, would diminish. All impacts discussed in this section are relative to the No Action alternative.

As described at the end of Section 4.1.2, Alternatives 2a and 2b vary from one another in terms of the threshold amount of vessel ownership which counts as ownership of the associated LEFG permits and the expected difference between the alternatives in terms of lending practices and consolidation of LEFG permits and IFQ (the primary impact mechanism) is expected to be minor. To the degree that the alternatives have impacts on lending or consolidation, Alternative 2b might possibly result in slightly more than Alternative 2a. The difference between the two alternatives may be substantial with respect to the opportunities for the few individuals it may affect but is likely to be negligible with respect to the aggregate impacts discussed in this section.

Summary: The following is a summary of the potential socio-economic impacts of either action alternative.

West Coast LEFG Harvesters.

- Some potential increase in net revenue and efficiency of vessel operations through consolidation and increased scale of operation and decreased financing costs.
- An impact on equity related to the opportunity for further consolidation.
- Some increase in social cohesion within the fleet.

- An increase in paper work for vessels owners related to the need to submit ownership interest information.
- A possible fee in association with increased program administrative costs for NMFS.

Harvesters in Other Fisheries.

- Some redistribution of Alaska IFQ away from vessels that participate in Alaska but not in the West Coast LEFG fishery.
- A possible increase in acquisition of LEFG permits by Alaska vessels that hire out to catch Alaska IFQ owned by West Coast LEFG participants and the attendant increase in profits and possible efficiency based on scale of operation.
- Vessels displaced as a result of consolidation may have some impact on other fisheries.

Crew.

- Consolidation may lead to fewer jobs but increased wages for remaining jobs.

Processors.

- Processing companies tied to a particular port may be affected if there is some geographic redistribution (see section on communities).

Communities.

- Potential for some harvest redistribution among ports (seems likely to be minor).
- An increase in social connections within the fleet.
- A possible small decrease in the lending business of financial institutions.

Agencies.

- An increase in administrative workload related to the need to collect, store, and track vessel ownership information.

Section 3.3 describes the potentially affected socioeconomic environment including:

- Fixed gear sablefish harvesting operations
- Harvesting operations in other fisheries
- Crew
- Processors
- Communities
- Management Agencies

As discussed in Section 4.1.2, the primary direct impact mechanisms are as follows.

1. A potential effect on arrangements that involve financial interests secured through vessel ownership in vessels:
    a. a redistribution of risks, financing transaction costs, and related profits from institutional lenders toward the private parties involved in a transaction, and
    b. more social connections between buyers and sellers than would be the case if borrowers were qualified by institutional lenders.
2. An uncertain but at most modest effect on the distribution of limited entry privileges among fishing operations:
    a. Some degree of increased opportunity for consolidation of Alaskan IFQ on vessels that also participate in the West Coast LEFG fishery,
    b. Some degree of increased opportunity for consolidation of LEFG permits on vessels that fish in both fisheries, and
    c. Some degree of increased opportunity for acquisition of LEFG permits by vessels that previously fished only in the Alaskan IFQ fishery.
3. An increase in the administrative effort required to track and enforce the control limits.

Fixed Gear Harvesting Operations

For the fixed gear sablefish harvesters, the proposed alternatives may affect profits and efficiency. There may also be some social effects.

The opportunity for larger operations (i.e. those constrained by the three-permit limit) to consolidate more harvest privileges (either by acquiring West Coast LEFG permits or by hiring out to WC&AK participants to harvest Alaska IFQ) may increase economic profits and fleet efficiency through economies of scale. The degree of the current constraint and consequently the opportunity provided by the action alternative (as described in Section 4.1.2) is modest for the fleet as a whole but may be important to some individuals.

The action alternatives may facilitate within-sector financing whereby the seller retains possession of a vessel as security for a loan (see discussion in Section 4.1.2). To the degree that additional seller financing of buyers is facilitated by an action alternative, the potential economic and social impacts for such sellers include:

- generating profits from financing the sale (either through charging an interest rate or a higher sale price);
- increasing the number of potential buyers by lowering transaction costs and financing barriers for potential buyers (which contributes to the profits in the first bullet and may speed the process of finding a buyer, reducing transaction costs for the seller); and
- a strengthened social network by facilitating entry of a community member or other known individual into the fishery.

The potential economic and social impacts for the vessel buyer in these situations include:

- access to financing and or lower financing costs than if financial institutions are the only option;
- competition from more potential buyers; and
- entry into a fleet with more social cohesion.

The current control rule and all-or-none accounting method is intended to err on the side of precaution in trying to ensure that the three-permit control rule is not undermined by private business arrangements which might convey control without conveying majority ownership interest. It also makes it more likely that there will be a greater number of harvesters that are totally independent of one another. The control rule is intended to disperse ownership of harvest rights among more individuals, balancing the efficiency outcome which would occur from unrestricted consolidation with objectives related to equity and dispersing income among communities.

One mechanism by which control might be asserted over a greater number of permits is through lending to finance the purchase of a vessel. At present, seller financing is reported to be a common practice in the industry. There exists opportunity to secure a loan associated with a vessel through a maritime lien, which does not result in the associated LEFG permits being counted against the lender. However, a common industry practice is to maintain security interest by retaining vessel ownership until the loan is paid. Such lending might be turned into leverage over a permit and the activities of a particular vessel. The current all-or-none rule reduces the opportunity to use that type of mechanism where its use is dependent on securing at least part ownership in a vessel. As discussed in Section 4.1.2, the action alternatives would provide opportunity to secure vessel financing through part ownership without tripping the control rule, potentially opening an avenue for circumventing the permit control rule. However, only those seller-financed transactions inhibited by the three-permit limit might be facilitated by one of the action alternatives. Additionally, even where the three-permit limit has presented an obstacle, members of industry may have found alternative ways to secure their loans, further reducing the potential effect through this impact mechanism. The action alternatives provide a limited exception for 20 percent (or 30 percent) ownership of two vessels without tripping the control criteria. This means that the maximum control over LEFG permits that an individual could have would be 100% ownership over three permits (as under No Action), plus up to 20 percent (or 30 percent) ownership in two vessels each of which were registered to three LEFG permits, (none of the permits on those vessels could be owned in any part by the individual). In other words, while the maximum number of permits an individual or entity could control, as control is determined under the LEFG permit program, is 9 LEFG permits, but the maximum number of permits over which an individual could have majority interest control would remain at 3. The options stop well short of providing the opportunity for an entity to have controlling interest in a vessel (50 percent interest). Impacts on financial institutions are discussed in the section on communities.

As a result of the additional vessel ownership information required to track and enforce compliance with this provision, under the action alternatives most owners of vessels registered with LEFG permits would likely be subject to the requirement to submit vessel ownership interest forms specifying each individual's share of ownership, increasing their paperwork burden.[17] There may also be an increase in fees charged to permit owners. LEFG permits and their associated tier limits are the main components of an LEFG IFQ. The MSA requires that costs of administering the program be recovered through fees, up to a maximum of 3% of ex-vessel revenue. Collecting the additional information would increase administrative workload and hence cost of administering and enforcing the program. These additional costs may be passed on to participants through fees, increasing vessel costs and resulting in a minor adverse impact on vessel profits.

Harvesters in Other Fisheries

As indicated in Section 4.1.2, an action alternative could result in shifts in fishing privileges among participants. On the one hand, there would be some decreased opportunity for Alaskan only vessels (AKO participants) to fish Alaska IFQ for WC&AK participants, as there would be a reduction in a constraint that currently limits WC&AK participants' ability to fish for one another. On the other hand, a few AKO participants that fish for WC&AK vessels might have a new opportunity to buy LEFG permits (become WC&AK vessels) without sacrificing income they earn by hiring out to fish Alaska IFQ for WC&AK vessels. However, there are already a large number of AKO vessels that have the opportunity to acquire LEFG permits and do not exercise such opportunity. The addition of a few more AKO vessels to the pool of potential participants is not expected to have a notable effect in new entry to the LEFG fishery by what are currently AKO participants.

The main impact mechanism by which other fisheries might be affected is consolidation. Section 4.1.2 indicates that under the action alternatives, there is some limited possibility that LEFG permits and Alaska IFQ may be consolidated onto fewer vessels, increasing competition and exacerbating management problems. Because of the limited number of entities affected, any impact would be expected to be relatively minor. This might then generate some surplus capital (vessels) that would be sold into other fisheries. Most US fisheries are under some form of rationalization program that would limit the effects of this surplus capital.

Crew

If there is some consolidation of LEFG permits and/or Alaska IFQ on to fewer vessels, then the income of crew members on vessels from which the permits/IFQ are moved may decrease while there may be a gain on the vessels to which the permits/IFQ are moved. If the loss of West Coast permits or Alaska IFQ result in a vessel going out of business then, rather than a decrease in income, there may be a net job loss. As described in Section 4.1.2., the degree of consolidation is expected to be minor.

Processors

[17] Currently, all vessel owners that are businesses (corporations) have to file an ownership interest form at renewal, but they do not provide percent ownership for individual shareholders. Vessel owners who are individual partners (husband/wife) would now have to file ownership interest forms and report relative ownership in the vessel. Also, vessels with multiple owners (corporations and individuals) would need to report relative ownership in the vessels. Businesses would continue to file ownership interest listing shareholders but would now need to provide percent of ownership for each shareholder.

Section 4.1.2 identifies some possibility of a geographic redistribution of harvest and landings, to the degree that LEFG permits are consolidated onto WC&AK vessels and that WC&AK vessels tend to have a different geographic distribution than West Coast only participants. Such a redistribution may affect processors (and processing-dependent jobs) that are dependent on the landings in a particular port. Processing companies that purchase through a number of ports would be less affected. Any redistribution of permits among owners is expected to be relatively minor (as described in Section 4.1.2 and the following section on communities), and it is uncertain whether or not there would be a geographic difference in the distribution of the harvesting activity of the owners receiving the permits.

Communities

Geographic distribution. Some increased consolidation of LEFG permits on vessels that participate on the West Coast and in Alaska is expected. The current fleet of WC&AK vessels tends to be distributed somewhat differently than those that participate only on the West Coast, with vessels from Washington and northern Oregon ports being more likely to participate in Alaskan fisheries than vessels from other ports (Tables 4-16). Whether geographic distribution is affected depends on the degree to which WC&AK acquire additional LEFG permits and the geographic area from which those additional LEFG permits come. With respect to consolidation, one of the primary motivations for the action is to allow the harvest of more Alaska IFQ to be consolidated on WC&AK operations, rather than allowing WC&AK operations to consolidate more LEFG permits. Nevertheless, some additional consolidation of LEFG permits may occur. If WC&AK operations acquire LEFG permits from West Coast-only vessels that operate in the same geographic region of the West Coast as the WC&AK operations, then there may be no net geographic impact would be expected. If they acquire permits from other regions on the West Coast, then some geographic redistribution may occur.

Tables 4-16. Counts of vessels by principal port and whether the vessels participated only on the West Coast LEFG fishery or also in Alaskan Fisheries (2012).

	West Coast Only	West Coast and Alaska Participation	Total
Puget Sound	-	3	3
North Washington Coast	8	2	10
South & Central WA Coast	8	4	12
Astoria	4	1	5
Newport	13	1	14
Brookings	9	-	9
Coos Bay	11	-	11
Crescent City	3	-	3
Eureka	4	-	4
Fort Bragg	6	1	7
Bodega Bay	2	-	2
San Francisco (excl. Bodega Bay)	4	-	4
Monterey	5	1	6
Morro Bay	6	-	6
Santa Barbara	1	-	1
Totals	84	13	97

With respect to the Alaska IFQ program, there could be some additional consolidation of harvest of Alaska IFQ on WC&AK vessels. Most of the Alaska IFQ consolidation would be expected to occur among existing WC&AK operations (i.e. those constrained by the West Coast LEFG control rule).

Social Connections. As discussed in Section 4.1.2, facilitation of seller financing may increase the degree to which buyers known to the seller are sold vessels, increasing social connections and cohesion within the fleet and community under the action alternatives.

Financial Institutions. Financial institutions are often part of local fishing communities. Under the action alternatives, financial institutions could lose some business if the control rule criteria have been inhibiting seller financing. Such inhibitions would likely be occurring only where the three-permit limit would be encountered and where means of securing lender interest, other than retaining ownership of the vessel, were not viable or cost effective (e.g. use of a maritime lien).

Agency Costs

Currently, to monitor the three permit limit, the agency need only keep track of a list of the individuals with some ownership interest in the permits and in the vessels. Under the action alternatives, the agency would have the additional cost of tracking whether an individual had more or less than a given percent and records would have to be updated each time an individual's share of ownership changes or a permit is transferred from one vessel to another. The action alternatives may require the tracking of ownership interests through multiple layers. For example, if the ABC Partnership owns 80% of a vessel and Mr. A owns 20% of a vessel but also owns a share of the ABC Partnership, Mr. A might then be considered to own in excess of 20% of the vessel. Such tracking will also add to program administrative costs.

Prior to the fixed gear sablefish program review, incremental costs associated with this IFQ were likely minimal, although at this time no quantitative assessment of incremental costs has been done. However, the actions being considered during this review process, if recommended and approved, would implement an electronic fish ticket and modify the control rules. These actions may introduce additional incremental costs. For example, implementation of modified control rules could require additional vessel ownership interest forms from some, as well as new database programming requirements that would take time and would require additional funding to implement. These are examples of additional incremental costs that could be tracked and partially recovered through implementation of a cost recovery program.

NOAA FISHERIES
West Coast Region

Implementation of Electronic Fish Tickets for Sablefish Landings

Agenda Item F.6.a

NOAA FISHERIES
West Coast Region

Problem Summary

- As of 2014, Federal permit numbers are not being recorded consistently on state landing receipts.
- The current catch accounting system is subject to inaccuracy and time delays, and is incapable of distinguishing between landings in the primary (tier) and daily trip limit (DTL) fisheries.
- OIG: “NOAA does not have adequate data and does not track or enforce landings overage violations in the Pacific Sablefish Permit Stacking IFQ.”

NOAA FISHERIES
West Coast Region

Purpose and Need

The purpose of the electronic fish ticket measure is to consider the implementation of a Federal requirement for an electronic fish ticket to capture essential fishery catch data for non-trawl groundfish fisheries. This measure is needed to improve catch accounting and to enforce sablefish tier limits in the primary fishery such that the integrity of the catch share program is maintained. In addition, there is a need to improve the timeliness of the data for management and enforcement of the fixed gear fisheries.

NOAA FISHERIES
West Coast Region

Electronic Fish Tickets

- **Electronic fish ticket** means a software program or data files meeting data export specifications approved by NMFS that are used to send landing data to the Pacific States Marine Fisheries Commission (PSMFC).

- **First Receiver** means a person who receives, purchases, or takes custody, control, or possession of catch onshore directly from a vessel.

NOAA FISHERIES

West Coast Region

Current Range of Alternatives
Alternative 1

(No Action) There are currently no Federal regulations requiring electronic fish ticket documentation for sablefish landings in the primary (tier) sablefish fishery, within the larger limited entry fixed gear (LEFG) fishery or within the OA fishery, which are managed under daily, weekly, and bimonthly trip limits.

NOAA FISHERIES
West Coast Region

Current Range of Alternatives
Alternative 2

A Federal requirement that **all tier** deliveries be recorded on an electronic fish ticket that documents the associated Federal groundfish permit number.

Current Range of Alternatives
Alternative 3

NOAA FISHERIES
West Coast Region

A Federal requirement that **all limited entry permit sablefish deliveries (primary/tier and DTL)** be recorded on an electronic fish ticket that documents the associated Federal groundfish permit number.

Current Range of Alternatives
Alternative 4

NOAA FISHERIES

West Coast Region

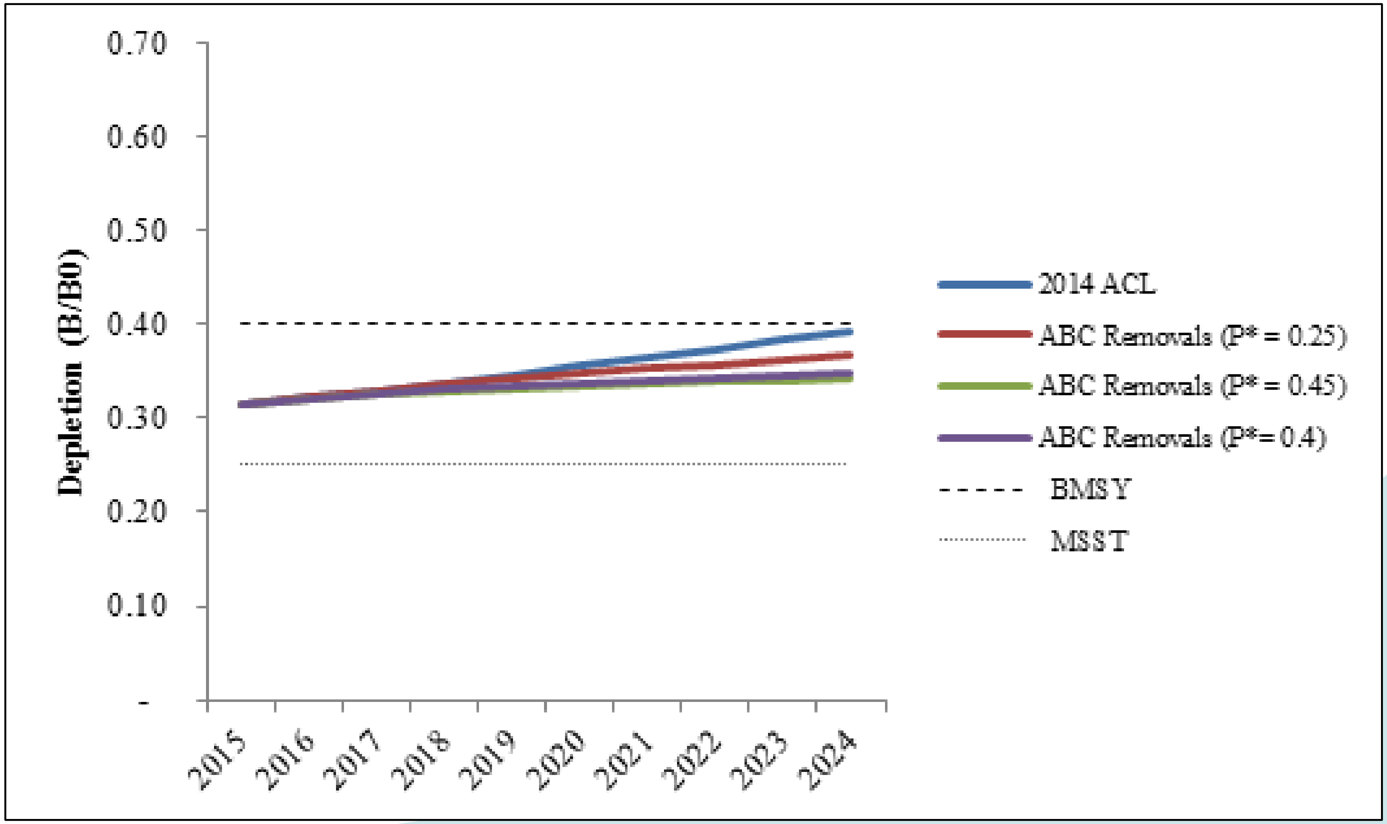
A Federal requirement that **all sablefish deliveries (primary/tier, DTL, and OA)** be recorded on an electronic fish ticket that documents the associated Federal groundfish permit number.

Biological Considerations

NOAA FISHERIES
West Coast Region

Based on the most recent stock assessment, the sablefish stock is in the precautionary zone.

Agenda Item F.7.a, Attachment 4: Preliminary Draft of, "Groundfish Harvest Specifications and Management Measures and Amendment 24: Draft Environmental Impact Statement"



Socio-Economic Considerations Industry

NOAA FISHERIES
West Coast Region

- Under the action alternatives, the burden of implementation will primarily fall on sablefish first receivers.

- Each first receiver will need to have a computer with internet access.

- Fishermen may find a reduced number of first receivers capable of recording sablefish landings on electronic fish tickets

Socio-Economic Considerations
First Receivers

NOAA FISHERIES

West Coast Region

The number of additional first receivers required to use electronic tickets under each alternative, by state and coastwide.

(Table 4-6 in Agenda Item F.6.a, Attachment 2)

	Washington	Oregon	California	Coastwide
Alternative 1	0	0	0	0
Alternative 2	9	4	20	33
Alternative 3	9	4	40	53
Alternative 4	13	11	53	77

Socio-Economic Considerations First Receivers

NOAA FISHERIES

West Coast Region

Burden hour estimates for coastwide first receivers.

(Adapted from Table 4-14 in Agenda Item F.6.a, Attachment 2)

	Number of sablefish landings per year	Total number of first receivers submitting electronic tickets	Burden hour estimate (hours per year)	Burden hour estimate (minutes per month per first receiver)
Alternative 1	4,851	0	0	0
Alternative 2	639	56	72	7
Alternative 3	2,682	76	369	24
Alternative 4	4,851	100	666	33

Socio-Economic Considerations State and Federal Agencies

NOAA FISHERIES

West Coast Region

- Implementation of an electronic fish ticket would be separate from, and in addition to, existing state reporting requirements.

Electronic fish ticket data from first receiver → **PSMFC** → **State of landing, management and enforcement agencies** → **PacFIN**

Council Decision Analysis Document
Agenda Items F.6.a, Attachment 2

- Rules for assessing permit control (for own/control limit) – Select ***FPA***
- Federal Electronic Landing Reports – Select ***FPA***

Own and Control Limit

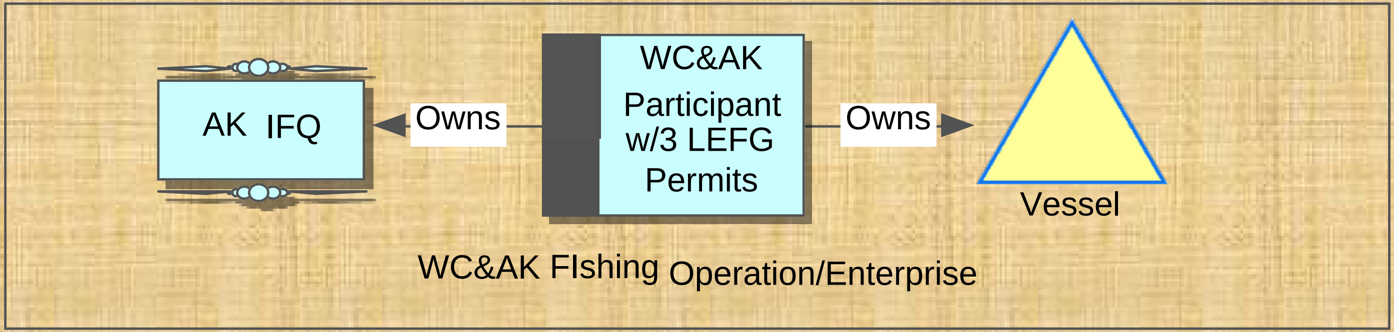
- 3 Permit Own/Control Limit
- Counting toward the limit
  - Partial ownership of any permit
  - Partial ownership of a vessel – permits registered to that vessel (leased or “held” permits)
  - E.g. A person gets to the three permit limit by being
    - an owner-operator of
      - a vessel and
      - the associated LEFG permit,

    and
    - part owner of another vessel which leases two LEFG permits

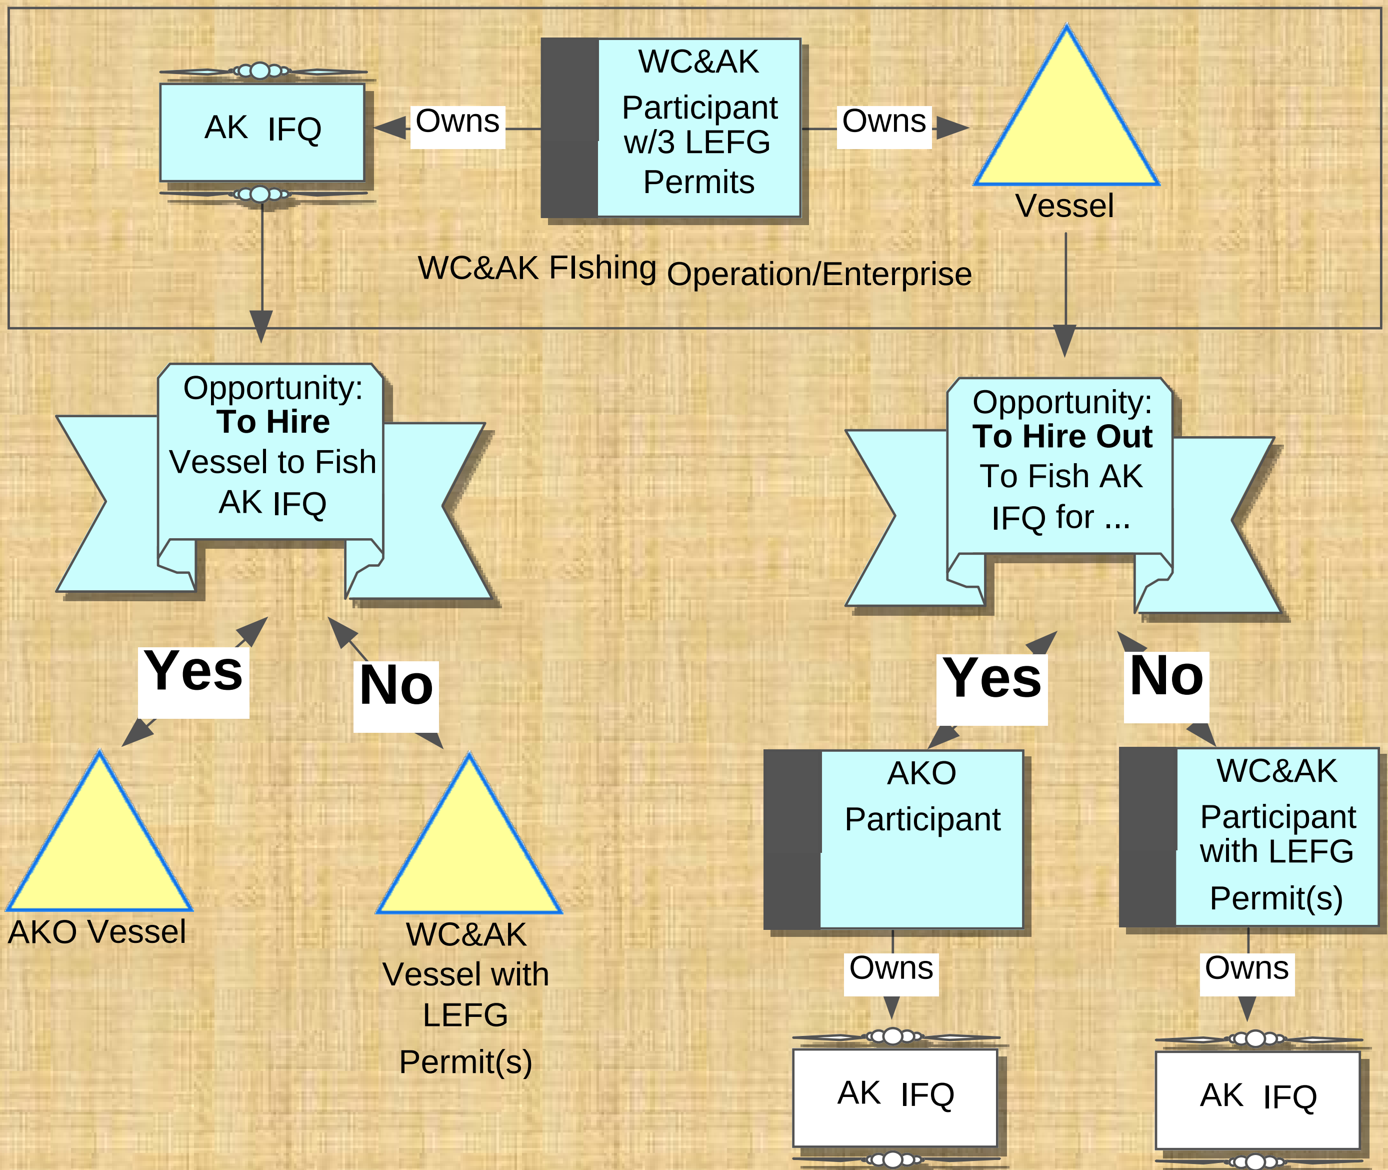
Assessing Permit Control and Alaska Fisheries

- Limitation on West Coast fishing operations' abilities to work with each other
- Cross participation in Alaska halibut and sablefish IFQ fisheries
  - In general, Alaska sablefish and halibut IFQ owners must either
    - be present during fishing, or
    - with a grandfather exception
      - hire a vessel to fish IFQ for them
      - 20% vessel ownership required
  - 20% vessel ownership counts for LEFG permit control

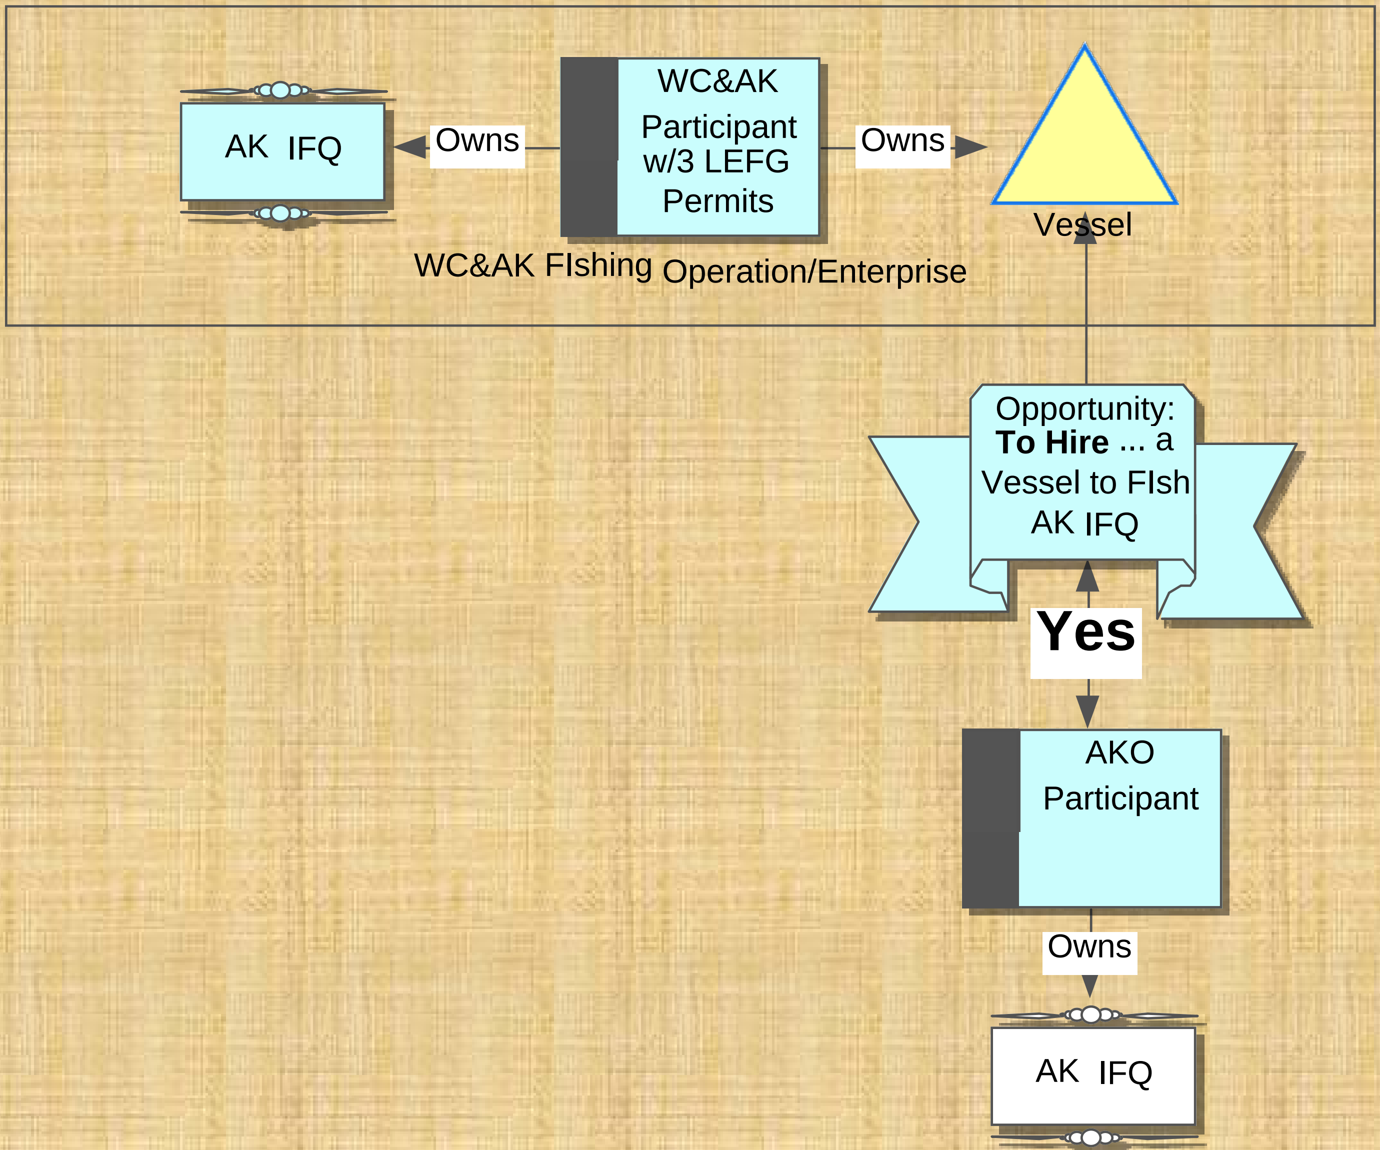
Assessing Permit Control and Alaska Fisheries



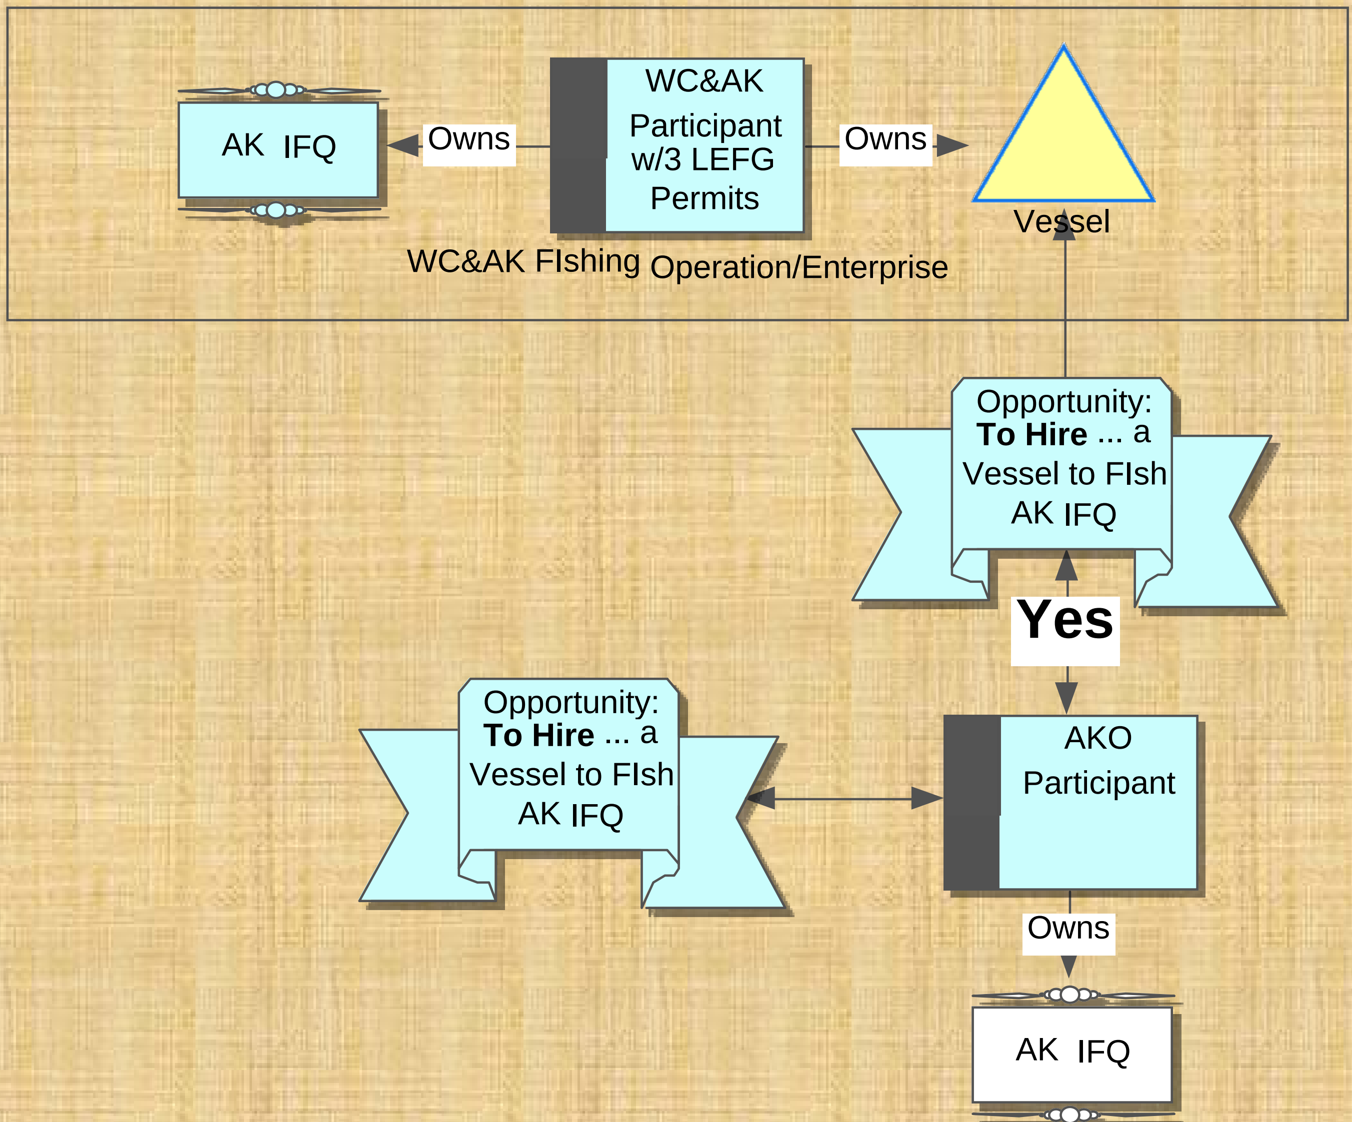
Assessing Permit Control and Alaska Fisheries



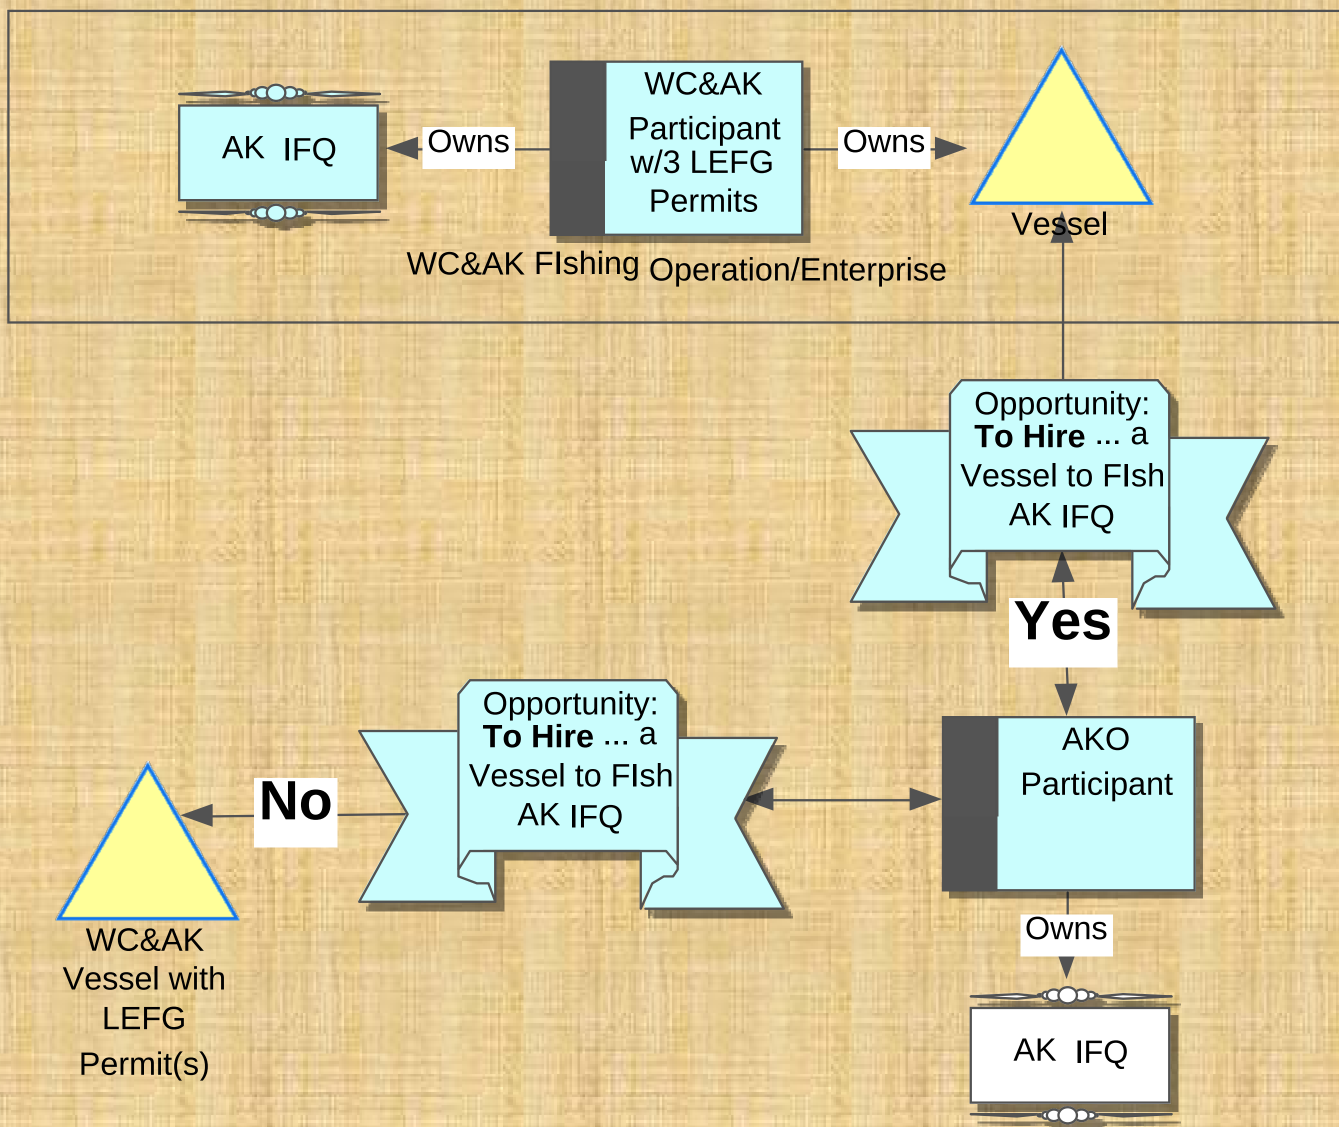
Assessing Permit Control and Alaska Fisheries



Assessing Permit Control and Alaska Fisheries



Assessing Permit Control and Alaska Fisheries



Assessing Permit Control Action Alternatives

- Action alternatives

  exempt the permits

  associated with up to two vessels,

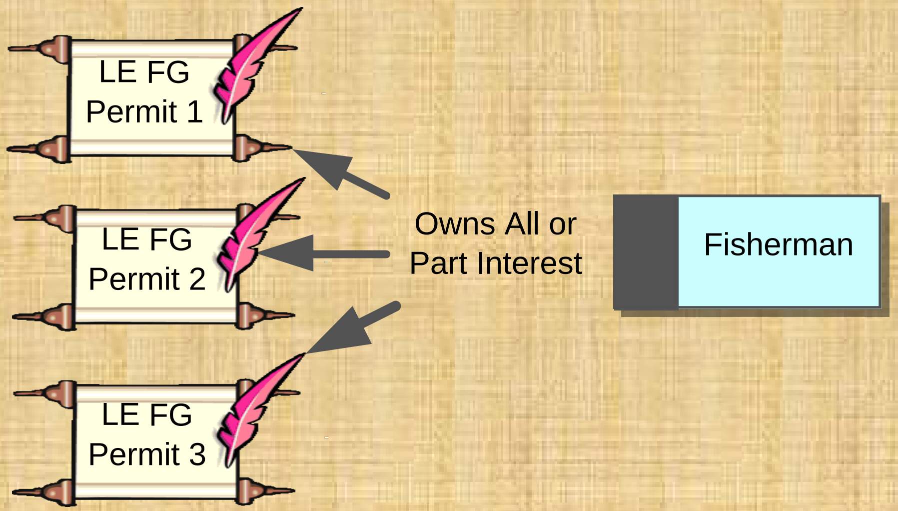
  so long as

  – no direct permit ownership, and

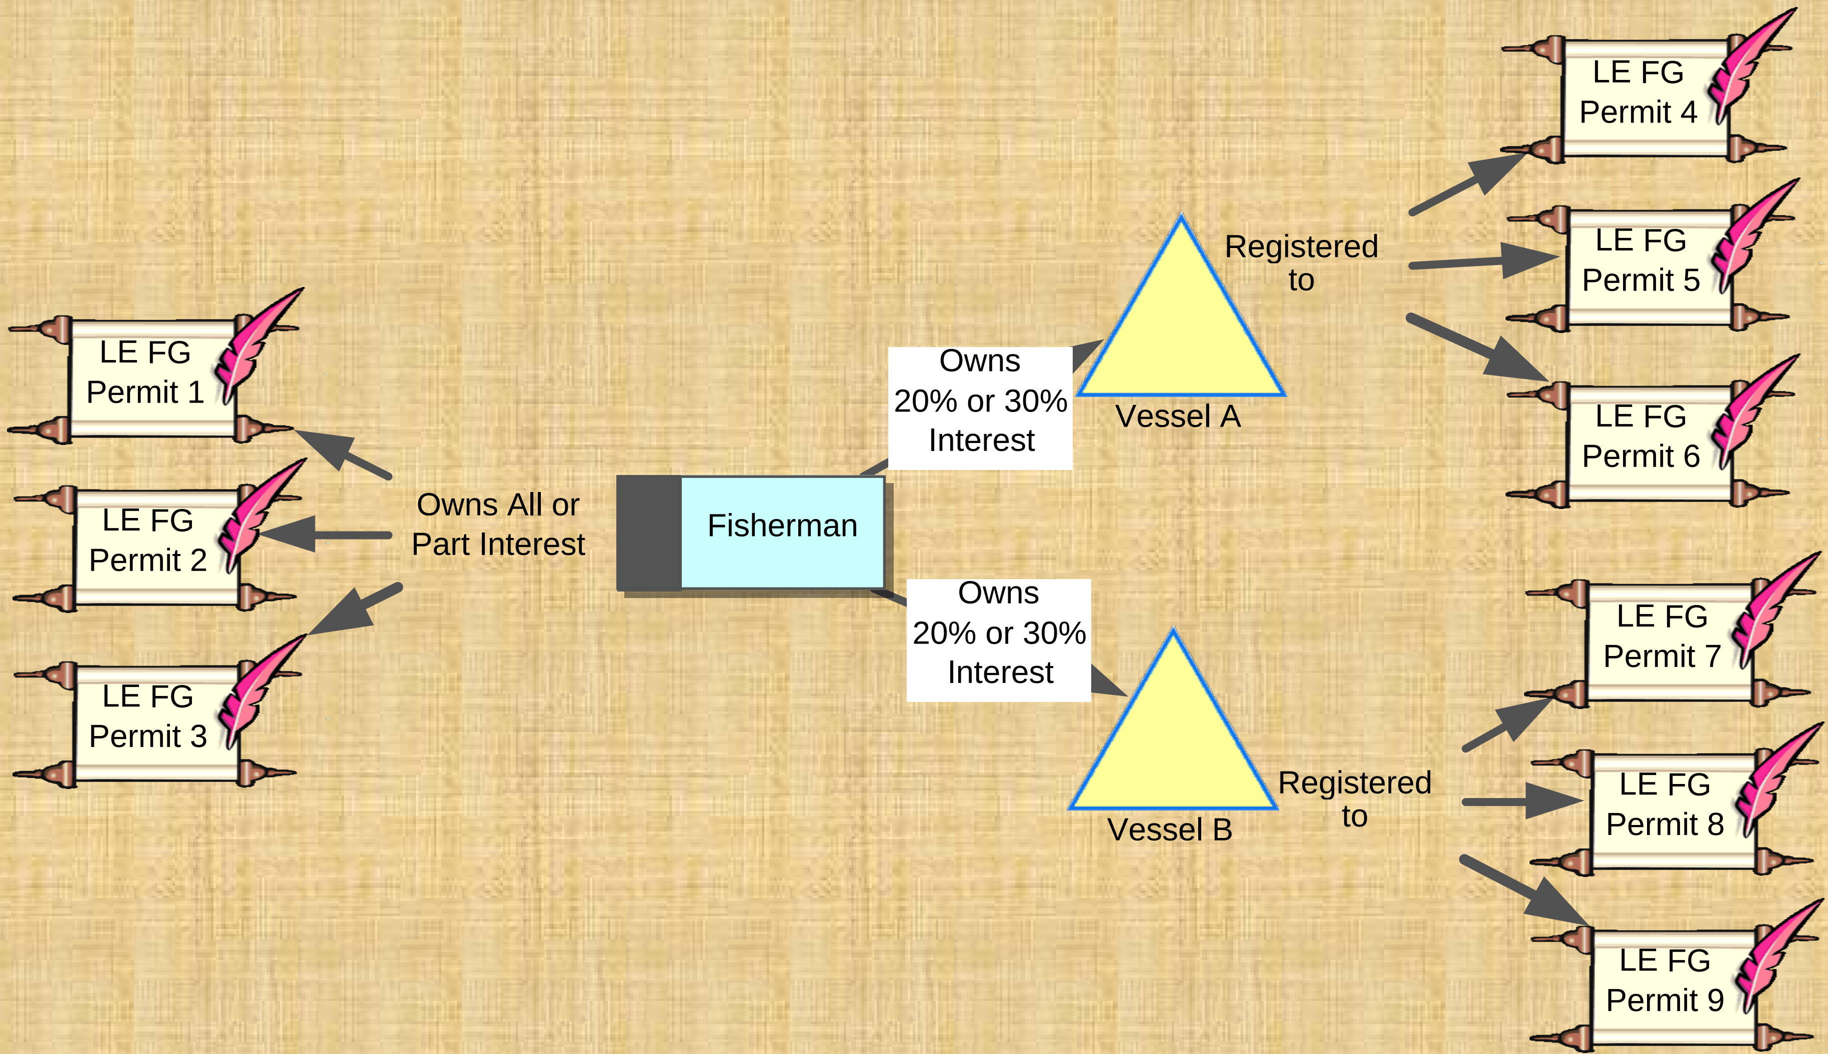
  – vessel ownership not more than

    - Action Alternative 2a – 20% **(PPA)**
    - Action Alternative 2b – 30%

Maximum Control Under Status Quo



Maximum Control
Under Action Alternatives

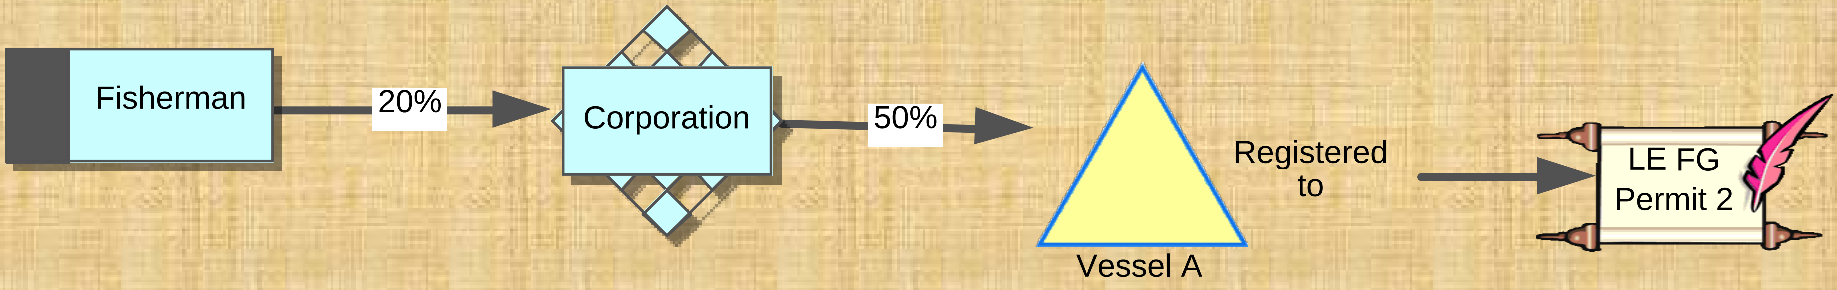


Details to Work Out

- Collective Ownership (e.g. corporation or partnership)
  - Before it was just a matter of “some” percent
  - Need to determine the percent owned

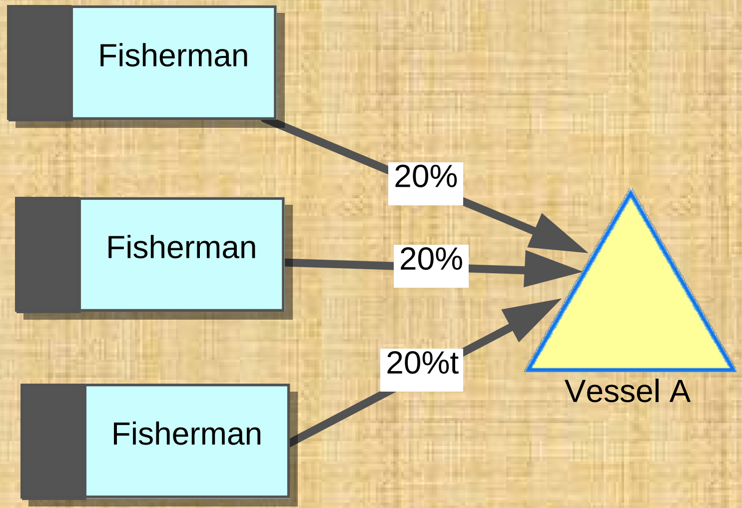
- Coordinated Ownership –
  - Potential for control to exceed the intended 20% or 30% threshold.

Collective Ownership : Determining the Percent a Person Owns



- Strawman Suboption 1 – Entire Interest Pass Thru
  - – fishermen owns 50% share of vessel A
- Strawman Suboption 2 – Pro-rata Pass Thru
  - – fishermen owns 10% share of vessel A (20% x 50%)

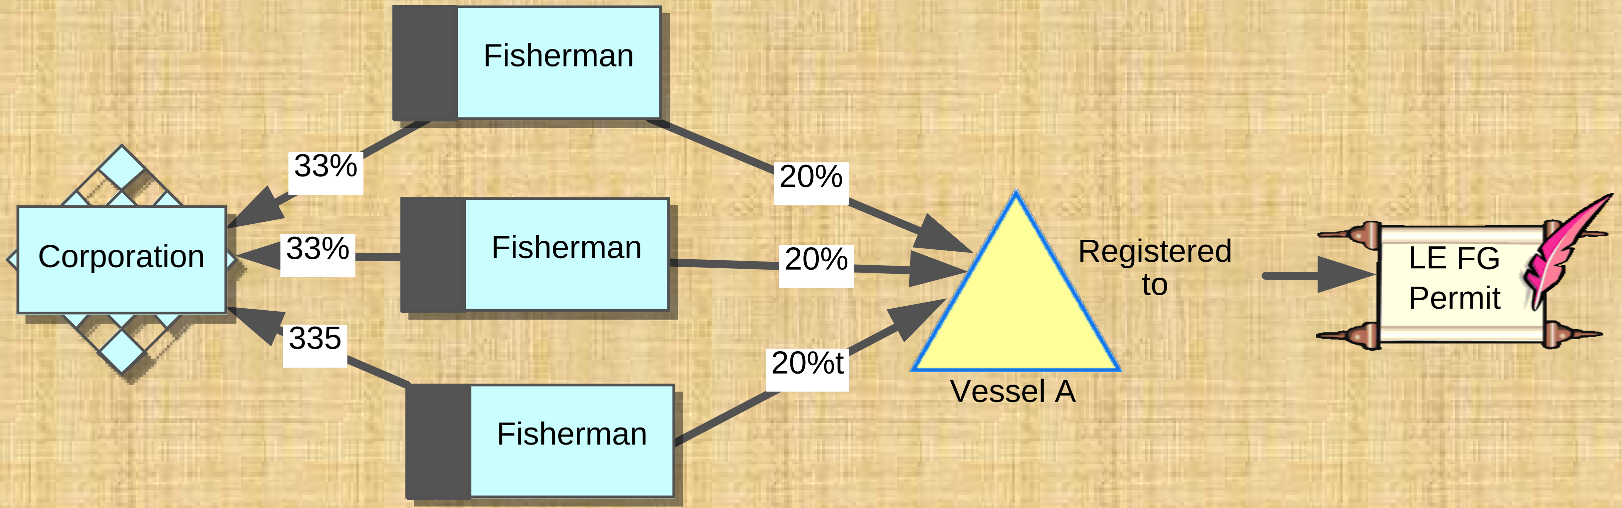
Coordinated Ownership



- Example
  - Each separately own 20 percent of a vessel which leases a permit.

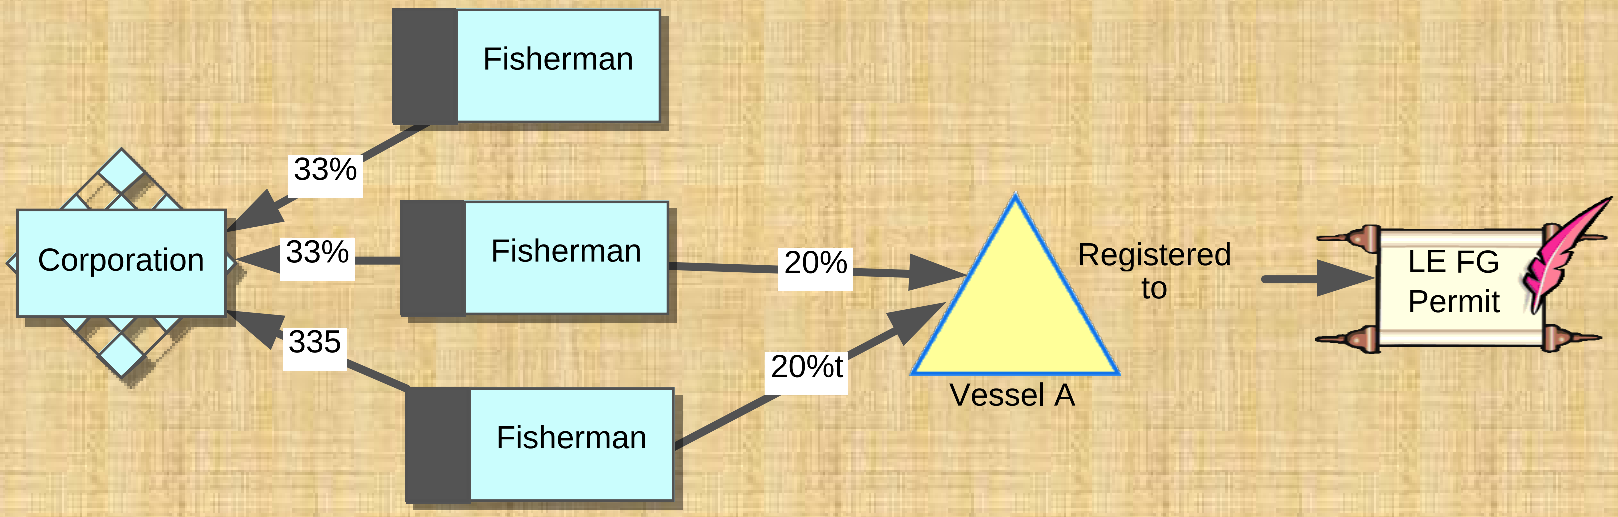
  - Action alternatives would exempt each vessel owner

Coordinated Ownership



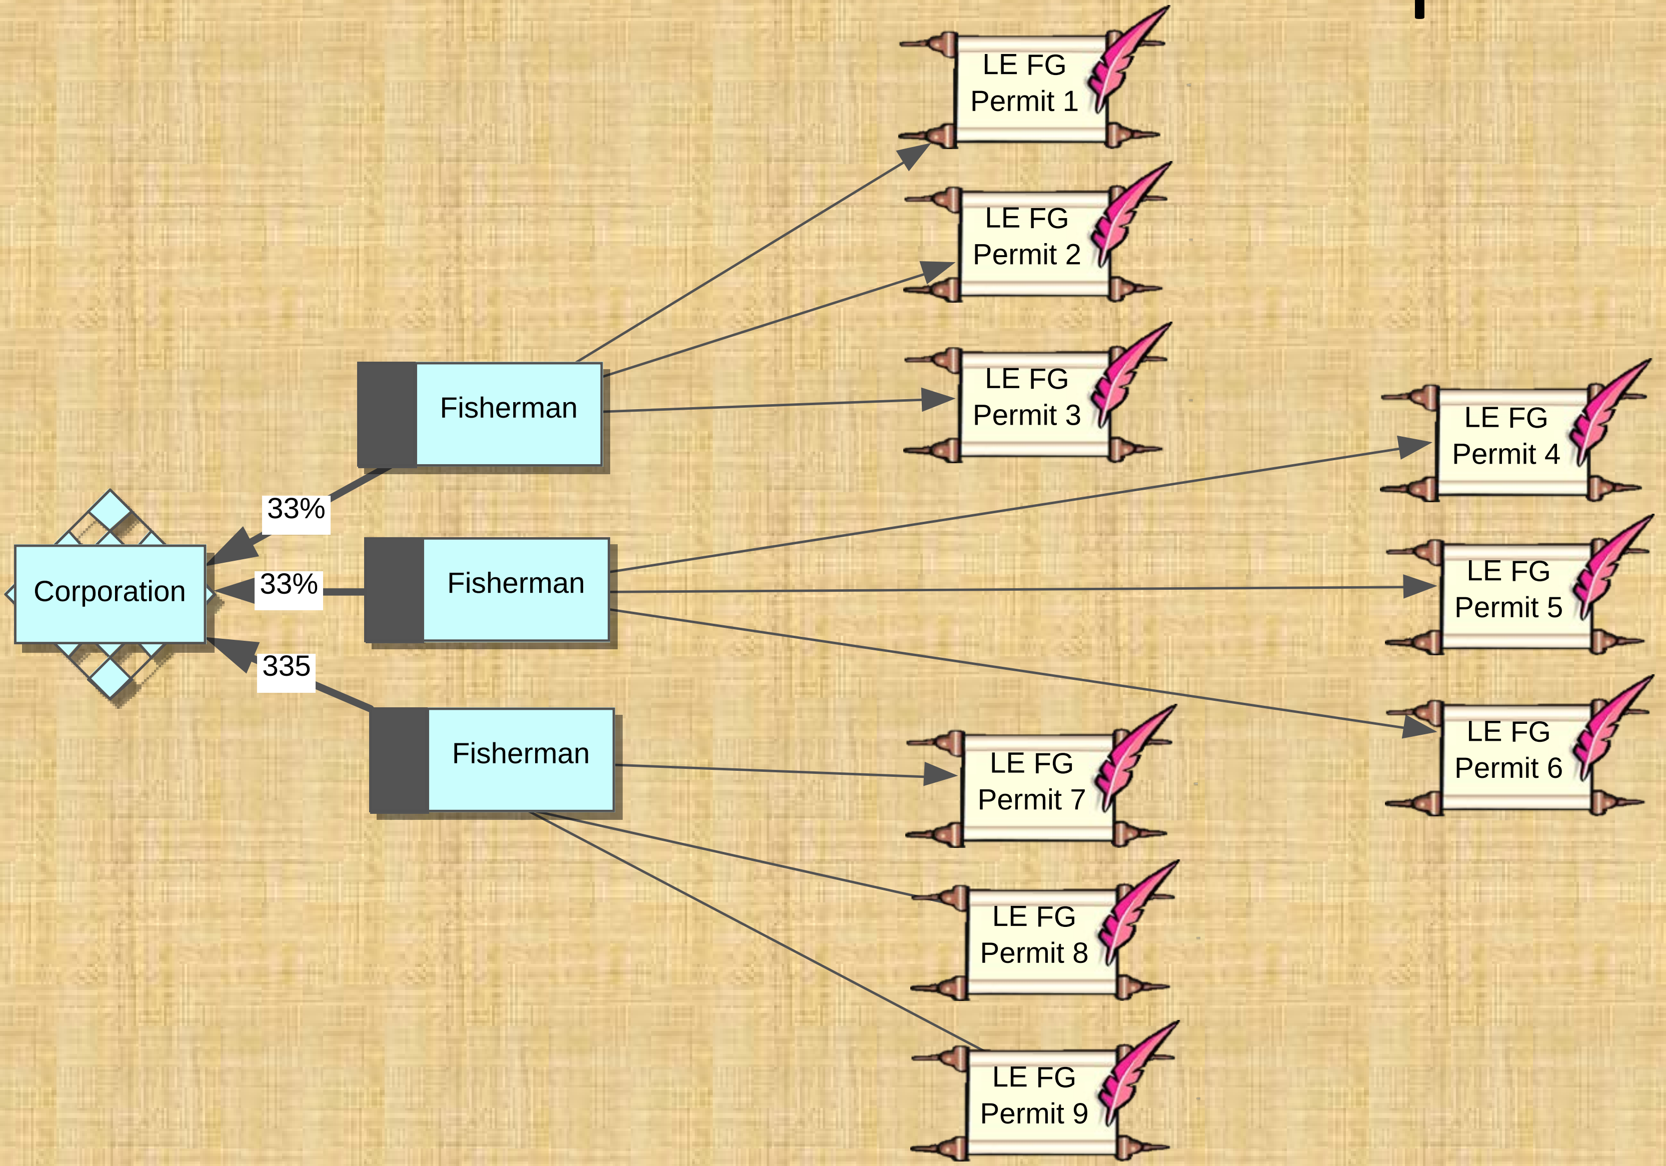
- Example
  - Each separately own 20 percent of a vessel which leases a permit.
  - Action alternatives would exempt each vessel owner
  - Control could be coordinated through a corporation

Coordinated Ownership



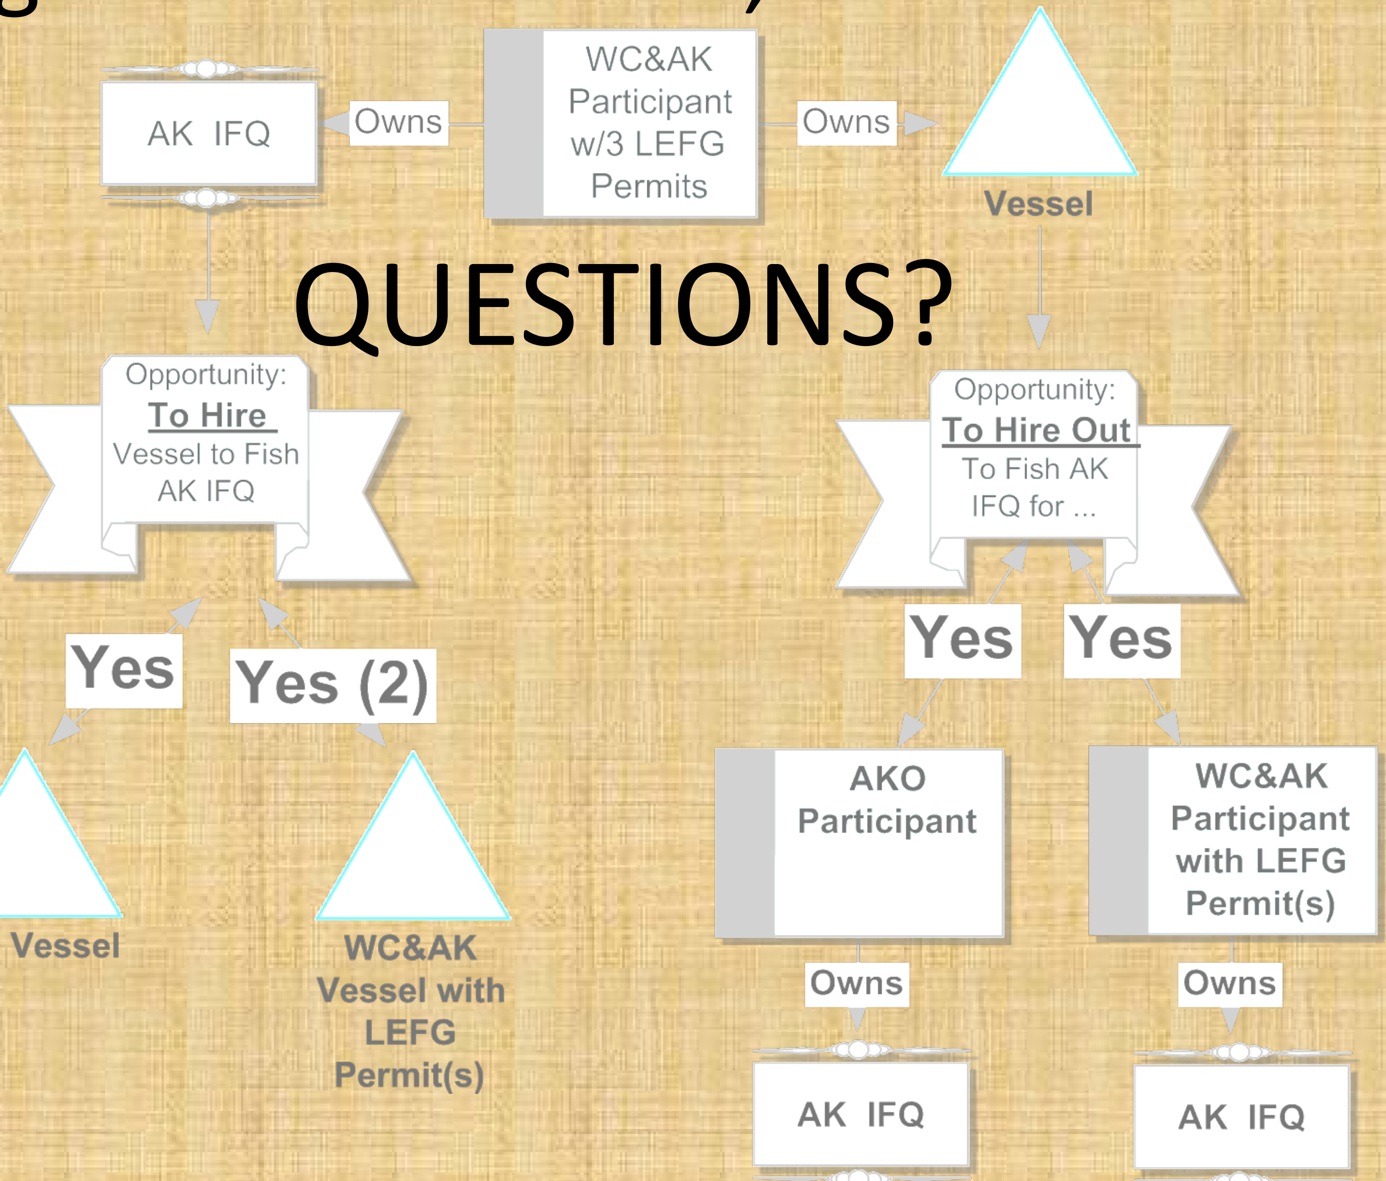
- The Coordinated Ownership Strawman Suboption would limit the exception.
- Members of a collective could own no more than 40% ownership interest in a vessel.

Coordinated Ownership



Council Decision Analysis Document
Agenda Items F.6.a, Attachment 2

QUESTIONS?



IMPLEMENTATION ISSUES ASSOCIATED WITH ELECTRONIC FISH TICKETS

Agenda Item F.6.a, Attachment 2, *Action to the Fixed Gear Sablefish Fishery Managed under the Pacific Coast Groundfish Fishery Management Plan*, analyzes the alternatives regarding implementation of an electronic fish ticket for sablefish landings in the Pacific Coast Groundfish Fishery. During development of this analysis, several implementation issues have been identified. These issues are listed below in the form of open-ended questions. NMFS plans to release a supplemental NMFS Report that addresses these questions.

Issue 1: Under Alternative 4, for open access, daily trip limit, sablefish landings, how will fishermen know whether they will have to land to a first receiver that has electronic fish ticket capabilities? In other words, what is the threshold for open access sablefish landings such that an electronic fish ticket is required?

Issue 2: What burden(s) are placed on the state management agencies?

Issue 3: Would first receivers be required to have some type of current, valid first receiver site license?

Issue 4: Would incidentally caught species on sablefish directed trips be required to be recorded on the electronic ticket?

Issue 5: Could transport tickets still be used? How would this work?

PFMC

ADDENDUM TO THE OWN/CONTROL LIMITS MEASURE: A NMFS-PROPOSED ALTERNATIVE AND CONCERNS REGARDING THE EXISTING PRELIMINARY PREFERRED ALTERNATIVE (PPA)

NMFS-proposed alternative: Under this alternative, eligible owner(s) of vessel(s) registered to a sablefish-endorsed limited entry permit could apply to the National Marine Fisheries Service (NMFS) for a limited exemption from the control rules. The exemption, if granted, would allow the person to own up to 20 percent of up to two vessels registered to other tier-endorsed limited entry permits without having the permits registered to the vessel(s) count against the individual's three-permit own/control limit. Additionally, members of a corporation would be restricted from owning, collectively, more than 40 percent of a vessel under the exemption (see "Strawman Suboption on Coordinated Ownership", Section 2.2.2 of *Action to the Fixed Gear Sablefish fishery Managed under the Pacific Coast Groundfish Fishery Management Plan*).

The current control rules would remain in place; any level of ownership in a sablefish tier-endorsed permit is a count of one towards the three-permit own/hold control rules and any level of ownership in a vessel registered to a sablefish tier-endorsed permit is also a count of one towards the three-permit own/hold limit.

To be considered eligible to receive this limited exemption from the control rules, the vessel owner must own tier-endorsed permits, Alaska sablefish individual fishing quota (IFQ), and vessel(s) that participate in both West Coast and Alaska sablefish fisheries. Currently, this is the only recently documented group of individuals that have had their ability to attain their tiers negatively impacted by the own/control limit. However, if there are other documented circumstances where this has been an issue, NMFS encourages the public to bring these issues to the attention of NMFS and the Pacific Fishery Management Council so that if other eligibility criteria are warranted they can be considered.

A tentative process for implementing this alternative is outlined as follows. If a vessel owner wants to apply for an exemption from the current control rules, NMFS would require the vessel owner to submit a letter to NMFS requesting the limited exemption, a copy of the vessel's current U.S. Coast Guard (USCG) vessel documentation form 1270, credible evidence of their eligibility to apply for the exemption, and an ownership interest form that shows both relative percent ownership amounts when there are multiple vessel owners and/or percent ownership of all shareholders of a business entity that owns the vessel(s). The request for exemption could be made at any time during the year and there would be no requirement to renew it annually. However, if any of the ownership interest amounts change or any vessel owners change (added or deleted) from that previously reported, the vessel owner must notify NMFS within 30 calendar days and resubmit a revised ownership interest form and USCG form1270.

Concerns regarding the existing preliminary preferred alternative (PPA): The PPA's proposed method for calculating vessel ownership for compliance with the control rules potentially adds three new layers of complexity to the existing regulations: (1) the 20 percent calculation for vessel owners, (2) capping that level of ownership at two vessels, and (3) potentially tracking the relative ownership of vessels across members of corporations to ensure it is within the 40 percent limit (if the strawman option on coordinated ownership is adopted, page 23 of Agenda Item

F.6.a, Attachment 2) . The administrative burden affects both NMFS and many vessel owners in the permit stacking program; NMFS would now have to calculate and track vessel ownership information at three levels and every vessel owner that is not the sole owner of their vessel would be required to fill out a vessel ownership interest form and understand and comply with increasingly complex regulations. Moreover, the scope of this PPA appears overly-broad when compared with the scope of the problem that is being addressed. The main problem being addressed here occurs when West Coast tier-endorsed permit owners also own Alaska sablefish IFQ and have been granted an owner on board exemption in Alaska that allows them to fish their Alaska IFQ on a vessel in which they have at least 20 percent ownership without being on board that vessel. If that vessel then also participates in the West Coast sablefish primary fishery , any tier-endorsed permits registered to that vessel count towards the vessel owner’s three-permit own/control limit, which can prevent the vessel owner from fishing tier-endorsed permits they own without exceeding the control limit. There are currently 97 vessels that participate in the West Coast LEFG fishery; of these vessels, only 13 participate in both the Alaska sablefish IFQ program and the West Coast permit stacking program. Under the PPA, the control rules would be modified for the entire permit stacking program in order to address an issue that only affects a minority of the fleet, but adds an increased administrative burden to all vessel owners and increased complexity to the regulations.

Although the outcome of this new alternative is likely to be very similar to the existing PPA, the approach is different. Instead of requiring many vessel owners to send vessel ownership information to NMFS (the majority of whom do not operate in Alaska) only the vessel owners who want the exemption would need to apply for it. The qualification standard for the exemption remains the same, but it is placing the burden on those who want the exemption to request it.

ENFORCEMENT CONSULTANTS REPORT ON FIXED GEAR SABLEFISH CATCH SHARE PROGRAM REVIEW, INCLUDING FEDERAL ELECTRONIC FISH TICKETS FOR OPEN ACCESS SABLEFISH DELIVERIES

The Enforcement Consultants (EC) has reviewed the documents pertaining to Agenda Item F.6 and has the following comments.

Modify the Own/Control Limit:

At the April Council meeting, the Council selected the following as the Preliminary Preferred Alternative (PPA) for this issue:

> Alternative 2a (PPA): No action for permit ownership (any percentage ownership in a permit is a count of 1); however, holding a permit is counted only if the vessel owner has a greater than 20% share. Partial vessel ownership is capped at two vessels, i.e. the 20% or less ownership in a vessel exemption could only be used twice. After this two-permit exception is reached, then any permits registered to a vessel, wholly- or partially-owned by the entity, would count toward the three permit limit, as described under No Action.

The PPA's proposed method for calculating vessel ownership for compliance with the control rules adds new layers of complexity to the existing regulations. Under this alternative, National Marine Fisheries Service (NMFS) will have the additional administrative responsibility of calculating and tracking vessel ownership information at multiple levels. Every vessel owner that is not the sole owner of their vessel will be required to understand and fill out a vessel ownership interest form in order to comply with the new regulations.

Alternatively, the NMFS-recommended alternative (Agenda Item F.6.b, NMFS Report 2) would produce a similar outcome, but with a diminished regulatory and administrative burden; the calculation of ownership would remain the same, but only the vessel owners who want the exemption would need to apply for the requested exemption. The qualification standard for the exemption remains the same, but places the requirement to request that exemption on those who want the exemption.

If the Council decides to move ahead with an action alternative, the EC endorses the NMFS-recommended alternative as described in Agenda Item F.6.b, NMFS Report 2. The EC evaluated three issues in coming to a consensus on its recommendation: complexity of regulation, regulatory burden on the individual and fleet, and the administrative burden on NMFS. To achieve the desired outcome of the PPA (increased flexibility regarding permit ownership calculation), increased regulatory complexity is a given. It is our assessment the NMFS alternative will lessen the regulatory burden on the fleet at large, while lessening the administrative burden on the NMFS.

Requiring Federal Electronic Fish Tickets for West Coast Sablefish Deliveries:

The Department of Commerce (DOC) Office of Inspector General (OIG) recently completed an audit of the West Coast Sablefish Limited Entry Permit (LEP) Tier Fishery and reported the following:

1. NOAA does not have adequate data and does not track or enforce landings overages violations in the Pacific Sablefish Permit Stacking individual fishing quota (IFQ).

2. In addition to its incomplete controls over monitoring Pacific Sablefish landings, NOAA has also not effectively enforced restrictions on landings overages. As noted in table 2, we identified 189 instances where actual landings exceeded the allowed landings for individual permits from 2008 through 2013. Although the majority of the overages were not significant as compared to the fishery's daily trip limit, 12 of the overages totaled 32,607 pounds. NOAA did not take any action to correct the overages, such as requiring the purchase or leasing of an additional permit, reducing allowable landings in the subsequent fishing year, or referring the violation to Office of Law Enforcement (OLE).

The OIG report included the following recommendations:

> (1) Require all Limited Entry Fixed Gear Sablefish deliveries to be recorded on the Pacific States Marine Fisheries Commission (PSMFC) e fish ticket.
>
> (2) Use the IFQ Vessel Account System to load and track fixed gear sablefish tier deliveries.

A decision on Recommendation 2 may be premature in that other options for tracking tier deliveries may be identified, but for the EC, Recommendation 1 is a vital enforcement tool, not only for LEP sablefish, but for all West Coast sablefish deliveries.

Moving to an electronic format will provide multiple benefits to industry, science, management, and enforcement, such as:

> For industry, data electronically entered into the system can be verified and validated at the time of entry by the buyer/first receiver and provides a tool for those buyers to capture and track fish tickets, generate tax reports, and summarize data for their own internal purposes.
>
> For enforcement, as reported by the EC at the April 2014 Council meeting, enforcement of landing overage violations, both tier/daily trip limit (DTL) and open access (OA) deliveries could be greatly enhanced through access to accurate, near real time tracking of landings against tier limits, conversion to DTL landing limits when tiers are exhausted, and daily/weekly OA deliveries. Each of these delivery scenarios creates unique enforcement challenges for federal and state enforcement personnel. For example, the following questions may arise: What is the status of a vessel's tier(s)? Which tiers are/were credited to a particular landing? Is/was the owner on board? Is the DTL

delivery within limits? Is the OA delivery within limits, daily, weekly, or cumulatively? What is the potential for an illegal split delivery, i.e. underreporting? How many daily deliveries were made by a given vessel during a reporting week, month, or bi-monthly period? What was the cumulative total of those deliveries? And in which state(s) were the deliveries made?

OA deliveries are exceedingly challenging for state dockside enforcement. E-ticket reporting would improve cumulative trip limit monitoring immensely. The current OA regulations allow for 300 lb/day, or 1 landing per week of up to 800 lb, not to exceed 1,600 lb/2months. Therefore, for the daily limit, up to six deliveries may need to be tracked over a two month period, while a minimum of two deliveries may need to be tracked over that same two month period for the weekly limit.

Implementation Issues Associated with Electronic Fish Tickets: Agenda Item F.6.b

Issue 1: Threshold for E-Ticket deliveries

Some have suggested that for Alternative 4, (all deliveries be recorded on the e-ticket) a sub-option should be developed establishing a threshold for e-ticket reporting, i.e. 100 or 200 pounds. The rationale for this suggestion being that e-reporting of small deliveries places a significant burden on buyers. To the contrary, the EC believes establishing a reporting threshold would create needless regulatory complexity to this proposed reporting process. It could potentially create confusion for buyers to have to determine whether paper or electronic reporting is appropriate for relatively small deliveries. In discussions with some buyers, they indicate that one simple reporting rule for all West Coast Sablefish deliveries is their preferred option.

Through discussions with Pacific Council staff, the EC has determined that over the past three years there were 981 OA sablefish deliveries of 200 pounds or less made on the West Coast, averaging 327 deliveries per year. 25 percent (245 or approximately 82 trips a year) of those deliveries were comprised of 50% or less of sablefish. 67 percent (657 or approximately 220 trips a year) were 100 percent sablefish. It is our conclusion that the vast majority of all these trips were targeted DTL or OA sablefish trips. Consequently, the threshold concept is not viable in that it will not address the EC cumulative trip limit monitoring problems, because all deliveries, small or large, need to be tracked and monitored against either DTL or OA cumulative trip limits.

Issue 2: What burden(s) are placed on the state management agencies?

The EC has no comment other than to point out that e-ticket reporting is already accepted for all commercial landings in Oregon. Washington continues to make progress in moving in a similar direction and California is in discussion with PSMFC exploring the functionality of e-ticket reporting.

Issue 3: Would first receivers be required to have some type of current, valid Federal first receiver (FR) site license?

The EC does not believe a Federal FR site license needs to or should be a requirement for West Coast sablefish deliveries. The Federal FR license is used in trawl rationalization as a means for deploying catch monitors (CM) and implementing elements of the CM Program, i.e. evaluating site/facilities capabilities and requirements, none of which are elements of the sablefish LEP or OA fisheries. A state buyer's license would be a continuing requirement.

Issue 4: Would incidentally caught species on sablefish directed trips be required to be recorded on the e-ticket?

Yes, complete recording of the trip is, at a minimum, desired, if not necessary, particularly where the e-ticket is used in lieu of paper reporting.

Issue 5: Could transportation tickets still be used?

Yes, in the same way the states use this process under their current regulations.

In conclusion, the EC recommends:

(1) If modifications to the own/control limit are deemed appropriate by the Council, adopt the NMFS-recommended alternative listed in Agenda Item F.6.b, NMFS Report 2.
(2) Adopt Alternative 4: A federal requirement that all sablefish deliveries (primary/tier, DTL, and OA) be recorded on an e-ticket that documents the associated federal groundfish permit number (with the exception of OA, which may have either a federal vessel documentation number or a state number, per specific state requirements).
(3) All incidentally caught species associated with the sablefish delivery should be recorded on the e-ticket with no minimum threshold exception.

GROUNDFISH ADVISORY SUBPANEL REPORT ON FIXED GEAR SABLEFISH CATCH SHARE PROGRAM REVIEW, INCLUDING FEDERAL ELECTRONIC FISH TICKETS OR OPEN ACCESS SABLEFISH DELIVERIES

The Groundfish Advisory Subpanel (GAP) received a review document of the sablefish limited entry fixed gear (LEFG) program and an Environmental Assessment Regulatory Impact Review (EARIR) for amendments to the program from Mr. Jim Seger and Ms. Ariel Jacobs. The GAP reviewed Table 5-1, which contained the preliminary conclusions of the work group on the success of the Council's LEFG sablefish permit stacking program. The 10 original objectives and the resulting findings of the program suggest it has significantly achieved what the Council had hoped to accomplish with a quota share alternative.

The authors of the review left four questions for constituent comment under section 5.2. The questions were reviewed by the members of the GAP. The four questions are as follows with GAP comments.

1. <u>The number of the Tier 3 permits stacked with two other permits increased consistently from the initiation of the program through 2008, but declined thereafter.</u> What may have caused the significant decrease that occurred from 2008 to 2012? During that time the occurrence of Tier 3 permits that were triple stacked dropped from 43 down to 22, almost as low as in the first full year of the program (Table 3-4)

   The GAP members could not account for this other than there may have been some operations that were retiring at this time that could account for some of the shift.

2. <u>What may have caused the apparently significant drop in fixed gear sablefish landings and dependence for Puget Sound ports since 2008. (Figure 3-14)</u>

   As the program has matured so have the markets. There are a number of fish buyers that make arrangements with other buyers or shoreside processing plants in other ports to offload product in order to accommodate vessels whose fish they historically have purchased from. The plant where product is delivered may not be the plant taking ultimate receipt of the product, but is likely receiving an off load fee and processing fee. Hence, other options have become available to the fleets.

3. <u>Is other fishery or processor information available concerning improvement in product quality or size of fish under the stacking program (e.g., targeting by location or depth, different product forms, etc.)</u>

   Since the program was implemented the directed sablefish fleet has moved off some of their shallower fishing grounds in order to avoid different rock fish species that have become over fished. The avoidance of yelloweye rockfish is one example. With regards to marketing, the resource is still very dependent on Asian markets. However, sablefish is more aggressively marketed in the United States as a high end product.

4. What might be the cause of the rapid increase in longline-to-trawl price differential for sablefish since 2010 that is not shared by the pot gear landings (Figure 3-22)

   The GAP could not account for this, but notes that in British Columbia, almost all its sablefish is harvested by pots and they receive similar prices as Alaska and Pacific Council sablefish when exported. Additionally, pot sablefish in S.E. Alaska and in the Bering Sea and Aleutians receive the same price for iced J-cut fish as the longline fleet from the shorebased processors.

   The GAP unanimously endorsed the following changes under Phase 1 of the LEFG program.

   The GAP supports the NMFS proposed alternative found in Agenda Item F.6.b, NMFS Report 2, which reads: "Under this alternative, eligible owner(s) of vessel(s) registered to a sablefish-endorsed limited entry permit could apply to the National Marine Fisheries Service (NMFS) for a limited exemption from the control rules."

   The exemption, if granted, would allow the same outcome as the Council's PPA.

   This option was described by staff as also requiring the vessel owner to apply to NMFS in order to receive the exemption. This option would eliminate requirements from the entire LEFG fleet submitting proof of ownership papers and limiting the paper work to only those who were in need of the exemption. The analysis identifies 13 operations in the Pacific Council area of authority that also have sablefish individual fishing quota (IFQ) rights in Alaska. It is believed several of these annually request an exemption.

   The analysis identified two strawman suboptions for determining how the ownership interest held by an entity such as a corporation or partnership accrues to the individual owners of that entity. The GAP recommends Strawman Suboption (2), which is as follows.

   Pro-Rata Ownership Interest Passes Through – If an entity owns a vessel, any individuals with a share in the ownership of that entity are counted as having a share in ownership of the vessel proportional to their actual share in ownership of the entity (e.g., if a corporation owns 50 percent of a vessel, and two individuals each own 50 percent of the corporation then for purpose of evaluating the three permit control limit those two individuals are each counted as having 25 percent ownership in that vessel)

   This approach is the same as that used in the Trawl Rationalization Program. It is for this reason and for a clear understanding of ownership assignments that the GAP favors this option.

   The GAP was originally willing to support a strawman suboption on coordinated ownership, however it was concluded by staff that this option may not achieve any additional benefits than existing status quo restrictions currently provide. For this reason the GAP chose to not endorse this option.

Electronic Fish Ticket Alternatives

The GAP supports Alternative 4, Federal requirement that all sablefish deliveries (primary/tier, daily-trip-limit [DTL], and open access [OA]) be recorded on an electronic fish ticket that documents the associated Federal groundfish permit number.

GAP recommendations for Phase 2 of the review are as follows.

1. Develop a program that combines the DTL and tier limit fisheries. This option would be much more cost effective for a vessel operator that is currently expending fuel for many single trips.

2. Allow the existing tier permits to be fished either with longline gear or pot gear and examine allowing pot gear to fish shallower than the existing fixed gear Rockfish Conservation Area (RCA) depths limitations.

   With the discussion this week on possibly moving yelloweye rockfish from the non-nearshore sector to the nearshore sector and the recent issue with shortraker and rougheye rockfish this option would allow for fixed gear to minimize its interaction with rockfish and the associated protective restrictions.

PFMC
06/22/14

GROUNDFISH MANAGEMENT TEAM REPORT ON THE FIXED GEAR SABLEFISH CATCH SHARE PROGRAM REVIEW, INCLUDING FEDERAL ELECTRONIC FISH TICKETS FOR OPEN ACCESS SABLEFISH DELIVERIES

The Groundfish Management Team (GMT) received a presentation from Ms. Ariel Jacobs (National Marine Fisheries Service, West Coast Region) and Mr. Jim Seger (Council staff) on Phase I of the Fixed Gear Sablefish Catch Share Program Review (Agenda Item F.6.a, Attachment 1), including the potential actions by the Council on electronic fish tickets for sablefish landings and modifications to the own/control limit. Due to the complexity of ownership options, permit control considerations, and competing workload priorities at this meeting, the GMT did not have an opportunity to study and discuss the components of the program in detail; the GMT has no comments to offer on these topics at this time. Regarding the use of Federal electronic fish tickets and the findings of The Office of Inspector General's (OIG) report on National Oceanic and Atmospheric Administration (NOAA) catch share programs (U.S. Dept. of Commerce 2014), the GMT offers the following comments and observations.

Federal electronic fish tickets for the sablefish fishery

The GMT sees advantages to electronic fish tickets in improving the timeliness of landings data available for coastwide management, especially for inseason tracking of the sablefish fishery sectors, and supports their use should the Council recommend them as a tool to assist in more efficient fishery management. However, the GMT points out that management has been successful using paper fish tickets, as shown by our ability to track and monitor fishery impacts in relation to achieving harvest guidelines (HGs) and staying within annual catch limits (ACLs). The fixed gear sablefish fishery has remained below (but has approached) the non-trawl allocation in 17 of the past 18 years (Figure 1; excerpted from Agenda Item F.6.a, Attachment 1, June 2014), the one exception being 1997.

The GMT also discussed whether electronic tickets would reduce errors. Using electronic fish tickets may reduce some types of errors relative to fish tickets (e.g., transcription errors). However, we note that errors will undoubtedly continue to be made, whether this occurs when completing traditional paper landing receipts, punching numbers into an electronic device by first receivers, or through transcription and data entry errors further up the line. Electronic tickets can prevent some more obvious errors, where the entry should be limited to one or only a few specific possibilities, but is not expected to reduce transcription errors, etc.

The Office of Inspector General (OIG) report NOAA catch share programs

Ms. Jacob's presentation included excerpts from a recent report by Department of Commerce's Office of the Inspector General on catch share programs. Some on the GMT were surprised and puzzled by the following conclusion and provide comment to clarify potential misunderstandings:

> "NOAA does not have adequate data and does not track or enforce landings overage violations in the Pacific Sablefish Permit Stacking Individual Fishing Quota (IFQ). NOAA currently does not monitor Pacific Sablefish landings on an individual permit basis during

> a fishing season. Instead, it only monitors landings for the entire fishery as a whole, using a paper-based system that is subject to compromise and the multiple possibilities of error associated with any manual process. In addition, we identified 189 instances where actual landings exceeded the allowed landings for individual permits from 2008 through 2013."

Members of the GMT understand that the data exists to track and enforce landings overage violations. A number of violations and overages were presented in the OIG report that were based on these data, which suggests that the data we have now should be adequate to detect violations. The violations are also relatively minor in terms of the poundage involved. Of the 189 violations, 110 were over by an average of 30 lbs. Only 12 were over 1,000 lbs. We cannot double-check to see if their numbers are correct because their methods were not provided.

The report does not mention state enforcement activities, and the GMT wants to point out that some of the overages they found could have been cited by state enforcement instead of Federal enforcement. States actively track landings against individual tiers and cite violations. Several of us are also involved with Pacific Fishery Information Network (PacFIN) and have pointed out in the past few years that there are issues tracking tier landings across states. This is more of a coordination problem, and a problem regarding data that was being recorded (or not recorded) on fish tickets, rather than a data problem or a paper fish ticket problem (i.e., this situation could have occurred whether using paper or electronic fish tickets). The PacFIN database is adequate to track landings against permits.

Lastly, enforcement of the tiers and the incentives of the catch share program have served their ultimate purpose of keeping catch to target levels. And in the trip limit fisheries, management performance and enforcement have performed to expectations (Figure 1).

We fully agree that the data system could be improved, and that electronic fish tickets may provide for more timely access to data from all three states. However, many on the GMT strongly disagree with the point that the data are inadequate. And while electronic fish tickets would make the system easier to enforce, it will not make the system impervious to “compromise” and “errors.” As we note above, quality control of fish tickets involves professional judgment/experience that cannot be replaced by fully electronic reporting.

We make these comments because the report’s findings did not seem completely accurate, which might color the Council’s view of urgency and management priorities. We do not agree with the view that the sablefish data issues are such that they question the very integrity of management. Given all the competing initiatives at play, the system can continue to function adequately without electronic fish tickets if the Council wishes to prioritize other matters over electronic fish tickets.

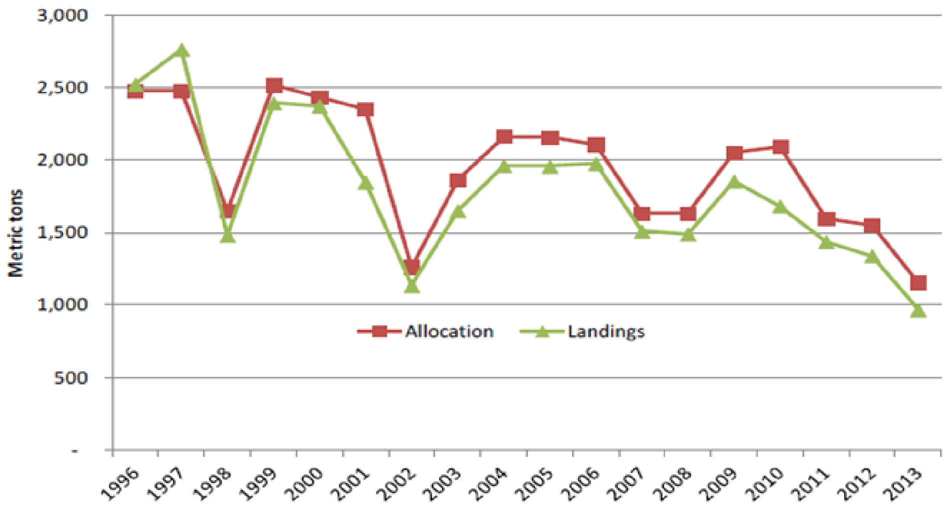

Figure 3-4. LEFG sablefish allocations and landings, 1996 through 2013. Years prior to 2002 include the mop-up and DTL fisheries, while years from 2002 to 2013 are for the primary season only.

Figure 1. Limited entry fixed gear sablefish allocations and landings, 1996 through 2013. Excerpt taken from [Agenda Item F.6.a, Attachment 1, June 2014](#).

Issue 2: What burden(s) are placed on the state management agencies?

Issue 3: Would first receivers be required to have some type of current, valid first receiver site license?

Issue 4: Would incidentally caught species on sablefish directed trips be required to be recorded on the electronic ticket?

Issue 5: Could transport tickets still be used?

NOAA FISHERIES
West Coast Region

Agenda Item F.6.b, NMFS Report 2:

Addendum to the Own/Control Limits Measure: A NMFS-Proposed Alternative and Concerns Regarding the Existing Preliminary Preferred Alternative (PPA)

NMFS-Proposed Alternative

NOAA FISHERIES
West Coast Region

- Eligible owner(s) of vessel(s) registered to a sablefish-endorsed limited entry permit could apply to NMFS for a limited exemption from the control rules
- To be eligible to apply the vessel owner must own tier-endorsed permits, Alaska sablefish IFQ, and vessels that participate in both West Coast and Alaska sablefish fisheries
- The exemption would allow the person to own up to 20% of up to two vessels registered to other tier-endorsed limited entry permits without having the permits registered to the vessel(s) count against the individual's three-permit own/control limit

Agenda Item F.6.b
Supplemental SSC Report
June 2014

SCIENTIFIC AND STATISTICAL COMMITTEE REPORT ON FIXED GEAR SABLEFISH CATCH SHARE PROGRAM REVIEW, INCLUDING FEDERAL ELECTRONIC FISH TICKETS FOR OPEN ACCESS SABLEFISH DELIVERIES

The Scientific and Statistical Committee (SSC) discussed the Pacific Coast Groundfish Limited Entry Fixed Gear Sablefish Permit Stacking Program Review (Agenda Item F.6.a, Attachment 1) with Mr. Jim Seger. The analysis incorporates suggestions made by the SSC at the April meeting. The SSC concurs with the preliminary conclusions in Section 5.0 (Preliminary Conclusions and Questions). Periodic retrospective evaluations such as this are useful for determining the efficacy of Council management programs. The SSC recommends the Council consider including collection of permit price and fishery participant data as described in Section 4.0 (Research Needs) in Section 6.0 (Council Recommendations).

Agenda item F6

Pacific Fishery Management Council
7700 NE Ambassador Place, Suite 101
Portland, Oregon 97220-1384

Dear Council Members:

I propose that the council consider changes to the sablefish DTL fishery. The goal would be to have a year round, stable sablefish fishery for fishermen, managers and law enforcement.

My idea on how to do this is:

1. Select a window period. I propose we use 2007-2012. During those years it was a boom time in the fishery. A lot of people spent a lot of money buying permits. To ensure their investment is realized, this window period would work well.
2. Figure out the percentage of DTL each permit caught during the window period and convert those pounds to the permit for a year round fishery.

In the past the council has always allocated the fish to the fishermen who have depended on the fishery. The council should allocate the DTL fish to fishermen that have been fishing in the DTL fishery. The unendorsed permits would be included in the allocation.

The benefit from this change:

Law enforcement: will not have to spend their time on monitoring landings and trying to determine if hundreds of boats are over thier limit by 10 pounds per trip.

Fishermen: can fish these pounds on their own time frame, there will be less need for high grading, it provides stability to plan out your entire fishing year without having to worry about if the DTL fishery will go up, or down, or cut off.

Managers: will be able to plan their year round fishery one time, no spending time on in-season changes, and no more staff time on monitoring and guessing effort. They can also implement the fishery close to the maximum pounds without fear of going over.

Observers: since this is not a full retention IQ program, all they have to do is observe on a selected boat the tier amount during some point of the year. For example, the fishermen must give the observer company a one month advance notice of when they will be fishing on their tier amount. This way there would be no change in how the observer program operates, they just plan for their trips.

Overall, I see this proposed change providing flexibility and stability for all parts of the industry. Thank you for considering my proposal.

Jeff Miles. GAP, F/V Top Gun (541)-260-0941

Agenda Item F.3 Omnibus and F.6 Fixed GearPublic Comment

Dear Chair Lowman and Council Members:

My husband , Bob Eder and I are owner/operators of the F/V Timmy Boy , based in Newport Oregon. We fish for sablefish under the LE Fixed Gear program, and also participate in the trawl IQ program, using fixed gear.

We are submitting this letter as public comment under two agenda items, as I have received varying guidance from NMFS and Council staff as to where this would best fit.

We would like to propose a rule change to 50 CFR 660, Subpart C, Section 660.12 (a) (11). This rule currently provides that it is a violation to fail to remove all fish from the vessel at landing (as defined in § 660.11) and prior to beginning a new fishing trip. "Land or Landing" is defined in the regulations as: "To begin transfer of fish, offloading fish, or to offload fish from any vessel. Once transfer of fish begins, all fish aboard the vessel are counted as part of the landing. "

Recently, we've received various interpretations as to how this rule is applied, depending on whether it is Fixed Gear Limited Entry Sablefish, or Trawl IQ Sablefish. It appears that if it is our trawl sablefish, it can be unloaded at 2 different locations, as long as they are both licensed first receivers. Conversely, it appears that if it is fixed gear sablefish, the rule is being interpreted to require we offload all our fish at one time, which, practically speaking, means at one location.

We'd like a rule change so that when we come in with a load of fixed gear sablefish, we can unload some to a buyer at a public hoist, for example, and then deliver the remainder to our main processor. Fish tickets , paper or in the future, electronic, would be written at both places for the amount sold, and the LE fixed gear permit numbers would be on the tickets so the fish is accounted for.

One of the reasons we'd like to do this is so we can potentially add value to our fish. We'd like to sell to an emerging live sablefish market, which does pay premium prices. We may also want to deliver fish across the dock and sell some of our fish to our own fish company for custom processing. In either event, the rule currently prohibits our ability to develop markets for our fixed gear fish, other than selling the entire load at one place for one set of prices.

A change in the rule as described above would provide for additional economic opportunity and development, to benefit the entire coast wide fixed gear fleet, and the public it serves.

Thank you for your consideration.

Sincerely,

Michele Longo Eder and Bob Eder
F/V Timmy Boy

FISHERIES IN 2015-2016 AND BEYOND: HARVEST SPECIFICATIONS, MANAGEMENT MEASURES, AND AMENDMENT 24

The process to adopt the 2015-2016 harvest specifications and management measures began in June 2013 and culminates at this meeting with final action scheduled under Agenda Item F.7. Final action is also scheduled under this agenda item for Amendment 24, which would amend the Fishery Management Plan (FMP) to include default harvest control rules that would be used in future bienniums, unless modified by the Council, to establish harvest specifications; and to designate some FMP species as ecosystem component (EC) species. Amendment 24, coupled with the long-term impact analysis (referred to as the Tier analysis), is designed to streamline the analytical process, substantially reduce future workload, and increase the probability that future harvest specifications are implemented January 1. Detailed descriptions of anticipated Council actions are described in Agenda Item F.7.a, Attachment 1.

At its April 2014 meeting, the Council adopted final overfishing limits (OFLs) as recommended by the Scientific and Statistical Committee, acceptable biological catches (ABCs) that incorporate scientific uncertainty buffers, and annual catch limits (ACLs) for stocks and stock complexes (Agenda Item F.7.a, Attachment 2). Relative to the slope rockfish complexes, the Council's preliminary preferred decision was to maintain the status quo complex structures. Further, the Council recommended a coastwide sorting requirement for rougheye and blackspotted rockfish. The Council also took final action to designate the following species as EC species: finescale codling (aka Pacific flatnose), soupfin shark, spotted ratfish, all endemic skates except longnose skate, and all endemic grenadiers. Lastly, the Council selected preliminary preferred fishery structures and narrowed the list of new management measures under consideration for implementation in 2015 (see Attachment 1, page 4).

Council Action, below, lists seven decisions that must be made under Agenda Item F.7. The substance of each of these decisions is briefly described below.

- <u>Decisions 1 & 2</u>: Establish a new target year to rebuild cowcod and adopt revised 2016 OFL and ABC values for cowcod. Table 2 in Attachment 2 contains the estimated time to rebuild cowcod under a range of ACLs. The projected 2016 cowcod OFL and ABC under the Council's preferred alternative differs slightly from those specifications adopted in April (the 2016 OFL changed from 66 mt to 68 mt and the 2016 ABC under a P* of 0.45 changed from 59 mt to 62 mt).
- <u>Decision 3</u>: Confirm EC species designations and provide guidance on the associated FMP language (Attachment 8).
- <u>Decision 4</u>: Select the final preferred alternative for managing the slope rockfish complexes (Attachment 4).
- <u>Decisions 5 & 6</u>: Confirm final 2015-2016 harvest specifications for all groundfish stocks and stock complexes. Adopt final preferred fishery structures, including two-year allocations for overfished species and harvest guidelines for nearshore rockfish, and determine which new management measures should be implemented in regulation starting in 2015 (Attachments 1 and 3-6).

- Decision 7: Adopt a preferred alternative for Amendment 24 to the FMP, which modifies the procedures described in the FMP so that, in the absence of Council action, harvest specification values based on default harvest control rules for one or more stocks or stock complexes may be published in Federal regulations. During any biennial decision-making process the Council may depart from these default values by deciding to modify the harvest control rule for one or more management units. After deciding a final preferred alternative for Amendment 24, the Council should provide guidance on the necessary FMP language (Attachment 8).

Agenda Item F.7.a, Attachment 3 includes the Executive Summary from the preliminary draft Environmental Impact Statement (DEIS), which provides an overview of the proposed action alternatives and environmental impacts. Further, the attachment summarizes the Council's preliminary preferred fishery structures and management measures for the 2015-2016 fisheries. Agenda Item F.7.a, Attachments 4 and 7 contain the preliminary DEIS and Stock Assessment and Fishery Evaluation document, respectively, which are available electronically only.

The process and schedule for adopting the 2015-2016 and beyond harvest specifications and management measures relies on earlier decision-making and the publication of a DEIS prior to final Council action at this meeting. It is important to note there is less scope for the Council to make substantial changes when crafting the final preferred alternative because of this altered schedule made necessary by the National Environmental Policy Act requirements and a January 1, 2015 implementation target. The final preferred alternative can only vary slightly from any one of the alternatives evaluated in the DEIS so that forecasted impacts fall within the range of those disclosed in the DEIS. If the final preferred alternative does not meet those criteria, it is likely that the DEIS would have to be revised to disclose any substantially different impacts, republished for public review, and scheduled for final decision-making at a future Council meeting. This would probably preclude the objective of implementing new regulations on January 1, 2015 (the start of the next management period).

Council Action:

1. **Adopt a T_{TARGET} for the cowcod rebuilding plan;**
2. **Adopt revised values for the 2016 cowcod OFL and ABC;**
3. **Confirm EC species designations and provide guidance on the associated FMP language;**
4. **Adopt a final preferred alternative for slope rockfish stock complexes;**
5. **Confirm final 2015-2016 harvest specifications for all groundfish stocks and stock complexes;**
6. **Adopt final 2015-2016 season structures and management measures, including new management measures; and**
7. **Adopt a final preferred Amendment 24 alternative and provide guidance on the associated FMP language.**

b. Reports and Comments of Advisory Bodies and Management Entities
c. Public Comment
d. **Council Action:** Confirm Final 2015-2016 Harvest Specifications; Adopt Final Management Measures; Adopt Final Preferred Alternatives for Amendment 24 Default Harvest Control Rules

PFMC
05/30/14

ACTION ITEM CHECKLIST

#	Category	Sector	Measure
2015-2016 Harvest Specifications			
1	OFL		Confirm SSC-recommended OFLs including a revised 2016 cowcod OFL
2	ABC		Confirm P*[1] and ABCs. Adopt revised 2016 cowcod ABC
3	ACL		Confirm FPA ACLs[2]
4	ACT		Confirm 4 mt ACT for cowcod
5	Rebuilding		Confirm rebuilding plan parameters including a new T_{TARGET} for cowcod
2015-2016 Stock Complexes			
6			Confirm EC species' designations and associated FMP language to be implemented under Amendment 24
7			Confirm FPA to manage kelp greenling coastwide, WA cabezon, and leopard shark in the Other Fish complex
8			Decide FPA for Slope Rockfish complexes

[1] The FPA P* decision was 0.45 for all stocks and complexes except arrowtooth (0.40), lingcod south (0.40), longspine thornyheads (0.40), sablefish (0.40), shortspine thornyheads (0.40), spiny dogfish (0.40), starry flounder (0.40), and the Other Flatfish complex (0.40).

[2] The FPA ACL decision was to set the ACL equal to the ABC for all non-overfished species except that a constant catch approach was used for OR/CA black rockfish (1,000 mt), Dover sole (50,000 mt), longnose skate (2,000 mt), Pacific cod (1,600 mt), shortbelly rockfish (50 mt), and widow rockfish (2,000 mt). For overfished species, except cowcod and petrale sole, the FPA ACL was based on the SPR rate in the current rebuilding plan. For petrale sole, the ACL was based on the 25-5 harvest control rule. For cowcod, the SPR rate in the current rebuilding plan was translated into an exploitation rate since the XDB-SRA model cannot use SPR rates. A new rebuilding plan is required for cowcod.

2015-2016 Allocations and Harvest Guidelines (HG)			
9	Fishery HG		Confirm or modify amounts deducted from the ACL to account for groundfish mortality in Tribal, non-groundfish fisheries, EFPs[3], and research
10	HG		Confirm or modify HGs for species managed within a complex • Blue rockfish in California within the nearshore rockfish complexes north and south of 40°10' • Blackgill rockfish within the slope rockfish complex south of 40°10'
11	Allocations	Trawl/Non-Trawl	Confirm or modify 2-year trawl and non-trawl allocations for • Overfished species: bocaccio, canary, cowcod, petrale[4], and yelloweye • Longnose skate: trawl (90%) and non-trawl (10%) allocation • Shelf rockfish north trawl (60.2%) and non-trawl (39.8%) allocation • Shelf rockfish south trawl (12.2%) and non-trawl (87.8%) allocation
12	Set-Aside	Within Trawl, At-Sea	Confirm or modify the at-sea whiting set-asides adopted in April
13	HG	Non-Trawl	Confirm or modify 2-year within non-trawl HGs or within non-trawl shares for • Overfished species including bocaccio, canary, cowcod, and yelloweye[5] • Black rockfish: 58% OR, 42% CA • Blue rockfish: 40-10 adjustment for CA • Blackgill south of 40°10': 40-10 adjustment; 60% limited entry and 40% open access fixed gears • Sablefish south of 36º: 55% limited entry and 45% open access fixed gears • Nearshore rockfish HG north of 40°10'

[3] The Council will confirm or modify the PPA EFP set-asides under Agenda Item F.5. Those values will be finalized under Agenda Item F.7.
[4] The Amendment 21 allocation for petrale sole has been suspended since the stock is overfished and under a rebuilding plan. The action alternatives analyzed the status quo allocation (35 mt to non-trawl and remainder to trawl), which is the PPA. Further, the Council requested an analysis that would give 15 mt to the non-trawl sector and the remainder to the trawl sector.
[5] The action alternatives analyzed the trawl/non-trawl and within non-trawl allocations from the September 2013 scorecard. Further, the Council requested analysis that would move 0.6 mt from the non-nearshore fishery to the nearshore fishery.

2015-2016 Season Structures			
14		Treaty Fisheries	Management measures
15		Shorebased IFQ	Trawl RCA, non-IFQ trip limits
16		Non-Nearshore	Non-Trawl RCA seaward configuration, trip limits (including sablefish)
17		Nearshore	Non-Trawl RCA shoreward configuration, trip limits
18		WA Recreational	Season dates, bag limits, length limits, area closures
19		OR Recreational	Season dates, bag limits, length limits, area closures
20		CA Recreational	Season dates, bag limits, length limits, area closures
2015-2016 Adjustments to Existing or Routine Measures			
21		Trawl	RCA boundary adjustments to better approximate depth, including the 200 fm modified line in Oregon and a 60 fm line in California
22		Trawl	Using underutilized set-asides in the projections for the shorebased IFQ carryover
23		Non-Trawl	Trip limit adjustments for lingcod N. of 40°10' N lat. (increase), slope rockfish N. of 40°10' N lat. (decrease), bocaccio S. of 34°27' N. lat. (increase), and shelf rockfish S. of 34°27' N. lat. (increase)
24		Non-Trawl - Rec	Modifications to groundfish retention regulations in the Pacific halibut fisheries[6]

[6] Action to modify the groundfish retention allowances in the Pacific halibut fishery would occur during the development of the annual Catch Sharing Plan.

New Management Measures for in implementation in 2015-2016			
25		Trawl	Establish new trawl RCA coordinates for 300 and 350 fm boundaries
26		Non-Trawl	Provide for lingcod retention in Periods 1, 2, and 6.
27		Non-Trawl – Rec	Implement a one fish canary rockfish sub-bag limit for the Oregon recreational fisheries
Amendment 24 – Default Harvest Control Rules			
28			Select a final preferred alternative for default harvest control rules that would be used in future bienniums, unless modified by the Council, to establish future harvest specifications
29			Provide guidance on FMP language to implement Amendment 24

Agenda Item F.7.a
Attachment 2
June 2014

PREFERRED 2015 AND 2016 HARVEST SPECIFICATIONS FOR GROUNDFISH STOCKS AND STOCK COMPLEXES

Summary of Tables included in this attachment:

- Table 1. Preferred harvest specifications for stocks and stock complexes for 2015-2016. The harvest control rule used to calculate the ABCs and ACLs are shown in the right column.
- Table 2. Estimated time to rebuild and exploitation rate relative to alternative 2015-2016 ACLs for cowcod south of 40º10' N lat.
- Table 3. Option 1 state harvest guidelines for the Nearshore Rockfish complex north of 40º10' N lat. in 2015 and 2016 under preferred harvest specifications.
- Table 4. Option 2 state harvest guidelines for the Nearshore Rockfish complex north of 40º10' N lat. in 2015 and 2016 under preferred harvest specifications.
- Table 5. Option 3 state harvest guidelines for the Nearshore Rockfish complex north of 40º10' N lat. in 2015 and 2016 under preferred harvest specifications.
- Table 6. Preferred blue rockfish harvest guidelines for California fisheries in 2015 and 2016.
- Table 7. Preferred 2015 and 2016 OFL and ABC contributions (in mt), and proposed harvest guidelines (in mt) for blackgill rockfish south of 40º10' N lat.

Table 1. Preferred harvest specifications for stocks and stock complexes for 2015-2016. The harvest control rule used to calculate the ABCs and ACLs are shown in the right column.

Stock*	Area	2015			2016			Harvest Control Rule

June 2014

EXECUTIVE SUMMARY AND DESCRIPTION OF THE PREFERRED SEASON STRUCTURES AND MANAGEMENT MEASURES, AN EXCERPT FROM THE PRELIMINARY DEIS

Executive Summary

INTRODUCTION

This document provides information about, and analyses of, setting groundfish harvest specifications and establishing related management measures for 2015 and subsequent years for fisheries covered by the Pacific Coast Groundfish Fishery Management Plan (hereafter, Groundfish FMP or FMP), which are developed by the Pacific Fishery Management Council (Council) in collaboration with the National Marine Fisheries Service (NMFS). Groundfish harvest specifications are set every 2 years for a 2-year period. In addition to harvest specifications and management measures for the 2015-16 biennial period, this document evaluates the impacts of setting harvest specifications and management measures over the long term. These actions must conform to the Magnuson-Stevens Fishery Conservation and Management Act (MSA), the principal legal basis for fishery management within the Exclusive Economic Zone (EEZ), which extends from the outer boundary of the territorial sea to a distance of 200 nautical miles from shore. The states manage their fisheries, including nearshore rockfish fisheries in the territorial sea, in a manner consistent with, or more restrictive than, the Groundfish FMP and Federal implementing regulations.

THE PROPOSED ACTIONS

The proposed action has three components: 1) Establishing harvest specifications and management measures for the 2015-2016 biennial management period, 2) changing groundfish stock complexes and designating ecosystem component species, and 3) amending the Groundfish FMP to describe how the Council would use default harvest control rules (HCRs) in their decision-making process in future biennial cycles and to clarify what are considered new and routine management measures during the biennial process. In all cases the alternative of No Action is also considered. This EIS includes an analysis of the long-term impacts of biennial harvest specifications and foreseeable adjustments to routine management measures to support decision-making in future biennial periods.

ALTERNATIVES

Table ES-1 summarizes the alternatives and options evaluated in this EIS.

Establishing Harvest Specifications and Management Measures for the 2015-2016 Biennial Management Period

Harvest specifications are established for each managed stock or stock complex in the Grondfish FMP. Specifications include the overfishing limit (OFL), the allowable biological catch (ABC), and the annual catch limit (ACL). Catch above the OFL constitutes overfishing. The ABC is a precautionary reduction from the OFL to account for scientific uncertainty in the OFL specification and management error. Section 4.4 in the Groundfish FMP describes the method usually used to determine this precautionary reduction. It involves two quantities, sigma (σ) and P*. Sigma represents variability in stock assessment results and P* represents the probability of catch at the ABC resulting in overfishing. A formula incorporating these two values produces a percentage value representing the precautionary reduction. Sigma is determined by the SSC while the Council chooses P*, which according to the Groundfish FMP, cannot exceed 0.45.

Overall catch is managed to the ACL. For most stocks the ACL is set equal to the ABC but the ACL may be set below the ABC for a variety of reasons. The Council may also set an annual catch target (ACT) to establish a higher level of precaution, particularly if there is greater uncertainty about the true level of catch due to estimation error.

Management measures include adjustments to and allocations of ACLs, adjustments to existing management measures including those designated as routine, and adoption of new management measures. During the biennial cycle existing, routine measures may be adjusted and new measures established. These management measures are mainly intended to control groundfish catch and improve monitoring of the fishery. Allocations establish overall limits for different groundfish fishery sectors (segments of the overall fishery distinguished by gear type, permit programs, target species, and other factors) as a basis for controlling catch. Many allocations have been included in the FMP and the same proportions are applied from period to period; others may be modified biennially based on conditions in the fishery. Harvest guidelines may also be used to aid the implementation of management measures that takes into account fishing opportunity in different fishery sectors. Catch control tools for the commercial groundfish fishery include individual fishing quota (IFQ), vessel allocations of sablefish catch opportunity to certain fixed gear, cumulative landing (or trip) limits, and closed areas to reduce bycatch of species of concern, predominantly overfished species. Recreational catch control tools include time and area closures and bag limits. Catch monitoring is accomplished by at-sea observers and dockside accounting for commercial catch and landings, and sampling and observation of recreational fisheries. Management measure alternatives are structured to provide sufficient fishing opportunity to achieve but not exceed ACLs. The alternatives are:

The Council considered four alternatives for 2015-2016 harvest specifications and management measures.

No Action

Harvest specifications values in place on January 1, 2014, would remain in effect for the 2015-2016 period (see Table 2-3 for the numerical values and basis for these harvest specifications). Management measures in place on December 31, 2014 would remain in place during the 2015-2016 biennial period. However, the Council may take inseason action to adjust routine management measures during the biennium.

The Preferred Alternative

Annual catch limits (ACLs) for most species are determined based on the ACLs being set equal to the ABCs with a P* value of 0.45. The ACLs for arrowtooth, lingcod south of 40°10 N. lat., longspine thornyhead north and south of 34°27 N. lat., sablefish north and south of 36° N. lat., shortspine thornyhead north and south of 34°27 N. lat., spiny dogfish, and starry flounder would be determined based on the ACLs being set equal to the ABCs with a P* value of 0.40. For some stocks ACLs are set below the ABC, in which case the P* value does necessarily determine the ACL. Overfished species ACLs are set based on rebuilding plans except for cowcod south of 40º10' N. lat., for which a new stock assessment is available. The ACL is increased from 3 mt to 10 mt and an annual catch target (ACT) of 4 mt is established. For this stock Constant catch ACLs for Dover sole and widow rockfish are increased from their 2014 values. Table 2-4 contains the preferred 2015 and 2016 harvest specifications.

Under the Preferred Alternative enhanced accountability measures to control mortality of rougheye rockfish and a sorting requirement for rougheye and blackspotted rockfish are implemented. These measures allow catch to be more accurately and responsively tracked while the rougheye rockfish/blackspotted rockish stock remains within the current slope rockfish complexes. Stocks are removed from the Other Fish complex; most are designated ecosystem component species while spiny dogfish is managed separately with its own harvest specifications. The Washington, Oregon, and California kelp greenling stocks, the Washington cabezon stock, and leopard shark remain in the Other

Fish complex. Some species currently not in the Groundfish FMP are designated EC species.[1] The EC classification is described in National Standard 1 Guidelines. EC species are monitored but not actively managed. They are species that are caught incidentally in relatively small amounts. If monitoring indicates an increasing trend in catch for an EC species, reclassification and/or appropriate management measures may be considered. In addition to moving many of the species in the Other Fish complex to the EC species designation, the Council designated several species not currently in the Groundfish FMP as EC species.

Catch control measures are established and adjusted in order to attain but not exceed the Preferred Alternative ACLs.

Alternative 1

Where applicable, ABCs are determined based on a P* value of 0.45, and the ACL is set equal to the ABC. For several stocks the ACL is set below the ABC and so the P* value does not necessarily determine the ACL. Instances where the ACL is below the ACL include specification of a fixed or constant catch level, precautionary adjustments using the 40-10 and 25-5 rules, and the use of the harvest rate specified in a rebuilding plan. Table 2-5 shows the harvest specifications for each stock under Alternative 1.

Catch control measures are established and adjusted in order to attain but not exceed the Alternative 1 ACLs.

Alternative 2

Where applicable, ACLs are determined based on the ACLs being set equal to the ABCs with a P* value of 0.25. As described above for Alternative 1, ACLs may be set below the ABC, in which case the P* value does necessarily determine the ACL. Table 2-6 contains the harvest specifications under Alternative 2.

Catch control measures are established and adjusted in order to attain but not exceed the Alternative 2 ACLs.

Amendment 24

This amendment would incorporate a description of the default harvest control rule (HCR) concept into the Groundfish FMP, which is intended to make clear that if the Council does not take action to modify an HCR, the default HCR is used, applying the best available scientific information, to calculate harvest specification numerical values. This approach helps make clear that most of the time the Council is either reapplying existing harvest policies or making modest changes within the framework set out in the Groundfish FMP and consistent with the Magnuson-Stevens Act. This action also provides an opportunity to evaluate the long-term impacts of biennial harvest specifications and management measures process in this EIS. This is intended to allow more focused analyses of future biennial actions. The description of the types of management measures that are established and adjusted during the biennial process would also be clarified as part of Amendment 24. As part of the biennial process new management measures may be implemented and existing, “routine” management measures adjusted; for example, existing catch control tools are usually changed in response to changes in ACLs. Routine measures are already part of the regulations and the effects of using these measures were previously

[1] Designating EC species requires amending in Groundfish FMP to change the classification of currently managed species and incorporate species not currently included in the FMP. These changes would be part of Amendment 24, described below.

analyzed. This allows National Marine Fisheries Service to use a simpler process to implement these regulatory changes under applicable law. Four alternatives are evaluated.

No Action

The Groundfish FMP is not amended.

Alternative 1

The default HCRs would use a P* value of **0.45** to determine the ABC, where applicable, using the best available scientific information. During the biennial harvest specifications process the Council can take action to modify the HCR and harvest specifications for the next biennial period would be based on the new HCR. FMP language describing the types of management measures developed and implemented as part of the biennial process is revised for clarification.

Alternative 2

The default HCRs would use a P* value of **0.25** to determine the ABC, where applicable, using the best available scientific information. During the biennial harvest specifications process the Council can take action to modify the HCR and harvest specifications for the next biennial period would be based on the new HCR. FMP language describing the types of management measures developed and implemented as part of the biennial process is revised for clarification.

Alternative 3

The default HCRs are the HCRs used during the previous biennial cycle. Harvest specifications are computed using the best available scientific information (such as the most recent stock assessment). During the biennial harvest specifications process the Council can take action to modify the HCR and harvest specifications for the next biennial period would be based on the new HCR. FMP language describing the types of management measures developed and implemented as part of the biennial process is revised for clarification.

IMPACTS OF THE PROPOSED ACTIONS

Groundfish

Table 2-2 through Table 2-5 show 2015-2016 harvest specifications under each of the alternatives including No Action. Under the Preferred Alternative harvest control rules change for seven of the 40 stocks or stock complexes (not including Pacific whiting) for which ACLs are established. These changes are:

- The Dover sole constant catch ACL is increased from 25,000 mt to 50,000 mt
- The ACLs for shortspine thornyhead stocks north and south of 34°27' N. lat. are proportions of the coastwide ABC; the ABC is determined using a P* value of 0.4 rather than 0.45
- Spiny dogfish is removed from the Other Fish complex and managed with its own ACL, which is set equal to the ABC using a P* value of 0.4
- The constant catch ACL for widow rockfish is increased from 1,500 mt to 2,000 mt

- For the Nearshore Rockfish North complex the 40-10 precautionary adjustment is applied to determine the China rockfish contribution to the stock complex ACL (which is determined as the sum of constituent species' ACL contributions)
- The Other Fish complex ACL is equal to the complex ABC set equal 0.45 consistent with the removal of many species from the complex, including spiny dogfish

Based on a new stock assessment, harvest specifications for cowcod, an overfished species, are changed. The Council will chooses a new target rebuilding year for the stock at its June 2014 meeting. The Council chose a 10 mt ACL for this stock, which is consistent with the current rebuilding plan SPR-based harvest rate of 82.7%. The Council also established an annual catch target (ACT) of 4 mt as an additional precautionary measure. Catch will be managed to stay below the ACT.

ACLs for 14 of the stocks or stock complexes would increase in 2015 compared to 2014 ACLs (No Action).

Section 4.1 evaluates the biological impacts of preferred 2015-2016 harvest specifications on a select list of groundfish stocks focusing on 1) overfished stocks currently managed under rebuilding plans, 2) stocks where the Council chose a range of alternative ACLs for analysis, 3) stocks and stock complexes where total catches in recent years have been at least 80 percent of specified ACLs, and 4) stocks preferred to be removed from a status quo stock complex and managed with stock-specific harvest specifications.

Section 4.2 evaluates deductions from and allocations of the ACLs and modifications to routine management measures to control catch so that the ACLs established under the alternatives are not exceeded. Commercial fishery management measures subject to modification include catch control tools including individual fishing quota (IFQ) annual quota pound issuance, establishing tier limits for the limited entry sablefish primary season, modifying cumulative landing limits for other fisheries and species, and changes to the boundaries of time area closures to control bycatch of overfished species and other species where there is a conservation concern. Recreational management measures subject to modification include bag limits and time/area closures (seasons). At its June meeting the Council will also consider adopting several new management measures related to harvest specifications.

Section 4.8 evaluates the long-term biological impacts of setting harvest specifications and Section 4.9 describes the impacts of the range of potential modifications to routine management measures that may be made in the foreseeable future.

Socioeconomic Environment (Fishing Communities)

Under the Preferred Alternative coastwide non-whiting ex-vessel revenue is projected to increase by $16 million in 2015 compared to No Action 2014 ACLs and management measures. This represents a $19.3 million increase from annual average inflation-adjusted ex-vessel revenue, 2003-2012. Recreational angler trips are expected in increase between 167,000 and 3.9 million marine angler trips depending on the management option chosen under the Preferred Alternative. Resulting commercial and recreational income accruing to fishing communities under the Preferred Alternative would increase by between $27.3 million and $49.3 million depending on the option chosen.

For the foreseeable future changes in ex-vessel revenue, net revenue (a proxy for commercial fishery profits), recreational angler trips, and personal income will be partly a function of fishing opportunity determined by stock yield and management measures. Based on assumptions about yield and potential policies for setting harvest specifications (as described in the Amendment 24 alternatives) catches are expected to increase under most model scenarios, assuming management succeeds in achieving management objectives for stock biomass size and related fishing mortality levels. Fishing opportunity could decline if stock yields are below the most likely conditions and more conservation management policies, such as using a P* value of 0.25 to determine the ABC, were used for all stocks. Recent average catch is in most cases lower than projected ACLs under scenarios combining different assumptions about potential yield and policies for determining ABCs. These scenarios suggest that revenue and personal income is likely to increase over the long term. However, historically there has been a lot of inter-annual volatility in ex-vessel revenue in both a positive and negative direction. Declines in revenue can occur because of unaccounted for changes in yield and changing market conditions affecting prices.

Essential Fish Habitat

Over both the short and long term the adverse impacts of fishing on groundfish essential fish habitat (EFH) is expected to be similar to adverse impacts experienced in the past. These adverse impacts result from fishing gear coming in contact with the seafloor, disrupting both physical characteristics and biogenic habitat such as corals and sponges. The Council has implemented a variety of mitigation measures to address adverse impacts, and other management measures, such as Groundfish Closed Areas to control bycatch, have mitigated adverse impacts as an ancillary effect. The Council is currently reviewing the groundfish EFH designation and mitigation measures established by Amendment 19 and could establish additional mitigation measures as part of the review process. The review process will not be completed before the 2015-2016 biennial period begins.

California Current Ecosystem

The Atlantis California Current Ecosystem Model was used to simulate the effects of the range of harvest policies that may be implemented in the foreseeable future. Since ecosystem effects take a long time to be manifested, it is not possible to distinguish between short- and long-term policy choices. The alternatives considered for the 2015-2016 biennial harvest specifications parallel those considered under Amendment 24 so in general the alternatives with a more conservative policy (2015-2016 Alternative 2 and Amendment 24 Alternative 2, P*=0.25) can be equated as can the alternatives with the most risk prone policy (2015-2016 Alternative 1, Amendment 24 Alternative 1, P*=0.45). Scenarios bracketing the range of harvest policies and ecosystem productivity regimes were modeled. Scenarios with very high harvest levels and low ecosystem productivity had the most pronounced effects, resulting in significant direct effects (effects of fishing on harvested stocks) and detectable indirect effects (effects on other ecosystem components in response to changes in the abundance of harvested stocks). It is important to note that these scenarios are deterministic, in other words there is no provision for a management response to new information about stock status. In the real world, the Council and NMFS would respond to new information showing that substantial adverse effects are occurring by reducing catch limits.

Total system biomass, a general measure of indirect effects, ranged from a decline of 8% from the benchmark scenario (recent average catch, most likely ecosystem productivity state) for the low productivity-high catch scenario to an increase of 5% under high productivity-low catch scenario. For most stocks low catch was represented by recent average catch streams. Thus if catch does not change substantially from recent levels few if any indirect effects would be predicted.

One important caveat to these simulations is that catch levels for Pacific whiting were not varied, since the alternatives evaluated within this EIS do not include varying whiting harvest. However, this species has an important structuring role in the California Current Ecosystem both as forage during early life stages and a piscivore (fish eater) when adult. Pacific whiting stock size is highly variable in response to conditions affecting recruitment of juveniles into the fishable, adult population. Though the model does not include these episodic recruitment events, the high and low ecosystem productivity states considered here may bracket the productivity of Pacific whiting, as well as the other groundfish stocks evaluated within this EIS. For Pacific whiting, by years 25-30, the high productivity scenarios (under recent average catches) yields abundance that is 1.16 times higher than base productivity, and low productivity yields abundance that is 0.78 times that of base productivity. Therefore, the model results address alternative levels of whiting productivity, though not alternative whiting harvest levels.

Protected Species

Protected species include those listed under the Endangered Species Act (ESA) and the Marine Mammal Protection Act (MMPA). NMFS has also agreed to consider the effects of actions on seabirds not listed under the ESA. ESA-listed species of concern include several kinds of fish (eulachon, green sturgeon, salmon), the humpback whale, leatherback sea turtle, and the short-tailed albatross.

Similar to other environmental components, the impacts of the proposed action on protected species during the 2015-2016 biennial period, measured in terms of take and resulting mortality, is only relevant within a long-term context considering the effect of such take on population size and viability. For ESA-listed species NMFS Protected Resources Division and the US Fish and Wildlife Service have consulted on the effects of the groundfish fishery. Information on effects is provided in Biological Opinions, which contain Incidental Take Statements (ITSs). The ITSs include estimates of the number of listed species likely to be taken, a determination of whether take levels jeopardize the continued existence of the species and measures that NMFS must implement to mitigate estimated levels of take. If these take levels are exceeded consultations may be reinitiated and new mandatory measures identified.

All marine mammals are protected under the MMPA. The objective of the Act is to allow marine mammals to reach their optimum sustainable population level and to reduce human caused serious injury and mortality to the maximum extent practicable. Through periodic stock assessments the potential biological removal level of a stock is estimated. A marine mammal population can meet or sustain the optimum population when human caused mortality is below this level. Takes for all segments of the groundfish fishery, except for the sablefish pot fishery, have been determined to have a remote likelihood of or no known serious injuries or mortalities. The sablefish pot fishery has been determined to cause occasional serious injury or mortality.

At-sea observer coverage allows total marine mammal interactions to be estimated. Non-ESA listed species taken in the groundfish fishery include

- California sea lion: Shoreside groundfish trawl, California halibut trawl, non-nearshore fixed gear sablefish, nearshore fixed gear, at-sea hake (Pacific whiting)[2]
- Harbor seal: California halibut trawl, non-nearshore fixed gear sablefish, nearshore fixed gear, at-sea hake (Pacific whiting)
- Northern elephant seal: Shoreside groundfish trawl, California halibut trawl, non-nearshore fixed gear sablefish, at-sea hake (Pacific whiting)
- Harbor porpoise: California halibut trawl
- Dall's porpoise: At-sea hake (Pacific whiting)
- Pacific white-sided dolphin: Shoreside groundfish trawl
- Risso's dolphin: Shoreside groundfish trawl
- Common bottlenose dolphin: Non-nearshore fixed gear

If estimated takes substantially increase such that overall human caused serious injury or mortality exceeded potential biological removal remedial actions would be taken.

[2] California halibut trawl is a state managed fishery and only subject to the proposed action with respect to catch accounting to ensure that ACLs are not exceeded.

Non-ESA listed seabirds are also taken in the groundfish fishery. The only species with more than negligible observed takes is the black-footed albatross. Mitigation measures in the process of being implemented to reduce the risk of takes of ESA-listed short-tailed albatross will likely have a mitigating effect for this species as well.

There is no information to conclude that under any of the alternatives the level of take of protected species will change substantially from historical baseline levels in either the short or long term.

Non-Groundfish Species

Groundfish fisheries catch a range of non-groundfish species in small amounts proportional to catch of groundfish. Some of these species—such as Pacific halibut, Dungeness crab, and salmon—are commercially valuable and have directed fisheries. Commercially valuable species are managed under other Council FMPs, other Federal authority, or by the states. Fishing mortality in the groundfish fishery is taken into account when managing such directed fisheries. Catch of non-groundfish species as a percent of total catch during 2003-2011 varied between 1.4% (3,801 mt) iand 5.9% (8,551 mt). Non-groundfish catch amounts did not correlate with total catch so it is not possible to predict how changes in target species fishing opportunity would affect non-groundfish catch. There is no information is conclude that non-groundfish catch is likely to exceed the historical range of catch over either the short or long term. Fishery observer data allows catch levels to be estimated so that if a substantial change in catch is detected, such that a conservation concern arises, mitigation measures could be implemented.

Chapter 4

4.2 Impacts of 2015-2016 Management Measures to Groundfish Stocks

This section describes how management measures function so that groundfish catch may achieve, but not exceed, ACLs. This constitutes the impact mechanism linking harvest specifications to the direct and indirect biological impacts on groundfish stocks. The principal impact is the level of fishing mortality and secondarily changes in stock structure due to age-specific mortality patterns. Harvest specifications are determined based on the Groundfish FMP framework to achieve optimum yield.

The section is organized by alternative and within each alternative by fishery sector. The first management measure step is to determine set asides deducted from ACLs to account for various fishing activities and allocate the resulting fishery HGs. Management measures are then developed based on catch projections so that fishing mortality does not exceed allocations and the overall ACLs. Subsequent sections evaluate how management measures applied to groundfish fishery sectors are projected to prevent allocations and the overall ACLs from being exceeded.

4.2.1 No Action (see Agenda Item F.7.a, Attachment 4, Electronic Version of the DEIS)

4.2.2 Preferred Alternative

Table 4-1 through Table 4-6 contains the harvest specifications and allocations analyzed under the Preferred Alternative. A description of the harvest control rules used to calculate the ACLs can be found in Chapter 2, Section XXX.

4.2.2.1 Deductions from the ACL and Allocations

Under all action alternatives, off-the-top deductions from the ACL were updated based on the most recent information on fishery performance and need. The deductions from the ACL are held constant across all action alternatives. Amounts deducted that are from the ACL to accommodate groundfish mortality from scientific research, incidental open access fisheries, and EFPs can be modified based on inseason projections (see Section XXX). A description of the calculations are provided below.

Tribal Fishery: Tribal fisheries consist of trawl (bottom, mid-water, and whiting), fixed gear, and troll. The tribal amounts in the April 17, 2014 regulations were updated with the most recent tribal requests (see Agenda Item H.10.b, Supplemental Tribal Report, November 2013 and Agenda Item H.10.b, Supplemental Tribal Report 2, November 2013).

Research: Research activities include the NMFS trawl survey, International Pacific Halibut Commission longline survey, and other Federal and state research. The Council approach is that off-the-top deductions from the ACL should be equal to the maximum historical scientific research catch from 2005-2012, except for canary rockfish and yelloweye rockfish. The Council policy for canary and yelloweye rockfish was not based on the maximum historical value. The Council considered the high canary rockfish catch of 7.2 mt in 2006 from the NMFS trawl survey a rare event since surveys in later years encountered substantially less canary. The Council adopted a 4.5 mt canary rockfish set-aside, which is higher than the average research catch from 2005-2012. For yelloweye rockfish, the Council adopted a 3.3 mt research set-aside based on anticipated research needs of the International Pacific Halibut Commission (1.1 mt), Washington Department of Fish and Wildlife (1 mt), Oregon Department of Fish & Wildlife (1 mt), and other projects (0.2 mt).

Incidental Open Access: Deductions from ACLs are made to account for groundfish mortality in the incidental open access fisheries. The off-the-top deductions from the ACL for all species, except longnose skate, were derived from the maximum historical values in the 2007-2012 WCGOP Groundfish Mortality reports (see http://tinyurl.com/nv3pddm). The recommended set-aside for longnose skate was based on data from the 2009-2012 Total Mortality reports, the years in which longnose skate were reported separately from the Other Fish category.

Exempted Fishing Permits: The Council adopted one EFP and associated off-the-top deductions from the ACL for 2015-2016 for public review. The EFP seeks to test the effectiveness of vertical hook-and-line gear to selectively harvest midwater species such as yellowtail rockfish (Agenda Item H.2.a, Attachment 4, November 2013).[1]

Recreational (Sablefish north of 36° N. latitude only): The allocation framework for sablefish north of 36° N. latitude specifies that the anticipated recreational catches of sablefish be deducted from the ACL prior to the commercial limited entry and open access allocations. The set-aside is the maximum historical value from recreational fisheries from 2004-2012 (Table 4-5).

[1] The Council is considering EFPs for participants in the catch share program. See Section XXX (Cumm affects) for more details.

4.2.2.2 Overview of Management Measures

The following bullet points summarize management measure changes by sector under the Preferred Alternative. A more detailed discussion of management measures by sector follows. New measures, discussed under Chapter 2, Section XXX and analyzed in Appendix B, would be implemented. New management measures that are specific to a sector are described below.

The Council is also considering a range of state-specific nearshore HGs to keep mortality of nearshore rockfish north of 40°10' N. latitude at or within the ACL. Appendix B, Section XXX contains the management measures for the commercial nearshore (OR and CA) and recreational fisheries (WA, OR, and CA) that are necessary to stay within the range of state-specific HGs adopted by the Council at their April meeting. The Council is scheduled to adopt preferred nearshore HGs north of 40°10' N. latitude, which would be implemented under the action alternatives, at the June Council meeting.

- The shorebased IFQ fishery would operate under the same management measures as No Action, with a few modifications. The No Action trawl RCA configuration (see Section XXX) would be modified to 100 fm shoreward and 150 fm seaward in the area 40°10 to 48°10' N. latitude, year-round. The IFQ would be issued based the 2015-2016 ACLs and resulting trawl allocations under the Preferred Alternative. Underutilized off-the-top deductions from the ACL (tribal, research, incidental open access, and EFPs) may be taken into consideration when considering the projections for surplus carryover. Legal-sized Pacific halibut IBQ would be limited to 15 percent of the Area 2A total constant exploitation yield (TCEY) for legal size halibut (net weight), not to exceed 100,000 pounds (45 mt) annually for legal size halibut (net weight), which is a 30,000 pound (14 mt) reduction from status quo. A scientific sorting requirement for rougheye/blackspotted would be implemented which would improve the data used in management. Further, deeper RCA boundary lines and/or bycatch reduction areas for midwater gears would be defined in regulation and would be available to reduce rougheye/blackspotted rockfish mortality inseason, if needed (e.g., boundary lines that approximate the 300 and 350 fm depth contours).
- The at-sea whiting co-ops would operate under the same management measures described under No Action with a few modifications. Allocations would be issued based the 2015-2016 ACLs and resulting at-sea trawl allocations under the Preferred Alternative. Adjustments to the at-sea whiting set-asides would be necessary to accommodate the restructuring of the Other Fish complex, which removed spiny dogfish from the complex. A scientific sorting requirement for rougheye/blackspotted could be implemented which could improve the data used in management. Further, bycatch reduction areas for midwater gears would be defined in regulation and would be available to reduce rougheye/blackspotted rockfish mortality inseason, if needed (e.g., boundary lines that approximate the 300 and 350 fm depth contours).
- The non-nearshore fixed gear fishery would operate under the same management measures as No Action, except trip limits increases for several species, including sablefish, bocaccio and shelf rockfish south of 34°27' N. latitude, are proposed to attain the ACLs under the Preferred Alternative. The prohibition on lingcod retention in Periods 1, 2, and 6 would be removed and trip limits increased for both limited entry and open access. Trip limit decreases for slope rockfish north of 40°10' N. latitude are proposed to reduce mortality of rougheye/blackspotted rockfish. A scientific sorting requirement for rougheye/blackspotted would be implemented which could improve the data used in management.
- The nearshore fixed gear fishery would operate under the same management measures as No Action with a few modifications. Trip limit decreases or non-retention may be required for nearshore rockfish to keep mortality at or within the complex ACL or the state-specific nearshore

rockfish HGs. The prohibition on lingcod retention in Periods 1, 2, and 6 may be removed and trip limits increased for both limited entry and open access.

- Tribal fisheries would operate under the harvest guidelines and allocations under the Preferred Alternative. Tribal fisheries would be managed using the same measures described under No Action. Additionally, a scientific sorting requirement for rougheye/blackspotted would be implemented which would improve the data used in management.
- Washington recreational fisheries would operate under the same management measures as No Action, except the season dates for the depth closure in the North Coast (Marine Areas 3 and 4) would be shorter than under No Action. In the South Coast (Marine Area 2), the prohibition on lingcod retention seaward of 30 fathoms in the area south of 46°58' N. latitude on Fridays and Saturdays from July to August 31 would be removed. Lastly, in the Columbia River Area (Marine Area 1), the southern boundary for the year-round lingcod closure would be moved three miles north. Changes to groundfish retention in Pacific halibut fisheries could also be proposed. Bag limit decreases or non-retention may be required for nearshore rockfish to keep mortality at or within the complex ACL or state-specific nearshore rockfish HGs.
- Oregon recreational fisheries would operate under the same management measures as under the No Action Alternative except that the cabezon sub-bag limit would be removed, a one fish canary sub-bag limit would be implemented, and changes to groundfish retention in Pacific halibut fisheries could be proposed. Bag limit decreases or non-retention may also be required for nearshore rockfish to keep mortality at or within the complex ACL or state-specific nearshore rockfish HGs.
- Season lengths and depth restrictions were explored for the California recreational fisheries. The lingcod bag limit would be increased from two to three fish. Bag limit decreases, season length reduction, or non-retention may be required for nearshore rockfish to keep mortality at or within the complex ACL or state-specific nearshore rockfish HGs. All other management measures would be the same as under No Action.

4.2.2.3 Impact (Groundfish Mortality) Shorebased IFQ – Preferred Alternative

The No Action trawl RCA configuration (see Section XXX) would be modified to 100 fm shoreward and 150 fm seaward in the area 40°10 to 48°10' N. latitude, year-round. The shorebased IFQ would be issued based the preferred 2015-2016 ACLs and resulting trawl allocations (Table 4-7 and Table 4-8). Notable IFQ increases from No Action include Dover sole, petrale, longspine thornyheads north, sablefish, shortpine thornyhead, widow rockfish, yellowtail, and Other Flatfish. Underutilized off-the-top deductions from the ACL (tribal, research, incidental open access, and EFPs) may be taken into consideration when considering the projections for surplus carryover (see Appendix B, Section XXX).

The shoreside trawl rationalization program keeps the trawl sector bycatch of halibut within expectations by requiring that trawlers account for their total mortality of all halibut in round weight (legal and sublegal sized). Therefore, to determine a trawl bycatch mortality limit the amount of halibut pounds available to the trawl fleet will be determined by expanding the expected legal sized halibut mortality (net weight) into a round weight legal+sublegal sized amount. To achieve this, the following conversions will be applied.

- Net weight to round weight conversion: multiply by the IPHC net weight to round weight conversion factor in use at the time of each year's the calculation.
- Legal to legal+sublegal sized conversion factor: multiply by the ratio of legal sized halibut to legal+sublegal sized halibut from the most up-to-date NMFS analysis of trawl fishery bycatch available at the time of each year's calculation.

After these conversions, 10 mt will be subtracted to cover bycatch mortality in the at-sea whiting fishery and trawl fishery south of 40°10’ N. lat, and the remainder will be issued as IBQ, to be used to cover Pacific halibut mortality by vessels operating in the shoreside trawl IFQ program. Under all action alternatives, legal-sized Pacific halibut IBQ would be limited to 15 percent of the Area 2A total constant exploitation yield (TCEY) for legal size halibut (net weight), not to exceed 100,000 pounds annually for legal size halibut (net weight), which is a 30,000 pound reduction from status quo.

A risk analysis was conducted to evaluate the risk of exceeding the spiny dogfish ACL (see Section XXX, Appendix B). The effectiveness of GCAs to reduce spiny dogfish mortality in the shorebased IFQ sector was also explored in Appendix B. Given the low risk of exceeding the spiny dogfish ACL, the Council recommended continuing with trip limit management of spiny dogfish in the shorebased IFQ sector and they did not recommend spiny dogfish GCAs.

Management measures to reduce rougheye/blackspotted rockfish catch, including rougheye/blackspotted GCAs and/or rockfish excluders for the at-sea whiting vessels were considered but rejected (see Chapter 2, Section XXX and Appendix B). Instead, the Council recommended that a scientific sorting requirement for rougheye/blackspotted could be implemented which could improve the data used in management. Further, management measures to reduce rougheye/blackspotted rockfish catch could be implemented, including 300 and 350 seaward trawl RCA boundaries and bycatch reduction areas for vessels using midwater gears, if necessary.

Table 4-7. Preferred Alternative – Shorebased IFQ. Projected mortality for IFQ species compared to the allocations or set-asides under the Preferred Alternative for 2015. No action estimates of mortality are provided (right panel).

a/ Pacific halibut is managed using IBQ, see regulations at §660.140. Starting in 2015, the maximum IBQ allocation is 45 mt, see (§660.55 (m)). There is no projection model for Pacific halibut bycatch.
b/ As stated in regulations (§660.55 (m)), a Pacific halibut set-aside of 10 mt, to accommodate bycatch in the at-sea Pacific whiting fisheries and in the shorebased trawl sector south of 40°10' N. latitude. (estimated to 5 mt each). There is no projection model for Pacific halibut bycatch.
c/ The 2014 Pacific whiting TAC was unavailable during the preparation of the EIS, therefore the 2013 values were used.

a/ Pacific halibut is managed using IBQ, see regulations at §660.140. Starting in 2015, the maximum IBQ allocation is 45 mt, see (§660.55 (m)). There is no projection model for Pacific halibut bycatch.
b/ As stated in regulations (§660.55 (m)), a Pacific halibut set-aside of 10 mt, to accommodate bycatch in the at-sea Pacific whiting fisheries and in the shorebased trawl sector south of 40°10’ N. latitude. (estimated to 5 mt each). There is no projection model for Pacific halibut bycatch.
c/ The 2014 Pacific whiting TAC was unavailable during the preparation of the EIS, therefore the 2013 values were used.

4.2.2.4 Impact (Groundfish Mortality) At-Sea Whiting Co-ops – Preferred Alternative

The at-sea whiting co-ops would operate under the same management measures described under No Action with a few modifications. The 2015-2016 allocations for the catcher-processor and mothership sectors under the Preferred Alternative for 2015-2016 are provided in Table 4-9 and compared to No Action.

At-sea whiting set-asides for some species would be increased compared to No Action (Table 4-10), based on recent fishery data. Further, adjustments would be necessary to accommodate the restructuring of the Other Fish complex, which removed spiny dogfish from the complex (Chapter 2, Section). The proposed Other Fish complex contains nearshore species which are not typically encountered in the at-sea whiting sectors. As such, the Council determined it was not necessary to specify an Other Fish complex set-aside. A range of spiny dogfish set-asides from 163 mt to 725 mt was analyzed along with a risk analysis for all sectors of exceeding the spiny dogfish ACL (see Section XXX, Appendix B). The effectiveness of GCAs to reduce spiny dogfish mortality was also explored in Appendix B. Given the low risk of exceeding the spiny dogfish ACL, the Council did not recommend spiny dogfish set-asides nor did they recommend spiny dogfish GCAs for the at-sea sectors.

Management measures to reduce rougheye/blackspotted rockfish catch, including rougheye/blackspotted GCAs and/or rockfish excluders for the at-sea whiting vessels were considered but rejected (see Chapter 2, Section XXX and Appendix B). Instead, the Council recommended a scientific sorting requirement for rougheye/blackspotted would be implemented which could improve the data used in management. Further, management measures to reduce rougheye/blackspotted rockfish catch could be implemented, including bycatch reduction areas for vessels using midwater gears, if necessary.

Table 4-9. Preferred Alternative – At-Sea. Allocations for the catcher-processor (CP) and mothership sectors (MS) under the Preferred Alternative for 2015-2016. The No Action allocations are provided (right panel) for reference.

a/As stated in §660.55 (m), the Pacific halibut set-aside is 10 mt, to accommodate bycatch in the at-sea Pacific whiting fisheries and in the shorebased trawl sector south of 40°10’ N. latitude (estimated to 5 mt each).
b/ In 2014, spiny dogfish was managed as part of the Other Fish complex. Starting in 2015-2016, spiny dogfish will be managed separately.

4.2.2.5 Limited Entry and Open Access Fixed Gear– Preferred Alternative

Impact (Groundfish Mortality) – Non-Nearshore North of 36° N. latitude

Management measures and projected mortality for the non-nearshore fishery north of 36° N. latitude under the Preferred Alternative is largely influenced by the sablefish ACL, which would be calculated with a P* of 0.40 (Table 4-5), and the resulting sablefish allocations (Table 4-11 and Table 4-12). Trip limit increases for sablefish would be proposed (Table 4-13) and would be routinely adjusted to achieve the limited entry and open access sablefish allocations (Table 4-11 and Table 4-12). The prohibition on lingcod retention in Periods 1, 2, and 6 would be removed and trip limits increased for both limited entry and open access fixed gears (see Appendix B, Section XXX). Trip limits for other species may also be adjusted to attain the ACL or achieve other conservation goals.

Trip limit decreases for slope rockfish north of 40°10’ N. latitude are proposed to reduce rougheye/blackspotted rockfish mortality (Table XXX and Appendix B, Section XXX). A scientific sorting requirement for rougheye/blackspotted would be implemented which could improve the data used in management.

The overfished species mortality, as a result of harvesting the sablefish allocations, was evaluated using 2002-2012 WCGOP data in the non-nearshore model. Under the Preferred Alternative, trawl and non-trawl allocations were established for overfished species. Further, the non-nearshore fishery was also allocated a share of the non-trawl allocation for bocaccio, canary, and yelloweye (Table 4-14). Routine adjustments of the non-trawl RCA (same as No Action, See XXX) would occur in the event the projected overfished species mortality is expected to exceed the non-nearshore share or non-trawl allocation (e.g., changing from 100 to 125 fm). RCA changes can also be accommodated to provide greater access to target species when overfished species mortality is projected to be within the non-nearshore share or non-trawl allocation (e.g., changing from 125 to 100 fm). Table 4-15 contains the projected mortality groundfish for the non-nearshore fishery.

Table 4-11. Preferred Alternative: Limited entry sablefish FMP allocations north of 36 N. latitude for 2015-2016.

Year	ACL	Sablefish Com. HG	Limited Entry Share	LEFG Share (mt)				Estimated Tier Limits (lbs) a/		
				Total Catch Share	Landed Catch Share a/	Primary Season Share	DTL Share	Tier 1	Tier 2	Tier 3
2015	4,793	4,281	3,878	1,629	1,571	1,336	236	41,175	18,716	10,695
2016	5,241	4,684	4,244	1,782	1,719	1,461	258	45,053	20,479	11,702

a/ The limited entry fixed gear total catch share is reduced by the anticipated discard mortality of sablefish, based on WCGOP data from 2002 to 2012. In 2015-2016, 17.7 percent of the sablefish caught are anticipated to be discarded and 20 percent are expected to die.

Table 4-12. Preferred Alternative: Open access FMP allocations north of north of 36 N. latitude for 2015-2016.

Year	Open Access Total Catch Share (mt)	Open Access Landed Catch Share (mt) a/
2015	402	388
2016	440	425

a/ The open access total catch share is reduced by the anticipated discard mortality of sablefish, based on WCGOP data from 2002 to 2012. In 2015-2016, 17.7 percent of the sablefish caught are anticipated to be discarded and 20 percent are expected to die.

Table 4-13. Preferred Alternative. Sablefish trip limits north of 36° N. latitude for limited entry and open access fixed gears for 2015-2016.

Year	Fishery	Jan-Feb	Mar-Apr	May-Jun	July-Aug	Sept-Oct	Nov-Dec
2015	Limited Entry	1,025 lb/week, not to exceed 3,075 lb/ 2 months					
	Open Access	300 lb/ day, or 1 landing per week of up to 900 lb, not to exceed 1,800 lb/ 2 months					
2016	Limited Entry	1,275 lb/week, not to exceed 3,375 lb/ 2 months					
	Open Access	300 lb/ day, or 1 landing per week of up to 1,000 lb, not to exceed 2,000 lb/ 2 months

Impact (Groundfish Mortality) Non-Nearshore South of 36° N. latitude

Management measures and projected groundfish mortality for the non-nearshore fishery south of 36° N. latitude under the Preferred Alternative is largely influenced by the sablefish ACL, which would be calculated with a P* of 0.40 (Table 4-5). Anticipated catch of sablefish south of 36^{o} N latitude under the Preferred Alternative would be approximately equal to the 2015-2016 sablefish allocations and resulting landed catch shares for limited entry and open access fixed gears (Table 4-16). Increases to the sablefish trip limits would be proposed (Table 4-17) and would be routinely adjusted to achieve the limited entry and open access sablefish allocations (Table 4-16). Additionally, trip limit increases are proposed for bocaccio and shelf rockfish south of 34°27’ N. latitude to increase attainment of the non-trawl allocations (Table 4-18, See Appendix B Section XXX for historical attainment). Trip limits for other species may also be adjusted to attain the ACL or achieve other conservation goals.

Under the Preferred Alternative, trawl and non-trawl allocations would be established for overfished species. Further, the non-nearshore fishery would be allocated a share of the non-trawl allocation for bocaccio, canary, and yelloweye to ensure that total non-trawl catches remained within the non-trawl allocations for these overfished species (Table 4-14). Routine adjustments of the non-trawl RCA (same as No Action, See Section XXX) would occur in the event the projected overfished species mortality is expected to exceed the non-nearshore share or non-trawl allocation (Table 4-14). RCA changes can also be accommodated to provide greater access to target species when overfished species mortality is projected to be within the non-nearshore share or non-trawl allocation (e.g., changing from 125 to 100 fm).

A scientific sorting requirement for rougheye/blackspotted would be implemented which could improve the data used in management.

Table 4-16 Preferred Alternative: Short-term sablefish allocations south of 36 N. latitude for the non-trawl sector, limited entry and open access for 2015-2016.

Year	Commercial HG	Non-Trawl Allocation	LE FG Total Catch Share	Directed OA Total Catch Share	LE FG Landed Catch Share a/	Directed OA Landed Catch Share a/
2015	1,714	994	547	447	531	432
2016	1,875	1,088	598	489	581	472

a/ The limited entry and open access fixed gear total catch shares are reduced by the anticipated discard mortality of sablefish, based on WCGOP data from 2002 to 2012. In 2015-2016, 17.7 percent of the sablefish caught are anticipated to be discarded and 20 percent are expected to die.

Table 4-17. Preferred Alternative. Sablefish trip limits south of 36° N. latitude for limited entry and open access fixed for 2015-2016.

	OA	No Action	750	closed	750	1,000 lbs/2 months		
		Preferred	1,500	closed	1,500 lbs/2 months			

Impact (Groundfish Mortality) Nearshore – Preferred Alternative

There are Federal limits and state quotas (or harvest guideline) for nearshore species that constrain target species landings in the commercial nearshore fishery. State harvest guidelines between recreational and commercial fisheries may be adjusted by each state between or within years, so are not displayed herein. State harvest guidelines for each sector are established to ensure that the non-trawl allocation provided to each state is not exceeded while providing fishing opportunities for both sectors. The Preferred Alternative is based on the expectation that landings in the Oregon nearshore fishery (Table 4-19) will be equal to their allocations, except for lingcod where the historical average landings are assumed and except for black rockfish for which the state landing cap would have to be reduced from 137.9 mt to 120.0 mt to remain under the yelloweye rockfish catch share shown in Table 4-20. In California, nearshore fishery allocations are unable to be achieved given the current overfished species shares allocated to the nearshore fishery and state. As such, landings are reduced to stay within the nearshore fishery overfished species shares of the non-trawl allocation. Nearshore fishery landings are influenced by a variety of factors, including weather and market, and can vary annually. As such, there is substantial uncertainty surrounding the estimated landings under the action alternatives, which in turn influence the projected overfished species mortality and socioeconomic analysis. In the event fishery performance is lower than the allocations, mortality of groundfish species will be lower.

Trawl and non-trawl allocations for overfished species, would be implemented under the Preferred Alternative. Specifically, the nearshore fishery would be managed to stay within its share of the non-trawl allocation for bocaccio, canary, and yelloweye or the overall non-trawl allocations (Table 4-20). In the event the projected overfished species mortality is expected to exceed the nearshore share or non-trawl allocation, routine adjustments of the shoreward non-trawl RCA or reduced trip limits for nearshore species could occur. RCA changes can also be accommodated to provide greater access to target species when overfished species mortality is projected to be within the nearshore share or non-trawl allocation (e.g., changing from 20 to 30 fm).

Under the Preferred Alternative, the Council is considering a range of state-specific nearshore HGs to keep mortality of nearshore rockfish north of 40°10’ N. latitude at or within the ACL. Appendix B, Section XXX contains the management measures for the nearshore fisheries that are necessary to stay within the range of state-specific HGs adopted at the April Council meeting. The Council is scheduled to adopt preferred nearshore HGs north of 40°10’ N. latitude at the June Council meeting.

The Council is also considering removing the prohibition on lingcod retention in Periods 1, 2, and 6 and increasing trip limits for both limited entry and open access fixed gears (see Appendix B, Section XXX). In the event this option is selected for implementation, the estimated lingcod landings (Table 4-19) and the projected overfished species mortality would be updated (Table 4-20).

Table 4-19. Preferred Alternative. Expected landings under the Preferred Alternative (mt) in 2015-2016. Target species landings by area are also shown (far right panel).

4.2.2.6 Impact (Groundfish Mortality) Tribal Fisheries – Preferred Alternative

Tribal fisheries would operate under the harvest guidelines and allocations displayed in Table 4-1, Table 4-3, and Table 4-5. Tribal fisheries would be managed using the same measures described under No Action.

4.2.2.7 Washington Recreational – Preferred Alternative

Primary catch controls for the Washington recreational fishery are season dates, depth closures, bag limits, and GCAs, including YRCAs. Under the Preferred Alternative, Washington recreational fisheries would operate under the 2015 and 2016 ACLs (Table 4-1 and Table 4-3) and Washington recreational harvest guidelines (HGs) for overfished species (Table 4-21).

Table 4-21. Preferred Alternative: Washington recreational harvest guidelines for 2015 and 2016.

Stock	2015	2016
CANARY ROCKFISH	3.4	3.5
YELLOWEYE ROCKFISH	2.9	3.1

Groundfish Season Structure

Under the Preferred Alternative, the Washington recreational fishery would be open year-round for groundfish, except lingcod. Washington would continue to prohibit the retention of canary and yelloweye rockfish in all areas.

Depth restrictions are the primary tool used to keep recreational mortality of yelloweye and canary rockfish within specified HGs. Restrictions limiting the depth where groundfish fisheries are permitted are more severe in the area north of the Queets River (Marine Areas 3 and 4) where yelloweye and canary rockfish abundance is higher and therefore caught incidentally at a higher rate. Depth restrictions are less restrictive moving south where incidental catch of yelloweye and canary becomes progressively less.

Management measures under the Preferred Alternative differ only slightly from the No Action Alternative. Under the Preferred Alternative, the depth closure in the North Coast (Marine Areas 3 and 4) would be in place from May 9th through Labor Day rather than from May 1 through September 30. In the South Coast (Marine Area 2), the prohibition on lingcod retention seaward of 30 fathoms in the area south of 46°58 on Fridays and Saturdays from July to August 31 would be removed and in the Columbia River Area (Marine Area 1), the southern boundary for the year round lingcod closure would be moved three miles north. The primary intent of these changes is to simplify management measures for recreational anglers while maintaining total mortality projections that stay within Washington's HGs for overfished species. Management measures, in addition to those analyzed in the 2013-14 EIS were implemented in 2013 through inseason action to respond to higher than anticipated encounters with yelloweye rockfish. These additional management measures reduced the potential for encounters with overfished species and provide some leeway to refine and streamline management measures described under the No Action Alternative. Table 4-22 summarizes key features of the Washington recreational regulations under the Preferred Alternative.

Table 4-22. Preferred Alternative. Washington Recreational Seasons and Groundfish Retention Restrictions.

e/ Retention of lingcod prohibited in deepwater areas at all times.
f/ Retention of groundfish, except sablefish and Pacific cod, prohibited with Pacific halibut on board on days open to the all depth Pacific halibut fishery.</td></tr>
</table>

North Coast (Marine Areas 3 and 4)

The retention of bottomfish is prohibited seaward of a line approximating 20 fm from May 9th through the first Monday in September, except, lingcod, Pacific cod and sablefish can be retained seaward of 20 fm on days open to recreational fishing for Pacific halibut. Fishing for, retention, or possession of groundfish and Pacific halibut is prohibited in the C-shaped YRCA.

South Coast (Marine Area 2)

The retention of bottomfish, except rockfish, is prohibited seaward of 30 fm from March 15 through June 15, except sablefish and Pacific cod retention is allowed May 1 through June 15. Retention of lingcod is allowed seaward of 30 fm on days open to the primary Pacific halibut season. Fishing for, retention, or possession of lingcod is prohibited in deepwater areas seaward of a line extending from 47°31.70' N. latitude, 124°45.00' W. longitude to 46°38.17' N. latitude, 124°30.00' W. longitude year-round, except as allowed on days open to the Pacific halibut fishery (Figure 4-1). Fishing for, retention or possession of bottomfish or Pacific halibut is prohibited in the South Coast YRCA and Westport Offshore YRCA (See Section XXX).

Columbia River (Marine Area 1)

Retention of bottomfish, except sablefish and Pacific cod, is prohibited with Pacific halibut onboard during the all-depth recreational halibut fishery from May 1 through September 30. Fishing for, retention, or possession of lingcod in deepwater areas seaward of a line extending 46°38.17 N. latitude, 124°21.00' W. longitude to 46°28.00' N. latitude, 124°21.00' W. longitude is prohibited year-round (Figure 4-1).

Area Restrictions

Under the Preferred Alternative, fishing for, retention, or possession of groundfish and halibut during the Washington recreational groundfish and Pacific halibut fisheries would be prohibited in the C-shaped YRCA in the north coast and the South Coast and Westport YRCAs in the south coast.

Fishing for, retention, or possession of lingcod would be prohibited seaward of a line connecting the following coordinates from the Queets River (47°31.70' N. latitude, 124° 45.00' W. longitude) to 46°28.00' N. latitude, 124°21.00' W. longitude, year round except as allowed in Washington Marine Area 2 on days open to the primary Pacific halibut fishery (Figure 4-1).

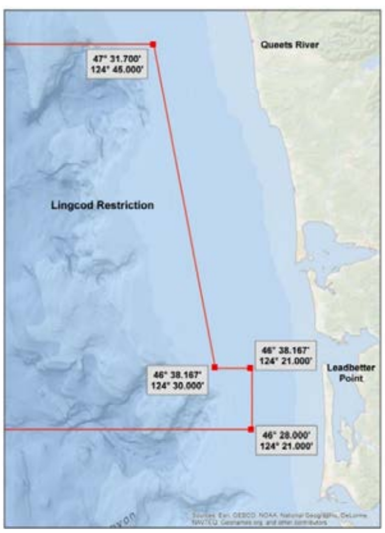

Figure 4-1. Preferred Alternative. Washington Lingcod Restricted Area.

Other Measures

Nearshore Rockfish HGs: Under the Preferred Alternative, the Council is considering a range of state-specific nearshore HGs to keep mortality of nearshore rockfish north of 40°10' N. latitude at or within the

ACL. Appendix B, Section XXX contains the management measures for the Washington recreational fisheries that are necessary to stay within the range of state-specific HGs adopted at the April Council meeting. The Council is scheduled to adopt preferred nearshore HGs north of 40°10’ N. latitude at the June Council meeting.

Groundfish Bag Limits: Groundfish bag limits would be the same under the Preferred Alternative as they are under the No Action alternative. The recreational groundfish bag limit, including rockfish and lingcod, would be 12 fish per day. Of the 12 recreational groundfish allowed to be landed per day, sub-limits of 10 rockfish and, two lingcod apply. The recreational bag limit also includes a sub-limit of two cabezon in Marine Areas 1-3 and one cabezon in Marine Area 4.

Lingcod Seasons and Size Limits: Under the Preferred Alternative, the lingcod seasons would be the same as they are under the No Action Alternative. In Marine Areas 1 through 3 (Washington-Oregon border at 46°16’ N. latitude to Cape Alava at 48°10’ N. latitude) the lingcod season would be open from the Saturday closest to March 15 through the Saturday closest to October 15. In Marine Area 4, (Cape Alava to the U.S. Canadian border) the lingcod season would be open from April 16 through October 15, or the Saturday closest to October 15 if that Saturday comes before October 15, whichever is earlier. Lingcod seasons under the Preferred Alternative would be structured the same as they were under the No Action Alternative. Under the Preferred Alternative the lingcod seasons and size limits by area are as follows:

- Marine Areas 1-3: March 14 through October 17 in 2015 and March 12 through October 15 in 2016. Minimum size, 22 inches.
- Marine Area 4: April 16 through October 15 in 2015 and April 16 to October 15 in 2016. Minimum size, 22 inches.

Cabezon Size Limit: Under the Preferred Alternative, there is an 18 inch minimum size limit for cabezon in Marine Area 4 (Cape Alava to the U.S. Canadian border).

Pacific Halibut Seasons: It is expected that the Pacific halibut seasons in 2015 and 2016 would be similar to the halibut seasons in 2013 and 2014. There are no changes to the restrictions on groundfish retention during the Pacific halibut season proposed under the Preferred Alternative. However, modifications to the groundfish retention rules during the all-depth Pacific halibut openings may be proposed under the Pacific halibut Catch Sharing Plan process (see Appendix B, Section XXX).

Additional Management Measures Analyzed: No additional management measures were analyzed for the Preferred Alternative. Currently available management measures will be used to keep recreational harvests of overfished species within specified HGs for 2015-2016.

Impact (Groundfish Mortality)

Projected mortality for Washington’s recreational fishery is based upon the previous season’s harvest estimated by the Ocean Sampling Program (OSP) and incorporated in Recreational Fishery Information Network (RecFIN). Table 4-23 summarizes the projected mortality for overfished and non-overfished species under the Preferred Alternative.

It should be noted that the precision of recreational groundfish catch estimates based upon previous seasons will continue to be influenced by factors such as the length and success of salmon and halibut seasons, weather and unforeseen factors.

Washington’s Ocean Sampling Program is able to produce estimates of groundfish catch with a one month lag time. Management measures such as more restrictive depth closures, area closures, groundfish retention restrictions, or changes to seasons can be considered and implemented through emergency changes to state regulations if inseason catch reports indicate that recreational harvests of overfished or non-overfished species are exceeding pre-season projections to the point where HGs are at risk of being exceeded.

4.2.2.8 Oregon Recreational – Preferred Alternative

Primary catch controls for the Oregon recreational fishery are season dates, depth closures, bag limits, and GCAs, including yelloweye rockfish conservation areas (YRCAs). The Preferred Alternative analyzes the Oregon recreational fishery with the 2015 and 2016 ACLs (Table 4-1 and Table 4-3), and Oregon recreational harvest guidelines (HGs) for overfished species (Table 4-24), which directly influence the recommended management measures. Key target species with a state quota or Federal HG are also shown, such as black rockfish which has a HG of 440.4 mt.[2] Projected mortality under the Preferred Alternative for the Oregon recreational fisheries is shown in Table 4-25.

[2] The black rockfish ACL is allocated 58 percent to Oregon and 42 percent to California. Of the Oregon portion, Oregon state rule specifies that 76 percent is allocated to the recreational fishery with 24 percent to the commercial fishery. Similarly for nearshore rockfish species, state regulations allocate 48.7 percent of the Oregon portion to the recreational fishery.

Table 4-24. Oregon recreational Federal harvest guidelines (in mt) and state quotas under the Preferred Alternative for 2015-2016.

[a/] Includes kelp and other greenlings.

Groundfish Season Structure

Under the Preferred Alternative, the Oregon recreational groundfish fishery would be open offshore year-round, except from April 1 to September 30 when fishing is only allowed shoreward of 40 fathoms, as defined by waypoints (Figure 4-2). Closing the fishery outside of 40 fathoms from April 1 to September 30, months when angler effort and yelloweye rockfish encounters are greatest, mitigates mortality of yelloweye rockfish. Projected mortality of yelloweye and canary rockfish are within the HG, therefore the shore-based fishery would be open year-round.

	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec
Bottomfish Season	Open all depths			Open < 40 fm						Open all depths		
Marine Bag Limit [1]	Ten (10)											
Lingcod Bag Limit	Three (3)											
Flatfish Bag Limit [2]	Twenty Five (25)											

1 Marine bag limit includes all species other than lingcod, salmon, steelhead, Pacific halibut, flatfish, surfperch, sturgeon, striped bass, pelagic tuna and mackerel species, and bait fish such as herring, anchovy, sardine, and smelt.

2 Flounders, soles, sanddabs, turbots and halibuts except Pacific halibut.

Figure 4-2. Preferred Alternative. Oregon recreational groundfish season structure and bag limits under the Preferred Alternative.

Area Closures

The Stonewall Bank YRCA has been in place since 2006 and would also remain under the Preferred Alternative (Figure 4-3). The YRCA is located approximately 15 miles west of the Port of Newport and consists of the high-relief area of Stonewall Bank, an area of high yelloweye rockfish encounters. No recreational fishing for groundfish and Pacific halibut can occur within this YRCA, which is bounded by the following waypoints specified in Table 4-26.

Two options for extending the status quo Stonewall Bank YRCA for 2015-2016 recreational fisheries, should they become necessary, are also shown in Figure 4-3 and are defined by the coordinates in Table 4-26.

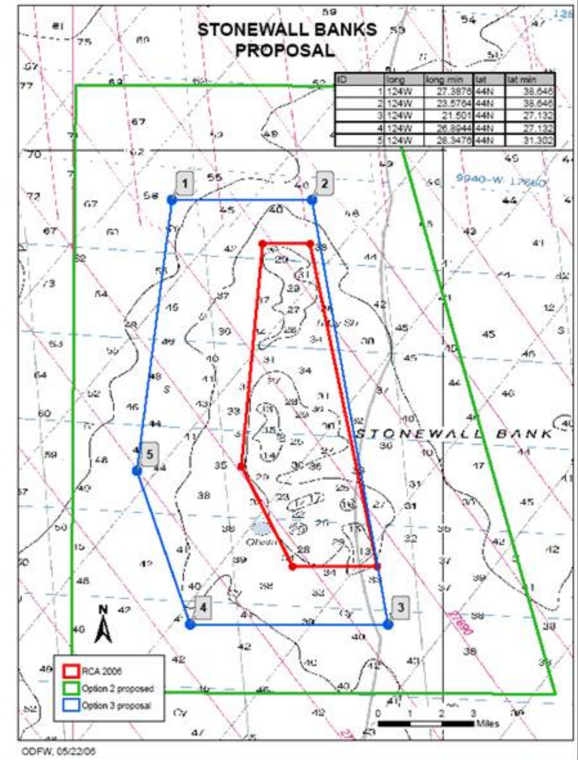

Figure 4-3. Preferred Alternative. The Stonewall Bank Yelloweye Rockfish Conservation Area where recreational fishing for groundfish and Pacific halibut is prohibited.

Groundfish Bag Limits and Size Limits

Under the Preferred Alternative, a marine fish daily bag limit of 10 fish in aggregate would be implemented, the same as under No Action, for 2015-2016. The marine bag includes all species other than lingcod, salmon, steelhead, Pacific halibut, flatfish, surfperch, sturgeon, striped bass, pelagic tuna and mackerel species, and bait fish such as herring, anchovy, sardine and smelt. The seasonal one fish sub-bag limit for cabezon which was in place under No Action would be removed under the Preferred Alternative. Cabezon mortality would be limited via state regulations. A flatfish daily bag limit of 25, which includes all soles and flounders except Pacific halibut, would be allowed in addition to the marine fish daily bag limit. Additionally a three-fish bag limit would be allowed for lingcod. Retention of canary and yelloweye rockfish would continue to be prohibited under the Preferred Alternative.

The following minimum size limits applied to 2013-2014 Oregon recreational fisheries and would be carried forward under the Preferred Alternative:

- Lingcod – 22 in.
- Cabezon – 16 in.
- Kelp greenling – 10 in.

Under the Preferred Alternative, the recreational Pacific halibut fisheries should be able to proceed as in 2013 and 2014, in regards to days and areas open, etc., depending on the halibut quota. Since 2009, only sablefish and Pacific cod may be retained in the Pacific halibut fishery at any depth in the area north of Humbug Mountain, Oregon. South of Humbug Mountain, groundfish may be retained in areas open to groundfish (e.g., less than 30 fm) when halibut are onboard the vessel. There are no changes to the restrictions on groundfish retention during the Pacific halibut season proposed under the Preferred Alternative. However, modifications to the groundfish retention rules during the Pacific halibut openings may be proposed under the Pacific halibut Catch Sharing Plan process (see Appendix B, Section XXX).

Under the Preferred Alternative, the Council is considering a range of state-specific nearshore HGs to keep mortality of nearshore rockfish north of 40°10' N. latitude at or within the ACL. Appendix B, Section XXX contains the management measures for the Oregon recreational fisheries that are necessary to stay within the range of state-specific HGs adopted at the April Council meeting. The Council is scheduled to adopt preferred nearshore HGs north of 40°10' N. latitude at the June Council meeting.

Additional Management Measures Analyzed

Under the Preferred Alternative, two additional management measures were analyzed for the Oregon recreational fisheries: allowing limited retention of canary rockfish and modifying the groundfish species allowed to be retained during all-depth Pacific halibut openings. Additionally, a variety of season structure (depths and months) were modeled to determine potential mortality to overfished species.

Inseason Management Tools

Oregon has a responsive port-based monitoring program through the Ocean Recreational Boat Survey (ORBS) and regulatory processes in place to track mortality and take actions inseason, if necessary. The following are suggested management measures that could be implemented inseason if the fishery does not proceed as expected.

Inseason management tools, designed to mitigate mortality, include bag limit adjustments (including non-retention), length limit adjustments, gear restrictions, and season, days per week, depth, and area closures.

Season, depth, days open per week, and area closures are the primary inseason tools for limiting yelloweye rockfish and canary rockfish mortality, since retention of these species is already prohibited. If catch rates indicate that the bycatch harvest targets for yelloweye rockfish would be reached prematurely, offshore depth closures may be implemented inseason at 30, 25, or 20 fathoms as these two species are less abundant nearshore, and release survival rates are higher in shallow waters. Additionally, days per week may also be closed to reduce mortality. ODFW would monitor inseason progress toward recreational harvest targets for canary rockfish and yelloweye rockfish. Regulations would depend upon the timing of the determination for their need.

Adjustments to the marine fish daily bag limit to no more than 10 fish may be implemented to achieve season duration goals in the event of accelerated or decelerated black rockfish or other nearshore rockfish harvest. The lingcod daily bag limits may be adjusted to no more than 3 fish in the event the marine bag limit changes or the halibut catch limit is reduced from 2013 levels. Season and/or area closures may also be considered if harvest targets are projected to be attained. Closing one or more days per week is an inseason tool that could be used to limit mortality. Closing certain days each week would help lengthen the duration of a fishery approaching an HG.

Non-retention and/or length restrictions are the likely inseason tools to use for cabezon and kelp greenling, as release survival is very high. They may also be used to reduce mortality of nearshore species, such as nearshore rockfish species, especially when combined with the use of descending devices.

Gear restrictions and/or release technique requirements may be implemented to reduce the impact of overfished rockfish since a variety of descending devices are available. SSC recommended and Council-approved mortality rates for canary and yelloweye rockfish when descending devices are used will be implemented in 2014 (see Appendix A for documentation).

Directed yellowtail rockfish and/or flatfish fisheries may be implemented inseason, as were implemented in 2004, in the event of a closure of the recreational groundfish fishery due to attainment Federal or state HGs or targets. Specific gear restrictions may be implemented in the event that yellowtail rockfish and/or flatfish fisheries remain open during a groundfish closure. Additionally, the fishery may be expanded to waters seaward of the RCA, promoting directed yellowtail rockfish opportunity. Directed flatfish fisheries would be legal year round and open shoreward of 40 fathoms during any period the groundfish fishery has any depth restrictions (e.g., 40, 30, 25, 20, and 50 fathom lines). The flatfish fishery would not have any depth restrictions when the groundfish fishery has no depth restrictions. Fisheries would be monitored to ensure that mortality of yelloweye and canary rockfish are within the harvest targets/guidelines.

In the event that the duration of total season is reduced from 12 months; the nearshore waters are closed to groundfish fishing due to management of nearshore species; or the Pacific halibut catch limit is reduced from 2013 levels, the fishery may be expanded to waters seaward of the RCA that is in effect at the time, promoting directed yellowtail rockfish and offshore lingcod opportunity. Fisheries would be monitored to ensure that mortality of yelloweye rockfish and canary rockfish is not in excess of the HGs.

4.2.2.9 California Recreational – Preferred Alternative

The 2015-2016 California recreational groundfish projected mortality and season structure under the Preferred Alternative are based on CDFW's updated RecFISH model. Model projections were calculated for the five recreational groundfish management areas using updated 2011 and 2012 RecFIN estimates; overfished species mortality are reported statewide. Table 4-27 depicts the Preferred Alternative overfished species harvest guidelines for the 2015-2016 California recreational groundfish seasons.

Table 4-27. Preferred Alternative: California recreational allocations/harvest guidelines for 2015-2016.

Stock	**2015**	**2016**

CANARY	24.3	25.0
COWCOD*	2.6	2.6
YELLOWEYE	3.4	3.7

*Non-trawl allocation

Groundfish Seasons and Area Restrictions

Under the Preferred Alternative, tradeoffs between season lengths and depth restrictions were explored (Options 1, 2, and 3). Because the non-trawl allocation for cowcod will increase to 2.6 mt in 2015-2016, all three Options allow depth restrictions to be modified from 50 fm to 60 fm in the Southern Management Area. Under Option 1, longer seasons and status quo (or No Action) depth restrictions were examined. Option 2 explored longer seasons north of Point Conception and limited additional opportunity in deeper depths in the Northern and Mendocino Management Areas; the area where the depths restrictions are the most restrictive under status quo regulations (20 fm). Option 3 examined shorter seasons and deeper depths north of Point Conception. The three fish lingcod bag limit can be accommodated under all Options.

Option 1

Under Option 1, the depth restrictions would be the same as the No Action Alternative and the season lengths would be extended for all areas north of Point Conception from March 1 through December 31 (Figure 4-4). Due to lower yelloweye rockfish mortality in recent years the season lengths in the areas north of Point Conception can be extended. Black rockfish mortality limits the season length at the current depth restrictions. Under this option, the portion of the recreational catch share is exceeded by 1.7 mt, but could be accommodated by the residual from the commercial fishery. The mortality of cowcod and bocaccio in the Southern Management Area are projected to be far below the respective harvest guidelines. Season length in the Southern Management Area would remain the same as status quo, March 1st – December 31st, but the depth restriction would be modified from 50 fm to 60 fm to resume access to deeper depths allowed in 2012 prior to an inseason action.

Management Area	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec
Northern	Closed		Mar 1 – Dec 31 <20 fm									
Mendocino	Closed		Mar 1 –Dec 31 <20 fm									
San Francisco	Closed		Mar 1 – Dec 31 <30 fm									
Central	Closed		Mar 1 – Dec 31 <40 fm									
Southern	Closed		Mar 1 – Dec 31 <60fm									

Figure 4-4. Preferred Alternative (Option 1): California recreational groundfish season structure and depth restrictions for 2015-2016 with maximized season length.

Option 2

Due to lower yelloweye rockfish encounter rates in recent years, the season length north of Point Conception can be extended to April 1st through December 31st (Figure 4-5). In addition, under Option 2, deeper depth restrictions are analyzed in the Northern and Mendocino Management Areas for part of the year; the depth restriction would be 20 fm from April 1st through September 30th, then increase to 30 fm from October 1st through December 31st. The depth and season in all other areas would be unchanged from Option 1.

When depth restrictions are liberated, it becomes more challenging to predict angler behavior and uncertainty in the yelloweye rockfish projections increases. Further, the RecFISH model assumes proportion of catch by depth and those proportions of catch can change when depth is increased, which results in underestimates of mortality. The relatively low effort during October 1st through December 31st makes it possible to allow access to deeper depths without greatly increasing the risk of exceeding the yelloweye rockfish harvest guideline. Black rockfish mortality remains within the state recreational share under this option.

Management Area	**Jan**	**Feb**	**Mar**	**Apr**	**May**	**Jun**	**Jul**	**Aug**	**Sep**	**Oct**	**Nov**	**Dec**
Northern	Closed			April 1 – Sep 30 <20 fm, Oct 1– Dec 31 <30 fm								
Mendocino	Closed			April 1 – Sep 30 <20 fm, Oct 1– Dec 31 <30 fm								
San Francisco	Closed			April 1 – Dec 31 <30 fm								
Central	Closed			April 1 – Dec 31 <40 fm								
Southern	Closed		Mar 1 – Dec 31 <60 fm									

Figure 4-5. Preferred Alternative (Option 2): California recreational groundfish season structure and depth restrictions for 2015-2016.

Option 3

Under Option 3, tradeoffs between increased depth and season lengths north of Point Conception were explored. By allowing access to deeper depths, encounters with overfished shelf rockfish species are expected to increase. In order to keep mortality of overfished species from exceeding harvest guidelines, season lengths north of Point Conception would be reduced (Figure 4-6). Similar to Option 2, when depth restrictions are modified uncertainty increases, as effort shifts to deeper depths may be greater than projected, resulting in mortality exceeding projected values.

Season length in the Southern Management Area would also be reduced to the May 15th to August 15th to explore reductions in catch savings on cowcod, bocaccio, or other species. In recent years, bocaccio and cowcod encounters have increased, making it more difficult to model projected mortality. Given these concerns, examining a shorter season in the Southern Management Area is prudent in the event inseason action would be necessary to keep catches within allowable levels. California scorpionfish would remain open year round to 60 fm.

Management Area	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec
Northern	Closed				May15–Aug15<30fm			Closed				
Mendocino	Closed				May15–Aug15<30fm			Closed				
San Francisco	Closed				May15–Aug15<40fm			Closed				
Central	Closed				May15–Aug15<50fm			Closed				
Southern	Closed				May15–Aug15<60fm			Closed				

Figure 4-6. Preferred Alternative (Option 3): California recreational groundfish season structure and depth restrictions for 2015-2016.

Other Measures

Nearshore Rockfish HGs: Under the Preferred Alternative, the Council is considering a range of state-specific nearshore HGs to keep mortality of nearshore rockfish north of 40°10' N. latitude at or within the ACL. Appendix B, Section XXX contains the management measures for the California recreational fisheries that are necessary to stay within the range of state-specific HGs adopted at the April Council meeting. The Council is scheduled to adopt preferred nearshore HGs north of 40°10' N. latitude at the June Council meeting.

Groundfish Bag Limits and Size Limits: Under The Preferred Alternative, the groundfish bag limits or size limits are the same as under No Action except for the following:

- Lingcod: The No Action bag limit for lingcod is two fish. Under the Preferred Alternative, lingcod bag limit would increase from two fish to three fish. The mortality (in metric tons) as a result of the increase in the bag limit for Options 1, 2, and 3 is provided in Table 4-28. An increase in the lingcod bag limit from two to three fish could be accommodated statewide with the aforementioned season and depth restrictions under all options. The Council is not proposing any changes to the lingcod minimum size restriction. Increases to overfished species mortality as a result of this increase are expected to be minimal (if any).

Additional Management Measures Analyzed: None

Table 4-28. Preferred Alternative: California recreational projected mortality of non-overfished species for 2015-2016 under Option 1, Option 2, and Option 3. Results in parenthesis reflect lingcod mortality with a three fish bag limit.

	Projected Mortality (mt)		
Stock	**Option 1**	**Option 2**	**Option 3**
Black Rockfish	232.5*	219.7	110.3
Blue Rockfish	65.2	62.2	22.9
Cabezon	42.5	40.2	16.9
California scorpionfish	81.1	81.1	13.3
Greenlings	24.7	22.4	8.7
Lingcod	296.2 (356.4)	280.9 (338.0)	111.0 (134.0)
Minor Nearshore Rockfish North	15.6	15.4	6.7
Minor Nearshore Rockfish South	376.5	365.4	118.6
Widow Rockfish	4.2	3.8	1.5

**Mortality exceeds the recreational portion of the California catch share of 230.8 mt. Further discussion provided under the text describing Option 1.*

Impact (Groundfish Mortality)

Projected mortality for bocaccio, canary rockfish, cowcod, and yelloweye rockfish for all Options under the Preferred Alternative can be found in Table 4-29. Under all the Options contemplated under the Preferred Alternative the projected mortality of cowcod, bocaccio, canary and yelloweye rockfish increases compared to the No Action alternative, due to the increased season lengths or deeper depth restrictions. The number of angler trips is expected to increase under the Options allowing for increased opportunity for both private/rental boats (PR) and commercial passenger fishing vessels (CPFV). Projections for non-overfished species for the Preferred Alternative under each Option are provided in Table 4-28.

Similar to the No Action Alternative, if overfished species encounters are tracking higher or lower than projected, inseason action could be taken, which could include closing one or more recreational groundfish management areas, restricting recreational fishery seasons and/or modifying depth restrictions. As in the No Action Alternative, the YRCAs would be available and could be implemented inseason if catches are projected to exceed harvest guidelines.

Table 4-29. Preferred Alternative: California recreational projected mortality of overfished species for 2015-2016 under Option 1, Option 2 and Option 3.

Stock	California Recreational 2015 HG (mt)	California Recreational 2016 HG (mt)	Projected Mortality (mt)		
			Option 1	Option 2	Option 3
BOCACCIO	178.8	185.6	117.5	117.6	23.5
CANARY	24.3	25.0	19.8	19.8	10.6
COWCOD			1.2	1.2	0.3
YELLOWEYE	3.4	3.7	2.8	2.9	2.7

a/The non-trawl allocation of cowcod is 2.6 mt.

Executive Summary

INTRODUCTION

This document provides information about, and analyses of, setting groundfish harvest specifications and establishing related management measures for 2015 and subsequent years for fisheries covered by the Pacific Coast Groundfish Fishery Management Plan (hereafter, Groundfish FMP or FMP), which are developed by the Pacific Fishery Management Council (Council) in collaboration with the National Marine Fisheries Service (NMFS). Groundfish harvest specifications are set every 2 years for a 2-year period. In addition to harvest specifications and management measures for the 2015-16 biennial period, this document evaluates the impacts of setting harvest specifications and management measures over the long term. These actions must conform to the Magnuson-Stevens Fishery Conservation and Management Act (MSA), the principal legal basis for fishery management within the Exclusive Economic Zone (EEZ), which extends from the outer boundary of the territorial sea to a distance of 200 nautical miles from shore. The states manage their fisheries, including nearshore rockfish fisheries in the territorial sea, in a manner consistent with, or more restrictive than, the Groundfish FMP and Federal implementing regulations.

THE PROPOSED ACTIONS

The proposed action has three components: 1) Establishing harvest specifications and management measures for the 2015-2016 biennial management period, 2) changing groundfish stock complexes and designating ecosystem component species, and 3) amending the Groundfish FMP to describe how the Council would use default harvest control rules (HCRs) in their decision-making process in future biennial cycles and to clarify what are considered new and routine management measures during the biennial process. In all cases the alternative of No Action is also considered. This EIS includes an analysis of the long-term impacts of biennial harvest specifications and foreseeable adjustments to routine management measures to support decision-making in future biennial periods.

ALTERNATIVES

Table ES-1 summarizes the alternatives and options evaluated in this EIS.

Establishing Harvest Specifications and Management Measures for the 2015-2016 Biennial Management Period

Harvest specifications are established for each managed stock or stock complex in the Grondfish FMP. Specifications include the overfishing limit (OFL), the allowable biological catch (ABC), and the annual catch limit (ACL). Catch above the OFL constitutes overfishing. The ABC is a precautionary reduction from the OFL to account for scientific uncertainty in the OFL specification and management error. Section 4.4 in the Groundfish FMP describes the method usually used to determine this precautionary reduction. It involves two quantities, sigma (σ) and P*. Sigma represents variability in stock assessment results and P* represents the probability of catch at the ABC resulting in overfishing. A formula incorporating these two values produces a percentage value representing the precautionary reduction. Sigma is determined by the SSC while the Council chooses P*, which according to the Groundfish FMP, cannot exceed 0.45.

Overall catch is managed to the ACL. For most stocks the ACL is set equal to the ABC but the ACL may be set below the ABC for a variety of reasons. The Council may also set an annual catch target (ACT) to establish a higher level of precaution, particularly if there is greater uncertainty about the true level of catch due to estimation error.

Management measures include adjustments to and allocations of ACLs, adjustments to existing management measures including those designated as routine, and adoption of new management measures. During the biennial cycle existing, routine measures may be adjusted and new measures established. These management measures are mainly intended to control groundfish catch and improve monitoring of the fishery. Allocations establish overall limits for different groundfish fishery sectors (segments of the overall fishery distinguished by gear type, permit programs, target species, and other factors) as a basis for controlling catch. Many allocations have been included in the FMP and the same proportions are applied from period to period; others may be modified biennially based on conditions in the fishery. Harvest guidelines may also be used to aid the implementation of management measures that takes into account fishing opportunity in different fishery sectors. Catch control tools for the commercial groundfish fishery include individual fishing quota (IFQ), vessel allocations of sablefish catch opportunity to certain fixed gear, cumulative landing (or trip) limits, and closed areas to reduce bycatch of species of concern, predominantly overfished species. Recreational catch control tools include time and area closures and bag limits. Catch monitoring is accomplished by at-sea observers and dockside accounting for commercial catch and landings, and sampling and observation of recreational fisheries. Management measure alternatives are structured to provide sufficient fishing opportunity to achieve but not exceed ACLs. The alternatives are:

The Council considered four alternatives for 2015-2016 harvest specifications and management measures.

No Action

Harvest specifications values in place on January 1, 2014, would remain in effect for the 2015-2016 period (see Table 2-2 for the numerical values and basis for these harvest specifications). Management measures in place on December 31, 2014 would remain in place during the 2015-2016 biennial period. However, the Council may take inseason action to adjust routine management measures during the biennium.

The Preferred Alternative

Annual catch limits (ACLs) for most species are determined based on the ACLs being set equal to the ABCs with a P* value of 0.45. The ACLs for arrowtooth, lingcod south of 40°10 N. lat., longspine thornyhead north and south of 34°27 N. lat., sablefish north and south of 36° N. lat., shortspine thornyhead north and south of 34°27 N. lat., spiny dogfish, and starry flounder would be determined based on the ACLs being set equal to the ABCs with a P* value of 0.40. For some stocks ACLs are set below the ABC, in which case the P* value does necessarily determine the ACL. Overfished species ACLs are set based on rebuilding plans except for cowcod south of 40º10' N. lat., for which a new stock assessment is available. The ACL is increased from 3 mt to 10 mt and an annual catch target (ACT) of 4 mt is established. For this stock Constant catch ACLs for Dover sole and widow rockfish are increased from their 2014 values. Table 2-3 contains the preferred 2015 and 2016 harvest specifications.

Under the Preferred Alternative enhanced accountability measures to control mortality of rougheye rockfish and a sorting requirement for rougheye and blackspotted rockfish are implemented. These measures allow catch to be more accurately and responsively tracked while the rougheye rockfish/blackspotted rockish stock remains within the current slope rockfish complexes. Stocks are removed from the Other Fish complex; most are designated ecosystem component species while spiny dogfish is managed separately with its own harvest specifications. The Washington, Oregon, and California kelp greenling stocks, the Washington cabezon stock, and leopard shark remain in the Other

Fish complex. Some species currently not in the Groundfish FMP are designated EC species.[1] The EC classification is described in National Standard 1 Guidelines. EC species are monitored but not actively managed. They are species that are caught incidentally in relatively small amounts. If monitoring indicates an increasing trend in catch for an EC species, reclassification and/or appropriate management measures may be considered. In addition to moving many of the species in the Other Fish complex to the EC species designation, the Council designated several species not currently in the Groundfish FMP as EC species.

Catch control measures are established and adjusted in order to attain but not exceed the Preferred Alternative ACLs.

Alternative 1

Where applicable, ABCs are determined based on a P* value of 0.45, and the ACL is set equal to the ABC. For several stocks the ACL is set below the ABC and so the P* value does not necessarily determine the ACL. Instances where the ACL is below the ACL include specification of a fixed or constant catch level, precautionary adjustments using the 40-10 and 25-5 rules, and the use of the harvest rate specified in a rebuilding plan. Table 2-4 shows the harvest specifications for each stock under Alternative 1.

Catch control measures are established and adjusted in order to attain but not exceed the Alternative 1 ACLs.

Alternative 2

Where applicable, ACLs are determined based on the ACLs being set equal to the ABCs with a P* value of 0.25. As described above for Alternative 1, ACLs may be set below the ABC, in which case the P* value does necessarily determine the ACL. Table 2-5 contains the harvest specifications under Alternative 2.

Catch control measures are established and adjusted in order to attain but not exceed the Alternative 2 ACLs.

Amendment 24

This amendment would incorporate a description of the default harvest control rule (HCR) concept into the Groundfish FMP, which is intended to make clear that if the Council does not take action to modify an HCR, the default HCR is used, applying the best available scientific information, to calculate harvest specification numerical values. This approach helps make clear that most of the time the Council is either reapplying existing harvest policies or making modest changes within the framework set out in the Groundfish FMP and consistent with the Magnuson-Stevens Act. This action also provides an opportunity to evaluate the long-term impacts of biennial harvest specifications and management measures process in this EIS. This is intended to allow more focused analyses of future biennial actions. The description of the types of management measures that are established and adjusted during the biennial process would also be clarified as part of Amendment 24. As part of the biennial process new management measures may be implemented and existing, “routine” management measures adjusted; for example, existing catch control tools are usually changed in response to changes in ACLs. Routine measures are already part of the regulations and the effects of using these measures were previously

[1] Designating EC species requires amending in Groundfish FMP to change the classification of currently managed species and incorporate species not currently included in the FMP. These changes would be part of Amendment 24, described below.

analyzed. This allows National Marine Fisheries Service to use a simpler process to implement these regulatory changes under applicable law. Four alternatives are evaluated.

No Action

The Groundfish FMP is not amended.

Alternative 1

The default HCRs would use a P* value of **0.45** to determine the ABC, where applicable, using the best available scientific information. During the biennial harvest specifications process the Council can take action to modify the HCR and harvest specifications for the next biennial period would be based on the new HCR. FMP language describing the types of management measures developed and implemented as part of the biennial process is revised for clarification.

Alternative 2

The default HCRs would use a P* value of **0.25** to determine the ABC, where applicable, using the best available scientific information. During the biennial harvest specifications process the Council can take action to modify the HCR and harvest specifications for the next biennial period would be based on the new HCR. FMP language describing the types of management measures developed and implemented as part of the biennial process is revised for clarification.

Alternative 3

The default HCRs are the HCRs used during the previous biennial cycle. Harvest specifications are computed using the best available scientific information (such as the most recent stock assessment). During the biennial harvest specifications process the Council can take action to modify the HCR and harvest specifications for the next biennial period would be based on the new HCR. FMP language describing the types of management measures developed and implemented as part of the biennial process is revised for clarification.

Table ES-1. Schematic of the elements of the alternatives.

Element	No Action	Preferred Alternative	Alternative 1	Alternative 2
2015-16 harvest specifications and management measures	Rollover 2014 harvest specifications and management measures	Council preferred harvest specifications; adjust management measures as necessary	Harvest specifications based on p*=0.45; adjust management measures as necessary	Harvest specifications based on p*=0.25; adjust management measures as necessary

	No Action	The Preferred Option	Option 1
Stock complex reorganization and designation of Ecosystem Component Species	Slope Rockfish and Other Fish complexes not reorganized; EC species not designated	Slope Rockfish complex not reorganized; measures to monitor and manage rougheye and blackspotted rockfish catch implemented; spiny dogfish removed from Other Fish complex and managed; other species removed and designated EC species; some species not already in the FMP added as EC species	Rougheye rockfish (including blackspotted rockfish) and shortraker rockfish removed from the slope rockfish complexes and managed as a new coastwide rougheye-blackspotted-shortraker (RBS) complex

	No Action	Alternative 1	Alternative 2	Alternative 3
Amendment 24 (default HCRs and management measure process)	No Amendment	Default HCR with ABC based on **P*=0.45**; amend Section 6.2 to clarify “new” vs. “routine” measures	Default HCR with ABC based on **P*=0.25**; amend Section 6.2 to clarify “new” vs. “routine” measures	Default HCR with ABC based on **current P***; amend Section 6.2 to clarify “new” vs. “routine” measures

IMPACTS OF THE PROPOSED ACTIONS

Groundfish

Table 2-2 through Table 2-5 show 2015-2016 harvest specifications under each of the alternatives including No Action. Under the Preferred Alternative harvest control rules change for seven of the 40 stocks or stock complexes (not including Pacific whiting) for which ACLs are established. These changes are:

- The Dover sole constant catch ACL is increased from 25,000 mt to 50,000 mt
- The ACLs for shortspine thornyhead stocks north and south of 34º27' N. lat. are proportions of the coastwide ABC; the ABC is determined using a P* value of 0.4 rather than 0.45
- Spiny dogfish is removed from the Other Fish complex and managed with its own ACL, which is set equal to the ABC using a P* value of 0.4
- The constant catch ACL for widow rockfish is increased from 1,500 mt to 2,000 mt
- For the Nearshore Rockfish North complex the 40-10 precautionary adjustment is applied to determine the China rockfish contribution to the stock complex ACL (which is determined as the sum of constituent species’ ACL contributions)
- The Other Fish complex ACL is equal to the complex ABC set equal 0.45 consistent with the removal of many species from the complex, including spiny dogfish

Based on a new stock assessment, harvest specifications for cowcod, an overfished species, are changed. The Council will chooses a new target rebuilding year for the stock at its June 2014 meeting. The

Council chose a 10 mt ACL for this stock, which is consistent with the current rebuilding plan SPR-based harvest rate of 82.7%. The Council also established an annual catch target (ACT) of 4 mt as an additional precautionary measure. Catch will be managed to stay below the ACT.

ACLs for 14 of the stocks or stock complexes would increase in 2015 compared to 2014 ACLs (No Action).

Section 4.1 evaluates the biological impacts of preferred 2015-2016 harvest specifications on a select list of groundfish stocks focusing on 1) overfished stocks currently managed under rebuilding plans, 2) stocks where the Council chose a range of alternative ACLs for analysis, 3) stocks and stock complexes where total catches in recent years have been at least 80 percent of specified ACLs, and 4) stocks preferred to be removed from a status quo stock complex and managed with stock-specific harvest specifications.

Section 4.2 evaluates deductions from and allocations of the ACLs and modifications to routine management measures to control catch so that the ACLs established under the alternatives are not exceeded. Commercial fishery management measures subject to modification include catch control tools including individual fishing quota (IFQ) annual quota pound issuance, establishing tier limits for the limited entry sablefish primary season, modifying cumulative landing limits for other fisheries and species, and changes to the boundaries of time area closures to control bycatch of overfished species and other species where there is a conservation concern. Recreational management measures subject to modification include bag limits and time/area closures (seasons). At its June meeting the Council will also consider adopting several new management measures related to harvest specifications.

Section 4.8 evaluates the long-term biological impacts of setting harvest specifications and Section 4.9 describes the impacts of the range of potential modifications to routine management measures that may be made in the foreseeable future.

Socioeconomic Environment (Fishing Communities)

Under the Preferred Alternative coastwide non-whiting ex-vessel revenue is projected to increase by $16 million in 2015 compared to No Action 2014 ACLs and management measures. This represents a $19.3 million increase from annual average inflation-adjusted ex-vessel revenue, 2003-2012. Recreational angler trips are expected in increase between 167,000 and 3.9 million marine angler trips depending on the management option chosen under the Preferred Alternative. Resulting commercial and recreational income accruing to fishing communities under the Preferred Alternative would increase by between $27.3 million and $49.3 million depending on the option chosen.

For the foreseeable future changes in ex-vessel revenue, net revenue (a proxy for commercial fishery profits), recreational angler trips, and personal income will be partly a function of fishing opportunity determined by stock yield and management measures. Based on assumptions about yield and potential policies for setting harvest specifications (as described in the Amendment 24 alternatives) catches are expected to increase under most model scenarios, assuming management succeeds in achieving management objectives for stock biomass size and related fishing mortality levels. Fishing opportunity could decline if stock yields are below the most likely conditions and more conservation management policies, such as using a P* value of 0.25 to determine the ABC, were used for all stocks. Recent average catch is in most cases lower than projected ACLs under scenarios combining different assumptions about potential yield and policies for determining ABCs. These scenarios suggest that revenue and personal income is likely to increase over the long term. However, historically there has been a lot of inter-annual volatility in ex-vessel revenue in both a positive and negative direction. Declines in revenue can occur because of unaccounted for changes in yield and changing market conditions affecting prices.

Essential Fish Habitat

Over both the short and long term the adverse impacts of fishing on groundfish essential fish habitat (EFH) is expected to be similar to adverse impacts experienced in the past. These adverse impacts result from fishing gear coming in contact with the seafloor, disrupting both physical characteristics and biogenic habitat such as corals and sponges. The Council has implemented a variety of mitigation measures to address adverse impacts, and other management measures, such as Groundfish Closed Areas to control bycatch, have mitigated adverse impacts as an ancillary effect. The Council is currently reviewing the groundfish EFH designation and mitigation measures established by Amendment 19 and could establish additional mitigation measures as part of the review process. The review process will not be completed before the 2015-2016 biennial period begins.

California Current Ecosystem

The Atlantis California Current Ecosystem Model was used to simulate the effects of the range of harvest policies that may be implemented in the foreseeable future. Since ecosystem effects take a long time to be manifested, it is not possible to distinguish between short- and long-term policy choices. The alternatives considered for the 2015-2016 biennial harvest specifications parallel those considered under Amendment 24 so in general the alternatives with a more conservative policy (2015-2016 Alternative 2 and Amendment 24 Alternative 2, P*=0.25) can be equated as can the alternatives with the most risk prone policy (2015-2016 Alternative 1, Amendment 24 Alternative 1, P*=0.45). Scenarios bracketing the range of harvest policies and ecosystem productivity regimes were modeled. Scenarios with very high harvest levels and low ecosystem productivity had the most pronounced effects, resulting in significant direct effects (effects of fishing on harvested stocks) and detectable indirect effects (effects on other ecosystem components in response to changes in the abundance of harvested stocks). It is important to note that these scenarios are deterministic, in other words there is no provision for a management response to new information about stock status. In the real world, the Council and NMFS would respond to new information showing that substantial adverse effects are occurring by reducing catch limits.

Total system biomass, a general measure of indirect effects, ranged from a decline of 8% from the benchmark scenario (recent average catch, most likely ecosystem productivity state) for the low productivity-high catch scenario to an increase of 5% under high productivity-low catch scenario. For most stocks low catch was represented by recent average catch streams. Thus if catch does not change substantially from recent levels few if any indirect effects would be predicted.

One important caveat to these simulations is that catch levels for Pacific whiting were not varied, since the alternatives evaluated within this EIS do not include varying whiting harvest. However, this species has an important structuring role in the California Current Ecosystem both as forage during early life stages and a piscivore (fish eater) when adult. Pacific whiting stock size is highly variable in response to conditions affecting recruitment of juveniles into the fishable, adult population. Though the model does not include these episodic recruitment events, the high and low ecosystem productivity states considered here may bracket the productivity of Pacific whiting, as well as the other groundfish stocks evaluated within this EIS. For Pacific whiting, by years 25-30, the high productivity scenarios (under recent average catches) yields abundance that is 1.16 times higher than base productivity, and low productivity yields abundance that is 0.78 times that of base productivity. Therefore, the model results address alternative levels of whiting productivity, though not alternative whiting harvest levels.

Protected Species

Protected species include those listed under the Endangered Species Act (ESA) and the Marine Mammal Protection Act (MMPA). NMFS has also agreed to consider the effects of actions on seabirds not listed under the ESA. ESA-listed species of concern include several kinds of fish (eulachon, green sturgeon, salmon), the humpback whale, leatherback sea turtle, and the short-tailed albatross.

Similar to other environmental components, the impacts of the proposed action on protected species during the 2015-2016 biennial period, measured in terms of take and resulting mortality, is only relevant within a long-term context considering the effect of such take on population size and viability. For ESA-listed species NMFS Protected Resources Division and the US Fish and Wildlife Service have consulted on the effects of the groundfish fishery. Information on effects is provided in Biological Opinions, which contain Incidental Take Statements (ITSs). The ITSs include estimates of the number of listed species likely to be taken, a determination of whether take levels jeopardize the continued existence of the species and measures that NMFS must implement to mitigate estimated levels of take. If these take levels are exceeded consultations may be reinitiated and new mandatory measures identified.

All marine mammals are protected under the MMPA. The objective of the Act is to allow marine mammals to reach their optimum sustainable population level and to reduce human caused serious injury and mortality to the maximum extent practicable. Through periodic stock assessments the potential biological removal level of a stock is estimated. A marine mammal population can meet or sustain the optimum population when human caused mortality is below this level. Takes for all segments of the groundfish fishery, except for the sablefish pot fishery, have been determined to have a remote likelihood of or no known serious injuries or mortalities. The sablefish pot fishery has been determined to cause occasional serious injury or mortality.

At-sea observer coverage allows total marine mammal interactions to be estimated. Non-ESA listed species taken in the groundfish fishery include

- California sea lion: Shoreside groundfish trawl, California halibut trawl, non-nearshore fixed gear sablefish, nearshore fixed gear, at-sea hake (Pacific whiting)[2]
- Harbor seal: California halibut trawl, non-nearshore fixed gear sablefish, nearshore fixed gear, at-sea hake (Pacific whiting)
- Northern elephant seal: Shoreside groundfish trawl, California halibut trawl, non-nearshore fixed gear sablefish, at-sea hake (Pacific whiting)
- Harbor porpoise: California halibut trawl
- Dall’s porpoise: At-sea hake (Pacific whiting)
- Pacific white-sided dolphin: Shoreside groundfish trawl
- Risso’s dolphin: Shoreside groundfish trawl
- Common bottlenose dolphin: Non-nearshore fixed gear

If estimated takes substantially increase such that overall human caused serious injury or mortality exceeded potential biological removal remedial actions would be taken.

Non-ESA listed seabirds are also taken in the groundfish fishery. The only species with more than negligible observed takes is the black-footed albatross. Mitigation measures in the process of being implemented to reduce the risk of takes of ESA-listed short-tailed albatross will likely have a mitigating effect for this species as well.

There is no information to conclude that under any of the alternatives the level of take of protected species will change substantially from historical baseline levels in either the short or long term.

[2] California halibut trawl is a state managed fishery and only subject to the proposed action with respect to catch accounting to ensure that ACLs are not exceeded.

Non-Groundfish Species

Groundfish fisheries catch a range of non-groundfish species in small amounts proportional to catch of groundfish. Some of these species—such as Pacific halibut, Dungeness crab, and salmon—are commercially valuable and have directed fisheries. Commercially valuable species are managed under other Council FMPs, other Federal authority, or by the states. Fishing mortality in the groundfish fishery is taken into account when managing such directed fisheries. Catch of non-groundfish species as a percent of total catch during 2003-2011 varied between 1.4% (3,801 mt) iand 5.9% (8,551 mt). Non-groundfish catch amounts did not correlate with total catch so it is not possible to predict how changes in target species fishing opportunity would affect non-groundfish catch. There is no information is conclude that non-groundfish catch is likely to exceed the historical range of catch over either the short or long term. Fishery observer data allows catch levels to be estimated so that if a substantial change in catch is detected, such that a conservation concern arises, mitigation measures could be implemented.

[Intentionally Blank]

Chapter 1 INTRODUCTION

1.1 How this Document is Organized

This document provides information about, and analyses of, setting groundfish harvest specifications and establishing related management measures for 2015 and subsequent years for fisheries covered by the Pacific Coast Groundfish Fishery Management Plan (hereafter, Groundfish FMP or FMP), which are developed by the Pacific Fishery Management Council (Council) in collaboration with the National Marine Fisheries Service (NMFS). Groundfish harvest specifications are set every 2 years for a 2-year period. In addition to harvest specifications and management measures for the 2015-16 biennial period, this document evaluates the impacts of setting harvest specifications and management measures over the long term. These actions must conform to the Magnuson-Stevens Fishery Conservation and Management Act (MSA), the principal legal basis for fishery management within the Exclusive Economic Zone (EEZ), which extends from the outer boundary of the territorial sea to a distance of 200 nautical miles from shore. The states manage their fisheries, including nearshore rockfish fisheries in the territorial sea, in a manner consistent with, or more restrictive than, the Groundfish FMP and Federal implementing regulations.

In addition to addressing MSA mandates, this document is an environmental impact statement (EIS), pursuant to the National Environmental Policy Act (NEPA) of 1969, as amended. This document is organized so that it contains the analyses required under NEPA. The proposed action must also comply with other applicable laws, which are enumerated in Chapter 6. While this EIS provides supporting information, the procedural and analytical requirements for legal mandates other than NEPA (including findings made by NMFS) may be addressed in other documents (see Chapter 6).

The EIS is organized in the following chapters and appendices:

- Chapter 1 explains why the action is being considered for the groundfish fisheries in 2015-16 and subsequent biennial cycles, including revisions to established groundfish rebuilding plans. The purpose and need statement defines the scope of the subsequent analysis.

- Chapter 2 outlines the No Action and action alternatives that have been considered to address the defined purpose and need. The Council recommends a preferred alternative from among these alternatives, which provides the basis for establishing or revising the harvest specifications and management measure regulations governing groundfish fisheries in 2015–16 and beyond. A second set of alternatives is used to evaluate a decision-making framework for establishing harvest specifications, which would be incorporated into the FMP through Amendment 24. This set of alternatives serves as the basis for evaluating the long-term impacts of setting harvest specifications and management measures.

- Chapter 3 describes the environmental components affected by the proposed action, which are groundfish and other marine fish, fishery sectors, fishing communities, protected species, essential fish habitat (EFH), and the marine ecosystem.

- Chapter 4 describes the direct, indirect, and cumulative effects of the proposed action, including the No Action and preferred alternatives, on the environmental components described in Chapter 3.

- Chapter 5 details how this action meets 10 National Standards set forth in the MSA (Section 301(a)) and groundfish FMP goals and objectives, as well as MSA-related scoping requirements and public meeting opportunities afforded through the Council process.

- Chapter 6 provides information on those laws and executive orders, in addition to the MSA, with which an action must be consistent. This chapter also describes in greater detail the NEPA process for this action, including all of the steps (Notice of Intent, scoping process under NEPA, etc.) required by the Council on Environmental Quality (CEQ) and NOAA Administrative Order (NAO) 216-6.

- Chapter 7 is the bibliography.

- Appendix A, Model Documentation, documents the models and methods used to estimate potential catches (harvest impacts) under the alternatives, and related effects on personal income and employment in fishing communities.

- Appendix B, Detailed Analysis of Management Measures, contains a focused evaluation of the performance and effects of new management measures or adjustment to existing management measures and the range of options considered by the Council and NMFS.

- Appendix C, FMP Amendment Language, contains changes to the Groundfish FMP proposed by the Council as part of the proposed action.

When implemented, the 2015-16 harvest specifications and management measures will succeed those established for the 2013-2014 biennial period and stay in place until subsequent changes are made in future biennial cycles.

1.2 Proposed Actions, Purpose and Need

1.2.1 The Proposed Action

The proposed actions are in three components: 1) Establishing harvest specifications and management measures for the 2015-2016 biennial management period, 2) changing groundfish stock complexes and designating ecosystem component species, and 3) amending the Groundfish FMP to describe how the Council would use default harvest control rules (HCRs) in their decision-making process in future biennial cycles and to clarify what are considered new and routine management measures during the biennial process. In all cases the alternative of No Action is also considered. This EIS includes an analysis of the long-term impacts of biennial harvest specifications and foreseeable adjustments to routine management measures to support decision-making in future biennial periods.

1.2.1.1 2015-2016 Biennial Harvest Specifications and Management Measures

Using the “best available scientific information,” the proposed action is to establish harvest specifications every 2 years, including the overfishing limits (OFLs), acceptable biological catches (ABCs), and annual catch limits (ACLs) for each management unit[3], consistent with the policies and procedures the Council has established for these actions and the requirements of the Pacific Coast Groundfish Fishery Management Plan (Groundfish FMP); the Magnuson-Stevens Act (MSA)—particularly the 10 National Standards enumerated in §301(a) of the MSA; and other applicable law.

Seven Pacific Coast groundfish species are currently "overfished" and managed under rebuilding plans implemented by Secretarial amendment. Within the rebuilding plans, T_{TARGET} is the key rebuilding parameter. T_{TARGET} is the projected year by which an overfished species will be rebuilt. Any change to T_{TARGET} must be demonstrated by the need to rebuild the stock in as short a time as possible, taking into account the status and biology of the stock, the needs of fishing communities, and the interaction of the stock within the marine ecosystem. Every 2 years the Council considers the best available scientific information (principally new or updated stock assessments) and determines whether it is necessary to adjust any of the existing harvest specifications or management measures necessary to achieve but not exceed ACLs. Adjustments to harvest specifications may involve changing the underlying harvest control rule.[4] These adjustments must be consistent with the MSA and the Groundfish FMP. The proposed action includes setting harvest specifications and management measures for the 2015-2016 biennial period and revising Federal regulations at 50 CFR 660, Subparts C through G accordingly.

1.2.1.2 Stock Complex Reorganization and Designation of Ecosystem Component Species

The proposed action is also to change the organization of the Slope Rockfish and Other Fish stock complexes used to manage west coast groundfish fisheries. National Standard 1 Guidelines at 50 CFR 660.310(d)(8) describe stock complexes and reasons for using them in management. A stock complex is "a group of stocks that are sufficiently similar in geographic distribution, life history, and vulnerabilities to the fishery such that the impact of management actions on the stocks is similar." Stocks may be grouped into complexes for various reasons, including where stocks in a multispecies fishery cannot be targeted independent of one another and MSY cannot be defined on a stock-by-stock basis; where there is insufficient data to measure their stock status; or when it is not feasible for fishermen to distinguish individual stocks among their catch. Most groundfish species are managed in a stock complex are data poor stocks without full stock assessments. However, some stocks within the complexes have been assessed.

The Other Fish complex historically contained various non-target species that were often bycatch (not retained, landed, sold, or kept for personal use). The ecosystem component (EC) species designation is described in National Standard 1 Guidelines at 50 CFR 600.310(d)(5). EC species should be a non-target stock; not subject to overfishing determined to be overfished, or approaching the overfished threshold or become so in the absence of management measures; and not generally retained for sale or personal use. Because many of the species in the Other Fish complex fit the criteria for designating EC species, it makes sense to reclassify them in this category. EC species are not considered "in the fishery" and ACLs are not set for them. Other species not currently included in the Groundfish FMP are considered for EC species designation, because they are occasionally caught and closer monitoring of these catches could help identify potential conservation problems, for example if catches began to dramatically increase.

[3] Management units are stocks occurring throughout the west coast EEZ ("coastwide"), geographic subdivisions of stocks in the EEZ, and geographically subdivided stock complexes composed of more than one managed species.

[4] "Harvest control rule" means the methods adopted to determine harvest specifications, based on criteria in the MSA and Groundfish FMP. Harvest specifications are the numerical values determined by applying the harvest control rule (or harvest policy) to the best available scientific information about the status and characteristics of a stock or management unit.

1.2.1.3 Default Harvest Control Rules and Rebuilding Plan Revision Criteria

The proposed action includes Amendment 24 to the Groundfish FMP, which modifies the harvest specification procedures described in the Plan so that, in the absence of Council action, harvest specification values based on default harvest control rules for one or more stocks may be established. During any biennial decision-making process the Council may depart from these default values by deciding to modify the harvest control rule for one or more management unit. Such changes would form the basis of the "action alternatives" in future impact analyses. Reducing the number of decision points is expected to reduce the amount of Council and committee time spent on harvest specification deliberations as well as reduce the scope of action and analysis needed for implementation

1.2.1.4 Evaluation of the Long-Term Impacts of Setting Biennial Harvest Specifications and Management Measures

To evaluate environmental impacts of these periodic changes over a longer time period, estimates of harvest specification values for a 10-year sample period (2015-24) are evaluated in Chapter 4. The ability to establish and adjust harvest levels is the first major tool at the Council's disposal to exercise its resource stewardship responsibilities. Each biennial fishing period, the Council assesses the biological, social, and economic condition of the groundfish fishery and updated MSY estimates or proxies for specific stocks (management units) where new information on the population dynamics is available. Based upon the best scientific information available, the Council will evaluate the current level of fishing relative to the MSY level for stocks where sufficient data are available and recommend harvest specifications for the subsequent 2-years. The Council recommended harvest specification are published in Federal regulation. The evaluation of the long-term impacts of setting harvest specifications and related management measures for the foreseeable future is intended to encompass the range of likely impacts that could occur over more than just the next biennial management period (2015-16). Section 6.6 discusses the methods that will be use to evaluate unforeseen environmental impacts in future biennial periods (2017-18 and subsequent).

1.2.2 Purpose and Need

The purpose of the proposed action is to conserve and manage groundfish fishery resources to prevent overfishing, to rebuild overfished stocks, to ensure conservation, to facilitate long-term protection of essential fish habitat (EFH), and to realize the full potential of the Nation's fishery resources (MSA §2(a)(6)). These harvest specifications are set consistent with the optimum yield (OY) harvest management framework described in Chapter 4 of the Groundfish FMP.

In addition to the above conservation objective, the use of default HCRs (Amendment 24) coupled with the evaluation of the long-term impacts of the action is needed to streamline the administrative and regulatory processes involved in setting specifications for the Pacific Coast groundfish fishery, while, at the same time, maintaining consistency with the MSA and other applicable law. Evaluating the environmental impacts of setting harvest specifications and apportionment of harvest levels (described in Groundfish FMP Chapter 5) and related fishery regulations (described in Groundfish FMP Section 6.2), as needed, over the long term will make the regulatory process more efficient and provide more information to stakeholders about the future status and management of fisheries. The initial evaluation of the range of impacts expected over the long term will be followed up with focused evaluation when regulations are periodically adjusted. This two tier approach to evaluating harvest specifications should meet the following objectives:

- Maintain or improve the timeliness of scientific input into the decision-making process.
- Articulate and apply adaptive management principles, which are embodied in the Groundfish FMP, when evaluating the effects of periodic changes.

- Build workload assessment and priority setting into the process for identifying and recommending management measures, consistent with administrative resources and conservation objectives.
- Incorporate guidance on preparing efficient and timely NEPA reviews, including tiering of environmental documents and incorporation by reference.[5]
- Include decision-making procedures for setting harvest specifications that allow reasonably accurate forecasts of impacts for a period longer than 2 years. This could involve the Council adopting default procedures for setting harvest specifications (which the Council could override if circumstances warrant).
- Present information to decision-makers and the public in an effective and usable format.
- Ensure a transparent process where decisions and their rationale are clearly explained to the public before Council decisions so that the public has the opportunity to provide meaningful input.
- Build an administrative record that effectively explains the rationale for the decision.

To the degree possible, periodic adjustments to these harvest specifications should involve small changes from the harvest management objectives of the previous period so as to minimize socioeconomic disruption.

Reorganizing stock complexes needs to be considered to ensure that overfishing is not occurring on stocks managed within complexes. This supports the objectives of the MSA described above. Stock complex harvest specifications are set consistent with the harvest management framework described in Chapter 4 of the Groundfish FMP.

1.2.3 Geographic Context

Federally-managed Pacific groundfish fisheries occurring within the EEZ off the coasts of Washington, Oregon, and California (WOC) establish the geographic context for the proposed action. West coast communities engaged in these fisheries are also part of the context (see Figure 1-1). Although this is the Federal fishery management area, the states manage the fisheries in the territorial sea to meet the goals and objectives of the Groundfish FMP.[6]

[5] See the March 6, 2012 Memorandum from Nancy H. Sutley, Chair, Council on Environmental Quality, on this topic.

[6] The impact evaluation focuses on the Federal fishery management area, which is distinct from the action area as defined by the Endangered Species Act and specified in applicable Biological Opinions.

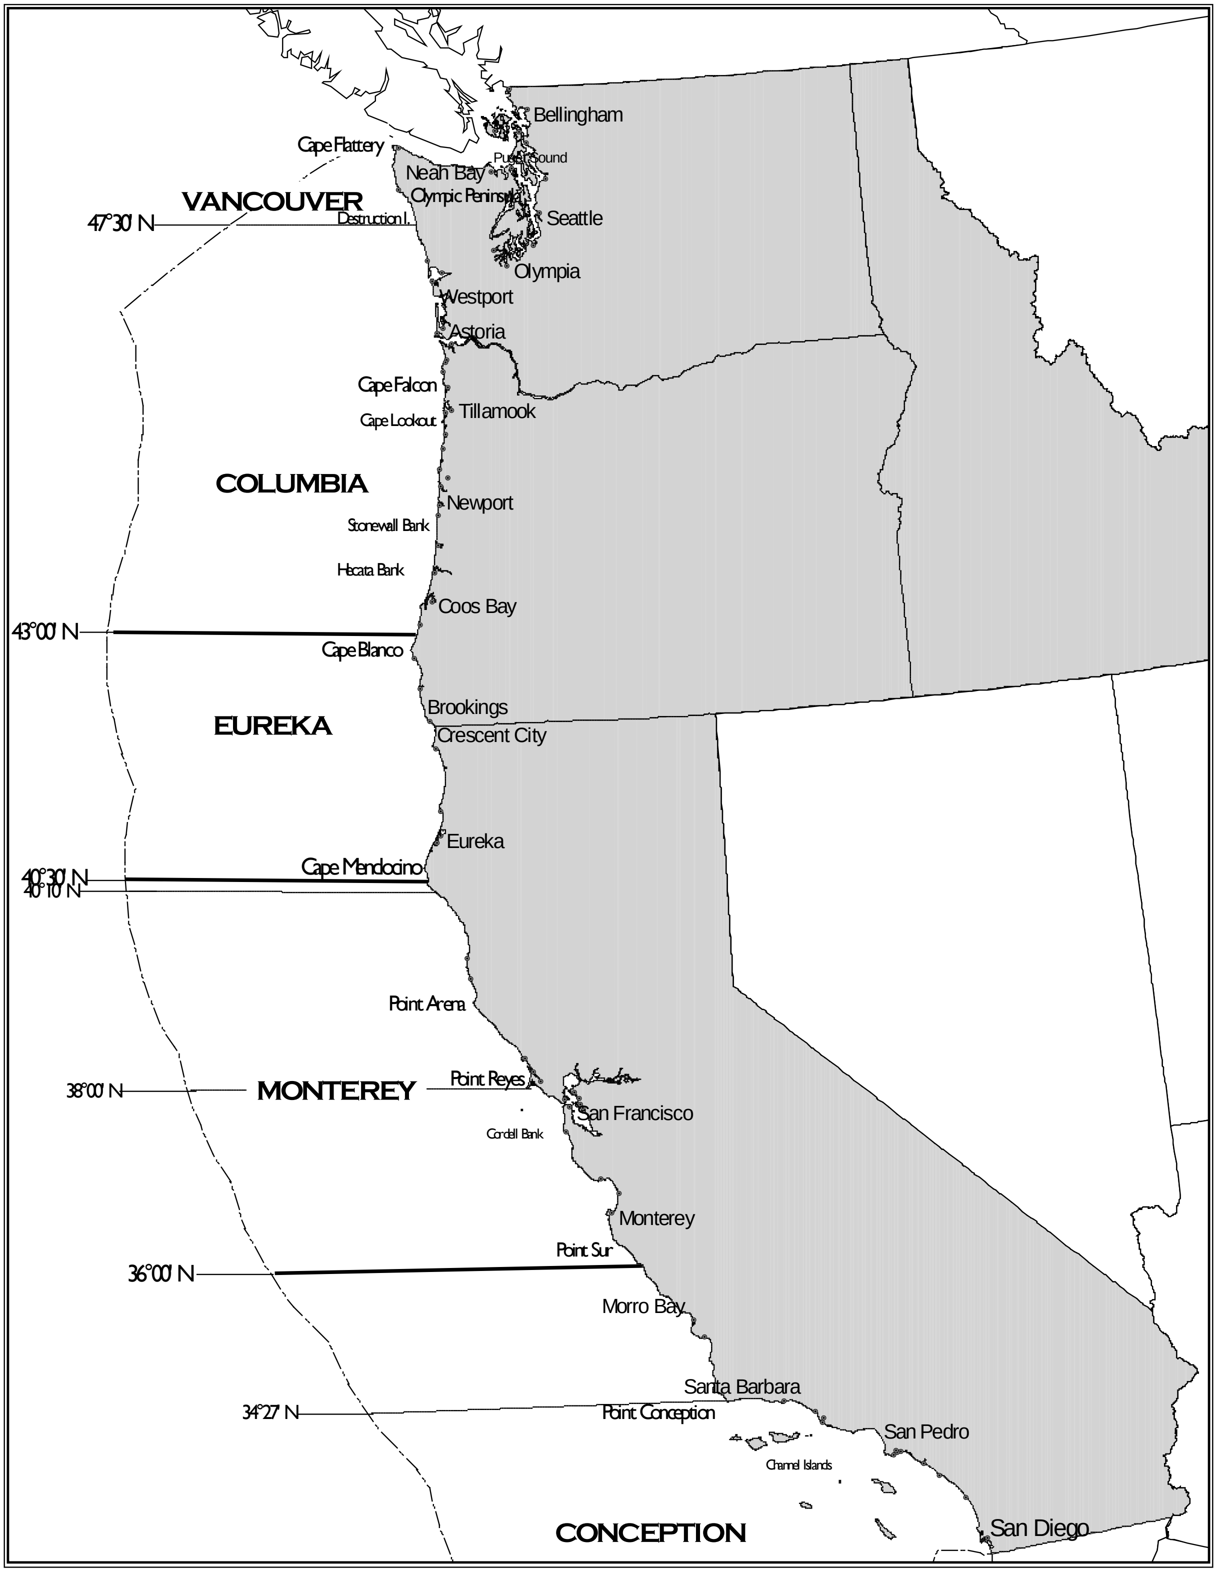

Figure 1-1.The action area, showing major coastal communities and groundfish management areas.

Chapter 2 ALTERNATIVES

The alternatives are based on the proposed actions described in Section 1.2.1:

> Harvest Specifications and Management Measures for the 2015-2016 Biennial Period: Recommending harvest specifications and management measures for the 2015-2016 biennial period, which would be published in Federal regulations and remain effective until changed.
>
> Reorganizing the Other Fish and Slope Rockfish Complexes and Designating Ecosystem Component Species: Changing the composition of the Other Fish and Slope Rockfish stock complexes, creating a new stock complex for some current constituents of the Slope Rockfish complexes, removing stocks from the Other Fish complex for single stock management or designation as EC species, and designating species not already in the FMP as EC species.
>
> Amend the Groundfish FMP to Describe Default Harvest Control Rules and Management Measures Considered during the Biennial Decision Cycle: Default harvest control rule (HCR) framework used to calculate default ACLs. Default ACLs represent a starting point for Council decision-making on catch limits for the next biennial period. Management measures considered during the biennial management and regulatory amendment processes better described

Stock complex reorganization and EC species are considered options nested under the range of alternatives for the biennial and FMP amendment actions. Table 2-1 summarizes the alternatives, which are described in subsequent sections.

Table 2-1. Schematic of the elements of the alternatives.

Element	No Action	Preferred Alternative	Alternative 1	Alternative 2
2015-16 harvest specifications and management measures	Rollover 2014 harvest specifications and management measures	Council preferred harvest specifications; adjust management measures as necessary	Harvest specifications based on p*=0.45; adjust management measures as necessary	Harvest specifications based on p*=0.25; adjust management measures as necessary
	No Action	**The Preferred Option**		**Option 1**
Stock complex reorganization and designation of Ecosystem Component Species	Slope Rockfish and Other Fish complexes not reorganized; EC species not designated	Slope Rockfish complex not reorganized; measures to monitor and manage rougheye and blackspotted rockfish catch implemented; spiny dogfish removed from Other Fish complex and managed; other species removed and designated EC species; some species not already in the FMP added as EC species		Rougheye rockfish (including blackspotted rockfish) and shortraker rockfish removed from the slope rockfish complexes and managed as a new coastwide rougheye-blackspotted-shortraker (RBS) complex
	No Action	**Alternative 1**	**Alternative 2**	**Alternative 3**
Amendment 24 (default HCRs and management measure process)	No Amendment	Default HCR with ABC based on **P*=0.4**5; amend Section 6.2 to clarify "new" vs. "routine" measures	Default HCR with ABC based on **P*=0.25**; amend Section 6.2 to clarify "new" vs. "routine" measures	Default HCR with ABC based on **current P***; amend Section 6.2 to clarify "new" vs. "routine" measures

2.1 Alternatives for the 2015-2016 Biennial Period

The components of the proposed action described above are long-term changes to the biennial decision-making process that will be incorporated into the Groundfish FMP by amendment. The Council must also adopt harvest specifications and management measures for the 2015-2016 biennial period.

This section describes four "integrated" alternatives, including the No Action alternative, that could be implemented to manage groundfish fisheries during the 2015-2016 period. They are integrated in the sense that each alternative includes a suite of harvest specifications and related management measures, thus comprising a complete management program. These measures are described in more detail in Chapter 4, because they are the mechanism by which harvest specifications and other Groundfish FMP policies are implemented. These management measures regulate the behavior of fishery participants, which determines the environmental impacts. In this sense they are part of the impact mechanism connecting the objectives of the action (described in Chapter 1) to the expected effects on the human environment.

These integrated alternatives are described in Sections 2.1.1.1 through 2.1.1.2.

Harvest specifications include ACLs for all stocks and stock complexes managed under the Pacific Coast Groundfish FMP (PFMC and NMFS 2011). Management measures are designed to keep the mortality of these stocks and stock complexes at or below the catch limits. Many Pacific Coast groundfish stocks are caught together in the fishery, and the MSA requires the Council and NMFS to rebuild overfished stocks in a time period "as short as possible, taking into account the status and biology of any overfished stocks of fish, the needs of fishing communities … and the interaction of the overfished stock of fish within the marine ecosystem…" (MSA, sec. 304(e)(4)(A)). Given the nature of the fishery and this mandate, integrated alternatives, which describe the management program (i.e., harvest specifications and management measures), are used for the impact evaluation.

Harvest specifications comprise three metrics applied to all groundfish stocks and stock complexes using the best available scientific information:

- The overfishing limit (OFL), indicating a level of catch mortality above which overfishing is occurring;
- The acceptable biological catch (ABC), a reduction from the OFL to account for scientific uncertainty in estimates, based on Scientific and Statistical Committee (SSC) recommendations; and
- The ACL set at or below the ABC and the basis for managing catch mortality.

Existing management measures include deductions from the ACLs which are used to account for catch in research activities, tribal, recreational, and incidental catch in non-groundfish fisheries; allocation of fishing opportunity to various components or "sectors" of the fishery (long-term formal allocations in the FMP or short-term two-year allocations); and various management measures that may be adjusted through regulatory action (described in detail as part of No Action, see Section 4.2). The Council is also proposing several new accountability measures to improve program performance and fishing opportunity, among other purposes.

The management programs represented by each of the integrated alternatives are assembled in step-wise fashion. The Council and NMFS first decide the harvest specifications and then management measures are proposed to keep total catch mortality within the ACLs specified for each alternative. The analysis of the integrated alternatives provides a better understanding of how the amount of allowable species harvest affects different fisheries and coastal fishing communities.

2.1.1 Harvest Specifications

The harvest specifications alternatives for 2015-16 are constructed to be consistent with the Amendment 24 alternatives described in Section 2.3:

- No Action: 2014 harvest specifications and management measures as of January 1, 2014.
- Preferred: Council-preferred harvest specifications for 2015-16.
- Alternative 1: Where applicable, ACLs determined based on a P* value of 0.45. For ACLs set below to the ABC, the P* value does not necessarily determine the ACL.
- Alternative 2: Where applicable, ACLs determined based on a P* value of 0.25.

Under any of the default HCR frameworks considered for Amendment 24 (described in Alternatives 1-3), the Council has the flexibility to choose ACLs that are different from the defaults for use in the next biennial period, as long as they are consistent with the framework in the Groundfish FMP and the MSA. This framework is described in Chapter 4 of the Groundfish FMP. Groundfish FMP Section 4.4 describes methods for determining the OFL and ABC values according to three categories related to the amount of information available for the stock. Groundfish FMP Sections 4.6 and 4.7 describe adjustments to the ABC to determine the ACL; the annual catch target (ACT), if used; and the application of the optimum yield concept. This includes the 25-5 and 40-10 precautionary reductions and procedures for developing and revising rebuilding plans for overfished species. Procedures for such adjustments vary according to the same three categories described in FMP Section 4.4

2.1.1.1 No Action

Under the No Action alternative, the harvest specifications values in place on January 1, 2014, would remain in effect for the 2015-2016 period (Table 2-2). A detailed description of existing management measures and their associated impacts to groundfish stocks under No Action is presented by fishery in Section 4.2.

2.1.1.2 Preferred Alternative

Table 2-3 contains the preferred 2015 and 2016 harvest specifications. The ACLs for most species are determined based on the ACLs being set equal to the ABCs with a P* value of 0.45. The ACLs for arrowtooth, lingcod south of 40°10 N. lat., longspine thornyhead north and south of 34°27 N. lat., sablefish north and south of 36° N. lat., shortspine thornyhead north and south of 34°27 N. lat., spiny dogfish, and starry flounder would be determined based on the ACLs being set equal to the ABCs with a P* value of 0.40. As described above for Alternative 1, ACLs may be set below the ABC, in which case the P* value does necessarily determine the ACL. The impacts of adjusting and implementing new management measures (described in Section 2.1.2) in response to the harvest specifications under The Preferred Alternative are presented by fishery in Section 4.2.

The preferred alternative changes the ACLs for Dover sole and widow rockfish, from the No Action constant catch strategies of 25,000 mt and 1,500 mt, respectively for the two species to 50,000 mt and 2,000 mt, respectively. An additional ACL alternative of 3,000 mt for widow rockfish is analyzed in Chapter 4.

The status quo slope rockfish complexes north and south of 40º10’ N lat. are preferred; however, unlike status quo, a sorting requirement would be specified for rougheye and blackspotted rockfish. An alternative structure for the slope rockfish complexes where rougheye, blackspotted, and shortraker rockfish are removed from the current complexes and managed in a new coastwide complex is analyzed in this EIS in Chapter 4.

The preferred alternative for the Other Fish complex also differs from No Action. Spiny dogfish is removed from the status quo Other Fish complex and managed with stock-specific harvest specifications. All the skates and Pacific grenadier currently managed under the Other Fish complex, along with all other endemic skates and grenadiers are designated as Ecosystem Component (EC) species. Additionally, spotted ratfish, soupfin shark, and finescale codling are designated as EC species under the preferred alternative. The remaining stocks managed under the preferred Other Fish complex are the California, Oregon, and Washington stocks of kelp greenling; the Washington stock of cabezon; and leopard shark.

Section 2.2 further describes these options.

2.1.1.3 Alternative 1 – Default HCRs use a P* Value of 0.45

Table 2-4 contains the harvest specifications under Alternative 1. Where applicable, ABCs are determined based on a P* value of 0.45, and the ACL is set equal to the ABC. The rightmost column in Table 2-4 shows the ACL harvest control rule for each stock under Alternative 1. For several stocks the ACL is set below the ABC and so the P* value does not necessarily determine the ACL. Instances where the ACL is below the ACL include specification of a fixed or constant catch level, precautionary adjustments using the 40-10 and 25-5 rules, and the use of the harvest rate specified in a rebuilding plan. The impacts of adjusting and implementing new management measures (described in Section 2.1.2) in response to the harvest specifications under Alternative 1 are presented by fishery in Section 4.2.

The No Action ACLs of 25,000 mt and 1,500 mt for Dover sole and widow rockfish, respectively are analyzed under Alternative 1.

The slope rockfish and Other Fish complexes under Alternative 1 are structured the same as under the preferred alternative.

2.1.1.4 Alternative 2 – Default HCRs use a P* Value of 0.25

Table 2-5 contains the harvest specifications under Alternative 2. Where applicable, ACLs are determined based on the ACLs being set equal to the ABCs with a P* value of 0.25. As described above for Alternative 1, ACLs may be set below the ABC, in which case the P* value does necessarily determine the ACL. The impacts of adjusting and implementing new management measures (described in Section 2.1.2) in response to the harvest specifications under Alternative 2 are presented by fishery in Section 4.2.

The No Action ACLs of 25,000 mt and 1,500 mt for Dover sole and widow rockfish, respectively are analyzed under Alternative 2.

The slope rockfish and Other Fish complexes under Alternative 2 are structured the same as under the preferred alternative, but the ACLs are based on setting the contribution ABCs of component stocks based on a P* of 0.25.

Table 2-2. Harvest specifications for stocks and stock complexes for 2015-2016 under No Action. The harvest control rule used to calculate the ACLs are shown in the right column.

Stock*	Area	OFL	ABC	ACL	ACL Harvest Control Rule

2.1.2 Management Measures

Management measures considered as part of the biennial process, fall into three broad categories: adjustments to and allocations of ACLs, adjustments to existing management measures including those designated as routine, and adoption of new management measures. Existing measures include:

- Limited entry permits which restrict the number of vessels that may use specified gear types to catch allocated groundfish. Limited entry permits define the groundfish trawl sector (further subdivided among vessels delivering catch shoreside, catcher vessels delivering Pacific whiting to at-sea mothership processors, and at-sea Pacific whiting catcher-processors) and the limited entry fixed gear sector, which uses longline and pot gear, mainly to catch sablefish.
- Groundfish closed areas, principally Rockfish Conservation Areas (RCAs), imposed to exclude fishing vessels from areas of high bycatch of species of concern, predominantly overfished species. Enforcement of these closed areas is supported by requirements for commercial vessels retaining groundfish to carry a vessel monitoring system (VMS) that transmits their position to enforcement officials.
- Catch control tools including IFQs in the shoreside trawl sector, co-ops and associated allocations in the at-sea whiting sectors, permit and vessel-specific sablefish allocations in the limited entry fixed gear sector (called "tier limits"), and 2-month cumulative landing limits used in all sectors for certain species and/or at certain times of the year. Bycatch in the at-sea whiting fishery is accommodated by set-asides from the trawl allocation. Recreational catch is primarily controlled by time/area closures, bag limits, and size limits.

Several new management measures or adjustments to existing measures, including routine measures, are recommended for implementation in 2015, designed to meet the goals and objectives specified in the FMP. The following section provides an overview of the new measures which are evaluated under all action alternatives. A focused evaluation of the performance and effects of the new management measures and range of options considered can be found in Appendix B. The impacts of adjusting exiting management measures under the action alternatives, including routine measures, can be found in Section 4.2. Section 2.5.7 contains the measures that were considered but rejected for implementation at this time.

2.1.2.1 Modifications to the Boundaries Defining Existing RCAs

RCAs are large area closures intended to protect a complex of species, such as overfished shelf rockfish species. The boundaries for RCAs are defined by straight lines connecting a series of latitude and longitude coordinates that approximate depth contours. A set of coordinates are defined for each depth contour used as a management line and the RCA structures are implemented by gear and/or fishery (e.g., trawl RCA, a non-trawl RCA, and recreational RCAs). Under the action alternatives, changes to selected coordinates are proposed that more closely approximate the boundaries with depth contours based on the best available data. These modifications would maintain the intent of the RCAs by providing improved and more efficient access to target species while minimizing interactions with overfished species.

Changes to the boundaries defining RCAs in Oregon and California are proposed and are designed to better approximate depth which is consistent with the original methodology used to establish the coordinates. Starting on January 1, 2013 new waypoints, designed to better approximate depth, were implemented for the 200 fm line in Oregon. This resulted in some unintended consequences relative to the 200 fm line that is modified to provide greater access to petrale sole (referred to in regulation as the modified 200 fm line). Updated coordinates for the modified 200 fm line are proposed to resolve this problem. In California, adjustments are proposed off Del Mar (six waypoints) and San Diego (two waypoints) to better approximate the actual depth.

2.1.2.2 New Trawl RCAs Boundaries Approximating 300 and 350 fm

Management measures designed to reduce the catch of rougheye/blackspotted rockfish for all commercial sectors are proposed under the action alternatives. A recent rougheye/blackspotted rockfish assessment indicates that the west coast stock is currently 47 percent of the unexploited biomass (above the B_{MSY} proxy of $B_{40\%}$). Harvest rates of rougheye/blackspotted rockfish have been close to or above the F_{MSY} proxy of $F_{50\%}$ for rockfish since the mid-1980s, including four of the last 10 years. The Council recommended analysis of new trawl RCAs boundaries approximating the 300 and 350 fm depth contours as a measure to reduce rougheye/blackspotted rockfish mortality.

2.1.2.3 *A*llow Retention of Lingcod by Fixed Gear Vessels in Periods 1, 2, and 6

Since the 1990s lingcod retention has been prohibited in Periods 1, 2, and 6 for both the limited entry and open access fixed gear sectors to reduce catch of male lingcod during the nest-guarding season. There are no seasonal closures for lingcod for the shorebased IFQ or Oregon recreational fisheries. Under the action alternatives, it is proposed that lingcod retention be allowed during Periods 1, 2, and 6 at a level which would reduce discarding but prevent targeting.

2.1.2.4 Shorebased IFQ Surplus Carry-Over

Current regulations provide for a carry-over provision that allows a limited amount of surplus QP or IBQ pounds in a vessel account to be carried over from one year to the next or allows a deficit in a vessel account in one year to be covered with QP or IBQ pounds from a subsequent year, up to a carry-over limit (50 CFR 660.140(e)(5)). The carry-over provision was designed to increase individual flexibility for harvesters, improve economic efficiency, and achieve optimum yield (OY) while preserving the conservation of stocks. This proposed measure would consider unused amounts that were set-aside for tribal, recreational and incidental catch in non-groundfish fisheries relative to the issuance of carry-over for the trawl IFQ fishery, in the event the trawl allocation for a species has been exceeded, but there is surplus quota eligible for carry-over.

2.1.2.5 Oregon Recreational Fisheries: Canary Rockfish Bag Limit

Canary rockfish is an overfished species managed under a rebuilding plan. For the recreational fisheries, canary retention is prohibited. A sub-bag limit for canary rockfish in Washington, Oregon, and California was analyzed. The preferred alternative is to only allow retention in the Oregon recreational fisheries to minimize discards of canary rockfish and inform the stock assessment, while preventing targeting.

2.1.2.6 Washington and Oregon Recreational - Allow Retention of Bottom Fish during All-Depth Halibut Seasons

Retention of all groundfish, lingcod only, or flatfish only during the Pacific halibut fishery is currently allowed in both the Pacific halibut and groundfish regulations. This management measure would change the retention allowances by area to reduce discards of incidentally caught groundfish during the Pacific halibut fishery.

2.1.2.7 Washington Recreational – Modify or Eliminate Boundaries for Lingcod Closures

Yelloweye rockfish is an overfished species currently managed under a rebuilding plan. In 2012, deep-water lingcod closures were implemented in Washington to reduce encounters with yelloweye rockfish in the South Coast (Marine Catch Area 2) and Columbia River (Marine Catch Area 1) management areas. Under the action alternatives, modifications of the boundary lines are proposed to more effectively reduce encounters with yelloweye and canary rockfish and streamline regulations making them easier for anglers to understand.

2.2 Stock Complex Reorganization and Designation of Ecosystem Component Species

After consideration at the June and September 2013 Council meetings, the Council adopted three options for restructuring the slope rockfish complexes north and south of 40º10' N lat. However, at the March 2014 Council meeting NMFS recommended narrowing analysis to one option. Council deliberations focused on concern with fishing mortality on rougheye rockfish; a new stock assessment (Hicks, *et al.* 2013) indicates that spawning biomass declined relatively steeply in the 1980s and 1990s while cumulative coastwide catch since 2008 has exceeded the rougheye OFL contribution to the slope rockfish complexes.

The Other Fish complex historically contained various non-target species that were often bycatch (not retained, landed, sold, or kept for personal use). Stock complexes composed of species with similar distribution and/or life history characteristics are preferable so that the constituent stocks are similar in terms of vulnerability to overfishing and susceptibility to particular fisheries (by gear type, for example). The ecosystem component (EC) species designation is described in National Standard 1 Guidelines at 50 CFR 600.310(d)(5). EC species should be a non-target stock; not subject to overfishing determined to be overfished, or approaching the overfished threshold or become so in the absence of management measures; and not generally retained for sale or personal use. Because many of the species in the Other Fish complex fit the criteria for designating EC species, it makes sense to reclassify them in this category. EC species are not considered "in the fishery" and ACLs are not set for them.

2.2.1 No Action

Under No Action the Slope Rockfish and Other Fish complexes are not reorganized and no EC species are designated

2.2.2 The Preferred Option

The Preferred Option, maintains the slope rockfish stock complexes as they are currently structured north and south of 40°10' N. lat. Management measures that could control mortality of rougheye rockfish while it remains within the current slope rockfish complexes are described in Section 4.2 and include a sorting requirement for rougheye and blackspotted rockfish in order to more accurately and responsively track catch.

The Council considered but rejected establishing a rougheye and blackspotted fishery harvest guideline, identifying "hotspots" closures where rougheye CPUE is higher, and mandating rockfish excluder devices in midwater trawl nets designed to target Pacific whiting (see Appendix B, Section XXX and Section 2.5).

The Other Fish complex is reorganized. Spiny dogfish is removed from the complex and managed as a separate stock with its own harvest specifications. Several other species are removed from the Other Fish complex and the list of management unit species and designated EC species (see Table 2-6). Additional species not currently in the FMP are designated EC species. The Washington, Oregon and California kelp greenling stocks; the Washington Cabezon stock; and leopard shark remain in the Other Fish complex.

Table 2-6 Groundfish species proposed to be designated as Ecosystem Component species.

Proposed EC Species	Previous Status

Aleutian skate (*Bathyraja aleutica)*	Not previously in the FMP
Bering/sandpaper skate (*B. interrupta)*	Not previously in the FMP
Big skate (*Raja binoculata)*	MUS (Other Fish)
California skate (*R. inornata)*	MUS (Other Fish)
Roughtail/black skate (*Bathyraja trachura)*	Not previously in the FMP
All other skates (Endemic species in the family *Arhynchobatidae)*	Not previously in the FMP
Pacific grenadier (*Coryphaenoides acrolepis)*	MUS (Other Fish)
Giant grenadier (*Albatrossia pectoralis)*	Not previously in the FMP
All other grenadiers (Endemic species in the family *Macrouridae)*	Not previously in the FMP
Finescale codling (aka Pacific flatnose) (*Antimora microlepis)*	MUS (Other Fish)
Ratfish (*Hydrolagus colliei)*	MUS (Other Fish)
Soupfin shark (*Galeorhinus zyopterus)*	MUS (Other Fish)

2.2.3 Option 1

Under this option, rougheye rockfish (including blackspotted rockfish) and shortraker rockfish would be removed from the slope rockfish complexes north and south of 40°10' N lat. and managed as a new coastwide rougheye/blackspotted/shortraker (RBS) complex. An OFL, ABC, and ACL would be established for the proposed RBS complex. These species are for the complex because it is difficult to differentiate them based on appearance alone.

Managing RBS as a new complex would increase the range of potential management measures that could more directly control catch of these species. For example, IFQ specific to the stock could be issued. On the other hand, establishing an ACL for a complex with these species could raise various allocation-related issues.

2.3 Alternatives for Using Default Harvest Control Rules to Compute ACLs (Amendment 24)

An HCR is used to determine the numerical value of an ACL based on a reduction from the overfishing limit (OFL). Chapter 4 in the Groundfish FMP describes the policies and procedures used to establish HCRs and determine the numerical values for harvest specifications (OFLs, ABCs, and ACLs).[7] HCRs include the following elements (although not all elements apply to all stocks):

- Harvest rate (unless a different ACL adjustment is used, see below)
- Reduction from the OFL to the ABC (P*-Sigma adjustment)
- ACL adjustment below the ABC based on overfished species rebuilding plans, fixed reductions from the overfishing limit, constant catch policies, precautionary reduction for stocks where biomass is below B_{MSY}, etc. Table 2-7 summarizes the typical adjustments that are based on stock status

[7] Annual catch targets (ACTs) and harvest guidelines (HGs) are used to identify harvest management objectives but are considered accountability (management) measures rather than specifications.

Table 2-7. Default harvest control rules framework for ACL reduction from ABC applied according to stock status.

Healthy Stocks (Biomass above the MSY proxy)	Precautionary Zone Stocks (Biomass below the MSY proxy but above the overfished threshold)	Overfished Stocks (Biomass below the overfished threshold)
ACL=ABC (no adjustment)	Precautionary reduction[8] from the ABC: • 40-10 for non-flatfish • 25-5 for flatfish	Implement rebuilding plan

The action alternatives for Amendment 24 require amending the Groundfish FMP to describe a "default harvest control rule (HCR) framework" used to determine default ACLs. Under this framework, unless the Council takes explicit action to change a default HCR, the ACL implemented for a stock is based on the default HCR applied to the best scientific information. In the event of a change in stock status, the HCR appropriate for the stock's new status would be applied as shown in Table 2-7. For stocks managed under the Groundfish FMP the most recent stock assessment approved by the Council is usually considered the best scientific information. During the biennial harvest specifications process the November Council meeting usually serves as a cutoff point for introducing new scientific information into the decision-making process.

Under the action alternatives the default HCRs include a specified P* value used to compute default ACLs. Default ACLs are initially computed but the Council can then choose a harvest specification value different from the default value as long as the new value complies with the Groundfish FMP and the MSA, and the rationale for the change is sufficiently documented.

2.3.1 No Action – The Groundfish FMP is Not Amended

Under No Action the FMP is not amended to describe the default HCR framework, to provide a decision framework for determining adequate progress on rebuilding plans, or to establish a process for considering management measures not considered during the biennial process.

For the purpose of analysis, it is assumed that, under no action, management measures and harvest specifications in place on December 31, 2014, would remain in effect for the 2015-2016 period. For the evaluation of the long-term impacts of setting harvest specifications and management measures average catch from the recent past is used to approximate fishing mortality and revenue.

2.3.2 Alternative 1 – Default HCRs Use a P* Value of 0.45

Under this alternative the Groundfish FMP would be amended to describe the HCR framework and better describe the types of management measures considered during the biennial management and regulatory amendment processes.

Default ABCs would be computed using P*=0.45. Default ACLs would be computed based on the HCR currently in place (e.g., ACL=ABC, constant catch, precautionary reduction from the ABC) unless a new

[8] Section 4.6.1 in the Groundfish FMP describes the 40-10 and 25-5 precautionary reductions. These numbers define the linear reduction in the ACL from the ABC in relation to stock depletion. In the case of 40-10 this means that the linear reduction begins when depletion is at 40% and the ACL reaches zero when depletion is at 10% (note however, that a rebuilding plan would be implemented when depletion falls below 25%). Similarly, 25-5 defines a linear reduction starting at 25% depletion and a zero ACL at 5% depletion (likewise superseded by an overfished threshold of 12.5%).

assessment shows that stock biomass has changed such that a different procedure is specified in the FMP and a different HCR applies (see Table 2-7). For example, if stock biomass has fallen below the MSY proxy, the appropriate precautionary adjustment would be applied (e.g., 40-10 or 25-5 rules applied to the ABC) to compute the default ACL or if stock biomass falls below the overfished/rebuilding threshold the interim rebuilding rule would be used to determine the default ACL. Likewise, if an increase in stock biomass changes stock status the procedure for the updated status would be used to compute the default ACL. These changes in how the default ACL is calculated based on the stock's status would not automatically trigger the need for a new NEPA analysis to amend the ACLs in Federal regulations.

2.3.3 Alternative 2 – Default HCRs Use a P* Value of 0.25

Under this alternative the Groundfish FMP is amended to describe the HCR framework, provide a decision framework for determining adequate progress on rebuilding plans, and better describe the types of management measures considered during the biennial management and regulatory amendment processes.

Default ABCs would be computed using P*=0.25. Default ACLs would be computed based on the HCR currently in place (e.g., ACL=ABC, constant catch, precautionary reduction from the ABC). Like Alternative 1, a change in stock status would trigger a change in the default ACL.

2.3.4 Alternative 3 (Preliminary Preferred Alternative) – Use the HCRs in Place in the Previous Period as the Defaults

Under this alternative the Groundfish FMP is amended to describe the HCR framework, provide a decision framework for determining adequate progress on rebuilding plans, and better describe the types of management measures considered during the biennial management and regulatory amendment processes.

Default ABCs would be computed using the current P*. Default ACLs would be computed based on the HCR currently in place (e.g., ACL=ABC, constant catch, precautionary reduction from the ABC). Like Alternative 1, a change in stock status would trigger a change in the default ACL.

The Council chose preferred harvest specifications for the 2015-2016 period at its April 2014 meeting. This is the final preferred alternative so the HCRs used to determine 2015-16 harvest specifications would be the default HCRs for the next (2017-2018) biennial period. In addition, these harvest specifications are used as the defaults to analyze this alternative.

2.4 Management Measures Considered During the Biennial Decision Cycle (Amendment 24)

Section 6.2 in the Groundfish FMP describes the process for establishing and adjusting management measures. New management measures may be adopted during the biennial specifications process and may also be classified as routine measures. Routine management measures are those that the Council determines are likely to be adjusted on an annual or more frequent basis to effectively achieve the intended purpose. Routine management measures may be adjusted as part of the biennial decision-making process and "inseason" during any biennial management period.

There is an important procedural difference between new management measures and those that have already been classified as routine. All measures are "new" when first proposed. The need, impacts, and rationale for a new measure must be analyzed before it can be classified as routine. Once classified as routine, it is assumed that the effects of subsequent adjustments have been largely evaluated so the threshold for needing additional analysis when adjustments are made is set higher.

Evaluating the impacts of new management measures can add substantially to the overall workload associated with the biennial harvest specifications process. One way to streamline the harvest specification process would be to prioritize new management measures that the Council deems necessary for the next biennial cycle and those for which analysis and Council consideration could be deferred to a separate process. As part of this prioritization process the Council would consider whether the measure is necessary to meet conservation objectives for the next biennial cycle or these objectives can be achieved by adjusting routine measures. Section 6.2 in the Groundfish FMP describes the regulatory amendment process, which is a two-meeting process that can occur at any time according to Council discretion. A regulatory amendment process could occur periodically according to an agreed schedule outside those Council meetings devoted to the biennial process. After completing the biennial process, the Council could prioritize management measures proposed, but not taken up, during the biennial process for consideration under the upcoming regulatory amendment process.

Under Amendment 24 Section 6.2 in the FMP would be amended to better describe processes. In addition, the Council adopted Council Operation Procedure 9, better describing the biennial process.

2.5 Alternatives Considered but Rejected from Further Analysis

2.5.1 Revising Rebuilding Plans (Amendment 24)

Groundfish FMP section 4.6.3.4 describes guidelines for revising rebuilding plans in response to new information about progress towards rebuilding. Consideration was given to revising this section to describe more specific decision rules based on based an overfished species management strategy evaluation (MSE) being developed by Dr. Andre Punt, University of Washington and Council SSC. This MSE tool is not yet complete; it is anticipated that results may be available to address the question of decision rules during a future biennial management cycle.

2.5.2 P* Values Outside of the 0.25 – 0.45 Range

P* values greater than 0.45 are not sanctioned under the FMP, so ABCs based on P* values greater than 0.45 are not analyzed in this EIS. The Council also formally adopted Alternative 2 for analysis in this EIS, which contemplates setting all 2015 and 2016 ABCs using a P* value of 0.25. Lower P* values were not considered in the analysis.

2.5.3 Reorganizing Nearshore Rockfish Stock Complexes

The Council initially considered alternative structures for the nearshore rockfish complexes north and south of 40º10’ N lat., but rejected any alternatives to the status quo complexes because it was judged the status quo nearshore rockfish complexes were comprised of species with similar life histories and distributions, and were managed under relatively conservative state nearshore FMPs and/or management strategies.

2.5.4 Reorganizing the Shelf Rockfish Stock Complexes

The Council initially considered alternative structures for the shelf rockfish complexes north and south of 40º10’ N lat., but rejected any alternatives to the status quo complexes because it was judged there was no compelling need to restructure these complexes given the stocks are currently well protected from overfishing by the current RCA configurations.

2.5.5 Additional Alternatives for Reorganizing the Slope Rockfish Stock Complexes

The Council initially considered additional alternative structures for the slope rockfish complexes north and south of 40º10' N lat., but rejected these additional alternatives to the status quo complexes because it was judged this would cause an unnecessary delay in completing the analyses in this EIS and risked delaying implementation of new regulations beyond January 1, 2015. The additional alternatives rejected from detailed analysis are documented in Agenda Item C.8.a, Attachment 1 in the April 2014 Council briefing book.

2.5.6 Reorganizing the Other Flatfish Stock Complexes

The Council initially considered alternative structures for the Other Flatfish complex, but rejected any alternatives to the status quo complex because it was judged the status quo Other Flatfish complex was comprised of species with similar life histories, distributions, and vulnerabilities to potential overfishing.

2.5.7 Various New Management Measures

Several new management measures were considered by the Council but rejected for implementation in the 2015-2016 regulatory package. Some measures were rejected all together while others were forwarded for consideration in the off-year management measures process. Descriptions of the management measures are provided below and detailed analysis can be found in Appendix B.

New Groundfish Conservation Areas (GCAs)

Management measures designed to reduce the catch of rougheye/blackspotted rockfish for all commercial sectors are proposed under the action alternatives. A recent rougheye/blackspotted rockfish assessment indicates that the west coast stock is currently 47 percent of the unexploited biomass (above the B_{MSY} proxy of B40%). Harvest rates of rougheye/blackspotted have been close to or above the F_{MSY} proxy of $F_{50\%}$ for rockfish since the mid-1980s, including four of the last 10 years. The Council initially considered establishing new Groundfish Conservation Areas (GCAs) to reduce mortality of rougheye/blackspotted rockfish for one or more commercial sectors if other existing management measures prove ineffective. The Council's Scientific and Statistical Committee (SSC) reviewed the initial analysis of a rougheye/blackspotted rockfish GCA, contained in Appendix B, and made several recommendations for improving the methodology before it is used in management. The Council considered the draft analysis but rejected it for implementation in the 2015-2016 regulatory package since the methodological changes could not be accomplished in a timely manner. The Council is scheduled to further consider development of GCAs for rougheye/blackspotted rockfish in the off-year management measures process.

Similarly, under the action alternatives, spiny dogfish is proposed to be removed from the Other Fish complex and managed with stock-specific harvest specifications. GCAs were initially considered to reduce mortality of spiny dogfish for one or more fishing sectors if other existing management measures prove ineffective. The Council considered but rejected implementation of spiny dogfish GCAs given the results of an analysis that indicates a very low probability of exceeding the proposed spiny dogfish ACL (see Appendix B). That is, the Council believes the existing management measures should be sufficient to keep spiny dogfish catch within the proposed ACLs and thus rejected further consideration of spiny dogfish GCAs.

Modify or Remove Commercial Gear Restrictions when Targeting Flatfish in Selected Groundfish Conservation Areas

In California, commercial vessels using a specific gear configuration designed to target flatfish species are authorized to fish in several GCAs, including the non-trawl RCA, Cowcod Conservation Area, Farallon Islands, and Cordell Banks. The Council considered the draft analysis of these measures but rejected them for implementation in the 2015-2016 regulatory package, given several complex issues that could not be resolved in a timely manner. The Council is scheduled to consider these measures in the off-year management measures process.

Rockfish Excluder for Trawl Vessels Targeting Pacific Whiting

As noted previously, the Council is exploring management measures designed to reduce the catch of rougheye/blackspotted rockfish for all commercial sectors. Initially, the Council considered requiring excluder devices to reduce the catch of rougheye rockfish in whiting fisheries (i.e., Pacific whiting IFQ trips, catcher processor, and mothership trawl sectors). While some research on rockfish excluders in the west coast Pacific whiting fisheries has been conducted, additional work is needed to resolve performance issues (e.g., clogging when Pacific whiting catch rates are high) and to explore the efficacy of the excluder on a broader range of vessel lengths (e.g., catcher-processers). Further, additional time is needed to conduct an appropriate impact analysis, including estimated costs to purchase an excluder if the regulation was implemented. The Council considered the draft analysis of this measure but rejected it for implementation in the 2015-2016 regulatory package, given several complex issues that could not be resolved in a timely manner.

Washington and Oregon Recreational: Implement a 50 Fathom Management Line

Depth restrictions are commonly used in the Washington and Oregon recreational fisheries to reduce mortality of overfished species while providing access to target species. Initially the proposed measure analyzed implementing the necessary coordinates for establishing a 50 fm management line in Oregon. After further consideration, the Council recommended such consideration for Washington as well. The Council considered but rejected implementing the 50 fm management line in the 2015-2016 regulatory package, given complexities in the analysis which could not be resolved in a timely manner. The Council is scheduled to consider these measures in the off-year management measures process.

Harvest Guidelines for China Rockfish North of 40º10’ N lat.

The Council initially considered an analysis of state-specific or regional harvest guidelines (HGs) of China rockfish north of 40º10’ N lat. given its status in the precautionary zone. The Council rejected a detailed analysis of HGs for China rockfish north of 40º10’ N lat. The HGs were so low they would have caused a significant disruption of nearshore groundfish fisheries. The lack of confidence in the data-moderate assessment results for China rockfish compelled the Council to prioritize a full assessment or a more thorough data-moderate assessment) of China rockfish next year before considering the necessity of a more conservative management strategy for this stock.

Chapter 3 AFFECTED ENVIRONMENT

NMFS and Council staff scoped the range of environmental components that could be significantly affected by the proposed actions. This chapter describes the affected environment in terms of these components. The affected environment reflects conditions as they exist before the proposed actions are implemented and provides a baseline for considering effects. This chapter is organized into the following sections:

Section 3.1: Groundfish
Section 3.2: The socioeconomic environment
Section 3.3: The California Current Ecosystem
Section 3.4: Essential fish habitat
Section 3.5: Protected species
Section 3.6: Non-groundfish

3.1 Groundfish

Section 3.1 in the Groundfish FMP enumerates the management unit species. All species in the family *Scorpaenidae* occurring in state and Federal waters off of Washington, Oregon, and California are considered part of the management unit. The systematics of this family is not completely settled and there are known to be cryptic species, so it is assumed that more than the 89 species listed in Section 3.1 of the FMP comprise the management unit. Informally, species are grouped morphologically as roundfish (6 species), rockfish (62 species enumerated but likely more in the management unit), and flatfish (12 species). There are nine other species outside these categories, including sharks, rays, ratfish, and morids. However, under the proposed action most of these species would be designated Ecosystem Component (EC) species, which are monitored as bycatch but do not require harvest specifications. Of these nine, only leopard shark, longnose skate, and spiny dogfish would remain managed species ("in the fishery") under the proposed action.

The species managed under the FMP are distributed throughout the EEZ and occupy diverse habitats at all stages in their life history.[9] In addition, many of the stocks have geographic ranges that extend beyond the U.S. EEZ into Canadian or Mexican waters. The life history traits of the groundfish species have important implications on stock assessment and how the stocks are managed. This is because fishing changes population abundance of the target species, as well as affects life-history traits and population dynamics and may also affect yield.

---

[9] For management purposes species occurrence and habitat are identified at a gross level according to latitudinal and depth boundaries. Nearshore and continental shelf and slope zones define depth-habitat regions (with the latter two commonly referred to as the shelf and the slope). Important latitudinal biogeographic boundaries incorporated into management include Point Conception (34°27' N. lat.) and Cape Mendocino including the undersea Cape Mendocino Ridge (for management, a line just south of the Cape at 40°10' N. lat. is a primary boundary).

Rockfish vary greatly in their morphological and behavioral traits, with some species being semi-pelagic and found in mid-water schools, and others leading solitary, sedentary, bottom-dwelling lives. Rockfish inhabit a wide range of depths, from nearshore kelp forests and rock outcrops to varied deepwater (greater than 150 fm) habitats on the continental slope. Despite the range of behaviors and habitats, most rockfish share general life history characteristics, which include slow growth rates, bearing live young, and large but infrequent recruitment events. These life history characteristics contribute to relatively low average productivity that may reduce their ability to withstand heavy exploitation, especially during periods of unfavorable environmental conditions.

Roundfish managed under the FMP include lingcod, cabezon, kelp greenling Pacific cod, sablefish, and Pacific whiting. In general, the species referred to as roundfish are faster growing with shorter life spans then many of the rockfish, and have external fertilization with some species having large and highly variable recruitment events.

Cabezon and kelp greenling are found in nearshore habitats and are targets in recreational and nearshore commercial fisheries. Lingcod occur coastwide in rocky shelf and nearshore habitats. They too are popular targets in recreational and commercial hook-and-line fisheries.

Sablefish is the most commercially valuable groundfish species, and they occur in deeper waters, being most abundant between 200 and 1,000 m, and found as deep as 3,000 m. Adult sablefish commonly occur over sand and mud in deep marine waters, but have also been found over hard-packed mud and clay bottoms in the vicinity of submarine canyons.

The coastal stock of Pacific whiting is semi-pelagic and is the most abundant single-species groundfish population in the California Current system, making it both commercially and ecologically important. The stock is characterized by highly variable recruitment patterns and a relatively short lifespan.

Flatfish (order *Pleuronectiformes*) are so called because they have asymmetrical skulls with both eyes on the same side of the head. Of the 12 flatfish species in the FMP arrowtooth flounder, Dover sole, English sole, petrale sole, and starry flounder stocks have been assessed and are managed to stock-specific ACLs while the remaining, unassessed species (butter sole, curlfin sole, flathead sole, Pacific sanddab, rex sole, rock sole, and sand sole) are managed within the Other Flatfish complex. Most of the flatfish species are distributed coastwide in waters of the continental shelf with the exception of arrowtooth flounder, butter sole, and flathead sole, which are found on the continental shelf in waters north of central California. Starry flounder, Pacific sanddab, butter sole, curlfin sole, sand sole, and rock sole are primarily found in more nearshore areas while Dover sole, flathead sole, and petrale sole are found in deeper waters. The remaining species show more variation in depth distribution. Many flatfish species migrate seasonally from shallow water summer feeding grounds on the continental shelf to deep water spawning grounds over the continental slope . Though there are variations between species, most of the flatfishes are found on soft bottom such as sand or sandy gravel substrates and mud; however, some are found in eelgrass habitats and, in the case of arrowtooth flounder, occasionally over low-relief rock-sponge bottoms .

For each groundfish species, detailed information on habitat utilization patterns, fisheries that harvest the species, geographic range, migrations and movements, reproduction, growth and development, and trophic interactions are fully described in Appendix B2 to the final EIS titled "The Pacific Coast Groundfish Fishery Management Plan, EFH Designation and Minimization of Adverse Impacts.

The 2014 Stock Assessment and Fishery Evaluation (SAFE) document (PFMC 2014), available on the Council website at www.pcouncil.org, describes distribution and life history, stock status and management history, stock productivity, and fishing mortality attributes of each assessed stock in detail.

The SAFE also describes of stock assessment methods employed and the harvest specification framework including methods used to determine these specifications.

3.2 Socioeconomic Environment

Section 3.2 in the 2013-14 Groundfish Harvest Specifications FEIS (as well as EISs for earlier biennial periods) describes commercial fisheries targeting groundfish and characterizes west coast fishing communities with respect to groundfish fisheries. That information is a useful resource upon which the current description is based. The 2014 Groundfish SAFE document contains a series of tables summarizing landings and ex-vessel revenue in groundfish fisheries, landings and revenue by port, and indicators of fishery participation. These data may be summarized here to highlight current fishery trends. Both long-term historical landings, revenue, and price data (the full PacFIN database time series) and a recent a 10-year baseline period of 2003-2012 are used to characterize fisheries and communities.

3.2.1 Revenue Trends for Commercially Important Groundfish

Although more than 90 species are managed under the Groundfish FMP, the ten highest ranked species (or species groups[10]) accounted for 92% of nominal shoreside ex-vessel revenue during the baseline period, as seen in Figure 3-1. (The revenues used to produce the figure do not include Pacific whiting processed at-sea; if included, whiting would represent a larger share. These at-sea fisheries are described below.) Furthermore, just five species—sablefish, Pacific whiting, Dover sole, petrale sole, and shortspine thornyhead accounted for 84% of all revenue. For that reason, when considering commercial fisheries, the socioeconomic evaluation in this EIS will focus on these relatively few species and the major rockfish species groups (managed as stock complexes). There are other groundfish species that have greater value in recreational fisheries and are discussed below in section 3.2.5. Furthermore, other species may have greater economic importance within particular groundfish fisheries. In the summaries of trends in these fisheries, or "sectors," below, these species with greater economic importance are highlighted.

Figure 3-2, Table 3-1, and Figure 3-3 provide an overview of ex-vessel revenue trends for these economically important species. Figure 3-2 shows the trend in inflation-adjusted revenue for all groundfish landings (including at-sea whiting) in terms of the deviation from the long-term mean (the shoreside data series goes back to 1981 while the at-sea series begins in 1997).[11] The panels in Figure 3-3 present trends in the same way for each of the 10 highest revenue earning species referenced above. Table 3-1 shows the long-term (1981-2012) and recent past (2003-2012) values for landings, revenue, and price-per-pound, and the ratio of recent past values and long-term values.

As seen in Table 3-1, the long-term trend in shoreside groundfish revenue shows a sharp decline in the 1990s into the early 2000s, principally in reaction to management measures imposed when several groundfish were declared overfished and put under rebuilding plans. The 2003-2012 baseline period represents an increasing trend from the low point (shown in terms of the deviation from the mean in Figure 3-2) in 2002. Average annual landings for all shoreside groundfish were about the same in the recent past (2003-2012) compared to the long-term, while the average revenue ratio is 77% due to declines in average price-per-pound (Table 3-1). Examining changes by groundfish species and groups shows a mix of trends. Perhaps the most notable long-term trend is the increasing importance of sablefish and Pacific whiting relative to total shoreside groundfish revenue. For example, in 1981 sablefish accounted for just 12% of shoreside revenue while in 2012 the share was 38%. The domestic Pacific

[10] Rockfish species comprising these groups may be found in [reference docs with PacFIN info].

[11] Shoreside data was obtained from the PacFIN vdrfd table while at-sea data compes from the npac4900_spcomp table.

whiting fishery did not develop until the early 1990s; in 1992 shoreside whiting had an 8% share, in 2012 it was 38%. (As noted above, this does not include at-sea whiting revenues, which are recorded in a different database. Adding revenues from those fisheries would boost whiting's relative importance.) Other species, particularly rockfish, have substantially declined as a share of revenue. In total these species have fallen from a 48% share of revenue in 1981 to an 8% share in 2012 (PFMC 2014, Table 2b).

Looking more closely at Table 3-1, four species show increases in revenue comparing the recent past to the long term: sablefish, Pacific whiting, nearshore rockfish, and black rockfish. Except for Pacific whiting, no species shows an increase in average annual landings, so revenue increases are driven by changes in price per pound. Revenues from sablefish show a spike in 2011. Japan is an important market for west coast sablefish; because the 2011 earthquake and tsunami disrupted Japanese domestic fisheries, increased demand for west coast product drove prices higher. Over the long-term (see the panel for sablefish in Figure 3-3) sablefish revenue has been somewhat volatile but an increasing trend since 2002 is apparent even without the 2011 revenue spike.

Table 3-2 shows the coefficient of variation (CV) for inflation-adjusted, annual ex-vessel revenue over the long-term (1981-2012) and the baseline period (2003-2012) for the highest revenue species and species groups. The coefficient of variation is simply the standard deviation divided by the mean and provides an indicator of inter-annual volatility in revenues. The right hand column shows the ratio of the baseline period CV to the long-term CV. Taken together, these metrics allow comparison among species and species groups of any trends in volatility. Because the CV values are usually smaller for the baseline period, these values may be more useful for comparisons between species rather than over time within a species. However, the ratio values present a relative measure of magnitude. A ratio close to one indicates about the same level of variation in the short term (baseline) as in the long term; values less than one suggest less variation in the short term compared to the long term. Only one species, petrale sole, has a ratio greater than one. This may be due to the sharp decline in catches beginning in 2011. Comparing these values to the panels in Figure 3-3 suggests that some of the high CV values (otherwise interpreted as instances of "volatility") are more likely driven by long-term declines in catch. Dover sole offers a good example of a long-term decline that has flattened during the baseline period, resulting in a relatively high CV value for the long term but a relatively low value in the short term.

3.2.2 Revenue Trends in Commercial Groundfish Fishery Sectors

Fishery managers frequently view groundfish fisheries in terms of fishery "sectors."[12] These sectors are defined by the permit status of participating vessels, gear type, target species, and various other historical factors. The Council allocates fishing opportunity (or the amount of fish vessels in a particular sector may harvest) either as part of the biennial process or through rules that have been established in the Groundfish FMP. Fishery sectors may receive a fixed allocation of the ACL for particular management units (stocks, geographic subdivisions of stocks, and stock complexes); in other cases fishery managers may identify a catch amount as a management objective (e.g., a harvest guideline, "HG") or simply as an accounting mechanism to prevent ACLs from being exceeded. Section 4.2 describes the allocation schemes under consideration as part of the proposed action.

The characterization of commercial groundfish fisheries here is presented in terms of the following fishery sectors:

- **Pacific whiting trawl** is composed of at-sea and shoreside fisheries (which is a segment of the IFQ fishery, described below). The at-sea sector is subdivided between mothership processing vessels accepting fish from catcher boats and catcher-processor vessels. The shoreside fishery deliverers to processing plants on land with Westport and Ilwaco, Washington, and Astoria, Oregon, being the principal ports for shoreside landings.
- **Non-whiting trawl/shorebased IFQ** catches a variety of other species, although sablefish and some flatfish are the main revenue earners. Beginning in 2011 this fishery has been managed under an individual fishing quota (IFQ) program. This fishery is now usually referred to as "shorebased IFQ," because an important feature of this management program is a relaxation on allowed gear types used by these permitted vessels. As a result, landings of sablefish by gear types other than trawl have emerged as an important part of the revenue earned by permitted vessels in this sector. In addition, midwater trawl is being used to target non-whiting species.
- **Fixed gear (longline and pot) fisheries** are divided between "limited entry" and "open access" from a regulatory standpoint, but fishery managers more commonly characterize the "non

[12] Data presented in this section use sector definitions included in the PacFIN vdrfd table. The coding is based on data available within the database including gear type, species composition of landings, and Federal permit status. Global criteria for these sectors are landings from within the Pacific Council management area landed in west coast ports. Relatively small amounts of groundfish coming from other areas, such as Puget Sound, Canada or Alaska, but landed in a west coast port are thus not included in the landings figures for these sectors.

nearshore" sector—primarily targeting sablefish—and a "nearshore" sector targeting various nearshore groundfish species.

- A variety of other sectors have been characterized for the purpose of management and data presentation, but in aggregate they account for a very small proportion of landings and revenue.

Figure 3-4 shows the share of landings (top panel) and inflation-adjusted ex-vessel revenue (bottom panel) by groundfish fishery sector for the 2003-2012 baseline period. Pacific whiting fisheries dominate in terms of landings, accounting for 88% of the total. However, because whiting fetches a low price per pound, those sectors accounted for only 39% of inflation-adjusted ex-vessel revenue. Shorebased IFQ accounts for the next largest share of landings and revenue, 10% and 34% respectively. Fixed gear landings fetch a relatively higher price so while those sectors accounted for only a little more than 2% of landings, they garnered a quarter of groundfish revenue, primarily in the non nearshore sector that targets sablefish.[13]

Figure 3-5 shows revenue trends for groundfish sectors over the baseline period. Revenues have been more stable for non-whiting sectors compared to whiting. One way of assessing variability is the coefficient of variation (the standard deviation divided by the mean). The values for the sectors (over the baseline period) shown in the figure are as follows: non-whiting trawl (including non-trawl IFQ in 2011-2012): 0.131; shoreside whiting trawl: 0.584; non nearshore fixed gear: 0.269; nearshore fixed gear 0.074; at-sea catcher-processors: 0.503; at-sea mothership catcher vessels: 0.551.

[13] The dahl_sector column in the PacFIN vdrfd table is used to categorize landings and revenue by groundfish fishery sectors.

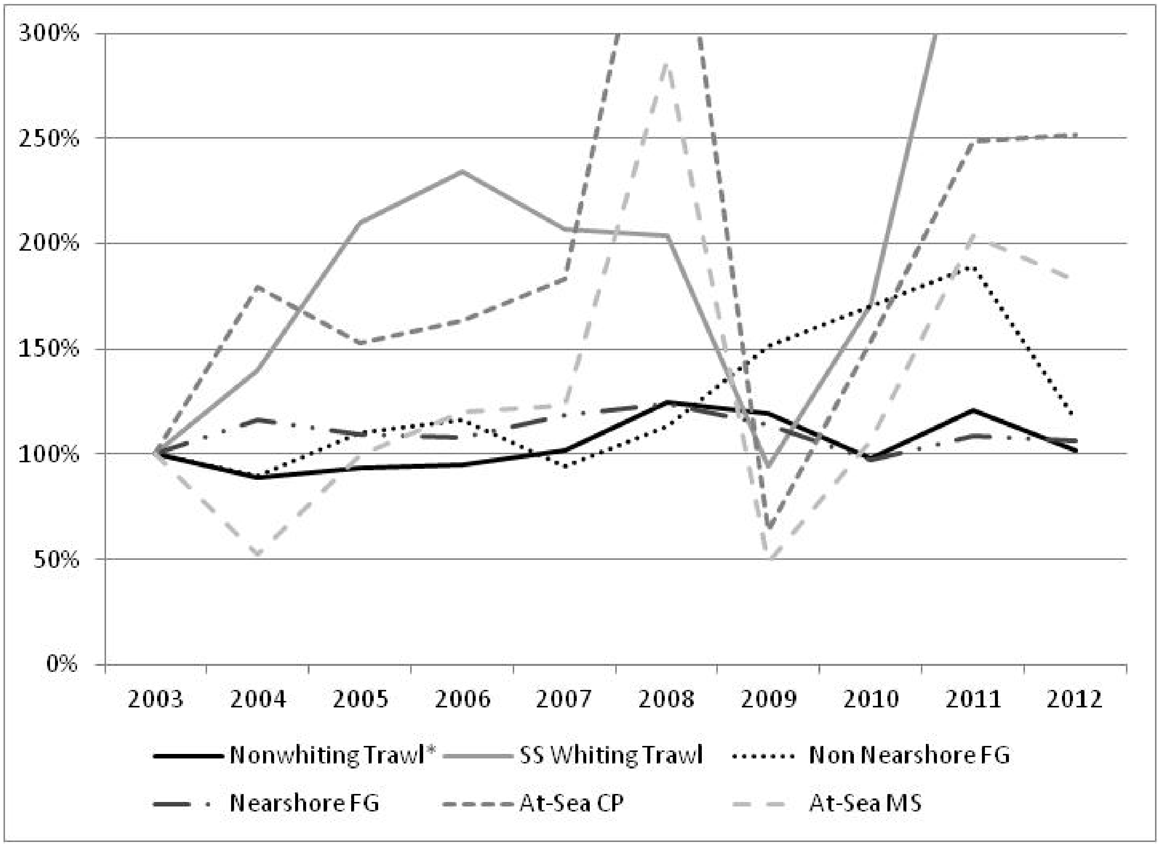

Figure 3-5. Ex-vessel revenue trends (inflation adjusted, 2012, from groundfish only) for groundfish fishery sectors, 2003-2013; 2003=100. *Non-whiting trawl includes non-trawl IFQ in 2011-2012. Value outside figure scale (>300%): 2008 at-sea CP whiting 408%, 2011 shoreside whiting 342%. (Source: PFMC 2014 Tables 12b and 14b).

3.2.2.1 Pacific Whiting Fisheries

As mentioned above, the Pacific whiting fishery is further subdivided into three sectors, two of which operate with at-sea processing operations and the other with trawl vessels delivering to shoreside processing plants.[14] The allocation of Pacific whiting among these sectors (after deductions from the ACL for tribal fisheries and other activities) is specified in the Groundfish FMP: 42% to shoreside catcher vessels, 34% to the catcher-processors, and 24% to mothership catcher vessels. Figure 3-6 shows the share of revenue among these sectors during the baseline period. There is a 4% difference between the allocation shares and revenue for catcher-processors and shoreside catcher vessels, indicating that catcher-processor vessels have on average commanded a higher price for whiting deliveries or else harvested relatively more of their allocation. However, catcher-processor whiting prices are imputed since there is no actual sale from catcher to processor in these integrated operations. Therefore, the revenue differences could be at least partly an artifact of this imputation.

[14] The at-sea sectors are distinguished by their operational characteristics. Because the shoreside segment of the Pacific whiting fishery includes vessels that participate in other trawl fisheries, a catch-based definition is used: trips where the landing is composed of at least 50% whiting are classified as part of the shoreside whiting fishery.

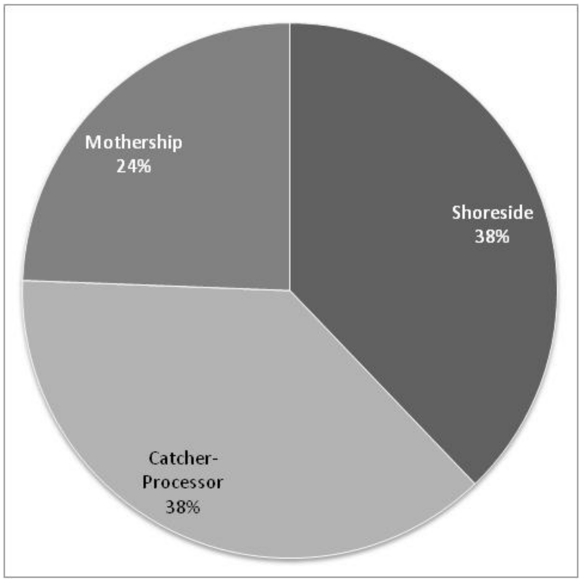

Figure 3-6. Share of inflation-adjusted (2012) ex-vessel revenue for unprocessed Pacific whiting by fishery sector, 2003-2012.

As noted above, whiting catch and revenue can be quite variable from year to year, mainly due to the underlying variation in stock productivity. The long-term trend is shown in Figure 3-3; Figure 3-7 shows revenue by whiting sector during the baseline period against the left vertical axis and annual catch limits (in metric tons) against the right vertical axis. This depiction shows that variation in catch limits has a major influence on revenue, which has been somewhat mitigated by increasing real prices for whiting. The average inflation-adjusted price per pound for shoreside deliveries was $0.06 in 2009 and $0.14 in 2012, which likely explains why the decline in revenues in 2012 was not as steep as in 2009 even though the catch limit in 2012 was below the average for the baseline period.

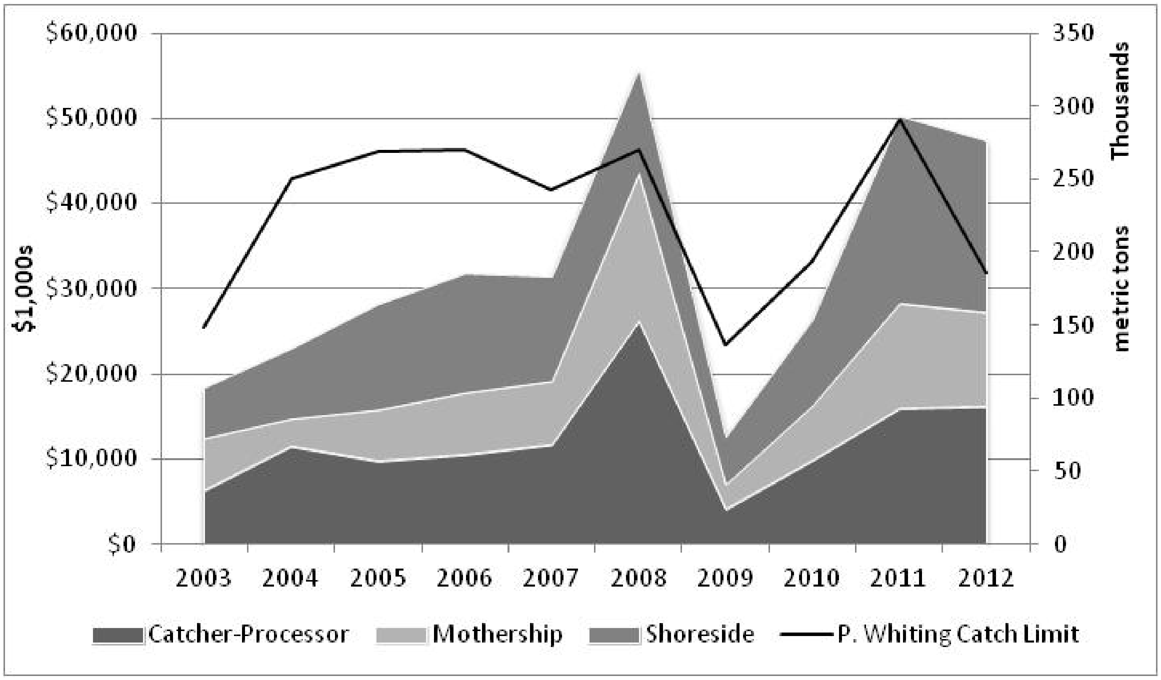

Figure 3-7. Inflation adjusted ex-vessel revenue by sectors ($1,000s, left vertical axis) and catch limits (metric tons 1,000s, right vertical axis) for Pacific whiting, 2003-2012. (Source: PFMC 2014, Table 14b) and various groundfish harvest specifications EISs.

3.2.2.2 Shoreside Non-whiting Trawl/IFQ Fishery

As discussed above, management of the shoreside non-whiting trawl fishery changed substantially in 2011 with the implementation of the IFQ program. Although quota share trading was delayed until 2014 (partly a program feature and later extended due to litigation), trading in quota pounds—the annual allocation of "fishing opportunity"—was permitted from the outset. This allows individual harvesters to adjust their "IFQ portfolios" to better match the actual fishing strategies they wish to pursue, at least in the short term.

Table 3-3 compares ex-vessel revenue by species for the shoreside non-whiting trawl fishery prior to 2011 and the two segments of the IFQ fishery (trawl and non-trawl) that trawl permit holders have pursued in 2011 and 2012. The trawl segment has retained a similar pattern of landings, with revenue for the fishery as a whole dominated by sablefish, Dover sole, petrale sole, and thornyheads. Use of these categories to some extent masks specialist strategies that harvesters may pursue such as winter fishing on the continental slope for Dover sole, thornyheads, and sablefish, and fishing in shallower depths for various flatfish and sablefish during summer months. The trawl segment pursues a more diverse set of strategies compared to the non-trawl segment, which targets sablefish almost exclusively.

Table 3-4 compares the two segments with respect to the top-earning species, sablefish, for the period 2009-2012, which brackets implementation of the shorebased IFQ program. As discussed above, 2011 was anomalous because of the historically high prices sablefish fetched. Perhaps partly due to this, in the latter two years the non-trawl segment has garnered 40% of the ex-vessel revenue from sablefish even though they represent only about a third of the vessels in the fishery (see Table 3-5). Another feature of the shorebased IFQ fishery highlighted by Table 3-5 is the specialization by gear type; only 4-5% of the participating vessels used both trawl and non-trawl in either 2011 or 2012.

Table 3-3. Average annual ex-vessel revenue (inflation adjusted $1,000s, 2012, and percent of total revenue from groundfish landings) for the shoreside non-whiting trawl fishery (2003-2010, 2011-2012) and IFQ non-trawl fishery (2011-2012). (For the non-trawl fishery Other Groundfish includes thornyheads.) (Source: PFMC 2014, Tables 4b and 5b).

	Trawl 2003-2010	Percent	Trawl IFQ 2011-2012	Percent	Non-trawl IFQ 2011-2012	Percent
Sablefish	$9,032	32.7%	$7,451	31.7%	$6,254	97.7%

Non-trawl only	26	23
Total	**98**	**90**

Fishery managers have noted an increase in vessels targeting widow and yellowtail rockfish with midwater trawl gear over the past few years. In the 1980s there was a large fishery employing this strategy, which effectively disappeared as the need to rebuild overfished stocks resulted in increased management restrictions. Both the rebuilding of the widow rockfish stock and implementation of IFQ management has facilitated the reemergence of this fishery on a limited scale. For perspective, Figure 3-8 shows the historical trend for landings of widow and yellowtail rockfish by trawl gear.

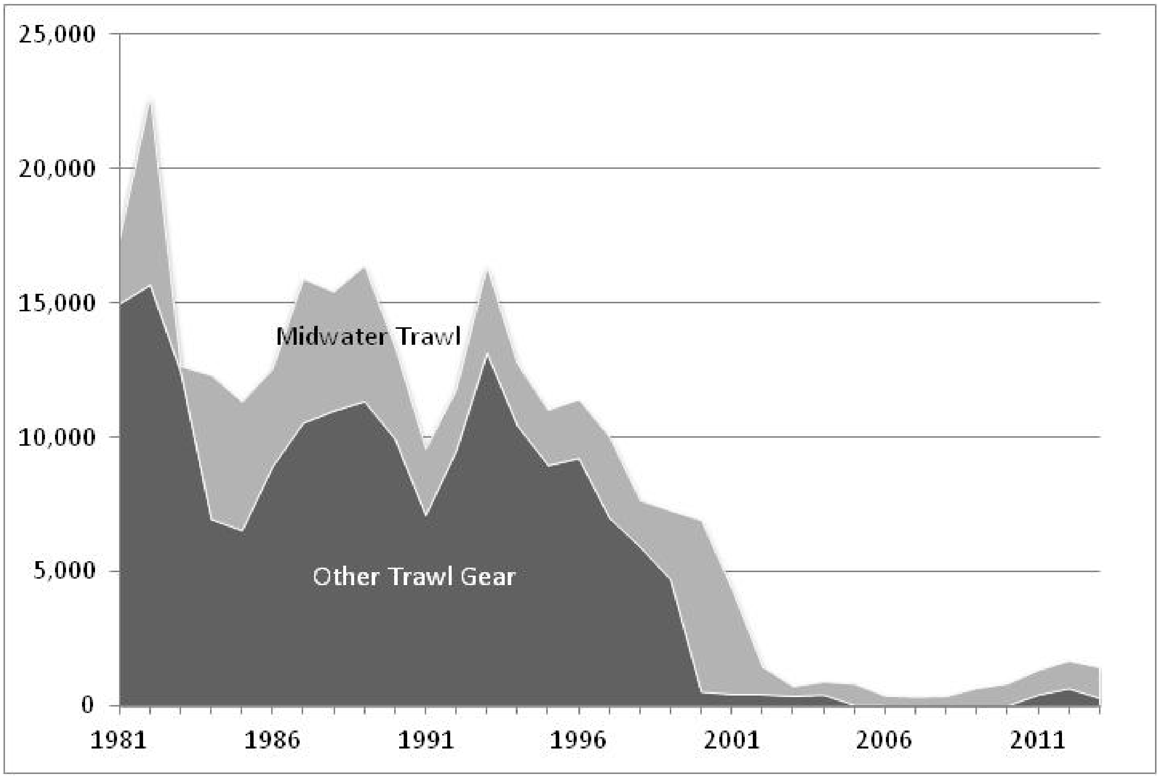

Figure 3-8. Landings of widow and yellowtail rockfish by trawl gear, 1981-2013

The figure indicates an uptick in landings of these species since 2009. Looking more closely at the midwater fishery, Table 3-6 shows landings and revenue from trips in the commercial fishery where widow and yellowtail rockfish made up at least 50% of the total landing by weight. This criterion is used as proxy for trips targeting these species. Surprisingly, the number of trips (estimated by counting fish ticket numbers) fell substantially after 2010; in 2010 there were 497 trips based on this estimate while there were 11, 67, and 74 trips in 2011-2013 respectively. However, overall landings and revenue from these two species in 2013 exceeded the summed amounts in previous years. Landings composition is used as a proxy for target strategy in compiling these data but it is impossible to determine whether the intended target and the landings composition correspond in all cases. In other words, some portion of these trips could represent instances where the intended target was Pacific whiting even though the majority of landing was made up of other species.

Table 3-6. Landings and inflation adjusted revenue for trips with midwater trawl gear targeting widow/yellowtail, 2010-2013. (Source: PacFIN vdrfd 3/18/2014)

Other	24	$1,546	<1	$145	5	$2,606	5	$3,874

3.2.2.3 Non-nearshore Fixed Gear Fishery

The non-nearshore fixed gear fishery is composed of vessels with a gear-endorsed Federal limited access permit ("limited entry fixed gear") and vessels without such permits ("open access," although they may hold state limited entry permits). The limited entry portion of the fleet has more catch opportunity for the primary target species, sablefish, through vessel level catch limits (based on the associated permit “tier” status) and higher cumulative landing limits.[15] Vessels with Federal limited entry permits accounted for 77% of overall inflation-adjusted revenue from sablefish during the baseline period even though open-access vessels accounted for 68% of participating vessels during the baseline period.

Figure 3-9 shows the distribution of ex-vessel revenue by species during the baseline period for the non-nearshore fishery (including both the sablefish and non-sablefish portions). Sablefish accounts for the most revenue, both because of its share of landings and its high value, followed by thornyheads. A variety of other species, mainly rockfish, account for the remainder of groundfish landings and revenue.

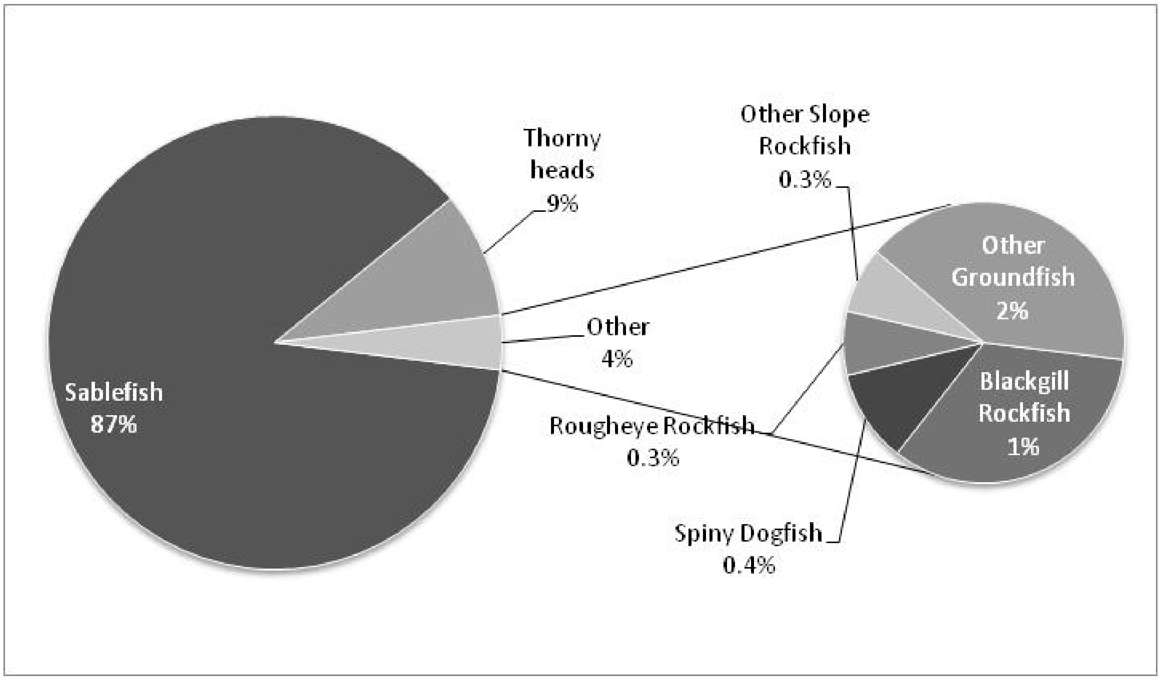

Figure 3-9. Non-nearshore fixed gear ex-vessel revenue by groundfish species or species group in inflation-adjusted (2012) dollars, $1,000s, 2003-2012. Source: PacFIN vdrfd 8/14/13.

Blackgill rockfish and spiny dogfish have been of particular interest to fishery managers over stock conservation concerns. Tables 8a and 8b in the 2014 Groundfish SAFE (PFMC 2014) provide landings and revenue data for species important in the non-nearshore fishery, including these two species. Figure 3-10 presents these data graphically. Blackgill rockfish landings and inflation-adjusted revenue averaged 56 mt and $566,000 annually during the 2003 to 2012 baseline period while for spiny dogfish these figures were 77 mt and $41,300 out of total annual average landings and revenue of 331 mt and $17.3 million. In 2013 trip limits for blackgill rockfish were reduced. Preliminary PacFIN data (vdrfd table, 3/19/2014) show that 16 mt valued at $50,000 was landed in 2013, a substantial decline from the peak in the 2011.

[15] Although for data and management a distinction is made between trips targeting sablefish and trips where sablefish are not landed (implying some other target), during the baseline period 97% of revenue was earned on sablefish-targeted trips.

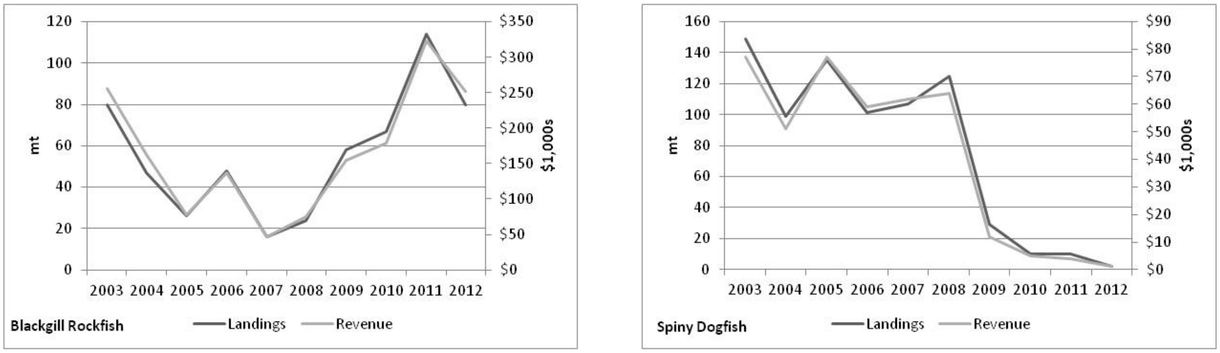

Figure 3-10. Landings and revenue (inflation adjusted, 2012) for blackgill rockfish (left) and spiny dogfish (right) in the nonnearshore fixed fishery.

3.2.2.4 Nearshore Fixed Gear Fishery

Although the nearshore fixed gear fishery accounted for less than 0.5% of coastwide groundfish landings during the baseline period, it garnered 5% of total revenue. Much of the fish from the fishery commands high ex-vessel and retail prices, with live fish markets catering to Asian communities in California as an important destination. Although a small portion of coastwide ex-vessel revenue, the nearshore fishery is regionally important, as discussed in section 3.2.8.

Figure 3-11 shows the distribution of revenue by species or species group during the baseline period. Although a relatively few species (cabezon, brown rockfish, gopher rockfish, blue rockfish, lingcod, and kelp greenling) account almost three-quarters of the revenue, a diverse array of other rockfish species are also caught and make up the balance of the landings. Table 3-7 shows the species included in "Other Nearshore Rockfish" category in SAFE Table 9b (PFMC 2014). Within this category, again just a few species account for a majority of landings but a wide range of rockfish species are landed as indicated by the long list of species names listed for the remaining 5%.[16]

[16] The names in this table are from the CNAME column associated with PacFIN species id codes (SPID), which include species and various market categories. Note that species composition adjustments are applied in generating the PacFIN vdrfd table.

3.2.2.5 Other Commercial Fisheries Catching Groundfish

Groundfish are caught in a variety of other circumstances including by vessels targeting groundfish with gear types other than trawl or fixed gear, fisheries for species other than groundfish and catching groundfish incidentally (referred to by managers as the "incidental open access sector" and the "exempted trawl sector"), vessels targeting groundfish pursuant to an EFP, and research catches. (Tribal fisheries are considered separately and discussed below). Catches in these sectors are negligible from a socioeconomic standpoint, accounting for 2% of inflation-adjusted groundfish ex-vessel revenue during the baseline period. But this catch can be very important to fishery managers in terms of accounting for overfished species catch, because ACLs for some of these stocks tend to be very low, imposing constraints on target fisheries. Figure 3-12 shows the breakdown of revenue from these sectors for the baseline period. Figure 3-13 shows the proportion of ex-vessel revenue derived from various species and species groups for these miscellaneous sectors. About three-quarters of revenue come from species other than groundfish, which is expected since most of the sectors discussed here are not targeting groundfish.

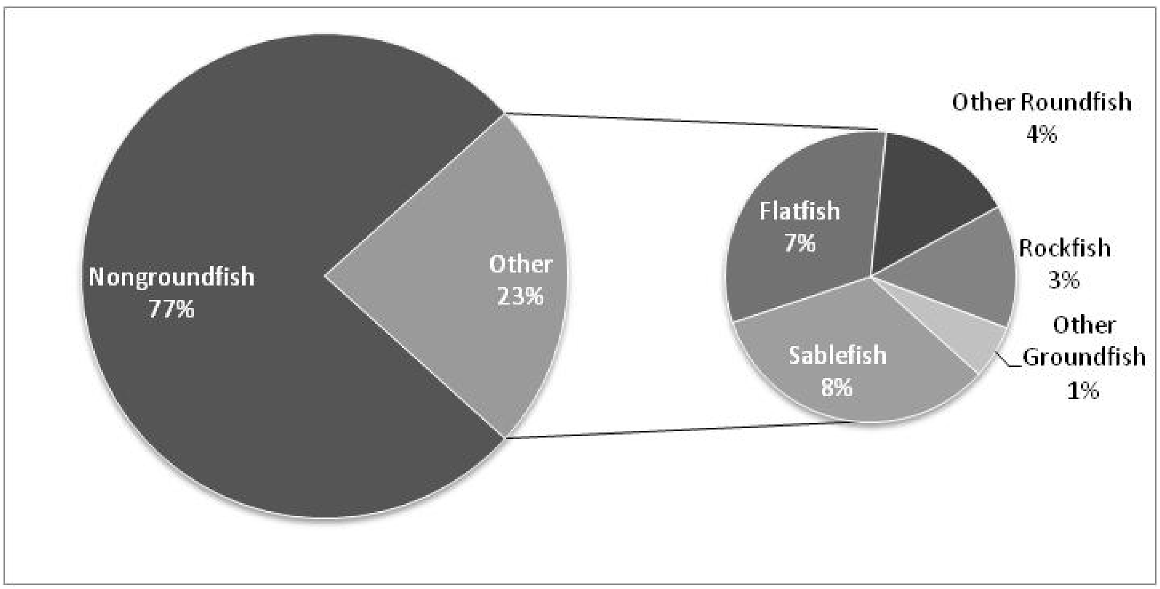

Figure 3-13. Inflation adjusted ex-vessel revenue by species composition from non-target and other miscellaneous groundfish sectors, 2003-2012. Source: vdrfd 8/23/13 based on procedure for Table 10a-b in the 2014 Groundfish SAFE (PFMC 2014).

3.2.3 Participation Trends in Commercial Groundfish Fisheries

Figure 3-14 shows annual counts of vessels (based on vessel ID) and landings (based on fish ticket ID) for the nearshore and non-nearshore fixed gear sectors and the non-whiting IFQ trawl sector during the baseline period. Participation in the nearshore fishery and trawl fisheries declined over the baseline period while non-nearshore participation remained relatively stable. In the nearshore fishery 453 vessels made landings in 2003, declining to 321 vessels in 2012. However, the annual number of landings in the nearshore fishery has remained fairly stable. The IFQ trawl fishery saw steep declines in 2004 (due to the vessel buyback program) and 2011 (likely a result of the implementation of IFQ management) in both vessel participation and the number of landings. The non-nearshore fixed fishery has remained fairly stable with respect to both metrics.

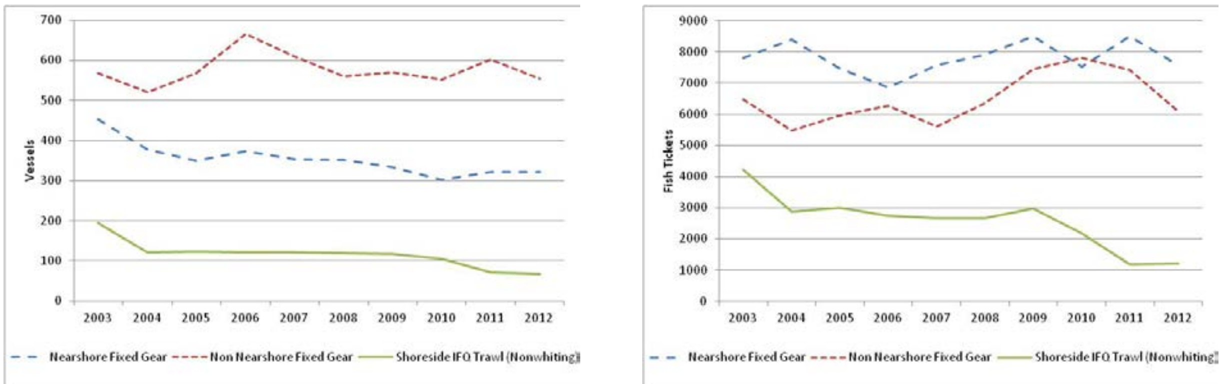

Figure 3-14. Number of vessels (left) and landings (right) by sector, 2003-2012. (PacFIN vdrfd 05/04/14)

3.2.4 Tribal Groundfish Fisheries

Past Groundfish Harvest Specifications EISs, including the 2013-2014 FEIS, describe tribal fisheries and Section 6.2.5 in the Groundfish FMP describes the special status of these fisheries. Several Pacific Northwest Indian tribes have treaty rights to fish for groundfish in their usual and accustomed fishing grounds. The Federal government has accommodated these fisheries through a regulatory process described at 50 CFR 660.50. Tribal fishery management is coordinated through the Council process so catches can be accounted for when developing management measures. West coast treaty tribes in Washington State have formal allocations for sablefish, black rockfish, and Pacific whiting. For other species without formal allocations, the tribes propose trip limits to the Council, which the Council tries to accommodate while ensuring that catch limits are not exceeded. Whether formally allocated or not, tribal catches are accounted through set-asides, which are deducted along with certain other sources of catch to determine the fishery harvest guideline, the overall limit commercial and recreational fisheries are managed to.

Because tribes have sovereign rights to manage their fisheries, the tribal sectors do not have an equivalent regulatory dimension like the commercial sectors discussed above. These sectors, described below, are identified more for data presentation purposes, although they do relate to target strategy.

The Makah tribe participates in whiting fisheries with both a mothership and shorebased component. On average, the treaty fisheries have accounted for 12 percent of total whiting landings and at-sea deliveries since 2005, generating an average of about $4 million (inflation-adjusted) per year.

The Tribal non-whiting sector is defined by groundfish landings other than whiting and thus includes a variety of gear types. Hook-and-line gear represents by far the largest portion of average annual revenue for the 2003-2012 period at 70 percent, followed by bottom trawl, accounting for 28 percent (see PFMC 2014, Table 13b). In the hook-and-line fishery 97% of baseline period inflation-adjusted revenue comes from sablefish. This is similar to the commercial fixed gear sectors where sablefish is the most important component of baseline revenues. Trawl fishery landings are more diverse; the largest proportion of baseline revenue comes from rockfish, at 36%, followed by Pacific cod, petrale sole, Dover sole, and sablefish. Together these species accounted for 84% of baseline period Tribal non-whiting sector revenue for trawl gear.

While all four coastal tribes have longline fleets, only Makah currently has a trawl fleet. The Makah Tribe's trawl fleet has reduced from 10 vessels to 5 active (8 eligible) vessels due in part to reduced markets. Buyers in Neah Bay have reduced the number of trucks taking fish to processors since the closure to limited entry trawl of the area shoreward of the RCA north of Cape Alava went into place. Makah trawl fisheries pursue two basic strategies – bottom trawl and midwater trawl. In an agreement with NMFS and the Council, the Tribe has had an observer program in place since 2003 to monitor maximum retention. Maximum retention is defined as retention of all marketable species and all overfished species. The program has a target observation rate of approximately 15% of all trawl trips in a given year, though recent staffing issues and fishing patterns have made that difficult to achieve across both midwater and bottom trawl strategies in all years. For example, there were insufficient observations to conduct an analysis on 2011 bottom trawl fisheries. Likewise, there was not enough effort in 2013 midwater trawl to conduct an analysis due to confidentiality requirements and the bottom trawl coverage was similar to 2011 levels. However, for 2011 and 2012 midwater and 2012 bottom trawl, coverage was above target levels (i.e. 45.7%, 24.4%, and 23%, respectively). As such the analysis here is conducted for midwater trawl in 2011 and both midwater and bottom trawl in 2012. Prior years' analyses can be found in past Specifications and Management Measures EISs.

Management of the Makah trawl fishery is focused on avoidance of canary rockfish (an overfished species) in both strategies and widow rockfish in midwater trawls. Makah Fisheries Management combines their maximum retention policy with an observer program to verify the accuracy of bycatch accounting (i.e., if observed bycatch rates are not substantially different than unobserved bycatch rates, managers are reasonably certain that landings reflect total mortality for overfished species).

For 2012 comparisons of bycatch rates in observed versus unobserved landings were conducted for bottom trawl to test for differences in retention of canary rockfish (Table 3-8and Table 3-9). Separate analyses (*t* tests) were performed for vessels that carried an observer and all vessels combined (i.e., including those vessels that had no observer coverage during the year. Bycatch rates were also compared for three separate target strategies in bottom trawl (these are labeled "flatfish", "deep", and "P. cod") in addition to examining all targets combined to examine whether bycatch was more prevalent in one strategy than the other. The flatfish strategy was defined as trips that focused on the most predominantly targeted flatfishes: Dover, English, and petrale soles. The deep strategy focused on landings composed mostly of Dover sole, shortspine thornyhead, and skates. The Pacific cod (P. cod) strategy was defined as trips where that was the predominant species landed. Two-tailed *t* tests found no significant difference between observed and unobserved trips for vessels that carried an observer during the year. Likewise, no significant difference was measured between all observed and unobserved trips. Bycatch was not predominantly associated with a particular target strategy for bottom trawl in 2012.

Midwater trawl fisheries were similarly analyzed for differences in retention of both canary and widow rockfish (either of which may be constraining), as a proportion of target species (i.e. yellowtail and redstriped rockfish). Two-tailed paired *t* tests were conducted for both 2011 and 2012 since all vessels carried an observer during each year (Table 3-10 and Table 3-11). No significant differences were found between observed versus unobserved landings for either canary or widow rockfish in either year.

Table 3-8. Comparisons of canary rockfish bycatch rates (measured as pounds of canary rockfish divided by pounds of target category) for bottom trawl vessels that carried an observer at least once during 2012.

Year	Target Species	Mean Bycatch Rates		d.f.	*t*	*p*
		Observed	Unobserved			
2012	Flatfish	0.005601	0.003717	4	0.791121	0.47314

2012	Canary	0.004668	0.001495	2	2.347229	0.143455
	Widow	0.130594	0.091766	2	0.710896	0.550872

3.2.5 Recreational Fisheries

Recreational fisheries are an important part of fishery-related economic activity. However, because recreational catch is not sold it is more difficult to impute the economic value of these fisheries. Past Groundfish Harvest Specifications EISs have characterized recreational fisheries in terms of fishing effort (angler trips) to quantify spatio-temporal differences in west coast recreational fisheries. Income impacts reported in Chapter 4 to evaluate short-term (2 year) effects of the proposed action do include estimated economic impacts from recreational fishing activities.

Recreational fisheries are broadly sub-divided between private anglers and commercial passenger fishing vessels (CPFVs), commonly referred to as charter vessels. Private anglers fish from shore or their own boats while charter vessels take paying passengers.

Table 3-12 shows bottomfish/halibut angler trips compared to trips targeting other species.[17] Overall, private and charter trips, which are subject to management measures described in this EIS, comprise 19% of all trips. Figure 3-15 shows bottomfish/halibut trips by state and year and Figure 3-16 shows the distribution of these trips by port area. Overall, the number of angler trips has shown a 77% increase over the 2004-2012 period. California, and especially Southern California, accounts for the vast majority of angler trips due to its large coastal population and milder year round weather.

Table 3-12. Total Angler trips by type and mode, 2004-2012. (Source: GMT state reps)

Mode	Bottomfish/Halibut	Other	Total
Charter	3,253,463 (10.4%)	1,764,526 (5.7%)	5,017,989 (16.1%)
Private	2,580,419 (8.3%)	4,259,283 (13.6%)	6,839,702 (21.9%)
Man-made	1,579,756 (5.1%)	10,592,088 (33.9%)	12,171,844 (39.0%)
Beach/Bank	30,985 (0.1%)	7,148,962 (22.9%)	7,179,947 (23.0%)
Grand Total	7,444,623 (23.9%)	23,764,858 (76.1%)	31,209,482 (100.0%)

[17] Because it is hard to distinguish between trips targeting bottomfish and those targeting Pacific halibut these trip types are combined. The tables and graphs presented in this section use data 2004-2012, because 2003 data is incomplete.

	2004	2005	2006	2007	2008	2009	2010	2011	2012
California	242,998	774,814	429,022	470,522	456,397	498,380	495,482	722,705	705,303

3.2.6 Costs in Commercial Groundfish Fisheries

Figure 3-17 presents estimates of the breakdown in costs for different segments of the groundfish trawl fishery provided by the Economic Data Collection (EDC) program, which was enacted to monitor the economic effects of the 2011 transition of the West Coast groundish trawl fishery to a catch share (IFQs, co-ops) program.

Figure 3-17. Estimated costs in different segments of the trawl fishery.

3.2.7 Buyers and Processors

Table 3-13 and Table 3-14 show the geographic and sector distribution of first receivers based on the processor ID field in the PacFIN database. (Note that a single firm may own several entities with different IDs so these numbers may overstate the number of independent firms engaged in processing groundfish. A comparison to counts based on processor names stored in the database showed a negligible difference.) A first receiver may be an entity that both buys and processes fish or a buyer or transportation company serving as a middleman between purchasing locations and processing facilities. The count of first receivers (based on ID) has declined by about 20% both for those accepting groundfish and those accepting any species. From a sector perspective the largest declines have been the counts of first receivers accepting trawl-caught groundfish from the shoreside sectors. This may represent consolidation within the buyer/processor sector.

Table 3-13. Count of first receivers (based on processor ID) that accepted groundfish and total number (accepting any species) by state and coastwide, 2003-2012. (Source: vdrfd 8/29/13.)

Total	1051	972	891	884	870	791	847	786	768	817

Table 3-14. Count of first receivers (based on processor ID) that accepted groundfish, by major groundfish fishery sector, 2003-2012. (Source: vdrfd 8/29/13.)

Groundfish Fishery Sector	2003	2004	2005	2006	2007	2008	2009	2010	2011	2012
Shorebased IFQ Trawl (Whiting)	12	10	10	14	14	15	17	20	9	9
Non-whiting Trawl	65	57	52	49	49	47	45	36	26	25
Shorebased IFQ Non-trawl									20	19
Non Nearshore Fixed Gear	202	211	183	198	205	187	201	178	179	203
Nearshore Fixed Gear	133	153	142	140	131	132	145	124	120	121

Table 3-15 shows the distribution of first receivers of groundfish with respect to purchase amounts over the entire 2003-2012 baseline period. Note that the bin intervals are logarithmic, emphasizing the highly skewed distribution of purchases. While 91% of first receivers purchased $1,000 or less over the period, they accounted for less than 0.1% of total purchases during the baseline period. At the end of the scale, only 5% of first receivers recorded total purchase amounts of $1 million or more but accounted for 94% of total purchases.

Table 3-15. Distribution of groundfish first receivers (by ID) by total purchase amount (nominal dollars), 2003-2012. (Source: vdrfd 3/19/2014)

Interval	Count	Percent	Purchases	Percent
<=$1,000	964	91%	$110,061	<0.1%
$1,001-$99,999	28	3%	$965,567	0.2%
$10,000-$999,999	10	1%	$7,703,195	1.2%
$100,000-$999,999	4	0.4%	$32,941,423	5.2%
>=$1,000,000	55	5%	$596,283,531	93.5%

3.2.8 Fishing Communities

As in the 2013-14 Groundfish Harvest Specifications EIS, fishing communities are described below in terms of landings by IOPAC port group. (See Table 9 in NOAA Technical Memorandum NMFS-NWFSC-111 for ports included in these port groups. The IOPAC Input-Output Model for Pacific Coast Fisheries is used to evaluate personal income impacts of proposed management measures.)

The 18 port groups used in IOPAC are:

Washington State:

1. Puget Sound
2. North Washington Coast
3. South and Central Washington Coast

Oregon:

4. Astoria (and other Columbia River ports in Oregon)
5. Tillamook
6. Newport
7. Coos Bay
8. Brookings

California: [18]

9. Crescent City (North Coast)
10. Eureka (North Coast)
11. Fort Bragg (North Coast)
12. Bodega Bay (North-Central Coast)
13. San Francisco (North-Central Coast)
14. Monterey (South-Central Coast)
15. Morro Bay (South-Central Coast)
16. Santa Barbara (South Coast)
17. Los Angeles (South Coast)
18. San Diego (South Coast)

Fisher characteristics of these port groups are shown in Table 3-16 and Table 3-20. Port groups (and as applicable California recreational reporting regions) are also used to organize the evaluation of impacts to fishing communities in Chapter 4.

[18] The regions noted in parenthesis show the approximate correlation between port groups and California state reporting regions for recreational fisheries.

3.2.8.1 Dependence and Engagement in Groundfish Fisheries

Table 23 in the 2014 Groundfish SAFE document (PFMC 2014) presents values for community engagement and dependence on commercial groundfish fisheries. Engagement is defined as groundfish ex-vessel revenue in the port as a percent of coastwide groundfish ex-vessel revenue for the 2003-2012 baseline period. Similarly, dependence is defined as groundfish ex-vessel revenue in the port as percent of total ex-vessel revenue in port during the baseline period. (For these calculations revenues are inflation-adjusted to 2012 dollar values.)

Engagement and dependence values can be developed for recreational fisheries using a similar methodology. For recreational fisheries the metric is the number of angler trips. Engagement is measured by dividing the number of groundfish-directed angler trips in the port by the coastwide number of groundfish angler trips during the baseline period. Dependence is measured by dividing the number of groundfish-directed angler trips in the port by the total number of angler trips in the port during the baseline period.

Table 3-16 presents summary information on commercial fishery engagement and dependence by port group as well as indicating the primary and secondary groundfish fishery sectors. The fishery sectors are identified based on the share of inflation-adjusted ex-vessel revenue the sector accounts for out of total groundfish revenue within the port.

In terms of engagement in commercial fisheries (share of coastwide revenue) South and Central Washington, Astoria, and Newport top the list. In contrast, ports with high dependence values are much more geographically dispersed with Morro Bay at the top of the rankings followed by Puget Sound and the North Washington Coast. These ports tend to be mid-ranking in terms of engagement. Southern California ports (Santa Barbara, Los Angeles, and San Diego) are neither highly engaged nor dependent on commercial groundfish fisheries.

Trawl fisheries (counting both the whiting and non-whiting segments) dominate the coast from the South and Central Washington Coast port group to Fort Bragg, California. The non-nearshore fixed gear fishery is important in Central and Southern California and the Puget Sound region. (Note that the North Washington Coast port group includes ports in the Straits of Juan de Fuca at the entrance to Puget Sound.)

Table 3-16. Commercial fishery engagement and dependence scores and rank, primary and secondary fisheries, for the 2003-2012 baseline period for each Port Group. Based on 2012 inflation-adjusted ex-vessel revenue.

Port Group	Engagement	Engagement Rank	Dependence	Dependence Rank	Primary Fishery	Secondary Fishery
Puget Sound	4.8%	9	43.6%	3	Non Nearshore Fixed Gear	Shoreside Non-whiting Trawl*
North WA coast	6.6%	5	44.7%	2	Non Nearshore Fixed Gear	Shoreside Non-whiting Trawl*
South and central WA coast	14.0%	3	14.2%	11	Shoreside Whiting Trawl	Non Nearshore Fixed Gear
Astoria	18.0%	1	37.2%	4	Shoreside Non-whiting Trawl*	Shoreside Whiting Trawl
Tillamook	0.3%	18	5.3%	15	Nearshore Fixed Gear	Shoreside Non-whiting Trawl*
Newport	15.0%	2	30.1%	7	Shoreside Whiting Trawl	Shoreside Non-whiting Trawl*
Coos Bay	8.4%	4	21.8%	9	Shoreside Non-whiting Trawl*	Non Nearshore Fixed Gear
Brookings	5.3%	7	32.1%	6	Shoreside Non-whiting Trawl*	Non Nearshore Fixed Gear
Crescent City	2.4%	13	10.0%	13	Shoreside Non-whiting Trawl*	Nearshore Fixed Gear
Eureka	6.0%	6	26.2%	8	Shoreside Non-whiting Trawl*	Non Nearshore Fixed Gear
Fort Bragg	5.1%	8	36.4%	5	Shoreside Non-whiting Trawl*	Non Nearshore Fixed Gear
Bodega Bay	0.4%	17	3.7%	16	Non Nearshore Fixed Gear	Shoreside Non-whiting Trawl*
San Francisco	2.5%	12	9.2%	14	Shoreside Non-whiting Trawl*	Non Nearshore Fixed Gear
Monterey	2.7%	11	16.0%	10	Non Nearshore Fixed Gear	Shoreside Non-whiting Trawl*
Morro Bay	4.5%	10	64.7%	1	Non Nearshore Fixed Gear	Nearshore Fixed Gear
Santa Barbara	1.4%	15	2.7%	18	Non Nearshore Fixed Gear	Nearshore Fixed Gear
Los Angeles	1.5%	14	3.2%	17	Non Nearshore Fixed Gear	Nearshore Fixed Gear
San Diego	1.0%	16	10.1%	12	Non Nearshore Fixed Gear	Nearshore Fixed Gear

*Shoreside Non-whiting Trawl includes Non-trawl IFQ in 2011-2012.

Table 3-17. Recreational fishery engagement and dependence scores and rank for the 2003-2012 baseline period.

[Similar table for recreational fisheries / GMT data request]

Table 3-18. Top-ranked ports by groundfish fishery sector, based on inflation adjusted ex-vessel revenue 2003-2012. Percent share of coastwide sector revenue for the entire baseline period shown in parenthesis and total share accounted for by the three top-ranked ports in each category shown in the bottom row. Source: vdrfd 8/27/13 based on method used for data in the 2014 Groundfish SAFE Table 20.

	Whiting Trawl	Non-whiting Trawl*	Non Nearshore	Nearshore
1	Newport (33%)	Astoria (28%)	Newport (15%)	Morro Bay (31%)
2	So. & Cent. WA Coast (31%)	Coos Bay (13%)	So. & Cent. WA Coast (11%)	Brookings (27%)
3	Astoria (30%)	Newport (12%)	Puget Sound (9%)	Crescent City (12%)
Total share:	94%	53%	35%	70%

*Includes non-trawl IFQ sector in 2011-2012.

Table 3-18 shows the top-ranked ports for each major groundfish fishery sector in terms of inflation adjusted ex-vessel revenue during the baseline period. Newport, Astoria, and the South and Central Washington Coast are in the top-three of the rankings for the trawl (whiting and non-whiting) and non nearshore fishery sectors. The nearshore fishery figures more prominently on the Oregon-California border and in the Morro Bay port group. (Note that non nearshore fixed gear fisheries are also important in these three ports as evidenced by the primary and secondary fisheries identified in Table 3-16.) Table 3-18 also shows the share of coastwide sector revenue accounted for by each port and the sum for the top-ranked ports. Revenue from whiting trawl and the nearshore sector are relatively concentrated in the top-ranked ports at 94% and 70% respectively (but note that for nearshore the top two ports alone account for 58% of coastwide sector revenue).

The rankings and shares shown in Table 3-18 are also consistent with the use of the Gini coefficient in the 2013-14 Groundfish Harvest Specifications EIS to summarize the uniformity of the distribution of groundfish ex-vessel revenue across sectors and ports.[19] Using this statistic, the shoreside whiting trawl sector is the most concentrated with respect to distribution across ports. (In fact, relatively few ports have any shoreside whiting sector landings at all.) The nearshore sector ranks second. Table 3-19 repeats the across-port evaluation included in the 2013-14 EIS using inflation-adjusted ex-vessel revenue for the baseline period and the fishery sectors listed in Table 3-18 (except that non-whiting trawl and non-trawl IFQ are not combined). Generally speaking, ports with lower overall groundfish revenue have a less uniform distribution among sectors, because fewer sectors operate out of those ports. This is most clearly evidenced by Southern California ports, which rank near the bottom in terms of engagement (share of coastwide groundfish revenue) and also have the least uniform distribution among sectors. Notable exceptions to this inverse correlation include the North Washington Coast (engagement rank of 5, Gini coefficient rank of 4), Crescent City (13 and 17), Bodega Bay (17 and 14), and Morro Bay (10 and 18).

[19]The Gini coefficient is a measure of the statistical dispersion of a data distribution, ranging between 0 and 1. A value of 0 indicates that all data points in a distribution are identical while a value of 1 indicates the maximum degree of diversity in the data set. This statistic is often used to measure national-level income distribution where a value of 0 indicates that everyone receives the same income, and a value of 1 would indicate that virtually all income goes to one individual. Its use in the 2013-2014 Harvest Specifications EIS was not intended to imply any particular policy objective (e.g., a more uniform distribution of ex-vessel revenue) but merely to describe the uniformity of the distribution of groundfish ex-vessel revenue among west coast ports and between fisheries sectors within those ports.

Table 3-19. Distribution of ex-vessel revenue among commercial groundfish fishery sectors within port groups, 2003-2012, using Gini coefficient. Ranking is from least uniform (1) to most uniform (18) distribution.

Port Group	Gini Coefficient	Gini Coefficient Rank
Puget Sound	0.62175	8
North WA coast	0.70677	4
South and central WA coast	0.54597	12
Astoria	0.60903	11
Tillamook	0.63016	6
Newport	0.43195	16
Coos Bay	0.62709	7
Brookings	0.25685	15
Crescent City	0.42600	17
Eureka	0.67958	5
Fort Bragg	0.61146	9
Bodega Bay	0.50349	14
San Francisco	0.60921	10
Monterey	0.53330	13
Morro Bay	0.39445	18
Santa Barbara	0.71094	3
Los Angeles	0.78504	2
San Diego	0.79624	1

Figure 3-18 contains panels showing trends in top-ranked ports' share of revenue during the baseline period for each major fishery sector listed in Table 3-18. These figures are based on total revenue accounted for by the sector in the port as a share of coastwide revenue for that sector. These values are then shown in terms of percent change over the baseline period, starting in 2003. Values greater than 100% indicate the share is higher than in 2003 while values below 100% indicate the share is less than it was in 2003.

With the exception of the shoreside whiting trawl sector, the top-ranked port (represented by the solid line in each case) increased its share over the baseline period. For non-whiting trawl and non nearshore fixed gear the share of revenue for the second- and third-ranked ports is actually below what it was in 2003. For the nearshore sector the first- and second-ranked ports (Morro Bay and Brookings) are fairly stable in terms of changes in their revenue shares while the third-ranked port (Crescent City) shows a decline of more than 60% from its 2003 share of coastwide sector revenue. At 12% of coastwide nearshore sector revenue for the baseline period as a whole, Crescent City is a distant third compared to Morro Bay and Brookings.

The shoreside whiting fishery is concentrated in the top three port groups, which account for 94% of coastwide sector revenue. While Newport's share of revenue declined over the baseline period, Astoria and the South and Central Washington Coast (SCWC) (essentially, Westport and the port of Ilwaco) show an inverse correlation in revenue changes. For example, in 2009 Astoria's share increased while SCWC's share decreased, while in 2010 the reverse is true. These trends may be a function of processing capacity in these ports. When landings are lower, they may be more evenly distributed, because no ports meet their processing capacity limit. When landings are high, ports with surplus capacity could increase their share of landings. The top-ranked shoreside whiting ports are also unusual in that the second- and third-ranked ports, SCWC and Astoria, show increases in their revenue share from 2003 compared to first-ranked Newport; its share declined by about one fifth (from 40% of coastwide sector revenue in 2005 to 27% in 2007) and has stayed below its 2003 share since then.

There is a trend towards increasing concentration of ex-vessel revenue in major fishing ports. This may indicate a general trend toward agglomeration (the concentration of firms specializing in an activity, such as fish processors and shipyards, in a geographic area.) Figure 3-19 displays data used for Table 3-18 and Figure 3-18 to evaluate trends in concentration of revenue within ports over the baseline period. For all groundfish fisheries, the share of coastwide revenue flowing to the top-three ranked ports increased, especially after 2009. This trend appears to be driven primarily by landing patterns in the shoreside trawl/IFQ fishery. Conversely, the concentration of revenue from the nearshore fishery is fairly stable over time but highly concentrated, with the top-three ports accounting for about 70% of coastwide revenue.

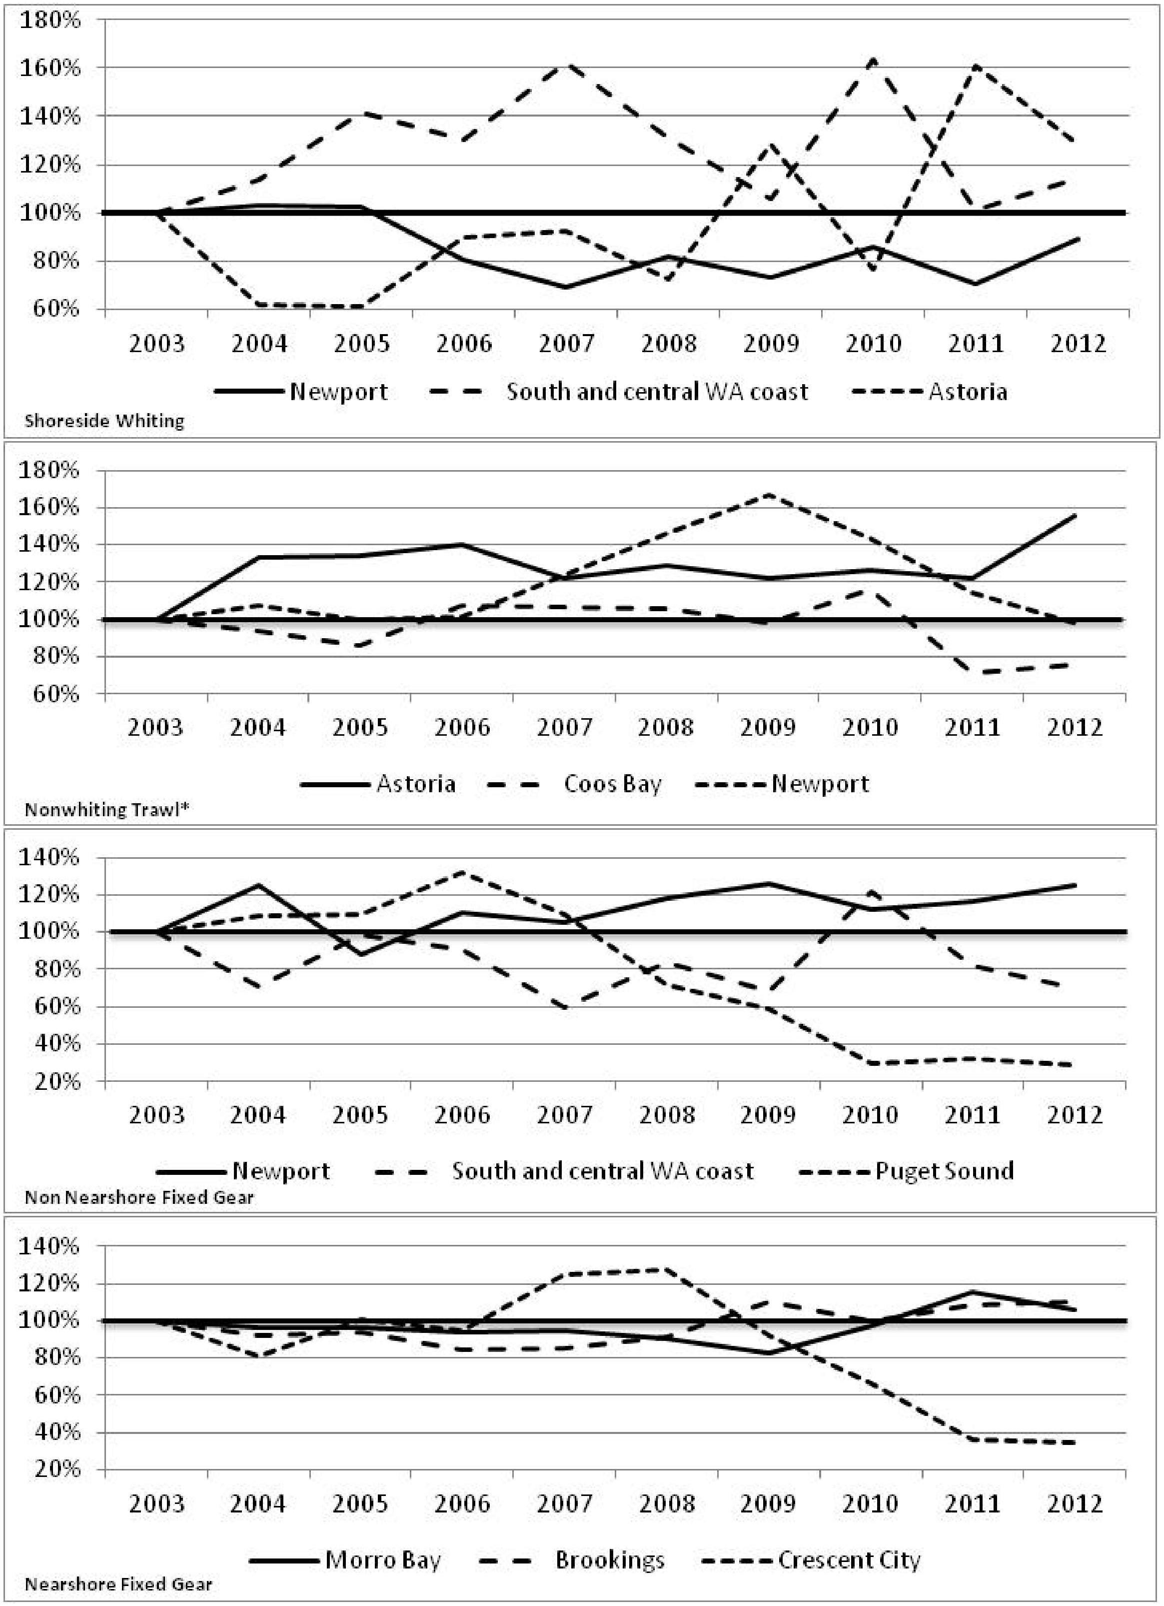

Figure 3-18. Trends in top-ranked ports' share of inflation-adjusted ex-vessel revenue by fishery sector. (2003=100%). *Non-whiting trawl includes non-trawl IFQ sector landings in 2011 and 2012.

3.2.8.2 Community Vulnerability

Past Groundfish Harvest Specifications EISs have catalogued various demographic and fishery statistics to characterize west coast fishing communities with respect to their socioeconomic vulnerability to groundfish fishery management actions. These methods combine the concepts of engagement in and dependence on groundfish fisheries with resilience to assess community vulnerability. Communities that may be disproportionately affected by adverse impacts can thus be identified. Vulnerability assessment is also a tool for determining whether measures to rebuild overfished species stocks address the MSA mandate that the time period for rebuilding an overfished species "be as short as possible, taking into account the status and biology of any overfished stocks of fish, *the needs of fishing communities*, recommendations by international organizations in which the United States participates, and the interaction of the overfished stock within the marine ecosystem;…" (emphasis added).

Each vulnerability analysis conducted as part of the Groundfish Harvest Specifications impact evaluation (2007-2008, 2011-2012, 2013-2014, and this EIS for 2015-2016) has used different units of analysis and methods for scoring or rating a community's vulnerability. [20] While the 2007-2008 EIS used ports, the 2011-2012 and 2013-2014 EIS analyses used counties as the unit of analysis. Beginning with the 2013-2014 EIS a social vulnerability index prepared by the Hazards and Vulnerability Research Institute at the University of South Carolina was used in place of resiliency scores developed specifically for the EIS analysis. The use of this index is carried forward, using an updated version available from the Institute's

[20] The 2007-2008 Harvest Specifications FEIS (see Appendix A) included a community vulnerability analysis based on fishery and demographic data at the individual port level. A similar analysis was repeated in the 2011-2012 Harvest Specifications FEIS at the county level (see Appendix E). The 2011-2012 analyses, modeled after the original 2007-2008 analysis used the following metrics to score community resiliency: industry diversity, population density, unemployment rate, and percentage of the population living below the poverty line. Except for enumeration of basic population characteristics in the decennial census, U.S. Census Bureau demographic information is based on sample data. A statistical analysis conducted in conjunction with the 2011-2012 EIS exercise suggests that in many cases even at the county level there are not statistically meaningful differences in demographic characteristics (given the margin of error in sample data) between adjacent counties. Therefore, attempting a vulnerability analysis at a finer scale may be misleading.

website (the SoVI® 2006-10 Index).[21] The current analysis is also different in that it uses a weighted average (based on population) of the SoVI scores for counties within each of the 18 IOPAC port groups to derive a single vulnerability score for each port group.[22]

Each analysis has also differed somewhat in the methodology used to assign an overall vulnerability rating to the unit of analysis (port, county, port group). Generally speaking, these methods involved ranking communities by the various indicators and identifying communities as vulnerable if they rank near the top (top one-third, top quartile) for engagement or dependence and resilience/vulnerability. However, the 2013-2014 analysis only presented ratings for each component (engagement, dependence, vulnerability) in high, medium, and low categories without presenting an overall vulnerability assessment.

In the current analysis the engagement, dependence, and adjusted SoVI values for each IOPAC port group were scaled to values between 0 and 1. Commercial fishery engagement and dependence scores, shown in Table 3-20, are based on inflation-adjusted ex-vessel revenue during the 2003-2012 baseline period. Table 3-20 also shows the primary and secondary commercial groundfish fisheries in each port, defined as the fisheries accounting for the largest and second largest shares of groundfish ex-vessel revenue in the port. Table 3-21 shows the scores for recreational fisheries. Recreational data were only available for all port areas from 2004, so the data series is 1 year shorter than that used for commercial fisheries. A combined score was calculated by summing the charter and private recreational scores and rescaling the results between 0 and 1. Finally, these scores were summed and rescaled to derive an overall composite score, shown in Table 3-22 along with the scaled, population-adjusted SoVI scores.

[21] According to the website (http://webra.cas.sc.edu/hvri/products/sovi.aspx) "SoVI® 2006-10 marks a change in the formulation of the SoVI® metric from earlier versions. New directions in the theory and practice of vulnerability science emphasize the constraints of family structure, language barriers, vehicle availability, medical disabilities, and healthcare access in the preparation for and response to disasters, thus necessitating the inclusion of such factors in SoVI®. Extensive testing of earlier conceptualizations of SoVI®, in addition to the introduction of the U.S. Census Bureau's five-year American Community Survey (ACS) estimates, warrants changes to the SoVI® recipe, resulting in a more robust metric. These changes, pioneered with the ACS-based SoVI® 2005-09 carry over to SoVI® 2006-10, which combines the best data available from both the 2010 U.S. Decennial Census and five-year estimates from the 2006-2010 ACS."

[22] The IOCPAC port groups are constructed to coincide with county boundaries, because the IOPAC model uses input data at that scale. Each port group encompasses one or more counties. The SoVI Index contains both positive and negative values. To simplify calculation, the index values for each county were re-scaled to positive values (with the lowest value in the data set becoming zero). The index values were then multiplied by the fractional value of the county's population relative to the summed population value for the IOPAC port group. These values were then averaged to derive a score for port groups consisting of multiple counties.

Table 3-20. Scaled engagement and dependence scores for commercial fisheries, based on inflation adjusted ex-vessel revenue, 2003-2012.

	Normalized Engagement	Engagement Rank	Normalized Dependence	Dependence Rank	Primary Fishery	Secondary Fishery

Figure 3-20 shows the component scores for each port in a stacked bar chart to aid in assessing the relatively level of vulnerability. These results can be interpreted in any number of ways to classify ports as vulnerable and, as in past analyses, "most vulnerable." Table 3-23 presents the results in a simple ranking (1 = highest composite score) and compares that to the results from previous vulnerability analyses. The top third ranked ports (1-6) are highlighted as one potential definition of vulnerable. These six port areas (Astoria, Tillamook, Newport, Brookings, Crescent City, and Eureka) were rated vulnerable in at least one of the previous analysis. These ports are geographically concentrated, comprising the entire Oregon coast except for Coos Bay, and Northern California. On the other hand, several port groups that may have qualified as vulnerable in past analyses are not in the top one-third of ranked ports in the current analysis.[23] These include the Washington Coast port groups, Coos Bay, Fort Bragg, Monterey, and Los Angeles. All these ports have summed composite scores greater than 2, as shown in Figure 3-20, along with Morro Bay, and Los Angeles. (Recreational engagement accounts for a large component of the Los Angeles summed value as seen in Table 3-21, indicating that it holds a dominate position in terms of recreational groundfish effort.)

Rather than considering a port group as either vulnerable or not vulnerable, the rankings for all the ports can be used as a factor in evaluating actions that may have concentrated regional effects rather than coastwide effects. Any such disproportionate effects are likely to be a function of the mix of fisheries in a port (if management measures will have a greater effect on a particular fishery sector compared to others) or the species targeted or incidentally caught by the fisheries in a port (if management measures will have a greater effect on the catch of a particular species or species group).

[23] The unit of analysis in first two analyses were counties, so the status of IOPAC port groups, the current unit of analysis was inferred as described in the table footnotes.

3.3 Essential Fish Habitat

The MSA (sec. 303(a)(7)) requires Councils to include in each FMP a description of essential fish habitat (EFH) for all managed species and measures to minimize to the extent practicable adverse effects on such habitat caused by fishing.[24] The Pacific Council has described EFH for all species managed under its four FMPs (Coastal Pelagic Species, Highly Migratory Species, Groundfish, and Salmon). EFH is defined as "waters and substrate necessary to fish for spawning, breeding, feeding or growth to maturity" (MSA sec. 3). Regulatory guidelines (50 CFR 600, Subpart J) elaborate that the words "essential" and "necessary" mean EFH should be sufficient to "support a population adequate to maintain a sustainable fishery and the managed species' contributions to a healthy ecosystem." Groundfish EFH is described in the FMP as:

- Depths less than or equal to 3,500 m (1,914 fm) to mean higher high water level (MHHW) or the upriver extent of saltwater intrusion, defined as upstream and landward to where ocean-derived salts measure less than 0.5 ppt during the period of average annual low flow.
- Seamounts in depths greater than 3,500 m as mapped in the EFH assessment geographic information system (GIS).
- Areas designated as Habitat Areas of Particular Concern (HAPC) not already identified by the above criteria.

The regulatory guidelines also establish authority for Councils to designate HAPC, based on the vulnerability and ecological value of specific habitat types. The Groundfish FMP identifies these HAPCs:

- Estuaries
- Canopy kelp
- Seagrass
- Rocky reefs
- Specified "areas of interest"

Chapter 7 in the Groundfish FMP describes groundfish EFH (Section 7.2) and HAPCs (Section 7.3). The current EFH and HAPC descriptions were incorporated into the FMP in 2006 through Amendment 19 to the FMP. The Council also established measures to mitigate the adverse impacts of fishing on groundfish EFH, which are described in FMP Chapter 6 (Management Measures). These mitigation measures include gear restrictions (Section 6.6), time/area closures (Section 6.8), and measures to control fishing capacity (Section 6.9). As acknowledged in Section 7.4 of the FMP, "Some of the management measures … have been implemented specifically to mitigate adverse impacts to EFH while others may have another primary purpose … but may have a corollary mitigating effect on adverse impacts to EFH."

The FEIS accompanying FMP Amendment 19 (NMFS 2005) included an evaluation of the adverse effects of fishing on groundfish EFH, and previous EISs for biennial harvest specifications and management measures (PFMC and NMFS 2011; PFMC and NMFS 2012) have assessed the effects on groundfish EFH of changes to catch limits and associated management measures. Changes to the Trawl RCA boundaries have come under increased scrutiny, because of their corollary mitigating effects; in 2014 NMFS prepared an environmental assessment (NMFS 2013d) for a Council-proposed change to the Trawl RCA that would open areas that had been closed to trawl fishing for several years. This action, like many other actions, has changed the baseline for considering impacts of the proposed action on EFH.

[24] A Federal agency authorizing, funding, or undertaking actions that may adversely affect EFH must consult with NMFS on measures to mitigate such impacts. Councils or Federal or state agencies may also advise NMFS on such actions.

Information from these documents may be incorporated into the baseline description in this section with citation.

In 2010 the Council developed a process and schedule for a 5-year review of "…the EFH description and identification, HAPC designations, and information on fishing impacts and nonfishing impacts…" as specified in Section 7.6 of the Groundfish FMP. This review began in 2011 under the auspices of the Council's Ad Hoc EFH Review Committee (EFHRC). During the first phase of the review the EFHRC and NMFS scientists updated and compiled available ecological, habitat, and fishing effort data, and used this information to develop a set of maps intended to support Council decision-making related to EFH (NMFS 2013b). A synthesis report based on these data was published in April 2013 (NMFS 2013b), completing the second phase.

In the third phase of the review, now underway, the Council is considering proposals for potential modifications to EFH conservation areas (discussed further below), which were implemented as part of Amendment 19 to the Groundfish FMP.

3.3.1 Effects of Fishing on Groundfish EFH

Fishing gear principally affects groundfish EFH when it comes into contact with benthic habitat. The gear type and configuration and the vulnerability of particular habitat types factor into assessments of the adverse impacts of fishing, as was done in the Amendment 19 FEIS (NMFS 2005). Section 3.5 in that document is a comprehensive and detailed description of fishing gear that is, or has been, used in the fishery management area and how they interact with benthic habitat. Section 3.2.4 in the FEIS summarizes the relative impacts of gear types by habitat type with those conclusions further consolidated in Table 3-24 showing the range of recovery times by habitat category and gear type.[25] Generally, for a given habitat type dredge and trawl gear are likely to have a greater effect than other bottom contacting gear types (e.g., demersal longline and pot gear, demersal, or Scottish, seine), because the contact is more extensive. With respect to biogenic and hard bottom habitats, Section 3.2.3.1 notes that corals, anemones, sponges, sea pens, and sea whips are highly sensitive habitat that may be substantially modified with relatively little fishing effort, and

> There have not been many studies of how these organisms recover from initial impact; however, growth rates of corals in particular suggest that recovery is in excess of seven years and likely to be much longer. The sensitivity and recovery indices prepared for the Risk Assessment should be interpreted with the caveat that very little science is available to understand the vulnerability of corals, anemones, sponges, sea pens, and sea whips to fishing impacts. It is plausible that the sensitivity and recovery times of corals, anemones, sponges, sea pens, and sea whips are underestimated and a precautionary approach may be warranted. (Page 3-15, internal citation omitted)

The full phase one report (Groundfish Essential Fish Habitat Review Committee 2012) cites more recent work that suggests recovery times on the order of 100 years for hard corals found off of Alaska. The longest recovery time shown in Table 3-24 is the upper range for recovery of offshore biogenic habitat

[25] See Appendix 10 to the Risk Assessment (MRAG Americas Inc., *et al.* 2004) for a full description of the methodology for the derivation of these recovery times. Note that Table 4-1 in NMFS (2014b) shows recovery times by gear type and habitat type as adapted from the EFH FEIS and Phase 2 Synthesis Report (NMFS 2005; NMFS 2013b). The categories and resulting values differs somewhat from what is displayed here. Bottom trawl, for example, ranges from 0.4 years for soft shelf habitat to 2.8 years for various hard and mixed habitats. Single values, rather than ranges are presented for habitat/fishing gear categories in Table 4-1, so the 0.4-2.8 range refers to all habitat categories.

from dredge gear (which was prohibited under Amendment 19). This likely represents an estimate for deepwater hard corals.

Table 3-24. Average recovery times, in years, for constituent habitat types by habitat category and fishing gear type, based on (a) Table 3-1 in Amendment 19 FEIS (NMFS 2005) and (b)Table a.3.2 in Appendix to Groundfish EFH Synthesis Report (NMFS 2013a)

(a)

Habitat Category	Bottom Trawl	Dredge Gear	Hook and Line	Nets	Pots and Traps
Nearshore Biogenic	1.5 - 9	2.6 - 11	0 - 1	0.5 - 4	0 - 1
Nearshore Hard Bottom	1 - 2	1.5 - 2.5	0 - 0.5	0.5 - 1	0 - 0.5
Nearshore Unconsolidated Bottom	0.1 - 0.3	0.2 - 0.6	0 - 0.5	0 - 0.5	0 - 0.5
Offshore Biogenic	2.3 - 55.7	2.7 - 63	0.1 - 17.6	1.2 - 41.5	0.2 - 17.2
Offshore Hard Bottom	1.8 - 10	1.8 - 12	0.3 - 3	0.8 - 7	0.3 - 2.6
Offshore Unconsolidated Bottom	0.5 - 5.7	0.7 - 6.5	0.1 - 1.9	0.4 - 4.6	0.1 - 2.8

(b)

Substrate Type	Bottom Trawl	Midwater Trawl	Fixed Gear Distance	Fixed Gear Point
Hard shelf	2.8	na	0.1	0.1
Hard upper slope	2.8	na	0.3	0.1
Hard lower slope	2.8	na	0.3	0.1
Mixed shelf	2.8	na	0.4	0.1
Mixed upper slope	2.8	na	0.4	0.1
Mixed lower slope	2.8	na	0.4	0.1
Soft shelf	0.4	na	0.4	0.1
Soft upper slope	1.0	na	0.4	0.1
Soft lower slope	1.0	na	0.4	0.1

Fixed Gear Distance: fixed gear represented by a distance metric (i.e., longline gear and pot gear)
Fixed Gear Point: fixed gear represented by a point metric (i.e., hook-and-line gear other than longline gear)

“Structure forming” benthic macroinvertebrates are of interest because of their potential role as groundfish habitat. Section 3.2.3.2 in the Amendment 19 FEIS notes the supporting role of corals in complex marine communities elsewhere in the world (e.g., reef forming hermatypic corals mostly occurring in the tropics) but based on available evidence reaches no conclusion about the importance of these macroinvertebrates as groundfish habitat. The synthesis report referenced above notes that kelp beds are known to be important habitat for many groundfish species, especially juveniles, but little new information about other biogenic areas has been collected since the Amendment 19 analysis (NMFS 2013b, p. 27).

Table 3-25 summarizes information from Table 4a.2 in the synthesis report on the distribution of fishing effort by habitat type.[26] For all gear types most fishing effort occurred on soft substrate on the upper slope, ranging from 77% for midwater trawl to 55% for fixed gear. Table 3-26 displays relative fishing effort. This metric was derived by dividing the amount of fishing effort in percent by area of each habitat type by percent and rescaling the values in percent (meaning the resulting values sum to 100% for each gear type). By this measure the biggest relative impact has been on mixed substrate on the upper slope.

[26] The synthesis report includes the Salish Sea (Puget Sound region) in its summary; this region is excluded here because it is outside the fishery management area. Reported depth zones refer to the continental shelf and slope. The break between the shelf and slope, measured by depth, is 140 meters (Gross 1972). Bottom and midwater trawl fishing effort is measured by trawl distance in meters; fixed gear effort is measured in number of fishing events.

However, mixed substrate comprises only 1% of the total area by substrate type while soft substrate accounts for 91%. The lower slope is essentially unaffected, because, aside from the difficulty of fishing at greater depth, Amendment 19 included a mitigation measure prohibiting bottom trawling in depths greater than 700 fathoms, which for the depth zones used in the synthesis report constitutes the shoreward boundary of the lower slope. Fixed gear effort is more evenly distributed across habitat types; measured relative to habitat area, a larger proportion of the fixed gear effort / habitat area ratio occurs on hard substrate.

Table 3-25. Distribution of fishing effort, 2002-2010, (percent) by gear type and habitat type (substrate x depth zone) summarized from Tables A3a.5, A3a.6, and A3.a7 in NMFS (2013b).

	Depth Zone			
Substrate	**Shelf**	**Upper slope**	**Lower slope**	**All Depths**
Bottom Trawl				
Hard	0.3%	1.5%	0.0%	1.8%
Mixed	0.2%	1.9%	0.0%	2.1%
Soft	37.0%	59.0%	0.1%	96.1%
All Substrates	**37.6%**	**62.4%**	**0.1%**	**100.0%**
Midwater Trawl				
Hard	0.2%	3.1%	0.0%	3.3%
Mixed	1.2%	5.5%	0.0%	6.8%
Soft	12.6%	76.7%	0.6%	89.9%
All Substrates	**14.1%**	**85.2%**	**0.7%**	**100.0%**
Fixed Gear				
Hard	9.3%	6.5%	0.5%	16.3%
Mixed	3.4%	5.7%	0.5%	9.6%
Soft	19.0%	55.0%	0.1%	74.1%
All Substrates	**31.7%**	**67.3%**	**1.1%**	**100.0%**

Table 3-26. Relative fishing impact metric by gear type and habitat type derived from Table 2.1 (distribution of habitat types) and Tables A3a.5, A3a.6, and A3.a7 in NMFS (2013b).

	Depth Zone		
Substrate	**Shelf**	**Upper slope**	**Lower slope**
Bottom Trawl			
Hard	2.9%	7.3%	<0.1%
Mixed	6.0%	43.5%	0%
Soft	21.2%	18.9%	<0.1%
Midwater Trawl			
Hard	0.9%	7.1%	<0.1%
Mixed	15.3%	61.5%	0%
Soft	3.4%	11.6%	<0.1%
Fixed Gear			
Hard	23.0%	8.7%	0.4%
Mixed	24.0%	36.2%	*
Soft	3.0%	4.8%	<0.1%

*Fixed gear fishing events are reported for lower slope mixed substrate while the area of this habitat type is reported as zero. Therefore, fixed gear fishing effort in that habitat type is excluded from the calculation.

As noted above, landings data sugests that groundfish trawl vessels are using midwater trawl gear to target species other than whiting, principally widow and yellowtail rockfish. This fishery would likely have impacts similar to the midwater trawl fishery for Pacific whiting except that it may occur in different times and areas. A final rule is expected in 2014 to reduce chafing gear restrictions on the codends of midwater trawl nets. (The codend is a baglike apparatus at the terminus of the net where the fish collect. It has a “zipper” mechanism to allow it to be detached or opened to retrieve the fish once the net has been brought aboard the vessel.) Chafing gear protects the codend; in the case of midwater gear this is more relevant to when the codend is pulled up the stern ramp of the vessel rather than contact with the seafloor. The EA associated with this rulemaking (PFMC and NMFS 2013) describes potential impacts of the gear modification including habitat impacts of the gear. In summary, because of the way midwater trawl nets are designed, harvesters try to avoid bottom contact.

3.3.2 Non-Fishing Impacts

Adverse effects from activities other than fishing are not part of the proposed action but contribute to cumulative effects (see Section 4.15). Appendix D to the Groundfish FMP incorporates a 2003 report prepared by NMFS cataloging the types of activities affecting groundfish EFH. Activities identified in the appendix include those onshore, such as non-point and point source discharge of pollutants and coastal construction, and those in the marine environment including dredging, dredge spoil disposal, and marine mining. Section 4.4 in the synthesis report (NMFS 2013b) updates information on non-fishing impacts based on spatially explicit data compiled by Halpern, et al. (2008). The main findings of the analysis are that these impacts are more intense in nearshore areas. Offshore impacts are more intense in the northern portion of the fishery management area compared to the southern area.

3.3.3 EFH Mitigation Measures

3.3.3.1 Gear Restrictions

Amendment 19 made permanent an existing prohibition on the use of bottom trawl gear with footropes larger than eight inches in diameter shoreward of a line approximating the 100 fathom depth contour, as described in Section 6.6.1.1 of the Groundfish FMP. These footrope restrictions were originally implemented to discourage trawling in areas where bycatch of overfished rockfish species are more abundant. Because these are generally areas of rocky habitat the prohibition also had an important mitigation effect for EFH. Amendment 19 also implemented prohibitions on dredge and beam trawl gear, because of their adverse impact on groundfish EFH.

Amendment 20 ("trawl rationalization") established the individual fishing quota (IFQ) program for trawl-endorsed groundfish limited access permit holders. The program allows these permit holders to use any legal groundfish gear. As a consequence, since implementation in 2011, a portion of landings have been made with fixed gear.[27] (See section 3.7.2.2 for more information.) In 2011-2012 fixed gear landings in the IFQ fishery accounted for about 40% of total landings by weight and 21% of trips measured by counting fish tickets, excluding trips targeting whiting. Although these measures do not correlate directly with fishing effort, they do suggest that some trawl effort has been substituted by fixed gear effort, and fixed gear has less adverse impacts on groundfish EFH (for example as measured by recovery time, shown in Table 3-24). Estimated recovery times for fixed gear interactions with hard substrate are shorter than for bottom trawl, even comparing recovery from trawl on soft substrate to fixed gear on hard substrate. Thus, even though rocky habitat is more accessible by fixed gear compared to trawl, the net effect of such gear switching is likely beneficial.

3.3.3.2 Time/Area Fishing Restrictions

As part of Amendment 19, 34 areas were closed to bottom trawl gear and 16 areas were closed to bottom contact commercial fishing gear other than demersal seine gear. (Section 6.8.5 in the Groundfish FMP enumerates these areas.) A bottom trawl footprint closure, covering all areas deeper than 700 fathoms, was also instituted (described in FMP section 6.8.6). These closures are designed specifically to mitigate the adverse impacts of fishing on EFH.

Marine protected areas (MPAs) may mitigate adverse impacts of fishing, although these areas may be established with a broader set of objectives. As noted in Groundfish FMP section 6.8.7, the closed areas implemented by Amendment 19 meet the definition for MPAs established by EO 13158. The Amendment 19 EIS (NMFS 2005) catalogued extant MPAs at that time. Although most MPAs have been established by states in state waters, there are also five Federal National Marine Sanctuaries on the west coast that meet the MPA definition. Table 3-27 summarizes data from the National MPA Center's MPA Inventory on the areas under MPA management off the west coast by government level and type of restriction. NMFS is shown separately from other Federal agencies, because the EFH closures account for a large proportion of the total area. Excluding closed areas implemented by NMFS, commercial fishing is prohibited in 3% of the remaining areas and fishing is restricted in 36%. Recreational fishing gear, which is predominantly hook-and-line, has negligible adverse impacts on EFH.

[27] Note that vessels using fixed gear in the shorebased IFQ program are subject to the non-trawl RCAs.

Table 3-27. West coast MPA area (sq. km.) summarized by fishing restrictions. Source: National MPA Center, March 2013 MPA Inventory, http: //marineprotectedareas.noaa.gov/dataanalysis/mpainventory/.

	NMFS	Other Federal	State	Local	Partnership	Total

Total	386,991.9	33,640.0	6,663.0	0.1	79.8	427,374.8

The Council and NMFS have also implemented Groundfish Conservation Areas (GCAs) to prevent commercial and, in some cases, recreational vessels from targeting groundfish in areas where catch of overfished groundfish species is likely to be high. These areas do not have EFH mitigation as an objective, nor are they considered MPAs (and are not included in the MPA Inventory described above). However, as an ancillary effect they do mitigate the adverse effects on EFH by prohibiting fishing within their boundaries. The GCAs include two Cowcod Conservation Areas (CCAs) off Southern California and Rockfish Conservation Areas (RCAs) designated for specified gear types. The CCAs have had the same boundaries since they were implemented in 2001. Trawl RCA boundaries change periodically during the year and annually since first implemented in September 2003 (see Table 3-28). Changes in RCA configurations and the recovery times for constituent habitat types are a consideration in defining the environmental baseline. See Section 4.2 for a description of this management measure as implemented during the 2015-2016 biennial period.

Table 3-28. Limited entry trawl RCA depth boundaries by year and month, 2002-2012, including inseason changes.

[m]The "modified" depth" line is modified to exclude certain petrale sole areas from the RCA.
[a]Selective flatfish trawl required shoreward of the RCA north of 40 10
[z]Additional closure 0-10fm around Farallon Islands

In April 2013 the Council recommended changing the trawl RCA boundaries north of 40°10'. N. lat. (near Cape Mendocino, California) to 100 and 150 fathoms from the current configuration, which varies somewhat during the year by has a maximum extent of 75 to 200 fathoms. Although such changes are usually considered an "inseason action" that allows an abbreviated rulemaking process, in this case NMFS determined that more detailed analysis and a full (notice and comment) rulemaking was required. A major factor in making this determination was the that the Council's recommendation that would open fishing grounds that had been off limits for a long enough time so that they may have recovered from impacts caused by bottom trawl gear (based on the estimates shown in Table 3-24). NMFS provided a draft EA to the Council at its September 2013 meeting (see Agenda Item G.6.b) at which time the Council reaffirmed their previous recommendation.

NMFS published a final rule on April 17, 2014 (79 FR 21639) implementing a modification of the Council proposal and made the final EA available (NMFS 2014b). The EA evaluated the Council recommendation and the NMFS modification. The change implemented by NMFS retains a seaward boundary of 200 fathoms between 40°10'. N. lat. and 45°46'. N. lat. (Cape Falcon, Oregon) but otherwise implements the Council's recommendation.[28] The rationale for this modification is that "this area has been largely closed to groundfish bottom trawling since 2004" (79 FR 21641) allowing EFH in this area to recover from the adverse impacts of fishing. Furthermore, opening this area could impair the Council's ongoing review of EFH, discussed above, because "some of the groundfish EFH proposals that may be considered by the Council during its review include proposals for new EFH conservation areas within the portion of the RCA that has essentially been closed to groundfish bottom trawling year-round since 2004" (79 FR 21641). Any change to this portion of the RCA should therefore not occur until the review process is complete and any new conservation areas implemented. Finally, NMFS notes that "this area may currently have greater conservation value than portions of the actual 'core' RCA" between 100 and 150 fathoms. Although this core area has been continuously closed to bottom trawl since September 2002, pink shrimp trawl gear has been allowed in this area (along with a few other activities, such as NMFS trawl surveys, which also occur in other depth zones). Pink shrimp trawling occurs shallower than 150 fathoms and thus not in the 150-200 fathom area proposed to be opened.

NMFS states that the Council did not "sufficiently acknowledge or contribute additional analysis to minimize the potential for adverse impacts on the identified area as compared to other recommended areas, and did not provide sufficient rationale when they made their initial recommendation…" (April 17, 2014 letter from William W. Stelle, Jr., Regional Administrator, to Dorothy Lowman, Pacific Council Chair). NMFS explains that the Council needs to consider the MSA's requirement to "minimize to the extent practicable adverse effects" to EFH as part of a fishery management plan (MSA Sec. 303(a)(7)). To do so, the Council needs to demonstrate that the economic impact is "substantial enough" to outweigh potential adverse impacts to EFH. This evaluation standard is based on the description of practicability in Federal regulations at 50 CFR 600.815(a)(2)(iii): "…Councils should consider the nature and extent of the adverse effect on EFH and the long and short-term costs and benefits of potential management measures to EFH, associated fisheries, and the nation, consistent with National Standard 7" ("Conservation and management measures shall, where practicable, minimize costs and avoid unnecessary duplication").[29]

[28] From November through February a modified 200 fathom line is implemented, which has "cutouts" to allow access to areas productive for Petrale sole catch.
[29] "Practicable" has a narrower definition the "practical." Something is practical if it is useful or convenient while practicable means doable or feasible. A time machine would be very practical but not practicable.

These findings by NMFS have implications for evaluating Council recommendations for changes to RCA boundaries in the context of considering "routine" management measures. Even though the trawl RCA boundaries have been changed frequently in the past (see Table 4-6 in NMFS 2014b) in cases where this management measure has allowed areas of EFH to recover from the adverse effects of fishing, sufficient rationale is expected to demonstrate that the benefits of an RCA change outweigh the adverse effects of potentially subjecting a recovered area to renewed adverse effects. As discussed in the NMFS EA (NMFS 2014b), fishing activity is by no means spatially uniform. By the same token, both past adverse effects and future effects resulting from a proposal will vary within a large area such as the 150-200 fathom zone that NMFS concluded should not be opened. Depending on available data, analyses should take this into account. Past efforts have not generally taken into account the mitigation effects of RCAs at such a discrete level. For example, maps of fishing effort in the EFH Phase 2 report do not display RCA boundaries (see, for example, http://efh-catalog.coas.oregonstate.edu/platesK/).

3.3.3.3 Fishing Effort

Section 7.4 in the Groundfish FMP identifies reductions in fishing effort as another way to reduce adverse impacts. The assumption is that reduced fishing effort correlates with a decline in the frequency and extent of gear contact with benthic habitat constituting groundfish EFH. Section 7.4 cites various extant measures to limit capacity, "loosely defined as the number, size, and configuration of vessels participating in a fishery." These include state and Federal license limitation programs ("limited entry"), an industry/government permit and vessel buyback program for Federal trawl-endorsed permits implemented in 2003, and the trawl rationalization program, which implemented IFQ management in the shoreside trawl fishery and co-op management in the at-sea whiting fishery. Past Groundfish Harvest Specification EISs and the Amendment 20 EIS describe these programs in detail.

Table 3-29 shows annual counts of vessels landing at least one pound of groundfish by gear type. Coastwide, fixed gear vessel counts have varied between 889 and 744 with a slight downward trend; trawl vessel counts show a clear downward trend from a high of 206 in 2003 to a low of 85 in 2012. A big drop can be seen between 2003 and 2004 when the vessel buyback occurred and after 2010 when the IFQ program was implemented.

Table 3-29. Counts by year, state and coastwide, and gear type of vessels landing at least 1 lb of groundfish (PacFIN vdrfd 1/29/14 using dahl_sector field for groundfish trawl and fixed gear sectors not including at-sea whiting).

State	Gear Type	2003	2004	2005	2006	2007	2008	2009	2010	2011	2012
Washington	Fixed Gear	108	89	112	124	91	68	74	70	84	63
	Trawl	28	19	23	27	25	19	16	19	14	12

	Trawl	90	51	52	51	51	45	40	39	24	25
Coastwide	Fixed Gear	883	779	796	889	837	780	793	744	821	775
	Trawl	206	130	132	132	133	129	125	117	87	85

Figure 3-22 shows measures of fishing effort based on trawl tow set and retrieval times and locations recorded in trawl logbooks and available from the logbook subsystem on PacFIN.[30] Tow time (panel a)

[30] No filters were applied on the records aside from the dates; thus, the totals cover a range of trawl strategies. Using the PacFIN_target field in the lbk_tow table, the most common targets (based on number of tows) are Dover sole, thornyheads, and sablefish individually or combined ("DTS") accounting for 43% of tows in the time period. The second most common strategy, at 15%, is "nearshore mixed," which covers vessels fishing shoreward of the RCA mainly for flatfish. Pacific whiting accounts for 8% of tows and 8% of tows had no target identified. California halibut and ridgeback prawn, nongroundfish targets, accounted for 4% of tows.

declined substantially over the time period while tow distance (panel b) shows more fluctuation with a decline in 2011 and 2012. However, CPUE, measured by dividing landings by tow distance, increased after implementation of IFQ management in 2011. It should be noted that some of the inter-annual variations could be based on incomplete reporting in logbooks.[31]

3.4 California Current Ecosystem

In April 2013 the Council adopted the Pacific Coast Fishery Ecosystem Plan for the U.S. Portion of the California Current Large Marine Ecosystem (PFMC 2013, Pacific Coast FEP). This document contains a wealth of information on characteristics of the California Current large marine ecosystem (CCE) where the groundfish fishery occurs and the types of impacts fisheries and other anthropogenic activities have on ecosystem dynamics and marine habitat. Information from this document is incorporated by reference. Previous EISs prepared for biennial harvest specifications also contain information about this ecosystem and fishery effects. The information in sections 3.4.1 and 3.4.2 is based on sections 3.1 and 3.2 in the Pacific Coast FEP.

[31] An analysis of the tow location fields found that about 2% of the 205,328 tows made in the 2003-2012 period had a zero or null value in one or more of the location fields. An additional 2% or 3,683 records had the same values in the set and retrieval position fields resulting in a zero distance. Non reporting (zero or null values) declined steadily over the period from 4.6% in 2003 to 0.04% in 2012.

Chapter 4 in the Pacific Coast FEP (PFMC 2013) describes the effects of human activities and climate on the CCE. Information from the FEP and other sources is summarized here to characterize impacts of groundfish and other fisheries (section 3.4.3), other human activities (section 3.4.4), and climate (section 3.4.5).

Coincident with the development of the Pacific Coast FEP, NMFS has been developing the Integrated Ecosystem Assessment (IEA) of the CCE. This is "a formal synthesis and quantitative analysis of all relevant scientific information—biological, geological, physical, economic, and social—in relation to ecosystem management objectives" (Levin and Schwing 2011b). The IEA includes the development of a suite of indicators used to periodically report on the status of the CCE. Section 3.4.7 summarizes recent IEA reports on CCE status using these indicators.

For the purpose of impact analysis, ecosystem is characterized as the web of trophic relationships within the system and how system structure (relative abundance of constituent organisms) may change in response to human activities, specifically fisheries targeting groundfish.[32]

3.4.1 Overview of California Current Large Marine Ecosystem

The California Current Ecosystem (CCE) is composed of a major eastern boundary current, the California Current, which is dominated by strong coastal upwelling, and is characterized by fluctuations in physical conditions and productivity over multiple time scales (Mann and Lazier 1996; Parrish, *et al.* 1981). Food webs in these types of ecosystems tend to be structured around coastal pelagic species that exhibit boom-bust cycles over decadal time scales (Bakun 1996; Checkley and Barth 2009; Fréon, *et al.* 2009). By contrast, the top trophic levels of such ecosystems are often dominated by highly migratory species such as salmon, tuna, billfish and marine mammals, whose dynamics may be partially or wholly driven by processes in entirely different ecosystems, even different hemispheres. Ecosystems analogous to the CCE include other shelf and coastal systems, such as the currents off the western coasts of South America and Spain.

The CCE contains a diverse array of species, most of which make a relatively modest contribution to the energy flow within the ecosystem (Field and Francis 2006). Because the flow of energy is more of a "food web" than a "food chain," the species of the CCE do not neatly divide into clearly delineated trophic levels (for example, an organism may eat a prey item and also eat items that its prey eats), except at the highest and lowest levels. Most CCE species do not occupy a single trophic level and may occupy multiple trophic levels, particularly when considering changes that occur over the course of their life as they change both their size and feeding preferences.

3.4.2 Role of Groundfish in the California Current Ecosystem

3.4.2.1 Groundfish Trophic Role

Groundfish occupy a range of trophic niches and habitats, but most species are considered to be at either middle or higher trophic levels. The following characterization is based on diet analysis contained in Dufault, et al. (2009):

- High trophic level carnivorous fish feeding largely on juvenile and adult stages of other groundfish, as well as forage fishes, mesopelagic fishes, and squid. These include large flatfish (arrowtooth flounder, Pacific halibut, petrale sole); deep, large rockfish (shortspine thornyhead,

[32] The *trophic level* of an organism is the position it occupies in a food chain or food web. Trophic relationships express the pattern of consumption and by extension the flow of energy through the system.

darkblotched rockfish, rougheye rockfish); sablefish; skates and rays (longnose, Bering, and big skates); soupfin shark; deep, small rockfish (longspine thornyhead, sharpchin and splitnose rockfish); Pacific grenadier; and lingcod (Dufault, *et al.* 2009, feeding guild H).

- Mid to high trophic level fish that feed on zooplankton. These include Pacific hake (whiting); canary rockfish; shallow large rockfish (redstripe, yelloweye, black and blue rockfish); mid-water rockfish (widow rockfish, Pacific Ocean perch, yellowtail rockfish); spiny dogfish; and spotted ratfish (Dufault, *et al.* 2009, feeding guilds B and G).
- Mid to high trophic level fish that feed on benthic invertebrates. These include shallow, small rockfish (rosethorn, greenstriped, and pygmy rockfish); English sole; and small flatfish (Dover sole, rex sole, Pacific sanddab, and deepsea sole) (Dufault, *et al.* 2009, feeding guild E).

Many species may have more varied diets than indicated by the above. For example, many species, including most rockfish, are omnivorous mid-trophic level predators that may be piscivorous at times but also feed on krill, gelatinous zooplankton, benthic invertebrates, and other prey. Pacific hake (whiting), the most abundant groundfish in the CCE, have different food habits at different life stages. Younger, smaller hake feed primarily on euphausiids and shrimps, switching to an increasing proportion of herring, anchovies and other fishes (as well as other hake) as they reach 45-55 cm length, and are almost exclusively piscivorous by 70-80 cm.

3.4.2.2 Trophic Role of Non-Groundfish Species that are the Prey of or that Prey upon Groundfish Species

This group of species is necessarily more broad and diverse than the groundfish species discussed above. Species discussed in this section include the higher trophic level piscivores that prey upon groundfish at varying life stages and sizes. Species discussed in this section also include the lower trophic level species that are eaten by groundfish. Some of these species are protected under the MMPA or ESA, some are themselves target species for other fisheries, and some are neither targeted nor protected. Most of these species are only directly affected by the fisheries when they are taken as bycatch with groundfish gear. Otherwise, these species are primarily indirectly affected by how each of the alternatives either increases or decreases their prey availability or the abundance of their predators.

Using the Dufault, et al. (2009) characterizations in combination with the large species group distinctions discussed in section 3.2 of the Pacific Coast FEP, non-groundfish species directly or indirectly affected by this action may be described by their trophic levels and prey groups. Dufault and colleagues did not have adequate data to include all CCE species in their diet analysis, particularly at the lower trophic levels. These broad species groups are intended to generally characterize the trophic roles of non-groundfish species that prey upon or that are the prey of groundfish:

- Piscivorous Marine Mammals and Seabirds: Includes all CCE pinnipeds, small cetaceans, and all toothed whales except Transient Killer Whales, which feed on other mammals. Includes all CCE seabirds, which are primarily or exclusively piscivorous (Dufault et al. 2009, feeding guilds C and I).
- High trophic level carnivorous fish: Chinook salmon, albacore, giant grenadier, and large demersal sharks (sixgill and sleeper sharks) (Dufault, et al. 2009, feeding guilds C, H, and I).
- Lower trophic level fish and invertebrates that are preyed upon by groundfish: northern anchovy; Pacific sardine; Pacific herring; shrimps (crangon and mysid); large zooplankton (euphausiids, chaetognaths, pelagic shrimp, pelagic polychaetes, pasiphaeids); deposit feeders (amphipods, isopods, small crustacean, snails, ghost shrimp, sea cucumbers, worms, sea slugs, barnacles, solenogaster, hermit crabs); megazoobenthos (Dungeness crab, tanner crab, spiny lobster, pinchbug crabs, red rock crab, graceful rock crab, spider crabs, grooved tanner crab, bairdi,

scarlet king crab, and California king crab); deep vertical migrators (myctophids, blue lanternfish, California headlightfish, Pacific viperfish, northern lampfish, garnet lanternfish); miscellaneous nearshore fish (white croaker, sculpin, midshipman); and other benthic filter feeders (geoduck, barnacles, clams, scallops, and other bivalves, urchins).

3.4.3 Effects of Managing to B_{MSY}

Fishery removals affect the relative abundance of different species. Broadly speaking, stock-specific management seeks to maximize yield based on compensatory growth resulting from reducing the population size (see Rose, *et al.* 2001, for an overview of compensatory processes). Notionally, yield is maximized (MSY) when stock size is about half its unfished size (although for individual stocks B_{MSY} may be somewhat larger or smaller relative to unfished size). Since fisheries catch a relatively small range of the different organisms within the CCE, this activity is likely to change the relative abundance of species. This results in a direct effect on the fished population (evaluated in other sections of this EIS mainly based on single species stock assessments).

The Pacific Coast FEP section 3.3.2 describes species interactions, which may be altered by changes in relative population size due to fishing. For example, reduction in a predator population may allow a prey population to increase. Density dependent interactions such as competition for habitat or parasitism may decrease as the population of one or both interacting species declines. These effects are proximate to the change in abundance but indirectly related to the action (fishing). Thus, while from an ecosystem perspective they may be considered direct effects, relative to the action evaluated in this EIS they are indirect. From this perspective the effects of fishing on the ecosystem are principally indirect and cumulative.

A specific example of an indirect effect is described in the Pacific Coast FEP. On unfished rocky reefs the abundance of larger, piscivorous rockfish species is higher relative to more abundant, smaller, fast-growing, and early-maturing rockfish species (Jagielo, *et al.* 2003; Yoklavich, *et al.* 2002; Yoklavich, *et al.* 2000). In contrast, the larger piscivorous rockfish are relatively less abundant on heavily fished rocky reefs. This may be due to a "depensatory" effect resulting from the smaller fish eating the larvae of the larger fish (MacCall 2002; Walters and Kitchell 2001). When the local population of the larger predatory fish is reduced the population of smaller fish increases and they in turn consume a greater share of the large fishes' spawning output, limiting recruitment to the adult population. This demonstrates the structuring role of higher trophic level organisms that can be disrupted by fishing. Empirical and theoretical research suggests such effects could be more widespread in terms of species and habitats (Baskett, *et al.* 2006; Levin, *et al.* 2006).

Kaplan, et al. (2012) used the Atlantis ecosystem simulation model to assess the cumulative effects of fisheries on the CCE.[33] This work provides the most specific assessment of the effects of fishing by different fleets on various ecosystem components and indicators of ecosystem health. Their simulation starts with initial conditions approximating 2005-2008 and then projects forward 50 years. The authors compared the effects of 20 individual fishing fleets operating in the CCE and the combined effects of these fleets, using the unfished ecosystem (as determined by the model) as a comparative benchmark and "status quo" defined as all fisheries operating at constant fishing mortality rates derived from recent catches.

Four major fleets were identified based on total catch and economic importance. In the simulations these fleets have large negative impacts on target and bycatch species (measured in terms of the change from status quo) along with indirect effects on other species:

[33] See Horne, et al. (2010) for a description of the structure and parameterization of the CCE implementation.

- Bottom trawl indirectly affected small shallow rockfish and zooplankton (krill), with their populations increasing due to the reduction in predation. [34]
- Fixed gear indirectly affected mesozooplankton (copepods), which increased.
- Hake (whiting) trawl indirectly resulted in increases of small planktivores, large piscivorous flatfish, Dover sole, shortbelly rockfish, and shrimp.
- In contrast to the other three fleets, CPS purse seine had indirect effects throughout the food web. Reduction in squid (cephalopods) abundance resulted in a large increase in krill and microzooplankton. This in turn led to increases in planktivores such as salmon and myctophids (vertical migrators). Although CPS purse seine also targets small and large planktivores (sardine and mackerel), small planktivores showed almost no response to fishing while large planktivore biomass increased 2.65 times from the status quo level (all fisheries operating), because of increases in large zooplankton.

The authors also evaluate impacts in terms of nine ecosystem attributes based on those used for the CCE Integrated Ecosystem Assessment project (Levin and Schwing 2011a) and the IndiSeas project (Shin, *et al.* 2010). Fleets with the strongest negative impact on these attributes (based on the average value of the attribute scores for each fleet) were those described above plus pink shrimp trawl (with hake trawl considered separately in its at-sea and shoreside components because of differences in total removals). Figure 3-23, adapted from Kaplan, et al. (2012) Figure 3, shows the effect of these fleets on selected ecosystem attributes (chosen because they varied by ≥5% from status quo). As noted above, all fleets show negative impacts as measured by the targeted biomass/catch indicator. This attribute received the largest negative score among the nine attributes for all the major fleets shown in Figure 3-23 except for bottom trawl and non-nearshore fixed gear. For those two fleets the piscivore indicator received the largest negative score. Bottom trawl and CPS purse seine had notable (>5%) positive effects on the krill attribute and bottom trawl was the only fleet to have a negative effect on the healthy assessed stocks attribute.

[34] The model uses 60 functional groups, some containing single species and others species aggregations.

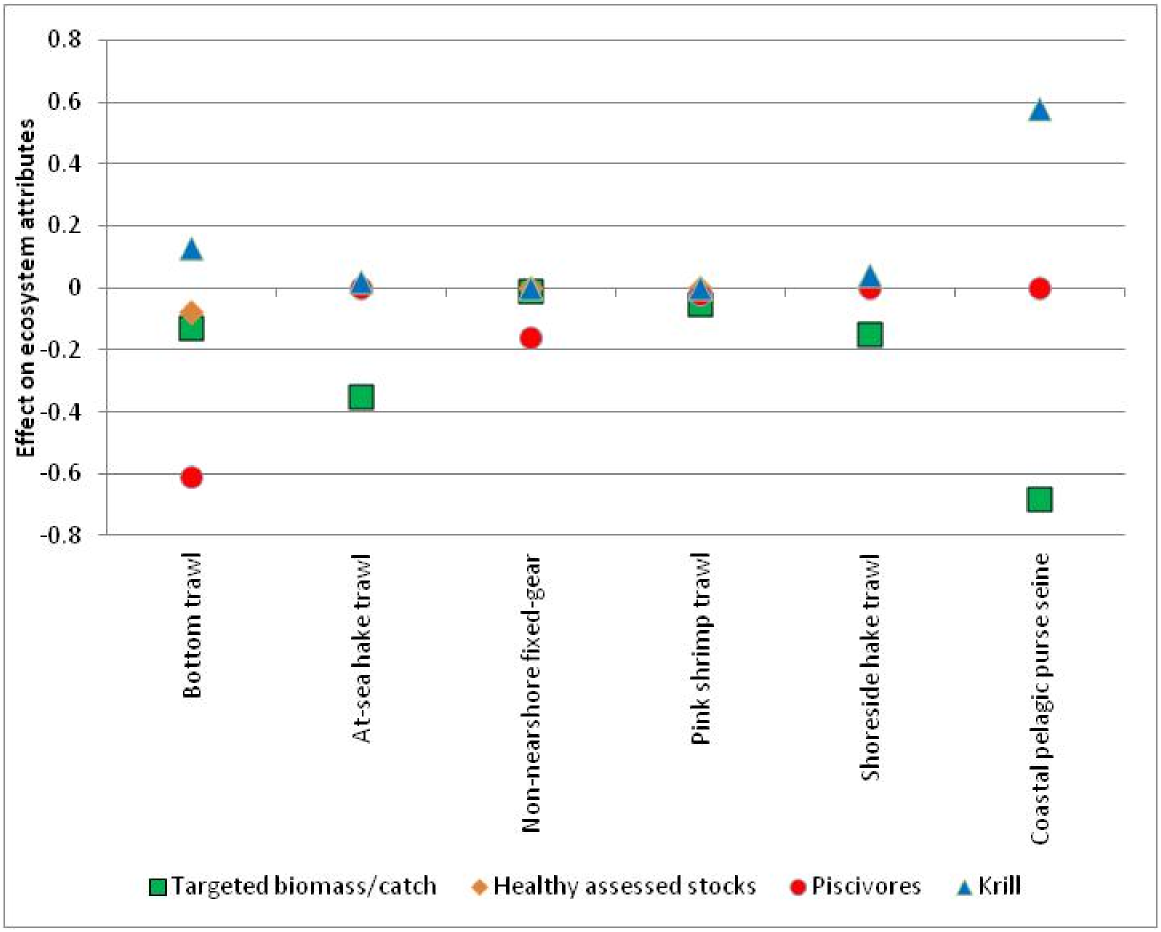

Figure 3-23. Effect of six individual fleets on four ecosystem attributes. Adapted from Kaplan et al. (2012), Figure 3. Values represent the proportional difference between a simulation at status quo (all fleets operating) and one in which the specified fleet was omitted. Zero represents no change from status quo.

Figure 3-24 represents the effect on ecosystem attributes of successively adding fleets, with fleets ordered by their negative impacts from most to least. (This figure appears in the supplement to Kaplan et al. with attribute scores rescaled between 1, the value in the unfished state, and 0, the lowest recorded value for the attribute. It is based on the data presented in Figure 4 in the paper.) The major fleets discussed above account for most of the impacts. Targeted biomass, mean trophic level of the catch, healthy assessed stocks, and piscivores show increasing negative impacts with the addition of fleets (with the exception of a slight increase in mean trophic level as additional fleets are added after the major fleets). Forage fish increases with each fleet addition and krill increases once CPS purse seine is added, which results in a corresponding increase in total biomass.

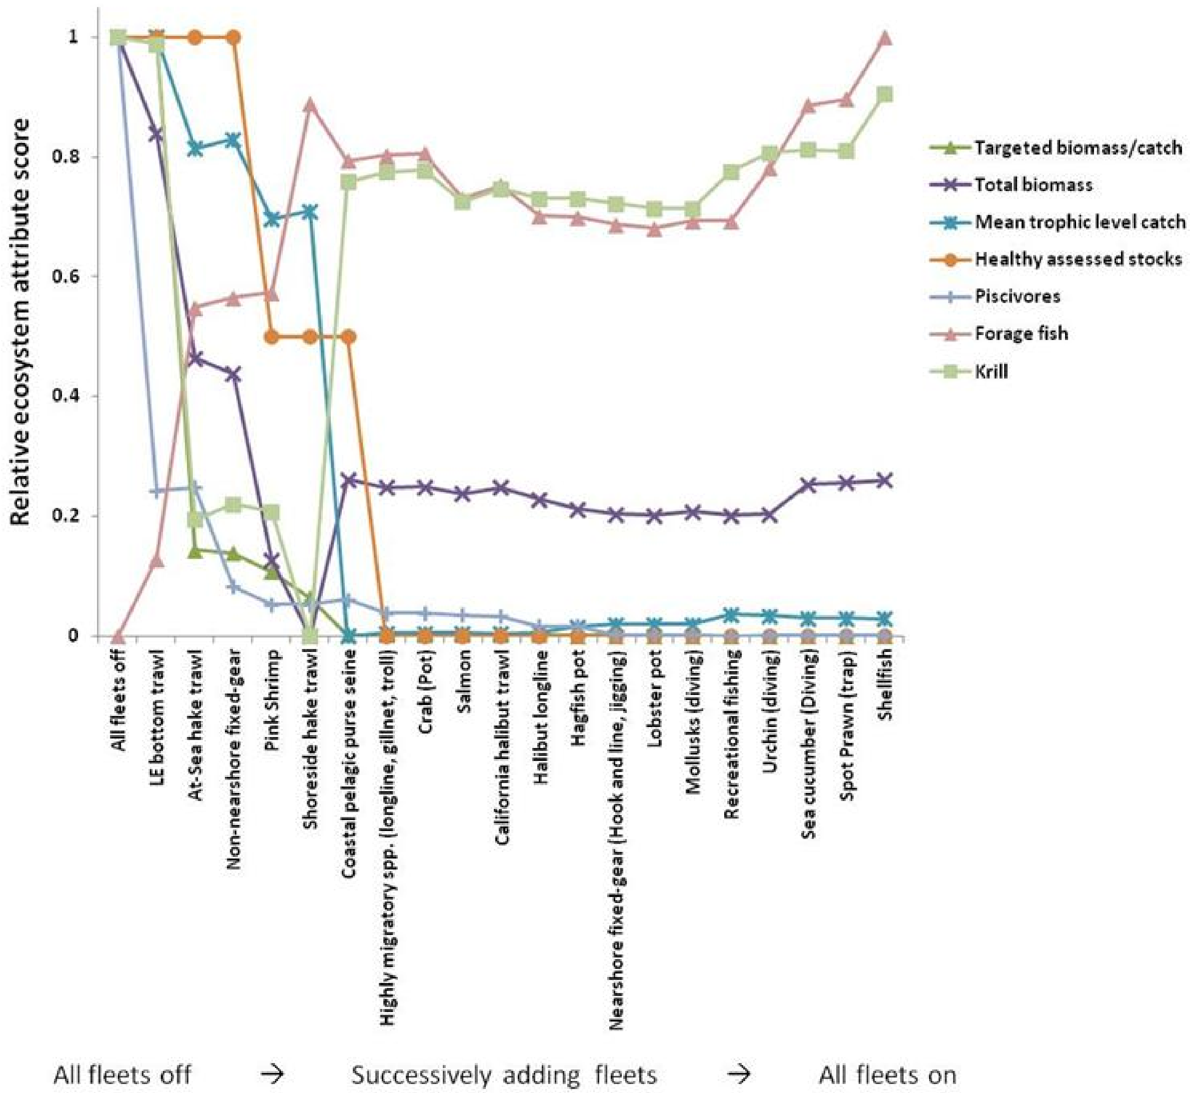

Figure 3-24. Ecosystem attributes, as affected by the successive addition of each fleet, ordered from the fleet with the strongest to the weakest negative impacts. Symbols indicate the value of each individual attribute. Ecosystem attribute scores (y-axis) are rescaled to be between 0 and 1. Values of 1 represent the highest or unfished value of the attribute, and 0 represents the lowest value of the attribute calculated for any combination of fleets. Source: Figure S1 in the Supplement to Kaplan, et al. (2012).

Finally, the authors evaluated the effects of fleet interactions. First, the effect of combinations of four major fleets (bottom trawl, fixed gear, hake fleets, and CPS purse seine) on change in the biomass of 60 functional species groups defined in the Atlantis CCE model was evaluated. Second, the effect of these fleet combinations on the ecosystem attributes discussed above was evaluated. These collective effects could be additive, the combined effect on an ecosystem attribute equals the sum of the effects measured by the attribute values for each of the individual fleets; positive, the combined effect results in an attribute value greater than the sum of individual effects; or negative, the combined effect results in an attribute value less than the sum of the individual effects.

Combined effects were by and large additive (equal to the sum of the individual fleet effects); 93% of interactions in the case of changes in the biomass of functional groups. Only 2% of the interactions were negative (biomass lower than the sum of biomasses resulting from modeling the individual fleets). For the ecosystem attributes there were no negative interactions and only two attributes involved in positive interactions.

In addition to the effects of changes in the relative abundance due to fishing, the age and size structure of fish populations may be altered (see pp. 138-139 in PFMC 2013). If sufficient information is available, size/age truncation (because fishing subjects larger/older fish to relatively higher mortality) can be accounted for in stock assessments. But indirect effects may remain unquantified. Larger/older females are not only relatively more fecund but produce more robust eggs, contributing to greater larval survival and potentially increased recruitment to the adult (or fished) population. Population behaviors, such as migration, may be affected by changes in population structure. Size/age truncation along with reduced population size may also reduce overall resiliency of the population to environmental shocks.

3.4.4 Activities other than Fishing

Other human activities, aside from fishing, that affect the CCE mostly occur in estuarine and freshwater habitats (the latter affecting the productivity of salmon and other species that enter streams and rivers to reproduce).[35]

The Annual State of the California Current Ecosystem Report presented to the Council in November 2012 (Agenda Item K.3.a, Supplemental Attachment 1, November 2012) identified several indicators to track non-fishing ecosystem impacts:

- Benthic structures, such as oil rigs, wells and associated anchorings, modifies or destroys marine habitat. But these structures also provide colonization sites for marine organisms and attract structure-associated fishes and invertebrates. Related activities can disturb epifaunal communities, which may provide feeding or shelter habitat for species of interest. Benthic organisms, especially prey species, may recolonize disturbed areas, but this may not occur if the composition of the substrate is drastically changed or if facilities are left in place after production ends.
- Commercial shipping vessels transit through the CCE, concentrating in approaches to major ports (e.g., Seattle, Los Angeles). Increased trade volume may lead to more ship strikes of protected species and underwater noise, which can affect fish spawning, migration, communication, and recruitment.
- Terrestrial runoff (nonpoint source pollution) increases nutrients in freshwater and estuarine areas. Excessive nutrients accelerate eutrophication, which produces a wide range of other impacts on aquatic ecosystems and fisheries, including: algae blooms; declines in aquatic vegetation; mass mortality of fish and invertebrates through poor water quality (e.g., via oxygen depletion and elevated ammonia levels); and alterations in long-term natural community dynamics.

The 2014 Annual State of the California Ecosystem Report (NMFS 2014a) reports that

> Non-fisheries human activities in the CCE that may negatively impact the ecosystem are generally low with stable or declining trends. Nutrient input is an exception: it is elevated, although it shows a declining trend at the coast-wide scale. (page 1)

[35] Human-induced climate change is discussed in the following section.

3.4.5 System Forcing and Climate Change

Climate encompasses a variety of physical forces affecting the input of energy into the CCE and the distribution of energy and material through the system through water movement. Climate change is a long-term trend over a time scale that makes it essentially unidirectional in relation to human activities.

The CCE is characterized by fluctuations in physical conditions over multiple time scales. This physical forcing in the CCE is correlated with changes in species' biomass and population productivity. Particular system states favor some species over others. Many of these fluctuations have been shown to be a consequence of larger scale changes in ocean conditions throughout the Pacific, including changes observed in the tropics (the El Niño/Southern Oscillation, ENSO) and changes in the north Pacific and subarctic (indexed by the Pacific Decadal Oscillation, PDO, and the North Pacific Gyre Oscillation, NGPO). ENSO is a higher-frequency inter-annual phenomenon while the PDO/NGPO fluctuate at lower frequency (years or decades). At a gross level there are two system states—a warm water regime and a cold water regime—precipitated by cyclical climate events and characterized by these and other indices and signals.

During the ENSO warm water phase (El Niño conditions):

> primary and secondary productivity (e.g., phytoplankton and zooplankton) [is lower], often leading to reduced recruitment of many groundfish species, lower survival of salmon smolts, and distributional shifts (to the north, as well as onshore from offshore waters) of most migratory species (such as coastal pelagics, HMS, and Pacific hake). For example market squid abundance (and catches) often decline to very low levels during El Niño events, and rebound strongly during strong La Niña [cold water] events. Highly migratory species such as tunas and billfish are also more frequently available to fishermen during El Niño events, and recreational fishing effort often shifts to those and other warm water targets, and away from rockfish and other cooler water species, particularly in the waters of the Southern California Bight. (Agenda Item K.3.a, Supplemental Attachment 1, November 2012)

The PDO is characterized by longer warm and cold regimes. Productivity is higher during cold regimes and lower during warm regimes. However, the PDO does not predict sea surface temperatures in the CCE as reliably as in more northerly regions. Thus while the cold regime is associated with higher productivity, the PDO does not explain all of the observed variability in the productivity of a population. The NGPO is linked to changes in salinity and chlorophyll-a (a remotely sensed indicator of primary production).

The introduction to section 4.5 in the Pacific Coast FEP provides the following concise assessment of the effects of climate change in the CCE:

> Climate change is expected to lead to substantial changes in physical characteristics and dynamics within the marine environment, with complex and interacting impacts to marine populations, fisheries and other ecosystem services (Doney, *et al.* 2012; Harley, *et al.* 2006; Scavia, *et al.* 2002). Three major aspects of future climate change that will have direct effects on the CCE are: ocean temperature, pH (acidity versus alkalinity) of ocean surface waters, and deep-water oxygen. Globally by 2050, ocean temperatures on average are expected to rise at least 1°C (by the most conservative estimates in IPCC 2007), while at the same time, ocean pH in the upper 500m has steadily been decreasing (becoming more acidic, aka "ocean acidification") at a rate of approximately -0.0017 pH per year (Byrne, *et al.* 2010). On a more regional basis within the CCE, deep-water oxygen levels have shown a steady and relatively rapid decrease since the mid 1980's (Bograd, *et al.* 2008; McClatchie, *et al.* 2010). These three factors are linked: ocean

> temperature affects ocean pH, ocean temperature and deep water oxygen levels both can be controlled by large scale circulation patterns, and primary production can affect both oxygen and pH (Gilly, *et al.* 2013). All three factors show long-term trends and decadal-scale variance similar to changes in the PDO (Mantua, *et al.* 1997) and North Pacific Gyre Oscillation (Di Lorenzo, *et al.* 2008) climate signals. In addition to these three large-scale aspects of climate change, some more immediate and localized aspects of climate change observed in coastal marine ecosystem include: intensification of upwelling (Bakun 1990; Schwing and Mendelssohn 1997), changes in phenology (phenology refers to the relationship between a periodic biological phenomenon and climatic conditions) (Bograd, *et al.* 2009), and changes in the frequency and intensity of existing interannual and interdecadal climate patterns (Yeh, *et al.* 2009, CCIEA 2012, and references therein). Substantial changes in weather and precipitation patterns will also affect snowpack, stream flow, river temperatures and other aspects of freshwater habitat, with tremendous real and potential consequences to the future productivity and sustainability of anadromous resources such as salmon (Crozier, *et al.* 2008; Mantua and Francis 2004). (page 165)

The following summarizes the effects of these changes as described in the Pacific Coast FEP (pages 165-169):

- Increasing water temperature is likely to cause northward shifts in the distribution of marine species in the CCE. This may result in the disappearance of some species from localities. Overall primary productivity decline due to thermal stratification of ocean waters is also likely. Seasonal upwelling of deep ocean waters, an important contributor to local productivity, could be disrupted.
- The ocean has absorbed about a quarter of the atmospheric carbon dioxide resulting from human activity; because of basic chemical processes this is making ocean waters more acidic (lowering the pH). Acidification is expected to affect shell-producing organisms, making it more difficult to form them, because shell material is composed of calcium carbonate, which degrades more quickly as water becomes more acidic. Although ongoing impacts resulting from acidification are highly uncertain (partly because the capacity for organisms to adapt to changes in pH is not fully understood), a major concern is that pH change could reduce plankton production, which, as the base of the food chain, would have far-reaching effects.
- Through various processes, dissolved oxygen levels in CCE waters could decline due to warming. This could increase the extent and duration of so-called “dead zones”: areas where upwelling of deeper low-dissolved-oxygen water moves into the continental shelf benthic zone. A decline in dissolved oxygen in deep ocean waters could result in more extensive effects. This has a direct effect, killing organisms trapped in the dead zone; over the long term particular species’ available habitat could be reduced.
- Intensified upwelling is a documented result of warming (Bakun 1990; Schwing and Mendelssohn 1997) due to stronger alongshore winds. Since upwelled water is more nutrient rich, this could lead to greater productivity.
- Changes in the frequency and duration of major climate patterns discussed above (ENSO, PDO, NGPO) may be linked to warming.
- The timing of seasonal upwelling seems to be changing with an earlier start in the south and later start in north as observed in the past 5 years (Bjorkstedt, *et al.* 2012). Along with changes in climate patterns, this could prompt changes in the phenology of physical and biological events (phenology refers to the relationship between a periodic biological phenomenon and climatic conditions).

3.4.6 Implications of Climate Change for Groundfish Fisheries

Water temperature, current patterns, water chemistry, and other features contributing to system dynamics, such as coastal upwelling, are likely to be affected by climate change. These physical factors in turn will affect biological components, such as physiology, productivity, and species distribution. On a global scale Cheung, et al. (2013) demonstrate that the mean temperature of the catch (MTC) has increased across 52 large marine ecosystems. MTC reflects species' temperature preferences, changing distribution, and resulting changes in catch composition. At a local scale Pinskey and Fogarty (2012) examined the interaction between the northward shift in target species distribution and fishery response in the Northeast U.S. In most cases MTC increased while the mean latitude of catch was slower to shift compared to the mean latitude of species (based on fishery independent data for four target species). Both operational factors (e.g., home port preference) and the regulatory environment contributed to slowing the geographic shift in fishing compared to target species distribution.

Focusing on the Northeast Pacific, Ainsworth, et al. (2011) used five Ecopath with Ecosim (EwE) foodweb models representing regions from Southeast Alaska to the Northern California Current to model climate change in terms of primary production, zooplankton community structure, range shifts, ocean acidification, and deoxygenation. Landings and biomass for composite species groups and ecosystem-scale biodiversity were used as response variables. Cumulatively, landings fell by 77% to 85% depending on the strength of climate effect scenario used.

According to Ainsworth, et al. (2011) range shifts as a single factor account for a 54% reduction in fisheries landings and is the dominant aspect of climate change in the analysis. Examined as a single factor it contributed to an increase in biomass but effects varied by functional group. The distribution of pelagic species was most affected while range shift resulted in declines in large piscivorus fish biomass. Range shifts also strongly influence mean trophic level of both catch and the ecosystem. Range shifts is also the only factor that had an appreciable effect on biodiversity.

3.4.7 Baseline Status of the California Current Ecosystem

Andrews, et al. (2011) identified a suite of indicators as part of the development of the CCE IEA. For groundfish, salmon, and green sturgeon indicators focus on population size and structure; for ecosystem health indicators focus on community composition and material and energy flows. Hazen, et al. (2011) summarize five indices or signals used to measure low frequency climate forcing in the CCE. The Council's Ecosystem Plan Development Team provided a summary report on the status of the CCE in 2012 (Agenda Item K.3.a, Supplemental Attachment 1, November 2012) that uses selected indicators identified as part of the IEA (NOAA NMFS 2012). The IEA team provides a report to the Council on the current status of the CCE annually. These reports and indictors are used to briefly characterize the baseline status of the CCE here.

The Council received the most recent Annual State of the California Current Ecosystem Report (NMFS 2014a) at their March 2014 meeting. The Report describes trends in various indices to characterize current CCE conditions, which are briefly summarized below for climate forcing and ecological integrity.

Figure 3-25 (excerpted from the Report) shows trends in the Multivariate ENSO Index (MEI), PDO, and NGPO. The symbols to the right of each graph indicate that there is no recent trend in these indices and the most recent 5-year mean is within one standard deviation of the full mean time series. Between 2010 and 2012 the tropical Pacific moved from La Niña conditions to ENSO-neutral conditions and strong upwelling in 2012 (off Central and Southern California) and 2013 (coastwide) promoted higher productivity. These years recorded some of the highest upwelling anomalies (deviation from the mean for relevant indices) ever recorded.

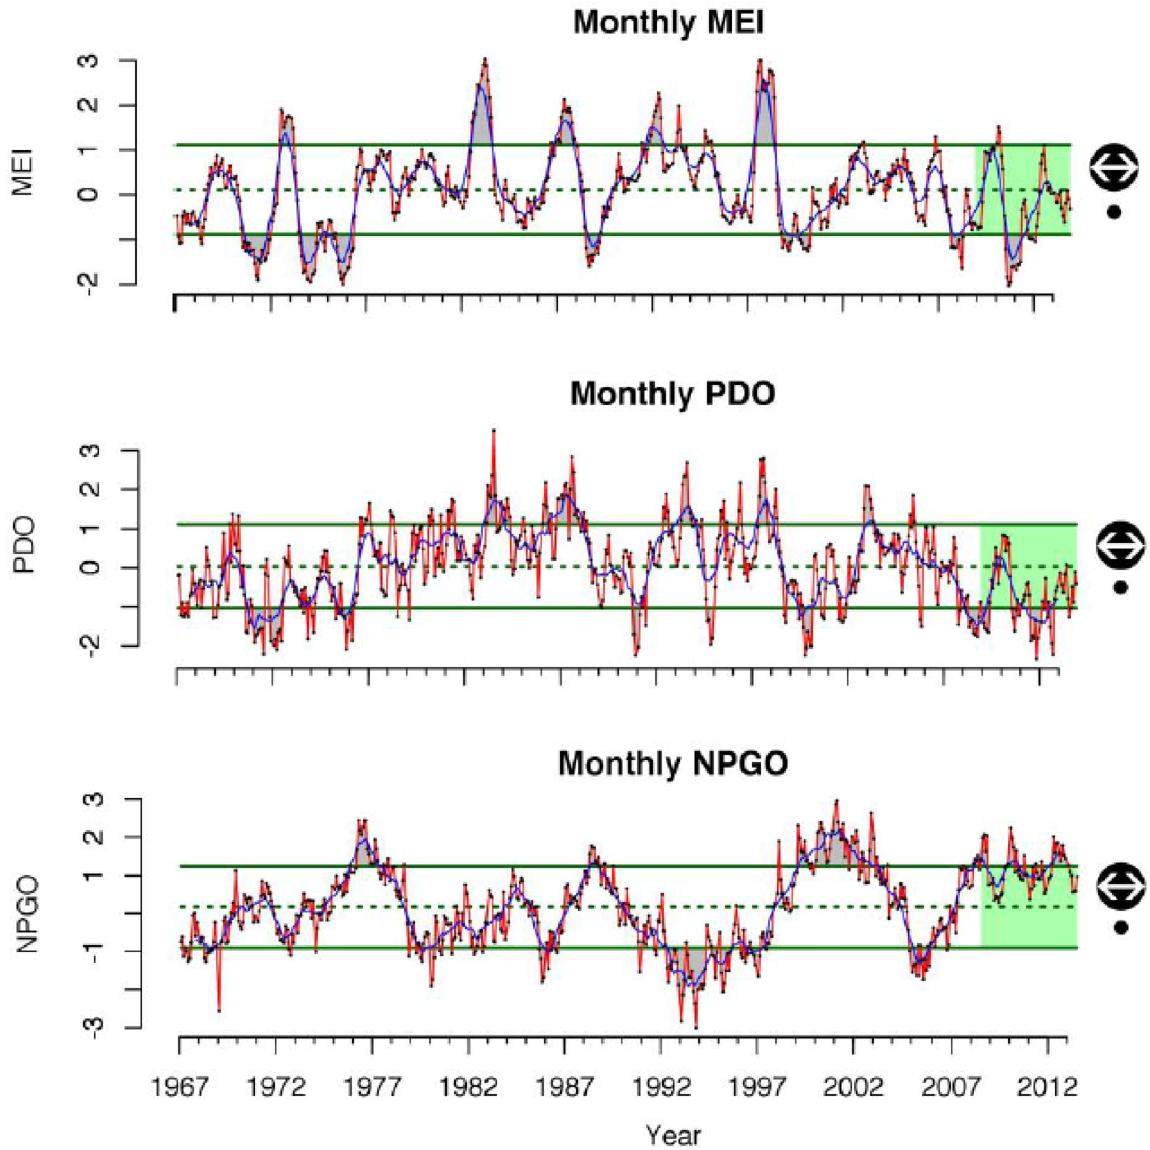

Figure 3-25. Monthly values of basin-scale climate indicators used to assess environmental variability impacts in the California Current ecosystem. The three time series are Multivariate ENSO Index (MEI), Pacific Decadal Oscillation (PDO), and North Pacific Gyre Oscillation (NPGO). The blue line shows the 12-month running average. (Excerpted from NMFS 2014a)

Low dissolved oxygen (DO), a function of upwelling bringing oxygen poor water into coastal waters, is of concern because it can result in the die-off of less mobile organisms (e.g., benthic invertebrates) and habitat compression for pelagic species. Because DO is associated with upwelling low-oxygen (hypoxic) conditions are more common in summer months. While DO levels at monitoring stations showed no trend and were within on standard deviation of the time series mean, the location of these stations may not adequately cataloghypoxic conditions in nearshore waters.

Ocean acidification results from increasing amounts of carbon dioxide absorbed in oceanic waters and can affect marine organisms with calcium carbonate structures. Acidification is measured indirectly by the aragonite saturation with values near or less than 1 indicating acidic conditions for at least two key animals: the larvae of oysters and the pelagic snail *Limacina helicina*. *L. helicina* is an important food source for pink salmon and herring and to a lesser degree for other salmonids. There is no clear temporal trend in aragonite saturation; however, seasonal pulses of acidified water occur off Oregon, which are believed to be of natural origin, caused by the decomposition of organic matter and carbon dioxide release as it sinks toward the seafloor.

The Report presents these indices to characterize ecological integrity:

- Northern copepod biomass anomaly
- Copepod species richness off Washington and Oregon
- Anchovy, sardine, and forage diversity
- Chinook salmon abundance
- Groundfish stock status
- Mean trophic level of west coast groundfishes
- California sea lion pup production

This range of metrics is intended to characterize the relative condition of ecologically important, managed, or protected species assemblages.

Northern copepod species are a valuable source of nutrition for pelagic species and have been relatively more abundant (but without clear trend) in recent years. Copepod species richness negatively correlates with southward transport of sub-Arctic waters, high abundance of lipid-rich northern copepods, and increased growth and survival of some species. As one might expect, this index substantiates conditions indicated by the northern copepod anomaly index. Northern anchovy and sardine along with other larval fish are important components of the forage base. Survey data collected in 2013 off Central CCE show a marked increase in forage, especially young-of-the-year (YOY) rockfish while in the Northern CCE region there has been a decline in forage abundance.

Chinook salmon, aside from their cultural and economic importance, migrate over great distances and are part of both marine and freshwater ecosystems. An index of escapement (adult salmon reaching spawning grounds) for various runs is used to assess condition. Generally, escapement has been near the time series average.

Harvest specifications are, of course, intended to control fishing mortality with respect to stock status so that indicator from the Report is partially a function of the proposed action. Figure 3-26 (excerpted from the 2014 Report) shows a phase or “Kobe” plot to summarize groundfish stock status. The vertical axis shows fishing mortality relative to the ABC (representing a precautionary reduction from the overfishing threshold) while the horizontal axis shows current biomass in proportion to B_{MSY}, the management target. The Report concludes “In general, results suggest that most groundfish populations that have been formally assessed in the CCE are at or above their target biomass levels, and most are at or below half of the total allowable catch or mortality level.” The Report presents an Ecosystem mean trophic level (MTL) index, the weighted average of the trophic levels in a sample, based on the West Coast Bottom Trawl Survey. Ecosystem MTL declined in the aughts but has remained a low but fairly stable level over the past 5 years. Changes in MTL are strongly driven by the abundance of Pacific hake (whiting), spiny dogfish, and sablefish, which are higher trophic level groundfish species. These conditions may be beneficial for other predators such as squid, salmon, tuna, and seabirds.

California sea lion pup production is used as an indicator of the status of upper trophic level species, because sea lions are common throughout the CCE and sensitive to changing conditions. In 2012, pups at the San Miguel Island rookery (a monitoring site) were in poor condition and emaciated animals were stranding on mainland beaches, leading NMFS to declare an Unusual Mortality Event for sea lion pups in

March 2013. Thus, despite robust growth in the California sea lion population overall, the cause of this event is being investigated with an eye towards forage dynamics.

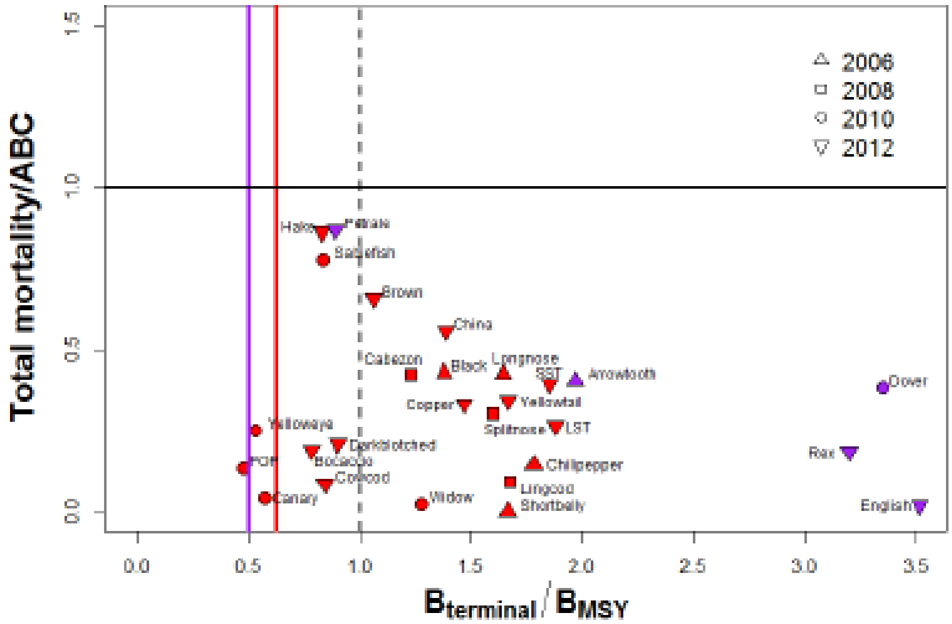

Figure 3-26. Stock status of all California Current groundfish assessed since 2007.
The vertical broken line indicates the target biomass reference point. The vertical solid lines indicate the limit reference point showing an overfished status (red for elasmobranchs, rockfishes, and roundfishes; purple for flatfishes). The horizontal line indicates overfishing threshold wherein total mortality exceeds the allowable biological catch (ABC). Symbols indicate the terminal year of the assessment in which the reference points are determined. (Excerpted from NMFS 2014a)

3.5 Protected Species

The term protected species refers to organisms for which killing, capture, or harm is prohibited under several Federal laws unless authorized. Incidental *take* of these species in the course of their operations may be allowed under provisions of applicable law.[36] The laws, listed below, include procedures to determine whether these impacts are of sufficient magnitude to require regulatory action to reduce the impact. This section describes protected species that may be encountered in groundfish fisheries in the context of actions and standards pursuant to these laws.

3.5.1 Applicable Law

Protected species are species listed under the ESA, the Marine Mammal Protection Act (MMPA), the Migratory Bird Treaty Act (MBTA), and EO 13186. See Chapter 6 for further discussion of these laws.

---

[36] Under the Endangered Species Act take is defined as to harass, harm, pursue, hunt, shoot, wound, kill, trap, capture, or collect, or to attempt to engage in any such conduct. Harm is further defined by regulation to include significant habitat modification or degradation that results in death or injury to listed species by significantly impairing essential behavioral patterns, including breeding, feeding, or sheltering. Take is defined under the Marine Mammal Protection Act as “to harass, hunt, capture, collect, or kill, or attempt to harass, hunt, capture, collect, or kill any marine mammal” (50 CFR 216.4).

- The ESA protects species in danger of extinction "throughout all or a significant part of their range," and mandates the conservation of critical habitat. The ESA defines "species" as a "any subspecies of fish or wildlife or plants, and any distinct population segment of any species of vertebrate fish or wildlife which interbreeds when mature." A species is listed as "endangered" if it is in danger of extinction throughout a significant portion of its range and "threatened" if it is likely to become an endangered species within the foreseeable future throughout all, or a significant part, of its range.
- The MMPA guides marine mammal protection and conservation. Stock assessments are conducted annually for strategic stocks and every three years for non-strategic stocks. "Strategic stocks" are those with a human-caused mortality and injury level that exceeds the potential biological removal level (defined as "the maximum number of animals, not including natural mortalities, that may be removed from a marine mammal stock while allowing that stock to reach or maintain its optimum sustainable population…") Marine mammal populations with an abundance that falls below its optimum sustainable level are listed as "depleted." All marine mammal species are protected under the MMPA, regardless of species or stock listings under the ESA.
- The MBTA implements treaties and conventions between the U.S. and Canada, Japan, Mexico, and the former Soviet Union for the protection of migratory birds. Under the MBTA, it is unlawful to take, kill, or possess migratory birds. In addition, Executive Order 13186, *Responsibilities of Federal Agencies to Protect Migratory Birds*, directs Federal agencies to negotiate Memoranda of Understanding with the United States Fish and Wildlife Service (USFWS) that would obligate agencies to evaluate the impact on migratory birds as part of any NEPA process. NMFS has entered in such an MOU. All migratory seabird species are protected under the MBTA and EO 13186, regardless of species or stock listings under the ESA.

3.5.2 Species Listed Under the Endangered Species Act

Past groundfish harvest specifications EISs (PFMC and NMFS 2011; PFMC and NMFS 2012) have described ESA-listed species that may be encountered in the Pacific Coast groundfish fishery. ESA-listed species are described in the sections below based on the consultation history for the groundfish fishery.

On December 7, 2012, NMFS released a biological opinion on the effects of the continued operation of the fishery (NMFS 2012a) on certain marine species. On November 21, 2012, the U.S. Fish and Wildlife Service released a biological opinion covering the effects of the continued operation of the fishery on short-tailed albatross, marbled murrelet, California least tern, southern sea otter, and bull trout (USFWS 2012). The most recent consultation on the effects of the fishery on ESA-listed salmonids was completed in 2006 and remains current (NMFS 2006).[37] The information in these documents is incorporated by reference.

3.5.2.1 Salmonids Covered by the 2006 Biological Opinion

Table 3-10 in the 2013-2014 groundfish harvest specifications FEIS (PFMC and NMFS 2011; PFMC and NMFS 2012) lists species and evolutionarily significant units occurring in the action area and is reproduced below (Table 3-30). The FEIS also describes the evolutionary significant units (ESUs) potentially affected by the proposed action.

[37] On January 22, 2013, NMFS requested the reinitiation of the biological opinion for listed salmonids to address changes in the fishery, including the trawl rationalization program and the emerging midwater trawl fishery. This consultation is expected to be completed in late 2014 and include the effects of the biennial management process in its scope. At this time the biological opinion for this consultation is not available and its conclusions cannot be described in this EIS.

Table 3-30 Endangered Species Act Status of West Coast salmon and steelhead (highlighted ESUs are those subject to the 2006 consultation).

Species/	ESU	Status
Salmon		
Sockeye	Snake rive	Endangered
	Ozette Lake	Threatened
Chinook	**Sacramento River Winter-run**	Endangered
	Upper Columbia River Spring-run	Endangered
	Snake River Spring/Summer -run	Threatened
	Snake River Fall-run	Threatened
	Puget Sound	Threatened
	Lower Columbia River	Threatened
	Upper Willamette River	Threatened
	Central Valley Spring-run	Threatened
	California Coastal	Threatened
	Central Valley Fall and Late Fall-run	Species of Concern
Coho	Central California Coast	Endangered
	Southern Oregon/Northern California	Threatened
	Lower Columbia River	Threatened
	Oregon Coast	Threatened
	Puget Sound/Strait of Georgia	Species of Concern
Chum	Hood Canal Summer-run	Threatened
	Columbia River	Threatened
Steelhead	Southern California	Endangered
	Upper Columbia River	Threatened
	Central California Coast	Threatened
	South Central California Coast	Threatened
	Snake River Basin	Threatened
	Lower Columbia River	Threatened
	California Central Valley	Threatened
	Upper Willamette River	Threatened
	Middle Columbia River	Threatened
	Northern California	Threatened
	Puget Sound	Threatened
	Oregon Coast	Species of Concern

NMFS first consulted under the ESA on the effects of the fishery on listed salmonids in 1990 and reinitiated consultation several times thereafter. The 2006 biological opinion covers certain Chinook salmon ESUs most likely to be affected by the fishery, as listed in Table 3-30.[38] Although other salmon and steelhead species are taken in the fishery, consultations before 2006 determined that the amounts were limited such that further consultation was unnecessary.

The incidental take statement in a 1999 biological opinion identified an expected level of take of 11,000 Chinook salmon per year for the Pacific whiting fishery and 9,000 Chinook salmon for the bottom trawl fishery. Bycatch of other salmonid species is modest so no specified threshold was established for any other salmonid. Consultation under Section 7 of the ESA was reinitiated in 2006, because take exceeded

[38] "An ESU, or evolutionarily significant unit, is a Pacific salmon population or group of populations that is substantially reproductively isolated from other conspecific populations and that represents an important component of the evolutionary legacy of the species. The ESU policy (56 FR 58612) for Pacific salmon defines the criteria for identifying a Pacific salmon population as a distinct population segment (DPS), which can be listed under the ESA." Source: http://www.nmfs.noaa.gov/pr/glossary.htm#esu

these estimates in 2005 for the whiting fishery and two out of three years between 2002 and 2004 for the bottom trawl fishery. This resulted in the 2006 supplemental biological opinion evaluating whether additional mitigation measures were needed to prevent the activity from jeopardizing the continued existence of the species (NMFS 2006).

Section 5.1 in the 2007-2008 groundfish harvest specifications FEIS includes a detailed summary of the information in the 2006 biological opinion. Since 2009 the West Coast Groundfish Observer Program has released reports estimating salmonid bycatch in groundfish fisheries. Table 3-31 and Table 3-32 provide summary information from the most recent report available (Al-Humadh, *et al.* 2012). Chinook salmon accounted for 91% of all salmonids caught in groundfish fisheries, 2002-2010. And the Pacific whiting (hake) fishery sectors caught two-thirds of the total. Table 3-33 shows annual catches by fishery sector of Chinook salmon and all other salmonids grouped. (As indicated in Table 3-33 pink salmon comprise almost two-thirds of the non-Chinook salmonids caught in the groundfish fishery.) Since 2005 when Chinook salmon bycatch in the whiting fisheries exceeded the 11,000 fish threshold to reinitiate the ESA Section 7 consultation neither of the incidental take statement levels in the 2006 biological opinion have been exceeded. The 2006 biological opinion expressed NMFS's intent to establish regulatory authority to close nearshore areas to fishing by the shoreside whiting sector as part of the 2007-2008 groundfish biennial harvest specifications. The at-sea whiting fishery employs voluntary measures to minimize Chinook salmon bycatch. Chinook salmon bycatch has fallen substantially over the 2002-2010 period as shown in Figure 3-27 and was 23% of the 2002 value in 2010.

As noted in the 2006 biological opinion, the Pacific whiting fishery sectors are fully observed, either through onboard observers in the at-sea sectors or dockside monitoring in shoreside sectors, where full retention of catch is required.[39] Other groundfish fishery sectors have not had full observer coverage and bycatch must be estimated. However, the groundfish bottom trawl fishery (or shorebased IFQ fishery) has been fully observed beginning in 2010. As noted in the WCGOP report (Al-Humadh, *et al.* 2012), "Point estimates of bycatch fluctuate due to a number of non-biological factors, including annual variation in observer coverage rates, fishing behavior, and various physical characteristics. Currently, it is not possible to fully quantify uncertainty for bycatch estimates presented in this report, as measures of the variability associated with all data sources are not available." And, as noted in the 2006 biological opinion, the distribution of salmon bycatch in the groundfish trawl fishery is highly skewed; a few tows account for a large fraction of total bycatch. With full observer coverage in the bottom trawl / shorebased IFQ fishery since 2011, uncertainty in bycatch estimates has been reduced. (Almost all bycatch occurs in trawl fisheries.)

Figure 3-28 shows Chinook salmon bycatch in the groundfish bottom trawl fishery by geographic area, season, and depth range for the years 2006-2010 based on data in Table 1 in Al-Humadh et al. (Al-Humadh, *et al.*). (That report presents bycatch estimates by strata that combine these dimensions.) Table 3-33 presents the average bycatch rates for these dimensions for the same period. The highest bycatch rates are for North of Cape Falcon, the winter season, and inside 125 fathoms. Looking at total estimated Chinook salmon bycatch for 2006-2010 by the strata presented in Al-Humadh et al. (2012), the following strata ranked in the top quartile and are listed in ascending order of bycatch here:

- Cape Falcon to Cape Blanco, winter, 125-250 fathoms
- North of Cape Falcon, winter, 125-250 fathoms
- Cape Blanco to Cape Mendocino, winter, 125-250 fathoms
- North of Cape Falcon, winter, 0-125 fathoms
- South of Cape Mendocino, summer, 0-125 fathoms

[39] See Section 3.2.2 for descriptions of the fishery sectors discussed here.

- North of Cape Falcon, summer, 0-125 fathoms

Table 3-31. Summary from Table 5 in Al-Humadh et al. (Al-Humadh, *et al.*) of bycatch by species and fishery sector. (Table 5 caption: Estimated bycatch of salmon (no. of fish) in all U.S. west coast fisheries observed by the West Coast Groundfish Observer Program (WCGOP) and the At-Sea Hake Observer Program (A-SHOP) from 2002-2010, as well as salmon bycatch in shoreside Pacific hake sectors.)

	Non-whiting	Whiting sectors	Total	Percent
Chinook	37,466	51,620	89,086	91%
Chum	51	735	786	1%

South of Cape Mendocino	0.015				

3.5.2.2 Species Covered by the 2012 NMFS Biological Opinion

Section 1.2 in the most recent biological opinion (NMFS 2012a) describes the past ESA Section 7 consultations on the continued operation of the Pacific Coast groundfish fishery.[40] Among other sources, this biological opinion used a biological assessment completed in mid-2012 by NMFS NWR SFD (NMFS 2012b) and a risk assessment drafted by the NMFS NWFSC in early 2012 (NWFSC 2012). Based on this information, and previous interactions observed in the Pacific Coast groundfish fishery, NMFS PRD determined that the fishery is likely to likely to adversely affect the following listed species and critical habitat:

- Eulachon (*Thaleichthys pacificus*)
- Green sturgeon (*Acipenser medirostris*) and their critical habitat
- Humpback whales (*Megaptera novaeangliae*)
- Steller sea lions (*Eumetopias jubatus*)[41]
- Leatherback sea turtles (*Dermochelys coriacea*) and their critical habitat

The following ESA-listed species occur in the fishery management area but NMFS SFD determined that the fishery is not likely to adversely affect them or their critical habitat:

- Green sea turtles (*Chelonia mydas*)
- Olive ridley sea turtles (*Lepidochelys olivacea*)
- Loggerhead sea turtles (*Caretta caretta*)
- Sei whales (*Balaenoptera borealis*)
- North Pacific right whales (*Eubalaena japonica*)
- Blue whales (*Balaenoptera musculus*)
- Fin whales (*Balaenoptera physalus*)
- Sperm whales (*Physter macrocephalus*)
- Southern Resident killer whales (*Orcinus orca*)
- Guadalupe fur seals (*Arctocephalus townsendi*)
- Critical habitat of Steller sea lions.

Section 2.2 in the current biological opinion describes the status of species and critical habitat subject to the consultation. Section 2.11 describes the rationale for reaching a “not likely to adversely affect” determination for the species listed above.

Section 2.1 in the current biological opinion describes the methods used to determine the effects of the Pacific Coast groundfish fishery with respect to two standards found in the ESA: whether the fishery is likely to “jeopardize the continued existence of a listed species” or result in “destruction or adverse modification” of critical habitat. “To jeopardize…” is defined in regulations as “to engage in an action that would be expected, directly or indirectly, to reduce appreciably the likelihood of both the survival and recovery of a listed species in the wild by reducing the reproduction, numbers, or distribution of that species” (50 CFR 402.02). Destruction or adverse modification of critical habitat was evaluated based on

[40] NMFS PRD also consulted on the operation of the fishery for 2012 only (PFMC and NMFS 2011). That biological opinion found effects consistent with those described in the current biological opinion.
[41] The eastern DPS of Stellar sea lions (the population segment occurring in the action area) was removed from the list of threatened species under the ESA on November 4, 2013 (78 FR 66140). Therefore, Federal agencies will no longer need to consult with NMFS under Section 7 of the ESA regarding actions that may affect the eastern DPS of Stellar sea lions. Protections under the MMPA would continue, however.

provisions in the ESA as interpreted by the agency.[42] These methods were applied to eulachon, green sturgeon (and critical habitat), humpback whales, Stellar sea lions, and leatherback sea turtles (and critical habitat), the species and critical habitat where preliminary findings suggested that the proposed action is likely to have an adverse effect.

Based on the analysis, NMFS PRD documented the effects of continued operation of the Pacific Coast groundfish fishery on species and habitat. These finding are summarized below.

Eulachon – Southern DPS (Threatened)

Eulachon are found in the eastern north Pacific Ocean from northern California to southwest Alaska and into the southeastern Bering Sea. The eulachon southern DPS is defined from the Mad River in northern California, north to the Skeena River in British Columbia. Eulachon are an anadromous fish. Adults migrate from the ocean to freshwater creeks and rivers where they spawn from late winter through early summer. The offspring hatch and migrate back to the ocean to forage until maturity. Once juvenile eulachon enter the ocean, they move from shallow nearshore areas to deeper areas over the continental shelf. There is little information available about eulachon movements in nearshore marine areas and the open ocean.

Because catches are not concentrated in a particular area or population components, the fishery is not expected to "have a measureable effect on the species' structure or diversity." The action affects species abundance and potentially population productivity. Productivity is a concern, because of the substantial decline in spawner abundance over the last 20 years. The cumulative effect, as characterized in the biological opinion, of climate change and modification of freshwater habitat contribute to this decline. Based on conservative assumptions about species abundance, the fishery is expected to "take 0.0052 percent of the estimated eulachon population and overall [account for] less than 0.1 percent of the total bycatch from U.S. fisheries." In conclusion "The level of take expected for the proposed action is therefore so small that we do not anticipate it would have any notably deleterious effect on the species, nor would it add materially to the ongoing effects already occurring in the action area."

NMFS recently considered whether the 2012 opinion should be reconsidered for eulachon in light of new information from the 2011 fishery and the proposed chafing gear modifications and determined that information about the eulachon bycatch in 2011 and chafing gear regulations does not change the extent of effects of the action, or any other basis to require reinitiation of the December 7, 2012 biological opinion. Therefore, the December 7, 2012 biological opinion meets the requirements of section 7(a)(2) of the ESA and implementing regulations at 50 CFR 402 and no further consultation was required.

Green Sturgeon – Southern DPS (Threatened)

The North American green sturgeon southern DPS is defined as coastal and Central Valley populations, south of the Eel River in California. Green sturgeon critical habitat is designated from 0 to 60 fm (74 FR 52300)

The biological opinion's assessment focuses on the Southern DPS of green sturgeon. The Pacific Coast groundfish fishery is not likely to further restrict the geographic distribution of green sturgeon along the coast or extent of spawning habitat in freshwater rivers. Southern DPS green sturgeon are at moderate to high risk of extinction because of the low estimated abundance of adults, and historically fisheries have

[42] Memorandum from William T. Hogarth to Regional Administrators, Office of Protected Resources, NMFS (Application of the "Destruction or Adverse Modification" Standard Under Section 7(a)(2) of the Endangered Species Act) (November 7, 2005).

been the primary source of mortality. Based on available data, fisheries other than the federally-managed groundfish fishery are estimated to incidentally capture 1,219 to 1,512 Southern DPS green sturgeon (adults and subadults) per year. This represents 20 to 69 percent of the total subadult and adult population, depending on the estimate of abundance used (2,188-6,250 subadults and adults, combined). It is estimated that fisheries for which no data are available account for the annual removal of an additional 1 to 4 percent of the population. Based on population models, these fisheries (excluding the Federal groundfish fishery) may be affecting the continued survival and recovery of Southern DPS green sturgeon. Green sturgeon take in the Pacific Coast groundfish fishery, when considered within the context of these sources of mortality and other cumulative effects, results in a comparatively small increase in the mortality imposed on the subadult and adult population. The majority of the green sturgeon incidentally caught in the fishery are expected to be released alive and to survive. In most years mortality due to the groundfish fishery would be low (0.03 to 0.09 percent of the total subadult and adult population). In the worst case (not expected to occur more than 2 years within a period of 9 years), mortalities would account for 0.1 to 0.3 percent of the total subadult and adult population. In summary, the lack of substantial impacts on the Southern DPS green sturgeon based on the low expected sublethal and lethal impacts of the fishery supports the conclusion that the proposed fishing will not appreciably reduce the likelihood of survival and recovery of the species.

With respect to critical habitat for green sturgeon, prey resources within the action area may be affected by non-point source and point source discharges, oil spills, dredged material disposal activities, renewable ocean energy installations, low oxygen “dead zones,” bottom-trawl fishing activities, and climate change. These activities and factors may also affect water quality and migratory corridors for green sturgeon. Although use of bottom-trawl gear may disturb benthic habitats and remove prey resources, existing gear restrictions provide a measure of protection for green sturgeon critical habitat. In addition, the expected effects of the proposed fishing on the prey resources are likely to be low given the opportunistic feeding behavior of green sturgeon and the likely dynamic nature of benthic prey. The low expected impacts to green sturgeon prey resources supports the conclusion that the Pacific Coast groundfish fishery is not likely to reduce the value of designated critical habitat for the conservation of Southern DPS green sturgeon.

Humpback Whale (Endangered)

Humpback whales are found in all oceans of the world. For management under the MMPA, stocks of humpback whales are defined based on feeding areas, with the whales feeding off California, Oregon, and Washington currently considered one stock. The most recent population estimate of humpback whales in the North Pacific Ocean is 21,808 (CV=0.04). The most recent estimated abundance of the CA/OR/WA feeding stock is 2,043 whales (CV=0.10), with a minimum population estimate of 1,878 whales. The maximum expected rate of annual increase for the species as a whole ranges from an estimated 7.3 to 8.6 percent, with a maximum plausible rate of 11.8 percent annually. North Pacific populations as a whole grew by an estimated 6.8 percent annually over the period from 1966 to 2006. The annual growth rate for the CA/OR/WA feeding stock is estimated at 7.5 percent. The Pacific Coast groundfish fishery affects the CA/OR/WA feeding stock, within the context of effects to the globally-listed species. Occurrence of the CA/OR/WA feeding stock overlaps the most with the spatial extent of the groundfish fixed gear fishery. There is uncertainty about the number of past entanglements attributed to fixed gear fishing, but based on precautionary assumptions NMFS PRD estimated that an average of 0.89 humpback whales may be injured or killed by the Pacific Coast groundfish fishery, annually.

The MMPA identifies the concept of potential biological removal (PBR) in assessing the effects of mortality on marine mammal stocks (see further discussion below). Based on the portion of the stock occurring in the west coast EEZ at any given time, PBR within the action area is estimated at 11.3 whales. On average, NMFS PRD estimated that 7.19 human-caused serious injuries or mortalities of CA/OR/WA humpback whales are likely to occur annually. This annual average is below the current PBR. Based on past annual variability, the average estimate likely will be exceeded in some years, up to a maximum of 16.25 injuries or mortalities in a single year. However, on average human-caused humpback injuries and mortalities will be below PBR allowing the stock to grow toward its optimum sustainable population level.

NMFS PRD also evaluated effects with respect to the potential change in the rate of population increase. It concluded that the population growth rate will decrease by approximately 0.04 percent due to groundfish fishing and by approximately 0.37 percent from all human sources, including groundfish fishing. Based on food-web modeling, trophic effects of the Pacific Coast groundfish fishery will likely be minor and in fact may positively affect the abundance of krill (prey of humpback whales) through removal of predators.

Because of uncertainty in the estimates of fishery-caused serious injury/mortality two other methods for estimating the maximum mortality rate potentially imposed by all west coast fisheries were examined (NWFSC 2012). These methods result in estimates of 61 and 88 whales killed annually. The biological opinion discusses reasons to conclude these estimates are implausibly high.

NMFS PRD concluded that impacts of the Pacific Coast groundfish fishery, when combined with other human sources of serious injury/mortality, are not likely to substantially reduce the population abundance or the growth trend of the stock. The lack of substantial impacts on the CA/OR/WA humpback whale stock combined with the increasing population trend for this listed entity supports the conclusion that the proposed fishing will not reduce appreciably the likelihood of both survival and recovery of the species in the wild by reducing the reproduction, numbers, or distribution.

The incidental take statement (ITS) for humpback whales in the current biological opinion was conditional on the issuance of a permit to authorize the incidental, but not intentional, taking of individuals pursuant to MMPA section 101(a)(5)(E). This permit was issued on September 4, 2013 (78 FR 54553) based on a Negligible Impact Determination (NID) as required by the MMPA. Therefore, the ITS for CA/OR/WA humpback whale stock is now valid.

Pursuant to the MMPA the WA/OR/CA sablefish pot fishery is listed as a Category II fishery, because of interaction with humpback whales. (See Section 3.5.3 for an explanation of these MMPA fishery categorizations.)

Steller Sea Lions (Delisted)

The eastern DPS of Steller sea lions is a single population that ranges from southeast Alaska to southern California, including inland waters of Washington State and British Columbia. The total population estimate is a range between 58,334 and 72,223 sea lions, with a minimum population estimate of 52,847 sea lions. The population has increased at a rate of approximately 3.1 percent in recent decades. Methods, as described above for humpback whales, were used to assess the effects of the Pacific Coast groundfish fishery on the eastern DPS of Steller sea lions.

NMFS PRD estimated that on average 13.88 Steller sea lions would be seriously injured or killed incidental to groundfish fishing, annually. When added together, NMFS PRD estimated a total of 60.55 sea lions seriously injured or killed annually from fisheries bycatch, including fishing in the Pacific Coast groundfish fishery. When combined with the estimate from Allen and Angliss (Allen and Angliss 2012) for other sources of injury or mortality of 15.2, the total is 75.75 sea lions per year. The PBR for this DPS is 2,378 sea lions. The estimated number of all human-caused serious injuries and mortalities anticipated to occur in future years from all sources, including the proposed fishing, is approximately 3.19

percent of the PBR. Based on food-web modeling, NFMS PRD also concluded that trophic effects of the Pacific Coast groundfish fishery will be minor. The serious injury/mortality estimate results in a decrease in the population growth rate of about 0.03 percent due to groundfish fishing and by approximately 0.14 percent from all human sources including the groundfish fishery.

Based on the evaluation, NFMS PRD concluded that impacts of groundfish fishing, in addition to other human sources, are not likely to substantially reduce the population abundance or trend. The lack of substantial impacts on the eastern DPS combined with the increasing population trend for this listed entity supports the conclusion that the groundfish fishery will not reduce appreciably the likelihood of both survival and recovery of the species in the wild by reducing the reproduction, numbers, or distribution.

Subsequent to conclusion of this consultation NMFS removed the eastern DPS of Stellar sea lions from the list of threatened and endangered species under the authority of the ESA. This delisting became effective December 4, 2013 (78 FR 66140). Section 3.5.3 discusses past and present impacts of the groundfish fishery on non-ESA listed marine mammals. However, since the 2012 NMFS biological opinion contains information relevant to evaluating impacts, the eastern DPS of Stellar sea lions is discussed here.

Leatherback Sea Turtles (Endangered)

Leatherback sea turtles face a variety of threats depending on the region in which they occur; they are widely distributed across the oceans of the world. Identified threats in the marine environment include direct harvest, debris entanglement and ingestion, fisheries bycatch, and boat collisions, among other threats. In the Pacific Ocean, nesting aggregations occur in the eastern Pacific (primarily in Mexico and Costa Rica) and in the western Pacific (primarily Indonesia, the Solomon Islands, and Papua New Guinea). Leatherbacks that occur within the ESA action area are most likely to originate from nesting aggregations of the western Pacific. The abundance of leatherback sea turtles is currently unknown; however, the most recent global estimate for nesting females is 34,500 turtles. The trend for the western Pacific subpopulation has been declining over the past four decades; however, estimates of breeding females slightly increased from 2000 to 2007 (2,700 to 4,500 turtles in 2007 compared to 1,775 to 1,900 turtles in 2000), although this is likely due to additional nesting sites that were not previously factored into the estimate (Dutton, *et al.* 2007). Given recent monitoring over the last few years, however, the trend continues to decline (C. Fahy, pers. comm., NOAA Fisheries SWR, July 18, 2012, as cited in NMFS 2012a). NMFS PRD concluded that 0.38 turtles would be killed annually due to groundfish fishing and a total of 5.82 turtles killed due to all activities occurring in the ESA action area. Given that the anticipated mortality attributed to the proposed fishing is less than one turtle per year on average and no more than one turtle in a single year, the groundfish fishery is likely to result in a very small increase to the level of mortality already authorized for the species both inside and outside of the action area.

In addition to the direct and indirect effects to the species, the proposed fishing is likely to result in some bycatch of jellyfish, which will reduce prey availability in critical habitat. However, based on the general predicted pattern of food-web modeling, it is unlikely that the conservation value of critical habitat will be substantially impacted by food-web interactions caused by the groundfish fishery.

NMFS PRD concluded that groundfish fishing contributes a very small additional impact to those of other human sources. It also concluded that the conservation value of critical habitat will not be substantially impacted. In conclusion, effects of the groundfish fishery, when combined with effects of other human sources in the action area, are not anticipated to result in an appreciable change to the population abundance or trend. A lack of an appreciable change in population abundance or trend supports the conclusion that the Pacific Coast groundfish fishery will not appreciably reduce the likelihood of both survival and recovery of the species in the wild by reducing the reproduction, numbers, or distribution.

Likewise, a lack of substantial impact on the conservation value of critical habitat supports the conclusion that the proposed fishing will not adversely modify critical habitat.

Incidental Take Statement

The current biological opinion contains an incidental take statement, or ITS. Incidental take is defined as take that is incidental to, and not the purpose of, the carrying out of an otherwise lawful activity. The ITS is a formal statement of the estimated take of a listed species within a defined time period and is connected to provisions in the ESA that allow takes incidental to an otherwise lawful agency action, if the action is performed in compliance with the terms and conditions of this incidental take statement. Based on analysis in the biological opinion, take at or below this level has been determined not to cause "jeopardy." Actual takes that exceed the level identified in the ITS are a basis for reinitiating the section 7 consultation, which entails a new analysis of "jeopardy" or adverse habitat modification and new terms and conditions for the continuation of the proposed action. The ITS in the current biological opinion is summarized below.

- Incidental take of **southern DPS eulachon** occurs as a result of bycatch and handling in the fisheries, or mortalities resulting from encounter with fishing gear, as a consequence of fishing activity. Take of eulachon in the proposed action is expected to not exceed 1,004 fish per year. This take is expected to occur in the limited groundfish bottom trawl (shorebased IFQ) and at-sea hake (Pacific whiting) fisheries.
- Under the proposed action, incidental take of **Southern DPS green sturgeon** because of bycatch and handling in the fishery is not expected to exceed 28 fish per year; however, incidental take could be higher in some years. Therefore, this take statement allows for incidental take of up to 86 Southern DPS green sturgeon per year in no more than 2 years within a period of 9 consecutive years.
- Incidental take of **humpback whales** occurs as a result of entanglement with fishing gear, as a consequence of fishing activity. This take is expected to occur in the sablefish pot/trap fishery. The incidental take limit for humpback whales is a 5-year average of 1 humpback whale injury or mortality per year, and up to 3 humpback whale injuries or mortalities in any single year.
- Incidental take of **Steller sea lions** occurs as a result of entanglement with fishing gear as a consequence of fishing activity. This take is expected to occur in limited entry trawl (shorebased IFQ) and at-sea hake (Pacific whiting) fisheries. The incidental take limit for Steller sea lions is a 5-year average of 14 Steller sea lion injuries or mortalities per year, and up to 45 Steller sea lion injuries or mortalities in a single year.
- Incidental take of **leatherback sea turtles** occurs as a result of entanglement with fishing gear as a consequence of fishing activity. This take is expected to occur in the sablefish pot/trap fishery. The incidental take limit for leatherback sea turtles is a 5-year average of 0.38 leatherback sea turtle injury or mortality per year, and up to 1 leatherback sea turtle injury or mortality in a single year.

Reasonable and Prudent Measures, Terms and Conditions

Terms and conditions implement reasonable and prudent measures (50 CFR 402.14), both of which are described in the current ITS. These must be carried out for the exemption to the general ESA prohibition of take resulting from the consultation to apply. The current ITS enumerates reasonable and prudent measures and associated terms and conditions as summarized here:

- NMFS establishes a Pacific Coast Groundfish and Endangered Species Workgroup (PCGW) in cooperation with the USFWS and the Council. The PCGW will meet at least biennially to develop recommendations on methods for monitoring take and additional mitigation measures as needed. The PCGW has been organized as a Council committee and held its first meeting in November 2013.
- NMFS will analyze available data to detect changes in fishing effort by gear type as a consequence of implementation of the shorebased IFQ program and biennially report results. The PCGW will provide recommendations on the design of the analysis.
- The WCGOP will provide summaries of observed takes of the species considered in the biological opinion, and NMFS will report fleet-wide estimates of total take biennially. WCGOP will immediately report takes of leatherback sea turtles as well as any opportunistically observed whale or sea turtle entanglements.
- As appropriate, the NWFSC will update the risk assessment (NWFSC 2012).

3.5.2.3 Species Covered by the 2012 USFWS Biological Opinion

In 2011 a short-tailed albatross was observed killed in operations of a sablefish longline vessel. On July 30, 2012, at the request of NMFS, USFWS initiated a formal section 7 consultation on the effects of continued operation of the Pacific Coast groundfish fishery on the ESA-listed species enumerated above at the beginning of section 3.5.2. In the consultation USFWS concurred with NMFS's conclusion (NMFS 2012b) that operation of the Pacific Coast groundfish fishery is not likely to adversely affect marbled murrelet, California least tern, southern sea otter, bull trout or bull trout critical habitat. Therefore, the Section 7 consultation and biological opinion focused on the effects of the fishery on short-tailed albatross. Prior to the conclusion of the consultation the Council was notified that USFWS would include in the terms and conditions that NMFS establish regulations requiring the use of streamer lines on commercial groundfish longline vessels 55 feet in length or greater. The current biological opinion (USFWS 2012) was published on November 21, 2012. In November 2013, the Council took final action to recommend a regulatory package to implement the streamer line requirement (USFWS 2012).

In the 19th and early 20th centuries the short-tailed albatross population was decimated by hunting for feathers, oil, and fertilizer. By 1949 no breeding pairs were observed and the species was thought to be extinct. Subsequently, breeding colonies were found on two small volcanic islands in the western Pacific.[43] The population has been recovering since the 1950s. A third breeding colony is being established on another volcanic island through translocation of chicks. A breeding pair successfully hatched and reared a chick on Midway Island in 2011 and 2012, suggesting that a breeding colony may eventually establish there as well. With recovery, short-tailed albatross's foraging range has been reestablished and in recent years they have reappeared with more regularity in the west coast EEZ. Short-tailed albatross prefer foraging area over the continental shelf where food resources are more abundant. Population growth and habitat preference has increased its vulnerability to the Pacific Coast fisheries and other anthropogenic effects in the action area.

The USFWS's recovery plan for short-tailed albatross (USFWS 2012) lists the following criteria for delisting the species:

- The total breeding population of short-tailed albatross reaches a minimum of 1,000 pairs; (population totaling 4,000 or more birds); AND

[43] Both breeding sites, Torishima Island and the Senkaku Islands, are under the jurisdiction of Japan, although China and Taiwan dispute the claim to the Senkaku Islands. Eighty to eighty-five percent of the breeding population is estimated to breed on Torishima Island.

- The 3-year running average growth rate of the population as a whole is ≥6% for ≥7 years; AND
- At least 250 breeding pairs exist on two island groups other than Torishima [one of the two original breeding colony sites], each exhibiting ≥6% growth for ≥7 years; AND
- A minimum of 75 pairs occur on a site or sites other than Torishima and the Senkaku [the two original breeding colony sites]

As of the 2011-12 breeding season, the population is estimated at 3,441 birds and 851 breeding pairs. The population growth rate is estimated at about 6.5%.

Injury and mortality occurs primarily in longline fisheries. Birds dive on baited hooks as they are deployed during fishing operations. They may become hooked, pulled underwater, and drown or otherwise be injured or killed when interacting with the gear in this fashion.

In the biological opinion, USFWS describes the risk assessment methodology used in the NMFS biological assessment to estimate annual mortality of short-tailed albatross due to the operation of the Pacific Coast groundfish fishery. In the risk assessment the occurrence of black-footed albatross, a closely related species, was used as a surrogate to evaluate injury and mortality, because short-tailed albatross interactions are too rare to derive meaningful statistics. Essentially, the risk assessment scales WCGOP estimates of black-footed albatross mortality in the fishery based on the relative size of the two species' populations. Adjustment factors are included in the equation to account for unobserved mortality ("dropoff") and differences in the distribution of the two species relative to the action area considered in the biological opinion.[44] The resulting groundfish fixed gear (longline) mortality estimate is 0.8 birds per year. The risk assessment includes a sensitivity analysis based on uncertainty in the WCGOP mortality estimates and alternative dropoff rates. This produced a range of annual mortality rates between 0.3 (0% dropoff rate, lower 90% confidence interval on WCGOP estimate) and 1.9 (45% dropoff rate, upper confidence interval on WCGOP estimate). Although unquantified in the sensitivity analysis, it is noted that these estimates could be biased by uncertainty about actual exposure of short-tailed albatross to the groundfish fishery (i.e., occurrence in the action area considered in the biological opinion) and unknown differences in black-footed and short-tailed albatross behavior that could affect vulnerability to the gear. The biological opinion concludes that the estimated mortality of ~1 short-tailed albatross per year will not appreciably affect the population growth rate.

The incidental take allowed is one short-tailed albatross per year due to continued operation of the Pacific Coast groundfish fishery (including both fixed gear and trawl). The take limit will be calculated based on an average of no more than two birds in any two-year period to accommodate inter-annual variation. The extent of future take will be assessed using documented takes of short-tailed albatross and estimates of interactions with the surrogate species (black-footed albatross) based on observer reports.

Terms and conditions in the ITS include NMFS implementing regulations to require the use of streamer lines on commercial longline vessels in the Pacific Coast groundfish fishery and establishing the Pacific Coast Groundfish and Endangered Species Workgroup also mandated by the NMFS biological opinion described above. As noted above, the development of a regulatory package occurred in the Council process. At its November 2013 meeting the Council adopted a preferred alternative from a range evaluated in a draft EA (USFWS). The preferred alternative requires streamer lines be deployed during setting operations on commercial fixed gear vessels 55 feet or greater in length with a safety exception in

[44] A complete description of the methodology can be found on pages 24-28 of the biological opinion (USFWS).

the event of rough weather, which would be triggered by a National Weather Service forecast of a gale wind warning.[45]

3.5.3 Marine Mammals not Listed under the Endangered Species Act

The MMPA requires all commercial fisheries to be placed in one of three categories, based on the relative frequency of incidental serious injuries and mortalities of marine mammals in the fishery:

- Category I designates fisheries with frequent serious injuries and mortalities incidental to commercial fishing;
- Category II designates fisheries with occasional serious injuries and mortalities;
- Category III designates fisheries with a remote likelihood or no known serious injuries or mortalities.

Annually NMFS Office of Protected Resources publishes an updated List of Fisheries with these categorizations. NMFS published the final 2014 List of Fisheries on March 14, 2014 (79 FR 14418). The WA/OR/CA sablefish pot is a Category II fishery; all other groundfish fisheries are Category III.

As discussed above, potential biological removal, PBR, is used to assess the effects of human-caused incidental mortality under the MMPA. PBR represents the maximum level of human-caused mortality a stock can sustain and still have a high likelihood of achieving its optimum sustainable population level. PBR is calculated as N_{min}* 0.5 R_{max} * F, where N_{min} is the minimum current population size, R_{max} is the maximum annual rate of increase for the species or stock, and F is a recovery factor that ranges from 0.1 to 1 depending on the conservation status of the stock (Barlow, *et al.* 1995). PBR is reported in stock assessment reports and the most recent estimates of PBR can be found in Carretta et al. (2013).[46]

Table 3-34 shows non-ESA listed marine mammal stocks with observed interactions in groundfish fisheries. Stock definitions, PBR estimates, and estimates of human-caused and fishery-caused serious injury / mortality are taken from Caretta, et al. (2013). (The fishery component is a subset of all human-caused serious injury / mortality.) Stock assessment reports include a breakdown of serious injury / mortality by fishery based on observer information. As noted in the table footnote, where no estimate for groundfish fisheries is reported, but there is an estimate based on stranded animals, that is reported under the groundfish fishery column. Note that in most cases the stock assessment report data are presented as minimum estimates. The table also includes observed interactions and estimates of annual average interactions using WCGOP and A-SHOP (At-Sea Hake Observer Program) data reported in Jannot, et al. (2011).[47] Overall take could only be estimated from observed interactions for three species; California sea lion, harbor seal, and northern elephant seal. This information is used to assess past effects of groundfish fisheries.

Table 3-35 is similar in format but reports remaining non-ESA listed species occurring in the fishery management area but with no observed interactions in the Pacific Coast groundfish fishery. Since there are no observer interactions, the groundfish fishery column shows estimates based on strandings, if reported. These observations could not be attributed to any particular fishery.

---

[45] Section 1.2 in NMFS (2013c) describes the elements of streamer lines. They are deployed above the groundline as it is paid out from the vessel and creates "a moving fence around the sinking groundline reducing or eliminating bird interactions."

[46] Marine mammal stock assessment reports are available at http://www.nmfs.noaa.gov/pRBSars/region.htm.

[47] Jannot et al. (2011) report estimated takes by year. These values are averaged in Table 3-33 to derive the annual estimate.

Estimates of total human-caused serious injury / mortality are below the PBR for all these stocks. Minimum estimates of fishery-caused serious injury / mortality is less than 1% of the PBR for most of the stocks. The California sea lion stock, the Monterey harbor porpoise stock, the Washington inland waters harbor porpoise stock, Pacific white-sided dolphin stock, and both common dolphin stocks have fractions between 1% and 10% of PBR. The average annual mortality estimate for California sea lion derived from Jannot, *et al.* (2011) is greater than the estimate from all fisheries from the stock assessment report but is still a small fraction of the large PBR for this stock. These data suggest that mortality of non-ESA listed marine mammal stocks occurring in the fishery management area caused by the operation of the Pacific Coast groundfish fishery will not prevent these stocks from reaching their optimum sustainable population level.

Observed takes reported in Jannot *et al.* (2011) break down by fishery sector / gear type as follows:

- California sea lion: Shoreside groundfish trawl, California halibut trawl, non-nearshore fixed gear sablefish, nearshore fixed gear, at-sea hake (Pacific whiting)[48]
- Harbor seal: California halibut trawl, non-nearshore fixed gear sablefish, nearshore fixed gear, at-sea hake (Pacific whiting)
- Northern elephant seal: Shoreside groundfish trawl, California halibut trawl, non-nearshore fixed gear sablefish, at-sea hake (Pacific whiting)
- Harbor porpoise: California halibut trawl
- Dall’s porpoise: At-sea hake (Pacific whiting)
- Pacific white-sided dolphin: Shoreside groundfish trawl
- Risso’s dolphin: Shoreside groundfish trawl
- Common bottlenose dolphin: Non-nearshore fixed gear

Animals may interact with the gear or the vessel in a variety of ways. Interactions and takes are a function of gear type and co-occurrence of fisheries and species. Anderson, et al. (Andersen, *et al.* 2008) present criteria for classifying marine mammal fishery interactions with respect to serious injury. These criteria are with respect to hook-and-line gear (or entanglement in lines associated with gear without hooks, such as pot / trap gear). Marine mammals may be hooked externally, in the mouth region, or ingest the hook. They can also become entangled in the gear. In trawl fisheries the animal is more likely to be caught by the gear and become injured or drown. Large cetaceans are less likely to incur serious injury from hooks but gear entanglement can lead to serious injury in a variety of ways.

Large cetaceans have not been observed directly interacting with the gear in groundfish trawl fisheries. However, a 1997 paper (Fertl and Leatherwood 1997), reviewed global data and found that interactions do occur. These interactions are result of overlap between areas of high prey density for cetaceans and productive fishing areas. Furthermore, cetaceans may be attracted to trawls if fishing operations enhance prey opportunity or because of discards. Most of the interactions documented in this paper are between fishing vessels and various species of dolphins, like those listed above. Minke, humpback, and fin whales are the large cetacean species documented in this paper. Cetaceans are more often caught in midwater gear compared to bottom trawl, because this gear type more often targets pelagic species of interest to cetaceans, are towed at high speeds, and are large.

Saez, et al. (2013) report results of a fishery-large cetacean co-occurrence model for the west coast EEZ. The large cetaceans evaluated are blue whales, fin whales, gray whales, humpback whales, and sperm whales. Gray whales are not listed under the ESA. The gray whale migration is generally very near to shore, crossing through a variety of anthropogenic threats, including fixed-gear fisheries. Sablefish

[48] California halibut trawl is a state managed fishery and only subject to the proposed action with respect to catch accounting to ensure that ACLs are not exceeded.

longline and trap occur farther offshore than migrating gray whales and subsequently pose generally lower entanglement risk. However they are considered high risk fisheries considering all whale species, especially in central and northern California.

3.5.4 Seabirds not Listed under the Endangered Species Act

Section 3.1.4.5 in the 2013-14 Groundfish Harvest Specifications FEIS includes an overview of the occurrence and abundance of seabirds in the fishery management area. This information is reproduced here.

The California current system supports a diverse array of seabird species. Species found off the west coast include resident species and transitory species (migrating or foraging). All the California Current system seabirds are highly mobile and require an abundant food source to support their high metabolic rates (Ainley, *et al.* 2005). The abundance of most seabird species on the west coast is influenced by similar physical and biological factors, such as oceanic productivity and prey availability (Ainley, *et al.* 2005; Tyler, *et al.* 1993). Specifically, the seasonal and latitudinal distribution of seabirds is defined by the intensity of coastal upwelling, which delivers nutrient-rich water and supports higher prey biomass in surface waters accessible to seabirds (Tyler, *et al.* 1993). On the west coast, upwelling is most intense south of Cape Blanco, Oregon (42° 50' N lat.) (Bakun, *et al.* 1974; Barth, *et al.* 2000).

Three distinct oceanic seasons have traditionally been defined for the U.S. west coast: the Upwelling, Oceanic, and Davidson Current seasons. The distribution of seabirds varies by season. During the upwelling season in the late spring and summer, northerly winds transport surface waters southward and away from the coast. Commonly-observed visiting species in summer include the sooty shearwater (*Puffinus griseus*), Northern fulmar (*Fulmarus glacialis*), and black-footed albatross (*Phoebastria nigripes*) (Tyler, *et al.* 1993). In the fall (Oceanic season), northerly winds and upwelling intensity decrease, and sea surface temperature reaches its annual maximum. Several species that nest farther south in Mexico and southern California move northward, including the brown pelican (*Pelecanus occidentalis*) and storm-petrels. As winter approaches, these species again return south and breeders from boreal nesting colonies become more abundant, particularly off of California (Tyler, *et al.* 1993). The winter months along the west coast are characterized by warmer water delivered by the Davidson current and reduced levels of primary production (Davidson Current season). Seabird abundance during this time is generally low (Tyler, *et al.* 1993).

Table 3-36 summarizes information in Jannot, et al. (2011) on non-ESA listed seabird interactions in groundfish fisheries. The breakdown of interactions by fishery / gear type is as follows:

- Black-footed albatross (*Phoebastria nigripes*): Non-nearshore fixed gear fishery and at-sea whiting fishery
- Brandt's cormorant (*Phalacrocorax penicillatus*): Trawl and fixed gear fisheries.
- Brown pelican *(Pelecanus occidentalis*): Non-nearshore fixed gear fishery
- Common murre (*Uria aalge*): Shoreside trawl, fixed gear fisheries, and at-sea whiting fishery
- Leach's storm petrel (*Oceanodroma leucorhoa*): shoreside trawl
- Northern fulmar (*Fulmarus glacialis*): Shoreside trawl and non-nearshore fixed gear
- Sooty shearwater (*Puffinus griseus*): Non-nearshore fixed gear and at-sea whiting
- Western gull (*Larus occidentalis)*: Non nearshore fixed gear

3.6 Non-groundfish Species Caught in Groundfish Fisheries

The 2013-2014 Groundfish Harvest Specifications FEIS (PFMC and NMFS 2012) describes non-groundfish catch with particular attention to commercially important species. These economically important species include:

- Pacific halibut
- California halibut
- Dungeness crab
- Pink shrimp
- Several species of salmon
- Ridgeback and spot prawns

Information on the life history, distribution, and fisheries for these species may be found in the 2013-2014 FEIS, summarized here:

- Pacific halibut (*Hippoglossus stenolepis*) is a bottom-dwelling, right-eyed flatfish species from the family of flounders called *Pleuronectidae.* Pacific halibut are taken with trawl, as well as commercial and recreational fixed gears as they co-occur with groundfish stocks, including canary and yelloweye rockfish. As part of the trawl rationalization program Pacific halibut bycatch is managed with individual bycatch quota (IBQ), which limits bycatch mortality to quota levels. According to observer data, halibut bycatch in the trawl fishery averaged 204 mt annually from 2003 to 2010 but was only 32 mt in 2011. This demonstrates that IBQ has been effective in reducing halibut bycatch.
- California halibut (*Paralichthys californicus*) are a left-eyed flatfish of the family *Bothidae*. California halibut is taken incidentally in the groundfish fishery.
- Off the west coast, Dungeness crab is most abundant in nearshore areas from central California to the Washington-Canada border. Dungeness crab is found to a depth of about 180 m. Dungeness crab is taken incidentally, or harmed unintentionally, by groundfish gears. In some areas, interactions with Dungeness crab by nearshore flatfish trawls are a concern. Concentrating vessel effort in shallow water during the summer months (<75 fm) affects Dungeness crab in the north because they are less likely to survive discard during their summer molting season.
- Off the U.S. West Coast Pacific pink shrimp (*Pandalus jordani*) are harvested with trawl gear from Northern Washington to Central California, with the majority of the catch taken off the coast of Oregon. Concentrations of pink shrimp are associated with well-defined areas of green mud and muddy-sand bottoms. Most of the pink shrimp catch is taken with trawl gear with a minimum mesh size of one inch to three-eighths of an inch between the knots. Shrimp trawlers commonly take groundfish in association with shrimp, rather than the reverse. In the past, the pink shrimp fishery had been responsible in some years for a large proportion of canary rockfish incidental catch. However, the catch of groundfish has been reduced through the use of bycatch reduction devices (BRDs) which are required on all vessels in this fishery. BRDs are added to the trawl net and divert finfish out of the codend of the net, where the shrimp catch is accumulated.
- Salmon are anadromous fish, spending a part of their life in ocean waters, but returning to freshwater rivers and streams to spawn and then die. Groundfish fisheries catch salmon incidentally and the salmon troll fishery has an incidental catch of groundfish. Biological opinions addressing the take of ESA-listed salmon are summarized in Section 3.5.2.
- Ridgeback prawns (*Sicyonia ingentis*) are found from Monterey, California south to Baja California, Mexico, in depths of 145 m to 525 m. Spot prawns (*Pandalus platyceros*) are the largest of the pandalid shrimp and range from Baja California, Mexico, north to the Aleutian

Islands and west to the Korean Strait. The Ridgeback prawn fishery occurs exclusively in California, centered in the Santa Barbara Channel and off Santa Monica Bay. Spot prawn fisheries are state-managed. The use of trawl gear to target spot prawns has been banned in all three states; the spot prawn pot fishery that remains is considered to have no incidental bycatch of depleted groundfish species.

As suggested above, for most of these species it is the incidental catch of groundfish in fisheries targeting these species rather than the other way round. Groundfish catch in non-groundfish fisheries is accounted for through set asides, described in Section **Error! Reference source not found.**.

The West Coast Groundfish Observer Program's Groundfish Management Multiyear Data Product (Bellman, *et al.* 2013) includes catch estimates of nongroundfish species in groundfish fisheries. Focusing on groundfish directed fisheries (limited entry permit vessels, open access vessels targeting groundfish, tribal fisheries targeting groundfish), some 334 nongroundfish species or groups (including partially or unidentified species) were observed caught from 2002 to 2012. Nongroundfish catch, by weight, accounts for about 2% of total catch in these fisheries. Table 3-37 shows the most commonly caught nongroundfish by weight in rank order and accounting for just over 90% of the catch. About 54% of the nongroundfish catch by weight is invertebrate species, including crabs followed by grenadiers and sharks, each accounting for about 5%.

Table 3-37. Most commonly caught nongroundfish species, by weight, 2002-2012. (Source:

	Species	Catch (mt)	Percent of total nongroundfish catch	Cumulative Percent
1	Dungeness Crab	18,430	29.0%	29.0%
2	Humboldt Squid	8,848	13.9%	42.9%
3	Walleye Pollock	6,726	10.6%	53.5%
4	Pacific Halibut	4,897	7.7%	61.2%
5	Squid Unid	4,657	7.3%	68.5%
6	Tanneri Tanner Crab	3,609	5.7%	74.2%
7	King (Chinook) Salmon	2,427	3.8%	78.0%
8	Giant Grenadier	2,001	3.1%	81.1%
9	Shark Unid	1,129	1.8%	82.9%
10	Silver (Coho) Salmon	1,024	1.6%	84.5%
11	Grenadier Unid	877	1.4%	85.9%
12	Tanner Crab Unid	828	1.3%	87.2%
13	Brown Cat Shark	821	1.3%	88.5%
14	American Shad	808	1.3%	89.7%
15	Pacific Sardine	807	1.3%	91.0%

As shown in Table 3-38, Dungeness crab, which is the most economically important species listed above, are mostly caught in the shoreside trawl and tribal shoreside fisheries.

Table 3-38. Total catch of economically important nongroundfish (mt) by fishery sector, 2002-2012.

Species	Shoreside Trawl*	Nearshore Fixed Gear	Non nearshore Fixed Gear	Non Tribal At-Sea Hake	Shoreside Hake	Tribal At-Sea Hake	Tribal Shoreside	Total	Pct all Non groundfish
Dungeness Crab	3,352	133	83	<0.5	1		14,862	18,430	48%
Pacific Halibut	2,078	18	685	14	5	2	2,095	4,897	13%
King (Chinook) Salmon	56	3	1	69	75	36	2,188	2,427	6%
Silver (Coho) Salmon	<0.5	1	<0.5	1	3	2	1,016	1,024	3%
California Halibut	61	19	5	<0.5	<0.5			86	<0.5%
Pink (Humpback) Salmon	<0.5		<0.5	<0.5	12	8	17	36	<0.5%
Pink Shrimp	<0.5				0			<0.5	<0.5%
Ridgeback Prawn		<0.5						<0.5	<0.5%

Figure 3-29 shows catch of all non-groundfish by fishery sector. The tribal shoreside accounted for the largest share, 32%.

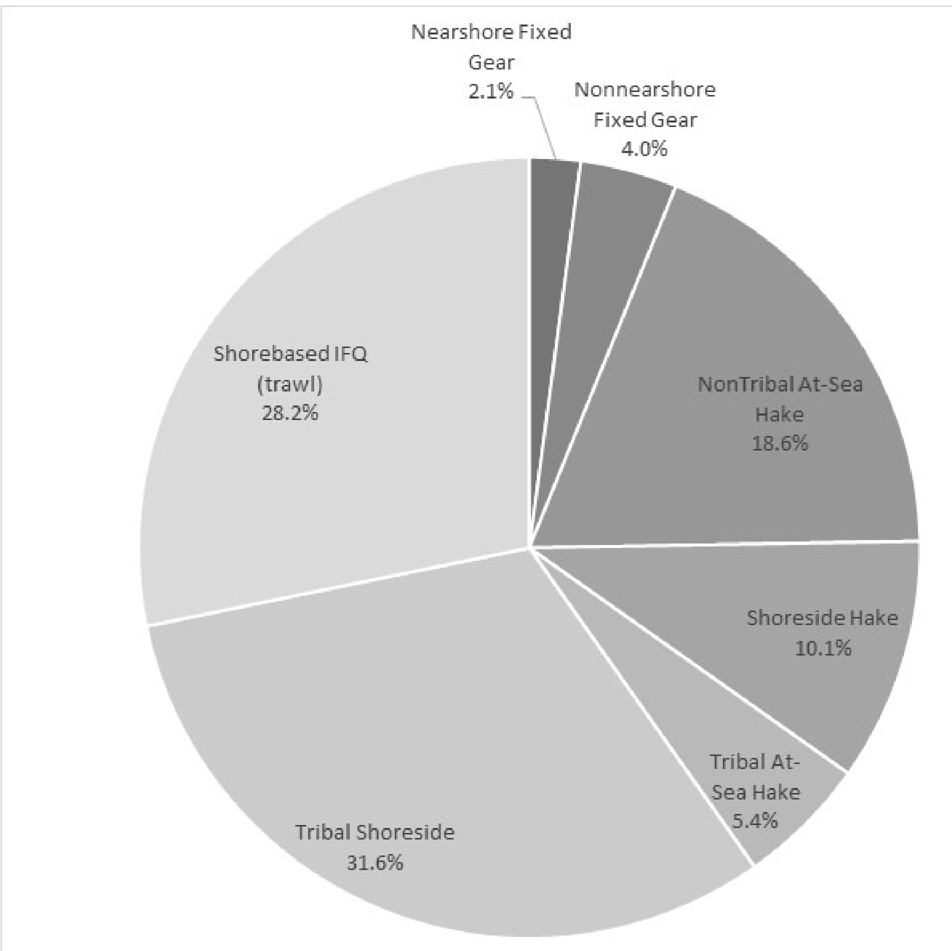

Figure 3-29. Catch of non-groundfish by groundfish fishery sector, 2003-2011. (Shorebased IFQ includes the limited entry trawl sector before 2011 and the non-trawl IFQ sector in 2011.)

Figure 3-30 shows catch of non-groundfish species as a percent of total catch during the baseline period for groundfish fishery sectors (as shown in Figure 3-29). The proportion varies between 1.4% (3,801 mt) in 2011 and 5.9% (8,551 mt) in 2009. Non-groundfish catch amounts show no correlation with total catch during this period (R-squared = 0.031).

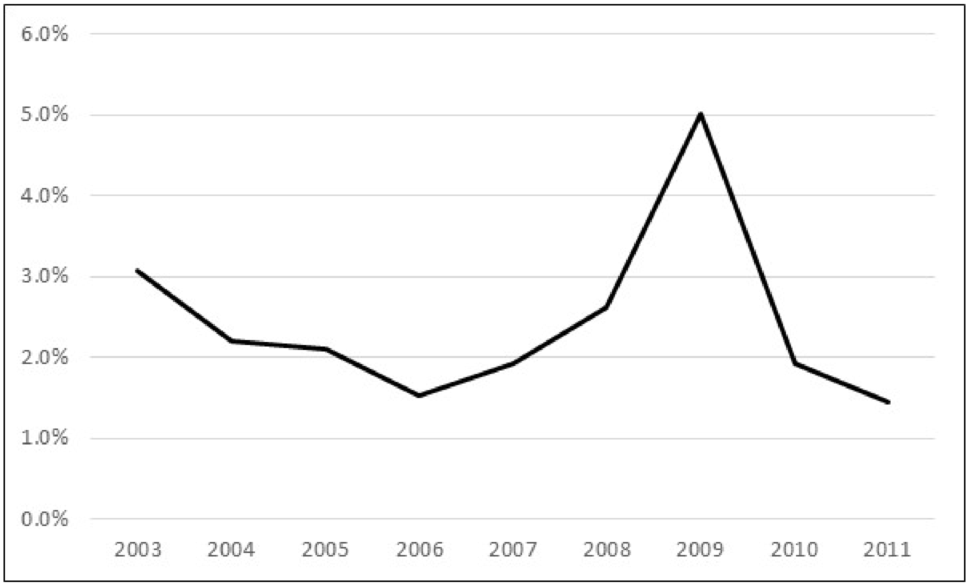

Figure 3-30. Catch of non-groundfish species as a percent of total catch in groundfish fishery sectors, 2003-2011.

Chapter 4 IMPACTS OF THE ALTERNATIVES

This chapter is organized into 14 sections. Sections 4.1 through 4.7 evaluate the impacts of alternative harvest specifications and management measures for the 2015-2016 biennial period. These sections are organized by environmental component, similar to Chapter 3, except that establishing management measures is considered an impact connecting the ACLs, or catch limits, to the ultimate impact on the environment. These sections cover harvest specifications, management measures, the socioeconomic environment, essential fish habitat, the California Current ecosystem, protected species, and non-groundfish. Sections 4.8 through 4.14 look at the long-term impacts of setting harvest specifications and management measures; these impacts are related to the Amendment 24 alternatives, which establish the default harvest control framework that would be used in setting harvest specifications beginning with the 2017-2018 biennial period. Section 4.15 evaluates cumulative impacts. The impacts of proposed changes to Slope Rockfish and Other Fish complexes and the designation of ecosystem component species are described in Section 4.1.

4.1 Biological Impacts of 2015-16 Biennial Harvest Specifications on Groundfish Stocks

This section evaluates the biological impacts of preferred 2015-2016 harvest specifications on a select list of groundfish stocks (the 2014 Stock Assessment and Fishery Evaluation document (PFMC 2014) provides more detailed information on all west coast groundfish stocks and the biological effects under the groundfish harvest specification framework). The focus of this section are on those overfished stocks currently managed under rebuilding plans, the stocks where the Council chose a range of alternative ACLs for analysis, those stocks and stock complexes where total catches in recent years have been at least 80 percent of specified ACLs, and those stocks preferred to be removed from a status quo stock complex and managed with stock-specific harvest specifications.

4.1.1 Overfished Groundfish Stocks

There are currently six overfished rockfish stocks (bocaccio south of 40º10’ N lat., canary rockfish, cowcod south of 40º10’ N lat., darkblotched rockfish, Pacific ocean perch, and yelloweye rockfish) and one overfished flatfish stock (petrale sole) managed under rebuilding plans. New assessments and rebuilding analyses for these overfished stocks do not indicate any need to modify existing rebuilding plans since all these analyses indicate progress towards rebuilding is on track and, in most cases, ahead of schedule. The only exception is cowcod where the new assessment and rebuilding analysis indicate the maximum time to rebuild the stock according to the MSA (i.e., T_{MAX}) is sooner than the target year to rebuild the stock (i.e., T_{TARGET}). Therefore, the Council’s preferred alternative is to maintain all the existing rebuilding plans with the exception of specifying a new T_{TARGET} for cowcod. Table 4-1 provides the estimated times to rebuild and rebuilding probabilities under alternative harvest control rules for the overfished stocks according to the most recent rebuilding analyses.

The choice of maintaining status quo rebuilding plans is underscored by the fact only one new rebuilding analysis was prepared in 2013; all the other rebuilding plan considerations for 2015 and beyond are informed by rebuilding analyses prepared in 2011 and thoroughly analyzed in the 2013-2014 harvest specifications and management measures process (PFMC and NMFS 2012). In fact, only catch reports were developed in 2013 for canary rockfish, POP, and yelloweye rockfish based on the SSC's advice that there was little new information to inform new assessments (or rebuilding analyses). While new assessments were conducted for bocaccio, darkblotched rockfish, and petrale sole, the SSC advised against preparing new rebuilding analyses since each of these stocks was predicted to be rebuilt by at least the start of 2015. The SSC recommended to stay the course with these rebuilding plans and conduct new assessments in 2015 to confirm the optimistic predictions in the 2013 assessments.

There are no differences in impacts for overfished species relative to the 2015-2016 alternatives, which are structured within a P* range of 0.25 to 0.45, except for petrale sole. The rockfish rebuilding plans specify conservative harvest control rules that result in 2015 and 2016 ACLs far below the ABCs calculated using a P* of 0.25. However, since the harvest control rule specified in the petrale sole rebuilding plan is the 25-5 rule and since the stock is projected to be above its B_{MSY} target in 2015 and 2016, the 2015 and 2016 petrale ACLs are equal to the ABCs and therefore vary by P* alternative.

The following sections provide more detail on overfished groundfish species' impacts. The 2014 Stock Assessment and Fishery Evaluation (SAFE) document provides further information on the distribution and life history, stock status and management history, stock productivity, and fishing mortality of each overfished species (PFMC 2014).

Table 4-1. Estimated time to rebuild and harvest control rule relative to alternative 2015-2016 ACLs for overfished west coast groundfish stocks (no changes to rebuilding plans were recommended for any of these stocks except cowcod where the target year to rebuild (T_{TARGET}) was changed to X).

a/ All bocaccio alternatives have been reduced from the rebuilding analysis results by 6% to represent the portion of the stock south of 40°10' N lat.

4.1.1.1 Bocaccio South of 40º10' N lat.

A bocaccio stock assessment update (Field 2011b) and rebuilding analysis (Field 2011a) were prepared in 2011. The 2011 bocaccio assessment was originally scheduled to be an update of the 2009 full assessment; however, the STAT some limited changes in the 2009 model structure since a strict update estimated that the 2010 year class was extraordinarily and unrealistically strong, based on length frequency data collected in the 2010 NMFS trawl survey. The modified update was ultimately reviewed, endorsed by the SSC, and adopted for use in management decision-making. The 2011 bocaccio rebuilding analysis indicated rebuilding progress was well ahead of schedule with a predicted median year to rebuild of 2021 or one year earlier than the target rebuilding year (Field 2011a). The Council elected to maintain the revised rebuilding plan implemented in 2011.

An update of the 2011 bocaccio assessment model was prepared in 2013, which confirmed the 2009 and 2010 year classes were indeed strong (Field 2013). The assessment estimated a depletion of 31.4 percent at the start of 2013 and predicted the stock would rebuild by 2015. The SSC recommended maintaining the current rebuilding plan for the 2015-2016 management cycle and a full assessment be done in 2015 to confirm this prediction. The SSC further recommended against preparing a rebuilding analysis in 2013; therefore, the 2011 rebuilding analysis (Field 2011a) was used to inform the projections in Table 4-1.

The Council's preferred alternative is to maintain the rebuilding plan and wait for the next assessment to confirm whether the estimated strong recruitment will result in successfully rebuilding the stock as predicted.

Under the preferred alternative of maintaining the current bocaccio rebuilding plan, the probability of successful rebuilding by the T_{TARGET} of 2022 is 60% and the probability of rebuilding by T_{MAX} is 90% (Table 4-1) using the projections from the 2011 rebuilding analysis. The probabilities would undoubtedly be higher if a new bocaccio rebuilding analysis was prepared based on the 2013 assessment since the strength of recent recruitments was higher than previously estimated.

4.1.1.2 Canary Rockfish

The 2007 canary assessment estimated relative depletion level was 32.4 percent at the start of 2007 (Stewart 2008b). This was a significant departure from the previous assessment and largely driven by a higher assumed steepness (h = 0.51) relative to past assessments. The 2007 canary rebuilding analysis (Stewart 2008a) predicted the SPR harvest rate in the rebuilding plan (88.7%) would rebuild 42 years earlier (2021) than the originally estimated rebuilding schedule (2063). A modification of the Amendment 16-4 canary rockfish rebuilding plan specifying a target rebuilding year of 2021 while maintaining the SPR harvest rate of 88.7% was implemented in 2009.

The 2009 canary assessment (Stewart 2009c), an update of the 2007 assessment, estimated stock depletion at 23.7% at the start of 2009. This change in stock status was due to a lower estimate of initial, unfished biomass (B_0) largely attributable to the inclusion of revised historical California catches from a formal reconstruction of 1916-1980 California catch data (Ralston, *et al.* 2010). The 2009 canary rebuilding analysis (Stewart 2009a) predicted the stock would not rebuild to the target year of 2021 with at least a 50% probability even in the absence of fishing-related mortality starting in 2011 ($T_{F=0}$). The rebuilding plan was revised by changing the target to rebuild the stock to 2027 while maintaining the 88.7% SPR harvest rate; the revised rebuilding plan was implemented in 2011.

Another update assessment was prepared in 2011 (Wallace and Cope 2011), which estimated stock depletion was 23.2 percent at the start of 2011. This change in stock status was due to a lower estimate of initial, unfished biomass (B_0) largely attributable to the inclusion of revised historical Oregon catches from a formal reconstruction of Oregon catch data. For the period 2000-2011, the spawning biomass was estimated to have increased from 11.2 percent to 23.2 percent of the unfished biomass level.

The 2011 canary rebuilding analysis (Wallace 2011) predicted the stock would not rebuild to the target year of 2027 with at least a 50% probability. The rebuilding plan was revised slightly by changing the target to rebuild the stock to 2030 while maintaining the 88.7% SPR harvest rate; the revised rebuilding plan was implemented in 2013.

The SSC recommended against preparing a new canary rockfish rebuilding analysis in 2013; therefore, the 2011 rebuilding analysis (Wallace 2011) was used to inform the rebuilding projections in Table 4-1. A canary catch report was provided in 2013 (Agenda Item F.5.a, Attachment 9, June 2013), which indicated 2010-2012 total catches were below specified ACLs/OYs.

The Council's preferred alternative is to maintain the canary rockfish rebuilding plan and wait for new information that might compel a change in course. The probabilities of rebuilding by the specified canary T_{TARGET} of 2030 and the estimated T_{MAX} of 2050 are 54.6% and 75%, respectively (Table 4-1).

4.1.1.3 Cowcod South of 40º10' N lat.

A new cowcod assessment of the stock in the Southern California Bight was conducted in 2013 (Dick and MacCall 2013), which estimated stock depletion to be 33.9 percent of unfished spawning biomass at the start of 2013. The 2013 assessment suggested that cowcod in the Southern California Bight constitute a smaller, but more productive stock than was estimated from previous assessments. Median unfished and 2013 spawning biomasses were estimated to be 1,549 mt and 524 mt, respectively.

The 2013 assessment used the Extended Depletion-Based Stock Reduction Analysis (XDB-SRA) modeling platform to estimate stock status, scale, and productivity. Dick et al. (2013) fit five fishery-independent data sources: four time series of relative abundance (CalCOFI larval abundance survey, Sanitation District trawl surveys, NWFSC trawl survey, and NWFSC hook-and-line survey), and the 2002 Yoklavich et al. (2007) visual survey estimate of absolute abundance.

The 2013 rebuilding analysis (Dick and MacCall 2014) was unique in that the Punt rebuilding program (Punt 2005) was not used given its incompatibility with XDB-SRA. In each rebuilding model run, 15,000 simulated trajectories were generated using draws from the joint posterior distribution. Since XDB-SRA does not provide the information required to calculate spawning potential ratios, age-specific quantities from the 2009 rebuilding analysis were used to translate harvest control rules (SPR=82.7%) into exploitation rates (E=0.007 calculated as catch/estimated age 11+ biomass). Similar to the previous cowcod rebuilding analysis, variability in future recruitment was expressed as a weighted set of different states of nature (parameter values), rather than random deviations from an average stock-recruitment relationship. While the previous rebuilding analysis accounted only for uncertainty in the Beverton-Holt steepness parameter, the current analysis accounts for uncertainty in all estimated model parameters. Estimates of total cowcod mortality have not exceeded the ACL (or OY) in any year since 2003. The estimate of median time to rebuild under the current harvest rate (2020) is 48 years earlier than the current target year of 2068.

The Council's preferred alternative is to maintain the harvest rate in the current cowcod rebuilding plan. The SSC recommended that the cowcod ACL contribution for the area north of Point Conception be computed by applying the fishing mortality rate corresponding to the ACL for south of Point Conception to the biomass north of Point Conception from DB-SRA. This was considered more scientifically justified than the past approach of doubling the ACL value from south of Point Conception to produce the ACL for the entire area since the DB-SRA estimate of biomass north of Point Conception is considerably lower than for the stock in the assessed area in the Southern California Bight. The preferred 2015 and 2016 ACL using the status quo harvest rate and the SSC-recommended methodology is 10 mt, which compares to a 16 mt ACL calculated using the convention of doubling the assessed area ACL to determine the cowcod harvest limit for the entire area south of 40°10' N lat. The Council's preferred alternative also specifies an ACT of 4 mt, which defines the allowable harvest in all fisheries. The 6 mt difference between the ACL and the ACT would enable more research activities that may take cowcod to benefit future stock assessments. One of the research activities the Council hoped to expand is the current NWFSC hook-and-line survey in the Southern California Bight. The Council recommended that survey be extended into the CCAs to better estimate stock size.

The current T_{TARGET} in the cowcod rebuilding plan is 2068, which is nine years later than the new estimate of T_{MAX} of 2057 (Table 4-1). Therefore, the Council will have to modify the target rebuilding year. One of the considerations in this decision is the great uncertainty in the estimated cowcod biomass (Figure 4-1), which may compel a T_{TARGET} later than the median year to rebuild the stock of 2020, or one year later than $T_{F=0}$, under the preferred alternative. Specifying the median year to rebuild the stock provides only a 50% probability of meeting the rebuilding objective, while specifying a later year increases that probability. The probability of rebuilding by the new T_{MAX} of 2057 under the preferred alternative is 88.4%; however, if total catches are maintained closer to the preferred ACT of 4 mt, the probability of rebuilding by T_{MAX} is estimated to be closer to 91.5% (Table 4-1). The probabilities of rebuilding by the new T_{TARGET} will be calculated after the preferred T_{TARGET} is decided and will be published in the FEIS.

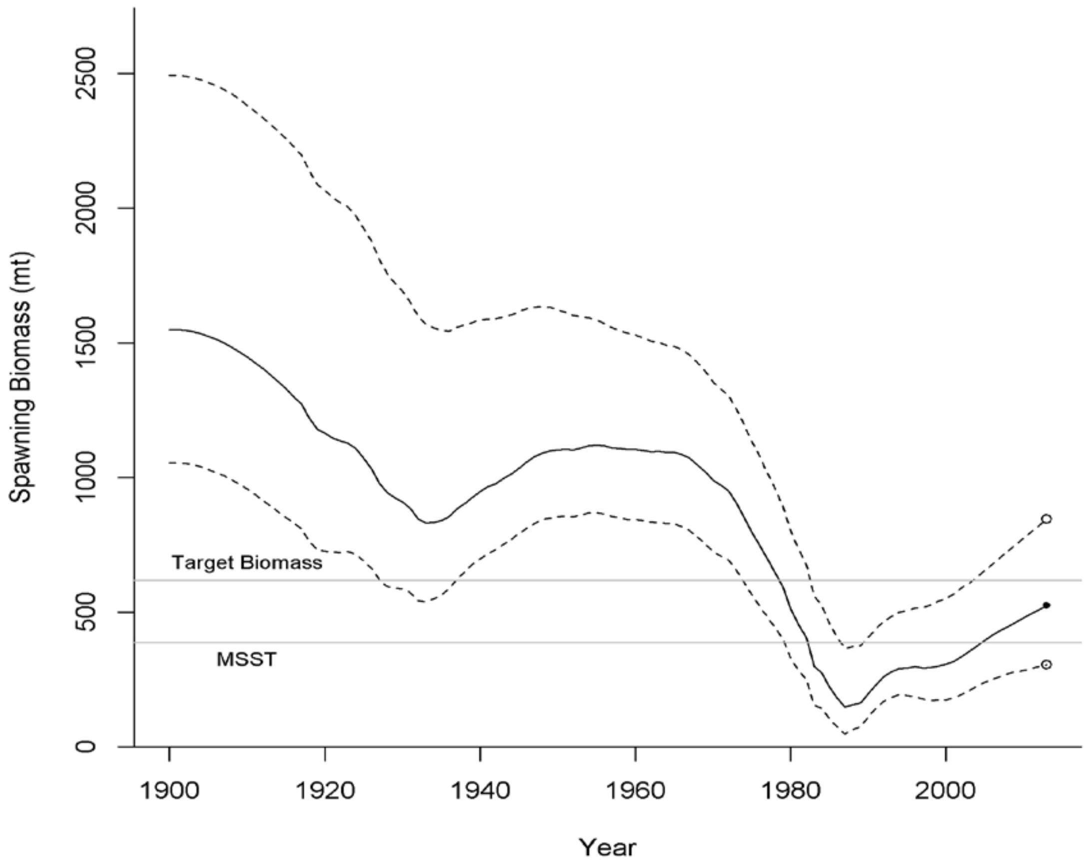

Figure 4-1. Distribution of cowcod spawning biomass trajectories from the 2013 base model (median = solid line, 5th and 95th percentile = dashed lines), relative to Target Biomass (40% of unfished biomass) and the Minimum Stock Size Threshold (MSST, 25% of unfished biomass). Circles indicate values in 2013.

4.1.1.4 Darkblotched Rockfish

A full darkblotched stock assessment in 2013 (Gertseva and Thorson 2013) estimated a stock depletion of 36 percent at the start of 2013. The assessment also predicts the stock will be rebuilt by the start of 2015. The improved stock status and rebuilding outlook were largely attributed to 1) reduced fishing mortality under the rebuilding program; 2) inferences that follow from more favorable perceptions of steepness, fecundity, and age at maturity of the stock; and 3) length and age data indicating relatively large recruitments in 1999, 2000, and 2008. The SSC recommended maintaining the current rebuilding plan for the 2015-2016 management cycle and a full assessment be done in 2015 to confirm this prediction. The SSC further recommended against preparing a rebuilding analysis in 2013; therefore, the 2011 rebuilding analysis (Stephens 2011) was used to inform the rebuilding projections in Table 4-1.

The Council's preferred alternative is to maintain the rebuilding plan and wait for the next assessment to confirm whether the stock will successfully rebuild as predicted.

Under the preferred alternative of maintaining the current darkblotched rebuilding plan, the probability of successful rebuilding by the T_{TARGET} of 2025 is 100% and the probability of rebuilding by T_{MAX} is also 100% (Table 4-1) using the projections from the 2011 rebuilding analysis.

4.1.1.5 Pacific Ocean Perch

A full assessment in 2011 estimated a stock depletion of 19.1 percent at the start of 2011 (Hamel and Ono 2011). The significant decrease in the estimated depletion of the stock was largely due to a much higher estimate of initial, unfished biomass (B_0). Previous assessments assumed a large recruitment in the late 1950s provided the higher biomass to support the estimated removals by the foreign fleets without any data to support that assumption. The assumption in the 2011 assessment is that the large foreign fleet catch fished the biomass down to critical levels, thus resulting in a substantially larger B_0 estimate. The 2011 assessment also estimated a longer sequence of higher recruitment based on fitting to the data available for early years of the assessment period. The 2011 rebuilding analysis (Hamel 2011) predicted rebuilding would not occur by the target year of 2020 with at least a 50% probability even in the absence of fishing-related mortality beginning in 2013 (i.e., $T_{F=0}$). Therefore the rebuilding plan was revised by changing the target rebuilding year to 2051 while maintaining the constant SPR harvest rate of 86.4%.

The SSC recommended against preparing a new POP rebuilding analysis in 2013; therefore, the 2011 rebuilding analysis (Hamel 2011) was used to inform the rebuilding projections in Table 4-1. A POP catch report was provided in 2013 (Agenda Item F.5.a, Attachment 10, June 2013), which indicated 2010-2012 total catches were below specified ACLs/OYs.

The Council's preferred alternative is to maintain the rebuilding plan and wait for new information that might compel a change in course. The probabilities of rebuilding by the specified POP T_{TARGET} of 2051 and the estimated T_{MAX} of 2071 are 50% and 73%, respectively (Table 4-1).

4.1.1.6 Petrale Sole

The 2013 petrale assessment (Haltuch, *et al.* 2013) estimated a stock depletion of 22.3 percent of its unfished biomass at the start of 2013 and short of the prediction from the 2011 rebuilding analysis; spawning biomass is predicted to reach the B_{MSY} target by the start of 2014. The 2013 stock assessment continued with the coastwide stock assessment, but was restructured to summarize petrale sole landings by the port of landing and combined Washington and Oregon into a single fleet. The down-weighting of the trawl CPUE index used in the 2011 assessment was largely responsible for the more pessimistic result and the one year lag in rebuilding relative to the previous assessment. However, the estimation of recent recruitments indicated two very strong year classes (2007 and 2008) recruiting into the spawning population, which increases the likelihood of imminent success in rebuilding this stock. The SSC recommended against preparing a new petrale sole rebuilding analysis in 2013; therefore, the 2011 rebuilding analysis (Haltuch 2011) was used to inform the rebuilding projections in Table 4-1.

The Council's preferred alternative is to maintain the rebuilding plan and wait for the next assessment to confirm whether the stock will successfully rebuild as predicted. The probabilities of rebuilding by the specified petrale T_{TARGET} of 2016 and the estimated T_{MAX} of 2021 are 100% (Table 4-1).

The petrale sole ACLs do vary by the 2015-2016 P* alternatives analyzed in this EIS. This is because the rebuilding strategy for petrale sole is to use the 25-5 rule, which progressively lowers the ACL relative to ABC the farther below the stock is from the B_{MSY} target of $B_{25\%}$. However, since the petrale stock is predicted to be above the B_{MSY} target in 2015 and 2016, the ACLs equal the ABCs and are affected by the P* choice. The preferred (and Alternative 1) 2015 and 2016 ACLs under a P* of 0.45 are 2,816 mt and 2,910 mt, respectively. The Alternative 2 ACLs are 2,310 mt and 2,386 mt in 2015 and 2016, respectively under a P* of 0.25. While implementation of Alternative 2 ACLs would predict a higher petrale biomass in the foreseeable future since removals in 2015 and 2016 would be less, the P* choice does not directly affect rebuilding probabilities since the stock is projected to be rebuilt now, before the start of 2015.

4.1.1.7 Yelloweye Rockfish

The benchmark 2009 yelloweye assessment estimated a stock depletion of 20.3 percent of initial, unfished biomass at the start of 2009 (Stewart, *et al*. 2009). The resource was modeled as a single stock, but with three explicit spatial areas: Washington, Oregon and California. Each area was modeled simultaneously with its own unique catch history and fishing fleets (recreational and commercial), with the stocks linked via a common stock-recruit relationship with negligible adult movement among areas. The assumed level of historical removals and estimated steepness were identified as the main axes of uncertainty.

The 2009 yelloweye rebuilding analysis (Stewart 2009b) was used to inform a revised rebuilding plan that was implemented under FMP Amendment 16-5. The revised rebuilding plan implemented in 2011 specified a constant harvest rate (SPR = 76%) strategy (the ramp-down strategy was abandoned) and a target year to rebuild the stock of 2074.

The 2011 yelloweye assessment (Taylor and Wetzel 2011), an update of the 2009 assessment, estimated stock depletion at 21.4 percent of initial, unfished biomass at the start of 2011. The update assessment results were very similar to those in the previous assessment. The 2011 yelloweye rebuilding analysis (Taylor 2011) indicated rebuilding progress was on schedule and no revisions were made to the rebuilding plan.

The SSC recommended against preparing a new yelloweye rockfish rebuilding analysis in 2013; therefore, the 2011 rebuilding analysis (Taylor 2011) was used to inform the rebuilding projections in Table 4-1. A yelloweye catch report was provided in 2013 (Agenda Item F.5.a, Attachment 11, June 2013), which indicated 2010-2012 total catches were below specified ACLs/OYs.

The Council's preferred alternative is to maintain the yelloweye rebuilding plan and wait for new information that might compel a change in course. The probabilities of rebuilding by the specified yelloweye T_{TARGET} of 2074 and the estimated T_{MAX} of 2083 are 62.1% and 72.9%, respectively (Table 4-1).

4.1.2 Non-Overfished Stocks with Annual Catch Limit Alternatives Identified for Analysis

4.1.2.1 Dover Sole

The 2011 Dover sole assessment indicated the stock was healthy with an increasing abundance trend. Spawning stock biomass depletion was estimated to be 83.7 percent of unfished biomass at the start of 2011 (Hicks and Wetzel 2011). The 2011 Dover sole assessment is data-rich and the species is readily tracked in the NMFS trawl survey (most survey tows are positive for Dover).

The spawning biomass of Dover sole reached a low in the mid-1990s before beginning to increase throughout the last decade. The estimated depletion has remained above the 25 percent biomass target and it is unlikely that the stock has ever fallen below this threshold. Throughout the 1970s, 1980s, and

1990s the exploitation rate and SPR generally increased, but never exceeded the SPR 30 percent F_{MSY} target. Recent exploitation rates on Dover sole have been much lower than F_{MSY}, even with increased catch levels since 2007.

Two ACL alternatives for 2015 and 2016 are analyzed: 1) the status quo ACL of 25,000 mt and 2) the preferred ACL of 50,000 mt. Given the productivity of the stock and constraints on fishing, projections assuming a 25,000 mt constant annual catch predict the stock would remain above the target B_{MSY} level in the next ten years even under the more pessimistic and less likely low state of nature in the assessment decision table (Table 4-2). The higher ACL of 50,000 mt is predicted to be sustainable; Table 4-2 indicates that future mortalities assuming full OFL removals in 2013-2022 would maintain the stock above the target level of $B_{25\%}$ under the most likely base case model in the 2011 assessment. This high catch stream in the decision table predicts a decline in spawning biomass in the ten-year projection to a level above the B_{MSY} target; the decline would be predicted to be less under a revised projection since 2013 and 2014 catches were well below the OFL (and below the 25,000 mt ACL). The average annual 2015-2022 catch in Table 4-2, assuming OFL removals, is higher (50,350 mt) than the alternative ACL of 50,000 mt.

Industry requested the higher 50,000 mt Dover sole ACL to improve supply and create a better market for Dover sole. The effective limit of Dover sole in the 2015 and 2016 shorebased IFQ fishery is likely to be driven by the sablefish allocation, which is increasing slightly relative to No Action. Sablefish quota is needed to target Dover sole and the other DTS species using trawl gear. Sablefish IFQ quota is also used in a single-species target fishery using fixed gears. The competition and price for sablefish quota is affected by Asian sablefish demand and supply from north Pacific fisheries outside the west coast EEZ (e.g., BC and the Gulf of Alaska fisheries). It may be the case that the supply and demand of west coast Dover sole will remain limited until there is an increased harvestable surplus of sablefish above the levels preferred for 2015 and 2016. On the other hand, access to a larger volume of Dover sole may allow west coast processors to develop better markets for Dover sole. To the extent that trawl IFQ fishermen can more selectively target quality Dover sole without running out of sablefish quota, a higher catch can be expected achieving a greater positive socioeconomic impact on trawl fishing communities.

The preferred Dover ACL of 50,000 mt is accommodated under Alternative 1 since the 2015 and 2016 ABCs calculated using a P* of 0.45 are greater than 50,000 mt. While the preferred Dover ACL is accommodated under Alternative 2 in 2015, it is not accommodated in 2016 since the ABC calculated using a P* of 0.25 is less than 50,000 mt (46,429 mt). The No Action ACL of 25,000 mt is accommodated under all the alternatives.

Table 4-2. Projected spawning biomass and depletion of Dover sole under three catch streams and two states of nature (the low state of nature and base case models) analyzed in the 2011 stock assessment, from Hicks and Wetzel (2011).

Catch Stream	Year	Catch (mt)	State of nature			
			Low $M_f = 0.110$ $M_m = 0.125$		Base case $M_f = 0.117$ $M_m = 0.142$	
			Spawning biomass (mt)	Depletion	Spawning biomass (mt)	Depletion
OFL	2013	90,411	240,029	70.20%	377,601	80.40%

	2021	12,158	223,398	65.30%	349,654	74.40%
	2022	12,157	224,732	65.70%	351,296	74.80%

4.1.2.2 Widow Rockfish

The 2011 widow rockfish assessment indicated the stock was healthy with a spawning biomass depletion of 51 percent at the start of 2011 (He, *et al*. 2011). The assessment indicated the estimated spawning stock biomass had increased steadily from a low of 30.6 percent at the start of 2001 and the estimated relative spawning stock biomass never dropped below the 25 percent MSST.

Widow rockfish are caught mostly in midwater trawls used to target Pacific whiting and, before 2002 and after trawl rationalization was implemented in 2011, used to target widow and yellowtail rockfish. The exploitation rate was above the target SPR of 50 percent (i.e., $F<F_{MSY}$) until the late 1970s when trawl catches in the target midwater fishery increased to rates beyond the target. This continued until the stock was declared overfished and managed under a rebuilding plan. Harvest declined dramatically and the estimated SPR harvest rates increased rapidly above target F_{MSY}. The increase in biomass during the past decade was the result of reduced catches rather than strong year-classes. The stock was declared rebuilt in 2013 based on the results of the 2013 assessment.

Three ACL alternatives for 2015 and 2016 are analyzed: 1) the status quo ACL of 1,500 mt, 2) an ACL of 3,000 mt, and 3) the preferred ACL of 2,000 mt. Decision table projections in the 2011 assessment assumed constant annual catches varying between 1,500 and 3,000 mt (

Table 4-3). A 3,000 mt constant annual catch is predicted to maintain the stock above the target B_{MSY} level in the next ten years under the more likely state of nature in the assessment (

Table 4-3). However, there is great uncertainty in the stock's estimated biomass, relative productivity (steepness was fixed), and other aspects of the stock's dynamics.

Industry requested a higher widow rockfish ACL than the status quo 1,500 mt to access healthy yellowtail rockfish in the trawl IFQ fishery and to be less constrained by widow rockfish bycatch in the whiting-directed trawl fisheries. The Council's preferred alternative of 2,000 mt provides a slightly higher allowable harvest than under the No Action alternative while maintaining a relatively conservative management strategy for widow given the great uncertainty in the stock's estimated biomass, productivity, and depletion.

The preferred widow rockfish ACL of 2,000 mt is accommodated under all the alternatives since it is less than the 2015 and 2016 ABCs calculated under a P* of 0.25 (the lowest ABC rule analyzed). Likewise, the No Action ACL of 1,500 mt is accommodated for the same reason.

Table 4-3. Widow rockfish decision table (from He *et al.* 2011).

Management decision	Year	Catch (mt)	State of nature			
			h = 0.41		Base case (*h*=0.76)	
			Depletion (%)	Spawning biomass (mt)	Depletion (%)	Spawning biomass (mt)
Constant catch (1,500 mt)	2011	600	30.0%	22,765	51.1%	36,342
	2012	600	29.4%	22,288	50.7%	36,053
	2013	1,500	28.6%	21,686	49.9%	35,514
	2014	1,500	27.2%	20,619	48.5%	34,473
	2015	1,500	26.1%	19,839	47.5%	33,785
	2016	1,500	25.6%	19,443	47.2%	33,585
	2017	1,500	25.7%	19,515	47.8%	34,014
	2018	1,500	26.4%	19,993	49.2%	35,022
	2019	1,500	27.2%	20,655	51.1%	36,325
	2020	1,500	28.1%	21,354	53.1%	37,737
	2021	1,500	29.0%	22,029	55.1%	39,182
	2022	1,500	29.9%	22,648	57.1%	40,603
Constant catch (2,000 mt)	2011	600	30.0%	22,765	51.1%	36,342
	2012	600	29.4%	22,288	50.7%	36,053
	2013	2,000	28.6%	21,686	49.9%	35,514
	2014	2,000	26.8%	20,332	48.1%	34,184
	2015	2,000	25.4%	19,283	46.7%	33,223
	2016	2,000	24.6%	18,639	46.1%	32,770
	2017	2,000	24.4%	18,486	46.3%	32,967
	2018	2,000	24.7%	18,755	47.5%	33,759
	2019	2,000	25.3%	19,217	49.0%	34,860
	2020	2,000	26.0%	19,720	50.7%	36,082
	2021	2,000	26.6%	20,197	52.5%	37,347
	2022	2,000	27.2%	20,609	54.3%	38,596

Management decision	Year	Catch (mt)	State of nature			
			h = 0.41		Base case (*h*=0.76)	
			Depletion (%)	Spawning biomass (mt)	Depletion (%)	Spawning biomass (mt)
Constant catch (2,500 mt)	2011	600	30.0%	22,765	51.1%	36,342
	2012	600	29.4%	22,288	50.7%	36,053

4.1.3 Non-Overfished Stocks with Higher Annual Catch Limit Attainment Rates or Preferred to be Removed from a Status Quo Stock Complex and Managed with Stock-Specific Harvest Specifications

4.1.3.1.1 Cabezon in Oregon

Cope and Key (2009) estimated the spawning biomass depletion of the Oregon substock of cabezon (*Scorpaenichthys marmoratus*) was 52% at the start of 2009. The stock was managed as a component of the Other Fish complex until 2011 when the stock was removed from the complex and managed under stock-specific specifications.

Total estimated catch by sector in 2004-2012 is provided in Table 4-4, with an estimated average annual catch of 43.1 mt. Oregon recreational catches were obtained from a March 23, 2014 Recreational

Fisheries Information Network (RecFIN) query by querying for landed catch (A) plus the reported dead catch (B1).

Table 4-4. Estimated total catch (in mt) of cabezon in Oregon by sector, 2004-2012.

Grand Total	**44.6**	**46.1**	**38.5**	**38.3**	**41.5**	**46.6**	**40.2**	**47.3**	**44.6**

The 2015 and 2016 OFL and ABC are 49 mt and 47 mt (P* = 0.45), respectively. Total estimated catch in 2004-2012 of Oregon cabezon has never been over the 2015 OFL or ABC (Figure 4-2), although the 2011 total catch was equal to the new preferred ABC. The estimated cumulative 2004-2012 catch was 87.9% and 91.9% of the cumulative 2015 OFL and ABC, respectively. Continued management of this stock under the default harvest control rules is predicted to be sustainable.

The preferred alternative for Oregon cabezon is the same as Alternative 1 (ACL = ABC using a P* of 0.45). The alternative 2 ACL of 38 mt in 2015 and 2016 will likely cause the Oregon recreational cabezon to be shorter; however, this may not have a significant impact on projected angler trips since the regulatory action when attaining this ACL early is to go to non-retention of cabezon. If, as suspected, the recreational fishery targets many different groundfish species, non-retention of cabezon is not likely to deter anglers. The nearshore commercial landings of cabezon would also likely be less under Alternative 2, which would decrease economic benefits to the industry.

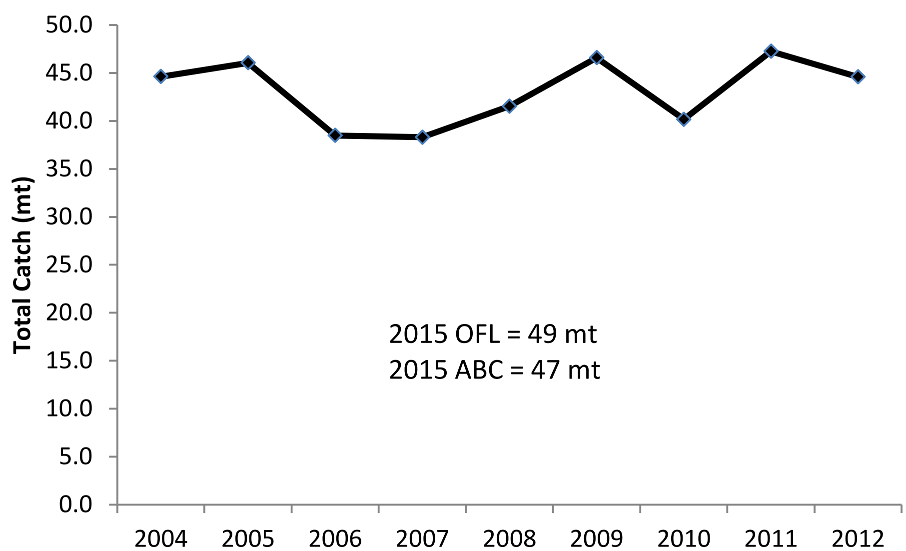

Figure 4-2. Estimated total catch of cabezon in Oregon, 2004-2012, relative to the preferred 2015 OFL and ABC.

4.1.3.2 Sablefish North of 36º N lat.

The 2011 sablefish (*Anoplopoma fimbria*) assessment estimated spawning stock biomass to be at 33 percent of its unfished biomass at the beginning of 2011 (Stewart, *et al.* 2011). The resource was modeled as a single stock; however, there is some dispersal to and from offshore seamounts and along the coastal waters of the continental U.S., Canada, Alaska, and across the Aleutian Islands to the western Pacific which was not explicitly accounted for in this analysis. They are found in waters as from 27-1,000 fm but are most common in the 110-550 fm depth zone.

Sablefish is a major target species in offshore fixed gear and bottom trawl fisheries and is the most valuable commercial groundfish stock on a per pound basis. While the assessment is coastwide and coastwide OFLs and ABCs are specified for the stock, ACLs are apportioned north and south of 36º N lat. since long-term formal allocations have been decided for the portion of the population north of 36º N lat. Only the population north of 36º N lat. has experienced catches with high attainment rates relative to specified ACLs/OYs; the percent difference in the cumulative 2002-2012 catch of sablefish south of 36º N lat. has been 27.1% of the cumulative 2015 ACL.

The preferred coastwide OFL of 7,857 mt is projected from the 2011 assessment. The preferred ABC of 7,173 mt is based on a P* of 0.4. The coastwide ABC is apportioned 73.6% to the north based on the average annual 2003-2010 proportion of estimated swept-area biomass from the NWFSC trawl survey. The 2015 40-10 adjusted ACL for sablefish north of 36º N lat. is 4,793 mt.

Total catches by sector of sablefish north of 36º N lat. are provided in Table 4-5. The cumulative 2002-2012 total catch of sablefish north of 36º N lat. was 19.5% higher than the cumulative 2015 ACL, although the OY (now ACL) was only exceeded in 2007 due to a data glitch in a PacFIN data feed which has now been fixed. In hindsight, the 2015 ACL was exceeded in 9 of the 11 years analyzed (Figure 4-3). Sablefish is one of the most closely tracked species in the U.S. west coast groundfish fishery and the chance of overfishing the stock in 2015 and 2016 is low.

The preferred ACLs for sablefish north of 36º N lat. are 4,793 mt and 5,241 mt in 2015 and 2016, respectively and are based on an ABC using a P* of 0.4 and application of the 40-10 rule to calculate the ACLs. In contrast, the Alternative 1 ACLs of 5,012 mt and 5,467 mt in 2015 and 2016, respectively are based on a higher ABC with the 40-10 rule applied and the Alternative 2 ACLs of 4,114 mt and 4,540 mt in 2015 and 2016, respectively are based on a lower ABC with the 40-10 rule applied. Therefore, with fewer 2015-2016 sablefish removals relative to Alternative 1, the stock would reach the B_{MSY} target faster under the preferred alternative. However, the preferred removals would be higher than under Alternative 2, which would project a slower attainment of the B_{MSY} target under the preferred alternative relative to Alternative 2.

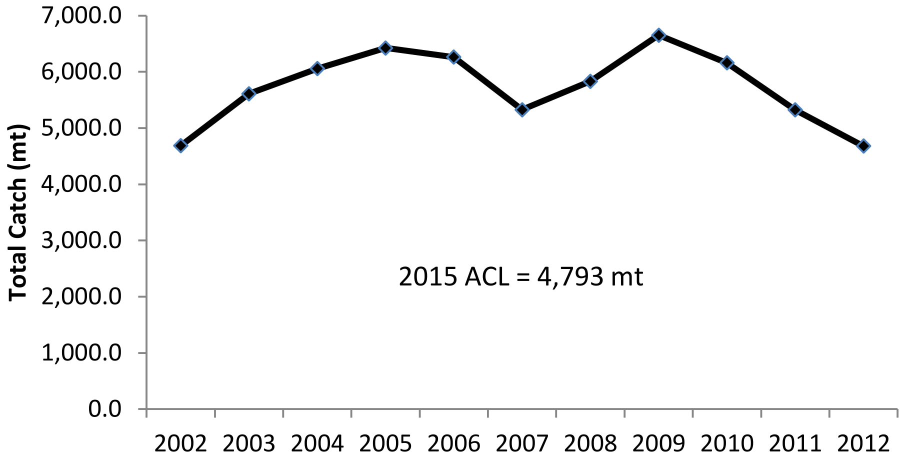

Figure 4-3. Estimated total catch of sablefish north of 36º N lat., 2002-2012 relative to the preferred 2015 ACL.

4.1.3.3 Spiny Dogfish

Gertseva and Taylor (2011) estimated the spawning stock output of spiny dogfish to be 44,660 thousands of fish, which represented 63% of the unfished spawning output level at the start of 2011. While this depletion level indicated the stock was healthy, fishing at the target SPR of 45% was predicted to severely reduce the spawning output over the long term because of the extremely low productivity and other reproductive characteristics of the stock.

The SSC's recommended change in the proxy F_{MSY} harvest rate to calculate the OFL for this stock from an SPR of 45% to an SPR of 50% addresses the conservation need for a more conservative OFL (see the 2014 Stock Assessment and Fishery Evaluation document (PFMC 2014) for more information on the meta-analysis used to recommend the new proxy F_{MSY} harvest rate for elasmobranchs). The new preferred 2015 and 2016 OFLs based on the 50% SPR harvest rate of 2,523 and 2,503 mt, respectively compare to 2015 and 2016 OFLs based on the status quo 45% SPR harvest rate of 2,921 and 2,893 mt, respectively.

Total annual catches of spiny dogfish from 2004-2012 by sector of the groundfish fishery are provided in Table 4-6. Spiny dogfish catches prior to 2004 were not included in the biological impact analysis due to a lack of confidence in the precision of catch estimates derived from the Marine Recreational Fisheries Statistical Survey (MRFSS), which was the basis of California recreational catch estimates prior to implementation of the California Recreational Fisheries Survey (CRFS) in 2004. Spiny dogfish catches in recreational fisheries by state were generated from a March 15, 2014 Recreational Fisheries Information Network (RecFIN) query by querying for landed catch (A) plus the reported dead catch (B1). Since spiny dogfish catches in the Washington recreational fishery are reported in the Unidentified Sharks category, the A + B1 catches of Unidentified Sharks were used with an assumption 100% of that reported catch was spiny dogfish. Gertseva and Taylor (2011) made a similar assumption in the 2011 assessment. Catches by sector in the non-tribal at-sea hake fishery (Catcher-Processors and Mothership) were generated from a NMFS Alaska Fisheries Information Network NORPAC database query on March 14, 2014. Catches for all other sectors were generated from the Groundfish Mortality Multiyear Data Product database provided by the NMFS NWFSC WCGOP program.

Figure 4-4 compares the 2004-2012 annual total catches of spiny dogfish to the preferred 2016 OFL and ABC limits (2016 limits are slightly lower than 2015 limits so these values were chosen). In hindsight, the stock did not exceed the 2016 OFL and experience overfishing during the time series (Figure 4-4). The 2016 ABC was exceeded twice (2005 and 2008) primarily due to high bottom trawl catches (Table 4-6). Trawl catches seem to have stabilized at levels below the 2016 ABC in recent years with the lowest bottom trawl catches occurring since 2011 when the sector was rationalized under IFQ management (catches in the trawl IFQ sector since 2011 are the sum of those in the limited entry trawl permit – fixed gear, limited entry trawl permit – trawl gear, and shoreside hake categories in Table 4-6) While spiny dogfish is not an IFQ species, the distribution of bottom trawl effort in the shorebased IFQ sector changed dramatically since implementation of trawl rationalization. Total catches of spiny dogfish in 2012 were the lowest in the time series.

Managing the stock with its own OFL and ABC starting in 2015 will provide more direct catch accounting and control. There does not appear to be a high risk of the stock being subject to overfishing in the next management cycle. If further catch controls are needed in the future to reduce impacts, the Council and NMFS can consider a trawl allocation designating the species as an IFQ species through a regulatory amendment. However, determining an equitable catch history-based allocation of quota shares by trawl permit may be very difficult given the uncertain catch history of spiny dogfish (dogfish are rarely landed and have been discarded in most fisheries). In the meantime, cumulative landing limits and area closures are the catch control tools available to manage spiny dogfish (PFMC and NMFS 2012).

The cumulative catch of spiny dogfish in 2004-2012 was 39.4% less than the cumulative 2016 OFL (the 2016 OFL times the number of years in the analysis (9)), indicating the preferred harvest specifications and the total catch since 2004 have not created a significant biological risk for the stock of spiny dogfish on the U.S. west coast.

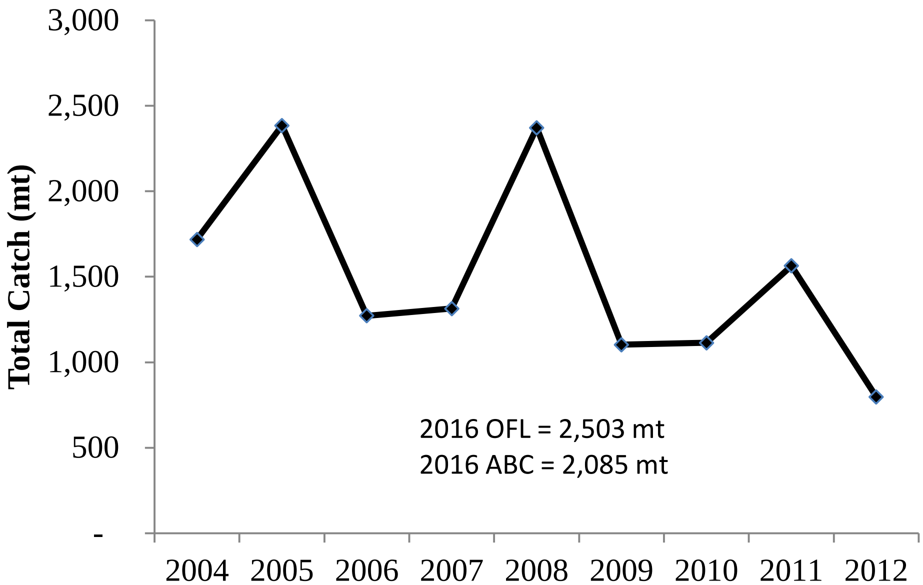

Figure 4-4. Estimated total catch of spiny dogfish, 2004-2012 relative to the preferred 2016 OFL and ABC.

The preferred alternative is to set the 2015 and 2016 spiny dogfish ACLs equal to the ABCs calculated using a P* of 0.4. These ACLs are 2,101 mt and 2,085 mt in 2015 and 2016, respectively. The choice of a higher P* (thus higher ABCs) in 2015 and 2016 than those used to determine the 2014 status quo ABC contribution of spiny dogfish to the Other Fish complex (i.e., P* = 0.3) was based on the SSC addressing the uncertainty in the proxy F_{MSY} harvest rate used to decide the spiny dogfish OFL. The SSC meta-analysis of proxy F_{MSY} harvest rates for elasmobranchs led to a more conservative proxy harvest rate of SPR = 50%. Therefore, with less uncertainty in estimating the OFL, the Council preferred a higher P* and lesser ABC buffer to determine the ACL. The risk of exceeding the 2015 and 2016 ACLs is therefore lower with a lower risk of spiny dogfish bycatch constraining fishing opportunities on healthy target stocks.

The preferred ACLs for spiny dogfish are lower than the the Alternative 1 ACLs (2,303 mt and 2,285 mt in 2015 and 2016, respectively) and higher than the Alternative 2 ACLs (1,551 mt and 1,540 mt in 2015 and 2016, respectively). Therefore, predicted spiny dogfish biomass in the foreseeable future would be lower under Alternative 1 and higher under Alternative 2 relative to the preferred alternative.
