Recruitment deviations of shortbelly from 1960-2005 were estimated in the 2007 assessment; however, there was greater confidence in relative year class strength from 1975-2005. The model suggested a long period of poor recruitment through most of the 1990s, associated with a significant decline in biomass. The interesting conclusion of the 2007 shortbelly assessment was how apparent environmental determinants of shortbelly recruitment and not fishing mortality affected biomass and stock status.

Fishing Mortality

Shortbelly rockfish are not targeted in any west coast fisheries and are incidentally caught in very small amounts. Love et al. (2002) reported that shortbelly rockfish were commonly caught incidentally with trawl gear in the San Francisco-Monterey region during the development of the trawl fishery in the 1930s and 1940s when they were often referred to as steamer rockcod, as they tended to be common in the steamer lanes south of San Francisco. However, as a result of the small size and poor marketability, only modest domestic landings (1 to 65 mt per year) have been reported in the last 25 years. Historical landings were almost certainly less. Phillips (1939) reported that *S. jordani* accounted for 1 lb out of 332,630 lbs examined in Monterey wholesale fish markets between 1937 and 1938. Nitsos (1965) reported trace amounts (approximately 1,000 lbs out of 1,920,000 lbs landed) of *S. jordani* landed in Monterey ports from trawlers in 1962-1963, but none were reported from ports other than Monterey. There was historically a short period in which large numbers of shortbelly were caught during the foreign fisheries of the 1960s and 1970s (Rogers 2003b). These landings (nearly 15,000 mt through 1976, over half of which was taken in 1966) were presumably incidental to the targeting of other rockfish and Pacific hake. Only in the early days of the foreign fisheries (the mid-1960s) were Pacific hake pursued in large numbers south of Cape Mendocino, which is when the bulk of documented historical landings of shortbelly occurred. Since the early 1970s the Pacific hake fishery has been prosecuted primarily off of Oregon and Washington, and to a lesser extent off of Northern California (generally north of Cape Mendocino).

The available data for historical bycatch rates of shortbelly rockfish are extremely sparse. Shortbelly have been caught incidentally, at times in large numbers, by trawlers targeting other semi-pelagic rockfish (usually chilipepper and widow rockfish). As large hauls of shortbelly are not marketable but occasionally foul the mesh of typical groundfish trawls, more experienced fishermen generally recognize shortbelly sign (as well as habitat preferences) on their acoustics, and work to actively avoid schools. Bycatch monitoring programs conducted north of Cape Mendocino in the mid-1980s suggested very negligible levels of bycatch, such that shortbelly were less than 0.25% of total catches in all fishing strategies (which included nearshore flatfish, bottom rockfish, midwater rockfish and whiting, shrimp and the deepwater complex), including less than 0.05% for midwater trawl whiting and rockfish (Pikitch 1988). Very little contemporary information is available for the region south of Mendocino. However, all of these data were collected far north of the usual range of shortbelly. Data processed from the West Coast Groundfish Observer Program suggests that approximately one mt of shortbelly rockfish were caught and discarded in trawl fisheries south of Mendocino. As regulatory measures have closed the vast majority of habitat optimal to adult shortbelly, such trace landings are to be expected in recent years, and comparable data prior to these closures does not exist.

Field et al. (2007) acknowledged the uncertain historical estimates of shortbelly bycatch and therefore explored higher and lower bycatch streams in the 2007 assessment. Varying the historical catch assumptions in the assessment did not result in meaningful deviations from the base model results; therefore, they concluded it was unlikely fishing mortality had any substantive impact on the stock since the days of the foreign fisheries.

1.1.4.17 Shortspine Thornyhead

Distribution and Life History

Shortspine thornyhead (*Sebastolobus alascanus*) are found in the waters off of the West Coast of the United States from northern Baja California to the Bering Sea. They are found from 20 to over 1,500 m in depth. The majority of the spawning biomass occurs in the oxygen minimum zone between 600 and 1,400 m, where longspine thornyheads are most abundant (Bradburn, *et al.* 2011; Jacobson and Vetter 1996). The distribution of the smallest shortspine thornyheads suggests that they tend to settle at around 100–400 m and are believed to have ontogenetic migration down the slope, although large individuals are found across the depth range.

Shortspine thornyhead do not appear to be distributed evenly across the west coast, with higher densities of thornyheads in shallower areas (under 500 m) off of Oregon and Washington, and higher densities in deeper areas off of California. The mean latitude of the largest shortspine is slightly further north than of the medium sizes, suggesting the possibility of either a J-shaped migration, differential patterns of recruitment, or regional differences in exploitation history.

Although their densities vary, shortspine thornyheads are present in almost all trawlable areas below 500 m. They are caught in 91% of the trawl survey hauls below 500 m and 94% of the commercial bottom trawl hauls below 500 m. In camera tows, thornyheads are seen to be spaced randomly across the sea floor (Wakefield 1990), indicating a lack both of schooling and territoriality.

Genetic studies of stock structure do not suggest separate stocks along the west coast. Siebenaller (1978) and Stepien (1995) found few genetic differences among shortspine thornyheads along the Pacific coast. Stepien (1995), however, did suggest that there may be a separate population of shortspine thornyhead in the isolated area around Cortes Bank off San Diego, California. Stepien (1995) also suggested that juvenile dispersion might be limited in the area where the Alaska and California currents split. This occurs towards the northern boundary of the assessment area, near 48° N lat.

Stepien et al. (2000), using a more discerning genetic material (mtDNA), found evidence of a pattern of genetic divergence corresponding to geographic distance. However, this study, which included samples collected from southern California to Alaska, did not identify a clear difference between stocks even at the extremes of the range. No such pattern was seen in longspine thornyhead, which suggests that the shorter pelagic stage (~1 yr vs. ~2 yrs) of shortspine may contribute to an increased genetic separation with distance.

Shortspine thornyheads along the west coast spawn pelagic, gelatinous masses between December and May (Erickson and Pikitch 1993; Pearson and Gunderson 2003; Wakefield 1990). Juveniles settle at around 1 year of age (22- 27 mm in length), likely in the range of 100-200 m (Vetter and Lynn 1997), and migrate down the slope with age and size, although large individuals are found across the depth range.

Shortspine thornyhead grow very slowly, but may continue growing throughout their lives, reaching maximum lengths of over 70 cm. Females appear to reach larger sizes than do males. Maturity in females has been estimated as occurring near 18 cm, at 8-10 years of age (Pearson and Gunderson 2003), although new information suggests that patterns of maturity may be more complex.

Shortspine and longspine thornyheads have historically been caught with each other and with Dover sole and sablefish, making up the DTS fishery. Other groundfish species that frequently co-occur in these deep waters include a complex of slope rockfishes, rex sole, longnose skate, roughtail skate, Pacific grenadier, giant grenadier, Pacific flatnose as well as non-groundfish species such as Pacific hagfish and a diverse complex of eelpouts. Shortspine thornyheads typically occur in shallower water than the shallowest longspine thornyheads, and migrate to deeper water as they age. When shortspines have reached a depth where they overlap with longspines, they are typically larger than the largest longspines. Shortspine thornyhead stomachs have been found to include longspine thornyheads, suggesting a predator-prey linkage between the two species.

Thornyheads spawn gelatinous masses of eggs which float to the surface. This may represent a significant portion of the upward movement of organic carbon from the deep ocean (Wakefield 1990). Thornyheads have been observed in towed cameras beyond the 1,280 m limit of the current fishery and survey, but their distribution, abundance, and ecosystem interactions in these deep waters are relatively unknown.

Stock Status and Management History

Beginning in 1989, both thornyhead species were managed as part of the deepwater complex with sablefish and Dover sole (DTS). In 1991, the Council first adopted separate ABC levels for thornyheads and catch limits were imposed on the thornyhead group. Harvest guidelines (HGs) were instituted in 1992 along with an increase in the minimum mesh size for bottom trawl fisheries. In 1995 separate landing limits were placed on shortspine and longspine thornyheads and trip limits became more restrictive. Trip limits (predominantly 2-month limits on cumulative vessel landings) have often been adjusted during the year since 1995 in order to not exceed the HG or OY for that year. At first, the HG for shortspine thornyhead was set higher than the ABC (1,500 vs. 1,000 mt in 1995-1997) in order to allow a greater catch of longspine thornyhead, which was considered a relatively underutilized and healthy stock. In 1999 the OY was set at less than 1,000 mt and remained close to that level through 2006. As a result of the 2005 shortspine assessment, catch limits increased to about 2,000 mt per year and have remained near that level to the present.

Since early 2011, trawl harvest of each thornyhead species has been managed under the PFMC's catch share, or individual fishing quota (IFQ), program. Whereas the trip limits previously used to limit harvest restricted only the amount of fish each vessel could land, individual vessels fishing under the catch-share program are now held accountable for all of the quota-share species they catch.

The most recent stock assessment of west coast longspine thornyhead was done in 2013. This was the fifth assessment done for longspines, but only the second in which it was assessed individually (earlier assessments were of longspine and shortspine thornyheads in combination). Previous assessments were conducted by Jacobson (Jacobson 1990; 1991), Ianelli et al. (1994), Rogers et al. (1997), and Fay (2006). The 1990 and 1991 assessments were very similar. Important features included reviews of available biological data, and analyses of trends in mean lengths from port samples and catch rates calculated from logbook data. Swept-area and video biomass estimates were used to estimate average biomass levels and exploitation rates in the Monterey to US-Vancouver management areas. The available data were used to conduct per-recruit analyses of yield, revenue, and spawning biomass, and to develop estimates of the then target level of $F_{35\%}$.

Ianelli et al. (Ianelli, *et al.* 1994) assessed the coastwide abundance of longspine and shortspine thornyheads based on slope survey data, an updated analysis of the logbook data, and fishery length-composition data to estimate the parameters of length-based Stock Synthesis models, under different assumptions regarding discarding practices.

The assessment of thornyheads in 1997 covered the area from Central California at 36° N lat. to the U.S.-Canada border (Rogers, *et al.* 1997). The STAR Panel expressed concern that management requires more detailed information on thornyheads than could be obtained from the available data. In 1998, two separate stock assessments covering the area north of 36° N lat. were prepared and accepted by the Council (NMFS and OT 1998; Rogers, *et al.* 1998). A synthesis of these two assessments was used to set the harvest specifications 1999 and 2000. Given that the synthesis estimated 1999 depletion at 32 percent of virgin biomass, the Council used the precautionary 40-10 policy to set the OYs for those two years.

There were a range of uncertainties in the 2001 assessment of shortspine thornyhead, in 2001, not the least of which was the estimated biomass (Piner and Methot 2001). The assessment was extended south to Point Conception (in contrast to past surveys, which were limited to stocks north of the 36° N latitude management area boundary). The authors concluded the 2001 spawning biomass ranged between 25 percent and 50 percent of unexploited spawning biomass. As was also the case in the 1998 assessment, the uncertainty in abundance largely revolved around the uncertainty in recruitment and survey q, or catchability, of shortspine thornyhead in slope surveys. The authors also concluded that the trend in stock biomass was increasing and the stock was not depleted. Based on estimated biomass and application of the GMT-recommended F=0.75M principle (which approximated an $F_{50\%}$ proxy harvest rate for shortspine thornyhead), the assessment authors and GMT recommended a slight increase in the ABC and OY for 2002. They also recommended that the harvest specifications be set for two areas divided by Point Conception at 34º27’ N lat., rather than the previous policy to separate the management areas at the Conception-Monterey border (36º N lat.). Despite the uncertainty in biomass estimates and determination of whether shortspine thornyhead should be treated as a “precautionary zone” stock, these recommendations did treat the stock as such by applying the 40-10 adjustment.

The 2005 stock assessment estimated the shortspine thornyhead spawning stock biomass to be at 62.9 percent of its initial, unfished biomass in 2005 (Hamel 2006c). The 2005 assessment extended the southern border of the assessment area from Point Conception to the Mexican border (32.5º N latitude). Including the entire Conception area resulted in a larger basis for unfished biomass, given that this area was estimated to contain nearly half of the stock’s total west coast biomass. It was noted that there could be regional management concerns with this stock because while the assessment OY was coastwide, there are differences in historic exploitation rates north and south of Point Conception. It was also noted the biomass estimate south of Pt. Conception was more uncertain than that in the north.

The 2013 stock assessment estimated the shortspine thornyhead spawning stock biomass to be at 74.2 percent of its initial, unfished biomass in 2013 (Taylor and Stephens 2013). A longer time series of the coastwide NWFSC trawl survey biomass estimates were included in this assessment relative to the 2005 assessment. Therefore, the STAT concluded there was no greater uncertainty in the biomass south of Pt. Conception relative to estimates for the rest of the coast. As in the previous assessment, no age data were used in the 2013 assessment and growth parameters were fixed at the same values used in 2005.

Stock Productivity

Taylor and Stephens (2013) estimated annual shortspine recruitment using a Beverton-Holt stock-recruitment function and assuming a steepness value of 0.6. Most 2013 rockfish assessments used a steepness prior of 0.779, estimated from a meta-analysis of rockfish assessment results. This value might be expected in the 2013 longspine assessment; however, rockfish ecology and reproduction are quite different from those of thornyheads, which (for example) do not give birth to live young but rather spawn floating egg masses.

Steepness in the shortspine thornyhead assessment was fixed at 0.6 both in the 2005 and 2013 models (Hamel 2006c; Taylor and Stephens 2013). This value was justified based on consistency between the modeling approach and management targets, in addition to being within a range of biologically reasonable values.

Annual deviations about this stock-recruitment curve were estimated for the years 1944 through 2012. Estimated recruitments do not show high variability, and the uncertainty in each estimate is greater than the variability between estimates. The 2013 shortspine assessment is relatively uninformative of relative year class strength since ages were not used in the model (thornyheads are notoriously difficult to age). Therefore, a length-based assessment with an assumed steepness is used to determine recruitment.

Fishing Mortality

Landings of shortspine were estimated to have risen to a peak of 4,815 mt in 1989, followed by a sharp decline during a period of trip limits and other management measures imposed in the 1990s. Since the institution of separate trip limits for shortspine and longspine thornyheads, the fishery had more moderate removals of between 1,000 and 2,000 mt per year from 1995 through 1998. Landings fell below 1,000 mt per year from 1999 through 2006, then rose to 1,531 in 2009 and have declined since that time.

Exploitation rates in terms of spawning potential ratio indicates that the exploitation slightly exceeded the F_{MSY} target for a single year in 1985 and then for the period 1989-1994. However, the stock status is estimated to have never fallen below the $B_{40\%}$ management target.

1.1.4.18 Spiny Dogfish

Distribution and Life History

In the Northeast Pacific, spiny dogfish (*Squalus suckleyi*) occur from the Gulf of Alaska, with isolated individuals found in the Bering Sea, southward to San Martin Island, in southern Baja California. They are extremely abundant in waters off British Columbia and Washington, but decline in abundance southward along the Oregon and California coasts (Ebert 2003; Ebert, *et al.* 2010).

The U.S. west coast spiny dogfish stock likely has interaction and overlap with dogfish observed off British Columbia. About 1,300 dogfish were tagged along the coast of Washington from 1942-1946, during the period of the strong directed fishery for dogfish. Only 50 of these fish were recaptured and had tags returned (4%), of which 54% were recaptured within U.S. coastal waters, while 32% were recaptured in coastal Canada and 12% in the inside waters of Puget Sound and the Strait of Georgia. One fish was recaptured in coastal Japanese waters (7 years after being tagged). Because many of the releases were close to the U.S.-Canada border, and the fractions do not take into account the relative fishing pressure within each area, this study is of limited use in providing reliable information about dogfish movement rates.

A spatial population dynamics model (Taylor 2008), which included these tagging data (along with much larger tagging experiments conducted in Canada and inside U.S. waters of Puget Sound) estimated movement rates of about 5% per year between the U.S. coastal sub-population of dogfish and that found along the west coast of Vancouver Island in Canada. The model also estimated movement rates of less than 1% per year between the U.S. coastal sub-population of dogfish and that in the Puget Sound.

These sharks appear to prefer areas in which the water temperature ranges from 5 to 15° C, often making latitudinal and depth migrations to follow this optimal temperature gradient (Brodeur, *et al.* 2009). There is also evidence of seasonal movement along the coast based on both tagging data and timing of historical fisheries (Ketchen 1986). One estimate of the seasonal movement along the Pacific coast is a North-South shift of about 600 km from winter to summer (Taylor 2008). This seasonal pattern is not as extreme as that found among spiny dogfish in Atlantic waters of the U.S., which are likely due to larger fluctuations in temperature. Dogfish have also been captured in high-seas salmon gillnets across the North Pacific between about 40° and 50° N lat. (Nakano and Nagasawa 1996), but the extent of these wide-ranging pelagic movements is poorly understood.

The biology and life history of spiny dogfish are relatively well studied (Campana, *et al.* 2009; Di Giacomo, *et al.* 2009; Taylor 2008; Tribuzio 2009; Tribuzio, *et al.* 2009; Tribuzio, *et al.* 2010; Vega, *et al.* 2009). This species is an opportunistic feeder that consumes a wide range of prey (whatever is abundant). Schooling pelagic fish, such as herring, make up the majority of its diet. They also feed on invertebrates such as shrimp, crab and squid. In turn, dogfish are preyed upon by larger cod, hake, and other spiny dogfish (Beamish, *et al.* 1992; Brodeur, *et al.* 2009; Tanasichuk, *et al.* 1991). Larger species of sharks, as well as seals and killer whales, also feed on dogfish.

Spiny dogfish have internal fertilization and ovoviviparous development. The internal development takes place over 22-24 months, the longest gestation period known for sharks. The number of pups in each litter ranges between 5 and 15 individuals depending on the size of the female (larger females bearing more pups). The size at birth is generally between 20 and 30 cm for both genders. Male spiny dogfish are reported to grow faster than females, but females reach larger sizes. This species is the latest maturing (with 50% female maturity reported at 35.5 years) and longest lived of all elasmobranchs (Cortes 2002; Saunders and McFarlane 1993; Smith, *et al.* 1998; Taylor 2008). Life history traits of spiny dogfish make the species highly susceptible to overfishing and slow to recover from stock depletion since its slow growth, late maturation, and low fecundity are directly related to recruitment and spawning stock biomass (Holden 1974; King and McFarlane 2003).

Stock Status and Management History

Spiny dogfish on the U.S. west coast have been utilized for almost a thousand years, with those in Puget Sound first used by Native Americans (Bargmann 2009). The exploitation of spiny dogfish in coastal waters, however, started in the 20th century. Even though the history of spiny dogfish utilization on the U.S. west coast included a brief but intense commercial fishery in the 1940s, in general this species is not highly prized and is mostly taken as bycatch in other fisheries.

Prior to 1936, coastal catches of spiny dogfish were extremely minimal, but in 1936, shortly after it was discovered that livers of spiny dogfish have high level of vitamin A, a large scale fishery for dogfish developed in the Pacific Northwest. Before World War II, Northeast Pacific dogfish livers could not compete with the cheaper and more potent sources of vitamin A from Europe. But when World War II started and European supplies were cut, dogfish shark livers became the major source of vitamin A in the United States, and the spiny dogfish fishery grew rapidly along the Pacific coast. The processed liver oils were used in pharmaceuticals, food processing, and animal feed (Bargmann 2009; Ketchen 1986).

During the liver fishery, dogfish were targeted by three major gear groups, including setlines, set nets, and bottom trawls. The timing of the dogfish liver fishery coincided with the development of bottom trawling in the U.S. Northwest, and though at the onset of the fishery the catches by trawl were low, by the mid-1940s trawling was the dominant type of fishing for dogfish.

In 1945, a sharp decline in spiny dogfish catches began. This decline occurred despite continued strong demand for vitamin A and high prices for dogfish livers, but because of decreased availability of the species in the Northeast Pacific (Bargmann 2009; Ketchen 1986). In 1950, with the advent of synthetic vitamins, demand for spiny dogfish livers declined and catches in the Northeast Pacific virtually ended.

Between 1950 and 1974, the landings of spiny dogfish remained minimal. By the late 1950s it was reported that species availability had increased. Also, in the late 1950s-early 1960s, dogfish earned a bad reputation among fishermen. They were blamed for driving off commercially valuable species such as herring and mackerel, while consuming large numbers of them. Spiny dogfish have also been observed biting through nets to get to their fish prey, releasing many of them and damaging fishing gear in the process. They were also reported damaging gear when become entangled in commercial nets. As a result, fishermen were trying to avoid areas with higher chances of dogfish catches (such as soft bottoms, for example) to prevent encountering dogfish and potentially damaging their gear.

A market opportunity for dogfish developed in the mid-1970s. In Europe, spiny dogfish has long been used an inexpensive source of human food, for fish and chips in particular. A decline in the European dogfish supply provided an opportunity for developing an export dogfish food fishery on the U.S. west coast. Also, during the late 1970s, shark cartilage started to be used in cancer treatment, and a portion of spiny dogfish catches have since been sold for medical research and treatment (Gregory Lippert, WDFW, pers. com. as cited by Gertseva and Taylor (2011)). As before, three types of gear were involved in catching dogfish (bottom trawl, setlines, and sunken gill nets), but since the mid-1980s catches by gillnets have been minimal.

Spiny dogfish is a common bycatch species, often caught in other fisheries and largely discarded. For instance, it has long been incidentally caught in the hake fishery, which is almost exclusively conducted with mid-water trawls. Large-scale harvesting of Pacific hake in the U.S. began in 1966, when factory trawlers from the Soviet Union and other countries began targeting this stock. After the 200-mile U.S. EEZ was declared in 1977, a joint-venture fishery was initiated between U.S. trawlers and Soviet factory trawlers acting as motherships (larger, slower ships for fish processing and storage while at sea). By 1989 the U.S. fleet capacity had grown to a level sufficient to harvest the entire quota, and no further foreign fishing was allowed. The Pacific hake fishery is currently 100% observed at sea and data on bycatch species, including spiny dogfish, is being routinely collected.

Spiny dogfish on the U.S. west coast has been managed under the Other Fish complex since implementation of the Groundfish FMP by the Council in 1982. In 2005, reduction in the Other Fish ABC was implemented due to removal of the California substock of cabezon from the Other Fish complex. The same year, a 50% precautionary OY reduction was implemented to accommodate uncertainty associated with managing unassessed stocks. In 2006, a trip limit for spiny dogfish was imposed for U.S. west coast waters which varied between 45 and 91 mt per two months for all gears. In 2009, another ABC reduction was implemented due to removal of longnose skate from the Other Fish complex and the 50% OY reduction was maintained.

In 2011, reduction in the Other Fish OFL was implemented due to removal of the Oregon substock of cabezon from the Other Fish complex. The 50% precautionary reduction to the ACL was maintained; however, a scientific uncertainty buffer was specified as an ABC of 7,742 mt under the Amendment 23 framework.

Gertseva and Taylor (2011) estimated the spawning stock output of spiny dogfish to be 44,660 thousands of fish (95% confidence interval: 8,937-80,383), which represents 63% of the unfished spawning output level. While this depletion level indicates the stock is currently healthy, fishing at the target SPR of 45% is expected to severely reduce the spawning output over the long term because of the extremely low productivity and other reproductive characteristics of the stock. The Council partially addressed this by setting a more conservative spiny dogfish ABC for 2013 by specifying a P* of 0.3.

The Council further decided to manage spiny dogfish with stock-specific harvest specifications beginning in 2015. The SSC also investigated establishing a more conservative F_{MSY} harvest rate for spiny dogfish and other elasmobranchs in recognition of their lower productivity. The SSC recommended and the Council adopted a more conservative proxy 50% SPR harvest rate as an interim measure for elasmobranchs. The 50% SPR was based on an SSC meta-analysis of Chondrichthyes species using the posterior distribution for F_{MSY}/M values as reported by Zhou et al. (2012). The SSC said they may further investigate sustainable harvest rates for Council-managed elasmobranchs as more information becomes available in the future.

Stock Productivity

Spiny dogfish have a relatively low stock productivity due to slow growth, late maturation, and low fecundity. The fecundity of dogfish in the Northeast Pacific Ocean has been well studied, with pregnant females having relatively few pups per litter (5 to 15), and with relatively little variability among individuals. Unlike fish producing millions of eggs, the low fecundity of dogfish suggests both low productivity in general and a more direct connection between spawning output and recruitment than for many species.

Gertseva and Taylor (2011) modeled the spiny dogfish spawner-recruit relationship using a new functional form that was recently added to the Stock Synthesis platform, which allowed a more explicit modeling of pre-recruit survival between the stage during which embryos can be counted in pregnant females to their recruitment as age 0 dogfish. This new method may be useful for a variety of low fecund species, as well as providing additional flexibility in the spawner-recruit relationship that may be explored for any stock. The method is an expansion and improvement on similar approaches previously applied to dogfish (Taylor 2008; Wood, *et al.* 1979), which assumed a linear decline in age 0 survival as a function of population density. While steepness was not estimated or assumed in the conventional sense of a Beverton-Holt stock-recruitment relationship, a value for steepness can be calculated using a formula provided by Gertseva and Taylor (2011). The calculated value of steepness is 0.28, indicating a great degree of compensation or density-dependent recruitment.

Fishing Mortality

During the last 10 years, relative exploitation rates (catch/summary biomass) are estimated to have hovered around 1% and SPR is estimated to be well above pre-2015 management target of SPR 45%. The 2011 assessment identified a period during the vitamin A fishery in the 1940s when the exploitation rate exceeded the current F_{MSY} proxy harvest rate.

1.1.4.19 Splitnose Rockfish South of 40°10’ N Lat.

Distribution and Life History

Splitnose rockfish (*Sebastes diploproa*) are distributed from the northern Gulf of Alaska (Prince William Sound) to central Baja California and occur at depths between 91-795 meters. Adults are the most abundant between British Columbia and southern California at depths from 215 to 350 meters (Alverson, *et al.* 1964; Gunderson and Sample 1980; Love, *et al.* 2002). The species is distinguished by having a deeply notched upper jaw, which inspired its Greek name diploproa, meaning "double prow". Splitnose rockfish are commonly seen on low-relief mud fields of the continental shelf and upper slope, often near isolated rock, cobble or shell debris. Solitary individuals are often found resting on the seafloor, although they occasionally form schools that move more than 100 meters in the water column (Love, *et al.* 2002; Rogers 1994).

Splitnose rockfish co-occur with an assemblage of slope rockfish, including Pacific ocean perch (*Sebastes alutus*), darkblotched rockfish (*Sebastes crameri*), yellowmouth rockfish (*Sebastes reedi*), and sharpchin rockfish (*Sebastes zacentrus*) off Washington and Oregon, and stripetail rockfish (*Sebastes saxicola*), darkblotched rockfish and shortspine thornyhead (*Sebastolobus alascanus*) off central California. Pacific ocean perch and darkblotched rockfish are the most abundant members of that assemblage off the coasts of Oregon and Washington, but splitnose rockfish and darkblotched rockfish dominate off the northern coast of California. Lesser amounts of splitnose have also been noted in the deepwater DTS assemblage and with shrimp catch (Rogers 1994; Rogers and Pikitch 1992; Weinberg 1994).

There are no clear stock delineations for splitnose rockfish in the U.S. waters. No molecular markers have yet been developed for this species, and no genetic data are currently available to suggest the presence of several stocks (Waples, *et al.* 2008). No distinct breaks are seen in the fishery landings and catch distributions. Survey catches imply a continuous distribution. The spatial dynamic cluster analysis of the Northwest Fisheries Science Center (NWFSC) survey abundance indices (Cope and Punt 2009) provided no evidence of spatial stock structure for splitnose rockfish off Washington, Oregon, and California.

Splitnose rockfish are documented in the literature to live to at least 86 years (Bennett, *et al.* 1982), although a fish encountered in a NMFS survey was aged at 103 years old. This is a small species – the maximum size reported in the literature is 46 cm (Love, *et al.* 2002); the vast majority of individuals caught in NMFS surveys were under 44 cm in fork length, although a few fish larger than this were caught.

Splitnose rockfish exhibit sexual dimorphism in growth. Although the males grow to their maximum lengths earlier than females, females reach larger sizes than males (Boehlert 1980; Love, *et al.* 2002). It was hypothesized that life history characteristics may vary with latitude, but that is uncertain. Boehlert and Kappenman (1980) detected greater size-at-age with increasing latitude and suggested more rapid growth of fish in the northern end of their range. Analysis of the NWFSC shelf-slope survey data did not show a distinct gradient in growth rate between north and south, although the asymptotic length (Linf) exhibits a latitudinal gradient (Gertseva, *et al.* 2009). Growth of splitnose rockfish was found to correlate with climate and environmental variables, including sea surface temperature, the El Niño Southern Oscillation (ENSO) index, and the Pacific Decadal Oscillation (PDO) (Black 2009; Black, *et al.* 2008); more information is needed to develop climate-growth relationships for stock assessment purposes.

Female splitnose rockfish off California mature at 6-9 years old (18-23 cm long) (Echeverria 1987), and their fecundity increases with size (Phillips 1964). Splitnose rockfish mature somewhat later off British Columbia - both males and females reach 50% maturity at size of 27 cm (Westrheim 1975). Like other rockfishes, splitnose utilize internal fertilization and bear live young (Love, *et al.* 2002). This species can exhibit a long reproductive season, with young larvae found in all months off southern California, from January to September off central California, from March to September in Oregon, and in July off Washington (Love, *et al.* 2002; Moser, *et al.* 2000).

Young juveniles live at the surface for several months, then go through a transitory midwater residence, and finally settle to benthic habitats near the end of their first year of life (Love, *et al.* 2002). During their first year, splitnose have been found living among drifting vegetation in Puget Sound and southern California, and under floating objects in Queen Charlotte Sound, British Columbia (Shaffer, *et al.* 1995). Pelagic juvenile splitnose feed on calanoid copepods and amphipods (Shaffer, *et al.* 1995), while benthic juveniles and adults eat krill, copepods, sergestid shrimps and amphipods. Splitnose are prey of Steller sea lions and other pinnipeds (Love, *et al.* 2002).

Size-composition data for splitnose rockfish show a strong gradient of body size with depth, with smaller fish in shallow waters, suggesting ontogenetic movements of splitnose rockfish to deeper waters with increasing size and age, a common phenomenon in the genus *Sebastes* (Boehlert 1980).

Stock Status and Management History

Limits on domestic rockfish catches were first instituted in 1983, with splitnose rockfish managed as a part of the *Sebastes* complex, which included around 50 species. The ABC for the *Sebastes* complex was estimated for each International North Pacific Fisheries Council (INPFC) area along the coast based on historic landings. In 1994, the *Sebastes* complex was divided into southern and northern management areas, and harvest guidelines were established for the complex in each area. The southern area included Conception, Monterey and Eureka INPFC areas, and the northern area included Columbia and U.S.-Vancouver INPFC areas.

In response to a concern that deepwater species off Oregon and Washington might have been overharvested, Rogers (1994) conducted a preliminary assessment of splitnose rockfish, which focused on compiling and reviewing the available data. However, since the data were sparse and no evident trends in biomass or mean size were detected, the results were inconclusive. In 1996 the status of several rockfish species, which were part of the *Sebastes* complex, were assessed (Rogers, *et al.* 1996), and ABCs for splitnose rockfish in the southern area were calculated to be 868 mt for the southern management area and 274 mt for the northern management area. These amounts were not specified individually, but included in the total ABCs for the *Sebastes* complex.

In 1998, unusually high splitnose rockfish landings drove *Sebastes* complex harvests in the southern management area sharply upward. In 1999, for the first time, splitnose rockfish were individually separated from the southern *Sebastes* complex. Individual ABCs and OYs for splitnose rockfish in that area have been specified along with splitnose-specific trip limits since then. The ABC for the southern management area was set at 868 mt, as estimated in the 1996 assessment of the remaining rockfish in the *Sebastes* complex (Rogers, *et al.* 1996).

Additionally in 1999, the general *Sebastes* complex was divided into nearshore, shelf, and slope assemblages, and the dividing line between the northern and southern management areas was shifted southward to 40º10’ N lat., near Cape Mendocino. Since that time, in the northern area, splitnose has been managed under trip limits for minor slope rockfish. In 2000, harvest specifications for splitnose rockfish were set for the Conception and Monterey areas only, and 48 mt for the Eureka area were added to the northern minor rockfish ABC. Also, a precautionary adjustment of the OY (reduced from the ABC by 25%) was specified to account for the limited nature of the assessment. In 2000, the ABC and OY for splitnose rockfish south of 40º10’ N lat. were reduced based on the revised F_{MSY} harvest rate policy. During the last 10 years, the coastwide landings and total catch of splitnose rockfish were relatively low, and the limits established for the area south of 40º10’ N lat. have not been exceeded.

Gertseva et al. (2009) assessed splitnose rockfish coastwide and determined the stock was healthy with a depletion of 66 percent at the start of 2009. Since 1999, the splitnose spawning output was estimated to have been increasing in response to below-average removals and above-average recruitment during the last decade. At the beginning of 2009 the estimated spawning stock output was 8,426 million eggs. Uncertainty in the model was explored though asymptotic variance estimates and sensitivity analyses. Asymptotic confidence intervals were estimated within the model and reported throughout the assessment for key model parameters and management quantities. Uncertainty in recent recruitment was used to define alternative states of nature and develop the decision table.

Stock Productivity

Steepness of the stock-recruitment curve was fixed at a value of 0.58 in the 2009 splitnose rockfish assessment, as estimated by a meta-analysis for unassessed rockfish. Recruitment deviations were estimated for each year between 1960 and 2006, which was the period best informed by the data based on evaluation of the variance of the recruitment deviations. Prior to 1960 and after 2006, recruits were taken deterministically from the stock-recruit curve. The model estimated above-average recruitments in the most recent years beginning 1999 (), which along with low catches during the last decade determine a population increase in recent and early forecast years. Uncertainty in recent recruitment was used to define alternative states of nature and develop the decision table.

Fishing Mortality

Splitnose rockfish have been taken incidentally in fisheries such as the trawl fisheries targeting POP, mixed slope rockfish, and other deepwater targets, but have not been a commercial target species. Splitnose rockfish were lightly exploited until the 1940s, when the trawl fishery for rockfish first became important. With the development of the POP fishery (a species with which splitnose rockfish co-occur), spawning output of splitnose rockfish began to decline. A sharp drop in the 1960s was associated with large harvests of POP by foreign trawl fleets operating in the U.S. EEZ. Another drop occurred in 1998 when the increased availability of splitnose rockfish led to high removals off California. Since 1999, the splitnose spawning output was estimated to have been increasing in response to below-average removals and above-average recruitment during the last decade.

It was decided to continue management of splitnose rockfish with stock-specific specifications south of 40°10’ N lat. and under the Slope Rockfish complex north of 40°10’ N lat. when the coastwide splitnose rockfish assessment was first used to inform management in 2011. A north-south apportionment based on the average 1916-2008 assessed area catch resulting in 64.2 percent stock-specific specification in the southern area and 35.8 percent for the contribution of splitnose rockfish to the Slope Rockfish North complex was used to apportion harvest specifications since 2011. The Council recommended continuing this management strategy largely due to the implications of determining the uncertain catch history by trawl permit to initially allocate trawl splitnose quota shares (QS) under Amendment 20. Since splitnose rockfish are not targeted and predominantly discarded at sea, little data would be available to determine catch history.

1.1.4.20 Starry Flounder

Distribution and Life History

Starry flounder (*Platichthys stellatus*) have a very broad geographic distribution around the rim of the North Pacific Ocean and have been recorded from Los Angeles to the Aleutian Islands, although they are rare south of Point Conception (Kramer and O'Connell 1995; Orcutt 1950). Off the U.S. west coast starry flounder are found commonly in nearshore waters, especially in the vicinity of estuaries (Baxter 1999; Kimmerer 2002; NOAA 1990; Orcutt 1950; Pearson 1989; Sopher 1974). It has quite a shallow bathymetric distribution, with most individuals occurring in waters less than 80 m, although specimens have been collected off the continental shelf in excess of 350 m (Kramer and O'Connell 1995; Orcutt 1950). They are most often found on gravel, clean shifting sand, hard stable sand, and mud substrates.

Spawning occurs primarily during the winter months of December and January, at least in central California (Orcutt 1950); it may occur somewhat later in the year (February-April) off British Columbia and Washington (Hart 1988; Love 1996). Egg/larval development apparently takes about 2-3 months to occur. Offspring principally remain within the estuaries until age two, when many have migrated to the adjacent ocean habitats (Baxter 1999; Kimmerer 2002; Orcutt 1950). Reproductive maturity occurs at age two years for males and age three years for females, when the fish are 28 cm and 35 cm, respectively. Tagging studies have shown that fish are relatively sedentary and move little during their adult lives (Love 1996); however, there is little information on regional variation in stock structure.

Starry flounder consume crabs, shrimps, worms, clams and clam siphons, other small mollusks, small fish, nemertean worms, and brittle stars (Hart 1988).

Stock Status and Management History

The U.S. west coast starry flounder stock was assessed in 2005 (Ralston 2006). The assessment was based on the assumption of separate biological populations north and south of the California-Oregon border. The assessment used catch data, relative abundance indices derived from trawl logbook data, and an index of age-1 abundance from trawl surveys in the San Francisco Bay and Sacramento-San Joaquin River estuary. Unlike most other groundfish stock assessments, no age- or length-composition data were directly used in the assessment. Both the northern and southern populations were estimated to be above the target level of 40 percent of virgin spawning biomass (44 percent in Washington-Oregon and 62 percent in California), although the status of this data-poor species remained fairly uncertain compared to that of many other groundfish species. One of the most significant areas of uncertainty in the assessment was the estimate of natural mortality rate, which was quite high (0.30 for females and 0.45 for males).

Starry flounder were managed in the Other Flatfish complex until 2007, when the stock was removed from the complex and managed with stock-specific specifications determined from the assessment. Starry flounder have never been overfished or subject to overfishing.

Stock Productivity

Recruitment deviations were estimated in both the northern and southern starry flounder assessment models, although selectivity patterns were fixed external to the model after analysis of trawl length composition information from the PacFIN-BDS data base and sport length composition information from the RecFIN data base. Growth and other life history parameters were also fixed, largely based on a detailed study of starry flounder by Orcutt (1950). Finally, spawner-recruit steepness ($h = 0.80$) and recruitment variability ($\sigma r = 1.00$) were also held constant.

Starry flounder is a relatively productive stock with a PSA productivity score of 2.15. They are also not vulnerable to potential overfishing ($V = 1.04$).

Fishing Mortality

Starry flounder are mostly caught in nearshore recreational fisheries. Historically, they were also caught in nearshore trawl efforts; however, this catch is rare today given that Washington and California have closed their state nearshore waters to trawling. Both the northern and southern stocks were estimated to be well above the $B_{25\%}$ B_{MSY} threshold ($B_{44\%}$ in Washington-Oregon and $B_{62\%}$ in California). In addition, recent exploitation rates have been well below the F_{MSY} proxy for flatfish. Recent landings in both areas have been less than 20% of the calculated ABC/OFL.

1.1.4.21 Widow Rockfish

Distribution and Life History

Widow rockfish (*Sebastes entomelas*) range from Albatross Bank off Kodiak Island to Todos Santos Bay, Baja California, Mexico (Eschmeyer, *et al.* 1983; Miller and Lea 1972; NOAA 1990). They occur over hard bottoms along the continental shelf (NOAA 1990) and prefer rocky banks, seamounts, ridges near canyons, headlands, and muddy bottoms near rocks. Large widow rockfish concentrations occur off headlands such as Cape Blanco, Cape Mendocino, Point Reyes, and Point Sur. Adults form dense, irregular, midwater and semi-demersal schools deeper than 100 m at night and disperse during the day (Eschmeyer, *et al.* 1983; NOAA 1990; Wilkins 1986). All life stages are pelagic, but older juveniles and adults are often associated with the bottom (NOAA 1990). All life stages are fairly common from Washington to California (NOAA 1990). Pelagic larvae and juveniles co-occur with yellowtail rockfish, chilipepper, shortbelly rockfish, and bocaccio larvae and juveniles off Central California (Reilly, *et al.* 1992).

Widow rockfish are ovoviviparous, have internal fertilization, and brood their eggs until released as larvae (NOAA 1990; Reilly, *et al.* 1992). Mating occurs from late fall-early winter. Larval release occurs from December through February off California, and from February through March off Oregon. Juveniles are 21 mm to 31 mm at metamorphosis, and they grow to 25 cm to 26 cm over three years. Age and size at sexual maturity varies by region and sex, generally increasing northward and at older ages and larger sizes for females. Some mature in three years (25 cm to 26 cm), 50 percent are mature by four years to five years (25 cm to 35 cm), and most are mature in eight years (39 cm to 40 cm) (NOAA 1990). The maximum age of widow rockfish is 28 years, but rarely over 20 years for females and 15 years for males (NOAA 1990). The largest size is 53 cm and about 2.1 kg (Eschmeyer, *et al.* 1983; NOAA 1990).

Widow rockfish are carnivorous. Adults feed on small pelagic crustaceans, midwater fishes (such as age-one or younger Pacific whiting), salps, caridean shrimp, and small squids (Adams 1987; NOAA 1990). During spring, the most important prey item is salps, during the fall fish are more important, and during the winter widow rockfish primarily eat sergestid shrimp (Adams 1987). Feeding is most intense in the spring after spawning (NOAA 1990). Pelagic juveniles are opportunistic feeders, and their prey consists of various life stages of calanoid copepods, and euphausiids (Reilly, *et al.* 1992).

Stock Status and Management History

Widow rockfish are an important commercial species from British Columbia to central California, particularly since 1979, when Oregon trawl fisherman demonstrated the ability to make large catches at night using midwater trawl gear. Many more participants have entered the fishery since that time, and landings of widow rockfish have increased rapidly (Love, *et al.* 2002). Widow rockfish are a minor component of the recreational groundfish fisheries.

Williams et al. (2000) assessed the coastwide stock of widow rockfish in 2000. The spawning output level (8,223 mt eggs), based on that assessment and a revised rebuilding analysis (Punt and MacCall 2002) adopted by the Council in June 2001, was at 23.6 percent of the unfished level (33,490 mt eggs) in 1999. The widow rockfish stock was declared overfished in 2001 based on this assessment result.

It was concluded in the 2003 assessment (He, *et al.* 2003) that the widow rockfish stock size was at 24.7 percent of the unfished biomass and that stock productivity was considerably lower than previously thought. Data sparseness was a significant problem in this widow rockfish assessment. Results from the 2003 widow rockfish rebuilding analysis were used to develop the first widow rockfish rebuilding plan, which was adopted in April 2004 under Amendment 16-3 to the groundfish FMP. The rebuilding plan established a target rebuilding year of 2038 and a harvest control rule of F = 0.0093 (with a P_{MAX} of 60 percent).

A full assessment was completed in 2005 for widow rockfish (He, *et al.* 2006a). In addition to including the new data from 2003 to 2004, this assessment added an index of relative abundance based on the triennial survey data and estimated the power coefficient of the midwater juvenile survey index instead of using a fixed value. The base model estimated that spawning biomass declined steadily since the early 1980s and that spawning output in 2004 was 31 percent of the unexploited level, above the Council's overfished threshold. Further, spawning output in the base model was estimated to have never dropped below the 25 percent overfished threshold. Alternative model runs, which were considered to be only slightly less plausible than the base model, however, indicated that the stock had been below $B_{25\%}$. The 2005 rebuilding analysis indicated that the stock was much closer to reaching a rebuilt biomass than previously estimated: under the 2005 rebuilding analysis (He, *et al.* 2006b), T_{MIN} was estimated to be 2013, compared to a T_{MIN} of 2026 in the 2003 analysis (He, *et al.* 2003). This rebuilding analysis was used to modify the widow rockfish rebuilding plan, which was adopted under Amendment 16-4 in 2006. The target rebuilding year under the modified rebuilding plan was 2015 and the harvest control rule was an SPR harvest rate of 95 percent.

An updated assessment was done in 2007 (He, *et al.* 2008) using the same age-based model (written in ADMB) and data compiling procedures used in the previous assessment. New data from 2005 and 2006, including catches, age composition, and a CPUE time series, were included in the 2007 assessment. Sources of uncertainty include a questionable source of information (Oregon bottom trawl logbook data); the validity of the fixed natural mortality rate used; the estimation of stock-recruitment relationships, which also led to uncertainty in the rebuilding analysis; the appropriateness of using the Santa Cruz juvenile survey data; and stock structure issues including relationship to the Canadian stock. The estimated total biomass in 2006 was 120,132 mt and the estimated 2006 spawning biomass was 47,478 mt. Spawning biomass in the 2007 assessment is higher than in the 2005 assessment primarily because of the relatively strong recruitment in 2003 by the 2000 cohort. The estimated current depletion rate is 35.5 percent of the unfished spawning output. The ABC for 2007 is 5,334 mt and the harvest guideline is 368 mt. It is estimated that the population will recover to the target in 2009, which is six years earlier than the target year in the rebuilding plan. Based on these results, the SSC recommended no changes to the rebuilding plan.

Future research needs include reliable abundance indices, continue the long-term recruitment index and midwater juvenile trawl survey, ability to infer direct and indirect estimates of year class strengths, better understand the relationship between environmental conditions in the California Current Ecosystem, improve short-term forecasts of productivity, biomass levels and allowable catches from stock assessments, new discard data, evaluate the utility of hydro-acoustic surveys, increase age-collection programs to increase sample size, and determination of age-composition for the triennial survey.

A full assessment of widow rockfish was conducted in 2011 (He, *et al.* 2011), which indicated the spawning stock biomass was successfully rebuilt with a depletion of 51 percent at the start of 2011. However, there is considerable uncertainty regarding the new stock assessment's finding that the stock has rebuilt. Productivity and status of this stock are highly uncertain because the available biomass indices are not informative. Nonetheless, the SSC considered the base model of the new widow rockfish assessment to be the best available science.

Stock Productivity

The major axis of uncertainty in the new widow rockfish assessment is steepness, which defines the relative productivity of the stock. The SSC recommended fixing the steepness parameter at 0.76 in the assessment, due to the lack of information to reliably estimate steepness. The steepness parameter of 0.76 is the median value in the distribution of steepness parameters of assessed rockfish species in the Dorn (2002b) meta-analysis. The decision table in the assessment was developed to bracket model uncertainty in widow rockfish productivity with alternative values of steepness. The 12.5 percent and 87.5 percent quantiles from the prior distribution on h translate into steepness values of 0.54 and 0.95, respectively. This range was considered reasonable to account for the uncertainty associated with steepness. It was, however, agreed by the STAT and the SSC to shift this range to a lower steepness value to (a) take account of the data which, while not greatly informative, did provide some evidence for a lower steepness value, and (b) provide continuity by considering the value of steepness used in the 2009 assessment (0.41). As a result, steepness values of 0.41 and 0.90 were used for the low and high states of nature in the assessment decision table.

The high uncertainty in the steepness of the stock-recruitment relationship and the lack of recent strong recruitments compels a precautionary approach to managing widow rockfish. If the pessimistic state of nature is correct (h = 0.41), then annual constant catches of up to 1,500 mt are projected to maintain spawning stock biomass above the MSST during the 10-year projection period (i.e., 2013-2022).

The base model in the 2011 widow assessment estimated a time series of recruitment of age-0 fish from 1948 to 2009. The highest recruitment occurred in 1970 (Figure 23). Recruitments remained generally low in the early 1990s and have been very low since 2001, as compared to the long-term average. As in the past widow assessments, uncertainties in estimation of recruitment remain high.

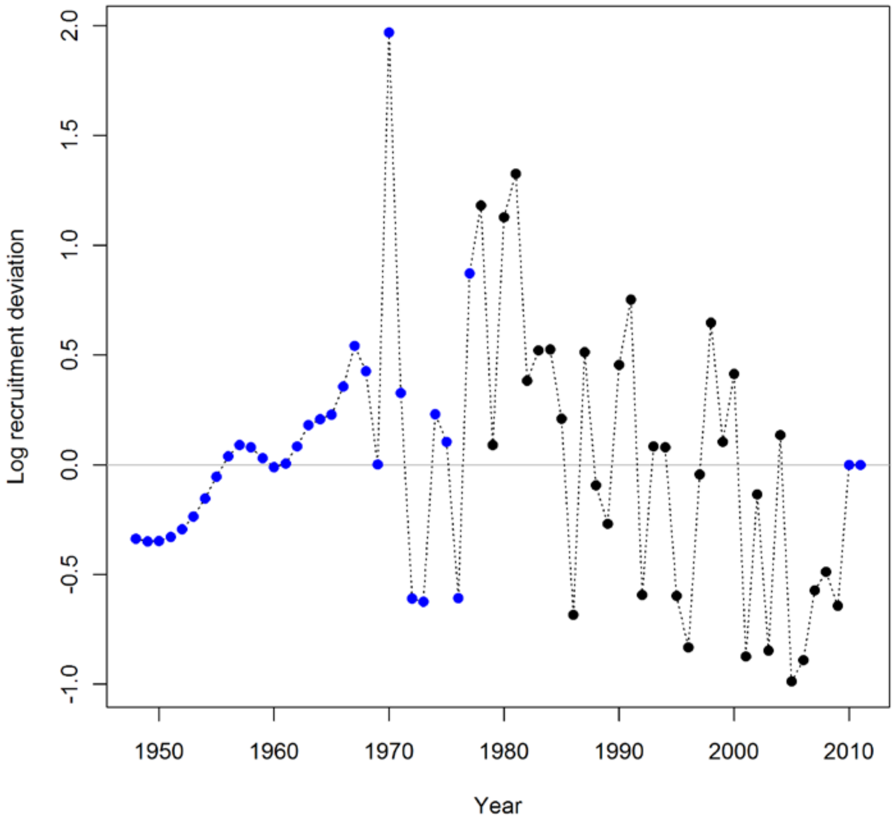

Figure 23. Time series of estimated recruitments from the base model in the 2011 widow rockfish assessment.

Fishing Mortality

Widow rockfish are caught mostly in midwater trawls used to target Pacific whiting and, before 2002, used to target widow and yellowtail rockfish. The exploitation rate was above the target SPR of 50 percent (i.e., $F<F_{MSY}$) until the late 1970s when trawl catches in the target midwater fishery increased to rates beyond the target. This continued until the stock was declared overfished and managed under a rebuilding plan. Harvest declined dramatically and the estimated SPR harvest rates increased rapidly above target F_{MSY}. The increase in biomass during the past decade was the result of reduced catches rather than strong year-classes.

Lower OYs specified in 2005-2010 were not exceeded as the fishery was managed to avoid widow bycatch and the percent of OY attainment decreased with time during that period. The percent attainment of the 2011 IFQ allocation was 40 percent. The at-sea whiting sectors have been better able to avoid widow rockfish in recent years with the lowest bycatch rates (widow catch/whiting catch) observed in the past couple of years.

Management uncertainty is low since widow rockfish is a trawl-dominant species and there is mandatory 100 percent observer coverage in trawl fisheries.

1.1.4.22 Yellowtail Rockfish North of 40º10’ N lat.

Distribution and Life History

Yellowtail rockfish (*Sebastes flavidus*) range from San Diego, California, to Kodiak Island, Alaska (Fraidenburg 1980; Gotshall 1981; Lorz, *et al.* 1983; Love, *et al.* 2002; Miller and Lea 1972; Norton and MacFarlane 1995). The center of yellowtail rockfish abundance is from Oregon to British Columbia (Fraidenburg 1980). Yellowtail rockfish are a common, demersal species abundant over the middle shelf (Carlson and Haight 1972; Fraidenburg 1980; Tagart 1991; Weinberg 1994). Yellowtail rockfish are most common near the bottom, but not on the bottom (Love, *et al.* 2002; Stanley, *et al.* 1994). Yellowtail rockfish adults are considered semi-pelagic (Stanley, *et al.* 1994; Stein, *et al.* 1992) or pelagic, which allows them to range over wider areas than benthic rockfish (Pearcy 1992). Adult yellowtail rockfish occur along steeply sloping shores or above rocky reefs (Love, *et al.* 2002). They can be found above mud with cobble, boulder and rock ridges, and sand habitats; they are not, however, found on mud, mud with boulder, or flat rock (Love, *et al.* 2002; Stein, *et al.* 1992). Yellowtail rockfish form large (sometimes greater than 1,000 fish) schools and can be found alone or in association with other rockfishes (Love, *et al.* 2002; Pearcy 1992; Rosenthal, *et al.* 1982; Stein, *et al.* 1992; Tagart 1991). These schools may persist at the same location for many years (Pearcy 1992).

Yellowtail rockfish are viviparous (Norton and MacFarlane 1995) and mate from October to December. Parturition peaks in February and March and from November to March off California (Westrheim 1975). Young-of-the-year pelagic juveniles often appear in kelp beds beginning in April and live in and around kelp in midwater during the day, descending to the bottom at night (Love, *et al.* 2002; Tagart 1991). Male yellowtail rockfish are 34 cm to 41 cm in length (five years to nine years) at 50 percent maturity, females are 37 cm to 45 cm (six years to ten years) (Tagart 1991). Yellowtail rockfish are long-lived and slow-growing; the oldest recorded individual was 64 years old (Fraidenburg 1980; Tagart 1991). Yellowtail rockfish have a high growth rate relative to other rockfish species (Tagart 1991). They reach a maximum size of about 55 cm in approximately 15 years (Tagart 1991). Yellowtail rockfish feed mainly on pelagic animals, but are opportunistic, occasionally eating benthic animals as well (Lorz, *et al.* 1983). Large juveniles and adults eat fish (small Pacific whiting, Pacific herring, smelt, anchovies, lanternfishes, and others), along with squid, krill, and other planktonic organisms (euphausiids, salps, and pyrosomes) (Love, *et al.* 2002; Phillips 1964; Rosenthal, *et al.* 1982; Tagart 1991).

Stock Status and Management History

Until the late 1990s, yellowtail rockfish were harvested as part of a directed midwater trawl fishery. Yellowtail rockfish are common in both commercial and recreational fisheries throughout its range and commonly occur with canary and widow rockfishes (Cope and Haltuch 2012). Despite historically large removals and its popularity in commercial and recreational fisheries, its association with those highly regulated species has greatly decreased removals over the last decade. From the end of 2002 through 2010, implementation of the RCAs and small landings limits designed to only accommodate incidental bycatch eliminated directed mid-water fishing opportunities for yellowtail rockfish in non-tribal trawl fisheries. A limited opportunity to target yellowtail rockfish in the trawl fishery has been available since 2011 under the trawl rationalization program, yet low quotas for widow rockfish, canary rockfish, and for other constraining stocks has continued to limit mid-water targeting of yellowtail rockfish.

Yellowtail rockfish are currently managed with stock-specific harvest specifications north of 40º10’ N lat. and within the southern Shelf Rockfish complex south of 40º10’ N lat. There has never been an assessment of the southern stock and the OFL contribution of yellowtail rockfish to the southern Shelf Rockfish complex is based on a DB-SRA estimate.

Yellowtail rockfish on the U.S. west coast north of 40º10’ N lat. were assessed in 1984 (Weinberg, *et al.* 1984), 1986 (Coleman 1986), 1988 (Tagart 1988), 1993 (Tagart 1993), 1996 (Tagart and Wallace 1996), and 1997 (Tagart, *et al.* 1997) to determine harvest specifications for the stock. A full assessment in 2000 (Tagart, *et al.* 2000) was the first that estimated stock status with an estimated depletion of 60.5% at the start of 2000. Lai et al. (2003) updated the 2000 assessment and estimated stock depletion was 46% at the start of 2003. Another assessment update was prepared in 2005 (Wallace and Lai 2006) with an estimated depletion of 55% at the start of 2005.

A new data-moderate assessment of yellowtail rockfish north of 40º10’ N lat. was conducted in 2013 (Cope and Dick 2014). The estimated depletion at the start of 2013 was 69% and the spawning biomass was estimated to be 38,168 mt. This was a large biomass increase relative to previous estimates and largely due to low removals in the last 10 years.

Stock Productivity

The posterior median estimate of steepness in the 2013 yellowtail rockfish assessment is 0.79, indicating a relatively productive stock. However, this estimate may not be as informative of relative stock productivity. Due to the low susceptibility of yellowtail rockfish to fisheries removals, the vulnerability to overfishing of yellowtail rockfish is relatively low (V = 1.88), though the productivity of this species is also relatively low (P = 1.33) based on other life history traits, including a longevity to almost 70 years.

Fishing Mortality

Fishing mortality of yellowtail rockfish north of 40º10’ N lat. was relatively high in the 1980s and 1990s with direct targeting by mid-water trawl gear of yellowtail and widow rockfish. The elimination of that fishery in 2003 to reduce impacts on widow rockfish (and canary rockfish to some degree), coupled with RCA implementation, significantly reduced fishing mortality of yellowtail rockfish. The decision table in the 2013 assessment predicts the stock will keep building under the average annual catch estimated in the assessment (1,376 mt) and would remain at a healthy level in the next 10 years (i.e., above B_{MSY}) at catch levels over 4 times that amount.

1.1.5 Groundfish Stock Complexes

There are eight stock complexes for which ACLs were specified through the 2013-2014 management cycle. These complexes are the Nearshore, Shelf, and Slope Rockfish complexes north and south of 40°10’ N lat., the Other Flatfish, and the Other Fish complexes.

Most of the component stocks comprising the stock complexes are unassessed category 3 stocks with OFLs that are determined using data-poor methods such as DBSRA, DCAC, or average historical catch (see Section 1.1.1). In cases where assessments were used to inform OFLs for component stocks managed in stock complexes, the OFLs were projected from those assessments using proxy F_{MSY} harvest rates. A more detailed description of the assessed stocks managed in stock complexes follows.

1.1.5.1 Nearshore Rockfish North and South of 40°10’ N Lat.

The nearshore rockfish complexes north and south of 40º10’ N lat. are comprised of both assessed and unassessed species. Of the stocks managed in the nearshore rockfish complexes, only blue rockfish in California north of Pt. Conception, brown rockfish, China rockfish, copper rockfish, and gopher rockfish in California north of Pt. Conception have been assessed. The following section defines these complexes in terms of their component stocks and provides further detail on those component stocks that have been assessed.

The Nearshore Rockfish complex north of 40°10' N lat. is composed of the following species: black and yellow rockfish (*Sebastes chrysomelas*); blue rockfish (*S. mystinus*); brown rockfish (*S. auriculatus*); calico rockfish (*S. dalli*); China rockfish (*S. nebulosus*); copper rockfish (*S. caurinus*); gopher rockfish (*S. carnatus*); grass rockfish (*S. rastrelliger*); kelp rockfish (*S. atrovirens*); olive rockfish (*S. serranoides*); quillback rockfish (*S. maliger*); and treefish (*S. serriceps*). These stocks are all unassessed with the exception of brown rockfish, blue rockfish in California, China rockfish, and copper rockfish.

The Nearshore Rockfish complex south of 40°10' N lat. is further subdivided into the following management categories: 1) shallow nearshore rockfish [comprised of black and yellow rockfish (*Sebastes chrysomelas*), China rockfish (*S. nebulosus*), gopher rockfish (*S. carnatus*), grass rockfish (*S. rastrelliger*), and kelp rockfish (*S. atrovirens*)], and 2) deeper nearshore rockfish [comprised of black rockfish (*S. melanops*), blue rockfish (*S. mystinus*), brown rockfish (*S. auriculatus*), calico rockfish (*S. dalli*), copper rockfish (*S. caurinus*), olive rockfish (*S. serranoides*), quillback rockfish (*S. maliger*), and treefish (*S. serriceps*)]. With the exception of the blue rockfish stock occurring in waters off California north of Point Conception (i.e., 34°27' N lat. to 40°10' N lat.) and gopher rockfish north of Point Conception (34°27' N lat.), all of the Nearshore Rockfish South stocks are unassessed. The blue rockfish stock was estimated to be at 29.7 percent of its unfished biomass in 2007; therefore, the stock is considered to be in the precautionary zone. Spawning biomass depletion of gopher rockfish north of Point Conception was estimated to be at 97 percent of its unfished biomass in 2005.

Blue Rockfish in California

Distribution and Life History

Blue rockfish (*Sebastes mystinus*) range from the Gulf of Alaska to northern Baja California, although they are most commonly found between Oregon and central California (Love, *et al.* 2002). They inhabit kelp forests and rocky reefs in relatively shallow depths usually to about 90 meters (50 fm) (Miller and Lea 1972; Reilly 2001), but have been landed as deep as 549 meters (300 fm) (Love, *et al.* 2002). Blue rockfish are residential, with their movements restricted to a small area, usually near the kelp canopy or pinnacles for shelter and spatial orientation (Jorgensen, *et al.* 2006; Lea, *et al.* 1999; Miller and Geibel 1973). Genetic evidence suggests distinct subpopulations of blue rockfish with a biogeographic barrier at Cape Mendocino, California (Cope 2004). More recently, evidence suggests the presence of two genetically distinct cryptic species in central California (Burford, *et al.* 2011).

Blue rockfish are primarily "selective opportunity" planktivores (Gotshall, *et al.* 1965; Love and Ebeling 1978). As juveniles, they feed on planktonic crustacea, hydroids, and algae (Miller and Geibel 1973). Adults also consume fish, squid, tunicates, scyphozoids, bull kelp nori, and pelagic gastropods (Hobson, *et al.* 1996; Lea, *et al.* 1999; Love, *et al.* 2002). Many of these prey items are made available from the relaxation of upwelling or southerly winds, explaining high blue rockfish numbers in the summer off central and northern California, where these conditions are well developed (Hobson and Chess 1988; Love, *et al.* 2002). Due to their great abundance in kelp forests, blue rockfish juveniles are recognized as a key species in the piscivore trophic web of these ecosystems (Hallacher and Roberts 1985).

Stock Status and Management History

The blue rockfish stock in California waters north of Pt. Conception was assessed in 2007 and the stock's depletion was estimated to be 29.7% of its unfished spawning output at the start of 2007 (Key, *et al.* 2008). Blue rockfish were not a highly sought species historically, but an increase in catches in the 1970s resulted in a continuous decline in spawning biomass through the early 1990s. The abundance of blue rockfish was at the management target (SB40%) in 1980 and at the overfished threshold in 1982., Spawning biomass reached a minimum (10% of unexploited) in 1994 and 1995; however, there has been a constant increase since then.

During the 2009 and 2010 biennial specifications process, the Council contemplated removing blue rockfish from the Nearshore Rockfish complexes. Blue rockfish was managed within the Nearshore Rockfish complexes because of scientific uncertainty and management needs, given the interaction of blue rockfish with other nearshore species. When blue rockfish occur offshore they can be targeted separately from other nearshore rockfish, but those that occur inshore mix with other nearshore rockfish stocks. Blue rockfish are managed under the California nearshore management plan which has mandatory sorting requirements for landed catch. Landings are routinely tracked and monitored, thereby reducing management uncertainty. For more efficient state management, blue rockfish remains a component stock within the Nearshore Rockfish complexes. The OFL contribution of blue rockfish is projected from the 2007 assessment using the proxy $F_{50\%}$ F_{MSY} harvest rate and apportioning 87.3 percent of the OFL based on average catches of the assessed stock south of 40°10' N lat. (Key, *et al.* 2008). The OFL contribution of blue rockfish south of 34º27' N lat. is based on DCAC. The assessed portion of the blue rockfish stock is categorized as a category 2 stock, and the unassessed portion south of 34º27' N lat. is categorized as a category 3 stock. The Council has implemented precautionary management of the California population of blue rockfish since 2009 by setting a harvest guideline for California fisheries based on the sum of the 40-10 adjusted ACL contribution north of Pt. Conception and the ABC contribution south of Pt. Conception. This HG has not been exceeded since then.

Stock Productivity

A Beverton-Holt steepness of 0.58 was assumed in the 2007 blue rockfish assessment based on the median steepness in the rockfish meta-analysis done at that point in time. The GMT's PSA analysis indicates a relatively high vulnerability to potential overfishing (V = 2.01) due partly to a relatively low relative productivity (P = 1.22) (Table 2).

Recruitment is variable and highly uncertain for blue rockfish. There was little information other than the pre-recruitment index in the recent years to inform the 2007 assessment model about recruitments. Recruitment appeared to be high in the 1960s, and more recently strong year classes appeared in 1993 and 1998. The late 1970s showed all time low recruitment, with 2006 among the 3 lowest recruitment years estimated.

Fishing Mortality

Blue rockfish have been an important part of the recreational fishery in California since the late 1950s (Mason 1998; Reilly, *et al.* 1993; Wilson-Vandenberg, *et al.* 1996). Commonly taken by Commercial Passenger Fishing Vessels (CPFVs, aka partyboats), skiffs, and divers, it is among the most frequently caught species north of Point Conception (Karpov, *et al.* 1995). However, since the mid-1980s the California recreational catch has declined significantly, especially in the south. This may be a result of overfishing from the more heavily populated southern coast (Love, *et al.* 1998), where there is more angling opportunity due to more favorable access and ocean conditions (Bennett, *et al.* 2004); poor recruitment resulting from a long-term shift away from preferred cold, productive waters (Jarvis, *et al.*

2004; Love, *et al.* 2002); or the effect of increasingly strict fishing regulations. Fishing mortality exceeded current target levels from the mid 1970s through the late 1990s, but has been close to target levels since 2000.

The California blue rockfish catch has played a relatively minor role in the commercial fishery compared to the recreational fishery. This has remained true, even with the advent of the live-fish fishery in the late 1980s, although the contribution of blue rockfish has been increasing in recent years. Since the preferred dinner plate-sized catch for this fishery results in immature fish being targeted in many cases, there is concern over the potential implications of the increasing effort in this fishery. Selection of younger, smaller individuals has led to lower lifetime egg production and consequently, threatened population viability (O'Farrell and Botsford 2005; O'Farrell and Botsford 2006).

Brown Rockfish

Distribution and Life History

Brown rockfish (*Sebastes auriculatus*) are distributed from Prince William Sound to southern Baja California in Mexico, but are most abundant on the U.S. west coast south of Bodega Bay, California (Love, *et al.* 2002). They occur from very shallow inshore waters out to 135 m (74 fm). Brown rockfish are a sedentary rockfish found in shallow water and bays (Eschmeyer, *et al.* 1983), among sheltering weed-covered rocks or around pilings (Lamb and Edgell 1986). Brown rockfish show distinct genetic differentiation by distance in coastal populations off California (Buonaccoursi, *et al.* 2005), though no distinct break is obvious to define substocks. Life history information is not spatially resolved. While coastwide populations may be subject to localized depletion because of reef-specific associations and small home ranges, no subpopulations have been distinguished.

Brown rockfish have been aged to 34 years (Love, *et al.* 2002).

Stock Status and Management History

Brown rockfish are managed in the northern and southern Nearshore Rockfish complexes. A single coastwide data-moderate assessment of brown rockfish was conducted in 2013 (Cope, *et al.* 2014). The assessment estimated the brown rockfish stock to be healthy with a depletion of 42% of its unfished biomass at the start of 2013. The brown rockfish assessment used a CPUE index of the California recreational fisheries derived from dockside intercept surveys during 1980-2003 and an observer-based recreational CPUE index from California Party Fishing Vessels (CPFV; i.e., charter boats) during 1999-2011 as indices of abundance. No indices were constructed for north of 40º10’ N lat. since this is a rare species north of Cape Mendocino. While coastwide landings were used in the assessment, only about 1% of the cumulative coastwide landings of brown rockfish were from fisheries north of 40º10’ N lat. It was assumed that the population in the north followed the same trends as the southern population.

Stock Productivity

Brown rockfish has a notably elevated vulnerability to overfishing (V = 1.99) but a relatively high productivity score for a rockfish (P = 1.72) in the GMT’s PSA analysis (Table 2).

Fishing Mortality

China Rockfish

Distribution and Life History

China rockfish (*Sebastes nebulosus*) range from Kachemak Bay in the Gulf of Alaska to Redondo Beach and Nicholas Island in the Southern California Bight but are most abundant from Prince William Sound to northern California (Love, *et al.* 2002). They occur primarily in nearshore and shelf waters in depths ranging from 3 to 128 m. Chinas are a solitary species associated with high relief habitats, especially boulder fields with many crevices. They are territorial and a study off Vancouver Island indicates that individuals are likely to move 10 m or less within their territories.

China rockfish are long-lived with the oldest age reported at 79 years (Love, *et al.* 2002). Males and females mature at about the same size and age with some fish mature at 26 cm and all fish mature at 30 cm. The maximum size is reported to be 45 cm. Larval release occurs off California from January to June peaking in January. Larvae are released later in the season in the Gulf of Alaska during April to August with peak release in May.

Chinas prey on benthic organisms including brittle stars, crabs, shrimps, chitons, and small fishes. Nudribranchs, octopi, snails, and red abalone were observed prey for China rockfish off central and northern California.

Stock Status and Management History

China rockfish are managed in the northern and southern Nearshore Rockfish complexes. Separate data-moderate assessments of China rockfish north and south of 40º10’ N lat.[6] were conducted in 2013 (Cope, *et al.* 2014). The China rockfish population south of 40º10’ N lat. was estimated to be healthy with a depletion of 66% of its unfished biomass at the start of 2013. However, the population north of 40º10’ N lat. was estimated to be more depleted and in the precautionary zone with a depletion ratio of 37% at the start of 2013. The southern China rockfish assessment used a CPUE index of the California recreational fisheries derived from dockside intercept surveys during 1980-2003, as well as an observer-based recreational CPUE index from CPFVs during 1999-2011 as indices of abundance. The northern China rockfish assessment used a CPUE index of the Oregon and northern California recreational fisheries derived from dockside intercept surveys during 1980-2003 and an Oregon onboard charter boat index during 2001-2012 as indices of abundance and assumed the population off Washington followed the same trends.

The Council decided to continue to manage China rockfish in the Nearshore Rockfish complexes in 2015-2016. The Council expressed interest in conducting a full assessment of China rockfish with greater focus on modeling state-specific indices of abundance. There was also the suggestion of exploring an Oregon nearshore commercial index which can be theoretically constructed given Oregon’s logbook program (an effort metric can be derived from logbook data). Available age and length composition data may also help inform some of the China rockfish dynamics.

[6] Separate China rockfish data-moderate assessments were also conducted north and south of the California-Oregon border at 42º N lat. at the Council’s request. The SSC recommended the Council’s choice of a management line for China rockfish should dictate which assessments should be used to set harvest specifications. The Council’s decision to continue to manage the stock within the Nearshore Rockfish complexes north and south of 40º10’ N lat. in 2015 and beyond rendered the second set of assessments stratified at 42º N lat. moot.

Stock Productivity

The productivity score for China rockfish is relatively low (P = 1.33) and there is a major vulnerability to potential overfishing (V = 2.23).

Fishing Mortality

China rockfish are an important species in the nearshore recreational and commercial fisheries on the west coast. They are particularly valuable in the commercial live-fish fishery where their unique coloration and high quality flesh commands the highest prices for rockfish delivered as a live product on the west coast. California and Oregon allow nearshore commercial fisheries while Washington does not.

Fishing mortality of China rockfish south of 40º10' N lat. has been well below the F_{MSY} harvest rate. The XDB-SRA base model estimates that median MSY for southern China rockfish is 32 mt per year (Table 6), and the fishing mortality rate in 2012 was 28% of F_{MSY}. However, that is not the case for the population north 40º10' N lat. The XDB-SRA base model estimates that median MSY for northern China rockfish is 9 mt per year, and the fishing mortality rate in 2012 was 191% of F_{MSY}. Figure 24 depicts total estimated catch of China rockfish north of 40º10' N lat. relative to the 2015 OFL and ACL contributions to the complex. The cumulative 2004-2012 total estimated catch of China rockfish north of 40º10' N lat. was 191% and 221% of the cumulative 2015 OFL and ACL contributions, respectively. Maintaining these catch levels is predicted to lead to continued stock decline.

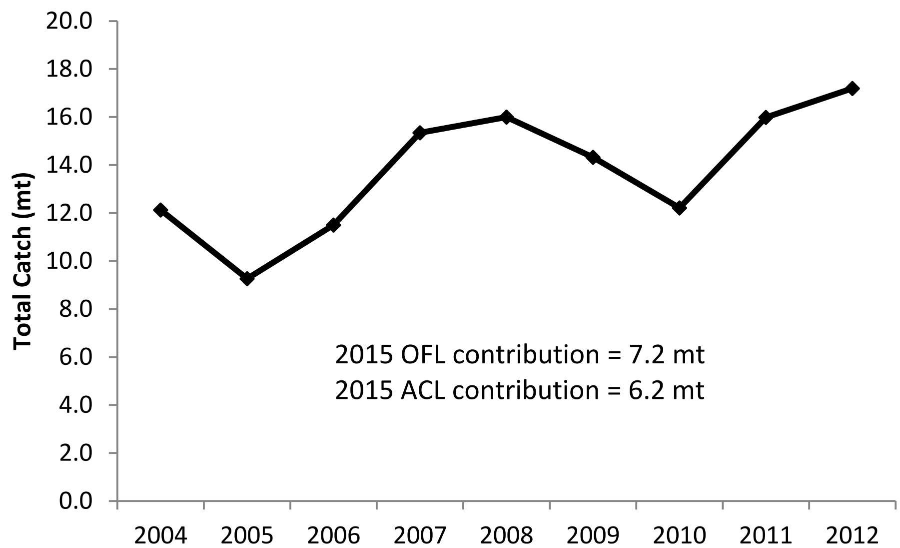

Figure 24. Estimated total catch of China rockfish north of 40º10' N lat. in 2004-2012 relative to the preferred 2015 OFL contribution and ACL contribution.

Copper Rockfish

Distribution and Life History

Copper rockfish (*Sebastes caurinus*) are a deep bodied and spiny rockfish that range from Kachemak Bay in the Gulf of Alaska to Isla San Benito in central Baja California and are common from Port Valdez, Alaska to northern Baja California (Love, *et al.* 2002). They range in depth from the subtidal zone to 183 m. Subadult and adult copper rockfish are found primarily in boulder fields and over high relief rocks, although they also inhabit low relief rock substrata. They perch on the substrata or hover a few meters above the bottom in aggregations and as solitary individuals (Love, *et al.* 2002). Depending on the habitat and the geographic location, coppers are often found with vermilion, brown, black, dusky, silvergray, yelloweye, quillback, or tiger rockfishes. Coppers have small home ranges in high relief habitats (<10 m^2) and large home ranges in low relief habitats (<4,000 m^2).

Stock Status and Management History

Copper rockfish are managed in the northern and southern Nearshore Rockfish complexes. Separate data-moderate assessments of copper rockfish north and south of 34º27' N lat. were conducted in 2013 (Cope, *et al.* 2014). Both copper rockfish populations were estimated to be healthy with depletions of 76% and 48% of unfished biomass at the start of 2013 in the southern and northern populations, respectively. The southern copper rockfish assessment used a CPUE index of the California recreational fisheries derived from dockside intercept surveys during 1980-2003, as well as an observer-based recreational CPUE index from CPFVs during 1999-2011 as indices of abundance. The northern copper rockfish assessment used the same CPUE indices as in the southern model with the addition of an Oregon onboard charter boat index during 2001-2012 as indices of abundance and assumed the population off Washington followed the same trends.

Stock Productivity

Fishing Mortality

Gopher Rockfish

Distribution and Life History

Gopher rockfish (*Sebastes carnatus*) range from Eureka, California, to San Roque, central Baja California (Miller and Lea 1972), but are most common from Mendocino County to Santa Monica Bay, California (Love 1996). Gopher rockfish is a residential and demersal species, associated with kelp beds or rocky reefs, from the intertidal to about 264 ft (80 m), most commonly between 30 and 120 ft (9-37 m) (Eschmeyer, *et al.* 1983; Love 1996; Love, *et al.* 2002). One tagging study off central California (Lea, *et al.* 1999) revealed that gopher rockfish exhibit minor patterns of movement (<1.5 nm, 2.8 km) with all fish being recaptured on the same reef system where they were tagged. Another study, conducted by Matthews (1986), reported movements up to 1.2 km (0.65 nm) by gopher rockfish that traveled from a low-relief natural reef to a high-relief artificial reef. The change in substrate type may have been a factor in the movement in the Matthews study.

Gopher rockfish settle out of the plankton as large larvae (2 cm. or less in length) primarily in the canopies of giant and bull kelp (*Macrocystis pyrifera* and *Nereocystis luetkeana*, respectively) where they remain close to the fronds (Love, *et al.* 2002). Settlement occurs primarily in June and July. With growth, older individuals move down the kelp stipes to the bottom where they take up residence in rocks and crevices. They are largely territorial with home ranges of 10-12 m^2 (Love, *et al.* 2002).

Gopher rockfish are closely related to black-and-yellow rockfish (*Sebastes chrysomelas*) and kelp rockfish (*Sebastes atrovirens*). Gopher and black-and-yellow rockfish are distinct morphologically by color and inhabit different depth ranges (gopher have a deeper depth range), but cannot be distinguished genetically (Love, *et al*. 2002). This presents an interesting phenomenon in how speciation in rockfish may occur. There are theories that interbreeding may be lessened by individuals only breeding with others of the same color. If it is determined the two species are actually one, then the name *S. carnatus* will prevail since it was described first (Love, *et al.* 2002).

Stock Status and Management History

Gopher rockfish was assessed for the first time in 2005 and estimated stock depletion under the base model was 97% of its unfished biomass at the start of 2005 (Key*, et al.* 2006). Although the distribution of gopher rockfish extends south into the Southern California Bight, the assessment was restricted to the stock north of Point Conception. The assessment is based on landings and length composition data from commercial and recreational fisheries (primarily hook and line gear) and an index of relative abundance (CPUE) from the CPFV Sportfish Survey database. These data sources were used to estimate population trends from 1965 to 2004. There are no fishery-independent indices of stock biomass for gopher rockfish. Assessment results indicate an upward trend in gopher rockfish biomass since the 1980s and estimates of 2005 abundance ranged between 60 percent and 110 percent of average unfished stock size; this range of depletion levels is the result of alternative emphases in the model given to the CPFV in the CPUE index, a data element identified as a major source of uncertainty.

During the 2007-2008 biennial specifications process, the Council decided to continue managing gopher rockfish within the Nearshore Rockfish South complex since there was adequate resource protection under the California nearshore management plan and managing gopher rockfish with stock-specific harvest specifications could disrupt that plan. The OFL contribution of gopher rockfish north of 34º27' N lat. is projected from the 2005 assessment (Key*, et al.* 2006) using the proxy $F_{50\%}$ F_{MSY} harvest rate. The OFL contribution of gopher rockfish south of 34º27' N lat. is based on DCAC. The assessed portion of the gopher rockfish stock is categorized as a category 1 stock and the unassessed portion south of 34º27' N lat. is categorized as a category 3 stock.

Stock Productivity

Recruitments were modeled in the 2005 assessment assuming a Beverton-Holt relationship, with steepness fixed at h=0.65 and recruitment variability fixed at sigma r = 0.5. Recruitment deviations were estimated for the period 1965-2000. This stock showed evidence of weak recruitment in the 1970s, with peaks in the mid-1980s and mid-1990s. Recruitment estimates in the 1970s are not reliable since length information was not available until the 1980s. Overall, recruitment has been variable throughout the entire time series.

The PSA productivity score of 1.56 for gopher rockfish indicates a moderate relative productivity among rockfish species. There is a relatively low vulnerability of potential overfishing (V = 1.76) for the stock.

Fishing Mortality

Gopher rockfish have been a minor component of the commercial and recreational rockfish fishery since at least the late 1960s. In 1980, an estimated 63 mt of gopher rockfish were landed commercially north of Point Conception, with a decrease in landings in the mid-1980s. Landings then began to increase, with a peak in the fishery occurring in 1992 when approximately 74 mt were landed. Since then, landings have slightly decreased over time. Lower recent landings in 2003 and 2004 (13 and 15 mt, respectively) are in part due to more restrictive federal limits placed on rockfishes. Hook-and-line gears have been the dominant gear type used during the 1969 to 2004 period accounting for 98% of commercial landings.

The recreational gopher rockfish fishery for California ports north of Point Conception peaked during a five-year period in the early 1990s, with 2001 and 2003 also being productive years. Since 1983, anglers caught the greatest proportion of gopher rockfish from private and rental boats (71%), followed next by party and charter boats (27%). However, in more recent years (1997 to 2004) these proportions have changed, with the private and rental boats taking 59% of gopher rockfish in the recreational fishery and 41% by the party and charter boats. Also since 1983, gopher rockfish have ranked 25th in northern California recreational fishery landings, accounting for approximately 1% of the total harvest for all recreationally caught fishes. However, gopher rockfish made up approximately 50% of the estimated take of the shallow nearshore rockfishes and 6% of all nearshore rockfish species combined. Additionally, recent catches have been influenced by size and bag limits.

Starting in the late 1980s the premium quality live- fish market developed (Larson and Wilson-Vandenberg 2001). Currently, nearly all gopher rockfish are landed in this condition due to a more lucrative high-demand market. As a result of the increasing demand for live- fish the average price per pound has risen steadily from a low of less than $2.00/lb at the inception of the live- fish market to approximately $6.15/lb in 2004 (unadjusted for inflation).

Recent exploitation rates are estimated to have been well below the F_{MSY} proxy for rockfish.

1.1.5.2 Shelf Rockfish North and South of 40°10’ N Lat.

The shelf rockfish complexes north and south of 40º10’ N lat. are comprised of both assessed and unassessed species. Of the stocks managed in the shelf rockfish complexes, chilipepper rockfish north of 40º10’ N lat. (the assessment for the northern stock only covers the area from 40º10’ N lat. to Cape Blanco, OR at 43º N lat. – see section 1.1.4.7 for more details), greenspotted rockfish, greenstriped rockfish, and stripetail rockfish have been assessed. The following section defines these complexes in terms of their component stocks and provides further detail on those component stocks that have been assessed.

The Shelf Rockfish complex north of 40°10' N lat. is comprised of the following species: bronzespotted rockfish (*Sebastes gilli*); bocaccio (*Sebastes paucispinis*); chameleon rockfish (*S. phillipsi*); cowcod (*S. levis*); dusky rockfish (*S. ciliatus*); dwarf-red rockfish (*S. rufianus*); flag rockfish (*S. rubrivinctus*); freckled rockfish (*S. lentiginosus*); greenblotched rockfish (*S. rosenblatti*); greenspotted rockfish (*S. chlorostictus*); greenstriped rockfish (*S. elongatus*); halfbanded rockfish (*S. semicinctus*); harlequin rockfish (*S. variegatus*); honeycomb rockfish (*S. umbrosus*); Mexican rockfish (*S. macdonaldi*); pink rockfish (*S. eos*); pinkrose rockfish (*S. simulator*); pygmy rockfish (*S. wilsoni*); redstripe rockfish (*S. proriger*); rosethorn rockfish (*S. helvomaculatus*); rosy rockfish (*S. rosaceus*); silvergray rockfish (*S. brevispinis*); speckled rockfish (*S. ovalis*); squarespot rockfish (*S. hopkinsi*); starry rockfish (*S. constellatus*); stripetail rockfish (*S. saxicola*); swordspine rockfish (*S. ensifer*); tiger rockfish (*S. nigrocinctus*); and vermilion rockfish (*S. miniatus*).

The Shelf Rockfish complex south of 40°10’ N lat. is composed of the following species: bronzespotted rockfish (*Sebastes gilli*); chameleon rockfish (*S. phillipsi*); dusky rockfish (*S. ciliatus*); dwarf-red rockfish (*S. rufianus*); flag rockfish (*S. rubrivinctus*); freckled rockfish (*S. lentiginosus*); greenblotched rockfish (*S. rosenblatti*); greenspotted rockfish (*S. chlorostictus*); greenstriped rockfish (*S. elongatus*); halfbanded rockfish (*S. semicinctus*); harlequin rockfish (*S. variegatus*); honeycomb rockfish (*S. umbrosus*); Mexican rockfish (*S. macdonaldi*); pink rockfish (*S. eos*); pinkrose rockfish (*S. simulator*); pygmy rockfish (*S. wilsoni*); redstripe rockfish (*S. proriger*); rosethorn rockfish (*S. helvomaculatus*); rosy rockfish (*S. rosaceus*); silvergray rockfish (*S. brevispinis*); speckled rockfish (*S. ovalis*); squarespot rockfish (*S. hopkinsi*); starry rockfish (*S. constellatus*); stripetail rockfish (*S. saxicola*); swordspine rockfish (*S. ensifer*); tiger rockfish (*S. nigrocinctus*); vermilion rockfish (*S. miniatus*); and yellowtail rockfish (*S. flavidus*).

Greenspotted Rockfish

Distribution and Life History

Greenspotted rockfish (*Sebastes chlorostictus*) are found in waters off the west coast of North America, ranging from Copalis Head, Washington to Isla Cedros, Baja California (approximately 25º to 47º N lat.). Abundance of this species is greatest from northern Baja California to Mendocino County in California. Greenspotted rockfish associate with several benthic habitat types between depths of 30-363 m, although adults are most common between 60 and 240 m (Love, *et al.* 2002).

Greenspotted rockfish are a long-lived and slow growing species, with sedentary adults associating with a wide variety of benthic habitats. Maximum reported age is 51 years (Benet, *et al.* 2009). Estimates of maximum length for greenspotted rockfish are in the vicinity of 50 cm. Benet et al. (2009) report maximum fork length as 48 cm for central California. Miller and Gotshall (1965) report 51 cm total length for the same area, but did not attempt to distinguish between greenspotted rockfish and pink rockfish (*Sebastes eos*), which grow to 56 cm (Love, *et al.* 2002). Commercial port samplers in California have reported individuals larger than 50 cm fork length (up to 57 cm), although fish of this size appear to be rare (CALCOM, 2011). In southern California, Love et al. (1990) report maximum length as 50 cm total length. Sexual dimorphism is not apparent in greenspotted rockfish (Benet, *et al.* 2009; Lenarz and Wyllie Echeverria 1991; Mason 1998), although latitudinal differences in weight-at-length, length-at-age, and size-at-maturity have been observed.

Seasonal maturation and size at maturity vary with latitude, a trend commonly seen in rockfishes (Benet, *et al.* 2009; Love, *et al.* 1990). In central and northern California, spawning months have been reported from March to September, with peak parturition from April to June (Benet, *et al.* 2009; Wyllie Echeverria 1987). In southern California spawning months begin in February and extend through July, with peak parturition in April (Love, *et al.* 1990). Benet et al. (2009) estimate length at 50% maturity for female greenspotted as 26 cm, consistent with a previous estimate of 27 cm (Wyllie Echeverria 1987) based on females from the same area. In southern California, Love et al. (1990) report length at 50% maturity as 22 cm (converted to fork length from total length). Love et al. (1990) detected evidence of multiple broods in females from southern California (ovaries containing eyed larvae and large numbers of fertilized or unfertilized eggs). No evidence of multiple broods was found in studies of greenspotted rockfish north of Point Conception (Benet, *et al.* 2009; Wyllie Echeverria 1987).

Several studies have reported on habitat associations for greenspotted rockfish. Yoklavich et al. (2000) quantified deep, rocky habitat in Monterey Bay. They observed smaller greenspotted rockfish in shallow depths (75-174 m), and reported strong associations with heterogeneous habitats (cobble-mud, mud-boulder, rock-mud, and rock-ridge). Laidig et al. (2009) studied habitat associations of demersal fishes from a manned submersible in central California, observing 809 greenspotted rockfish. They mainly encountered immature individuals (86% of greenspotted were <25 cm), identifying positive associations with all habitat types (boulder, brachiopod beds, cobble) other than mud. The predominance of juvenile rockfish in the study area suggests that the areas and depths surveyed may be nursery grounds for juvenile rockfish and/or transitional zones as individuals move toward adult habitats (Laidig, *et al.* 2009). Juvenile greenspotted rockfish are commonly seen in traps targeting spot prawn in Monterey Bay, usually in low-relief habitats (Dick, *et al.* 2011).

Adult greenspotted rockfish are generally sedentary, and associate with a wide range of habitat types. Yoklavich et al. (2000) observed 426 greenspotted rockfish (fourth highest abundance of observed species) in Monterey Bay, noting that adults were common near rocky outcrops, ridges, caves, and overhangs. Anderson et al. (2009) described greenspotted rockfish as characteristic of transition zones between hard and soft sediments, based on in situ observations across Cordell Bank in central California.

They classified habitat for greenspotted rockfish over a range of spatial scales. At the finest scale (1-10s of m), greenspotted were found to have weak associations with four of five possible categories: mud, boulders, cobbles, and rock (sand being the fifth category). At intermediate scales (10-100s of m) Anderson et al. (2009) characterized greenspotted habitat as depths between 100-300 m and soft and mixed sediment types.

Movements of greenspotted rockfish have been monitored using acoustic tagging experiments. Starr et al. (2002) implanted acoustic tags in six adults in Monterey Bay, finding that adults exhibit limited horizontal movement and almost no vertical movement. They also identified two movement patterns. In the first pattern, 94% of time was spent within a 0.58 km2 area. The second pattern involved larger movements, with excursions up to 3 km, but 60% of time was spent within the 1.6 km^2 study area. Lowe et al. (2009) monitored 4 adult greenspotted rockfish near oil platforms in southern California using acoustic tags. Probabilities of detection near the release sites dropped by 14% in one year of monitoring. Two individuals returned to their release sites after a 7-month absence.

Williams and Ralston (2002) studied the distribution and co-occurrence of rockfishes over continental shelf and slope habitats using fishery-independent trawl survey data. Greenspotted rockfish were consistently caught (>80% co-occurrence) with bocaccio, chilipepper, stripetail (*S. saxicola*), and shortbelly rockfish. Williams and Ralston (2002) proposed species assemblages for management purposes, including greenspotted in a "southern shelf" assemblage along with bocaccio, chilipepper, shortbelly, stripetail, greenstriped, and cowcod. Since greenspotted rockfish is not a primary target of commercial fisheries, its association with other desirable shelf rockfish species (e.g., bocaccio and chilipepper) is likely a driving force behind historical exploitation of this species.

Molecular systematic studies (Hyde and Vetter 2007) report that greenspotted rockfish are closely related to pink rockfish and greenblotched rockfish (*S. rosenblatti*). Greenspotted rockfish can be distinguished from pink and greenblotched rockfishes by a smooth lower jaw, lacking scales found on the lower mandibles of the other two species (Love, *et al.* 2002).

Stock Status and Management History

The 2011 greenspotted rockfish assessment conducted for the portion of the stock off California was modeled as two area assessments north and south of Point Conception at 34º27' N lat. The assessment indicates the stock is in the precautionary zone with spawning biomass depletions of 30.6 percent and 37.4 percent for the stocks north and south of Point Conception, respectively. The stocks have shown substantial biomass increases since implementation of the RCAs in 2003. Shelf rockfish are particularly well protected by the RCAs, and greenspotted rockfish catches have been negligible since 2003. The Council recommended continuing to manage greenspotted rockfish within the Shelf Rockfish complexes since catch histories were too uncertain to allocate QS in the IFQ fishery. The OFL contribution of greenspotted rockfish to the Shelf Rockfish North complex was based on apportioning 22.2 percent of the projected OFLs from the assessment for the stock north of Point Conception, which is the average estimated catch proportion in the assessment for the stock occurring in the area between 40°10' N lat. and the California-Oregon border at 42° N lat. The OFL contribution for the portion of the stock occurring north of 42° N lat. was derived using DBSRA. The SSC categorized the assessed portion of the stock as a category 2 stock since recruitments were not estimated. The unassessed portion of the stock was categorized as a category 3 stock.

Stock Productivity

Length and age composition data available for the 2011 greenspotted rockfish assessment contained insufficient information to reliably resolve year-class strength. Both base models assumed that recruitment followed a deterministic Beverton-Holt stock-recruitment relationship, so trends in recruitment reflected trends in estimated spawning output.

While the productivity score for greenspotted rockfish is relatively low (P = 1.39), the susceptibility score is sufficiently low to estimate a medium vulnerability to potential overfishing (V = 1.98).

Fishing Mortality

Greenspotted rockfish are not usually a primary target of commercial or recreational fisheries. Regulations affecting this species are typically intended to alter fishing mortality of primary targets and/or overfished species. For example, implementation of RCAs statewide and CCAs in southern California has greatly reduced fishing mortality for greenspotted rockfish in the past decade.

Historical harvest rates for greenspotted rockfish peaked in the mid-1980s in southern California, but continued to rise in northern California until about a decade later. SPR harvest rates exceeded the current proxy MSY value in northern California from 1973-2000, and from 1969-1998 in southern California. Biomass in both regions is currently below target (<40% unfished spawning output), but above the MSST, and equilibrium SPR harvest rates have been below the proxy MSY level since 2001 in the north and since 1999 in the south.

Greenstriped Rockfish

Distribution and Life History

Greenstriped rockfish (*Sebastes elongatus*) can be found in abundance from British Columbia to Northern Baja California, but range from Chirikof Island in the Aleutian Islands (Gulf of Alaska) to central Baja California (Love, *et al.* 2002). Adults may inhabit depths between 12 and 500 meters, but are more commonly found between 100 and 250 m, and adults typically move to deeper water as they mature (Love, *et al.* 2002; Shaw and Gunderson 2006). This species of rockfish is found with other congeners or alone in a wide range of habitats, which include rocky outcroppings. However, unlike most other species of rockfish they seem to prefer mud or sand bottoms (Love, *et al.* 2002; Shaw and Gunderson 2006).

A genetic study of greenstriped rockfish was recently undertaken by Jon Hess (pers. comm., NWFSC, NOAA as cited in by Hicks et al. (2009)) to study the stock structure of greenstriped rockfish. The genetic variability was remarkably low and showed less variability than most other rockfish species, even when including samples from Puget Sound. However, latitudinal differences in life-history traits have been observed.

Typical of other species of the genus *Sebastes*, greenstriped rockfish are long-lived with maximum observed ages greater than 50 years (Love, *et al.* 2002). Females grow larger than males, but typically mature at about the same length, between 18 and 24 cm, which corresponds to an age between 7 and 10 years. A latitudinal cline in maturity has been observed with fish maturing at a smaller size in the southern areas (Wyllie Echeverria 1987).

Greenstriped rockfish give birth to live young and the fecundity of a 0.5 kilogram female is on average around 200,000 eggs (Dick 2009), although a wide range of fecundity has been reported (Love, *et al.* 2002). The reproductive development of males and females is slightly offset with mating occurring in December through February, fertilization occurring in early spring, and parturition occurring about a month later in late spring (Shaw and Gunderson 2006). Females have the ability to store sperm during the time between copulation and fertilization to ensure the availability of spermatozoa when oocyte maturation has occurred (Shaw and Gunderson 2006). However, in southern latitudes, parturition may occur from January to July and females in Southern California may release two broods during this time (Love, *et al.* 2002). Juveniles settle to the bottom at about 3 cm in length in autumn and are commonly found along the interface of fine sand and clay. Maturing adults typically move to deeper water (Love, *et al.* 2002).

A wide range of prey items make up the diet of greenstriped rockfish. They will feed from the water column or the bottom on such things as fish, krill, shrimps, copepods, amphipods, and squid. Other fish species may prey on greenstriped rockfish. They have been found in the stomachs of king salmon (Love, *et al.* 2002). Reefs with small numbers of piscivorous rockfish had much higher numbers of small rockfish, such as greenstriped rockfish, than reefs with high numbers of piscivorous rockfish (PFMC 2006).

Stock Status and Management History

Greenstriped rockfish are a bycatch species with little market value mainly due to its small size, and it has been reported that fillets from this species have a short shelf life (Love, *et al.* 2002). As a result, there has not been a long-term directed fishery for this species. However, greenstriped rockfish are often observed in landings from various fisheries, although in small proportions. The most common occurrence of greenstriped rockfish is in trawl fisheries, but they are often caught in recreational fisheries, especially when fishing vessels drift off of the rocks.

After many attempts to start trawl fisheries off the west coast of the United States in the late 1800s, the availability of the otter trawl and the diesel engine in the mid-1920s helped the trawl fisheries expand (Douglas 1998). The trawl fisheries really became established during World War II when demand increased for shark livers and bottomfish. A mink food fishery also developed during World War II (Jones and Harry 1960). Foreign fleets began fishing for rockfish in the mid 1960s until the EEZ was implemented in 1977 (Rogers 2003b). Since 1977, landings of rockfish were high until management restrictions were implemented in 2000.

Greenstriped rockfish are often caught in bottom trawls, but a long-term directed fishery has not occurred for this species and historical discarding rates are not well known. There have been many reports of greenstriped rockfish occurring in various fisheries, even as early as 1884 (Goode 1884). Fishermen report that greenstriped rockfish are ubiquitous, but are rarely if ever caught in great numbers.

A coastwide assessment of greenstriped rockfish was done in 2009, which indicated stock depletion was at 81% of its unfished biomass at the start of 2009 (Hicks, *et al.* 2009). The coastwide greenstriped harvest specifications were apportioned beginning in 2011 using the mean of the 2003-2008 swept area biomass estimates north of 40°10’ N lat. (84.5 percent) from the NMFS trawl survey. This stock has continued to be managed within the Shelf Rockfish complexes due to the complications associated with managing this species with IFQs. Species pulled out of a complex managed with IFQs must be converted into an IFQ management unit under the Amendment 20 rules. Greenstriped rockfish is a trawl-dominant bycatch species that is rarely landed due to their diminutive size and low market desirability. An initial allocation of quota share for greenstriped would be less than straightforward given the unreliable catch history. The SSC rated the greenstriped stock as category 2 on the basis of the very uncertain catch history in the 2009 assessment that prevented the estimation of discrete year classes.

Stock Productivity

Recruitment deviations were estimated in the 2009 assessment starting in 1970. The estimates showed that recruitment was highly variable for greenstriped rockfish with high values in 1971, 1984, 1993, and 1998, and low estimates of recruitment in the 1990s, early 1970s, and 2006. The age data from the

NWFSC trawl survey were very consistent with these estimates and precisely showed a very strong 1993 cohort.

While the greenstriped productivity score is relatively low (P = 1.28), the susceptibility to high exploitation was also low leading to a medium vulnerability to potential overfishing (V = 1.88).

Fishing Mortality

The spawning output of greenstriped rockfish reached a low in the late 1990s before beginning to increase throughout the last decade. The estimated depletion has remained above the 40% of unfished spawning output target and it is unlikely that the stock has ever fallen below this threshold. Throughout the 1970s, 1980s, and 1990s the exploitation rate and SPR have generally increased and occasionally exceeded current estimates of the harvest rate limit (SPR = 50%). Recent exploitation rates on greenstriped rockfish have been very small, which is primarily due to management actions in the late 1990s and early 2000s to rebuild other species.

Stripetail Rockfish

Distribution and Life History

Stripetail rockfish (*Sebastes saxicola*) are found from Yakutat Bay in the eastern Gulf of Alaska to Bahia Sebastian Vizcaino in central Baja California, but are more common from coastal British Columbia to southern California (Love, *et al.* 2002). They occur in depths ranging from 25 to 547 m but are most abundant between 100 and 200 m. Adult stripetail are benthically oriented and are most often associated mud, sand, and other low relief habitats. Stripetails are found in the same habitats as splitnose rockfish, greenstriped rockfish, Dover sole, and thornyheads.

Stripetail rockfish live at least 38 years and females grow faster (after reaching maturity) and achieve a larger size than males. Stripetail rockfish are relatively small-sized rockfish with a maximum size of 41 cm and 1 kg (Love, *et al.* 2002). Female stripetails along the California coast are mature by 18 cm or about 9 years of age. Off California, larval release occurs from November to March with peak release occurring off central and northern California in February and in December in the Southern California Bight (Love, *et al.* 2002). Females produce between 15,000 and 230,000 eggs.

Stripetails are primarily water column planktivores feeding mainly on krill and copepods. They are preyed on by a number of predators including Chinook salmon.

Stock Status and Management History

Stripetail rockfish are managed in the northern and southern Shelf Rockfish complexes. They are a relatively minor component stock to these complexes since stripetail are not targeted nor landed in large amounts.

A new data-moderate assessment of stripetail rockfish was conducted in 2013, which indicated the stock was healthy with a depletion exceeding 77.5% (Cope, *et al.* 2014). The 2013 assessment did not produce a reliable estimate of the scale of the stock's biomass; therefore, the SSC did not recommend using the OFL estimates in the assessment. However, the SSC did recommend the available data in the assessment provided strong evidence that the stock was well above the target B_{MSY} and that the assessment results could be used for status determination. Given that the assessment-based OFLs were not endorsed by the SSC, the OFL continues to be based on a DBSRA methodology and the stock is therefore categorized as a category 3 stock.

Stock Productivity

Two recruitment events reported in trawl studies off California from 1973-1993 occurred during El Ninos (Love, *et al.* 2002). It is not clear from the literature whether this is a representative recruitment pattern for the stock.

The PSA productivity score of 1.39 for stripetail rockfish indicates a relatively low productivity among rockfish species. There is a moderate vulnerability of potential overfishing (V = 1.8) for the stock.

Fishing Mortality

Stripetail rockfish are not targeted in commercial or recreational fisheries due to their small size. However, they are caught incidentally in bottom trawl fisheries due to their occurrence in low relief, trawlable habitats. They are rarely landed in current trawl fisheries although they were frequently landed and sold for animal food in the 1950s and 1960s. The stock has never experienced overfishing with the exploitation rate remaining well below the proxy SPR = 50% F_{MSY} harvest rate for rockfish.

1.1.5.3 Slope Rockfish North and South of 40°10’ N Lat.

The slope rockfish complexes north and south of 40º10’ N lat. are comprised of both assessed and unassessed species. Of the stocks managed in the slope rockfish complexes, aurora rockfish, blackgill rockfish south of 40º10’ N lat., rougheye rockfish (and blackspotted rockfish), and sharpchin rockfish have been assessed. There is an older assessment of bank rockfish that was done in 2000 (Piner, *et al.* 2000) that was limited in area and is not used in current management. The following section defines these complexes in terms of their component stocks and provides further detail on those component stocks that have been assessed.

The Slope Rockfish complex north of 40°10' N lat. is comprised of the following species: aurora rockfish (*Sebastes aurora*); bank rockfish (*S. rufus*); blackgill rockfish (*S. melanostomus*); blackspotted rockfish (*S. melanostictus*); redbanded rockfish (*S. babcocki*); rougheye rockfish (*S. aleutianus*); sharpchin rockfish (*S. zacentrus*); shortraker rockfish (*S. borealis*); splitnose rockfish (*S. diploproa*); and yellowmouth rockfish (*S. reedi*).

The Slope Rockfish complex south of 40°10' N lat. is composed of the following species: aurora rockfish (*Sebastes aurora*), bank rockfish (*S. rufus*), blackgill rockfish (*S. melanostomus*), POP (*S. alutus*), redbanded rockfish (*S. babcocki*), rougheye rockfish (*S. aleutianus*), sharpchin rockfish (*S. zacentrus*), shortraker rockfish (*S. borealis*), and yellowmouth rockfish (*S. reedi*).

Aurora Rockfish

Distribution and Life History

Aurora rockfish (*Sebastes aurora*) are encountered between the Queen Charlotte Islands (British Columbia, Canada) south to mid-Baja California (Mexico). Off of the United States, they are common from northern Oregon to southern California, and are most abundant in the area around Point Conception, California. They occur at depths from 200 to 700 m (~100 to 400 fm) with the median depth increasing to the south, such that they are most abundant from 350 to 550 m in the north and 400 to 600 m in the south.

While there are areas of greater abundance off of northern Oregon and especially off of Point Conception, California, the population appears continuous over the entire coast, so that there is no clear point for stock delineation. Survey catches exhibit a continuous distribution along the entire coast, though with areas of higher and lower abundances along the coast.

Aurora rockfish is a long-lived rockfish species, with maximum observed age of 125 years on the U.S. west coast based upon otoliths aged in the 2013 assessment (Hamel, *et al.* 2013). This is slightly greater than the maximum of 118 years seen by Thompson and Hannah (2010) and consistent with a maximum age greater than 75 as reported by Love et al. (2002). As with many rockfish species, aurora rockfish exhibit both spatially varying and sexually dimorphic growth, with females reaching a slightly larger size than males. Off of Oregon, females reached an asymptotic length of 36.9 cm, while males reached only 33.6 cm (Thompson and Hannah 2010). Asymptotic size and size at age decreases with latitude, and since the bulk of the stock is south of Oregon, the average asymptotic lengths are quite a bit lower than those reported above.

Thompson and Hannah (2010) found the age at 50% maturity for female aurora rockfish to be 12.56 years and the length at 50% maturity to be 25.54 cm. Maturity data collected coastwide during the 2012 NWFSC trawl survey found similar values, though with more evidence of atresia in older and larger fish than observed in the Thomson and Hannah study.

Aurora rockfish larvae have been collected off of California in months ranging from November to August, with abundance peaking in May and June, corresponding to the observation of females with developed embryos from March to May off of California and in May in Oregon (Love, *et al.* 2002). Thompson and Hannah (2010) also found that parturition peaked in May off of Oregon. Auroras settle on the bottom when they reach a length of about 3.3 cm (Love, *et al.* 2002).

Aurora rockfish display ontogenetic movement, with smaller fish found in shallower waters (below 400-450 m). They are distributed over both hard and soft substrates (Love, *et al.* 2002).

Aurora rockfish co-occurs with many prominent groundfish targets such as Dover sole, sablefish, thornyheads and hake, though are most reported in the catch of splitnose rockfish. Aurora rockfish contributes to the overall California Current ecosystem as both predator on crustaceans and small fishes, and as prey to larger fishes, marine mammals, and large squid. Juvenile aurora rockfishes are preyed on by salmon, birds, and other fishes (Love 2011).

Several aspects of aurora rockfish population biology are affected by the ecosystem. The recruitment of many species of rockfish appears to be high in 1999, suggesting that environmental conditions influence the spawning success and survival of larvae and juvenile rockfish, including aurora rockfish. The mechanism behind this observation is not well understood, but zooplankton abundance, changes in water temperature and currents, distribution of prey and predators, and amount and timing of upwelling are all possible linkages. Changes in the environment may also directly influence age-at-maturity, fecundity, growth, and survival, which can affect stock status determination and its susceptibility to fishing. Thompson and Hannah (2010) found variations in growth corresponding to individual years based upon dendrochronological techniques and otoliths, and found a correlation between an observed growth anomaly in otoliths and sea level in individual years.

Stock Status and Management History

Aurora rockfish reside in deep waters below 200 m. The primary gear type that has been used to catch aurora rockfish and other deepwater rockfish has been trawl gear. The use of trawls off the west coast of the United States dates to the late 1800s, though there was little fishery expansion until the availability of the otter trawl and the diesel engine in the mid-1920s (Douglas 1998). Trawl fisheries were mainly conducted on the shelf and became more established during World War II when demand increased for groundfish. Mink farms were also a major destination of groundfish removals in the 1940s and 1950s (Jones and Harry 1960). Foreign fleets began fishing for rockfish, including deeper waters of the slope, in the mid-1960s, with declining participation until the 200-mile EEZ was implemented in 1977 (Rogers 2003b). Peaks in the foreign catch have typically been seen in the mid-1960s for rockfishes, but for aurora rockfish, the largest catches were taken in the early 1970s. Foreign fishing was limited in the northern regions by 1970, shifting effort southward and more into aurora rockfish habitat. After 1977, domestic landings of rockfish increased rapidly until about 1990. Subsequent declines in rockfish landings were driven by declining biomass levels and implementation of new, more restrictive management practices, particularly between 1997 and 2002.

Documented and estimated removals of aurora rockfish do not reach consistently large levels until the 1980s. Aurora rockfish are and have been historically most commonly taken from central California to Oregon, tightly coupled with catches of splitnose rockfish. The term “rosefish” was often used to describe either splitnose or aurora rockfish and has been used as a reporting category in California since 1982. Aurora rockfish remains largely a non-targeted member of the slope rockfish complexes.

Limits on select rockfishes, which included the co-occurring species splitnose, were established in 1982. The first imposed catch limits on a coastwide *Sebastes* complex (aurora being one of the 50 rockfishes in the complex) were instituted in 1983. This complex was divided into two management areas north and south of 43º N lat. (separating the Eureka and Columbia INPFC areas) in 1994. Ongoing concern that shelf and slope rockfishes may be undergoing overfishing led the attempt by Rogers et al. (1996) to describe the status of most rockfishes contained in the *Sebastes* complex. Aurora rockfish information content was low, so only estimates of exploitation rates were provided, indicating the stock was undergoing very high exploitation rates relative to biomass estimates in both management areas.

The *Sebastes* complex was subsequently divided into nearshore, shelf, and slope complexes effective in the year 2000, and the dividing line between the northern and southern management areas was shifted to 40º10’ N. lat. Aurora rockfish has been managed under trip limits for the minor slope rockfish complex in both the north and south management areas from 2000-2010. Beginning in 2011, bottom trawl catches of slope rockfish north and south of 40º10’ N lat. have been managed under an IFQ system.

The first assessment of the west coast stock of aurora rockfish was conducted in 2013 (Hamel, *et al.* 2013); the assessment estimated stock depletion was at 64 percent of its unfished equilibrium at the start of 2013 and had never dropped below its B_{MSY} target (Figure 25). The assessment was a length-based full assessment with natural mortality identified as the major axis of uncertainty. The SSC categorized aurora rockfish as a category 1 stock based on the assessment. However, the uncertainty in estimated biomass in the 2013 assessment was greater than for other category 1 assessments resulting in a higher sigma value for defining the ABC buffer (see section 1.2.2 for more details).

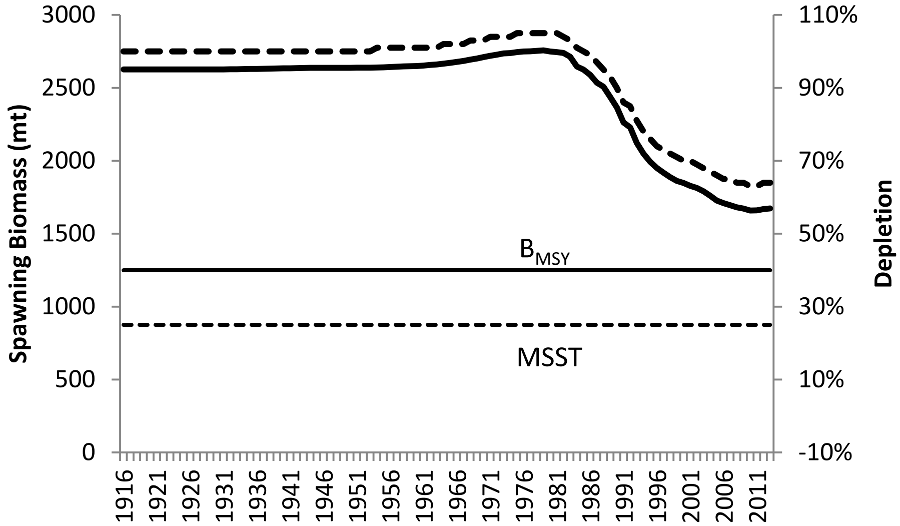

Figure 25. Time series of estimated spawning biomass and depletion of aurora rockfish, 1916-2013.

Stock Productivity

Steepness was fixed to the mean of the most recent rockfish steepness prior (h = 0.779; Thorson, 2013) in the 2013 assessment. Recruitment deviations were estimated from 1916 (the beginning of the modeling period), with a ramp towards bias correction beginning in 1962, full-bias adjustment beginning in 1970 and ending in 2008, and a ramping back down to no bias correction in 2012. Two of the largest contemporary recruitment events are found in 1999 and 2007 (Figure 26). Despite the inclusion of estimated ageing error, discerning individual year classes remains difficult and significant correlation exists between the estimated strength of adjacent year classes, which may be primarily due to ageing error rather than actual correlation in recruitment strength.

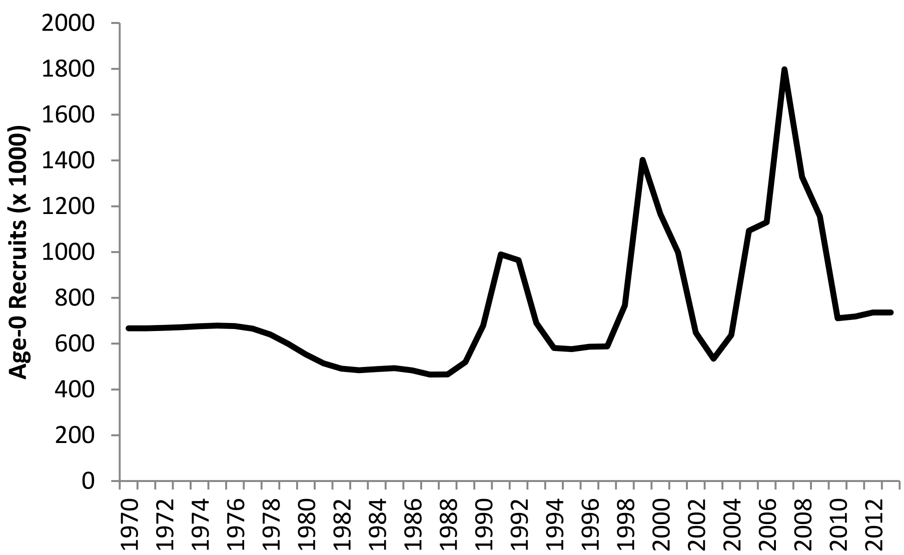

Figure 26. Time series of estimated age-0 recruits of aurora rockfish on the U.S. west coast, 1970-2013.

Fishing Mortality

The 2013 estimates that exploitation of aurora rockfish has been relatively low, with total catch estimated to have exceeded the current management harvest-rate limits in only 2 years, during the early peak in trawl catch (1990 and 1992) (Figure 27). Recent levels of removals have remained moderate. There seems to be very low risk that current removals are causing overfishing.

While stock-specific OFLs/ABCs were not historically set for aurora rockfish specifically, the reauthorized Magnuson-Stevens Act of 2006 and FMP Amendment 23 required OFLs for all species in a management plan, including those managed in stock complexes. The first OFL contributions were calculated using DB-SRA and provided in 2011. The 2015 and beyond OFLs are projected from the 2013 assessment. Recent catches since 2002 have been below the new 2015 OFL and ABC (Figure 28).

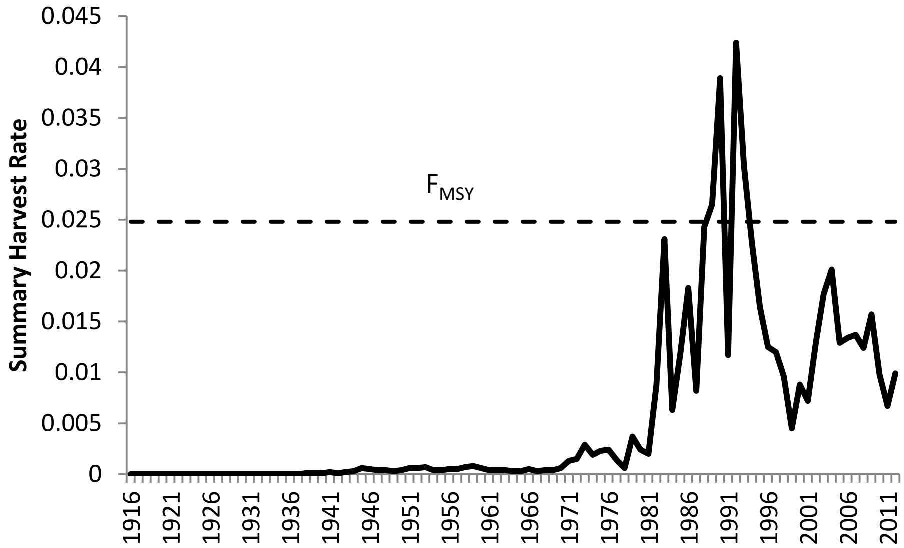

Figure 27. Time-series of estimated summary harvest rate for the west coast stock of aurora rockfish, 1916-2012. The dashed line is the harvest rate at the overfishing F_{MSY} proxy.

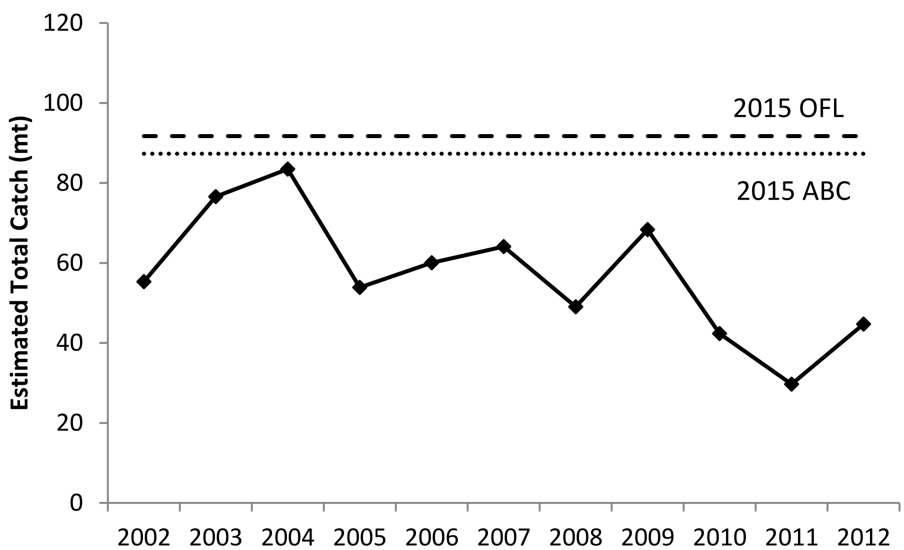

Figure 28. Estimated coastwide total annual catch of aurora rockfish in 2002-2012 relative to the proposed 2015 OFLs and 2015 ABCs (summed north and south of 40°10’ N lat. to compare to coastwide catches).

Blackgill Rockfish

Distribution and Life History

Blackgill rockfish (*Sebastes melanostomus*), also known at times as blackmouth rockfish or deepsea rockfish, range from at least central Vancouver Island to central Baja California (Love, *et al.* 2002). However, the species is relatively uncommon north of Cape Mendocino and occurs in the greatest densities in the Southern California Bight (SCB). The name very accurately describes the most identifying characteristic of adult blackgill rockfish, in that they have black pigmentation on the rear edge of their gill cover, as well as in the fold above the upper jaw and inside of the mouth. The rest of the fish appears pink with brown and white blotches underwater, or reddish with distinct brown saddles upon capture. It is a medium-sized (to about 62 cm maximum length) and deep bodied species. Additional descriptions and meristics can be found in Love et al. (2002) for adults and Moser (1996) for larvae and juveniles.

Hyde and Vetter (2007) did not find any evidence for close molecular or evolutionary relationships between blackgill and other rockfish species. Blackgill were found to be moderately related with several other slope or deep shelf species (*S. aurora*, *S. phillipsi, S. gilli*, *S. diploproa*, and *S. melanosema*) as well to a suite of mostly rare and poorly known species from the Gulf of California (*S. sinensis*, *S. peduncularis*, and *S. cortezi*) or southern California.

Blackgill are a slope rockfish species, and are generally rare in waters less than 100 meters and most abundant in waters between 300 and 500 meters depth. Love et al. (2002) report a depth distribution of 87 to 768 meters; however, from ten years of data from the NWFSC combined trawl survey, only one haul greater than 600 meters encountered blackgill (that tow was at 647 meters) and the shallowest fish was encountered at 133 meters. Survey data suggest that smaller fish tend to be encountered in shallower water and larger fish in deeper water; survey data also suggest few small fish in waters north of Cape Mendocino. Juveniles are often seen over soft bottom habitats with low relief. Adults are usually associated with high relief rocky outcrops, canyons or deep rock pinnacles, although fishermen often report taking them in midwater (Kronman 1999; Love, *et al.* 2002).

Little is known about the population structure of blackgill rockfish. Like most rockfish, larvae and juveniles circulate in the plankton for 3-4 months. Love et al. (2002) report that some juveniles may be pelagic for up to 7 months; however, this may be atypical. Thus, like most shelf and slope species, blackgill likely disperse over fairly long distances before settling to the bottom. Abundance south of the U.S./Mexico border is uncertain, but there appear to be substantial numbers and catches of blackgill in many areas, and pelagic juveniles have been found as far south as Punta Abreojos, in southern Baja California (Moser and Ahlstrom 1978). The CalCOFI Ichthyoplankton survey has been used to develop or explore indices of relative abundance for several rockfish species for which larvae can be morphologically identified to species (Moser, *et al.* 2000), and such indices have been used as relative abundance indices for assessments of bocaccio (Field, *et al.* 2009) and shortbelly rockfish (Field, *et al.* 2008) as well as northern anchovy (Jacobson and Lo 1994), Pacific sardine (Hill, *et al.* 2008), and California sheephead (Alonzo, *et al.* 2008). Unfortunately, blackgill rockfish are not among the species that have been historically sorted to the species level using morphological methods, although recent developments have led to the potential to use genetic methods to identify historical and contemporary Sebastes from the ichythyoplankton archives (e.g., (Taylor, *et al.* 2004), J. Hyde, FRD/SWFSC, unpublished data). Thus, it is possible that these collections could provide relative abundance information from past and contemporary monitoring programs.

Moser and Ahlstrom also found that blackgill represented approximately 16% of the total number of rockfish specimens encountered in a series of midwater trawls for late larvae and juvenile stage rockfish done in the early 1970s (prior to most historical exploitation). By contrast, from ongoing pelagic juvenile surveys run by the Fisheries Ecology Division used to develop juvenile (pre-recruit) indices for some species, blackgill rockfish comprised only about 3% of juveniles collected from the southern California region from 2004 through 2010 (K. Sakuma and J. Field, unpublished data as cited in Field and Pearson (2011)). However, these results are not likely to be comparable unless seasonal and depth of survey efforts are accounted for; the Moser and Ahlstrom (1978) study in particular fished depths ranging from 0 to 600 meters using an Isaacs-Kidd midwater trawl, while the FED survey uses a considerably larger (modified Cobb) midwater trawl and typically only fishes at 30 meters headrope depth. There is at least some potential to consider relative abundance indices of age-0 juveniles from the FED/SWFSC survey in the future, although given the very slow growth and difficulty in ageing of blackgill rockfish, it is unlikely that validation of survey indices or improved understandings of high frequency variation in year class strength will be of substantial near term benefit to the model.

Nearly 2/3rds of all U.S. landings are from waters south of Point Conception, for which blackgill accounted for as much as 20 to 30% of total *Sebastes* landings in the SCB during the 1980s, when deep water fixed gear fisheries rapidly expanded (more details in catch history section). Nearly all of the remaining landings took place between Conception and Cape Mendocino, such that less than 1.3% of historical California landings have come from waters north of Cape Mendocino. Landings in Oregon waters are even less, and only trace landings of blackgill are reported from Washington waters. Trawl survey abundance data (discussed later in the document) are consistent with these results, although they represent the period following the greatest extent of exploitation: surveys that took place from the 1970s through the late 1990s had virtually no coverage in southern waters where blackgill are the most abundant.

Blackgill rockfish have among the deepest distribution of all of the California Current *Sebastes* (although the three *Sebastolobus* species are common at considerably greater depths), and live at the edge of the low oxygen (hypoxic) conditions that characterize the slope waters of the California Current. Below these depths, species diversity declines to a smaller suite of species that have adapted to cope with low oxygen waters, notably the DTS complex species (Dover sole, thornyheads and sablefish), which have evolved a range of adaptive strategies including metabolic suppression, slow growth rates, late ages at maturity, and ambush (rather than active searching) predation methods (Childress and Seibel 1998; Jacobson and Vetter 1996; Koslow, *et al.* 2000; Vetter and Lynn 1997). These low oxygen waters, known as the oxygen minimum zone (OMZ), are a natural feature of the Eastern Pacific Rim and other regions characterized by high surface productivity and/or the upwelling of oxygen-poor source waters (Helly and Levin 2004). The California Current has a relatively deeper OMZ than the Equatorial Eastern Tropical Pacific (ETP) or the Humboldt Current (Helly and Levin 2004), with the zone starting at approximately 500 to 600 meters depth in the waters off of southern and central California. The observation that blackgill are likely the most deeply distributed medium-size Sebastes (at least in southern California Current waters) suggests that they have adapted to live on the edge of the OMZ, where oxygen availability is rapidly declining relative to shelf waters, although no Sebastes species appears able to tolerate the very low oxygen conditions within the OMZ itself.

Seibel (2011) describes two oxygen thresholds that are temperature dependent (as opposed to species or situation-specific), one in which virtually all species are capable are of physiologically adjusting or adapting to declining oxygen availability, and a second for which no further adjustment or adaptation in aerobic O2 utilization is possible. Seibel (2011) describes this latter threshold as one at which "organisms that are not specifically adapted to low O2 will suffer physiological stress and eventual death." Importantly, this threshold falls just below the currently observed oxygen levels throughout the slope waters of much of the California Current, inferring that any expansion of the OMZ in this region is likely to have tremendous impacts on the vertical distribution of populations and the species composition of ecosystems. Equally importantly, there is already some evidence of a shoaling (shallowing) of the depth of the OMZ throughout the California Current (Bograd, *et al.* 2008; Whitney, *et al.* 2007), with Bograd et al. (2008) reporting oxygen declines of 20-30% at depths of approximately 300 to 500 meters in the waters of the Southern California Bight, the region in which most of the blackgill biomass resides. A shoaling of the OMZ has been predicted to be a likely or plausible response to global climate change due to the fact that oxygen is less soluble in warmer waters, and warming is also expected to increase stratification in the upper ocean, which will both reduce oxygen supply and increase oxygen demand at depth (Keeling, *et al.* 2010; Sarmiento, *et al.* 1998; Seibel 2011).

For blackgill rockfish, it is the shoaling of the OMZ at depth that is likely to be the greatest long-term threat, as such a shoaling would likely represent a severe compression of the available habitat for this species. McClatchie et al. (2010) evaluated potential scenarios for hypoxia to impact the habitat of cowcod (Sebastes levis), a rebuilding shelf species that is a focus of management in the SCB. They found that as much as 37% of deep (240-350 m) cowcod habitat is currently affected by hypoxia, but that if the current trends of a shoaling OMZ continue for 20 years, this could increase to 55% of deep habitat, as well as an additional 18% of habitat in the 180 to 240 m depth range. These numbers would presumably differ substantially for blackgill rockfish, which have a very different (considerably deeper) distribution; due to their proximity to the OMZ, they may be at considerably greater risk to the longer-term impacts of shoaling. Moreover, changes in the characteristics and dynamics of the OMZ could lead to changes in the forage base for blackgill, which are described as foraging primarily on mesopelagic fishes which undergo dial migrations from the edge of the OMZ to surface waters in order to feed.

As previously mentioned, blackgill have been described as having a strong affinity for deep water habitat, particularly around offshore banks, canyons and areas of high depth gradients. They have been described as feeding on small mesopelagic fishes, such as myctophids and bathylagids (Love, *et al.* 2002). Isaacs and Schwartzlose (1965), Genin et al. (1988), Koslow (2000) and Genin (2004) describe the mechanisms by which vertical migrants, such as zooplankton and mesopelagic fishes, become trapped by topographic features. High densities of deepwater adapted resident species are consequently found in the relatively small, confined areas where these diurnally-migrating prey become aggregated. Such observations are consistent with the reports by fishermen of isolated deep banks, pinnacles or other habitat features often hosting very large numbers of fish over a relatively small spatial range, such that vertical hook and line gear (which can be more precisely targeted at small habitat features) is the gear of choice for targeting these species (as opposed to horizontal, or set, hook and line gear often used to target species in deeper slope waters, such as sablefish and thornyheads, which tend to be more widely dispersed).

With respect to predators and predation mortality, it is likely that sablefish and shortspine thornyheads are among the most important predators of blackgill rockfish. Both species are large (up to 100 and 75 cm, respectively, although individuals greater than 80 or 65 cm of either species are uncommon) and largely piscivorous ambush predators that are typically (along with longspine thornyhead and Dover sole) the most abundant and commercially important groundfish in the continental slope ecosystem (Lauth 2000). Food habits information for adult sablefish found that *Sebastolobus* and *Sebastes* species, particularly Sebastolobus altivelis, are key prey items, representing 15% to 30% of total prey by volume (Buckley, *et al.* 1999; Laidig, *et al.* 1997). Similarly, shortspine thornyhead preyed heavily on S. altivelis, unidentified *Sebastes*, and other fishes (Buckley, *et al.* 1999). Although no *S. melanostomus* were conclusively identified in either study, other slope rockfish species (*S. crameri*, *S. diploproa*, and *S. alutus*) were. The lack of specimens is likely due to both studies' focused sampling in northern California, Oregon and Washington slope waters, rather than the south-central and southern California waters in which *S. melanostomus* are most abundant.

Length data for both of these predators (sablefish and shortspine thornyheads) and their prey suggest that predation is low on fishes smaller than 5 cm, high on fishes ranging from 5 cm through 20 cm, and drops off notably for larger prey. However, the diet data summarized here were largely of smaller (40-60 cm) predators, and larger predators likely consume (or consumed) a broader range of prey. In the most recent stock assessment for longspine thornyhead (Sebastolobus altivelis), the base model suggested a declining or stable population (Fay 2006); however, it was noted that an ecosystem model of the northern California Current indicated that abundance of longspines should be increasing due to declines in predation mortality associated with declines in their primary predators (Field, *et al.* 2006). Survey biomass trends for longspine thornyheads, while limited to a relatively narrow time period and associated with considerable uncertainty, also suggested an increasing biomass trend. These observations led to exploration of both time and age-varying natural mortality rates for *S. altivelis* as informed by changes in predator biomass and estimates of predator consumption (Fay and Field, unpublished data as cited in Field and Pearson (2011)). Results suggest that, for this species, predation-related factors should be taken into account for future single-species stock assessments. Comparable evaluations could, and probably should, be done for blackgill rockfish and other slope species, for which their likely most important sources of predation mortality have themselves undergone significant changes in abundance.

Stock Status and Management History

Blackgill rockfish have historically represented a minor part of California rockfish landings north of Point Conception, but a substantial fraction of landings occur south of Conception. Based on consultations with fishery participants, Butler et al. (1999a) and Kronman (1999) defined the southern California targeted fishery for blackgill rockfish as being a relatively recent phenomenon. Although longline fishing had long been the primary means of catching rockfish in southern California waters, increased participation and declines in the catches of many highly desired shelf species (such as vermilion rockfish and cowcod) contributed to a gradual shift in effort towards deeper and more offshore waters. Moreover, improvements in technology and gear (such as loran, affordable acoustic systems, electric line haulers) helped ease the difficulties of fishing (and relocating good fishing sites) in deeper waters. Additionally, set nets (gillnets) also began to be deployed at a larger scale in southern California in the 1970s and 1980s, often targeting deep reefs for large bocaccio, cowcod, blackgill, bank and other rockfish species.

Such developments seem to have been associated with a geographic expansion of the regions fished, such that fishing locations were sequentially depleted and new fishing locations discovered and developed over time. The first stock assessment for blackgill rockfish (Butler, *et al.* 1999a) noted that there was significant evidence for sequential depletion of blackgill rockfish in localized areas. This included reports from fishery participants that many pinnacles or other fishing sites that routinely yielded 20,000 pounds of blackgill per trip in the early days of the fishery were now only yielding 500 or so pounds per trip and were often covered with lost gear. Similarly, in a review of historical southern California fisheries, Kronman (1999) also documented the rapid growth and development of the blackgill fishery specifically as one in which fishermen would often “completely decimate” rockfish spots with deep fishing vertical line gear, based on the accounts of the participants themselves. Consequently, there was an ongoing shift to newer fishing spots, generally further offshore and to greater depths, as well as greater experimentation with alternative gears and target species.

These observations suggest the potential for a situation in which the stock may have undergone the “sequential depletion” of biomass from available habitat patches. If so, this would suggest that a traditional (non-spatial) stock assessment assumption of evenly distributed fishing mortality across space is substantially flawed. In fact, if the fishery were sequentially depleting specific areas, the length frequency information would not be likely to suggest a shift to smaller fish over time as the length frequencies could essentially reflect “unfished” population structure for the duration over which the new habitats were discovered and exploited. The consequences of failing to recognize such patterns can lead to overexploitation and collapse, and such processes have been described for several marine invertebrate populations (Karpov et al. 2000, Orensanz et al. 2000) as well as temperate water reef fishes (Epperly and Dodrill 1995, Rudershausen et al. 2008). Ongoing efforts to analyze historical block summary data have the potential to identify such shifts and consider whether such factors are likely to be important for west coast groundfish species such as blackgill, as well as to determine whether there is sufficient data to estimate spatial effects or develop spatially-explicit models more capable of accounting for such factors.

Management of blackgill rockfish has generally not been to the species level, but rather as part of the "*Sebastes* complex" in the Pacific Fishery Management Council era (prior to which management was under the direction of the California Department of Fish and Game). The PFMC allowable biological catches (ABC) of blackgill have historically been grouped together with eleven other species of minor rockfishes called "remaining rockfish" and all "other" rockfish. The PFMC historically used trip limits, and later cumulative trip limits (over set time periods), to slow the pace of harvest based on allowable biological catch and to promote a year-round fishery. For all commercial gear types, the limits were initiated in 1983 when the PFMC imposed a monthly limit of 40,000 pounds per trip for the entire coastwide *Sebastes* complex, a limit that stayed in place through 1990. After recognizing the differential spatial distribution of the remaining rockfishes and the fisheries that target them, harvest limits on both open access and limited entry fisheries were divided between the northern and southern *Sebastes* complexes, and trip limits began to be implemented at variable levels over both time (month and year) and space (north and south of Mendocino), often with species-specific limits in addition to the overall limit on *Sebastes* catches. Although early limits applied to both trawl and fixed gears, beginning in 1995 fixed gear limits (hook and line and pot, primarily, as gill nets were phased out through the 1990s) were set to 10,000 lbs of *Sebastes* per trip, which persisted through the 1990s.

Consequently, prior to 1999 cumulative trip limits had been historically high relative to landings of blackgill rockfish from individual trips, and unlikely to have impacted fishing for blackgill and catches. Limits were dramatically reduced in 1999 for the southern *Sebastes* complex; 2-month cumulative limit of 3,500 pounds for limited entry and 3,600 pounds per month for open access. Since 2000, blackgill has been managed as part of the Minor Slope Rockfish sub-group, with limits ranging from 3,000-50,000 pounds per 2 months; Tables 1-3 show the trip limits implemented since 2000 for this complex for the limited entry trawl, limited entry fixed gear and open access fixed gear fisheries. Table 4 shows the total estimated catches of blackgill (including discards) south of 40° 10' for the period since 2001, during which time catches have typically ranged well below allowable levels.

In 2001 the Cowcod Conservation area was established outside of 20 fathoms and directly excludes directed groundfish fishing from an expansive area in the Conception and southern Monterey INPFC areas.[7] This regulation has had a tremendous impact on the southern fixed gear fleet that targets blackgill, as the deep offshore banks and features that characterize the CCAs in deep water are optimal habitat for this species. By contrast, the shelf closures (rockfish conservation areas) implemented to protect rebuilding shelf species (such as bocaccio, cowcod, canary and widow rockfish) have presumably had a negligible direct effect, as the depths closed in the RCAs do not encompass the depths at which most blackgill are encountered. Such measures may have had an indirect effect, by virtue of shifting trawl effort to deeper waters, although for much of California the overall effect has been a sharp decline in active participation in the trawl fishery more generally.

The first assessment for blackgill rockfish was conducted in 1998 and estimated stock depletion was between 40 and 54 percent of its unfished equilibrium at the start of 1998 (Butler, *et al.* 1999a). That assessment assumed a unit stock in southern and central California (Conception INPFC area) and was

7 As the current trawl survey also excludes this region from trawl gear impacts, the area of the CCAs is shown in later maps of survey CPUE for blackgill rockfish, in Figure 13

based on a stock reduction analysis assuming constant recruitment. The dynamics of the simple model were tuned to average mortality rates from catch curves and landings data. Fishery selectivity was assumed to mirror maturity at size/age; trends in fishable/mature biomass were then estimated.

A second blackgill rockfish stock assessment was completed in 2005 indicating a stock depletion of 52 percent (Helser 2006). This assessment expanded the geographic range of that in Butler et al. (1999a), including both the Monterey and Conception INPFC areas, where over 90 percent of the landings have occurred. The assessment was based on catch and length composition data from commercial fisheries and indices of relative abundance and size composition from the AFSC shelf trawl survey and the AFSC slope survey. The modeling approach included fishery and survey length compositions to explicitly estimate selectivity. The assumed natural mortality rate was identified as a key axis of uncertainty for this stock.

The most recent blackgill rockfish assessment, conducted in 2011 for the stock south of 40º10' N lat. (Field and Pearson 2011), estimated the stock was below target with a depletion of 30 percent of its unfished biomass at the start of 2011 (Figure 29). The spawning output of blackgill rockfish was at high levels in the mid-1970s, but began to decline steeply in the late 1970s through the 1980s, consistent with the rapid development and growth of the targeted fishery. The biomass reached a low of approximately 18 percent of the unfished level in the mid-1990s. Since that time, catches have declined and spawning output has increased. The estimated depletion level in 2011 is 30.2 percent.

Catch data used in the assessment are generally reliable throughout the time period, although there is a lot of uncertainty in catch data prior to the early 1980s. Ageing is very difficult for this species, which appears to have highly variable size at age, as well as apparent regional differences in growth rates and potentially other life history traits. The lack of a reliable, long-term, fishery-independent survey index that reflects abundance from the entire range of the stock is problematic. In general, natural mortality and growth parameters comprised the greatest contribution to model uncertainty.

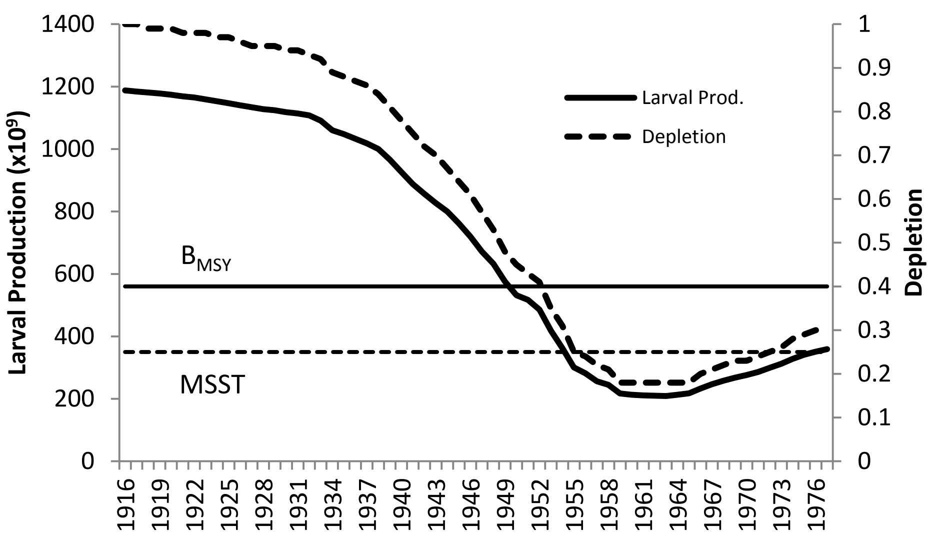

Figure 29. Time series of estimated spawning output and depletion of blackgill rockfish south of 40º10' N lat., 1950-2011.

Stock Productivity

In the 2013 assessment, the Beverton-Holt model was used to describe the stock-recruitment relationship. The log of the unexploited recruitment level was treated as an estimated parameter; recruits were taken deterministically from the stock-recruit curve. Recruitment deviations were not estimated, as the lack of obvious cohorts in either age or length data and the high degree of ageing uncertainty make plausible estimates unlikely. The estimated recruitment is projected to be at relatively high levels due to the fixed value of steepness (h = 0.76); this trend, however, is consistent with the trends from the survey data.

Blackgill rockfish have a relatively high potential vulnerability to overfishing (V = 2.08) driven by a combination of low productivity (P = 1.22) and relatively high susceptibility to being caught in the fishery (Table 2). The low productivity is due to the stock being long-lived (max. age = 87 yrs; (Love, *et al.* 2002)), with late maturation, and relatively low natural mortality (Table 5).

Fishing Mortality

Catches of blackgill rockfish primarily occur in the Southern California Bight south of Point Conception (34º27' N. lat.) where the species is caught in both directed fixed gear (hook-and-line) and historically, gillnet fisheries. Landings of this species are estimated to have risen slowly from very low levels (approximately 20-30 mt) in the 1950s, and then climbed rapidly in the 1970s and 1980s as improvements in technology and declines in other target species led fishermen to target blackgill rockfish in deeper and more offshore waters. Landings peaked in the mid-1980s at just over 1,000 mt, but have declined to approximately 100 mt to 150 mt in recent years.

The 2011 depletion estimate indicated the stock was in the precautionary zone compelling the Council to reduce impacts to prevent overfishing and allow the stock to rebuild back to its target biomass. The Council and NMFS implemented stringent harvest guidelines of 106 and 110 mt for 2013 and 2014, respectively corresponding to calculated 40-0 reductions. Specifying HGs created a sorting requirement for the stock allowing better inseason catch monitoring. The Council further established an apportionment of the non-trawl allocation of 60 percent to limited entry and 40 percent to open access fixed gears, which reflects the historical distribution of catch between the limited entry and open access fixed gear sectors from 2005-2010. Non-trawl landing limits for blackgill south of 40º10' N lat. were reduced beginning in 2013 to prevent targeting of the stock. Cumulative landing limits for blackgill south of 40º10' N lat. were reduced from 40,000 lbs/2 months for slope rockfish including blackgill to 40,000 lbs/ 2 months with a sublimit of 1,375 lbs/2 months for blackgill for the limited entry fixed gear sector. Open access cumulative landing limits south of 40º10' N lat. were reduced from 10,000 lbs/2 months for slope rockfish including blackgill to 10,000 lbs/ 2 months with a sublimit 475 lbs/2 months for blackgill. While final catch accounting of groundfish in 2013 groundfish fisheries will not be available until the end of 2014, landed catch of blackgill has been reduced significantly and fishermen report blackgill targeting is no longer occurring.

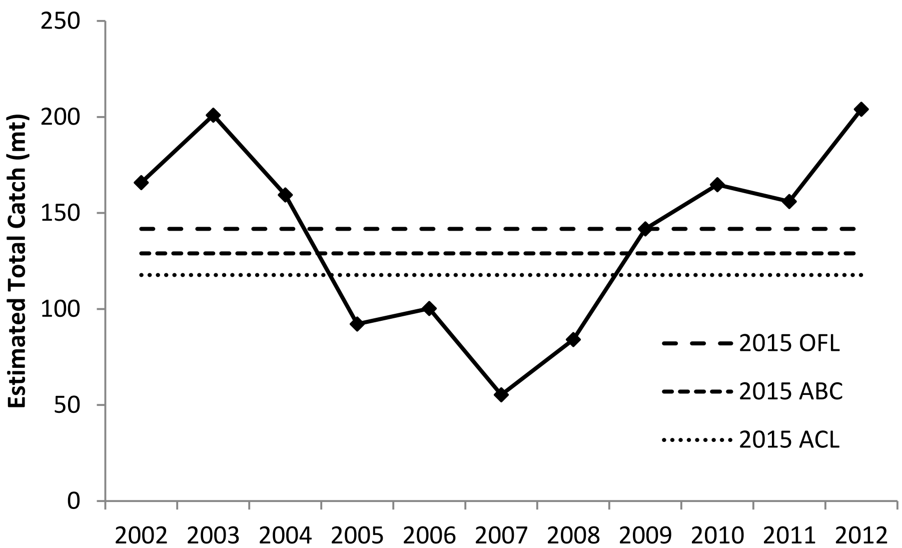

Figure 31. Estimated coastwide total annual catch of blackgill rockfish in 2002-2012 relative to the proposed 2015 OFLs, 2015 ABCs, and 2015 ACLs (summed north and south of 40º10' N lat. to compare to coastwide catches).

Rougheye/Blackspotted Rockfish

Distribution and Life History

Rougheye rockfish (*Sebastes aleutianus*) and blackspotted rockfish (*S. melanostictus*) are slope rockfish that share broad overlap in their depth and geographic distributions from the Eastern Aleutian Islands along the North American continental margin to southern Oregon, with blackspotted rockfish's range extending east beyond the Aleutian chain to the Pacific Coast of Japan (Gharrett, *et al.* 2005; Hawkins, *et al.* 2005; Orr and Hawkins 2008). It is very difficult to visually distinguish between the two species and they have been persistently confused in surveys and catches. It has only been from recent genetic studies in the early 2000s that the two separate species have been identified and described (Orr and Hawkins 2008).

Both species are encountered at depths shallower than 100 m to at least 439 m, however, blackspotted rockfish tend to be more prevalent in deeper waters (Hawkins et al. 2005, Orr and Hawkins 2008). Genetic information is not available to provide positive species identification in historical survey and landings information, but these data indicate that density of the nominal rougheye rockfish complex decreases sharply south of the Oregon-California border at 42° N lat. Studies suggest that rougheye rockfish account for a greater proportion of the species complex along the coast of Washington and Oregon than in Alaskan waters (Gharrett, *et al.* 2005; Hawkins, *et al.* 2005; Orr and Hawkins 2008). Recent discussions with port samplers in southern Oregon suggest that both rougheye and blackspotted rockfish are encountered with some regularity in the commercial trawl and fixed-gear landings in Charleston, Port Orford, and Brookings, with blackspotted rockfish composing approximately one third to one half of identified specimens (C. Good and N. Wilsman, ODFW, pers. comm. as cited in Hicks et al. 2013).

The west coast of the U.S. is the southern portion of the range of rougheye rockfish, and it is likely that the population north of the U.S.-Canada border is not a separate stock. The connectivity of rougheye populations throughout its range is unknown.

Compared with other rockfish species on the west coast of the U.S., rougheye rockfish life-history is poorly described and the recent resurrection of two species (rougheye and blackspotted rockfishes) has further complicated the understanding of life-history characteristics. Rougheye rockfish are often associated with boulders and steep habitats, and are typically found alone or in small aggregations (Love, *et al.* 2002). Younger fish may school and are often found in shallower waters on the shelf, and larger fish may form larger aggregations in the Pacific Northwest during the autumn and winter.

Rougheye rockfish give birth to live young with larvae released between February and June and at lengths between 4.5-5.3 mm (Love, *et al.* 2002). There are no studies on the fecundity of rougheye rockfish on the west coast of the U.S.

A wide range of prey items make up the diet of rougheye rockfish. Crangid and pandalid shrimps make up the majority of their diets, and larger individuals, greater than 30 cm, feeding upon other fishes (Love 2011). They are also known to feed upon gammarid amphipods; mysids, crabs, polychaetes, and octopuses (Love 2011; Love, *et al.* 2002).

Stock Status and Management History

Rougheye and blackspotted rockfish (henceforth denoted as rougheye) are landed as part of the minor slope rockfish complexes north and south of 40º10’ N lat.; however, they are rarely caught in the south. The historical reconstruction of landings for rougheye rockfish suggests that fixed gear fisheries have caught rougheye rockfish since the turn of the 20th century and landings in the trawl fishery are estimated to have increased into the 1940s. Landings remained relatively constant throughout the 1950s and into the 1960s before the foreign trawl fleet increased catches into the 1970s. The declaration of the EEZ resulted in the buildup of a domestic fleet and landings increased rapidly into the late 1980s and early 1990s. Subsequently, landings declined in the late 1990s and have been between 100 and 200 mt in recent years. Trawl, longline, and Pacific whiting at-sea trawl fisheries make up the majority of the catch.

Rougheye rockfish are a desirable market species and discarding has been low, historically. However, management restrictions (e.g., trip limits) have resulted in increased discarding since 2000. Trawl rationalization was introduced in 2011, and since then very little discarding of rougheye rockfish has occurred.

Hicks et al. (2013) conducted the first assessment of the U.S. west coast stock of rougheye and blackspotted rockfish as a complex of two species. The coastwide population was modeled assuming parameters for combined sexes (a single-sex model) and assuming removals beginning in 1916. The predicted spawning biomass from the base model generally showed a slight decline over the entire time series with a period of steeper decline during the 1980s and 1990s. Since 2000, the spawning biomass has stabilized and possibly increased because of reduced catches and above average recruitment in 1999. The 2013 spawning biomass relative to unfished equilibrium spawning biomass was estimated to be 47 percent of its unfished equilibrium at the start of 2013. The stock has been estimated to be healthy throughout the time series in the new assessment (Figure 32).

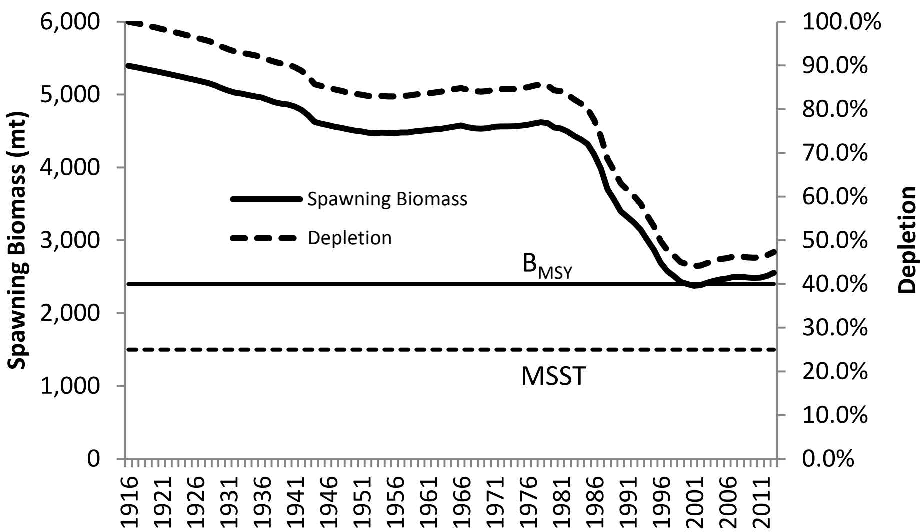

Figure 32. Time series of estimated spawning biomass and depletion of rougheye/blackspotted rockfish, 1916-2013 (from Hicks et al. 2013).

Stock Productivity

A steepness parameter was fixed at 0.779 in the 2013 assessment based on a steepness meta-analysis for west coast rockfishes (Jim Thorson, NWFSC). There is little information regarding recruitment prior to 1980, and the uncertainty in these estimates is expressed in the assessment. Estimates of recruitment appear to oscillate between periods of low and high recruitment. The four largest recruitments were estimated in 1999, 1998, 2001, and 1988, and the four smallest recruitments were estimated in 2002, 2006, 2005, and 1995 (Figure 33).

Rougheye rockfish have the highest potential vulnerability to overfishing (V = 2.27) driven by a combination of low productivity (P = 1.17) and relatively high susceptibility to being caught in the fishery (Table 2). The low productivity is due to the stock being long-lived (max. age = 205 yrs; (Love, *et al.* 2002)), with late maturation, and relatively low natural mortality (Table 5).

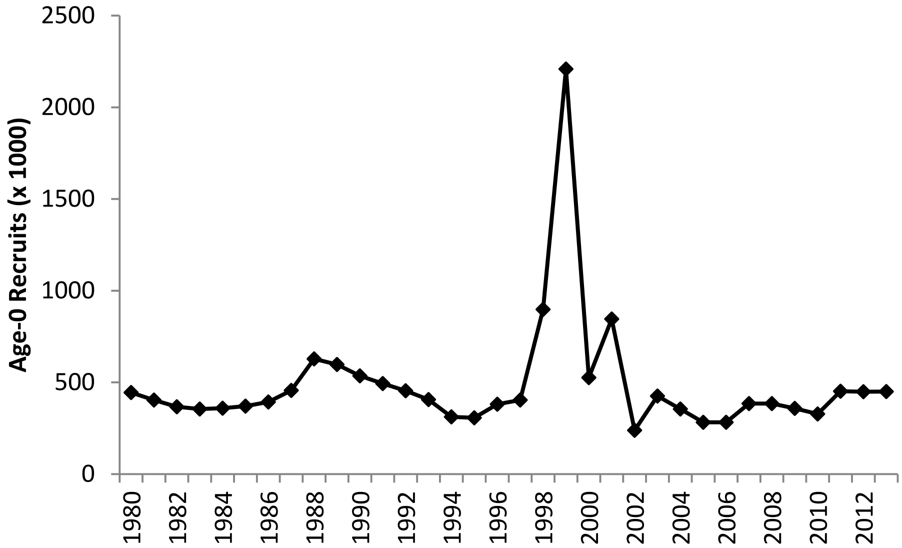

Figure 33. Time series of estimated age-0 recruits of rougheye/blackspotted rockfish on the U.S. west coast, 1980-2013(from Hicks et al. 2013).

Fishing Mortality

Rougheye rockfish are not often targeted by a specific fishery, but are desirable and marketable, thus are typically retained when captured. They are often captured in bottom trawl, mid-water trawl, and longline fisheries. Small numbers have been observed in pot, shrimp, and recreational fisheries.

After many attempts to start trawl fisheries off the west coast of the United States in the late 1800s, the availability of the otter trawl and the diesel engine in the mid-1920s helped the trawl fisheries expand (Douglas 1998). Trawl fisheries really became established during World War II when demand increased for shark livers and bottomfish. A mink food fishery also developed during World War II (Jones and Harry 1960). Foreign fleets began fishing for rockfish in the mid-1960s until the EEZ was implemented in 1977 (Rogers 2003b). Since 1977, landings of rockfish were high until management restrictions were implemented in 2000. Longline catches of rougheye rockfish are present from the turn of the century and continue in recent years, targeting sablefish and halibut.

A long-term directed fishery has not occurred for rougheye rockfish and historical discarding practices are not well known. Rougheye rockfish inhabit deeper water as adults, which were fished less often historically.

Throughout the 1980s and 1990s exploitation rates (1-SPR) were mostly above target levels (Figure 34). Recent exploitation rates on rougheye rockfish were predicted to be near target levels.

While stock-specific OFLs/ABCs were not historically set for rougheye rockfish specifically, the reauthorized Magnuson-Stevens Act of 2006 and FMP Amendment 23 required OFLs for all species in a management plan, including those managed in stock complexes. The first OFL contributions were calculated using DB-SRA and provided in 2011. The 2015 and beyond OFLs are projected from the 2013 assessment. Recent catches since 2002 have been above the new 2015 OFL since 2008 (Figure 35).

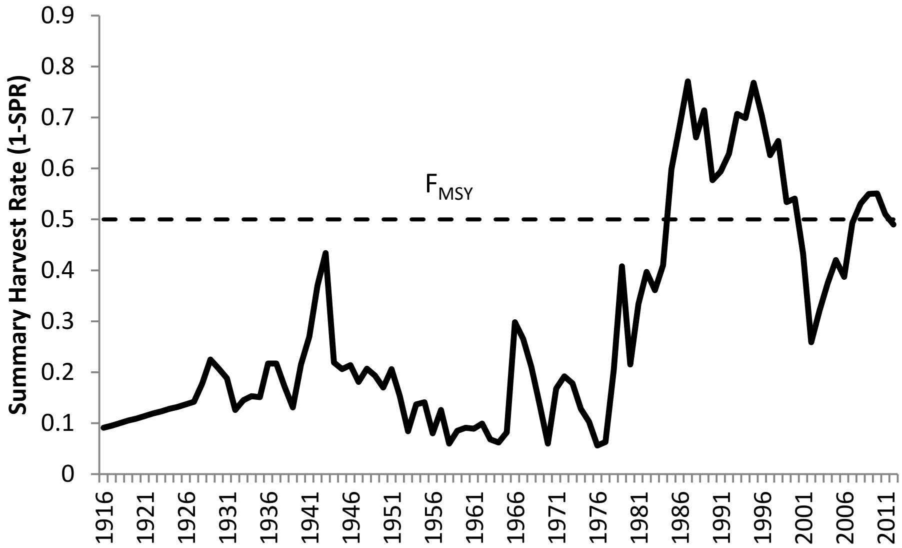

Figure 34. Time-series of estimated summary harvest rate for the west coast stocks of rougheye and blackspotted rockfish, 1916-2012. The dotted line is the harvest rate at the overfishing F_{MSY} proxy.

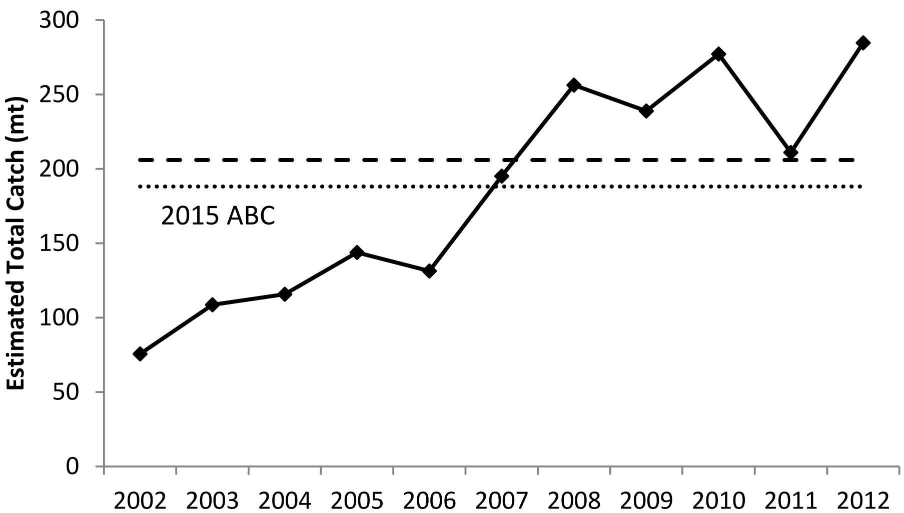

Figure 35. Estimated coastwide total annual catch of rougheye and blackspotted rockfish in 2002-2012 relative to the proposed 2015 OFLs and 2015 ABCs (summed north and south of 40º10' N lat. to compare to coastwide catches).

Sharpchin Rockfish

Distribution and Life History

Sharpchin rockfish (*Sebastes zacentrus*) range from the western Aleutian Islands (Attu Is.) to Southern California, though the core range is northern California to the Gulf of Alaska in waters between 100 m and 300 m (Love, *et al.* 2002). There is no indication of population structure in sharpchin rockfish. Sharpchin rockfish is a smaller-sized rockfish that inhabits waters up to 500 m, typically over muddy-rock habitats.

Mitochondrial DNA analyses indicate sharpchins are related mostly to harlequin, Puget Sound, and pygmy rockfishes (Love, *et al.* 2002).

Sharpchin rockfishes live to at least 58 years (Love, *et al.* 2002). Females attain a larger size than males with a reported maximum size of 45 cm (Love, *et al.* 2002). Off Oregon and Washington, the size at 50% maturity for females is 22cm with all females being mature at 30 cm. The size at 50% maturity is larger for samples farther north with 25 cm and 28 cm reported off British Columbia and the Gulf of Alaska, respectively. Larval releases occur from March to June off California and Oregon and during July off British Columbia.

Sharpchin eat a variety of prey including krill, shrimps, gammarid amphipods, copepods, and small fishes.

Stock Status and Management History

Sharpchin rockfish are managed in the northern and southern Slope Rockfish complexes.

A new data-moderate assessment of sharpchin rockfish was conducted in 2013, which indicated the stock was healthy with a depletion of 89% at the start of 2013 (Cope, *et al.* 2014). The SSC recommended the 2013 assessment be used for setting harvest specifications and upgraded the stock from a category 3 to a category 2 stock. The 2015 and 2016 OFLs are 382 and 372 mt, respectively. The coastwide OFLs were apportioned 80% to the north of 40º10' N lat. and 20% to the south to determine the OFL contributions to the Slope Rockfish complexes based on swept area biomass estimates from the triennial survey.

Stock Productivity

A high steepness of 0.95 was estimated in the 2013 sharpchin rockfish assessment, which is particularly high for a rockfish.

Sharpchin have a relatively low productivity (P = 1.36) and a relatively high vulnerability (V = 2.05) to overfishing based on the PSA scores derived prior to the 2013 assessment (Table 2).

Fishing Mortality

Sharpchin are not a major commercial target, though they are taken in large numbers and commonly seen in trawls that target Pacific ocean perch. They are taken most commonly of Oregon and Washington with POP, darkblotched, splitnose, and yellowmouth rockfish. While they are common in west coast bottom trawl catches, their smaller size makes them less valuable than the larger rockfish species. They are rarely taken in recreational fisheries.

1.1.5.4 Other Flatfish

The Other Flatfish complex contains most of the flatfish species managed in the Groundfish FMP (with the exception of arrowtooth flounder, Dover sole, English sole, petrale sole, and starry founder). These species include butter sole (*Isopsetta isolepis*), curlfin sole (*Pleuronichthys decurrens*), flathead sole (*Hippoglossoides elassodon*), Pacific sanddab (*Citharichthys sordidus*), rex sole (*Glyptocephalus zachirus*), rock sole (*Lepidopsetta bilineata*), and sand sole (*Psettichthys melanostictus*).

Pacific Sanddabs

Distribution and Life History

Pacific sanddab (*Citharichthys sordidus*) is a left-eyed flounder of the family Paralichthyidae and is widely distributed along the Pacific west coast from the Bering Sea to Cabo San Lucas, Baja California (Arora 1951; Hart 1988; Kramer and O'Connell 1995; Love, *et al.* 2005; Miller and Lea 1972; Rackowski and Pikitch 1989). Early studies reported that the species is the most abundant in the north-central portion of California from Eureka to San Francisco, but were also fairly common in southern California (Rackowski and Pikitch 1989). Early studies also reported that the species is usually found at depths between 18m and 275m and most commonly found at depths between 35m and 95m (Arora 1951; Demory 1971; Hart 1988; Miller and Lea 1972; Roedel 1953). On Oregon's continental shelf, Pacific sanddab is the most abundant small flatfish on sandy-bottom in the depths between 74 and 102 m (Pearcy 1978). Young Pacific sanddab (ages 0 and 1) are also found to be concentrated in the same depth range (Donohoe 2000). Pacific sanddab was also found to be relatively more abundant in shallow waters at higher latitudes (Chamberlain 1979).

Pacific sanddab are generally not considered a primary target for commercial fisheries along the U.S. west coast, but they are nevertheless highly prized by the commercial and recreational fisheries for their excellent edibility (CDFG 2001), and have long been an important component of the nearshore flatfish fishery, commanding a high price in fresh fish markets (Arora 1951). Commercial catches of Pacific sanddab were mostly from bottom trawl fisheries, and there is a long history of catches. Recreational catches of Pacific sanddab are from the hook and line fishery and most of this catch is from southern California waters. Some recreational anglers target Pacific sanddab in southern California, mostly from small boats and CPFVs (CDFG 2001).

Pacific sanddabs can growth to 35cm in length. They are sexually dimorphic, with females attaining larger sizes than males. Analysis of growth rates for both sexes between the southern and northern areas (divided at the California-Oregon border at 42º N lat.) showed no significant difference in growth rates for both sexes between the two areas.

There are no genetic or tagging studies informing stock structure of Pacific sanddab along the U.S. Pacific coast. Bottom trawl surveys in recent years (both NWFSC and triennial surveys) showed that Pacific sanddab are commonly caught along the coastal areas of all U.S. waters.

Pacific sanddabs play an important role in the coastal ecosystems in the U.S. waters, particularly because they are a relatively abundant species and are important prey items to a wide range of marine predators, including piscivorous fishes, sea mammals, and sea birds (Field, *et al.* 2006; Levin, *et al.* 2006).

Stock Status and Management History

Pacific sanddabs have been under federal management since the implementation of the groundfish FMP in 1982 and managed within the Other Flatfish complex of unassessed flatfish species. The management performance in recent years for Pacific sanddab has been good; the average 2005-2012 total annual catch has been about 23% of the stock's ACL/OY contribution to the Other Flatfish complex.

A coastwide assessment of Pacific sanddab was done in 2013 indicating the stock was at 95.5% of its unfished biomass (He, *et al.* 2013). The SSC recommended in 2013 that this assessment not be used for deciding harvest specifications since the scale of the stock's biomass could not be adequately estimated. However, the status estimate was precise enough to conclude the stock was well above the B_{MSY} proxy of $B_{25\%}$. The SSC recommended the stock continue to be categorized as a category 3 stock given the OFL estimate from the assessment depends on the biomass estimate, which was not estimated with adequate precision. The OFL estimate is therefore based on the DBSRA method used since 2011. The 2015 and 2016 OFL contribution of Pacific sanddab to the Other Flatfish complex is 4,801 mt.

Stock Productivity

A steepness prior of 0.8 was used in the 2013 assessment. Annual recruitment deviations were estimated between 1966 and 2011. Annual recruitment deviations were treated in a log-normal distribution with σ_R fixed at 0.45. Low recruitments occurred from the early 2000s to the mid-2000s. Recruitments in recent years have been at or above the long term average, with a strong recruitment in 2010.

The PSA productivity score of 2.4 indicates a very high relative productivity of Pacific sanddabs. This leads to a very low vulnerability (V = 1.25) of potential overfishing for the stock.

Fishing Mortality

There is a long history of commercial catches on Pacific sanddab (Barss 1976). Sette and Fiedler (1928) reported that landings of flatfish in California waters were first reported in 1892. The first available landings of Pacific sanddab in Oregon waters were in 1942 (Karnowski, *et al.* 2012). There were also commercial catches for mink foods in both California and Oregon waters in the 1950s and 1960s (Best 1959; Best 1961; Nitsos and Reed 1965). Reported total catches of Pacific sanddab were high in the late 1920s. And there was an increasing trend from the 1960s and reached the highest catch level in the late 1990s. Discards of Pacific sanddab in commercial trawl fisheries were high, primarily due to its small size (Sampson 2002). Catches of the species in recent years were in the range of 200 mt and 400 mt, well below the OFL contribution of the stock to the Other Flatfish complex of 4,801 mt.

1.1.5.5 Other Fish

The Other Fish stock complex contains all the unassessed groundfish FMP species that are neither rockfish (family *Scorpaenidae*) nor flatfish, except for spiny dogfish which was newly assessed in 2011. These species include big skate (*Raja binoculata*), California skate (*Raja inornata*), leopard shark (*Triakis semifasciata*), soupfin shark (*Galeorhinus zyopterus*), spiny dogfish (*Squalus acanthias*), finescale codling (*Antimora microlepis*), Pacific grenadier (*Coryphaenoides acrolepis*), ratfish

(*Hydrolagus colliei*), cabezon (*Scorpaenichthys marmoratus*) (off Washington), and kelp greenling (*Hexagrammos decagrammus*).

A new assessment of spiny dogfish was done in 2011 indicating a healthy status with a spawning biomass depletion of 63% of its unfished biomass in 2011 (Gertseva and Taylor 2011). The spiny dogfish contribution to the complex 2013 and 2014 OFLs were projected from the new assessment using the proxy $F_{45\%}$ F_{MSY} harvest rate. The SSC categorized the stock as a category 2 stock since recruitments were not estimated.

The Other Fish complex is currently an aggregation of species with different life history characteristics and depth distributions. The historical catch of many of the component stocks is poorly understood with some stocks missing any record of landings on the west coast. The SSC recommended in 2012 this complex be re-evaluated for the next management cycle and to give consideration to adding new species related to the component species of the complex into the FMP and re-grouping species with similar vulnerabilities, ecological interactions, and distributions.

The Council proposes reconfiguring the Other Fish complex for 2015 and beyond to be comprised only of kelp greenling stocks coastwide, the Washington stock of cabezon, and leopard shark. The other species currently managed in the Other Fish complex are proposed to be designated as Ecosystem Component species.

1.1.6 Ecosystem Component Species

1.2 The Groundfish Harvest Specification Framework and Harvest Specifications for Fisheries in 2015 and Beyond

West coast groundfish stocks are managed under a harvest specification framework that considers scientific and management uncertainties. The first specification decided is the overfishing limit (OFL), which is the maximum sustainable yield (MSY) estimated for the stock and the legal harvest limit beyond which constitutes overfishing. The OFL is determined either by applying the harvest rate estimated to result in a biomass capable of sustaining MSY (i.e., F_{MSY}) recommended by the Council's Scientific and Statistical Committee (SSC) to an estimate of exploitable biomass in the case of assessed stocks or through an approved data-poor method (e.g., depletion-corrected average catch (DCAC) or depletion-based stock reduction analysis (DBSRA)) in the case of unassessed stocks. Regardless of the method or data informing the calculation of an OFL, there is scientific uncertainty in the estimation of an OFL. The Pacific Coast Groundfish Fishery Management Plan (FMP) mandates a precautionary buffer to address this uncertainty by prescribing an acceptable biological catch (ABC) harvest level that is less than the OFL. A further reduction from the ABC can be specified when setting an annual catch limit (ACL) that accounts for management uncertainty, socioeconomic considerations, ecological considerations, conservation objectives, and/or other considerations the Council and NMFS wish to address. Since the ACL can be set equal to the ABC, the ABC is the highest harvest level that can be considered for west coast groundfish stocks.

The following sections describe in detail the science informing 2015 and 2016 harvest specification decisions. Table 8 summarizes the 2014, 2015, and 2016 harvest specifications for west coast groundfish stocks.

Table 8. Status quo 2014 harvest specifications and final preferred overfishing limits (OFLs in mt), acceptable biological catches (ABCs in mt), annual catch limits (ACLs in mt), and ecosystem component species designations for west coast groundfish stocks and stock complexes in 2015 and 2016 (stocks with new assessments in bold).

a/ 2015 and 2016 harvest specifications assume the status quo stock complex structure. See "Slope RF" worksheet for stock complex alternatives.

b/ No OFL or ABC contribution for these stocks given the lack of an approved method.

c/ No harvest specifications adopted since these species are not currently managed in the FMP.

1.2.1 Overfishing Limits

The OFL is the MSY harvest level associated with the current stock abundance and is the estimated or proxy MSY harvest level, which is the harvest threshold above which overfishing occurs. The methods for determining OFL are based on the best available science and the recommendation of the SSC; therefore, alternatives are not developed for this reference point.

Amendment 23, which was adopted in December 2010 and implemented in 2011, revised the descriptions of species categories used in the development of harvest specifications. The first category (category 1) includes those species with relatively data-rich quantitative stock assessments that are developed on the basis of catch-at-age, catch-at-length, or other data. Recruitments are estimated for category 1 stocks. OFLs and overfished/rebuilding thresholds can generally be calculated for these species. The second category (category 2) includes species for which some biological indicators are available yet data informing an assessment are limited. Category 2 assessments include a new class of data-moderate assessments where catch data and one or more indices of abundance inform the status and estimated biomass of the stock, but age and length compositional data are excluded. This type of assessment allows for a more expeditious assessment review than the category 1 benchmark assessments, which require a rigorous review process[8], thus enabling more stocks to be assessed in an assessment cycle. Two data-moderate assessment models were approved for the 2013 assessment cycle (which informs management decision-making for 2015 and beyond): extended depletion-based stock reduction analysis (XDBSRA) and extended simple stock synthesis (exSSS). The third category (category 3) includes minor species which are caught and where the only available information is catch-based data. When setting the 2015 and 2016 OFLs for category 1 or 2 species, the F_{MSY} harvest rate or a proxy was applied to the estimated exploitable biomass. A policy of using a default harvest rate as a proxy for the fishing mortality rate that is expected to achieve MSY is also referred to as the F_{MSY} control rule or maximum fishing mortality threshold (MFMT) harvest rate. Catch-based methods are generally used to determine the OFL for category 3 species.

New stock assessments, stock assessment updates and rebuilding analyses recommended by the SSC as the "best available science" and suitable for use in setting biennial harvest specifications were approved by the Council for setting the 2015 and 2016 biennial harvest specifications. Eight full stock assessments, eight data-moderate stock assessments, and one stock assessment update were prepared to inform the 2015 and 2016 harvest specifications. Full stock assessments, those that consider the appropriateness of the assessment model and that revise the model as necessary, were prepared for the following stocks: aurora rockfish, cowcod south of 34º27' N lat., darkblotched rockfish, longspine thornyhead, petrale sole, Pacific sanddabs, rougheye/blackspotted rockfish (analyzed as a complex of two stocks), and shortspine thornyhead. These were the first west coast assessments for aurora rockfish, rougheye/blackspotted rockfish, and Pacific sanddabs. OFLs were estimated for seven of these eight stocks; the exception being Pacific sanddabs where the assessment was recommended to inform stock status but not estimates of current biomass or OFL. Eight stocks were assessed using the approved data-moderate models: brown rockfish, China rockfish, copper rockfish, English sole, rex sole, sharpchin rockfish, stripetail rockfish, and yellowtail rockfish north of 40º10' N lat. OFLs were estimated for seven of these eight stocks; the exception being stripetail rockfish where the assessment was recommended to inform stock status but not estimates of current biomass or OFL. A stock assessment update, which incorporates new data through existing models without changing the model, was prepared for bocaccio. For stocks that did not have new assessments or an update prepared, the Council considered OFLs projected in the most recent stock assessment or update or estimated using historical landings data.

[8] The review process for new benchmark assessments includes a Stock Assessment Review (STAR) panel review and a subsequent review by the Council's Scientific and Statistical Committee (SSC). Only those assessments that are endorsed by the SSC are considered for formal adoption in the Council process.

Two data-poor methods, depletion-corrected average catch (DCAC) and depletion-based stock reduction analysis (DBSRA), used to determine most of the category 3 OFLs since 2011 were recommended for use in determining 2015 and 2016 OFLs for unassessed stocks, where there was enough harvest data to use these methods. Average historical catch was used to determine OFLs for stocks where the historical catches were too sparse to use DCAC or DBSRA methods.

For 2015 and 2016, default harvest rates were used as a proxy for the fishing mortality rate that is expected to achieve the MSY (F_{MSY}). A proxy is used because there is insufficient information for most Pacific Coast groundfish stocks to establish a species-specific F_{MSY}. In 2015 and 2016, the following default harvest rate proxies, based on SSC recommendations, were used: $F_{30\%}$ for assessed flatfish, $F_{40\%}$ for Pacific whiting, $F_{50\%}$ for rockfish (including thornyheads), $F_{50\%}$ for spiny dogfish, and $F_{45\%}$ for other groundfish such as sablefish and lingcod. The FMP allows default harvest rate proxies to be modified as scientific knowledge improves for a particular species.

Table 9 compares the 2015 and 2016 OFLs with the 2014 OFL for stocks managed with stock-specific harvest specifications. The OFLs are specified for all the stocks and stock complexes actively managed in the fishery, as required by the FMP. The 2014 OFLs in Table 9 were projected from stock assessments done in 2011 or earlier. The 2015 and 2016 OFLs in Table 9 include the results of stock assessments done in 2013. The OFL contributions for the cowcod stock south of 40º10' N lat. are shown as area-specific OFL contributions because they were derived using different methodologies. The Conception area OFLs for cowcod were projected from the 2013 rebuilding analysis (Dick and MacCall 2013a) and the Monterey area OFLs were derived using DBSRA. Although the area-specific OFL contributions for cowcod are displayed in Table 9, the OFL is specified for the entire stock south of 40°10' N lat. and not for each area. The 2014 OFL and 2015 and 2016 OFL contributions of individual stocks within the six Rockfish complexes, the Other Flatfish complex, and the Other Fish complex are shown in italics in **Error! Reference source not found.**. The OFL contributions for the individual stocks were summed to derive the complex OFLs. **Error! Reference source not found.** assumes the status quo stock complex structure for the slope rockfish complexes. However, the Council is contemplating a restructuring of these complexes. The Council also recommended restructuring the status quo Other Fish complex by removing spiny dogfish and managing that stock with stock-specific harvest specifications (Table 9), designating the skates, grenadiers, soupfin shark, finescale codling, and ratfish stocks as Ecosystem Component species, and managing kelp greenling, the Washington stock of cabezon, and leopard shark in a reconfigured Other Fish complex.

The preferred 2015 and 2016 OFLs for west coast groundfish stocks and stock complexes used the same policies (e.g., F_{MSY} harvest rates and methodologies) used to determine the 2014 OFLs (i.e., No Action) with the following exceptions:

- The spiny dogfish F_{MSY} proxy harvest rate was changed from $F_{45\%}$ to $F_{50\%}$;
- Spiny dogfish is recommended to be removed from the Other Fish complex and managed with stock-specific harvest specifications;
- The skates, Pacific grenadier, finescale codling, soupfin shark, and ratfish stocks are removed from the Other Fish complex and designated as Ecosystem Component species;
- Those endemic skate and grenadier species not previously managed in the FMP are recommended to be added to the FMP and designated as Ecosystem Component species; and
- Kelp greenling, the Washington stock of cabezon, and leopard shark are recommended for management in a new Shallow Roundfish complex (there is also an alternative to manage these stocks individually with stock-specific harvest specifications).

Table 9. Specified 2014 OFLs (i.e., No Action alternative) (mt) and preferred 2015 and 2016 OFLs (mt) for west coast groundfish stocks stock complexes (overfished stocks in CAPS, stocks with new assessments in bold, substock contributions to a stock OFL in *italics*).

a/ Values for these specifications are the sum of known contributions of component stocks. The 2014 OFL is not comparable to the 2015 and 2016 OFLs since the Other Fish complex was restructured by designating most of the component species as Ecosystem Component species.

b/ No OFL contribution for these stocks given the lack of an approved method.

1.2.2 Acceptable Biological Catches

The 2014, 2015, and 2016 ABCs are annual catch specifications that are the stock or stock complex's OFL reduced by an amount associated with the scientific uncertainty in estimating the OFL. Under the FMP harvest specification framework, scientific advice that is relatively uncertain will result in ABCs that are relatively lower, all other things being equal (i.e., a precautionary reduction in catch will occur due purely to scientific uncertainty in estimating the OFL). The ABC is the catch level that ACLs may not exceed. As explained in more detail below, the SSC recommended a two-step approach referred to as the P* approach for determining ABCs. In the P* approach, the SSC determines the amount of scientific uncertainty associated with estimating the OFL in stock assessments, referred to as the sigma (σ) value. Since the OFL is estimated by applying the harvest rate estimated or assumed to produce MSY (i.e., F_{MSY}) to the exploitable biomass and since assumed proxy F_{MSY} harvest rates by taxa are currently used to estimate the OFL, the variance in estimating biomass is the metric used for determining sigma. The Council chooses its preferred level of risk of overfishing, which is designated as the overfishing probability[9] (P*) (see Section 1.2.1). The scientists then apply the P* value to the sigma value to determine the amount by which the OFL is reduced to establish the ABC. The SSC's recommendations for sigma and the reductions from OFL associated with different P* values are science-based recommendations; therefore, alternatives to these values are not analyzed.

The SSC assigned each species in the groundfish fishery to one of three categories based on the level of information available about the species. Table 10 shows the criteria used by the SSC to categorize stocks. The SSC's recommended sigma value for category 1 stocks is based on a statistical analysis of the variance within and among stock assessments. The meta-analysis used stock assessments from 17 data-rich stocks to determine the proxy sigma value for category 1 stocks. The general methodology used by the SSC subcommittees to assess among-assessment uncertainty was to compare previous stock assessments and stock assessment updates[10], and consider the logarithms of the ratios of the biomass estimates for each pair of assessments and their reciprocals using the last 20 years from an assessment. This provides a distribution of stock size differences in log-space and, if this variation is averaged over species, provides a general view of total biomass variation (represented as sigma - σ) that emerges among repeat assessments of stocks, while embracing a wide range of factors that affect variability in results. The SSC indicated that biomass is most likely the dominant source of uncertainty; however, it is anticipated that other factors will need to be considered in the future.

[9] The overfishing probability (P*) is the probability of overfishing a stock or stock complex (i.e., exceeding the specified OFL) based solely on the scientific uncertainty in estimating the OFL.

[10] Stock assessment updates were excluded from the meta-analysis unless they were the most recent assessment conducted (in which case the original full assessment upon which the update was based was excluded from the meta-analysis) because of constraints imposed by the Terms of Reference for groundfish stock assessments on how much update assessments could change from the last full assessment.

Table 10. Criteria used by the SSC to categorize stocks based on the quantity and quality of data informing the estimate of OFL. Stock categories are used in deciding 2015 and 2016 ABCs that accommodate the uncertainty in estimating OFLs.

Category	Sub-category	Criteria
Category 1 - Data rich stocks. OFL based on F_{MSY} or F_{MSY} proxy from model output. ABC based on P* buffer.		
1	a	Reliable compositional (age and/or size) data sufficient to resolve year-class strength and growth characteristics. Only fishery-dependent trend information available. Age/size structured assessment model.
1	b	As in 3a, but trend information also available from surveys. Age/size structured assessment model.
1	c	Age/size structured assessment model with reliable estimation of the stock-recruit relationship.
Category 2 - Data moderate. OFL derived from model output (or natural mortality).		
2	a	M*survey biomass assessment (as in Rogers 1996).
2	b	Historical catches, fishery-dependent trend information only. An aggregate population model is fit to the available information.
2	c	Historical catches, survey trend information, or at least one absolute abundance estimate. An aggregate population model is fit to the available information.
2	d	Full age-structured assessment, but results are substantially more uncertain than assessments used in the calculation of the P* buffer. The SSC will provide a rationale for each stock placed in this category. Reasons could include that assessment results are very sensitive to model and data assumptions, or that the assessment has not been updated for many years.
Category 3 - Data poor. OFL derived from data-poor methods using historical catch.		
3	a	No reliable catch history. No basis for establishing OFL.
3	b	Reliable catch estimates only for recent years. OFL is average catch during a period when stock is considered to be stable and close to B_{MSY} equilibrium on the basis of expert judgment.
3	c	Reliable aggregate catches during period of fishery development and approximate values for natural mortality. Default analytical approach DCAC.
3	d	Reliable annual historical catches and approximate values for natural mortality and age at 50% maturity. Default analytical approach DBSRA.

Based on this analysis, the SSC recommended using the biomass variance statistic of $\sigma = 0.36$ for category 1 stocks. In cases where the stock biomass estimated in the most recent assessment has a variance greater than the variance estimated for that stock's category, the assessment's estimated biomass variance is used instead. The stock biomass estimated in the 2011 widow rockfish assessment was judged to have a greater variance than the sigma of 0.36 used for other category 1 stocks. In this case, the SSC recommended using a sigma value of 0.41 for deciding the widow rockfish ABC. Likewise, the 2013 assessment for aurora rockfish also indicated a greater variance than the sigma of 0.36 used for other category 1 stocks. In that case, a sigma value of 0.39 was chosen for deciding the aurora rockfish ABC. Each P* is mapped to its corresponding buffer fraction. The Council then recommends an appropriate P* value. When the P* approach is used, the upper limit of P* allowed by the FMP is 0.45.

Since there is greater scientific uncertainty for category 2 and 3 stocks relative to category 1 stocks, the scientific uncertainty buffer is generally greater than that recommended for category 1 stocks. The SSC recommended sigma values for category 2 and 3 stocks of 0.72 and 1.44, respectively (i.e., two and four times the sigma for category 1 stocks). The specific values of 0.72 and 1.44 were recommended by the SSC and considered to be the best available scientific information; however, the values are not based on a formal analysis of assessment outcomes and could change substantially when the SSC reviews additional analyses in future management cycles.

Table 11 shows the relationship between the values for sigma and the buffer for a range of values for P*.

1.2.2.1 Considerations for Deciding the Overfishing Probability (P*) When Specifying an Acceptable Biological Catch

The overfishing probability metric (P*) is technically defined as the probability of overfishing a stock based on the scientific uncertainty in estimating the OFL. This definition has generated much debate in the Council's harvest specification decision-making process. One side of the debate maintains the literal definition of the overfishing probability. The counter argument is that P* is the Council's level of risk tolerance that the OFL will be exceeded. Both arguments have merit but the latter argument is more tractable in the Council process and is a more accurate representation of how the P* value is decided.

The one problem with the literal definition of P* is that not all assessments are alike. The SSC recognizes this and has recommended a proxy value of sigma (0.36) for category 1 stocks, which are stocks that have assessments with estimated recruitment deviations (i.e., the strength of individual year classes is estimated). However, the SSC acknowledges that the proxy sigma for category 1 stocks may not represent the relative uncertainty of all category 1 stocks. For this reason, sigma is estimated in new category 1 assessments. If the estimated sigma is greater than the proxy value of 0.36, then the estimated sigma is used rather than the proxy value. However, the true scientific uncertainty is not estimated well in this process. Assessments vary greatly in the amount of uncertainty that is characterized in the assessment model. It is common that one or more parameters are either estimated outside the model or assumed based on the assessment scientist's best judgment. In such cases, the uncertainty associated with that parameter is also not estimated nor characterized in any way within the assessment. For instance, the 2011 sablefish assessment (Stewart, *et al.* 2011) appears to estimate current biomass with significant uncertainty. However, within that assessment many of the key parameters that affect the estimated biomass such as growth and natural mortality are explicitly estimated within the model[11]. The confidence interval associated with the ending year biomass estimate appears quite large relative to other assessments since the uncertainties associated with estimated growth and natural mortality are included within the overall assessment uncertainty. This compares to many other assessments, such as splitnose rockfish in 2009 (Gertseva, *et al.* 2009) or longspine thornyhead in 2013 (Stephens and Taylor 2013) where many parameters are assumed and fixed (e.g., natural mortality and steepness) and the estimated biomass variance appears smaller. However, this is not necessarily the case; more of the true uncertainty in estimated biomass is characterized in the sablefish assessment.

The spectrum of assessment approaches vary between fully Bayesian models with most key parameters estimated (e.g., sablefish in 2011) to deterministic models with most parameters fixed (e.g., longspine thornyhead in 2013). Within the spectrum are parameter estimations using informed or diffuse priors. Given this variety of approaches and the degree to which uncertainty is characterized, it is hard to pursue a formulaic approach where the P* decision hinges on the scientific uncertainty associated with estimating the OFL. For the most part, the relative uncertainty in estimating the OFL is addressed with the SSC's sigma specification. The Council's P* decision is therefore most appropriately considered as a risk assessment given many sources of uncertainty regarding the true state of nature for a stock.

1.2.2.2 Preferred 2015 and 2016 Acceptable Biological Catches

The ABCs for actively-managed stock complexes were determined by summing ABC values of the component stocks. Table 12 and Table 13 depict the potential alternative 2015 and 2016 ABCs, respectively for stocks and stock complexes across a range of P* values from 0.25 to 0.45. The Council

[11] Stock-recruitment steepness (h), another parameter that affects the estimate of biomass, is fixed at an assumed 0.6 in the 2011 sablefish assessment.

selected a P* value of 0.45 for most category 1 stocks. With a P* value of 0.45, a sigma value of 0.36 corresponds with a reduction of 4.4 percent from the OFL when deriving the ABC. For sablefish, the thornyheads, and assessed flatfish stocks, the Council selected a P* value of 0.4. The preferred 2015 and 2016 ABCs used the same policies (i.e., stock categories, sigma and P* values) used to determine the 2014 No Action ABCs with the following exceptions:

- Aurora rockfish was changed from a category 3 to a category 1 stock based on the new benchmark stock assessment adopted in 2013 (Hamel, *et al.* 2013). Therefore, the sigma of 1.44 for category 3 stocks was used to determine the 2014 ABC and a stock-specific sigma of 0.39 estimated for aurora rockfish was used to determine the 2015 and 2016 ABCs. The same P* of 0.45 was used to determine 2014, 2015, and 2016 ABCs;
- Rougheye/blackspotted rockfish was changed from a category 3 (for rougheye alone) to a category 2 stock based on the new benchmark stock assessment adopted in 2013 (Hicks, *et al.* 2013). The SSC decided to designate the rougheye/blackspotted assemblage of stocks as category 2 since the assessment was for the complex of these two hard to distinguish stocks;
- English sole and yellowtail rockfish north of 40º10' N lat. were changed from category 1 to category 2 stocks based on their new data-moderate assessments;
- Brown rockfish, China rockfish, copper rockfish, rex sole, and sharpchin rockfish were changed from category 3 stocks to category 2 stocks based on new data-moderate assessments for these stocks in 2013; and
- Shortspine thornyhead was changed from a category 1 stock to a category 2 stock based on the lack of age data in the new benchmark assessment for this stock in 2013 (Taylor and Stephens 2013). The same P* value of 0.4 was used to determine the 2014, 2015, and 2016 ABCs.

Table 11. Relationship between P* and the percent reduction of the OFL for deciding the 2015 and 2016 ABCs for category 1, aurora rockfish, widow rockfish, category 2, and category 3 stocks based on σ values of 0.36, 0.39, 0.41, 0.72, and 1.44, respectively.

P*	Assessment Uncertainty (σ)

a/ No ABC contribution for these stocks given the lack of an approved method for estimating the OFL.

1.2.3 Annual Catch Limits

Annual catch limits (ACLs) are specified for each stock and stock complex that is "in the fishery" as specified under the FMP framework. An ACL is a harvest specification set equal to the ABC or below the ABC in consideration of conservation objectives, management uncertainty, socioeconomic considerations, ecological considerations, and other factors (e.g. rebuilding considerations) needed to meet management objectives. Sector-specific ACLs may be specified in cases where a sector has a formal, long-term allocation of the harvestable surplus of a stock or stock complex. The ACL counts all sources of fishing-related mortality including landed catch, discard mortalities, research catches, and set-asides for exempted fishing permits (EFPs).

Under the FMP, the biomass level that produces MSY (B_{MSY}) is defined as the precautionary threshold. When the biomass for an assessed category 1 or 2 stock falls below the precautionary threshold, the harvest rate will be reduced to help the stock return to the B_{MSY} level, which is the management target for groundfish stocks. If a stock biomass is larger than B_{MSY}, the ACL may be set equal to or less than ABC. Because B_{MSY} is a long-term average, the true biomass could be below B_{MSY} in some years and above B_{MSY} in other years. Even in the absence of overfishing, biomass may decline to levels below B_{MSY} due to natural fluctuations in recruitment. The minimum stock size threshold (MSST) is the biomass threshold for declaring a stock overfished. When spawning stock biomass falls below the MSST, a rebuilding plan must be developed that determines the strategy for rebuilding the stock in the shortest time possible while considering impacts to fishing-dependent communities and other factors. When spawning stock biomass is below B_{MSY} yet above the MSST, the stock is considered to be in the precautionary zone. The current proxy B_{MSY} and MSST reference points for west coast groundfish stocks are as follows:

- Assessed flatfish stocks: B_{MSY} = 25 percent of initial biomass or $B_{25\%}$; MSST = 12.5 percent of initial biomass or $B_{12.5\%}$ (PFMC and NMFS 2011); and
- All other assessed groundfish stocks: B_{MSY} = 40 percent of initial biomass or $B_{40\%}$; MSST = 25 percent of initial biomass or $B_{25\%}$.

These reference points are only used to manage assessed stocks since they require estimates of spawning stock biomass.

West coast groundfish stocks are managed with harvest control rules that calculate ACLs below the ABCs when spawning biomass is estimated to be in the precautionary zone. These harvest control rules are designed to prevent a stock from becoming overfished. The FMP defines the 40-10 harvest control rule for stocks with a B_{MSY} proxy of $B_{40\%}$ that are in the precautionary zone. The analogous harvest control rule for assessed flatfish stocks is the 25-5 harvest control rule. Both ACL harvest control rules are applied after the ABC deduction is made. The further the stock biomass is below the precautionary threshold, the greater the reduction in ACL relative to the ABC, until at $B_{10\%}$ for a stock with a B_{MSY} proxy of $B_{40\%}$ or $B_{5\%}$ for a stock with a B_{MSY} proxy of $B_{25\%,}$ the ACL would be set at zero[12] (Figure 36). These harvest policies foster a quicker return to the B_{MSY} level and serve as an interim rebuilding policy for stocks that are below the MSST. The Council may recommend setting the ACL higher than what the default ACL harvest control rule specifies as long as the ACL does not exceed the ABC, complies with the requirements of the MSA, and is consistent with the FMP and National Standard Guidelines. Additional precautionary adjustments may be made to an ACL if necessary to address management

[12] The lower $B_{10\%}$ and $B_{5\%}$ thresholds in the precautionary ACL harvest control rules are used to establish the slope of the ACL curve in Figure 36. These precautionary ACL control rules only apply for stocks in the precautionary zone ($B_{MSY} > B_{CURRENT} >$ MSST). A rebuilding plan governs the ACL harvest control rule for any stock that falls below the MSST and is designated as overfished.

uncertainty, conservation concerns, socioeconomic concerns, ecological considerations, and the other factors that are considered when setting ACLs.

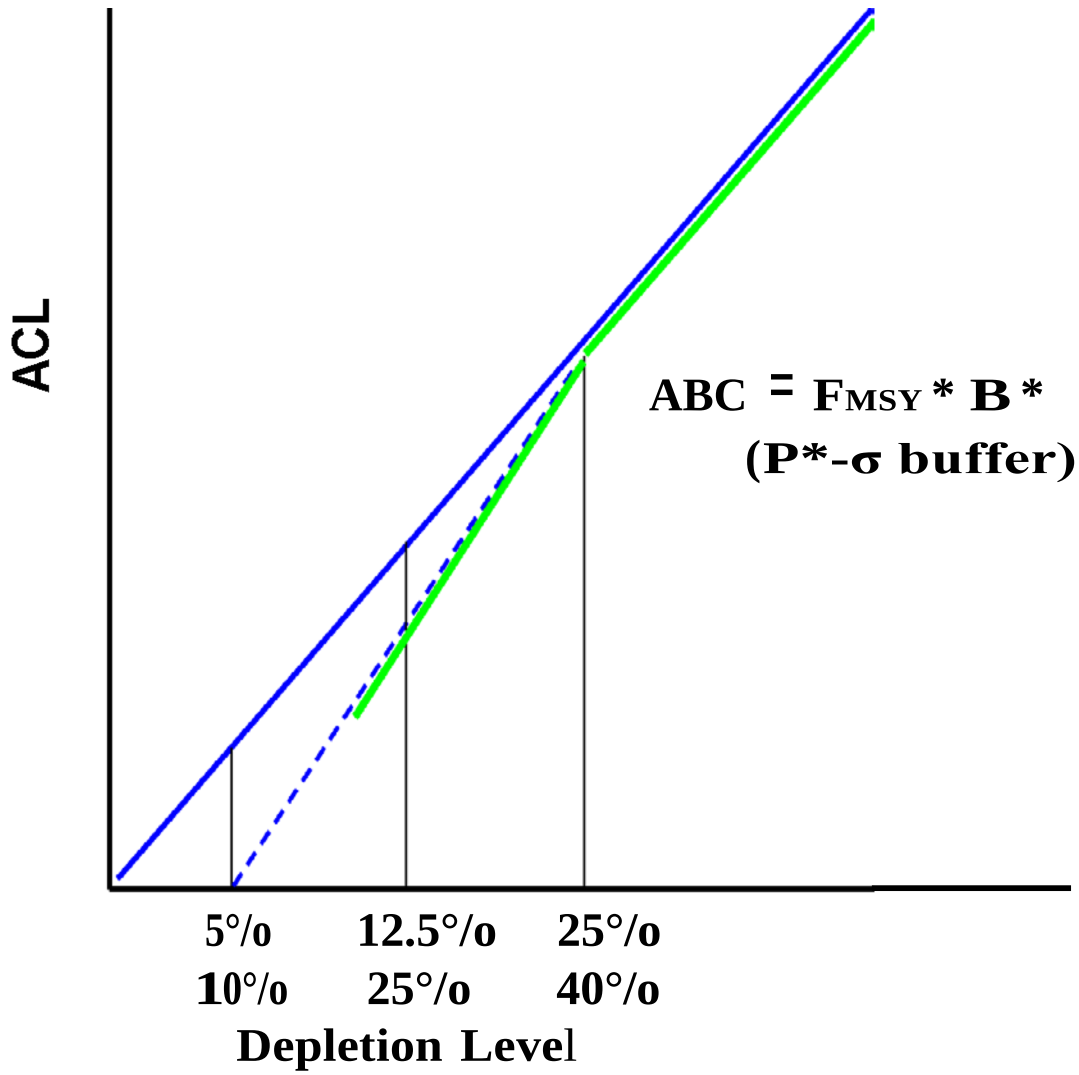

Figure 36. Conceptual diagram of the 25-5 and 40-10 ACL harvest control rules used to manage assessed west coast flatfish and other groundfish species, respectively, that are in the precautionary zone.

The ACL serves as the basis for invoking accountability measures (AMs), which are management measures or mechanisms used to address any management uncertainty that may result in exceeding an ACL. If ACLs are exceeded more often than 1 in 4 years, then AMs, such as catch monitoring and inseason adjustments to fisheries, need to improve or additional AMs may need to be implemented. Additional AMs may include setting an annual catch target (ACT), which is a specified level of harvest below the ACL. The use of ACTs may be especially important for a stock subject to highly uncertain inseason catch monitoring. A sector-specific ACT may serve as a harvest guideline (HG) for a sector or may be used strategically in a rebuilding plan to attempt to reduce mortality of an overfished stock more than the rebuilding plan limits prescribe.

The Council has the discretion to adjust the ACLs for uncertainty on a case-by-case basis. In cases where there is a high degree of uncertainty about the condition of the stock or stocks, the ACL may be reduced accordingly. Most category 3 species are managed in a stock complex (such as the minor rockfish complexes and the Other Flatfish complex) where harvest specifications are set for the complex in its entirety. For stock complexes, the ACL will be less than or equal to the sum of the individual component ABCs. The ACL may be adjusted below the sum of component ABCs as appropriate.

For most stocks and stock complexes, the Council elected to use the same general policies for deciding 2015 and 2016 ACLs as were used for deciding the 2014 ACLs (No Action) (Table 14). The No Action ACLs are the 2014 ACLs specified in Federal regulations.

Section 4.6.3 of the FMP states the Council's general policies on rebuilding overfished stocks. Section 4.6.3.1 of the FMP specifies the overall goals of rebuilding programs are to (1) achieve the population size and structure that will support the MSY within a specified time period that is as short as possible, taking into account the status and biology of the stock, the needs of fishing communities, and the interaction of the stock of fish within the marine ecosystem; (2) minimize, to the extent practicable, the adverse social and economic impacts associated with rebuilding, including adverse impacts on fishing communities; (3) fairly and equitably distribute both the conservation burdens (overfishing restrictions) and recovery benefits among commercial, recreational, and charter fishing sectors; (4) protect the quantity and quality of habitat necessary to support the stock at healthy levels in the future; and (5) promote widespread public awareness, understanding and support for the rebuilding program. These overall goals are derived from and consistent with the requirements of the MSA. The first goal embodies MSA National Standard 1 (NS1) and the requirements for rebuilding overfished stocks found at MSA section 304(e)(4)(A). The third goal is required by MSA section 304(e)(4)(B). The fourth and fifth goals represent additional policy preferences of the Council that recognize the importance of habitat protection to the rebuilding of some fish stocks and the desire for public outreach and education on the complexities—biological, economic, and social issues—involved with rebuilding overfished stocks. Overfished groundfish species are those with spawning biomasses that have dropped below the Council's MSST (i.e., 25 percent of initial spawning biomass or $B_{25\%}$ for all groundfish species other than flatfish where the MSST is $B_{12.5\%}$). The FMP requires these stocks to be rebuilt to a target biomass that supports MSY (i.e., B_{MSY} or $B_{40\%}$ for all groundfish species other than flatfish where the target is $B_{25\%}$).

Rebuilding plans are in place for six overfished rockfish species, as well as petrale sole, where assessments have indicated spawning biomass has declined to below the MSST. New full and updated assessments and rebuilding analyses were done in 2013 inform the 2015 and 2016 harvest specifications for many of the overfished species. New full assessments were conducted for cowcod, darkblotched rockfish, and petrale sole in 2013; however, a new rebuilding analysis was only prepared for cowcod. The results of the new assessments for darkblotched rockfish and petrale sole indicated those stocks would be rebuilt by 2015 and 2014, respectively. The SSC did not recommend new rebuilding analyses for these two stocks given their imminent rebuilding expectation. An update assessment for bocaccio was prepared in 2013. Like darkblotched, the stock is predicted to rebuild by 2015 and the SSC therefore recommended no new rebuilding analysis be prepared. Catch reports for canary rockfish, Pacific ocean perch, and yelloweye rockfish were prepared in 2013. These catch reports indicated total catches were within limits prescribed in these stocks' respective rebuilding plans.

Table 14. The status quo (No Action) 2014 and preferred 2015 and 2016 annual catch limits (ACLs in mt) for west coast groundfish stocks and stock complexes (stocks with new assessments in bold).

1.3 Historical Landings and Revenue in Groundfish Fisheries

The following tables were compiled using data downloaded in April 2013 from the PacFIN vdrfd table and the NorPAC 4900 table for at-sea Pacific whiting sectors. Groundfish fisheries are defined within the vdrfd table in the "dahl_sector" column. Nominal dollar values adjusted for inflation using Bureau of Economic Analysis Table 1.1.9 "Implicit Price Deflators for Gross Domestic Product, 1995=100" dated March 28, 2013.

List of Tables

Table Table 1a. Landings (shoreside commercial and tribal) by species group (mt), 1981-2012.

PROPOSED GROUNDFISH FMP AMENDMENT LANGUAGE FOR DEFAULT HARVEST CONTROL RULES AND FOR DESIGNATION OF ECOSYSTEM COMPONENT SPECIES UNDER AMENDMENT 24

This document presents proposed Groundfish FMP amendment language being considered as Amendment 24. The 2015-16 and Beyond Biennial Harvest Specifications EIS describes the three alternatives under consideration in addition to the alternative of No Action. Under No Action the FMP is not amended. Amendment language consistent with the objectives of these alternatives is presented below. Separate from the alternatives, designation of Ecosystem Component Species and a number of technical changes and updates to the FMP are proposed under Amendment 24.

- ~~Strikethrough~~ indicates text moved or deleted
- Underline indicates new text

Double underline indicates moved text at its new location

Alternative 1 – Default HCRs Use a P* Value of 0.45

Under this alternative the Groundfish FMP is amended to describe the harvest control rule (HCR) framework and establish new criteria for management measures that may be considered during the biennial process.

Default ACLs would be computed using the HCRs currently in place and used to compute ACLs for the previous biennial period except that, where applicable, a P* value of 0.45 would be used.

Amendment Language

5.1 General Overview of the Harvest Specifications and Management Process

The specifications and management process, in general terms, occurs as follows:

1. The Council will determine the MSY or MSY proxy and OFL for each major stock. Typically, the MSY proxy will be in terms of a fishing mortality rate ($F_{x\%}$,) and OFL will be the $F_{x\%}$ applied to the current biomass estimate. The MSY is the maximum long-term average yield expected from annual application of the MSY (or proxy) harvest policy under prevailing ecological and environmental conditions.
2. The Council and SSC will determine an appropriate scientific uncertainty buffer to set the ABC below the OFL. The ABC accommodates the uncertainty in estimating the OFL and may be determined using either a straight percentage reduction of the OFL as recommended by the SSC or by the P* approach.
3. Every species will either have its own designated ACL or be included in a multispecies ACL. Species which are included in a multispecies ACL may also have individual ACLs, have individual HGs, or be included in a HG for a subgroup of the multispecies ACL.
4. To determine the ACL for each stock, the Council will determine the best estimate of current abundance and its relation to its precautionary and overfished thresholds. If the abundance is above the precautionary threshold, the ACL will be equal to or less than the ABC. If abundance falls below the precautionary threshold, the ACL will be reduced according to the harvest control rule for that stock. If abundance falls below the overfished/rebuilding threshold, the ACL will be

set according to the interim rebuilding rule until the Council develops a formal rebuilding plan for that species.

5. For any stock or stock complex where the Secretary identifies that overfishing is occurring, the Council will take remedial action to end overfishing and prevent the stock or stock complex from falling below the minimum stock size threshold. For any stock the Secretary has declared overfished or approaching the overfished condition, or for any stock the Council determines is in need of rebuilding, the Council will implement such periodic management measures as are necessary to rebuild the stock by controlling harvest mortality, habitat impacts, or other effects of fishing activities that are subject to regulation under this biennial process. These management measures will be consistent with any approved rebuilding plan.
6. The Council may reserve and deduct a portion of the ACL of any stock to provide for compensation for vessels conducting scientific research authorized by NMFS. Prior to the research activities, the Council will authorize amounts to be made available to a research reserve. However, the deduction from the ACL will be made in the year after the "compensation fishing"; the amounts deducted from the ACL will reflect the actual catch during compensation fishing activities.
7. The Council will identify stocks which are likely to be fully harvested (i.e., the ACL or ACT/HG achieved) in the absence of specific management measures and for which allocation between LE and open access sectors of the fishery is appropriate.
8. The groundfish resource is fully utilized by U.S. fishing vessels and seafood processors. The Council may entertain applications for foreign or joint venture fishing or processing at any time, but fishing opportunities may be established only through amendment to this FMP. This section supersedes other provisions of this FMP relating to foreign and joint venture fishing.

Notwithstanding the above, the harvest controls from the previous biennium (referred to as default harvest control rules, or default HCRs) are applied to the best available scientific information to determine the numerical values of the harvest specifications for the next biennial period. The default HCR would establish the harvest specifications based on the F_{MSY} (or proxy value) used in the previous biennium applied to the best current estimate of stock biomass to determine the OFL (as in bullet #1). The ABC is determined by applying the uncertainty buffer (as in bullet #2) used in the previous biennium except that if the P* approach was used, a value of 0.45 is applied. The ACL is determined as described in bullet #4 using the appropriate method for current stock status, if known. Thus, if based on the best available science, it is determined that stock status has changed from healthy to the precautionary zone, the methods outlined in Section 4.6.1 would be applied. If a stock has recovered such that stock size is now above the MSY biomass target, the default harvest control sets the ACL equal to the ABC using a P* value of 0.45, if applicable. If the status is not known, the same method used in the previous cycle is used to compute the default HCR. In the case of a stock managed under a rebuilding plan, the default HCR is the one described in the current rebuilding plan (see Appendix F). The SSC will advise the Council on whether adequate progress toward ending overfishing and rebuilding the affected fish stock is being made.

For any stock (or other management units) the Council may take action to depart from the default harvest control rules described in the previous paragraph, after considering the harvest specifications or other relevant factors as long as such changes are consistent with the framework described in Chapter 4 of this FMP, the MSA, and other applicable law.

Current harvest control rules (and related harvest policies as applicable) will be listed in the SAFE document, which will be presented to the Council and the public (and in Appendix F for stocks managed under rebuilding plans).

6.2 General Procedures for Establishing and Adjusting Management Measures

…

C. Management Measures Rulemaking For Actions Developed Through the Three-Council-Meeting Biennial Specifications Process and Two *Federal Register* Rules

These include (1) management action developed through During the biennial specifications process the Council may propose: (21) management measures being to be classified as routine the first time these measures are used; or (32) adjustments to measures previously classified as routine, such as trip limits that vary by gear type, closed seasons or areas, and in the recreational fishery, bag limits, size limits, time/area closures, boat limits, hook limits, and dressing requirements the first time these measures are used. These also; or (3) new management measures, which are those management measures where the impacts have not been previously analyzed and/or have not been previously implemented in regulations. Examples of new measures that may be proposed during the biennial process include: changes to or imposition of gear regulations; imposition of landings limits, frequency limits, or limits that differ by gear type; closed areas or seasons used for the first time on any species or species group or gear type.

The Council will develop and analyze the proposed management actions over the span of at least two Council meetings (usually April and June) and provide the public advance notice and opportunity to comment on both the proposals and the analysis prior to and at the second Council meeting. If a management measure is designated as routine under this procedure, specific adjustments of that measure can subsequently be announced in the *Federal Register* by notice, as described in the previous paragraphs. The Secretary will publish a proposed rule in the *Federal Register* with an appropriate period for public comment followed by publication of a final rule in the *Federal Register*.

As described in Section 5.4, the three-Council-meeting biennial specifications process refers to two the following decision-making schedule: meetings.

1. The Council will develop proposed harvest specifications during the first meeting (usually November). They will finish drafting harvest specifications and develop the management measures during the second meeting (usually April).

2. The Council will develop and analyze the proposed management actions over the span of at least two Council meetings (usually April and June) and provide the public advance notice and opportunity to comment on both the proposals and the analysis prior to and at the second Council meeting.

3. Finally, at the third meeting, the Council will make final recommendations to the Secretary on the complete harvest specifications and management measures biennial management package (usually June). For the Council to have adequate information to identify proposed management measures for public comment at the first management measures meeting, the identification of issues and the development of proposals normally must begin at a prior Council meeting.

If a management measure is designated as routine under this procedure, specific adjustments of that measure can subsequently be announced in the *Federal Register* by notice, as described in the previous paragraphs. The Secretary will publish a proposed rule in the *Federal Register* with an appropriate period for public comment followed by publication of a final rule in the *Federal Register*.

D. Full Rulemaking For Actions Normally Requiring at Least Two Council Meetings and Two *Federal Register* Rules (Regulatory Amendment)

These include any proposed new management measures to be classified as routine, including those considered ~~that is~~ highly controversial, or any measure that directly allocates the resource. ~~These also include management measures that are intended to have permanent effect and are discretionary, and for which the impacts have not been previously analyzed.~~ These ~~Full~~ full rulemakings will normally use a two-Council-meeting process, although additional meetings may be required to fully develop the Council's recommendations on a full rulemaking issue. Regulatory measures to implement an FMP amendment will be developed through the full rulemaking process. The Secretary will publish a proposed rule in the *Federal Register* with an appropriate period for public comment followed by publication of a final rule in the *Federal Register*.

Alternative 2 – Default HCRs Use a P* Value of 0.25

Under this alternative the Groundfish FMP is amended to describe the HCR framework and establish new criteria for management measures that may be considered during the biennial process.

Default ACLs would be computed using the HCRs currently in place and used to compute ACLs for the previous biennial period except that, where applicable, a P* value of 0.25 would be used.

The same revisions to Section 6.2 (General Procedures for Establishing and Adjusting Management Measures) described above for Alternative 1 would be made under Alternative 2.

Amendment Language

5.1 General Overview of the Harvest Specifications and Management Process

The specifications and management process, in general terms, occurs as follows:

1. The Council will determine the MSY or MSY proxy and OFL for each major stock. Typically, the MSY proxy will be in terms of a fishing mortality rate ($F_{x\%}$,) and OFL will be the $F_{x\%}$ applied to the current biomass estimate. The MSY is the maximum long-term average yield expected from annual application of the MSY (or proxy) harvest policy under prevailing ecological and environmental conditions.
2. The Council and SSC will determine an appropriate scientific uncertainty buffer to set the ABC below the OFL. The ABC accommodates the uncertainty in estimating the OFL and may be determined using either a straight percentage reduction of the OFL as recommended by the SSC or by the P* approach.
3. Every species will either have its own designated ACL or be included in a multispecies ACL. Species which are included in a multispecies ACL may also have individual ACLs, have individual HGs, or be included in a HG for a subgroup of the multispecies ACL.
4. To determine the ACL for each stock, the Council will determine the best estimate of current abundance and its relation to its precautionary and overfished thresholds. If the abundance is above the precautionary threshold, the ACL will be equal to or less than the ABC. If abundance falls below the precautionary threshold, the ACL will be reduced according to the harvest control rule for that stock. If abundance falls below the overfished/rebuilding threshold, the ACL will be set according to the interim rebuilding rule until the Council develops a formal rebuilding plan for that species.
5. For any stock or stock complex where the Secretary identifies that overfishing is occurring, the Council will take remedial action to end overfishing and prevent the stock or stock complex from falling below the minimum stock size threshold. For any stock the Secretary has declared overfished or approaching the overfished condition, or for any stock the Council determines is in

need of rebuilding, the Council will implement such periodic management measures as are necessary to rebuild the stock by controlling harvest mortality, habitat impacts, or other effects of fishing activities that are subject to regulation under this biennial process. These management measures will be consistent with any approved rebuilding plan.

6. The Council may reserve and deduct a portion of the ACL of any stock to provide for compensation for vessels conducting scientific research authorized by NMFS. Prior to the research activities, the Council will authorize amounts to be made available to a research reserve. However, the deduction from the ACL will be made in the year after the "compensation fishing"; the amounts deducted from the ACL will reflect the actual catch during compensation fishing activities.
7. The Council will identify stocks which are likely to be fully harvested (i.e., the ACL or ACT/HG achieved) in the absence of specific management measures and for which allocation between LE and open access sectors of the fishery is appropriate.
8. The groundfish resource is fully utilized by U.S. fishing vessels and seafood processors. The Council may entertain applications for foreign or joint venture fishing or processing at any time, but fishing opportunities may be established only through amendment to this FMP. This section supersedes other provisions of this FMP relating to foreign and joint venture fishing.

Notwithstanding the above, the harvest controls from the previous biennium (referred to as default harvest control rules, or default HCRs) are applied to the best available scientific information to determine the numerical values of the harvest specifications for the next biennial period. The default HCR would establish the harvest specifications based on the F_{MSY} (or proxy value) used in the previous biennium applied to the best current estimate of stock biomass to determine the OFL (as in bullet #1). The ABC is determined by applying the uncertainty buffer (as in bullet #2) used in the previous biennium except that if the P* approach was used, a value of 0.25 is applied. The ACL is determined as described in bullet #4 using the appropriate method for current stock status, if known. Thus, if based on the best available science, it is determined that stock status has changed from healthy to the precautionary zone, the methods outlined in Section 4.6.1 would be applied. If a stock has recovered such that stock size is now above the MSY biomass target, the default harvest control sets the ACL equal to the ABC using a P* value of 0.25, if applicable. If the status is not known, the same method used in the previous cycle is used to compute the default HCR. In the case of a stock managed under a rebuilding plan, the default HCR is the one described in the current rebuilding plan (see Appendix F). The SSC will advise the Council on whether adequate progress toward ending overfishing and rebuilding the affected fish stock is being made.

For any stock (or other management units) the Council may take action to depart from the default harvest control rules described in the previous paragraph, after considering the harvest specifications or other relevant factors as long as such changes are consistent with the framework described in Chapter 4 of this FMP, the MSA, and other applicable law.

Current harvest control rules (and related harvest policies as applicable) will be listed in the SAFE document, which will be presented to the Council and the public (and Appendix F for stocks managed under rebuilding plans).

Alternative 3 – Use the HCRs in Place in the Previous Period as the Defaults

Section 5.1 of the FMP would be amended in the same way as under Alternative 1, except that P* values in place during the previous biennium would be substituted for the references to a P* value of 0.45 in the first paragraph

The same revisions to Section 6.2 (General Procedures for Establishing and Adjusting Management Measures) described above for Alternative 1 would be made under Alternative 3.

Amendment Language

5.1 General Overview of the Harvest Specifications and Management Process

The specifications and management process, in general terms, occurs as follows:

1. The Council will determine the MSY or MSY proxy and OFL for each major stock. Typically, the MSY proxy will be in terms of a fishing mortality rate ($F_{x\%}$,) and OFL will be the $F_{x\%}$ applied to the current biomass estimate. The MSY is the maximum long-term average yield expected from annual application of the MSY (or proxy) harvest policy under prevailing ecological and environmental conditions.
2. The Council and SSC will determine an appropriate scientific uncertainty buffer to set the ABC below the OFL. The ABC accommodates the uncertainty in estimating the OFL and may be determined using either a straight percentage reduction of the OFL as recommended by the SSC or by the P* approach.
3. Every species will either have its own designated ACL or be included in a multispecies ACL. Species which are included in a multispecies ACL may also have individual ACLs, have individual HGs, or be included in a HG for a subgroup of the multispecies ACL.
4. To determine the ACL for each stock, the Council will determine the best estimate of current abundance and its relation to its precautionary and overfished thresholds. If the abundance is above the precautionary threshold, the ACL will be equal to or less than the ABC. If abundance falls below the precautionary threshold, the ACL will be reduced according to the harvest control rule for that stock. If abundance falls below the overfished/rebuilding threshold, the ACL will be set according to the interim rebuilding rule until the Council develops a formal rebuilding plan for that species.
5. For any stock or stock complex where the Secretary identifies that overfishing is occurring, the Council will take remedial action to end overfishing and prevent the stock or stock complex from falling below the minimum stock size threshold. For any stock the Secretary has declared overfished or approaching the overfished condition, or for any stock the Council determines is in need of rebuilding, the Council will implement such periodic management measures as are necessary to rebuild the stock by controlling harvest mortality, habitat impacts, or other effects of fishing activities that are subject to regulation under this biennial process. These management measures will be consistent with any approved rebuilding plan.
6. The Council may reserve and deduct a portion of the ACL of any stock to provide for compensation for vessels conducting scientific research authorized by NMFS. Prior to the research activities, the Council will authorize amounts to be made available to a research reserve. However, the deduction from the ACL will be made in the year after the “compensation fishing”; the amounts deducted from the ACL will reflect the actual catch during compensation fishing activities.
7. The Council will identify stocks which are likely to be fully harvested (i.e., the ACL or ACT/HG achieved) in the absence of specific management measures and for which allocation between LE and open access sectors of the fishery is appropriate.
8. The groundfish resource is fully utilized by U.S. fishing vessels and seafood processors. The Council may entertain applications for foreign or joint venture fishing or processing at any time, but fishing opportunities may be established only through amendment to this FMP. This section supersedes other provisions of this FMP relating to foreign and joint venture fishing.

Notwithstanding the above, the harvest controls from the previous biennium (referred to as default harvest control rules, or default HCRs) are applied to the best available scientific information to determine the numerical values of the harvest specifications for the next biennial period. The default HCR would establish the harvest specifications based on the F_{MSY} (or proxy value) used in the previous biennium applied to the best current estimate of stock biomass to determine the OFL (as in bullet #1). The ABC is determined by applying the uncertainty buffer (as in bullet #2) used in the previous biennium. The ACL is determined as described in bullet #4 using the appropriate method for current stock status, if known. Thus, if based on the best available science, it is determined that stock status has changed from healthy to the precautionary zone, the methods outlined in Section 4.6.1 would be applied. If a stock has recovered such that stock size is now above the MSY biomass target, the default harvest control sets the ACL equal to the ABC using the P* value used in the previous biennium, if applicable. If the status is not known, the same method used in the previous cycle is used to compute the default HCR. In the case of a stock managed under a rebuilding plan, the default HCR is the one described in the current rebuilding plan (see Appendix F). The SSC will advise the Council on whether adequate progress toward ending overfishing and rebuilding the affected fish stock is being made.

For any stock (or other management units) the Council may take action to depart from the default harvest control rules described in the previous paragraph, after considering the harvest specifications or other relevant factors as long as such changes are consistent with the framework described in Chapter 4 of this FMP, the MSA, and other applicable law.

Current harvest control rules (and related harvest policies as applicable) will be listed in the SAFE document, which will be presented to the Council and the public (and in Appendix F for stocks managed under rebuilding plans).

Other Technical Changes and Updates Proposed to be Included in Amendment 24

1.1 History of the FMP

…

Amendment 24 was approved in [insert date] to describe the use of default harvest control rules in the biennial harvest specifications process and to clarify the descriptions of new and routine management measures that may be implemented during the biennial process. Amendment 24 also designated some species as Ecosystem Component Species and incorporated a variety of technical changes to the FMP.

2.2 Operational Definition of Terms

…

Ecosystem Component Species are FMP species that are not actively managed in the fishery (i.e., no harvest specifications are specified for these species). Ecosystem component species are not targeted, are not generally retained for sale or personal use, are not subject to overfishing, and are not overfished or approaching an overfished condition (see section 4.4.4 for more detail).

$F_{SPR\ x\%}$ is the fishing mortality rate that will produce a given spawning potential ratio. The SPR is the average fecundity of a recruit over its lifetime when the stock is fished divided by the average fecundity of a recruit over its lifetime when the stock is unfished. The SPR is based on the principle that a certain biomass of fish has to survive in order to spawn and replenish the stock at a sustainable level.

Set-aside is the amount of yield of an actively managed stock or stock complex that is deducted from an ACL or sector allocation. A set-aside deducted from an ACL is designed to accommodate catch in Tribal fisheries, research fisheries, exempted fishing permit activities, and bycatch in non-groundfish fisheries. A set-aside deducted from a sector allocation is designed to accommodate catch for a portion of the sector where within-sector allocations are not specified (e.g., set-asides for the at-sea whiting sectors for many stocks are deducted from formal trawl allocations to accommodate expected bycatch).

3.1 Species Managed by this Fishery Management Plan

Table 3-1 in the FMP is proposed to be modified to remove those species designated as Ecosystem Component species and to include more of the actively managed rockfish explicitly in the table (e.g., blackspotted rockfish). Inclusion of text (see below) and a new Table 3-2 is added to list the Ecosystem Component species, including the endemic skates in the family *Arhynchobatidae* and the endemic grenadiers in the family *Macrouridae* as FMP species.

…

Table 3-1 is the listing of species actively managed under this FMP.

Table 3-1. Common and scientific names of species ~~included~~ actively managed in this FMP.

All other skates	Endemic species in the family *Arhynchobatidae*
Pacific grenadier	*Coryphaenoides acrolepis*
Giant grenadier	*Albatrossia pectoralis*
All other grenadiers	Endemic species in the family *Macrouridae*
Finescale codling (aka Pacific flatnose)	*Antimora microlepis*
Ratfish	*Hydrolagus colliei*
Soupfin shark	*Galeorhinus zyopterus*

4.3 Determination of MSY, or MSY Proxy and B_{MSY}

As a description of the current proxy F_{MSY} harvest rates by taxa used to calculate OFLs, the following language responsive to the SSC's and Council's decision to change the proxy F_{MSY} harvest rate for elasmobranchs is recommended in the second paragraph in section 4.3:

…

The problem with an F_{MSY} control rule is that it is tightly linked to an assumed level of density-dependence in recruitment, and there is insufficient information to determine the level of density-dependence in recruitment for many west coast groundfish stocks. Therefore, the use of approximations or proxies is necessary. Absent a more accurate determination of F_{MSY}, the Council will apply default MSY proxies. The 2015 ~~current (2011)~~ default F_{MSY} proxies are: $F_{30\%}$ for flatfish, $F_{40\%}$ for whiting, $F_{50\%}$ for rockfish (including thornyheads), $F_{50\%}$ for elasmobranchs, and $F_{45\%}$ for all species such as sablefish and lingcod. ~~However,~~ The default F_{MSY} proxies ~~values~~ ($F_{30\%}$, $F_{40\%}$, $F_{45\%}$, and $F_{50\%}$) are science-based values that are ~~provided here as examples only and are~~ expected to be modified from time to time as scientific knowledge improves. The default F_{MSY} proxies in use for the current biennial harvest specifications period can be found in the Groundfish Stock Assessment and Fishery Evaluation (SAFE) document. If available information is sufficient, values of F_{MSY}, B_{MSY}, and more appropriate harvest control rules may be developed for any species or species group.

Agenda Item F.7.a
Supplemental Attachment 9
June 2014

ECONOMIC IMPACTS UNDER THE HARVEST GUIDELINE OPTIONS FOR MINOR NEARSHORE ROCKFISH NORTH OF 40^0 10' NORTH LATITUDE

Economic impacts under the harvest guideline (HG) options for the minor nearshore rockfish complex north of 40^0 10´ North latitude were analyzed for the affected commercial and recreational fisheries. Under certain annual catch limit (ACL) alternatives, the GMT projects that the HG options would impact landings by portions of the Nearshore Open Access (OA) commercial fishery sector operating in Oregon and Northern California waters; and also on effort levels in recreational fisheries in Northern California, Oregon and, Washington.

Description of Harvest Guideline Options for Minor Nearshore Rockfish

- Option 1 ("No Action"): Continue to manage the Nearshore Rockfish complex, holding impacts to the complex-level ACL in each region.
- Option 2: Manage the Nearshore Rockfish complex according to state-specific harvest guidelines stratified at 40°10′ N. latitude reflecting apportionment based on the miles of coastline in each state.
- Option 3: Manage the Nearshore Rockfish complex according to state-specific harvest guidelines stratified at 40°10′ N. latitude reflecting apportionment based on the historical recreational and commercial catch between 2004 and 2012.
- Option 4: Manage the Nearshore Rockfish complex according to state-specific harvest guidelines stratified at 40°10′ N. latitude reflecting a hybrid method of apportionment based on miles of coastline for China, quillback and copper rockfish and historical recreational and commercial catch between 2004 and 2012 for the remaining species in the complex.

Economic Impact Measures

Nearshore Open Access Commercial Fishery

Impacts on projected landings of minor nearshore rockfish by the commercial Nearshore OA sector by area (Oregon and Northern California) were translated into ex-vessel revenue impacts using average ex-vessel value per landed roundweight pound observed in 2013. Ex-vessel revenue impacts were distributed to likely landings ports (port areas) using the 2013 distribution of minor nearshore rockfish landings in port areas north of $40^0$10´ North latitude. The projected ex-vessel revenue impacts were translated into income impacts using IO-PAC commercial fishery income impact coefficients for West Coast port areas developed for analyzing commercial fisheries impacts under the 2015-16 Groundfish harvest specifications alternatives[1].

Recreational Fisheries

Where available, the GMT's projections for recreational angler effort (number of angler-trips) under the relevant HG options were translated into income impacts using IO-PAC recreational fishery income impact multipliers for angler-trips originating from West Coast port areas. These multipliers were developed for analyzing recreational fishery impacts under the 2015-16 Groundfish harvest specifications alternatives. In cases where impacts on recreational fishing effort are expected but are currently not

[1] IO-PAC is set of models used for estimating commercial and recreational fishery-related economic impacts. Fisheries industry detail in IO-PAC is estimated from economic data surveys of expenditures by vessels and processors and by recreational anglers participating in West Coast groundfish fisheries. The model is maintained by Northwest Fisheries Science Center and used by the Pacific Fishery Management Council to estimate economic impacts of West Coast fishery management actions (Leonard and Watson 2011).

quantifiable due to outstanding uncertainties in how HG options would be implemented, qualitative indicators of the direction and magnitude of expected impacts are presented.

Economic Impact Results

The GMT projected a range of commercial fisheries landings impacts under the HG options, depending on how successful Nearshore OA fishery participants may be in avoiding encounters with minor nearshore rockfish. The endpoints of the range are labeled "best case" and "worst case", respectively. If harvesters are able to avoid discarding so that all nearshore rockfish catch were landed, then the best case landings scenario would result. However if nearshore rockfish encounter rates are high so that discarding is necessary, then in order to accommodate the additional discard mortality the lower, worst case nearshore rockfish landings scenario would result.

Impacts were projected for affected commercial fisheries port areas and/or recreational fisheries management areas for each relevant minor nearshore rockfish HG option under the Council's Preferred ACL Alternative. Indicators are also presented for expected impacts under the minor nearshore rockfish harvest HG with respect to ACL Alternative 2 (P*=0.25). Ex-vessel revenue and personal income impacts resulting from effects of the minor nearshore rockfish HG options on landings by the nearshore OA sector in affected port areas are shown in Table 1 and Table 2. Table 1 shows projected impacts under the HG options on affected port areas in Oregon and Northern California compared with impacts if the Preferred ACL alternative were selected. Table 2 compares impacts on the same list of affected port areas compared with projected impacts if the P*=0.25 ACL Alternative (Alternative 2) were selected. In both cases the baseline values against which the changes (gains or losses) are measured represent ex-vessel revenue and income impacts from the entire range of species caught by the Nearshore OA fishery, not just the portion attributable to harvest of nearshore rockfish complex species.

Nearshore Open Access Commercial Fishery Impacts

Table 1 shows all Oregon port areas would be adversely affected under all four HG options, with the greatest impacts projected under HG Option 2. The most heavily impacted port area under HG Option 2 is Coos Bay-Brookings, which is projected to lose up to 8.5 percent (worst case) of its Preferred Alternative ex-vessel revenue and income from Nearshore OA fisheries. Table 2 shows additional reductions in ex-vessel revenue and income from the already lower levels under Alternative 2 of approximately six percent for Coos Bay-Brookings under all four HG options. Ex-vessel revenue and income from Nearshore OA fisheries in the Crescent City-Eureka Port Area are projected to increase from their levels under Alternative 2 by up to approximately 10 percent under HG Option 3 (best case).

Table 1. Projected change in ex-vessel revenue and personal income impacts by affected Port Area under the Minor Nearshore Rockfish HG Options compared with corresponding levels projected for the entire range of species caught in the fishery under the Preferred ACL Alternative.

Recreational Fishery Impacts

Table 3 and Table 4 show estimated recreational angler-trips and associated personal income impacts for areas where effects on recreational effort under the HG options are quantifiable. Table 3 shows projected effort and income impacts under the HG options for the Northern California Management Area compared with the corresponding quantities under the Preferred ACL alternative, season option 1 and status quo nearshore rockfish HG. Table 4 compares projected impacts for all Washington Coast Port Areas compared with ACL Alternative 2 (P*=0.25) and nearshore rockfish HG Option 3, compared with ACL Alternative 2 (P*=0.25) and status quo nearshore rockfish HG. Preliminary analysis of the Oregon recreational fishery[2] indicates that under ACL Alternative 2 (P*=0.25), even prohibiting retention of nearshore rockfish year-round would still result in exceeding the recreational share of the Oregon HG by approximately 2 percent. Reducing recreational harvest of nearshore rockfish to stay within the HG would require closing the Oregon recreational fishery one or more months during the year (Table 5).

Results in Table 3 indicate projected declines in Northern California Management Area effort and income impacts compared with the Preferred Alternative under all four nearshore rockfish HG options, ranging from -4,400 angler-trips and $327 thousand (-18 percent) in personal income impacts under HG Option 1 to -2,600 angler-trips and $191 thousand (-11 percent) in personal income impacts under HG Option 3.

[2] Once state-specified harvest guidelines are chosen by the Council, Oregon will need to conduct its state process to determine the commercial and recreational sharing of that HG. This preliminary analysis was done assuming the sharing percentages currently in place in Oregon regulations.

Results in Table 4 show projected declines under HG Option 3 compared with Alternative 2 (P*=0.25) for all Washington Coast Port Areas of 19.4 thousand angler-trips (-58 percent) and $3.6 million income impact (-64 percent)[3].

It is difficult to quantify the effects on Washington and Oregon angler effort under scenarios where nearshore rockfish retention is prohibited for one or more months. Since nearshore rockfish species are not targeted by most anglers (average catch is less than one per angler-trip), non-retention of nearshore rockfish by itself may not have much impact on angler effort. However, the cumulative effect of new management measures needed to stay within the nearshore rockfish HGs on top of management measures already in place to reduce encounters with overfished species may combine to discourage anglers from participating in recreational fisheries.

To illustrate the potential economic impact resulting from prohibition of nearshore rockfish retention in Washington and Oregon recreational fisheries under certain HG options, it is thought that impacts ranging from a 10 percent reduction under the less restrictive HG options to a 20 percent reduction in angler-trips targeting groundfish under the most restrictive HG option may be expected. By comparison, in 2012 there were 24,200 recreational bottomfish trips originating from Washington coastal ports and 72,500 recreational bottomfish trips originating from Oregon coastal ports. Together these trips generated an estimated $10.6 million in personal income impacts in Washington and Oregon coastal communities, an average of about $110 personal income impacts per angler-trip.

SUPPLMENTAL ANALYSES FOR APPENDIX B OF THE PRELIMINARY DRAFT 2015-2016 GROUNDFISH HARVEST SPECIFICATIONS AND MANAGEMENT MEASURES

The following attachments contain a revision and an addition to Appendix B of the Preliminary Draft 2015-2016 Groundfish Harvest Specifications and Management Measures, provided by members of the Groundfish Management Team (Agenda Item F.7.a, Attachment 5 – Electronic Only and Agenda Item F.7.a, Attachment 6 - Excerpts). The first analysis, B.7 Non-Trawl: Lingcod Trip Limit Increases, is intended to replace the analysis contained in Appendix B. The second, Lingcod Bag Limit Analyses, is an addition to Appendix B.

Year	Washington [1/]	Oregon		California N. 40°10′ N. Lat.

B.6 Non-Trawl: Slope Rockfish Trip Limit Reductions

Analysis of this management measure was not received by the Advanced Briefing Book deadline; it is expected to be delivered as a Supplemental GMT Report.

B.7 Non-Trawl: Lingcod Trip Limit Increases

Need for Action

For 2013-2014 groundfish fisheries, lingcod has been managed, in part, by cumulative bi-monthly trip limits designed to keep catches within the respective ACLs. Trip limits may be adjusted inseason as a result of inseason tracking patterns (higher/lower than projected). This applies to lingcod taken in both the non-nearshore (all three states) and nearshore fisheries (Oregon and California only).

At its April 2014 meeting, the Pacific Fishery Management Council (Council) directed the Groundfish Management Team (GMT) to complete an analysis of various lingcod trip limit and open season options for the west coast commercial non-trawl fixed-gear fishery to estimate economic and biological impacts. Current trip limits and open seasons are given in (No Action = Option 1a). The proposed trip limit and open season configurations (Options 1b and 1c) are summarized in Table B-32, with all trip limits reported in lb per vessel.

Initial analyses were provided to the Council at the April meeting for trip limit options during the open season (Agenda Item C.4.b, REVISED GMT Report, April 2014; pages 39-52 and below in Section B.8) and options for lingcod retention during the currently closed periods (Agenda Item C.4.b, REVISED

GMT Report, April 2014; pages 52-63). This document combines results of those previous, separate analyses. Additional details can be found in that April 2014 GMT statement.

Table B-37. No Action Option (Option 1a) for the limited entry and open access non-trawl fixed-gear trip limits (in lb) in effect in 2014 that apply to both north and south of 40°10' N. latitude.

Fleet	Jan/Feb	Mar/Apr	May/Jun	Jul/Aug	Sep/Oct	Nov/Dec[a]
Limited entry	closed	closed	800	800	800	400/closed
Open access	closed	closed	400/month			400/closed

[a]The lingcod commercial fishery is closed from December 1st of a given year through April 30th of the subsequent year (five months total). Therefore, the Nov/Dec trip limit applies only to November.

A critical point in the analysis of lingcod trip limits is how proposed increases in the coastwide trip limit structure may affect the mortality of overfished species (OFS) – primarily the OFS rockfish species, in both the non-nearshore and nearshore fisheries. The approach to these proposed trip limit increases does assume that OFS mortality will not be affected in the non-nearshore fishery because any lingcod catch is mostly incidental to the targeting of sablefish; fishing behavior will likely not change because the main target will continue to be sablefish, the much more lucrative fishery. Therefore, it is assumed that any increase in lingcod mortality (landings) will only affect OFS mortality in the Oregon and California nearshore fisheries (Washington has not had a commercial nearshore fishery since 1995).

Additionally, it is prudent to point out that there is probably little to no chance of increased China rockfish impacts under Alternative 1b and 2a (below). Opening the closed season for lingcod retention will not cause increase catch of any rockfish species (OFS or China), because the proposed increases are equal to or less than average encounter rates of lingcod during the closed season (based on WCGOP bycatch rates during December-April). Increasing the lingcod trip limit during the open season showed some increase in OFS for the 50% increase. On the other hand, the increase in canary rockfish was significant when lingcod was increased by 100%. It is expected that other nearshore rockfish mortality to also increase under that scenario (2b).

Table B-38. Lingcod commercial coastwide trip limits (reported in lb per vessel) comparing the No Action Option (Option 1a) to options that increase the bi-monthly trip limit to 1,200 lb and 1,600 lb for the limited entry sector and increases to 600 lb per month and 800 lb per month for the open access sector (Options 1b, and 1c). Also presented are proposed trip limits that establish trip limits for periods 1 and 2 and December, with period 2 closed south of 40°10' N. latitude for both sectors (Options 2a and 2b).

Option 2b	100 lb/month	closed	400 lb/month (100 lb for Dec)			

Background

Lingcod was declared overfished in 1999. In 2005, the stock was designated as rebuilt and a coastwide trip limit structure was established that has essentially stayed the same since. Lingcod trip limits have not been modified since 2005 for the limited entry (LE) sector and since 2007 for the open access sector (OA). Since 2007, no inseason adjustments have been made due to fishing mortality concerns for lingcod. At least one industry request was made for an inseason trip limit increase but was not supported by the GMT (Agenda Item E.2.b, Supplemental GMT Report 2, April 2008). This was because the GMT was concerned that any increase in lingcod trip limits and subsequent targeting could have resulted in increased bycatch of canary and yelloweye rockfish. Regarding the OA sector, the GMT expressed concerns that since the number of participants in that fishery was unlimited (as is still the case), any increase in lingcod trip limits could have led to a rapid expansion in the fishery, without any corresponding accountability measures for bycatch of overfished species. And finally, since the trip limits at that time weren't being attained in either the LE or OA fisheries, the GMT did not support an increase.

Since 2008, the coastwide commercial non-trawl fixed-gear catch of lingcod averaged 82.9 mt (Figure B-22) with the majority of landings made by the OA sector. In 2011 and 2012, total mortality by the non-trawl fixed-gear fleet was 3.0 percent and 3.5 percent, respectively, of the non-trawl allocation. For the 2015-2016 biennial management cycle, the Council is considering increases in lingcod trip limits for both the LE and OA non-trawl fixed-gear sectors to provide more fishing opportunity to the fishing communities in the three states. Additionally, a request was made by industry to explore the possibility of allowing the fleet to land modest amounts during those periods, or months, that are currently closed. This analysis estimates the potential harvest mortality under the various trip limit scenarios and open seasons to assist the Council in its decision for a Preferred Alternative. It also provides estimated mortality

amounts for overfished species that are taken in the nearshore commercial fisheries for Oregon and California when lingcod are also taken (Washington does not have a commercial nearshore fishery).

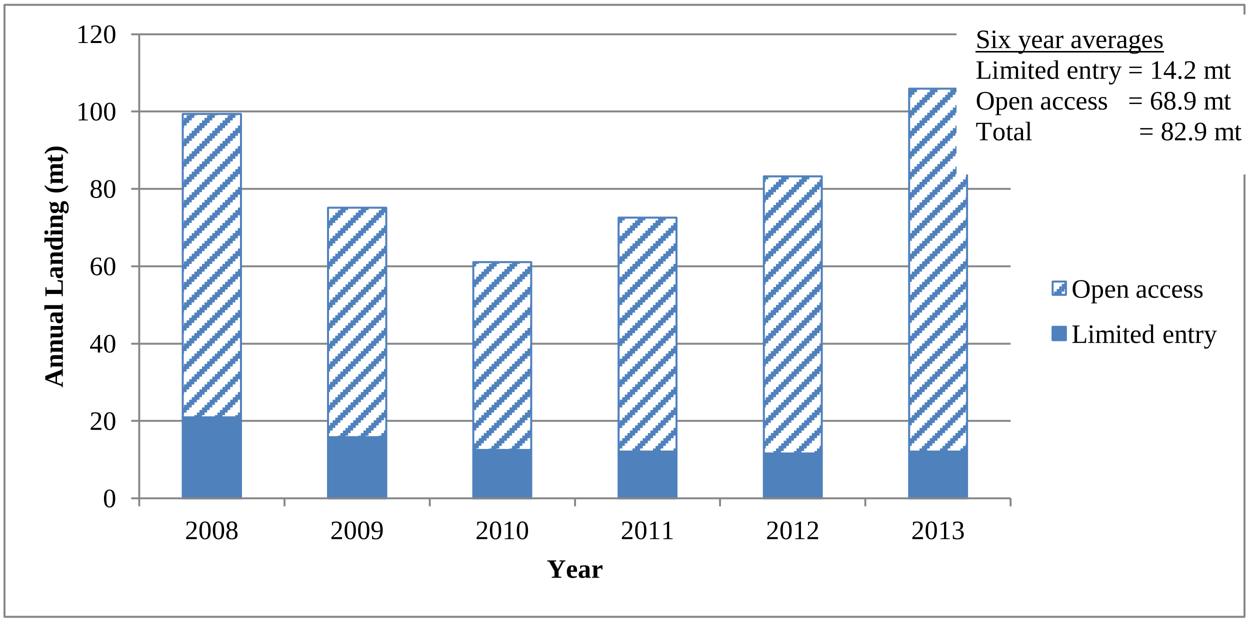

Figure B-22. Coastwide landings of lingcod by the commercial non-trawl fixed-gear fleet for both the limited entry and open access sectors from 2008 to 2013. The 2013 data are preliminary (data source: PacFIN vdrfd).

Methods

A catch-based fleet capacity trip limit model was used, and based on the years from 2008 to 2012. Commercial landings data from PacFIN's vdrfd table were extracted on April 22, 2014 for analysis. Filters were applied to only include: 1) landings made by non-IFQ, shorebased vessels (this applied to 2011 and 2012), 2) hook-and-line or trap gear, 3) Dahl sectors 5 to 10, 12, and 15[16], 4) for the nearshore bycatch model, only those Oregon and California lingcod landings that also showed nearshore species landings, and 5) port of landing north and south of 40°10' N. latitude to identify management area. The model uses a method that establishes a proportion for each participating vessel per period whereby that vessel's actual harvest mortality, as reported from the commercial dealer receipts, is compared to the theoretical maximum that that vessel could have taken. This proportion percentage is then applied to the proposed trip limit for each vessel for each period of allowable fishing. After completing this for all vessels for all periods, the estimated harvest for the fleet is summed for a final annual estimate which is then compared to the annual ACL and/or the non-trawl allocation portion of the ACL.

In addition to the above routine, a portion of the estimated landings under the various trip limit scenarios was identified as those made in conjunction with landings of nearshore species (above). These estimated lingcod landings then inputted into the GMT's nearshore bycatch model to provide estimates of the mortality of overfished species.

More details on methods can be found in Agenda Item C.4.b, REVISED GMT Report, April 2014 (pages 39-52).

[16] Dahl sectors are: 5 nearshore (limited entry), 6 nearshore (open access), 7 non-nearshore (limited entry), 8 non-nearshore (open access), 9 non-nearshore non-sablefish (limited entry), 10 non-nearshore non-sablefish (open access), 12 incidental open access, and 15 commercial non-groundfish.

Results

Lingcod mortality estimates are provided in Table B-34 and Table B-35 for the combined sector options under the different P* values for 2015 and 2016. A final LE and OA sector summary is presented in Table B-36, and lastly overfished species mortality estimates are provided in Table B-37. More detail regarding these estimates is provided below. Also, a comprehensive discussion about trip limits for periods 1 and 2 and December is included in Agenda Item C.4.b, REVISED GMT Report, April 2014, pages 52-63).

Table B-39. Lingcod coastwide commercial mortality estimates using the status quo season structure (closed during periods 1, 2 and December coastwide) comparing No Action (Option 1a) to Options 1b and 1c. The limited entry bimonthly trip limits are shown, along with open access monthly trip limits in parentheses.

LIMITED ENTRY + OPEN ACCESS (coastwide) at P* = 0.45						
	Proposed Bimonthly and Monthly Trip Limits (lb)	Estimated Take (mt)	2015		2016	
			Non-trawl Allocation (mt)	Percent of Allocation	Non-trawl Allocation (mt)	Percent of Allocation
Option 1a	800 (400)	88.9	1,950.7	4.6%	1,857.8	4.8%
Option 1b	1,200 (600)	122.3	1,950.7	6.3%	1,857.8	6.6%
Option 1c	1,600 (800)	155.1	1,950.7	8.0%	1,857.8	8.3%

LIMITED ENTRY + OPEN ACCESS (coastwide) at P* = 0.25						
	Proposed Bimonthly and monthly Trip Limits (lb)	Estimated Take (mt)	2015		2016	
			Non-trawl Allocation (mt)	Percent of Allocation	Non-trawl Allocation (mt)	Percent of Allocation
Option 1a	800 (400)	88.9	1,444.1	6.2%	1,375.4	6.5%
Option 1b	1,200 (600)	122.3	1,444.1	8.5%	1,375.4	8.9%
Option 1c	1,600 (800)	155.1	1,444.1	10.7%	1,375.4	11.3%

Note: For the limited entry sector, the November trip limits are 400 lb under Option 1a, 600 lb under Option 1b, and 800 lb under Option 1c. The non-trawl allocations are a combination of those for north and south of 40°10' N. latitude as presented in Agenda Item C.4.a, Supplemental REVISED Attachment 2:, April 2014.

Table B-40. Lingcod coastwide commercial mortality estimates under Options 2a and 2b. Season structure modifications for each sector are shown in Table B-33.

LIMITED ENTRY + OPEN ACCESS (coastwide) at P* = 0.45					
		2015		2016	
Option	Estimated Take (mt)	Non-trawl Allocation (mt)	Percent of Allocation	Non-trawl Allocation (mt)	Percent of Allocation
Option 2a	135.1	1,950.7	6.9%	1,857.8	7.3%
Option 2b	173.4	1,950.7	8.9%	1,857.8	9.3%

LIMITED ENTRY + OPEN ACCESS (coastwide) at P* = 0.25					
		2015		2016	
Option	Estimated Take (mt)	Non-trawl Allocation (mt)	Percent of Allocation	Non-trawl Allocation (mt)	Percent of Allocation
Option 2a	135.1	1,444.1	9.4%	1,375.4	9.8%
Option 2b	173.4	1,444.1	12.0%	1,375.4	12.6%

Notes: South of 40°10' N. latitude the fishery will continue to be closed. The non-trawl allocations are a combination of those for north and south of 40°10' N. latitude as presented in Agenda Item C.4.a Supplement REVISED Attachment 2, April 2014.

Table B-41. Summary of overall coastwide commercial lingcod mortality estimates for the limited entry and open access sectors for Options 1a, 1b, 1c, 2a, and 2b.

	Trip Limits		Mortality Estimates		
Option	Limited Entry (bi-monthly)	Open Access (monthly)	Limited Entry	Open Access	Total
1a (No Action)	800	400	16.9	72.0	88.9
1b	1,200	600	24.7	97.6	122.3
1c	1,600	800	31.8	123.3	155.1
2a	1,200	600	30.2	104.9	135.1
2b	1,600	800	37.9	135.5	173.4

Note: These trip limit amounts in this table refer to the bi-monthly limited entry sector, whereas the OA sector trip limits are set on a per month basis at one-half the limited entry amount. Refer to Table B-33 for the detailed summary of the actual trip limit amounts.

Table B-42. Overfished species mortality estimates (mt) under the No Action Option (1a), Option 1b, and Option 1c (season structure maintained with periods 1 and 2 and December closed), and under the 2a and 2b options that reflect the season structure modification (i.e., open January – December). These values were calculated by using the five-year commercial averages (2008-2012) of the nearshore species inserted into the nearshore bycatch model.

	Estimated mortality under options with the current season structure in place		
	Option 1a – 800 lb	Option 1b – 1,200 lb	Option 1c – 1,600 lb
Bocaccio	0.4	0.4	0.4
Canary rockfish	6.5	6.6	6.7
Cowcod	0.0	0.0	0.0
Darkblotched rockfish	0.2	0.2	0.2
Yelloweye rockfish	1.1	1.2	1.3

	Estimated mortality under options with an expanded season structure	
	Option 2a – 1,200 lb	Option 2b – 1,600 lb
Bocaccio	0.4	0.4
Canary rockfish	6.7	6.8
Cowcod	0.0	0.0
Darkblotched rockfish	0.2	0.2
Yelloweye rockfish	1.2	1.3

Comparison of Options (Options 1a, 1b, and 1c)

Under Options 1a, 1b and 1c, the coastwide bi-monthly trip limit structure would be maintained whereby commercial retention of lingcod is permitted during periods 3 (May/June), 4 (July/August), 5 (September/October) and November. Retention of lingcod would not be allowed during period 1 (January/February), period 2 (March/April) and in December. Under these three options, trip limit adjustments are considered only for the management area north of 40°10' N. latitude. South of 40°10' N. latitude, the status quo trip limits and season structure would remain in effect for all three options.

No Action (Option 1a)

For 2014, the lingcod commercial bi-monthly non-trawl fixed-gear trip limit for the LE sector is 800 lb per period with 400 lb for November. Fishing would continue to be closed during periods 1 and 2 and December. For the OA sector, trip limits are set at 400 lb per month. Again, periods 1 and 2 and December are closed. These amounts apply on a per vessel basis and apply to all three states. Under the No Action Option (Option 1a), the expected harvest mortality, for both the P* = 0.45 and P* = 0.25 approach, would be less than 10 percent of the non-trawl allocation (Table B-34). The total combined LE and OA mortality would be 88.9 mt.

Fishing Activity Under Option 1a

Under the No Action Option, fishing activity is not expected to change. The number of vessels that will fish would be expected to be about the same as have participated in the fishery over the last few years (Table B-38). In addition, fishing effort per vessel and fishing area are expected to be similar under Option 1a.

Table B-43. Number of vessels in the non-nearshore and nearshore fisheries that made lingcod landings (regardless of the amount) for the three states from 2008 to 2012. Includes both LE and OA vessels.

State	2008	2009	2010	2011	2012	5-Year Avg.
Washington	44	32	37	31	41	37
Oregon	228	219	196	200	202	209
California	251	222	206	223	264	233

Biological Impacts Under Option 1a

With no expected increase in mortality, there are no anticipated biological impacts.

Projected Overfished Species Mortality Under Option 1a

A critical consideration in the lingcod fishery are those catches (landings) that are made in conjunction with nearshore species. These nearshore fishery landings are those that are applied to the nearshore bycatch model as a component necessary for the estimation of overfished species (OFS) mortality. With no expected increase in the take of lingcod and no expected change in fishing behavior under this option, it is also expected that no increase in OFS mortality will be experienced.

Stock Status

Currently, the coastwide lingcod stock is considered healthy. As of the last stock assessment, the point estimate for the depletion of the spawning output (= spawning biomass) at the start of 2009 was 61.9 percent for north of 40°10' N. latitude , 73.7 percent south of 40°10' N. latitude, and 67.0 percent coast wide (Hamel et al. 2009).

Socioeconomic Impacts Under Option 1a

None are expected.

Option 1b

Option 1b maintains the closures during periods 1 and 2 and December. This option also increases the current LE sector trip limit from 800 lb per two months to 1,200 lb per two months and increases the November trip limit from 400 lb to 600 lb. The OA sector trip limit would increase from 400 lb per month to 600 lb per month. The original management measure consideration for this option was to analyze trip limit increases only for the fishery north of 40°10' N. latitude. Trip limit amounts south of 40°10' N. latitude are to be left as is (i.e., remain status quo). Mortality would be expected to increase from 88.9 mt. Under No Action Option 1a to 122.3 mt (37.6 percent increase) under Option 1b, with the majority of this increase coming from the OA sector. Here too, the expected landings mortality would be less than 10 percent of the non-trawl allocation amount at both the P* = 0.45 and P* = 0.25 levels.

Fishing Activity Under Option 1b

With larger trip limits (from 800 lb to 1,200 lb per period for the LE sector and from 400 lb to 600 lb per month for the OA sector) it is reasonable to expect an increase in overall mortality. Table B-36 shows mortality will increase from 88.9 mt (No Action) to 122.3 mt under Option 1b. Despite this expected increase, the total annual mortality will still be substantially less than the non-trawl allocation amount. It is speculated that this modest increase would not generate a surge in fishing activity.

Biological Impacts Under Option 1b

Because the stock is considered very healthy, the 37.6 percent increase (33.4 mt) will have a relatively minor effect on the stock's status. A total mortality of 122.3 mt represents < 10 percent of the non-trawl fixed gear allocation. Projected mortality would not jeopardize the stock's status nor cause the fishery to exceed the non-trawl allocation portion of the annual ACL.

Projected Overfished Species Mortality Under Option 1b
Two overfished species are of major concern: canary and yelloweye rockfish. These two species have been (and will continue to be) the most constraining component of the lingcod fishery and largest concern when considering lingcod trip limit increases. Under this option, both species will experience an approximate 0.1 mt increase from the No Action Option. As per the Preferred Alternative, canary rockfish has a directed nearshore allocation of 6.7 mt (2015) and 6.9 mt (2016) and yelloweye rockfish has a directed nearshore allocation of 1.2 mt (2015) and 1.3 mt (2016). The projected mortality under this option (6.6 mt for canary and 1.2 mt for yelloweye) are equal to or less than the Preferred Alternative nearshore allocations.

Stock Status

Similar to the No Action Option 1a, the stock is expected to remain healthy with no adverse effects from this modest increase in harvest mortality.

Socioeconomic Impacts Under Option 1b

Under this option, the projected increase in total annual landings for both the non-nearshore and nearshore fisheries would be approximately 75,200 lb (34.1 mt). Using the most recent commercial landings data from 2013 as a benchmark, the average coastwide price is $2.50 per pound. Applied to the projected increase of 75,200 lb, the fishery could earn an additional $188,000 compared to the No Action status quo amount – all else being equal.

Option 1c
Option 1c maintains the closures during periods 1 and 2 and December. This option also increases the current LE sector trip limit from 800 lb per two months to 1,600 lb per two months and increases the OA sector trip limit from 400 lb per month to 800 lb per month. The original management measure consideration for this option was to analyze trip limit increases only for the fishery north of 40°10' N. latitude. Trip limit amounts south of 40°10' N. latitude are to remain status quo. Mortality would be expected to increase from 88.9 mt under No Action Option 1a to 155.1 mt (a 74.5 percent increase), with the majority of this increase, again coming from the OA sector. Under this option the projected landings mortality would be less than 10 percent of the non-trawl allocation amount at P* = 0.45 but would be just over 10% (for both 2015 and 2016) for P* = 0.25 (Table B-34).

Fishing Activity Under Option 1c

With larger trip limits (from 800 lb to 1,600 lb per period for the LE sector and from 400 lb to 800 lb per month for the OA sector), it is reasonable to expect an increase in overall mortality. It is possible that there may be a change in fishing behavior with more participants participating in the fishery, but presently it is difficult to estimate what that number may be. Table B-36 shows mortality will increase from 88.9 mt (No Action) to 155.1 mt under Option 1c. Despite this expected increase, the total annual mortality will still be substantially less than the non-trawl allocation amount.

Biological Impacts Under Option 1c

Because the stock is considered very healthy, the 74.5 percent increase (66 mt) compared to the No Action Option will have a relatively minor effect on the stock's status. A total mortality of 155.1 mt under this option represents 10.7 percent of the non-trawl allocation for 2015.

Projected Overfished Species Mortality Under Option 1c
As is the case under Option 1b canary and yelloweye rockfish are the two species that have been (and will continue to be) the most constraining component of the lingcod fishery and largest concern when considering lingcod trip limit increases. Under this option, both species will experience an approximate 0.2 mt increase from the No Action option projection. As per the Preferred Alternative, canary rockfish

has a directed nearshore allocation of 6.7 mt (2015) and 6.9 mt (2016) and yelloweye rockfish has a directed nearshore allocation of 1.2 mt (2015) and 1.3 mt (2016). The projected mortality of canary under this option is 6.7 mt, which is equal to the Preferred Alternative nearshore allocation (this mortality is 0.2 mt more than the nearshore allocation under than the No Action option estimate of 6.5 mt). For yelloweye, projected mortality under this option is 1.3 mt, which exceeds the Preferred Alternative nearshore allocation for 2015 by 0.1 and equals the Preferred Alternative nearshore allocation for 2016. A mortality of 1.3 mt exceeds the mortality under No Action estimated impact by 0.2 mt.

Stock Status

Similar to the No Action Option 1a, the stock is expected to remain healthy with no adverse effects from this increase in harvest mortality.

Socioeconomic Impacts Under Option 1c

Under this option, the projected increase compared to the No Action Option in total annual coastwide landings would be approximately 146,000 lb (66 mt). Applying the $2.50 per pound value described above provides an estimate that the fishery could earn an additional $365,000 compared to the No Action status quo amount – all else being equal.

Options Overview (Options 2a and 2b)

Under Options 2a and 2b, the coastwide trip limit structure would be modified to accommodate modest trip limits for periods 1 and 2 and December for both the LE and OA sectors (Table B-32). Under these two options, the take of lingcod would be allowed during all periods and months during the year, but only for the management area north of 40°10' N. latitude. South of 40°10' N. latitude, retention of lingcod would continue to be prohibited for both sectors during March and April. Trip limits would also be increased from May-November under these options relative to No Action (Option 1). See Table B-33for trip limit details.

Option 2a

The intent of Option 2a is to allow retention and landings of lingcod that would otherwise be discarded during the closed season, in addition to increasing trip limits during the currently open season to increase attainment of the non-trawl allocation. Under this option north of 40°10' N. latitude, the LE sector would have a 200 pound trip limit per two months for periods 1 and 2 and 200 lb for December. This sector would also have a 1,200 pound trip limit for periods 3 through 5 and 600 lb in November. South of 40°10' N. latitude, the LE sector would have a 200 lb per two-month limit for periods 1 and 200 pounds for December. The sector would continue to have an 800 lb per two-month limit for periods 3 through 5 and 400 lb for November. Period 2 would remain closed.

For the OA sector north of 40°10' N. latitude, the monthly trip limit would be 100 lb during periods 1 and 2 and 100 lb in December. Additionally, this sector would have a 600 pound monthly trip limit for periods 3 through 5 and November. For the OA sector south of 40°10' N. latitude, a 100 lb per month trip limit would apply for period 1 and for December. Period 2 would remain closed and all the other months would continue to have a 400 lb per month trip limit.

Under this option south of 40°10' N. latitude, March and April would continue to be closed to the retention of lingcod for both the LE and OA sectors. This is proposed because the additional opportunity to fish for lingcod south of 40°10′ N. latitude in period 2, when rockfish is closed, presents the possibility of additional mortality of overfished rockfish as well as discarding of other healthy rockfish species while targeting lingcod. See Table B-33 for a summary of trip limit details.

Fishing Activity Under Option 2a

With larger trip limits compared to the No Action Option it is reasonable to expect a modest increase in overall annual lingcod mortality. Compared to the projection for the No Action Option (88.9 mt), the projected mortality would be 135.1 mt, an increase of 46.2 mt (52 percent). Despite this projected increase, the total annual mortality will still be substantially less than the non-trawl allocation amounts (Table B-35). For 2015 and 2016, with a P* = 0.45, the projected percent of the non-trawl allocation would be 6.9 percent and 7.3 percent, respectively. Under a P* = 0.25 scenario, the projected percent of the non-trawl allocation for 2015 and 2016 would be 9.4 percent and 9.8 percent, respectively.

Biological Impacts Under Option 2a

Because the stock is considered very healthy, the 46.2 mt increase will have a relatively minor effect on the stock's status. Lingcod mortality is expected to increase, though encounter rates are not, as participants in the fishery will retain some lingcod encountered (at 100 percent mortality) rather than discard all lingcod encountered (with an estimated 7 percent mortality). For example, the increased trip limit during the open season is not expected to change fishing behavior (i.e., fishing effort or fishing area). Likewise, allowing retention during December-April at the amounts shown in Table B-33 is not expected to cause increased fishing effort or change in fishing locations (see Agenda Item C.4.b, REVISED GMT Report, April 2014; pages 52-63). Hence, there would be no expected increase in lingcod encounter rates under this option relative to the No Action Option.

Projected Overfished Species Mortality Under Option 2a

With the combination of higher trip limits for the traditional fishing periods coupled with the modest trip limits for the periods that before were closed, projected mortality for canary rockfish is expected to increase. Under the No Action Option 1a, the projected canary rockfish mortality is 6.5 mt (Table B-37), whereas under Option 2a that mortality amount would be 6.7 mt. This projected canary rockfish mortality would equal the Preferred Alternative nearshore allocation of 6.7 mt in 2015 and not exceed the 6.9 mt in 2016~~)~~ but would exceed the No Action mortality estimate (6.5 mt). Yelloweye rockfish mortality under Option 2a is 1.2 mt, which is the same as shown under Option 1b and equal to the Preferred Alternative nearshore allocation for 2015, but 0.1 mt higher than expected under No Action (1a).

Stock Status

Under Option 2a, no adverse changes to lingcod stock status are expected compared to the No Action Option since lingcod mortality has been far below the non-trawl allocation and is expected to remain so under Option 2a. Estimated lingcod mortality under this option is expected to range between 7.8 percent and 11.0 percent of the non-trawl allocation (Table B-35). Given This level of increase in mortality is far below levels that would result in overfishing and are not expected to adversely affect stock status.

Socioeconomic Impacts Under Option 2a

Allowing fishery participants to retain incidentally encountered lingcod that were previously discarded would increase revenue from current operations targeting other species within incidental lingcod encounters. In 2013, the average price per pound coast wide averaged $2.50 per pound. This amount, applied to the projected increase (approximately 102,000 lb) would result in a coastwide gross estimated ex-vessel increase of approximately $255,000. While low trip limits make it unlikely that fishery participants will choose to target lingcod, such targeting may become worthwhile if the price per pound makes the trip profitable, despite the relatively low trip limits. If trip limits cannot be attained or if fuel or other variable costs make it unprofitable, or alternatively opportunity costs are too high to justify changing targets, directed effort may not be economically viable and trips targeting lingcod may be unlikely. However, it needs to be pointed out that some vessels do target lingcod on some trips, so any increase would benefit these participants.

Option 2b

The intent of Option 2b is also to allow retention and landings of lingcod that would otherwise be discarded during the closed season, in addition to increasing trip limits during the currently open season. Under this option north of 40°10' N. latitude the LE sector would have a 200 pound trip limit per 2 months periods 1 and 2 and 200 lb for December (the same as for Option 2a). However, this sector would also have a 1,600 pound trip limit for periods 3 through 5 and 800 lb in November. For the OA sector north of 40°10' N. latitude, the monthly trip limit would be 100 lb during periods 1 and 2 and 100 lb in December, but the sector would have an 800 pound monthly trip limit for periods 3 through 5 and November. For the OA sector south of 40°10' N. latitude, a 100 lb per month trip limit would apply for period 1 and for December. All the other months would continue to have a 400 lb per month trip limit. Again, as per Option 2a, south of 40°10' N. latitude, the retention of lingcod would be prohibited for both the LE and OA sectors during March and April to prevent the possibility of additional mortality of overfished rockfish as well as discarding of other healthy rockfish species while targeting lingcod. See Table B-33 for a summary of trip limit details.

Fishing Activity Under Option 2b

With larger trip limits compared to the No Action (Option 1a) and Option 2a, it is reasonable to expect an increase in overall annual lingcod mortality. Compared to the projection for the No Action Option (88.9 mt), the projected mortality would be 173.4 mt for Option 2b, an increase of 84.5 mt. Despite this projected increase, the total annual mortality will be substantially less than the non-trawl allocation amounts (Table B-35). For 2015 and 2016, with a P* = 0.45, the projected percent of the non-trawl allocation would be 8.9 percent and 9.3 percent, respectively. Under a P* = 0.25 scenario, the projected percent of the non-trawl allocation for 2015 and 2016 would be 12.0 percent and 12.6 percent, respectively. This assumes that no new OA participants would enter the fishery. However, given that this trip limit option would provide a modest increase to potential OA participants, it is reasonable to assume that an increase in the number of participants could occur.

Biological Impacts Under Option 2b

Because the stock is considered healthy, the 84.5 mt increase compared to the No Action Option will have a relatively minor effect on the stock's status. Lingcod mortality is expected to increase as participants in the fishery will retain some lingcod encountered (at 100 percent mortality) rather than discard all lingcod encountered (with an estimated 7 percent mortality), as occurs now during the closed season. There may be an increase in lingcod encounter rates under this option relative to the No Action Option, because trip limits during the currently open season would double (Table B-33). The likelihood and impact of this potential increase in effort would be very difficult to quantify. Despite this, however, it is probable that additional sets during a trip may occur to target lingcod (after catching trip limits for other species). This could increase impacts to OFS, as well as China rockfish.

Projected Overfished Species Mortality Under Option 2b

With the combination of higher trip limits for the traditional fishing periods coupled with the modest trip limits for those periods that before were closed, projected mortality for canary is expected to increase. Under Option 1c, the projected canary rockfish mortality is 6.7 mt (Table B-37), whereas under Option 2b that projected mortality amount would also be 6.8 mt. This projected canary mortality is 0.3 mt higher than shown under No Action (Table B-37) and 0.4 mt higher than the Preferred Alternative allocation. For yelloweye rockfish, the projected mortality under this option will be 1.3 mt, whereas it is 1.2 mt for Option 2a. This projected yelloweye mortality is 0.2 mt higher than shown under No Action, exceeds the Preferred Alternative nearshore allocation for 2015 by 0.1, and equals the Preferred Alternative nearshore allocation for 2016.

Stock Status

Under Option 2b, no changes to lingcod stock status are expected compared to the No Action Option since lingcod mortality has been far below the non-trawl allocation and expected to remain so under Option 2b. Estimated lingcod mortality under this option is expected to range between 10.1 percent and 14.3 percent of the non-trawl allocation (Table B-35). Given the projected increase in mortality that is projected to occur, the level of increase is still expected to be far below levels that would result in overfishing and are not expected to adversely affect stock status.

Socioeconomic Impacts Under Option 2b

Allowing fishery participants to retain more lingcod (some of which were incidentally caught and discarded under status quo) would increase revenue from current operations targeting other species within incidental lingcod encounters. This may also increase revenue by incentivizing increased targeting or change in behavior during the May-November period when trip limits double relative to No Action (Table B-33). In 2013, the average price per pound coast wide averaged $2.50 per pound. This amount, applied to the projected total (approximately 186,000 lbs.) compared to the No Action Option total would result in a coastwide gross estimated ex-vessel amount of approximately $465,000 more than the No Action Option total. While moderate trip limits make it feasible that fishery participants will choose to target lingcod, such targeting may become more worthwhile if an increase in the overall average price per pound makes the trip profitable. It is speculated that if trip limits cannot be attained or if fuel or other variable costs make it unprofitable, or alternatively opportunity costs are too high to justify changing targets, directed effort may not be economically viable and trips targeting lingcod could be unlikely.

B.8 Non-Trawl: Allow Lingcod retention in Periods 1, 2, and 6

Need for Action

Lingcod retention is prohibited in Periods 1, 2, and part of 6 for both limited entry and open access fixed gears under the status quo regulations. In recent years, lingcod mortality has been far below the ACL north and south of 42° N. latitude with 25 percent and 13 percent attainment in 2011 and 34 percent and 16 percent in 2012, respectively. Public testimony at the September 2013 Council meeting requesting some level of retention during periods 1, 2, and 6. The request was made to land lingcod that are incidentally caught and discarded, with the suggestion that trip limits might be set low enough to prevent changes in fishermen’s behavior (i.e., prevent targeting). Higher trip limits than those needed to allow for incidental take may further increase attainment of the non-trawl allocation of the ACL, but bycatch of overfished species while targeting lingcod is a consideration. The proposed change would allow lingcod retention in the restricted access state permitted nearshore fishery in California and Oregon, the open access nearshore fishery in Oregon, and the limited-entry and open access non-nearshore fixed gear fisheries in California, Oregon and Washington.

Background

The prohibition on retention of lingcod during specific periods has been in effect for commercial fixed gear fisheries since the 1990s to improve the conservation of lingcod after being declared overfished. The closure was put in place to minimize impacts on lingcod during their spawning season, which is from December to April (Hamel et al. 2009). Females move in to depths shallower than 50 fm to spawn and males guard nests from predation. Although females do not spend much time in the spawning area, males are concentrated in these shallow waters guarding the eggs during winter and spring months (Love 1996). The season closure for the fixed gear fishery was presumably designed to reduce catch of these males while concentrated during the nest-guarding season to facilitate rebuilding of the stock.

Lingcod was declared rebuilt in 2009, when the status was determined to be 61.9 percent for the northern component and 73.7 percent for the southern component. The coastwide status was 67.0 percent at the beginning of 2009, well above the 40 percent target spawning stock biomass (Hamel *et al.* 2009). As a

LINGCOD BAG LIMIT ANALYSIS

Background:

For 2013-2014 recreational groundfish fisheries, lingcod have been managed within a non-trawl allocation of 1186 mt in 2014; lingcod does not have a recreational harvest guideline specified in regulation. In recent years mortality of lingcod south of 42° N. latitude has been far below the non-trawl allocation. In 2012, approximately 27 percent (314 mt) of the allocation was attained. Within the non-trawl sector, the recreational fishery comprised approximately 24 percent of the total mortality in 2012. Total mortality reports from the West Coast Groundfish Observer Program indicate that the majority of mortality in the non-trawl sector is attributed to the recreational fishery (Table 1).

Currently lingcod are subject to a two fish bag limit; other recreational management measures include the same season and depth restrictions as many other groundfish, as well as a minimum size limit of 22 inches. The current size limit was implemented in 2012 and access to higher lingcod abundance in deeper waters has been limited due to the need to protect overfished species. As a result, few management measures are available to increase the harvest of lingcod.

Table 1. Total mortality (in metric tons) of lingcod south of 42° N. latitude in the non-trawl sectors, 2009-2012 (source: West Coast Groundfish Total Mortality Reports).

Year	Commercial (non-Trawl)	Recreational	Total non-Trawl
2009	37.7	129.6	167.3
2010	26.8	94.6	121.4
2011	29.8	225.2	255.0
2012	33.0	281.4	314.4

2015-2016 Management Considerations:
Lingcod south of 42° N. latitude is a healthy stock which has been underutilized in recent years. Utilization of the stock has been limited somewhat by restrictive depth constraints and season structures implemented to protect overfished stocks. In order to more fully utilize the non-trawl lingcod allocation, the Council requested analysis of increasing the lingcod bag limit from two fish to a three fish bag limit.

Range of Management Options for Consideration

Option 1- No Action: Maintain current two fish bag limit for lingcod
Under Option 1, the lingcod bag limit would remain two fish. Anglers will be forced to discard lingcod in excess of the bag limit, increasing the likelihood of encounters with overfished species.

Biological Impacts Under Option 1
Projected Impacts
Under Option 1, the projected mortality to lingcod in the recreational fishery under a two fish bag limit is 244.4 mt. Table 2 summarizes projected mortality to all overfished species.

Table 2. Projected mortality to overfished species under No Action.

Species	Projected Mortality (mt)
Bocaccio	100.1
Canary Rockfish	16.3
Cowcod	1.0
Yelloweye Rockfish	1.7

Stock Status
The stock was declared rebuilt in 2005 (Jagielo and Wallace, 2005) and the recent assessment indicates the sock remains above target biomass, with increasing abundance (Hamel et. al. 2009). Under Option 1, no change to stock status is expected.

Option 2: Increase the bag limit from two to three fish
Under Option 2, the lingcod bag limit would be increased statewide from two to three fish.

RecFIN data from 2011 to 2012 were used to analyze lingcod mortality as a result of increasing the bag limit. Using the RecFIN Hypothetical Bag Limit Analysis tool, estimates of increased mortality were calculated using A+B1+B2 fish. For the purpose of this analysis, A fish include sampled dead fish, B1 fish includes both fillets and fish discarded dead, and B2 fish includes mainly live discarded fish in excess of bag limits or undersized fish. Since the bag analysis tool does not estimate the proportion of fish that were undersized, this analysis assumes that all discarded fish were of legal size, biasing mortality estimates high. As the most conservative estimate, the analysis also assumes that all B2 fish would be available if the bag limit were increased.

Biological Impacts Under Option 2
Projected Impacts
Under Option 2, projected mortality to lingcod is expected to increase by approximately 20 percent (399.7 mt) under a three fish bag limit and PPA season structure[1]. The increase in projected mortality (155.3 mt) as a result of Option 2 can be accommodated within the non-trawl allocation, especially given historically low attainment.

Additional changes to management measures related to lingcod in the non-trawl sector are also being considered – specifically modifications to the spawning closure for the commercial non-trawl sectors. The cumulative mortality of both proposed changes is not expected to exceed the non-trawl allocation let alone the ACL.

Impacts on Overfished Species
Table 3 summarizes mortality of overfished species under Option 2. If anglers spend more time on the water fishing for an additional lingcod, the number of encounters with overfished species may increase, although any increase is difficult to quantify. While some increase in overfished species mortality can be expected over Option 1, sufficient buffer is available to accommodate the increased impacts (if realized) without exceeding the respective recreational HGs or the non-trawl allocation for cowcod.

[1] The PPA season structure corresponds to Alternative 1 (Option1).

Table 3. California recreational projected mortality of overfished species for 2015-2016 under Option 2.

Species	Projected Mortality (mt)
Bocaccio	117.5
Canary Rockfish	26.7
Cowcod	1.2
Yelloweye Rockfish	2.9

Stock status
Under Option 2**,** no change to stock status is expected compared to Option 1.

Socioeconomic Impacts
Increasing the lingcod bag limit would provide anglers with increased opportunity, which may encourage anglers to take more trips. As a result, coastal communities and business that support recreational fishing could experience minor increases to revenue compared to No Action, though such increases are difficult to quantify or attribute solely to the increased bag limit.

Note: This is an updated version of Section 4.4 in *Preliminary Draft of "Groundfish Harvest Specifications and Management Measures and Amendment 24: Draft Environmental Impact Statement"* included in the June 2014 Briefing Book as Agenda Item F.7.a, Attachment 4.

4.4 Impacts of 2015-2016 Harvest Specifications and Management Measures on Essential Fish Habitat

4.4.1 Impact Mechanism

Setting harvest specifications does not directly affect essential fish habitat (EFH). Furthermore, an analysis of groundfish trawl logbook data does not reveal any clear relationship between catch limits and fishing effort (see Appendix A). As discussed in Section 3.3.3.3, fishing effort in the shoreside trawl fishery has declined substantially since 2010 while catch generally increased. This change in fishing effort is likely a function of the introduction of IFQ management and related changes in fishery operations. Section 3.2.3 reports participation trends in groundfish fixed gear and trawl fisheries during the baseline period. Non-nearshore fixed gear fishery participation has remained relatively stable while nearshore fixed gear fishery participation has declined. The trend in effective fishing effort is not directly related to participation, but it is unlikely that fishing effort increased during the baseline period, based on information on participation presented in Section 3.2.3 and the analysis of trawl logbook data presented in Section 3.3.3.3. Alternative harvest specifications proposed for the 2015-2016 biennial period are indistinguishable with respect to the effect on EFH. To the degree that the amount and spatio-temporal distribution of gear-specific fishing effort does not change from historical patterns, adverse impacts to EFH from the groundfish fishery are likely to be equivalent to the historical impacts described in Section 3.3, which serves as a proxy for describing the impacts of the No Action Alternative (summarized below).

The proposed action does indirectly mitigate adverse impacts to EFH from fishing through the use of time/area closures. As discussed in Section 3.3, Groundfish Conservation Areas (GCAs), established as top-down measures to reduce bycatch of overfish species, have an ancillary mitigating impact on the adverse impacts of groundfish fisheries on EFH by prohibiting fishing within these areas.[1] If an area is closed for an extended period of time, the EFH within it may recover from these adverse impacts. Estimates of recovery times for EFH are shown in Table 3-24 by habitat and gear type causing the impact. These range from less than a year to decades. Although the maximum recovery time shown in the table is 56 years (the upper end of the range of recovery times for offshore biogenic habitat impacted by trawl gear), estimates range into centuries for some deepwater coral species.

4.4.2 NMFS Implementation of Council Recommendation on Trawl RCA in 2014

Under the action alternatives the trawl RCA boundaries would be changed to 100 to 150 fathoms year round in the area north of 40°10' N lat. to 48°10' N lat. (the RCA south of this latitude already has 100-150 fm boundaries). As discussed in Section 3.3, the Council originally proposed this change in April 2013 as an inseason action. NMFS prepared an environmental assessment (EA) to evaluate the impacts to EFH of this proposal (NMFS 2014b). The Council reviewed a draft of the EA at their September 2013 meeting and reiterated the proposed change. In April 2014 NMFS published a final rule (79 FR 21639) that partially implemented the Council proposal but established the seaward boundary between 40°10' N lat. and 45°46'

[1] Other closed areas, principally EFH Conservation Areas, were established with the objective of mitigating such impacts or (in the case of MPAs) addressing a variety of objectives closely related to habitat protection. However, establishing or modifying these areas is not part of the proposed action.

N lat. at 200 fathoms.[2] This configuration thus represents No Action with respect to the trawl RCA. The difference between the No Action Alternative and the action alternatives is therefore only the area between the 150 fm depth contour and 200 fm seaward boundary between 40°10' N lat. and 45°46' N lat. Under all of the action alternatives the 150-200 fm (modified) zone of the trawl RCA would be opened to bottom trawl fishing.

The preamble to the final rule identifies several reasons for the decision not to open the aforementioned portion of the trawl RCA. An overarching reason is that "there is insufficient record to conclude that the seaward boundary modification … minimizes adverse effects on groundfish EFH caused by fishing to the extent practicable." NMFS notes that the area has been closed to bottom trawling since 2004 and "benethic habitats may have, to some extent, recovered from previous groundfish bottom trawling impacts." NMFS also cites the Council's ongoing 5-year review of groundfish EFH identification and related ~~mitigated~~ mitigation measures implemented by Amendment 19 to the Groundfish FMP. As part of this process proposals have come to light for new EFH conservation areas that impinge on the 150-200 fm (modified) zone. For this reason, NMFS concluded that opening this area would be "premature." In response to a comment NMFS provides still another reason for keeping this portion of the RCA in place: "…it may have greater conservation value than portions of the actual 'core' RCA (between the 100 fm and 150 fm lines…)" which would remain closed under the Council's proposal. Although this core area has been continuously closed to bottom trawl since September 2002, pink shrimp trawl gear has been allowed in this area (along with a few other activities, such as NMFS trawl surveys, which also occur in other depth zones). Pink shrimp trawling occurs shallower than 150 fathoms and thus not in the 150-200 fathom area proposed to be opened.

NMFS states that the Council did not "sufficiently acknowledge or contribute additional analysis to minimize the potential for adverse impacts on the identified area as compared to other recommended areas, and did not provide sufficient rationale when they made their initial recommendation…" (April 17, 2014 letter from William W. Stelle, Jr., Regional Administrator, to Dorothy Lowman, Pacific Council Chair). NMFS explains that the Council needs to consider the MSA's requirement to "minimize to the extent practicable adverse effects" to EFH as part of a fishery management plan (MSA Sec. 303(a)(7)). To do so, the Council needs to demonstrate that the economic impact is "substantial enough" to outweigh potential adverse impacts to EFH. This evaluation standard is based on the description of practicability in Federal regulations at 50 CFR 600.815(a)(2)(iii): "…Councils should consider the nature and extent of the adverse effect on EFH and the long and short-term costs and benefits of potential management measures to EFH, associated fisheries, and the nation, consistent with National Standard 7" ("Conservation and management measures shall, where practicable, minimize costs and avoid unnecessary duplication").[3]

These findings by NMFS have implications for evaluating Council recommendations for changes to RCA boundaries in the context of considering "routine" management measures. Even though the trawl RCA boundaries have been changed frequently in the past (see Table 4-6 in NMFS 2014b) in cases where this management measure has allowed areas of EFH to recover from the adverse effects of fishing, sufficient rationale is expected to demonstrate that the benefits of an RCA change outweigh the adverse effects of potentially subjecting a recovered area to renewed adverse effects.

A problem with this rationale is that neither the characteristics of EFH (with respect to vulnerability and recovery time) nor the distribution of fishing effort are spatially uniform, as mentioned in the NMFS EA

[2] During November through February (bimonthly periods 6 and 1) the modified 200 fathom line is implemented. These modifications allow access to areas where petrale sole are abundant.

[3] "Practicable" has a narrower definition the "practical." Something is practical if it is useful or convenient while practicable means doable or feasible.

(NMFS 2014b). This makes it difficult to assess the conservation value of the area as a whole and likewise the actual adverse impact that might occur if the area was opened to bottom trawling.

To investigate the question of the benefits to EFH afforded by the 150-200 fm area an analysis was undertaken using ArcGIS™ geographic information software (version 10.2). Polygons were created representing the three depth-based portions of the RCA in the area between 40°10' N lat. and 45°46' N lat. using waypoint lines for the 75 fm, 100 fm, 150 fm, and 200 fm (modified by "cutouts" to allow access to petrale sole fishing grounds) depth contours and the adjacent areas outside of the RCA. When these lines are combined to generate a single polygon feature class additional polygons are formed by the 200 fm modified line crossing the 150 fm line. In some cases, especially where the sea bottom drops off steeply, these could be errors resulting from one line being drawn without reference to the other. Another possibility is that these represent intentional "cutouts" to increase fishing opportunity.

The polygon feature layer representing RCA zones was then intersected with the Habitat Weighted Cumulative Fishing Effort layer created as part of the EFH 5-year review and available at http://efh-catalog.coas.oregonstate.edu/effort/. The Habitat Weighted Cumulative Fishing Effort layer is composed of 2 x 2 km polygon grid cells with an index score assigned to each grid cell (NMFS 2013a).[4] A high cell score may be interpreted as more fishing effort directed at more sensitive areas. (It should be noted that the habitat weighting does not take into account occurrence of hard corals.) Since the intersection resulted in grid cells along the RCA lines to be split, the index values were normalized by adjusting impact index values proportionately (i.e., impact value * (cell area / 4 sq. km.)).

As noted above, impacts are unevenly distributed spatially. This results in a highly skewed distribution of impact index values. This is illustrated in Figure 4-35, which shows the frequency distribution of adjusted (area normalized) impact metric values. The bins used in this distribution are based on multiples of the standard deviation of the population. The standard deviation is greater than the mean and 69% of the cells have values equal to or less than the mean. Ninety-nine percent of the values are less than five standard deviations above the mean. This demonstrates that there are a few outlier values with very high scores relative to the mean. In other words, there are a few grid cells where fishing effort and habitat sensitivity combine to produce high values. Keeping an entire area closed while only a few discrete areas may exceed the putative "conservation value" threshold may not justifying continued closure of an entire area.

Table 4-159 presents a range of summary statistics based on the GIS analysis. The first row shows the unadjusted values while all the remaining rows use the adjusted impact metric. The percent of grid cells clipped in the overlay operation is shown to demonstrate why the area adjustment to the impact metric was made. The impact value is presented as a total (the sum of values within an RCA zone) and an average (the sum divided by the area of the RCA zone). The last three rows present the impact metric only for values

[4] The feature class metadata abstract states "We overlaid commercial groundfish fishing effort (based on West Coast Observer Program data, 2002 - 2010) for the bottom trawl, midwater trawl and select fixed-gear fleets with benthic habitat types off the coast or WA,OR, and CA, out to the 1,600 m isobath. Benthic habitat was classified into nine categories, which combined attributes of three depth strata and three bottom hardness categories. The depth strata were shelf, upper slope and lower slope. Bottom hardness was classified as hard, mixed or soft. Weighting for each of the nine benthic habitat categories was assigned based on fleet type (bottom, midwater, fixed line and fixed point). The model grain was a gridded 2 x 2 km surface. Each gridcell represent data from three or more unique vessels over the modeling time frame (2002 - 2010). Details of this model can be found in the EFH Phase II report and associated appendices." Although not stated explicitly, the impact metric column, ALL_IMPACT is defined as "Cumulative groundfish fishery effort X weighted benthic habitat types" indicating that multiplication was the operation used.

less than five standard deviations above the mean. This excludes potential outlier values to better represent “average” impact levels within a zone.

The~~se data~~ average index values contradict the conclusion reached by NMFS and discussed in the Final Rule that the 150- 200 (modified) zone is less impacted than the 100-150 fm zone, based on the magnitude of the summed impact values for each zone. The average index value for the 100-150 fm zone is 15,711, which is less than the average value of 19,560 for the 150-200 fm (modified) zone. However, the documentation for the Habitat Weighted Cumulative Fishing Effort ~~layer does not specify whether~~indicates that shrimp trawl and NMFS trawl surveys are ~~accounted for~~ not included in the fishing effort component of the impact metric. As noted above, the rationale presented by NMFS is partly based on the fact that these activities occur only in depths less than 150 fathoms.

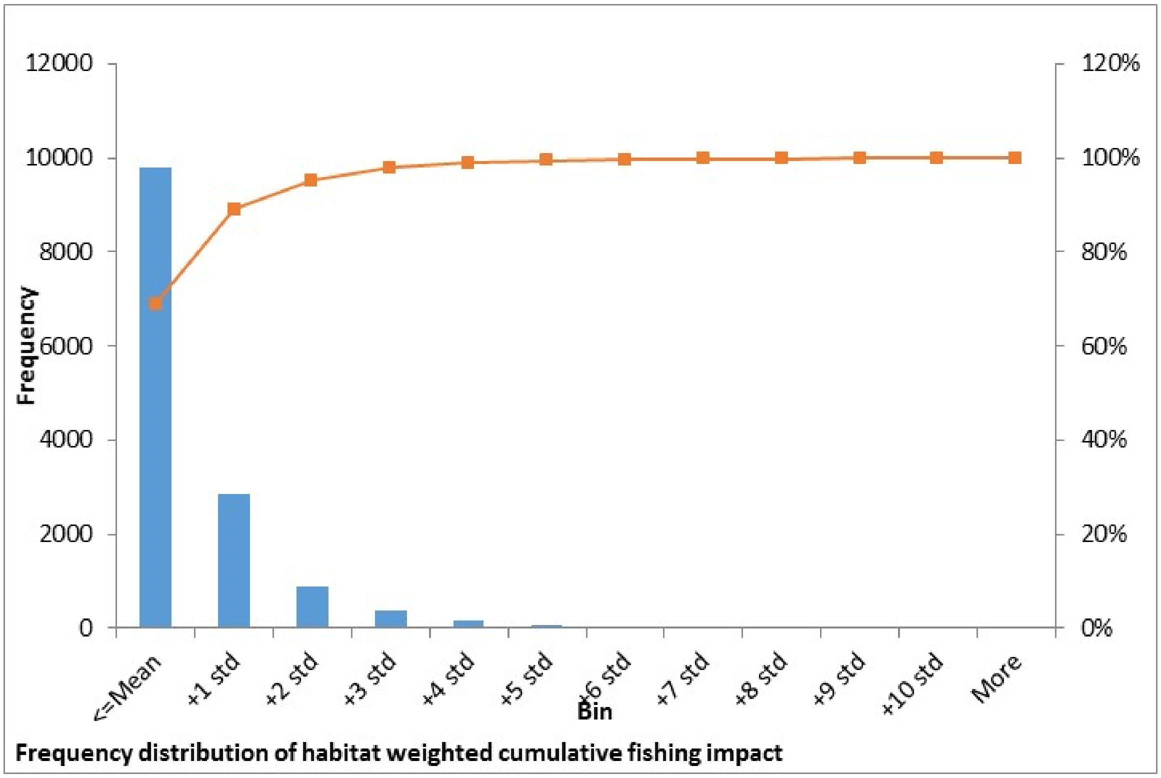

Figure 4-34. Frequency distribution of habitat weighted cumulative fishing effort index values between 40°10’ N lat. and 45°46’ N lat. (columns) and cumulative percent of the total count (line).

Table 4-159. Summary statistics for area adjusted habit-weighted cumulative fishing effort layer by RCA depth zone between 40°10' N lat. and 45°46' N lat.

	Shoreward of 75 fm	75-100 fm	100-150 fm	150-200 fm (modified)	Seaward of 200 fm (modified)	Possible "cut-outs"
Summed Impact	178,404,764	171,415,525	84,795,897	102,546,519	803,699,491	17,334,798

* Summed impact divided by area (sq. km.) of polygon

To examine the socioeconomic importance of these areas, trawl RCA trawl logbook data from a period before the RCA was implemented, 1998-2001, was analyzed to evaluate the economic benefits derived from fishing in the different trawl RCA zones.[5] Set positions were obtained from the PacFIN logbook subsystem (lbk_tow table) along with set time, up time, and hail weight. Tow duration was computed by subtracting up time from set time, accounting for instances where the up time was on the following day from the set time. The tow set position was used to create a point feature layer in ArcGIS and a spatial join was performed on the polygon layer for the RCA zones.[6] This allowed RCA zone names assigned in the polygon layer attribute table to be added to each record in the logbook point layer attribute table. The spatial join rule used was to assign attributes to the point layer record falling within a polygon in the RCA zone layer.

Table 4-160 shows three metrics derived from the GIS analysis to evaluate the economic importance of the RCA zones. These are the number of tows, the total duration of all tows made, and the total of the hail weights for all the tows. The metric values have been normalized to account for the varying sizes of different zones (the ~~adjusted impact~~socioeconomic metric divided by the area ~~in square kilometers~~ of the zone in square kilometers). The number of tows where a null value appears for the hail weight is shown as a percent of all tows. These null values are assumed to represent omitted data. The data are presented for six areas: the depth zones comprising the configurations of the trawl RCA (75-100 fm, 100-150 fm, 150-

[5] PacFIN gear IDs were used for to exclude sets using midwater gear. The logbook database covers the Federal groundfish bottom trawl fishery so activity in the state-managed shrimp trawl fishery is not included. As discussed in Section 3.2, groundfish fishery landings declined precipitously between 1997 and 1998 and remained relatively low in the years afterward. In order to have a more consistent data set 1998 was chosen as the cutoff for the time series.

[6] Since only set positions were used, this analysis does not account for tow tracks that crossed from one zone into another somewhere along the length of the tow track. Since a lot of the fishing effort occurred near the 150 fm isobath some amount of the metric quantity ascribed to one zone may have occurred in the other.

200 fm), the adjacent shoreward and seaward areas, and the presumed petrale cutout areas. Figure 4-35 presents data for the trawl RCA zones graphically for easier interpretation.

Excluding the presumed petrale cutout areas, in the period before RCA implementation (1998-2001) the 100-150 fm zone shows the highest area normalized metric values, suggesting that it was the most important area economically, followed by 150-200 fm (modified) zone.[7] This indicates that this area generated socioeconomic benefits that may be sufficient to demonstrate that keeping this area closed is impracticable as defined in Federal regulations at 50 CFR 600.815(2)(ii) and (iii). This definition of practicability asks Councils to consider "the nature and extent of adverse effect[s]" and the "long and short-term costs and benefits" of mitigation measures. Analysis using the Habitat Weighted Cumulative Fishing Effort layer suggests that the 150-200 fm (modified) zone has experienced impacts greater than the 100-150 fm zone, ~~that~~ which would be remain closed under the Council's proposal, an indication that the~~is~~ 150-200 fm (modified) zone ~~area~~ does not have special conservation value, while substantial socioeconomic benefits could be realized if the 150-200 fm (modified) were accessible to the trawl fishery.

Another factor identified in the Final Rule discussed above (and in Section 3.3.3.2) is the potential for areas within the 150-200 fm (modified) zone to be closed specifically to mitigate the adverse effects of fishing. This could occur as part of the Council's ongoing review of EFH designation and mitigation measures in the Groundfish FMP. Information was not obtained from proponents in time to compare locations using GIS and determine their importance with respect to the RCA configuration. The Council would have to consider whether the future benefits in terms of impact mitigation accruing from any closures outweigh the ongoing socioeconomic costs of keeping the 150-200 fm zone closed if ~~it is~~is the closures are unnecessary with respect to the stated objective of reducing catch of overfished species.

Table 4-160. No of tows, total tow duration, and total hail weight summed by depth zone, per sq. km. for areas between 40°10' N lat. and 45°46' N lat. 1998-2001. Tows made with midwater gear excluded. (PacFIN lbk_tow, 6/9/14)

Depth Zone	No. of tows	Tow Duration	Hail Weight	Hail Wt Null Values (%)
<75 fm	0.28	0.79	273	0%
75-100 fm	1.90	6.20	2,579	2%
100-150 fm	2.57	10.10	4,027	1%
150-200 fm (m)	2.09	9.97	3,441	1%
"Cut outs"	4.57	16.42	7,930	1%
>200 fm (m)	0.35	2.33	672	1%

[7] The presumed petrale cutout areas represent a special case. First, without more investigation it cannot be confirmed that these areas, where the 200 fm (modified) line crosses the 150 fm line are intential cutouts or errors in designating waypoints for the two lines. Nonetheless, the metrics suggest that a lot of fishing effort is concentrated in these areas, which would make sense if they are important fishing grounds. Overall, they demonstrate the point made above that impacts are not spatially uniform, so privileging the ancillary conservation benefits of the RCAs may not be a practicable approach to mitigating adverse impacts.

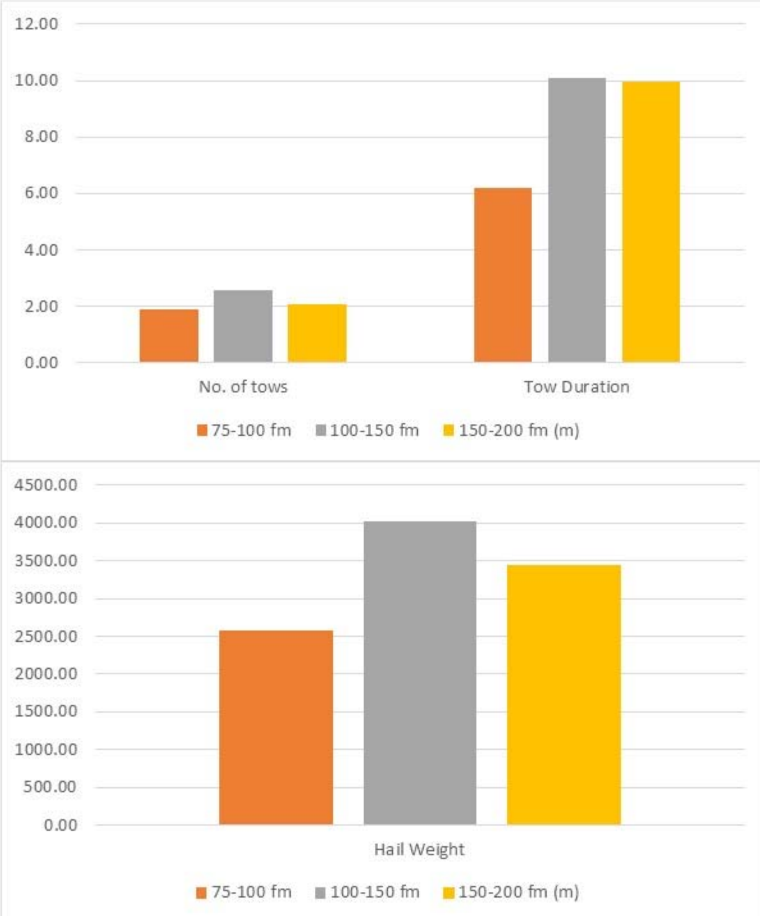

Figure 4-35. Graphical representation of logbook economic metrics for areas of the RCA between 40°10' N lat. and 45°46' N lat., 1998-2001.

4.4.3 Summary of the Impact of the Alternatives on Essential Fish Habitat

4.4.3.1 The No Action Alternative

Under No Action the harvest specifications and management measures in place in 2014 would continue in effect, although inseason action could be taken to adjust routine management measures. As noted above, the characterization of the environmental baseline in Section 3.3 is the best available summary of the impact in the future, because there are no models or methodology available to estimate the amount and spatial distribution of fishing effort, and thus effects on EFH, resulting from the proposed action. Using information about the environmental baseline, the following possible effects are noted:

- Based on historical trends, fishing effort in the bottom trawl portion of the shoreside IFQ fishery is not likely to increase. Bottom trawl effort fell substantially with the implementation of IFQ management (see Figure 3-22). Bottom trawl gear has greater adverse impacts to groundfish EFH compared to other gear types.
- A portion of the shoreside IFQ fishery is using fixed gear to catch their IFQ. Fixed gear has less adverse impact on groundfish EFH compared to bottom trawl. Hard substrate (rocky habitat) is more accessible to fixed gear but recovery times are shorter for fixed gear even in comparison to bottom trawl gear for soft substrate, which is generally rated to recover faster from the adverse impacts of fishing.

- In 2014 NMFS partially implemented a Council recommendation to reduce the size of the trawl RCA between 40°10' N lat. and 48°10' N lat. The environmental baseline now includes the trawl activity in these open areas for the remainder of 2014. Under No Action, trawl fishing would continue to be permitted in these areas.

4.4.3.2 The Preferred Alternative

As discussed in Section 4.4.1, a correlation between the size of target species ACLs and bottom trawl fishing effort estimated from logbook data could not be identified. At some level of magnitude, it is reasonable to conclude that fishing opportunity, dictated overall by ACLs and mediated by sector allocations and related management measures, affects fishing effort. A crude way of representing the difference between Alternative 1 and No Action is the difference between the sum of all the ACLs under each alternative. The sum of Alternative 1 ACLs for 2015 (not including Pacific whiting) is 44,736 mt greater than No Action, a 53 percent increase. Put another way, out of the 38 stocks for which ACLs are established and a comparison can be made with No Action, 25 show an increase from No Action.[8] However, 25,000 mt of this difference in the ACL is represented by the increase in the Dover sole ACL; as discussed in Section 4.3.2.6, there is not enough historical evidence to demonstrate that this increase would be accompanied by a comparable increase in catch. The sum of the non-whiting ACLs for 2015, 129,060 mt, is larger than summed values for any year during the baseline period when the largest value was 119,371 mt. (It is important to bear in mind that the stock definitions for which individual ACLs are set have changed over time. Thus these sums are not exactly comparable, but at this gross scale the changes in the recent past have probably not by themselves substantially affected fishery behavior.) While no conclusion can be made about how ACLs and resulting fishing opportunity may affect the distribution of fishing effort, it is reasonable to conclude that fishing effort is more likely to increase than to decrease.

Under the Preferred Alternative, the Council reiterates its previous recommendation on changing the trawl RCA boundary. Because of NMFS action in 2014, the effect of this recommendation would be to open the area from 150 fm to 200 fm between 40°10' N lat. and 45°46' N lat. This would have adverse impacts to EFH that had fully recovered from the past effects of bottom trawl in this area.

4.4.3.3 Alternative 1

Under No Action there are 10 stocks where the ACL is set equal to the ABC and a P* value less than 0.45 is used. Under Alternative 1 the P* value used is 0.45 in all cases, indicating a policy change from No Action (however, six of these stocks have ACLs set for geographic subdivisions of a coastwide value so effectively the P* policy choice only comes into play in seven cases). Otherwise, ACLs are expected to increase in cases where spawning stock abundance is increasing. The sum of the 2015 ACLs under Alternative 1 is 106,733 mt; the main difference from the Preferred Alternative is that the No Action ACL of 25,000 mt for Dover sole would apply under Alternative 1 rather than the Preferred alternative ACL of 50,000 mt.

The Council recommendation to change the trawl RCA boundary from 150 fm to 200 fm between 40°10' N lat. and 45°46' N lat. would apply under this alternative. There is no information demonstrating that a substantial change in fishing effort is likely under this alternative. Management measures with mitigating effects on the adverse impacts of fishing are the same as No Action, except for the proposed change in the seaward boundary of the trawl RCA described above, which may increase adverse impacts from fishing on EFH, to the extent that recovered EFH is subject to bottom trawl. Except for this change, it is reasonable

---

[8] Because spiny dogfish is removed from the Other Fish complex, which has further changes through the designation of EC species, only 38 out of 40 ACLs for the 2015-2016 biennium can be compared.

to conclude that the impacts of Alternative 1 would not be discernibly different from the effects under No Action.

4.4.3.4 Alternative 2

Under No Action there are 25 stocks where the ACL is set equal to the ABC based on a P* value. Under Alternative 2 the P* value used is 0.25 in all cases, indicating a policy change from No Action (however, six of these stocks, have ACLs set for geographic subdivisions of a coastwide value so effectively the P* policy choice comes into play in 22 cases). The sum of the 2015 ACLs under Alternative 2 is 82,512 mt, which is 1,814 mt less than the sum of No Action ACLs. At a gross level, this suggests that fishing opportunity, fishing effort, and resulting adverse impacts on EFH is not likely to increase compared to No Action.

The Council recommendation to change the trawl RCA boundary from 150 fm to 200 fm between 40°10' N lat. and 45°46' N lat. would apply under this alternative. There is no information demonstrating that a substantial change in fishing effort is likely under this alternative. Management measures with mitigating effects on the adverse impacts of fishing are the same as No Action, except for the proposed change in the seaward boundary of the trawl RCA described above, which may increase adverse impacts from fishing on EFH, to the extent that recovered EFH is subject to bottom trawl. Except for this change, it is reasonable to conclude that the impacts of Alternative 2 would not be discernibly different from the effects under No Action.

4 Impacts of the Alternatives

4.8 Biological Impacts of Alternative Long Term Biennial Harvest Specifications on Groundfish Stocks

This section evaluates the predicted biological impacts of alternative long term harvest specifications on a select list of groundfish stocks. The focus of this section are on those overfished stocks currently managed under rebuilding plans, the economically most important target stocks that are the backbone of the current fishery, and those stocks and stock complexes that were historically important targets of the west coast groundfish fishery. This evaluation notes the projected depletion trends under the range of scenarios modeled. The results of this analysis are presented by taxon and, for rockfish, further stratified by depth strata (i.e., nearshore, shelf, and slope).

The long term analysis in this EIS used projections of spawning stock depletion, spawning stock biomass, and total biomass of key assessed groundfish stocks through 2024 under a wide range of catch streams or harvest control rules, as well as across the states of nature that captured the key axes of uncertainty in stock assessments. An important caveat in the analysis is that the base case state of nature in these projections is the most probable. The Terms of Reference for stock assessments directs the states of nature modeled in assessment decision tables be developed as stochastically as possible with the base case state of nature being the median or most probable case (i.e., 50% likelihood) and the low and high states of nature bracketing the base case having half the probability (i.e., 25% likelihood) as the base case. In all cases, the highest catch stream modeled is the harvest control rule of ACL = ABC under a P* of 0.45; the highest catch streams are from the high state of nature models under this harvest control rule. The lowest catch streams, depending on the stock, are modeled using either the harvest control rule ACL = ABC under a P* of 0.25, the 2014 ACL scenario, or under the “recent year average catch” scenario. The lowest catch streams are from the low state of nature models under one of these harvest control rule scenarios.

The states of nature developed in groundfish stock assessments can best be thought of as bracketing the key axes of uncertainty that affect stock productivity. Stock assessments vary by how many of the key population dynamics parameters are estimated. The more parameters that are estimated, the more the true uncertainty in the assessment is characterized. However, no assessments attempt to estimate all parameters that describe stock dynamics. For example, those assessments that are done in Stock Synthesis (the assessment platform used for the majority of current groundfish stock assessments) will often try to estimate steepness of the stock-recruitment function (h) or the instantaneous rate of natural mortality (M), but seldom both parameters. Both h and M are measures of relative stock productivity (high h and high M are indicators of strong stock productivity) and their estimates are confounded (that is, assumptions or priors used to estimate one of these parameters will affect the estimate of the other). Therefore, when one of these parameters is freely estimated, the other is usually assumed and fixed in the assessment. In this case, the fixed parameter is usually what is varied to determine the states of nature in the assessment. The high state of nature is therefore indicative of an “optimistic” assumption that affects high stock productivity and the low state of nature indicates a more “pessimistic” lower productivity assumption.

It is important to note that all biomass projections are deterministic in that future recruitment and total removals (i.e., total catch), as well as the fixed parameters in the assessment, are assumed. Decision tables in assessments that show variable future catch streams by state of nature also explore the implications of using a catch stream that is projected to be sustainable for the base case model (i.e., future biomass is projected to remain above B_{MSY}) for the other states of nature to address the question, “what is predicted to happen if the alternative state of nature is the actual one for the stock?”. However, the purpose of this analysis is to probe a broader range of biomasses and catches for select groundfish stocks to better posit how these outcomes affect the stocks and the fishery. The highest and lowest biomasses and catches in this analysis are highly unlikely and any case where all these stocks are in equilibrium at these high or low biomasses is implausible.

Since the main objective of this long term impact analysis is to specifically discuss impacts at the extremes of plausibility (i.e., analyzing the highest and lowest catch streams using the high and low states of nature models), this analysis does not map directly to the 2015-2016 alternatives analyzed in this EIS. However, when linking this long term impact analysis with the 2015-2016 alternatives analyzed in this EIS, the base case model is always assumed since that is the most probable assessment model. In all cases, Alternative 1 is the ACL = ABC using a P* of 0.45 and Alternative 2 is the ACL = ABC using a P* of 0.25 (in both cases the appropriate precautionary reduction to the ACL, either the 40-10 or the 25-5 rule, is made when the stock is projected to be below the B_{MSY} target). The No Action Alternative is the 2014 ACL and the Preferred Alternative varies by stock.

4.8.1 Long Term Impacts of Assessed Flatfish Species

Of all the assessed flatfish species, only the projections for rex sole were not available in time for this analysis.

The proxy biomass reference points that direct management of assessed flatfish species are a target biomass (B_{MSY}) depletion ratio of 0.25 (depletions at or above this threshold indicate a healthy stock) and a Minimum Stock Size Threshold (MSST) of 0.125 (depletions below this threshold indicate an overfished stock). Depletions between the B_{MSY} threshold and the MSST indicate stocks in the precautionary zone. The default ACL harvest control rule for flatfish in the precautionary zone is to implement the “25-5” rule which is a reduction in the ACL from the ABC (see {PFMC, 2014 #563} for more details).

Most of the flatfish species are not caught at levels commensurate with high attainment of ACLs, with the exception of petrale sole, which is an important trawl target. Therefore, the high catch streams for these species under even the base case models are unlikely. Flatfish species managed in the FMP are mostly trawl-dominant (i.e., on average, 90% or more of the catch occurs in the trawl fishery), with the exception of Pacific sanddabs and starry flounder, which are a significant species in trawl and recreational fisheries. Given the dominance of flatfish as a trawl species, catch monitoring uncertainty is low. Therefore, there is very low risk of depleting flatfish stocks through overfishing.

4.8.1.1 Arrowtooth Flounder

The modeled catch scenarios for arrowtooth flounder range from 3,088 mt per year based on the recent year average catches to an annual average catch in 2015-2024 of 37,915 mt based on the ACL = ABC with a P* of 0.45 catch scenario under the high state of nature (Table 4-1). Projected arrowtooth depletions under all states of nature are sustainable assuming the respective states of nature, except maintaining the 2014 ACL under the low state of nature is projected to drive depletion just below B_{MSY} by the end of the projection period (Figure 4-1, Figure 4-2, and Figure 4-3). All the 2015-2016 alternatives are sustainable under the base case model (Figure 4-1).

Table 4-1. Predicted average annual catches (mt) in 2015-2024 by state of nature and catch scenario for arrowtooth flounder.

State of Nature	Catch Scenario	2015-24 Average Annual Catch
Base	2014 ACL (No Action Alt.)	5,758
	ABC Removals (P* = 0.25; Alt. 2)	6,364
	ABC Removals (P* = 0.4; Pref. Alt.)	7,125
	ABC Removals (P* = 0.45; Alt. 1)	7,307
	Recent Year Average Total Catch Removals	3,088
High	2014 ACL	5,758
	ABC Removals (P* = 0.25)	33,968
	ABC Removals (P* = 0.4)	37,184
	ABC Removals (P* = 0.45)	37,915
	Recent Year Average Total Catch Removals	3,088
Low	2014 ACL	5,758
	ABC Removals (P* = 0.25)	4,001
	ABC Removals (P* = 0.4)	4,624
	ABC Removals (P* = 0.45)	4,789
	Recent Year Average Total Catch Removals	3,088

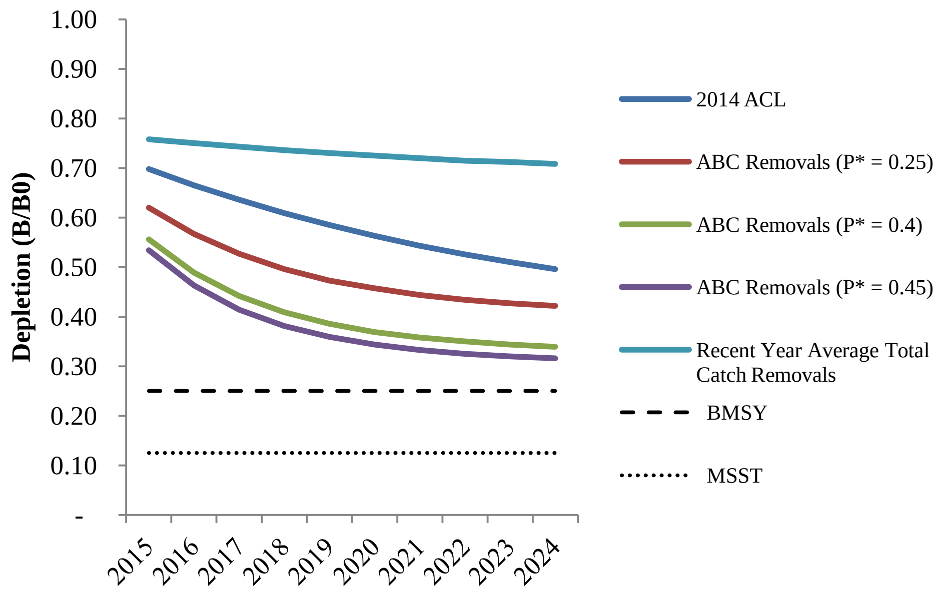

Figure 4-1. Projected depletion under alternative catch streams under the base case state of nature model for arrowtooth flounder.

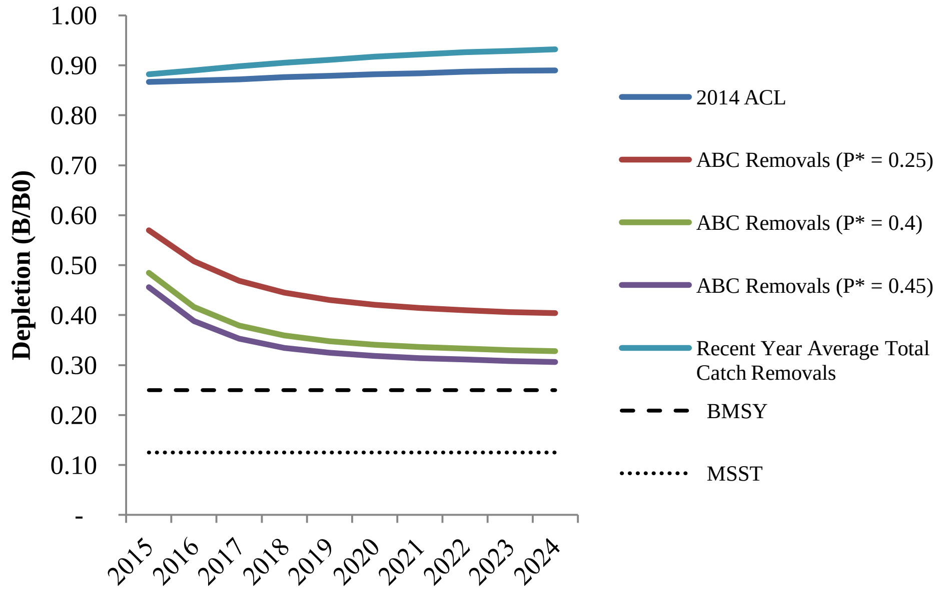

Figure 4-2. Projected depletion under alternative catch streams under the high state of nature model for arrowtooth flounder.

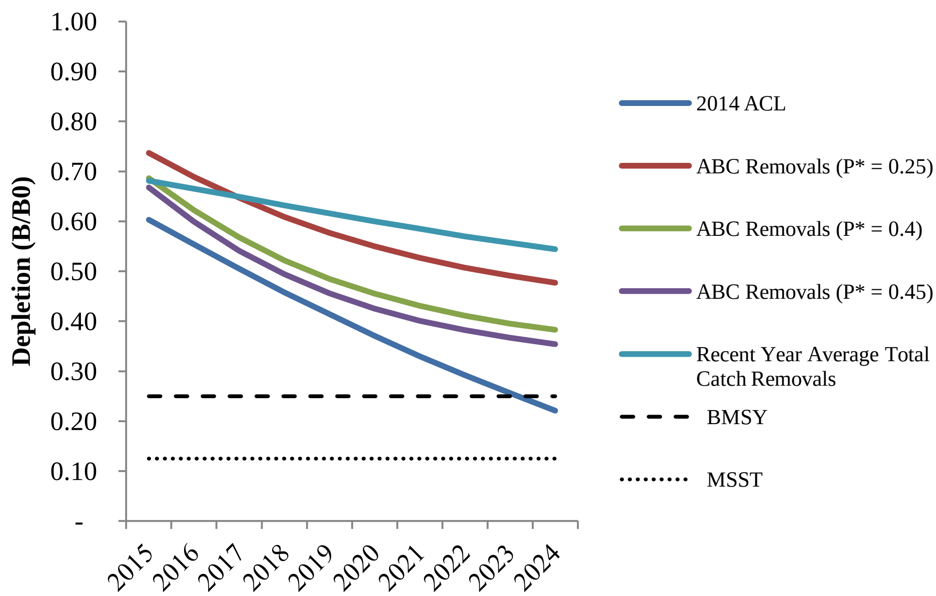

Figure 4-3. Projected depletion under alternative catch streams under the low state of nature model for arrowtooth flounder.

4.8.1.2 Dover Sole

The modeled catch scenarios for Dover sole range from 7,551 mt per year based on the recent year average catches to an annual average catch in 2015-2024 of 91,249 mt based on the ACL = ABC with a

P* of 0.45 catch scenario under the high state of nature (Table 4-2). Projected Dover sole depletions under all states of nature are sustainable assuming the respective states of nature (Figure 4-4, Figure 4-5, and Figure 4-6). While the preferred Dover sole alternative of a 50,000 mt constant catch has not been projected or modeled in this long term analysis, the total removals and biomass trajectory assuming full attainment of the ACL in the next ten years is very similar to the Alternative 2 scenario (ABC Removals using a P* of 0.25) under the base case model in Figure 4-4.

Table 4-2. Predicted average annual catches (mt) in 2015-2024 by state of nature and catch scenario for Dover sole.

State of Nature	Catch Scenario	2015-24 Average Annual Catch
Base	2014 ACL (No Action Alt.)	25,000
	ABC Removals (P* = 0.25; Alt. 2)	50,630
	ABC Removals (P* = 0.45; Alt. 1)	56,611
	Recent Year Average Total Catch Removals	7,551
High	2014 ACL	25,000
	ABC Removals (P* = 0.25)	81,641
	ABC Removals (P* = 0.45)	91,249
	Recent Year Average Total Catch Removals	7,551
Low	2014 ACL	25,000
	ABC Removals (P* = 0.25)	34,880
	ABC Removals (P* = 0.45)	39,069
	Recent Year Average Total Catch Removals	7,551

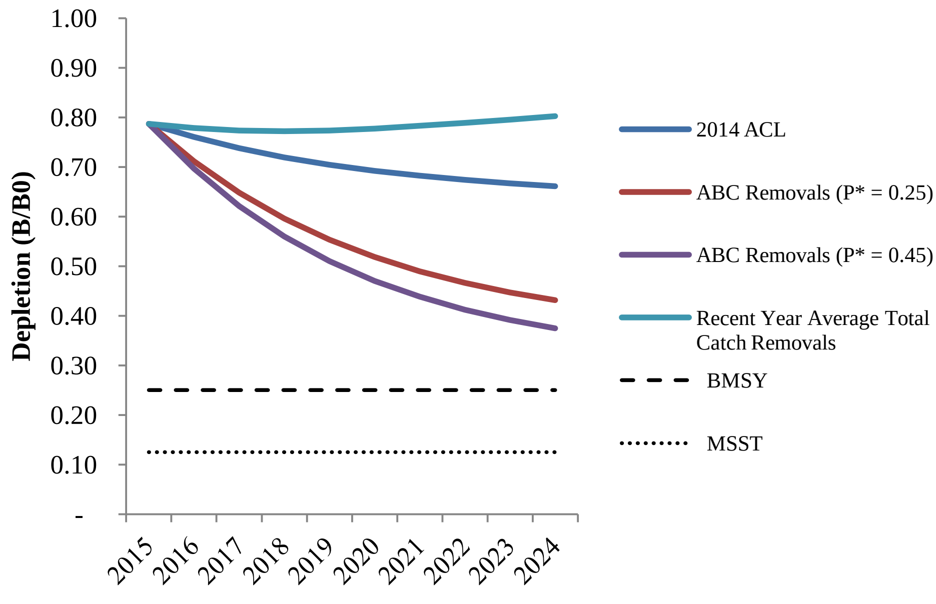

Figure 4-4. Projected depletion under alternative catch streams under the base case state of nature model for Dover sole.

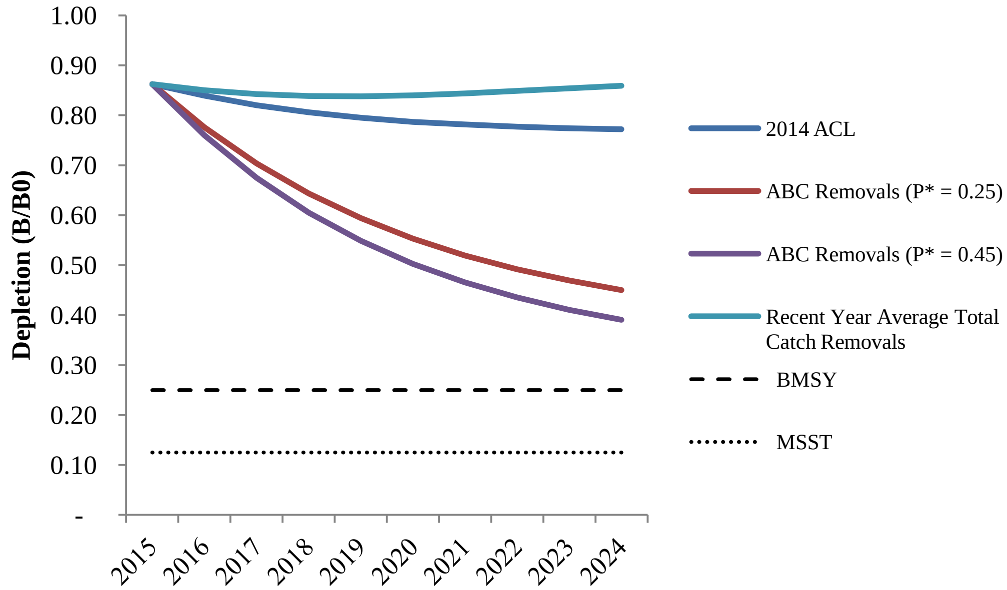

Figure 4-5. Projected depletion under alternative catch streams under the high state of nature model for Dover sole.

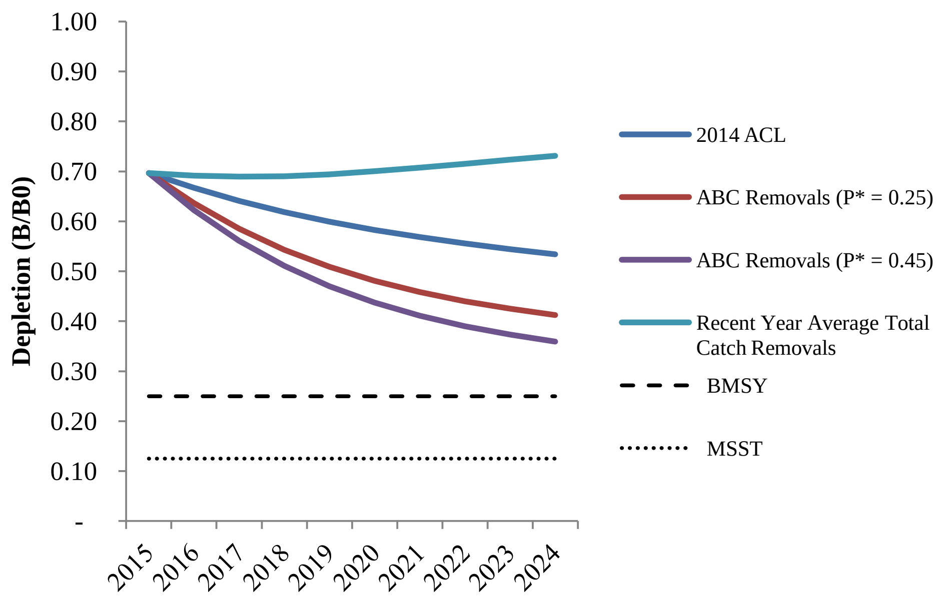

Figure 4-6. Projected depletion under alternative catch streams under the low state of nature model for Dover sole.

4.8.1.3 English Sole

The modeled catch scenarios for English sole range from 207 mt per year based on the recent year average catches to an annual average catch in 2015-2024 of 7,461 mt based on the ACL = ABC with a P* of 0.45 catch scenario under the high state of nature (Table 4-3). Projected English sole depletions under all catch scenarios and states of nature are predicted to be sustainable, except maintaining the 2014 ACL is predicted to drive the stock down below the B_{MSY} target into the precautionary zone under the base case and low state of nature models (Figure 4-7, Figure 4-8, and Figure 4-9).

Table 4-3. Predicted average annual catches (mt) in 2015-2024 by state of nature and catch scenario for English sole.

State of Nature	Catch Scenario	2015-24 Average Annual Catch
Base	2014 ACL (No Action Alt.)	5,645
	ABC Removals (P* = 0.25; Alt. 2)	4,423
	ABC Removals (P* = 0.45; Alt. 1; Pref. Alt.)	5,479
	Recent Year Average Total Catch Removals	207
High	2014 ACL	5,645
	ABC Removals (P* = 0.25)	6,011
	ABC Removals (P* = 0.45)	7,461
	Recent Year Average Total Catch Removals	207
Low	2014 ACL	5,645
	ABC Removals (P* = 0.25)	3,585
	ABC Removals (P* = 0.45)	4,447
	Recent Year Average Total Catch Removals	207

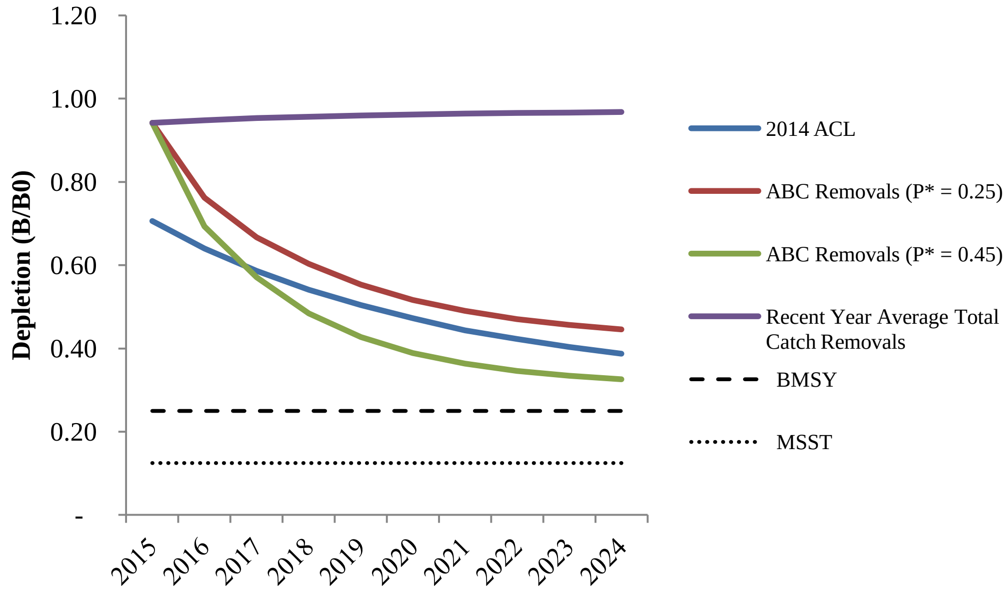

Figure 4-8. Projected depletion under alternative catch streams under the high state of nature model for English sole.

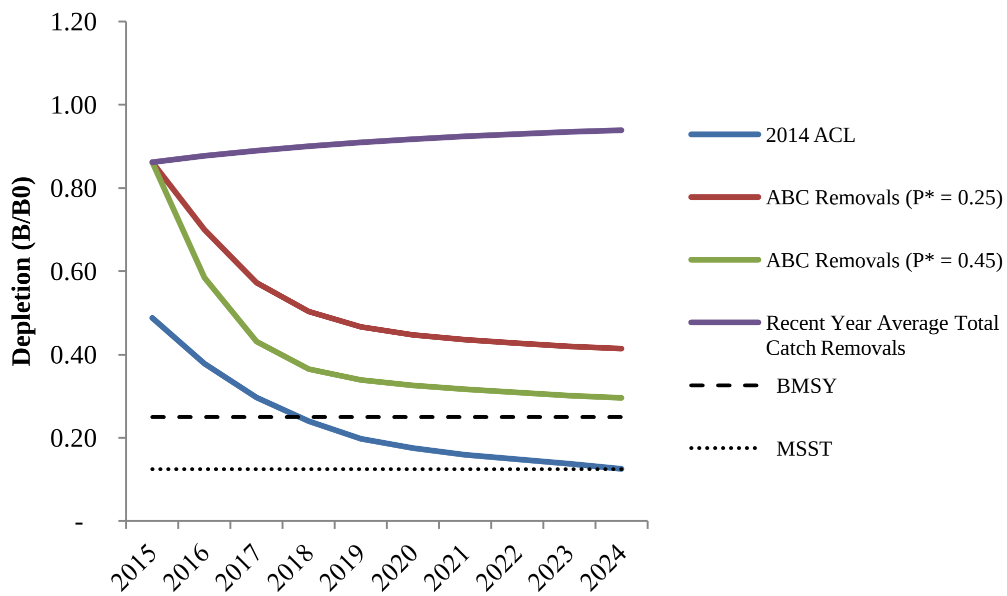

Figure 4-9. Projected depletion under alternative catch streams under the low state of nature model for English sole.

4.8.1.4 Petrale Sole

The modeled catch scenarios for petrale sole range from 939 mt per year based on the recent year average catches to an annual average catch in 2015-2024 of 3,170 mt based on the ACL = ABC with a P* of 0.45

catch scenario under the high state of nature (Table 4-4). Projected petrale sole depletions under all states of nature are sustainable assuming the respective states of nature, except the stock is estimated to be less than the target B_{MSY} depletion level in the beginning of the projection period under the base case and low state of nature models (Figure 4-10, Figure 4-11, and Figure 4-12).

Table 4-4. Predicted average annual catches (mt) in 2015-2024 by state of nature and catch scenario for petrale sole.

State of Nature	Catch Scenario	2015-24 Average Annual Catch
Base	2014 ACL (No Action Alt.) ABC Removals (P* = 0.25; Alt. 2) ABC Removals (P* = 0.45; Alt. 1; Pref. Alt.) Recent Year Average Total Catch Removals	2,652 2,522 2,771 939
High	2014 ACL ABC Removals (P* = 0.25) ABC Removals (P* = 0.45) Recent Year Average Total Catch Removals	2,652 2,919 3,170 939
Low	2014 ACL ABC Removals (P* = 0.25) ABC Removals (P* = 0.45) Recent Year Average Total Catch Removals	2,652 2,191 2,439 939

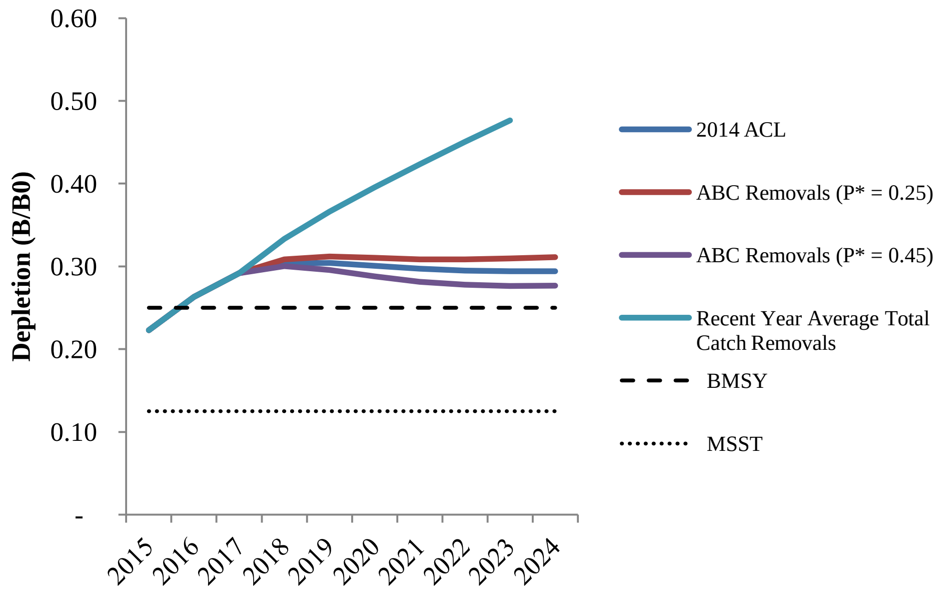

Figure 4-10. Projected depletion under alternative catch streams under the base case state of nature model for petrale sole.

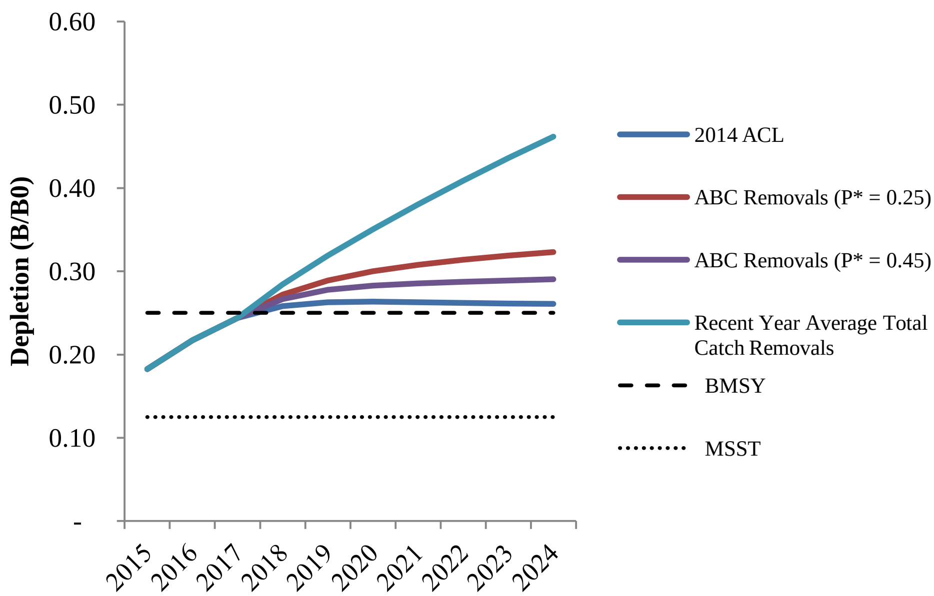

Figure 4-12. Projected depletion under alternative catch streams under the low state of nature model for petrale sole.

4.8.2 Long Term Impacts of Assessed Nearshore Rockfish Species

Of the assessed nearshore rockfish species, long term projections were not provided in time for brown, China, and copper rockfish nor for California scorpionfish. Nearshore rockfish are dominant in the non-trawl fisheries (both commercial and recreational) and therefore have a higher catch monitoring uncertainty than trawl-dominant species. The assessments are also generally more uncertain since there are no fishery-independent indices of abundance (i.e., no nearshore surveys) informing abundance trends. Most nearshore rockfish assessments rely on fishery CPUE indices and the fisheries compositional data (i.e., age and length data from sampled fisheries) to inform stock status and dynamics. Therefore, there is considerably more uncertainty in the long term projections for nearshore rockfish than for the other species analyzed in this EIS.

4.8.2.1 Black Rockfish in California and Oregon

The modeled catch scenarios for southern black rockfish off California and Oregon range from 554 mt per year based on the recent year average catches to an annual average catch in 2015-2024 of 2,032 mt based on the ACL = ABC with a P* of 0.45 catch scenario under the high state of nature (Table 4-5). Projected southern black rockfish depletions under all states of nature are sustainable assuming the respective states of nature (Figure 4-13, Figure 4-14, and Figure 4-15). Note the default harvest control rule of 1,000 mt/year cannot be accommodated under the low state of nature due to a lack of exploitable biomass at that level of harvest (Table 4-5 and Figure 4-15).

Table 4-5. Predicted average annual catches (mt) in 2015-2024 by state of nature and catch scenario for black rockfish in California and Oregon.

State of Nature	Catch Scenario	2015-24 Average Annual Catch
Base	ABC Removals (P* = 0.25; Alt. 2)	1,044
	ABC Removals (P* = 0.45; Alt. 1)	1,220
	ACL Removals (1,000 mt constant catch; No Action Alt.; Pref. Alt.)	1,000
	Recent Year Average Total Catch Removals	554
High	ABC Removals (P* = 0.25)	1,739
	ABC Removals (P* = 0.45)	2,032
	ACL Removals (1,000 mt constant catch)	1,000
	Recent Year Average Total Catch Removals	554
Low	ABC Removals (P* = 0.25)	715
	ABC Removals (P* = 0.45)	836
	Recent Year Average Total Catch Removals	554

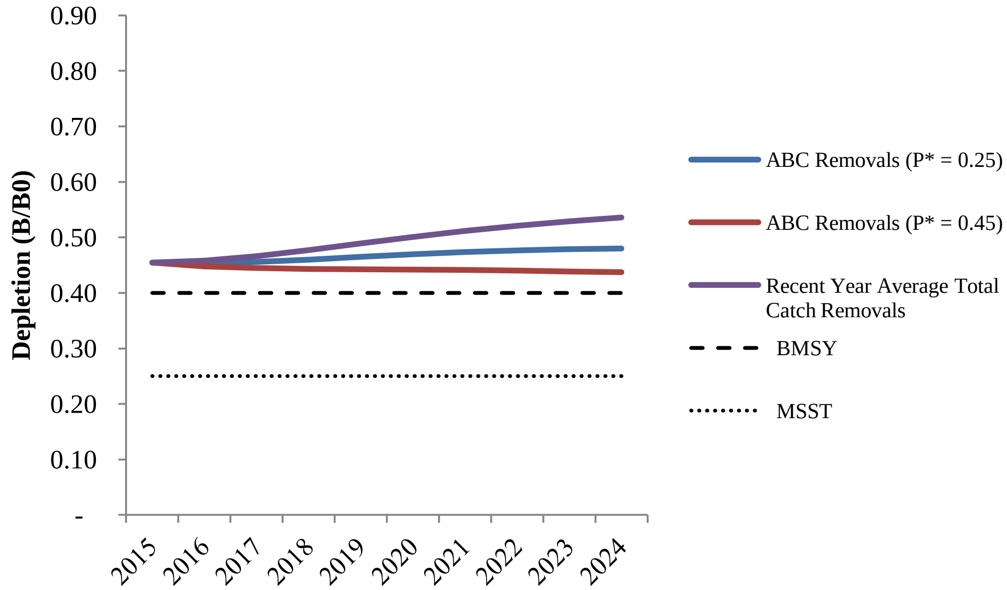

Figure 4-15. Projected depletion under alternative catch streams under the low state of nature model for black rockfish in California and Oregon.

4.8.2.2 Black Rockfish in Washington

The modeled catch scenarios for northern black rockfish off Washington range from 134 mt per year based on the ACL = ABC with a P* of 0.25 catch scenario under the low state of nature to an annual average catch in 2015-2024 of 592 mt based on the ACL = ABC with a P* of 0.45 catch scenario under the high state of nature (Table 4-6). Projected northern black rockfish depletions under the base case and high states of nature are sustainable assuming the respective states of nature (Figure 4-16 and Figure 4-17). All of these catch scenarios are under the B_{MSY} target under the low state of nature (Figure 4-18). The stock is estimated to be currently overfished under the low state of nature but projected to increase in abundance under all the catch scenarios except the constant catch of the 2014 ACL, which drives the stock to a lower abundance during the projection period (Figure 4-18).

Table 4-6. Predicted average annual catches (mt) in 2015-2024 by state of nature and catch scenario for black rockfish in Washington.

State of Nature	Catch Scenario	2015-24 Average Annual Catch
Base	2014 ACL (No Action Alt.)	409
	ABC Removals (P* = 0.25; Alt. 2)	325
	ABC Removals (P* = 0.45; Alt. 1; Pref. Alt.)	381
	ACL Removals (40-10 rule)	395
	Recent Year Average Total Catch Removals	219
High	2014 ACL	409

4.8.2.3 Gopher Rockfish South of 40º10’ N lat.

The average annual catch of gopher rockfish in 2015-2024 varies between 77 mt (the ABC removals using a P* of 0.25 for the low state of nature) to 229 mt (the 2014 ACL) (Table 4-7). The 2014 gopher

ACL contribution projected forward is not predicted to be sustainable under any of the states of nature and is predicted to drive the stock to an overfished condition under the base case and low state of nature models (Figure 4-19, Figure 4-20, and Figure 4-21). However, all the other catch scenarios are predicted to be sustainable under all the states of nature. The most likely projection is the recent year average total catch removals under the base case since access to gopher rockfish will likely be constrained by limits imposed on the entire Southern Nearshore Rockfish complex.

Table 4-7. Predicted average annual catches (mt) in 2015-2024 by state of nature and catch scenario for gopher rockfish south of 40º10’ N lat.

State of Nature	Catch Scenario	2015-24 Average Annual Catch
Base	2014 ACL (No Action Alt.)	229
	ABC Removals (P* = 0.25; Alt. 2)	139
	ABC Removals (P* = 0.45; Alt. 1; Pref. Alt.)	156

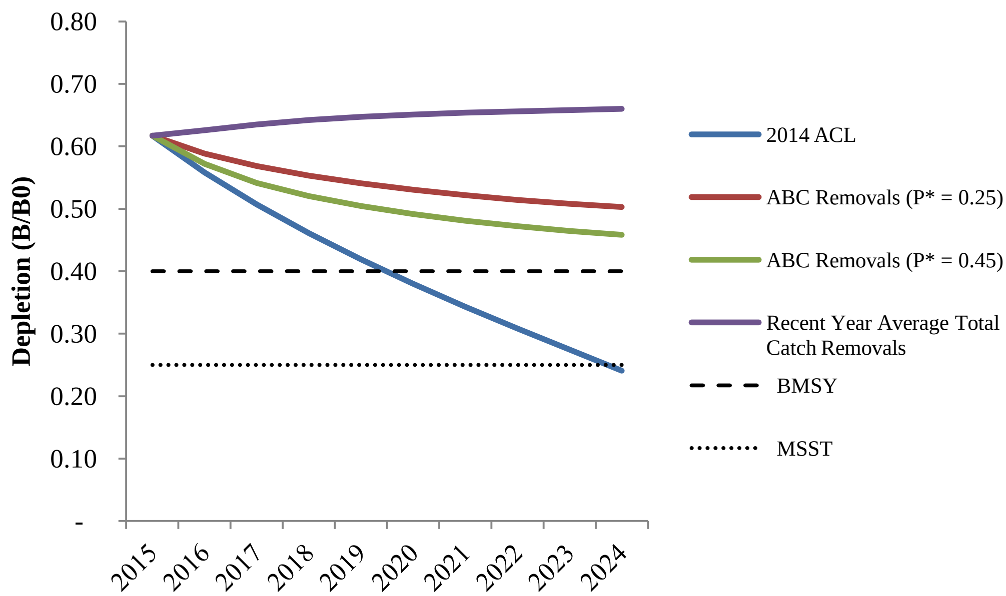

Figure 4-21. Projected depletion under alternative catch streams under the low state of nature model for gopher rockfish south of 40º10' N lat.

4.8.3 Long Term Impacts of Assessed Shelf Rockfish Species

Of the assessed shelf rockfish species, only the greenspotted rockfish projections were not provided in time for this analysis. Shelf rockfish are caught by both the trawl and fixed gear sectors, although there is some variation between species on their relative selectivities to different gears. For instance, greenstriped rockfish, while not targeted in any fishery, tend to be more readily caught in trawl gears than fixed gears. Catch monitoring precision therefore varies by species based on their relative gear selectivity with more certain catch estimation for those species dominant to the trawl fishery given the 100% observer coverage for those fleets. Current overfishing risks are low for shelf rockfish in general and have been since implementation of RCAs over ten years ago.

4.8.3.1 Bocaccio South of 40º10’ N lat.

The modeled catch scenarios for bocaccio south of 40º10’ N lat. range from 150 mt per year based on the recent year average catch scenario to an annual average catch in 2015-2024 of 1,431 mt based on the ACL = ABC with a P* of 0.45 catch scenario under the high state of nature (Table 4-8). Projected bocaccio depletions under the base case and high states of nature are sustainable assuming the respective states of nature (Figure 4-22 and Figure 4-23). All of these catch scenarios are in the precautionary zone under the B_{MSY} target at the beginning of the projection period under the low state of nature (Figure 4-24). The stock is estimated to undergo rebuilding under the low state of nature with all catch scenarios. All catch scenarios under the low state of nature except the ABC removals (under both P*s of 0.45 and 0.25) are predicted to be over the B_{MSY} target by the end of the projection period (Figure 4-24).

Table 4-8. Predicted average annual catches (mt) in 2015-2024 by state of nature and catch scenario for bocaccio south of 40º10’ N lat.

State of Nature	Catch Scenario	2015-24 Average Annual Catch
Base	2014 ACL (No Action Alt.)	338
	ABC Removals (P* = 0.25; Alt. 2)	1,127
	ABC Removals (P* = 0.45; Alt. 1)	1,314
	Recent Year Average Total Catch Removals	150
	ACL Removals (SPR = 77.7%; Pref. Alt.)	563
High	2014 ACL	338
	ABC Removals (P* = 0.25)	1,225
	ABC Removals (P* = 0.45)	1,431
	Recent Year Average Total Catch Removals	150
	ACL Removals (SPR = 77.7%)	609
Low	2014 ACL	338
	ABC Removals (P* = 0.25)	729
	ABC Removals (P* = 0.45)	839
	Recent Year Average Total Catch Removals	150
	ACL Removals (SPR = 77.7%)	383

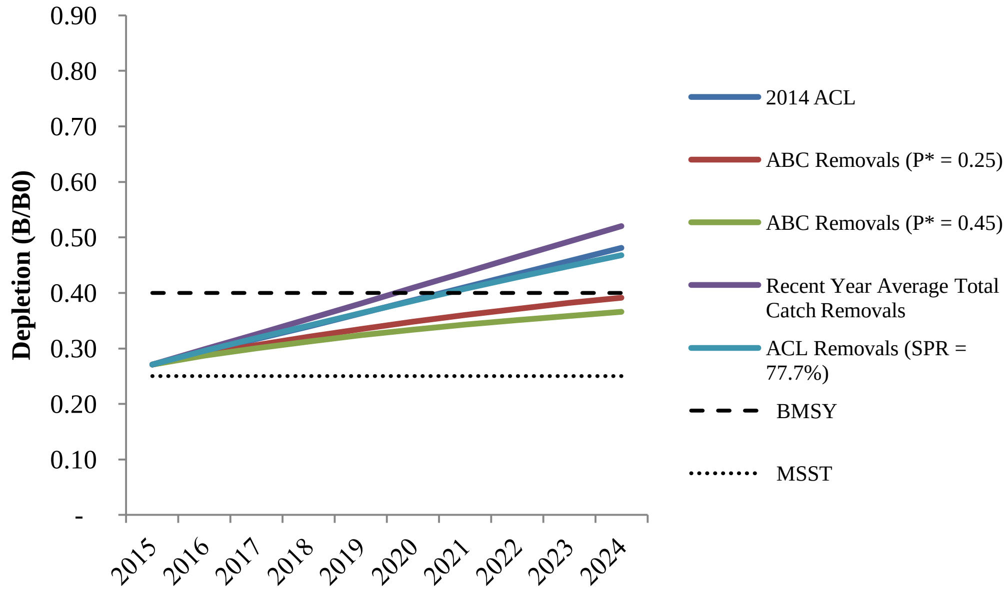

Figure 4-24. Projected depletion under alternative catch streams under the low state of nature model for bocaccio south of 40º10' N lat.

4.8.3.2 Canary Rockfish

The modeled catch scenarios for canary rockfish range from 47 mt per year based on the recent year average catch scenario to an annual average catch in 2015-2024 of 1,337 mt based on the ACL = ABC with a P* of 0.45 catch scenario under the high state of nature (Table 4-9). Projected canary rockfish depletions for all catch scenarios under the base case state of nature are shown to be in the precautionary zone and are predicted to rebuild but not by the end of the projection period (Figure 4-25). Projected canary depletions for all catch scenarios under the high state of nature are sustainable (Figure 4-26). Projected canary depletions for all catch scenarios under the low state of nature are predicted to keep the stock at very low levels of depletion under the MSST with very little or no rebuilding (Figure 4-27).

Table 4-9. Predicted average annual catches (mt) in 2015-2024 by state of nature and catch scenario for canary rockfish.

State of Nature	Catch Scenario	2015-24 Average Annual Catch
Base	2014 ACL (No Action Alt.)	119
	ABC Removals (P* = 0.25; Alt. 2)	556
	ABC Removals (P* = 0.45; Alt. 1)	652
	ACL Removals (SPR = 88.7%; Pref. Alt.)	145

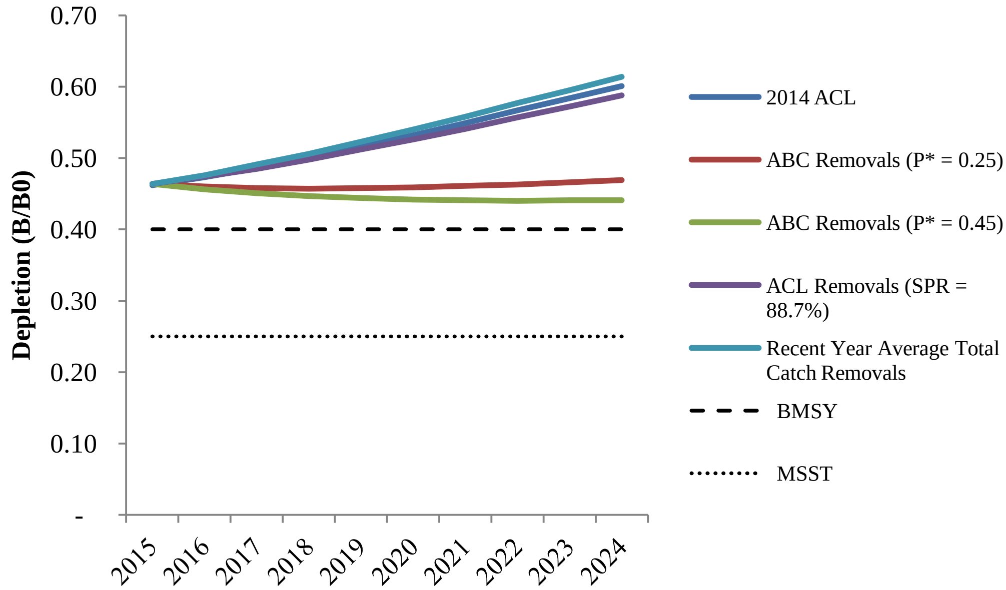

Figure 4-26. Projected depletion under alternative catch streams under the high state of nature model for canary rockfish.

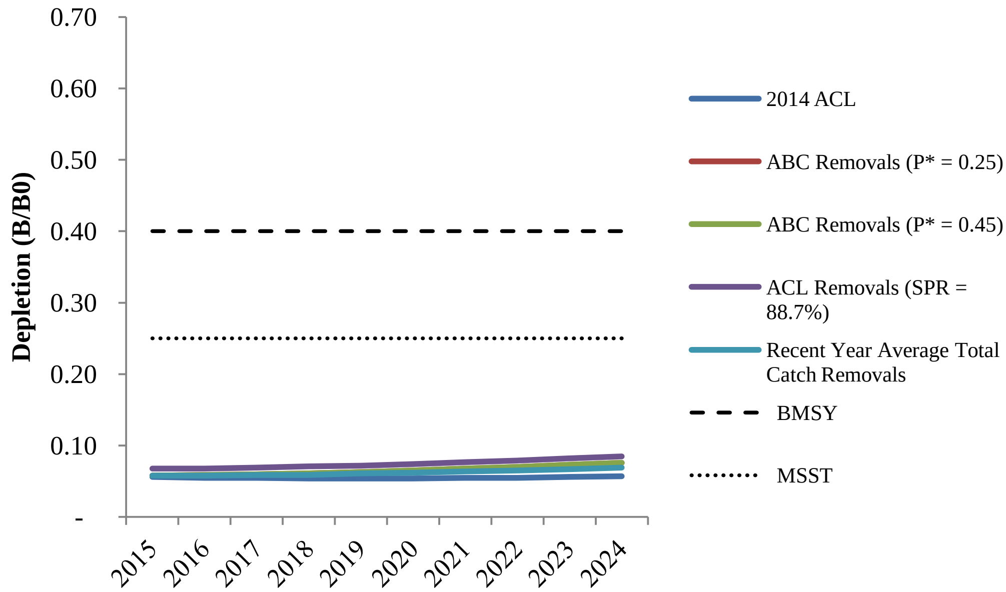

Figure 4-27. Projected depletion under alternative catch streams under the low state of nature model for canary rockfish.

4.8.3.3 Chilipepper Rockfish

The modeled catch scenarios for chilipepper range from 330 mt per year based on the recent year average catches to an annual average catch in 2015-2024 of 2,252 mt based on the ACL = ABC with a P* of 0.45

catch scenario under the high state of nature (Table 4-10). Projected chilipepper depletions under all states of nature are sustainable during the projection period assuming the respective states of nature except for the ABC removals at a P* of 0.45 under the low state of nature, which causes the stock to drop below the B_{MSY} threshold into the precautionary zone (Figure 4-28, Figure 4-29, and Figure 4-30).

Table 4-10. Predicted average annual catches (mt) in 2015-2024 by state of nature and catch scenario for chilipepper rockfish.

State of Nature	Catch Scenario	2015-24 Average Annual Catch
Base	2014 ACL (No Action Alt.)	1,618
	ABC Removals (P* = 0.25; Alt. 2)	1,922
	ABC Removals (P* = 0.45; Alt. 1; Pref. Alt.)	2,216

4.8.3.4 Cowcod

While the management unit for the cowcod stock managed under the rebuilding plan is for the population south of 40º10’ N lat., the long term projections analyzed in this section are only for the assessed population south of Pt. Conception at 34º27' N lat. The range of average annual cowcod catch contributions in 2015-2024 from the Southern California Bight across the catch scenarios analyzed and states of nature modeled in the 2013 assessment is 1-93 mt (Table 4-11). The stock is projected to rebuild under the base case scenario for all catch scenarios except the highest one (ACL = ABC using a P* of 0.45), where the biomass trends to a slightly lower depletion (Figure 4-31). All the ABC removal scenarios are predicted to keep the stock in the precautionary zone, while the lower catch scenarios (i.e., 2014 ACL, ACL removal using an SPR rate of 82.7% (or equivalent exploitation fraction[1]), and recent year average total catch removals) are predicted to rebuild the stock within the next ten years. The stock is estimated to be healthy with all catch scenarios being sustainable under the high state of nature (Figure 4-32). In contrast, the estimated depletion under the low state of nature is below the MSST with a slightly increasing trend under all catch scenarios (Figure 4-33). None of the catch scenarios under the low state of nature are predicted to rebuild the stock within ten years, although the lower catch streams up to the ABC removals using a P* of 0.25 are predicted to increase biomass above the MSST within ten years.

Table 4-11. Predicted average annual catches (mt) in 2015-2024 by state of nature and catch scenario for cowcod south of 34º27' N lat.

State of Nature	Catch Scenario	2015-24 Average Annual Catch
Base	2014 ACL (No Action Alt.)	2
	ABC Removals (P* = 0.25; Alt. 2)	35
	ABC Removals (P* = 0.4)	46
	ABC Removals (P* = 0.45; Alt. 1)	49
	ACL Removals (SPR = 82.7% in Conception area; Pref. Alt.)	9
	Recent Year Average Total Catch Removals	1
High	2014 ACL	2
	ABC Removals (P* = 0.25)	68
	ABC Removals (P* = 0.4)	86
	ABC Removals (P* = 0.45)	93
	ACL Removals (SPR = 82.7% in Conception area)	12
	Recent Year Average Total Catch Removals	1
Low	2014 ACL	2
	ABC Removals (P* = 0.25)	15
	ABC Removals (P* = 0.4)	21
	ABC Removals (P* = 0.45)	22
	ACL Removals (SPR = 82.7% in Conception area)	6
	Recent Year Average Total Catch Removals	1

[1] The 2013 cowcod assessment was conducted in an XDB-SRA platform which does not accommodate SPR harvest rates. Therefore, the 2013 cowcod rebuilding analysis calculated an equivalent exploitation fraction of allowable harvest/age 11+ biomass to the status quo SPR harvest rate of 82.7% (E = 0.007) to project impacts.

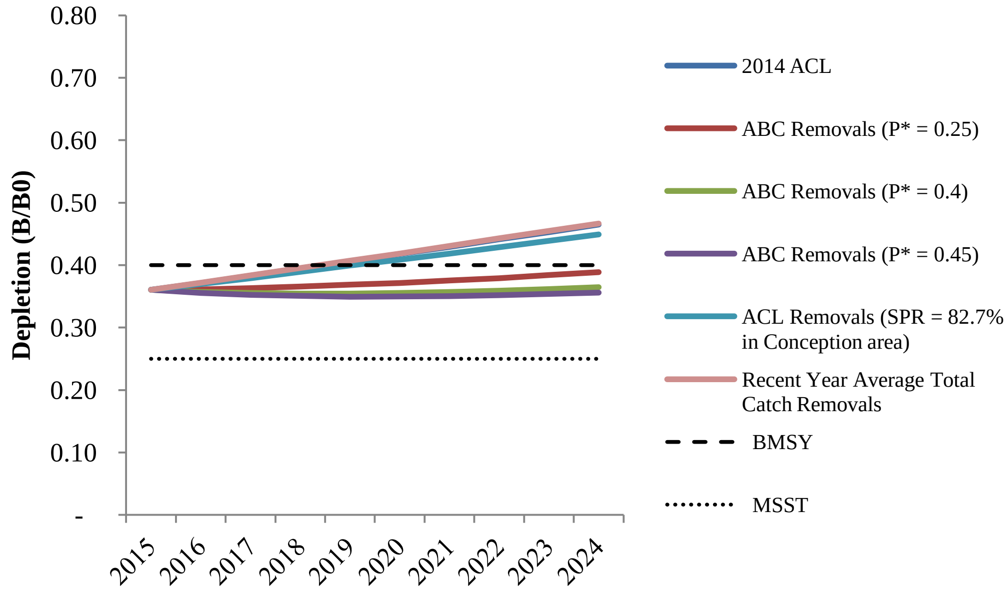

Figure 4-31. Projected depletion under alternative catch streams under the base case state of nature model for cowcod south of 34º27' N lat.

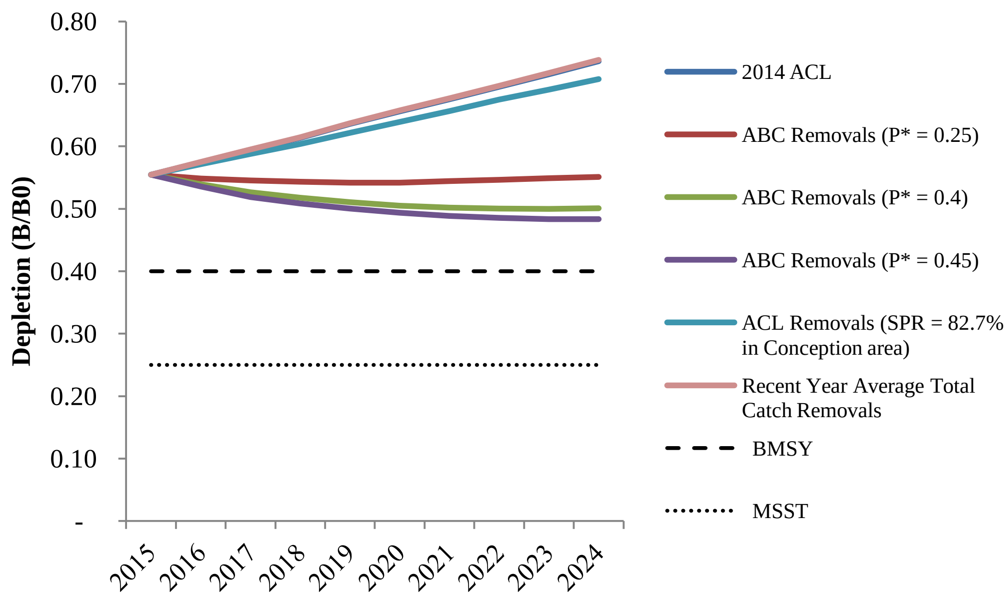

Figure 4-32. Projected depletion under alternative catch streams under the high state of nature model for cowcod south of 34º27' N lat.

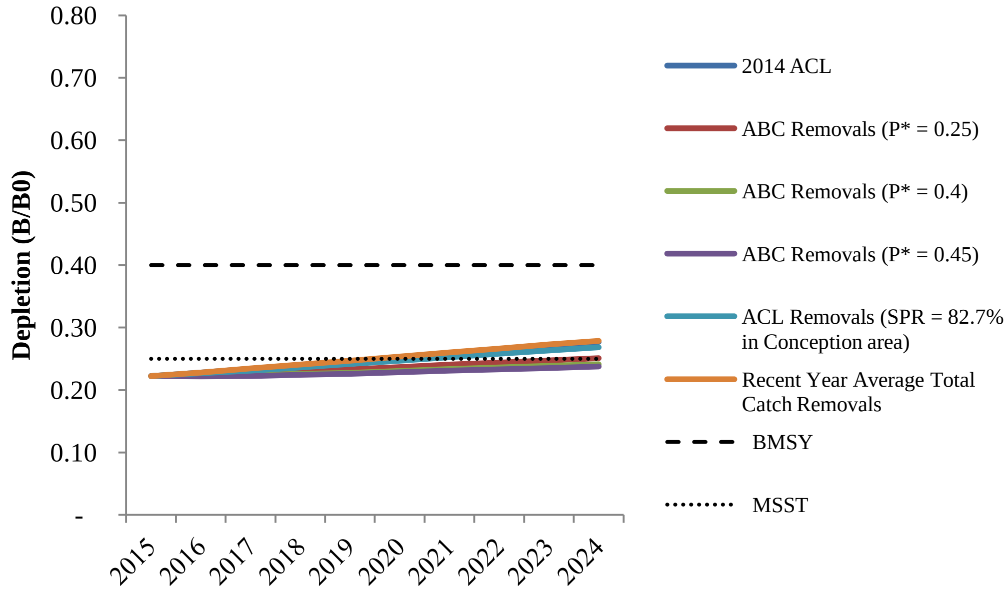

Figure 4-33. Projected depletion under alternative catch streams under the low state of nature model for cowcod south of 34º27' N lat.

4.8.3.5 Greenstriped Rockfish

The modeled catch scenarios for greenstriped rockfish range from 21 mt per year based on the recent year average catches to an annual average catch in 2015-2024 of 10,211 mt based on the ACL = ABC with a P* of 0.45 catch scenario under the high state of nature (Table 4-12). Projected greenstriped depletions under all catch scenarios and states of nature are predicted to be sustainable (Figure 4-34, Figure 4-35, and Figure 4-36). The most likely trajectory for greenstriped is the recent year average total catch scenario under the base case model since greenstriped are not targeted and do not tend to aggregate, which might otherwise cause sporadically high catches.

Table 4-12. Predicted average annual catches (mt) in 2015-2024 by state of nature and catch scenario for greenstriped rockfish.

State of Nature	Catch Scenario	2015-24 Average Annual Catch
Base	ABC Removals (P* = 0.25; Alt. 2)	857
	ABC Removals (P* = 0.45; Alt. 1; Pref. Alt.)	1,201
	Recent Year Average Total Catch Removals	21
High	ABC Removals (P* = 0.25)	7,365
	ABC Removals (P* = 0.45)	10,211
	Recent Year Average Total Catch Removals	21
Low	ABC Removals (P* = 0.25)	156
	ABC Removals (P* = 0.45)	221
	Recent Year Average Total Catch Removals	21

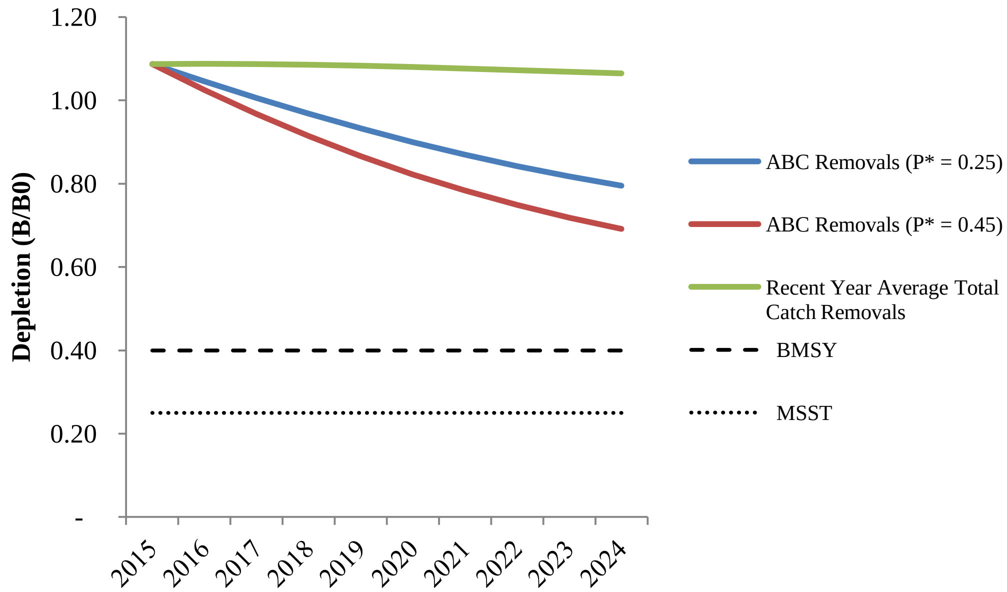

Figure 4-35. Projected depletion under alternative catch streams under the high state of nature model for greenstriped rockfish.

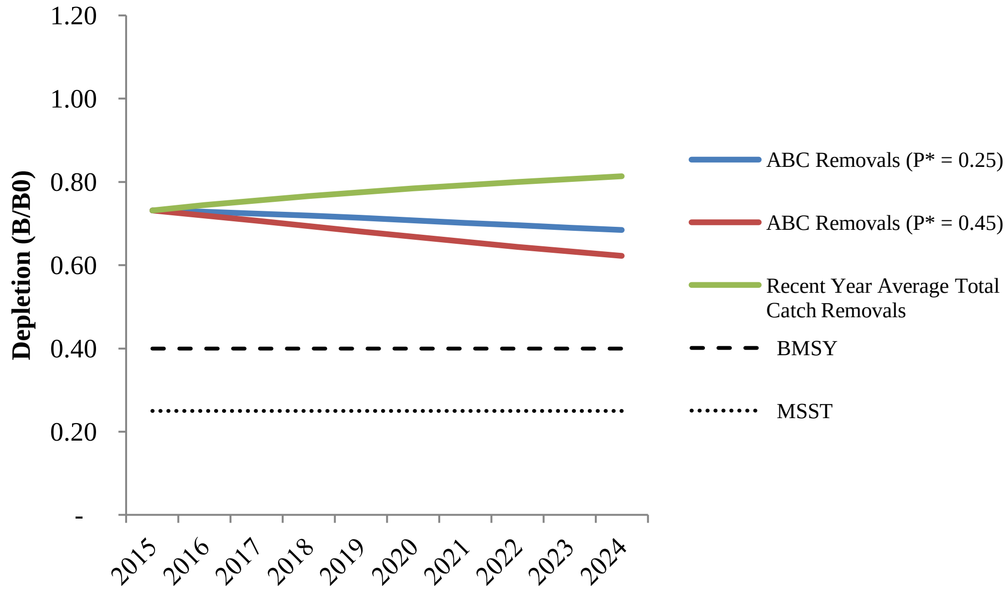

Figure 4-36. Projected depletion under alternative catch streams under the low state of nature model for greenstriped rockfish.

4.8.3.6 Widow Rockfish

The modeled catch scenarios for widow rockfish range from 247 mt per year based on the recent year average catches to an annual average catch in 2015-2024 of 4,648 mt based on the ACL = ABC with a P* of 0.45 catch scenario under the high state of nature (Table 4-13). Projected widow depletions under the base case and high states of nature are sustainable during the projection period assuming the respective states of nature (Figure 4-37 and Figure 4-38). Projected widow depletions under the low state of nature keeps the stock in the precautionary zone during the projection period (Figure 4-39). All the catch scenarios except the 3,000 mt constant catch scenario under the low state of nature predict some stock rebuilding. The 3,000 mt constant catch scenario under the low state of nature is predicted to reach an asymptote at the MSST during the projection period (Figure 4-39).

Table 4-13. Predicted average annual catches (mt) in 2015-2024 by state of nature and catch scenario for widow rockfish.

State of Nature	Catch Scenario	2015-24 Average Annual Catch
Base	ABC Removals (P* = 0.25; Alt. 2)	3,709
	ABC Removals (P* = 0.45; Alt. 1)	4,402
	Recent Year Average Total Catch Removals	247
	ACL Removals (1,500 mt constant catch; No Action Alt.)	1,500
	ACL Removals (3,000 mt constant catch)	3,000
High	ABC Removals (P* = 0.25)	3,915
	ABC Removals (P* = 0.45)	4,648
	Recent Year Average Total Catch Removals	247
	ACL Removals (1,500 mt constant catch)	1,500
	ACL Removals (3,000 mt constant catch)	3,000
Low	ABC Removals (P* = 0.25)	2,131
	ABC Removals (P* = 0.45)	2,493
	Recent Year Average Total Catch Removals	247
	ACL Removals (1,500 mt constant catch)	1,500
	ACL Removals (3,000 mt constant catch)	3,000

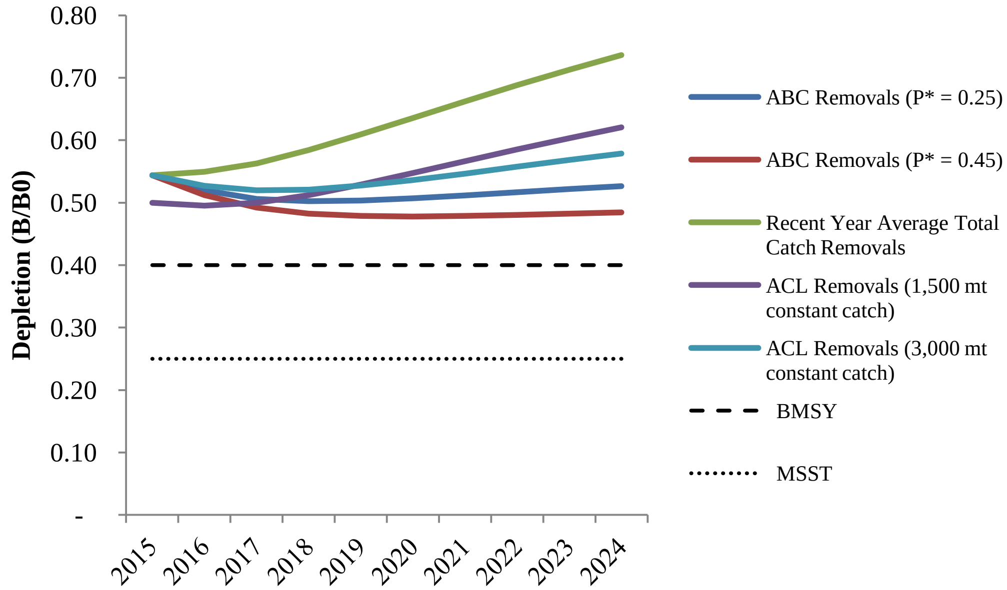

Figure 4-38. Projected depletion under alternative catch streams under the high state of nature model for widow rockfish.

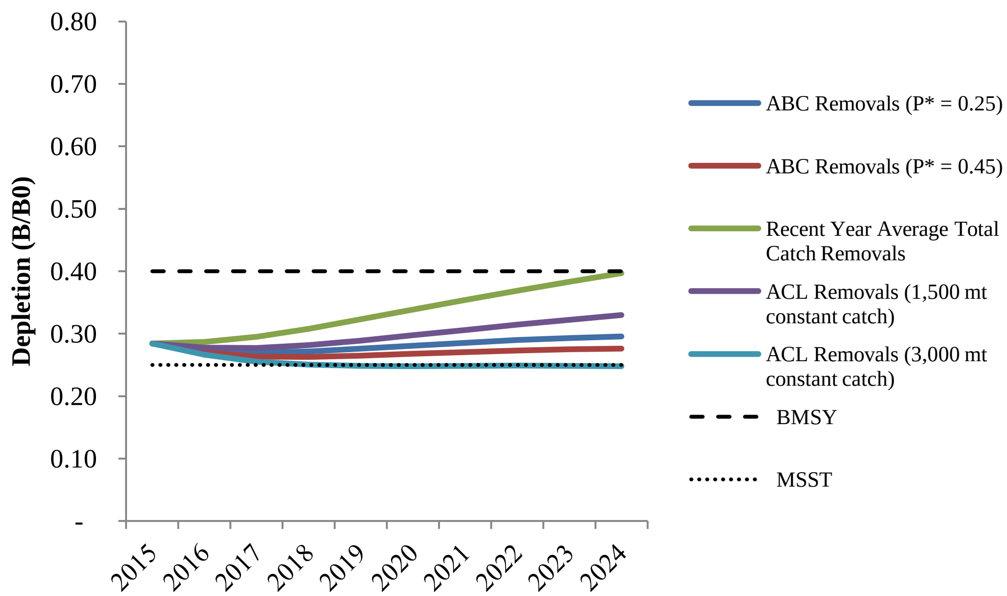

Figure 4-39. Projected depletion under alternative catch streams under the low state of nature model for widow rockfish.

4.8.3.7 Yelloweye Rockfish

The modeled catch scenarios for yelloweye rockfish range from 10 mt per year based on the recent year average catch scenario to an annual average catch in 2015-2024 of 76 mt based on the ACL = ABC with a

P* of 0.45 catch scenario under the high state of nature (Table 4-14). Projected yelloweye rockfish depletions for all catch scenarios under the base case state of nature are predicted to undergo rebuilding and increase in abundance from below the MSST into the precautionary zone during the projection period (Figure 4-40). Projected yelloweye depletions for all catch scenarios under the high state of nature are predicted to keep the stock in the precautionary zone during the projection period (Figure 4-41). Projected yelloweye depletions for all catch scenarios under the low state of nature are predicted to keep the stock at very low levels of depletion under the MSST with very little or no rebuilding (Figure 4-42).

Table 4-14. Predicted average annual catches (mt) in 2015-2024 by state of nature and catch scenario for yelloweye rockfish.

State of Nature	Catch Scenario	2015-24 Average Annual Catch
Base	2014 ACL (No Action Alt.)	18
	ABC Removals (P* = 0.25; Alt. 2)	29
	ABC Removals (P* = 0.45; Alt. 1)	41
	ACL Removals (SPR = 76%; Pref. Alt.)	19

4.8.3.8 Yellowtail Rockfish North of 40º10' N lat.

The modeled catch scenarios for yellowtail rockfish north of 40º10' N lat. range from 1,551 mt per year based on the recent year average catches to an annual average catch in 2015-2024 of 9,805 mt based on the ACL = ABC with a P* of 0.45 catch scenario under the high state of nature (Table 4-15). Projected yellowtail rockfish depletions under all states of nature are sustainable assuming the respective states of nature (Figure 4-43, Figure 4-44, and Figure 4-45).

Table 4-15. Predicted average annual catches (mt) in 2015-2024 by state of nature and catch scenario for yellowtail rockfish north of 40º10' N lat.

State of Nature	Catch Scenario	2015-24 Average Annual Catch
Base	2014 ACL (No Action Alt.)	4,382

4.8.4 Long Term Impacts of Assessed Slope Rockfish Species

4.8.4.1 Aurora Rockfish

The modeled catch scenarios for aurora rockfish range from 34 mt per year based on the 2014 ACL contribution (based on a data-poor OFL that preceded the OFL estimated from the 2013 assessment and a 16.6% ABC deduction from the OFL based on the stock then being categorized as a cat. 3 stock under a P* of 0.45) to an annual average catch in 2015-2024 of 144 mt based on the ACL = ABC with a P* of 0.45 catch scenario under the high state of nature (Table 4-16). Projected aurora rockfish depletions under all states of nature are sustainable assuming the respective states of nature (Figure 4-46, Figure 4-47, and Figure 4-48).

Table 4-16. Predicted average annual catches (mt) in 2015-2024 by state of nature and catch scenario for aurora rockfish.

State of Nature	Catch Scenario	2015-24 Average Annual Catch
Base	2014 ACL contribution (No Action Alt.)	34
	ABC Removals (P* = 0.25; Alt. 2)	72
	ABC Removals (P* = 0.45; Alt. 1; Pref. Alt.)	87
	Recent Year Average Total Catch Removals	46
High	2014 ACL contribution	34

4.8.4.2 Blackgill Rockfish South of 40º10' N lat.

The modeled catch scenarios for blackgill rockfish south of 40º10' N lat. range from an annual average catch of 55 mt per year based on the ACL = ABC with a P* of 0.25 catch scenario under the low state of nature to an annual average catch in 2015-2024 of 224 mt based on the ACL = ABC with a P* of 0.45 catch scenario under the high state of nature (Table 4-17). Projected blackgill rockfish depletions under the base case state of nature for all catch scenarios keep the stock within the precautionary zone during the projection period except for the ABC removals under a P* of 0.25, where the depletion is projected to rebuild to the B_{MSY} threshold by the end of the projection period (Figure 4-49). Projected blackgill rockfish depletions under the high state of nature are sustainable for all catch scenarios (Figure 4-50). Projected blackgill rockfish depletions under the low state of nature for all catch scenarios are predicted to rebuild from below the MSST into the precautionary zone during the projection period (Figure 4-51).

Table 4-17. Predicted average annual catches (mt) in 2015-2024 by state of nature and catch scenario for blackgill rockfish south of 40°10' N lat.

State of Nature	Catch Scenario	2015-24 Average Annual Catch

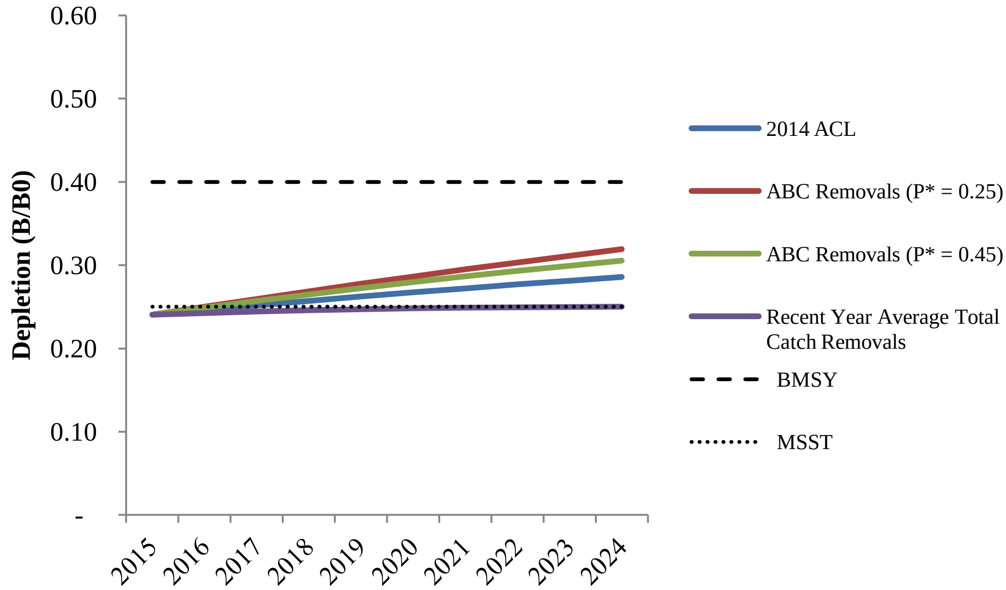

Figure 4-51. Projected depletion under alternative catch streams under the low state of nature model for blackgill rockfish south of 40º10' N lat.

4.8.4.3 Darkblotched Rockfish

The modeled catch scenarios for darkblotched rockfish range from an annual average catch of 108 mt per year based on the recent year average catch scenario to an annual average catch in 2015-2024 of 2,003 mt based on the ACL = ABC with a P* of 0.45 catch scenario under the high state of nature (Table 4-18). Projected darkblotched rockfish depletions under the base case and high states of nature for all catch scenarios are predicted to be sustainable during the projection period (Figure 4-52 and Figure 4-53). Projected darkblotched rockfish depletions under the low state of nature for all catch scenarios are predicted to rebuild from below the MSST into the precautionary zone during the projection period (Figure 4-54).

Table 4-18. Predicted average annual catches (mt) in 2015-2024 by state of nature and catch scenario for darkblotched rockfish.

State of Nature	Catch Scenario	2015-24 Average Annual Catch
Base	2014 ACL (No Action Alt.)	330
	ABC Removals (P* = 0.25; Alt. 2)	484

4.8.4.4 Longspine Thornyheads

The modeled catch scenarios for longspine thornyheads range from an annual average catch of 942 mt per year based on the recent year average catch scenario to an annual average catch in 2015-2024 of 6,620 mt based on the ACL = ABC with a P* of 0.45 catch scenario under the high state of nature (Table 4-19). Projected longspine thornyhead depletions under all states of nature for all catch scenarios are predicted to be sustainable during the projection period (Figure 4-55, Figure 4-56, and Figure 4-57).

Table 4-19. Predicted average annual catches (mt) in 2015-2024 by state of nature and catch scenario for longspine thornyheads.

State of Nature	Catch Scenario	2015-24 Average Annual Catch
Base	2014 ACL (No Action Alt.)	2,305
	ABC Removals (P* = 0.25; Alt. 2)	2,683
	ABC Removals (P* = 0.4; Pref. Alt.)	3,395
	ABC Removals (P* = 0.45; Alt. 1)	3,631

4.8.4.5 Pacific Ocean Perch

The modeled catch scenarios for Pacific ocean perch range from 59 mt per year based on the recent year average catch scenario to an annual average catch in 2015-2024 of 1,805 mt based on the ACL = ABC with a P* of 0.45 catch scenario under the high state of nature (Table 4-20). Projected POP depletions for all catch scenarios except the ABC removals (both the P* of 0.25 and 0.45 scenarios) under the base case state of nature are predicted to undergo rebuilding and increase in abundance from below the MSST into the precautionary zone during the projection period; the ABC removal scenarios keep the stock below the MSST during the projection period (Figure 4-58). Projected POP depletions for all catch scenarios under the high state of nature are predicted to be sustainable during the projection period (Figure 4-59). Projected POP depletions for all catch scenarios under the low state of nature are predicted to keep the stock at very low levels of depletion under the MSST with very little or no rebuilding (Figure 4-60).

Table 4-20. Predicted average annual catches (mt) in 2015-2024 by state of nature and catch scenario for Pacific ocean perch.

State of Nature	Catch Scenario	2015-24 Average Annual Catch

4.8.4.6 Rougheye/Blackspotted Rockfish

The modeled catch scenarios for rougheye/blackspotted rockfish range from an annual average catch of 60 mt per year based on the 2014 ACL contribution (based on a data-poor OFL that preceded the OFL estimated from the 2013 assessment and a 16.6% ABC deduction from the OFL based on the stock then being categorized as a cat. 3 stock under a P* of 0.45) to an annual average catch in 2015-2024 of 319 mt based on the ACL = ABC with a P* of 0.45 catch scenario under the high state of nature (Table 4-21). Projected rougheye/blackspotted rockfish depletions under the base case and high states of nature for all catch scenarios are predicted to be sustainable during the projection period (Figure 4-61 and Figure 4-62). Projected rougheye/blackspotted rockfish depletions under the low state of nature for all catch scenarios are predicted to rebuild from the precautionary zone to above the B_{MSY} threshold during the projection period (Figure 4-63).

4.8.5 Long Term Impacts of Assessed Roundfish Species

Of the assessed roundfish species, only cabezon in California is missing from this analysis.

4.8.5.1 Cabezon in Oregon

The modeled catch scenarios for cabezon in Oregon range from 24 mt per year based on the ACL = ABC with a P* of 0.25 catch scenario under the low state of nature to an annual average catch in 2015-2024 of 88 mt based on the ACL = ABC with a P* of 0.45 catch scenario under the high state of nature (Table 4-25). Projected Oregon cabezon depletions under the base case and high states of nature for all catch scenarios are predicted to be sustainable during the projection period (Figure 4-73 and Figure 4-74). Projected Oregon cabezon depletions under the low state of nature for the ABC removals with a P* of 0.25 catch scenario is predicted to rebuild from below the MSST to above the B_{MSY} threshold during the projection period (Figure 4-75). The ABC removals with a P* of 0.45 under the low state of nature is predicted to rebuild the stock from below the MSST but keeps the stock in the precautionary zone during the projection period (Figure 4-75). The 2014 ACL and recent year average catch scenarios are predicted to drive the stock to lower levels of depletion below the MSST under the low state of nature (Figure 4-75).

Table 4-25. Predicted average annual catches (mt) in 2015-2024 by state of nature and catch scenario for cabezon in Oregon.

State of Nature	Catch Scenario	2015-24 Average Annual Catch

4.8.5.2 Lingcod North of 40º10' N lat.

The modeled catch scenarios for lingcod north of 40º10' N lat. range from an annual average catch of 893 mt per year based on the recent year average catch scenario to an annual average catch in 2015-2024 of 3,696 mt based on the ACL = ABC with a P* of 0.45 catch scenario under the high state of nature (Table 4-26). Projected northern lingcod depletions under all states of nature for all catch scenarios are predicted to be sustainable during the projection period (Figure 4-76, Figure 4-77, and Figure 4-78).

Table 4-26. Predicted average annual catches (mt) in 2015-2024 by state of nature and catch scenario for lingcod north of 40º10' N lat.

State of Nature	Catch Scenario	2015-24 Average Annual Catch
Base	2014 ACL (No Action Alt.)	2,878
	ABC Removals (P* = 0.25; Alt. 2)	2,499
	ABC Removals (P* = 0.45; Alt. 1; Pref. Alt.)	3,060
	Recent Year Average Total Catch Removals	893
High	2014 ACL	2,878
	ABC Removals (P* = 0.25)	3,002
	ABC Removals (P* = 0.45)	3,696
	Recent Year Average Total Catch Removals	893
Low	2014 ACL	2,878
	ABC Removals (P* = 0.25)	2,115
	ABC Removals (P* = 0.45)	2,570
	Recent Year Average Total Catch Removals	893

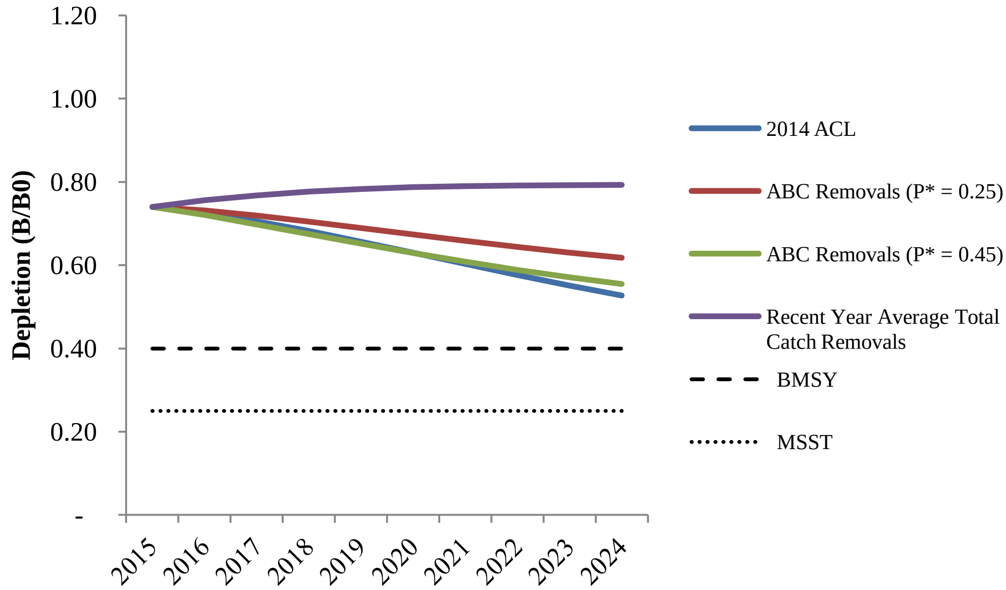

Figure 4-78. Projected depletion under alternative catch streams under the low state of nature model for lingcod north of 40º10' N lat.

4.8.5.3 Lingcod South of 40º10' N lat.

The modeled catch scenarios for lingcod south of 40º10' N lat. range from an annual average catch of 175 mt per year based on the recent year average catch scenario to an annual average catch in 2015-2024 of 1,624 mt based on the ACL = ABC with a P* of 0.45 catch scenario under the high state of nature (Table 4-27). Projected southern lingcod depletions under all states of nature for all catch scenarios are predicted to be sustainable during the projection period (Figure 4-79, Figure 4-80, and Figure 4-81).

Table 4-27. Predicted average annual catches (mt) in 2015-2024 by state of nature and catch scenario for lingcod south of 40°10' N lat.

State of Nature	Catch Scenario	2015-24 Average Annual Catch
Base	2014 ACL (No Action Alt.)	1,063
	ABC Removals (P* = 0.25; Alt. 2)	859
	ABC Removals (P* = 0.4; Pref. Alt.)	1,092

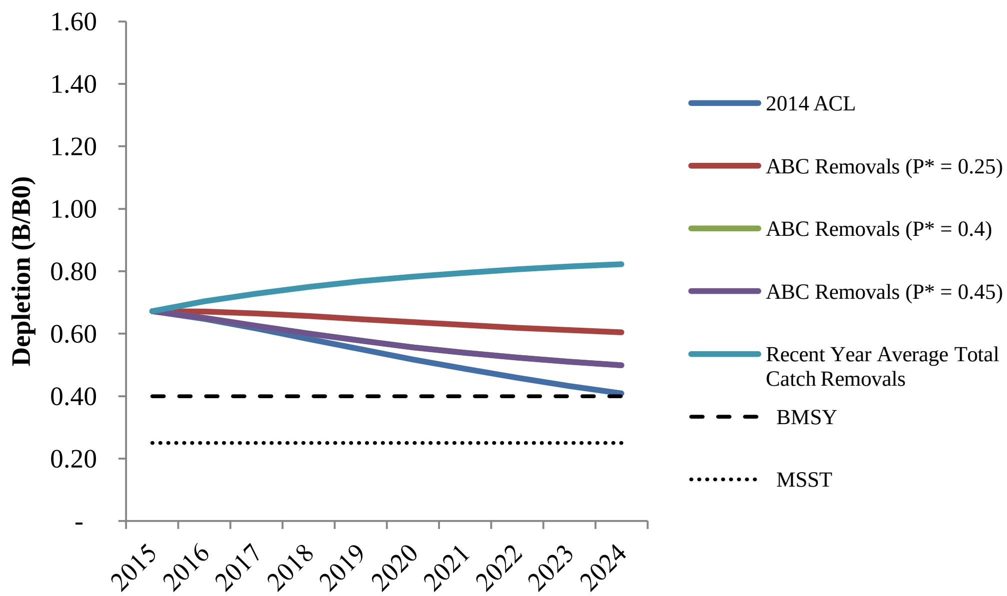

Figure 4-81. Projected depletion under alternative catch streams under the low state of nature model for lingcod south of 40º10' N lat.

4.8.5.4 Sablefish

The modeled catch scenarios for sablefish range from 4,086 mt per year based on the ACL = ABC with a P* of 0.25 catch scenario under the low state of nature to an annual average catch in 2015-2024 of 12,335 mt based on the ACL = ABC with a P* of 0.45 catch scenario under the high state of nature (Table 4-28). Projected sablefish depletions for all catch scenarios under the base case state of nature are predicted to increase in abundance but remain in the precautionary zone during the projection period (Figure 4-82). Projected sablefish depletions for all catch scenarios under the high state of nature are predicted to be sustainable during the projection period (Figure 4-83). Projected sablefish depletions for all catch scenarios under the low state of nature are predicted to keep the stock at very low levels of depletion under the MSST with very little or no rebuilding (Figure 4-84).

Table 4-28. Predicted average annual catches (mt) in 2015-2024 by state of nature and catch scenario for sablefish.

State of Nature	Catch Scenario	2015-24 Average Annual Catch
Base	2014 ACL (No Action Alt.)	5,909
	ABC Removals (P* = 0.25; Alt. 2)	7,358
	ABC Removals (P* = 0.45; Alt. 1)	8,542
	ABC Removals (P*= 0.4; Pref. Alt.)	8,258
High	2014 ACL	5,909
	ABC Removals (P* = 0.25)	10,630
	ABC Removals (P* = 0.45)	12,335
	ABC Removals (P*= 0.4)	11,926
Low	2014 ACL	5,909
	ABC Removals (P* = 0.25)	4,086
	ABC Removals (P* = 0.45)	4,749
	ABC Removals (P*= 0.4)	4,590

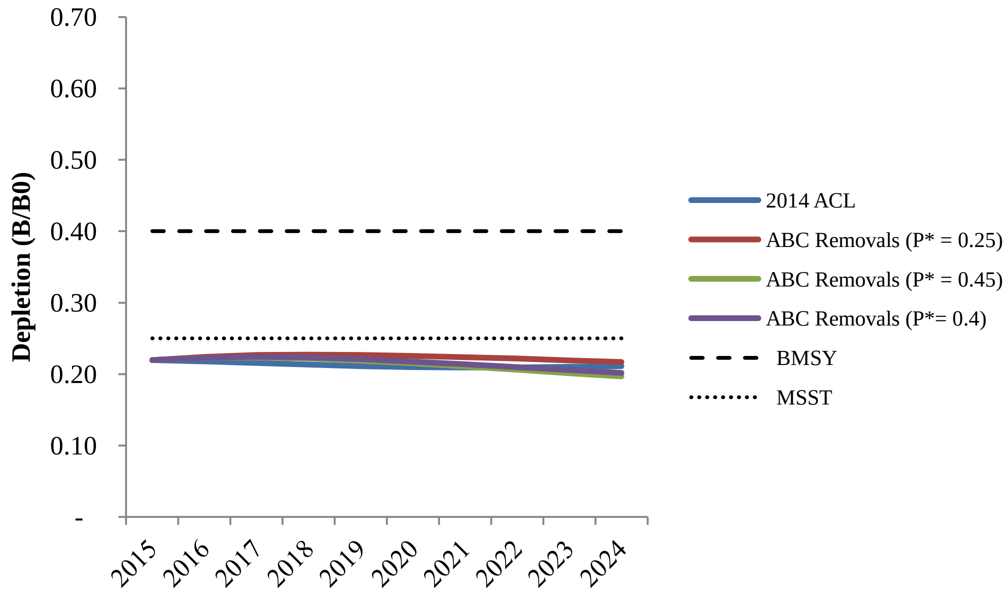

Figure 4-84. Projected depletion under alternative catch streams under the low state of nature model for sablefish.

4.8.6 Long Term Impacts of Assessed Elasmobranch Species

4.8.6.1 Longnose Skate

The modeled catch scenarios for longnose skate range from an annual average catch of 999 mt per year based on the recent year average catch scenario to an annual average catch in 2015-2024 of 2,892 mt based on the ACL = ABC with a P* of 0.45 catch scenario under the high state of nature (Table 4-29). Projected longnose skate depletions under the base case and high states of nature for all catch scenarios are predicted to be sustainable during the projection period (Figure 4-85 and Figure 4-86). Projected longnose skate depletions under the low state of nature for the recent year average catch scenario is predicted to be sustainable, but the other catch scenarios are predicted to drive the stock below the B_{MSY} threshold and into the precautionary zone during the projection period (Figure 4-87).

Table 4-29. Predicted average annual catches (mt) in 2015-2024 by state of nature and catch scenario for longnose skate.

State of Nature	Catch Scenario	2015-24 Average Annual Catch
Base	ABC Removals (P* = 0.25; Alt. 2)	2,014
	ABC Removals (P* = 0.45; Alt. 1)	2,382
	ACL Removals (2,000 mt constant catch; No Action Alt.; Pref. Alt.)	2,000
	Recent Year Average Total Catch Removals	999
High	ABC Removals (P* = 0.25)	2,446
	ABC Removals (P* = 0.45)	2,892
	ACL Removals (2,000 mt constant catch)	2,000
	Recent Year Average Total Catch Removals	999

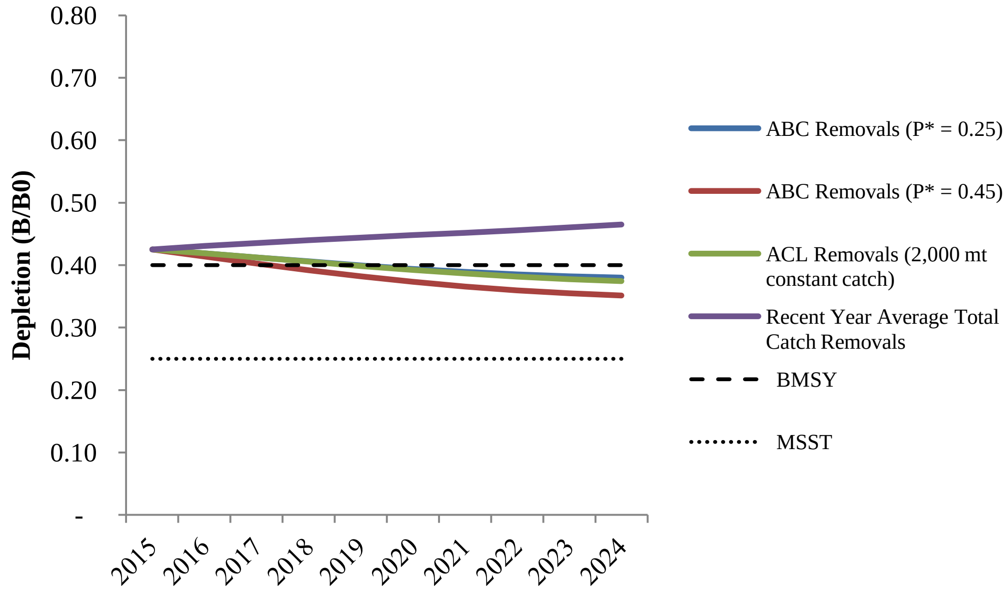

Figure 4-87. Projected depletion under alternative catch streams under the low state of nature model for longnose skate.

4.8.6.2 Spiny Dogfish

The modeled catch scenarios for spiny dogfish range from an annual average catch of 482 mt per year based on the ACL = ABC with a P* of 0.25 catch scenario under the low state of nature to an annual average catch in 2015-2024 of 5,503 mt based on the ACL = ABC with a P* of 0.45 catch scenario under the high state of nature (Table 4-30). Projected spiny dogfish depletions under the base case and high states of nature for all catch scenarios are predicted to be sustainable during the projection period (Figure 4-88 and Figure 4-89). Projected spiny dogfish depletions for all catch scenarios under the low state of nature are predicted to keep the stock in the precautionary zone during the projection period (Figure 4-90).

Table 4-30. Predicted average annual catches (mt) in 2015-2024 by state of nature and catch scenario for spiny dogfish.

State of Nature	Catch Scenario	2015-24 Average Annual Catch

Agenda Item F.7.a
Supplemental Attachment 13
June 2014

RECOMMENDED CLARIFICATION IN PROPOSED AMENDMENT 24 FMP LANGUAGE CHANGES

For Amendment 24 Alternatives 1, 2, 3 (see Agenda Item F.7.a, Attachment 8, June 2014), the following change in the proposed amendment language for Section 5.1 is recommended. The recommended change would replace the third sentence from the end of the first paragraph of proposed amendment language in Section 5.1. The current proposed language and the recommended revision is the same in all three action alternatives.

Original Sentence (see Agenda Item F.7.a, Attachment 8, June 2014)

If the status is not known, the same method used in the previous cycle is used to compute the default HCR.

Recommended Revised Sentences

If the status has not changed or is unknown, the same method used in the previous cycle is used to compute the default HCR. This includes cases where a constant catch HCR was used in the previous cycle to set the ACL below the ABC, in which case the same constant catch numerical value is used as the default ACL for the next biennial cycle.

Rationale for the Recommended Revised Sentences

The intent of the FMP language with respect to implementing a default harvest control rule (HCR) process is to be able to specify, as a default, the harvest control rules previously analyzed with as much flexibility to incorporate new science as possible. Changes in stock status that affect a 40-10 or 25-5 ACL deduction, if that is the default, would be reflected automatically in the default specifications. Likewise, any methodological, science-based change in the OFL or the sigma value affecting an ABC specification, would automatically be the default in the specifications. In cases where P* is used to determine ABCs, the default P* would vary among the alternatives as described.

Otherwise, the default rule, whether it be a previously analyzed constant catch (i.e., constant ACL) strategy or a specific series of ACLs that are part of a strategy that is designed to endure longer than one biennial cycle (e.g., a yelloweye ramp-down type of strategy) would be specified as the default except in cases where the ACL exceeds the default ABC.

{Table 1 N: revised at 75 FR 82296, 12/30/2010; revised at 76 FR 27508, 05/11/2011; revised at 76 FR 38313, 6/30/2011; revised at 76 FR 79122, 12/21/2011; revised at 77 FR 22679, 04/17/2012; revised at 78 FR 580, 01/03/2013; revised RCA boundaries at 79 FR 21639, 4/17/2014; corrected the revised RCA boundaries, 79 FR 27196, 5/13/2014}

Table 1 (North) to Part 660, Subpart D -- Limited Entry Trawl Rockfish Conservation Areas and Landing Allowances for non-IFQ Species and Pacific Whiting North of 40°10' N. Lat.

This table describes Rockfish Conservation Areas for vessels using groundfish trawl gear. This table describes incidental landing allowances for vessels registered to a Federal limited entry trawl permit and using groundfish trawl or groundfish non-trawl gears to harvest individual fishing quota (IFQ) species.

Other Limits and Requirements Apply -- Read § 660.10 - § 660.399 before using this table 04012014

TABLE 1 (North)

		JAN-FEB	MAR-APR	MAY-JUN	JUL-AUG	SEP-OCT	NOV-DEC
	Rockfish Conservation Area (RCA)[1/]:						
1	North of 48°10' N. lat.	shore - modified[2/] 200 fm line[1/]	shore - 200 fm line[1/]	shore - 150 fm line[1/]		shore - 200 fm line[1/]	shore - modified[2/] 200 fm line[1/]
2	48°10' N. lat. - 45°46' N. lat.	100 fm line[1/] - 150 fm line[1/]					
3	45° 46' N. lat. - 40°10' N. lat.	100 fm line[1/] - modified[2/] 200 fm line[1/]	100 fm line[1/] - 200 fm line[1/]				100 fm line[1/] - modified[2/] 200 fm line[1/]

Selective flatfish trawl gear is required shoreward of the RCA; all bottom trawl gear (large footrope, selective flatfish trawl, and small footrope trawl gear) is permitted seaward of the RCA. Large footrope and small footrope trawl gears (except for selective flatfish trawl gear) are prohibited shoreward of the RCA. Midwater trawl gear is permitted only for vessels participating in the primary whiting season. **Vessels fishing groundfish trawl quota pounds with groundfish non-trawl gears, under gear switching provisions at § 660.140, are subject to the limited entry groundfish trawl fishery landing allowances in this table, regardless of the type of fishing gear used. Vessels fishing groundfish trawl quota pounds with groundfish non-trawl gears, under gear switching provisions at § 660.140, are subject to the limited entry fixed gear non-trawl RCA, as described in Tables 1 (North) and 1 (South) to Part 660, Subpart E.**

See § 660.60, § 660.130, and § 660.140 for Additional Gear, Trip Limit, and Conservation Area Requirements and Restrictions. See §§ 660.70-660.74 and §§ 660.76-660.79 for Conservation Area Descriptions and Coordinates (including RCAs, YRCA, CCAs, Farallon Islands, Cordell Banks, and EFHCAs).

State trip limits and seasons may be more restrictive than federal trip limits, particularly in waters off Oregon and California.

4	**Minor nearshore rockfish & Black rockfish**	300 lb/ month
5	**Whiting**	
6	midwater trawl	Before the primary whiting season: CLOSED. -- During the primary season: mid-water trawl permitted in the RCA. See §660.131 for season and trip limit details. -- After the primary whiting season: CLOSED.
7	large & small footrope gear	Before the primary whiting season: 20,000 lb/trip. -- During the primary season: 10,000 lb/trip. -- After the primary whiting season: 10,000 lb/trip.
8	**Cabezon**	
9	North of 46°16' N. lat.	Unlimited
10	46°16' N. lat. - 40°10' N. lat.	50 lb/ month
11	**Shortbelly**	Unlimited
12	**Spiny dogfish**	60,000 lb/ month
13	**Longnose skate**	Unlimited
14	**Other Fish** [3/]	Unlimited

1/ The Rockfish Conservation Area is an area closed to fishing by particular gear types, bounded by lines specifically defined by latitude and longitude coordinates set out at §§ 660.71-660.74. This RCA is not defined by depth contours, and the boundary lines that define the RCA may close areas that are deeper or shallower than the depth contour. Vessels that are subject to the RCA restrictions may not fish in the RCA, or operate in the RCA for any purpose other than transiting.

2/ The "modified" fathom lines are modified to exclude certain petrale sole areas from the RCA.

3/ "Other fish" are defined at § 660.11 and include sharks (except spiny dogfish), skates (except longnose skate), ratfish, morids, grenadiers, and kelp greenling.

To convert pounds to kilograms, divide by 2.20462, the number of pounds in one kilogram.

{Table 1 S: revised at 75 FR 82296, 12/30/2010; revised at 76 FR 27508, 05/11/2011; revised at 76 FR 38313, 6/30/2011; revised at 78 FR 580, 01/03/2013}

Table 1 (South) to Part 660, Subpart D -- Limited Entry Trawl Rockfish Conservation Areas and Landing Allowances for non-IFQ Species and Pacific Whiting South of 40^{o}10' N. Lat.

This table describes Rockfish Conservation Areas for vessels using groundfish trawl gear. This table describes incidental landing allowances for vessels registered to a Federal limited entry trawl permit and using groundfish trawl or groundfish non-trawl gears to harvest individual fishing quota (IFQ) species.

Other Limits and Requirements Apply -- Read § 660.10 - § 660.399 before using this table

25	**Longnose skate**	Unlimited						
26	**Other fish[6/]**	Unlimited						

1/ The Rockfish Conservation Area is an area closed to fishing by particular gear types, bounded by lines specifically defined by latitude and longitude coordinates set out at §§ 660.71-660.74. This RCA is not defined by depth contours (with the exception of the 20-fm depth contour boundary south of 42° N. lat.), and the boundary lines that define the RCA may close areas that are deeper or shallower than the depth contour. Vessels that are subject to RCA restrictions may not fish in the RCA, or operate in the RCA for any purpose other than transiting.

2/ Bocaccio, chilipepper and cowcod are included in the trip limits for minor shelf rockfish and splitnose rockfish is included in the trip limits for minor slope rockfish.

3/ "Other flatfish" are defined at § 660.11 and include butter sole, curlfin sole, flathead sole, Pacific sanddab, rex sole, rock sole, and sand sole.

4/ For black rockfish north of Cape Alava (48°09.50' N. lat.), and between Destruction Is. (47°40' N. lat.) and Leadbetter Pnt. (46°38.17' N. lat.), there is an additional limit of 100 lb or 30 percent by weight of all fish on board, whichever is greater, per vessel, per fishing trip.

5/ The minimum size limit for lingcod is 22 inches (56 cm) total length North of 42° N. lat. and 24 inches (61 cm) total length South of 42° N. lat.

6/ "Other fish" are defined at § 660.11 and include sharks (except spiny dogfish), skates (except longnose skates), ratfish, morids, grenadiers, and kelp greenling. Cabezon are included in the trip limits for "other fish."

To convert pounds to kilograms, divide by 2.20462, the number of pounds in one kilogram.

TABLE 2 (South)

1/ The Rockfish Conservation Area is an area closed to fishing by particular gear types, bounded by lines specifically defined by latitude and longitude coordinates set out at §§ 660.71-660.74. This RCA is not defined by depth contours (with the exception of the 20-fm depth contour boundary south of 42° N. lat.), and the boundary lines that define the RCA may close areas that are deeper or shallower than the depth contour. Vessels that are subject to RCA restrictions may not fish in the RCA, or operate in the RCA for any purpose other than transiting.

2/ POP is included in the trip limits for minor slope rockfish. Blackgill rockfish have a species specific trip sub-limit within the minor slope rockfish cumulative limit. Yellowtail rockfish are included in the trip limits for minor shelf rockfish. Bronzespotted rockfish have a species specific trip limit.

3/ "Other flatfish" are defined at § 660.11 and include butter sole, curlfin sole, flathead sole, Pacific sanddab, rex sole, rock sole, and sand sole.

4/ The commercial mimimum size limit for lingcod is 24 inches (61 cm) total length South of 42° N. lat.

5/ "Other fish" are defined at § 660.11 and include sharks (except spiny dogfish), skates (except longnose skates), ratfish, morids, grenadiers, and kelp greenling. Cabezon and longnose skate are included in the trip limits for "other fish."

To convert pounds to kilograms, divide by 2.20462, the number of pounds in one kilogram.

{Table 3N revised at 75 FR 82296, 12/30/2010; revised at 76 FR 11381, 03/02/2011; revised at 76 FR 27508, 05/11/2011, revised at 76 FR 38313, 6/30/2011; revised at 76 FR 79122, 12/21/2011; revised at 78 FR 580, 01/03/2013; revised at 78 FR 49190, 08/13/2013; revised at 78 FR 72586, 12/03/2013}

Table 3 (North). Continued

		NOV-DEC 2013	JAN-FEB	MAR-APR	MAY-JUN	JUL-AUG	SEP-OCT	NOV-DEC
26	**SALMON TROLL** *(subject to RCAs when retaining all species of groundfish, except for yellowtail rockfish and lingcod, as described below)*							
27	North	Salmon trollers may retain and land up to 1 lb of yellowtail rockfish for every 2 lbs of salmon landed, with a cumulative limit of 200 lb/month, both within and outside of the RCA. This limit is within the 200 lb per month combined limit for minor shelf rockfish, widow rockfish and yellowtail rockfish, and not in addition to that limit. Salmon trollers may retain and land up to 1 lingcod per 15 Chinook per trip, plus 1 lingcod per trip, up to a trip limit of 10 lingcod, on a trip where any fishing occurs within the RCA. This limit only applies during times when lingcod retention is allowed, and is not "CLOSED." This limit is within the per month limit for lingcod described in the table above, and not in addition to that limit. All groundfish species are subject to the open access limits, seasons, size limits and RCA restrictions listed in the table above, unless otherwise stated here.						
28	**PINK SHRIMP NON-GROUNDFISH TRAWL** *(not subject to RCAs)*							
29	North	**Effective April 1 - October 31:** Groundfish: 500 lb/day, multiplied by the number of days of the trip, not to exceed 1,500 lb/trip. The following sublimits also apply and are counted toward the overall 500 lb/day and 1,500 lb/trip groundfish limits: lingcod 300 lb/month (minimum 24 inch size limit); sablefish 2,000 lb/month; canary, thornyheads and yelloweye rockfish are PROHIBITED. All other groundfish species taken are managed under the overall 500 lb/day and 1,500 lb/trip groundfish limits. Landings of these species count toward the per day and per trip groundfish limits and do not have species-specific limits. The amount of groundfish landed may not exceed the amount of pink shrimp landed.						

TABLE 3 (North) cont'd

1/ The Rockfish Conservation Area is an area closed to fishing by particular gear types, bounded by lines specifically defined by latitude and longitude coordinates set out at §§ 660.71-660.74. This RCA is not defined by depth contours (with the exception of the 20-fm depth contour boundary south of 42° N. lat.), and the boundary lines that define the RCA may close areas that are deeper or shallower than the depth contour. Vessels that are subject to RCA restrictions may not fish in the RCA, or operate in the RCA for any purpose other than transiting.

2/ Bocaccio, chilipepper and cowcod rockfishes are included in the trip limits for minor shelf rockfish. Splitnose rockfish is included in the trip limits for minor slope rockfish.

3/ "Other flatfish" are defined at § 660.11 and include butter sole, curlfin sole, flathead sole, Pacific sanddab, rex sole, rock sole, and sand sole.

4/ For black rockfish north of Cape Alava (48°09.50' N. lat.), and between Destruction Is. (47°40' N. lat.) and Leadbetter Pnt. (46°38.17' N. lat.), there is an additional limit of 100 lbs or 30 percent by weight of all fish on board, whichever is greater, per vessel, per fishing trip.

5/ The minimum size limit for lingcod is 22 inches (56 cm) total length North of 42° N. lat. and 24 inches (61 cm) total length South of 42° N. lat.

6/ "Other fish" are defined at § 660.11 and include sharks (except spiny dogfish), skates (except longnose skates), ratfish, morids, grenadiers, and kelp greenling. Cabezon are included in the trip limits for "other fish."

To convert pounds to kilograms, divide by 2.20462, the number of pounds in one kilogram.

38	**Other fish[5/]**	Unlimited						
39	**RIDGEBACK PRAWN AND, SOUTH OF 38°57.50' N. LAT., CA HALIBUT AND SEA CUCUMBER NON-GROUNDFISH TRAWL**							
40	**NON-GROUNDFISH TRAWL Rockfish Conservation Area (RCA) for CA Halibut, Sea Cucumber & Ridgeback Prawn:**							
41	*40° 10' N. lat. - 38° 00' N. lat.*	*100 fm line[1/] - 200 fm line[1/]*		*100 fm line[1/] - 150 fm line[1/]*				*100 fm line[1/] - 200 fm line[1/]*
42	*38° 00' N. lat. - 34° 27' N. lat.*	*100 fm line[1/] - 150 fm line[1/]*						
43	*South of 34° 27' N. lat.*	*100 fm line[1/] - 150 fm line[1/] along the mainland coast; shoreline - 150 fm line[1/] around islands*						
44		Groundfish: 300 lb/trip. Species-specific limits described in the table above also apply and are counted toward the 300 lb groundfish per trip limit. The amount of groundfish landed may not exceed the amount of the target species landed, except that the amount of spiny dogfish landed may exceed the amount of target species landed. Spiny dogfish are limited by the 300 lb/trip overall groundfish limit. The daily trip limits for sablefish coastwide and thornyheads south of Pt. Conception and the overall groundfish "per trip" limit may not be multiplied by the number of days of the trip. Vessels participating in the California halibut fishery south of 38°57.50' N. lat. are allowed to (1) land up to 100 lb/day of groundfish without the ratio requirement, provided that at least one California halibut is landed and (2) land up to 3,000 lb/month of flatfish, no more than 300 lb of which may be species other than Pacific sanddabs, sand sole, starry flounder, rock sole, curlfin sole, or California scorpionfish (California scorpionfish is also subject to the trip limits and closures in line 31).						
45	**PINK SHRIMP NON-GROUNDFISH TRAWL GEAR** *(not subject to RCAs)*							
46	South	Effective April 1 - October 31: Groundfish: 500 lb/day, multiplied by the number of days of the trip, not to exceed 1,500 lb/trip. The following sublimits also apply and are counted toward the overall 500 lb/day and 1,500 lb/trip groundfish limits: lingcod 300 lb/ month (minimum 24 inch size limit); sablefish 2,000 lb/ month; canary, thornyheads and yelloweye rockfish are PROHIBITED. All other groundfish species taken are managed under the overall 500 lb/day and 1,500 lb/trip groundfish limits. Landings of all groundfish species count toward the per day, per trip or other species-specific sublimits described here and the species-specific limits described in the table above do not apply. The amount of groundfish landed may not exceed the amount of pink shrimp landed.						

1/ The Rockfish Conservation Area is an area closed to fishing by particular gear types, bounded by lines specifically defined by latitude and longitude coordinates set out at §§ 660.71-660.74. This RCA is not defined by depth contours (with the exception of the 20-fm depth contour boundary south of 42° N. lat.), and the boundary lines that define the RCA may close areas that are deeper or shallower than the depth contour. Vessels that are subject to RCA restrictions may not fish in the RCA, or operate in the RCA for any purpose other than transiting.

2/ POP is included in the trip limits for minor slope rockfish. Blackgill rockfish have a species specific trip sub-limit within the minor slope rockfish cumulative limits. Yellowtail rockfish is included in the trip limits for minor shelf rockfish. Bronzespotted rockfish have a species specific trip limit.

3/ "Other flatfish" are defined at § 660.11 and include butter sole, curlfin sole, flathead sole, Pacific sanddab, rex sole, rock sole, and sand sole.

4/ The commercial mimimum size limit for lingcod is 24 inches (61 cm) total length South of 42° N. lat.

5/ "Other fish" are defined at § 660.11 and include sharks (except spiny dogfish), skates (except longnose skate), ratfish, morids, grenadiers, and kelp greenling. Cabezon are included in the trip limits for "other fish."

To convert pounds to kilograms, divide by 2.20462, the number of pounds in one kilogram.

Agenda Item F.7.b
Supplemental CDFW Report 1
June 2014

CALIFORNIA DEPARTMENT OF FISH AND WILDLIFE REPORT ON THE 2015-2016 BIENNIAL HARVEST SPECIFICATIONS AND MANAGEMENT MEASURES

The California Department of Fish and Wildlife (CDFW) offers the following comments for management approaches of nearshore rockfish in 2015 and 2016 and beyond.

CDFW acknowledges the preferred management options in the Washington and Oregon Departments of Fish and Wildlife (WDFW/ODFW) report for management of nearshore stocks (Agenda Item F.7.b, Supplemental WDFW/ODFW Report) and supports individual flexibility in managing nearshore stocks within respective state processes. While all of the states may have different approaches to nearshore fishery management, one commonality is the understanding that a one-size fits all approach may not work for all.

During adoption of the 2013 data moderate stock assessments, many complexities were identified in the application of assessment results to nearshore rockfish management. Since these complexities will require ongoing discussion about how to proceed in the future and will likely take time to resolve, CDFW is supportive of the general management approach outlined by WDFW and ODFW for 2015 and 2016. We believe these interim measures strike a balance between responding to the newest science and minimizing disruptions to the fishery.

CDFW proposes the following approach for managing the nearshore complex from 40°10’ N lat. to 42° N lat. which recognizes our differing management needs and ability to respond to inseason actions:

- Establish a harvest guideline for minor nearshore rockfish between 42° N lat. (Oregon/California border) and 40°10’ N lat. (Cape Mendocino) which would be specified in federal regulations. This harvest guideline would be specified at 23.7 mt (Table 1; Supplemental WDFW/ODFW Report); a number which represents the No Action alternative in the EIS [i.e., expected commercial landings (Table 4-39) combined with projected recreational mortality (Table 4-50)].

- In accordance with CDFW’s policy to provide a stable fishery and minimize inseason disruptions, seasons will continue to be designed and modeled preseason in order to maximize fishing opportunity while expecting to keep harvest within specified harvest guidelines. CDFW employs the use of multi-month closures early in the year as part of the overall design to ensure that limits are not exceeded. While we are committed to our inseason tracking process and taking actions as needed in response to the latest information, season structures are designed with an expectation that we will not need to take inseason action.

- CDFW will continue to monitor harvest levels of nearshore fisheries inseason and to share catch tracking information with the other states.

- CDFW will continue to employ the same approach used for monitoring of other species with an established state harvest guideline (e.g. blue, canary, and yelloweye rockfish). Harvest levels will be monitored inseason and if projected catches are expected to exceed harvest limits we would take appropriate action in coordination with the National Marine Fisheries Service.

The 2013 data moderate stock assessment and review process was less than optimal and many lessons were learned on how to better improve the process for the future. CDFW is encouraged to see that those comments are being considered during planning and prioritization for groundfish stock assessments in 2015 (Agenda Item F.8.b, NWFSC Report).

To prevent future confusion or delays in management and regulatory development, CDFW believes a broader discussion on nearshore species assessments and management needs to occur outside the stock assessment cycle before engaging in additional full or data moderate nearshore rockfish assessments. Addressing these complex issues during a stock assessment review or on the Council floor is not optimal. If this does not occur, the issues experienced during the 2013 assessment cycle (i.e., boundary issues) are likely to be repeated again especially as the Council is currently considering the use of data moderate assessments for nearshore stocks that have been previously assessed at state boundaries (e.g. blue and gopher rockfish). CDFW also believes that these discussions should be holistic and address the complex as a whole instead of focusing solely on a few individual species as is currently being done now.

CDFW also notes that there is disconnect between management of overfished species and nearshore stocks. Overfished species are allocated to the states according to state boundaries for some sectors, but target stocks are not necessarily aligned with those same boundaries. This reduces the flexibility of the states to effectively manage their recreational and commercial nearshore fisheries. Establishing individual state harvest guidelines in federal regulations instead of sector specific limits would provide needed flexibility for state management and allow states to work out sector allocations within the respective state delegations. CDFW hopes that issues such as this would also be included in a broader scale discussion of nearshore rockfish management moving forward.

GROUNDFISH ADVISORY SUBPANEL REPORT ON FISHERIES IN 2015-2016 AND BEYOND: HARVEST SPECIFICATIONS, MANAGEMENT MEASURES, AND AMENDMENT 24

The Groundfish Advisory Subpanel (GAP) met with members of the Groundfish Management Team (GMT), Mr. John DeVore, and Ms. Kelly Ames to consider management measures for the 2015-16 cycle, and offers the following comments.

In this statement, the GAP uses the checklist found at Agenda Item F.7.a, Attachment 1, Action Item.

Recognizing that the Council is behind on its agenda, the GAP has identified the following items as ones that: 1) the GAP has identified as departing from the preliminary preferred alternative (PPA) or final preferred alternative (FPA); 2) the GAP specifically supports and adds clarification or details; or 3) is a change from our recommendations in April. However, our comments on all of the items on the checklist will at least be in the Council record.

The important ones to the GAP are:

- No. 6. Confirm EC species' designations
- No. 8. Decide FPA for Slope Rockfish complexes
- No. 9. Confirm or modify amounts deducted from the ACL
- No. 11. Trawl/non-trawl: Confirm or modify 2-year trawl and non-trawl allocations for: Overfished species: bocaccio, canary, cowcod, petrale and yelloweye
- No. 13 Non-trawl: Confirm or modify 2-year within-non-trawl HGs or within non-trawl shares for: Ovefished species including bocaccio, canary, cowcod and yelloweye
- No. 13 Non-trawl: Confirm or modify 2-year within-non-trawl HGs or within non-trawl shares for: Nearshore rockfish HG north of 40° 10'
- No. 15 Shorebased IFQ: Trawl RCA, non-IFQ trip limits
- No. 16. Non-nearshore: Non-trawl RCA seaward configuration, trip limits (including sablefish)
- No. 17 Non-Trawl RCA shoreward configuration, trip limits
- No. 18 WA recreational
- No. 19 OR recreational
- No. 20 CA recreational
- No. 21 Trawl: RCA boundary adjustments to better approximate depth
- No. 22 Trawl: Using underutilized set-asides
- No. 23 Non-trawl: Trip limit adjustments
- No. 25 Trawl: Establish new trawl RCA coordinates for 300 and 350 fm boundaries
- No. 26 Non-trawl: Provide for lingcod retention in Periods, 1, 2 and 6
- No. 27 Non-trawl recreational: One-fish canary sub-bag limit

2015-2016 Harvest Specifications

1. Confirm SSC-recommended OFLs including a revised 2016 cowcod OFL

Reference document(s)	Page(s), section, table or chart
F.7.a, Att. 2, Preferred 2015 and 2016 Harvest Specifications	Table I

→ The GAP confirms the SSC recommendations, including the revised cowcod 2016 OFL of 68 tons.

2. Confirm P* and ABCs. Adopt revised 2016 cowcod ABC

Reference document(s)	Page(s), section, table or chart
F.7.a, Att. 2, Preferred 2015 and 2016 Harvest Specifications	Table 1

→ The GAP confirms the SSC recommendations, including the revised cowcod 2016 ABC of 62 tons.

3. Confirm FPA ACLs

Reference document(s)	Page(s), section, table or chart
F.7.a, Att. 2, Preferred 2015 and 2016 Harvest Specifications	Table 1

→ The GAP agrees with the Final Preferred Alternative ACLs as listed in Table 1 of Attachment 2.

4. Confirm 4 mt ACT for cowcod

Reference document(s)	Page(s), section, table or chart
F.7.a, Att. 2, Preferred 2015 and 2016 Harvest Specifications	Table 1

→ The GAP agrees with the Final Preferred Alternative ACTs of 4 mt in 2015 and 2016, as listed in Attachment 2, Table 2.

5. Confirm rebuilding plan parameters including a new T_{TARGET} for cowcod ABC

Reference document(s)	Page(s), section, table or chart
F.7.a, Att. 2, Preferred 2015 and 2016 Harvest Specifications F.7.a, Att. 4, Draft Environmental Impact Statement	Table 2 Page 127, section 4.1.1.3

→ The GAP agrees with the Final Preferred Alternative T_{TARGET} of 2020 for cowcod as listed in Table 2 and corresponding to the preferred ACT.

2015-2016 Stock Complexes

6. Confirm EC species' designations and associated FMP language to be implemented under Amendment 24

Reference document(s)	Page(s), section, table or chart
F.7.a, Att. 8, Proposed Groundfish FMP Amendment Language	Table 3-2

→ The GAP agrees with the species listed in Table 3-2 in Attachment 8 as ecosystem component (EC) species. GAP members discussed Pacific grenadier (*Coryphaenoides acrolepis*) at length in April 2013 and determined it would fit well as an EC species.

Further, we understand National Marine Fisheries Service (NMFS) has concerns about removing Pacific grenadier from the fishery management plan (FMP). To that end, we reiterate our comments from April 2013, D.3.b, GAP Report on Stock Assemblages:

> "The GAP recommends an alternative for analysis that removes Pacific grenadier from the FMP. Pacific grenadier, as well as the other endemic grenadier species, are caught incidentally in West Coast fisheries and are not targeted. Furthermore, since these are deepwater species, catch of grenadiers are restricted since the prohibition on trawling deeper than 700 fm went into effect in 2006 with the final rule implementing Amendment 19. Since 2006, the average annual landings of grenadiers is 127.7 mt. Finally, the GAP notes the core distribution of grenadiers is much deeper than the 700 fm limit for West Coast trawl fisheries. Therefore, if harvest were to increase from the recent year average, there would be no biological effect of any significance since the fishery cannot access the core population."

7. Confirm FPA to manage kelp greenling coastwide, WA cabezon, and leopard shark in the Other Fish complex ABC

Reference document(s)	Page(s), section, table or chart
F.7.a, Att. 4, Draft Environmental Impact Statement	Table 4-16

→ The GAP agrees with this management change.

8. Decide FPA for Slope Rockfish complexes

Reference document(s)	Page(s), section, table or chart
F.7.a, Att. 4, Draft Environmental Impact Statement	Page 8, Table 2-1, preferred option

→ The GAP recommends the Council adopt its preliminary preferred alternative as the final preferred option, which would maintain the status quo slope rockfish complex and establish a new scientific sorting requirement for rougheye, shortraker, and blackspotted rockfish. This sorting requirement will better inform management decisions in the future by better tracking catches while not creating an unbearable burden for the industry (See related item, No. 25, in this document).

2015-2016 Allocations and Harvest Guidelines (HG)

9. Confirm or modify amounts deducted from the ACL to account for groundfish mortality in Tribal, non-groundfish fisheries, EFPs and research

Reference document(s)	Page(s), section, table or chart
F.7.a, Att. 4, Draft Environmental Impact Statement F.7.b, Supplemental Tribal Report	Pages 1-2

→ The GAP agrees with the changes recommended in the supplemental Tribal report. Increasing the Tribal set-asides will help account for increasing encounters of some species as those stocks continue to rebuild.

10. Confirm or modify HGs for species managed within a complex:

- Blue rockfish in California within the nearshore rockfish complexes north and south of 40°10'

Reference document(s)	Page(s), section, table or chart
F.7.a, Att. 2, Preferred 2015 and 2016 Harvest Specifications	Table 6

→ The GAP agrees with these, as also confirmed in our April 2014 GAP report.

- Blackgill rockfish within the slope rockfish complex south of 40°10'

Reference document(s)	Page(s), section, table or chart
F.7.a, Att. 2, Preferred 2015 and 2016 Harvest Specifications	Table 7

→ The GAP agrees with these, as also confirmed in our April 2014 GAP report.

11. Trawl/non-trawl: Confirm or modify 2-year trawl and non-trawl allocations for:

- Overfished species: bocaccio, canary, cowcod, petrale and yelloweye

Reference document(s)	Page(s), section, table or chart
F.7.a, Att. 4, Draft Environmental Impact Statement)	Page 223, Table 4-52

→ The GAP recommends the allocations for these species as listed in Table 4-52 of the DEIS (the preferred alternative), including allocating 35 mt of petrale to the non-trawl sector. An excerpt of the table is below.

Table 4-52. Preferred Alternative. Stock specific fishery harvest guidelines (HG) or annual catch targets (ACT) and allocations for 2015 (in mt).

Stock	Area	Fishery HG or ACT	Allocation Type	Trawl		Non-trawl	
				%	Mt	%	Mt
BOCACCIO	S of 40°10' N. lat.	340.7	Biennial	N/A	81.9	N/A	258.8
CANARY	Coastwide	106.8	Biennial	N/A	56.9	N/A	49.9
COWCOD a/	S of 40°10' N. lat.	4.0	Biennial	N/A	1.4	N/A	2.6
DARKBLOTCHED	Coastwide	317.2	Amendment 21	95%	301.3	5%	15.9
POP	N of 40°10' N. lat.	143.0	Amendment 21	95%	135.9	5%	7.2
PETRALE SOLE	Coastwide	2,579.4	Biennial	N/A	2,544.4	N/A	35.0
YELLOWEYE	Coastwide	12.2	Biennial	N/A	1.0	N/A	11.2

- Longnose skate: trawl (90%) and non-trawl (10%) allocation

Reference document(s)	Page(s), section, table or chart
F.7.a, Att. 4, Draft Environmental Impact Statement	Page 223, Table 4-52

→ The GAP recommends the allocations for longnose skate as listed above (preferred alternative), as we also supported in our April 2014 GAP report.

- Shelf rockfish north trawl (60.2%) and non-trawl (39.8%) allocation

Reference document(s)	Page(s), section, table or chart
F.7.a, Att. 4, Draft Environmental Impact Statement	Page 223, Table 4-52

→ The GAP recommends the allocations for shelf rockfish as listed above (preferred alternative), as we also supported in our April 2014 GAP report.

- Shelf rockfish south trawl (12.2%) and non-trawl (87.8%) allocation

Reference document(s)	Page(s), section, table or chart
F.7.a, Att. 4, Draft Environmental Impact Statement	Page 223, Table 4-52

→ The GAP recommends the allocations for shelf rockfish as listed above (preferred alternative), as we also supported in our April 2014 GAP report.

12. Within trawl/at-sea: Confirm or modify the at-sea whiting set-asides adopted in April

Reference document(s)	Page(s), section, table or chart
F.7.a, Att. 4, Draft Environmental Impact Statement	Page 235, Table 4-60

→ The GAP agrees with the set-asides listed in the table referenced above.

13. Non-trawl: Confirm or modify 2-year within non-trawl HGs or within non-trawl shares for:

- Overfished species including bocaccio, canary, cowcod, and yelloweye

Reference document(s)	Page(s), section, table or chart
F.7.a, Att. 4, Draft Environmental Impact Statement F.7.a, Att. 6, Excerpted Portions of Appendix B	Page 227, Table 4-56 Table B-37

→ The GAP discussed the need for a buffer in both the nearshore and non-nearshore sectors in the event some yelloweye was transferred between sectors.

Under the current preferred alternatives, yelloweye impacts to nearshore fishery are 1.2 mt out of 1.2 mt share. The non-nearshore impacts are 0.5 mt out of 1.1 mt. Thus, the proposal is to move 0.6 mt from non-nearshore to nearshore to assist with potential yelloweye impacts due to increased lingcod trip limits and a year-round fishery north of 40° 10' (See also Nos. 23 and 26, below).

However, the GAP was concerned that the only adjustment available for the non-nearshore sector is to move the RCA line deeper, from 100 to 150 fathoms, which would prevent the attainment of targeted fisheries.

At the same time, the risk of exceeding the yelloweye ACL is low, according to GMT analysis.

Therefore, the GAP suggests transferring 0.4 mt (instead of 0.6) from the non-nearshore sector to the nearshore sector.

- Black rockfish: 58% OR, 42% CA

Reference document(s)	Page(s), section, table or chart
F.7.a, Att. 4, Draft Environmental Impact Statement	Page 220, Section 4.22

→ The GAP recommends these percentages will work for Oregon and California; they are the same percentages that have been used in the past.

- Blue rockfish: 40-10 adjustment for CA

Reference document(s)	Page(s), section, table or chart
F.7.a, Att. 2, Preferred 2015 and 2016 Harvest Specifications	Table 7

→ The GAP agrees with this; this management measure has been in place since the 2007-08 biennial specifications.

- Blackgill south of 40°10': 40-10; 60% limited entry and 40% open access fixed gears

Reference document(s)	Page(s), section, table or chart
F.7.a, Att. 2, Preferred 2015 and 2016 Harvest Specifications	Table 7

→ The GAP agrees; these percentages have been in place since the 2013-14 biennial specifications.

- Sablefish south of 36º: 55% limited entry and 45% open access fixed gears

Reference document(s)	Page(s), section, table or chart
F.7.a, Att. 4, Draft Environmental Impact Statement	Section 4.2.2

→ The GAP agrees; this is status quo as listed in the draft Environmental Impact Statement (DEIS).

- Nearshore rockfish HG north of 40°10'

Reference document(s)	Page(s), section, table or chart
F.7.a, Att. 4, Draft Environmental Impact Statement F.7.b Supplemental WDFW/ODFW report F.7.b, Supplemental CDFW report	

→ The GAP struggled with this issue. At the April meeting, the GAP agreed to the hybrid option, as we wrote in our statement. That was the assumption going into this meeting.

However, subsequent reports from the states (joint WDFW/ODFW and CDFW) prompted the GAP to discuss various options for management of nearshore rockfish.

Recognizing the necessity of remaining below 69 mt coastwide, the GAP reconsidered the hybrid option. At the same time, we considered the ability of the states to manage nearshore rockfish through an inseason process. California has noted its process takes longer and the ability to manage inseason is more difficult. Washington and Oregon can respond to inseason action much more quickly.

We also appreciate that all three states have a good reputation for working together.

Therefore, California has proposed a Federal 23.7 mt harvest guideline. Washington and Oregon have proposed joint management of the nearshore sector (45.3 mt). The consensus of the GAP is that this situation will work (we note that California's proposal of 23.7 mt is below what it would have received in the hybrid option) and the states will be accountable for staying below 69 mt total coastwide.

2015-2016 Season Structures

14. Treaty fisheries: Management measures

Reference document(s)	Page(s), section, table or chart
F.7.a, Att. 4, Draft Environmental Impact Statement	

→ The treaty tribes' representative on the GAP said only one change is being implemented: a slight modification in how the bi-monthly trip limits will be managed inseason to stay within the overall harvest targets as well as estimated impacts to overfished species.

15. Shorebased IFQ: Trawl RCA, non-IFQ trip limits

Reference document(s)	Page(s), section, table or chart
F.7.a, Att. 4, Draft Environmental Impact Statement	Section 4.4.2
F.7.a, Att. 3, Executive Summary and PPA	Page 10, 11

→ The GAP remains frustrated with the reasons for Council-recommended modifications of the trawl Rockfish Conservation Area (RCA) adjustments being disapproved by NMFS. In April, the GAP commented on its desire to move forward with the action the Council made regarding the RCA in September 2013:

From our April statement:

"The GAP has requested the RCA changes go into effect in period 6 of 2013 and all of 2014, but they have not yet been implemented, despite the Council adopting those changes in September 2013. Ideally, the GAP would like to see those modifications – a seaward boundary of 150 fathoms and a shoreward boundary of 100 fathoms, for all periods – roll over into both 2015 and 2016.

"From the September 2013 PFMC decision document:

"**Consideration of Trawl Rockfish Conservation Area (RCA) Boundary Modifications**

"The Council reaffirmed their April action to establish a trawl RCA configuration between 40°10' and 48°10' N. lat. with a 100 fm shoreward boundary and 150 fm seaward boundary beginning in Period 6 in 2013 through

2014."

"By shrinking the RCA, fishermen will be able to access more areas and species other than slope rockfish. This would aid in reducing effort on rougheye rockfish. Moreover, the trawl fleet is a rationalized fishery and has IFQ for species of concern."

At this point, the GAP reiterates its desire for the preliminary preferred alternative of 100 fm shoreward and 150 fm seaward RCA lines for the area 40°10' to 48°10' N. lat., year-round.

If that is not possible, the 200-fm-modified RCA line between 40°10' to 46° N. lat., year-round, would be preferred.

16. Non-nearshore: Non-Trawl RCA seaward configuration, trip limits (including sablefish)

Reference document(s)	Page(s), section, table or chart
Pending GMT analysis	

→ The GAP understands part of this relates to analysis of non-trawl impacts relative to moving the seaward non-trawl 200 fm and 250 fm RCA management lines. The GAP generally supports this as an option, particularly if needed to protect species of concern or in the case of rougheye. However, the GAP recommends that if the Council uses these management lines, it should do so discriminately and not encompass the whole area north of 40° 10' N. lat.

→ For sablefish, the GAP recommends the sablefish trip limits under Alternative 3 in the DEIS, which is the Preliminary Preferred Alternative (PPA):

Table 4-105. Alternative 3. Sablefish trip limits north of 36° N. latitude for limited entry and open access fixed gears for 2015-2016.

Year	Fishery	Jan-Feb	Mar-Apr	May-Jun	July-Aug	Sept-Oct	Nov-Dec
2015	Limited Entry	1,025 lb/week, not to exceed 3,075 lb/ 2 months					
2015	Open Access	300 lb/ day, or 1 landing per week of up to 900 lb, not to exceed 1,800 lb/ 2 months					
2016	Limited Entry	1,275 lb/week, not to exceed 3,375 lb/ 2 months					
2016	Open Access	300 lb/ day, or 1 landing per week of up to 1,000 lb, not to exceed 2,000 lb/ 2onths					

Table 4-109. Alternative 3. Sablefish trip limits south of 36° N. latitude for limited entry and open access fixed gears for 2015-2016.

Industry south of 36° N. Latitude: ***request*** **no action**

Year	Fishery	Jan-Feb	Mar-Apr	May-Jun	July-Aug	Sept-Oct	Nov-Dec
2015	Limited Entry	2,000 lb/week					
	Open Access	320 lb/ day, or 1 landing per week of up to 1,600 lb, not to exceed 3,200 lb/ 2 months					
2016	Limited Entry	2,000 lb/week					
	Open Access	320 lb/ day, or 1 landing per week of up to 1,600 lb, not to exceed 3,200 lb/ 2 months					

The GAP further notes that it may be necessary in the future to reduce slope rockfish trip limits for fixed gear north of 40°10'.

17. Nearshore: Non-Trawl RCA shoreward configuration, trip limits

Reference document(s)	Page(s), section, table or chart
F.7.a, Att. 4, Draft Environmental Impact Statement	Sect. 4.2

→ The GAP prefers the Council's April preliminary preferred alternative. To accommodate the potential increase in lingcod trip limits and a year-round fishery, the GAP would prefer to keep the RCA lines the same, if needed.

18. WA recreational: Season dates, bag limits, length limits, area closures

Reference document(s)	Page(s), section, table or chart
F.7.a, Att. 4, Draft Environmental Impact Statement F.7.a, Att. 3, Executive Summary and PPA	Sect. 4.2 Page 24+, Tables 4-21, 4-22

→ The GAP agrees with all of the recreation management measures in the preferred alternative as listed in Att. 3 (beginning on Page 24) for Washington as outlined in the DEIS.

19. OR recreational: Season dates, bag limits, length limits, area closures

Reference document(s)	Page(s), section, table or chart
F.7.a, Att. 4, Draft Environmental Impact Statement F.7.a, Att. 3, Executive Summary and PPA	Sect. 4.2 Page 29+, Tables 4-24 and 4-26, figure 4-2

→ The GAP agrees with all of the recreation management measures in the preferred alternative as listed in Att. 3 (beginning on Page 29) for Oregon as outlined in the DEIS.

20. CA recreational: Season dates, bag limits, length limits, area closures

Reference document(s)	Page(s), section, table or chart
F.7.b, Supplemental Revised CDFW report 2	

→ The GAP supports the recreational recommendations as presented in Agenda Item F.7.b, REVISED Supplemental CDFW Report No. 2 for season structures and RCA configurations.

Regarding the lingcod bag limit, we recommend a split bag limit within the state for lingcod: three lingcod for the Mendocino and North Coast areas (north of 38.57.5 N. lat.) and two lingcod south of that latitude line. Justification is due to the concern of the Commercial Passenger Fishing Vessel (CPFV) fleet in the Central and San Francisco zones with possible impacts to several species of concern that would require inseason action resulting of loss of time on the water.

The GAP has no objection to increasing the bag limit on lingcod to three below Point Conception at 34° N. latitude, since the species of concern mentioned above are quite rare in that area.

Further, we support the recreational recommendations as stated in Agenda Item F.7.b. Supplemental CDFW Report No. 1 regarding a California harvest guideline of 23.7 mt for the nearshore complex and other described management measures.

2015-2016 Adjustments to Existing or Routine Measures

21. Trawl: RCA boundary adjustments to better approximate depth, including the 200 fm modified line in Oregon and a 60 fm line in California

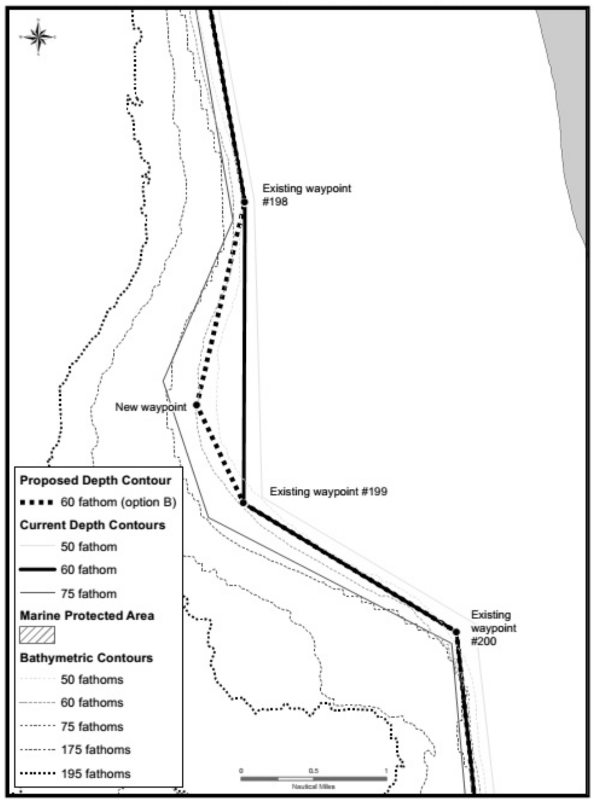
Reference document(s)	Page(s), section, table or chart
F.7.a, Att. 6, Excerpted Portions of Appendix B	Section B.1

→ The GAP agrees these 200-fm changes should be made to conform to depth contours (the preferred option, Option 1).

Del Mar 60 Fathom RCA Changes

While industry favors its recommended correction submitted in April, the GAP realizes that absent the appropriate fine-scale cartography that shows the less-than-60 fathom ridge, the Council would be unable to grant this request. Thus the GAP favors the GMT-recommended 60 fathom line changes as shown below for Del Mar.

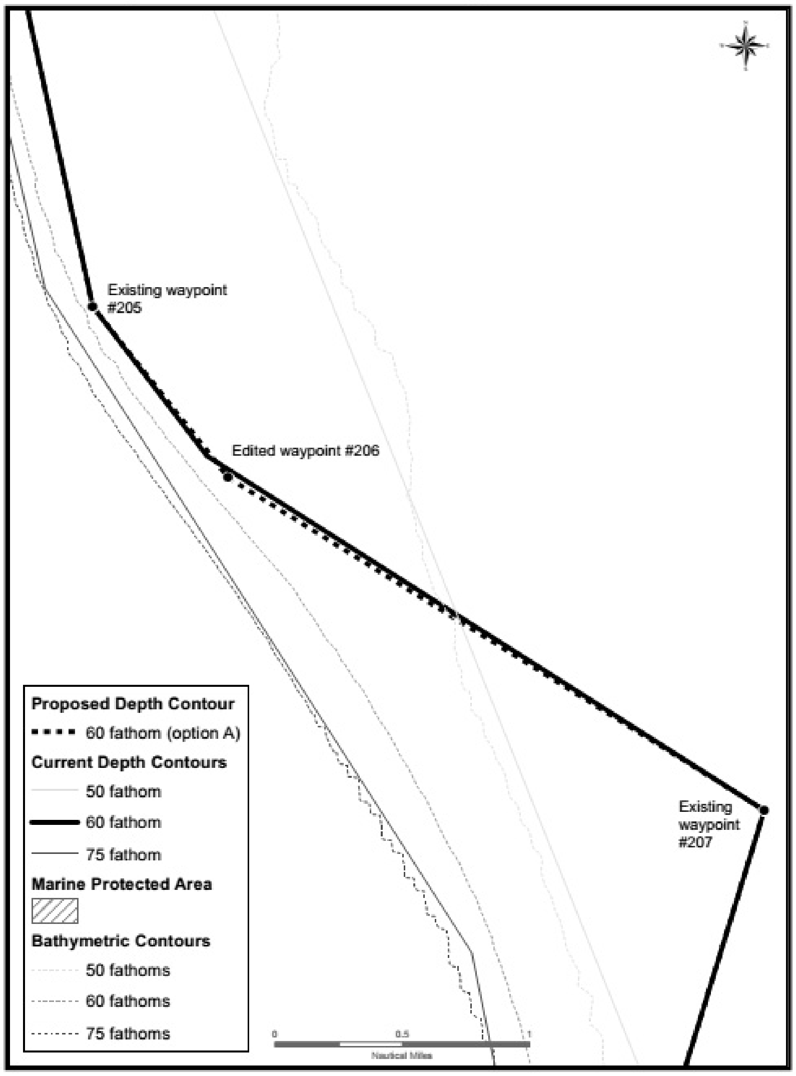
Proposed 60 Fathom RCA Line Changes - Del Mar



South of Del Mar RCA Changes

Both of the 60 fathom changes for south of Del Mar would be acceptable to the GAP (see below). However, existing waypoint #207 may be misprinted in the Code of Federal Regulations as it appears to be well inside the 50 fathom line. This was confirmed by Mr. Bob Leos of the GMT.

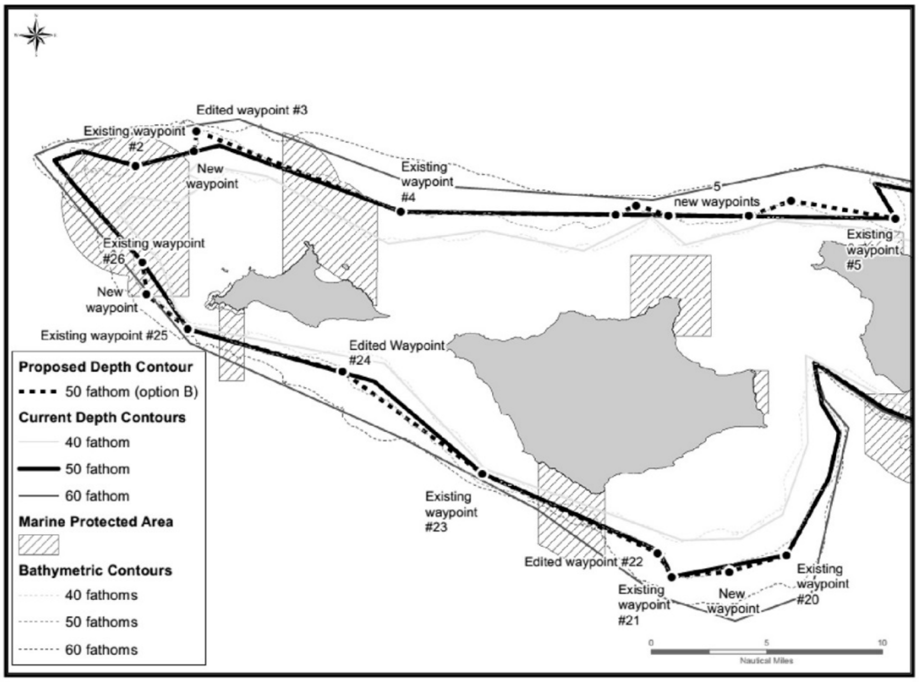
Proposed 60 Fathom RCA Line Changes - South of Del Mar



Channel Islands 50 Fathom RCA Line Changes

For the 50 fathom line in the Channel Islands, the GAP favors and greatly appreciates the following GMT option.

Proposed 50 Fathom RCA Line Changes - Northern Channel Islands



22. Trawl: Using underutilized set-asides in the projections for the shorebased IFQ carryover

Reference document(s)	Page(s), section, table or chart
Pending analysis	

→ No analysis had been done by the time the GAP considered this, but using underutilized set-asides for shorebased IFQ carryover is just common sense. In that regard, the GAP agrees with this concept. Simply, this is a reliable way to allow for carryover without taking up a lot of Council staff or NMFS time.

23. Non-trawl: Trip limit adjustments for lingcod N. of 40°10' N. lat. (increase), slope rockfish N. of 40°10' N. lat. (decrease), bocaccio S. of 34°27' N. lat. (increase), and shelf rockfish S. of 34°27' N. lat. (increase)

Reference document(s)	Page(s), section, table or chart
Appendix B F.7.b, Supplemental Revised CDFW report 2 F.7.a, Supplemental Analyses for Appendix B	 Page 104; Page 113

→ The GAP considered trip limit adjustments for lingcod N. of 40°10' N. lat. and agrees with increasing the limits. However, more discussion about that and the options for a year-round lingcod fishery are discussed in this document, No. 26.

Regarding slope rockfish, the GAP has no comment, as the analysis has not been completed yet.

With regard to bocaccio, the GAP agrees with Option 2A, which equates to 750 lbs. bimonthly for limited entry and 250 lbs. bimonthly for open access.

For shelf rockfish, the GAP agrees that Option 2A would be best. It equates to 4,000 lbs. bimonthly for limited entry when the season is open for non-trawl and 1,500 lbs. bimonthly when open for open access. This would be sufficient to address the uncertainty in overfished species (OFS) impacts.

24. Non-trawl recreational: Modifications to groundfish retention regulations in the Pacific halibut fisheries

Reference document(s)	Page(s), section, table or chart

→ The GAP understands this would allow the Council more flexibility in the halibut catch-sharing plan and supports these changes.

New Management Measures for Implementation in 2015-2016

25. Trawl: Establish new trawl RCA coordinates for 300 and 350 fm boundaries

Reference document(s)	Page(s), section, table or chart
Pending GMT analysis/statement	

→ The GAP reviewed the draft GMT analysis and had several questions:

Since this is in the 2015-16 annual harvest specifications and management measures process, does the Council intend to use them during this cycle? Many on the GAP were under the impression that voluntary reductions and mandatory sorting requirements would be used in 2015-16, to help inform the Council as to whether any management measures would be required in 2017-18. The GAP believes this approach is prudent and meets the needs of both the agency and the fleet.

If the Council chooses this as the preferred management option, how does the Council intend to implement this tool? How do we accurately measure all the sectors catch and is there a threshold for each sector that would need to be met in order to implement additional management measures?

Furthermore, data reports that show rougheye catch are on different timelines for different sectors. For example, the whiting fleets have a 24-hour turnaround time thanks to industry-funded tracking (both area-specific and catch estimates), so they know each day where the rougheye hotspots are for their vessels. However, data for open access fleets, for example, have at a minimum a two-month lag time. The GAP questions the ability of the Council/NMFS to use inseason measures effectively based on incomplete catch information.

One of the reasons there was so much industry buy-in for voluntary reduction measures was due to the belief that the Council and NMFS supported use of these measures for the 2015-2016 season. The threat of establishing these types of measures being utilized in the 2015-2016 management period is draconian and undermines the voluntary efforts of the industry to work together. At best these measures create skepticism and distrust of the process. At worst, it pits sectors of the industry against each other, which is what we were trying to avoid.

This whole discussion is frustrating to the GAP because it appears the rougheye issue is a manufactured crisis that we are constantly revisiting. This is especially troubling, given that the recent stock assessment acknowledges the stock is healthy at 7 percent above target and continuing to grow.

The Council discussion at the time of this request was basically: Do what you can in the time given. Clearly, the GMT analysis is not done. Can the Council even take, let alone consider, final action on an incomplete analysis? The GAP cannot comment on an incomplete analysis nor does the GMT or Council have time to address any concerns raised by GAP members.

The maximum depth distribution of rougheye is in the 250-fathom range. That would seem to indicate the analysis of these lines really is for comparison only – and not intended to be established – as it seems clear they would not be necessary or appropriate.

One portion of the GMT analysis considered the use of Bycatch Reduction Areas (BRAs). However, the regulations state "Bycatch Reduction Areas may be implemented in the Pacific whiting fishery: as an automatic action for species with a sector-specific allocation." Therefore, it follows that since there are no sector-specific allocations of rougheye, then these proposed reduction areas are not available tools in the whiting fishery.

To recap: 1) a full assessment has been done (which shows the rougheye stock is healthy); 2) industry reacted immediately to institute *voluntary* inseason reductions in 2014 and begin sorting shoreside (see F.7.c, Public Comment, pages 7-15); and 3) a mandatory scientific sorting requirement – at the suggestion of fishermen and processors – will be implemented in 2015 and beyond.

It is clear that industry's actions demonstrate we are taking this issue seriously and making progress on rougheye/blackspotted reductions but need more time to consider the effect of these changes before looking at, let alone implementing, management measures such as draconian RCA line changes.

26. Non-trawl: Provide for lingcod retention in Periods 1, 2, and 6

Reference document(s)	Page(s), section, table or chart
F.7.b, Supplemental CDFW Revised Report No. 2	

The GAP prefers the option listed in the CDFW Supplemental Revised Report No. 2. A 600 lb./200 lb. option in period 6 for limited entry vessels north of 40° 10' N. lat. would be a better option – and more representative of fishing behavior -- with the correlating limits during the summer months. Corresponding trip limits for LE and OA south of 40° 10' N. lat. also are preferred by the GAP. The alternative choice is similar, but with lower limits in the summer, and can be found in Table B-43 on Page 93 of Excerpts from Appendix B. The most important issue to fixed gear and open access fishermen is to have a year-round lingcod fishery.

From CDFW Supplemental Revised Report No. 2:

Table 1. Preferred trip limits for limited entry and open access lingcod north of 40° 10' N latitude.

	Jan/Feb	Mar/Apr	May/Jun	Jul/Aug	Sept/Oct	Nov/Dec
Limited Entry	200	200	1,200	1,200	1,200	600/200
Open Access	100	100	600	600	600	600/100

Table 2. Preferred trip limits for limited entry and open access lingcod south of 40° 10' N latitude.

	Jan/Feb	Mar/Apr	May/Jun	Jul/Aug	Sept/Oct	Nov/Dec
Limited Entry	200	CLOSED	800	800	800	400/200
Open Access	100	CLOSED	400	400	400	400/100

27. Non-trawl recreational: Implement a one fish canary rockfish sub-bag limit for the Oregon recreational fisheries

Reference document(s)	Page(s), section, table or chart
Agenda Item F7a, Att6, Excerpted portions of Appendix B	Option 1, page 124

→ The GAP recommends Option 1, retention of one canary rockfish per day, as a sub-bag limit of miscellaneous groundfish daily bag limit of 10.

This has been a popular request from Oregon anglers. As the canary stock rebuilds, canary rockfish are hard to avoid. Landing some also would provide some biological data via dockside sampling to help inform future assessments and management. Furthermore, canary retention may also reduce impacts to other nearshore species such as black rockfish.

Amendment 24 – Default Harvest Control Rules

28. Select a final preferred alternative for default harvest control rules that would be used in future bienniums, unless modified by the Council, to establish future harvest specifications

Reference document(s)	Page(s), section, table or chart
F.7.a, Att. 8, Proposed Groundfish FMP Amendment Language	Page 5

→ The GAP recommends Alternative 3, Use the harvest control rules (HCRs) in place in the previous period (biennium) as defaults.

29. Provide guidance on FMP language to implement Amendment 24

Reference document(s)	Page(s), section, table or chart
F.7.a, Att. 8, Proposed Groundfish FMP Amendment Language	Page 5+

→ The GAP understands there will be some slight wording change but agrees conceptually with the changes.

PFMC
06/24/14

FISHERIES IN 2015-2016 AND BEYOND HARVEST SPECIFICATIONS, MANAGEMENT MEASURES AND AMENDMENT 24

Contents

The Groundfish Management Team (GMT) reviewed and discussed the materials provided under Agenda Item F.7, including the Action Item Checklist (Agenda Item F.7.a., Attachment 1), which itemizes the anticipated Council actions. For several items, the GMT did not identify a need for further discussion; therefore, those items are not detailed in this report. The remaining items are discussed below in the order they appear in the Action Item Checklist.

A summary of GMT recommendations can be found at the end of the statement.

2015-2016 Harvest Specifications

Checklist Item #2: Confirm P* and ABCs. Adopt revised 2016 cowcod ABC

In November 2013, the Council selected their final preferred P* values, working from the November 2013 GMT Supplemental Report under Agenda Item H.6. In Tables 1 and 2 of the GMT statement, four species (arrowtooth flounder, Pacific cod, shortbelly rockfish and yelloweye rockfish) were mistakenly omitted. The wording of the Council motions, setting P* of 0.45 for all species unless stated otherwise (arrowtooth flounder was added as an exception in an amendment to the motion), resulted in a change in P* for Pacific cod, shortbelly rockfish and yelloweye rockfish from 0.40 to 0.45. Speaking with the motion maker and reviewing the record, it is the GMT's understanding that the change from status quo P* for these three species was unintended. **The GMT recommends that the Council consider revisiting their P* decision for Pacific cod, shortbelly rockfish and yelloweye rockfish.** The GMT notes that the annual catch limit (ACL) harvest control rule (HCR) for these three species is independent of the allowable biological catch (ABC), so if the Council were to revise their P* decision there would be no downstream effects to the ACLs, harvest guidelines (HGs), management measures, etc.

Checklist Item #5: Confirm rebuilding plan parameters including a new T_{target} for cowcod

The draft environmental impact statement (DEIS) states that the Council could consider setting a later year for T_{target} than the median time to rebuild, considering uncertainty in assessment. In concept, this approach may prevent having to revise the rebuilding plan in the next cycle if something changes. Alternatively, the Council could adopt the median time to rebuild which theoretically means that there would be a 50 percent chance of re-specifying T_{target} with the next assessment.

It is our understanding that a full assessment may be desirable in the next few years (i.e. rather than catch reports) given that there may be new information from visual surveys in the cowcod conservation area (CCA). We note that cowcod assessments are fairly uncertain due to relatively little data to inform them. While there is some administrative burden to altering T_{target} with each subsequent rebuilding analysis, the Council should weigh this against the perception of giving themselves additional time to rebuild by extending the T_{target} beyond the median time to rebuild. Ultimately, the GMT would like to see an approach whereby a window of rebuilding probability is specified (i.e. rather than focusing on a point estimate date) with thresholds indicating whether adequate progress is being made toward rebuilding. We are optimistic that the explorations of alternative rebuilding scenarios, which is intended to inform rebuilding revision rules, (Agenda Item G.7.a, Attachment 2, September 2013) currently being conducted by Chantel Wentzel can inform development of such an approach.

2015-2016 Stock Complexes

Checklist Item #6: Confirm EC species' designations and associated FMP language to be implemented under Amendment 24

The GMT was informed at this meeting that NMFS is looking for more information on the Council's recommendation to designate Pacific Grenadier as an ecosystem component (EC) species. The GMT provides a discussion on EC designation for Pacific Grenadier under Agenda Item F.7.b, Supplemental GMT Report 2

2015-2016 Allocations and Harvest Guidelines (HGs)

Checklist Item #9: Confirm or modify amounts deducted from the ACL to account for groundfish mortality in Tribal, non-groundfish fisheries, EFPs and Research.

Tribal

The GMT notes that Tables 4-51 and 4-53 in the DEIS (Agenda Item F.7.a, Attachment 4) need to be updated to reflect the set aside increases requested by the Makah Tribe in their May 21, 2014 letter to NMFS (Agenda Item F.7.b, Supplemental Tribal Report). That request was to increase English sole from 91 mt to 200 mt, Pacific cod from 400 mt to 500 mt, widow rockfish from 60 mt to 100 mt, yellowtail rockfish from 677 mt to 1,000 mt, and to include a set aside for spiny dogfish of 275 mt.

Research

The GMT provided an update to research catch under the Inseason agenda item at this meeting (Agenda Item F.4.b, Supplemental GMT Report), following initial catch reports from the trawl survey, and discussed whether an adjustment to the canary rockfish set aside is necessary. Research catch of canary rockfish in the NMFS trawl survey to date is estimated to be 2.2 mt. The Council approach is that off-the-top deductions should be equal to the maximum historical scientific research catch from 2005-2012, except for canary rockfish and yelloweye rockfish. The Council policy for yelloweye and canary rockfish was not to adopt the maximum historical catch. The Council considered the high research catch for canary rockfish in 2006 from the NMFS trawl survey a rare event and adopted a set aside of 4.5 mt, which is higher than the average research catch (2005-2012), but lower than the maximum historical value.
Recent canary rockfish catch under research has been variable in recent years but has not exceeded the 4.5 mt set aside. (2010: 1.9 mt, 2011: 0.62 mt, 2012: 3.75 mt and 2013 (preliminary): 1.5 mt). Considering the research catch from 2010-2013, the GMT does not think there is sufficient cause to recommend an increase to the canary set aside for 2015-2016.

Checklist Item #13: Confirm or modify 2-year within non-trawl HGs or within non-trawl shares for 2015-2016

Nearshore Rockfish North of 40°10' N. lat.

Since the last Council meeting, state Council representatives have discussed the implications of harvest guidelines on the Nearshore Rockfish Complex for recreational and commercial fisheries in each state. The magnitude of reduction in catch needed to remain below harvest guidelines is disproportionate among states with the greatest reductions required in Oregon, while California and Washington can still provide status quo management under at least some of the harvest guideline options. In the case of California, this is due to the already reduced season length and shallower depth restrictions in the recreational fishery (5.5 months) and shallower depth restrictions in the commercial fishery to limit mortality on yelloweye rockfish.

The California Department of Fish and Wildlife (CDFW) report (Agenda Item F.7.b., Supplemental CDFW Report 1) proposes a Federal harvest guideline of 23.7 mt, which represents the mortality under the CDFW Preferred Alternative, which is the same as the No Action alternative mortality north of 40°10 N. latitude, in the EIS [i.e., expected commercial landings (Table 4-39) combined with projected recreational mortality (Table 4-50)].

The Oregon Department of Fish and Wildlife (ODFW) and Washington Department of Fish and Wildlife (WDFW) report (Agenda Item F.7.b., Supplemental WDFW/ODFW Report) outlines a trigger for inseason consultation and coordination at 62 mt or 75 percent attainment of each state's respective status quo harvest levels as noted in Table 1 of their report. The GMT acknowledges the commitment of the states to keep catch to the 69 mt coastwide ACL. The GMT recommends that inseason tracking and scheduling of the consultation call(s) are completed early enough to include projected impacts of mortality for discarded fish if non-retention of nearshore rockfish is necessary to stay within the coastwide ACL. Questions have arisen relative to the timing of season openings, the different pace of recreational and commercial fisheries in each state, and the potential for inequity in attainment between states at the time in which inseason action becomes necessary.

The GMT provides a summary of the cumulative mortality in the Oregon and Washington recreational and commercial fisheries during 2008-2012 by month to show the seasonality of the fisheries relative to the proposed 75 percent trigger, Appendix A, Figure 2. In addition the mortality in 2012 alone was analyzed to provide a more recent depiction of the rate of catch accumulation as catch has increased significantly in recent years and use of data in previous years may under project the rate of mortality accumulation Appendix A, Figure 3. These figures indicate that the trigger is likely to be reached between June and July under status quo conditions, though the one to one and a half month lag in the recreational fishery data will not allow analysts to realize it has been reached until August and mortality will continue to accrue during the intervening period and until action is taken after consultation.

The ODFW report under F.3 (Agenda Item F.3.b., Supplemental ODFW Report) proposes further analysis of Nearshore Rockfish complex management under the omnibus package. In the long-term, the states may be most satisfied by a state level management system that provides ACLs for each state resulting from assessments stratified at state boundaries. The GMT analysis of state specific harvest guidelines (HG) for the Nearshore Rockfish complex (Agenda Item F.7.a, Attachment 5) points out the inadequacy of any allocation method to truly represent the relative abundance along the coast to facilitate allocation and differential regulations over time necessitating assessment and management at a state level to facilitate improved management. ODFW has indicated that they have sufficient infrastructure to assess and manage nearshore stocks within their waters. The higher species diversity makes this less feasible in the waters off of California where 12 species of Nearshore Rockfish other than black rockfish occur (Love et al. 2002) and management would benefit from a federal nexus to provide regular assessment with assistance from the Science Centers.

Establishing an improved management system that is responsive to the needs of each state is beyond the scope of the 2015-2016 regulatory specifications process and should be addressed either in the omnibus package or in the 2017-2018 regulatory specification process. In the interim, the proposed actions of the states may be sufficient to prevent an ACL overage and will be dependent on our ability to project and track catch during the course of the season. The management measures to remain within this value have not been specified up front and will be developed inseason depending on the nature of the concern. The proposed California recreational and commercial management measures are projected to keep mortality within the HG of 23.7 mt, which is lower than all but the lowest allocation under the miles of coastline HG allocation option analyzed by the GMT (Agenda Item F.7.a, Attachment 6). California can take inseason action to keep mortality within the California state HG if needed. The GMT recognizes that these are interim measures while an improved management system can be developed that accounts for differing management between states and the potential for differing levels of depletion that results. While stock assessment authors may prefer alternative stratifications, the GMT feels that independent state ACLs based on assessments stratified at state lines would facilitate management at the state level in the future.

Checklist Item #13: Within non-trawl: Two-Year Yelloweye Sharing- consider transferring 0.6 mt of the yelloweye rockfish non-trawl allocation fishery HG from the non-nearshore to nearshore

The GMT provided an initial analysis regarding transferring 0.6 mt of the yelloweye rockfish non-trawl allocation fishery HG from the non-nearshore to the nearshore commercial fixed gear sectors under Agenda Item F.7.a., Attachment 6. The GMT provides additional analysis and discussion this issue in Agenda Item F.7.b., Supplemental GMT Report 2.

Currently, projected mortality of yelloweye rockfish is 0.6 - 0.7 mt lower than the catch share for non-nearshore fixed gear, and 0.0 to 0.1 mt lower than the catch share for nearshore fisheries. These projections are point estimates, and based on average catch over a number of years. Historical catch data show high variability in yelloweye catch among years – a simulation analysis was used to demonstrate that estimated yelloweye mortality in the fixed gear fisheries may range somewhere between approximately 40% of the point estimated (low) to approximately 175% of the point estimate (high), 90% of the time. This variability should be taken into account when catch share decisions are made. Some buffer between catch projections and catch share may lead to higher stability for these fisheries. We show that the commercial non-trawl sector would have exceeded the 2015 allocation (PPA) in 2 of 10 years. Finally, we show that the probability of west coast fisheries exceeding the ACL is 0.7 percent under status quo, and 2.1 percent if 0.6 mt of yelloweye is moved from the non-nearshore fishery to the nearshore fishery, and the entire amount is taken by the nearshore fishery.

The analyses associated with transferring up to 0.6 mt of yelloweye allocation from the non-nearshore to the nearshore sector considered both the risk of the total coastwide catch exceeding the ACL, which is low under any level of transfer, and the risk of individual sectors exceeding their allocation, which is more difficult to quantify due to variability among years and uncertainty in the estimated catches. However, a transfer from the non-nearshore sector that has had a larger buffer to the nearshore sector (for which various other management measure are being explored) is likely to reduce the overall risk of a sector exceeding its allocation.

The GMT recommends that the Council consider annual variability and the probability of exceeding the ACL when deciding whether to move 0.6 mt (or less) of yelloweye rockfish from the non-nearshore fishery to the nearshore fishery. The GMT notes that buffers between the point estimate and the catch share may reduce the chance of exceeding the catch share.

2015-2016 Season Structures

Checklist Item #15: Trawl RCA

Modified trawl RCA seaward boundary line between 40° 10' N. latitude and 45° 46' N. latitude

Currently, depth-based management tools for bottom trawl gears include rockfish conservation areas (RCA), which are used to control catch of species (e.g. target species, bycatch species, and overfished species). In the event the Council's preferred alternative RCA, which includes a 150 fm seaward RCA from 40'10 to 45° 46' N. latitude year round, is unavailable per NMFS inseason disapproval, the Groundfish Advisory Panel (GAP) has requested implementation of the seaward 200 modified line year round. Given the low bycatch rates for overfished species in the rationalized fishery, the GAP recommends increasing access to target stocks through implementation of the seaward modified 200 fathom line. This action would allow fishing participants to further demonstrate individual accountability of the shorebased trawl Individual Fishing Quota (IFQ) program to minimize bycatch and incidental catch of overfished species. This action is needed to enable participants the ability to more fully and efficiently utilize their quota pounds, while still meeting the Council's goal for sustainability of the Pacific Coast groundfish fishery. Low attainments of some economically important species and implementation of the seaward modified 200 fathom line would allow trawlers to take advantage of opportunities to maximize the potential of their business plans, while allowing the IFQ system to minimize risks to stocks of concern.

The trawl RCA Environmental Assessment (EA) prepared by NMFS demonstrates that the risk of exceeding Annual Catch Limits (ACLs) of any species or contribution Overfishing Limits (OFLs) for species within a complex by implementing the 200 fathom modified seaward boundary line between 40° 10' N. latitude and 45° 46' N. latitude is unlikely. Overfished species impacts were analyzed in the EA to characterize impacts of the implementation of the 200 fathom modified line, with a heightened emphasis on canary rockfish, darkblotched rockfish, Pacific ocean perch, yelloweye rockfish, and petrale sole. Other non-target species were analyzed in the EA, with an emphasis on spiny dogfish, longnose skate, aurora rockfish, rougheye rockfish, and shortraker rockfish. The analysis of impacts to overfished species and other non-target species under year-round implementation of the 200 fathom modified petrale line indicate that there is little risk in catch exceeding the ACL.

Regarding potential Essential Fish Habitat (EFH) impacts, the RCA EA analyzed spatial differences between the 200 fathom RCA line and the 200 fathom-"modified" line (Figure 4-4 and 4-5 in the EA) with petrale cutouts. In addition, qualitative information was provided in table 4-2 in the EA to help ascertain whether each cutout was deliberate. Furthermore, a thorough investigation of the proportion of substrate types (probable hard, mixed, and soft substrates) within the different depth zones between 40° 10' N. and 48° 10' N. latitude was completed.[1] Due to the limitations of scale from the available GIS data layers, defining substrate type percentage break-outs within each individual petrale cutout would likely not be sufficiently informative, and may be overly speculative given the small size of many of these cutouts. Since these areas have largely been open to bottom trawl gear intermittently for a number of years, much of these areas have likely been impacted at some point in recent years, and therefore have not had a chance for habitat recovery, even if effort within them is not necessarily spatially uniform. Furthermore, preliminary logbook analysis provided in Table 4-160 in Agenda Item F.7.a, REVISED Supplemental Attachment 11 suggests that petrale sole cutout areas have a very high degree of bottom trawl effort, with higher proportional (1) number of tows, (2) tow duration, and (3) total hail weight. **Therefore, the GMT concludes exceeding ACLs of any species or contribution OFLs for species within a complex, or adverse impacts to EFH is unlikely to occur by opening the petrale cut outs with a seaward year-round 200 fathom-modified line between 40° 10' N. and 45° 46' N. latitude.**

Checklist Item #16: Non-trawl trip limits (including sablefish)
Regarding the non-trawl coastwide sablefish trip limit analysis (Agenda Item F.7.a, Attachment 6, June 2014, B.10), the GMT would like to clarify a specific sentence. That sentence, found on page 119, third paragraph, states that "Projected attainment values for the four sablefish daily trip limit (DTL) fisheries under the No Action Alternative are within the range generally recommended by the Council, of between 90 and 95 percent…". The GMT does not recall the Council making that specific recommendation. Instead, the GMT often provides a range of alternatives, sometimes resulting in projections equaling or slightly exceeding 100 percent. Sablefish landings are variable among years, and depend on things such as weather, price, and successfulness of other fisheries. The Council often considers all of these factors, along with how far the fishery has advanced into the season, before making their trip limit decision. This is a matter of measuring risk. In some cases, the Council has set trip limits when projections showed 100 percent attainment, whereas in other cases the Council has selected trip limits showing projections lower than 100 percent.

Checklist Item #20: Season dates, bag limits, length limits, area closures
The GMT recommends the Council consider the CDFW preferred California Recreational Season and Depth Restrictions for 2015-2016 as described in the CDFW state report (Agenda Item F.7.b, REVISED Supplemental CDFW Report 2). The season and depth restrictions in each management area are depicted in Figure 1, which are projected to keep the mortality of target and overfished stocks presented in Table 1 and Table 2 within their respective harvest limits. In addition, an increase in the lingcod bag limit from be two to three fish, statewide can

[1] (1) 75-100 fathoms, (2) 100-150 fathoms (the core RCA not requested for opening), and (3) 150-200 fathoms (with further investigation within these depths between 40° 10' N. and 45° 46' N. latitude, and between 45° 46' N. and 48° 10' N. latitude).

be accommodated and is proposed under the CDFW preferred alternative. Though angler trips from this option are not yet available for review, they are within the range presented in the EIS.

Management Area	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec
Northern	Closed				May 15 – Oct 31 <20 fm						Closed	
Mendocino	Closed				May 15 – Oct 31 <20 fm						Closed	
San Francisco	Closed			April 15 – Dec 31 <30 fm								
Central	Closed			April 1 – Dec 31 <40 fm								
Southern	Closed		Mar 1 – Dec 31 <60 fm									

Figure 1. CDFW Preferred Alternative: California recreational groundfish season structure and depth restrictions for 2015-2016.

Table 1. CDFW Preferred Alternative: California recreational projected mortality of overfished species for 2015-2016.

Species	**Projected Mortality (mt)**
Bocaccio	117.2
Canary Rockfish	18.2
Cowcod	1.2
Yelloweye Rockfish	2.1

Table 2. CDFW Preferred Alternative: California recreational projected mortality of non-overfished species for 2015-2016. Results in parenthesis reflect lingcod mortality with a three fish bag limit.

Species	**Projected Mortality (mt)**
Black Rockfish	187.3
Blue Rockfish	58.4
Cabezon	37.1
California scorpionfish	81.1
Greenlings	17.8
Lingcod	258.7(311.3)
Minor Nearshore Rockfish North	11.8
Minor Nearshore Rockfish South	352.8
Widow Rockfish	3.6

2015-2016 Adjustments to Existing or Routine Measures

Checklist Item #22: Using underutilized set-asides in the projections for the shorebased IFQ carryover

The Council requested consideration of the likelihood that set asides will be harvested when considering the risk that carryover will cause unacceptable overage. In brief, the GMT looks to set asides together with projections of harvest across all sectors when presenting the inseason risk analysis to the example. We did so this past March and we recommended that carryover be issued for all species (Agenda Item D.4.b, Supplemental GMT Report).

We also had hoped to include a more in-depth analysis of the trends and dynamics of carryover here. We have analysis and a simulation approach that demonstrates that carryover will keep catch below the quota pounds (QP) amount issued over a multi-year period except in certain deficit QP usage situations (i.e. the deficit would have to be large enough to offset earlier surpluses in the evaluation period). We have noted multiple times that interpretations of the carryover program have taken implementation away from the original intent (D.8.b, Supp GMT, June 2012, H.5.b, Supp GMT, September 2012, H.3.b, Supp GMT March 2013). The intent was to issue carryover automatically without the inseason risk decision that is being required now. We would reiterate that the inseason risk analysis involved more workload of the team and NMFS staff than it should. We could not write our analysis up in full by this time and suggest taking it up under discussions of long-term fixes to the carryover.

Under Agenda Item F.4, the Council discussed NMFS's letter on a recent court ruling that states that shorebased IFQ species with ABC=ACL would not be permitted carryover in the 2014 season. This resulted in 19 of 30 shorebased IFQ species being allowed to have carryover. Table 3 shows a breakdown of species with carryover allowed and not allowed for 2014 and the percent attainment for that IFQ species in 2013. Sixteen of 19 species with allowances for carryover had attainment rates of less than 50 percent. Notable species for which carryover was allowed and had attainment greater than 50 percent were Dover sole, shortspine thornyhead, and longspine thornyhead. Of the remaining 11 species that carryover was not permitted for, 8 species had attainment less than 50 percent. Some on the team question the logic of the decision. If that logic is extended and we manage on how much that could theoretically be taken instead of on how much we project/expect to be used, then it would call into question bag and trip limit management. If everyone that was eligible to take the full trip and limits did, then catch would exceed the levels we were managing to.

Table 3. Percent Attainment of Sector Quota for Shorebased IFQ species in 2013 permitted and not permitted for carryover in 2014. (Generated from NOAA West Coast Groundfish IFQ Application on 06/22/2014 10:47 AM)

IFQ Species	Sector Quota (lbs)	Total Catch (lbs)	Percent Attainment
Carryover Permitted			
Bocaccio rockfish (S of 40^{o} 10')	165,126	28,332	17.16%
Canary rockfish	87,964	22,526	25.61%
Cowcod (S of 40^{o} 10')	2,205	486	22.04%
Darkblotched rockfish	587,976	256,485	43.62%
Dover sole	49,018,682	17,583,083	35.87%
Longspine thornyheads (N of 34^{o} 27')	4,100,267	2,400,808	58.55%
Minor shelf rockfish (N of 40^{o} 10')	1,119,948	65,686	5.87%
Minor shelf rockfish (S of 40^{o} 10')	178,574	44,443	24.89%
Minor slope rockfish (N of 40^{o} 10')	1,712,835	431,244	25.18%
Other flatfish	9,236,501	1,767,468	19.14%
Pacific cod	2,480,830	339,657	13.69%
Pacific halibut (IBQ) (N of 40^{o} 10')	236,660	72,707	30.72%
Pacific ocean perch (N of 40^{o} 10')	241,241	108,062	44.79%
Sablefish (N of 36^{o})	4,030,050	4,080,318	101.25%
Sablefish (S of 36^{o})	1,327,800	200,064	15.07%
Shortspine thornyheads (N of 34^{o} 27')	3,054,183	1,825,663	59.78%
Shortspine thornyheads (S of 34^{o} 27')	110,231	8,150	7.39%
Widow rockfish	2,191,016	907,513	41.42%
Yelloweye rockfish	2,205	139	6.30%
Carryover Not Permitted			
Arrowtooth flounder	8,479,264	5,365,841	63.28%
Chilipepper rockfish (South of 40^{o} 10')	2,423,983	870,774	35.92%
English sole	14,032,486	486,273	3.47%
Lingcod (N of 40^{o} 10')	2,695,305	749,955	27.82%
Lingcod (S of 40^{o} 10')	1,089,993	36,814	3.38%
Minor slope rockfish (S of 40^{o} 10')	829,181	258,778	31.21%
Pacific whiting	216,707,790	215,218,208	99.31%
Petrale sole	5,110,315	4,695,933	91.89%
Splitnose rockfish (S of 40^{o} 10')	3,346,838	101,757	3.04%
Starry flounder	1,656,774	7,705	0.47%
Yellowtail rockfish (N of 40^{o} 10')	5,809,905	1,585,755	27.29%

Nonetheless, we see little practical effect of this latest carryover policy for most species. Because attainment is so low, there is likely little interest in receiving the carryover QP. The carryover may matter to some individual operations, but on the whole, if people cannot use the QP issued for the year, then they will not be looking to use the surplus from the prior year. Carryover is most beneficial for stocks where attainment levels are high.

Based on this new ruling, the GMT suggests that the Council may need to re-examine how ACLs are calculated as the court ruling is different from the past approach of rely on ACL/ABC/OFL projections.

Checklist Item #23: Non-trawl trip limit adjustments for lingcod N. of 40º10' N. lat. (increase), slope rockfish N. of 40º10' N. lat. (decrease), bocaccio S. of 34º27' N. lat. (increase), and shelf rockfish S. of 34º27' N. lat. (increase)

The GMT comments on #23 will be forthcoming in GMT Report 3.

New Management Measures for Implementation in 2015-2016

Checklist Item #25: Establish New RCA Coordinates for 300 and 350 fathom boundaries
At the April 2013 meeting, the Council requested "... trawl RCA boundary alternatives at 300 fm and 350 fms for analysis." The regulatory definition of trawl gears includes bottom trawl and midwater gears, and as such, the GMT analyzed the impacts of implementing depth closures for bottom trawl gears targeting Dover sole, thornyheads, and sablefish, and midwater gears targeting Pacific whiting (i.e., shorebased IFQ and at-sea). The available analysis can be found in Agenda Item F.7.b Supplemental GMT Report 2.

Expansion of Seaward of RCA Boundaries
Depth-based management tools for bottom trawl gears include RCAs to control catch of species, for example, target species, bycatch species, and overfished species. Currently, the shoreward boundary is 100 fathoms and the seaward RCA boundary from 48°10' to 45°46' N. latitude is 150 fathoms and 200 fathoms from 45°46' to 40°10' N. latitude. The GMT was only able to conduct a cursory exploration of the impacts of expanding the RCA to 250 fathoms, based on the data summarized in Agenda Item F.7.b Supplemental GMT Report 2.

However, that analysis of impacts does capture the essential difference between leaving the area open and closing out to 250 fm in terms of rougheye impacts. Likewise, it should be easy to understand the difference in magnitude of the implications from placing the RCA line at 250 fm and closing everything beyond 100 fm without knowing exactly what species might be caught and in what amounts. This is unlikely to be predicted with a high degree of certainty regardless, since we have never had occasion to use such measures in conjunction with the IFQ fishery.

Substantial reductions of rougheye rockfish would be expected if fishing were prohibited from the 100 fathom shoreward boundary to a seaward 250 fathom (Table 1, Agenda Item F.7.b Supplemental GMT Report 2). From 2002-2012, 75 percent (105 mt) of rougheye were caught on observed hauls from 150 fathom to 250 fathom. In that same time period, 37 percent of the observed bottom trawl hauls occurred in bottom depths from 150 to 250 fathom (Table 3, Agenda Item F.7.b Supplemental GMT Report 2). Changes in target species catch per unit effort (CPUE) and overfished species bycatch rates, as a result of expanding the seaward RCA boundary to 250 fathom would also be expected though there was insufficient time for analysis. Future analysis should also consider analyzing only 2011-2012 data, years in which the bottom trawl sector was rationalized as different patterns may be evident.

New Management Measures - 300 and 350 fathom RCA

It is the GMT's understanding that the proposal to establish new coordinates approximating the 300 and 350 fathom depth contours were intended to provide options for reducing encounters with rougheye rockfish. Under this scenario, fishing would be allowed from 300/350 fathoms to 700 fathoms. Approximately 94 percent of observed hauls occurred in the area 150 to 300 fathoms and 97 percent from 150 to 350 fathoms, a substantial disruption to fishing operations (Table 3, Agenda Item F.7.b Supplemental GMT Report 2). Under this scenario, new fishing opportunities and target strategies would need to be explored from 300/350 fathoms to 700 fathoms. Changes in target species CPUE and overfished species bycatch rates, as a result of expanding the seaward RCA boundary to 300/350 fathoms are also expected though there was insufficient time for analysis.

Application of the 300 and 350 fathom Line to Midwater Gears

Currently, the only depth-based management tool available for the Pacific whiting sectors are called Bycatch Reduction Areas (BRA), since vessels are allowed to fish in the trawl RCA during the primary whiting season (i.e., the trawl RCAs do not apply). BRA apply to vessels on Pacific whiting trips using midwater gear during the primary whiting season and prohibit fishing shoreward of the 75, 100, and 150 fathom depth contours (see regulations at 660.131(c)(4) Subpart D). BRAs are automatic actions implemented by NMFS when NMFS projects that a sector will exceed an allocation for a non-whiting groundfish species specified for that sector before the sector's whiting allocation is projected to be reached.

For 2015-2016, the Council has not proposed sector-specific allocations for rougheye/blackspotted. As such, the criteria for NMFS to use automatic actions for implementing BRAs do not appear to be satisfied. This is in contrast to RCA adjustments for bottom trawl gears which are recommended by the Council and, most typically, implemented through inseason action. The GMT recommends that if the Council is interested in BRAs to control rougheye rockfish catch that they be designated as routine and not as an automatic action.

At-Sea Sectors

Rougheye rockfish catches by depth in depths in areas shoreward of 300 or 350 fathoms can be found in Table 1 of Agenda Item F.7.b Supplemental GMT Report 2. From 2002-2012, 92 percent of the at-sea hauls occurred in depths shallower than 300 fathoms (Table 3, Agenda Item F.7.b Supplemental GMT Report 2). As such, it appears that prohibiting fishing shallower than 300 fathoms could result in a substantial disruption of fishing operations compared to historical activities. Changes in Pacific whiting CPUE and overfished species bycatch rates, as a result of concentrating fishing activity on the slope are also expected though there was insufficient time for analysis. Future analysis should also consider analyzing only 2011-2012 data, years in which the at-sea sectors were rationalized as different patterns may be evident. Further, evaluating the individual sectors (e.g., CP and MS) might also be warranted.

Shorebased Midwater Whiting

As noted in Agenda Item F.7.b Supplemental GMT Report 2, the WCGOP data contained average depth of fishing, instead of bottom depth. As such, the summary of impacts, similar to what was provided above for the at-sea and bottom trawl sector, were not able to be derived.

Summary

Changes in target species CPUE and overfished species bycatch rates are also expected under these management measure proposals but were not able to be analyzed. For example, if deeper areas were closed off to bottom trawling, then effort shifts to more shoreward areas could severely curtail fishery operations due to limited availability of canary and yelloweye quota. Possible changes in revenue, other incidental species (e.g. Shelf Rockfish Complex), effects on port communities, etc. should ideally be explored prior to implementation; however, there was insufficient time to perform these analyses prior to or at this meeting.

The GMT was only able to conduct limited analysis to facilitate decision-making in the time available between the April and June Council meetings. With more time we could have more fully analyzed available catch data to explore the possible effects on target and incidental species from the use of any of the lines, by sector. The GMT anticipates that a detailed consideration of the impacts would be considered in the specific circumstances calling for their possible use.

While some on the team worry about the analysis that could not be done, others emphasize that this was intended to "add tools to the toolbox." The lines are not for immediate implementation. While recognizing that opportunity for public input on impacts was limited at this meeting and that more analysis could be done, many of the impacts analysis pointed to as shortcomings here could be closely examined if circumstances called for a close look. Likewise impacts could be more carefully and more effectively considered in the specific circumstances calling for their possible use. It is often more useful to compare and contrast impacts against other options available at the time. At this time, we do not have immediate need for the lines. And the impacts of the lines would be speculative. Yet we can say with some confidence that the 300 and 350 fathom lines would reduce bycatch of rougheye more than the existing 250 fm line and cause no more adverse economic consequences than the other tools available in the case that existing lines and tools are insufficient (i.e. a complete closure or a closure out to 700 fm might be necessary). The Council therefore may wish to include the lines for this contingency. In this view, the decision on how much "analysis" is sufficient to justify the policy purpose is not the GMT's to make.

The GMT also recommends that future efforts attempt to identify more discrete area closures, similar to the rougheye groundfish conservation area analysis, which was moved into the Omnibus prioritization. The Council has successfully implemented yelloweye rockfish conservation areas, for example, in lieu of closing larger areas of the coast.

Checklist Item #26: Non-Trawl: Allow Lingcod Retention in Periods 1, 2, and 6

The GMT will have a statement on item #26 in Supplemental GMT Report 3.

Checklist Item #27: Recreational: Canary Rockfish Bag Limit

In April 2014, the Council forwarded (limited) retention of canary rockfish in the recreational fishery in Oregon only. Retention in California and Washington were eliminated from further consideration at that time. Since April, the GMT attempted to clarify the background information and the analysis.

Under the current regulation of non-retention for canary rockfish, annual impacts from the Oregon recreational fishery are projected to be 3.1 mt, from discard mortality. The analysis indicates that allowing a one fish sub-bag limit (of the 10 fish daily bag limit, no more than one may be a canary rockfish) would increase the annual projected impacts to 8.1 mt, which is 3.6 mt (30 percent) below the preferred alternative Oregon recreational fishery HG of 11.7 mt in 2015. Allowing canary rockfish to be part of the regular bag limit (10 fish), with no sub-limit, is projected to increase impacts to 9.5 mt, still under the Oregon recreational HG by 19 percent.

Concern has been expressed that increasing mortality from the recreational fishery could impact the canary rockfish rebuilding progress. However, the GMT understands that the rebuilding plan assumes that the entire ACL is attained annually. The annual total mortality from the Oregon recreational fishery (and all fisheries) is variable and uncertain; however, the estimated additional catch is within that margin of error around the HG.

The GMT also expressed concern regarding potential for changes in angler behavior that could increase canary rockfish mortality resulting from allowing a one fish bag limit to exceed projections from a bag analysis. Despite these concerns, the GMT is supportive of a one fish bag limit as buffers are in place to accommodate unaccounted for mortality and the capability of ODFW to implement timely inseason action to prohibit retention inseason to curtail accrual of canary rockfish mortality. The GMT notes that this a one fish bag limit will allow for biological sampling of landed catch to obtain otoliths and other pertinent biological information on retained catch to better inform future assessments.

Amendment 24 – Default Harvest Control Rules

Checklist Item #28: Select a final preferred alternative for default harvest control rules that would be used in future bienniums, unless modified by the Council, to establish future harvest specifications

The GMT did not have time to discuss the harvest control rules at this meeting. The GMT continues to support Alternative 3 as being the most reflective of how the Council has operated and will most likely continue to operate in the future.

GMT Recommendations

Subject	Title	GMT Input
Checklist Item #2	Confirm P* and ABCs. Adopt revised 2016 cowcod ABC	Consider revisiting their P* decision for Pacific cod, shortbelly rockfish and yelloweye rockfish
Checklist Item #5	Confirm rebuilding plan parameters including a new T-target for cowcod	No recommendation
Checklist Item #6	Confirm EC species' designations and associated FMP language to be implemented under Amendment 24.	The GMT provides clarification under F.7.b Supplemental GMT Report 2
Checklist Item #9	Confirm or modify amounts deducted from the ACL to account for groundfish mortality in Tribal, non-groundfish fisheries, EFPs and Research.	Revise the set asides to reflect the updates to tribal fisheries The GMT does not recommend increasing the canary rockfish set aside for 2015-2016
Checklist Item #13	Confirm or modify 2-year within non-trawl HGs or within non-trawl shares for 2015-2016.	Consider annual variability and the probability of exceeding the ACL when deciding whether to move 0.6 mt (or less) of yelloweye rockfish from the non-nearshore fishery to the nearshore fishery.
Checklist Item #15	Trawl RCA	The GMT concludes that adverse impacts to EFH would not likely occur by opening, year-round, the petrale cut outs with a year-round 200 fathom-modified line between 40° 10' N. and 45° 46' N. latitude.
Checklist Item #16	Non-trawl trip limits	No recommendation
Checklist Item #20	Season dates, bag limits, length limits, area closures	The GMT recommends the Council consider the revised Final Preferred California Recreational Season and Depth Restrictions as described in the CDFW state report.
Checklist Item #22	Using underutilized set-asides in the projections for the shorebased IFQ carryover.	The GMT suggests that the Council may need to re-examine how ACLs are calculated as the court ruling is different from the past approach of rely on ACL/ABC/OFL projections.

Subject	Title	GMT Input
Checklist Item #23	Non-trawl trip limit adjustments for lingcod N. of 40º10' N. lat. (increase), slope rockfish N. of 40º10' N. lat. (decrease), shortspine thornyhead N. of 34º27' N. lat. (no change) bocaccio S. of 34º27' N. lat. (increase), and shelf rockfish S. of 34º27' N. lat. (increase).	See Agenda Item F.7.b, Supplemental GMT Report 3
Checklist Item #25	Establish New RCA Coordinates for 300 and 350 fm boundaries.	No recommendation
Checklist Item #26	Allow Lingcod Retention in Periods 1, 2, and 6.	See Agenda Item F.7.b, Supplemental GMT Report 3
Checklist Item #27	Canary Rockfish Bag Limit	The GMT is supportive of a one-fish sub-bag limit.
Checklist Item #28	Select a final preferred alternative for default harvest control rules that would be used in future bienniums, unless modified by the Council, to establish future harvest specifications.	The GMT continues to support Alternative 3.

Appendix A. Historical Nearshore Rockfish Catches.

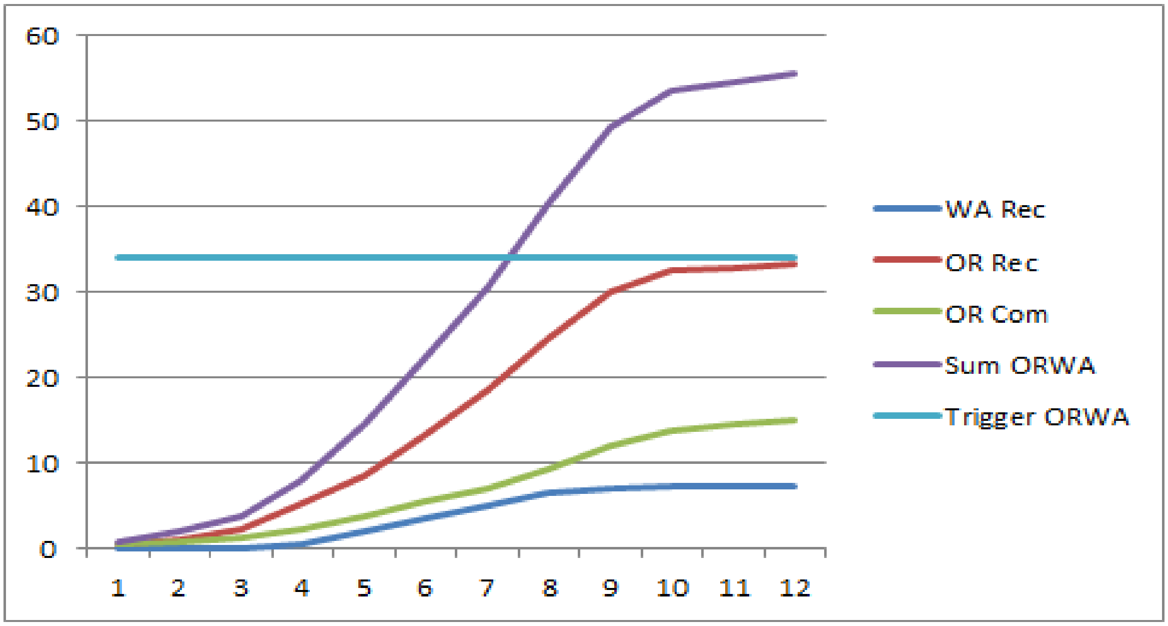


Figure 2. Average monthly cumulative Nearshore Rockfish complex mortality in the Washington and Oregon fisheries from 2008-2012 compared to trigger proposed in the WDFW/ODFW state report.

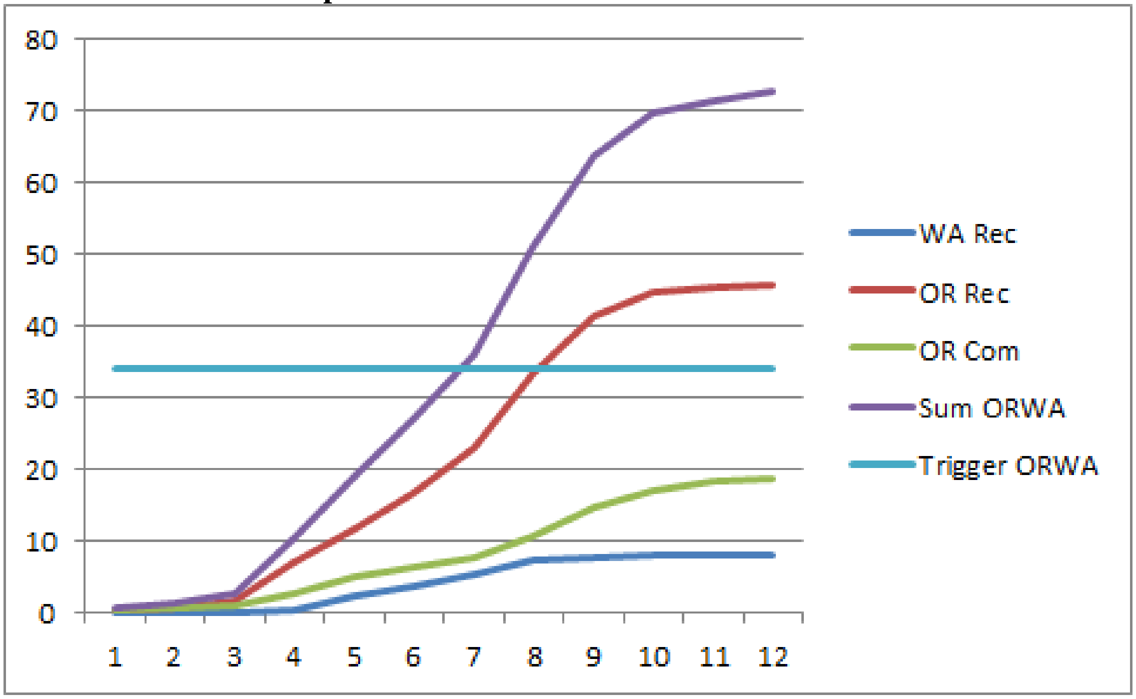

Figure 3. Average monthly cumulative Nearshore Rockfish complex mortality in the Washington and Oregon fisheries from 2012 compared to trigger proposed in the WDFW/ODFW state report.

GROUNDFISH MANAGEMENT TEAM REPORT ON FISHERIES IN 2015-2016 AND BEYOND HARVEST SPECIFICATIONS, MANAGEMENT MEASURES, AND AMENDMENT 24

Checklist Items #26 and #26 – Trip Limit Analyses

The remaining management measures shown in **Agenda Item F.7.a, Attachment 6**, June 2014: are provided below. Those management measures deal with trip limit alternatives for lingcod, slope rockfish, shortspine thornyhead, bocaccio rockfish, and shelf rockfish. They also summarize allowing lingcod retention during the currently closed period (December – April).

Checklist Item #23: Non-trawl trip limit adjustments for lingcod N. of 40º10' N. lat. (increase), slope rockfish N. of 40º10' N. lat. (decrease), bocaccio S. of 34º27' N. lat. (increase), and shelf rockfish S. of 34º27' N. lat. (increase)

Slope Rockfish N. of 40º10' N. latitude

The GMT reviewed the trip limit analysis submitted at this meeting, (Agenda Item F.7.b, Supplemental GMT Report 2) and provides the following guidance regarding the use of trip limits for slope rockfish for the non-trawl fishery north of 40°10' N. latitude. In sum, the GMT does not believe that reductions to trip limits will provide meaningful reductions to rougheye rockfish mortality, because rougheye rockfish is mostly caught incidentally while targeting sablefish (i.e., is mostly not targeted). Rougheye rockfish represents only a small fraction of overall catch (i.e., highly valued sablefish is the main target), and only a portion of the slope rockfish complex. Therefore, trip limits will likely not reduce rougheye rockfish mortality substantially, especially during unobserved trips.

Lingcod north of 40°10' N. latitude, shortspine thornyhead north of 34°27' N. latitude, bocaccio south of 34°27' N. latitude, and shelf rockfish south of 34°27' N. latitude

Trip limit analyses were completed for the 2015-2016 biennial management cycle for lingcod north of 40°10' N. latitude, shortspine thornyhead north of 34°27' N. latitude, and for bocaccio and the minor shelf rockfish complex south of 34°27' N. latitude in Agenda Item F.7.a, Attachment 6 for each of the trip limits in Table 1. We want to highlight for the Council that the lingcod analysis summarized here was revised and included in Agenda Item F.7.a., Supplemental Attachment 10. In addition, this lingcod analysis should be used only for current "summer" fishery (i.e., for the months May – November), and assumes no lingcod retention for December-April (i.e., "winter" months). See Item #26 for combined "summer" and "winter" lingcod trip limit analyses.

The estimated mortality amounts for these four fishery sectors are as follows.

Table 1 . Proposed trip limits for the four fishery sectors analyzed for the 2015-2016 biennial management cycle. Trip limits are reported in pounds per vessel per two-month period (or by month for the OA lingcod sector), when fishing is allowed. For lingcod, reference to Agenda Item F.7.a Supplemental Attachment 10, June 2014. For the other fishery sectors, reference to Agenda Item F.7.a Attachment 6, June 2014.

Fishery Sector	Option 1a - No Action	Option 1b (no winter retention)	Option 1c (no winter retention)
Lingcod LE	800 lb/2 months	1,200 lb/2 months	1,600 lb/2 months
Lingcod OA	400 lb/month	600 lb/month	800 lb/month

Fishery Sector	Option 1 - No Action	Option 2a	Option 2b
Shortspine thornyhead LE only	2,000 lb for periods 1-3 2,500 lb for periods 4-6	2,250 lb for periods 1-3 2,500 lb for periods 4-6	2,500 lb for all periods
Bocaccio LE	300 lb for periods 1 & 3 500 lb for periods 4-6	750 lb/2 months	1,000 lb/2 months
Bocaccio OA	100 lb for periods 1 & 3 200 lb for periods 4-6	250 lb/2 months	500 lb/2 months
Minor shelf rockfish complex LE	3,000 lb/2 months	4,000 lb/2 months	5,000 lb/2 months
Minor shelf rockfish complex OA	750 lb/2 months	1,500 lb/2 months	2,500 lb/2 months

For lingcod, Option 1b estimates a combined limited entry (LE) and open access (OA) mortality of 56.9 mt (4.2 percent of the lingcod non-trawl allocation amount). Option 1c estimates a combined LE + OA mortality of 75.9 mt (5.6 percent of the allocation). For shortspine thornyheads, Option 2a has a mortality estimate of 80.3 mt (96.4 percent of the non-trawl allocation). Option 2b has a mortality estimate of 83.4 mt (98.9 percent of the allocation). For bocaccio, Option 2a has a combined LE + OA mortality estimate of 8.8 mt (3.4 percent of the non-trawl allocation). Option 2b has a combined LE + OA mortality estimate of 15.5 mt (6 percent of the allocation). For the minor shelf rockfish complex, Option 2a has a combined LE + OA mortality estimate of 399 mt (29 percent of the non-trawl allocation). Option 2b has a combined LE + OA mortality estimate of 416 mt (30 percent of the allocation).

The GMT recommends that the Council consider Option 1b for lingcod if the Council is only interested in increasing trip limits and not providing for winter retention (analysis of the combined trip limit and retention is provided below in item #26 below). This alternative moderately increases May-October trip limits (e.g., increase by 400 lbs / 2 months for LE).

The GMT recommends status quo (No Action alternative) trip limit amounts for shortspine thornyhead because any increased trip limits could cause the total estimated attainment to exceed the allocation amount.

The GMT recommends Alternative 2a for bocaccio (very modest trip limit increases) mainly because bocaccio is still considered an overfished species and until the stock is declared no longer overfished, it is prudent to continue to manage the stock conservatively. West Coast Groundfish Observer Program (WCGOP) data were examined for the bocaccio fishery regarding potential mortality impacts to overfished species in the southern California bocaccio sector. Of those trips that were observed during 2011 and 2012 that had bocaccio, no encounters of overfished species were noted. Nevertheless, it can be assumed that some overfished species are probably taken occasionally, albeit in small quantities. Increased on-board observer data would facilitate better mortality estimates of overfished species taken in this fishery.

Lastly, the GMT recommends Alternative 2a for the minor shelf rockfish complex mainly because of the uncertainty associated with mortality of overfished species taken in this fishery sector. Despite this uncertainty, however, there are several items that need to be pointed out. Yelloweye rockfish are uncommon south of central California and are infrequently taken in the shelf rockfish fishery. Canary rockfish, while more common than yelloweye in southern California, are most abundant from central California north and tend not to be encountered in the southern California fisheries. Bocaccio, while taken in southern California with an apparent increasing stock status, are actively managed with its own conservative trip limits in what is a very small fishery. The number of vessels that have tapped into the bocaccio limited entry sector, for example, has averaged less than 10 per year for the past four or five years. There is a very limited interaction with cowcod, and since there is a complete prohibition on the take of cowcod by the fixed-gear fisheries; the commercial fleet avoids them as much as possible.

Checklist Item #26: Non-Trawl: Allow Lingcod Retention in Periods 1, 2, and 6 (along with combined Options taken from #23 (above).

The GMT provided an analysis to evaluate impacts of allowing lingcod retention by the commercial non-trawl fisheries during the currently closed season (December through the following April). Lingcod had a full stock assessment in 2009, when it was found to be fully recovered. Lingcod mortality has been far below the ACL north and south of 42^{o} N. latitude, with 34 percent and 16 percent attainment in 2012, respectively. The primary concern of this measure is impacts to overfished species. Two options were provided in the analysis. Option 1 used WCGOP data to estimate encounter rates during the currently closed season (Table 2). The winter trip limits shown under Option 1 in this statement are lower than the average expected catch of lingcod during the currently closed season (i.e., when lingcod are not targeted and must be discarded at sea). Hence, the GMT suggests that proposed Option 1 trip limits under this management measure (during December – April) represents the incidental catch of lingcod (i.e., non-targeted) during winter months. Since this level of catch may be incidental, it is unlikely that fishing behavior would change, and therefore overfished species impacts should be similar to No Action. The other option analyzed provides for landings that are higher than what are incidentally caught during the currently closed season. Therefore, fishing behavior may be more likely to change if this option is chosen (e.g., increased targeting) and catch of overfished species (e.g., yelloweye rockfish) may increase.

Table 2. Proposed commercial fixed gear trip limits for north and south of 40°10′ N. latitude by sector, under Option 1 for the currently closed season (December - April). The remaining trip limits (May - October) are status quo limits currently available during the open season. This table was excerpted from Agenda Item F.7.a, Attachment 6, June 2014. See Table 6 for combined trip limits ("winter" and "summer" and changes regarding LE and OA South).

Sector	Jan - Feb	Mar - Apr	May - Jun	Jul - Aug	Sep - Oct	Nov - Dec	
LE North	200 lb/2 months		800 lb/ 2 months			400 lb	100 lb
LE South	200 lb/2 months		800 lb/ 2 months			400 lb	100 lb
OA North	100 lb/ month		400 lb/ month				100 lb
OA South	100 lb/ month		400 lb/ month				100 lb

A motion was made at the April 2014 Council meeting to task the GMT to complete an analysis that considers the following trip limit options for both the LE and OA non-trawl fixed-gear lingcod fishery sectors that examines a modified season structure. Table 3 trip limit options analyzed.

Table 3. Lingcod commercial coastwide trip limits for the non-trawl fixed-gear fisheries, showing "summer" and "winter" lingcod alternatives.

Proposed lingcod trip limits that apply to the area **NORTH** of 40°10' N. latitude with a year-long season structure						
LE	Jan/Feb	Mar/Apr	May/Jun	Jul/Aug	Sep/Oct	Nov/Dec
Option 2a	200 lb/2 mo	200 lb/2 mo	1,200 lb	1,200 lb	1,200 lb	600 lb Nov, 200 lb Dec
Option 2b	200 lb/2 mo	200 lb/2 mo	1,600 lb	1,600 lb	1,600 lb	800 lb Nov, 200 lb Dec
OA						
Option 2a	100 lb/mo	100 lb/mo	600 lb/month (100 lb Dec)			
Option 2b	100 lb/mo	100 lb/mo	800 lb/month (100 lb Dec)			

Proposed lingcod trip limits that apply to the area **SOUTH** of 40°10' N. latitude with a year-long season structure						
LE	Jan/Feb	Mar/Apr	May/Jun	Jul/Aug	Sep/Oct	Nov/Dec
Option 2a	200 lb/2 mo	Closed	800 lb	800 lb	800 lb	400 lb Nov, 200 lb Dec
Option 2b	200 lb/2 mo	Closed	800 lb	800 lb	800 lb	400 lb Nov, 200 lb Dec
OA						
Option 2a	100 lb/mo	Closed	400 lb/month (100 lb Dec)			
Option 2b	100 lb/mo	Closed	400 lb/month (100 lb Dec)			

The trip limits in Table 3 result in the following lingcod mortality estimates (Table 4) and the overfished species mortality (Table 5) for 2015 (under a P*0.45 approach).

Table 4. Lingcod coastwide commercial mortality estimates (mt) under Option 2a and Option 2b with the percent attainment of the non-trawl allocation.

Limited entry + open access coastwide lingcod mortality estimates (mt) at p*=0.45			
Option	Estimated take (mt)	Non-trawl allocation	Percent of Allocation
2a	135.1	1,950.7	6.9%
2b	73.4	1,950.7	8.9%

Note: South of 40°10' N. latitude the fishery will continue to be closed. The non-trawl allocations are a combination of those for north and south of 40°10' N. latitude as presented in Agenda Item C.4.a Supplemental REVISED Attachment 2, April 2014.

Table 5. Overfished species mortality estimates (mt) under Option 2a and Option 2b that reflect a coastwide season structure modification.

	Coastwide estimated mortality (mt) of OFS under options with an expanded season structure	
	Option 2a	Option 2b
Bocaccio	0.4	0.4
Canary rockfish	6.7	6.8
Cowcod	0.0	0.0
Darkblotched rockfish	0.2	0.2
Yelloweye rockfish	1.2	1.3

Recommendation:

If the Council wants to increase lingcod trip limits during both the "summer" and "winter" seasons, then the GMT recommends the Council adopt Option 2a from Table 6, which increases lingcod trip limits for LE and OA, north and south of 40º 10' N. latitude during "winter" and "summer" seasons. The GMT expects no change in fishing behavior or in catch of overfished species by allowing incidental catch of lingcod during the currently closed season ("winter"; December – April).

If the Council chooses to allow "winter" retention of lingcod, while retaining status quo "summer" trip limits, then the GMT recommends the trip limit structure shown in Table 5, with the exception of LE and OA south of 40º 10' N. latitude, where lingcod retention would continue to be prohibited during March and April. This is because rockfish retention is prohibited during this period south of 40º 10' N. latitude.

CALIFORNIA DEPARTMENT OF FISH AND WILDLIFE REPORT ON 2015-2016 BIENNIAL HARVEST SPECIFICATIONS AND MANAGEMENT MEASURES

The California Department of Fish and Wildlife (CDFW) hosted a teleconference in early June to discuss potential groundfish regulation changes for 2015 and 2016 and to solicit input from the public to help develop the State's recommendation to the Council. Participants on the call represented all fishing sectors throughout the state. While there were differing opinions expressed on preferred management measures, most on the call expressed a desire to extend the seasons in the recreational fishery wherever possible and to provide for increased lingcod opportunities in the commercial fishery and allow some incidental-level catch in months that are presently closed. Maintaining a precautionary approach and preventing early closure of fisheries was important to all participants.

Based in part on public input received during the teleconference, CDFW offers the following recommendations for Council consideration in deciding final preferred season structures and management measures for 2015-16.

California Commercial Fisheries

Season Structures

CDFW supports maintaining the status quo RCA boundaries for the commercial nearshore fishery (20 fm[1] between 42° N and 40° 10' N latitude; 30 fm between 40° 10' N latitude and 34° 27' N. latitude; 60 fm south 34° 27' N. latitude) as the Final Preferred Alternative. In the event that more yelloweye are made available to the nearshore fishery, deeper depth restrictions north of 40° 10' N latitude may be explored.

Management Measures

Lingcod Trip Limits

CDFW supports option 2a for increasing the lingcod trip limit for the limited entry and open access sectors north of 40° 10' N latitude (Table 1). In addition, CDFW supports providing access to lingcod during periods 1, 2, and 6 for north of 40° 10' N latitude and for periods 1 and 6 south of 40° 10' N latitude (Table 2).

Table 1. Preferred trip limits for limited entry and open access lingcod north of 40° 10' N latitude.

	Jan/Feb	Mar/Apr	May/Jun	Jul/Aug	Sept/Oct	Nov/Dec
Limited Entry	200	200	1,200	1,200	1,200	600/200
Open Access	100	100	600	600	600	600/100

Table 2. Preferred trip limits for limited entry and open access lingcod south of 40° 10' N latitude.

	Jan/Feb	Mar/Apr	May/Jun	Jul/Aug	Sept/Oct	Nov/Dec
Limited Entry	200	CLOSED	800	800	800	400/200
Open Access	100	CLOSED	400	400	400	400/100

[1] The 20 fm RCA is defined by depth, not waypoints.

California Recreational Fishery

Season Structure

In accordance with CDFW's policy to provide a stable fishery and minimize inseason disruptions, seasons are designed to maximize fishing opportunity while keeping harvest within specified harvest guidelines. This includes multi-month closures early in the year as part of the overall design to ensure that limits are not exceeded. Although allowable levels of cowcod and yelloweye rockfish increased slightly compared to prior years, canary rockfish and minor nearshore rockfish north of 40° 10' N latitude constrain the recreational fishery and are one of the main factors affecting season lengths.

CDFW supports the following recreational RCA configuration and season structures (Fig 1). The season structure prioritizes increasing season lengths when possible, maintaining a precautionary approach, and recognizing the constraints imposed from canary and minor nearshore rockfish. Compared to the 2014 season structure, the proposal for 2015-16 would provide a modest increase in season length in the Mendocino management area (2 months), the San Francisco management area (6 weeks) and the Central management area (one month), while the Southern management area would maintain its season length but allow for an increase in allowable fishing depth to 60 fathoms. The Northern area would remain at status-quo seasons and depths.

Management Area	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec
Northern	Closed				May 15 – Oct 31 <20fm						Closed	
Mendocino	Closed				May 15 – Oct 31 <20fm						Closed	
San Francisco	Closed			April 15 – Dec 31 <30fm								
Central	Closed			April 1 – Dec 31 <40fm								
Southern	Closed		Mar 1 – Dec 31 <60 fm									

Figure 1. California recreational groundfish season structure for 2015-2016.

Management Measures

CDFW supports the No Action alternative for groundfish bag limits and size limits with one exception - lingcod bag limit. Increasing the lingcod bag limit from two fish to three fish is intended to provide more opportunity for anglers to achieve their allocation of lingcod. Mortality of lingcod in recent years has been far less than the non-trawl allocation; therefore increasing the bag limit to three fish is not expected to exceed the non-trawl allocation, let alone the entire ACL.

Lingcod was last assessed in 2009 and at that time the stock was healthy, with a depletion level of 74%. Ten year catch projections in the assessment indicate that the depletion level at the start of 2015 would be 68.4%. Given that mortality has been far below the ACL in each of the years since the assessment was conducted, it is likely that depletion is actually much higher (i.e. more optimistic). Although the stock assessment did have considerable uncertainty, it is clear that the stock is healthy with a depletion level well above 40%, and a small increase in projected catches by both the commercial and recreational sectors is not expected to pose undue risk to this stock or affect stock status.

Agenda Item F.7.b
REVISED Supplemental GMT Report 2
June 2014

GROUNDFISH MANAGEMENT TEAM REPORT ON FURTHER ANALYSIS OF SELECT HARVEST SPECIFICATIONS AND MANAGEMENT MEASURES FOR 2015-2016

Contents

Establish New Rockfish Conservation Area (RCA) Coordinates – 300 and 350 fathoms

Section B.2 under Agenda Item F.7.a, Attachment 6, Excerpt of Appendix B of the Preliminary Draft Environmental Impact Statement (EIS), provides background information about how the proposed 300 and 350 fathom rockfish conservation area (RCA) lines were created (i.e., using GIS software and the judgment of the analyst) and how they might be further modified. The proposed waypoints for these lines were provided for the area north of 40°10' N. latitude only. The proposed waypoints could be further modified if any of the following are desired by the Council: match the proposed RCA lines to the existing 250 fathom RCA line when they cross that existing RCA line; create proposed RCA lines that are "bumped out" and parallel the existing 250 fathom RCA line; and/or engage the fishing industry and fisheries enforcement officers in the practicalities associated with implementing these proposed lines and modifying them as appropriate.

For this analysis, observer data were used: West Coast Groundfish Observer data (WCGOP) and North Pacific Observer data (NORPAC). Haul level PacFIN landings data were not analyzed in time to be submitted as part of this report but total landings and average annual price for targeted species from 2002-2012 were used. "Rougheye/blackspotted" in this analysis combines rougheye, blackspotted, and an undifferentiated rougheye/shortraker group. Depth bins in Tables 1-7 were based on average depth of fishing for bottom trawl gears (limited entry trawl/catch shares sector) and shoreside whiting sector, and bottom depth (rather than fishing depth) was used for the at-sea whiting sector. Depth bins were defined by existing and proposed RCA lines to investigate incremental change in rougheye/blackspotted catch as depths increased. Latitude bins were defined by existing latitudinal breaks for RCAs in regulation. Figures 1-3 are basic maps of these latitudinal areas and the proposed and existing RCA lines.

When considering the following analysis and time period analyzed (2002-2012), the following should be noted:

- the 100-150 fathom area has been closed coastwide to bottom trawl since 2004 and is referred to as the "core RCA" area;
- the 150-200 fathom area from 45° 46 to 40° 10' N. latitude has been closed in some years since 2004, except for when the petrale modified RCA has been in place;
- outside of the depths and areas mentioned above, fishing has occurred except when RCA areas have been closed seasonally;
- the bottom trawl gear category used in this analysis (within the Limited Entry trawl/catch shares sector) and the shoreside whiting sector (midwater trawl gear) have been part of the catch shares fishery (individual fishing quota or IFQ) since 2011; an analysis of rougheye/blackspotted catch before and after 2011 may be informative but time to do so at this meeting was not available; and
- the shoreside whiting sector was subject to full retention as an exempted fishing permit fishery (EFP) since the 1990s. No observer coverage was required for this sector during

this period. This explains why the data years available for this sector were 2011-2012 only, and why the number of hauls in this sector were much lower than for the other two (Table 3). The data years available for the at-sea whiting sector and bottom trawl gear category were 2002-2012.

The relevance of using set, up, or average fishing depth information from the WCGOP data for this analysis has been a topic of GMT discussion during this meeting. For bottom trawl gears, these variables would seem appropriate but for midwater gears used in the shoreside whiting sector, using this variable may be questionable. Though bottom depth would be more appropriate for this analysis because RCAs approximate depth regardless of where in the water column fishing is occurring, bottom depth information is not available from the WCGOP. Given the available data, a spatial analysis using latitude and longitude coordinates of fishing locations for the shoreside whiting sector would be a better way of characterizing fishing effort in the depth and latitude ranges presented below. However, time was not available for this analysis at this meeting. For midwater gears used by the at-sea whiting sector, both fishing and bottom depth information are available from the NORPAC, and bottom depth was used in this analysis.

Biological impacts:

Table 1 provides estimates of total observed catch of rougheye/blackspotted. Table 2 provides estimates of average observed rougheye/blackspotted catch per target species haul; i.e., total catch of rougheye/blackspotted (Table 1) divided by the total number of hauls that caught a targeted species (Table 3). Pacific whiting is the target for the at-sea whiting sector; Dover sole, thornyheads, and sablefish (DTS) were the target species for the bottom trawl gears; and sablefish is the target for the LE/OA fixed gear sectors. All nominal and species group market categories were included for the DTS target species (e.g., nominal shortspine thornyhead) and species groups (e.g., undifferentiated rougheye/shortraker group) were included for this analysis. Table 4 provides estimates of average observed catch per haul of target species in each sector. Tables 5-7 provide information about rougheye/blackspotted catch within latitude and depth bins, by sector.

<u>No Action:</u> In Tables 1-7, the following depth bins are relevant to No Action: 100-150, 150-200, and 200-250 fathoms.

<u>Options:</u> In Tables 1-7, the following depth bins are relevant to the proposed RCA lines: 250-300, 300-350, and greater than 350 fathoms.

Table 1. Rougheye/blackspotted rockfishes, total observed catch (metric tons), by fishery sector and depth (fathoms), north of 40° 10' N. lat., 2002-2012. Shoreside whiting is from 2011-2012 only. Average fishing depth was used for bottom trawl and shoreside whiting; bottom depth was used for at-sea whiting.

	0 – 100	100 – 150	150 – 200	200 – 250	250 – 300	300 – 350	> 350

45°46' - 40°10'	0.32	4.25	13.75	3.97	1.40	1.06

Socioeconomic impacts:

When considering average observed catch per haul of Pacific whiting, the shoreside and at-sea whiting sectors have rates relatively consistent through all depth ranges, 100 fathoms to greater than 350 fathoms (Table 4). Average observed catch per haul of DTS for bottom trawl gears generally increased as depth increased (Table 4). This suggests that targeted species may be caught in depths deeper than the deepest Trawl RCA line currently in regulation (250 fathoms). However, the number of hauls from which this information was derived is small for the shoreside whiting sector in particular (Table 3). Despite the potential ability of these sectors to catch their target species in deeper depths, the cost to reach these areas, in terms of fuel and time, and potential risks for safety at sea, may increase.

The following tables provide information about the estimated value of target species in each depth and latitude bin. Relative proportions for each sector were calculated for each depth/latitude combination based on the observed catch of target species across each sector. Each proportion was then multiplied by the total landings of the target species across all years during the 2002-2012 time period (pounds; PacFIN landings data). Finally, this target species landings estimate for each depth/latitude combination was multiplied by the average annual price per pound for that target species (average annual price, 2002-2012). These values were standardized by haul for each depth/latitude combination (total value / number of years) and shown in Table 8, Table 9, and
Table 10.

Table 8. Bottom trawl gears (limited entry trawl/catch shares sector), average revenue per year of target species, by latitude and average depth (fathoms), north of 40° 10’ N. lat., 2002-2012.

Discussion

As mentioned above, depth ranges were chosen at 50 fathom increments to explore whether rougheye/blackspotted catch in the midwater and bottom trawl sectors showed concentrations across different depths. The latitudinal breaks in this analysis are based on current regulations associated with existing RCA lines. However, these latitudinal ranges are large. For example, 45°46' to 40°10' N. lat. covers an area from northern California to just south of the Columbia River (Figure 2). It may be worthwhile to explore smaller, more discrete latitudinal areas to more precisely focus in on high rougheye/blackspotted bycatch areas; we did not have time to do so at this meeting.

Other information about areas with higher bycatch rates of rougheye/blackspotted, such as information presented by Dave Fraser relative to the at-sea and shoreside whiting sectors, may be helpful for informing other, more discrete latitudinal (and depth) areas such as groundfish conservation areas (GCAs) or "hot spots" (Agenda Item C.9.b, Supplemental GMT Report, April 2014). If the Council chose to evaluate different or more management lines than those that have been used in regulation, we provide the following for a historical perspective. Since the inception of RCAs on the west coast, we have implemented RCAs within the following number of management areas north of 40° 10' N. latitude: one area (2002-2006), seven areas (2007-2008), four areas (2007-part of 2014), and three areas (part of 2014).

For bottom trawl gears, the highest total catch of rougheye/blackspotted rockfishes (2002-2012) were observed between 48°10' and 45°46' for the 150-200 and 200-250 fathom depth areas (Table 5). The corresponding average revenue per year of DTS is moderate in these areas (Table 8). The average revenue per year of DTS is highest in areas between 45°46' N. lat. and 40°10' N. lat. where bottom depths are 200 fathoms or more (Table 8). The corresponding total observed catch of rougheye/blackspotted (2002-2012) in these depth/latitude areas was lower than in other areas (Table 5).

For the shoreside whiting sector, the highest total catch of rougheye/blackspotted rockfishes (2002-2012) were observed between 48°10' and 45°46' for the 100-150 and 150-200 fathom depth areas (Table 6). The corresponding average revenue per year of Pacific whiting was high in these areas (Table 9). The average revenue per year of the target species is highest in areas between 48° 10' and 45° 46' N. latitude for the areas between 100-200 fathoms, and 45° 46' to 40° 10' N. latitude for the 100-250 fathoms (Table 9). The corresponding total observed catch of rougheye/blackspotted (2002-2012) in these depth/latitude areas was low (Table 6).

For the at-sea whiting sector, the highest total catch of rougheye/blackspotted rockfishes (2002-2012) were observed between 48° 10' and 45° 46' for the depth area from 200 fathoms and higher (Table 7). The corresponding average revenue per year of Pacific whiting was moderate to high in these areas (

Table 10). The average revenue per year of the target species is highest in areas between 48° 10' and 45° 46' N. latitude in depths from 200 fathoms and deeper, and from 100-300 fathoms between 45° 46' and 40° 10' N. latitude (

Table 10). The corresponding total observed catch of rougheye/blackspotted (2002-2012) in these depth/latitude areas ranged from low to high (Table 7).

There has been some discussion about the ability of rougheye/blackspotted rockfishes, as well as rockfishes (*Sebastes spp.*) in general, to survive in depths deeper than 250 fathoms. The recent stock assessment for blackgill rockfish indicated that this species has "among the deepest distribution of all of the California Current *Sebastes* and live at the edge of the low oxygen (hypoxic) conditions that characterize the slope waters of the California Current" (Agenda Item G.4.a, Attachment 13, September 2011). The stock assessment also reported that blackgill are known to have a depth distribution of 48-420 fathoms (87-768 meters) but only one blackgill rockfish was caught in a haul greater than 328 fathoms (600 meters) in the ten years that the NWFSC combined bottom trawl survey has been conducted. It should be noted that the historical nomenclature of rougheye and blackspotted rockfishes have been confused with shortraker and blackgill rockfishes, so the current understanding of the depth distribution of blackgill rockfish may or may not be directly comparable to rougheye/blackspotted rockfish. Regarding rougheye and blackspotted rockfishes, the Alaska Fisheries Science Center (AFSC) surveys from 1961-2005 (7,775 tows) found blackspotted rockfish in deeper depths than rougheye rockfish; both were observed in depths up to 275 fathoms. Also of note, two rougheye rockfish were caught with midwater trawl gear in the Gulf of Alaska at a maximum gear depth of 275-500 fathoms over 985-1,038 fathoms of bottom depth (Orr and Hawkins, 2007). Although these may be rare occurrences, the presence of rougheye away from the bottom suggests that management decisions related to midwater fisheries should not be focused purely on bottom depths or oxygen levels, but ideally be based on spatial areas where rougheye occur. However, as stated above, the GIS analysis required could not be conducted in time for this meeting. Such an analysis would be best done under Agenda Item F.3.a in the Omnibus List.

GMT Discussion on Ecosystem Component Species' Designations

The GMT was informed at this meeting that the National Marine Fisheries Service (NMFS) is looking for more information on the Council's recommendation to designate Pacific grenadier as an ecosystem component (EC) species. We understand the questions relate to Pacific grenadier's marketability and the stock possibly being the focus of targeting by some vessels. We also understand that there are some inconsistent statements in the groundfish fishery management plan (FMP), which states that there is a developing fishery for grenadiers, and the Draft environmental impact statement (EIS), which states that they are "not explicitly targeted and their low value does not provide an incentive to develop target strategies." The National Standard 1 (NS1) Guidelines point to targeting as a factor as possibly disqualifying a stock for EC species designation. And given that Pacific grenadier show landings of ~ 130 metric of tons per year, the question is whether the stock is really appropriate for designation as an EC species.

With all the issues we are considering at this meeting, we did not have time to fully summarize the information and analysis that we have brought forth in GMT reports from the September 2013 and November 2013 Council meetings, and in other statements regarding classification of stocks in the FMP.

We did not have time to attempt to capture and synthesize the Council's reasoning and use of all the information we and others presented when making the EC species recommendation. We can speak, however, to the matter of how the GMT attempted to present the policy choices to the Council. We did not see that policy choice as revolving around the question of whether Pacific grenadier was targeted or not. Instead we saw the decision as presenting novel circumstances. The EC species concept is new and there is not much experience applying it. We try and explain how we viewed the policy decision.

First, we were aware that Pacific grenadier is landed, marketed, and possibly targeted in some regions, mainly in Central California, and advised the Council to this fact. The complicating factor was that giant grenadier is caught in similar magnitudes and faces the same risk of overfishing as Pacific grenadier. Giant grenadier is not targeted or marketable however. Some people may be marketing California grenadier.

With the data available, we thought we could look to many factors in helping the Council decide how to classify stocks in the Groundfish FMP. In taking a risk-based view, we recommended that the Council look to the risk of overfishing as the primary factor for evaluating the FMP's classification of stocks. In this view, the targeting and retention language in the Guidelines were really proxies for weighing that risk and the relative need for conservation and management. We saw them as helpful guides but not necessarily determinative for all stocks. And in some cases, we thought that other evidence might show that they might not be the best guides to conservation and management need.

To illustrate this, we pointed out that overfishing could be of high concern even for species that are only caught incidentally and discarded. The risk could be higher for such a stock than for a stock that is targeted and marketable. We pointed to spiny dogfish as an example from the Groundfish FMP where this was the case. It would be contrary to the Magnuson-Stevens Act to not be concerned over overfishing risk just because a stock was not landed or sold.

Moreover, the Northwest Fisheries Science Center (NWFSC) was able to produce overfishing limits (OFLs) and acceptable biological catches (ABCs) for the grenadiers. We also had reliable estimates of how total catch compared to those harvest specifications. We thought that these numbers provided a much more direct way for the Council to evaluate conservation and management need than did the NS1 Guidelines EC species criteria.

With this information, the risk of overfishing either stock seemed low. It was also noted that the OFLs were based on the NWFSC bottom trawl survey and so biomass estimates were likely on the low side. The survey does not go deeper than 700 fathoms. Grenadiers habitat extends beyond 700 fathoms.

In sum, we thought it was reasonable for the Council to bring Giant grenadier into the FMP or to designate them as EC species. We just did not see a basis for treating them differently as to their FMP classification because they are caught in very similar amounts and face the same general risk of overfishing. We saw the Council's policy decision as centering on the question of whether that risk was high enough to warrant conservation and management as an "in the fishery" species. We did not think the differential marketability of Pacific grenadier presented clear reason to classify it differently.

Of note, the recommendation on Pacific grenadier was made in the context of reorganization of the Other Fish stock complex. As that complex was completely reorganized, it was likely that Pacific grenadier would be an "individually managed" species if left as an FMP species. We also broached the issue of bringing in all grenadier species because of catch accounting reasons. There are several species of grenadier that can be difficult to identity and so managing them as either an EC species or in the fishery complex could further accurate identification.

Increased access to WCGOP data allowed us to produce new looks at grenadier catches that we did not produce last fall (Figure 4 and Figure 5). This data suggests that giant grenadier and Pacific grenadier are retained to similar degrees and that catches of giant grenadier are greater than those for Pacific grenadier.

Lastly, as we noted under Agenda Item F.3.b Supplemental GMT Report, the Council has yet to have much discussion on what requirements might go along with EC species designation. We envisioned that they will be monitored to the same extent as they are now. Changes in landings can be tracked and brought to the Council's attention. The trawl survey will continue to catch grenadiers and periodic updates of their biomass estimates would low evaluation of population trends. Yet the Council may wish to consider doing more. We understand that similar issues are being considered under Ecosystem Initiative 1 and the unmanaged forage fish.

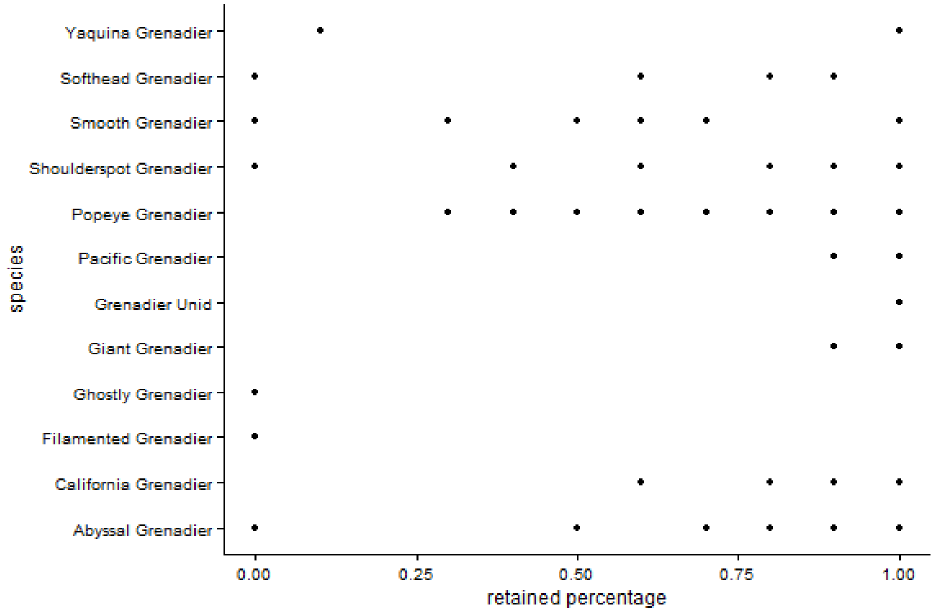

Figure 4. Annual retention species from observed trips across all sectors monitored by WCGOP (2002-2012). For context, more than 90 percent of the catch comes in the bottom trawl fishery.

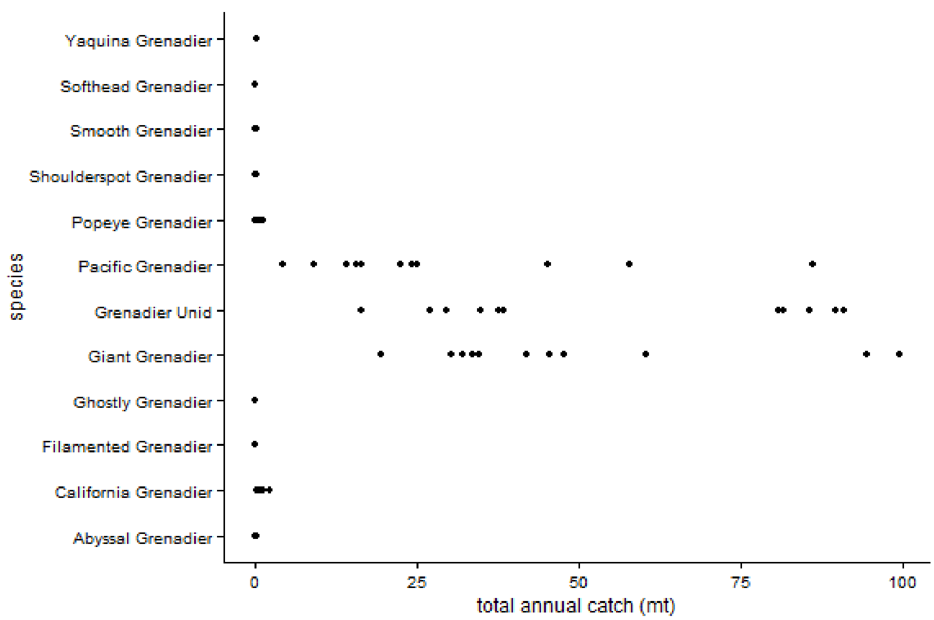

Figure 5. Annual observed total catch across all sectors, 2002-2012. Estimates are not expanded and intended only to show relative catches among grenadier species.

Two-year Yelloweye Rockfish Sharing (Non-Trawl) - Evaluating the Uncertainty of Yelloweye Rockfish Catches in the Nearshore and Non-Nearshore Commercial Fixed Gear Sectors

The GMT discussed the management measure designed to move 0.6 mt of yelloweye rockfish from the non-nearshore fixed gear sector to the nearshore fixed gear sector (see Agenda Item F.7.a, Attachment 6, June 2014; B.4 pages 27-40). The intent of this measure is to reduce the probability of the nearshore fixed gear sector from exceeding its catch share of yelloweye rockfish. Clarifications and additional analyses are provided below.

We understand that the Council may recommend moving any amount between 0.0 mt to 0.6 mt between the two sectors (e.g., the Council could choose to move 0.3 mt from the non-nearshore sector to the nearshore sector). This analysis provides results only for the upper extreme potential shift between sectors (0.6 mt). Results for anything in between may be roughly interpolated from these results.

Yelloweye Rockfish Share Between Sectors

Yelloweye rockfish has been a constraining species for attaining target species by both the non-nearshore and nearshore fixed gear fisheries for more than a decade. The Council considers the two-year allocations for yelloweye rockfish every biennial cycle based on projected impacts, i.e., forecasts of total fishing mortality provided by the GMT, and other factors. The nearshore and non-nearshore sectors are assigned a "share" of the non-trawl allocation. The sector's shares and projected impacts (i.e., total fishing mortality) under the Preliminary Preferred Alternative (PPA), both with and without a transfer of 0.6 mt, are shown in Table 11. Without a transfer (No Action) the non-nearshore fishery shows a surplus buffer of 0.6 to 0.7 mt, whereas the nearshore fishery shows a buffer of 0.0 to 0.1 mt. On the other hand, if a 0.6 mt transfer were made from non-nearshore to nearshore, then the projected catch for the non-nearshore fishery would be only 0.0 to 0.1 mt lower than its catch share, whereas the nearshore fishery would realize a buffer of 0.6 to 0.7 mt between its projected yelloweye catch and its share.

Table 11. The sector shares and projected impacts of yelloweye rockfish with and without the transfer of 0.6 mt (under Preliminary Preferred).

		Without transfer		With transfer	
		2015	**2016**	**2015**	**2016**
Nonnearshore	Share	1.1	1.2	0.5	0.6
	Projection	0.5	0.5	0.5	0.5
	Difference	0.6	0.7	0.0	0.1
Nearshore	Share	1.2	1.3	1.8	1.9
	Projection	1.2	1.2	1.2	1.2
	Difference	0.0	0.1	0.6	0.7

[a/]Note that in Agenda Item F.7.a, Attachment 6, June 2014, the nearshore projected catches were based on no action (1.1 mt). Those projections were change in this table to Preliminary Preferred projections for consistency

Summary of Results

One of the main conclusions of the report shown in Agenda Item F.7.a, Attachment 6, June 2014 (B.4, pages 27-40) was that there was a high level of variability in annual yelloweye catches for both the nearshore and non-nearshore fishery, and this variability should be taken into account when deciding upon yelloweye sharing between these sectors (Table 11). Presently, projected catches are provided as point estimates based on average historical catches. Annual variability should be taken into account when evaluating these projections relative to harvest targets.

Mortality of yelloweye rockfish from 2003–2012 ranged from 0.1 mt to 2.5 mt for the nearshore fishery and 0.3 to 1.6 mt for the non-nearshore fishery (Table 12). Highlighted cells represent those years where the yelloweye rockfish mortality would have exceeded the Preliminary Preferred catch share for 2015. These sectors, combined, would have exceeded each of their 2015 PPA catch share on five occasions; the non-trawl commercial fishery as a whole, however, would have exceeded their allocation (at the 2015 PPA level) of yelloweye rockfish only twice in 10 years.

Table 12. Variability of total mortality estimates for yelloweye rockfish in the nearshore and non-nearshore commercial fixed gear sectors, 2003-2012. Highlighted cells represent cases where the catch would have exceeded the 2015 catch share (1.1 mt for non-nearshore and 1.2 mt for nearshore) and the sum of the two catch shares (2.3 mt). Data source: West Coast Groundfish Observer Data (WCGOP), GMMultiYr_DataProduct Dec. 23, 2013.

	2003	2004	2005	2006	2007	2008	2009	2010	2011	2012
Nearshore	0.3	1.1	0.9	0.8	1.9	2.5	0.5	0.1	0.8	1.8
Non-nearshore	1.6	1.1	0.6	0.7	0.7	0.8	1.2	0.3	0.3	0.3
Total	1.9	2.2	1.5	1.5	2.6	3.3	1.7	0.4	1.1	2.1

Numerous tables were provided in Agenda Item F.7.a, Attachment 6, June 2014, B.4 (pages 27-40) that further illustrate annual variation in yelloweye mortality by the fixed gear fisheries. Summarized results from some of these tables are shown in Table 13. A challenge to the management of yelloweye (and other infrequently caught species) is that the variability in mortality estimates is a combination of the variability in encounter rates and the sampling error associated with extrapolating from the fraction of those rare encounters that are observed. The large sampling error suggests that observation error is a large part of the variability in observed mortality. This uncertainty should not prevent the council from taking action, but illustrates the challenges in projecting the impacts of any management measure and the difficulty in quantifying those impacts if and when they occur. To put this sampling error into perspective, for the nearshore fishery, the 90% interval around the point estimate ranges from 47% of the point estimate (e.g., about half) to 171% of the estimate (i.e., about double).

Table 13. Comparison of nearshore and non-nearshore observer effort (trips) and catch of yelloweye rockfish (mt) using various metrics. Data source: WCGOP.

Metric	Nearshore	Non-nearshore
Average number of trips observed (2003-2012)	288	331
% WCGOP coverage (2003-2012)	5.4%	19.7%
Average % of observed trips with yelloweye (2004-2012)	9.8%	3.6%
Catch share (Preferred Alt., 2015)	1.2	1.1
Projected catch (Preferred Alt, 2015)	1.1	0.5
Avg. mortality (2003-2012)	1.1	0.8
Std. Dev. mortality (2003-2012)	0.8	0.4
Estimated sampling error (90% interval of estimated catch / true catch)	47% – 171%	37% – 179%

Impacts to the Nearshore Fishery

Under the PPA, the nearshore fishery season structure would remain as described in Agenda Item F.7.a, Attachment 3, June 2014. The shoreward RCA would remain at 30 fathoms for Oregon and 20 fathoms for northern California (north of 40º 10´ N. latitude). Landings of target species would remain as shown in Table 4-19 in that attachment. However, the Council is considering actions that may increase the catch of yelloweye rockfish by the nearshore fishery (i.e., increase lingcod trip limits). Clearly, since we provide point estimates for projected yelloweye catch relative to harvest targets, any increase in harvesting lingcod, or other management measures that may liberalize this fishery, may result in projected yelloweye catch that may exceed the nearshore allocation.

Shifting as much as 0.6 mt of yelloweye rockfish to the nearshore fishery would provide socioeconomic benefits. Those beneficial impacts may include:

- California and Oregon
    - Provide the opportunity to increase trip limits for lingcod during May - October, and allow lingcod retention during the currently closed season (December – April).
- Oregon
    - Increase landings of black rockfish from 120 mt (PPA) to 137.9 mt (state landing cap).
    - Increase the likelihood of retaining the 30 fm RCA (moved from 20 fm to 30 fm in 2013).
- California

- Increase landings of nearshore species.
- Move the RCA from 20 fm to 30 fm north of 40º 10´ N. latitude.

Table 14. Projected yelloweye rockfish mortality estimates (metric tons; Oregon and California combined when considering alternative RCA structures for California north of 40°10' N. latitude. Projections are shown for the No Action alternative and the PPA if the current non-trawl RCA shoreward boundary were changed from 20 fathoms to 30 fathoms.

	20 fathoms	30 fathoms	Change
No Action	1.1	1.5	+0.4
PPA	1.2	1.5	+0.3

Shifting as much as 0.6 mt of yelloweye rockfish from the non-nearshore fishery to the nearshore fishery may therefore allow increased landings and revenue of lingcod and other nearshore groundfish species. Allowing this sector to fish to 30 fathoms (instead of 20 fathoms) may also open (or help to keep open) productive fishing grounds, which may result in fewer days at sea, higher revenue per day, and less gear conflicts. In addition, allowing fishing out to 30 fathom may reduce the catch of other nearshore rockfish which, depending on Council Action, may become a constraining species group for commercial and recreational fisheries.

Additional yelloweye impacts relative to management measures currently being considered by the Council, and relative to potential increases in landings, are shown in Table 15.

Table 15. Projected increase in yelloweye rockfish catch by the nearshore fixed gear fishery under various management measures and increased landings, relative to those shown for the PPA.

Action	Yelloweye Impact
Increase Lingcod Trip Limit Coastwide (Alt 2a)[a]	+0.1
Increase Lingcod Trip Limit Coastwide (Alt 2b)[a]	+0.2
Increase Oregon Landings of black rockfish from 120 mt to 138.7 mt	+0.1
Increase RCA for northern California from 20 fm to 30 fm	+0.3

[a]These increased trip limits include allowing lingcod retention during the closed season for both limited entry (200 lbs / 2 months) and open access (100 lbs / month). The GMT projects no additional yelloweye mortality at these lingcod trip limits during the closed season, because no additional effort or targeting for lingcod would be expected (see Agenda Item F.7.a, Supplemental Attachment 10, June 2014, Table B-38).

Impacts to the Non-Nearshore Fishery

Shifting the entire 0.6 mt from the non-nearshore fishery to the nearshore fishery would result in no buffer for the non-nearshore fishery (Table 11), and therefore increase the likelihood of yelloweye catches exceeding the non-nearshore catch share. In the event this fishery exceeded its catch share, the primary management measure available to reduce yelloweye catch is to move the seaward boundary of the non-trawl RCA deeper. Table 16 illustrates the projected yelloweye rockfish mortality at available RCAs. The No Action and PPA provides for a 100 fathoms seaward RCA.

Table 16. Projected yelloweye rockfish mortality for the non-nearshore fixed gear fishery under PPA sablefish allocations for 100 fathom (PPA), 125 fathom, and 150 fathom seaward RCAs.

Seaward RCA	Yelloweye Mortality (mt)
100 fm (PPA)	0.5
125 fm	0.4
150 fm	0.2

Moving the RCA deeper in this fishery may close productive fishing grounds which may (a) cause vessels to travel farther (increasing fuel cost) and fish longer (more days at sea) to catch their sablefish tier limit or daily trip limit, and (b) increase gear conflicts.

Other Considerations

Importance of Fishery Stability

Stability in fisheries is important, as it is in any business. The way we currently manage these fixed gear fisheries may, in general, lead to instability. For example, using point estimates (average landings) to project catches for fisheries that show variable catches annually, promotes instability in management measures applied to the fishery because these fisheries show high inter-annual variation in catches (see Table 12 and Table 13). The likelihood of exceeding annual harvest limits increases as the buffer between the projected catch estimate and the harvest limit decreases.

Fairness

Some may argue that there is inequity in the current yelloweye catch share situation, where one sector (i.e., non-nearshore fixed gear) appears to have a substantial yelloweye buffer relative to projected catch whereas the other sector (nearshore) has little to no buffer before reaching its catch share. Note that what may be most important is not whether one sector exceeds its catch share, but instead that the sectors combined do not exceed the sum of their catch shares. Regardless, the inter-annual variability of yelloweye catch should be addressed and the risk of exceeding catch shares discussed when making a decision to adjust the current catch share structure.

Remaining below the ACL

The ultimate goal is to ensure that groundfish fisheries remain below their ACLs. Even though GMT scorecards typically project that most of the yelloweye rockfish ACL will be harvested (e.g., for 2015, the PPA projects that 15.6 of 18.0 mt of the ACL will be taken; see Agenda Item F.7.a, Attachment 3, June 2014), in reality, all fisheries combined have not caught more than 70 percent of the ACL during recent years (Table 17Table 16). Reasons include: (a) set-asides are based on high or highest catches attained and (b) even though some sectors may exceed their allocation, it is unlikely that all sectors will exceed each of their allocations at the same time. The result has been annual catches much lower than the ACL or OY (Table 16).

Table 17. Annual yelloweye rockfish mortality relative to the ACL (or OY) for 2008-2012. Data: from the West Coast Groundfish Observer Program Reports on Estimated Discard and Catch.

Year	Mortality (mt)	ACL (or OY)	% of ACL
2012	12	17	68%
2011	9	17	52%
2010	8	14	54%
2009	11	17	63%
2008	12	20	58%

Simulations to Explore the Risk of Exceeding the Coastwide ACL

A simple simulation exercise was conducted to explore the risk of exceeding the coastwide ACL for yelloweye. This analysis follows the general idea of previous GMT work on estimating risk associated with spiny dogfish and rougheye rockfish, but due to time limitations is not as thorough (see Agenda Item C.4.b, REVISED GMT Report, April 2014 and Agenda Item F.7.a, Attachment 6, June 2014).

First, the recorded catches from each sector were examined for trends over the period 2004 to 2011 which had the most complete and accessible data. Catch of yelloweye declined significantly (based on linear model fit to estimated mortality) for the Tribal Shoreside and Washington Recreational sectors. The largest changes occurred prior to 2007. The more recent period from 2007-2011 had no significant trends in catch for any sector and therefore was chosen as the basis for the analysis. The average and standard deviation of catch was calculated for each sector. These values were then used to simulate values from a normal distribution of catches for each sector. Some sectors had zero values in some years which made the use of a lognormal assumption problematic. The simulated values were truncated at zero to avoid negative values, but were not limited below the allocation for any sector, thus allowing simulated values to exceed the allocations. The simulated sector-specific catches were summed to form a simulated distribution of total coastwide catch.

The simulation was then repeated with a set of changes intended to provide an upper bound to the potential impact of a shift of 0.6 mt from the non-nearshore fixed gear sector to the nearshore fixed gear sector. Although the projected increase for the nearshore sector is only 0.1, the simulated values were increased by 0.6 to provide an upper limit. Furthermore, the standard deviation of the simulated catches from the nearshore sector was doubled, again to provide a conservative estimate of potential changes, not because the variability is expected to increase. Lastly, the non-nearshore sector simulations were left unchanged under the assumption that a reduction of 0.6 mt from the allocation would not further constrain that sector. Research catch set-asides are difficult to predict for future years so as a conservative estimate, the 2014 set-aside value of 3.3 mt was added to the total simulated catch in all cases.

The resulting distribution of simulated coastwide catches (Figure 6) show that the overall probability of exceeding the 18 mt ACL for 2015 is less than 0.7 percent under the status-quo patterns and increases to 2.1 percent with the changes made to provide an upper limit for the magnitude of the increase under a transfer of 0.6 from the non-nearshore allocation to the nearshore sectors. The probabilities associated with the higher 19 mt ACL for 2016 are 0.4 percent and 1.1 percent, with and without the change in allocations.

This simulation exercise depends on numerous simplifying assumptions, including the assumption that future catches will have the same mean and standard deviation as catches over the period 2007-2011, that variability in catches among sectors are independent. Past patterns have depended on inseason management measures to keep catches within the sector shares and such measures will continue to be used in the future in ways that are difficult to include in this simple analysis. This analysis also did not include the estimation uncertainty that was explored in greater detail in Agenda Item F.7.a, Attachment 6, June 2014 (B.4, pages 27-40). Future catch projections would ideally include both true variability in catch and estimation uncertainty. Therefore, the probabilities calculated here should only be considered as qualitative estimates of the relatively low risk of exceeding the ACL and the relatively small increase in that risk even if the average catch increased by 0.6 mt, which is unlikely under the management measure being considered.

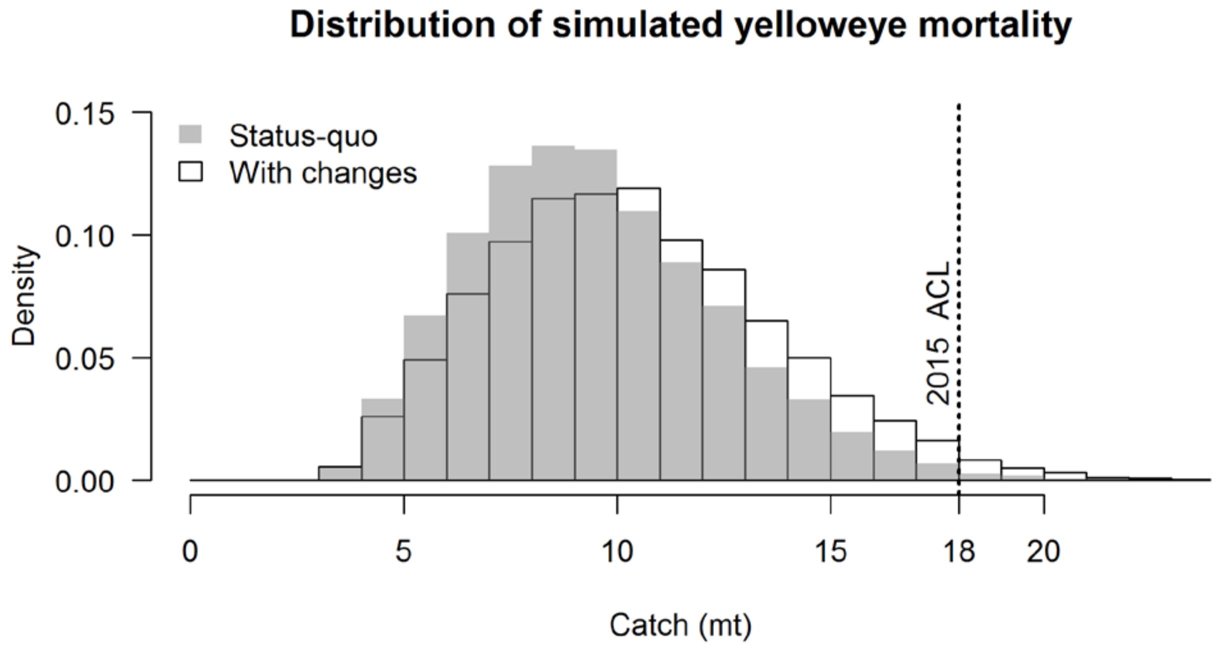

Figure 6. Distribution of simulated yelloweye catches under status-quo management measures and with maximum changes associated with a shift of 0.6 mt allocation from the non-nearshore to the nearshore (blue). The simulations depend on many simplifying assumptions and are intended to represent an upper bound of the impact of changes in allocations.

Recommendations

The GMT recommends that the Council consider annual variability and the probability of exceeding the ACL when deciding whether to move 0.6 mt (or less) of yelloweye rockfish from the non-nearshore sector to the nearshore sector. The GMT notes that buffers between the point estimate and the catch share may reduce the chance of exceeding the catch share.

Slope Rockfish Trip Limit Reductions

The Council requested an evaluation of a trip limit targeted at rougheye rockfish similar to what was established and implemented for blackgill rockfish in 2013. After much consideration of the data, the GMT concluded that a trip limit would not likely be effective for reducing fishing mortality on rougheye.

We recommend instead that the Council look to area-based management measures like hotspots or rockfish conservation areas to reduce encounters with rougheye for the fixed gear sectors. Such area measures are under consideration within the omnibus management measures planning.

If the Council wishes to further consider trip limits, we would suggest looking to switching the limited entry fishery to a ratio based trip limit like in place for open access. Many on the team are skeptical that the ratio approach would be effective. It could be analyzed for implementation outside this main management measures process.

Limited time prevents us from fully summarizing all the analyses we considered in reaching this conclusion. To summarize the reason supporting the finding:

1. Only a few percentage of vessels in the limited entry and open access sectors are actually taking the existing limits.
2. Sablefish provide the main economic incentive in the fishery and rougheye and other slope rockfish appear to be caught incidentally. Trip limits are effective to the degree that they affect the incentive to target. They do not create a disincentive to avoid the incidentally caught fish and fish over the limit can simply be discarded.

The analysis is based on landings data from PacFIN as well as observer data from the West Coast Groundfish Observer Program. The focus is mainly on areas north of 40^0 10’ N. latitude because that is where the bulk of rougheye catch is taken.

Seasonal Patterns in Slope Rockfish Landings

Periods 3 thru 5 (May thru October) are where the majority of slope rockfish are landed in the open access and limited fixed gear sectors (

Table 18; Figure 7 and Figure 8). For one thing, we note that this pattern would make inseason adjustments impractical because of the timing with which we would know if landings are tracking high or low and in which a trip limit change could be implemented.

Table 18. Total landings of limited entry slope rockfish north by period combined over 2007-2013.

Period	Lbs. landed	Percent
1	17,722	2%
2	90,175	8%
3	293,048	26%
4	322,068	29%
5	349,671	32%
6	33,521	3%

Table 19. Total open access north landings of slope rockfish by period over 2007-2013.

Period	Lbs. landed	Percent
1	3,703	4%
2	11,497	12%
3	27,606	28%
4	23,665	24%
5	26,394	27%
6	5,170	5%

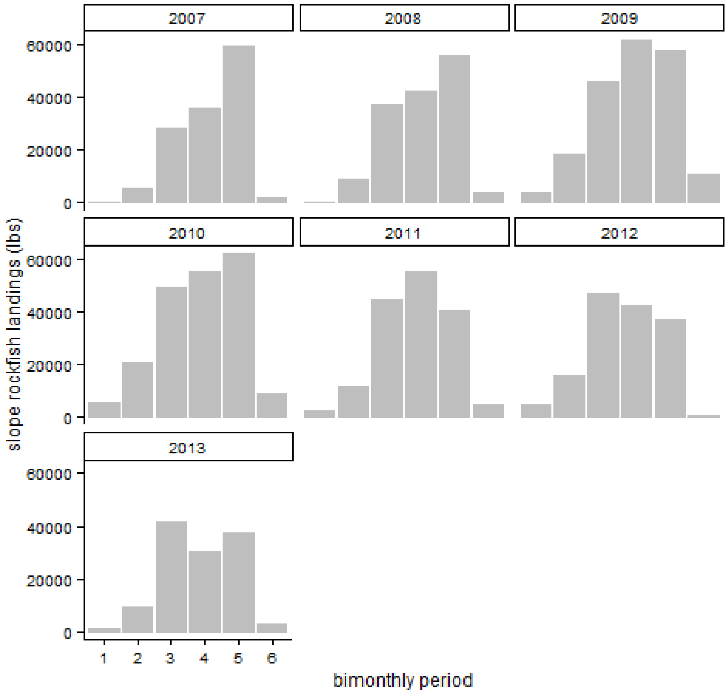

Figure 7. Limited entry fixed gear landings of slope rockfish by bimonthly period and year in the north.

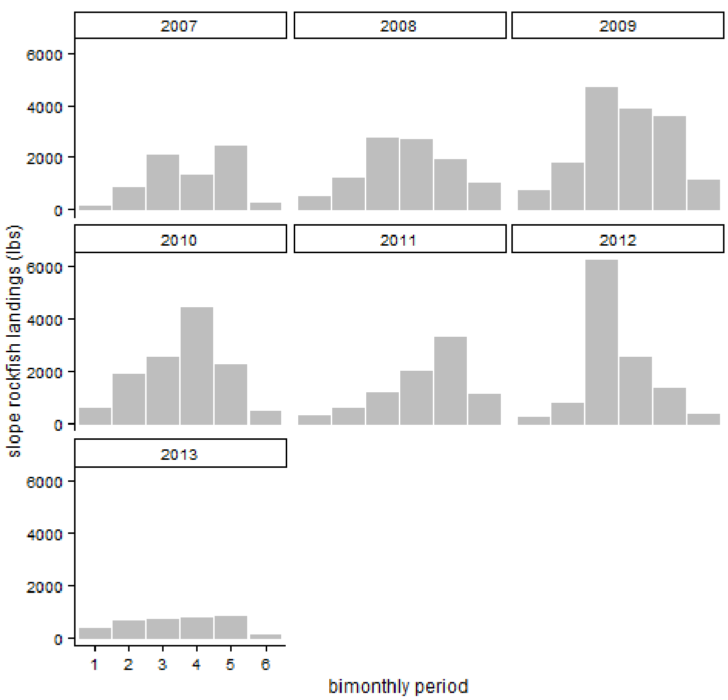

Figure 8. Open access fixed gear landings of slope rockfish by year and period in the north.

The Council targeted a trip limit at blackgill while leaving it in the slope rockfish south stock complex. The GMT and Council were comfortable with the likely effectiveness of that trip limit because of targeting of blackgill in the south. In contrast, the GMT does not see reason to believe rougheye have been widely targeted. Likewise, we do not see indication that vessels differentiate among the slope rockfish and we understand that the various slope species are similarly marketable. To affect the landings of rougheye, a trip limit would likely still be best focused on all species as a whole as opposed to specifically on rougheye. Figure 3 shows that the slope species are retained to similar degrees. Figure 4 and Figure 5 show that rougheye (REYE), blackgill (BLGL), Darkblotched (DBRK), and redbanded (RDBD) are the most frequently caught species.

Table 20 shows that rougheye have contributed less revenue on a vessel basis than blackgill. With blackgill, vessels reportedly set gear in different locations specifically to target the species. For rougheye we did not see such a pattern. The data reported in

Table 21 show that sablefish are caught 99.9 percent of the fixed gear hauls showing that hauls are not being set just to target slope rockfish. Sablefish provides the main economic incentive. We would therefore expect the trip limit for rougheye would create less of an incentive than did the trip limit for blackgill.

Likewise, we do not see indication that vessels differentiate among the slope rockfish and we understand that the various slope species are similarly marketable. To affect the landings of rougheye, a trip limit would likely still be best focused on all species as a whole as opposed to specifically on rougheye. Figure 9 shows that the slope species are retained to similar degrees. Figure 10 and Figure 11 show that rougheye (REYE), blackgill (BLGL), Darkblotched (DBRK), and redbanded (RDBD) are the most frequently caught species.

Table 20. Comparison of rougheye and blackgill in terms of their contribution to vessel revenues in the fixed gear sectors, 2007-2013. The set of vessels used here includes only vessels making landings of the species in at least six of the seven years. Data for blackgill is only for areas south of 36^0 N. latitude.

	Average Revenue		Average Percent Revenue		90th Percentile Revenue		90th Percentile Revenue	
Year	Rougheye	Blackgill	Rougheye	Blackgill	Rougheye	Blackgill	Rougheye	Blackgill
2007	$415.08	$2,042.52	0.46%	12.71%	$1,611.91	$6,619.80	1.64%	44.29%
2008	$587.85	$3,390.13	0.66%	9.78%	$1,554.38	$8,419.80	1.41%	20.32%
2009	$928.49	$5,901.00	0.70%	11.80%	$2,875.66	$13,330.40	1.89%	42.14%
2010	$873.50	$6,970.48	0.70%	12.00%	$1,725.18	$17,995.60	1.50%	36.17%
2011	$814.38	$10,714.26	0.53%	11.35%	$2,027.02	$5,554.40	1.10%	46.97%
2012	$929.38	$4,930.70	1.07%	16.99%	$2,096.47	$11,412.00	2.66%	74.60%
2013	$1,061.29	$422.09	1.71%	4.36%	$2,214.68	$1,015.60	2.99%	5.93%

Table 21. Haul level catches of sablefish and slope rockfish on observed fixed gear sets, 2002-2012.

2002-12	Total lbs	% of lbs	# of sets	% of sets
North of 40 10' N lat.				
Total sets	11,716,974	100.0%	8,644	100.0%
Sablefish	11,303,171	96.5%	8,633	99.9%
Slope rockfish (all)	413,804	3.7%	5,278	61.1%
Rougheye/blackspotted	169,152	1.5%	2,418	28.0%
Shortraker	36,738	0.3%	703	8.1%
Rougheye/shortraker	49,361	0.4%	244	2.8%
South of 40 10' N. lat.				
Total sets	1,833,997	100.0%	2,999	100.0%
Sablefish	1,695,176	92.4%	2,909	97.0%
Slope rockfish (all)	138,821	8.2%	1,268	43.6%
Rougheye/blackspotted	2,543	0.1%	55	1.9%
Shortraker	81	0.0%	7	0.2%

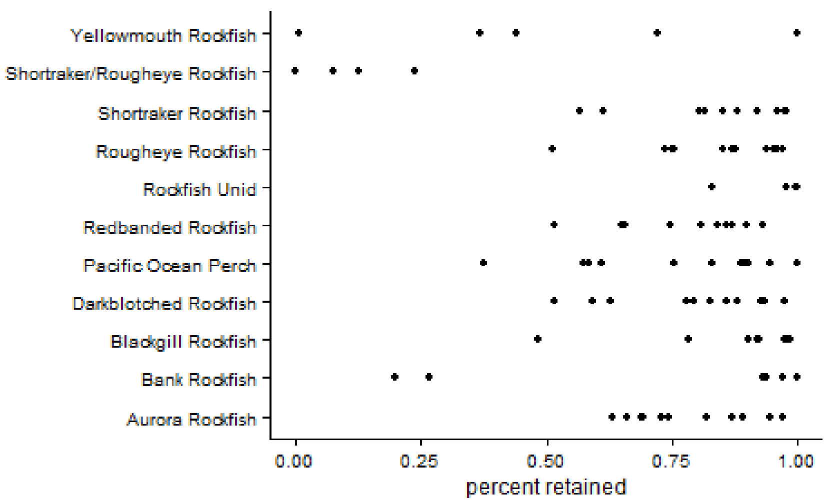

Figure 9. Annual retention rates of slope rockfish caught in the nonnearshore fixed gear sectors. This suggests that most slope rockfish

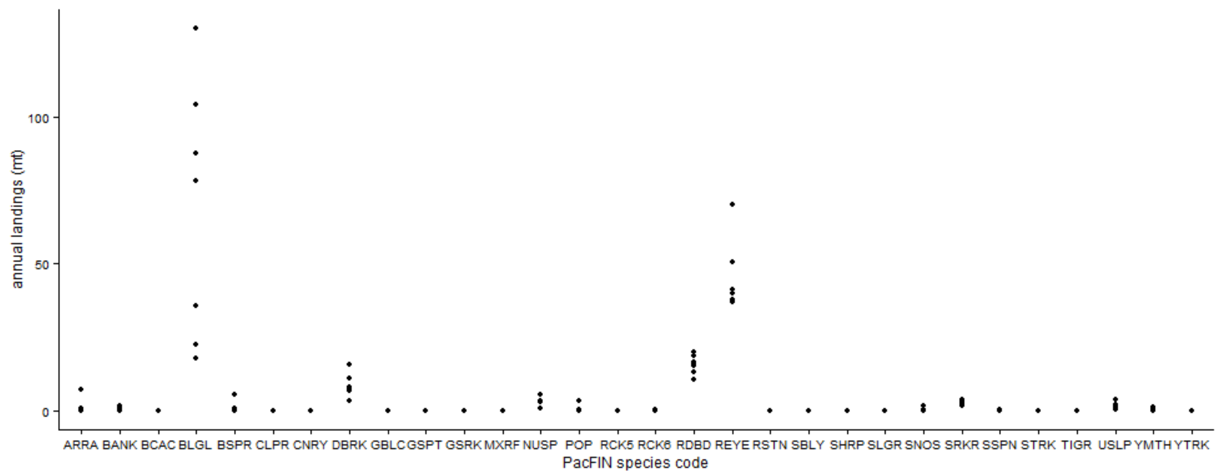

Figure 10. Annual landings by species under the slope rockfish market category under the open access and limited entry slope rockfish trip limits, 2007-2013.

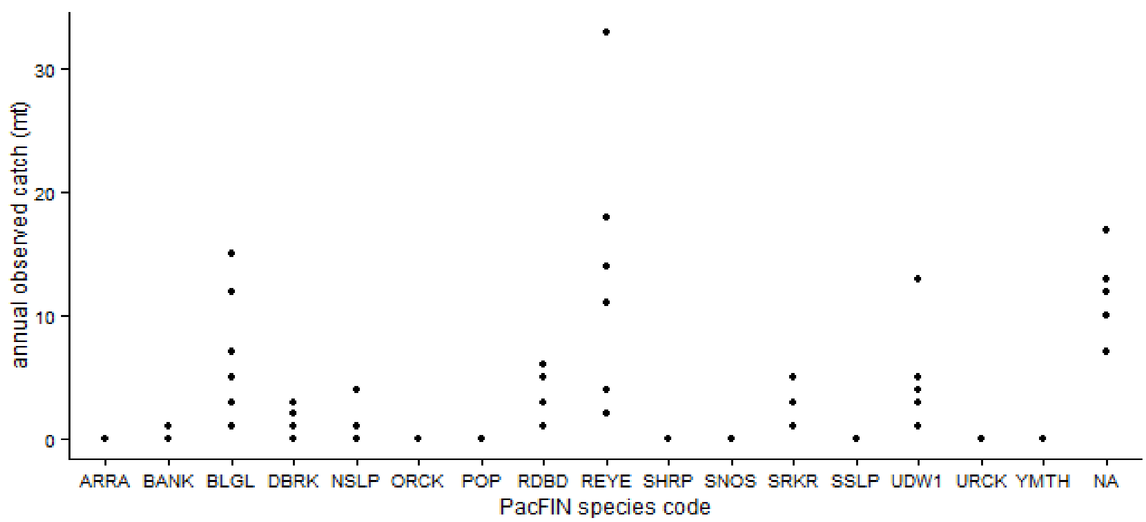

Figure 11. Observed catches (i.e. not expanded to total catches) of slope rockfish 2007-2012.

A Small Percentage of Vessels Are Taking the Current Limits

The current slope rockfish limits in the north are 4,000 lbs per bimonthly period for limited entry. For open access, it is a true trip limit where the weight of slope rockfish can be no more than 25 percent of the weight of sablefish landed. Darkblotched is included as a slope rockfish for purposes of the trip limits.

So few vessels are taking the trip limit that we had trouble displaying the data in a way that abides the “rule of three” that is intended to protect confidentiality. No vessels in the limited entry sector have taken their limits in period 1,2, or 6. We can only report to the 90th percentile level by year while still complying with the rule of 3. Figure 12 shows bimonthly landings up to that 90th percentile level. The upper 10th percentile in this set of years includes a minimum of 3, a maximum of 7, and an average and median of ~5 vessels per period (i.e. there could between 3 and 7 but most likely only 5 vessels past the rightmost points in the figure). Table 22 shows that between 3.7 percent and 14.6 percent of vessels take at least 3,600 lbs of slope rockfish in at least one period over 2007-2013.

As for the open access sector, fewer than 10 percent of vessels take the full amount of slope rockfish allowed by the 25 percent limit. We did not have time to identify a way of reporting how many vessels took the full limit while complying with the rule of 3.

Nonetheless, these patterns in the limited entry and open access sectors suggest that trip limit reductions would not greatly reduce landings. Again, we would worry that the trip limit would create regulatory discards that would reduce landings but not reduce total mortality.

Figure 12. Percentiles of sablefish landings by period, for periods 3-5, and year in the Limited Entry North sector.

Table 22. Number of unique vessels landing at least 3,600 lbs of slope rockfish in a period ("high liners") by year vs. total unique vessels making landings in the LE north sector.

YEAR	"High Liners"	All	% of Hi-Liners
2007	9	69	13.0%
2008	8	76	10.5%
2009	12	82	14.6%
2010	8	85	9.4%
2011	3	81	3.7%
2012	8	77	10.4%
2013	6	64	9.4%

Table 23. Open access north – slope rockfish as a percentage of sablefish landed per trip (e.g., in 2010 the 90th percentile means that weight of slope rockfish was 15 percent or less of the weight of sablefish landed on 90 percent of the trips).

	2007	2008	2009	2010	2011	2012	2013
50th	0%	0%	0%	0%	0%	0%	0%
70th	0%	1%	3%	2%	2%	2%	1%
80th	2%	3%	7%	6%	5%	5%	3%
90th	12%	10%	19%	15%	16%	19%	11%

Patterns in the depth and latitude of sets made on trips where rougheye and shortraker are caught

Lastly, we examined trips that catch rougheye or shortraker to see how they compare against trips that do not catch these species. The following plots (Figure 13 - Figure 16) compare all sets made on a trip so as to compare patterns in the latitude and depth. The plots follow the same structure. The outer shape is a violin plot, which is similar to a histogram but is smooth (instead of binned") and turned vertical and mirrored. In short, the "peaks" contain more sets than the "valleys. Inside the violin plots are boxplots, which display the median (thick middle line) and the 25th and 75th percentiles on the lower and upper edges of the box. The median identifies the midpoint at which half of the sets fall above and below.

As expected, trips that catch rougheye or shortraker make sets further north than those that do not. They also tend to make hauls shallower than the trips that do not.

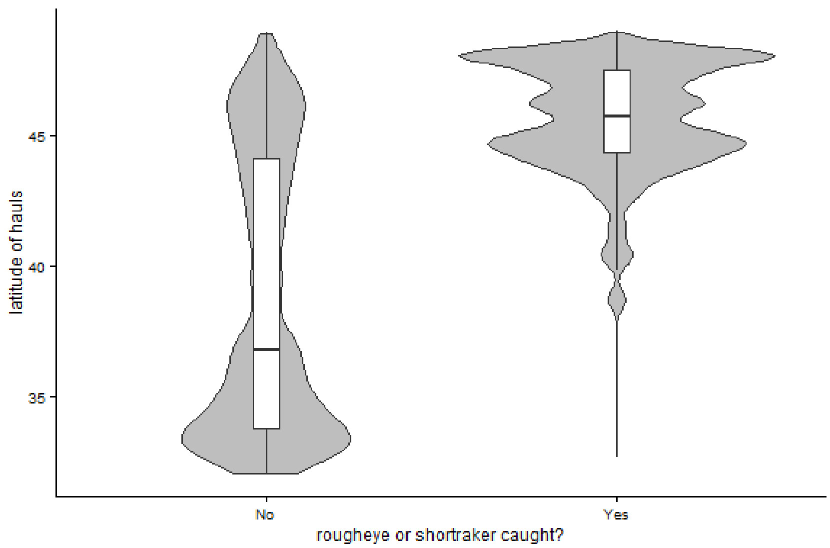

Figure 13. Comparing sets by latitude coastwide. See text above for explanation.

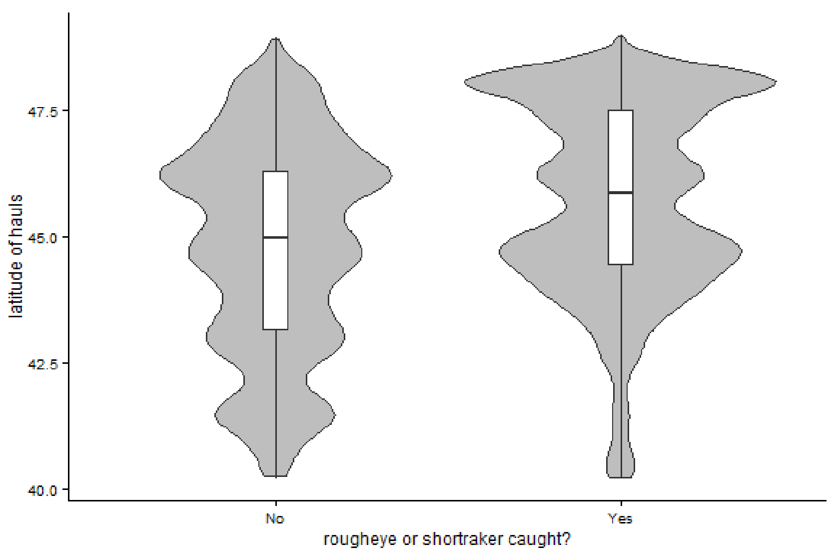

Figure 14. Comparing latitude of sets in the area just north of 40^{o} 10’ N. latitude. See text above for explanation.

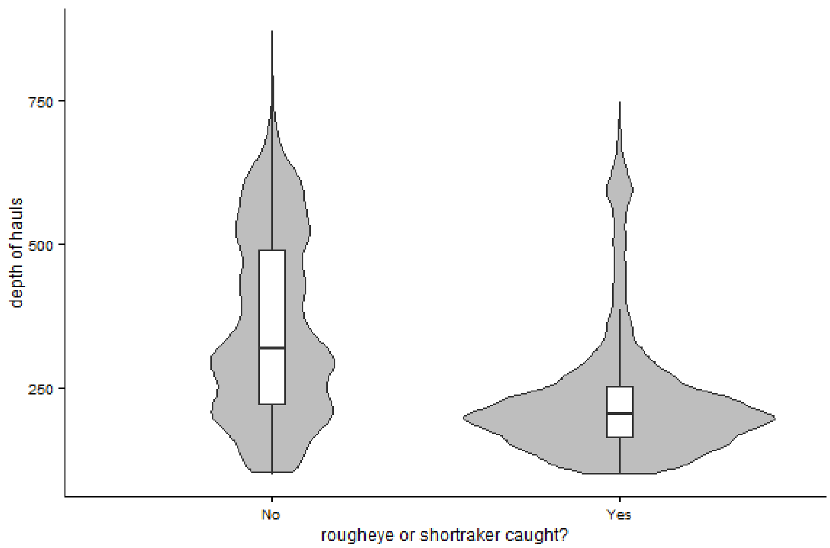

Figure 15. Comparing trips by depth of sets in areas coastwide. See text above for explanation.

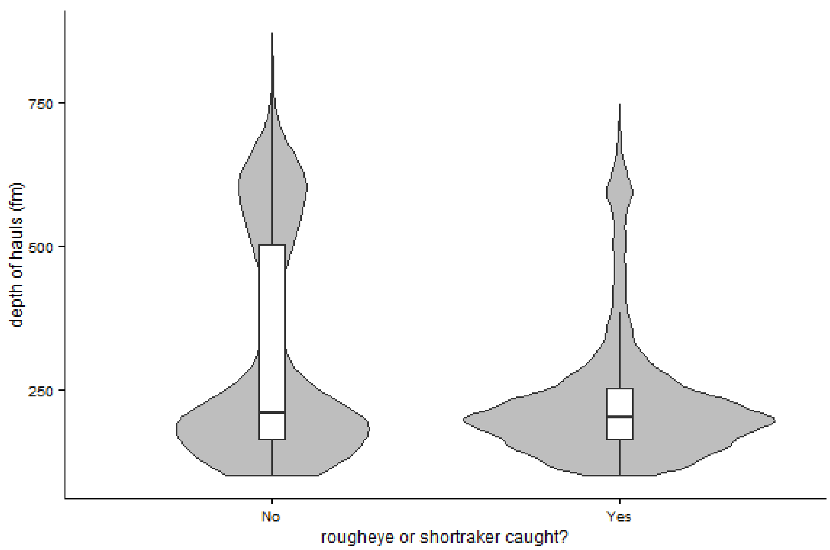

Figure 16. Comparing trips by depth of sets in areas north of 40⁰ 10’ N. latitude. See text above for explanation.

SCIENTIFIC AND STATISTICAL COMMITTEE REPORT ON FISHERIES IN 2015-2016 AND BEYOND: HARVEST SPECIFICATIONS, MANAGEMENT MEASURES, AND AMENDMENT 24

The Scientific and Statistical Committee (SSC) reviewed various documents related to establishing harvest specifications for the 2015-2016 fisheries and for Amendment 24 to the Groundfish Fishery Management Plan. The supplemental material for this agenda item became available during the SSC meeting. Therefore, the SSC did not have time to review it.

Cowcod Overfishing Level (OFL)

The SSC recommends the updated 2016 OFL of 68 mt for cowcod (Table 1, Agenda Item F.7, Attachment 2).

Harvest Specifications Draft Environmental Impact Statement

Dr. Kit Dahl and Mr. John DeVore provided the SSC with an overview of the Draft Environmental Impact Statement (DEIS) (Agenda Item F.7 Attachment 4). The DEIS is a comprehensive evaluation of the long- and short-term environmental and socioeconomic impacts of future catches. The short-term analyses (Sections 4.1 – 4.7) are related to the 2015-2016 fisheries while the long-term analyses (Sections 4.8 - 4.12) relate to the process of determining default harvest specifications.

Socioeconomic and Biological Analyses

Most of the short-term socioeconomic analyses are based on models which have been previously reviewed by the SSC. However, the methods used for projecting trawl catches for 2015-2016 fisheries have not been reviewed. The SSC was briefed on the methods and finds them to be reasonable. The projections of attainment are likely to be very uncertain given the fishery may still be in a transitional phase to the catch share program. The SSC has also not reviewed the approach used to evaluate the implications of trip limits for lingcod during the closed season. The SSC should review this analysis for the 2017-2018 harvest specifications process.

The projected long-term socioeconomic impacts are highly uncertain. Historical variation in ex-vessel revenue is due to many factors, such as management and changes in markets, and it is not clear how these factors will impact revenue in the future. However, the SSC agrees that the evaluation of long-term socioeconomic impacts is reasonable given the available information.

The biological analyses in the DEIS have been updated based on previous comments by the SSC. These analyses are sufficiently complete.

Atlantis Model Results

The Atlantis model is used in the DEIS to explore the long-term biological implications of the default harvest specifications. The SSC reviewed a preliminary version of the analysis based on this model in April 2014. The analysis has been updated based on the suggestions from the SSC. In particular, results are now provided to evaluate impacts on marine mammal and seabird populations. A methodology panel is scheduled (June 30 - July 2, 2014) to review the Atlantis model and report to the Council in September 2014.

The outcomes of the Atlantis model are scaled to results for a benchmark scenario in which productivity is set to base levels and catches are based on the 'recent averages' scenario. Across a broad range of catch levels, there do not appear to be large impacts of the groundfish fishery on other components of the ecosystem, although, and as expected, biomass levels for target species are lower for the higher catch scenarios.

SAFE Document

Mr. John DeVore summarized the contents of the draft groundfish SAFE document (Agenda Item F.7 Attachment 7). The draft SAFE follows the revised National Standard 2 guidelines for SAFE documents and has been developed with input from NMFS staff and stock assessment teams. It contains a considerable amount of information which will be valuable to the Council, scientists, and the public. The SSC will be involved in the review of the next version of the document through its Groundfish and Economics Subcommittees. The SSC highlights that the time needed to update this document every biennial cycle may be substantial.

Re: Makah Treaty Groundfish Fisheries in 2015-2016

Dear Mr. Stelle:

We have been asked to write to you on behalf of the Makah Indian Tribe. Pursuant to 50 C.F.R. § 660.324(d), we wrote to you on November 4, 2013, to describe the Tribe's intended groundfish fisheries in 2015 and 2016 and its requests for treaty groundfish regulations and allocations to accommodate those fisheries.

In our November 4, 2013, letter, we noted that the Tribe intended to request increases in the tribal set asides for yellowtail rockfish, widow rockfish and Pacific cod in 2015 and 2016. However, we explained that, because of then-current market constraints, the Tribe had not yet determined the amount of the increases it would request. We stated that Tribal representatives would confer with your staff to determine those amounts before the June 2014 Pacific Fishery Management Council meeting. Tribal representatives have since conferred with your staff regarding increases in tribal set asides for these and one other species (English sole).

In accordance with the procedures adopted by the Pacific Fishery Management Council and National Marine Fisheries Service for revisions to tribal requests for groundfish regulations and allocations (which allow for requested revisions to be submitted before the June Council meeting), the Tribe now requests the following increases in tribal set asides for 2015 and 2016:

English sole, currently 91, mt increase to 200 mt;

Pacific cod, currently 400, mt increase to 500 mt;

widow rockfish, currently 60, mt increase to 100 mt; and yellowtail rockfish, currently 677, mt increase to 1000 mt.

In addition, the Tribe is anticipating an impact of 275 mt for spiny dogfish.

In all other respects, the Tribe's requests for treaty groundfish regulations and allocations for 2015 and 2016 remain as described in our November 4, 2013, letter.

Makah representatives will be available to discuss any questions you or your staff may have regarding these matters at the upcoming Council meeting.

Sincerely,

ZIONTZ & CHESTNUT

Proposed 2015-2016 Tribal Management Measures

Black Rockfish - The 2015 and 2016 tribal harvest guidelines will be set at 30,000 pounds for the management area between the US/Canada border and Cape Alava, and 10,000 pounds for the management area located between Destruction Island and Leadbetter Point. No tribal harvest restrictions are proposed for the management area between Cape Alava and Destruction Island.

Sablefish - The 2015 and 2016 tribal set asides for sablefish will be set at 10 percent of the Monterey through Vancouver area ACL minus approximately 1.6 percent to account for estimated discard mortality. Allocations among tribes and among gear types, if any, will be determined by the tribes.

Pacific cod - The tribes will be subject to a 500 mt harvest guideline each year for 2015 and 2016.

For all other tribal groundfish fisheries the following trip limits will apply:

Thornyheads - Tribal fisheries will be restricted to 17,000 lbs/2 months for shortspine thornyheads and 22,000 lbs/2 months for longspine thornyheads. Those limits would be accumulated across vessels into a cumulative fleetwide harvest target for the year. The limits available to individual fishermen will then be adjusted inseason to stay within the overall harvest target as well as estimated impacts to overfished species

Canary Rockfish - Tribal fisheries will be restricted to a 300 pound per trip limit.

Other Minor Nearshore, Shelf and Slope Rockfish - Tribal fisheries will be restricted to a 300 pound per trip limit for each species group, except that redstripe rockfish will be restricted to 800 pounds per trip.

Yelloweye Rockfish - The tribes will continue developing depth, area, and time restrictions in their directed Pacific halibut fishery to minimize impacts on yelloweye rockfish. Tribal fisheries will be restricted to 100 pounds per trip.

Lingcod - Tribal fisheries will be subject to a 250 mt harvest guideline each year for 2015 and 2016.

Spiny Dogfish – Tribal fisheries for dogfish in 2015 and 2016 would be restricted to 275 mt each year. Targeting of dogfish by treaty fishermen in 2015 and 2016 would be conducted while staying within current estimates of impacts on overfished species.

Full Retention - The tribes will require full retention of all overfished rockfish species as well as all other marketable rockfishes during treaty fisheries.

Makah Trawl Fisheries for 2015 and 2016

Midwater Trawl Fishery - Treaty midwater trawl fishermen will be restricted to a total catch of yellowtail rockfish for the entire fleet of 1,000 mt. Their landings of widow rockfish must not exceed 10 percent of the cumulative poundage of yellowtail rockfish landed by a given vessel for the year for a total catch of 100 mt. The tribe may adjust cumulative limits for any two-month period to minimize the incidental catch of canary and widow rockfish.

Bottom Trawl Fishery - Treaty fishermen using bottom trawl gear will be subject to trip limits similar to those applied in recent years for shortspine and longspine thornyhead, Dover sole, English sole, rex sole, arrowtooth flounder, and other flatfish. These are 110,000 lbs/2 months for Dover sole, English sole, and Other Flatfish; 150,000 lbs/2 months for arrowtooth flounder; 17,000 lbs/2 months for shortspine thornyhead; and 22,000 lbs/2 months for longspine thornyhead. For all species these bi-monthly limits in place at the beginning of the season will be combined across periods and the fleet to create a cumulative harvest target. The limits available to individual fishermen will then be adjusted inseason to stay within the overall harvest target as well as estimated impacts to overfished species. For petrale sole, fishermen would be restricted to 220 mt for the entire year. Because of the relatively modest expected harvest, all other trip limits for the tribal fishery will be those in place in recent years and will not be adjusted downward, nor will time restrictions or closures be imposed, unless in-season catch statistics demonstrate that the tribe has taken ½ of the harvest in the tribal area. Fishermen will be restricted to small footrope (≤ 8 inches) trawl gear. Exploration of the use of selective flatfish trawl gear may be conducted.

Observer Program - The Makah Tribe has an observer program in place to monitor and enforce the limits proposed above.

WASHINGTON AND OREGON DEPARTMENTS OF FISH AND WILDLIFE REPORT ON 2015-2016 BIENNIAL HARVEST SPECIFICATIONS AND MANAGEMENT MEASURES

The Washington and Oregon Departments of Fish and Wildlife would like to reiterate our understanding regarding the management of stocks in state waters and our concerns with the use of data moderate assessments for nearshore stocks north of 40°10' N. latitude, and describe our preferred management approach for 2015 and 2016 (and, potentially, beyond).

As we noted in March (Agenda Item D.5.b Supplemental WDFW/ODFW/CDFW Report), the Magnuson-Stevens Fishery Conservation and Management Act (MSA) clearly indicates that the states' jurisdiction and authority within its respective boundaries, to include state waters, is not diminished by the MSA. As such, our understanding is that the portions of nearshore rockfish and roundfish stocks (e.g., China, copper, and brown rockfish, cabezon, and kelp greenling) occurring in state waters are under the states' respective jurisdictions and are not subject to federal management.

While the Pacific Fishery Management Council (Council) process provides an opportunity for the states to share information, the states independently manage their nearshore fisheries through separate licensing/permitting requirements, data collection and research programs, and stakeholder communication efforts. The Council recognized this during development of the Groundfish Fishery Strategic Plan (plan), adopted in 2000. The plan envisions that "Council management may be simplified by removing some species from the FMP through delegation or deferral to state management" and there is a management policy recommendation to: "Consider delegating or deferring nearshore rockfish and other groundfish species, such as scorpionfish, greenling, and cabezon, to the States." The plan also discusses the complexity and enforcement challenges inherent in having differing fishery among the states and how the Council and National Marine Fisheries Service (NMFS) are not well suited to assess the biological requirements of many of these local populations, to assess the social and economic issues associated with them, or to monitor localized fisheries. We assert that these issues are perhaps even more relevant today.

Again, as stated previously in March, the states have concerns with the use of the data moderate assessment approach, which uses catch history and—in these cases—recreational fishery-dependent indices of abundance, to determine the status of nearshore stocks as our respective nearshore fisheries are significantly different and have changed over time. It is likely that the catch histories, on which these nearshore assessments were based, were affected by these state-specific regulatory changes, rather than reflective of changes in abundance.

We believe that these concerns could be addressed through the development of reliable full assessments to the extent that data are available, which we think would be the appropriate next step. These full assessments should provide coastwide and state-specific information useful to management. While most, if not all, of these particular stocks occur exclusively in state waters, those assessments could also apportion overfishing limits between state and federal waters for management purposes, as appropriate.

While the states have considered alternatives for non-retention of these stocks, which could be specified preseason, the minor nearshore rockfish species are not targeted and our respective nearshore fisheries are the best (and, in some cases, the only) opportunity to collect biological data (e.g., age structures, maturity information, lengths and weights, etc.) on these stocks. Having non-retention restrictions in place at the start of our seasons would significantly hamper our abilities to have to full assessments in the future.

So, until those full assessments for nearshore stocks are completed and accepted for management, with the understanding that full assessments may not be available in the near future due to the lack of available data in some fisheries and areas, given the abilities of the states to monitor and manage our fisheries, we would propose the following management approach:

1. WDFW and ODFW commit to monitoring the harvest levels of their nearshore fisheries inseason and to coordinating with the other states if inseason action were needed.

2. Each state would manage its fisheries in a manner that would essentially treat "status quo" harvest levels as harvest guidelines.

3. Collectively, the states' "status quo" harvest levels of nearshore rockfish would exceed the nearshore rockfish complex annual catch limits (ACLs) for 2015 and 2016; therefore, WDFW and ODFW commit to consult and coordinate with the other states upon attainment of 75% of our respective "status quo" harvest levels. Table 1 describes what the states' harvest guidelines would be and what 75% of those respective guidelines are. We would conduct a conference call; each state would report its current harvest and projected catch estimate and decide whether any inseason action was needed.

    a. As ODFW and WDFW can take inseason action expeditiously, the harvest guidelines for Oregon and Washington would be state harvest guidelines and would not be specified in federal regulations.

    b. We would ask the California Department of Fish and Wildlife how they would like California's harvest guideline for nearshore rockfish north of 40°10' N. latitude specified and what their proposed management approach is, if different than this.

4. ODFW and WDFW commit to providing inseason updates on our respective nearshore fisheries to the Council at the September and November meetings in 2015 and 2016.

Table 1. Annual state-specific harvest guidelines (HGs) for the nearshore rockfish complex north of 40°10' N. lat. for 2015-2016, and 75% of each HG that would trigger consultation and coordination.

	Harvest Guideline	75% of HG
Washington	10.5	8
Oregon	48.4	36
California	23.7	18
	Total	**62**

Madame Chair members of the Council: For the record my name is Bill James. I am the fishery consultant for Port San Luis Commercial Fishermen's Association in Avila Beach California. For the years of 2015-2016 we request the Council to raise the commercial bi-monthly trip limits for both Shallow Nearshore Species and Deeper Nearshore species to 1000 pounds per two month period for the entire year.

south of 40:10. Equal monthly trip limits in each period makes for a consistent catch and ease of remembering the limit for fishing. In the past years Commercial Nearshore Fishermen have not attained the ACL. Higher trip limits are necessary to take advantage of good weather conditions to make up for some of the rough weather conditions we have been experiencing in the last several years. Our fishing vessels are typically smaller vessels averaging around 24 feet in length.

Also please open lingcod in the months that Nearshore Species can be caught. Also, if possible please raise the monthly limit on lingcod.

Thank you, Bill James

PFMC

Dear Dr. Donald McIsaac,

For over a decade the shelf rockfish quota for non-trawl open access has been the same for me along the south coast of Big Sur (200-300 lbs/2mo.)

I am writing this letter in the hope that you can raise this quota to at least that enjoyed by those south of Pt. Conception, (750-1000 lbs/2mo.) We have an abundance of fish in my area and all the fish I catch goes to local markets.

Also, I hope you can change the fish area from 30 fathoms out to 40 fathoms as it is for sport fishing. At this time, a sport fisherman can catch as much fish in a week for himself as I can in two months for the local people.

Thank you for your consideration.

Sincerely yours,

Brett Gourley

RE: 2015-2016 rockfish seasons, Agenda Item F.7

Dear Chair Lowman and Council Members:

The Humboldt Area Saltwater Anglers, Inc. (HASA) have discussed the Preferred Preliminary Alternatives set forth by the Council regarding the 2015/2016 rockfish seasons. Our organization and its members prefer to allow recreational fishing opportunity from April 1st through September 30th (20 fathoms) and October 1st to December 31st (30 fathoms). We also support a three bag limit for lingcod.

Part of our mission statement with HASA is to maintain angling opportunities, and a primary effort that HASA has conducted over the years is to educate the public on reducing the yelloweye bycatch allocation for our area by expressing the importance of rockfish descending devices. HASA has provided over 300 of the devices to sportfishers free of charge to help reduce yelloweye mortality, as well as other species. We are currently in the process of purchasing more of these devices to distribute to our sportfishers in the areas of Shelter Cove, CA to Trinidad, CA, and continue our efforts to educate the public and reduce yelloweye bycatch and mortality.

We appreciate the opportunity for providing public input on this matter, and do not hesitate to contact me if you would like any additional information.

Sincerely,

Cliff Hart

Cliff Hart, President

Dr. Don McIsaac,

I fish commercially with an open access license along the Big Sur coast in Central California (40°10' N. lat. - 34°27' N. lat.) I launch a 12' aluminum skiff from the beach at Mill Creek (port 516) and Big Creek (port 515). I've been fishing from these ports both sport and commercially for 25 years.

Because of the much needed management of the Minor Shelf rock fish, vermillion, lingcod, and bocaccio populations have increased dramatically. For this reason I write to you in hope that you'll consider modestly increasing the trip limits for vermillion to 400lbs/2mos and bocaccio to 300lbs/2mos through the open season. The lingcod population has improved and the current limits are working well for us and the fish.

Another issue I'd like to address is our depth limit. For over 100 miles from Carmel to Cambria there isn't a pier or harbor and the only method of commercially fishing is to launch a small skiff from shore. As far as I've seen, there are five other fisherman along this coast who are fishing by this method. Because of this, the 30 fathom depth limit is confining and makes my small fishing business nearly unviable because of the conditions (wind, swell, distance) I must travel through to reach the 150 fathom depth limit. Increasing the inner limit to 40 fathoms and decreasing the outer limits to 110 fathoms would help us tremendously as it would enable us to safely fish a more accessible area.

Please feel free to give me a call or email if you'd like to discuss further details about fishing on the Big Sur coast. Thank you for your time and consideration in this matter,

Sincerely,

Mark Seefeldt

May 10th, 2014

Pacific Fishery Management Council
7700 N.E. Ambassador Place, Suite 101
Portland, OR 97220-1384

Ms. Kelly Ames

I write you in regard to fishing on the Big Sur coast (40°10' N. lat. - 34°27' N. lat.). I've been fishing sport for 14 years and currently fish commercially with an open access license. I fish a small skiff by myself and sell to our local markets.

On the Big Sur coast I have noticed a large population increase over the past decade in the following species: vermillion, lingcod, and bocaccio. For this reason I'm inquiring into the possibility of larger trip limits such as those south of Pt. Conception (750-1000lbs/2 months) or something more than our current 200-300lbs/2 months and 100-200lbs/ 2 months for bocaccio.

I'd also like to request that a change in our depth limits be considered as well, from the inner 30 fathom limit to 40 fathoms, and from outer 150 fathom limit to 125 fathoms.

Your consideration in this matter is greatly appreciated.

Sincerely,

David Seefeldt

RE: RETAIN ROUGHEYE ROCKFISH IN MINOR SLOPE COMPLEX AND ALLOW INDUSTRY TO USE VOLUNTARY MEASURES TO REDUCE CATCHES

Dear Chair Lowman,

Please accept these comments on behalf of Midwater Trawlers Cooperative, United Catcher Boats, Fishermen's Marketing Association, West Coast Seafood Processors Association, Fishing Vessel Owners Association, Pacific Whiting Conservation Cooperative, Oregon Trawl Commission, Point Conception Groundfishermen's Association, and the Coos Bay Trawlers Association. Collectively, we represent the majority of at-sea and shoreside whiting harvesters and processors as well as a major portion of traditional bottom trawlers, shoreside seafood processors, and members of the fixed gear fleet utilizing long line gear.

We submitted a written public comment at the April 2014 PFMC meeting detailing industry-wide efforts to develop and promote a unified position to retain rougheye rockfish in the minor slope complex and to further allow the industry to use voluntary measures to reduce their rougheye catches. Several members of the industry also traveled to Vancouver, Washington to provide compelling oral testimony supporting this recommendation.

The Council voiced support for our efforts and our recommended approach by adopting a Preliminary Preferred Alternative (PPA) to maintain rougheye rockfish within the minor slope complex along with a mandatory scientific sorting requirement for management in 2015-2016. Our coalition fully supports the PPA and has done additional work to notify and educate affected industry members about this important topic.

This comment reiterates and expands upon why retaining rougheye in the minor slope complex while using voluntary measures to reduce catch, is most appropriate. It also summarizes the additional industry-led activities that have taken place since the April PFMC meeting.

Retain Rougheye Rockfish in the Minor Slope Complex

In September 2013, after consideration of several different data sets the Council decided to defer further consideration of reorganizing the minor slope complex until the next management specifications cycle. National Marine Fisheries Service (NMFS) was not fully comfortable with this recommendation and asked the Council to reconsider the issue in 2014 when NMFS offered to provide additional information for Council consideration. In April 2014, after considering additional analysis from NMFS and the Groundfish Management Team, as well as advisory body and stakeholder input, the Council once again had a robust discussion about the issue and determined that retaining rougheye rockfish in the slope complex was the preferred alternative for management. The Council further supported the concept that the industry should be allowed to use voluntary measures to reduce their rougheye catches. The Council will take final action on this issue at the June PFMC meeting.

The affected industry continues to support the Council's PPA and we encourage the Council to review our detailed comment from April 2014 in support of this position. The Council heard through various advisory body and public comments that there is no conservation concern identified and/or demonstrated with rougheye rockfish and that removing rougheye and shortraker from the complex and creating a new complex is both costly and disruptive. There are limited Council, NMFS, and state resources available to conduct the rulemaking that would be necessary to make changes – particularly if there is a need to allocate this species among sectors or individual vessels. At best this will lead to a disincentive for the fleets to work together to voluntarily reduce catch and at worst it will pit the sectors against each other, which benefits no one. With no conservation concern at present it seems most reasonable and wise to follow a path already laid by industry.

The Council and industry have been proactive on this issue. The burden on the Council and NMFS is to ensure that overfishing is not occurring now or will not occur in the near future. This has been done. The Council prioritized a full stock assessment for rougheye rockfish and the results were that the stock is healthy at 47% of its unfished biomass. Further, modeling demonstrates that even at catch levels projected to be higher than the proposed ABC, the stock will continue to grow over the next several years. The SSC approved this assessment for use in management as the best available science.

Allow the Industry to Use Voluntary Measures to Reduce Catches

The industry has made a concerted effort to work collaboratively in developing solutions that reduce impacts on rougheye rockfish -- solutions that did not and will not require an Environmental Impact Statement to implement, solutions that are in use and effective today. A critical first step was to gain an understanding of where, when, and how the industry encounters rougheye. The whiting sectors currently use tools to track catch tow-by-tow and species-by-species; therefore information was readily available to this sector. Because of limitations in how non-whiting landings are reported to the fleet on fish tickets and in PacFIN, non-whiting trawlers and the fixed gear fleet are working with shoreside processors to develop tools to better understand and react to their species-specific impacts, which include requesting information from their observers, port samplers, or processing plants on how much of their catch contains rougheye rockfish. The Council heard about these measures in April when many of us reported on what steps we had already taken to address this issue.

Since the April 2014 Council meeting several industry activities have occurred. We met again as an industry-wide group in May to discuss the April decisions and plan for the June meeting (Attachment 1). In addition, each sector shared more detail on what they had done and are doing to raise awareness about the issue and to document steps being taken to address catch levels. Lastly, on behalf of the industry coalition, MTC reached out to the state of Oregon for assistance in developing an informational flyer that can be used by any sector for outreach and educational purposes. This flyer will also be placed in gear stores and distributed to seafood processors in an attempt to reach industry members who are not represented by formal organizations.

In preparation for the May industry meeting we sought information on what the catch of rougheye rockfish has been so far in 2014. Unfortunately there was not a lot of information available, as some of the states had not provided updated information to the PacFIN database since March. In the future, the Council's recommended scientific sorting requirement and industry-led efforts to better track species-specific catch by coordination amongst processors, harvesters, observers, and port samplers will likely lead to improved data availability to managers and industry.

Below is a summary of the activities each affected sector has taken to address this issue.

Fixed-Gear
The Fishing Vessel Owners Association (FVOA) notified fixed gear-endorsed-limited entry permit holders about the issue, which included outreach to non-FVOA member fishermen. FVOA Manager Bob Alverson sent a letter to all fixed gear endorsed permit holders to inform them about the issue and the need to reduce both direct and incidental catches of rougheye (Attachment 2).

Traditional Bottom Trawl
The Oregon Trawl Commission (OTC) used its newsletter to notify all Oregon-based trawl permit holders. This newsletter is also available on the OTC's website at http://www.ortrawl.org/wp-content/uploads/2014/05/Wheelhouse-Spring-2014.pdf . In addition, the issue was discussed at the May OTC meeting held in Astoria. Many traditional trawlers have been connecting with their observers, port samplers, and processing plants in an effort to determine their past and current catches. Trawl representatives from the Council's Groundfish Advisory Panel have

also been spreading information through word of mouth on the issue and the need to be aware and reduce catches.

Whiting
The whiting sectors have taken a number of steps to address this issue in addition to the information sharing that goes on between organizations and their members.

The *catcher processor cooperative* Board reviewed past rougheye catch information and identified areas of high rougheye catch occurrence. They agreed to several measures, including:

- Carry flexible grate rockfish excluders for use when fishing in known rougheye bycatch areas to minimize rougheye bycatch.
- Collect and record tow-specific rougheye rockfish amounts (numbers and total weight) that are reported to the PWCC Executive Director.
- Establish rougheye rockfish kg/mt of hake rate that triggers action to prevent subsequent tows from exceeding the trigger.
- Establish policy whereby the PWCC Executive Director and Board track daily catches and will consider further actions as warranted.

The *mothership sector* also took action through its cooperative. The mothership bycatch committee as well as the Board met and adopted the following protocols:

- Distribute maps of historic Rougheye bycatch to the members
- Distribute high bycatch tow alerts and VMS tracks for hauls exceeding a specified rate
- Establish a set of "relocation" triggers based on a 3-day rolling average exceeding a certain rate
- Additionally, Mothership operators will incorporate Rougheye information in the daily ship reports.

The *shoreside whiting* sector's risk pool also discussed the issue through its bycatch committee and then through the cooperative's Board of Directors. The group encouraged vessel captains to use Sea State's "Preliminary Fish Ticket Entry" form to report the plant tally of rougheye after each landing, to help provide more real time information on rougheye encounters. Sea State will then use the information to produce alerts and VMS trackline maps. Individual shoreside whiting vessel owners (both risk pool members and non-members) have invested hundreds of thousands of dollars into the development of rockfish excluders to reduce the take of non-target species – this development will continue.

Seafood Processors
The West Coast Seafood Processors Association notified its members of the issue and the likelihood of a mandatory scientific reporting requirement beginning in 2015 (Attachment 3). WCSPA also asked that the plants begin sorting rougheye and shortraker now and further to share that information back with vessel captains.

Conclusion

The undersigned organizations represent a majority of the industry affected by changes to rougheye rockfish management. We take this issue very seriously. We are actively reaching out and educating our respective fleets about the importance of reducing our catch of rougheye rockfish. We have summarized these activities here in this public comment. More detailed oral testimony will be provided by each sector during the June PFMC meeting.

We continue to support retaining rougheye rockfish in the minor slope complex and strongly recommend that the Council adopt the PPA from April as the Final Preferred Alternative in June. Based on the sum of the evidence the stock is healthy and industry collaboration is proving effective. Therefore, the PPA is both reasonable and justified. Finally, we remind the Council that past voluntary efforts to reduce catches on other species have worked. Moreover, we have successfully demonstrated that we have the ability to effectively share information through our existing infrastructures and to work together across sectors and fleets to achieve favorable results.

Thank you for your consideration.

PFMC / West Coast Rougheye Rockfish Issue

Industry Meeting – Proposed Agenda

Tuesday, May 20th

3pm

In person at United Catcher Boats (Seattle) and Midwater Trawlers Cooperative (Newport) offices or by conference call

1. Welcome and Introductions

2. Review of April PFMC recommendations & scheduled June Decisions
    a. PPA to retain rougheye in the minor slope complex with a mandatory sorting requirement beginning in 2015
    b. Allow industry to use voluntary measures to reduce rougheye catches
    c. Take mandatory use of rockfish excluders off the table
    d. Some discussion about recatagorizing the stock assessment
    e. FPA in June
        i. Additional analysis on removing rougheye and shortraker to own complex with an OFL, ABC and ACL
        ii. NMFS / Council wants to hear more detail on what the fleet is doing to address the problem

3. Review any new landings data that is available

4. Industry response to April decisions / actions
    a. Fixed gear
    b. Bottom trawl
    c. Whiting
        i. Catcher / processors
        ii. Motherships
        iii. Shoreside
    d. Shoreside seafood processors

5. Joint public comment for June

6. Other?

Adjourn

May 21, 2014

Notice to Fixed-Gear Permit Holders

Dear Fixed-Gear Fishermen:

This notice is directed to those that fish off of Washington, Oregon, and California with fixed-gear, primarily hook-and-line gear. The National Marine Fisheries Service has notified the Pacific Council and the commercial fishing industry that they are concerned about the harvest levels of Rougheye and Shortraker Rockfish from all fishing sectors. Based on a recent (and the first formal) stock assessment, NMFS is concerned that the Over Fishing Level (OFL) prescribed by the assessment would have been exceeded in recent years had it had been in place. NMFS and the Council have asked the industry to voluntarily reduce their catches of rougheye rockfish in order to avoid more draconian mandatory measures such as restrictive trip limits and closed areas.

Even though there has been a bi-monthly trip limit of 4000 lbs. for these fish, NMFS is concerned that the collective harvest by all fleets on the West Coast may be exceeding what is provided for under the Magnuson-Steven's Act. **You are therefore asked that, to the extent that you can, please do not target rougheye rockfish and avoid the incidental catch of Shortraker and Rougheye Rockfish if at all possible. The Council could push the RCA line out to 200 fathoms if longliners don't help out on this.** Please find an historical catch by all gear groups on the back side of this sheet.

There is a coast-wide attempt by the different gear groups to reduce their catch of these two species during 2014. Currently NMFS and the Council have taken preliminary action to allow the industry to voluntarily reduce their catches. If industry can reduce their catches, it will greatly reduce the chances that any extraordinary restrictions from the NMFS or the Pacific Council will be implemented. This letter is being sent out as an industry effort to notify people of the problem and coordinated with efforts with other affected industry members such as the bottom trawl and whiting fleets.

Sincerely,

Robert D. Alverson
Manager

Week in Review

April 11, 2014

IMPORTANT NOTE

The Council summary contains several important items on the last page that all members should read. If you have any questions, please contact Rod.

PACIFIC FISHERY MANAGEMENT COUNCIL SUMMARY

The complete list of Council actions will be available on the Council's web site early next week (http://www.pcouncil.org). Shown below are issues that we believe are especially important to our members.

*****ROUGHEYE ROCKFISH*** – The good news is that the Council did not create a separate stock complex for rougheye / shortraker / blackspotted rockfish, nor is it discussing rougheye excluders. The Council did ask the Groundfish Management Team to analyze two additional seaward RCA lines – 300 fathoms and 350 fathoms – in case some sort of closure is needed. The Council will also look at identifying discrete temporary closure areas north of 40°10' in the event they are needed. However, ALL OF THIS IS CONTINGENT ON THE INDUSTRY FOLLOWING THROUGH ON VOLUNTARY AVOIDANCE PLANS. Industry groups will be getting together in the near future to work through options for keeping rougheye catch low and we will be following up with you. One thing you should begin to do right now is sort out rougheye rockfish at the dock. This will be required starting in 2015 but it will be good to get in practice and train your dock crews how to do it. If one of your boats has large catches of rougheye, warn them about it and ask them to change their strategy or fishing location if possible. This applies to all fishing sectors: whiting, trawl, fixed gear, and open access. Educate your boats on the need to avoid rougheye when fishing for slope rockfish in the north. It is not illegal to catch them but if too many come in we will be facing management actions that will not be pleasant. If you have any questions, please contact Rod.

RE: 2015-2016 rockfish seasons, Agenda Item F.7
Dear Chair Lowman and Council Members:

My name is Dick Woolsey. I am a recreational sports fisherman that fishes out of Eureka, California. The fish stocks along the Northern California coast have rebounded nicely due to the restrictive measures that have been put into place to protect overfished species. Recent surveys and catch data have shown that our fishery is now quite healthy. We are the most heavily regulated area in the state and take into consideration weather conditions along the north coast, we do not get a lot of opportunity to fish and therefore there is no reason not to expand our season. **My preference for the 2015-2016 sports rockfish season would allow recreational fishing from April 1stthrough September 30th (20 fathoms) and October 1st to December 31st (30 fathoms). I also support a three bag limit for lingcod.**

I appreciate the opportunity to provide public input on this matter, and do not hesitate to contact me if you would like any additional information.

Sincerely,
Dick Woolsey

Subject:
To: pfmc.comments@noaa.gov

Hi,

I am writing this letter in support of increasing our recreational time for fishing through December 31st. Also, I support the 3 bag limit for lingcod.

Thank you so much for considering our request for a longer ground fish season up here on the North Coast. Our area depends on our fishing industry and the increased time will bring more tourist dollars into our community. We are very concerned about fish in general and treasure this resource that we want to see last for generations. We are doing our own research and data gathering in this area. There is an abundance of groundfish and with our ocean conditions limiting our ability to fish, the extra days and depth won't have a negative impact on the fish.
And..... It is not the recreational fisherman who is doing the damage. Last year I saw hundreds of small yellow fish floating out in the ocean that had been dumped by some trawler. I got a photo of the fish, but not the trawler. That dump upset the fleet. The fish were scattered over a one mile area and it was awful. The small time fisher folks use caution and release devices to help save the fish that we are not to keep. None of us want to deplete a fish stock and we respect the limits that are set. We are asking that you review our ocean conditions and days we are able to fish by our own standards.

I am sorry if this isn't the type of letter you were looking for, but it is one I felt compelled to write and send. Please do all you can to give us the longer season. Thank you!

Pamlyn Millsap

Chair Lowman and Council Members,

My husband and I attended the April Council meeting in Vancouver in hopes of testifying against possible closures of both Kelp Greenling and Near Shore Species. Unfortunately, the Council was running so late that we did not get the opportunity to do so. Because of a mistake in the SSC science for the Kelp Greenling the closures will not happen, I assume, unless better scientific data is brought forward. Now, we find ourselves in the same position with the same arguments for the nearshore complex. Reductions in this completely untargeted fishery seem to be imminent, based only on catch data. Charter boats and recreational fishermen will also again be asked to take a hit for the near shore fisheries species that ha ve catch data only and no "real" science to base this important managing decision upon.

Let's visit the real world for a minute. I don't know how it works in other area's, but I would like to explain to you when and why charter boats and recreational fishermen in Garibaldi catch so few Blue Rockfish. Except for two or three weeks in August, there is such an abundance of Black Rockfish that we are unable to get the hooks and weights down through them to catch anything else. By mid-August the Blacks are evidently so full of bait that they couldn't eat another thing if they had to, much less be attracted by anything the fishermen might have to have to offer. Then , we do start to catch a few Blues though we'd rather not as they are too small to satisfy our customers or most recreational fisherman. We are in a "Catch 22" situation here where scientists are saying, with little real science or assessments to back up their "assumptions", that if we catch more fish, the stock is in danger of being overfished and if we catch less, then the stock must be in trouble! To the fishermen , of course, you usually catch more fish because there are more of them down there than usual, and if you catch less of them, it's time to try somewhere else. Catch data alone simply cannot be used to designate a problem with any species. The fishermen have agreed to work with fishery managers using real stock assessments to identify and protect species that are in danger of being overfished, but they did not agree to being managed by assumptions and a lack of data or "data poor" assessments .

We understand that ODFW has several other measurements about the Near Shore species that NMFS isn't using to help determine their stock status and health. The ODFW created a Nearshore Plan several years ago. Many Oregon fishermen support a request by Oregon and Washington Depts. of Fish and Wildlife to remove these small, near shore fisheries from federal management and turn it over to the states. Both states have a proven track record in managing species for the benefit of all, even the fishermen. Turning this responsibility over to the state agencies would benefit the Council and NMFS who appear to not have the time or money to do proper assessments for the smaller fisheries. Oregon and Washington both have the science available and the expertise to manage them. At the very least, NMFS could be instructed to use (and help pay for) the science that has already been done by the states.

Unnecessary reductions in quota for the Nearshore Rockfish Complex, especially when one species at a time is taken out, can do real economic harm. Charter boats in Oregon have approximately six months in which to make a living that must last all year. Many mistakes have been made with the "data poor" and "data moderate" standards, and we would like to request that the Council correct them before any unwarranted actions are taken that can literally destroy so many fishermen's livelihoods. Economic problems would multiply many times over for all our Coastal Communities if our charter and recreational fleets were shut down or seasons shortened. There would be far reacing consequences to our tourism businesses and trades as well if any of our fisheries are shut down or our seasons shortened. This applies to our commercial fisheries as well. While deliberating this issue, we hope the Council takes into account National Standard #8 of the MSA to "Consider fishing communities to provide for their sustained participation and to minimize adverse impacts". We would also like to remind NMFS again that while Oceana and other NGO's often threaten lawsuits for their numerous fishery "crisis" management schemes, NMFS could just as easily be sued for major, unwarranted economic impacts to the fishing fleets and coastal communities.

Thank you,

Mick and Linda Buell

Re: F.7.c, public comment / Near shore Rockfish management

Dear Ms. Lowman and Council members

The aforementioned Washington ocean recreational fishery groups support the current management system for nearshore Rockfish off the Washington coast for 2015-16.

Washington has a different near shore management approach than Oregon and California. This has led to significant differences in catch histories for all nearshore stocks, including nearshore rockfish, cabezon, and kelp greenling.

When salmon began to decline in the late 1970s Washington charter boats and recreational fishermen diversified their target strategies to other species in order to stay viable. The commercial hook and line fishery was very small and many, if not most, were charter boat operators trying to survive. The primary target was Black Rockfish as it is today.

Over time, working with WDFW, we supported reductions in Rockfish bag limits to avoid localized depletion and maintain a sustainable fishery. WDFW reduced the rockfish bag limit from 15 to 12 in 1992, closed the commercial nearshore fishery in 1995, and reduced the rockfish bag limit again from 12 to 10 in 1996.

Washington closed its commercial fishery almost 20 years ago. It does not make sense to use Oregon's recreational CPUE, which competes with an Oregon commercial fishery, to determine the status of nearshore stocks off Washington. Further, given these proactive, conservative measures and the sustainable level of harvest that has occurred off Washington for the last 60-70 years, it is difficult to comprehend and explain why we should have to do anything at all to constrain our recreational fisheries on these stocks.

Although occasionally encountered, nearshore rockfish, cabezon, and kelp greenling are not targeted species. While “non retention” seems like it wouldn't cause any harm, we question why an angler shouldn't be able to keep those incidentally caught fish when the stock is “healthy” (i.e., above B40%)?

Our industry has been responsible and pro-active with regard to conservation and management measures to assure the sustainable use of our fishery resource.

Once again, we urge you to set allowable harvests and craft management measures for 2015-16 that maintain our current closely monitored fishery.

Respectfully yours,

Agenda Item F.8
Situation Summary
June 2014

INITIAL STOCK ASSESSMENT PLANS AND TERMS OF REFERENCE (TOR) FOR GROUNDFISH AND COASTAL PELAGIC SPECIES

This agenda item concerns planning for new groundfish stock assessments that are anticipated to be completed in 2015, which will be used to inform the harvest specifications and management measures decisions for groundfish fisheries in 2017 and beyond.

The decision on which stocks to assess next year entails whether the assessment should be a full assessment that requires peer review by a stock assessment review (STAR) Panel, a data-moderate assessment (all data-moderate assessments are proposed to be reviewed in one STAR Panel), or an update assessment that requires only a review by the Council's SSC. Council policy on this subject has been to schedule no more than ten full assessments in a given year with no more than two full assessments reviewed at each STAR Panel. Given the proposal to dedicate a STAR Panel to data-moderate assessments, only eight full assessments are contemplated to be done next year. A maximum of five STAR Panels should be considered for next year. Dr. Michelle McClure and Dr. Jim Hastie, National Marine Fisheries Service Northwest Fisheries Science Center (NWFSC), will report on proposed stock assessments and a proposed 2015 stock assessment review schedule (Agenda Item F.8.b, NWFSC Report). As a further aid to a decision on potentially doing full assessments for any of the stocks that were assessed in 2013 using data-moderate methods, Agenda Item F.8.a, Attachment 1 documents the available age and length composition data for those stocks. The Oregon Department of Fish and Wildlife (ODFW) also provides a report detailing the data they have collected to inform any assessment of kelp greenling, China rockfish, copper rockfish, or quillback rockfish (Agenda Item F.8.b, ODFW Report).

There are three Terms of Reference (TOR) that guide the stock assessment process; one specifies how the next assessment process should occur and defines the roles and responsibilities of various entities contributing to this process, one guides the development of rebuilding analyses used to develop harvest specifications and rebuilding plans for overfished species, and one that guides how new methods are reviewed and recommended for scientific activities that inform analyses used in management decision-making. These TOR have been reviewed by some members of the SSC and others, and are included as Agenda Item F.8.a, Attachments 2, 3, and 4, respectively. Staff from the Northwest and Southwest Fisheries Science centers have also proposed some modifications to the stock assessment TOR (Attachment 1), which are proposed in a "track changes" format, to bolster the TOR with respect to new National Standard 2 guidelines. Additionally, Council staff has proposed changes to the stock assessment TOR from the perspective of the Coastal Pelagic Species management and assessment process in Attachment 5. The Council may want to modify these TOR for the upcoming assessment cycle.

The Council will consider the input from NMFS, the advisory bodies, and the public before providing a preliminary decision on 2015-2016 stock assessment priorities by species, type of assessment (full, data-moderate, or update), and language for the three draft TOR. The Council is scheduled to make final decisions on stock assessment planning at their September meeting.

Council Action:

1. **Adopt for Public Review the List of Stocks to be Assessed in 2015;**
2. **Adopt for Public Review the Preliminary TOR for the Groundfish and Coastal Pelagic Species Stock Assessment and Review Process for 2015-2016;**
3. **Adopt for Public Review the Preliminary SSC Terms of Reference for Groundfish Rebuilding Analysis;**
4. **Adopt for Public Review the Preliminary TOR for the Methodology Review Process for Groundfish and Coastal Pelagic Species; and**
5. **Adopt for Public Review the 2015 Groundfish Stock Assessment Review Schedule.**

Reference Materials:

1. Agenda Item F.8.a, Attachment 1: Available Age and Length Composition Data for the Nine Data-Moderate Stocks Assessed in 2013.
2. Agenda Item F.8.a, Attachment 2: Draft Terms of Reference for the Groundfish and Coastal Pelagic Species Stock Assessment and Review Process for 2015-2016.
3. Agenda Item F.8.a, Attachment 3: Draft Terms of Reference for the Groundfish Rebuilding Analysis for 2015-2016.
4. Agenda Item F.8.a, Attachment 4: Draft Terms of Reference for the Methodology Review Process for Groundfish and Coastal Pelagic Species.
5. Agenda Item F.8.a, Attachment 5: Recommended Changes to the Groundfish/CPS Stock Assessment Terms of Reference, Reflecting Coastal Pelagic Species Management and Assessment Schedules.
6. Agenda Item F.8.b, NWFSC Report: Initial Stock Assessment Plans and TOR, Northwest Fisheries Science Center Report.
7. Agenda Item F.8.b, ODFW Report: Stock Assessment Data Available for Kelp Greenling, and China, Copper and Quillback Rockfishes for the 2015-16 Stock Assessment Cycle.

Agenda Order:

a. Agenda Item Overview — John DeVore
b. Reports and Comments of Advisory Bodies and Management Entities
c. Public Comment
d. **Council Action:** Adopt for Public Review a Preliminary List and Schedule of Stocks for Assessment in 2015, the Stock Assessment and Methodology Review TOR for Groundfish and Coastal Pelagic Species, and the Rebuilding TOR for Groundfish

TERMS OF REFERENCE

FOR THE

GROUNDFISH AND COASTAL PELAGIC SPECIES STOCK ASSESSMENT AND REVIEW PROCESS FOR ~~2013~~2015-~~2014~~2016

DRAFT

~~NOVEMBER~~MAY, ~~2012~~2014

Published by the Pacific Fishery Management Council

TABLE OF CONTENTS

1. INTRODUCTION

The purpose of this document is to outline the guidelines and procedures for the Pacific Fishery Management Council's (Council) groundfish and coastal pelagic species (CPS) stock assessment review (STAR) process and to clarify expectations and responsibilities of the various participants. This document applies to assessments of species managed under the Pacific Coast Groundfish Fishery Management Plan and Management Plan for the CPS. The STAR process has been designed to provide for peer review as referenced in the 2006 Reauthorization of the Magnuson-Stevens Fishery Conservation and Management Act (RMSA), which states that "the Secretary and each Regional Fishery Management Council may establish a peer review process for that Regional Fishery Management Council for scientific information used to advise the Regional Fishery Management Council about the conservation and management of the fishery (see Magnuson-Stevens Act section 302(g)(1)(E))." National Standard 2 (NS2) of the Magnuson-Stevens Fishery Conservation and Management Act (MSA) (published July 19, 2013) provides guidance and standards to be followed when establishing a peer review process pursuant to MSA section 302(g)(1)(E) including guidance on the timing, scope of work, peer reviewer selection and transparency. The STAR process follows these standards and is fully compliant with NS2.

The STAR~~is~~ ~~peer review~~ process is designed to investigate the technical merits of stock assessments and other scientific information used by the Council's Scientific and Statistical Committee (SSC). The process outlined here is not a substitute for the SSC, but should work in conjunction with the SSC. This document is included in the Council's Statement of Organization, Practices and Procedures as documentation of the review process that underpins scientific advice from the SSC.

The review of stock assessments requires a routine, dedicated effort that simultaneously meets the needs of NMFS, the Council, and others. Program reviews, in-depth external reviews, and peer-reviewed scientific publications are used by federal and state agencies to provide quality assurance for the basic scientific methods employed to produce stock assessments. The extended time frame required for such reviews is not suited to the routine examination of assessments that are, generally, the primary basis for harvest recommendations. The SSC has developed a separate terms of reference for reviewing new methods that might be used in stock assessments, including methods and tools to incorporate ecosystem processes.

The STAR process is a key element in an overall procedure designed to review the technical merits of stock assessments and other relevant scientific information. This process allows the Council to make timely use of new fishery and survey data, analyze and understand these data as thoroughly as possible, provide opportunity for public comment, assure that the results are as accurate and error-free as possible, and identify the best available science for management decisions. Parties involved in implementing the STAR process are Council members, Council staff, members of Council Advisory Bodies, including the SSC, the Groundfish and CPS Management Teams (GMT and CPSMT), the Groundfish Advisory SubPanel (GAP) and CPS Advisory Subpanel (CPSAS), the National Marine Fisheries Service (NMFS), state agencies, and interested persons.

This current version of the STAR terms of reference (TOR) reflects recommendations from previous participants in the STAR process, including STAR panel members, SSC members, stock assessment teams (STATs), Council staff, and Council advisory groups. Nevertheless, no set of guidelines can be expected to deal with every contingency, and all participants should anticipate the need to be flexible and address new issues as they arise.

Stock assessments are conducted to assess the abundance and trends of fish stocks, and provide the fundamental basis for management decisions regarding appropriate harvest levels. Assessments use statistical population models to integrate and simultaneously analyze survey, fishery, and biological data. Environmental and ecosystem data may also be integrated in stock assessments. Hilborn and Walters (1992)[1] define stock assessments as “the use of various statistical and mathematical calculations to make quantitative predictions about the reactions of fish populations to alternative management choices.” In this document, the term “stock assessment” includes activities, analyses and reports, beginning with data collection and continuing through to scientific recommendations presented to the Council and its advisors. To best serve their purpose, stock assessments should attempt to identify and quantify major uncertainties, balance realism and parsimony, and make best use of the available data.

There are four distinct types of assessments, which are subject to different review procedures. A “full assessment” is a new assessment or an assessment that may be substantially different from the previously conducted assessment. A full assessment involves a re-examination of the underlying assumptions, data, and model parameters previously used to assess the stock. Full assessments are reviewed via the full STAR process. There is a limit on the number of full assessments that can be conducted and reviewed during an assessment cycle. Some assessment models have relatively few modeling or data issues and provide relatively stable results as new data are added, such that it is not necessary to develop a completely new assessment every time the species is assessed. In these cases, an “update assessment” may be preferable. An “update assessment” is defined as an assessment that maintains the model structure of the previous full assessment and is generally restricted to the addition of new data to previously evaluated time series that have become available since the last assessment. Update assessments are reviewed by the relevant subcommittee of the SSC (Groundfish or CPS) rather than by a STAR panel. A “data-moderate assessment” is a third type of assessment that incorporates historical catch data and one or more indices of abundance (e.g., trawl survey or fishery CPUE indices). Data-moderate assessments are limited in that compositional data (i.e., length or age data) are restricted from the assessment to make such assessments less complicated and enable more expeditious review. Conceptually, data-moderate assessments are designed for groundfish stocks to be reviewed by the SSC Groundfish Subcommittee. However, in 2013, data-moderate assessments will be reviewed by a full STAR panel since these assessment methodologies will be used for the first time in the Council process. A “catch report” is a fourth type of assessment product that applies when only limited new information is available to inform the assessment. Catch reports are reviewed by the relevant subcommittee of the SSC (Groundfish or CPS).

The RMSA recently changed the terminology and process for determining harvest levels. The previous Allowable/Acceptable Biological Catch (ABC) has been replaced by the Overfishing Limit (OFL). However, the largest allowable harvest level is still the ABC (now “Acceptable Biological Catch”), which is buffered from the OFL based on the risk of overfishing adopted by the Council (which must be less than 50%). The P* (overfishing probability) approach uses a probability of overfishing (which the Council has set to be less than or equal to 45% or 0.45) and a measure of uncertainty in the assessment of current stock status (σ, the standard error of the

[1] Hilborn, R., and C. J. Walters. 1992. Quantitative fisheries stock assessment: Choice, dynamics and uncertainty. Chapman and Hall.

biomass estimate in log space) to determine the appropriate buffer with which to reduce the harvest level from the OFL to the ABC (Ralston et al. 2011[2]). The Annual Catch Limit (ACL) is equivalent to what the Council previously called the Optimum Yield (OY). For groundfish species, the upper limit for the ACL is calculated using the 40-10 harvest control rule (and 25-5 rule for flatfish species) while for CPS, each species has a specific control rule to calculate the Harvest Guideline (HG), which is the upper limit for the ACL for CPS. The Annual Catch Target (ACT) is the targeted catch level, representing a further reduction from the ACL to account for management/implementation uncertainty. The OFL must be given in the stock assessment (along with, in some cases, σ). The ABC is determined from the OFL given σ and P*. For CPS, the assessment reports the application of the HG control rule. The OFL, ABC, ACL, any ACTs, and (for CPS) the HGs are reported in the Council's Stock Assessment and Fishery Evaluation (SAFE) report or the relevant National Environmental Policy Act (NEPA) analysis of alternative harvest specifications.

2. Stock Assessment Prioritization

Stock assessments for Pacific sardine and Pacific mackerel are conducted annually, with full assessments occurring every third year, and update assessments during interim years. Assessments for groundfish species are conducted every other year as part of the biennial harvest specification cycle. A relatively small number of the more than 90 species in Council's Groundfish Fishery Management Plan are selected each cycle for full or update assessments. To implement the RMSA requirements to establish ABCs and OFLs for all species in fishery management plans, simple assessment methods such as Depletion-Corrected Average Catch (DCAC)[3] and Depletion-Based Stock Reduction Analysis (DB-SRA)[4] have now been applied to the majority of groundfish species. It is the goal of the Council to substantially increase the number of groundfish stocks with full assessments.

In April 2006, the SSC recommended, and the Council adopted, a new approach to prioritize groundfish species for full and update stock assessments based on: 1) economic or social importance of the species, 2) vulnerability and resilience of the species, 3) time elapsed since the last assessment (NMFS advises assessments to be updated at least every five years), 4) amount of data available for the assessment, 5) potential risk to the stock from the current or foreseeable management regime, and 6) qualitative trends from surveys (when available). It was also recommended that overfished groundfish stocks that are under rebuilding plans be evaluated each assessment cycle to ensure adequate progress towards achieving stock recovery.

The proposed stocks for full, update, and data-moderate assessments should be discussed and finalized by the Council at least a year in advance of a new assessment cycle to allow sufficient time to assemble relevant data and arrange STAR panels. The 2015~~3~~ stock assessment plan for groundfish and CPS stocks is provided in Appendix A.

3. STAR Goals and Objectives

The goals and objectives of the groundfish and CPS STAR process are to:

[2] Ralston, S., Punt, A.E., Hamel, O.S., DeVore, J. and R.J. Conser. 2011. An approach to quantifying scientific uncertainty in stock assessment. *Fishery Bulletin* 109: 217-231.
[3] MacCall, A. D. 2009. Depletion-corrected average catch: a simple formula for estimating sustainable yields in data-poor situations. *ICES Journal of Marine Science* 66: 2267-2271.
[4] Dick, E. J. and A. D. MacCall. 2011. Depletion-Based Stock Reduction Analysis: A catch-based method for determining sustainable yields for data-poor stocks. *Fisheries Research* 110: 331-341.

1) ensure that stock assessments represent the best scientific information available~~scientific information~~ and facilitate the use of this information by the Council to adopt OFLs, ABCs, ACLs, (HGs), and ACTs;
2) meet the mandates of the Magnuson-Stevens Fisheries Conservation and Management Act (MSA) and other legal requirements;
3) follow a detailed calendar and fulfill explicit responsibilities for all participants to produce required reports and outcomes;
4) provide an independent external review of stock assessments;
5) increase understanding and acceptance of stock assessments and peer reviews by all members of the Council family;
6) identify research needed to improve assessments, reviews, and fishery management in the future; and
7) use assessment and review resources effectively and efficiently.

4. Roles and Responsibilities of STAR participants

4.1. Shared Responsibilities

All parties have a stake in assuring adequate technical review of stock assessments. NMFS, as the designee of the Secretary of Commerce, must determine that the best scientific advice has been used when it approves fishery management recommendations made by the Council. The Council uses advice from the SSC to determine that the information on which it bases its recommendations represents the best available science. Scientists and fishery managers providing technical documents to the Council for use in management need to assure that their work is technically correct.

The Council, NMFS and the Secretary of Commerce share primary responsibility to create and foster a successful STAR process. The Council oversees the process and involves its standing advisory bodies, especially the SSC. For groundfish, NMFS provides a stock assessment coordinator (SAC) to facilitate and assist in overseeing the process, while for CPS a designated SWFSC staff member performs this role. Together NMFS and the Council consult with all interested parties to plan and prepare TOR, and develop a calendar of events with a list of deliverables for final approval by the Council. NMFS and the Council share fiscal and logistical responsibilities and both should ensure that there are no conflicts of interest in the process[5].

The STAR process is sponsored by the Council, because the Federal Advisory Committee Act

[5] The ~~proposed~~ final NS2 guidelines state: ~~"Peer reviewers who are federal employees must comply with all applicable federal ethics requirements. Peer reviewers who are not federal employees~~ a~~must comply with the following provisions. Peer reviewers must not have any real or perceived conflicts of interest with the scientific information, subject matter, or work product under review, or any aspect of the statement of work for the peer review. For purposes of this section, a~~ "[A] conflict of interest is any financial or other interest which conflicts with the service of the individual on a review panel because it: (A) Could significantly impair the reviewer's objectivity; or (B) Could create an unfair competitive advantage for a person or organization; (C) Except for those situations in which a conflict of interest is unavoidable, and the conflict is promptly and publicly disclosed, no individual can be appointed to a review panel if that individual has a conflict of interest that is relevant to the functions to be performed. Conflicts of interest include, but are not limited to, the personal financial interests and investments, employer affiliations, and consulting arrangements, grants, or contracts of the individual and of others with whom the individual has substantial common financial interests, if these interests are relevant to the functions to be performed". ~~Potential reviewers must be screened for conflicts of interest in accordance with the procedures set forth in the NOAA Policy on Conflicts of Interest for Peer Review subject to OMB's Peer Review Bulletin."~~

(FACA) limits the ability of NMFS to establish advisory committees. FACA specifies a procedure for convening advisory committees that provide consensus recommendations to the federal government. The intent of FACA was three-fold: to limit the number of advisory committees; to ensure that advisory committees fairly represent affected parties; and to ensure that advisory committee meetings, discussions, and reports are carried out and prepared in full public view. Under FACA, advisory committees must be chartered by the Department of Commerce through a rather cumbersome process. However, the Sustainable Fisheries Act exempts the Council from FACA per se, but requires public notice and open meetings similar to those under FACA.

4.2. STAR Panel Responsibilities

The role of the STAR panel is to conduct a detailed technical evaluation of a full stock assessment to advance the best available scientific information to the Council. The specific responsibilities of the STAR panel are to:

1) review draft stock assessment documents, data inputs, and analytical models along with other pertinent information (e.g., previous assessments and STAR panel reports, when available);
2) discuss the technical merits and deficiencies of the input data and analytical methods during the open review panel meeting, work with the STATs to correct deficiencies, and, when possible, suggest new tools or analyses to improve future assessments; and
3) develop STAR panel reports for all reviewed species to document meeting discussion and recommendations.

The STAR panel chair has, in addition, the responsibility to: 1) develop a STAR panel meeting agenda; 2) ensure that STAR panel participants follow the TOR; 3) guide the STAR panel and the STAT to mutually agreeable solutions; and 4) coordinate review of revised stock assessment documents before they are forwarded to the SSC.

Groundfish and CPS STAR panels include a chair appointed from the relevant SSC subcommittee (Groundfish or CPS), and three other experienced stock assessment analysts knowledgeable of the specific modeling approaches being reviewed. Of these three other members, at least one should be appointed from the Center for Independent Experts (CIE) and at least one should be familiar with west coast stock assessment practices. Selection of STAR panelists should be based on expertise, independence ~~aim for~~a balance between outside expertise and in-depth knowledge of west coast fisheries, data sets available for those fisheries, and modeling approaches applied to west coast groundfish and CPS, and be free of conflicts of interest. Expertise in ecosystem models or processes, and knowledge of the role of groundfish and CPS in the ecosystem is also desirable, particularly if the assessment includes ecosystem models or environmental processes. For groundfish, an attempt should be made to identify one reviewer who can consistently attend all STAR panel meetings in an assessment cycle. The pool of qualified technical reviewers is limited; therefore, staffing of STAR panels is subject to constraints that can make it difficult to meet the conditions above.

Selected ~~R~~reviewers should not have financial or personal conflicts of interest with the scientific information, subject matter, or work product under review, either current to the meeting, within the previous year (at minimum), or anticipated. ~~–~~STAR panel reviewers who are federal employees should comply with all applicable federal ethics requirements. Reviewers who are not federal employees will be screened for conflicts of interest either through existing financial disclosure processes used by the SSC and CIE, or under the NOAA Policy on Conflicts of Interest for Peer Review Subjects.

Reviewers should not have contributed or participated in the development of the work product or scientific information under review and reviewer responsibilities should rotate across the available pool of qualified reviewers, when possible.

STAR panel meetings should also include representatives of the relevant management team (MT) and advisory panel (AP), with responsibilities as laid out in these TOR, and a Council staff member to help advise the STAR panel and assist in recording meeting discussions and results. The STAR panel, STATs, the MT and AP representatives, and the public are all legitimate meeting participants who should be accommodated in discussions. It is the STAR panel chair's responsibility to coordinate discussion and public comment so that the assessment review is completed on time.

The STAR process is by design a transparent process. STAR panel meetings are open to the public and are announced on the Council's website, through Council meeting notices and in the Federal Register at least 14 days prior to the panel meeting. The Council posts b~~B~~ackground materials ~~are posted on the Council's~~son its ftp site prior to the panel meeting and makes hard copies ~~can be made~~ available upon request. A STAR panel normally meets for one week. The number of assessments reviewed per panel should not exceed two, except in extraordinary circumstances if the SSC and NMFS agree that it is advisable, feasible, and/or necessary. When separate assessments are conducted at the sub-stock level (i.e., black rockfish), each assessment is considered an independent full assessment for review purposes. Contested assessments, in which alternative assessments are brought forward by competing STATs using different modeling approaches, would typically require additional time (and/or panel members) to review adequately, and should be scheduled accordingly. While contested assessments are likely to be rare, they can be accommodated within the STAR process. The STAR panel should thoroughly evaluate each analytical approach, comment on the relative merits of each, and, when conflicting results are obtained, identify the reasons for the differences. The STAR panel is also charged with selecting a preferred base model.

STAR Panel Requests for Additional Analyses

STAR panel meetings are not workshops. In the course of a meeting, the panel may ask the STAT for a reasonable number of sensitivity runs, request additional details on the proposed base model presented, or ask for further analyses of alternative runs. It is not unusual for the review to result in a change to the initial base model (given that both the STAR panel and the STAT agree). However, the STAR panel is not authorized to conduct an alternative assessment representing its own views that are distinct from those of the STAT, nor can it impose an alternative assessment on the STAT. Similarly, the panel should not impose their preferred methodologies when this is a matter of professional opinion. Rather, if the panel finds an assessment to be inadequate, it should document its opinion and suggest potential remedial measures for the STAT to take to rectify perceived shortcomings of the assessment. For groundfish species, the SSC reviews the STAR panel report and recommends whether an assessment should be further reviewed at the so-called "mop-up" panel meeting, a meeting of the SSC's Groundfish subcommittee that occurs after all of the STAR panels, primarily to review rebuilding analyses for overfished stocks. If a recommendation on whether to send the assessment to the mop-up panel meeting is needed before the full SSC is able to review the STAR panel report, the SSC Chair, Vice Chair, and Groundfish Subcommittee Chair will make a preliminary decision. This recommendation is subject to confirmation by the full SSC at its next scheduled meeting. For CPS, if an assessment is found not to be acceptable for use in management, a full assessment would be conducted the following year.

The STAR panels are expected to be judicious in their requests of the STATs. Large changes in data (such as wholesale removal of large data sets) or in analytical methods often result in such great changes to the assessment that they cannot be adequately reviewed during the course of the STAR panel meeting. Therefore, caution should be exercised in making such changes, and in many cases such changes should be relegated to future research recommendations and/or methodology review. If a groundfish STAR panel agrees that significant changes are necessary, and the assessment is not otherwise acceptable, a recommendation for further review at the mop-up panel is warranted. Similarly, if the STAR panel agrees that the assessment results strongly indicate that current F_{MSY} value or management target and threshold are inappropriate, it should identify this in its report and recommend further analysis to support a change to more appropriate values.

STAR panel requests to the STAT for additional model runs or data analyses must be clear, explicit, and in writing. They should reflect the consensus opinion of the entire panel and not the minority view of a single individual or individuals. The STAR panel requests and recommendations should be listed within the STAR panel's report along with rationale and the STAT response to each request.

To the extent possible, analyses requested by the STAR panel should be completed by the STAT during the STAR panel meeting. It is the obligation of the STAR panel chair, in consultation with other panel members, to prioritize requests for additional analyses. In situations where a STAT arrives with a well-constructed, thoroughly investigated assessment, it may be that the panel finishes its review earlier than scheduled (i.e., early dismissal of a STAT). If follow-up work by the STAT is required after the review meeting (such as MCMC integration of an alternative model created during the STAR panel meeting), this should be completed before the briefing book deadline for the Council meeting at which the assessment is scheduled for review. It is the STAR panel chair's responsibility to track STAT progress. In particular, the chair is responsible for communicating with the STAT to determine if the revised stock assessment document is complete. Any post-STAR drafts of the stock assessment must be reviewed by the STAR panel chair. The assessment document can only be given to Council staff for distribution after it has been endorsed by the STAR panel chair, and when it is accompanied by a complete and approved STAR panel report. Likewise, the final draft that is published in the Council's SAFE document must also be approved by the STAR panel chair prior to being accepted by Council staff.

For some stocks selected for full assessments, the available data may prove to be insufficient to support a category 1 assessment. In such cases, the STAT should consider whether simpler approaches appropriate for a category 2 assessment can be applied. Simpler approaches usually make stronger assumptions and estimate fewer parameters, but are less demanding of data. It is the responsibility of the STAR panel, in consultation with the STAT, to consider the strength of inferences that can be drawn from analyses presented, and identify major uncertainties. If useful results have been produced, the STAR panel should review the appropriateness and reliability of the methods used to draw conclusions about stock status and/or exploitation rates, and either recommend or reject the analysis on the basis of its ability to provide useful information into the management process. If the STAR panel agrees that important results have been generated, it should forward its findings and conclusions to the SSC and the Council for consideration in setting of OFLs, ABCs, and ACLs (for groundfish) and HGs (for CPS). A key section of the assessment is that on research needed to improve the assessment. Highlighting research priorities should increase the likelihood that future stocks assessments can be raised to category 1.

Uncertainty and Decision Tables in Groundfish Stock Assessments

The STAR panel review focuses on technical aspects of the stock assessment. It is recognized that no model or data set is perfect or issue free. Therefore, outputs of a broad range of model runs should be evaluated to better define the scope of the accepted model results. The panel should strive for a risk-neutral perspective in its deliberations, and discuss the degree to which the accepted base model describes and quantifies the major sources of uncertainty in the assessment. Confidence intervals for model outputs, as well as other measures of uncertainty that could affect management decisions, should be provided in completed stock assessments and the reports prepared by STAR panels. The STAR panel may also provide qualitative comments on the probability of results from various model runs, especially if the panel does not consider the probability distributions calculated by the STAT capture all major sources of uncertainty. However, as a scientific peer review body, the STAR panel should avoid matters of policy. Assessment results from model runs that are technically flawed or questionable on other grounds should be identified by the panel and excluded from the alternatives upon which management advice is to be developed.

During the review meeting, the STAR panel and the STAT should strive to reach a consensus on a single base model. Once a base model is agreed upon, it is essential that uncertainty around the base model be captured and communicated to managers. One way to accomplish this objective is to bracket the base model with what is agreed to be the major axis of uncertainty (e.g., spawner-recruit steepness, the virgin level of recruitment, the natural mortality rate, survey catchability, etc.; and, less often, recent year-class strength, weights on conflicting CPUE series, etc.). Alternative models should show contrast in their management implications, which, in practical terms, means that that they should result in different estimates of current stock size and status, and the OFL. Markov chain Monte Carlo (MCMC) integration, where possible, is an acceptable method for reporting uncertainty about the base model. However, point estimates from the Maximum Likelihood Estimation (MLE) method should be used for status determinations even when MCMC outputs are available.

Once alternative models, which capture the overall degree of uncertainty in the assessment, are formulated, a 2-way decision table (alternative models versus management actions) should be developed to illustrate the repercussions of uncertainty to managers. The ratio of probabilities of alternative models should be 25:50:25, with the base model being twice as likely as the low and high stock size alternatives. Potential methods for assigning probabilities to alternative models include using the statistical variance of the model estimates of stock size, posterior Monte Carlo simulation, or expert judgment, but other approaches are acceptable as long as they are fully documented. An ideal bracketing of the base model is one for which the geometric mean of the high and low stock size alternative model final biomass levels approximates the base model biomass level. This is because the distribution of possible stock sizes is necessarily bounded at the low end, while the right tail can extend much further from the point estimate, and thus the probability density should look more log-normal than normal. If the bracketing models are far from this ideal (e.g., if the base model is closer to the upper bracketing model in absolute terms than to the lower bracketing model), the three levels should be reconsidered and either one or more of them adjusted (such that, in certain cases, if there is a great deal of confidence in the bracketing models, the base model could be reconsidered), or a justification for the severely non-lognormal structure of alternatives be given. Similarly, if more than one dimension is used to characterize uncertainty, resulting in, for example, a 3-by-3 decision table, careful consideration of how the complete table brackets the uncertainty should be undertaken.

Areas of Disagreement

STATs and STAR panels are required to make an honest attempt to resolve any areas of disagreement during the meeting. Occasionally, fundamental differences of opinions may remain between the STAR panel and STAT that cannot be resolved during the STAR panel meeting. In such cases, the STAR panel must document the areas of disagreement in its report. While identifying areas of disagreement, the following questions should be discussed at the meeting:

1) Are there any differences in opinion about the use or exclusion of data?
2) Are there any differences in opinion about the choice of the base model?
3) Are there any differences in opinion about the characterization of uncertainty?

The STAT may choose to submit a supplemental report supporting its view, but in that case, an opportunity must be given to the STAR panel to prepare a rebuttal. These documents would then be appended to the STAR panel report as part of the record of the review meeting. In some cases STAR panel members may have fundamental disagreements among themselves that cannot be resolved during the review meeting. In such cases, STAR panel members may prepare a minority report that would also become part of the record of the review meeting. The SSC would then review all information pertaining to STAR panel and STAR panel/STAT disputes, and issue its recommendation.

STAR Panel Report

The STAR panel report should be developed and approved by the full panel shortly after the STAR panel meeting. The STAR panel chair appoints members of the panel to act as rapporteurs and draft the report (or specific sections thereof) according to the STAR panel chair guidance on format and level of detail. The STAR panel chair is responsible for preparing the final draft of the panel report, obtaining panel approval, providing a copy for STAT review and comment, and submitting it to the Council in a timely fashion (i.e., by briefing book deadline).

The STAR panel report should include:

- Summary of the STAR Panel meeting:
    - Names and affiliations of STAR panel members, STAT and STAR panel advisors;
    - Brief overview of the meeting (where the meeting took place, what species was assessed, what was the STAR panel recommendation, etc.);
    - Brief summary of the assessment model and the data used;
    - List of analyses requested by the STAR panel, the rationale for each request, and a brief summary of the STAT response to the request;

- Description of the base model and, for groundfish species, the alternative models used to bracket uncertainty;
- Comments on the technical merits and/or deficiencies in the assessment and recommendations for remedies;
- Areas of disagreement regarding STAR panel recommendations:
    - Between the STAR panel and STAT(s).
    - Among STAR panel members (including concerns raised by MT and AP representatives);
- Unresolved problems and major uncertainties, e.g., any special issues that complicate the assessment and/or interpretation of results;
- Management, data, or fishery issues raised by the MT or AP representatives during the STAR panel; and
- Prioritized recommendations for future research and data collection, including methodology and ecosystem considerations for the subsequent assessment.

For groundfish species, the STAR panel also makes a recommendation on whether the next assessment of the same species should be full or update, and explain reasons for its recommendation.

The STAR panel report should be made available for review by the STAT with adequate time prior to the briefing book deadline (i.e., a week in most circumstances, but at minimum a full 24 hours, in cases when the time between the STAR panel and the deadline is particularly compressed) so that the STAT can comment on issues of fact or differences in interpretation. If differences of opinion come up during review of the STAR panel report, the STAR panel and STAT should attempt to resolve them. Otherwise, the areas of disagreement must be documented in the STAR panel report.

The chair will also solicit comment on the draft report from the MT and AP representatives. The purpose of this is limited to ensuring that the report is technically accurate and reflects the discussion that occurred at meeting, and should not be viewed as an opportunity to reopen debate on issues. The STAR panel chair is the final arbiter on wording changes suggested by STAT and the MT and AP representatives as the report is the panel's report of the meeting. Any detailed commentary by MT and AP representatives should be drafted separately, reviewed by the full advisory body, and included in the briefing book.

The STAR panel chair is responsible for providing the Council staff with the final version of the STAR panel report. The STAR panel chair is also expected to attend the SSC meeting and, if requested, MT meetings and the relevant portions of the Council meetings, where stock assessments and harvest projections are discussed, explain the reviews, and provide technical information and advice. The final STAR panel reports ~~is~~are posted on the Council's website at http://www.pcouncil.org/groundfish/stock-assessments/ and http://www.pcouncil.org/coastal-pelagic-species/stock-assessment-and-fishery-evaluation-safe-documents/. [COMMENT: The CPS STAR panel reports are not posted here as of now; they are posted in the respective briefing books. Can they be posted here for parity and to make them easy to find?]

4.3. Stock Assessment Team Responsibilities

The STAT is responsible for conducting a complete and technically sound stock assessment that conforms to accepted standards of quality, and in accordance with these TOR. The STAT is responsible for preparing three versions of the stock assessment document:

1) a "draft" for discussion during the STAR panel meeting;
~~2)~~ a "revised draft" for presentation to the SSC, the Council, and relevant MT and AP;
2) and
3) a "final version" to be published in the Council's SAFE document or posted on the Council's web site.

The draft assessment document should follow the outline in Appendix B with an executive summary as in the template in Appendix C. In the draft document, the STAT should identify a candidate base model, fully-developed and well-documented, for the STAR panel to review. For CPS, the STAT should submit a draft assessment document to the STAR panel chair and Council staff two weeks prior to the STAR panel meeting. For groundfish, a draft assessment document should be submitted by the STAT to the STAR panel chair, Council staff, and the NMFS Stock Assessment Coordinator (SAC) three full weeks prior to the STAR panel meeting, to determine whether the document is sufficiently complete to undergo review. If the draft assessment is judged complete, the draft assessment and supporting materials would be distributed to the STAR panel and relevant MT and AP representatives two weeks prior to the STAR panel meeting. If the assessment document does not meet minimum criteria of the TOR, the review would be postponed to a subsequent assessment cycle or to the mop-up panel. The mop-up panel generally is not able to review more than two assessments. Therefore, the review options are limited for assessments not completed on time. The STAT is also responsible for bringing model files and data (in digital format) to the STAR panel meeting so that they can be analyzed on site.

In most cases, the STAT should produce a revised draft of the assessment document within three weeks of the end of the STAR panel meeting. The revised draft must include a point-by-point response of the STAT to each of the STAR panel's recommendations. The revised draft must be finalized before the briefing book deadline for the Council meeting at which the assessment is scheduled for review. Post-STAR drafts must be reviewed and approved by the STAR panel chair prior to being submitted to Council staff. This review is limited to editorial issues, verifying that all required elements are included, and confirming that the document reflects the discussion and decisions made during the STAR panel.

The final version of the assessment document is produced after the assessment has been reviewed by the SSC. Other than changes recommended by the SSC, only editorial and other minor alterations should be made to the revised draft for the final version. Electronic versions of the final assessment document, model files, and key output files should be submitted by the STATs to Council staff (for CPS) and to Council staff and the SAC (for groundfish) for inclusion in a stock assessment archive. Any tabular data that are inserted into the final documents in an object format should also be submitted in alternative forms (e.g., spreadsheets), which allow selection of individual data elements.

A STAT for which no base model was endorsed by a STAR panel should, in most cases, provide the pre-STAR draft assessment (or corrected/ updated version thereof, as agreed upon with the STAR panel) to the Council by the briefing book deadline. If the STAR panel, nonetheless, recommends using outputs of certain sensitivity runs to bracket uncertainty in the assessment, the results of those runs should be appended to the draft assessment and provided to the Council and its advisory bodies.

STATs are strongly encouraged to develop assessments in a collaborative environment by forming working groups, holding pre-assessment workshops, and consulting with other stock assessment and ecosystem assessment scientists. STAT meetings with Integrated Ecosystem Assessment (IEA) teams are strongly encouraged to evaluate alternative models and analyses that incorporate ecosystem considerations and cross-FMP interactions that may affect stock dynamics. When new data sources or methods, which could be used in many assessments or are likely contentious, are planned for inclusion in the assessment, they should ideally be reviewed by a methodology panel. STATs should identify whether such new data sources or methods will be proposed for inclusion in assessments as early as feasible so that it is possible to hold a methodology review panel if one is needed. Irrespective of whether a methodology review panel takes place, the STAR panel should be provided with model runs with and without the new data sources so that it can evaluate the sensitivity of model outputs to these data sources.

STATs should coordinate early in the process with state representatives and other data stewards to ensure timely availability of data. STATs are also encouraged to organize independent meetings with industry and interested parties to discuss data and issues. The STAT should initiate contact with the AP representative early in the assessment process, keep the AP informed of the data being used and respond to any concerns that are raised. The STAT should also contact the MT representative for information about changes in fishing regulations that may influence model structure and the way data are used in the assessment. The STAT should be well represented at the STAR panel meeting to ensure timely completion of the STAR panel requests. Barring exceptional circumstances, STAT members who are not attending the STAR panel meeting, should be available remotely to assist with responses when needed. Each STAT conducting a full assessment should appoint a representative to attend the Council meeting where the assessment is scheduled to be reviewed and give presentations of the assessment to the SSC and other Council advisory bodies. In addition, the STAT should be prepared to respond to MT requests for model projections for the MT's to develop ACL alternatives.

For stocks that are estimated to be below overfished thresholds (or those previously declared overfished and not yet rebuilt), the STAT must complete a rebuilding analysis according to the SSC's TOR for Rebuilding Analyses and prepare a document that summarizes the analysis results. For groundfish, it is recommended that this rebuilding analysis be conducted using the software developed by Dr. André Punt (University of Washington). Groundfish rebuilding analyses are reviewed at the mop-up panel.

4.4. National Marine Fisheries Service Responsibilities

The NMFS Northwest Fisheries Science Center (NWFSC) and the Southwest Fisheries Science Center (SWFSC) assist in organizing stock assessment reviews of groundfish and CPS, respectively. For groundfish, the NMFS provides a stock assessment coordinator (SAC) to facilitate and assist in overseeing the STAR process.

The NMFS (through the SAC for groundfish and a designated SWFSC staff member for CPS) works with the STATs and other STAR process participants to develop a proposed list of stocks to be assessed for the consideration by the Council. NMFS also develops a draft STAR panel schedule for the Council review. NMFS identifies STAR panel members based on criteria for reviewer qualifications, and, for groundfish, makes every effort to designate one independent reviewer who can attend all STAR panel meetings to provide consistency among reviews. The costs associated with these reviewers are borne by the NMFS. The NMFS also helps organize STAR panel meetings and develops meeting schedules.

The NMFS (along with the Council staff and the STAR panel chair) coordinates with the STATs to facilitate delivery of required materials by scheduled deadlines and in compliance with the TOR. The NMFS also assists Council staff and the STAR panel chair in a pre-review of assessment documents, to assure they are received on time and complete, and in a post-STAR review of the revised assessment document for consistency with the TOR.

4.5. Council Staff Responsibilities

The role of Council staff is to coordinate, monitor, and document the STAR process to ensure compliance with these TOR.

Council staff coordinates with the STAR panel chair and the NMFS (the SAC in the case of groundfish; a designated SWFSC staff member for CPS) in a pre-review of assessment documents, to assure they are complete and received on time. If an assessment document is not in compliance with the TOR, Council staff returns the assessment document to the STAT with a list of deficiencies, a notice that the deadline has expired, or both. Council staff also coordinates with the STAR panel chair, STAT, and the NMFS in a post-STAR review of the revised assessment document for consistency with the TOR. When inconsistencies are identified, the STAT is requested to make appropriate revisions in time for briefing book deadlines.

Council staff attends and monitors all STAR panel meetings to ensure continuity and adherence to the TOR and the independent review requirements of Council Operating Procedure 4. If inconsistencies with the TOR occur during STAR panel meetings, Council staff coordinates with the STAR panel chair to develop solutions to correct the inconsistencies. Council staff also attends and monitors the SSC review of stock assessments to ensure compliance with the TOR.

Council staff is responsible for timely issuance of meeting notices and distribution of stock assessments and other appropriate documents to relevant groups. Council staff also collects and maintains electronic copies of assessment documents, STAR panel, SSC, MT and AP reports, as well as letters from the public and any other relevant documents. These documents are typically published in the Council's SAFE document or posted on the Council's web site.

4.6. Management Team Responsibilities

The MT is responsible for identifying and evaluating potential management actions based on the best available scientific information. Particularly, the MT uses stock assessment results and other information to make ACL and ACT recommendations to the Council.

A MT representative, usually appointed by the MT chair, is responsible to attend the STAR panel meeting and serve as advisor to the STAT and STAR panel on changes in fishing regulations that may influence data used in the assessment and the nature of the fishery in the future. The MT representative does not serve as a member of the STAR panel.

Successful separation of science (e.g., STAT and STAR panels) from management (e.g., MT) depends on assessment reviews being completed by the time the MT meets to discuss preliminary ACL and ACT recommendations. The MT should not seek revision or additional review of the stock assessments after they have been endorsed by the STAR panel. The MT chair should communicate any unresolved issues to the SSC for consideration. The MT, however, can request additional model projections from the STAT, to fully evaluate potential management actions.

4.7. Advisory Panel Responsibilities

An AP representative, usually appointed by the AP chair, is responsible to attend the STAR panel meeting and serve as advisor to the STAT and STAR panel. The AP representative should review the data sources being used in the assessment prior to development of the stock assessment model and insure that industry concerns regarding the adequacy of data used by the STAT are communicated and addressed early in the assessment process. The AP representative does not serve as a member of the STAR panel, but, as a legitimate meeting participant, may provide appropriate information and advice to the STAT and STAR panel during the meeting.

The AP representative (along with STAT and STAR panel chair, if requested) is expected to attend the MT meeting at which preliminary ACL and ACT recommendations are developed. The AP representative is also expected to attend subsequent MT and Council meetings where the relevant harvest recommendations are discussed.

4.8. Scientific and Statistical Committee Responsibilities

The Council's SSC plays multiple roles within the STAR process and provides the Council and its advisory bodies with technical advice related to the stock assessments and the STAR process. The SSC assigns a member of its relevant subcommittee (Groundfish or CPS) to act as the STAR panel chair. The STAR panel chair attends the assigned STAR panel meeting and fulfills responsibilities described in the section "STAR Panel Responsibilities".

The STAR panel chair presents the STAR panel report at the SSC and Council meetings at which stock assessments are reviewed. If requested, the STAR panel chair also attends the MT meeting, at which preliminary ACL and ACT recommendations are developed, to discuss the STAR panel report and assist with interpreting the assessment results.

The full SSC conducts a final review of the stock assessment. This review should not repeat the detailed technical review conducted by the STAR panel. The SSC also reviews the STAR panel recommendations and serves as arbitrator to resolve disagreements between the STAT and the STAR panel if such disagreements occurred during the review meeting. The SSC is responsible for reviewing and endorsing any additional analytical work requested from the STAT by the MT after the stock assessment has been reviewed by the STAR panel. To insure independence in the SSC review, the SSC members who served on the STAT or STAR panel for the stock assessment being reviewed are required to recuse themselves; their involvement in the review being limited to providing factual information and answering questions.

The SSC is responsible for making OFL recommendations to the Council. The SSC is also responsible for assigning groundfish species managed by the Council to a specific category (or tier) based on definitions of species categories in Appendix E. It is also the SSC's responsibility to determine when it is appropriate to make changes to proxies or the use of estimated values of F_{MSY} and B_{MSY}.

5. DATA-MODERATE ASSESSMENTS FOR GROUNDFISH SPECIES

Data-moderate assessments for groundfish species are a refinement over the adopted data-poor methods (i.e., Depletion-Corrected Average Catch (DCAC) and Depletion-Based Stock Reduction Analysis (DB-SRA)) that use catch data to inform harvest specifications for category

3 stocks. Data-moderate assessments are used for category 2 stocks; the defining distinction between category 2 and category 3 stocks is that abundance trend information is incorporated in a category 2 assessment (Appendix E).

Two data-moderate assessment methods have been endorsed for the 2013-14 assessment cycle: 1) extended DB-SRA (XDB-SRA) and 2) extended Simple Stock Synthesis (exSSS). In both cases, abundance trend information (e.g., survey or fishery CPUE indices) is included in the assessment.

ExSSS assumes that recruitment is related deterministically to the stock-recruitment relationship and allows index data to be used for maximum likelihood status and parameter estimation. The Markov chain Monte Carlo (MCMC) or Sample Importance Resample (SIR) algorithm (perhaps implemented using Adaptive Importance Sampling) can be used to quantify uncertainty for exSSS-based assessments. XDB-SRA can be implemented within a Bayesian framework, with the priors for the parameters updated based on index data. The additional parameters in XDB-SRA compared with DB-SRA include the catchability coefficient (q), and the extent of observation variance additional to that inferred from sampling error (a). The priors for these parameters are a weakly informative log-normal and a uniform distribution, respectively.

While data-moderate assessments are less complicated than full assessments, and can potentially be reviewed more expeditiously than full assessments, a full STAR panel is scheduled in 2013 to review data-moderate assessments for the first time (see Appendix A). Comparison of alternative methods (XDB-SRA and exSSS) is encouraged, but it is acceptable to present an assessment using a single modeling approach. The STAR panel can make requests of the STATs for additional runs, but should not impose an alternative method if STATs consider this is not appropriate for the stock concerned. In the event that more than one model is presented, the panel should recommend adoption of a preferred model, if one can be identified, for use in management.

Data-moderate stock assessment reports should follow the template in Appendix D.

6. UPDATE ASSESSMENTS

For CPS, update assessments typically occur during two years out of every three. For groundfish, the initial recommendation whether the next assessment should be full or update is made by the STAR panel during the STAR panel meeting. The final recommendation is made by the SSC.

An update assessment is generally restricted to the addition of new data that have become available since the last full assessment. It must carry forward the fundamental structure of the last full assessment reviewed and endorsed by a STAR panel, the SSC, and the Council. Assessment structure here refers to the population dynamics model, data sources used as inputs to the model, the statistical platform used to fit model to the data, and how the management quantities used to set harvest specifications are calculated. Particularly, when an update assessment is developed, no substantial changes should be made to:

1) the particular sources of data used;
2) the software used in programming the assessment;
3) the assumptions and structure of the population dynamics model underlying the stock assessment;
4) the statistical framework for fitting the model to the data and determining goodness of fit; and
5) the analytical treatment of model outputs in determining management reference points.

Major changes to the assessment should be postponed until the next full assessment. Minor alternations to the input data and the assessment can be considered as long as the update assessment clearly documents and justifies the need for such changes. A step-by-step transition (via sensitivity analysis) from the last full assessment to an update assessment under review should be provided. Minor alterations can be considered under only two circumstances: first, when the addition of new data reveals an unanticipated sensitivity of model, and second, when there are clear and straightforward improvements in the input data and how it is processed and analyzed for use in the model. Examples of minor alterations include: 1) changes in how compositional data are pooled across sampling strata; 2) the weighting of the various data components (including the use of methods for tuning the variances of the data components); 3) changes in the time periods for the selectivity blocks; 4) correcting data entry errors; and 5) bug fixes in software programming. This list is not meant to be exhaustive, and other alterations can be considered if warranted. Ideally, improved data or methods used to process and analyze data would be reviewed by the SSC prior to being used in assessments.

Review of Update Assessments

Update assessments are reviewed by members of the relevant SSC subcommittee (Groundfish or CPS), during a single meeting. Review typically requires one or two days with an option of early dismissal of a STAT. The STAT is responsible for producing the update assessment document and submitting it to Council staff in a timely manner, before the relevant SSC subcommittee reviews the assessment. The document should follow the outline in Appendix B. The STAT, however, can reference the last full assessment (or other relevant documentation) for description of methods, data sources, stock structure, etc., given that they have not been changed. Any new information to the assessment must be presented in sufficient detail for the subcommittee to determine whether the update meets the Council's requirement to use the best available scientific information.

The document must include a retrospective analysis illustrating the model performance with and without the most recent data (new to the update assessment) and discuss whether the new data and update assessment results are sufficiently consistent with those from the last full assessment. The assessment document should include a detailed step-by-step transition from the last full assessment to the update under review. The updated decision table, if there is one, should be of the same format as in the last full assessment; it should highlight differences among alternative models defined using the same axes of uncertainty as those in the last full assessment.

In addition to the update assessment document, Council staff will also provide the subcommittee with a copy of the last full stock assessment reviewed via the STAR process and the associated STAR panel report. The chair of the subcommittee designates a lead reviewer from the subcommittee members for each update assessment to document the meeting discussion, produce a review report, and ensure that each review is conducted according to the TOR. MT and the AP representatives also participate in the review.

The review of update assessments is not expected to require additional model runs or extensive analytical requests during the meeting, although changes in assessment outputs may necessitate some model exploration. The review focuses on two main questions:

1) Does the assessment meet the criteria of a stock assessment update?
2) Can the results of the update assessment form the basis of Council decision making?

If the answer to either of these questions is negative, a full stock assessment for the species would typically be recommended for the next assessment cycle (for groundfish) or the next year (for CPS). For groundfish, if the subcommittee agrees that the update assessment results require additional, but limited exploration before being endorsed for management use, further review at the mop-up meeting, at the end of the assessment cycle, could be recommended. In cases like this, the subcommittee needs to develop a list of requests for the STAT to address before the mop-up meeting.

Shortly after the meeting, the subcommittee issues a review report that includes: 1) comments on the technical merits and/or deficiencies of the update assessment; 2) explanation of areas of disagreement between the subcommittee and STAT (if any); and 3) recommendations on the adequacy of the update assessment for use in management. The report may also include subcommittee recommendations for modifications that should be made when the next full assessment is conducted.

The report is reviewed by the full SSC at the next Council meeting. If the subcommittee review concludes that it is not possible to use the update assessment, the SSC is responsible for evaluating all model runs examined during the review meeting and providing recommendations on an appropriate fishing level to the Council.

7. CATCH REPORTS

In certain cases (e.g., cowcod in 2011) only limited new data are available to inform the assessment. In such cases, it is appropriate for the STAT to provide a catch report, which documents recent removals and compares them to the ACLs established for the stock. For a catch report, the STAT does not need to conduct model runs since, if the estimated removals of a species are near the value projected by the previous assessment/rebuilding analysis, no new insight would be obtained by rerunning the assessment model.

Catch reports are reviewed by the relevant SSC subcommittee (Groundfish or CPS) during a single meeting (that during which update assessments are reviewed). The STAT is responsible for producing the catch report and submitting it to Council staff in a timely manner, before the relevant subcommittee reviews it. The report should be brief, but provide enough details on how total removals were estimated. It should provide only essential information about the stock and refer to the last assessment (or other relevant documentation) for full description of methods, data sources, model structure, etc. used to estimate the status of the stock and generate projections.

In common with a review of an assessment update, Council staff will provide the subcommittee with the catch report, along with a copy of the last full stock assessment reviewed via the STAR process, and the associated STAR panel report. The chair of the subcommittee will designate a lead reviewer from the subcommittee members for each catch report to document the meeting discussion, produce a review report, and ensure that each review is conducted according to the TOR. The report is reviewed by the full SSC at the next Council meeting. The MT and AP representatives also participate in the review.

APPENDIX A: ~~2013~~ 2015 GROUNDFISH AND CPS STOCK ASSESSMENT REVIEW CALENDAR

Review Meeting	Initial Review Deadline	Document Distribution Dates	STAR Panel Dates	Location	Species
~~Data-Moderate Panel~~TBD	~~April 8~~	~~April 15~~	~~April 22-26~~	~~Santa Cruz, CA~~	~~Brown rockfish, China rockfish, copper rockfish, English sole, rex sole, sharpchin rockfish, stripetail rockfish, vermilion rockfish, and yellowtail rockfish~~
~~GF Panel 1~~	~~April 22~~	~~April 29~~	~~May 13-17~~	~~Seattle, WA~~	~~Petrale sole and darkblotched rockfish~~
~~GF Update and catch reports~~	~~May 22~~	~~May 29~~	~~June 18~~	~~Garden Grove, CA~~	~~Bocaccio rockfish update; canary rockfish, Pacific ocean perch, and yelloweye rockfish catch reports~~
~~GF Panel 2~~	~~June 17~~	~~June 24~~	~~July 8-12~~	~~Seattle, WA~~	~~Rougheye rockfish and aurora rockfish~~
~~GF Panel 3~~	~~July 1~~	~~July 8~~	~~July 22-25~~	~~Seattle, WA~~	~~Shortspine thornyheads and longspine thornyheads~~
~~GF Panel 4~~	~~July 15~~	~~July 22~~	~~August 5-9~~	~~Santa Cruz, CA~~	~~Cowcod and Pacific sanddabs~~

APPENDIX B: OUTLINE FOR STOCK ASSESSMENT DOCUMENTS

This is a general outline of elements that should be included in stock assessment reports for groundfish and CPS managed by the Pacific Fishery Management Council. Not every item listed in the outline is relevant (or available) for every assessment. Therefore, this outline should be considered a flexible guideline on how to organize and communicate stock assessment results. Items with asterisks (*****) are optional for draft assessment documents prepared for STAR panel meetings but should be included in the final document.

A. Title page and list of preparers **–** the names and affiliations of the stock assessment team (STAT) either alphabetically or as first and secondary authors.

B. Executive Summary (should follow the template in Appendix B).

C. Introduction
   1. Scientific name, distribution, the basis for the choice of stock structure, including regional differences in life history or other biological characteristics that should form the basis of management units.
   2. A map showing the scope of the assessment and depicting boundaries for fisheries or data collection strata.
   3. Important features of life history that affect management (e.g., migration, sexual dimorphism, bathymetric demography).
   4. Ecosystem considerations (e.g., ecosystem role and trophic relationships of the species, habitat requirements/preferences, relevant data on ecosystem processes that may affect stock or parameters used in the stock assessment, and/or cross-FMP interactions with other fisheries). This section should note if environmental correlations or food web interactions were incorporated into the assessment model. The length and depth of this section would depend on availability of data and reports from the IEA, expertise of the STAT, and whether ecosystem factors are informational to contribute quantitative information to the assessment.
   5. Important features of current fishery and relevant history of fishery.
   6. Summary of management history (e.g., changes in mesh sizes, trip limits, or other management actions that may have significantly altered selection, catch rates, or discards).
   7. Management performance, including a table or tables comparing Overfishing Limit (OFL), Annual Catch Limit (ACL), Harvest Guideline (HG) [CPS only], landings, and catch (i.e., landings plus discard) for each area and year
   8. Description of fisheries for this species off Canada, Alaska and/or Mexico, including references to any recent assessments of those stocks.

D. Assessment
   1. Data
      a. Landings by year and fishery (PacFIN is the standard source for all commercial landings), historical catch estimates, discards (generally specified as a percentage of total catch in weight and in units of mt), catch-at-age, weight-at-age, abundance indices (typically survey and CPUE data), data used to estimate biological parameters (e.g., growth rates, maturity schedules, and natural mortality) with coefficients of variation (CVs) or variances if available. Include complete tables and figures and date of extraction.

   b. Sample size information for length and age composition data by area, year, gear, market category, etc., including both the number of trips and fish sampled.
   c. All data sources that include the species being assessed, which are used in the assessment, and provide the rationale for data sources that are excluded.
   d. Clear description of environmental or ecosystem data if included in the assessment.
2. History of modeling approaches used for this stock – changes between current and previous assessment models
   a. Response to STAR panel recommendations from the most recent previous assessment.
   b. Report of consultations with AP and MT representatives regarding the use of various data sources in the stock assessment.
   c. If environmental or ecosystem data are incorporated, report of consultations with technical teams that evaluated ecosystem data or methodologies used in the assessment.
3. Model description
   a. Complete description of any new modeling approaches.
   b. Definitions of fleets and areas.
   c. Assessment program with last revision date (i.e., date executable program file was compiled).
   d. List and description of all likelihood components in the model.
   e. Constraints on parameters, selectivity assumptions, natural mortality, treatment of age reading bias and/or imprecision, and other fixed parameters.
   f. Description of stock-recruitment constraints or components.
   g. Description of how the first year that is included in the model was selected and how the population state at the time is defined (e.g., B_0, stable age structure, etc.).
   h. Critical assumptions and consequences of assumption failures.
4. Model selection and evaluation
   a. Evidence of search for balance between model realism and parsimony.
   b. Comparison of key model assumptions, include comparisons based on nested models (e.g., asymptotic vs. domed selectivities, constant vs. time-varying selectivities).
   c. Summary of alternate model configurations that were tried but rejected.
   d. Likelihood profile for the base-run (or proposed base-run model for a draft assessment undergoing review) configuration over one or more key parameters (e.g., M, h, Q) to show consistency among input data sources.
   e. Residual analysis for the base-run configuration (or proposed base-run model in a draft assessment undergoing review) e.g., residual plots, time series plots of observed and predicted values, or other approaches. Note that model diagnostics *are* required in draft assessments undergoing review.
   f. Convergence status and convergence criteria for the base-run model (or proposed base-run).
   g. Randomization run results or other evidence of search for global best estimates.
   h. Evaluation of model parameters. Do they make sense? Are they credible?
   i. Are model results consistent with assessments of the same species in Canada and Alaska? Are parameter estimates (e.g., survey catchability) consistent with estimates for related stocks?
5. Point-by-point response to the STAR panel recommendations**.* Not required in draft assessment undergoing review**.

6. Base-model(s) results
    a. Table listing all explicit parameters in the stock assessment model used for base model, their purpose (e.g., recruitment parameter, selectivity parameter) and whether or not the parameter was actually estimated in the stock assessment model.
    b. Population numbers at age × year × sex (if sex-specific *M*, growth, or selectivity) (May be provided as a text or spreadsheet file).* **Not required in draft assessment undergoing review**.
    c. Time-series of total, 1+ (if age 1s are in the model), summary, and spawning biomass (and/or spawning output), depletion relative to B_0, recruitment and fishing mortality or exploitation rate estimates (table and figures).
    d. Selectivity estimates (if not included elsewhere).
    e. Stock-recruitment relationship.
    f. OFL, ABC and ACL (and/or ABC and OY or HG) for recent years.
    g. Clear description of units for all outputs.
    h. Clear description of how discard is included in yield estimates.
    i. Clear description of environmental or ecosystem data if included in the assessment.
7. Uncertainty and sensitivity analyses. The best approach for describing uncertainty and the range of probable biomass estimates in groundfish assessments may depend on the situation. Important factors to consider include:
    a. Parameter uncertainty (variance estimation conditioned on a given model, estimation framework, data set choice, and weighting scheme), including likelihood profiles for important assessment parameters (e.g., natural mortality). This also includes expressing uncertainty in derived outputs of the model and estimating CVs using appropriate methods (e.g., bootstrap, asymptotic methods, Bayesian approaches, such as MCMC). Include the CV of spawning biomass in the first year for which an OFL has not been specified (typically end year +1 or +2).
    b. Sensitivity to data set choice and weighting schemes (e.g., emphasis factors), which may also include a consideration of recent patterns in recruitment.
    c. Sensitivity to assumptions about model structure, i.e., model specification uncertainty.
    d. Retrospective analysis, where the model is fitted to a series of shortened input data sets, with the most recent years of input data being dropped.
    e. Historical analysis (plot of actual estimates from current and previous assessments).
    f. Subjective appraisal of the magnitude and sources of uncertainty.
    g. If a range of model runs is used to characterize uncertainty it is important to provide some qualitative or quantitative information about relative probability of each. If no statements about relative probability can be made, then it is important to state that all scenarios (or all scenarios between the bounds depicted by the runs) are equally likely
    h. If possible, ranges depicting uncertainty should include at least three runs: (a) one judged most probable; (b) at least one that depicts the range of uncertainty in the direction of lower current biomass levels; and (c) one that depicts the range of uncertainty in the direction of higher current biomass levels. The entire range of uncertainty should be carried through stock projections and decision table analyses.

E. Harvest control rules (CPS only)

The OFL, ABC and HG harvest control rules for actively managed species apply to the U.S. (California, Oregon, and Washington) harvest recommended for the next fishing year and are defined as follows:

- OFL = BIOMASS * F_{MSY} * U.S. DISTRIBUTION
- ABC = BIOMASS * BUFFER * F_{MSY} * U.S. DISTRIBUTION
- ACL LESS THAN OR EQUAL TO ABC
- HG = (BIOMASS-CUTOFF)* FRACTION * U.S. DISTRIBUTION
- ACT EQUAL TO HG OR ACL, WHICHEVER VALUE IS LESS

where FMSY is the fishing mortality rate that maximizes catch biomass in the long-term.

Implementation for Pacific Sardine

1. BIOMASS is the estimated stock biomass (ages 1+) at the start of the next year from the current assessment,
2. CUTOFF (150,000 mt) is the lowest level of estimated biomass at which harvest is allowed,
3. FRACTION is an environment-based percentage of biomass above the CUTOFF that can be harvested by the fisheries. Given that the productivity of the sardine stock has been shown to increase during relatively warm-water ocean conditions, the following formula has been used to determine an appropriate (sustainable) FRACTION value:

   FRACTION = $0.248649805(T_2) - 8.190043975(T) + 67.4558326$,

   where T is the running average sea-surface temperature at Scripps Pier, La Jolla, California during the three preceding years. Under the harvest control rule, FRACTION is constrained and ranges between 5% and 15% depending on the value of T.
4. U.S. DISTRIBUTION is the percentage of BIOMASS in U.S. waters (87%).

Implementation for Pacific Mackerel

1. BIOMASS is the estimated stock biomass (ages 1+) at the start of the next year from the current assessment,
2. CUTOFF (18,200 mt) is the lowest level of estimated biomass at which harvest is allowed,
3. FRACTION (30%) is the fraction of biomass above CUTOFF that can be taken by fisheries, and
4. U.S. DISTRIBUTION (70%) is the average fraction of total BIOMASS in U.S. waters.

The CUTOFF and FRACTION values applied in the Council's harvest policy for mackerel are based on simulations published by MacCall et al. in 1985.

F. Reference points (groundfish only)

1. Unfished spawning stock biomass, summary age biomass, and recruitment, along with unfished spawning stock output.
2. Reference points based on $B_{40\%}$ for rockfish and roundfish and on $B_{25\%}$ for flatfish (spawning biomass and/or output, SPR, exploitation rate, equilibrium yield).
3. Reference points based on default SPR proxy (spawning biomass and/or output, SPR, exploitation rate, equilibrium yield).

4. Reference points based on MSY (if estimated) (spawning biomass and/or output, SPR, exploitation rate, equilibrium yield).
5. Equilibrium yield curve showing various B_{MSY} proxies.

G. Harvest projections and decision tables (groundfish only) *** Not required in draft assessment undergoing review**.
    1. Harvest projections and decision tables (i.e., a matrix of alternative models (states of nature) versus management actions) should cover the plausible range of uncertainty about current stock biomass and a set of candidate fishing mortality targets used for the stock. See section *"Uncertainty and Decision Tables in Groundfish Stock Assessment"* (this document, pp.12-13) on how to define alternative states of nature. Management decisions in most cases represent the sequence of catches including estimate of OFL based on F_{MSY} (or its proxy) and those obtained by applying the Council 40-10 harvest policy to each state of nature; however other alternatives may be suggested by the GMT as being more relevant to Council decision making. OFL calculations should be based on the assumption that future catches equal ABCs and not OFLs.
    2. Information presented should include biomass, stock depletion, and yield projections of OFL, ABC and ACL for ten years into the future, beginning with the first year for which management action could be based upon the assessment.

H. Regional management considerations.
    1. For stocks where current practice is to allocate harvests by management area, a recommended method of allocating harvests based on the distribution of biomass should be provided. The MT advisor should be consulted on the appropriate management areas for each stock.
    2. Discuss whether a regional management approach makes sense for the species from a biological perspective.
    3. If there are insufficient data to analyze a regional management approach, what are the research and data needs to answer this question?

I. Research needs (prioritized).

J. Acknowledgments: include STAR panel members and affiliations as well as names and affiliations of persons who contributed data, advice or information but were not part of the assessment team. *** Not required in draft assessment undergoing review.**

K. Literature cited.

L. An appendix with the complete parameter and data in the native code of the stock assessment program. (For a draft assessment undergoing review, these listings can be provided as text files or in spreadsheet format.)

APPENDIX C: TEMPLATE FOR AN EXECUTIVE SUMMARY

Items with asterisks (*****) are optional for draft assessment documents prepared for STAR panel meetings but should be included in the final document.

Stock	Species/area, including an evaluation of any potential biological basis for regional management.
Catches	Trends and current levels - include table for last ten years and graph with long term data.
Data and assessment	Date of last assessment, type of assessment model, data available, new information, and information lacking.
Stock biomass	Trends and current levels relative to virgin or historic levels, description of uncertainty-include table for last 10 years and graph with long term estimates.
Recruitment	Trends and current levels relative to virgin or historic levels-include table for last 10 years and graph with long term estimates
Exploitation status	Exploitation rates (i.e., total catch divided by exploitable biomass, or the annual SPR harvest rate) - include a table with the last 10 years of data and a graph showing the trend in fishing mortality relative to the target (y-axis) plotted against the trend in biomass relative to the target (x-axis).
Ecosystem considerations	A summary of reviewed environmental and ecosystem factors that appear to be correlated with stock dynamics, e.g., variability in the physical environment that directly or indirectly affects the vital rates (growth, survival, productivity/recruitment) of fish stocks, and/or trophic interactions that affect predators and prey. Note what, if any, ecosystem factors are used in the assessment and how.
Reference points (groundfish)/ Harvest control rules (CPS)	Groundfish: Management targets and definition of overfishing, including the harvest rate that brings the stock to equilibrium at $B_{40\%}$ (the B_{MSY} proxy) and the equilibrium stock size that results from fishing at the default harvest rate (the F_{MSY} proxy). Include a summary table that compares estimated reference points for SSB, SPR, Exploitation Rate and Yield based on SSB proxy for MSY, SPR proxy for MSY, and estimated MSY values. CPS: Results of applying the control rule to compute the harvest guideline, including specification of each of the quantities on which the harvest guideline is based (BIOMASS, CUTOFF, FRACTION, U.S. DISTRIBUTION)
Management performance	Catches in comparison to OFL, ABC, [HG], and OY/ACL values for the most recent 10 years (when available), overfishing levels, actual catch and discard. Include OFL (encountered), OFL (retained) and OFL (dead) if different due to discard and discard mortality.
Unresolved problems and major uncertainties	Any special issues that complicate scientific assessment, questions about the best model scenario, etc.
Decision table (groundfish only)*	Projected yields (OFL, ABC and ACL), spawning biomass, and stock depletion levels for each year. OFL calculations should be based on the assumption that future catches equal ABCs and not OFLs.
Research and data needs	Identify information gaps that seriously impede the stock assessment.
Rebuilding Projections*	Reference to the principal results from rebuilding analysis if the stock is overfished. For groundfish, see Rebuilding Analysis terms of reference for detailed information on rebuilding analysis requirements.

APPENDIX D: TEMPLATE FOR A DATA-MODERATE ASSESSMENT

1. Title page and list of preparers – the names and affiliations of the stock assessment team (STAT).
2. Introduction: Scientific name, distribution, basic biology (growth, longevity, ecology), the basis for the choice of stock unit(s)(no more than 1-2 paragraphs).
3. Development of indices (used and rejected). Novel approaches should be fully documented.
4. Survey of other data available for assessment: sample sizes by year and source of lengths, and ages (read and unread)--in case there is interest in conducting a full assessment in the future.
5. Selection of method (exSSS or XDB-SRA; authors “encouraged” to do both).
6. Assessment model
    a. Specification of priors / production function (defaults OK)
    b. Initial runs using catch-only methods (DB-SRA or SSS (or both))
    c. Diagnostics
        i. Evaluation of convergence
        ii. Residual plots
        iii. Posterior predictive intervals (if Bayesian)
        iv. Time-trajectories of biomass, depletion, etc.
        v. Sensitivity analyses using alternative catch streams, alternative priors for depletion, etc.
7. Estimates of OFL (median of the distribution), and
8. Estimates of stock status.

APPENDIX E: DEFINITIONS OF SPECIES CATEGORIES FOR GROUNDFISH ASSESSMENTS

Category 3: **Data poor**. OFL is derived from historical catch.	**a**	No reliable catch history. No basis for establishing OFL.
	b	Reliable catches estimates only for recent years. OFL is average catch during a period when stock is considered to be stable and close to BMSY equilibrium on the basis of expert judgment.
	c	Reliable aggregate catches during period of fishery development and approximate values for natural mortality. Default analytical approach DCAC.
	d	Reliable annual historical catches and approximate values for natural mortality and age at 50% maturity. Default analytical approach DB-SRA.
Category 2: **Data moderate**. OFL is derived from model output (or natural mortality).	**a**	M*survey biomass assessment (as in Rogers 1996).
	b	Historical catches, fishery-dependent trend information only. An aggregate population model is fit to the available information.
	c	Historical catches, survey trend information, or at least one absolute abundance estimate. An aggregate population model is fit to the available information.
	d	Full age-structured assessment, but results are substantially more uncertain than assessments used in the calculation of the P* buffer. The SSC will provide a rationale for each stock placed in this category. Reasons could include that assessment results are very sensitive to model and data assumptions, or that the assessment has not been updated for many years.
Category 1: **Data rich**. OFL is based on F_{MSY} or F_{MSY} proxy from model output. ABC based on P* buffer.	**a**	Reliable compositional (age and/or size) data sufficient to resolve year-class strength and growth characteristics. Only fishery-dependent trend information available. Age/size structured assessment model.
	b	As in 1a, but trend information also available from surveys. Age/size structured assessment model.
	c	Age/size structured assessment model with reliable estimation of the stock-recruit relationship.

GROUNDFISH REBUILDING ANALYSIS FOR ~~2013~~2015-~~2014~~2016

DRAFT

~~SEPTEMBER~~MAY, ~~2012~~2014

Published by the Pacific Fishery Management Council

TABLE OF CONTENTS

1. INTRODUCTION

Amendment 11 to the Groundfish Fishery Management Plan (FMP) established a default overfished threshold equal to 25% of the unexploited female spawning output[1] (B_0), or 50% of B_{MSY}, if known. By definition, groundfish stocks falling below that level were designated to be in an overfished state ($B_{25\%} = 0.25 \times B_0$[2]). To reduce the likelihood that stocks would decline to that point, the policy specified a precautionary threshold equivalent to 40% of B_0. The policy required that the ACL, when expressed as a fraction of the allowable biological catch, be progressively reduced at stock sizes less than $B_{40\%}$. Because of this linkage, $B_{40\%}$ has sometimes been interpreted to be a proxy measure of B_{MSY}, i.e., the female spawning output that results when a stock is fished at F_{MSY}. In fact, theoretical results support the view that a robust biomass-based harvesting strategy for most rockfish (*Sebastes* spp.) would be to maintain stock size at about 40% of the unfished level (Clark 1991, 2002). In the absence of a credible estimate of B_{MSY}, which can be very difficult to estimate (MacCall and Ralston 2002), $B_{40\%}$ is a suitable proxy to use as a rebuilding target for most groundfish.

The recently revised Magnuson-Stevens Fishery Conservation and Management Act (MSA) requires that U.S. fishery management councils avoid overfishing by setting annual catch limits (ACLs). Stock assessments now will provide overfishing level (OFL) estimates, and an acceptable biological catch (ABC) will be derived from the OFL by reducing the OFL to account for scientific uncertainty. The ACL cannot exceed the ABC.
Following the 2008 assessment season, the Pacific Fishery Management Council ("Council") revised the reference points for flatfish, as separate from other groundfish species. The new reference points include an MSY proxy fishing rate of $F_{30\%}$, a target spawning output of $B_{25\%}$ and an overfished threshold of $B_{12.5\%}$. Similarly, the 40:10 policy has been replaced by a 25:5 policy for flatfish.

Under the MSA, rebuilding plans are required for stocks that have been designated to be in an overfished state. Amendment 12 of the Groundfish FMP provided a framework within which rebuilding plans for overfished groundfish resources could be established. Amendment 12 was challenged in Federal District Court and found not to comply with the requirements of the MSA

[1] The absolute abundance of the mature portion of a stock is loosely referred to here in a variety of ways, including: population size, stock biomass, stock size, spawning stock size, spawning biomass, spawning output; i.e., the language used in this document is sometimes imprecise. However, the best fundamental measure of population abundance to use when establishing a relationship with recruitment is spawning output, defined as the total annual output of eggs (or larvae in the case of live-bearing species), accounting for maternal effects (if these are known). Although spawning biomass is often used as a surrogate measure of spawning output, for a variety of reasons a non-linear relationship often exists between these two quantities (Rothschild and Fogarty 1989; Marshall *et al*. 1998). Spawning output should, therefore, be used to measure the size of the mature stock when possible.
[2] Estimates of stock status are typically obtained by fitting statistical models of stock dynamics to survey and fishery data. In recent years, the bulk of stock status determinations have been based on Stock Synthesis 3, an age- and size-structured population dynamics model (Methot 2005, 2007). Stock assessment models can be fitted using Maximum Likelihood or Bayesian methods. For both types of estimation methods, a stock is considered to be in an overfished state if the best point estimate of stock size is less than 25% (rockfish and roundfish) and 12.5% (flatfish) of unfished stock size. This corresponds to the maximum likelihood estimate for estimation methods based on Maximum Likelihood methods, to the maximum of the posterior distribution (MPD) for estimation methods in which penalties are added to the likelihood function, and to the mode of the posterior distribution for Bayesian analyses. The median of the Bayesian posterior is not used for determination of overfished status.

because rebuilding plans did not take the form of an FMP, FMP amendment, or regulation. In response to this finding, the Council developed Amendment 16-1 to the Groundfish FMP which covered three issues, one of which was the form and content of rebuilding plans.

The Council approach to rebuilding depleted groundfish species, as described in rebuilding plans, was re-evaluated and adjusted under Amendment 16-4 in 2006 so they would be consistent with the opinion rendered by the Ninth Circuit Court of Appeals in *Natural Resources Defense Council, Inc. and Oceana, Inc.* v. *National Marine Fisheries Service, et al.,* 421 F.3d 872 (9^{th} Cir. 2005), and with National Standard 1 of the MSA. The court affirmed the MSA mandate that rebuilding periods "be as short as possible, taking into account the status and biology of any overfished stocks of fish, the needs of fishing communities, recommendations by international organizations in which the United States participates, and the interaction of the overfished stock of fish within the marine ecosystem" (Section 304(e)). The court opinion also recognized that some harvest of overfished species could be accommodated under rebuilding plans to avoid severe economic impacts to West Coast fishing communities dependent on groundfish fishing. Under Amendment 16-4 rebuilding plans, more emphasis was placed on shorter rebuilding times and the trade-off between rebuilding periods and associated socioeconomic effects.

Rebuilding Plans include several components, one of which is a rebuilding analysis. Simply put, a rebuilding analysis involves projecting the status of the overfished resource into the future under a variety of alternative harvest strategies to determine the probability of recovery to B_{MSY} (or its proxy) within a pre-specified time-frame.

2. Overview of the Calculations Involved in a Rebuilding Analysis

This document presents guidelines for conducting a basic groundfish rebuilding analysis that meets the minimum requirements that have been established by the Council's Scientific and Statistical Committee (SSC), those of Amendment 16-1 of the Groundfish FMP, and those arising from the 9^{th} Circuit Court decision. It also outlines the appropriate documentation that a rebuilding analysis needs to include. These basic calculations and reporting requirements are essential elements in all rebuilding analyses to provide a standard set of base-case computations, which can then be used to compare and standardize rebuilding analyses among stocks. The steps when conducting a rebuilding analysis are:

1. Estimation of B_0 (and hence B_{MSY} or its proxy).
2. Selection of a method to generate future recruitment.
3. Specification of the mean generation time.
4. Calculation of the minimum and maximum times to recovery.
5. Identification and analysis of alternative harvest strategies and rebuilding times.

The specifications in this document have been implemented in a computer package developed by Dr André Punt (University of Washington). This package can be used to perform rebuilding analyses for routine situations. However, the SSC encourages analysts to explore alternative assumptions, calculations and projections that may more accurately capture uncertainties in stock rebuilding than the default standards identified in this document, and which may better represent

stock-specific concerns. In the event of a discrepancy between the generic calculations presented here and a stock-specific result developed by an individual analyst, the SSC groundfish subcommittee will review the issue and recommend which results to use.
The SSC also encourages explicit consideration of uncertainty in projections of stock rebuilding (see Section 8 below).

2.1. Estimation of B_0

B_0 is defined as mean unexploited female spawning output. The default approach for estimating B_0 for rebuilding analyses is to base it on some form of spawner-recruit model because most of the recent assessments of west coast groundfish have been based on stock assessments that integrate the estimation of the spawner-recruit model with the estimation of other population dynamic parameters. These stock assessments therefore link the recruitments for the early years of the assessment period with the average recruitment corresponding to B_0.

Stock assessment models that integrate the estimation of the spawner-recruit model also provide estimates of B_{MSY}. However, at this time, the SSC recommends that these estimates not be used as the target for rebuilding because they may not be robust. Rather, the rebuilding target should be taken to be the agreed proxy for B_{MSY} (e.g. $0.4B_0$ for most groundfish stocks) in all cases.

The recruitment process depends on the environment in addition to female spawning output. For example, the decadal-scale regime shift that occurred in 1977 (Trenberth and Hurrell 1994) is known to have strongly affected ecosystem productivity and function in both the California Current and the northeast Pacific Ocean (Roemmich and McGowan 1995; MacCall 1996; Francis *et al*. 1998; Hare *et al*. 1999). With the warming that ensued, West Coast rockfish recruitment appears to have been adversely affected (Ainley *et al*. 1993; Ralston and Howard 1995). In principle, B_0 and the approach used to generate future recruitment (see below) could take account of regime-shift effects on productivity. However, this would need to be justified (and the assumptions used for projection purposes would need to be consistent with those on which the assessment was based).

2.2. Selection of a Method to Generate Future Recruitment

One can project the population forward once the method for generating future recruitment has been specified, given the current state of the population from the most recent stock assessment (terminal year estimates of numbers at age and their variances) and the rebuilding target. The current default approach for generating future recruitment is to use the results of a fitted spawner-recruit model (e.g., the Beverton-Holt or Ricker curves), in particular because SS3-based assessments all assume a structural spawner-recruit model, either estimating or pre-specifying the steepness of the curve[3]. Moreover, this approach is consistent with that recommended above for setting B_0. This approach can, however, be criticized because stock productivity is constrained to behave in a pre-specified manner according to the particular spawner-recruit model chosen, and there are different models to choose from, including the

[3] The "steepness" of a spawner-recruit curve is related to the slope at the origin and is a measure of a stock's productive capacity. It is expressed as the proportion of virgin recruitment that is produced by the stock when reduced to $B_{20\%}$, and ranges between 0.2 and 1.0.

Beverton-Holt and Ricker formulations. These two models can produce very different reference points, but are seldom distinguishable statistically. Moreover, there are statistical issues when a spawner-recruit model is estimated after the assessment is conducted, including: (1) time-series bias (Walters 1985), (2) the "errors in variables problem" (Walters and Ludwig 1981), and (3) non-homogeneous variance and small sample bias (MacCall and Ralston 2002). Thus, analyses based on a spawner-recruit model should include a discussion of the rationale for the selection of the spawner-recruit model used, and refer to the estimation problems highlighted above and whether they are likely to be relevant and substantial for the case under consideration. A rationale for the choice of spawner-recruit model should also be provided. In situations where steepness is based on a spawner-recruit meta-analysis (e.g., Dorn 2002), the reliability of the resulting relationship should be discussed.

2.3. Specification of the Mean Generation Time

The mean generation time should be calculated as the mean age of the net maturity function. A complication that can occur in the calculation of mean generation time, as well as B_0 (see above), is when growth and/or reproduction have changed over time. In such instances, the parameters governing these biological processes should typically be fixed at their most recent, contemporary, values, as this best reflects the intent of "prevailing environmental conditions" as stated in the NMFS Guidelines for National Standard 1. Exceptions may occur if there are good reasons for an alternative specification (e.g., using growth and maturity schedules that are characteristic of a stock that is close to B_{MSY}).

2.4. Calculation of the Minimum and Maximum Times to Recovery

The minimum time to recovery (denoted T_{MIN}) is defined as the median time (i.e. 50% probability) for a stock to recover to the target stock size, starting from the time when a rebuilding plan was actually implemented (usually the year after the stock was declared overfished) to when the target level is first achieved, assuming no fishing occurs.

Although no longer used directly in Council decision-making for overfished stocks, rebuilding analyses should report the maximum time to recovery (denoted T_{MAX}). T_{MAX} is ten years if T_{MIN} is less than 10 years. If T_{MIN} is greater than or equal to 10 years, T_{MAX} is equal to T_{MIN} plus one mean generation. Likewise, rebuilding analyses should report an estimate of the median number of years needed to rebuild to the target stock size if all future fishing mortality is eliminated from the first year for which the Council is making a decision about[4] ($T_{F=0}$). This will typically differ from T_{MIN}.

Finally, when a stock rebuilding plan has been implemented for some time and recruitments have been estimated from an assessment, it may be that explicit, year-specific estimates of recruitment are available for the earliest years of the rebuilding time period. In such instances, rebuilding forecasts should be conducted setting the recruitments from the start of the rebuilding plan to the current year based on the estimates from the most recent assessment, rather than through re-sampling methods (see above) because this reflects the best available information regarding the recruitment during the rebuilding period.

[4] This year will generally not be the current year, but rather the year following the current two-year cycle.

2.5. Alternative Harvest Strategies during Rebuilding

The Council is required to rebuild overfished stocks in a time period that is as short as possible, but can extend this period to take into account the needs of fishing communities. The simplest rebuilding harvest strategy to simulate and implement is a constant harvest rate or "fixed F" policy. Such strategies should also mean that encounter rates with overfished species remain relatively constant over time, which is unlikely to be the case for constant catch strategies. All rebuilding analyses should, therefore, minimally consider fixed F (or SPR) strategies. However, many other strategies are possible, including constant catch and phase-in strategies, in which catch reductions are phased-in. In these latter cases, analysts should always assess whether fishing mortality rates exceed F_{MSY} (or its proxy), as this would constitute overfishing.

Analysts should consider a broad range of policy alternatives to give the Council sufficient scope on which to base a decision. The following represent the set of harvest strategies which have been identified by the GMT – all rebuilding analyses should minimally include these strategies:

1) eliminate all harvest beginning in the next management cycle (i.e., estimate $T_{\mathrm{F=0}}$),
2) apply the harvest rate that would generate the ACL specified for the current year (i.e., the latest year specified in regulations),
3) apply the spawning potential ratio[5] or relevant harvest control rule in the current rebuilding plan,
4) apply the harvest rate that is estimated to lead to a 50% probability of recovery by the current T_{TARGET},
5) apply the harvest rate that is estimated to lead to a 50% probability of recovery by the T_{MAX} from the current cycle,
6) apply the harvest rate that is estimated to lead to a 50% probability of recovery by the T_{MAX} from the previous cycle,
7) apply the default (e.g. 40-10 or 25-5) harvest policy, and
8) apply the ABC harvest rate (i.e., F_{MSY} less the uncertainty buffer).

For all of these strategies, except for numbers 1 and 8, the median catch streams from each run should be used as the harvest strategy in a follow-up run to evaluate the result of following the actual catch advice from the harvest policies above. In other words each of strategies 2-7 should be run twice; once with a given sequence of harvest rates and then using the median catches obtained from the first run. If the catch for a given year under one of the harvest strategies exceeds the ABC for that year, the catch should be set to the ABC (this is done automatically in the rebuilding software).

These polices should be implemented within the projection calculations in the year for which the Council is making a decision. For example, for assessments conducted in 2013 (using data up to 2012), the harvest decisions pertain to OFLs, ABCs and ACLs for 2015 and 2016. In this case, the catches for 2013 and 2014 should be set to the ACLs established by the Council for those years.

---

[5] The Spawning Potential Ratio (SPR) is a measure of the expected spawning output-per-recruit, given a particular fishing mortality rate and the stock's biological characteristics, i.e., there is a direct mapping of SPR to *F* (and *vice versa*). SPR can therefore be converted into a specific fishing mortality rate in order to calculate ACLs.

Many other harvest policies could be implemented by the Council. Consequently, analysts should be prepared to respond to requests by the Council for stock-specific projections on an individual case-by-case basis.

3. EVALUATING PROGRESS TOWARDS REBUILDING

There are no agreed criteria for assessing the adequacy of the progress towards rebuilding for species that are designated to be in an overfished state and are under a Rebuilding Plan. The SSC currently reviews each stock on a case-by-case basis, considering the following two questions: (1) have cumulative catches during the period of rebuilding exceeded the cumulative ACL that was available, and (2) what is the difference between the year in which recovery is predicted to occur under the current SPR ($T_{REBUILD}$) and the currently-adopted T_{TARGET}? If the difference between $T_{REBUILD}$ and $T_{TARGEST}$ is minor, progress towards rebuilding is considered to be adequate. In contrast, if the difference between $T_{REBUILD}$ and T_{TARGET} is major, it will be necessary to define a new T_{TARGET}. As an initial step in this direction, a new maximum time to rebuild T^N_{MAX} will be computed based on the specifications outlined in Section 5. Analysts will be asked to assess whether the currently-adopted SPR will readily rebuild the stock before T^N_{MAX}.

Adequacy of progress will be evaluated when the SSC groundfish subcommittee reviews the draft rebuilding plans. Analysts should provide the information needed to address the two questions listed above. If the SSC agrees that progress is not sufficient, the draft rebuilding analysis documents will need to be updated to include T^N_{MAX} and the probability that the currently adopted harvest rate (SPR) will rebuild the stock before T^N_{MAX}.

4. DECISION ANALYSES / CONSIDERING UNCERTAINTY

The calculation of T_{MIN} and the evaluation of alternative harvest strategies involve projecting the population ahead taking account of uncertainty about future recruitment. There are several reasons for considering model and parameter uncertainty when conducting a rebuilding analysis. For example, if several assessment model scenarios were considered equally plausible by the assessment authors or, alternatively, one model was preferred by the assessment authors and another was preferred by the STAR Panel. Accounting for implementation uncertainty (i.e. the realized catch differing from the set ACL) is needed for cases in which the catch of the overfished stock is likely to differ appreciably from the set ACLs.

The uncertainty associated with parameters, such as the rate of natural mortality and the current age-structure of the population, can also be taken into account. This can be achieved in a variety of ways. For example, if the uncertainty relates to the parameters within one structural model, this uncertainty can be reflected by basing projections on a number of samples from a distribution which reflects this uncertainty (such as a Bayesian posterior distribution or bootstrap samples). Alternatively, if there are multiple models (e.g. different structural assumptions regarding data weights, use of data sources, etc.) projections can be conducted for each model and the results appropriately weighted when producing the final combined results if the uncertainty pertains to alternative structural models. In the case of assessments for which a decision table has been produced, the weights assigned to each model on which the decision table is based would be those assigned by the STAR Panel (and endorsed/modified by the SSC). Implementation uncertainty can take many forms. Two common ways to model implementation uncertainty are (a) the realized catch is distributed about the ACL (i.e. the catch equals the ACL on average), and (b) the realized catch is distributed about the ACL, but the expected catch is less [or greater] than the ACL. The latter case is appropriate if past data suggest that ACLs will be undercaught given management arrangements.

5. DOCUMENTATION

The analysts are responsible for conducting a complete and technically sound rebuilding analysis that conforms to accepted standards of quality, and in accordance with these TOR. It is important for analysts to document their work so that any rebuilding analysis can be repeated by an independent investigator at some point in the future. Therefore, all stock assessments and rebuilding analyses should include tables containing the specific data elements that are needed to adequately document the analysis. Clear specification of the exact assessment scenario(s) used as the basis for the rebuilding analysis is essential. Linkages with the most recent stock assessment document should be clearly delineated (e.g., through references to tables or figures). This is important because assessments often include multiple scenarios that usually have important implications with respect to stock rebuilding. The rebuilding analysis document should follow the outline below.

1) Title page and list of preparers – the names and affiliations of the analysts either alphabetically or as first and secondary authors.
2) Summary – condensed overview and results of the rebuilding analyses.
3) Introduction – scientific name; years when species declared overfished; summary of assessment efforts (when first assessed, brief overview of subsequent assessments and rebuilding analyses).
4) Overview of the most recent stock assessment – main assumptions, estimated stock status, sources of uncertainty, alternative states of nature used in the decision table, median and 95% intervals for: (a) summary / exploitable biomass, (b) spawning output (in absolute terms and relative to the target level), (c) recruitment, (d) catch, (e) landings (if different from catch), (f) OFL, (g) ABC, and (h) SPR for the actual harvest strategy selected by the Council.
5) Management performance under rebuilding – brief overview and a table comparing Overfishing Limit (OFL), Annual Catch Limit (ACL), and catch (i.e., landings plus discard) for each year of the rebuilding period.
6) Rebuilding calculations
    - Specifications for the software used for the analysis (including the version number); date on which the analysis was conducted; the program's input files (should be included as an Appendix).
    - The rationale for the approach used to estimate B_0 and to generate future recruitment.
    - The biological information on which the projections are based (e.g. natural mortality rate by age and sex, individual weight by age and sex, maturity by age, fecundity by age, selectivity-at-age by sex (and fleet), population numbers (by age and sex) for the

year the rebuilding plan commenced, population numbers (by age and sex) for the present year).
  - Description of how fishing mortality is allocated (and selectivity applied) to each fleet for rebuilding analyses based on multiple fleets.
  - Description of how uncertainty in input parameters from the stock assessment in the rebuilding analysis is accounted for.
  - List and description of alternate rebuilding strategies analyzed.
7) Results
  - Summary of rebuilding reference points. For each alternative model, a table (see Table 1 for an example based on canary rockfish) should be produced which lists: (a) the year in which the rebuilding plan commenced, (b) the present year, (c) the first year that the evaluated harvest policy calculates the ACL, (d) T_{MIN}, (e) mean generation time, (f) T_{MAX}, (g) $T_{F=0}$, (h) the estimate of B_0 and the target recovery level, (i) the current SPR, (j) the current T_{TARGET} and (k) the estimate of current stock size.
  - Results of harvest policy projections (see, for examples, Tables 2-5; Figures 1-3). The following information should be provided for each harvest policy evaluated: (a) the first year in which recovery to the target level occurs with at least 0.5 probability, (b) the SPR for the first year of the projection period, (c) the probability of recovery by the current T_{TARGET}, (d) the probability of recovery by the current T_{MAX}, (e) probability of the stock dropping below the female spawning biomass in the present year and the year the stock was declared overfished, (f) tables of median time-trajectories (from the present year to T_{MAX}) of: (i) spawning output relative to the target level, (ii) probability of being at or above the target level, (iii) OFL, and (iv) ABC. Median time-trajectories of SPR should be provided for the projection based on the 40:10 rule (as applied to the ABC) and any phase-in harvest policies that have been specified.
8) Acknowledgements
9) Literature cited

The software and data files on which the rebuilding analyses are based should be archived with the stock assessment coordinator. Much of the biological information will be stored in the input file for the projection software and does not need to be repeated unless there is good reason to do so. For cases in which the projections take account of uncertainty about the values for the biological parameters (e.g., using the results from bootstrapping or samples from a Bayesian posterior distribution), some measure of the central tendency of the values (e.g., the mode or median) should be provided and the individual parameter values should be archived with the stock assessment coordinator. Rebuilding analyses may be based on selectivity-at-age vectors constructed by combining estimates over fleets. If this is the case, the rebuilding analysis needs to document how the composite selectivity-at-age vector was constructed.

TERMS OF REFERENCE

FOR THE

METHODOLOGY REVIEW PROCESS FOR GROUNDFISH AND COASTAL PELAGIC SPECIES

DRAFT

~~JANUARY 20~~MAY, ~~2012~~2014

Published by the Pacific Fishery Management Council

Introduction

This document lays out general procedures for methodology and data reviews related to the assessment and management of coastal pelagic species (CPS) and groundfish by the Pacific Fishery Management Council (Council). It clarifies the responsibilities of the proponents of new methods or data sets proposed for use in CPS or groundfish stock assessment and the responsibilities of participants in the review process. Each review is likely to have additional requirements that will be defined in a set of Specific Terms of Reference (TOR), which should conform to the general terms defined in this document. Although these General Terms of Reference focus on methodology and data reviews for CPS and groundfish stock assessments, they may be applied to methods in other areas, including economic analyses and ecosystem-based fishery management. In the text below the term "methodology review" should be understood to mean "methodology and data review".

The methodology review process provides for peer review as referenced in the 2006 Reauthorization of the Magnuson-Stevens Fishery Conservation and Management Reauthorization Act (MSRA), which states that "the Secretary and each Regional Fishery Management Council may establish a peer review process for that Regional Fishery Management Council for scientific information used to advise the Regional Fishery Management Council about the conservation and management of the fishery" (MSRA section 302(g)(1)(E)). The peer review process is not a substitute for the Council's Scientific and Statistical Committee (SSC), and should work in conjunction with the SSC. This document will be included in the Council's Statement of Organization, Practices and Procedures as documentation of part of the review process that underpins the SSC's scientific advice.

Parties involved in implementing the peer review process described here are the Council; Council staff; members of Council Advisory Bodies, including the SSC; the relevant Management Team and Advisory Panel (CPSMT and CPSAS for CPS, and GMT and GAP for groundfish); the National Marine Fisheries Service (NMFS); state agencies; and interested persons (including external reviewers).

Unlike Stock Assessment Review (STAR) Panels, methodology review panels do not occur on a regular timetable but are instead established by the Council to provide peer and in-depth review of major changes to the methodology on which stock assessments are based. Consequently, the outcomes from a methodology review are recommendations regarding whether a particular methodology should be applied in future stock assessments, and on recommended (or required) improvements and modifications. Existing methodologies could be reviewed, particularly if they are key to stock assessments and have not been reviewed for many years or if incremental changes in how the methodology is applied have occurred.

Methodology reviews may be appropriate when a major new data source is introduced or when a major change in the stock assessment modeling is contemplated. In both cases, a methodology review is needed when the change(s) from how assessments have been conducted in the past are deemed to be more than what a STAR Panel can reasonably be expected to handle. The introduction of a new survey will generally require a methodology review, as will a change to a new stock assessment modeling platform. However, changes to the structure of a previously reviewed assessment model (e.g., changes in selectivity year-blocking) fall within the scope of a standard STAR Panel review.

No explicit guidelines for what topics can be covered in a methodology review are provided here, but typical examples would be evaluation of: (a) proposed major new data types which if included in an assessment could change its outcomes markedly (e.g., the aerial survey for Pacific sardine), (b) proposed changes to the design of existing surveys, (c) existing data inputs to assessments which have not been reviewed in depth by a Council-sponsored peer-review panel for many years (e.g., the egg production method for Pacific sardine), (d) data or model results that contribute to ecosystem-based management of CPS and groundfish stocks, and (e) proposed major changes to stock assessment methods that fall outside the scope of a normal STAR Panel review (for example, a change to the stock assessment modelling platform).

Changes to harvest control rules could also be considered by a methodological review. Care must be taken to separate the scientific analysis supporting the change (e.g. the structure and technical aspects of simulation studies used to compare a revised control rule against the *status quo*) and the management objectives used to measure performance (e.g. minimize year-to-year catch variance, maximize long-term average catch, etc.). The former are amenable to methodological review (provided adequate background analyses have been completed), but the latter are management decisions – not well suited to a methodological review.

These TOR reflect how previous methodology reviews have been undertaken. Nevertheless, no set of guidelines can be expected to deal with every contingency, and all participants should anticipate the need to be flexible and address new issues as they arise.

Methodology Review Goals and Objectives

The general goals and objectives for the methodology review process are to:

1. Ensure that research surveys, data collection, data analyses and other scientific techniques in support of CPS and groundfish stock assessments are the best available scientific information and facilitate the use of information by the Council.
2. Provide recommendations regarding whether, and if so, how a particular methodology can be applied in future stock assessments.
3. Meet the MSRA and other legal requirements.
4. Follow a detailed calendar and fulfil explicit responsibilities for all participants to produce required outcomes and reports.
5. Provide an independent external review of survey and analytical methods used to develop data to inform CPS and groundfish stock assessments.
6. Increase understanding and acceptance of CPS and groundfish research methodologies and review by all members of the Council family.
7. Identify research needed to improve assessments, reviews, surveys, analyses, and fishery management in the future.

Responsibilities of Methodology Review Participants

Shared Responsibilities

All parties have a stake in ensuring adequate technical review of stock assessments and the information on which they are based. The National Marine Fisheries Service (NMFS), as the designee of the Secretary of Commerce, must determine that the best scientific advice has been used when it approves fishery management recommendations made by the Council. The Council uses statements from the SSC to determine whether the information on which it will base its recommendation represents the "best available" science. Fishery managers and scientists providing technical documents to the Council for use in management need to ensure their work is technically correct.

The Council, NMFS, and the Secretary of Commerce share primary responsibility to create and foster a successful peer review process. The Council will oversee the process and involve its standing advisory committees, especially the SSC. The SSC will designate a member to coordinate, oversee, and facilitate each methodology review. Together, NMFS and the Council will consult with all interested parties to plan, prepare terms of reference, and develop a calendar of events for each methodology review and a list of deliverables for final approval by the Council. NMFS and the Council will share fiscal and logistical responsibilities and both should ensure that there are no conflicts of interest in the process[1].

The peer-review process is sponsored by the Council, because the Federal Advisory Committee Act (FACA) limits the ability of NMFS to establish advisory committees. FACA specifies a procedure for convening advisory committees that provide consensus recommendations to the federal government. The intent of FACA was to limit the number of advisory committees; ensure that advisory committees fairly represent affected parties; and ensure that advisory committee meetings, discussions, and reports are carried out and prepared in full public view. Under FACA, advisory committees must be chartered by the Department of Commerce through a rather cumbersome process. However, the Sustainable Fisheries Act exempts the Council from FACA per se, but requires public notice and open meetings similar to those under FACA.

Management Team Responsibilities

The Management Team (MT) is responsible for identifying and evaluating potential management actions based on the best available scientific information. In particular, the MT makes Annual Catch Limit (ACL) and Annual Catch Target (ACT) recommendations to the Council.

A representative of the relevant MT may be appointed by the MT chair and, if appointed, will serve as a liaison to the methodology review panel meeting and will participate in discussions. The MT representative will not serve as a member of the Panel. The MT representative should be prepared to advise the Panel on fishing regulations or practices that may influence data used in assessments and the nature of the fishery in the future (this will be more relevant for some of the topics which are considered by methodology reviews than others).

[1]The proposed NS2 guidelines state: “Peer reviewers who are federal employees must comply with all applicable federal ethics requirements. Peer reviewers who are not federal employees must comply with the following provisions. Peer reviewers must not have any real or perceived conflicts of interest with the scientific information, subject matter, or work product under review, or any aspect of the statement of work for the peer review. For purposes of this section, a conflict of interest is any financial or other interest which conflicts with the service of the individual on a review Panel because it: (A) Could significantly impair the reviewer’s objectivity; or (B) Could create an unfair competitive advantage for a person or organization. (C) Except for those situations in which a conflict of interest is unavoidable, and the conflict is promptly and publicly disclosed, no individual can be appointed to a review Panel if that individual has a conflict of interest that is relevant to the functions to be performed. Conflicts of interest include, but are not limited to, the personal financial interests and investments, employer affiliations, and consulting arrangements, grants, or contracts of the individual and of others with whom the individual has substantial common financial interests, if these interests are relevant to the functions to be performed. Potential reviewers must be screened for conflicts of interest in accordance with the procedures set forth in the NOAA Policy on Conflicts of Interest for Peer Review subject to OMB’s Peer Review Bulletin.”

Advisory Panel Responsibilities

It is the responsibility of the AP representative to ensure that AP concerns regarding the issue being reviewed are conveyed to the Panel. The chair of the AP may appoint a representative to participate in a methodology review. If appointed, the AP representative will serve as an advisor to the review meeting. The AP representative will participate in review discussions as an advisor to the Panel, in the same capacity as the MT advisor. The AP representative may provide appropriate data and advice to the review meeting and will report to the AP on the meeting.

Scientific and Statistical Committee Responsibilities

The SSC will assign at least one member to each methodology review. This member will chair the review meeting, and present the report of the meeting to the SSC and the Council. The SSC will review any additional analytical work arising from the review meeting, will serve as arbitrator to resolve disagreements that arose during the review meeting, and will make recommendations to the Council (e.g. whether the reviewed methodology provides the "best available science", and hence could be used for stock assessment and developing conservation and management measures).

Council Staff Responsibilities

Council staff will be assigned to coordinate, monitor and document the review process. Council staff will be responsible for timely issuance of meeting notices and distribution of appropriate documents. Council staff will coordinate with the panel chair and NMFS to assure that all documents are received on time, and are complete. Council staff will coordinate materials and presentations for Council meetings relevant to Council decision making. Council staff will also collect and maintain file copies of reports from each methodology review, the documents considered during the review, SSC, Management Team, and Advisory Panel comments and reports, letters from the public, and any other relevant information.

A primary role for Council staff assigned to each methodology review will be to monitor review meetings and SSC activities to ensure compliance with these TOR. Council staff will identify inconsistencies with the TOR that occur during review meetings and work with the panel chair to develop solutions and to correct them. Council staff will work with the panel chair to finalize the panel report and provide it to the Council.

National Marine Fisheries Service Responsibilities

NMFS will assign a coordinator to work with the Council, other agencies, groups, or interested persons that carry out assessment work to assist in organizing methodology reviews. The NMFS coordinator will identify independent panellists following criteria for reviewer qualifications. The costs associated with these reviewers will be borne by NMFS. The NMFS coordinator will work with methodology proponents to facilitate delivery of materials by scheduled deadlines and in compliance with other requirements of these terms of reference, to the extent possible and with the assistance of the assigned Council staff officer and the panel chair.

General Review Panel Responsibilities

The objective of a methodology review panel is to complete a detailed evaluation of a topic selected by the Council which could have a major impact on stock assessments or the provision of scientific advice and to make a recommendation regarding whether the methodology represents the best available scientific information for the Council. The general responsibilities of the Panel are to:

1. review documents pertinent to the topic under consideration;
2. evaluate the technical merits and deficiencies of the proposed method(s) during the panel meeting and work with the proponents to correct deficiencies;
3. provide recommendations for alternative methods or modifications to proposed methods, or both, as appropriate during the panel meeting;
4. provide recommendations on application of the methods to the stock assessment and/or management process;
5. document meeting discussions;
6. provide complete panel reports.

The panel chair has, in addition, the responsibility to:

7. review revised documents and panel reports before they are forwarded to the SSC.

Review panels may have additional responsibilities that are defined in the Specific Terms of Reference for the review.

Panel Composition

Methodology review panels normally include a chair, at least one "external" member (i.e., who is outside the Council family and not involved in management or assessment of West Coast fisheries, often designated by the Center for Independent Experts [CIE]), and at least two additional members. Selection of the external and independent panellists should aim for balance between outside expertise of the topic being reviewed and in-depth knowledge of West Coast fisheries, data sets available for those fisheries, and relevant modelling approaches. Reviewers should not have financial or personal conflicts of interest, either current to the meeting, within the previous year (at minimum), or anticipated. Panellists should be knowledgeable about the specific approaches being reviewed. In addition to panel members, methodology review meetings will include Council staff to help advise the Panel and assist in recording meeting discussions and results, and may include MT and AP representatives with responsibilities as laid out above. The length of a methodology review meeting will be selected by the SSC and could range one to five days.

The panel chair is responsible for: 1) developing an agenda, 2) ensuring that the Panel follows the TOR, 3) guiding the participants in the review (proponents and Panel) to mutually agreeable solutions, 4) coordinating review of documents, and 5) providing Council staff with a camera ready and suitable electronic version of the panel report. The Panel, those proposing the methodology, the MT and AP representatives, and the public are legitimate meeting participants that should be accommodated during discussions. It is the panel chair’s responsibility to manage discussions and public comment so that work can be completed.

Conduct of a Review

The Panel’s review solely concern technical aspects of the method. It is therefore important that the Panel strive for a risk neutral perspective in its reports and deliberations. Methods or results that have a flawed technical basis, or are questionable on other grounds, should be identified by the Panel and a recommendation made that they should excluded from consideration in developing management advice. The Panel should comment on the degree to which the uncertainty associated with the method being reviewed is quantified (e.g. through confidence or prediction intervals) because uncertainty is taken into account during the management process.

Recommendations and requests to the proponents for additional or revised analyses must be clear, explicit, and in writing. Panel recommendations and requests to the proponents should reflect the consensus opinion of the entire Panel and not the minority view of a single individual or individuals on the Panel. A written summary of discussion on significant technical points and lists of all panel requests and recommendations and requests to the proponents are required in the panel report, which should be completed (at least in draft form) prior to the end of the review meeting. It is the chair and Panel's responsibility to carry out any follow-up review of work that is required.

The Panel's primary duty is to conduct a peer review of the proposed methodology. Methodology panel meetings are not workshops, although the involvement of the Panel in shaping the methodology is greater during methodology reviews than during STAR Panels. This is particularly the case when the outside reviewers have considerably more experience with a given methodology than the proponents and the reviewers from within the Council family. In the course of this review, the Panel may ask for a reasonable number of additional analyses, as well as for additional details of the proposed methodology. It would not be unusual for this evaluation to result in a change to the initial methodology, provided both the Panel and the proponents agree. Panels are expected to be judicious in their requests of the proponents, recognizing that some issues uncovered during a review are best flagged as research priorities (and use of the methodology possibly deferred until those issues are resolved). The Panel should not impose as a requirement their preferred methodologies when such is a matter of professional opinion. Rather, if the Panel finds that a method is inadequate, it should document and report that opinion.

Panels and proponents are required to make an honest attempt to resolve any areas of disagreement during the review meeting. Occasionally, fundamental differences of opinion remain between the Panel and the proponents that cannot be resolved by discussion. In such cases, the Panel must document the areas of disagreement in its report. In exceptional circumstances, the proponents may choose to submit a supplemental report supporting its view, but in the event that such a step is taken, an opportunity must be given to the Panel to prepare a rebuttal. These documents will then be appended to panel report as part of the record of the review meeting. Panel members may have fundamental disagreements that cannot be resolved during the meeting. In such cases, panel members may prepare a minority report that will become part of the record of the review meeting. The SSC will then review all information pertaining to Panel or Panel/proponent disputes, and issue a recommendation.

Additional analyses required by the Panel should be completed by the proponents during the review meeting. It is the obligation of the panel chair, in consultation with other panel members, to prioritize requests for additional analyses. If follow-up work by the proponents is required after the review meeting, then it is the Panel's responsibility to track progress. In particular, the chair is responsible for communicating with proponents (by phone, e-mail, or any other convenient means) to determine if the revised analyses and documents are complete and ready to be presented to the SSC.

Review Panel Report

The panel chair is responsible for preparing the final draft of the panel report, obtaining the Panel's approval, and providing the report to the Council for inclusion in the Briefing Book. The chair will appoint members of the Panel (the "external" members and other members) to act as rapporteurs who will draft the report according to guidance by the panel chair on format and level of detail. The aim of the report is to provide information to the SSC on whether it should recommend the methodology for use in Council assessments and, if necessary, what additional work must be completed before the methodology can be used. The report is not meant as a detailed summary of the methodology, nor is it meant to be the minutes of the meeting. The report may include Appendices which summarize work presented to the Panel in response to requests. The chair will solicit comment on the draft report from the proponents and the MT and AP advisors. The purpose of this review is limited to ensuring that the report is technically accurate, and reflects the discussion that occurred at the meeting, and should not be viewed as an opportunity to reopen debate on issues. The chair will be the final arbiter on wording changes suggested by proponents and the MT and AP advisors—i.e., the report is the Panel's report of the meeting. Any detailed commentary by MT and AP advisors should be drafted separately, reviewed by full advisory body, and included in the Briefing Book.

Suggested Template for Methodology Review Panel Report

- Summary of the Methodology Review Panel meeting, containing:
  - names and affiliations of panel members;
  - topic(s) being reviewed; and
  - list of analyses requested by the Panel, the rationale for each request, and a brief summary the responses to each request.
- Comments on the technical merits and/or deficiencies of the methodology and recommendations for remedies. Comments should address each of the following issues:
  - What are the data requirements of the methodology?
  - What are the situations/stocks for which the methodology is applicable?
  - What are the assumptions of the methodology?
  - Is the methodology correct from a technical perspective?
  - How robust are results to departures from the assumptions of the methodology?
  - Does the methodology provide estimates of uncertainty? How comprehensive are those estimates?
  - Will the new methodology or data set result in improved stock assessments or management advice?
- Areas of disagreement regarding panel recommendations:
  - among panel members (including concerns raised by the MT and AP representatives); and
  - between the panel and proponents.
- Unresolved problems and major uncertainties, e.g., any issues that could preclude use of the methodology.
- Management, data or fishery issues raised by the public and MT and AP representatives during the panel review.
- Prioritized recommendations for future research and data collection.

General Responsibilities Proponents of New Methodology or Data Sets

New methods or data sets will be used in producing CPS or groundfish stock assessments (or in providing management advice) if there is a reasonable expectation that doing so will result in an improved assessment relative to a status quo assessment that did not use the new method or data set.

Proposing a New Methodology for Review

The proponents of new methods or data sets for use in CPS or groundfish stock assessments will submit a 1-2 page proposal for consideration by the SSC and the Council. The proposal should be submitted by the briefing book deadline of the appropriate Council meeting, and should address the following:

- Title
- Name of proposers (including the researchers who will participate at the methodology review and will be expected to conduct analyses during that review).
- How the proposed methodology will improve assessment and management for the stock(s) in question.
- Outline of methods (field and analytical).

Proponents of methods to be reviewed should be prepared to present their proposal to the SSC, the relevant MT, and the full Council. Proponents should also include a description of the funding, logistics, or other factors that would indicate the likelihood of success of the proposed methodology

The proposed methodology should be field tested, and preferably there will be available data for one or more years. Untested or experimental methods are typically not appropriate for this type of review.

Methodology reviews are intended for methods or data sets that apply to a range of stocks. A STAR Panel would be more appropriate for reviewing methods or data sets that apply to only one or to a small number of related stocks.

Responsibilities of Methodology Proponents

If the Council recommends review of the methodology, the proponents will appoint a representative to coordinate work with the Panel and attend the panel meeting. A representative of the proponents should attend the SSC meeting at which the outcomes from the panel review are discussed.

The proponents are responsible for preparing two versions of the methodology review document:

1) a "draft", including an executive summary, for discussion during the review meeting; and
2) a "final" version for presentation to the SSC, the Council, and the relevant Management Team and Advisory Panel.

The proponents will distribute "draft" documents fully describing the methodology to the Panel, Council staff, and the MT and AP representatives at least two weeks prior to the review meeting. The proponents are responsible for bringing analysis methods and relevant data (in digital format) to the review meeting so that data can be analyzed on site and sensitivity analyses conducted. In most cases, the proponents should produce a revised document outlining the methodology (and preliminary results / responses to the panel recommendations) three weeks after the end of the panel meeting (including any internal agency review).

The proponents and the Panel may disagree on technical issues, but “final” documents must include a point-by-point response by the proponents to each of the panel recommendations.

The draft and final reports on the methodology should include information that addresses the following:

- Data requirements of a new methodology or documentation of how information in a new data set was collected.
- The situations/stocks for which the methodology or data are applicable.
- The assumptions of the methodology and whether those assumptions are likely to be satisfied by data sets to which the method would be applied.
- An evaluation of robustness of the methodology to departures from the underlying assumptions.
- An application of a new methodology to real or simulated data, including an evaluation of the bias and accuracy of the results.
- An evaluation of how the new method(s) or data set(s) would improve stock assessments or the provision of management advice.

Agenda Item F.8.a
Attachment 5
June 2014

RECOMMENDED CHANGES TO THE GROUNDFISH/CPS STOCK ASSESSMENT TERMS OF REFERENCE, REFLECTING COASTAL PELAGIC SPECIES MANAGEMENT AND ASSESSMENT SCHEDULES

The edits below are recommended to bring the joint groundfish/CPS terms of reference in line with recent changes to the management and assessment schedules for Pacific sardine and Pacific mackerel. Suggested deletions are in strikethrough, and suggested additions are underlined.

Global: The term "HG control rule" should be changed to "harvest control rule."

Page 6 (In 2, Stock Assessment Prioritization):
"Stock assessments for Pacific sardine ~~and Pacific mackerel~~ are conducted annually, with full assessments occurring every third year, and update assessments during interim years. Full stock assessments for Pacific mackerel are conducted every four years, with catch-only projection estimates also conducted two years after each full assessment. Assessments for groundfish species….."

Page 7 (In 4.1, Shared Responsibilities):
Delete "assuring" and replace with "ensuring."

Page 11 (In *STAR panel requests for addition analyses*):
"…If the STAR panel agrees that important results have been generated, it should forward its findings and conclusions to the SSC and the Council for consideration in setting of OFLs, ABCs, and ACLs (for groundfish and CPS), and HGs (for CPS only). A key section of the assessment is that on research needed to improve the assessment. Highlighting research priorities should increase the likelihood that future stocks assessments can be raised to category 1."

Page 18 (In 6, Update Assessments):
"For ~~CPS~~ Pacific sardine, update assessments typically occur during two years out of every three. For Pacific mackerel, catch-only projection estimates occur every four years, alternating with full assessments. For groundfish, the initial…."

Page 26 (In Implementation for Pacific Sardine):

1. BIOMASS is the estimated stock biomass (ages 1+) at the start of the next year from the current assessment,
2. CUTOFF (150,000 mt) is the lowest level of estimated biomass at which harvest is allowed,
3. FRACTION is an environment-based percentage of biomass above the CUTOFF that can be harvested by the fisheries. Given that the productivity of the sardine stock has been shown to increase during relatively warm-water ocean conditions, the following formula has been used to determine an appropriate (sustainable) FRACTION value:

   FRACTION = $0.248649805(T^2) - 8.190043975(T) + 67.4558326$, where T is the running average sea-surface temperature at Scripps Pier, La Jolla, California during the three preceding years. Under the harvest control rule, FRACTION is constrained and ranges between 5% and 15% depending on the value of T.

4. U.S. DISTRIBUTION is the percentage of BIOMASS in U.S. waters (87%).

NOTE: at its April 2014 meeting, the Council adopted a new FRACTION formula and SST index for immediate use in calculating the sardine OFL, and for future use in calculating the HG, after the Council takes final action. The new FRACTION formula is $E_{msy} = -18.46452 + 3.25209T - 0.19723T^2 + 0.0041863T^3$, with the Temperature term (T) derived from the CalCOFI SST index.

Agenda Item F.8.b
NWFSC Report
June 2014

INITIAL STOCK ASSESSMENT PLANS AND TOR
NORTHWEST FISHERIES SCIENCE CENTER REPORT

Groundfish Stock Assessment Prioritization For 2015

In April, NWFSC provided the Council and its advisors with a table which summarized numerous informational elements relevant to the selection of species for 2015. Although the Council did not address this issue in April, Dr. Jim Hastie had opportunities to conduct productive, preliminary discussions with the SSC and GAP during that meeting. Those discussions have resulted in some revisions to the assessment suggestions for 2015 that were included in the April table (see attached). As in April, there has been no attempt to derive a systematic overall priority rating from the factors that are included in the table. Color-coding in the table is intended to draw attention to factors that support consideration of a species for assessment in 2015, with green representing the upper tier, and yellow the intermediate tier, *for that factor*.

The upper half of first page of the attached table focuses on species which we believe are the most compelling candidates for some level of assessment (or data report). The first columns indicate what level/type of assessment we think would be appropriate. Our highest priorities are marked with capital 'X's and highlighted in green (e.g. black rockfish), with less compelling choices designated by lower-case 'x's, in yellow. For several species, an assessment could be conducted as one of two or three different types, and the selection of a particular type (if any) will depend on workload considerations, species' priority, and other factors. The next set of columns summarizes information from the most recent assessment (excluding data-poor), if one exists. The column showing the year of the most recent assessment is colored green for stocks that are unassessed or were last assessed before 2009. Stocks assessed in 2009 or 2011 are colored yellow. This section includes the current category in which each species is managed, the last estimated depletion level, and an indicator for rebuilding stocks.

The next column shows the PSA (vulnerability) score for each species. Frequently, the highest PSA values are presented as red, to indicate the stocks' higher vulnerability. However, since greater vulnerability elevates the importance for assessing a stock, those values are colored green in this table. Next is a block of 5 columns containing information regarding the importance of each stock to commercial and recreational fisheries. The commercial columns show the ranking of each species, on the basis of shoreside, ex-vessel revenue (2008-2012), for all gears and for hook-and-line gears. The recreational columns rank species on the basis of landed catch amounts for the entire coast, for California, and for Oregon and Washington, combined. In addition to the green and yellow coloring, situations where rebuilding species ranked outside the top-30 but are constraining for a fleet were highlighted in pink. The next two columns report the estimated fishing mortality in 2012, for each species as a percentage of its ABC and OFL (or the species' contributions to assemblage ABCs and OFLs). Where necessary, catch and specifications were combined across multiple areas, for purposes of this table. The final column provides a qualitative indication of the suitability of the NWFSC's bottom-trawl survey to provide index and biological information to support an assessment. Species' cells for which the survey is most informative are colored green.

The list of species in the upper block of page 1 is a larger list than could likely be completed in 2015, even if the least time-consuming option were selected for each species. Given issues that arose in the 2013 data-moderate assessment and review process, it is probably desirable to limit the number of species assessed in that manner to 4, so that assessments using both modeling platforms can be completed and reviewed for each species. There should also be a balance between species utilizing survey and fishery CPUE abundance indices, as the latter are more analytically demanding. In many cases, models must be developed for multiple areas, which increases the development and review burden. The issue of single species requiring multiple assessment models is also a concern in the STAR process. Often, multiple modeling areas are dictated by differences in the available data, as with black rockfish. In determining how many species can be assigned to a particular STAR panel, attention should be paid to how many separate models the panel will be asked to review. Several of these are indicated by an 'x2' notation, after the species name.

Bocaccio, darkblotched, and petrale sole are suggested assessments, because they may have completed the process of rebuilding. Because petrale has had a full assessment in each of the last 3 cycles, it is suggested for an update. Bocaccio and darkblotched are suggested for full assessments, based the SSC's prior recommendations. Black rockfish is an extremely important species to both the commercial and recreational fisheries and has not been assessed since 2007. Similarly, canary rockfish received its last full assessment in 2007, and NWFSC staff have been working throughout the winter to review and streamline the inputs used in this assessment. Though widow rockfish was determined to be rebuilt in 2011, considerable uncertainty was associated with that finding. Given industry interest in renewing a targeted mid-water fishery for widow, a full assessment in 2015 is suggested. Given that black rockfish will likely be assessed with two separate area models, the strongly recommended species would fill 3 panels, leaving room for two additional species, or one requiring multiple models. At the April Council meeting, the SSC noted that current estimates of historical catch for kelp greenling in Oregon are very different from the time series that was used in the 2005 assessment of that area. This development makes Oregon kelp greenling a strong candidate for a new full assessment. The amount of kelp greenling biological data that is available from California fisheries is not believed to be adequate to support a full assessment.

The 2011 sablefish assessment showed the stock to be stabilizing after a period of decline during the late 2000s; however, its status was squarely in the middle of the precautionary zone. Given the economic importance of this species and the soundness of the last assessment, an update is suggested. Another stock suggested for an update is lingcod, last assessed in 2009. Although this species has been relatively lightly exploited, we are likely to be able to utilize student help in conducting the updates of the northern and southern models. Additionally, updating this assessment will support anticipated research by UW and The Nature Conservancy to examine the effects of lingcod predation on rockfish recovery.

The 2013 data-moderate assessment for northern China rockfish was a subject of considerable discussion at the March Council meeting. Barring the ability to establish a CPUE index for

China rockfish in Washington waters, it is suggested that, in 2015, a new data-moderate or full assessment be conducted for Oregon waters and California north of 40°10', along with a data-poor assessment for Washington. If the Council wishes to have China rockfish assessed with an area boundary at the OR-CA border, then the options suggested above would apply to Oregon waters. If a full assessment were chosen for the area including Oregon, with either boundary, the Council could consider adding a full for the corresponding California area. There is a considerable amount of recreational length data in California, however, the only age structures were collected prior to 1990. Oregon, on the other hand has considerable length data and age structures from recent commercial and recreational fisheries, and also has a nearshore logbook that may yield useful CPUE information. Several other species are identified as candidates for data-moderate assessments. Of these, only arrowtooth flounder and bank rockfish are apt to benefit from trawl survey abundance indices. The remaining species comprise a suite of important nearshore species that have not received full assessments since 2007, if ever. Data reports are suggested for yelloweye rockfish and Pacific ocean perch in 2015.

The lower part of page 1 shows information for all remaining previously-assessed, category 1 and 2 species. The second page of the table shows species that have only been assessed previously with data-poor methods. in the upper section, and a selection of the remaining species that have some high-priority aspects, in terms of PSA score, fleet importance, or ABC attainment. The last page of the table includes all of the remaining species for which only data-poor assessments have been conducted.

Although the Council is not scheduled to take final action on the 2015 assessment schedule until September, it would be very useful to have as clear a statement of Council priorities as is possible during the June discussion of this topic. Many of the species under consideration for full or update assessments have not been assessed for 5 or more years. In many such cases, there may be a substantial inventory of un-aged otoliths, and the additional 3 months of ageing time may be quite important.

A final important issue relating to planning and workload involves the management line that the Council intends to use for delineating northern and southern areas in the next round of specifications, and whether the Council is expecting that all existing data-poor and data-moderate assessments for such species would need to be re-modeled, with partitioning at the OR-CA border. This would require numerous new data-poor assessments, and potentially re-apportionment of catch limits for some other species. This workload could impact the number of other new assessments that could be conducted, and should be identified as a priority before other assignments are finalized.

Background Information Pertaining to Selection of Groundfish Stocks for Assessment in 2015.

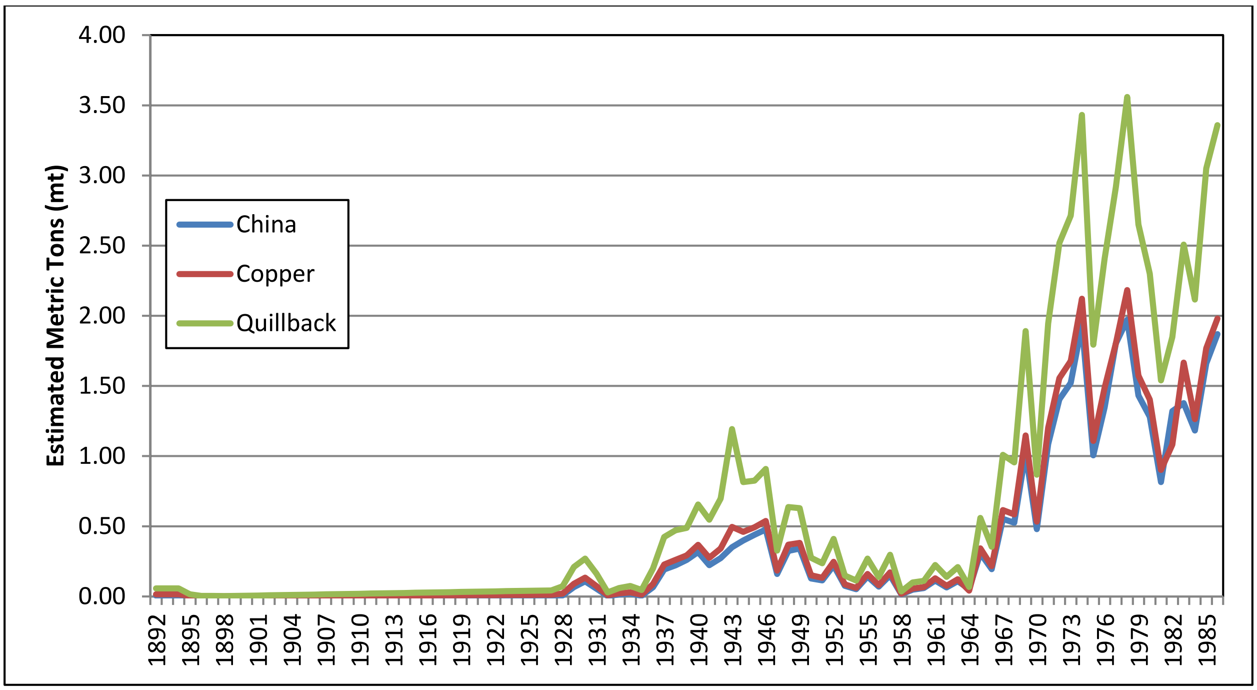
STOCK ASSESSMENT DATA AVAILABLE FOR KELP GREENLING, AND CHINA, COPPER AND QUILLBACK ROCKFISHES FOR THE 2015-16 STOCK ASSESSMENT CYCLE

This report details the Oregon Department of Fish and Wildlife (ODFW) data and information available for kelp greenling (*Hexagrammos decagrammus*), and china (*Sebastes nebulosus*), copper (*S. caurinus*) and quillback rockfishes (*S. malinger*). These data will help to inform decision makers as priorities are set for species assessments for the upcoming 2015-16 stock assessment cycle.

Commercial Data

Commercial catch: Most commercial catch of these species off Oregon is taken using hook and line gear types such as bottom longline, pole and line, or vertical longline. A relatively small amount is taken by trawl gear. Historical estimates of commercial catch are available for china, copper and quillback rockfishes in Oregon's commercial historical reconstruction (1892-1986; Karnowski et al. 2014; Figure 1). These estimates are based on several historical sources of data of large market categories to which species compositions are applied. These data are freely available from ODFW, in addition to an ODFW informational report (Karnowski et al. 2014) detailing the methodology that is available online[1]. There are no historical catch data available for kelp greenling in this reconstruction.

Figure 1: Oregon historical commercial catch reconstruction time series for china, copper and quillback rockfishes (1892 – 1986; Karnowski et al. 2014).



Contemporary commercial catches directly from ODFW are available via our fish ticket database (i.e. landing receipts), which feed directly into the Pacific Fisheries Information Network (PacFIN). These

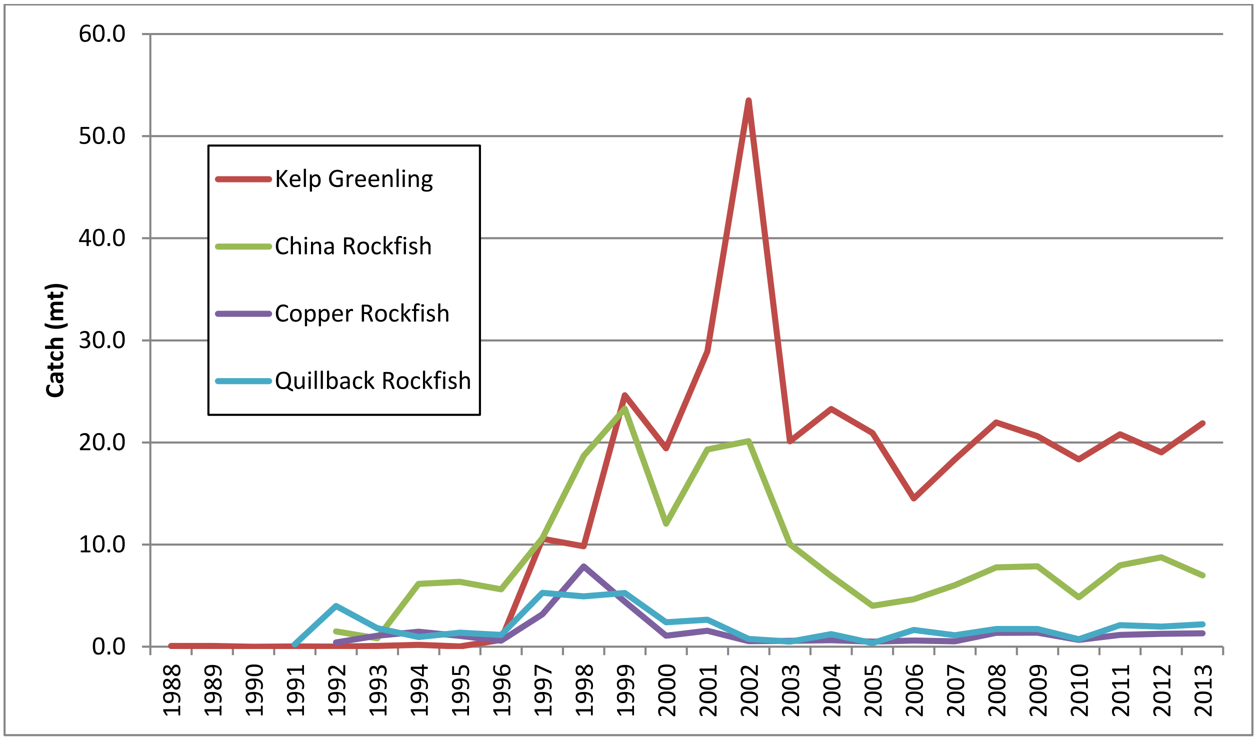
[1] http://www.dfw.state.or.us/MRP/publications/docs/ODFW_Info_Rpt%202014-02_Historic_Reconstruction_Oregon_Commercial_Fish_Landings.pdf

data are freely available to stock assessors, but ODFW staff can also assist assessors with obtaining PacFIN downloads or raw fish ticket information.

There are commercial landings available for kelp greenling from 1988 to present (Figure 2). In Oregon, kelp greenling are landed as part of a greenling market category that can include extremely minor amounts of rock greenling (*Hexagrammos lagocephalus*). Species compositions are routinely taken, but the market category is consistently > 99% kelp greenling. PacFIN does not allow for non-rockfish species compositions, but they are available directly from ODFW. Oregon greenling landings in PacFIN are also at the market category level (Greenlings; alpha code: KGL1).

There are PacFIN estimates of commercial landings for china and copper rockfish from 1992 to present and for quillback rockfish from 1991 to present (Figure 2). Prior to 1999, these three rockfishes were landed as part of the Other Rockfish market category (PacFIN alpha code: URCK; ODFW species code: 410) and from 2000 – 2007, they were landed as part of the Nearshore Rockfish market category (401). In 2008, the Nearshore Rockfish market category was separated into 11 individual nearshore rockfish species, including china, copper and quillback rockfishes, and these species have been recorded individually on fish tickets since that time. When the multi-species market categories were in place, species compositions were routinely collected by ODFW port biologists (Table 1; 1980-2013). In PacFIN, catch data for these three species prior to 2008 applies these species compositions to produce catch estimates by individual species. However, species compositions for fixed gear landings are sparse prior to 1991/1992 (Table 1), and the few that were taken did not contain any of the three species of interest. This leads to PacFIN estimates of zero catch for these species from 1981-1991/1992. On the other hand, the Karnowski et al. (2014) historical reconstruction used aggregated species composition and landing data from 1985-1993 to derive average proportions for each species in each market category, and applied these proportions to historical fixed gear catches to estimate species specific catches, including China, copper, and quillback rockfish. Methods similar to Karnowski et al. (2014) could be used to estimate catches for the time period which is not covered by the historical reconstruction and in which PacFIN estimates zero catch for these species. ODFW staff can assist with developing more exact methods for this application.

Figure 2: PacFIN commercial catch (mt) for china, copper and quillback rockfishes and kelp greenling (1988-2013).



Commercial discards: There are two potential sources of information for these four species, including the logbook program from the nearshore commercial groundfish fishery and the federal observer program, which observes this fishery as part of the observed fixed gear fleet. This fishery is a state-managed limited entry fishery that operates in nearshore waters and targets a variety of nearshore groundfish to supply primarily the live fish market. The limited entry permit program began in 2004. Annual logbook compliance in this fishery averages 85% (SD = 9.3%) from 2004 – 2013 and in recent years, has been greater than 95%. Data can be aggregated at the trip- or set-level and consist of pounds discarded (legal or sub-legal sized) by each of these four individual species. Additional work would be needed to evaluate the integrity of this data, as quality can depend on the species in question and a wide range of additional considerations. Though confidential, logbook data is available upon request from ODFW.

Additionally, the West Coast Groundfish Observer Program (WCGOP) observes the nearshore groundfish fishery as part of their non-catch share fishery observer program. From 2004 – 2011 (all years freely available), WCGOP observed an average of 7.6% of landings from the Oregon commercial nearshore fishery[2]. Annual summaries of the observed catch, discarded catch, and percent observed by species are available online[3] (Table 2). Disaggregated data are available to stock assessors directly from WCGOP.

[2] http://www.nwfsc.noaa.gov/research/divisions/fram/observation/data_products/sector_products.cfm

[3] http://www.nwfsc.noaa.gov/research/divisions/fram/observation/data_products/sector_products.cfm#obs

Commercial length/weight composition: ODFW port biologists routinely collect biological information from commercially landed catches throughout Oregon that include length, weight and age structures. These are commonly referred to as “market samples”. Length samples are available for china rockfish from 1995 – present, for quillback rockfish and kelp greenling for 1998 – present and for copper rockfish from 1999 – present (Table 3). Weights are available for copper and quillback rockfishes and kelp greenling from 2000 – present and for china rockfish in 1995 and 2000- present (Table 4). These data are available on request from ODFW or can be downloaded from PacFIN.

Commercial Ages: Table 5 shows the number of age structures collected for all available years for each species from market samples. Additionally, Table 6 shows those that have been aged and the percent of structures aged from the available years and overall. Most of the commercial catch is marketed live, which limits the number of age structures that can be obtained.

No market sample age structures from copper rockfish or kelp greenling have been aged, but most China rockfish and quillback rockfish structures have been aged. Age structures are also collected from the recreational fisheries and through special projects; however, the protocols for collecting samples from these programs differ from those collected as market samples. These samples are documented in later sections in this document.

Market samples also provide additional associated biological information, such as length and weights of landed fish, which would provide information on species- and Oregon- specific growth rates when combined with age structures.

Commercial CPUE: There are several sources available for commercial catch-per-unit-effort (CPUE) indices. The first potential source is the commercial nearshore fishery logbook program. As mentioned previously, this fishery is a state-managed fishery that operates in nearshore waters and targets a variety of nearshore groundfish. CPUE indices could be created using numbers of hooks, hours fishing, numbers of people, or combinations of these (e.g. hook-hours). These data could be aggregated at the trip- or set-level and consist of pounds landed by each of these four individual species. Additional work would be needed to evaluate the integrity of this data, as quality can depend on the species in question and a wide range of additional considerations. The second potential source is ODFW fish ticket data. These data would consist of catch per trip or per day. A final source would be the WCGOP, which observes the commercial nearshore groundfish fishery as part of their non-catch share fishery observer program. From 2004 – 2011 (all years freely available), WCGOP observed an average of 7.6% of landings from the Oregon commercial nearshore fishery[4]. Combinations of these data sources could also be a viable option for a CPUE index for any of these four species. For example, catch could be estimated from fish tickets and combined with an effort estimate from the nearshore logbooks.

Recreational Data

Recreational catch: Recreational catch estimates have been derived from at least three distinct sampling programs, which have varied in occurrence, sampling protocols, and estimation methods over time. The basis for catch estimates available from the Recreational Fishery Information Network (RecFIN) also vary over time (Table 7).The Oregon Recreational Boat Sampling (ORBS) has been collecting data on sport catch and effort since the late 1970s. These data are available from 1979 – present for all four species in various forms and represent ocean boat catches only. From 1979 to 1989, there are ORBS data available in numbers of fish by individual species (Figure 3). Since monitoring sport salmon catches is the primary focus of ORBS, data on other species during this early time period were aggregated to a set of five categories. All rockfish species were part of a generic “rockfish” category and kelp greenling were part

[4] [4] http://www.nwfsc.noaa.gov/research/divisions/fram/observation/data_products/sector_products.cfm

of a “miscellaneous” category. Data from these categories were separated by species using species composition data taken during the same time period, though potentially, these compositions were not taken methodically. The level at which species compositions were collected in ORBS has changed over the years. Figure 4 documents how trip type classifications and protocols for collecting species compositions have changed over time in ORBS. These data would need to be expanded to account for unsampled ports and time periods, but similar expansions have been developed for other species, including yelloweye rockfish (2009) and cabezon (2009) for other assessments. These data are only available by request from ODFW and are not available on RecFIN.

Figure 3: Numbers of fish (unexpanded) for kelp greenling, and china, copper and quillback rockfishes in legacy ORBS data.

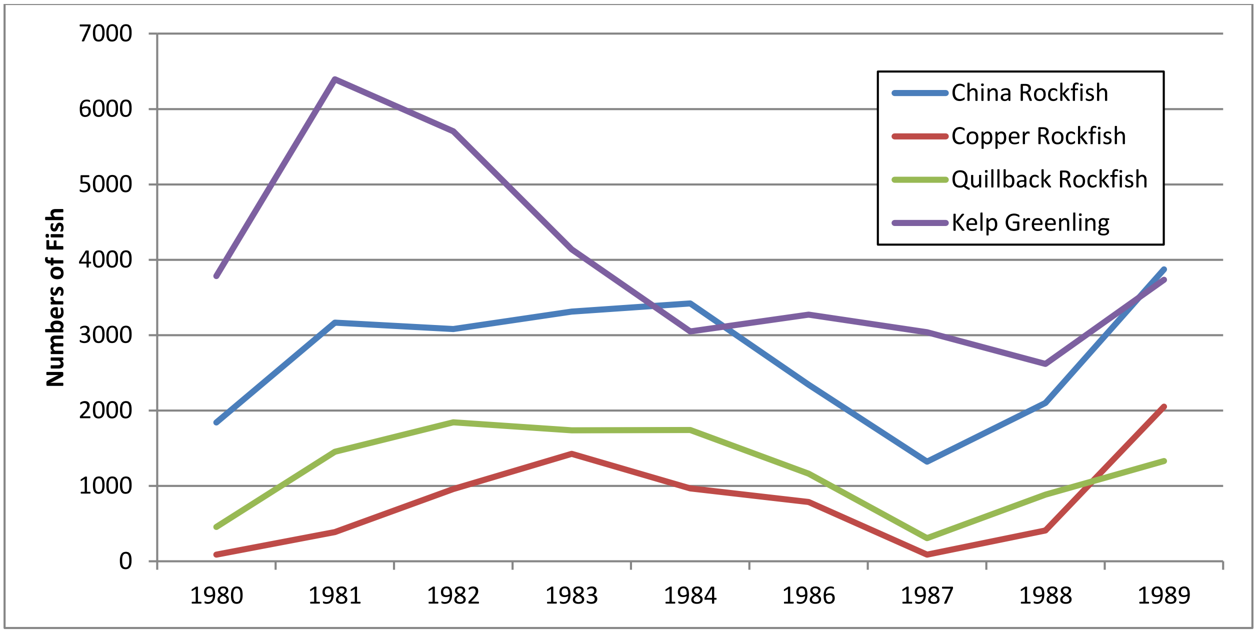


Figure 4: Timeline of bottomfish species composition collection and sampling, 1979 – present.

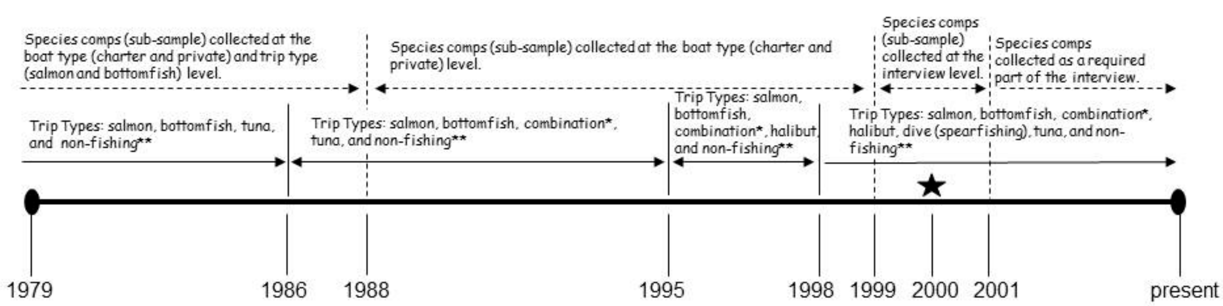


* From 1986-1994, the “combination” trip type was assigned only to charter trips that targeted both salmon and bottomfish. From 1995-1997, the “combination” trip type was assigned to both charter and private trips that targeted salmon and bottomfish. In 1998, the definition of “combination” was expanded to include any trip that targeted salmon and another species/species group (e.g. salmon/halibut, salmon/bottomfish, etc.)

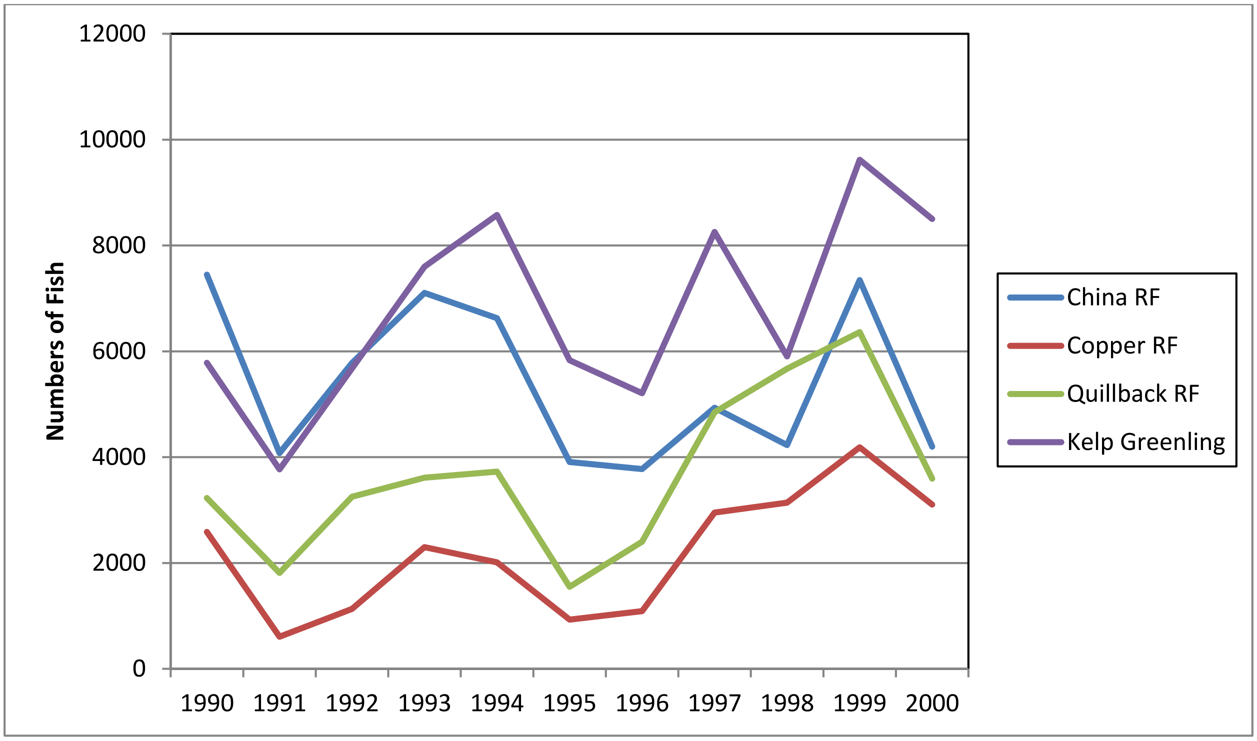
** From 1979-1998, dive trips on which anglers spearfished were included in the “non-fishing” trip type category.

★ From 1979-1999, information was collected on bottomfish catch only; no information was collected on released bottomfish. In 2000, samplers collected data on released lingcod and halibut. From 2001-present, samplers collect information on releases of all bottomfish.

There are also ORBS data from 1990 – 2000 with applied species compositions that are expanded for unsampled ports and times (Figure 5). These data constitute the ocean boat catches in RecFIN from 1993 to 2000 and consist of numbers of fish. It is unclear at this time why data from 1990-1992 were not included in the RecFIN database, but it is available directly from ODFW. From 1993 to present, all ocean boat mode data on RecFIN are from ORBS, and are available directly from RecFIN or from ODFW.

To convert numbers of fish to biomass, measurements of fish weights are needed. These sources are discussed in another section below. For the yelloweye rockfish and cabezon assessments, average weights from RecFIN were used, in addition to internal ODFW sources, such as ORBS or from specific special projects.

Figure 5: Numbers of fish (expanded for unsampled ports and times) for kelp greenling, and china, copper and quillback rockfishes in legacy ORBS data. Data shown from 1993-2000 are available on RecFIN.



ORBS data represent ocean boat data (charter and private) only. There are data on other fishing modes from the Marine Recreational Fisheries Statistics Survey (MRFSS), available on RecFIN from 1980 – 2003. These modes include several shore based categories, including "man-made" and "beach/bank", or a combined "shore modes". From 1980 to 1989, recreational ocean boat catches are also from MRFSS. There are no data on RecFIN from 1990-1992. Annual catch estimates for MRFSS shore modes are sporadic for both china and quillback rockfish (non-zero catch estimates in five years and six years between 1980 and 2003, respectively), but are more consistent for copper rockfish (non-zero catch estimates in 19 years between 1980 and 2003). There are non-zero kelp greenling catch estimates for MRFSS shore modes for all years between 1980 and 2003. However, ODFW cautions that the kelp greenling estimates may be inflated and are working to find alternative data sources to document shore-side catches.

There are also shore-based catch data available from the Shore and Estuary Boat Survey (SEBS) from mid-2003 to mid-2005. This survey was an extension of the MRFSS protocols with a few minor changes.

Catch estimates are available on RecFIN. There are no recent estimates of shore-based catches after SEBS was terminated in 2005. There are no catch estimates for china rockfish in SEBS, but the other three species are available.

Recreational discard: There are MRFSS estimates for discarded catch available on RecFIN from 1980 – 2000. For selected fishing modes, china rockfish discards are available from 1980 – 1989, quillback rockfish discards are available in 1982 and 1984 and copper rockfish for 1980-1982, 1987 and 2002. Kelp greenling discards are available from 1980 – 2003.

ORBS has also been collecting information on discarded fish since 2001 (Table 8). These data consist of numbers of fish discarded and are collected when anglers are interviewed dockside. These data are also expanded for unsampled days using boat counts in each sampled port. The expanded data are available on RecFIN from 2001 to present.

An additional source of recreational discards includes the State Sport Observer (SSO) program, which the ODFW maintains as a state program to observe on-board activity of the charter boat (CPFV) fleet. The SSO program was initiated as a pilot program in 2001, and became a permanent program in 2003. Recently, staff from ODFW and the Southwest Fishery Science Center developed a relational database with the data collected in this program (Monk et al. 2013). These data are confidential but available by request through the ODFW. Data are aggregated at the drift- or trip-level and consist of numbers of discarded fish by individual species (Table 9).

Recreational length/weight composition: MRFSS has annual average lengths and weights for all four species on RecFIN from 1980 – 1989, though not for each mode for all those years.

ORBS subsamples recreational catch to obtain biological data, such as length, weight, sex (when applicable) and scans for various types of tags. Average lengths and weights from 1993 to present in RecFIN are based on ORBS data. The number of length and associated weight samples for each of the four species from ORBS is available in Table 10 (2001-2014). ODFW notes that the average lengths and weights available on RecFIN are different than those based on the raw data because of the post-processing protocols that RecFIN applies to those data.

Limited information is available on discard lengths from the SSO database. Lengths are only collected on discarded fish, but can be compared to retained catch length compositions recorded by the ORBS program. Initially, observers measured as many discarded fish as possible (2003-2009) but more recently, as many as possible were measured but no more than 10 fish per drift (2010 – present). Samples are very limited for all three of the rockfish species (n = 41 for all three), but samples are slightly higher for kelp greenling (n = 81). Minimum size limits for kelp greenling have been in place in the recreational fishery since 2004. Fish weights (W) are calculated in the database using fork length (L; equation: $W = aL^b$), but are not directly measured at sea.

Recreational Ages: Age structures are collected from recreational fisheries routinely, but the majority of structures collected from these species have not been aged. There have been recreational structures collected for all four species from 1998 to present (Table 11). There were some kelp greenling samples aged from the majority of those years, but the three rockfishes were only aged in a relatively small number of years (Tables 12 and 13). These recreational samples also provide additional associated biological information, such as length and weights of fish, which would provide information on species- and Oregon- specific growth rates when combined with age structures.

Recreational CPUE: There are effort data available from ORBS from 1986 to 2000 in numbers of trips and anglers. These data are also expanded to account for unsampled times in the sampled ports. However, these data have not yet been disaggregated to the species-level, and are currently only available at the category levels mentioned previously (e.g. rockfish and miscellaneous).

From 2001 to present, ORBS has effort estimates of numbers of boats and anglers. Angler effort is estimated from the interview and boat counts are obtained through a camera network in the major ports. ORBS also collects information on hours fished during interviews; however, this can be a misleading estimate of time actually spent bottomfishing, as trips are often combinations of several types of fishing and crabbing.

Additionally, there are effort data from the MRFSS and SEBS programs available (1980 – 2005, collectively). Interview-level data, which contains estimates of catch per angler, can be requested directly from RecFIN.

The SSO database also contains information on effort of the recreational charter fleet (Monk et al. 2013). These data can be aggregated at the trip- or drift-level, depending on the type of effort measurement, and consist of number of observed anglers, drift hours, and some information on gear at the trip level, including number of hooks. As part of the Council's "data-moderate" assessment process, CPUE indices for copper and china rockfish have been developed from this data.

Special Project and Research Biological Data

Length, weight, age structures and other biological data are often collected by ODFW for "special projects" and research. Special project samples are typically fishery samples collected in a manner similar to commercial market samples or recreational age samples. They may represent targeted sampling for a specific purpose (e.g., estimating maturity curves, see next paragraph), or samples that did not meet standard protocols for any number of reasons. Depending on how they were collected, a number of these samples may be integrated with standard fishery samples, especially where sample size is lacking. These samples are often associated with additional material such as maturity status, gonad samples, or tissue samples. The same types of information are also collected during targeted, fishery independent research projects which often mimic commercial or recreational fishing practices. Tables 14, 15, 16, 17, and 18 tabulate the number of available lengths, weights, age structures, ages, and percent of structures aged respectively by species and source for special project and research samples. Samples designated as from an unknown source are typically fishery samples that lack a record of whether they were collected from a recreational or commercial fishery.

Maturity Information

In 2011, ODFW staff published a report that detailed age- and length-at-maturity data for quillback rockfish and length-at-maturity for china rockfish (Hannah and Blume 2011). Additionally, in 2014, ODFW staff published a report that detailed age- and length-at-maturity for copper rockfish (Hannah 2014). These data are based on histological evaluation of ovaries, generally considered more reliable than macroscopic evaluation. Samples were collected from recreational landings on the central Oregon coast.

ODFW efforts continue to evaluate length- and age-at-maturity for kelp greenling in Oregon waters. A recent review of available maturity samples revealed a critical data gap for kelp greenling less than 25 centimeters. In 2013, efforts to collect fish through fishing, beach seining and trapping have yielded new samples in the appropriate size range that are currently being processed. Additional sampling efforts are anticipated in 2014.

Regulations

Management and regulation changes over time dramatically impact the context in which fishery-dependent data is viewed. ODFW has compiled information on regulation and major management changes over time for both commercial and recreational groundfish fisheries in a database format. The SSO database contains a table with all relevant sport regulations from 2001-2010. These are available to assessors upon request.

New Black Rockfish Assessment Data

All of the Oregon data sources utilized in the 2007 assessment are available with updated information. This includes additional catch, biological (length, weight and age) and tagging data. Additionally, black rockfish landings are estimated in the commercial historical reconstruction (1892 – 1986). More details on how the historical catch estimates were developed are available in Karnowski et al. 2014.

Agenda Item F.8.b
Supplemental CPSMT Report
June 2014

COASTAL PELAGIC SPECIES MANAGEMENT TEAM REPORT ON INITIAL STOCK ASSESSMENT PLANS AND TERMS OF REFERENCE (TOR) FOR GROUNDFISH AND COASTAL PELAGIC SPECIES

The Coastal Pelagic Species Management Team (CPSMT) reviewed the recommended changes to the Groundfish/CPS Stock Assessment Terms of Reference (Attachment 5, Agenda Item F.8.a), and supports the changes listed.

The CPSMT recognizes that catch-only projections do not include data other than recent catch and that factors such as recruitment are relevant in adequately projecting stock biomass. The CPSMT requests clarification of expectations for catch-only population projections with regards to recruitment assumptions, and is willing to work with the Scientific and Statistical Committee (SSC) and CPS Stock Assessment Teams (STAT) to develop appropriate guidelines in the Terms of Reference.

The CPSMT agrees with CPS STAT members that a proposed change to the deadline for CPS stock assessment drafts to three weeks ahead of Stock Assessment Review Panel review meetings is unnecessary for CPS assessments. The draft groundfish stock assessments go through a pre-review process, necessitating the three-week deadline. This rationale does not apply to CPS assessments, given the smaller number of assessments and STAT members, as compared to groundfish.

PFMC
06/23/14

GROUNDFISH ADVISORY SUBPANEL REPORT ON INITIAL STOCK ASSESSMENT PLANS & TERMS OF REFERENCE (TOR) FOR GROUNDFISH AND COASTAL PELAGIC SPECIES

The Groundfish Advisory Subpanel (GAP) discussed with Dr. Ian Taylor stock assessment planning for 2015 and wishes to recommend the following for Council consideration.

Full Assessments

The GAP agrees with the Science and Statistical Committee's (SSC) recommendations and supports doing full assessments for the following stocks in 2015:

Black rockfish
Bocaccio
Canary rockfish
Darkblotched rockfish
Widow rockfish
China rockfish

Black rockfish is a very important stock for the nearshore sectors and the 2007 assessment is now considered out of date.

The 2013 bocaccio assessment projected the stock would be rebuilt at the start of 2015. The SSC recommends a full assessment be conducted in 2015 to confirm that prediction.

Canary rockfish is a very important stock coastwide for all groundfish sectors, and the last full assessment was conducted in 2007. The Northwest Fisheries Science Center also invested a considerable amount of effort this winter organizing the data that would inform a new assessment.

The 2013 darkblotched assessment projected the stock would be rebuilt at the start of 2015. The SSC recommends a full assessment be conducted in 2015 to confirm that prediction.

The 2011 widow rockfish assessment was highly uncertain and there were many issues that could not be resolved in the 2011 assessment review process (the 2011 assessment was further reviewed at the September 2011 mop-up panel). The GAP supports increasing midwater trawl fishing opportunities for widow and yellowtail rockfish and a new, fully vetted assessment will reduce risks and likely increase available yields for future fishing opportunities.

The GAP recommends conducting a full assessment of China rockfish in 2015. There were many issues in the data-moderate assessment for the population north of 40º10' N. lat. and the GAP recommends a full assessment that would allow the incorporation of composition data and a more thorough vetting of data and modeling issues than could be done in a very busy 2013 data-moderate assessment review panel.

The GAP also recommends conducting a new full assessment for cowcod. There is great uncertainty in the recent 2013 assessment and new data, including a new remotely operated vehicle (ROV) survey in the Cowcod Conservation Areas, may better inform a cowcod assessment.

The GAP recommends conducting a full assessment for kelp greenling. This is an important species for the nearshore fishing sectors. Further, the 2005 assessment of the Oregon population of kelp greenling is now considered flawed, given the Marine Recreational Fisheries Statistical Survey catch data informing the assessment and other data issues discussed during the 2005 assessment review process.

Data-Moderate Assessments

The GAP recommends conducting data-moderate stock assessments for the following four species:

Arrowtooth flounder
Bank rockfish
Quillback rockfish
Blue rockfish

Arrowtooth flounder was last assessed in 2007 and that assessment is now considered out of date. The biomass projections from that assessment, which were largely influenced by the strong 1999 year class, predicted a steep decline despite evidence in the trawl survey and in trawl catches that stock abundance is increasing at a great rate. Projected overfishing limits (OFLs) from the 2007 assessment are now getting so low that annual quotas for arrowtooth are changing trawl fishery distribution to avoid arrowtooth effectively turning this abundant stock into a constraining species.

Bank rockfish was last assessed in 2000 and is so out of date that data-poor methods (DB-SRA) are used to determine OFLs. With the Council action to reduce targeting of blackgill rockfish in southern California, this is an increasingly important target stock and should use more robust methods to determine status and OFLs.

Quillback rockfish is now one of the most vulnerable unassessed stocks to potential overfishing according to the Groundfish Management Team's Productivity and Susceptibility Assessment. This is an important stock for nearshore fisheries north of 40º10' N lat. and should be assessed.

Blue rockfish was last assessed in 2007, and that assessment is now considered out of date. The stock is an important one for nearshore fisheries off California and Oregon, and should be assessed.

Update Assessments

The GAP recommends conducting update assessments for the following species:

Petrale sole
Sablefish
Chilipepper rockfish

The 2013 petrale sole assessment projected the stock would be rebuilt by the start of 2014. The SSC recommends a 2015 assessment to confirm that result. Further, full assessments have been conducted in the last three consecutive assessment cycles for petrale sole, and the SSC recommends an update assessment to confirm its rebuilt status.

Sablefish is the most valuable stock to the west coast groundfish fishery on a per pound basis. The 2011 assessment was a very thorough one that predicted the 2008 and 2010 year classes recruiting into the fishery were above average. The SSC recommends the next assessment of sablefish could be an update, and the GAP recommends one be conducted to better estimate these incoming year classes.

The GAP recommends an update assessment of chilipepper rockfish be done since the 2007 assessment is now considered out of date. Further, the Southwest Fisheries Science Center expressed an interest in doing an update assessment of chilipepper and the GAP agrees.

Catch Reports

Lastly, the GAP is recommending providing catch reports for Pacific ocean perch and yelloweye rockfish in 2015 to evaluate management performance relative to staying within prescribed annual catch limits for these overfished stocks. The SSC recommended continuing to produce catch reports for these two stocks until data that can inform new assessments for these slow-growing stocks becomes available.

Summary of GAP Recommendations:

Full assessments:

1) **Black rockfish**
2) **Bocaccio**
3) **Canary rockfish**
4) **Darkblotched Rockfish**
5) **Widow rockfish**
6) **China rockfish**
7) **Cowcod**
8) **Kelp greenling**

Data moderate assessments:

1) **Arrowtooth flounder**
2) **Bank rockfish**
3) **Quillback rockfish**
4) **Blue rockfish**

Update assessments:

1) **Petrale sole**
2) **Sablefish**
3) **Chilipepper rockfish**

Catch reports:

1) **POP**
2) **Yelloweye rockfish**

Agenda Item F.8.b
Supplemental GMT Report
June 2014

GROUNDFISH MANAGEMENT TEAM REPORT ON INITIAL STOCK ASSESSMENT PLANS AND TERMS OF REFERENCE (TOR) FOR GROUNDFISH AND COASTAL PELAGIC SPECIES

The Groundfish Management Team (GMT) considered issues pertaining to the planning of 2015 stock assessments, to inform the 2017-2018 management cycle.

The National Marine Fisheries Service (NMFS) Northwest Fisheries Science Center (NWFSC) provided a report on prioritization of species in Agenda Item F.8.b, NWFSC Report. This report includes a mix of rebuilding species, species in need of updated assessments, and possible data reports. The report also discusses that if another data moderate stock assessment review (STAR) panel is done, that it cover fewer species than what was attempted in 2013.

Terms of Reference

It is the GMT's understanding that the Scientific and Statistical Committee (SSC) is going to review and comment on the terms of reference (TOR) documents over the summer, in time for inclusion in the September Council meeting advanced briefing book (Agenda Item F.8.b., Supplemental SSC Report). Therefore, the GMT is delaying our specific comments on the contents of the TORs until we are able to review the SSC's recommendations in September.

Data used in assessments

We would like to see at least an informal method developed for considering trans-boundary stocks across their entire range. For example, many of our rockfish stocks' ranges extend well up into British Columbia and Alaska or down into Mexico. Taking into account what is known about biomass and stock structure throughout a species' range could improve our assessments off the west coast.

Data-limited methods

The GMT discussed the need to explore available data in detail well in advance. In the last round of data-limited assessments we saw that if there is very little fishery-independent or fishery-dependent data, then any assessment model will result in low biomass estimates. Likewise, there were questions about stratification and the effect of management on stock dynamics that were not explored as thoroughly as they could have been prior to STAR Panels. The GMT suggests that we should be working with the Science Centers and the states to better explore this prior to the next round of assessments (i.e. meetings of GMT STAR representative with assessor well in advance of the Panel meeting).

Stocks to be assessed in 2015

The GMT understands that which stocks to assess is ultimately the decision of the NWFSC based on input from the Council, available resources, and other logistical factors. Given the limited time available at this meeting, we did not seek to recreate a full list of planned assessments or to prioritize any of our recommendations, but offer considerations on select species to inform prioritizing assessments. These recommendations are summarized in Table 1 below, along with the recommendations from the NWFSC report in Table 2 and Table 3. There are several concerns that have been raised with the data moderate assessments for nearshore species. The GMT suggests that China rockfish is a strong candidate for a full assessment. It is unclear whether there is enough data to move from a data moderate to a full assessment, but regardless, we would like to see one of the STAR panels dedicated to resolving the issues identified with China rockfish (i.e. even if it is still a data moderate assessment, similar to cowcod). Kelp greenling is another species that would benefit from a full assessment. While new data collection efforts off Washington will not provide information for this assessment cycle, there are also available data from Oregon (Agenda Item F.8.b, ODFW Report) for kelp greenling and other nearshore species. The GMT recommends that at least one STAR Panel be dedicated to China rockfish and kelp greenling.

The GMT discussed other nearshore species that might also be high priorities for assessment. While all nearshore species suffer from lack of a fishery-independent index, making full assessments difficult, some on the GMT would like to see quillback rockfish prioritized as a full assessment and gopher and olive rockfish prioritized at least for a data moderate assessment. Further, as mentioned above in the section on data-moderate methods, some on the GMT would like to see further exploration of all available catch per unit of effort data (e.g. California private boat data, Oregon commercial logbook data, etc.) particularly for nearshore species.

Some GMT members would also like to see sablefish prioritized as a full assessment. Sablefish is a valuable stock that has been in the precautionary zone for a considerable time. The Council has reduced its P* to try to speed recovery of the stock in addition to the 40-10 reductions to harvest. While the last sablefish assessment was one of the most thorough that has been done for the stock, it was conducted in 2011. There may be some risk of "wasting" a STAR Panel slot on what would essentially be an update, but some on the GMT argue that the stock is important enough and has been in the precautionary zone long enough to warrant a close look at the new data and assumptions going into the assessment.

Further, some on the GMT think that rougheye is a priority for full assessment. There were a number of issues identified in the last assessment, and major management changes are being implemented based on the estimated biomass compared to current catch. Staff at the Washington Department of Fish and Wildlife have also identified a number of otoliths that are newly available for ageing. There were a number of other data weighting questions that were identified for a workshop that did not happen. Some on the GMT would also like to see exploration of methods to split blackspotted rockfish out to raise this from a Category 2 to a Category 1 assessment.

Some on the GMT would like to explore whether there is information available for a data moderate assessment of shortraker rockfish. Likewise, there is some interest in looking at vermilion rockfish and exploring questions of stock structure and differentiating it from similar species (i.e. sunset rockfish). Current harvest specifications do not account for the fact that vermilion has been confused with a very similar looking species, sunset rockfish (*Sebastes crocotulus*) south of Point Conception. This continues to make assessment south of Conception challenging, but a new assessment focused on the area north of Point Conception could improve the harvest specification for vermilion.

It is our understanding that lingcod is prioritized by the Science Center in part because there may be students available to contribute to those assessments. The GMT disagrees that this is a priority given the higher priorities listed above. This stock has been recently assessed, is rebuilt, and depletion is well above 40 percent in both regions. Attainment has been well below the annual catch limit, making assessment a low priority from a management perspective. In addition, the Council is considering opening the lingcod fishery during the winter months for the first time in many years, beginning in January 2015 (under Agenda Item F.7). If the winter lingcod fishery is opened in 2015, very limited, if any, information will be available to inform how the change in fishing season might be affecting the lingcod stock if the assessment is done in 2015.

Finally, the GMT would like to see catch reports expanded to provide the error (i.e. the standard deviation) around catch projections for rebuilding species.

Table 1. GMT suggestions on stock assessments that could be prioritized for 2015 and that differ from the NWFSC priorities.

Full	Update	Data Moderate	Data Report
kelp greenling [a]		gopher rockfish	
China rockfish [a]		olive rockfish

Initial Stock Assessment Plans For 2015

Dr. James Hastie

Overview

- Four 'Full' STAR Panels
  - May not be able to do 8 different species, if some have several models for evaluation
  - Nearshore indices more difficult/complex than from surveys
- Up to 3 Updated assessments
- One STAR with Data-Moderate assessments for 3 species
  - Multiple regions and modeling platforms
- The SSC has suggested a new approach for an integrated suite of modeling alternatives for some species
- Options in Briefing Book have been narrowed to reflect SSC and GAP comments

Revised 2015 Stock Assessment Candidates

Key					
(green)	Higher Priority	X	Recommended	(pink)	Constraining (& not ranked in top-30)
(yellow)	Lower Priority	x	Potential	(orange)	From prior Data-Poor assessment

Conclusion

- Early identification of species for Full assessments is important for prioritizing ageing activities
- More consideration of workload and data availability will follow June Council guidance
- Work with SSC to scope out planning for Assessment & Review of nearshore species like China Rockfish
  - Where efforts to develop full models for all areas may not be successful
- Important for assessment authors to know how their species are likely to be managed (geographically)

Agenda Item F.8.b
Supplemental SSC Report
June 2014

SCIENTIFIC AND STATISTICAL COMMITTEE REPORT ON INITIAL STOCK ASSESSMENT PLANS AND TERMS OF REFERENCE (TOR) FOR GROUNDFISH AND COASTAL PELAGIC SPECIES

The Scientific and Statistical Committee (SSC) reviewed the documents associated with stock assessment planning, focusing in particular on the Northwest Fisheries Science Center (NWFSC) Report (Agenda Item F.8.b, NWFSC Report) and the set of draft Terms of Reference documents for: the Groundfish and Coastal Pelagic Species Stock Assessment and Review Process (Agenda Item F.8.a, Attachment 2); Groundfish Rebuilding Analyses (Agenda Item F.8.a, Attachment 3); and the Methodology Review Process for Groundfish and Coastal Pelagic Species (Agenda Item F.8.a, Attachment 4).

Stock Assessment Planning

Dr. Owen Hamel (NWFSC) summarized the information in the NWFSC Report. The SSC is in general agreement with the NWFSC regarding which stocks should receive full or update assessments during 2015.

The SSC recommends the following stocks for full assessments:

- bocaccio rockfish (overfished and projected to be almost rebuilt);
- darkblotched rockfish (overfished and projected to be almost rebuilt);
- canary rockfish (overfished and not fully assessed since 2007);
- black rockfish (not fully assessed since 2007);
- widow rockfish (fully assessed in 2011 and subject to relatively high uncertainty); and
- China rockfish (never fully assessed, data-moderate assessment in 2013).

Given the STAR Panel process during 2015 could accommodate reviews of eight full stock assessments, it is reasonable to consider one or two additional stocks for full assessments. Only one additional full assessment could be reviewed if black rockfish is assessed as separate northern and southern stocks by separate stock assessment teams, as occurred in 2007. Otherwise, two additional full assessments could be reviewed.

The NWFSC Report identifies 10 stocks that could be considered as lower priority candidates for full stock assessments during 2015 (chilipepper, China, quillback and yelloweye rockfish, cowcod, kelp greenling, lingcod, Pacific ocean perch, petrale sole, and sablefish). The SSC did not come to a strong unified opinion regarding which of these stocks should be given highest priority for a full assessment, other than China rockfish. However, there were arguments made in support of full assessments for sablefish, rougheye rockfish, yelloweye rockfish, and kelp greenling. The SSC notes that the last assessment for kelp greenling used a catch series that is now considered to be incorrect.

It is likely that a mix of methods will be needed to assess some stocks. For example, a full age-structured model could be applied to that geographic portion of a stock's range for which age-composition data are available, and a data-moderate assessment could be developed for the remaining geographic portion. Such an approach might be sensible for nearshore species such as

China rockfish or kelp greenling, for which reasonable age-composition data sets are available for Oregon and not for the other states. Species being assessed using multiple assessment methods should be reviewed at a single STAR Panel.

The SSC supports the NWFSC Report recommendation that petrale sole receive an update assessment during 2015. The SSC recommends that sablefish be an update assessment during 2015 if this stock does not receive a full assessment.

The SSC also supports the NWFSC Report recommendation that the data-moderate STAR Panel should review assessments for no more than four species. It is likely that each species will require assessment models for multiple geographic regions. Furthermore, each species and region will need to be assessed using the two types of data-moderate assessment models (XDB-SRA and exSSS).

Terms of Reference Documents

The SSC reviewed the set of draft Terms of Reference documents for the 2015-16 biennial cycle, Attachments 2-4. Attachment 2 includes revisions to make the Terms of Reference consistent with new National Standard 2 Guidelines regarding standards for peer review. Other than those changes, the draft Terms of Reference documents are essentially unmodified versions of the Terms of Reference approved by the Council during 2012 for the last stock assessment cycle. A number of changes to the draft Terms of Reference documents were suggested and discussed. The SSC's Groundfish and CPS Subcommittees will work during the summer to develop a set of revised Terms of Reference documents that indicate all the suggested changes. These revised documents will be available in the September Council Briefing Book for review by the Council and its advisory bodies.

Agenda Item F.9
Situation Summary
June 2014

OMNIBUS REGULATION CHANGES PART II

Under Agenda Item F.3 the Council is slated to have developed an initial list of candidate management measures. During the Council meeting week other management measures candidates may have arisen, particularly under the Fixed Gear Sablefish Catch Share Program Review (Agenda Item F.6). Under this agenda item, the Council is slated to add to the list any additional candidates that may have arisen during the week and finalize the list of candidates. Additionally, the Council may wish to provide guidance with respect to those items on which it would like the most background information provided at the September Council meeting.

Council Task:

1. Finalize list of management measure candidates including those that may have arisen during the week.
2. Provide guidance of level of background detail desired for the September prioritization package.

Reference Materials:

None.

Agenda Order:

a. Agenda Item Overview — Jim Seger and Kelly Ames
b. Reports and Comments of Advisory Bodies and Management Entities
c. Public Comment
d. **Council Action**: Identify Management Measure Candidates and Provide Guidance on Analysis Needed for Final Prioritization at the September Council Meeting

PFMC
5/29/14

UPDATED COMPILATION OF POSSIBLE GROUNDFISH MANAGEMENT MEASURES FOR COUNCIL CONSIDERATION

This document provides the initial unprioritized list of potential management measure topics, updated based on Council action taken under F.3 and other agenda items at the June 2014 meeting. Items added to the list during the meeting are shaded.

Acronyms and abbreviations used in the following table:

COP – Council Operating Procedure
CP – Catcher Processor
IFQ – Individual Fishing Quota
LEFG – Limited Entry Fixed Gear
MS – Mothership
OA – Open Access
QP – Quota Pounds
QS – Quota Shares
Rec – Recreational
TOR – Terms of Reference
VMS – Vessel Monitoring System

Table 1. Unprioritized list of groundfish related workload items and initial candidate groundfish management measures grouped by category and sector.

	Sector	**Short Title**	
A. Items on Which Council Action Has Been Completed Which Still Entail Some Workload[1]			
1.	Trawl, Non-Trawl, Rec	2015-2016 Harvest Specifications and Management Measures and Amendment 24 (June 2014)	
2.	Trawl and Non-Trawl	Seabird Rule - Mandatory Streamers for vessels ≥ 55’	
3.	Trawl and Non-Trawl	Clarify Catch Accounting Rules for Amendment 21	
4.	Trawl and Non-Trawl	Fishery Declaration Enhancements	
5.	Trawl IFQ, MS, & CP	Cost Recovery Corrections	
6.	Trawl IFQ & MS	Electronic Monitoring Exempted Fishing Permits (if final in June 2014)	
7.	Trawl IFQ & MS	Pacific Dawn Lawsuit Appeal to District Court (Whiting Allocation)	
8.	Trawl IFQ & MS	Whiting Cleanup Rule, Including Maximized Retention Regulations	
9.	Trawl CP	Glacier Fish Co Lawsuit (Cost Recovery)	
10.	Trawl IFQ	Joint Registration and Prohibition of Processing IFQ Sablefish	
11.	Trawl IFQ	Move Shorebased Whiting Season Opening Dates	
12.	Trawl IFQ	Continue Adaptive Management Program Pass-Through	
13.	Trawl IFQ	Update eTicket for Web-based Submissions	
14.	Trawl IFQ	Rule for Forfeitures for Exceeding Aggregate NonWhiting Control Limit	
15.	LEFG	Revise Limited Entry Fixed Gear Permit Control Rule (If Recommended)	
16.	LEFG and OA	Require E-Tickets for Sablefish Landings (If Recommended)	
17.	LEFG and OA	Sablefish North of 36 Degrees - Allocation Correction	
18.	LEFG and OA	Logbooks for Fixed Gear	
19.	OA	Amendment 22 - Open Access License Limitation	

[1] This list includes actions anticipated at the June 2014 meeting. Workload primarily involves NMFS and Council staff, however GMT and state staffs may be involved. Several items in this category are also covered under Agenda Item F.1.b, NMFS Report.

	Sector	Short Title	
B. Immediate and Long-Term Commitments			
Currently on the Year at a Glance Schedule (See Agenda Item C.6.a, Attachment 1)			
20.	Trawl, Non-Trawl, Rec	Inseason Management (Sept 2014 and beyond, excluding March 2015)	
21.	Trawl, Non-Trawl, Rec	Adopt Final Stock Assessment Plan and TOR for 2015 (Sept 2014)	
22.	Trawl, Non-Trawl, Rec	Develop a COP for Groundfish Methodology Review Process (Sept and Nov 2014)	
23.	Trawl, Non-Trawl, Rec	Omnibus Regulations Changes (Sept and Nov 2014, Mar-June 2015)	
24.	Trawl, Non-Trawl, Rec	Essential Fish Habitat: Phase 3 of the 5 Year Review (Sept 2014)	
25.	Trawl, Non-Trawl, Rec	Amendment 25: Comprehensive Ecosystem-Based Amendment (Sept 2014 and Mar 2015)[2]	
26.	Trawl, Non-Trawl, Rec	2015 Pacific Halibut Catch Sharing Plan (Sept and Nov 2014)[3]	
27.	Trawl, Non-Trawl, Rec	2015 Incidental Regulations for Pacific Halibut (Mar and Apr 2015)3	
28.	Trawl, Non-trawl, Rec	Stock Assessments for 2017-2018 Biennium (June 2015)	
29.	Trawl, Non-Trawl, Rec	Start of the Process to Establish 2017-2018 Specifications and Regulations (June 2015)	
30.	Trawl IFQ & MS	Electronic Monitoring Regulations (Sept 2014, June 2015)	
31.	Non-Trawl	Discard mortality rates for nearshore fisheries (GMT - #1)	
Items on the Horizon			
32.	Trawl IFQ, MS, & CP	Five Year Review (Starts in 2016)	
33.	Trawl IFQ	QS/QP Control Rule - Safe Harbor for Risk Pools - post 5-year review	
34.	Trawl IFQ	Resolve Long-term Whiting Surplus Carryover Provision - post 5-year review	
C. Candidate Items for Prioritization in September			
35.	Trawl, Non-Trawl, Rec	Rebuilding Revision Rules (signal vs. noise)	
36.	Trawl, Non-Trawl, Rec	Further Consideration for Reorganizing Stock Complexes	
37.	Trawl and Non-Trawl	Groundfish Conservation Areas for Rougheye Rockfish	
38.	Trawl and Non-Trawl	New Dressed to Round Conversion Factors for Sablefish	
39.	Trawl and Non-Trawl	Increase VMS Ping Rates	
40.	Trawl and Non-Trawl (LE)	Eliminate Permit Size Endorsements	
41.	Trawl and Non-Trawl	Seabird Avoidance Devices for Vessels less than 55 feet	
42.	Trawl IFQ, MS & CP	Revise Length of Time Required for the Trawl Fleet to Retain Records	
43.	Trawl IFQ (& MS &CP?)	Fishery Declaration Enhancements (With Gear Stowed and Testing Gear)	
44.	Trawl IFQ, MS & CP	Year Round Whiting Season and Other Modifications	
45.	Trawl IFQ, MS & CP	Revise Regulations on At-Sea and Shoreside Flow Scales	

[2] Scheduled to occur under an Ecosystem agenda item but involves amending the groundfish Fishery Management Plan and groundfish staff.
[3] Scheduled to occur under a Pacific halibut agenda item but may involve groundfish considerations and/or staff that also work on groundfish.

	Sector	Short Title	
46.	Trawl IFQ	Gear Use - Multiple Gears Onboard and Use	
47.	Trawl IFQ and LE Pot	Remove Certain Area-Management Restrictions	
48.	Trawl IFQ	Remove Certain Restrictions on Trawl Gear Configuration	
49.	Trawl IFQ	Resolve Long-term Non-Whiting Surplus Carryover Provision	
50.	Trawl IFQ	Carryover when Management Units Change	
51.	Trawl IFQ	Allow Trading of Previous Year Quota Pounds in Current Year	
52.	Trawl IFQ	Widow Rockfish QS Reallocation	
53.	Trawl IFQ	Discard Survival Credit for Lingcod and Sablefish	
54.	Trawl IFQ	Require Posting of First Receiver Site Licenses

66.	Trawl, Non-Trawl, Rec	Create 60-Mile Bank RCA Lines (GAP – #2)	
67.	Trawl, Non-Trawl	Correct Blackgill Allocation (GAP – #3)	
68.	Trawl, Non-Trawl, Rec	Defer Nearshore Management to Oregon and Washington (GAP – #4)	
69.	LE FG	Combine the Fixed Gear LE DTL Fishery and Tier Fishery (GAP – #5)	
70.	Trawl, Non-Trawl	Provide for Retrieval of Derelict Trawl Gear in RCAs (GAP – #6)	
71.	Trawl, Non-Trawl, Rec	Allow Between Season Transfer of Unneeded Overfished Species (GAP – #7)	
72.	LE FG	Require Permit Price Reporting for LE FG Permit Transfers (F6 – SSC)	
73.	LE FG	Convert Daily Trip Limits to a Tier Endorsement (F6 – GAP)	
74.	LE FG	Combine Longline and Fishpot into a Single Fixed Gear Limited Entry Gear Endorsements (F6 – GAP)	
75.	LE FG	Move the Seaward RCA Line Closer to Shore for Pot Vessels (F6 – GAP)	
76.	LE FG	Require All Fishpots be Returned to Shore at the End of Each Trip (F6 - Council)	

ENFORCEMENT CONSULTANTS REPORT ON OMNIBUS REGULATION CHANGES, PART II

The Enforcement Consultants (EC) has reviewed the documents pertaining to Agenda Item F.9 and discussed outcomes from Agenda Item F.3, Omnibus Regulation Changes, Part I, and has the following comments.

Regarding vessel monitoring system (VMS) ping rate, the EC recommends the Council task Council staff with researching technology options via available providers to address the questions raised by the Council at the April Council meeting, with regard to technology capabilities having potential to enhance VMS effectiveness in West Coast fisheries monitoring.

PFMC

Agenda Item F.9.b
Supplemental GAP Report
June 2014

GROUNDFISH ADVISORY PANEL REPORT ON OMNIBUS REGULATION CHANGES PART II

After contemplating Council action under agenda item F.3, the Groundfish Advisory Subpanel (GAP) has the following comments regarding consideration of Omnibus Regulations Changes Part II.

The GAP supports the Council motion that established a list of activities/actions that will be considered and prioritized in September.

During Council deliberation, the GAP was requested to provide clarification about GAP recommendation #7 from the Agenda Item F.3.b, Supplemental GAP Report: "Exploration of flexible regulations that allow the transfer of overfished species between sectors to prevent stranding target fish." The GAP request is specific to the within trawl use of choke species and is not intended to include discussion or promote changes to any of the existing allocations. The goal of this suggestion is to begin the conversation about how choke species can be better utilized and/or shared within the trawl sectors to ensure attainments of optimum yield for all target species. At this time, the GAP has no suggestions for the mechanics of how this could function, but believes it is a topic that warrants discussion and analysis.
