In recent years, the ACL (formerly OY) for the Nearshore Rockfish complex north of 40º10' N lat. has typically had a high attainment rate. The bulk of the harvest has occurred in nearshore recreational fisheries in all three states and nearshore commercial fisheries in California and Oregon. The preferred ACL for the northern nearshore rockfish complex in 2015 and 2016 is 69 mt, a 26.6% decrease from the 2014 ACL of 94 mt. Most of this decrease is due to new assessments for brown, China, and copper rockfish, as well as a blue rockfish ACL contribution that is trending downwards. Figure 4-5 depicts the annual total catch estimated in 2004-2012 for the complex relative to the preferred 2015 OFL and ACL. In only one year in this time period (2009) has total catch been below the preferred 2015 ACL. In hindsight, total catch has been at or above the preferred 2015 OFL in 5 of the 9 years analyzed.

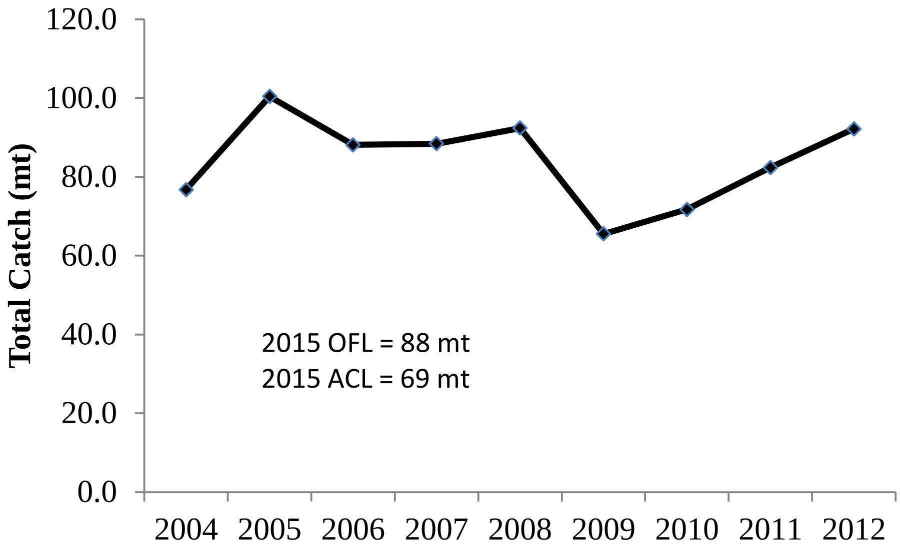

Figure 4-5. Estimated total catch of nearshore rockfish north of 40º10' N lat. in 2004-2012 relative to the preferred 2015 OFL and ACL.

Table 4-7 shows the 2004-2012 total catches of species in the northern Nearshore Rockfish complex by sector. Northern Nearshore Rockfish catches prior to 2004 were not included in the biological impact analysis due to a lack of confidence in the precision of catch estimates derived from the Marine Recreational Fisheries Statistical Survey (MRFSS), which was the basis of California recreational catch estimates prior to implementation of the California Recreational Fisheries Survey (CRFS) in 2004. Northern Nearshore Rockfish catches in recreational fisheries by state were generated from a March 18, 2014 RecFIN query by querying for landed catch (A) plus the reported dead catch (B1). Catch estimates for the Redwood District (Humboldt and Del Norte counties) were used in the query to represent catches north of 40º10' N lat. Catches for all other sectors were generated from the Groundfish Mortality Multiyear Data Product database provided by the NMFS NWFSC WCGOP program.

Two of the assessed stocks managed in the northern Nearshore Rockfish complex (blue rockfish in California and China rockfish) are in the precautionary zone. Both stocks are category 2 stocks with the status of China rockfish informed by a 2013 data-moderate assessment (PFMC 2014). Blue rockfish catches in California have been managed with a statewide HG since 2009. The HG was calculated using the default 40-10 ACL harvest control rule. Total mortality has been maintained within the HG and the stock is predicted to be increasing in abundance. The Council is considering HG management for the entire complex to be implemented in 2015.

Other assessed stocks managed in the northern Nearshore Rockfish complex include brown rockfish in California, copper rockfish, and gopher rockfish in California. All of these stocks are estimated to be healthy.

The preferred 2015 and 2016 ACL of 69 mt for the complex is the same as the Alternative 1 ACL. This compares to the Alternative 2 ACL of 40 mt using a P* of 0.25 to calculate the ABC contributions of component stocks. The Alternative 2 ACL would provide greater conservation benefits to component stocks of concern (e.g., China rockfish), but would further impact nearshore commercial and recreational fisheries already facing a 26.6% decrease in allowable harvest relative to the No Action ACL for this high attainment complex.

China Rockfish North of 40º10' N lat.

The populations of China rockfish (*Sebastes nebulosus*) north and south of 40º10' N lat. were assessed by Dick and Cope (2014) in a new 2013 data-moderate assessment. The southern population was estimated to be healthy with an estimated depletion of 72% at the start of 2013. However, the northern population, managed as a component stock in the northern Nearshore Rockfish complex, was estimated to at 33% of unfished biomass at the start of 2013 (*cite new figure of SpB and depl time series*), and hence in the precautionary zone.

(*insert new figure of SpB and depl time series*)

China rockfish have a shallow distribution and are most common in the 10-50 fm zone (Love, *et al.* 2002). They are primarily caught in nearshore commercial fisheries in California and Oregon, as well as nearshore recreational fisheries in waters off all three states. Table 4-8 provides the estimated annual catches of China rockfish north of 40º10' N lat. by sector in 2004-2012. The average annual total catch in 2004-2012 is estimated to be 13.8 mt.

The estimated 2015 OFL contribution of China rockfish in the north Nearshore Rockfish complex is 7.2 mt. Under the preferred P* of 0.45, the 2015 ABC contribution is 6.6 mt and the 40-10 adjusted ACL contribution is 6.2 mt. Figure 4-6 depicts total estimated catch of China rockfish north of 40º10' N lat. relative to the 2015 OFL and ACL contributions to the complex. The cumulative 2004-2012 total estimated catch of China rockfish north of 40º10' N lat. was 191% and 221% of the cumulative 2015 OFL and ACL contributions, respectively. Maintaining these catch levels is predicted to lead to continued stock decline (*need final decision table with depletion projections*).

It is reasonable to assume that as the ACL decreases for the northern Nearshore Rockfish complex, the risk of potential overfishing decreases for China rockfish. Therefore, the Alternative 2 ACL for the complex likely entails less risk to China rockfish than the preferred/Alternative 1 ACL.

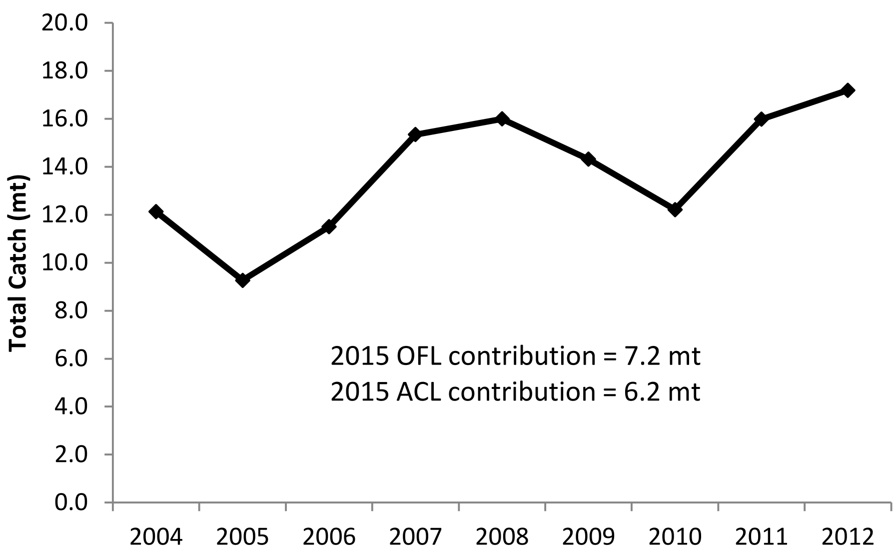

Figure 4-6. Estimated total catch of China rockfish north of 40º10' N lat. in 2004-2012 relative to the preferred 2015 OFL contribution and ACL contribution.

4.1.4.2 Slope Rockfish Complexes North and South of 40º10' N lat.

Alternative Slope Rockfish complex structures are under consideration due primarily to concerns about catches exceeding new OFL contributions for rougheye/blackspotted and shortraker rockfish. The following sections address potential biological risks for rougheye/blackspotted and shortraker rockfish, as well as considerations for an alternative structure to the status quo slope rockfish complexes north and south of 40º10' N lat.

Rougheye/Blackspotted Rockfish

Rougheye and blackspotted rockfish are currently managed in the Slope Rockfish complexes north and south of 40º10' N lat., although they are a very minor component of the southern Slope Rockfish complex. Both species share broad overlap in their depth and geographic distributions from the Eastern Aleutian Islands along the North American continental margin to southern Oregon, with blackspotted rockfish's range extending east beyond the Aleutian chain to the Pacific Coast of Japan (Gharrett, *et al.* 2005; Hawkins, *et al.* 2005; Orr and Hawkins 2008). It is very difficult to visually distinguish between the two species and they have been persistently confused in surveys and catches. It has only been from recent genetic studies in the early 2000s that the two separate species have been identified and described (Orr and Hawkins 2008).

Hicks et al. (2013) conducted the first assessment of the U.S. west coast stock of rougheye and blackspotted rockfish as a complex of two species. The coastwide population was modeled assuming parameters for combined sexes (a single-sex model) and assuming removals beginning in 1916. The predicted spawning biomass from the base model generally showed a slight decline over the entire time series with a period of steeper decline during the 1980s and 1990s. Since 2000, the spawning biomass has stabilized and possibly increased because of reduced catches and above average recruitment in 1999. The 2013 spawning biomass relative to unfished equilibrium spawning biomass was estimated to be 47 percent of its unfished equilibrium at the start of 2013. The stock has been estimated to be healthy throughout the time series in the new assessment (Figure 4-7).

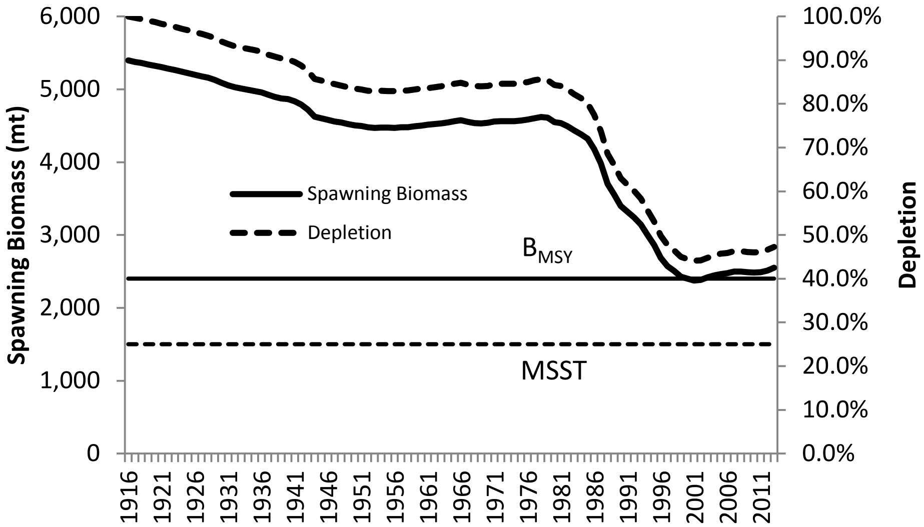

Figure 4-7. Time series of estimated spawning biomass and depletion of rougheye/blackspotted rockfish, 1916-2013 (from Hicks et al. 2013).

Total estimated annual catches of rougheye/blackspotted by sector of the groundfish fishery in 2002-2012 are provided in Table 4-9. Catches by sector in the non-tribal at-sea hake fishery (Catcher-Processors and Mothership) were generated from a NMFS Alaska Fisheries Information Network NORPAC database query on March 14, 2014. Catches for all other sectors were generated from the Groundfish Mortality Multiyear Data Product database provided by the NMFS NWFSC WCGOP program. Catches by sector in Table 4-9 are the sum of rougheye/blackspotted rockfish catches plus the proportion of rougheye/blackspotted rockfish catches reported in the shortraker-rougheye market category.

Figure 4-8 compares the 2002-2012 annual total catches of rougheye/blackspotted rockfish to the preferred 2015 OFL and ABC limits (2015 limits are slightly lower than 2016 limits so these values were chosen). In hindsight, the stock has exceeded the 2015 OFL and experienced overfishing since 2008 during the time series (Figure 4-4). The 2007 catch also slightly exceeded the 2015 ABC.

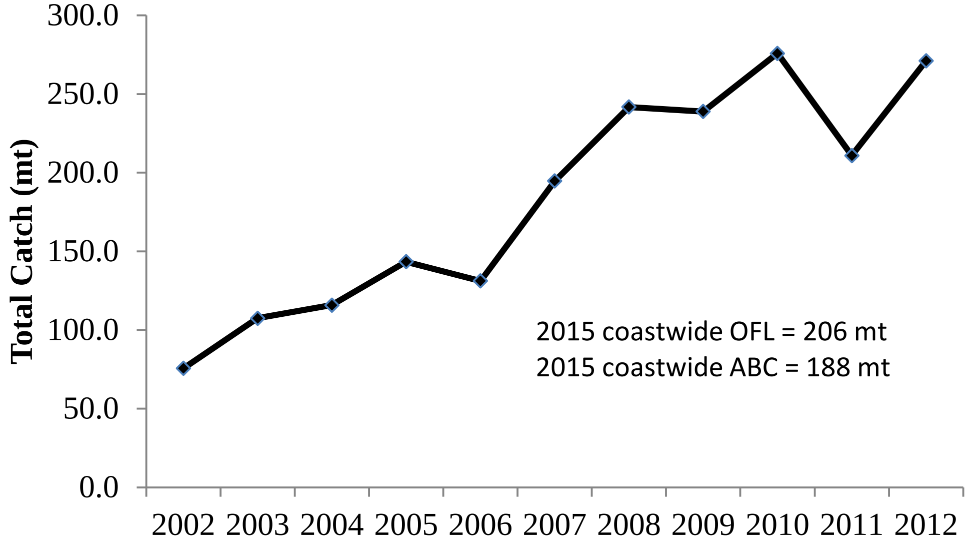

Figure 4-8. Estimated total catch of rougheye/blackspotted rockfish, 2002-2012 relative to the preferred 2015 OFL contribution and ABC contribution.

The cumulative coastwide catch of rougheye/blackspotted rockfish in 2002-2012 was 97% of the cumulative 2015 OFL (the 2015 OFL times the number of years in the analysis (11)); however, the cumulative catch since 2008 was 120.2% of the cumulative OFL for that period. This indicates there may be a concern for maintaining the observed harvest levels since 2008. Notwithstanding the recent catches, the average 2015-2024 catch predicted to stabilize the population at the proxy B_{MSY} level of $B_{40\%}$ is 266 mt (Table 4-10) or 145.8% and 107.4% of the average 2002-2012 and 2008-2012 catches, respectively. The 2015-2024 equilibrium yield catch assumes the F_{MSY} harvest rate estimated in the 2013 assessment (SPR = 29.6%). To the extent the actual F_{MSY} harvest rate for the stock is closer to or over the estimated F_{MSY} harvest rate in the 2013 assessment, the risk of future overfishing under status quo management is lessened. Additionally, a forward projection of rougheye/blackgill depletion using the base model in the 2013 assessment and assuming annual removals in the next ten years equal to the 2008-2012 average total catch of these species of 247.7 mt predicts the stock(s) would remain healthy with a depletion above the B_{MSY} proxy of 0.4 (Figure 4-9).

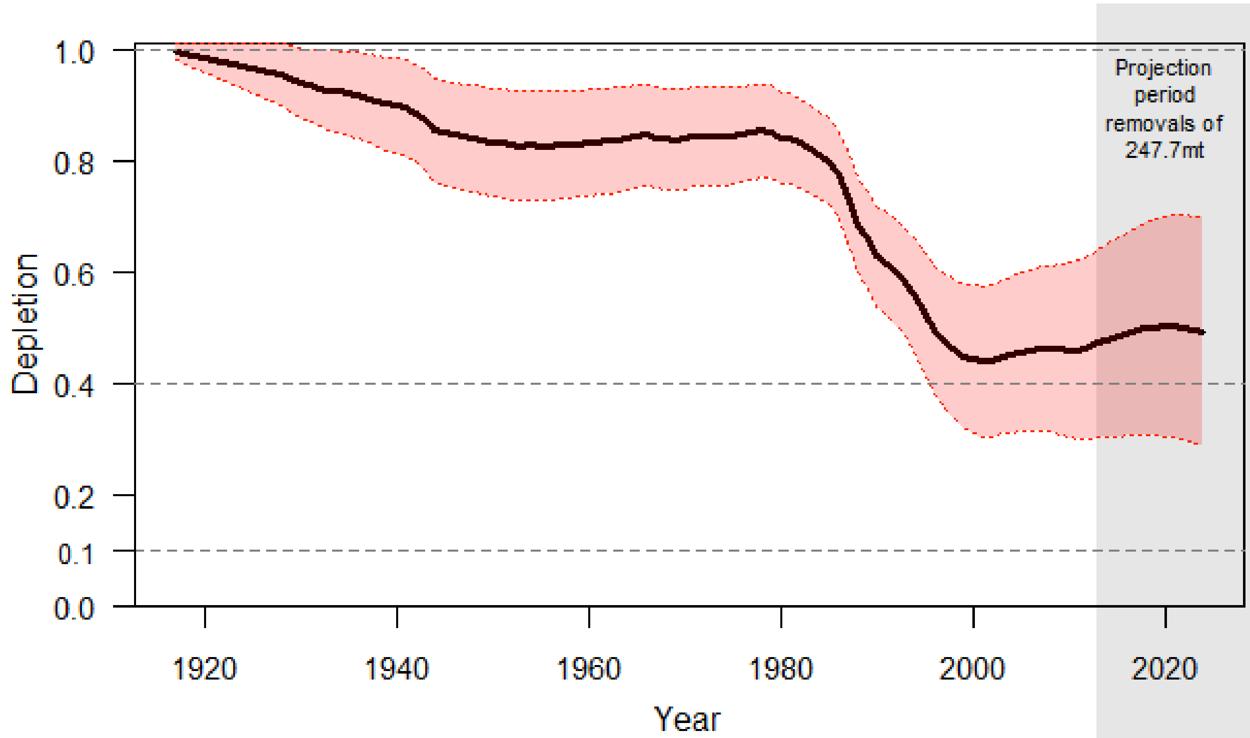

Figure 4-9. Projected depletion of rougheye/blackspotted rockfish through 2024 assuming annual removals of 247.7 mt. Shading indicates the estimated 95% confidence interval about estimated depletion.

Since 2011, slope rockfish targeting in the bottom trawl fishery has decreased dramatically (only 17% of the 2011 quota of the northern slope rockfish was attained) under IFQ management. The 2011 catch levels are more likely than those preceding implementation of trawl rationalization. Higher than normal catch of rougheye in the 2011 catcher-processor (CP) sector occurred because the CP sector fished much later in the year and concentrated effort more than usual off northern Washington where large numbers of hake were aggregated. This is not typical behavior as evidenced by highly variable catch and effort distribution in the CP sector.

The center of distributions for rougheye and blackspotted rockfish is the Gulf of Alaska and these species are at the fringe of their distributions on the U.S. west coast. The 2013 assessment of the rougheye-blackspotted rockfish complex in the Gulf of Alaska estimated an age 3+ biomass of almost 43,000 mt and predicted an increasing trend in that biomass (Shotwell and Hanselman 2013). The recommended 2015 OFL for Gulf of Alaska fisheries is 1,518 mt (ABC = 1,262 mt). It is likely the small proportion of removals in west coast fisheries will have little effect on overall stock status.

Considerations for restructuring the slope rockfish complexes to either manage rougheye/blackspotted in a coastwide management unit or in a coastwide rougheye/blackspotted/shortraker complex will also reduce risk of future overfishing but could disrupt limited entry trawl and fixed gear fisheries. Risk of future overfishing may also be mitigated by establishing an HG for rougheye/blackspotted rockfish, which would establish a sorting requirement and aid in inseason catch monitoring. Fishermen would have to carefully track their catches to avoid rougheye and blackspotted rockfish or risk an inseason action to close areas where these species are caught. The HG could be allocated by sector, but the contention associated with this would likely require more process and time than available in the 2015-

2016 specifications decision-making cycle. A shared HG would put industry on notice and allow them to devise strategies for reducing impacts on rougheye/blackspotted rockfish with less immediate disruption of the fishery. Risk of overfishing could be evaluated in the next management cycle before slope rockfish restructuring and sector allocations are considered necessary.

The preferred ABC/ACL contributions of rougheye/blackspotted rockfish to the complex is the same as under Alternative 1 (188 mt and 193 mt in 2015 and 2016, respectively coastwide). This compares to coastwide ABC/ACL contributions of 127 mt and 130 mt in 2015 and 2016, respectively under Alternative 2. If harvest of rougheye and blackspotted rockfish in 2015 and 2016 were constrained to the ABC/ACL levels, the biomasses of these species would be slightly higher in the foreseeable future under Alternative 2.

Table 4-9. Estimated total catch of rougheye/blackspotted rockfish by sector, 2002-2012.

Shortraker Rockfish

Shortraker rockfish (*Sebastes borealis*) is an unassessed category 3 stock on the U.S. west coast. This is one of the largest rockfish species with a broad distribution throughout the North Pacific, from Japan, the Okhotsk Sea, and southeastern Kamchatka to the Bering Sea and Aleutian Islands south to Point Conception (Love, *et al.* 2002). They are common from at least eastern Kamchatka to British Columbia, and are considered at the fringe of their population on the U.S. west coast.

Shortraker are caught in both trawl and fixed gear fisheries on the slope (Table 4-11), almost exclusively off Washington. Total catch of shortraker rockfish has been estimated to be at or above the 2015 OFL contribution in 9 of the 11 years analyzed (Figure 4-10). Trawl catches have been decreasing since the recent year high in 2007. However, the fixed gear fishery on the slope had a recent year high catch in 2012. It is unknown how much of this catch was targeted and how much was incidental to sablefish targeting. Given the large size and higher market value of shortraker, some targeting is likely. A reduction in cumulative landing limits for rougheye and shortraker could reduce some of this targeting and impacts in this sector. Such efforts appear to have been successful in reducing southern blackgill rockfish mortalities in 2013 in fixed gear fisheries that were targeting that stock.

The vast majority of the shortraker rockfish biomass and catch occurs north of the west coast EEZ in waters off British Columbia and Alaska. It is likely the small proportion of removals in west coast fisheries will have little effect on overall stock status.

The preferred ABC/ACL contribution of shortraker rockfish to the complex is the same as under Alternative 1 (15.7 mt in 2015 and 2016 coastwide). This compares to a coastwide ABC/ACL contributions of 7.1 mt in 2015 and 2016 under Alternative 2. If harvest of shortraker rockfish in 2015 and 2016 were constrained to the ABC/ACL level, the biomass of this species would be slightly higher in the foreseeable future under Alternative 2.

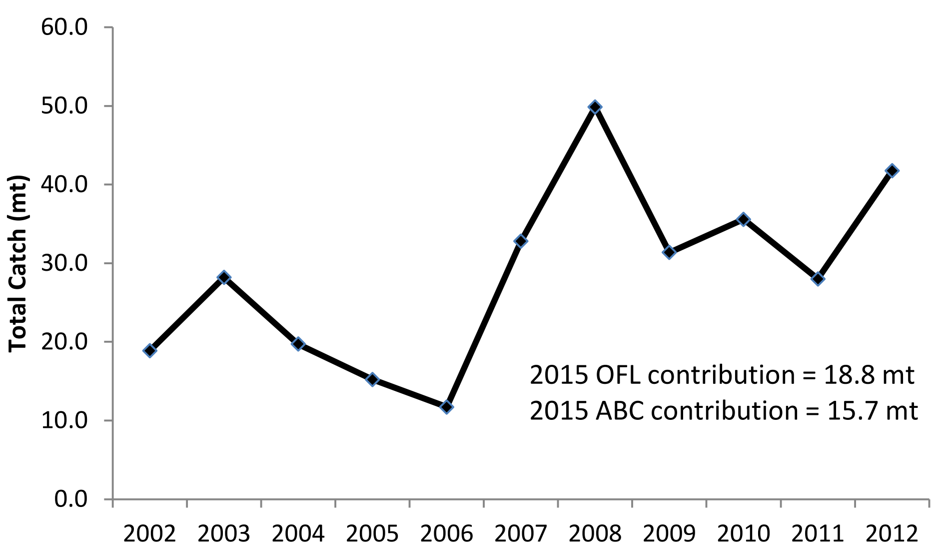

Figure 4-10. Estimated total catch of shortraker rockfish, 2002-2012 relative to the preferred 2015 OFL contribution and ABC contribution.

Table 4-11. Estimated total catch of shortraker rockfish by sector, 2002-2012.

Alternative Slope Rockfish Stock Complexes

The two alternative slope rockfish complex alternatives decided for detailed analysis are the No Action status quo slope rockfish complexes north and south of 40º10' N lat. (preferred) and an alternative structure where rougheye, blackspotted, and shortraker rockfish are removed from the status quo complexes and managed together in a new coastwide complex. The preferred alternative for the slope rockfish complexes has one feature different from the No Action alternative; a sorting requirement is specified for rougheye and blackspotted rockfish. The alternative analyzed for the slope rockfish complexes that contemplates managing a coastwide rougheye/blackspotted/shortraker complex (RBS complex) would establish a shared fishery harvest guideline that would be used as the limit for non-tribal groundfish fisheries. Specification of a sorting requirement for rougheye and blackspotted rockfish under the preferred alternative will improve catch estimation and inseason monitoring for these stocks. The alternative of managing a coastwide rougheye/blackspotted/shortraker rockfish complex will also improve catch monitoring; however, catches would be monitored and estimated at the level of the complex aggregation for the three species combined (i.e., the species would not be separately sorted).

The preferred alternative for the slope rockfish complex north of 40º10' N lat. specifies 2015 OFLs and ABCs of 1,804 mt and 1,669 mt, respectively. Total estimated catches during 2002-2012 have been well under the preferred harvest specifications for the next management period with the maximum catch during that period (568.5 mt) being 34% of the proposed 2015 ABC for the complex (Table 4-12, Figure 4-11). The preferred alternative for the slope rockfish complex south of 40º10' N lat. specifies 2015 OFLs and ABCs of 806 mt and 698 mt, respectively. Total estimated catches during 2002-2012 have been well under the preferred harvest specifications for the next management period with the maximum catch during that period (508 mt) being 73% of the proposed 2015 ABC for the complex (Table 4-13, Figure 4-12). There is little risk of exceeding the proposed harvest limits for these two complexes in 2015 or 2016.

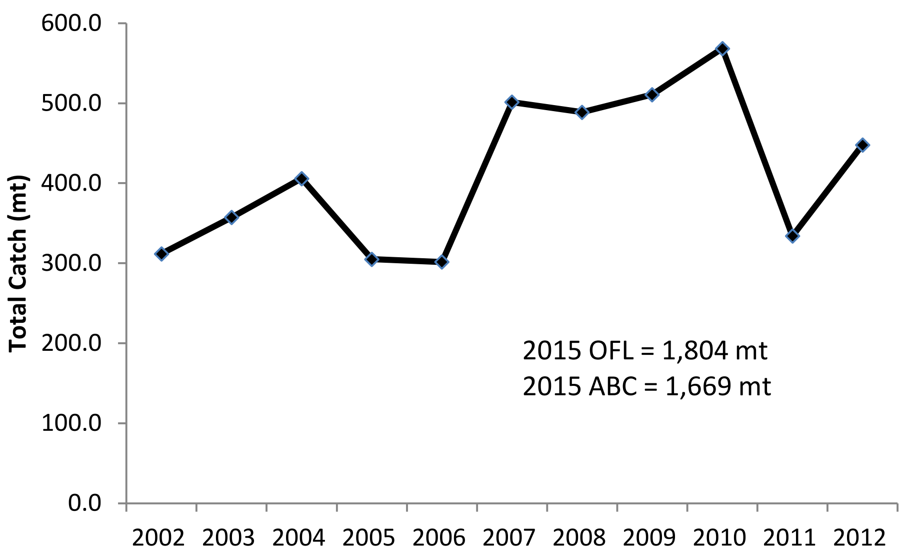

Figure 4-11. Estimated total catch of stocks in the Slope Rockfish complex north of 40º10' N lat., 2002-2012.

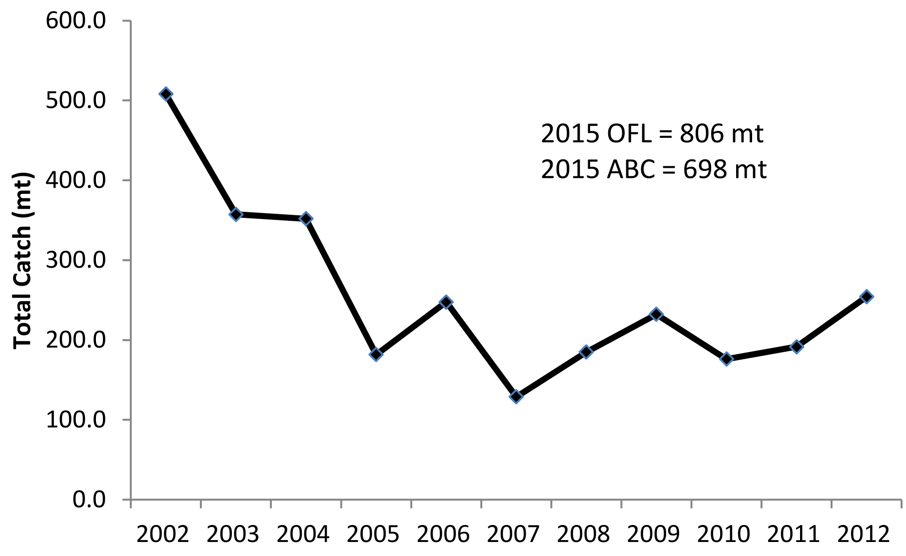

Figure 4-12. Estimated total catch of stocks in the Slope Rockfish complex south of 40º10' N lat. by sector, 2002-2012.

The 2015 and 2016 OFLs and ABCs for the alternative coastwide RBS complex would be the summed contribution of the OFLs and ABCs of the three component stocks. The 2015 OFL and ABC for the alternative RBS complex are 225 mt and 204 mt, respectively. While these were never harvest limits historically, catches of these three species in aggregate have been consistently over the 2015 RBS complex ABC since 2007 (Table 4-14 and Figure 4-13), a pattern similar to and driven by the historical catches of rougheye and blackspotted rockfish (Figure 4-8).

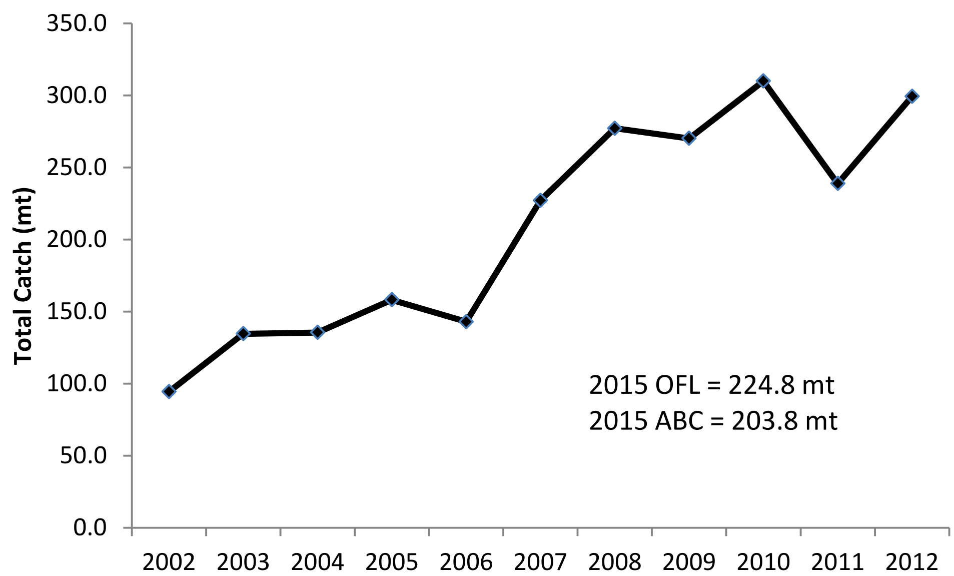

Figure 4-13. Estimated total catches by sector of rougheye/blackspotted/shortraker rockfish, 2002-2012.

The concerns for rougheye, blackspotted, and shortraker catches in excess of their component OFLs since 2007 (for shortraker rockfish and the alternative RBS complex) or 2008 (for rougheye/blackspotted rockfish) are discussed above for these individual stocks.

While status quo management of slope rockfish, which might lead to a logical prediction that catches of rougheye/blackspotted would remain above the component OFL and ABC may not risk driving stock depletion down below the target B_{MSY} level (as indicated in Figure 4-9), the Council and NMFS are concerned with the implications of exceeding the assessment-based OFLs. Managing these stocks in a separate coastwide complex is one way to address these concerns. However, the preferred alternative is to manage these stocks in the status quo complexes with a sorting requirement for rougheye and blackspotted rockfish. Public and GAP testimony on this issue indicated that removing these stocks from the status quo complexes would be disruptive to industry. Further, any measures that would require new sector allocations for these stocks would be a divisive and protracted process that cannot be done in time for the 2015-16 decision-making cycle that anticipates implementation of new regulations on January 1, 2015. Therefore, as part of the preferred alternative, the Council and NMFS expect industry to take voluntary measures to avoid these stocks. A sorting requirement will enable better catch monitoring and estimation, which should help industry more quickly realize when catches are approaching a concerning level. Further, lower slope rockfish cumulative landing limits are being considered for the non-trawl sectors to remove any incentive to target these stocks.

Industry awareness of this problem, coupled with the sorting requirement, should facilitate avoidance of rougheye. Realizing this issue was emerging, the catcher-processor fleet started to pay attention to rougheye catches by their fleet and move from areas where higher rougheye bycatch was occurring in 2013. Using the services of a private contractor, Sea State, Inc., the fleet was apprised in real time of areas where rougheye bycatch was relatively high so vessels could move to other areas to target whiting. Total catch of rougheye in 2013 by the CP fleet was 11.2 mt, down significantly from the high 2011 catch of 74.4 mt (Table 4-9). The whiting vessels in the Mothership fleet and the shorebased IFQ trawl fleet also use Sea State and can enact a similar strategy to reduce their impacts. If the non-whiting vessels in the shorebased IFQ trawl fleet can use Sea State or other strategies to avoid rougheye areas, then the risk of potential overfishing of rougheye is greatly ameliorated.

Neither the preferred alternative nor the RBS complex alternative, where all sectors would be managed under a shared fishery harvest guideline, contemplates modifying the current formal sector allocations. However, the Council stated they may consider removing these stocks from the status quo complexes in the future and modifying formal sector allocations for slope rockfish if voluntary measures do not decrease total catch impacts to prevent potential overfishing of rougheye in the next two years. Other potential accountability measures that can be considered in the future include rockfish excluders in trawl nets and implementation of Groundfish Conservation Areas (i.e., closing discrete areas where rougheye are more prevalent).

4.1.4.3 Other Fish

The status quo Other Fish complex is comprised of all the unassessed groundfish FMP species that are neither rockfish (family *Scorpaenidae*) nor flatfish, except for spiny dogfish which was assessed in 2011. These species include big skate (*Raja binoculata*), California skate (*Raja inornata*), leopard shark (*Triakis semifasciata*), soupfin shark (*Galeorhinus zyopterus*), spiny dogfish (*Squalus acanthias*), finescale codling (*Antimora microlepis*), Pacific grenadier (*Coryphaenoides acrolepis*), ratfish (*Hydrolagus colliei*), cabezon (*Scorpaenichthys marmoratus*) (off Washington), and kelp greenling (*Hexagrammos decagrammus*).

The status quo Other Fish complex is an aggregation of species with different life history characteristics, depth distributions, and vulnerabilities to potential overfishing. Therefore, the preferred alternative is to restructure this complex by removing spiny dogfish and managing this stock coastwide with its own harvest specifications (see section 4.1.3.3); and removing all the skates, Pacific grenadier, soupfin shark, spotted ratfish, and finescale codling by designating them as Ecosystem Component species (see section 1.1.1). The remaining stocks (i.e., kelp greenling, Washington cabezon, and leopard shark) are preferred to be the only stocks managed in the Other Fish complex in 2015-2016.

The preferred 2015 and 2016 harvest specifications for the Other Fish complex are the summed contributions of OFL and ABC contributions of those component stocks with an SSC-endorsed OFL estimate. The SSC endorsed OFL estimates for kelp greenling in California (118.9 mt based on a DB-SRA estimate calculated in 2011), leopard shark (167.1 mt based on a DB-SRA estimate calculated in 2011), and the Washington substock of cabezon. The SSC endorsed a new OFL estimate for Washington cabezon based on a DB-SRA methodology that assumes depletion in 2010 equals that inferred from the 2009 assessment for Oregon (48%, (Cope and Key 2009). Since the 2016 harvest specifications are based on assumed ABC removals of Washington cabezon in 2015, the 2016 specifications are dependent on the preferred P*. The Council chose a P* of 0.45 for Washington cabezon, which determines 2015 and 2016 OFL contributions of 4.5 mt and 4.8 mt, respectively (Table 4-15). The SSC originally recommended a similar methodological approach for estimating OFL contributions for kelp greenling in Oregon and Washington that used a depletion estimated from the 2005 kelp greenling assessment for the Oregon substock (Cope and MacCall 2006). However, the SSC did not endorse the 2015 and 2016 OFLs for the Oregon and Washington substocks of kelp greenling after realizing the catch stream used to determine the DB-SRA OFL estimate of kelp greenling in Oregon was dramatically different than the catch stream in the 2005 assessment. Therefore, there are no OFL or ABC contributions for kelp greenling in Washington and Oregon to inform the 2015 and 2016 harvest specifications for the reconfigured Other Fish complex. The preferred 2015 and 2016 OFL for the Other Fish complex is 291 mt. The preferred 2015 and 2016 ABCs for the Other Fish complex are 242 mt and 243 mt, respectively and are based on a P* of 0.45 for the component stocks with known OFL contributions.

Total catches of stocks in the reconfigured Other Fish complex have not exceeded the preferred 2015 OFL or ABC during 2004-2012 (Figure 4-14). Total estimated annual catches of stocks in the Other Fish complex by sector of the groundfish fishery in 2004-2012 are provided in Table 4-16. All commercial catch estimates were from the WCGOP Multi-year Data Product and recreational catches of Washington cabezon and leopard shark were obtained from March 22 and 23, 2014 RecFIN queries of landed catch (A) and reported dead catch (B1). Recreational catches of kelp greenling by state were provided by the GMT. The average annual total catch of stocks in the Other Fish complex during 2004-2012 was 70.9 mt. The cumulative 2004-2012 catch of these stocks was 24.3% and 29.3% of the preferred 2015 OFL and ABC, respectively. There is little risk of the complex OFL or ABC being exceeded in the 2015-2016 management cycle.

The preferred 2015 and 2016 ACLs of 242 and 243 mt, respectively are the same as under Alternative 1. This compares to the 2015 and 2016 ACL of 110 mt under Alternative 2. The Alternative 2 ACL has a higher risk of being exceeded (assuming the same management measures and no inseason adjustment) than the preferred ACLs. Total catch in 2006 was slightly lower (108.5 mt) than the Alternative 2 ACL (Table 4-16).

The preferred alternative for a restructured Other Fish complex is more compliant to the FMP and National Standard 1 guidelines than the No Action structure that managed disparate species with different vulnerabilities to overfishing, different distributions, and different interactions with fisheries together in one complex. Removing spiny dogfish from the complex and managing that stock on its own also reduces the risk of overharvesting that stock relative to the status quo strategy of managing spiny dogfish within the complex. There are no immediate concerns with managing kelp greenling, Washington cabezon, and leopard shark together in a complex.

Table 4-15. Washington cabezon OFLs and ABCs for 2015 and 2016, assuming different depletion levels and ABC catches in 2015 (preferred harvest specification contributions to the Other Fish complex in bold).

4.1.5 Ecosystem Component Species

Under the preferred alternative the following species would be designated Ecosystem Component (EC) species: big skate, California skate, all other endemic skates, soupfin shark, finescale codling, Pacific grenadier, all other endemic grenadier species, and spotted ratfish. An EC species can be so designated if it is not targeted, is not subject to overfishing or being overfished in the absence of conservation measures, and not generally retained for sale or personal use. No harvest specifications or management reference points are required for EC species; however, there is a monitoring requirement to determine changes in their status or their vulnerability to the fishery. If new information shows than an EC species' vulnerability to overfishing has increased, the stock should be reclassified as "in the fishery". Any designation of a species as an EC species or a change from an EC designation to a species considered to be "in the fishery" requires an FMP amendment. Designating these species as EC species is part of the purpose and need for Amendment 24.

The Council directed the GMT to focus on species in the Other Fish complex for reclassification of their FMP status. The GMT evaluated the species currently in the Other Fish complex and also took a broader look at non-FMP species to evaluate whether these species should be included in the FMP because they are either in the fishery or their inclusion in the FMP as an EC species made sense to address ecosystem considerations or to enhance monitoring of other EC species. In consideration of determining whether species were in the fishery or not, the GMT analyzed fish species caught predominantly in Federal waters and not managed under other FMPs or by the states. Further filtering of candidate FMP species for an EC designation was done by flagging species that had either less than 1 mt of average catch per year from 2007-2011 or more than a 1 mt of catch (rounded to the nearest mt) but less than 50 percent retention (i.e., 50 percent or more of the catch is discarded) and a PSA score of ~2.0 and lower. Then to create an overlapping range of non-FMP species, all stocks related to species in the Other Fish complex with an average catch per year of 1 mt and higher were included (Table 4-17, Table 4-18, and Table 4-19).

The GMT also evaluated NWFSC trawl survey catches and provided some ad hoc biomass and OFL estimates for non-FMP species. Survey biomass estimates and associated OFL estimates are included in Table 4-17 and Figure 4-15. Biomass estimates have also been calculated for all additional species that are encountered by the NWFSC Groundfish Trawl Survey. Biomass estimates are based on the most recent 3 years of survey abundance available at the time of this analysis (Figure 4-15) and are only calculated for species that were encountered in all 3 years. A small subset of these species that were encountered annually, were seen in so few tows that the survey biomass estimates are unlikely to provide reliable estimates of biomass or OFL contributions. These species are Aleutian skate, Pacific sleeper shark, other slickheads (including tubeshoulders), and snailfish, all of which have occurred in fewer than 100 tows total (and never more than 20 tows in any given year). Of these species, Aleutian Skate is the only one for which an OFL contribution was presented in Table 4-17.

The OFL contributions for Other Skates and Other Grenadiers should not be directly compared to the average catches listed in these categories in Table 4-17. Landings in both of these groups have often not been identified to the species level. For instance, for the years 2007–2011, the average catch of unidentified skates was 725 mt, but this average includes longnose skate in the years prior to the individual management of that species. For the years 2010–2012, when longnose skate was landed separately, the unidentified skate landings averaged 305 mt, but this number still likely included large amounts of big skate. In contrast, the estimated 24.9 mt OFL contribution for Other Skates is based on survey observations of only starry skate and deepsea skate. Likewise, in the case of grenadiers, the average catch of unidentified grenadiers has been 135 mt for the years 2007–2011, but this is likely to include large amounts of Pacific grenadier that was not identified by species in landings records. That number should therefore not be compared to the 40.1 mt estimated OFL contribution for Other Grenadiers which is based on survey observations of smooth grenadier, popeye grenadier, softhead grenadier and California grenadier. It is noted that if all species are combined then the sum of all skate catches have been below the sum of all skate OFL contributions and the sum of all grenadier catches has been below the sum of all grenadier OFL contributions.

Big skate, California skate, and Pacific grenadier are FMP species currently managed in the Other Fish complex. The GMT recommended bringing all the other endemic skates in the family *Arhynchobatidae* and the endemic grenadiers in the family *Macrouridae* into the FMP regardless of whether they are designated as EC species or not. The practical reason for this is skates and grenadiers have been landed in unspecified market categories and, with little or no available compositional sampling of these landings, the landed amounts of each species are uncertain. Therefore, more accurate estimation of OFLs using catch-based methods such as DCAC or DB-SRA can be made for the respective aggregations of skates and grenadiers. The preferred alternative adds these species to the FMP. The preferred alternative also designates these species as EC species, which entails a monitoring requirement to better understand fishing impacts.

All of the species proposed for an EC designation have relatively low vulnerabilities to potential overfishing (Table 4-17) and none are explicitly targeted. For example, of the skates that are caught on the west coast, longnose skate have been the most frequently landed and are presumably targeted by some trawl vessels. However, longnose skate is not proposed for an EC designation and continued management of longnose skate with stock-specific harvest specifications is preferred. The amount of unidentified skate catch has lowered from what is reported in Table 4-17 to an average of 305 mt over 2010-2012. The main reason for this is that longnose skate was removed from the Other Fish complex beginning in 2009 and sorting of the species was implemented then. Considering the 305 mt of unidentified skate catch still occurring, there is no data to inform species composition. Assuming that none is longnose skate, then average catch of the all other skates combined would be about 50 percent of their combined OFLs for all other skates. Aleutian skate, the skate species with the highest catch relative to its estimated OFL: in Table 4-17, was seen in fewer than 20 tows over the course of several years of the trawl survey (Figure 4-15). Aleutian skate is abundant in the waters off Alaska, with a biomass estimate for the Eastern Bering Sea and Aleutian Islands of 33,293 mt (Ormseth 2012). This is second only to Alaska skate in estimated abundance in that area. This suggests that the biomass estimate of 72 mt for the west coast represents the tail of the stock's distribution. Monitoring of the catch of all endemic skates by bringing them into the FMP and the Federal management framework coupled with an EC designation will provide a better sense if this is targeted catch or unavoidable bycatch that is landed because there is some market value.

Grenadiers are present and occasionally caught on the west coast with Pacific grenadier being the most landed of the grenadier species. However, they are not explicitly targeted and their low value does not provide an incentive to develop target strategies. The "Catch/OFL" and "Biomass Estimate" metrics shown in Table 4-17 are misleading for grenadier. Grenadiers are distributed as deep as 1,350 fm. The depth limit for the west coast trawl fishery is 700 fm and the NMFS trawl survey only goes as deep as 550 m (300 fm). Therefore, OFLs are underestimated for grenadiers since neither the fishery nor the survey operates in the species' overall depth distribution, which will bias catch-based or survey-based estimates low. This also is an indicator of the low vulnerability of grenadiers to potential overfishing.

A designation of spotted ratfish as an EC species is based on the fact that this species is easily identifiable and is not marketed. The catch relative to its estimated OFL is just over 10% (Table 4-17). Likewise, finescale codling (AKA Pacific flatnose) and soupfin shark are not targeted and are good candidates for an EC designation. Soupfin shark have not been targeted since the end of the Vitamin A fishery (synthetic vitamin A now supplies any demand). The stock may extend into deeper waters but is largely taken by gillnet gears in California that target species not managed in the Groundfish FMP. Based on the 2007-2011 averages, over 80 percent of the catch comes from sectors managed elsewhere. The Council's ability to control catch through this FMP is therefore limited.

All of the proposed EC species designations reflect the lack of a conservation concern for these species, the lack of targeting of these species, and the lack of an ability to effectively control harvest of these species since much of the bycatch of these species occurs in fisheries outside the Council's jurisdiction. There is also a benefit to establishing a monitoring requirement through an EC designation to ensure that these fishery conditions do not change such that risks due to potential overfishing of these species do not emerge. The inclusion of all endemic skates in the family *Arhynchobatidae* and the endemic grenadiers in the family *Macrouridae* into the FMP will allow more precise catch monitoring without the need for a sorting requirement for these species since skates and grenadiers are generally landed in unidentified species' market categories (e.g., Unidentified Skates).

The preferred alternative of removing the existing FMP species recommended for an EC designation from the Other Fish complex also reduces the risks to the other species left in the complex. This is because some of the recommended EC species were effectively inflator stocks to the complex with relatively larger OFL contributions that increased the risk of overfishing more vulnerable stocks managed in the complex. For example, under the No Action Other Fish complex, Pacific grenadier contributed 1,519 mt to the complex OFL, which increased the risk of overharvesting co-managed species of concern such as spiny dogfish.

Table 4-17. PSA scores, average catch, OFL estimates, and biomass estimates for Other Fish-related candidate stocks from Agenda Item H.4.b, GMT Report 2, November 2013. Biomass estimates with darker shading are those for which the survey has few encounters and is unlikely to provide reliable estimates. The Catch/OFL column represents the ratio of average catch (2007–2011) to the OFL estimate for those cases where these values are both available and reasonable to compare.

*Note: Only 15.6% of the catch of Soupfin Shark comes in the FMP's commercial and recreational sectors. The remainder is taken in the California Halibut and other non-FMP sectors.

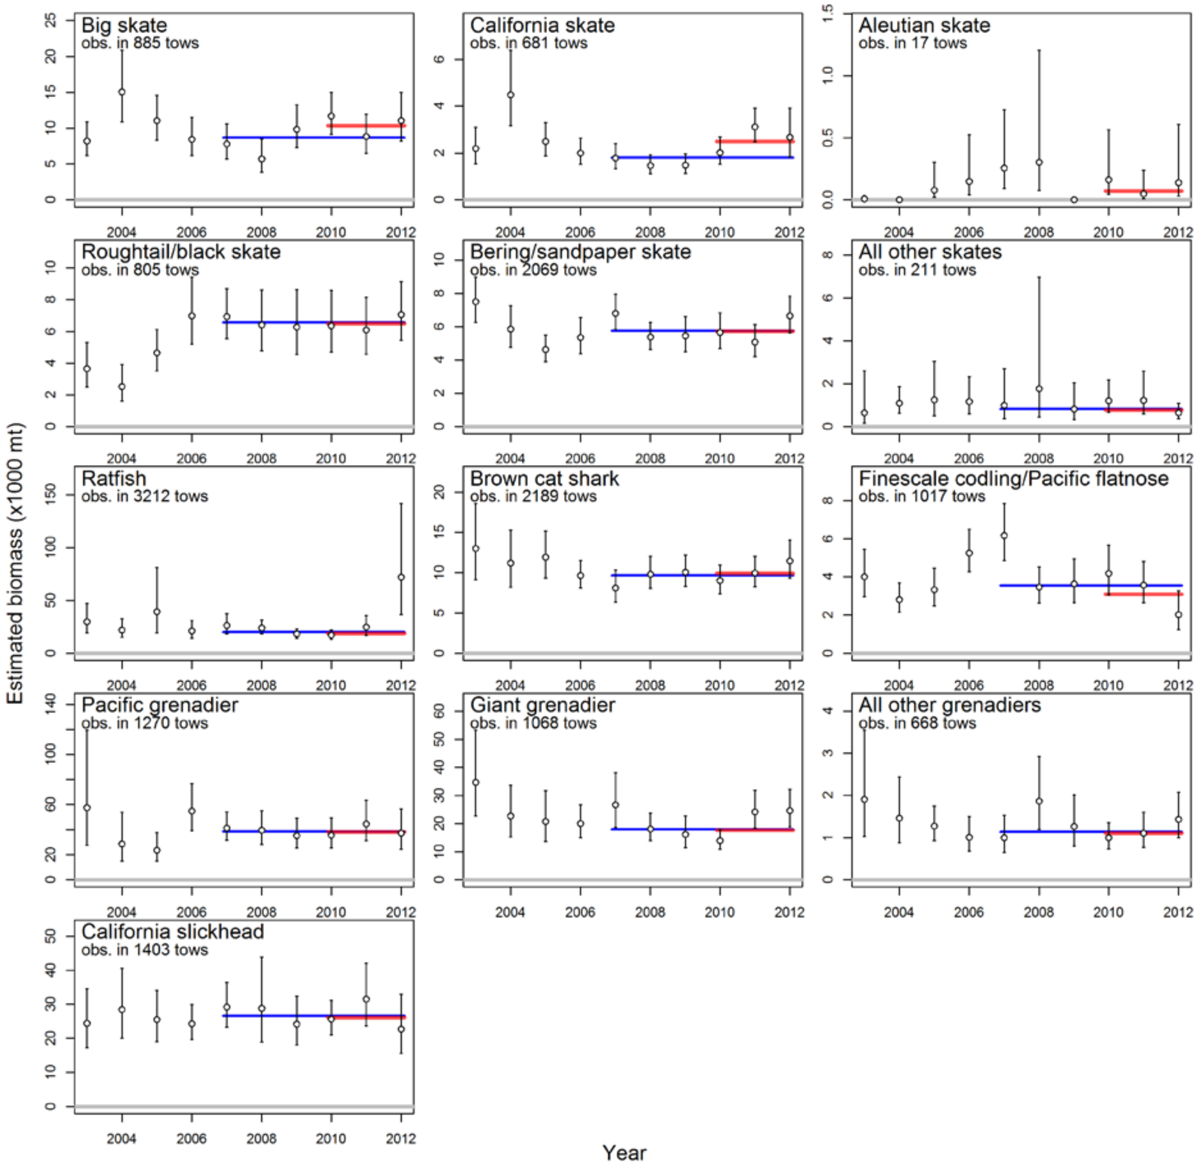

Figure 4-15. Time series of estimated survey biomass for species included in Agenda Item H.6.a, Supplemental Attachment 6, November 2013. The time period covers 2003–2012, with estimated 95% confidence intervals. Horizontal lines indicate weighted average value over the most recent 6-year and 3-year periods. No 6-year average for Aleutian skate is reported because they were not encountered in the 2009 survey. Number of observations refers to total number of tows that included the species out of a total of 6,453 tows for this 10-year period.

4.2 Impacts of 2015-2016 Management Measures to Groundfish Stocks

This section describes how management measures function so that groundfish catch may achieve, but not exceed, ACLs. This constitutes the impact mechanism linking harvest specifications to the direct and indirect biological impacts on groundfish stocks. The principal impact is the level of fishing mortality and secondarily changes in stock structure due to age-specific mortality patterns. Harvest specifications are determined based on the Groundfish FMP framework to achieve optimum yield.

The section is organized by alternative and within each alternative by fishery sector. The first management measure step is to determine set asides deducted from ACLs to account for various fishing activities and allocate the resulting fishery HGs. Management measures are then developed based on catch projections so that fishing mortality does not exceed allocations and the overall ACLs. Subsequent sections evaluate how management measures applied to groundfish fishery sectors are projected to prevent allocations and the overall ACLs from being exceeded.

4.2.1 No Action

4.2.1.1 Deductions from the ACL and Allocations

Deductions from most groundfish ACLs, called off-the-top deductions, are made to account for groundfish mortality in the Pacific Coast treaty Indian tribal fisheries, scientific research, nongroundfish target fisheries (hereinafter incidental open access fisheries), and, as necessary, EFPs. Off-the-top deductions from the sablefish north of 36° N. latitude ACL are slightly different due to the sablefish allocation framework and include groundfish mortality in tribal fisheries, research, recreational fisheries, and EFPs. Sufficient yield set-aside must be available to accommodate the anticipated groundfish mortality from the aforementioned activities. Deductions from the ACL to account for these activities are important accountability measures that increase the probability that catches will remain at or below the ACLs.

Amounts deducted that are from the ACL to accommodate groundfish mortality from scientific research, incidental open access fisheries, and EFPs can be modified based on inseason projections. For activities that are completed before a Council meeting, the best available information would be used to estimate the amount deducted from the ACL that would not be used in the calendar year and that amount would be reapportioned back to the groundfish fishery. The process to reapportion is structured to be done through an inseason action published in the Federal Register following a Council meeting. At a Council meeting, the Council would review set-asides and recommend full reapportionment, partial reappointment, or no reapportionment. The specified amount of groundfish would be reapportioned back to the “fishery harvest guideline” and out to the sectors in proportion to the original allocations for the calendar year. Because the fishery activity must be completed before reapportionment occurs, reapportionment would likely only occur later in the year after the September or November Council meetings. For sectors that are already closed for the year, or in the case of the Shorebased IFQ Program, after September 1 where QS accounts are no longer open or able to transfer QP, the Council must determine whether to reopen those sectors or, for the Shorebased IFQ Program, whether to reactivate those accounts.

Table 4-20 and Table 4-22 details the deductions from the ACLs for No Action and the following paragraphs describe how off-the-top deductions were calculated under No Action. Table 4-21 details the allocations analyzed under the No Action alternative.

Tribal Fishery: Tribal fisheries consist of trawl (bottom, mid-water, and whiting), fixed gear, and troll. The requested tribal amounts are based on those in the April 17, 2014 regulations.

Research: Research activities include the NMFS trawl survey, International Pacific Halibut Commission longline survey, and other Federal and state research. The Council approach is that off-the-top deductions should be equal to the maximum historical scientific research catch from 2005-2012, except for canary rockfish and yelloweye rockfish. The Council policy for canary and yelloweye rockfish was not based on the maximum historical value. The Council considered the high canary rockfish catch of 7.2 mt in 2006 from the NMFS trawl survey a rare event since surveys in later years encountered substantially less canary. The Council adopted a 4.5 mt canary rockfish set-aside, which is higher than the average research catch from 2005-2012. For yelloweye rockfish, the Council adopted a 3.3 mt research set-aside based on anticipated research needs of the International Pacific Halibut Commission (1.1 mt), Washington Department of Fish and Wildlife (1 mt), Oregon Department of Fish & Wildlife (1 mt), and other projects (0.2 mt).

Incidental Open Access: Deductions from ACLs are made to account for groundfish mortality in the incidental open access fisheries. The off-the-top deductions for all species, except longnose skate, were derived from the maximum historical values in the 2007-2011 WCGOP Groundfish Mortality reports (see http://tinyurl.com/nv3pddm). The recommended set-aside for longnose skate was based on data from the 2009-2011 Total Mortality reports, the years in which longnose skate were reported separately from the Other Fish category.

Exempted Fishing Permits: The Council recommended three EFPs and associated off-the-top deductions for 2013-2014 cycle which would remain under No Action. The first EFP seeks to test the effectiveness of trolled longline gear to selectively harvest chilipepper rockfish in waters off central California (Agenda Item E.3.a, Attachment 1, November 2011). The second EFP seeks to test the effectiveness of vertical hook-and-line gear to selectively harvest midwater species such as yellowtail rockfish (Agenda Item E.3.a, Attachment 2, November 2011). The third EFP seeks to survey the distribution and size of overfished species in the Rockfish Conservation Area (RCA) off the central coast of California using hook-and-line and trap gear (Agenda Item E.3.a, Attachment 3, November 2011). No total catch limits or off-the-top deductions are required for the third EFP since those catches will be covered using QP allocated in the shorebased IFQ fishery or trip limits for non-IFQ species.

Recreational (Sablefish north of 36° N. latitude only): The allocation framework for sablefish north of 36° N. latitude specifies that anticipated recreational catches of sablefish be deducted from the ACL prior to the commercial limited entry and open access allocations. The set-aside is the maximum historical value from recreational fisheries from 2004-2011 (Table 4-22).

Table 4-22. No Action. Estimates of tribal, research, recreational (Rec) and EFP mortality (in mt), used to calculate the fishery sablefish commercial harvest guideline north of 36° N. latitude under No Action.

Stock	ACL (mt)	Tribal Share (mt) a/	Research (mt)	Rec. (mt)	EFP (mt)	Commercial HG (mt)
Sablefish N. of 36° N. lat.	4,349	435	26	6.1	4	3,878

a/ The sablefish allocation to Pacific coast treaty Indian Tribes is 10 percent of the sablefish ACL for the area north of 36° N. lat. This allocation represents the total amount available to the treaty Indian fisheries before deductions for discard mortality.

4.2.1.2 Shorebased IFQ – No Action

The shorebased IFQ fishery is described in Section 3.xxx. Principle management measures for the shorebased IFQ fishery include:

- Catch Controls: IFQ and individual bycatch quota (IBQ) for Pacific halibut north of 40°10' N. latitude are the primary catch control tools in the shorebased IFQ fishery. South of 40°10' N. latitude, Pacific halibut is managed with a set-aside. The 2014 IFQ and IBQ used in the analysis of No Action can be found in Table 4-23. Additionally, cumulative monthly landing limits (hereinafter trip limits) for non-IFQ species and Pacific whiting outside the primary season dates apply to each vessel (see regulations Table 1 North and South to Part 660, Subpart D). Once a vessel reaches a limit, the species or species complex can no longer be retained and sold.
- Accumulation limits: The maximum number of QS and QP an entity may control in the shorebased IFQ fishery is limited by accumulation limits (defined in regulation at 50 CFR 660.111). These limits vary according to the management unit for the stock or stock complex and are intended to prevent the consolidation of quota holdings by just a few entities.
- Carry-over provision: The carry-over provision allows a limited amount of surplus QP or IBQ pounds in a vessel account to be carried over from one year to the next or allows a deficit in a vessel account in one year to be covered with QP or IBQ pounds from a subsequent year, up to a carryover limit. The carry-over provision is anticipated to increase individual flexibility for harvesters, improve economic efficiency, and achieve OY while preserving the conservation of stocks. The eligible percentages used for the carry-over provision may be modified during the biennial specifications and management measures process, based on a Council inseason recommendation and as approved by NMFS.
- Monitoring and Reporting: All trips in the shorebased IFQ fishery are monitored at sea by the West Coast Groundfish Observer Program (WCGOP) and landings are tracked by electronic fish tickets, verified by catch monitors. Together, these two programs provide robust, near-real time tracking and reporting of IFQ species and Pacific halibut IBQ.
- Gear Restrictions: IFQ species may be harvested with groundfish trawl or legal groundfish nontrawl gear. Trawl gear restrictions prohibit certain types of gear that may be used in rocky habitat, reducing habitat impacts and also limiting overfished species bycatch for those species that inhabit rocky substrate. Further, gear restrictions minimize catch of overfished species while allowing sufficient access to target species. For example, the selective flatfish trawl net, which is required shoreward of the trawl RCA north of 40°10' N. latitude, reduces rockfish bycatch while efficiently catching flatfish. Scottish seine gear is exempted from trawl RCA closures in the area between 38° N. latitude and 36° N. latitude and depths less than 100 fm because the gear has demonstrated low bycatch rates of overfished species. IFQ species can also be harvested with legal nontrawl gears.
- RCAs: Vessels harvesting IFQ must abide by RCA closures, which are specified by gear type

(Table 4-25 and Table 4-26). For example, vessels fishing with legal groundfish nontrawl gear must abide by the non-trawl RCA while vessels fishing with bottom trawl gear must abide by the trawl RCA. These RCA features were designed to provide sufficient access to target species while minimizing bycatch of overfished species.

- Bycatch Reduction Areas: Bycatch on Pacific whiting trips can be mitigated by implementing bycatch reduction areas. These areas restrictions apply to vessels on Pacific whiting trips using mid-water gear during the primary whiting season and limit fishing to depths greater than any of the specified management lines between 75 fm and 150 fm (see regulations at 660.131(c)(4) Subpart D).
- Ocean Conservation Zones: Chinook salmon bycatch on Pacific whiting trips can be mitigated by implementing the ocean salmon conservation zones. These zones apply to vessels on Pacific whiting trips using mid-water gear during the primary whiting season and restrict fishing to depths seaward of 100 fm.
- Other Groundfish Conservation Areas (GCA) – Several other GCAs exist and provide overfished species and habitat protection. Though limited bottom trawling occurs south of Point Conception at 34°27' N. latitude in the Southern California Bight, bottom trawling and other bottom fishing activities are prohibited in two discrete areas called the CCAs (Figure 4-16.a). Closed EFH areas are used to protect bottom habitat from the adverse effects of trawl gear (see regulations at 660.75). Three areas off the Washington coast are designed to reduce bycatch of yelloweye rockfish. North Coast Area B and South Coast Area B are closed to commercial fishing (Figure 4-16.a and b). South Coast Area A is a voluntary “area to be avoided” for commercial groundfish fisheries.

Impact (Groundfish Mortality)

The projected groundfish mortality for IFQ species under No Action, as a result of implementing the above mentioned management measures, can be found in Table 4-23. Additionally, Table 4-23 includes mortality estimates for 2011 and 2012 for comparison. Groundfish mortality of non-IFQ species is not projected using a model; however historical data from 2011 and 2012 are provided for comparison (Table 4-24).

Table 4-23. No Action – Shorebased IFQ. Projected mortality for IFQ species and Pacific halibut compared to the allocations or set-asides under No Action (2014 values). Year end estimates of mortality for 2011 and 2012 are provided for reference (right panel).

South Coast Area A is an area to be voluntarily avoided.

4.2.1.3 At-Sea Whiting Co-ops – No Action

The at-sea sector is composed of catcher-processors and motherships that target Pacific whiting with mid-water trawl gear and process at sea. Management measures include allocations for Pacific whiting, canary rockfish, darkblotched rockfish, POP, and widow rockfish and set-asides for bycatch species. Further, measures are established that restrict the Pacific whiting season dates and provide for bycatch reduction areas and ocean salmon conservation zones, similar to the shorebased IFQ fishery (Section 4.2.1.2).

The at-sea sector is managed under a system of cooperatives (co-ops) that are somewhat like IFQs except that the harvest privilege is assigned to a group, the co-op, instead of an individual. The members of the group then decide how and when the collectively-held harvest privilege would be used. The trawl rationalization program establishes a set of rules for the formation of co-ops in the at-sea mothership sector that provide a strong incentive for catcher vessels to form co-ops associated with a mothership processor (see regulations at 660.150). In the case of the catcher-processor sector, a single, voluntary co-op has been in existence for some time. In that instance the allocation to the sector is essentially an allocation to the co-op. Further, a catcher-processor permit endorsement is required, which essentially closes this sector to new entrants; a move intended to lend greater stability to the functioning of the current, voluntary co-op. Regulations at 660.160 outline the catcher-processor co-op provisions.

Impact (Groundfish Mortality)

Under No Action, allocations for Pacific whiting, canary rockfish, darkblotched rockfish, POP, and widow rockfish and set-asides for bycatch species established in 2014 would remain for 2015-2016 (Table 4-27 and Table 4-28). Groundfish mortality in the at-sea sectors, as a result of the above-mentioned management measures, is not formally estimated. The allocations may be considered the highest estimate of groundfish mortality since the fishery is managed to stay within the allocations.

Table 4-27. No Action – At-Sea. Allocations for the catcher-processor (CP) and mothership sectors (MS) under the No Action alternative for 2015-2016 (values in regulation on April 17, 2014). Historical mortality for 2011 and 2012 by sector is provided (right panel) for reference.

a/ NORPAC query on January 30, 2014.
b/As stated in §660.55 (m), the Pacific halibut set-aside is 10 mt, to accommodate bycatch in the at-sea Pacific whiting fisheries and in the shorebased trawl sector south of 40°10’ N. latitude (estimated to 5 mt each).

4.2.1.4 Limited Entry and Open Access Fixed Gear Management – No Action

Limited entry and open access fixed gear sectors are described in Section 3.XXX. Catch controls for both the incidental and directed open access fishery include trip limits and the nontrawl RCA (Table 4-26). Table 4-29 and Table 4-30 summarizes the principle management measures for the limited entry and open access fixed gear vessels. The sablefish stock is the primary target (in volume) for both the limited entry and open access fixed gear sectors. A variety of nearshore species (e.g., black rockfish, nearshore rockfish complex, cabezon, lingcod, and kelp greenling) are targeted by a large number of vessels, but in relatively low volume.

Table 4-31 and Table 4-32 summarize the FMP allocations of sablefish for limited entry and open access north of 36° N. latitude under No Action. South of 36° N. latitude, the FMP allocation of sablefish is 42 percent to the trawl sector and 58 percent to the non-trawl sector. A short-term allocation between the limited entry and open access fixed gear sectors of 55 percent and 45 percent, respectively, is established (Table 4-33). Trip limits intended to attain the allocations under No Action can be found in Table 4-34 and Table 4-35.

One non-trawl RCA is implemented for the limited entry and open access fixed gear fisheries (Table 4-26). Routine RCA adjustments can be made for four northern subareas bounded by Cape Mendocino at 40°10' N. latitude, 43° N. latitude, Cascade Head, Point Chehalis at 46.888° N. latitude, and the U.S.-Canada border. These adjustments may be necessary inseason to reduce projected catches of non-target species, typically yelloweye and canary rockfish, while providing access to target species. Changes can also be accommodated to provide greater access to target species when overfished species mortality is projected to be within the non-nearshore share or non-trawl allocation (e.g., changing from 125 to 100 fm).

The nontrawl RCA seaward boundary south of 40°10' N. latitude under the No Action Alternative is defined by management lines specified with waypoints at roughly 150 fathoms (fm) to avoid areas where bocaccio, canary and yelloweye rockfish are most abundant.

Other GCAs include the North Coast Area B Yelloweye Rockfish Conservation Area (YRCA) in Washington, which has been closed to limited entry and open access fixed gears since 2007 (Figure 4-16.b). Additionally, the South Coast Areas A and B YRCAs and the “C-shaped” YRCA in waters off northern Washington are voluntary “areas to be avoided” (Figure 4-16.c and Figure 4-17). Fishing is not allowed in the CCAs (Figure 4-16.a) under the No Action Alternative, except for some nearshore commercial fishing opportunities described in the nearshore section.

The models used project overfished species catches in the limited entry and directed open access fisheries and inform management measures are stratified by area of fishing shoreward (nearshore) or seaward (non-nearshore) of the nontrawl RCA (see Appendix A). Therefore, the estimates of groundfish mortality under No Action and the action alternatives are presented using the same strata.

Table 4-29. No Action – Limited Entry Fixed Gear. Summary of limited entry fixed gear fishery management measures under the No Action Alternative based on regulations as of April 17, 2014.

Cumulative limits	• Cumulative trip limits for most species, specific to geographic area (See regulations Table 2 North and South to Part 660, Subpart E) Sablefish trip limits are presented in Table 4-34. • Primary sablefish fishery managed with tier limits in Table 4-31. • Canary and yelloweye landings prohibited coastwide • South of 40°10' N. latitude landings of cowcod and bronzespotted rockfish prohibited
Size limits	Lingcod • North of 42° N. lat. minimum size limit 22 inches total length • South of 42° N. lat. minimum size limit 24 inches total length
Gear restrictions	• Longline, trap or pot marked at the surface, at each terminal end, with a pole, flag, light, radar reflector, and a buoy • Must be attended at least once every 7 days • Traps must have biodegradable escape panels
Seasons	• Primary sablefish fishery from 4/1 to 10/31 • Permit stacking of up to 3 permits is allowed in primary sablefish fishery • Additional seasonal restrictions may be implemented via routine action or the fishery may "close" for some species or some areas during the year through inseason action
GCAs	YRCA • North Coast Commercial YRCA (WA) closed to commercial fixed gears • North Coast Recreational YRCA (WA) is a voluntary area to be avoided • Westport Offshore Recreational YRCA (WA) is a voluntary area to be avoided
	CCA Fishing is prohibited in CCAs with the following exceptions: • Fishing for "other flatfish" when using no more than 12 hooks, #2 or smaller • Fishing for rockfish and lingcod shoreward of 20 fm
	• Farallon Islands commercial fishing for groundfish is prohibited shoreward of 10 fm with the following exceptions: Fishing for "other flatfish" when using no more than 12 hooks, #2 or smaller • Cordell Banks Commercial fishing for groundfish is prohibited in depths less than 100 fm
	EFH Fishing with all bottom contact gear, including longline and pot/trap gear, is prohibited within the following EFH conservation areas: Thompson Seamount, President Jackson Seamount, Cordell Bank (50 fm (91 m) isobath), Harris Point, Richardson Rock, Scorpion, Painted Cave, Anacapa Island, Carrington Point, Judith Rock, Skunk Point, Footprint, Gull Island, South Point, and Santa Barbara. Fishing with bottom contact gear is also prohibited within the Davidson Seamount
Nontrawl RCAs	• North of 46°16' N. lat. Shoreline to 100 fm • 46°16'- 42° N. lat. 30 to 100 fm • 42°-40°10' N. lat. 20 fm depth contour to 100 fm • 40°10'-34°27' N. lat. – 30 to 150 fm • South of 34°27' N. lat. – 60 to 150 fm Fishing is prohibited in nontrawl RCAs with the following exception: Fishing for "other flatfish" when using no more than 12 hooks, #2 or smaller
Monitoring	• VMS required • WCGOP observer coverage when requested
Reporting	• VMS declarations

Table 4-30. No Action – Open Access. Summary of open access fishery management measures under the No Action Alternative based on regulations as of April 17, 2014.

Cumulative	• Cumulative trip limits for most species, specific to trawl type and geographic area (See

limits	regulations Table 2 North and South to Part 660, Subpart E) • Canary and yelloweye landings prohibited coastwide • South of 40°10' N. latitude landings of cowcod and bronzespotted rockfish prohibited
Gear restrictions	• Longline, trap, pot, hook-and-line (fixed or mobile), setnet (anchored gillnet or trammel net (south of 38° N. lat. only), spear, and non-groundfish trawl gear for: pink shrimp, ridgeback prawn, and California halibut or sea cucumbers (south of Pt. 38°57.50' N. lat.) Non-groundfish trawl gear: • Is exempt from the limited entry trawl gear restrictions • Footrope (>19") prohibited in EFH Fixed gear: • Must be marked at the surface, at each terminal end, with a pole, flag, light, radar reflector, and a buoy; vertical hook-and-line gear that is closely tended may be marked only with a single buoy of sufficient size to float the gear • Must be attended at least once every 7 days • Fishing for groundfish with set nets is prohibited in the fishery management area north of 38°00.00' N. lat. • Traps must have biodegradable escape panels • Spears may be propelled by hand or by mechanical means
Seasons	Seasonal restrictions may be implemented via routine action or the fishery may "close" for some species or some areas during the year through inseason action
GCAs	YRCA • North Coast Commercial YRCA (WA) closed to commercial fixed gears • North Coast Recreational YRCA (WA) is a voluntary area to be avoided • Westport Offshore Recreational YRCA (WA) is a voluntary area to be avoided • Salmon Troll YRCA. Fishing for salmon is prohibited
	CCA Fishing is prohibited in CCAs with the following exceptions: • Fishing for "other flatfish" when using no more than 12 hooks, #2 or smaller • Fishing for rockfish and lingcod shoreward of the 20 fm
Open Access nontrawl RCAs	• North of 46°16' N. lat. Shoreline to 100 fm • 46°16'- 42° N. lat. 30 to 100 fm • 42°-40°10' N. lat. 20 fm depth contour to 100 fm • 40°10'-34°27' N. lat. – 30 to 150 fm • South of 34°27' N. lat. – 60 to 150 fm Fishing is prohibited in nontrawl RCAs with the following exception: Fishing for "other flatfish" when using no more than 12 hooks, #2 or smaller
Monitoring	• VMS required • WCGOP observer coverage when requested
Reporting	• VMS declarations

Table 4-31. No Action: Limited entry sablefish FMP allocations north of 36 N. latitude, based on values in regulation on April 17, 2014.

Open Access	300 lb/day, or 1 landing per week of up to 1,600 lb, not to exceed 3,200 lb/2 months					

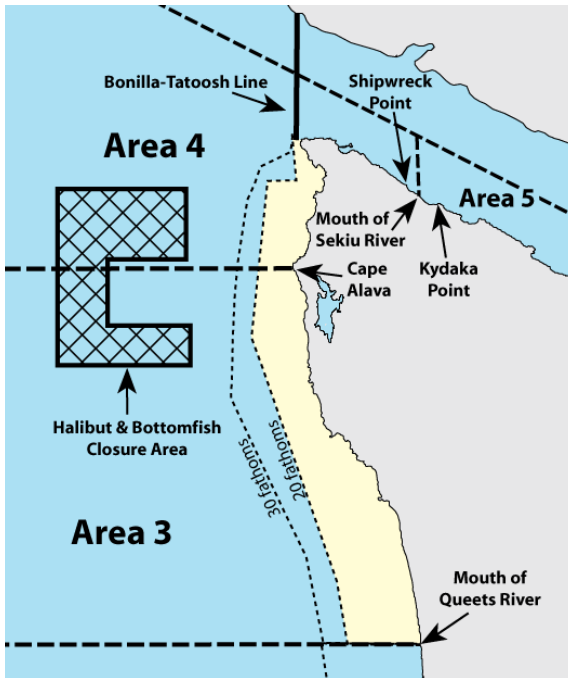

Figure 4-17. No Action. The current "C-shaped" Yelloweye Rockfish Conservation Area in waters off northern Washington where recreational groundfish and Pacific halibut fishing is prohibited.

Impact (Groundfish Mortality) – Non-Nearshore North of 36° N. latitude

The non-nearshore model projects mortality of overfished and non-overfished species for the limited entry fixed gear and the open access sectors north of 36° N. latitude and seaward of the nontrawl RCA based on the northern sablefish ACL. The sablefish north stock is the primary target and provides the main source of revenue in both sectors. The bycatch projections are based on the assumption that the limited entry and open access allocations for sablefish, less any discard mortality, are completely harvested.

Interactions with overfished species, primarily yelloweye rockfish and canary rockfish, require adjustments to management measures in the non-nearshore fisheries. Seaward adjustments of the nontrawl RCA boundary are the main management measure for reducing catches of these two stocks. Changes to the shoreward boundary (e.g., changing from 150 to 100 fm) can also be accommodated to provide greater access to target species when overfished species mortality is projected to be within the non-nearshore share or non-trawl allocation.

Management measures and projected mortality for the non-nearshore fishery north of 36° N. latitude under No Action is largely influenced by the sablefish ACL, which would be calculated with a P* of 0.40

(Table 4-20), and the resulting sablefish allocations (Table 4-31 and Table 4-32). Current trip limits (Table 4-34) would be routinely adjusted to achieve the limited entry and open access sablefish allocations (Table 4-31 and Table 4-32). Trip limits for other species (e.g., slope rockfish, shelf rockfish, etc.) may also be adjusted to attain the ACL or achieve other conservation goals.

The overfished species mortality, as a result of harvesting the sablefish allocations, were evaluated using 2002-2011 WCGOP data in the non-nearshore model. Under No Action, trawl and non-trawl allocations were established for overfished species. Further, the non-nearshore fishery was also allocated a share of the non-trawl allocation for bocaccio, canary, and yelloweye (Table 4-36). Routine adjustments of the seaward non-trawl RCA (Table 4-26) would occur in the event the projected overfished species mortality is expected to exceed the non-nearshore share or non-trawl allocation (Table 4-36). RCA changes can also be accommodated to provide greater access to target species when overfished species mortality is projected to be within the non-nearshore share or non-trawl allocation (e.g., changing from 125 to 100 fm). Table 4-37 contains the projected mortality groundfish for the non-nearshore fishery.

Table 4-36. No Action – Non-Nearshore fishery: Overfished species shares for the non-nearshore fixed gear fishery under No Action (mt), based on the Preferred Alternative for 2014 in the 2013-2014 FEIS.

Stock	Area	Total Projected OFS Mortality 2015-2016 (mt)	Shares 2015/2016 (mt)	Non-Trawl Allocation (mt)

Impact (Groundfish Mortality) – Non-Nearshore South of 36° N. latitude

Management measures and projected groundfish mortality for the non-nearshore fishery south of 36° N. latitude under No Action is largely influenced by the sablefish ACL, which would be calculated with a P* of 0.40 (Table 4-20). Anticipated catch of sablefish south of 36º N latitude under No Action would be approximately equal to the 2015-2016 sablefish allocations and resulting landed catch shares for limited entry and open access fixed gears (Table 4-33). The current trip limits (Table 4-35) would be routinely adjusted to achieve the limited entry and open access sablefish allocations (Table 4-33). Trip limits for other species (e.g., slope rockfish, shelf rockfish, etc.) may also be adjusted to attain the ACL or achieve other conservation goals.

Under No Action, trawl and non-trawl allocations would be established for overfished species. Further, the non-nearshore fishery would be allocated a share of the non-trawl allocation for bocaccio, canary, and yelloweye (Table 4-36). Routine adjustments of the non-trawl RCA (Table 4-26) would occur in the event the projected overfished species mortality is expected to exceed the non-nearshore share or non-trawl allocation (Table 4-36). Changes can also be accommodated to provide greater access to target species when overfished species mortality is projected to be within the non-nearshore share or non-trawl allocation (e.g., changing from 125 to 100 fm).

Impact (Groundfish Mortality) – Nearshore – No Action

The nearshore model projects mortality of overfished species based on the expected landings of nearshore species by the limited entry and opens access sectors shoreward of the nontrawl RCA coastwide. The majority of vessels participating in nearshore commercial fisheries do not hold Federal limited entry permits. The most common gear used is jig gear; however, some vessels use longline gear to target nearshore species and, in fewer instances, pots or traps are used in the nearshore fishery.

California and Oregon limit entry to the nearshore groundfish fishery by requiring a state limited entry permit to take nearshore groundfish species. Washington does not allow a nearshore commercial fishery. More conservative state quotas than those specified in Federal regulations exist for most nearshore species, and state trip limits apply in these cases. State trip limits are designed to stay within nearshore species quotas while providing a year-round opportunity, if possible. Federal management measures for west coast nearshore commercial groundfish fisheries are typically stratified north and south of 40°10' N. latitude, with some measures stratified north and south of 42° N. latitude and others stratified south of 34°27’ N. latitude.

In Oregon, two types of state limited entry permits are issued – black and blue rockfish permits with a nearshore endorsement and black and blue rockfish permits without a nearshore endorsement. Limited entry permit holders without a nearshore endorsement may land commercial quantities of black and blue rockfish under state cumulative trip limits (currently two-month periods), with an additional total of 15 lbs per day of any combination of other nearshore groundfish species and two rockfish species with Federal designation as shelf rockfish (tiger and vermilion). Vessels that also have a nearshore endorsement permit, in addition to the black/blue limited entry permit, may land commercial quantities of other nearshore groundfish species up to the state’s cumulative trip limits and the Federal limits for tiger and vermilion rockfish. For vessels that do not hold a state permit or endorsement, an incidental landing limit of no more than 15 pounds per day of any combination of black rockfish, blue rockfish, and/or other nearshore fish is allowed, with a few exceptions. Salmon trollers with a valid troll permit may land 100 pounds of black rockfish, blue rockfish, or a combination thereof in the same landing in which a salmon is landed. These rockfish may only be landed dead. If the cumulative landing of black and blue rockfish combined in the salmon troll fishery reaches 3,000 pounds in any calendar year, then each salmon troll vessel is limited to 15 pounds of black rockfish, blue rockfish, or a combination thereof per troll landing for the remaining calendar year. Trawlers may land up to 1,000 pounds of black rockfish, blue rockfish, or a combination thereof per calendar year, and these fish must be 25 percent or less of the total poundage of each landing and be landed dead.

In California, limited entry permit holders, as well as open access fishermen, who have either a shallow nearshore fishery or deeper nearshore fishery permit administered by the California Department of Fish and Wildlife (CDFW) may land minor nearshore rockfish from either the shallow nearshore or deeper nearshore complexes, respectively. Trip limits for shallow nearshore rockfish, deeper nearshore rockfish, cabezon, greenlings, and California scorpionfish vary by period. There is some nearshore commercial fishing allowed in the CCAs (Figure 4-16) in depths shallower than 20 fm under the No Action Alternative. Only southern minor nearshore rockfish, (both shallow and deeper nearshore rockfish), California scorpionfish, cabezon, greenlings, California sheephead, and ocean whitefish are allowed to be retained in depths less than 20 fm in the CCAs.

There are Federal limits and state quotas (or harvest guidelines) for nearshore species that limit target species landings in the commercial nearshore fishery (Table 4-38). State harvest guidelines between recreational and commercial fisheries may be adjusted by each state between or within years, so are not displayed herein. State harvest guidelines for each sector are established to ensure that the non-trawl allocation provided to each state is not exceeded while providing fishing opportunities for both sectors. The nearshore fishery is also managed to stay within the nearshore share for overfished species (Table 4-41) or the overall non-trawl overfished species allocations. Trawl, non-trawl, and within non-trawl allocations for overfished species, which were established in the 2013-2014 biennium, would be implemented under No Action. Under the No Action alternative, catch of canary rockfish in California exceeds the catch sharing agreement with Oregon (Table 4-38) as well as the nearshore share of the non-trawl allocation. However, total catch of canary from both commercial and recreational fisheries is within the non-trawl allocation. In the event the projected overfished species mortality is expected to exceed the non-trawl allocation, routine adjustments of the shoreward non-trawl RCA (Table 4-26) or reduced trip limits for nearshore species could occur. RCA changes can also be accommodated to provide greater access to target species when overfished species mortality is projected to be within the nearshore share or non-trawl allocation (e.g., changing from 20 to 30 fm).

The No Action alternative is based on the expectation that landings in the nearshore fishery will be similar to recent historical average landings from 2008-2012 (Table 4-39 and Table 4-40), which is lower than most of the state quotas. Nearshore fishery landings are influenced by a variety of factors, including weather and market, and can vary annually (Table 4-40). As such, there is substantial uncertainty surrounding the estimated landings under No Action and the action alternatives, which in turn may influence the projected overfished species mortality and socioeconomic analysis. In the event fishery performance is better than the five year average, mortality of groundfish species will be higher; however the fishery will still be managed to ensure combined commercial and recreational catches stay within the non-trawl allocation.

Table 4-38. No Action. Nearshore species quotas between state and sector under No Action.

4.2.1.5 Tribal Fisheries – No Action

Tribal fisheries consist of trawl (bottom, mid-water, and whiting), fixed gear, and troll. Principle management controls in the tribal fisheries include set-asides, HGs, and trip limits. Tribal set-asides are outlined in Table 4-20, which represent the values in the April 17, 2014 regulations. The Washington coastal tribes (Makah, Quileute, Hoh, and Quinault) conducted their groundfish fisheries in 2014 with the trip limits shown in Table 4-42 and the following allocations:

- The sablefish allocation was 10 percent of the sablefish ACL north of 36° N. latitude (4,349 mt). The allocation of 435 mt was further reduced by 1.5 percent for discard mortality, to produce landed catch allocations of 428 mt.
- Black rockfish was managed with a HG of 30,000 pounds north of Cape Alava, Washington at 48°09'30" N. latitude, and 10,000 pounds between Destruction Island, Washington at 47°40' N. latitude and Leadbetter Point, Washington at 46°38'10" N. latitude. There were no harvest restrictions on black rockfish between Cape Alava and Destruction Island.
- Lingcod had a 250 mt HG.
- Pacific cod had a 400 mt tribal HG.
- Longspine and shortspine thornyheads were managed to the cumulative limits with those limits accumulated across vessels into a cumulative fleetwide harvest target for the year.
- The Makah Tribe would manage the midwater trawl fisheries as follows: Yellowtail rockfish taken in the directed tribal mid-water trawl fisheries are subject to a catch limit of 677 mt for the entire fleet. Landings of widow rockfish must not exceed 10 percent of the weight of yellowtail rockfish landed, for a given vessel, throughout the year. These limits may be adjusted by the tribe inseason to minimize the incidental catch of canary rockfish and widow rockfish, provided the catch of yellowtail rockfish does not exceed 677 mt for the fleet.
- The 2014 Pacific whiting TAC had not been adopted at the time of the analysis, therefore the 2013 harvest level and allocations are used under No Action. In 2013 the U.S. TAC of 269,745 mt for Pacific whiting resulted in a start of the year tribal allocation of 63,205 mt that NMFS

based on the percentage requested by Makah (17.5 percent of the U.S. TAC) and an additional amount to accommodate the Quileute's developing fishery (78FR26526).

Impact (Groundfish Mortality)

All mid-water landing limits were subject to inseason adjustments to minimize the take of both canary and widow rockfish. Full rockfish retention programs, where all overfished and marketable rockfish are retained, as well as a Makah trawl observer program, were in place to provide catch accountability.

Table 4-42. The No Action: Tribal fishery based on regulations as of April 17, 2014.

Cumulative limits	Full retention of rockfish Rockfish taken during open competition tribal commercial fisheries for Pacific halibut would not be subject to trip limits. Thornyheads • Shortspine thornyhead cumulative trip limits are 17,000-lb per 2 months • Longspine thornyhead cumulative trip limits are 22,000-lb per 2 months Canary rockfish 300 lb per trip Yelloweye rockfish 100 lb per trip Makah Tribe midwater trawl fisheries: Yellowtail rockfish taken in the directed tribal mid-water trawl fisheries are subject to a catch limit of 677 mt for the entire fleet. Landings of widow rockfish must not exceed 10 percent of the weight of yellowtail rockfish landed, for a given vessel, throughout the year. These limits may be adjusted by the tribe inseason to minimize the incidental catch of canary rockfish and widow rockfish, provided the catch of yellowtail rockfish does not exceed 677 mt for the fleet. Minor shelf rockfish and minor slope rockfish. Redstripe rockfish are subject to an 800 lb (363 kg) trip limit. Minor shelf (excluding redstripe rockfish), and minor slope rockfish groups are subject to a 300 lb (136 kg) trip limit per species or species group, or to the non-tribal limited entry fixed gear trip limit for those species if those limits are less restrictive than 300 lb (136 kg) per trip. Limited entry fixed gear trip limits are specified in Table 2 (North) to subpart E of this part. Other rockfish, including minor nearshore, minor shelf, and minor slope rockfish 300 lb per trip limit per species or species group, or to the nontribal limited entry trip limit for those species if those limits are less restrictive than 300 lb (136 kg) per trip. Lingcod are subject to an overall catch of 250 mt for all treaty fishing. Flatfish and other fish (bottom trawl). • For Dover sole, English sole, other flatfish 110,000 lbs (49,895 kg) per 2 months; and for arrowtooth flounder 150,000 lbs (68,039 kg) per 2 months. The Dover sole and arrowtooth limits in place at the beginning of the season would be combined across periods and the fleet to create a cumulative harvest target. The limits available to individual vessels would then be adjusted inseason to stay within the overall harvest targets and overfished species limits. • Petrale sole – are subject to a fleetwide harvest target of 220 mt. Trawl vessels are restricted to small footrope trawl gear. Pacific whiting -The tribal allocation for 2011 is 63,205 mt. Pacific cod - Managed to the tribal HG of 400 mt. Spiny dogfish - limited entry trip limits for the non-tribal fisheries apply
Monitoring	• The Makah Tribe shoreside observer program to monitor and enforce Makah limits.
Reporting	• VMS declarations for trawl only

4.2.1.6 Washington Recreational – No Action

Primary catch controls for the Washington recreational fishery are season dates, depth closures, bag limits, and GCAs, including YRCAs. Yelloweye rockfish and canary rockfish are the two overfished stocks primarily caught in the Washington recreational fishery and seaward adjustments of the recreational RCAs are the main management measure for reducing catches of these two stocks. Under the No Action Alternative, Washington recreational fisheries would operate under the 2014 ACLs (Table 4-20) including an 18 mt for yelloweye rockfish ACL and 119 mt canary rockfish ACLs, and the associated Washington recreational HGs of 2.9 mt for yelloweye rockfish and 3.1 for canary rockfish (Table 4-43).

Table 4-43. No Action – Washington Recreational. Harvest guidelines (HG) for the Washington recreational fisheries under the No Action Alternative.

Species	HG (mt)
CANARY	2.9
YELLOWEYE	3.1

Groundfish Seasons and Area Restrictions

Season Structure

Under the No Action Alternative, the Washington recreational fishery would be open year-round for groundfish, except lingcod. Retention of canary and yelloweye rockfish in all areas would continue to be prohibited under No Action.

Depth restrictions are the primary tool used to keep recreational mortality of yelloweye and canary rockfish within specified HGs. Restrictions limiting the depth where groundfish fisheries are permitted are more severe in the area north of the Queets River (Marine Areas 3 and 4) where yelloweye and canary rockfish abundance is higher and therefore caught incidentally at a higher rate. Depth restrictions are fewer in the south coast where incidental catch of yelloweye and canary becomes progressively less. Table 4-44 summarizes key features of the Washington recreational regulations under the No Action Alternative.

Table 4-44. No Action. Washington Recreational Seasons and Groundfish Retention Restrictions.

Marine Area	Jan	Feb	Mar	Apr	May	June	July	Aug	Sep	Oct	Nov	Dec
3 & 4 (N. Coast)	Open all depths				Open <20 fm May 1-Sep 30 a/					Open all depths		
2 (S. Coast)	Open all depths g/		Open <30 fm Mar 15 - June 15 b/, c/, d/, g/			Open all depths except lingcod prohibited on Fri. and Sat. >30 fm e/,g			Open all depths g/			
1 (Col. R.)	Open all depths g/				Open all depths f/, g/					Open all depths g/		

a/ Groundfish retention prohibited >20 fm except, retention of lingcod, Pacific cod and sablefish is allowed seaward of 20 fm on days when Pacific halibut is open.
b/ Retention of sablefish and Pacific cod allowed seaward of 30 fm from May 1- June 15.
c/ Retention of rockfish allowed seaward of 30 fm.
d/ Retention of lingcod allowed seaward of 30 fm on days that the primary halibut season is open.
e/ Retention of lingcod prohibited >30 fm, south of 46°58 on Fri. and Sat. from July 1 – August 31.
f/ Retention of groundfish, except sablefish and Pacific cod, prohibited with Pacific halibut on board.
g/ Retention of lingcod prohibited in deepwater areas at all times.

North Coast (Marine Areas 3 and 4): The retention of bottomfish is prohibited seaward of a line approximating 20 fm from May 1- September 30, except lingcod, Pacific cod and sablefish can be retained seaward of 20 fm on days that Pacific halibut fishing is open. Fishing for, retention, or possession of groundfish and Pacific halibut is prohibited in the C-shaped YRCA (Figure 4-18).

South Coast (Marine Area 2): The retention of bottomfish, except rockfish, is prohibited seaward of 30 fm from March 15 through June 15, except sablefish and Pacific cod retention is allowed May 1 through June 15. Retention of lingcod is allowed seaward of 30 fm on days open to the primary Pacific halibut season. The retention of lingcod is prohibited south of 46°58' N. latitude and seaward of 30 fm on Fridays and Saturdays from July 1 through August 31. Fishing for, retention, or possession of lingcod is prohibited in deepwater areas seaward of a line extending from 47°31.70' N. latitude, 124°45.00' W. longitude to 46°38.17' N. latitude, 124°30.00' W. longitude year-round, except as allowed on days open to the Pacific halibut fishery (Figure 4-18). Fishing for, retention or possession of bottomfish or Pacific halibut is prohibited in the South Coast YRCA and Westport Offshore YRCA (Figure 4-18).

Columbia River (Marine Area 1): Retention of bottomfish, except sablefish and Pacific cod, is prohibited with halibut onboard from May 1 through September 30, and fishing for, retention, or possession of lingcod in deepwater areas seaward of a line extending from 46°38.17 N. latitude, 124°21.00' W. longitude to 46°25.00' N. latitude, 124°21.00' W. longitude year-round (Figure 4-18).

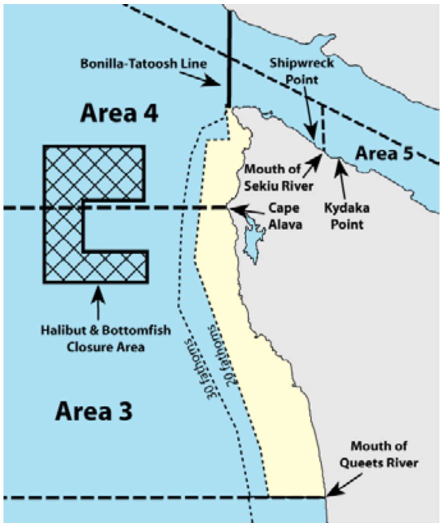
Area Restrictions

Under the No Action Alternative, fishing for, retention, or possession of groundfish and halibut during the Washington recreational groundfish and Pacific halibut fisheries would be prohibited in the C-shaped YRCA in the north coast and the South Coast and Westport YRCAs in the south coast (Figure 4-18.a and .b).

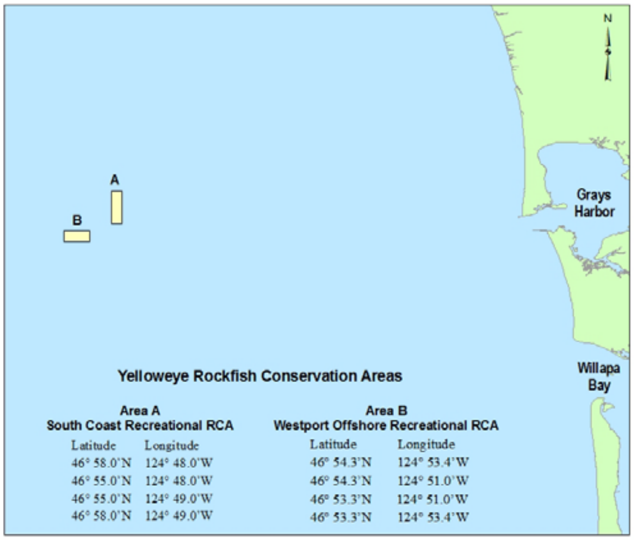
Fishing for, retention, or possession of lingcod would be prohibited seaward of a line connecting the following coordinates from the Queets River (47°31.70' N. latitude, 124° 45.00' W. longitude) to

46°25.00’ N. latitude, 124°21.00’ W. longitude, year round except as allowed in Washington Marine Area 2 on days open to the primary Pacific halibut fishery (Figure 4-18.c).

a.



b.



c.

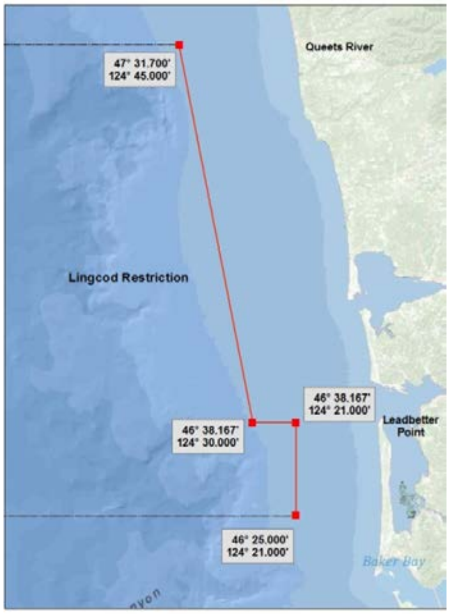


Figure 4-18. No Action Washington recreational area restrictions. a. C-Shaped YRCA; b. Washington South Coast and Westport YRCAs; c. Lingcod Restricted Area.

Groundfish Bag Limits

Under the No Action Alternative the recreational groundfish bag limit, including rockfish and lingcod, would be 12 fish per day. Of the 12 recreational groundfish allowed to be landed per day, sub-limits of 10 rockfish and, two lingcod apply. The recreational bag limit would also include a sub-limit of two cabezon in Marine Areas 1-3 and one cabezon in Marine Area 4.

Lingcod Seasons and Size Limits

The lingcod season in Marine Areas 1 through 3 (Washington-Oregon border at 46°16’ N. latitude to Cape Alava at 48°10’ N. latitude) would be open from the Saturday closest to March 15 through the Saturday closest to October 15, which was March 15 through October 18 in 2014. Marine Area 4 (Cape Alava to the U.S. Canadian border) would be open from April 16 through October 15, or the Saturday closest to October 15; whichever is earlier, which was April 16 through October 15 in 2014.

Under the No Action Alternative the lingcod seasons and size limits by area would be as follows:

- Marine Areas 1-3: March 14 through October 17 in 2015 and March 12 through October 15 in 2016. Minimum size, 22 inches.
- Marine Area 4: April 16 through October 15 in 2015 and April 16 to October 15 in 2016. Minimum size, 22 inches.

Cabezon Size Limit

Under the No Action Alternative, there is an 18 inch minimum size limit for cabezon in Marine Area 4 (Cape Alava to the U.S. Canadian border).

Pacific Halibut Seasons

It is expected that the Pacific halibut seasons in 2015 and 2016 would be similar to the halibut seasons in 2013 and 2014. There are no changes to the restrictions on groundfish retention during the Pacific halibut season proposed under the No Action Alternative.

Additional Management Measures Analyzed

No additional management measures were analyzed for the No Action Alternative. Status quo management measures would be used to keep recreational harvests of overfished species within specified HGs.

Inseason Management Response

Projected mortality for Washington’s recreational fishery is based upon the previous season’s harvest estimated by the Ocean Sampling Program (OSP) and incorporated in Recreational Fishery Information Network (RecFIN). It should be noted that the precision of recreational groundfish catch estimates based upon previous seasons would continue to be influenced by factors such as the length and success of salmon and halibut seasons, weather and unforeseen factors.

Washington’s Ocean Sampling Program is able to produce estimates of groundfish catch with a one month lag time. Management measures such as more restrictive depth closures, area closures, groundfish retention restrictions, or changes to seasons can be considered and implemented through emergency changes to state regulations if inseason catch reports indicate that recreational harvests of overfished species or non-overfished species are exceeding pre-season projections to the point where HGs are at risk of being exceeded.

Impact (Groundfish Mortality)

Projected mortality for overfished and non-overfished species under the No Action Alternative is summarized in Table 4-45.

Table 4-45. No Action – Washington Recreational. Projected mortality for overfished species under the No Action Alternative.

Stock	2015	2016
CANARY ROCKFISH	0.63	0.63
YELLOWEYE ROCKFISH	2.65	2.65

4.2.1.7 Oregon Recreational – No Action

Primary catch controls for the Oregon recreational fishery are season dates, depth closures, bag limits, and GCAs, including YRCAs. The No Action Alternative analyzes the Oregon recreational fishery under the 2014 ACLs (Table 4-20) and Oregon recreational HGs or state quotas (Table 4-46).

Table 4-46. No Action. Oregon recreational Federal harvest guidelines (HG) or state quotas under the No Action Alternative (mt).

Stock	HG a/
CANARY ROCKFISH	11.1
YELLOWEYE ROCKFISH	2.6
Black Rockfish OR	440.8
Greenlings b/	5.2
Nearshore Rockfish North of 40°10 N. Lat.c/	54.6
--Blue Rockfish	*41.0*
--Other Nearshore Rockfish	*13.6*

a/ Federal HG are established for canary and yelloweye rockfish only. The state process in Oregon establishes quotas for black rockfish, blue rockfish, other nearshore rockfish, and greenlings (all species). Black and blue rockfish are managed to a combined state quota, the estimated quotas by species are represented in this table. The state quotas are not intended to be implemented in Federal regulation, they are only provided as information.
b/ Includes kelp and other greenlings
c/ Includes blue rockfish

Groundfish Seasons and Area Restrictions

<u>Season structure</u>

Under the No Action Alternative, the Oregon recreational groundfish fishery would be open offshore year-round, except from April 1 to September 30 when fishing is only allowed shoreward of 40 fathoms, as defined by waypoints (Figure 4-19). Closing the fishery outside of 40 fathoms from April 1 to September 30, months when angler effort and yelloweye rockfish encounters are greatest, mitigates mortality of yelloweye rockfish. Projected mortality of yelloweye and canary rockfish are within the Federal HGs, therefore the shore-based fishery would be open year-round.

	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec
Bottomfish Season	Open all depths			Open < 40 fm						Open all depths		
Marine Bag Limit [1]	Ten (10)			1 Fish Cabezon Sub-Bag [2]						Ten (10)		
Lingcod Bag Limit	Three (3)											
Flatfish Bag Limit [3]	Twenty Five (25)											

1 Marine bag limit includes all species other than lingcod, salmon, steelhead, Pacific halibut, flatfish, surfperch, sturgeon, striped bass, pelagic tuna and mackerel species, and bait fish such as herring, anchovy, sardine, and smelt

2 From April 1 through September 30, the marine bag limit is Ten (10) fish per day, of which no more than one (1) may be cabezon.

3 Flounders, soles, sanddabs, turbots and halibuts except Pacific halibut

Figure 4-19. No Action. Oregon recreational groundfish season structure and bag limits under the No Action Alternative.

Area Closures

The Stonewall Bank YRCA has been in place since 2006 and would also remain under the No Action alterative (Figure 4-20). The YRCA is located approximately 15 miles west of the Port of Newport and consists of the high-relief area of Stonewall Bank, an area of high yelloweye rockfish encounters. No recreational fishing for groundfish and Pacific halibut can occur within this YRCA, which is bounded by the waypoints contained in Figure 4-20.

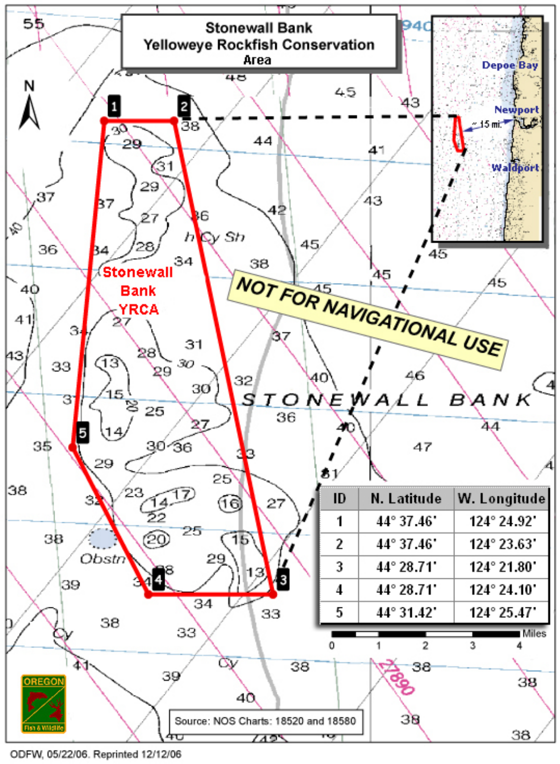

Figure 4-20. No Action. The Stonewall Bank Yelloweye Rockfish Conservation Area where recreational fishing for groundfish and Pacific halibut is prohibited.

Groundfish Bag Limits and Size Limits

Under the No Action Alternative, the marine fish daily bag limit of 10 fish in aggregate that was allowed in 2013-2014 Oregon recreational fisheries would carry forward for 2015-2016 (Figure 4-19). The marine bag includes all species other than lingcod, salmon, steelhead, Pacific halibut, flatfish, surfperch, sturgeon, striped bass, pelagic tuna and mackerel species, and bait fish such as herring, anchovy, sardine and smelt. During April through September, there was a one fish sub-bag limit for cabezon (of the 10 fish marine bag limit no more than one could be cabezon). This cabezon sub-bag limit would also carry forward for 2015-2016. A flatfish daily bag limit of 25, which includes all soles and flounders except Pacific halibut, was allowed in addition to the marine fish daily bag limit. Additionally a three-fish bag limit was allowed for lingcod. Retention of canary and yelloweye rockfish was prohibited in 2013-2014 and would continue to be prohibited under the No Action Alternative.

The following minimum size limits applied to 2013-2014 Oregon recreational fisheries and would be carried forward under the No Action Alternative:

- Lingcod – 22 in.
- Cabezon – 16 in.
- Kelp greenling – 10 in.

Pacific Halibut

Under the No Action Alternative, the recreational Pacific halibut fisheries should be able to proceed as in 2013 and 2014, in regards to days and areas open, etc., depending on the halibut quota. Since 2009, only sablefish and Pacific cod may be retained in the Pacific halibut fishery at any depth in the area north of Humbug Mountain, Oregon. South of Humbug Mountain, groundfish may be retained in areas open to groundfish (e.g., less than 30 fm) when halibut are onboard the vessel. It is expected that groundfish retention in the all-depth Pacific halibut fishery would be similarly limited in 2015 and 2016, under the No Action Alternative.

Additional Management Measures Analyzed

Adjustments to routine and currently available management measures would be used to keep recreational harvests of overfished species within specified Federal HGs under No Action.

Inseason Management Tools

Oregon has a responsive port-based monitoring program through ORBS, and regulatory processes in place to track mortality and take actions inseason if necessary. The following are suggested management measures that could be implemented inseason if the fishery does not proceed as expected.

Inseason management tools, designed to mitigate mortality, include bag limit adjustments (including non-retention), length limit adjustments, gear restrictions, and season, days per week, depth, and area closures.

Season, depth, days open per week, and area closures are the primary inseason tools for limiting yelloweye rockfish and canary rockfish mortality, since retention of these species is prohibited. If catch rates indicate that the bycatch harvest targets for yelloweye rockfish would be reached prematurely, offshore depth closures may be implemented inseason at 30, 25, or 20 fathoms as these two species are less abundant nearshore and release survival rates are higher in shallow waters. Additionally, days per week may also be closed to reduce mortality. ODFW would monitor inseason progress toward recreational harvest targets for canary rockfish and yelloweye rockfish. Regulations would depend upon the timing of the determination for their need.

Adjustments to the marine fish daily bag limit to no more than 10 fish may be implemented to achieve season duration goals in the event of accelerated or decelerated black rockfish or other nearshore rockfish harvest. The lingcod daily bag limits may be adjusted to no more than 3 fish in the event the marine bag limit changes or the halibut catch limit is reduced from 2013 levels. Season and/or area closures may also be considered if harvest targets are projected to be attained. Closing one or more days per week is an inseason tool that could be used to limit mortality. Closing certain days each week would help lengthen the duration of a fishery approaching an HG.

Non-retention and length restrictions are the likely inseason tools to use for cabezon and greenling, as release survival is very high. They may also be used to reduce mortality of nearshore species, such as black rockfish and other nearshore rockfish species.

Gear restrictions and/or release technique requirements may be implemented to reduce the impact of overfished rockfish since a variety of descending devices are available. SSC recommended and Council-approved mortality rates for canary and yelloweye rockfish when descending devices are used will be implemented in 2014 (see Appendix A for documentation).

Directed yellowtail rockfish and/or flatfish fisheries may be implemented inseason, as were implemented in 2004, in the event of a closure of the recreational groundfish fishery due to attainment Federal or state HGs or targets. Specific gear restrictions may be implemented in the event that yellowtail rockfish and/or flatfish fisheries remain open during a groundfish closure. Additionally, the fishery may be expanded to waters seaward of the RCA, promoting directed yellowtail rockfish opportunity. Directed flatfish fisheries would be legal year round and open shoreward of 40 fathoms during any period the groundfish fishery has any depth restrictions (i.e. 40, 30, 25, and 20 fathom lines). The flatfish fishery would not have any depth restrictions when the groundfish fishery has no depth restrictions. Fisheries would be monitored to ensure that mortality of yelloweye and canary rockfish are within the harvest targets/guidelines.

In the event that the duration of total season is reduced from 12 months; the nearshore waters are closed to groundfish fishing due to management of nearshore species; or the Pacific halibut catch limit is reduced from 2013 levels, the fishery may be expanded to waters seaward of the RCA that is in effect at the time, promoting directed yellowtail rockfish and offshore lingcod opportunity. Fisheries would be monitored to ensure that mortality of yelloweye rockfish and canary rockfish is not in excess of the HGs.

Impact (Projected Mortality)

The annual projected mortality presented in Table 4-47 is anticipated, given the season structure and bag limits detailed above. Table 4-48 shows the recent mortality of the ten most landed species in the Oregon recreational fishery, including black rockfish. Species in Table 4-48, other than black rockfish, have not been modeled in the past. This table represents recent mortality under similar season structure and bag limits to what will be in place under the No Action Alternative.

* Blue Rockfish is managed separately from the rest of the nearshore rockfish complex under Oregon state regulations

4.2.1.8 California Recreational – No Action

Season structures and projected mortality under the No Action Alternative is based on CDFW's updated RecFISH model. Model projections were calculated for the five recreational groundfish management areas using updated 2011 and 2012 RecFIN estimates and overfished species mortality are reported statewide. Under No Action, trawl and non-trawl allocations for overfished species were established (Table 4-49). The California recreational fishery was allocated a share of the non-trawl allocation, through use of a HG, for bocaccio, canary, and yelloweye to ensure that total non-trawl catches remained within the non-trawl allocations for these overfished speices. Under the No Action Alternative, depth restrictions and season length remain unchanged statewide (PFMC and NMFS 2011).

Table 4-49. No Action – California Recreational: Overfished species allocations (mt) to the non-trawl sector and shares (mt) for the California recreational fisheries under No Action, which is based on the Preferred Alternative for 2014 in the 2013-2014 FEIS.

Stock	Non-Trawl Allocation	California Recreational HG
Bocaccio	249.6	172.5
Canary	47.4	23
Cowcod	1.9	
Darkblotched	15.5	
POP	35	
Petrale Sole	6.8	
Yelloweye	11.2	3.4

Groundfish Seasons and Area Restrictions

The following recreational season applied in 2014 would remain in place under the No Action Alternative (Figure 4-21). All divers and shore-based anglers are exempt from the seasonal closures for rockfish, cabezon, greenlings, lingcod, and California scorpionfish.

Management Area	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec
Northern	Closed				May 15–Oct 31 <20fm						Closed	
Mendocino	Closed				May 15–Sept 1 <20fm				Closed			
San Francisco	Closed					Jun 1 – Dec 31 <30fm						
Central	Closed				May 1 – Dec 31 <40fm							
Southern	Closed		Mar 1 – Dec 31 <50fm									

Figure 4-21. No Action: California recreational groundfish season structure based on regulations as of April 17, 2014.

Groundfish Bag Limits and Size Limits

Under the No Action Alternative, a statewide 10 fish rockfish, cabezon, and greenling (RCG) complex bag limit with a sub-bag limit of 3 fish for bocaccio and cabezon would remain in place. Retention of bronzespotted rockfish, canary rockfish, cowcod, and yelloweye rockfish would continue to be prohibited under the No Action Alternative. The following bag limits would also apply:

- California scorpionfish – 5 fish
- Leopard shark – 3 fish (state regulations only)
- Lingcod – 2 fish
- Soupfin shark – 1 fish (state regulations only)

There is no bag limit for Pacific sanddab, petrale sole and starry flounder. A bag limit of 10 fish of any one species within the 20 finfish maximum bag limit would apply to the remaining species in the Groundfish FMP.

The following minimum size limits for the California recreational fisheries would remain under the No Action Alternative:

- California scorpionfish – 10 inches
- Cabezon – 15 inches
- Kelp greenling – 12 inches
- Leopard shark – 36 inches (state regulations only)
- Lingcod – 22 inches

Based on the ReFISH model, updated with 2011 and 2012 data from RecFIN, all overfished species are projected to be within allowable limits under the No Action Alternative (Table 4-50). These values are pre-season projections and actual mortality may differ.

Impact (Groundfish Mortality)

CDFW closely monitors yelloweye rockfish and cowcod – performing weekly tracking using preliminary CRFS field reports. These preliminary CFRS reports are converted into an anticipated catch value in metric tons using catch and effort data from previous years. This weekly "proxy" value is then used to approximate catch during the five to eight week lag time in CRFS catch estimates. If angler effort or bycatch of overfished groundfish species changes dramatically from prior years, actual mortality can be higher or lower than projected. Based on the inseason tracking, if any of the overfished species harvest guidelines are projected to be attained inseason, CDFW could enact emergency management actions to slow and/or reduce catches; management measures include closing one or more recreational groundfish management areas, restricting recreational fishery seasons, and/or modifying depth restrictions.

Projections for non-overfished species are provided in Table 4-50. In 2009, four yelloweye rockfish conservation areas (YRCA) were adopted in the Northern and Mendocino Management Areas for use in management. The YRCAs include habitat in both state and federal waters and can be implemented inseason (if needed) to reduce yelloweye rockfish mortality. To date, these YRCAs have not been implemented and would remain available under all alternatives.

Table 4-50. No Action – California Recreational: Projected mortality (mt) under No Action (using 2014 data) for the California Recreational fisheries.

Stock	Projected Mortality	California Recreational HG

4.2.2 Preferred Alternative

Table 4-51 through Table 4-56 contains the harvest specifications and allocations analyzed under the Preferred Alternative. A description of the harvest control rules used to calculate the ACLs can be found in Chapter 2, Section XXX.

4.2.2.1 Deductions from the ACL and Allocations

Under all action alternatives, off-the-top deductions from the ACL were updated based on the most recent information on fishery performance and need. The deductions from the ACL are held constant across all action alternatives. Amounts deducted that are from the ACL to accommodate groundfish mortality from scientific research, incidental open access fisheries, and EFPs can be modified based on inseason projections (see Section 4.2.1.1). A description of the calculations are provided below.

Tribal Fishery: Tribal fisheries consist of trawl (bottom, mid-water, and whiting), fixed gear, and troll. The tribal amounts in the April 17, 2014 regulations were updated with the most recent tribal requests (see Agenda Item H.10.b, Supplemental Tribal Report, November 2013 and Agenda Item H.10.b, Supplemental Tribal Report 2, November 2013).

Research: Research activities include the NMFS trawl survey, International Pacific Halibut Commission longline survey, and other Federal and state research. The Council approach is that off-the-top deductions from the ACL should be equal to the maximum historical scientific research catch from 2005-2012, except for canary rockfish and yelloweye rockfish. The Council policy for canary and yelloweye rockfish was not based on the maximum historical value. The Council considered the high canary rockfish catch of 7.2 mt in 2006 from the NMFS trawl survey a rare event since surveys in later years encountered substantially less canary. The Council adopted a 4.5 mt canary rockfish set-aside, which is higher than the average research catch from 2005-2012. For yelloweye rockfish, the Council adopted a 3.3 mt research set-aside based on anticipated research needs of the International Pacific Halibut Commission (1.1 mt), Washington Department of Fish and Wildlife (1 mt), Oregon Department of Fish & Wildlife (1 mt), and other projects (0.2 mt).

Incidental Open Access: Deductions from ACLs are made to account for groundfish mortality in the incidental open access fisheries. The off-the-top deductions from the ACL for all species, except longnose skate, were derived from the maximum historical values in the 2007-2012 WCGOP Groundfish Mortality reports (see http://tinyurl.com/nv3pddm). The recommended set-aside for longnose skate was based on data from the 2009-2012 Total Mortality reports, the years in which longnose skate were reported separately from the Other Fish category.

Exempted Fishing Permits: The Council adopted one EFP and associated off-the-top deductions from the ACL for 2015-2016 for public review. The EFP seeks to test the effectiveness of vertical hook-and-line gear to selectively harvest midwater species such as yellowtail rockfish (Agenda Item H.2.a, Attachment 4, November 2013).[49]

Recreational (Sablefish north of 36° N. latitude only): The allocation framework for sablefish north of 36° N. latitude specifies that the anticipated recreational catches of sablefish be deducted from the ACL prior to the commercial limited entry and open access allocations. The set-aside is the maximum historical value from recreational fisheries from 2004-2012 (Table 4-55).

[49] The Council is considering EFPs for participants in the catch share program. See Section XXX (Cumm affects) for more details.

Table 4-51. Preferred Alternative. 2015 ACLs and estimates of tribal, EFP, research, and incidental open access (OA) mortality (in mt), used to calculate the fishery harvest guideline (HG).

a/ Formal allocations are represented in the black shaded cells and would be specified in regulation in Tables 1b and 1e. The other values in the allocation columns are 1) off the top deductions, 2) set asides from the trawl allocation (at-sea petrale only) 3) ad-hoc allocations recommended under the action Alternatives, 4) HG for the recreational fisheries for canary and YE.

b/ South of 40°10' N. lat.

c/ EFPs are amounts set aside to accommodate anticipated applications. Values in this table represent the estimates from the 15-16 biennial cycle.

d/ Includes NMFS trawl shelf-slope surveys, the IPHC halibut survey, and expected impacts from SRPs and LOAs.

e/ The GMT's best estimate of impacts as analyzed in the 2015-2016 Environmental Impact Statement (Appendix B), which are currently specified in regulation.

f/ Tribal values in the allocation column represent the the values in regulation. Projected impacts are the tribes best estimate of catch.

g/ Projected impacts are derrived from GMT projection models.

b/ South of 40°10' N. lat.

c/ EFPs are amounts set aside to accommodate anticipated applications. Values in this table represent the estimates from the 13-14 biennial cycle, which are currently specified in regulation.

d/ Includes NMFS trawl shelf-slope surveys, the IPHC halibut survey, and expected impacts from SRPs and LOAs.

e/ The GMT's best estimate of impacts as analyzed in the 2013-2014 Environmental Impact Statement (Appendix B), which are currently specified in regulation.

f/ Tribal values in the allocation column represent the the values in regulation. Projected impacts are the tribes best estimate of catch.

g/ Projected impacts are derrived from GMT projection models.

4.2.2.2 Overview of Management Measures

The following bullet points summarize management measure changes by sector under the Preferred Alternative. A more detailed discussion of management measures by sector follows. New measures, discussed under Chapter 2, Section XXX and analyzed in Appendix B, would be implemented. New management measures that are specific to a sector are described below.

The Council is also considering a range of state-specific nearshore HGs to keep mortality of nearshore rockfish north of 40°10' N. latitude at or within the ACL. Appendix B, Section XXX contains the management measures for the commercial nearshore (OR and CA) and recreational fisheries (WA, OR, and CA) that are necessary to stay within the range of state-specific HGs adopted by the Council at their April meeting. The Council is scheduled to adopt preferred nearshore HGs north of 40°10' N. latitude, which would be implemented under the action alternatives, at the June Council meeting.

- The shorebased IFQ fishery would operate under the same management measures as No Action, with a few modifications. The No Action trawl RCA configuration (see Table 4-25) would be modified to 100 fm shoreward and 150 fm seaward in the area 40°10 to 48°10' N. latitude, year-round. The IFQ would be issued based the 2015-2016 ACLs and resulting trawl allocations under the Preferred Alternative. Underutilized off-the-top deductions from the ACL (tribal, research, incidental open access, and EFPs) may be taken into consideration when considering the projections for surplus carryover. Legal-sized Pacific halibut IBQ would be limited to 15 percent of the Area 2A total constant exploitation yield (TCEY) for legal size halibut (net weight), not to exceed 100,000 pounds (45 mt) annually for legal size halibut (net weight), which is a 30,000 pound (14 mt) reduction from status quo. A scientific sorting requirement for rougheye/blackspotted would be implemented which would improve the data used in management. Further, deeper RCA boundary lines and/or bycatch reduction areas for midwater gears would be defined in regulation and would be available to reduce rougheye/blackspotted rockfish mortality inseason, if needed (e.g., boundary lines that approximate the 300 and 350 fm depth contours).
- The at-sea whiting co-ops would operate under the same management measures described under No Action with a few modifications. Allocations would be issued based the 2015-2016 ACLs and resulting at-sea trawl allocations under the Preferred Alternative. Adjustments to the at-sea whiting set-asides would be necessary to accommodate the restructuring of the Other Fish complex, which removed spiny dogfish from the complex. A scientific sorting requirement for rougheye/blackspotted could be implemented which could improve the data used in management. Further, bycatch reduction areas for midwater gears would be defined in regulation and would be available to reduce rougheye/blackspotted rockfish mortality inseason, if needed (e.g., boundary lines that approximate the 300 and 350 fm depth contours).
- The non-nearshore fixed gear fishery would operate under the same management measures as No Action, except trip limits increases for several species, including sablefish, bocaccio and shelf rockfish south of 34°27' N. latitude, are proposed to attain the ACLs under the Preferred Alternative. The prohibition on lingcod retention in Periods 1, 2, and 6 would be removed and trip limits increased for both limited entry and open access. Trip limit decreases for slope rockfish north of 40°10' N. latitude are proposed to reduce mortality of rougheye/blackspotted rockfish. A scientific sorting requirement for rougheye/blackspotted would be implemented which could improve the data used in management.
- The nearshore fixed gear fishery would operate under the same management measures as No Action with a few modifications. Trip limit decreases or non-retention may be required for nearshore rockfish to keep mortality at or within the complex ACL or the state-specific nearshore

rockfish HGs. The prohibition on lingcod retention in Periods 1, 2, and 6 may be removed and trip limits increased for both limited entry and open access.

- Tribal fisheries would operate under the harvest guidelines and allocations under the Preferred Alternative. Tribal fisheries would be managed using the same measures described under No Action. Additionally, a scientific sorting requirement for rougheye/blackspotted would be implemented which would improve the data used in management.
- Washington recreational fisheries would operate under the same management measures as No Action, except the season dates for the depth closure in the North Coast (Marine Areas 3 and 4) would be shorter than under No Action. In the South Coast (Marine Area 2), the prohibition on lingcod retention seaward of 30 fathoms in the area south of 46°58’ N. latitude on Fridays and Saturdays from July to August 31 would be removed. Lastly, in the Columbia River Area (Marine Area 1), the southern boundary for the year-round lingcod closure would be moved three miles north. Changes to groundfish retention in Pacific halibut fisheries could also be proposed. Bag limit decreases or non-retention may be required for nearshore rockfish to keep mortality at or within the complex ACL or state-specific nearshore rockfish HGs.
- Oregon recreational fisheries would operate under the same management measures as under the No Action Alternative except that the cabezon sub-bag limit would be removed, a one fish canary sub-bag limit would be implemented, and changes to groundfish retention in Pacific halibut fisheries could be proposed. Bag limit decreases or non-retention may also be required for nearshore rockfish to keep mortality at or within the complex ACL or state-specific nearshore rockfish HGs.
- Season lengths and depth restrictions were explored for the California recreational fisheries. The lingcod bag limit would be increased from two to three fish. Bag limit decreases, season length reduction, or non-retention may be required for nearshore rockfish to keep mortality at or within the complex ACL or state-specific nearshore rockfish HGs. All other management measures would be the same as under No Action.

4.2.2.3 Impact (Groundfish Mortality) Shorebased IFQ – Preferred Alternative

The No Action trawl RCA configuration (see Table 4-25) would be modified to 100 fm shoreward and 150 fm seaward in the area 40°10 to 48°10’ N. latitude, year-round. The shorebased IFQ would be issued based the preferred 2015-2016 ACLs and resulting trawl allocations (Table 4-57 and Table 4-58). Notable IFQ increases from No Action include Dover sole, petrale, longspine thornyheads north, sablefish, shortpine thornyhead, widow rockfish, yellowtail, and Other Flatfish. Underutilized off-the-top deductions from the ACL (tribal, research, incidental open access, and EFPs) may be taken into consideration when considering the projections for surplus carryover (see Appendix B, Section XXX).

The shoreside trawl rationalization program keeps the trawl sector bycatch of halibut within expectations by requiring that trawlers account for their total mortality of all halibut in round weight (legal and sublegal sized). Therefore, to determine a trawl bycatch mortality limit the amount of halibut pounds available to the trawl fleet will be determined by expanding the expected legal sized halibut mortality (net weight) into a round weight legal+sublegal sized amount. To achieve this, the following conversions will be applied.

- Net weight to round weight conversion: multiply by the IPHC net weight to round weight conversion factor in use at the time of each year’s the calculation.
- Legal to legal+sublegal sized conversion factor: multiply by the ratio of legal sized halibut to legal+sublegal sized halibut from the most up-to-date NMFS analysis of trawl fishery bycatch available at the time of each year’s calculation.

After these conversions, 10 mt will be subtracted to cover bycatch mortality in the at-sea whiting fishery and trawl fishery south of 40°10’ N. lat, and the remainder will be issued as IBQ, to be used to cover Pacific halibut mortality by vessels operating in the shoreside trawl IFQ program. Under all action alternatives, legal-sized Pacific halibut IBQ would be limited to 15 percent of the Area 2A total constant exploitation yield (TCEY) for legal size halibut (net weight), not to exceed 100,000 pounds annually for legal size halibut (net weight), which is a 30,000 pound reduction from status quo.

A risk analysis was conducted to evaluate the risk of exceeding the spiny dogfish ACL (see Section XXX, Appendix B). The effectiveness of GCAs to reduce spiny dogfish mortality in the shorebased IFQ sector was also explored in Appendix B. Given the low risk of exceeding the spiny dogfish ACL, the Council recommended continuing with trip limit management of spiny dogfish in the shorebased IFQ sector and they did not recommend spiny dogfish GCAs.

Management measures to reduce rougheye/blackspotted rockfish catch, including rougheye/blackspotted GCAs and/or rockfish excluders for the at-sea whiting vessels were considered but rejected (see Chapter 2, Section XXX and Appendix B). Instead, the Council recommended that a scientific sorting requirement for rougheye/blackspotted could be implemented which could improve the data used in management. Further, management measures to reduce rougheye/blackspotted rockfish catch could be implemented, including 300 and 350 seaward trawl RCA boundaries and bycatch reduction areas for vessels using midwater gears, if necessary.

Table 4-57. Preferred Alternative – Shorebased IFQ. Projected mortality for IFQ species compared to the allocations or set-asides under the Preferred Alternative for 2015. No action estimates of mortality are provided (right panel).

a/ Pacific halibut is managed using IBQ, see regulations at §660.140. Starting in 2015, the maximum IBQ allocation is 45 mt, see (§660.55 (m)). There is no projection model for Pacific halibut bycatch.
b/ As stated in regulations (§660.55 (m)), a Pacific halibut set-aside of 10 mt, to accommodate bycatch in the at-sea Pacific whiting fisheries and in the shorebased trawl sector south of 40°10' N. latitude. (estimated to 5 mt each). There is no projection model for Pacific halibut bycatch.
c/ The 2014 Pacific whiting TAC was unavailable during the preparation of the EIS, therefore the 2013 values were used.

4.2.2.4 Impact (Groundfish Mortality) At-Sea Whiting Co-ops – Preferred Alternative

The at-sea whiting co-ops would operate under the same management measures described under No Action with a few modifications. The 2015-2016 allocations for the catcher-processor and mothership sectors under the Preferred Alternative for 2015-2016 are provided in Table 4-59 and compared to No Action.

At-sea whiting set-asides for some species would be increased compared to No Action (Table 4-60), based on recent fishery data. Further, adjustments would be necessary to accommodate the restructuring of the Other Fish complex, which removed spiny dogfish from the complex (Chapter 2, Section). The proposed Other Fish complex contains nearshore species which are not typically encountered in the at-sea whiting sectors. As such, the Council determined it was not necessary to specify an Other Fish complex set-aside. A range of spiny dogfish set-asides from 163 mt to 725 mt was analyzed along with a risk analysis for all sectors of exceeding the spiny dogfish ACL (see Section XXX, Appendix B). The effectiveness of GCAs to reduce spiny dogfish mortality was also explored in Appendix B. Given the low risk of exceeding the spiny dogfish ACL, the Council did not recommend spiny dogfish set-asides nor did they recommend spiny dogfish GCAs for the at-sea sectors.

Management measures to reduce rougheye/blackspotted rockfish catch, including rougheye/blackspotted GCAs and/or rockfish excluders for the at-sea whiting vessels were considered but rejected (see Chapter 2, Section XXX and Appendix B). Instead, the Council recommended a scientific sorting requirement for rougheye/blackspotted would be implemented which could improve the data used in management. Further, management measures to reduce rougheye/blackspotted rockfish catch could be implemented, including bycatch reduction areas for vessels using midwater gears, if necessary.

Table 4-59. Preferred Alternative – At-Sea. Allocations for the catcher-processor (CP) and mothership sectors (MS) under the Preferred Alternative for 2015-2016. The No Action allocations are provided (right panel) for reference.

a/As stated in §660.55 (m), the Pacific halibut set-aside is 10 mt, to accommodate bycatch in the at-sea Pacific whiting fisheries and in the shorebased trawl sector south of 40°10' N. latitude (estimated to 5 mt each).
b/ In 2014, spiny dogfish was managed as part of the Other Fish complex. Starting in 2015-2016, spiny dogfish will be managed separately.

4.2.2.5 Limited Entry and Open Access Fixed Gear– Preferred Alternative

Impact (Groundfish Mortality) – Non-Nearshore North of 36° N. latitude

Management measures and projected mortality for the non-nearshore fishery north of 36° N. latitude under the Preferred Alternative is largely influenced by the sablefish ACL, which would be calculated with a P* of 0.40 (Table 4-55), and the resulting sablefish allocations (Table 4-61 and Table 4-62). Trip limit increases for sablefish would be proposed (Table 4-63) and would be routinely adjusted to achieve the limited entry and open access sablefish allocations (Table 4-61 and Table 4-62). The prohibition on lingcod retention in Periods 1, 2, and 6 would be removed and trip limits increased for both limited entry and open access fixed gears (see Appendix B, Section XXX). Trip limits for other species may also be adjusted to attain the ACL or achieve other conservation goals.

Trip limit decreases for slope rockfish north of 40°10' N. latitude are proposed to reduce rougheye/blackspotted rockfish mortality (Table XXX and Appendix B, Section XXX). A scientific sorting requirement for rougheye/blackspotted would be implemented which could improve the data used in management.

The overfished species mortality, as a result of harvesting the sablefish allocations, was evaluated using 2002-2012 WCGOP data in the non-nearshore model. Under the Preferred Alternative, trawl and non-trawl allocations were established for overfished species. Further, the non-nearshore fishery was also allocated a share of the non-trawl allocation for bocaccio, canary, and yelloweye (Table 4-64). Routine adjustments of the non-trawl RCA (same as No Action, Table 4-26) would occur in the event the projected overfished species mortality is expected to exceed the non-nearshore share or non-trawl allocation (e.g., changing from 100 to 125 fm). RCA changes can also be accommodated to provide greater access to target species when overfished species mortality is projected to be within the non-nearshore share or non-trawl allocation (e.g., changing from 125 to 100 fm). Table 4-65 contains the projected mortality groundfish for the non-nearshore fishery.

Table 4-61. Preferred Alternative: Limited entry sablefish FMP allocations north of 36 N. latitude for 2015-2016.

Year	ACL	Sablefish Com. HG	Limited Entry Share	LEFG Share (mt)				Estimated Tier Limits (lbs) a/		
				Total Catch Share	Landed Catch Share a/	Primary Season Share	DTL Share	Tier 1	Tier 2	Tier 3
2015	4,793	4,281	3,878	1,629	1,571	1,336	236	41,175	18,716	10,695
2016	5,241	4,684	4,244	1,782	1,719	1,461	258	45,053	20,479	11,702

a/ The limited entry fixed gear total catch share is reduced by the anticipated discard mortality of sablefish, based on WCGOP data from 2002 to 2012. In 2015-2016, 17.7 percent of the sablefish caught are anticipated to be discarded and 20 percent are expected to die.

Table 4-62. Preferred Alternative: Open access FMP allocations north of north of 36 N. latitude for 2015-2016.

Year	Open Access Total Catch Share (mt)	Open Access Landed Catch Share (mt) a/
2015	402	388
2016	440	425

a/ The open access total catch share is reduced by the anticipated discard mortality of sablefish, based on WCGOP data from 2002 to 2012. In 2015-2016, 17.7 percent of the sablefish caught are anticipated to be discarded and 20 percent are expected to die.

Table 4-63. Preferred Alternative. Sablefish trip limits north of 36° N. latitude for limited entry and open access fixed gears for 2015-2016.

Year	Fishery	Jan-Feb	Mar-Apr	May-Jun	July-Aug	Sept-Oct	Nov-Dec
2015	Limited Entry	1,025 lb/week, not to exceed 3,075 lb/ 2 months					
	Open Access	300 lb/ day, or 1 landing per week of up to 900 lb, not to exceed 1,800 lb/ 2 months					
2016	Limited Entry	1,275 lb/week, not to exceed 3,375 lb/ 2 months					
	Open Access	300 lb/ day, or 1 landing per week of up to 1,000 lb, not to exceed 2,000 lb/ 2 months

Impact (Groundfish Mortality) Non-Nearshore South of 36° N. latitude

Management measures and projected groundfish mortality for the non-nearshore fishery south of 36° N. latitude under the Preferred Alternative is largely influenced by the sablefish ACL, which would be calculated with a P* of 0.40 (Table 4-55). Anticipated catch of sablefish south of 36º N latitude under the Preferred Alternative would be approximately equal to the 2015-2016 sablefish allocations and resulting landed catch shares for limited entry and open access fixed gears (Table 4-66). Increases to the sablefish trip limits would be proposed (Table 4-67) and would be routinely adjusted to achieve the limited entry and open access sablefish allocations (Table 4-66). Additionally, trip limit increases are proposed for bocaccio and shelf rockfish south of 34°27’ N. latitude to increase attainment of the non-trawl allocations (Table 4-68, See Appendix B Section XXX for historical attainment). Trip limits for other species may also be adjusted to attain the ACL or achieve other conservation goals.

Under the Preferred Alternative, trawl and non-trawl allocations would be established for overfished species. Further, the non-nearshore fishery would be allocated a share of the non-trawl allocation for bocaccio, canary, and yelloweye to ensure that total non-trawl catches remained within the non-trawl allocations for these overfished species (Table 4-64). Routine adjustments of the non-trawl RCA (same as No Action, Table 4-26) would occur in the event the projected overfished species mortality is expected to exceed the non-nearshore share or non-trawl allocation (Table 4-64). RCA changes can also be accommodated to provide greater access to target species when overfished species mortality is projected to be within the non-nearshore share or non-trawl allocation (e.g., changing from 125 to 100 fm).

A scientific sorting requirement for rougheye/blackspotted would be implemented which could improve the data used in management.

Table 4-66 Preferred Alternative: Short-term sablefish allocations south of 36 N. latitude for the non-trawl sector, limited entry and open access for 2015-2016.

Year	Commercial HG	Non-Trawl Allocation	LE FG Total Catch Share	Directed OA Total Catch Share	LE FG Landed Catch Share a/	Directed OA Landed Catch Share a/
2015	1,714	994	547	447	531	432
2016	1,875	1,088	598	489	581	472

a/ The limited entry and open access fixed gear total catch shares are reduced by the anticipated discard mortality of sablefish, based on WCGOP data from 2002 to 2012. In 2015-2016, 17.7 percent of the sablefish caught are anticipated to be discarded and 20 percent are expected to die.

Table 4-67. Preferred Alternative. Sablefish trip limits south of 36° N. latitude for limited entry and open access fixed for 2015-2016.

Impact (Groundfish Mortality) Nearshore – Preferred Alternative

There are Federal limits and state quotas (or harvest guideline) for nearshore species that constrain target species landings in the commercial nearshore fishery (Table 4-38). State harvest guidelines between recreational and commercial fisheries may be adjusted by each state between or within years, so are not displayed herein. State harvest guidelines for each sector are established to ensure that the non-trawl allocation provided to each state is not exceeded while providing fishing opportunities for both sectors. The Preferred Alternative is based on the expectation that landings in the Oregon nearshore fishery (Table 4-69) will be equal to their allocations, except for lingcod where the historical average landings are assumed and except for black rockfish for which the state landing cap would have to be reduced from 137.9 mt to 120.0 mt to remain under the yelloweye rockfish catch share shown in Table 4-70. In California, nearshore fishery allocations are unable to be achieved given the current overfished species shares allocated to the nearshore fishery and state. As such, landings are reduced to stay within the nearshore fishery overfished species shares of the non-trawl allocation. Nearshore fishery landings are influenced by a variety of factors, including weather and market, and can vary annually (Table 4-40). As such, there is substantial uncertainty surrounding the estimated landings under the action alternatives, which in turn influence the projected overfished species mortality and socioeconomic analysis. In the event fishery performance is lower than the allocations, mortality of groundfish species will be lower.

Trawl and non-trawl allocations for overfished species, would be implemented under the Preferred Alternative. Specifically, the nearshore fishery would be managed to stay within its share of the non-trawl allocation for bocaccio, canary, and yelloweye or the overall non-trawl allocations (Table 4-70). In the event the projected overfished species mortality is expected to exceed the nearshore share or non-trawl allocation, routine adjustments of the shoreward non-trawl RCA (Table 4-26) or reduced trip limits for nearshore species could occur. RCA changes can also be accommodated to provide greater access to target species when overfished species mortality is projected to be within the nearshore share or non-trawl allocation (e.g., changing from 20 to 30 fm).

Under the Preferred Alternative, the Council is considering a range of state-specific nearshore HGs to keep mortality of nearshore rockfish north of 40°10' N. latitude at or within the ACL. Appendix B, Section XXX contains the management measures for the nearshore fisheries that are necessary to stay within the range of state-specific HGs adopted at the April Council meeting. The Council is scheduled to adopt preferred nearshore HGs north of 40°10' N. latitude at the June Council meeting.

The Council is also considering removing the prohibition on lingcod retention in Periods 1, 2, and 6 and increasing trip limits for both limited entry and open access fixed gears (see Appendix B, Section XXX). In the event this option is selected for implementation, the estimated lingcod landings (Table 4-69) and the projected overfished species mortality would be updated (Table 4-70).

Table 4-69. Preferred Alternative. Expected landings under the Preferred Alternative (mt) in 2015-2016. Target species landings by area are also shown (far right panel).

4.2.2.6 Impact (Groundfish Mortality) Tribal Fisheries – Preferred Alternative

Tribal fisheries would operate under the harvest guidelines and allocations displayed in Table 4-51, Table 4-53, and Table 4-55. Tribal fisheries would be managed using the same measures described under No Action.

4.2.2.7 Washington Recreational – Preferred Alternative

Primary catch controls for the Washington recreational fishery are season dates, depth closures, bag limits, and GCAs, including YRCAs. Under the Preferred Alternative, Washington recreational fisheries would operate under the 2015 and 2016 ACLs (Table 4-51 and Table 4-53) and Washington recreational harvest guidelines (HGs) for overfished species (Table 4-71).

Table 4-71. Preferred Alternative: Washington recreational harvest guidelines for 2015 and 2016.

Stock	2015	2016
CANARY ROCKFISH	3.4	3.5
YELLOWEYE ROCKFISH	2.9	3.1

Groundfish Season Structure

Under the Preferred Alternative, the Washington recreational fishery would be open year-round for groundfish, except lingcod. Washington would continue to prohibit the retention of canary and yelloweye rockfish in all areas.

Depth restrictions are the primary tool used to keep recreational mortality of yelloweye and canary rockfish within specified HGs. Restrictions limiting the depth where groundfish fisheries are permitted are more severe in the area north of the Queets River (Marine Areas 3 and 4) where yelloweye and canary rockfish abundance is higher and therefore caught incidentally at a higher rate. Depth restrictions are less restrictive moving south where incidental catch of yelloweye and canary becomes progressively less.

Management measures under the Preferred Alternative differ only slightly from the No Action Alternative. Under the Preferred Alternative, the depth closure in the North Coast (Marine Areas 3 and 4) would be in place from May 9th through Labor Day rather than from May 1 through September 30. In the South Coast (Marine Area 2), the prohibition on lingcod retention seaward of 30 fathoms in the area south of 46°58 on Fridays and Saturdays from July to August 31 would be removed and in the Columbia River Area (Marine Area 1), the southern boundary for the year round lingcod closure would be moved three miles north. The primary intent of these changes is to simplify management measures for recreational anglers while maintaining total mortality projections that stay within Washington's HGs for overfished species. Management measures, in addition to those analyzed in the 2013-14 EIS were implemented in 2013 through inseason action to respond to higher than anticipated encounters with yelloweye rockfish. These additional management measures reduced the potential for encounters with overfished species and provide some leeway to refine and streamline management measures described under the No Action Alternative. Table 4-72 summarizes key features of the Washington recreational regulations under the Preferred Alternative.

Table 4-72. Preferred Alternative. Washington Recreational Seasons and Groundfish Retention Restrictions.

<table>
<tr><th>Marine Area</th><th>Jan</th><th>Feb</th><th>Mar</th><th>Apr</th><th>May</th><th>June</th><th>July</th><th>Aug</th><th>Sep</th><th>Oct</th><th>Nov</th><th>Dec</th></tr>

c/ Retention of rockfish allowed seaward of 30 fm.
d/ Retention of lingcod allowed seaward of 30 fm on days that the primary halibut season is open.
e/ Retention of lingcod prohibited in deepwater areas at all times.
f/ Retention of groundfish, except sablefish and Pacific cod, prohibited with Pacific halibut on board on days open to the all depth Pacific halibut fishery.</td></tr>
</table>

North Coast (Marine Areas 3 and 4)

The retention of bottomfish is prohibited seaward of a line approximating 20 fm from May 9th through the first Monday in September, except, lingcod, Pacific cod and sablefish can be retained seaward of 20 fm on days open to recreational fishing for Pacific halibut. Fishing for, retention, or possession of groundfish and Pacific halibut is prohibited in the C-shaped YRCA (Figure 4-18).

<u>South Coast (Marine Area 2)</u>

The retention of bottomfish, except rockfish, is prohibited seaward of 30 fm from March 15 through June 15, except sablefish and Pacific cod retention is allowed May 1 through June 15. Retention of lingcod is allowed seaward of 30 fm on days open to the primary Pacific halibut season. Fishing for, retention, or possession of lingcod is prohibited in deepwater areas seaward of a line extending from 47°31.70' N. latitude, 124°45.00' W. longitude to 46°38.17' N. latitude, 124°30.00' W. longitude year-round, except as allowed on days open to the Pacific halibut fishery (Figure 4-22). Fishing for, retention or possession of bottomfish or Pacific halibut is prohibited in the South Coast YRCA and Westport Offshore YRCA (Figure 4-18).

<u>Columbia River (Marine Area 1)</u>

Retention of bottomfish, except sablefish and Pacific cod, is prohibited with Pacific halibut onboard during the all-depth recreational halibut fishery from May 1 through September 30. Fishing for, retention, or possession of lingcod in deepwater areas seaward of a line extending 46°38.17 N. latitude, 124°21.00' W. longitude to 46°28.00' N. latitude, 124°21.00' W. longitude is prohibited year-round (Figure 4-22).

Area Restrictions

Under the Preferred Alternative, fishing for, retention, or possession of groundfish and halibut during the Washington recreational groundfish and Pacific halibut fisheries would be prohibited in the C-shaped YRCA in the north coast and the South Coast and Westport YRCAs in the south coast (Figure 4-18).

Fishing for, retention, or possession of lingcod would be prohibited seaward of a line connecting the following coordinates from the Queets River (47°31.70' N. latitude, 124° 45.00' W. longitude) to 46°28.00' N. latitude, 124°21.00' W. longitude, year round except as allowed in Washington Marine Area 2 on days open to the primary Pacific halibut fishery (Figure 4-22).

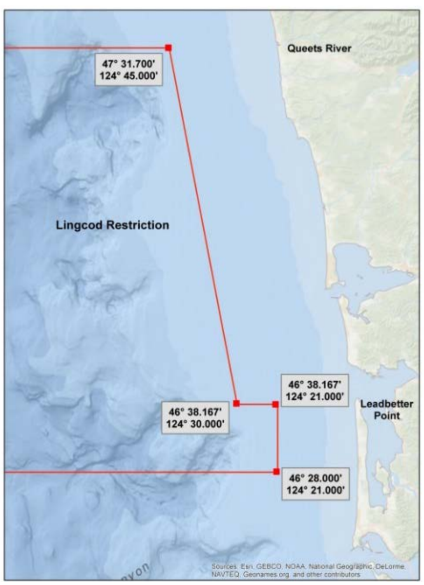

Figure 4-22. Preferred Alternative. Washington Lingcod Restricted Area.

Other Measures

Nearshore Rockfish HGs: Under the Preferred Alternative, the Council is considering a range of state-specific nearshore HGs to keep mortality of nearshore rockfish north of 40°10' N. latitude at or within the ACL. Appendix B, Section XXX contains the management measures for the Washington recreational fisheries that are necessary to stay within the range of state-specific HGs adopted at the April Council meeting. The Council is scheduled to adopt preferred nearshore HGs north of 40°10' N. latitude at the June Council meeting.

Groundfish Bag Limits: Groundfish bag limits would be the same under the Preferred Alternative as they are under the No Action alternative. The recreational groundfish bag limit, including rockfish and lingcod, would be 12 fish per day. Of the 12 recreational groundfish allowed to be landed per day, sub-limits of 10 rockfish and, two lingcod apply. The recreational bag limit also includes a sub-limit of two cabezon in Marine Areas 1-3 and one cabezon in Marine Area 4.

Lingcod Seasons and Size Limits: Under the Preferred Alternative, the lingcod seasons would be the same as they are under the No Action Alternative. In Marine Areas 1 through 3 (Washington-Oregon border at 46°16' N. latitude to Cape Alava at 48°10' N. latitude) the lingcod season would be open from the Saturday closest to March 15 through the Saturday closest to October 15. In Marine Area 4, (Cape Alava to the U.S. Canadian border) the lingcod season would be open from April 16 through October 15, or the Saturday closest to October 15 if that Saturday comes before October 15, whichever is earlier. Lingcod seasons under the Preferred Alternative would be structured the same as they were under the No Action Alternative. Under the Preferred Alternative the lingcod seasons and size limits by area are as follows:

- Marine Areas 1-3: March 14 through October 17 in 2015 and March 12 through October 15 in 2016. Minimum size, 22 inches.
- Marine Area 4: April 16 through October 15 in 2015 and April 16 to October 15 in 2016. Minimum size, 22 inches.

Cabezon Size Limit: Under the Preferred Alternative, there is an 18 inch minimum size limit for cabezon in Marine Area 4 (Cape Alava to the U.S. Canadian border).

Pacific Halibut Seasons: It is expected that the Pacific halibut seasons in 2015 and 2016 would be similar to the halibut seasons in 2013 and 2014. There are no changes to the restrictions on groundfish retention during the Pacific halibut season proposed under the Preferred Alternative. However, modifications to the groundfish retention rules during the all-depth Pacific halibut openings may be proposed under the Pacific halibut Catch Sharing Plan process (see Appendix B, Section XXX).

Additional Management Measures Analyzed: No additional management measures were analyzed for the Preferred Alternative. Currently available management measures will be used to keep recreational harvests of overfished species within specified HGs for 2015-2016.

Impact (Groundfish Mortality)

Projected mortality for Washington's recreational fishery is based upon the previous season's harvest estimated by the Ocean Sampling Program (OSP) and incorporated in Recreational Fishery Information Network (RecFIN). Table 4-73 summarizes the projected mortality for overfished and non-overfished species under the Preferred Alternative.

It should be noted that the precision of recreational groundfish catch estimates based upon previous seasons will continue to be influenced by factors such as the length and success of salmon and halibut seasons, weather and unforeseen factors.

Washington's Ocean Sampling Program is able to produce estimates of groundfish catch with a one month lag time. Management measures such as more restrictive depth closures, area closures, groundfish retention restrictions, or changes to seasons can be considered and implemented through emergency changes to state regulations if inseason catch reports indicate that recreational harvests of overfished or non-overfished species are exceeding pre-season projections to the point where HGs are at risk of being exceeded.

4.2.2.8 Oregon Recreational – Preferred Alternative

Primary catch controls for the Oregon recreational fishery are season dates, depth closures, bag limits, and GCAs, including yelloweye rockfish conservation areas (YRCAs). The Preferred Alternative analyzes the Oregon recreational fishery with the 2015 and 2016 ACLs (Table 4-51 and Table 4-53), and Oregon recreational harvest guidelines (HGs) for overfished species (Table 4-74), which directly influence the recommended management measures. Key target species with a state quota or Federal HG are also shown, such as black rockfish which has a HG of 440.4 mt.[50] Projected mortality under the Preferred Alternative for the Oregon recreational fisheries is shown in Table 4-75.

[50] The black rockfish ACL is allocated 58 percent to Oregon and 42 percent to California. Of the Oregon portion, Oregon state rule specifies that 76 percent is allocated to the recreational fishery with 24 percent to the commercial fishery. Similarly for nearshore rockfish species, state regulations allocate 48.7 percent of the Oregon portion to the recreational fishery.

Table 4-74. Oregon recreational Federal harvest guidelines (in mt) and state quotas under the Preferred Alternative for 2015-2016.

Stock	HGs and State Quotas a/	
	2015	**2016**
CANARY ROCKFISH	11.7	12.0

--*Other Nearshore Rockfish*		

a/ Federal HG are established for canary and yelloweye rockfish only. The state process in Oregon establishes quotas for black rockfish, blue rockfish, other nearshore rockfish, and greenlings (all species). Black and blue rockfish are managed to a combined state quota, the estimated quotas by species are represented in this table. The state quotas are not intended to be implemented in Federal regulation, they are only provided as information.
b/ Includes kelp and other greenlings

--*Blue Rockfish*	*17.5*
--*Other Nearshore Rockfish*	*13.0*

[a/] Includes kelp and other greenlings.

Groundfish Season Structure

Under the Preferred Alternative, the Oregon recreational groundfish fishery would be open offshore year-round, except from April 1 to September 30 when fishing is only allowed shoreward of 40 fathoms, as defined by waypoints (Figure 4-23). Closing the fishery outside of 40 fathoms from April 1 to September 30, months when angler effort and yelloweye rockfish encounters are greatest, mitigates mortality of yelloweye rockfish. Projected mortality of yelloweye and canary rockfish are within the HG, therefore the shore-based fishery would be open year-round.

	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec
Bottomfish Season	Open all depths			Open < 40 fm						Open all depths		
Marine Bag Limit [1]	Ten (10)											
Lingcod Bag Limit	Three (3)											
Flatfish Bag Limit [2]	Twenty Five (25)											

1 Marine bag limit includes all species other than lingcod, salmon, steelhead, Pacific halibut, flatfish, surfperch, sturgeon, striped bass, pelagic tuna and mackerel species, and bait fish such as herring, anchovy, sardine, and smelt.
2 Flounders, soles, sanddabs, turbots and halibuts except Pacific halibut.

Figure 4-23. Preferred Alternative. Oregon recreational groundfish season structure and bag limits under the Preferred Alternative.

Area Closures

The Stonewall Bank YRCA has been in place since 2006 and would also remain under the Preferred Alternative (Figure 4-24). The YRCA is located approximately 15 miles west of the Port of Newport and consists of the high-relief area of Stonewall Bank, an area of high yelloweye rockfish encounters. No recreational fishing for groundfish and Pacific halibut can occur within this YRCA, which is bounded by the following waypoints specified in Table 4-76.

Two options for extending the status quo Stonewall Bank YRCA for 2015-2016 recreational fisheries, should they become necessary, are also shown in Figure 4-24 and are defined by the coordinates in Table 4-76.

Table 4-76. Preferred Alternative. Coordinates for the Stonewall Bank currently as specified in regulation, Option 2 and Option 3 for the expanding the Stonewall Bank area closure under.

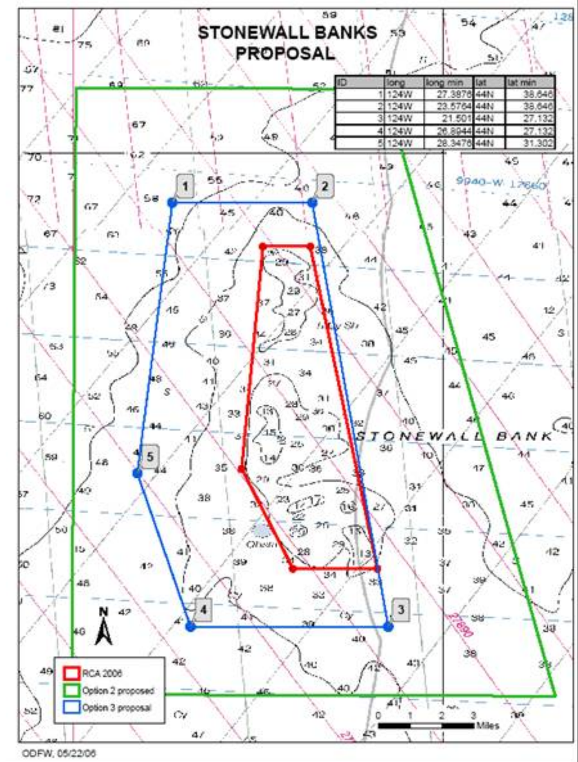

Figure 4-24. Preferred Alternative. The Stonewall Bank Yelloweye Rockfish Conservation Area where recreational fishing for groundfish and Pacific halibut is prohibited.

Groundfish Bag Limits and Size Limits

Under the Preferred Alternative, a marine fish daily bag limit of 10 fish in aggregate would be implemented, the same as under No Action, for 2015-2016. The marine bag includes all species other than lingcod, salmon, steelhead, Pacific halibut, flatfish, surfperch, sturgeon, striped bass, pelagic tuna and mackerel species, and bait fish such as herring, anchovy, sardine and smelt. The seasonal one fish sub-bag limit for cabezon which was in place under No Action would be removed under the Preferred Alternative. Cabezon mortality would be limited via state regulations. A flatfish daily bag limit of 25, which includes all soles and flounders except Pacific halibut, would be allowed in addition to the marine fish daily bag limit. Additionally a three-fish bag limit would be allowed for lingcod. Retention of canary and yelloweye rockfish would continue to be prohibited under the Preferred Alternative.

The following minimum size limits applied to 2013-2014 Oregon recreational fisheries and would be carried forward under the Preferred Alternative:

- Lingcod – 22 in.
- Cabezon – 16 in.
- Kelp greenling – 10 in.

Under the Preferred Alternative, the recreational Pacific halibut fisheries should be able to proceed as in 2013 and 2014, in regards to days and areas open, etc., depending on the halibut quota. Since 2009, only sablefish and Pacific cod may be retained in the Pacific halibut fishery at any depth in the area north of Humbug Mountain, Oregon. South of Humbug Mountain, groundfish may be retained in areas open to groundfish (e.g., less than 30 fm) when halibut are onboard the vessel. There are no changes to the restrictions on groundfish retention during the Pacific halibut season proposed under the Preferred Alternative. However, modifications to the groundfish retention rules during the Pacific halibut openings may be proposed under the Pacific halibut Catch Sharing Plan process (see Appendix B, Section XXX).

Under the Preferred Alternative, the Council is considering a range of state-specific nearshore HGs to keep mortality of nearshore rockfish north of 40°10' N. latitude at or within the ACL. Appendix B, Section XXX contains the management measures for the Oregon recreational fisheries that are necessary to stay within the range of state-specific HGs adopted at the April Council meeting. The Council is scheduled to adopt preferred nearshore HGs north of 40°10' N. latitude at the June Council meeting.

Additional Management Measures Analyzed

Under the Preferred Alternative, two additional management measures were analyzed for the Oregon recreational fisheries: allowing limited retention of canary rockfish and modifying the groundfish species allowed to be retained during all-depth Pacific halibut openings. Additionally, a variety of season structure (depths and months) were modeled to determine potential mortality to overfished species.

Inseason Management Tools

Oregon has a responsive port-based monitoring program through the Ocean Recreational Boat Survey (ORBS) and regulatory processes in place to track mortality and take actions inseason, if necessary. The following are suggested management measures that could be implemented inseason if the fishery does not proceed as expected.

Inseason management tools, designed to mitigate mortality, include bag limit adjustments (including non-retention), length limit adjustments, gear restrictions, and season, days per week, depth, and area closures.

Season, depth, days open per week, and area closures are the primary inseason tools for limiting yelloweye rockfish and canary rockfish mortality, since retention of these species is already prohibited. If catch rates indicate that the bycatch harvest targets for yelloweye rockfish would be reached prematurely, offshore depth closures may be implemented inseason at 30, 25, or 20 fathoms as these two species are less abundant nearshore, and release survival rates are higher in shallow waters. Additionally, days per week may also be closed to reduce mortality. ODFW would monitor inseason progress toward recreational harvest targets for canary rockfish and yelloweye rockfish. Regulations would depend upon the timing of the determination for their need.

Adjustments to the marine fish daily bag limit to no more than 10 fish may be implemented to achieve season duration goals in the event of accelerated or decelerated black rockfish or other nearshore rockfish harvest. The lingcod daily bag limits may be adjusted to no more than 3 fish in the event the marine bag limit changes or the halibut catch limit is reduced from 2013 levels. Season and/or area closures may also be considered if harvest targets are projected to be attained. Closing one or more days per week is an inseason tool that could be used to limit mortality. Closing certain days each week would help lengthen the duration of a fishery approaching an HG.

Non-retention and/or length restrictions are the likely inseason tools to use for cabezon and kelp greenling, as release survival is very high. They may also be used to reduce mortality of nearshore species, such as nearshore rockfish species, especially when combined with the use of descending devices.

Gear restrictions and/or release technique requirements may be implemented to reduce the impact of overfished rockfish since a variety of descending devices are available. SSC recommended and Council-approved mortality rates for canary and yelloweye rockfish when descending devices are used will be implemented in 2014 (see Appendix A for documentation).

Directed yellowtail rockfish and/or flatfish fisheries may be implemented inseason, as were implemented in 2004, in the event of a closure of the recreational groundfish fishery due to attainment Federal or state HGs or targets. Specific gear restrictions may be implemented in the event that yellowtail rockfish and/or flatfish fisheries remain open during a groundfish closure. Additionally, the fishery may be expanded to waters seaward of the RCA, promoting directed yellowtail rockfish opportunity. Directed flatfish fisheries would be legal year round and open shoreward of 40 fathoms during any period the groundfish fishery has any depth restrictions (e.g., 40, 30, 25, 20, and 50 fathom lines). The flatfish fishery would not have any depth restrictions when the groundfish fishery has no depth restrictions. Fisheries would be monitored to ensure that mortality of yelloweye and canary rockfish are within the harvest targets/guidelines.

In the event that the duration of total season is reduced from 12 months; the nearshore waters are closed to groundfish fishing due to management of nearshore species; or the Pacific halibut catch limit is reduced from 2013 levels, the fishery may be expanded to waters seaward of the RCA that is in effect at the time, promoting directed yellowtail rockfish and offshore lingcod opportunity. Fisheries would be monitored to ensure that mortality of yelloweye rockfish and canary rockfish is not in excess of the HGs.

4.2.2.9 California Recreational – Preferred Alternative

The 2015-2016 California recreational groundfish projected mortality and season structure under the Preferred Alternative are based on CDFW's updated RecFISH model. Model projections were calculated for the five recreational groundfish management areas using updated 2011 and 2012 RecFIN estimates; overfished species mortality are reported statewide. Table 4-77 depicts the Preferred Alternative overfished species harvest guidelines for the 2015-2016 California recreational groundfish seasons.

Table 4-77. Preferred Alternative: California recreational allocations/harvest guidelines for 2015-2016.

Stock	**2015**	**2016**
BOCACCIO	178.8	185.6
CANARY	24.3	25.0
COWCOD*	2.6	2.6
YELLOWEYE	3.4	3.7

*Non-trawl allocation

Groundfish Seasons and Area Restrictions

Under the Preferred Alternative, tradeoffs between season lengths and depth restrictions were explored (Options 1, 2, and 3). Because the non-trawl allocation for cowcod will increase to 2.6 mt in 2015-2016, all three Options allow depth restrictions to be modified from 50 fm to 60 fm in the Southern Management Area. Under Option 1, longer seasons and status quo (or No Action) depth restrictions were examined. Option 2 explored longer seasons north of Point Conception and limited additional opportunity in deeper depths in the Northern and Mendocino Management Areas; the area where the depths restrictions are the most restrictive under status quo regulations (20 fm). Option 3 examined shorter seasons and deeper depths north of Point Conception. The three fish lingcod bag limit can be accommodated under all Options.

Option 1

Under Option 1, the depth restrictions would be the same as the No Action Alternative and the season lengths would be extended for all areas north of Point Conception from March 1 through December 31 (Figure 4-25). Due to lower yelloweye rockfish mortality in recent years the season lengths in the areas north of Point Conception can be extended. Black rockfish mortality limits the season length at the current depth restrictions. Under this option, the portion of the recreational catch share is exceeded by 1.7 mt, but could be accommodated by the residual from the commercial fishery. The mortality of cowcod and bocaccio in the Southern Management Area are projected to be far below the respective harvest guidelines. Season length in the Southern Management Area would remain the same as status quo, March 1st – December 31st, but the depth restriction would be modified from 50 fm to 60 fm to resume access to deeper depths allowed in 2012 prior to an inseason action.

Management Area	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec
Northern	Closed		Mar 1 – Dec 31 <20 fm									
Mendocino	Closed		Mar 1 –Dec 31 <20 fm									
San Francisco	Closed		Mar 1 – Dec 31 <30 fm									
Central	Closed		Mar 1 – Dec 31 <40 fm									
Southern	Closed		Mar 1 – Dec 31 <60fm									

Figure 4-25. Preferred Alternative (Option 1): California recreational groundfish season structure and depth restrictions for 2015-2016 with maximized season length.

Option 2

Due to lower yelloweye rockfish encounter rates in recent years, the season length north of Point Conception can be extended to April 1st through December 31st (Figure 4-26). In addition, under Option 2, deeper depth restrictions are analyzed in the Northern and Mendocino Management Areas for part of the year; the depth restriction would be 20 fm from April 1st through September 30th, then increase to 30 fm from October 1st through December 31st. The depth and season in all other areas would be unchanged from Option 1.

When depth restrictions are liberated, it becomes more challenging to predict angler behavior and uncertainty in the yelloweye rockfish projections increases. Further, the RecFISH model assumes proportion of catch by depth and those proportions of catch can change when depth is increased, which results in underestimates of mortality. The relatively low effort during October 1st through December 31st makes it possible to allow access to deeper depths without greatly increasing the risk of exceeding the yelloweye rockfish harvest guideline. Black rockfish mortality remains within the state recreational share under this option.

Management Area	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec
Northern	Closed			April 1 – Sep 30 <20 fm, Oct 1– Dec 31 <30 fm								
Mendocino	Closed			April 1 – Sep 30 <20 fm, Oct 1– Dec 31 <30 fm								
San Francisco	Closed			April 1 – Dec 31 <30 fm								
Central	Closed			April 1 – Dec 31 <40 fm								
Southern	Closed		Mar 1 – Dec 31 <60 fm									

Figure 4-26. Preferred Alternative (Option 2): California recreational groundfish season structure and depth restrictions for 2015-2016.

<u>Option 3</u>

Under Option 3, tradeoffs between increased depth and season lengths north of Point Conception were explored. By allowing access to deeper depths, encounters with overfished shelf rockfish species are expected to increase. In order to keep mortality of overfished species from exceeding harvest guidelines, season lengths north of Point Conception would be reduced (Figure 4-27). Similar to Option 2, when depth restrictions are modified uncertainty increases, as effort shifts to deeper depths may be greater than projected, resulting in mortality exceeding projected values.

Season length in the Southern Management Area would also be reduced to the May 15th to August 15th to explore reductions in catch savings on cowcod, bocaccio, or other species. In recent years, bocaccio and cowcod encounters have increased, making it more difficult to model projected mortality. Given these concerns, examining a shorter season in the Southern Management Area is prudent in the event inseason action would be necessary to keep catches within allowable levels. California scorpionfish would remain open year round to 60 fm.

Management Area	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec

Southern	Closed				May15–Aug15<60fm				Closed			

Figure 4-27. Preferred Alternative (Option 3): California recreational groundfish season structure and depth restrictions for 2015-2016.

Other Measures

<u>Nearshore Rockfish HGs</u>: Under the Preferred Alternative, the Council is considering a range of state-specific nearshore HGs to keep mortality of nearshore rockfish north of 40°10' N. latitude at or within the ACL. Appendix B, Section XXX contains the management measures for the California recreational fisheries that are necessary to stay within the range of state-specific HGs adopted at the April Council meeting. The Council is scheduled to adopt preferred nearshore HGs north of 40°10' N. latitude at the June Council meeting.

<u>Groundfish Bag Limits and Size Limits</u>: Under The Preferred Alternative, the groundfish bag limits or size limits are the same as under No Action except for the following:

- <u>Lingcod</u>: The No Action bag limit for lingcod is two fish. Under the Preferred Alternative, lingcod bag limit would increase from two fish to three fish. The mortality (in metric tons) as a result of the increase in the bag limit for Options 1, 2, and 3 is provided in Table 4-78. An increase in the lingcod bag limit from two to three fish could be accommodated statewide with the aforementioned season and depth restrictions under all options. The Council is not proposing any changes to the lingcod minimum size restriction. Increases to overfished species mortality as a result of this increase are expected to be minimal (if any).

Additional Management Measures Analyzed: None

Table 4-78. Preferred Alternative: California recreational projected mortality of non-overfished species for 2015-2016 under Option 1, Option 2, and Option 3. Results in parenthesis reflect lingcod mortality with a three fish bag limit.

Stock	Projected Mortality (mt)

Widow Rockfish	4.2	3.8	1.5

**Mortality exceeds the recreational portion of the California catch share of 230.8 mt. Further discussion provided under the text describing Option 1.*

Impact (Groundfish Mortality)

Projected mortality for bocaccio, canary rockfish, cowcod, and yelloweye rockfish for all Options under the Preferred Alternative can be found in Table 4-79. Under all the Options contemplated under the Preferred Alternative the projected mortality of cowcod, bocaccio, canary and yelloweye rockfish increases compared to the No Action alternative, due to the increased season lengths or deeper depth restrictions. The number of angler trips is expected to increase under the Options allowing for increased opportunity for both private/rental boats (PR) and commercial passenger fishing vessels (CPFV). Projections for non-overfished species for the Preferred Alternative under each Option are provided in Table 4-78.

Similar to the No Action Alternative, if overfished species encounters are tracking higher or lower than projected, inseason action could be taken, which could include closing one or more recreational groundfish management areas, restricting recreational fishery seasons and/or modifying depth restrictions. As in the No Action Alternative, the YRCAs would be available and could be implemented inseason if catches are projected to exceed harvest guidelines.

a/ The cowcod fishery harvest guideline is further reduced to an ACT of 4 mt.
b/ Pacific whiting TAC forecasts for 2015-2016 were unavailable during the preparation of the EIS, therefore the 2013 values were used.

Table 4-84. Alternative 1. Sablefish north of 36° N. latitude ACLs, off-the-top deductions from the ACL used to calculate the commercial harvest guideline (mt).

Stock	Year	ACL	Tribal Share a/	EFP	Research	Rec	Commercial HG
Sablefish N. 36° N. lat.	2015	5,012	501	1	26	6.1	4,478
	2016	5,467	547	1	26	6.1	4,887

a/ The sablefish allocation to Pacific coast treaty Indian Tribes is 10 percent of the sablefish ACL for the area north of 36° N. lat. This allocation represents the total amount available to the treaty Indian fisheries before deductions for discard mortality.

Table 4-85. Alternative 1. Overfished Species.

4.2.3.1 Overview of Management Measure Changes

The following bullet points summarize management measure changes by sector under Alternative 1 compared to the Preferred Alternative. A more detailed discussion of management measures by sector follows. New measures, discussed under Chapter 2, Section XXX and analyzed in Appendix B, would be implemented. New management measures that are specific to a sector are described below.

The Council is also considering a range of state-specific nearshore HGs to keep mortality of nearshore rockfish north of 40°10' N. latitude at or within the ACL. Appendix B, Section XXX contains the management measures for the commercial nearshore (OR and CA) and recreational fisheries (WA, OR, and CA) that are necessary to stay within the range of state-specific HGs adopted by the Council at their April meeting. The Council is scheduled to adopt preferred nearshore HGs north of 40°10' N. latitude, which would be implemented under the action alternatives, at the June Council meeting.

- The shorebased IFQ fishery would operate under the same management measures as described under the Preferred Alternative, except that the shorebased IFQ would be issued based the 2015-2016 ACLs and resulting trawl allocations under Alternative 1.
- The at-sea whiting co-ops would operate under the same management measures described under the Preferred Alternative.
- The non-nearshore fixed gear fishery would operate under the same management measures as under the Preferred Alternative, except that additional trip limit increases are proposed to attain the higher sablefish ACLs under Alternative 1.
- The nearshore fixed gear fishery would operate under the same management measures as the Preferred Alternative.
- Tribal fisheries would operate under the harvest guidelines and allocations under Alternative 1. Tribal management measures would be the same as described under the No Action alternative.
- Washington recreational fisheries would operate under the same management measures as the Preferred Alternative.
- Oregon recreational fisheries would operate under the same management measures as the Preferred Alternative.
- California recreational fisheries would operate under the same management as the Preferred Alternative.

4.2.3.2 Impact (Groundfish Mortality) – Shorebased IFQ – Alternative 1

The shorebased IFQ fishery would operate under the same management measures as described under the Preferred Alternative, except that the shorebased IFQ would be issued based the 2015-2016 ACLs and resulting trawl allocations under Alternative 1 (Table 4-86 and Table 4-87). Notable IFQ increases from No Action include petrale, longspine thornyheads north, sablefish, shortpine thornyhead, yellowtail, and Other Flatfish.

Table 4-86. Alternative 1 – Shorebased IFQ. Projected mortality for IFQ species compared to the allocations or set-asides under Alternative 1 for 2015. No action estimates of mortality are provided (right panel).

a/ Pacific halibut is managed using IBQ, see regulations at §660.140. Starting in 2015, the maximum IBQ allocation is 45 mt, see (§660.55 (m)). There is no projection model for Pacific halibut bycatch.
b/ As stated in regulations (§660.55 (m)), a Pacific halibut set-aside of 10 mt, to accommodate bycatch in the at-sea Pacific whiting fisheries and in the shorebased trawl sector south of 40°10' N. latitude. (estimated to 5 mt each). There is no projection model for Pacific halibut bycatch.
c/ The 2014 Pacific whiting TAC was unavailable during the preparation of the EIS, therefore the 2013 values were used.

4.2.3.3 Impact (Groundfish Mortality) – At-Sea Whiting Co-ops – Alternative 1

The at-sea whiting co-ops would operate under the same management measures described under the Preferred Alternative with an equivalent level of projected groundfish mortality.

4.2.3.4 Limited Entry and Open Access Fixed Gear – Alternative 1

Impact (Groundfish Mortality) – Non-Nearshore North of 36° N. latitude

Management measures and projected mortality for the non-nearshore fishery north of 36° N. latitude under Alternative 1 is largely influenced by the sablefish ACL, which would be calculated with a P* of 0.45 (Table 4-88), and the resulting sablefish allocations (Table 4-88 and Table 4-89). Trip limit increases for sablefish would be proposed (Table 4-90) and would be routinely adjusted to achieve the limited entry and open access sablefish allocations (Table 4-88 and Table 4-89). The prohibition on lingcod retention in Periods 1, 2, and 6 would be removed and trip limits increased for both limited entry and open access fixed gears to better attain the non-trawl allocation (see Appendix B, Section XXX). Trip limits for other species may also be adjusted to attain the ACL or achieve other conservation goals.

Trip limit decreases for slope rockfish north of 40°10' N. latitude are proposed to reduce mortality of rougheye/blackspotted rockfish (Table XXX and Appendix B, Section XXX). A scientific sorting requirement for rougheye/blackspotted/blackspotted would be implemented which could improve the data used in management.

The overfished species mortality, as a result of harvesting the sablefish allocations, was evaluated using 2002-2012 WCGOP data in the non-nearshore model. Under Alternative 1, trawl and non-trawl allocations were established for overfished species. Further, the non-nearshore fishery was also allocated a share of the non-trawl allocation for bocaccio, canary, and yelloweye (Table 4-91). In the event the projected overfished species mortality is expected to exceed the non-nearshore share or non-trawl allocation, routine adjustments of the seaward non-trawl RCA boundary (Table 4-29) could occur. Changes to RCA boundaries can also be accommodated to provide greater access to target species when overfished species mortality is projected to be within the non-nearshore share or non-trawl allocation (e.g., changing from 125 to 100 fm). Table 4-92 contains the projected mortality groundfish for the non-nearshore fishery under Alternative 1.

Table 4-88 Alternative 1. Limited entry sablefish FMP allocations north of 36 N. latitude for 2015-2016.

Year	Sablefish Com. HG	Limited Entry Share	LEFG Share (mt)				Estimated Tier Limits (lbs) a/		
			LE FG Total Catch Share	Landed Catch Share a/	Primary Season Share	LEFG DTL Share	Tier 1	Tier 2	Tier 3
2015	4,478	4,057	1,704	1,644	1,397	247	43,071	19,578	11,187
2016	4,887	4,428	1,860	1,794	1,525	269	47,010	21,368	12,210

a/ The limited entry fixed gear total catch share is reduced by the anticipated discard mortality of sablefish, based on WCGOP data from 2002 to 2012. In 2015-2016, 17.7 percent of the sablefish caught are anticipated to be discarded and 20 percent are expected to die.

Table 4-89 Alternative 1. Open access FMP allocations (mt) north of north of 36 N. latitude for 2015-2016.

Year	Open Access Total Catch Share	Open Access Landed Catch Share [a/]
2015	421	406
2016	459	443

a/ The open access total catch share is reduced by the anticipated discard mortality of sablefish, based on WCGOP data from 2002 to 2012. In 2015-2016, 17.7 percent of the sablefish caught are anticipated to be discarded and 20 percent are expected to die.

Table 4-90 Alternative 1. Sablefish trip limits north of 36° N. latitude for limited entry and open access fixed gears for 2015-2016.

Year	Fishery	Jan-Feb	Mar-Apr	May-Jun	July-Aug	Sept-Oct	Nov-Dec
2015	Limited Entry	1,075 lb/week, not to exceed 3,225 lb/ 2 months					
	Open Access	300 lb/ day, or 1 landing per week of up to 950 lb, not to exceed 1,900 lb/ 2 months					
2016	Limited Entry	1,175 lb/week, not to exceed 3,525 lb/ 2 months					
	Open Access	300 lb/ day, or 1 landing per week of up to 1,025 lb, not to exceed 2,050 lb/ 2 months

Impact (Groundfish Mortality) Non-Nearshore South of 36° N. latitude

Management measures and projected groundfish mortality for the non-nearshore fishery south of 36° N. latitude under Alternative 1 is largely influenced by the sablefish ACL, which would be calculated with a P* of 0.45 (Table 4-93). Anticipated catch of sablefish south of 36º N latitude under Alternative 1 would be approximately equal to the 2015-2016 sablefish allocations and resulting landed catch shares for limited entry and open access fixed gears (Table 4-93). Increases to the sablefish trip limits would be proposed (Table 4-94) and would be routinely adjusted to achieve the limited entry and open access sablefish allocations (Table 4-93). Additionally, trip limit increases are proposed for bocaccio and shelf rockfish south of 34°27’ N. latitude to attain the non-trawl allocations (Table 4-68). Trip limits for other species may also be adjusted to attain the ACL or achieve other conservation goals.

Under Alternative 1, trawl and non-trawl allocations would be established for overfished species. Further, the non-nearshore fishery would be allocated a share of the non-trawl allocation for bocaccio, canary, and yelloweye (Table 4-91). Routine adjustments of the non-trawl RCA (Table 4-26) would occur in the event the projected overfished species mortality is projected to exceed the non-nearshore share or non-trawl allocation (Table 4-91). Changes to RCA boundaries can also be accommodated to provide greater access to target species when overfished species mortality is projected to be within the non-nearshore share or non-trawl allocation (e.g., changing from 125 to 100 fm).

Table 4-93. Alternative 1. Short-term sablefish allocations south of 36 N. latitude for the non-trawl sector, limited entry and open access for 2015-2016.

Year	ACL	Commercial HG	Non-Trawl Allocation	LE FG Total Catch Share	Directed OA Total Catch Share	LE FG Landed Catch Share a/	Directed OA Landed Catch Share b/
2015	1,798	1,793	1,040	572	468	555	451
2016	1,961	1,956	1,134	624	511	606	492

a/ The limited entry and open access fixed gear total catch shares are reduced by the anticipated discard mortality of sablefish, based on WCGOP data from 2002 to 2012. In 2015-2016, 17.7 percent of the sablefish caught are anticipated to be discarded and 20 percent are expected to die.

Table 4-94. Alternative 1. Sablefish trip limits south of 36° N. latitude for limited entry and open access fixed for 2015-2016.

Year	Fishery	Jan-Feb	Mar-Apr	May-Jun	July-Aug	Sept-Oct	Nov-Dec
2015	Limited Entry	2,125 lb/ week					
	Open Access	320 lb/day, or 1 landing per week of up to 1,600 lb, not to exceed 3,200 lb/2 months					
2016	Limited Entry	2,200 lb/ week					
	Open Access	330 lb/day, or 1 landing per week of up to 1,650 lb, not to exceed 3,300 lb/2 months					

Impact (Groundfish Mortality) Nearshore

The commercial nearshore fishery would operate under the same management measures and are projected to have the same groundfish impacts as described under the Preferred Alternative.

4.2.3.5 Impact (Groundfish Mortality) Tribal Fisheries – Alternative 1

Tribal fisheries would operate under the harvest guidelines and allocations displayed in Table 4-80,

Table 4-82, and Table 4-84. Tribal fisheries would be managed using the same measures described under the Preferred Alternative.

4.2.3.6 Washington Recreational – Alternative 1

The Washington recreational fisheries would operate under the same management measures and are projected to have the same groundfish impacts as described under the Preferred Alternative.

4.2.3.7 Oregon Recreational – Alternative 1

The Oregon recreational fisheries would operate under the same management measures and are projected to have the same groundfish impacts as described under the Preferred Alternative.

4.2.3.8 California Recreational – Alternative 1

The California recreational fisheries would operate under the same management measures and are projected to have the same groundfish impacts as described under the Preferred Alternative.

4.2.4 Alternative 2 – P* 0.25

4.2.4.1 Set Asides and Allocations

Table 4-95 through Table 4-100 contains the harvest specifications and allocations under Alternative 2. A description of the harvest control rules used to calculate the ACLs can be found in Section XXX.

Table 4-95. Alternative 2. 2015 ACLs and estimates of tribal (Trib), EFP, research (Res.), and incidental open access (OA) groundfish mortality in metric tons, used to calculate the fishery harvest guideline (HG), under Alternative 2.

	2016	4,540	454	26	6.1	1	4,053

a/ The sablefish allocation to Pacific coast treaty Indian Tribes is 10 percent of the sablefish ACL for the area north of 36° N. lat. This allocation represents the total amount available to the treaty Indian fisheries before deductions for discard mortality.

Table 4-100. Overfished Species Scorecard.

4.2.4.2 Overview of Management Measure Changes

The following bullet points summarize management measure by sector under Alternative 2. If adopted by the Council, new management measures discussed under Section 2.1.2 and Appendix C would be implemented.

The Council is also considering a range of state-specific nearshore HGs to keep mortality of nearshore rockfish north of 40°10’ N. latitude at or within the ACL. Appendix B, Section XXX contains the management measures for the commercial nearshore (OR and CA) and recreational fisheries (WA, OR, and CA) that are necessary to stay within the range of state-specific HGs adopted by the Council at their April meeting. The Council is scheduled to adopt preferred nearshore HGs north of 40°10’ N. latitude, which would be implemented under the action alternatives, at the June Council meeting.

- The shorebased IFQ fishery would receive IFQ based on the 2015-2016 ACLs and resulting trawl allocations under Alternative 2, which are generally lower than under No Action and the Preferred Alternative. The IFQ fishery would operate under the same management measures as described under the Preferred Alternative.
- The at-sea whiting co-ops would operate under the same allocations and management measures described under the Preferred Alternative.
- Allocations and harvest guidelines for the tribal fishery would be issued based the 2015-2016 ACLs under Alternative 2. The tribal fishery would operate under the same management measures described under the Preferred Alternative.
- The non-nearshore fixed gear fishery would operate under the same management measures under the Preferred Alternative, except trip limits decreases for several species, including sablefish, would be necessary to stay within the lower ACLs under Alternative 2.
- The nearshore fixed gear fishery would operate under the same management measures as the Preferred Alternative, except trip limits decreases for several species would be necessary to stay within the lower ACLs under Alternative 2. Greater trip limit decreases or longer periods of non-retention may be required for nearshore rockfish to keep mortality at or within the complex ACL or the state-specific nearshore rockfish HGs under Alternative 2, compared to the Preferred Alternative.
- Tribal fisheries would operate under the harvest guidelines and allocations under Alternative 2. Tribal fisheries would be managed using the same measures described under the Preferred Alternative.
- Washington recreational fisheries would operate under the same management measures as described under the Preferred Alternative. Greater reductions to bag limits or longer periods of non-retention may be required for nearshore rockfish to keep mortality at or within the complex ACL or the state-specific nearshore rockfish HGs under Alternative 2, compared to the Preferred Alternative.
- Oregon recreational fisheries would operate under the same management measures as the Preferred Alternative. Greater reductions to bag limits or longer periods of non-retention may be required for nearshore rockfish to keep mortality at or within the complex ACL or the state-specific nearshore rockfish HGs under Alternative 2, compared to the Preferred Alternative.
- Season lengths and depth restrictions were explored for the California recreational fisheries under Alternative 2. Bag limit reductions for kelp greenling (10 to 2) and California Scorpionfish (5 to 3) and increases for lingcod (2 to 3) are proposed under Alternative 2. Greater reductions to bag limits or longer periods of non-retention may be required for nearshore rockfish to keep mortality

at or within the complex ACL or the state-specific nearshore rockfish HGs under Alternative 2, compared to the Preferred Alternative.

4.2.4.3 Impact (Groundfish Mortality) – Shorebased IFQ – Alternative 2

The shorebased IFQ fishery would operate under the same management measures as described under the Preferred Alternative, except that the shorebased IFQ would be issued based the 2015-2016 ACLs and resulting trawl allocations under Alternative 2 (Table 4-95, Table 4-97, and Table 4-99) and resulting trawl allocations (Table 4-101 and Table 4-102). Notable IFQ decreases from No Action include petrale and arrowtooth flounder. Notable increases from No Action include longspine thornyhead and yellowtail.

Table 4-101. Alternative 2 – Shorebased IFQ. Projected mortality for IFQ species and Pacific halibut compared to the allocations or set-asides under Alternative 2 for 2015. No action estimates of mortality are provided (right panel).

a/ Pacific halibut is managed using IBQ, see regulations at §660.140. Starting in 2015, the maximum IBQ allocation is 45 mt, see (§660.55 (m)).

b/ As stated in regulations (§660.55 (m)), a Pacific halibut set-aside of 10 mt, to accommodate bycatch in the at-sea Pacific whiting fisheries and in the shorebased trawl sector south of 40°10' N. latitude (estimated to 5 mt each).

4.2.4.4 Impact (Groundfish Mortality) – At-Sea Whiting Co-ops – Alternative 2

The at-sea whiting co-ops would operate under the same management measures described under the Preferred Alternative with equivalent levels of groundfish mortality.

4.2.4.5 Limited Entry and Open Access Fixed Gear– Alternative 2

Impact (Groundfish Mortality) Non-Nearshore North of 36° N. latitude

Management measures and projected mortality for the non-nearshore fishery north of 36° N. latitude under Alternative 2 are largely influenced by the sablefish ACL, which would be calculated with a P* of 0.25 (Table 4-103), and the resulting sablefish allocations (Table 4-103 and Table 4-104). Trip limit decreases for sablefish would be proposed (Table 4-105) and would be routinely adjusted to achieve the limited entry and open access sablefish allocations (Table 4-103 and Table 4-104).). The prohibition on lingcod retention in Periods 1, 2, and 6 would be removed and trip limits increased for both limited entry and open access fixed gears (see Appendix B, Section XXX).

Trip limit decreases for slope rockfish north of 40°10' N. latitude are proposed to reduce rougheye/blackspotted rockfish mortality (Table XXX and Appendix B, Section XXX). A scientific sorting requirement for rougheye/blackspotted would be implemented which could improve the data used in management.

The overfished species mortality, as a result of harvesting the sablefish allocations, were evaluated using 2002-2012 WCGOP data in the non-nearshore model. Under Alternative 2, trawl and non-trawl allocations were established for overfished species. Further, the non-nearshore fishery was also allocated a share of the non-trawl allocation for bocaccio, canary, and yelloweye (Table 4-106). Routine adjustments of the non-trawl RCA (same as No Action, Table 4-29) would occur in the event the projected overfished species mortality is expected to exceed the non-nearshore share or non-trawl allocation. Changes to RCA boundaries can also be accommodated to provide greater access to target species when overfished species mortality is projected to be within the non-nearshore share or non-trawl allocation (e.g., changing from 125 to 100 fm). Table 4-107 contains the projected mortality groundfish for the non-nearshore fishery under Alternative 2.

Table 4-103. Alternative 2: Limited entry sablefish FMP allocations north of 36 N. latitude for 2015-2016.

Year	ACL	Com. HG	Limited Entry Share	LEFG Share (mt)				Estimated Tier Limits (lbs) a/		
				LE FG Total Catch Share	Landed Catch Share a/	Primary Season Share	LEFG DTL Share	Tier 1	Tier 2	Tier 3
2015	4,114	3,670	3,325	1,396	1,347	1,145	202	35,297	16,044	9,168
2016	4,540	4,053	3,672	1,542	1,488	1,264	223	38,985	17,720	10,126

a/ The limited entry fixed gear total catch share is reduced by the anticipated discard mortality of sablefish, based on WCGOP data from 2002 to 2012. In 2015-2016, 17.7 percent of the sablefish caught are anticipated to be discarded and 20 percent are expected to die.

Table 4-104. Alternative 2: Open access FMP allocations north of north of 36 N. latitude for 2015-2016.

Year	Open Access Total Catch Share (mt)	Open Access Landed Catch Share (mt) a/
2015	345	333
2016	381	367

a/ The open access total catch share is reduced by the anticipated discard mortality of sablefish, based on WCGOP data from 2002 to 2012. In 2015-2016, 17.7 percent of the sablefish caught are anticipated to be discarded and 20 percent are expected to die.

Table 4-105. Alternative 2. Sablefish trip limits north of 36° N. latitude for limited entry and open access fixed gears for 2015-2016.

Year	Fishery	Jan-Feb	Mar-Apr	May-Jun	July-Aug	Sept-Oct	Nov-Dec
2015	Limited Entry	875 lb/week, not to exceed 2,625 lb/ 2 months					
	Open Access	300 lb/ day, or 1 landing per week of up to 800 lb, not to exceed 1,600 lb/ 2 months					
2016	Limited Entry	975 lb/week, not to exceed 2,925 lb/ 2 months					
	Open Access	300 lb/ day, or 1 landing per week of up to 850 lb, not to exceed 1,700 lb/ 2 months

Impact (Groundfish Mortality Non-Nearshore South of 36° N. latitude)

Management measures and projected groundfish mortality for the non-nearshore fishery south of 36° N. latitude under Alternative 2 is largely influenced by the sablefish ACL, which would be calculated with a P* of 0.25 (Table 4-99). Anticipated catch of sablefish south of 36º N latitude under Alternative 2 would be approximately equal to the 2015-2016 sablefish allocations and resulting landed catch shares for limited entry and open access fixed gears (Table 4-108). Decreases to the sablefish trip limits would be proposed (Table 4-109) and would be routinely adjusted to achieve the limited entry and open access sablefish allocations (Table 4-108). Additionally, trip limit increases are proposed for bocaccio and shelf rockfish south of 34°27’ N. latitude to attain the non-trawl allocations (Table 4-68).

Under Alternative 2, trawl and non-trawl allocations would be established for overfished species. Further, the non-nearshore fishery would be allocated a share of the non-trawl allocation for bocaccio, canary, and yelloweye to ensure that total non-trawl catches remained within the non-trawl allocations for these overfished species (Table 4-106). Routine adjustments of the non-trawl RCA (same as No Action, Table 4-29) would occur in the event the projected overfished species mortality is expected to exceed the non-nearshore share or non-trawl allocation (Table 4-108). Changes can also be accommodated to provide greater access to target species when overfished species mortality is projected to be within the non-nearshore share or non-trawl allocation (e.g., changing from 125 to 100 fm).

Table 4-108 Alternative 2: Short-term sablefish allocations south of 36 N. latitude for the non-trawl sector, limited entry and open access for 2015-2016.

2015	1,475	1,470	853	469	384	456	371
2016	1,629	1,624	942	518	424	504	410

a/ The limited entry and open access fixed gear total catch shares are reduced by the anticipated discard mortality of sablefish, based on WCGOP data from 2002 to 2012. In 2015-2016, 17.7 percent of the sablefish caught are anticipated to be discarded and 20 percent are expected to die.

Table 4-109. Alternative 2. Sablefish trip limits south of 36° N. latitude for limited entry and open access fixed for 2015-2016.

Year	Fishery	Jan-Feb	Mar-Apr	May-Jun	July-Aug	Sept-Oct	Nov-Dec
2015	Limited Entry	1,975 lb/week					
	Open Access	300 lb/ day, or 1 landing per week of up to 1,500 lb, not to exceed 3,000 lb/ 2 months					
2016	Limited Entry	2,050 lb/week					
	Open Access	310 lb/ day, or 1 landing per week of up to 1,550 lb, not to exceed 3,100 lb/ 2 months					

Impact (Groundfish Mortality) Nearshore – Alternative 2

There are Federal limits and state quotas for nearshore species that limit target species landings in the commercial nearshore fishery (Table 4-38). Alternative 2 is based on the expectation that landings in the Oregon nearshore fishery will be equal to their allocations (Table 4-109), except for lingcod, which is based on the historical average landings. In California, nearshore fishery allocations are unable to be achieved given the current overfished species allocations. As such, landings are reduced to stay within the nearshore fishery overfished species allocations. Nearshore fishery landings are influenced by a variety of factors, including weather and market, and can vary annually (Table 4-40). As such, there is substantial uncertainty surrounding the estimated landings under the action alternatives, which in turn influence the projected overfished species mortality and socioeconomic analysis. In the event fishery performance is lower than the allocations, mortality of groundfish species will be lower.

The Council is also considering removing the prohibition on lingcod retention in Periods 1, 2, and 6 and increasing trip limits for both limited entry and open access fixed gears (see Appendix B, Section XXX). In the event this option is selected for implementation, the estimated lingcod landings (Table 4-109), and the projected overfished species mortality would be updated (Table 4-111).

Trawl and non-trawl allocations for overfished species, would be implemented under Alternative 2 (Table 4-111). Specifically, the nearshore fishery would be managed to stay within its share of the non-trawl allocation for bocaccio, canary, and yelloweye. Under Alternative 2, catch of canary and yelloweye rockfish in California exceed the catch sharing agreements with Oregon (Table 4-111); however total catch of canary and yelloweye by both states is within the non-trawl allocation. In the event the projected overfished species mortality is expected to exceed the nearshore fishery share or the non-trawl allocation, routine adjustments of the non-trawl RCA (Table 4-29) or reductions to trip limits would occur. Changes can also be accommodated to provide greater access to target species when overfished species mortality is projected to be within the nearshore share or non-trawl allocation (e.g., changing from 20 to 30 fm).

Table 4-110. Alternative 2. Expected landings under Alternative 2, compared to the Federal and state limits. Target species landings by area are also shown (far right panel).

4.2.4.6 Impact (Groundfish Mortality) Tribal Fisheries – Alternative 2

Tribal fisheries would operate under the harvest guidelines and allocations displayed in Table 4-95, Table 4-97, and Table 4-99. Tribal fisheries would be managed using the same measures described under the Preferred Alternative.

4.2.4.7 Washington Recreational – Alternative 2

Washington recreational fisheries would operate under the same management measures and are projected to have the same groundfish mortality under Alternative 2 as under the Preferred Alternative.

Impact (Groundfish Mortality)

Projected mortality to overfished and non-overfished species and angler effort in 2015 and 2016 under Alternative 2 are expected to be similar to previous seasons however, if anger effort and fishing success result in catch estimates higher than what is projected, inseason action through state regulations such as modifications to seasons, groundfish retention and closed areas may be considered to ensure catches do not exceed harvest guideline.

4.2.4.8 Oregon Recreational – Alternative 2

Under Alternative 2 the Oregon recreational Federal HGs for yelloweye and canary rockfish remain the same as under all other action alternatives. The black rockfish ACL will decrease, which decreases the Oregon recreational state quota from 440.8 mt to 406.0 mt in 2015 and 408.2 mt in 2016 (Table 4-112). XXX Under this alternative, yelloweye rockfish allocations directly relate to the recommended management measures and prevent the full utilization of the black rockfish state harvest cap. Therefore, even though there is a reduction in the black rockfish state harvest cap, the fisheries would operate under the same management measures as under the Preferred Alternative.

Under the Preferred Alternative, the Council is considering a range of state-specific nearshore HGs to keep mortality of nearshore rockfish north of 40°10' N. latitude at or within the ACL. Appendix B, Section XXX contains the management measures for the Oregon recreational fisheries that are necessary to stay within the range of state-specific HGs adopted at the April Council meeting. The Council is scheduled to adopt preferred nearshore HGs north of 40°10' N. latitude at the June Council meeting.

Impact (Groundfish Mortality)

The Council is considering a range of state-specific nearshore HGs to keep mortality of nearshore rockfish north of 40°10' N. latitude at or within the ACL. Appendix B, Section XXX contains the management measures for the Oregon recreational fisheries that are necessary to stay within the range of state-specific HGs adopted at the April Council meeting. The Council is scheduled to adopt preferred nearshore HGs north of 40°10' N. latitude at the June Council meeting.

Table 4-112. Alternative 2. Oregon recreational Federal HGs or state quotas under the No Action Alternative and Alternative 2, with a P* of 0.25. XXX

Stock	HG or State Quotas a/		
	No Action	Alternative 2	
		2015	2016
CANARY ROCKFISH	11.1	11.7	12.0

Black Rockfish	440.8	406.0	408.2
Kelp Greenling b/	N/A	TBD	TBD
Nearshore Rockfish N. 40°10 N. lat. a/	N/A	TBD	TBD
--*Blue Rockfish*			
--*Other Nearshore rockfish*			

a/ Federal HG are established for canary and yelloweye rockfish only. The state process in Oregon establishes quotas for black rockfish, blue rockfish, other nearshore rockfish, and greenlings (all species). Black and blue rockfish are managed to a combined state quota, the estimated quotas by species are represented in this table. The state quotas are not intended to be implemented in Federal regulation, they are only provided as information.
b/ Includes kelp and other greenlings

4.2.4.9 California Recreational – Alternative 2

While harvest limits on overfished species do not change under Alternative 2, the ABC values from a P* of 0.25 applied to all target species reduce the harvest limits relative to Alternatives 1 and 3 requiring additional recreational management measures under all Options. The three fish lingcod bag limit can be accommodated under all the Options of this Alternative.

Groundfish Seasons and Area Restrictions

Option 1

Under Alternative 2, the lower black rockfish ACL apportioned to the recreational fishery would limit the season length north of Point Conception to May 1 to December 31, a one month reduction from Alternative 1 (Figure 4-28). To maintain this season, while remaining below harvest limits under the lower ACLs for kelp greenling and California scorpionfish, bag limits would need to be reduced. This would require a reduction from 10 fish to two fish for kelp greenling and from five fish to three fish for California scorpionfish. The season length in the Southern Management Area would remain March 1st through December 31st with a 60 fm depth restriction.

Management Area	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec
Northern	Closed				May 1 – Dec 31 <20 fm							
Mendocino	Closed				May 1 –Dec 31 <20 fm							
San Francisco	Closed				May 1 – Dec 31 <30 fm							
Central	Closed				May 1 – Dec 31 <40 fm							
Southern	Closed		Mar 1 – Dec 31 <60fm									

Figure 4-28. Alternative 2 (Option 1): California recreational groundfish season structure and depth restrictions for 2015-2016 with maximized season length.

Option 2

As in Option 1, the season in management areas north of Point Conception would be May 1 to Dec 31 to keep black rockfish mortality below the lower ACLs under a P* of 0.25 for target stocks, while the season in the Southern Management Area would remain March 1st – December 31st (Figure 4-29). The split depth season in the Northern and Mendocino Management Areas starting in 20 fm from May 1 to Sept 30 to 30 fm from October 1st through Dec 31st could be accommodated. As in Option 1 the kelp greenling bag limit would need to be reduced from ten fish to two fish and for California scorpionfish, from five fish to three fish, to keep mortality below harvest limits without further reduction to season lengths.

Management Area	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec
Northern	Closed				May 1 – Sep 30 <20 fm, Oct 1– Dec 31 <30 fm							
Mendocino	Closed				May 1 – Sep 30 <20 fm, Oct 1– Dec 31 <30 fm							
San Francisco	Closed				May 1 – Dec 31 <30 fm							
Central	Closed				May 1 – Dec 31 <40 fm							
Southern	Closed		Mar 1 – Dec 31 <60fm									

Figure 4-29. Alternative 2 (Option 2): California recreational groundfish season structure and depth restrictions for 2015-2016.

Option 3

Under Option 3, season length and depth restrictions are the same as those described in Option 3 of Alternative 3 and Alternative 1, analyzing mortality from a depth restriction 10 fm deeper than the No Action Alternative. In order to keep catches within allowable limits, season lengths north of Point Conception were reduced to May 15th through August 15th to prevent yelloweye rockfish mortality from exceeding the harvest guidelines (Figure 4-30). The reduced season length north of Point Conception reduces the kelp greenling mortality to below the harvest limit even with the current ten fish bag limit.

Season length in the Southern Management Area would be reduced by seven months relative to the No Action Alternative while maintaining the 60 fm depth restriction. This is intended to illustrate the magnitude of reduction in mortality that can be achieved by a reduction in season length and to bracket the low end of the seasons analyzed to facilitate implementation inseason if needed. California scorpionfish would remain open year round to 60 fm. A reduction in the California scorpionfish bag limit from five fish to three fish is necessary to keep mortality below the lower harvest limit under Alternative 2, to maintain year round fishing opportunity.

Similar to Option 3 in Alternative 1 when depth restrictions are modified uncertainty increases, as effort shifts to deeper depths may be greater than projected, resulting in mortality exceeding projected values. If inseason monitoring projects mortality is expected to exceed allowable limits inseason action to implement shallower depth restrictions or close the fishery prematurely may be necessary.

Management Area	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec
Northern	Closed				May15–Aug15<30fm				Closed			
Mendocino	Closed				May15–Aug15<30fm				Closed			
San Francisco	Closed				May15–Aug15<40fm				Closed			
Central	Closed				May15–Aug15<50fm				Closed			
Southern	Closed				May15–Aug15<60fm				Closed			

Figure 4-30. Alternative 2 (Option 3): California recreational groundfish season structure and depth restrictions for 2015-2016.

Groundfish Bag Limits and Size Limits

Under Alternative 2, groundfish bag limits and size limits are the same as No Action, except for the following:

Lingcod – The No Action bag limit for lingcod is two fish. The Council is proposing to increase the bag limit from two fish to three fish. The increase in the bag limit is expected to increase total lingcod mortality by 17% south of Point Conception and 21% north of Point Conception (the mortality in metric tons is provided for option 1, 2, and 3 –in Table 4-114). An increase in the lingcod bag limit from two to three fish can be accommodated statewide with the aforementioned season and depth restrictions under all options. The Council is not proposing any changes to the lingcod minimum size restriction. There are no expected increases to overfished species as a result of this increase.

Kelp Greenling- Analyses used in the 2013-2014 regulatory specification analysis (http://www.pcouncil.org/groundfish/current-season-management/current-management-cycle/) provide the results expected from a decrease in mortality with lower bag limits. A reduction in the bag limit from ten fish to two fish corresponding to a 20.6 percent reduction in mortality would be necessary to reduce mortality to below the harvest limits under Options 1 and 2 (the mortality in metric tons is provided for Options 1 and 2 –in Table 4-114).

California Scorpionfish - The bag limit management measure analysis for this biennium in section X.X provides the decrease in mortality expected with lower bag limits. A reduction in the bag limit from five fish to three fish corresponding to a reduction in mortality of 21.9 percent would be necessary to reduce mortality to below the harvest limits while maintaining the status quo fishing season (the mortality in metric tons is provided for Options 1, 2, and 3 (Table 4-114).

Impact (Groundfish Mortality)

With all Options under Alternative 2, the projected mortality of, bocaccio, canary rockfish, cowcod and yelloweye rockfish is expected to increase compared to the No Action Alternative, due to the increased season lengths or deeper depth restrictions with the exception of bocaccio and cowcod in Option 3 (Table 4-113). The number of angler trips is expected to increase under the Options allowing increased opportunity for both private/rental boats (PR) and the commercial passenger fishing vessels (CPFV). Projections for non-overfished species under Alternative 2 for each Option are provided in Table 4-114.

The same inseason management actions as the No Action Alternative and Alternative 1 are available if allowable limits are projected to be exceeded. The YRCAs described under No Action would also be available under this Alternative.

4.3 Socioeconomic Impacts of 2015-2016 Harvest Specifications and Management Measures

This section evaluates the effects of the alternatives (see Section 2.x) on fishery participants and fishing communities. Section 3.2 describes the economic status of these affected groups during the baseline period 2003-2012 based on historical commercial landings data, estimates of recreational fishing activity, and census data. Here, various methods are used to estimate how conditions may change from the baseline, either by continuing to apply the ACLs and management measures in effect in 2014 (No Action) or under the action alternatives, which are organized around different combinations of ACLs for key species. ACLs for other groundfish species categories may or may not vary depending on the alternative.

4.3.1 Models and Data

The GMT has developed several methods or models to project catch of overfished and principal target species in different groundfish fisheries, or "sectors." (Appendix A) For commercial and tribal fisheries these catch (or landings) estimates are converted to ex-vessel revenue estimates by applying historical price information derived from the PacFIN database. A landings distribution model is then used to estimate where landings are likely to occur and the resulting port-level ex-vessel revenue. The landings distribution model was reviewed by the SSC in September 2011. A description of the model and SSC review comments can be found at http://www.pcouncil.org/wp-content/uploads/G5a_ATT6_DIST_MDL_SEPT2011BB.pdf and http://www.pcouncil.org/wp-content/uploads/G5b_SUP_SSC_SEPT2011BB.pdf.

Another measure used to compare impacts on commercial fisheries under the alternatives is the estimated change in total accounting net revenues by each directed shoreside groundfish vessel sector. Results are presented for vessels engaged in shoreside whiting, non-whiting trawl, limited entry fixed gear, and directed open access sectors.

In addition to ex-vessel revenue, the effect of the alternatives on coastal communities (ports where commercial groundfish landings are made) is evaluated by estimating personal income generated ("income impacts") and resulting employment. These metrics are derived from the IOPAC model developed by economists at the NWFSC.[51] Personal income impact is a valuable metric because in addition to earnings received by harvesters, it also captures effects on processors, local input suppliers, and some retail businesses in the communities. However since personal income impacts are generated by an economic model and only produced for the base years and the alternative scenarios being evaluated, there is no existing time series of personal income impacts that can be used to establish baseline conditions in the communities. Consequently personal income impacts are not used to compare effects under the alternatives against historic conditions, but rather solely to illustrate the differences between the alternatives (including No Action) in terms of regional economic effects that can be expected in coastal communities.

Personal income impact results are also used to project the average change in employment and overall unemployment rates in each community under the alternatives.

The relationship between ex-vessel revenue, accounting net revenue, and commercial fisheries income (and employment) impacts can seem confusing. However, the starting point for all three measures is the same. Ex-vessel revenues represent the total amounts paid by first receivers to harvesters for deliveries or "landings" of raw fish. Ex-vessel revenues therefore represent gross income received by harvesters (and a corresponding cost to first receivers). Accounting net revenues are a rough estimate of the "profit" or return to investment earned by harvesting vessels. Net revenues are calculated by subtracting estimated operating costs and prorated fixed cost components from total ex-vessel revenues received by a vessel. Vessel cost components are estimated for each groundfish sector based on data collected through annual economic data reports for the IFQ fisheries sectors and periodic cost-earnings surveys for the non-IFQ fleets.[52]

Commercial fisheries income impacts measure the combined effects of fish harvesting and processing activities in a given port. These are calculated by treating a portion of the costs paid by harvesting vessels as expenditures in local economies. These expenditures in turn drive additional spending by the

[51] Commercial fishing sectors in IOPAC are based on vessel costs and earnings estimates gathered using systematic data collection efforts. Since cost and earnings for tribal vessels have not been formally surveyed, estimates of community income, employment and net revenue impacts attributable to activities by the tribal groundfish fleet are not calculated. Landings from tribal groundfish fisheries are concentrated in communities along the Washington Coast.

[52] Net revenue is an upward-biased indicator of profitability, since the underlying fisheries data collection efforts do not capture all of the costs associated with operating commercial fishing vessels.

businesses and individuals supplying inputs and services, as well as by local restaurants and retail outlets patronized by people involved in the fishing industry and other affected businesses. Similarly expenditures for inputs and labor used to process fish and distribute seafood products will drive additional economic activity. The sum of all economic activity triggered by the landing of fish and subsequent processing and distribution of seafood products is termed the multiplier effect and is calculated using impact models such as IOPAC. Income impacts are the portion of the total multiplier effect that is paid as wages and salaries to workers and proprietors residing in the local economy.

Since recreationally-caught fish are not sold, a different metric—recreational angler trips—is used to compare the impacts of the alternatives on recreational fisheries. Estimates of numbers of recreational angler trips are made for each state by management region. Recreational fisheries income impacts are calculated by applying estimated average per-trip expenditures to the number of recreational angler trips, and then modeling the additional spending those expenditures generate as the funds flow through the local economy. Estimated average trip expenditures are derived from periodic angler economic surveys.[53] The sum of all economic activity triggered by expenditures made by recreational anglers is termed the multiplier effect and is calculated using impact models such as IOPAC. Income impacts are the portion of the total multiplier effect that is paid as wages and salaries to workers and proprietors residing in the local economies.

Employment impacts generated by commercial and recreational fisheries activities are calculated from the income impacts by applying estimated average income per job in the affected industries in the local economy. Most of the total income and employment effects are the effects of the direct expenditures by the originating industry sectors, e.g., fish harvesters, seafood processors and the guides, tackle shops, hotels and restaurants that service recreational anglers. The additional income and employment impacts generated from re-spending by support businesses, input suppliers and their employees are termed indirect and induced effects. Total impacts are the sum of all direct, indirect and induced effects.

Change in unemployment rates are calculated by adding or subtracting the estimated change in local employment impact to the estimated number of unemployed workers in the local labor force[54].

The models used to project harvest by fisheries sector, and the socioeconomic impacts associated with those activities are detailed in Appendices A and C and summarized in the sections below.

The socioeconomic impacts of the alternatives are evaluated using the following comparisons.

4.3.1.1 Commercial and Tribal Groundfish Fisheries: Change in total ex-vessel revenue (and accounting net revenue) from No Action from the 2003-2012 baseline by fishery sector

In Section 4.3.2.1 the alternatives are compared based on data summarized in Table 4-116 and Table 4-117 showing projected ex-vessel revenues by groundfish fisheries sectors under the proposed management alternatives. Revenue estimates are based on projected landings estimates shown in Table 4-115. All comparisons are with respect to the No Action Alternative unless otherwise indicated. Projections assume average ex-vessel prices observed in 2013. Effects are presented according to groundfish fishery "sectors," which are described in Section 3.2.2. It should be noted that shoreside whiting trawl is presented separately from non-whiting trawl, although both sectors, along with a nontrawl fixed gear component, have comprised the shorebased IFQ fishery beginning in 2011. As

[53] For example: Gentner, Brad, and Scott Steinback. 2008. The Economic Contribution of Marine Angler Expenditures in the United States, 2006. U.S. Dep. Commerce, NOAA Tech. Memo. NMFS-F/SPO-94, 301 p.

[54] Estimated unemployment by county is based on 2012 county labor force and employment statistics from the U.S. Bureau of Labor Statistics http://www.bls.gov/data/

explained in Section 3.2.2.2, because vessels fishing under the IFQ program may use any legal groundfish gear, the terminology is moving away from referring to "trawl" sectors. Participants in the IFQ fishery may use fixed gear, principally to target sablefish, while species such as Pacific whiting and flatfish will continue to be harvested with trawl gear since they are not vulnerable to fixed gear. In the evaluations of alternatives below, in some cases the terminology "trawl" sector may include non-trawl components of the shorebased IFQ fishery.

In modeling commercial fishery impacts, it is assumed that effort that is displaced or discouraged by management measures under a particular alternative is not able to switch readily into another fishery in the same region, or another region elsewhere along the coast. Thus the numbers reported probably represent something of an upper bound on regional economic impacts on commercial fisheries, or the maximum amount of displacement that could be expected to occur under the alternatives. This also means that the models may not necessarily be able to distinguish subtle differences resulting from relatively fine distinctions between the alternatives if those differences lie within the models' margins of error. Economic impact models like IOPAC are calibrated to represent a baseline or "snapshot" of the economy at a particular point in time. Consequently these models are best able to address impacts of scenarios that are not too far removed from the realm of what has occurred in the recent past (i.e., five to ten years) during which time the local economy has developed its characteristic structure. Analysis of scenarios that represent particularly large departures from baseline conditions that are well beyond experience of the recent past may therefore result in somewhat biased estimates of total economic impacts.

Catch projection in the shorebased IFQ fishery (which has historically accounted for almost 45 percent of groundfish ex-vessel revenue, see Section 3.2.2.2) was based on catch in 2013. Because of the scheduling of this EIS process, data for the last weeks of that year were not yet available at the time catch projection modeling was conducted. As a result fishing patterns in late 2013 had to be inferred from the seasonal distribution apparent in the prior two years under the IFQ fishery.

Under IFQ management, where harvesters are individually accountable for covering their catch with matching QP, quotas for rebuilding stocks function like performance standards. While the direct revenue realized from landing the small amounts of available rebuilding species stocks is negligible, these stocks leverage access to much higher levels of target species landings.[55] Consequently a higher allocation of, e.g., canary rockfish to the shorebased IFQ fishery may generate more actual revenue than is forecast using the current catch projection models.

In addition to the limitations in catch projection models, stock recruitment variability and catch monitoring uncertainty mean that actual catches may differ from the projections. If encounters with rebuilding species run higher than projected, reductions in trip limits or adjustments to the RCAs may be necessary inseason. While overall target species landings may not be increased directly, higher overfished species ACLs may provide an additional buffer against the need to impose more restrictive inseason measures if actual mortality proves to be higher than modeled.

For Pacific whiting a total allowable catch (TAC) is determined annually consistent with the Agreement with Canada on Pacific Hake/Whiting; 73.88 percent of the TAC is allocated to U.S. fisheries. As noted in Chapter 2 the actual TACs and related allocations to U.S. fisheries for 2015 and 2016 were not known at the time this document was prepared. To model the socioeconomic impacts of the alternatives the same

[55] The at-sea whiting fishery, managed with co-ops, has similar accountability mechanisms. While the same 2013 Pacific whiting TAC must be assumed for forecasting revenue and income impacts in the whiting fisheries under the alternatives, similar dynamics in terms of fleet performance in response to bycatch limits are likely to play out in these fisheries.

TAC, U.S. allocation, and sector allocations—equal to those set for 2013—were used for No Action and all of the action alternatives. Note however there is some variation in estimated ex-vessel revenues earned by the shoreside whiting IFQ sector under the action alternatives chiefly due to variation in ACLs or other inferred management measures for constraining bycatch species such as POP and canary rockfish.

To facilitate comparison of the effects under the alternatives with the experience of the recent past,

	No Action	2015_PA	2015_A1	2015_A2	2016_PA	2016_A1	2016_A2
Shoreside Sectors:							
Whiting	*22.5*	+2.9%	+2.4%	+1.1%	+2.7%	+2.2%	+0.9%

Table 4-118 and Table 4-119 show the change in groundfish ex-vessel revenue by fishery sector from the baseline period described in Section 3.2.2 in absolute and percentage terms. The baseline used is average annual inflation-adjusted ex-vessel revenue from 2003 to 2012. In order to be more directly comparable with the revenue impact estimates under the alternatives the 2003-2012 annual average baseline is expressed in terms of inflation-adjusted $2013.

In addition, Table 4-120 and Table 4-121 report projected aggregate accounting net revenues (an indicator of profitability) for the non-tribal, directed, shoreside groundfish sectors in terms of dollar and percentage change from No Action, respectively. Accounting net revenues are calculated as the difference between the ex-vessel value of landings and the estimated costs incurred in achieving those landings. Estimates are based on a comparison of landings revenues projected under the alternatives with landings and average costs reported in economic data reports (for IFQ sectors) and cost-earnings surveys of samples of vessels in the remaining groundfish sectors. Values reported are "total cost net revenues" which include pro-rations of certain estimated fixed cost components in addition to the variable costs directly associated with each groundfish fishery sector.

Table 4-115. Projected combined commercial and tribal fisheries landings (mt) of non-overfished west coast groundfish species and species complexes under No Action and the 2015-16 Action Alternatives ("PA"= Preferred Alternative).

4.3.1.2 Recreational Fisheries: Change in marine angler trips from No Action under the alternatives

In Section 4.3.2.2 impacts of the alternatives on recreational fisheries are compared using the data summarized in Table 4-134 showing projected numbers of marine area angler boat trips taken in groundfish plus Pacific halibut recreational fisheries under the proposed management alternatives. All comparisons are with respect to the No Action Alternative unless otherwise indicated.

In modeling recreational fishery impacts, it is assumed that anglers who are displaced or discouraged by management measures under a particular alternative are not able to switch readily into a different fishery in the same region or another region elsewhere along the coast. Thus the numbers reported below probably represent something of an upper bound on regional economic impacts on recreational fisheries, or the maximum amount of displacement likely to occur under the alternatives. This also means that the models may not necessarily be able to distinguish subtle differences resulting from relatively fine distinctions between the alternatives if those differences lie within the models' margins of error.

Also note that impacts projected for most management areas vary little if at all under most of the action alternatives. This is for two main reasons: (1) certain groundfish species are not generally caught by recreational anglers, and (2) measures used to manage recreational fisheries to stay within the common ACLs and HGs for cowcod, bocaccio and yelloweye rockfish allow little or no flexibility to respond to variation in ACLs for other recreational target species.

Recreational fisheries impacts are compared at the coastwide and individual state levels. Comparison of income impacts at the sub-state regional level are discussed under the communities impacts section, below.

4.3.1.3 Communities: Change in personal income and employment from No Action under the alternatives and change from the 2003-12 baseline in ex-vessel revenue

Change in personal income (income impacts) and employment-related measures for communities under the alternatives are compared in Section 4.3.2.3. These effects are a function of the projected changes in commercial and recreational fishing activity described above. Comparisons are with respect to the No Action Alternative unless otherwise indicated. Impacts were estimated using NWFSC IOPAC input-output model and convey combined direct, indirect, and induced economic effects resulting from projected changes in recreational angling, commercial fishing, fish processing and related input supply and support activities.

For simplification and ease of combining and comparing impacts from commercial and recreational fishing activities, coastal ports are grouped regionally into the following community groups:

- Puget Sound: ports in combined King, Mason, Pierce, San Juan, Skagit, Snohomish, Thurston and Whatcom counties in Washington.
- Washington Coast: ports in combined Jefferson, Clallam, Grays Harbor and Pacific counties in Washington.
- Astoria-Tillamook: ports in combined Clatsop and Tillamook counties in Oregon.
- Newport: ports in Lincoln County Oregon.
- Coos Bay – Brookings: ports in combined Lane, Douglas, Coos and Curry counties in Oregon.
- Crescent City – Eureka: ports in combined Del Norte and Humboldt counties in California.
- Fort Bragg – Bodega Bay: ports in combined Mendocino and Sonoma counties in California.
- San Francisco: ports in combined Marin, Alameda, Contra Costa, San Francisco and San Mateo counties in California.

- Santa Cruz – Monterey – Morro Bay: ports in combined Santa Cruz, Monterey and San Luis Obispo counties in California.
- Santa Barbara – Los Angeles – San Diego: ports in combined Santa Barbara, Ventura, Los Angeles, Orange and San Diego counties in California.

Commercial fishery and recreational fishery impacts are calculated and displayed separately. Impacts are calculated by applying income and employment multipliers generated using IOPAC regional impact models to the projected levels of local expenditures by commercial harvesters, processors and recreational anglers under the alternatives. Although strictly speaking, the commercial and recreational impact components are not directly additive due to the slightly different estimation procedures used, in the following discussion, income impacts generated by combined commercial and recreational fishing activities are presented at the community level in order to provide an index to facilitate comparison of effects under the alternatives.

Economic impact models like IOPAC are calibrated to represent a baseline or "snapshot" of the economy at a particular point in time. Consequently these models are best able to address impacts of scenarios that are within the realm of what may have occurred over the past five to ten years. Analysis of scenarios that represent particularly large departures from baseline conditions may therefore result in biased impact estimates.

As noted above, it is assumed that commercial and recreational fishing effort displaced or discouraged under a particular alternative is not able to switch readily into a different fishery in the same region or another region elsewhere along the coast. Therefore the numbers reported below probably represent something of an upper bound on community income and employment impacts, or the maximum amount of short term economic disruption likely to occur under the alternatives. Also as noted above, the impact models are not necessarily able to distinguish subtle differences resulting from relatively fine distinctions between the alternatives if those differences lie within the models' margins of error.

Projected changes in measures of personal income and employment in community groups under the alternatives are shown in the following tables. Table 4-129 displays the dollar change in commercial fishery income impacts from No Action. Table 4-130 displays the same information in terms of percentage change. Table 4-131 and Table 4-132 display the projected change in commercial fishery employment impacts from No Action in terms of in number of total jobs (combined full-time and part-time) and percentage change, respectively. Table 4-133 displays the projected change in regional unemployment rates from No Action in each community resulting from the commercial fishery employment impacts. Table 4-134 and Table 4-135 display recreational fishery income impacts in terms of change in dollars and percentage change, respectively. Table 4-136. Change in recreational fishery employment impacts (from No Action) by community group (number of jobs).

Table 4-138 and Table 4-139 display the combined commercial plus recreational fishery income impacts for each community group under the alternatives in terms of change in dollars and percentage change, respectively, subject to the caveat in the preceding paragraph.

As discussed above, estimates of personal income for the full range of baseline years are not available for comparison. Therefore, Table 4-146 and Table 4-147 use the change in total commercial groundfish ex-vessel revenue to compare impacts under the alternatives against the baseline for each community group. The baseline, described above, is average annual inflation-adjusted average ($2013) ex-vessel revenue during 2003-12.

4.3.1.4 Processors

Section 4.3.2.4 describes impacts to processors under the proposed management alternatives using the comparison in Table 4-148 and Table 4-149, which show the change in projected processor purchases of groundfish landings from No Action in dollar and percentage terms, respectively. These are actually estimates of ex-vessel revenues paid to harvesters but are used here as a measure of the value of raw material inputs available to groundfish processors. Comparisons are with respect to the No Action Alternative unless otherwise indicated. The projections assume average 2013 ex-vessel prices. Results are summarized for whiting and combined non-whiting groundfish species.

In modeling impacts on processors, it is assumed that effects of the management measures under a particular alternative are not avoidable by simply buying from another fishery in the same region or from another region elsewhere along the coast. Thus the numbers reported below probably represent something of an upper bound on regional economic impacts on processors, or the maximum amount of economic disruption likely to occur under the alternatives. Also note that the models used to estimate impacts are not necessarily able to distinguish subtle differences resulting from relatively fine distinctions between the alternatives if those differences lie within the models' margins of error.

4.3.1.5 Impacts on Non-market and Non-use Values

EISs evaluating previous harvest specifications discussed effects related to non-market and non-use (NMNU) values. These are non-consumptive uses that range from recreational enjoyment of the environment (e.g., wildlife viewing) to option or existence value (benefit derived from the knowledge that these resources will be available in the future or simply that environmental quality is maintained). There is no information to directly determine these preferences with respect to the resources most directly affected by the proposed action (groundfish species). Since all the alternatives evaluated here (including No Action) are consistent with FMP goals and MSA National Standards, which among other things include the objective of maintaining or rebuilding fish stocks to MSY (or proxy) biomass, there are not likely to be substantive differences among the alternatives in terms of NMNU values.

4.3.1.6 Impacts on Vessel Safety

The differences between the integrated alternatives in terms of their possible effects on vessel safety are expected to be negligible. Any proposed differences between the alternatives in RCA boundaries, thereby potentially pushing vessels to fish in much deeper waters or much closer to shore, are minimal and therefore are not expected to adversely impact vessel safety. Also the introduction of the fixed gear sablefish permit stacking program and the individual quota program for groundfish trawl fisheries during prior management cycles has relieved pressure on vessels to pursue “use-it-or-lose-it” periodic trip limits.

4.3.1.7 Impacts on Other Indicators of Social Welfare

The effect of the integrated alternatives on other indicators of community social welfare (e.g., poverty, divorce rates, graduation/dropout rates, incidents of domestic violence, etc.) cannot be directly measured, but are expected to be negligible. Change in personal income in communities may be used as a rough proxy for other socioeconomic effects to the degree change in these indicators correlates with potential change in income. However, changes in the broader regional economy (“cumulative effects”) and long term trends in fishery-related employment are more likely to drive these indicators of social well being than the short term economic effects of the alternatives.

4.3.2 Direct and Indirect Economic Impacts of the Alternatives

4.3.2.1 Commercial and Tribal Groundfish Fisheries

No Action

Under No Action, total shoreside ex-vessel revenues from groundfish landings of $82.3 million are projected in 2014. This total includes the following projections for shoreside groundfish sectors: Whiting Trawl $22.5 million; Non-whiting Trawl and Non-trawl IFQ $28.9 million; Limited Entry Fixed Gear $11.8 million; Nearshore Open Access $3.5 million; Non-nearshore Open Access $4.9 million; Tribal groundfish (including shoreside tribal whiting) $10.7 million; and Incidental Open Access $0.1 million. In addition, $31.5 million ex-vessel revenue equivalent[56] from At-Sea Non-Tribal whiting (combined Motherships and Catcher Processors), and $9.1 million ex-vessel revenue equivalent from At-Sea Tribal whiting (Mothership) fisheries are projected under No Action. These same amounts for the tribal and non-tribal at-sea whiting fisheries are also projected under all the action alternatives.

There is no projected change from No Action for groundfish landings by the Incidental Open Access and At-sea whiting sectors under the action alternatives. Therefore discussion of results for these sectors is omitted from the summary of impacts, below. Also note that a small amount of revenue projected from groundfish landings by EFP and miscellaneous fisheries has been omitted from the tables and the relevant discussion of impacts.

[56] Ex-vessel revenue equivalent is the estimated value of Pacific whiting delivered as raw material inputs to at-sea mothership floating processers plus the imputed value of Pacific whiting caught by at-sea catcher-processors.

Comparing estimated commercial shoreside ex-vessel revenue to average annual (inflation adjusted) revenue during the 2003-12 baseline, revenue increases by $3.6 million (5 percent) for all shoreside groundfish fisheries combined. Projected shoreside whiting ex-vessel revenue accounts for most of this change, increasing by $9.6 million (75 percent) from the baseline under No Action due to relatively high Pacific whiting ACL in 2013 and recently-observed high ex-vessel prices. Changes from the baseline for non-whiting fishery sectors are all negative. The combined non-nearshore limited entry and open access fixed gear sector shows a decline of $1.1 million (-6 percent), and revenue in the non-whiting IFQ sector declines under No Action by $4.9 million (-14 percent).

Total shoreside directed groundfish net accounting revenues ("profits") for participating groundfish sectors are estimated to be $19.7 million under No Action. Sectors with greatest estimated net revenues under No Action are Whiting ($10 million), Non-whiting trawl ($6.7 million), and Limited entry fixed gear ($1.8 million).

The Preferred Alternative (PA)

The Preferred Alternative (PPA) is a combination of selected components from Alternative 1 and Alternative 2 plus increased ACLs for Dover sole and widow rockfish. Projections were made for both years of the management cycle (2015 and 2016), although for simplicity unless the general pattern changes between the two years, only results for 2015 are discussed below.

Total shoreside sectors' ex-vessel revenue under the Preferred Alternative is projected to be the highest among the action alternatives. Compared with No Action, total shoreside ex-vessel revenue under the PA is projected to increase by $16 million (20 percent) in 2015.

Projected revenues are higher than under No Action for every shorebased groundfish sector. The greatest absolute and percentage increase in revenue is projected for the IFQ sector: $12.8 million (45 percent) in 2015.

Comparing estimated commercial shoreside ex-vessel revenue to average annual (inflation adjusted) revenue during the 2003-12 baseline, revenue increases by $19.3 million (28 percent) in 2015 for all shoreside groundfish sectors combined. Projected shoreside whiting ex-vessel revenue accounts for most of this, increasing from the baseline by 80 percent due to the relatively high assumed Pacific whiting ACL and ex-vessel prices. Changes from the baseline for non-whiting fishery sectors are all positive but smaller in dollar terms. The non-whiting IFQ sector shows the second largest absolute and percentage increase among non-whiting fishery sectors, increasing from the baseline by $8 million (24 percent) in 2015.

Total shoreside directed groundfish net accounting revenues ("profits") for participating groundfish sectors are projected to be $8.8 million higher under the Preferred Alternative than under No Action. The sector with greatest estimated absolute change in net revenues over No Action is Non-whiting trawl, which increases by $6.7 million (100 percent). The largest increase in percentage terms is Open access nearshore which increases by $0.5 million (132 percent).

Alternative 1

Under this alternative projected revenues are higher than No Action for every shorebased groundfish sector. The greatest absolute increase in revenue is projected for the IFQ sector: $4.9 million (17 percent) in 2015. The greatest percentage increase in revenue is projected for the nearshore open access sector: $0.8 million (24 percent) in 2015.

Comparing estimated commercial shoreside ex-vessel revenue to average annual (inflation adjusted) revenue during the 2003-12 baseline, revenues increase by $19.3 million (28 percent) in 2015 for all shoreside groundfish fisheries combined. Again most of the projected increase is shoreside whiting ex-vessel revenues, which increases from the baseline by 79 percent in 2015 due to the relatively high assumed Pacific whiting ACL and ex-vessel prices. Changes from the baseline for non-whiting fishery sectors are all positive but relatively small in dollar terms. The non-nearshore fixed gear sector shows the largest dollar increase among the non-whiting fishery sectors, increasing from the baseline by $1.1 million (6 percent) in 2015. The nearshore open access fixed gear sector shows the largest percentage increase among the non-whiting fishery sectors, increasing from the baseline by 23 percent in 2015.

Total shoreside directed groundfish net accounting revenues ("profits") for participating groundfish sectors are projected to be $4.1 million higher under the Alternative than under No Action. The sector with greatest estimated absolute change in net revenues over No Action is Non-whiting trawl, which increases by $2 million (29 percent). The largest increase in percentage terms is Open access nearshore which increases by $0.5 million (132 percent).

Alternative 2

Total aggregated shoreside sectors' ex-vessel revenue under Alternative 2 is projected to be the lowest among the action alternatives. Compared with No Action, under Alternative 2 total shoreside ex-vessel revenue is projected to decrease by $0.4 million (-1 percent) in 2015, and increase by $1.8 million (2 percent) in 2016.

Projected revenue changes from No Action under Alternative 2 across groundfish sectors are mixed. The greatest absolute increase in revenue for 2015 is projected for the Nearshore Open access sector at $0.5 million (13 percent). In 2016 the largest increases are projected for the Nearshore Open access sector at $0.5 million (13 percent) and Limited Entry fixed gear sector at $0.5 million (4 percent). The greatest absolute decrease in revenue for 2015 is projected for the Limited Entry fixed gear sector at -$0.6 million (-5 percent) in 2015, and the Non-whiting IFQ sector at -$0.1 million (-0.2 percent) in 2016. The largest percentage increase in both 2015 and 2016 is projected for the Nearshore Open access sector at 13 percent ($0.5 million). The largest percentage decreases are for the Non-nearshore Open access sector in 2015 at -5 percent (-$0.3 million), and the Non-whiting IFQ sector at -0.2 percent (-$0.1 million) in 2016.

Comparing estimated commercial shoreside ex-vessel revenue to average annual (inflation adjusted) revenue during the 2003-12 baseline, revenue increases by $2.9 million (4 percent) for all shoreside groundfish sectors combined in 2015, and $4.9 million (7 percent) in 2016. Again most of the projected increase is shoreside whiting ex-vessel revenues, increasing from the baseline by 77 percent in both 2015 and 2016 due to the relatively high assumed Pacific whiting ACL and ex-vessel prices. Changes from the baseline for non-whiting fishery sectors are mixed. The Non-whiting IFQ sector shows the largest dollar and percentage decrease among the fishery sectors, decreasing from the baseline by $5.4 million (-16 percent) in 2015 and $4.9 million (-15 percent) in 2016. The non-nearshore fixed gear sector is also negatively affected relative to the baseline under this alternative. The nearshore open access sector shows the largest dollar and percentage increase among the non-whiting fishery sectors, increasing from the baseline by 13 percent ($0.4 million) in both 2015 and 2016.

Total shoreside directed groundfish net accounting revenues ("profits") for participating groundfish sectors are projected to be $0.1 million lower under the Alternative in 2015 than under No Action. The sector with greatest estimated absolute decline in net revenues over No Action is Non-whiting trawl, which decreases by $0.3 million (-4 percent). The sector with greatest estimated increase in net revenues over No Action in both absolute and percentage terms is Open access nearshore, which increases by $0.3

million (70 percent). The sector with the largest decrease in percentage terms is Open access non-nearshore which decreases by $0.1 million (-23 percent).

Table 4-116. Change in groundfish ex-vessel revenues from No Action by groundfish harvest sector under the 2015-16 alternatives ($million).

4.3.2.2 Recreational Fisheries

Each action alternative for recreational fisheries includes three optional scenarios describing projected angler effort impacts under three different sets of possible management measures. Options 1 and 2 apply to the Preliminary Preferred Alternative, Alternative 1 and Alternative 2 (although note that Option 1 and Option 2 have identical impacts under Alternative 2. Projected impacts under Option 3 are identical under all three action alternatives and have the most highly negative effects on projected angler effort.

No Action

Projected angler effort levels under the No Action alternative are derived from estimates developed independently by each state. No Action for Washington's recreational fishery is based on total bottomfish plus Pacific halibut marine-area angler boat trips taken in 2012. For Oregon's fishery, the annual average of marine area bottomfish plus Pacific halibut angler boat trips recorded during 2010 to 2012 is used to quantify No Action. California's angler effort level under No Action is based on average annual bottomfish boat trips recorded during 2011-2012.

Under No Action, a total of 835,500 groundfish and Pacific halibut trips are projected coastwide. Sixty two percent of these are charter boat trips with the remainder taken on private boats. The breakdown by state is: Washington 33,600 trips (18,100 charter + 15,500 private), Oregon 90,200 trips (38,500 charter + 51,600 private), and California 711,800 (465,100 charter + 246,600 private).

Washington Recreational – No Action

Under the No Action Alternative, management measures necessary to keep recreational harvest of yelloweye rockfish within harvest guidelines require closure or significant restriction of the groundfish fishery in areas deeper than 20 and 30 fathoms along a substantial portion of the Washington coast, restrictions on groundfish retention during peak recreational fishing periods, and closed areas. While these restrictions have been effective at keeping recreational catch of overfished species under specified harvest guidelines in the past, they are limiting recreational fishing opportunity.

Projected impacts to overfished and non-overfished species and angler effort in 2015 and 2016 under status quo management measures are expected to be similar to previous seasons however, if anger effort and fishing success result in catch estimates higher than what is projected, additional fishing restrictions will be considered and could be implemented through state regulations to ensure that harvest of overfished species does not exceed harvest guidelines. If necessary, additional restrictions to groundfish management measures could result in fewer anglers participating in recreational fisheries which would put additional burden on coastal communities that are economically dependent on recreational fishing.

Oregon Recreational – No Action

Depth restrictions for the recreational groundfish fishery are the primary management method used to keep overfished yelloweye and canary rockfish mortality within their respective HGs in the Oregon recreational fisheries. Depth restrictions reduce mortality of overfished species because catch rates and discard mortality rates for those species are lesser in shallower depths. The depth restrictions under the No Action Alternative are all-depths from Jan-Feb, inside 40 fathoms from Apr-Sep, and all depths Oct-Dec (Figure 4-19).

Although depth restrictions reduce mortality of overfished species, they can also decrease angler trips by reducing the quantity and quality of fishable bottomfish grounds. Ports are disproportionately affected by depth restrictions due to varying amounts of fishing grounds by depth. For example, Newport is relatively unaffected by a 40 fathom depth restriction because the majority (98%) of bottomfish grounds are shallower than 20 fathoms (Figure 4-31). In contrast, Winchester Bay and Florence are greatly impacted by depth restrictions because nearly all bottomfish grounds are deeper than 40 fathoms. Other ports, such as Garibaldi and Gold Beach, where the majority of bottomfish grounds are between 20-40 fathoms, are relatively unaffected by 40 fathoms depth restrictions, but are greatly affected by 20 fathoms depth restrictions.

Under the No Action Alternative, mortality of canary and yelloweye rockfish in the groundfish fishery and the Pacific halibut fishery are projected to be within allocations and expected angler trips are anticipated to be similar to what has been seen in recent years (

Table 4-122 and

Table 4-123). However, projections are based on past catch rates and angler trips, and greater than expected values for these parameters could necessitate more conservative inseason depth restrictions and/or closures of the fisheries.

California Recreational – No Action

Under the No Action Alternative, California communities will continue to be negatively impacted by existing shallow depth restrictions and shortened seasons. The California recreational groundfish fishery has historically operated in deeper depths with longer seasons (PFMC 2003); however, with more restrictive recreational harvest guidelines for overfished groundfish species, communities in all management areas coastwide have seen drastic reductions in season length and considerable increases in depth restrictions. Management areas north of Point Arena have seen the most restrictive season and depth constraints. Due to these restrictions placed on the groundfish fishery and other marine fisheries in the region (e.g., salmon), many communities along the North Coast have seen a decrease in angler effort. In particular, the northern California ports of Crescent City, Humboldt Bay, Shelter Cove, and Fort Bragg have seen their season length slowly reduced over the past decade. The port of Crescent City often competes with the Oregon ports of Brookings and Gold Beach, where fewer restrictions and lower fuel prices have attracted many anglers who once fished out of Crescent City (Pomeroy et al. 2010).

The Preliminary Preferred Alternative and Alternative 1

Impacts under recreational fisheries Alternative 1 and the Preliminary Preferred Alternative are identical in all cases.

Under the Preliminary Preferred Alternative Option 1, an increase of 25,800 angler trips is projected from No Action coastwide, all in California. Trips increase by 4,400 (22 percent) in the North Coast region, 3,700 (47 percent) in the upper North-Central Coast region, 8,900 (18 percent) in the lower North-Central Coast region and 8,800 (8 percent) in the South-Central Coast region. No change from No Action is projected for California's South Coast region or for recreational fisheries in Washington and Oregon.

Under the Preliminary Preferred Alternative Option 2, an increase of 16,700 angler trips is projected from No Action, all in California. Trips increase by 2,700 (13 percent) in the North Coast region, 2,900 (37 percent) in the upper North-Central Coast region, 6,700 (13 percent) in the lower North-Central Coast region and 4,400 (4 percent) in the South-Central Coast region. No change from No Action is projected for California's South Coast region or for recreational fisheries in Washington and Oregon.

Under the Preliminary Preferred Alternative Option 3, a decrease of 394,700 angler trips is projected from No Action, all in California. This represents more than half of total California angler trips under No Action. Trips decrease by 6,100 (-30 percent) in the North Coast region, by 1,300 (-16 percent) in the upper North-Central Coast region, by 31,300 (-63 percent) in the lower North-Central Coast region, by 62,900 (-58 percent) in the South-Central Coast region, and by 293,100 (-56 percent) in the South Coast region. No change from No Action is projected for California's South Coast region or for recreational fisheries in Washington and Oregon.

Washington Recreational – Alternative 1

Management measures under Alternative 1 modify the time period that the 20 fathom depth restriction is in place in the North Coast (Marine Areas 3 and 4) and provides recreational fishing access to deepwater areas off the North Coast for a small amount of time prior to the opening of the recreational halibut fishery and again late in the summer. Angler effort in May is driven in large part by recreational halibut opportunities while angler effort in September is driven by salmon and albacore tuna opportunities. The modification to the depth restriction in this area is designed to occur when angler effort is low, prior to the opening of recreational halibut fisheries in May or, focused on other fishing opportunities such as salmon and albacore tuna in September after Labor Day.

In 2012, a large deepwater area covering all of the South Coast (Marine Area 2) and a large portion of the Columbia River (Marine Area 1) was closed to lingcod retention year round to reduce encounters with yelloweye rockfish by anglers targeting lingcod. Implementation of this large closed area allows for the removal of the prohibition on lingcod retention in the area seaward of 30 fathoms, south of 46°58' on Fridays and Saturday from July 1 through August 31, a regulation that was somewhat complicated, making regulations easier to follow while keeping yelloweye mortalities from exceeding Washington recreational harvest guidelines. Additional review of the deepwater lingcod closure area in Marine Area 1 and discussions with recreational anglers in this area indicate that moving the southern boundary three miles north covers the area where increased yelloweye encounters were a concern.

Projected impacts to overfished species and angler effort in 2015 and 2016 under Alternative 1 management measures are expected to be similar to previous seasons however, if anger effort and fishing success result in catch estimates higher than what is projected, additional fishing restrictions may be considered to ensure that harvest of overfished species do not exceed harvest guidelines.

Washington state specific harvest guidelines for the nearshore rockfish complex, including china rockfish, and cabezon under Alternative 1 could be reached before the end of the year and, as such, inseason action through state regulations may be considered to ensure catches do not exceed harvest guidelines. If necessary, additional restrictions to groundfish management measures could result in fewer anglers participating in recreational fisheries which would put an additional burden on coastal communities that are economically dependent on recreational fishing.

Oregon Recreational – Alternative 1

Table 4-124 shows the allocations, or model targets, for overfished species and key target species for the Oregon recreational fisheries under Alternative 1, the same as the No Action Alternative.

Oregon recreational management measures and community impacts under the Preferred Alternative are expected to be the same as the No Action Alternative; except the seasonal cabezon sub-bag limit would be removed. Cabezon impacts would be limited via state processes. Any management measures necessary to reduce impacts on nearshore rockfish complex or greenlings would be done through the state process.

Table 4-124. Oregon recreational harvest guidelines (in mt) under the Alternative 1 (P* = 0.45) for 2015-2016.

Species	2015	2016
Black Rockfish	440.4	440.4

Other Greenlings	TBD	TBD

* includes blue rockfish

California Recreational – Alternative 1

Table 4-125 shows the season lengths under Alternative 1 Options 1, 2 and 3 compared with No Action. Implications for community impacts under each Option are discussed below.

Option 1

Under Option 1, season lengths would be increased in every Management Area north of Point Conception compared to the No Action Alternative, which will provide for increased fishing opportunity thereby affording greater economic benefit to ports in the region. This will be particularly true for coastal communities in the Northern and Mendocino Management Areas, especially in March, November and December when effort is otherwise low since other fisheries (e.g. Pacific halibut and salmon) are closed. Opening the season on March 1st and extending the season in the Northern and Mendocino Management Area through December 31 will increase fishing opportunity four and a half months and six and a half months, respectively.

While the season length in the Southern Management Area would not be extended, a deeper depth restriction of 60 fm depth will increase fishing opportunity by opening more fishing grounds. While the economic effects of such a change in depth restriction are not quantified, industry has commented that deeper depth restrictions provide significant improvements in fishing opportunity that affect their business (PMFC, March 2013, H.3.c, Public Comment).

Option 2

The benefits from changes to season lengths and depth restrictions under Option 1 apply to Option 2 as well. While the current depth restrictions in the Northern and Mendocino Management Areas have greatly reduced yelloweye rockfish impacts, anglers are still confined to fishing within 20 fm year round. A deeper depth restriction of 30 fm from October 1 to December 31 in the Northern and Mendocino Management Areas will allow access to more fishing grounds, when fishing effort is historically low compared to summer months. Although this increased fishing opportunity may attract some anglers to the coast during months of the 30 fm depth restriction, changes in effort are expected to be relatively minor.

Option 3

A ten fathom increase in depth restriction for each of the management areas north of Point Conception (relative to No Action) would require substantial reductions in season lengths to keep overfished species impacts within harvest guidelines given the high uncertainty in projected impacts.

The season under Option 3 would be reduced relative to No Action by two and a half months in the Northern Management Area, by 16 days in the Mendocino Management Area reduced, reduced by four months in the San Francisco Management Area, and reduced by five months in the Central management area. Compared to Option 2, the season in the Northern Management Area would be reduced by six months, the Mendocino Management Area reduced by five and a half months, while the San Francisco and Central Management Areas would have a six month reduction in season length.

In the Southern Management Area, loss of seven months of season relative to the No Action alternative would result in a severe reduction in trips. The limited opportunity for California scorpionfish during the closed months of fishing for the RCG complex is not expected to draw as much effort as the forgone opportunities. In addition, any increase in effort as a result of the deeper depth restriction relative to status quo is not quantified and is not expected to compensate for the loss of fishing season during March and April as well as September through and December, when the RCG complex is one of few opportunities available in the absence of pelagic species which are distributed further to the south or offshore that time of year.

While a deeper depth restriction would increase fishing opportunity, the effect in terms of additional trips is not quantified. However, the reduction in season length would translate to a greatly reduced number of fishing trips. Mortality estimates do not account for the use of descending devices in the release of overfished species, which began in 2013. If anglers use descending devices with sufficient frequency, future projections may indicate sufficient reduction in mortality to allow increased opportunity in deeper depths as the devices have been shown to greatly reduce mortality on released rockfish.

Table 4-125. Preliminary Preferred Alternative: Summary of season structures under No Action, Option 1, Option 2, and Option 3. Season length (in months) is included in parenthesis.

Management Area	Season Length and Number of months			
	No Action	Option 1	Option 2	Option 3
Northern	May 15 – Oct 31 (5.5)	Mar 1 – Dec 31 (10)	Apr 1 – Dec 31 (9)	May 15 – Aug 15 (3)
Mendocino	May 15 – Sep 1 (3.5)	Mar 1 – Dec 31 (10)	Apr 1 – Dec 31 (9)	May 15 – Aug 15 (3)
San Francisco	June 1 – Dec 31 (7)	Mar 1 – Dec 31 (10)	Apr 1 – Dec 31 (9)	May 15 – Aug 15 (3)
Central	May 1- Dec 31 (1)	Mar 1 – Dec 31 (10)	Apr 1 – Dec 31 (9)	May 15 – Aug 15 (3)
Southern	Mar 1 – Dec 31 (10)	Mar 1 – Dec 31 (10)	Mar 1 – Dec 31 (10)	May 15 – Aug 15 (3)

Alternative 2

Under Alternative 2 Option 1, a decrease of a total of 19,300 angler trips (-3 percent) is projected from No Action in California although impacts vary considerably by region. Trips increase by 1,000 (5 percent) in the North Coast region, by 2,100 (26 percent) in the upper North-Central Coast region, by 4,500 (9 percent) in the lower North-Central Coast region, but decrease by 26,800 (-25 percent) in the South-Central Coast region. No change from No Action is projected for California's South Coast region or for recreational fisheries in Washington and Oregon.

Impacts under Alternative 2 Option 2 are the same as under Alternative 2 Option 1.

Impacts under Alternative 2 Option 3 are the same as under Alternative 1 - the Preliminary Preferred Alternative Option 3.

California Recreational – Alternative 2

Table 4-126 shows the season lengths under Alternative 2 Options 1, 2 and 3 compared with No Action. Implications for community impacts under each Option are discussed below.

Option 1

Combined with reduced yelloweye rockfish mortality in recent years informing the catch projection model, the relatively higher ACL will allow increased fishing opportunity north of Point Conception where they are more commonly encountered. This will provide increased economic benefit to coastal communities in the region from expenditures by anglers fishing in the area during the open months of the season. Compared to the Alternative 1 and Alternative 3, the season north of Point Conception would be one month shorter since April would have to remain closed to keep black rockfish mortality within the lower harvest limit under Alternative 2. Extending the season in the Northern and Mendocino Management Area through December 31 will increase fishing opportunity, especially in November and December when effort is low and other fisheries such as Pacific halibut and salmon are closed.

The reduced bag limit for kelp greenling will mainly affect anglers fishing north of Point Conception where the majority of these encounters occur. This will decrease fishing opportunity for shore based anglers who regularly encounter kelp greenling as well as boat based anglers fishing in waters within 20 fm. In addition, reduced bag limits for California scorpionfish will adversely affect anglers south of Point Conception where the vast majority of encounters occur, having a disproportionate affect during January and February when the season is closed for many groundfish species and pelagic species have moved south into Mexican waters and are unavailable. During this period of the year, California scorpionfish are targeted more frequently and the reduced bag limit of three fish will diminish fishing opportunity for this species. However the effects of bag limit changes on effort have not been quantified.

Option 2

The season length can be extended north of Point Conception relative to status quo due to the increase in ACLs as a result of rebuilding and recent reductions in yelloweye rockfish impacts. The season would be one month shorter than under Alternative 1 or Alternative 3, opening May 1 instead of April 1. The current depth restrictions in the Northern and Mendocino Management Areas are the shallowest in the state with anglers confined to fishing within 20 fm year round under status quo regulations, thereby greatly reduced OFS impacts. A deeper depth restriction of 30 fm from October to December in the Northern and Mendocino Management Areas will allow access to more fishing grounds, at a time when fishing effort is relatively low compared to summer months. Although this increased fishing opportunity may attract some anglers, changes in effort are expected to be relatively minor and are not accounted for in economic modeling, which quantifies only the increase in the number of expected fishing trips with an increase in season length. As noted under Option 1, the reduced bag limits for kelp greenling and California scorpionfish would diminish the quality of fishing opportunity, but the economic effects of this are not quantified.

While the season length in the Southern Management Area would not be extended, a deeper depth restriction of 60 fm will increase fishing opportunity by opening more fishing grounds. While the economic effects of changes in depth restriction are not quantified, industry has commented that deeper depth restrictions provide significant improvements in fishing opportunity that affect their business (PMFC, March 2013, H.3.c, Public Comment). A three fish California scorpionfish bag limit may reduce effort. Qualitatively, the greatest impact would be in January and February when California scorpionfish is one of a few fishing opportunities available in the Southern Management Area. At this time of the year most other groundfish fisheries are closed and pelagic species are unavailable.

Option 3

A ten fathom deeper depth restriction in each of the management areas north of Point Conception would require substantial reductions in season lengths to keep overfished species impacts within harvest guidelines. The season under Option 3 would be reduced in the Northern Management Area relative to No Action by two and a half months, in the Mendocino Management Area it would be reduced by 16 days, San Francisco Management Area reduced by four months and the Central management area reduced by five months. Compared to Option 1, the season in the northern management area would be reduced by five months, the Mendocino Management Area reduced by four and a half months, San Francisco Management Area reduced by five months and the Central management area reduced by five months.

In the Southern Management Area, loss of seven months of season relative to the No Action alternative would result in a severe reduction in the number of fishing trips. Any increase in effort as a result of the deeper depth restriction relative to the status quo is not quantified but is not expected to compensate for the loss of fishing season at a time when the RCG complex is one of few opportunities available. The limited opportunity for California scorpionfish during the closed months of fishing for the RCG complex is not expected to draw as much effort as the forgone opportunities. Furthermore a reduced bag limit for California scorpionfish would still be necessary under this alternative to maintain the status quo year round season length south of Point Conception given the ACLs in Alternative 2. This would diminish fishing opportunity for anglers in the Southern Management Area where California scorpionfish are predominantly encountered, with greater effects during January and February when few other opportunities are available as discussed in Option 1 and Option 2.

While a deeper depth restriction would increase fishing opportunity, the effect in terms of increased effort is not quantified, but the reduction in season length would translate into a greatly reduced number of fishing trips during the season. Mortality estimates do not account for the use of descending devices in the release of overfished species, which began in 2013.

Table 4-126. Alternative 2: Summary of season structures under No Action in addition Option 1, Option 2, and Option 3. Season length (in months) is included in parenthesis.

Management Area	Season Length and Number of months			
	No Action	Option 1	Option 2	Option 3
Northern	May 15 – Oct 31 (5.5)	May 1 – Dec 31 (8)	May 1 – Dec 31 (8)	May 15 – Aug 15 (3)
Mendocino	May 15 – Sep 1 (3.5)	May 1 – Dec 31 (8)	May 1 – Dec 31 (8)	May 15 – Aug 15 (3)
San Francisco	June 1 – Dec 31 (7)	May 1 – Dec 31 (8)	May 1 – Dec 31 (8)	May 15 – Aug 15 (3)
Central	May 1- Dec 31 (8)	May 1 – Dec 31 (8)	May 1 – Dec 31 (8)	May 15 – Aug 15 (3)
Southern	Mar 1 – Dec 31 (10)	Mar 1 – Dec 31 (10)	Mar 1 – Dec 31 (10)	May 15 – Aug 15 (3)

4.3.2.3 Communities

No Action

Coastwide:

Compared to the 2003-12 baseline period, total groundfish ex-vessel revenue would increase by $12.4 million coastwide, or 18 percent under the No Action Alternative. Relative to the baseline period, No Action would produce the second smallest increase in ex-vessel revenue among the alternatives.

The average estimated coastwide unemployment rate under No Action is 9.3 percent (based on 2012 county statistics).

Estimated coastwide commercial fishery income impacts under the No Action alternative are $111.2 million. Estimated coastwide recreational fishery income impacts under the No Action alternative are $145.6 million.

Estimated coastwide commercial fishery employment impacts under the No Action alternative are 2,300 jobs. Estimated coastwide recreational fishery income impacts under the No Action alternative are 3,000 jobs.

Puget Sound:

Compared to the 2003-12 baseline period, groundfish ex-vessel revenue would decrease by $1.5 million in Puget Sound, or -46 percent under the No Action Alternative.

The average estimated unemployment rate in the region under No Action is the lowest among the coastal communities at 7.6 percent (based on 2012 county statistics).

Combined commercial plus recreational fisheries income impacts in the port area under No Action are $3 million.

Combined commercial plus recreational fisheries employment impacts in the port area under No Action are 44 jobs.

Washington Coast:

Compared to the 2003-12 baseline period groundfish ex-vessel revenue would increase by $4.6 million on the Washington Coast, or 32 percent under the No Action Alternative. Note that revenues from landings in tribal groundfish fisheries are included in these totals but not in the income impact results since cost and earnings data for tribal vessels have not been formally surveyed.

The average estimated unemployment rate in the region under No Action is 10.6 percent (based on 2012 county statistics).

Combined commercial plus recreational fisheries income impacts in the port area under No Action are $21.7 million.

Combined commercial plus recreational fisheries employment impacts in the port area under No Action are 464 jobs.

Astoria – Tillamook:

Compared to the 2003-12 baseline period, groundfish ex-vessel revenue would increase by $5.7 million in Astoria-Tillamook, or 45 percent under the No Action Alternative.

The average estimated unemployment rate in the region under No Action is 7.8 percent (based on 2012 county statistics).

Combined commercial plus recreational fisheries income impacts in the port area under No Action are $31 million.

Combined commercial plus recreational fisheries employment impacts in the port area under No Action are 510 jobs.

Newport:

Compared to the 2003-12 baseline period groundfish ex-vessel revenue would increase by $3.7 million in Newport, or 35 percent under the No Action Alternative.

The average estimated unemployment rate in the region under No Action is 9.3 percent (based on 2012 county statistics).

Combined commercial plus recreational fisheries income impacts in the port area under No Action are $27 million.

Combined commercial plus recreational fisheries employment impacts in the port area under No Action are 532 jobs.

Coos Bay – Brookings:

Compared to the 2003-12 baseline period, groundfish ex-vessel revenue would decrease by $0.9 million in Coos Bay - Brookings, or -10 percent under the No Action Alternative.

The average estimated unemployment rate in the region under No Action is 9.6 percent (based on 2012 county statistics).

Combined commercial plus recreational fisheries income impacts in the port area under No Action are $14.4 million.

Combined commercial plus recreational fisheries employment impacts in the port area under No Action are 367 jobs.

Crescent City – Eureka:

Compared to the 2003-12 baseline period, groundfish ex-vessel revenue would decrease by $2.4 million in Crescent City - Eureka, or -40 percent under the No Action Alternative.

The average estimated unemployment rate in the region under No Action is the highest among the coastal communities at 10.9 percent (based on 2012 county statistics).

Combined commercial plus recreational fisheries income impacts in the port area under No Action are $7.3 million.

Combined commercial plus recreational fisheries employment impacts in the port area under No Action are 163 jobs.

Fort Bragg – Bodega Bay:

Compared to the 2003-12 baseline period groundfish ex-vessel revenue would increase by $0.2 million in Fort Bragg – Bodega Bay, or 6 percent under the No Action Alternative.

The average estimated unemployment rate in the region under No Action is 8 percent (based on 2012 county statistics).

Combined commercial plus recreational fisheries income impacts in the port area under No Action are $6.9 million.

Combined commercial plus recreational fisheries employment impacts in the port area under No Action are 204 jobs.

San Francisco Area:

Compared to the 2003-12 baseline period groundfish ex-vessel revenue would decrease by $0.6 million in the San Francisco Area, or -35 percent under the No Action Alternative.

The average estimated unemployment rate in the region under No Action is 8.2 percent (based on 2012 county statistics).

Combined commercial plus recreational fisheries income impacts in the port area under No Action are $10.3 million.

Combined commercial plus recreational fisheries employment impacts in the port area under No Action are 203 jobs.

Santa Cruz – Monterey – Morro Bay:

Compared to the 2003-12 baseline period, groundfish ex-vessel revenue would increase by $1.9 million in the Santa Cruz – Monterey – Morro Bay region, or 37 percent under the No Action Alternative.

The average estimated unemployment rate in the region under No Action is 10.4 percent (based on 2012 county statistics).

Combined commercial plus recreational fisheries income impacts in the port area under No Action are $18.4 million.

Combined commercial plus recreational fisheries employment impacts in the port area under No Action are 491 jobs.

Santa Barbara – Los Angeles – San Diego:

Compared to the 2003-12 baseline period groundfish ex-vessel revenue would increase by $1.7 million in the Santa Barbara – Los Angeles – San Diego region, or 61 percent under the No Action Alternative.

The average estimated unemployment rate in the region under No Action is 10 percent (based on 2012 county statistics).

Combined commercial plus recreational fisheries income impacts in the port area under No Action are $116.7 million.

Combined commercial plus recreational fisheries employment impacts in the port area under No Action are 2,300 jobs.

The Preferred Alternative

Coastwide:

Compared to the 2003-12 baseline period, total groundfish ex-vessel revenue would increase by $28.4 million coastwide in 2015 (41 percent). Relative to the baseline period, this alternative would produce the largest increase in ex-vessel revenue among the alternatives.

The change in commercial fisheries–related employment is projected to decrease the average coastwide unemployment rate under the Preferred Alternative (compared with No Action) by 0.003 percent (based on 2012 county statistics).

Coastwide combined commercial plus recreational fishery income impacts under the Preferred Alternative are projected to increase over No Action by $27.3 million (11 percent) under recreational option 1 and by $26.3 million (10 percent) under recreational option 2, but decrease by $49.2 million (-19 percent) under recreational option 3.

Coastwide combined commercial plus recreational fishery employment impacts under the Preferred Alternative are projected to increase over No Action by 529 jobs (10 percent) under recreational option 1 and by 510 jobs (10 percent) under recreational option 2, but decrease by 957 jobs (-18 percent) under recreational option 3.

Puget Sound:

Compared to the 2003-12 baseline period, groundfish ex-vessel revenue would decrease by $1 million (-31 percent) in the port area in 2015.

The change in commercial fisheries–related employment is projected to decrease the average regional unemployment rate under the Preferred Alternative (compared with No Action) by 0.001 percent (based on 2012 county statistics).

Combined commercial plus recreational fishery income impacts in the port area under the Preferred Alternative are projected to increase over No Action by $0.9 million (29 percent) under all three recreational options.

Combined commercial plus recreational fishery employment impacts in the port area under the Preferred Alternative are projected to increase over No Action by 11 jobs (26 percent) under all three recreational options.

Washington Coast:

Compared to the 2003-12 baseline period groundfish ex-vessel revenue would increase by $5.8 million on the Washington Coast in 2015 (40 percent). Note that revenues from landings in tribal groundfish fisheries are included in these totals but not in the income impact results since cost and earnings data for tribal vessels have not been formally surveyed.

The change in commercial fisheries–related employment is projected to decrease the average regional unemployment rate under the Preferred Alternative (compared with No Action) by 0.009 percent (based on 2012 county statistics).

Combined commercial plus recreational fishery income impacts in the port area under the Preferred Alternative are projected to increase over No Action by $1.5 million (7 percent) under all three recreational options.

Combined commercial plus recreational fishery employment impacts in the port area under the Preferred Alternative are projected to increase over No Action by 26 jobs (6 percent) under all three recreational options.

Astoria – Tillamook:

Compared to the 2003-12 baseline period, groundfish ex-vessel revenue would increase by $10.9 million (85 percent) in Astoria-Tillamook in 2015.

The change in commercial fisheries–related employment is projected to decrease the average regional unemployment rate under the Preferred Alternative (compared with No Action) by 0.026 percent (based on 2012 county statistics).

Combined commercial plus recreational fishery income impacts in the port area under the Preferred Alternative are projected to increase over No Action by $7.9 million (25 percent) under all three recreational options.

Combined commercial plus recreational fishery employment impacts in the port area under the Preferred Alternative are projected to increase over No Action by 114 jobs (22 percent) under all three recreational options.

Newport:

Compared to the 2003-12 baseline period groundfish ex-vessel revenue would increase by $4.9 million (46 percent) in Newport in 2015.

The change in commercial fisheries–related employment is projected to decrease the average regional unemployment rate under the Preferred Alternative (compared with No Action) by 0.119 percent (based on 2012 county statistics).

Combined commercial plus recreational fishery income impacts in the port area under the Preferred Alternative are projected to increase over No Action by $1.6 million (6 percent) under all three recreational options.

Combined commercial plus recreational fishery employment impacts in the port area under the Preferred Alternative are projected to increase over No Action by 27 jobs (5 percent) under all three recreational options.

Coos Bay – Brookings:

Compared to the 2003-12 baseline period, groundfish ex-vessel revenue would increase by $1.9 million (20 percent) in Coos Bay – Brookings in 2015.

The change in commercial fisheries–related employment is projected to decrease the average regional unemployment rate under the Preferred Alternative (compared with No Action) by 0.032 percent (based on 2012 county statistics).

Combined commercial plus recreational fishery income impacts in the port area under the Preferred Alternative are projected to increase over No Action by $4.2 million (29 percent) under all three recreational options.

Combined commercial plus recreational fishery employment impacts in the port area under the Preferred Alternative are projected to increase over No Action by 84 jobs (23 percent) under all three recreational options.

Crescent City – Eureka:

Compared to the 2003-12 baseline period, groundfish ex-vessel revenue would decrease by $0.6 million (-10 percent) in Crescent City – Eureka in 2015.

The change in commercial fisheries–related employment is projected to decrease the average regional unemployment rate under the Preferred Alternative (compared with No Action) by 0.086 percent (based on 2012 county statistics).

Combined commercial plus recreational fishery income impacts in the port area under the Preferred Alternative are projected to increase over No Action by $3.6 million (50 percent) under recreational option 1, $3.5 million (48 percent) under recreational option 2, and $2.8 million (39 percent) under recreational option 3.

Combined commercial plus recreational fishery employment impacts in the port area under the Preferred Alternative are projected to increase over No Action by 69 jobs (42 percent) under recreational option 1, 66 jobs (40 percent) under recreational option 2, and 52 jobs (32 percent) under recreational option 3.

Fort Bragg – Bodega Bay:

Compared to the 2003-12 baseline period groundfish ex-vessel revenue would increase by $1.2 million (32 percent) in Fort Bragg – Bodega Bay in 2015.

The change in commercial fisheries–related employment is projected to decrease the average regional unemployment rate under the Preferred Alternative (compared with No Action) by 0.010 percent (based on 2012 county statistics).

Combined commercial plus recreational fishery income impacts in the port area under the Preferred Alternative are projected to increase over No Action by $2 million (29 percent) under recreational option 1, $2 million (28 percent) under recreational option 2, and $1.6 million (23 percent) under recreational option 3.

Combined commercial plus recreational fishery employment impacts in the port area under the Preferred Alternative are projected to increase over No Action by 51 jobs (25 percent) under recreational option 1, 50 jobs (24 percent) under recreational option 2, and 42 jobs (21 percent) under recreational option 3.

San Francisco Area:

Compared to the 2003-12 baseline period groundfish ex-vessel revenue would increase by $0.1 million (5 percent) in the San Francisco Area in 2015.

The change in commercial fisheries–related employment is projected to decrease the average regional unemployment rate under the Preferred Alternative (compared with No Action) by 0.001 percent (based on 2012 county statistics).

Combined commercial plus recreational fishery income impacts in the port area under the Preferred Alternative are projected to increase over No Action by $2.9 million (28 percent) under recreational option 1, $2.5 million (24 percent) under recreational option 2, and decrease by $3.6 million (-35 percent) under recreational option 3.

Combined commercial plus recreational fishery employment impacts in the port area under the Preferred Alternative are projected to increase over No Action by 55 jobs (27 percent) under recreational option 1, 49 jobs (24 percent) under recreational option 2, and decrease by 64 jobs (-32 percent) under recreational option 3.

Santa Cruz – Monterey – Morro Bay:

Compared to the 2003-12 baseline period, groundfish ex-vessel revenue would increase by $3.2 million (63 percent) in the Santa Cruz – Monterey – Morro Bay region in 2015.

The change in commercial fisheries–related employment is projected to decrease the average regional unemployment rate under the Preferred Alternative (compared with No Action) by 0.011 percent (based on 2012 county statistics).

Combined commercial plus recreational fishery income impacts in the port area under the Preferred Alternative are projected to increase over No Action by $2.4 million (13 percent) under recreational option 1, $1.9 million (10 percent) under recreational option 2, and decrease by $4.7 million (-26 percent) under recreational option 3.

Combined commercial plus recreational fishery employment impacts in the port area under the Preferred Alternative are projected to increase over No Action by 76 jobs (16 percent) under recreational option 1, 67 jobs (14 percent) under recreational option 2, and decrease by 67 jobs (-14 percent) under recreational option 3.

Santa Barbara – Los Angeles – San Diego:

Compared to the 2003-12 baseline period groundfish ex-vessel revenue would increase by $2.1 million (76 percent) in the Santa Barbara – Los Angeles – San Diego region in 2015.

The change in commercial fisheries–related employment is projected to slightly decrease the average regional unemployment rate under the Preferred Alternative (compared with No Action) (based on 2012 county statistics).

Combined commercial plus recreational fishery income impacts in the port area under the Preferred Alternative are projected to increase over No Action by $0.5 million (0.4 percent) under recreational option 1and option 2, and decrease by $61.2 million (-53 percent) under recreational option 3.

Combined commercial plus recreational fishery employment impacts in the port area under the Preferred Alternative are projected to increase over No Action by 16 jobs (0.7 percent) under recreational option 1 and option 2, and decrease by 1,182 jobs (-51 percent) under recreational option 3.

Alternative 1

Coastwide:

Compared to the 2003-12 baseline period, total groundfish ex-vessel revenue would increase by $21.2 million coastwide in 2015 (30 percent). Relative to the baseline period, this alternative would produce the second largest increase in ex-vessel revenue among the alternatives.

The change in commercial fisheries–related employment is projected to decrease the average regional unemployment rate under the Alternative (compared with No Action) by 0.002 percent (based on 2012 county statistics).

Coastwide combined commercial plus recreational fishery income impacts under the Alternative 1 are projected to increase over No Action by $15 million (6 percent) under recreational option 1 and by $14 million (5 percent) under recreational option 2, but decrease by $61.6 million (-24 percent) under recreational option 3.

Coastwide combined commercial plus recreational fishery employment impacts under the Alternative 1 are projected to increase over No Action by 336 jobs (10 percent) under recreational option 1 and by 316 jobs (10 percent) under recreational option 2, but decrease by 1,150 jobs (-22 percent) under recreational option 3.

Puget Sound:

Compared to the 2003-12 baseline period, groundfish ex-vessel revenue would decrease by $1.2 million (-35 percent) in Puget Sound in 2015.

The change in commercial fisheries–related employment is projected to slightly decrease the average regional unemployment rate under the Alternative (compared with No Action) (based on 2012 county statistics).

Combined commercial plus recreational fishery income impacts in the port area under the Alternative are projected to increase over No Action by $0.6 million (19 percent) under all three recreational options.

Combined commercial plus recreational fishery employment impacts in the port area under the Alternative are projected to increase over No Action by 8 jobs (18 percent) under all three recreational options.

Washington Coast:

Compared to the 2003-12 baseline period groundfish ex-vessel revenue would increase by $5.6 million on the Washington Coast in 2015 (39 percent). Note that revenues from landings in tribal groundfish fisheries are included in these totals but not in the income impact results since cost and earnings data for tribal vessels have not been formally surveyed.

The change in commercial fisheries–related employment is projected to decrease the average regional unemployment rate under the Alternative (compared with No Action) by 0.007 percent (based on 2012 county statistics).

Combined commercial plus recreational fishery income impacts in the port area under the Alternative are projected to increase over No Action by $1.1 million (5 percent) under all three recreational options.

Combined commercial plus recreational fishery employment impacts in the port area under the Alternative are projected to increase over No Action by 21 jobs (5 percent) under all three recreational options.

Astoria – Tillamook:

Compared to the 2003-12 baseline period, groundfish ex-vessel revenue would increase by $8.2 million (64 percent) in Astoria-Tillamook in 2015.

The change in commercial fisheries–related employment is projected to decrease the average regional unemployment rate under the Alternative (compared with No Action) by 0.013 percent (based on 2012 county statistics).

Combined commercial plus recreational fishery income impacts in the port area under the Alternative are projected to increase over No Action by $3.6 million (12 percent) under all three recreational options.

Combined commercial plus recreational fishery employment impacts in the port area under the Alternative are projected to increase over No Action by 55 jobs (11 percent) under all three recreational options.

Newport:

Compared to the 2003-12 baseline period groundfish ex-vessel revenue would increase by $4.4 million (41 percent) in Newport in 2015.

The change in commercial fisheries–related employment is projected to decrease the average regional unemployment rate under the Alternative (compared with No Action) by 0.069 percent (based on 2012 county statistics).

Combined commercial plus recreational fishery income impacts in the port area under the Alternative are projected to increase over No Action by $0.8 million (3 percent) under all three recreational options.

Combined commercial plus recreational fishery employment impacts in the port area under the Alternative are projected to increase over No Action by 16 jobs (3 percent) under all three recreational options.

Coos Bay – Brookings:

Compared to the 2003-12 baseline period, groundfish ex-vessel revenue would increase by $0.3 million (3 percent) in Coos Bay – Brookings in 2015.

The change in commercial fisheries–related employment is projected to decrease the average regional unemployment rate under the Alternative (compared with No Action) by 0.015 percent (based on 2012 county statistics).

Combined commercial plus recreational fishery income impacts in the port area under the Alternative are projected to increase over No Action by $1.6 million (11 percent) under all three recreational options.

Combined commercial plus recreational fishery employment impacts in the port area under the Alternative are projected to increase over No Action by 39 jobs (11 percent) under all three recreational options.

Crescent City – Eureka:

Compared to the 2003-12 baseline period, groundfish ex-vessel revenue would decrease by $1.9 million (-31 percent) in Crescent City – Eureka in 2015.

The change in commercial fisheries–related employment is projected to decrease the average regional unemployment rate under the Alternative (compared with No Action) by 0.026 percent (based on 2012 county statistics).

Combined commercial plus recreational fishery income impacts in the port area under the Alternative are projected to increase over No Action by $1.1 million (16 percent) under recreational option 1, $1 million (14 percent) under recreational option 2, and $0.4 million (5 percent) under recreational option 3.

Combined commercial plus recreational fishery employment impacts in the port area under the Alternative are projected to increase over No Action by 26 jobs (16 percent) under recreational option 1, 23 jobs (14 percent) under recreational option 2, and 9 jobs (6 percent) under recreational option 3.

Fort Bragg – Bodega Bay:

Compared to the 2003-12 baseline period groundfish ex-vessel revenue would increase by $0.9 million (23 percent) in Fort Bragg – Bodega Bay in 2015.

The change in commercial fisheries–related employment is projected to decrease the average regional unemployment rate under the Alternative (compared with No Action) by 0.008 percent (based on 2012 county statistics).

Combined commercial plus recreational fishery income impacts in the port area under the Alternative are projected to increase over No Action by $1.3 million (19 percent) under recreational option 1, $1.3

million (18 percent) under recreational option 2, and $0.9 million (13 percent) under recreational option 3.

Combined commercial plus recreational fishery employment impacts in the port area under the Alternative are projected to increase over No Action by 41 jobs (20 percent) under recreational option 1, 40 jobs (20 percent) under recreational option 2, and 33 jobs (16 percent) under recreational option 3.

San Francisco Area:

Compared to the 2003-12 baseline period groundfish ex-vessel revenue would decrease by $0.4 million (-25 percent) in the San Francisco Area in 2015.

The change in commercial fisheries–related employment is projected to slightly decrease the average regional unemployment rate under the Alternative (compared with No Action) (based on 2012 county statistics).

Combined commercial plus recreational fishery income impacts in the port area under the Alternative are projected to increase over No Action by $1.8 million (17 percent) under recreational option 1, $1.4 million (14 percent) under recreational option 2, and decrease by $4.7 million (-46 percent) under recreational option 3.

Combined commercial plus recreational fishery employment impacts in the port area under the Alternative are projected to increase over No Action by 34 jobs (17 percent) under recreational option 1, 28 jobs (14 percent) under recreational option 2, and decrease by 85 jobs (-42 percent) under recreational option 3.

Santa Cruz – Monterey – Morro Bay:

Compared to the 2003-12 baseline period, groundfish ex-vessel revenue would increase by $3.1 million (61 percent) in the Santa Cruz – Monterey – Morro Bay region in 2015.

The change in commercial fisheries–related employment is projected to decrease the average regional unemployment rate under the Alternative (compared with No Action) by 0.011 percent (based on 2012 county statistics).

Combined commercial plus recreational fishery income impacts in the port area under the Alternative are projected to increase over No Action by $2.2 million (12 percent) under recreational option 1, $1.7 million (9 percent) under recreational option 2, and decrease by $5 million (-27 percent) under recreational option 3.

Combined commercial plus recreational fishery employment impacts in the port area under the Alternative are projected to increase over No Action by 75 jobs (15 percent) under recreational option 1, 67 jobs (14 percent) under recreational option 2, and decrease by 68 jobs (-14 percent) under recreational option 3.

Santa Barbara – Los Angeles – San Diego:

Compared to the 2003-12 baseline period groundfish ex-vessel revenue would increase by $2.2 million (82 percent) in the Santa Barbara – Los Angeles – San Diego region.

The change in commercial fisheries–related employment is projected to slightly decrease the average regional unemployment rate under the Alternative (compared with No Action) (based on 2012 county statistics).

The average estimated unemployment rate in the region under the Alternative is projected to decrease slightly compared with No Action (based on 2012 county statistics).

Combined commercial plus recreational fishery income impacts in the port area under the Alternative are projected to increase over No Action by $0.7 million (0.6 percent) under recreational option 1 and option 2, and decrease by $61 million (-52 percent) under recreational option 3.

Combined commercial plus recreational fishery employment impacts in the port area under the Alternative are projected to increase over No Action by 20 jobs (0.9 percent) under recreational option 1and option 2, and decrease by 1,177 jobs (-51 percent) under recreational option 3.

Alternative 2

Coastwide:

Compared to the 2003-12 baseline period, total groundfish ex-vessel revenue would increase by $12 million coastwide in 2015 (17 percent). Relative to the baseline period, this alternative would produce the lowest total coastwide increase in ex-vessel revenue among the alternatives.

The change in commercial fisheries–related employment is projected to slightly decrease the average regional unemployment rate under the Alternative (compared with No Action) (based on 2012 county statistics).

Coastwide combined commercial plus recreational fishery income impacts under Alternative 2 are projected to decrease over No Action by $2.8 million (-1 percent) under recreational option 1 and option 2, and decrease by $74.7 million (-29 percent) under recreational option 3.

Coastwide combined commercial plus recreational fishery employment impacts under the Alternative 2 are projected to decrease over No Action by 30 jobs (-0.6 percent) under recreational option 1 and option 2, and decrease by 1,423 jobs (-27 percent) under recreational option 3.

Puget Sound:

Compared to the 2003-12 baseline period, groundfish ex-vessel revenue would decrease by $1.6 million (-47 percent) in Puget Sound in 2015.

The change in commercial fisheries–related employment is projected to slightly increase the average regional unemployment rate under the Alternative (compared with No Action) (based on 2012 county statistics).

Combined commercial plus recreational fishery income impacts in the port area under the Alternative are projected to decrease compared with No Action by $0.06 million (-2 percent) under all three recreational options.

Combined commercial plus recreational fishery employment impacts in the port area under the Alternative are projected to decrease compared with No Action by 1 job (-3 percent) under all three recreational options.

Washington Coast:

Compared to the 2003-12 baseline period groundfish ex-vessel revenue would increase by $4.8 million on the Washington Coast in 2015 (34 percent). Note that revenues from landings in tribal groundfish fisheries are included in these totals but not in the income impact results since cost and earnings data for tribal vessels have not been formally surveyed.

The change in commercial fisheries–related employment is projected to increase the average regional unemployment rate under the Alternative (compared with No Action) by 0.001 percent (based on 2012 county statistics).

Combined commercial plus recreational fishery income impacts in the port area under the Alternative are projected to decrease compared with No Action by $0.08 million (-0.4 percent) under all three recreational options.

Combined commercial plus recreational fishery employment impacts in the port area under the Alternative are projected to decrease compared with No Action by 2 jobs (-0.5 percent) under all three recreational options.

Astoria – Tillamook:

Compared to the 2003-12 baseline period, groundfish ex-vessel revenue would increase by $5.8 million (45 percent) in Astoria-Tillamook in 2015.

The change in commercial fisheries–related employment is projected to decrease the average regional unemployment rate under the Alternative (compared with No Action) by 0.001 percent (based on 2012 county statistics).

Combined commercial plus recreational fishery income impacts in the port area under the Alternative are projected to increase compared with No Action by $0.1 million (0.3 percent) under all three recreational options.

Combined commercial plus recreational fishery employment impacts in the port area under the Alternative are projected to increase compared with No Action by 3 jobs (0.6 percent) under all three recreational options.

Newport:

Compared to the 2003-12 baseline period groundfish ex-vessel revenue would increase by $3.6 million (34 percent) in Newport in 2015.

The change in commercial fisheries–related employment is projected to increase the average regional unemployment rate under the Alternative (compared with No Action) by 0.012 percent (based on 2012 county statistics).

Combined commercial plus recreational fishery income impacts in the port area under the Alternative are projected to decrease compared with No Action by $0.2 million (-0.6 percent) under all three recreational options.

Combined commercial plus recreational fishery employment impacts in the port area under the Alternative are projected to decrease compared with No Action by 3 jobs (-0.5 percent) under all three recreational options.

Coos Bay – Brookings:

Compared to the 2003-12 baseline period, groundfish ex-vessel revenue would decrease by $1.3 million (-13 percent) in Coos Bay – Brookings in 2015.

The change in commercial fisheries–related employment is projected to increase the average regional unemployment rate under the Alternative (compared with No Action) by 0.006 percent (based on 2012 county statistics).

Combined commercial plus recreational fishery income impacts in the port area under the Alternative are projected to decrease compared with No Action by $0.5 million (-3 percent) under all three recreational options.

Combined commercial plus recreational fishery employment impacts in the port area under the Alternative are projected to decrease compared with No Action by 15 jobs (-4 percent) under all three recreational options.

Crescent City – Eureka:

Compared to the 2003-12 baseline period, groundfish ex-vessel revenue would decrease by $2.4 million (-40 percent) in Crescent City – Eureka in 2015.

The change in commercial fisheries–related employment is projected to decrease the average regional unemployment rate under the Alternative (compared with No Action) by 0.002 percent (based on 2012 county statistics).

Combined commercial plus recreational fishery income impacts in the port area under the Alternative are projected to increase compared with No Action by $0.03 million (0.4 percent) under recreational option 1 and option 2, and decrease by $0.5 million (-7 percent) under recreational option 3.

Combined commercial plus recreational fishery employment impacts in the port area under the Alternative are projected to increase compared with No Action by 3 jobs (2 percent) under recreational option 1 and option 2, and decrease by 8 jobs (-5 percent) under recreational option 3.

Fort Bragg – Bodega Bay:

Compared to the 2003-12 baseline period groundfish ex-vessel revenue would increase by $0.1 million (3 percent) in Fort Bragg – Bodega Bay in 2015.

The change in commercial fisheries–related employment is projected to slightly increase the average regional unemployment rate under the Alternative (compared with No Action) (based on 2012 county statistics).

Combined commercial plus recreational fishery income impacts in the port area under the Alternative are projected to increase compared with No Action by $0.03 million (0.4 percent) under recreational option 1 and option 2, and decrease by $0.3 million (-4 percent) under recreational option 3.

Combined commercial plus recreational fishery employment impacts in the port area under the Alternative are projected to increase compared with No Action by 3 jobs (1 percent) under recreational option 1 and option 2, and decrease by 3 jobs (-1.5 percent) under recreational option 3.

San Francisco Area:

Compared to the 2003-12 baseline period groundfish ex-vessel revenue would decrease by $0.6 million (-36 percent) in the San Francisco Area in 2015.

The change in commercial fisheries–related employment is projected to slightly decrease the average regional unemployment rate under the Alternative (compared with No Action) (based on 2012 county statistics).

Combined commercial plus recreational fishery income impacts in the port area under the Alternative are projected to increase compared with No Action by $0.7 million (6 percent) under recreational option 1 and option 2, and decrease by $5.1 million (-50 percent) under recreational option 3.

Combined commercial plus recreational fishery employment impacts in the port area under the Alternative are projected to increase compared with No Action by 13 jobs (7 percent) under recreational option 1 and option 2, and decrease by 93 jobs (-46 percent) under recreational option 3.

Santa Cruz – Monterey – Morro Bay:

Compared to the 2003-12 baseline period, groundfish ex-vessel revenue would increase by $1.9 million (38 percent) in the Santa Cruz – Monterey – Morro Bay region in 2015.

The change in commercial fisheries–related employment is projected to decrease the average regional unemployment rate under the Alternative (compared with No Action) by 0.004 percent (based on 2012 county statistics).

Combined commercial plus recreational fishery income impacts in the port area under the Alternative are projected to decrease compared with No Action by $2.6 million (-14 percent) under recreational option 1 and option 2, and decrease by $6.2 million (-34 percent) under recreational option 3.

Combined commercial plus recreational fishery employment impacts in the port area under the Alternative are projected to decrease compared with No Action by 31 jobs (-6 percent) under recreational option 1 and option 2, and decrease by 103 jobs (-21 percent) under recreational option 3.

Santa Barbara – Los Angeles – San Diego:

Compared to the 2003-12 baseline period groundfish ex-vessel revenue would increase by $1.5 million (56 percent) in the Santa Barbara – Los Angeles – San Diego region in 2015.

The change in commercial fisheries–related employment is projected to slightly increase the average regional unemployment rate under the Alternative (compared with No Action) (based on 2012 county statistics).

Combined commercial plus recreational fishery income impacts in the port area under the Alternative are projected to decrease compared with No Action by $0.2 million (-0.2 percent) under recreational option 1 and option 2, and decrease by $62 million (-53 percent) under recreational option 3.

Combined commercial plus recreational fishery employment impacts in the port area under the Alternative are projected to decrease compared with No Action by 1 job (-0 percent) under recreational option 1 and option 2, and decrease by 1,198 jobs (-52 percent) under recreational option 3.

Table 4-129. Change in commercial fishery income impacts (from No Action) under the action alternatives by community group ($1,000).

4.3.2.4 Processors

No Action

Under No Action, total purchases of groundfish landings by shoreside processors of $82.6 million are projected. This total includes projected purchases of $28.6 million of whiting, and $54 million in deliveries of combined non-whiting groundfish species. (Note: Average ex-vessel values observed for groundfish deliveries in 2013 are assumed).

The Preferred Alternative

Compared with No Action, under the Preferred Alternative total groundfish purchases by processors are projected to increase by $16 million (19 percent) in 2015 and $18.5 million (22 percent) in 2016. Purchases of whiting are the same as under No Action, while deliveries of combined non-whiting groundfish species increase by 30 percent in 2015 and 34 percent in 2016. These values describe the highest level of non-whiting groundfish and total groundfish purchases among the action alternatives.

Alternative 1

Compared with No Action, under Alternative 1 total groundfish purchases by processors are projected to increase by $8.8 million (11 percent) in 2015 and $11.3 million (14 percent) in 2016. Purchases of whiting are the same as under No Action, while deliveries of combined non-whiting groundfish species increase by 16 percent in 2015 and 21 percent in 2016. These values describe the second highest overall level of non-whiting groundfish and total groundfish purchases among the action alternatives.

Alternative 2

Compared with No Action, under the Alternative 2 total groundfish purchases by processors are projected to decrease by $0.4 million (-1 percent) in 2015 and increase by $1.8 million (2 percent) in 2016. Purchases of whiting are the same as under No Action, while deliveries of combined non-whiting groundfish species decrease by 1 percent in 2015 and increase by 3 percent in 2016. These values describe the lowest overall level of non-whiting groundfish and total groundfish purchases among the action alternatives.

4.3.2.5 Effects on the IFQ Fishery of Alternative ACLs for Widow Rockfish and Pacific Whiting

In addition to the No Action and Preferred ACL alternatives for widow rockfish of 1,500 mt the Council also considered an alternative widow rockfish ACL of 3,000 mt. Results of the 3,000 mt widow rockfish ACL analysis could be applied to any of the action alternatives analyzed above. Widow rockfish are encountered in the Pacific whiting fishery and have also historically been a midwater trawl target species along with yellowtail rockfish. Consequently, in conjunction with the TAC decision that is ultimately adopted for Pacific whiting (in a separate action), the ACL decision for widow rockfish will help determine (1) to what degree the Pacific whiting fisheries, particularly the at-sea catcher-processor and mothership sectors, will be able to harvest their Pacific whiting allocations, and (2) the potential to expand opportunities in the non-whiting midwater trawl fishery for widow and yellowtail rockfish.

Effects of alternative Pacific whiting TACs on the trawl fishery

Table 4-150 shows a range of possible whiting sector allocations derived from an historical analysis of Pacific whiting harvest limits (OY, U.S. TAC) during 2005-2013. Note that during most of this period widow rockfish was being managed under a rebuilding plan. In addition to the 2013 whiting allocation levels assumed in alternatives, four scenarios are shown including the lowest and highest values observed for each whiting sector during the 2005-2013 period, and two additional scenarios, one derived by subtracting 50 percent from the lowest scenario, and another by adding 50 percent to the highest scenario, respectively. These are based on examination of “final” sector allocations during the 2005-2013 period (i.e., after all in-season reallocations) and consequently the potential sector allocations shown do not necessarily adhere to the initial intersector allocation shares of the Pacific whiting commercial harvest guideline specified in the FMP (i.e., at-sea Catcher-Processors 34%, at-sea Motherships 24% and Shorebased IFQ sector 42%; see PFMC 2011). The hypothetical whiting sector allocations shown are used to (1) illustrate associated impacts on whiting sector ex-vessel revenues (i.e., the equivalent of what would be paid to catcher vessel operators upon delivery to the processors), and (2) estimate potential ex-vessel revenue impacts generated by the shoreside midwater trawl fishery for widow and yellowtail rockfish.

Shoreside sector Pacific whiting allocations shown in Table 4-150 under the alternative U.S. TAC scenarios range from 20,369 mt to 147,446 mt. The highest and lowest final allocations for the shoreside sector were 98,297 mt which occurred in 2013 and 40,738 mt in 2009, respectively. By comparison, the allocation assumed for the shoreside sector under the alternatives is 85,697 mt, the original shoreside sector allocation in 2013.

Allocations under the alternative TACs for the whiting mothership sector range from 12,017 mt to 87,131 mt. The highest and lowest final allocations for the sector were 58,087 mt in 2008 and 24,034 mt in 2009, respectively. The allocation assumed for the mothership sector under the alternatives is 48,969 mt, the original mothership sector allocation in 2013.

Allocations under the alternative TACs for the catcher-processor sector range from 17,688 mt to 173,684 mt. The highest and lowest final allocations for the sector were 115,789 mt recorded in 2008 and 35,376 mt in 2009, respectively. By comparison, the allocation for the catcher-processor sector assumed under the alternatives is 69,373 mt, the original catcher-processor sector allocation in 2013.

Table 4-151 shows the potential whiting sector ex-vessel revenues associated with the range of Pacific whiting TAC alternatives shown in Table 4-150. Estimated potential revenues under the alternatives are also shown for comparison. Revenues are projected by assuming all sectors take their entire allocation delivered at average 2013 shoreside ex-vessel prices. Ex-vessel revenues for the catcher-processor sector are imputed to represent the equivalent value for the volume of whiting harvested by catcher-processors.

Table 4-151 shows potential ex-vessel revenues for the three combined, non-Tribal commercial whiting sectors ranging from $13.3 million to $108.6 million, compared with a projected level of $54.3 million under the integrated alternatives. Potential mothership sector revenues under the whiting TAC scenarios are shown to range from $3.2 million to $23.2 million compared with a projected level of $12.8 million under the alternatives. Catcher-processor sector (equivalent) revenues under the whiting TAC scenarios range from $4.7 million to $46.2 million, compared with $18.5 million projected under the alternatives.

Shoreside sector revenues under the whiting TAC scenarios range from $5.4 million to $39.2 million compared with $22.8 million projected under the alternatives. Based on patterns observed in the 2013 fishery, about 44 percent of shoreside whiting ex-vessel revenues is projected to derive from landings delivered to Newport, with Astoria projected to receive about 34 percent, and ports on the Washington coast receiving about 21 percent of total shoreside Pacific whiting sector ex-vessel revenues.

Effects of alternative widow rockfish ACLs on the trawl fishery

As mentioned above, the widow rockfish ACL will partially determine to what extent the shoreside trawl sector is able to conduct a midwater trawl fishery targeting on widow and yellowtail rockfish. Each commercial whiting sector will leverage its available widow rockfish (and the other bycatch species) to maximize Pacific whiting catch up to the sector's allocation. Having assured that the bycatch requirements of the Pacific whiting harvest are satisfied, additional widow rockfish quota available to the shoreside trawl sector will likely be used in the midwater fishery for widow rockfish and yellowtail rockfish.

Table 4-152 shows potential Pacific whiting catch by the three non-Tribal commercial whiting sectors under the different widow rockfish ACL and intersector allocation options and two sets of assumed widow rockfish bycatch rates: (1) the average widow rockfish bycatch rate over 2005-2011 (during which period widow rockfish was being managed under a rebuilding plan), and (2) the maximum annual bycatch rate observed during that period. Unshaded cells in Table 4-152 indicate scenarios where the widow rockfish ACL is not likely to constrain Pacific whiting harvest even under the "Highest plus 50 percent" Pacific whiting TAC option for that sector shown in Table 4-150. Conversely the shaded cells indicate scenarios where under the assumed widow rockfish ACL and bycatch rate the sector may be unable to harvest up to its "Highest plus 50 percent" Pacific whiting TAC option.[57]

A key point to note here is that under the higher assumed widow rockfish bycatch rate, the mothership and catcher-processor sectors may become limited by widow rockfish bycatch under both of the widow rockfish ACL alternatives. However under the average assumed 2005-2011 widow rockfish bycatch rates, no sector appears to be potentially limited by widow rockfish bycatch under either widow rockfish ACL alternative. The difference in bycatch rates observed between the sectors is thought to be primarily due to the different areas and times of year in which the sectors' fisheries usually occur.

Another implication of this analysis is that Table 4-152 indicates the shoreside whiting sector appears not to be limited by widow rockfish bycatch under either widow rockfish ACL alternative. Assuming adequate widow bycatch has been allotted to take the shoreside sector's "Highest plus 50 percent" whiting allocation, Table 4-153 calculates potential maximum harvest and ex-vessel revenue in a directed widow rockfish-yellowtail rockfish fishery under the widow rockfish ACL alternatives. Table 4-153 shows that assuming the average 2001 widow-yellowtail encounter (landing) rate and 2013 ex-vessel

[57] In is important to note that in recent years, largely due to the effectiveness of avoidance measures, widow rockfish bycatch has not imposed a constraint on the ability of the Tribal or non-tribal whiting fisheries to harvest their sector allocations of Pacific whiting.

prices, combined landings of widow plus yellowtail rockfish in a directed fishery may have an ex-vessel value between approximately $1.2 million and $1.6 million under the 1,500 mt widow ACL alternative, and between $3.9 million and $4.3 million under the 3,000 mt widow ACL alternative, depending on the assumed bycatch rate.

By way of comparison, PacFIN landings data show that the widow-yellowtail midwater trawl fishery in 2001 landed approximately 1,700 mt of widow rockfish and 1,500 mt of yellowtail rockfish. At an average ex-vessel price of about $1,000 per metric ton, the total ex-vessel value of these landings was approximately $3.7 million. Landings from that fishery were widely distributed in ports north of 40°10' N. latitude. The greatest share (35 percent) were landed in Astoria, with 15 percent landed in Newport, 15 percent on the Washington coast, 13 percent in Puget Sound ports, 6 percent in Brookings, 6 percent in Eureka, 5 percent in Coos Bay, and 3 percent in Crescent City.

Landings data from the midwater IFQ fishery in more recent years may indicate a much lower widow rockfish encounter rate than was evident in 2001 (Table 3-6). In 2001 the ratio of yellowtail rockfish landings to widow rockfish landings was approximately 0.85:1 (1,471 mt yellowtail to 1,729 mt widow). In 2013 the same ratio in an admittedly much smaller fishery was 1.8:1 (391 mt yellowtail to 214 mt widow). Using the 2013 landings ratio in place of the 2001 statistic implies that potential yellowtail rockfish landings and associated ex-vessel revenue in the midwater fishery may be more than double the amounts shown in Table 4-153.

Table 4-150. Range of potential Pacific whiting allocations by sector based on actual annual 2005-2013 final sector allocations compared with values projected under the alternatives (mt).*

	Shoreside Sector		Mothership Sector		Catcher-Processor Sector		Total implied combined commercial whiting sectors' TAC (mt)
ACL Scenario	**mt**	**year**	**mt**	**year**	**mt**	**year**	
Lowest minus 50%	20,369	-	12,017	-	17,688	-	50,074
Lowest	40,738	(2009)	24,034	(2009)	35,376	(2009)	100,148
Highest	98,297	(2013)	58,087	(2008)	115,789	(2008)	272,173
Highest plus 50%	147,446	-	87,131	-	173,684	-	408,260
2013 (Assumed under the Alternatives)	85,697	(2013)	48,969	(2013)	69,373	(2013)	204,039

* Based on examination of "final" sector allocations each year during the period (i.e., after all in-season reallocations). Note that the potential sector allocations shown do not necessarily adhere to intersector allocation shares in the FMP.

Table 4-151. Potential Pacific whiting sector ex-vessel revenues under the range of Pacific whiting sector allocations compared with values projected under the alternatives ($ million)*

HG Scenario	Shoreside Sector	Mothership Sector	Catcher-Processor Sector	Commercial Whiting Sectors Total
Lowest minus 50%	5.4	3.2	4.7	13.3
Lowest	10.8	6.4	9.4	26.6
Highest	26.2	15.5	30.8	72.4
Highest plus 50%	39.2	23.2	46.2	108.6
2013 Original (Assumed under the Alternatives)	22.8	13.0	18.5	54.3

* Assuming average 2013 shoreside ex-vessel prices and all sectors take their entire allocations.

Ex-vessel revenues for the catcher-processor sector represent the equivalent value of raw whiting harvested.

Table 4-152. Projected potential whiting catch at the average and maximum widow bycatch rates for whiting sectors during 2005-2011.*

Widow ACL Alt. (mt)	Widow Allocation Option	Projected potential whiting catch (mt) at the average widow bycatch rate			Projected potential whiting catch (mt) at the highest widow bycatch rate		
		Shoreside	MS	CP	Shoreside	MS	CP
1,500	No Action	741,282	122,534	356,860	373,244	78,601	171,152
3,000	No Action	1,759,416	122,534	356,860	885,885	78,601	171,152

*Highlighted cells show projected maximum potential whiting catch levels that are lower than the "Highest plus 50%" whiting HG, indicating a potential widow rockfish bycatch constraint under that scenario.

Table 4-153. Potential residual widow and yellowtail rockfish harvest by the shoreside trawl sector after assumed "Highest plus 50%" whiting harvest guideline has been taken.*

Widow ACL Alt. (mt)	Widow Allocation Alternative	Using average 2005-2011 whiting-per-widow bycatch rate			Using maximum 2005-2011 whiting-per-widow bycatch rate		
		Widow mt	Yellowtail mt	Revenue $,000	Widow mt	Yellowtail mt	Revenue $,000
1,500	No Action	796	678	$1,589	601	512	$1,200
3,000	No Action	2,161	1,839	$4,314	1,966	1,673	$3,925

*Note: Assumes average and highest whiting-per-widow bycatch rates observed during 2005-2011, average yellowtail-per-widow landings rates observed in 2001, and 2013 widow and yellowtail rockfish ex-vessel prices.

4.3.2.6 Impacts of alternative ACLs for Dover sole

Under the individual quota program Dover sole has become one of the primary targets of the shorebased trawl fleet. In testimony to the Council, industry representatives have argued that raising the ACL for Dover sole above the No Action level of 25,000 mt would increase vessel QP use caps for the stock and could help attract larger volume retail and food service outlets. The 50,000 mt ACL for Dover sole under the current preferred alternative would result in a commercial fishery harvest guideline of 48,406 mt and an assumed allocation of approximately 45,981 mt to the shorebased IFQ sector.

To the extent markets are able to absorb more Dover sole, a higher ACL may result in greater harvest levels and revenue. However at some point participants may not have sufficient QP for co-occurring target species (thornyheads, sablefish, etc.) and constraining overfished species that are caught with Dover sole, thus limiting harvesters' ability to freely target Dover sole.

From 2003 to 2012 historical catch of Dover sole ranged from a high of 12,475 mt in 2009 to a low of 7,134 mt in 2012. Over the same period the ACL ranged from a high of 25,000 mt in 2011 and 2012 to a low of 7,440 mt at the beginning of the time series. The highest catch level (12,475 mt in 2009) occurred under an ACL of 16,500 mt (Figure 4-32).

Figure 4-33 compares trends over the 2003-2012 time period in ex-vessel prices ($/lb) and ACL attainment (catch/ACL). The figure shows the ACL attainment share fluctuating starting from a very high level when the ACL was relatively low prior to 2007 to attainment levels around 30 percent in 2011 and 2012. It is noteworthy that the lowest attainment levels in the time series occurred under IFQ management, however it is not clear what factors contributed to the recent apparently declining trend in Dover sole catch and ACL attainment since 2009. It may also be noteworthy that current dollar average ex-vessel prices (total revenue / total landings) for Dover sole were the highest for the time series in the most recent years (2011 and 2012), having recovered from their lowest levels recorded during relatively higher harvests in 2009 and 2010. In inflation-adjusted terms, average Dover sole ex-vessel prices have been fairly flat and were slightly lower in 2012 than at the beginning of the time series in 2002.

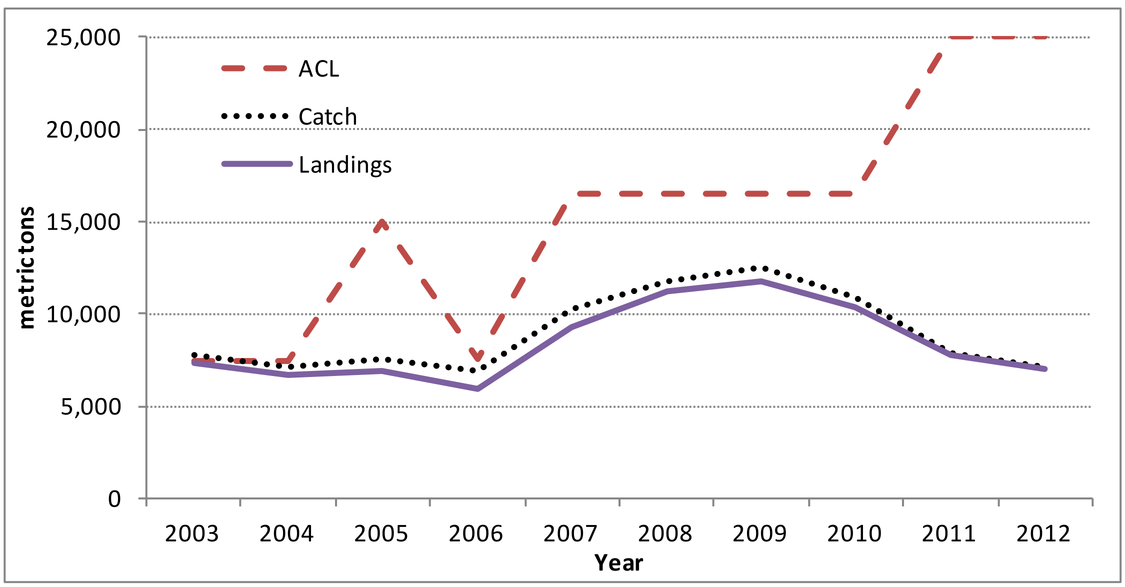

Figure 4-32. ACLs, catch and landings for Dover sole: 2003-2012

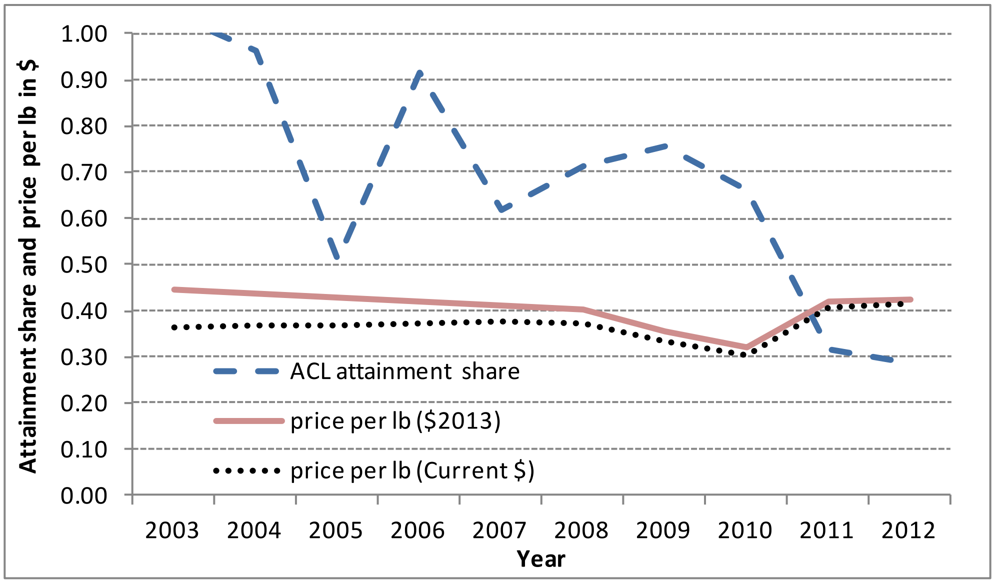

Figure 4-33. Attainment share (catch/ACL) and price per pound in current and inflation-adjusted $2013 for Dover sole: 2003-2012

4.3.2.7 Implications of attainment assumptions for Dover sole and widow rockfish on IFQ sector revenues and community impacts

Revenue and income impacts for IFQ sector fisheries were generally modeled assuming historic average 2011-2013 attainment rates (total QPs debited / sector allocation) would apply under the 2015-16 alternatives. On average during 2011-2013, approximately 35 percent of the IFQ sector allocation of Dover sole and approximately 43 percent of the IFQ sector allocation of widow rockfish were debited as quota ponds caught. Applying these percentages to the IFQ sector allocations under the Preferred Alternative (Dover sole 45,981 mt, and widow rockfish 1,457 mt) resulted in estimated catch of about 15,700 mt of Dover sole and about 600 mt of widow rockfish. In addition, approximately 2,450 mt of yellowtail rockfish are projected to be landed under the preferred alternative by the IFQ sector. Assuming average 2013 ex-vessel prices per mt of $970 for Dover sole, $1,050 for widow rockfish and $1,110 for yellowtail rockfish, these landings would generate ex-vessel values of approximately $15 million for Dover sole, $0.6 million for widow rockfish and $2.7 million for yellowtail rockfish.

However if larger shares of the IFQ sector allocations for these species were able to be caught and landed at the same exvessel price levels, then ex-vessel values would be correspondingly higher. As a polar case, if virtually the entire IFQ sector allocations of 45,981 mt for Dover sole and 1,457 mt for widow rockfish were able to be landed at the average 2013 ex-vessel prices, then ex-vessel revenues of approximately $44 million for Dover sole and $1.5 million for widow rockfish would be realized. Increased landings of widow rockfish in the midwater fishery would also leverage increased landings of yellowtail rockfish. Applying the 2013 landings ratio of 1.8 mt of yellowtail rockfish per mt of widow rockfish implies that the additional 857 mt of widow landings (1,457 - 600) would be accompanied by up to 1,500 mt of additional yellowtail rockfish landings. Valued at the average 2013 ex-vessel price for yellowtail rockfish, these landings would result in an additional $1.7 million in yellowtail rockfish ex-vessel revenue.

Note that these calculations ignore the possible effects of decreased ex-vessel prices with increasing harvests and difficulties associated with catch of other co-occurring species. The likely increases in catch of overfished species and co-occurring target species (other than yellowtail rockfish) are not accounted for in these simple calculations. It is uncertain whether existing allocations of constraining overfished species or target species such as sablefish would be sufficient to allow attainment of the entire IFQ sector allocation of Dover sole, or to what degree harvesters would prioritize using relatively scarce and valuable sablefish quota to leverage increased harvests of Dover sole.

Most of the potential increases in ex-vessel revenue and associated income and employment impacts resulting from increased landings of Dover sole, widow rockfish and yellowtail rockfish ex-vessel would accrue to port areas with involvement in trawl IFQ fisheries. Based on 2013 landings patterns, the three port areas with the highest involvement in the shorebased whiting fishery are Newport (45 percent), Astoria (34 percent) and Washington Coast (Westport: 21 percent). The seven port areas with greatest involvement in non-whiting trawl IFQ fisheries are Astoria (37 percent), Coos Bay (16 percent), Eureka (10 percent), Newport (9 percent), Fort Bragg (8 percent), Brookings (6 percent) and Washington Coast (Westport: 6 percent).

4.3.2.8 New Management Measures for Commercial Fisheries

4.3.2.9 New Management Measures for Recreational Fisheries

4.4 Impacts of 2015-2016 Harvest Specifications and Management Measures on Essential Fish Habitat

4.4.1 Impact Mechanism

Setting harvest specifications does not directly affect essential fish habitat (EFH). Furthermore, an analysis of groundfish trawl logbook data does not reveal any clear relationship between catch limits and fishing effort (see Appendix A). As discussed in Section 3.3.3.3, fishing effort in the shoreside trawl fishery has declined substantially since 2010 while catch generally increased. The effort is likely a function if the introduction of IFQ management and related changes in fishery operations. Section 3.2.3 reports participation trends in groundfish fixed gear and trawl fisheries during the baseline period. Non-nearshore fishery participation has remained relatively stable while nearshore fishery participation has declined. The trend in effective fishing effort is not directly related to participation, but it is unlikely that fishing effort increased during the baseline period, based on information on participation presented in Section 3.2.3 and the analysis of trawl logbook data presented in Section 3.3.3.3. Alternative harvest specifications proposed for the 2015-2016 biennial period are indistinguishable with respect to the effect on EFH. To the degree that the amount and spatio-temporal distribution of gear-specific fishing effort does not change from historical patterns, adverse impacts to EFH from the groundfish fishery are likely to be equivalent to the historical impacts described in Section 3.3, which serves as a proxy for describing the impacts of the No Action Alternative (summarized below).

The proposed action does indirectly mitigate adverse impacts to EFH from fishing through the use of time/area closures. As discussed in Sections 3.3 and 4.4, Groundfish Conservation Areas (GCAs), established as top-down measures to reduce bycatch of overfish species, have an ancillary mitigating impact on the adverse impacts of groundfish fisheries on EFH by prohibiting fishing within these areas.[58] If an area is closed for an extended period of time, the EFH within it may recover from these adverse impacts. Estimates of recovery times for EFH are shown in Table 3-24 by habitat and gear type causing

[58] Other closed areas, principally EFH Conservation Areas, were established with the objective of mitigating such impacts or (in the case of MPAs) addressing a variety of objectives closely related to habitat protection. However, establishing or modifying these areas is not part of the proposed action.

the impact. These range from less than a year to decades. Although the maximum recovery time shown in the table is 56 years (the upper end of the range of recovery times for offshore biogenic habitat impacted by trawl gear), estimates range into centuries for some deepwater coral species.

4.4.2 NMFS Implementation of Council Recommendation on Trawl RCA in 2014

Under the action alternatives the trawl RCA boundaries would be changed to 100 to 150 fathoms year round in the area north of 40°10’ N lat. to 48°10’ N lat. (the RCA south of this latitude already has 100-150 fm boundaries). As discussed in Section 3.3, the Council originally proposed this change in April 2013 as an inseason action. NMFS prepared an environmental assessment (EA) to evaluate the impacts to EFH of this proposal (NMFS 2014b). The Council reviewed a draft of the EA at their September 2013 meeting and reiterated the proposed change. In April 2014 NMFS published a final rule (79 FR 21639) that partially implemented the Council proposal but established the seaward boundary between 40°10’ N lat. and 45°46’ N lat. at 200 fathoms.[59] This configuration thus represents No Action with respect to the trawl RCA. The difference between the No Action Alternative and the action alternatives is therefore only the area between the 150 fm depth contour and 200 fm seaward boundary between 40°10’ N lat. and 45°46’ N lat.

The preamble to the final rule identifies several reasons for the decision not to open the aforementioned portion of the trawl RCA. An overarching reason is that “there is insufficient record to conclude that the seaward boundary modification … minimizes adverse effects on groundfish EFH caused by fishing to the extent practicable.” NMFS notes that the area has been closed to bottom trawling since 2004 and “benethic habitats may have, to some extent, recovered from previous groundfish bottom trawling impacts.” NMFS also cites the Council’s ongoing 5-year review of groundfish EFH identification and related mitigated measures implemented by Amendment 19 to FMP. As part of this process proposals have come to light for new EFH conservation areas within this area. For this reason, NMFS concluded that opening this area would be “premature.” In response to a comment NMFS provides still another reason for keeping this portion of the RCA in place: “…it may have greater conservation value than portions of the actual ‘core’ RCA (between the 100 fm and 150 fm lines…)” which would remain closed under the Council’s proposal.

4.4.3 Summary of the Impact of the Alternatives on Essential Fish Habitat

4.4.3.1 The No Action Alternative

Under No Action the harvest specifications and management measures in place in 2014 would continue in effect, although inseason action could be taken to adjust routine management measures. As noted above, the characterization of the environmental baseline in Section 3.3 is the best available summary of the impact in the future, because there are no models or methodology available to estimate the amount and spatial distribution of fishing effort, and thus effects on EFH, resulting from the proposed action. Using information about the environmental baseline, the following possible effects are noted:

- Based on historical trends, fishing effort in the bottom trawl portion of the shoreside IFQ fishery is not likely to increase. Bottom trawl effort fell substantially with the implementation of IFQ management (see Figure 3-22). Bottom trawl gear has greater adverse impacts to groundfish EFH compared to other gear types.
- A portion of the shoreside IFQ fishery is using fixed gear to catch their IFQ. Fixed gear has less adverse impact on groundfish EFH compared to bottom trawl. Hard substrate (rocky habitat) is

[59] During November through February (bimonthly periods 6 and 1) the modified 200 fathom line is implemented. These modifications allow access to areas where petrale sole are abundant.

more accessible to fixed gear but recovery times are shorter for fixed gear even in comparison to bottom trawl gear for soft substrate, which is generally rated to recover faster from the adverse impacts of fishing.

- In 2014 NMFS partially implemented a Council recommendation to reduce the size of the trawl RCA between 40°10' N lat. and 48°10' N lat. The environmental baseline now includes the trawl activity in these open areas for the remainder of 2014. Under No Action, trawl fishing would continue to be permitted in these areas.

No Action: The current trawl RCA configuration, including the partial implementation of the Council action to open additional area between trawl RCA between 40°10' N lat. and 48°10' N lat.

4.4.3.2 The Preferred Alternative

As discussed in Section 4.4.1, a correlation between the size of target species ACLs and bottom trawl fishing effort estimated from logbook data could not find a correlation. At some of level of magnitude, it is reasonable to conclude that fishing opportunity, dictated overall by ACLs and mediated by sector allocations and related management measures, affects fishing effort. A crude way of representing the difference between Alternative 1 and No Action is the difference between the sum of all the ACLs under each alternative. The sum of Alternative 1 ACLs for 2015 (not including Pacific whiting) is 44,736 mt greater than No Action, a 53% increase. Put another way, out of the 38 stocks for which ACLs are established and a comparison can be made with No Action, 25 show an increase from No Action.[60] However, 25,000 mt of this difference in the ACL is represented by the increase in the Dover sole ACL; as discussed in Section 4.3.2.6, there is not enough historical evidence to demonstrate that this increase would be accompanied by a comparable increase in catch. The sum of the non-whiting ACLs for 2015, 129,060 mt, is larger than summed values for any year during the baseline period when the largest value was 119,371 mt. (It is important to bear in mind that the stock definitions for which individual ACLs are set have changed over time. Thus these sums are not exactly comparable, but at this gross scale the changes in the recent past have probably not by themselves substantially affected fishery behavior.) While no conclusion can be made about how ACLs and resulting fishing opportunity may affect the distribution of fishing effort, it is reasonable to conclude that fishing effort is more likely to increase than to decrease.

Under the Preferred Alternative, the Council reiterates its previous recommendation on changing the trawl RCA boundary. Because of NMFS action in 2014, the effect of this recommendation would be to open the area from 150 fm to 200 fm between 40°10' N lat. and 45°46' N lat. This would have adverse impacts to EFH that had fully recovered from the past effects of bottom trawl in this area.

4.4.3.3 Alternative 1

Under No Action there are 10 stocks where the ACL is set equal to the ABC and a P* value less than 0.45 is used. Under Alternative 1 the P* value used is 0.45 in all cases, indicating a policy change from No Action (however, six of these stocks, have ACLs set for geographic subdivisions of a coastwide value so effectively the P* policy choice only comes into play in seven cases). Otherwise, ACLs are expected to increase in cases where spawning stock abundance is increasing. The sum of the 2015 ACLs under Alternative 1 is 106,733 mt; the main difference from the Preferred Alternative is that the No Action ACL of 25,000 mt would apply under Alternative 1 rather than the Preferred alternative ACL of 50,000 mt.

[60] Because spiny dogfish is removed from the Other Fish complex, which has further changes through the designation of EC species, only 38 out of 40 ACLs for the 2015-2016 biennium can be compared.

The Council recommendation to change the trawl RCA boundary from 150 fm to 200 fm between 40°10' N lat. and 45°46' N lat. would apply under this alternative. With no information demonstrating that a substantial change in fishing effort is likely, and management measures with mitigating effects on the adverse impacts of fishing the same as No Action, it is reasonable to conclude that the impacts of Alternative 1 would not be discernibly different from the effects under No Action.

4.4.3.4 Alternative 2

Under No Action there are 25 stocks where the ACL is set equal to the ABC based on a P* value. Under Alternative 2 the P* value used is 0.25 in all cases, indicating a policy change from No Action (however, six of these stocks, have ACLs set for geographic subdivisions of a coastwide value so effectively the P* policy choice comes into play in 22 cases). . The sum of the 2015 ACLs under Alternative 2 is 82,512 mt, which is 1,814 mt less than the sum of No Action ACLs. At a gross level, this suggests that fishing opportunity, fishing effort, and resulting adverse impacts on EFH is not likely to increase compared to No Action.

The Council recommendation to change the trawl RCA boundary from 150 fm to 200 fm between 40°10' N lat. and 45°46' N lat. would under this alternative. With no information demonstrating that a substantial change in fishing effort is likely, and management measures with mitigating effects on the adverse impacts of fishing the same as No Action, it is reasonable to conclude that the impacts of Alternative 2 would not be discernibly different from the effects under No Action.

4.5 Impacts of 2015-2016 Harvest Specifications and Management Measures on the California Current Ecosystem

As discussed in Section 4.12, Kaplan (2014, reproduced in Appendix A) used the Atlantis California Current Ecosystem Model to evaluate the harvest policies proposed in the Amendment 24 alternatives to simulate and evaluate food web impacts of groundfish fisheries. As discussed by Kaplan, direct and indirect impacts only begin to manifest themselves over the long term (he used a simulation period of 30 years). While the 2015-2016 alternatives are similar are broadly similar to the Amendment 24 Alternatives used to evaluate long-term impacts, they would only be relevant with respect to ecosystem impacts if they were kept in place for a longer time period than 2 years. However, the whole purpose of the biennial process is to adaptively adjust harvest specifications and management measures in light of new information about the status of stocks. The Council may also take into account broader effects, such as indirect and cumulative ecosystem effects when it biennial considers adjustments to harvest specifications and management measures. Starting in 2012, the Council has been receiving annual reports from NOAA's California Current Integrated Ecosystem Assessment Program to support such considerations.

The Atlantis simulation compared groundfish removals to a recent average catch benchmark to evaluate a broad range of potential harvest policies encompassing the alternatives considered in this EIS. Only at very high catch levels relative to historic catch would substantial indirect (food web) effects be manifested.[61] However, within the Atlantis model these harvest levels led to substantial depletion of groundfish stocks. The policy framework and biennial process allows continual adjustment in reaction to new information. It is highly likely that if the 2015-2016 harvest specifications were found to contribute to an increasing depletion trend for a stock harvest policies would be changed in response during a subsequent biennial period.

[61] It is important to keep in mind that the evaluation is relative to baseline conditions. Section 3.2.3 reviews another Atlantis simulation (Kaplan, *et al.* 2012) that evaluated food web effects of fisheries relative to an unfished state.

For information on the impacts to the CCE of setting harvest specifications see Section 4.12.

4.6 Impacts of 2015-2016 Harvest Specifications and Management Measures on Protected Species

Setting harvest specifications does not directly affect protected species. Furthermore, an analysis of groundfish trawl logbook data does not reveal any clear relationship between catch limits and fishing effort (see Appendix A). As discussed in Section 3.3.3.3, fishing effort in the shoreside trawl fishery has declined substantially since 2010 while catch generally increased. Equivalent information is unavailable for fixed gear fisheries. Section 3.2.3 reports participation trends in groundfish fixed gear and trawl fisheries during the baseline period. Non-nearshore fishery participation has remained relatively stable while nearshore fishery participation has declined. The trend in effective fishing effort is not directly related to participation, but it is unlikely that fishing effort increased during the baseline period. Alternative harvest specifications proposed for the 2015-2016 biennial period are indistinguishable with respect to the effect on protected species. To the degree that the amount and spatio-temporal distribution of gear-specific fishing effort does not change from historical patterns, adverse impacts to protected species from the groundfish fishery are likely to be equivalent to the historical impacts described in Section 3.5, which serves as a proxy for describing the impacts of the No Action Alternative.

NMFS has prepared Incidental Take Statements for species listed under the ESA taken in groundfish fisheries. A Biological Opinion for salmonids was prepared in 1999 and supplemented in 2006. Based on these Opinions the expected level of take the Pacific whiting fishery is 11,000 Chinook salmon per year and 9,000 Chinook salmon in the bottom trawl fishery (NMFS 2006). Bycatch of other salmonid species is modest so no specified threshold was established for any other salmonid.

A Biological Opinion for take of other listed species by the groundfish fishery was prepared in 2012 (NMFS 2012a). NMFS PRD initially found that of the listed species occurring in the ESA action area, the continued operation of the groundfish fishery could adversely impact the eulachon southern DPS, southern DPS of green sturgeon, humpback whales, Stellar sea lions, and leatherback sea turtles. The eastern Stellar sea lion DPS was subsequently delisted. Section 3.5.2.2 describes the ITS from this Biological Opinion. At this time there is no information to indicate the fishery has changed in a way such that these ITS levels are likely to be exceeded during the next biennial period. Under the terms and conditions in the BO NMFS established a Pacific Coast Groundfish and Endangered Species Workgroup (PCGW) in cooperation with the USFWS and the Council. The PCGW held its second meeting in February 2014. If new information shows that the levels specified in the ITS have been exceeded NMFS will reinitiate consultation and develop any necessary mitigation measures through that process.

The USFWS initiated a Section 7 consultation with NMFS for species in its area of responsibility. USFWS concurred with NMFS's conclusion (NMFS 2012b) that operation of the Pacific Coast groundfish fishery is not likely to adversely affect marbled murrelet, California least tern, southern sea otter, bull trout or bull trout critical habitat. T herefore, the Section 7 consultation and Biological Opinion focused on the effects of the fishery on short-tailed albatross. Prior to the conclusion of the consultation the Council was notified that USFWS would include in the terms and conditions that NMFS establish regulations requiring the use of streamer lines on commercial groundfish longline vessels 55 feet in length or greater. The current biological opinion (USFWS 2012) was published on November 21, 2012. In November 2013, the Council took final action to recommend a regulatory package to implement the streamer line requirement (USFWS 2012). The final rule implementing these requirements is pending.

Section 3.5.3 summarizes available information on marine mammals protected by the MMPA but not listed under the ESA. Estimates of total human-caused serious injury / mortality are below the PBR for all these stocks (Carretta, *et al.* 2013). The West Coast Groundfish Observer Program reports observed interactions with marine mammals (Jannot, *et al.* 2011). These data suggest that mortality of non-ESA listed marine mammal stocks occurring in the fishery management area caused by the operation of the Pacific Coast groundfish fishery will not prevent these stocks from reaching their optimum sustainable population level. There is no information to indicate that continued operation of the fishery in the 2015-2016 biennial period will lead to an increase in serious injury / mortality of non-ESA-listed marine mammals.

Section 3.5.4 reviews information on impacts of the groundfish fishery on seabirds not listed under the ESA. Of the species observed taken in the groundfish fishery (Jannot, *et al.* 2011) the black-footed albatross is listed as Vulnerable on the IUCN Red List and the sooty shearwater is listed as Vulnerable and the northern fulmar is listed as Near Threatened (note that these are global assessments and regional population status may differ). As shown in Table 3-36, groundfish fisheries are estimated to take a maximum of 93.5 black-footed albatrosses annually and 1.7 northern fulmars. There is no information to indicate that continued operation of the fishery in the 2015-2016 biennial period will lead to an increase in the take of non-ESA-listed seabirds.

4.6.1 Summary of the Impacts of the Alternatives

No Action Alternative: There is no information to conclude that protected species takes will differ substantially from the average level of takes during the baseline period. A substantial increase in the level of take would trigger action under applicable law to mitigate any increased take, if necessary.

Preferred Alternative: There is no information to conclude that protected species takes will differ substantially from the average level of takes during the baseline period. A substantial increase in the level of take would trigger action under applicable law to mitigate any increased take, if necessary.

Alternative 1: There is no information to conclude that protected species takes will differ substantially from the average level of takes during the baseline period. A substantial increase in the level of take would trigger action under applicable law to mitigate any increased take, if necessary.

Alternative 2: There is no information to conclude that protected species takes will differ substantially from the average level of takes during the baseline period. A substantial increase in the level of take would trigger action under applicable law to mitigate any increased take, if necessary.

4.7 Impacts of 2015-2016 Harvest Specifications and Management Measures on Non-groundfish

Section 3.6 describes non-groundfish species caught in groundfish fisheries based on WCGOP estimates (Bellman, *et al.* 2013). Non-groundfish catch in groundfish sectors varies between 1.2% and 5.0% during the baseline period. There is no correlation between total catch and non-groundfish catch for these years. Therefore, there it is not possible to predict how non-groundfish catch will vary among the alternatives. It is reasonable to conclude that across all the alternatives non-groundfish catch would be in the historical range. Tribal shoreside and at-sea whiting sectors accounted for 38% of non-groundfish catch. Management measures for these sectors are not directly established as part of the proposed action. Instead, the Federal government, through the Council process, reaches an agreement on the level of catch that will occur in the tribes' usual and accustomed fishing grounds. Non-groundfish catch declined in the shorebased IFQ/trawl sector, which account for the largest proportion of non-groundfish catch in commercial sectors at 28%, over the baseline period from 7.7% (2,240 mt) in 2003 to 3.4% (809 mt) in 2011. The drop in 2011 could be an ancillary effect of trawl rationalization if changes in fishing strategies has an indirect effect on non-groundfish catch. Gear switching could be a factor, because fixed gear fisheries have lower bycatch of non-groundfish. The shorebased IFQ sector is subject to IBQ for Pacific halibut, which is effective in controlling bycatch mortality of this commercially important species

4.7.1 Summary of the Impacts of the Alternatives

No Action Alternative: There is no information to conclude that non-groundfish catch will differ substantially from the average level during the baseline period. Fishery monitoring allows any such change to be detected. Over the long-term, if continuing catch of a non-groundfish species in the groundfish fishery triggered a conservation concern appropriate mitigation measures could be implemented through other Federal/state authorities or pursuant to the Groundfish FMP.

Preferred Alternative: There is no information to conclude that non-groundfish catch will differ substantially from the average level during the baseline period. Fishery monitoring allows any such change to be detected. Over the long-term, if continuing catch of a non-groundfish species in the groundfish fishery triggered a conservation concern appropriate mitigation measures could be implemented through other Federal/state authorities or pursuant to the Groundfish FMP.

Alternative 1: There is no information to conclude that non-groundfish catch will differ substantially from the average level during the baseline period. Fishery monitoring allows any such change to be detected. Over the long-term, if continuing catch of a non-groundfish species in the groundfish fishery triggered a conservation concern appropriate mitigation measures could be implemented through other Federal/state authorities or pursuant to the Groundfish FMP.

Alternative 2: There is no information to conclude that non-groundfish catch will differ substantially from the average level during the baseline period. Fishery monitoring allows any such change to be detected. Over the long-term, if continuing catch of a non-groundfish species in the groundfish fishery triggered a conservation concern appropriate mitigation measures could be implemented through other Federal/state authorities or pursuant to the Groundfish FMP.

4.8 Biological Impacts of Alternative Long Term Biennial Harvest Specifications on Groundfish Stocks

This section evaluates the predicted biological impacts of alternative long term harvest specifications on a select list of groundfish stocks. The focus of this section are on those overfished stocks currently managed under rebuilding plans, the economically most important target stocks that are the backbone of the current fishery, and those stocks and stock complexes that were historically important targets of the west coast groundfish fishery. This evaluation notes the projected depletion trends under the range of scenarios modeled. The results of this analysis are presented by taxon and, for rockfish, further stratified by depth strata (i.e., nearshore, shelf, and slope).

The long term analysis in this EIS used projections of spawning stock depletion, spawning stock biomass, and total biomass of key assessed groundfish stocks through 2024 under a wide range of catch streams or harvest control rules, as well as across the states of nature that captured the key axes of uncertainty in stock assessments. An important caveat in the analysis is that the base case state of nature in these projections is the most probable. The Terms of Reference for stock assessments directs the states of nature modeled in assessment decision tables be developed as stochastically as possible with the base case state of nature being the median or most probable case (i.e., 50% likelihood) and the low and high states of nature bracketing the base case having half the probability (i.e., 25% likelihood) as the base case. In all cases, the highest catch stream modeled is the harvest control rule of ACL = ABC under a P* of 0.45; the highest catch streams are from the high state of nature models under this harvest control rule. The lowest catch streams, depending on the stock, are modeled using either the harvest control rule ACL =

ABC under a P* of 0.25, the 2014 ACL scenario, or under the "recent year average catch" scenario. The lowest catch streams are from the low state of nature models under one of these harvest control rule scenarios.

The states of nature developed in groundfish stock assessments can best be thought of as bracketing the key axes of uncertainty that affect stock productivity. Stock assessments vary by how many of the key population dynamics parameters are estimated. The more parameters that are estimated, the more the true uncertainty in the assessment is characterized. However, no assessments attempt to estimate all parameters that describe stock dynamics. For example, those assessments that are done in Stock Synthesis (the assessment platform used for the majority of current groundfish stock assessments) will often try to estimate steepness of the stock-recruitment function (h) or the instantaneous rate of natural mortality (M), but seldom both parameters. Both h and M are measures of relative stock productivity (high h and high M are indicators of strong stock productivity) and their estimates are confounded (that is, assumptions or priors used to estimate one of these parameters will affect the estimate of the other). Therefore, when one of these parameters is freely estimated, the other is usually assumed and fixed in the assessment. In this case, the fixed parameter is usually what is varied to determine the states of nature in the assessment. The high state of nature is therefore indicative of an "optimistic" assumption that affects high stock productivity and the low state of nature indicates a more "pessimistic" lower productivity assumption.

It is important to note that all biomass projections are deterministic in that future recruitment and total removals (i.e., total catch), as well as the fixed parameters in the assessment, are assumed. Decision tables in assessments that show variable future catch streams by state of nature also explore the implications of using a catch stream that is projected to be sustainable for the base case model (i.e., future biomass is projected to remain above B_{MSY}) for the other states of nature to address the question, "what is predicted to happen if the alternative state of nature is the actual one for the stock?". However, the purpose of this analysis is to probe a broader range of biomasses and catches for select groundfish stocks to better posit how these outcomes affect the stocks and the fishery. The highest and lowest biomasses and catches in this analysis are highly unlikely and any case where all these stocks are in equilibrium at these high or low biomasses is implausible.

Since the main objective of this long term impact analysis is to specifically discuss impacts at the extremes of plausibility (i.e., analyzing the highest and lowest catch streams using the high and low states of nature models), this analysis does not map directly to the 2015-2016 alternatives analyzed in this EIS. However, when linking this long term impact analysis with the 2015-2016 alternatives analyzed in this EIS, the base case model is always assumed since that is the most probable assessment model. In all cases, Alternative 1 is the ACL = ABC using a P* of 0.45 and Alternative 2 is the ACL = ABC using a P* of 0.25 (in both cases the appropriate precautionary reduction to the ACL, either the 40-10 or the 25-5 rule, is made when the stock is projected to be below the B_{MSY} target). The No Action Alternative is the 2014 ACL and the Preferred Alternative varies by stock.

4.8.1 Long Term Impacts of Assessed Flatfish Species

Of all the assessed flatfish species, only the projections for rex sole were not available in time for this analysis.

The proxy biomass reference points that direct management of assessed flatfish species are a target biomass (B_{MSY}) depletion ratio of 0.25 (depletions at or above this threshold indicate a healthy stock) and a Minimum Stock Size Threshold (MSST) of 0.125 (depletions below this threshold indicate an overfished stock). Depletions between the B_{MSY} threshold and the MSST indicate stocks in the precautionary zone. The default ACL harvest control rule for flatfish in the precautionary zone is to implement the “25-5” rule which is a reduction in the ACL from the ABC (see (PFMC 2014) for more details).

Most of the flatfish species are not caught at levels commensurate with high attainment of ACLs, with the exception of petrale sole, which is an important trawl target. Therefore, the high catch streams for these species under even the base case models are unlikely. Flatfish species managed in the FMP are mostly trawl-dominant (i.e., on average, 90% or more of the catch occurs in the trawl fishery), with the exception of Pacific sanddabs and starry flounder, which are a significant species in trawl and recreational fisheries. Given the dominance of flatfish as a trawl species, catch monitoring uncertainty is low. Therefore, there is very low risk of depleting flatfish stocks through overfishing.

4.8.1.1 Arrowtooth Flounder

The modeled catch scenarios for arrowtooth flounder range from 3,088 mt per year based on the recent year average catches to an annual average catch in 2015-2024 of 37,915 mt based on the ACL = ABC with a P* of 0.45 catch scenario under the high state of nature (Table 4-154). Projected arrowtooth depletions under all states of nature are sustainable assuming the respective states of nature, except maintaining the 2014 ACL under the low state of nature is projected to drive depletion just below B_{MSY} by the end of the projection period (Figure 4-34, Figure 4-35, and Figure 4-36). All the 2015-2016 alternatives are sustainable under the base case model (Figure 4-34).

Table 4-154. Predicted average annual catches (mt) in 2015-2024 by state of nature and catch scenario for arrowtooth flounder.

State of Nature	Catch Scenario	2015-24 Average Annual Catch
Base	2014 ACL (No Action Alt.)	5,758
	ABC Removals (P* = 0.25; Alt. 2)	6,364
	ABC Removals (P* = 0.4; Pref. Alt.)	7,125
	ABC Removals (P* = 0.45; Alt. 1)	7,307
	Recent Year Average Total Catch Removals	3,088
High	2014 ACL	5,758
	ABC Removals (P* = 0.25)	33,968
	ABC Removals (P* = 0.4)	37,184
	ABC Removals (P* = 0.45)	37,915
	Recent Year Average Total Catch Removals	3,088
Low	2014 ACL	5,758
	ABC Removals (P* = 0.25)	4,001
	ABC Removals (P* = 0.4)	4,624
	ABC Removals (P* = 0.45)	4,789
	Recent Year Average Total Catch Removals	3,088

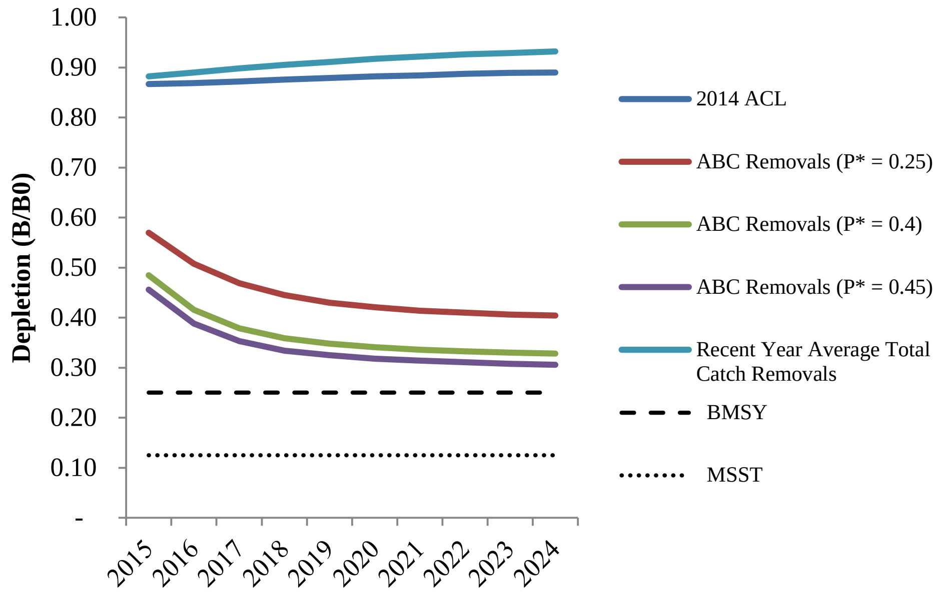

Figure 4-35. Projected depletion under alternative catch streams under the high state of nature model for arrowtooth flounder.

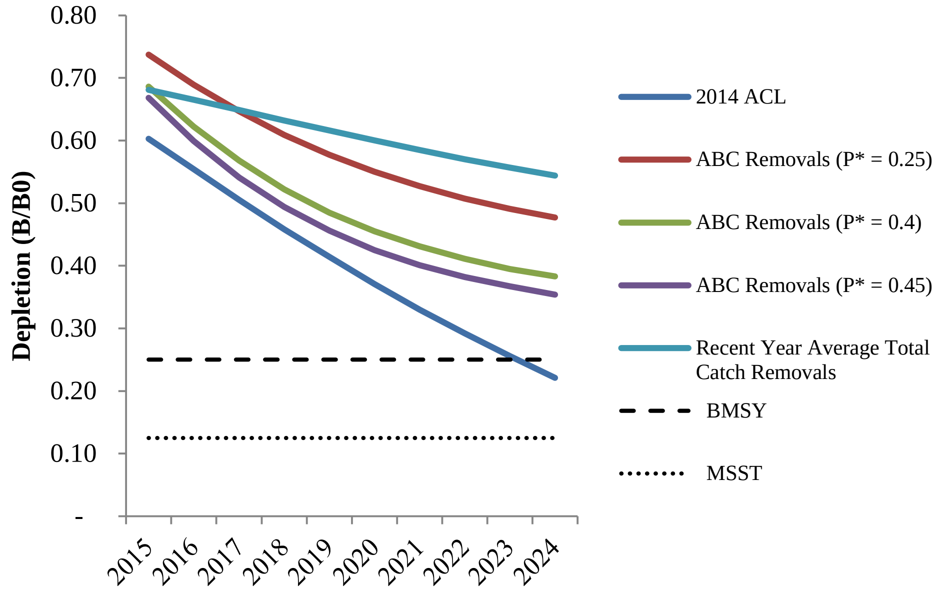

Figure 4-36. Projected depletion under alternative catch streams under the low state of nature model for arrowtooth flounder.

4.8.1.2 Dover Sole

The modeled catch scenarios for Dover sole range from 7,551 mt per year based on the recent year average catches to an annual average catch in 2015-2024 of 91,249 mt based on the ACL = ABC with a P* of 0.45 catch scenario under the high state of nature (Table 4-155). Projected Dover sole depletions under all states of nature are sustainable assuming the respective states of nature (Figure 4-37, Figure 4-38, and Figure 4-39). While the preferred Dover sole alternative of a 50,000 mt constant catch has not been projected or modeled in this long term analysis, the total removals and biomass trajectory assuming full attainment of the ACL in the next ten years is very similar to the Alternative 2 scenario (ABC Removals using a P* of 0.25) under the base case model in Figure 4-37.

Table 4-155. Predicted average annual catches (mt) in 2015-2024 by state of nature and catch scenario for Dover sole.

State of Nature	Catch Scenario	2015-24 Average Annual Catch
Base	2014 ACL (No Action Alt.)	25,000
	ABC Removals (P* = 0.25; Alt. 2)	50,630
	ABC Removals (P* = 0.45; Alt. 1)	56,611
	Recent Year Average Total Catch Removals	7,551
High	2014 ACL	25,000
	ABC Removals (P* = 0.25)	81,641
	ABC Removals (P* = 0.45)	91,249
	Recent Year Average Total Catch Removals	7,551
Low	2014 ACL	25,000
	ABC Removals (P* = 0.25)	34,880

	ABC Removals (P* = 0.45) Recent Year Average Total Catch Removals	39,069 7,551

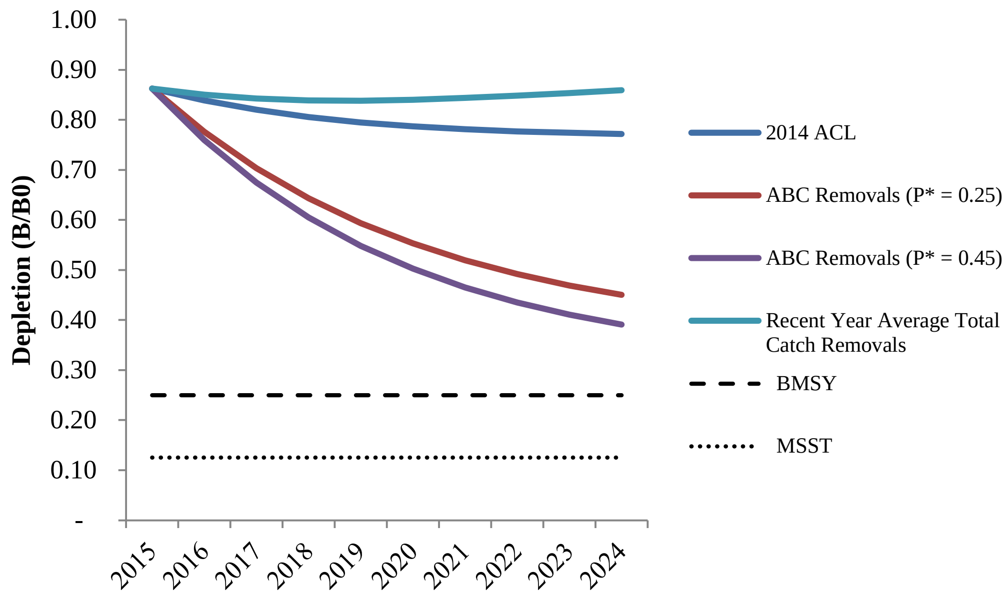

Figure 4-38. Projected depletion under alternative catch streams under the high state of nature model for Dover sole.

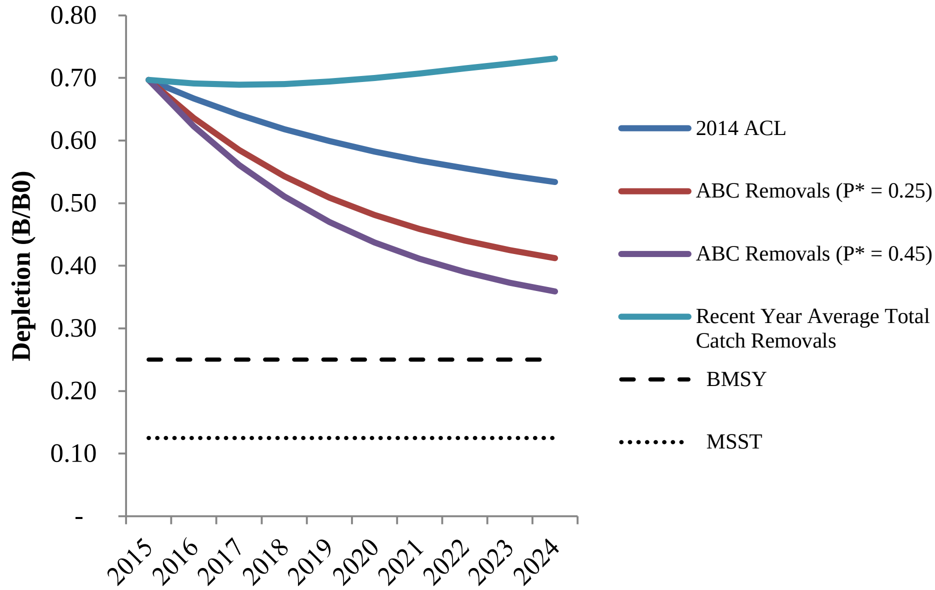

Figure 4-39. Projected depletion under alternative catch streams under the low state of nature model for Dover sole.

4.8.1.3 English Sole

The modeled catch scenarios for English sole range from 207 mt per year based on the recent year average catches to an annual average catch in 2015-2024 of 7,461 mt based on the ACL = ABC with a P* of 0.45 catch scenario under the high state of nature (Table 4-156). Projected English sole depletions under all catch scenarios and states of nature are predicted to be sustainable, except maintaining the 2014 ACL is predicted to drive the stock down below the B_{MSY} target into the precautionary zone under the base case and low state of nature models (Figure 4-40, Figure 4-41, and Figure 4-42).

Table 4-156. Predicted average annual catches (mt) in 2015-2024 by state of nature and catch scenario for English sole.

State of Nature	Catch Scenario	2015-24 Average Annual Catch
Base	2014 ACL (No Action Alt.)	5,645
	ABC Removals (P* = 0.25; Alt. 2)	4,423
	ABC Removals (P* = 0.45; Alt. 1; Pref. Alt.)	5,479
	Recent Year Average Total Catch Removals	207
High	2014 ACL	5,645
	ABC Removals (P* = 0.25)	6,011
	ABC Removals (P* = 0.45)	7,461
	Recent Year Average Total Catch Removals	207
Low	2014 ACL	5,645
	ABC Removals (P* = 0.25)	3,585

	ABC Removals (P* = 0.45) Recent Year Average Total Catch Removals	4,447 207

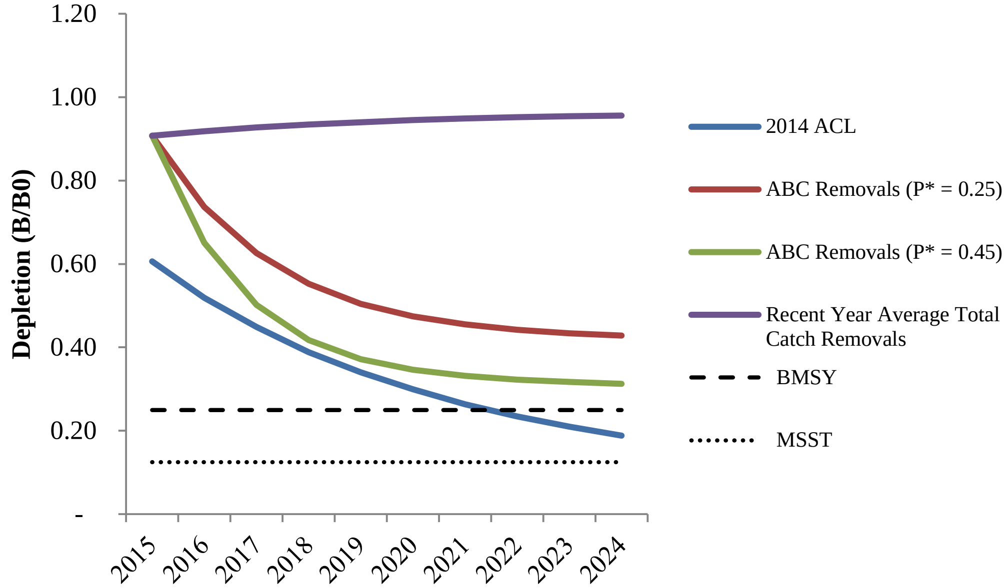

Figure 4-40. Projected depletion under alternative catch streams under the base case state of nature model for English sole.

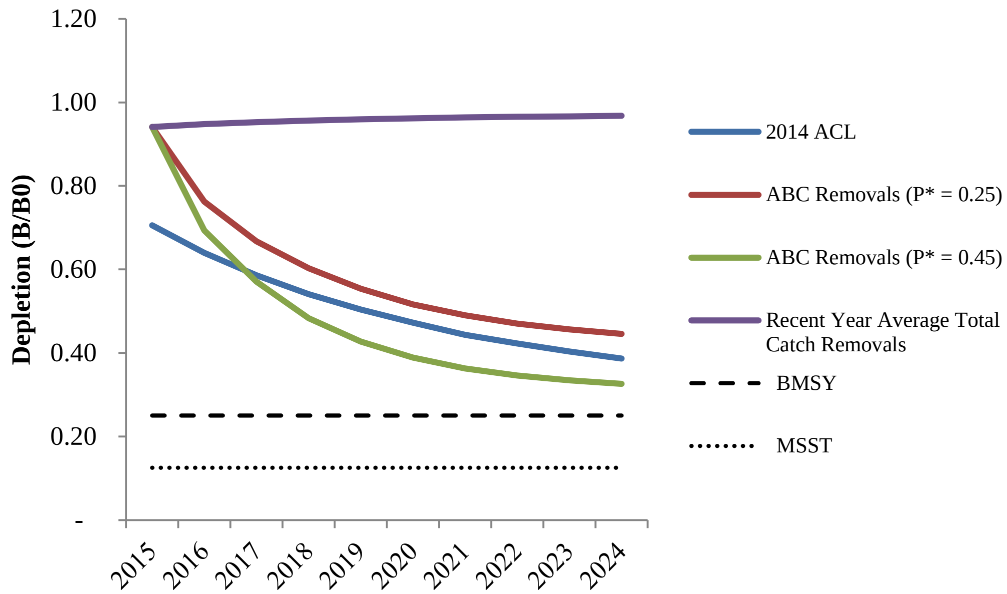

Figure 4-41. Projected depletion under alternative catch streams under the high state of nature model for English sole.

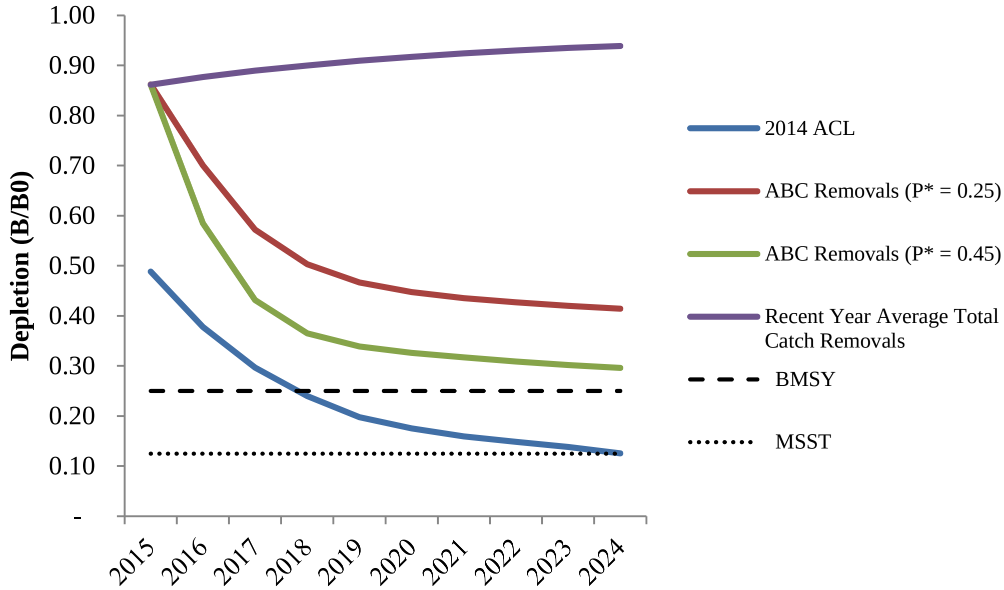

Figure 4-42. Projected depletion under alternative catch streams under the low state of nature model for English sole.

4.8.1.4 Petrale Sole

The modeled catch scenarios for petrale sole range from 939 mt per year based on the recent year average catches to an annual average catch in 2015-2024 of 3,170 mt based on the ACL = ABC with a P* of 0.45 catch scenario under the high state of nature (Table 4-157). Projected petrale sole depletions under all states of nature are sustainable assuming the respective states of nature, except the stock is estimated to be less than the target B_{MSY} depletion level in the beginning of the projection period under the base case and low state of nature models (Figure 4-43, Figure 4-44, and Figure 4-45).

Table 4-157. Predicted average annual catches (mt) in 2015-2024 by state of nature and catch scenario for petrale sole.

State of Nature	Catch Scenario	2015-24 Average Annual Catch
Base	2014 ACL (No Action Alt.)	2,652
	ABC Removals (P* = 0.25; Alt. 2)	2,522
	ABC Removals (P* = 0.45; Alt. 1; Pref. Alt.)	2,771
	Recent Year Average Total Catch Removals	939
High	2014 ACL	2,652
	ABC Removals (P* = 0.25)	2,919
	ABC Removals (P* = 0.45)	3,170
	Recent Year Average Total Catch Removals	939
Low	2014 ACL	2,652
	ABC Removals (P* = 0.25)	2,191
	ABC Removals (P* = 0.45)	2,439
	Recent Year Average Total Catch Removals	939

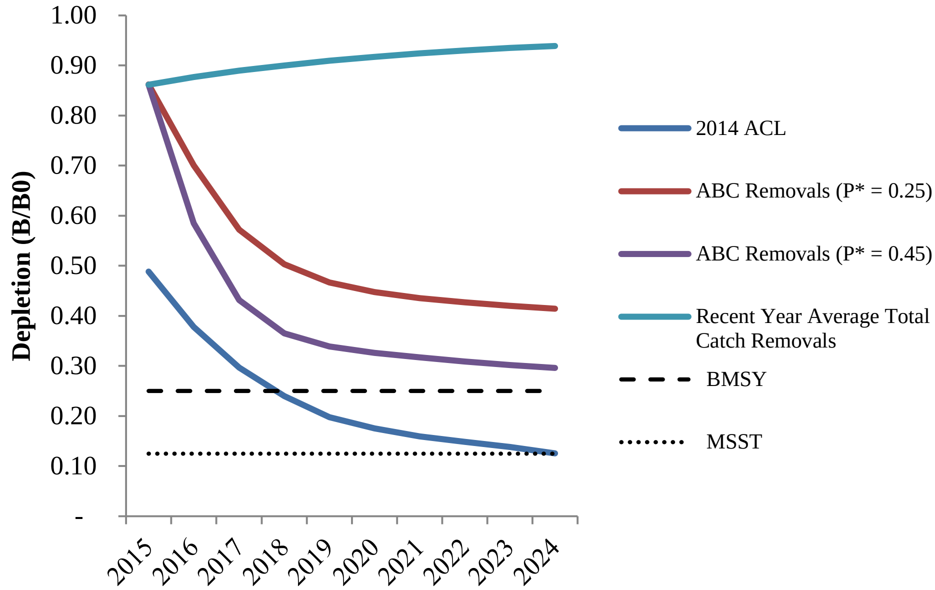

Figure 4-45. Projected depletion under alternative catch streams under the low state of nature model for petrale sole.

4.8.2 Long Term Impacts of Assessed Nearshore Rockfish Species

Of the assessed nearshore rockfish species, long term projections were not provided in time for brown, China, and copper rockfish nor for California scorpionfish. Nearshore rockfish are dominant in the non-trawl fisheries (both commercial and recreational) and therefore have a higher catch monitoring uncertainty than trawl-dominant species. The assessments are also generally more uncertain since there are no fishery-independent indices of abundance (i.e., no nearshore surveys) informing abundance trends. Most nearshore rockfish assessments rely on fishery CPUE indices and the fisheries compositional data (i.e., age and length data from sampled fisheries) to inform stock status and dynamics. Therefore, there is considerably more uncertainty in the long term projections for nearshore rockfish than for the other species analyzed in this EIS.

4.8.2.1 Black Rockfish in California and Oregon

The modeled catch scenarios for southern black rockfish off California and Oregon range from 554 mt per year based on the recent year average catches to an annual average catch in 2015-2024 of 2,032 mt based on the ACL = ABC with a P* of 0.45 catch scenario under the high state of nature (Table 4-158). Projected southern black rockfish depletions under all states of nature are sustainable assuming the respective states of nature (Figure 4-46, Figure 4-47, and Figure 4-48). Note the default harvest control rule of 1,000 mt/year cannot be accommodated under the low state of nature due to a lack of exploitable biomass at that level of harvest (Table 4-158 and Figure 4-48).

Table 4-158. Predicted average annual catches (mt) in 2015-2024 by state of nature and catch scenario for black rockfish in California and Oregon.

State of Nature	Catch Scenario	2015-24 Average Annual Catch
Base	ABC Removals (P* = 0.25; Alt. 2)	1,044
	ABC Removals (P* = 0.45; Alt. 1)	1,220
	ACL Removals (1,000 mt constant catch; No Action Alt.; Pref. Alt.)	1,000
	Recent Year Average Total Catch Removals	554
High	ABC Removals (P* = 0.25)	1,739
	ABC Removals (P* = 0.45)	2,032
	ACL Removals (1,000 mt constant catch)	1,000
	Recent Year Average Total Catch Removals	554
Low	ABC Removals (P* = 0.25)	715
	ABC Removals (P* = 0.45)	836
	Recent Year Average Total Catch Removals	554

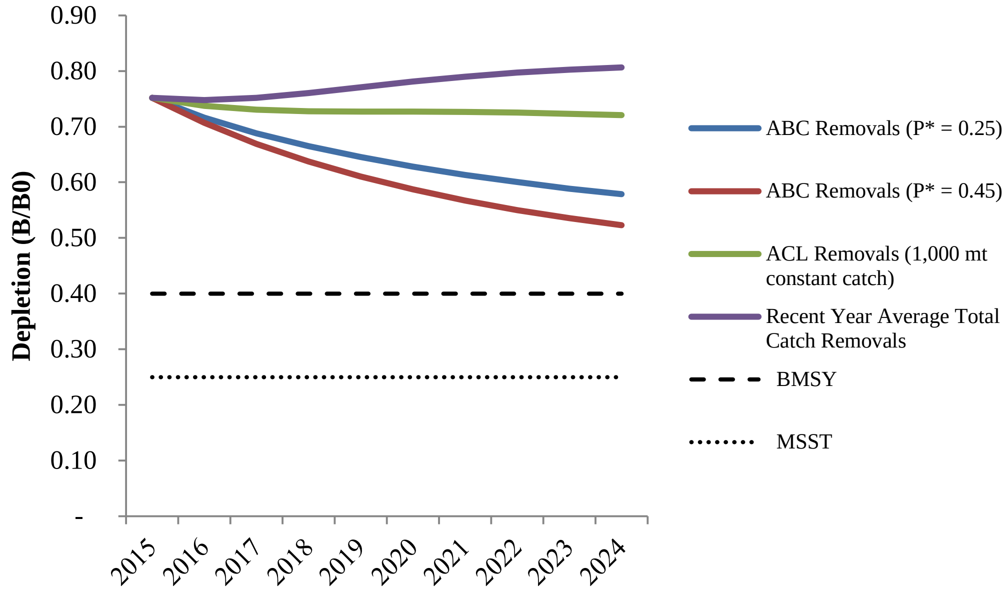

Figure 4-47. Projected depletion under alternative catch streams under the high state of nature model for black rockfish in California and Oregon.

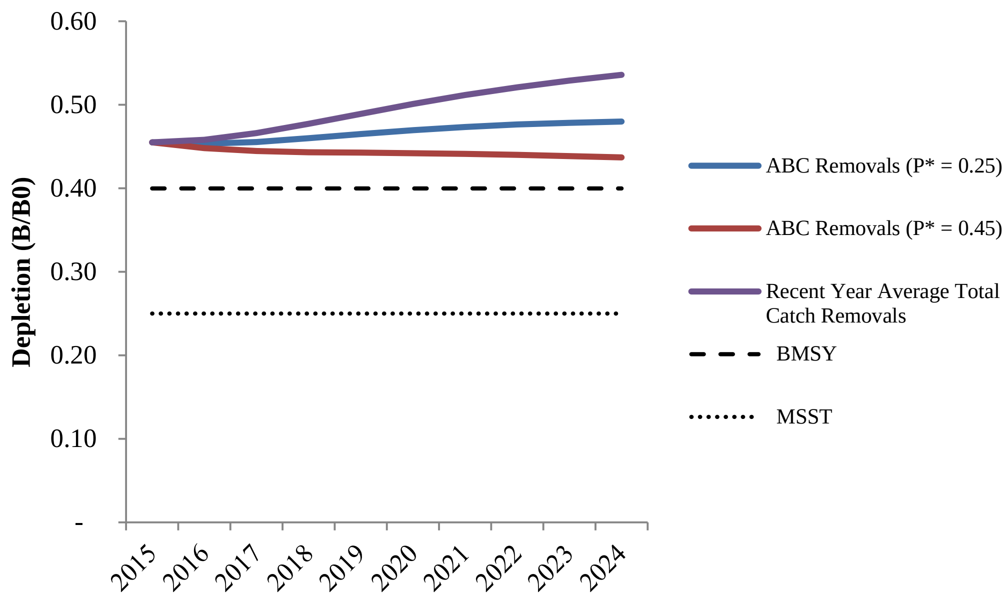

Figure 4-48. Projected depletion under alternative catch streams under the low state of nature model for black rockfish in California and Oregon.

4.8.2.2 Black Rockfish in Washington

The modeled catch scenarios for northern black rockfish off Washington range from 134 mt per year based on the ACL = ABC with a P* of 0.25 catch scenario under the low state of nature to an annual average catch in 2015-2024 of 592 mt based on the ACL = ABC with a P* of 0.45 catch scenario under the high state of nature (Table 4-159). Projected northern black rockfish depletions under the base case and high states of nature are sustainable assuming the respective states of nature (Figure 4-49 and Figure 4-50). All of these catch scenarios are under the B_{MSY} target under the low state of nature (Figure 4-51). The stock is estimated to be currently overfished under the low state of nature but projected to increase in abundance under all the catch scenarios except the constant catch of the 2014 ACL, which drives the stock to a lower abundance during the projection period (Figure 4-51).

Table 4-159. Predicted average annual catches (mt) in 2015-2024 by state of nature and catch scenario for black rockfish in Washington.

State of Nature	Catch Scenario	2015-24 Average Annual Catch
Base	2014 ACL (No Action Alt.)	409
	ABC Removals (P* = 0.25; Alt. 2)	325
	ABC Removals (P* = 0.45; Alt. 1; Pref. Alt.)	381
	ACL Removals (40-10 rule)	395
	Recent Year Average Total Catch Removals	219
High	2014 ACL	409
	ABC Removals (P* = 0.25)	488

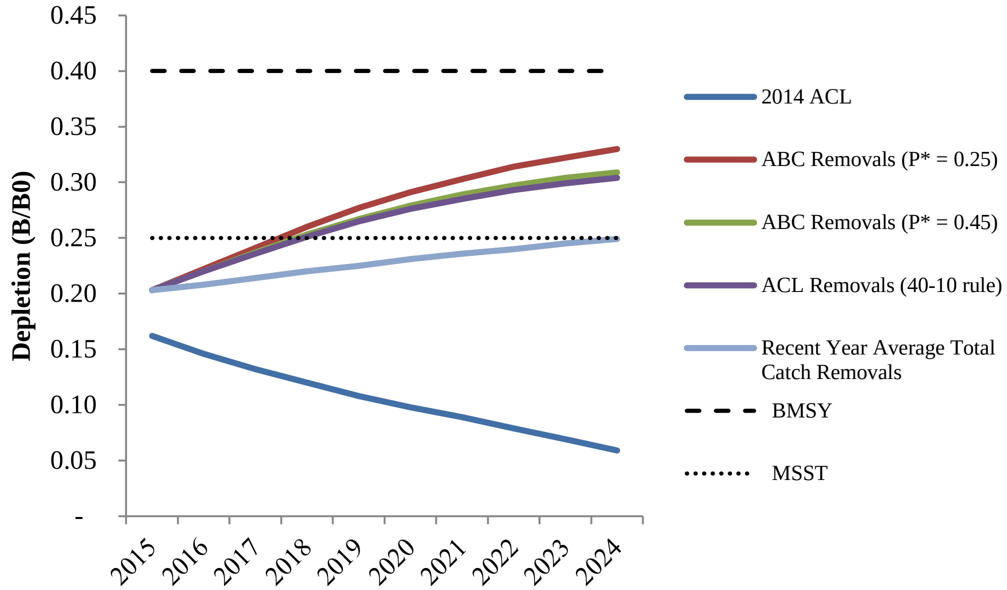

Figure 4-51. Projected depletion under alternative catch streams under the low state of nature model for black rockfish in Washington.

4.8.2.3 Gopher Rockfish South of 40º10' N lat.

The average annual catch of gopher rockfish in 2015-2024 varies between 77 mt (the ABC removals using a P* of 0.25 for the low state of nature) to 229 mt (the 2014 ACL) (Table 4-160). The 2014 gopher ACL contribution projected forward is not predicted to be sustainable under any of the states of nature and is predicted to drive the stock to an overfished condition under the base case and low state of nature models (Figure 4-52, Figure 4-53, and Figure 4-54). However, all the other catch scenarios are predicted to be sustainable under all the states of nature. The most likely projection is the recent year average total catch removals under the base case since access to gopher rockfish will likely be constrained by limits imposed on the entire Southern Nearshore Rockfish complex.

Table 4-160. Predicted average annual catches (mt) in 2015-2024 by state of nature and catch scenario for gopher rockfish south of 40º10' N lat.

State of Nature	Catch Scenario	2015-24 Average Annual Catch
Base	2014 ACL (No Action Alt.)	229
	ABC Removals (P* = 0.25; Alt. 2)	139
	ABC Removals (P* = 0.45; Alt. 1; Pref. Alt.)	156
	Recent Year Average Total Catch Removals	81

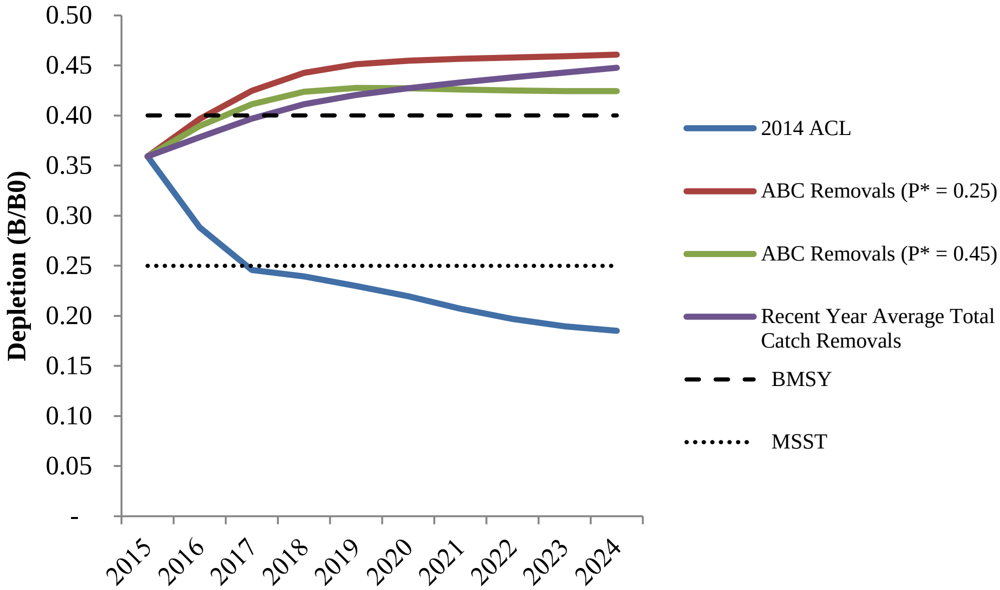

Figure 4-54. Projected depletion under alternative catch streams under the low state of nature model for gopher rockfish south of 40º10' N lat.

4.8.3 Long Term Impacts of Assessed Shelf Rockfish Species

Of the assessed shelf rockfish species, only the greenspotted rockfish projections were not provided in time for this analysis. Shelf rockfish are caught by both the trawl and fixed gear sectors, although there is some variation between species on their relative selectivities to different gears. For instance, greenstriped rockfish, while not targeted in any fishery, tend to be more readily caught in trawl gears than fixed gears. Catch monitoring precision therefore varies by species based on their relative gear selectivity with more certain catch estimation for those species dominant to the trawl fishery given the 100% observer coverage for those fleets. Current overfishing risks are low for shelf rockfish in general and have been since implementation of RCAs over ten years ago.

4.8.3.1 Bocaccio South of 40º10' N lat.

The modeled catch scenarios for bocaccio south of 40º10' N lat. range from 150 mt per year based on the recent year average catch scenario to an annual average catch in 2015-2024 of 1,431 mt based on the ACL = ABC with a P* of 0.45 catch scenario under the high state of nature (Table 4-161). Projected bocaccio depletions under the base case and high states of nature are sustainable assuming the respective states of nature (Figure 4-55 and Figure 4-56). All of these catch scenarios are in the precautionary zone under the B_{MSY} target at the beginning of the projection period under the low state of nature (Figure 4-57). The stock is estimated to undergo rebuilding under the low state of nature with all catch scenarios. All catch scenarios under the low state of nature except the ABC removals (under both P*s of 0.45 and 0.25) are predicted to be over the B_{MSY} target by the end of the projection period (Figure 4-57).

Table 4-161. Predicted average annual catches (mt) in 2015-2024 by state of nature and catch scenario for bocaccio south of 40º10' N lat.

State of Nature	Catch Scenario	2015-24 Average Annual Catch
Base	2014 ACL (No Action Alt.)	338

4.8.3.2 Canary Rockfish

The modeled catch scenarios for canary rockfish range from 47 mt per year based on the recent year average catch scenario to an annual average catch in 2015-2024 of 1,337 mt based on the ACL = ABC with a P* of 0.45 catch scenario under the high state of nature (Table 4-162). Projected canary rockfish depletions for all catch scenarios under the base case state of nature are shown to be in the precautionary zone and are predicted to rebuild but not by the end of the projection period (Figure 4-58). Projected canary depletions for all catch scenarios under the high state of nature are sustainable (Figure 4-59). Projected canary depletions for all catch scenarios under the low state of nature are predicted to keep the stock at very low levels of depletion under the MSST with very little or no rebuilding (Figure 4-60).

Table 4-162. Predicted average annual catches (mt) in 2015-2024 by state of nature and catch scenario for canary rockfish.

State of Nature	Catch Scenario	2015-24 Average Annual Catch
Base	2014 ACL (No Action Alt.)	119
	ABC Removals (P* = 0.25; Alt. 2)	556
	ABC Removals (P* = 0.45; Alt. 1)	652
	ACL Removals (SPR = 88.7%; Pref. Alt.)	145

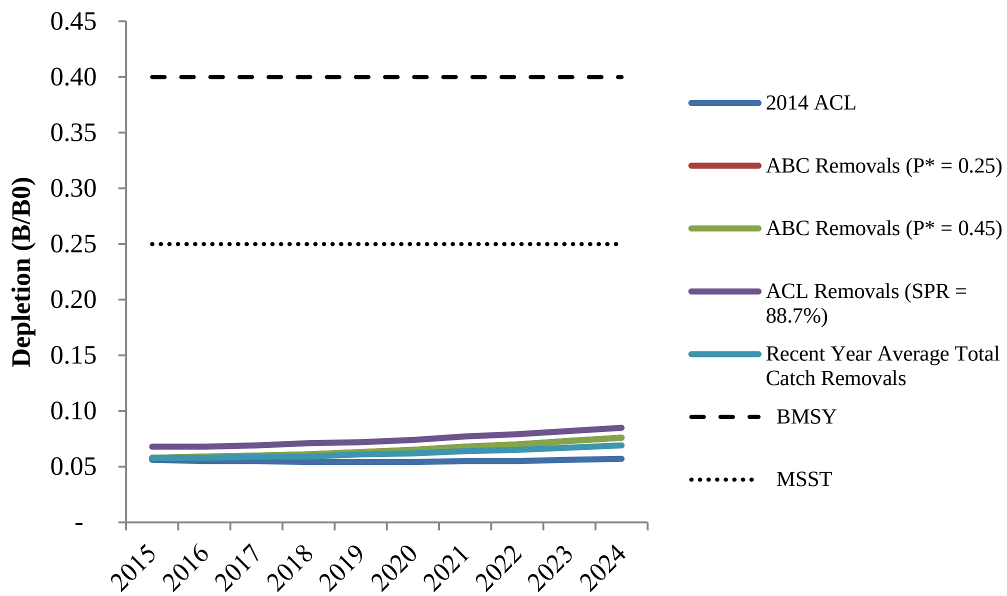

Figure 4-60. Projected depletion under alternative catch streams under the low state of nature model for canary rockfish.

4.8.3.3 Chilipepper Rockfish

The modeled catch scenarios for chilipepper range from 330 mt per year based on the recent year average catches to an annual average catch in 2015-2024 of 2,252 mt based on the ACL = ABC with a P* of 0.45

catch scenario under the high state of nature (Table 4-163). Projected chilipepper depletions under all states of nature are sustainable during the projection period assuming the respective states of nature except for the ABC removals at a P* of 0.45 under the low state of nature, which causes the stock to drop below the B_{MSY} threshold into the precautionary zone (Figure 4-61, Figure 4-62, and Figure 4-63).

Table 4-163. Predicted average annual catches (mt) in 2015-2024 by state of nature and catch scenario for chilipepper rockfish.

State of Nature	Catch Scenario	2015-24 Average Annual Catch
Base	2014 ACL (No Action Alt.)	1,618

4.8.3.4 Cowcod

While the management unit for the cowcod stock managed under the rebuilding plan is for the population south of 40º10’ N lat., the long term projections analyzed in this section are only for the assessed population south of Pt. Conception at 34º27' N lat. The range of average annual cowcod catch contributions in 2015-2024 from the Southern California Bight across the catch scenarios analyzed and states of nature modeled in the 2013 assessment is 1-93 mt (Table 4-164). The stock is projected to rebuild under the base case scenario for all catch scenarios except the highest one (ACL = ABC using a P* of 0.45), where the biomass trends to a slightly lower depletion (Figure 4-64). All the ABC removal scenarios are predicted to keep the stock in the precautionary zone, while the lower catch scenarios (i.e., 2014 ACL, ACL removal using an SPR rate of 82.7% (or equivalent exploitation fraction[62]), and recent year average total catch removals) are predicted to rebuild the stock within the next ten years. The stock is estimated to be healthy with all catch scenarios being sustainable under the high state of nature (Figure 4-65). In contrast, the estimated depletion under the low state of nature is below the MSST with a slightly increasing trend under all catch scenarios (Figure 4-66). None of the catch scenarios under the low state of nature are predicted to rebuild the stock within ten years, although the lower catch streams up to the ABC removals using a P* of 0.25 are predicted to increase biomass above the MSST within ten years.

Table 4-164. Predicted average annual catches (mt) in 2015-2024 by state of nature and catch scenario for cowcod south of 34º27' N lat.

State of Nature	Catch Scenario	2015-24 Average Annual Catch
Base	2014 ACL (No Action Alt.)	2
	ABC Removals (P* = 0.25; Alt. 2)	35
	ABC Removals (P* = 0.4)	46
	ABC Removals (P* = 0.45; Alt. 1)	49
	ACL Removals (SPR = 82.7% in Conception area; Pref. Alt.)	9
	Recent Year Average Total Catch Removals	1
High	2014 ACL	2
	ABC Removals (P* = 0.25)	68
	ABC Removals (P* = 0.4)	86
	ABC Removals (P* = 0.45)	93
	ACL Removals (SPR = 82.7% in Conception area)	12
	Recent Year Average Total Catch Removals	1
Low	2014 ACL	2
	ABC Removals (P* = 0.25)	15
	ABC Removals (P* = 0.4)	21
	ABC Removals (P* = 0.45)	22
	ACL Removals (SPR = 82.7% in Conception area)	6
	Recent Year Average Total Catch Removals	1

[62] The 2013 cowcod assessment was conducted in an XDB-SRA platform which does not accommodate SPR harvest rates. Therefore, the 2013 cowcod rebuilding analysis calculated an equivalent exploitation fraction of allowable harvest/age 11+ biomass to the status quo SPR harvest rate of 82.7% (E = 0.007) to project impacts.

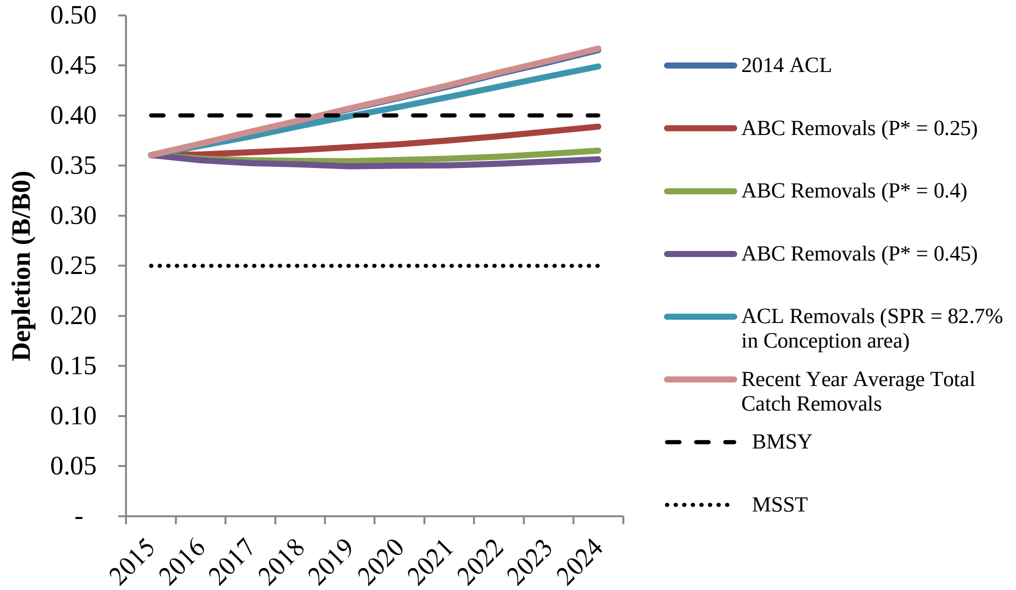

Figure 4-64. Projected depletion under alternative catch streams under the base case state of nature model for cowcod south of 34º27' N lat.

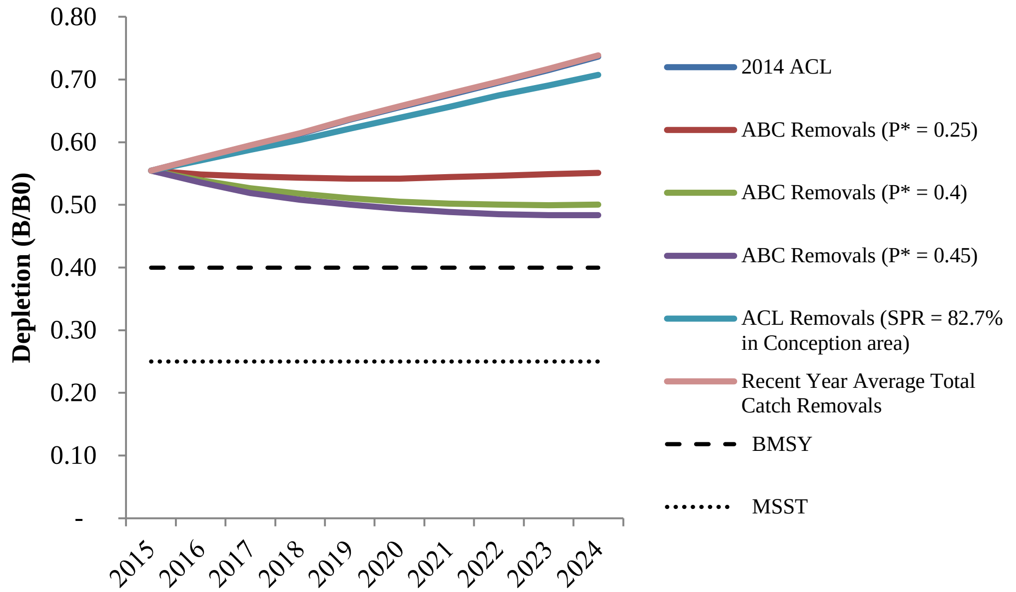

Figure 4-65. Projected depletion under alternative catch streams under the high state of nature model for cowcod south of 34º27' N lat.

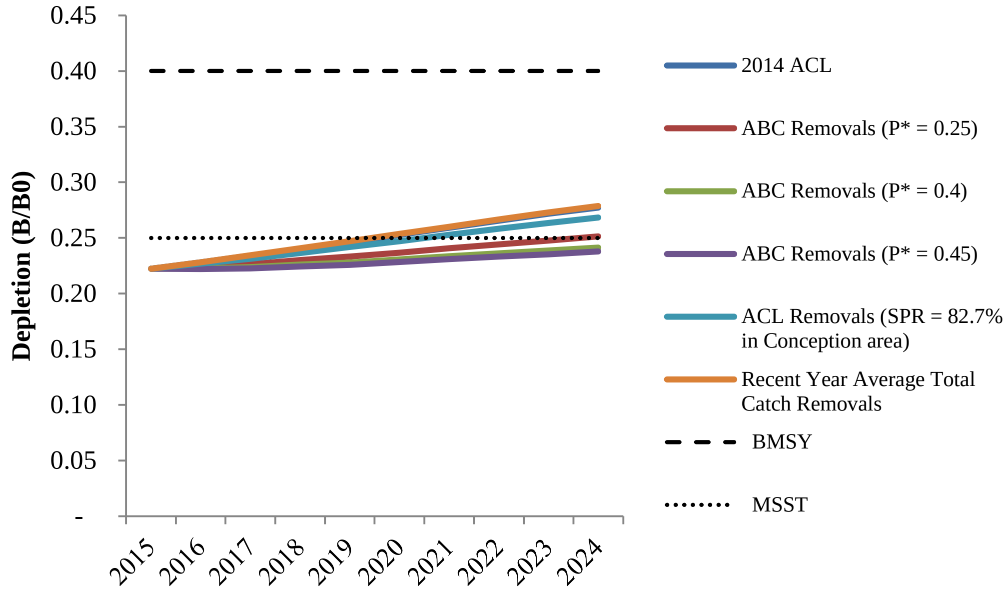

Figure 4-66. Projected depletion under alternative catch streams under the low state of nature model for cowcod south of 34º27' N lat.

4.8.3.5 Greenstriped Rockfish

The modeled catch scenarios for greenstriped rockfish range from 21 mt per year based on the recent year average catches to an annual average catch in 2015-2024 of 10,211 mt based on the ACL = ABC with a P* of 0.45 catch scenario under the high state of nature (Table 4-165). Projected greenstriped depletions under all catch scenarios and states of nature are predicted to be sustainable (Figure 4-67, Figure 4-68, and Figure 4-69). The most likely trajectory for greenstriped is the recent year average total catch scenario under the base case model since greenstriped are not targeted and do not tend to aggregate, which might otherwise cause sporadically high catches.

Table 4-165. Predicted average annual catches (mt) in 2015-2024 by state of nature and catch scenario for greenstriped rockfish.

State of Nature	Catch Scenario	2015-24 Average Annual Catch
Base	ABC Removals (P* = 0.25; Alt. 2)	857
	ABC Removals (P* = 0.45; Alt. 1; Pref. Alt.)	1,201
	Recent Year Average Total Catch Removals	21
High	ABC Removals (P* = 0.25)	7,365
	ABC Removals (P* = 0.45)	10,211
	Recent Year Average Total Catch Removals	21
Low	ABC Removals (P* = 0.25)	156
	ABC Removals (P* = 0.45)	221
	Recent Year Average Total Catch Removals	21

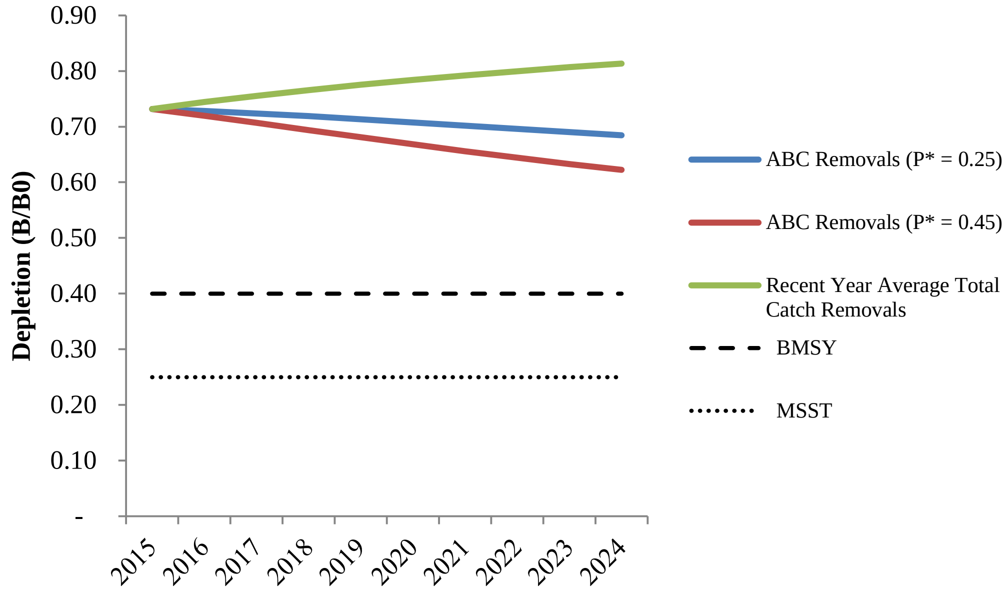

Figure 4-69. Projected depletion under alternative catch streams under the low state of nature model for greenstriped rockfish.

4.8.3.6 Widow Rockfish

The modeled catch scenarios for widow rockfish range from 247 mt per year based on the recent year average catches to an annual average catch in 2015-2024 of 4,648 mt based on the ACL = ABC with a P* of 0.45 catch scenario under the high state of nature (Table 4-166). Projected widow depletions under the base case and high states of nature are sustainable during the projection period assuming the respective states of nature (Figure 4-70 and Figure 4-71). Projected widow depletions under the low state of nature keeps the stock in the precautionary zone during the projection period (Figure 4-72). All the catch scenarios except the 3,000 mt constant catch scenario under the low state of nature predict some stock rebuilding. The 3,000 mt constant catch scenario under the low state of nature is predicted to reach an asymptote at the MSST during the projection period (Figure 4-72).

Table 4-166. Predicted average annual catches (mt) in 2015-2024 by state of nature and catch scenario for widow rockfish.

State of Nature	Catch Scenario	2015-24 Average Annual Catch
Base	ABC Removals (P* = 0.25; Alt. 2)	3,709
	ABC Removals (P* = 0.45; Alt. 1)	4,402
	Recent Year Average Total Catch Removals	247
	ACL Removals (1,500 mt constant catch; No Action Alt.)	1,500
	ACL Removals (3,000 mt constant catch)	3,000

4.8.3.7 Yelloweye Rockfish

The modeled catch scenarios for yelloweye rockfish range from 10 mt per year based on the recent year average catch scenario to an annual average catch in 2015-2024 of 76 mt based on the ACL = ABC with a

P* of 0.45 catch scenario under the high state of nature (Table 4-167). Projected yelloweye rockfish depletions for all catch scenarios under the base case state of nature are predicted to undergo rebuilding and increase in abundance from below the MSST into the precautionary zone during the projection period (Figure 4-73). Projected yelloweye depletions for all catch scenarios under the high state of nature are predicted to keep the stock in the precautionary zone during the projection period (Figure 4-74). Projected yelloweye depletions for all catch scenarios under the low state of nature are predicted to keep the stock at very low levels of depletion under the MSST with very little or no rebuilding (Figure 4-75).

Table 4-167. Predicted average annual catches (mt) in 2015-2024 by state of nature and catch scenario for yelloweye rockfish.

State of Nature	Catch Scenario	2015-24 Average Annual Catch

4.8.3.8 Yellowtail Rockfish North of 40º10' N lat.

The modeled catch scenarios for yellowtail rockfish north of 40º10' N lat. range from 1,551 mt per year based on the recent year average catches to an annual average catch in 2015-2024 of 9,805 mt based on the ACL = ABC with a P* of 0.45 catch scenario under the high state of nature (Table 4-168). Projected yellowtail rockfish depletions under all states of nature are sustainable assuming the respective states of nature (Figure 4-76, Figure 4-77, and Figure 4-78).

4.8.4 Long Term Impacts of Assessed Slope Rockfish Species

4.8.4.1 Aurora Rockfish

The modeled catch scenarios for aurora rockfish range from 34 mt per year based on the 2014 ACL contribution (based on a data-poor OFL that preceded the OFL estimated from the 2013 assessment and a 16.6% ABC deduction from the OFL based on the stock then being categorized as a cat. 3 stock under a P* of 0.45) to an annual average catch in 2015-2024 of 144 mt based on the ACL = ABC with a P* of 0.45 catch scenario under the high state of nature (Table 4-169). Projected aurora rockfish depletions under all states of nature are sustainable assuming the respective states of nature (Figure 4-79, Figure 4-80, and Figure 4-81).

Table 4-169. Predicted average annual catches (mt) in 2015-2024 by state of nature and catch scenario for aurora rockfish.

State of Nature	Catch Scenario	2015-24 Average Annual Catch
Base	2014 ACL contribution (No Action Alt.)	34

4.8.4.2 Blackgill Rockfish South of 40º10' N lat.

The modeled catch scenarios for blackgill rockfish south of 40º10' N lat. range from an annual average catch of 55 mt per year based on the ACL = ABC with a P* of 0.25 catch scenario under the low state of nature to an annual average catch in 2015-2024 of 224 mt based on the ACL = ABC with a P* of 0.45 catch scenario under the high state of nature (Table 4-170). Projected blackgill rockfish depletions under the base case state of nature for all catch scenarios keep the stock within the precautionary zone during the projection period except for the ABC removals under a P* of 0.25, where the depletion is projected to rebuild to the B_{MSY} threshold by the end of the projection period (Figure 4-81). Projected blackgill rockfish depletions under the high state of nature are sustainable for all catch scenarios (Figure 4-82). Projected blackgill rockfish depletions under the low state of nature for all catch scenarios are predicted to rebuild from below the MSST into the precautionary zone during the projection period (Figure 4-83).

4.8.4.3 Darkblotched Rockfish

The modeled catch scenarios for darkblotched rockfish range from an annual average catch of 108 mt per year based on the recent year average catch scenario to an annual average catch in 2015-2024 of 2,003 mt based on the ACL = ABC with a P* of 0.45 catch scenario under the high state of nature (Table 4-171). Projected darkblotched rockfish depletions under the base case and high states of nature for all catch scenarios are predicted to be sustainable during the projection period (Figure 4-84 and Figure 4-85). Projected darkblotched rockfish depletions under the low state of nature for all catch scenarios are predicted to rebuild from below the MSST into the precautionary zone during the projection period (Figure 4-86).

4.8.4.4 Longspine Thornyheads

The modeled catch scenarios for longspine thornyheads range from an annual average catch of 942 mt per year based on the recent year average catch scenario to an annual average catch in 2015-2024 of 6,620 mt based on the ACL = ABC with a P* of 0.45 catch scenario under the high state of nature (Table 4-172). Projected longspine thornyhead depletions under all states of nature for all catch scenarios are predicted to be sustainable during the projection period (Figure 4-87, Figure 4-88, and Figure 4-89).

Table 4-172. Predicted average annual catches (mt) in 2015-2024 by state of nature and catch scenario for longspine thornyheads.

4.8.4.5 Pacific Ocean Perch

The modeled catch scenarios for Pacific ocean perch range from 59 mt per year based on the recent year average catch scenario to an annual average catch in 2015-2024 of 1,805 mt based on the ACL = ABC with a P* of 0.45 catch scenario under the high state of nature (Table 4-173). Projected POP depletions for all catch scenarios except the ABC removals (both the P* of 0.25 and 0.45 scenarios) under the base case state of nature are predicted to undergo rebuilding and increase in abundance from below the MSST into the precautionary zone during the projection period; the ABC removal scenarios keep the stock below the MSST during the projection period (Figure 4-90). Projected POP depletions for all catch scenarios under the high state of nature are predicted to be sustainable during the projection period (Figure 4-91). Projected POP depletions for all catch scenarios under the low state of nature are predicted to keep the stock at very low levels of depletion under the MSST with very little or no rebuilding (Figure 4-92).

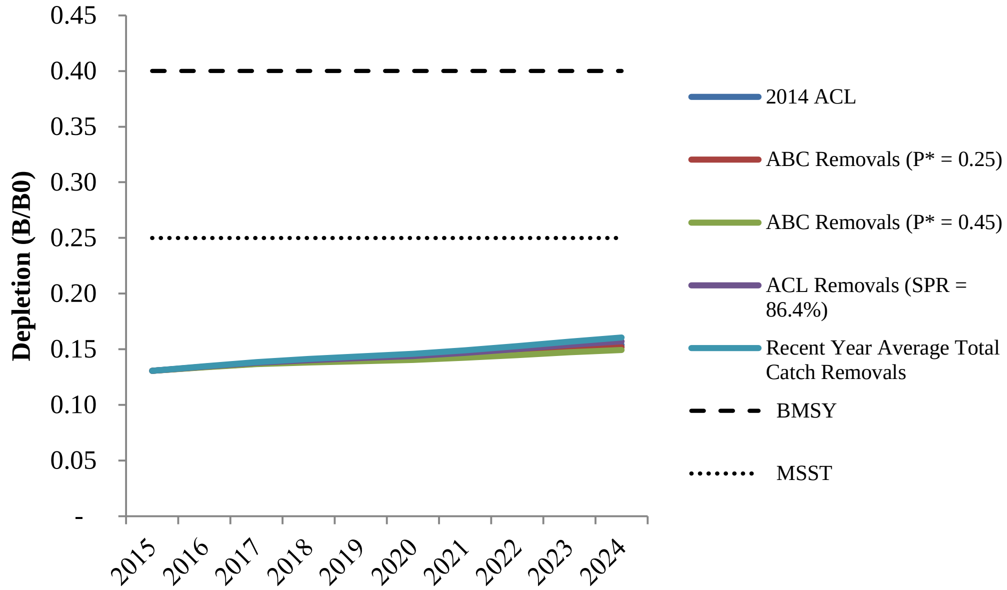

Figure 4-92. Projected depletion under alternative catch streams under the low state of nature model for Pacific ocean perch.

4.8.4.6 Rougheye/Blackspotted Rockfish

The modeled catch scenarios for rougheye/blackspotted rockfish range from an annual average catch of 60 mt per year based on the 2014 ACL contribution (based on a data-poor OFL that preceded the OFL estimated from the 2013 assessment and a 16.6% ABC deduction from the OFL based on the stock then being categorized as a cat. 3 stock under a P* of 0.45) to an annual average catch in 2015-2024 of 319 mt based on the ACL = ABC with a P* of 0.45 catch scenario under the high state of nature (Table 4-174). Projected rougheye/blackspotted rockfish depletions under the base case and high states of nature for all catch scenarios are predicted to be sustainable during the projection period (Figure 4-93 and Figure 4-94). Projected rougheye/blackspotted rockfish depletions under the low state of nature for all catch scenarios are predicted to rebuild from the precautionary zone to above the B_{MSY} threshold during the projection period (Figure 4-95).

Table 4-174. Predicted average annual catches (mt) in 2015-2024 by state of nature and catch scenario for rougheye/blackspotted rockfish.

State of Nature	Catch Scenario	2015-24 Average Annual Catch

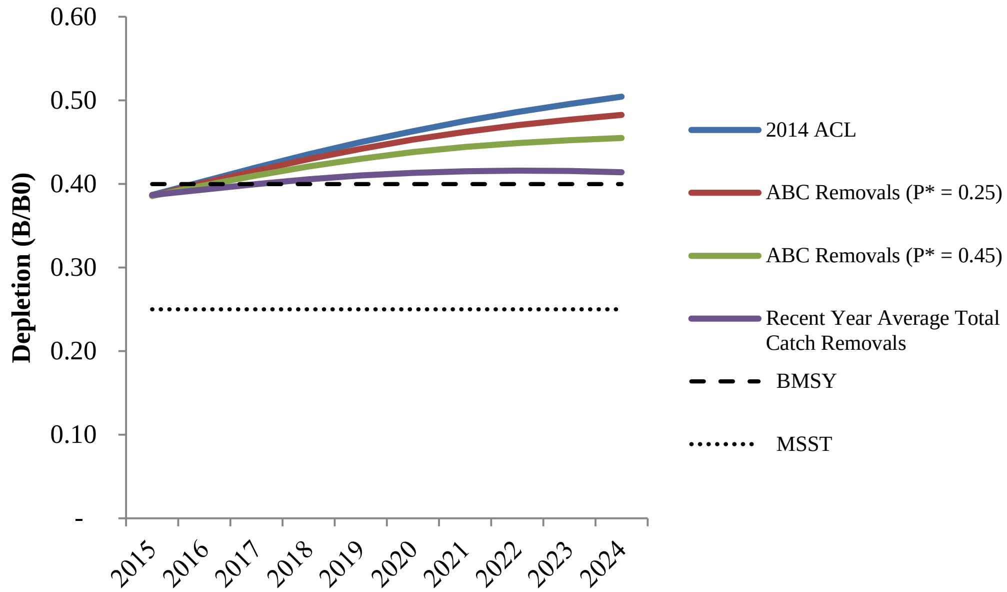

Figure 4-95. Projected depletion under alternative catch streams under the low state of nature model for rougheye/blackspotted rockfish.

4.8.4.7 Shortspine Thornyheads

The modeled catch scenarios for shortspine thornyheads range from an annual average catch of 754 mt per year based on the ACL = ABC with a P* of 0.25 catch scenario under the low state of nature to an annual average catch in 2015-2024 of 8,011 mt based on the ACL = ABC with a P* of 0.45 catch scenario under the high state of nature (Table 4-175). Projected shortspine thornyhead depletions under all states of nature for all catch scenarios are predicted to be sustainable during the projection period (Figure 4-96, Figure 4-97, and Figure 4-98).

4.8.4.8 Splitnose Rockfish

The modeled catch scenarios for splitnose rockfish range from an annual average catch of 70 mt per year based on the recent year average catch scenario to an annual average catch in 2015-2024 of 3,036 mt based on the ACL = ABC with a P* of 0.45 catch scenario under the high state of nature (Table 4-176). Projected splitnose rockfish depletions under all states of nature for all catch scenarios are predicted to be sustainable during the projection period (Figure 4-99, Figure 4-100, and Figure 4-101).

Table 4-176. Predicted average annual catches (mt) in 2015-2024 by state of nature and catch scenario for splitnose rockfish.

4.8.4.9 Sharpchin Rockfish

The modeled catch scenarios for sharpchin rockfish range from an annual average catch of 7 mt per year based on the recent year average catch scenario to an annual average catch in 2015-2024 of 636 mt based on the ACL = ABC with a P* of 0.45 catch scenario under the high state of nature (Table 4-177). Projected sharpchin rockfish depletions under all states of nature for all catch scenarios are predicted to be sustainable during the projection period (Figure 4-102, Figure 4-103, and Figure 4-104).

Table 4-177. Predicted average annual catches (mt) in 2015-2024 by state of nature and catch scenario for sharpchin rockfish.

4.8.5 Long Term Impacts of Assessed Roundfish Species

Of the assessed roundfish species, only cabezon in California is missing from this analysis.

4.8.5.1 Cabezon in Oregon

The modeled catch scenarios for cabezon in Oregon range from 24 mt per year based on the ACL = ABC with a P* of 0.25 catch scenario under the low state of nature to an annual average catch in 2015-2024 of 88 mt based on the ACL = ABC with a P* of 0.45 catch scenario under the high state of nature (Table 4-178). Projected Oregon cabezon depletions under the base case and high states of nature for all catch scenarios are predicted to be sustainable during the projection period (Figure 4-105 and Figure 4-106). Projected Oregon cabezon depletions under the low state of nature for the ABC removals with a P* of 0.25 catch scenario is predicted to rebuild from below the MSST to above the B_{MSY} threshold during the projection period (Figure 4-107). The ABC removals with a P* of 0.45 under the low state of nature is predicted to rebuild the stock from below the MSST but keeps the stock in the precautionary zone during the projection period (Figure 4-107). The 2014 ACL and recent year average catch scenarios are predicted to drive the stock to lower levels of depletion below the MSST under the low state of nature (Figure 4-107).

4.8.5.4 Sablefish

The modeled catch scenarios for sablefish range from 4,086 mt per year based on the ACL = ABC with a P* of 0.25 catch scenario under the low state of nature to an annual average catch in 2015-2024 of 12,335 mt based on the ACL = ABC with a P* of 0.45 catch scenario under the high state of nature (Table 4-181). Projected sablefish depletions for all catch scenarios under the base case state of nature are predicted to increase in abundance but remain in the precautionary zone during the projection period (Figure 4-114). Projected sablefish depletions for all catch scenarios under the high state of nature are predicted to be sustainable during the projection period (Figure 4-115). Projected sablefish depletions for all catch scenarios under the low state of nature are predicted to keep the stock at very low levels of depletion under the MSST with very little or no rebuilding (Figure 4-116).

Table 4-181. Predicted average annual catches (mt) in 2015-2024 by state of nature and catch scenario for sablefish.

State of Nature	Catch Scenario	2015-24 Average Annual Catch
Base	2014 ACL (No Action Alt.)	5,909
	ABC Removals (P* = 0.25; Alt. 2)	7,358
	ABC Removals (P* = 0.45; Alt. 1)	8,542

4.8.6 Long Term Impacts of Assessed Elasmobranch Species

4.8.6.1 Longnose Skate

The modeled catch scenarios for longnose skate range from an annual average catch of 999 mt per year based on the recent year average catch scenario to an annual average catch in 2015-2024 of 2,892 mt based on the ACL = ABC with a P* of 0.45 catch scenario under the high state of nature (Table 4-182). Projected longnose skate depletions under the base case and high states of nature for all catch scenarios are predicted to be sustainable during the projection period (Figure 4-117 and Figure 4-118). Projected longnose skate depletions under the low state of nature for the recent year average catch scenario is predicted to be sustainable, but the other catch scenarios are predicted to drive the stock below the B_{MSY} threshold and into the precautionary zone during the projection period (Figure 4-119).

Table 4-182. Predicted average annual catches (mt) in 2015-2024 by state of nature and catch scenario for longnose skate.

4.9 Long-term Impacts of Establishing and Adjusting Management Measures for Groundfish Fisheries

Management measures are the primary link between management objectives (such as harvest specifications) and environmental impacts. Management measures affect behavior (most directly, fishing activity), which in turn determines how resources are affected and the location and intensity of benefits and costs for human communities. For this reason the effects of management measures are evaluated in their own right in this section.

This section describes the long-term effects of the application of different types of management measures during the biennial management process by linking their potential impacts to the environmental components evaluated in this chapter. As discussed in section 3.2, the Groundfish FMP distinguishes between new measures and routine measures. The categories of management measures discussed below encompasses measures that may be considered routine or new. For example, a change in the configuration of an RCA (a type of closed area) may be considered routine, if the boundary lines and configuration were used in the past; it would be considered a new measure if a new boundary line or configuration is proposed. Since these categories of management measures are applied continuously with changes such as just described, they are an important aspect of the long-term impacts of groundfish fishery management.

This section describes the types of management measure adjustments and associated impacts anticipated when harvest specifications are implemented in future biennial cycles. A comprehensive description of management measures and application by sector can be found in Section XXX (reference Chapter 4, Description of No Action Management Measures). Section XXX provides a more detailed look at the measures proposed for implementation in regulations for the 2015-16 biennial period.

This section does not evaluate every possible adjustment in management measures (e.g., changes to RCA configurations, trip limit adjustments, bag and sub-bag limits) given the range of ACL projections under the various states of nature. Many or most changes in routine measures result in impacts of the same type and intensity. Furthermore, individually, the specific impacts of such adjustments are usually too small to predict.

As specified in the FMP, the principal management measures available to control fishing mortality in the west coast groundfish fisheries are:

- Measures to reduce bycatch and bycatch mortality
- Defining authorized fishing gear and regulating the configuration and deployment of fishing gear, including mesh size in nets and escape panels or ports in traps
- Restricting catches by defining prohibited species and establishing landing, trip frequency, bag, and size limits
- Establishing fishing seasons and closed areas
- Limiting fishing capacity or effort through permits, licenses and endorsements, and quotas, or by means of input controls on fishing gear, such as restrictions on trawl size/shape or longline length or number of hooks or pots. Fishing capacity may be further limited through programs that reduce participation in the fishery by retiring permits and/or vessels

Management measures may also be imposed for habitat protection, resource conservation, or social or economic reasons consistent with the criteria, procedures, goals, and objectives set forth in the FMP.

Management measures are normally imposed, adjusted, or removed at the beginning of the biennial fishing period when revised harvest specifications are implemented. Inseason adjustments, including automatic actions by the NMFS Regional Administrator, may be imposed, adjusted, or removed during the biennial period based on projected mortality relative to the ACL. New management measures may be developed through a regulatory or FMP amendment.

4.9.1 Commercial Fisheries

Commercial management measures have been applied to lengthen the duration of the fishery, so as not to disturb traditional fishing and marketing patterns; to reduce discards and waste, or; to discourage targeted fishing of some stocks. In cases where protection of an overfished or depleted stock is required, limits may differ by gear type or closed areas or seasons may be established.

Impact mechanisms and the types and intensity of impacts for each type of measure are discussed below. In general, all these measures are intended to reduce the mortality of certain groundfish species in order to achieve but not exceed ACLs. Measures may be developed to reconcile this principal objective with other objectives, such as maximizing commercial fishing opportunity and related socioeconomic benefits.

Season Restrictions: Time and area restrictions can be reviewed as related types of measures in two dimensions. Fishing seasons prohibit fishing during specified periods and are at least implicitly applied to a certain area. Time/area restrictions control fishing effort with the possibility of concentrating fishing effort on stocks or portions of stocks based on the availability in time and space. For example, such restrictions may direct fishing effort toward or away from spawning fish, a particular age or size class, or fish that are seasonable available due to their migratory pattern.

Groundfish Conservation Areas: Areas where it is unlawful to take and retain, possess, or land groundfish with commercial gear. Impacts are similar to season restrictions by limiting fishing opportunity by time and area. As stocks rebuild or if lower overfished species bycatch rates occur, less restrictive GCAs will likely be implemented. Conversely, if progress toward rebuilding is not proceeding consistent with the rebuilding plan and MSA, new stocks are declared overfished, or higher than anticipated overfished species bycatch rates occur, more restrictive GCAs may be implemented.

IFQ and IBQ: These tools divide the total amount of quota into shares controlled by individual fishermen or groups of fishermen (cooperatives).

Cumulative Landing Limits (also known as trip limits): These are limits on the pounds of fish a vessel may land in a period. Adjustments to cumulative landing limits influence fishing mortality, either directly through catch or indirectly by reducing fishing effort ("time on the water").

Take and Retain Prohibitions: These restrictions discourage targeting because retention and thus sale is prohibited. This type of measure is functionally equivalent to a trip limit set at zero.

Size Limits: Limits the size of fish (usually by length) that may be retained by a commercial fishing vessel. There can also be limits on "headed" or fillet sizes, which are easier to monitor onshore and can be correlated to the original size of the fish. Size limits change age-specific fishing mortality (fishery selectivity) and therefore can control mortality by life stage (e.g., juveniles, spawning stock).

Gear Restrictions: Gear definitions and restrictions are used to protect juvenile fish (trawl mesh size), to disable lost gear so that it no longer catches fish (biodegradable escape panels for pots), to slow the rates of catch in particular sectors (hook limits), to reduce bycatch of non-target species (trawl configuration requirements), and to protect marine habitat (trawl roller gear size restrictions).

4.9.2 Recreational Fisheries

In addition to the broad management objectives mentioned in Section XXX recreational management measures are also designed to avoid waste, spread catch over a large number of anglers, protect juvenile fish, and enhance the quality of the recreational fishing experience.

The requirement to rebuild stocks that have been declared overfished is an important consideration when establishing and adjusting recreational management measures. Presently, the following species are encountered in the recreational fisheries and are declared overfished: bocaccio south of 40°10 N. latitude, canary, cowcod south of 40°10 N. latitude, and yelloweye rockfish. Season and depth closures, including specific area closures are the primary management measure adjustments used to reduce overfished species mortality.

Most bag limits, size limits, and area closures in the recreational fisheries have been designated as “routine”.

Impact mechanisms and the types and intensity of impacts for each type of measure are discussed below. In general, all these measures are intended to reduce the mortality of certain groundfish species in order to achieve but not exceed ACLs. Measures may be developed to reconcile this principal objective with other objectives, such as maximizing recreational fishing opportunity and related socioeconomic benefits.

4.9.3 Impact Mechanisms

Season Restrictions: Time and area restrictions can be reviewed as related types of measures in two dimensions. Fishing seasons prohibit fishing during specified periods and are at least implicitly applied to a certain area. Time/area restrictions control fishing effort with the possibility of concentrating fishing effort on stocks or portions of stocks based on the availability in time and space. For example, such restrictions may direct fishing effort toward or away from spawning fish, a particular age or size class, or fish that are seasonable available due to their migratory pattern.

Recreational Rockfish Conservation Areas: Areas where it is unlawful to take and retain, possess, or land groundfish with recreational gear. Impacts are similar to season restrictions by limiting fishing opportunity by time and area.

Bag Limits, Boat Limits, Hook Limits: These are limits on: 1) the number of fish an angler may keep, 2) the total number of fish that may be retained aboard a vessel (no matter who aboard caught them), 3) on the number of hooks on any given fishing line. Bag and boat limits include fish taken in both state and federal waters. Changes in these limits influence fishing mortality, either directly through catch or indirectly by reducing fishing effort (“time on the water”) due to a change in the perceived value of the recreational experience.

Take and Retain Prohibitions: Discourages targeting species because of restrictions on anglers taking and retaining certain species. This type of measure is functionally equivalent to a bag or boat limit set at zero.

Prohibited Sale: Groundfish taken in the course of recreational groundfish fishing cannot be sold. No money revenue is realized, which otherwise could offset costs, increase the value of the activity, and therefore stimulate more fishing effort.

Size Limits: Limits the size of fish (usually by length) that may be retained by an angler. There can also be limits on fillet sizes, which are easier to monitor onshore and can be correlated to the original size of the fish. Size limits change age-specific fishing mortality (fishery selectivity) and therefore can control mortality by life stage (e.g., juveniles, spawning stock).

Gear Restrictions: Only hook-and-line or spear can be used for recreational fishing. This limits the efficiency (CPUE) and other gear-specific adverse impacts. If prohibited gear would enhance the angler experience, restrictions would reduce the value of recreational activity.

4.9.4 Impacts

Figure 4-123 diagrams the impact mechanisms, or causal relationships, for recreational and commercial management measures based on the above descriptions. Measures may control fishing effort, possibly in time and space (seasons, RCAs, take and retain prohibitions, prohibited sale); directly control fishing mortality (bag and boat limits, size limits); or control gear (hook limits, gear restrictions). This in turn affects the pattern of fishing effort, fishing efficiency (CPUE), and fishery selectivity. These intermediate effects determine fishing mortality and angler experience; there may other incidental effects that are not the principal objective of the management measures. Finally, these effects can be described with respect to the environmental components evaluated in this EIS.

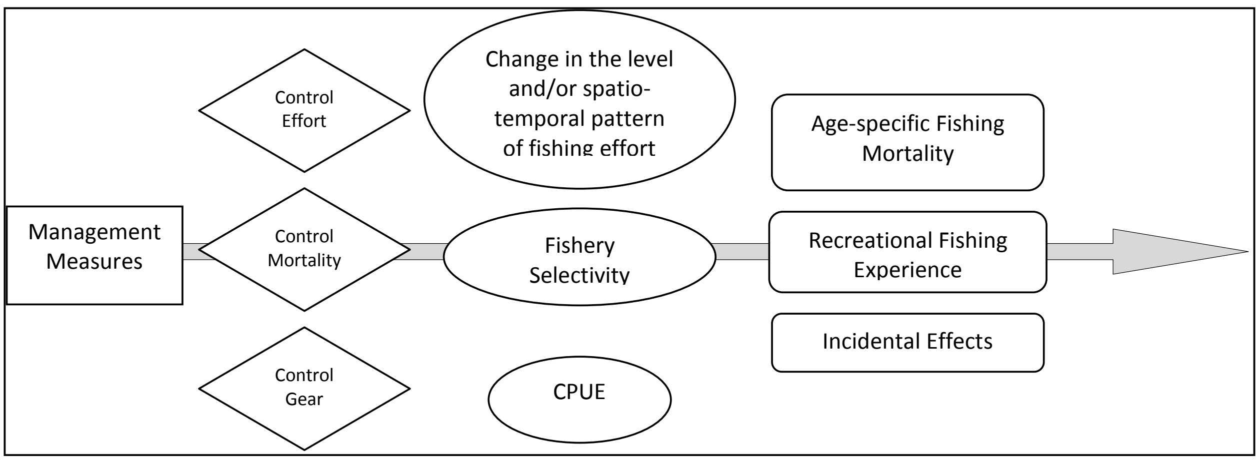

Figure 4-123. Summary of impact mechanisms for recreational management measures.

4.9.4.1 Groundfish Stocks

- By limiting fishing effort, time/area restrictions (seasons, RCAs) reduce groundfish mortality, which is usually the primary objective of such measures. Time/area restrictions are particularly effective in reducing mortality of … (species, life stage). Age-specific mortality may be an input to stock assessments and the effect of time/area closures would be accounted for in this way.
- Bag, boat, and trip limits have a direct effect on groundfish fishing mortality by restricting how many fish may be retained.
- Hook limits and other gear restrictions reduce the efficiency of the fishing gear and thus CPUE, indirectly affecting fishing mortality.
- Prohibiting the take and retention discourages targeting, which decreases mortality. These measures may provide an additional disincentive for vulnerable species (e.g., overfished species). Prohibiting commercial sale is a more general disincentive to increasing fishing effort, because the financial cost of the activity cannot be offset by revenue.
- Size limits affect fishery selectivity. This can help to increase yield by focusing catch on larger fish or conversely by discouraging catch of sexually mature fish.

4.9.4.2 California Current Ecosystem

- Changes in age-specific fishing mortality affect stock structure and relative abundance. Section 3.3 describes how these factors influence ecosystem structure.
- Reduced fishing effort may correlate with a reduction in vessel-related pollution. The direct effect is likely negligible but may have cumulative impacts. If other boat-based recreational activities are substituted (e.g., targeting other species) there would be no net change in the effect.

4.9.4.3 Essential Fish Habitat

- Adverse impacts to groundfish EFH due to fishing are a function of the type of gear used. Recreational gear is hook-and-line and infrequently contacts benthic groundfish EFH. Because of the small size of the gear even when contacting the bottom, adverse impacts are negligible. Therefore, other measures affecting fishing effort (reducing aggregate gear contact) also have a negligible effect on EFH.

4.9.4.4 Non-Groundfish Species

- The impact mechanism and effects are the same for non-groundfish species as for groundfish (reduction in fishing effort, mortality, change in fishery selectivity). Most catch of non-groundfish would be regulated under other authorities (other Council FMPs, state management programs) and any “bycatch mortality” is accounted for in the management of those stocks.

4.9.4.5 Protected Species

- Measures that control fishing effort and its spatio-temporal distribution (time/area closures) influence interactions between recreational vessels and protected species (marine mammals, seabirds, other ESA-listed species) according to their seasonal occurrence in the management area. Effects could include injurious/fatal interactions with fishing gear or vessels and adverse effects on behavior from non-injurious interactions. Because of gear restrictions recreational fishing employs relatively light hook-and-line gear so fatal interactions are unlikely.

4.9.4.6 Anglers and Fishing Communities

- Measures that affect fishing effort (time/area closures) influence the size and distribution of recreational expenditures. Changes in expenditure affect coastal communities that have recreational fishing engaged businesses. Measures may also affect the quality of the recreational fishing experience, which could indirectly affect fishing effort and related expenditures. These include limits on catch (bag and boat limits, take and retain prohibitions), prohibition of commercial sale, and gear restrictions. In long-term, management measures that maintain or increase target species abundance could enhance the recreational fishing experience by increasing CPUE and resulting in adaptive management feedback where management restriction are relaxed.

4.9.5 Summary

Table 4-184 summarizes the effects of the commercial and recreational groundfish management measures described above on the environmental components evaluated in this EIS.

4.10 Long-term Impacts of Setting Harvest Specifications on the Socioeconomic Environment

4.10.1 Impact Evaluation Methods

4.10.1.1 Revenue Volatility

As a preface to the considering socioeconomic impacts, future fishery performance should be considered with respect to historical inter-annual volatility in ex-vessel revenue. Such changes can be in response to a variety of factors, including management (the proposed action), prices, and other environmental factors. Figure 3-2 shows the deviation from the 1981-2012 long-term mean of total annual inflation-adjusted groundfish revenue (including at-sea Pacific whiting sectors). Figure 4-124 is similar except that it is based on data from 1998 to 2012 and shows nonwhiting and whiting revenue separately. As discussed below, groundfish revenues dropped precipitously and remained below the long-term average starting in 2008. Although above the mean in 2009, there is considerable volatility in following years, especially for Pacific whiting. High prices for sablefish likely contributed to the spike in nonwhiting revenue in 201. The time series does not necessarily suggest a trend of increasing revenue going forward; rather, the historical record suggests that inherent volatility will cause revenue to periodically fall to—or below—the average.

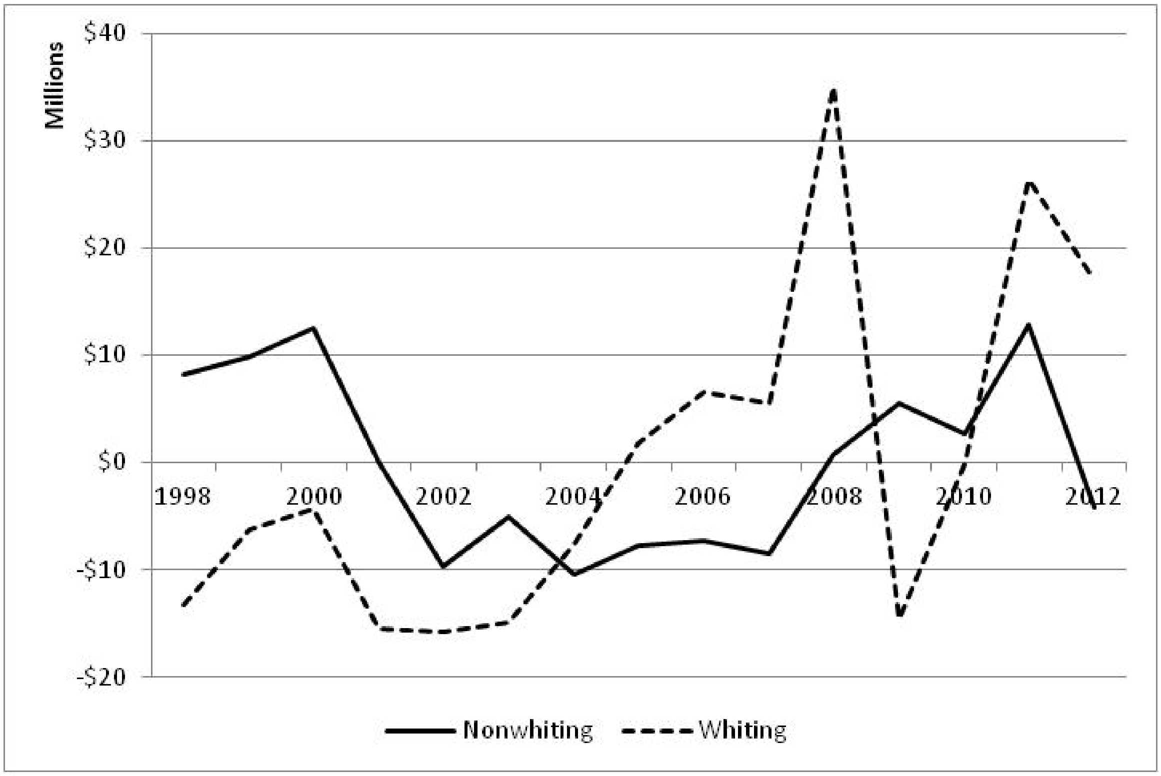

Figure 4-124. Deviation from the mean for inflation adjusted ex-vessel revenue from nonwhiting and whiting fisheries, 1998-2012.

By way of comparison, Table 4-185 shows some metrics for the absolute and relative variability in inflation-adjusted ex-vessel revenue for different species groups. For the entire time series the absolute variation (the range between the maximum value and minimum value) for groundfish is about $73 million; crab, HMS, and salmon show a greater range while CPS and shrimp are very close to the value for groundfish. The lower panels in the table show the coefficient of variation (CV), a relative measure of variability. For the entire time series groundfish shows the smallest relative variability; the only instance where groundfish shows greater relative variability than another group is in the 1998-2011 period where the Other species group (generally, various state-managed species) has a lower CV.

Table 4-185. Absolute variation in ex-vessel revenue (range between maximum and minimum value) in inflation-adjusted $1,000s during 1981-2011, and coefficient of variation for three time periods, by species group.

	CPS	Crab	Ground fish	HMS	Other	Salmon	Shellfish	Shrimp
Absolute Variation (inflation-adjusted $1,000s)								
1981-2011	$73,237	$121,503	**$73,389**	$95,012	$52,950	$112,882	$26,564	$73,090
Coefficients of Variation (CV)								
1981-2011	0.348	0.397	**0.247**	0.516	0.397	0.924	1.343	0.507
1981-1997	0.290	0.307	**0.092**	0.486	0.385	0.774	0.819	0.387
1998-2011	0.358	0.271	**0.149**	0.175	0.132	0.618	0.537	0.339

Table 4-186. Maximum year-on-year decline in inflation-adjusted revenue, 1982-2011, by species group; showing year of maximum decline and the amount of the decline in $millions, and in percent.

	CPS	Crab	Groundfish	HMS	Other	Salmon	Shellfish	Shrimp	All Species
Year	1998	1991	**1998**	1985	1998	2008	1998	2003	1998
$mil	-$47	-$39	**-$38**	-$57	-$14	-$71	-$12	-$32	-$139
Percent	-78%	-53%	**-35%**	-54%	-35%	-84%	-94%	-48%	-37%

Table 4-186 presents information on the maximum year-on-year revenue decline by species group. In addition to revenue for all species, 1997-98 also showed the maximum decline for the CPS (-78%), Groundfish (-35%), Other (-35%), and Shellfish (-94%) species groups. Although the maximum decline in percent terms is smaller for groundfish than all other groups except "Other," in absolute dollar terms Groundfish's largest single-year decline, $38 million, is larger than Other, Shellfish, and Shrimp. More generally, all of the maximum 1-year declines occurred after 1990 except for HMS. The comparisons show that revenue from groundfish revenues are not unusually volatile compared to other west coast fisheries. Expressed as percent, the maximum year-on-year change for groundfish, -35%, is close to the value for all species, -37%.

Note that these data represent a longer time series than the 2003-2012 baseline period used elsewhere. During the baseline period the maximum year-on-year decline was between 2011 and 2012 at $20.7 million or -22%. However, this statistic is somewhat misleading, because 2011 recorded the largest year-on-year gain of $23.9 million or 34%. Applying the historical data to describe socioeconomic impact over the long-term future suggests that inter-annual volatility in revenues is to be expected and could be as much as a one-third gain or drop. Since ACLs remain constant at 2014 values under No Action, exogenous factors, such as changes in prices, would likely be more important than management (the proposed action) in determining ex-vessel revenue. The fact that record setting declines in revenue occurred in four of the eight groups shown in Table 4-186 suggests that management of the groundfish fishery at that time was not a primary factor in the decline in revenue.

4.10.1.2 Stock Assessment Projections

Historical catch is compared to potential catch to evaluate the impact of the alternatives. The analysis focuses on a subset of species that generate most of the ex-vessel revenue in commercial fisheries and/or are important targets in recreational groundfish fisheries. For No Action, it is assumed that the 2014 ACLs are carried forward for some indefinite period.[63] For No Action, historical catch is compared to those ACLs; cases where historical average catch is greater than a 2014 ACL could represent an adverse socioeconomic impact. Projected aggregate catch (the sum of catch over the 2015-2024 projection period) is used to evaluate the potential effect of the action alternatives. Catch under both the base case and high state of nature are used for Alternative 1, the base case and the low state of nature for Alternative 2, and just the base case for Alternative 3. Pairing the high state of nature with Alternative 1 and the low state of nature with Alternative 2 is intended to "bookend" the potential yields in the projections. Minimum aggregate catch is also considered although not associated with any of the alternatives. This is either the recent average catch stream or P*=0.25 ACL catch stream for the stocks considered here. Favoring the base case state of nature recognizes that the base case represents the most likely scenario for any policy choice.

Projected catches are based on the assumption that the entire ACL is caught; in other words total fishing mortality is equal to the ACL. In order to make these scenarios more comparable to historical

[63] Routine management measures, defined as those already in place, can be changed inseason. These routine changes usually involve some form of catch control to ensure that ACLs are not exceeded.

information they have been adjusted by applying the historical ACL catch attainment rates based on WCGOP data (Bellman, *et al.* 2013). It should be noted that adjusting the projections in this way likely under-represents future yield and catch. First, since the projections assume that the stock is being reduced each year by the entire ACL, catches below that level (the assumption made in applying attainment rates) would likely result in some additional yield in future years. Second, technical and market changes could lead to higher attainment rates for some species. Adjusting the ACLs in this way as a proxy for catch would under-represent potential future catch if attainment rates increase.

As discussed in Section 4.9, it is important to bear in mind that these projections assume perfect information and no management error. As a result, over the projection period yields converge towards an equilibrium related to MSY. In the case of stocks above the B_{MSY} proxy yields decline as the stock is fished down towards the B_{MSY} level while stocks below B_{MSY} increase towards that level. Changes in stock productivity and recruitment that cannot be predicted add to uncertainty about what future yields may actually be. Resulting misspecification of catch limits would result in forgone fishing opportunity (if specifications are low compared to actual stock status) or stock depletion (if specifications are too high).

4.10.2 Commercial Fisheries: Shorebased IFQ and Non-nearshore Fixed Gear

4.10.2.1 No Action Alternative

During the baseline period shoreside groundfish limited entry fisheries have accounted for 70% of inflation-adjusted ex-vessel revenue from non-tribal groundfish fisheries; with at-sea whiting included the fraction rises to 94%. inflation adjusted (2012 prices) ex-vessel revenue during the 2003-2012 baseline period ranged from $23.1 to $36.8 million for the limited entry groundfish bottom trawl fishery (including vessels fishing with fixed gear since 2011 under the IFQ program) and averaged $29.8 million. Comparable figures for the non-nearshore fixed fishery are $11.8-$29.2 million and an average of $18.2 million. Under No Action it is expected that revenues would range similarly.

The evaluation below considers No Action ACLs more broadly with respect to fishery performance. While this analysis uses data for all groundfish fisheries (to simplify comparisons to ACLs, which apply to all groundfish catch), the species considered are primarily caught in shorebased IFQ and non-nearshore fixed gear fisheries. (Recreational fishing mortality is also accounted for in the management scheme while only commercial data are considered here. For the species in question recreational catch is negligible.

Table 4-187 shows average annual catch of these commercially important species compared to the 2014 ACLs.[64] Commercial catch attainment (the fraction of the ACL caught in commercial fisheries) for the 2003-2012 period is also shown. Historically, low ACLs for overfished species have affected fishery performance, because management measures that discourage catch of these species can also limit fishing opportunity for target stocks. Individual accountability in the shorebased IFQ fishery is changing fishery strategies in a variety of ways and the greater flexibility afforded harvesters in pursuing fishing strategies may improve their ability to avoid catching stocks for which they have relatively few quota pounds. Since these types of behavioral changes cannot be predicted, one must rely on the assumption stated above, that at a gross level the magnitude of the ACL affects performance. In this regard, comparing historical catch attainment to catch as a fraction of the 2014 ACL may be indicative. The 2014 ACL for sablefish, the most commercially valuable species, would likely have the largest impact on fishery performance. During the baseline period mostly of each ACL was caught (an attainment rate of 95%) and average catch during the baseline period exceeds the 2014 ACL. This suggests that coastwide revenue under No Action is likely to be lower compared to the baseline. By this logic, cases where average

[64] See Figure 3-1 for a breakdown of total shoreside ex-vessel revenue by species.

annual catch during the baseline period divided by the 2014 ACL (the right most column in Table 4-187) is greater than baseline period catch attainment (the third column from the left in Table 4-187) could result in lower revenue compared to the baseline period. Arrowtooth flounder is the only target species aside from sablefish where this holds true (and arrowtooth is a relatively unimportant species, accounting for only 1.2% of coastwide inflation-adjusted revenue during the baseline period). For overfished species shown in Table 4-187 this relationship holds true only for POP.

Table 4-187. Comparison of 2003-2012 catch to ACLs for commercially important stocks. (Catch estimates from WCGOP multi-year data product.)

Stock	2003-2012 Average Annual Catch	2003-2012 ACL Attainment	2014 ACL	Catch/ 2014 ACL
Arrowtooth Flounder	3,399	42%	5,758	59%
Dover Sole	8,981	63%	25,000	36%

YELLOWEYE	3	16%	18	15%

*Sum of geographically defined component ACLs.

4.10.2.2 Action Alternatives

Table 4-188 compares baseline catch to potential catch, using adjusted ACLs as a proxy, based on stock assessment projections for major target species in the groundfish trawl and non-nearshore fixed fisheries. As shown in the table, these species account for almost four-fifth of landings by weight and value of groundfish by the trawl and non-nearshore sectors. As discussed above, ACL catch is adjusted based on historical attainment rates. (These attainment rates are based on total catch for all sectors, but trawl and non-nearshore fixed gear account for most of the catch of these species.) For each alternative and state of nature scenario the ratio between projected aggregate catch and aggregate catch during the 2003-2012 baseline period is shown. These ratios make it easier to compare the difference between the alternatives in terms of potential revenues. Because potential ex-vessel revenue is likely to be influenced by many other factors aside from fishing opportunity, these results are not presented in terms of potential revenue; the ratios are meant to give a general indication of possible revenue differences from baseline conditions.

The ratios for Alternative 1 (P*=0.45) and the high state of nature range from 1.4 for Petrale sole to 6.3 for Dover sole; the ratio for these stocks combined is 4.1. Sablefish accounts for the largest fraction of groundfish revenues in this sector (almost two-fifths of nominal revenue during the baseline period) and has a ratio of 1.7. Nominal revenue from sablefish averaged $23.5 million per year for these fishery sectors during the baseline period. Under the base case state of nature the difference between the adjusted ACLs and baseline catch is not as great. For sablefish the ratio is only 1.2. On the other hand, the Dover sole adjusted ACL is almost four times as large as baseline catch. For the 2015-2016 biennial period the Council is proposing to increase the Dover sole ACL from 25,000 mt to 50,000 mt. Although historically harvesters have caught a relatively small fraction of smaller ACLs, this suggests there may be an opportunity to garner higher revenue in the future if demand for Dover sole is sufficient. Annual average nominal revenue from Dover sole landed by these sectors is $6.6 million.[65]

Even under the low state of nature scenario Alternative 2 (P*=0.25) does not differ greatly when adjusted ACLs are compared to baseline catch. The exception is Dover sole with a ratio of 2.4 under the low state of nature. This skews the ratio value for these stocks combined, which is 1.3. If Dover sole is removed, the resulting ratio is 0.6. Likewise, under the base case state of nature the ratio is 1.0 when Dover sole is excluded. Coincidentally, the ratios for sablefish are also 0.6 and 1.0 under these two state of nature scenarios. Depending on how effective harvesters could be in catching Dover sole while avoiding species with relatively low ACLs, revenue may not be much different under Alternative 2 than it was during the baseline period.

Alternative 3 (default P* values), shown for the base case state of nature, could result in slightly higher catches compared to the baseline level of catch; the ratio of adjusted ACLs to baseline catch is 1.4. Note that under this scenario the Dover sole ACL is a constant value of 25,000 mt, which is lower than the ABC harvest level even with a P* of 0.25. Given that the Council is proposing an increase in the ACL to 50,000 mt for the 2015-2016 biennial period the scenario shown in Table 4-188 likely under-represents fishing opportunity and potential catch of this species under Alternative 3. Excluding Dover sole, recognizing some of the anomalies resulting from the projections across all scenarios, Alternatives 2 and 3 have adjusted ACL catch proxies equal to baseline catch. Excluding Dover sole, nominal ex-vessel revenue for these species from the trawl and non-nearshore fixed gear average $35 million per year during the baseline period for these sectors.

The minimum catch streams from the projections for the low state of nature are also shown. These are not adjusted based on historical attainment, because in most cases they represent historical average catch rather than a fully attained ACL. The ratio for these stocks combined is 0.8, which suggests adverse socioeconomic impacts, because catches would likely be below those during the baseline period.

[65] Nominal revenue estimates cited here include the non-trawl portion of the shorebased IFQ fishery.

Table 4-188. Catch proxies for major target species in the trawl and non-nearshore fixed gear fisheries. Percent of total groundfish landings in these sectors by weight and nominal value; baseline catch and attainment; cumulative ACLs, adjusted cumulative ACLs and ratio of adjusted ACLs to baseline catch for the action alternatives and the minimum catch streams. Results shown for high, low, and base states of nature scenarios. Note that the minimum catch stream is not adjusted for attainment. Historical catch from Bellman (2013). Stocks combined for thornyheads (longspine and shortspine), and sablefish (north and south of 36° N. lat.).

4.10.3 Commercial Fisheries: Pacific Whiting

Pacific whiting fisheries show greater revenue volatility compared to non-whiting fisheries as indicated in Figure 3-5. For the shoreside whiting fishery inflation-adjusted ex-vessel revenue ranged from $7.7 to $25.8 million and averaged $13.6 million during the 2003-2012 baseline period. For the two at-sea sectors the range was $8.1-$46.6 million with an average of $21.4 million.

Potential future variability in future revenue can be characterized in terms of the CVs for whiting sectors' inflation-adjusted ex-vessel revenue during the baseline period. Table 4-189 shows CVs for revenue from whiting and non-whiting trawl fisheries and for the catch limits on which allocations to these fisheries are based during the baseline period. Whiting fisheries show much higher variability in revenue compared to non-whiting trawl. This at least partly explained by the variability in catch limits; the CV for whiting catch limits is more than double that for non-whiting catch limits.

Table 4-189. CVs for inflation adjsuted ex-vessel revenue and catch limits for whiting and non-whiting trawl fisheries, 2003-2012. (CV for non-whiting catch limits is the sum of commercially important non-whiting species' ACLs.)

Fishery	Revenue	Catch Limit
Whiting		0.25
Shoreside	0.44	
C-P	0.50	
Mothership	0.55	
Non-whiting	0.13	0.12

Non-tribal Pacific whiting sectors ex-vessel revenue under the No Action alternative used to evaluate 2015-2016 ACLs and management measures is $54 million. During the baseline period whiting fisheries (including tribal sectors) landed between 79% and 99% of the catch limit with no strong relationship between the limit and attainment. Since historical variability in revenue has been about twice that of ACLs (Table 4-189), it is likely that exogenous factors play an important role in both attainment and revenues.

In coming years a value similar to this range of revenues during the baseline period may be expected under any of the alternatives, including No Action. However, given the high variability in Pacific whiting abundance, values outside this range could also occur. For example the 2014 U.S. share of the TAC for Pacific whiting is 316,206 mt. Using the 2013 shoreside average price per pound for whiting and assuming the entire non-tribal allocation were caught, this translates into about $27 million for the non-tribal shoreside sector and $37 million for the combined two non-tribal at-sea sectors. While $37 million would lie within the 2003-2012 historical range of revenues for the combined at sea sectors, for the shoreside sector $27 million would lie slightly above the 2003-2012 historical range.

Ten-year projections were not made for Pacific whiting, because yield is highly variable and long-term projections were deemed unrealistic. It is also important to note that the proposed action does not include setting harvest specifications for Pacific whiting; these are set in an intergovernmental forum between the U.S. and Canada. However, whiting is considered in this impact evaluation because ex-vessel revenue from these fisheries is an important component of ex-vessel revenue for the target fisheries.

During the baseline period total ex-vessel revenue from Pacific whiting (including the at-sea sectors) ranged from $16.9 to $66.8 million and this range holds going back to 1997, the first year that at-sea data are available.

4.10.4 Commercial Nearshore Fixed Gear and Recreational Fisheries

4.10.4.1 No Action Alternative

The commercial nearshore fishery is prohibited in Washington but occurs in Oregon and California waters. Recreational fisheries occur primarily in state waters off all three states. Generally, the nearshore commercial fishery and recreational fishery target the same species: black rockfish, blue rockfish, cabezon, lingcod, greenlings, principally kelp greenling, and other rockfish grouped in the nearshore complexes (geographically subdivided north and south of 40°10’ N. lat.).

The nearshore fixed gear sector accounted for 5% of inflation-adjusted revenue from shoreside fisheries during the baseline period. Although this fishery sector is not very significant from a coastwide perspective, as discussed in Sections 3.2.2.4 and 3.2.8 it makes up an important component of groundfish revenue in some coastal communities, particularly in southern Oregon and Northern California. This revenue (from groundfish) ranged from $2.9 million to $4.2 million and averaged $3.6 million. Under No Action it is likely that comparable levels of revenue would be generated.

Recreational groundfish fisheries are managed with time/area closures and bag limits to limit angler effort and catch. Generally, recreational fisheries are managed to limit catch overfished species, yelloweye and canary rockfish in Washington and Oregon, and also cowcod and bocaccio in California. Comparable management measures would be implemented under No Action as those described in Section 4.3. As in the 2015-2016 biennial period, under No Action over the long term these measures would be regularly adjusted in response to new information about catch.

Table 4-190 compares 2005-2012 catch, ACL attainment, and 2014 ACLs for stocks that are targets in nearshore commercial and recreational fisheries. As in Table 4-187, historical catch divided by the 2014 ACL to give an indication of whether more restrictive management measures may be needed to control catch in the future. Average annual catch in previous years is close to or exceeds the 2014 ACL for black rockfish and Cabazon in Oregon and California, and minor nearshore rockfish north. Black rockfish and minor nearshore rockfish north are mostly caught in recreational fisheries. Thus, under No Action over the long term it is likely that recreational management measures would have to take these stocks into account.

Table 4-190. Comparison of commercial nearshore fixed gear and recreational catch (mt), 2005-2012 to ACLs for commercially important nearshore stocks and stock complexes. Commercial catch estimates from WCGOP multi-year data product (Bellman, *et al.* 2013). Recreational catch estimates from RecFIN Recent Estimate Tabulation, http://www.recfin.org/data/estimates/tabulate-recent-estimates-2004-current.

Stock	Average Annual Catch 2005-2012	Attainment	2014 ACL	Catch / 2014 ACL	Comm.-Rec. Split	
Black Rockfish (OR-CA)	608	84%	409	149%	27%	73%
Black Rockfish (WA)	224	35%	1,000	22%	0%	100%
Cabezon (California)	59	61%	158	37%	46%	54%
Cabezon (OR-WA) [a/]	48	109%	47	103%	54%	46%
Lingcod Coastwide [b/]	441	19%	3,941	11%	12%	88%
Minor Nearshore RF North	85	65%	94	90%	39%	61%
Minor Nearshore RF South	485	69%	990	49%	19%	81%

a/ Attainment based on ACLs in 2011-2012 only.

b/ Lingcod has been managed under different geographic units; for comparison catch limits and catch is presented coastwide.

Recreational fisheries can also be evaluated with respect to angler fishing effort. For the 2015-2016 biennial period bottomfish + Pacific halibut marine angler boat trips under No Action are estimated at 835,000 (see Table 4-x) generating personal income of $XX million. During the baseline period (2004-2012) bottomfish + Pacific halibut marine angler boat trips averaged 648,000 annually. As described in Section 3.2.5, California accounted for 82% of marine angler boat trips during the baseline period and the Los Angeles- Orange County-San Diego region alone accounted for 48% of these trips. The change in the number of boat trips over time has been more variable but also greater in California compared to the other two states. The number of these trips averaged 586,203 from 2006 to 2010 but then jumped to an average of 836,837 in 2011-2012. Over the long term, recreational effort and resulting personal income is likely to be within the range of the baseline period.

4.10.4.2 Action Alternatives

Table 4-191 presents data similar to Table 4-188 but for nearshore species important in commercial fixed gear and recreational fisheries. For the Nearshore Rockfish complexes blue rockfish is used as a proxy, because it is the only stock in these complexes for which a projection could be produced. In this case ACLs were only available for the 2005-2012 period so the projected ACLs were adjusted for both the time series difference (by multiplying by 0.8) and historical ACL attainment. Since blue rockfish is managed as part of a complex no historical ACL attainment rate was applied as part of the adjustment. As result, the ratios shown for this species are higher than would otherwise be the case. Species in the Nearshore Rockfish complexes accounted for 22% of landings and 43% of revenue from the commercial fixed gear sector during the baseline period.

Table 4-191. Catch proxies for major target species in nearshore fixed gear and recreational fisheries. Percent of total groundfish landings in these sectors by weight and nominal value; baseline catch and attainment; cumulative ACLs, adjusted cumulative ACLs and ratio of adjusted ACLs to baseline catch for the action alternatives and the minimum catch streams. Results shown for high, low, and base states of nature scenarios. Note that the minimum catch stream is not adjusted for attainment. Historical catch from Bellman (2013). Geographic stocks combined for black rockfish, cabezon and lingcod.

				Alt 1 (P*=0.45)

[a/] Blue rockfish adjusted for time period only (see text for explanation)
[b/] Excluding blue rockfish

Alternative 1 under the high state of nature the overall ratio (excluding blue rockfish) is 1.7, which may be biased downward somewhat by the very low attainment rate for lingcod. Across all fishery sectors (including recreational) the attainment rate for lingcod is only 15%. However, this bias may be counteracted by the high value for blue rockfish, which as discussed above does not take into account attainment rates. Under the base case state of nature scenarios the catch proxies across all the action alternatives differ little from baseline catch with ratios of 1.0 for Alternative 2 and 3 and 1.1 for Alternative 1. For Alternative 2 under the low state of nature scenario the ratio is 0.6 suggesting adverse impacts. Note that the ratio for blue rockfish is 0.3; if blue rockfish status and stock dynamics are actually representative of the species in the Nearshore Rockfish complexesthe adverse impacts could be greater than indicated by combined species ratio (which excludes blue rockfish and by extension the Nearshore Rockfish complexes). As noted above, the Nearshore Rockfish complexes comprise a large proportion of ex-vessel revenue from the commercial nearshore fishery. The minimum catch stream scenario represents a substantial reduction in potential catch compared to the baseline, which would result in severe adverse impacts. The minim catch stream results in catch proxy ratio of 0.5 overall; this is outside of the range of default HCR policies of the alternatives but represents the low end of projected catches.

4.10.5 Buyers and Processors

Data are not available to estimate processor revenues so ex-vessel revenue is used in groundfish harvest specifications impact analyses as a measure of the flow of raw fish into the production process. Although prices for processed fish may not correlate directly with this input cost, the discussion of revenue impacts discussed above for fishery sectors may indicate the relative impact of the alternatives on processors.

Processors would also likely play a role in stimulating demand for particular fish products by developing new products for example. This is relevant to productive, currently under-utilized species such as flatfish.

4.10.6 Fishing Communities

Section 3.2.8 summarizes the economic characteristics of west coast fishing communities during the 2003-2012 baseline period, focusing on the distribution of ex-vessel revenue and the relative importance of different groundfish fishery sectors among ports. Setting harvest specifications has an indirect effect on fishing opportunity, which, along with other factors such as price and allocations, determines the amount of ex-vessel revenue flowing to a particular fishing community. As noted above, the No Action alternative for 2015-2016 harvest specifications uses a 2014 commercial ex-vessel revenue estimate of $124 million, which is the basis for estimating the regional distribution of personal income impacts, shown in Table 4-x. These distributions are based on landing patterns in 2013, and should be broadly similar to the information on landings distributions during the baseline period, as described in Section 3.2.8. All other factors being equal, one would expect the amount and distribution of income to fishing communities would be comparable over the long term if harvest specifications remained at their 2014 values.

As discussed in the previous sections evaluating fishery sector impacts, under the action alternatives catch could increase or decrease relative to baseline catches.

It is not possible to predict changes in community characteristics due to exogenous factors; the description of communities in Section 3.2 during the baseline period is the best characterization of future conditions if exogenous factors do not change. These factors, which could affect the amount and distribution of ex-vessel revenue and income, include:

- Changes in the relative prices of fish and fish products leading to changes in fishery behavior including the amounts landed and the distribution of landings.
- An increase in ACL attainment for a particular species due to technical factors (e.g., more selective fishing gear)
- A decrease in ACL attainment for target species because of increases in stock abundance of non-target species not accounted for in No Action ACLs (the "rebuilding paradox").
- Changes in the distribution of landings due to agglomeration (geographic concentration of related firms)
- Public and private initiatives intended to support the continued viability of fishing communities

As discussed in Section 3.2.8, geographic trends in landings during the baseline period suggest increasing agglomeration at fewer ports. This is likely driven by the shorebased IFQ fishery, which accounts for the largest proportion of coastwide groundfish revenue. But harvest specifications are unlikely to be a substantial contributor to this trend, because exogenous factors are likely to have a greater influence on landing patterns. For example, concentration of processing facilities could be mediated by owner/operator preferences and overland transport costs related to trucking fish from landing sites to processing facilities. Under No Action, ACLs would remain constant over time so one might expect the trends shown in Figure 3-19 to continue until a plateau is reached. On the other hand, if stock abundance increases without a corresponding increase in catch limits (the "rebuilding paradox"), and harvesters are unable to avoid catching stocks with low ACLs, their ability to attain target species' ACLs could be impeded. This could affect fishing communities differently depending on the operational characteristics of their fleets. While techniques and technologies to more selectively target species and avoid those with low catch limits might be expected to eventually spread to all fishery participants, local fishing grounds vary with respect to the occurrence of low ACL species (such as overfished/rebuilding species). The FEIS for Groundfish FMP Amendment 20 (PFMC 2010) identified ports "adjacent to fishing grounds with high constraining overfished species abundance" (p. 530). While that analysis focused on overfished species, if ACLs remain constant while species abundance increases, various other species could become a limiting factor for local fisheries. Interventions outside the biennial process, such as the trawl rationalization adaptive management program, are likely to have a much greater effect on the distribution of landings.

As discussed above, potential catch under the action alternatives is likely to be close to baseline period catch, based on the adjusted cumulative ACLs ratios. The influence of exogenous factors, discussed with respect to the No Action Alternative, would be equally influential if ACLs and resulting management measures were established under any of the three ACL policies. Alternative 2 implements a larger precautionary reduction from the OFL compared to Alternatives 1 and 3 (although under the proposed Amendment 24 procedures the Council could modify the default ACLs). The lower ACLs under Alternative 2 would be more limiting in terms in cases where the proportion of the ACL caught (the attainment rate) increases towards 100%. Differential socioeconomic impacts to fishing communities under any set of ACLs would more likely result from differences between catch limits for stocks under any of the alternatives rather than the broader policy differences represented by the action alternatives.

4.10.7 Summary of the Impacts of the Alternatives

All other factors being equal, ex-vessel revenue, personal income, and employment is likely to remain within the range exhibited during the recent past. Table 4-192 shows the maximum and minimum total annual revenue for whiting and non-whiting fisheries and all groundfish fisheries from 1998 to 2012. This period was chosen because 1997-98 represents a breakpoint where there was sudden precipitous decline in groundfish ex-vessel revenue. For groundfish fisheries as a whole revenue ranged from $63.5 million to $128.2 million. This is the best estimate of the likely range in future real revenues recognizing many factors that could affect actual landings, beyond the biological yield from stocks. The most important of these uncertainties is the true future yield from stocks. The fraction of this yield that is actually landed is almost as important. Changing ACL attainment is a function of technical innovation and market demand. Technical innovation (including institutional arrangements such as risk pools) allows harvesters to better match actual catch in a multi-species fisheries to harvest limits.

Table 4-192. Maximum and minimum annual inflation adjusted (2012) revenue for non-whiting and whiting fishery sectors, and all groundfish.

	Revenue	Year
Nonwhiting		
Min	$46,774,698	2004
Max	$70,008,542	2011
Whiting		
Min	$16,013,680	2002
Max	$66,819,804	2008
Total		
Min	$63,484,665	2002
Max	$128,212,249	2011

The No Action Alternative established 2014 ACLs for the indefinite future. The No Action Alternative in Section **Error! Reference source not found.** (socioeconomic impacts of 2015-2016 harvest specifications and management measures) provides a first approximation of ex-vessel revenue and personal income impacts under the long-term No Action Alternative. In that section annual coastwide commercial and tribal ex-vessel revenue for No Action is estimated to be $124 million near the maximum for the 1998-2012 period. The annual average for the 2003-2012 baseline period is $91 million. This difference is mainly explained by the increasing Pacific whiting TAC since 2009, because the 2015-2016 No Action Alternative uses 2013 revenues.

Since No Action implements static ("constant catch") ACLs, over the long term the discrepancy between these ACLs and actual abundance could lead to adverse socioeconomic impacts since additional yield that might otherwise be available for harvest would not be accommodated under these ACLs. A prime example is Dover sole, where the 2014 policy is a 25,000 mt constant catch limit. Furthermore, the so-called rebuilding paradox, where increasing abundance of a stock makes it more difficult for them to be avoided in a multi-species fishery, could result in the imposition of restrictive management measures affecting fishing opportunity for other species. Even in catch share fisheries, where there is greater scope for innovation, technical limitations could prevent harvesters from attaining their target species quotas.

The action alternatives policies allow higher harvests than No Action. Table 4-193 compares No Action ACLs to the annual average of the 10-year catch streams for action alternatives under different state of nature scenarios for the commercially and recreational species presented above. The ratio of the 2014 ACL to the annual average catch stream also presented. For the trawl and non-nearshore target species combined the ratios for the base case state of nature range from 1.9 times the 2014 ACLs under Alternative 1 to 1.1 time the 2014 ACLs under Alternative 3. For Alternative 2 the ratio 1.6 for the base case. Alternative 3 has a smaller ratio than the more risk averse policy (P*=0.25) under Alternative 2 because of the default constant catch ACL of 25,000 mt for Dover sole. As discussed elsewhere, the Council proposes doubling this ACL to 50,000 mt for 2015-2016, so the combined species ratio for Alternative 3 is unrealistically biased downward. For the nearshore commercial and recreational fishery target species these ratios are small, ranging from 1.1 under Alternative 1 to 0.9 for Alternative 2.

Table 4-193. Comparison of ACLs for the alternatives for selected stocks

		Annual Average ACLs				
Stock	**2014 ACL**	**Alt 1 High**	**Alt 1 Base**	**Alt 2 Low**	**Alt 2 Base**	**Alt 3 Base**

As noted above, the deterministic projections used to evaluate long-term impacts of the action alternatives assume perfect information so that stock biomasses tend to converge on the policy target (B_{MSY} or proxy thereof). In a decision table the state of nature scenarios are intended to bracket uncertainty around key model parameters; here they are presented to bracket potential catch if lower probability parameter values are the “true” values. But in a multispecies fishery involving a variety of different targeting strategies it is likely that one or more stocks will fall below their target biomasses, because of factors other than management policy dictating catch. According to the management framework more restrictive catch limits would be required for those stocks, potentially affecting harvesters who cannot avoid catching those species. Given the range of unpredictable exogenous factors influencing the proposed action (setting harvest specifications and related management measures) it is likely that future ex-vessel revenue from the groundfish fishery across the action alternatives will be within the range of annual values recorded for the baseline period.

Benefits to harvesters are a function of net revenue or "profits," a function of costs, including opportunity costs. Figure 3-17 shows the estimated breakdown of costs by category for the shorebased IFQ and at-sea co-op fisheries. Wages are the largest component of costs for the trawl component; for the fixed gear segment quota is the largest share and wages are a smaller fraction of total costs. Changes in net revenue would result from changes in the price of these costs components relative to ex-vessel prices for fish.

4.11 Long-term Impacts of Setting Harvest Specifications and Management Measures on Essential Fish Habitat

Setting harvest specifications does not directly affect essential fish habitat (EFH). Furthermore, an analysis of groundfish trawl logbook data does not reveal any clear relationship between catch limits and fishing effort (see Appendix A). As discussed in Section 3.3.3.3, fishing effort in the shoreside trawl fishery has declined substantially since 2010 while catch generally increased. Section 3.2.3 reports participation trends in groundfish fixed gear and trawl fisheries during the baseline period. Non-nearshore fishery participation has remained relatively stable while nearshore fishery participation has declined. The trend in effective fishing effort is not directly related to participation, but it is unlikely that fishing effort increased during the baseline period. Considering the lack of a clear relationship between seeting harvest specifications and fishing effort it is not possible to distinguish the effect on EFH of the long-term Amendment 24 alternatives. To the degree that the amount and spatio-temporal distribution of gear-specific fishing effort does not change from historical patterns, adverse impacts to EFH from the groundfish fishery are likely to be equivalent to the historical impacts described in Section 3.3, which serves as a proxy for describing the impacts of the No Action Alternative.

Groundfish fisheries have negligible impact to the water column itself, parts of which are designated EFH under other FMPs. Benthic habitats are disturbed by gear types the contact the bottom. These effects are summarized in Section 3.3 and described in more detail elsewhere (NMFS 2005; NMFS 2013b; NMFS 2014b).

The proposed action does indirectly mitigate adverse impacts to EFH from fishing through the use of time/area closures. As discussed in Sections 3.3 and 4.4, Groundfish Conservation Areas (GCAs), established as top-down measures to reduce bycatch of overfish species, have an ancillary mitigating impact on the adverse impacts of groundfish fisheries on EFH by prohibiting fishing within these areas.[66] If an area is closed for an extended period of time, the EFH within it may recover from these adverse impacts. Estimates of recovery times for EFH are shown in Table 3-24 by habitat and gear type causing the impact. These range from less than a year to decades. Although the maximum recovery time shown in the table is 56 years (the upper end of the range of recovery times for offshore biogenic habitat impacted by trawl gear), estimates range into centuries for some deepwater coral species. However, Table A.3a.2 in NMFS (2013a) shows a maximum recovery time across gear types and habitat categories of 3.2 years.

While some GCA configurations, such as the Cowcod Conservation Areas, have remained static since implementation, in the case of the trawl RCA boundaries change seasonally and year to year to optimize fishing opportunity versus bycatch avoidance. Inseason changes of this kind involve moving seaward and shoreward boundaries of the RCA using sets of waypoints published in Federal regulations that

[66] Other closed areas, principally EFH Conservation Areas, were established with the objective of mitigating such impacts or (in the case of MPAs) addressing a variety of objectives closely related to habitat protection. However, establishing or modifying these areas is not part of the proposed action.

approximate different depth contours. The depths closed to trawl gear by RCAs also vary latitudinally. Over time waypoints comprising a particular depth boundary have been changed so that they better approximate the actual depth contours. These improvements in accuracy are generally minor with respect to the area affected and thus have negligible potential impact on EFH related to permitting fishing in areas that were previously inside the trawl RCA. As an example, Appendix C to the 2013-2014 Groundfish Harvest Specifications FEIS (PFMC and NMFS 2012) includes an analysis of proposed changes to RCA waypoints to improve their accuracy.

It is likely that as overfished species stocks rebuild and other measures are implemented that more effectively and efficiently control catch of species with low ACLs, the rationale for maintaining GCAs, at least in their present configurations, will diminish. However, the need to control catch because of the changed status of other species could lead to the implementation of new GCAs. For example, for the 2015-2016 biennial period the Council is developing new trawl RCA boundaries that could be implemented inseason to control the catch of rougheye rockfish. It is also possible that over the long term time/area closures could be developed with the dual objectives of controlling catch and mitigating adverse impacts of fishing to EFH. This might be the case if one or more stocks with intrinsically low yield are found to associate with benthic habitat types that have long recovery times.

In the past RCA boundaries were changed frequently as a routine matter based on the premise that the effects of such changes had been previously analyzed when a particular RCA configuration was initially implemented. However, as discussed in Sections 3.3 and 4.4, as part of a 2014 rulemaking to modify the trawl RCA boundary, NMFS identified criteria for considering adverse impacts to EFH from such changes, including the history of fishing that may have caused adverse impacts, the estimated recovery time of the EFH in the area where fishing will be permitted, and related habitat conservation considerations (such as proposals to close the area to fishing specifically to protect EFH). These criteria would be taken into consideration in focused analyses for RCA changes judged to have more than a 'minimal and temporary' adverse impact to EFH. As with the bycatch objective of RCAs, evaluation of adverse impact to EFH would consider the tradeoff of conservation and socioeconomic costs and benefits based on the practicability standard in Federal regulations at 50 CFR 600.815(a)(2)(iii).

4.11.1 Summary of the Impacts of the Alternatives

4.12 Long-term Impacts of Setting Harvest Specifications and Management Measures on the California Current Ecosystem

4.12.1 Impact Evaluation Methods

Section 3.4.3 reviews published results from the use of the California Current Atlantis Ecosystem Model to evaluate the cumulative effects of fishery removals on ecosystem structure. Kaplan (2014, reproduced in Appendix A) conducted a similar evaluation of the harvest policies proposed in the Amendment 24 alternatives to simulate and evaluate food web impacts of groundfish fisheries. As noted by Kaplan, these simulations do not take into account stressors such as habitat damage by fishing gear, climate change, or ocean acidification.

The analysis uses the 10-year projections from groundfish stock assessments but extends the simulation period to 30 years in order to better reveal food web effects. Selected catch streams from the stock assessment projections were used for the first 10 years of the simulation; catch projections were extended for at least another 20 years based on the fishing mortality rates experienced in the tenth year of the projection period. The state of nature scenarios from the stock assessment projections were converted to ecosystem productivity by transferring the productivity parameters lnRo (log of initial, unfished number of recruits), steepness (h), and natural mortality (M) from the assessments to the ecosystem model.[67] Four catch streams are modeled:

- **High Catch Stream**: ABC removals of P* = 0.45 when the stock assessments assumed the stocks were in their high states of nature. This extreme scenario assumes a median catch scalar across Atlantis functional groups of 10.3x, relative to the benchmark Recent Average catches (ranging from 1.7x for Sablefish to 618x for Small shallow rockfish)
- **Moderately High Catch Stream**: ABC removals of P* = 0.45 when the stock assessment assumed the stock was in its base case state of nature. The exception is for Atlantis functional groups that include overfished species, for which the moderately high catch stream corresponds to catches equal to the 2014 ACL. Overall, the moderately high catch stream assumes a median catch scalar across Atlantis functional groups of 2.7x, relative to the benchmark Recent Average catches (ranging from 1.1x for Sablefish to 68x for Small shallow rockfish). Catches of groups with overfished species are scaled by less than or equal to 2.8x their benchmark Recent Average catches.
- **Recent Average Catch Stream**: Recent Average Catch when the stock assessment assumed the stock was in its base case state of nature.
- **Low Catch Stream**: The lower of recent average catch or ABC removals of P*=0.25, when the stock assessment assumed the stock was in its low state of nature.

Since the Pacific whiting (hake) fishery is outside the scope of the actions in this EIS, whiting catch was not varied between scenarios.

Results are reported with respect to the following metrics, which correspond to the metrics reported in Section 3.4.3 from Kaplan (2012):

- mean trophic level of the catch
- mean trophic level of biomass
- ratio of target species biomass to catch
- total system biomass
- abundance of piscivorous fish (trophic level >= 4)
- abundance of forage fish
- abundance of krill (euphausiids)
- the number of healthy assessed stocks above B25 (flatfish) or B40
- the number of healthy non-assessed stocks above B25 (flatfish) or B40
- abundance of marine mammals and birds ("median depletion" of these stocks)

The two 'healthy stocks' metrics require an estimate of B_{25} or $B_{40,}$ and the abundance of marine mammals and birds metric requires an estimate of B_{100}. These were calculated based on an unfished Atlantis simulation with base productivity and no fishing.

[67] In the discussion here, the term "state of nature" can be confusing. As discussed elsewhere in this EIS, the term refers to uncertainty about the true value of key parameters in the stock assessments. Low and high state of nature parameter values represent the tails of the likelihood distribution for the value. Within a stock assessment, these distributions are developed independent of any explicit consideration of ecosystem state.

Each of the ten metrics is standardized relative to its value in a benchmark management scenario that projects a base case productivity state of all stocks in the ecosystem model, with recent average catches projected into the future.

4.12.2 Evaluation of the Alternatives

The simulations bracket the harvest specification policies of the alternatives to evaluate the broadest possible range of impacts. The Low Catch scenario corresponds to the lower of Recent Average Catch or the policy in Alternative 2 (P*=0.25) while the benchmark simulation (Recent Average Catch, base case productivity) is representative of No Action. As noted above, recent average catch under base case productivity is the benchmark for comparison. (Thus in Table 4-194values are 1.00 across all the metrics for this scenario.) The High and Moderately High Catch scenarios bracket Alternative 1. Alternative 3 (default, or 2014, HCRs) is intermediate in this range, especially assuming the base case state of nature. Combining four catch stream scenarios with three ecosystem productivity states results in 12 sets of results. Since the 10-year metrics show the same trends as the metrics from averaging values for years 25-30, the focus below is on the year 25-30 metrics, which are displayed in Table 4-194.

4.12.2.1 Direct Impacts Assuming Base Ecosystem Productivity

Three metrics represent direct impacts to harvested stocks: Ratio of Target Species Biomass to Catch, Abundance of Piscivores, and Number of Healthy Assessed Stocks.

Under base productivity of the ecosystem model, the Low Catch scenario (analogous to Alternative 2) led to ecosystem metrics within 1% of the Recent Average Catch scenario benchmark scenario (No Action). This is due to the underlying catch streams themselves, since for most functional groups Recent Average Catches are equal to Low Catch streams.

The primary impact of increased catches (High Catch streams, analogous to Alternative 1 and high state of nature) is on the Abundance of Piscivores, which directly reflects the abundance of groundfish fishery target species. The High Catch streams caused a ~50% reduction in Abundance of Piscivores, and the Moderately High catch streams caused a ~25% reduction in this metric. The Number of Healthy Assessed Stocks and Ratio of Target Species Biomass to Catch metrics reflect the abundance of both groundfish and other stocks. These two metrics decline by at most ~20% after 25-30 years of High Catch and ~15% after 25-30 years of Moderately High Catch. Other ecosystem metrics responded by less than 5%. By years 25-30 the Abundance of Krill increases slightly due to indirect effects discussed below. Overall, the metrics that best reflect food web effects (rather than effects of direct harvest) suggest minimal impacts of the tested harvests.

The sensitivity of the three metrics representing direct impacts to harvested stocks (Ratio of Target Species Biomass to Catch, Abundance of Piscivores and Number of Healthy Assessed Stocks) to increased catches should be expected *a priori.* Relative to the benchmark scenario (Recent Average Catch, base case productivity, representative of No Action), the High Catch scenario (analogous to Alternative 1, high state of nature) involves a median catch increase across Atlantis functional groups of 10.3x, and the Moderately High Catch scenario involves a median catch increase of 2.7x.

The main direct impact predicted by the ecosystem model under High Catch is full depletion of Large flatfish (e.g., arrowtooth flounder), Small shallow rockfish, and Dover sole (to ~0 biomass by year 30, see Table 4-195). Species that show 30-70% declines in biomass under the High Catch stream (analogous to Alternative 1, high state of nature), relative to biomasses under the benchmark catch stream (Recent Average Catch, base case productivity, representative of No Action) include sablefish, Small demersal sharks, Yelloweye and Cowcod, Shallow Large Rockfish, Deep large rockfish, and Large Demersal Predators such as lingcod.

Like the High Catch Scenario, the Moderately High Catch streams (analogous to Alternative 1, base case state of nature) led to substantial declines for several functional groups: nearly 100% for Dover sole, ~40% for Large flatfish, and ~25% for Large Demersal predators after 25-30 years. The abundance of all other groups was within approximately 15% of the benchmark simulation (No Action analogue). Within the ecosystem model, these three groups can sustain the benchmark, but can't sustain the large increases in catch (e.g., an 11-fold increase for Dover sole) assumed under Moderately High Catch, or the much higher increases assumed under High Catch.

These simulations assume specified catches (years 1-10) and constant fishing mortality rates for (years 11-30) with no management feedback. This implies no management response to new information about stock status, which is unlikely. In fact, the biennial harvest specifications process is the mechanism for making such adjustments. Maintaining policies resulting in high catch streams when productivity results in biomass decline (depletion) is unlikely given the feedback mechanisms in the management system.[68]

4.12.2.2 Indirect impacts, Assuming Base Ecosystem Model Productivity

Under the base ecosystem productivity state, higher catches (Under High Catch or Moderately High Catch, Alternative 1 analogues) led to moderate indirect effects through the food web; abundance of krill was predicted to increase by 1-8% by years 25-30, as predators (groundfish) on krill were removed (Table 4-194). Similarly, shrimp biomass increased in abundance by 3-19%. The strongest indirect effect of the High Catch scenario was an increase in a predator of krill, Large planktivores (mackerel) (30% increase under High Catch and ~10% increase under Moderately High catch). A predator on large planktivores, Miscellaneous pelagic sharks, also therefore increased, though by less than 10%. Cephalopods declined slightly (≤ 6%) due to shark predation (Table 4-195).

As predation and competition by harvested groundfish decreased in scenarios with higher catch, Miscellaneous nearshore fish (croaker, sculpin) and Shortbelly rockfish both increased 4% (under Moderately High Catch) and 12% and 8%, respectively (under High Catch). These two groups have low and constant fishing mortality rates that are not varied here, thus the responses are due to food web effects only.

Dolphins and porpoises increased 6% under High catch and 2% under Moderately High catch, and other mammal and bird groups showed less than 1% response to increased catches (Table 4-195). All other vertebrate and invertebrate groups responded to High Catches by <5%. Overall, the ecosystem model predicted a limited food web response, which should be viewed as a qualitative prediction of potential ecosystem response.

4.12.2.3 Low and High Ecosystem Productivity

Kaplan (2014, reproduced in Appendix A) also evaluated the effect of changes in ecosystem model productivity, in combination with the four catch streams. In these simulations the productivity of the ecosystem model was adjusted to approximate the productivity implied by the 'States of Nature' from the 37 stock assessments, as well as the Pacific whiting (hake) stock assessment.

Similar to when the ecosystem was assumed at base productivity, in high productivity and low productivity states, most ecosystem metrics declined by less than 5% relative to their benchmark values

[68] A management strategy evaluation approach would be necessary to simulate these feedback mechanisms.

by Year 10 or Year 25-30 (Table 4-194). Again, the exceptions are Ratio of Target Species Biomass/Catch (which partially reflects groundfish species tested with the catch streams), and Abundance of Piscivores and Number of Healthy Assessed Stocks (which echo the direct effects forced with the catch streams).

The most extreme mismatch between ecosystem productivity and catch streams occurred in the low productivity state and High Catch scenario, where Abundance of Piscivores fell to 42% of the value in the benchmark scenario by years 25-30. This is due to declines in the same species noted above for the base productivity state and High Catch scenario, with the addition of 20-25% declines in abundance of Pacific whiting (hake), Deep small rockfish, and Small flatfish. This is a direct result of the parameterization of lower productivity for these stocks in this scenario. In particular, compared to base productivity, at low productivity increasing catches from Recent Average Catch to High Catch led to stronger declines (~ 20% additional decline) in the Yelloweye and cowcod, Deep large rockfish, Small flatfish, Large demersal predators, and Small demersal sharks (dogfish) functional groups. Therefore, the direct impact of the catch streams on these species or groups is stronger in the low productivity state compared to high productivity.

4.12.3 Summary of the Impacts of the Alternatives

In summary, the main effect of the action alternatives, bracketed by the catch streams used in the Atlantis California Current Ecosystem Model simulations, was on the groundfish stocks directly harvested in these simulations. This is reflected in the ecosystem metrics of Piscivores, Number of Healthy Assessed Stocks, and Target Biomass/catch.

Food web effects were evident but not common. In the Moderately High catch scenario, and especially in the High catch scenario, the Atlantis ecosystem model predicted some indirect effects via krill, species linked to krill, and some prey of groundfish. Low catch streams, and resulting model dynamics, are similar to the No Action benchmark (Recent Average Catch, base productivity).

Ecosystem model high and low productivity states likely bracket the range of uncertainty regarding stock productivity, but it is difficult to place probabilities on these alternate ecosystem model productivities. Overall, most ecosystem metrics responded by <5% regardless of the productivity assumed in the ecosystem model. However, the three ecosystem metrics that directly reflect groundfish abundance are more sensitive to the catch streams at low ecosystem productivity states.

Alternative 3 (2014 HCRs, representing the defaults) was not explicitly modeled with respect to the catch streams from the stock assessment projections. For 13 stocks the default HCR is ACL=ABC and P*=0.45, the policy applied to all stocks under Alternative 1.[69] For other stocks, the default HCRs result in lower ACL values. The sum of the catch streams for Alternative 3 under the base case state of nature is one-third the sum for Alternative 1 under the high state of nature (equivalent to the High Catch scenario used in the Atlantis simulation) and 3.5 times the sum for the Recent Average Catch stream under the base case (the benchmark or No Action scenario in the Atlantis simulation). This suggests that Alternative 3 would have direct and indirect impacts intermediate between the Moderately High Catch scenario (Alternative 1, base case state of nature) and the Recent Average Catch benchmark scenario. However, as discussed in Section 4.10, historical catch (or recent average catch) has been well below catch limits for most stocks. While ACL attainment could increase for some target stocks, it is very

[69] These stocks are aurora rockfish, blackgill rockfish S of 40º10’ N lat., blue rockfish S of 42º N lat. , cabezon (CA), cabezon (OR), chilipepper rockfish, English sole, gopher rockfish S of 40º10’ N lat., greenstriped rockfish, lingcod N of 40º10’ N lat., petrale sole, rougheye/blackspotted rockfish, and splitnose rockfish.

unlikely that it will approach the aggregate level of the catch streams used in this evaluation, which are based on full attainment of ACLs for all stocks.

Table 4-194. Value of ecosystem metrics, average over years 25-30. (from Table A4 in Kaplan 2014, reproduced in Appendix A) 'Productivity' refers to productivity of the ecosystem model, which is forced by catch streams (low, high, moderately high, or recent average) taken from stock assessments. Values are reported relative to benchmark scenario (Base productivity and Recent Average catch stream).

	Mean trophic level of the catch	Mean trophic level of biomass	Ratio of target species biomass to catch	Total system biomass	Abundance of piscivores	Abundance of forage fish	Abundance of krill (euphausiids)	Num. healthy assessed stocks	Num. healthy non-assessed stocks	Abundance of birds and mammals
Low Productivity, Low Catch	0.99	0.99	1.00	0.97	1.17	1.03	0.98	1.00	1.00	1.00
Low Productivity, 'Recent Average' Catch	0.99	0.99	0.99	0.97	1.16	1.03	0.98	1.00	1.00	1.00

Refractory detritus	1.00	1.00	1.00	0.99

4.13 Long-term Impacts of Setting Harvest Specifications and Management Measures on Protected Species

Setting harvest specifications does not directly affect protected species. Furthermore, an analysis of groundfish trawl logbook data does not reveal any clear relationship between catch limits and fishing effort (see Appendix A). As discussed in Section 3.3.3.3, fishing effort in the shoreside trawl fishery has declined substantially since 2010 while catch generally increased. Equivalent information is unavailable for fixed gear fisheries. Section 3.2.3 reports participation trends in groundfish fixed gear and trawl fisheries during the baseline period. Non-nearshore fishery participation has remained relatively stable while nearshore fishery participation has declined. The trend in effective fishing effort is not directly related to participation, but it is unlikely that fishing effort increased during the baseline period. Over the long term, alternative harvest policies represented by the Amendment 24 alternatives are indistinguishable with respect to the effect on protected species. To the degree that the amount and spatio-temporal distribution of gear-specific fishing effort does not change from historical patterns, adverse impacts to protected species from the groundfish fishery are likely to be equivalent to the historical impacts described in Section 3.5, which serves as a proxy for describing the impacts of the No Action Alternative.

NMFS and USFWS have engaged in Section 7 consultations with respect to the effects of the groundfish fishery on ESA-listed species; Section 3.5.2 summarizes the resulting Incidental Take Statements. Over the long term, exceeding these levels would likely trigger reinitation of the Section 7 consultation and the development of additional measures to ensure takes do not jeopardize the continued existence of listed species.

Marine mammals not listed under the ESA are still protected under the MMPA. Estimated takes of non-ESA-listed marine mammals in groundfish fisheries are unlikely to result in PBR being exceeded if takes are generally similar to what has been experienced during the baseline period. This should allow these species to recover to their OSP levels.

Seabirds not listed under the ESA are incidentally killed in groundfish fisheries. Generally, the level of mortality is negligible with respect to the population status of these species. Black-footed albatross has the highest number of estimated mortalities across observed species (Jannot, *et al.* 2011) and is listed as Vulnerable on the IUCN Red List. Mitigation measures being implemented in fixed gear fisheries based on the USFWS Section 7 consultation for short-tailed albatross are likely to also reduce mortality of this species.

<u>No Action Alternative</u>: There is no information to conclude that protected species takes will differ substantially from the average level of takes during the baseline period. A substantial increase in the level of take would trigger action under applicable law to mitigate any increased take, if necessary.

<u>Alternative 1</u>: There is no information to conclude that protected species takes will differ substantially from the average level of takes during the baseline period. A substantial increase in the level of take would trigger action under applicable law to mitigate any increased take, if necessary.

<u>Alternative 2</u>: There is no information to conclude that protected species takes will differ substantially from the average level of takes during the baseline period. A substantial increase in the level of take would trigger action under applicable law to mitigate any increased take, if necessary.

<u>Alternative 3</u>: There is no information to conclude that protected species takes will differ substantially from the average level of takes during the baseline period. A substantial increase in the level of take would trigger action under applicable law to mitigate any increased take, if necessary.

4.14 Long-term Impacts of Setting Harvest Specifications and Management Measures on Non-groundfish Species

Section 3.6 describes non-groundfish species caught in groundfish fisheries based on WCGOP estimates (Bellman, *et al.* 2013). Over the long-term it is not possible to predict how non-groundfish catch could change, especially since there is no correlation between total catch and non-groundfish catch during the baseline period (2003-2011). Non-groundfish are not targeted and infrequently landed on groundfish directed trips for economic and regulatory reasons. These factors are unlikely to change in the foreseeable future. Therefore, patterns of non-groundfish catch during the baseline period provide the best available information for future catch.

Tribal shoreside and at-sea whiting sectors accounted for 38% of non-groundfish catch. Management measures for these sectors are not directly established as part of the proposed action. Instead, the Federal government, through the Council process, reaches an agreement on the level of catch that will occur in the tribes' usual and accustomed fishing grounds. Non-groundfish catch declined in the shorebased IFQ/trawl sector, which account for the largest proportion of non-groundfish catch in commercial sectors at 28%, over the baseline period from 7.7% (2,240 mt) in 2003 to 3.4% (809 mt) in 2011. The drop in 2011 could be an ancillary effect of trawl rationalization if changes in fishing strategies has an indirect effect on non-groundfish catch. Gear switching could be a factor, because fixed gear fisheries have lower bycatch of non-groundfish. The shorebased IFQ sector is subject to IBQ for Pacific halibut, which is effective in controlling bycatch mortality of this commercially important species

4.14.1 Summary of the Impacts of the Alternatives

No Action Alternative: There is no information to conclude that non-groundfish catch will differ substantially from the average level during the baseline period. Fishery monitoring allows any such change to be detected. Over the long-term, if continuing catch of a non-groundfish species in the groundfish fishery triggered a conservation concern appropriate mitigation measures could be implemented through other Federal/state authorities or pursuant to the Groundfish FMP.

Alternative 1: There is no information to conclude that non-groundfish catch will differ substantially from the average level during the baseline period. Fishery monitoring allows any such change to be detected. Over the long-term, if continuing catch of a non-groundfish species in the groundfish fishery triggered a conservation concern appropriate mitigation measures could be implemented through other Federal/state authorities or pursuant to the Groundfish FMP.

Alternative 2: There is no information to conclude that non-groundfish catch will differ substantially from the average level during the baseline period. Fishery monitoring allows any such change to be detected. Over the long-term, if continuing catch of a non-groundfish species in the groundfish fishery triggered a conservation concern appropriate mitigation measures could be implemented through other Federal/state authorities or pursuant to the Groundfish FMP.

Alternative 3: There is no information to conclude that non-groundfish catch will differ substantially from the average level during the baseline period. Fishery monitoring allows any such change to be detected. Over the long-term, if continuing catch of a non-groundfish species in the groundfish fishery triggered a conservation concern appropriate mitigation measures could be implemented through other Federal/state authorities or pursuant to the Groundfish FMP.

4.15 Cumulative Impacts

A cumulative effects analysis is required by the Council on Environmental Quality (CEQ) (40 CFR part 1508.7). The purpose of a cumulative effects analysis is to consider the combined effects of many actions on the human environment over time that would be missed if each action were evaluated separately. CEQ guidelines recognize that it is not practical to analyze the cumulative effects of an action from every conceivable perspective, but rather, the intent is to focus on those effects that are truly meaningful. This Section of the EIS addresses the significance of the expected cumulative impacts as they relate to the federally managed groundfish fishery.

4.15.1 Affected Resources

In Chapter 3 (Description of the Affected Environment) the environmental components affected by the proposed action are identified and described. Therefore, the significance of the cumulative effects will be discussed in relation to those affected environmental components as grouped below:

- Groundfish and (Section 3.1)
- The socioeconomic environment or human communities (Section 3.2)
- Essential fish habitat and (Section 3.3)
- The California Current ecosystem (Section 3.4)

- Protected species (Section 3.5)
- Non-groundfish fish stocks and (Section 3.6)

4.15.2 Geographic Boundaries

The analysis of impacts focuses on actions related to the management unit species in the Groundfish FMP. The geographic scope of the affected resources listed above is EEZ of the states of Washington, Oregon, and California.

4.15.3 Temporal Boundaries

The temporal scope of past and present actions for the affected resources encompasses actions that occurred after FMP implementation (1982) and more specifically during the baseline period, 2003-2012, which is the temporal context within which affected resources are described in Chapter 3. For endangered species and other protected resources, the scope of past and present actions is determined by analysis pursuant to the ESA and MMPA, including biological opinions for the groundfish fishery and marine mammal stock assessment reports. The temporal scope of future actions for all affected resources extends about 10 years into the future. This period was chosen in order to characterize conditions during future biennial management periods for which harvest specifications and management measures will be set. A 10-year time period allows comparisons to made to the 10-year baseline period.

4.15.4 Effects of Past, Present, and Reasonably Foreseeable Future Actions Other than the Proposed Action

A regular cycle of stock assessment, setting harvest specifications, and establishing related management measures allows the Council and NMFS to regularly assess the status of the fisheries and to make necessary adjustments to ensure that there is a reasonable expectation of meeting the objectives of the Groundfish FMP and the Magnuson-Stevens Act, especially the objective of achieving optimum yield. Achieving OY involves monitoring stock characteristics (fishing mortality, recruitment, etc.) and formally assessing stocks where the data are available. The management framework is adaptive such that the receipt of new information informs decisions about setting harvest limits in future years through each biennial harvest specifications cycle. Compliance with this regulatory regime should result in positive long-term outcomes taking into account the cumulative impacts of past, present, and reasonably foreseeable future Federal fishery management actions. Constraining fishing effort through regulatory actions can often have negative short-term socioeconomic impacts. These impacts are usually necessary to bring about long-term sustainability of a given resource, which should, in the long-term, promote positive effects on human communities, especially those that are economically dependent upon groundfish stocks.

Past and present actions and their effects are described in Chapter 3. This forms the environmental baseline. The cumulative effect results from the combination of the effects of these past and present actions, reasonably foreseeable future actions, and the proposed action. Ongoing and reasonably foreseeable actions with detectable effects are summarized below. (Note that establishing harvest specifications and management measures for future bienniums is part of the proposed action.)

<u>Fishery Management Related</u>

- <u>Past groundfish harvest specifications and management measures.</u> Past harvest specifications (or misspecifications) contribute to the current status of managed stocks. Management measures directly or indirectly control catch, affecting stock status, fishing opportunity, harvester costs and net revenue, and personal income and employment in fishing communities.

- Review of groundfish essential fish habitat designation and mitigation measures. The Council has completed Phase II of a three-phase review process. Phase I compiled available information on Pacific Coast groundfish habitat associations, fishing activities, prey species, and many other elements of groundfish EFH. During Phase II proposals for revised designations of groundfish EFH and additional mitigation measures were solicited and eight proposals were reviewed and reported on to the Council in November 2013. In Phase III the Council will consider action to amend the components of groundfish EFH.
- The Council's Fishery Ecosystem Plan. The Council is developing measures to protect unfished and unmanaged forage fish species pursuant to an initiative identified in the FEP. This action involves amending all current FMPs to prohibit targeted harvest of specified forage species. These protections could benefit both currently unmanaged fish stocks and managed stocks that depend on forage fish.
- Regulatory adjustments to the trawl rationalization program. Through a series of rulemakings based on Council recommendations, a variety of adjustments to the trawl rationalization program are being implemented. In general, these measures are intended to make rationalized fisheries operate more efficiently and/or clarify the intent of regulations. Measures that have been implemented or are in the rulemaking process include eliminating the prohibition on further quota pound trading after December 15 each year, changing requirements for observer/catch monitor contractors, and establishing fees to recover costs of the program as required by the MSA. Future measures include establishing a common start date for the Pacific whiting season for all sectors and allowing a vessel to be registered to permits with both trawl and fixed gear endorsements and user the resulting combined limit. The Council is also developing a regulatory package to allow electronic monitoring as an alternative to human observers. Beginning in 2014, the Council will prioritize the development of all new management measures not implemented through the biennial process. The first of these "omnibus" considerations is scheduled for the June 2014 Council meeting. This will create a useful inventory of external fishery related actions.
- Seabird avoidance measures. A regulatory package to implement requirements from the Section 7 consultation for short-tailed albatross is currently in development.
- Regulation of fisheries for species other than groundfish. Other fisheries contribute to mortality of environmental components also affected by groundfish fisheries, particularly protected species. (Catch of groundfish in nongroundfish fisheries is regulated and accounted for through the biennial management process and therefore directly affected by the proposed action.) Adverse impacts from other gear types may also combine with impacts to EFH from groundfish gear. Fishery removals from all sources also have long-term effects on the trophic structure of the California Current ecosystem.

Not Related to Fishing

- Water pollution. A variety of activities introduce chemical pollutants and sewage and cause changes in water temperature, salinity, dissolved oxygen, and suspended sediment into the marine environment. Although these activities tend to affect nearshore waters, they adversely impact identified affected biological resources if a substantial part of their life cycle occurs in these waters. Examples of these activities include, but are not limited to, agriculture, port maintenance, coastal development, marine transportation, marine mining, dredging, and the disposal of dredged material. Wherever these activities co-occur, they are likely to work additively or synergistically to decrease habitat quality and may indirectly constrain the sustainability of the managed resources, non-target species, and protected resources.
- Other authorities to conserve biological resources considered in this EIS. The MSA (50 CFR 600.930) imposes an obligation on other Federal agencies to consult with the Secretary of Commerce on actions that may adversely affect EFH. NMFS also reviews certain activities that

are regulated by Federal, state, and local authorities causing adverse effects to the marine environment through processes required by Section 404 of the Clean Water Act and Section 10 of the Rivers and Harbors Act. The jurisdiction of these activities is in “waters of the U.S.” and includes both riverine and marine habitats. under the Fish and Wildlife Coordination Act (Section 662) agencies must consult with the USFWS over certain activities affecting freshwater habitats. This Act provides another avenue for review of actions by other Federal and state agencies that may impact resources that NMFS manages. NMFS and the USFWS share responsibility for implementing the ESA. Activities that may jeopardize the continued existence of a species listed under the Act may be regulated directly and through the designation of critical habitat for such species. This provides a way for NMFS to review actions by other entities that may impact endangered and protected resources whose management units are under NMFS’ jurisdiction.

- Cyclical and ongoing climate change. Sections 3.4.5 (System Forcing and Climate Change), 3.4.6 (Implications of Climate Change for Groundfish Fisheries), and 3.4.7 (Baseline Status of the California Current Ecosystem) describe the effects of climate on ecosystem components. Cyclical phenomena include ENSO, PDO, and NGPO. As noted in Section 3.4.6, range shifts of target species may cause the biggest climate change related impact on fisheries

Sections 4.15.4.1 through 4.15.4.6 discuss the effects of these actions on the environmental components evaluated in this EIS. **Error! Reference source not found.**, below, summarizes the effects of these past, present, and reasonably foreseeable future actions on the environmental components evaluated in this EIS.

4.15.4.1 Groundfish Stocks

Past groundfish harvest specifications and management measures. Misspecification of catch limits and management error resulted in overfishing and overfished stocks, primarily rockfish species. Improvements in stock assessment methods and the management system have ended almost all overfishing since the beginning of this century. Rebuilding plans have been implemented and overfished stocks’ stock sizes are increasing. The OFL has been exceeded occasionally for some stocks but not persistently enough (e.g., more than once in four years) to require broad reevaluation of the management system. The OFL contribution for some stocks managed in complexes may have been exceeded.

Review of groundfish essential fish habitat designation and mitigation measures. Mitigation measures that reduce adverse impacts to EFH may result in increased stock productivity.

The Council’s Fishery Ecosystem Plan. Forage fish protection measures may have a marginal effect on maintaining stock abundance of pretty species for piscivorous groundfish. The Council has more information to inform management decision-making through Annual State of the Ecosystem reports.

Regulatory adjustments to the trawl rationalization program. Since these adjustments primarily focus on program efficiency and reducing harvester costs they will have negligible impacts on groundfish stock status.

Seabird avoidance measures. These measures have negligible impacts on groundfish stock status.

Regulation of fisheries for species other than groundfish. These measures

Water pollution. Impacts are localized in nearshore areas and marine project areas where they occur. Therefore, water pollution has negligible impacts on groundfish stock status.

Other authorities to conserve biological resources considered in this EIS. These authorities do not affect groundfish management and therefore have negligible impacts on groundfish stock status.

Cyclical and ongoing climate change. Warm water phases in cyclical climate phenomena decreases the productivity of many groundfish stocks. Climate change may lead to range shifts decreasing local abundance of groundfish.

4.15.4.2 Socioeconomic Environment

Past groundfish harvest specifications and management measures. Implementation of stock rebuilding measures in the late 1990s caused a substantial decline in fishing opportunity and ex-vessel revenue.

Review of groundfish essential fish habitat designation and mitigation measures.

The Council's Fishery Ecosystem Plan. This initiative could potentially have negative short-term socioeconomic impacts if actions taken to protect forage species and unmanaged species resulted in reduced harvest opportunity for managed species.

Regulatory adjustments to the trawl rationalization program.

Seabird avoidance measures. These measures impose modest capital costs on fixed gear vessels to install tori lines and may increase operational costs modestly for these vessels.

Regulation of fisheries for species other than groundfish. Management regulations for other fisheries will have negligible impacts on groundfish ex-vessel revenue but may affect total revenue accruing to fishing communities.

Water pollution. Nearshore water quality has negligible impacts on groundfish stock productivity and therefore is unlikely to affect ex-vessel revenue.

Other authorities to conserve biological resources considered in this EIS. Reinitiation of Section 7 consultations for ESA-listed species affected by the groundfish fishery could result in additional reasonable and prudent measures and terms and conditions. These measures could reduce fishing opportunity and/or increase operational costs. Since there is no information to suggest that the operation of the groundfish fishery will change substantially in the foreseeable future, it is unlikely that groundfish fisheries would impose substantially higher takes on listed species; the same is true for marine mammals and seabirds not listed under the ESA. However, other external factors (e.g., water pollution, climate change) could affect population productivity, changing the assessment of the contributory impacts of the groundfish fishery.

Cyclical and ongoing climate change. Over the very long term (>10 years), sea level rise and changes in storm activity could increase costs for maintaining and/or replacing fishery-related infrastructure in fishing communities. If infrastructure is not maintained/replaced in a port, fishery landings would be made elsewhere, reducing income in the affected port.

4.15.4.3 Essential Fish Habitat

Past groundfish harvest specifications and management measures. Groundfish Conservation Areas, which are closed to specified gear types to reduce bycatch of overfished species, have been implemented through the harvest specifications process beginning in 2003. EFH may have recovered from the adverse impacts of fishing in areas continuously closed to fishing for sufficient time. The length of time needed depends on habitat type and gear type (see Section 3.3.1). As discussed in Section 3.3.3.2, NMFS has indicated that any decision to change the configurations of GCAs that would open areas of potentially recovered habitat would need sufficient rationale and likely could not occur until the current review process is completed. This will have continued positive impacts on EFH.

Review of groundfish essential fish habitat designation and mitigation measures. The current review could result in the Council adopting additional mitigation measures to address the adverse impacts of fisheries on EFH. The Council is scheduled to initiate an FMP amendment process for this purpose in the second half of 2014. It may be several years before any such amendment is finalized.

The Council's Fishery Ecosystem Plan. One of the initiatives identified consequent of the FEP is a cross-FMP EFH initiative. The concept is to "identify habitat areas that are considered highly productive or biodiverse under more than one FMP" and coordinate mitigation measures. However, the Council has not yet scheduled any action related to this initiative so it is not reasonably foreseeable.

Regulatory adjustments to the trawl rationalization program. These regulatory changes by and large have negligible effects on EFH except for proposed regulations to define chafing gear on midwater trawl codends. The draft EA for this action concludes that it will result in "a minimal increase in contact with benthic habitat as the result of additional chafing gear coverage, particularly relative to soft bottom and minimal to no increase in contact with hard bottom."

Seabird avoidance measures. These measures do not affect fisheries in a way that would change the level of adverse impacts to EFH from fishing.

Regulation of fisheries for species other than groundfish. Other gear types have negligible to no impact on groundfish EFH. Regulatory changes for other fisheries is unlikely to affect groundfish EFH.

Water pollution. Water pollution has localized adverse impacts to groundfish EFH, for example in estuaries (designated as a habitat area of particular concern).

Other authorities to conserve biological resources considered in this EIS. As described above, NMFS has several means under which it can review non-fishing actions of other Federal or state agencies that may impact NMFS' managed resources and the habitat on which they rely prior to permitting or implementation of those projects. This serves to minimize the extent and magnitude of direct and indirect negative impacts those actions could have on habitat utilized by resources under NMFS' jurisdiction.

Cyclical and ongoing climate change. The way in which climate forcing will affect EFH is not well understood. Effects will depend on the location of EFH and changes in climate forcing vectors such as water temperature and chemistry, currents, and upwelling.

4.15.4.4 California Current Ecosystem

Past groundfish harvest specifications and management measures. As discussed in Section 3.4.3, simulation indicates that past groundfish harvests have had substantial direct effects on managed groundfish stocks but modest indirect effects on other components of the ecosystem.

Review of groundfish essential fish habitat designation and mitigation measures. Groundfish EFH is also habitat for other benthic biota ranging from interstitial microorganisms to sponges and corals. The Atlantis simulation described in Section 4.11 did not take into account adverse impacts to EFH.

The Council's Fishery Ecosystem Plan. The purpose of the FEP is to enhance the Council's species-specific management programs with more ecosystem science, broader ecosystem considerations, and management policies that coordinate Council management across its Fishery Management Plans and the California Current Ecosystem. To the degree this purpose is met, the FEP may have a marginal positive effect on the CCE as measured by the indicators described in Section 3.4.3. However, as discussed in that section and Section 4.12, the range of harvest policies likely to be implemented by the Council do not result in substantial indirect impacts as measured through model simulation.

Regulatory adjustments to the trawl rationalization program. These changes have a negligible effect on the CCE. Even if increased program efficiency allows higher attainment of allocations, Atlantis simulation suggests that substantially higher harvest would be necessary to result in more than negligible changes in ecosystem indicators.

Seabird avoidance measures. Abundance of marine mammals and seabirds is one of the metrics used in the Atlantis CCE Model evaluation of harvest specifications policies (Section 4.12). This implies that greater abundance is a positive ecosystem attribute. The seabird avoidance measures are intended to reduce the mortality of seabirds in fixed fisheries and thus would have a positive impact on the CCE.

Regulation of fisheries for species other than groundfish. As noted in Section 3.4.3, simulation results suggest that CPS purse seine fisheries have substantial indirect effects on CCE attributes. A substantial change in current harvest policies would be necessary to produce a discernible change in ecosystem attributes.

Water pollution. As already noted, relative to the fishery management area, pollution is concentrated in relatively small areas generally along the coastline closest to terrestrial sources. Therefore, pollution has a relatively marginal effect on the ecosystem of affected resources.

Other authorities to conserve biological resources considered in this EIS. As noted above, these authorities may have a small effect on the overall quality of marine habitats. To the degree that these improvements contribute to the productivity of component organisms, there may be a marginal benefit to the CCE.

Cyclical and ongoing climate change. Cyclical changes have transient effects on the productivity of constituent organisms and thus CCE structure. These variations may be considered part of the baseline. Climate change is likely to have moderate to severe impacts on CCE structure.

4.15.4.5 Protected Species

Past groundfish harvest specifications and management measures. Past fishery management actions taken through the FMP process have had a positive cumulative effect on ESA-listed and MMPA-protected species through the reduction of fishing effort (potential interactions) and implementation of gear requirements.

Review of groundfish essential fish habitat designation and mitigation measures. Mitigation measures adopted through this review process that restrict fishing by area would reduce the likelihood of fishery interactions with protected species in those areas.

The Council's Fishery Ecosystem Plan. There are no initiatives stemming from the FEP likely to change fishery interaction rates with protected species.

Regulatory adjustments to the trawl rationalization program. There is no information to determine how these changes may affect overall fishing effort or interaction rates. Establishing a common start date for all Pacific whiting fishery sectors takes into account minimizing Chinook salmon bycatch. To the degree that measures to increase operational efficiency allow harvesters to increase CPUE there may be a marginal beneficial impact.

Seabird avoidance measures. These measures will have direct positive impacts by reducing mortality of seabirds in fixed gear fisheries.

Regulation of fisheries for species other than groundfish. Other fisheries also take protected species and therefore contribute to cumulative effects in terms of total mortality. The cumulative effects analysis in relevant biological opinions (NMFS 2006; NMFS 2012a) contain detailed information on these other sources of mortality (see Section 3.5.2).

Water pollution. Of the ESA-listed species likely to be adversely affected by the proposed action (see Section 3.6.2), Chinook salmon, eulachon, and green sturgeon reside or transit coastal and estuarine waters where pollution from terrerestrial sources may be locally concentrated. These species may be adversely affected. The biological opinion (NMFS 2012a) identifies the adverse impact of water pollution on green sturgeon prey resources.

Other authorities to conserve biological resources considered in this EIS. NMFS authority under the ESA (and USFWS authority for seabirds) directly affects prosecution of the groundfish fishery so that it does not jeopardize the continued existence of any listed species. Permitting of activities under the MMPA is intended to achieve optimal sustainable population levels for marine mammals for both ESA-listed and non-listed marine mammals.

Cyclical and ongoing climate change. As with other biological resources climate change is likely to affect population productivity and occurrence. Effects may be beneficial or adverse depending on the species and its requirements. The net effect of climate change on protected species cannot be predicted.

4.15.4.6 Non-groundfish Species

Past groundfish harvest specifications and management measures. Biennial specifications and management measures generally have not regulated the catch of non-groundfish species except for Pacific halibut, but have affected fishing opportunity and behavior, which may indirectly affect bycatch of these species. Catch of these species is monitored the effect on population abundance is negligible.

Review of groundfish essential fish habitat designation and mitigation measures. Any benefit from the development of additional mitigation measures could benefit non-groundfish species that also depend on groundfish EFH.

The Council's Fishery Ecosystem Plan. No initiatives are identified that address bycatch.

Regulatory adjustments to the trawl rationalization program. None of these measures are likely to materially affect non-groundfish bycatch.

Seabird avoidance measures. These measures are not likely to materially affect bycatch of non-groundfish, because they are intended to be minimally disruptive to fishing operations.

Regulation of fisheries for species other than groundfish. Non-groundfish species with directed fisheries are managed under other Council FMPs, other Federal authorities, or state authority (e.g., Dungeness crab, Pacific halibut, Pacific sardine, salmon, squid; see Table 3-36). For those species catch in groundfish fisheries is generally accounted for when determining catch limits and management measures for target fisheries.

Water pollution. As discussed for other biological resources, water pollution could adversely affect species that occur in coastal or estuarine areas where pollution levels are elevated.

Other authorities to conserve biological resources considered in this EIS. These authorities (habitat protection, measures pursuant to the ESA) are likely to have negligible effect on protected species bycatch, given how indirectly they would affect productivity of non-groundfish populations.

Cyclical and ongoing climate change. As with other biological resources, climate change could positively or negatively affect non-groundfish population productivity and occurrence. The overall effect cannot be predicted.

4.15.5 Summary of the Direct and Indirect Effects of the Proposed Actions

This section briefly summarizes the direct and indirect effects of the proposed actions evaluated in this DEIS. The Council considered changes to the slope rockfish stock complexes but decided not to make a change and address the underlying conservation concern (high catches of rougheye and shortraker rockfish relative to their contributing OFLs) that are described in Section 2.5. The Council's preferred alternative was not to take this action but instead establish a sorting requirement and inseason management measures to better monitor and control catch of these stocks. The Council also reorganized the Other Fish complex by reducing it to three stocks, cabezon in Washington, kelp greenling, and leopard shark. The other stocks in this complex are either designated separate stocks to be managed with their own specifications or as ecosystem component species, which are monitored but not actively managed. These changes are expected to have both short-term and long-term positive effects in terms of better attaining management objectives.

The evaluation of the Amendment 24 proposed action considers the long-term impacts of setting harvest specifications and management measures through the biennial process. As discussed in Chapter 1, "long-term" is generally considered to be 10 years although in specific contexts (e.g., California Current ecosystem) effects are better discerned in simulation over 25-30 years.

4.15.5.1 2015-2016 Biennial Harvest Specifications Including Changes to the Other Fish Complex and Designation of EC Species

Groundfish Stocks (Section 4.1): For stocks whose status is known, none are projected to decline from a higher status to a lower one (healthy to precautionary zone, precautionary zone to overfished) during the 2015-2016 period. Petrale sole is projected to achieve target biomass and be declared rebuilt during the 2015-2016 period. Changes to the Other Fish complex and designation of EC species will allow more effective monitoring and stock specific management for more stocks. The proposed action has overall positive effects on groundfish stocks.

Management Measures (Section 4.2): Management measures are projected to keep catches below ACLs while maximizing fishing opportunity within this constraint.

Socioeconomic Environment (Section 4.3): Total projected ex-vessel revenue under the preferred alternative is expected to increase by $16 million in 2015 and $19.3 million from annual average revenue during the baseline period. The proposed action has an overall positive effect on the socioeconomic environment.

Essential Fish Habitat (Section 4.4): Bottom trawl gear has greater adverse impacts to EFH compared to other gear types, although fixed gear is more readily deployed on rocky habitats that have slower recovery times from the adverse effects of fishing. The amount and spatiotemporal distribution of fishing effort are the primary impact mechanisms. While fishing opportunity under the preferred alternative (measured by projected landings) is forecast to increase by about 10% from No Action, recent historical data suggest that CPUE in the bottom trawl fishery has also been increasing. Furthermore, there is scant evidence in historical data for a direct correlation between increased fishing opportunity (measured by ACLs) and changes in fishing effort. Under the action alternatives the seaward boundary of the trawl RCA between 40°10 N. lat. and 48°10' N lat. would be changed from 200 to 150 fathoms. This area may contains regions where EFH has recovered from the adverse effects of trawl gear. Given this uncertainty and the fact that no major regulatory changes affecting the operational characteristics of the groundfish fishery are reasonably foreseeable, it is likely that the effect of the proposed action will be mixed.

California Current Ecosystem (Section 4.5): Harvest policies are likely to result in catches within the range of historical catch and not result in substantial indirect effects as measured by ecosystem indicators. It is likely that the effects of the proposed action will be neutral.

Protected Species (Section 4.6): Harvest specifications and management measures are projected to result in higher catches compared to No Action and baseline levels. As noted above, catch levels and resulting fishing effort are insufficiently correlated to predict that the proposed action would increase fishery interactions with protected species. Given this uncertainty and the fact that no major regulatory changes affecting the operational characteristics of the groundfish fishery are anticipated, it is likely that the effect of the proposed action will be neutral.

Non-groundfish Species (Section 4.7. There is no information to indicate that bycatch of non-groundfish species will differ from baseline levels. It is likely that the effects of the proposed action will be neutral.

4.15.5.2 Amendment 24

Groundfish Stocks (Section 4.8): The proposed action has overall neutral effects on groundfish stocks.

Management Measures (Section 4.9): Over the long term, only adjustments of routine management measures are considered. The objective of routine management measures is to control catch so that catches do not exceed ACLs. Management measures are not an affected environmental component but rather an impact mechanism intermediate between stock conservation objectives (reflected by ACLs) and ultimate impacts on the environmental components evaluated in other sections of the EIS

Socioeconomic Environment (Section 4.10): Ex-vessel revenue is a function of fishing opportunity determined by catch limits and related management measures, technical factors (e.g., the ability of harvesters to catch target species while avoiding species with low ACLs), and market demand. For many stocks recent average catch represents the low end of 10-year projections. Harvest policies have a relatively modest effect on catch limits compared to variability in stock productivity, which is outside the control of management. External factors, primarily trawl rationalization, may lead to more agglomeration with a larger proportion of landings in fewer ports. The proposed action has overall neutral effects on the socioeconomic environment.

Essential Fish Habitat (Section 4.11): The amount and spatiotemporal distribution of fishing effort are the primary impact mechanisms for the proposed action on EFH. As discussed above, over the long term stock productivity has a much larger influence on fishing opportunity compared to harvest policies. Catch levels and resulting fishing effort are insufficiently correlated to predict that the proposed action would increase the level of adverse impacts to EFH from fishing. Given this uncertainty and the fact that no major regulatory changes affecting the operational characteristics of the groundfish fishery are reasonably foreseeable, it is likely that the effect of the proposed action will be neutral.

California Current Ecosystem (Section 4.12): Harvest policies are likely to result in catches within the range of historical catch and not result in substantial indirect effects as measured by ecosystem indicators. It is likely that the effects of the proposed action will be neutral.

Protected Species (Section 4.13): The amount and spatiotemporal distribution of fishing effort are the primary impact mechanisms for the proposed action on protected species. As discussed above, over the long term stock productivity has a much larger influence on fishing opportunity compared to harvest policies. Catch levels and resulting fishing effort are insufficiently correlated to predict that the proposed action would increase fishery interactions with protected species. Given this uncertainty and the fact that no major regulatory changes affecting the operational characteristics of the groundfish fishery are reasonably foreseeable, it is likely that the effect of the proposed action will be neutral.

Non-groundfish Species (Section 4.14). There is no information to indicate that bycatch of non-groundfish species will differ from baseline levels. It is likely that the effects of the proposed action will be neutral.

4.15.6 Magnitude and Significance of Cumulative Effects

In determining the magnitude and significance of the cumulative effects, the additive and synergistic effects of the proposed action, as well as past, present, and future actions, must be taken into account. This analysis of total cumulative effects considers: (1) impacts from past and present actions, forming the environmental baseline; PLUS (2) reasonably foreseeable future actions; PLUS (3) impacts from the proposed action and alternatives.

Table 4-196 summarizes the combined effects of past, present and reasonably foreseeable future actions other than the proposed action and alternatives (summarized above) affecting the environmental components evaluated in this EIS. Table 4-197 summarizes the conclusions made above on the impacts of past, present, and reasonably foreseeable actions when combined with the impacts of the proposed actions. Based on these assessments the magnitude and significance of cumulative effects are determined.

Groundfish: Positive cumulative effect, because 2015-2016 harvest specifications and management measures and long-term harvest policies are intended to return or maintain stocks at levels at or above their target biomass levels. There is a risk that catch limits could be mis-specified and/or that management measures to not prevent ACLs from being exceeded. Because of precautionary reductions built into the management framework the likelihood that overfishing will occur is low. Over time catch data systems and stock assessment techniques are improving, lessening the likelihood of mis-specification and/or overfishing.

Socioeconomic Environment: Mixed cumulative effect, because 2015-2016 harvest specifications and management measures are forecast to result in increased ex-vessel revenue. Over the long term it is likely that year-on-year declines in ex-vessel revenue due to changes in target stocks yield outside of the management system. However, there is no information indicating that year-to-year revenue volatility will exceed baseline variability. External factors (trawl rationalization) could lead to greater agglomeration and ex-vessel revenue being concentrated in fewer fishing communities.

Essential Fish Habitat: Positive cumulative impact, because external actions (existing EFH protections, EFH review process) have implemented and may lead to additional measures to mitigate the adverse impacts of fishing on groundfish EFH. Changes to RCA configurations will be evaluated for potential effects on groundfish EFH that has recovered from the adverse effects of fishing.

California Current Ecosystem: Neutral, because Atlantis California Current Ecosystem Model simulations indicate that harvest policies would not result in substantial changes as measured by ecosystem indicators. External factors (climate change) could result in adverse effects, such as range shifts and changes in physical dynamics of the system (water temperature, pH, currents, upwelling) but the nature and magnitude of these effects cannot be precisely predicted.

Protected Species: Positive, because external actions (ESA Section 7 consultations, MMPA permitting) evaluates cumulative impacts and identifies mitigation measures, which may be required. Most protected species populations affected by the proposed actions are recovering.

Non-groundfish Species: Neutral, because no substantial change in bycatch of non-groundfish species is expected either from short-term (2015-2016) or long-term (Amendment 24) management of the groundfish fishery. Bycatch of non-groundfish species in negligible compared to target catch of non-groundfish species or stock yield where known.

Table 4-196. Summary effects of past, present and reasonably foreseeable future actions on the environmental components evaluated in this EIS.

Environmental Component	Past Actions	Present Actions	Reasonably Foreseeable Future Actions	Combined Effects of Past, Present, Future Actions
Groundfish Stocks	**Mixed** Most stocks above or near target biomass; however, some stocks remain overfished	**Positive** The current management framework is effective in rebuilding stocks to the target biomass and achieving optimum yield	**Positive** No actions are identified that would reduce the effectiveness of the management framework	**Mixed** No actions are identified that would reduce the effectiveness of the management framework; however misspecification of catch limits and management error could occur; climate change may reduce local abundance
Socioeconomic (Human Communities)	**Mixed** Fishery resources have supported profitable industries but management measures associated with stock rebuilding have curtailed fishing opportunities; trawl rationalization increased operational flexibility	**Mixed** Stock status and yield have allowed fishery revenues to increase; falling participation and agglomeration may concentrate revenues in fewer communities	**Positive** No actions are identified that would accelerate falling participation and agglomeration	**Mixed** Stock status and yield have allowed fishery revenues to increase; falling participation and agglomeration may concentrate revenues in fewer communities
Essential Fish Habitat	**Positive** Evidence suggests that trawl fishing effort is falling; past actions have mitigated adverse effects of fishing on EFH	**Mixed** Trawl fishing effort stable; ongoing actions continue to mitigate adverse effects of fishing on EFH; Trawl RCA boundary change proposed	**Positive** Trawl fishing effort not likely to increase; future actions likely to enhance the mitigation of adverse effects of fishing on EFH	**Positive** Trawl fishing effort not likely to increase; future actions likely to enhance the mitigation of adverse effects of fishing on EFH
California Current Ecosystem	**Mixed** Based on simulations, the development of fisheries has had both positive and negative indirect effects on ecosystem attributes	**Neutral** Ongoing prosecution of fisheries at current levels not expected to change ecosystem attributes from the baseline; other actions likely have negligible impacts	**Mixed** Ongoing prosecution of fisheries at current levels not expected to change ecosystem attributes from the baseline; climate change likely to have moderate to severe impacts	**Mixed** Ongoing prosecution of fisheries at current levels not expected to change ecosystem attributes from the baseline; climate change likely to have moderate to severe impacts

Environmental Component	Past Actions	Present Actions	Reasonably Foreseeable Future Actions	Combined Effects of Past, Present, Future Actions
Protected Species	**Mixed** Protected species take modest in groundfish fisheries and documented through observer program; requirements of ESA, MMPA and OAL implemented	**Positive** Most populations increasing; ESA and MMPA mitigation addressed and ongoing	**Positive** Most populations increasing; future adverse effects likely to be addressed through ESA and MMPA	**Positive** Most populations increasing; adverse effects likely to be addressed through ESA and MMPA
Non-groundfish Species	**Neutral** Bycatch in groundfish fisheries is negligible	**Neutral** Bycatch in groundfish fisheries is negligible	**Neutral** Bycatch in groundfish fisheries is negligible	**Neutral** Bycatch in groundfish fisheries is negligible

Table 4-197. Summary of the cumulative effects of the proposed actions.

Affected Resources	Baseline*	Past, Present, and Reasonably Foreseeable Future Actions	2015-2016 Harvest Specifications and Management Measures	Amendment 24 Proposed Action	Cumulative Effects
Groundfish Stocks	Positive (Section 3.1)	Mixed	Positive	Neutral	Positive
Human Communities	Mixed (Section 3.2)	Mixed	Positive	Neutral	Mixed
Essential Fish Habitat	Positive (Section 3.3)	Positive	Mixed	Neutral	Positive
California Current Ecosystem	Neutral (Section 3.4)	Mixed	Neutral	Neutral	Mixed
Protected Species	Positive (Section 3.5)	Positive	Neutral	Neutral	Positive
Non-Groundfish Stocks	Neutral (Section 3.6)	Neutral	Neutral	Neutral	Neutral

*Although the temporal scope of past and present actions for the affected resources encompasses actions that occurred after FMP implementation (1982) the baseline period is 2003-2012, the temporal context within which affected resources are described in Chapter 3.

Impact Definitions for Table 4-196 and Table 4-197:

- Positive
  - Groundfish Stocks, Non-groundfish Species, Protected Species: actions that increase stock size
  - Essential Fish Habitat: actions that improve or reduce disturbance of habitat
  - California Current Ecosystem: actions that do not substantially change ecosystem indicators (see Section 3.4.3 for a description of indicators used with the Atlantis CCE Model)
  - Socioeconomic (Human Communities): actions that increase revenue and wellbeing of fishermen and/or associated businesses
- Mixed: Both positive and negative effects that are not offsetting
- Neutral: Positive and/or negative effects are negligible or positive and negative effects are offsetting
- Negative
  - Groundfish Stocks, Non-groundfish Species, Protected Species: actions that decrease stock size
  - Essential Fish Habitat: actions that degrade or increase disturbance of habitat
  - Socioeconomic (Human Communities): actions that decrease revenue and wellbeing of fishermen and/or associated businesses

Chapter 5 CONSISTENCY WITH THE GROUNDFISH FMP AND MSA NATIONAL STANDARDS

5.1 FMP Goals and Objectives

The Groundfish FMP contains 3 broad goals and 17 objectives intended to achieve those goals. Past EISs for rebuilding plans and harvest specifications describe how the actions address each objective. The proposed actions evaluated in the current EIS address the goals and objectives in a similar fashion as described in the previous groundfish harvest specifications EISs.

5.2 National Standards

An FMP or plan amendment and any pursuant regulations must be consistent with ten national standards contained in the MSA (§301). These are:

National Standard 1 states that conservation and management measures shall prevent overfishing while achieving, on a continuing basis, the OY from each fishery for the United States fishing industry.

The harvest specification action alternatives are consistent with the OY harvest management framework described in Chapter 4 of the Groundfish FMP. FMP Chapter 4 describes OY as "a decisional mechanism for resolving the Magnuson Stevens Act's multiple purposes and policies, implementing an FMP's objectives and balancing the various interests that comprise the national welfare." The OY harvest management framework (as revised by Amendment 23 to the Groundfish FMP) is consistent with revised National Standard 1 Guidelines. The OFL is the estimate of catch level above which overfishing is occurring, or the estimate of MFMT applied to a stock's abundance. The ABC is a level of annual catch that accounts for the scientific uncertainty in the estimate of OFL and any other scientific uncertainty. Chapter 4 in the Groundfish FMP describes an ABC control rule, ABC values described in this document were determined following that control rule. The ACL is the level of annual catch that serves as the basis for invoking Accountability Measures. The ACL may equal but may not exceed the ABC. The ACL may be set lower than the ABC to account for a wide range of factors. The application of the OY harvest management framework to the specifications described in this document should result in ACLs that reduce the likelihood of overfishing.

The revised National Standard 1 guidelines set forth principles on which stock complexes should be organized, including that stocks within a complex should be similar in terms of geographic distribution, life history, and vulnerability to the fishery. Changes to the Shelf Rockfish and Other Fish stock complexes were considered as part of the proposed action. The Council determined that reorganizing the Shelf Rockfish complexes, by removing rougheye and blackgill rockfish and creating a coastwide complex is not the most effective way to address current conservation concerns. Instead, increased monitoring coupled with inseason management changes, if necessary, are proposed. The Other Fish stock complex is reduced to three stocks that share greater similarity in terms of life history and fishery susceptibility. Spiny dogfish is removed and managed with its own ACL to address conservation concerns with catch of this species. Other species are designated EC species, because active management is unnecessary but monitoring of their catch will continue.

Because of past overfishing seven groundfish stocks are currently declared overfished. Widow rockfish was determined to be rebuilt in 2011 and will no longer be managed under a rebuilding plan beginning in 2013. Petrale sole was declared overfished in 2010 based on a revision to the OY harvest management framework that incorporates estimates of B_{MSY} of $B_{25\%}$ and MSST of $B_{12.5\%}$ for flatfish. Petrale sole is estimated to be rebuilt in 2015, but will be managed under its rebuilding plan for the 2015-16 biennial cycle. The rebuilding plan species the 25-5 precautionary reduction from the ABC to set the rebuilding ACL.

The remaining overfished species will be managed under the current rebuilding plan SPR harvest rate. The Council will choose a new target year for cowcod but has established a precautionary ACL of 10 mt associated with a median rebuilding year of 2020. Catches will be managed to a 4 mt ACT in recognition of uncertainty about current stock assessment results.

Section 304(e) introduces a tradeoff formulated as specifying a time to rebuild "as short as possible, taking into account the status and biology of any overfished stocks, the needs of fishing communities, … and the interaction of the overfished stock of fish within the marine ecosystem…" The proposed action is evaluated based on these considerations in Chapter 4 of this EIS.

National Standard 2 states that conservation and management measures shall be based on the best scientific information available.

The best available science standard applies to the following areas in relation to this proposed action: stock assessments, rebuilding analyses, and methods for determining management reference points (OFL, ABC, ACL, etc.), which forms the basis for determining harvest levels, and the evaluation of socioeconomic impacts. The supporting science is discussed below.

The harvest specifications (specifically, ACLs) considered under the proposed action (the action alternatives, including the Preferred Alternative), are based on the most recent stock assessments, developed through the peer-review STAR process. As part of the management cycle the Council recommends which stocks should be assessed in advance of current decision-making. Only a small proportion of the 80+ managed groundfish species are regularly assessed, because of a combination of factors. For many stocks there may not be enough data to support a full assessment (the FMP describes a classification system based on the availability of data). For unassessed stocks proxy methods must be used to determine reference points. Stocks may be subjected to little or no fishing pressure, or determined to have low vulnerability, and thus less in need of regular assessment. Finally, there is a limit on the institutional resources needed to carry out the assessments (i.e., fishery scientists). In some cases a previous assessment may be updated; this means that the underlying model is not reevaluated but the model is re-run with the addition of more recent data from the period since the last full assessment. The 2014 Groundfish SAFE document reviews the basis for alternative harvest specifications and references the stock assessments that were used. It also describes the methods that were used to determine reference points for harvest specifications (OFL, ABC, ACL, etc.) for stocks and stock complexes.

The No Action Alternative specifications do not benefit from the new assessments and updates conducted as part of the current management cycle. For those stocks No Action does not represent the best available science.

The NWFSC has developed a model application, called IO-Pac, for estimating personal income impacts of commercial fishing on the west coast. This model is documented in Appendix A.

National Standard 3 states that, to the extent practicable, an individual stock of fish shall be managed as a unit throughout its range, and interrelated stocks of fish shall be managed as a unit or in close coordination.

Groundfish ACLs are set for management units, which include stocks, stock complexes, or geographic subdivisions thereof. Stock complexes group co-occurring species, many of which have not been formally assessed. The 2014 Groundfish SAFE document describes how ACLs for stock complexes are developed based on ABC estimates of component stocks. Stocks within these complexes are not managed individually for a variety of reasons including the lack of assessments, lack of reliable catch data at the species level, or they constitute a small portion of catches. If a stock within a complex is individually assessed it may be managed under a separate harvest limit, when practicable.

Stocks with their own ACLs are managed throughout the range of that stock (as opposed to the species), although issues do arise in the case of stocks straddling international borders. For this reason, allocation of the harvestable surplus of Pacific whiting between the U.S. and Canada is subject to international agreement.

Separate ACLs may be set for geographic subcomponents of a stock for management purposes. However, the development of subcomponent ACLs is based on managing these stocks throughout their range within U.S. waters. As part of the proposed action the Council is considering a change in the scope of subcomponent ACLs for lingcod that would better reflect biological and fishery characteristics. Currently lingcod is managed in two area components, north and south of 42° N. lat.. Under the proposed action the dividing line would be moved to 40°10’ N. lat., near Cape Mendocino. Cape Mendocino is a biogeographic boundary and as such 40°10’ N. lat. is commonly used in groundfish fishery management for the differential application of management measures.

National Standard 4 states that conservation and management measures shall not discriminate between residents of different states. If it becomes necessary to allocate or assign fishing privileges among various United States fishers, such allocation shall be (A) fair and equitable to all such fishers; (B) reasonably calculated to promote conservation; and (C) carried out in such manner that no particular individual, corporation, or other entity acquires an excessive share of such privileges.

The proposed measures will not discriminate between residents of different states.

Allocation decisions are also made as part of the biennial harvest specifications process for those stocks for which formal allocations have not been established under the FMP. Section 4.2 describes these allocation decisions. Emphasis is placed on equitable division while ensuring conservation goals. Decision-making on these allocations occurs through the Council process, which facilitates substantial participation by state representatives. Generally, state proposals are brought forward when alternatives are crafted and integrated to the degree practicable.

National Standard 5 states that conservation and management measures shall, where practicable, consider efficiency in the utilization of fishery resources; except that no such measure shall have economic allocation as its sole purpose.

Measures have been taken to reduce fishing capacity in the limited entry trawl fleet and nontrawl fleets, including: fixed gear permit stacking program implemented by FMP Amendment 14, the trawl vessel buyback program, and catch share management implemented by FMP Amendment 20. Reducing excess capacity is expected to improve the efficiency in the utilization of fishery resources as well as reduce the levels of incidental catch.

Catch share management in the at-sea whiting sectors and the shorebased IFQ fishery promote efficiency of utilization by reducing regulatory discards. Vessels in these fisheries are subject to 100 percent observer coverage, which improves catch accounting.

National Standard 6 states that conservation and management measures shall take into account and allow for variations among, and contingencies in, fisheries, fishery resources, and catches.

Management measures reflect differences in catch, and in particular bycatch, of overfished species, among different fisheries. For example, different RCA configurations are established for different gear types (trawl versus fixed gear) and the catch control tools also differ. For example, at-sea whiting fisheries are managed by co-ops, the shorebased IFQ fishery by IFQs, and limited entry fixed gear fishery for sablefish by vessel-level allocations (permit stacking). Within these fisheries and in the open access sector cumulative trip limits are used for particular management units and/or during certain times of the year. Recreational fisheries are managed with area closures and bag limits proposed by the states and appropriate to the catches and characteristics of each state's recreational fishery.

National Standard 7 states that conservation and management measures shall, where practicable, minimize costs and avoid unnecessary duplication.

Generally, by coordinating management, monitoring, and enforcement activities between the three west coast states, duplication, and thus cost, is minimized. Appendix B evaluates proposed management measures in detail, including consideration of associated costs and duplication.

National Standard 8 states that conservation and management measures shall, consistent with the conservation requirements of this Act (including the prevention of overfishing and rebuilding of overfished stocks), … take into account the importance of fishery resources to fishing communities in order to (A) provide for the sustained participation of such communities, and (B) to the extent practicable, minimize adverse economic impacts on such communities.

This document evaluates the effects of the alternatives on fishing communities (see section 4.3). These effects were taken into account in choosing the preferred "integrated alternative" (incorporating harvest specifications and related management measures). The alternatives are structured to allow a comparison of the tradeoffs between the requirements of the MSA. The requirements in Section 304(e)(4)(A) of the MSA include rebuilding overfished stocks in as short a time possible, taking into account the needs of fishing communities, and minimizing adverse economic impacts to fishing communities. Each integrated alternative contains a suite of ACLs for overfished species associated with a particular rebuilding strategy (target year and harvest rate) and management measures needed to constrain catches to these harvest levels. Target species catch for each alternative is projected based on these management measures, which allows an estimate of resulting ex-vessel revenue and personal income impacts at the community level (with the port group area the unit of analysis for community impacts). In this way the 'rebuild in as short a time as possible' standard can be contrasted with the 'needs of fishing communities' standard to demonstrate what level of catch or bycatch of overfished species is necessary to address adverse impacts to fishing communities.

National Standard 9 states that conservation and management measures shall, to the extent practicable, (A) minimize bycatch and (B) to the extent bycatch cannot be avoided, minimize the mortality of such bycatch.

Minimizing bycatch, of overfished species in particular, is an important component of the alternatives. Through the use of GCAs fishing effort is reduced in areas where overfished species are most abundant, thereby reducing potential bycatch. As noted above, catch share management, particularly in the shorebased IFQ fishery, has reduced bycatch by eliminating most regulatory discards (some non-target species are managed with cumulative trip limits, which may induce some level of regulatory discards). Nontrawl sectors use cumulative trip limits as the principal catch control tool. Because trip limits are based on landings, when they are set at a low level to discourage directed and incidental catch of overfished species, this can result in regulatory discards.

The petrale sole rebuilding plan established objectives reflecting that it is an important target species for vessels using groundfish bottom trawl gear (managed under the shorebased IFQ fishery). The rebuilding plan allows a limited target fishery to continue, which in concert with IFQ management minimizes discards.

The at-sea whiting sectors are managed under bycatch limits for selected overfished species. Mandatory co-ops in the mothership sector are allocated a portion of these sector bycatch limits and are accountable for keeping catch of these species within their allocation. The catcher-processor operates as a single, voluntary co-op responsible for the bycatch limit assigned to the sector.

As noted above, the at-sea whiting sectors and shorebased IFQ fishery are subject to 100 percent observer coverage. While necessary for catch accounting under IFQ/co-op management, observers also allow complete monitoring of total catch (including bycatch). The limited entry fixed gear sector and directed open access fisheries are subject to partial observer coverage. This observer data is used to develop bycatch rate estimates, which can be used to forecast and account for total catch of all managed species.

National Standard 10 states that conservation and management measures shall, to the extent practicable, promote the safety of human life at sea.

RCAs may affect safety if more vessels elect to fish seaward of the closed areas and are more exposed to bad weather conditions. Individual accountability under catch share management has resulted in vessels fishing more often seaward of the RCA in order to avoid catch of species such as canary and yelloweye rockfish, for which the allocations and resulting available QP are limited. As harvesters gain experience with the management program they may be able to develop opportunities to fish shoreward of RCAs while avoiding catch of these species, resulting in more inshore fishing.

The moratorium on quota share trading is expected to sunset beginning in 2013, which may lead to further capacity reduction and increased profits in the trawl sector. This may result in more investment in vessels and equipment that would enhance safety. Less efficient vessels are expected to leave the trawl fishery as part of this consolidation, which may eliminate older, less safe vessels.

For vessels electing to increase the amount of time fishing seaward of RCAs, implementing a VMS capable of sending distress calls could provide some mitigation. Although units with this capability have been approved for use, vessel owners are not required to purchase a unit with this capability. Also, by providing near real-time vessel position data, VMS could aid in search and rescue operations.

5.3 Other Applicable MSA Provisions

Harvest specifications are set based on targets established in overfished species rebuilding plans, which conform to Section 304(e) Rebuild Overfished Fisheries. Rebuilding plans contain the elements required by Section 304(e)(4) and discussed in the NS1 Guidelines (50 CFR 600.310).

NMFS prepared an EIS evaluating programmatic measures designed to identify and describe west coast groundfish EFH (NMFS), and minimize potential fishing impacts on west coast groundfish EFH. The Council took final action amending the groundfish FMP to incorporate new EFH provisions in November 2005. NMFS partially approved the amendment in March 2006. Implementing regulations became effective in June 2006. The effects of the proposed actions on groundfish EFH are within the scope of effects evaluated in the programmatic groundfish EFH EIS. The Council commenced a 5-year review of its groundfish EFH designation in December 2010. Section 4.1.4 in this EIS describes impacts of the proposed action on EFH, consistent with the EFH assessment requirements of 50 CFR 600.920 (e)(3).

5.4 Public Scoping under MSA

The Council process, which is based on stakeholder involvement and allows for public participation and public comment on fishery management proposals during Council, subcommittee, and advisory body meetings, is the principal mechanism to scope the biennial specifications process. The advisory bodies involved in groundfish management include the GMT, with representation from state, Federal, and tribal fishery scientists; and the Groundfish Advisory Subpanel (GAP), whose members are drawn from the commercial, tribal, and recreational fisheries, fish processors, and environmental advocacy organizations. Meetings of the Council and its advisory bodies constitute the Council scoping process, involving the development of alternatives and consideration of the impacts of the alternatives. In addition to Council-sponsored meetings, the Washington Department of Fish and Wildlife (WDFW), ODFW and CDFG held public hearings to solicit input on the formulation of management measures.

Table 5-1 summarizes Council decision-making steps in developing biennial harvest specifications and management measures.

Table 5-1.Summary of Council decision-making during biennial harvest specifications process.

Council meeting	Council Actions
June 20-25, 2013	Set schedule for developing 2015-16 harvest specifications and conduct preliminary review of stock status information.
September 12-17, 2013	Adopt new stock assessments for use in management, OFLs, and a range of ABC values; prioritize a range of new management measures for preliminary analysis.
November 1-6, 2013	Adopt overfished species rebuilding analyses; adopt ABCs for analysis; identify tentative range of allocation alternatives. Review exempted fishing permits for 2015-16. Adopt new management measures for detailed analysis.
April 5-10, 2014	Adopt preferred alternative ACLs and narrow the range of allocations and management measures under consideration.
June 20-25, 2014	Adopt final preferred alternative including all elements for the 2015-16 management program.

Chapter 6 NEPA AND OTHER APPLICABLE LAWS

This chapter will be updated as necessary.

6.1 National Environmental Policy Act

The CEQ has issued regulations specifying the requirements for NEPA documents (40 CFR 1500 – 1508), and NOAA's agency policy and procedures for NEPA can be found in NOAA Administrative Order 216-6 (NAO 216-6). The required elements of an Environmental Impact Statement (EIS) and the public process associated with an EIS are specified in both CEQ's regulations and NAO 216-6.

The required elements of an EIS are as follows (as per NAO 216-6 5.04b):

- A cover sheet and table of contents;
- A discussion of the purpose and need for the action;
- A summary of the EIS, including the issues to be resolved, and in the FEIS, the major conclusions and areas of controversy including those raised by the public;
- Alternatives, as required by Sections 102(2)(C)(iii) and 102(2)(E) of NEPA;
- A description of the affected environment;
- A succinct description of the environmental impacts of the proposed action and alternatives, including cumulative impacts;
- A listing of agencies and persons consulted, and to whom copies of the EIS are sent;
- A ROD, in the case of a FEIS, and;
- An index and appendices, as appropriate.

Comments received on this DEIS will be considered and responded to in the FEIS. After the comments are considered, NMFS will publish a Notice of Availability for a 30-day public comment period for the FEIS and will conclude the NEPA process with a Record of Decision documenting whether to approve, partially approve, or disapprove this proposed action under the MSA.

6.2 Notice of Intent and Public Scoping Under NEPA

The National Marine Fisheries Service in coordination with the Pacific Fishery Management Council published a Notice of Intent (NOI) on August 22, 2013 (78 FR 52133), to announce the intent to develop and prepare an EIS. This EIS will include analysis of the long-term impacts of setting harvest specifications (including OFLs, ABCs, and ACLs) and management measures including the 2015-16 biennial period, pursuant to the Pacific Coast Groundfish Fishery Management Plan.

The purpose of the NOI was to alert the interested public of the commencement of the scoping process and to provide for public participation in compliance with the National Environmental Policy Act. The scoping process is the first and best opportunity for the public to raise issues and concerns for the Council and NMFS to consider during the development of the harvest specifications and management measures. The Council and NMFS rely on input during scoping to both identify management measures and develop alternatives that meet the objectives of the Pacific Coast Groundfish FMP.

The public comment period was open for thirty days, ending on September 23, 2013. One comment was received during the thirty-day public comment period from the National Park West Coast Region. The comments focus on west coast marine areas managed by the National Park Service.

6.3 Related NEPA documents

The following NEPA documents provide information and analyses related to the effects of this proposed action:

- Trailing Actions for the Pacific Coast Groundfish Trawl Rationalization Program, Including 1. Pacific Halibut Trawl Bycatch Mortality Limit (Amendment 21-1); 2. Exemption from the Prohibition on Processing At Sea in the Shorebased IFQ Program, DRAFT Environmental Assessment. Published by the Pacific Fishery Management Council in July 2011. (http://www.pcouncil.org/groundfish/fishery-management-plan/amendment-21-1/)
- Proposed Harvest Specifications and Management Measures for the 2013-2014 Pacific Coast Groundfish Fishery and Amendment 21-2 to the Pacific Coast Groundfish Fishery Management Plan; Final Environmental Impact Statement. Published by the Pacific Fishery Management Council and NMFS in September 2012. (http://www.pcouncil.org/groundfish/fishery-management-plan/amendment-21-2/)
- Amendment 23: Considerations for a New Harvest Specification Framework that Incorporates Revised National Standard 1 Guidelines to Prevent Overfishing, Environmental Assessment. Published by the Pacific Fishery Management Council and NMFS in September 2010. (http://www.pcouncil.org/groundfish/fishery-management-plan/fmp-amendment-23/)
- Allocation of Harvest Opportunity between Sectors of the Pacific Coast Groundfish Fishery (Amendment 21 to the Groundfish FMP); Final Environmental Impact Statement Including Regulatory Impact Review and Initial Regulatory Flexibility Analysis. Published by the Pacific Fishery Management Council and NMFS in June 2010.(http://www.pcouncil.org/groundfish/fishery-management-plan/fmp-amendment-21/)
- Rationalization of the Pacific Coast Groundfish Limited Entry Trawl Fishery (Amendment 20 to the Groundfish FMP); Final Environmental Impact Statement Including Regulatory Impact Review and Initial Regulatory Flexibility Analysis. Published by the Pacific Fishery Management Council and NMFS in June 2010. (http://www.pcouncil.org/groundfish/fishery-management-plan/fmp-amendment-20/#EIS)

Information may be incorporated by reference from these documents into this EIS. Council on Environmental Quality (CEQ) regulations (40 CFR 1502.21) state "Agencies shall incorporate material into an environmental impact statement by reference when the effect will be to cut down on bulk without impeding agency and public review of the action. The incorporated material shall be cited in the statement and its content briefly described." When information from the above document is incorporated, these procedures are followed within the body of this EIS.

6.4 Preparers and Listing of Agencies and Persons Consulted

The following people wrote the EIS:

- Kelly Ames, Pacific Fishery Management Council: Sections

- Christopher "Kit" Dahl, Pacific Fishery Management Council: Sections
- John DeVore, Pacific Fishery Management Council: Sections
- Kerry Griffin, Pacific Fishery Management Council: Sections
- Becky Renko, National Marine Fisheries Service, Northwest Region: Sections
- Edward Waters, Contracting Economist: Sections

This EIS was prepared and evaluated in consultation with the National Marine Fisheries Service and the Pacific Fishery Management Council. In addition, members of the Groundfish Management Team (GMT) and the Scientific and Statistical Committee (SSC) prepared and reviewed portions of the analyses and provided technical advice during the development of the EIS. Members of Council advisory bodies are listed in rosters available at http://www.pcouncil.org/council-operations/council-and-committees/council-and-committee-rosters/. In addition the following persons were consulted or were involved in reviewing drafts of the document:

- Sarah Biegel, NMFS NWR, NEPA Coordinator
- Ryan Couch, NOAA GC, Attorney
- Kevin Duffy, NMFS NWR, Groundfish Section
- Mariam McCall, NOAA GC, Attorney
- Sarah Williams, NMFS NWR, Groundfish Section
- Becky Renko, NMFS NWR, Groundfish Section

6.5 DEIS Distribution List

The Council makes the EIS available on its website so anyone with computer access may download a copy of the document. Electronic copies on CD-ROM and paper copies are made available upon request. The Council distributes a notice of availability for the EIS through its electronic mail list, which includes state and Federal agencies, tribes, and individuals. Copies of the FEIS are sent to anyone who comments on the DEIS. In addition, NMFS distributes copies of the EIS to the following agencies:

- Department of Interior,
- Department of State,
- U.S. Coast Guard Commander Pacific Area,
- Marine Mammal Commission,
- Pacific States Marine Fisheries Commission, and
- Environmental Protection Agency.

As part of the review process for consistency with applicable laws such as the CZMA, NMFS also distributes the EIS to the following coastal states and agencies:

- Washington Coastal Zone Management Program, Shoreline Environmental Assistance, Department of Ecology, Washington State;
- Ocean-Coastal Management Program, Department of Land Conservation and Development, State of Oregon; and
- California Coastal Commission.

Members of the public may also request to be on the distribution list. The following individuals have requested copies of the EIS:

TBD

In addition, a Notice of Availability of the DEIS is also published in the *Federal Register*. The DEIS is available for a 45-day public comment period. During this time, any member of the public may call the Council office and request a copy of the DEIS for their review.

Questions concerning this document and requests for additional copies of this document may be addressed to:

6.6 Addressing NEPA in Subsequent Biennial Cycles

The adoption and adjustment of regulations for managing the groundfish fishery (including harvest specifications and management measures) is an ongoing, adaptive process. Changes in the type and intensity of environmental impacts tend not to differ substantially from one period to the next. With this view in mind this EIS evaluates the impacts of the ongoing action over a longer time period than 2 years. Biennial changes to the management program may then be subject to more focused analyses, as described below based on Council on Environmental Quality (CEQ) guidelines for supplementing and/or tiering from a previously prepared NEPA document.

When harvest specifications (and related management measures) are periodically adjusted, NMFS will determine whether to supplement this EIS or prepare a tiered NEPA analysis. These methods and the circumstances where they could be applied are discussed below.

CEQ regulations identify two conditions that trigger the need to "supplement" a NEPA document: (1) Has the agency made substantial changes in the proposed action that are relevant to environmental concerns?; (2) Are there significant new circumstances or information relevant to environmental concerns and bearing on the proposed action or its impacts? (See 40 CFR 1502.9(c)(1)). If the answer to these questions is "no," then no additional NEPA analysis is needed. The rationale for the agency's "no" finding must be adequately documented in the administrative record. Agencies, including NMFS, have used a "supplemental information report" (SIR) format to document these findings. Circumstances where this EIS would be supplemented could arise if the Council makes substantial changes to harvest policies, such as changing proxy values for F_{MSY} or adopting several new rebuilding plans for key stocks.

Alternatively, if circumstances have changed such that additional NEPA documentation may be required, the concept of "tiering," introduced in CEQ regulations, would be used: "Whenever a broad environmental impact statement has been prepared (such as a program or policy statement) and a subsequent statement or environmental assessment is then prepared on an action included within the entire program or policy (such as a site specific action) the subsequent statement or environmental assessment need only summarize the issues discussed in the broader statement and incorporate discussions from the broader statement by reference and shall concentrate on the issues specific to the subsequent action." (40 CFR 1502.20) If, when harvest specifications and management measures are periodically adjusted, it is determined that this EIS does not address the environmental impacts of the proposed action, a subsequent tiered NEPA document would be prepared. The tiered NEPA document would be narrowly focused on those aspects of the proposal that may have environmental impacts different from those identified in this EIS. For example, the tiered NEPA document could focus on changes to harvest control rules that were not analyzed in this EIS.

6.7 Administrative Procedure Act

The Administrative Procedures Act, or APA, governs the Federal regulatory process and establishes standards for judicial review of Federal regulatory activities. Most Federal rulemaking, including regulations promulgated pursuant to the MSA, are considered "informal," which is determined by the controlling legislation. Provisions at 5 U.S.C. 553 establish rulemaking procedures applicable to the proposed action. Section 6.2 in the Groundfish FMP (PFMC 2011) specifies that biennial harvest specifications and management measures require 'full notice-and-comment rulemaking' to implement the regulations necessary to implement the Council recommendation. The rulemaking associated with this proposed action will be conducted in accordance with the APA and procedures identified in section 304 of the MSA.

6.8 Additional Laws and Executive Orders Applicable to the Proposed Action

In addition to the Magnuson-Stevens Act (see Chapter 5), the National Environmental Policy Act, and the Administrative Procedure Act there are other laws and Federal Executive Orders that may impose substantive and procedural requirements on the proposed action. These other laws and executive orders are described below.

6.8.1 Coastal Zone Management Act:

Section 307(c)(1) of the Federal Coastal Zone Management Act (CZMA) of 1972 requires all Federal activities that directly affect the coastal zone be consistent with approved state coastal zone management programs to the maximum extent practicable. A determination as to whether the proposed action is would be implemented in a manner that is consistent to the maximum extent practicable with the enforceable policies of the approved coastal zone management programs of Washington, Oregon, and California will be submitted to the responsible state agencies for review under Section 307(c)(1) of the CZMA. The relationship of the groundfish FMP with the CZMA is discussed in Section 11.7.3 of the Groundfish FMP. The Groundfish FMP has been found to be consistent with the Washington, Oregon, and California coastal zone management programs.

6.8.2 Endangered Species Act

The Endangered Species Act of 1973 (ESA) was signed on December 28, 1973, and provides for the conservation of species that are endangered or threatened throughout all or a significant portion of their range, and the conservation of the ecosystems on which they depend. The ESA replaced the Endangered Species Conservation Act of 1969; it has been amended several times.

A "species" is considered endangered if it is in danger of extinction throughout all or a significant portion of its range. A species is considered threatened if it is likely to become an endangered species within the foreseeable future.

Federal agencies are directed, under section 7(a)(1) of the ESA, to utilize their authorities to carry out programs for the conservation of threatened and endangered species. Federal agencies must also consult with NMFS or USFWS, under section 7(a)(2) of the ESA, on activities that may affect a listed species.

These interagency consultations, or section 7 consultations, are designed to assist Federal agencies in fulfilling their duty to ensure Federal actions do not jeopardize the continued existence of a species or destroy or adversely modify critical habitat. Should an action be determined to jeopardize a species or result in the destruction or adverse modification of critical habitat, NMFS or USFWS will suggest Reasonable and Prudent Alternatives (RPAs) that would not violate section 7(a)(2).

Biological opinions document whether the Federal action is likely to jeopardize the continued existence of listed species, or result in the destruction or adverse modification of critical habitat. Where appropriate, biological opinions provide an exemption for the "take" of listed species while specifying the extent of take allowed, the Reasonable and Prudent Measures (RPMs) necessary to minimize impacts from the Federal action, and the Terms and Conditions with which the action agency must comply.

This section will be updated with finding from the most recent BiOps.

6.8.3 Marine Mammal Protection Act

The MMPA of 1972 is the principle Federal legislation that guides marine mammal species protection and conservation policy in the United States. Under the MMPA, NMFS is responsible for the management and conservation of 153 stocks of whales, dolphins, porpoise, as well as seals, sea lions, and fur seals; while the USFWS is responsible for walrus, sea otters, and the West Indian manatee.

Off the west coast, the Steller sea lion (*Eumetopias jubatus*) eastern stock, Guadalupe fur seal (*Arctocephalus townsendi*), and Southern sea otter (*Enhydra lutris*) California stock are listed as threatened under the ESA. The sperm whale (*Physeter macrocephalus*) Washington, Oregon, and California stock, humpback whale (*Megaptera novaeangliae*) Washington, Oregon, and California - Mexico Stock, blue whale (*Balaenoptera musculus*) eastern north Pacific stock, and Fin whale (*Balaenoptera physalus*) Washington, Oregon, and California stock are listed as depleted under the MMPA. Any species listed as endangered or threatened under the ESA is automatically considered depleted under the MMPA.

Pursuant to the MMPA, the List of Fisheries (LOF) classifies U.S. commercial fisheries into one of three Categories according to the level of incidental mortality or serious injury of marine mammals:

I. frequent incidental mortality or serious injury of marine mammals
II. occasional incidental mortality or serious injury of marine mammals
III. remote likelihood of/no known incidental mortality or serious injury of marine mammals

The Marine Mammal Protection Act (MMPA) mandates that each fishery be classified by the level of serious injury and mortality of marine mammals that occurs incidental to each fishery is reported in the annual Marine Mammal Stock Assessment Reports for each stock. On the 2012 List of Fisheries the WA/OR/CA sablefish pot fishery is listed as a category II fishery due to interactions with humpback whales. All other west coast groundfish fisheries are listed as category III fisheries. (See http://www.nmfs.noaa.gov/pr/interactions/lof/final2012.htm. [update with Final 2013 LOF when available].)

Commercial fishing vessels participating in Category I or II fisheries must be covered by a Federal permit under the MMPA. For most fisheries, including all west coast fisheries, a blanket permit is issued for all Federal or state permits authorizing participation in the fishery.

6.8.4 Migratory Bird Treaty Act

The MBTA of 1918 was designed to end the commercial trade of migratory birds and their feathers that, by the early years of the 20th century, had diminished the populations of many native bird species. The MBTA states that it is unlawful to take, kill, or possess migratory birds and their parts (including eggs, nests, and feathers) and is a shared agreement between the United States, Canada, Japan, Mexico, and Russia to protect a common migratory bird resource. The MBTA prohibits the directed take of seabirds, but the incidental take of seabirds does occur.

6.8.5 Paperwork Reduction Act

The Paperwork Reduction Act requires that agency information collections minimize duplication and burden on the public, have practical utility, and support the proper performance of the agency's mission.

6.8.6 Regulatory Flexibility Act

The Regulatory Flexibility Act requires government agencies to assess the effects that regulatory alternatives would have on small entities, including small businesses, and to determine ways to minimize those effects. A fish-harvesting business is considered a “small” business by the Small Business Administration if it has annual receipts not in excess of $4.0 million. For related fish-processing businesses, a small business is one that employs 500 or fewer persons. For wholesale businesses, a small business is one that employs not more than 100 people. For marinas and charter/party boats, a small business is one with annual receipts not in excess of $6.5 million. If the projected impact of the regulation exceeds $100 million, it may be subject to additional scrutiny by the Office of Management and Budget

6.8.7 Executive Order12866 (Regulatory Impact Review)

EO 12866, Regulatory Planning and Review, covers a variety of regulatory policy considerations and establishes procedural requirements for analysis of the benefits and costs of regulatory actions. It directs agencies to choose those approaches that maximize net benefits to society, unless a statute requires another regulatory approach. The agency must assess both the costs and the benefits of the intended regulation and, recognizing that some costs and benefits are difficult to quantify, propose or adopt a regulation only after reasoned determination the benefits of the intended regulation justify the costs. In reaching its decision, the agency must use the best reasonably obtainable information, including scientific, technical and economic data, about the need for and consequences of the intended regulation. NMFS requires the preparation of a regulatory impact review (RIR) for all regulatory actions of public interest. The purpose of the analysis is to ensure the regulatory agency systematically and comprehensively considers all available alternatives, so the public welfare can be enhanced in the most efficient and cost-effective way. The RIR addresses many of the items in the regulatory philosophy and principles of EO 12866.

6.8.8 Executive Order 12898 (Environmental Justice)

EO 12898 obligates Federal agencies to identify and address “disproportionately high adverse human health or environmental effects of their programs, policies, and activities on minority and low-income populations in the United States” as part of any overall environmental impact analysis associated with an action. NOAA guidance, NAO 216-6, at Section 7.02, states that “consideration of EO 12898 should be specifically included in the NEPA documentation for decision-making purposes.” Agencies should also encourage public participation, especially by affected communities during scoping, as part of a broader strategy to address environmental justice issues.

6.8.9 Executive Order 13132 (Federalism)

EO 13132, which revoked EO 12612, an earlier federalism EO, enumerates eight "fundamental federalism principles." The first of these principles states "Federalism is rooted in the belief that issues that are not national in scope or significance are most appropriately addressed by the level of government closest to the people." In this spirit, the EO directs agencies to consider the implications of policies that may limit the scope of or preempt states' legal authority. Preemptive action having such "federalism implications" is subject to a consultation process with the states; such actions should not create unfunded mandates for the states; and any final rule published must be accompanied by a "federalism summary impact statement."

6.8.10 Executive Order 13175 (Consultation and Coordination with Indian Tribal Government)

EO 13175 is intended to ensure regular and meaningful consultation and collaboration with tribal officials in the development of Federal policies that have tribal implications, to strengthen the United States government-to-government relationships with Indian tribes, and to reduce the imposition of unfunded mandates upon Indian tribes.

The Secretary recognizes the sovereign status and co-manager role of Indian tribes over shared Federal and tribal fishery resources. In Section 302(b)(5), the MSA reserves a seat on the Council for a representative of an Indian tribe with Federally-recognized fishing rights from California, Oregon, Washington, or Idaho.

The U.S. government formally recognizes the four Washington coastal tribes (Makah, Quileute, Hoh, and Quinault) have treaty rights to fish for groundfish. In general terms, the quantification of those rights is 50 percent of the harvestable surplus of groundfish available in the tribes' U and A fishing areas (described at 50 CFR 660.324). Each of the treaty tribes has the discretion to administer their fisheries and to establish their own policies to achieve program objectives.

6.8.11 Executive Order 13186 (Responsibilities of Federal Agencies to Protect Migratory Birds)

EO 13186 supplements the MBTA (above) by requiring Federal agencies to work with the USFWS to develop memoranda of agreement to conserve migratory birds. NMFS is in the process of implementing a memorandum of understanding. The protocols developed by this consultation will guide agency regulatory actions and policy decisions in order to address this conservation goal. The EO also directs agencies to evaluate the effects of their actions on migratory birds in environmental documents prepared pursuant to the NEPA.

6.9 Findings

The Council process and this EIS are intended, where possible, to meet the public involvement requirements and provide the information and analysis necessary to address the mandates described above. Mandates that require additional analysis, documentation, and process not met through NEPA are discussed in section 6.10 below. The information and analysis in this EIS supports the following findings with respect to other applicable law.

<u>Coastal Zone Management Act</u>: Harvest specifications and management measures for 2015-2016 are not expected to affect any state's coastal management program.

ESA: NMFS and USFWS conducted a section 7 consultations to determine whether activities authorized under groundfish regulations in 2013 and subsequent years are likely to jeopardize the continued existence of any species listed under the ESA. Findings (Incidental Take Statements, Reasonable and Prudent Measures, etc.) are summarized here.

Marine Mammal Protection Act: Section 4.x describes new information about the incidental take of marine mammals and section 4.x assesses the effects of the proposed action on marine mammals. Although the operation of groundfish fisheries may differ from previous management cycles there is insufficient information to predict whether the effects on marine mammals will differ from previous management cycles.

Migratory Bird Treaty Act: The proposed action is unlikely to cause the incidental take of seabirds protected by the Migratory Bird Treaty Act to differ substantially from levels in previous years. Past EISs evaluating the impact of groundfish harvest specifications evaluated impacts to seabirds and concluded that the proposed action will not significantly impact seabirds. (Section 4.x evaluated impacts of the proposed action on protected species)

Paperwork Reduction Act: The proposed action, as implemented by any of the alternatives considered in this EIS, does not require collection-of-information subject to the Paperwork Reduction Act.

Executive Order 12898 (Environmental Justice): The proposed action will not result in disproportionate adverse impacts to low income and minority communities (see section 4.x).

Executive Order 13132 (Federalism): The proposed action does not have federalism implications subject to EO 13132.

Executive Order 13175 (Consultation and Coordination with Indian Tribal Government): Harvest specifications and management measures for 2015-2016 have been developed in consultation with the affected tribe(s) and, insofar as possible, with tribal consensus.

Executive Order 13186 (Responsibilities of Federal Agencies to Protect Migratory Birds): See the finding for the Migratory Bird Treaty Act, above.

6.10 Mandates Addressed Through Separate or Parallel Processes

6.10.1 ESA

NMFS Northwest Region Sustainable Fisheries Division consulted with the Protected Resources Division and with the USFWS pursuant to section 7(a)(2) of the ESA on the effects of the operation of the Pacific coast groundfish fishery in 2013 and subsequent years. Outcomes implemented outside of the biennial harvest specifications process are summarized here.

6.10.2 Executive Order 12866 (Regulatory Impact Review) and the Regulatory Flexibility Act

NMFS develops the necessary analysis and documentation needed to address these mandates as part of the Federal rulemaking process implementing groundfish harvest specifications and management measures. These analyses rely substantially on the contents of this EIS and the socioeconomic impact evaluation in Chapter 4 and baseline information in Chapter 3, which have been developed in conjunction with NMFS NWR staff to provide information needed for the Regulatory Impact Review and Regulatory Flexibility Act analyses.

Management Measures under the Preferred Alternative

B.1 Changes to Rockfish Conservation Area Coordinates

Need for Action

Rockfish Conservation Areas (RCA) are a type of commercial and recreational fishery management measure used to keep catches within annual catch limits (ACLs). RCAs affect the collective behavior of harvesters by preventing fishing in areas where bycatch of overfished species is particularly high. Their extent varies by area, season and gear type to allow access to target species while minimizing bycatch. The boundaries of RCAs are described by depth contours since a correlation between depth and the distribution (or catch) of overfished species has been demonstrated through an analysis of trawl logbook and survey data. The boundary depth contours defined by waypoints in Federal regulations (at 50 CFR 660.71-660.74) only approximate actual isobaths for two reasons. First, the waypoints defining the lines were defined using available bathymetry data, which have improved over time. Second, for enforcement purposes the lines defined by the waypoints are a more generalized, or simplified, representation of isobaths. Often, changes to the coordinates that define RCA are often recommended during the biennial cycle to more closely align with the latest data on bathymetry.

Other measures more directly constrain catch on an individual vessel level. These are:

- Individual fishing quota (IFQ) management for the shoreside trawl fleet (with cumulative landing
- limits for some non-target, non-overfished management units)
- Co-op allocations to the at-sea whiting fleets (catcher vessels delivering to at-sea processors and
- catcher-processors)
- Permit-based sablefish allocations to vessels in the limited entry fixed gear fleet during the
- primary season
- Daily and cumulative landing limits for the open access fixed gear sectors and limited entry fixed
- gear outside the primary season
- State restricted access permit programs for the non-trawl fixed-gear sectors, such as the nearshore fisheries for Oregon and California

Only catch share management directly controls total catch of most management unit species (including all overfished species) in the trawl sectors with all catch monitored by observers. Daily trip limits and 2-month limits in other sectors only control landings; overfished species total catch (mostly bycatch) must be imputed based on partial observer coverage. RCAs add another layer of precaution by affecting collective behavior and their use is more important in managing those sectors not under catch shares since overfished species bycatch cannot be directly controlled.

Inseason management allows measures to be periodically adjusted during the biennial period based on new information and catch projections. These management measures are described in more detail in Section 2.3 of the EIS.

B.1.1 Oregon: Adjustments to the 200 fm Modified Line

Coordinates for the 200 fathom (fm) RCA line in Oregon were revised beginning January 1, 2013 to better align with depth contours (See 2013-2014 FEIS). However, coordinates for the 200-fm modified RCA, which are modified to provide access to shallower waters where petrale sole concentrations are greater (called petrale cut-outs), were not simultaneously adjusted. The result was areas where the petrale cut-outs on the 200 fm modified line were deeper than the 200 fm RCA (Figure B-1).

Management Options

No Action: The RCA coordinates currently in regulation would remain and in some areas the 200 fm modified line with petrale cut-outs would be deeper than the 200 fm line.

Option 1 (Preferred): Revise coordinates such that the 200 fm modified line is not deeper than the 200 fm line (Table B-1).

Table B-1. Coordinate list for proposed modification to 200 fm-modified RCA coordinates.

ID	Name	Degrees, decimal minutes	Decimal degrees
79	Current waypoint	44°46.87'N, 124°38.20'W	44.781243, -124.636738
1	OR proposed modification	44°48.25'N, 124°40.61'W	44.8041, -124.6769
2	OR proposed modification	44°42.24'N, 124°48.05'W	44.704, -124.8008
3	OR proposed modification	44°41.35'N, 124°48.03'W	44.6892, -124.8005

B.1.2 Modifications to the Boundaries Defining Rockfish Conservation Areas off California

The following proposed modifications to current RCA boundary waypoints were adopted by the Pacific Fishery Management Council, at its April 2014 meeting, for analysis:

- Adjustments to the 60 fm RCA boundary waypoints off Del Mar and San Diego, California (Agenda Item H.3.b GMT Report, November 2013 and Agenda Item C.9.b GAP Report, April 2014)

An additional analysis is included that addresses a proposal for RCA boundary waypoint adjustments around the northern Channel Islands, California.

B.1.2.1 Modifications of the 60 fm Depth Contour: Two Southern California Bight Proposals

During the 2013-2014 biennial management cycle, the 60 fm depth contour was used as the shoreward boundary of the non-trawl RCA south of 34°27' N. lat. The depth contours defining the boundaries of RCAs are listed in trip limit tables published in Federal regulations and in periodic Public Notices announcing changes to groundfish management measures (see http://tinyurl.com/lty84jx). This boundary is intended to reduce bycatch of overfished species (OFS) such as bocaccio, canary, cowcod, and yelloweye rockfishes while providing access to target species.

Need for Action

The current 60 fm depth contour specified in regulation at 50 CRF 660.72(f) approximates the 60 fm isobath. To allow better access to non-trawl fishing areas for target species while maintaining the intent of the 60 fm line, better alignment of the 60 fm line with the 60 isobath is necessary for waters off California.

<u>Management Options</u>

<u>No Action</u>: Under No Action (described in section 2.4.1 of the 2013-2014 EIS) the 60 fm depth contour created by the waypoints currently listed at 50 CRF 660.72(f) would be retained in 2015-2016 and beyond.

<u>Options</u>: Under the Options, the 60 fm depth contour would more closely align with actual bathymetry in one of the two 60 fm proposals. These changes are based on proposals submitted by industry to modify the 60 fm RCA by modifying existing waypoints and/or adding new waypoints to the existing set(s). One sub-proposal addresses modifications west of Del Mar, California and the second-sub proposal addresses a modification west of San Diego, California.

Del Mar Option

- Modify the 60 fm contour between waypoints #198 and 199 by adding five new waypoints, and
- Modify the 60 fm contour between waypoints #198 and #200 by adjusting waypoint #199

Industry submitted the above proposed adjustments to allow increased access to fishing areas currently closed as a result of the existing RCA shoreward boundary. However, as proposed (see above reference, and Table B-2 and Figure B-2), the proposed boundary adjustments off the Del Mar area would move a section of the shoreward 60 fm RCA shoreward boundary into waters deeper than 75 fm. Additionally, one waypoint that is proposed to be edited (#199) actually moves the 60 fm RCA shoreward boundary to waters less than 50 fm. Given that these are the waypoint coordinates that were submitted as is and analyzed as such, it does not appear that such adjustments should be accommodated. It appears that there is no alternate way to address industry's proposal at this time. In the future, however, industry may wish to re-submit a different set of coordinates for consideration.

For this proposal, had the adjustments been deemed reasonable (at least from the initial analysis standpoint), fishing opportunities would have been increased for those members of the fleet fishing out of the greater San Diego area. Also, there would have been no conflicts with existing MPAs.

San Diego: Option A and Option B

Industry also submitted another proposal to accommodate an adjustment to the 60 fm RCA shoreward boundary west of San Diego that would allow better access to a tip of a reef. This proposal was submitted to consider one of two options.

- Option A: Modify the 60 fm contour between waypoints #205 and #207 by adjusting waypoint #206, or
- Option B: Modify the 60 fm contour between waypoints #206 and #207 by adding a new waypoint

As proposed, Option A requests that the 60 fm waypoint #206 be moved whereas Option B requests that a new waypoint be inserted between waypoint #206 and #207. Moving the existing waypoint #206, as proposed, results in a move of approximately 228 meters (approximately 250 yards).

Table B-2 through Table B-4 show the waypoint adjustments outlined above for both proposals. Figure B-2 and Figure B-3 also show the waypoint adjustments with Figure B-3 restricted to the Option A proposal. At the April 2013 Council meeting, the GAP recommended two Southern California Bight adjustments be analyzed by the Groundfish Management Team (GMT) for consideration by the Council. The Groundfish Advisory Subpanel (GAP) pointed out that with existing lines; it is difficult to fish a particular reef in this area in a prevailing current. The GAP also pointed out that there is some room to the south and west of the reef that would fix this problem if either of the two options were implemented for the San Diego proposal.

Upon review and analysis, an alternate option is presented here. This alternate option better aligns the RCA shoreward boundary to the 60 fm contour and eliminates the proposed access to fishing areas that are much deeper than 60 fm. Under this alternate option proposal, one new waypoint is added (proposed waypoint #5) between existing waypoint # 198 and existing waypoint #199. It removes the addition of new waypoints #1, #2, #3, and #4 and eliminates modifying existing waypoint # 199. The detailed adjustments for this new set of coordinate adjustments are presented in Table B-3 and Figure B-3.

Comparison of the Management Options

Biological Impacts: The non-trawl fixed-gear fisheries do not require logbooks to be completed and as such, it is very difficult to determine the species that may be taken in the proposed area and/or adjacent areas. Reporting of fishing areas is limited to documentation of Fish and Wildlife catch block numbers on the commercial landings receipts. These, however, cover 10x10 mile grids and do not lend themselves to accurate accounting of what species were caught from any specific areas. To the degree that there is not enough precise correlation between recorded catch by species and recorded fishing areas (blocks) under the action alternatives, there could be an increase of OFS, other fish species, and the take of protected species in the opened areas.

Under Option B, the issue of having access to fishing areas much deeper than 60 fm in this area is eliminated. The industry proposed option would have allowed fishing in an area as deep as 195 fm (Figure B-2). This alternate option better aligns the RCA shoreward boundary to the 60 fm contour. Under this alternate option, no biological impacts would be expected.

Socioeconomic Impacts: The changes proposed under the action alternatives may have a marginal socioeconomic benefit for the shoreside non-trawl fixed gear fishery managed under an RCA with a 60 fm contour as its shoreward boundary. Access to this additional small area would be beneficial to the fishing community from the greater San Diego area. The change in management cost, primarily those associated with law enforcement of the RCA boundaries, may be problematic.

Table B-2. Coordinate list for proposed modifications to the 60 fm RCA shoreward boundary off Del Mar, California.

	Boundary Line	Coordinates
ID	**Name**	**Degrees, decimal minutes**
198	Current waypoint (keep)	32°57.39' N, 117°18.72' W

Option B would be to add this waypoint between waypoints #206 and #207. ***Bathymetry based on NOAA National Geophysical Data Center, U.S. Coastal Relief Model, Retrieved May, 2014, http://www.ngdc.noaa.gov/mgg/coastal/crm.html.***

B.1.2.2 Modifications of the 50 fm Depth Contour: Northern Channel Islands Proposal

During the 2013-2014 biennial management cycle, the 50 fm depth contour was used as the shoreward boundary of the recreational RCA (660.360). This boundary is intended to reduce bycatch of overfished species (OFS) such as bocaccio, canary, cowcod, and yelloweye rockfishes.

Need for Action

The current 50 fm depth contour specified in regulation at 50 CRF 660.72(c) approximates the 50 fm isobath around the north Channel Islands – San Miguel, Santa Rosa, and Santa Cruz. To allow better access to non-trawl fishing areas for non-OFS species while maintaining the intent of the 50 fm line, better alignment of the 50 fm line with the 50 isobath is necessary for waters off California.

<u>Management Options</u>

<u>No Action</u>: Under No Action (described in section 2.4.1 of the 2013-2014 EIS) the 50 fm depth contour created by the waypoints currently listed at 50 CRF 660.72(c) would be retained in 2015-2016 and beyond.

<u>Options</u>: Under the Options the 50 fm depth contour would more closely align with actual bathymetry in one of the two 50 fm proposals. These changes are based on proposals submitted by industry to modify the 50 fm RCA by modifying existing waypoints and adding new waypoints to the existing set(s).

- Modify the 50 fm depth contour between waypoints #2 and #4 by adjusting waypoint #3 with a new set of coordinates,
- Modify the 50 fm depth contour between waypoints #4 and #5 by adding five new waypoints,
- Modify the 50 fm depth contour between waypoints #20 and #21 by adding a new waypoint,
- Modify the 50 fm depth contour between waypoints #21 and #23 by adjusting waypoint #22,
- Modify the 50 fm depth contour between waypoints #23 and #25 by adjusting waypoint #24, and
- Modify the 50 fm depth contour between waypoints #25 and #26 by adding a new waypoint.

One problem to note is that the new point inserted between waypoint 25 and 26 causes the modified 50 fm line to cross over the 60 fm line.

Table B-5 shows the revised coordinates for the proposed changes as outlined above. Figure B-4 also shows the waypoint adjustments.

Upon review and analysis, an alternate option is presented here. For the Northern Channel Islands, this new alternate proposed option would better align the RCA shoreward boundary to the 50 fm contour around the Northern Channel Islands. In doing so, it would also provide more fishing areas. This proposal would adjust existing waypoint #3 and add a new waypoint between the existing waypoint #2 and the adjusted waypoint #3. All the other proposed industry adjustments are left as proposed. The details of this alternate option are given in Table B-6 and Figure B-6.

Northern Channel Islands

Industry submitted a proposal to make a number of waypoint adjustments around the northern Channel Islands, California, to accommodate increased fishing opportunities. This proposal was not part of the April 2014 Council meeting motion, but is included in this analysis to address an additional proposal that was received late. The GMT did note in their November 2013 statement (<u>Agenda Item H.3.b GMT Report, November 2013</u>) that it did not have the time (at that time) to determine if there were other waypoints that should be added to the list (the Del Mar and San Diego proposals). This Channel Islands proposal should be considered in reference to that comment.

The proposed waypoint adjustments do overlap with some existing MPAs around the Channel Islands. Also, Essential Fish Habitat (EFH) areas need to be considered, although none were specifically cross-referenced for this analysis. Specific coordinates of EFH area may be found in Federal Regulations 50 CFR 660.75-79. Aside from concerns regarding MPAs and EFHs, access to these areas would be beneficial to the fishing community from the greater Santa Barbara area.

Comparison of the Management Options

Biological Impacts: Increased opportunity for the recreational sector would be accommodated by these changes. The likelihood that increased encounters with overfished species may also occur, would probably be minimal. However, no quantitative evaluations have been made to explore this possibility. When the 50 fm contour was implemented, it eliminated some confusion about fishing the 14 mile bank and 60 mile bank for rockfish (as these seamounts are both between 50 and 60 fm deep).

Under the alternate option, more fishing area would be allowed, without an expected increase in overfished species encounters. This is surmised because the increased area does not extend into appreciably deeper habitat where increased encounters of overfished species could potentially occur.

Socioeconomic Impacts: The changes proposed under the action alternatives may have a marginal socioeconomic benefit for the recreational fishery managed under an RCA with a 50 fm contour as its shoreward boundary. Access to this additional small area would be beneficial to the fishing community from the greater Santa Barbara area, but to what degree it is unknown. The change in management cost, primarily those associated with law enforcement of the RCA boundaries, may be problematic.

Table B-5. Coordinate list for proposed modifications to the 50 fm boundary around the northern Channel Islands, California.

	Boundary Line	Coordinates
ID	Name	Degrees, decimal minutes
2	Current waypoint (keep)	34°07.80' N, 120°30.99' W
3	Proposed modification (modify #3)	34°08.770' N, 120°25.740' W
4	Current waypoint (keep)	34°05.85' N, 120°17.13' W
--	Proposed modification (add after #4)	34°05.73' N, 120°05.93' W
--	Proposed modification (add after #4)	34°06.140' N, 120°04.860' W

Proposed 50 Fathom RCA Line Changes - Northern Channel Islands

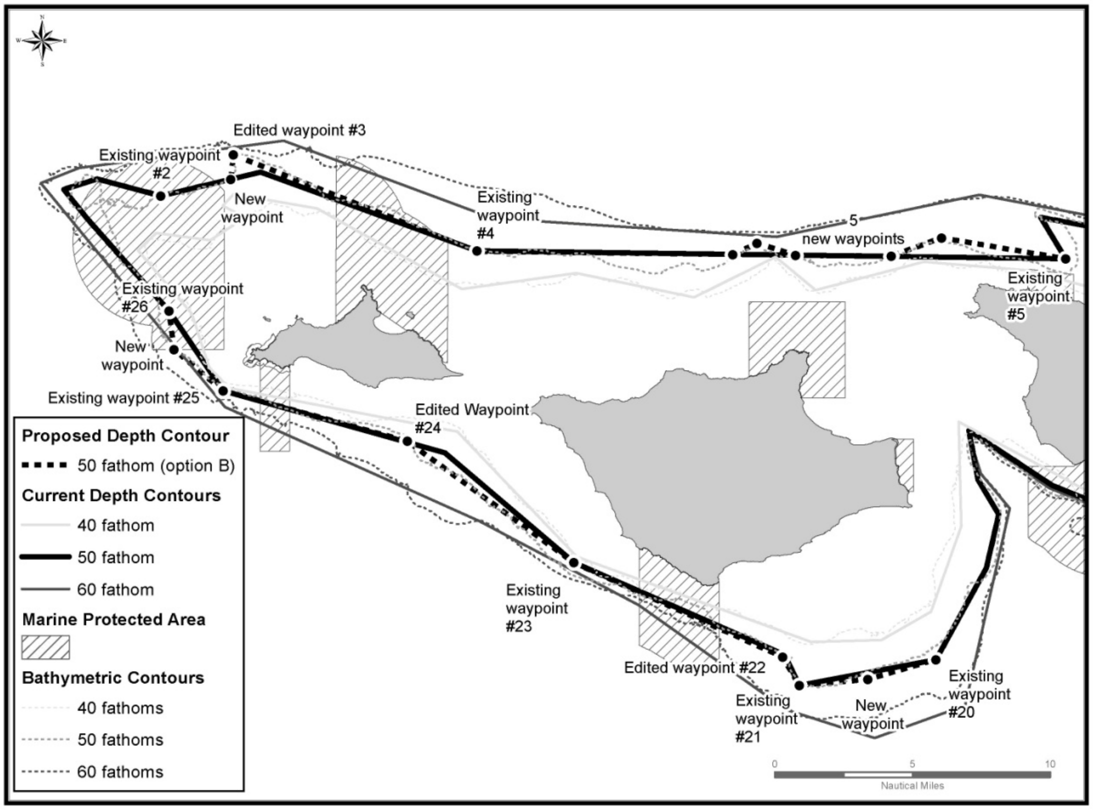

Figure B-6. Modification to the 50 fm contour around the northern Channel Islands of San Miguel, Santa Rosa, and Santa Cruz Islands, California, proposed by CDFW. ***Bathymetry based on NOAA National Geophysical Data Center, U.S. Coastal Relief Model, Retrieved May, 2014, http://www.ngdc.noaa.gov/mgg/coastal/crm.html.***

B.2 Establish New Rockfish Conservation Area Coordinates – 300 and 350 fm

Need for Action

The Pacific Fishery Management Council (the Council) requested that the Groundfish Management Team (GMT) propose coordinates for and analyze possible 300 and 350 fm Rockfish Conservation Areas (RCAs) north of 40°10' N. latitude. These RCAs were proposed as possible management measures to aid in reducing catch of rougheye and blackspotted rockfish during the 2015-16 biennium and could potentially be applied to all sectors through routine or inseason action. The GMT intends to provide analysis of these areas by sector for the June 2014 Council meeting. Other analysis regarding RCA changes can be found in the Final Environmental Assessment for Trawl RCA Boundary Modifications, completed by the National Marine Fisheries Service (NMFS) in February 2014.

Management Options

No Action: The deepest RCA boundaries available in regulation would be 250 fm.

Options: At this time, the following latitude and longitude coordinates (i.e., waypoints) are provided as a starting point for the discussion that is needed to refine and identify possible 300 and 350 fm lines (Table B-7 and Table B-8). These waypoints were developed using geographic information system (GIS) software (ArcGIS 10.1) and are based on 300 and 350 fm bathymetry contours.[1] More information, such as the files used to create these lines, will be available for the public at the following FTP site: ftp://ftp.pcouncil.org/pub/GMT/Proposed_300_350_RCAs/. Given other workload, the GMT was not able to produce an analysis of impacts resulting from these lines for the June Briefing Book. The GMT aims to produce a supplemental report at the June Council meeting focused on logbook and observer data to characterize how catch of target species and bycatch of rougheye and other species would be altered by the RCA boundary lines. The proposed waypoints are provided now to get feedback from the fishing industry regarding how these lines may affect their operations and how the lines might be improved to achieve objectives (e.g., reduce rougheye rockfish catch while retaining productive fishing grounds for other species).

Figure B-7 provides an example of issues that emerged when developing these proposed waypoints. First, the 300 and 350 fm bathymetry contours are very detailed and creating RCA lines directly following these contours would not be practical. Therefore, these contours were approximated and straightened using several tools available in ArcGIS.[2] Second, there were several areas where the existing 250 fm RCA line (unmodified for petrale, defined in regulation at §660.74) touched or overlapped the 300 and 350 fm bathymetry contours.[3] When this occurred, the GMT analyst visually and manually adjusted these lines to pull them outside of the 250 fm RCA (Figure B-8 provides an example). More information about where these manual adjustments were made can be provided in June if requested.

Given the availability and resolution of the data and the complexity of certain features like undersea canyons, matching RCA boundary lines to actual bathymetry is difficult. The original and current purpose of boundary lines is not to match the bathymetry perfectly, but to create regulatory lines that

[1] Source of bathymetry contours: NOAA National Geophysical Data Center, http://www.ngdc.noaa.gov/mgg/bathymetry/relief.html (accessed 5/19/14).

[2] The following ArcGIS 10.1 tools were used to develop, simplify, and straighten the 300 fm and 350 fm bathymetry contour lines: “Neighborhood Selection (Geostatistical Analyst)”, “Simplify Line (Cartography)”, and the “Edit Vertices” tools.

[3] The coordinates of existing RCA boundary lines, including the 250 fm line, can be downloaded from the NMFS West Coast Region’s website: http://www.westcoast.fisheries.noaa.gov/fisheries/management/groundfish_closures/rockfish_areas.html

approximate depth contours, would be enforceable, and would be effective at lowering bycatch to the desired degree. To overcome this difficultly when the currently existing RCAs were first developed, RCA lines such as the 250 fm line were manually adjusted after feedback from the fishing industry, enforcement, and the GMT (i.e., RCAs were designed to approximate bathymetry contours).

The 300 and 350 fm RCA lines and waypoints shown in this document could be viewed as the first of many steps. Adjusting these lines could be the next step of the process. Various methods can be used to adjust these lines to approximate the depth contours while at the same time being enforceable, understandable, logical, and be effective at lowering bycatch. One approach that may be used to adjust these base lines is the traditional approach that was used when RCAs were first created (i.e., through consultations with NMFS, States, Tribes, GAP, GMT, EC, etc.). Various analytical tools can be applied to help this process and ensure that existing RCA lines that are shallower (e.g., 250 fm line) do not cross the new “deeper” RCA lines (i.e., the 300 and 350 fm lines). One approach that can be applied to ensure that lines do not cross is to set the RCAs equal at those locations. That is, when the 300 or 350 fm line crosses the 250 fm line, the 300 or 350 fm line would simply follow the 250 fm line. This approach is often used now to correct RCA lines that cross. An example of this approach is shown in Figure B-9. Other approaches could also be applied. For example, one could simply extend the existing 250 fm line in increments (e.g., by 0.5 nm, 1 nm, 3 nm, etc.) to create new RCAs that do not necessarily approximate depth contours but instead, follow the pattern of shallower RCA lines that currently exist. An example of this novel approach is shown in Figure B-10.

Table B-7. Proposed waypoints (decimal degrees) for the proposed 300 fm RCA line.

Figure B-7. An example of where the existing 250 fm Trawl RCA (unmodified for petrale sole) overlaps with the 300 and 350 fm bathymetry contours

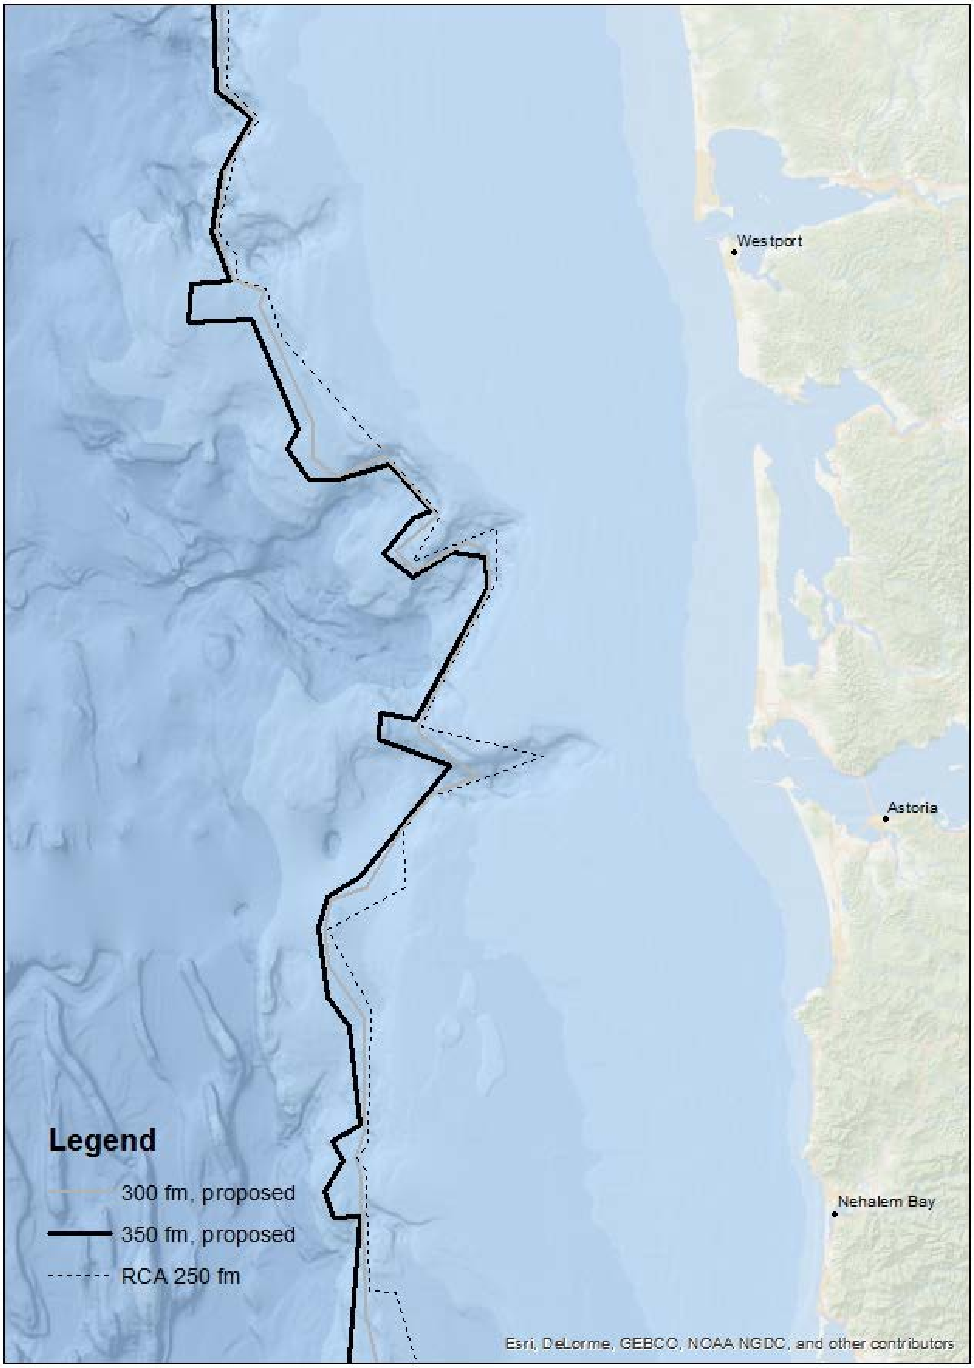

Figure B-8. An example of manual adjustments to the proposed 300 and 350 fm lines where they overlap with the existing 250 fm RCA line (unmodified for petrale sole).

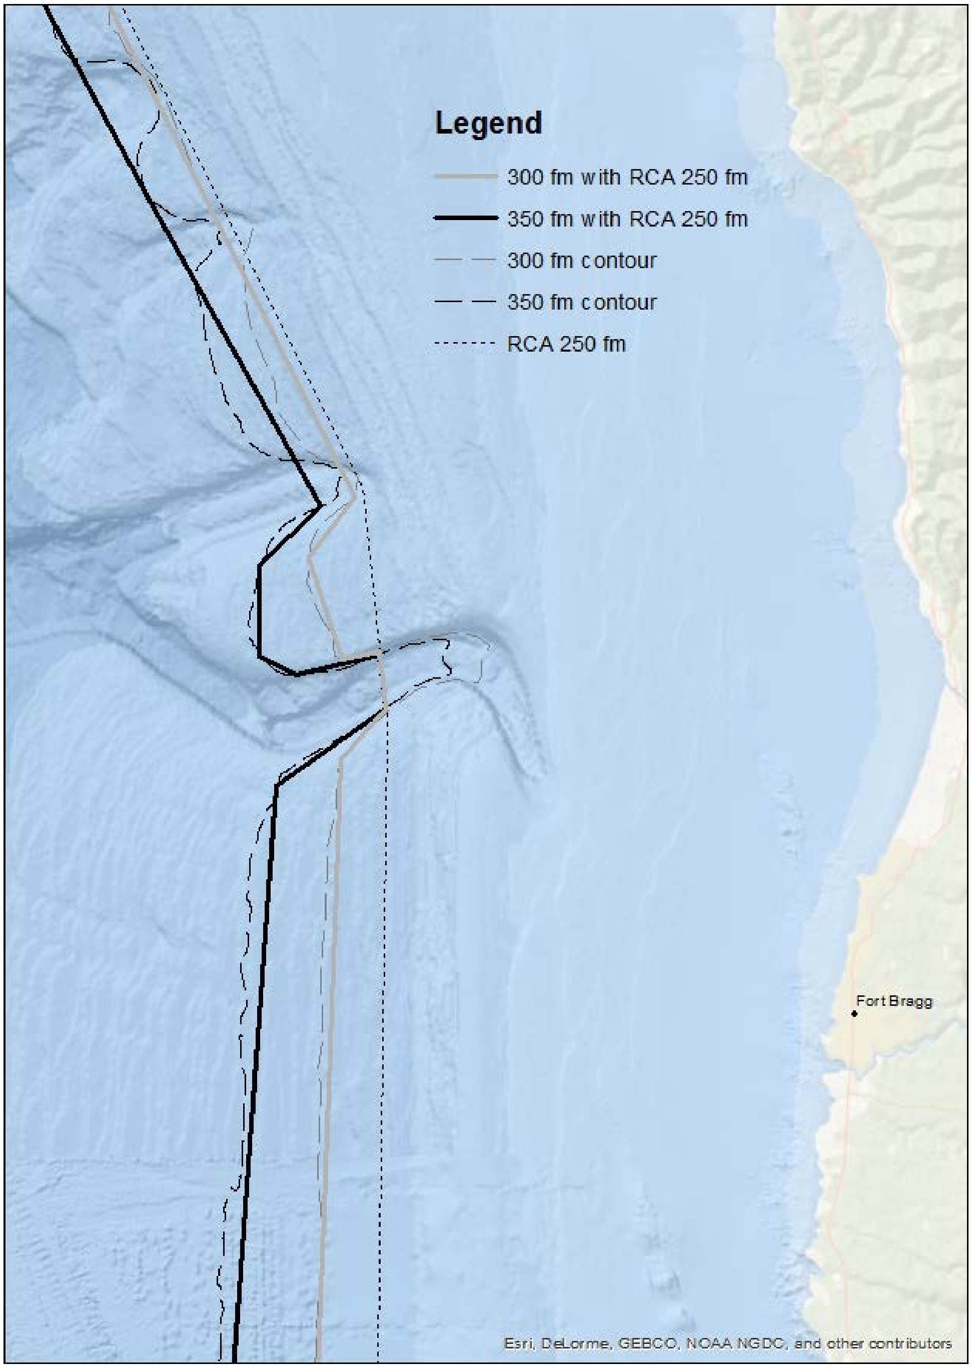

Figure B-9. An example of an approach to deal with areas where new RCA lines, based on 300 and 350 fm bathymetry contours, cross an existing RCA line (e.g., 250 fm line). In these areas, the new RCA lines could follow the existing RCA line.

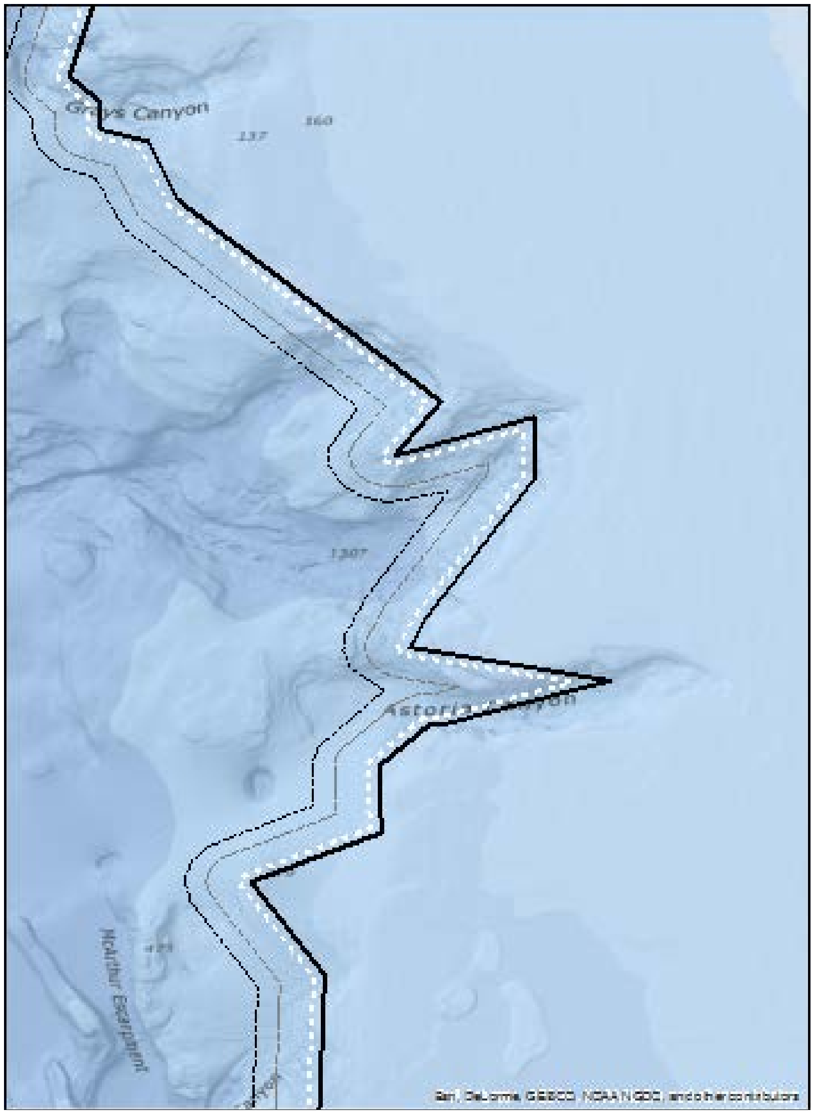

Figure B-10. An example of an approach to create new RCA lines by extending an existing 250 fm line in increments (e.g., by 0.5 nm, 1.5 nm, and 3 nm). These lines would follow the pattern of the existing RCA line which does not approximate bathymetry contours in all areas.

B.3 Trawl: Set-asides to cover carryover if trawl allocation exceeded

Analysis of this management measure was not received by the Advanced Briefing Book deadline; it is expected to be delivered as a Supplemental GMT Report.

B.4 Within Non-Trawl: Two-Year Yelloweye Sharing - Evaluating uncertainty of yelloweye catches in the nearshore and non-nearshore commercial fixed gear sectors

Need for Action

The Council is considering transferring 0.6 mt of the yelloweye rockfish non-trawl allocation fishery harvest guideline (HG) from the non-nearshore sector to the nearshore sector. Nearshore sector landings are often constrained due to amount of yelloweye rockfish provided to the nearshore sector. Further, shoreward adjustments of the non-trawl RCA (e.g., changing from 30 to 20 fm) are implemented when the yelloweye rockfish nearshore share or the non-trawl HG is projected to be exceeded. The Council considers the two-year allocations for yelloweye rockfish every biennial cycle based on the projected impacts, i.e., forecasts of total fishing mortality, provided by the GMT and other factors. The nearshore and non-nearshore sectors are assigned a "share" of the non-trawl allocation. The sectors' shares and projected impacts (i.e., total fishing mortality) for yelloweye are shown in Table B-9.

Table B-9. The sector shares and project impacts of yelloweye rockfish with and without the transfer of 0.6 mt.

		Without transfer		With transfer	
		2015	2016	2015	2016
non-nearshore	share	1.1	1.2	0.5	0.6
	projection	0.5	0.5	0.5	0.5
	difference	0.6	0.7	0.0	0.1
nearshore	share	1.2	1.3	1.8	1.9
	projection	1.1	1.1	1.1	1.1
	difference	0.1	0.2	0.7	0.8

The projected impacts and projection methods of yelloweye catch for 2015-2016 are more fully discussed in section 4.2.2.5 and Appendix A of the DEIS. The nearshore projected impacts are under discussion as well and may be subject to change depending on the Council's recommendations on the harvest guideline for the nearshore rockfish stock complex and related management measures.

The GMT has advised the Council, most recently in April that the catch estimates and model projections are subject to considerable uncertainty that the team has yet to fully evaluate.[4] This analysis uses a Monte Carlo simulation approach based on West Coast Groundfish Observer Program (WCGOP) sampling rates and observed patterns of yelloweye catch in these sectors to gauge the relative level of uncertainty surrounding yelloweye catches. This uncertainty is relevant here because, as shown in Table B-9, the 0.6 mt transfer would completely remove the buffer between the projected catch and the sector share in the non-nearshore sector and increase the buffer in the nearshore sector. And as it stands now, there is only a 0.1 to 0.2 mt buffer between the nearshore sectors' share and projected catch.

Background and Context

The GMT has been focused on the uncertainty in two separate but related estimates: (1) the retrospective annual estimates of total mortality produced by the Northwest Fisheries Science Center (NWFSC); and (2) the GMT's forecasts/projected impacts. The simulations used here focus primarily on evaluating the first. The uncertainty seen in the simulation results can then be related to the projected impacts and aid with interpretation of how confident we can be in those forecasts.

[4] PFMC Briefing Book April 2014, Agenda Item C.8.b, Supplemental GMT Report.

For highly discarded species like yelloweye, catch is not known with certainty because not all catch is observed. Annual mortality estimates are produced with statistical sampling and estimation methods that are inherently uncertain. The purpose of the GMT's catch projections is to inform the Council on what the annual catch estimates might be under a given management measure scenario. Like most all forecasts, they involve uncertainty as well. With the non-nearshore and nearshore projection models, the GMT provides the Council with point estimates of catch without any quantitative measure of uncertainty around those estimates. The Council, recognizing that the forecasts are uncertain, has often taken a precautionary approach in establishing sector shares and more formal sector allocations. The level of precaution or tolerable risk is a key policy decision. With increased access to and additional years of data from WCGOP, the GMT has begun attempts at better quantifying the uncertainty and informing the Council of the risks.

As brief background, uncertainty in measurements and estimation can be thought of in terms of accuracy and precision. These two terms are used differently among technical disciplines, but here we think of accuracy in terms of bias.[5] An unbiased estimate will accurately reflect the true value yet do so subject to some level of precision. Absent perfect precision, repeated estimates/measurements will vary from one another with the degree of variability proportional to the precision of the estimate/measurement. Highly imprecise estimates will vary widely, but if repeated and unbiased, the average of the estimates will reflect the true value accurately. In contrasting circumstances, it would be possible to have highly precise but inaccurate estimates/measurements. In such cases, repeated estimates/measurements would vary little but vary around something other than the true value.

WCGOP sampling and catch estimation methods are designed to produce unbiased, accurate estimates. There is little that can be done easily to evaluate if the accuracy is being achieved (the observer effect/bias where fishing vessels operate differently when an observer is aboard making the observations non-representative). Here we assume that are indeed accurate and that precision is the main source of uncertainty.

The precision of an estimate will vary largely based on two main variables: (1) the sampling rate/coverage level, and; (2) the variability and frequency of the event being measured. In general, precision will be greater with higher sampling coverage and regular, frequent catch events. In contrast, for a given level of sampling coverage, precision will be lower to the degree that the event is rare and variable.

Lastly, sampling uncertainty from limited precision would exist even if the unit being measured is fixed or static (e.g. the circumference of the Earth). The event we are focused on here is the yelloweye catch over a year, which is not likely to be fixed. Catch is expected to vary from year to year depending on fishing effort, the areas fished, changes in management regulations, etc. Moreover, the expectations for a rebuilding stock like yelloweye is that the catch rate will increase as the stock increases in abundance and expands its distribution, increases in density, or both. Imprecision in estimates makes upward trends difficult to detect. Increases in catch from one year to the next might be signal or could just be sampling noise. The same is true for downward trends where the encounter rate may have truly decreased. Making predictions about future catch with noisy historical data makes the forecasting challenge even more so.

Patterns of Yelloweye Catch and Observer Coverage in the Nearshore and Non-nearshore Sectors
As shown in Table B-10, annual estimates of yelloweye catch have shown a high degree of variability in both the nearshore and non-nearshore fixed gear sectors. As highlighted above, sampling error is likely a major component of the variability. Consistent with the latter, variability has been higher in the nearshore sector where sampling coverage levels have been lower (Table B-11 and Table B-12).

[5] For example, see Box 1.2 in National Research Council. Review of Recreational Fisheries Survey Methods. Washington, DC: The National Academies Press, 2006.

Variability can be described in absolute terms (i.e., in the unit of measurement), which in this case is catch weight expressed as metric tons (mt), or in relative terms (e.g. the coefficient of variation, which expresses the variability relative to the average value). Considering variability in absolute terms is important because the Council considers and recommends allocations and less formal apportionments of catch in terms of metric tons. Table B-10(c) displays the variability seen in metric tons by comparing the annual estimates against the grand mean (i.e., the average across all available annual estimates).

Relative measures of variability are also useful, especially for comparing variability between the sectors. For example, an estimate that is truly more imprecise than another may appear more precise when viewed in absolute terms simply because its average value is smaller. Table B-10 (b) shows one form of relative variability by comparing the annual estimates in each sector to the estimates made in the previous years. In the nearshore sector, estimates have dropped by 80 percent and increased by more than 800 percent. The non-nearshore sector has experience less variability in this measure, yet has seen a 75 percent drop and a 50 percent gain. Table B-10 (d) shows the percent difference of the annual estimates compared to the average over the timeframe ("grand mean"). This measure is of interest because such grand means of bycatch ratios currently serve as the foundation for the GMT's projection models for these sectors. Both sectors show wide variability on this measure as well further underscoring the challenge of forecasting yelloweye catches.

Table B-10. Variability of total mortality estimates for yelloweye rockfish in the nearshore and non-nearshore commercial fixed gear sectors, 2003-2012.

(a) NWFSC Total Mortality Estimate (source: GMMultiYr_DataProduct Dec. 23, 2013)

	2003	2004	2005	2006	2007	2008	2009	2010	2011	2012
Nearshore	0.3	1.1	0.9	0.8	1.9	2.5	0.5	0.1	0.8	1.8
Non-nearshore	1.6	1.1	0.6	0.7	0.7	0.8	1.2	0.3	0.3	0.3

(b) Annual estimate relative to estimate of previous year

	2003	2004	2005	2006	2007	2008	2009	2010	2011	2012
Nearshore	--	3.67	0.82	0.89	2.38	1.32	0.20	0.20	8.00	2.25
Non-nearshore	--	0.69	0.55	1.17	1.00	1.14	1.50	0.25	1.00	1.00

(c) Difference (mt) between annual estimate and 2003-2012 average in each sector (nearshore = 1.1 mt, non-nearshore = 0.8 mt)

	2003	2004	2005	2006	2007	2008	2009	2010	2011	2012
Nearshore	-0.8	0.0	-0.2	-0.3	0.8	1.4	-0.6	-1.0	-0.3	0.7
Non-nearshore	0.8	0.3	-0.2	-0.1	-0.1	0.0	0.4	-0.5	-0.5	-0.5

(d) Difference between annual estimate and 2003-2012 average relative to average (i.e., the values reported in (c) divided by the average).

	2003	2004	2005	2006	2007	2008	2009	2010	2011	2012
Nearshore	0.27	1.00	0.82	0.73	1.73	2.27	0.45	0.09	0.73	1.64
Non-nearshore	2.00	1.38	0.75	0.88	0.88	1.00	1.50	0.38	0.38	0.38

Overview of the Data Used and Aim of the Simulation Methods
WCGOP provided the observer data sets matched to the data used for the GMT's nearshore and non-nearshore projection models. These datasets are considered confidential and therefore are available only to a subset of the team that have confidentiality agreements in place with WCGOP.

The basic observer coverage statistics for the non-nearshore and nearshore sectors are shown in Table B-11 and Table B-12. The WCGOP coverage rates reported in those tables were taken from a table downloadable from their Sector Data Products webpage.[6] For the non-nearshore sector, we are focused on the area north of 36° N. latitude and the observer coverage levels reported in Table B-11 combine the Limited Entry Sablefish Endorsed, Non-Sablefish-Endorsed Fixed Gear, and Open Access vessels that are classified as part of this sector.

By design, WCGOP focuses on observing a certain percentage of landings as opposed to certain percentage of trips. Likewise the bycatch ratios WCGOP uses to expand observed discard to the total fleet are expressed in terms of landed catch. However, for simplicity of modeling the simulations presented here use trip as the main unit of analysis.

If trips contributed the same level of overall landings per year, the two would be equivalent. Yet this is not the case and some trips contribute a higher portion of the landings in both the nearshore and non-nearshore sectors. If coverage levels were reported in terms of the trips observed per year, then the coverage would be lower in both sectors. Nonetheless, we do not expect our choice to focus the simulation on trips instead of landings to affect the usefulness of the simulation results. If WCGOP maintains the same sampling plan and general levels of observer coverage, then the relationship between observer coverage and landings per trip would be expected to hold. And if so, the simulations should provide means to evaluate the general patterns we should expect to continue into the future.

The frequency with which yelloweye have been encountered by trip is one of the main variables in the simulations. Figure B-11 and Figure B-12 report the total number of trips with yelloweye catch observed ("non-zero" trips) divided by total observed trips for the nearshore and non-nearshore sectors. As those shown, the per trip frequency of yelloweye catch in the nearshore sectors has been over double of that seen in the non-nearshore sectors. The per trip frequency has varied in both over the time series.

The other main variable of interest is the magnitude of catch on non-zero trips. Whereas the frequency of yelloweye catch on a trip in the non-nearshore sectors is half of that in the nearshore sectors, the magnitude of catch on non-zero trips is over twice, on average, of the catches in the nearshore sectors (Figure B-13 and Figure B-14). The distribution of non-zero catches across all years of the non-nearshore and nearshore data are further displayed in Figure B-15 thru Figure B-18.

Table B-11. Summary of nearshore sector WCGOP observations used to establishing the frequency with which yelloweye are encountered on a trip and the level at which the sector is observed each year. The "*" in 2003 indicates that the statistic could not be displayed because of confidentiality.

Year	2002	2003	2004	2005	2006	2007	2008	2009	2010	2011	2012
Trips Observed	--	108	367	308	341	303	225	239	253	349	386
Trips w/ yelloweye	--	*	34	16	25	45	29	17	11	38	65
% of observed trips with yelloweye	--	*	9%	5%	7%	15%	13%	7%	4%	11%	17%
WCGOP coverage %	--	2%	7%	5%	7%	6%	4%	4%	5%	6%	8%

Table B-12. Summary of non-nearshore sector WCGOP observations used to establishing the frequency with which yelloweye are encountered on a trip and the level at which the sector is observed each year.

Year	2002	2003	2004	2005	2006	2007	2008	2009	2010	2011	2013
Trips Observed	102	269	256	251	275	358	335	304	512	443	304
Trips w/ yelloweye	21	25	13	18	13	10	10	8	4	7	9
% of observed trips with yelloweye	21%	9%	5%	7%	5%	3%	3%	3%	1%	2%	3%
WCGOP coverage %	18%	17%	12%	27%	17%	22%	29%	7%	22%	22%	22%

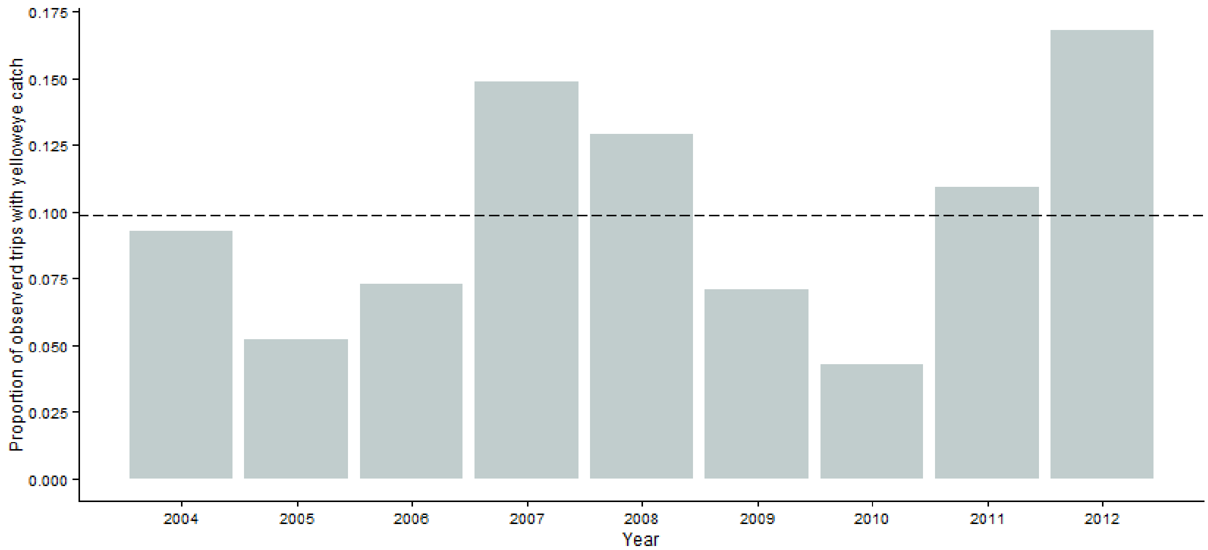

Figure B-11. Annual proportion of observed trips in the nearshore commercial fixed gear sectors where yelloweye were encountered. The 2004-2012 average is displayed by the dashed line (2003 was excluded because of confidentiality).

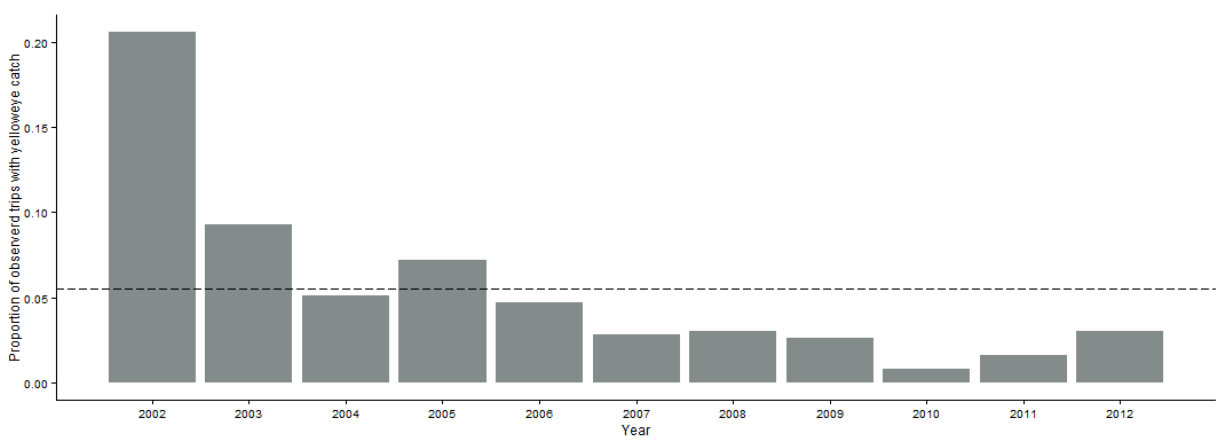

Figure B-12. Annual proportion of observed trips in the non-nearshore commercial fixed gear sectors where yelloweye were encountered. The 2002-2012 average displayed by the dashed line.

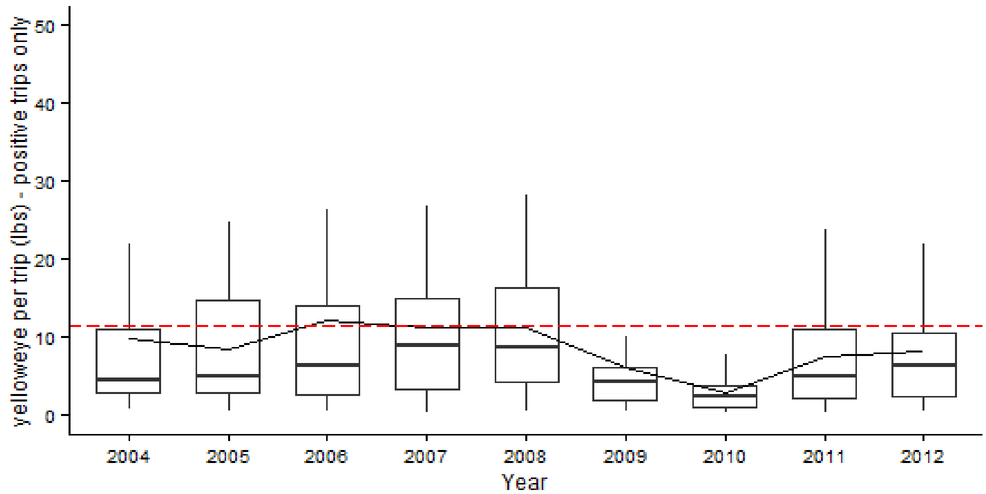

Figure B-13. Boxplots of yelloweye catches (zeros excluded) by trip and year in the nearshore commercial fixed gear sectors. Outer edges of the boxes show the 25th and 75th percentile levels with the middle line representing the median value. The solid line connects the average value for each year. In all but 2010, the averages are noticeably larger than the median because of large catch events. The dashed line shows the 2004-2012 average ("grand mean"). Outliers are not displayed because of confidentiality. A y-axis extending to 200 would display all outliers with room to spare. To give some sense of the range of the outliers, the average of the top 5 percent of all trips, across all years is 68 lb.

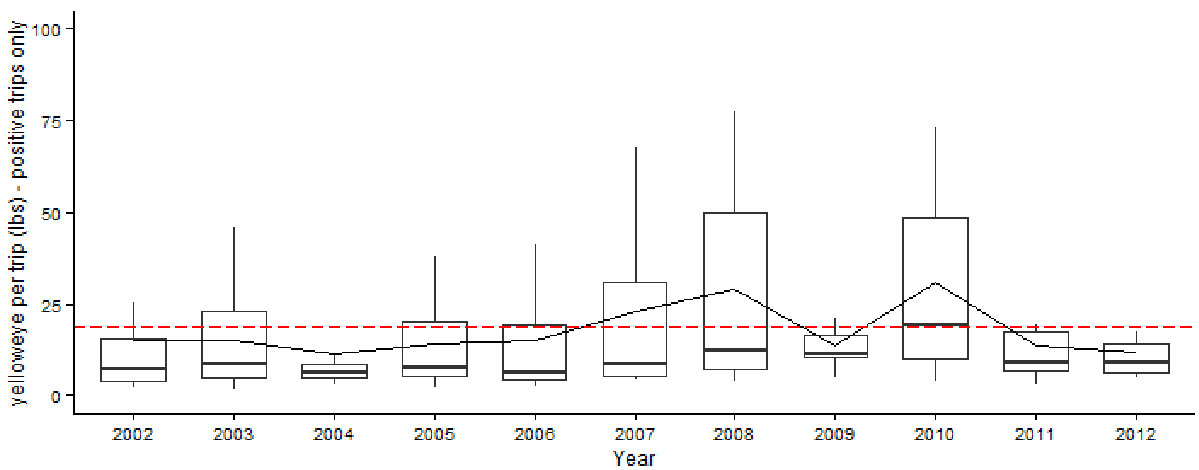

Figure B-14. Boxplots of yelloweye catches (zeros excluded) by trip and year in the non-nearshore commercial fixed gear sectors. See Figure B-13 for explanation of boxplots and lines. Outliers are not displayed because of confidentiality. A y-axis extending to 175 would display all outliers with room to spare. To give some sense of the range of the outliers, the average of the top 5 percent of all trips, across all years is 103 lb.

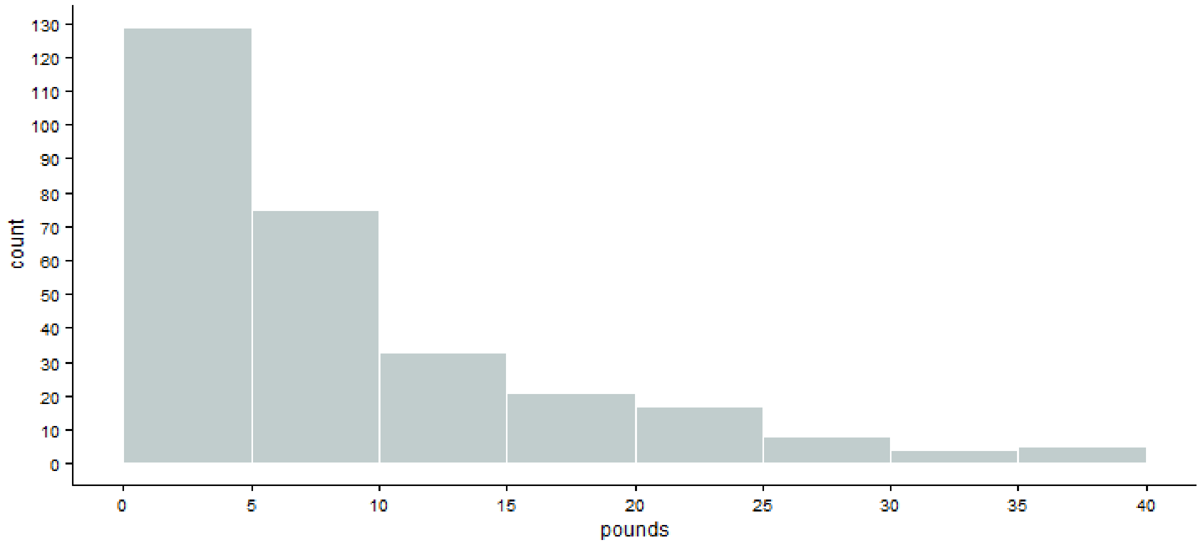

Figure B-15. Histogram showing nearshore catches of yelloweye rockfish over 2002-2012 on observed non-zero trips for catches less than 40 lb (lb) (bins are in increments of 5 lb).

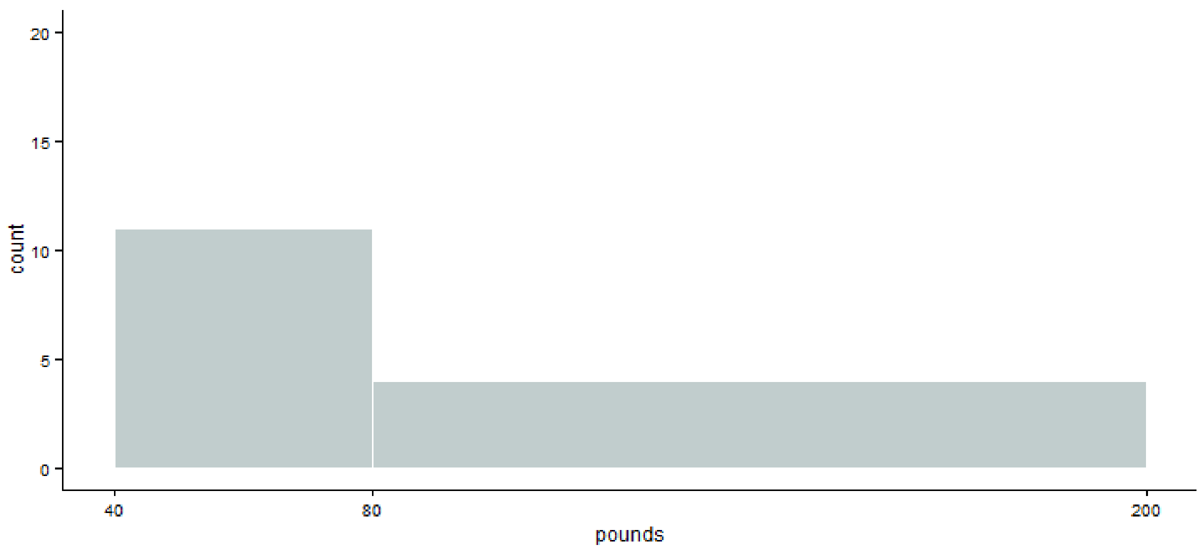

Figure B-16. Histogram showing nearshore catches of yelloweye rockfish 2002-2012 on observed non-zero trips for catches greater than 40 lb over (irregular bins of 40-80 lb and 80-200 lb were chosen to preserve confidentiality).

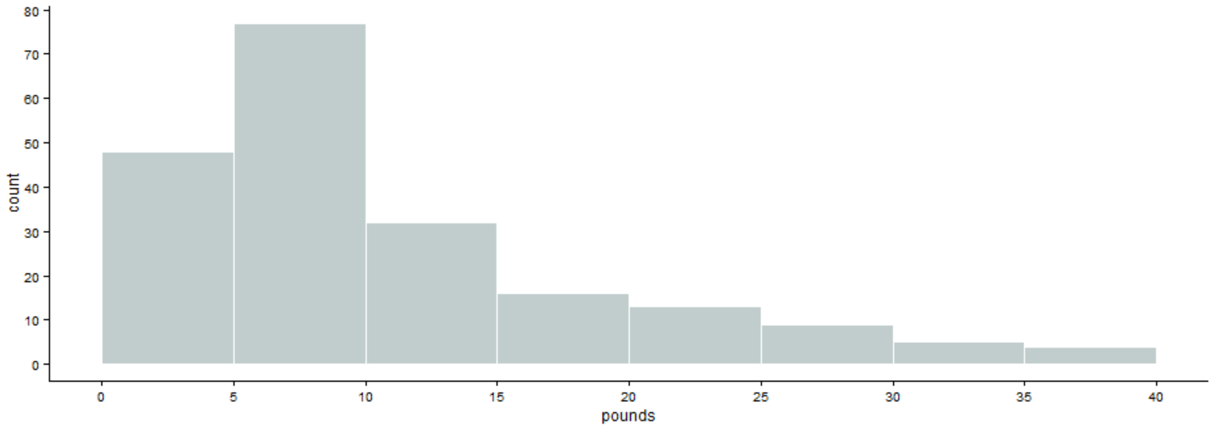

Figure B-17. Histogram showing non-nearshore catches of yelloweye rockfish over 2002-2012 on observed non-zero trips for catches less than 40 lb (bins are in increments of 5 lb).

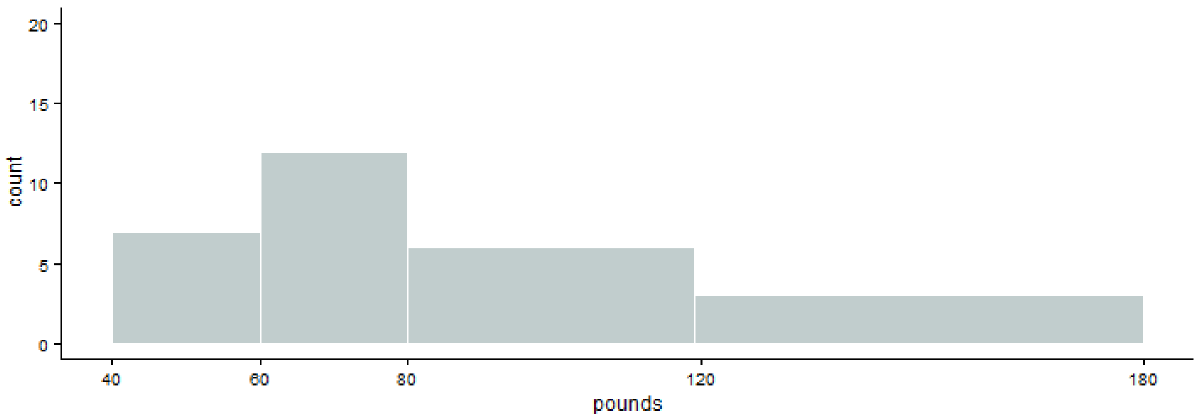

Figure B-18. Histogram showing non-nearshore catches of yelloweye rockfish 2002-2012 on observed non-zero trips for catches greater than 40 lb over (irregular bins of 40-60 lb, 60-80 lb, 80-120 lb, 120-180 lb were chosen to preserve confidentiality).

The Simulation Steps
There are two main parts to the simulations. The first constructs a universe of 100,000 fishing trips where the yelloweye catch per trip is the main variable of interest. The second involves randomly sampling from this set of trips. Each involves several steps described in the following list. The simulation was conducted in the program R.

1. Simulate the universe of 100,000 trips and yelloweye catch per trip for each sector based on the pattern of non-zero trips and the magnitude of catches observed on those trips:
   - Generate 100,000 binomial runs representing whether the trip caught yelloweye or not (i.e., 1 = yelloweye caught, 0 = no yelloweye caught). The binomial probability of a non-zero trip was itself randomly drawn from a random normal distribution based on the mean and standard deviation observed over the relevant time periods in each sector. The draws were truncated to prevent negative numbers using the "truncnorm" package.
   - The magnitude of catch per trip was drawn from a random lognormal distribution generated from the mean and standard deviation of actual trip level catches observed by WCGOP over the full data series of non-zero yelloweye trips.
   - The simulated catch per trip was produced by multiplying the catch per trip by the 1 or 0 drawn from the binomial random draws.
   - The simulated trip catch was capped at twice the observed maximum catch because the lognormal random distribution with a large number of draws produces a few implausibly large catches.

2. Sample from the universe of simulated trips based on varying coverage levels and produce a simulated "true" and estimated annual catch for 10,000 runs:
   - The total number of trips and observer coverage level per simulation run were randomly drawn from normal distributions based on the means and standard deviations from the actual WCGOP data.
   - The total number of trips drawn then set the sample size for the run (i.e., if the total number of trips was 100, 100 samples would be drawn from the set of 100,000 trips). The "true" annual catch was then calculated by summing the catches from all the selected trips.
   - This draw of the total trips per run was then sampled with the sample size set to the number of observed trips (the total trips multiplied by the coverage percentage drawn for the run). The simulated estimated annual catch was the calculated by summing the catch from these trips divided by the coverage level.

The simulated samples were all taken using R's sample function. All samples were taken without replacement. The input parameters for the random draws and years of data used for each are identified in Table B-13. In the nearshore sectors, observer coverage was low in 2003 and therefor data from that year was excluded. All years of data were used for the non-nearshore sectors except for the binomial probability of non-zero yelloweye trips. As can be seen in Figure B-12, there appears to be a downward trend in the number of trips encountering yelloweye in those sectors, and so based on this apparent trend, we chose to use data from only 2004-2012.

Table B-13. Input values for the simulations.

		Nonearshore	Nearshore
binomial probability of non-zero trip (normal)	*mean*	3.6%	9.0%
	s.d.	2.0%	5.0%
	truncated	0% - 20%	0% - 25%
	years used	2004-2012	2004-2012
non-zero catch events (lognormal)	*mean/mean.log*	27.4 / 2.77	11.6 / 1.78
	s.d./s.d.log	31.6 / 1.03	17.7 / 1.18
	years used	2002-2012	2004-2012
total trips per run (normal)	*mean*	1,776	4,995
	s.d.	923	1,533
	truncated	500-5000	500-10,000
	years used	2002-2012	2004-2012
observer coverage per run (normal)	*mean*	19.5%	5.8%
	s.d.	6.3%	1.3%
	truncated	5% - 30%	2%-20%
	years used	2002-2012	2004-2012

Table B-14. The first ten of the 100,000 simulated trips from the nearshore simulation provided to show the basic structure of the simulations. The second step of the simulation involved drawing random samples of varying sizes from the "Lb. Caught" column.

Trip	Encounter?	Lb. if Yes	Lb. Caught
1	1	16.5	16.5
2	0	31.3	0.0
3	0	17.1	0.0
4	0	2.6	0.0
5	0	6.3	0.0
6	0	4.8	0.0
7	1	1.3	1.3
8	0	3.0	0.0
9	0	7.6	0.0
10	0	4.3	0.0

Simulation Metrics and Results

The metrics produced by the simulations focus on the relative degree of precision and variability that we should expect with the annual catch estimates of yelloweye. The metrics reported here, each calculated as a ratio, include:

- *Variability in the "true" catch* (*"True" Variability*): this metric reports how the simulated "true" catch in each run differed from the average across all runs. It is calculated as the simulated true catch in each run divided by the average.
- *Annual fluctuation* (*"True" Ann. Fluctuation and Estimated Ann. Fluctuation*): this metric was calculated by dividing the simulated true catch and catch estimate in a run by

the same in the prior run. This metric allows some evaluation of the year to year variation we might expect in actual catch rates and in the catch estimates.

- *Sampling error* (*Estimated Error*): represents the ratio of the simulated estimate of catch and the simulated true catch in each run (i.e., a value over 1 indicates an overestimate and under 1 is an underestimate).
- *Annual Estimate relative to the 10 Year Average* (Estimated to 10 Year Avg.): this ratio expresses how far the simulated catches in each run differed from a 10 year average. The 10 year average was calculated by dividing the 10,000 runs into increments of 10. This metric is meant to tbe comparable to the long-term average catch ratios t serves as the basis for the GMT's current catch projection models.

We do not report metrics of the simulated catches in absolute terms, i.e., pounds or metric tons, because we did not attempt to reproduce WCGOP's actual sampling design and catch estimation methods in the simulations. WCGOP uses a more complicated multi-stage, stratified sampling design and employs catch estimation methods intended to support the areas and sector of interest to the Council. In addition, in the nearshore sectors yelloweye that are released with certain fishing gears are assumed to survive depending on depth. The simulations do not attempt to model the depth or gear of catch. For this and other reasons, the simulated catch amounts are therefore not expected to precisely match the real catch estimates.

The simulated estimates of annual catch are, however, close in terms of general magnitude to the estimates produced over 2003-2012. The metrics of relative variability should therefore provide useful insight into the relative precision of the existing WCGOP catch estimates and the GMT's projection model outputs.

At the same, sampling theory holds that WCGOP's stratified sampling design should produce more precise estimates than the simple random sampling we use in the simulation. We view the metrics of relative precision as rough measures of the degree of variability we might expect under the range of observer coverage and patterns of yelloweye experienced to date. Understanding how these factors influence the general magnitude of uncertainty and variability is our primary aim. We did not attempt to precisely quantify the statistical variance in the data and the simulations may overstate the variability to some degree. Yet as seen below, the results are not inconsistent with the level of variability actually seen in the sectors over 2003-2012 (Table B-10).

The results are shown in Table B-15 and Table B-16. We report multiple statistics for each metric, including the mean and median and the 10th and 90th percentile values. We also provide information about a number of other percentile levels constructed as intervals. For example, the 50 percent interval is bounded by the 25th and 75th percentiles and the 90 percent interval is bounded by the 5th and 95th percentile. To contrast the way the values can be read: the 90th percentile reports a "one-sided" look and indicates that 90 percent of all runs fell below that value, and in turn, that only 10 percent fell above it. The 90 percent interval, on the other hand, provides a "two-sided" look and indicates that 90 percent of the runs fell within that interval, and in turn, that only 10 percent of the runs were either higher or lower than the values on each end of the interval. Likewise, the intervals could be viewed in a "one-sided" manner by looking to only one end (e.g., the upper end of the 50 percent interval is the 75th percentile, therefore only 25 percent of the runs came in larger than the value it reports).

Table B-15. Results from the nearshore simulation. See the bulleted list in the text for the definition of the metrics.

	"True"		Estimated

Discussion

We only give brief discussion of the results here so as to aid the reader and illustrate how we envisioned the simulation metrics could be used. The full GMT will review and comment on this analysis at the June meeting and provide the Council with additional interpretations relevant to the decision on the potential 0.6 mt transfer. The GMT will also provide information on the potential management measure changes (e.g., trip limits and changes to RCA boundaries) that the transfer might involve.

As to the results here, we begin by noting that the average sampling error metric shows a high degree of accuracy in both sectors, as is expected with random sampling. Across all runs, the catch estimate was 1.002 times the true estimate in the non-nearshore and 0.997 in the nearshore (i.e., 0.2 percent and 0.3 percent off).

At the same time, the catch estimates showed variability across individual runs. Under the conditions run in the simulations , we would expect catch estimates to be within ~30 percent of the true catch half of the time in the non-nearshore sectors, and ~20 percent in the nearshore sectors. Looking more toward the extremes, 10 percent of the runs in the non-nearshore simulations fell higher or lower than 0.37 and 1.86 times the true value (i.e., 63 percent lower and 86 percent higher). That same interval for the nearshore simulations is 0.47 to 1.71. Somewhat counter intuitively, the nearshore simulation shows more precision than the non-nearshore simulation despite having lower coverage levels. It may be that the lower frequency of non-zero trips in the non-nearshore counteracts the expected effect of higher observer coverage.

While the sampling error is an important consideration, in reality the “true” catch is never known and the Council can only respond to the estimates of the true catch. So understanding the expected year to year variability in the catch estimates is of most interest here.

Considering the degree of year to year fluctuation in the estimates, the results show that on average the estimates were 1.43 times the previous’ years estimate in the nearshore and 1.88 times in the non-nearshore. The use of ratios and the influence of large outliers may make the mean values of limited value here. The intervals provide a fuller picture. Looking at the 50 percent interval, we see that half of the runs fluctuated between 0.62 and 1.61 over the previous year in the nearshore and 0.54 and 1.88 in the non-nearshore. The 8 fold increase seen in the nearshore catch estimate between 2010 and 2011 (Table B-10(b)) would have fallen within the upper 1 percent of the nearshore simulation runs (not shown in Table B-15).

With the 10 year average metric, we see half the runs in the non-nearshore coming in 0.58 to 1.34 times the size of their respective 10 year averages and 0.67 to 1.27 times in the nearshore simulation runs. Considering only the situation where the 10 year average to underestimate the catch estimate, the catch was double the average around 5 percent of the non-nearshore runs. Not reported in the table, yet the average of the upper 5th percentile values was 2.44. In the nearshore simulations, the variation was lower with the upper 5th percentile populated by values greater than 1.85 times their respective 10 year average with an average value of 2.15.

Lastly, as can been seen in the metrics reported for the simulated true catches, the simulated true catches showed considerable variation as well. The variability in the probability of encountering yelloweye on trip and variability in the size of the catch when encountered created a range of simulated annual catches. This variable signal in the annual catches drives a lot of the noise seen in the simulated catch estimates.

B.5 Within Non-Trawl: Consideration of State-Specific Nearshore Rockfish Harvest Guidelines North of 40°10' N. latitude

Need for Action

In April 2014, the Council requested analysis of options for allocation of the Nearshore Rockfish complex north of 40°10' N. latitude to keep morality at or within the ACL including 1) No Action, 2) utilizing the miles of coastline north of 40°10' N. Lat., 3) the recent recreational and commercial historical catch from 2004-2012 (Agenda Item C.4.b, Supplemental GMT Report 2), and 4) a hybrid allocation method which uses miles of coastline for copper, China and quillback rockfishes and historical catch from 2004-2012 for the remaining species. In options 1 and 2, blue rockfish apportionment was initially based on stock assessment lines (California vs. Washington-Oregon assessment), with subsequent allocation between Oregon and Washington based on recreational and commercial historical catch from 2004-2012. Miles of coastline was not used to apportion blue rockfish between Oregon and Washington because of the large disparity in historical catch (Agenda Item C.4.b, Supplemental GMT Report 2, Tables 2 and 3) which indicated a decline in relative abundance along the coast not reflected when allocation is conducted using miles of coastline.

Catch data used to apportion the coastwide annual catch limit (ACL) under the two harvest guideline (HG) options using historical catch have been updated since the April meeting. Prior RecFIN queries for recreational catch data included inland areas in Washington not managed by the Pacific Fishery Management Council. The updates resulted in changes to the Nearshore Rockfish complex harvest guideline options (i.e., proportions of the ACL distributed among states), primarily to the historical catch option, but still reflect the range of HG Options recommended for analysis by the Council in April.

This analysis provides information on the implications of state-specific Nearshore Rockfish complex HG for the area north of 40°10' N. Lat. Options for the state-specific HGs are based on historical catch and miles of coastline in California, Oregon and Washington, as described above. Management under HGs from alternate allocation options are compared to the No Action alternative of status quo management for the Nearshore Rockfish complex with an ACL north of 40°10′ N. Lat.. The management measures needed to prevent mortality from exceeding complex level HGs and the implication for stock status and fishery participants are analyzed for each option.

Background

Under No Action, the Nearshore Rockfish complex overfishing limit (OFL) consists of contributions of the component stocks to the entire complex, stratified at 40°10′ N. Lat. Under status quo management, a complex level ACL is assigned to each region north and south of that management boundary (see the draft environmental impact statement; DEIS). This analysis provides the implications for the nearshore fisheries from instituting a HG in each state (Table B-17). Note that Nearshore Rockfish complex mortality from the tribal fishery is negligible and the tribes will notify the Council if this is expected to change in the future.

We evaluate three options for implementing HGs, in addition to No Action, for each state north of 40°10′ N. Lat. The first is stratified on the basis of miles of coastline, using the length of the three nautical mile boundary line delineating state and federal waters as a proxy for coastline length in each state (see Appendix 1). The second method is based on average historical catch for all sectors between 2004 and 2012. The third is based on a hybrid method applying miles of coastline to stocks that are ubiquitously distributed along the coast (i.e., China, quillback and copper rockfish), while the historical catch method is applied to those remaining species that show a cline in abundance also noted in scientific literature, including blue rockfish allocated by assessed areas north and south of the California-Oregon border and allocated between Oregon and Washington using historical catch. This analysis is intended to help better understand the needs of the fishing community relative to the constraints from management under state-specific harvest guidelines.

Ideally, allocating catch would involve a measure of relative abundance along the coast, but no such index is currently available for nearshore rockfish. In the absence of these data, two proxy methods of allocating have been presented; historical catch from 1916-2012 and the miles of coastline within the assessed area (Agenda Item C.4.b, GMT Report 2, April 2014; Agenda Item C.9.b, GMT Report 2, April 2014). The three options analyzed herein were developed after considerations were made regarding these original allocation methods. There are implications of these decisions for the commercial nearshore and recreational sectors in each state that make this a contentious issue. There are, however, scientific principles that can help inform sound decisions in the selection of allocations resulting in harvest guidelines. Examples of considerations for the three options analyzed in this paper are described below.

Considerations for Allocation Options

Considerations for Option 2: Miles of Coastline

Allocation using miles of coastline within each assessed area may prevent potential over-allocation to over-harvested areas that can result when historical catch is used. This method provided an alternative to catch based allocation alternatives. The primary assumption of this method is that the relative abundance is consistent along the coast. This assumption may not be valid for species that decline in abundance toward the ends of their range, or if habitat is not proportional to coastline distance or if stocks have been overharvested in a given sub-region. Although, for species such as China, quillback, copper and blue rockfishes that are relatively common throughout the assessed range, the distribution of habitat is unlikely to be perfectly uniform between states. Hence, this method may over-allocate or under-allocate, depending on which assumptions are violated. In instances where regulations and mortality for ubiquitously distributed species varies greatly among states, and a declining trend in catch per unit effort (CPUE) or assessments results in a portion of the species range, the historical catch method may be preferred over miles of coastline to prevent over allocation of fish at the edge of their range. Thus the assumption of uniform distribution is likely violated when miles of coastline is applied to species such as blue, olive, brown, gopher, black and yellow and grass rockfish, as indicated by the distribution of catch in PacFIN and RecFIN, and in published literature showing the range of each species indicating that they are less common or absent to the north (Love et al. 2002).

Considerations for Option 3: Average Historical Catch

When historical catch is employed to allocate among states, there is potential for over-allocation to states that harvested the most fish. Table B-17 contains commercial mortality (the average landings (mt) in the commercial fishery from PacFIN plus discard mortality estimated from the nearshore projection model) and recreational mortality (mt) (RecFIN) of nearshore rockfish stocks north of 40°10′ N. Lat. from 2004-2012. The Scientific and Statistical Committee (SSC) advised that "historical catches of nearshore species by state may not reflect biomass by state because of major differences in the management among states" (Agenda Item D.5.b., SSC Report, March 2014). Allocation using historical catch assumes that catch is proportional to abundance, which may not be the case due to differences in management among states. The annual catch by sector (Figure B-19) and annual, average, and range of catches by sector from 2004-2012 (Table B-17) reflect a combination of regulations, permitting systems, participation, constraints from overfished species and relative abundance of each species.

Overfished species constraints affected regulations on target stocks (e.g., seasons, depth restrictions and trip limits), limiting harvest to varying degrees among states from 2004 to 2012. A description of how regulations have varied over this period in each state and sector is provided in Appendix 2. Notable changes in regulations to reduce yelloweye rockfish mortality include a shallower depth restriction in the California and southern Oregon nearshore commercial fisheries starting in 2009 when the shoreward rockfish conservation area (RCA) boundary was moved from 30 fm to 20 fm to reduce yelloweye rockfish mortality. This adversely affected the ability of the fishery participants in California and Oregon to access deeper nearshore species. Depth restrictions and season lengths in the California recreational fishery have been severely limited by yelloweye rockfish mortality since 2008 after overages in 2007 necessitated inseason action to reduce season lengths and shallower depth restrictions to 20 fm (Appendix 2), which has continued in order to minimize yelloweye rockfish mortality. In addition, the Oregon recreational fishery was limited to shallower depth restriction of 20 fm from 40 fm part of the year starting in 2007, shifting effort onto Nearshore Rockfish habitat. The Washington recreational fishery has had consistent regulations since 2005, when depth restrictions of 20 fm and 30 fm went into place during part of the year shifting effort onto shallower depths.

Differential management among states shown above may differentially affect catch among states. It should be noted that other factors may also affect catch (e.g., environment, markets, distribution, and abundance). Figure B-19 provides annual catch patterns for the various sectors among states. For example, Nearshore Rockfish mortality in the California recreational and commercial fisheries declined abruptly in the years after their respective 20 fm depth restrictions were implemented. The Washington recreational catch has remained relatively steady over the 9-year period shown Figure B-19, as it was shown above that regulations have remained somewhat constant since 2005 (see Appendix 2). Interestingly, Oregon commercial and recreational Nearshore Rockfish catches have shown increases since many restrictions shown in Appendix 2 were put in place. It should be pointed out that much of this Oregon Nearshore Rockfish increase may be attributed to blue rockfish catch.

The differential management among states, along with differing degrees of participation in each sector among states, affects historical catch and thus allocation, which may cause it to deviate from representation of relative abundance along the coast. For example, Washington prohibited their commercial nearshore fishery and reduced their bag limit to ten fish in 1995 as a precautionary measure to preserve recreational fishing opportunities for the future, which might have been subject to further restrictions if allocation were shared with a commercial fishery. The participation in angler trips between Washington, Oregon and California are expected to vary affecting mortality due to season lengths, perceived opportunity (bag limits, depth restrictions) and angler population size in each state. In addition, Oregon and California have differing commercial permitting systems for their fisheries. These factors, and those shown in previous paragraphs, may cause allocations based on historical catch to deviate from relative abundance. Those areas with more liberal regulations or higher participation are likely to have disproportionately high nearshore rockfish mortality compared to the actual relative abundance along the coast.

For species with strong clines in abundance along the coast, the historical catch based method may capture the trend and allocate accordingly, where allocation by miles of coastline would not due to the assumption of uniform distribution. The aforementioned changes and differences in management should be considered when evaluating the true needs of the fishing communities and potential bias in allocation in each region and provide an impetus for weighing the assumptions regarding miles of coastline as an alternative method depending on the distribution of the species among other circumstances.

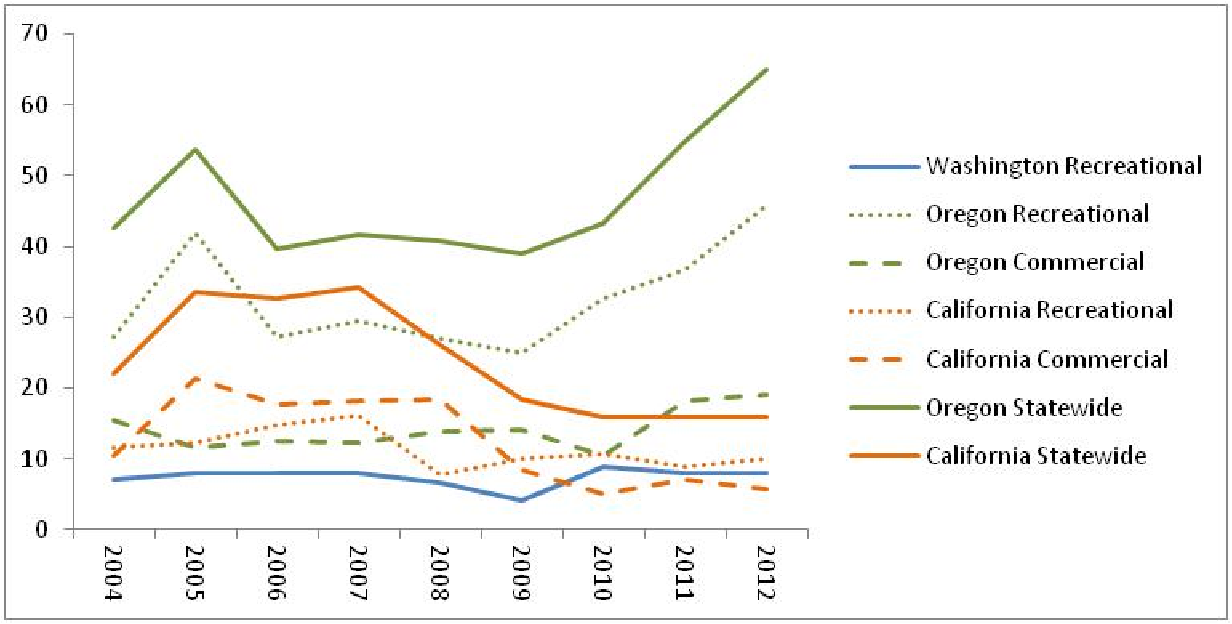

Figure B-19. Nearshore Rockfish Complex mortality estimates (mt) by state and sector in each year from 2004-2012.

Table B-17. Nearshore Rockfish Complex mortality estimates (mt) by state and sector in each year from 2004-2012 as well as the average and range of mortality from periods with less constraint (2004-2007) and greater constraint (2008-2012) from yelloweye rockfish. Recreational data were from RecFIN for Washington (ocean boat only), Oregon (ocean boat only), and California (ocean boat, shore, and estuary).

Year	Washington Recreational	Oregon Recreational	California Recreational	Oregon Commercial	California Commercial N. 40°10′ N. Lat.	Total
2004	7.06	27.18	11.61	15.40	10.46	71.71
2005	7.96	41.90	12.21	11.74	21.28	95.09
2006	8.00	27.20	14.84	12.47	17.85	80.36
2007	7.95	29.42	16.14	12.41	18.23	84.15
2008	6.72	26.91	7.69	13.84	18.38	73.54
2009	4.26	24.88	10.01	14.15	8.39	61.69
2010	8.99	32.78	10.82	10.57	5.16	68.32
2011	8.10	36.66	8.84	18.28	7.02	78.9
2012	7.93	45.88	10.10	19.06	5.84	88.81
2013	6.23	38.1	9.3	NA\1	NA\1	NA
Average 2004-2007	7.74	31.43	13.70	13.01	16.96	82.83
Range 2004-2007	7.06-8.00	27.18 - 41.90	11.61 - 16.14	11.74 - 15.40	10.46 - 21.38	71.71 – 95.09
Average 2008-2012	7.20	33.42	9.49	15.18	8.96	74.25

Average 2004-2012	7.44	32.53	11.36	14.21	12.51	78.06
Range 2004-2012	4.26-8.99	24.88 - 45.88	7.69 -16.14	10.57 - 19.06	5.16 -21.28	61.69 – 95.09

Considerations for Option 4: Hybrid Method

While either method may deviate from the true relative abundance along the coast, which is unknown, consideration of which assumptions are violated for a given species may be helpful in deciding which method is more appropriate. Allocation by historical catch may be preferred in instances where a strong natural decline in abundance from the center of a species range occurs, in which case use of miles of coastline alone would cause an over-allocation to areas at the edge of their range where they are less common. This is the case for some of the nearshore rockfish species for which abundance may naturally decline or become non-existent north or south of 40°10′ N. Lat. (e.g., gopher, olive, black and yellow, brown, kelp and grass rockfish; Table B-17). Miles of coastline may be more appropriate for those species that are more uniformly distributed within the entire region over which allocations are being made (e.g., copper, China, and quillback rockfishes). Blue rockfish may be allocated according the stratifications of assessments at 42° N. latitude since two stocks have been identified and are predominantly distributed on either side with further allocation using appropriate methods discussed above depending on the trends in abundance in the region in question.

The Groundfish Management Team (GMT) provides some considerations to allow the Council an alternate way to evaluate the allocation options in a way that extends beyond the needs of the fishery. These methods attempt to approximate the relative abundance of component species given the assumptions implicit in their application to provide a logical basis for allocation. Where the range appears to reach its edge within the management area, average catch may be a more reasoned approach and where large differences in catch occur along the range of an otherwise ubiquitously distributed species in the region, miles of coastline may be preferable, to avoid violation of assumptions implicit in each method. Future off-year scientific research designed to quantify catch and abundance relative to available habitat would greatly improve allocation methods.

Pros and Cons of Each Option in Light of Considerations Presented

The pros and cons of each method given considerations regarding allocation with each are described in Table B-18.

Table B-18. Comparison of the pros and cons of each Nearshore Rockfish complex allocation option.

Allocation Option	Pro	Con
Miles of Coastline	Less potential for over allocation to depleted areas than historical catch if harvest is more reflective of management policies than fish abundance. Provides an alternative to catch based allocation methods	Some species are far less common at the edge of their range and would be over-allocated to some areas since the method assumes abundance is proportional to miles of coastline.
Historical Catch (2004-2012)	Reflects the recent historical pattern of commercial and recreational fisheries. Accounts varying trends in abundance with latitude at the edge of a species range.	Potential for over-allocation to areas that are more depleted. Overfished species constraints limited harvest to varying degrees between states affecting allocations. Doesn't address areas where commercial fisheries are prohibited.
Hybrid Option	Minimizes allocation biases presented by application of historical catch to areas with higher removals/depletion and miles of coastline for species at the edge of their range.	Still does not reflect differences in reef habitat and relative abundance across states, but neither do the other options. Still subject to the biases of each method, but attempts to minimize the degree of bias given apparent trends in abundance and distribution of component stocks.

Comparison of Historical Mortality and Projected Mortality under the Preferred Alternative and No Action to Nearshore Harvest Guideline Allocation Alternatives

The projected mortality in each state and sector under the No Action Option, Preferred Alternative Alternative 4, the average mortality between 2004 and 2012, and the range of catch during this period are presented in Table B-19. There are no nearshore rockfish mortality projection models for the trawl and non-nearshore fishery, but based on historical data, mortality in the trawl and non-nearshore fisheries is expected to be trace (Agenda Item C.4.a, Attachment 3, Table 4-13). Mortality in 2013 is not yet available for the nearshore fixed gear fishery, but this information is available for the recreational fishery, which demonstrates that mortality in the most recent year of the recreational fishery was 6.2 mt for Washington, 38.1 mt for Oregon and 9.3 mt for California.

Projections for nearshore rockfish for all coastwide sectors north of 40°10′ N. Lat. total 76.7 mt under no action. The average catch for 2004-2012 is 81.6 mt for all sectors combined; results for each state are also provided for comparison under each alternative. The projected mortality under the Preferred Alternative is 80.0 mt without harvest guidelines or interstate coordination of catch tracking and inseason response, making it difficult to reduce mortality to prevent overages against the shared aggregate ACL. The average catch as well as projected mortality under the SQ and Preferred Alternative (Table B-19) will exceed the 2015-2016 ACL of 69 mt, indicating that management measures will likely be needed to reduce aggregate mortality. Decisions on the part of the Council relative to allocations will involve tradeoffs potentially affecting fishing opportunity in each state.

The methods used to project mortality for 2015-2016 with methods approved by the SSC in each recreational and commercial fishery are described below:

Nearshore Fixed Gear: The commercial nearshore model projects mortality of overfished species and targeted nearshore species based on the expected (e.g., landings of nearshore rockfish, black rockfish, kelp greenling, cabezon, lingcod, and California scorpionfish (S of 40°10'N Lat.). The nearshore model applies past discard rates (from the West Coast Groundfish Observer Program; WCGOP) to expected landings by depth, along with depth-specific discard mortality rates, to estimate total mortality of discarded and landed nearshore species. The GMT notes that the nearshore commercial bycatch projection model estimates discard of nearshore species based on expected landings coupled with discard rates provided by WCGOP; however, discard rates are based on past management measures. If trip limits (and expected landings) are reduced dramatically, the model may grossly underestimate discard.

Washington Recreational: The Washington recreational model uses historical catch to project total mortality of overfished and nearshore rockfish species. Nearshore rockfish projected impacts for this analysis used the historical high catch by species from the 2009 through 2013 time period as the projected impacts under the No Action Alternative. Washington does not have a nearshore commercial fishery so projections of nearshore rockfish have not been needed to ensure that catch stays within sector specific allocations. This analysis includes nearshore rockfish caught in all recreational fisheries including those targeting salmon and halibut and any restrictions to nearshore rockfish retention would be applied to all fisheries. Recreational fishing effort in salmon and halibut fisheries can vary annually contributing to variable encounter rates with nearshore rockfish. Using the 2009-2013 high catch to model projected impacts results in more conservative management measures, that are expected to keep catch of nearshore rockfish within the range of HG options for the Washington recreational fishery. Catch by month and management area during this time period was used to estimate projected impacts for the WA Nearshore Rockfish complex HG Options. The proportion of nearshore rockfish caught by depth and month for each management area was used with current surface release mortality rates to estimate discard mortality by month.

Oregon Recreational: The Oregon recreational catch projection model uses the last 3 years of data in producing projections of nearshore rockfish mortality. Table B-19 displays the results of the Oregon recreational model projections of nearshore rockfish mortality under Alternative 3.

California Recreational: The California recreational catch projection model used mortality in 2011 and 2012 as the base data for projections. Three options are available for the season structure for the California recreational fishery and the projected mortality of 15.6 mt, 15.4 mt and 6.7 mt, respectively, with the season with the highest projected mortality of Nearshore Rockfish complex displayed in Table B-17.

Table B-19. Projected Nearshore Rockfish complex mortality under the No Action Alternative, the Preferred Alternative, average mortality from 2004-2012 and, allocation under each HG alternative by state and sector (in mt).

Sector	No Action Mortality	Projected Mortality under Preferred Alt	Average Mortality and Range 2004-2012	HG Miles of Coastline	HG Historical Catch	HG Hybrid Approach

1/The state of Washington has not had a commercial nearshore fishery since 1995.
2/For Oregon, projected landings and additional discard mortality for each column are: No Action (15.0 mt + 0.1 mt), Preferred Alternative (18.3 + 0.1 mt), 2004-2012 average (14.21 + .08 mt), Option 1 (9.6 + 0.05 mt), Option 2 (10.7 + 0.06 mt), and Option 3 (10.4 + 0.06 mt).
3/The California commercial blue rockfish mortality estimate for 2008 from PacFIN reflected expansion of a single sample to a value of 21.6 mt, which is not representative of expected mortality from landing receipts from CFIS totaling 7.8 mt. The projected impacts and average mortality from the PacFIN estimate is provided in brackets.

Management Options

Option 1: No Action: Continue to manage the Nearshore Rockfish complex, holding impacts to the complex level ACL in each region.

Option 2: Miles of Coastline: Manage the Nearshore Rockfish complex according to state specific harvest guidelines stratified at 40°10′ N. Lat. reflecting apportionment based on the miles of coastline in each state.

Option 3: Historical Catch: Manage the Nearshore Rockfish complex according to state specific harvest guidelines stratified at 40°10′ N. Lat. reflecting apportionment based on the historical recreational and commercial catch between 2004 and 2012.

Option 4: Hybrid Method: Manage the Nearshore Rockfish complex according to a state specific harvest guidelines stratified at 40°10′ N. Lat. reflecting a hybrid method of apportionment based on miles of coastline for China, quillback and copper rockfish and the historical recreational and commercial catch between 2004 and 2012 for the remaining species.

Data and Examples of Available Management Measures

Washington

Recreational: The Washington recreational fishery was modeled for season structure alternatives necessary to keep total mortality of overfished species within state specific HGs in the draft DEIS. Projected moralities for nearshore rockfish were not included in that analysis. Additional management measures needed to keep nearshore rockfish catch under the WA HG alternative are explored here. For the most part, nearshore rockfish are not targeted in Washington's recreational fisheries and retention is incidental while anglers target other groundfish, salmon and halibut. The primary tool analyzed to reduce total mortality of nearshore rockfish is non-retention. Projected mortality for nearshore rockfish was analyzed based on the season structure under the Preferred Alterantive for the Washington recreational fishery. Note that mortality estimates, allocations and projections do not include mortality from the Puget Sound or Strait of Juan de Fuca since they are not managed with the Council process. In addition, mortality from shore based modes are not accounted for in estimates, projections or allocations.

Commercial: Washington has prohibited a commercial nearshore fishery since 1995.

Oregon

Recreational: The Oregon recreational fishery was modeled for various season structure scenarios to keep impacts to overfished species within the sector-specific HGs (canary and yelloweye rockfish) in the DEIS. Mortalities of key non-overfished species, given those season structures, were also projected in the DEIS. Further management measures, such as sub-bag limit or non-retention, will likely be needed to reduce impacts to the nearshore rockfish complex. Oregon intends to develop the within-Oregon commercial-recreational split through state processes. Determining which management measures are necessary to stay within that split will also occur through state processes. Note that mortality estimates, allocations and projections do not include mortality from the shore based modes as they have not been sampled in recent years. The mortality in these modes continues, though it is not reflected in estimates or allocations. Since they are excluded from allocations and estimates, it is assumed that the results are consistent with the outcome had they been included in both, though further analysis by the GMT is warranted. Discussion of their inclusion in future estimates or retrospectively for this analysis is a point of consideration for the Council and the GMT in June.

Commercial: The Oregon commercial nearshore fishery was modeled assuming the shoreward RCA at 30 fm for all options. The input for this model is estimated landings of Other Nearshore Rockfish. Discard rates were applied to these estimated landings to project discard of Nearshore Rockfish (based on WCGOP data). Depth-specific mortality rates were then applied to the discarded portion of the catch to estimate discard mortality. Total mortality may then be estimated by summing the landings and estimated discard mortality.

Management measures will likely have to be implemented to reduce mortality of Nearshore Rockfish (including blue rockfish) for each of the harvest guideline options. Under the Preferred Alternative and No Action, state trip limits for vessels with nearshore endorsed black rockfish and blue rockfish permits (i.e., nearshore permitted vessels) would remain at approximately 700 lb per 2-month period for Nearshore Rockfish (not including blue rockfish). Vessels with black rockfish and blue rockfish permits would also be allowed to retain 1,000 to 1,700 lb per period of black rockfish and blue rockfish (combined) under the Preferred Alternative. See the DEIS for more information regarding state permit system.

Landings are monitored closely during the season (i.e., near-real time), which provide the opportunity to implement and evaluate impacts of reduced (or increased) trip limits. Trip limit options may include (a) trip limit reductions to allow for year-around deliveries of Nearshore Rockfish or (b) less severe trip limits during part of the year but at some point, impose no retention (i.e., all Nearshore Rockfish encountered would be discarded). Note that separate blue rockfish trip limits may be considered, because blue rockfish and black rockfish are currently managed under a combined trip limit. It is uncertain at this point (a) when trip limits may be imposed and (b) what the trip limit levels should be under the harvest guideline options.

California

Recreational: The current California recreational catch projection model (RecFISH) was used to project mortality with a given season and depth restriction under each of the Options. These data and analytical methods allowed mortality to be projected from combinations of season lengths and bag limit that keep nearshore rockfish mortality within respective harvest guideline under each of the Options. California recreational catch estimates and projections account for mortality in all modes including shore and boat based angling and saltwater areas including bays and estuaries.

Commercial: PacFIN data were used for overall minor nearshore rockfish complex landings summaries whereby a simple five-year average (2008-2012) was used as a proxy for mortality estimates. Because PacFIN data were used, PacFIN estimates do not include discard mortality amounts. However, estimated discard mortality for nearshore rockfish have been included by using those generated by the nearshore bycatch model. California's Commercial Fishery Information System (CFIS) data were used for nearshore permit license summaries. Lastly, the GMT's nearshore bycatch projection model was used to estimate overfished species (OFS) mortality in the commercial nearshore fixed gear fishery.

Management measures for the northern California nearshore rockfish fishery, currently in place, include a shoreward RCA boundary of 20 fm, trip limits for both black rockfish and the minor nearshore rockfishes as a sub-trip limit of the overall nearshore rockfish complex, a state nearshore permit system, and a gear restriction that limits the number of hooks one may use within one mile of shore. The most obvious management measure change that may need to be considered to achieve necessary mortality reductions would be a reduction in the black rockfish/other minor nearshore rockfish trip limit structure. Under No Action, the current trip limit is set at 8,500 lb per vessel per bi-monthly period for all six periods. Of that bi-monthly amount, no more than 1,200 lb may be species other than black rockfish. It is this part that needs to be more closely examined as a possible source for a management measure change. A trip limit reduction in this sub-trip limit amount could also partially address concerns regarding the mortality of overfished species. Another trip limit option would be to design trip limits specific to each period rather than have an "across-the-boards" single amount for all six periods. Lastly, a management measure option could be to have one or possibly two periods closed to fishing. A sub-option to this seasonal closure approach may be to close the fishery for one month in one or more periods.

B.5.1 Comparison of Options under the Preferred ACL Alternative (P* 0.45)

B.5.1.1 Option 1: No Action

Continue to manage the Nearshore Rockfish complex, holding impacts to the complex level ACL in each region. Under the No Action Option (Option 1), the Nearshore Rockfish complex would be subject to the ACL for all sectors and states combined. The Nearshore Rockfish complex is stratified at 40°10′ N. Lat. with an ACL of 69 mt to the north and 1,049 mt to the south in 2015 with a P* of 0.45 under the preferred specifications.

Fishing Activity under Option 1 (No Action)

Washington

Recreational: Under the No Action Alternative, the Washington recreational fishery would be open year-round for groundfish, except lingcod. Washington would continue to prohibit the retention of canary and yelloweye rockfish in all areas. Washington has a 12 fish daily bag limit with sub bag limits of 10 rockfish, 2 lingcod and 1 (northern management area) or 2 (southern management areas) cabezon. Depth restrictions are the primary tool used to keep overfished species impacts below state HGs. Depth restrictions are more sever in the area north of the Queets River (Marine Area 3 and 4) where encounters with yelloweye and canary rockfish are the greatest. Management measures under the Preferred Alternative differ only slightly from the No Action Alternative. Under the Preferred Alternative, the depth closure in the North Coast (Marine Areas 3 and 4) would be in place from May 9th through Labor Day rather than from May 1 through September 30. In the South Coast (Marine Area 2), the prohibition on lingcod retention seaward of 30 fm in the area south of 46°58 N. latitude on Fridays and Saturdays from July to August 31 would be removed and in the Columbia River Area (Marine Area 1), the southern boundary for the year round lingcod closure would be moved three miles north.

Commercial: Closed

Oregon

Recreational: Currently the recreational fishery has a 10-fish marine bag limit in federal regulations. State regulations have reduced that bag limit to 7 fish. The fishery is open to all depth January-March and October-December and restricted to inside of 40 fm (30 fm in state rule) April-September. Blue rockfish has a state-specified landing cap and is tracked separately from the other nearshore rockfish. Other nearshore rockfish also have a state-specified landing cap (13.6 mt), in place since 2002, and are tracked inseason. When the landing cap of either are approached the state takes inseason action, usually going to non-retention of that species or group, while the remainder of the fishery season structure and regulations remain unchanged.

Commercial: As of 2014, state-specified landing caps for the commercial nearshore fishery are 14.2 mt (Other Nearshore Rockfish excluding blue rockfish) and 137.9 mt (black rockfish and blue rockfish combined). The number of limited entry permits currently issued is 51 for black and blue rockfish without the nearshore endorsement and 70 for black and blue rockfish with the nearshore endorsement.

Management measures for the Oregon commercial fishery under No Action would be similar to those described for the Preferred Alternative (see the DEIS). The RCA may remain at 30 fm because impacts to overfished species are projected to fall below the Oregon share for yelloweye rockfish and canary rockfish. Trip limits will remain low for non-permitted vessels (see DEIS) to cover incidental catch of certain nearshore species (e.g., 15 lb per trip of black rockfish, blue rockfish, other nearshore rockfish, and other nearshore species for vessels using legal commercial nearshore fishing gear; other trip limits are available for incidental catch in salmon troll fisheries and in trawl fisheries). State-regulated trip limits for permitted vessels would likely remain at current levels (i.e., 700 lb per period of Nearshore rockfish complex, excluding blue rockfish, and 1,000 lb to 1,700 lb per period for black rockfish and blue rockfish combined (Table B-20). These limits are lower than those shown in Federal regulation.

Table B-20. Oregon commercial nearshore trip limits (No Action) for permitted vessels during 2014. Limits for vessels without black rockfish and blue rockfish permits, and those without a nearshore endorsement, are much lower than shown below to accommodate incidental catch (see DEIS). These trip limits are more conservative than those shown in Federal regulation.

Oregon Commercial Nearshore Trip Limits (lb; 2014)	Jan/Feb	Mar/Apr	May/Jun	Jul/Aug	Sep/Oct	Nov/Dec
Black rockfish + blue rockfish	1,000	1,200	1,700	1,600	1,200	1,000
Other nearshore rockfish (excluding blue rockfish)	700	700	700	700	700	700

California

Recreational: Currently the recreational fishery is subject to a 10 fish Rockfish Cabezon and Greenling bag limit with restricted seasons and depths in each of 5 management areas to limit mortality on overfished and target stocks. The season length in the California recreational fishery under the status quo ACL Alternative in the Northern Management Area is May 15th to October 31st with a depth restriction of 20 fm to keep mortality of yelloweye rockfish below the HG for the recreational fishery. Under the Preferred ACL Alternative, California recreational season and depth restriction Option 1 would allow a March 1 to December 31 season and 20 fm depth restrictions given harvest limits/guidelines on overfished and target stocks in 2015-2016, without limitations from a state Nearshore Rockfish complex HG.

Commercial: At present, the Nearshore Rockfish complex is managed in four regions: the North Coast Region is from 42° N. Lat. (the Oregon-California border) to 40°10' N. Lat. (near Cape Mendocino). Current trip limits and open and closed periods in each region are provided in Table B-21 below. Depth restrictions vary by region with a 20 fm depth restriction to the north of 40°10′ N. Lat., 30 fm south to Point Conception at 34°27′ N. Lat. and 60 fm south of 34°27′ N. Lat.. Currently gear restrictions restrict fishery participants to 15 hooks per line with no more than 150 hooks in use to take nearshore fish stocks within one mile of shore within certain Fish and Wildlife Districts. In addition, the fishery is a subject to a state restricted access permit system for the shallow nearshore fishery. To enter this shallow nearshore fishery, two existing permits must be purchased and transferred to a new participant within the same management region; one of those permits must then be surrendered back to the Department. The intent of this method is to achieve capacity goals for the fishery and reduce participation relative to historical levels to help prevent overharvest. There are no transferable permits for the deeper nearshore rockfish fishery, preventing new entry at the present.

Most fish are sold live for a premium relative to dead fish. This creates an impetus to fish in shallower depths where mortality is lower compared to deeper depths, thus discards are subject to a relatively low mortality compared to depths greater than 30 fm where discards are deemed 100 percent dead.

Notwithstanding the options presented in this analysis, a major factor that influenced fishing activity in California's northern management region was the change of the RCA shoreward boundary from 30 fm to 20 fm to avoid yelloweye rockfish encounters, beginning in 2009. The effects of this boundary change are apparent when examining the commercial landings over the past decade (Figure B-17). California's northern commercial fishery experienced a 55 percent decrease in harvest from 2008 to 2009 and a 39 percent decrease from 2009 compared to 2010.

Table B-21. California commercial federal cumulative two-month trip limits (No Action) for 2014 that apply to the vessel and to the permit holder for the shallow and deeper nearshore rockfish sectors. Trip limits per two-month period (reported in lb) are the same for both the federal limited entry and open access entry sectors used by the state's restricted access nearshore rockfish fishery program.

NORTH Between 42° and 40°10' N. Lat.	Jan/Feb	Mar/Apr	May/Jun	Jul/Aug	Sep/Oct	Nov/Dec
Black rockfish + minor nearshore rockfishes. No more than 1,200 lb of which may be species other than black rockfish (applies to all periods)	8,500	8,500	8,500	8,500	8,500	8,500

Note: For the shallow nearshore fishery, permit holders may catch and land the two-month trip limit only in the region in which their permit is issued. Holders of a deeper nearshore rockfish permit may catch and land deeper nearshore rockfish anywhere in the state where and when fishing is permitted.

Biological Impacts under Option 1 (No Action)

Projected Nearshore Rockfish Mortality

The projected mortality in each state and sector under Option 1 are summarized in Table B-22. Further description of the mortality in each state and sector is provided in the text below.

Table B-22. Projected Nearshore Rockfish mortality (mt) north of 40°10′ N. Lat. from each state and sector under Option 1 (No Action).

	Washington		Oregon		California		Grand Total
	Rec	Com	Rec	Com	Rec	Com	
	10.5	Closed	30.5	15.1	11.7	8.9	76.7
State Total	10.5		45.6		20.6		

<u>Washington</u>

Recreational: Projected mortality of the Nearshore Rockfish complex under the No Action Option and Preferred Alternative is 10.5 mt. Season length and structure are the same for both alternatives.

Commercial: Closed

<u>Oregon</u>

Recreational: The projected landings under the No Action Option for blue rockfish is 17.5 mt, for other nearshore rockfish 13.0 mt, for total nearshore rockfish mortality of 30.5 mt.

Commercial: The projected landings of Nearshore Rockfish under the No Action Option is 15.0 mt in aggregate, and consists of blue rockfish (4.6 mt) and the remaining species of Nearshore Rockfish (10.4 mt). The nearshore projection model provides an additional estimate of discard mortality at 0.07 mt (blue rockfish and other nearshore rockfish combined), resulting in a total mortality of 15.07 mt for Nearshore Rockfish complex in the Oregon nearshore commercial fishery. This is lower than shown under the Preferred Alternative (see the DEIS), where projected landings are 18.3 mt for Nearshore Rockfish (and additional discard mortality projected at 0.1 mt).

<u>California</u>

Recreational: The aggregate mortality of Nearshore Rockfish complex in the Northern Management Area under the No Action Option would be 11.7 mt of which 2.5 mt would be blue rockfish. Under the Preferred Alternative ACL a season length as long as March 1 – December 31 could be accommodated, which would result in an aggregate mortality of Nearshore Rockfish complex of 15.6 mt of which 3.3 mt would be blue rockfish.

Commercial: The aggregate mortality in the Minor Nearshore Rockfish complex under the No Action Option is projected to be 8.9 mt. This aggregate does not include black rockfish. In the north, blue rockfish take is expected to be 4.9 mt out of the 8.9 mt aggregate total.

Projected Overfished Species Mortality under Option 1 (No Action)

<u>Washington</u>

Recreational: The projected overfished species mortality under the No Action Option and the season structure under the Washington recreational Preferred Alternative is 2.83 mt of yelloweye rockfish and 0.75 mt of canary rockfish which are below the WA recreational HG.

Commercial: Closed

<u>Oregon</u>

Recreational: The projected overfished species mortality under the No Action Option is 2.2 mt of yelloweye rockfish and 3.2 mt of canary rockfish, the same as under the Preferred Alternative. These projections are below the sector-specific HG.

Commercial: The projected overfished species mortality under No Action Option is 0.8 mt of yelloweye rockfish and 0.9 mt of canary rockfish. These projections are slightly different than shown under Preferred Alternative, where yelloweye rockfish mortality was projected at 0.9 mt and canary rockfish mortality was projected at 1.1 mt. These projections are equal to or less than the Oregon catch share.

<u>California</u>

Recreational: The overfished species mortality projected to accrue under the No Action Option are 1.7 mt of yelloweye rockfish, 16.3 mt of canary rockfish, 100.1 mt of bocaccio and 1.0 mt of cowcod. Under the Preferred Alternative overfished species mortality projected to accrue are 2.9 mt of yelloweye rockfish, 19.8 mt of canary rockfish, 117.6 mt of bocaccio and 1.2 mt of cowcod. The projected impacts are within the respective harvest limits/guidelines.

Commercial: The overfished species mortality projected to accrue under the No Action Alternative for north of 40°10' N. Lat. are 0.3 mt of yelloweye rockfish, 0.7 mt of canary rockfish, 0.4 mt of bocaccio and 0.0 mt of cowcod. Under the Preferred Alternative, overfished species mortality projected to accrue are 0.2 mt of yelloweye rockfish, 0.5 mt of canary rockfish, 0.4 mt of bocaccio and 0.0 mt of cowcod. The projected impacts are within the respective harvest limits/guidelines.

Stock Status

Nearshore Rockfish

None of the stocks of nearshore species are currently deemed overfished. Recent aggregate mortality for all sectors has perennially exceeded the 2015-2016 ACL of 69 mt in all but two of nine years between 2004 and 2012 (Table B-17). Steps to reduce mortality should be taken to prevent further overharvest relative to 2015-2016 ACLs and reduce the potential for stocks to be harvested down to overfished status.

Overfished Species

The mortality of overfished species is projected to remain below their respective harvest limits/guidelines. Thus the stock status and rebuilding plans for overfished species are not expected to be adversely affected under No Action Option 1.

Socioeconomic Impacts under Option 1 (No Action)

Washington

Recreational: Under the No Action Option, and the season structure under the Washington recreational Preferred Alternative, management measures necessary to keep recreational harvest of yelloweye rockfish within harvest guidelines require closure or significant restriction of the groundfish fishery in areas deeper than 20 and 30 fm along a substantial portion of the Washington coast, restrictions on groundfish retention during peak recreational fishing periods, and closed areas. While these restrictions have been effective at keeping recreational catch of overfished species under specified harvest guidelines in the past, they are limiting to recreational fishing opportunity. Under the No Action Alternative, angler trips are expected to be similar to what was seen in 2013 and 2014.

Commercial: Closed

Oregon

Recreational: Under the No Action Option, the season structure, bag limits, and most other management measures will remain the same as in 2013 and 2014. Therefore, angler trips and associated expenditures are expected to remain similar to what was seen in 2013 and 2014.

Commercial: Under the No Action Option, landing caps, trip limits, and RCA boundaries are expected to remain the same as in 2013 and 2014. Therefore, trips, expenditures, landings, and revenues are expected to remain similar to that seen in 2013 and 2014. Note that even though management measures would remain similar between Preferred Alternative and No Action, landings of Nearshore Rockfish under Preferred Alternative (18.3 mt) may be higher than that shown under No Action (15.0 mt).

California

Recreational: Under the No Action Option the season and depth restrictions will remain the same as in 2014, but 4.5 months of additional fishing opportunity (4,379 angler trips) would be forgone in the Northern Management Area relative to what could be afforded given the harvest specifications and allocations of overfished and target stocks in 2015-2016 under the Preferred Alternative ACL.

Commercial: Under the No Action Option the state restricted access permit system, federal trip limits, season and depth restrictions will remain the same as in 2014. However, routine inseason adjustments could be recommended by the Council if any of the fishery sectors displayed harvest behavior that deviate substantially from the expected amounts. As a result, no adversely affected changes to the socio-economic interests of coastal communities would be anticipated.

B.5.1.2 Option 2: Miles of Coastline

Option 2 is to manage the Nearshore Rockfish complex according to state-specific harvest guidelines stratified north and south of 40°10′ N. Lat., with apportionment north based on the miles of coastline in each state as reflected in Table B-23. The 3 nm state boundary was measured as the proxy for miles of coastline.

Table B-23. Allocations of Nearshore Rockfish north of 40°10′ N. Lat. under Option 2 derived using miles of coastline in each state.

Species	**Contribution**	**WA%**	**OR%**	**CA%**	**WA mt**	**OR mt**	**CA mt**
Black-and-yellow	*0.01*	0.26	0.49	0.25	0.00	0.01	0.00
Blue (CA)	*17.00*	0.00	0.00	1.00	0.00	0.00	17.00
Blue (OR & WA)	*26.94*	0.34	0.66	0.00	9.26	17.68	0.00
Brown	*1.75*	0.26	0.49	0.25	0.45	0.86	0.43
Calico	*0.00*	0.26	0.49	0.25	0.00	0.00	0.00
China	*6.20*	0.26	0.49	0.25	1.60	3.06	1.54
Copper	*9.71*	0.26	0.49	0.25	2.51	4.79	2.41
Gopher	*0.00*	0.26	0.49	0.25	0.00	0.00	0.00

Quillback	*6.15*	0.26	0.49	0.25	1.59	3.04	1.52
Treefish	*0.18*	0.26	0.49	0.25	0.05	0.09	0.04
Total	68.76				15.68	29.93	23.15

Fishing Activity under Option 2 Compared to Option 1 (No Action)

Washington

Recreational: The Washington HG under Option 2 is 15.68 mt which is higher than the project impacts Under No Action (Option 1). Therefore, the Washington recreational fishery would operate under the season structure described under the Preferred Alternative with no additional management measures needed to keep the catch of nearshore rockfish under the WA HG for this HG Option.

Commercial: Closed

Oregon

Under Option 2, the Oregon Nearshore Rockfish complex harvest guideline is lower than the current combined commercial and recreational state-specified landing caps and average annual catches. We showed above that expected Nearshore Rockfish mortality for Oregon fisheries combined is 45.6 mt for No Action and 48.9 mt for Preferred Alternative. The Oregon harvest guideline under this option is 29.9 mt (Table B-23), or 34 percent lower than expected mortality under No Action and 39 percent lower than expected under Preferred Alternative. State landing caps for both commercial and recreational fisheries will have to be reduced dramatically to accommodate this lower target. It is the GMT's understanding that Oregon intends to develop the commercial-recreational split of the Oregon HG through subsequent state processes.

Recreational: Once the state determines the sector-specific allocation, management measures will need to be examined, then implemented through state rules. A preliminary examination of possible management measures has begun. A bag limit analysis revealed that the majority of anglers encounter less than one nearshore rockfish per trip. Therefore changes in bag limit will likely not be a viable option. The likely measure will be non-retention for some months of the fishing season, incorporating discard mortality for the non-retention months into the impact projections. Since most anglers encounter less than one nearshore rockfish per angler trip and they are generally not targeted, prohibiting retention during certain months, is not expected to influence the number of angler trips, how often, when or where anglers go fishing. It may require anglers to be on the water longer to fill their daily bag limit, however since the majority of anglers do not fill their entire bag each day, this is anticipated to have minimal impacts.

Commercial: Under Option 2, the RCA depth restriction of 30 fm would remain in place because projected catch of overfished species would remain at or below the Oregon catch share. Measures other than depth management will have to be implemented to reduce the mortality of Nearshore Rockfish (including blue rockfish) under this option. For example, under No Action, the commercial fishery was projected to land 15 mt of Nearshore Rockfish (including blue rockfish), resulting in total mortality of 15.1 mt, including discard. Using proportions of current landing caps and average landings between Oregon recreational and commercial fisheries (see Preferred Alternative in the DEIS), the Oregon commercial fishery would receive 9.6 mt of Nearshore Rockfish (including blue rockfish), or a reduction of 36 percent relative to No Action and a 48 percent reduction relative to Preferred Alternative. These reductions may require lower trip limits, periods of non-retention, or some combination of the two. In addition, a new and separate landing cap and trip limit for blue rockfish may be required to remain within the harvest guideline under Option 2 (currently, blue rockfish is managed using landing caps and trip limits in combination with black rockfish).

It should be pointed out that trip limit reductions may not equate to a 1:1 reduction in total landings. In other words, if it were required to reduce landings by 36 percent, then it may be necessary to reduce trip limits by much more than 36 percent relative to No Action. In most fisheries, relatively few individuals or vessels reach trip limits. Most vessels land somewhat less than trip limit levels. As such, if trip limits were solely used to reduce landings, and if the Oregon recreational to commercial ratio (split) remained the same as under No Action, then trip limit reductions would likely have to be much more than 36 percent (i.e., trip limits for this fishery would need to be much lower than 700 lb x 0.64 = 448 lb per period under Option 1). There are other considerations that industry and ODFW staff must discuss and analyze before effective trip limits can be identified. For example, impacts of trip limits vary with the season in which they are applied. Finally, trip limits can be applied along with periods of non-retention, which will alter the level of the trip limit needed. Preferences by the Oregon nearshore fleet need to be identified and additional modeling is required before more specificity can be provided.

California

Recreational: Under Option 2, 23.15 mt would be allocated to California, of which, the recreational catch share is 12.9 mt, accommodating a May 1 to October 31 season with a 20 fm depth restriction in the Northern Management Area. While this would provide an additional half month of fishing opportunity relative to the status quo, the recreational fishing season would have to be reduced by four months relative to the longest season under the Preferred Alternative of March 1 to December 31st. Other alternatives to address overages relative to the catch share include a reduced bag limit or non-retention of Nearshore Rockfish species during part of the season.

Commercial: Under Option 2 the RCA depth restriction of 20 fm would remain in place as well as the trip limit structure. Because the minor nearshore rockfish complex harvest has been at or below the ACLs in recent years (see Figure (cite the correct figure)), it is not anticipated that Option 2 will have an adverse effect on the northern nearshore rockfish fishery; thus fishing activity is expected not to change. However, trip limit reductions could be implemented should the need arise, with possible decreases that may be as much as 30 percent less than the current trip limit amount. Another possibility to be considered is to have period closures. Additionally, California's northern management region is somewhat isolated from the adjacent region(s). Because of this, northern region participants tend not to fish in other management regions (for those holding a deeper nearshore rockfish permit), nor would they be likely to because the trip limits for the northern region are higher than any of the other regions. Also, it is not expected that holders of a deeper nearshore rockfish permit, who may also hold a shallow permit in any of the other southerly regions, would travel to the northern management region to fish because they would only be allowed to catch and land the deeper nearshore rockfishes – their shallow nearshore permit would not be valid north of 40°10' N. Lat.. In effect, it would probably not be economically justifiable for them to fish north of 40°10' N. latitude.

Biological Impacts Under Option 2 Compared to Option 1

Projected Nearshore Rockfish Mortality

The projected mortality in each state and sector under Option 2 are summarized in Table B-24. Further description of the mortality in each state and sector is provided in the text below.

Table B-24. Projected Nearshore Rockfish mortality (mt) north of 40°10′ N. Lat. from each state and sector under Option 2 (miles of coastline). Sector-specific allocations within states are provided as an example and are based on No Action. These intra-state allocations are subject to change.

	Washington		Oregon		California		Total
	Rec	Com	Rec	Com	Rec	Com	
Mortality	10.5	Closed	20.3	9.6	12.6	10.3	63.3
State Total	10.5		29.9		22.9		
Allocation	15.68		29.93		23.15		69
Projected Percent Attainment	66.9%		100%		98.9%		91.7%

Washington

Recreational: Under Option 1 the projected Washington recreational catch falls below the WA HG of 15.68 mt with catch projected to be 10.5 mt. No negative biological impacts are expected.

Commercial: Closed

Oregon

Recreational: Under this option impacts to nearshore rockfish will need to be reduced. Oregon intends to allocate between the commercial and recreational sectors, and take management measures to stay within those allocations, through subsequent state processes. The most likely management measure will be non-retention of nearshore rockfish for some months of the fishing season. Table B-25 below shows the projected landings under the preferred season structure and the projected discard mortality from non-retention by month of the other nearshore rockfish and blue rockfish. Both are calculated on a month by month basis, as that is the smallest time unit currently available in the Oregon recreational model. To project total impacts, and determine which months might need to have non-retention, the landings for months open are added to the release mortality for non-retention months.

Table B-25. Oregon recreational fishery impacts (in mt) by month under preferred season structure and non-retention for the nearshore rockfish.

Projections	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec
Other Nearshore Rockfish												
Landings under SQ regulations	0.19	0.24	0.58	0.90	1.64	2.13	2.59	2.91	1.22	0.43	0.10	0.06
Non-retention release mortality	0.08	0.10	0.23	0.33	0.61	0.79	0.96	1.08	0.45	0.17	0.04	0.03
Blue Rockfish												
Landings under SQ regulations	0.27	0.34	0.82	1.25	2.24	2.90	3.54	3.98	1.66	0.61	0.14	0.09
Non-retention release mortality	0.27	0.11	0.27	0.39	0.70	0.91	1.10	1.24	0.52	0.21	0.05	0.03

As one example, non-retention in the months of July and August would reduce impacts of other nearshore rockfish species (not including blue rockfish) from 13 mt to 9.5 mt, or a 27 percent reduction. It is the GMT's understanding that Oregon intends to go through their public process to get angler input on which months to have non-retention.

Commercial: Under this option, commercial management measures will be applied to reduce Nearshore Rockfish mortality to 9.6 mt (including blue rockfish), or a 36 percent reduction relative to No Action (and 48 percent reduction relative to Preferred Alternative). This value may change depending on decisions regarding the Oregon recreational-commercial split. Regardless of the management measure applied (e.g., trip limits and/or non-retention), mortality will be reduced. Therefore, no negative biological impacts are expected under this option.

California

Recreational: The projected mortality on nearshore rockfish under Option 2 with a May 1 to October 31 season in the Northern Management Area with a 20 fm depth restriction is 12.6 mt of which 2.8 mt would be blue rockfish. These mortality projections are below the recreational catch share of the California allocation of 12.9 mt under this option.

Commercial: No anticipated negative biological impacts are expected for this option compared to Option 1. Because this option (as well as Options 3 and 4) could require reductions in harvest, biological impacts could actually be reduced to a small degree depending upon the amount of the reduction. Since California's northern fishery has taken less than 10 mt per year on average during the past five years, resultant decreases would be small.

Projected Overfished Species Mortality

Washington

Recreational: Projected overfished species impacts under this Option are the same as for the season structure under the Washington recreational Preferred Alternative.

Commercial: Closed

Oregon

Recreational: A preliminary examination of overfished species impacts due to management measures that may be required under this option projects less than 0.01 percent increase in canary and yelloweye rockfish impacts, assuming no other changes to angler behavior.

Commercial: Under Option 2, if fishermen behavior remains the same as under No Action regarding fishing locations and fishing methods, but increased discarding of Nearshore Rockfish becomes necessary, then mortality of overfished species will remain unchanged relative to No Action. If, on the other hand, selection of fishing locations changes dramatically because of changes in trip limits or required non-retention of Nearshore Rockfish, then overfished species impacts may increase or decrease, depending on geographic locations selected. The direction or level of this potential change in catch of overfished species cannot be predicted in this analysis.

California

Recreational: Assuming season lengths under Option 1 of the Preferred Alternative in Management Areas south of $40^{o}10'$ N. Lat. and the May 1 to October 31 season with a 20 fm depth restriction in the Northern Management Area, overfished species mortality projected to accrue under Option 2 are 2.7 mt of yelloweye rockfish, 21.4 mt of canary rockfish, 118.3 mt of bocaccio and 1.2 mt of cowcod. The projected impacts are within the respective harvest limits/guidelines.

Commercial: Mortality of canary and yelloweye rockfish has been near the respective allocation amounts for these two species. As such, under Option 2 (as well as Options 3 and 4), projected mortality may have to be reduced. Using the nearshore bycatch model as a predictor, decreases in the black rockfish component may need to be considered as a means to achieve the necessary projected mortality decreases for these two overfished species so as to not exceed their allocations.

Stock Status

Nearshore Rockfish

None of the stocks in the Nearshore Rockfish complex are currently deemed overfished. The proposed HG under this option will facilitate implementation of inseason actions to prevent the aggregate ACL from being exceeded, decreasing the risk of overfishing component stocks. Thus, the stock status would not be adversely affected by management measures under Option 2.

Overfished Species

Under Option 2 (miles of coastline), the overfished species mortality is expected to be below the harvest limits/guidelines. Thus stock status and rebuilding plans would not be adversely affected by management measures under Option 2.

Socio-economic Impacts compared to Option 1

Washington

Recreational: The socio-economic impacts would be the same under this Option compared to the No Action Option. Socio-economic impacts would continue to be driven by management measures necessary to keep the Washington recreational fishery within the WA HG for yelloweye and canary rockfish. Recreational fishing effort is expected to be the same under Option 2 as under the management measures and season structure for the Washington recreational Preferred Alternative.

Commercial: Closed

Oregon

Recreational: Since most anglers encounter less than one nearshore rockfish per angler trip and they are generally not targeted, management measures necessary to reduce mortality of nearshore rockfish species is not expected to impact angler behavior, angler trips, nor any other socio-economic indicators. However, additional outreach and education on species identification will likely be necessary to help anglers stay within retention/non-retention regulations. It is impossible to predict how the additive impact of adding this regulation to others already in place might impact anglers' decisions on fishing activities.

Commercial: It is uncertain whether fishing behavior (i.e., fishing location and fishing gear) will change under this option relative to No Action (see above). However, if allocations remain the same between Oregon recreational and commercial fisheries, then landings may be reduced from 15.0 mt (No Action) to between 9.6 mt (maximum, if reduced trip limits resulted in avoiding Nearshore Rockfish altogether resulting in no discards, which is unlikely) to 7.2 mt (if encounters were similar to No Action and discarding was necessary, some of which will not survive. The 2013 price per pound for Other Nearshore Rockfish (weighted average including blue rockfish) was $3.80 per pound for Oregon nearshore fisheries (PacFIN). Under the potential scenarios shown here, lost ex-vessel revenue may range from $45,238 to $65,344 relative to No Action (the loss is higher relative to Preferred Alternative). Additional impacts may be incurred by vessels and crew if the decision is made to fish in less productive areas to avoid Other Nearshore Rockfish, for example. If such of a choice is made, then it may require extra time and fuel to catch other targeted species relative to No Action.

California

Recreational: Under Option 2, the season length would increase by a half month (205 angler trips) relative to the status quo fishery in the Northern Management Area, but the season would be reduced by four months (4,175 angler trips) relative to the longest proposed season with the Preferred Alternative ACLs (Option 1) resulting in lost revenue from those in coastal communities dependent on recreational fishing for their livelihoods.

Commercial: The northern commercial fishery is still recovering from the 2011 tsunami event and the loss of buyers during the past year or two. Currently, there is only one major active buyer in Crescent City. The economic structure of the northern area (essentially only Crescent City) is in a rebuilding phase with no expected time frame, at the present, that predicts when a return to status quo would be reestablished. This, however, is not a result of the options themselves, but an artifact of unavoidable events that have impacted this area. (See also the comments in the Change in Fishing Activity section, above.)

B.5.1.3 Option 3 Historical Catch

Option 3 is to manage the Nearshore Rockfish complex according to a state specific harvest guidelines stratified at 40°10′ N. Lat. reflecting apportionment based on the recreational and commercial historical catch between 2004 and 2012 reflected in Table B-26.

Table B-26. Allocations of Nearshore Rockfish north of 40°10′ N. Lat. under Option 3 (historical catch) derived using the historical recreational and commercial catch between 2004 and 2012.

Species	Contribution	WA%	OR%	CA%	WA mt	OR mt	CA mt
Black-and- yellow	0.01	0	0.21	0.79	0	0	0.01
Blue (CA)	17	NA	NA	1	0	0	17
Blue (OR & WA)	26.94	0.06	0.94	NA	1.67	25.27	0
Brown	1.75	0	0.08	0.92	0	0.14	1.61
Calico	0	NA	NA	NA	0	0	0
China	6.2	0.18	0.68	0.14	1.13	4.21	0.86
Copper	9.71	0.13	0.53	0.34	1.24	5.14	3.34
Gopher	0	0	0.29	0.71	0	0	0
Grass	0.55	0	0.49	0.51	0	0.27	0.28
Kelp	0.01	NA	NA	NA	0	0	0
Olive	0.26	0	0.03	0.97	0	0.01	0.25
Quillback	6.15	0.16	0.47	0.36	1.01	2.91	2.23
Treefish	0.18	0	0	1	0	0	0.18
Total					5.05	37.94	25.76

<u>Fishing Activity under Option 3 Compared to Option 1</u>

<u>Washington</u>

Recreational: The Washington recreational fishery would operate under season structure and management measures described under the Preferred Alternative. However because the WA HG under Option 3 is lower than the historical catch, additional management measures would be needed to keep nearshore rockfish catch under the WA HG for this option. To keep total mortality under the WA HG, retention of nearshore rockfish would not be permitted for a portion of the year. Attainment of the WA HG under this alternative is projected to occur by June 1 with retention of nearshore rockfish prohibited for the remaining 7 months of the year. Alternate combinations of months when nearshore rockfish would be prohibited may be explored.

Commercial: Closed

<u>Oregon</u>

Under Option 3, the Oregon Nearshore Rockfish complex harvest guideline is lower than the current combined commercial and recreational state-specified landing caps and average annual catches, but higher than Option 2. We showed under No Action for Nearshore Rockfish that the expected mortality for recreational and commercial fisheries combined is 45.6 mt (the expected mortality under Preferred

Alternative is 48.9 mt). The Oregon harvest guideline under this option is 37.9 mt (Table B-26), 17 percent lower than expected mortality under No Action, and 22 percent lower than expected mortality under Preferred Alternative. State landing caps for both commercial and recreational fisheries will have to be reduced to accommodate this lower target. As noted under Option 2, Oregon intends to develop or modify the commercial-recreational split of the Oregon HG through state processes.

Recreational: Similar to Option 2, a combination of months of retention and months of non-retention will likely be required to keep impacts within the Oregon recreational HG.

Commercial: Similar to No Action, the RCA depth restriction of 30 fm would remain in place. However, as shown for Option 2, trip limits and/or no-retention may be needed to reduce mortality relative to No Action or Preferred Alternative. Trip limit reductions will be less severe than shown under Option 2. For example, using proportions of current landing caps and average landings between Oregon recreational and commercial fisheries (see Preferred Alternative in the DEIS), the Oregon commercial fishery would receive 11.2 mt of Nearshore Rockfish (including blue rockfish), or a reduction of 25 percent relative to No Action and a reduction of 39 percent relative to Preferred Alternative. This reduction may require either lower trip limits, periods of non-retention, or some combination for Nearshore Rockfish (excluding blue rockfish), along with a separate landing cap and separate trip limit for blue rockfish (see Option 2 for more details).

As shown for Option 2, trip limit reductions may not equate to a 1:1 reduction in total landings. In other words, if it were required to reduce landings by 25 percent, then it may be necessary to reduce trip limits by more than 25 percent. If trip limits (and/or non-retention) were solely used to reduce landings, and if the Oregon recreational-commercial allocation remained the same as under No Action, then trip limit reductions would likely have to be much lower than 700 lb x 0.75 = 525 lb per period. How much lower is uncertain. ODFW staff will meet with industry to identify most preferred management measures, and subsequent trip limit modeling will be performed based on options selected. See Option 2 for more details.

California

Recreational: Under Option 3, 25.3 mt would be allocated to California, of which the recreational catch share is 14.07 mt, accommodating a April 15 to December 31 season with a 20 fm depth restriction in the Northern Management Area. While this would provide an additional three months of fishing opportunity relative to the status quo, the recreational fishing season would have to be reduced by one and a half months relative to the longest season under the Preferred Alternative of March 1 to December 31st. Other alternatives to address overages relative to the catch share include a reduced bag limit or non-retention of Nearshore Rockfish species during part of the season.

Commercial: Same as Option 2.

Biological Impacts Under Option 2 Compared to Option 1

Projected Nearshore Rockfish Mortality

The projected mortality in each state and sector under Option 3 are summarized in Table B-27. Further description of the mortality in each state and sector is provided in the text below.

Table B-27. Projected Nearshore Rockfish mortality (mt) north of 40°10′ N. Lat. from each state and sector under Option 3 (historical catch). Sector-specific allocations within states are provided as an example and are based on No Action. These intra-state allocations are subject to change.

	Washington		**Oregon**		**California**		**Total**
	Rec	Com	Rec	Com	Rec	Com	
Mortality	5.1	Closed	26.8	11.2	14.2	11.45	68.7
State Total	5.1		37.9		25.7		
Allocation	5.05		37.94		25.76		68.75
Projected Percent Attainment	100%		100%		99.7%		99.9%

Washington

Recreational: Under Option 3, additional management measures will be implemented to reduce nearshore rockfish mortality in the Washington recreational fishery by approximately 52 percent compared to Option 1 (No Action).

Commercial: Closed

Oregon

Recreational: Under Option 3, similar to Option 2, non-retention will likely be required to keep impacts within the Oregon recreational HG. Table B-25 has the projections by month for the nearshore rockfish complex minus blue rockfish for retention and non-retention.

Commercial: Under this option, commercial management measures will be applied to reduce Nearshore Rockfish mortality to 11.2 mt, or a 25 percent reduction relative to No Action and 39 percent reduction relative to Preferred Alternative. This value may change depending on decisions regarding the Oregon recreational-commercial spit. Regardless of the management measure applied (e.g., trip limits are non-retention), mortality will be reduced. Therefore, no negative biological impacts are expected under this option.

California

Recreational: The projected mortality on nearshore rockfish under Option 3 with an April 15 to December 31 season with a 20 fm depth restriction in the Northern Management Area is 14.2 mt, of which 3.0 mt would be blue rockfish. These mortality projections are below the recreational catch share of the California allocation of 14.35 mt under this option.

Commercial: The projected mortality on nearshore rockfish under Option 3 is estimated to be 5.6 mt with no other management changes implemented.

Projected Overfished Species Mortality

Washington

Recreational: No additional overfished species mortality is projected compared to the No Action alternative.

Commercial: Closed

Oregon

Recreational: A preliminary examination of overfished species impacts due to management measures that may be required under this option projects less than 0.01 percent increase in canary and yelloweye rockfish impacts. This assumes no other changes to angler behavior.

Commercial: Same as Option 2.

California

Recreational: Assuming season lengths under Option 1 of the Preferred Alternative in Management Areas south of 40°10′ N. Lat. and the April 15 to December 31 season with a 20 fm depth restriction in the Northern Management Area, overfished species mortality projected to accrue under Option 3 are 2.8 mt of yelloweye rockfish, 21.4 mt of canary rockfish, 118.3 mt of bocaccio and 1.2 mt of cowcod. The projected impacts are within the respective harvest limits/guidelines.

Commercial: Same as Option 2.

Stock Status

Nearshore Rockfish

None of the stocks in the Nearshore Rockfish complex are currently deemed overfished. The proposed HG under this option will facilitate implementation of inseason actions to prevent the aggregate ACL from being exceeded, decreasing the risk of overfishing component stocks. Thus, the stock status would not be adversely affected by management measures under Option 3.

Overfished Species

The projected mortalities of overfished species under Option 3 are the same as No Action (Option 1), which are below the respective harvest limits/guidelines. No adverse effects on stock status or rebuilding progress are expected under Option 3.

Socio-economic Impacts Under Option 3 compared to Option 1

Washington

Recreational: Socio-economic impacts would continue to be affected by management measures necessary to keep the Washington recreational fishery within the WA HG for overfished species (yelloweye and canary rockfish). In addition, under Option 3, recreational fishing opportunity would be further reduced. Prohibiting retention of nearshore rockfish for a portion of the season on top of other management measures already in place to protect overfished species may discourage angler participation in recreational fisheries. While it's difficult to predict angler behavior, any reduction in angler fishing effort will have negative socioeconomic impacts.

Commercial: Closed

Oregon

Recreational: Same as under Option 2 and Option 1 (No Action).

Commercial: It is uncertain whether fishing behavior (i.e., fishing location and fishing gear) will change under this option relative to No Action (see Option 2 above). However, if allocations remain the same between Oregon recreational and commercial fisheries, then landings may be reduced from 15.0 mt (No Action) to between 11.2 mt (maximum, if reduced trip limits result in avoiding Nearshore Rockfish altogether causing no discards, which is unlikely) to approximately 9.5 mt (if encounters were similar to No Action and discarding was necessary, some of which will not survive). The 2013 price per pound for

Nearshore Rockfish (weighted average including blue rockfish) was $3.80 per pound for Oregon nearshore fisheries (PacFIN). Under the potential scenarios shown here, lost ex-vessel revenue may range from approximately $31,834 to $46,076 relative to No Action (the loss is higher relative to Preferred Alternative). Additional impacts may be incurred by vessels and crew if the decision is made to fish in less productive areas to avoid Nearshore Rockfish, for example. If such of a choice is made, then it may require extra time and fuel to catch other targeted species relative to No Action.

California

Recreational: Under Option 4, the season length would increase by three months (1,825 angler trips) relative to the status quo fishery in the Northern Management Area, but the season would be reduced by one and a half months (2,555 angler trips) relative to the longest season afforded under the Preferred Alternative ACLs (Option 1), resulting in lost revenue from those in coastal communities dependent on recreational fishing for their livelihoods.

Commercial: Same as Option 2.

B.5.1.4 Option 4 Hybrid Method

Option 4 is to manage the Nearshore Rockfish complex according to a state specific harvest guidelines stratified at 40°10′ N. Lat. reflecting a hybrid method of apportionment based on miles of coastline for China, quillback and copper rockfish and the historical catch between 2004 and 2012 for the remaining species reflected in Table B-28.

Table B-28. Allocations of Nearshore Rockfish north of 40°10′ N. Lat. under Option 4 derived using miles of coastline for China, quillback and copper rockfish and the historical recreational and commercial catch between 2004 and 2012 for the remaining species.

Species	Contribution	WA%	OR%	CA%	WA mt	OR mt	CA mt
Black-and-yellow	0.01	0	0.21	0.79	0	0	0.01
Blue (CA)	17	NA	NA	1	0	0	17
Blue (OR & WA)	26.94	0.06	0.94	NA	1.67	24.27	0
Brown	1.75	0	0.08	0.92	0	0.14	1.61
Calico	0	NA	NA	NA	0	0	0
China	6.2	0.26	0.49	0.25	1.6	3.06	1.54
Copper	9.71	0.26	0.49	0.25	2.51	4.79	2.41
Gopher	0	0	0.29	0.71	0	0	0
Grass	0.55	0	0.49	0.51	0	0.27	0.28
Kelp	0.01	NA	NA	NA	0	0	0
Olive	0.26	0	0.03	0.97	0	0.01	0.25
Quillback	6.15	0.26	0.49	0.25	1.59	3.04	1.52
Treefish	0.18	0	0	1	0	0	0.18
Total					7.37	36.58	24.8

Fishing Activity under Option 4 Compared to Option 1

Washington

Recreational: The Washington recreational fishery would operate under season structure and management measures described under the Preferred Alternative. However because the WA HG under Option 4 is lower than the historical nearshore rockfish catch, additional management measures would be needed to keep nearshore rockfish catch under the WA HG. To keep total mortality under the WA HG, retention of nearshore rockfish would be prohibited for a portion of the year. The WA HG under Option 4 is higher than Option 3 and so the time period when retention of nearshore rockfish would be prohibited would be slightly shorter. Attainment of the WA HG under this alternative is projected to occur in mid-July with retention of nearshore rockfish prohibited for the remaining 5.5 months of the year. Alternate combinations of months when nearshore rockfish would be prohibited may be explored.

Commercial: Closed

Oregon

Under Option 4, the Oregon harvest guideline is similar to that shown under Option 3; Option 4 provides a harvest guideline of 36.6 mt and Option 3 shows a harvest guideline of 37.9 mt. As such, overall impacts will be similar between Option 4 and Option 3. See Option 3 for more details.

Recreational: Similar to Options 2 and 3 above, non-retention will likely be required for some months to keep impacts within the Oregon recreational HG.

Commercial: Similar to Option 3, with slightly more restrictive management measures. If the recreational-commercial split remains the same as shown under No Action, then commercial Nearshore Rockfish mortality is expected to be 10.5 mt under Option 4 (whereas expected mortality under Option 3 is 11.2 mt). This represents a reduction of 30 percent to No Action and 43 percent relative to Preferred Alternative.

California

Recreational: Under Option 4, 24.8 mt would be allocated to California, of which, the recreational catch share is 13.79 mt, accommodating a May 1 to November 30 season with a 20 fm depth restriction in the Northern Management Area. While this would provide an additional two and month and a half of fishing opportunity relative to the status quo, the recreational fishing season would have to be reduced by three months relative to the longest season under the Preferred Alternative of March 1 to December 31st. Other alternatives to address overages relative to the catch share include a reduced bag limit or non-retention of Nearshore Rockfish species during part of the season.

Commercial: Same as Option 2.

Biological Impacts Under Option 4 Compared to Option 1

Projected Nearshore Rockfish Mortality

The projected mortality in each state and sector under Option 4 are summarized in Table B-29. Further description of the mortality in each state and sector is provided in the text below.

Table B-29. Projected Nearshore Rockfish mortality north of 40°10′ N. Lat. from each state and sector under Option 4 (hybrid). Sector-specific allocations within states are provided as an example and are based on No Action. These intra-state allocations are subject to change.

	Washington		**Oregon**		**California**		**Total**
	Rec	Com	Rec	Com	Rec	Com	
Mortality	7.37	NA	26.13	10.45	13.34	11.2	68.49
State Total	7.37		36.58		24.54		
Allocation	7.37		36.58		24.80		69
Projected Percent Attainment	100%		100%		98.9%		99.6%

<u>Washington</u>
Recreational: Under Option 4, additional management measures will be implemented to reduce nearshore rockfish mortality in the Washington recreational fishery by 27 percent compared to Option 1.

Commercial: Closed

<u>Oregon</u>
Recreational: Similar to Options 2 and 3 above, a combination of months of retention and non-retention will be required.

Commercial: If the recreational-commercial split remains the same as shown under No Action, then commercial Nearshore Rockfish mortality is expected to be 10.5 mt under Option 4, a 30 percent reduction relative to No Action. Management measures will be used to reduce mortality to the target level. Therefore, no biological impacts are expected under this option.

<u>California</u>
Recreational: The projected mortality on nearshore rockfish under Option 4 with a May 1 to November 30 season with a 20 fm depth restriction in the Northern Management Area is 13.34 mt, of which 2.88 mt would be blue rockfish. These mortality projections are below the recreational catch share of the California allocation of 13.79 mt under this option.

Commercial: Same as Option 2.

Projected Overfished Species Mortality

<u>Washington</u>
Recreational: No additional overfished species mortality is projected compared to the No Action alternative.

Commercial: Closed

<u>Oregon</u>

Recreational: A preliminary examination of overfished species impacts due to management measures that may be required under this option projects less than 0.01 percent increase in canary and yelloweye rockfish impacts.

Commercial: Same as Options 2 and 3.

California

Recreational: Assuming season lengths under Option 1 of the Preferred Alternative in Management Areas south of 40°10′ N. Lat. and the May 1 to October 31 season with a 20 fm depth restriction in the Northern Management Area, overfished species mortality projected to accrue under Option 4 are 2.8 mt of yelloweye rockfish, 21.6 mt of canary rockfish, 118.3 mt of bocaccio and 1.2 mt of cowcod. The projected impacts are within the respective harvest limits/guidelines.

Commercial: Same as Option 2.

Stock Status

Nearshore Rockfish

None of the stocks in the Nearshore Rockfish complex are currently deemed overfished. The proposed HG under this option will facilitate implementation of inseason actions to prevent the aggregate ACL from being exceeded, decreasing the risk of overfishing component stocks. Thus, the stock status would not be adversely affected by management measures under Option 4.

Overfished Species

The projected mortalities under Option 4 are the same as No Action (Option 1), which are below the respective harvest limits/guidelines. No adverse effects on stock status or rebuilding progress are expected under Option 4.

Socio-economic Impacts under Option 4 Compared to Option 1

Washington

Recreational: Socio-economic impacts would continue to be affected by management measures necessary to keep the Washington recreational fishery within the WA HG for overfished species (yelloweye and canary rockfish). In addition, under Option 4, recreational fishing opportunity would be further reduced. Prohibiting retention of nearshore rockfish for a portion of the season on top of other management measures already in place to protect overfished species may discourage angler participation in recreational fisheries. While it's difficult to predict angler behavior, any reduction in angler fishing effort will have negative socioeconomic impacts.

Commercial: NA

Oregon

Recreational: Same as above Options

Commercial: Socio-economic impacts are between those shown for Options 2 and 4, if recreational-commercial split remain similar to No Action. It is uncertain whether fishing behavior (i.e., fishing location and fishing gear) will change under this option relative to No Action (see Options 2 and 3 above). However, if allocations remain the same between Oregon recreational and commercial fisheries, then landings may be reduced from 15.0 mt (No Action) to between 10.5 mt (maximum, if reduced trip limits result in avoiding Nearshore Rockfish altogether causing no discards, which is unlikely) to 8.6 mt (if encounters were similar to No Action and discarding was necessary, some of which will not survive). The 2013 price per pound for Nearshore Rockfish (weighted average including blue rockfish) was $3.80 per pound for Oregon nearshore fisheries (PacFIN). Under the potential scenarios shown here, lost ex-vessel revenue may range from $37,698 to $53,615 relative to No Action (the loss is higher relative to Preferred Alternative). Additional impacts may be incurred by vessels and crew if the decision is made to fish in less productive areas to avoid Nearshore Rockfish, for example. If such of a choice is made, then it may require extra time and fuel to catch other targeted species relative to No Action.

California

Recreational: Under Option 4, the season length would increase by one and a half months (589 angler trips) relative to the status quo fishery in the Northern Management Area, but the season would be reduced by three months (3,790 angler trips) relative to the longest season that can be afforded under the Preferred Alternative ACLs (Option 1) resulting in lost revenue from those in coastal communities dependent on recreational fishing for their livelihoods.
Commercial: Socio-economic impacts will be similar (slightly worse) than described under Option 3.

Discussion

Under status quo management and the Preferred Alternative seasons, the 69 mt ACL for the Nearshore Rockfish complex are projected to be exceeded. Even with coordinated interstate catch tracking of Nearshore Rockfish complex mortality, inseason action may prove difficult without harvest guidelines for each state on which to base the need for inseason action to reduce mortality as the ACL does not specify amounts to be taken by each state/sector. Establishing harvest guidelines for each state will provide a trigger for inseason action to prevent aggregate mortality from exceeding the ACL. The GMT hopes that the background information regarding proposed methods forming the basis for allocation and implications of each option for the fisheries in each state provided will help inform an allocation decision by the Council and to prevent future ACL overages, while minimizing adverse effects on the fishery.

Appendix 1. Methods used to measure the coastline for each state north of 40°10′ N. latitude.

At the March 2014 Council meeting, the Council requested that the Groundfish Management Team (GMT) calculate the length of the coastlines of California (north of 40°10′ N. latitude), Oregon, and Washington, as a way of approximating the nearshore habitat off each state. Though there may be alternative methods for approximating nearshore habitat, the GMT used the state-federal maritime boundary, i.e., the 3 nautical mile (nm) line, to estimate proportions of coastline among states (Figure B-21) as a starting point for this analysis.[7] Results of this analytical method (e.g., measurement of the 3 nm line (Table B-30) could be used as a basis for allocating Nearshore Rockfish among states. Details regarding this method are described below.

Proportion based on the 3 nm state-federal maritime boundary

Congress established the 3 nm as the boundary between state and federal jurisdiction over the seafloor with the Submerged Lands Act (SLA) of 1953 (43 U.S.C. §1301 et seq.). The 3 nm was established from the official shoreline, called the U.S. normal baseline, which "coincides with the low water line depicted on NOAA charts and includes closing lines across the entrances of legal bays and rivers, consistent with international law."[8] The baseline is approved by the interagency U.S. Baseline Committee and was last evaluated in 2002. The 200 nm exclusive economic zone (EEZ) and 12 nm Territorial Sea boundaries extend from this same baseline.

Shapefiles (i.e., files used in ArcGIS) of the 3 nm boundary, the 200 nm EEZ boundary, and the western U.S. states were downloaded and projected to allow for measurement in ArcGIS (Table B-31). An "addition" was made by the analyst to connect the northern portion of the 3 nm boundary to the EEZ boundary that the U.S. shares with Canada because the shapefiles for these two boundary lines do not connect or overlap (See Figure B-21). The connection was made based on the Bonilla-Tatoosh line defined in Washington's regulations (WAC 220-16-490). The resulting 3 nm boundary line was then measured from the U.S./Canada border to what serves as the WA/OR boundary for the purposes of groundfish management (46°16' N. lat.), to the OR/CA boundary (42° N. lat.), and to the OR/CA boundary to 40°10' N. latitude. The resulting measurements are shown in Table B-30.

This represents one of numerous methods available to measure or approximate miles of coastline. Other methods that the GMT looked at included directly measuring the shoreline (with and without inclusion of islands).[9] A visual comparison of the difference in detail between datasets (i.e., 3 nm line dataset compared to a shoreline dataset) is provided in Figure B-21, which represents a magnified excerpt of Figure B-20. Measurements of coastline may vary depending on many factors including the projected coordinate system used when measuring distances of features depicted on the map (e.g., UTM Zone 10N or WGS 1984), the spatial resolution of the map, image, or file that is used to create the shoreline dataset and the method for defining the shoreline (e.g., mean low water vs. high water). Defining the shoreline is a legal and policy matter as much as a scientific one.[10] These are matters of cartography of which GMT members have limited knowledge.

[7] If desired by the Council, the GMT could provide other methods.

[9] The following shoreline dataset was used: NOAA et al. 1994. "NOA80K/ALLUS80K: Medium Resolution Digital Vector U.S. Shoreline shapefile Long Island Sound GIS project area." Available at: http://woodshole.er.usgs.gov/openfile/of2005-1162/data/basemaps/coastline/nos80k_faq.htm (accessed 5/21/14).

[10] According to the NOAA Shoreline Website, there is "no legal reference that designates one specific shoreline as the legal shoreline. Furthermore, there is no simple answer to this question as there are many legal, technical, and general uses of the terms related to shoreline (shoreline, coastline, baseline, mean high-water line, mean-low water line, etc.)." Source: "What is the legal U.S. shoreline?" Available at: http://shoreline.noaa.gov/faqs.html?faq=4 (accessed 5/21/14).

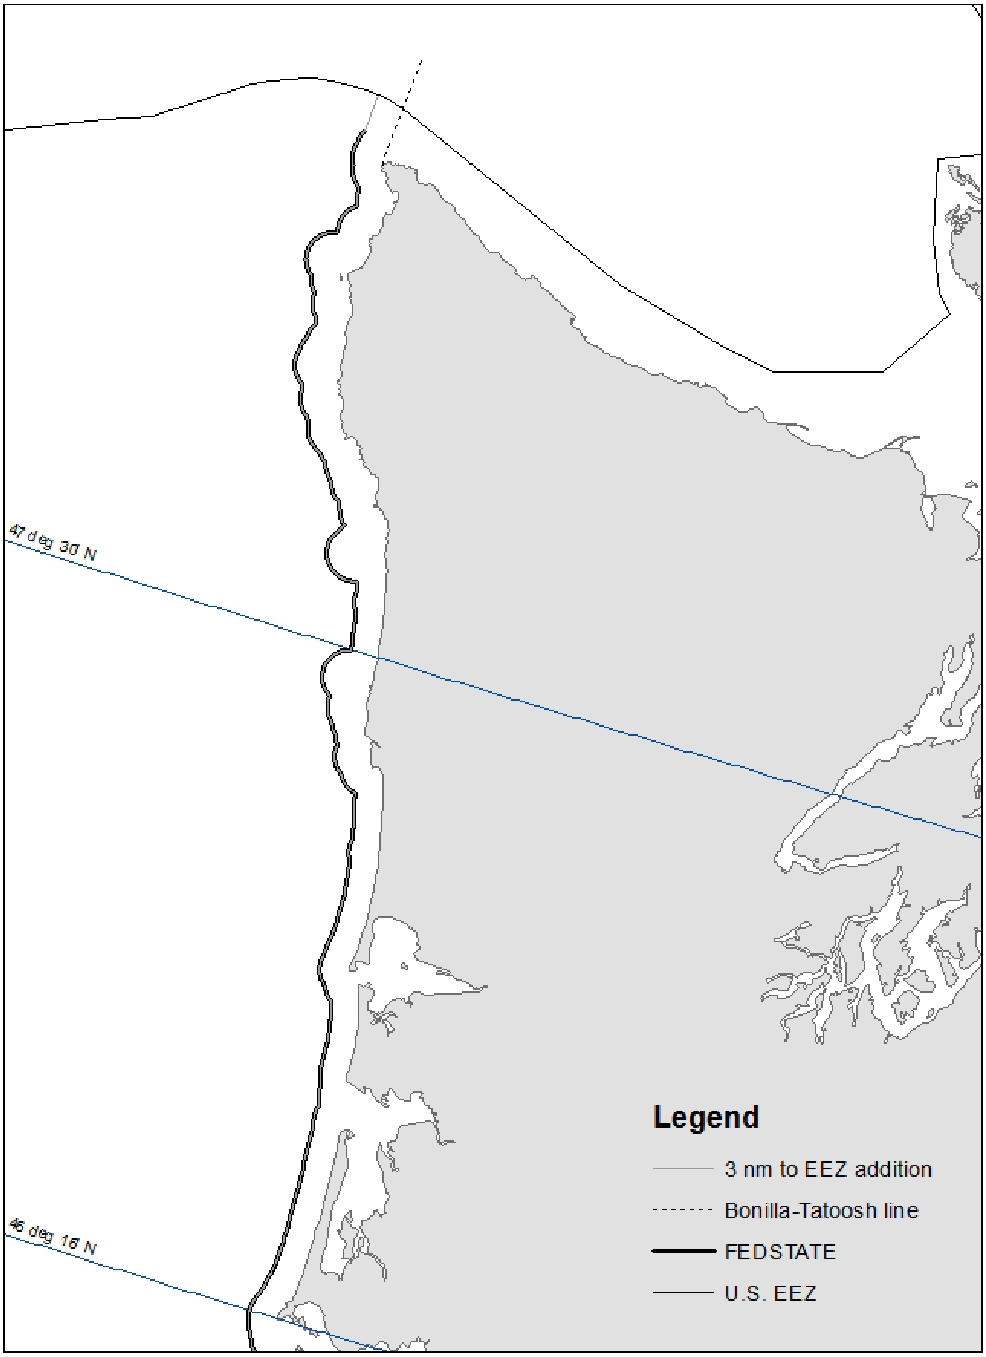

Figure B-20. Detail to show contrast between the coastline and the 3 nm state-federal maritime boundary from the U.S./Canada EEZ to the WA/OR groundfish management line (46°16' N lat.). The connection made from the 3 nm boundary with the EEZ is also shown.

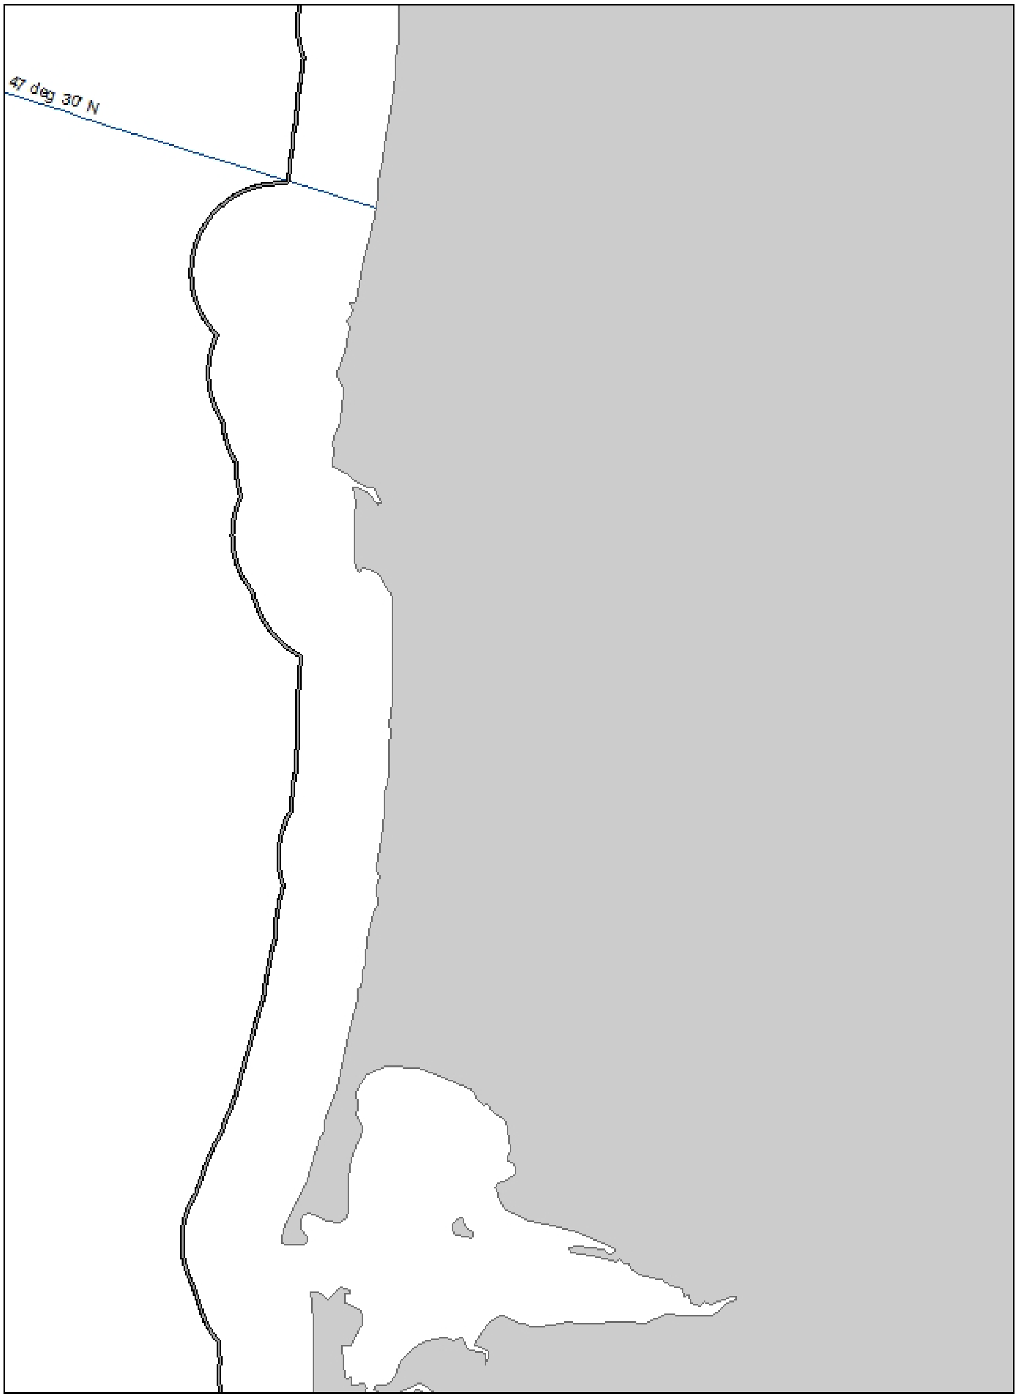

Figure B-21. Detail of Figure B-20, showing differences between the 3 nm line and the shoreline.

Table B-30. Distance estimates using 3 nm state-federal maritime boundary. These differ from what was provided in Agenda Item C.4.b, Washington Department of Fish and Wildlife (WDFW) Report, April 2014.[11]

State	Distance (km)	Percentage of Coastline
Washington	280.01	26.0%
Oregon	530.97	49.3%
Northern California	265.58	24.7%
Total	1,076.56	100%

3 nm state boundary	Bureau of Ocean Energy Management. 2002. Submerged Lands Act Boundary. Available at: http://www.marinecadastre.gov/Data/default.aspx (5/19/14).
Latitude lines	Created by GMT analyst, using the following latitude boundaries: 40°10' N., 42° N., and 46°16' N.
Bonilla-Tatoosh line	Created by GMT analyst, using the following coordinates in Washington state regulation at: WAC 220-16-490.

[11] The estimates provided in Table 1 differ from what was provided in the WDFW Report due to the following: 1) the Washington and Northern California proportions were accidentally transposed in the WDFW Report, and 2) the state-federal maritime line (SLA line) used for this GMT analysis utilized a different shapefile source. That is, the U.S. Geological Survey was the source of the SLA line for the WDFW Report and the Bureau of Ocean Energy Management was the source for this GMT analysis.

B.6 Non-Trawl: Slope Rockfish Trip Limit Reductions

Analysis of this management measure was not received by the Advanced Briefing Book deadline; it is expected to be delivered as a Supplemental GMT Report.

B.7 Non-Trawl: Lingcod Trip Limit Increases

Need for Action

For 2013-2014 groundfish fisheries, lingcod has been managed, in part, by cumulative bi-monthly trip limits designed to keep catches within the respective ACLs. Trip limits may be adjusted inseason as a result of inseason tracking patterns (higher/lower than projected). This applies to lingcod taken in both the non-nearshore (all three states) and nearshore fisheries (Oregon and California only).

At its April 2014 meeting, the Pacific Fishery Management Council (Council) directed the Groundfish Management Team (GMT) to complete an analysis of various lingcod trip limit and open season options for the west coast commercial non-trawl fixed-gear fishery to estimate economic and biological impacts. Current trip limits and open seasons are given in Table B-32 (No Action = Option 1a). The proposed trip limit and open season configurations (Options 1b and 1c) are summarized in Table B-33, with all trip limits reported in lb per vessel.

Initial analyses were provided to the Council at the April meeting for trip limit options during the open season (Agenda Item C.4.b, REVISED GMT Report, April 2014; pages 39-52 and below in XXX) and options for lingcod retention during the currently closed periods (Agenda Item C.4.b, REVISED GMT

Report, April 2014; pages 52-63 and below in XXX). This document combines results of those previous, separate analyses. Additional details can be found in that April 2014 GMT statement.

Table B-32. No Action Option (Option 1a) for the limited entry and open access non-trawl fixed-gear trip limits (in lb) in effect in 2014 that apply to both north and south of 40°10' N. latitude.

Fleet	Jan/Feb	Mar/Apr	May/Jun	Jul/Aug	Sep/Oct	Nov/Dec[a]
Limited entry	closed	closed	800	800	800	400/closed
Open access	closed	closed	400/month			400/closed

[a]The lingcod commercial fishery is closed from December 1st of a given year through April 30th of the subsequent year (five months total). Therefore, the Nov/Dec trip limit applies only to November.

A critical point in the analysis of lingcod trip limits is how proposed increases in the coastwide trip limit structure may affect the mortality of overfished species (OFS) – primarily the OFS rockfish species, in both the non-nearshore and nearshore fisheries. The approach to these proposed trip limit increases does assume that OFS mortality will not be affected in the non-nearshore fishery because any lingcod catch is mostly incidental to the targeting of sablefish; fishing behavior will likely not change because the main target will continue to be sablefish, the much more lucrative fishery. Therefore, it is assumed that any increase in lingcod mortality (landings) will only affect OFS mortality in the Oregon and California nearshore fisheries (Washington has not had a commercial nearshore fishery since 1995).

Additionally, it is prudent to point out that there is probably little to no chance of increased China rockfish impacts under Alternative 1b and 2a (below). Opening the closed season for lingcod retention will not cause increase catch of any rockfish species (OFS or China), because the proposed increases are equal to or less than average encounter rates of lingcod during the closed season (based on WCGOP bycatch rates during December-April). Increasing the lingcod trip limit during the open season showed some increase in OFS for the 50% increase. On the other hand, the increase in canary rockfish was significant when lingcod was increased by 100%. It is expected that other nearshore rockfish mortality to also increase under that scenario (2b).

Table B-33. Lingcod commercial coastwide trip limits (reported in lb per vessel) comparing the No Action Option (Option 1a) to options that increase the bi-monthly trip limit to 1,200 lb and 1,600 lb for the limited entry sector and increases to 600 lb per month and 800 lb per month for the open access sector (Options 1b, and 1c). Also presented are proposed trip limits that establish trip limits for periods 1 and 2 and December, with period 2 closed south of 40°10' N. latitude for both sectors (Options 2a and 2b).

Proposed lingcod trip limits based on the No Action Option (1a) and Options 1b and 1c						
Limited entry	Jan/Feb	Mar/Apr	May/Jun	Jul/Aug	Sept/Oct	Nov/Dec
Option 1a	closed	closed	800	800	800	400 (Nov only)

Option 2a	100 lb/month	closed	600 lb/month (100 lb for Dec)			
Option 2b	100 lb/month	closed	800 lb/month (100 lb for Dec)			

Background

Lingcod was declared overfished in 1999. In 2005, the stock was designated as rebuilt and a coastwide trip limit structure was established that has essentially stayed the same since. Lingcod trip limits have not been modified since 2005 for the limited entry (LE) sector and since 2007 for the open access sector (OA). Since 2007, no inseason adjustments have been made due to fishing mortality concerns for lingcod. At least one industry request was made for an inseason trip limit increase but was not supported by the GMT (Agenda Item E.2.b, Supplemental GMT Report 2, April 2008). This was because the GMT was concerned that any increase in lingcod trip limits and subsequent targeting could have resulted in increased bycatch of canary and yelloweye rockfish. Regarding the OA sector, the GMT expressed concerns that since the number of participants in that fishery was unlimited (as is still the case), any increase in lingcod trip limits could have led to a rapid expansion in the fishery, without any corresponding accountability measures for bycatch of overfished species. And finally, since the trip limits at that time weren't being attained in either the LE or OA fisheries, the GMT did not support an increase.

Since 2008, the coastwide commercial non-trawl fixed-gear catch of lingcod averaged 82.9 mt (Figure B-22) with the majority of landings made by the OA sector. In 2011 and 2012, total mortality by the non-trawl fixed-gear fleet was 3.0 percent and 3.5 percent, respectively, of the non-trawl allocation. For the 2015-2016 biennial management cycle, the Council is considering increases in lingcod trip limits for both the LE and OA non-trawl fixed-gear sectors to provide more fishing opportunity to the fishing communities in the three states. Additionally, a request was made by industry to explore the possibility of allowing the fleet to land modest amounts during those periods, or months, that are currently closed. This analysis estimates the potential harvest mortality under the various trip limit scenarios and open seasons to assist the Council in its decision for a Preferred Alternative. It also provides estimated mortality

amounts for overfished species that are taken in the nearshore commercial fisheries for Oregon and California when lingcod are also taken (Washington does not have a commercial nearshore fishery).

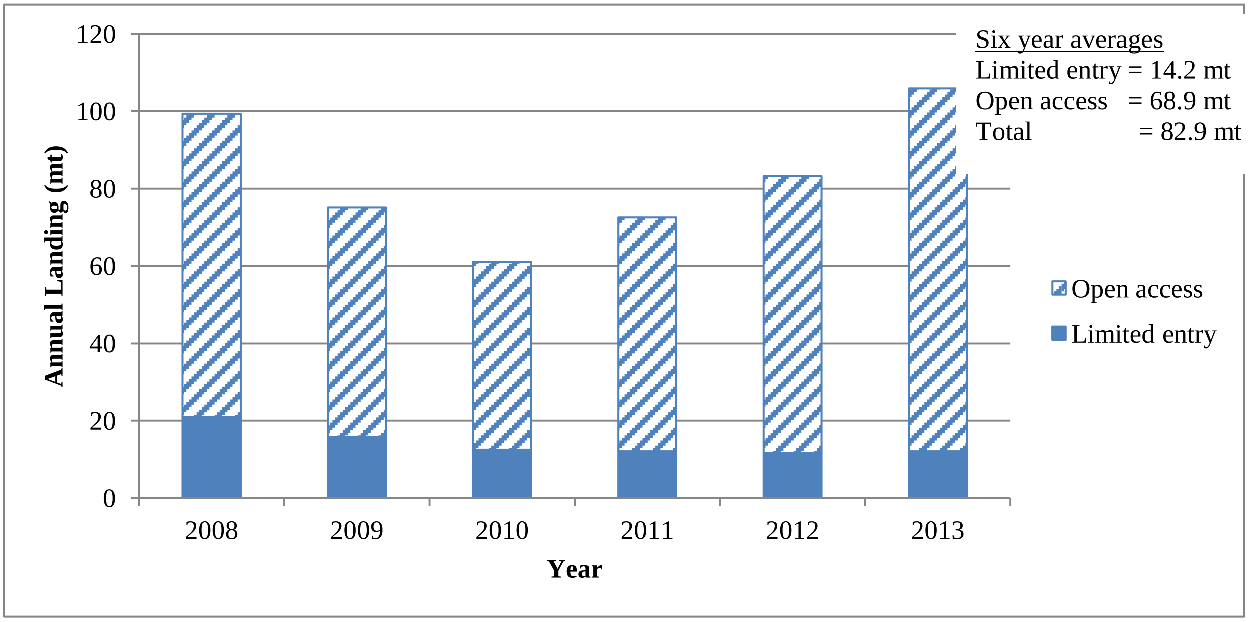

Figure B-22. Coastwide landings of lingcod by the commercial non-trawl fixed-gear fleet for both the limited entry and open access sectors from 2008 to 2013. The 2013 data are preliminary (data source: PacFIN vdrfd).

Methods

A catch-based fleet capacity trip limit model was used, and based on the years from 2008 to 2012. Commercial landings data from PacFIN's vdrfd table were extracted on April 22, 2014 for analysis. Filters were applied to only include: 1) landings made by non-IFQ, shorebased vessels (this applied to 2011 and 2012), 2) hook-and-line or trap gear, 3) Dahl sectors 5 to 10, 12, and 15[12], 4) for the nearshore bycatch model, only those Oregon and California lingcod landings that also showed nearshore species landings, and 5) port of landing north and south of 40°10' N. latitude to identify management area. The model uses a method that establishes a proportion for each participating vessel per period whereby that vessel's actual harvest mortality, as reported from the commercial dealer receipts, is compared to the theoretical maximum that that vessel could have taken. This proportion percentage is then applied to the proposed trip limit for each vessel for each period of allowable fishing. After completing this for all vessels for all periods, the estimated harvest for the fleet is summed for a final annual estimate which is then compared to the annual ACL and/or the non-trawl allocation portion of the ACL.

In addition to the above routine, a portion of the estimated landings under the various trip limit scenarios was identified as those made in conjunction with landings of nearshore species (above). These estimated lingcod landings then inputted into the GMT's nearshore bycatch model to provide estimates of the mortality of overfished species.

More details on methods can be found in Agenda Item C.4.b, REVISED GMT Report, April 2014 (pages 39-52).

[12] Dahl sectors are: 5 nearshore (limited entry), 6 nearshore (open access), 7 non-nearshore (limited entry), 8 non-nearshore (open access), 9 non-nearshore non-sablefish (limited entry), 10 non-nearshore non-sablefish (open access), 12 incidental open access, and 15 commercial non-groundfish.

Results

Lingcod mortality estimates are provided in Table B-34 and Table B-35 for the combined sector options under the different P* values for 2015 and 2016. A final LE and OA sector summary is presented in Table B-36, and lastly overfished species mortality estimates are provided in Table B-37. More detail regarding these estimates is provided below. Also, a comprehensive discussion about trip limits for periods 1 and 2 and December is included in Agenda Item C.4.b, REVISED GMT Report, April 2014, pages 52-63).

Table B-34. Lingcod coastwide commercial mortality estimates using the status quo season structure (closed during periods 1, 2 and December coastwide) comparing No Action (Option 1a) to Options 1b and 1c. The limited entry bimonthly trip limits are shown, along with open access monthly trip limits in parentheses.

LIMITED ENTRY + OPEN ACCESS (coastwide) at P* = 0.45						
	Proposed Bimonthly and Monthly Trip Limits (lb)	Estimated Take (mt)	2015		2016	
			Non-trawl Allocation (mt)	Percent of Allocation	Non-trawl Allocation (mt)	Percent of Allocation
Option 1a	800 (400)	88.9	1,950.7	4.6%	1,857.8	4.8%
Option 1b	1,200 (600)	122.3	1,950.7	6.3%	1,857.8	6.6%
Option 1c	1,600 (800)	155.1	1,950.7	8.0%	1,857.8	8.3%

LIMITED ENTRY + OPEN ACCESS (coastwide) at P* = 0.25						
	Proposed Bimonthly and monthly Trip Limits (lb)	Estimated Take (mt)	2015		2016	
			Non-trawl Allocation (mt)	Percent of Allocation	Non-trawl Allocation (mt)	Percent of Allocation
Option 1a	800 (400)	88.9	1,444.1	6.2%	1,375.4	6.5%
Option 1b	1,200 (600)	122.3	1,444.1	8.5%	1,375.4	8.9%
Option 1c	1,600 (800)	155.1	1,444.1	10.7%	1,375.4	11.3%

Note: For the limited entry sector, the November trip limits are 400 lb under Option 1a, 600 lb under Option 1b, and 800 lb under Option 1c. The non-trawl allocations are a combination of those for north and south of 40°10' N. latitude as presented in Agenda Item C.4.a, Supplemental REVISED Attachment 2:, April 2014.

Table B-35. Lingcod coastwide commercial mortality estimates under Options 2a and 2b. Season structure modifications for each sector are shown in Table B-33.

LIMITED ENTRY + OPEN ACCESS (coastwide) at P* = 0.45					
		2015		2016	
Option	Estimated Take (mt)	Non-trawl Allocation (mt)	Percent of Allocation	Non-trawl Allocation (mt)	Percent of Allocation
Option 2a	151.7	1,950.7	7.8%	1,857.8	8.2%
Option 2b	197.0	1,950.7	10.1%	1,857.8	10.6%

LIMITED ENTRY + OPEN ACCESS (coastwide) at P* = 0.25					
		2015		2016	
Option	Estimated Take (mt)	Non-trawl Allocation (mt)	Percent of Allocation	Non-trawl Allocation (mt)	Percent of Allocation
Option 2a	151.7	1,444.1	10.5%	1,375.4	11.0%
Option 2b	197.0	1,444.1	13.6%	1,375.4	14.3%

Notes: South of 40°10' N. latitude the fishery will continue to be closed.
The non-trawl allocations are a combination of those for north and south of 40°10' N. latitude as presented in Agenda Item C.4.a Supplement REVISED Attachment 2, April 2014.

Table B-36. Summary of overall coastwide commercial lingcod mortality estimates for the limited entry and open access sectors for Options 1a, 1b, 1c, 2a, and 2b.

	Trip Limits		Mortality Estimates		
Option	Limited Entry (bi-monthly)	Open Access (monthly)	Limited Entry	Open Access	Total
1a (No Action)	800	400	16.9	72.0	88.9
1b	1,200	600	24.7	97.6	122.3
1c	1,600	800	31.8	123.3	155.1
2a	1,200	600	27.4	124.3	151.7
2b	1,600	800	35.9	161.1	197.0

Note: These trip limit amounts in this table refer to the bi-monthly limited entry sector, whereas the OA sector trip limits are set on a per month basis at one-half the limited entry amount. Refer to Table B-33 for the detailed summary of the actual trip limit amounts.

Table B-37. Overfished species mortality estimates (mt) under the No Action Option (1a), Option 1b, and Option 1c (season structure maintained with periods 1 and 2 and December closed), and under the 2a and 2b options that reflect the season structure modification (i.e., open January – December). These values were calculated by using the five-year commercial averages (2008-2012) of the nearshore species inserted into the nearshore bycatch model.

	Estimated mortality under options with the current season structure in place		
	Option 1a – 800 lb	Option 1b – 1,200 lb	Option 1c – 1,600 lb
Bocaccio	0.4	0.4	0.4
Canary rockfish	6.5	6.6	6.7
Cowcod	0.0	0.0	0.0
Darkblotched rockfish	0.2	0.2	0.2
Yelloweye rockfish	1.1	1.2	1.3

	Estimated mortality under options with an expanded season structure	
	Option 2a – 1,200 lb	Option 2b – 1,600 lb
Bocaccio	0.5	0.5
Canary rockfish	7.0	7.4
Cowcod	0.0	0.0
Darkblotched rockfish	0.2	0.2
Yelloweye rockfish	1.2	1.3

Comparison of Options (Options 1a, 1b, and 1c)

Under Options 1a, 1b and 1c, the coastwide bi-monthly trip limit structure would be maintained whereby commercial retention of lingcod is permitted during periods 3 (May/June), 4 (July/August), 5 (September/October) and November. Retention of lingcod would not be allowed during period 1 (January/February), period 2 (March/April) and in December. Under these three options, trip limit adjustments are considered only for the management area north of 40°10' N. latitude. South of 40°10' N. latitude, the status quo trip limits and season structure would remain in effect for all three options.

No Action (Option 1a)

For 2014, the lingcod commercial bi-monthly non-trawl fixed-gear trip limit for the LE sector is 800 lb per period with 400 lb for November. Fishing would continue to be closed during periods 1 and 2 and December. For the OA sector, trip limits are set at 400 lb per month. Again, periods 1 and 2 and December are closed. These amounts apply on a per vessel basis and apply to all three states. Under the No Action Option (Option 1a), the expected harvest mortality, for both the P* = 0.45 and P* = 0.25 approach, would be less than 10 percent of the non-trawl allocation (Table B-34). The total combined LE and OA mortality would be 88.9 mt.

Fishing Activity Under Option 1a

Under the No Action Option, fishing activity is not expected to change. The number of vessels that will fish would be expected to be about the same as have participated in the fishery over the last few years (Table B-38). In addition, fishing effort per vessel and fishing area are expected to be similar under Option 1a.

Table B-38. Number of vessels in the non-nearshore and nearshore fisheries that made lingcod landings (regardless of the amount) for the three states from 2008 to 2012. Includes both LE and OA vessels.

State	2008	2009	2010	2011	2012	5-Year Avg.
Washington	44	32	37	31	41	37
Oregon	228	219	196	200	202	209
California	251	222	206	223	264	233

Biological Impacts Under Option 1a

With no expected increase in mortality, there are no anticipated biological impacts.

Projected Overfished Species Mortality Under Option 1a

A critical consideration in the lingcod fishery are those catches (landings) that are made in conjunction with nearshore species. These nearshore fishery landings are those that are applied to the nearshore bycatch model as a component necessary for the estimation of overfished species (OFS) mortality. With no expected increase in the take of lingcod and no expected change in fishing behavior under this option, it is also expected that no increase in OFS mortality will be experienced.

Stock Status

Currently, the coastwide lingcod stock is considered healthy. As of the last stock assessment, the point estimate for the depletion of the spawning output (= spawning biomass) at the start of 2009 was 61.9 percent for north of 40°10' N. latitude , 73.7 percent south of 40°10' N. latitude, and 67.0 percent coast wide (Hamel et al. 2009).

Socioeconomic Impacts Under Option 1a

None are expected.

Option 1b

Option 1b maintains the closures during periods 1 and 2 and December. This option also increases the current LE sector trip limit from 800 lb per two months to 1,200 lb per two months and increases the November trip limit from 400 lb to 600 lb. The OA sector trip limit would increase from 400 lb per month to 600 lb per month. The original management measure consideration for this option was to analyze trip limit increases only for the fishery north of 40°10' N. latitude. Trip limit amounts south of 40°10' N. latitude are to be left as is (i.e., remain status quo). Mortality would be expected to increase from 88.9 mt. Under No Action Option 1a to 122.3 mt (37.6 percent increase) under Option 1b, with the majority of this increase coming from the OA sector. Here too, the expected landings mortality would be less than 10 percent of the non-trawl allocation amount at both the P* = 0.45 and P* = 0.25 levels.

Fishing Activity Under Option 1b

With larger trip limits (from 800 lb to 1,200 lb per period for the LE sector and from 400 lb to 600 lb per month for the OA sector) it is reasonable to expect an increase in overall mortality. Table B-36 shows mortality will increase from 88.9 mt (No Action) to 122.3 mt under Option 1b. Despite this expected increase, the total annual mortality will still be substantially less than the non-trawl allocation amount. It is speculated that this modest increase would not generate a surge in fishing activity.

Biological Impacts Under Option 1b

Because the stock is considered very healthy, the 37.6 percent increase (33.4 mt) will have a relatively minor effect on the stock's status. A total mortality of 122.3 mt represents < 10 percent of the non-trawl fixed gear allocation. Projected mortality would not jeopardize the stock's status nor cause the fishery to exceed the non-trawl allocation portion of the annual ACL.

Projected Overfished Species Mortality Under Option 1b

Two overfished species are of major concern: canary and yelloweye rockfish. These two species have been (and will continue to be) the most constraining component of the lingcod fishery and largest concern when considering lingcod trip limit increases. Under this option, both species will experience an approximate 0.1 mt increase from the No Action Option. As per the Preferred Alternative, canary rockfish has a directed nearshore allocation of 6.7 mt (2015) and 6.9 mt (2016) and yelloweye rockfish has a directed nearshore allocation of 1.2 mt (2015) and 1.3 mt (2016). The projected mortality under this option (6.6 mt for canary and 1.2 mt for yelloweye) are equal to or less than the Preferred Alternative nearshore allocations.

Stock Status

Similar to the No Action Option 1a, the stock is expected to remain healthy with no adverse effects from this modest increase in harvest mortality.

Socioeconomic Impacts Under Option 1b

Under this option, the projected increase in total annual landings for both the non-nearshore and nearshore fisheries would be approximately 75,200 lb (34.1 mt). Using the most recent commercial landings data from 2013 as a benchmark, the average coastwide price is $2.50 per pound. Applied to the projected increase of 75,200 lb, the fishery could earn an additional $188,000 compared to the No Action status quo amount – all else being equal.

Option 1c

Option 1c maintains the closures during periods 1 and 2 and December. This option also increases the current LE sector trip limit from 800 lb per two months to 1,600 lb per two months and increases the OA sector trip limit from 400 lb per month to 800 lb per month. The original management measure consideration for this option was to analyze trip limit increases only for the fishery north of 40°10' N. latitude. Trip limit amounts south of 40°10' N. latitude are to remain status quo. Mortality would be expected to increase from 88.9 mt under No Action Option 1a to 155.1 mt (a 74.5 percent increase), with the majority of this increase, again coming from the OA sector. Under this option the projected landings mortality would be less than 10 percent of the non-trawl allocation amount at P* = 0.45 but would be just over 10% (for both 2015 and 2016) for P* = 0.25 (Table B-34).

Fishing Activity Under Option 1c

With larger trip limits (from 800 lb to 1,600 lb per period for the LE sector and from 400 lb to 800 lb per month for the OA sector), it is reasonable to expect an increase in overall mortality. It is possible that there may be a change in fishing behavior with more participants participating in the fishery, but presently it is difficult to estimate what that number may be. Table B-36 shows mortality will increase from 88.9 mt (No Action) to 155.1 mt under Option 1c. Despite this expected increase, the total annual mortality will still be substantially less than the non-trawl allocation amount.

Biological Impacts Under Option 1c

Because the stock is considered very healthy, the 74.5 percent increase (66 mt) compared to the No Action Option will have a relatively minor effect on the stock's status. A total mortality of 155.1 mt under this option represents 10.7 percent of the non-trawl allocation for 2015.

Projected Overfished Species Mortality Under Option 1c

As is the case under Option 1b canary and yelloweye rockfish are the two species that have been (and will continue to be) the most constraining component of the lingcod fishery and largest concern when considering lingcod trip limit increases. Under this option, both species will experience an approximate

0.2 mt increase from the No Action option projection. As per the Preferred Alternative, canary rockfish has a directed nearshore allocation of 6.7 mt (2015) and 6.9 mt (2016) and yelloweye rockfish has a directed nearshore allocation of 1.2 mt (2015) and 1.3 mt (2016). The projected mortality of canary under this option is 6.7 mt, which is equal to the Preferred Alternative nearshore allocation (this morality is 0.2 mt more than the nearshore allocation under than the No Action option estimate of 6.5 mt). For yelloweye, projected mortality under this option is 1.3 mt, which exceeds the Preferred Alternative nearshore allocation for 2015 by 0.1 and equals the Preferred Alternative nearshore allocation for 2016. A mortality of 1.3 mt exceeds the mortality under No Action estimated impact by 0.2 mt.

Stock Status

Similar to the No Action Option 1a, the stock is expected to remain healthy with no adverse effects from this increase in harvest mortality.

Socioeconomic Impacts Under Option 1c

Under this option, the projected increase compared to the No Action Option in total annual coastwide landings would be approximately 146,000 lb (66 mt). Applying the $2.50 per pound value described above provides an estimate that the fishery could earn an additional $365,000 compared to the No Action status quo amount – all else being equal.

Options Overview (Options 2a and 2b)

Under Options 2a and 2b, the coastwide trip limit structure would be modified to accommodate modest trip limits for periods 1 and 2 and December for both the LE and OA sectors (Table B-32). Under these two options, the take of lingcod would be allowed during all periods and months during the year, but only for the management area north of 40°10' N. latitude. South of 40°10' N. latitude, retention of lingcod would continue to be prohibited for both sectors during March and April. Trip limits would also be increased from May-November under these options relative to No Action (Option 1). See Table B-33 for trip limit details.

Option 2a

The intent of Option 2a is to allow retention and landings of lingcod that would otherwise be discarded during the closed season, in addition to increasing trip limits during the currently open season to increase attainment of the non-trawl allocation. Under this option north of 40°10' N. latitude, the LE sector would have a 200 pound trip limit per two months for periods 1 and 2 and 200 lb for December. This sector would also have a 1,200 pound trip limit for periods 3 through 5 and 600 lb in November. For the OA sector, the monthly trip limit would be 100 lb during periods 1 and 2 and 100 lb in December. Additionally, this sector would have a 600 pound monthly trip limit for periods 3 through 5 and November.

Under this option south of 40°10' N. latitude, March and April would continue to be closed to the retention of lingcod. This is proposed because the additional opportunity to fish for lingcod south of 40°10′ N. latitude in period 2, when rockfish is closed, presents the possibility of additional mortality of overfished rockfish as well as discarding of other healthy rockfish species while targeting lingcod. Aside from these considerations, the same trip limit amounts would apply for both sectors as is proposed for north of 40°10' N. latitude. See Table B-33 for a summary of trip limit details.

Fishing Activity Under Option 2a

With larger trip limits compared to the No Action Option it is reasonable to expect a modest increase in overall annual lingcod mortality. Compared to the projection for the No Action Option (88.9 mt), the projected mortality would be 151.7 mt, an increase of 62.8 mt (70.6 percent). Despite this projected increase, the total annual mortality will still be substantially less than the non-trawl allocation amounts

(Table B-35). For 2015 and 2016, with a P* = 0.45, the projected percent of the non-trawl allocation would be 7.8 percent and 8.2 percent, respectively. Under a P* = 0.25 scenario, the projected percent of the non-trawl allocation for 2015 and 2016 would be 10.5 percent and 11.0 percent, respectively.

Biological Impacts Under Option 2a

Because the stock is considered very healthy, the 62.8 mt increase will have a relatively minor effect on the stock's status. Lingcod mortality is expected to increase, though encounter rates are not, as participants in the fishery will retain some lingcod encountered (at 100 percent mortality) rather than discard all lingcod encountered (with an estimated 7 percent mortality). For example, the increased trip limit during the open season is not expected to change fishing behavior (i.e., fishing effort or fishing area). Likewise, allowing retention during December-April at the amounts shown in Table B-33 is not expected to cause increased fishing effort or change in fishing locations (see Agenda Item C.4.b, REVISED GMT Report, April 2014; pages 52-63). Hence, there would be no expected increase in lingcod encounter rates under this option relative to the No Action Option.

Projected Overfished Species Mortality Under Option 2a

With the combination of higher trip limits for the traditional fishing periods coupled with the modest trip limits for the periods that before were closed, projected mortality for canary rockfish is expected to increase. Under the No Action Option 1a, the projected canary rockfish mortality is 6.5 mt (Table B-36), whereas under Option 2a that mortality amount would be 7.0 mt. This projected canary rockfish mortality would exceed the Preferred Alternative nearshore allocation (6.7 mt in 2015 and 6.9 mt in 2016) and the No Action mortality estimate (6.5 mt). Yelloweye rockfish mortality under Option 2a is 1.2 mt, which is the same as shown under Option 1b and equal to the Preferred Alternative nearshore allocation for 2015, but 0.1 mt higher than expected under No Action (1a).

Stock Status

Under Option 2a, no adverse changes to lingcod stock status are expected compared to the No Action Option since lingcod mortality has been far below the non-trawl allocation and is expected to remain so under Option 2a. Estimated lingcod mortality under this option is expected to range between 7.8 percent and 11.0 percent of the non-trawl allocation (Table B-35). Given This level of increase in mortality is far below levels that would result in overfishing and are not expected to adversely affect stock status.

Socioeconomic Impacts Under Option 2a

Allowing fishery participants to retain incidentally encountered lingcod that were previously discarded would increase revenue from current operations targeting other species within incidental lingcod encounters. In 2013, the average price per pound coast wide averaged $2.50 per pound. This amount, applied to the projected increase (approximately 138,500 lb) would result in a coastwide gross estimated ex-vessel increase of approximately $346,000. While low trip limits make it unlikely that fishery participants will choose to target lingcod, such targeting may become worthwhile if the price per pound makes the trip profitable, despite the relatively low trip limits. If trip limits cannot be attained or if fuel or other variable costs make it unprofitable, or alternatively opportunity costs are too high to justify changing targets, directed effort may not be economically viable and trips targeting lingcod may be unlikely. However, it needs to be pointed out that some vessels do target lingcod on some trips, so any increase would benefit these participants.

Option 2b

The intent of Option 2b is also to allow retention and landings of lingcod that would otherwise be discarded during the closed season, in addition to increasing trip limits during the currently open season. Under this option north of 40°10' N. latitude the LE sector would have a 200 pound trip limit per 2 months periods 1 and 2 and 200 lb for December (the same as for Option 2a). However, this sector would also have a 1,600 pound trip limit for periods 3 through 5 and 800 lb in November. For the OA sector, the monthly trip limit would continue to be100 lb during periods 1 and 2 and 100 lb in December, but the sector would have an 800 pound monthly trip limit for periods 3 through 5 and November. Again, as per Option 2a, south of 40°10' N. latitude, the retention of lingcod would be prohibited during March and April to prevent the possibility of additional mortality of overfished rockfish as well as discarding of other healthy rockfish species while targeting lingcod. See Table B-33 for a summary of trip limit details.

Fishing Activity Under Option 2b

With larger trip limits compared to the No Action (Option 1a) and Option 2a, it is reasonable to expect an increase in overall annual lingcod mortality. Compared to the projection for the No Action Option (88.9 mt), the projected mortality would be 197 mt for Option 2b, an increase of 108.1 mt. Despite this projected increase, the total annual mortality will be substantially less than the non-trawl allocation amounts (Table B-35). For 2015 and 2016, with a P* = 0.45, the projected percent of the non-trawl allocation would be 10.1 percent and 10.6 percent, respectively. Under a P* = 0.25 scenario, the projected percent of the non-trawl allocation for 2015 and 2016 would be 13.6 percent and 14.3 percent, respectively. This assumes that no new OA participants would enter the fishery. However, given that this trip limit option would provide a modest increase to potential OA participants, it is reasonable to assume that an increase in the number of participants could occur.

Biological Impacts Under Option 2b

Because the stock is considered healthy, the 108 mt increase compared to the No Action Option will have a relatively minor effect on the stock's status. Lingcod mortality is expected to increase as participants in the fishery will retain some lingcod encountered (at 100 percent mortality) rather than discard all lingcod encountered (with an estimated 7 percent mortality), as occurs now during the closed season. There may be an increase in lingcod encounter rates under this option relative to the No Action Option, because trip limits during the currently open season would double (Table B-33). The likelihood and impact of this potential increase in effort would be very difficult to quantify. Despite this, however, it is probable that additional sets during a trip may occur to target lingcod (after catching trip limits for other species). This could increase impacts to OFS, as well as China rockfish.

Projected Overfished Species Mortality Under Option 2b

With the combination of higher trip limits for the traditional fishing periods coupled with the modest trip limits for those periods that before were closed, projected mortality for canary is expected to increase. Under Option 1c, the projected canary rockfish mortality is 6.7 mt (Table B-36), whereas under Option 2b that projected mortality amount would increase to 7.4 mt. This projected canary mortality is 0.9 mt higher than shown under No Action (Table B-37) and 0.5 to 0.7 mt higher than the Preferred Alternative allocation. For yelloweye rockfish, the projected mortality under this option will be 1.3 mt, whereas it was 1.2 mt for Option 2a. This projected yelloweye mortality is 0.2 mt higher than shown under No Action, exceeds the Preferred Alternative nearshore allocation for 2015 by 0.1, and equals the Preferred Alternative nearshore allocation for 2016.

Stock Status

Under Option 2b, no changes to lingcod stock status are expected compared to the No Action Option since lingcod mortality has been far below the non-trawl allocation and expected to remain so under Option 2b. Estimated lingcod mortality under this option is expected to range between 10.1 percent and 14.3 percent of the non-trawl allocation (Table B-35). Given the projected increase in mortality that is projected to occur, the level of increase is still expected to be far below levels that would result in overfishing and are not expected to adversely affect stock status.

Socioeconomic Impacts Under Option 2b

Allowing fishery participants to retain more lingcod (some of which were incidentally caught and discarded under status quo) would increase revenue from current operations targeting other species within incidental lingcod encounters. This may also increase revenue by incentivizing increased targeting or change in behavior during the May-November period when trip limits double relative to No Action (Table B-33). In 2013, the average price per pound coast wide averaged $2.50 per pound. This amount, applied to the projected total compared to the No Action Option total would result in a coastwide gross estimated ex-vessel amount of approximately $596,000 more than the No Action Option total. While moderate trip limits make it feasible that fishery participants will choose to target lingcod, such targeting may become more worthwhile if an increase in the overall average price per pound makes the trip profitable. It is speculated that if trip limits cannot be attained or if fuel or other variable costs make it unprofitable, or alternatively opportunity costs are too high to justify changing targets, directed effort may not be economically viable and trips targeting lingcod could be unlikely.

B.8 Non-Trawl: Allow Lingcod retention in Periods 1, 2, and 6

Need for Action

Lingcod retention is prohibited in Periods 1, 2, and part of 6 for both limited entry and open access fixed gears under the status quo regulations. In recent years, lingcod mortality has been far below the ACL north and south of 42° N. latitude with 25 percent and 13 percent attainment in 2011 and 34 percent and 16 percent in 2012, respectively. Public testimony was received from Mr. Jeff Miles at the September 2013 Council meeting requesting some level of retention during periods 1, 2, and 6. The request was made to land lingcod that are incidentally caught and discarded, with the suggestion that trip limits might be set low enough to prevent changes in fishermen's behavior (i.e., prevent targeting). Higher trip limits than those needed to allow for incidental take may further increase attainment of the non-trawl allocation of the ACL, but bycatch of overfished species while targeting lingcod is a consideration. The proposed change would allow lingcod retention in the restricted access state permitted nearshore fishery in California and Oregon, the open access nearshore fishery in Oregon, and the limited-entry and open access non-nearshore fixed gear fisheries in California, Oregon and Washington.

Background

The prohibition on retention of lingcod during specific periods has been in effect for commercial fixed gear fisheries since the 1990s to improve the conservation of lingcod after being declared overfished. The closure was put in place to minimize impacts on lingcod during their spawning season, which is from December to April (Hamel et al. 2009). Females move in to depths shallower than 50 fm to spawn and males guard nests from predation. Although females do not spend much time in the spawning area, males are concentrated in these shallow waters guarding the eggs during winter and spring months (Love 1996). The season closure for the fixed gear fishery was presumably designed to reduce catch of these males while concentrated during the nest-guarding season to facilitate rebuilding of the stock.

Lingcod was declared rebuilt in 2009, when the status was determined to be 61.9 percent for the northern component and 73.7 percent for the southern component. The coastwide status was 67.0 percent at the beginning of 2009, well above the 40 percent target spawning stock biomass (Hamel *et al.* 2009). As a result, there is no longer a lingcod closed season for individual fishing quota (IFQ fisheries; trawl and fixed gear) or Oregon and California recreational fisheries. The Council is now considering eliminating the spawning season closures in the commercial fixed gear fishery since the lingcod stock has rebuilt and increasing season length may result in higher attainment of the ACL.

Current RCA closures prevent access to much of the lingcod stock, and length restrictions may already as short as they can be while maintaining desirable fillets. Trip limits that are appreciably higher than needed to accommodate bycatch may lead to increase targeting of lingcod, which co-occur with overfished rockfish species. Increasing the season length while maintaining moderate trip limits to allow incidental take may be the most viable means of increasing attainment of the ACL without increasing interactions with overfished species.

Lingcod predate on rockfish both as juveniles and adults. Rockfish and lingcod co-occur on rocky reef habitat and lingcod are currently discarded by participants in the fishery that encounter them while fishing for rockfish during the closed period for lingcod. While mortality on discarded lingcod is relatively low (~7 percent) reflecting hooking and handling mortality since they do not suffer from barotrauma, rockfish discarded by those targeting lingcod exhibit mortalities ranging from 30 – 54 percent in depths less than 30 fm and 100 percent mortality in depths greater than 30 fm. The main concern, therefore, is that targeting of lingcod will result in increased mortality for overfished rockfish species and the potential for the sector allocations to be exceeded.

One important consideration is that period 2 is closed for rockfish retention in the nearshore fishery south of 40°10′ N. latitude. Allowing any retention of lingcod during period 2 in the south may result in increased rockfish bycatch and discard. Maintaining a closure for lingcod during the corresponding months of March and April shoreward of the RCA may be considered under each of the options analyzed to prevent greatly increased rockfish discard mortality in the region in question.

In order to evaluate the potential benefits and impacts from retention by various fixed gear sectors (i.e. nearshore vs. non-nearshore, limited entry vs. open access) under the existing regulations, trip limits were developed to reflect current bycatch rates and to emulate trip limits that are currently allowed during other months. Based on these principals, the following options were analyzed:

Management Options

Option 1: No Action – maintain prohibition on retention of lingcod in the commercial fixed gear fisheries in periods 1, 2 and 6 (December).

Option 2**:** Allow retention of lingcod in commercial fixed gear fisheries during periods 1, 2 and 6 at incidental-catch levels equivalent to average current encounters during the closed periods of 100 lb. per month in the open access fishery and 200 lb. per two month period in the limited entry fishery (i.e., to allow the retention of discarded bycatch).

Option 3**:** Allow retention of lingcod in commercial fixed gear fisheries during periods 1, 2 and 6 with trip limits of 400 lb per month in the open access fishery and 800 lb per two month period in the limited entry fishery (i.e., equivalent to the trip limits during current open months).

Data

Catch and effort for lingcod were estimated for the closed season (December – April) and the open season (May – November). Estimates were calculated and evaluated for the nearshore fixed gear commercial fishery and the non-nearshore fixed gear commercial fishery. Data from WCGOP from 2002-2011 provided lingcod catch (discard and retained) by trip. PacFIN data (2007-2012) provided the average number of trips per vessel per month, average number of vessels fishing per month, and recent landings by the fleet. Lingcod catch per trip (from WCGOP) was then expanded to estimate average lingcod catch per vessel per month (PacFIN data) used in deriving trip limits reflecting incidental catch levels.

Only WCGOP data from the nearshore fixed gear fishery were used to provide maximum bycatch-rate estimates during the current closed period. Encounters with lingcod seaward of the RCA during winter months (the current closed period) are infrequent relative to encounters by the nearshore fixed gear fishery (i.e., many of the larger lingcod are shallow during the spawning season). As such, allowing retention in the non-nearshore fishery that is far higher than their incidental encounter rates during December –April would likely not result in a substantial increase in lingcod targeting. Densities of lingcod seaward of the RCA are low during the December-April period and increased effort for lingcod (i.e., targeting) may not make economic sense for that fishery. For example, the average lingcod catch during the closed periods for the nearshore fishery is 35 lb per trip, whereas the average lingcod catch for the non-nearshore fishery is 7.2 lb per trip during the same periods (WCGOP data). Note that lingcod catch (discard + retained) during the open periods (May – November) are 39 lb per trip for nearshore fixed gear and 43.2 lb per trip for the non-nearshore fishery. The higher encounter rate during the open season makes sense, since this is during the non-spawning season and many larger adults migrate back to deeper waters.

Comparison of Options

Option 1: No Action
Under the No Action Option, retention of lingcod by the fixed gear fishery is prohibited in periods 1, 2 and 6 with the exception of November when a 400 lb. per month trip limit is allowed in both the limited entry and open access fisheries.

Fishing Activity in Commercial Fixed Gear Fisheries under Option 1

The nearshore fixed gear fishery in California and Oregon are subject to state-limited entry permits, while Washington does not allow a commercial fishery in the nearshore. The non-nearshore fixed gear fishery is prosecuted in all three states. Both nearshore and non-nearshore fishery trip limits are divided at 40°10′ N. latitude. The limited entry and open access (Federal) fixed gear trip limits in each period or month are provided in Table B-39.

It is important to point out that the nearshore rockfish fishery south of 40°10′ N. latitude is currently closed in period 2 (March and April), whereas the nearshore rockfish fishery is open year round to the north. The non-nearshore fishery operates year round and primarily targets sablefish. In the nearshore fishery, an average of 3.3 trips per month was taken during the closed season by a monthly average of 82 vessels during 2007-2012. During the open season, an average of 4.2 trips per month and 168 vessels per month took place during the open season. The higher effort during the open season coincides with months of relatively fair weather, allowing greater fishing opportunities.

Table B-39. Commercial fixed gear trip limit regulations for lingcod north and south of 40°10′ N. latitude by sector with closed periods (in gray) under Option 1.

Sector	Jan - Feb	Mar - Apr	May - Jun	Jul - Aug	Sep - Oct	Nov - Dec	
LE North	Closed		800 lb./ 2 months			400 lb.	Closed
LE South	Closed		800 lb./ 2 months			400 lb.	Closed
OA North	Closed		400 lb./ month				Closed
OA South	Closed		400 lb./ month				Closed

Biological Impacts under Option 1

Projected Lingcod Mortality
Under the no action alternative, lingcod mortality in the fixed gear fisheries during periods 1, 2 and 6 are expected to be the same as recent years in the past, assuming trip limits for other co-occurring target species do not change. If the trip limits for other target species during the closed season increase, the number of lingcod and overfished species encountered and discarded may increase. At present a 7

percent discard mortality rate reflecting rod and reel gear is anticipated for released lingcod[13]. The landings of lingcod in the last five years for each sector from Washington, Oregon and California are provided in the Table B-40. An average of 52.5 mt of lingcod mortality from the fixed gear fishery north of 42° N. latitude and 31.4 mt to the south are expected under the no action alternative based on the average mortality in 2011 and 2012 from WCGOP total mortality reports. The non-trawl allocations in 2014 were stratified at of 42° N. latitude and mortality from the non-trawl fishery in 2011 and 2012 were 21 percent and 49 percent of the respective allocations north and south, respectively indicating that the fishery has fallen far short of attainment under the current regulations.

Table B-40. Landings of lingcod in nearshore and non-nearshore fixed gear fisheries in California North and South of 40°10′ N. latitude, Oregon and Washington under status quo regulations (Option 1).

Period	Sector			
	Washington	Oregon	California North of 40°10′ N. latitude	California South of 40°10′ N. latitude
Nearshore LE	NA	2.85	0.47	0.52
Nearshore OA	NA	25.70	4.41	15.32
Non-Nearshore LE	3.26	5.10	1.60	0.62
Non-Nearshore OA	2.03	12.85	1.94	3.19

Projected Overfished Species Mortality

In 2011 and 2012 an average of 1.6 mt of yelloweye rockfish, 1.6 mt of canary rockfish, 0 mt of cowcod and 2.8 mt of bocaccio mortality were estimated to have occurred in the fixed gear fishery in pursuit of all targets both in the nearshore and non-nearshore. These estimates reflect the expected mortality under the no action alternative. However, for comparison of alternatives, we provide the no-action projected impacts by using the GMT Overfished Species Nearshore Model. These projected impacts, using 5-year average landed catches from PacFIN (2008-2012) as model inputs, are shown in Table B-41. The projected impacts under Option 1 (No Action) using the Nearshore Model for the Oregon and California nearshore fisheries north and south of 40°10' N latitude are provided in Table B-41. Note that the projected impacts are different than the average mortality shown by WCGOP. The inter-annual variability for overfished species impacts is high, and the projection model estimates long-term average impacts.

Table B-41. Projected mortality for OFS (in mt) from the nearshore bycatch projection model using the lingcod mortality from year round fishing projected from the 5-year average landings of lingcod and targeted nearshore species as inputs. California north and south reflects the management line separating them at 40°10' N latitude.

Species	Oregon	CA North	CA South	Total
Bocaccio	0.00	0.00	0.46	0.46
Canary rockfish	0.93	0.53	5.59	7.05
Cowcod	0.00	0.00	0.00	0.00
Darkblotched	0.12	0.00	0.07	0.18
Yelloweye rockfish	0.82	0.22	0.12	1.16

Stock Status

[13] http://www.pcouncil.org/groundfish/current-season-management/past-management-cycles/2009-2010-final-environmental-impact-statement/, pg. 307.

Lingcod
Though once overfished, the lingcod stock was deemed rebuilt after the most recent assessment in 2009 and are now considered healthy (>40 percent of historical biomass). The coastwide stock status was estimated to be 67 percent of historical spawning stock biomass, with the stock south of 42° N. latitude at 61.9 percent and north of 42° N. latitude at 73.7 percent. Current harvest is far below the non-trawl allocation and will not adversely affect the stock status.

Overfished Species
Under Option 1, the mortality of overfished species is projected to remain the same as recent years, which is expected to be below the sector specific fixed gear allocations. Thus the stock status of overfished species and rebuilding plans would be unaffected.

Socioeconomic Impacts under Option 1

Under the no action alternative, lingcod caught as bycatch during the closed months of the fishing season are discarded and revenues from landing them is forgone by participants in the fishery. In addition, no targeted fishery for lingcod is permitted during the closed months preventing effort from being exerted to increase attainment of the ACL, resulting in forgone revenue from directed effort. Thus fishery participants and coastal communities will continue to forgo potential revenue from converting lingcod discards to landings.

Option 2
Option 2 would allow retention of lingcod in fixed gear fishery during periods 1, 2 and 6 at incidental levels equivalent to the average encounter rates observed during the closed periods in recent years (WCGOP, 2002-2011) and expanded by recent fishing effort (PacFIN, 2008-2012). The trip limits would be 100 lb. per month for the open access fishery and 200 lb. per two month period in the limited entry fishery (Table B-42).

Change in Fishing Activity Compared to Option 1

The average estimates of discarded lingcod during the closed months in each sector from WCGOP provided the basis for the trip limits under Option 2 provided in Table B-42. The intent of Option 2 is to allow retention and landings of lingcod that would otherwise be discarded during the closed season. The encounter rates in the nearshore fishery were much higher than the non-nearshore fishery during the closed period (35 lb per trip versus 7 lb per trip, respectively) since lingcod move onshore during the winter and spring months for spawning. Thus estimates from the nearshore fishery were used as the basis for discard rates to better accommodate incidental take and convert more discards to landings. An attempt was made to adjust trip limits to account for discarding due to length restrictions during the open season, but discarding may also be due to overages against the trip limits in open months, which were confounding. Given the average lb of lingcod encountered with and without accounting for discarding of 80 and 117 lb. per month, respectively, we provide a bracketed value for trip limits of 100 lb. per month for the open access fishery and 200 lb. per two month period for the limited entry fishery (Table B-43).

Since the average encounters per month across all nearshore fishery participants were used as the basis for trip limits, many vessels encountered more lingcod than the average (Figure B-23). Thus many vessels would still incidentally encounter more lingcod than the trip limits would allow them to retain, which would still be discarded under Option 2. As seen in Figure B-23, with a trip limit of 100 lb per month, 69.5 percent of the trips would not exceed the trip limit, but 30.5 percent of trips would continue to discard some of the encountered lingcod. Trends in the percent of trips with a given amount of catch per month were examined for both longline and vertical hook and line gear. While those fishing with longline gear encountered nearly 10 lb. per month more than vertical hook-and-line gear, the difference was not great enough to justify the added complexity of trip limits for each gear type. Thus the values for all nearshore participants combined were used to derive trip limits irrespective of gear type.

The landing restrictions under Option 2 are not expected to result in additional mortality of other target stocks or overfished rockfish species. While fisheries are expected to be prosecuted in a similar fashion to Option 1, the additional opportunity for lingcod south of 40°10′ N. latitude in period 2 when rockfish is closed presents the possibility of additional mortality of overfished rockfish as well as discarding of other healthy rockfish species while targeting lingcod. While this is a possibility, the landing restrictions may be low enough that participants in the fishery may not opt to target lingcod during the closed season for rockfish in period 2 as the revenue generated from lingcod alone may not be sufficient to be profitable on its own. Thus, the landing restrictions are expected to be sufficiently low to prevent an appreciable increase in overfished species mortality, even if trip limits are attained.

Table B-42. Average lingcod discard rates from WCGOP, fishing effort from PacFIN, and projected lingcod catch for open and closed seasons. The average number of trips per vessel per month, combined with the average lingcod catch rate, formed the basis for the lingcod trip limits under Option 2 intended to allow retention of incidental catch.

Figure B-23. Projected catch of lingcod per month during the closed season by individual vessels (percent) in the nearshore fixed gear fishery.

Biological Impacts Compared to Option 1

Lingcod Mortality

Lingcod mortality is expected to increase, though encounter rates are not, as participants in the fishery will retain some lingcod encountered (at 100 percent mortality) rather than discard all lingcod encountered (at 7 percent mortality). There would be no expected increase in lingcod encounter rates under this option relative to Option 1. Increased targeting during the closed period is not expected under Option 2, because trip limits were set to reflect incidental catch rates. The projected mortality of lingcod under this alternative is provided in Table B-44.

Table B-44. Projected landings of lingcod in nearshore and non-nearshore fixed gear fisheries in California North and South of 40°10′ N. latitude, Oregon and Washington under Option 2.

Period	Sector			
	Washington	Oregon	California South of 40°10′ N. latitude	California North of 40°10′ N. latitude
Nearshore LE	NA	3.49	0.55	1.70
Nearshore OA	NA	29.94	5.02	17.34
Non-Nearshore LE	3.67	5.91	1.70	0.70
Non-Nearshore OA	2.0	14.59	2.13	3.44

Overfished Species Mortality

Under Option 2, no additional mortality of overfished species is anticipated since trip limits are set low enough to only accommodate conversion of already encountered but discarded lingcod to landings while targeting other species. Only the nearshore fishery south of 40°10′ N. latitude would be expected to incur additional mortality in period 2 if trip limits of lingcod were targeted, since rockfish is closed during this period. Given that trip limits are set low enough that targeting of lingcod alone is unlikely to be profitable, overfished species mortality is expected to be similar to that under Option 1. If the open access fishery increases effort in nearshore waters to target lingcod, there may be a minor increase in rockfish bycatch including overfished species.

Data Uncertainty Compared to Option 1
Though the trip limits are set to allow retention of lingcod encountered as bycatch, it may encourage some additional effort from the open access fishery, presenting some uncertainty in the lingcod and overfished species mortality. If selective gear is employed, any increase in open access effort may be exerted with minimal unintended consequences in the form of overfished species bycatch. If period 2 remains closed south of 40°10′ N. latitude, there will be less uncertainty in mortality as any additional effort targeting lingcod during the rockfish closure would result in additional bycatch of rockfish relative to Option 1. Though opening lingcod retention for open access during period 2 south of Point Conception could result in increased uncertainty in lingcod and overfished species impacts relative to Option 1, it is expected that trip limits may be low enough to prevent lingcod targeting; therefore, rockfish mortality is expected to be similar to Option 1.

Stock Status

Lingcod
Under Option 2**,** no changes to lingcod stock status are expected compared to the no action alternative since lingcod mortality has been far below the non-trawl allocation and expected to remain so under Option 2. Given the projected increase in impacts, the level of increase is expected to be far below levels that would result in overfishing and are not expected to adversely affect stock status.

Overfished Species
Under Option 2**,** no changes to the stock status or rebuilding progress of overfished species are expected since mortality is projected to remain below the sector specific harvest limits for the nearshore and non-nearshore fisheries.

Socio-economic Impacts compared to Option 1

Allowing fishery participants to retain incidentally encountered lingcod that were previously discarded would increase revenue from current operations targeting other species within incidental lingcod encounters. In 2013, the average price per pound coast wide ranged from $0.36 to $3.62 per lb. depending on the month, state and sector providing $36 to $362 per month of potential revenue from lingcod assuming the trip-limit can be attained. While the low trip limits make it unlikely that fishery participants will choose to target lingcod, such targeting may become worthwhile if the price per pound makes the trip profitable, despite the relatively low trip limits. If the trip-limit cannot be attained or if fuel or other variable costs make it unprofitable, or alternatively opportunity costs are too high to justify changing targets, directed effort may not be economically viable and trips targeting lingcod may be unlikely.

Option 3
Option 3 would allow retention of lingcod in fixed gear fishery during periods 1, 2 and 6 with trip limits of 400 lb per month in the open access fishery and 800 lb per two month period in the limited entry fisheries.

Change in Fishing Activity Compared to Option 1

The intent of Option 3 is to allow trip limits for lingcod that are the same as the status quo in months currently open to fishing in both the open access and limited entry fisheries during periods 1, 2 and 6 (Table B-45). If effort is the same as the months currently open to fishing at the current trip limits, landings are expected to be lower than those observed in the open months as the trip limits would be the same, but effort is lower during the winter and early spring due to weather. The fishing effort for lingcod would be expected to increase during periods 1, 2 and 6 relative to the no action alternative. The magnitude of the increase in mortality depends on changes in fishing behavior of the limited entry fishery and the number of participants in the open access fishery which is difficult to predict.

Approximately eight percent of trips fishing for nearshore rockfish species during the closed months encountered more lingcod than can be retained under the 400 lb. per month open access trip limits and one percent encountered more than the 800 lb. per two month limited entry trip limits during open months (Figure B-23). It should be noted that even at the trip limit levels of 400 lb. per month for open access or 800 lb. per two months in the limited entry fishery, some participants would still be discarding lingcod even if the current trip limits during the open season were employed during the closed season (Figure B-23). Thus the trip limits under Option 3 will continue to limit landings for some trips and reduce lingcod mortality relative to an unregulated fishery.

The effort in the limited entry fishery is capped by the number of permit holders, thus the 800 lb. per two month trip-limit may increase targeting/harvest relative to other options, but the number of participants is fixed, limiting the magnitude of potential increase relative to the open access fishery. Both open access and limited entry non-nearshore fisheries primarily target sablefish, and the magnitude of the revenue generated by allowing retention of lingcod in this fishery is not expected to cause increased targeting of lingcod because the revenue they would generate is far lower than from sablefish landings. In addition, lingcod encounters are less common in the non-nearshore fishery than in the nearshore fishery during the closed season (see Table B-45), when lingcod move onshore to spawn during the winter and early spring (Love 1996). Lingcod encounters in the nearshore fishery peak during the summer month during the open season. In the nearshore fishery, the increased trip limits are expected to increase revenues and lingcod targeting. It is uncertain whether the increase would be sufficiently high to drive increased participation of latent capacity. Weather is also a factor in that the closed period coincides with a period of more inclement weather, which is expected to limit the amount of additional effort that may be exerted under Option 3.

Table B-45. Proposed commercial fixed gear trip limits for north and south of 40°10′ N. latitude by sector under Option 3.

Sector	Jan - Feb	Mar - Apr	May - Jun	Jul - Aug	Sep - Oct	Nov - Dec
LE North	800 lb./ 2 months					
LE South	800 lb./ 2 months					
OA North	400 lb./ month					
OA South	400 lb./ month					

Biological Impacts Compared to Option 1

Lingcod mortality is expected to increase relative to the no action alternative, though it is difficult to determine the extent to which effort will increase. If additional entrants begin fishing in the open access fishery, impacts may increase further than shown here. The low increase in potential revenue makes extreme increases in effort unlikely especially considering that attainment is likely to fall short of the trip limit if targeting lingcod proves difficult. The 800 lb. per two month trip limit on the limited entry fishery may allow additional landings relative to other options, but the number of participants is limited by the number of permit holders.

To project lingcod mortality for the limited entry and open access sectors under Option 3, recent mortality during the open period was expanded to the currently closed periods (i.e., Periods 1, 2 and the second half of 6) using historical proportions of catch by time. The standard fleet capacity trip limit model documented under the analysis of trip limits for 2015-2016 was used to calculate the projected lingcod mortalities for the following fishery sectors per state including limited entry/nearshore open access (Oregon and California only) and Non-nearshore limited entry (all three states) /Non-nearshore open access (in all three states). Using the 1995-1997 period during which lingcod was open to fishing year round, the proportional take per period and/or month was calculated and used to emulate those proportions of catch by time for mortality projections. The projected annual mortalities (mt) were then calculated using the 2008-2012 set of landings as the trip limit base period. The proportions of catch by period and/or month were used to estimate the mortality during the closed months given the recent mortality during the base period. Assuming the trip limit is attained by all participants that landed lingcod during the open season, impacts on lingcod would increase in the nearshore fishery. The resulting lingcod mortalities for the fixed gear fisheries are provided in Table B-46.

Table B-46. Projected landings of lingcod in nearshore and non-nearshore fixed gear fisheries in California North and South of 40°10′ N. latitude, Oregon and Washington under Option 3.

Sector	Washington	Oregon	California	
			North of 40°10' N. Latitude	South of 40°10' N. Latitude
Nearshore LE	NA	3.89	0.71	0.69
Nearshore OA	NA	36.65	6.88	23.55
Non-nearshore LE	4.78	7.27	1.92	0.82
Non-nearshore OA	3.13	19.83	2.72	4.55

Overfished Species Mortality

The nearshore overfished species projection model was applied to calculate the OFS mortalities using five-year averages for Oregon (north of 42° N latitude) and California (between 42° N latitude and 40°10' N latitude and south of 40°10' N latitude). Under Option 3, the higher estimated catch of lingcod was imputed in the model to project the relative increase in overfished species impacts expected with trip limits shown in Table B-46. The result is an estimated percent increase in mortality in the nearshore fishery of 6.9 percent (0.08 mt) for yelloweye rockfish, 6.1 percent (0.43 mt) for canary rockfish, 6.5 percent (0.03 mt) for bocaccio and no increase in cowcod. The resulting overfished species mortality and magnitude of increase relative to status quo (in brackets) in Oregon and regions of California are presented in Table B-47.

There is no model for projecting the mortality of overfished species in the non-nearshore fishery using lingcod mortality. The assumption is made that overfished rockfish mortality will not increase in the non-nearshore fishery because it is unlikely that the trip limit will lead to additional targeting lingcod. Relatively few lingcod are encountered while targeting sablefish, especially during the winter and early spring when lingcod move onshore to spawn. If the open access fishery increases effort in nearshore waters to target lingcod, there may be an unanticipated increase in rockfish bycatch including overfished species, though the moderate trip limits for lingcod are expected to prevent excessive additional effort from the open access fishery. Relative to the contributions from the remainder of the year, the allocation to the fixed gear sectors and the ACL, the projected increase in overfished species mortality in Table B-47 are negligible.

Table B-47. Projected mortality for OFS from the nearshore bycatch projection model using the 5-year averages compared to what the OFS mortality projected increases would be with the addition of increased lingcod mortality amounts for periods 1, 2, and the second half of 6, applying the current trip limit structure (amounts) to the closed periods.

Species	Oregon	California North of 40°10' N latitude	California South of 40°10' N latitude	Total
Bocaccio	0.00 (+0.0)	0.00 (+0.0)	0.49 (+0.03)	0.49 (+0.03)
Canary rockfish	1.00 (+0.07)	0.55 (+0.02)	5.93 (+0.34)	7.48 (+0.43)
Cowcod	0.00	0.00	0.00	0.00
Darkblotched	0.13 (+0.01)	0.00 (+0.0)	0.07 (+0.0)	0.20 (+0.02)
Yelloweye rockfish	0.88 (+0.06)	0.23 (+0.01)	0.12 (+0.0)	1.24 (+0.08)

Data Uncertainty Compared to Option 1
Though the trip limits under Option 3 are set to allow retention of lingcod encountered as bycatch and facilitate attainment of the non-trawl allocation, it may encourage some additional effort from the open access fishery. The open access and limited entry fixed gear fisheries cannot retain rockfish in California waters during period 2 south of 40°10' N latitude, thus discarding of rockfish, including overfished species, may increase under Option 3. If the prohibition on retention of lingcod south of 40°10' N latitude in period 2 is maintained, uncertainty in overfished species bycatch projections and discard mortality of healthy rockfish stocks would be reduced. If selective gear is employed, open access effort may be exerted with less unintended consequences in the form of overfished species bycatch.

Stock Status

Lingcod
Under Option 3**,** no changes to lingcod stock status are expected since lingcod mortality is projected to be far below the non-trawl allocation. Given the projected increase in impacts, the level of increase is expected to be far below levels that would result in overfishing.

Overfished Species
The projected increase overfished species mortality under Option 3 is projected to result in mortality that is still below their respective harvest limits. Thus the stock status and rebuilding plans are not expected to be adversely affected by the regulations under Option 3.

Socio-economic Impacts compared to Option 1

Landing of fish previously discarded as bycatch would increase revenues for participants in the fishery and increase the profitability of existing operations by increasing marginal revenue per trip at no or limited additional cost. For those who choose to target lingcod, the revenue generated from landing lingcod may make a few trips per bi-monthly period worth taking to attain the moderate landings under the trip limit as long as the price per pound and landings make the trip economically viable. In 2013, the average price per pound coast wide ranged from $0.36 to $3.62 per lb. depending on the month, state and sector resulting in $144 to $1448 per month of potential revenue from lingcod assuming the trip-limit can be attained. If the trip-limit cannot be attained or if fuel and other variable costs exceed revenue or alternatively opportunity costs are too high to justify changing targets, directed effort may not be economically viable and trips targeting lingcod may be unlikely.

B.9 Non-Trawl: Trip Limit Adjustment for Shortspine Thornyhead N., Bocaccio S., and Shelf Rockfish S.

Need for Action

For 2013-2014 groundfish fisheries, shortspine thornyhead (north of 34°27' N. latitude), bocaccio (south of 34°27' N. latitude) and the minor shelf rockfish complex (south of 34°27' N. latitude), have been managed, in part, by cumulative bi-monthly trip limits, designed to keep catches within the respective ACLs. As a result of inseason tracking patterns (higher/lower than projected), trip limits may be adjusted inseason. For shortspine thornyheads, bocaccio, and the shelf rockfish complex, trip limit increases were implemented on August 13, 2013 as per the GMT's June 2013 Inseason Adjustment statement (http://www.pcouncil.org/wp-content/uploads/F9b_SUP_GMT_JUN2013BB.pdf). These trip limit options are in addition to those increases seen in 2013. The fishery sectors considered in the following analyses are the non-trawl fixed-gear fisheries.

The trip limit models used for these species/sectors are catch-based fleet capacity models, whereby the proportional take of the theoretical maximum (for the selected base years and species) that could have been made by each participating vessel is used to estimate take for various trip limit amounts per vessel per period (bi-monthly or monthly); the sum of which represents the estimated annual catch or mortality. When possible, the final estimated mortality was adjusted by also adding the estimates of discard mortality for the respective fishery sectors. One assumption built into this model is that vessels participation does not vary significantly from the base years used in calculations. However, with the open access fishery (OA), that assumption may be in jeopardy if high enough trip limits prompt individuals to jump into what they perceive as a developing lucrative fishery. Another assumption is that any vessel that landed at least 80 percent of its theoretical maximum period amount would probably take 100 percent of an increased period amount. This 20 percent buffer amount compensates for a form of within-fleet latent capacity. Additionally, estimated discard mortality amounts were calculated using the West Coast Groundfish Observer Program (WCGOP) Groundfish Mortality Reports for 2011 and 2012 and factored into the final projected estimates.

2015-2016 Management Considerations

For the 2015-2016 biennial management cycle, trip limit options for the above fishery sectors are analyzed relative to the No Action Option (based on the 2014 amounts) and two additional options, based on a P* of 0.45 and P* of 0.25, which establish fishery harvest guideline amounts for the non-trawl fixed-gear sectors. Estimated mortality is provided that also incorporates discard mortality using estimated amounts derived from WCGOP Groundfish Mortality Reports. Trip limits under any option could be adjusted inseason as needed to attain, but not exceed, a given catch limit (non-trawl allocation portion of the annual ACL).

Generally speaking, bocaccio and shelf rockfish south of 34°27' N latitude have been underutilized during recent years relative to non-trawl sector allocations, whereas shortspine thornyhead utilization north of 34°27' N latitude has been much higher (Table B-48) .

Table B-48. Comparison of estimated mortality (mt) and the non-trawl allocations (including the recreational sector) from 2011 through 2013 for the following non-trawl, fixed-gear fisheries: shortspine thornyheads (SSTH) – north of 34°27' N latitude, bocaccio – south of 34°27' N latitude, and the minor shelf rockfish complex – south of 34°27' N latitude (Note: Limited entry (LE) and open access sectors are combined and 2013 data are preliminary).

	2011			2012			2013		
	Non-trawl	Est. mort.	% of non-trawl	Non-trawl	Est. mort.	% of non-trawl	Non-trawl	Est. mort.	% of non-trawl
SSTH	76	72.9	95.4%	76	63.2	83.2%	74	59.3	80.1%
Bocaccio	58.6	2.3	3.9%	58.6	3.3	5.6%	73.2	2.3	3.1%
Shelf RF	626.9	19.9	3.2%	626.9	23.1	3.7%	586.5	16.2	2.8%

Table B-49. Expected mortality (mt) under No Action and under the Preliminary Preferred Alternative for the non-trawl sector for 2015-2016 for the following non-trawl, fixed-gear fisheries: shortspine thornyheads (SSTH) – north of 34°27' N latitude, bocaccio – south of 40° 10' N latitude, and the minor shelf rockfish complex – south of 40°10' N latitude (Note: Limited entry (LE) and open access sectors are combined and 2013 data are preliminary)

Species or Complex	No Action	Preliminary Preferred (P*=0.45)		Preliminary Preferred (P* = 0.25)	
		2015	2016	2015	2016
SSTH	77.3	84.3	83.3	61.4	60.8
Bocaccio	4.5	258.8	268.7	258.8	268.7
Shelf RF	387	1,383.2	1,384.0	659.7	659.7

B.9.1 Shortspine Thornyhead North of 34°27' North Latitude Management Measures

For 2013-14 west coast groundfish fisheries, shortspine thornyhead have been managed to sector specific harvest guidelines (95 percent trawl and 5% percent non-trawl). Because the recreational sector does not utilize this species, all analyses and totals represent only the commercial fishery. The HG for the non-trawl fixed gear fishery is expected to increase from 73.3 mt (in 2014) to 84.3 mt in 2015 and 83.3 mt in 2016 (Table B-49). The most recent assessment of shortspine thornyhead (Taylor 2013), indicates the stock is healthy with an estimated spawning stock biomass of 74.2 percent of its initial, unfished biomass. As a result, the Council requested analysis of higher trip limits for the LE sector north of 34°27' N. latitude. The 2014 commercial management measures for shortspine thornyhead are described in Table B-50.

Table B-50. Shortspine thornyhead management measures north of 34 °27' N latitude for the 2014 commercial fishery.

Fishery	
Commercial	Sorting requirement for all commercial landings
Limited Entry Trawl	Managed under IFQ
Limited Entry Fixed Gear	Bi-monthly limit management Current trip limits north of 34°27' N latitude are: Periods 1 -3: “2,000 lb/ 2 months” Periods 4 -6: “2,500 lb/ 2 months” Bi-monthly trip limits can be adjusted through routine in-season action
Open Access Fixed Gear	“CLOSED”

2015-2016 Management Considerations
For the 2011-2013 non-trawl sector (which is allocated 5 percent of the annual take north of 34°27' N latitude) catches were between 80 percent and approximately 90 percent of the allocation (Table B-48). The shortspine thornyhead non-trawl fixed-gear fishery north of 34°27' N latitude is restricted to the LE entry sector. The open access sector is not allowed to retain shortspine thornyhead, where the discard mortality is relatively small (e.g., 0.78 mt during 2012 WCGOP Groundfish Mortality Report). During the 2011-2012 management cycle, 116 LE vessels (85 percent of the LE fleet) landed less than 20 percent of the theoretical maximum amount they could have landed under the trip limits that were in place at the time.

Management Options

Option 1 – No Action: Maintain current shortspine thornyhead trip limits for the limited entry sector north of 34°27' N latitude. Under Option 1, the 2014 trip limits (Table B-51) would remain in place for the LE sector, and the OA sector would remain closed.

Option 2a – Increase trip limits for the limited entry sector north of 34°27' N latitude: Under Option 2a, increased bi-monthly trip limits north of 34°27' N latitude were investigated to determine what the projected morality would be compared to the No Action Option (Table B-51).

Option 2b: Further trip limits for the limited entry sector north of 34°27' N latitude: Under Option 2b moderate trip increases, compared to Option 2a, are explored (Table B-51)..

Biological Impacts Under Option 1

Projected Mortality
Under No Action, projected mortality for shortspine thornyhead north of 34°27' N latitude is 77.3 mt for the LE fixed-gear sector (with no open access fishery allowed). At this level of harvest, the projected mortality represents 92 percent of the 2015 HG (84.3 mt) and 93 percent of the 2016 HG (83.3 mt) at a P* value of 0.45 (Table B-49). At a P* value of 0.25 this exceeds the 2015 HG (61.4 mt) by 26 percent and exceeds the 2015 HG (60.8 mt) by 27 percent. This mortality is expected to be within the HG at the current level of vessel participation only at a P* value of 0.45. This assumes that the vast majority of vessels will continue to take less than 20 percent of their theoretical maximum allowable amount.

Stock Status
The shortspine thornyhead stock was determined to be healthy in the last stock assessment (Taylor 2013) and projections under status-quo catches showed little change in stock status.

Overfished Species Mortality

Overfished species (OFS) are encountered by non-nearshore fixed gear fisheries, which also catch shortspine thornyhead. For example in 2013, non-nearshore fixed gear fishery mortality for OFS was bocaccio rockfish South 40°10' N. latitude (2.62 mt), canary rockfish (0.12 mt), darkblotched rockfish (9.04 mt), Pacific ocean perch (0.41 mt), yelloweye rockfish (0.34 mt), and petrale sole (0.83 mt). It is expected that similar catches may be observed under Option 1 (No Action) during 2015 and 2016.

The non-nearshore fishery primarily targets sablefish. Other species, such as shortspine thornyhead, are incidentally caught (not targeted) and retained. In addition, many of the OFS (e.g., canary and yelloweye rockfish primarily live at shallower depths than shortspine thornyhead, and therefore largely do not co-occur.

Mortality of Rougheye, Blackspotted, and Shortraker Rockfish

Other species are encountered by non-nearshore fixed gear fisheries, which also catch shortspine thornyhead. For example, rougheye rockfish was taken by the non-nearshore fixed gear fisheries (when shortspine thornyheads were also landed) as follows: 29.7 mt in 2011, 26.2 mt in 2012, and 19.4 mt in 2013. Shortraker rockfish was also taken as follows: 2.5 mt in 2011, 4.53 mt in 2012, and 0.16 mt in 2013. Lastly, blackspotted rockfish was taken as follows: 0.25 mt in 2011, 4.53 mt in 2012, and 0.16 mt in 2013. However, increases in shortspine thornyhead trip limits are not expected to have any additional impact on the mortality of these species because shortspine thornyhead are incidentally caught while fixed gear fishermen are targeting other higher-valued species. For example, slope rockfish and shortspine thornyhead catch is primarily incidental for fishermen targeting sablefish. Fishing effort and fishing behavior (i.e., selection of fishing locations) are not expected to change due to shortspine thornyhead trip limit increases. Therefore, mortality of these three species of rockfish is not expected to change.

Options 2a and 2b – Increase trip limits for the limited entry sector north of 34°27' N latitude

Under Option 2, increased bi-monthly trip limits north of 34°27' N latitude were investigated to determine what the projected morality would be compared to the No Action Option.

Individual vessel landings reported in PacFIN (table vdrfd) from 2011-2012 for the LE sector were used to analyze catch limits by the fleet. The years 2011 and 2012 were ultimately chosen as the basis for this model because they are the most representative of current and future fishing behavior for the three states. Even though the vast majority of vessels take less than 20 percent of their theoretical maximum annual amount, a small increase in the bi-monthly trip limits could cause the fishery to reach or exceed the HG (non-trawl allocation portion of the annual ACL).

Limited Entry Bi-monthly Trip Limit Options

The LE entry trip limit options for the shortspine thornyhead non-trawl fixed gear fishery north of 34°27' N latitude are shown in Table B-51. Option 2a provides for an increase from 2,000 lb to 2,250 lb per bi-monthly period for periods 1 - 3, and does not change the trip limit for periods 4-6, which remain at No Action level of 2,500 lb per bi-monthly period. Option 2b provides for an increase from 2000 lb to 2,500 lb per bi-monthly period for periods 1-3, resulting in 2,500 lb per bi-monthly period for the entire year (Option 2b).

Table B-51. Comparison of projected landings of shortspine thornyhead in the LE non-trawl fixed-gear sector north of 34°27' N. latitude under No Action (Option 1) and increases for periods 1-3 only (Option 2a) and setting the trip limits to 2,500 lb per period for all six periods (Option 2b).

	Limited Entry Shortspine Thornyhead North 34°27' N. Latitude at a **P* of 0.45**					
	Bi-monthly Trip Limits	Projected	HG (mt)		% of HG	
Options	(in lb)	landings (mt)	2015	2016	2015	2016
Option 1	2,000 for periods 1-3 and 2,500 for periods 4-5	77.3	84.3	83.3	91.7 %	92.8%
Option 2a	2,250 for periods 1-3 and 2,500 for periods 4-5	80.3	84.3	83.3	95.3 %	96.4%
Option 2b	2,500 for all six periods	83.4	84.3	83.3	98.9 %	100.1%

	Limited Entry Shortspine Thornyhead North 34°27' N. Latitude at a **P* of 0.25**					
	Bi-monthly Trip Limits	Projected	HG (mt)		% of HG	
Options	(in lb)	landings (mt)	2015	2016	2015	2016
Option 1	2,000 for periods 1-3 and 2,500 for periods 4-5	77.3	61.4	60.8	126%	127%
Option 2a	2,250 for periods 1-3 and 2,500 for periods 4-5	80.3	61.4	60.8	131%	132%
Option 2b	2,500 for all six periods	83.4	61.4	60.8	136%	137%

Biological Impacts Under Options 2a and 2b

Projected Mortality
Under Option 2a and Option 2b, the projected mortality of shortspine thornyhead north of 34°27' N latitude would result in the fishery nearly reaching its HG (Option 2a) and exceeding it (Option 2b) under a P*=0.45 approach (Table B-49). Expected catches under these options are expected to exceed the HG using a P*=0.25 approach.

Stock status
While the stock is considered healthy, no negative consequences would probably result from trip limit increases shown in Table B-51. The IFQ mortality since 2011 ranged from 50 to 60 percent of its allocation. That, coupled with the non-trawl fixed-gear allocation of 5 percent indicates that the projected mortality would not likely jeopardize the stock's health.

Overfished Species Mortality
Details shown in Option 1 also apply to Options 2a and 2b. In addition, increases in shortspine thornyhead trip limits are not expected to have any additional impact on overfished species mortality, because shortspine thornyhead are incidentally caught while fixed gear fishermen are targeting other higher-valued species (i.e., sablefish). Fishing effort and fishing behavior (i.e., selection of fishing locations) are not expected to change due to shortspine thornyhead trip limit increases. Therefore, overfished species impacts are not expected to change.

Mortality of Rougheye, Blackspotted, and Shortraker Rockfish
As was pointed out for Option 1, an increase in shortspine thornyhead trip limits are not expected to have any additional impact on the mortality of these species. If increases in catch of slope rockfish were to occur following increases to shortspine thornyhead trip limits, it is expected that such increases would be minimal because shortspine thornyheads are not the primary target species.

Impact to Industry

Higher trip limits for shortspine thornyhead could increase access to healthy stocks, resulting in increased ex-vessel value, although the amount is difficult to quantify. Changes as a result of this action may not have a large effect on the stock per se; the possibility of exceeding harvest limits could have a negative impact on the fishery, albeit a small impact because the take of shortspine thornyheads in this sector represents a bycatch amount of the sablefish fishery. The latest anecdotal information received from the industry, regarding the 2014 sablefish fishery, indicates that demand may experience an upswing, which could result in an increased mortality of thornyheads.

B.9.2 Bocaccio South of 34°27' North Latitude Management Measures

For 2013-2014 California groundfish fisheries, bocaccio has been managed to sector specific harvest amounts (i.e., trawl, non-trawl, recreational). The HG for non-trawl fixed gear is expected to increase in 2015 and 2016 to 80.1 mt and 83.1 mt respectively (Table B-53). The 2011 update assessment (Field 2013) indicated that a strong 2010 year class is moving through the fishery (particularly south of 34°27' N. latitude) and as such, encounters (and discarding) have increased. This, combined with the information that recent mortality of this stock is far below the non-trawl harvest guideline (Table B-53), prompted the Council to request an analysis of higher trip limits for the LE and OA sectors south of 34°27' N. latitude. The 2014 commercial management measures for bocaccio rockfish are described in Table B-52.

Table B-52. Bocaccio management measures south of 34°27' N. latitude for the 2014 commercial groundfish fisheries.

Fishery	
Commercial	Sorting requirement for all commercial landings
Limited Entry Trawl	Managed under IFQ
Limited Entry Fixed Gear	Bi-monthly limit management. Current limits south of 34°27' N. latitude are: Period 1: “*300 lb/2 months*” Period 2: Closed Period 3: “*300 lb/2 months*” Periods 4-6: *“500 lb/2 months”* Bi-monthly limits can be adjusted through routine in-season action.
Open Access	Bi-monthly limit management. Closed Period 2 Current limits south of 34°27' N. latitude are: Period 1: *“100 lb/2 months”* Period 2: Closed Period 3: *“100 lb/2 months”* Periods 4-6: *“200 lb/2 months”* Bi-monthly limits can be adjusted through routine in-season action.

2015-2016 Management Considerations
Fewer than 10 LE vessels land bocaccio south of 34°27' N. latitude, while the number of OA vessels landing this species is roughly twice as many. Total mortality estimates reported from WCGOP indicate that approximately six percent of the non-trawl fixed gear HG was attained in 2012 (Table B-53). Encounters are expected to increase as the bocaccio population continues to rebuild (i.e. rebuilding paradox). During the 2011-2012 management cycle, 5 LE vessels (83 percent of the six vessels that landed bocaccio) landed less than 20 percent of the theoretical maximum amount of bocaccio they could have landed south of 34°27' N. latitude. In the OA sector, 28 of 39 vessels (72%) that landed bocaccio south of 34°27' N. latitude landed less than 20 percent of their theoretical maximum amount of bocaccio.

Table B-53. Total bocaccio mortality (in mt) in the non-trawl fixed gear sector (LE and OA combined) south of 40°10' N latitude from 2011-2012. (source: WCGOP)

Year	Mortality	HG	% HG
2011	2.3	58.6	4 %
2012	3.3	58.6	6 %

Management Options

Option 1-No Action: Maintain current trip limits for LE and OA sectors south of 34°27' N latitude.
Under Option 1, the 2014 trip limits (Table B-52) would remain in place for both LE and OA sectors.

Option 2a: Increase trip limits for LE and OA sectors south of 34°27' N latitude: Under Option 2a moderate trip increases, compared to Option 1- No Action, are explored (Table B-56).

Option 2b: Further increase trip limits for LE and OA sectors south of 34°27' N latitude: Under Option 2b moderate trip increases, compared to Option 2a, are explored (Table B-56).

Biological Impacts Under Option 1: No Action

Projected Impacts
Under No Action, projected mortality for bocaccio south of 34°27' N latitude is 1.0 mt and 3.5 mt for the LE and OA sectors, respectively (Table B-54). Between 40°10' and 34°27' N. latitude, average landings (2011 and 2012) for both sectors combined were 0.9 mt. The projected landings for the entire area south of 40°10' N. latitude under No Action is therefore 5.4mt (Table B-53), which is well below the HGs for 2015 and 2016 (258.8 mt and 268.7 mt, respectively) for both P*=0.45 and P*=0.25 (Table B-53).

Table B-54. Summary of bocaccio projected landings south of 40°10' N. latitude (by sector) under No action.

Area	Limited Entry	Open Access
40°10' to 34°27' N. lat.	0.9	
South of 34°27' N. lat.	1.0	3.5
Total	5.4	

Stock Status
The bocaccio stock south of 40°10' N. latitude was formally designated as overfished in 1999. The current stock assessment (Field, 2013) indicates an increasing abundance trend and progress towards rebuilding (Field, 2011). Under Option 1, no changes in progress towards rebuilding are expected.

Overfished Species Mortality

Bocaccio mortality has been minimal south of 34°27' N latitude. Annual average landings from 2008 to 2013 for the LE and OA sectors were 0.2 mt and 1.08 mt, respectively (Table B-55). During this five-year period, a total of only six vessels participated in the LE fishery and 52 in the OA fishery where bocaccio was taken. Of the 52 vessels in the OA fishery, only two averaged more than 0.1 mt of bocaccio per year; one at 0.18 mt and the other at 0.13 mt.

Table B-55. Bocaccio landings (mt) by sector and year from 2008 – 2012 for the non-trawl, non-nearshore fixed-gear fisheries south of 34°27' N latitude. Data source: PacFIN.

Sector	Sector description	Year and landings (mt)					Total	5-yr avg.
		2008	2009	2010	2011	2012		
7	Non-nearshore LE			0.00	0.02	0.36	0.39	0.08
8	Non-nearshore OA	0.04		0.00	0.00	0.16	0.21	0.04
9	Non-nearshore non-sablefish LE	0.17	0.05			0.40	0.62	0.12
10	Non-nearshore non-sablefish OA	1.16	0.73	0.66	1.17	1.28	5.01	1.00
12	Incidental OA	0.08	0.02	0.03	0.05	0.02	0.20	0.04
	LE total						1.00	0.20
	OA total						5.42	1.08

Note: Since these are PacFIN amounts (table vdrfd) and not West Coast Groundfish Observer Program estimates, no discard mortality estimates are included.

A range of bocaccio trip limits and calculated projected mortality under three alternatives for both the LE and OA sectors was analyzed (Table B-56). The years 2011 and 2012 were used because they were the most representative of current and future fishing behavior, with the assumption that potential trip limit increases would not significantly change fishing behavior (i.e. the number of vessels increasing per fishery sector).

Table B-56 . Projected mortality for bocaccio under a range of Options for the LE and OA fixed gear fisheries south of 34°27' N latitude.

No Action Option 1							
Sector	Period and trip limit (lb)						Total estimated mortality (mt)
	1	2	3	4	5	6	
LE FG	300	closed	300	500	500	500	1.2
OA FG	100	closed	100	200	200	200	2.0

Option 2a							
Sector	Period and trip limit (lb)						Total estimated mortality (mt)
	1	2	3	4	5	6	
LE FG	750	closed	750	750	750	750	1.7
OA FG	250	closed	250	250	250	250	5.0

Option 2b							
Sector	Period and trip limit (lb)						Total estimated mortality (mt)
	1	2	3	4	5	6	
LE FG	1,000	closed	1,000	1,000	1,000	1,000	2.3
OA FG	500	closed	500	500	500	500	9.9

Currently, projected mortality for bocaccio in the GMT scorecard is informed by two sources of data – the sablefish bycatch projection model for the area between 40°10' N latitude and 36° N latitude and by trip limit models south of 34°27' N latitude. Mortality between 36° N latitude and 34°27' N latitude (i.e., Morro Bay port complex) in not currently accounted.
WCGOP data were examined for the area south of 36° N latitude to estimate mortality of co-occurring overfished species (OFS; canary, darkblotched, and yelloweye rockfish) that may occur as a result of increases to the bocaccio rockfish trip limits in the LE and OA sectors. WCGOP data from 2011 to 2012 revealed that no OFS were encountered on the observed bocaccio trips during this time frame. Given the small sample size (5 vessels) informing the data and location of fishing, it is reasonable to assume that some OFS are encountered as bycatch, albeit in very small and unquantifiable amounts.

Mortality of Rougheye, Blackspotted, and Shortraker Rockfish
Other species are encountered by non-nearshore fixed gear fisheries, which also catch bocaccio. However, this is not the case for rougheye, blackspotted, and shortraker rockfish if we use the 2011 and 2012 mortality amounts as examples. During these years, no recorded landings of these three species of rockfish were made when landings of bocaccio were made. This is due primarily to the fact that these three species are infrequently taken south of 40°10' N. latitude.

<u>Options 2a and 2b: Increase trip limits for LE and OA sectors south of 34°27' N latitude</u>
Under Option 2, increased bi-monthly trip limits south of 34°27' N. latitude were investigated to accommodate increased encounters and minimize discarding as the stock continues to rebuild.

Individual landings reported in PacFIN from 2011-2012 for LE and OA sectors were used to analyze catch limits by the fleet. Although the HG for bocaccio applies to the entire area south of 40°10' N latitude, only modifications to trip limits south of 34°27' N latitude were investigated (i.e., trip limits between 40°10' and 34°27' N. latitude were status quo). For analytical and managerial ease, bi-monthly trip limits are assumed the same for each period. The years 2011 and 2012 were chosen as the basis for this model because they may be representative of current and future fishing behavior. Average landings during this time period for the area between 40°10' and 34°27' N latitude were added to the analytical options to project landings for the entire area south of 40° 10' N latitude.

Limited Entry Bi-Monthly Trip Limit Options

The LE bi-monthly trip limit options for bocaccio south of 34°27' N. latitude range from 750 lb/2 months (Option 2a) to 1,000 lb/2 months (Option 2b; Table B-57). In recent years the majority of vessels have taken less than half of the maximum trip limit during any given period.

Open Access Bi-Monthly Trip Limit Options

The OA bi-monthly trip limits range from 250 lb/2 months (Option 2a) to 500 lb/2 months (Option 2b; Table B-57). Participation in the OA sector has traditionally been more variable than LE, making it difficult to predict catch and fleet behavior; therefore it is possible that landings could be higher than projected.

Projected landings under each option for the LE and OA sectors are provided (Table B-57). These options are not mutually exclusive. , That is, the Council could recommend a different option for each sector.

Table B-57. Comparison of projected landings (mt) of bocaccio in the LE and OA sectors under No Action trip limits (Option 1), and two options with trip limit increases (Options 2a and 2b) to the 2015 non-trawl HG (258.8 mt) and the 2016 non-trawl (268.7 mt). Trip limit increases apply only to the open periods (currently period 2 (March/April) is closed). This applies to a P* of 0.45 and 0.25. Projected landings between 40°10' and 34° 27' N. latitude are based on average landings during 2011-2012.

2015							
	LE S. 34°27' N. lat.		OA S. 34°27' N. lat.		Projected Landings (mt) 40°10' -34°27' N. lat.		
Option	Trip limit (lb.)	Projected Landings (mt)	Trip limit (lb.)	Projected Landings (mt)		Total (mt)	% of Non-trawl Allocation
Option 1	300 for periods 1 and 3 500 for periods 4-6	1.0	100 for periods 1 and 3 and 200 for periods 4-6	3.5	0.9	5.4	2.0%
Option 2a	750 – all open periods	1.7	250 - all open periods	6.2	0.9	8.8	3.4%
Option 2b	1,000 – all open periods	2.2	500 - all open periods	12.4	0.9	15.5	6.0%

2016							
	LE S. 34°27' N. lat.		OA S. 34°27' N. lat.		Projected Landings (mt) 40°10' -34°27' N. lat.		
Option	Trip limit (lb.)	Projected Landings (mt)	Trip limit (lb.)	Projected Landings (mt)		Total (mt)	% of Non-trawl Allocation
Option 1	300 for periods 1 and 3 500 for periods 4-6	1.0	100 for periods 1 and 3and 200 for periods 4-6	3.5	0.9	5.4	1.9%
Option 2a	750 – all open periods	1.7	250 - all open periods	6.2	0.9	8.8	3.3%
Option 2b	1,000 – all open periods	2.2	500 - all open periods	12.4	0.9	15.5	5.8%

Note: Although status quo provides for differential trip limits by period (i.e. lower in Periods 1 and 3, and higher in Periods 4-6), for purposes of this analysis a constant trip limit amount was analyzed for all open periods.

Biological Impacts

Under Option 2a, landings are projected to increase approximately 70 percent (0.7 mt) and 63 percent (3.4 mt) in the LE and OA sectors respectively compared to No Action (Option 1; Table B-57). While under Option 2b projected landings are expected to increase by 120 percent (1.2 mt) in the LE sector and 187 percent (10.1 mt) in the OA sector compared to No Action. Similar to Option 1, mortality for bocaccio south of 40°10' N. latitude is projected to be well below the non-trawl fixed gear HGs (i.e., 3.4% to 6.0% of the non-trawl harvest guideline; Table B-57).

Stock Status

Similar to Option 1, no changes to rebuilding progress are expected.

Overfished Species Mortality
Same as Option 1. In addition, increases in bocaccio limits relative to Option 1 are not expected to have any additional impact on overfished species mortality, because bocaccio are incidentally caught while fixed gear fishermen are targeting other higher-valued species (i.e., sablefish). Fishing effort and fishing behavior (i.e., selection of fishing locations) are not expected to change due to bocaccio trip limit increases. Therefore, overfished species impacts are not expected to change.

Mortality of Rougheye, Blackspotted, and Shortraker Rockfish
Same as No Action Option 1: no impacts expected.

Impacts to Industry

Higher trip limits for bocaccio may convert discards into retained fish, thus increasing landings, resulting in increased ex-vessel value, although the amount is difficult to quantify. Changes as a result of this action may not have a large effect on the sectors as a whole, but could be of importance to some individuals in each sector.

B.9.3 Minor Shelf Rockfish Complex South of 34°27' North Latitude Management Measures

Although the shelf rockfish complex is managed as a single stock south of 40°10´ N. latitude, trip limit options analyzed herein are for the management area south of 34°27' N. latitude. For 2013-14 California groundfish fisheries, the minor shelf rockfish complex south of 40°10´ N. latitude has been managed to sector specific allocations (i.e. trawl, 12.2% and non-trawl, 87.8%). Shelf rockfish are not formally allocated within non-trawl sectors, that is, the non-trawl commercial LE and OA sectors, as well as the recreational sector, share the non-trawl allocation. The non-trawl allocation south of 40°10´ N. latitude is expected to increase substantially from 615 mt in 2014 to 1,383.2 mt in 2015 and 1,384.0 mt in 2016 at a P* = 0.45 (Table B-59). At P* = 0.25, the 2015 and 2016 allocations would be 659.7 mt for both years. Based on an industry request, the Council requested analysis of higher trip limits for LE and OA sectors south of 34°27' N. latitude. The 2014 commercial management measures for shelf rockfish south of 34°27' N. latitude are described in Table B-58.

Table B-58. Shelf rockfish management measures for the 2014 commercial groundfish fisheries, south of 34°27' N. latitude.

Fishery	
Commercial	Sorting requirement for all commercial landings
Limited Entry Trawl	Managed under IFQ
Limited Entry Fixed Gear	Bi-monthly limit management. Current limits south of 34°27' N. latitude are: Period 1: *"3,000 lb/2 months*" Period 2: Closed Period 3: *"3,000 lb/2 months*" Periods 4-6: *"4,000 lb/2 months"* Bi-monthly limits can be adjusted through routine in-season action.
Open Access	Bi-monthly limit management. Current limits south of 34°27' N. latitude are: Period 1: *"750 lb/2 months"* Period 2: Closed Period 3: *"750 lb/2 months"* Periods 4-6: *"1,000 lb/2 months"* Bi-monthly limits can be adjusted through routine in-season action.

2015-2016 Management Considerations

Participation in the fixed gear shelf rockfish fishery south of 34°27' N. latitude is limited, with fewer than 30 vessels operating in the OA sector and six vessels in the LE sector during 2011 and 2012. Total mortality estimates reported from WCGOP indicate that approximately 61 percent of the non-trawl allocation south of 40° 10´ N. latitude was attained in 2012 (Table B-58). If an intersector allocation (i.e. trawl, non-trawl allocations) had been in place in 2009 and 2010, attainment would have been approximately 47 and 31 percent in each year respectively, although the recreational sector accounts for the majority of the total estimated mortality (Table B-59). During the 2011-2012 management cycle, nine LE vessels that made shelf rockfish landings (100 percent of LE vessels making shelf rockfish landings) landed less than 20 percent of the theoretical maximum amount of shelf rockfish they could have landed. In the OA sector, 42 vessels (84 percent) landed less than 20 percent of their theoretical maximum amount. Data indicate that few participants attained greater than half of the allowable limit, averaging approximately 240 lb/2mo and 280 lb/2mo in the LE and OA fleets respectively during 2011 and 2012.

Table B-59. Total Mortality (in mt) in the minor shelf rockfish complex non-trawl fixed gear sector (LE and OA combined) south of 40°10' N. latitude from 2009-2012. (source: WCGOP)

Year	Commercial (non-trawl)	Recreational	Non-Trawl Allocation	% Non-trawl Allocation
2009	8.3	246	615	41%
2010	14.2	212	615	37%
2011	19.9	326	615	53%
2012	23.1	354	615	61%

Management Options

<u>Option 1-No Action: No increase to trip limits for shelf rockfish south of 34°27' N. latitude:</u> Under Option 1, the 2014 trip limits would remain in place for both LE and OA sectors.

Option 2a: Increase trip limits for LE and OA sectors south of 34°27' N. latitude: Under Option 2a, increased, compared to Option 1, were investigated (Table B-61).

Option 2b: Further increase trip limits for LE and OA sectors south of 34°27' N latitude: Under Option 2b moderate trip increases, compared to Option 2a, are explored (Table B-61).

Biological Impacts Under Option 1

Projected Impacts

Under No Action, projected mortality for minor shelf rockfish south of 34°27' N. latitude is 3.9 mt and 14.3 mt for the LE and OA sectors, respectively (Table B-60); between 40° 10' N. and 34° 27' N. latitude, average landings during 2011 and 2012 were 16.1 mt for both sectors combined. Assuming that take in the recreational fishery south of 40° 10' N. latitude is unchanged from 2012 (354 mt; WCGOP Groundfish Mortality Report, 2012); projected mortality of shelf rockfish south of 40° 10' N. latitude is 387 mt. This represents 28 percent of 2015 allocation of 1,383.2 mt under P* of 0.45, and 58.7 percent of the 2015 allocation of 659.7 mt under P* of 0.25. For 2016, this represents 28 percent of the 2016 allocation of 1,384.0 mt under P* of 0.45, and 58.7 percent of the 2016 allocation of 659.7 mt under P* = 0.25.

Table B-60. Summary of commercial minor shelf rockfish landings south of 40° 10' N. latitude (by sector) under No Action.

Area	Limited Entry	Open Access
40° 10' to 34° 27' N. lat.	16.1	
South of 34° 27' N. lat.	3.9	14.3
Total	34.3	

Stock Status

The minor shelf rockfish complex south of 40° 10' N. latitude is comprised mainly of unassessed stocks, with the exception of greenspotted rockfish and greenstriped rockfish. The greenspotted rockfish assessment indicated the stock is in the precautionary zone; greenstriped rockfish was considered healthy. Greenspotted rockfish have shown a substantial increase in biomass since the RCAs were implemented in 2003 (2013-2014 FEIS). Given that shelf rockfish are particularly well protected by the RCAs, the shelf rockfish ACL is expected to increase in 2015-16, and only 31-67 percent of the non-trawl allocation has been caught during recent years (Table B-59), no changes to stock status are expected under No Action.

Overfished Species Mortality

Under the No Action Option, there is no anticipated increase to the mortality of OFS.

Mortality of Rougheye, Blackspotted, and Shortraker Rockfish

Other species are encountered by non-nearshore fixed gear fisheries, which also catch minor shelf rockfishes. However, this is not the case for rougheye, blackspotted, and shortraker rockfish if we use the 2011 and 2012 mortality amounts as examples. During these years, no recorded landings of these three species of rockfish were made when landings of minor shelf rockfish were made. This is due primarily to the fact that these three species are infrequently taken south of 40°10' N. latitude.

Options 2a and b: Increase trip limits for LE and OA sectors south of 34° 27' N. latitude

Under Option 2, increased bi-monthly trip limits south of 34° 27' N. latitude were investigated, which may afford greater opportunity under the increased non-trawl allocation.

Individual vessel landings reported in PacFIN from 2011-2012 for LE and OA sectors were used to analyze catch limits by the fleet. Although the allocation for the minor shelf rockfish complex applies to the entire area south of 40° 10' N. latitude, only modifications to trip limits south of 34° 27' N. latitude were investigated (i.e. trip limits between 40° 10' and 34° 27' N. latitude were status quo). For analytical and managerial ease, bi-monthly limits are assumed the same in each period. The years 2011 and 2012 were ultimately chosen as the basis for this model because they may be representative of current and future fishing behavior. Average commercial landings between 40° 10' and 34° 27' N. latitude during this time period and the 2012 recreational total mortality reported by WCGOP for the area south of 40° 10' N. latitude were added to the analytical options to project mortality for the entire area south of 40° 10' N. latitude.

Limited Entry Bi-Monthly Trip Limit Options

The LE bi-monthly trip limit options for minor shelf rockfish complex south of 34° 27' N. latitude are shown in Table B-61. These options range from 4,000 lb/2 months (Option 2a) to 5,000 lb/2 months (Option 2b). In recent years the majority of vessels have taken less than half of the maximum trip limit during any given period. The proposed trip limit increases apply only to the existing open periods.

Open Access Bi-Monthly Trip Limit Options

The OA bi-monthly trip limit options for minor shelf rockfish complex south of 34° 27' N. latitude are shown in Table B-61. These options range from 1,500 lb/2 months (Option 2a) to 2,500 lb/2 months (Option 2b). Although no effort shift occurred during previous inseason actions, participation in the OA sector has traditionally been more unpredictable than LE, making it difficult to predict catch and fleet behavior; therefore it is possible that projected landings (Table B-61) could be higher than expected if the trip limit is increased sufficiently enough to encourage entry into the fishery by new participants.

Projected landings under each Option for the LE and OA sectors are provided (Table B-61). These Options are not mutually exclusive, that is, the Council could recommend a different option for each sector.

Table B-61. Comparison of minor shelf rockfish projected landings south of 40o 10′ N. latitude in the LE and OA sectors under No Action (Option 1), and two options with trip limit increases (Options 2a and 2b) to the 2015 and 2016 HGs under P*=0.45 (1,282.2 mt and 1,383.0 mt respectively) and the 2015 and 2016 HGs under P*=0.25 (659.7 mt). . Projected landings between 40° 10' and 34° 27' N. latitude are based on average landings during 2011-2012. (Note: recreational catch were derived from the 2012 WCGOP Groundfish Mortality Report.)

	P*=0.45 (2015 allocation = 1,382.2 mt and 2016 allocation = 1,384.0 mt)								
	Limited Entry S. 34° 27' N. lat.		Open Access S. 34° 27' N. lat.		Projected Landings 40° 10' -34° 27' N. lat	Projected Recreational Catch	Total	% of Non-trawl Allocation	
Option	Trip limit	Projected Landings	Trip limit	Projected Landings				2015	2016

Opt. 2b	5,000	5.4	2,500	39.9	16.4	354	416	63.1%

Biological Impacts

Projected Mortality

Under Option 2a, landings are projected to increase approximately 10 percent (0.4 mt) and 68 percent (9.7 mt) in the LE and OA sectors respectively compared to No Action (Option 1; Table B-61). Under Option 2b projected landings are expected to increase by 38 percent (1.5 mt) in the LE sector and 179 percent (25.6 mt) in the OA sector compared to No Action. Similar to Option 1, mortality of shelf rockfish south of 40° 10' N. latitude is projected to be well below the non-trawl allocation (Table B-61).

Stock Status

Similar to Option 1, no changes to stock status are expected as a result of this action. The increase in projected landings will keep mortality well within the non-trawl allocation (Table B-61) and no changes to the current RCAs structure have been proposed (i.e. the RCA protections afforded under option 1 will remain in place).

Overfished Species Mortality

There may be a small increase in the bycatch of OFS, but at present, no quantifiable method has been explored to determine how much this may be. Any increase in trip limit is expected to increase fishing effort for shelf rockfish species. Likewise, increased catch of overfished species would likely occur. The amount of the increase is uncertain and cannot be estimated at this time. This could be an issue that would affect more the OA sector since this fishery is open-ended compared to the LE sector. It is difficult to estimate how many new participants that could enter the fishery as a result of increased trip limits, and thus the extent of increased OFS mortality.

Mortality of Rougheye, Blackspotted, and Shortraker Rockfish
Same as Option 1.

Impacts to Industry

Higher trip limits could increase harvest given the sizeable increase in the non-trawl allocation; although difficult to quantify, increased ex-vessel value could be expected as a result. Given the relative size of the fleet, changes as a result of this action may not have a large effect on the sectors as a whole, but could be of importance to some individuals in each sector.

B.10 Non-Trawl: Coastwide Sablefish Trip Limits

Need for Action

This section discusses projected landings and associated cumulative landing limits ("trip limits") for the four fixed gear sablefish, daily trip limit (DTL) fisheries. They include limited entry (LE) and open access (OA) fisheries, north and south of 36° North latitude. Hereafter, they will be referred to as follows: LE North, LE South, OA North, and OA South. The two northern fixed gear sablefish DTL fisheries account for approximately 13.5 percent of the northern sablefish ACL, while the southern ones account for approximately 58 percent of the southern ACL (during 2015, under the Preferred Alternative).

Proposed trip limits for 2015 and 2016 in these fisheries were produced GMT landing forecast models (described briefly below, and in detail in the 2011-2012 Groundfish Harvest Specifications Environmental Impact Statement; EIS).

While the tables show trip limits in this section as simply bimonthly, weekly, or daily, it is worth noting that the language in regulation applies each limit in a specific way when there is a mix of limits for the different time periods, within one fishery. This is the case for the two open access sablefish DTL fisheries. For example, the limits in regulation under No Action for the OA North fishery read as follows: "300 lb. per day or one landing per week of up to 800 lb., not to exceed 1,600 lb. per two months".

Analytical description

The purposes of this analysis are to produce and compare trip limits and predicted landings between the No Action Alternative and the other alternatives, for the four fixed gear, sablefish DTL fisheries. The ACLs, regional allocations, harvest guidelines and fishery landed shares vary among the alternatives.

Proposed trip limits under the alternatives for 2015 and 2016 were produced with the objective of keeping projected catch within the proposed management targets, which resulted from different values of the sablefish P-star (P*) and corresponding ACL, harvest guidelines, and shares for the areas north and south of 36° N. latitude. Forecasted landings under the action alternatives were intentionally constrained to between 90 and 95 percent of the landings share for each fishery, in order to produce trip limits which are likely to result in high attainment of the harvest guideline, while maintaining a sufficiently precautionary remainder; one that is appropriate for the uncertainty associated with use of the forecast models, and the accuracy of the estimated landings data used as model inputs. This strategy has been used over the past several years in inseason management, in the 2013-14 Groundfish Harvest Specifications EIS, and most recently in establishing trip limits for 2014, at the November, 2013 meeting of the Pacific Fishery Management Council (PFMC). These annual trip limit schedules can be adjusted through the inseason process as early as the preceding November meeting of the PFMC, as well as throughout the year, in order to account for updated data, or changes in science or policy.

Model description

The catch projection models used in this analysis are multiple linear regression models that relate trip limits and other predictor variables to bimonthly or monthly landings, separately for each fishery. They are also used for inseason management. Detailed descriptions of the models can be found in Appendix A. of the 2011-2012 harvest specifications EIS. Models were originally produced by members of the GMT, Oregon Department of Fish and Wildlife (ODFW), National Oceanic and Atmospheric Administration (NOAA) Southwest Fisheries Science Center (SWFSC) and Northwest Fisheries Science Center (NWFSC) in 2006 (limited entry) and 2009 (open access). Changes in model specification are made as needed over time, to increase accuracy of projections where possible. Changes since the 2013-14 harvest specifications include: Limited entry models were translated from SAS to R. In the LE North model, sablefish ex-vessel price (adjusted for inflation) was added as a predictor, separate regressions were carried out for each bimonthly period, and landings were predicted similarly to the open access models, where predicted landings equals predicted number of vessels participating, times the average landed catch per bimonthly period. The Producer Price Index from the U.S. Bureau of Labor Statistics for "fresh and frozen seafood" was used to deflate the time series of ex-vessel prices in the LE North model. New landings data through 2012 were added to all four models. The time range of data included in each model varies between from 2004-2012, to 2007-2012, depending on its information content for making projections. Accuracy of prediction varies among the four models. Of the four, the best fit of predicted to actual, bimonthly landings is produced by the LE North model, with an R^2 value of 0.956. Under the most recent data, the worst fit between predicted and actual landings comes from the LE South model, with an R^2 value of 0.528. We are still able to manage the LE South DTL fishery to a high level of attainment through inseason management and close tracking of data throughout the year, in spite of the relatively low model fit seen under the current data.

Model input data

Landings and catch data were acquired from PacFIN using the query "slct_ves_sabl_arid_DTL_tab_no_EFP.sql". This query pulls vessel-daily landings data from tables that separate fixed gear, sablefish DTL landings from sablefish primary landings, on a vessel-daily basis, using software and an algorithm and developed by PacFIN and NWR staff in 2010 and 2011. For the LE North fishery, the software tracks landings accumulation by vessel, against their sablefish endorsed tier permits. If the vessel has active sablefish endorsed primary tier permits attached, the season is open, and there is room on the attached permits, landings are counted as primary. When either the tier permits on the vessel are exhausted, or the season ends, landings are then counted as DTL. The algorithm in the software adheres to the specific federal regulations concerning primary and DTL landings in 50 CFR 660.232.

Accounting for discards and discard mortality

Harvest guidelines applicable the sablefish DTL fisheries were reduced in order to account for discard mortality, which resulted in landed shares for use in projection modeling to predict landings, and determine necessary trip limits. A harvest guideline is defined as numerical management harvest objective which is not a quota. These are either cited in regulation or calculated from other higher level numerical management objectives appearing in regulation.

The applicable harvest guideline was multiplied by 16.6 percent (discard rate estimate), and by 20 percent (discard mortality rate estimate). Then that product (estimated dead discarded sablefish) was subtracted from the harvest guideline, resulting in a "landed share", which projected landings should be beneath, in order to keep total catch within the harvest guideline. The estimated discard rate used by GMT was taken from the report "Estimated Discard and Catch of Groundfish Species in the 2012 US West Coast Fisheries", by the West Coast Groundfish Observer Program, of the NWFSC. The discard mortality rate estimate was taken from information in Davis (2001, LTtp://onlinelibrary.wiley.com/doi/10.1111/j.1095-8649.2001.tb00495.x/abstract), Shirrippa and Colbert (2005, LTtp://www.pcouncil.org/wp-content/uploads/Sable05_complete.pdf), and Shirrippa (2007, LTtp://www.pcouncil.org/wp-content/uploads/Sable07v3_0.pdf). Shirrippa (2005) used experimental data and sea surface temperature to predict varying release mortality by gear. The GMT considered that Davis (2001) demonstrated high sensitivity to temperature and deck time, along with high variability of predicted discard mortality in Shirrippa (2005) informed by sea surface temperature data, and adopted an estimate of 20 percent. This value was also adopted by Taylor 2011 in the current sablefish stock assessment.

Values for landed shares among the alternatives

Landed share values for each of the DTL fisheries are shown by year, fishery and alternative below in Table B-62 and Figure B-24.

Table B-62. Landed shares for each of the fixed gear sablefish, DTL fisheries, used for making projections, under each of the alternatives.

	LE N	OA N	LE S	OA S
No Action 2014	214	319	483	393
Preferred Alternative 2015	236	388	531	432
Preferred Alternative 2016	258	425	581	472
Alt. 1 2015	247	406	555	451
Alt. 1 2016	269	443	606	492
Alt. 2 2015	202	333	455	370
Alt. 2 2016	223	367	503	409

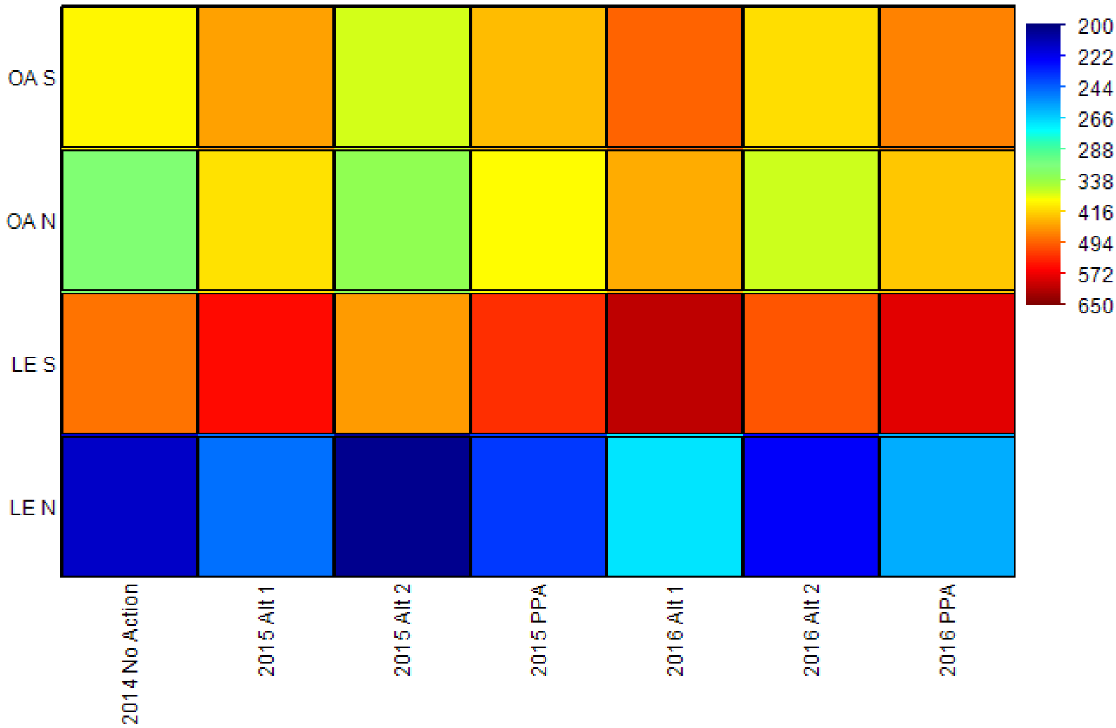

Figure B-24. Heatmap showing variation in potential landed shares used for making projections, for each of the fixed gear sablefish DTL fisheries, under each of the alternatives.

B.10.1 No Action Alternative

Area restrictions

Under No Action, the following RCA boundaries for use of fixed gear, from 2014 regulations, would remain in place for 2015 and 2016 (Table B-63, from Table 2 North, and South, to Part 660, Subpart E, Codified Federal Regulations).

Table B-63. Rockfish Conservation Area (RCA) boundaries for fixed gear, under the No Action Alternative.

Area	Jan-Feb	Mar-Apr	May-Jun	Jul-Aug	Sep-Oct	Nov-Dec
North of 46° 16'	shoreline - 100 fm line					
42° - 46° 16’	30 fm line - 100 fm line					
40° 10’ - 42°	20 fm depth contour - 100 fm					
34° 27’ - 40° 10’	30 fm - 150 fm line					
South of 34° 27’ (w/islands)	60 fm line – 150 fm line (also applies around islands)					

Trip limits and projected impacts under No Action

The No Action trip limit structures for 2014 in each fishery are presented in Table B-64. The No Action Alternative resulted in projected attainments ranging between 71 and 99 percent, using the best available data, and 2014 trip limits set in the November, 2013 council meeting (Table B-65). The aim throughout all the alternatives was to enable harvest of a high proportion of the landed share, yet accommodate uncertainty. The GMT and the Council considered, while constructing and adopting them, respectively, the uncertainty in the landings data (in terms of correctly separating sablefish DTL fishery landings from those of the sablefish primary fishery, and IFQ landings) along with uncertainty associated with making model-based projections.

These trip limits can be adjusted as needed inseason, to influence higher or lower catch as the year progresses. We strove to produce trip limits with a predictable and temporally uniform structure, which was appreciated by the GAP in their statement at the November 2011 council meeting, and subsequent meetings.

Table B-64. Trip limits for sablefish DTL fisheries under the No Action Alternative (2014).

Fleet	Area	Bimonthly limit	Weekly limit	Daily limit
LE	**N**	2,850	950	NA
OA	**N**	1,600	800	300
LE	**S**	NA	2,000	NA
OA	**S**	3,200	1,600	300

Projected attainment values for the four sablefish DTL fisheries under the No Action Alternative are within the range generally recommended by the Council, of between 90 and 95 percent, with the exception of the OA North fishery, which has a projected attainment of 99 percent, and the OA South fishery, which has been maintained at a lower level in recent years, partially to allow some buffer for the LE South fishery (Table B-65). The reason for the higher than usual projected attainment in the OA North fishery under Alternative 1 is that actual landings have been running much lower than projected for the past two years, under recent poor sablefish market conditions.

Table B-65. Model-projected landings under the No Action Alternative, for the fixed-gear, sablefish DTL fisheries. Landed shares and projected impacts are in metric tons (mt) of landed catch.

No Action	LE N	OA N	LE S	OA S	South sum
Projected landings	204.4	316.7	437.8	279.7	717.5
Landed share	214	319	483	393	876.0
Percent attainment	95%	99%	91%	71%	82%
Difference	9.6	2.3	45.2	113.3	158.5

B.10.2 Preferred Alternative – Sablefish Trip Limits

Preferred Alternative for 2015

Trip limits and projected impacts under the Preferred Alternative for 2015

The trip limit structures for each fishery in 2015 under Preferred Alternative are presented in Table B-66. Differences between Preferred Alternative and No Action limits also appear in the table. Trip limits are generally higher under Preferred Alternative than for No Action. Higher limits were needed to influence similar attainment, under the higher shares. Differences range from 25 lb per week smaller for the OA South, to 225 lb per two months higher in the LE North fishery.

Table B-66. Trip limits under the Preferred Alternative, No Action Alternative, and comparison between them, for the fixed-gear, sablefish, DTL fisheries for 2015. Limits are in lb of landed catch per time period listed.

		2015 Preferred			No Action			Difference		
fleet	area	bimo	week	day	bimo	week	day	bimo	week	day
LE	**N**	3,075	1,025	NA	2,850	950	NA	225	75	NA
OA	**N**	1,800	900	300	1,600	800	300	200	100	0
LE	**S**	NA	2,100	NA	NA	2,000	NA	NA	100	NA
OA	**S**	3,200	1,575	315	3,200	1,600	300	0	-25	15

Projected landings, attainment and remainder in 2015, under the Preferred Alternative are presented in Table B-67. The same metrics are also presented for the No Action Alternative, and the differences between these two alternatives, in the table.

Attainment rates are very similar between the Preferred Alternative and No Action with the exception of the OA North fishery for reasons explained in No Action section; attainment rates are nearly equal for each fishery, among the action alternatives by design. The amount of landed catch projected is consistently higher under the Preferred Alternative than No Action; between 15.4 mt and 58.4 mt higher, due to the higher trip limits, produced to influence similar attainment under the higher landed shares of the Preferred Alternative.

Table B-67. Model-projected landings under the Preferred Alternative, No Action Alternative, and comparison between them, in the fixed-gear, sablefish, DTL fisheries for 2015. Landed shares and projected landings are in metric tons (mt).

2015 Preferred	**LE N**	**OA N**	**LE S**	**OA S**	**South sum**
Projected landings	219.7	358.3	496.3	310.2	806.4
Landed share	236	388	531	432	963.0
Percent attainment	93%	92%	93%	72%	84%

Preferred Alternative for 2016

Trip limits and projected impacts under Preferred Alternative for 2016

The trip limit structures in 2016 under the Preferred Alternative for each fishery are presented in Table B-68. Differences between the Preferred Alternative and No Action limits also appear in the table. Trip limits are generally higher under the Preferred Alternative than for No Action. Higher limits were needed to influence similar attainment under the higher shares. Differences range from 25 lb per week higher for the OA South, to 525 lb per two months higher in the LE North fishery. The daily limit for the OA North fishery remains unchanged under all alternatives.

Table B-68. Trip limits under the Preferred Alternative, No Action Alternative, and comparison between them, for the fixed-gear, sablefish, DTL fisheries for 2016. Limits are in lb of landed catch per time period listed.

		2016 Preferred			**No Action**			**Difference**		
fleet	area	bimo	week	day	bimo	week	day	bimo	week	day
LE	**N**	3,375	1,125	NA	2,850	950	NA	525	175	NA
OA	**N**	2,000	1,000	300	1,600	800	300	400	200	0
LE	**S**	NA	2,175	NA	NA	2,000	NA	NA	175	NA
OA	**S**	3,250	1,625	325	3,200	1,600	300	50	25	25

Projected landings, attainment, and remainder under the Preferred Alternative are presented in Table B-69. The same values for the No Action Alternative are also presented in the table, and the differences between these two alternatives.

Attainment rates are very similar between the Preferred Alternative and No Action with the exception of the OA North fishery, for reasons explained in No Action section; attainment rates are nearly equal for each fishery, among the action alternatives by design. The amount of landed catch projected is consistently higher under the Preferred Alternative than No Action; between 36.7 mt and 105.5 mt higher, due to the higher trip limits produced in order to influence the same attainment under the higher landed shares of the Preferred Alternative.

Table B-69. Model-projected landings under the Preferred Alternative, No Action Alternative, and comparison between them, in the fixed-gear, sablefish, DTL fisheries for 2016. Landed shares and projected landings are in metric tons (mt).

B.11 Recreational: Canary Rockfish Sub-Bag Limit in Oregon Fisheries

Need for Action

Although the canary rockfish stock is a category 1 stock, some unresolved problems and uncertainties have been identified in the stock assessment. The current stock abundance is relatively uncertain. In part this is because the only measure of relative abundance does not occur in the primary habitat (rocky reef) of canary, and many other, rockfish. Future stock abundances are also uncertain because the bottom trawl survey primarily catches very large (and old) canary rockfish, which means recruitment events (of young individuals) are difficult to determine or verify. The last full assessment (Stewart 2009) indicated that historical and current relationship between canary rockfish distribution and habitat features should be investigated to provide more precise estimates of abundance from the surveys, and to guide survey augmentations that could better track rebuilding through targeted application of newly developed survey technologies.

Uncertainties of the current and future abundance of the canary rockfish stock could be improved if recreational groundfish fishery data were available. The recreational fishery occurs almost entirely over rocky reef habitats, therefore the recreational fishery catch rates could be used to provide an index of relative abundance (catch per unit effort; CPUE) of canary rockfish from their primary habitat. Additionally, since recreational fishery gears catch smaller and younger canary rockfish than trawls, biological data from the recreational fishery could be used to better detect recruitment events needed to better track rebuilding.

For recreational fishery catch to aid in the data used for future canary rockfish stock assessments, retention of canary rockfish would have to be permitted. Since anglers are currently required to discard all canary rockfish catch, biological samples are currently obtained from infrequent illegal landings. The number of canary rockfish reported to have been discarded by anglers is too uncertain to be used as a CPUE index in an assessment. Allowing retention so dockside creel samplers can verify the species and collect and biological samples could address some of the stock assessment uncertainty.

Determine or verify future canary rockfish abundances (recruitment)
Since there is a large gap in sizes and ages of canary rockfish caught by trawl surveys used in the assessment, it takes at least ten years to verify recruitment signals using NWFSC bottom trawl survey data alone; the SWFSC pre-recruit pelagic trawl survey catches Age-0 fish and the NWFSC bottom trawl survey is selective for 40-50 cm fish (based on peak of length frequency distributions), which roughly corresponds to females Age-10 and older (Wallace and Cope 2011).

Since recreational gears are selective for intermediate size and age fish relative to the trawl surveys (> 30 cm; Figure B-25), recruitment signals from the pre-recruit survey could be verified in as few as three to five years (corresponding ages for 30 cm females) by using biological data from the recreational fishery (instead of ten years for the bottom trawl).

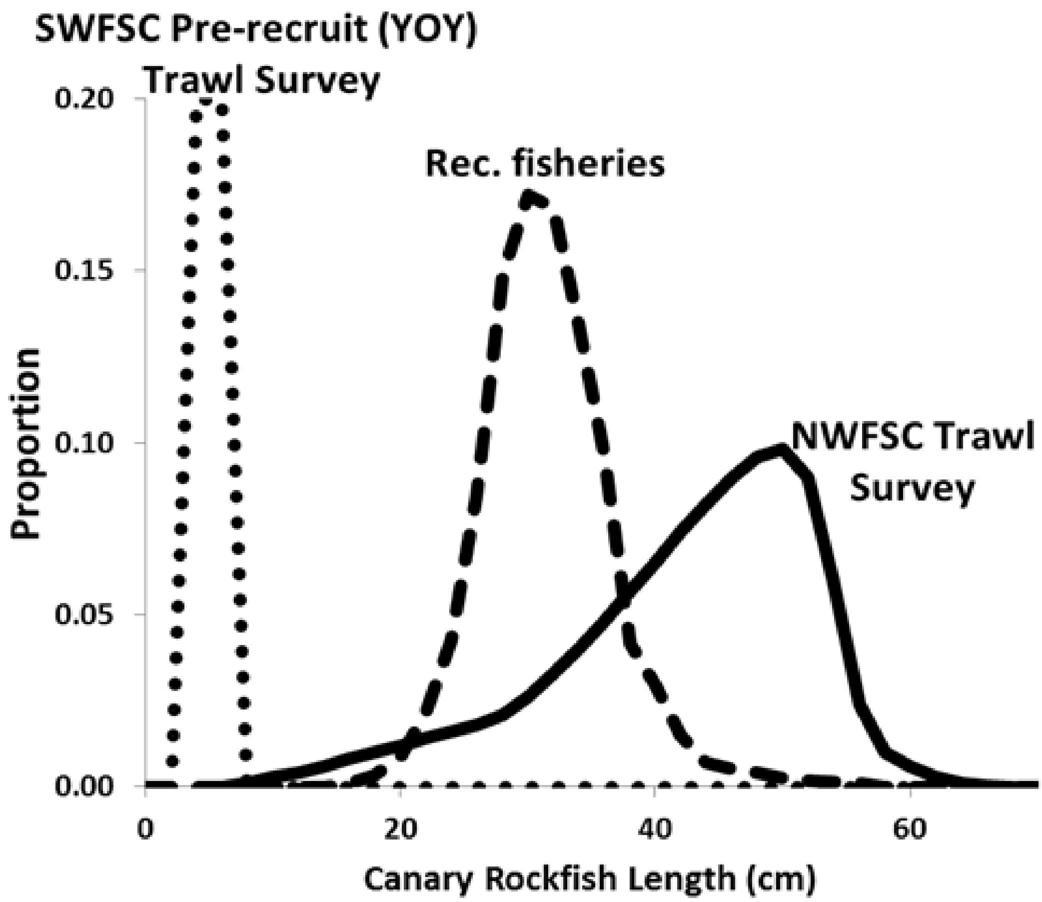

Figure B-25 Canary rockfish length frequency comparison for the trawl surveys and the recreational fisheries. NFWSC curve is an approximation for combined sexes from 2003-2010, from Figure 11 of the Canary rockfish assessment (Wallace and Cope 2011). Recreational data from RecFIN query, 2006-2013; OR, WA, and CA (pooled due to infrequency of (illegal) catches).

Increase accuracy of removals
Allowing retention of canary rockfish in the recreational fisheries could improve the accuracy of canary rockfish removal estimates because catches could then be landed and verified by dockside creel samplers. In contrast, anglers are currently required to discard all canary rockfish encountered, and angler reported

data is consequently needed to determine discard mortality. Potential sources of uncertainty in discard mortality estimates from angler reported data include: (1) misidentification of the species discarded (2) misreporting of the quantity released and (3) misreporting of the factors that affect which discard mortality rate will be applied to their discards (i.e., depth of capture and if a descending device was used).

Allowing retention of canary rockfish may be a cost-effective and, viable solution to improving removal estimates. For example, it would be impractical and unsafe to require small private recreational boats (generally less than 22 feet) to carry observers to monitor discards.

Though canary rockfish has a coastwide OFL and ACL, each state's recreational fishery has its own HG. And each of the West Coast states manages their recreational groundfish fishery independently of each other (e.g. season length, bag limits) to stay within their HG. Therefore analysis of allowing canary rockfish retention was completed on a state by state basis. Under the Preferred Alternative, canary retention was selected only for the Oregon recreational fisheries. As such, the description of the Preferred Alternative is described below whereas the analysis for Washington and Oregon is contained in the Considered but Rejected for Implementation Section, B.20.

Management options

Status Quo**:** Retention of canary rockfish will remain prohibited in the Oregon recreational fisheries.

Option 1**:** One canary rockfish per day, which will be a sub-bag limit of the miscellaneous groundfish daily bag limit of ten (includes rockfish, cabezon, greenlings, elasmobranchs) in the Oregon recreational fisheries.

Option 2**:** Up to ten canary rockfish per day, as part of the federal miscellaneous groundfish daily bag limit, may be reduced under state regulations (currently seven fish) in the Oregon recreational fisheries.

Abundance index of canary rockfish from their primary habitat (rocky reef)off of Oregon
Currently, the only index of relative abundance used in the canary rockfish stock assessment (for adults), the NWFSC bottom trawl survey, occurs in marginal habitat utilized by the species (i.e., sand or flat bottom; Love 2002; Johnson et al. 2003) and does not appear to be detecting a possibly increasing population trend occurring in their primary habitat (i.e., rocky reef). Since 2008 catch frequencies on Oregon recreational groundfish trips, which occurs over rocky reef in all depths, have increased while they have remained stable for trawl survey tows (Figure B-26).

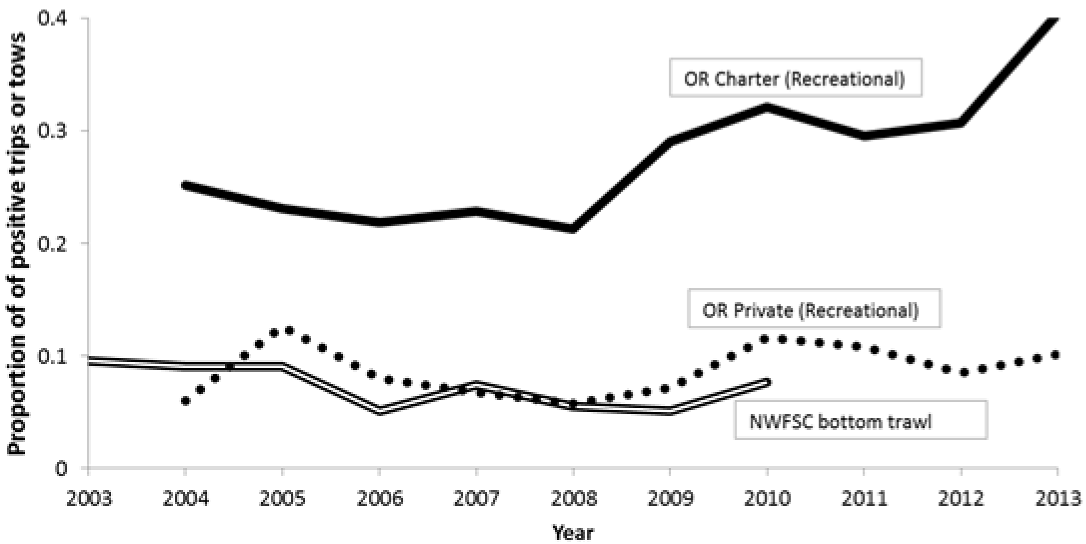

Figure B-26. Comparison of canary rockfish relative abundances from marginal habitat (sand and flat bottom; NWSFC bottom trawl survey) and primary habitat (rocky reef; OR charter and OR recreational groundfish fisheries).

Although the Oregon recreational groundfish fishery provides a measure of relative abundance of canary rockfish in their primary habitat, it has not been used as an index in assessments because it is based on uncertain data (David Sampson, Oregon State University, personal communication). If this uncertainty were resolved by allowing retention of canary rockfish (catches would be landed and verified by creel samplers), then a recreational index of abundance could potentially be incorporated into the canary rockfish assessment, in a similar fashion as used in the black rockfish assessment (logistic regression; Sampson 2007).

There would be minimal to no additional costs to management to develop a recreational CPUE index of abundance for canary rockfish, as the marine recreational creel survey already obtains the necessary data (assuming retention was allowed) for catch and effort accounting. Further, a recreational canary rockfish index of abundance would be robust due to high sample sizes (~9,000-10,000 recreational groundfish interviews per year), year-round coverage, and fine spatial data (i.e., by depth and reef quadrant). Given this wide-scale temporal and fine spatial coverage, it may be possible to apply a post-hoc survey design to the data (e.g., randomly selecting 100 samples from each reef area by a time period).

In order for a recreational canary rockfish catch per unit effort (CPUE) index to be indicative of population trends (and therefore useful to the assessment), fishing behavior would have to be relatively standardized (e.g., would be difficult to determine population trends if some targeted canary rockfish while others did not). By limiting the canary rockfish to one per angler per day, there would less incentive for anglers to target them, and a relatively standardized fishing behavior would be expected (harvests would be from incidental catches). Additionally, post-hoc methods could be used to standardize fishing behavior by limiting catch rate comparison to similar locations (reef block and depth), times, boat types (charter or private), and even by individual vessels (sample data contains unique vessel information; name of boat for charters and registration number for private boats).

No increase to the projected rebuilding time
The Oregon recreational fishery is projected to remain within the most recent canary rockfish HG (11.1 mt in 2014) for all canary rockfish harvest alternatives (Table B-70), and by doing so, no delays to the

projected rebuilding time would occur (assume full attainment of ACLs). The projected difference in mortality between non-retention (3.1 mt; bag limit=0) and a one fish sub-bag limit (8.1 mt) is attributed to the infrequency of canary rockfish catches by recreational anglers. Since 2009, 73 percent (13,536 of 18,703) of canary rockfish caught by recreational anglers has been from trips where the number of anglers outnumbered the canary rockfish catch (Figure B-27). Accordingly, all of those canary rockfish would have been legal to harvest had the bag limit been one. And had they kept their catch, the discarded mortality impacts from released fish would have been greatly reduced (3.0 mt vs. 0.8 mt, respectively), since their discarded dead catch would have been converted to harvested dead catch.

Since most of the catch comes from trips where anglers catch fewer than one canary rockfish per person, an increase in the bag limit from one to seven[14] (8.1 mt vs. 9.5 mt, respectively) is projected to have much less effect on mortality (Table B-70); only 24 percent (4,548 of 18,703) of past canary rockfish catch has been from trips where anglers caught greater than one but less than or equal to seven canary rockfish (Figure B-27). A bag limit of seven would result in the conversion of near all discarded catch to harvested, as 97 percent of canary rockfish caught by recreational anglers have been from those who caught seven of fewer. The only remaining discards would come from the very infrequent large volume catches 'lightning strikes'.

Projections of catch if retention were permitted are based on the assumption that no targeting would have occurred, as anglers did not have incentive to catch them in the past due to the harvest prohibition. While it is unrealistic to assume that no targeting will occur, targeting is expected to be minimal because canary rockfish catches are greater in deep depths (>30 fm; Figure B-28), and to maximize their catch rates, they would have to leave the shallower depths where the catch rates of their primary target species (black rockfish) and others are greatest. Further, the majority of recreational anglers tend to fish seaward of 30 fm (76 percent) when they are permitted to fish all-depths. In short, in order to target canary rockfish, they would be paying more in fuel, driving further, and leaving the most productive shallow depths.

Table B-70. Projected canary rockfish total (grey boxes), discard, and harvest mortality for each harvest option. Projected harvests (# of fish) are shown to demonstrate sample sizes of biological samples that may be attained by allowing retention. (The current bag limit of seven fish in Oregon state regulations was used for this analysis, rather than the ten fish bag limit in federal regulations)

[14] The current bag limit specified in Oregon state regulations, in federal regulations the bag limit is ten.

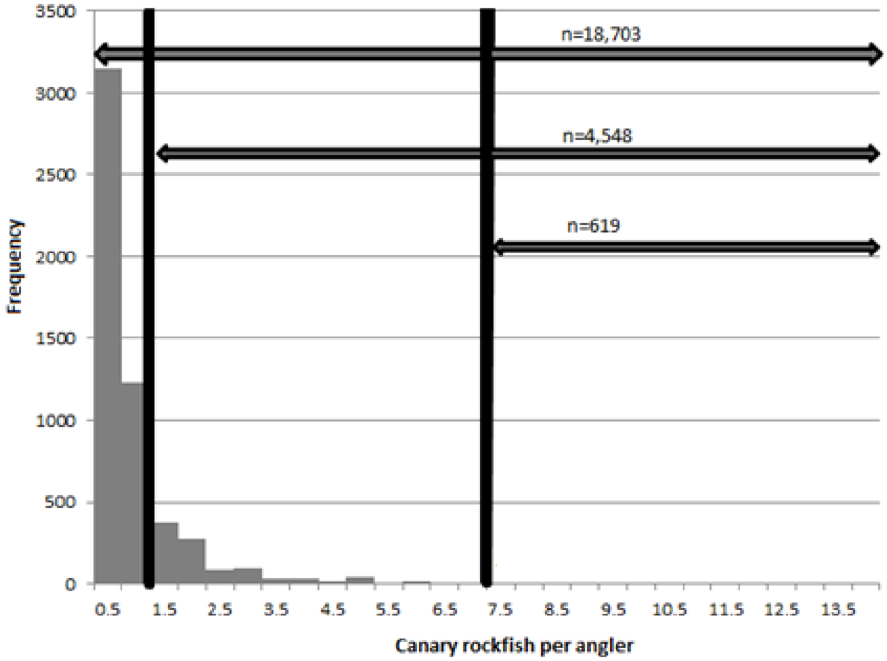

Figure B-27. Canary rockfish catch rate (bars) frequencies for trips that caught one or more and the corresponding quantity of canary rockfish associated with those trips (numbers by arrows), 2009-current.

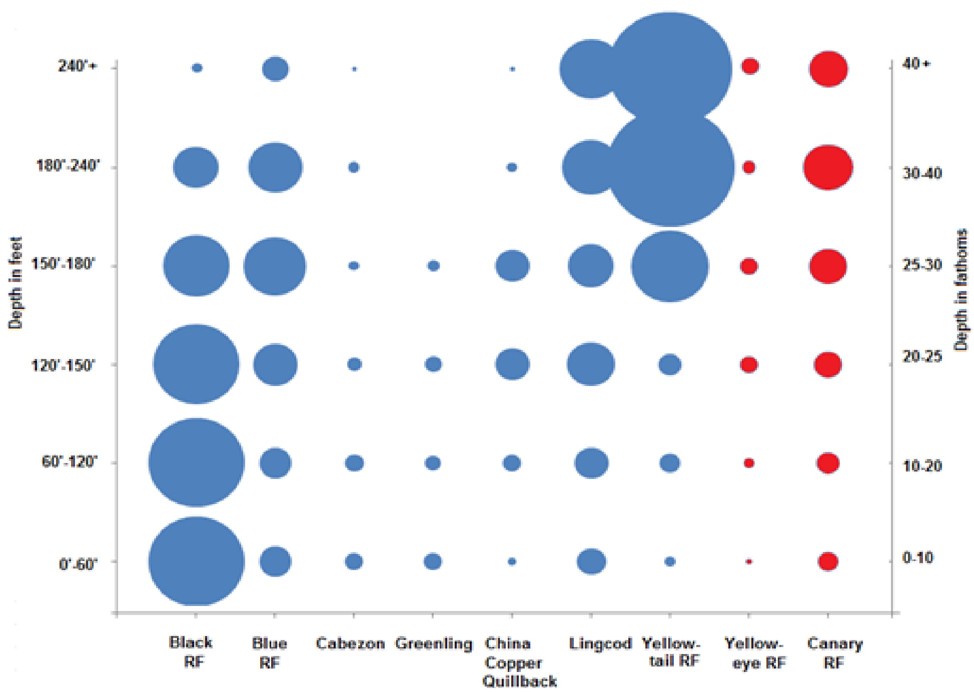

Figure B-28. Relative catch rates by depth of overfished species and harvestable species constituting the bulk of recreational fishery landings.

Projection methods

Canary rockfish mortality was projected for the harvest options via application of a conversion factor (Formula 1) to the output of the canary rockfish mortality model (of the Oregon recreational groundfish model). The conversion factor converted discarded catch of canary rockfish from historic trips to harvested catch up to the boat limit (aggregate of individual bag limits) and any catch in excess of the boat limit remained as discarded (retention was modeled at a boat level because anglers continue to fish and share their catch until the bag limits of all have been caught). For example, if the bag limit was one and seven anglers discard five canary rockfish, then five were converted to harvested (boat limit) and two remained as discarded (excess of boat limit).

Formula 1: Conversation factor applied to the canary rockfish mortality model to project mortality of canary rockfish if harvest (H) were permitted. M=Mortality; H=harvested (1 or 7); CR=Canary rockfish per angler.

$$M_{Baglimit(H)} = \text{Discard } M_{BagLimit=0}\left[\frac{\#Fish_{CR > Baglimit(H)}}{\#Fish_{Baglimit=0}}\right] + \#Fish_{Baglimit=0}\left[\frac{\#Fish_{CR \leq Baglimit(H)}}{\#Fish_{Baglimit=0}}\right]\left[\frac{\text{FishWeight (kg)}}{.001 \text{ (kg to mt)}}\right]$$

Reduces discarded catch due to harvest

Converts discarded catch to harvest catch

Reduce waste of the resource

As previously described in the projected impact section, allowing harvest converts discard mortality (waste) to harvest mortality. Instead of wasting 3.0 mt of canary rockfish by prohibiting retention, this could be reduce to 0.8 mt with a bag limit of one and 0.1 mt with a bag limit of seven (the current bag limit in Oregon state regulations). A sub-bag limit of one fish should prevent most targeting of canary rockfish, while allowing retention of those canary rockfish that are incidentally encountered. A bag limit of up to seven (state regulation) or ten (federal regulation) could change angler behavior, such as targeting areas of canary rockfish. Additionally, allowing retention of incidentally encountered canary rockfish could aid anglers in filling their bag with less time on the water.

Possible reduction of impact to healthy species

The following rationale has been proposed by anglers: canary rockfish are "abundant", and if allowed to keep one, impacts to other harvested groundfish species would be reduced by 14 percent; as anglers could substitute one of the seven fish they are allowed to catch (current bag limit) with a canary rockfish (thereby reducing impacts by $1/7^{th}$ or 14 percent).

This reduction *would only apply to trips in which both a bag limit attainment and catch of canary rockfish occurred*. Since limits only occur in less than 20 percent of trips (19.4 percent; 6,371 of 32,769 trips; Figure B-29) and canary rockfish are only caught during 13 percent of trips that had limited (828 of 6,371), the projected reduction in catch of harvestable species by allowing canary retention is only 0.3 percent (19.4 percent x 13 percent x 14 percent), not the hypothesized 14 percent. In short, the $1/7^{th}$ reduction in catch from allowing canary retention would only apply to the 2.5 percent of trips that limit and have canary rockfish catch.

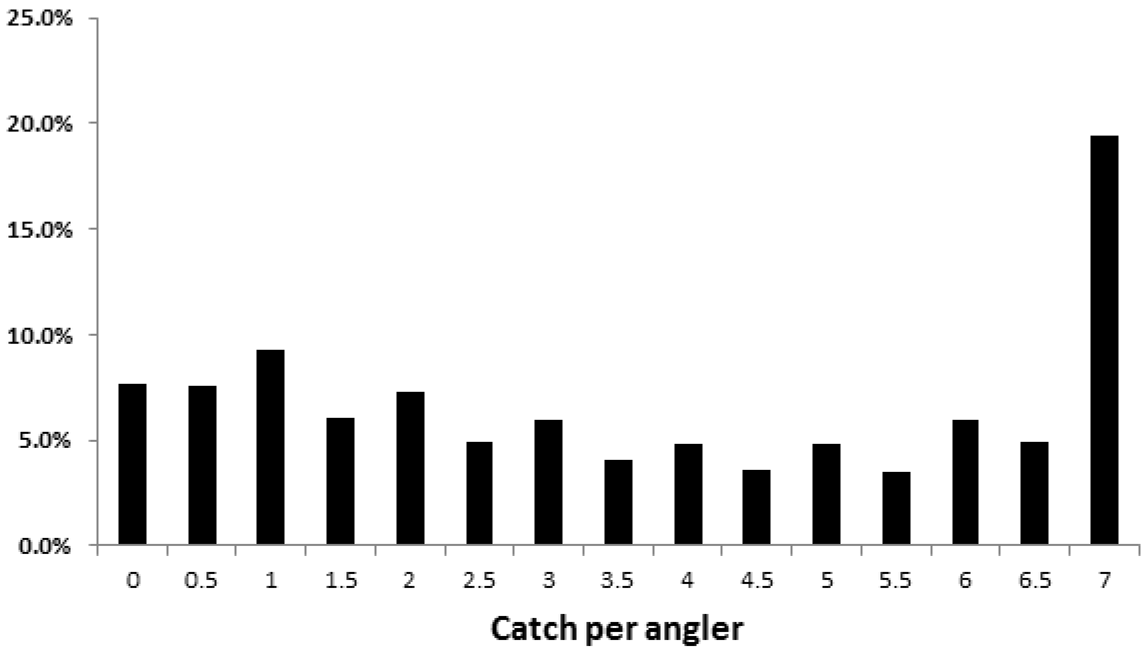

Figure B-29. Percentage of angler trips that caught 0-7 miscellaneous groundfish bag limit. Data is from 32,769 bottomfish trips that occurred from 2009-2013.

Discussion

The potential new recreational fishery data sources could be acquired without additional monetary costs (i.e., dockside creel survey needed to collect the data already exists) or delays to the projected rebuilding times of canary rockfish. No delays to the projected rebuilding times would be expected because the recreational fishery currently only obtains a fraction of the harvest guideline (e.g., 29 percent of the Oregon recreational HG in 2013) and could therefore continue to stay within the harvest guideline even if several thousand canary rockfish were landed (rebuilding analyses assume 100 percent of ACLs harvested).

In summary, allowing retention of canary rockfish in the recreational fishery could be a simple, cost-effective, and impact neutral (to projected rebuilding times) method to increase the understanding of canary rockfish, and therefore provide the Council better information to manage of one the most important groundfish stocks.

B.12 Retain groundfish, lingcod only, or flatfish only during the Pacific halibut fisheries

Need for Action

Recreational Pacific halibut anglers have expressed a desire to change the regulation that prohibits them from harvesting groundfish on “all-depth” days (while in possession of a halibut). Many anglers have stated that they travel 15-30 miles offshore for halibut and fish in waters 100 fm (600 feet) or greater. Going that far, they would like to be able to retain more than just one halibut (e.g. other species incidentally encountered) Additionally, after reeling up a lingcod, or other bottomfish, from those depths they would like to be able to retain them, for their efforts. Anglers participating in the groundfish fishery are allowed to keep halibut incidentally encountered on days when the nearshore halibut fishery is open. The reasoning for the groundfish retention prohibition on "all-depth" days is unclear to anglers because it does not pertain to groundfish that can be harvested, but rather as a means to reduce discard (catch-and-release) mortality of overfished species, specifically yelloweye rockfish.

In order to keep yelloweye rockfish mortality within sector-specific limits, regulations to limit how often recreational anglers fish deep water reefs (>40 fm; 240 feet) are used as the primary management tool; anglers fishing deep reefs more commonly encounter yelloweye rockfish than those fishing shallower reefs, and a higher percentage of those released die due to barotrauma inflicted injuries. The additive effects of high catch rates and high discard mortality rates are too excessive to provide anglers much opportunity to fish deep water reefs, and still keep the groundfish fishery open year round.

Since groundfish anglers target reefs, depth restrictions are used to prevent groundfish anglers from fishing deep reefs during the greatest effort months (April-September). Halibut anglers are permitted to fish beyond the groundfish depth restrictions because this is where the fishery has historically occurred, and because halibut anglers actively avoid reefs (to prevent gear loss and because halibut fishing is better over gravel or sand habitat). The regulation prohibiting retention of groundfish is used to prevent anglers from also targeting groundfish (over the deep reefs) during their halibut trip. Allowing retention of groundfish by halibut anglers on "all-depth" days while intended to allow retention of incidentally encountered groundfish while halibut fishing, could also create a loophole allowing anglers to target groundfish any depth they choose under the guise of 'halibut fishing' on "all-depth" days, and reducing the effectiveness of the groundfish depth restrictions.

If allowed to retain groundfish, some halibut anglers would be expected to (and have told state agency staff that they would) target deep water reefs because they are already in the area and because there is a perception that trophy lingcod (highly desirable to recreational anglers) are more common over deep reefs than shallow water reefs.

Due to somewhat different regulations and fishing behaviors between the Washington and Oregon Pacific halibut fisheries, analysis for each state are separated below.

B.12.1 Washington

Recreational halibut fisheries in Washington are restricted to reduce encounters with overfished species, particularly yelloweye rockfish. Depth restrictions are the primary tool used to reduce encounters with overfished species. Depth by management area become more prohibitive as you move from south to north along the coast due to increasing rocky relief habitat along the northern Washington coast and the increased likelihood of encounters with yelloweye and canary rockfish. While groundfish fisheries are restricted to the nearshore area, recreational halibut fisheries are permitted in the deeper water because this is where the largest concentrations of halibut occur. To reduce encounters with yelloweye and canary rockfish during the recreational halibut fishery, groundfish retention restrictions are in place; these restrictions vary by management area. In the North Coast management area (Neah Bay and La Push), groundfish retention is prohibited seaward of 20 fm from May 1 through September 30 with the exception that lingcod, Pacific cod and sablefish can be retained on days open to recreational halibut fishing. In the south coast (Westport), lingcod retention is allowed seaward of the 30 fm depth restriction, which is in place from March 15 through June 15, on days the recreational halibut fishery is open. In the Columbia River management area (Ilwaco/Chinook), only sablefish and Pacific cod are allowed with halibut on board from May 1 through September 30.

Season length also varies by management area (Table B-71). Recreational halibut seasons in recent years in the North Coast (Neah Bay and La Push) and South Coast (Westport) management areas typically last fewer than 10 days; the halibut season lasted four days in the North Coast and five days in the South Coast in 2013. In contrast, the Columbia River area recreational halibut season has lasted from May through September for the most recent seasons. Even though the North and South Coast management areas include more habitat typically associated with yelloweye and canary rockfish, the short season length limits the opportunity for encounters with overfished species during the recreational halibut fishery.

Table B-71. Recreational halibut season length (days) by management area.

	2009	2010	2011	2012	2013
North Coast (Neah Bay / La Push)	6	7	8	7	4
South Coast (Westport)	11	7	7	5	5
Columbia River	37	48	40	60	66

Management Measures by Area

Recent changes to groundfish retention management measures associated with the recreational halibut fisheries in the North and South Coast management areas may provide insight when considering groundfish retention during the recreational halibut fishery in areas such as the Columbia River where it is currently prohibited (with exception of Pacific cod and sablefish).

South Coast (Westport)

In 2010, changes to the Pacific Fishery Management Council's Pacific Halibut Catch Sharing Plan were implemented that allowed lingcod retention in the area seaward of the 30 fm depth restriction on days open to the recreational halibut fishery. Prior to 2010, only Pacific cod and sablefish could be retained seaward of 30 fm from May 1 through June 15 (reflecting the time period that the primary halibut fishery would likely be open). An additional management measure change that permitted rockfish retention seaward of the 30 fm depth restriction was analyzed in the 2011-2012 Harvest Specification and Management Measures Environmental Impact Statement and implemented in 2011. Table B-72 summarizes the most common groundfish encountered (retained and released groundfish) on recreational halibut trips in the South Coast (Westport) management area from 2006 through 2013. Black rockfish and lingcod make up the bulk of groundfish encountered during recreational halibut trips in the South Coast region.

Table B-72. Groundfish encounters (retained + released) per 100 recreational halibut angler trips in the South Coast management area.

Species	2006	2007	2008	2009	2010	2011	2012	2013

Yelloweye RF	1	2
Bocaccio	1	0

North Coast (Neah Bay and La Push)

In 2013, groundfish regulations were changed through inseason action to address increased yelloweye rockfish encounters in the North Coast management area. The change revised the time period that groundfish retention seaward of 20 fm is prohibited from June 1 through September 30 to May 1 through September 30. In addition, because encounters with yelloweye rockfish primarily increased in the recreational halibut fishery, groundfish retention during the recreational halibut fishery was changed from allowing all groundfish seaward of 20 fm on days open to halibut fishing to limiting groundfish retention to lingcod, sablefish and Pacific cod on days open to the recreational halibut fishery.

Similar to the South Coast management area, black rockfish and lingcod are the most common groundfish encountered on recreational halibut trips. Changes in 2013 to revise the length of time the depth closure is in place and limit the amount of groundfish that can be retained on halibut trips did reduce encounters with yelloweye rockfish compared to the average per angler encounter rate between 2009 and 2012 (Table B-74). In addition to somewhat lower encounter rates of yelloweye rockfish after the management change, in 2013 61 percent of the yelloweye rockfish were encountered in waters deeper than 20 fm compared to 83 percent in 2012, reducing the total morality of yelloweye on recreational halibut trips.

Table B-74. Groundfish encounters (retained + released) per 100 halibut angler trips in the North Coast management area.

Columbia River

Management measures associated with groundfish retention on recreational halibut trips in the Columbia River area have remained unchanged since 2005 with only Pacific cod and sablefish allowed when a halibut is on board from May 1 through September 30. There are no depth restrictions associated with the recreational groundfish fishery in this area as there are in the North Coast and South Coast management areas. In 2012, a lingcod restriction was implemented to reduce encounters with yelloweye rockfish associated with anglers targeting lingcod in deep water in the Columbia River area.

The species composition of groundfish encountered on recreational halibut trips in the Columbia River area is different than what is reported in the North Coast and South Coast management areas with Spiny dogfish and flatfish comprising a large proportion of the groundfish encountered (Table B-75). Overfished species encounters on recreational halibut trips are lower in the Columbia River area than in the North Coast and South Coast management area (Table B-76).

Recently, anglers have expressed interest in revising regulations to allow lingcod retention during the recreational halibut fishery in this area.

Table B-75. Groundfish encounters (retained + released) per 100 halibut angler trips in the Columbia River management area.

Summary

In Washington, due to the regional variability in encounters with all groundfish species, including overfished species and regional differences in the length of the recreational halibut season, consideration for allowing groundfish retention during recreational halibut fishing should be evaluated on a management area basis.

Encounters with yelloweye and canary rockfish on recreational halibut trips is lower in the Columbia River management area than in other areas and expanding the groundfish species allowed on halibut trips might be a viable alternative for the recreational halibut fishery that occurs in this area along the Washington coast. However, this management area extends to Cape Falcon, Oregon and so it is important to consider groundfish encounters in the Oregon recreational halibut fishery which may be different from the Washington recreational fishery. In addition, each state has separate harvest guidelines for yelloweye and canary rockfish and allowing retention of these overfished species would have to be evaluated to include trade-offs to other fishing opportunities in other management regions in both sates depending on each states projected attainment of their state specific harvest guidelines.

It is difficult to project whether or not anglers would spend more time fishing in deepwater areas targeting groundfish such as lingcod where encounters with overfished species is higher if retention were allowed on recreational halibut trips. But, analysis of the recent changes to management measures in the North Coast and South Coast suggest that encounters with overfished species is likely to increase.

B.12.2 Oregon

Although many halibut anglers would be expected to target groundfish is allowed to do so (and some have told ODFW staff that they would), the actual percentage that would is unknown. Therefore, additional yelloweye rockfish impacts by allowing retention of groundfish were projected across a wide range of percentages (of halibut anglers that would also target groundfish; Figure B-30). If none of the halibut anglers targeted groundfish, no additional yelloweye rockfish impacts would be expected to occur from the halibut fishery; however, the impacts could be substantial if a greater percentage of targeting occurs. For example, yelloweye rockfish mortality from the Oregon halibut fishery would be expected to increase to 1.4 mt (from 0.8 mt) if as few as 20 percent of anglers targeted groundfish during halibut trips. If this percentage increases to 75 percent, then yelloweye rockfish impacts from the halibut fishery alone are expected to exceed the 2013 harvest guideline level (similar to the HG for 2015 and 2016) for all Oregon recreational fisheries.

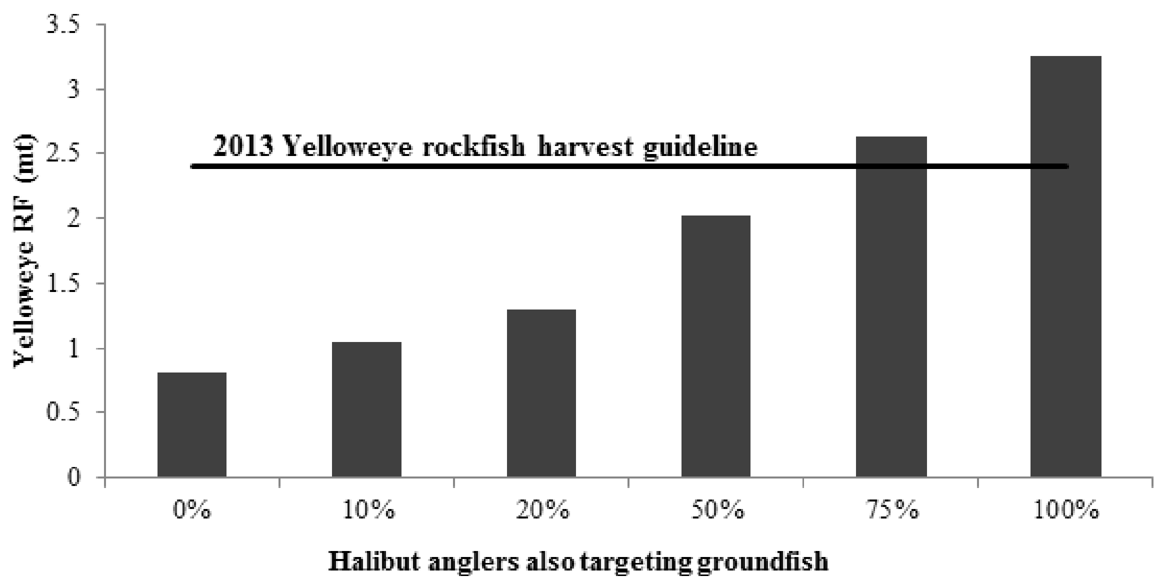

Figure B-30. Projected mortality of yelloweye rockfish from the Oregon recreational halibut fishery if halibut anglers were allowed to retain groundfish during halibut trips for various degrees of targeting of groundfish by halibut anglers. Since the percentage of anglers that would target groundfish during their halibut trip is unknown, mortality is shown for a wide range of targeting. The horizontal black line represents the 2013 harvest guideline for all Oregon recreational fisheries.

Since there is currently little room for any additional yelloweye rockfish mortality, sacrifices would likely have to be made to the recreational groundfish fishery, in the form of more restrictive regulations, in order to allow retention of groundfish by halibut anglers. While further regulations would come at great costs to groundfish anglers (e.g., shorter seasons, lesser bag limits, more restrictive depths), the benefits to halibut anglers are expected to be minimal. Allowing halibut anglers to retain incidental groundfish catches does not provide much benefit because these catches are infrequent (based on angler reports to ORBS to be 0.3 fish per halibut trip) and primarily consist of species that are overfished or non-desired (e.g., sharks, skates, and arrowtooth flounder; Figure B-31). Although anglers would be pleased if allowed to retain desirable species, such as lingcod or petrale sole, their trip satisfaction is much more dependent on whether or not they catch a halibut, their primary target. Further, allowing retention of groundfish would not increase halibut effort (the best measure of value of recreational fisheries) because the fishery is already at full capacity (quotas always caught).

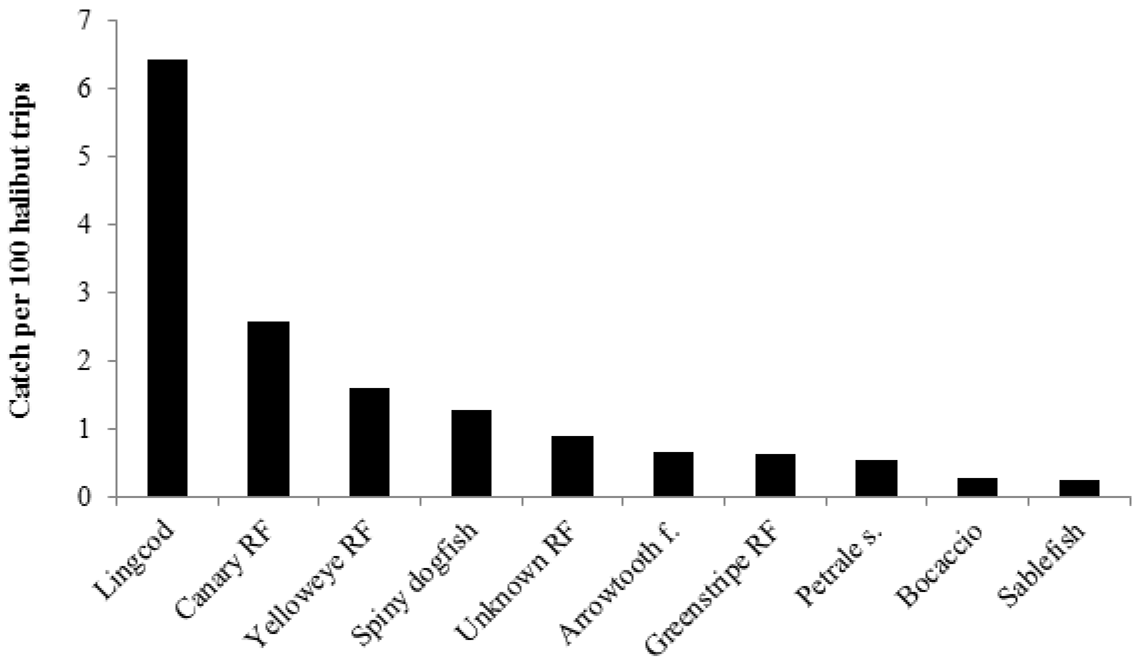

Figure B-31. Catch rates of the top ten most commonly encountered groundfish species by recreational halibut anglers in Oregon.

A modification to allow halibut anglers to harvest groundfish species that are not associated with reef habitat (i.e. other flatfish species), and thereby extending the current rule which allows sablefish and Pacific cod has also been requested. Lingcod and rockfish would remain prohibited as they are primarily associated with reef habitat. This modification could reduce the risk (incentive for anglers to target deep reefs) and may provide some additional harvest opportunities and increase angler satisfaction.

Adoption of the any change to these regulations would also have to be implemented via the Pacific Halibut Catch Share Plan, wherein the regulatory language for incidental groundfish retention for halibut fisheries is housed.

Management Options

No action: No groundfish except for sablefish and Pacific cod can be retained during all-depth halibut season while in possession of a halibut

Option 1: All groundfish can be retained during all-depth halibut season
Option 2: No groundfish except for sablefish, Pacific cod, and flatfish may be retained during all-depth halibut season while in possession of a halibut --or-- specify the groundfish can be retained except for rockfish and lingcod

Management Measures Considered but Rejected

The Council requested analysis of several new management measures which were rejected for implementation in the 2015-2016 harvest specifications and management measures process. Some of the management measures were forwarded for further consideration and prioritization within the Omnibus Regulation Changes while others were rejected all together. A summary of the analysis conducted to date is contained below.

B.13 Groundfish Closure Areas for Rougheye Rockfish and Spiny Dogfish

Groundfish closure areas (GCAs) are a management measure intended to help reduce catch of non-target species that have been identified as a possible concern. GCAs such as RCAs are currently in place as one tool to keep catches of overfished species below their respective overfishing levels (OFLs) (and annual catch limits; ACLs). For the 2015-16 Pacific Coast groundfish fishery, GCAs for rougheye rockfish and/or spiny dogfish are being considered. The Groundfish Management Team (GMT) was asked to provide analysis to aid the Pacific Fishery Management Council (Council) in deliberations on this matter. This report provides a description of the analysis and some results. Also note that due to the short time frame between the March and April 2014 Council meetings, the full GMT did not have an opportunity to review this report by the April Briefing Book deadline. However, the GMT will have an opportunity to review and provide comments at the April Council meeting. In addition, the GMT did not have time to explore many analyses that may be needed, such as in-depth analysis of inter-annual and intra-annual variation. Guidance from the Council and the Scientific and Statistical Committee (SSC) on analyses that may be beneficial but not shown here is requested. For example, the GMT seeks guidance from the SSC regarding the most appropriate metric to identify concentrations of stocks along the U.S. west coast.

B.13.1 Rougheye rockfish groundfish closure area (GCA)

To aid consideration of groundfish closure area(s) for rougheye rockfish, an analysis was conducted to identify areas where rougheye may be caught in significantly higher proportion than in other areas. For identification of these "hot spots", a cluster analysis of high catch locations was conducted. Observer data collected from the following sectors were used: at-sea whiting, non-nearshore fixed gear, and individual fishing quota (IFQ). Focus was on midwater trawl gear (at-sea whiting and IFQ sectors), fixed gears (non-nearshore fixed gear), and bottom trawl gear (IFQ sector). Data relative to fixed gears used by the IFQ sector were not analyzed in time for this report. More detail about the data and methods, as well as additional figures resulting from different analytical assumptions, are found below. In addition, our analysis up to this point includes exploration of different methods and assumptions for identifying hot spots. The resulting figures may vary in the location and size of these hot spots. This suggests that further exploration may be needed; also, these results should be considered in addition to other information about the behavior of rougheye rockfish and these fishery sectors (e.g., from fisheries scientists, managers, and participants).

At-sea whiting sector

Areas where statistically significant clusters of high bycatch ratios (rougheye rockfish-to-Pacific whiting) and low bycatch ratios are shown in Figure B-32. All data for this sector were located north of 40° 10' N latitude.

Non-nearshore fixed gear sector

Areas where statistically significant clusters of high bycatch ratios (rougheye-to-sablefish) and low bycatch ratios are shown in Figure B-33. The area north of 42° N latitude was the focus of this figure due to the occurrence of hot spots in this area.

Individual fishing quota sector

Areas where statistically significant clusters of high bycatch ratios and low bycatch ratios are shown in Figure B-34 and Figure B-35. For midwater trawl observations, rougheye rockfish-to-Pacific whiting was the bycatch ratio used in the analysis. The area north of 43° N latitude was the focus of Figure B-34 due to the occurrence of hot spots in this area. For bottom trawl observations, rougheye-to-all other groundfish was the bycatch ratio used. This area north of 42° N latitude was the focus of Figure B-35 due to the occurrence of hot spots in this area.

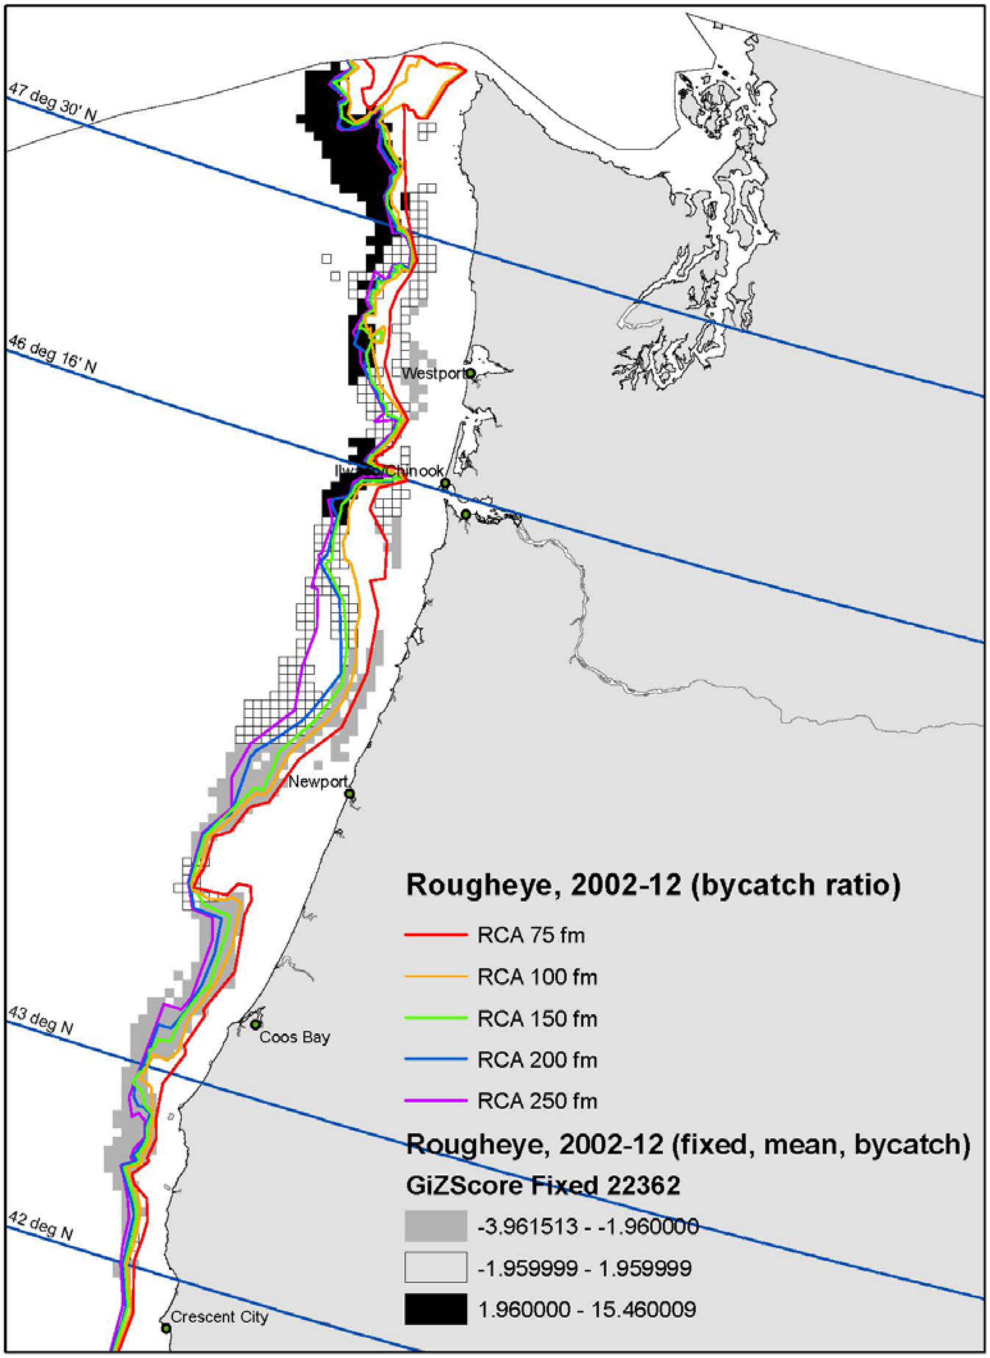

Figure B-32. Hot and cold spots of rougheye rockfish in the at-sea whiting sector, 2002-12.

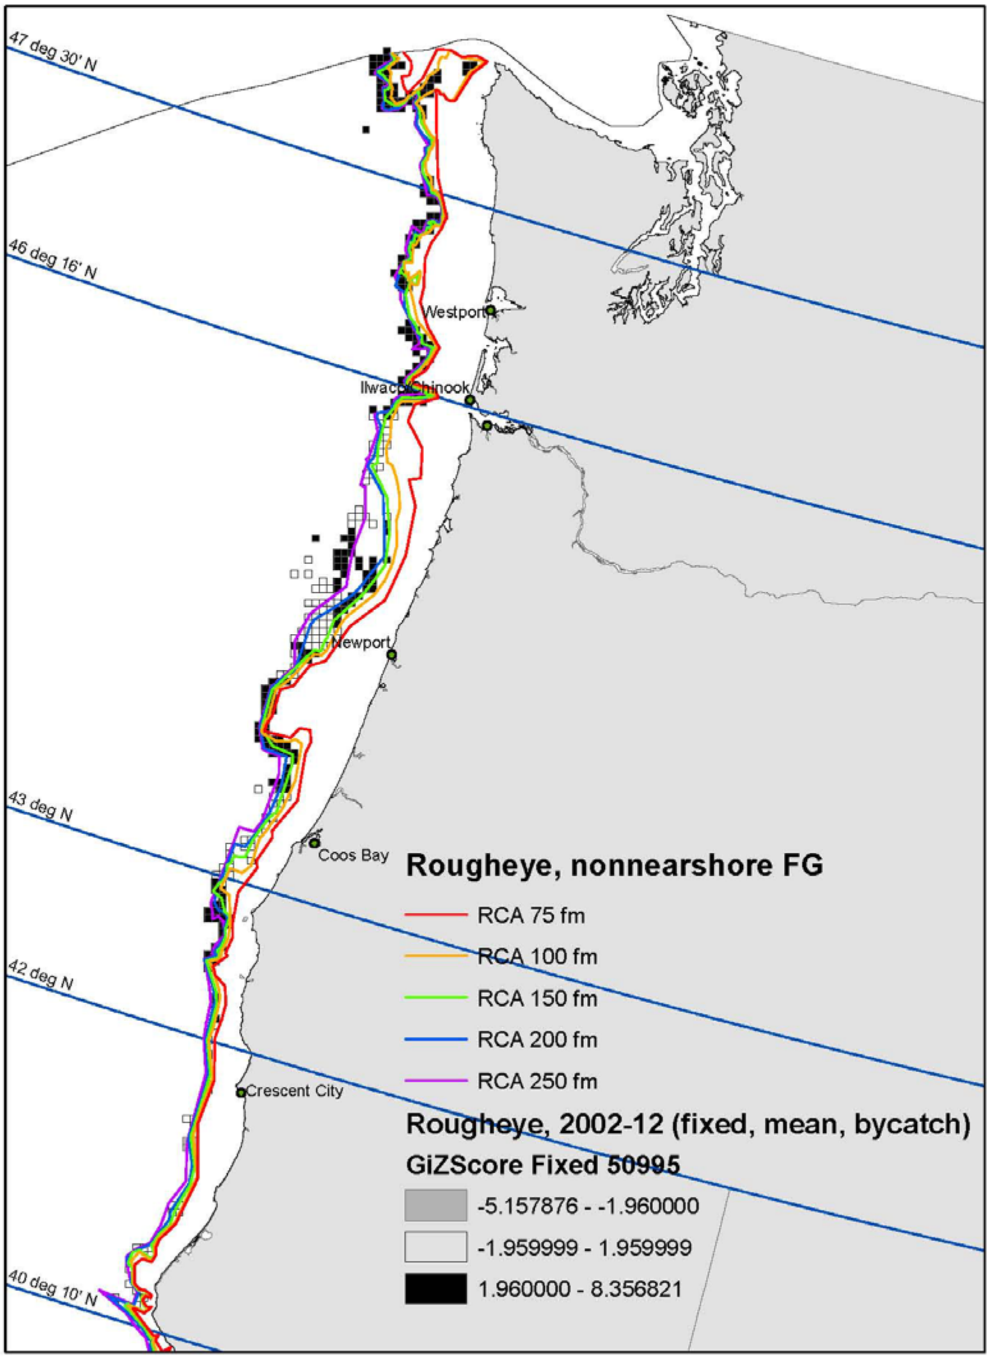

Figure B-33. Hot and cold spots of rougheye rockfish in the non-nearshore fixed gear sector, 2002-12.

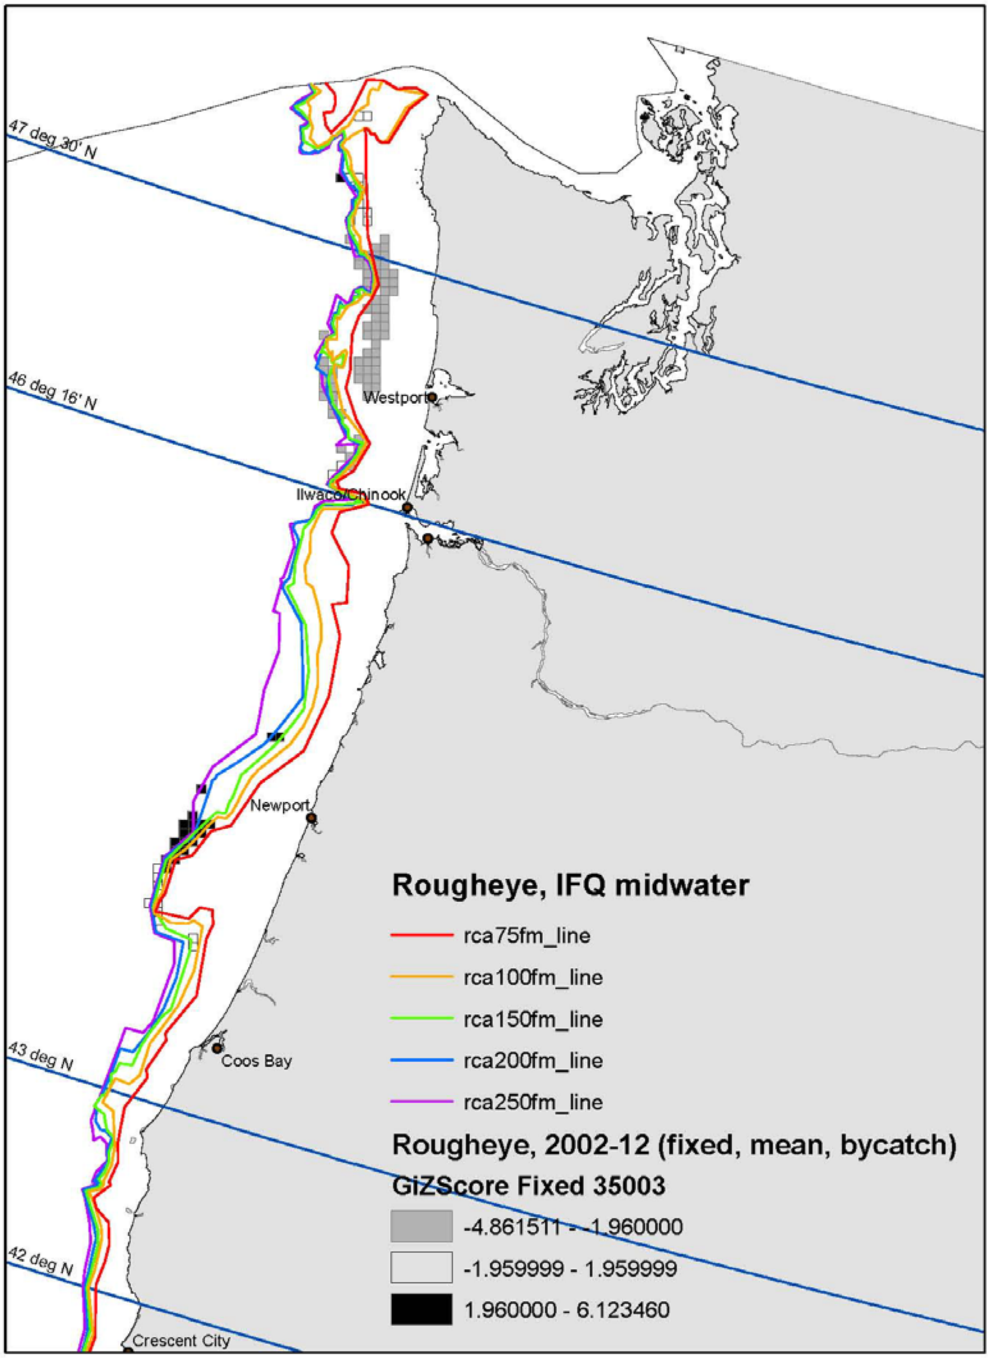

Figure B-34. Hot and cold spots of rougheye rockfish in the IFQ sector, midwater trawl, 2002-11.

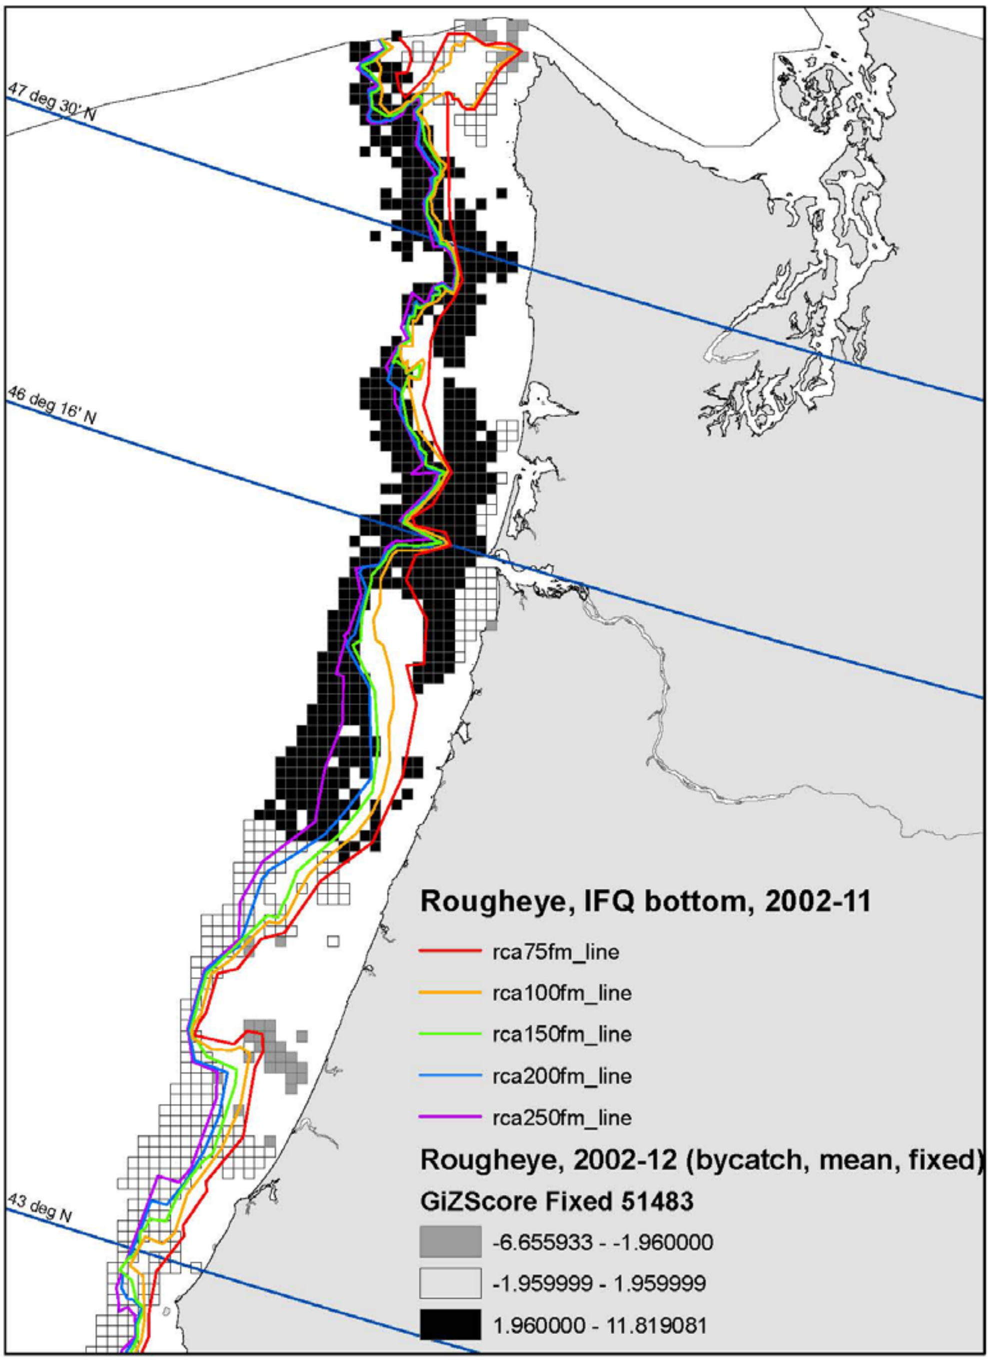

Figure B-35. Hot and cold spots of rougheye rockfish in the IFQ sector, bottom trawl, 2002-11.

B.13.2 Spiny dogfish shark groundfish closure area (GCA)

To aid consideration of groundfish closure area(s) for spiny dogfish shark, an analysis was conducted to identify areas where spiny dogfish may be caught in significantly higher proportion than in other areas. For identification of these "hot spots", the method used to identify hot spots for rougheye rockfish was also used for spiny dogfish. Observer data collected from the following sectors were used: at-sea whiting and catch shares (individual fishing quota or IFQ) sectors. Focus was on midwater trawl gear (at-sea whiting and IFQ sectors), fixed gears (non-nearshore fixed gear sector), and bottom trawl gear (IFQ sector). Data relative to fixed gears used by the IFQ sector were not analyzed in time for this report. More detail about the data and methods used are found in Appendix A. In addition, our analysis up to this point includes exploration of different methods and assumptions for identifying hot spots. The resulting figures may vary in the location and size of these hot spots. This suggests that further exploration may be needed; also, these results should be considered in addition to other information about the behavior of spiny dogfish and these fishery sectors (e.g., from fisheries scientists, managers, and participants).

At-sea whiting sector

Areas where statistically significant clusters of high bycatch ratios (spiny dogfish-to-whiting) and low bycatch ratios are shown in Figure B-36. All data for this sector were located north of 40° 10' N latitude.

Non-nearshore fixed gear sector

Areas where statistically significant clusters of high bycatch ratios (rougheye-to-sablefish) and low bycatch ratios are shown in Figure B-37. The area north of 42° N latitude was the focus of this figure due to the occurrence of hot spots in this area.

Individual fishing quota sector

Areas where statistically significant clusters of high bycatch ratios and low bycatch ratios are shown in Figure B-38 and Figure B-39. For midwater trawl observations, rougheye rockfish-to-Pacific whiting was the bycatch ratio used in the analysis. The area north of 43° N latitude was the focus of Figure B-38 due to the occurrence of hot spots in this area. For bottom trawl observations, rougheye-to-all other groundfish was the bycatch ratio used. This area north of 42° N latitude was the focus of Figure B-39 due to the occurrence of hot spots in this area.

Figure B-38. Hot and cold spots of spiny dogfish in the IFQ sector, midwater trawl, 2002-11.

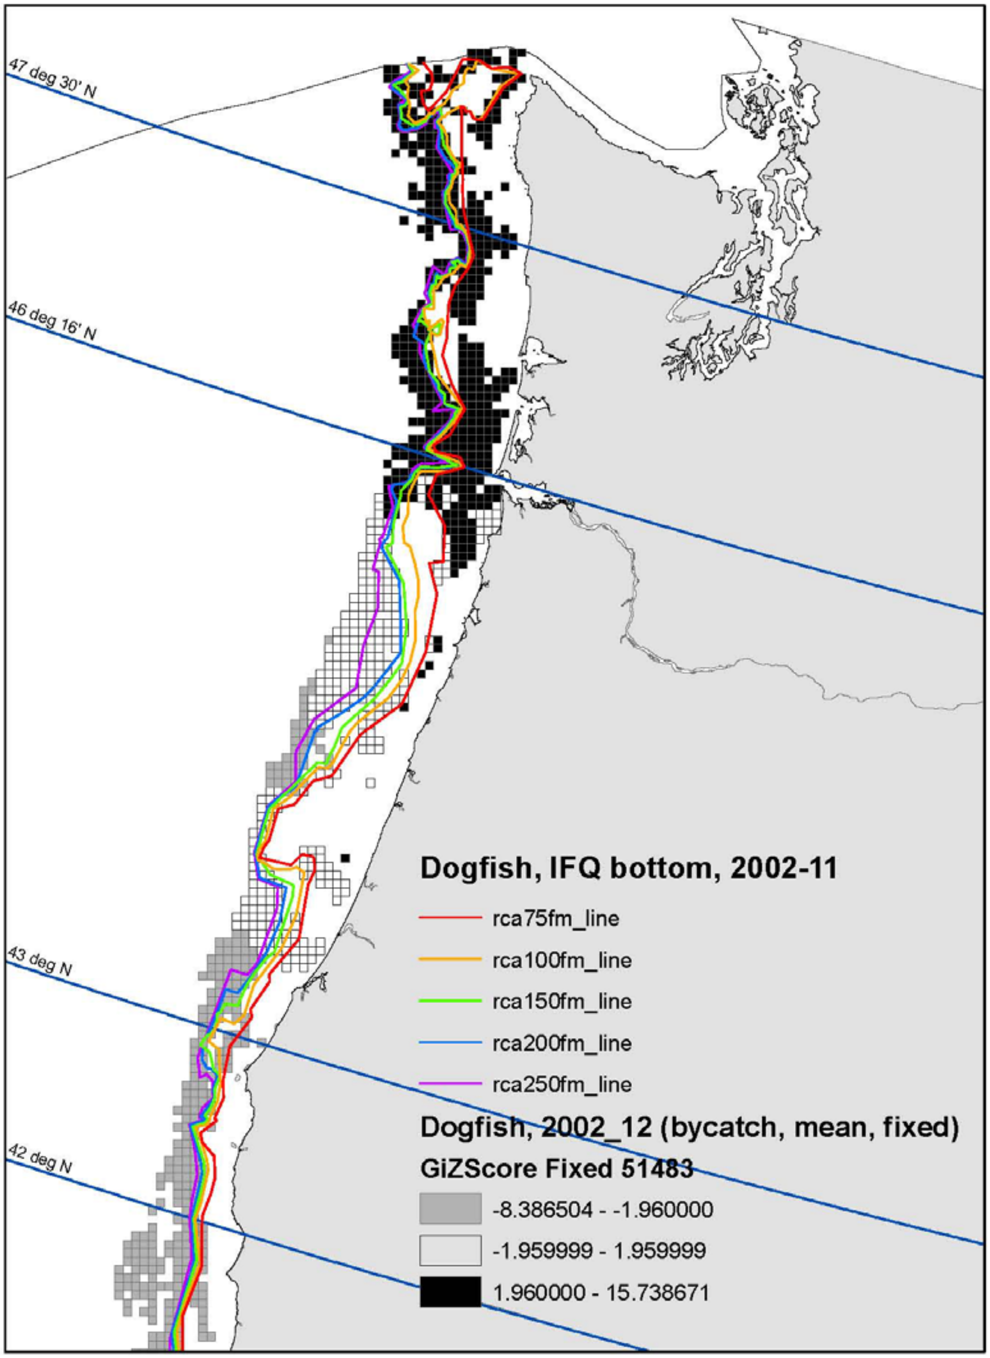

Figure B-39. Hot and cold spots of spiny dogfish in the IFQ sector, bottom trawl, 2002-11.

Description of hot and cold spot analysis: data and methods

Three datasets were made available for this analysis: a West Coast Groundfish Observer Program (WCGOP) dataset used as the input for the Fixed Gear Projection Model used by the GMT (non-nearshore fixed gear sector, 2002-12); a WCGOP dataset that provided information about the IFQ sector (2002-11); and a North Pacific Observer Program (NORPAC) dataset provided by the Pacific States Marine Fisheries Commission (PSMFC) specifically for this analysis (at-sea whiting sector, 1980-2012; 2002-12 were used for this analysis). Though the data were available, the IFQ sector using fixed gear was not analyzed for this report due to time limitations.

The available data were also subject to the following filter. For the IFQ sector using midwater trawl, only those hauls associated with a "Pacific whiting trip" were included in this analysis. A Pacific whiting trip was defined as a trip whose landings (lb) comprised of at least 50 percent Pacific whiting. Additionally, some observations in the datasets were identified as either rougheye or shortraker rockfish ("UDW1" in the WCGOP datasets and "XXXX" in the NORPAC dataset). These observations were combined with the rougheye observations.

For the spatial analysis, each haul and associated catch were attributed to a point location. This location was defined as either the midpoint of each haul or set (for the NORPAC observations) or the average latitude and longitude coordinates of each haul (for the WCGOP observations).

Bycatch ratios (rougheye-to-target species or spiny dogfish-to-target species) were associated with each of these locations. Pacific whiting was defined as the target species for the at-sea whiting sector and IFQ sector using midwater trawl. Sablefish was defined as the target species for the non-nearshore fixed gear sector. For the IFQ sector using bottom trawl, all groundfish excluding rougheye and spiny dogfish were combined and defined as the target for this sector. The natural log of these bycatch ratios and their locations were used as the inputs for this spatial analysis. Hauls that caught the target species but did not catch either rougheye rockfish or spiny dogfish were assigned a bycatch ratio equal to one-half of the minimum bycatch ratio (0.5 * min bycatch ratio) for that bycatch species and sector. This was done to avoid invalid values when taking the natural log (i.e., ln(0) does not result in a valid value). Table B-77 shows the number of observations (hauls) available for this analysis and the number of hauls where no bycatch was reported.

Table B-77. Number of observations (hauls) in this analysis with no bycatch.

Sector	Years with bycatch obs.	Bycatch/Target ratio	Total # of hauls	Hauls with no bycatch	Hauls with no bycatch, %
At-sea whiting	2002-2012	Rougheye/Whiting	21,854	16,960	78%
		Dogfish/Whiting	21,854	10,227	47%
Non-nearshore fixed gear	2002-2012	Rougheye/Sablefish	11,542	8,940	77%
		Dogfish/Sablefish	11,542	7,366	64%
ITQ fixed gear*	2010-11	Rougheye/Sablefish	2,138	1,660	78%
		Dogfish/Sablefish	2,138	1,825	85%
ITQ midwater	2002-2011	Rougheye/Whiting	1,728	1,340	78%
		Dogfish/Whiting	1,728	352	20%
ITQ bottom	2002-2011	Rougheye/All groundfish	37,071	30,311	82%
		Dogfish/All groundfish	37,071	20,411	55%

*This sector was not included in time for this report but will be made available if requested.

A geographic information system software (ArcGIS 10.1) was then used to depict these points and values graphically. First, the west coast exclusive economic zone (EEZ) was divided into 5 km by 5 km grids. For each fishery sector, each haul location and corresponding attributes (e.g., bycatch ratio) were plotted with these grids. Only grids that contained haul locations were selected for further consideration. This grid size was considered to be an appropriate size for adhering to confidential data protocols (i.e., at least three distinct vessels were present within each grid that is depicted in each figure) in the final step of this analysis.

These grids and associated bycatch ratios were then used as inputs for the identification of hot spots. That is, the grid value was aggregated as the mean of the bycatch ratios within that grid. The Hot Spot Analysis (Getis-Ord Gi*) tool, part of the Spatial Analyst extension in ArcGIS, was used. The Getis-Ord Gi* statistic estimates the relationship between grids and identifies clusters of grids with high or low values. Z-scores and p-values are estimated for each grid and used to evaluate statistical significance.

The last step in the hot spot analysis evaluated and showed only those grids where at least three distinct vessels were present in each grid, to adhere to confidential data protocols. The resulting output (figure) shows only these grids and highlights where statistically significant clusters of high bycatch ratios are present (grids with z-scores of 1.96 or higher) and statistically significant clusters of low bycatch ratios are present (grids with z-scores of -1.96 or lower). That is, the pattern of bycatch ratios across these highlighted grids, relative to their neighbors, has a high probability (95 percent confidence level) of occurring due to non-random spatial processes. All other grids (z-scores between 1.96 and -1.96) indicate that the bycatch ratios within them are likely due to random spatial processes.

The relationship between grids can be conceptualized in different ways. For this report, figures that resulted from applying a fixed distance threshold were shown. That is, each grid and its attributes (e.g., bycatch ratio) were evaluated relative to all grids within a threshold distance. Grids outside of this threshold distance were not evaluated. Additional figures not shown in this report were generated using a different spatial conceptualization, an inverse distance threshold. This method also evaluates each grid and its attributes relative to all grids within a threshold distance. However, grids outside of this threshold are evaluated to have some degree of influence (weight) on the grid of interest. Figure B-40 is an example of a result when using this method for identifying hot and cold spots of rougheye rockfish in the at-sea whiting sector. Note that the pattern of hot spots is different than what is shown using a fixed distance method Figure B-32); further evaluation is needed to better understand what is driving these differences in results.

In addition to exploring different spatial conceptualizations, we evaluated outputs resulting from the exclusion of hauls with no bycatch. As mentioned above, the number of hauls where this was the case is shown in Table B-77. Figure B-37 shows an example of a result of this evaluation, a hot spot off of southern California. This evaluation also identified hot spots off of Oregon and Washington but these are not shown in this figure.

Finally, we offer the following considerations. Figure B-32 through Figure B-39 are the result of this data processing and analysis process, and should be considered within this context. Further exploration of the data and methods to identify hot spots could include, but are not limited to, the following: 1) identify hot spots using inter-annual and intra-annual time frames; 2) further evaluate the sensitivity of the results to spatial relationships between observations (e.g., inverse distance); 3) evaluate different distance thresholds between observations (i.e., other than the minimum distance to ensure that each grid has at least one neighbor); 4) evaluate dogfish catch only (rather than the dogfish-to-sablefish bycatch ratio) due to some targeting of spiny dogfish in the fixed gear sectors; and 5) evaluate an alternative target (i.e., denominator for the bycatch ratio) for the IFQ sector such as only Dover sole, thornyheads, and sablefish combined, some other species (e.g., lingcod), or species group (e.g., slope rockfish).

Note that the decision to use catch ratios or simply catch as the metric will result in different conclusions. The GMT seeks guidance regarding the metric that is most applicable to the question being answered. For example, an alternative to using a denominator that represents the catch of target species is to simply overlay the significant clusters for the catch of bycatch species against the relative densities of target species catch (e.g., Figure B-42). This demonstrates that conclusions may be much different depending on the metric selected; Figure B-42 shows that highest catches of rougheye rockfish is off northern Washington, whereas Figure B-32 demonstrates that the highest catch ratios (rougheye catch divided by whiting catch) may occur off central Washington, central Oregon, and southern Oregon).

For the IFQ sector using fixed gear that was not included in this report, the following subsequent analyses could be conducted: combine these observations with the non-nearshore fixed gear sector; evaluate this sector independently, noting that only two years of data are currently available to the GMT; and/or assume that the behavior of this sector is similar to the non-nearshore fixed gear sector and no further evaluation is necessary.

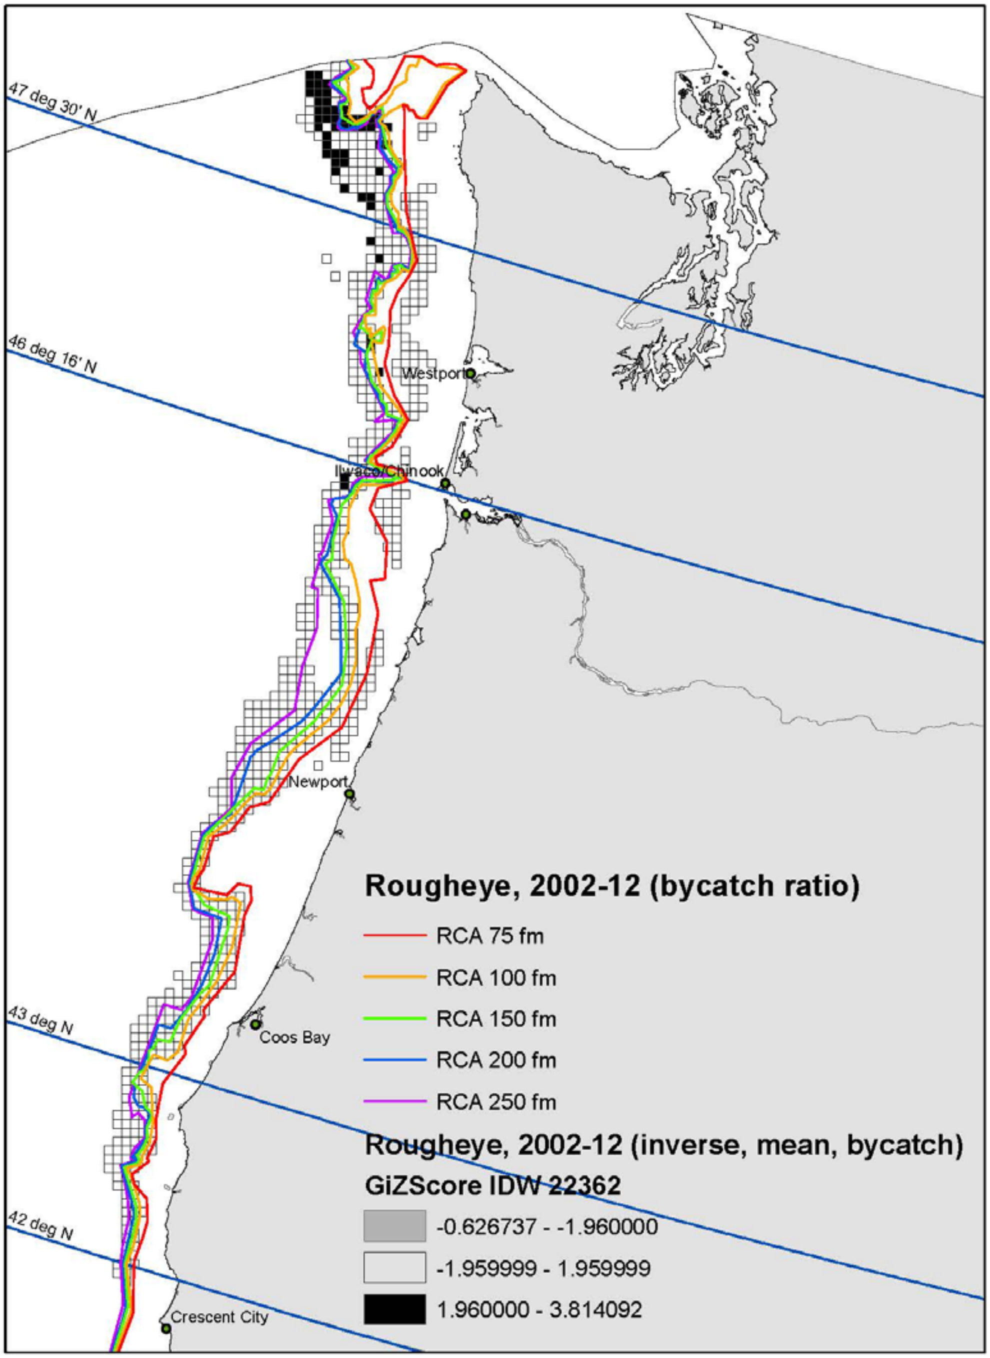

Figure B-40. Hot and colds spots of rougheye in the at-sea whiting sector, using the inverse distance method.

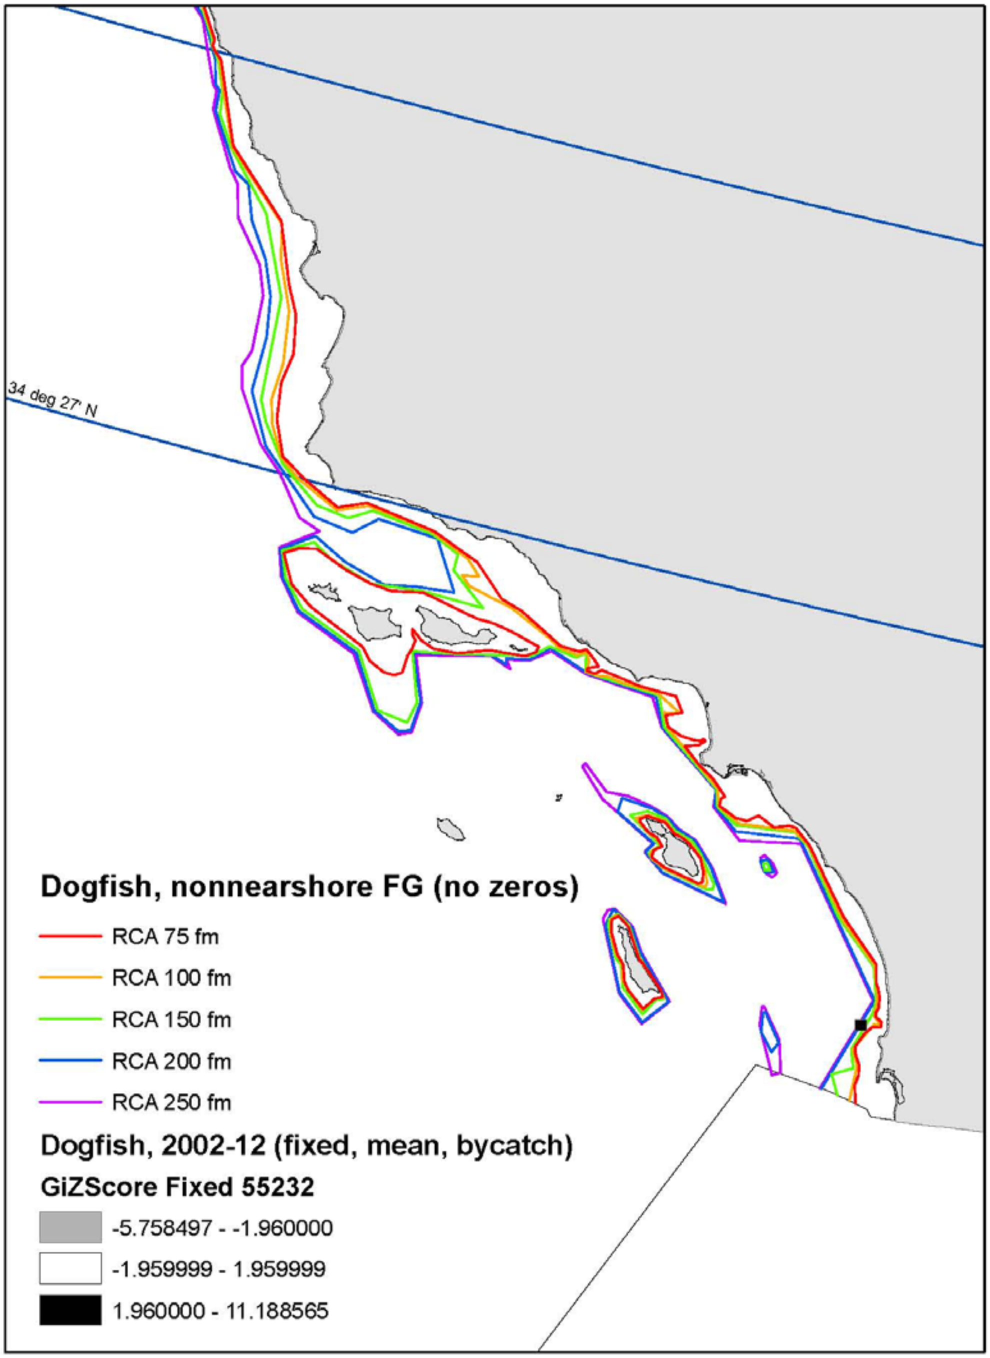

Figure B-41. Hot and colds spots of spiny dogfish in the non-nearshore fixed gear sector, using the fixed distance method and excluding hauls with zero bycatch; southern California only.

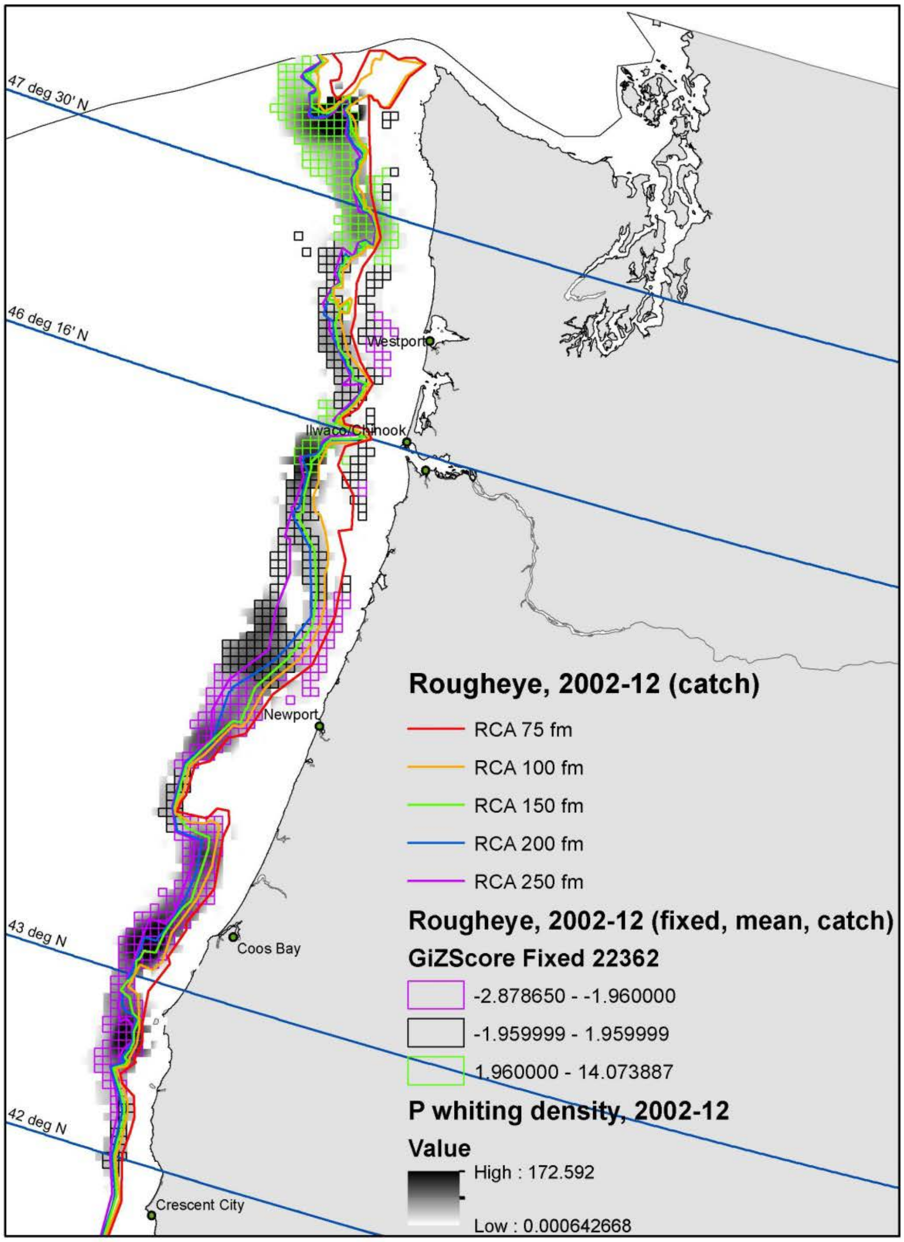

Figure B-42. Catch of rougheye rockfish north of 40° 10´ N latitude by the non-Tribal at-sea whiting sector. Data were acquired from NORPAC (2002-2012). Areas where high levels of catch are clustered are shown by the green-shaded boxes (i.e., north of 47° 30´ N latitude; z-scores greater than or equal to 1.96), moderate catches are shown by the empty boxes, and areas of low catches are shown by the solid purple boxes (z-scores less than or equal to -1.96). Density plots of Pacific whiting catch are shown in the background (i.e., darkest = highest catch of target species).

B.14 Two-Year Trawl and Non-Trawl Allocation of Petrale Sole

In November 2013, the Council requested data to inform a two-year trawl and non-trawl allocation of petrale sole. Under the current action alternatives, the non-trawl sector is allocated 35 mt and the remaining amount is allocated to the trawl sector (2,544 mt). The Council expressed interest in an approach that would allocate 15 mt to the non-trawl sector and the remainder to the trawl sector (2,564 mt). Historical mortality by sector can be found in Table B-78. In recent years, both the trawl allocation and the ACL for petrale sole have been greater than 95 percent attained. As such, it may be logical to assume that an increased allocation of petrale sole to the trawl sector would be utilized. Recent year catches by the non-trawl sector have been less than 2 mt, therefore a 15 mt allocation could be sufficient.

Table B-78. Historical Mortality of Petrale Sole, by sector, from 2002-2012.

B.15 Trawl: At-Sea Set-Asides for Spiny Dogfish Shark

Introduction

The Council requested that 163 mt to 725 mt be analyzed as a range of potential set aside levels of Spiny Dogfish be analyzed for the at sea whiting sectors ("At Sea" sectors). Here we use a basic Monte Carlo simulation approach to evaluate that range in the context of annual Spiny Dogfish bycatch as a whole.

The goal of the simulations is to provide a look at patterns of total annual dogfish mortality under the No Action scenario; and, then to describe how those patterns might be affected if an At Sea set aside were established at a particular level. This second goal also allows for an evaluation of how often catch in the At Sea sectors might reach the various set aside levels and thereby require action by the Council, by the sector participants, or both to avoid an overage of the set aside. In addition to the 163 mt and 725 mt amounts requested by the Council, we look at intermediate values of 300 mt and 500 mt as At Sea set asides to provide additional contrast.

The ACL and harvest guidelines (HG) the Council is considering for 2015-2016 are displayed in Table B-79. To simplify the simulations, we focused only the lower of the preliminary preferred ACLs ("Preferred Alternative ACLs"), which is 1,897 mt. And we focused on the ACL instead of the HG because the simulations take into account the amounts deducted from the ACL to produce the Fishery HG (i.e. tribal catches are part of the simulations and other amounts, e.g. research, are assumed to be fixed yet still added to the total simulated catch).

The high variability of Spiny Dogfish catch makes the choice of a set aside challenging. As shown below, the At Sea sectors, primarily the catcher processor sector, can be major sources of Spiny Dogfish catch. In turn, set asides for the At Sea sectors could be effectively used to lower the probability of an ACL overage. However, the high variability in catch across all sectors means that in some years the At Sea set aside levels would not prevent overages that would be caused primarily by high catch years in other sectors. In addition, the high variability means that in many years the At Sea sectors could reach their set aside level and be negatively affected while catch in total remains below the ACL. The same would be true for other sectors. The simulation results shown below help demonstrate this dynamic.

The factors leading to high and low catches of Spiny Dogfish in each sector are uncertain. We therefore explored multiple simulations based on different assumptions about the frequency of annual Spiny Dogfish catch rates. All approaches considered, however, suggest that total Spiny Dogfish catch is more likely than not to remain below the Preferred Alternative ACLs proposed for 2015 and 2016 whether new set asides are established or not. While not recommending the simulation results as precise forecasts, we do interpret the results as suggesting that overages of the Spiny Dogfish ACL would be expected to occur with low to moderate frequency, from less than 10 percent to less than 30 percent of the time, depending on assumptions about current conditions in the bottom trawl and non-nearshore fixed gear sectors. Furthermore, under these low to moderate probabilities of an annual overage we can conclude with some confidence that that there is less than a 50 percent probability that Spiny Dogfish catch would fail the performance standard of exceeding an ACL more than once in four years suggested by the National Standard 1 (NS1) Guidelines.

The analysis presented in this section was not reviewed by the full GMT. The full GMT will review the analysis at the April meeting and will advise the Council accordingly.

Table B-79. The Spiny Dogfish annual catch limit (ACL) and harvest guideline (HG) amounts under consideration for 2015 and 2016.

	2015 ACL	2015 HG	2016 ACL	2016 HG
Preferred Alternative	1,912	1,737	1,897	1,722
P-star = 0.25	1,552	1,377	1,540	1,365
P-star = 0.45	2,303	2,128	2,285	2,110

Spiny Dogfish Catch and Outline of the Data and Simulation Approach

The patterns and management history of Spiny Dogfish catch were evaluated in the 2013-14 EIS. An extra year of catch estimates, as well as some revisions to past years' estimates, have become available since that analysis was completed. However, the Council recommended no new management measures for Spiny Dogfish in the current 2013-2014 management period and the management circumstances for Spiny Dogfish remain largely unchanged from last cycle. Here we focus on the most salient aspects of Spiny Dogfish catch to the simulations and the At Sea set aside consideration. The 2013-14 EIS can be consulted for a more thorough treatment of the history of the Council's management of Spiny Dogfish. The total mortality estimates used in this analysis are displayed in Table B-80.

A few key characteristics of Spiny Dogfish catch led the GMT to explore this simulation approach for this cycle. First, catch of Spiny Dogfish has been highly variable across a number of sectors (Figure B-43). With such variability, point estimates and focus on single sectors is of limited value for forecasting. The reality is that Spiny Dogfish catch is unpredictable and may fall over a wide range both at the sector level and in total. The simulations provide a means of exploring this range of outcomes and the relative frequency of catch events across sectors.

Second, in most years total mortality on the stock has remained below the ACLs being considered for 2015-2016. Catch only exceeded those levels twice since 2003 and approached them in two other years (Table B-80). And in those years catch was considerably over the average in one or more sectors. So it is the combination of variability across a sector that appears to be key to evaluating the risk of ACL overages for Spiny Dogfish. The simulation approach is a convenient method of evaluating the variability in sectors in combination.

Lastly, Spiny Dogfish have been caught mostly as incidental bycatch in recent years. Targeting and marketability have been on the decline. No management measures are thought to directly affect incentives to target or avoid Spiny Dogfish and so it appears that variations in catch rates have been the result of outside factors like management measures targeted at other stocks. The high and low catch years in each sector very much appear to be behaving as stochastic, random variables whose pattern can be described with simple statistical/phenomenological models.

The input data for the simulation is based on the total mortality estimates shown in Table B-80and Table B-82. The simulations focus on the sectors where catch has been relatively high and variable. Those where catch has been relatively low and stable are combined into an Other category. The catch estimates from these combined sectors are displayed elsewhere in the 2015-2016 analysis. The simulations fix the catch from these sectors at the 2009-2012 average of 36 mt.

To account for variations in fishing activities in each sector from year to year, the ratio of Spiny Dogfish to total catch of all species is the main unit of analysis used in the simulations (Table B-82). For the At

Sea commercial and tribal sectors, the denominator used to calculate the ratio is total catch of all species. For the other sectors, we used total landings of all species as the denominator.

Table B-80. Total annual estimated fishing mortality (mt) of Spiny Dogfish by sector (sources: PacFIN npac4900 for the At Sea landings, WCGOP's GMMultiYr_DataProduct (23-Dec-2013 version), state recreational data). Note that total fishing mortality assumes 50 percent survival of fish discarded in the fixed gear sectors.

TSS	11,989	2008-2012 average

Simulation methods and Scenarios

We performed all simulations with the R statistical program.[15] For each sector, we took the natural logarithm of the annual Spiny Dogfish catch ratios shown in Table B-82, calculated the means and standard deviations for each sector, and then inputted those into R's function for generating lognormal random variables. The lognormal parameters used for each sector are shown in Table B-84, displayed as means and coefficients of variation (CVs). To produce simulated catch in metric tons for each sector, we used the function to generate 100,000 estimates of annual catch ratios and then multiplied them by the total catch amounts displayed in Table B-83.

[15] R Core Team (2013). R: A language and environment for statistical computing. R Foundation for Statistical Computing, Vienna, Austria. URL http://www.R-project.org/. Boxplots and time series plots were produced using the ggplot2 package: H. Wickham. ggplot2: elegant graphics for data analysis. Springer New York (2009).

We chose the lognormal probability distribution to model the annual catch ratios in each sector because higher rates of catch in a year would tend to have a multiplicative effect on deviations from average. In addition, the catch ratios only take non-negative values; and, for multiple sectors, the observed catches have large coefficients of variation and are skewed toward higher values than would be expected under a normal, bell-curve. Lognormal distributions are commonly used for random variables having these two characteristics.

Simulating catch in this manner is a statistical/phenomenological approach where the goal is to describe the observed pattern rather than to identify and model the factors or causal process that produce the pattern. The fundamental assumption is that the pattern can described by parameters of a statistical distribution (e.g. mean and standard deviation) and that future annual catches will be drawn from this distribution. In essence, the main assumption is that the future as has the past. This approach is common in many methods used by the GMT and others yet it is an oversimplification to say that Spiny Dogfish bycatch is a random variable that will simply follow a fixed probability distribution over time.

Because of this and the uncertainty in the drivers of Spiny Dogfish bycatch, we explored multiple simulations scenarios based on different probability distributions and parameters. Two are presented here. The first ("Simulation 1") uses all 10 years of data for every sector. The second ("Simulation 2") uses only a subset of those years for sectors where we saw evidence for more recent change in the patterns of Spiny Dogfish catch. The intent of Simulation 2 is to reflect possible change in recent conditions in a few key sectors. The years and corresponding lognormal estimates for the annual Spiny Dogfish catch ratios used in Simulation 2 are displayed in Table B-84.

To arrive at the set of years used in Simulation 2, we evaluated patterns across the ten year time series for each sector (Figure B-44). Welches t-tests were used to compare the Spiny Dogfish catch ratios over the 2003-2007 and 2008-2012 periods as well as a number of other splits of earlier and later time periods where visual evaluation of the time series suggested such differences might exist. Statistically significant differences in the later-year average catch ratios of Spiny Dogfish exist for the non-nearshore fixed gear (2009-2012), bottom trawl (2009-2012), and shoreside whiting sectors (2008-2012).[16]

Other indications of changed trends in these sectors were apparent as well. First, discard patterns of Spiny Dogfish changed substantially after 2008 in the non-nearshore fixed gear sectors. The percentage of total mortality coming from discarded Spiny Dogfish increased in those sectors from an average of 31.5 percent over 2003-2008 to 87.4 percent over 2009-2012. Such a change suggests a major change in the marketability of Spiny Dogfish in that sector after 2008. In addition, log-linear regression on the time series data shows decreasing trends in the bottom trawl and non-nearshore fixed gear sector over 2008-2012. The shoreside whiting sector shows an increasing trend over the full ten years.[17] Based on this evidence, we selected the Simulation 2 set of years with the intent of contrasting the full set of full 2003-2012 period with patterns that may better reflect recent conditions in the fisheries.

[16] *Non-nearshore fixed gear*: -7.04, df = 6.5, p-value < 0.001*; bottom trawl*: t = -4.16, df = 6.3, p-value = 0.005; *shoreside whiting*: t = 2.66, df = 7.11, p-value = 0.03.

[17] *Bottom trawl*: -12.5% per year over 2008-2012, Adj. $R^2 = 0.62$, p = 0.03; *non-nearshore fixed gear sector*: -33.5% per year over 2008-2012, Adj. $R^2 = 0.67$, p = 0.04; *shoreside whiting sector*: +29.8% per year over 2003-2012, Adj. $R^2 = 0.68$, p = 0.002.

Table B-84. Years used in the two simulation scenarios and observed lognormal means and coefficients of variation for each sector.

	Scenario 1	Mean	CV	Scenario 2	Mean	CV
Bottom trawl (BT)	2003 - 2012	0.03568	44.3%	2009-2012	0.02242	33.6%
Fixed Gear (FG)		0.06583	70.3%	2009-2012	0.02806	25.5%
Catcher Processor (CP)		0.00354	272.7%	2003-2012	Same as Scenario 1	
Mothership (MS)		0.00074	136.1%	2003-2012	Same as Scenario 1	
Shoreside Whiting (SS)		0.00130	146.2%	2008-2012	0.00183	74.4%
Tribal At Sea (TAS)		0.01144	33.5%	2003-2012	Same as Scenario 1	
Tribal Shoreside (TSS)		0.00615	244.4%	2003-2012	Same as Scenario 1	

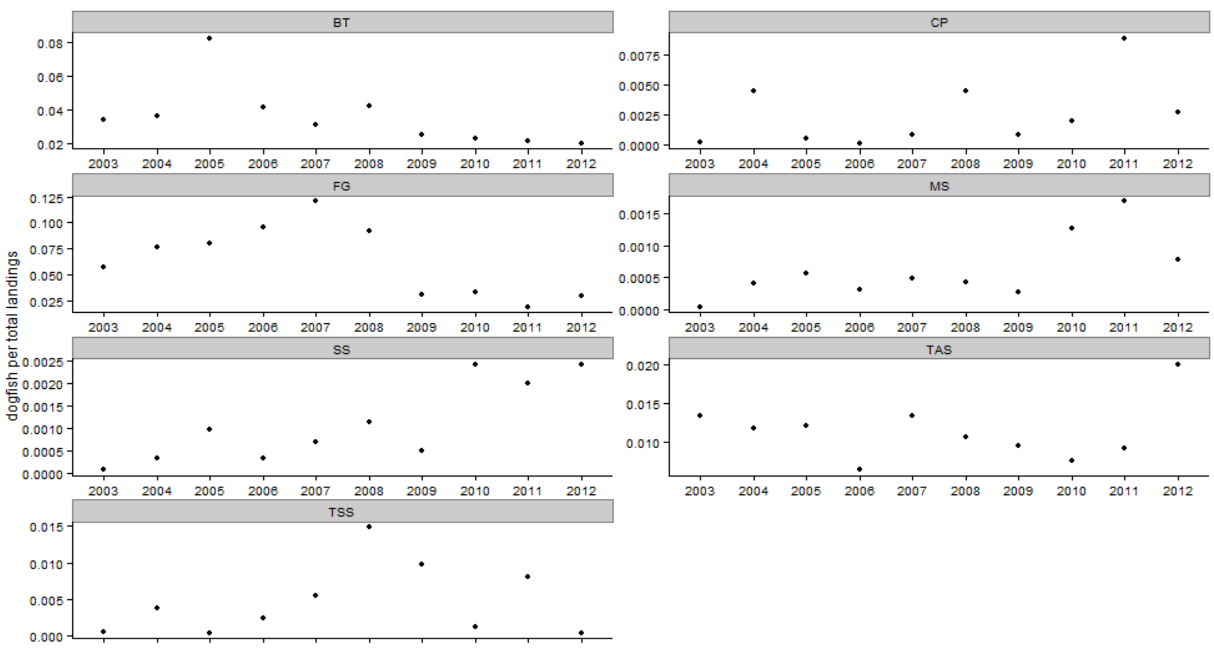

Figure B-44. Ratios of total Spiny Dogfish catch per landings of all stocks by year and sector, 2003-2012, displayed as time series. More recent years in the bottom trawl (2009-2012), non-nearshore fixed gear (2009-2012) and shoreside whiting sectors (2008-2012) show statistically significant differences from the respective early years. No such differences were detected for the other four sectors.

We also evaluated the 2003-2012 time series for correlation between sectors and for serial (a.k.a. auto-) correlation within sectors. As to the latter, the only sector showing serial correlation over 2003-2012 was the non-nearshore fixed gear sector (Durbin-Watson statistic, d = 1.079, p-value = 0.03). Serial correlation describes the situation where difference from the mean value tend follow a pattern across time (i.e. high catch years would be likely to follow one another). This would be of interest here because ACL overages could occur in streaks and mean that, in some periods, overages would occur more often the average probability of an overage would suggest. At the same time, catch would remain below the ACL for streaks as well. The serial correlation in the non-nearshore fixed gear sector is likely due to the change seen after 2008 in discarding (i.e. the above average catch ratios appear in the early part of the 2003-2012 time period and below average values in the later period). We did not attempt to incorporate the serial correlation into the simulations. Comparing Simulation 1 with Simulation 2 allows exploration of the impact of the changed discarding behavior in the sector.

As to correlation in catch among sectors, this too could make overages more likely as high catch years in sectors would tend to occur together. Evaluating the time series, statistically significant correlation did exist between the mothership and shoreside whiting sectors (r = 0.93, $p < 0.001$) over 2003-2012. And marginally significant (at the alpha = 0.05 level) moderately high positive correlation was detected between the At Sea sectors (r = 0.611, p = 0.06) and between the catcher processor sector and shoreside whiting sector (r = 0.610, p = 0.06). We explored the sensitivity of the simulations to these correlation coefficients using a multivariate random number generator. However, the results differed only by roughly 0.5 percent from the results in Simulation 1 and Simulation 2 and so are not shown here as to simplify the presentation.

Simulation Results and Discussion

The results for the No Action scenario for Simulation 1 and Simulation 2 are summarized in Table B-85. The performance metrics shown that table and the tables below include:

- *Avg. total catch (mt)*: the average annual total catch over all simulation runs.
- *% with overages*: the percentage of simulation runs were the annual total catch was greater than 1,897 mt.
- *Avg. overage amount*: the average size of overages in metric tons.
- *Avg. At Sea catch when overage*: the average total catch from the At Sea sectors in runs where there was an overage.
- *% of years At Sea catch >= Set Aside*: the percentage of runs with a total catch greater than 1,897 mt if the At Sea sector was capped e set aside amount (e.g., 163, 300, 500, 725)
- *% of years where 4-year average At Sea Catch >= 1,897*: we computed rolling averages with a window period of 4 years. This statistic reports the number of years where that rolling average was over the ACL.

Table B-85. Simulation results for the No Action scenario. See text for explanation.

	"No Action"				
	Avg. total catch (mt)	% with overages	Avg. overage amount (mt)	Avg. At Sea catch when overage (mt)	% of years where 4-year avg >= 1,187
Sim. 1	1,583	22.6%	421	566	10.9%
Sim. 2	1,212	6.5%	303	1,186	0.1%

While we do not view the simulations as providing precise forecasts, the general pattern they show suggests that overages of the ACL would occur with low to moderate frequency. Under both Simulation 1 and Simulation 2, the total catch of Spiny Dogfish remains below the Preferred Alternative ACL levels for 2015 and 2016 on average. And the frequency of overages in both Simulation 1 and Simulation 2 is lower than the level at which ACL averages of more than one per four-year period become of concern.

To elaborate, considering just the number of overages (i.e. not the magnitude of the overage), the expectation for seeing overages in a 4 year period can be evaluated as binomial probabilities. Table B-86 displays the theoretical binomial probabilities of observing 0-4 overages over a four year period for a range of probabilities of experiencing an annual overage. For example, if the probability of annual overage is 30 percent then we would expect to see exactly one overage 26.5 percent of the time over the four years. And we would expect to see more than one overage 34.8 percent of the time. Therefore, based on the frequency of annual overages in Simulation 1, we would expect to see more than 1 overage less than 20 percent of time in a four year period. And for Simulation 2, we would expect less than a 5 percent chance of seeing more than 1 overage.

The 4-year rolling average statistic reported above was also inspired by the NS1 Guidelines ACL performance standard. More than a simple count of overages, the rolling average gives some sense of the magnitude of overages and is more in line with the SSC's advice about average catch over a multi-year period being the important mark for preventing overfishing. This advice applies especially to a stock like Spiny Dogfish where the harvest control rule takes into account the stock's relatively "slow" population dynamics. Annual overages of the ACL would not be expected to affect the stock's status much. As long as catch stays at or below the ACL on average then the expectations for harvest control rule remain unaffected. As reported in Table B-85, in Simulation 1 the 4-year rolling average is above the ACL only 11 percent of the runs, and in Simulation 2, in only 0.1 percent of the runs. Under the assumptions of the simulation models, we would not expect average catch to deviate too far from the ACL.

To explore the effect of the At Sea set side, we capped the total At Sea catch at each level and calculated the same performance statistics as for the No Action scenario (Table B-87). The general impact of each set aside level can be evaluated by comparing the results to the No Action scenario and to one another. For example, if the At Sea set aside were set at 500 mt then the frequency of overages in Simulation 1 drops by around 5 percent. The other consideration shown is that the At Sea sectors reached that set aside level in roughly 14 percent of the simulation runs. Then at the 300 mt set aside scenario, the percentage of overages drops roughly 3 percent from 500 mt scenario yet the At Sea sectors reached that level in 10 percent more of the simulation runs. The GMT can expand this initial set of performance metrics if the Council wishes to explore the issue further.

Lastly, a portion of the simulation runs produced what we deemed implausibly high results (e.g., catches of Spiny Dogfish reached into the 10,000+ range). We therefore capped the highest value in the simulations at twice the observed maximum catch of Spiny Dogfish, in terms of metric ton, for each sector. The doubling of the maximum catch was thought to be a conservative assumption, yet it does affect the simulation results. As an illustration of the effect, the capping affected roughly 4 percent of the simulation runs for the catcher processor sector. While the capping affected the estimate of the average size of an overage and the average catch for each sector, we do not see much effect on the number of simulated overages. For instance, of the 100,000 runs in the base Simulation 1 only 12 of the catcher processor's capped runs were under the ACL (i.e. 0.012 percent). The GMT may further discuss this capping of the lognormal results at the April meeting.

Table B-86. Theoretical binomial probabilities for the number of overages over a four-year period at various probabilities of an annual overage (e.g., if the annual probability of an overage is 0.25 then the probability of observing more than 1 overage in four years is 26.2 percent).

	Annual prob. of an ACL overage									
Prob. of # of overages:	**0.05**	**0.10**	**0.15**	**0.20**	**0.25**	**0.30**	**0.35**	**0.40**	**0.45**	**0.50**
0	81.5%	65.6%	52.2%	41.0%	31.6%	24.0%	17.9%	13.0%	9.2%	6.3%

Sector-level Patterns and Comparing Simulation 1 and Simulation 2

As shown above, the results between Simulation 1 and Simulation 2 are markedly different. The difference is attributable largely to the changed patterns in the bottom trawl and fixed gear sectors. The magnitude and variability of catch in both to decrease substantially in Simulation 2 as can be seen by comparing the distributions of simulation runs shown in Figure B-45 and Figure B-46. Looking to the bottom trawl sector, the median simulated catch hardly shifts in Simulation 2 (Figure B-45) relative to Simulation 1 (Figure B-46).

The catcher processor sector, in comparison, shows much larger differences in Simulation 2 than Simulation 1 demonstrating that catch in that sector is largely responsible for overage years in Simulation 2. In overage years, the 25th percentile of simulated catcher processor catches is above 1,000 mt. And a large portion of the catcher processor simulated catches in overage years is pushed up against the level at which catch for the sector was capped. This suggests that in the conditions modeled in Simulation 2 extreme catch events in the catcher processor sector are largely what drive total catch above the ACL. Yet overages are less than half as frequent in Simulation 2 as they are in Simulation 1, again, because of the major differences in the mean and standard deviations used for the bottom trawl and non-nearshore fixed gear sectors.

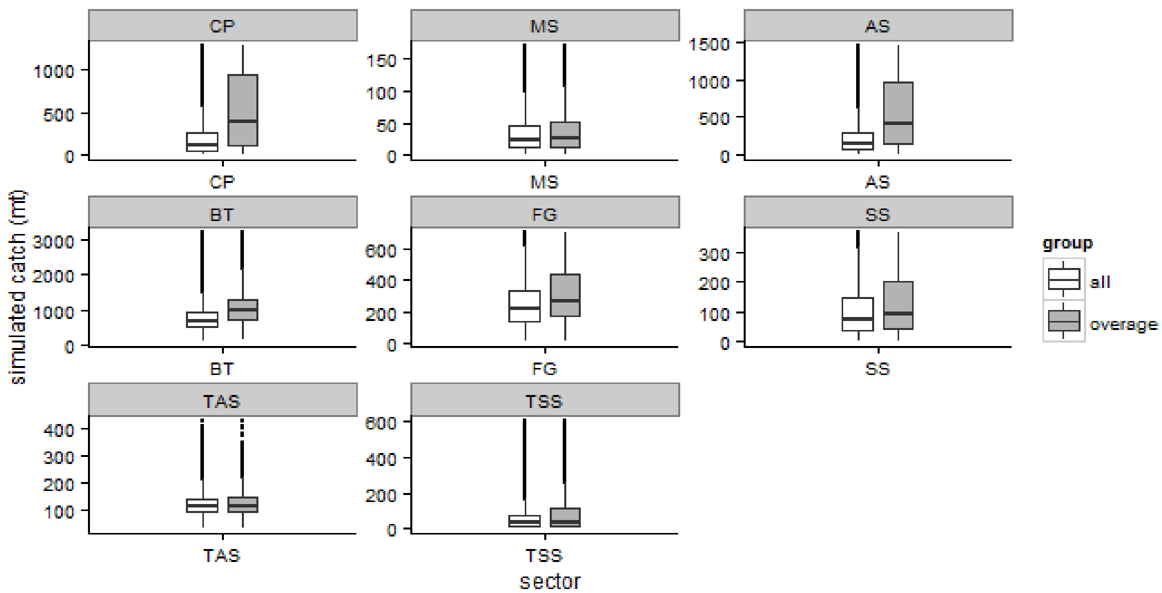

Figure B-45. Simulated catches by sector, including the At Sea sectors combined, for Simulation 1. The shaded boxes include only the simulation runs where the total catch was over the proposed ACL. See Figure B-43 for explanation of boxplots.

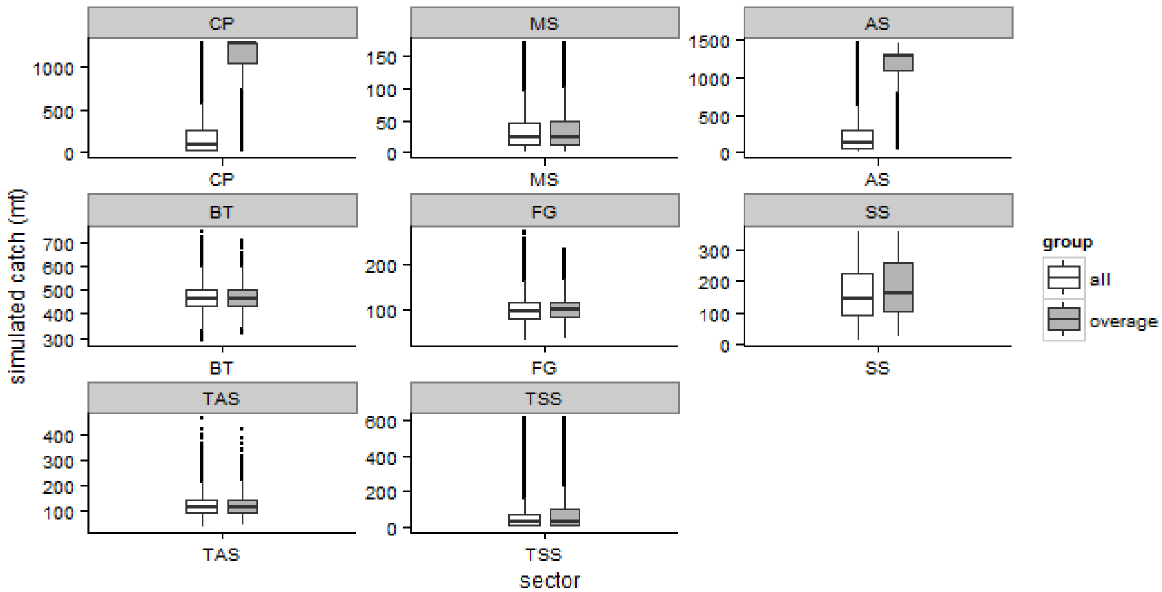

Figure B-46. Simulated catch by sector, including the At Sea sectors combined, for Simulation 2. The shaded boxes include only the simulation runs where the total catch was over the proposed ACL. See Figure B-43 for explanation of boxplots.

Other Analyses Explored

The results presented here are based on the idea that Spiny Dogfish catch in each sector follows a lognormal distribution following the means and standard deviations observed in the past. We also explored using the Gamma probability distribution as the basis for the simulations. The Gamma distribution is also commonly used where coefficients of variation are greater than 50 percent.[18] Without capping the simulated catches as was done in Simulation 1 and Simulation 2, the gamma based simulation using all 2003-2012 observations showed 19 percent of the runs reaching the overage level. This is largely consistent with the Simulation 1 results.

The Gamma and lognormal distributions assume that high catch events are less likely to occur than events closer to the mean. To explore sensitivity to that assumption, we also consider basing the simulations on uniform probability distributions where observed catches were as likely to occur in a year as any other. This approach also showed results that were consistent with Simulation 1 with overages occurring in ~17 percent of the runs. The implied assumption is that annual catch in each sector could be no larger than already observed. While this may be problematic when evaluating sector-level simulated catches, when focused on total catch across all sectors the method is akin to the widely used bootstrap method for evaluating uncertainty in data where the probability distribution is unknown. Again, however, all are based on the assumption that the future will continue to follow the same pattern as in the past.

Lastly, while we did not run multiple simulations to explore the sensitivity to the assumed whiting catches to which the simulated catch ratios are applied, we did explore the issue for the At Sea sectors using the bootstrap methods for calculating confidence intervals. The results are reported in Table B-88 and displayed graphically in Figure B-47 and Figure B-48. The bootstraps and confidence intervals were

[18] Benjamin M. Bolker, Ecological Models and Data in R (2005).

computed using the boot package in R.[19] As in the simulations, the ratios were assumed to follow a lognormal distribution (i.e. the bootstrap replicates calculated the lognormal mean). The confidence intervals shown in Table B-88 were calculated with the BCa method.[20] As that table shows, large whiting catches can push the expected Spiny Dogfish catch higher with the upper 95th percentile intervals skewed high. Initial explorations of the data did not show a statistically significant relationship between total whiting catch and the ratio of Spiny Dogfish catch to total whiting catch (i.e. the average bycatch ratio does not appear to change as a function of how much whiting is caught).

The GMT can incorporate different assumptions about the whiting catch in each sector at or after the April meeting after the 2015 Total Allowable Catch for whiting is determined.

Table B-88. Bootstrap 95 percentile confidence intervals for the ratio of Spiny Dogfish to whiting catch in the catcher processor and mothership sectors applied to four levels of possible whiting catches. See text for explanation.

Conclusion

Choosing sector set asides for Spiny Dogfish in such circumstances of high catch variability is challenging compared to situations when catch is stable relative to average levels. These simulations were intended to given the Council a thorough evaluation of variability in catch and how that variability affects: (1) the probability that the Spiny Dogfish will be exceeded and (2) how often the At Sea sector might be expected to reach given levels of an At Sea set aside. The simulation results suggest that the At Sea sectors, mainly the catcher process sector, are major contributors to the risk of ACL overages. However, the simulations also suggest that the risk should be weighed against the variability of catch seen in other sectors with the bottom trawl and non-nearshore fixed gear sectors in particular. If the catches observed in those sectors over 2009-2012 are indicative of what is likely to occur in 2015-2016, then the likelihood of a Spiny Dogfish ACL overage would be low. The GMT may discuss these results and further advise the Council at the April meeting.

B.16 Trawl: Use of excluder devices to reduce catch of rougheye rockfish in non-tribal at-sea and shoreside Pacific whiting fisheries

This analysis evaluates the potential mandatory use of excluder devices for reducing the catch of rougheye rockfish in the non-Tribal at-sea and shoreside Pacific whiting trawl sectors. Alternatives ranged from mandatory use for all trips north of 40° 10′ N latitude, to mandatory use only within limited areas (e.g., areas with highest rougheye rockfish catches). Although this analysis shows that use of excluder devices in these midwater Pacific whiting trawl sectors may reduce the catch of rougheye rockfish, it also shows that these reductions alone may not be enough to prevent exceeding the 2015 component OFL. Numerous assumptions were necessary to perform this analysis. Guidance is sought from various advisory groups (e.g., SSC, GAP, and EC) and the Council regarding these assumptions and to further refine this analysis.

Overview

The National Marine Fisheries Service (NMFS) recommended that the Council analyze removing or reorganizing blackgill, rougheye, and shortraker rockfishes from the minor slope complexes (north and south) because recent average catches (2007-2012) would have exceeded the 2015 OFL contributions for these component species (Agenda Item H.4.b, Supplemental NMFS Report, November 2013). The NMFS believed that management measures applied to address these OFL-contribution overages without removing these species from or reorganizing the slope rockfish complexes may be unnecessarily disruptive to fisheries and result in more complicated regulations. Subsequent Council discussion during the November 2013 meeting resulted in motions to analyze various management measures for reducing catch of rougheye rockfish by west coast commercial fisheries. If proven effective, some of these management measures may reduce the catch of rougheye rockfish (and other slope-rockfish species) with or without removing them from the complexes. One motion was to evaluate the use of excluder devices to reduce the catch of rougheye rockfish in shoreside and at-sea Pacific whiting fisheries (PFMC, Motion 30, November 2013). This analysis focuses on that motion. A hot-spot analysis, designed to identify areas with high catch ratios of rougheye-to-Pacific whiting is also included within this group of management measures, see above. These analyses may be considered collectively.

Background

This report focuses on reducing catch of rougheye rockfish in the non-Tribal at-sea and shoreside-whiting fisheries using bycatch reduction devices (BRDs) that are commonly referred to as excluder devices (e.g., mesh or grid ramps installed in trawls that lead to escape windows). Use of excluder devices to reduce catch addresses species selectivity based on a gear change (i.e., a change in fishing gear that promotes differential selectivity for different species). In this case, the theory is that trawl-gear modifications (e.g., the installation of excluder devices and escape windows) may reduce the catch of rougheye rockfish while minimizing escapement (or loss) of Pacific whiting.

Excluder Devices (general)

Excluder devices, along with escape windows, may be installed in trawls to “sort” fish (and invertebrates) by size and/or species while towing at fishing depth. These devices may take on various designs and shapes, such as rigid or flexible grids/grates/meshes, that “block” the trawl somewhere in front of the codend (e.g., at the fore end of the intermediate), thereby forcing larger individuals or species out of the net through escape windows (e.g., at the top of the trawl) while allowing smaller individuals or species to pass between the bars or meshes and into the codend. Some examples of excluder devices include those placed in shrimp trawls to exclude fishes (Hannah and Jones 2007), bottom trawls to exclude Pacific halibut while retaining groundfish (Lomeli and Wakefield 2013a, 2014), bottom trawls to exclude rockfishes and large roundfishes (e.g., sablefish) while retaining flatfishes (Lomeli (PSMFC) and Wakefield (NMFS-NWFSC), personal communication), and pelagic trawls to exclude salmon and rockfish while retaining most Pacific whiting (Lomeli and Wakefield 2012).

Excluder Devices Tested in Pacific Whiting Fisheries
Initial Trial: Lomeli and Wakefield (2012) described two excluder-device designs that were developed to increase escapement of rockfish and salmon while maintaining the catch of Pacific whiting in pelagic trawls. Although results of this study suggested the potential of these designs for reducing Chinook salmon bycatch, the designs were less effective for reducing the catch of widow rockfish. In addition, the authors described other limitations to this study that included small sample sizes of bycatch species and fishing under non-commercial conditions (i.e., trials were primarily conducted with the terminal end of the codend open).

Second Trial with Improved Results: A pilot study was conducted in 2013 that implemented recommendations made at a collaborative workshop by vessel owners, captains and crew, seafood company operators, regional net manufacturers, and gear researchers (Lomeli and Wakefield 2013b). The workshop participants concluded that a flexible sorting grid showed most promise for an excluder device designed for reducing rockfish bycatch from pelagic trawls targeting Pacific whiting.

The pilot study (Lomeli and Wakefield 2013b) was conducted during 2012 off Oregon and Washington on board a commercial trawl vessel. Results were relatively successful: one design (Design-B) retained a relatively high proportion of Pacific whiting (>93 percent by weight) while reducing the catch of rougheye rockfish by 95 percent, widow rockfish by 83 percent, and yellowtail rockfish by 69 percent (by weight). Note that although the size (length) of Pacific whiting was similar for retained and “escaped” individuals, Pacific whiting encountered during the study were relatively small (mean fork lengths ranged from 36.4 to 40.0 grams, approximately 300 gram fish).

It is important to note that Lomeli and Wakefield (2013b) showed that excluder designs used during this trial were effective only under low-to-moderate fish volumes. When whiting volumes were large, the designs tended to clog and the hauls were aborted early. Tows in this fishery may exhibit catch volumes exceeding 75 mt in less than 30 minutes. For these cases, the excluder design described by Lomeli and Wakefield (2013b) may be ineffective at reducing rougheye rockfish bycatch while maintaining catch levels of target species. This excluder design may be useful for Pacific whiting fishermen during low-to-moderate catch rates, but the authors noted that further refinement of the excluders would be needed to properly function under heavy fish volumes.

Third Trial - Most Promising Results: Additional sea trials were conducted in 2013 to evaluate a new BRD design (Design C) developed to exclude rockfish from pelagic trawls targeting Pacific whiting (Lomeli and Wakefield 2013c; personal communication). During these trials, widow rockfish was the primary rockfish species caught. Results showed their overall bycatch was reduced 26.6 percent by weight. The retention of Pacific whiting was 92.3 percent by weight. Single haul catches of Pacific whiting ranged from 40 to 100 mt. Catches producing over 90 mt of Pacific whiting were observed for haul durations less than 2.5 hours. However, clogging would occur under heaviest fish volumes (i.e., when over 90 mt of Pacific whiting were caught in less than 45 minutes of towing). This excluder design could potentially be useful for Pacific whiting fishermen during moderate-to-high catch rates, but further refinement of the excluder would be needed to properly function under heavy fish volumes.

It was unfortunate that rougheye rockfish and other rockfish species larger than widow rockfish were not encountered during the 2013 trials. The authors of this study suggest that escapement would likely be higher than 26.6 percent for rougheye and other rockfish species that are larger than widow rockfish. Further refinements and testing are needed to improve the performance of this excluder-device design under highest fish volumes (i.e., > 90 mt in less than 45 minutes of towing).

Catch of Rougheye Rockfish – By sector

In order to evaluate any potential effect of this measure to rougheye rockfish mortality, the average catch by sector north of 40° 10´ N latitude was calculated using 2008-2012 WCGOP data (Table B-89). Using these data, non-Tribal at-sea whiting and shoreside whiting catch represent 18.8 percent and 4.7 percent (totaling 23.5 percent) of the rougheye rockfish catch across all sectors. The annual average catch of rougheye rockfish for these sectors combined was 58.8 mt north of 40° 10´ N latitude. Of this 58.8 mt caught by non-Tribal whiting fisheries, 80.1 percent was caught by the at-sea sectors while 19.9 percent was caught by the shoreside whiting fishery. Note that for some cases, inter-annual variation is high within sectors (Table B-89).

Table B-89. Five-year average, minimum, and maximum mortality (mt; 2008-2012) of rougheye rockfish by sector. Data were from WCGOP and includes retained and discarded fish. Note that some landings included a rougheye/shortraker combined category. These combined landings had little effect on sector-specific results, except for the Non-nearshore Fixed Gear sector, where average catch was 72.0 mt (including the rougheye/shortraker category) and 55.9 mt (without the rougheye/shortraker category). These landings do not include blackspotted rockfish.

Sector	5-year Average Catch (mt; 2008-2012)	Min – Max (mt; 2008-2012)
Incidental	0.9	0.3 – 2.2
LE shoreside trawl	90.2	47.7 – 143.8
IFQ Fixed Gear (2011-2012)	18.7	15.6 – 21.7
Nearshore Fixed Gear	0.1	0.0 – 0.05
Non-nearshore Fixed Gear	72.0	41 – 89.1
Non-Tribal At-Sea Pacific Whiting	47.1	8.7 – 78.6
Pink Shrimp	0.0	0 – 0.02
Shoreside Pacific Whiting	11.7	0.6 – 47.1
Tribal At-Sea Pacific Whiting	1.2	0 – 2.9
Tribal shoreside trawl	19.7	15.2 – 33.5

Area of Rougheye Catch by the Non-Tribal At-Sea Whiting Fishery

Table B-89 provides an example of an ongoing analysis intended to identify areas where high or low values of rougheye catch may be clustered spatially during the 2002-2012 time period. More refined results of this analysis and more detail about the methods can be found in section B.13 herein. In Figure B-49, any rougheye rockfish caught on a haul was attributed to a point location, the midpoint of that haul, and hauls that did not catch rougheye were excluded. These points were then evaluated spatially to determine whether there were areas where high catch levels of rougheye were clustered. Figure B-49 shows areas where higher levels of catch are clustered (boxes outlined in green) seaward of 150 – 200 fm and north of the Oregon-Washington border. The largest area with higher catch densities is north of 47^{o} 30' N latitude. Areas with moderate catch densities (empty boxes) are generally seen off the Oregon coast. Areas where lower levels of catch are clustered (boxes outlined in purple) were found to occur south of the Oregon-California border. Relative catch densities of Pacific whiting are also shown in Figure B-49, with highest densities occurring in areas with the darkest shading. Pacific whiting catch is typically highest off of northern Washington and numerous areas along the Oregon coast.

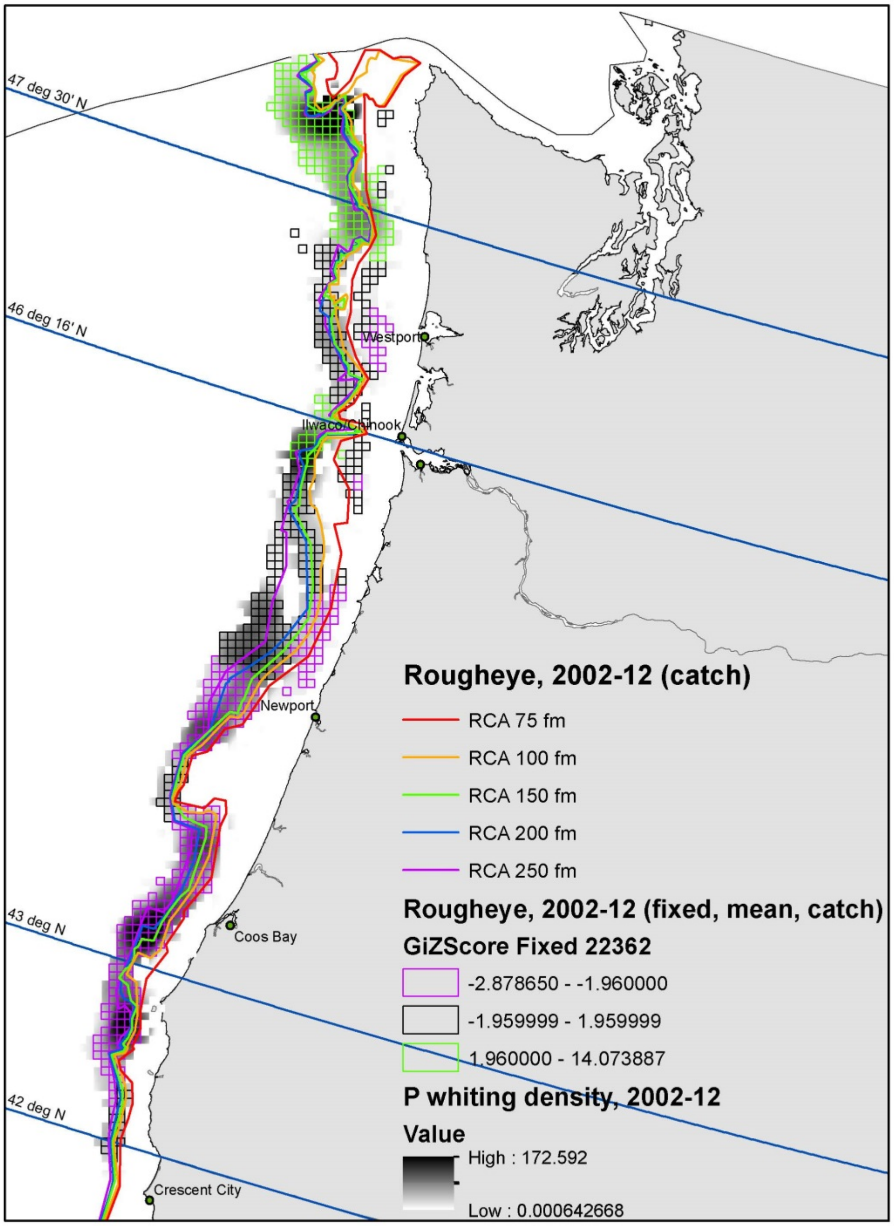

Figure B-49. Catch of rougheye rockfish north of 40° 10´ N latitude by the non-Tribal at-sea whiting sector. Data were acquired from NORPAC (2002-2012). Areas where high levels of catch are clustered are shown by the boxes outlined in green (i.e., north of 47° 30´ N latitude; z-scores greater than or equal to 1.96), moderate catches are shown by the empty boxes, and areas of low catches are shown as boxes outlined in purple (z-scores less than or equal to -1.96). Density plots of Pacific whiting catch are shown in the background (i.e., darkest = highest catch of target species).

More recent catches for rougheye rockfish and Pacific whiting (2008-2012) are shown by depth and area for the non-tribal at-sea whiting sectors (2008-2012) in Table B-90 and Table B-91, respectively. During these years, most rougheye rockfish were caught between 200 fm and 400 fm by the at-sea sectors (Table B-89). Conversely, most whiting catch was also caught over bottom depths ranging from 200 fm and 400 fm (Table B-91). Similar to that shown in Table B-89, although most rougheye rockfish catch by the non-Tribal at-sea whiting sectors occurred off the Washington coast (81.8 percent; Table B-90), whiting catches by these sectors were more evenly distributed between Washington (46.6 percent) and Oregon (51.5 percent; Table B-91).

Table B-90. Rougheye rockfish catch (2008-2012) by area and depth for non-Tribal at-sea Pacific whiting sectors, north of 40° 10′ N. latitude. Average catch (mt) and percentage of catch are shown by depth and area. Data were acquired from NORPAC and include only one code for rougheye rockfish. NoCAL = California north of north of 40° 10′ latitude; NoWA = Washington north of 47° 30′ N. latitude; SoWA = Washington between the Oregon-Washington border and 47° 30′ N. latitude.

Management Options

Data shown above was used to evaluate alternatives. The baseline catch (mt) for rougheye rockfish north of 40° 10´ N latitude is shown in Table B-89 for non-Tribal at-sea sectors (47.1 mt) and the shoreside whiting sector (11.7 mt). Proportions of rougheye rockfish catch shown in Table B-90 B were then applied to both the non-Tribal shoreside whiting and at-sea whiting catches (Table B-89) to estimate the contribution of catches by depth and area. Although these percentages were based only on at-sea sector catches, we applied them to the shoreside whiting sector to estimate their catch by area and depth. We were unable to analyze depth- and area-specific WCGOP data for the shoreside whiting sector prior to the deadline for this analysis. If requested by the Council, we can provide more accurate depth-area catches of rougheye rockfish for the shoreside whiting sector by June.

Since shoreside whiting is part of the shoreside IFQ sector (IFQ whiting and non-whiting trawl; IFQ fixed gear), for this analysis, we assumed that vessels declaring Pacific whiting mid-water trawl were part of the shoreside-whiting "sector".

For the action alternatives, we assumed that reductions of rougheye rockfish catch when using excluder devices would be similar among all non-Tribal whiting sectors (i.e., non-Tribal shoreside whiting and non-Tribal at-sea whiting sectors).

Lomeli and Wakefield (2013b; personal communication) provided two "rougheye rockfish escapement percentages", depending on gear design and trial (see above). The most effective design resulted in a 95 percent reduction of rougheye rockfish catch (Lomeli and Wakefield, 2013b); however, that design was prone to clogging at high Pacific whiting catch rates. A second design showed 26.6 percent reduction in catch of widow rockfish, even under high catch rates of Pacific whiting (Lomeli and Wakefield 2013c; personal communication). Unfortunately these latter trials were conducted in areas with no rougheye rockfish. It is likely that exclusion of rougheye rockfish would have been greater than that shown by widow rockfish, because rougheye are typically larger. Hence, for this analysis, we assumed that rougheye rockfish reduction would be 50 percent for non-Treaty at-sea whiting and shoreside whiting sectors (which is between 26.6 percent and 95 percent, but weighted closer to the lower escape percentage). This analysis will assume that that the excluder design (and specifications) are similar to that shown by Lomeli and Wakefield (2013c; personal communication) during the third trial. Specifications for the most appropriate design can be provided by Lomeli (PSMFC) and Wakefield (NOAA).

No Action: Midwater trawl design would be implemented as specified in current regulations, and would be allowed in all areas and periods specified in current regulations. Declaration reports would also be filed as shown in current regulations.

Current regulations do not preclude the use of excluder devices and escape windows by any trawl fishery along the U.S. west coast. Hence, under No Action, excluder devices may be used voluntarily by any of the trawl sectors, if so desired. This voluntary action may reduce the catch of rougheye rockfish by midwater trawl sectors targeting Pacific whiting without additional regulation. However, for this analysis, it is assumed that voluntary use of excluder devices in the various Pacific whiting trawl sectors does not occur, and that fishing behavior will emulate that seen during 2008-2012. It is likely that some voluntary use will occur, and that fishing behavior may change in 2015-2016 relative to the recent past. These changes cannot be easily quantified, however, and are therefore not included in this analysis.
Under no action, it is assumed that the 5-year average (2008-2012) catch of rougheye rockfish will occur, with no impact to whiting catch (Table B-92).

Table B-92. Projected rougheye rockfish catch (mt) under No Action. Catch was estimated as the 5-year average (2008-2012) from WCGOP data.

Variable	Non-Tribal At-Sea Whiting	Non-Tribal Shoreside Whiting	Total
Rougheye Rockfish Catch (mt)	47.1	11.7	58.8 mt
Relative Impact to Whiting Fisheries	None	None	

Option 1 (most restrictive): For all non-Tribal midwater whiting trawl sectors for the area North of 40^{o} 10´ N. latitude, the current regulations would be modified as follows:

(1) The midwater trawl design, as specified under current regulations, would be modified to require excluder devices and escape windows while fishing for Pacific whiting, to increase escapement of rockfish (including rougheye rockfish) while minimizing escapement of Pacific whiting. Specifications to be provided at a later date through consultations with Dr. Waldo Wakefield (NOAA) and Mr. Mark Lomeli (PSMFC), fishing industry representatives, and net manufacturers.
(2) Non-Tribal midwater whiting fisheries (all sectors) shall be allowed in all areas and periods as specified in current regulations, with trawl modifications described in Option 1, (1) above.
(3) Declaration reports would be filed as shown in current regulation.

Under Option 1, it is assumed that 50 percent of the rougheye rockfish encountered by non-Tribal whiting fisheries would escape at fishing depth and survive. Hence, rougheye rockfish catch by these sectors would be 50 percent lower than the 5-year average (or 29.4 mt; Table B-93).

This action would result in some loss of Pacific whiting during each haul (see Lomeli and Wakefield, 2013b,c), and therefore, additional fishing effort (numbers of hauls) may be needed to fully attain quotas. Lomeli and Wakefield (2013c; personal communication) showed that up to 8 percent of Pacific whiting encountered may escape the trawl when using excluder devices, if clogging does not occur. Hence this action may increase towing duration (or number of tows) required to achieve whiting allocations by at least 8 percent. This is likely a low estimate, because a much higher percentage of Pacific whiting might escape the trawl at fishing depth (or released (bled) from the trawl at the surface) when clogging of the excluder device occurs. Finally, although it is uncertain how much fishing time may be lost due to handling and repair requirements when using excluder devices, impacts would be highest under this alternative (Table B-93).

Table B-93. Projected rougheye rockfish catch (mt) under Option 1, where excluder devices would be used for all non-Tribal whiting trips (at-sea and shoreside) north of 40° 10′ N. latitude. Rougheye rockfish catch was estimated as 50 percent of the 5-year average (2008-2012; WCGOP data). Pacific whiting loss may be > 8 percent per haul. Potential impact to whiting fisheries is demonstrated by number of negative symbols (largest impact = most negative symbols); this measure is subjective.

Variable	Non-Tribal At-Sea Whiting (mt)	Non-Tribal Shoreside Whiting (mt)	Total Catch (mt)
Rougheye Rockfish Catch (mt)	23.5	5.9	29.4
Relative Impact to Whiting Fisheries	(----)	(----)	

Option 2: For all non-Tribal midwater whiting trawl sectors and the area North of 40° 10′ N. latitude, if any fishing occurs between the 200 fm RCA and 400 fm "GCA" (to be specified at a later date), then the current regulations would be modified as follows:

(1) The midwater trawl design, as specified under current regulations, would be modified to require excluder devices and escape windows while fishing for Pacific whiting, to increase escapement of rockfish (including rougheye rockfish) while minimizing escapement of Pacific whiting. Specifications to be provided at a later date through consultations with Dr. Waldo Wakefield (NOAA) and Mr. Mark Lomeli (PSMFC), fishing industry representatives, and net manufacturers.
   a. Midwater trawl specifications shown in current regulations (unmodified) would be allowed only if fishing occurred outside of the 200 fm – 400 fm "GCA" (to be determined at a later date) for all hauls during a Pacific whiting declared trip.

(2) Non-Tribal midwater whiting fisheries (all sectors) would be allowed during all periods specified under current regulations, with the additional restrictions shown in Option 2, (1) above.

(3) Declaration reports would be filed as shown in current regulation, but modified to identify the intent of fishing within the "GCA" with an excluder.

Under Option 2, it is assumed that 50 percent of the rougheye rockfish encountered by non-Tribal whiting fisheries when using excluder devices would escape at fishing depth and survive. The highest estimate of rougheye rockfish mortality under this scenario would be to assume that all fishing within the 200 – 400 fm "GCA" north of 40° 10′ N. latitude is conducted with excluder devices installed (and these trips would not venture outside of the "GCA"). Consequently, it follows that all sets made outside of the "GCA" would be conducted without an excluder device. In actual practice, those declaring to fish inside the "GCA" with an excluder would likely make some tows outside of the GCA with the excluder during the same trip. In addition, it is likely that some individuals may voluntarily use excluders even if no hauls are made inside a "GCA". Hence, under the worst-case scenario (i.e., reductions only applied to rougheye catch inside the "GCA"), 33.6 mt of rougheye rockfish would be caught (Table B-94): 26.9 mt by the at-sea whiting sectors and 6.7 mt by the shoreside whiting trips (see Table B-90 for proportions among sectors).

This action would result in some loss of Pacific whiting during each haul when excluders are used (see Lomeli and Wakefield, 2013b,c), and therefore, additional fishing effort (numbers of hauls) may be required to fully attain the whiting quota. Lomeli and Wakefield (2013c; personal communication) showed that up to 8 percent of Pacific whiting encountered may escape the trawl when using excluder devices, if clogging does not occur. Table B-91 shows that 69.6 percent of the Pacific whiting is caught between 200 and 400 fm. Hence this action may increase towing duration (or number of tows) required to achieve whiting allocations by at least 5.6 percent (on average across all areas and depths). This is likely a low estimate, because a much higher percentage of Pacific whiting will escape the trawl when clogging of the excluder device occurs. In addition, some hauls will likely be made outside of the 200 – 400 fm "GCA" with the excluder device installed. Finally, it is uncertain how much fishing time may be lost due to handling and repair requirements when using excluder devices, but this additional impact is likely (Table B-94).

Table B-94. Projected rougheye rockfish catch (mt) under Option 2, where excluder devices would be used for non-Tribal whiting trips (at-sea and shoreside) made between 200 – 400 fm and north of 40^{o} 10′ N. latitude. Rougheye rockfish catch was estimated as 50 percent of the 5-year average (2008-2012; WCGOP data) when excluder devices were used, and 100 percent of the 5-year average when excluder devices were not used. Projected rougheye rockfish catch is divided between at-sea whiting (80.1 percent) and shoreside whiting (19.9 percent). Pacific whiting loss may be > 5.6 percent per haul (on average for all depths combined). Potential impact to whiting fisheries demonstrated by number of negative symbols (largest impact = most negative symbols); this measure is subjective.

Variable	Non-Tribal At-Sea Whiting (mt)	Non-Tribal Shoreside Whiting (mt)	Total Catch (mt)
Rougheye Rockfish Catch (mt)	26.9	6.7	33.6
Relative Impact to Whiting Fisheries	(--)	(--)	

Option 3: For all non-Tribal midwater whiting trawl sectors, if any fishing occurs between the 200 fm RCA and 400 fm GCA (to be specified at a later date) and north of 46^{o} 16′ N. latitude, then the current regulations would be modified as follows:

(1) The midwater trawl design, as specified under current regulations, would be modified to require excluder devices and escape windows while fishing for Pacific whiting, to increase escapement of rockfish (including rougheye rockfish) while minimizing escapement of Pacific whiting. Specifications to be provided at a later date through consultations with Dr. Waldo Wakefield (NOAA) and Mr. Mark Lomeli (PSMFC), fishing industry representatives, and net manufacturers.
   a. Midwater trawl specifications shown in current regulations (unmodified) would be allowed only if fishing occurred outside of the 200 fm – 400 fm "GCA" (to be determined at a later date) for all hauls during a Pacific whiting declared trip.

(2) Non-Tribal midwater whiting fisheries (all sectors) would be allowed during all periods specified under current regulations, with the additional restrictions shown in Option 3, (1) above.

(4) Declaration reports would be filed as shown in current regulation, but modified to identify the intent of fishing within the "GCA" with an excluder.

Under Option 3, it is assumed that 50 percent of the rougheye rockfish encountered by non-Tribal whiting fisheries when using excluder devices would escape at fishing depth and survive. The highest estimate of rougheye rockfish mortality under this scenario would be to assume that all fishing within the 200 – 400 fm "GCA" north of 46^{o} 16′ N. latitude would be conducted with excluder devices installed (and these trips would not venture outside of the "GCA"). Consequently, it follows that all sets made outside of the "GCA" would be conducted without an excluder device. In actual practice, those declaring to fish inside the "GCA" off Washington with an excluder would likely make some tows outside of the GCA with the excluder during the same trip. In addition, it is likely that some individuals may voluntarily use excluders even if no hauls are made inside of a "GCA". Hence, under the worst-case scenario (i.e., reductions only applied to rougheye catch inside the "GCA"), 38.0 mt of rougheye rockfish would be caught (Table B-95): 30.4 mt by the at-sea whiting sectors and 7.6 mt by the shoreside whiting trips (see Table B-90 for proportions among sectors).

This action would result in some loss of Pacific whiting during each haul that excluder devices were used (see Lomeli and Wakefield, 2013b,c), and therefore, additional fishing effort (numbers of hauls) may be required to catch quotas. Lomeli and Wakefield (2013c; personal communication) showed that up to 8 percent of Pacific whiting encountered may escape the trawl when using excluder devices, if clogging does not occur. Table B-91 shows that 29 percent of the Pacific whiting is caught north of 46° 16′ N latitude and between 200 and 400 fm. Hence this action may increase towing duration (or number of tows) required to achieve whiting allocations by at least 2.3 percent (on average across all areas and depths). This is likely a low estimate, because a much higher percentage of Pacific whiting will escape the trawl when clogging of the excluder device occurs. In addition, some hauls will likely be made outside of the 200 – 400 fm "GCA" when fishing north of 46° 16′ N latitude with the excluder device installed. Finally, it is uncertain how much fishing time may be lost due to handling and repair requirements when using excluder devices, but this additional impact is likely (Table B-95).

Table B-95. Projected rougheye rockfish catch (mt) under Option 3, where excluder devices would be used for non-Tribal whiting trips (at-sea and shoreside) made between 200 – 400 fm for declared trips north of 46° 16′ N. latitude. Rougheye rockfish catch was estimated as 50 percent of the 5-year average (2008-2012; WCGOP data) when excluder devices were used, and 100 percent of the 5-year average when excluder devices were not used. Projected rougheye rockfish catch is divided between at-sea whiting (80.1 percent) and shoreside whiting (19.9 percent). Pacific whiting loss may be > 2.3 percent per haul (on average for all depths combined). Potential impact to whiting fisheries demonstrated by number of negative symbols (largest impact = most negative symbols); this measure is subjective.

Variable	Non-Tribal At-Sea Whiting (mt)	Non-Tribal Shoreside Whiting (mt)	Total Catch (mt)
Rougheye Rockfish Catch (mt)	30.4	7.6	38.0
Relative Impact to Whiting Fisheries	(-)	(-)	

Option 4: For all non-Tribal midwater whiting trawl sectors, if any fishing occurs north 47° 30′ N. latitude (all depths), then the current regulations would be modified as follows:

(1) The midwater trawl design, as specified under current regulations, would be modified to require excluder devices and escape windows while fishing for Pacific whiting, to increase escapement of rockfish (including rougheye rockfish) while minimizing escapement of Pacific whiting. Specifications to be provided at a later date through consultations with Dr. Waldo Wakefield (NOAA) and Mr. Mark Lomeli (PSMFC), fishing industry representatives, and net manufacturers.

   a. Any declared trips south 47° 30′ N. latitude (where all tows during the declared trips would be made) would not require a rockfish excluder.

(2) Non-Tribal midwater whiting fisheries (all sectors) would be allowed during all periods specified under current regulations, with the additional restrictions shown in Option 4, (1) above.
(3) Declaration reports would be filed as shown in current regulation, but modified to identify the intent of fishing within the "GCA" with an excluder.

Under Option 4, it is assumed that 50 percent of the rougheye rockfish encountered by non-Tribal whiting fisheries when using excluder devices would escape at fishing depth and survive. The highest estimate of rougheye rockfish mortality under this scenario would be to assume that all fishing within "GCA" (i.e., north of 46^{o} 16´ N. latitude) would be conducted with excluder devices installed (and these trips would not venture outside of the "GCA"). Consequently, it follows that all sets made outside of the "GCA" would be conducted without an excluder device. In actual practice, those declaring to fish inside the "GCA" off Washington with an excluder would likely make some tows outside of the "GCA" with the excluder during the same trip. In addition, it is likely that some individuals may voluntarily use excluders, even if no hauls are made inside a "GCA". Hence, under the worst-case scenario (i.e., reductions only applied to rougheye catch inside of "GCAs"), 38.6 mt of rougheye rockfish would be caught (Table B-96): 30.9 mt by the at-sea whiting sectors and 7.7 mt by the shoreside whiting trips (see Table B-90 for proportions among sectors).

This action would result in some loss of Pacific whiting during each haul that excluder devices were used (see Lomeli and Wakefield, 2013b,c), and therefore, additional fishing effort (numbers of hauls) may be required to catch quotas. Lomeli and Wakefield (2013c; personal communication) showed that up to 8 percent of Pacific whiting encountered may escape the trawl when using excluder devices, if clogging does not occur. Table B-91 shows that 32.6 percent of the Pacific whiting is caught north of 47^{o} 30´ N latitude at all depths. Hence this action may increase towing duration (or number of tows) required to achieve whiting allocations by at least 2.6 percent (on average across all areas and depths). This is likely a low estimate, because a much higher percentage of Pacific whiting will escape the trawl (or be released (bled) from the trawl at the surface) when clogging of the excluder device occurs. In addition, some hauls will likely be made outside "GCA" with the excluder device installed. Finally, it is uncertain how much fishing time may be lost due to handling and repair requirements when using excluder devices, but this additional impact is likely and would be lowest among the action alternatives (Table B-96).

Table B-96. Projected rougheye rockfish catch (mt) under Option 4, where excluder devices would be used for non-Tribal whiting sector (at-sea and shoreside) trips declared north of 47^{o} 30´ N. latitude (all depths). Rougheye rockfish catch was estimated as 50 percent of the 5-year average (2008-2012; WCGOP data) when excluder devices were used, and 100 percent of the 5-year average when excluder devices were not used. Projected rougheye rockfish catch is divided between at-sea whiting (80.1 percent) and shoreside whiting (19.9 percent). Pacific whiting loss may be > 2.6 percent per haul (on average for all depths combined). Potential impact to whiting fisheries demonstrated by number of negative symbols (largest impact = most negative symbols); this measure is subjective.

	Non-Tribal At-Sea Whiting (mt)	Non-Tribal Shoreside Whiting (mt)	Total Catch (mt)
Rougheye Rockfish Catch (mt)	30.9	7.7	38.6
Relative Impact to Whiting Fisheries	(-)	(-)	

Biological Impacts
This analysis demonstrated that rougheye rockfish caught by non-Tribal at-sea and shoreside Pacific whiting sectors may range from 58.8 mt (No Action) to 29.1 mt (Option 1; Table B-97). Other options

were explored, where excluders would be required only on trips where at least one haul was conducted within specific depth ranges exhibiting highest rougheye rockfish catch (i.e., between 200 and 400 fm, "GCA") and/or within specific latitude ranges (i.e., north of 47^o 30' N latitude; Table B-97) regardless of depth. Option 1 provided the largest rougheye rockfish savings but would also result in the most wide-spread use of excluder devices and highest escapement of Pacific whiting across the fleets (i.e., excluders would be required for all trips north of 40^o 10′ N latitude). Rougheye rockfish catch for Options 2 – 4 are up to 9 mt higher than that shown for Option 1, but substantially lower than shown under No Action. It is important to note that there is virtually no difference in rougheye rockfish catch (or whiting escapement) between Options 3 and 4 (Table B-97). Option 3 would require excluders along the entire Washington coast when fishing is anticipated to occur between 200 and 400 fm (within the "GCA"), whereas Option 4 would require excluders only be used when fishing occurs north of 47^o 30' N latitude (all depths).

The 2015 and 2016 component OFLs for rougheye rockfish north of 40^o 10' N latitude are 201.9 mt and 206.8 mt. The five-year average catch (2008-2012) by all fisheries (250.1 mt; Table B-89) would exceed this 2015 component OFL by 48.2 mt under No Action. Options 1 – 4 may reduce the catch of rougheye rockfish by 20.2 mt (Option 4) to 29.4 mt (Option 1). These reductions alone may not be enough to prevent exceeding the 2015 component OFL for rougheye rockfish north of 40^o 10' N latitude (i.e., 201.9 mt), or the 2015 component OFL coastwide (i.e., 206 mt). It is important to note that these projections are based on 5-year average catches. Annual projections could be much higher (or lower), if minimum or maximum historical catch values were used, or if some upper or lower percentile for catches were applied to the projection. In addition, including more or fewer years for the baseline average may change interpretations.

Impacts to whiting and bycatch species that escape the trawl under Options 1 –4 relative to No Action are uncertain. The potential mortality for those species escaping the trawl through the escape windows is unknown and would be unaccounted. Escapement at fishing depth of both whiting and bycatch species could be much higher than shown under Options 1 – 4 if clogging of the BRD occurs. Furthermore, if clogging occurs, it is likely that some fish may have to be bled at the surface before bringing the net up the trawl ramp. Mortality for fish bled at the surface would likely approximate 100 percent. These fish would be accounted for by 100 percent observer coverage.

Table B-97. Summary of biological and socio-economic impacts by alternative. The "relative impact to whiting fisheries" is a subjective measure, with no quantitative basis.

Alternative	Excluder Requirement	Rougheye Rockfish Catch (mt)	Projected Additional Whiting Escapement (%)	Relative Impact to Whiting Fisheries
No Action	None	58.8	0.0%	No Impact
1	North 40^o 10′ N latitude (all depths)	29.4	> 8.0%	(----)
2	North 40^o 10′ N latitude (200-400 fm)	33.6	> 5.6%	(---)
3	North 46^o 16′ N latitude (200-400 fm)	38.0	> 2.3%	(--)
4	North 47^o 30′ N latitude (all depths)	38.6	> 2.6%	(-)

Socioeconomic Impacts

The expense incurred by purchasing flexible excluders for shoreside midwater trawls (and trawls for catcher vessels in the at-sea whiting fishery) may approximate $22,000, based on research gear-related expenses (Lomeli (PSMFC) and Wakefield (NOAA), personal communication). These BRDs are built within a straight tube of netting designed to be inserted (i.e., zippered) between the intermediate section of the trawl and the packer/stuffing tube forward of the codend. The price for catcher-processor (C/P) trawls will likely be higher, because the trawls are larger.

Relative impacts by alternative are shown in Table B-97. Implementation of a new gear regulation requiring use of excluder devices in midwater whiting trawls for non-Tribal at-sea and shoreside whiting sectors may reduce the catch efficiency for whiting (i.e., there will be some additional escapement), increase net handling time (e.g., if fish and debris need to be removed forward of or from the excluder after each haul), and require net modifications. For example, when clogging occurs, the vessel may have to bleed or release fish from the net until the volume at the clog can be brought up the stern ramp without further damaging the intermediate section of the trawl net in front of the excluder. The time required to bleed fish, the economic loss of fish bled from the net, and repair costs to the net will likely represent economic impacts. Since these trips are 100 percent observed, fish bled from the net at the surface would be deducted from the quota. It is uncertain how often this may occur. At any rate, each of these outcomes may increase the operating costs of fishing operations. In addition, reduced efficiency may result in additional hauls and time at sea to attain the quota of Pacific whiting. Additional time at sea equates to not only additional expense, but also additional exposure to hazards.

The most complex regulations may be the most difficult (and expensive) to enforce. Note that some analyses focused on use of excluders only under a single condition (i.e., north or south of a specific latitude), whereas others incorporated both latitudinal split and depth requirements (i.e., 200 – 400 fm). The latter requirements would clearly be the most complex to manage.

Discussion and Considerations

For this report, five options were provided for consideration (including No Action). Additional options may be considered after input from the public and advisory groups (e.g., GAP, EC, SSC, and GMT). Council guidance is needed to refine this analysis (i.e., add and/or delete options). For example, gear regulations are difficult to define and enforce, hence, comments from the EC (and all advisory groups) must be weighed when considering regulatory changes to fishing gear. In addition, regulatory complexity is highest when regulating by latitude and depth, versus regulating by latitude only.

For options where midwater trawls with excluders are required for fishing within specific areas or depths (i.e., to legally fish within a “GCA”), the Council may consider recommending measures to minimize complexity for enforcement. Some examples include: (a) intended fishing trips within these special “GCAs” must be declared prior to leaving port, which would require a new declaration category in regulation, and (b) only a midwater trawl with a legal excluder device installed may be onboard during trips where any hauls occur inside a “GCA” (i.e., no other trawl may be onboard).

If regulations are adopted that define new fishing gear (i.e., installation of an excluder device and escape windows), the regulation could be specific only where needed to ensure adequate escapement of rockfishes at fishing depth. Specificity could be minimal and only apply to the most important aspects of the excluder and escape windows (e.g., length and width of grids within a panel that allow passage of whiting while blocking the passage of larger rockfish). Different sizes of vessels and different operators may require different designs (i.e., placement within the trawl due to different types of nets, etc.). It may be advantageous if fishermen were allowed the flexibility to fine-tune the device for their specific net and fishing operations to ensure that whiting escapement is minimal while maximizing escapement of rockfish. It would be beneficial for experts to convene to help draft regulatory language that ensures appropriate escapement along with adequate flexibility. In addition to NMFS regulatory writers and

Council staff, these experts may include Pacific whiting vessel owners/operators (shoreside whiting vessels, catcher vessels, and catcher/processors), net manufactures, and researchers.

For this draft, impacts were estimated using a 5-year average catch of rougheye rockfish in non-Tribal at-sea and shoreside Pacific whiting fisheries. Other averages could be used (e.g., 6-year average, which would reduce the baseline value for rougheye rockfish catch). It has also been suggested that the average and a range (e.g., minimum and maximum catches over a longer time period) be used to estimate rougheye rockfish impacts. This would provide some measure of risk that the Council may evaluate when selecting alternatives. If this measure moves forward, we seek guidance from the SSC and the Council regarding bycatch amounts that may be most appropriate for projecting catches of rougheye rockfish among alternatives (i.e., 5-year average, 6-year average, 75^{th} percentile, etc.).

Interannual variability may result in different outcomes than predicted here. Annual catches of rougheye rockfish are highly variable (see Table B-89). This variability may be due to areas and times that fishing occur (e.g., fishing occurs where Pacific whiting may be most abundant, and this may change from year to year depending on environmental conditions). In addition, Pacific whiting ACLs vary annually, which may directly impact the amount of fishing effort. Finally, sizes of Pacific whiting may vary annually. For example, the majority of the Pacific whiting catch in 2013 was age 3, which approximates individual weights of about 360 grams and lengths of 36-38 cm. In 2014, the majority of Pacific whiting catch is expected to be age 4, which are typically 40-43 cm and may average approximately 500 g. It is likely that larger Pacific whiting may exhibit higher escapement than smaller individuals when using excluder devices. This information collectively illustrates that encounter rates with rougheye rockfish will likely vary from year to year, and retention (or escapement) of Pacific whiting may vary depending on clogging rates and sizes of Pacific whiting available (e.g., larger Pacific whiting may exhibit highest escapement when using excluder devices).

Fishermen behavior should be considered when selecting alternatives. Fishing strategies may change if stock complexes are reorganized, or if consequences of exceeding component OFLs become recognized. Fishermen may voluntarily use excluder devices when fishing in areas with known high concentrations of rougheye rockfish, or may avoid these areas all together if consequences of catching rougheye rockfish are high. On the other hand, fishermen may be more inclined to fish within areas of high rougheye rockfish concentrations if excluder devices selectively enhance their escapement from trawls.

It is important to note that research results are always tenuous. Sample sizes are typically small (i.e., number of vessels, types of vessels, fishing areas, bycatch species encountered, etc.). The effectiveness of a new gear design is uncertain until applied to the commercial fishery under purely commercial conditions. Furthermore, research results described here were conducted on shoreside-whiting vessels. The net types used by these vessels are similar to those used by catcher vessels in the mothership sector. However, nets used by C/Ps are much larger. The design, cost, and effectiveness may be much different for C/Ps. Input from the GAP and others is necessary to help elucidate potential costs and benefits among sectors.

Finally, the potential escapement rate for rougheye rockfish using excluders was assumed to be 50 percent, which was less than the midpoint between rougheye rockfish escapement during Trial 2 (= 95 percent escapement by weight) and widow rockfish escapement during Trial 3 (= 26 percent escapement by weight). There were no rougheye rockfish available to the trawl during Trial 3. The authors of the excluder research projects point out that rougheye rockfish, which are generally larger than widow rockfish, would exhibit higher escapement than widow rockfish using the excluder devices. Guidance is sought from the SSC regarding the most appropriate assumption for rougheye rockfish escapement when excluder devices are used.

To summarize, the socio-economic and biological impacts may be more (or less) than described here. The pros and cons of applying research results to regulation should be considered. Input from the public and advisory groups will be paramount when considering this management measure.

B.17 Non-Trawl: Sablefish Trip Limits under the Harvest Specifications Alternatives

As described in Section B.10, a range of sablefish trip limits for the limited entry and open access sectors were explored under the sablefish ACL alternatives (Preferred, Alternative 1, and Alternative 2). Section B.10 details the Preferred Alternative whereas the sections below detail the analysis for trip limits under Alternatives 1 and 2.

B.17.1 Alternative 1 – Sablefish Trip Limits

Alternative 1, P*0.45 for 2015

*Trip limits and projected impacts under Alternative 1, P*0.45 for 2015*

The trip limit structures in 2016 under Alternative 1 for each fishery are presented in Table B-98. Differences between the Alternative 1 and No Action limits also appear in the table. Trip limits are higher under Alternative 1 than for No Action. Higher limits were needed to influence similar attainment, under the higher shares. Differences range from zero for bimonthly and weekly limits and 20 pound higher daily limits in the OA South fishery, to 375 lb per two months higher in the LE North fishery. The daily limit in the OA North fishery does not change among the alternatives.

Table B-98. Trip limits under Alternative 1, No Action Alternative, and comparison between them, for the fixed-gear, sablefish, DTL fisheries for 2015. Limits are in lb of landed catch per time period listed.

		2015 Alt. 1, P*0.45			2014 No action trip limits			Difference		
fleet	area	bimo	week	day	bimo	week	day	bimo	week	day
LE	**N**	3,225	1,075	NA	2,850	950	NA	375	125	NA
OA	**N**	1,900	950	300	1,600	800	300	300	150	0
LE	**S**	NA	2,125	NA	NA	2,000	NA	NA	125	NA
OA	**S**	3,200	1,600	320	3,200	1,600	300	0	0	20

Projected landings, attainment, and remainder amounts under Alternative 1 are presented in Table B-99. The same values for the No Action Alternative are also presented in the table, as well as the differences between these two alternatives.

Attainment rates are very similar between Alternative 1 and No Action, with the exception of the OA North fishery, for reasons explained in the No Action section; attainment rates are nearly equal for each fishery, among the action alternatives by design. The amount of landed catch projected is consistently higher under Alternative 1 than No Action; between 25.9 mt and 73.8 mt higher, due to the higher trip limits which were produced, in order to influence similar attainment under the higher landed shares of Alternative 1.

Table B-99. Model-projected landings under Alternative 1, No Action Alternative, and comparison between them, in the fixed-gear, sablefish, DTL fisheries for 2015. Landed shares and projected landings are in metric tons (mt).

2015 Alt. 1, P*0.45	LE N	OA N	LE S	OA S	South sum
Projected landings	230.3	380.0	511.6	327.0	838.6
Landed share	247	406	555	451	1,006.0
Percent attainment	93%	94%	92%	72%	83%

Alternative 1, P*0.45 for 2016

Trip limits and projected impacts under Alternative 1, P=0.45 for **2016***

The potential trip limit structures for 2016 under Alternative 1 are presented in Table B-100 for each fishery. Differences between the Alternative 1 and No Action limits also appear in the table. Trip limits are substantially higher under Alternative 1 than for No Action. Higher limits were needed to influence similar attainment, under the higher shares. Differences range from 30 lb per day higher for the OA South, to 675 lb per two months higher in the LE North fishery. The daily limit in the OA North fishery does not change among the alternatives.

Table B-100. Trip limits under Alternative 1, No Action Alternative, and comparison between them, for the fixed-gear, sablefish, DTL fisheries for 2015. Limits are in lb of landed catch per time period listed.

		2016 P*=0.45			2014 No action trip limits			Difference		
fleet	area	bimo	week	day	bimo	week	day	bimo	week	day

OA	**N**	2,050	1,025	300	1,600	800	300	450	225	0
LE	**S**	NA	2,200	NA	NA	2,000	NA	NA	200	NA
OA	**S**	3,300	1,650	330	3,200	1,600	300	100	50	30

Projected landings, attainment, and remainder under the Alternative 1 are presented in Table B-101. The same values for the No Action Alternative, and the differences between these two alternatives, are also presented in the table.

Attainment rates are very similar between Alternative 1 and No Action, with the exception of the OA North fishery, for reasons explained in No Action section; attainment rates are nearly equal for each fishery, among the action alternatives by design. The amount of landed catch projected is consistently higher under the Alternative 1 than No Action; between 47.6 mt and 121.8 mt higher, due to the higher trip limits which were produced in order to influence similar attainment under the higher landed shares of the this alternative.

Table B-101. Model-projected landings under Alternative 1, No Action Alternative, and comparison between them, in the fixed-gear, sablefish, DTL fisheries for 2016. Landed shares and projected landings are in metric tons (mt).

B.17.2 Alternative 2 – Sablefish Trip Limits

Alternative 2, P*=0.25 for 2015

Trip limits and projected impacts under Alternative 2, P=0.25 for* ***2015***

The trip limit structures in 2015 under Alternative 2 are presented in Table B-102 for each fishery. Differences between the Alternative 2 and No Action limits also appear in the table. Trip limits are generally lower under Alternative 2 than for No Action. Lower limits were needed to influence similar attainment, under the lower shares. Differences range from zero, no difference in weekly or bimonthly limits, for the OA North, to 225 lb per two months lower in the LE North fishery. The daily limit in the OA North fishery does not change among the alternatives.

Table B-102. Trip limits under Alternative 2, the No Action Alternative, and comparison between them, for the fixed-gear, sablefish, DTL fisheries for 2015. Limits are in lb of landed catch per time period listed.

		2015 Alt. 2, P*0.25			2014 No action trip limits			Difference

Uncertainty surrounding future ex-vessel prices in the LE North fishery

The main axis of uncertainty in the LE North fishery was ex-vessel price. This is one predictor in the model, and projected landings depend upon assumptions regarding future prices. We addressed this by showing three scenarios for projected landings according to potential ex-vessel price, for each of the alternatives.

The current 2014 projection for the LE North fishery assumes a uniform seasonal ex-vessel price throughout 2014, at the current 2013 bimonthly average ex-vessel price of $2.57 per pound. Assumptions about ex-vessel price in the LE North fishery under the alternatives are shown in Table B-106 and Table B-107. From 2004 through 2011, the bimonthly price followed a predictable seasonal pattern, peaking with the highest prices ever in fall of 2011. However, during 2012 and 2013, that pattern disappeared, and was replaced with one of general decline, following the 2011 boom. However, current landings data show some small increases in prices, and some market reports tell of a potential recovery for the sablefish market, to an unknown degree. Thus, a working assumption of a uniform seasonal price was assumed for projections, since the beginning date, and extent of a potential recovery is not known with any certainty.

Uncertainty in the forecasted landings in this fishery is bracketed by using the lowest and highest bimonthly price during 2013. Projected attainment under the alternatives using the low price was between 86 and 88 percent, and for the high price, projected attainment was between 99 and 101 percent of the landed share (Table B-106 and Table B-107).

B.18 Non-Trawl: Remove or Modify the Commercial Gear Restrictions for Flatfish

Overview

The current commercial gear restriction for the “Other Flatfish” complex in the waters off California reads, “South of 42° N. lat., when fishing for "other flatfish," vessels using hook-and-line gear with no more than 12 hooks per line, using hooks no larger than "Number 2" hooks, which measure 11 mm (0.44 inches).” The intent of this management measure was initially to prevent bycatch of overfished rockfish while fishing for members of the “Other Flatfish” complex including Pacific sanddab. Similar regulations in place in the recreational fishery, which uses similar vertical hook and line gear, were removed because they did not provide additional protection, as originally intended. Bycatch rates when targeting Pacific sanddabs and “Other Flatfish” are very low irrespective of the gear employed, thus gear restrictions are not needed to limit bycatch. Removal or liberalization of gear restrictions would simplify regulations and allow the fixed gear fleet to effectively target and attain trip limits of ”Other Flatfish”.

Background

Starting in 2004, gear restrictions were implemented for the commercial and recreational fisheries to allow some risk adverse targeted fishing opportunity for Pacific sanddabs inside the RCA, while minimizing bycatch of overfished species. In 2009, the analogous gear restriction on the recreational fishery was removed because encounter rates with overfished species in the fishery were so low that gear restrictions did not provide additional protection, as originally intended. In subsequent years removal of the gear restrictions in the recreational fishery have not resulted in a noticeable increase in overfished species impacts. The Council also considered removing the gear restriction from the commercial fishery in 2011, but it was not implemented due to initial concerns regarding potential for incidental take of petrale sole – a stock which had recently been declared overfished (Agenda Item I.4.b, Supplemental GMT Report 2, April 2010).

The Council has again requested analysis of removing the gear restriction in the California commercial fixed gear fishery south of 42° N latitude to enable fishery participants to more efficiently target "Other Flatfish", particularly Pacific sanddabs. In addition to the No Action Option, three other options were analyzed to bracket the potential range of regulatory modifications for Council consideration. These include maintaining the gear restriction but modifying the weight and number of hooks allowed (Option 2); eliminating the gear restriction and prohibiting access to the groundfish conservation areas (GCAs) (Option 3); and eliminating the gear restriction while still allowing fishing in GCAs, but adding a landing limit to prevent species other than "Other Flatfish" from being retained while fishing in the GCAs (Option 4).

Summary of Options

Option 1: No Action – maintain gear restrictions on fishing for "Other Flatfish" and maintain access to the Groundfish Conservation Areas (GCA), which includes the Cowcod Conservation Areas (CCA), Farallon Islands, Cordell Bank, and RCAs. Only allow "Other Flatfish" in the GCA to be retained when the specified gear is used.

Option 2: Modify the gear restriction to eliminate weight restriction and limit the number of hooks to no more than 300 hooks per set and use of a maximum of 600 hooks per vessel using hooks no larger than "Number 2" hooks, which measure 11 mm (0.44 inches). Maintain access inside the RCA. Prohibit access to the CCA, Farallon Islands and Cordell Bank when targeting the "Other Flatfish" complex. Only allow "Other Flatfish" to be retained in the RCA when the specified gear is used.

Option 3: Eliminate the gear restriction on fishing for "Other Flatfish", while prohibiting fishing within the GCA~~s~~.

Option 4: Eliminate the gear restrictions and allow fishing within the GCA when targeting "Other Flatfish". Add a landing restriction preventing the landing of any species other than the "Other Flatfish" complex while in possession of "Other Flatfish".

Data
Commercial fixed gear state landing receipt data from historical data (1995-1999) from California waters were used to examine catch composition prior to regulation and provide proxy bycatch rates for trips targeting Pacific sanddab (>50 percent of landings composed of Pacific sanddabs). Recent state landing receipt data (2008-2012) were used to evaluate recent catch composition and bycatch rates. Raw WCGOP onboard sampling data from (2003-2011) were examined, but insufficient data was available to inform recent bycatch rates.

Comparison of Options

Option 1: No Action

Under Option 1 (No Action), the current gear restrictions would remain in place. Fishing inside GCAs for "Other Flatfish" is only allowed when using this gear.

Fishing Activity in Commercial Fixed Gear Fisheries under Option 1

An average of 150 trips per year were made between 2008 and 2012 in California that targeted Pacific sanddabs[1]. California scorpionfish was the next most common species composing 9.6 percent of the landings, almost exclusively caught south of Point Conception. Examination of landing receipts from recent years 2008-2012 indicates that 86 percent of landings from trips that targeted Pacific sanddab were composed of Pacific sanddabs. The landings of each remaining species landed composed less than 0.8 percent of the total indicating that most other species were relatively uncommon when targeting Pacific sanddab. This indicates that the primary target within the "Other Flatfish" is Pacific sanddabs and limited bycatch accrues with the current fishing activity. In addition, the remaining species within the "Other Flatfish" are not common in the catch when targeting Pacific sanddab (<0.01 mt of any one species) and thus assumed to be relatively uncommon and/or primarily caught as incidental take while pursuing other species.

In part, the limited effort exerted in targeting "Other Flatfish" may be due to an inability to efficiently harvest Pacific sanddab under the current gear restrictions. Of the non-trawl sectors, the recreational fishery accounts for the majority (79.7 mt, 92 percent) of mortality; commercial and recreational fisheries combined 86.5 mt, less than 9 percent of the 986.5 mt non-trawl allocation on average. Under the current regulations on the "Other Flatfish" complex, mortality from the fixed gear fleet averaged 7.2 mt in 2011-2012, less than one percent of the total the non-trawl allocation of 986.5 mt. Currently the trip limit for the "Other Flatfish" complex in the limited entry fishery is "5000 lb./month", while in the open access fishery the trip limit is "3,000 lb./month, no more than 300 lb. of which may be species other than Pacific sanddabs". The hook and weight restrictions in place prevent the deployment of longline gear and relegate the fishery to vertical hook-and-line fishing, which limits the ability of the limited gear fishery to attain the trip limits.

No data on the distribution of effort in state vs. federal waters are available from Vessel Monitoring System (VMS) declarations or log books. Given the differences in bathymetry with distance from shore along the coast, fishing in state or federal waters may be more prevalent in some areas than others. The proportion of the grounds in state or federal waters depends on the distance of the primary depth distribution of "Other Flatfish" species from shore in each area. When depth changes abruptly with distance from shore, effort may be more focused in state waters; whereas gradual changes in bathymetry may result in more effort exerted in federal waters. The depth distribution of species in the "Other Flatfish" complex indicates that all species except rex sole are predominantly distributed in depths shallower than other federally-managed flatfish species including petrale sole (Table B-108, Love 1996).

The "Other Flatfish" are almost exclusively fished over soft bottoms where encounters with overfished rockfish species and other rocky reef species are exceedingly uncommon, negating concern regarding bycatch while fishing within the GCA, as long as gear is deployed over soft bottom when targeting members of the "Other Flatfish" complex. In addition, retention of groundfish species occurring over rocky reef habitat is prohibited in GCAs, thus removing the impetus to target them. Lastly, the hooking and handling discard mortality rate for petrale sole is expected to be 7 percent when rod and reel is used[21], thus flatfish discarded due to prohibition on retention in the RCA are expected to experience relatively low mortality.

[21] http://www.pcouncil.org/groundfish/current-season-management/past-management-cycles/2009-2010-final-environmental-impact-statement/, pg. 307.

Table B-108. Depth distribution and habitat preference of component species in the "Other Flatfish" complex (Love 1996).

Species	Common Depth	Depth Range	Habitat Preference
Sand Sole	<50 fm	1 - 284 fm	Soft
Rock Sole	<50 fm	0 - 316 fm	Pebble, semi-rocky
Butter Sole	25 - 60 fm	9 - 234 fm	Soft
Pacific Sanddab	25 - 75 fm	0 - 300 fm	Soft
Curlfin Sole	NA	24 - 291 fm	Soft
Flathead Sole	<100 fm	3 -300 fm	Soft
Rex Sole	50 -200 fm	0 - 475 fm	Soft

Biological Impacts under Option 1

Projected "Other Flatfish" Mortality

The fixed gear fishery took an average of 7.2 mt or 0.7 percent of the non-trawl allocation coastwide in 2011 and 2012 (Table B-109) and similar tonnage is expected to accrue in the fixed gear fisheries under the No Action Option. The majority of the mortality in the "Other Flatfish" complex is from Pacific sanddab comprising 89.6 percent of the total. Under the No Action option, mortality of "Other Flatfish" would be expected to be the same as in recent years, assuming trip limits for other co-occurring target species and fishing behavior do not change.

Table B-109. Average mortality the "Other Flatfish" complex coastwide in the recreational and commercial fixed gear fisheries by sector from 2011-2012. (source: West Coast Groundfish Total Mortality reports)

Species	Average Fixed Gear Mortality (mt)	Average Recreational Mortality (mt)	Ave Non- Trawl Mortality Total (mt)	Percent Mortality from Fixed Gear
Butter Sole	0.00	0.01	0.01	0%
Curlfin Turbot	0.00	0.00	0.00	NA
Flatfish Unid	0.12	3.87	3.99	3%
Flathead Sole	0.50	0.00	0.50	100%
Pacific Sanddab	5.12	72.34	77.46	7%
Rex Sole	0.18	0.00	0.18	100%
Rock Sole	0.08	1.24	1.32	6%
Sand Sole	0.28	2.28	2.55	11%
Sanddab Unid	0.97	0.00	0.97	100%
Total	7.24	79.73	86.47	8%

Projected Overfished Species Mortality

Commercial landings from fixed gear trips between 2008 and 2012 targeting Pacific sanddabs, indicate that less than 0.1 percent of the catch was composed of petrale sole (<0.01 mt on average) and bocaccio

(<0.01 mt on average). The resulting bycatch rates relative to landings of sanddabs are 0.0005 mt of petrale sole per ton of sanddab and 0.001 mt of bocaccio per ton of sanddab. No canary rockfish, yelloweye rockfish or cowcod were observed in the landings in large part due to prohibition on their retention. Attempts to analyze discard data from the WCGOP were unsuccessful since very few records of sampled trips targeting Pacific sanddab were available. Historical landing receipt data from 1994 to 1999 when rockfish retention was allowed, showed that less than 0.01 mt each of canary rockfish, yelloweye rockfish, bocaccio or cowcod were landed when targeting Pacific sanddabs, and only 0.06 mt of petrale sole was taken on average. The contribution to overfished species impacts from fixed gear fishery participants targeting "Other Flatfish" are expected to be extremely low and compose a small fraction of the total given the bycatch rates observed in the absence of gear restrictions in the past.

Additional mortality on petrale sole is not expected to be negligible since they cannot be retained within the non-trawl RCA, are typically found in depths greater than those occupied by the "Other Flatfish" and discards are expected to have a low mortality rate since they do not suffer from barotrauma. In addition, bycatch rates for petrale sole in state landing receipt data (1994 to 1999) were exceedingly low while targeting sanddabs. This indicates that effort will be focused on shallower depths to target sanddabs and deeper waters where petrale sole are more commonly encountered will be avoided (Table B-108, Love 1996).

Fishery participants infrequently encounter overfished species while targeting sanddabs and species in the "Other Flatfish" complex since gear is deployed over soft bottoms where cowcod, canary rockfish, yelloweye rockfish and bocaccio are extremely rare and in depths shallower than the primary depth distribution of petrale sole.

Data Uncertainty

Historical landing receipt data from 1994 to 1999 for trips targeting Pacific sanddabs were used as a proxy for bycatch rates may over-project mortality due to the possibility that gear was set over rocky reef habitats in addition to sandy bottoms where Pacific sanddabs are found on the same set or different sets on the same trip. This would bias bycatch rates high compared to what might accrue when fishing only over soft bottom to target Pacific sanddabs. The landings data used to calculate these "bycatch rates" are from landings rather than total catch, so some of the small or unmarketable fish discarded on the trip may not accounted for in the landings. In addition, the recent landing receipts used to evaluate current bycatch rates do not provide an accurate projection of bycatch for prohibited species since their retention is prohibited and not reflected in landings data. The estimated mortality for 2011 and 2012 from WCGOP may be biased high relative to impacts from California since they are coastwide including mortality in Oregon and Washington as well.

Stock Status

<u>"Other Flatfish" Complex</u>

The "Other Flatfish" complex is comprised mainly of unassessed stocks. A full assessment conducted in 2013 for Pacific sanddab indicated the stock status was healthy at 96 percent of its unfished spawning stock biomass. Despite not being adopted for use in management, it was acknowledged that this stock was extremely healthy.

<u>Overfished Species</u>

The depletion of each overfished species in 2013 was as follows, cowcod (34 percent), bocaccio (31 percent), canary rockfish (24 percent), yelloweye rockfish (22.3 percent) and petrale sole (22 percent). While cowcod, bocaccio, canary and yelloweye rockfish, and petrale sole have been historically encountered while targeting Pacific sanddabs, bycatch rates have been extremely low. Thus mortality from the targeting of "Other Flatfish" does not contribute appreciably to the aggregate mortality of overfished species and is not expected to adversely affect their stock status or rebuilding progress.

Socioeconomic Impacts under Option 1
The current gear restrictions prevent the fixed gear fishery from being able to effectively harvest healthy "Other Flatfish" stocks. Thus gear restrictions would continue to prevent the fixed gear fishery from attaining monthly trip limits. Forgone yield of Pacific sanddabs or other species in the "Other Flatfish" complex due to the gear restrictions would prevent fishery participants and coastal communities from more fully benefiting from increased ex-vessel revenue.

Option 2

Under Option 2, the gear restriction would be modified to eliminate weight restriction and limit the number of hooks to no more than 300 hooks per set and use of up to 600 hooks per vessel using hooks no larger than "Number 2" hooks, which measure 11 mm (0.44 inches). In addition, access to the rockfish conservation area would be maintained, but prohibit access to the CCA, Farallon Islands and Cordell Bank when targeting the "Other Flatfish" complex. Lastly, only "Other Flatfish" could be retained when fishing in the RCA with the specified gear onboard.

Change in Fishing Activity Compared to Option 1
Hook size restrictions would still be less than size 2 hooks, which are not expected to affect efficiency, but will maintain selectivity for smaller mouthed flatfish species. As a result of removing the weight restriction fishery participants may employ longline gear instead of or in addition to vertical hook-and-line gear deployed with rod and reel as the primary means of fishing. The 12 hook per line restriction would be replaced with a more liberal restriction of no more the 300 hooks per set and use of no more than 600 hooks per vessel. The gear restriction changes are intended to increase efficiency in targeting "Other Flatfish" while maintaining an impetus to focus effort where the target species is likely to reside, on soft bottom, which might be otherwise lost if a hook restriction on the number of hooks was removed completely making placement of gear less discriminant. The restriction on the number of hooks may also motivate participants to check their gear frequently to retrieve their catch, which may reduce mortality on encountered bycatch species. Vessels would still have access to fish in the RCA where adult sanddab habitat is often distributed depending on the bathymetry of the region. Fishing in the waters around the Farallon Islands and Cordell Bank as well as the CCA would be prohibited. Allowing only retention of other flatfish while fishing in the RCA with the proscribed gear will remove the impetus to fish near hard substrate where bycatch of overfished species may occur.

The proposed actions would increase the efficiency of vessels targeting "Other Flatfish" while maintaining precautionary limitations on the number of hooks, areas that can be fished and species that can be retained to focus effort on areas with soft bottoms where overfished species are uncommon. Under this alternative, effort is expected to increase as the opportunity would be more profitable than under the No Action alternative. The magnitude of the increase in participation is difficult to anticipate since there is an open access component to the fishery. The sub-trip limit of no more than 300 lb per month for "Other Flatfish" species other than Pacific sanddabs may not provide much of an incentive to target the remaining species. Thus effort is expected to be focused on Pacific sanddabs, which data indicate can be targeted with negligible bycatch. Closure of the small areas around the Farallon Islands, Cordell Banks and habitat residing within the CCA are unlikely to adversely affect participation since areas in the RCA hold sufficient adult Pacific sanddab biomass to allow productive targeting. Closure of these smaller areas is intended to focus effort on areas with large expanses of soft bottom habitat, preventing bycatch of rocky reef species.

Biological Impacts Compared to Option 1
<u>Other Flatfish Mortality</u>

The mortality of component species in the “Other Flatfish” complex under Option 2 is expected to increase relative to Option 1, given the increase in the number of allowable hooks. If participation also increases, mortality would be expected to be even higher but still within the non-trawl allocation. “Other Flatfish” effort from the fixed gear fishery would have to increase by more than 10 fold to exceed the non-trawl allocation assuming a twelve fold increase in capacity with 48 hooks (for four rods with 12 hooks each) vs. a 600 hook restriction, while accounting for recent mortality in the recreational fishery in 2011 and 2012. The projection may be biased high considering that some of the catch expanded by the increased capacity originated from Oregon and Washington where the current gear restrictions would not change.

Overfished Species Mortality

Under this option, overfished species mortality was estimated using a combination of historical and recent landings data to inform how much, if any, increase in mortality would be expected as a result of increasing the number of allowable hooks. Given the paucity of WCGOP data and the biases with recent data (i.e., non-retention of some OFS), historical data from a time period when rockfish and sanddabs could be retained on the same trip was used as a proxy to estimate bycatch rates of OFS. This historical bycatch rate was then applied to the allowable take of sanddabs to estimate the OFS mortality that could be expected assuming the entire non-trawl allocation of 327.7 mt Pacific sanddabs after subtracting recent recreational mortality is taken by the commercial fixed gear fishery. Since retention of bocaccio and petrale sole is currently allowed, recent bycatch rates were calculated and used to estimate OFS mortality assuming the entire Pacific sanddab contribution to the non-trawl allocation of is utilized.

Historical data revealed higher bycatch rates of rockfish taken with Pacific sanddabs in recent years though the rates were still negligible. This is not unexpected given that regulations at the time permitted mixed trips (i.e., targeting hard bottom and soft bottom species on the same trip). Applying these higher bycatch rates to recent data increases impacts of OFS relative to No Action (Table B-110). The actual mortality may be lower since these estimates assume attainment of the entire sanddab non-trawl allocation. This analysis is simply meant to highlight the maximum bycatch expected given target species allocations and even under this extreme example, OFS impacts would still be low, especially when compared to sources of mortality from other sectors.

Although projected mortality using recent bycatch rates could only be calculated for bocaccio rockfish and petrale sole, these projections better inform what is more likely to occur out on the water for these two species. Projected mortality for both of these stocks, assuming full attainment of Pacific sanddabs, is at least half of that calculated using historical bycatch rates.

Overall, mortality of overfished species under Option 2 is expected to be similar to Option 1. Though the total mortality may increase slightly due to the increase in number of hooks, bycatch rates on a per hook basis are extremely low and not expected to increase; therefore any increased mortality if realized is expected to be negligible.

Table B-110. Comparison of projected mortality of overfished species in the fixed gear fishery while targeting Pacific sanddabs and other flatfish in recent years (2008-2012) and historically (1994-1999) prior to gear restrictions. Projected mortality is based on full attainment of the non-trawl allocation (after accounting for recreational mortality).

Species	Recent Bycatch Rate	Projected Mortality assuming recent bycatch rate(mt)	Historical Bycatch Rate	Projected Mortality assuming historical bycatch (mt)
Canary	NA	NA	0.00056	0.18
Yelloweye	NA	NA	0.00011	0.04
Bocaccio	0.00116	0.38	0.00197	0.65
Cowcod	NA	NA	0.00087	0.29
Petrale	0.00047	0.16	0.01703	5.58

Data Uncertainty Compared to Option 1

The uncertainties noted under Option 1 relative to the data also apply under Option 2. In addition, there is greater uncertainty in participation. While it was assumed that all of the remaining non-trawl allocation of Pacific sanddabs is taken after accounting for recreational catch, mortality may be lower as market conditions may prevent sufficient effort from being exerted to reach attainment.

Stock Status

Other Flatfish

Mortality of other flatfish would be expected to increase compared to Option 1, but is expected to be far below the non-trawl allocation, let alone the ACL. Thus, the stock status is not expected to be affected.

Overfished Species

Under Option 2 no changes in stock status and rebuilding progress are expected compared to Option 1.

Socio-economic Impacts compared to Option 1

Allowing greater capacity through an increase in the number of hooks and eliminating weight restrictions allowing the use of longlines, would make the fishery more efficient and increase revenue. This would provide an additional facet to the portfolio of fishing opportunities available to the fixed gear fleet during periods when more profitable opportunities are unavailable. The revenue from additional landings would provide increased income to coastal communities.

Option 3

Under Option 3 the gear restrictions on fishing for "Other Flatfish" would be eliminated and fishing within the GCAs would be prohibited.

Change in Fishing Activity Compared to Option 1

Under Option 3, there would be no restriction on the number or size of hooks or the weights used in targeting "Other Flatfish," but access inside the GCAs would not be permitted. Since most adult sanddabs are found in depths deeper than those open the shoreward RCA line in most management regions (except south of Point Conception), fleet behavior would likely be affected under this option. Although vessels could catch sanddabs more efficiently if the gear restriction is removed, they would not be able to access waters inside the RCA where the target species is found; thus fishing activity is likely to be lower compared to Option 1.

Biological Impacts Compared to Option 1

Other Flatfish Mortality

In areas north of Point Conception the shoreward fixed gear RCA is 30 fm or shallower, and grounds in deeper waters where adult sanddabs are available would be inaccessible. Thus the ability to harvest sanddabs efficiently with hook-and-line gear would be limited by a lack of access to adult Pacific sanddab habitat in deeper waters within the RCA north of Point Conception. Though the magnitude of reduction is difficult to determine, if RCAs are closed to fishing, effort and mortality are expected to decrease under this option.

Overfished Species Mortality

Mortality of overfished species under Option 3 is expected to be lower than Option 1 because vessels would be excluded from fishing inside RCAs where the few encounters would be expected to occur. If effort were directed to shallower depths, in targeting members of the other flatfish complex, mortality rates of what few overfished rockfish are encountered are expected to be reduced due to the lower barotrauma experienced in shallower depths. Any increase in mortality resulting from eliminating the gear restriction would be offset by lack of access inside the RCAs north of Point Conception. South of Point Conception, the shoreward RCA line is 60 fm allowing access to adult Pacific sanddab, thus mortality of cowcod and bocaccio may increase slightly compared to Option 1 as a result of increased efficiency with the elimination of gear restrictions. The aggregate mortality is expected to increase only slightly as the encounter rates are extremely low in any case.

Data Uncertainty Compared to Option 1

An additional uncertainty relative to Option 1 is whether effort would decrease substantially due to a lack of access to the RCA or whether effort would shift shoreward of the RCA in targeting "Other Flatfish" that occur in shallower depths. Current catch data indicates that the other species are relatively uncommon in the fixed gear fishery compared to Pacific sanddabs, making it unlikely that effort would be exerted in shallower waters. In addition, the greater capacity of the fishery in the absence of a limit on the number hooks that can be deployed increases uncertainty in the mortality that will result from this alternative.

Stock Status

Other flatfish

The mortality of "Other Flatfish" under Option 3 is projected to be far below the non-trawl allocation, thus the stock status is not expected to be affected.

Overfished Species

Bycatch rates for overfished species are expected to be sufficiently low as not to contribute appreciably to aggregate mortality from the fixed gear fishery. Under Option 3 no changes in stock status and rebuilding progress are expected compared to Option 1.

Socio-economic Impacts compared to Option 1

Under this alternative, assuming the current RCA restrictions north of Point Conception, fishery participants would not be able to access the primary depth distribution of adult Pacific sanddabs. While removal of the gear restrictions would allow deployment of an unlimited number or size of hooks or weights, the primary depth distribution of adult Pacific sanddabs would be inaccessible. This would adversely affect fishery participants that would otherwise benefit from landings of primary target species available within the RCA. Allowing the needed gear to be employed while denying access to adult Pacific sanddab is expected to result in a barrier to harvest that is more detrimental than Option 1, in which access is available, but not sufficient means to harvest given the current gear restrictions.

Option 4

Under Option 4, the gear restriction on fishing for members of the “Other Flatfish” complex would be eliminated, while allowing fishing within the GCAs when targeting them. A landing restriction would also be implemented that prohibits landings of species that are not “Other Flatfish” when members of the “Other Flatfish” complex are onboard.

Change in Fishing Activity Compared to Option 1

Under Option 4, fishery participants would not be subject to gear restrictions and could fish both inside and outside the GCAs, but the landing restriction would prohibit landing of any other species when “Other Flatfish” are onboard. The intent is to address enforcement concerns to prevent participants from landing fish for which retention is prohibited within the RCA while fishing for “Other Flatfish” within the GCAs. This would also have the consequence of prohibiting incidental catch of “Other Flatfish” when targeting other species outside the GCAs.

As a result of removing gear restrictions, fishery participants may deploy longline gear instead of or in addition to vertical hook-and-line gear deployed with rod and reel. Vessels would still be allowed to fish in the RCA, GCA, around the Farallon Islands and Cordell Banks to access marketable sized adult sanddabs, which are expected to be the primary target of fishing activity. The main concern is that if thousands of hooks are deployed in the RCA, it is more likely they will be deployed inadvertently over rocky reefs resulting in overfished species bycatch, since targeting may not be as focused on soft bottom habitat as it would be if a gear restriction was imposed. In the absence of gear restrictions, a landing restriction would be put in place as a disincentive to fish in the GCAs except where “Other Flatfish” are caught. This would help ensure that effort targeting “Other Flatfish” within the GCAs does not result in targeting of other species likely to reside on rocky reefs. Retention of such species in the GCAs is already prohibited, but the landing restriction would eliminate the impetus to target them within the GCAs under the guise of targeting “Other Flatfish”.

Fishing effort for “Other Flatfish” would be expected to increase under Option 3 as participants would have both access to the fishing grounds and the means to harvest the target stock. As long as the market demand will support an adequate price per pound to make the target worth pursuing relative to other opportunities due to equal or greater profit, additional entrants may participate. Once the market is saturated, the price per pound could decline and reduce the number of participants. The actual participation is difficult to predict, but is expected to increase relative to Option 1.

Biological Impacts Compared to Option 1

Other Flatfish Mortality

The mortality of component species in the “Other Flatfish” complex is expected to increase relative to Option 1 and be similar to that presented in Option 2. Removing gear restrictions would make it more likely that trip limits would be attained by participants if they had access to the primary depth distribution of adult Pacific sanddabs within the GCAs. While aggregate landings would be expected to increase as a result of eliminating gear restrictions, prohibition of landing “Other Flatfish” caught as bycatch while targeting other species, would moderate the increase in impacts to some degree since incidental “Other Flatfish” catch would have to be discarded in order to land other species.

Overfished Species Mortality

The potential overfished species impacts would be similar to projections provided under Option 2, with increased mortality relative to Option 1 as a result of eliminating gear restrictions while maintaining access to fishing grounds within the GCAs. Without a limitation on the number of hooks that can be deployed, targeting may be less discriminant relative to the habitat they set their gear, increasing the potential for fishing over rocky reef habitat where encounters with overfished rockfish species are more common.

In addition, the lack of a hook size restriction may increase the effectiveness of the gear in hooking larger overfished species and other non-target stocks should the gear be deployed near rocky substrate where bycatch species are likely to be encountered. Retention of groundfish species occurring over rocky reef habitat is prohibited in the GCAs, removing the impetus to target them, yet bycatch may still occur while fishing in the GCAs, especially if gear is not placed on soft bottom. Prohibition on landing other species when landing species in the "Other Flatfish" complex with fixed gear would further dissuade fishery participants from targeting rocky reef species and focus effort on soft bottom where the "Other Flatfish" are commonly found.

Data Uncertainty Compared to Option 1
If fishery participants are indiscriminant in the placement of their longline gear relative to small outcrops of rocky reef habitat in the absence of hook restrictions, uncertainty in the bycatch of overfished rockfish would be expected to increase relative to Option 1. The inability to land species other than members of the "Other Flatfish" complex would decrease the impetus to fish within the GCAs for species that inhabit rocky reef habitat, reducing uncertainty regarding encounters with overfished rockfish species, in part mitigating this concern.

Stock Status
<u>Other Flatfish</u>
The projected mortality of "Other Flatfish" under Option 4 is below the non-trawl allocation, thus the stock status is not expected to be affected.

<u>Overfished Species</u>
Under Option 4 no changes in stock status and rebuilding progress are expected compared to Option 1. Bycatch rates for overfished species are expected to be sufficiently low as not to contribute appreciably to aggregate mortality from the fixed gear fishery, thus the stock status and rebuilding plans of overfished species are not expected to be adversely affected.

Socio-economic Impacts compared to Option 1
Elimination of gear restrictions while allowing access to depths where adult Pacific sanddabs are encountered will increase the ability of fishery participants to attain trip limits. Increased landings of other flatfish would result in increased economic benefit to coastal communities. The prohibition on landing "Other Flatfish" with other species would reduce revenues from landings of incidental catch of "Other Flatfish" while targeting other species that would have to be forgone, but may be compensated for by increased harvest within the GCAs when targeting adult Pacific sanddabs and the remaining "Other Flatfish".

B.19 Within Non-Trawl: Analysis of Harvest Guidelines for Nearshore Rockfish North Complex with a P* of 0.25

This analysis provides the state harvest guideline allocations with three proposed methods reflected under Options 2, 3 and 4 when a P* of 0.25 under ACL Alternative 2 is applied to the Nearshore Rockfish complex. Management measures that may be used to keep mortality from exceeding the state harvest guidelines are also included. The preceding analysis was conducted applying the same allocation methods to the ACL resulting from a P* of 0.45, compared to the status quo and ACLs under the Preferred Alternative. Similar analyses are provided below to allow comparison of the implications of ACL Alternatives in terms of mortality, stock status and socio-economic impacts.

<u>**Review of Options**</u>

Option 1 (“No Action”): Continue to manage the Nearshore Rockfish complex, holding impacts to the complex level ACL in each region.

Option 2: Manage the Nearshore Rockfish complex according to a state specific harvest guidelines stratified at 40°10′ N. Lat. reflecting apportionment based on the miles of coastline in each state.

Option 3: Manage the Nearshore Rockfish complex according to a state specific harvest guidelines stratified at 40°10′ N. Lat. reflecting apportionment based on the historical recreational and commercial catch between 2004 and 2012.

Option 4: Manage the Nearshore Rockfish complex according to a state specific harvest guidelines stratified at 40°10′ N. Lat. reflecting a hybrid method of apportionment based on miles of coastline for China, quillback and copper rockfish and the historical recreational and commercial catch between 2004 and 2012 for the remaining species.

B.19.1 Comparison of Options

Option 1 (“No Action”)

Same as analysis under P* of 0.45, see Section B.5.1.1.

B.19.1.1 Option 2: Miles of Coastline (P* = 0.25)

Option 2 is to manage the Nearshore Rockfish complex according to state-specific harvest guidelines stratified north and south of 40°10′ N. Lat., with apportionment north based on the miles of coastline in each state as reflected in Table B-111. The 3 nm state boundary was measured as the proxy for miles of coastline.

Table B-111. Allocations of Nearshore Rockfish north of 40°10′ N. Lat under Option 2 derived using miles of coastline in each state (at P* = 0.25).

Species	Contribution	WA%	OR%	CA%	WA mt	OR mt	CA mt
Black and yellow	*0.0*	0.26	0.49	0.25	0.00	0.00	0.00
Blue (CA)	*12.7*	NA	NA	1.00	0.00	0.00	12.71
Blue (OR & WA)	*12.2*	0.34	0.66	0.00	4.16	8.08	0.00
Brown	*1.2*	0.26	0.49	0.25	0.31	0.58	0.29
Calico	-	NA	NA	NA	-	-	-
China	*4.2*	0.26	0.49	0.25	1.09	2.05	1.05
Copper	*6.5*	0.26	0.49	0.25	1.70	3.21	1.64
Gopher	-	NA	NA	NA	-	-	-
Grass	*0.2*	0.26	0.49	0.25	0.06	0.12	0.06

Total	*40.1*				8.1	15.5	16.5
							40.1

Option 2: Change in Fishing Activity Compared to Option 1

Washington

Recreational: The Washington HG under Option 2 is 8.1 mt which is lower than the projected impacts Under No Action (Option 1). The Washington recreational fishery would operate under season structure and management measures described under the Preferred Alternative. However because the WA HG under Option 2 is lower than the historical catch, additional management measures would be needed to keep nearshore rockfish catch under the WA HG for this alternative. To keep total mortality under the WA HG, retention of nearshore rockfish would not be permitted for a portion of the year. Attainment of the WA HG under this alternative is projected to occur in mid-August with retention of nearshore rockfish prohibited for 4.5 months from August 15 through December. Alternate combinations of months when nearshore rockfish would be prohibited may be explored.

Commercial: Closed

Oregon

Under Option 2, the Oregon Nearshore Rockfish complex harvest guideline is lower than the current combined commercial and recreational state-specified landing caps and average annual catches. We showed above that expected Nearshore Rockfish mortality for Oregon fisheries combined is 45.6 mt for No Action and 48.9 mt for Preferred Alternative. The Oregon harvest guideline under this option is 15.5 mt (Table B-111), or 66 percent lower than expected mortality under No Action and 68 percent lower than expected under Preferred Alternative. State landing caps for both commercial and recreational fisheries will have to be reduced dramatically to accommodate this lower target. The GMT understands that Oregon intends to develop the commercial-recreational split of the Oregon HG through subsequent state processes.

Recreational: Once the state determines the sector-specific allocation, management measures will need to be examined, and then implemented through state rules. A preliminary examination of possible management measures has begun. A bag limit analysis revealed that the majority of anglers encounter less than one nearshore rockfish per trip. Therefore changes in bag limit will likely not be a viable option. The likely measure will be non-retention for most or all of the fishing season, incorporating discard mortality for the non-retention months into the impact projections. Even though most anglers encounter less than one nearshore rockfish per angler trip and they are generally not targeted, prohibiting retention for most or all of the season, could influence the number of angler trips, how often, when or where anglers go fishing. Additionally, it may require anglers to be on the water longer to fill their daily bag limit. Since the majority of anglers do not fill their entire bag each day, this is anticipated to have minimal impacts in the short term, but there is the potential for long term or cumulative impacts.

Commercial: Under Option 2, the RCA depth restriction of 30 fm would remain in place because projected catch of overfished species would remain at or below the Oregon catch share. Measures other than depth management will have to be implemented to reduce the mortality of Nearshore Rockfish (including blue rockfish) under this option. For example, under No Action, the commercial fishery was projected to land 15 mt of Nearshore Rockfish (including blue rockfish), resulting in total mortality of 15.1 mt, including discard. Using proportions of current landing caps and average landings between Oregon recreational and commercial fisheries (see Preferred Alternative in the DEIS), the Oregon commercial fishery would receive 5.35 mt of Nearshore Rockfish (including blue rockfish), or a reduction of 65 percent relative to No Action and a 71 percent reduction relative to Preferred Alternative. If one assumes that catch of Nearshore Rockfish is incidental and unavoidable, then the No Action landings value (i.e., 15.0 mt) may be encountered, caught, and discarded under this scenario. Some of the discard will survive. The resulting mortality of Nearshore Rockfish under this assumption is estimated to be 6.49 mt, which would exceed the Oregon commercial allocation of 5.35 mt.

California

Recreational: Under Option 2, 16.5 mt would be allocated to California, of which, the recreational catch share is 9.18 mt, accommodating a May 1 to September 15 season with a 20 fm depth restriction in the Northern Management Area. This would provide one month less fishing opportunity relative to the status quo. The recreational fishing season would have to be reduced by five and a half months relative to the longest season under the Preferred Alternative of March 1 to December 31 to prevent the recreational share of Nearshore Rockfish complex from being exceeded. Other alternatives to address overages relative to the catch share include a reduced bag limit or non-retention of Nearshore Rockfish species during part of the season.

Commercial: Under Option 2 the RCA depth restriction of 20 fm would remain in place as well as the trip limit structure. Because the minor nearshore rockfish complex harvest has been at or below the ACLs in recent years (see), it is not anticipated that Option 2 will have an adverse effect on the northern nearshore rockfish fishery; thus fishing activity is expected not to change. However, trip limit reductions could be implemented should the need arise, with possible decreases that may be nearly 50 percent less than the current trip limit amount. Another possibility to be considered is to have period closures. Additionally, California's northern management region is somewhat isolated from the adjacent region(s). Because of this, northern region participants tend not to fish in other management regions (for those holding a deeper nearshore rockfish permit), nor would they be likely to because the trip limits for the northern region are higher than any of the other regions. Also, it is not expected that holders of a deeper nearshore rockfish permit, who may also hold a shallow permit in any of the other southerly regions, would travel to the northern management region to fish because they would only be allowed to catch and land the deeper nearshore rockfishes – their shallow nearshore permit would not be valid north of 40°10' N. latitude. In effect, it would probably not be economically justifiable for them to fish north of 40°10' N. latitude.

Option 2: Biological Impacts Compared to Option 1

Projected Nearshore Rockfish Mortality

The projected mortality in each state and sector under Option 4 are summarized in Table B-112. Further description of the mortality in each state and sector is provided in the text below.

Table B-112. Projected Nearshore Rockfish mortality north of 40°10′ N. Lat. from each state and sector under Option 2 (at P* = 0.25).

State	**Washington**		**Oregon**		**California**		**Total**
Sector	Recreational	Commercial	Recreational	Commercial	Recreational	Commercial	
Mortality	8.1	Closed	5.6	9.9	9	7.32	39.92
State Total	8.1		15.5		16.32		
Allocation	8.1		15.5		16.5		40.1
Percent	100%		100%		98.9%		99.6%

Washington

Recreational: Under Option 2 the projected Washington recreational catch of nearshore rockfish would decrease by approximately 23 percent compared to Option 1. No negative biological impacts are expected.

Commercial: Closed

Oregon

Recreational: Under this option, impacts to nearshore rockfish will need to be reduced. Oregon intends to allocate between the commercial and recreational sectors, and take management measures to stay within those allocations, through subsequent state processes. The most likely management measure will be non-retention of nearshore rockfish (other nearshore rockfish and/or blue rockfish[22]) for most or all of the fishing season. Table B-113 below shows the projected landings for the other nearshore rockfish and blue rockfish under the preferred season structure (Section 4.2.2.8) and the projected discard mortality from non-retention by month. Both are calculated on a month by month basis, as that is the smallest time unit currently available in the Oregon recreational model. To project total impacts, and determine which months might need to have non-retention, the landings for months open are added to the release mortality for non-retention months.

Table B-113. Oregon recreational fishery impacts (in mt) by month under preferred season structure and non-retention for the nearshore rockfish.

Projections	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec
Other Nearshore Rockfish												
Landings under SQ regulations	0.19	0.24	0.58	0.90	1.64	2.13	2.59	2.91	1.22	0.43	0.10	0.06
Non-retention release mortality	0.08	0.10	0.23	0.33	0.61	0.79	0.96	1.08	0.45	0.17	0.04	0.03
Blue Rockfish												
Landings under SQ regulations	0.27	0.34	0.82	1.25	2.24	2.90	3.54	3.98	1.66	0.61	0.14	0.09
Non-retention release mortality	0.27	0.11	0.27	0.39	0.70	0.91	1.10	1.24	0.52	0.21	0.05	0.03

As one example, non-retention for the entire year would reduce impacts of all nearshore rockfish species (including blue rockfish) from 30.5 mt to 10.6 mt, or a 65 percent reduction. The GMT understands that Oregon intends to go through their public process to get angler input on which months to have non-retention.

[22] In Oregon state regulations, blue rockfish is managed and has a state-specified landing cap separate from the remaining or "other nearshore" rockfish.

Commercial: Under this option, commercial management measures necessary to reduce Nearshore Rockfish mortality to near 5.35 mt (from No Action Mortality of 15.1 mt) would likely be non-retention, possibly year-around. Even with non-retention, estimated discard mortality (6.49 mt) would exceed the Oregon commercial allocation, if the recreational-commercial split remained the same as under No Action.

California

Recreational: The projected mortality on nearshore rockfish under Option 2 with a May 1 to September 15 season in the Northern Management Area with a 20 fm depth restriction is 9.0 mt of which 2.3 mt would be blue rockfish. These mortality projections are below the recreational catch share of the California allocation of 9.18 mt under this option.

Commercial: No anticipated negative biological impacts are expected for this option compared to Option 1. Because this option (as well as Options 3 and 4) could require reductions in harvest, biological impacts could actually be reduced to a small degree depending upon the amount of the reduction. Since California's northern fishery has taken less than 10 mt per year on average during the past five years, resultant decreases would be small. Nevertheless, under this option, commercial management measures will need to be applied to reduce nearshore rockfish mortality.

Projected Overfished Species Mortality

Washington

Recreational: Projected overfished species impacts under this Option are the same as for the season structure under the Washington recreational Preferred Alternative.

Commercial: Closed

Oregon

Recreational: A preliminary examination of overfished species impacts due to management measures that may be required under this option projects less than a 1 percent increase in canary and yelloweye rockfish impacts, assuming no other changes to angler behavior.

Commercial: Under Option 2, if fishermen behavior remains the same as under No Action regarding fishing locations and fishing methods, but increased discarding of Nearshore Rockfish becomes necessary, then mortality of Overfished Species will remain unchanged relative to No Action. If, on the other hand, selection of fishing locations changes dramatically because of changes in trip limits or required non-retention of Nearshore Rockfish, then overfished species impacts may increase or decrease, depending on geographic locations selected. The direction or level of this potential change in catch of overfished species cannot be predicted in this analysis.

California

Recreational: Assuming season lengths under Option 1 of ACL Alternative 2 in Management Areas south of 40°10′ N. latitude and the May 1 to September 15 season with a 20 fm depth restriction in the Northern Management Area, overfished species mortality projected to accrue under Option 2 are 2.6 mt of yelloweye rockfish, 17.9 mt of canary rockfish, 116.8 mt of bocaccio and 1.2 mt of cowcod. The projected impacts are within the respective harvest limits/guidelines.

Commercial: Harvest of canary and yelloweye rockfish has been near the respective allocation amounts for these two species. As such, under Option 2, projected mortality may have to be reduced. Using the nearshore bycatch model as a predictor, decreases in the black rockfish component may need to be considered as a means to achieve the necessary projected mortality decreases for these two overfished species so as to not exceed their allocations.

Stock Status

Nearshore Rockfish

None of the stocks in the Nearshore Rockfish complex are currently deemed overfished. The proposed HG under this option will facilitate implementation of inseason actions to prevent the aggregate ACL from being exceeded, decreasing the risk of overfishing component stocks. Thus, the stock status would not be adversely affected by management measures under Option 2.

Overfished Species

Under Option 2 (miles of coastline), the overfished species mortality is expected to be below the harvest limits/guidelines. Thus stock status and rebuilding plans would not be adversely affected management under Option 2.

Socio-economic Impacts compared to Option 1

Washington

Recreational: Socio-economic impacts would continue to be affected by management measures necessary to keep the Washington recreational fishery within the WA HG for overfished species (yelloweye and canary rockfish). In addition, under Option 2, recreational fishing opportunity would be further reduced. Prohibiting retention of nearshore rockfish for a portion of the season on top of other management measures already in place to protect overfished species may discourage angler participation in recreational groundfish fisheries. While it's difficult to predict angler behavior, any reduction in angler fishing effort will have negative socioeconomic impacts. If these management measures resulted in 10 percent fewer anglers participating in recreational groundfish fisheries, effort would be reduced by approximately 2,400 angler trips targeting bottomfish. This reduction would have negative economic impacts to coastal communities that are dependent on recreational fishing.

Commercial: Closed

Oregon

Recreational: Since most anglers encounter less than one nearshore rockfish per angler trip and they are generally not targeted, non-retention for a few months to reduce mortality of nearshore rockfish species is not expected to impact angler behavior, angler trips, nor any other socio-economic indicators. Non-retention for most or all of the season has the potential to influence angler behavior, but to what extent is unknown. Additional outreach and education on species identification will likely be necessary to help anglers stay within retention/non-retention regulations. It is impossible to predict how the additive impact of adding this regulation to others already in place might impact anglers' decisions on fishing activities.

Commercial: It is uncertain whether fishing behavior (i.e., fishing location and fishing gear) will change under this option relative to No Action (see above). However, if allocations remain the same between Oregon recreational and commercial fisheries, then landings may have to be reduced from 15.0 mt (No Action) to 0 mt (i.e., non-retention). The 2013 average price for Other Nearshore Rockfish (weighted average including blue rockfish) was $3.80 per pound for Oregon nearshore fisheries (PacFIN). Under the potential scenario shown here, lost ex-vessel revenue may reach $125,662 relative to No Action (the loss is higher relative to Preferred Alternative).

California

Recreational: Under Option 2, the season length would decrease by a month (1,983 angler trips) relative to the status quo fishery in the Northern Management Area. The season would be reduced by five and a half months (6,362 angler trips) relative to the Preferred Alternative ACL with the Option 1 season resulting in lost revenue from those in coastal communities dependent on recreational fishing for their livelihoods.

Commercial: The northern commercial fishery is still recovering from the 2011 tsunami event and the loss of buyers during the past year or two. Currently, there is only one major active buyer in Crescent City. The economic structure of the northern area (essentially only Crescent City) is in a rebuilding phase with no expected time frame, at the present, that predicts when a return to status quo would be reestablished. This, however, is not a result of the options themselves, but an artifact of unavoidable events that have impacted this area. (See also the comments in the Change in Fishing Activity section, above.)

B.19.1.2 Option 3: Historical Catch (P* = 0.25)

Option 3 is to manage the Nearshore Rockfish complex according to a state specific harvest guidelines stratified at 40°10′ N. latitude reflecting apportionment based on the historical catch between 2004 and 2012 reflected in Table B-114.

Table B-114. Allocations of Nearshore Rockfish north of 40°10′ N. Lat. under Option 3 (historical catch) derived using the historical recreational catch between 2004 and 2012.

Species	Contribution	WA%	OR%	CA%	WA mt	OR mt	CA mt

Sum Total	40.1				2.82	19.33	17.97
							40.11

<u>Option 3: Change in Fishing Activity Compared to Option 1</u>

<u>Washington</u>
Recreational: The Washington recreational fishery would operate under season structure and management measures similar to those described under the Preferred Alternative. However because the WA HG under Option 3 is not only lower than historical catch, it is lower than the discard mortality associated with non-retention of nearshore rockfish year round in all recreational fisheries including

salmon and halibut. To keep nearshore mortality under the WA HG for this Option the recreational bottomfish fishery would need to be closed for a significant portion of the year. Different combinations of months that could remain open to the recreational bottomfish fishery while still prohibiting retention of nearshore rockfish could be considered with similar results. For example, bottomfishing could remain open during only one of the peak high effort summer months (May-August) again, with nearshore rockfish retention prohibited, but would require the bottomfish fishery to be closed the remainder of the year to keep nearshore rockfish morality under the Option 3 WA HG.

Commercial: Closed

Oregon

Under Option 3, the Oregon Nearshore Rockfish complex harvest guideline is lower than the current combined commercial and recreational state-specified landing caps and average annual catches, but higher than Option 2. We showed under No Action for Nearshore Rockfish that the expected mortality for recreational and commercial fisheries combined is 45.6 mt (the expected mortality under Preferred Alternative is 48.9 mt). The Oregon harvest guideline under this option is 19.3 mt (Table B-114), 58 percent lower than expected mortality under No Action, and 60 percent lower than expected mortality under Preferred Alternative. State landing caps for both commercial and recreational fisheries will have to be reduced to accommodate this lower target. As noted under Option 2, Oregon intends to develop or modify the commercial- recreational split of the Oregon HG through state processes.

Recreational: Similar to Option 2, most or all of the season will require non-retention of nearshore rockfish species to keep impacts within the Oregon recreational HG.

Commercial: Similar to Option 2. Using the same assumptions as shown under Option 2, non-retention would be required year around. As such, resulting mortality of Nearshore Rockfish under these assumptions is estimated to be 6.49 mt, exceeding the Oregon commercial allocation of 5.35 mt. Hence, non-retention may be required year around.

California

Recreational: Under Option 3, 17.97 mt would be allocated to California, of which, the recreational catch share established by the state Fish and Game Commission is 10.0 mt, accommodating a May 1 to December 31 season with a 20 fm depth restriction in the Northern Management Area. This would reduce fishing opportunity by a month relative to the status quo. The recreational fishing season would have to be reduced by five and a half months relative to the longest season under the Preferred Alternative ACL of March 1 to December 31st. Other alternatives to address overages relative to the catch share include a reduced bag limit or non-retention of Nearshore Rockfish Species during part of the season.

Commercial: The same as Option 2.

Biological Impacts Compared to Option 1

Projected Nearshore Rockfish Mortality

The projected mortality in each state and sector under Option 3 are summarized in Table B-115. Further description of the mortality in each state and sector is provided in the text below.

Table B-115. Projected Nearshore Rockfish mortality north of 40°10′ N. Lat. from each state and sector under Option 3 (P* = 0.25).

State	**Washington**		**Oregon**		**California**		**Total**
Sector	Recreational	Commercial	Recreational	Commercial	Recreational	Commercial	
Mortality	2.8	Closed	13.13	6.2	9.4	5.6	37.13
State Total	2.82		19.33		15		
Allocation	2.82		19.33		17.97		40.12
Percent	100%		100%		83.5%		92.5%

Washington

Recreational: Under Option 3, additional management measures will be implemented to reduce nearshore rockfish mortality in the Washington recreational fishery by 73 percent compared to the No Action Option 1.

Commercial: Closed

Oregon

Recreational: Under Option 3, similar to Option 2, non-retention will likely be required for most or all of the season to keep impacts within the Oregon recreational HG. Table B-113 has the projections by month for the nearshore rockfish complex minus blue rockfish for retention and non-retention.

Commercial: Similar to Option 2, under this option, commercial management measures necessary to reduce Nearshore Rockfish mortality to near 6.2 mt (from No Action Mortality of 15.1 mt) would likely be non-retention year-around. Even with non-retention, estimated discard mortality (6.49 mt) would exceed the Oregon commercial allocation, if the recreational-commercial split remained the same as under No Action.

California

Recreational: The projected mortality on nearshore rockfish under Option 3 with a May 15 to September 30 season with a 20 fm depth restriction in the Northern Management Area is 9.4 mt of which 2.2 mt would be blue rockfish. These mortality projections are below the recreational catch share of the California allocation of 10.0 mt under this option.

Commercial: The projected mortality on nearshore rockfish under Option 3 is estimated to be 5.6 mt with no other management changes implemented.

Projected Overfished Species Mortality

Washington

Recreational: No additional overfished species mortality are projected compared to the No Action alternative. Overfished species impacts could be less than what is projected depending on the timing of the recreational bottomfish fishery closure necessary under this option.

Commercial: Closed

Oregon

Recreational: A preliminary examination of overfished species impacts due to management measures that may be required under this option projects less than 1 percent increase in canary and yelloweye rockfish impacts. This assumes no other changes to angler behavior.

Commercial: Same as Option 2.

California

Recreational: Assuming season lengths under Option 1 of ACL Alternative 2 in Management Areas south of 40°10′ N. Lat. and the May 15 to September 30 season with a 20 fm depth restriction in the Northern Management Area, overfished species mortality projected to accrue under Option 2 are 2.6 mt of yelloweye rockfish, 17.9 mt of canary rockfish, 116.8 mt of bocaccio and 1.2 mt of cowcod. The projected impacts are within the respective harvest limits/guidelines.

Commercial: The same as Option 2.

Stock Status

Nearshore Rockfish

None of the stocks in the Nearshore Rockfish complex are currently deemed overfished. The proposed HG under this option will facilitate implementation of inseason actions to prevent the aggregate ACL from being exceeded, decreasing the risk of overfishing component stocks. Thus, the stock status would not be adversely affected by management measures under Option 3.

Overfished Species

The projected mortality under Option 3 is the same as No Action (Option 1), which are below the respective harvest limits/guidelines. No adverse effects on stock status or rebuilding progress are expected under Option 3.

Option 3: Socio-economic Impacts compared to Option 1

Washington

Recreational: Socio-economic impacts would continue to be affected by management measures necessary to keep the Washington recreational fishery within the WA HG for overfished species (yelloweye and canary rockfish). In addition, under Option 3, not only would recreational fishing opportunity be further reduced by requiring non retention of nearshore rockfish in all recreational fisheries year round, it would also require the complete closure of the recreational bottomfish fishery for a significant portion of the year. Prohibiting retention of nearshore rockfish for a portion of the season on top of other management measures already in place to protect overfished species may discourage angler participation in recreational fisheries that remain open under nearshore rockfish retention restrictions. While it can be difficult to predict angler behavior when nearshore rockfish retention is prohibited, Option 3 will have direct and quantifiable reduction in the number of angler trips targeting bottomfish. Under Option 3, angler trips targeting bottomfish would be reduced by approximately 20,000 angler trips or 80 percent compared to the No Action Option resulting from closure of the bottomfish fishery. Closure of the recreational bottomfish fishery for a significant portion of the year will have significant negative socioeconomic impacts to coastal communities that are dependent on recreational fishing.

Commercial: NA

Oregon

Recreational: Same as under Option 2

Commercial: Same as under Option 2.

California

Recreational: Under Option 2, the season length would decrease by a month (787 angler trips) relative to the status quo fishery in the Northern Management Area. The season would be reduced by five and a half months (5,167 angler trips) relative to the Preferred Alternative ACL with the Option 1 season resulting in lost revenue from those in coastal communities dependent on recreational fishing for their livelihoods.

Commercial: The same as Option 2.

B.19.1.3 Option 4: Hybrid Method (P* = 0.25)

Option 4 is to manage the Nearshore Rockfish complex according to a state specific harvest guidelines stratified at 40°10′ N. latitude reflecting a hybrid method of apportionment based on miles of coastline for China, quillback and copper rockfish and the historical catch between 2004 and 2012 for the remaining species reflected in Table B-116.

Table B-116. Allocations of Nearshore Rockfish north of 40°10′ N. Lat. under Option 4 (P* = 0.25) derived using miles of coastline for China, quillback and copper rockfish and the historical commercial catch between 2004 and 2012 for the remaining species.

Species	Contribution	WA%	OR%	CA%	WA mt	OR mt	CA mt
Black and yellow	*0.0*	0.00	0.21	0.79	0.00	0.00	0.00
Blue (CA)	*12.7*	NA	NA	1.00	0.00	0.00	12.71
Blue (OR & WA)	*12.2*	0.06	0.94	NA	0.76	11.48	0.00
Brown	*1.2*	0.00	0.08	0.92	0.00	0.09	1.08
Calico	-	NA	NA	NA	-	-	-
China	*4.2*	0.26	0.49	0.25	1.08	2.07	1.04
Copper	*6.5*	0.26	0.49	0.25	1.69	3.23	1.62
Gopher	-	0.00	0.29	0.71	-	-	-
Grass	*0.2*	0.00	0.49	0.51	0.00	0.12	0.13
Kelp	*0.0*	NA	NA	NA	0.00	0.00	0.00
Olive	*0.1*	0.00	0.03	0.97	0.00	0.00	0.12
Quillback	*2.8*	0.26	0.49	0.25	0.72	1.38	0.69
Treefish	*0.1*	0.00	0.00	1.00	0.00	0.00	0.08
Sum Total	40.1				4.25	18.38	17.48
							40.11

Option 4: Change in Fishing Activity Compared to Option 1

Washington

Recreational: The Washington recreational fishery would operate under season structure and management measures similar to those described under the Preferred Alternative. However because the WA HG under Option 4 is lower than the historical nearshore rockfish catch, additional management measures would be needed to keep nearshore rockfish catch under the WA HG. To keep total mortality under the WA HG, retention of nearshore rockfish would be prohibited in all recreational fisheries year round. Projected impacts of nearshore rockfish under Option 4 are 4.3 mt, 0.05 mt higher than the WA HG. If angler effort and fishing success result in catch estimates higher than what is projected, inseason action through state regulations such as closure of the recreational bottomfish fishery may be considered to keep nearshore rockfish catch under the Option 4 WA HG.

Commercial: Closed

Oregon

Under Option 4, the Oregon harvest guideline is similar to that shown under Option 3; Option 4 provides a harvest guideline of 18.4 mt and Option 3 shows a harvest guideline of 19.3 mt. As such, overall impacts will be similar between Option 4 and Option 3. See Option 3 for more details.

Recreational: Similar to Options 2 and 3 above, non-retention will likely be required for most or all of the season to keep impacts within the Oregon recreational HG.

Commercial: Similar to Option 3. Using the same assumptions as shown under Option 3, non-retention may be required year around. As such, resulting mortality of Nearshore Rockfish under these assumptions is estimated to be 6.5 mt, exceeding the Oregon commercial allocation of 5.7 mt. Hence, non-retention would be required year around.

California

Recreational: Under Option 4, 17.48 mt would be allocated to California, of which, the recreational catch share established by the state Fish and Game Commission is 9.73 mt, accommodating a May 15 to September 30 season with a 20 fm depth restriction in the Northern Management Area. This would result in a one month reduction in fishing opportunity relative to the status quo. The recreational fishing season would have to be reduced by five and a half months relative to the longest season under the Preferred Alternative of March 1 to December 31st. Other alternatives to address overages relative to the catch share include a reduced bag limit or non-retention of Nearshore Rockfish Species during part of the season.

Commercial: The same as Option 2.

Option 4: Biological Impacts Compared to Option 1

Projected Nearshore Rockfish Mortality

The projected mortality in each state and sector under Option 4 are summarized in Table B-117. Further description of the mortality in each state and sector is provided in the text below.

Washington

Recreational: Under Option 4, additional management measures will be implemented to reduce nearshore rockfish mortality in the Washington recreational fishery by 59 percent compared to Option 1.

Commercial: NA

Oregon

Recreational: Similar to Options 2 and 3 above, a combination of months of retention and non-retention will be required. Table 8 has projected impacts by month for allowing retention and requiring non-retention.

Commercial: Similar to Options 2 and 3 above. Non-retention will likely be required. Even with non-retention, estimated discard mortality (6.5 mt) would exceed the Oregon commercial allocation (5.7 mt) if the recreational-commercial split remained the same as under No Action.

California
Recreational: Recreational: The projected mortality on nearshore rockfish under Option 4 with a May 15 to September 30 season with a 20 fm depth restriction in the Northern Management Area is 9.4 mt of which 2.2 mt would be blue rockfish. These mortality projections are below the recreational catch share of the California allocation of 9.7 mt under this option.

Commercial: The same as Option 2.

Table B-117. Projected Nearshore Rockfish mortality north of 40°10′ N. Lat. from each state and sector under Option 4 (P* = 0.25).

State	**Washington**		**Oregon**		**California**		**Total**
Sector	Recreational	Commercial	Recreational	Commercial	Recreational	Commercial	
Mortality	4.25	Closed	12.18	6.2	9.4	7.32	39.35
State Total	4.25		18.38		16.72		
Allocation	4.25		18.38		17.48		40.11
Percent	100%		100%		95.7%		98.1%

Option 4: Projected Overfished Species Mortality

Washington
Recreational: No additional overfished species mortality is projected compared to the No Action alternative. Overfished species mortality could be lower than what is projected if angler effort is reduced or if closure of the recreational bottomfish fishery is needed to keep nearshore rockfish mortality within the WA HG under Option 4.

Commercial: NA

Oregon
Recreational: A preliminary examination of overfished species impacts due to management measures that may be required under this option projects less than 1 percent increase in canary and yelloweye rockfish impacts.

Commercial: Same as Options 2 and 3.

California
Recreational: Assuming season lengths under Option 1 of ACL Alternative 2 in Management Areas south of 40°10′ N. latitude and the May 15 to September 30 season with a 20 fm depth restriction in the

Northern Management Area, overfished species mortality projected to accrue under Option 2 are 2.6 mt of yelloweye rockfish, 17.9 mt of canary rockfish, 116.8 mt of bocaccio and 1.2 mt of cowcod. The projected impacts are within the respective harvest limits/guidelines.

Commercial: That which applies to Option 2 would also apply for Option 4.

Stock Status

Nearshore Rockfish

None of the stocks in the Nearshore Rockfish complex are currently deemed overfished. The proposed HG under this option will facilitate implementation of inseason actions to prevent the aggregate ACL from being exceeded, decreasing the risk of overfishing component stocks. Thus, the stock status would not be adversely affected by management measures under Option 4.

Overfished Species

The projected mortality under Option 4 is the same as No Action (Option 1), which are below the respective harvest limits/guidelines. No adverse effects on stock status or rebuilding progress are expected under Option 3.

Socio-economic Impacts compared to Option 1

Washington

Recreational: Socio-economic impacts would continue to be affected by management measures necessary to keep the Washington recreational fishery within the WA HG for overfished species (yelloweye and canary rockfish). In addition, under Option 4, retention of nearshore rockfish in all recreational fisheries would be prohibited year round. If inseason catch estimates show that nearshore rockfish catch is higher than projected, closure of the recreational bottomfish fishery may be necessary to keep nearshore rockfish mortality within the WA HG under Option 4. Prohibiting retention of nearshore rockfish year round on top of other management measures already in place to protect overfished species is likely to discourage angler participation in recreational groundfish fisheries. While it's difficult to predict angler behavior, any reduction in angler fishing effort will have negative socioeconomic impacts. If these management measures resulted in 10 percent fewer anglers participating in recreational groundfish fisheries, effort would be reduced by approximately 2,400 angler trips targeting bottomfish. This reduction would have negative economic impacts to coastal communities that are dependent on recreational fishing.

Commercial: Closed

Oregon

Recreational: Similar to Options 2 and 3 above.

Commercial: Similar to Options 2 and 3 above.

California

Recreational: Under Option 2, the season length would decrease by a month (787 angler trips) relative to the status quo fishery in the Northern Management Area. The season would be reduced by five and a half months (5,167 angler trips) relative to the Preferred Alternative ACL with the Option 1 season resulting in lost revenue from those in coastal communities dependent on recreational fishing for their livelihoods.

Commercial: That which applies to Option 2 would also apply for Option 4.

Discussion

More restrictive management measures are needed to keep Nearshore Rockfish complex mortality below the state HGs resulting from allocation of ACL Alternative 2 with a P* of 0.25 to HGs. For Oregon and Washington, this lower HG may result in non-retention (i.e., discard), in some cases year around. It was shown that under full year non-retention in both the commercial and recreational fisheries, discard mortality may still exceed the Oregon state HGs under Options 2-4. This would result in forgone fishing opportunity and in some cases potentially severe socio-economic consequences compared to the Preferred Alternative ACL Alternative assuming a P* of 0.45 and the status quo ACL. The stock status is not expected to be greatly improved as a result of the ACLs from the lower P* and ACL Alternative 2. The Council may want to consider the trade-off between buffering against scientific uncertainty in the nearshore rockfish assessments and the socioeconomic consequences of lower ACLs for fishing communities in weighing the most appropriate P* value.

B.20 Recreational: Washington and California Canary Sub-Bag Limits

B.20.1 Washington

Retention of canary rockfish has been prohibited in Washington recreational fisheries since 2004 to keep mortality (including discard mortality) within the HG. Management measures are in place to keep total impacts of canary rockfish to state specific harvest guidelines (HG). The presumptive HGs are 3.4 mt for 2015 and 3.5 mt for 2016. Management measures vary by management area to reflect increasing encounters with canary rockfish as you move from south to north along the Washington coastline. Canary rockfish total mortality often falls well under the Washington HG a result of restrictive management measures in place to keep yelloweye rockfish total mortality under the state specific HG.

Management options
No Action**:** Retention of canary rockfish would remain prohibited

> Under the No Action option, anglers would continue to be required to discard all canary rockfish encountered during all recreational fishing.

Option1**:** One canary rockfish per day as a sub-limit to the rockfish bag limit of ten and the total groundfish bag limit of twelve.

Option2**:** Up to ten canary rockfish per day as part of the rockfish sub-bag limit.

Analysis
Projected Impacts under the No Action option
Under the No Action option management measures would be the same as those analyzed under the Preferred Alternative harvest specifications for canary rockfish (Section 4.2.2.7). The projected canary rockfish mortality would be 0.75 mt. The Washington recreational HG of 3.4 mt (2015) and 3.5 mt (2016) would not be attained.

Under Option 1, anglers would be allowed to retain one rockfish per day as part of the rockfish sub-bag limit of 10 and the total bottomfish bag limit of 12. All other management measures would be the same as those analyzed under the Preferred Alternative in Section 4.2.2.7.

Table B-118. Projected mortality (mt) of canary rockfish under canary sub-bag limit Option 1 and management measures under the Preferred Alternative (Section 4.2.2.7).

Washington canary HG 2015/2016	3.4 / 3.5
Projected Mortality	2.5

Under Option 2, anglers would be allowed to retain up to ten rockfish per day as part of the rockfish sub-bag limit of 10 and the total bottomfish bag limit of twelve. Management measures would be the same as those analyzed under the Preferred Alternative in Section 4.2.2.7.

Table B-119. Projected mortality (mt) of canary rockfish under canary sub-bag limit Option2 and management measures under the Preferred Alternative.

Washington canary HG 2015/2016	3.4 / 3.5
Projected Mortality	2.6

Methods

Washington Ocean Sampling Program (OSP) data as provided to RecFIN from 2009-2013 was used to project canary rockfish mortality for both sub-bag limit options. All canary rockfish encounters up to one (Option 1) or ten (Option 2) per angler were assumed to be retained. Canary per angler of more than one (or 10) was assumed discarded. Mortality for the discarded canary was estimated based on the proportion of canary caught by depth based on angler interview data with the corresponding surface release mortality rates applied. Mortality from the one canary bag limit analysis was added to the projected mortality for the Preferred Alternative management measures to project the total canary mortality for the canary sub-bag limit alternatives. The highest estimate of canary mortality over the 2009-2013 time period was used to project mortality for the sub-bag limit alternatives.

Discussion

If canary retention is allowed, actual estimates of canary mortality may be higher than what is estimated in this analysis due to the difficulty in projecting changes in angler behavior. Anglers that normally wouldn't encounter a canary rockfish during the course of their typical fishing trip under current regulations prohibiting canary retention may be inclined to fish longer with the hope of catching a canary rockfish or may seek out areas where canary rockfish abundance is higher if canary retention is allowed.

B.20.2 California

The California recreational fishery is currently managed to a canary harvest guideline (HG), of 23.0 mt in 2014; the presumptive HGs are expected to increase to 24.3 mt (2015) and 25.0 mt (2016; Table B-120). Retention of canary rockfish in the California recreational fishery is prohibited. The majority of canary encounters occur in the San Francisco Management Area, which is open six months of the year to depths of 30 fm, and in Central Management Area where access is allowed seven months of the year to depths of 40 fm.

Because canary rockfish have a high susceptibility to barotrauma [23], non-retention results in regulatory discarding and associated mortality that increases with depth of capture. Rather than adding the extra canary rockfish to their bag, anglers must discard them and fish longer to achieve their 10 fish Rockfish,

[23] Canary rockfish have a surface discard mortality of 100 percent in waters 30 fm or greater (Agenda Item D.5.b. GMT Report, April 2013)

Cabezon and Greenling (RCG) complex bag limit, which may increase the likelihood of encounters with other overfished species.

<u>Management Options</u>

<u>Option 1-No Action</u>: Maintain prohibition on retention of canary rockfish

<u>Option 2</u>: Increase the sub-bag limit to one fish within the rockfish-cabezon-greenling (RCG) complex bag limit under the Preferred Alternative season structure in Option 1

<u>Option 3</u>: Increase the sub-bag limit to one fish within the RCG complex bag limit under a decreased season length

2015-2016 Management Considerations

Anglers have reported that "they can't get away from canary rockfish" and that encounters are becoming more frequent in shallow waters. These encounters are not unexpected and are expected to increase as the population continues to rebuild (i.e. the rebuilding paradox). Due to barotrauma, a portion of discarded canary rockfish will not survive and anglers are forced to discard dead (or dying) fish rather than adding them to the 10 fish RCG complex bag limit. In order to minimize discards of canary rockfish, the Council requested analysis of a one fish sub-bag limit of canary rockfish within the 10 fish RCG complex bag limit. If retention were allowed angler behavior could change, as anglers may continue fishing in locations where canary rockfish are encountered rather than moving.

Under Option 1, retention of canary rockfish would continue to be prohibited and the season structure would be the same as in 2014. Anglers will be required to discard all canary rockfish while in pursuit of other fish, increasing time on the water and therefore the chance of encounters with other overfished species. Under No Action, the recreational HG will not be attained.

Under Option 2, anglers would be allowed a sub-bag limit of one canary rockfish within the RCG complex bag limit, with the Preferred Alternative season structure[24] in place (Figure B-50). See Section 4.2.2.9 for a description of season structure analyses.

Management Area	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec
Northern	Closed		Mar 1 – Dec 31 <20 fm									
Mendocino	Closed		Mar 1 – Dec 31<20 fm									
San Francisco	Closed		Mar 1 – Dec 31 <30 fm									
Central	Closed		Mar 1 – Dec 31<40 fm C									
Southern	Closed		Mar 1 – Dec 31 <60 fm									

Figure B-50. Preliminary Preferred Option season structure in 2015-2016 (Section 4.2.2.9).

Under Option 3, the season length was decreased to keep the projected mortality within the HG (Figure B-51). Because encounters with canary rockfish are highest in the San Francisco and Central Management Areas, reductions to season length in these regions are necessary to keep projected mortality within the HG. Conversely, projected mortality of canary rockfish is sufficiently low in the Northern and Mendocino Management Areas that, compared to No Action, increased season length can be afforded in those areas Encounters with canary rockfish are relatively uncommon south of Point Conception such that a 60 fm depth restriction can be accommodated. Increased mortality due to changes in angler

[24] The Preferred Alternative season structure corresponds to Alternative 1 (Option 1).

behavior is not easily quantifiable; as a result, a buffer was included in modeling to accommodate mortality that may arise from changes in angler behavior.

Management Area	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec
Northern	Closed				May 1 – Dec 31 <20 fm							
Mendocino	Closed				May 1 – Dec 31 <20 fm							
San Francisco	Closed				May 1 – Oct 30 <30fm						Closed	
Central	Closed				May 1 – Oct 30 <40fm						Closed	
Southern	Closed		Mar 1 – Dec 31 <60fm

Analysis

Biological Impacts under No Action

Projected Impacts

The projected mortality to canary rockfish would be 16.4 mt under Option 1; Table B-120 summarizes projected mortality to all overfished species. As the canary rockfish stock continues to rebuild some increased encounters (and discarding) would be expected, although the amount cannot be quantified.

Table B-120. Projected mortality to overfished species under No Action

Species	Projected Mortality (mt)
Bocaccio	100.1
Canary Rockfish	16.3
Cowcod	1.0
Yelloweye Rockfish	1.7

Stock Status

The stock was declared overfished in 1999 and harvest has been severely restricted in both the commercial and recreational fisheries since 2000. The latest assessment indicates stock biomass is increasing, and that recent management actions have curtailed removals such that overfishing has not occurred since before 1999 (Wallace and Cope, 2011).

Impacts under Option 1

Projected Impacts

No changes to stock status or rebuilding progress are expected.

RecFIN data from 2011 to 2012 was used to project canary rockfish mortality as a result of establishing a one fish sub-bag limit. Using the RecFIN Hypothetical Bag Limit Analysis tool, estimates of increased mortality of canary rockfish were calculated using A+B1+B2 fish. For the purpose of this analysis, A fish include sampled dead fish, B1 fish includes both fillets and dead discarded fish, while B2 fish includes mainly live discarded fish. As the most conservative estimate, the analysis also assumes that all B2 fish would be available if retention was permitted. All possible bags were set to the hypothetical limit to calculate increased mortality.

Impacts under Option 2

Projected Impacts

Under Option 2, canary rockfish mortality is projected to increase by 62 percent (10.3 mt) compared to Option 1. The HG is expected to be exceeded by 2.4 mt, given the cumulative projected mortality from both increased season length under Preferred Alternative season structure and a one fish sub-bag limit (Table B-121). If angler behavior changes as a result of allowing limited retention, actual mortality may be greater than projected, though the amount cannot be quantified.

Table B-121. Projected mortality (in mt) compared by option and percent of presumptive 2015 harvest guideline.

	Option 1	Option 2
Projected Mortality	16.4	26.7
% HG	67.5%	109.4%

Impacts on Overfished Species

Table B-122 summarizes projected mortality to all overfished species under Option 2. Due to increases in season length, some increased mortality is expected compared to No Action. Increased mortality to other overfished species as a result of the one fish canary sub-bag limit is expected to be minimal; yelloweye rockfish tend to be more solitary and are not known to school with canary rockfish, while bocaccio rockfish and cowcod are primarily distributed south of Point Conception where canary rockfish encounters are comparatively less common.

Table B-122. California recreational projected mortality of overfished species for 2015-2016 under Option 2.

Species	Projected Mortality (mt)
Bocaccio	117.5
Canary Rockfish	26.7
Cowcod	1.2
Yelloweye Rockfish	2.9

Stock status

Under Option 2**,** no changes to stock status or rebuilding progress are expected compared to Option1.

Socioeconomic Impacts

Given uncertainty in angler behavior, inseason action may be necessary to keep within the projected impacts. This may result in area closures, increased depth restrictions or early closure of the recreational fishery. Loss in revenue and opportunity can be expected, although the degree is difficult to quantify. However, some increased opportunity may be realized as a result of allowing limited retention of canary rockfish, it would not compensate for losses (in revenue and opportunity) due to early closures.

Impacts under Option 3

Projected Impacts

Under Option 3, mortality of canary rockfish is projected to increase by 20 percent (3.2 mt) compared to No Action (Table B-123). The HG is not expected to be exceeded, given the buffer to accommodate any changes of angler behavior. Given reductions in season length, attainment of non-overfished species harvest targets may not be realized, resulting in lost opportunity.

Table B-123. Projected mortality (in mt) compared by option and percent of presumptive 2015 harvest guideline.

	Option 1	Option 2	Option 3
Projected Mortality	16.4	26.7	20.7
% HG	67.5%	109.4%	85.2%

Impacts on Overfished Species

Table B-124 summarizes mortality to all overfished species under Option 3. Similar to Option 2, increased mortality to other overfished species as a result of a one canary rockfish sub-bag limit is expected to be minimal. Between the Options, differences in projected mortality of other overfished species are primarily due to the variation in the analyzed season lengths.

Table B-124. California recreational projected mortality of overfished species for 2015-2016 under Option 3.

Species	Projected Mortality (mt)
Bocaccio	117.6
Canary Rockfish	20.7
Cowcod	1.2
Yelloweye Rockfish	1.8

Stock status

Under Option 3**,** no changes to stock status or rebuilding progress are expected.

Socioeconomic Impacts

Under Option 3, reduced season length would result in forgone fishing opportunity with negative effects to the revenues of coastal communities in the central region of the state. While some increased opportunity can be expected as a result of allowing limited retention of canary rockfish, it is difficult to quantify and is not expected to offset the increased opportunity that would have been available given the season lengths that could be afforded with retention remaining prohibited (i.e. Preferred Alternative season structure Option1, Option 1).

B.21 Recreational: 50 fm Recreational RCA

In March 2014, the Council approved new mortality rates for canary and yelloweye rockfish (along with cowcod) for use when descending devices are used to release recreationally caught rockfish. These new mortality rates are the same between 30 and 50 fm, for surface released fish anything deeper than 30 fm had 100 percent mortality applied (Table B-125). Given the new mortality rate out to 50 fm, Oregon and Washington would like to have the management line at 50 fm, defined in regulation at 50 CFR §660.72(a), available for possible use in management.

Table B-125. Surface and descending device mortality rates for canary and yelloweye rockfish by depth bin

Species	Depth (fm)	Surface Mortality Rate	Descending Device Mortality Rate
Canary Rockfish	0-10	21%	21%
	10-20	37%	25%
	20-30	53%	25%
	30-50	100%	48%
	50-100	100%	57%
	>100	100%	100%
Yelloweye Rockfish	0-10	22%	22%
	10-20	39%	26%
	20-30	56%	26%
	30-50	100%	27%
	50-100	100%	57%
	>100	100%	100%

Management Measures under the Preferred Alternative

B.1 Changes to Rockfish Conservation Area Coordinates

Need for Action

Rockfish Conservation Areas (RCA) are a type of commercial and recreational fishery management measure used to keep catches within annual catch limits (ACLs). RCAs affect the collective behavior of harvesters by preventing fishing in areas where bycatch of overfished species is particularly high. Their extent varies by area, season and gear type to allow access to target species while minimizing bycatch. The boundaries of RCAs are described by depth contours since a correlation between depth and the distribution (or catch) of overfished species has been demonstrated through an analysis of trawl logbook and survey data. The boundary depth contours defined by waypoints in Federal regulations (at 50 CFR 660.71-660.74) only approximate actual isobaths for two reasons. First, the waypoints defining the lines were defined using available bathymetry data, which have improved over time. Second, for enforcement purposes the lines defined by the waypoints are a more generalized, or simplified, representation of isobaths. Often, changes to the coordinates that define RCA are often recommended during the biennial cycle to more closely align with the latest data on bathymetry.

Other measures more directly constrain catch on an individual vessel level. These are:

- Individual fishing quota (IFQ) management for the shoreside trawl fleet (with cumulative landing
- limits for some non-target, non-overfished management units)
- Co-op allocations to the at-sea whiting fleets (catcher vessels delivering to at-sea processors and
- catcher-processors)
- Permit-based sablefish allocations to vessels in the limited entry fixed gear fleet during the
- primary season
- Daily and cumulative landing limits for the open access fixed gear sectors and limited entry fixed
- gear outside the primary season
- State restricted access permit programs for the non-trawl fixed-gear sectors, such as the nearshore fisheries for Oregon and California

Only catch share management directly controls total catch of most management unit species (including all overfished species) in the trawl sectors with all catch monitored by observers. Daily trip limits and 2-month limits in other sectors only control landings; overfished species total catch (mostly bycatch) must be imputed based on partial observer coverage. RCAs add another layer of precaution by affecting collective behavior and their use is more important in managing those sectors not under catch shares since overfished species bycatch cannot be directly controlled.

Inseason management allows measures to be periodically adjusted during the biennial period based on new information and catch projections. These management measures are described in more detail in Section 2.3 of the EIS.

B.1.1 Oregon: Adjustments to the 200 fm Modified Line

Coordinates for the 200 fathom (fm) RCA line in Oregon were revised beginning January 1, 2013 to better align with depth contours (See 2013-2014 FEIS). However, coordinates for the 200-fm modified RCA, which are modified to provide access to shallower waters where petrale sole concentrations are greater (called petrale cut-outs), were not simultaneously adjusted. The result was areas where the petrale cut-outs on the 200 fm modified line were deeper than the 200 fm RCA (Figure B-1).

Management Options

No Action: The RCA coordinates currently in regulation would remain and in some areas the 200 fm modified line with petrale cut-outs would be deeper than the 200 fm line.

Option 1 (Preferred): Revise coordinates such that the 200 fm modified line is not deeper than the 200 fm line (Table B-1).

Table B-1. Coordinate list for proposed modification to 200 fm-modified RCA coordinates.

ID	Name	Degrees, decimal minutes	Decimal degrees
79	Current waypoint	44°46.87'N, 124°38.20'W	44.781243, -124.636738
1	OR proposed modification	44°48.25'N, 124°40.61'W	44.8041, -124.6769
2	OR proposed modification	44°42.24'N, 124°48.05'W	44.704, -124.8008
3	OR proposed modification	44°41.35'N, 124°48.03'W	44.6892, -124.8005
4	OR proposed modification	44°40.27'N, 124°49.11'W	44.6712, -124.8185
5	OR proposed modification	44°38.52'N, 124°49.11'W	44.642, -124.8185
6	OR proposed modification	44°21.73'N, 124°49.82'W	44.362167, -124.830333
7	OR proposed modification	44°17.57'N, 124°55.04'W	44.292833, -124.917333
80	Current waypoint (Deleted)	44°48.25'N, 124°40.62'W	44.804115, -124.676919
81	Current waypoint (Deleted)	44°41.34'N, 124°49.20'W	44.688998, -124.819945
82	Current waypoint (Deleted)	44°23.30'N, 124°50.17'W	44.388395, -124.8361781
83	Current waypoint	44°13.19'N, 124°58.66'W	44.219879, -124.977606

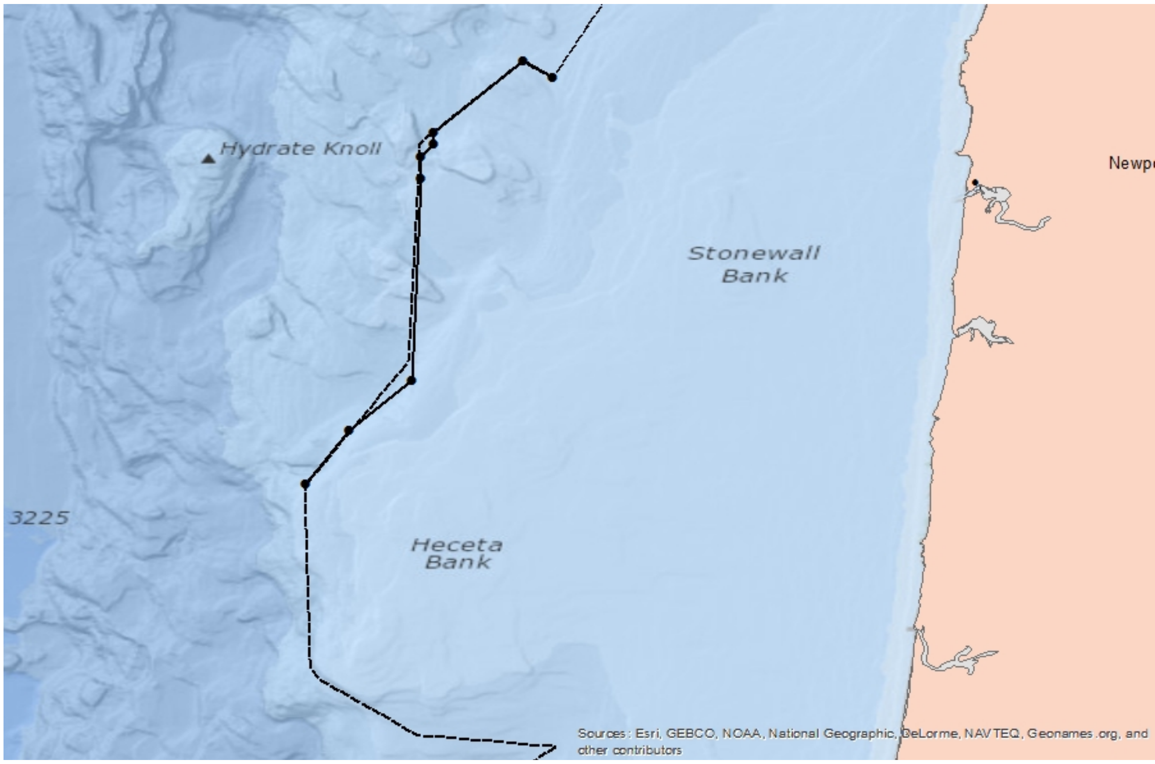

Figure B-1. Modification to the 200 fm "modified" (with petrale cut outs) depth contour. Dashed line represents the original 200 fm petrale line. Solid line represents proposed changes (which mimic the 200 fm line (without petrale cut outs).

B.1.2 Modifications to the Boundaries Defining Rockfish Conservation Areas off California

The following proposed modifications to current RCA boundary waypoints were adopted by the Pacific Fishery Management Council, at its April 2014 meeting, for analysis:

- Adjustments to the 60 fm RCA boundary waypoints off Del Mar and San Diego, California (Agenda Item H.3.b GMT Report, November 2013 and Agenda Item C.9.b GAP Report, April 2014)

An additional analysis is included that addresses a proposal for RCA boundary waypoint adjustments around the northern Channel Islands, California.

B.1.2.1 Modifications of the 60 fm Depth Contour: Two Southern California Bight Proposals

During the 2013-2014 biennial management cycle, the 60 fm depth contour was used as the shoreward boundary of the non-trawl RCA south of 34°27' N. lat. The depth contours defining the boundaries of RCAs are listed in trip limit tables published in Federal regulations and in periodic Public Notices announcing changes to groundfish management measures (see http://tinyurl.com/lty84jx). This boundary is intended to reduce bycatch of overfished species (OFS) such as bocaccio, canary, cowcod, and yelloweye rockfishes while providing access to target species.

Need for Action

The current 60 fm depth contour specified in regulation at 50 CRF 660.72(f) approximates the 60 fm isobath. To allow better access to non-trawl fishing areas for target species while maintaining the intent of the 60 fm line, better alignment of the 60 fm line with the 60 isobath is necessary for waters off California.

Management Options

No Action: Under No Action (described in section 2.4.1 of the 2013-2014 EIS) the 60 fm depth contour created by the waypoints currently listed at 50 CRF 660.72(f) would be retained in 2015-2016 and beyond.

Options: Under the Options, the 60 fm depth contour would more closely align with actual bathymetry in one of the two 60 fm proposals. These changes are based on proposals submitted by industry to modify the 60 fm RCA by modifying existing waypoints and/or adding new waypoints to the existing set(s). One sub-proposal addresses modifications west of Del Mar, California and the second-sub proposal addresses a modification west of San Diego, California.

Del Mar Option

- Modify the 60 fm contour between waypoints #198 and 199 by adding five new waypoints, and
- Modify the 60 fm contour between waypoints #198 and #200 by adjusting waypoint #199

Industry submitted the above proposed adjustments to allow increased access to fishing areas currently closed as a result of the existing RCA shoreward boundary. However, as proposed (see above reference, and Table B-2 and Figure B-2), the proposed boundary adjustments off the Del Mar area would move a section of the shoreward 60 fm RCA shoreward boundary into waters deeper than 75 fm. Additionally, one waypoint that is proposed to be edited (#199) actually moves the 60 fm RCA shoreward boundary to waters less than 50 fm. Given that these are the waypoint coordinates that were submitted as is and analyzed as such, it does not appear that such adjustments should be accommodated. It appears that there is no alternate way to address industry's proposal at this time. In the future, however, industry may wish to re-submit a different set of coordinates for consideration.

For this proposal, had the adjustments been deemed reasonable (at least from the initial analysis standpoint), fishing opportunities would have been increased for those members of the fleet fishing out of the greater San Diego area. Also, there would have been no conflicts with existing MPAs.

San Diego: Option A and Option B

Industry also submitted another proposal to accommodate an adjustment to the 60 fm RCA shoreward boundary west of San Diego that would allow better access to a tip of a reef. This proposal was submitted to consider one of two options.

- Option A: Modify the 60 fm contour between waypoints #205 and #207 by adjusting waypoint #206, or
- Option B: Modify the 60 fm contour between waypoints #206 and #207 by adding a new waypoint

As proposed, Option A requests that the 60 fm waypoint #206 be moved whereas Option B requests that a new waypoint be inserted between waypoint #206 and #207. Moving the existing waypoint #206, as proposed, results in a move of approximately 228 meters (approximately 250 yards).

Table B-2 through Table B-4 show the waypoint adjustments outlined above for both proposals. Figure B-2 and Figure B-3 also show the waypoint adjustments with Figure B-3 restricted to the Option A proposal. At the April 2013 Council meeting, the GAP recommended two Southern California Bight adjustments be analyzed by the Groundfish Management Team (GMT) for consideration by the Council. The Groundfish Advisory Subpanel (GAP) pointed out that with existing lines; it is difficult to fish a particular reef in this area in a prevailing current. The GAP also pointed out that there is some room to the south and west of the reef that would fix this problem if either of the two options were implemented for the San Diego proposal.

Upon review and analysis, an alternate option is presented here. This alternate option better aligns the RCA shoreward boundary to the 60 fm contour and eliminates the proposed access to fishing areas that are much deeper than 60 fm. Under this alternate option proposal, one new waypoint is added (proposed waypoint #5) between existing waypoint # 198 and existing waypoint #199. It removes the addition of new waypoints #1, #2, #3, and #4 and eliminates modifying existing waypoint # 199. The detailed adjustments for this new set of coordinate adjustments are presented in Table B-3 and Figure B-3.

Comparison of the Management Options

Biological Impacts: The non-trawl fixed-gear fisheries do not require logbooks to be completed and as such, it is very difficult to determine the species that may be taken in the proposed area and/or adjacent areas. Reporting of fishing areas is limited to documentation of Fish and Wildlife catch block numbers on the commercial landings receipts. These, however, cover 10x10 mile grids and do not lend themselves to accurate accounting of what species were caught from any specific areas. To the degree that there is not enough precise correlation between recorded catch by species and recorded fishing areas (blocks) under the action alternatives, there could be an increase of OFS, other fish species, and the take of protected species in the opened areas.

Under Option B, the issue of having access to fishing areas much deeper than 60 fm in this area is eliminated. The industry proposed option would have allowed fishing in an area as deep as 195 fm (Figure B-2). This alternate option better aligns the RCA shoreward boundary to the 60 fm contour. Under this alternate option, no biological impacts would be expected.

Socioeconomic Impacts: The changes proposed under the action alternatives may have a marginal socioeconomic benefit for the shoreside non-trawl fixed gear fishery managed under an RCA with a 60 fm contour as its shoreward boundary. Access to this additional small area would be beneficial to the fishing community from the greater San Diego area. The change in management cost, primarily those associated with law enforcement of the RCA boundaries, may be problematic.

Table B-2. Coordinate list for proposed modifications to the 60 fm RCA shoreward boundary off Del Mar, California.

	Boundary Line	Coordinates
ID	Name	Degrees, decimal minutes
198	Current waypoint (keep)	32°57.39' N, 117°18.72' W
--	Proposed modification (add after #198)	32°56.50' N, 117°19.80' W
--	Proposed modification (add after #198)	32°56.50' N, 117°19.72' W
--	Proposed modification (add after #198)	32°56.36' N, 117°19.06' W
--	Proposed modification (add after #198)	32°56.24' N, 117°19.04' W
--	Proposed modification (add after #198)	32°56.00' N, 117°19.16' W
199	Proposed modification (modify #199)	32°55.64' N, 117°18.46' W
200	Current waypoint (keep)	32°52.81' N, 117°17.09' W

Table B-3. Alternate option for the Del Mar proposal that modifies the 60 fm RCA shoreward boundary off Del Mar, California.

	Boundary Line	Coordinates
ID	Name	Degrees, decimal minutes
198	Current waypoint (keep)	32°57.39' N, 117°18.72' W
--	Proposed modification (add between waypoints #198 and #199)	32°56.00' N, 117°19.16' W
199	Current waypoint (keep)	32°55.64' N, 117°18.46' W

Table B-4. Coordinate list for proposed modifications to the 60 fm RCA shoreward boundary south of Del Mar, west of San Diego, California. This proposal is made under two Options: Option A would adjust waypoint #206 and Option B proposes to add a waypoint between waypoints #206 and #207.

B.1.2.2 Modifications of the 50 fm Depth Contour: Northern Channel Islands Proposal

During the 2013-2014 biennial management cycle, the 50 fm depth contour was used as the shoreward boundary of the recreational RCA (660.360). This boundary is intended to reduce bycatch of overfished species (OFS) such as bocaccio, canary, cowcod, and yelloweye rockfishes.

Need for Action

The current 50 fm depth contour specified in regulation at 50 CRF 660.72(c) approximates the 50 fm isobath around the north Channel Islands – San Miguel, Santa Rosa, and Santa Cruz. To allow better access to non-trawl fishing areas for non-OFS species while maintaining the intent of the 50 fm line, better alignment of the 50 fm line with the 50 isobath is necessary for waters off California.

Management Options

No Action: Under No Action (described in section 2.4.1 of the 2013-2014 EIS) the 50 fm depth contour created by the waypoints currently listed at 50 CRF 660.72(c) would be retained in 2015-2016 and beyond.

Options: Under the Options the 50 fm depth contour would more closely align with actual bathymetry in one of the two 50 fm proposals. These changes are based on proposals submitted by industry to modify the 50 fm RCA by modifying existing waypoints and adding new waypoints to the existing set(s).

- Modify the 50 fm depth contour between waypoints #2 and #4 by adjusting waypoint #3 with a new set of coordinates,
- Modify the 50 fm depth contour between waypoints #4 and #5 by adding five new waypoints,
- Modify the 50 fm depth contour between waypoints #20 and #21 by adding a new waypoint,
- Modify the 50 fm depth contour between waypoints #21 and #23 by adjusting waypoint #22,
- Modify the 50 fm depth contour between waypoints #23 and #25 by adjusting waypoint #24, and
- Modify the 50 fm depth contour between waypoints #25 and #26 by adding a new waypoint.

One problem to note is that the new point inserted between waypoint 25 and 26 causes the modified 50 fm line to cross over the 60 fm line.

Table B-5 shows the revised coordinates for the proposed changes as outlined above. Figure B-4 also shows the waypoint adjustments.

Upon review and analysis, an alternate option is presented here. For the Northern Channel Islands, this new alternate proposed option would better align the RCA shoreward boundary to the 50 fm contour around the Northern Channel Islands. In doing so, it would also provide more fishing areas. This proposal would adjust existing waypoint #3 and add a new waypoint between the existing waypoint #2 and the adjusted waypoint #3. All the other proposed industry adjustments are left as proposed. The details of this alternate option are given in Table B-6 and Figure B-6.

Northern Channel Islands
Industry submitted a proposal to make a number of waypoint adjustments around the northern Channel Islands, California, to accommodate increased fishing opportunities. This proposal was not part of the April 2014 Council meeting motion, but is included in this analysis to address an additional proposal that was received late. The GMT did note in their November 2013 statement (Agenda Item H.3.b GMT Report, November 2013) that it did not have the time (at that time) to determine if there were other

waypoints that should be added to the list (the Del Mar and San Diego proposals). This Channel Islands proposal should be considered in reference to that comment.

The proposed waypoint adjustments do overlap with some existing MPAs around the Channel Islands. Also, Essential Fish Habitat (EFH) areas need to be considered, although none were specifically cross-referenced for this analysis. Specific coordinates of EFH area may be found in Federal Regulations 50 CFR 660.75-79. Aside from concerns regarding MPAs and EFHs, access to these areas would be beneficial to the fishing community from the greater Santa Barbara area.

Comparison of the Management Options

Biological Impacts: Increased opportunity for the recreational sector would be accommodated by these changes. The likelihood that increased encounters with overfished species may also occur, would probably be minimal. However, no quantitative evaluations have been made to explore this possibility. When the 50 fm contour was implemented, it eliminated some confusion about fishing the 14 mile bank and 60 mile bank for rockfish (as these seamounts are both between 50 and 60 fm deep).

Under the alternate option, more fishing area would be allowed, without an expected increase in overfished species encounters. This is surmised because the increased area does not extend into appreciably deeper habitat where increased encounters of overfished species could potentially occur.

Socioeconomic Impacts: The changes proposed under the action alternatives may have a marginal socioeconomic benefit for the recreational fishery managed under an RCA with a 50 fm contour as its shoreward boundary. Access to this additional small area would be beneficial to the fishing community from the greater Santa Barbara area, but to what degree it is unknown. The change in management cost, primarily those associated with law enforcement of the RCA boundaries, may be problematic.

Table B-5. Coordinate list for proposed modifications to the 50 fm boundary around the northern Channel Islands, California.

	Boundary Line	Coordinates

B.2 Establish New Rockfish Conservation Area Coordinates – 300 and 350 fm

Need for Action

The Pacific Fishery Management Council (the Council) requested that the Groundfish Management Team (GMT) propose coordinates for and analyze possible 300 and 350 fm Rockfish Conservation Areas (RCAs) north of 40°10' N. latitude. These RCAs were proposed as possible management measures to aid in reducing catch of rougheye and blackspotted rockfish during the 2015-16 biennium and could potentially be applied to all sectors through routine or inseason action. The GMT intends to provide analysis of these areas by sector for the June 2014 Council meeting. Other analysis regarding RCA changes can be found in the Final Environmental Assessment for Trawl RCA Boundary Modifications, completed by the National Marine Fisheries Service (NMFS) in February 2014.

Management Options

No Action: The deepest RCA boundaries available in regulation would be 250 fm.

Options: At this time, the following latitude and longitude coordinates (i.e., waypoints) are provided as a starting point for the discussion that is needed to refine and identify possible 300 and 350 fm lines (Table B-7 and Table B-8). These waypoints were developed using geographic information system (GIS) software (ArcGIS 10.1) and are based on 300 and 350 fm bathymetry contours.[1] More information, such as the files used to create these lines, will be available for the public at the following FTP site: ftp://ftp.pcouncil.org/pub/GMT/Proposed_300_350_RCAs/. Given other workload, the GMT was not able to produce an analysis of impacts resulting from these lines for the June Briefing Book. The GMT aims to produce a supplemental report at the June Council meeting focused on logbook and observer data to characterize how catch of target species and bycatch of rougheye and other species would be altered by the RCA boundary lines. The proposed waypoints are provided now to get feedback from the fishing industry regarding how these lines may affect their operations and how the lines might be improved to achieve objectives (e.g., reduce rougheye rockfish catch while retaining productive fishing grounds for other species).

Figure B-7 provides an example of issues that emerged when developing these proposed waypoints. First, the 300 and 350 fm bathymetry contours are very detailed and creating RCA lines directly following these contours would not be practical. Therefore, these contours were approximated and straightened using several tools available in ArcGIS.[2] Second, there were several areas where the existing 250 fm RCA line (unmodified for petrale, defined in regulation at §660.74) touched or overlapped the 300 and 350 fm bathymetry contours.[3] When this occurred, the GMT analyst visually and manually adjusted these lines to pull them outside of the 250 fm RCA (Figure B-8 provides an example). More information about where these manual adjustments were made can be provided in June if requested.

Given the availability and resolution of the data and the complexity of certain features like undersea canyons, matching RCA boundary lines to actual bathymetry is difficult. The original and current purpose of boundary lines is not to match the bathymetry perfectly, but to create regulatory lines that

[1] Source of bathymetry contours: NOAA National Geophysical Data Center, http://www.ngdc.noaa.gov/mgg/bathymetry/relief.html (accessed 5/19/14).
[2] The following ArcGIS 10.1 tools were used to develop, simplify, and straighten the 300 fm and 350 fm bathymetry contour lines: "Neighborhood Selection (Geostatistical Analyst)", "Simplify Line (Cartography)", and the "Edit Vertices" tools.
[3] The coordinates of existing RCA boundary lines, including the 250 fm line, can be downloaded from the NMFS West Coast Region's website: http://www.westcoast.fisheries.noaa.gov/fisheries/management/groundfish_closures/rockfish_areas.html

approximate depth contours, would be enforceable, and would be effective at lowering bycatch to the desired degree. To overcome this difficultly when the currently existing RCAs were first developed, RCA lines such as the 250 fm line were manually adjusted after feedback from the fishing industry, enforcement, and the GMT (i.e., RCAs were designed to approximate bathymetry contours).

The 300 and 350 fm RCA lines and waypoints shown in this document could be viewed as the first of many steps. Adjusting these lines could be the next step of the process. Various methods can be used to adjust these lines to approximate the depth contours while at the same time being enforceable, understandable, logical, and be effective at lowering bycatch. One approach that may be used to adjust these base lines is the traditional approach that was used when RCAs were first created (i.e., through consultations with NMFS, States, Tribes, GAP, GMT, EC, etc.). Various analytical tools can be applied to help this process and ensure that existing RCA lines that are shallower (e.g., 250 fm line) do not cross the new "deeper" RCA lines (i.e., the 300 and 350 fm lines). One approach that can be applied to ensure that lines do not cross is to set the RCAs equal at those locations. That is, when the 300 or 350 fm line crosses the 250 fm line, the 300 or 350 fm line would simply follow the 250 fm line. This approach is often used now to correct RCA lines that cross. An example of this approach is shown in Figure B-9. Other approaches could also be applied. For example, one could simply extend the existing 250 fm line in increments (e.g., by 0.5 nm, 1 nm, 3 nm, etc.) to create new RCAs that do not necessarily approximate depth contours but instead, follow the pattern of shallower RCA lines that currently exist. An example of this novel approach is shown in Figure B-10.

Figure B-7. An example of where the existing 250 fm Trawl RCA (unmodified for petrale sole) overlaps with the 300 and 350 fm bathymetry contours

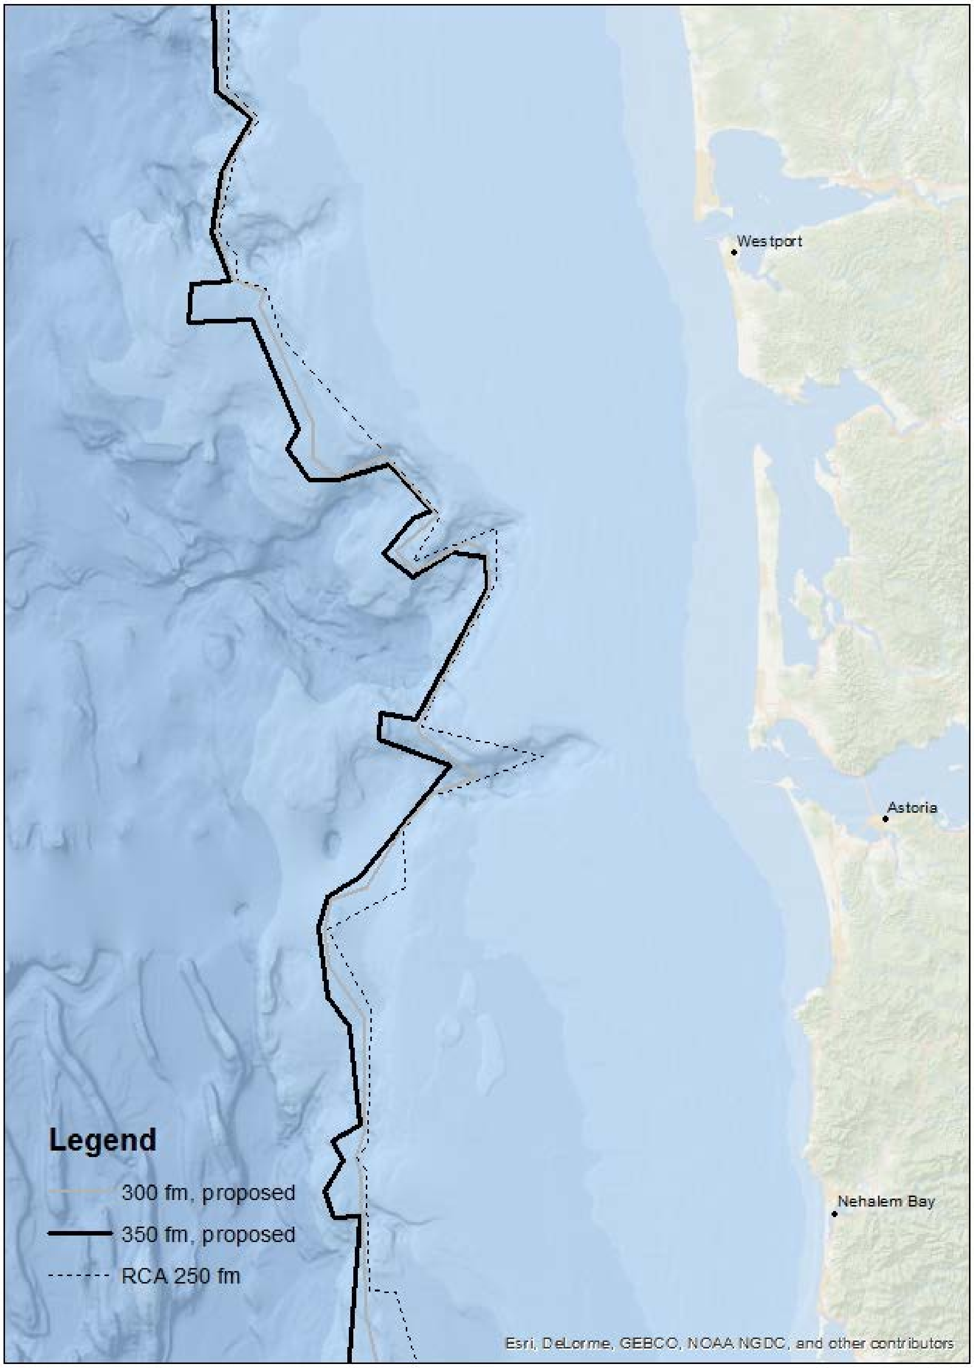

Figure B-8. An example of manual adjustments to the proposed 300 and 350 fm lines where they overlap with the existing 250 fm RCA line (unmodified for petrale sole).

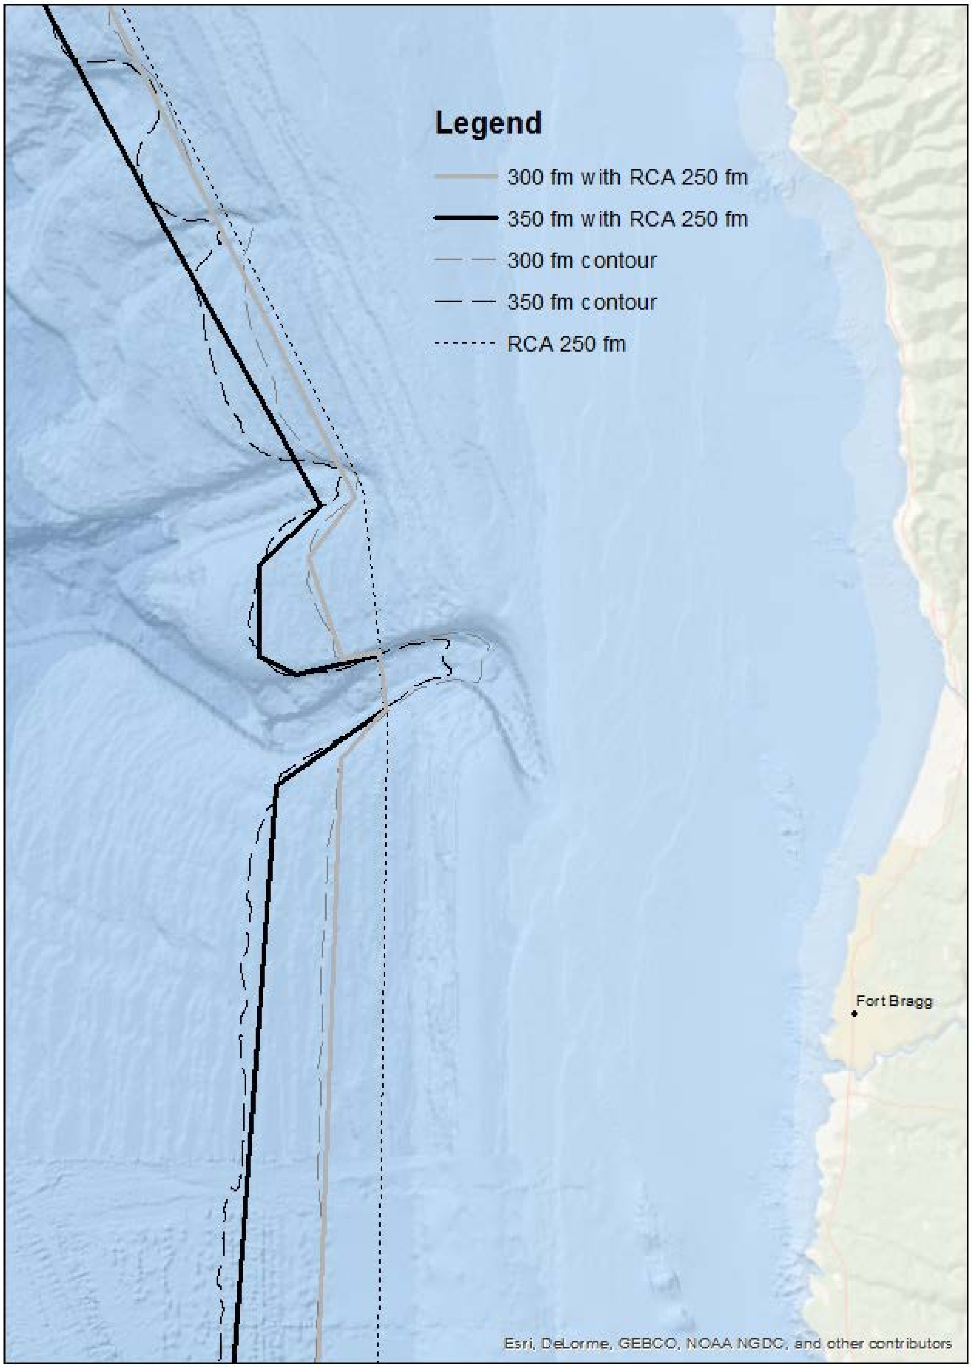

Figure B-9. An example of an approach to deal with areas where new RCA lines, based on 300 and 350 fm bathymetry contours, cross an existing RCA line (e.g., 250 fm line). In these areas, the new RCA lines could follow the existing RCA line.

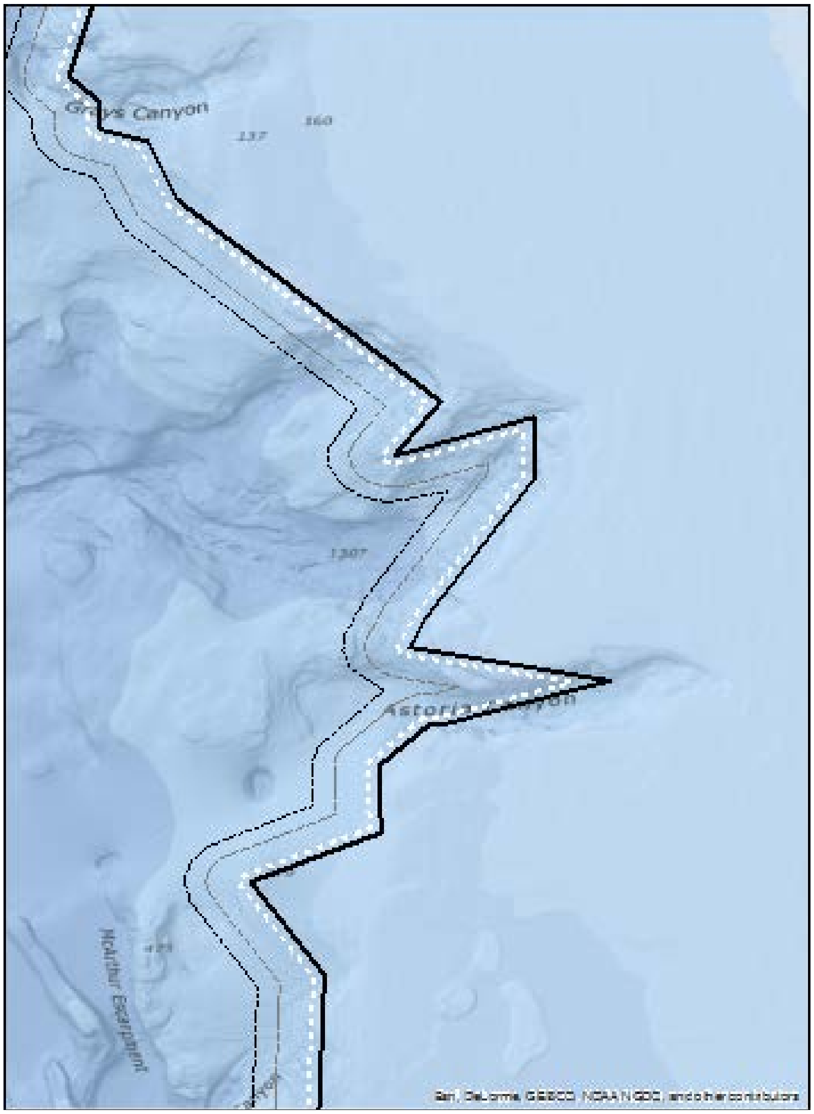

Figure B-10. An example of an approach to create new RCA lines by extending an existing 250 fm line in increments (e.g., by 0.5 nm, 1.5 nm, and 3 nm). These lines would follow the pattern of the existing RCA line which does not approximate bathymetry contours in all areas.

B.3 Trawl: Set-asides to cover carryover if trawl allocation exceeded

Analysis of this management measure was not received by the Advanced Briefing Book deadline; it is expected to be delivered as a Supplemental GMT Report.

B.4 Within Non-Trawl: Two-Year Yelloweye Sharing - Evaluating uncertainty of yelloweye catches in the nearshore and non-nearshore commercial fixed gear sectors

Need for Action

The Council is considering transferring 0.6 mt of the yelloweye rockfish non-trawl allocation fishery harvest guideline (HG) from the non-nearshore sector to the nearshore sector. Nearshore sector landings are often constrained due to amount of yelloweye rockfish provided to the nearshore sector. Further, shoreward adjustments of the non-trawl RCA (e.g., changing from 30 to 20 fm) are implemented when the yelloweye rockfish nearshore share or the non-trawl HG is projected to be exceeded. The Council considers the two-year allocations for yelloweye rockfish every biennial cycle based on the projected impacts, i.e., forecasts of total fishing mortality, provided by the GMT and other factors. The nearshore and non-nearshore sectors are assigned a "share" of the non-trawl allocation. The sectors' shares and projected impacts (i.e., total fishing mortality) for yelloweye are shown in Table B-9.

Table B-9. The sector shares and project impacts of yelloweye rockfish with and without the transfer of 0.6 mt.

		Without transfer		With transfer	
		2015	2016	2015	2016
non-nearshore	share	1.1	1.2	0.5	0.6
	projection	0.5	0.5	0.5	0.5
	difference	0.6	0.7	0.0	0.1
nearshore	share	1.2	1.3	1.8	1.9
	projection	1.1	1.1	1.1	1.1
	difference	0.1	0.2	0.7	0.8

The projected impacts and projection methods of yelloweye catch for 2015-2016 are more fully discussed in section 4.2.2.5 and Appendix A of the DEIS. The nearshore projected impacts are under discussion as well and may be subject to change depending on the Council's recommendations on the harvest guideline for the nearshore rockfish stock complex and related management measures.

The GMT has advised the Council, most recently in April that the catch estimates and model projections are subject to considerable uncertainty that the team has yet to fully evaluate.[4] This analysis uses a Monte Carlo simulation approach based on West Coast Groundfish Observer Program (WCGOP) sampling rates and observed patterns of yelloweye catch in these sectors to gauge the relative level of uncertainty surrounding yelloweye catches. This uncertainty is relevant here because, as shown in Table B-9, the 0.6 mt transfer would completely remove the buffer between the projected catch and the sector share in the non-nearshore sector and increase the buffer in the nearshore sector. And as it stands now, there is only a 0.1 to 0.2 mt buffer between the nearshore sectors' share and projected catch.

Background and Context

The GMT has been focused on the uncertainty in two separate but related estimates: (1) the retrospective annual estimates of total mortality produced by the Northwest Fisheries Science Center (NWFSC); and (2) the GMT's forecasts/projected impacts. The simulations used here focus primarily on evaluating the first. The uncertainty seen in the simulation results can then be related to the projected impacts and aid with interpretation of how confident we can be in those forecasts.

[4] PFMC Briefing Book April 2014, Agenda Item C.8.b, Supplemental GMT Report.

For highly discarded species like yelloweye, catch is not known with certainty because not all catch is observed. Annual mortality estimates are produced with statistical sampling and estimation methods that are inherently uncertain. The purpose of the GMT's catch projections is to inform the Council on what the annual catch estimates might be under a given management measure scenario. Like most all forecasts, they involve uncertainty as well. With the non-nearshore and nearshore projection models, the GMT provides the Council with point estimates of catch without any quantitative measure of uncertainty around those estimates. The Council, recognizing that the forecasts are uncertain, has often taken a precautionary approach in establishing sector shares and more formal sector allocations. The level of precaution or tolerable risk is a key policy decision. With increased access to and additional years of data from WCGOP, the GMT has begun attempts at better quantifying the uncertainty and informing the Council of the risks.

As brief background, uncertainty in measurements and estimation can be thought of in terms of accuracy and precision. These two terms are used differently among technical disciplines, but here we think of accuracy in terms of bias.[5] An unbiased estimate will accurately reflect the true value yet do so subject to some level of precision. Absent perfect precision, repeated estimates/measurements will vary from one another with the degree of variability proportional to the precision of the estimate/measurement. Highly imprecise estimates will vary widely, but if repeated and unbiased, the average of the estimates will reflect the true value accurately. In contrasting circumstances, it would be possible to have highly precise but inaccurate estimates/measurements. In such cases, repeated estimates/measurements would vary little but vary around something other than the true value.

WCGOP sampling and catch estimation methods are designed to produce unbiased, accurate estimates. There is little that can be done easily to evaluate if the accuracy is being achieved (the observer effect/bias where fishing vessels operate differently when an observer is aboard making the observations non-representative). Here we assume that are indeed accurate and that precision is the main source of uncertainty.

The precision of an estimate will vary largely based on two main variables: (1) the sampling rate/coverage level, and; (2) the variability and frequency of the event being measured. In general, precision will be greater with higher sampling coverage and regular, frequent catch events. In contrast, for a given level of sampling coverage, precision will be lower to the degree that the event is rare and variable.

Lastly, sampling uncertainty from limited precision would exist even if the unit being measured is fixed or static (e.g. the circumference of the Earth). The event we are focused on here is the yelloweye catch over a year, which is not likely to be fixed. Catch is expected to vary from year to year depending on fishing effort, the areas fished, changes in management regulations, etc. Moreover, the expectations for a rebuilding stock like yelloweye is that the catch rate will increase as the stock increases in abundance and expands its distribution, increases in density, or both. Imprecision in estimates makes upward trends difficult to detect. Increases in catch from one year to the next might be signal or could just be sampling noise. The same is true for downward trends where the encounter rate may have truly decreased. Making predictions about future catch with noisy historical data makes the forecasting challenge even more so.

Patterns of Yelloweye Catch and Observer Coverage in the Nearshore and Non-nearshore Sectors
As shown in Table B-10, annual estimates of yelloweye catch have shown a high degree of variability in both the nearshore and non-nearshore fixed gear sectors. As highlighted above, sampling error is likely a major component of the variability. Consistent with the latter, variability has been higher in the nearshore sector where sampling coverage levels have been lower (Table B-11 and Table B-12).

[5] For example, see Box 1.2 in National Research Council. Review of Recreational Fisheries Survey Methods. Washington, DC: The National Academies Press, 2006.

Variability can be described in absolute terms (i.e., in the unit of measurement), which in this case is catch weight expressed as metric tons (mt), or in relative terms (e.g. the coefficient of variation, which expresses the variability relative to the average value). Considering variability in absolute terms is important because the Council considers and recommends allocations and less formal apportionments of catch in terms of metric tons. Table B-10(c) displays the variability seen in metric tons by comparing the annual estimates against the grand mean (i.e., the average across all available annual estimates).

Relative measures of variability are also useful, especially for comparing variability between the sectors. For example, an estimate that is truly more imprecise than another may appear more precise when viewed in absolute terms simply because its average value is smaller. Table B-10 (b) shows one form of relative variability by comparing the annual estimates in each sector to the estimates made in the previous years. In the nearshore sector, estimates have dropped by 80 percent and increased by more than 800 percent. The non-nearshore sector has experience less variability in this measure, yet has seen a 75 percent drop and a 50 percent gain. Table B-10 (d) shows the percent difference of the annual estimates compared to the average over the timeframe ("grand mean"). This measure is of interest because such grand means of bycatch ratios currently serve as the foundation for the GMT's projection models for these sectors. Both sectors show wide variability on this measure as well further underscoring the challenge of forecasting yelloweye catches.

Table B-10. Variability of total mortality estimates for yelloweye rockfish in the nearshore and non-nearshore commercial fixed gear sectors, 2003-2012.

(a) NWFSC Total Mortality Estimate (source: GMMultiYr_DataProduct Dec. 23, 2013)

	2003	2004	2005	2006	2007	2008	2009	2010	2011	2012
Nearshore	0.3	1.1	0.9	0.8	1.9	2.5	0.5	0.1	0.8	1.8
Non-nearshore	1.6	1.1	0.6	0.7	0.7	0.8	1.2	0.3	0.3	0.3

(b) Annual estimate relative to estimate of previous year

	2003	2004	2005	2006	2007	2008	2009	2010	2011	2012
Nearshore	--	3.67	0.82	0.89	2.38	1.32	0.20	0.20	8.00	2.25
Non-nearshore	--	0.69	0.55	1.17	1.00	1.14	1.50	0.25	1.00	1.00

(c) Difference (mt) between annual estimate and 2003-2012 average in each sector (nearshore = 1.1 mt, non-nearshore = 0.8 mt)

	2003	2004	2005	2006	2007	2008	2009	2010	2011	2012
Nearshore	-0.8	0.0	-0.2	-0.3	0.8	1.4	-0.6	-1.0	-0.3	0.7
Non-nearshore	0.8	0.3	-0.2	-0.1	-0.1	0.0	0.4	-0.5	-0.5	-0.5

(d) Difference between annual estimate and 2003-2012 average relative to average (i.e., the values reported in (c) divided by the average).

	2003	2004	2005	2006	2007	2008	2009	2010	2011	2012
Nearshore	0.27	1.00	0.82	0.73	1.73	2.27	0.45	0.09	0.73	1.64
Non-nearshore	2.00	1.38	0.75	0.88	0.88	1.00	1.50	0.38	0.38	0.38

Overview of the Data Used and Aim of the Simulation Methods
WCGOP provided the observer data sets matched to the data used for the GMT's nearshore and non-nearshore projection models. These datasets are considered confidential and therefore are available only to a subset of the team that have confidentiality agreements in place with WCGOP.

The basic observer coverage statistics for the non-nearshore and nearshore sectors are shown in Table B-11 and Table B-12. The WCGOP coverage rates reported in those tables were taken from a table downloadable from their Sector Data Products webpage.[6] For the non-nearshore sector, we are focused on the area north of 36° N. latitude and the observer coverage levels reported in Table B-11 combine the Limited Entry Sablefish Endorsed, Non-Sablefish-Endorsed Fixed Gear, and Open Access vessels that are classified as part of this sector.

By design, WCGOP focuses on observing a certain percentage of landings as opposed to certain percentage of trips. Likewise the bycatch ratios WCGOP uses to expand observed discard to the total fleet are expressed in terms of landed catch. However, for simplicity of modeling the simulations presented here use trip as the main unit of analysis.

If trips contributed the same level of overall landings per year, the two would be equivalent. Yet this is not the case and some trips contribute a higher portion of the landings in both the nearshore and non-nearshore sectors. If coverage levels were reported in terms of the trips observed per year, then the coverage would be lower in both sectors. Nonetheless, we do not expect our choice to focus the simulation on trips instead of landings to affect the usefulness of the simulation results. If WCGOP maintains the same sampling plan and general levels of observer coverage, then the relationship between observer coverage and landings per trip would be expected to hold. And if so, the simulations should provide means to evaluate the general patterns we should expect to continue into the future.

The frequency with which yelloweye have been encountered by trip is one of the main variables in the simulations. Figure B-11 and Figure B-12 report the total number of trips with yelloweye catch observed ("non-zero" trips) divided by total observed trips for the nearshore and non-nearshore sectors. As those shown, the per trip frequency of yelloweye catch in the nearshore sectors has been over double of that seen in the non-nearshore sectors. The per trip frequency has varied in both over the time series.

The other main variable of interest is the magnitude of catch on non-zero trips. Whereas the frequency of yelloweye catch on a trip in the non-nearshore sectors is half of that in the nearshore sectors, the magnitude of catch on non-zero trips is over twice, on average, of the catches in the nearshore sectors (Figure B-13 and Figure B-14). The distribution of non-zero catches across all years of the non-nearshore and nearshore data are further displayed in Figure B-15 thru Figure B-18.

Table B-11. Summary of nearshore sector WCGOP observations used to establishing the frequency with which yelloweye are encountered on a trip and the level at which the sector is observed each year. The "*" in 2003 indicates that the statistic could not be displayed because of confidentiality.

Year	2002	2003	2004	2005	2006	2007	2008	2009	2010	2011	2012
Trips Observed	--	108	367	308	341	303	225	239	253	349	386
Trips w/ yelloweye	--	*	34	16	25	45	29	17	11	38	65
% of observed trips with yelloweye	--	*	9%	5%	7%	15%	13%	7%	4%	11%	17%
WCGOP coverage %	--	2%	7%	5%	7%	6%	4%	4%	5%	6%	8%

Table B-12. Summary of non-nearshore sector WCGOP observations used to establishing the frequency with which yelloweye are encountered on a trip and the level at which the sector is observed each year.

Year	2002	2003	2004	2005	2006	2007	2008	2009	2010	2011	2013
Trips Observed	102	269	256	251	275	358	335	304	512	443	304
Trips w/ yelloweye	21	25	13	18	13	10	10	8	4	7	9
% of observed trips with yelloweye	21%	9%	5%	7%	5%	3%	3%	3%	1%	2%	3%
WCGOP coverage %	18%	17%	12%	27%	17%	22%	29%	7%	22%	22%	22%

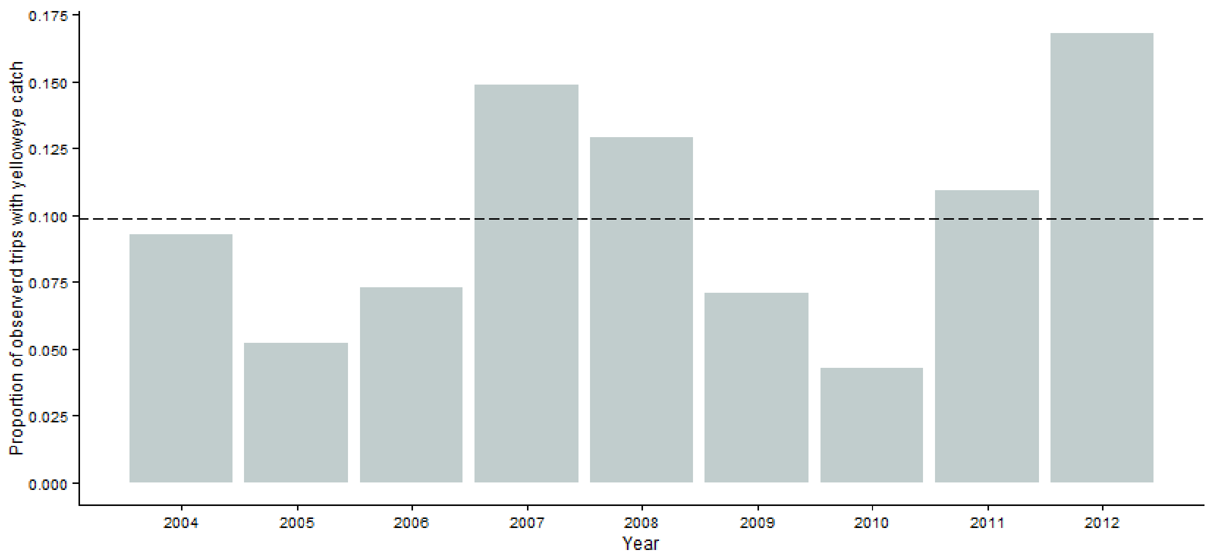

Figure B-11. Annual proportion of observed trips in the nearshore commercial fixed gear sectors where yelloweye were encountered. The 2004-2012 average is displayed by the dashed line (2003 was excluded because of confidentiality).

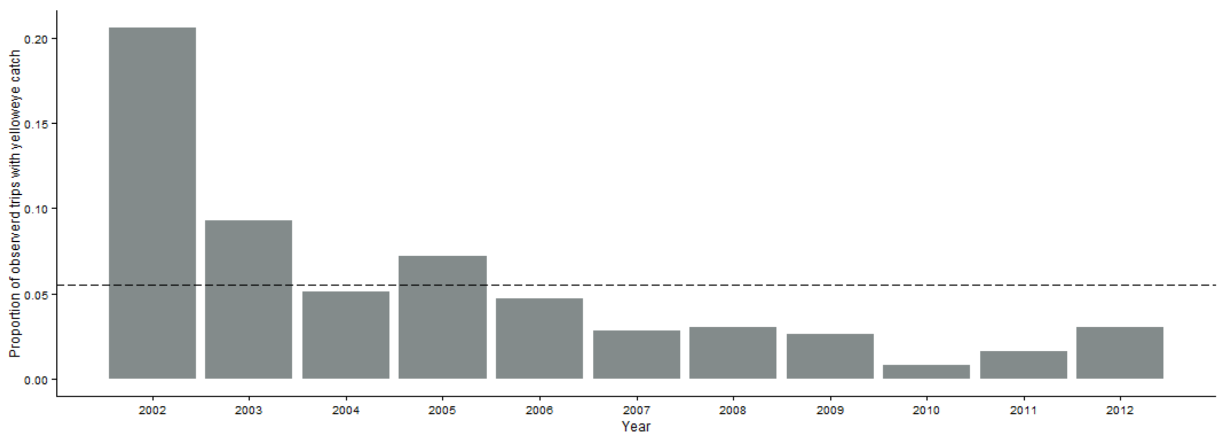

Figure B-12. Annual proportion of observed trips in the non-nearshore commercial fixed gear sectors where yelloweye were encountered. The 2002-2012 average displayed by the dashed line.

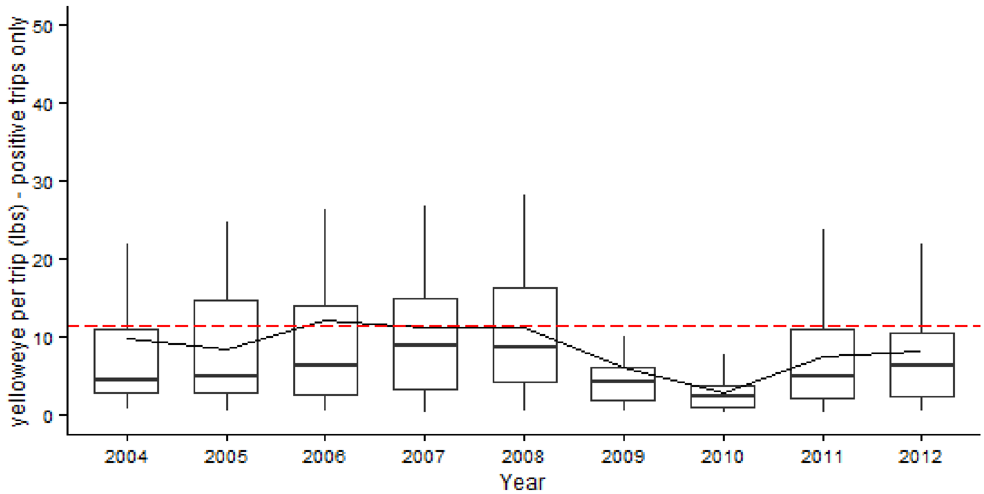

Figure B-13. Boxplots of yelloweye catches (zeros excluded) by trip and year in the nearshore commercial fixed gear sectors. Outer edges of the boxes show the 25th and 75th percentile levels with the middle line representing the median value. The solid line connects the average value for each year. In all but 2010, the averages are noticeably larger than the median because of large catch events. The dashed line shows the 2004-2012 average ("grand mean"). Outliers are not displayed because of confidentiality. A y-axis extending to 200 would display all outliers with room to spare. To give some sense of the range of the outliers, the average of the top 5 percent of all trips, across all years is 68 lb.

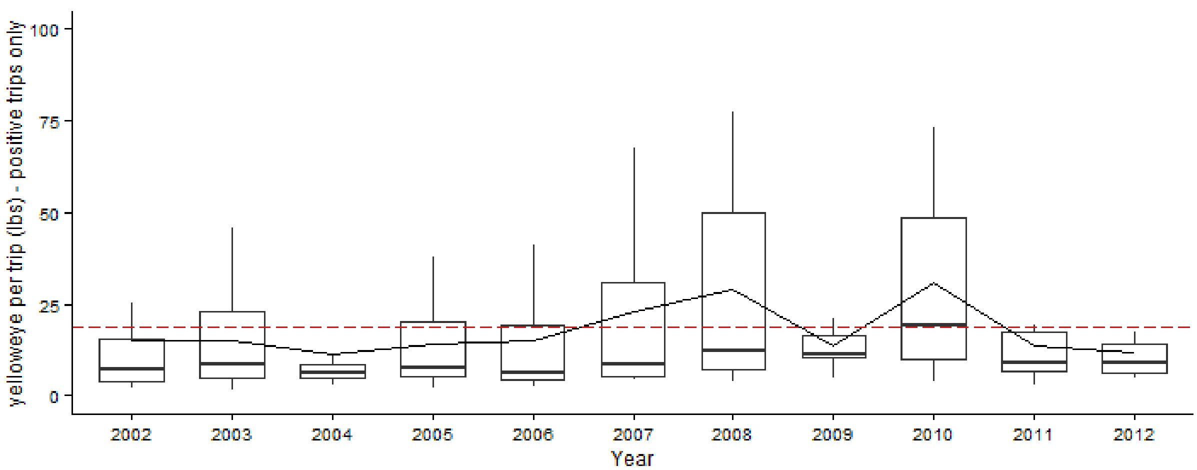

Figure B-14. Boxplots of yelloweye catches (zeros excluded) by trip and year in the non-nearshore commercial fixed gear sectors. See Figure B-13 for explanation of boxplots and lines. Outliers are not displayed because of confidentiality. A y-axis extending to 175 would display all outliers with room to spare. To give some sense of the range of the outliers, the average of the top 5 percent of all trips, across all years is 103 lb.

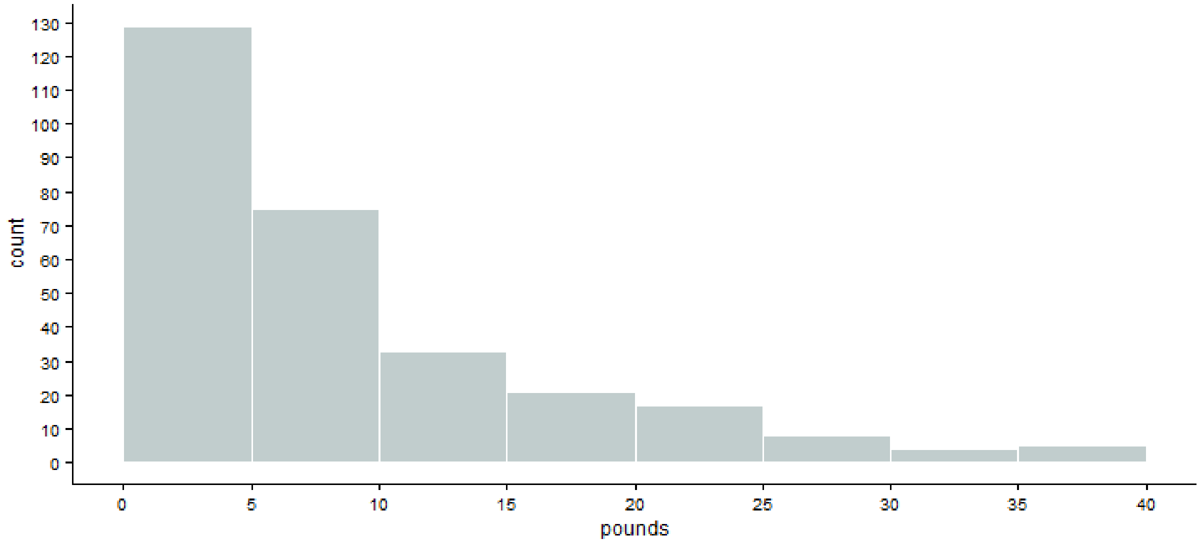

Figure B-15. Histogram showing nearshore catches of yelloweye rockfish over 2002-2012 on observed non-zero trips for catches less than 40 lb (lb) (bins are in increments of 5 lb).

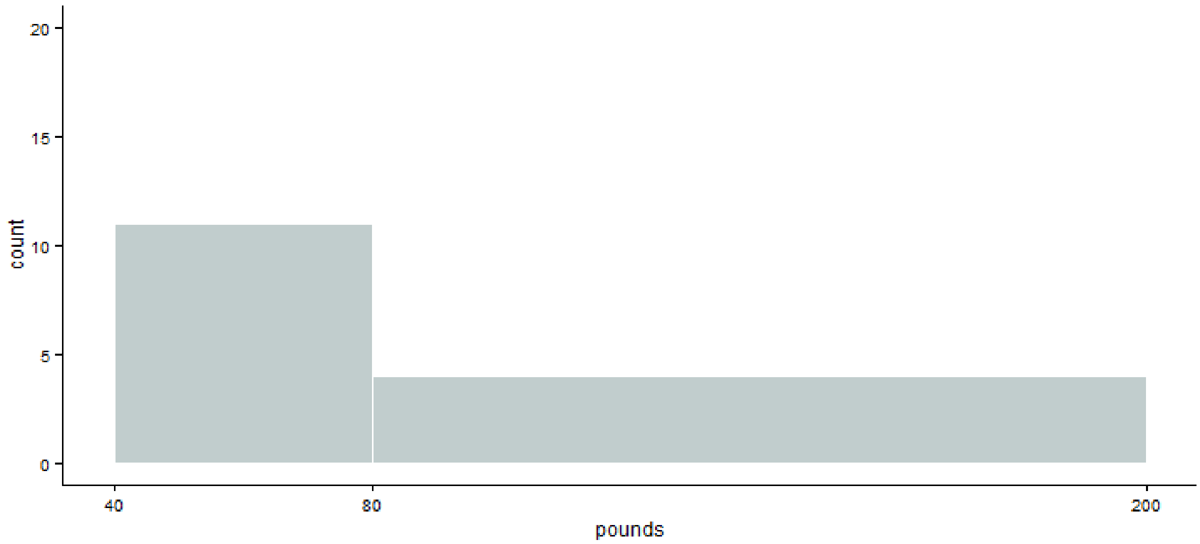

Figure B-16. Histogram showing nearshore catches of yelloweye rockfish 2002-2012 on observed non-zero trips for catches greater than 40 lb over (irregular bins of 40-80 lb and 80-200 lb were chosen to preserve confidentiality).

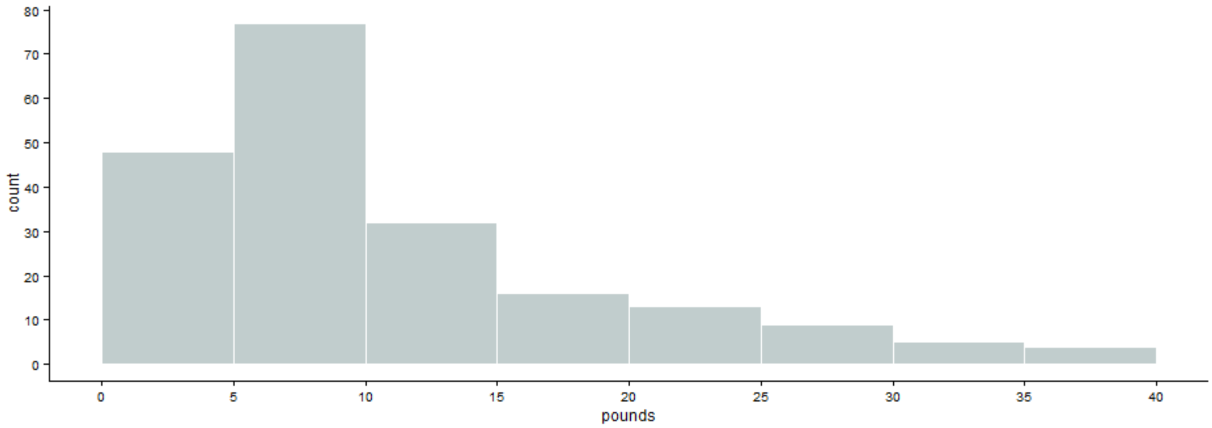

Figure B-17. Histogram showing non-nearshore catches of yelloweye rockfish over 2002-2012 on observed non-zero trips for catches less than 40 lb (bins are in increments of 5 lb).

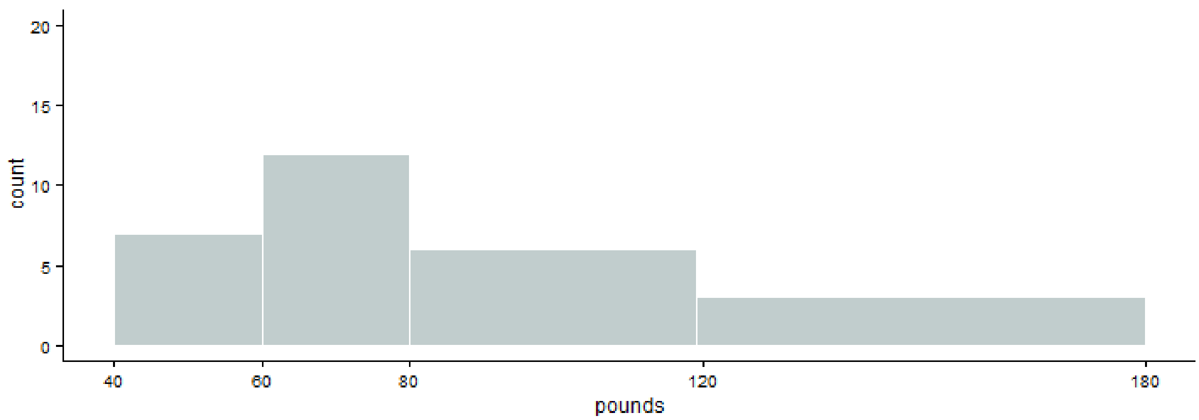

Figure B-18. Histogram showing non-nearshore catches of yelloweye rockfish 2002-2012 on observed non-zero trips for catches greater than 40 lb over (irregular bins of 40-60 lb, 60-80 lb, 80-120 lb, 120-180 lb were chosen to preserve confidentiality).

The Simulation Steps

There are two main parts to the simulations. The first constructs a universe of 100,000 fishing trips where the yelloweye catch per trip is the main variable of interest. The second involves randomly sampling from this set of trips. Each involves several steps described in the following list. The simulation was conducted in the program R.

1. Simulate the universe of 100,000 trips and yelloweye catch per trip for each sector based on the pattern of non-zero trips and the magnitude of catches observed on those trips:
   - Generate 100,000 binomial runs representing whether the trip caught yelloweye or not (i.e., 1 = yelloweye caught, 0 = no yelloweye caught). The binomial probability of a non-zero trip was itself randomly drawn from a random normal distribution based on the mean and standard deviation observed over the relevant time periods in each sector. The draws were truncated to prevent negative numbers using the "truncnorm" package.
   - The magnitude of catch per trip was drawn from a random lognormal distribution generated from the mean and standard deviation of actual trip level catches observed by WCGOP over the full data series of non-zero yelloweye trips.
   - The simulated catch per trip was produced by multiplying the catch per trip by the 1 or 0 drawn from the binomial random draws.
   - The simulated trip catch was capped at twice the observed maximum catch because the lognormal random distribution with a large number of draws produces a few implausibly large catches.

2. Sample from the universe of simulated trips based on varying coverage levels and produce a simulated "true" and estimated annual catch for 10,000 runs:
   - The total number of trips and observer coverage level per simulation run were randomly drawn from normal distributions based on the means and standard deviations from the actual WCGOP data.
   - The total number of trips drawn then set the sample size for the run (i.e., if the total number of trips was 100, 100 samples would be drawn from the set of 100,000 trips). The "true" annual catch was then calculated by summing the catches from all the selected trips.
   - This draw of the total trips per run was then sampled with the sample size set to the number of observed trips (the total trips multiplied by the coverage percentage drawn for the run). The simulated estimated annual catch was the calculated by summing the catch from these trips divided by the coverage level.

The simulated samples were all taken using R's sample function. All samples were taken without replacement. The input parameters for the random draws and years of data used for each are identified in Table B-13. In the nearshore sectors, observer coverage was low in 2003 and therefor data from that year was excluded. All years of data were used for the non-nearshore sectors except for the binomial probability of non-zero yelloweye trips. As can be seen in Figure B-12, there appears to be a downward trend in the number of trips encountering yelloweye in those sectors, and so based on this apparent trend, we chose to use data from only 2004-2012.

Table B-13. Input values for the simulations.

		Nonearshore	Nearshore
binomial probability of non-zero trip (normal)	*mean*	3.6%	9.0%
	s.d.	2.0%	5.0%
	truncated	0% - 20%	0% - 25%
	years used	2004-2012	2004-2012
non-zero catch events (lognormal)	*mean/mean.log*	27.4 / 2.77	11.6 / 1.78
	s.d./s.d.log	31.6 / 1.03	17.7 / 1.18
	years used	2002-2012	2004-2012
total trips per run (normal)	*mean*	1,776	4,995
	s.d.	923	1,533
	truncated	500-5000	500-10,000
	years used	2002-2012	2004-2012
observer coverage per run (normal)	*mean*	19.5%	5.8%
	s.d.	6.3%	1.3%
	truncated	5% - 30%	2%-20%
	years used	2002-2012	2004-2012

Table B-14. The first ten of the 100,000 simulated trips from the nearshore simulation provided to show the basic structure of the simulations. The second step of the simulation involved drawing random samples of varying sizes from the "Lb. Caught" column.

Trip	Encounter?	Lb. if Yes	Lb. Caught
1	1	16.5	16.5
2	0	31.3	0.0
3	0	17.1	0.0
4	0	2.6	0.0
5	0	6.3	0.0
6	0	4.8	0.0
7	1	1.3	1.3
8	0	3.0	0.0
9	0	7.6	0.0
10	0	4.3	0.0

Simulation Metrics and Results

The metrics produced by the simulations focus on the relative degree of precision and variability that we should expect with the annual catch estimates of yelloweye. The metrics reported here, each calculated as a ratio, include:

- *Variability in the "true" catch* (*"True" Variability*): this metric reports how the simulated "true" catch in each run differed from the average across all runs. It is calculated as the simulated true catch in each run divided by the average.
- *Annual fluctuation* (*"True" Ann. Fluctuation and Estimated Ann. Fluctuation*): this metric was calculated by dividing the simulated true catch and catch estimate in a run by

the same in the prior run. This metric allows some evaluation of the year to year variation we might expect in actual catch rates and in the catch estimates.

- *Sampling error* (*Estimated Error*): represents the ratio of the simulated estimate of catch and the simulated true catch in each run (i.e., a value over 1 indicates an overestimate and under 1 is an underestimate).
- *Annual Estimate relative to the 10 Year Average* (Estimated to 10 Year Avg.): this ratio expresses how far the simulated catches in each run differed from a 10 year average. The 10 year average was calculated by dividing the 10,000 runs into increments of 10. This metric is meant to tbe comparable to the long-term average catch ratios t serves as the basis for the GMT's current catch projection models.

We do not report metrics of the simulated catches in absolute terms, i.e., pounds or metric tons, because we did not attempt to reproduce WCGOP's actual sampling design and catch estimation methods in the simulations. WCGOP uses a more complicated multi-stage, stratified sampling design and employs catch estimation methods intended to support the areas and sector of interest to the Council. In addition, in the nearshore sectors yelloweye that are released with certain fishing gears are assumed to survive depending on depth. The simulations do not attempt to model the depth or gear of catch. For this and other reasons, the simulated catch amounts are therefore not expected to precisely match the real catch estimates.

The simulated estimates of annual catch are, however, close in terms of general magnitude to the estimates produced over 2003-2012. The metrics of relative variability should therefore provide useful insight into the relative precision of the existing WCGOP catch estimates and the GMT's projection model outputs.

At the same, sampling theory holds that WCGOP's stratified sampling design should produce more precise estimates than the simple random sampling we use in the simulation. We view the metrics of relative precision as rough measures of the degree of variability we might expect under the range of observer coverage and patterns of yelloweye experienced to date. Understanding how these factors influence the general magnitude of uncertainty and variability is our primary aim. We did not attempt to precisely quantify the statistical variance in the data and the simulations may overstate the variability to some degree. Yet as seen below, the results are not inconsistent with the level of variability actually seen in the sectors over 2003-2012 (Table B-10).

The results are shown in Table B-15 and Table B-16. We report multiple statistics for each metric, including the mean and median and the 10th and 90th percentile values. We also provide information about a number of other percentile levels constructed as intervals. For example, the 50 percent interval is bounded by the 25th and 75th percentiles and the 90 percent interval is bounded by the 5th and 95th percentile. To contrast the way the values can be read: the 90th percentile reports a "one-sided" look and indicates that 90 percent of all runs fell below that value, and in turn, that only 10 percent fell above it. The 90 percent interval, on the other hand, provides a "two-sided" look and indicates that 90 percent of the runs fell within that interval, and in turn, that only 10 percent of the runs were either higher or lower than the values on each end of the interval. Likewise, the intervals could be viewed in a "one-sided" manner by looking to only one end (e.g., the upper end of the 50 percent interval is the 75th percentile, therefore only 25 percent of the runs came in larger than the value it reports).

Table B-15. Results from the nearshore simulation. See the bulleted list in the text for the definition of the metrics.

	"True"				**Estimated**					
	Variability		Ann. Flucuation		Error		Ann. Fluctuation		to 10 Year Avg.	
Median	1.000		1.000		0.950		0.995		0.950

Discussion

We only give brief discussion of the results here so as to aid the reader and illustrate how we envisioned the simulation metrics could be used. The full GMT will review and comment on this analysis at the June meeting and provide the Council with additional interpretations relevant to the decision on the potential 0.6 mt transfer. The GMT will also provide information on the potential management measure changes (e.g., trip limits and changes to RCA boundaries) that the transfer might involve.

As to the results here, we begin by noting that the average sampling error metric shows a high degree of accuracy in both sectors, as is expected with random sampling. Across all runs, the catch estimate was 1.002 times the true estimate in the non-nearshore and 0.997 in the nearshore (i.e., 0.2 percent and 0.3 percent off).

At the same time, the catch estimates showed variability across individual runs. Under the conditions run in the simulations , we would expect catch estimates to be within ~30 percent of the true catch half of the time in the non-nearshore sectors, and ~20 percent in the nearshore sectors. Looking more toward the extremes, 10 percent of the runs in the non-nearshore simulations fell higher or lower than 0.37 and 1.86 times the true value (i.e., 63 percent lower and 86 percent higher). That same interval for the nearshore simulations is 0.47 to 1.71. Somewhat counter intuitively, the nearshore simulation shows more precision than the non-nearshore simulation despite having lower coverage levels. It may be that the lower frequency of non-zero trips in the non-nearshore counteracts the expected effect of higher observer coverage.

While the sampling error is an important consideration, in reality the "true" catch is never known and the Council can only respond to the estimates of the true catch. So understanding the expected year to year variability in the catch estimates is of most interest here.

Considering the degree of year to year fluctuation in the estimates, the results show that on average the estimates were 1.43 times the previous' years estimate in the nearshore and 1.88 times in the non-nearshore. The use of ratios and the influence of large outliers may make the mean values of limited value here. The intervals provide a fuller picture. Looking at the 50 percent interval, we see that half of the runs fluctuated between 0.62 and 1.61 over the previous year in the nearshore and 0.54 and 1.88 in the non-nearshore. The 8 fold increase seen in the nearshore catch estimate between 2010 and 2011 (Table B-10(b)) would have fallen within the upper 1 percent of the nearshore simulation runs (not shown in Table B-15).

With the 10 year average metric, we see half the runs in the non-nearshore coming in 0.58 to 1.34 times the size of their respective 10 year averages and 0.67 to 1.27 times in the nearshore simulation runs. Considering only the situation where the 10 year average to underestimate the catch estimate, the catch was double the average around 5 percent of the non-nearshore runs. Not reported in the table, yet the average of the upper 5th percentile values was 2.44. In the nearshore simulations, the variation was lower with the upper 5th percentile populated by values greater than 1.85 times their respective 10 year average with an average value of 2.15.

Lastly, as can been seen in the metrics reported for the simulated true catches, the simulated true catches showed considerable variation as well. The variability in the probability of encountering yelloweye on trip and variability in the size of the catch when encountered created a range of simulated annual catches. This variable signal in the annual catches drives a lot of the noise seen in the simulated catch estimates.

B.5 Within Non-Trawl: Consideration of State-Specific Nearshore Rockfish Harvest Guidelines North of 40°10' N. latitude

Need for Action

In April 2014, the Council requested analysis of options for allocation of the Nearshore Rockfish complex north of 40°10' N. latitude to keep morality at or within the ACL including 1) No Action, 2) utilizing the miles of coastline north of 40°10' N. Lat., 3) the recent recreational and commercial historical catch from 2004-2012 (Agenda Item C.4.b, Supplemental GMT Report 2), and 4) a hybrid allocation method which uses miles of coastline for copper, China and quillback rockfishes and historical catch from 2004-2012 for the remaining species. In options 1 and 2, blue rockfish apportionment was initially based on stock assessment lines (California vs. Washington-Oregon assessment), with subsequent allocation between Oregon and Washington based on recreational and commercial historical catch from 2004-2012. Miles of coastline was not used to apportion blue rockfish between Oregon and Washington because of the large disparity in historical catch (Agenda Item C.4.b, Supplemental GMT Report 2, Tables 2 and 3) which indicated a decline in relative abundance along the coast not reflected when allocation is conducted using miles of coastline.

Catch data used to apportion the coastwide annual catch limit (ACL) under the two harvest guideline (HG) options using historical catch have been updated since the April meeting. Prior RecFIN queries for recreational catch data included inland areas in Washington not managed by the Pacific Fishery Management Council. The updates resulted in changes to the Nearshore Rockfish complex harvest guideline options (i.e., proportions of the ACL distributed among states), primarily to the historical catch option, but still reflect the range of HG Options recommended for analysis by the Council in April.

This analysis provides information on the implications of state-specific Nearshore Rockfish complex HG for the area north of 40°10' N. Lat. Options for the state-specific HGs are based on historical catch and miles of coastline in California, Oregon and Washington, as described above. Management under HGs from alternate allocation options are compared to the No Action alternative of status quo management for the Nearshore Rockfish complex with an ACL north of 40°10′ N. Lat.. The management measures needed to prevent mortality from exceeding complex level HGs and the implication for stock status and fishery participants are analyzed for each option.

Background

Under No Action, the Nearshore Rockfish complex overfishing limit (OFL) consists of contributions of the component stocks to the entire complex, stratified at 40°10′ N. Lat. Under status quo management, a complex level ACL is assigned to each region north and south of that management boundary (see the draft environmental impact statement; DEIS). This analysis provides the implications for the nearshore fisheries from instituting a HG in each state (Table B-17). Note that Nearshore Rockfish complex mortality from the tribal fishery is negligible and the tribes will notify the Council if this is expected to change in the future.

We evaluate three options for implementing HGs, in addition to No Action, for each state north of 40°10′ N. Lat. The first is stratified on the basis of miles of coastline, using the length of the three nautical mile boundary line delineating state and federal waters as a proxy for coastline length in each state (see Appendix 1). The second method is based on average historical catch for all sectors between 2004 and 2012. The third is based on a hybrid method applying miles of coastline to stocks that are ubiquitously distributed along the coast (i.e., China, quillback and copper rockfish), while the historical catch method is applied to those remaining species that show a cline in abundance also noted in scientific literature, including blue rockfish allocated by assessed areas north and south of the California-Oregon border and allocated between Oregon and Washington using historical catch. This analysis is intended to help better understand the needs of the fishing community relative to the constraints from management under state-specific harvest guidelines.

Ideally, allocating catch would involve a measure of relative abundance along the coast, but no such index is currently available for nearshore rockfish. In the absence of these data, two proxy methods of allocating have been presented; historical catch from 1916-2012 and the miles of coastline within the assessed area (Agenda Item C.4.b, GMT Report 2, April 2014; Agenda Item C.9.b, GMT Report 2, April 2014). The three options analyzed herein were developed after considerations were made regarding these original allocation methods. There are implications of these decisions for the commercial nearshore and recreational sectors in each state that make this a contentious issue. There are, however, scientific principles that can help inform sound decisions in the selection of allocations resulting in harvest guidelines. Examples of considerations for the three options analyzed in this paper are described below.

Considerations for Allocation Options

Considerations for Option 2: Miles of Coastline

Allocation using miles of coastline within each assessed area may prevent potential over-allocation to over-harvested areas that can result when historical catch is used. This method provided an alternative to catch based allocation alternatives. The primary assumption of this method is that the relative abundance is consistent along the coast. This assumption may not be valid for species that decline in abundance toward the ends of their range, or if habitat is not proportional to coastline distance or if stocks have been overharvested in a given sub-region. Although, for species such as China, quillback, copper and blue rockfishes that are relatively common throughout the assessed range, the distribution of habitat is unlikely to be perfectly uniform between states. Hence, this method may over-allocate or under-allocate, depending on which assumptions are violated. In instances where regulations and mortality for ubiquitously distributed species varies greatly among states, and a declining trend in catch per unit effort (CPUE) or assessments results in a portion of the species range, the historical catch method may be preferred over miles of coastline to prevent over allocation of fish at the edge of their range. Thus the assumption of uniform distribution is likely violated when miles of coastline is applied to species such as blue, olive, brown, gopher, black and yellow and grass rockfish, as indicated by the distribution of catch in PacFIN and RecFIN, and in published literature showing the range of each species indicating that they are less common or absent to the north (Love et al. 2002).

Considerations for Option 3: Average Historical Catch

When historical catch is employed to allocate among states, there is potential for over-allocation to states that harvested the most fish. Table B-17 contains commercial mortality (the average landings (mt) in the commercial fishery from PacFIN plus discard mortality estimated from the nearshore projection model) and recreational mortality (mt) (RecFIN) of nearshore rockfish stocks north of 40°10′ N. Lat. from 2004-2012. The Scientific and Statistical Committee (SSC) advised that “historical catches of nearshore species by state may not reflect biomass by state because of major differences in the management among states” (Agenda Item D.5.b., SSC Report, March 2014). Allocation using historical catch assumes that catch is proportional to abundance, which may not be the case due to differences in management among states. The annual catch by sector (Figure B-19) and annual, average, and range of catches by sector from 2004-2012 (Table B-17) reflect a combination of regulations, permitting systems, participation, constraints from overfished species and relative abundance of each species.

Overfished species constraints affected regulations on target stocks (e.g., seasons, depth restrictions and trip limits), limiting harvest to varying degrees among states from 2004 to 2012. A description of how regulations have varied over this period in each state and sector is provided in Appendix 2. Notable changes in regulations to reduce yelloweye rockfish mortality include a shallower depth restriction in the California and southern Oregon nearshore commercial fisheries starting in 2009 when the shoreward rockfish conservation area (RCA) boundary was moved from 30 fm to 20 fm to reduce yelloweye rockfish mortality. This adversely affected the ability of the fishery participants in California and Oregon to access deeper nearshore species. Depth restrictions and season lengths in the California recreational fishery have been severely limited by yelloweye rockfish mortality since 2008 after overages in 2007 necessitated inseason action to reduce season lengths and shallower depth restrictions to 20 fm (Appendix 2), which has continued in order to minimize yelloweye rockfish mortality. In addition, the Oregon recreational fishery was limited to shallower depth restriction of 20 fm from 40 fm part of the year starting in 2007, shifting effort onto Nearshore Rockfish habitat. The Washington recreational fishery has had consistent regulations since 2005, when depth restrictions of 20 fm and 30 fm went into place during part of the year shifting effort onto shallower depths.

Differential management among states shown above may differentially affect catch among states. It should be noted that other factors may also affect catch (e.g., environment, markets, distribution, and abundance). Figure B-19 provides annual catch patterns for the various sectors among states. For example, Nearshore Rockfish mortality in the California recreational and commercial fisheries declined abruptly in the years after their respective 20 fm depth restrictions were implemented. The Washington recreational catch has remained relatively steady over the 9-year period shown Figure B-19, as it was shown above that regulations have remained somewhat constant since 2005 (see Appendix 2). Interestingly, Oregon commercial and recreational Nearshore Rockfish catches have shown increases since many restrictions shown in Appendix 2 were put in place. It should be pointed out that much of this Oregon Nearshore Rockfish increase may be attributed to blue rockfish catch.

The differential management among states, along with differing degrees of participation in each sector among states, affects historical catch and thus allocation, which may cause it to deviate from representation of relative abundance along the coast. For example, Washington prohibited their commercial nearshore fishery and reduced their bag limit to ten fish in 1995 as a precautionary measure to preserve recreational fishing opportunities for the future, which might have been subject to further restrictions if allocation were shared with a commercial fishery. The participation in angler trips between Washington, Oregon and California are expected to vary affecting mortality due to season lengths, perceived opportunity (bag limits, depth restrictions) and angler population size in each state. In addition, Oregon and California have differing commercial permitting systems for their fisheries. These factors, and those shown in previous paragraphs, may cause allocations based on historical catch to deviate from relative abundance. Those areas with more liberal regulations or higher participation are likely to have disproportionately high nearshore rockfish mortality compared to the actual relative abundance along the coast.

For species with strong clines in abundance along the coast, the historical catch based method may capture the trend and allocate accordingly, where allocation by miles of coastline would not due to the assumption of uniform distribution. The aforementioned changes and differences in management should be considered when evaluating the true needs of the fishing communities and potential bias in allocation in each region and provide an impetus for weighing the assumptions regarding miles of coastline as an alternative method depending on the distribution of the species among other circumstances.

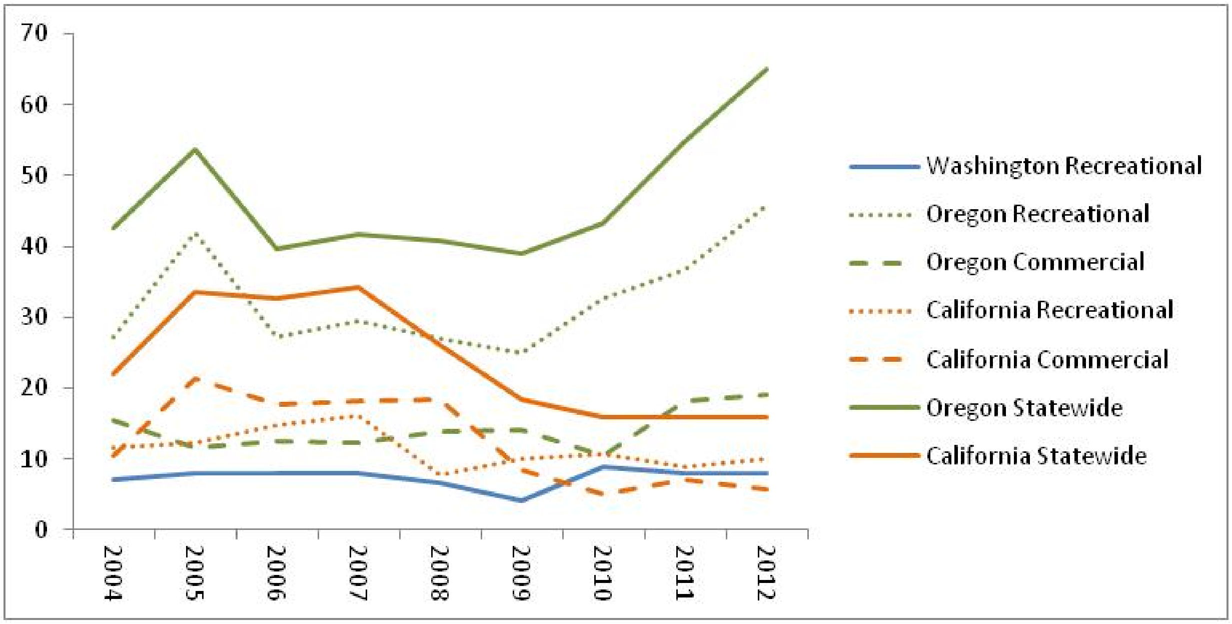

Figure B-19. Nearshore Rockfish Complex mortality estimates (mt) by state and sector in each year from 2004-2012.

Table B-17. Nearshore Rockfish Complex mortality estimates (mt) by state and sector in each year from 2004-2012 as well as the average and range of mortality from periods with less constraint (2004-2007) and greater constraint (2008-2012) from yelloweye rockfish. Recreational data were from RecFIN for Washington (ocean boat only), Oregon (ocean boat only), and California (ocean boat, shore, and estuary).

Year	Washington Recreational	Oregon Recreational	California Recreational	Oregon Commercial	California Commercial N. 40°10′ N. Lat.	Total
2004	7.06	27.18	11.61	15.40	10.46	71.71
2005	7.96	41.90	12.21	11.74	21.28	95.09
2006	8.00	27.20	14.84	12.47	17.85	80.36
2007	7.95	29.42	16.14	12.41	18.23	84.15
2008	6.72	26.91	7.69	13.84	18.38	73.54
2009	4.26	24.88	10.01	14.15	8.39	61.69
2010	8.99	32.78	10.82	10.57	5.16	68.32
2011	8.10	36.66	8.84	18.28	7.02	78.9
2012	7.93	45.88	10.10	19.06	5.84	88.81
2013	6.23	38.1	9.3	NA\1	NA\1	NA
Average 2004-2007	7.74	31.43	13.70	13.01	16.96	82.83
Range 2004-2007	7.06-8.00	27.18 - 41.90	11.61 - 16.14	11.74 - 15.40	10.46 - 21.38	71.71 – 95.09
Average 2008-2012	7.20	33.42	9.49	15.18	8.96	74.25
Range 2008-2012	4.26-8.99	24.88 - 45.88	7.69 - 10.82	10.57 - 19.06	5.16 - 18.38	61.69 – 88.81
Average 2004-2012	7.44	32.53	11.36	14.21	12.51	78.06
Range 2004-2012	4.26-8.99	24.88 - 45.88	7.69 -16.14	10.57 - 19.06	5.16 -21.28	61.69 – 95.09

Considerations for Option 4: Hybrid Method

While either method may deviate from the true relative abundance along the coast, which is unknown, consideration of which assumptions are violated for a given species may be helpful in deciding which method is more appropriate. Allocation by historical catch may be preferred in instances where a strong natural decline in abundance from the center of a species range occurs, in which case use of miles of coastline alone would cause an over-allocation to areas at the edge of their range where they are less common. This is the case for some of the nearshore rockfish species for which abundance may naturally decline or become non-existent north or south of 40°10′ N. Lat. (e.g., gopher, olive, black and yellow, brown, kelp and grass rockfish; Table B-17). Miles of coastline may be more appropriate for those species that are more uniformly distributed within the entire region over which allocations are being made (e.g., copper, China, and quillback rockfishes). Blue rockfish may be allocated according the stratifications of assessments at 42° N. latitude since two stocks have been identified and are predominantly distributed on either side with further allocation using appropriate methods discussed above depending on the trends in abundance in the region in question.

The Groundfish Management Team (GMT) provides some considerations to allow the Council an alternate way to evaluate the allocation options in a way that extends beyond the needs of the fishery. These methods attempt to approximate the relative abundance of component species given the assumptions implicit in their application to provide a logical basis for allocation. Where the range appears to reach its edge within the management area, average catch may be a more reasoned approach and where large differences in catch occur along the range of an otherwise ubiquitously distributed species in the region, miles of coastline may be preferable, to avoid violation of assumptions implicit in each method. Future off-year scientific research designed to quantify catch and abundance relative to available habitat would greatly improve allocation methods.

Pros and Cons of Each Option in Light of Considerations Presented

The pros and cons of each method given considerations regarding allocation with each are described in Table B-18.

Table B-18. Comparison of the pros and cons of each Nearshore Rockfish complex allocation option.

Allocation Option	Pro	Con
Miles of Coastline	Less potential for over allocation to depleted areas than historical catch if harvest is more reflective of management policies than fish abundance. Provides an alternative to catch based allocation methods	Some species are far less common at the edge of their range and would be over-allocated to some areas since the method assumes abundance is proportional to miles of coastline.
Historical Catch (2004-2012)	Reflects the recent historical pattern of commercial and recreational fisheries. Accounts varying trends in abundance with latitude at the edge of a species range.	Potential for over-allocation to areas that are more depleted. Overfished species constraints limited harvest to varying degrees between states affecting allocations. Doesn't address areas where commercial fisheries are prohibited.
Hybrid Option	Minimizes allocation biases presented by application of historical catch to areas with higher removals/depletion and miles of coastline for species at the edge of their range.	Still does not reflect differences in reef habitat and relative abundance across states, but neither do the other options. Still subject to the biases of each method, but attempts to minimize the degree of bias given apparent trends in abundance and distribution of component stocks.

Comparison of Historical Mortality and Projected Mortality under the Preferred Alternative and No Action to Nearshore Harvest Guideline Allocation Alternatives

The projected mortality in each state and sector under the No Action Option, Preferred Alternative Alternative 4, the average mortality between 2004 and 2012, and the range of catch during this period are presented in Table B-19. There are no nearshore rockfish mortality projection models for the trawl and non-nearshore fishery, but based on historical data, mortality in the trawl and non-nearshore fisheries is expected to be trace (Agenda Item C.4.a, Attachment 3, Table 4-13). Mortality in 2013 is not yet available for the nearshore fixed gear fishery, but this information is available for the recreational fishery, which demonstrates that mortality in the most recent year of the recreational fishery was 6.2 mt for Washington, 38.1 mt for Oregon and 9.3 mt for California.

Projections for nearshore rockfish for all coastwide sectors north of 40°10′ N. Lat. total 76.7 mt under no action. The average catch for 2004-2012 is 81.6 mt for all sectors combined; results for each state are also provided for comparison under each alternative. The projected mortality under the Preferred Alternative is 80.0 mt without harvest guidelines or interstate coordination of catch tracking and inseason response, making it difficult to reduce mortality to prevent overages against the shared aggregate ACL. The average catch as well as projected mortality under the SQ and Preferred Alternative (Table B-19) will exceed the 2015-2016 ACL of 69 mt, indicating that management measures will likely be needed to reduce aggregate mortality. Decisions on the part of the Council relative to allocations will involve tradeoffs potentially affecting fishing opportunity in each state.

The methods used to project mortality for 2015-2016 with methods approved by the SSC in each recreational and commercial fishery are described below:

Nearshore Fixed Gear: The commercial nearshore model projects mortality of overfished species and targeted nearshore species based on the expected (e.g., landings of nearshore rockfish, black rockfish, kelp greenling, cabezon, lingcod, and California scorpionfish (S of 40°10'N Lat.). The nearshore model applies past discard rates (from the West Coast Groundfish Observer Program; WCGOP) to expected landings by depth, along with depth-specific discard mortality rates, to estimate total mortality of discarded and landed nearshore species. The GMT notes that the nearshore commercial bycatch projection model estimates discard of nearshore species based on expected landings coupled with discard rates provided by WCGOP; however, discard rates are based on past management measures. If trip limits (and expected landings) are reduced dramatically, the model may grossly underestimate discard.

Washington Recreational: The Washington recreational model uses historical catch to project total mortality of overfished and nearshore rockfish species. Nearshore rockfish projected impacts for this analysis used the historical high catch by species from the 2009 through 2013 time period as the projected impacts under the No Action Alternative. Washington does not have a nearshore commercial fishery so projections of nearshore rockfish have not been needed to ensure that catch stays within sector specific allocations. This analysis includes nearshore rockfish caught in all recreational fisheries including those targeting salmon and halibut and any restrictions to nearshore rockfish retention would be applied to all fisheries. Recreational fishing effort in salmon and halibut fisheries can vary annually contributing to variable encounter rates with nearshore rockfish. Using the 2009-2013 high catch to model projected impacts results in more conservative management measures, that are expected to keep catch of nearshore rockfish within the range of HG options for the Washington recreational fishery. Catch by month and management area during this time period was used to estimate projected impacts for the WA Nearshore Rockfish complex HG Options. The proportion of nearshore rockfish caught by depth and month for each management area was used with current surface release mortality rates to estimate discard mortality by month.

Oregon Recreational: The Oregon recreational catch projection model uses the last 3 years of data in producing projections of nearshore rockfish mortality. Table B-19 displays the results of the Oregon recreational model projections of nearshore rockfish mortality under Alternative 3.

California Recreational: The California recreational catch projection model used mortality in 2011 and 2012 as the base data for projections. Three options are available for the season structure for the California recreational fishery and the projected mortality of 15.6 mt, 15.4 mt and 6.7 mt, respectively, with the season with the highest projected mortality of Nearshore Rockfish complex displayed in Table B-17.

Table B-19. Projected Nearshore Rockfish complex mortality under the No Action Alternative, the Preferred Alternative, average mortality from 2004-2012 and, allocation under each HG alternative by state and sector (in mt).

Sector	No Action Mortality	Projected Mortality under Preferred Alt	Average Mortality and Range 2004-2012	HG Miles of Coastline	HG Historical Catch	HG Hybrid Approach

Total All Sectors	**76.7**	**80.0**	**78.06 (61.69 – 95.09)**	**68.75**	**68.75**	**68.75**

1/The state of Washington has not had a commercial nearshore fishery since 1995.
2/For Oregon, projected landings and additional discard mortality for each column are: No Action (15.0 mt + 0.1 mt), Preferred Alternative (18.3 + 0.1 mt), 2004-2012 average (14.21 + .08 mt), Option 1 (9.6 + 0.05 mt), Option 2 (10.7 + 0.06 mt), and Option 3 (10.4 + 0.06 mt).
3/The California commercial blue rockfish mortality estimate for 2008 from PacFIN reflected expansion of a single sample to a value of 21.6 mt, which is not representative of expected mortality from landing receipts from CFIS totaling 7.8 mt. The projected impacts and average mortality from the PacFIN estimate is provided in brackets.

Management Options

Option 1: No Action: Continue to manage the Nearshore Rockfish complex, holding impacts to the complex level ACL in each region.

Option 2: Miles of Coastline: Manage the Nearshore Rockfish complex according to state specific harvest guidelines stratified at 40°10′ N. Lat. reflecting apportionment based on the miles of coastline in each state.

Option 3: Historical Catch: Manage the Nearshore Rockfish complex according to state specific harvest guidelines stratified at 40°10′ N. Lat. reflecting apportionment based on the historical recreational and commercial catch between 2004 and 2012.

Option 4: Hybrid Method: Manage the Nearshore Rockfish complex according to a state specific harvest guidelines stratified at 40°10′ N. Lat. reflecting a hybrid method of apportionment based on miles of coastline for China, quillback and copper rockfish and the historical recreational and commercial catch between 2004 and 2012 for the remaining species.

Data and Examples of Available Management Measures

Washington

Recreational: The Washington recreational fishery was modeled for season structure alternatives necessary to keep total mortality of overfished species within state specific HGs in the draft DEIS. Projected moralities for nearshore rockfish were not included in that analysis. Additional management measures needed to keep nearshore rockfish catch under the WA HG alternative are explored here. For the most part, nearshore rockfish are not targeted in Washington's recreational fisheries and retention is incidental while anglers target other groundfish, salmon and halibut. The primary tool analyzed to reduce total mortality of nearshore rockfish is non-retention. Projected mortality for nearshore rockfish was analyzed based on the season structure under the Preferred Alterantive for the Washington recreational fishery. Note that mortality estimates, allocations and projections do not include mortality from the Puget Sound or Strait of Juan de Fuca since they are not managed with the Council process. In addition, mortality from shore based modes are not accounted for in estimates, projections or allocations.

Commercial: Washington has prohibited a commercial nearshore fishery since 1995.

Oregon

Recreational: The Oregon recreational fishery was modeled for various season structure scenarios to keep impacts to overfished species within the sector-specific HGs (canary and yelloweye rockfish) in the DEIS. Mortalities of key non-overfished species, given those season structures, were also projected in the DEIS. Further management measures, such as sub-bag limit or non-retention, will likely be needed to reduce impacts to the nearshore rockfish complex. Oregon intends to develop the within-Oregon commercial-recreational split through state processes. Determining which management measures are necessary to stay within that split will also occur through state processes. Note that mortality estimates, allocations and projections do not include mortality from the shore based modes as they have not been sampled in recent years. The mortality in these modes continues, though it is not reflected in estimates or allocations. Since they are excluded from allocations and estimates, it is assumed that the results are consistent with the outcome had they been included in both, though further analysis by the GMT is warranted. Discussion of their inclusion in future estimates or retrospectively for this analysis is a point of consideration for the Council and the GMT in June.

Commercial: The Oregon commercial nearshore fishery was modeled assuming the shoreward RCA at 30 fm for all options. The input for this model is estimated landings of Other Nearshore Rockfish. Discard rates were applied to these estimated landings to project discard of Nearshore Rockfish (based on WCGOP data). Depth-specific mortality rates were then applied to the discarded portion of the catch to estimate discard mortality. Total mortality may then be estimated by summing the landings and estimated discard mortality.

Management measures will likely have to be implemented to reduce mortality of Nearshore Rockfish (including blue rockfish) for each of the harvest guideline options. Under the Preferred Alternative and No Action, state trip limits for vessels with nearshore endorsed black rockfish and blue rockfish permits (i.e., nearshore permitted vessels) would remain at approximately 700 lb per 2-month period for Nearshore Rockfish (not including blue rockfish). Vessels with black rockfish and blue rockfish permits would also be allowed to retain 1,000 to 1,700 lb per period of black rockfish and blue rockfish (combined) under the Preferred Alternative. See the DEIS for more information regarding state permit system.

Landings are monitored closely during the season (i.e., near-real time), which provide the opportunity to implement and evaluate impacts of reduced (or increased) trip limits. Trip limit options may include (a) trip limit reductions to allow for year-around deliveries of Nearshore Rockfish or (b) less severe trip limits during part of the year but at some point, impose no retention (i.e., all Nearshore Rockfish encountered would be discarded). Note that separate blue rockfish trip limits may be considered, because blue rockfish and black rockfish are currently managed under a combined trip limit. It is uncertain at this point (a) when trip limits may be imposed and (b) what the trip limit levels should be under the harvest guideline options.

California

Recreational: The current California recreational catch projection model (RecFISH) was used to project mortality with a given season and depth restriction under each of the Options. These data and analytical methods allowed mortality to be projected from combinations of season lengths and bag limit that keep nearshore rockfish mortality within respective harvest guideline under each of the Options. California recreational catch estimates and projections account for mortality in all modes including shore and boat based angling and saltwater areas including bays and estuaries.

Commercial: PacFIN data were used for overall minor nearshore rockfish complex landings summaries whereby a simple five-year average (2008-2012) was used as a proxy for mortality estimates. Because PacFIN data were used, PacFIN estimates do not include discard mortality amounts. However, estimated discard mortality for nearshore rockfish have been included by using those generated by the nearshore bycatch model. California's Commercial Fishery Information System (CFIS) data were used for nearshore permit license summaries. Lastly, the GMT's nearshore bycatch projection model was used to estimate overfished species (OFS) mortality in the commercial nearshore fixed gear fishery.

Management measures for the northern California nearshore rockfish fishery, currently in place, include a shoreward RCA boundary of 20 fm, trip limits for both black rockfish and the minor nearshore rockfishes as a sub-trip limit of the overall nearshore rockfish complex, a state nearshore permit system, and a gear restriction that limits the number of hooks one may use within one mile of shore. The most obvious management measure change that may need to be considered to achieve necessary mortality reductions would be a reduction in the black rockfish/other minor nearshore rockfish trip limit structure. Under No Action, the current trip limit is set at 8,500 lb per vessel per bi-monthly period for all six periods. Of that bi-monthly amount, no more than 1,200 lb may be species other than black rockfish. It is this part that needs to be more closely examined as a possible source for a management measure change. A trip limit reduction in this sub-trip limit amount could also partially address concerns regarding the mortality of overfished species. Another trip limit option would be to design trip limits specific to each period rather than have an "across-the-boards" single amount for all six periods. Lastly, a management measure option could be to have one or possibly two periods closed to fishing. A sub-option to this seasonal closure approach may be to close the fishery for one month in one or more periods.

B.5.1 Comparison of Options under the Preferred ACL Alternative (P 0.45)*

B.5.1.1 Option 1: No Action

Continue to manage the Nearshore Rockfish complex, holding impacts to the complex level ACL in each region. Under the No Action Option (Option 1), the Nearshore Rockfish complex would be subject to the ACL for all sectors and states combined. The Nearshore Rockfish complex is stratified at 40°10′ N. Lat. with an ACL of 69 mt to the north and 1,049 mt to the south in 2015 with a P* of 0.45 under the preferred specifications.

Fishing Activity under Option 1 (No Action)

Washington

Recreational: Under the No Action Alternative, the Washington recreational fishery would be open year-round for groundfish, except lingcod. Washington would continue to prohibit the retention of canary and yelloweye rockfish in all areas. Washington has a 12 fish daily bag limit with sub bag limits of 10 rockfish, 2 lingcod and 1 (northern management area) or 2 (southern management areas) cabezon. Depth restrictions are the primary tool used to keep overfished species impacts below state HGs. Depth restrictions are more sever in the area north of the Queets River (Marine Area 3 and 4) where encounters with yelloweye and canary rockfish are the greatest. Management measures under the Preferred Alternative differ only slightly from the No Action Alternative. Under the Preferred Alternative, the depth closure in the North Coast (Marine Areas 3 and 4) would be in place from May 9th through Labor Day rather than from May 1 through September 30. In the South Coast (Marine Area 2), the prohibition on lingcod retention seaward of 30 fm in the area south of 46°58 N. latitude on Fridays and Saturdays from July to August 31 would be removed and in the Columbia River Area (Marine Area 1), the southern boundary for the year round lingcod closure would be moved three miles north.

Commercial: Closed

Oregon

Recreational: Currently the recreational fishery has a 10-fish marine bag limit in federal regulations. State regulations have reduced that bag limit to 7 fish. The fishery is open to all depth January-March and October-December and restricted to inside of 40 fm (30 fm in state rule) April-September. Blue rockfish has a state-specified landing cap and is tracked separately from the other nearshore rockfish. Other nearshore rockfish also have a state-specified landing cap (13.6 mt), in place since 2002, and are tracked inseason. When the landing cap of either are approached the state takes inseason action, usually going to non-retention of that species or group, while the remainder of the fishery season structure and regulations remain unchanged.

Commercial: As of 2014, state-specified landing caps for the commercial nearshore fishery are 14.2 mt (Other Nearshore Rockfish excluding blue rockfish) and 137.9 mt (black rockfish and blue rockfish combined). The number of limited entry permits currently issued is 51 for black and blue rockfish without the nearshore endorsement and 70 for black and blue rockfish with the nearshore endorsement.

Management measures for the Oregon commercial fishery under No Action would be similar to those described for the Preferred Alternative (see the DEIS). The RCA may remain at 30 fm because impacts to overfished species are projected to fall below the Oregon share for yelloweye rockfish and canary rockfish. Trip limits will remain low for non-permitted vessels (see DEIS) to cover incidental catch of certain nearshore species (e.g., 15 lb per trip of black rockfish, blue rockfish, other nearshore rockfish, and other nearshore species for vessels using legal commercial nearshore fishing gear; other trip limits are available for incidental catch in salmon troll fisheries and in trawl fisheries). State-regulated trip limits for permitted vessels would likely remain at current levels (i.e., 700 lb per period of Nearshore rockfish complex, excluding blue rockfish, and 1,000 lb to 1,700 lb per period for black rockfish and blue rockfish combined (Table B-20). These limits are lower than those shown in Federal regulation.

Table B-20. Oregon commercial nearshore trip limits (No Action) for permitted vessels during 2014. Limits for vessels without black rockfish and blue rockfish permits, and those without a nearshore endorsement, are much lower than shown below to accommodate incidental catch (see DEIS). These trip limits are more conservative than those shown in Federal regulation.

Oregon Commercial Nearshore Trip Limits (lb; 2014)	Jan/Feb	Mar/Apr	May/Jun	Jul/Aug	Sep/Oct	Nov/Dec
Black rockfish + blue rockfish	1,000	1,200	1,700	1,600	1,200	1,000
Other nearshore rockfish (excluding blue rockfish)	700	700	700	700	700	700

California

Recreational: Currently the recreational fishery is subject to a 10 fish Rockfish Cabezon and Greenling bag limit with restricted seasons and depths in each of 5 management areas to limit mortality on overfished and target stocks. The season length in the California recreational fishery under the status quo ACL Alternative in the Northern Management Area is May 15th to October 31st with a depth restriction of 20 fm to keep mortality of yelloweye rockfish below the HG for the recreational fishery. Under the Preferred ACL Alternative, California recreational season and depth restriction Option 1 would allow a March 1 to December 31 season and 20 fm depth restrictions given harvest limits/guidelines on overfished and target stocks in 2015-2016, without limitations from a state Nearshore Rockfish complex HG.

Commercial: At present, the Nearshore Rockfish complex is managed in four regions: the North Coast Region is from 42° N. Lat. (the Oregon-California border) to 40°10' N. Lat. (near Cape Mendocino). Current trip limits and open and closed periods in each region are provided in Table B-21 below. Depth restrictions vary by region with a 20 fm depth restriction to the north of 40°10′ N. Lat., 30 fm south to Point Conception at 34°27′ N. Lat. and 60 fm south of 34°27′ N. Lat.. Currently gear restrictions restrict fishery participants to 15 hooks per line with no more than 150 hooks in use to take nearshore fish stocks within one mile of shore within certain Fish and Wildlife Districts. In addition, the fishery is a subject to a state restricted access permit system for the shallow nearshore fishery. To enter this shallow nearshore fishery, two existing permits must be purchased and transferred to a new participant within the same management region; one of those permits must then be surrendered back to the Department. The intent of this method is to achieve capacity goals for the fishery and reduce participation relative to historical levels to help prevent overharvest. There are no transferable permits for the deeper nearshore rockfish fishery, preventing new entry at the present.

Most fish are sold live for a premium relative to dead fish. This creates an impetus to fish in shallower depths where mortality is lower compared to deeper depths, thus discards are subject to a relatively low mortality compared to depths greater than 30 fm where discards are deemed 100 percent dead.

Notwithstanding the options presented in this analysis, a major factor that influenced fishing activity in California's northern management region was the change of the RCA shoreward boundary from 30 fm to 20 fm to avoid yelloweye rockfish encounters, beginning in 2009. The effects of this boundary change are apparent when examining the commercial landings over the past decade (Figure B-17). California's northern commercial fishery experienced a 55 percent decrease in harvest from 2008 to 2009 and a 39 percent decrease from 2009 compared to 2010.

Table B-21. California commercial federal cumulative two-month trip limits (No Action) for 2014 that apply to the vessel and to the permit holder for the shallow and deeper nearshore rockfish sectors. Trip limits per two-month period (reported in lb) are the same for both the federal limited entry and open access entry sectors used by the state's restricted access nearshore rockfish fishery program.

NORTH Between 42° and 40°10' N. Lat.	Jan/Feb	Mar/Apr	May/Jun	Jul/Aug	Sep/Oct	Nov/Dec
Black rockfish + minor nearshore rockfishes. No more than 1,200 lb of which may be species other than black rockfish (applies to all periods)	8,500	8,500	8,500	8,500	8,500	8,500

Note: For the shallow nearshore fishery, permit holders may catch and land the two-month trip limit only in the region in which their permit is issued. Holders of a deeper nearshore rockfish permit may catch and land deeper nearshore rockfish anywhere in the state where and when fishing is permitted.

Biological Impacts under Option 1 (No Action)

Projected Nearshore Rockfish Mortality

The projected mortality in each state and sector under Option 1 are summarized in Table B-22. Further description of the mortality in each state and sector is provided in the text below.

Table B-22. Projected Nearshore Rockfish mortality (mt) north of 40°10′ N. Lat. from each state and sector under Option 1 (No Action).

	Washington		Oregon		California		Grand Total
	Rec	Com	Rec	Com	Rec	Com	
	10.5	Closed	30.5	15.1	11.7	8.9	76.7
State Total	10.5		45.6		20.6		

Washington

Recreational: Projected mortality of the Nearshore Rockfish complex under the No Action Option and Preferred Alternative is 10.5 mt. Season length and structure are the same for both alternatives.

Commercial: Closed

Oregon

Recreational: The projected landings under the No Action Option for blue rockfish is 17.5 mt, for other nearshore rockfish 13.0 mt, for total nearshore rockfish mortality of 30.5 mt.

Commercial: The projected landings of Nearshore Rockfish under the No Action Option is 15.0 mt in aggregate, and consists of blue rockfish (4.6 mt) and the remaining species of Nearshore Rockfish (10.4 mt). The nearshore projection model provides an additional estimate of discard mortality at 0.07 mt (blue rockfish and other nearshore rockfish combined), resulting in a total mortality of 15.07 mt for Nearshore Rockfish complex in the Oregon nearshore commercial fishery. This is lower than shown under the Preferred Alternative (see the DEIS), where projected landings are 18.3 mt for Nearshore Rockfish (and additional discard mortality projected at 0.1 mt).

California

Recreational: The aggregate mortality of Nearshore Rockfish complex in the Northern Management Area under the No Action Option would be 11.7 mt of which 2.5 mt would be blue rockfish. Under the Preferred Alternative ACL a season length as long as March 1 – December 31 could be accommodated, which would result in an aggregate mortality of Nearshore Rockfish complex of 15.6 mt of which 3.3 mt would be blue rockfish.

Commercial: The aggregate mortality in the Minor Nearshore Rockfish complex under the No Action Option is projected to be 8.9 mt. This aggregate does not include black rockfish. In the north, blue rockfish take is expected to be 4.9 mt out of the 8.9 mt aggregate total.

Projected Overfished Species Mortality under Option 1 (No Action)

Washington

Recreational: The projected overfished species mortality under the No Action Option and the season structure under the Washington recreational Preferred Alternative is 2.83 mt of yelloweye rockfish and 0.75 mt of canary rockfish which are below the WA recreational HG.

Commercial: Closed

Oregon

Recreational: The projected overfished species mortality under the No Action Option is 2.2 mt of yelloweye rockfish and 3.2 mt of canary rockfish, the same as under the Preferred Alternative. These projections are below the sector-specific HG.

Commercial: The projected overfished species mortality under No Action Option is 0.8 mt of yelloweye rockfish and 0.9 mt of canary rockfish. These projections are slightly different than shown under Preferred Alternative, where yelloweye rockfish mortality was projected at 0.9 mt and canary rockfish mortality was projected at 1.1 mt. These projections are equal to or less than the Oregon catch share.

California

Recreational: The overfished species mortality projected to accrue under the No Action Option are 1.7 mt of yelloweye rockfish, 16.3 mt of canary rockfish, 100.1 mt of bocaccio and 1.0 mt of cowcod. Under the Preferred Alternative overfished species mortality projected to accrue are 2.9 mt of yelloweye rockfish, 19.8 mt of canary rockfish, 117.6 mt of bocaccio and 1.2 mt of cowcod. The projected impacts are within the respective harvest limits/guidelines.

Commercial: The overfished species mortality projected to accrue under the No Action Alternative for north of 40°10' N. Lat. are 0.3 mt of yelloweye rockfish, 0.7 mt of canary rockfish, 0.4 mt of bocaccio and 0.0 mt of cowcod. Under the Preferred Alternative, overfished species mortality projected to accrue are 0.2 mt of yelloweye rockfish, 0.5 mt of canary rockfish, 0.4 mt of bocaccio and 0.0 mt of cowcod. The projected impacts are within the respective harvest limits/guidelines.

Stock Status

Nearshore Rockfish

None of the stocks of nearshore species are currently deemed overfished. Recent aggregate mortality for all sectors has perennially exceeded the 2015-2016 ACL of 69 mt in all but two of nine years between 2004 and 2012 (Table B-17). Steps to reduce mortality should be taken to prevent further overharvest relative to 2015-2016 ACLs and reduce the potential for stocks to be harvested down to overfished status.

Overfished Species

The mortality of overfished species is projected to remain below their respective harvest limits/guidelines. Thus the stock status and rebuilding plans for overfished species are not expected to be adversely affected under No Action Option 1.

Socioeconomic Impacts under Option 1 (No Action)

Washington

Recreational: Under the No Action Option, and the season structure under the Washington recreational Preferred Alternative, management measures necessary to keep recreational harvest of yelloweye rockfish within harvest guidelines require closure or significant restriction of the groundfish fishery in areas deeper than 20 and 30 fm along a substantial portion of the Washington coast, restrictions on groundfish retention during peak recreational fishing periods, and closed areas. While these restrictions have been effective at keeping recreational catch of overfished species under specified harvest guidelines in the past, they are limiting to recreational fishing opportunity. Under the No Action Alternative, angler trips are expected to be similar to what was seen in 2013 and 2014.

Commercial: Closed

Oregon

Recreational: Under the No Action Option, the season structure, bag limits, and most other management measures will remain the same as in 2013 and 2014. Therefore, angler trips and associated expenditures are expected to remain similar to what was seen in 2013 and 2014.

Commercial: Under the No Action Option, landing caps, trip limits, and RCA boundaries are expected to remain the same as in 2013 and 2014. Therefore, trips, expenditures, landings, and revenues are expected to remain similar to that seen in 2013 and 2014. Note that even though management measures would remain similar between Preferred Alternative and No Action, landings of Nearshore Rockfish under Preferred Alternative (18.3 mt) may be higher than that shown under No Action (15.0 mt).

California

Recreational: Under the No Action Option the season and depth restrictions will remain the same as in 2014, but 4.5 months of additional fishing opportunity (4,379 angler trips) would be forgone in the Northern Management Area relative to what could be afforded given the harvest specifications and allocations of overfished and target stocks in 2015-2016 under the Preferred Alternative ACL.

Commercial: Under the No Action Option the state restricted access permit system, federal trip limits, season and depth restrictions will remain the same as in 2014. However, routine inseason adjustments could be recommended by the Council if any of the fishery sectors displayed harvest behavior that deviate substantially from the expected amounts. As a result, no adversely affected changes to the socio-economic interests of coastal communities would be anticipated.

B.5.1.2 Option 2: Miles of Coastline

Option 2 is to manage the Nearshore Rockfish complex according to state-specific harvest guidelines stratified north and south of 40°10′ N. Lat., with apportionment north based on the miles of coastline in each state as reflected in Table B-23. The 3 nm state boundary was measured as the proxy for miles of coastline.

Table B-23. Allocations of Nearshore Rockfish north of 40°10′ N. Lat. under Option 2 derived using miles of coastline in each state.

Species	**Contribution**	**WA%**	**OR%**	**CA%**	**WA mt**	**OR mt**	**CA mt**
Black-and-yellow	*0.01*	0.26	0.49	0.25	0.00	0.01	0.00
Blue (CA)	*17.00*	0.00	0.00	1.00	0.00	0.00	17.00

Fishing Activity under Option 2 Compared to Option 1 (No Action)

Washington

Recreational: The Washington HG under Option 2 is 15.68 mt which is higher than the project impacts Under No Action (Option 1). Therefore, the Washington recreational fishery would operate under the season structure described under the Preferred Alternative with no additional management measures needed to keep the catch of nearshore rockfish under the WA HG for this HG Option.

Commercial: Closed

Oregon

Under Option 2, the Oregon Nearshore Rockfish complex harvest guideline is lower than the current combined commercial and recreational state-specified landing caps and average annual catches. We showed above that expected Nearshore Rockfish mortality for Oregon fisheries combined is 45.6 mt for No Action and 48.9 mt for Preferred Alternative. The Oregon harvest guideline under this option is 29.9 mt (Table B-23), or 34 percent lower than expected mortality under No Action and 39 percent lower than expected under Preferred Alternative. State landing caps for both commercial and recreational fisheries will have to be reduced dramatically to accommodate this lower target. It is the GMT's understanding that Oregon intends to develop the commercial-recreational split of the Oregon HG through subsequent state processes.

Recreational: Once the state determines the sector-specific allocation, management measures will need to be examined, then implemented through state rules. A preliminary examination of possible management measures has begun. A bag limit analysis revealed that the majority of anglers encounter less than one nearshore rockfish per trip. Therefore changes in bag limit will likely not be a viable option. The likely measure will be non-retention for some months of the fishing season, incorporating discard mortality for the non-retention months into the impact projections. Since most anglers encounter less than one nearshore rockfish per angler trip and they are generally not targeted, prohibiting retention during certain months, is not expected to influence the number of angler trips, how often, when or where anglers go fishing. It may require anglers to be on the water longer to fill their daily bag limit, however since the majority of anglers do not fill their entire bag each day, this is anticipated to have minimal impacts.

Commercial: Under Option 2, the RCA depth restriction of 30 fm would remain in place because projected catch of overfished species would remain at or below the Oregon catch share. Measures other than depth management will have to be implemented to reduce the mortality of Nearshore Rockfish (including blue rockfish) under this option. For example, under No Action, the commercial fishery was projected to land 15 mt of Nearshore Rockfish (including blue rockfish), resulting in total mortality of 15.1 mt, including discard. Using proportions of current landing caps and average landings between Oregon recreational and commercial fisheries (see Preferred Alternative in the DEIS), the Oregon commercial fishery would receive 9.6 mt of Nearshore Rockfish (including blue rockfish), or a reduction of 36 percent relative to No Action and a 48 percent reduction relative to Preferred Alternative. These reductions may require lower trip limits, periods of non-retention, or some combination of the two. In addition, a new and separate landing cap and trip limit for blue rockfish may be required to remain within the harvest guideline under Option 2 (currently, blue rockfish is managed using landing caps and trip limits in combination with black rockfish).

It should be pointed out that trip limit reductions may not equate to a 1:1 reduction in total landings. In other words, if it were required to reduce landings by 36 percent, then it may be necessary to reduce trip limits by much more than 36 percent relative to No Action. In most fisheries, relatively few individuals or vessels reach trip limits. Most vessels land somewhat less than trip limit levels. As such, if trip limits were solely used to reduce landings, and if the Oregon recreational to commercial ratio (split) remained the same as under No Action, then trip limit reductions would likely have to be much more than 36 percent (i.e., trip limits for this fishery would need to be much lower than 700 lb x 0.64 = 448 lb per period under Option 1). There are other considerations that industry and ODFW staff must discuss and analyze before effective trip limits can be identified. For example, impacts of trip limits vary with the season in which they are applied. Finally, trip limits can be applied along with periods of non-retention, which will alter the level of the trip limit needed. Preferences by the Oregon nearshore fleet need to be identified and additional modeling is required before more specificity can be provided.

California

Recreational: Under Option 2, 23.15 mt would be allocated to California, of which, the recreational catch share is 12.9 mt, accommodating a May 1 to October 31 season with a 20 fm depth restriction in the Northern Management Area. While this would provide an additional half month of fishing opportunity relative to the status quo, the recreational fishing season would have to be reduced by four months relative to the longest season under the Preferred Alternative of March 1 to December 31st. Other alternatives to address overages relative to the catch share include a reduced bag limit or non-retention of Nearshore Rockfish species during part of the season.

Commercial: Under Option 2 the RCA depth restriction of 20 fm would remain in place as well as the trip limit structure. Because the minor nearshore rockfish complex harvest has been at or below the ACLs in recent years (see Figure (cite the correct figure)), it is not anticipated that Option 2 will have an adverse effect on the northern nearshore rockfish fishery; thus fishing activity is expected not to change. However, trip limit reductions could be implemented should the need arise, with possible decreases that may be as much as 30 percent less than the current trip limit amount. Another possibility to be considered is to have period closures. Additionally, California's northern management region is somewhat isolated from the adjacent region(s). Because of this, northern region participants tend not to fish in other management regions (for those holding a deeper nearshore rockfish permit), nor would they be likely to because the trip limits for the northern region are higher than any of the other regions. Also, it is not expected that holders of a deeper nearshore rockfish permit, who may also hold a shallow permit in any of the other southerly regions, would travel to the northern management region to fish because they would only be allowed to catch and land the deeper nearshore rockfishes – their shallow nearshore permit would not be valid north of 40°10' N. Lat.. In effect, it would probably not be economically justifiable for them to fish north of 40°10' N. latitude.

Biological Impacts Under Option 2 Compared to Option 1

Projected Nearshore Rockfish Mortality

The projected mortality in each state and sector under Option 2 are summarized in Table B-24. Further description of the mortality in each state and sector is provided in the text below.

Table B-24. Projected Nearshore Rockfish mortality (mt) north of 40°10′ N. Lat. from each state and sector under Option 2 (miles of coastline). Sector-specific allocations within states are provided as an example and are based on No Action. These intra-state allocations are subject to change.

	Washington		Oregon		California		Total
	Rec	Com	Rec	Com	Rec	Com	
Mortality	10.5	Closed	20.3	9.6	12.6	10.3	63.3
State Total	10.5		29.9		22.9		
Allocation	15.68		29.93		23.15		69
Projected Percent Attainment	66.9%		100%		98.9%		91.7%

Washington

Recreational: Under Option 1 the projected Washington recreational catch falls below the WA HG of 15.68 mt with catch projected to be 10.5 mt. No negative biological impacts are expected.

Commercial: Closed

Oregon

Recreational: Under this option impacts to nearshore rockfish will need to be reduced. Oregon intends to allocate between the commercial and recreational sectors, and take management measures to stay within those allocations, through subsequent state processes. The most likely management measure will be non-retention of nearshore rockfish for some months of the fishing season. Table B-25 below shows the projected landings under the preferred season structure and the projected discard mortality from non-retention by month of the other nearshore rockfish and blue rockfish. Both are calculated on a month by month basis, as that is the smallest time unit currently available in the Oregon recreational model. To project total impacts, and determine which months might need to have non-retention, the landings for months open are added to the release mortality for non-retention months.

Table B-25. Oregon recreational fishery impacts (in mt) by month under preferred season structure and non-retention for the nearshore rockfish.

Projections	**Jan**	**Feb**	**Mar**	**Apr**	**May**	**Jun**	**Jul**	**Aug**	**Sep**	**Oct**	**Nov**	**Dec**
Other Nearshore Rockfish												
Landings under SQ regulations	0.19	0.24	0.58	0.90	1.64	2.13	2.59	2.91	1.22	0.43	0.10	0.06
Non-retention release mortality	0.08	0.10	0.23	0.33	0.61	0.79	0.96	1.08	0.45	0.17	0.04	0.03
Blue Rockfish												
Landings under SQ regulations	0.27	0.34	0.82	1.25	2.24	2.90	3.54	3.98	1.66	0.61	0.14	0.09
Non-retention release mortality	0.27	0.11	0.27	0.39	0.70	0.91	1.10	1.24	0.52	0.21	0.05	0.03

As one example, non-retention in the months of July and August would reduce impacts of other nearshore rockfish species (not including blue rockfish) from 13 mt to 9.5 mt, or a 27 percent reduction. It is the GMT's understanding that Oregon intends to go through their public process to get angler input on which months to have non-retention.

Commercial: Under this option, commercial management measures will be applied to reduce Nearshore Rockfish mortality to 9.6 mt (including blue rockfish), or a 36 percent reduction relative to No Action (and 48 percent reduction relative to Preferred Alternative). This value may change depending on decisions regarding the Oregon recreational-commercial split. Regardless of the management measure applied (e.g., trip limits and/or non-retention), mortality will be reduced. Therefore, no negative biological impacts are expected under this option.

California

Recreational: The projected mortality on nearshore rockfish under Option 2 with a May 1 to October 31 season in the Northern Management Area with a 20 fm depth restriction is 12.6 mt of which 2.8 mt would be blue rockfish. These mortality projections are below the recreational catch share of the California allocation of 12.9 mt under this option.

Commercial: No anticipated negative biological impacts are expected for this option compared to Option 1. Because this option (as well as Options 3 and 4) could require reductions in harvest, biological impacts could actually be reduced to a small degree depending upon the amount of the reduction. Since California's northern fishery has taken less than 10 mt per year on average during the past five years, resultant decreases would be small.

Projected Overfished Species Mortality

Washington

Recreational: Projected overfished species impacts under this Option are the same as for the season structure under the Washington recreational Preferred Alternative.

Commercial: Closed

Oregon

Recreational: A preliminary examination of overfished species impacts due to management measures that may be required under this option projects less than 0.01 percent increase in canary and yelloweye rockfish impacts, assuming no other changes to angler behavior.

Commercial: Under Option 2, if fishermen behavior remains the same as under No Action regarding fishing locations and fishing methods, but increased discarding of Nearshore Rockfish becomes necessary, then mortality of overfished species will remain unchanged relative to No Action. If, on the other hand, selection of fishing locations changes dramatically because of changes in trip limits or required non-retention of Nearshore Rockfish, then overfished species impacts may increase or decrease, depending on geographic locations selected. The direction or level of this potential change in catch of overfished species cannot be predicted in this analysis.

California

Recreational: Assuming season lengths under Option 1 of the Preferred Alternative in Management Areas south of $40^{o}10'$ N. Lat. and the May 1 to October 31 season with a 20 fm depth restriction in the Northern Management Area, overfished species mortality projected to accrue under Option 2 are 2.7 mt of yelloweye rockfish, 21.4 mt of canary rockfish, 118.3 mt of bocaccio and 1.2 mt of cowcod. The projected impacts are within the respective harvest limits/guidelines.

Commercial: Mortality of canary and yelloweye rockfish has been near the respective allocation amounts for these two species. As such, under Option 2 (as well as Options 3 and 4), projected mortality may have to be reduced. Using the nearshore bycatch model as a predictor, decreases in the black rockfish component may need to be considered as a means to achieve the necessary projected mortality decreases for these two overfished species so as to not exceed their allocations.

Stock Status

Nearshore Rockfish

None of the stocks in the Nearshore Rockfish complex are currently deemed overfished. The proposed HG under this option will facilitate implementation of inseason actions to prevent the aggregate ACL from being exceeded, decreasing the risk of overfishing component stocks. Thus, the stock status would not be adversely affected by management measures under Option 2.

Overfished Species

Under Option 2 (miles of coastline), the overfished species mortality is expected to be below the harvest limits/guidelines. Thus stock status and rebuilding plans would not be adversely affected by management measures under Option 2.

Socio-economic Impacts compared to Option 1

Washington

Recreational: The socio-economic impacts would be the same under this Option compared to the No Action Option. Socio-economic impacts would continue to be driven by management measures necessary to keep the Washington recreational fishery within the WA HG for yelloweye and canary rockfish. Recreational fishing effort is expected to be the same under Option 2 as under the management measures and season structure for the Washington recreational Preferred Alternative.

Commercial: Closed

Oregon

Recreational: Since most anglers encounter less than one nearshore rockfish per angler trip and they are generally not targeted, management measures necessary to reduce mortality of nearshore rockfish species is not expected to impact angler behavior, angler trips, nor any other socio-economic indicators. However, additional outreach and education on species identification will likely be necessary to help anglers stay within retention/non-retention regulations. It is impossible to predict how the additive impact of adding this regulation to others already in place might impact anglers' decisions on fishing activities.

Commercial: It is uncertain whether fishing behavior (i.e., fishing location and fishing gear) will change under this option relative to No Action (see above). However, if allocations remain the same between Oregon recreational and commercial fisheries, then landings may be reduced from 15.0 mt (No Action) to between 9.6 mt (maximum, if reduced trip limits resulted in avoiding Nearshore Rockfish altogether resulting in no discards, which is unlikely) to 7.2 mt (if encounters were similar to No Action and discarding was necessary, some of which will not survive. The 2013 price per pound for Other Nearshore Rockfish (weighted average including blue rockfish) was $3.80 per pound for Oregon nearshore fisheries (PacFIN). Under the potential scenarios shown here, lost ex-vessel revenue may range from $45,238 to $65,344 relative to No Action (the loss is higher relative to Preferred Alternative). Additional impacts may be incurred by vessels and crew if the decision is made to fish in less productive areas to avoid Other Nearshore Rockfish, for example. If such of a choice is made, then it may require extra time and fuel to catch other targeted species relative to No Action.

California

Recreational: Under Option 2, the season length would increase by a half month (205 angler trips) relative to the status quo fishery in the Northern Management Area, but the season would be reduced by four months (4,175 angler trips) relative to the longest proposed season with the Preferred Alternative ACLs (Option 1) resulting in lost revenue from those in coastal communities dependent on recreational fishing for their livelihoods.

Commercial: The northern commercial fishery is still recovering from the 2011 tsunami event and the loss of buyers during the past year or two. Currently, there is only one major active buyer in Crescent City. The economic structure of the northern area (essentially only Crescent City) is in a rebuilding phase with no expected time frame, at the present, that predicts when a return to status quo would be reestablished. This, however, is not a result of the options themselves, but an artifact of unavoidable events that have impacted this area. (See also the comments in the Change in Fishing Activity section, above.)

B.5.1.3 Option 3 Historical Catch

Option 3 is to manage the Nearshore Rockfish complex according to a state specific harvest guidelines stratified at 40°10′ N. Lat. reflecting apportionment based on the recreational and commercial historical catch between 2004 and 2012 reflected in Table B-26.

Table B-26. Allocations of Nearshore Rockfish north of 40°10′ N. Lat. under Option 3 (historical catch) derived using the historical recreational and commercial catch between 2004 and 2012.

Species	Contribution	WA%	OR%	CA%	WA mt	OR mt	CA mt
Black-and- yellow	0.01	0	0.21	0.79	0	0	0.01
Blue (CA)	17	NA	NA	1	0	0	17
Blue (OR & WA)	26.94	0.06	0.94	NA	1.67	25.27	0
Brown	1.75	0	0.08	0.92	0	0.14	1.61
Calico	0	NA	NA	NA	0	0	0
China	6.2	0.18	0.68	0.14	1.13	4.21	0.86
Copper	9.71	0.13	0.53	0.34	1.24	5.14	3.34
Gopher	0	0	0.29	0.71	0	0	0
Grass	0.55	0	0.49	0.51	0	0.27	0.28
Kelp	0.01	NA	NA	NA	0	0	0
Olive	0.26	0	0.03	0.97	0	0.01	0.25
Quillback	6.15	0.16	0.47	0.36	1.01	2.91	2.23
Treefish	0.18	0	0	1	0	0	0.18
Total					5.05	37.94	25.76

Fishing Activity under Option 3 Compared to Option 1

Washington

Recreational: The Washington recreational fishery would operate under season structure and management measures described under the Preferred Alternative. However because the WA HG under Option 3 is lower than the historical catch, additional management measures would be needed to keep nearshore rockfish catch under the WA HG for this option. To keep total mortality under the WA HG, retention of nearshore rockfish would not be permitted for a portion of the year. Attainment of the WA HG under this alternative is projected to occur by June 1 with retention of nearshore rockfish prohibited for the remaining 7 months of the year. Alternate combinations of months when nearshore rockfish would be prohibited may be explored.

Commercial: Closed

Oregon

Under Option 3, the Oregon Nearshore Rockfish complex harvest guideline is lower than the current combined commercial and recreational state-specified landing caps and average annual catches, but higher than Option 2. We showed under No Action for Nearshore Rockfish that the expected mortality for recreational and commercial fisheries combined is 45.6 mt (the expected mortality under Preferred

Alternative is 48.9 mt). The Oregon harvest guideline under this option is 37.9 mt (Table B-26), 17 percent lower than expected mortality under No Action, and 22 percent lower than expected mortality under Preferred Alternative. State landing caps for both commercial and recreational fisheries will have to be reduced to accommodate this lower target. As noted under Option 2, Oregon intends to develop or modify the commercial-recreational split of the Oregon HG through state processes.

Recreational: Similar to Option 2, a combination of months of retention and months of non-retention will likely be required to keep impacts within the Oregon recreational HG.

Commercial: Similar to No Action, the RCA depth restriction of 30 fm would remain in place. However, as shown for Option 2, trip limits and/or no-retention may be needed to reduce mortality relative to No Action or Preferred Alternative. Trip limit reductions will be less severe than shown under Option 2. For example, using proportions of current landing caps and average landings between Oregon recreational and commercial fisheries (see Preferred Alternative in the DEIS), the Oregon commercial fishery would receive 11.2 mt of Nearshore Rockfish (including blue rockfish), or a reduction of 25 percent relative to No Action and a reduction of 39 percent relative to Preferred Alternative. This reduction may require either lower trip limits, periods of non-retention, or some combination for Nearshore Rockfish (excluding blue rockfish), along with a separate landing cap and separate trip limit for blue rockfish (see Option 2 for more details).

As shown for Option 2, trip limit reductions may not equate to a 1:1 reduction in total landings. In other words, if it were required to reduce landings by 25 percent, then it may be necessary to reduce trip limits by more than 25 percent. If trip limits (and/or non-retention) were solely used to reduce landings, and if the Oregon recreational-commercial allocation remained the same as under No Action, then trip limit reductions would likely have to be much lower than 700 lb x 0.75 = 525 lb per period. How much lower is uncertain. ODFW staff will meet with industry to identify most preferred management measures, and subsequent trip limit modeling will be performed based on options selected. See Option 2 for more details.

California

Recreational: Under Option 3, 25.3 mt would be allocated to California, of which the recreational catch share is 14.07 mt, accommodating a April 15 to December 31 season with a 20 fm depth restriction in the Northern Management Area. While this would provide an additional three months of fishing opportunity relative to the status quo, the recreational fishing season would have to be reduced by one and a half months relative to the longest season under the Preferred Alternative of March 1 to December 31st. Other alternatives to address overages relative to the catch share include a reduced bag limit or non-retention of Nearshore Rockfish species during part of the season.

Commercial: Same as Option 2.

Biological Impacts Under Option 2 Compared to Option 1

Projected Nearshore Rockfish Mortality

The projected mortality in each state and sector under Option 3 are summarized in Table B-27. Further description of the mortality in each state and sector is provided in the text below.

Table B-27. Projected Nearshore Rockfish mortality (mt) north of 40°10′ N. Lat. from each state and sector under Option 3 (historical catch). Sector-specific allocations within states are provided as an example and are based on No Action. These intra-state allocations are subject to change.

	Washington		**Oregon**		**California**		**Total**
	Rec	Com	Rec	Com	Rec	Com	
Mortality	5.1	Closed	26.8	11.2	14.2	11.45	68.7
State Total	5.1		37.9		25.7		
Allocation	5.05		37.94		25.76		68.75
Projected Percent Attainment	100%		100%		99.7%		99.9%

Washington

Recreational: Under Option 3, additional management measures will be implemented to reduce nearshore rockfish mortality in the Washington recreational fishery by approximately 52 percent compared to Option 1 (No Action).

Commercial: Closed

Oregon

Recreational: Under Option 3, similar to Option 2, non-retention will likely be required to keep impacts within the Oregon recreational HG. Table B-25 has the projections by month for the nearshore rockfish complex minus blue rockfish for retention and non-retention.

Commercial: Under this option, commercial management measures will be applied to reduce Nearshore Rockfish mortality to 11.2 mt, or a 25 percent reduction relative to No Action and 39 percent reduction relative to Preferred Alternative. This value may change depending on decisions regarding the Oregon recreational-commercial spit. Regardless of the management measure applied (e.g., trip limits are non-retention), mortality will be reduced. Therefore, no negative biological impacts are expected under this option.

California

Recreational: The projected mortality on nearshore rockfish under Option 3 with an April 15 to December 31 season with a 20 fm depth restriction in the Northern Management Area is 14.2 mt, of which 3.0 mt would be blue rockfish. These mortality projections are below the recreational catch share of the California allocation of 14.35 mt under this option.

Commercial: The projected mortality on nearshore rockfish under Option 3 is estimated to be 5.6 mt with no other management changes implemented.

Projected Overfished Species Mortality

Washington

Recreational: No additional overfished species mortality is projected compared to the No Action alternative.

Commercial: Closed

Oregon

Recreational: A preliminary examination of overfished species impacts due to management measures that may be required under this option projects less than 0.01 percent increase in canary and yelloweye rockfish impacts. This assumes no other changes to angler behavior.

Commercial: Same as Option 2.

California

Recreational: Assuming season lengths under Option 1 of the Preferred Alternative in Management Areas south of 40°10′ N. Lat. and the April 15 to December 31 season with a 20 fm depth restriction in the Northern Management Area, overfished species mortality projected to accrue under Option 3 are 2.8 mt of yelloweye rockfish, 21.4 mt of canary rockfish, 118.3 mt of bocaccio and 1.2 mt of cowcod. The projected impacts are within the respective harvest limits/guidelines.

Commercial: Same as Option 2.

Stock Status

Nearshore Rockfish

None of the stocks in the Nearshore Rockfish complex are currently deemed overfished. The proposed HG under this option will facilitate implementation of inseason actions to prevent the aggregate ACL from being exceeded, decreasing the risk of overfishing component stocks. Thus, the stock status would not be adversely affected by management measures under Option 3.

Overfished Species

The projected mortalities of overfished species under Option 3 are the same as No Action (Option 1), which are below the respective harvest limits/guidelines. No adverse effects on stock status or rebuilding progress are expected under Option 3.

Socio-economic Impacts Under Option 3 compared to Option 1

Washington

Recreational: Socio-economic impacts would continue to be affected by management measures necessary to keep the Washington recreational fishery within the WA HG for overfished species (yelloweye and canary rockfish). In addition, under Option 3, recreational fishing opportunity would be further reduced. Prohibiting retention of nearshore rockfish for a portion of the season on top of other management measures already in place to protect overfished species may discourage angler participation in recreational fisheries. While it's difficult to predict angler behavior, any reduction in angler fishing effort will have negative socioeconomic impacts.

Commercial: Closed

Oregon

Recreational: Same as under Option 2 and Option 1 (No Action).

Commercial: It is uncertain whether fishing behavior (i.e., fishing location and fishing gear) will change under this option relative to No Action (see Option 2 above). However, if allocations remain the same between Oregon recreational and commercial fisheries, then landings may be reduced from 15.0 mt (No Action) to between 11.2 mt (maximum, if reduced trip limits result in avoiding Nearshore Rockfish altogether causing no discards, which is unlikely) to approximately 9.5 mt (if encounters were similar to No Action and discarding was necessary, some of which will not survive). The 2013 price per pound for

Nearshore Rockfish (weighted average including blue rockfish) was $3.80 per pound for Oregon nearshore fisheries (PacFIN). Under the potential scenarios shown here, lost ex-vessel revenue may range from approximately $31,834 to $46,076 relative to No Action (the loss is higher relative to Preferred Alternative). Additional impacts may be incurred by vessels and crew if the decision is made to fish in less productive areas to avoid Nearshore Rockfish, for example. If such of a choice is made, then it may require extra time and fuel to catch other targeted species relative to No Action.

California

Recreational: Under Option 4, the season length would increase by three months (1,825 angler trips) relative to the status quo fishery in the Northern Management Area, but the season would be reduced by one and a half months (2,555 angler trips) relative to the longest season afforded under the Preferred Alternative ACLs (Option 1), resulting in lost revenue from those in coastal communities dependent on recreational fishing for their livelihoods.

Commercial: Same as Option 2.

B.5.1.4 Option 4 Hybrid Method

Option 4 is to manage the Nearshore Rockfish complex according to a state specific harvest guidelines stratified at 40°10′ N. Lat. reflecting a hybrid method of apportionment based on miles of coastline for China, quillback and copper rockfish and the historical catch between 2004 and 2012 for the remaining species reflected in Table B-28.

Table B-28. Allocations of Nearshore Rockfish north of 40°10′ N. Lat. under Option 4 derived using miles of coastline for China, quillback and copper rockfish and the historical recreational and commercial catch between 2004 and 2012 for the remaining species.

Species	Contribution	WA%	OR%	CA%	WA mt	OR mt	CA mt
Black-and-yellow	0.01	0	0.21	0.79	0	0	0.01
Blue (CA)	17	NA	NA	1	0	0	17
Blue (OR & WA)	26.94	0.06	0.94	NA	1.67	24.27	0
Brown	1.75	0	0.08	0.92	0	0.14	1.61
Calico	0	NA	NA	NA	0	0	0
China	6.2	0.26	0.49	0.25	1.6	3.06	1.54
Copper	9.71	0.26	0.49	0.25	2.51	4.79	2.41
Gopher	0	0	0.29	0.71	0	0	0

Fishing Activity under Option 4 Compared to Option 1

Washington

Recreational: The Washington recreational fishery would operate under season structure and management measures described under the Preferred Alternative. However because the WA HG under Option 4 is lower than the historical nearshore rockfish catch, additional management measures would be needed to keep nearshore rockfish catch under the WA HG. To keep total mortality under the WA HG, retention of nearshore rockfish would be prohibited for a portion of the year. The WA HG under Option 4 is higher than Option 3 and so the time period when retention of nearshore rockfish would be prohibited would be slightly shorter. Attainment of the WA HG under this alternative is projected to occur in mid-July with retention of nearshore rockfish prohibited for the remaining 5.5 months of the year. Alternate combinations of months when nearshore rockfish would be prohibited may be explored.

Commercial: Closed

Oregon

Under Option 4, the Oregon harvest guideline is similar to that shown under Option 3; Option 4 provides a harvest guideline of 36.6 mt and Option 3 shows a harvest guideline of 37.9 mt. As such, overall impacts will be similar between Option 4 and Option 3. See Option 3 for more details.

Recreational: Similar to Options 2 and 3 above, non-retention will likely be required for some months to keep impacts within the Oregon recreational HG.

Commercial: Similar to Option 3, with slightly more restrictive management measures. If the recreational-commercial split remains the same as shown under No Action, then commercial Nearshore Rockfish mortality is expected to be 10.5 mt under Option 4 (whereas expected mortality under Option 3 is 11.2 mt). This represents a reduction of 30 percent to No Action and 43 percent relative to Preferred Alternative.

California

Recreational: Under Option 4, 24.8 mt would be allocated to California, of which, the recreational catch share is 13.79 mt, accommodating a May 1 to November 30 season with a 20 fm depth restriction in the Northern Management Area. While this would provide an additional two and month and a half of fishing opportunity relative to the status quo, the recreational fishing season would have to be reduced by three months relative to the longest season under the Preferred Alternative of March 1 to December 31st. Other alternatives to address overages relative to the catch share include a reduced bag limit or non-retention of Nearshore Rockfish species during part of the season.

Commercial: Same as Option 2.

Biological Impacts Under Option 4 Compared to Option 1

Projected Nearshore Rockfish Mortality

The projected mortality in each state and sector under Option 4 are summarized in Table B-29. Further description of the mortality in each state and sector is provided in the text below.

Table B-29. Projected Nearshore Rockfish mortality north of 40°10′ N. Lat. from each state and sector under Option 4 (hybrid). Sector-specific allocations within states are provided as an example and are based on No Action. These intra-state allocations are subject to change.

	Washington		**Oregon**		**California**		**Total**
	Rec	Com	Rec	Com	Rec	Com	
Mortality	7.37	NA	26.13	10.45	13.34	11.2	68.49
State Total	7.37		36.58		24.54		
Allocation	7.37		36.58		24.80		69
Projected Percent Attainment	100%		100%		98.9%		99.6%

<u>Washington</u>
Recreational: Under Option 4, additional management measures will be implemented to reduce nearshore rockfish mortality in the Washington recreational fishery by 27 percent compared to Option 1.

Commercial: Closed

<u>Oregon</u>
Recreational: Similar to Options 2 and 3 above, a combination of months of retention and non-retention will be required.

Commercial: If the recreational-commercial split remains the same as shown under No Action, then commercial Nearshore Rockfish mortality is expected to be 10.5 mt under Option 4, a 30 percent reduction relative to No Action. Management measures will be used to reduce mortality to the target level. Therefore, no biological impacts are expected under this option.

<u>California</u>
Recreational: The projected mortality on nearshore rockfish under Option 4 with a May 1 to November 30 season with a 20 fm depth restriction in the Northern Management Area is 13.34 mt, of which 2.88 mt would be blue rockfish. These mortality projections are below the recreational catch share of the California allocation of 13.79 mt under this option.

Commercial: Same as Option 2.

Projected Overfished Species Mortality

<u>Washington</u>
Recreational: No additional overfished species mortality is projected compared to the No Action alternative.

Commercial: Closed

<u>Oregon</u>

Recreational: A preliminary examination of overfished species impacts due to management measures that may be required under this option projects less than 0.01 percent increase in canary and yelloweye rockfish impacts.

Commercial: Same as Options 2 and 3.

California

Recreational: Assuming season lengths under Option 1 of the Preferred Alternative in Management Areas south of 40°10′ N. Lat. and the May 1 to October 31 season with a 20 fm depth restriction in the Northern Management Area, overfished species mortality projected to accrue under Option 4 are 2.8 mt of yelloweye rockfish, 21.6 mt of canary rockfish, 118.3 mt of bocaccio and 1.2 mt of cowcod. The projected impacts are within the respective harvest limits/guidelines.

Commercial: Same as Option 2.

Stock Status

Nearshore Rockfish

None of the stocks in the Nearshore Rockfish complex are currently deemed overfished. The proposed HG under this option will facilitate implementation of inseason actions to prevent the aggregate ACL from being exceeded, decreasing the risk of overfishing component stocks. Thus, the stock status would not be adversely affected by management measures under Option 4.

Overfished Species

The projected mortalities under Option 4 are the same as No Action (Option 1), which are below the respective harvest limits/guidelines. No adverse effects on stock status or rebuilding progress are expected under Option 4.

Socio-economic Impacts under Option 4 Compared to Option 1

Washington

Recreational: Socio-economic impacts would continue to be affected by management measures necessary to keep the Washington recreational fishery within the WA HG for overfished species (yelloweye and canary rockfish). In addition, under Option 4, recreational fishing opportunity would be further reduced. Prohibiting retention of nearshore rockfish for a portion of the season on top of other management measures already in place to protect overfished species may discourage angler participation in recreational fisheries. While it's difficult to predict angler behavior, any reduction in angler fishing effort will have negative socioeconomic impacts.

Commercial: NA

Oregon

Recreational: Same as above Options

Commercial: Socio-economic impacts are between those shown for Options 2 and 4, if recreational-commercial split remain similar to No Action. It is uncertain whether fishing behavior (i.e., fishing location and fishing gear) will change under this option relative to No Action (see Options 2 and 3 above). However, if allocations remain the same between Oregon recreational and commercial fisheries, then landings may be reduced from 15.0 mt (No Action) to between 10.5 mt (maximum, if reduced trip limits result in avoiding Nearshore Rockfish altogether causing no discards, which is unlikely) to 8.6 mt (if encounters were similar to No Action and discarding was necessary, some of which will not survive). The 2013 price per pound for Nearshore Rockfish (weighted average including blue rockfish) was $3.80 per pound for Oregon nearshore fisheries (PacFIN). Under the potential scenarios shown here, lost ex-vessel revenue may range from $37,698 to $53,615 relative to No Action (the loss is higher relative to Preferred Alternative). Additional impacts may be incurred by vessels and crew if the decision is made to fish in less productive areas to avoid Nearshore Rockfish, for example. If such of a choice is made, then it may require extra time and fuel to catch other targeted species relative to No Action.

California

Recreational: Under Option 4, the season length would increase by one and a half months (589 angler trips) relative to the status quo fishery in the Northern Management Area, but the season would be reduced by three months (3,790 angler trips) relative to the longest season that can be afforded under the Preferred Alternative ACLs (Option 1) resulting in lost revenue from those in coastal communities dependent on recreational fishing for their livelihoods.
Commercial: Socio-economic impacts will be similar (slightly worse) than described under Option 3.

Discussion

Under status quo management and the Preferred Alternative seasons, the 69 mt ACL for the Nearshore Rockfish complex are projected to be exceeded. Even with coordinated interstate catch tracking of Nearshore Rockfish complex mortality, inseason action may prove difficult without harvest guidelines for each state on which to base the need for inseason action to reduce mortality as the ACL does not specify amounts to be taken by each state/sector. Establishing harvest guidelines for each state will provide a trigger for inseason action to prevent aggregate mortality from exceeding the ACL. The GMT hopes that the background information regarding proposed methods forming the basis for allocation and implications of each option for the fisheries in each state provided will help inform an allocation decision by the Council and to prevent future ACL overages, while minimizing adverse effects on the fishery.

Appendix 1. Methods used to measure the coastline for each state north of 40°10′ N. latitude.

At the March 2014 Council meeting, the Council requested that the Groundfish Management Team (GMT) calculate the length of the coastlines of California (north of 40°10′ N. latitude), Oregon, and Washington, as a way of approximating the nearshore habitat off each state. Though there may be alternative methods for approximating nearshore habitat, the GMT used the state-federal maritime boundary, i.e., the 3 nautical mile (nm) line, to estimate proportions of coastline among states (Figure B-21) as a starting point for this analysis.[7] Results of this analytical method (e.g., measurement of the 3 nm line (Table B-30) could be used as a basis for allocating Nearshore Rockfish among states. Details regarding this method are described below.

Proportion based on the 3 nm state-federal maritime boundary

Congress established the 3 nm as the boundary between state and federal jurisdiction over the seafloor with the Submerged Lands Act (SLA) of 1953 (43 U.S.C. §1301 et seq.). The 3 nm was established from the official shoreline, called the U.S. normal baseline, which "coincides with the low water line depicted on NOAA charts and includes closing lines across the entrances of legal bays and rivers, consistent with international law."[8] The baseline is approved by the interagency U.S. Baseline Committee and was last evaluated in 2002. The 200 nm exclusive economic zone (EEZ) and 12 nm Territorial Sea boundaries extend from this same baseline.

Shapefiles (i.e., files used in ArcGIS) of the 3 nm boundary, the 200 nm EEZ boundary, and the western U.S. states were downloaded and projected to allow for measurement in ArcGIS (Table B-31). An "addition" was made by the analyst to connect the northern portion of the 3 nm boundary to the EEZ boundary that the U.S. shares with Canada because the shapefiles for these two boundary lines do not connect or overlap (See Figure B-21). The connection was made based on the Bonilla-Tatoosh line defined in Washington's regulations (WAC 220-16-490). The resulting 3 nm boundary line was then measured from the U.S./Canada border to what serves as the WA/OR boundary for the purposes of groundfish management (46°16' N. lat.), to the OR/CA boundary (42° N. lat.), and to the OR/CA boundary to 40°10' N. latitude. The resulting measurements are shown in Table B-30.

This represents one of numerous methods available to measure or approximate miles of coastline. Other methods that the GMT looked at included directly measuring the shoreline (with and without inclusion of islands).[9] A visual comparison of the difference in detail between datasets (i.e., 3 nm line dataset compared to a shoreline dataset) is provided in Figure B-21, which represents a magnified excerpt of Figure B-20. Measurements of coastline may vary depending on many factors including the projected coordinate system used when measuring distances of features depicted on the map (e.g., UTM Zone 10N or WGS 1984), the spatial resolution of the map, image, or file that is used to create the shoreline dataset and the method for defining the shoreline (e.g., mean low water vs. high water). Defining the shoreline is a legal and policy matter as much as a scientific one.[10] These are matters of cartography of which GMT members have limited knowledge.

---

[7] If desired by the Council, the GMT could provide other methods.

3 nm state boundary	Bureau of Ocean Energy Management. 2002. Submerged Lands Act Boundary. Available at: http://www.marinecadastre.gov/Data/default.aspx (5/19/14).
Latitude lines	Created by GMT analyst, using the following latitude boundaries: 40°10' N., 42° N., and 46°16' N.
Bonilla-Tatoosh line	Created by GMT analyst, using the following coordinates in Washington state regulation at: WAC 220-16-490.

[11] The estimates provided in Table 1 differ from what was provided in the WDFW Report due to the following: 1) the Washington and Northern California proportions were accidentally transposed in the WDFW Report, and 2) the state-federal maritime line (SLA line) used for this GMT analysis utilized a different shapefile source. That is, the U.S. Geological Survey was the source of the SLA line for the WDFW Report and the Bureau of Ocean Energy Management was the source for this GMT analysis.

2/ The shoreward RCA was 20 fm from the California border to 43° N latitude, and 30 fm from 43° N. latitude to Washington border.

B.6 Non-Trawl: Slope Rockfish Trip Limit Reductions

Analysis of this management measure was not received by the Advanced Briefing Book deadline; it is expected to be delivered as a Supplemental GMT Report.

B.7 Non-Trawl: Lingcod Trip Limit Increases

Need for Action

For 2013-2014 groundfish fisheries, lingcod has been managed, in part, by cumulative bi-monthly trip limits designed to keep catches within the respective ACLs. Trip limits may be adjusted inseason as a result of inseason tracking patterns (higher/lower than projected). This applies to lingcod taken in both the non-nearshore (all three states) and nearshore fisheries (Oregon and California only).

At its April 2014 meeting, the Pacific Fishery Management Council (Council) directed the Groundfish Management Team (GMT) to complete an analysis of various lingcod trip limit and open season options for the west coast commercial non-trawl fixed-gear fishery to estimate economic and biological impacts. Current trip limits and open seasons are given in Table B-32 (No Action = Option 1a). The proposed trip limit and open season configurations (Options 1b and 1c) are summarized in Table B-33, with all trip limits reported in lb per vessel.

Initial analyses were provided to the Council at the April meeting for trip limit options during the open season (Agenda Item C.4.b, REVISED GMT Report, April 2014; pages 39-52 and below in XXX) and options for lingcod retention during the currently closed periods (Agenda Item C.4.b, REVISED GMT

Report, April 2014; pages 52-63 and below in XXX). This document combines results of those previous, separate analyses. Additional details can be found in that April 2014 GMT statement.

Table B-32. No Action Option (Option 1a) for the limited entry and open access non-trawl fixed-gear trip limits (in lb) in effect in 2014 that apply to both north and south of 40°10' N. latitude.

Fleet	Jan/Feb	Mar/Apr	May/Jun	Jul/Aug	Sep/Oct	Nov/Dec[a]
Limited entry	closed	closed	800	800	800	400/closed
Open access	closed	closed	400/month			400/closed

[a/]The lingcod commercial fishery is closed from December 1st of a given year through April 30th of the subsequent year (five months total). Therefore, the Nov/Dec trip limit applies only to November.

A critical point in the analysis of lingcod trip limits is how proposed increases in the coastwide trip limit structure may affect the mortality of overfished species (OFS) – primarily the OFS rockfish species, in both the non-nearshore and nearshore fisheries. The approach to these proposed trip limit increases does assume that OFS mortality will not be affected in the non-nearshore fishery because any lingcod catch is mostly incidental to the targeting of sablefish; fishing behavior will likely not change because the main target will continue to be sablefish, the much more lucrative fishery. Therefore, it is assumed that any increase in lingcod mortality (landings) will only affect OFS mortality in the Oregon and California nearshore fisheries (Washington has not had a commercial nearshore fishery since 1995).

Additionally, it is prudent to point out that there is probably little to no chance of increased China rockfish impacts under Alternative 1b and 2a (below). Opening the closed season for lingcod retention will not cause increase catch of any rockfish species (OFS or China), because the proposed increases are equal to or less than average encounter rates of lingcod during the closed season (based on WCGOP bycatch rates during December-April). Increasing the lingcod trip limit during the open season showed some increase in OFS for the 50% increase. On the other hand, the increase in canary rockfish was significant when lingcod was increased by 100%. It is expected that other nearshore rockfish mortality to also increase under that scenario (2b).

Table B-33. Lingcod commercial coastwide trip limits (reported in lb per vessel) comparing the No Action Option (Option 1a) to options that increase the bi-monthly trip limit to 1,200 lb and 1,600 lb for the limited entry sector and increases to 600 lb per month and 800 lb per month for the open access sector (Options 1b, and 1c). Also presented are proposed trip limits that establish trip limits for periods 1 and 2 and December, with period 2 closed south of 40°10' N. latitude for both sectors (Options 2a and 2b).

Proposed lingcod trip limits based on the No Action Option (1a) and Options 1b and 1c						
Limited entry	Jan/Feb	Mar/Apr	May/Jun	Jul/Aug	Sept/Oct	Nov/Dec
Option 1a	closed	closed	800	800	800	400 (Nov only)

Option 2a	100 lb/month	closed	600 lb/month (100 lb for Dec)			
Option 2b	100 lb/month	closed	800 lb/month (100 lb for Dec)			

Background

Lingcod was declared overfished in 1999. In 2005, the stock was designated as rebuilt and a coastwide trip limit structure was established that has essentially stayed the same since. Lingcod trip limits have not been modified since 2005 for the limited entry (LE) sector and since 2007 for the open access sector (OA). Since 2007, no inseason adjustments have been made due to fishing mortality concerns for lingcod. At least one industry request was made for an inseason trip limit increase but was not supported by the GMT (Agenda Item E.2.b, Supplemental GMT Report 2, April 2008). This was because the GMT was concerned that any increase in lingcod trip limits and subsequent targeting could have resulted in increased bycatch of canary and yelloweye rockfish. Regarding the OA sector, the GMT expressed concerns that since the number of participants in that fishery was unlimited (as is still the case), any increase in lingcod trip limits could have led to a rapid expansion in the fishery, without any corresponding accountability measures for bycatch of overfished species. And finally, since the trip limits at that time weren't being attained in either the LE or OA fisheries, the GMT did not support an increase.

Since 2008, the coastwide commercial non-trawl fixed-gear catch of lingcod averaged 82.9 mt (Figure B-22) with the majority of landings made by the OA sector. In 2011 and 2012, total mortality by the non-trawl fixed-gear fleet was 3.0 percent and 3.5 percent, respectively, of the non-trawl allocation. For the 2015-2016 biennial management cycle, the Council is considering increases in lingcod trip limits for both the LE and OA non-trawl fixed-gear sectors to provide more fishing opportunity to the fishing communities in the three states. Additionally, a request was made by industry to explore the possibility of allowing the fleet to land modest amounts during those periods, or months, that are currently closed. This analysis estimates the potential harvest mortality under the various trip limit scenarios and open seasons to assist the Council in its decision for a Preferred Alternative. It also provides estimated mortality

amounts for overfished species that are taken in the nearshore commercial fisheries for Oregon and California when lingcod are also taken (Washington does not have a commercial nearshore fishery).

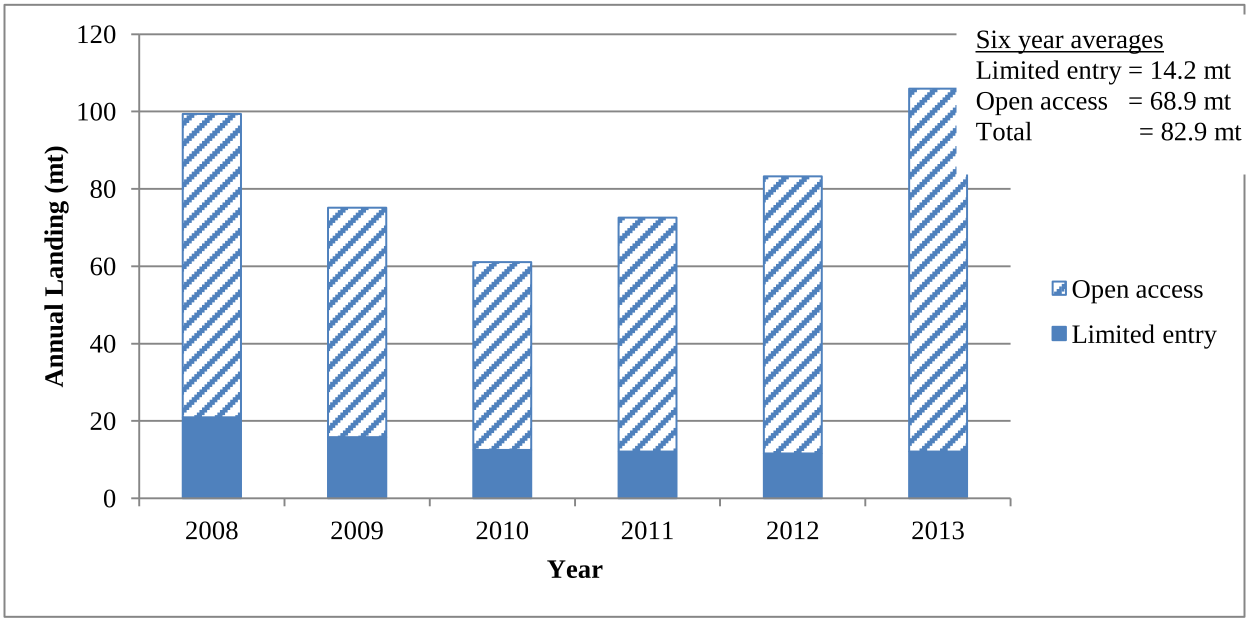

Figure B-22. Coastwide landings of lingcod by the commercial non-trawl fixed-gear fleet for both the limited entry and open access sectors from 2008 to 2013. The 2013 data are preliminary (data source: PacFIN vdrfd).

Methods

A catch-based fleet capacity trip limit model was used, and based on the years from 2008 to 2012. Commercial landings data from PacFIN's vdrfd table were extracted on April 22, 2014 for analysis. Filters were applied to only include: 1) landings made by non-IFQ, shorebased vessels (this applied to 2011 and 2012), 2) hook-and-line or trap gear, 3) Dahl sectors 5 to 10, 12, and 15[12], 4) for the nearshore bycatch model, only those Oregon and California lingcod landings that also showed nearshore species landings, and 5) port of landing north and south of 40°10' N. latitude to identify management area. The model uses a method that establishes a proportion for each participating vessel per period whereby that vessel's actual harvest mortality, as reported from the commercial dealer receipts, is compared to the theoretical maximum that that vessel could have taken. This proportion percentage is then applied to the proposed trip limit for each vessel for each period of allowable fishing. After completing this for all vessels for all periods, the estimated harvest for the fleet is summed for a final annual estimate which is then compared to the annual ACL and/or the non-trawl allocation portion of the ACL.

In addition to the above routine, a portion of the estimated landings under the various trip limit scenarios was identified as those made in conjunction with landings of nearshore species (above). These estimated lingcod landings then inputted into the GMT's nearshore bycatch model to provide estimates of the mortality of overfished species.

More details on methods can be found in Agenda Item C.4.b, REVISED GMT Report, April 2014 (pages 39-52).

[12] Dahl sectors are: 5 nearshore (limited entry), 6 nearshore (open access), 7 non-nearshore (limited entry), 8 non-nearshore (open access), 9 non-nearshore non-sablefish (limited entry), 10 non-nearshore non-sablefish (open access), 12 incidental open access, and 15 commercial non-groundfish.

Results

Lingcod mortality estimates are provided in Table B-34 and Table B-35 for the combined sector options under the different P* values for 2015 and 2016. A final LE and OA sector summary is presented in Table B-36, and lastly overfished species mortality estimates are provided in Table B-37. More detail regarding these estimates is provided below. Also, a comprehensive discussion about trip limits for periods 1 and 2 and December is included in Agenda Item C.4.b, REVISED GMT Report, April 2014, pages 52-63).

Table B-34. Lingcod coastwide commercial mortality estimates using the status quo season structure (closed during periods 1, 2 and December coastwide) comparing No Action (Option 1a) to Options 1b and 1c. The limited entry bimonthly trip limits are shown, along with open access monthly trip limits in parentheses.

LIMITED ENTRY + OPEN ACCESS (coastwide) at P* = 0.45						
	Proposed Bimonthly and Monthly Trip Limits (lb)	Estimated Take (mt)	2015		2016	
			Non-trawl Allocation (mt)	Percent of Allocation	Non-trawl Allocation (mt)	Percent of Allocation
Option 1a	800 (400)	88.9	1,950.7	4.6%	1,857.8	4.8%
Option 1b	1,200 (600)	122.3	1,950.7	6.3%	1,857.8	6.6%
Option 1c	1,600 (800)	155.1	1,950.7	8.0%	1,857.8	8.3%

LIMITED ENTRY + OPEN ACCESS (coastwide) at P* = 0.25						
	Proposed Bimonthly and monthly Trip Limits (lb)	Estimated Take (mt)	2015		2016	
			Non-trawl Allocation (mt)	Percent of Allocation	Non-trawl Allocation (mt)	Percent of Allocation
Option 1a	800 (400)	88.9	1,444.1	6.2%	1,375.4	6.5%
Option 1b	1,200 (600)	122.3	1,444.1	8.5%	1,375.4	8.9%
Option 1c	1,600 (800)	155.1	1,444.1	10.7%	1,375.4	11.3%

Note: For the limited entry sector, the November trip limits are 400 lb under Option 1a, 600 lb under Option 1b, and 800 lb under Option 1c. The non-trawl allocations are a combination of those for north and south of 40°10' N. latitude as presented in Agenda Item C.4.a, Supplemental REVISED Attachment 2:, April 2014.

Table B-35. Lingcod coastwide commercial mortality estimates under Options 2a and 2b. Season structure modifications for each sector are shown in Table B-33.

LIMITED ENTRY + OPEN ACCESS (coastwide) at P* = 0.45					
		2015		2016	
Option	Estimated Take (mt)	Non-trawl Allocation (mt)	Percent of Allocation	Non-trawl Allocation (mt)	Percent of Allocation
Option 2a	151.7	1,950.7	7.8%	1,857.8	8.2%
Option 2b	197.0	1,950.7	10.1%	1,857.8	10.6%

LIMITED ENTRY + OPEN ACCESS (coastwide) at P* = 0.25					
		2015		2016	
Option	Estimated Take (mt)	Non-trawl Allocation (mt)	Percent of Allocation	Non-trawl Allocation (mt)	Percent of Allocation
Option 2a	151.7	1,444.1	10.5%	1,375.4	11.0%
Option 2b	197.0	1,444.1	13.6%	1,375.4	14.3%

Notes: South of 40°10' N. latitude the fishery will continue to be closed.
The non-trawl allocations are a combination of those for north and south of 40°10' N. latitude as presented in Agenda Item C.4.a Supplement REVISED Attachment 2, April 2014.

Table B-36. Summary of overall coastwide commercial lingcod mortality estimates for the limited entry and open access sectors for Options 1a, 1b, 1c, 2a, and 2b.

	Trip Limits		Mortality Estimates		
Option	Limited Entry (bi-monthly)	Open Access (monthly)	Limited Entry	Open Access	Total
1a (No Action)	800	400	16.9	72.0	88.9
1b	1,200	600	24.7	97.6	122.3
1c	1,600	800	31.8	123.3	155.1
2a	1,200	600	27.4	124.3	151.7
2b	1,600	800	35.9	161.1	197.0

Note: These trip limit amounts in this table refer to the bi-monthly limited entry sector, whereas the OA sector trip limits are set on a per month basis at one-half the limited entry amount. Refer to Table B-33 for the detailed summary of the actual trip limit amounts.

Table B-37. Overfished species mortality estimates (mt) under the No Action Option (1a), Option 1b, and Option 1c (season structure maintained with periods 1 and 2 and December closed), and under the 2a and 2b options that reflect the season structure modification (i.e., open January – December). These values were calculated by using the five-year commercial averages (2008-2012) of the nearshore species inserted into the nearshore bycatch model.

	Estimated mortality under options with the current season structure in place		
	Option 1a – 800 lb	Option 1b – 1,200 lb	Option 1c – 1,600 lb
Bocaccio	0.4	0.4	0.4
Canary rockfish	6.5	6.6	6.7
Cowcod	0.0	0.0	0.0
Darkblotched rockfish	0.2	0.2	0.2
Yelloweye rockfish	1.1	1.2	1.3

	Estimated mortality under options with an expanded season structure	
	Option 2a – 1,200 lb	Option 2b – 1,600 lb
Bocaccio	0.5	0.5
Canary rockfish	7.0	7.4
Cowcod	0.0	0.0
Darkblotched rockfish	0.2	0.2
Yelloweye rockfish	1.2	1.3

Comparison of Options (Options 1a, 1b, and 1c)

Under Options 1a, 1b and 1c, the coastwide bi-monthly trip limit structure would be maintained whereby commercial retention of lingcod is permitted during periods 3 (May/June), 4 (July/August), 5 (September/October) and November. Retention of lingcod would not be allowed during period 1 (January/February), period 2 (March/April) and in December. Under these three options, trip limit adjustments are considered only for the management area north of 40°10' N. latitude. South of 40°10' N. latitude, the status quo trip limits and season structure would remain in effect for all three options.

<u>No Action (Option 1a)</u>

For 2014, the lingcod commercial bi-monthly non-trawl fixed-gear trip limit for the LE sector is 800 lb per period with 400 lb for November. Fishing would continue to be closed during periods 1 and 2 and December. For the OA sector, trip limits are set at 400 lb per month. Again, periods 1 and 2 and December are closed. These amounts apply on a per vessel basis and apply to all three states. Under the No Action Option (Option 1a), the expected harvest mortality, for both the P* = 0.45 and P* = 0.25 approach, would be less than 10 percent of the non-trawl allocation (Table B-34). The total combined LE and OA mortality would be 88.9 mt.

<u>Fishing Activity Under Option 1a</u>

Under the No Action Option, fishing activity is not expected to change. The number of vessels that will fish would be expected to be about the same as have participated in the fishery over the last few years (Table B-38). In addition, fishing effort per vessel and fishing area are expected to be similar under Option 1a.

Table B-38. Number of vessels in the non-nearshore and nearshore fisheries that made lingcod landings (regardless of the amount) for the three states from 2008 to 2012. Includes both LE and OA vessels.

State	2008	2009	2010	2011	2012	5-Year Avg.
Washington	44	32	37	31	41	37
Oregon	228	219	196	200	202	209
California	251	222	206	223	264	233

Biological Impacts Under Option 1a

With no expected increase in mortality, there are no anticipated biological impacts.

Projected Overfished Species Mortality Under Option 1a

A critical consideration in the lingcod fishery are those catches (landings) that are made in conjunction with nearshore species. These nearshore fishery landings are those that are applied to the nearshore bycatch model as a component necessary for the estimation of overfished species (OFS) mortality. With no expected increase in the take of lingcod and no expected change in fishing behavior under this option, it is also expected that no increase in OFS mortality will be experienced.

Stock Status

Currently, the coastwide lingcod stock is considered healthy. As of the last stock assessment, the point estimate for the depletion of the spawning output (= spawning biomass) at the start of 2009 was 61.9 percent for north of 40°10' N. latitude , 73.7 percent south of 40°10' N. latitude, and 67.0 percent coast wide (Hamel et al. 2009).

Socioeconomic Impacts Under Option 1a

None are expected.

Option 1b

Option 1b maintains the closures during periods 1 and 2 and December. This option also increases the current LE sector trip limit from 800 lb per two months to 1,200 lb per two months and increases the November trip limit from 400 lb to 600 lb. The OA sector trip limit would increase from 400 lb per month to 600 lb per month. The original management measure consideration for this option was to analyze trip limit increases only for the fishery north of 40°10' N. latitude. Trip limit amounts south of 40°10' N. latitude are to be left as is (i.e., remain status quo). Mortality would be expected to increase from 88.9 mt. Under No Action Option 1a to 122.3 mt (37.6 percent increase) under Option 1b, with the majority of this increase coming from the OA sector. Here too, the expected landings mortality would be less than 10 percent of the non-trawl allocation amount at both the P* = 0.45 and P* = 0.25 levels.

Fishing Activity Under Option 1b

With larger trip limits (from 800 lb to 1,200 lb per period for the LE sector and from 400 lb to 600 lb per month for the OA sector) it is reasonable to expect an increase in overall mortality. Table B-36 shows mortality will increase from 88.9 mt (No Action) to 122.3 mt under Option 1b. Despite this expected increase, the total annual mortality will still be substantially less than the non-trawl allocation amount. It is speculated that this modest increase would not generate a surge in fishing activity.

Biological Impacts Under Option 1b

Because the stock is considered very healthy, the 37.6 percent increase (33.4 mt) will have a relatively minor effect on the stock's status. A total mortality of 122.3 mt represents < 10 percent of the non-trawl fixed gear allocation. Projected mortality would not jeopardize the stock's status nor cause the fishery to exceed the non-trawl allocation portion of the annual ACL.

Projected Overfished Species Mortality Under Option 1b
Two overfished species are of major concern: canary and yelloweye rockfish. These two species have been (and will continue to be) the most constraining component of the lingcod fishery and largest concern when considering lingcod trip limit increases. Under this option, both species will experience an approximate 0.1 mt increase from the No Action Option. As per the Preferred Alternative, canary rockfish has a directed nearshore allocation of 6.7 mt (2015) and 6.9 mt (2016) and yelloweye rockfish has a directed nearshore allocation of 1.2 mt (2015) and 1.3 mt (2016). The projected mortality under this option (6.6 mt for canary and 1.2 mt for yelloweye) are equal to or less than the Preferred Alternative nearshore allocations.

Stock Status
Similar to the No Action Option 1a, the stock is expected to remain healthy with no adverse effects from this modest increase in harvest mortality.

Socioeconomic Impacts Under Option 1b
Under this option, the projected increase in total annual landings for both the non-nearshore and nearshore fisheries would be approximately 75,200 lb (34.1 mt). Using the most recent commercial landings data from 2013 as a benchmark, the average coastwide price is $2.50 per pound. Applied to the projected increase of 75,200 lb, the fishery could earn an additional $188,000 compared to the No Action status quo amount – all else being equal.

Option 1c
Option 1c maintains the closures during periods 1 and 2 and December. This option also increases the current LE sector trip limit from 800 lb per two months to 1,600 lb per two months and increases the OA sector trip limit from 400 lb per month to 800 lb per month. The original management measure consideration for this option was to analyze trip limit increases only for the fishery north of 40°10' N. latitude. Trip limit amounts south of 40°10' N. latitude are to remain status quo. Mortality would be expected to increase from 88.9 mt under No Action Option 1a to 155.1 mt (a 74.5 percent increase), with the majority of this increase, again coming from the OA sector. Under this option the projected landings mortality would be less than 10 percent of the non-trawl allocation amount at P* = 0.45 but would be just over 10% (for both 2015 and 2016) for P* = 0.25 (Table B-34).

Fishing Activity Under Option 1c
With larger trip limits (from 800 lb to 1,600 lb per period for the LE sector and from 400 lb to 800 lb per month for the OA sector), it is reasonable to expect an increase in overall mortality. It is possible that there may be a change in fishing behavior with more participants participating in the fishery, but presently it is difficult to estimate what that number may be. Table B-36 shows mortality will increase from 88.9 mt (No Action) to 155.1 mt under Option 1c. Despite this expected increase, the total annual mortality will still be substantially less than the non-trawl allocation amount.

Biological Impacts Under Option 1c
Because the stock is considered very healthy, the 74.5 percent increase (66 mt) compared to the No Action Option will have a relatively minor effect on the stock's status. A total mortality of 155.1 mt under this option represents 10.7 percent of the non-trawl allocation for 2015.

Projected Overfished Species Mortality Under Option 1c
As is the case under Option 1b canary and yelloweye rockfish are the two species that have been (and will continue to be) the most constraining component of the lingcod fishery and largest concern when considering lingcod trip limit increases. Under this option, both species will experience an approximate

0.2 mt increase from the No Action option projection. As per the Preferred Alternative, canary rockfish has a directed nearshore allocation of 6.7 mt (2015) and 6.9 mt (2016) and yelloweye rockfish has a directed nearshore allocation of 1.2 mt (2015) and 1.3 mt (2016). The projected mortality of canary under this option is 6.7 mt, which is equal to the Preferred Alternative nearshore allocation (this morality is 0.2 mt more than the nearshore allocation under than the No Action option estimate of 6.5 mt). For yelloweye, projected mortality under this option is 1.3 mt, which exceeds the Preferred Alternative nearshore allocation for 2015 by 0.1 and equals the Preferred Alternative nearshore allocation for 2016. A mortality of 1.3 mt exceeds the mortality under No Action estimated impact by 0.2 mt.

Stock Status

Similar to the No Action Option 1a, the stock is expected to remain healthy with no adverse effects from this increase in harvest mortality.

Socioeconomic Impacts Under Option 1c

Under this option, the projected increase compared to the No Action Option in total annual coastwide landings would be approximately 146,000 lb (66 mt). Applying the $2.50 per pound value described above provides an estimate that the fishery could earn an additional $365,000 compared to the No Action status quo amount – all else being equal.

Options Overview (Options 2a and 2b)

Under Options 2a and 2b, the coastwide trip limit structure would be modified to accommodate modest trip limits for periods 1 and 2 and December for both the LE and OA sectors (Table B-32). Under these two options, the take of lingcod would be allowed during all periods and months during the year, but only for the management area north of 40°10' N. latitude. South of 40°10' N. latitude, retention of lingcod would continue to be prohibited for both sectors during March and April. Trip limits would also be increased from May-November under these options relative to No Action (Option 1). See Table B-33 for trip limit details.

Option 2a

The intent of Option 2a is to allow retention and landings of lingcod that would otherwise be discarded during the closed season, in addition to increasing trip limits during the currently open season to increase attainment of the non-trawl allocation. Under this option north of 40°10' N. latitude, the LE sector would have a 200 pound trip limit per two months for periods 1 and 2 and 200 lb for December. This sector would also have a 1,200 pound trip limit for periods 3 through 5 and 600 lb in November. For the OA sector, the monthly trip limit would be 100 lb during periods 1 and 2 and 100 lb in December. Additionally, this sector would have a 600 pound monthly trip limit for periods 3 through 5 and November.

Under this option south of 40°10' N. latitude, March and April would continue to be closed to the retention of lingcod. This is proposed because the additional opportunity to fish for lingcod south of 40°10′ N. latitude in period 2, when rockfish is closed, presents the possibility of additional mortality of overfished rockfish as well as discarding of other healthy rockfish species while targeting lingcod. Aside from these considerations, the same trip limit amounts would apply for both sectors as is proposed for north of 40°10' N. latitude. See Table B-33 for a summary of trip limit details.

Fishing Activity Under Option 2a

With larger trip limits compared to the No Action Option it is reasonable to expect a modest increase in overall annual lingcod mortality. Compared to the projection for the No Action Option (88.9 mt), the projected mortality would be 151.7 mt, an increase of 62.8 mt (70.6 percent). Despite this projected increase, the total annual mortality will still be substantially less than the non-trawl allocation amounts

(Table B-35). For 2015 and 2016, with a P* = 0.45, the projected percent of the non-trawl allocation would be 7.8 percent and 8.2 percent, respectively. Under a P* = 0.25 scenario, the projected percent of the non-trawl allocation for 2015 and 2016 would be 10.5 percent and 11.0 percent, respectively.

Biological Impacts Under Option 2a

Because the stock is considered very healthy, the 62.8 mt increase will have a relatively minor effect on the stock's status. Lingcod mortality is expected to increase, though encounter rates are not, as participants in the fishery will retain some lingcod encountered (at 100 percent mortality) rather than discard all lingcod encountered (with an estimated 7 percent mortality). For example, the increased trip limit during the open season is not expected to change fishing behavior (i.e., fishing effort or fishing area). Likewise, allowing retention during December-April at the amounts shown in Table B-33 is not expected to cause increased fishing effort or change in fishing locations (see Agenda Item C.4.b, REVISED GMT Report, April 2014; pages 52-63). Hence, there would be no expected increase in lingcod encounter rates under this option relative to the No Action Option.

Projected Overfished Species Mortality Under Option 2a

With the combination of higher trip limits for the traditional fishing periods coupled with the modest trip limits for the periods that before were closed, projected mortality for canary rockfish is expected to increase. Under the No Action Option 1a, the projected canary rockfish mortality is 6.5 mt (Table B-36), whereas under Option 2a that mortality amount would be 7.0 mt. This projected canary rockfish mortality would exceed the Preferred Alternative nearshore allocation (6.7 mt in 2015 and 6.9 mt in 2016) and the No Action mortality estimate (6.5 mt). Yelloweye rockfish mortality under Option 2a is 1.2 mt, which is the same as shown under Option 1b and equal to the Preferred Alternative nearshore allocation for 2015, but 0.1 mt higher than expected under No Action (1a).

Stock Status

Under Option 2a, no adverse changes to lingcod stock status are expected compared to the No Action Option since lingcod mortality has been far below the non-trawl allocation and is expected to remain so under Option 2a. Estimated lingcod mortality under this option is expected to range between 7.8 percent and 11.0 percent of the non-trawl allocation (Table B-35). Given This level of increase in mortality is far below levels that would result in overfishing and are not expected to adversely affect stock status.

Socioeconomic Impacts Under Option 2a

Allowing fishery participants to retain incidentally encountered lingcod that were previously discarded would increase revenue from current operations targeting other species within incidental lingcod encounters. In 2013, the average price per pound coast wide averaged $2.50 per pound. This amount, applied to the projected increase (approximately 138,500 lb) would result in a coastwide gross estimated ex-vessel increase of approximately $346,000. While low trip limits make it unlikely that fishery participants will choose to target lingcod, such targeting may become worthwhile if the price per pound makes the trip profitable, despite the relatively low trip limits. If trip limits cannot be attained or if fuel or other variable costs make it unprofitable, or alternatively opportunity costs are too high to justify changing targets, directed effort may not be economically viable and trips targeting lingcod may be unlikely. However, it needs to be pointed out that some vessels do target lingcod on some trips, so any increase would benefit these participants.

Option 2b

The intent of Option 2b is also to allow retention and landings of lingcod that would otherwise be discarded during the closed season, in addition to increasing trip limits during the currently open season. Under this option north of 40°10' N. latitude the LE sector would have a 200 pound trip limit per 2 months periods 1 and 2 and 200 lb for December (the same as for Option 2a). However, this sector would also have a 1,600 pound trip limit for periods 3 through 5 and 800 lb in November. For the OA sector, the monthly trip limit would continue to be100 lb during periods 1 and 2 and 100 lb in December, but the sector would have an 800 pound monthly trip limit for periods 3 through 5 and November. Again, as per Option 2a, south of 40°10' N. latitude, the retention of lingcod would be prohibited during March and April to prevent the possibility of additional mortality of overfished rockfish as well as discarding of other healthy rockfish species while targeting lingcod. See Table B-33 for a summary of trip limit details.

Fishing Activity Under Option 2b

With larger trip limits compared to the No Action (Option 1a) and Option 2a, it is reasonable to expect an increase in overall annual lingcod mortality. Compared to the projection for the No Action Option (88.9 mt), the projected mortality would be 197 mt for Option 2b, an increase of 108.1 mt. Despite this projected increase, the total annual mortality will be substantially less than the non-trawl allocation amounts (Table B-35). For 2015 and 2016, with a P* = 0.45, the projected percent of the non-trawl allocation would be 10.1 percent and 10.6 percent, respectively. Under a P* = 0.25 scenario, the projected percent of the non-trawl allocation for 2015 and 2016 would be 13.6 percent and 14.3 percent, respectively. This assumes that no new OA participants would enter the fishery. However, given that this trip limit option would provide a modest increase to potential OA participants, it is reasonable to assume that an increase in the number of participants could occur.

Biological Impacts Under Option 2b

Because the stock is considered healthy, the 108 mt increase compared to the No Action Option will have a relatively minor effect on the stock's status. Lingcod mortality is expected to increase as participants in the fishery will retain some lingcod encountered (at 100 percent mortality) rather than discard all lingcod encountered (with an estimated 7 percent mortality), as occurs now during the closed season. There may be an increase in lingcod encounter rates under this option relative to the No Action Option, because trip limits during the currently open season would double (Table B-33). The likelihood and impact of this potential increase in effort would be very difficult to quantify. Despite this, however, it is probable that additional sets during a trip may occur to target lingcod (after catching trip limits for other species). This could increase impacts to OFS, as well as China rockfish.

Projected Overfished Species Mortality Under Option 2b

With the combination of higher trip limits for the traditional fishing periods coupled with the modest trip limits for those periods that before were closed, projected mortality for canary is expected to increase. Under Option 1c, the projected canary rockfish mortality is 6.7 mt (Table B-36), whereas under Option 2b that projected mortality amount would increase to 7.4 mt. This projected canary mortality is 0.9 mt higher than shown under No Action (Table B-37) and 0.5 to 0.7 mt higher than the Preferred Alternative allocation. For yelloweye rockfish, the projected mortality under this option will be 1.3 mt, whereas it was 1.2 mt for Option 2a. This projected yelloweye mortality is 0.2 mt higher than shown under No Action, exceeds the Preferred Alternative nearshore allocation for 2015 by 0.1, and equals the Preferred Alternative nearshore allocation for 2016.

Stock Status

Under Option 2b, no changes to lingcod stock status are expected compared to the No Action Option since lingcod mortality has been far below the non-trawl allocation and expected to remain so under Option 2b. Estimated lingcod mortality under this option is expected to range between 10.1 percent and 14.3 percent of the non-trawl allocation (Table B-35). Given the projected increase in mortality that is projected to occur, the level of increase is still expected to be far below levels that would result in overfishing and are not expected to adversely affect stock status.

Socioeconomic Impacts Under Option 2b

Allowing fishery participants to retain more lingcod (some of which were incidentally caught and discarded under status quo) would increase revenue from current operations targeting other species within incidental lingcod encounters. This may also increase revenue by incentivizing increased targeting or change in behavior during the May-November period when trip limits double relative to No Action (Table B-33). In 2013, the average price per pound coast wide averaged $2.50 per pound. This amount, applied to the projected total compared to the No Action Option total would result in a coastwide gross estimated ex-vessel amount of approximately $596,000 more than the No Action Option total. While moderate trip limits make it feasible that fishery participants will choose to target lingcod, such targeting may become more worthwhile if an increase in the overall average price per pound makes the trip profitable. It is speculated that if trip limits cannot be attained or if fuel or other variable costs make it unprofitable, or alternatively opportunity costs are too high to justify changing targets, directed effort may not be economically viable and trips targeting lingcod could be unlikely.

B.8 Non-Trawl: Allow Lingcod retention in Periods 1, 2, and 6

Need for Action

Lingcod retention is prohibited in Periods 1, 2, and part of 6 for both limited entry and open access fixed gears under the status quo regulations. In recent years, lingcod mortality has been far below the ACL north and south of 42° N. latitude with 25 percent and 13 percent attainment in 2011 and 34 percent and 16 percent in 2012, respectively. Public testimony was received from Mr. Jeff Miles at the September 2013 Council meeting requesting some level of retention during periods 1, 2, and 6. The request was made to land lingcod that are incidentally caught and discarded, with the suggestion that trip limits might be set low enough to prevent changes in fishermen's behavior (i.e., prevent targeting). Higher trip limits than those needed to allow for incidental take may further increase attainment of the non-trawl allocation of the ACL, but bycatch of overfished species while targeting lingcod is a consideration. The proposed change would allow lingcod retention in the restricted access state permitted nearshore fishery in California and Oregon, the open access nearshore fishery in Oregon, and the limited-entry and open access non-nearshore fixed gear fisheries in California, Oregon and Washington.

Background

The prohibition on retention of lingcod during specific periods has been in effect for commercial fixed gear fisheries since the 1990s to improve the conservation of lingcod after being declared overfished. The closure was put in place to minimize impacts on lingcod during their spawning season, which is from December to April (Hamel et al. 2009). Females move in to depths shallower than 50 fm to spawn and males guard nests from predation. Although females do not spend much time in the spawning area, males are concentrated in these shallow waters guarding the eggs during winter and spring months (Love 1996). The season closure for the fixed gear fishery was presumably designed to reduce catch of these males while concentrated during the nest-guarding season to facilitate rebuilding of the stock.

Lingcod was declared rebuilt in 2009, when the status was determined to be 61.9 percent for the northern component and 73.7 percent for the southern component. The coastwide status was 67.0 percent at the beginning of 2009, well above the 40 percent target spawning stock biomass (Hamel *et al.* 2009). As a result, there is no longer a lingcod closed season for individual fishing quota (IFQ fisheries; trawl and fixed gear) or Oregon and California recreational fisheries. The Council is now considering eliminating the spawning season closures in the commercial fixed gear fishery since the lingcod stock has rebuilt and increasing season length may result in higher attainment of the ACL.

Current RCA closures prevent access to much of the lingcod stock, and length restrictions may already as short as they can be while maintaining desirable fillets. Trip limits that are appreciably higher than needed to accommodate bycatch may lead to increase targeting of lingcod, which co-occur with overfished rockfish species. Increasing the season length while maintaining moderate trip limits to allow incidental take may be the most viable means of increasing attainment of the ACL without increasing interactions with overfished species.

Lingcod predate on rockfish both as juveniles and adults. Rockfish and lingcod co-occur on rocky reef habitat and lingcod are currently discarded by participants in the fishery that encounter them while fishing for rockfish during the closed period for lingcod. While mortality on discarded lingcod is relatively low (~7 percent) reflecting hooking and handling mortality since they do not suffer from barotrauma, rockfish discarded by those targeting lingcod exhibit mortalities ranging from 30 – 54 percent in depths less than 30 fm and 100 percent mortality in depths greater than 30 fm. The main concern, therefore, is that targeting of lingcod will result in increased mortality for overfished rockfish species and the potential for the sector allocations to be exceeded.

One important consideration is that period 2 is closed for rockfish retention in the nearshore fishery south of 40°10′ N. latitude. Allowing any retention of lingcod during period 2 in the south may result in increased rockfish bycatch and discard. Maintaining a closure for lingcod during the corresponding months of March and April shoreward of the RCA may be considered under each of the options analyzed to prevent greatly increased rockfish discard mortality in the region in question.

In order to evaluate the potential benefits and impacts from retention by various fixed gear sectors (i.e. nearshore vs. non-nearshore, limited entry vs. open access) under the existing regulations, trip limits were developed to reflect current bycatch rates and to emulate trip limits that are currently allowed during other months. Based on these principals, the following options were analyzed:

Management Options

Option 1: No Action – maintain prohibition on retention of lingcod in the commercial fixed gear fisheries in periods 1, 2 and 6 (December).

Option 2**:** Allow retention of lingcod in commercial fixed gear fisheries during periods 1, 2 and 6 at incidental-catch levels equivalent to average current encounters during the closed periods of 100 lb. per month in the open access fishery and 200 lb. per two month period in the limited entry fishery (i.e., to allow the retention of discarded bycatch).

Option 3**:** Allow retention of lingcod in commercial fixed gear fisheries during periods 1, 2 and 6 with trip limits of 400 lb per month in the open access fishery and 800 lb per two month period in the limited entry fishery (i.e., equivalent to the trip limits during current open months).

Data

Catch and effort for lingcod were estimated for the closed season (December – April) and the open season (May – November). Estimates were calculated and evaluated for the nearshore fixed gear commercial fishery and the non-nearshore fixed gear commercial fishery. Data from WCGOP from 2002-2011 provided lingcod catch (discard and retained) by trip. PacFIN data (2007-2012) provided the average number of trips per vessel per month, average number of vessels fishing per month, and recent landings by the fleet. Lingcod catch per trip (from WCGOP) was then expanded to estimate average lingcod catch per vessel per month (PacFIN data) used in deriving trip limits reflecting incidental catch levels.

Only WCGOP data from the nearshore fixed gear fishery were used to provide maximum bycatch-rate estimates during the current closed period. Encounters with lingcod seaward of the RCA during winter months (the current closed period) are infrequent relative to encounters by the nearshore fixed gear fishery (i.e., many of the larger lingcod are shallow during the spawning season). As such, allowing retention in the non-nearshore fishery that is far higher than their incidental encounter rates during December –April would likely not result in a substantial increase in lingcod targeting. Densities of lingcod seaward of the RCA are low during the December-April period and increased effort for lingcod (i.e., targeting) may not make economic sense for that fishery. For example, the average lingcod catch during the closed periods for the nearshore fishery is 35 lb per trip, whereas the average lingcod catch for the non-nearshore fishery is 7.2 lb per trip during the same periods (WCGOP data). Note that lingcod catch (discard + retained) during the open periods (May – November) are 39 lb per trip for nearshore fixed gear and 43.2 lb per trip for the non-nearshore fishery. The higher encounter rate during the open season makes sense, since this is during the non-spawning season and many larger adults migrate back to deeper waters.

Comparison of Options

Option 1: No Action
Under the No Action Option, retention of lingcod by the fixed gear fishery is prohibited in periods 1, 2 and 6 with the exception of November when a 400 lb. per month trip limit is allowed in both the limited entry and open access fisheries.

Fishing Activity in Commercial Fixed Gear Fisheries under Option 1

The nearshore fixed gear fishery in California and Oregon are subject to state-limited entry permits, while Washington does not allow a commercial fishery in the nearshore. The non-nearshore fixed gear fishery is prosecuted in all three states. Both nearshore and non-nearshore fishery trip limits are divided at 40°10′ N. latitude. The limited entry and open access (Federal) fixed gear trip limits in each period or month are provided in Table B-39.

It is important to point out that the nearshore rockfish fishery south of 40°10′ N. latitude is currently closed in period 2 (March and April), whereas the nearshore rockfish fishery is open year round to the north. The non-nearshore fishery operates year round and primarily targets sablefish. In the nearshore fishery, an average of 3.3 trips per month was taken during the closed season by a monthly average of 82 vessels during 2007-2012. During the open season, an average of 4.2 trips per month and 168 vessels per month took place during the open season. The higher effort during the open season coincides with months of relatively fair weather, allowing greater fishing opportunities.

Table B-39. Commercial fixed gear trip limit regulations for lingcod north and south of 40°10′ N. latitude by sector with closed periods (in gray) under Option 1.

Sector	Jan - Feb	Mar - Apr	May - Jun	Jul - Aug	Sep - Oct	Nov - Dec	
LE North	Closed		800 lb./ 2 months			400 lb.	Closed
LE South	Closed		800 lb./ 2 months			400 lb.	Closed
OA North	Closed		400 lb./ month				Closed
OA South	Closed		400 lb./ month				Closed

Biological Impacts under Option 1

Projected Lingcod Mortality
Under the no action alternative, lingcod mortality in the fixed gear fisheries during periods 1, 2 and 6 are expected to be the same as recent years in the past, assuming trip limits for other co-occurring target species do not change. If the trip limits for other target species during the closed season increase, the number of lingcod and overfished species encountered and discarded may increase. At present a 7

percent discard mortality rate reflecting rod and reel gear is anticipated for released lingcod[13]. The landings of lingcod in the last five years for each sector from Washington, Oregon and California are provided in the Table B-40. An average of 52.5 mt of lingcod mortality from the fixed gear fishery north of 42° N. latitude and 31.4 mt to the south are expected under the no action alternative based on the average mortality in 2011 and 2012 from WCGOP total mortality reports. The non-trawl allocations in 2014 were stratified at of 42° N. latitude and mortality from the non-trawl fishery in 2011 and 2012 were 21 percent and 49 percent of the respective allocations north and south, respectively indicating that the fishery has fallen far short of attainment under the current regulations.

Table B-40. Landings of lingcod in nearshore and non-nearshore fixed gear fisheries in California North and South of 40°10′ N. latitude, Oregon and Washington under status quo regulations (Option 1).

Period	Sector			
	Washington	Oregon	California North of 40°10′ N. latitude	California South of 40°10′ N. latitude
Nearshore LE	NA	2.85	0.47	0.52
Nearshore OA	NA	25.70	4.41	15.32
Non-Nearshore LE	3.26	5.10	1.60	0.62
Non-Nearshore OA	2.03	12.85	1.94	3.19

Projected Overfished Species Mortality
In 2011 and 2012 an average of 1.6 mt of yelloweye rockfish, 1.6 mt of canary rockfish, 0 mt of cowcod and 2.8 mt of bocaccio mortality were estimated to have occurred in the fixed gear fishery in pursuit of all targets both in the nearshore and non-nearshore. These estimates reflect the expected mortality under the no action alternative. However, for comparison of alternatives, we provide the no-action projected impacts by using the GMT Overfished Species Nearshore Model. These projected impacts, using 5-year average landed catches from PacFIN (2008-2012) as model inputs, are shown in Table B-41. The projected impacts under Option 1 (No Action) using the Nearshore Model for the Oregon and California nearshore fisheries north and south of 40°10' N latitude are provided in Table B-41. Note that the projected impacts are different than the average mortality shown by WCGOP. The inter-annual variability for overfished species impacts is high, and the projection model estimates long-term average impacts.

Table B-41. Projected mortality for OFS (in mt) from the nearshore bycatch projection model using the lingcod mortality from year round fishing projected from the 5-year average landings of lingcod and targeted nearshore species as inputs. California north and south reflects the management line separating them at 40°10' N latitude.

Species	Oregon	CA North	CA South	Total
Bocaccio	0.00	0.00	0.46	0.46
Canary rockfish	0.93	0.53	5.59	7.05
Cowcod	0.00	0.00	0.00	0.00
Darkblotched	0.12	0.00	0.07	0.18
Yelloweye rockfish	0.82	0.22	0.12	1.16

Stock Status

[13]http://www.pcouncil.org/groundfish/current-season-management/past-management-cycles/2009-2010-final-environmental-impact-statement/, pg. 307.

Lingcod
Though once overfished, the lingcod stock was deemed rebuilt after the most recent assessment in 2009 and are now considered healthy (>40 percent of historical biomass). The coastwide stock status was estimated to be 67 percent of historical spawning stock biomass, with the stock south of 42° N. latitude at 61.9 percent and north of 42° N. latitude at 73.7 percent. Current harvest is far below the non-trawl allocation and will not adversely affect the stock status.

Overfished Species
Under Option 1, the mortality of overfished species is projected to remain the same as recent years, which is expected to be below the sector specific fixed gear allocations. Thus the stock status of overfished species and rebuilding plans would be unaffected.

Socioeconomic Impacts under Option 1

Under the no action alternative, lingcod caught as bycatch during the closed months of the fishing season are discarded and revenues from landing them is forgone by participants in the fishery. In addition, no targeted fishery for lingcod is permitted during the closed months preventing effort from being exerted to increase attainment of the ACL, resulting in forgone revenue from directed effort. Thus fishery participants and coastal communities will continue to forgo potential revenue from converting lingcod discards to landings.

Option 2
Option 2 would allow retention of lingcod in fixed gear fishery during periods 1, 2 and 6 at incidental levels equivalent to the average encounter rates observed during the closed periods in recent years (WCGOP, 2002-2011) and expanded by recent fishing effort (PacFIN, 2008-2012). The trip limits would be 100 lb. per month for the open access fishery and 200 lb. per two month period in the limited entry fishery (Table B-42).

Change in Fishing Activity Compared to Option 1

The average estimates of discarded lingcod during the closed months in each sector from WCGOP provided the basis for the trip limits under Option 2 provided in Table B-42. The intent of Option 2 is to allow retention and landings of lingcod that would otherwise be discarded during the closed season. The encounter rates in the nearshore fishery were much higher than the non-nearshore fishery during the closed period (35 lb per trip versus 7 lb per trip, respectively) since lingcod move onshore during the winter and spring months for spawning. Thus estimates from the nearshore fishery were used as the basis for discard rates to better accommodate incidental take and convert more discards to landings. An attempt was made to adjust trip limits to account for discarding due to length restrictions during the open season, but discarding may also be due to overages against the trip limits in open months, which were confounding. Given the average lb of lingcod encountered with and without accounting for discarding of 80 and 117 lb. per month, respectively, we provide a bracketed value for trip limits of 100 lb. per month for the open access fishery and 200 lb. per two month period for the limited entry fishery (Table B-43).

Since the average encounters per month across all nearshore fishery participants were used as the basis for trip limits, many vessels encountered more lingcod than the average (Figure B-23). Thus many vessels would still incidentally encounter more lingcod than the trip limits would allow them to retain, which would still be discarded under Option 2. As seen in Figure B-23, with a trip limit of 100 lb per month, 69.5 percent of the trips would not exceed the trip limit, but 30.5 percent of trips would continue to discard some of the encountered lingcod. Trends in the percent of trips with a given amount of catch per month were examined for both longline and vertical hook and line gear. While those fishing with longline gear encountered nearly 10 lb. per month more than vertical hook-and-line gear, the difference was not great enough to justify the added complexity of trip limits for each gear type. Thus the values for all nearshore participants combined were used to derive trip limits irrespective of gear type.

The landing restrictions under Option 2 are not expected to result in additional mortality of other target stocks or overfished rockfish species. While fisheries are expected to be prosecuted in a similar fashion to Option 1, the additional opportunity for lingcod south of 40°10′ N. latitude in period 2 when rockfish is closed presents the possibility of additional mortality of overfished rockfish as well as discarding of other healthy rockfish species while targeting lingcod. While this is a possibility, the landing restrictions may be low enough that participants in the fishery may not opt to target lingcod during the closed season for rockfish in period 2 as the revenue generated from lingcod alone may not be sufficient to be profitable on its own. Thus, the landing restrictions are expected to be sufficiently low to prevent an appreciable increase in overfished species mortality, even if trip limits are attained.

Table B-42. Average lingcod discard rates from WCGOP, fishing effort from PacFIN, and projected lingcod catch for open and closed seasons. The average number of trips per vessel per month, combined with the average lingcod catch rate, formed the basis for the lingcod trip limits under Option 2 intended to allow retention of incidental catch.

Fishery and Period	Metrics	Values
Nearshore fishery (Dec-April; "closed")	Average Lingcod Catch per Trip (All Discarded; lb)	35.0 lb
	Average Number of Trips/Vessel/Month	3.3
	Average Number of Vessels Making Landings / Month	82
	Average Expected Lingcod Catch/Vessel/Month =(35 lb) x (3.3 trips/vessel/month) [a]	117 lb / month, or 234 lb / 2 mos
	Average Expected Landings / Vessel / Month, assuming 32% discard rate = (68%) x (117 lb)[b]	80 lb / month or 160 lb / 2 mos

Table B-43. Proposed commercial fixed gear trip limits for north and south of 40°10′ N. latitude by sector, under Option 2.

Sector	Jan - Feb	Mar - Apr	May - Jun	Jul - Aug	Sep - Oct	Nov - Dec	
LE North	200 lb./2 months		800 lb./ 2 months			400 lb.	100 lb.
LE South	200 lb./2 months		800 lb./ 2 months			400 lb.	100 lb.
OA North	100 lb./ month		400 lb./ month				100 lb.
OA South	100 lb./ month		400 lb./ month				100 lb.

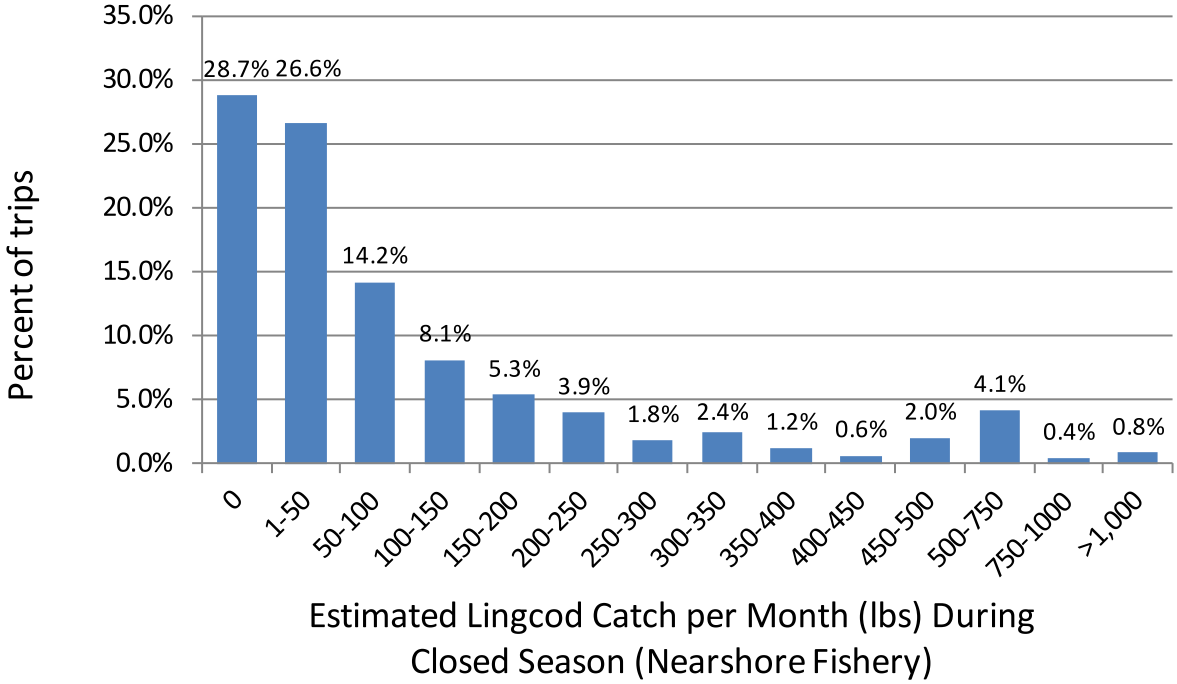

Figure B-23. Projected catch of lingcod per month during the closed season by individual vessels (percent) in the nearshore fixed gear fishery.

Biological Impacts Compared to Option 1

Lingcod Mortality

Lingcod mortality is expected to increase, though encounter rates are not, as participants in the fishery will retain some lingcod encountered (at 100 percent mortality) rather than discard all lingcod encountered (at 7 percent mortality). There would be no expected increase in lingcod encounter rates under this option relative to Option 1. Increased targeting during the closed period is not expected under Option 2, because trip limits were set to reflect incidental catch rates. The projected mortality of lingcod under this alternative is provided in Table B-44.

Table B-44. Projected landings of lingcod in nearshore and non-nearshore fixed gear fisheries in California North and South of 40°10′ N. latitude, Oregon and Washington under Option 2.

Period	Sector			
	Washington	Oregon	California South of 40°10′ N. latitude	California North of 40°10′ N. latitude
Nearshore LE	NA	3.49	0.55	1.70
Nearshore OA	NA	29.94	5.02	17.34
Non-Nearshore LE	3.67	5.91	1.70	0.70
Non-Nearshore OA	2.0	14.59	2.13	3.44

Overfished Species Mortality

Under Option 2, no additional mortality of overfished species is anticipated since trip limits are set low enough to only accommodate conversion of already encountered but discarded lingcod to landings while targeting other species. Only the nearshore fishery south of 40°10′ N. latitude would be expected to incur additional mortality in period 2 if trip limits of lingcod were targeted, since rockfish is closed during this period. Given that trip limits are set low enough that targeting of lingcod alone is unlikely to be profitable, overfished species mortality is expected to be similar to that under Option 1. If the open access fishery increases effort in nearshore waters to target lingcod, there may be a minor increase in rockfish bycatch including overfished species.

Data Uncertainty Compared to Option 1

Though the trip limits are set to allow retention of lingcod encountered as bycatch, it may encourage some additional effort from the open access fishery, presenting some uncertainty in the lingcod and overfished species mortality. If selective gear is employed, any increase in open access effort may be exerted with minimal unintended consequences in the form of overfished species bycatch. If period 2 remains closed south of 40°10′ N. latitude, there will be less uncertainty in mortality as any additional effort targeting lingcod during the rockfish closure would result in additional bycatch of rockfish relative to Option 1. Though opening lingcod retention for open access during period 2 south of Point Conception could result in increased uncertainty in lingcod and overfished species impacts relative to Option 1, it is expected that trip limits may be low enough to prevent lingcod targeting; therefore, rockfish mortality is expected to be similar to Option 1.

Stock Status

Lingcod

Under Option 2**,** no changes to lingcod stock status are expected compared to the no action alternative since lingcod mortality has been far below the non-trawl allocation and expected to remain so under Option 2. Given the projected increase in impacts, the level of increase is expected to be far below levels that would result in overfishing and are not expected to adversely affect stock status.

Overfished Species

Under Option 2**,** no changes to the stock status or rebuilding progress of overfished species are expected since mortality is projected to remain below the sector specific harvest limits for the nearshore and non-nearshore fisheries.

Socio-economic Impacts compared to Option 1

Allowing fishery participants to retain incidentally encountered lingcod that were previously discarded would increase revenue from current operations targeting other species within incidental lingcod encounters. In 2013, the average price per pound coast wide ranged from $0.36 to $3.62 per lb. depending on the month, state and sector providing $36 to $362 per month of potential revenue from lingcod assuming the trip-limit can be attained. While the low trip limits make it unlikely that fishery participants will choose to target lingcod, such targeting may become worthwhile if the price per pound makes the trip profitable, despite the relatively low trip limits. If the trip-limit cannot be attained or if fuel or other variable costs make it unprofitable, or alternatively opportunity costs are too high to justify changing targets, directed effort may not be economically viable and trips targeting lingcod may be unlikely.

Option 3

Option 3 would allow retention of lingcod in fixed gear fishery during periods 1, 2 and 6 with trip limits of 400 lb per month in the open access fishery and 800 lb per two month period in the limited entry fisheries.

Change in Fishing Activity Compared to Option 1

The intent of Option 3 is to allow trip limits for lingcod that are the same as the status quo in months currently open to fishing in both the open access and limited entry fisheries during periods 1, 2 and 6 (Table B-45). If effort is the same as the months currently open to fishing at the current trip limits, landings are expected to be lower than those observed in the open months as the trip limits would be the same, but effort is lower during the winter and early spring due to weather. The fishing effort for lingcod would be expected to increase during periods 1, 2 and 6 relative to the no action alternative. The magnitude of the increase in mortality depends on changes in fishing behavior of the limited entry fishery and the number of participants in the open access fishery which is difficult to predict.

Approximately eight percent of trips fishing for nearshore rockfish species during the closed months encountered more lingcod than can be retained under the 400 lb. per month open access trip limits and one percent encountered more than the 800 lb. per two month limited entry trip limits during open months (Figure B-23). It should be noted that even at the trip limit levels of 400 lb. per month for open access or 800 lb. per two months in the limited entry fishery, some participants would still be discarding lingcod even if the current trip limits during the open season were employed during the closed season (Figure B-23). Thus the trip limits under Option 3 will continue to limit landings for some trips and reduce lingcod mortality relative to an unregulated fishery.

The effort in the limited entry fishery is capped by the number of permit holders, thus the 800 lb. per two month trip-limit may increase targeting/harvest relative to other options, but the number of participants is fixed, limiting the magnitude of potential increase relative to the open access fishery. Both open access and limited entry non-nearshore fisheries primarily target sablefish, and the magnitude of the revenue generated by allowing retention of lingcod in this fishery is not expected to cause increased targeting of lingcod because the revenue they would generate is far lower than from sablefish landings. In addition, lingcod encounters are less common in the non-nearshore fishery than in the nearshore fishery during the closed season (see Table B-45), when lingcod move onshore to spawn during the winter and early spring (Love 1996). Lingcod encounters in the nearshore fishery peak during the summer month during the open season. In the nearshore fishery, the increased trip limits are expected to increase revenues and lingcod targeting. It is uncertain whether the increase would be sufficiently high to drive increased participation of latent capacity. Weather is also a factor in that the closed period coincides with a period of more inclement weather, which is expected to limit the amount of additional effort that may be exerted under Option 3.

Table B-45. Proposed commercial fixed gear trip limits for north and south of 40°10′ N. latitude by sector under Option 3.

Sector	Jan - Feb	Mar - Apr	May - Jun	Jul - Aug	Sep - Oct	Nov - Dec
LE North	800 lb./ 2 months					
LE South	800 lb./ 2 months					
OA North	400 lb./ month					
OA South	400 lb./ month					

Biological Impacts Compared to Option 1

Lingcod mortality is expected to increase relative to the no action alternative, though it is difficult to determine the extent to which effort will increase. If additional entrants begin fishing in the open access fishery, impacts may increase further than shown here. The low increase in potential revenue makes extreme increases in effort unlikely especially considering that attainment is likely to fall short of the trip limit if targeting lingcod proves difficult. The 800 lb. per two month trip limit on the limited entry fishery may allow additional landings relative to other options, but the number of participants is limited by the number of permit holders.

To project lingcod mortality for the limited entry and open access sectors under Option 3, recent mortality during the open period was expanded to the currently closed periods (i.e., Periods 1, 2 and the second half of 6) using historical proportions of catch by time. The standard fleet capacity trip limit model documented under the analysis of trip limits for 2015-2016 was used to calculate the projected lingcod mortalities for the following fishery sectors per state including limited entry/nearshore open access (Oregon and California only) and Non-nearshore limited entry (all three states) /Non-nearshore open access (in all three states). Using the 1995-1997 period during which lingcod was open to fishing year round, the proportional take per period and/or month was calculated and used to emulate those proportions of catch by time for mortality projections. The projected annual mortalities (mt) were then calculated using the 2008-2012 set of landings as the trip limit base period. The proportions of catch by period and/or month were used to estimate the mortality during the closed months given the recent mortality during the base period. Assuming the trip limit is attained by all participants that landed lingcod during the open season, impacts on lingcod would increase in the nearshore fishery. The resulting lingcod mortalities for the fixed gear fisheries are provided in Table B-46.

Table B-46. Projected landings of lingcod in nearshore and non-nearshore fixed gear fisheries in California North and South of 40°10′ N. latitude, Oregon and Washington under Option 3.

Sector	Washington	Oregon	California	
			North of 40°10' N. Latitude	South of 40°10' N. Latitude
Nearshore LE	NA	3.89	0.71	0.69
Nearshore OA	NA	36.65	6.88	23.55
Non-nearshore LE	4.78	7.27	1.92	0.82
Non-nearshore OA	3.13	19.83	2.72	4.55

Overfished Species Mortality

The nearshore overfished species projection model was applied to calculate the OFS mortalities using five-year averages for Oregon (north of 42° N latitude) and California (between 42° N latitude and 40°10' N latitude and south of 40°10' N latitude). Under Option 3, the higher estimated catch of lingcod was imputed in the model to project the relative increase in overfished species impacts expected with trip limits shown in Table B-46. The result is an estimated percent increase in mortality in the nearshore fishery of 6.9 percent (0.08 mt) for yelloweye rockfish, 6.1 percent (0.43 mt) for canary rockfish, 6.5 percent (0.03 mt) for bocaccio and no increase in cowcod. The resulting overfished species mortality and magnitude of increase relative to status quo (in brackets) in Oregon and regions of California are presented in Table B-47.

There is no model for projecting the mortality of overfished species in the non-nearshore fishery using lingcod mortality. The assumption is made that overfished rockfish mortality will not increase in the non-nearshore fishery because it is unlikely that the trip limit will lead to additional targeting lingcod. Relatively few lingcod are encountered while targeting sablefish, especially during the winter and early spring when lingcod move onshore to spawn. If the open access fishery increases effort in nearshore waters to target lingcod, there may be an unanticipated increase in rockfish bycatch including overfished species, though the moderate trip limits for lingcod are expected to prevent excessive additional effort from the open access fishery. Relative to the contributions from the remainder of the year, the allocation to the fixed gear sectors and the ACL, the projected increase in overfished species mortality in Table B-47 are negligible.

Table B-47. Projected mortality for OFS from the nearshore bycatch projection model using the 5-year averages compared to what the OFS mortality projected increases would be with the addition of increased lingcod mortality amounts for periods 1, 2, and the second half of 6, applying the current trip limit structure (amounts) to the closed periods.

Species	Oregon	California North of 40°10' N latitude	California South of 40°10' N latitude	Total
Bocaccio	0.00 (+0.0)	0.00 (+0.0)	0.49 (+0.03)	0.49 (+0.03)
Canary rockfish	1.00 (+0.07)	0.55 (+0.02)	5.93 (+0.34)	7.48 (+0.43)
Cowcod	0.00	0.00	0.00	0.00
Darkblotched	0.13 (+0.01)	0.00 (+0.0)	0.07 (+0.0)	0.20 (+0.02)
Yelloweye rockfish	0.88 (+0.06)	0.23 (+0.01)	0.12 (+0.0)	1.24 (+0.08)

Data Uncertainty Compared to Option 1

Though the trip limits under Option 3 are set to allow retention of lingcod encountered as bycatch and facilitate attainment of the non-trawl allocation, it may encourage some additional effort from the open access fishery. The open access and limited entry fixed gear fisheries cannot retain rockfish in California waters during period 2 south of 40°10' N latitude, thus discarding of rockfish, including overfished species, may increase under Option 3. If the prohibition on retention of lingcod south of 40°10' N latitude in period 2 is maintained, uncertainty in overfished species bycatch projections and discard mortality of healthy rockfish stocks would be reduced. If selective gear is employed, open access effort may be exerted with less unintended consequences in the form of overfished species bycatch.

Stock Status

Lingcod

Under Option 3**,** no changes to lingcod stock status are expected since lingcod mortality is projected to be far below the non-trawl allocation. Given the projected increase in impacts, the level of increase is expected to be far below levels that would result in overfishing.

Overfished Species

The projected increase overfished species mortality under Option 3 is projected to result in mortality that is still below their respective harvest limits. Thus the stock status and rebuilding plans are not expected to be adversely affected by the regulations under Option 3.

Socio-economic Impacts compared to Option 1

Landing of fish previously discarded as bycatch would increase revenues for participants in the fishery and increase the profitability of existing operations by increasing marginal revenue per trip at no or limited additional cost. For those who choose to target lingcod, the revenue generated from landing lingcod may make a few trips per bi-monthly period worth taking to attain the moderate landings under the trip limit as long as the price per pound and landings make the trip economically viable. In 2013, the average price per pound coast wide ranged from $0.36 to $3.62 per lb. depending on the month, state and sector resulting in $144 to $1448 per month of potential revenue from lingcod assuming the trip-limit can be attained. If the trip-limit cannot be attained or if fuel and other variable costs exceed revenue or alternatively opportunity costs are too high to justify changing targets, directed effort may not be economically viable and trips targeting lingcod may be unlikely.

B.9 Non-Trawl: Trip Limit Adjustment for Shortspine Thornyhead N., Bocaccio S., and Shelf Rockfish S.

Need for Action

For 2013-2014 groundfish fisheries, shortspine thornyhead (north of 34°27' N. latitude), bocaccio (south of 34°27' N. latitude) and the minor shelf rockfish complex (south of 34°27' N. latitude), have been managed, in part, by cumulative bi-monthly trip limits, designed to keep catches within the respective ACLs. As a result of inseason tracking patterns (higher/lower than projected), trip limits may be adjusted inseason. For shortspine thornyheads, bocaccio, and the shelf rockfish complex, trip limit increases were implemented on August 13, 2013 as per the GMT's June 2013 Inseason Adjustment statement (http://www.pcouncil.org/wp-content/uploads/F9b_SUP_GMT_JUN2013BB.pdf). These trip limit options are in addition to those increases seen in 2013. The fishery sectors considered in the following analyses are the non-trawl fixed-gear fisheries.

The trip limit models used for these species/sectors are catch-based fleet capacity models, whereby the proportional take of the theoretical maximum (for the selected base years and species) that could have been made by each participating vessel is used to estimate take for various trip limit amounts per vessel per period (bi-monthly or monthly); the sum of which represents the estimated annual catch or mortality. When possible, the final estimated mortality was adjusted by also adding the estimates of discard mortality for the respective fishery sectors. One assumption built into this model is that vessels participation does not vary significantly from the base years used in calculations. However, with the open access fishery (OA), that assumption may be in jeopardy if high enough trip limits prompt individuals to jump into what they perceive as a developing lucrative fishery. Another assumption is that any vessel that landed at least 80 percent of its theoretical maximum period amount would probably take 100 percent of an increased period amount. This 20 percent buffer amount compensates for a form of within-fleet latent capacity. Additionally, estimated discard mortality amounts were calculated using the West Coast Groundfish Observer Program (WCGOP) Groundfish Mortality Reports for 2011 and 2012 and factored into the final projected estimates.

2015-2016 Management Considerations

For the 2015-2016 biennial management cycle, trip limit options for the above fishery sectors are analyzed relative to the No Action Option (based on the 2014 amounts) and two additional options, based on a P* of 0.45 and P* of 0.25, which establish fishery harvest guideline amounts for the non-trawl fixed-gear sectors. Estimated mortality is provided that also incorporates discard mortality using estimated amounts derived from WCGOP Groundfish Mortality Reports. Trip limits under any option could be adjusted inseason as needed to attain, but not exceed, a given catch limit (non-trawl allocation portion of the annual ACL).

Generally speaking, bocaccio and shelf rockfish south of 34°27' N latitude have been underutilized during recent years relative to non-trawl sector allocations, whereas shortspine thornyhead utilization north of 34°27' N latitude has been much higher (Table B-48) .

Table B-48. Comparison of estimated mortality (mt) and the non-trawl allocations (including the recreational sector) from 2011 through 2013 for the following non-trawl, fixed-gear fisheries: shortspine thornyheads (SSTH) – north of 34°27' N latitude, bocaccio – south of 34°27' N latitude, and the minor shelf rockfish complex – south of 34°27' N latitude (Note: Limited entry (LE) and open access sectors are combined and 2013 data are preliminary).

	2011			2012			2013		
	Non-trawl	Est. mort.	% of non-trawl	Non-trawl	Est. mort.	% of non-trawl	Non-trawl	Est. mort.	% of non-trawl
SSTH	76	72.9	95.4%	76	63.2	83.2%	74	59.3	80.1%
Bocaccio	58.6	2.3	3.9%	58.6	3.3	5.6%	73.2	2.3	3.1%
Shelf RF	626.9	19.9	3.2%	626.9	23.1	3.7%	586.5	16.2	2.8%

Table B-49. Expected mortality (mt) under No Action and under the Preliminary Preferred Alternative for the non-trawl sector for 2015-2016 for the following non-trawl, fixed-gear fisheries: shortspine thornyheads (SSTH) – north of 34°27' N latitude, bocaccio – south of 40° 10' N latitude, and the minor shelf rockfish complex – south of 40°10' N latitude (Note: Limited entry (LE) and open access sectors are combined and 2013 data are preliminary)

Species or Complex	No Action	Preliminary Preferred (P*=0.45)		Preliminary Preferred (P* = 0.25)	
		2015	2016	2015	2016
SSTH	77.3	84.3	83.3	61.4	60.8
Bocaccio	4.5	258.8	268.7	258.8	268.7
Shelf RF	387	1,383.2	1,384.0	659.7	659.7

B.9.1 Shortspine Thornyhead North of 34°27' North Latitude Management Measures

For 2013-14 west coast groundfish fisheries, shortspine thornyhead have been managed to sector specific harvest guidelines (95 percent trawl and 5% percent non-trawl). Because the recreational sector does not utilize this species, all analyses and totals represent only the commercial fishery. The HG for the non-trawl fixed gear fishery is expected to increase from 73.3 mt (in 2014) to 84.3 mt in 2015 and 83.3 mt in 2016 (Table B-49). The most recent assessment of shortspine thornyhead (Taylor 2013), indicates the stock is healthy with an estimated spawning stock biomass of 74.2 percent of its initial, unfished biomass. As a result, the Council requested analysis of higher trip limits for the LE sector north of 34°27' N. latitude. The 2014 commercial management measures for shortspine thornyhead are described in Table B-50.

Table B-50. Shortspine thornyhead management measures north of 34 °27' N latitude for the 2014 commercial fishery.

Fishery	
Commercial	Sorting requirement for all commercial landings
Limited Entry Trawl	Managed under IFQ
Limited Entry Fixed Gear	Bi-monthly limit management Current trip limits north of 34°27' N latitude are: Periods 1 -3: “2,000 lb/ 2 months” Periods 4 -6: “2,500 lb/ 2 months” Bi-monthly trip limits can be adjusted through routine in-season action
Open Access Fixed Gear	“CLOSED”

2015-2016 Management Considerations
For the 2011-2013 non-trawl sector (which is allocated 5 percent of the annual take north of 34°27' N latitude) catches were between 80 percent and approximately 90 percent of the allocation (Table B-48). The shortspine thornyhead non-trawl fixed-gear fishery north of 34°27' N latitude is restricted to the LE entry sector. The open access sector is not allowed to retain shortspine thornyhead, where the discard mortality is relatively small (e.g., 0.78 mt during 2012 WCGOP Groundfish Mortality Report). During the 2011-2012 management cycle, 116 LE vessels (85 percent of the LE fleet) landed less than 20 percent of the theoretical maximum amount they could have landed under the trip limits that were in place at the time.

Management Options

Option 1 – No Action: Maintain current shortspine thornyhead trip limits for the limited entry sector north of 34°27' N latitude. Under Option 1, the 2014 trip limits (Table B-51) would remain in place for the LE sector, and the OA sector would remain closed.

Option 2a – Increase trip limits for the limited entry sector north of 34°27' N latitude: Under Option 2a, increased bi-monthly trip limits north of 34°27' N latitude were investigated to determine what the projected morality would be compared to the No Action Option (Table B-51).

Option 2b: Further trip limits for the limited entry sector north of 34°27' N latitude: Under Option 2b moderate trip increases, compared to Option 2a, are explored (Table B-51)..

Biological Impacts Under Option 1

Projected Mortality
Under No Action, projected mortality for shortspine thornyhead north of 34°27' N latitude is 77.3 mt for the LE fixed-gear sector (with no open access fishery allowed). At this level of harvest, the projected mortality represents 92 percent of the 2015 HG (84.3 mt) and 93 percent of the 2016 HG (83.3 mt) at a P* value of 0.45 (Table B-49). At a P* value of 0.25 this exceeds the 2015 HG (61.4 mt) by 26 percent and exceeds the 2015 HG (60.8 mt) by 27 percent. This mortality is expected to be within the HG at the current level of vessel participation only at a P* value of 0.45. This assumes that the vast majority of vessels will continue to take less than 20 percent of their theoretical maximum allowable amount.

Stock Status
The shortspine thornyhead stock was determined to be healthy in the last stock assessment (Taylor 2013) and projections under status-quo catches showed little change in stock status.

Overfished Species Mortality

Overfished species (OFS) are encountered by non-nearshore fixed gear fisheries, which also catch shortspine thornyhead. For example in 2013, non-nearshore fixed gear fishery mortality for OFS was bocaccio rockfish South 40°10' N. latitude (2.62 mt), canary rockfish (0.12 mt), darkblotched rockfish (9.04 mt), Pacific ocean perch (0.41 mt), yelloweye rockfish (0.34 mt), and petrale sole (0.83 mt). It is expected that similar catches may be observed under Option 1 (No Action) during 2015 and 2016.

The non-nearshore fishery primarily targets sablefish. Other species, such as shortspine thornyhead, are incidentally caught (not targeted) and retained. In addition, many of the OFS (e.g., canary and yelloweye rockfish primarily live at shallower depths than shortspine thornyhead, and therefore largely do not co-occur.

Mortality of Rougheye, Blackspotted, and Shortraker Rockfish
Other species are encountered by non-nearshore fixed gear fisheries, which also catch shortspine thornyhead. For example, rougheye rockfish was taken by the non-nearshore fixed gear fisheries (when shortspine thornyheads were also landed) as follows: 29.7 mt in 2011, 26.2 mt in 2012, and 19.4 mt in 2013. Shortraker rockfish was also taken as follows: 2.5 mt in 2011, 4.53 mt in 2012, and 0.16 mt in 2013. Lastly, blackspotted rockfish was taken as follows: 0.25 mt in 2011, 4.53 mt in 2012, and 0.16 mt in 2013. However, increases in shortspine thornyhead trip limits are not expected to have any additional impact on the mortality of these species because shortspine thornyhead are incidentally caught while fixed gear fishermen are targeting other higher-valued species. For example, slope rockfish and shortspine thornyhead catch is primarily incidental for fishermen targeting sablefish. Fishing effort and fishing behavior (i.e., selection of fishing locations) are not expected to change due to shortspine thornyhead trip limit increases. Therefore, mortality of these three species of rockfish is not expected to change.

Options 2a and 2b – Increase trip limits for the limited entry sector north of 34°27' N latitude
Under Option 2, increased bi-monthly trip limits north of 34°27' N latitude were investigated to determine what the projected morality would be compared to the No Action Option.

Individual vessel landings reported in PacFIN (table vdrfd) from 2011-2012 for the LE sector were used to analyze catch limits by the fleet. The years 2011 and 2012 were ultimately chosen as the basis for this model because they are the most representative of current and future fishing behavior for the three states. Even though the vast majority of vessels take less than 20 percent of their theoretical maximum annual amount, a small increase in the bi-monthly trip limits could cause the fishery to reach or exceed the HG (non-trawl allocation portion of the annual ACL).

Limited Entry Bi-monthly Trip Limit Options
The LE entry trip limit options for the shortspine thornyhead non-trawl fixed gear fishery north of 34°27' N latitude are shown in Table B-51. Option 2a provides for an increase from 2,000 lb to 2,250 lb per bi-monthly period for periods 1 - 3, and does not change the trip limit for periods 4-6, which remain at No Action level of 2,500 lb per bi-monthly period. Option 2b provides for an increase from 2000 lb to 2,500 lb per bi-monthly period for periods 1-3, resulting in 2,500 lb per bi-monthly period for the entire year (Option 2b).

Table B-51. Comparison of projected landings of shortspine thornyhead in the LE non-trawl fixed-gear sector north of 34°27' N. latitude under No Action (Option 1) and increases for periods 1-3 only (Option 2a) and setting the trip limits to 2,500 lb per period for all six periods (Option 2b).

	Limited Entry Shortspine Thornyhead North 34°27' N. Latitude at a **P* of 0.45**					
	Bi-monthly Trip Limits	Projected	HG (mt)		% of HG	
Options	(in lb)	landings (mt)	2015	2016	2015	2016
Option 1	2,000 for periods 1-3 and 2,500 for periods 4-5	77.3	84.3	83.3	91.7 %	92.8%
Option 2a	2,250 for periods 1-3 and 2,500 for periods 4-5	80.3	84.3	83.3	95.3 %	96.4%
Option 2b	2,500 for all six periods	83.4	84.3	83.3	98.9 %	100.1%

	Limited Entry Shortspine Thornyhead North 34°27' N. Latitude at a **P* of 0.25**					
	Bi-monthly Trip Limits	Projected	HG (mt)		% of HG	
Options	(in lb)	landings (mt)	2015	2016	2015	2016
Option 1	2,000 for periods 1-3 and 2,500 for periods 4-5	77.3	61.4	60.8	126%	127%
Option 2a	2,250 for periods 1-3 and 2,500 for periods 4-5	80.3	61.4	60.8	131%	132%
Option 2b	2,500 for all six periods	83.4	61.4	60.8	136%	137%

Biological Impacts Under Options 2a and 2b

Projected Mortality

Under Option 2a and Option 2b, the projected mortality of shortspine thornyhead north of 34°27' N latitude would result in the fishery nearly reaching its HG (Option 2a) and exceeding it (Option 2b) under a P*=0.45 approach (Table B-49). Expected catches under these options are expected to exceed the HG using a P*=0.25 approach.

Stock status

While the stock is considered healthy, no negative consequences would probably result from trip limit increases shown in Table B-51. The IFQ mortality since 2011 ranged from 50 to 60 percent of its allocation. That, coupled with the non-trawl fixed-gear allocation of 5 percent indicates that the projected mortality would not likely jeopardize the stock's health.

Overfished Species Mortality

Details shown in Option 1 also apply to Options 2a and 2b. In addition, increases in shortspine thornyhead trip limits are not expected to have any additional impact on overfished species mortality, because shortspine thornyhead are incidentally caught while fixed gear fishermen are targeting other higher-valued species (i.e., sablefish). Fishing effort and fishing behavior (i.e., selection of fishing locations) are not expected to change due to shortspine thornyhead trip limit increases. Therefore, overfished species impacts are not expected to change.

Mortality of Rougheye, Blackspotted, and Shortraker Rockfish

As was pointed out for Option 1, an increase in shortspine thornyhead trip limits are not expected to have any additional impact on the mortality of these species. If increases in catch of slope rockfish were to occur following increases to shortspine thornyhead trip limits, it is expected that such increases would be minimal because shortspine thornyheads are not the primary target species.

Impact to Industry

Higher trip limits for shortspine thornyhead could increase access to healthy stocks, resulting in increased ex-vessel value, although the amount is difficult to quantify. Changes as a result of this action may not have a large effect on the stock per se; the possibility of exceeding harvest limits could have a negative impact on the fishery, albeit a small impact because the take of shortspine thornyheads in this sector represents a bycatch amount of the sablefish fishery. The latest anecdotal information received from the industry, regarding the 2014 sablefish fishery, indicates that demand may experience an upswing, which could result in an increased mortality of thornyheads.

B.9.2 Bocaccio South of 34°27' North Latitude Management Measures

For 2013-2014 California groundfish fisheries, bocaccio has been managed to sector specific harvest amounts (i.e., trawl, non-trawl, recreational). The HG for non-trawl fixed gear is expected to increase in 2015 and 2016 to 80.1 mt and 83.1 mt respectively (Table B-53). The 2011 update assessment (Field 2013) indicated that a strong 2010 year class is moving through the fishery (particularly south of 34°27' N. latitude) and as such, encounters (and discarding) have increased. This, combined with the information that recent mortality of this stock is far below the non-trawl harvest guideline (Table B-53), prompted the Council to request an analysis of higher trip limits for the LE and OA sectors south of 34°27' N. latitude. The 2014 commercial management measures for bocaccio rockfish are described in Table B-52.

Table B-52. Bocaccio management measures south of 34°27' N. latitude for the 2014 commercial groundfish fisheries.

Fishery	
Commercial	Sorting requirement for all commercial landings
Limited Entry Trawl	Managed under IFQ
Limited Entry Fixed Gear	Bi-monthly limit management. Current limits south of 34°27' N. latitude are: Period 1: *"300 lb/2 months"* Period 2: Closed Period 3: *"300 lb/2 months"* Periods 4-6: *"500 lb/2 months"* Bi-monthly limits can be adjusted through routine in-season action.
Open Access	Bi-monthly limit management. Closed Period 2 Current limits south of 34°27' N. latitude are: Period 1: *"100 lb/2 months"* Period 2: Closed Period 3: *"100 lb/2 months"* Periods 4-6: *"200 lb/2 months"* Bi-monthly limits can be adjusted through routine in-season action.

2015-2016 Management Considerations
Fewer than 10 LE vessels land bocaccio south of 34°27' N. latitude, while the number of OA vessels landing this species is roughly twice as many. Total mortality estimates reported from WCGOP indicate that approximately six percent of the non-trawl fixed gear HG was attained in 2012 (Table B-53). Encounters are expected to increase as the bocaccio population continues to rebuild (i.e. rebuilding paradox). During the 2011-2012 management cycle, 5 LE vessels (83 percent of the six vessels that landed bocaccio) landed less than 20 percent of the theoretical maximum amount of bocaccio they could have landed south of 34°27' N. latitude. In the OA sector, 28 of 39 vessels (72%) that landed bocaccio south of 34°27' N. latitude landed less than 20 percent of their theoretical maximum amount of bocaccio.

Table B-53. Total bocaccio mortality (in mt) in the non-trawl fixed gear sector (LE and OA combined) south of 40°10' N latitude from 2011-2012. (source: WCGOP)

Year	Mortality	HG	% HG
2011	2.3	58.6	4 %
2012	3.3	58.6	6 %

Management Options

Option 1-No Action: Maintain current trip limits for LE and OA sectors south of 34°27' N latitude.
Under Option 1, the 2014 trip limits (Table B-52) would remain in place for both LE and OA sectors.

Option 2a: Increase trip limits for LE and OA sectors south of 34°27' N latitude: Under Option 2a moderate trip increases, compared to Option 1- No Action, are explored (Table B-56).

Option 2b: Further increase trip limits for LE and OA sectors south of 34°27' N latitude: Under Option 2b moderate trip increases, compared to Option 2a, are explored (Table B-56).

Biological Impacts Under Option 1: No Action

Projected Impacts
Under No Action, projected mortality for bocaccio south of 34°27' N latitude is 1.0 mt and 3.5 mt for the LE and OA sectors, respectively (Table B-54). Between 40°10' and 34°27' N. latitude, average landings (2011 and 2012) for both sectors combined were 0.9 mt. The projected landings for the entire area south of 40°10' N. latitude under No Action is therefore 5.4mt (Table B-53), which is well below the HGs for 2015 and 2016 (258.8 mt and 268.7 mt, respectively) for both P*=0.45 and P*=0.25 (Table B-53).

Table B-54. Summary of bocaccio projected landings south of 40°10' N. latitude (by sector) under No action.

Area	Limited Entry	Open Access
40°10' to 34°27' N. lat.	0.9	
South of 34°27' N. lat.	1.0	3.5
Total	5.4	

Stock Status
The bocaccio stock south of 40°10' N. latitude was formally designated as overfished in 1999. The current stock assessment (Field, 2013) indicates an increasing abundance trend and progress towards rebuilding (Field, 2011). Under Option 1, no changes in progress towards rebuilding are expected.

Overfished Species Mortality

Bocaccio mortality has been minimal south of 34°27' N latitude. Annual average landings from 2008 to 2013 for the LE and OA sectors were 0.2 mt and 1.08 mt, respectively (Table B-55). During this five-year period, a total of only six vessels participated in the LE fishery and 52 in the OA fishery where bocaccio was taken. Of the 52 vessels in the OA fishery, only two averaged more than 0.1 mt of bocaccio per year; one at 0.18 mt and the other at 0.13 mt.

Table B-55. Bocaccio landings (mt) by sector and year from 2008 – 2012 for the non-trawl, non-nearshore fixed-gear fisheries south of 34°27' N latitude. Data source: PacFIN.

Sector	Sector description	Year and landings (mt)					Total	5-yr avg.
		2008	2009	2010	2011	2012		
7	Non-nearshore LE			0.00	0.02	0.36	0.39	0.08
8	Non-nearshore OA	0.04		0.00	0.00	0.16	0.21	0.04
9	Non-nearshore non-sablefish LE	0.17	0.05			0.40	0.62	0.12
10	Non-nearshore non-sablefish OA	1.16	0.73	0.66	1.17	1.28	5.01	1.00
12	Incidental OA	0.08	0.02	0.03	0.05	0.02	0.20	0.04
	LE total						1.00	0.20
	OA total						5.42	1.08

Note: Since these are PacFIN amounts (table vdrfd) and not West Coast Groundfish Observer Program estimates, no discard mortality estimates are included.

A range of bocaccio trip limits and calculated projected mortality under three alternatives for both the LE and OA sectors was analyzed (Table B-56). The years 2011 and 2012 were used because they were the most representative of current and future fishing behavior, with the assumption that potential trip limit increases would not significantly change fishing behavior (i.e. the number of vessels increasing per fishery sector).

Table B-56 . Projected mortality for bocaccio under a range of Options for the LE and OA fixed gear fisheries south of 34°27' N latitude.

No Action Option 1							
Sector	Period and trip limit (lb)						Total estimated mortality (mt)
	1	2	3	4	5	6	
LE FG	300	closed	300	500	500	500	1.2
OA FG	100	closed	100	200	200	200	2.0

Option 2a							
Sector	Period and trip limit (lb)						Total estimated mortality (mt)
	1	2	3	4	5	6	
LE FG	750	closed	750	750	750	750	1.7
OA FG	250	closed	250	250	250	250	5.0

Option 2b							
Sector	Period and trip limit (lb)						Total estimated mortality (mt)
	1	2	3	4	5	6	
LE FG	1,000	closed	1,000	1,000	1,000	1,000	2.3
OA FG	500	closed	500	500	500	500	9.9

Currently, projected mortality for bocaccio in the GMT scorecard is informed by two sources of data – the sablefish bycatch projection model for the area between 40°10' N latitude and 36° N latitude and by trip limit models south of 34°27' N latitude. Mortality between 36° N latitude and 34°27' N latitude (i.e., Morro Bay port complex) in not currently accounted.
WCGOP data were examined for the area south of 36° N latitude to estimate mortality of co-occurring overfished species (OFS; canary, darkblotched, and yelloweye rockfish) that may occur as a result of increases to the bocaccio rockfish trip limits in the LE and OA sectors. WCGOP data from 2011 to 2012 revealed that no OFS were encountered on the observed bocaccio trips during this time frame. Given the small sample size (5 vessels) informing the data and location of fishing, it is reasonable to assume that some OFS are encountered as bycatch, albeit in very small and unquantifiable amounts.

Mortality of Rougheye, Blackspotted, and Shortraker Rockfish
Other species are encountered by non-nearshore fixed gear fisheries, which also catch bocaccio. However, this is not the case for rougheye, blackspotted, and shortraker rockfish if we use the 2011 and 2012 mortality amounts as examples. During these years, no recorded landings of these three species of rockfish were made when landings of bocaccio were made. This is due primarily to the fact that these three species are infrequently taken south of 40°10' N. latitude.

Options 2a and 2b: Increase trip limits for LE and OA sectors south of 34°27' N latitude
Under Option 2, increased bi-monthly trip limits south of 34°27' N. latitude were investigated to accommodate increased encounters and minimize discarding as the stock continues to rebuild.

Individual landings reported in PacFIN from 2011-2012 for LE and OA sectors were used to analyze catch limits by the fleet. Although the HG for bocaccio applies to the entire area south of 40°10' N latitude, only modifications to trip limits south of 34°27' N latitude were investigated (i.e., trip limits between 40°10' and 34°27' N. latitude were status quo). For analytical and managerial ease, bi-monthly trip limits are assumed the same for each period. The years 2011 and 2012 were chosen as the basis for this model because they may be representative of current and future fishing behavior. Average landings during this time period for the area between 40°10' and 34°27' N latitude were added to the analytical options to project landings for the entire area south of 40° 10' N latitude.

Limited Entry Bi-Monthly Trip Limit Options

The LE bi-monthly trip limit options for bocaccio south of 34°27' N. latitude range from 750 lb/2 months (Option 2a) to 1,000 lb/2 months (Option 2b; Table B-57). In recent years the majority of vessels have taken less than half of the maximum trip limit during any given period.

Open Access Bi-Monthly Trip Limit Options

The OA bi-monthly trip limits range from 250 lb/2 months (Option 2a) to 500 lb/2 months (Option 2b; Table B-57). Participation in the OA sector has traditionally been more variable than LE, making it difficult to predict catch and fleet behavior; therefore it is possible that landings could be higher than projected.

Projected landings under each option for the LE and OA sectors are provided (Table B-57). These options are not mutually exclusive. , That is, the Council could recommend a different option for each sector.

Table B-57. Comparison of projected landings (mt) of bocaccio in the LE and OA sectors under No Action trip limits (Option 1), and two options with trip limit increases (Options 2a and 2b) to the 2015 non-trawl HG (258.8 mt) and the 2016 non-trawl (268.7 mt). Trip limit increases apply only to the open periods (currently period 2 (March/April) is closed). This applies to a P* of 0.45 and 0.25. Projected landings between 40°10' and 34° 27' N. latitude are based on average landings during 2011-2012.

2015							
Option	LE S. 34°27' N. lat.		OA S. 34°27' N. lat.		Projected Landings (mt) 40°10' -34°27' N. lat.	Total (mt)	% of Non-trawl Allocation
	Trip limit (lb.)	Projected Landings (mt)	Trip limit (lb.)	Projected Landings (mt)			
Option 1	300 for periods 1 and 3 500 for periods 4-6	1.0	100 for periods 1 and 3 and 200 for periods 4-6	3.5	0.9	5.4	2.0%
Option 2a	750 – all open periods	1.7	250 - all open periods	6.2	0.9	8.8	3.4%
Option 2b	1,000 – all open periods	2.2	500 - all open periods	12.4	0.9	15.5	6.0%

2016							
Option	LE S. 34°27' N. lat.		OA S. 34°27' N. lat.		Projected Landings (mt) 40°10' -34°27' N. lat.	Total (mt)	% of Non-trawl Allocation
	Trip limit (lb.)	Projected Landings (mt)	Trip limit (lb.)	Projected Landings (mt)			
Option 1	300 for periods 1 and 3 500 for periods 4-6	1.0	100 for periods 1 and 3and 200 for periods 4-6	3.5	0.9	5.4	1.9%
Option 2a	750 – all open periods	1.7	250 - all open periods	6.2	0.9	8.8	3.3%
Option 2b	1,000 – all open periods	2.2	500 - all open periods	12.4	0.9	15.5	5.8%

Note: Although status quo provides for differential trip limits by period (i.e. lower in Periods 1 and 3, and higher in Periods 4-6), for purposes of this analysis a constant trip limit amount was analyzed for all open periods.

Biological Impacts

Under Option 2a, landings are projected to increase approximately 70 percent (0.7 mt) and 63 percent (3.4 mt) in the LE and OA sectors respectively compared to No Action (Option 1; Table B-57). While under Option 2b projected landings are expected to increase by 120 percent (1.2 mt) in the LE sector and 187 percent (10.1 mt) in the OA sector compared to No Action. Similar to Option 1, mortality for bocaccio south of 40°10' N. latitude is projected to be well below the non-trawl fixed gear HGs (i.e., 3.4% to 6.0% of the non-trawl harvest guideline; Table B-57).

Stock Status

Similar to Option 1, no changes to rebuilding progress are expected.

Overfished Species Mortality
Same as Option 1. In addition, increases in bocaccio limits relative to Option 1 are not expected to have any additional impact on overfished species mortality, because bocaccio are incidentally caught while fixed gear fishermen are targeting other higher-valued species (i.e., sablefish). Fishing effort and fishing behavior (i.e., selection of fishing locations) are not expected to change due to bocaccio trip limit increases. Therefore, overfished species impacts are not expected to change.

Mortality of Rougheye, Blackspotted, and Shortraker Rockfish
Same as No Action Option 1: no impacts expected.

Impacts to Industry

Higher trip limits for bocaccio may convert discards into retained fish, thus increasing landings, resulting in increased ex-vessel value, although the amount is difficult to quantify. Changes as a result of this action may not have a large effect on the sectors as a whole, but could be of importance to some individuals in each sector.

B.9.3 Minor Shelf Rockfish Complex South of 34°27' North Latitude Management Measures

Although the shelf rockfish complex is managed as a single stock south of 40°10´ N. latitude, trip limit options analyzed herein are for the management area south of 34°27' N. latitude. For 2013-14 California groundfish fisheries, the minor shelf rockfish complex south of 40°10´ N. latitude has been managed to sector specific allocations (i.e. trawl, 12.2% and non-trawl, 87.8%). Shelf rockfish are not formally allocated within non-trawl sectors, that is, the non-trawl commercial LE and OA sectors, as well as the recreational sector, share the non-trawl allocation. The non-trawl allocation south of 40°10´ N. latitude is expected to increase substantially from 615 mt in 2014 to 1,383.2 mt in 2015 and 1,384.0 mt in 2016 at a P* = 0.45 (Table B-59). At P* = 0.25, the 2015 and 2016 allocations would be 659.7 mt for both years. Based on an industry request, the Council requested analysis of higher trip limits for LE and OA sectors south of 34°27' N. latitude. The 2014 commercial management measures for shelf rockfish south of 34°27' N. latitude are described in Table B-58.

Table B-58. Shelf rockfish management measures for the 2014 commercial groundfish fisheries, south of 34°27' N. latitude.

Fishery	
Commercial	Sorting requirement for all commercial landings
Limited Entry Trawl	Managed under IFQ
Limited Entry Fixed Gear	Bi-monthly limit management. Current limits south of 34°27' N. latitude are: Period 1: *"3,000 lb/2 months*" Period 2: Closed Period 3: *"3,000 lb/2 months*" Periods 4-6: *"4,000 lb/2 months"* Bi-monthly limits can be adjusted through routine in-season action.
Open Access	Bi-monthly limit management. Current limits south of 34°27' N. latitude are: Period 1: *"750 lb/2 months"* Period 2: Closed Period 3: *"750 lb/2 months"* Periods 4-6: *"1,000 lb/2 months"* Bi-monthly limits can be adjusted through routine in-season action.

2015-2016 Management Considerations

Participation in the fixed gear shelf rockfish fishery south of 34°27' N. latitude is limited, with fewer than 30 vessels operating in the OA sector and six vessels in the LE sector during 2011 and 2012. Total mortality estimates reported from WCGOP indicate that approximately 61 percent of the non-trawl allocation south of 40° 10′ N. latitude was attained in 2012 (Table B-58). If an intersector allocation (i.e. trawl, non-trawl allocations) had been in place in 2009 and 2010, attainment would have been approximately 47 and 31 percent in each year respectively, although the recreational sector accounts for the majority of the total estimated mortality (Table B-59). During the 2011-2012 management cycle, nine LE vessels that made shelf rockfish landings (100 percent of LE vessels making shelf rockfish landings) landed less than 20 percent of the theoretical maximum amount of shelf rockfish they could have landed. In the OA sector, 42 vessels (84 percent) landed less than 20 percent of their theoretical maximum amount. Data indicate that few participants attained greater than half of the allowable limit, averaging approximately 240 lb/2mo and 280 lb/2mo in the LE and OA fleets respectively during 2011 and 2012.

Table B-59. Total Mortality (in mt) in the minor shelf rockfish complex non-trawl fixed gear sector (LE and OA combined) south of 40°10' N. latitude from 2009-2012. (source: WCGOP)

Year	Commercial (non-trawl)	Recreational	Non-Trawl Allocation	% Non-trawl Allocation
2009	8.3	246	615	41%
2010	14.2	212	615	37%
2011	19.9	326	615	53%
2012	23.1	354	615	61%

Management Options

Option 1-No Action: No increase to trip limits for shelf rockfish south of 34°27' N. latitude: Under Option 1, the 2014 trip limits would remain in place for both LE and OA sectors.

Option 2a: Increase trip limits for LE and OA sectors south of 34°27' N. latitude: Under Option 2a, increased, compared to Option 1, were investigated (Table B-61).

Option 2b: Further increase trip limits for LE and OA sectors south of 34°27' N latitude: Under Option 2b moderate trip increases, compared to Option 2a, are explored (Table B-61).

Biological Impacts Under Option 1

Projected Impacts

Under No Action, projected mortality for minor shelf rockfish south of 34°27' N. latitude is 3.9 mt and 14.3 mt for the LE and OA sectors, respectively (Table B-60); between 40° 10' N. and 34° 27' N. latitude, average landings during 2011 and 2012 were 16.1 mt for both sectors combined. Assuming that take in the recreational fishery south of 40° 10' N. latitude is unchanged from 2012 (354 mt; WCGOP Groundfish Mortality Report, 2012); projected mortality of shelf rockfish south of 40° 10' N. latitude is 387 mt. This represents 28 percent of 2015 allocation of 1,383.2 mt under P* of 0.45, and 58.7 percent of the 2015 allocation of 659.7 mt under P* of 0.25. For 2016, this represents 28 percent of the 2016 allocation of 1,384.0 mt under P* of 0.45, and 58.7 percent of the 2016 allocation of 659.7 mt under P* = 0.25.

Table B-60. Summary of commercial minor shelf rockfish landings south of 40° 10' N. latitude (by sector) under No Action.

Area	Limited Entry	Open Access
40° 10' to 34° 27' N. lat.	16.1	
South of 34° 27' N. lat.	3.9	14.3
Total	34.3	

Stock Status

The minor shelf rockfish complex south of 40° 10' N. latitude is comprised mainly of unassessed stocks, with the exception of greenspotted rockfish and greenstriped rockfish. The greenspotted rockfish assessment indicated the stock is in the precautionary zone; greenstriped rockfish was considered healthy. Greenspotted rockfish have shown a substantial increase in biomass since the RCAs were implemented in 2003 (2013-2014 FEIS). Given that shelf rockfish are particularly well protected by the RCAs, the shelf rockfish ACL is expected to increase in 2015-16, and only 31-67 percent of the non-trawl allocation has been caught during recent years (Table B-59), no changes to stock status are expected under No Action.

Overfished Species Mortality

Under the No Action Option, there is no anticipated increase to the mortality of OFS.

Mortality of Rougheye, Blackspotted, and Shortraker Rockfish

Other species are encountered by non-nearshore fixed gear fisheries, which also catch minor shelf rockfishes. However, this is not the case for rougheye, blackspotted, and shortraker rockfish if we use the 2011 and 2012 mortality amounts as examples. During these years, no recorded landings of these three species of rockfish were made when landings of minor shelf rockfish were made. This is due primarily to the fact that these three species are infrequently taken south of 40°10' N. latitude.

Options 2a and b: Increase trip limits for LE and OA sectors south of 34° 27' N. latitude

Under Option 2, increased bi-monthly trip limits south of 34° 27' N. latitude were investigated, which may afford greater opportunity under the increased non-trawl allocation.

Individual vessel landings reported in PacFIN from 2011-2012 for LE and OA sectors were used to analyze catch limits by the fleet. Although the allocation for the minor shelf rockfish complex applies to the entire area south of 40° 10' N. latitude, only modifications to trip limits south of 34° 27' N. latitude were investigated (i.e. trip limits between 40° 10' and 34° 27' N. latitude were status quo). For analytical and managerial ease, bi-monthly limits are assumed the same in each period. The years 2011 and 2012 were ultimately chosen as the basis for this model because they may be representative of current and future fishing behavior. Average commercial landings between 40° 10' and 34° 27' N. latitude during this time period and the 2012 recreational total mortality reported by WCGOP for the area south of 40° 10' N. latitude were added to the analytical options to project mortality for the entire area south of 40° 10' N. latitude.

Limited Entry Bi-Monthly Trip Limit Options
The LE bi-monthly trip limit options for minor shelf rockfish complex south of 34° 27' N. latitude are shown in Table B-61. These options range from 4,000 lb/2 months (Option 2a) to 5,000 lb/2 months (Option 2b). In recent years the majority of vessels have taken less than half of the maximum trip limit during any given period. The proposed trip limit increases apply only to the existing open periods.

Open Access Bi-Monthly Trip Limit Options
The OA bi-monthly trip limit options for minor shelf rockfish complex south of 34° 27' N. latitude are shown in Table B-61. These options range from 1,500 lb/2 months (Option 2a) to 2,500 lb/2 months (Option 2b). Although no effort shift occurred during previous inseason actions, participation in the OA sector has traditionally been more unpredictable than LE, making it difficult to predict catch and fleet behavior; therefore it is possible that projected landings (Table B-61) could be higher than expected if the trip limit is increased sufficiently enough to encourage entry into the fishery by new participants.

Projected landings under each Option for the LE and OA sectors are provided (Table B-61). These Options are not mutually exclusive, that is, the Council could recommend a different option for each sector.

Table B-61. Comparison of minor shelf rockfish projected landings south of 40o 10′ N. latitude in the LE and OA sectors under No Action (Option 1), and two options with trip limit increases (Options 2a and 2b) to the 2015 and 2016 HGs under P*=0.45 (1,282.2 mt and 1,383.0 mt respectively) and the 2015 and 2016 HGs under P*=0.25 (659.7 mt). . Projected landings between 40° 10' and 34° 27' N. latitude are based on average landings during 2011-2012. (Note: recreational catch were derived from the 2012 WCGOP Groundfish Mortality Report.)

	P*=0.45 (2015 allocation = 1,382.2 mt and 2016 allocation = 1,384.0 mt)								
	Limited Entry S. 34° 27' N. lat.		Open Access S. 34° 27' N. lat.		Projected Landings 40° 10' -34° 27' N. lat	Projected Recreational Catch	Total	% of Non-trawl Allocation	
Option	Trip limit	Projected Landings	Trip limit	Projected Landings				2015	2016
Opt. 1	3,000	3.9	750	14.3	16.1	354	387	28%	28%
Opt. 2a	4,000	4.3	1,500	24.0	16.1	354	399	29%	29%
Opt. 2b	5,000	5.4	2,500	39.9	16.4	354	416	30%	20%

	P*=0.25 (2015 and 2016 allocations = 659.7 mt)							
	Limited Entry S. 34° 27' N. lat.		Open Access S. 34° 27' N. lat.		Projected Landings 40° 10' -34° 27' N. lat	Projected Recreational Catch	Total	% of Non-trawl Allocations
Option	Trip limit	Projected Landings	Trip limit	Projected Landings				
Opt. 1	3,000	3.9	750	14.3	16.1	354	387	58.7%
Opt. 2a	4,000	4.3	1,500	24.0	16.1	354	399	60.5%
Opt. 2b	5,000	5.4	2,500	39.9	16.4	354	416	63.1%

Biological Impacts

Projected Mortality

Under Option 2a, landings are projected to increase approximately 10 percent (0.4 mt) and 68 percent (9.7 mt) in the LE and OA sectors respectively compared to No Action (Option 1; Table B-61). Under Option 2b projected landings are expected to increase by 38 percent (1.5 mt) in the LE sector and 179 percent (25.6 mt) in the OA sector compared to No Action. Similar to Option 1, mortality of shelf rockfish south of 40° 10' N. latitude is projected to be well below the non-trawl allocation (Table B-61).

Stock Status

Similar to Option 1, no changes to stock status are expected as a result of this action. The increase in projected landings will keep mortality well within the non-trawl allocation (Table B-61) and no changes to the current RCAs structure have been proposed (i.e. the RCA protections afforded under option 1 will remain in place).

Overfished Species Mortality

There may be a small increase in the bycatch of OFS, but at present, no quantifiable method has been explored to determine how much this may be. Any increase in trip limit is expected to increase fishing effort for shelf rockfish species. Likewise, increased catch of overfished species would likely occur. The amount of the increase is uncertain and cannot be estimated at this time. This could be an issue that would affect more the OA sector since this fishery is open-ended compared to the LE sector. It is difficult to estimate how many new participants that could enter the fishery as a result of increased trip limits, and thus the extent of increased OFS mortality.

Mortality of Rougheye, Blackspotted, and Shortraker Rockfish
Same as Option 1.

Impacts to Industry
Higher trip limits could increase harvest given the sizeable increase in the non-trawl allocation; although difficult to quantify, increased ex-vessel value could be expected as a result. Given the relative size of the fleet, changes as a result of this action may not have a large effect on the sectors as a whole, but could be of importance to some individuals in each sector.

B.10 Non-Trawl: Coastwide Sablefish Trip Limits

Need for Action
This section discusses projected landings and associated cumulative landing limits ("trip limits") for the four fixed gear sablefish, daily trip limit (DTL) fisheries. They include limited entry (LE) and open access (OA) fisheries, north and south of 36° North latitude. Hereafter, they will be referred to as follows: LE North, LE South, OA North, and OA South. The two northern fixed gear sablefish DTL fisheries account for approximately 13.5 percent of the northern sablefish ACL, while the southern ones account for approximately 58 percent of the southern ACL (during 2015, under the Preferred Alternative).

Proposed trip limits for 2015 and 2016 in these fisheries were produced GMT landing forecast models (described briefly below, and in detail in the 2011-2012 Groundfish Harvest Specifications Environmental Impact Statement; EIS).

While the tables show trip limits in this section as simply bimonthly, weekly, or daily, it is worth noting that the language in regulation applies each limit in a specific way when there is a mix of limits for the different time periods, within one fishery. This is the case for the two open access sablefish DTL fisheries. For example, the limits in regulation under No Action for the OA North fishery read as follows: "300 lb. per day or one landing per week of up to 800 lb., not to exceed 1,600 lb. per two months".

Analytical description
The purposes of this analysis are to produce and compare trip limits and predicted landings between the No Action Alternative and the other alternatives, for the four fixed gear, sablefish DTL fisheries. The ACLs, regional allocations, harvest guidelines and fishery landed shares vary among the alternatives.

Proposed trip limits under the alternatives for 2015 and 2016 were produced with the objective of keeping projected catch within the proposed management targets, which resulted from different values of the sablefish P-star (P*) and corresponding ACL, harvest guidelines, and shares for the areas north and south of 36° N. latitude. Forecasted landings under the action alternatives were intentionally constrained to between 90 and 95 percent of the landings share for each fishery, in order to produce trip limits which are likely to result in high attainment of the harvest guideline, while maintaining a sufficiently precautionary remainder; one that is appropriate for the uncertainty associated with use of the forecast models, and the accuracy of the estimated landings data used as model inputs. This strategy has been used over the past several years in inseason management, in the 2013-14 Groundfish Harvest Specifications EIS, and most recently in establishing trip limits for 2014, at the November, 2013 meeting of the Pacific Fishery Management Council (PFMC). These annual trip limit schedules can be adjusted through the inseason process as early as the preceding November meeting of the PFMC, as well as throughout the year, in order to account for updated data, or changes in science or policy.

Model description

The catch projection models used in this analysis are multiple linear regression models that relate trip limits and other predictor variables to bimonthly or monthly landings, separately for each fishery. They are also used for inseason management. Detailed descriptions of the models can be found in Appendix A. of the 2011-2012 harvest specifications EIS. Models were originally produced by members of the GMT, Oregon Department of Fish and Wildlife (ODFW), National Oceanic and Atmospheric Administration (NOAA) Southwest Fisheries Science Center (SWFSC) and Northwest Fisheries Science Center (NWFSC) in 2006 (limited entry) and 2009 (open access). Changes in model specification are made as needed over time, to increase accuracy of projections where possible. Changes since the 2013-14 harvest specifications include: Limited entry models were translated from SAS to R. In the LE North model, sablefish ex-vessel price (adjusted for inflation) was added as a predictor, separate regressions were carried out for each bimonthly period, and landings were predicted similarly to the open access models, where predicted landings equals predicted number of vessels participating, times the average landed catch per bimonthly period. The Producer Price Index from the U.S. Bureau of Labor Statistics for “fresh and frozen seafood” was used to deflate the time series of ex-vessel prices in the LE North model. New landings data through 2012 were added to all four models. The time range of data included in each model varies between from 2004-2012, to 2007-2012, depending on its information content for making projections. Accuracy of prediction varies among the four models. Of the four, the best fit of predicted to actual, bimonthly landings is produced by the LE North model, with an R^2 value of 0.956. Under the most recent data, the worst fit between predicted and actual landings comes from the LE South model, with an R^2 value of 0.528. We are still able to manage the LE South DTL fishery to a high level of attainment through inseason management and close tracking of data throughout the year, in spite of the relatively low model fit seen under the current data.

Model input data

Landings and catch data were acquired from PacFIN using the query “slct_ves_sabl_arid_DTL_tab_no_EFP.sql”. This query pulls vessel-daily landings data from tables that separate fixed gear, sablefish DTL landings from sablefish primary landings, on a vessel-daily basis, using software and an algorithm and developed by PacFIN and NWR staff in 2010 and 2011. For the LE North fishery, the software tracks landings accumulation by vessel, against their sablefish endorsed tier permits. If the vessel has active sablefish endorsed primary tier permits attached, the season is open, and there is room on the attached permits, landings are counted as primary. When either the tier permits on the vessel are exhausted, or the season ends, landings are then counted as DTL. The algorithm in the software adheres to the specific federal regulations concerning primary and DTL landings in 50 CFR 660.232.

Accounting for discards and discard mortality

Harvest guidelines applicable the sablefish DTL fisheries were reduced in order to account for discard mortality, which resulted in landed shares for use in projection modeling to predict landings, and determine necessary trip limits. A harvest guideline is defined as numerical management harvest objective which is not a quota. These are either cited in regulation or calculated from other higher level numerical management objectives appearing in regulation.

The applicable harvest guideline was multiplied by 16.6 percent (discard rate estimate), and by 20 percent (discard mortality rate estimate). Then that product (estimated dead discarded sablefish) was subtracted from the harvest guideline, resulting in a “landed share”, which projected landings should be beneath, in order to keep total catch within the harvest guideline. The estimated discard rate used by GMT was taken from the report “Estimated Discard and Catch of Groundfish Species in the 2012 US West Coast Fisheries”, by the West Coast Groundfish Observer Program, of the NWFSC. The discard mortality rate estimate was taken from information in Davis (2001, LTtp://onlinelibrary.wiley.com/doi/10.1111/j.1095-8649.2001.tb00495.x/abstract), Shirrippa and Colbert (2005, LTtp://www.pcouncil.org/wp-content/uploads/Sable05_complete.pdf), and Shirrippa (2007, LTtp://www.pcouncil.org/wp-content/uploads/Sable07v3_0.pdf). Shirrippa (2005) used experimental data and sea surface temperature to predict varying release mortality by gear. The GMT considered that Davis (2001) demonstrated high sensitivity to temperature and deck time, along with high variability of predicted discard mortality in Shirrippa (2005) informed by sea surface temperature data, and adopted an estimate of 20 percent. This value was also adopted by Taylor 2011 in the current sablefish stock assessment.

Values for landed shares among the alternatives

Landed share values for each of the DTL fisheries are shown by year, fishery and alternative below in Table B-62 and Figure B-24.

Table B-62. Landed shares for each of the fixed gear sablefish, DTL fisheries, used for making projections, under each of the alternatives.

	LE N	OA N	LE S	OA S
No Action 2014	214	319	483	393
Preferred Alternative 2015	236	388	531	432
Preferred Alternative 2016	258	425	581	472
Alt. 1 2015	247	406	555	451
Alt. 1 2016	269	443	606	492
Alt. 2 2015	202	333	455	370
Alt. 2 2016	223	367	503	409

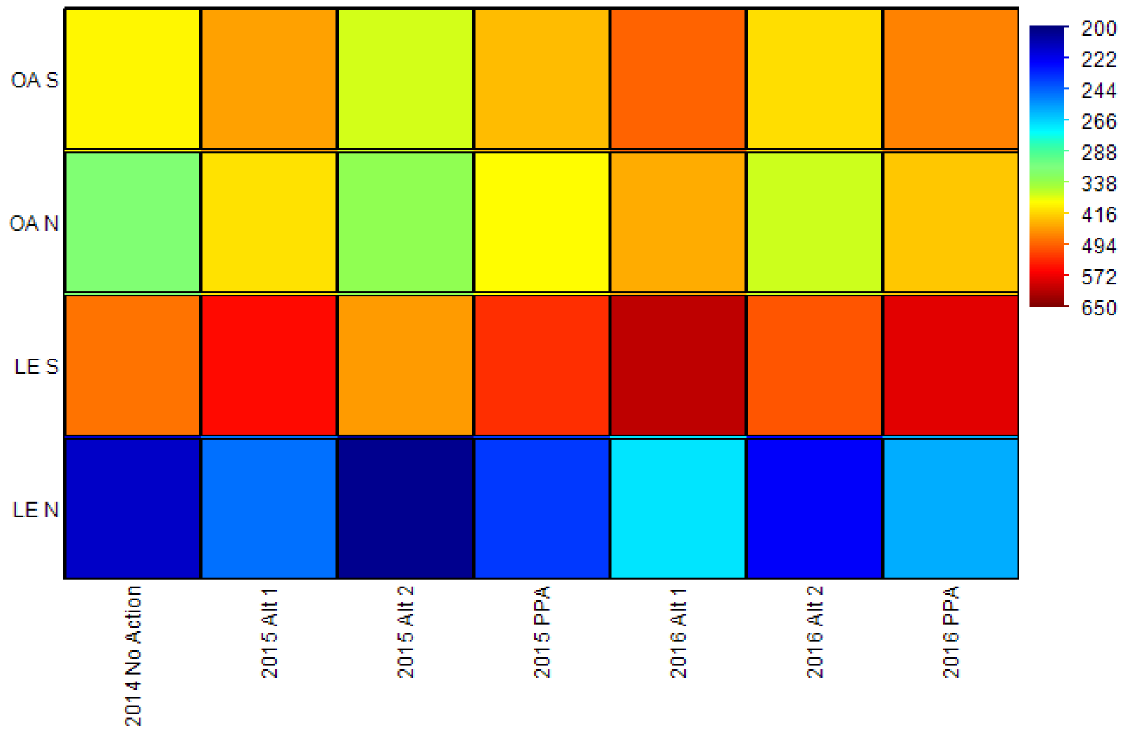

Figure B-24. Heatmap showing variation in potential landed shares used for making projections, for each of the fixed gear sablefish DTL fisheries, under each of the alternatives.

B.10.1 No Action Alternative

Area restrictions

Under No Action, the following RCA boundaries for use of fixed gear, from 2014 regulations, would remain in place for 2015 and 2016 (Table B-63, from Table 2 North, and South, to Part 660, Subpart E, Codified Federal Regulations).

Table B-63. Rockfish Conservation Area (RCA) boundaries for fixed gear, under the No Action Alternative.

Area	Jan-Feb	Mar-Apr	May-Jun	Jul-Aug	Sep-Oct	Nov-Dec
North of 46° 16'	shoreline - 100 fm line					
42° - 46° 16’	30 fm line - 100 fm line					
40° 10’ - 42°	20 fm depth contour - 100 fm					
34° 27’ - 40° 10’	30 fm - 150 fm line

Trip limits and projected impacts under No Action

The No Action trip limit structures for 2014 in each fishery are presented in Table B-64. The No Action Alternative resulted in projected attainments ranging between 71 and 99 percent, using the best available data, and 2014 trip limits set in the November, 2013 council meeting (Table B-65). The aim throughout all the alternatives was to enable harvest of a high proportion of the landed share, yet accommodate uncertainty. The GMT and the Council considered, while constructing and adopting them, respectively, the uncertainty in the landings data (in terms of correctly separating sablefish DTL fishery landings from those of the sablefish primary fishery, and IFQ landings) along with uncertainty associated with making model-based projections.

These trip limits can be adjusted as needed inseason, to influence higher or lower catch as the year progresses. We strove to produce trip limits with a predictable and temporally uniform structure, which was appreciated by the GAP in their statement at the November 2011 council meeting, and subsequent meetings.

Table B-64. Trip limits for sablefish DTL fisheries under the No Action Alternative (2014).

Fleet	Area	Bimonthly limit	Weekly limit	Daily limit
LE	**N**	2,850	950	NA
OA	**N**	1,600	800	300
LE	**S**	NA	2,000	NA
OA	**S**	3,200	1,600	300

Projected attainment values for the four sablefish DTL fisheries under the No Action Alternative are within the range generally recommended by the Council, of between 90 and 95 percent, with the exception of the OA North fishery, which has a projected attainment of 99 percent, and the OA South fishery, which has been maintained at a lower level in recent years, partially to allow some buffer for the LE South fishery (Table B-65). The reason for the higher than usual projected attainment in the OA North fishery under Alternative 1 is that actual landings have been running much lower than projected for the past two years, under recent poor sablefish market conditions.

Table B-65. Model-projected landings under the No Action Alternative, for the fixed-gear, sablefish DTL fisheries. Landed shares and projected impacts are in metric tons (mt) of landed catch.

No Action	LE N	OA N	LE S	OA S	South sum
Projected landings	204.4	316.7	437.8	279.7	717.5
Landed share	214	319	483	393	876.0
Percent attainment	95%	99%	91%	71%	82%
Difference	9.6	2.3	45.2	113.3	158.5

B.10.2 Preferred Alternative – Sablefish Trip Limits

Preferred Alternative for 2015

Trip limits and projected impacts under the Preferred Alternative for 2015

The trip limit structures for each fishery in 2015 under Preferred Alternative are presented in Table B-66. Differences between Preferred Alternative and No Action limits also appear in the table. Trip limits are generally higher under Preferred Alternative than for No Action. Higher limits were needed to influence similar attainment, under the higher shares. Differences range from 25 lb per week smaller for the OA South, to 225 lb per two months higher in the LE North fishery.

Table B-66. Trip limits under the Preferred Alternative, No Action Alternative, and comparison between them, for the fixed-gear, sablefish, DTL fisheries for 2015. Limits are in lb of landed catch per time period listed.

		2015 Preferred			**No Action**			**Difference**		
fleet	area	bimo	week	day	bimo	week	day	bimo	week	day
LE	**N**	3,075	1,025	NA	2,850	950	NA	225	75	NA
OA	**N**	1,800	900	300	1,600	800	300	200	100	0
LE	**S**	NA	2,100	NA	NA	2,000	NA	NA	100	NA
OA	**S**	3,200	1,575	315	3,200	1,600	300	0	-25	15

Projected landings, attainment and remainder in 2015, under the Preferred Alternative are presented in Table B-67. The same metrics are also presented for the No Action Alternative, and the differences between these two alternatives, in the table.

Attainment rates are very similar between the Preferred Alternative and No Action with the exception of the OA North fishery for reasons explained in No Action section; attainment rates are nearly equal for each fishery, among the action alternatives by design. The amount of landed catch projected is consistently higher under the Preferred Alternative than No Action; between 15.4 mt and 58.4 mt higher, due to the higher trip limits, produced to influence similar attainment under the higher landed shares of the Preferred Alternative.

Table B-67. Model-projected landings under the Preferred Alternative, No Action Alternative, and comparison between them, in the fixed-gear, sablefish, DTL fisheries for 2015. Landed shares and projected landings are in metric tons (mt).

2015 Preferred	**LE N**	**OA N**	**LE S**	**OA S**	**South sum**
Projected landings	219.7	358.3	496.3	310.2	806.4
Landed share	236	388	531	432	963.0
Percent attainment	93%	92%	93%	72%	84%
Remainder	16.3	29.7	34.7	121.8	156.6
No Action					
Projected landings	204.4	316.7	437.8	279.7	717.5

Percent attainment	-2%	-7%	3%	1%	2%
Remainder	6.6	27.4	-10.4	8.5	-1.9

Preferred Alternative for 2016

Trip limits and projected impacts under Preferred Alternative for 2016

The trip limit structures in 2016 under the Preferred Alternative for each fishery are presented in Table B-68. Differences between the Preferred Alternative and No Action limits also appear in the table. Trip limits are generally higher under the Preferred Alternative than for No Action. Higher limits were needed to influence similar attainment under the higher shares. Differences range from 25 lb per week higher for the OA South, to 525 lb per two months higher in the LE North fishery. The daily limit for the OA North fishery remains unchanged under all alternatives.

Table B-68. Trip limits under the Preferred Alternative, No Action Alternative, and comparison between them, for the fixed-gear, sablefish, DTL fisheries for 2016. Limits are in lb of landed catch per time period listed.

		2016 Preferred			**No Action**			**Difference**		
fleet	area	bimo	week	day	bimo	week	day	bimo	week	day
LE	**N**	3,375	1,125	NA	2,850	950	NA	525	175	NA
OA	**N**	2,000	1,000	300	1,600	800	300	400	200	0
LE	**S**	NA	2,175	NA	NA	2,000	NA	NA	175	NA
OA	**S**	3,250	1,625	325	3,200	1,600	300	50	25	25

Projected landings, attainment, and remainder under the Preferred Alternative are presented in Table B-69. The same values for the No Action Alternative are also presented in the table, and the differences between these two alternatives.

Attainment rates are very similar between the Preferred Alternative and No Action with the exception of the OA North fishery, for reasons explained in No Action section; attainment rates are nearly equal for each fishery, among the action alternatives by design. The amount of landed catch projected is consistently higher under the Preferred Alternative than No Action; between 36.7 mt and 105.5 mt higher, due to the higher trip limits produced in order to influence the same attainment under the higher landed shares of the Preferred Alternative.

Table B-69. Model-projected landings under the Preferred Alternative, No Action Alternative, and comparison between them, in the fixed-gear, sablefish, DTL fisheries for 2016. Landed shares and projected landings are in metric tons (mt).

2016 Preferred	LE N	OA N	LE S	OA S	South sum
Projected landings	241.0	402.5	543.3	344.2	887.5

B.11 Recreational: Canary Rockfish Sub-Bag Limit in Oregon Fisheries

Need for Action

Although the canary rockfish stock is a category 1 stock, some unresolved problems and uncertainties have been identified in the stock assessment. The current stock abundance is relatively uncertain. In part this is because the only measure of relative abundance does not occur in the primary habitat (rocky reef) of canary, and many other, rockfish. Future stock abundances are also uncertain because the bottom trawl survey primarily catches very large (and old) canary rockfish, which means recruitment events (of young individuals) are difficult to determine or verify. The last full assessment (Stewart 2009) indicated that historical and current relationship between canary rockfish distribution and habitat features should be investigated to provide more precise estimates of abundance from the surveys, and to guide survey augmentations that could better track rebuilding through targeted application of newly developed survey technologies.

Uncertainties of the current and future abundance of the canary rockfish stock could be improved if recreational groundfish fishery data were available. The recreational fishery occurs almost entirely over rocky reef habitats, therefore the recreational fishery catch rates could be used to provide an index of relative abundance (catch per unit effort; CPUE) of canary rockfish from their primary habitat. Additionally, since recreational fishery gears catch smaller and younger canary rockfish than trawls, biological data from the recreational fishery could be used to better detect recruitment events needed to better track rebuilding.

For recreational fishery catch to aid in the data used for future canary rockfish stock assessments, retention of canary rockfish would have to be permitted. Since anglers are currently required to discard all canary rockfish catch, biological samples are currently obtained from infrequent illegal landings. The number of canary rockfish reported to have been discarded by anglers is too uncertain to be used as a CPUE index in an assessment. Allowing retention so dockside creel samplers can verify the species and collect and biological samples could address some of the stock assessment uncertainty.

Determine or verify future canary rockfish abundances (recruitment)
Since there is a large gap in sizes and ages of canary rockfish caught by trawl surveys used in the assessment, it takes at least ten years to verify recruitment signals using NWFSC bottom trawl survey data alone; the SWFSC pre-recruit pelagic trawl survey catches Age-0 fish and the NWFSC bottom trawl survey is selective for 40-50 cm fish (based on peak of length frequency distributions), which roughly corresponds to females Age-10 and older (Wallace and Cope 2011).

Since recreational gears are selective for intermediate size and age fish relative to the trawl surveys (> 30 cm; Figure B-25), recruitment signals from the pre-recruit survey could be verified in as few as three to five years (corresponding ages for 30 cm females) by using biological data from the recreational fishery (instead of ten years for the bottom trawl).

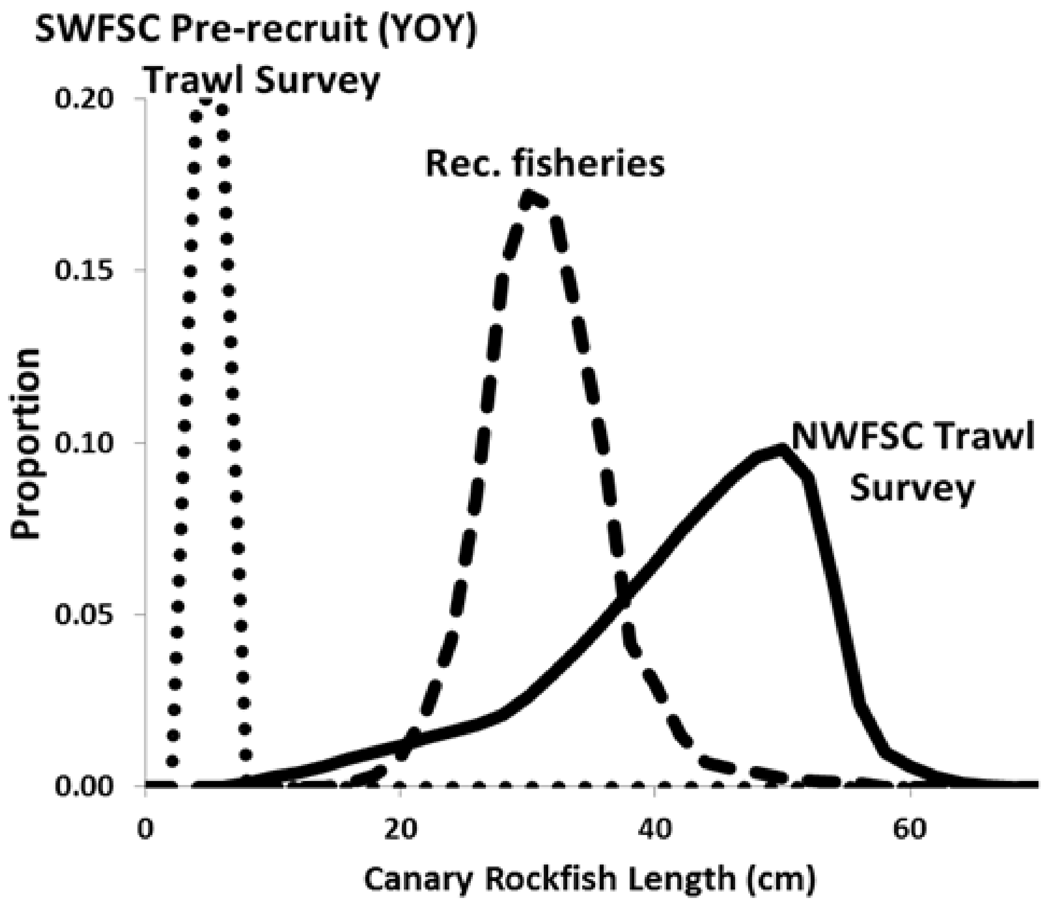

Figure B-25 Canary rockfish length frequency comparison for the trawl surveys and the recreational fisheries. NFWSC curve is an approximation for combined sexes from 2003-2010, from Figure 11 of the Canary rockfish assessment (Wallace and Cope 2011). Recreational data from RecFIN query, 2006-2013; OR, WA, and CA (pooled due to infrequency of (illegal) catches).

Increase accuracy of removals
Allowing retention of canary rockfish in the recreational fisheries could improve the accuracy of canary rockfish removal estimates because catches could then be landed and verified by dockside creel samplers. In contrast, anglers are currently required to discard all canary rockfish encountered, and angler reported

data is consequently needed to determine discard mortality. Potential sources of uncertainty in discard mortality estimates from angler reported data include: (1) misidentification of the species discarded (2) misreporting of the quantity released and (3) misreporting of the factors that affect which discard mortality rate will be applied to their discards (i.e., depth of capture and if a descending device was used).

Allowing retention of canary rockfish may be a cost-effective and, viable solution to improving removal estimates. For example, it would be impractical and unsafe to require small private recreational boats (generally less than 22 feet) to carry observers to monitor discards.

Though canary rockfish has a coastwide OFL and ACL, each state's recreational fishery has its own HG. And each of the West Coast states manages their recreational groundfish fishery independently of each other (e.g. season length, bag limits) to stay within their HG. Therefore analysis of allowing canary rockfish retention was completed on a state by state basis. Under the Preferred Alternative, canary retention was selected only for the Oregon recreational fisheries. As such, the description of the Preferred Alternative is described below whereas the analysis for Washington and Oregon is contained in the Considered but Rejected for Implementation Section, B.20.

Management options

Status Quo**:** Retention of canary rockfish will remain prohibited in the Oregon recreational fisheries.

Option 1**:** One canary rockfish per day, which will be a sub-bag limit of the miscellaneous groundfish daily bag limit of ten (includes rockfish, cabezon, greenlings, elasmobranchs) in the Oregon recreational fisheries.

Option 2**:** Up to ten canary rockfish per day, as part of the federal miscellaneous groundfish daily bag limit, may be reduced under state regulations (currently seven fish) in the Oregon recreational fisheries.

Abundance index of canary rockfish from their primary habitat (rocky reef)off of Oregon
Currently, the only index of relative abundance used in the canary rockfish stock assessment (for adults), the NWFSC bottom trawl survey, occurs in marginal habitat utilized by the species (i.e., sand or flat bottom; Love 2002; Johnson et al. 2003) and does not appear to be detecting a possibly increasing population trend occurring in their primary habitat (i.e., rocky reef). Since 2008 catch frequencies on Oregon recreational groundfish trips, which occurs over rocky reef in all depths, have increased while they have remained stable for trawl survey tows (Figure B-26).

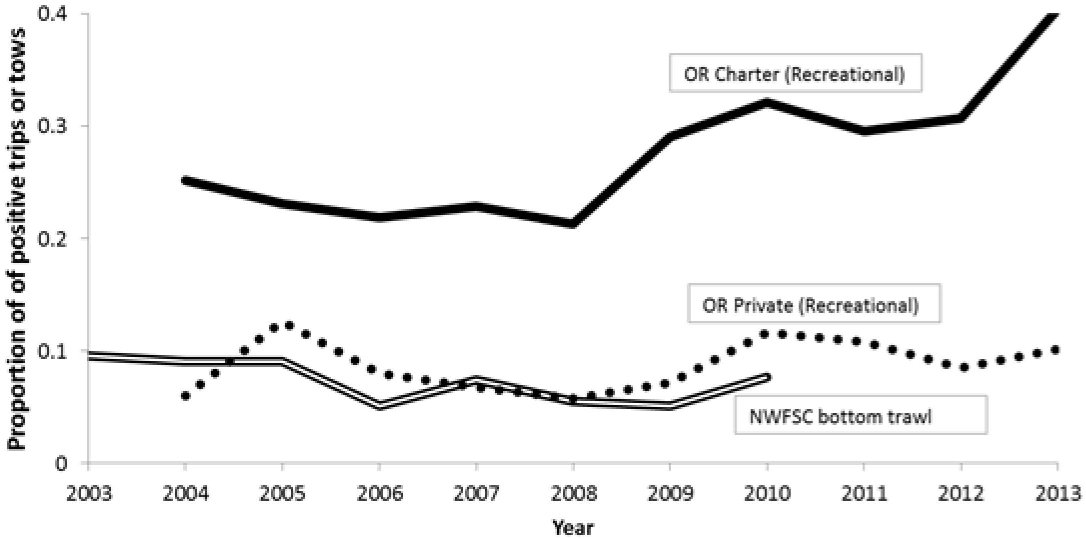

Figure B-26. Comparison of canary rockfish relative abundances from marginal habitat (sand and flat bottom; NWSFC bottom trawl survey) and primary habitat (rocky reef; OR charter and OR recreational groundfish fisheries).

Although the Oregon recreational groundfish fishery provides a measure of relative abundance of canary rockfish in their primary habitat, it has not been used as an index in assessments because it is based on uncertain data (David Sampson, Oregon State University, personal communication). If this uncertainty were resolved by allowing retention of canary rockfish (catches would be landed and verified by creel samplers), then a recreational index of abundance could potentially be incorporated into the canary rockfish assessment, in a similar fashion as used in the black rockfish assessment (logistic regression; Sampson 2007).

There would be minimal to no additional costs to management to develop a recreational CPUE index of abundance for canary rockfish, as the marine recreational creel survey already obtains the necessary data (assuming retention was allowed) for catch and effort accounting. Further, a recreational canary rockfish index of abundance would be robust due to high sample sizes (~9,000-10,000 recreational groundfish interviews per year), year-round coverage, and fine spatial data (i.e., by depth and reef quadrant). Given this wide-scale temporal and fine spatial coverage, it may be possible to apply a post-hoc survey design to the data (e.g., randomly selecting 100 samples from each reef area by a time period).

In order for a recreational canary rockfish catch per unit effort (CPUE) index to be indicative of population trends (and therefore useful to the assessment), fishing behavior would have to be relatively standardized (e.g., would be difficult to determine population trends if some targeted canary rockfish while others did not). By limiting the canary rockfish to one per angler per day, there would less incentive for anglers to target them, and a relatively standardized fishing behavior would be expected (harvests would be from incidental catches). Additionally, post-hoc methods could be used to standardize fishing behavior by limiting catch rate comparison to similar locations (reef block and depth), times, boat types (charter or private), and even by individual vessels (sample data contains unique vessel information; name of boat for charters and registration number for private boats).

No increase to the projected rebuilding time

The Oregon recreational fishery is projected to remain within the most recent canary rockfish HG (11.1 mt in 2014) for all canary rockfish harvest alternatives (Table B-70), and by doing so, no delays to the projected rebuilding time would occur (assume full attainment of ACLs). The projected difference in mortality between non-retention (3.1 mt; bag limit=0) and a one fish sub-bag limit (8.1 mt) is attributed to the infrequency of canary rockfish catches by recreational anglers. Since 2009, 73 percent (13,536 of 18,703) of canary rockfish caught by recreational anglers has been from trips where the number of anglers outnumbered the canary rockfish catch (Figure B-27). Accordingly, all of those canary rockfish would have been legal to harvest had the bag limit been one. And had they kept their catch, the discarded mortality impacts from released fish would have been greatly reduced (3.0 mt vs. 0.8 mt, respectively), since their discarded dead catch would have been converted to harvested dead catch.

Since most of the catch comes from trips where anglers catch fewer than one canary rockfish per person, an increase in the bag limit from one to seven[14] (8.1 mt vs. 9.5 mt, respectively) is projected to have much less effect on mortality (Table B-70); only 24 percent (4,548 of 18,703) of past canary rockfish catch has been from trips where anglers caught greater than one but less than or equal to seven canary rockfish (Figure B-27). A bag limit of seven would result in the conversion of near all discarded catch to harvested, as 97 percent of canary rockfish caught by recreational anglers have been from those who caught seven of fewer. The only remaining discards would come from the very infrequent large volume catches 'lightning strikes'.

Projections of catch if retention were permitted are based on the assumption that no targeting would have occurred, as anglers did not have incentive to catch them in the past due to the harvest prohibition. While it is unrealistic to assume that no targeting will occur, targeting is expected to be minimal because canary rockfish catches are greater in deep depths (>30 fm; Figure B-28), and to maximize their catch rates, they would have to leave the shallower depths where the catch rates of their primary target species (black rockfish) and others are greatest. Further, the majority of recreational anglers tend to fish seaward of 30 fm (76 percent) when they are permitted to fish all-depths. In short, in order to target canary rockfish, they would be paying more in fuel, driving further, and leaving the most productive shallow depths.

Table B-70. Projected canary rockfish total (grey boxes), discard, and harvest mortality for each harvest option. Projected harvests (# of fish) are shown to demonstrate sample sizes of biological samples that may be attained by allowing retention. (The current bag limit of seven fish in Oregon state regulations was used for this analysis, rather than the ten fish bag limit in federal regulations)

		Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec	Total

[14] The current bag limit specified in Oregon state regulations, in federal regulations the bag limit is ten.

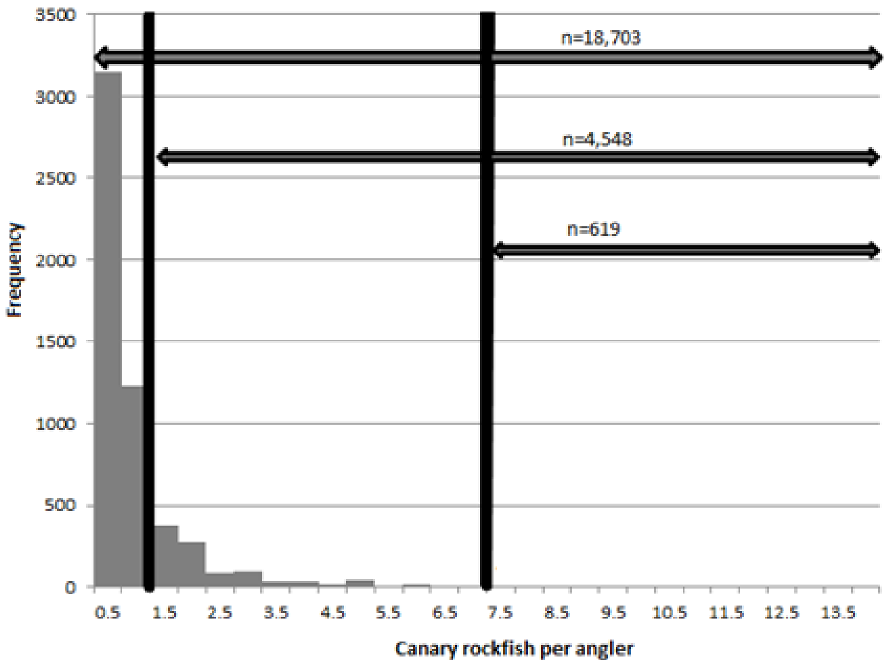

Figure B-27. Canary rockfish catch rate (bars) frequencies for trips that caught one or more and the corresponding quantity of canary rockfish associated with those trips (numbers by arrows), 2009-current.

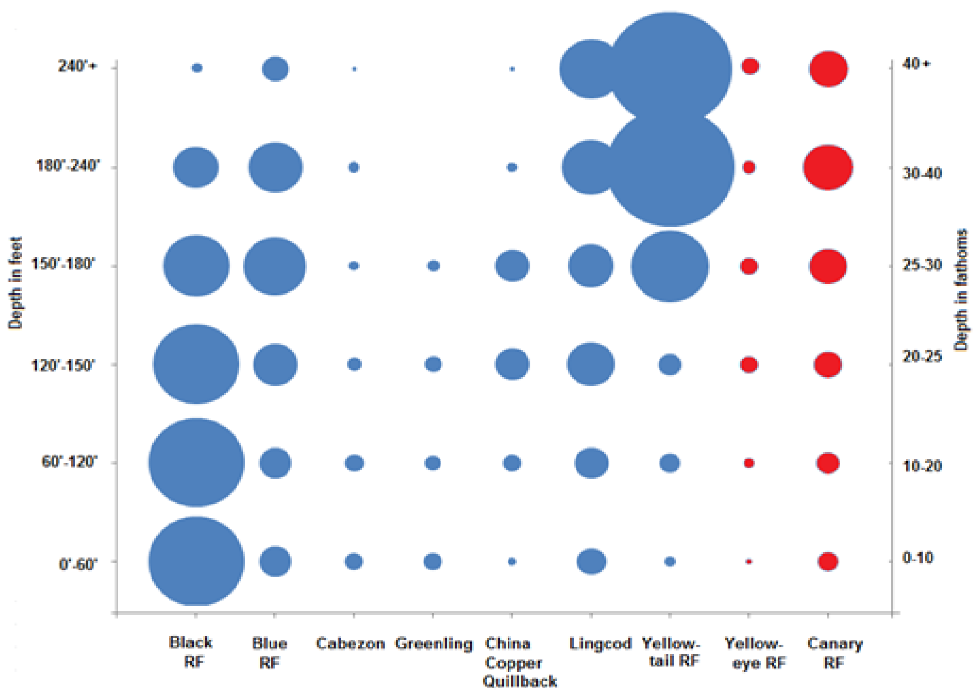

Figure B-28. Relative catch rates by depth of overfished species and harvestable species constituting the bulk of recreational fishery landings.

<u>Projection methods</u>

Canary rockfish mortality was projected for the harvest options via application of a conversion factor (Formula 1) to the output of the canary rockfish mortality model (of the Oregon recreational groundfish model). The conversion factor converted discarded catch of canary rockfish from historic trips to harvested catch up to the boat limit (aggregate of individual bag limits) and any catch in excess of the boat limit remained as discarded (retention was modeled at a boat level because anglers continue to fish and share their catch until the bag limits of all have been caught). For example, if the bag limit was one and seven anglers discard five canary rockfish, then five were converted to harvested (boat limit) and two remained as discarded (excess of boat limit).

Formula 1: Conversation factor applied to the canary rockfish mortality model to project mortality of canary rockfish if harvest (H) were permitted. M=Mortality; H=harvested (1 or 7); CR=Canary rockfish per angler.

$$M_{Baglimit(H)} = \text{Discard } M_{BagLimit=0}\left[\frac{\#Fish_{CR > Baglimit(H)}}{\#Fish_{Baglimit=0}}\right] + \#Fish_{Baglimit=0}\left[\frac{\#Fish_{CR \leq Baglimit(H)}}{\#Fish_{Baglimit=0}}\right]\left[\frac{\text{FishWeight (kg)}}{\text{.001 (kg to mt)}}\right]$$

Reduces discarded catch due to harvest | ***Converts discarded catch to harvest catch***

Reduce waste of the resource

As previously described in the projected impact section, allowing harvest converts discard mortality (waste) to harvest mortality. Instead of wasting 3.0 mt of canary rockfish by prohibiting retention, this could be reduce to 0.8 mt with a bag limit of one and 0.1 mt with a bag limit of seven (the current bag limit in Oregon state regulations). A sub-bag limit of one fish should prevent most targeting of canary rockfish, while allowing retention of those canary rockfish that are incidentally encountered. A bag limit of up to seven (state regulation) or ten (federal regulation) could change angler behavior, such as targeting areas of canary rockfish. Additionally, allowing retention of incidentally encountered canary rockfish could aid anglers in filling their bag with less time on the water.

Possible reduction of impact to healthy species

The following rationale has been proposed by anglers: canary rockfish are "abundant", and if allowed to keep one, impacts to other harvested groundfish species would be reduced by 14 percent; as anglers could substitute one of the seven fish they are allowed to catch (current bag limit) with a canary rockfish (thereby reducing impacts by $1/7^{th}$ or 14 percent).

This reduction *would only apply to trips in which both a bag limit attainment and catch of canary rockfish occurred*. Since limits only occur in less than 20 percent of trips (19.4 percent; 6,371 of 32,769 trips; Figure B-29) and canary rockfish are only caught during 13 percent of trips that had limited (828 of 6,371), the projected reduction in catch of harvestable species by allowing canary retention is only 0.3 percent (19.4 percent x 13 percent x 14 percent), not the hypothesized 14 percent. In short, the $1/7^{th}$ reduction in catch from allowing canary retention would only apply to the 2.5 percent of trips that limit and have canary rockfish catch.

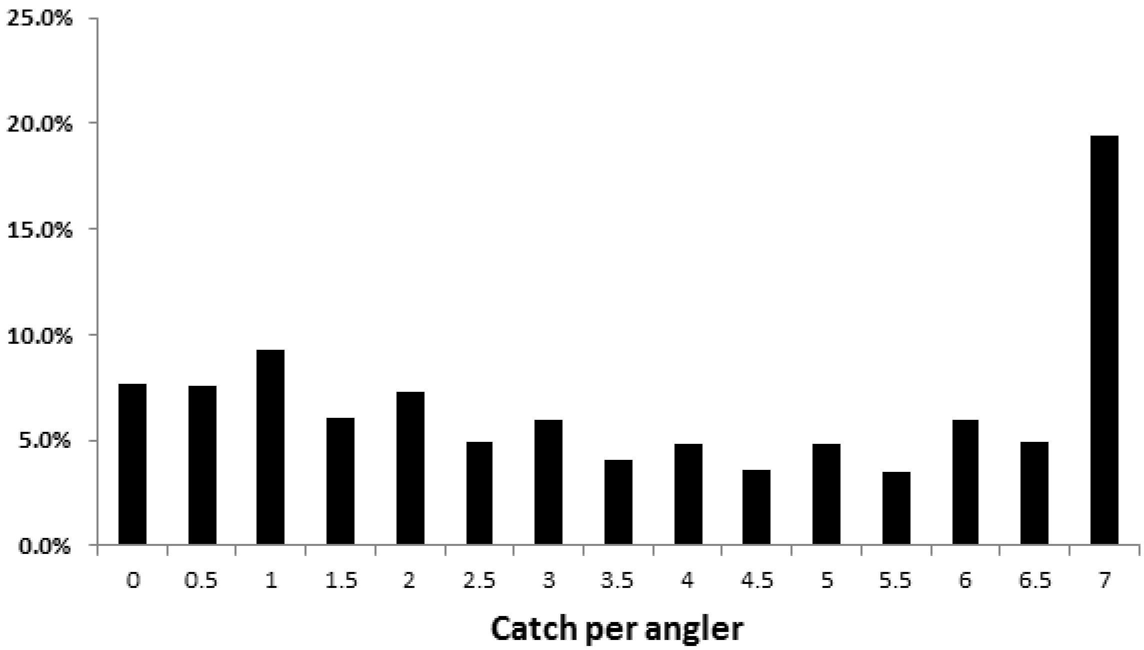

Figure B-29. Percentage of angler trips that caught 0-7 miscellaneous groundfish bag limit. Data is from 32,769 bottomfish trips that occurred from 2009-2013.

Discussion
The potential new recreational fishery data sources could be acquired without additional monetary costs (i.e., dockside creel survey needed to collect the data already exists) or delays to the projected rebuilding times of canary rockfish. No delays to the projected rebuilding times would be expected because the recreational fishery currently only obtains a fraction of the harvest guideline (e.g., 29 percent of the Oregon recreational HG in 2013) and could therefore continue to stay within the harvest guideline even if several thousand canary rockfish were landed (rebuilding analyses assume 100 percent of ACLs harvested).

In summary, allowing retention of canary rockfish in the recreational fishery could be a simple, cost-effective, and impact neutral (to projected rebuilding times) method to increase the understanding of canary rockfish, and therefore provide the Council better information to manage of one the most important groundfish stocks.

B.12 Retain groundfish, lingcod only, or flatfish only during the Pacific halibut fisheries

Need for Action
Recreational Pacific halibut anglers have expressed a desire to change the regulation that prohibits them from harvesting groundfish on “all-depth” days (while in possession of a halibut). Many anglers have stated that they travel 15-30 miles offshore for halibut and fish in waters 100 fm (600 feet) or greater. Going that far, they would like to be able to retain more than just one halibut (e.g. other species

incidentally encountered) Additionally, after reeling up a lingcod, or other bottomfish, from those depths they would like to be able to retain them, for their efforts. Anglers participating in the groundfish fishery are allowed to keep halibut incidentally encountered on days when the nearshore halibut fishery is open. The reasoning for the groundfish retention prohibition on "all-depth" days is unclear to anglers because it does not pertain to groundfish that can be harvested, but rather as a means to reduce discard (catch-and-release) mortality of overfished species, specifically yelloweye rockfish.

In order to keep yelloweye rockfish mortality within sector-specific limits, regulations to limit how often recreational anglers fish deep water reefs (>40 fm; 240 feet) are used as the primary management tool; anglers fishing deep reefs more commonly encounter yelloweye rockfish than those fishing shallower reefs, and a higher percentage of those released die due to barotrauma inflicted injuries. The additive effects of high catch rates and high discard mortality rates are too excessive to provide anglers much opportunity to fish deep water reefs, and still keep the groundfish fishery open year round.

Since groundfish anglers target reefs, depth restrictions are used to prevent groundfish anglers from fishing deep reefs during the greatest effort months (April-September). Halibut anglers are permitted to fish beyond the groundfish depth restrictions because this is where the fishery has historically occurred, and because halibut anglers actively avoid reefs (to prevent gear loss and because halibut fishing is better over gravel or sand habitat). The regulation prohibiting retention of groundfish is used to prevent anglers from also targeting groundfish (over the deep reefs) during their halibut trip. Allowing retention of groundfish by halibut anglers on "all-depth" days while intended to allow retention of incidentally encountered groundfish while halibut fishing, could also create a loophole allowing anglers to target groundfish any depth they choose under the guise of 'halibut fishing' on "all-depth" days, and reducing the effectiveness of the groundfish depth restrictions.

If allowed to retain groundfish, some halibut anglers would be expected to (and have told state agency staff that they would) target deep water reefs because they are already in the area and because there is a perception that trophy lingcod (highly desirable to recreational anglers) are more common over deep reefs than shallow water reefs.

Due to somewhat different regulations and fishing behaviors between the Washington and Oregon Pacific halibut fisheries, analysis for each state are separated below.

B.12.1 Washington

Recreational halibut fisheries in Washington are restricted to reduce encounters with overfished species, particularly yelloweye rockfish. Depth restrictions are the primary tool used to reduce encounters with overfished species. Depth by management area become more prohibitive as you move from south to north along the coast due to increasing rocky relief habitat along the northern Washington coast and the increased likelihood of encounters with yelloweye and canary rockfish. While groundfish fisheries are restricted to the nearshore area, recreational halibut fisheries are permitted in the deeper water because this is where the largest concentrations of halibut occur. To reduce encounters with yelloweye and canary rockfish during the recreational halibut fishery, groundfish retention restrictions are in place; these restrictions vary by management area. In the North Coast management area (Neah Bay and La Push), groundfish retention is prohibited seaward of 20 fm from May 1 through September 30 with the exception that lingcod, Pacific cod and sablefish can be retained on days open to recreational halibut fishing. In the south coast (Westport), lingcod retention is allowed seaward of the 30 fm depth restriction, which is in place from March 15 through June 15, on days the recreational halibut fishery is open. In the Columbia River management area (Ilwaco/Chinook), only sablefish and Pacific cod are allowed with halibut on board from May 1 through September 30.

Season length also varies by management area (Table B-71). Recreational halibut seasons in recent years in the North Coast (Neah Bay and La Push) and South Coast (Westport) management areas typically last fewer than 10 days; the halibut season lasted four days in the North Coast and five days in the South Coast in 2013. In contrast, the Columbia River area recreational halibut season has lasted from May through September for the most recent seasons. Even though the North and South Coast management areas include more habitat typically associated with yelloweye and canary rockfish, the short season length limits the opportunity for encounters with overfished species during the recreational halibut fishery.

Table B-71. Recreational halibut season length (days) by management area.

Management Measures by Area

Recent changes to groundfish retention management measures associated with the recreational halibut fisheries in the North and South Coast management areas may provide insight when considering groundfish retention during the recreational halibut fishery in areas such as the Columbia River where it is currently prohibited (with exception of Pacific cod and sablefish).

South Coast (Westport)

In 2010, changes to the Pacific Fishery Management Council's Pacific Halibut Catch Sharing Plan were implemented that allowed lingcod retention in the area seaward of the 30 fm depth restriction on days open to the recreational halibut fishery. Prior to 2010, only Pacific cod and sablefish could be retained seaward of 30 fm from May 1 through June 15 (reflecting the time period that the primary halibut fishery would likely be open). An additional management measure change that permitted rockfish retention seaward of the 30 fm depth restriction was analyzed in the 2011-2012 Harvest Specification and Management Measures Environmental Impact Statement and implemented in 2011. Table B-72 summarizes the most common groundfish encountered (retained and released groundfish) on recreational halibut trips in the South Coast (Westport) management area from 2006 through 2013. Black rockfish and lingcod make up the bulk of groundfish encountered during recreational halibut trips in the South Coast region.

Table B-72. Groundfish encounters (retained + released) per 100 recreational halibut angler trips in the South Coast management area.

Species	2006	2007	2008	2009	2010	2011	2012	2013
Black RF	273	134	100	157	95	73	84	151
Lingcod	35	23	59	43	73	135	119	82
Spiny dogfish	2	23	6	11	28	4	3	3

Flatfish	1	1	1	1	6	2	1	4
Canary RF	0	0	4	1	1	2	3	2
Yelloweye RF	0	0	2	2	1	1	2	3
Bocaccio	0	0	3	0	0	1	0	0

Average groundfish encounters during the four years prior (2006-2009) to the management change allowing lingcod retention on halibut trips is compared groundfish encounters during the four years after (2010-2013) (Table B-73). Allowing lingcod retention seaward of the 30 fm depth restriction on days open to the recreational halibut fishery increased the number of lingcod retained as expected but following the management change, encounters with yelloweye and canary rockfish doubled on average.

Table B-73. Groundfish encounters (retained + released) per 100 recreational halibut angler trips in the South Coast management area.

Species	Avg. 2006-2010	Avg. 2010-2013

Yelloweye RF	1	2
Bocaccio	1	0

North Coast (Neah Bay and La Push)

In 2013, groundfish regulations were changed through inseason action to address increased yelloweye rockfish encounters in the North Coast management area. The change revised the time period that groundfish retention seaward of 20 fm is prohibited from June 1 through September 30 to May 1 through September 30. In addition, because encounters with yelloweye rockfish primarily increased in the recreational halibut fishery, groundfish retention during the recreational halibut fishery was changed from allowing all groundfish seaward of 20 fm on days open to halibut fishing to limiting groundfish retention to lingcod, sablefish and Pacific cod on days open to the recreational halibut fishery.

Similar to the South Coast management area, black rockfish and lingcod are the most common groundfish encountered on recreational halibut trips. Changes in 2013 to revise the length of time the depth closure is in place and limit the amount of groundfish that can be retained on halibut trips did reduce encounters with yelloweye rockfish compared to the average per angler encounter rate between 2009 and 2012 (Table B-74). In addition to somewhat lower encounter rates of yelloweye rockfish after the management change, in 2013 61 percent of the yelloweye rockfish were encountered in waters deeper than 20 fm compared to 83 percent in 2012, reducing the total morality of yelloweye on recreational halibut trips.

Table B-74. Groundfish encounters (retained + released) per 100 halibut angler trips in the North Coast management area.

Species	2009	2010	2011	2012	Avg. 09-12	2013

Columbia River

Management measures associated with groundfish retention on recreational halibut trips in the Columbia River area have remained unchanged since 2005 with only Pacific cod and sablefish allowed when a halibut is on board from May 1 through September 30. There are no depth restrictions associated with the recreational groundfish fishery in this area as there are in the North Coast and South Coast management areas. In 2012, a lingcod restriction was implemented to reduce encounters with yelloweye rockfish associated with anglers targeting lingcod in deep water in the Columbia River area.

The species composition of groundfish encountered on recreational halibut trips in the Columbia River area is different than what is reported in the North Coast and South Coast management areas with Spiny dogfish and flatfish comprising a large proportion of the groundfish encountered (Table B-75). Overfished species encounters on recreational halibut trips are lower in the Columbia River area than in the North Coast and South Coast management area (Table B-76).

Recently, anglers have expressed interest in revising regulations to allow lingcod retention during the recreational halibut fishery in this area.

Table B-75. Groundfish encounters (retained + released) per 100 halibut angler trips in the Columbia River management area.

Summary

In Washington, due to the regional variability in encounters with all groundfish species, including overfished species and regional differences in the length of the recreational halibut season, consideration for allowing groundfish retention during recreational halibut fishing should be evaluated on a management area basis.

Encounters with yelloweye and canary rockfish on recreational halibut trips is lower in the Columbia River management area than in other areas and expanding the groundfish species allowed on halibut trips might be a viable alternative for the recreational halibut fishery that occurs in this area along the Washington coast. However, this management area extends to Cape Falcon, Oregon and so it is important to consider groundfish encounters in the Oregon recreational halibut fishery which may be different from the Washington recreational fishery. In addition, each state has separate harvest guidelines for yelloweye and canary rockfish and allowing retention of these overfished species would have to be evaluated to include trade-offs to other fishing opportunities in other management regions in both sates depending on each states projected attainment of their state specific harvest guidelines.

It is difficult to project whether or not anglers would spend more time fishing in deepwater areas targeting groundfish such as lingcod where encounters with overfished species is higher if retention were allowed on recreational halibut trips. But, analysis of the recent changes to management measures in the North Coast and South Coast suggest that encounters with overfished species is likely to increase.

B.12.2 Oregon

Although many halibut anglers would be expected to target groundfish is allowed to do so (and some have told ODFW staff that they would), the actual percentage that would is unknown. Therefore, additional yelloweye rockfish impacts by allowing retention of groundfish were projected across a wide range of percentages (of halibut anglers that would also target groundfish; Figure B-30). If none of the halibut anglers targeted groundfish, no additional yelloweye rockfish impacts would be expected to occur from the halibut fishery; however, the impacts could be substantial if a greater percentage of targeting occurs. For example, yelloweye rockfish mortality from the Oregon halibut fishery would be expected to increase to 1.4 mt (from 0.8 mt) if as few as 20 percent of anglers targeted groundfish during halibut trips. If this percentage increases to 75 percent, then yelloweye rockfish impacts from the halibut fishery alone are expected to exceed the 2013 harvest guideline level (similar to the HG for 2015 and 2016) for all Oregon recreational fisheries.

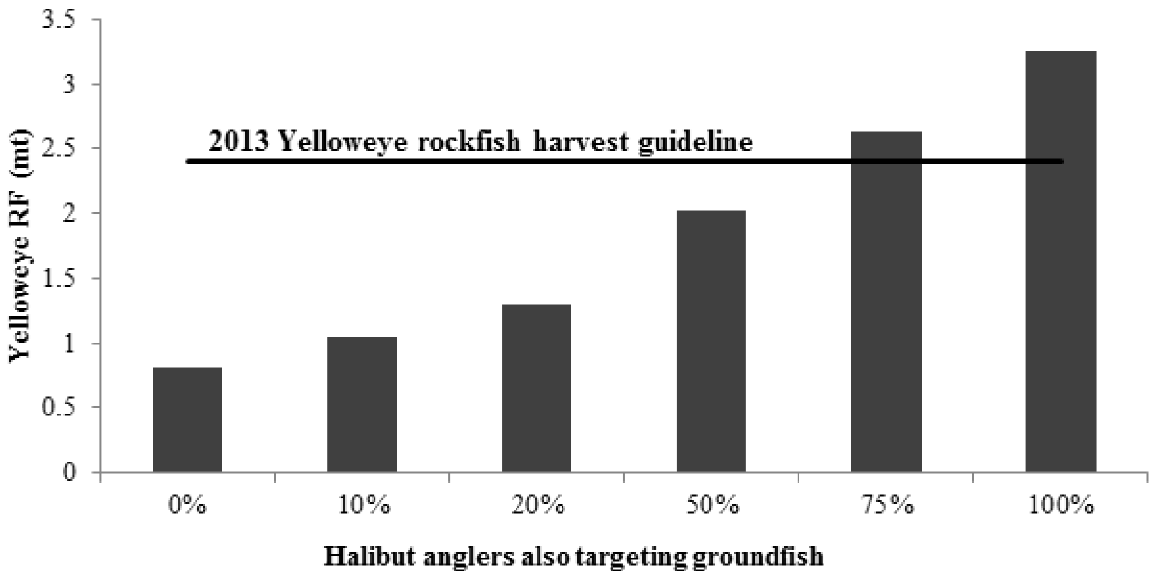

Figure B-30. Projected mortality of yelloweye rockfish from the Oregon recreational halibut fishery if halibut anglers were allowed to retain groundfish during halibut trips for various degrees of targeting of groundfish by halibut anglers. Since the percentage of anglers that would target groundfish during their halibut trip is unknown, mortality is shown for a wide range of targeting. The horizontal black line represents the 2013 harvest guideline for all Oregon recreational fisheries.

Since there is currently little room for any additional yelloweye rockfish mortality, sacrifices would likely have to be made to the recreational groundfish fishery, in the form of more restrictive regulations, in order to allow retention of groundfish by halibut anglers. While further regulations would come at great costs to groundfish anglers (e.g., shorter seasons, lesser bag limits, more restrictive depths), the benefits to halibut anglers are expected to be minimal. Allowing halibut anglers to retain incidental groundfish catches does not provide much benefit because these catches are infrequent (based on angler reports to ORBS to be 0.3 fish per halibut trip) and primarily consist of species that are overfished or non-desired (e.g., sharks, skates, and arrowtooth flounder; Figure B-31). Although anglers would be pleased if allowed to retain desirable species, such as lingcod or petrale sole, their trip satisfaction is much more dependent on whether or not they catch a halibut, their primary target. Further, allowing retention of groundfish would not increase halibut effort (the best measure of value of recreational fisheries) because the fishery is already at full capacity (quotas always caught).

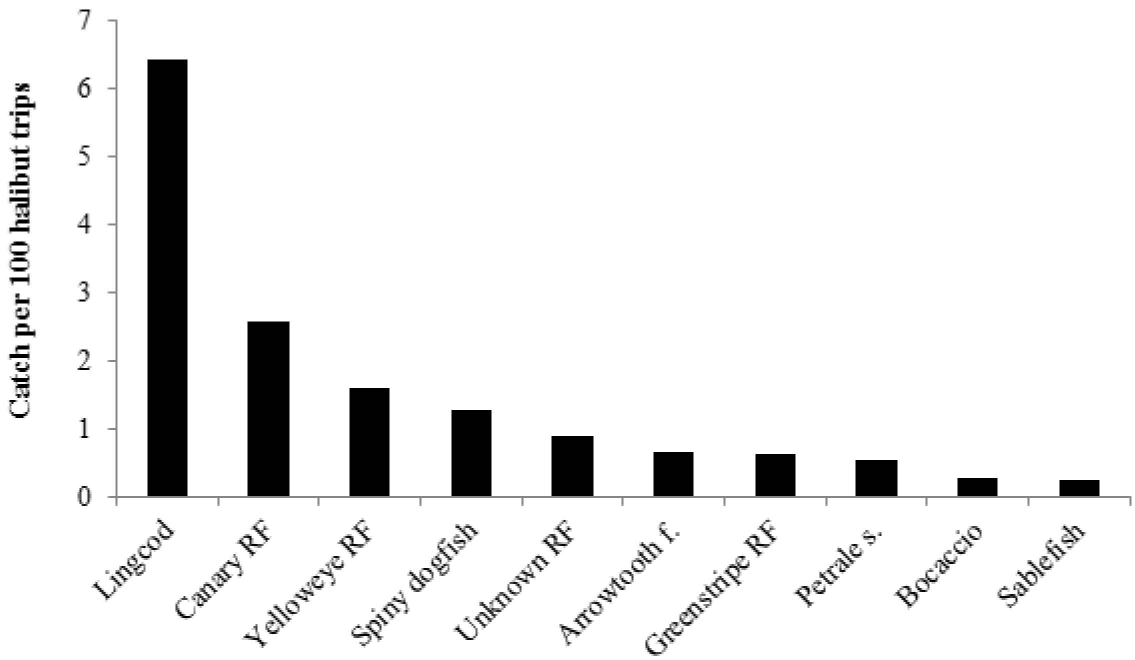

Figure B-31. Catch rates of the top ten most commonly encountered groundfish species by recreational halibut anglers in Oregon.

A modification to allow halibut anglers to harvest groundfish species that are not associated with reef habitat (i.e. other flatfish species), and thereby extending the current rule which allows sablefish and Pacific cod has also been requested. Lingcod and rockfish would remain prohibited as they are primarily associated with reef habitat. This modification could reduce the risk (incentive for anglers to target deep reefs) and may provide some additional harvest opportunities and increase angler satisfaction.

Adoption of the any change to these regulations would also have to be implemented via the Pacific Halibut Catch Share Plan, wherein the regulatory language for incidental groundfish retention for halibut fisheries is housed.

Management Options

No action: No groundfish except for sablefish and Pacific cod can be retained during all-depth halibut season while in possession of a halibut

Option 1: All groundfish can be retained during all-depth halibut season
Option 2: No groundfish except for sablefish, Pacific cod, and flatfish may be retained during all-depth halibut season while in possession of a halibut --or-- specify the groundfish can be retained except for rockfish and lingcod

1.1 Description and Status of Groundfish Stocks

There are over 90 stocks managed under the Pacific Coast Groundfish Fishery Management Plan (FMP). The actual number of FMP stocks is equivocal since all endemic species of the genus *Sebastes* are included and new species of this diverse genus are periodically described in the literature providing results of genetic/taxonomic research. These species include over 64 species of rockfish in the family *Scorpaenidae,* 7 roundfish species, 12 flatfish species, assorted shark, skate, and a few miscellaneous bottom-dwelling marine fish species. Table 1 depicts the latitudinal and depth distributions of groundfish species managed under the groundfish FMP, and Figure 1 depicts management area divisions.

The following sections contain information on the life histories of a subset of the groundfish managed under the groundfish FMP. While reading these sections, it is important to keep in mind how certain life history traits of the species have important implications on how the stocks are sustainably managed.

In contrast to the highly variable, and often volatile, population cycles of many coastal pelagic and invertebrate populations in the California Current, many of the resident groundfish in the California Current have evolved entirely different life history approaches to coping with environmental variability. Sablefish, Dover sole, spiny dogfish and a large number of rockfish (*Sebastes* and *Sebastolobus*) species have life spans that typically span decades, and in some extreme examples may reach ages of 100 or greater (Beamish, *et al.* 2006; Love, *et al.* 2002). Although large initial catches of many rockfish had given the impression that these stocks were also highly productive, a growing body of scientific evidence soon made it clear that many of these species were incapable of sustaining high intensity fishing pressure using modern fishing methods (Francis 1986; Gunderson 1977; Gunderson 1984; Leaman and Beamish 1984).

Among the concerns raised in some of the early research and analyses were that the large standing stocks of older individuals were simply maintaining themselves within the dynamic bounds of their ecosystem, and that the failure to consider the role of such longevity in Northeast Pacific groundfish could lead to management challenges. Factors such as extreme longevity, low natural mortality, increasing fecundity with age, and infrequent reproductive success (recruitment) were explicitly considered when initial harvest rate strategies were developed for the Council (Clark 1991). However, the paucity of data and magnitude of some of these factors as related to the low productivity of many species were not fully appreciated in many early studies, and are now known to be important considerations in developing harvest rate guidelines and management policies (Clark 2002; Dorn 2002a)Dorn, 2002 #490}. Consequently, harvest rates for many species have been reduced repeatedly in recent years to account for the improved knowledge regarding the overall productivity of these stocks. As new information continues to emerge regarding the significance of diverse age structures and other factors in sustaining groundfish resources (Berkeley 2004; Berkeley, *et al.* 2004; Bobko and Berkeley 2004), such information continues to be evaluated and incorporated into the stock assessment and assessment review processes that provide the scientific basis upon which management decisions are made.

Management of these groundfish species is based on principles outlined in the Magnuson-Stevens Fishery Management and Conservation Act (MSA), groundfish FMP, and National Standard Guidelines, which provide guidance on the 10 national standards in the MSA. Stock assessments are based on resource surveys, catch trends in west coast fisheries, and other data sources.

a/ Data from (Casillas, *et al.* 1998), (Eschmeyer, *et al.* 1983), (Hart 1988), (Miller and Lea 1972), (Love, *et al.* 2002), and NMFS survey data. Depth distributions refer to offshore distributions, not vertical distributions in the water column.
b/ The category "rockfish" includes all genera and species of the family Scorpaenidae, even if not listed, that occur in the Washington, Oregon, and California area.
c/ Only the southern stock of bocaccio south of 40º 10' N lat. is listed as overfished.
d/ Only two occurrences of harlequin rockfish south of 51º N lat. (off Newport, OR and La Push, WA; (Casillas, *et al.* 1998)).

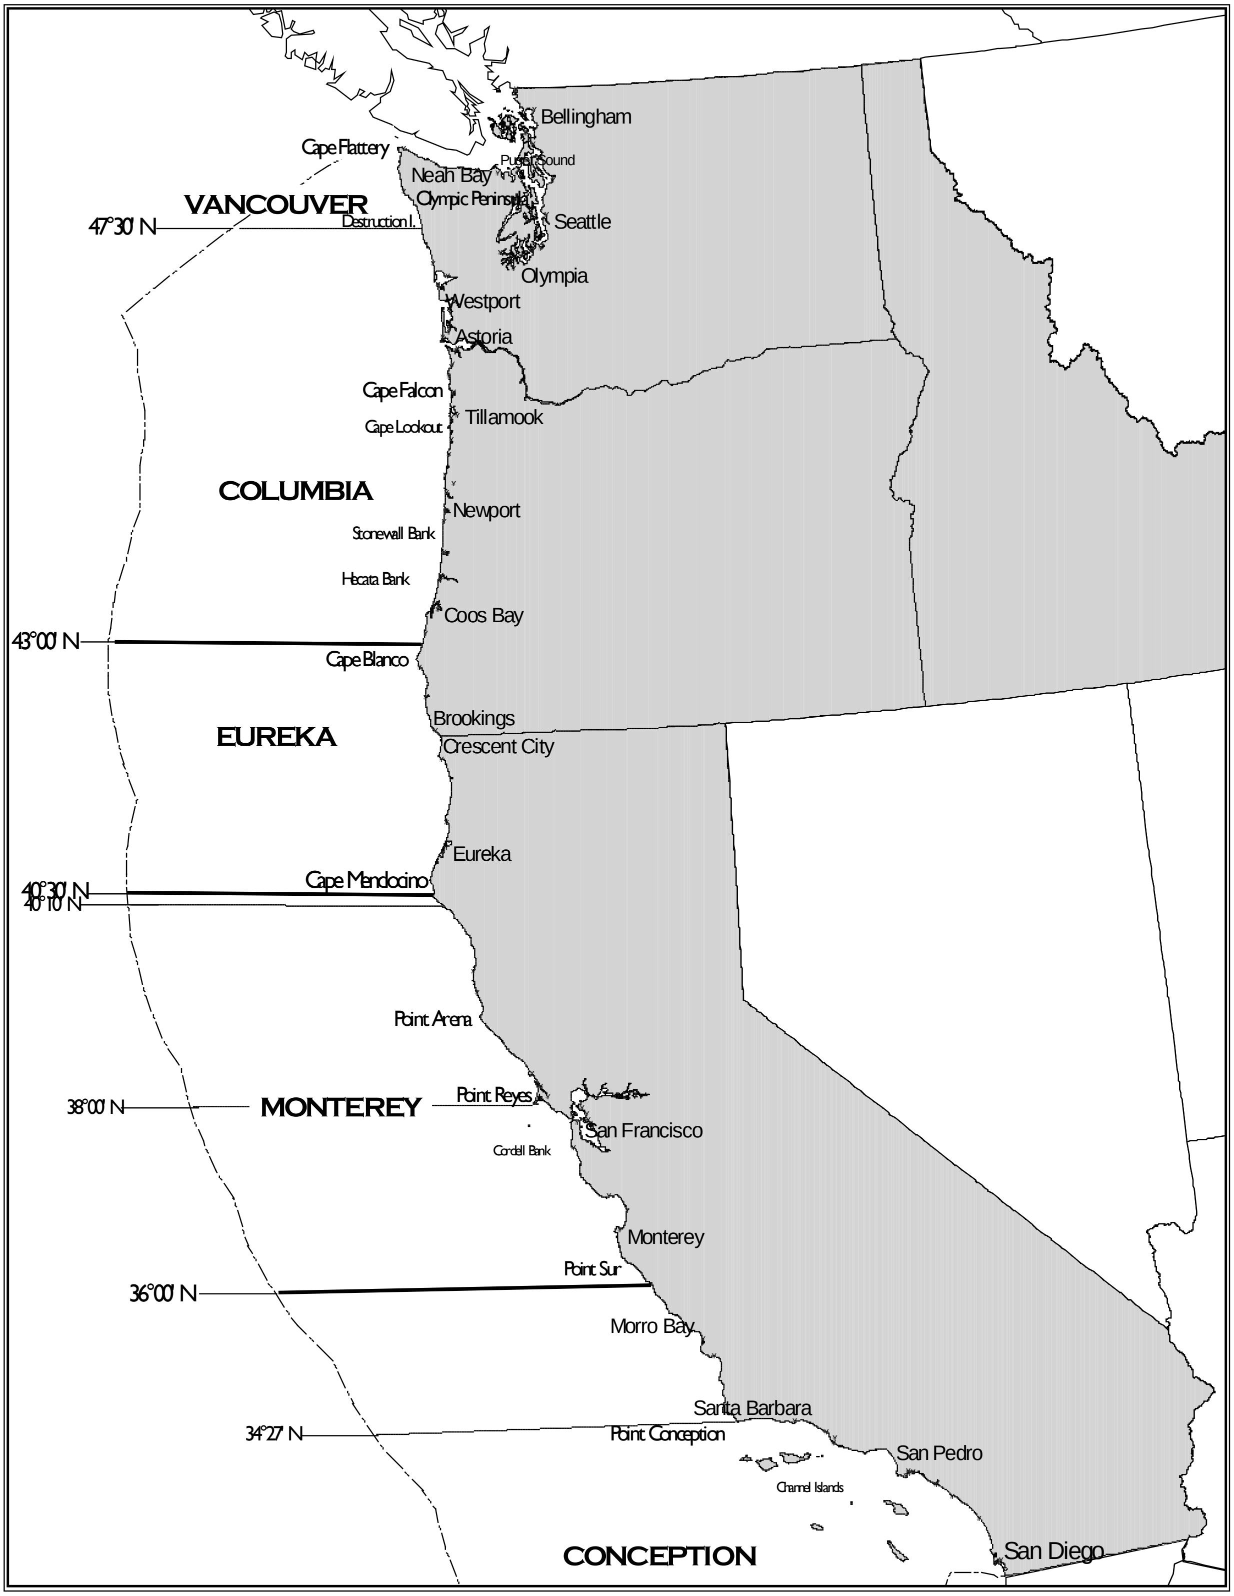

Figure 1. Fishery management lines on the U.S. west coast.

The passage of the Sustainable Fisheries Act in 1996 and the reauthorization of the MSA in 2006[1] incorporated the current conservation and rebuilding mandates into the MSA. These mandates—including abundance-based standard reference points for declaring the status of a stock (overfished; in a "precautionary" status; or at levels that can support maximum sustainable yield (MSY) (healthy or "rebuilt"))—were subsequently incorporated in the groundfish FMP with adoption of Amendments 11, 12, and 23. These reference points are determined relative to an estimate of "virgin" or unexploited spawning biomass of the stock, denoted as $B_{0,}$ which is defined as the average equilibrium abundance of a stock's spawning biomass before it is affected by fishing-related mortality.[2] B_0 is then used to estimate MSY, as identified in the MSA and National Standard Guidelines. MSY represents a theoretical maximum surplus production from a population of constant size; National Standard Guidelines define it as "the largest long-term average catch or yield that can be taken from a stock or stock complex under prevailing ecological and environmental conditions." For a given population and set of ecological conditions, there is a biomass that produces MSY (denoted as B_{MSY}), which is less than the equilibrium size in the absence of fishing (B_0). (Generally, population sizes above B_{MSY} are assumed to be less productive because of competition for resources or other density dependent factors.) The harvest rate used to achieve or sustain B_{MSY} is referred to as the Maximum Fishing Mortality Threshold (MFMT, denoted as F_{MSY}). Three harvest specification reference points, defined in the groundfish FMP, provide guidance in setting the harvest rate: an overfishing limit (OFL), an acceptable biological catch (ABC), and an annual catch limit (ACL) (see section 1.2 for more information on harvest specifications). The Council identifies the ACL as the management target for each species or species complex. When the stock biomass is determined to be lower than $B_{MSY,}$ the ACL is set to an adequately low level to rebuild the stock to a healthy level in a timely fashion.

The biomass level that produces MSY (i.e., B_{MSY}) is generally unknown and assumed to be variable over time due to long-term fluctuations in ocean conditions, so that no single value is appropriate. Furthermore, F_{MSY} is tightly linked to an assumed level of density dependence in recruitment, and there is insufficient information to determine that level for many west coast groundfish stocks. Therefore, the use of approximations or proxies is necessary; absent a more accurate determination of $F_{MSY,}$ the Council applies default MSY proxies (see section 1.1.1 for more details). The Council adopts management actions aimed to maintain abundance of each stock at or above the specified B_{MSY} target. The threshold for declaring a stock overfished is when the stock's spawning biomass declines to less than the specified Minimum Stock Size Threshold or MSST (i.e., 12.5% of B_0 or $B_{12.5\%}$ for assessed flatfish stocks and $B_{25\%}$ for all other groundfish stocks). A rebuilding plan that specifies how total fishing-related mortality is constrained to achieve an MSY abundance level within the legally allowed time is required by the MSA and groundfish FMP when a stock is declared overfished.

Of the more than 90 species managed under the groundfish FMP, only a portion are individually managed. Thus, the remaining species are managed and accounted for in groupings or stock complexes (see section 1.1.5) because individually they comprise a small part of the landed catch and, in general, insufficient information exists to develop the stock assessments necessary to set harvest specifications based on yield estimates. The Council has also decided to continue to manage some assessed stocks in complexes to avoid management complications such as disruption to the trawl rationalization program. Catch-based methods described in section 1.1.1 are used to set OFLs for unassessed stocks. Additionally, there is a category of stocks that are incidentally caught in groundfish fisheries for which

[1] The Magnuson-Stevens Act is again up for reauthorization in 2014.

[2] The current abundance of a stock relative to its unfished level is commonly written as a percentage or a proportion; this value represents the stock's depletion level. In addition to using a comparison between current spawning biomass and unfished spawning biomass to determine this reference point, some stock assessment authors compare current and unfished levels of spawning output or of total stock biomass, depending on the information that is available.

no harvest limits are specified. This category of stocks, termed Ecosystem Component (EC) species, are not considered to be in the fishery and are neither targeted nor generally retained for sale or personal use. EC species are determined not to likely become subject to overfishing or to be overfished in the absence of conservation and management measures. There is a monitoring requirement for species designated as EC to the extent that any new pertinent scientific information becomes available (e.g., catch trends, vulnerability, etc.) to determine changes in their status or their vulnerability to the fishery. The Council is proposing an EC designation for some species currently managed in the FMP, as well as other non-FMP species (see section 1.1.6).

1.1.1 Productivity and Susceptibility Assessment of Stocks to Overfishing

The vulnerability to potential overfishing of a stock to the fishery for each groundfish stock in the FMP was defined as a first step in assisting with two specific tasks set forth in the FMP: 1) to define species as either "in the fishery" or as an "ecosystem component," and 2) identify stock complexes. In addition, the vulnerability scores were considered when prioritizing stock assessments and determining data collection needs.

The Productivity-Susceptibility Assessment (PSA) approach of Patrick et al. (2009) was used to characterize vulnerability and has two components: 1) productivity as defined by life histories traits, and 2) susceptibility to current fishing practices. Each vulnerability component is comprised of several attributes (10 productivity and 12 susceptibility attributes) and the weighted mean score of all attributes defines the overall productivity and susceptibility score. Table 2 includes the vulnerability scores for all species in the FMP relative to the current fishery. Table 2 shows the vulnerability scores for currently overfished rockfish species relative to the fishery circa 1998. Scores are presented in two-dimensions, with productivity on the x-axis and susceptibility on the y-axis (Figure 2). Cope et al. (2011) established vulnerability reference points of unassessed west coast groundfish stocks to determine vulnerability groups as follows:

- V ≥2.2 indicate species of major concern.
- 2.0≤V<2.2 indicate species of high concern.
- 1.8≤V<2.0 indicate species of medium concern.
- V <1.8 indicate species of low concern.

Rockfish and elasmobranches showed the highest vulnerabilities (>2.0), with the deepest-residing members of those groups often the most vulnerable, though there were several species of nearshore rockfish (China, quillback, and copper rockfish) with some of the highest scored vulnerabilities. Flatfishes in general showed the lowest vulnerabilities.

In addition to scoring each productivity and susceptibility attribute, the quality of the data used for each score was also recorded (Table 2, Table 3, and Figure 3). Data quality is scored for each productivity and susceptibility attribute, with the overall data quality score calculated as the weighted mean of all attributes. A scoring scale of 1-5 was used, with the best data score being 5.

Recording the data quality can highlight vulnerability scores that can be improved with additional data or that should be interpreted with caution because of questionable data contribution. Data quality scores can also be used to justify future data collection on particular attributes.

In general, susceptibility was harder to score (lower data quality) than productivity. Flatfishes as a group had the least informed species, but elasmobranches and several rockfish species also showed low-quality data informing vulnerability scores (Table 2).

PSA analyses are anticipated to be re-done every biennial specifications cycle. Productivity scores are not expected to vary much over time since they are based on life history traits. However, susceptibility scores may vary based on changes in fishing practices and/or management, and an updated understanding of the stock's interaction with the fishery. As susceptibility scores change, so do the vulnerability scores.

Table 2. Overall scores and results of the Productivity and Susceptibility Assessment (PSA) ranked from most to least vulnerable to overfishing relative to the current west coast fishery based on the GMT's scoring.

Stock ID	Stock Name	Productivity	Susceptibility	Vulnerability
21	Copper rockfish	1.95	1.60	2.27
67	Rougheye rockfish	1.17	2.33	2.27
72	Shortraker rockfish	1.22	2.38	2.25

Table 3. Retrospective Productivity and Susceptibility Assessment (PSA) vulnerability scores of currently overfished rockfish species ranked from most to least vulnerable to overfishing relative to stock status and the fishery circa 1998, based on the GMT's scoring.

Stock Name	Stock ID	Susceptibility	Vulnerability
Bocaccio	25_H	2.72	2.43
Canary	23_H	2.84	2.52
Cowcod	10_H	2.68	2.57
Darkblotched	51_H	2.76	2.39
POP	92_H	2.32	2.08
Yelloweye	18_H	2.80	2.53

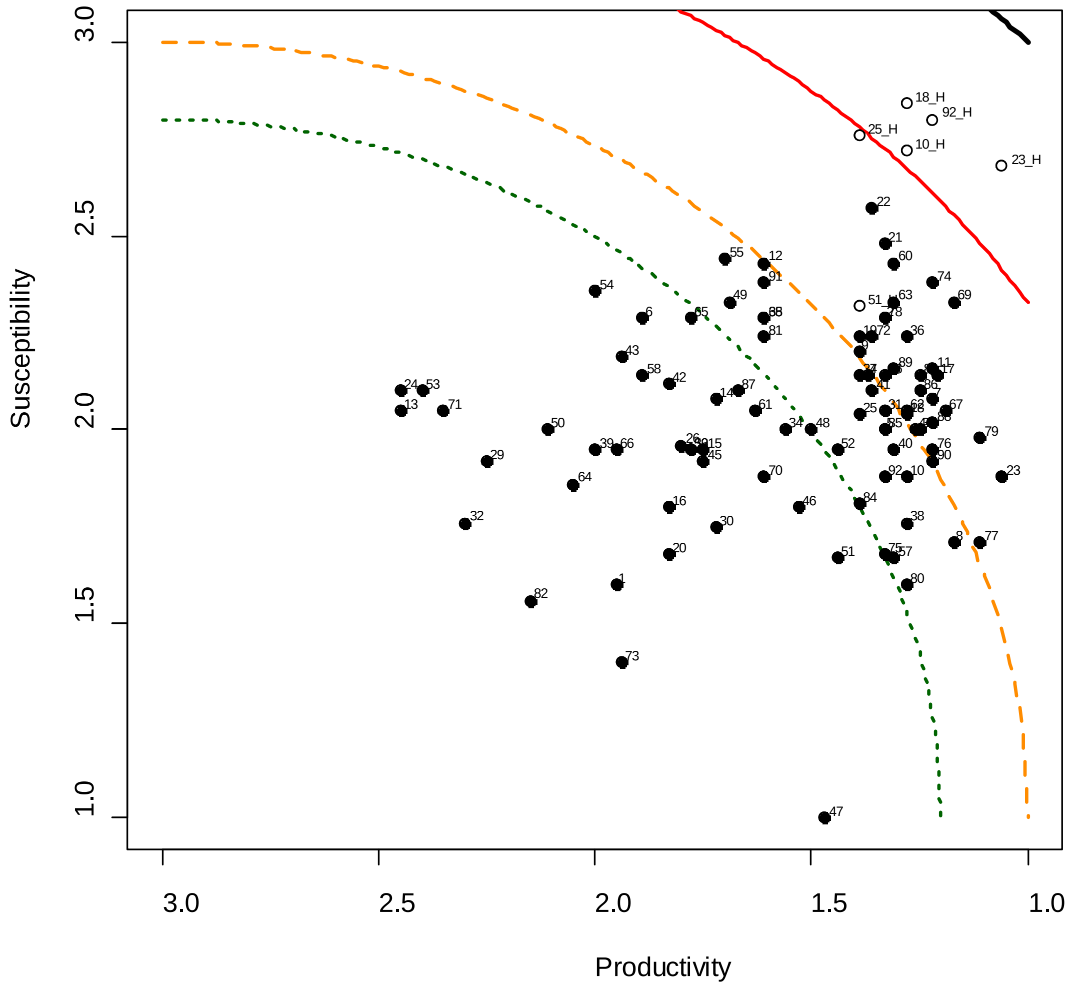

Figure 2. Productivity and Susceptibility Analysis (PSA) plot for species in the west coast groundfish FMP. Contours delineate areas of relative vulnerability (V, i.e. distance from the origin), with the highest vulnerability stocks above the solid red line (V = 2.2), high vulnerability above the orange broken line (V=2), medium vulnerability above the green dotted line (V=1.8) and the lowest vulnerability below the green dotted line. The maximum vulnerability (V=2.8) is indicated with the solid black line. Solid circles are based on current PSA scores. Open circles are based on PSA scores circa 1998. Numbers refer to the Stock ID in Table 2 and Table 3.

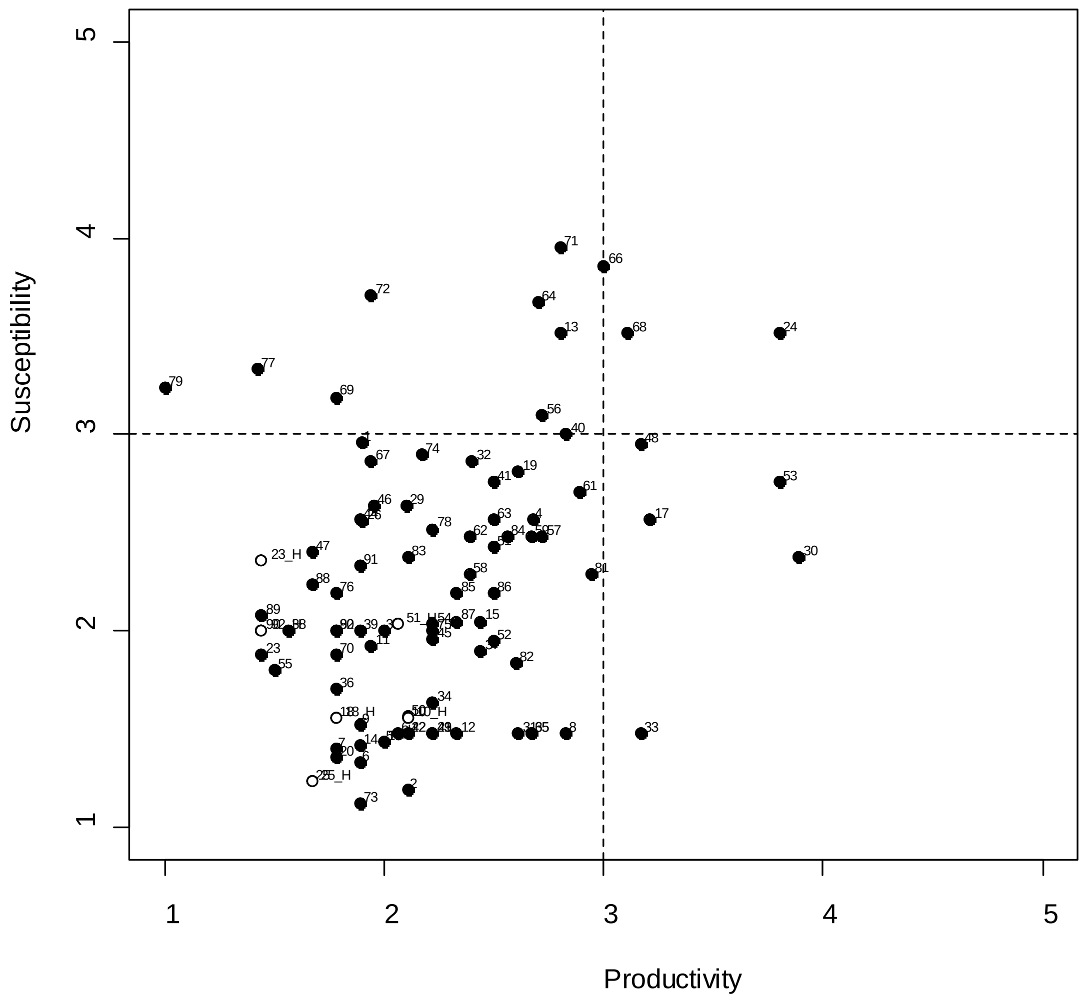

Figure 3. Data quality plots for the productivity and susceptibility scores in the PSA for each species (represented numerically in Table 2 and Table 3) in the west coast groundfish FMP. Higher scores indicate less data quality. Vertical and horizontal lines provide a general guide to relative data quality with values above 3 on either axis considered data-poor.

1.1.2 Stock Assessments and Rebuilding Analyses Used to Estimate Stock Status and Inform Management Decisions

Stock assessments are used for setting harvest specifications by providing estimates of MSY, OFL, the MFMT, the MSST, ABC, OY, and ACLs. Stock assessments are also used to determine the status of a fish population or subpopulation (stock) terms of estimating population size, reproductive status, fishing mortality, and sustainability. In the terms of the Groundfish FMP, stock assessments provide: 1) an estimate of the current biomass and reproductive potential, 2) an estimate of F_{MSY} (the harvest rate estimated to produce MSY) or proxy thereof translated into exploitation rate or spawning potential ratio (SPR; *cite section describing SPR*), 3) the estimated MSY biomass (B_{MSY}), or proxy thereof, 4) estimated unfished biomass (B_0), and 5) the estimated variance (e.g., confidence interval) for the current biomass estimate. With the exception of Pacific whiting, which is assessed annually as specified in the Agreement with Canada on Pacific Hake/Whiting, groundfish stock assessments are conducted on a two-year cycle. Given the large number of groundfish species and limited state and Federal resources, a subset of all groundfish stocks are assessed in each stock assessment cycle. Overfished species' stock assessments are typically conducted every two years, although a catch report can be substituted for an assessment to monitor compliance with adopted rebuilding plans. The process for setting groundfish specifications involves the adoption of new and updated stock assessments. During the biennial specification process, the SSC reviews stock assessments and rebuilding analyses for overfished species and makes recommendations to the Council relative to the standards of the best available science and the soundness of the scientific information relative to management decisions. The Council then approves all or a portion of the stock assessments, or recommends further analysis.

The perception of stock status and productivity for many stocks may change substantially between stock assessments. Such changes can result from technical changes in the model, including how a given assessment model is structured, the assumptions used to fix or estimate key parameters (i.e., whether parameters such as natural mortality and steepness are fixed, estimated freely, or estimated with an informative prior), and the evolution of methods for developing time series and estimates of uncertainty from different sources of raw data. The population dynamics of target species themselves are responsive to a mix of complex (and often poorly-understood) biological, oceanographic, and interspecies interactions. New data sources (e.g., new data, extensions of existing data sets, incorporation of environmental factors into assessments) can result in changes in parameter estimates and model outputs.

All stock assessments are subject to a peer review process, consistent with the MSA (§302(g)(1)(E)). The process considers components of the assessments starting with data collection and continuing through to scientific recommendations and information presented to the Council and its advisors. The terms of reference for the groundfish stock assessment process defines the expectations and responsibilities for various participants in the groundfish stock assessment review (STAR) process, and outlines the guidelines and procedures for a peer review process. The STAR process is a key element in an overall process designed to review the technical merits of stock assessments and other scientific information used by the SSC. This process allows the Council to make timely use of new fishery and survey data, to analyze and understand these data as completely as possible, to provide opportunity for public comment, and to assure that the results are as accurate and error-free as possible.

Harvest specifications, and the science used as the basis for management decision-making are derived from the most recent assessments and/or rebuilding analyses prepared for those stocks informed by an assessment. The newest assessments were those prepared and adopted in 2013 and the oldest assessments informing management decisions for fisheries in 2015 and beyond were prepared and adopted in 2005. Table 4 presents a summary of the management quantities estimated by base models of the most recent assessments informing management in 2015 and beyond. Table 5 lists life history parameters from the stocks assessed since 2005, excluding those done using XDB-SRA; steepness of the spawner-recruitment curve (h), recruitment variability (sigma-r), the von Bertalanffy Equation growth constant (k), and natural mortality (M) are each important contributors to the understanding of the productivity and resiliency of these stocks. Table 6 lists life history parameters from the stocks assessed in 2013 using XDB-SRA; B_{MSY}, F_{MSY}, M, B_{MSY}/B_0, and F_{MSY}/M inform the relative productivity and resiliency of these stocks.

All stock assessments, STAR panel reports, and rebuilding analyses used to inform management decisions on west coast groundfish stocks and fisheries can be found on the Council's web site at http://www.pcouncil.org/groundfish/stock-assessments/.

1.1.2.1 Types of Assessments Used in Managing Groundfish Stocks

The Council uses various types of assessments that range from data-rich full assessments (also known as benchmark assessments) to data-poor catch-based models used to only estimate an OFL. The Council decides which groundfish stocks will be assessed and, based on SSC recommendations, what type of assessment will be used (i.e., full, update, data-moderate) each cycle. These stock assessment priorities are decided in even years and assessments are conducted, reviewed, and adopted in odd years. Results from these assessments are used to inform management decisions for the following biennial cycle, which begins in the next odd year. The SSC reviews all assessments and recommends to the Council if they represent the best available science for the stock and whether and how they can be used to inform Council decisions.

The SSC categorizes stocks based on the type of assessment and the quality of data informing that assessment. The FMP harvest specification framework calls for increasing uncertainty buffers translated into lower ABCs (and ACLs) for stocks informed by less certain assessments (see section 1.2.2). Stock categories range from category 1, characterized by stocks informed by full assessments with reasonably good estimates of year class strength, to unassessed category 3 stocks where there is only a data-poor estimate of the OFL. A more detailed description of the assessment models used in current groundfish management follows.

Data-Poor Assessments

Data-poor assessments employ catch-based statistics to estimate an OFL for a stock. Since there are no survey or other abundance indices used in a data-poor assessment, stock status cannot be determined using these types of assessment. The most rudimentary data-poor assessment is simply average historical catch to estimate an OFL. However, there is great uncertainty whether that is a "true" OFL since the historical catch used to compute the average could have been unsustainably high. Therefore, the SSC categorizes stocks informed by a data-poor OFL as category 3 stocks, thus mandating a higher buffer to determine the ABC. While this category of data-poor methods are being characterized as "assessments" here, stocks with OFLs informed with data-poor methods are considered unassessed since there is no estimate of relative depletion or status. Other approved data-poor methods (DCAC and DB-SRA) more sophisticated than average catch are described below.

Depletion-Corrected Average Catch

The Depletion-Corrected Average Catch (DCAC) method provides an estimate of sustainable yield (the OFL) for data-poor stocks of uncertain status (MacCall 2009). DCAC adjusts historical average catch to account for one-time "windfall" catches that are the result of stock depletion, producing an estimate of yield that was likely to be sustainable over the same time period. Advantages of the DCAC approach for determining sustainable yield for data-poor stocks include: 1) minimal data requirements, 2) biologically-based adjustment to catch-based yield proxies with transparent assumptions about relative changes in abundance, and 3) simplicity in computing.

Depletion-Based Stock Reduction Analysis

The Depletion-Based Stock Reduction Analysis (DB-SRA) method extends the DCAC method by 1) restoring the temporal link between production and biomass, and 2) evaluating and integrating alternative hypotheses regarding changes in abundance during the historical catch period (Dick and MacCall 2011). This method combines DCAC's distributional assumptions regarding life history characteristics and stock status with the dynamic models and simulation approach of stochastic stock reduction analysis.

Data-Moderate Assessments

Data-moderate assessments are less complicated than full assessments and can therefore be reviewed more expeditiously. Unlike a full assessment, which is reviewed by a STAR panel and the SSC, only the SSC reviews a data-moderate assessment.

Data-moderate assessments combine catch-based methods with a time series of relative abundance estimates from one or more surveys or other types of abundance indices (e.g., CPUE time series). This type of assessment represents the minimal structure of an assessment used to determine stock status according to the NMFS National Stock Assessment Improvement plan (Mace, *et al.* 2001). These assessments exclude compositional age and length data, which are used to determine survey and/or fishery selectivities and to estimate other parameters in a full assessment model. The addition of compositional data complicates an assessment requiring more review time to understand what data are driving model results. Data-moderate assessments were therefore developed to increase the number of groundfish stocks assessed given the resources available to conduct and review assessments each cycle. There are two data-moderate assessment models in current use that have been reviewed and recommended by the SSC: Extended Simple Stock Synthesis (exSSS) and Extended Depletion-based Stock Reduction Analysis (XDB-SRA). These are described in more detail below.

Since data-moderate assessments are less informative than full assessments, the SSC categorizes stocks informed with such assessment as category 2 stocks.

Extended Simple Stock Synthesis

Extended Simple Stock Synthesis (exSSS) is based on sampling parameters (steepness, natural mortality and depletion) from prior distributions and using Stock Synthesis to solve for virgin recruitment (R0) given inputs for selectivity, growth, and fecundity. ExSSS extends Simple Stock Synthesis, originally a data-poor method reviewed by the SSC, by allowing index data (and potentially length and age data) to be used for parameter estimation using the Stock Synthesis platform. Parameter estimation for exSSS is either based on maximum likelihood or Bayesian (Markov chain Monte Carlo (MCMC)) methods. ExSSS assumes that recruitment is related deterministically to the stock-recruitment relationship. The outputs from exSSS include biomass trajectories, as well as estimates of (and measures of uncertainty for) the OFL. The prior for depletion is based on the results of a regression of depletion on the PSA vulnerability score (see section 1.1.1).

Extended Depletion-Based Stock Reduction Analysis

Extended Depletion-Based Stock Reduction Analysis (XDB-SRA), an extension of DB-SRA, is another model approved by the SSC for use in data-moderate assessments. XDB-SRA can be implemented within a Bayesian framework, with the priors for the parameters updated based on index data. The additional parameters in XDB-SRA compared with DB-SRA include the catchability coefficient (q), and the extent of observation variance additional to that inferred from sampling error (a). The priors for these parameters are a weakly informative log-normal and a uniform distribution, respectively.

Full Stock Assessments

Full, or benchmark, stock assessments are those where Stock Assessment Teams (STATs) can propose new models and explore new data to determine the status and dynamics of a fish stock. The Council has a rigorous process for first determining those stocks that will be assessed and, once determined, how they will be reviewed (the process is codified in the Stock Assessment and Review Terms of Reference, which is updated every other year; available at http://www.pcouncil.org/groundfish/stock-assessments/terms-of-reference/). Full assessments are more vigorously reviewed than other types of assessments since they are inherently more complicated. A week-long Stock Assessment Review (STAR) panel meeting occurs with STATs presenting assessment models to a panel of experts (typically comprised of one SSC Groundfish Subcommittee member who chairs the meeting, one west coast groundfish assessment expert, two independent reviewers from the Center of Independent Experts, one Groundfish Management Team advisor, one Groundfish Advisory Subpanel advisor, and a member of the Council staff). The STAR panel prepares a report recommending whether the assessment is robust enough to be used in management, along with other detailed recommendations on how to interpret assessment results and how to improve the assessment next time it is conducted. STAR panel reports also detail the model and data explorations that occurred during the review. The draft assessment and STAR panel report are then reviewed by the SSC. The assessment is only adopted for use in management decision-making if recommended by the SSC.

Stocks assessed with SSC-endorsed assessments are categorized either as category 1, category 2, or assigned a stock-specific category depending on the quality of data informing the assessment, relative uncertainty of model estimates, and/or whether individual year class strength (i.e., recruitment) is estimated.

Stock Synthesis

Most of the groundfish assessments on the U.S. west coast used to currently inform management decisions have been done in Stock Synthesis (SS). Stock Synthesis provides a statistical framework for calibration of a population dynamics model using a diversity of fishery and survey data. It is designed to accommodate both age and size structure in the population and with multiple stock sub-areas. Selectivity can be cast as age specific only, size-specific in the observations only, or size-specific with the ability to capture the major effect of size-specific survivorship. The overall model contains subcomponents which simulate the population dynamics of the stock and fisheries, derive the expected values for the various observed data, and quantify the magnitude of difference between observed and expected data. Some SS features include ageing error, growth estimation, spawner-recruitment relationship, movement between areas. SS is most flexible in its ability to utilize a wide diversity of age, size, and aggregate data from fisheries and surveys. The ADMB C++ software in which SS is written searches for the set of parameter values that maximize the goodness-of-fit, then calculates the variance of these parameters using inverse Hessian and MCMC methods. A management layer is also included in the model allowing uncertainty in estimated parameters to be propagated to the management quantities, thus facilitating a description of the risk of various possible management scenarios, including forecasts of possible annual catch limits. The structure of Stock Synthesis allows for building of simple to complex models depending upon the data available. The latest version of SS used in most of the assessments done in 2013 is version 3.24f (download available at http://nft.nefsc.noaa.gov/SS3.html).

Extended Depletion-Based Stock Reduction Analysis

XDB-SRA, described above, was used in the 2013 full assessment of cowcod in the Southern California Bight (see section 1.1.3.3). While XDB-SRA is an approved data-moderate assessment model, it can also be parameterized to incorporate compositional data[3].

Updated Assessments

An update assessment uses the model structure of the stock's last full, SSC-endorsed assessment, but is generally restricted to the addition of new data that have become available since the last full assessment. It must carry forward the fundamental structure of the last full assessment reviewed and endorsed by a STAR panel, the SSC, and the Council. Assessment structure here refers to the population dynamics model, data sources used as inputs to the model, the statistical platform used to fit model to the data, and how the management quantities used to set harvest specifications are calculated. Particularly, when an update assessment is developed, no substantial changes should be made to 1) the particular sources of data used, 2) the software used in programming the assessment, 3) the assumptions and structure of the population dynamics model underlying the stock assessment, 4) the statistical framework for fitting the model to the data and determining goodness of fit, and 5) the analytical treatment of model outputs in determining management reference points.

Major changes to the assessment should be postponed until the next full assessment. Minor alterations to the input data and the assessment can be considered as long as the update assessment clearly documents and justifies the need for such changes. A step-by-step transition (via sensitivity analysis) from the last full assessment to an update assessment under review should be provided. Minor alterations can be considered under only two circumstances: first, when the addition of new data reveals an unanticipated sensitivity of the model, and second, when there are clear and straightforward improvements in the input data and how it is processed and analyzed for use in the model. Examples of minor alterations include: 1) changes in how compositional data are pooled across sampling strata, 2) the weighting of the various data components (including the use of methods for tuning the variances of the data components), 3) changes in the time periods for the selectivity blocks, 4) correcting data entry errors, and 5) bug fixes in software programming. This list is not meant to be exhaustive, and other alterations can be considered if warranted. Ideally, improved data or methods used to process and analyze data would be reviewed by the SSC prior to being used in assessments.

The SSC reviews all updated assessments; a STAR panel review is not needed since the assessment only updates the last full, STAR panel-reviewed assessment.

1.1.2.2 Rebuilding Analyses

Rebuilding analyses use the results of stock assessments and project stock rebuilding periods under alternative harvest control rules in a stochastic fashion. In other words, a rebuilding analysis involves projecting the status of the overfished resource into the future under a variety of alternative harvest strategies to determine the probability of recovery to B_{MSY} (or its proxy) within a pre-specified time-frame. Rebuilding analyses are used to develop new rebuilding plans or in consideration for modifying existing rebuilding plans; rebuilding plans dictate the target year to rebuild a stock, the harvest control rules for rebuilding the stock, and any other special management measures designed to foster rebuilding. Rebuilding analyses also are used to determine the OFLs and ACLs for overfished stocks.

[3] Note that the 2013 cowcod assessment excluded compositional data within the model. However, the model was subject of the two-step (i.e., STAR panel and SSC) review process defined for full assessments.

The steps when conducting a rebuilding analysis are 1) estimation of B_0 (and hence B_{MSY} or its proxy), 2) selection of a method to generate future recruitment, 3) specification of the mean generation time (defined as the predicted time it would take for a mature female in the population to replace herself), 4) calculation of the minimum and maximum times to recovery, and 5) identification and analysis of alternative harvest strategies and rebuilding times. Most rebuilding analyses are done using software developed by Dr. André Punt from the University of Washington (informally termed the Puntalyzer; available at http://fish.washington.edu/people/punt/software.html).

The Puntalyzer uses "Monte Carlo simulation" to derive a probability estimate for a given rebuilding strategy. This method projects population growth many times in separate simulations. It accounts for possible variability by randomly choosing the value of a key variable, in this case total recruitment or recruits per spawner from a range of values. These values can be specified empirically, by listing some set of historical values, or by a relationship based on a model. The SSC recommends that the rebuilding analyses use historical values. Because of this variability in a key input value, each simulation will show a different pattern of population growth. As a result, a modeled population may reach the target biomass that defines a rebuilt stock (B_{MSY}) in a different year in each of the simulations.

This technique is first used to calculate minimal time to rebuild a stock given its level of depletion and productivity from the time of implementing the first rebuilding plan (T_{MIN}) in probabilistic terms, which is defined as the time needed to reach the target biomass in the absence of fishing with a 50 percent probability. In other words, in half the simulations the target biomass was reached in some year up to and including the computed T_{MIN}. Given T_{MIN}, the maximum legal time to rebuild (T_{MAX}) is computed as 10 years or by adding the value of one mean generation time to T_{MIN}, if T_{MIN} is greater than or equal to 10 years. In cases, where there is consideration for modifying an existing rebuilding plan, the shortest time to rebuild is calculated as the biological limit for the stock to rebuild in the absence of fishing beginning in the year the modified rebuilding plan is implemented; this limit is denoted, "$T_{F=0}$".

A target rebuilding year, T_{TARGET}, is set as a year at T_{MIN} (or $T_{F=0}$) or greater, which does not exceed T_{MAX} ,and which is as short as possible, taking into account the status and biology of the stock, the needs of fishing communities, and the interaction of the stock of fish within the marine ecosystem. Prior to Amendment 16-4, the Council set T_{TARGET} in part by considering the probability of rebuilding the stock by T_{MAX}. The Council may continue to review the probability of rebuilding the stock by T_{MAX} given differing harvest control rules, a reference parameter known as "P_{MAX}." The Magnuson-Stevens Act, however, simply requires that rebuilding periods be as short as possible, taking into account:

- the status and biology of any overfished stocks of fish;
- the needs of fishing communities;
- recommendations by international organizations in which the United States participates; and
- the interaction of the overfished stock of fish within the marine ecosystem (§304(e)(4)(A)(i)).

It is important to recognize that some of the terms introduced and described above represent policy decisions at the national level and the Council **does not have a choice** in setting their values. The dates for T_{MIN} and T_{MAX} are determined based on guidelines established at the national level. Mean generation time is a biological characteristic that cannot be chosen by policymakers. Thus, the Council cannot choose these values and then use them as a basis for management. Defined in national guidelines, T_{MIN} is a consequence of the productivity of the fish stock and is calculated by fishery biologists based on information they get from a particular stock. Similarly, T_{MAX}, which is calculated from T_{MIN}, does not represent a Council choice.

Policy flexibility comes into play in determining T_{TARGET}, or the time by which the stock is projected to rebuild. As explained earlier, the time to rebuild must be as short as possible, taking into account the status and biology of the stock, the needs of fishing communities, and the interaction of the stock of fish within the marine ecosystem. When developing a management strategy the Council can choose a fishing mortality rate and corresponding annual level of fishing. However, when rebuilding overfished species, the choice of the harvest control rule is based on the value of T_{TARGET}, keeping in mind that these values cannot be chosen independently of one another. In other words, the Council may choose one value and derive the other from it, but they cannot choose these values independently of the other.

The current groundfish rebuilding plan parameters are depicted in Table 7.

Table 4. Management quantities estimated from the most recent stock assessments informing management in 2015 and beyond.

1.1.3 Overfished Groundfish Stocks

There are six overfished west coast rockfish stocks (i.e., bocaccio south of 40º10' N lat., canary rockfish, cowcod south of 40º10' N lat., darkblotched rockfish, Pacific ocean perch, and yelloweye rockfish) and one overfished flatfish stock (i.e., petrale sole) at the start of 2013. All seven of these stocks are rebuilding and three (i.e., bocaccio south of 40º10' N lat., darkblotched rockfish, and petrale sole) are predicted to rebuild by the start of 2015. Descriptions of these overfished groundfish stocks follows.

Stock rebuilding parameters estimated from the most recent rebuilding analyses and current rebuilding parameters specified at the start of 2013 are provided in Table 7.

Table 7. Rebuilding parameters estimated in the most recent rebuilding analyses and specified in rebuilding plans for overfished groundfish stocks at the start of the 2013-2014 management cycle.

1.1.3.1 Bocaccio

Distribution and Life History

Bocaccio (*Sebastes paucispinis*) is a rockfish species that ranges from Stepovak Bay on the Alaskan Peninsula (as well as Kodiak Island, Alaska) to Punta Blanca, Baja California, Mexico (Hart 1988; Miller and Lea 1972). Love, et al. (2002) and Thomas and MacCall (2001) describe bocaccio distribution and life history. Bocaccio are historically most abundant in waters off central and southern California. The southern bocaccio stock is most prevalent in the 54-82 fm depth zone (Casillas, *et al.* 1998).

Bocaccio are found in a wide variety of habitats, often on or near bottom features, but sometimes over muddy bottoms. They are found both nearshore and offshore (Sakuma and Ralston 1995). Larvae and small juveniles are pelagic (Garrison and Miller 1982) and are commonly found in the upper 100 m of the water column, often far from shore (MBC 1987). Large juveniles and adults are semi-demersal and are most often found in shallow coastal waters over rocky bottoms associated with algae (Sakuma and Ralston 1995). Adults are commonly found in eelgrass beds, or congregated around floating kelp beds love (Love, *et al.* 1990; Sakuma and Ralston 1995). Young and adult bocaccio also occur around artificial structures, such as piers and oil platforms (MBC 1987). Although juveniles and adults are usually found around vertical relief, adult aggregations also occur over firm sand-mud bottoms (MBC 1987). Bocaccio move into shallow waters during their first year of life hart (Hart 1988), then move into deeper water with increased size and age (Garrison and Miller 1982).

Bocaccio are ovoviviparous (live young are produced from eggs that hatch within the female's body) (Garrison and Miller 1982; Hart 1988). Love et al. (1990) reported the spawning season to last nearly an entire year (>10 months). Parturition occurs during January to April off Washington, November to March off Northern and Central California, and October to March off Southern California (MBC 1987). Fecundity ranges from 20,000 to 2,300,000 eggs. In California, two or more broods may be born per year (Love, *et al.* 1990). The spawning season is not well known in northern waters. Males mature at three to seven years, with about half maturing in four to five years. Females mature at three to eight years, with about half maturing in four to six years (MBC 1987).

Maximum age of bocaccio was radiometrically determined to be at least 40 years, and perhaps more than 50 years. Bocaccio are difficult to age, and stock assessments used length measurement data and growth curves to estimate the age composition of the stock (Ralston and Ianelli 1998). Although recent assessments have described the true natural mortality rate as a key unknown for estimating stock status, recent assessments have used a value of 0.15 (which is associated with an 86 percent adult annual survival rate in the absence of fishing mortality).

Larval bocaccio eat diatoms, dinoflagellates, tintinnids, and cladocerans (Sumida and Moser 1984). Copepods and euphausiids of all life stages (adults, nauplii and egg masses) are common prey for juveniles (Sumida and Moser 1984). Both Phillips (1964) and Love et al. (2002) described bocaccio rockfish as almost exclusively piscivorous, and include other rockfish, Pacific whiting, sablefish, anchovy, mesopelagic fishes and squid as the key prey for large juvenile and adult bocaccio. Bocaccio are eaten by sharks, salmon, other rockfishes, lingcod, albacore, sea lions, porpoises, and whales (MBC 1987). Adult bocaccio are often caught with chilipepper rockfish and have been observed schooling with speckled, vermilion, widow, and yellowtail rockfish (Love, *et al.* 2002). As pelagic juveniles, they may compete with chilipepper, widow, yellowtail, shortbelly, and other pelagic juvenile rockfishes for both food and habitat (Reilly, *et al.* 1992).

Stock Status and Management History

Bocaccio are managed as two separate west coast populations. The southern stock exists south of Cape Mendocino and the northern stock north of Cape Mendocino (the northern stock density is limited south of 48° N lat. with increasing abundance off Cape Flattery, Washington and points north). It is unclear whether this stock separation implies stock structure. The distribution of the two populations and evidence of lack of genetic intermixing suggests stock structure, although MacCall (2002) reported some evidence for limited genetic mixing of the two populations. Nonetheless, assessment scientists and managers have treated the two populations as independent stocks north and south of Cape Mendocino.

Bocaccio have long been an important component of California rockfish fisheries. Catches increased to high levels in the 1970s and early 1980s as relatively strong year-classes recruited to the stock. The Council began to recommend increasingly restrictive regulations after an assessment of the southern stock in 1990 (Bence and Hightower 1990) indicated that fishing rates were too high. The southern stock suffered poor recruitment during the warm water conditions that prevailed off Southern California beginning in the late 1980s. The 1996 assessment (Ralston, *et al.* 1996) indicated the stock was in severe decline. NMFS formally declared the stock overfished in March 1999 after the groundfish FMP was amended to incorporate the tenets of the Sustainable Fisheries Act. MacCall et al. (1999) confirmed the overfished status of bocaccio and estimated spawning output of the southern stock to be 2.1 percent of its unfished biomass.

In the 2002 assessment (MacCall 2002) relative abundance increased slightly from the previous assessment (4.8 percent of unfished biomass), potential productivity (as evidenced from the steepness of the spawner/recruit relationship, which reflects the level of compensatory production at low stock sizes) appeared lower than previously thought, making for a more pessimistic outlook. Furthermore, the 2002 assessment revealed that although the 1999 year class was the strongest in several years, it was weak relative to the range of possibilities considered in the 1999 assessment. The 2002 rebuilding analysis (MacCall and He 2002) predicted the stock would not rebuild within maximum time legally possible (T_{MAX}) even with no fishing-related mortality. Total mortality in 2003 fisheries was restricted to less than 20 mt as a means of conserving the stock while minimizing adverse socioeconomic impacts to communities.

The 2003 bocaccio assessment (MacCall 2003b) estimated a higher stock biomass (7.4% depletion) relative to the 2002 assessment. The instantaneous rate of natural mortality was changed from 0.2 to 0.15. Additional CalCOFI data indicated an increasing abundance trend due to recruitment of the 1999 year class. This was corroborated by a dramatic increase in recreational CPUE, which was at a record high level in central California north of Pt. Conception. The 2003 rebuilding analysis suggested the stock could rebuild to B_{MSY} within 25 years while sustaining an OY of approximately 300 mt in 2004 (MacCall 2003a).

The 2003 assessment was updated in 2005 and 2007 (MacCall 2006b; MacCall 2008b) using the original 2003 base model (i.e., STATc) in SS1. These assessments were used to establish annual specifications and management measures consistent with a strategy of a higher OY than the impacts anticipated under the suite of management measures adopted. This strategy was designed to buffer the effects of a large recruitment event like that observed for the 1999 year class. Such effects include disruption to fisheries as experienced in previous years when fisheries closed early to avoid young bocaccio. This buffer strategy, which addressed the large, episodic recruitment pattern inherent in the stock's dynamics, became a tenet of the bocaccio rebuilding plan.

A bocaccio rebuilding plan was adopted by the Council in 2004 under Amendment 16-3 (PFMC 2004). The rebuilding plan established a target rebuilding year of 2023 and a harvest control rule of F = 0.0498 (with a rebuilding probability (P_{MAX}) of 70 percent). (It was later clarified in the 2005 rebuilding analysis (MacCall 2006a) that the target rebuilding year had been incorrectly stated in the rebuilding plan to be 2023 since the 2003 rebuilding analysis indicated that a 50 percent probability rebuilding would require 23 years, and that this assumed a beginning date of 2004 (the first simulated year). Therefore, the Council amended the rebuilding plan's target year to 2026.

A new rebuilding analysis was conducted in 2007 (MacCall 2008a) based on the results of the 2007 stock assessment (MacCall 2008b). The 2007 bocaccio rebuilding analysis showed a similar rebuilding trajectory to that adopted in Amendment 16-4 and the rebuilding plan was maintained for the 2009-2010 management cycle.

A new bocaccio assessment (Field, *et al.* 2009) and rebuilding analysis (Field and He 2009) were prepared in 2009. Field et al. (2009) extended the assessment north of Cape Mendocino to Cape Blanco, Oregon; the U.S. west coast stock north of this point has not been assessed. Indications of strong 2009 and 2010 year classes were projected to result in increased abundance. Depletion in 2011 was estimated at 26 percent (18.7 -33.1 percent), with the stock projected to be rebuilt by 2019. Based on these analyses, the Council changed the target year for rebuilding bocaccio from 2026 to 2022; the amended rebuilding plan was implemented in 2011.

A bocaccio stock assessment update (Field 2011b) and rebuilding analysis (Field 2011a) were prepared in 2011. The 2011 bocaccio assessment was originally scheduled to be an update of the 2009 full assessment; however, the STAT some limited changes in the 2009 model structure since a strict update estimated that the 2010 year class was extraordinarily and unrealistically strong, based on length frequency data collected in the 2010 NMFS trawl survey. The modified update was ultimately reviewed, endorsed by the SSC, and adopted for use in management decision-making. The 2011 bocaccio rebuilding analysis indicated rebuilding progress was well ahead of schedule with a predicted median year to rebuild of 2021 or one year earlier than the target rebuilding year (Field 2011a). The Council elected to maintain the revised rebuilding plan implemented in 2011.

An update of the 2011 bocaccio assessment model was prepared in 2013, which confirmed the 2009 and 2010 year classes were indeed strong (Field 2013). The assessment estimated a depletion of 31.4 percent at the start of 2013 (Figure 4) and predicted the stock would rebuild by 2015. The SSC recommended maintaining the current rebuilding plan for the 2015-2016 management cycle and a full assessment be done in 2015 to confirm this prediction. The SSC further recommended against preparing a rebuilding analysis in 2013.

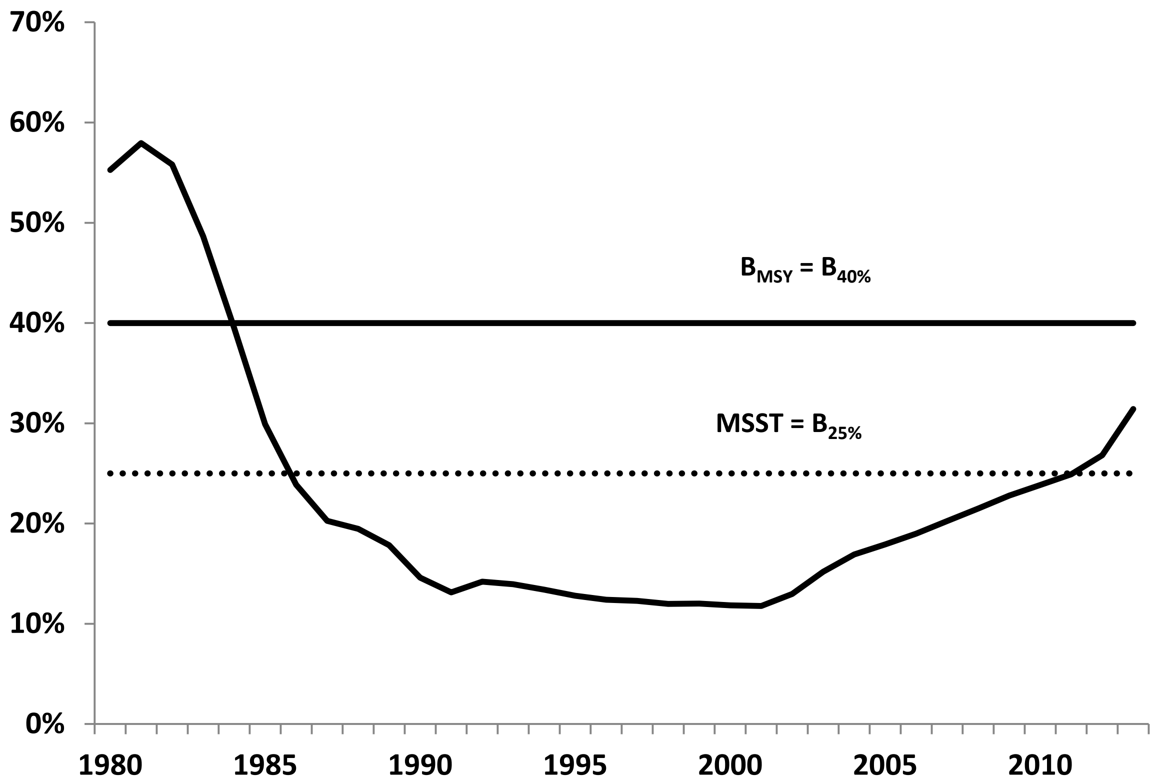

Figure 4. Relative depletion of bocaccio south of 40º10' N lat. from 1980 to 2013 based on the 2013 stock assessment update.

Stock Productivity Relative to Rebuilding Success

The 2013 bocaccio assessment produced a (very slightly) more optimistic estimation of steepness (from 0.595 to 0.614) relative to the 2011 model (the 2009 model had a point estimate of 0.573). Despite these modest changes, the overall trajectory of spawning output, relative spawning output, total biomass and recruitment are barely distinguishable as changed from the 2011 model, with the most important change being the relative strength of the 2010 year class. The strength of the 2010 year class is estimated with less uncertainty in the 2013 assessment.

Recruitment for bocaccio is highly variable, with a small number of year classes tending to dominate the catch in any given fishery or region. Adult abundance is highly variable even in the absence of fishing

(MacCall 2002). Recruitment appears to have been at very low levels throughout most of the 1990s, but the 1999 year class was the highest since 1988, and led to a substantive increase in abundance during the early 2000s. Several year classes of moderate strength (2003, 2005) occurred in the mid-2000s, and two recent very strong year classes (2009 and 2010) are now estimated to be comparable to (2009) and roughly double (2010) the size of the 1999 year class (Figure 5). These year classes were strongly evident in recreational length frequency data, in the NWFSC hook and line survey data (and length comps), and in the power plant impingement dataset modeled by Field (2013), as well as in an index (not included in the 2013 assessment update) of recreational CPUE. These strong year classes are already estimated to have resulted in an increase in abundance and spawning output, and should propel the stock spawning output to target levels by approximately 2015 as the 2010 year class continues to grow and mature. Preliminary estimates from the juvenile rockfish survey also indicate very strong abundance of young-of-the-year rockfish of many species (including bocaccio) in 2013, suggesting anecdotally that 2013 will also be a strong recruitment year for bocaccio, as well as for other species. However, these data are not incorporated in the 2013 update, which only includes data through 2012. Although poorly understood, the stock assessment suggests that recovery may be taking place more rapidly in the south, and recovery in the central/northern California region may be dependent on an influx of fish from the southern area.

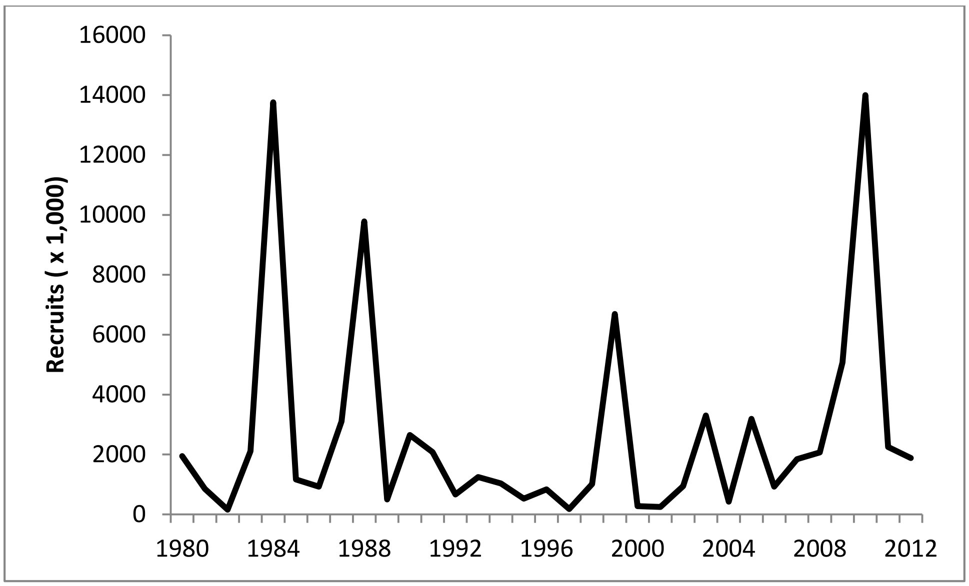

Figure 5. Estimated bocaccio recruitments, 1980-2012 (from Field 2013).

Fishing Mortality

The presence of a banner 2010 year class in the bocaccio stock is not entirely unexpected. Bocaccio stock production is characterized by high episodic recruitment and relatively rapid juvenile growth rates Field, et al. 2009. Juvenile bocaccio also recruit to shallow waters and are consequently caught in nearshore recreational fisheries as evidenced by dramatic spikes in both catch rates and the percentage of the total southern California rockfish catch that is bocaccio following strong recruitment events. Unlike most rockfish species where recruitment to fisheries usually takes several years due to low growth rates, juvenile bocaccio can recruit to nearshore fisheries in California within a year or two of parturition. Recruitment of the strong 1999 year class complicated management of California fisheries in 2001-2003, as this unpredictable event could not be reacted to in time given the lag in reconciling recreational catch estimates. Most species' rebuilding analyses are able to project recruitment into affected fisheries in time to decide and implement responsive management measures that will not compromise rebuilding plans.

However, the fast growth and unpredictable recruitment of bocaccio poses the unique problem of having to react to a large recruitment event in real time. This experience has led the Council to a strategy of adopting higher bocaccio OYs/ACLs and more conservative management measures that are predicted to result in catches much lower than these harvest limits. The rebuilding strategy has been formalized by deciding OYs/ACLs to determine rebuilding objectives and more stringent HGs for California. The buffer between the ACL (formerly the OY) and the HG accommodates the management uncertainty of an unforeseen recruitment event disrupting fisheries. Unlike an ACL, fisheries do not need to close upon attainment of an HG. The difference between the projected catch and the HG or ACL provides managers time to react to a strong recruitment to minimize mortality on bocaccio while minimizing disruptions to ongoing fisheries. This strategy has worked well to enhance bocaccio rebuilding while minimizing harm to California fishing communities.

Catch monitoring uncertainty is relatively high given the fact that a substantial amount of the total fishing mortality of bocaccio now occurs in the California recreational fishery, the sector with the largest bocaccio take in recent years. Recent recreational catch is estimated using the new California Recreational Fishing Survey (CRFS) program, which has been in existence since 2004. Prior to 2004, all recreational catch was estimated using the Marine Recreational Fisheries Statistical Survey (MRFSS) program, a survey methodology designed to understand long-term national trends in marine recreational catch and participation. The higher uncertainty in monitoring California recreational catches also translates into higher uncertainty in projecting recreational total mortalities. The fact that a substantial portion of the current take of bocaccio is in the California recreational fishery is another consideration for a relatively larger buffer between the predicted mortalities of bocaccio and the preferred ACLs.

Insert text and figure showing annual SPRs rel. to SPR of 77.7%

Rebuilding Duration and Probabilities

There is a high probability of successful bocaccio rebuilding by 2015 given the strength of recent year classes currently recruiting into the spawning population. The SSC has recommended a full assessment in 2015 to confirm this prediction.

1.1.3.2 Canary Rockfish

Distribution and Life History

Canary rockfish (*Sebastes pinniger*) are distributed in the northeastern Pacific Ocean from the western Gulf of Alaska to northern Baja California; however, the species is most abundant from British Columbia to central California (Hart 1988; Love, *et al.* 2002; Miller and Lea 1972). Adults are primarily found along the continental shelf shallower than 300 m, although they are occasionally observed in deeper waters. Juvenile canary rockfish are found in shallow and intertidal areas (Love, *et al.* 2002).

Canary rockfish spawn in the winter, producing pelagic larvae and juveniles that remain in the upper water column for 3-4 months (Love, *et al.* 2002). These juveniles settle in shallow water around nearshore rocky reefs, where they may congregate for up to three years (Boehlert 1980; Sampson 1996) before moving into deeper water. The mean size of individuals captured in the trawl survey shows a characteristic ontogenetic shift to deeper water with increasing body size. The degree to which this ontogenetic shift may be accompanied by a component of latitudinal dispersal from shallow rocky reefs is unknown. Canary rockfish are a medium to large-bodied rockfish; achieving a maximum size of around 70 cm. Female canary rockfish reach slightly larger sizes than males.

Adult canary rockfish primarily inhabit areas in and around rocky habitat. They form very dense schools, leading to an extremely patchy population distribution that is reflected in both fishery and survey encounter rates.

Canary rockfish are relatively long-lived, with a maximum observed age of 95 years, however only males are commonly observed above the age of 50, while females tend to be rare above age 30. The degree to which this pattern reflects behavioral differences translating to reduced availability to fishery and survey fishing gear, or an increase in relative mortality for older females has been the focus of much discussion and remains unclear. A similar pattern has been observed for yellowtail rockfish (*Sebastes flavidus*), a closely related, but more pelagic species with a similar distribution (Wallace and Lai 2006).

Canary rockfish off the west coast exhibit a protracted spawning period from September through March, probably peaking in December and January off Washington and Oregon (Hart 1988; Johnson, *et al.* 1982). Female canary rockfish reach sexual maturity at roughly eight years of age. Like many members of Sebastes, canary rockfish are ovoviviparous, whereby eggs are internally fertilized within females, and hatched eggs are released as live young bond 1979 (Bond 1979; Golden and Demory 1984; Kendall and Lenarz 1986). Canary rockfish are a relatively fecund species, with egg production being correlated with size (e.g., a 49-cm female can produce roughly 0.8 million eggs, and a female that has realized maximum length (approximately 60 cm) produces approximately 1.5 million eggs (Gunderson 1971).

Very little is known about the early life history strategies of canary rockfish. The limited research that has been conducted indicates that larvae are strictly pelagic (near the ocean surface) for a short period of time and begin to migrate to demersal waters during the summer of their first year of life. Larvae develop into juveniles around nearshore rocky reefs, where they may congregate for up to three years (Boehlert 1980; Sampson 1996) . Evaluations of length distributions by depth demonstrate an increasing trend in mean size of fish with depth (Methot and Stewart 2006). Since 1990, stock assessments have assumed a base natural mortality rate of 0.06 (94 percent adult annual survival when there is no fishing mortality). Due to the rarity of old females in both survey and catch data, female canary rockfish have long been assumed to have increasing natural mortality rates with age (Golden and Wood 1990).

Little is known about ecological relationships between canary rockfish and other organisms. Adult canary rockfish are often caught with bocaccio, sharpchin, yelloweye, and yellowtail rockfishes, and lingcod. Researchers have also observed canary rockfish associated with silvergray and widow rockfish. Young-of-the-year feed on copepods, amphipods, and young stages of euphausiids. Adult canary rockfish feed primarily on euphausiids, as well as pelagic shrimp, cephalopods, mesopelagic fishes and other prey (Brodeur and Percy 1984; Lee 2002; Phillips 1964). Small canary rockfish are consumed by seabirds, Chinook salmon, lingcod, and marine mammals.

Stock Status and Management History

Canary rockfish have long been an important component of rockfish fisheries. The Council began to recommend increasingly restrictive regulations after an assessment in 1994 (Sampson and Stewart 1994) indicated that fishing rates were too high. Wallace and Cope (2011) estimated that the abundance of the canary rockfish stock dropped below B_{MSY} ($B_{40\%}$) in 1983 and below the MSST in 1990, at which time the annual catch was more than double the current estimate of the MSY level. Harvest rates in excess of the current fishing mortality target for rockfish (SPR = 50%) is estimated to have begun in the late 1970s and persisted through 1999. Recent management actions appear to have curtailed the rate of removal such that overfishing has not occurred since 1999, and recent SPR values are in excess of 90 percent.

A 1999 stock assessment showed the stock had declined to 6.6 percent of unfished biomass in the northern area (Columbia and U.S. Vancouver management areas) (Crone, *et al.* 1999) and in the southern area (Conception, Monterey, and Eureka areas) (Williams, *et al.* 1999). The stock was declared overfished in January 2000. The first rebuilding analysis (Methot 2000) used results from the northern area assessment to project rates of potential stock recovery. The stock was found to have extremely low productivity, defined as production of recruits in excess of the level necessary to maintain the stock at its current, low level. Rates of recovery were highly dependent upon the level of recent recruitment, which could not be estimated with high certainty. The initial rebuilding OY for 2001 and 2002 was set at 93 mt based upon a 50 percent probability of rebuilding by the year 2057, a medium level for these recent recruitments, and maintaining a constant annual catch of 93 mt through 2002.

A coastwide 2002 canary rockfish assessment estimated stock depletion to be 7.9 percent at the start of 2002 (Methot and Piner 2002b). A canary rockfish rebuilding plan was adopted in 2003 under Amendment 16-2 based on the results of the 2002 rebuilding analysis (Methot and Piner 2002a). The rebuilding plan established a target rebuilding year of 2074 and the harvest control rule of F = 0.022 (with a P_{MAX} of 60 percent).

A full canary rockfish assessment was done in 2005 indicating a stock depletion of 9.0 percent at the start of 2005 (Methot and Stewart 2006). The assessment was based on two equally plausible models; one with differential male and female gear selectivities and one without gender-specific selectivities. A critical uncertainty in canary rockfish assessments was the lack of older, mature females in surveys and other assessment indices. There were two competing explanations for this observation. Older females could have a higher natural mortality rate, resulting in their disproportionate disappearance from the population. Alternatively, survey and fishing gears may be less effective at catching them, perhaps because older females are associated with habitat inaccessible to most trawl gear. If this is the case, then these fish (which, because of their higher spawning output, may make an important contribution to future recruitment) are part of the population, but remain poorly sampled. Methot and Stewart (2006) assumed a linear increase in female natural mortality from 0.06 at age 6 to approximately 0.09 at age 14. In the base model (differential male-female selectivity) B_0 was estimated to be 34,798 mt, resulting in a depletion level of 5.7 percent. In the alternate model (no difference in selectivity) B_0 was estimated to be 33,872 mt, with a depletion level of 11.3 percent. The steepness of the spawner-recruitment relationship, which largely determines the rate of increase in recruitment as the stock rebuilds, was estimated to be 0.33 in the base model, and 0.45 in the alternate model. The approved canary rockfish rebuilding analysis (Methot 2006) blended the two models by alternately re-sampling between the two input parameter sets.

The 2005 canary rebuilding analysis (Methot 2006) was used to inform the revised canary rebuilding plan adopted under Amendment 16-4, which specified a target rebuilding year of 2063 and a constant harvest strategy (SPR = 88.7%). Amendment 16-4 rebuilding plans were implemented in 2007.

The 2007 canary assessment estimated relative depletion level was 32.4 percent at the start of 2007 (Stewart 2008b). This was a significant departure from the previous assessment and largely driven by a higher assumed steepness (h = 0.51) relative to past assessments. The 2007 canary rebuilding analysis (Stewart 2008a) predicted the SPR harvest rate in the rebuilding plan (88.7%) would rebuild 42 years earlier (2021) than the originally estimated rebuilding schedule (2063). A modification of the Amendment 16-4 canary rockfish rebuilding plan specifying a target rebuilding year of 2021 while maintaining the SPR harvest rate of 88.7% was implemented in 2009.

The 2009 canary assessment (Stewart 2009c), an update of the 2007 assessment, estimated stock depletion at 23.7% at the start of 2009. This change in stock status was due to a lower estimate of initial, unfished biomass (B_0) largely attributable to the inclusion of revised historical California catches from a formal reconstruction of 1916-1980 California catch data (Ralston, *et al.* 2010). The 2009 canary rebuilding analysis (Stewart 2009a) predicted the stock would not rebuild to the target year of 2021 with at least a 50% probability even in the absence of fishing-related mortality starting in 2011 ($T_{F=0}$). The rebuilding plan was revised by changing the target to rebuild the stock to 2027 while maintaining the 88.7% SPR harvest rate; the revised rebuilding plan was implemented in 2011.

Another update assessment was prepared in 2011 (Wallace and Cope 2011), which estimated stock depletion was 23.2 percent at the start of 2011 (Figure 6). This change in stock status was due to a lower estimate of initial, unfished biomass (B_0) largely attributable to the inclusion of revised historical Oregon catches from a formal reconstruction of Oregon catch data. For the period 2000-2011, the spawning biomass was estimated to have increased from 11.2 percent to 23.2 percent of the unfished biomass level.

The 2011 canary rebuilding analysis (Wallace 2011) predicted the stock would not rebuild to the target year of 2027 with at least a 50% probability. The rebuilding plan was revised slightly by changing the target to rebuild the stock to 2030 while maintaining the 88.7% SPR harvest rate; the revised rebuilding plan was implemented in 2013.

A canary catch report was provided in 2013 (Agenda Item F.5.a, Attachment 9, June 2013), which indicated 2010-2012 total catches were below specified ACLs/OYs.

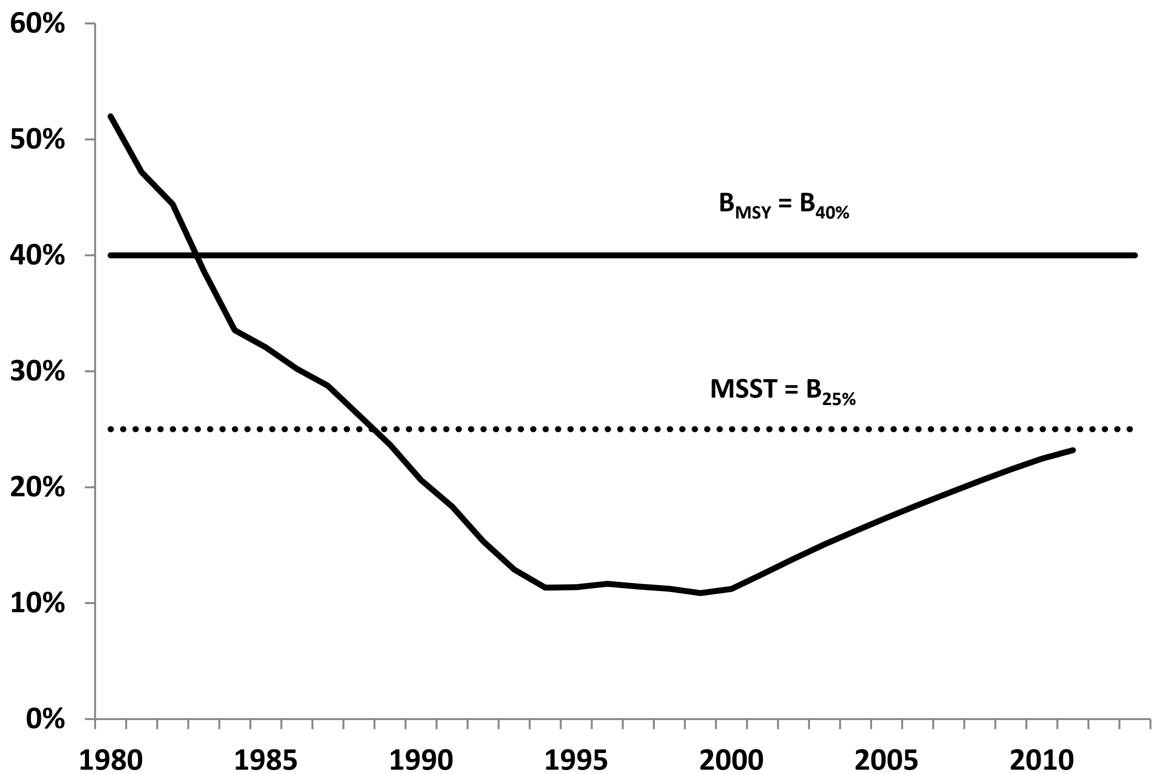

Figure 6. Relative depletion of canary rockfish from 1980 to 2011 based on the 2011 stock assessment update.

Stock Productivity Relative to Rebuilding Success

Steepness is assumed to be 0.511 in the latest full assessment (Stewart 2008b) and the subsequent updates to that assessment (Stewart 2009c; Wallace and Cope 2011). This is a moderate to relatively low value of steepness for rockfish, as compares to the prior mean steepness (0.779) derived from meta-analysis of west coast rockfish stocks used in 2013 assessments (e.g., darkblotched rockfish, see section 1.1.3.4).

Lower steepness implies a greater dependence on the size of the spawning population. The projected increase in the canary rockfish biomass from the 2011 assessment is very sensitive to the value for steepness and was projected to slow as below average recruitments begin to contribute to the spawning biomass.

Steepness is a difficult parameter to estimate and canary rockfish assessments are especially uninformative of steepness. The assumed canary steepness of 0.511 used in the last three assessments was based on the Dorn (2002a; Dorn 2002b) meta-analysis of west coast rockfish stocks The value used in many 2013 assessments was based on an update of the Dorn (2002a) analysis (J. Thorson, pers. comm.).

Wallace and Cope (2011) estimated canary rockfish recruitment deviations based on the data. After a period of above average recruitments, recent year-class strengths (1997-2010) have generally been low, with only 2 of the 10 years (2001 and 2007) producing large estimated recruitments (Figure 7). The strength of the 2007 year class is subject to greater uncertainty than other strong recruitment events in the last 30 years because of the limited number of years in which it has been observed. As the larger recruitments from the late 1980s and early 1990s move through the population in future projections, the effects of recent poor recruitment may tend to slow the rate of recovery.

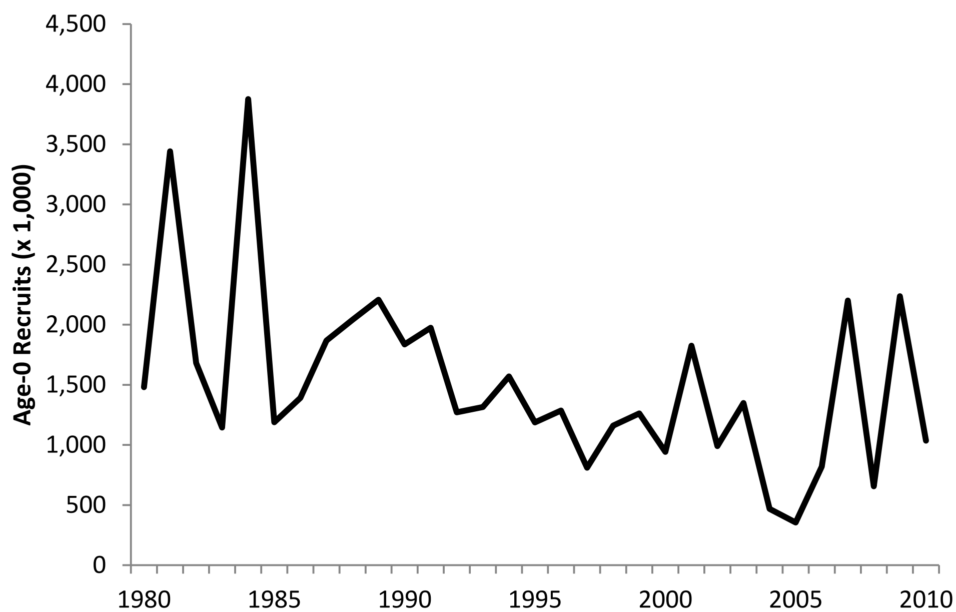

Figure 7. Estimated canary rockfish recruitments, 1980-2010 (from Wallace and Cope 2011).

Fishing Mortality

Fishing mortality rates for canary rockfish in excess of the current proxy F_{MSY} harvest rates for rockfish (SPR = 50%) are estimated to have begun in the late 1970s and persisted through 1999. Figure 8 depicts estimated annual harvest rates relative to the overfishing limit (F_{MSY}) and the current SPR harvest rate limit specified in the rebuilding plan. Recent management actions appear to have curtailed the rate of removal such that overfishing has not occurred since before 1999 and maintained harvest rates below the current rebuilding SPR since 2005. Relative exploitation rates (catch/biomass of age-5 and older fish) are estimated to have been less than 1% since 2001.

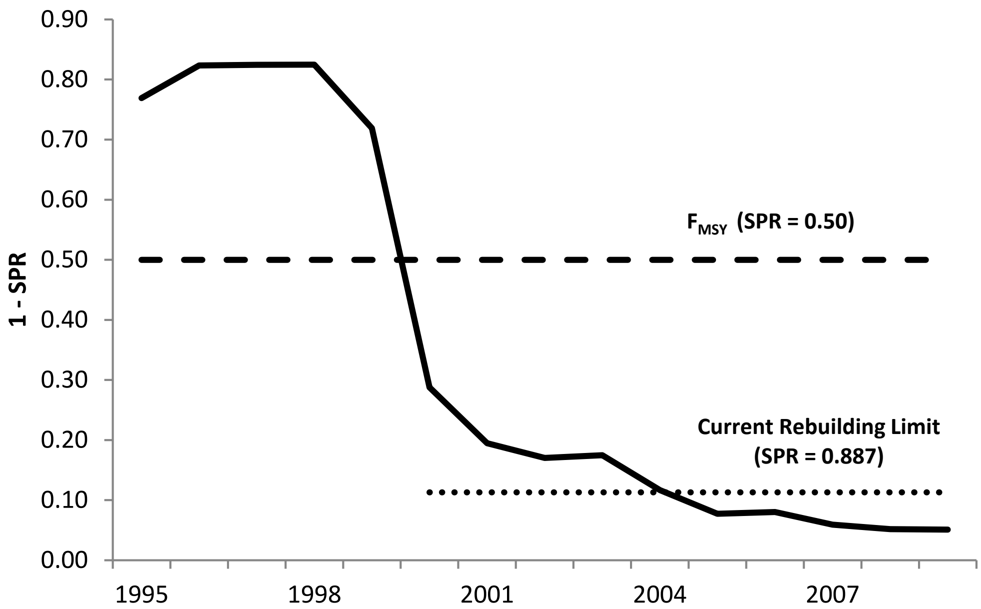

Figure 8. Estimated spawning potential ratio (SPR) of canary rockfish relative to the current F_{MSY} and rebuilding harvest rates, 1995-2010. One minus SPR is plotted so that higher exploitation rates occur on the upper portion of the y-axis.

Rebuilding Duration and Probabilities

Wallace 2013 estimated the canary rebuilding probability (P_{MAX}) under the current SPR harvest rate of 88.7% is 75 percent. There is a 50 percent probability of recovering by the current target year of 2030.

1.1.3.3 Cowcod

Distribution and Life History

Cowcod (*Sebastes levis*) is a species of large rockfish with a distribution from Newport, Oregon, to central Baja California, Mexico (Love et al., 2002). They are most common from Cape Mendocino (California) to northern Baja California, in depths from 50-300 m. Hess et al. (submitted) recently used genetic and otolith microchemistry tools to study cowcod population structure from California to Oregon. Specifically, they tested the hypothesis that a phylogeographic boundary exists at Point Conception. Their results supported a hypothesis of two primary lineages with a geographic boundary falling south of, rather than at Point Conception. Both lineages co-occur in the Southern California Bight (SCB), with no clear pattern of depth stratification or spatial structure within the Bight. Within lineages, there is evidence for considerable gene flow across the Point Conception boundary. Cowcod found north of Point Conception consist primarily of a single lineage, also found in northern areas of the SCB.

Cowcod are easily identified at all life stages, including larvae. Adults are piscivorous, with a diet consisting mainly of fishes, squids, and octopi. Cowcod are considered to be parademersal (transitional between a midwater pelagic and benthic species). Larvae develop into a pelagic juvenile stage, settling to benthic habitats after about 3 months. Juvenile cowcod were once thought to associate primarily with soft sediments, but Love and Yoklavich (Love and Yoklavich 2008), using visual surveys, found juveniles mainly associate with low-relief, hard substrate. Young-of-the-year were observed over a wide depth range (52-277 m), with juveniles slightly deeper, and adults mainly deeper than 150 m. Larger juveniles increasingly associate with high-relief, complex rocky substrate, the primary habitat for adult cowcod. Adult cowcod are generally solitary, but occasionally aggregate (Love, *et al.* 1990). Although cowcod are generally not migratory, they may move, to some extent, to follow food (Love 1996).

Cowcod are a long-lived, slow-growing species that require a decade or more to reach sexual maturity. Fertilization is internal, with females giving birth to planktonic larvae mainly during winter months. Spawning peaks in January in the Southern California Bight (MacGregor 1986) and large females may produce up to three broods per season (Love, *et al.* 1990). Larvae emerge at about 5.0 mm (MacGregor 1986).

Cowcod are a highly fecund species, with large females producing 2 million eggs (fecundity is dependent on size and ranges from 181,000 to 1,925,000 eggs) (Love, *et al.* 2002). Dick et al. (2009) found no evidence of increasing weight-specific fecundity (i.e., spawning output is roughly proportional to spawning biomass).

Maximum observed age for cowcod is 55 years (Love, *et al.* 2002). Dick et al. (2007) estimated the natural mortality rate (M) using three methods, reporting a range of values from 0.027 to 0.064 based on Beverton's (1992) method, a range of total mortality (Z) estimates from 0.038 to 0.072 based on catch curve analysis, and Hoenig's geometric mean regression. Females reach 90 percent of their maximum expected size by 42 years.

Little is known about ecological relationships between cowcod and other organisms. Small cowcod feed on planktonic organisms such as copepods. Juveniles eat shrimp and crabs, and adults eat fish, octopus, and squid (Allen 1982). Adults consume a wide range of prey items, but are primarily piscivorous (Love, *et al.* 2002).

Stock Status and Management History

While cowcod are not a major component of the groundfish fishery, they are highly desired by both recreational and commercial fishers because of their bright color and large size. The cowcod stock in the Conception area was first assessed in 1998 (Butler, *et al.* 1999b). Abundance indices decreased approximately tenfold between the 1960s and the 1990s, based on commercial passenger fishing vessel (CPFV) logs (Butler, *et al.* 1999b). Recreational and commercial catch also declined substantially from peaks in the 1970s and 1980s, respectively.

NMFS declared cowcod in the Conception and Monterey management areas overfished in January 2000, after Butler et al. (1999b) estimated the 1998 spawning biomass to be at 7 percent of B_0, well below the 25 percent overfishing threshold. Because cowcod is a fairly sedentary species, closed areas were established in 2002 to reduce cowcod mortality. Two Cowcod Conservation Areas (CCAs), in the Southern California Bight, were selected due to their high density of cowcod. The larger of the two areas (CCA West) is a 4200 square mile area west of Santa Catalina and San Clemente Islands. A smaller area (CCA East) is about 40 miles offshore of San Diego, and covers about 100 square miles. Bottom fishing is prohibited deeper than 20 fm within the CCAs.

A cowcod rebuilding analysis was completed in 2003 which validated the assumption that non-retention regulations and area closures had been effective in constraining cowcod fishing mortality (Butler, *et al.* 2003). These encouraging results were based on cowcod fishery-related landings in recreational and commercial fisheries, although the assessment included discard information only with respect to CPFV observations (which indicated negligible discards in that sector). This rebuilding review pointed out a common problem among the analyses of overfished species: reliance on landings (fishery-dependent) data for providing relative abundance values becomes increasingly difficult as the allowable catch is decreased and fishery observer data remains low. Monitoring stock status and recovery thus becomes increasingly difficult in the absence of fishery-independent surveys.

As in the 1999 assessment, the 2005 cowcod assessment (Piner, *et al.* 2006) considered only the cowcod population in Southern California Bight (from the US-Mexico border north to Point Conception) population, as this is the area in which cowcod are most abundant, adult habitat is most common, and catches are highest.. The 2005 assessment used only two data sources, the CPFV time series and the visual survey estimate data (Yoklavich, *et al.* 2007). The model was developed in Stock Synthesis 2, and although the base model estimated only three parameters (two of which were "nuisance parameters," the other was equilibrium recruitment), the STAR Panel determined that this simplicity was appropriate given the paucity of data. The assessment provided a set of results corresponding to three different values for assumed steepness (h), the key parameter in the stock-recruitment relationship (h=0.4, 0.5, and 0.6) and one the key uncertainties in the assessment. The assessment estimated that the 2005 spawning biomass was 18 percent of unfished levels and within a range of 14 to 21 percent depending on the value assumed for steepness, a considerably more optimistic result than the 1999 assessment. The corresponding 2005 cowcod rebuilding analysis (Piner 2006) was used to develop the cowcod rebuilding plan adopted in the groundfish FMP under Amendment 16-4. The rebuilding plan established a target rebuilding year of 2039 and an SPR of 90%.

A full cowcod assessment was conducted in 2007, which estimated spawning biomass to be 3.8 percent of its unfished level at the start of 2007 (Dick, *et al.* 2007). The 2007 cowcod assessment was an age-structured production model assuming a Beverton-Holt stock-recruitment function with deterministic recruitment, fit to the aggregated CPFV logbook index and the 2002 visual survey biomass estimate (Yoklavich, *et al.* 2007). Productivity parameters were fixed (steepness = 0.6, natural mortality = 0.055), leaving only virgin recruitment (R_0) to be estimated. Spawning biomass in 2007 was estimated to be between 3.4 percent and 16.3 percent of the unfished level. The poor precision of this estimate was due to 1) a lack of data to inform estimates of stock productivity, and 2) conflicting information from fishery-dependent and fishery–independent data. However, even the most optimistic model, which assumed a high-productivity stock and ignored declines in CPFV catch rates, suggested that spawning biomass was below 25 percent since 1980. Since retention of cowcod was prohibited and bycatch was thought to be minimal, it was considered unlikely that overfishing was an issue. It is likely that the 2007 base model underestimated the uncertainty about stock status given steepness and the natural mortality rate were treated as fixed and known in the model.

The 2007 assessment was originally prepared as an "update" stock assessment; however, while preparing the update, an error was discovered in the previous assessment's specification of the selectivity curve. Several revisions were proposed, including new estimates of historical landings, a corrected growth curve, and a two-fishery model. The 2007 assessment used Stock Synthesis 2, revised estimates of historical commercial catch, contained corrections to gear selectivity curves, utilized a revised growth curve, and separated the catch into commercial (all gears) and recreational fisheries rather than a single fishery. Recreational catches in the 2007 assessment were identical to those in the previous assessment, but estimates of commercial catches had been updated to reflect three additional data sources: 1) recovered port samples from Southern California (1983-1985), 2) regional summaries of total rockfish landings (1928-1968) provided by the NMFS SWFSC Environmental Research Division, and 3) California rockfish landings by region (1916-1927), published in CDF&G Fish Bulletin No. 105 (1958).

The 2007 rebuilding analysis (Dick and Ralston 2007) estimated a new T_{MAX} of 2098, 24 years later than the date estimated by Piner (2006), due in part to the corrections described above, but only 1 year earlier than the 2099 date estimated previously (Butler, *et al.* 2003). It was noted in the rebuilding analysis that rebuilding scenarios were extremely uncertain for this data-poor species, particularly with respect to steepness. Moreover, there was widespread concern about the ability to monitor the stock, and consequently to evaluate progress towards rebuilding in the future. The 2007 rebuilding analysis projections indicated that it would not be possible to rebuild the cowcod stock by 2039, even if all the catches are eliminated, and the estimated time to rebuild under the current harvest rate (SPR = 90%) was 26 years greater than the target year of 2039 adopted under Amendment 16-4. Therefore, a modification of the Amendment 16-4 cowcod rebuilding plan was implemented in 2007 which prescribed a target year of 2072 and an SPR harvest rate of 82.1%.

The 2007 cowcod assessment was updated in 2009, with stock depletion estimated to be 4.5 percent of its unfished level at the start of 2009 (Dick, *et al.* 2009). Estimates of female spawning stock biomass in 2009 were highly uncertain. Spawning biomass had declined from an unfished biomass of 2,101-2,461 mt to 93-441 mt in 2009. The 2009 cowcod rebuilding analysis (Dick, *et al.* 2009) was used to reconsider the cowcod rebuilding plan adopted under Amendment 16-4 as mandated in a legal challenge (*NRDC v. Locke*). The revised rebuilding plan, implemented in 2011, prescribed a target year of 2068 and an SPR harvest rate 82.7%.

A new cowcod assessment of the stock in the Southern California Bight was conducted in 2013 (Dick and MacCall 2013b), which estimated stock depletion to be 33.9 percent of unfished spawning biomass at the start of 2013 (Figure 9). The 2013 assessment suggested that cowcod in the Southern California Bight constitute a smaller, but more productive stock than was estimated from previous assessments. Median unfished and 2013 spawning biomasses were estimated to be 1,549 mt and 524 mt, respectively (Table 4).

The 2013 assessment used the XDB-SRA modeling platform to estimate stock status, scale, and productivity. Dick et al. (2013b) fit five fishery-independent data sources: four time series of relative abundance (CalCOFI larval abundance survey, Sanitation District trawl surveys, NWFSC trawl survey, and NWFSC hook-and-line survey), and the 2002 Yoklavich et al. (2007) visual survey estimate of absolute abundance.

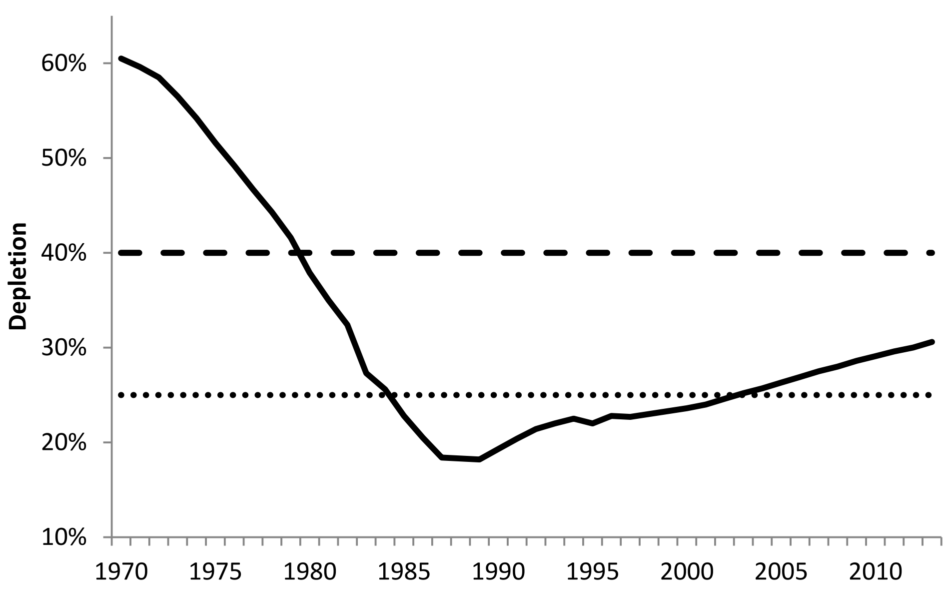

Figure 9. Relative depletion of cowcod south of 40°10’ N lat. from 1970 to 2013 based on the 2013 stock assessment. *Data from Table 38 – NOTE: different trajectory than Figure 94*

Stock Productivity Relative to Rebuilding Success

As in the previous assessment, production in the 2013 assessment is assumed to be a deterministic function of spawning biomass. Recruitment pulses may be evident in the abundance indices, but insufficient information is available to reliably estimate the relative strength of individual year classes.

Insert figure of B_{MSY}/B_0 & F_{MSY}/M?

Fishing Mortality

Estimated harvest rates for cowcod were highest during the mid-1980s (Figure 10). Retention of cowcod was prohibited from January 2001 to present. Dick and MacCall 2013 estimated that removals of cowcod have been less than 0.2% of vulnerable biomass since 2003. The estimated harvest rate that produces long term MSY (5.5%) is nearly twice the proxy (SPR = 50%) harvest rate from the last assessment (2.7%). Unlike previous assessments, the recent increasing trends in fishery-independent surveys allow the model to estimate the rate of increase in stock size. However, the 95% posterior interval for the MSY harvest rate (2.2% - 12.6%) reflects uncertainty in the data regarding overall productivity of the stock.

Median harvest rates around 1930 were near the MSY rate, then declined due to shifts in fishing effort and WWII (Figure 10). Following the war, catch rates slowly increased until about 1970, then rose quickly to a maximum of approximately 54% of vulnerable biomass in the mid-1980s. The MSY harvest rate estimated in the 2013 assessment is 5.5%, similar to the proxy ($B_{40\%}$) harvest rate of 5%, but higher than the SPR harvest rate in the 2009 assessment (2.7%). Median harvest rates were roughly 8-10 times the median MSY harvest rate in the mid-1980s, then declined to near zero after 2000, followed by steady increases in stock biomass.

Under the current SPR harvest rate specified in the rebuilding plan (82.7%), the median time to rebuild is 2020 (Dick and MacCall 2013a). This SPR harvest rate is equivalent to an exploitation rate (catch over age 11+ biomass) of 0.007 based on the 2009 assessment.

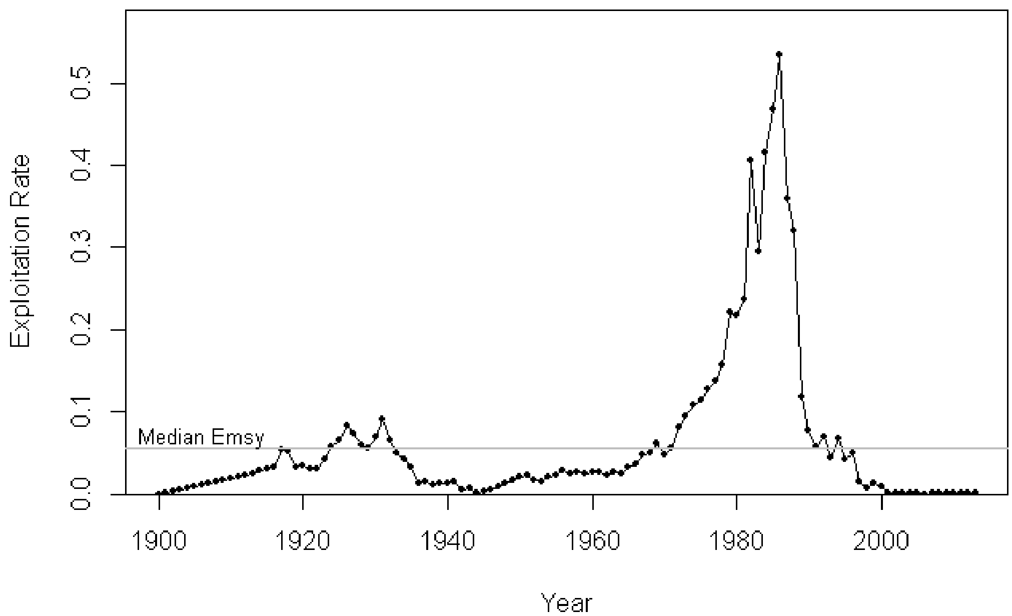

Figure 10. Time series of median harvest rates (total catch divided by age-11 and older biomass) from the base model in the 2013 cowcod assessment. The gray line is the estimated median harvest rate producing MSY.

Rebuilding Duration and Probabilities

The 2013 rebuilding analysis (Dick and MacCall 2013a) was unique in that the Punt rebuilding program (Punt 2005) was not used given its incompatibility with XDB-SRA. In each rebuilding model run, 15,000 simulated trajectories were generated using draws from the joint posterior distribution. Since the XDB-SRA platform is not compatible with spawning potential ratios, harvest control rules were translated into exploitation rates (E) calculated as catch/estimated age 11+ biomass. Similar to the previous cowcod rebuilding analysis, variability in future recruitment was expressed as a weighted set of different states of nature (parameter values), rather than random deviations from an average stock-recruitment relationship. While the previous rebuilding analysis accounted only for uncertainty in the Beverton-Holt steepness parameter, the current analysis accounts for uncertainty in all estimated model parameters. Estimates of total cowcod mortality have not exceeded the ACL (or OY) in any year since 2003. The estimate of median time to rebuild under the current harvest rate (2020) is 48 years earlier than the current target year of 2068.

1.1.3.4 Darkblotched Rockfish

Distribution and Life History

Darkblotched rockfish (*Sebastes crameri*) are found from Santa Catalina Island off Southern California to the Bering Sea (Miller and Lea 1972; Richardson and Laroche 1979). They are most abundant from Oregon to British Columbia. Darkblotched primarily occur on the outer shelf and upper slope off Oregon, Washington, and British Columbia (Richardson and Laroche 1979). Based upon genetic information and the absence of large scale gaps in catches, there are no clear stock delineations for darkblotched rockfish in U.S. waters. This does not mean there are not more fine scale groupings to be found, and in fact, darkblotched catches are characterized by infrequent large tows of larger fish. Distinct population groups have been found off the Oregon coast between 44°30' N lat. and 45°20' N lat. (Richardson and Laroche 1979). This species co-occurs with an assemblage of slope rockfish, including Pacific ocean perch (*Sebastes alutus*), splitnose rockfish (*Sebastes diploproa*), yellowmouth rockfish (*Sebastes reedi*), and sharpchin rockfish (*Sebastes zacentrus*).

Darkblotched rockfish mate from August to December, eggs are fertilized from October through March, and larvae are released from November through April love (Love, *et al.* 2002). Older larvae and pelagic juvenile darkblotched rockfish are found closer to the surface than many other rockfish species. Pelagic juvenile settle at 4 to 6 cm in length in about 55 to 200 m (Love, *et al.* 2002). As many other Sebastes, this species exhibits ontogenetic movement, with fish migrating to deeper waters as they mature and increase in size and age (Lenarz 1993; Nichol 1990).

Darkblotched rockfish are among the longer living rockfish; the data used in the most recent assessment (Gertseva and Thorson 2013) includes individuals that have been aged to be 98 years old. The maximum reported age of darkblotched rockfish is 105 years (Love, *et al.* 2002). As with many other *Sebastes* species, darkblotched rockfish exhibit sexually dimorphic growth; females reach larger sizes than males, while males attain maximum length earlier than females (Love, *et al.* 2002; Nichol 1990; Rogers, *et al.* 2000).

Darkblotched rockfish are ovoviviparous (Nichol and Pikitch 1994). Insemination of female darkblotched rockfish occurs from August to December, and fertilization and parturition occur from December to March off Oregon and California, and primarily in February off Oregon and Washington (Hart 1988; Nichol and Pikitch 1994; Richardson and Laroche 1979). Fecundity is dependent on size and ranges from 20,000 to 610,000 eggs.

Little is known about ecological relationships between darkblotched rockfish and other organisms. Pelagic juveniles feed on planktonic organisms such as copepods. Adults are often caught with other fish such as Pacific ocean perch and splitnose rockfish. Midwater animals such as euphausiids and amphipods dominate the diet of adult fish. Albacore and Chinook salmon consume pelagic juveniles (Hart 1988). Little is known about predation of adults.

Stock Status and Management History

Darkblotched rockfish are primarily with commercial trawl gear, as part of a complex of slope rockfish, which includes Pacific ocean perch (*Sebastes alutus*), splitnose rockfish (*Sebastes diploproa*), yellowmouth rockfish (*Sebastes reedi*), and sharpchin rockfish (*Sebastes zacentrus*). Catches of darkblotched rockfish first became significant in the mid-to-late 1940s due to increased demand for fish protein during World War II. During the mid-1960s to mid-1970s darkblotched rockfish were caught by both domestic and foreign fleets (Rogers 2003b). Domestic landings rose from late 1970s until the late 1980s, although limits on rockfish catch were first instituted in 1983, when darkblotched was rockfish managed as part of a group of around 50 species (designated as the Sebastes complex) (Rogers, *et al.* 2000). During the 2000s, progressive steps have been taken to reduce the catch of darkblotched rockfish, following the declaration of its overfished status in 2001.

The first full assessment of the darkblotched rockfish stock was conducted in 2000, which estimated stock depletion at 14–31 percent of its unfished level, depending on assumptions regarding the historic catch of darkblotched rockfish in the foreign fishery from 1965-1978 (Rogers, *et al.* 2000). The base model assumed 10 percent of foreign catch was comprised of darkblotched, leading to the conclusion that the spawning stock biomass was at 22 percent of its unfished level. NMFS declared darkblotched rockfish to be overfished in 2001 based on these results.

The 2001 rebuilding analysis for the stock (Methot and Rogers 2001) incorporated results of the 2000 Alaska Fishery Science Center triennial slope trawl survey and modeled a more recent time series of recruitments. Incorporating these data resulted in a downward revision of the estimated recruitment and abundance throughout the time series compared to what had been used in the Rogers et al. (2000) assessment. This led to a revised estimate of spawning stock biomass at the beginning of 2002 of 14 percent of its unfished level and a longer projected rebuilding period.

A 2003 assessment and rebuilding update for darkblotched rockfish (Rogers 2003a) estimated a lower depletion ($B_{11\%}$), but provided evidence of strong recent recruitment not yet recruited to the spawning population. This analysis was used to inform the darkblotched rockfish rebuilding plan adopted under Amendment 16-2, which established a target rebuilding year of 2030 and a fishing mortality rate of F = 0.027. A revised darkblotched rebuilding plan was implemented in 2004 that specified a higher harvest rate (F = 0.032) to avoid negative socioeconomic impacts.

The 2005 full darkblotched assessment estimated a spawning stock depletion of 16 percent of unfished biomass at the start of 2005 (Rogers 2005a). The assessment estimated strong recruitment of the 1999 and 2000 year classes. The 2005 rebuilding analysis (Rogers 2005b) was used to inform a revised rebuilding plan adopted under Amendment 16-4 and implemented in 2007. The revised rebuilding plan specified a target year of 2011 and a constant harvest rate strategy (SPR = 60.7%).

The 2007 darkblotched rockfish assessment estimated a stock depletion of 22.7 percent at the start of 2007 (Hamel 2008c). The 2007 darkblotched rebuilding analysis (Hamel 2008a) predicted the median time to rebuild would be 19 years later than the target year of 2011 under the SPR harvest rate adopted under Amendment 16-4. The Council revised the Amendment 16-4 rebuilding plan by specifying a target year to rebuild the stock of 2028 and decreasing the harvest rate (SPR = 62.1%).

The 2007 darkblotched assessment was updated in 2009 and 2011. The 2009 stock assessment update estimated a stock depletion of 27.5 percent at the start of 2009 (Wallace and Hamel 2009). The 2009 darkblotched rebuilding analysis (Wallace 2009) was used to inform a revised rebuilding plan, which was implemented in 2011 The revised rebuilding plan specified a target year to rebuild the stock of 2025 and decreased the harvest rate to SPR = 64.9%. The 2011 stock assessment update estimated a stock depletion of 30.2 percent at the start of 2009 (Stephens, *et al.* 2011). No revisions to the rebuilding plan were made based on the 2011 assessment update and accompanying rebuilding plan (Stephens 2011).

A full darkblotched stock assessment in 2013 (Gertseva and Thorson 2013) estimated a stock depletion of 36 percent at the start of 2013 (Figure 11). The assessment also predicts the stock will be rebuilt by the start of 2015. The improved stock status and rebuilding outlook were largely attributed to 1) reduced fishing mortality under the rebuilding program; 2) inferences that follow from more favorable perceptions of steepness, fecundity, and age at maturity of the stock; and 3) length and age data indicating relatively large recruitments in 1999, 2000, and 2008. The SSC recommended maintaining the current rebuilding plan for the 2015-2016 management cycle and a full assessment be done in 2015 to confirm this prediction. The SSC further recommended against preparing a rebuilding analysis in 2013.

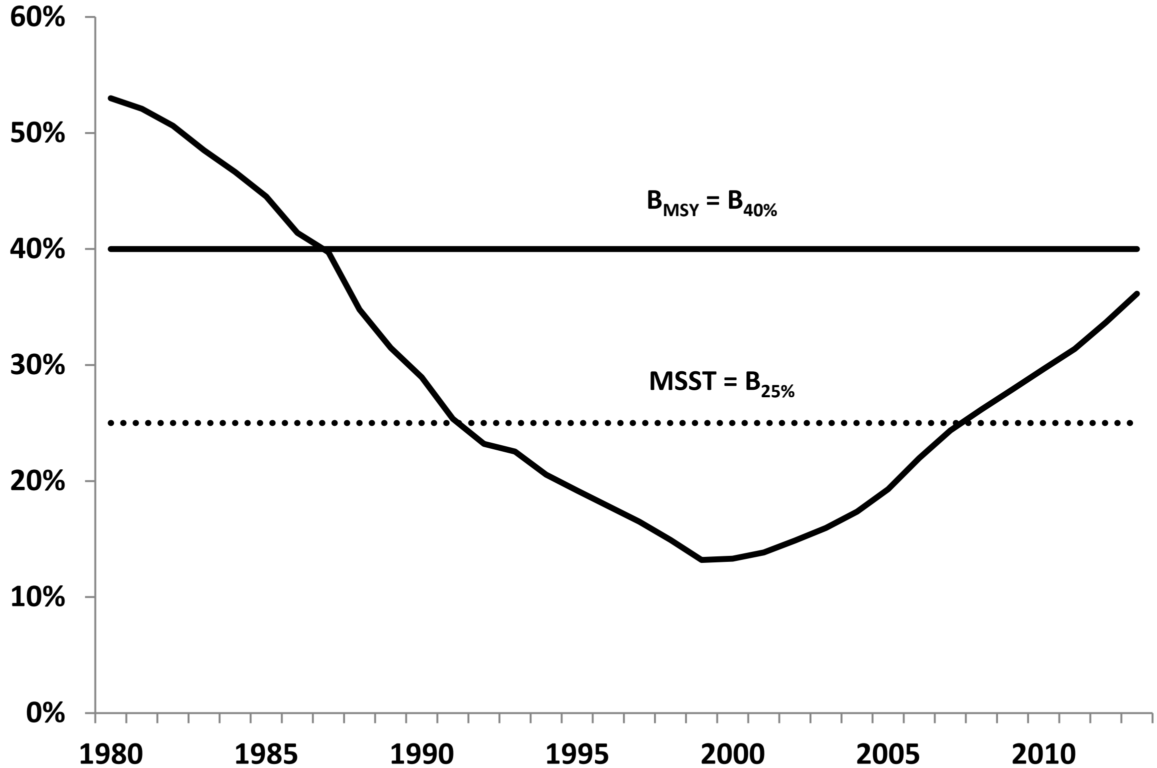

Figure 11. Relative depletion of darkblotched rockfish from 1980 to 2013 based on the 2013 stock assessment.

Stock Productivity Relative to Rebuilding Success

Gertseva and Thorson (2013) fixed steepness at its prior mean of 0.779. This prior was estimated using a likelihood profile approximation to a maximum marginal likelihood mixed-effect model for steepness from ten category 1 rockfish species off the U.S. west coast (Pacific ocean perch, bocaccio, canary, chilipepper, black, darkblotched, gopher, splitnose, widow, and yellowtail rockfish). Both northern and southern assessments of black rockfish were used, although the log-likelihood for each was given a 0.5 weighting, to ensure that the together these two assessments had an equal weighting to the other species. This likelihood profile model is intended to synthesize observation-level data from assessed species, while avoiding the use of model output and thus improving upon previous meta-analyses (Dorn 2002a; Forrest, *et al.* 2010). This methodology has been simulation tested, and has been recommended by the SSC for use in stock assessments.

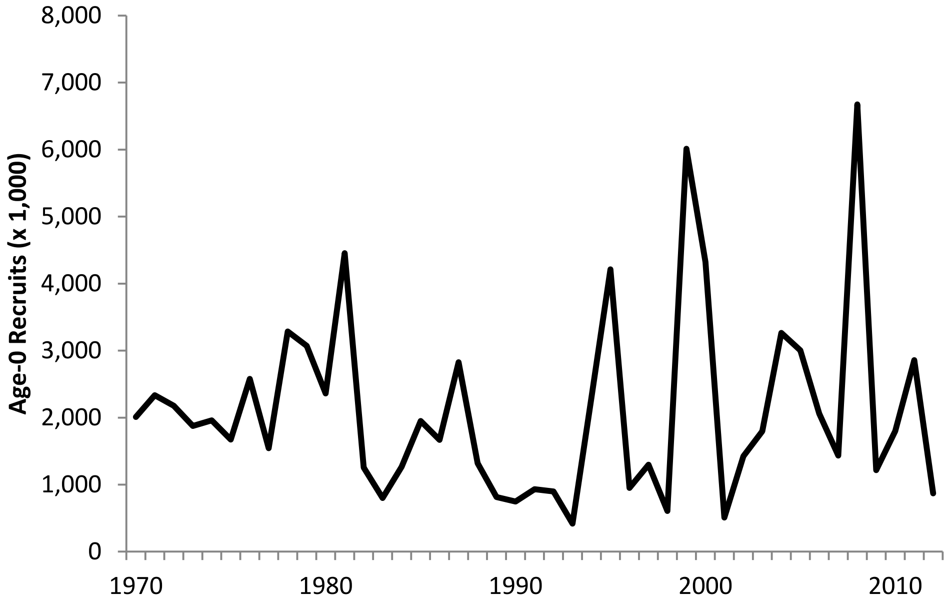

Figure 12. Estimated recruitments of darkblotched rockfish, 1970-2012.

Fishing Mortality

Historically, the spawning output of darkblotched rockfish dropped below the B_{MSY} target for the first time in 1987, as a result of intense fishing by foreign and domestic fleets. It continued to decline and reached the level of 13 percent of its unfished output in 1999. Since 2000, when the stock was declared overfished, the spawning output slowly increased primarily due to management regulations implemented for the stock.

Overfishing for darkblotched has not occurred in the last 10 years (Gertseva and Thorson 2013). Historically, the darkblotched rockfish has experienced overfishing in the 1980s and 1990s, during the peak years of the Pacific ocean perch fishery, as well as in the mid-1960s when foreign trawl fleets were targeting groundfish off the west coast. Exploitation rates were effectively decreased after the stock was declared overfished in 2000 and rebuilding measures were implemented.

Rebuilding Duration and Probabilities

The 2013 darkblotched assessment predicts the stock will be rebuilt by 2015. Therefore, rebuilding probabilities (both P_{MAX} and P_{TARGET}) are high for darkblotched under the harvest control rule in the rebuilding plan. The SSC is recommending a new assessment be done in 2015 to confirm that prediction.

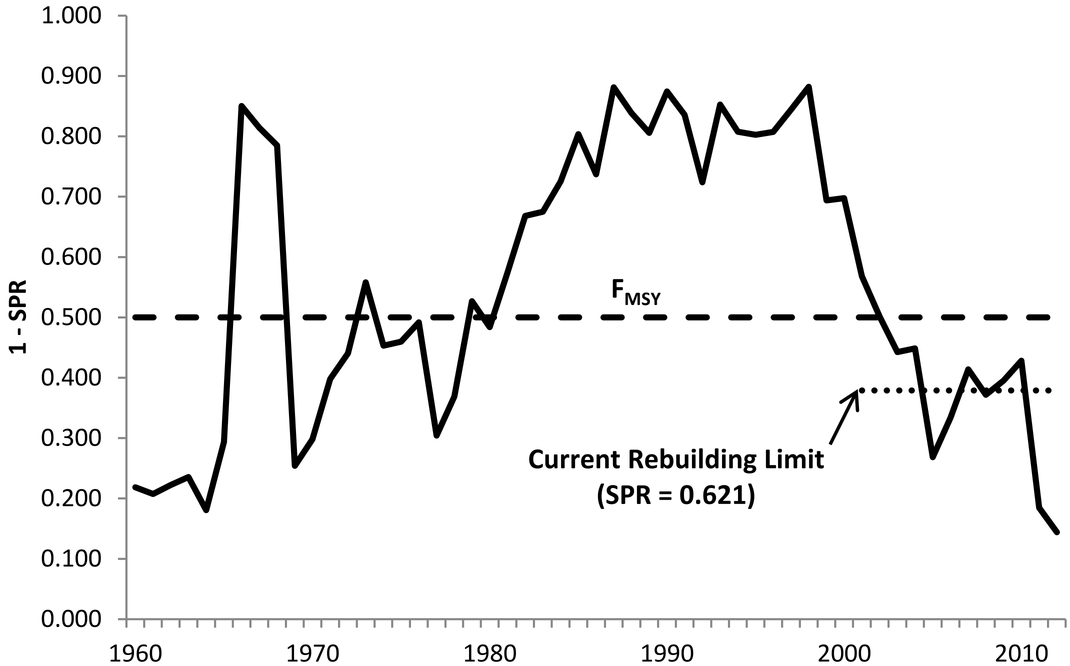

Figure 13. Time series of estimated SPR harvest rates of darkblotched rockfish, 1960-2012. One minus SPR is plotted so that higher exploitation rates occur on the upper portion of the y-axis.

1.1.3.5 Pacific Ocean Perch

Distribution and Life History

Pacific ocean perch (POP, *Sebastes alutus*) are most abundant in the Gulf of Alaska, and have been observed off of Japan, in the Bering Sea, and south to Baja California, although they are sparse south of Oregon and rare in southern California. (Eschmeyer, *et al.* 1983; Gunderson 1971; Miller and Lea 1972). They primarily inhabit waters of the upper continental slope (Dark and Wilkins 1994) and are found along the edge of the continental shelf (Archibald, *et al.* 1983). Pacific ocean perch occur as deep as 825 m, but usually are at 100 m to 450 m and along submarine canyons and depressions (NOAA 1990). Throughout their range, POP are generally associated with gravel, rocky, or boulder type substrate (Ito, *et al.* 1986). Larvae and juveniles are pelagic; subadults and adults are benthopelagic (living and feeding on the bottom and in the water column). Adults form large schools 30 m wide, to 80 m deep, and as much as 1,300 m long (NOAA 1990). They also form spawning schools (Gunderson 1971). Juvenile POP form ball-shaped schools near the surface or hide in rocks (NOAA 1990).

Pacific ocean perch winter and spawn in deeper water (>275 m). In the summer (June through August) they move to feeding grounds in shallower water (180 m to 220 m) to allow gonads to ripen (Archibald, *et al.* 1983; Gunderson 1971; NOAA 1990). They are slow-growing and long-lived; the maximum age has been estimated at about 98 years (Heifetz, *et al.* 2000). The can grow up to about 54 cm and 2 kg (Archibald, *et al.* 1983; Beamish 1979; Gunderson 1971; Ito, *et al.* 1986; Mulligan and Leaman 1992; NOAA 1990). POP are carnivorous. Larvae eat small zooplankton. Small juveniles eat copepods, and larger juveniles feed on euphausiids (krill). Adults eat euphausiids, shrimps, squids, and small fish. Immature fish feed throughout the year, but adults feed only seasonally, mostly April through August (NOAA 1990). POP predators include sablefish and Pacific halibut.

Stock Status and Management History

POP were harvested exclusively by U.S. and Canadian vessels in the Columbia and Vancouver INPFC areas prior to 1966. Large Soviet and Japanese factory trawlers began fishing for POP in 1965 in the Vancouver area and in the Columbia area a year later. Intense fishing pressure by these foreign fleets occurred from 1966 to 1975. The mandates of the MSA, passed by Congress in 1976, eventually ended foreign fishing within 200 miles of the United States coast.

The POP resource off the west coast was overfished before implementation of the groundfish FMP in 1982, and Council actions to conserve the resource likewise predate the FMP. Large removals of POP in the foreign trawl fishery, followed by significant declines in catch and abundance, led the Council to limit harvest beginning in 1979. A 20–year rebuilding plan for POP was adopted in 1981. Rebuilding under this original plan was largely influenced by a cohort analysis of 1966-1976 catch and age composition data (Gunderson 1979), updated with 1977-1980 data (Gunderson 1981), and an evaluation of trip limits as a management tool (Tagart, *et al.* 1980). This was the first time trip limits were used by the Council to discourage targeting and overharvest of an overfished stock, and it remains a management strategy in use today in the west coast groundfish fishery. In addition to trip limits, the Council significantly lowered the OY for POP. After twenty years of rebuilding under the original plan, the stock stabilized at a lower equilibrium than estimated in the pre-fishing condition. While continuing stock decline was abated, rebuilding was not achieved as the stock failed to increase in abundance to B_{MSY}.

Ianelli and Zimmerman (1998) estimated POP female spawning biomass in 1997 to be at 13 percent of its unfished level, thereby confirming that the stock was overfished. NMFS formally declared POP overfished in March 1999 after the groundfish FMP was amended to incorporate the tenets of the Sustainable Fisheries Act. The Council adopted and NMFS enacted more conservative management measures in 1999 as part of a redoubled rebuilding effort.

A 2000 POP assessment suggested the stock was more productive than originally thought (Ianelli, *et al.* 2000). A revised POP rebuilding analysis was completed and adopted by the Council in 2001 (Punt and Ianelli 2001). This analysis estimated a T_{MIN} of 12 years and a T_{MAX} of 42 years. It was noted in the rebuilding analysis that the ongoing retrospective analysis of historic foreign fleet catches was likely to change projections of POP rebuilding.

The 2003 POP assessment (Hamel, *et al.* 2003) incorporating updated survey and fishery data including the retrospective of foreign fleet catches (Rogers 2003b). The assessment covered areas from southern Oregon to the U.S. border with Canada, the southern extent of POP distribution. The overall conclusion was that the stock was relatively stable at approximately 28 percent of its unfished biomass ($B_{28\%}$). Of all the changes and additions to the data, the historical catch estimates had the greatest effect, resulting in lower estimates of both equilibrium unfished biomass (B_0) and MSY.

A POP rebuilding plan was adopted in 2003 under Amendment 16-2. The rebuilding plan was informed by a revised rebuilding analysis based on the 2000 assessment and conducted in 2001 (Punt and Ianelli 2001). The rebuilding plan established a target rebuilding year of 2027 and a harvest control rule of F = 0.0082 (with a P_{MAX} of 70 percent).

The 2003 assessment estimated a stock depletion of 28 percent at the start of 2003 (Hamel, *et al.* 2003). The 2003 rebuilding analysis (Punt, *et al.* 2003) was used to amend the harvest control rule and set annual POP OYs for the 2004-2006 period. The amended harvest control rule was F = 0.0257.

The 2003 POP assessment was updated in 2005, 2007, and 2009. The 2005 update assessment estimated a stock depletion of 23.4 percent of its unfished level at the start of 2005 (Hamel 2006b). The 2005 POP rebuilding analysis (Hamel 2006a) was used to inform revisions to the POP rebuilding plan. The revised rebuilding plan, which was adopted under Amendment 16-4, specified a target rebuilding year of 2017 and a constant harvest rate strategy (SPR = 86.4%).

The 2007 POP assessment update estimated a stock depletion of 27.5 percent at the start of 2007 (Hamel 2008d). The 2007 rebuilding analysis indicated rebuilding was progressing ahead of schedule (Hamel 2008b). No modifications to the rebuilding plan were made.

The 2009 POP assessment estimated a stock depletion of 28.6 percent at the start of 2009 (Hamel 2009b). The 2009 POP rebuilding analysis (Hamel 2009a) predicted rebuilding would not occur by the target year of 2017 with at least a 50% probability even in the absence of fishing-related mortality beginning in 2011 (i.e., $T_{F=0}$). Therefore the rebuilding plan was revised by changing the target rebuilding year to 2020 while maintaining the constant SPR harvest rate of 86.4%.

A full assessment in 2011 estimated a stock depletion of 19.1 percent at the start of 2011 (Hamel and Ono 2011). The significant decrease in the estimated depletion of the stock was largely due to a much higher estimate of initial, unfished biomass (B_0). Previous assessments assumed a large recruitment in the late 1950s provided the higher biomass to support the estimated removals by the foreign fleets without any data to support that assumption. The assumption in the 2011 assessment is that the large foreign fleet catch fished the biomass down to critical levels, thus resulting in a substantially larger B_0 estimate. The 2011 assessment also estimated a longer sequence of higher recruitment based on fitting to the data available for early years of the assessment period. The 2011 rebuilding analysis (Hamel 2011) predicted rebuilding would not occur by the target year of 2020 with at least a 50% probability even in the absence of fishing-related mortality beginning in 2013 (i.e., $T_{F=0}$). Therefore the rebuilding plan was revised by changing the target rebuilding year to 2051 while maintaining the constant SPR harvest rate of 86.4%.

A POP catch report was provided in 2013 (Agenda Item F.5.a, Attachment 10, June 2013), which indicated 2010-2012 total catches were below specified ACLs/OYs.

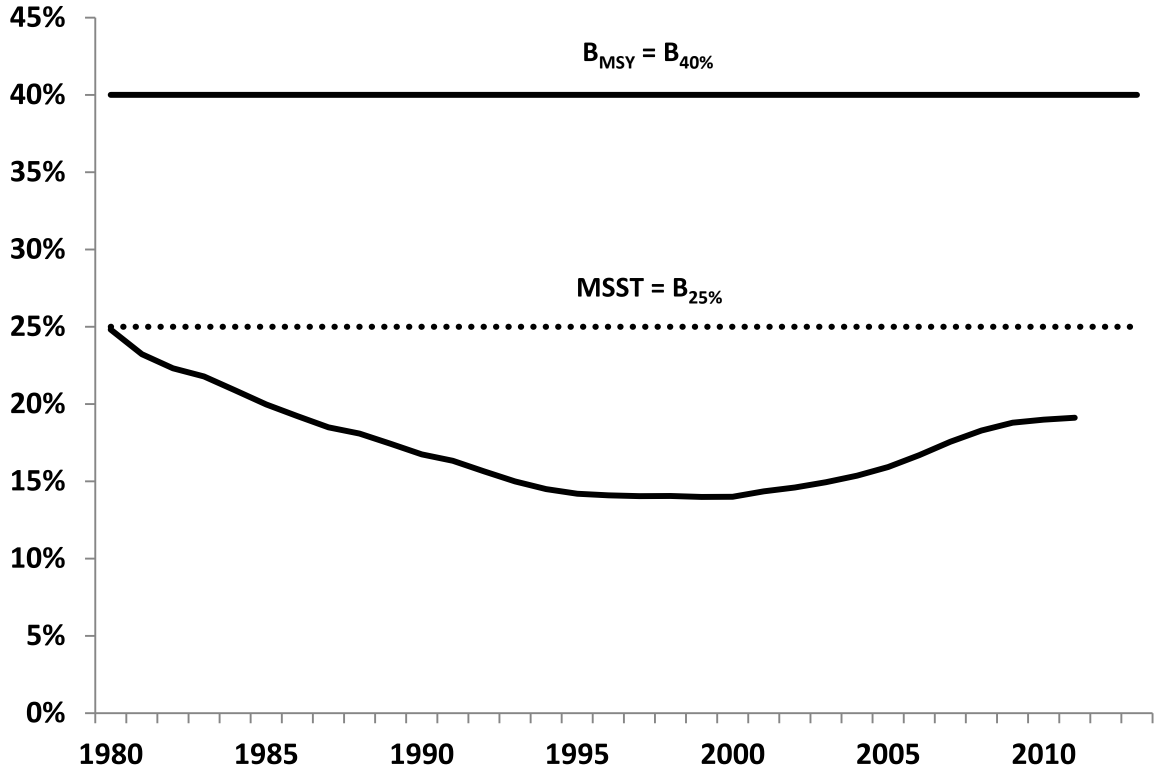

Figure 14. Relative depletion of Pacific ocean perch from 1980 to 2011 based on the 2011 stock assessment.

Stock Productivity Relative to Rebuilding Success

Stock-recruitment steepness was estimated external to the 2011 POP stock assessment base model at 0.4 (and then fixed in the model), which is low compared to steepness estimates from POP assessments conducted off Canada and Alaska. The 2011 assessment assumes no connectivity with the other assessed POP stocks in Canada and Alaska. POP off the U.S. west coast (mostly Washington and Oregon) are at the southern end of the range where there are enough POP to be commercially important, and the numbers seen are likely related to movement across the Canadian border, as well as reproductive success (recruitment) and fishing mortality north of the border. Given there is no evidence of stock structure in the meta-population of POP in the northeast Pacific and larval distribution of slope rockfish tends to be geographically widespread, this assumption of no connectivity with northern stocks is questionable. It is plausible that steepness is higher than determined in the 2011 assessment, which would tend to estimate a less depleted and more productive stock. The major axis of uncertainty in the assessment is steepness, with states of nature ranging from a low steepness of 0.35 to a higher value of 0.55. If steepness was as high as 0.55, the POP stock would be on the verge of being rebuilt at the start of 2011 (depletion = 39.9 percent) and projected to be rebuilt at the start of 2012. Under the base case model with a steepness of 0.4 and continuing to manage POP using the 86.4 percent SPR harvest rate in the current rebuilding plan, the stock is projected to be rebuilt by 2051.

Recruitment trends estimated in the 2011 POP assessment indicate that, like most assessed rockfish, recruitment has been relatively lower in the last few decades compared to the 1950s and 1960s. However, the 1999 and 2000 year classes are estimated to be above average and the 2008 year class recruitment, while uncertain, appears to be the largest in at least the past 50 years (Figure 15).

Fishing practices are unlikely to have any effect on stock productivity, given the low fishing mortality implemented under the rebuilding plan limits. There is no indication that fishing operations are likely to substantially interfere with or disturb reproductive behavior or juvenile survival.

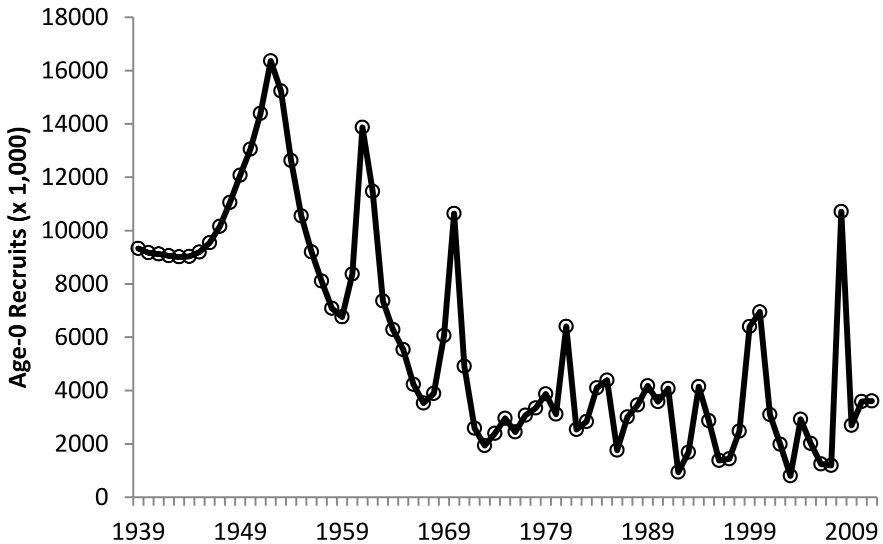

Figure 15. Time series of estimated (age-0) POP recruitments.

Fishing Mortality

POP are caught almost exclusively by groundfish trawl gear and predominantly bottom trawls operating on the outer continental shelf and slope north of 43º N lat. POP are distributed from 30-350 fm, with the core distribution between 110-220 fm.

According to the base model in the 2011 assessment, the fishing level has been below the proxy $F_{50\%}$ F_{MSY} harvest rate for the past 12 years (Figure 16), during which period the stock has begun to rebuild (Figure 14). The point estimates of summary (age 3+) biomass also show an upward trend over the past decade, increasing approximately 50 percent in that time.

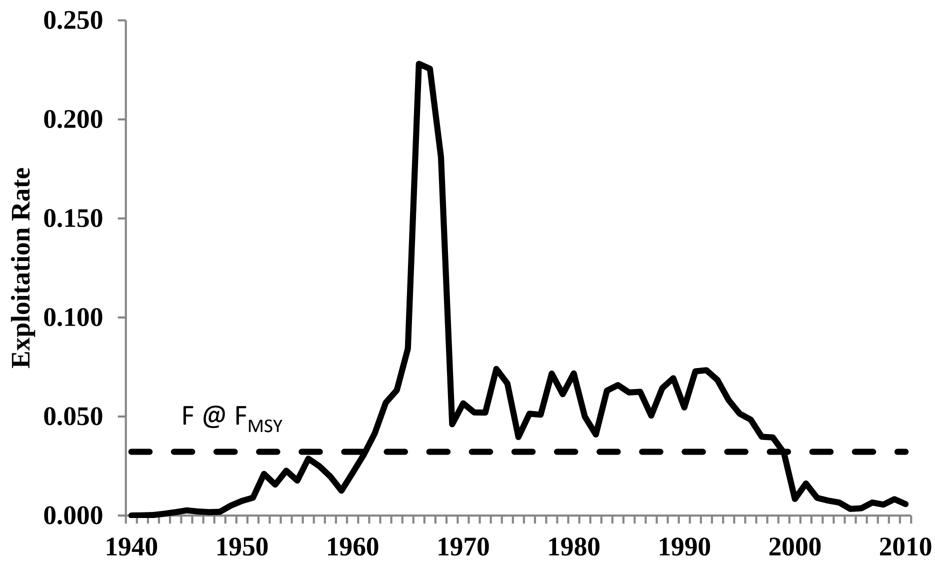

Figure 16. Time series of POP exploitation rates (catch/summary biomass), 1940-2010.

Rebuilding Duration and Probabilities

Hamel (2011) estimated a probability of rebuilding in the maximum time allowable (P_{MAX}) under the SPR harvest rate specified in the rebuilding plan of 72.3%. There is a 50% probability of rebuilding by the target year of 2051.

1.1.3.6 Petrale Sole

Distribution and Life History

Petrale sole (*Eopsetta jordani*) is a right-eyed flounder in the family Pleuronectidae ranging from the western Gulf of Alaska to the Coronado Islands, northern Baja California, (Hart 1988; Kramer and O'Connell 1995; Love, *et al.* 2002) with a preference for soft substrates at depths ranging from 0-550 m (Love, *et al.* 2002). In northern and central California petrale sole are dominant on the middle and outer continental shelf (Allen, *et al.* 2006).

There is little information regarding the stock structure of petrale sole off the U.S. Pacific coast. Tagging studies show adult petrale sole can move up to 350 - 390 miles, having the ability to be highly migratory with the possibility for homing ability (Alverson and Chatwin 1957; MBC 1987). Juveniles show little coastwide or bathymetric movement while studies suggest that adults generally move inshore and northward onto the continental shelf during the spring and summer to feeding grounds and offshore and southward during the fall and winter to deep water spawning grounds (Hart 1988; Love 1996; MBC 1987). Adult petrale sole can tolerate a wide range of bottom temperatures (Perry, *et al.* 1994).

Mixing of fish from multiple deep water spawning grounds likely occurs during the spring and summer when petrale sole are feeding on the continental shelf. Fish that were captured, tagged, and released off the northwest coast of Washington during May and September were subsequently recaptured during winter from spawning grounds off Vancouver Island (British Columbia, 1 fish), Heceta Bank (central Oregon, 2 fish), Eureka (northern California, 2 fish), and Halfmoon Bay (central California, 2 fish) (Pederson 1975). Fish tagged south of Fort Bragg (central California) during July 1964 were later recaptured off Oregon (11 fish), Washington (6 fish), and Swiftsure Bank (southwestern tip of Vancouver

Island, 1 fish) (D. Thomas, California Department of Fish and Game, Menlo Park, CA, cited by Samson and Lee (1999)).

The highest densities of spawning adults off of British Columbia, as well as of eggs, larvae and juveniles, are found in the waters around Vancouver Island. Adults may utilize nearshore areas as summer feeding grounds and non-migrating adults may stay there during winter (Starr and Fargo 2004).

Petrale sole spawn during the winter at several discrete deepwater sites (270-460 m) off the U.S. west coast, from November to April, with peak spawning taking place from December to February (Best 1960; Casillas, *et al.* 1998; Castillo 1995; Castillo, *et al.* 1993; Garrison and Miller 1982; Gregory and Jow 1976; Harry 1959; Love 1996; Moser 1996; Reilly, *et al.* 1994). Females spawn once each year and fecundity varies with fish size, with one large female laying as many as 1.5 million eggs (Porter 1964). Petrale sole eggs are planktonic, ranging in size from 1.2 to 1.3 mm, and are found in deep water habitats at water temperatures of 4–10 degrees C and salinities of 25–30 ppt (Alderdice and Forrester 1971; Best 1960; Gregory and Jow 1976; Ketchen and Forrester 1966). The duration of the egg stage can range from approximately 6 to 14 days (Alderdice and Forrester 1971; Casillas, *et al.* 1998; Hart 1988; Love 1996).

Petrale sole larvae are planktonic, ranging in size from approximately 3 to 20 mm, and are found up to 150 km offshore foraging upon copepod eggs and nauplii (Casillas, *et al.* 1998; Hart 1988; MBC 1987; Moser 1996). The larval duration, including the egg stage, spans approximately 6 months with larvae settling at about 2.2 cm in length on the inner continental shelf (Pearcy, *et al.* 1977). Juveniles are benthic and found on sandy or sand-mud bottoms (Eschmeyer, *et al.* 1983; MBC 1987) and range in size from approximately 2.2 cm to the size at maturity, 50% of the population is mature at approximately 38 cm and 41 cm for males and females, respectively (Casillas, *et al.* 1998). No specific areas have been identified as nursery grounds for juvenile petrale sole. In the waters off British Columbia, Canada larvae are usually found in the upper 50 m far offshore, juveniles at 19–82 m and large juveniles at 25–125 m (Starr and Fargo 2004).

Adult petrale sole achieve a maximum size of around 50 cm and 63 cm for males and females, respectively (Best 1963; Pedersen 1975). The maximum length reported for petrale sole is 70 cm (Eschmeyer, *et al.* 1983; Hart 1988; Love, *et al.* 2002) while the maximum observed break and burn age is 31 years (Haltuch, *et al.* 2013).

Petrale sole juveniles are carnivorous, foraging on annelid worms, clams, brittle star, mysids, sculpin, amphipods, and other juvenile flatfish (Casillas, *et al.* 1998; Ford 1965; Pearsall and Fargo 2007). Predators on juvenile petrale sole include adult petrale sole as well as other larger fish (Casillas, *et al.* 1998; Ford 1965) while adults are preyed upon by marine mammals, sharks, and larger fishes (Casillas, *et al.* 1998; Love 1996; Trumble 1995).

One of the ambushing flatfishes, adult petrale sole have diverse diets that become more piscivorous at larger sizes (Allen, *et al.* 2006). Adult petrale sole are found on sandy and sand-mud bottoms (Eschmeyer, *et al.* 1983) foraging for a variety of invertebrates including, crab, octopi, squid, euphausiids, and shrimp, as well as anchovies. hake, herring, sand lance, and other smaller rockfish and flatfish (Birtwell, *et al.* 1984; Casillas, *et al.* 1998; Ford 1965; Kravitz, *et al.* 1977; Love 1996; Pearsall and Fargo 2007; Reilly, *et al.* 1994). On the continental shelf petrale sole generally co-occur with English sole, rex sole, Pacific sanddab, and rock sole (Kravitz, *et al.* 1977).

Castillo (1992) and Castillo et al. (1995) suggest that density-independent survival of early life stages is low and show that offshore Ekman transportation of eggs and larvae may be an important source of variation in year class strength in the Columbia INPFC area. The effects of the Pacific Decadal Oscillation (PDO) on California current temperature and productivity (Mantua, *et al.* 1997) may also contribute to non-stationary recruitment dynamics for petrale sole. The prevalence of a strong late 1990s year class for many west coast groundfish species suggests that environmentally driven recruitment variation may be correlated among species with relatively diverse life history strategies.

Stock Status and Management History

Petrale sole were lightly exploited during the early 1900s. By the 1950s the petrale sole fishery was well-developed and showing clear signs of depletion and declines in catches and biomass. Haltuch et al. (2013) estimated petrale sole biomass on the U.S. west coast dropped below the $B_{25\%}$ management target during the 1960s and generally stayed there through 2013. The stock declined below the $B_{12.5\%}$ overfished threshold from the early1980s until the early 2000s (Figure 7). Since 2000 the stock has increased, reaching a peak of 14.2% of unfished biomass in 2005, followed by a decreasing trend through 2010. The petrale sole biomass currently shows an increasing trend with recent above-average year classes recruiting into the spawning biomass. The estimated relative depletion level in 2013 is 22.3 percent.

Early stock assessments only assessed petrale sole in the combined U.S.-Vancouver and Columbia INPFC areas (i.e., petrale in these areas were treated as a unit stock, using time series of data that began during the 1970s) (Demory 1984; Turnock, *et al.* 1993). The first assessment used stock reduction analysis and the second assessment used the length-based Stock Synthesis model. The third petrale sole assessment utilized the hybrid length-and-age-based Stock Synthesis 1 model, using data from 1977–1998 (Sampson and Lee 1999). Sampson and Lee (1999) estimated petrale sole stock depletion at 42 percent of unfished biomass at the start of 1999.

The 2005 petrale sole assessment (Lai, *et al.* 2006) was conducted assuming two separate stocks: the northern stock encompassing the U.S. Vancouver and Columbia INPFC areas and the southern stock including the Eureka, Monterey and Conception INPFC areas. Petrale sole in the north was estimated to be at 34 percent of unfished spawning stock biomass in 2005. In the south, the stock was estimated to be at 29 percent of unfished spawning stock biomass. Biomass trends were qualitatively similar in both areas, and also showed consistency with petrale sole trends in Canadian waters. Both stocks were estimated to have been below the Council's MSST of $B_{25\%}$[4] from the mid-1970s until very recently. Estimated harvest rates were in excess of the target fishing mortality rate of $F_{40\%}$[5] during this period as well. Petrale sole in both areas showed large recent increases in stock size, which was consistent with the strong upward trend in the shelf survey biomass index. In 2005, the STAR panel noted that the petrale sole stock trends were similar in both northern and southern areas in spite of the different modeling choices made for each area, and that a single coastwide assessment should be considered (Dorn, *et al.* 2006).

The 2009 petrale assessment estimated a stock depletion of 11.6 percent of its unfished biomass at the start of 2009 (Haltuch and Hicks 2009b). That result compelled NMFS to declare the stock overfished in 2010. The 2009 assessment treated petrale sole as a single coastwide stock, with the fleets and landings structured by state (WA, OR, CA) area of catch. Historical catches were extended back to 1876, the first year of estimated exploitation for the stock.

New proxy management reference points used to manage FMP flatfish stocks, such as petrale sole, were implemented in 2011 under FMP Amendment 16-5 (also referred to as Secretarial Amendment 1) in 2011 (PFMC and NMFS 2011). The proxy F_{MSY} harvest rate or MFMT of $F_{40\%}$, which is applied to the

[4] $B_{25\%}$ was the MSST or overfished threshold for all groundfish stocks from the implementation of Amendment 12 in 1998 through 2010.
[5] $F_{40\%}$ was the F_{MSY} proxy harvest rate for all flatfish stocks prior to 2011.

estimated exploitable biomass to determine the OFL, was changed to $F_{30\%}$; the B_{MSY} target of $B_{40\%}$ was changed to $B_{25\%}$; and the MSST of $B_{25\%}$, was changed to $B_{12.5\%}$. The SSC recommended these new proxy reference points to manage flatfish stocks based on a meta-analysis of the relative productivity of assessed west coast flatfish species and other assessed Pleuronectid species internationally. The precautionary ACL harvest control rule, referred to as the 25-5 rule and analogous to the 40-10 rule for other groundfish stocks (see Figure 36 and section 1.2.3 for more detail on these ACL harvest control rules), was also adopted for flatfish stocks under Amendment 16-5.

The 2009 rebuilding analysis (Haltuch and Hicks 2009a) was used to consider a petrale sole rebuilding plan for petrale sole, which was implemented under FMP Amendment 16-5. The rebuilding plan specified a target year of 2016 and the strategy of using the 25-5 harvest control rule after 2011 to set harvest levels (the 2011 ACL was set equal to the ABC to avoid unnecessary negative socioeconomic impacts). An emergency rule was implemented to reduce the 2010 petrale OY to 1,200 mt.

The 2011 petrale assessment estimated a stock depletion of 18 percent of its unfished biomass at the start of 2011 (Haltuch, *et al.* 2011). The assessment indicated an increasing spawning biomass trend with above average year classes recruiting into the spawning biomass. The 2011 rebuilding analysis (Haltuch 2011) indicated rebuilding was ahead of schedule and predicted spawning biomass would likely attain the B_{MSY} target of $B_{25\%}$ by the start of 2013. No modifications were made to the rebuilding plan based on this result.

The 2013 petrale assessment (Haltuch, *et al.* 2013) estimated a stock depletion of 22.3 percent of its unfished biomass at the start of 2013 and short of the prediction from the 2011 rebuilding analysis; spawning biomass is predicted to reach the B_{MSY} target by the start of 2014. The 2013 stock assessment continued with the coastwide stock assessment, but was restructured to summarize petrale sole landings by the port of landing and combined Washington and Oregon into a single fleet. The down-weighting of the trawl CPUE index used in the 2011 assessment was largely responsible for the more pessimistic result and the one year lag in rebuilding relative to the previous assessment. However, the estimation of recent recruitments indicated two very strong year classes (2007 and 2008; Figure 18) recruiting into the spawning population, which increases the likelihood of imminent success in rebuilding this stock.

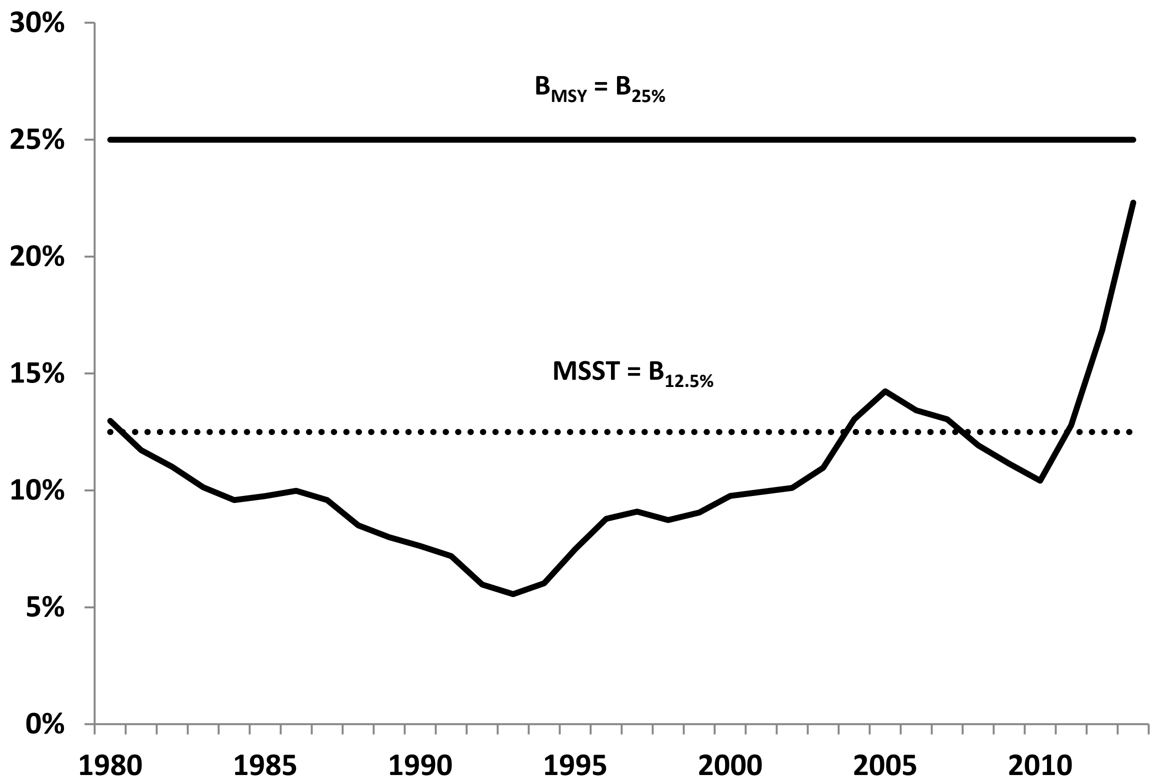

Figure 17. Relative depletion trend from 1980 to 2013 for petrale sole based on the 2013 stock assessment.

Stock Productivity Relative to Rebuilding Success

Petrale have high stock productivity with an estimated stock-recruitment steepness of 0.86 (Haltuch, *et al.* 2013); the prior for this estimate was based on a meta-analysis of flatfish species in the family *Pleuronectidae (Myers, et al. 1999)*. The time series of estimated recruitments shows a relationship with the decline in spawning biomass, punctuated by larger recruitments. The five weakest recruitments since 1934 are estimated to be from 1986, 1987, 1992, 1995, and 2001, while the five strongest recruitments since 1934 are estimated to be from 1939, 1966, 1998, 2007, and 2008. The 2007 and 2008 recruitments were the third and second largest estimated, respectively, behind only the record 1966 recruitment event (Figure 18). Until 2007, the most recent large recruitment event is estimated to be in 2006, which was smaller than the 1998 recruitment event.

The high stock productivity and the large recent recruitments contribute to a predicted quick recovery of the petrale sole stock. The 2013 petrale assessment predicts the stock will be successfully rebuilt by the start of 2014, with an estimated depletion of 26 percent.

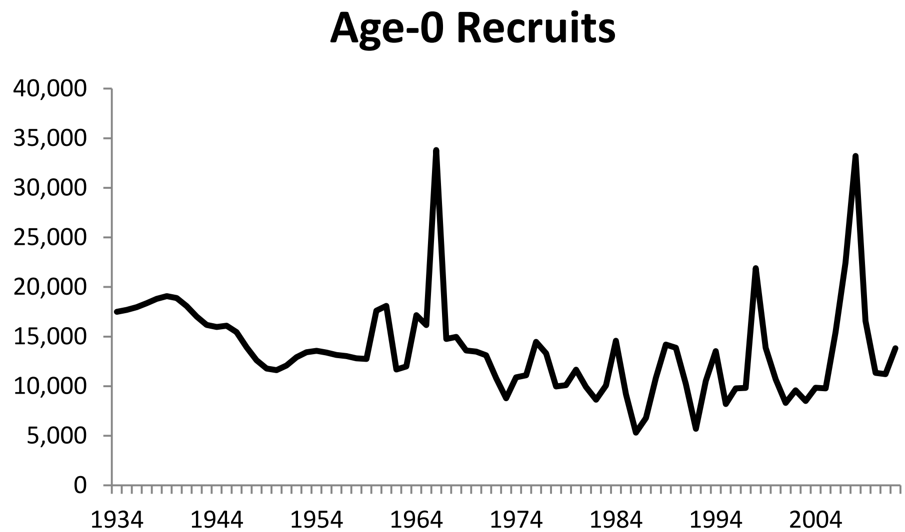

Figure 18. Time series of estimated (age 0) petrale sole recruitments, 1934-2012 (from Haltuch, *et al.* 2013).

Fishing Mortality

Most of the petrale sole catch is made by deep-water demersal trawls at depths of 164-252 fm. Recent petrale sole catch statistics exhibit marked seasonal variation, with substantial portions of the annual harvest taken from the spawning grounds in December and January. From the inception of the fishery in 1876 through the mid-1940s, the vast majority of catches occurred between March and October (the summer fishery), when the stock is dispersed over the continental shelf. The post-World War II period witnessed a steady decline in the amount and proportion of annual catches occurring during the summer months (March-October). Conversely, petrale catch during the winter season (November–February), when the fishery targets spawning aggregations, has exhibited a steadily increasing trend since the 1940s. Since the mid-1980s, catches during the winter months have been roughly equivalent to or exceeded catches throughout the remainder of the year. In 2009, catches of petrale sole began to be restricted due to declining stock size.

Petrale sole exhibit distinct seasonal depth migrations with higher abundance on the shelf during summer months and higher abundance in distinct spawning areas during winter months. Hence, RCA structures for this species could vary seasonally if RCA management is needed to control fishing mortality. The general pattern for petrale sole is a shallower depth distribution during the summer months (periods 3 and 4) and a deeper depth distribution during the winter months (periods 1 and 6). Petrale sole are typically in transition as they migrate between shallow and deeper depths during periods 2 and 5.

Petrale sole is a trawl-dominant species. Therefore, the uncertainty in catch monitoring and accounting is low, given the mandatory 100 percent observer coverage and near real-time reporting of total catches in the rationalized trawl fisheries.

Prior to 2010, when interim rebuilding measures were implemented, harvest rates were in excess of what is now considered the F_{MSY} limit of $F_{30\%}$ (i.e., SPR = 30%). Management measures implemented since 2010 have resulted in harvest rates below the F_{MSY} limit.

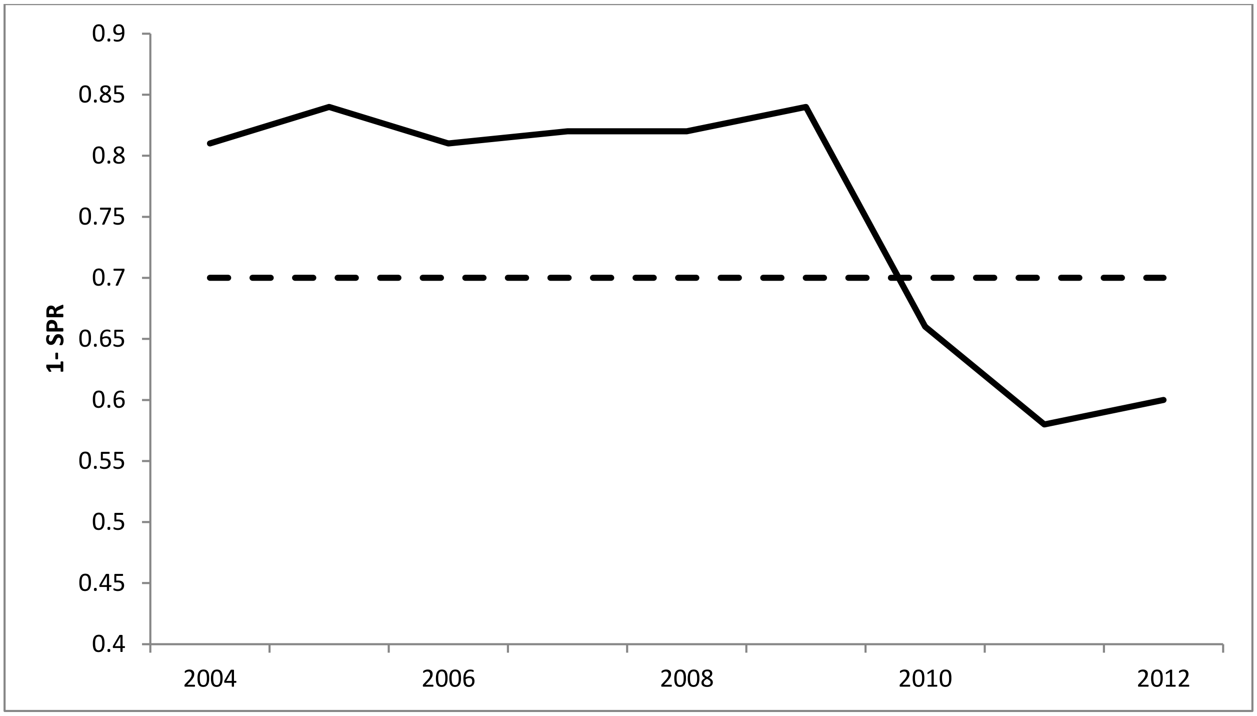

Figure 19. Estimated spawning potential ratio (SPR) of petrale sole, 2004-2012. One minus SPR is plotted so that higher exploitation rates occur on the upper portion of the y-axis. The management target is plotted as a dashed horizontal line and values above this reflect harvests in excess of the overfishing proxy based on the F_{MSY} harvest rate (SPR = 30%).

Rebuilding Duration and Probabilities

The 2013 petrale assessment predicts the stock will be rebuilt by 2014. Therefore, rebuilding probabilities (both P_{MAX} and P_{TARGET}) are high for petrale sole under the harvest control rule in the rebuilding plan. The SSC is recommending a new assessment be done in 2015 to confirm that prediction.

1.1.3.7 Yelloweye Rockfish

Distribution and Life History

Yelloweye rockfish (*Sebastes ruberrimus*) range from the Aleutian Islands, Alaska, to northern Baja California, Mexico, and are common from Central California northward to the Gulf of Alaska (Eschmeyer, *et al.* 1983; Hart 1988; Love, *et al.* 2002; Miller and Lea 1972; O'Connell and Funk 1986). Yelloweye rockfish occur in water 25 m to 550 m deep with 95 percent of survey catches occurring from 50 m to 400 m (Allen and Smith 1988). Yelloweye rockfish are bottom dwelling, generally solitary, rocky reef fish, found either on or just over reefs (Eschmeyer, *et al.* 1983; Hart 1988; Love, *et al.* 2002; Miller and Lea 1972; O'Connell and Funk 1986) . Boulder areas in deep water (>180 m) are the most densely populated habitat type, and juveniles prefer shallow-zone broken-rock habitat (O'Connell and Carlile 1993). They also reportedly occur around steep cliffs and offshore pinnacles (Rosenthal, *et al.* 1982). The presence of refuge spaces is an important factor affecting their occurrence (O'Connell and Carlile 1993).

Yelloweye rockfish are ovoviviparous and give birth to live young in June off Washington (Hart 1988). The age of first maturity is estimated at six years and all are estimated to be mature by eight years (Wyllie

Echeverria 1987). They can grow to 91 cm (Eschmeyer, *et al.* 1983; Hart 1988) and males and females probably grow at the same rates (Love 1996; O'Connell and Funk 1986). The growth rate levels off at approximately 30 years of age (O'Connell and Funk 1986) but they can live to be 118 years old (Love, *et al.* 2002). Yelloweye rockfish are a large predatory reef fish that usually feeds close to the bottom (Rosenthal, *et al.* 1982). They have a widely varied diet, including fish, crabs, shrimps and snails, rockfish, cods, sand lances, and herring (Love, *et al.* 2002). Yelloweye rockfish have been observed underwater capturing smaller rockfish with rapid bursts of speed and agility. Off Oregon the major food items of the yelloweye rockfish include cancroid crabs, cottids, righteye flounders, adult rockfishes, and pandalid shrimps (Steiner 1978). Quillback and yelloweye rockfish have many trophic features in common (Rosenthal, *et al.* 1982).

Stock Status and Management History

The first yelloweye rockfish stock assessment on the U.S. west coast was conducted in 2001 (Wallace 2002). This assessment incorporated two area assessments: one from Northern California using CPUE indices constructed from Marine Recreational Fisheries Statistical Survey (MRFSS) sample data and CDFG data collected on board commercial passenger fishing vessels, and the other from Oregon using Oregon Department of Fish and Wildlife (ODFW) sampling data. The assessment concluded yelloweye rockfish stock biomass in 2001 was at about 7 percent of unexploited biomass in Northern California and 13 percent of unexploited biomass in Oregon. The assessment revealed a thirty-year declining biomass trend in both areas with the last above average recruitment occurring in the late 1980s. The assessment's conclusion that yelloweye rockfish biomass was well below the 25 percent of unexploited biomass threshold for overfished stocks led to this stock being declared overfished in 2002. Until 2002, yelloweye rockfish were listed in the "remaining rockfish" complex on the shelf in the Vancouver, Columbia, and Eureka INPFC areas and the "other rockfish" complex on the shelf in the Monterey and Conception areas. As with the other overfished stocks, yelloweye rockfish harvest is now tracked separately and managed against a species-specific ACL.

In June 2002 the SSC recommended that managers should conduct a new assessment incorporating Washington catch and age data. This recommendation was based on evidence that the biomass distribution of yelloweye rockfish on the west coast was centered in waters off Washington and that useable data from Washington were available. Based on that testimony, the Council recommended completing a new assessment in the summer of 2002, before a final decision was made on 2003 management measures. Methot et al. (Methot, *et al.* 2003) did the assessment, which confirmed the overfished status (24 percent of unfished biomass) and provided evidence of higher stock productivity than originally assumed. The assessment also treated the stock as a coastwide assemblage. The 2002 rebuilding analysis (Methot and Piner 2002a) informed the yelloweye rockfish rebuilding plan adopted under FMP Amendment 16-3 in 2004. The rebuilding plan established a target rebuilding year of 2058 and a harvest control rule of F = 0.0153.

A coastwide 2006 yelloweye rockfish assessment estimated a stock depletion of 17.7 percent of the unfished level at the start of 2006 (Wallace, *et al.* 2006). New data sources in the assessment included WDFW 2002 submersible survey and the International Pacific Halibut Commission annual longline survey. Further revisions in the assessment included reducing natural mortality from 0.045 to 0.036 and increasing steepness from 0.437 to 0.45.

The 2006 rebuilding analysis (Tsou and Wallace 2006) was used to inform a revision of the yelloweye rebuilding plan under FMP Amendment 16-4. Given the significant negative socioeconomic impacts associated with the projected OYs under the constant harvest rate modeled in the rebuilding analysis, the Council elected to gradually ramp down the harvest rate beginning in 2007 before resuming a constant harvest rate rebuilding strategy in 2011. The harvest rate ramp-down strategy, which projected annual

OYs of 23 mt, 20 mt, 17 mt, and 14 mt, respectively in 2007-2011, was projected to extend rebuilding by less than one year relative to the more conservative constant harvest rate strategy analyzed. The ramp-down strategy afforded more time to consider new Yelloweye Rockfish Conservation Areas and other management measures designed to reduce the harvest rate to prescribed levels. Therefore, the Amendment 16-4 rebuilding plan incorporated the ramp-down strategy before resuming a constant harvest rate (SPR = 71.9%) in 2011. The rebuilding plan also specified a target rebuilding year of 2084.

The 2007 updated stock assessment for yelloweye rockfish estimated a stock depletion of 16.4 percent of initial, unfished biomass (Wallace 2008a). The long-term biomass trajectory in the 2007 updated assessment was very similar to that in the 2006 assessment. The 2007 rebuilding analysis (Wallace 2008b) indicated rebuilding progress was on track under the ramp-down strategy; therefore, no revisions were made to the rebuilding plan.

The benchmark 2009 yelloweye assessment estimated a stock depletion of 20.3 percent of initial, unfished biomass at the start of 2009 (Stewart, *et al*. 2009). The resource was modeled as a single stock, but with three explicit spatial areas: Washington, Oregon and California. Each area was modeled simultaneously with its own unique catch history and fishing fleets (recreational and commercial), with the stocks linked via a common stock-recruit relationship with negligible adult movement among areas. The assumed level of historical removals and estimated steepness were identified as the main axes of uncertainty.

The 2009 yelloweye rebuilding analysis (Stewart 2009b) was used to inform a revised rebuilding plan that was implemented under FMP Amendment 16-5. The revised rebuilding plan implemented in 2011 specified a constant harvest rate (SPR = 76%) strategy (the ramp-down strategy was abandoned) and a target year to rebuild the stock of 2074.

The 2011 yelloweye assessment (Taylor and Wetzel 2011), an update of the 2009 assessment, estimated stock depletion at 21.4 percent of initial, unfished biomass at the start of 2011 (Figure 20). The update assessment results were very similar to those in the previous assessment. The 2011 yelloweye rebuilding analysis (Taylor 2011) indicated rebuilding progress was on schedule and no revisions were made to the rebuilding plan.

A yelloweye catch report was provided in 2013 (Agenda Item F.5.a, Attachment 11, June 2013), which indicated 2010-2012 total catches were below specified ACLs/OYs.

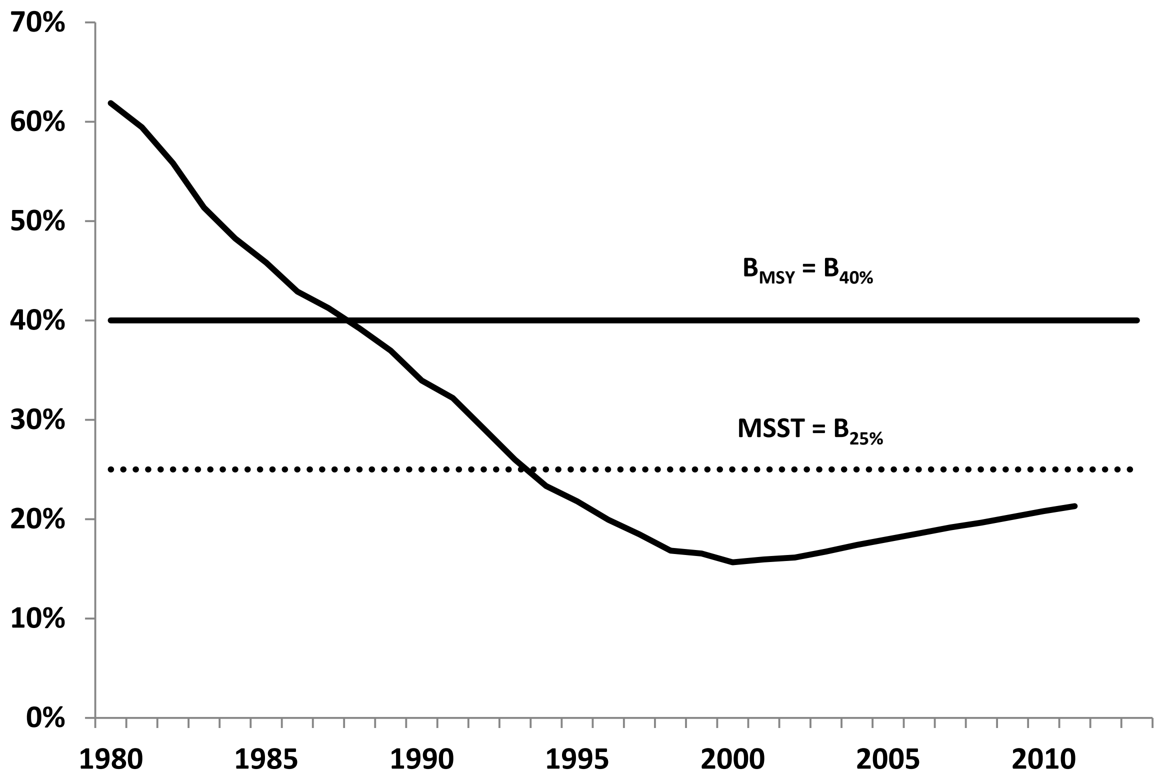

Figure 20. Relative depletion of yelloweye rockfish from 1980 to 2011 based on the 2011 stock assessment update.

Stock Productivity Relative to Rebuilding Success

Yelloweye year class strength is modeled as a deterministic process in the 2011 assessment with no estimation of the size of individual year classes. Therefore, the decline in estimated recruitment tracks closely to that of the spawning output (Figure 21). The decline is especially pronounced given the low (and likely imprecise) estimate for steepness of the stock-recruit relationship in the base-case model (0.441). The low estimated steepness in the assessment results in a prediction of very little surplus production and consequently estimates of low yields at B_{MSY} (MSY is estimated to be 58 mt under the F_{MSY} proxy SPR harvest rate of 50 percent). This relatively low stock productivity also predicts a long mean generation time of 46 years and a slow recovery rate under the very low harvest rate specified in the yelloweye rebuilding plan.

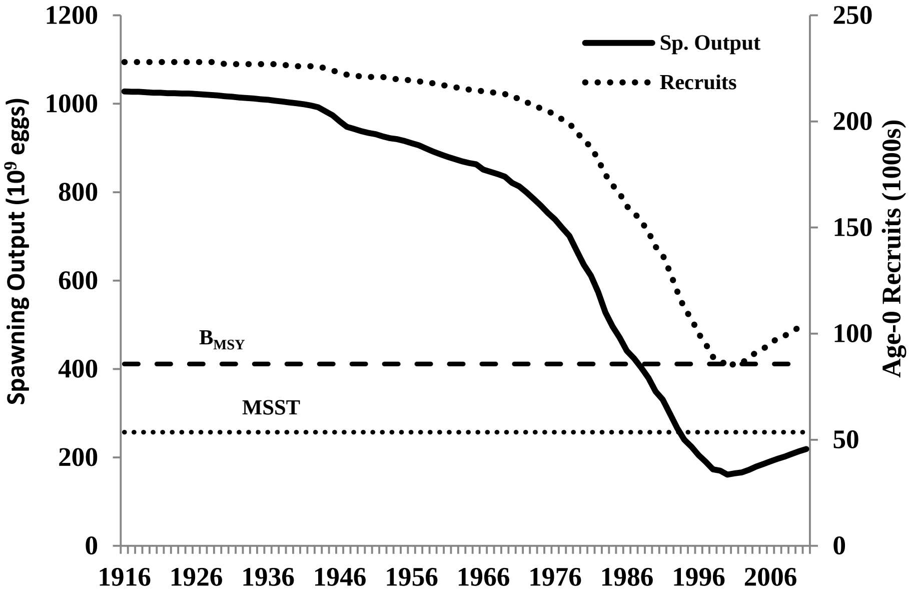

Figure 21. Time series of estimated yelloweye rockfish spawning output and recruitments for the base-case model in the 2011 assessment (Taylor and Wetzel 2011).

Fishing Mortality

Yelloweye rockfish are caught coastwide in all sectors of the fishery. Yelloweye are particularly vulnerable to hook-and-line gears, which are effective in the high relief habitats yelloweye reside. The current non-trawl RCA and the recreational depth closures are primarily configured based on yelloweye distribution and projected impacts in these hook-and-line fisheries. Small footrope trawls, including selective flatfish trawls, do not have the rollers and anti-chafing protection needed to fish in the high relief habitats yelloweye are found. Mandating these gears for trawl efforts on the shelf shoreward of the trawl RCA, the configuration of the trawl RCA, and a small IFQ allocation of yelloweye are the primary strategies currently used to minimize trawl impacts on yelloweye. Yelloweye are also a bycatch species in the Pacific halibut fishery (Love*, et al.* 2002).

Yelloweye rockfish are mostly encountered north of 36º N lat. Yelloweye occur in depths from 25 to 475 m and are most commonly found at depths from 91 to 180 m (Love*, et al.* 2002).

Fishing mortality rates estimated in the 2011 assessment have been in excess of the current F_{MSY} harvest rate for rockfish (SPR = 50 percent) from 1976 through 1999 (Figure 22). Relative exploitation rates (catch/biomass of age-8 and older fish) are estimated to have peaked at 12.7 percent in 1992, but have been at or less than 1.1 percent after 2001. The F_{MSY} exploitation rate assuming the proxy SPR of 50 percent is 2.2 percent. Annual yelloweye harvest rates in the 1976-1999 period averaged over five times the estimated F_{MSY} and spawning biomass declined rapidly during that period.

The commercial RCAs substantially reduce yelloweye impacts. North of 40º10’ N lat., the highest bycatch rates of yelloweye rockfish occur in waters less than 100 fm. Yelloweye rockfish have a patchy distribution and as such, using fleetwide bycatch rates over a large area (north and south of 40º10’ N lat.) may misrepresent actual catch rates. North of Cape Alava, yelloweye bycatch rates are lowest inside of the 60 fm line; bycatch rates would increase substantially if shoreward RCAs were moved from the 60 fm line to the 75 fm line. The seaward boundary of the non-trawl RCA extends out to 150 fm year round south of 40º10' N lat. The seaward boundary of the non-trawl RCA north of 40º10' N lat. is at 100 fm year round with a few exceptions where the seaward boundary is at 125 fm. Between 45º03.83' to 43º N lat. the seaward is at 125 fm year round.

Area closures and a prohibition on retention are the main strategies used to minimize recreational yelloweye impacts. The California recreational fishery is subject to depth restrictions that are more restrictive in the northern management areas where yelloweye are more prevalent. CDFG evaluated and has available four potential YRCAs which include habitat in both state and Federal waters where high yelloweye encounter rates have been documented. If implemented, YRCAs are anticipated to reduce yelloweye impacts during the open fishing seasons in both the Northern Groundfish Management Area and the North-Central North of Pt. Arena Groundfish Management Area, possibly allowing for a longer fishing season. To date, these YRCAs have not been implemented but would remain available management measures that can be routinely implemented inseason if needed. Depth management is the main tool used for controlling yelloweye rockfish fishing mortality in the Washington and Oregon recreational fisheries.

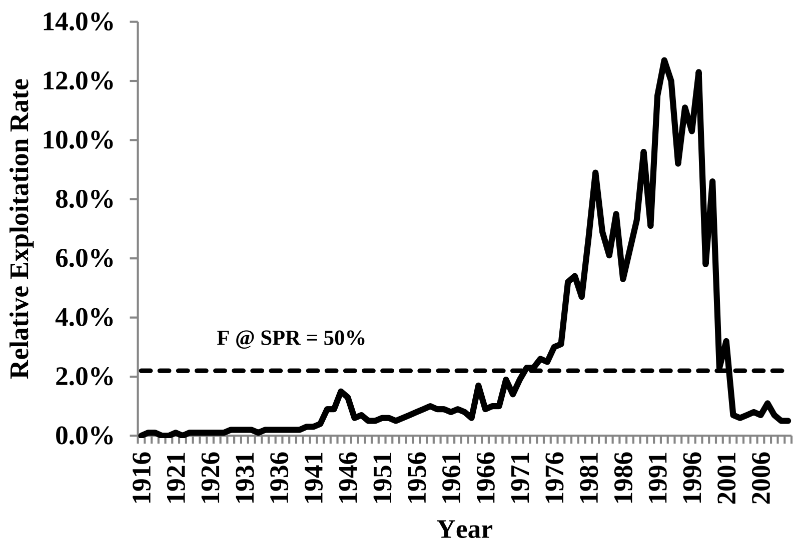

Figure 22. Time series of estimated relative exploitation rates (catch/biomass of age 8+ fish) of yelloweye rockfish, 1916-2010 (Taylor and Wetzel 2011).

Catch monitoring uncertainty is high given the relatively small contribution of yelloweye to rockfish market categories and the relatively large scale of recreational removals. In addition, since 2001, management restrictions have required nearly all yelloweye rockfish caught by recreational and commercial fishermen to be discarded at sea. Precisely tracking recreational catch inseason, especially in the California recreational fishery, has been a challenge.

Rebuilding Duration and Probabilities

Rebuilding under the SPR harvest rate specified in the rebuilding plan has a predicted P_{MAX} of 72.9 percent and a probability of rebuilding by the target year of 2074 of 62.1 percent.

1.1.4 Non-Overfished Groundfish Stocks

1.1.4.1 Arrowtooth Flounder

Distribution and Life History

Arrowtooth flounder (*Atheresthes stomias*) range from the southern coast of Kamchatka to the northwest Bering Sea and Aleutian Islands to San Simeon, California. Arrowtooth flounder is the dominant flounder species on the outer continental shelf from the western Gulf of Alaska to Oregon. They are members of the family Pleuronectidae, the right eyed flounders. Arrowtooth reach sizes of nearly 90 cm and can live to 27 years. Eggs and larvae are pelagic; juveniles and adults are demersal (Garrison and Miller 1982; NOAA 1990). Juveniles and adults are most commonly found on sand or sandy gravel substrates, but occasionally occur over low-relief rock-sponge bottoms. Arrowtooth flounder exhibit a strong migration from shallow water summer feeding grounds on the continental shelf to deep water spawning grounds over the continental slope (NOAA 1990). Depth distribution may vary from as little as 50 m in summer to more than 500 m in the winter (Garrison and Miller 1982; NOAA 1990; Rickey 1995).

Arrowtooth flounder are oviparous with external fertilization and eggs are about 2.5 mm in diameter. Spawning may occur deeper than 500 m off Washington (Rickey 1995). Arrowtooth are batch spawners (Rickey 1995). They spawn in the deeper continental shelf waters (>200 m) in the late fall through early spring and appear to move inshore during the summer (Zimmerman and Goddard 1996). The larvae spend approximately four weeks in the upper 100 m of the water column (Fargo and Starr 2001) and settle to the bottom in the late winter and early spring. Larvae eat copepods, their eggs, and copepod nauplii (Yang 1995; Yang and Livingston 1985). Juveniles and adults feed on crustaceans (mainly ocean pink shrimp and krill) and fish (mainly gadids, herring, and pollock) (Hart 1988; NOAA 1990).

Arrowtooth flounder exhibit two feeding peaks, at noon and midnight. Arrowtooth are piscivorous, but they also eat shrimp, worms, and euphausiids (Love 1996). Buckley et al. (1999) analyzed 380 arrowtooth stomachs that were collected in 1989 and 1992 from Oregon and Washington and found that hake (*Merluccius productus*) and unidentified gadids dominate their stomach contents (45 percent and 22 percent respectively) followed by herring (19 percent; *Clupea pallasi*), mesopelagics (0.5 percent), rex sole (1 percent; *Glyptocephalus zachirus*), slender sole (*Lyopsetta exilis*) and other small flatfish (3 percent), other arrowtooth (1.5 percent), other unidentified flatfish (1 percent), pandalid shrimp (~3 percent), and euphausiids (3 percent). Yang (1995) analyzed 1,144 stomachs from arrowtooth collected in the Gulf of Alaska, and found that walleye pollock (*Theragra chalcogramma*) composed 66 percent of the arrowtooth diet, although arrowtooth smaller than 40 cm primarily feed on capelin (*Mallotus villosus*), herring, and shrimp. Gotshall (1969) examined 425 arrowtooth stomachs from northern California throughout the 1960s and found that pandalid shrimp made up nearly 40 percent of the prey by volume, along with other shrimps, crabs, euphausiids, Pacific sanddabs (*Citharichthys sordidus*), and slender sole. However, Gotshall's samples were taken directly from shrimp beds, so higher concentrations of shrimp would be expected. It is clear that arrowtooth have a broad diet, consuming most of the common fish and invertebrates found on soft bottom substrate and in the water column.

Predators of juvenile arrowtooth include skates, dogfish, shortspine thornyhead, halibut, coastal sharks, orcas, toothed whales, and harbor seals (Field, *et al.* 2006). Adult arrowtooth are likely to be vulnerable only to the largest of these predators.

Female arrowtooth off Oregon reach 50 percent maturity at 8 years of age, and males at four years (Hosie 1976). Rickey (1995) found that the arrowtooth reach 50 percent maturity at lengths of 36.8 cm for females and 28 cm for males off Washington, and 44 cm for females and 29 cm for males off Oregon. As a comparison, female length at 50 percent maturity is 47 cm in the Gulf of Alaska (Turnock, *et al.* 2005) and 38 cm in British Columbia (Fargo and Starr 2001).

Stock Status and Management History

Arrowtooth are commonly caught by trawl fleets off Washington and Oregon, but they are frequently discarded due to low flesh quality. For this reason, the market for arrowtooth has been fairly limited over the last 50 years. It is likely that the stock off the U.S. west coast is linked to the population off British Columbia and, possibly, to the stock in the Gulf of Alaska. However, for assessment purposes it is assumed that the U.S. west coast population is a unit stock.

The west coast stock of arrowtooth flounder was assessed in 1993 (Rickey 1993), and a full stock assessment was done in 2007 (Kaplan and Helser 2008). Three components of the arrowtooth fishery were used in modeling: the mink food fishery in the 1950s-1970s; a targeted fillet/headed-and-gutted fishery that began around 1981; and a "bycatch fleet" that represents west coast trawl effort with arrowtooth bycatch, but no landings. Estimates of historical catch are highly uncertain. The model contains assumed fixed values for natural mortality and steepness of the stock-recruitment relationship. Likelihood profiles suggest that the estimates of biomass and depletion are not sensitive to values of steepness. Assumed values of natural mortality have a small effect on estimated depletion, but strongly influence the estimates of absolute biomass.

The base model shows a period of moderate depletion through the 1950s and 1960s, followed by a rebuilding of the stock beginning in the late 1970s. Strong year classes, in particular the 1999 year class, have led to an increase in the stock since the late 1990s. The spawning biomass at the beginning of 2007 was estimated to be 63,302 mt and 79 percent of the estimated unfished spawning biomass. Total biomass at the start of 2007 was estimated to be 85,175 mt. The 2007 stock assessment estimated that the arrowtooth stock has never fallen below the overfished threshold.

Stock Productivity

Arrowtooth flounder are a very productive stock with high growth rates, high natural mortality rates, and a high stock-recruitment steepness. A mean flatfish steepness of 0.8 was determined in a 2010 meta-analysis conducted by the SSC and described in the 2011-2012 specifications FEIS (PFMC and NMFS 2011). A steepness of 0.902 was assumed in the 2007 arrowtooth flounder assessment based on a flatfish meta-analysis conducted by Dorn (2002a). Arrowtooth received a relatively high productivity score of 1.95 in the PSA analysis (Table 2).

The 2007 assessment estimated strong recruitments for most years between 1998 and 2007, with a particularly strong recruitment of the 1999 year class. That year class has dominated the population and fishery for the last ten years but is now diminished through high natural mortality. However, the 2007 assessment projects a very healthy stock through 2018 under catch streams much higher than has been realized since then.

Fishing Mortality

The target F_{MSY} SPR harvest rate for arrowtooth is 30 percent. The 2007 assessment estimated annual SPR harvest rates between 1997 and 2006 of 49-75 percent, substantially lower than the target. The arrowtooth ACL/OY has never been exceeded.

Arrowtooth flounder are a trawl-dominant species and are not particularly valuable. Given that arrowtooth are caught on the northern shelf where Pacific halibut, darkblotched rockfish, and yelloweye rockfish are caught incidentally to arrowtooth, this is not a species with a high attainment since valuable quota for these highly constraining species would have to be invested to target arrowtooth. About 20 percent of the arrowtooth quota was attained in the 2012 fishery (cite). Management uncertainty is low with the 100 percent observer coverage for the trawl fleet under trawl rationalization. The PSA vulnerability score of 1.21 indicates a low concern of overfishing.

1.1.4.2 Black Rockfish off California and Oregon

Distribution and Life History

Black rockfish (*Sebastes melanops*) are found from Southern California (San Miguel Island) to the Aleutian Islands (Amchitka Island) and they occur most commonly from San Francisco northward (Hart 1988; Miller and Lea 1972; Phillips 1957; Stein and Hassler 1989). Black rockfish occur from the surface to greater than 366 m; however, they are most abundant at depths less than 54 m (Stein and Hassler 1989). Off California, black rockfish are found along with the blue, olive, kelp, black-and-yellow, and gopher rockfishes (Hallacher and Roberts 1985). The abundance of black rockfish in shallow water declines in the winter and increases in the summer (Stein and Hassler 1989). Densities of black rockfish decrease with depth during both the upwelling and non-upwelling seasons (Hallacher and Roberts 1985). Off Oregon, larger fish seem to be found in deeper water (20 m to 50 m) (Stein and Hassler 1989). Black rockfish off the northern Washington coast and outer Strait of Juan de Fuca exhibit no significant movement. However, fish appear to move from the central Washington coast southward to the Columbia River, but not into waters off Oregon. Movement displayed by black rockfish off the northern Oregon coast is primarily northward to the Columbia River (Culver 1986). Black rockfish form mixed sex, midwater schools, especially in shallow water (Hart 1988; Stein and Hassler 1989). Black rockfish larvae and young juveniles (<40 mm to 50 mm) are pelagic, but are benthic at larger sizes (Laroche and Richardson 1980).

Black rockfish have internal fertilization and annual spawning (Stein and Hassler 1989). Parturition occurs from February through April off British Columbia, January through March off Oregon, and January through May off California (Stein and Hassler 1989). Spawning areas are unknown, but spawning may occur in offshore waters because gravid (egg-carrying) females have been caught well offshore (Dunn and Hitz 1969; Hart 1988; Stein and Hassler 1989). Black rockfish can live to be more than 20 years in age. The maximum length attained by the black rockfish is 60 cm (Hart 1988; Stein and Hassler 1989). Off Oregon, black rockfish primarily prey on pelagic nekton (anchovies and smelt) and zooplankton such as salps, mysids, and crab megalops. Off Central California, juveniles eat copepods and zoea, while adults prey on juvenile rockfish, euphausiids, and amphipods during upwelling periods. During periods without upwelling they primarily consume invertebrates. Black rockfish feed almost exclusively in the water column (Culver 1986). Black rockfish are known to be eaten by lingcod and yelloweye rockfish (Stein and Hassler 1989).

Stock Status and Management History

A black rockfish assessment was completed in 2003 and pertained to the portion of the coastwide stock occurring off the coasts of Oregon and California (Ralston and Dick 2003) or the southern stock unit. Alternative harvest levels in the 2003 assessment were ranged to capture the major uncertainty of historical landings prior to 1978. Black rockfish catches prior to 1945 were assumed to be zero in the assessment. Many gaps in historical landings of black rockfish since 1945 were evident, and these landings were reconstructed using a variety of data sources. The base model assumed cumulative landings of black rockfish from all fisheries was 17,100 mt from 1945 to 1977. The 2003 assessment concluded the southern California-Oregon stock of black rockfish was in healthy condition with a 2002 spawning output estimated to be at 49 percent of its unexploited level.

The southern stock of black rockfish was again assessed in 2007 (Sampson 2008) using a similar approach and structure as the 2003 assessment. The 2007 assessment estimated the southern stock was at 70 percent of its unfished level at the start of 2007. The 2007 assessment was structured into six fisheries: a set of trawl, commercial non-trawl, and recreational fisheries for Oregon and California, respectively. The fisheries for each state were based on fish capture location rather than where they were landed and therefore represented separate geographic areas. The model in the 2007 assessment did not include any underlying spatial structure in the population dynamics. Like the previous southern stock assessment, abundance indices for tuning the assessment were based on recreational CPUE data with two independent indices available for each state. The standard research trawl surveys along the U.S. west coast do not operate in shallow enough water to catch appreciable numbers of black rockfish and therefore do not provide any fishery independent index of stock biomass for black rockfish. The 2007 assessment had two additional abundance indices that were not available for the previous assessment: a black rockfish pre-recruit index for 2001-2006 and estimates from a tag-recapture study of exploitable black rockfish abundance off Newport, Oregon for 2003-2005. The 2007 assessment for the southern stock of black rockfish used the same sex- and age-specific formulation for natural mortality (M) that was used in the assessment for northern black rockfish, but there is little evidence to confirm that the assumed formulation is correct. The 2003 assessment for southern black rockfish used much smaller values for M that were more consistent with observed values for the maximum age of southern black rockfish.

Stock Productivity

The 2007 southern black rockfish assessment assumed a steepness of 0.6 based on the Dorn meta-analysis of rockfish steepness done at that time. The revised rockfish steepness meta-analysis now predicts a mean steepness of 0.779. The PSA productivity score of 1.33 indicates a stock of moderate productivity.

The 2007 assessment estimated above-average recruitments in the 1990s (with particularly strong recruitments in 1994 and 1999), 2000, 2001, and 2007; and below-average recruitments during 2002-2006. These recruitments are projected to keep the stock healthy under the 1,000 mt constant catch strategy implemented in 2009.

Fishing Mortality

The nearshore commercial and recreational fisheries that take black rockfish are managed well in California and Oregon, and ACLs/OYs have not been exceeded. The PSA vulnerability score of 1.94 indicates a stock of medium concern for overfishing.

Over most of the stock's history the fishing rate has been less than the 50% SPR target fishing rate. The estimated spawning output has been above the target level during all years except 1991 to 1998, and has never dropped below the overfished level. The southern stock of black rockfish is estimated to be well above the overfished level.

1.1.4.3 Black Rockfish off Washington

Distribution and Life History

See the description of black rockfish distribution and life history in section 1.1.4.2.

Stock Status and Management History

The black rockfish stock found between Cape Falcon, Oregon and the U.S. Canadian border was first assessed in 1994 (Wallace and Tagart 1994). Estimated biomass was 60 percent of the unfished level and female egg production was estimated to be 43 percent of the unfished level. A harvest guideline of 517 mt for this area was specified beginning in 1995 based on assessment results. Catches remained well below the harvest guideline in the years subsequent to the assessment.

The 1999 assessment of the black rockfish stock north of Cape Falcon, Oregon determined the stock was at 45 percent of the unfished level (Wallace, *et al.* 1999). The population was regarded as healthy and stock abundance was estimated to be slightly increasing after a period of low abundance in the late 1980s and early 1990s.

The most recent assessment of the northern stock was done in 2007, which estimated a depletion of 53.4 percent of the unfished level (Wallace, *et al.* 2008). The base model for the 2007 assessment assumed a female natural mortality rate to be age-specific using age at first and full maturity for inflections (10 and 15). A constant natural mortality rate of 0.16 was assumed for males and young females (< 10 years of age), and a rate of 0.2 was assumed for old females (>=15 years of age). Model sensitivity analysis showed that model configurations using higher natural mortality for older females provided better overall fits to the data. In the model, spawning biomass and age 3+ biomass reached the lowest levels in 1995, following poor recruitment and intense fishing in the late 1980s. The population trajectory remained just above minimum stock size threshold, and the model indicated that the stock is currently well above the management target of $B_{40\%}$.

Stock Productivity

The 2007 assessment assumed a steepness 0.6 in the stock-recruitment relationship of the northern black rockfish stock based on the Dorn prior (as was done in the southern black rockfish assessment). Steepness may be even higher based on the revised prior of 0.779. The PSA productivity score of 1.33 indicates a stock of moderate productivity.

The 2007 assessment estimated strong recruitments in the 1990s (including strong recruitments in 1994 and 1999 as also estimated in the southern assessment) and above-average recruitments from 2002-2006.

Fishing Mortality

Total mortality of black rockfish off Washington has consistently been well below established ACLs/OYs. The stock is targeted in the Washington recreational fishery; however, that fishery is tightly regulated to minimize canary and yelloweye rockfish impacts. There is also a relatively low tribal take of black rockfish off Washington. There are no commercial nearshore fisheries off Washington.

Exploitation of black rockfish reached a peak in 1988 of 13 percent of the age 3+ biomass and remained near that level for 7 years, dropping precipitously between 1995 and 2000. In recent years exploitation has been relatively low (4-6 percent). Exploitation rate relative to spawning biomass indicate that harvest rates exceeded management targets between the mid 1980s through the mid 1990s for the northern stock of black rockfish.

The PSA vulnerability score of 1.94 indicates a stock of medium concern for overfishing.

1.1.4.4 Cabezon off California

Distribution and Life History

Cabezon (*Scorpaenichthys marmoratus*) are distributed along the entire west coast of the continental United States. They range from central Baja California north to Sitka, Alaska (Love 1996; Miller and Lea 1972). Cabezon are primarily a nearshore species found intertidally and among jetty rocks, out to depths of greater than 100 m (Love 1996; Miller and Lea 1972).

Cabezon are known to spawn in recesses of natural and manmade objects, and males are reported to show nest-guarding behavior (Garrison and Miller 1982). Spawning is protracted, and there appears to be a seasonal progression of spawning that begins off California in winter and proceeds northward to Washington by spring. Spawning off California peaks in January and February (O'Connell 1953) while spawning in Puget Sound (Washington State) occurs for up to 10 months (November-August), peaking in March–April (Lauth 1987). Laid eggs are sticky and adhere to the surface where deposited. After hatching, the young of the year spend 3–4 months as pelagic larvae and juveniles. Settlement takes place after the young fish have attained 3–5 cm in length (Lauth 1987; O'Connell 1953). It is apparent that females lay multiple batches in different nests, but whether these eggs are temporally distinct enough to qualify for separate spawning events is not understood (Lauth 1987; O'Connell 1953).

Stock Status and Management History

Cabezon in California waters was first assessed in 2003 and it estimated a depletion of 34.7 percent at the start of 2003 (Cope, *et al.* 2004). The assessment delineated two stocks (north and south) at the Oregon-California border, a distinction based on differences in the catch history, CPUE trends and biological parameters (mainly growth) between the two areas. Due to the lack of data for the northern population, the assessment focused on only the southern population. As with most nearshore groundfish stocks, this assessment lacked a fishery-independent index of abundance, and consequently relied on recreational CPUE indices and information about larval abundance.

The 2005 assessment modeled two California substocks north and south of Point Conception (Cope and Punt 2006). Historically, the recreational fishery had been the primary source of removals of cabezon in California; however, commercial catches had become a major source of removals in the ten years preceding the assessment because of the developing live-fish fishery. Removals were reconstructed back to 1916, when the commercial fishery began. The estimated stock depletions of the northern and southern substocks of cabezon at the start of 2005 were 40.1 percent and 28.3 percent, respectively.

The most recent cabezon assessment for cabezon occurring in waters off California, done in 2009, estimated a stock depletion of 48.3 percent of unfished biomass at the start of 2009 (Cope and Key 2009). The 2009 assessment modeled two California substocks, and also evaluated the population as a coastwide California stock. The SSC recommended combining the results of the area models for the two California substocks of cabezon for use in deciding statewide harvest specifications.

Stock Productivity

The 2009 cabezon assessment assumed a steepness of 0.7 for all models. The PSA productivity score of 1.72 indicates a stock of relatively high productivity.

Recruitment deviations were estimated from 1970-2006 for both of the assessed substocks. Recruitment patterns are distinctly different for the substocks occurring north and south of Pt. Conception at 34º27’ N lat. Large recruitment events in the 1970s and 1990s in the north and the south have increased spawning biomass to healthy levels. Interannual variation in recruitment is greater in the north. The large increase in biomass in the south was driven by a large 1999 recruitment, the largest seen in the time series. Large recruitments in the southern substock were estimated immediately after major El Niño events (e.g., 1984 and 1994 recruitments). Recruitment events for the northern substock appear to lag large recruitments in the south by a year.

Fishing Mortality

Exploitation of the southern cabezon substock began in the 1960s and caused a substantial decline in stock biomass. The large recruitments discussed above and a reduction in exploitation rates in the late 1990s and 2000s caused the substock to rebound to healthy levels. Exploitation in the north also increased in the 1960s, although fishing pressure was not as great. The spawning biomass of the northern substock declined, although not as dramatically as in the south. The stock rebounded with good recruitment and a reduction in fishing pressure.

The cabezon stock(s) off California were first assessed in 2003, and OYs were first specified in 2004. Specified OYs were exceeded in each year through 2006, but a reduction in cumulative landing limits adequately reduced fishing mortality starting in 2007. The percent of OY attainment ranged from 56 to 74 percent in the 2007-2010 period.

The PSA vulnerability score of 1.68 indicates a low risk of overfishing.

1.1.4.5 Cabezon off Oregon

Distribution and Life History

See the description of cabezon distribution and life history in section 1.1.4.4.

Stock Status and Management History

The 2009 assessment of the Oregon substock of cabezon (Cope and Key 2009) was the first for cabezon in Oregon waters; the assessment indicated a healthy stock status for Oregon cabezon at 52.4 percent depletion at the start of 2009. Only one index of abundance was used for modeling the Oregon cabezon substock (the Oregon Recreational Boat Survey or ORBS CPUE index). The Oregon model was robust to almost all data and parameter manipulation trials except the removal of the ORBS survey. Removal of the only abundance index causes the population to drop sharply below the overfished level and absolute biomass to be much smaller than in the base case. Unlike the assessments for the California substocks, the assessment of the Oregon cabezon substock does not show recent increases in spawning biomass. While the uncertainty in the estimated depletion level of the Oregon substock is generally low, uncertainty in the estimated spawning biomass is high.

Stock Productivity

Steepness in the 2009 assessment of the Oregon substock of cabezon was assumed to be 0.7. Recruitment in the Oregon substock of cabezon was estimated to be less dynamic than that for the California substocks. The PSA productivity score of 1.72 indicates a stock of relatively high productivity.

The assessment estimates large recruitments in 1999 and 2004. Uncertainty in estimating recruitment for the Oregon substock is less than the uncertainty in recruitment estimation for the California substocks.

Fishing Mortality

Cabezon exploitation in Oregon started in the 1970s and caused the biomass to decline. However, exploitation was not excessive and the estimated spawning biomass has always been above the B_{MSY} target.

The PSA vulnerability score of 1.68 indicates a low risk of overfishing.

1.1.4.6 California Scorpionfish

Distribution and Life History

California scorpionfish (*Scorpaena guttata*), also known locally as sculpin, is a generally benthic species found from central California to the Gulf of California in depths between the inter-tidal and about 170 m (Eschmeyer, *et al.* 1983; Love, *et al.* 1987). California scorpionfish generally inhabits rocky reefs, but in certain areas and seasons they aggregate over sandy or muddy substrate (Frey 1971; Love, *et al.* 1987). Catch rate analysis and tagging studies show that most, but not all, California scorpionfish migrate to deeper water to spawn during May-September (Love, *et al.* 1987). Tagging data suggest that they return to the same spawning site (Love, *et al.* 1987), but information is not available on non-spawning season site fidelity. California scorpionfish are quite mobile and may not be permanently tied to a particular reef (Love, *et al.* 1987).

California scorpionfish spawn from May through August, peaking in July (Love, *et al.* 1987). The species is oviparous, producing floating, gelatinous egg masses in which the eggs are embedded in a single layer (Orton 1955). California scorpionfish utilize the “explosive breeding assemblage” reproductive mode in which fish migrate to, and aggregate at traditional spawning sites for brief periods (Love, *et al.* 1987). These spawning aggregations have been targeted by fishermen. Few California scorpionfish are mature at one year of age, but over 50 percent are mature by age two and most are mature by age three (Love, *et al.* 1987).

The species feeds on a wide variety of foods, including crabs, fishes, octopi, isopods and shrimp, but juvenile Cancer crabs are the most important prey (Limbaugh 1955; Love, *et al.* 1987).

Stock Status and Management History

California scorpionfish were assessed in 2005 (Maunder, *et al.* 2006) in the southern California Bight south of Point Conception at 34º27’ N lat. to the U.S.-Mexico border. The stock assessment indicated the California scorpionfish stock was healthy with an estimated spawning stock biomass of 79.8 percent of its initial, unfished biomass in 2005.

In most years, 99 percent or more of the landings occur in the southern California ports. The California nearshore FMP includes California scorpionfish. The stock is managed by the state under provisions for improved fishery monitoring and research data collection.

Stock Productivity

A steepness value of 0.7 was assumed for California scorpionfish in the 2005 assessment. The PSA productivity score of 1.83 indicates a stock of relatively high productivity, especially for a rockfish.

The assessment noted a high recruitment variation in the stock and recruitments in the 1990s and early 2000s were estimated to be substantially above average. Relatively large recruitment events were estimated starting in 1984.

Fishing Mortality

A substantial but unknown portion of the stock occurs in Mexican waters. The exploitation of the stock in Mexican waters is unknown and the connectivity of that stock with the U.S. stock in the Southern California Bight is also unknown.

Commercial catch records for scorpionfish were available beginning in 1928. Commercial catches were the dominant removals until the 1990s when the recreational catch became dominant. High catches and low recruitments in the 1950s and 1960s precipitated a decline in biomass. Stock biomass has been on an increasing trend since the mid 1970s.

The PSA vulnerability score of 1.41 indicates a low risk of overfishing.

1.1.4.7 Chilipepper Rockfish South of 40º10' N Lat.

Distribution and Life History

Chilipepper rockfish (*Sebastes goodei*) are found from Magdalena Bay, Baja California, Mexico, to as far north as the northwest coast of Vancouver Island, British Columbia (Allen 1982; Hart 1988; Miller and Lea 1972). The region of greatest abundance is found between Point Conception and Cape Mendocino, California. Chilipepper have been taken as deep as 425 m, but nearly all in survey catches were taken between 50 and 350 m (Allen and Smith 1988). Adults and older juveniles usually occur over the shelf and slope; larvae and small juveniles are generally found near the surface. In California, chilipepper are most commonly found associated with deep, high relief rocky areas and along cliff drop-offs (Love, *et al.* 1990), as well as on sand and mud bottoms (MBC 1987). They are occasionally found over flat, hard substrates (Love, *et al.* 1990). Love (1996) does not consider this to be a migratory species. Chilipepper may travel as far as 45 m off the bottom during the day to feed (Love 1996). Chilipepper rockfish are described as an elongate fish with reduced head spines similar in appearance to both shortbelly rockfish (at smaller sizes, although shortbelly tend to be slimmer) and bocaccio rockfish (bocaccio tend to have larger mouths).

Chilipeppers are ovoviviparous and eggs are fertilized internally (Reilly, et al. 1992). Chilipepper school by sex just prior to spawning (MBC 1987). In California, fertilization of eggs begins in October and spawning occurs from September to April (Oda 1992) with the peak occurring during December to January (Love, *et al.* 2002). Chilipepper may spawn multiple broods in a single season (Love, *et al.* 2002). Females of the species are significantly larger, reaching lengths of up to 56 cm (Hart 1988). Males are usually smaller than 40 cm (Dark and Wilkins 1994). Males mature at two years to six years of age, and 50 percent are mature at three years to four years. Females mature at two years to five years with 50 percent mature at three years to four years (MBC 1987). Females may attain an age of about 27 years, whereas the maximum age for males is about 12 years (MBC 1987).

Larval and juvenile chilipepper eat all life stages of copepods and euphausiids, and are considered to be somewhat opportunistic feeders (Reilly, *et al.* 1992). In California, adults prey on large euphausiids, squid, and small fishes such as anchovies, lanternfish, and young Pacific whiting (Hart 1988; Love, *et al.* 2002). Chilipepper are found with widow rockfish, greenspotted rockfish, and swordspine rockfish (Love, *et al.* 2002). Juvenile chilipepper compete for food with bocaccio, yellowtail rockfish, and shortbelly rockfish (Reilly, *et al.* 1992). Pelagic juveniles are preyed upon by a wide range of predators, including seabirds, salmon, lingcod and marine mammals. Larger piscivorous fishes, marine mammals, and in recent years jumbo squid are among the predators of larger adults.

Stock Status and Management History

Chilipepper have been one of the most important commercial target species in California waters since the 1880s and were historically an important recreational target in Southern California waters. With the exception of excluding foreign fishing effort from the U.S. EEZ in the late 1970s, management actions were modest (and usually general to all rockfish and other groundfish) prior to the implementation of the Groundfish FMP in 1982. When the FMP was implemented, management for the groundfish trawl fishery was based on individual vessel trip limits, which were set at 40,000 lbs per trip on the Sebastes (all rockfish species) complex. These limits were maintained until 1991, when they were reduced to 25,000; in 1993 the trip limit system was revised from daily to biweekly trip limits, which were set at 50,000 lbs (south of Cape Mendocino). The trip limit regime continued to evolve in their absolute amounts and temporal duration (monthly, bimonthly) throughout the 1990s, with a general trend towards lower limits as conservation concerns arose for other rockfish species (particularly bocaccio rockfish in the region south of Mendocino). The chilipepper catch in the bottom trawl fishery has been managed under an IFQ system since 2011.

Chilipepper rockfish were assessed in 1998 (Ralston, *et al.* 1998), at which time the stock south of 40º10' N lat. was estimated to be at 46 percent to 61 percent of unfished biomass.

A full chilipepper assessment was conducted in 2007 (Field 2008). The 2007 assessment estimated a substantial increase in the spawning biomass of chilipepper rockfish in recent years, due to a strong 1999 year class as well as greatly reduced harvest rates in commercial and recreational fisheries. The 2007 assessment's base model result suggests a spawning biomass of 23,889 tons in 2006, corresponding to approximately 70 percent of the unfished spawning biomass of 33,390 tons and representing a near tripling of spawning biomass from the estimated low of 8,696 mt (26 percent of unfished) in 1999. The strong 1999 year class represents the largest estimated historical recruitment, and is the primary cause for the current population trajectory. There are no obvious signs of strong year classes since 1999, and coastwide pelagic juvenile surveys suggested average to low recruitment in years immediately preceding the assessment, suggesting that the stock may dip slightly in the near term.

The 2007 assessment was first used in 2008 to decide 2009 and 2010 chilipepper harvest specifications. The Council consideration for 2011 and 2012 was whether or not to remove chilipepper rockfish from the Shelf Rockfish North complex and manage it coastwide. Chilipepper rockfish are predominantly found south of 40°10' N lat. Prior to 2007 they were only assessed in the area south of 40°10' N lat. To date, chilipepper rockfish have been managed with stock-specific harvest specifications south of 40°10' N lat. and within the Shelf Rockfish North complex north of 40°10' N lat. When the stock assessment area was extended for the 2007 chilipepper stock assessment, it was extended to the stock's entire west coast range through waters off Oregon (chilipepper rockfish are not believed to occur in waters off Washington). However, it was decided to continue to manage chilipepper rockfish south of 40º10' N lat. with stock-specific harvest specifications and as part of the Shelf Rockfish complex north of 40°10' N lat.

Stock Productivity

Steepness in the 2007 assessment was fixed at 0.57, which was the mean of the prior probability distribution in the base model. Since steepness was thought to be poorly specified in the model, this parameter was chosen as the major axis of uncertainty. The decision table projected outcomes for a low productivity and a high productivity model using steepness values of 0.34 and 0.81, respectively. The PSA productivity score of 1.83 indicates a stock of relatively high productivity, especially for a rockfish.

There have been strong recruitments estimated for the stock in the late 1960s, early 1970s, and very strong recruitments in 1984 and 1999. The 1999 year class was the biggest recruitment event in the assessment time series, causing spawning biomass to increase substantially in the ten years preceding the assessment.

Fishing Mortality

Chilipepper rockfish have been one of the most important commercial target species in California since the late 1800s and was also a recreational target in southern California waters. Catches and exploitation rate has declined substantially since the early 1990s. While chilipepper has always been an important target species in California, the exploitation rate has rarely exceeded the F_{MSY} target of a 50 percent SPR. Exploitation rates declined substantially since the late 1990s with the implementation of more restrictive management measures to rebuild depleted stocks.

Throughout most of the past three decades, domestic landings have ranged between approximately 2,000 and 3,000 mt; however, since 2002 landings have averaged less than 100 mt per year. The highest exploitation rates occurred from the late 1980s through the mid 1990s, when they were above target levels and the stock was approaching its lowest estimated historical levels. From the late 1990s through the present, exploitation rates have been declining significantly down to incidental levels, as a result of management measures implemented to rebuild co-occurring depleted rockfish species (particularly bocaccio, but including canary, widow, cowcod and yelloweye). Discards are assumed to be negligible in the historical period; however, regulatory discards have been substantial in recent years, more than doubling the total catch relative to landings since 2002.

The PSA vulnerability score of 1.35 indicates a low risk of overfishing.

1.1.4.8 Dover Sole

Distribution and Life History

Dover sole (*Microstomus pacificus*) are distributed from the Navarin Canyon in the northwest Bering Sea and westernmost Aleutian Islands to San Cristobal Bay, Baja California, Mexico (Hagerman 1952; Hart 1988; NOAA 1990). Dover sole are a dominant flatfish on the continental shelf and slope from Washington to Southern California. Adults are demersal and are found from 9 m to 1,450 m, with highest abundance below 200 m to 300 m (Allen and Smith 1988). Adults and juveniles show a high affinity toward soft bottoms of fine sand and mud. Juveniles are often found in deep nearshore waters. Dover sole are considered to be a migratory species. In the summer and fall, mature adults and juveniles can be found in shallow feeding grounds, as shallow as 55 m off British Columbia (Westrheim and Morgan 1963). By late fall, Dover sole begin moving offshore into deep waters (400 m or more) to spawn. Although there is an inshore-offshore seasonal migration, little north-south coastal migration occurs (Westrheim and Morgan 1963).

Spawning occurs from November through April off Oregon and California in waters 80 m to 550 m depth at or near the bottom (Hagerman 1952; Hart 1988; NOAA 1990; Pearcy, *et al.* 1977). Dover sole are oviparous and fertilization is external. Larvae are planktonic and are transported to offshore nursery areas by ocean currents and winds for up to two years. Settlement to benthic living occurs mid-autumn to early spring off Oregon, and February through July off California (Markle, *et al.* 1992). Juvenile fish move into deeper water with age and begin seasonal spawning and feeding migrations upon reaching maturity.

Dover sole larvae eat copepods, eggs, and nauplii, as well as other plankton. Juveniles and adults eat polychaetes, bivalves, brittlestars, and small benthic crustaceans. Dover sole feed diurnally by sight and smell (Dark and Wilkins 1994; Gabriel and Pearcy 1981; Hart 1988; NOAA 1990). Dover sole larvae are eaten by pelagic fishes like albacore, jack mackerel and tuna, as well as sea birds. Juveniles and adults are preyed upon by sharks, demersally feeding marine mammals, and to some extent by sablefish (NOAA 1990). Dover sole compete with various eelpout species, rex sole, English sole, and other fishes of the mixed species flatfish assemblage (NOAA 1990).

Stock Status and Management History

Dover sole have been the target of trawl operations along the west coast of North America since World War II and were almost certainly caught prior to the war as incidental take in directed fisheries for English sole and petrale sole. Almost all of the harvests have been taken by groundfish trawl, and in particular as part of the Dover sole, shortspine thornyhead, longspine thornyhead, and sablefish (DTS) trawl fishery. Annual landings from U.S. waters averaged 6,700 mt during the 1960s, 12,800 mt during the 1970s, 18,400 mt during the 1980s, 12,400 mt during the 1990s, and 7,200 mt since 2000.

The 1997 Dover sole stock assessment (Brodziak, *et al.* 1997) treated the entire population from the Monterey area through the U.S.-Vancouver area as a single stock based on research addressing the genetic structure of the population. Under a range of harvest policies and recruitment scenarios, the 1997 model projected that spawning biomass would increase from the estimated year-end level in 1997 through the year 2000 due to growth of the exceptionally large 1991 year class and to the lower catches observed in the fishery since 1991.

Dover sole were next assessed in 2001, resulting in an estimated spawning stock size of 29 percent of the unexploited biomass (Sampson and Wood 2001). Although there was no clear trend in abundance, stocks steadily declined from the 1950s until the mid-1990s. The 1991 year class was the last strong one, consistent with the 1997 assessment.

The 2005 Dover sole assessment indicated the stock was above target levels and had an increasing abundance trend (Sampson 2005). The final base model estimated the unexploited spawning stock biomass to be slightly less than 300,000 mt and spawning biomass at the start of 2005 was estimated to be about 189,000 mt, equivalent to 63 percent of the unexploited level. Spawning biomass and age 5+ biomass (roughly corresponding to the exploitable biomass) were estimated to have reached their lowest points in the mid-1990s and rose steadily since. The estimated increases in biomass since the mid-1990s was due primarily to strong year classes in 1990 and 1991, and exceptionally strong year classes in 1997 and 2000.

A new Dover sole assessment was done in 2011, which indicated the stock was healthy with a 2011 spawning stock biomass depletion of 83.7 percent of unfished biomass (Hicks and Wetzel 2011).

Stock Productivity

Steepness in the 2011 Dover sole assessment was fixed at 0.8, the mean steepness estimated in the SSC's 2010 meta-analysis of flatfish productivity (PFMC and NMFS 2011). While the 2011 assessment was considered data-rich, estimates of steepness are uncertain partly because the stock has not been fished to low levels to understand potential recruitment at low spawning biomass. The PSA productivity score of 1.8 indicates a stock of relatively high productivity.

There is little information regarding recruitment prior to 1960. Estimates of recruitment appear to oscillate between periods of low recruitment and periods of high recruitment. The five largest recruitments were predicted in the years 2000, 1992, 1988, 1965, and 1991. The five smallest recruitments were predicted in 2003, 2002, 2004, 2006, and 1974.

Larger than average recruitments in the early 1960s resulted in an increase in the Dover sole spawning biomass. A period of smaller than average recruitments in the late 1970s and early 1980s, along with the highest catches on record caused a decline in spawning biomass throughout the 1980s. More recently, spawning biomass has been increasing. However, a recent increase in Dover sole catches and low estimated recruitment in the early 2000s seem to be resulting in a slight downward trend in spawning biomass.

Fishing Mortality

The spawning biomass of Dover sole reached a low in the mid-1990s before beginning to increase throughout the last decade. The estimated depletion has remained above the 25 percent biomass target and it is unlikely that the stock has ever fallen below this threshold. Throughout the 1970s, 1980s, and 1990s the exploitation rate and SPR generally increased, but never exceeded the SPR 30 percent F_{MSY} target. Recent exploitation rates on Dover sole have been much lower than F_{MSY}, even after management increased catch levels in 2007.

Given the productivity of the stock and constraints on fishing, projections assuming a 25,000 mt constant annual catch predict the stock would remain above the target B_{MSY} level in the next ten years even under the more pessimistic and less likely low state of nature in the assessment decision table. Higher ACLs than the preferred No Action ACL were initially considered but rejected from more detailed analysis since the current market is projected to limit the take of Dover sole in the next management cycle to less than 25,000 mt. Higher ACLs are predicted to be sustainable; future mortalities as high as the OFL (above the allowable ACL maximum of the ABC) would maintain the stock above the target level of $B_{25\%}$ under the most likely base case model in the 2011 assessment. The effective limit of Dover sole in the 2013 and 2014 shorebased IFQ fishery is likely to be driven by the sablefish allocation, which is decreasing relative to No Action. Sablefish quota is needed to target Dover sole and the other DTS species using trawl gear. Sablefish IFQ quota is also used in a single-species target fishery using fixed gears. The competition and price for sablefish quota is affected by Asian sablefish demand and supply from north Pacific fisheries outside the west coast EEZ (e.g., BC and the Gulf of Alaska fisheries). It may be the case that the supply and demand of west coast Dover sole will remain limited until there is an increased harvestable surplus of sablefish above the levels provided under the No Action and preferred ACLs.

Dover sole is a trawl-dominant species managed using IFQs in the rationalized fishery. Despite Dover sole being an important target species, only 35 percent of the 2011 quota was attained in the IFQ fishery.

The PSA vulnerability score of 1.54 indicates a low risk of overfishing.

1.1.4.9 English Sole

Distribution and Life History

English sole (*Parophrys vetulus*) are found from Nunivak Island in the southeast Bering Sea and Agattu Island in the Aleutian Islands, to San Cristobal Bay, Baja California Sur, Mexico (Allen and Smith 1988). In research survey data, nearly all occurred at depths greater than 250 m (Allen and Smith 1988). Adults and juveniles prefer soft bottoms composed of fine sands and mud (Ketchen 1956), but also occur in eelgrass habitats (Pearson and Owen 1992). English sole use nearshore coastal and estuarine waters as nursery areas (Krygier and Pearcy 1986; Rogers, *et al.* 1988). Adults make limited migrations. Those off Washington show a northward post-spawning migration in the spring on their way to summer feeding grounds and a southerly movement in the fall (Garrison and Miller 1982). Tagging studies have identified separate stocks based on this species' limited movements and meristic characteristics (Jow 1969).

Spawning occurs over soft-bottom mud substrates (Ketchen 1956) from winter to early spring, depending on the stock. Eggs are neritic and buoyant, but sink just before hatching (Hart 1988); juveniles and adults are demersal (Garrison and Miller 1982). Small juveniles settle in the estuarine and shallow nearshore areas all along the coast, but are less common in southerly areas, particularly south of Point Conception. Large juveniles commonly occur up to depths of 150 m. Although many postlarvae may settle outside of estuaries, most will enter estuaries during some part of their first year of life (Gunderson, et al. 1990). Some females mature as three-year-olds (26 cm), but all females over 35 cm long are mature. Males mature at two years (21 cm).

Larvae are planktivorous. Juveniles and adults are carnivorous, eating copepods, amphipods, cumaceans, mysids, polychaetes, small bivalves, clam siphons, and other benthic invertebrates (Allen 1982; Becker 1984; Hogue and Carey 1982; Simenstad, *et al.* 1979). English sole feed primarily by day, using sight and smell, and sometimes dig for prey (Allen 1982; Hulberg and Oliver 1979). A juvenile English sole's main predators are probably piscivorous birds such as great blue heron (*Ardia herodias*), larger fishes, and marine mammals. Adults may be eaten by marine mammals, sharks, and other large fishes.

Stock Status and Management History

English sole have been captured by the bottom trawl fishery operating off the western coast of North America for over a century. Stewart (2006) found that peak catches from the southern area occurred in the 1920s with a maximum of 3,976 mt of English sole landed in 1929, and peak catches from the northern area occurred in the 1940s to the 1960s with a maximum of 4,008 mt landed in 1948. Landings from both areas have generally declined since the mid-1960s and have been at nearly historical lows in recent years

The most recent stock assessment of English sole prior the current 2005 assessment was performed in 1993 (Sampson and Stewart 1993). That assessment considered the female portion of the stock off Oregon and Washington during the years 1977-1993. The English sole spawning biomass was found to be increasing and it was concluded that the fishery was sustainable at (then) contemporary harvest levels.

The 2005 assessment of English sole (Stewart 2006) modeled a single coastwide stock, although both commercial and fishery independent data sources were treated separately for a southern (INPFC Conception and Monterey) and a northern (INPFC Eureka, Columbia and U.S. Vancouver) area. The assessment found that English sole spawning biomass had increased rapidly over the last decade after a period of poor recruitments from the mid-1970s to the mid-1990s, which left the stock at nearly historically low levels. Strong year classes were estimated for 1995, 1996, and 1999. The data indicated that the 1999 year class may be the largest in the time-series. There was substantial uncertainty related to certain parameters in the assessment, specifically biomass, recruitment, and relative depletion, as indicated by the wide confidence intervals for those parameters. Nevertheless, sensitivity analyses indicated that the conclusion that current spawning biomass exceeds the target level ($B_{40\%}$) was robust to all three of these sources of uncertainty. The spawning biomass at the beginning of 2005 was estimated to be 31,379 mt, which corresponds to 91.5 percent of the unexploited equilibrium level. Total catches for 2004 were estimated to be 1,341 mt, of which 950 mt were landed.

The 2007 update assessment (Stewart 2008c) confirmed the magnitude of increased biomass through a large quantity of age data through 2006, which became available. The 2007 assessment also included data on fishery length and age (primarily from Washington) that was previously unavailable. These new data provided substantially improved information regarding recent year class strengths and current stock status. The spawning biomass at the beginning of 2007 was estimated to be 41,906 mt, which corresponded to 116 percent of the unexploited equilibrium level.

Cope et al. (2013) assessed English sole using the data-moderate exSSS model platform.

Stock Productivity

There is little evidence for a strong stock-recruitment relationship, with some of the largest recruitments occurring at moderate levels of spawning biomass. This corresponds to the relatively high estimate of steepness of 0.80 in the assessment. In general, recruitment deviations are well-informed by the data between 1940 and 2000.

Following two decades of low recruitments, strong year classes were estimated for 1995, 1998-2000, and 2002. The data indicate that the 1999 year class was the largest in the time-series.

The PSA productivity score of 2.25 indicates a very productive stock, which is true for most nearshore and shelf flatfishes.

Fishing Mortality

The estimated SPR for English sole has never been below the proxy target of 30 percent for flatfish. Exploitation rates were highest from the late 1940s to the early 1990s. Since 1992, the intensity of exploitation has been substantially less, resulting in higher SPR levels. This corresponds to a relative exploitation rate (catch/biomass of age 3 and older fish) history that is high from the late 1940s to the early 1990s, and steadily declining to very low levels over the last 15 years.

English sole are a trawl-dominant species. Management uncertainty is low with the 100 percent observer coverage for the trawl fleet under trawl rationalization. Very small amounts of English sole were landed in the 2011 IFQ fishery with only 1 percent of the quota attained. This is due to low trawl effort on the shelf since such efforts require investment of limited quota for Pacific halibut, darkblotched rockfish, and yelloweye rockfish.

The PSA vulnerability score of 1.19 shows a very low concern of overfishing on the stock.

1.1.4.10 Lingcod North and South of 40º10' N Lat.

Distribution and Life History

Lingcod (*Ophiodon elongatus*), a top order predator of the family Hexagrammidae, ranges from Baja California, Mexico, to Kodiak Island in the Gulf of Alaska. Lingcod are demersal at all life stages (Allen and Smith 1988; NOAA 1990; Shaw and Hassler 1989). Adult lingcod prefer two main habitat types: slopes of submerged banks 10 m to 70 m below the surface with seaweed, kelp, and eelgrass beds and channels with swift currents that flow around rocky reefs (Emmett, *et al.* 1991; Giorgi and Congleton 1984; NOAA 1990; Shaw and Hassler 1989). Juveniles prefer sandy substrates in estuaries and shallow subtidal zones (Emmett, *et al.* 1991; Hart 1988; NOAA 1990). As the juveniles grow they move to deeper waters. Adult lingcod are considered a relatively sedentary species, but there are reports of migrations of greater than 100 km by sexually immature fish (Jagielo 1990; Mathews and LaRiviere 1987; Matthews 1992; Smith, *et al.* 1990).

Mature females live in deeper water than males and move from deep water to shallow water in the winter to spawn (Forrester 1969; Hart 1988; Jagielo 1990; LaRiviere, *et al.* 1980; Mathews and LaRiviere 1987;

Matthews 1992; Smith, *et al.* 1990). Mature males may live their whole lives associated with a single rock reef, possibly out of fidelity to a prime spawning or feeding area (Allen and Smith 1988; LaRiviere, *et al.* 1980; Shaw and Hassler 1989). Spawning generally occurs over rocky reefs in areas of swift current (Adams 1986; Adams and Hardwick 1992; Giorgi and Congleton 1984; LaRiviere, *et al.* 1980). After the females leave the spawning grounds, the males remain in nearshore areas to guard the nests until the eggs hatch. Hatching occurs in April off Washington, but as early as January and as late as June at the geographic extremes of the lingcod range. Males begin maturing at about two years (50 cm), whereas females mature at three plus years (76 cm). In the northern extent of their range, fish mature at an older age and larger size (Emmett, *et al.* 1991 Adams, 1992 #438; Hart 1988; Mathews and LaRiviere 1987; Miller and Geibel 1973; Shaw and Hassler 1989). The maximum age for lingcod is about 20 years (Adams and Hardwick 1992).

Lingcod are a visual predator, feeding primarily by day. Larvae are zooplanktivores (NOAA 1990). Small demersal juveniles prey upon copepods, shrimps, and other small crustaceans. Larger juveniles shift to clupeids and other small fishes (Emmett, *et al.* 1991; NOAA 1990). Adults feed primarily on demersal fishes (including smaller lingcod), squids, octopi, and crabs (Hart 1988; Miller and Geibel 1973; Shaw and Hassler 1989). Lingcod eggs are eaten by gastropods, crabs, echinoderms, spiny dogfish, and cabezon. Juveniles and adults are eaten by marine mammals, sharks, and larger lingcod (Miller and Geibel 1973; NOAA 1990).

Stock Status and Management History

Lingcod have been a target of commercial fisheries since the early 1900s in California, and since the late 1930s in Oregon and Washington waters. Recreational fishermen have targeted lingcod since the 1920s in California. A smaller recreational fishery has taken place in Washington and Oregon since at least the 1970s. Although historically the catches of lingcod have been greater in the commercial sector than in the recreational sector, this pattern has been reversed since the late 1990s.

In 1997, Jagielo, et al. (1997) assessed the size and condition of the portion of the stock in the Columbia and Vancouver areas (including the Canadian portion of the Vancouver management area), and concluded the stock had fallen to below ten percent of its unfished size at 8.8 percent of its unfished biomass. The Council responded by imposing substantial harvest reductions coastwide, reducing the harvest targets for the Eureka, Monterey, and Conception areas by the same percentage as in the north.

In 1999, Adams, et al. (1999) assessed the southern portion of the stock and concluded the condition of the southern stock was similar to the northern stock with a depletion of $B_{15\%}$, thus confirming the Council had taken appropriate action to reduce harvest coastwide. Based on these assessments, the lingcod stock was declared overfished in 1999. A rebuilding plan establishing a target year of 2009 and harvest rates of F = 0.0531 and F = 0.0610 for fisheries in the northern and southern areas, respectively was adopted and implemented in 2000.

Jagielo et al. (2000) conducted a coastwide lingcod assessment and determined the total biomass increased from 6,500 mt in the mid-1990s to about 8,900 mt in 2000. In the south, the population had also increased slightly from 5,600 mt in 1998 to 6,200 mt in 2000. In addition, the assessment concluded previous aging methods portrayed an older population; whereas new aging efforts showed the stock to be younger and more productive. Therefore, the ABC and OY were increased in 2001 on the basis of the new assessment. A revised rebuilding analysis of coastwide lingcod (Jagielo and Hastie 2001) confirmed the major conclusions of the 2000 assessment and rebuilding analysis, but slightly modified recruitment projections to stay on the rebuilding trajectory to reach target biomass in 2009.

The lingcod rebuilding plan was formally adopted by the Council and incorporated into the FMP under Amendment 16-2. The rebuilding plan established a target rebuilding year of 2009 and the harvest control rule of F = 0.0531 for fisheries in the northern areas and F = 0.0610 for fisheries in the southern areas (with a P_{MAX} of 60 percent). Depth-based restrictions and a winter season fishing closure to protect nest-guarding males were also implemented as part of the rebuilding plan.

Jagielo et al. (2004) conducted a coastwide assessment for lingcod in 2003 that indicated the lingcod stock had achieved the rebuilding objective of $B_{40\%}$ in the north with a 68 percent depletion, but was at a 31 percent depletion in the south. The Council's SSC, working in concert with the lead assessment author, recalculated the coastwide lingcod stock status in March 2004 using actual 2003 harvests (the assessment, which was completed during 2003, assumed harvest would be equal to the specified OY in 2003). Their calculations indicated that the spawning biomass at the start of 2004 was within 99.3 percent of B_{MSY} ($B_{40\%}$) on a coastwide basis. The harvest control rule was recalculated to be F = 0.17 for fisheries in the northern areas and F = 0.15 for fisheries in the southern areas.

The 2005 coastwide assessment (Jagielo and Wallace 2006) again modeled two populations of lingcod north and south of 40º10' N. lat. On a coastwide basis, the lingcod population was concluded to be fully rebuilt, with the spawning biomass in 2005 estimated to be 64 percent of its unfished level. Within the separate area models current biomass was estimated to be closer to unfished biomass in the north ($B_{87\%}$) than in the south ($B_{24\%}$). Given that the lingcod stock is managed on a coastwide basis, the Council announced the lingcod stock to be fully rebuilt in 2005, which is four years earlier than the target rebuilding year established in the rebuilding plan.

The 2009 lingcod assessment modeled two populations north and south of the California-Oregon border at 42º N. lat. (Hamel, *et al.* 2009). Both populations were healthy with stock depletion estimated at 62 and 74 percent for the north and south, respectively.

The Council and NMFS elected to maintain the management line for lingcod at 40º10' N lat. by specifying separate ACLs north and south of that line. This action was intended to not overly encumber the commercial fishing industry, which is required to fish within a single management area within one trip. Specifying the lingcod management line at 42º N lat. would create two management areas stratified at 40º10' N lat. and 42º N lat. This would especially burden vessels home ported out of Brookings, Crescent City, Eureka, and Ft. Bragg, since they would have to restructure their current fishing practices to avoid a violation of the management line crossover provisions. It is stated in the 2009 assessment that a management break at Cape Mendocino would be likely more biologically accurate than stratifying the assessment north and south of 42º N lat. In general, given the crossover provisions and the other regulations that foster area management strategies, the fewer latitudinal management lines there are, the less burdened the offshore commercial fishery will be. Two major biogeographic breaks occur on the west coast at Pt. Conception at 34º27' N lat. and Cape Mendocino approximately at 40º10' N lat., and many stocks show differences north and south of these latitudes. These biogeographic breaks are probably the more appropriate latitudes to specify management lines, given how north-south physical processes such as current patterns tend to be different, creating stock differences for species affected by these different physical processes.

The lingcod STAT evaluated the swept area biomass estimates calculated annually (2003-2010) from the NMFS NWFSC trawl survey, which indicated that 48 percent of the lingcod biomass for the stock south of 42º N lat. occurred between 40º10' N lat. and 42º N lat. Therefore, 48 percent of the 2013 and 2014 OFLs projected in the 2009 lingcod assessment for the southern lingcod stock were added to OFLs proposed for the stock north of 40º10' N lat. Likewise, 48 percent of the projected OFLs for the southern stock were subtracted from the OFLs proposed for the stock south of 40º10' N lat. Given that the trawl survey is the main fishery-independent tuning index of biomass in the assessment, using swept area biomass from the trawl survey to estimate relative biomass north and south of 40º10’ N lat. was considered appropriate.

Stock Productivity

Steepness was fixed at 0.8 in the 2009 assessment. The PSA productivity score of 1.75 indicates a stock of relatively high productivity.

Recruitments in the north were estimated from 1928-2007, with bias correction ramping in from 1950 to 1964 as data became informative. The base model indicated a very strong recruitment event in 1964, a secondary event in 1970, and recent relatively strong recruitments in 1999-2002, with fairly high recruitment in 2006 as well. Recruitments in the south were estimated from 1928-2007, with bias correction ramping in from 1960 to 1974 as data became informative. The base model indicated relatively strong recruitment events in 1976, 1983, and 1999-2003, similar to the period of increased recruitment in the north, with a very high but uncertain recruitment in 2007.

Fishing Mortality

Lingcod exploitation coastwide was above the target rate for most of the 1970s through the 1990s, driving the stock below the MSST and into an overfished condition. The stock was successfully rebuilt by 2006 based on good recruitments and very low fishing mortality rates. The SPR for northern lingcod has been above the proxy target of 45 percent since 1998, and in recent years has been far above that level. The SPR for the southern lingcod stock has been above the proxy target of 45 percent since 2001, and in recent years has been far above that level.

The PSA vulnerability score for lingcod is 1.55, indicating a low risk of overfishing of the stock.

1.1.4.11 Longnose Skate

Distribution and Life History

Skates are the largest and most widely distributed group of batoid fish with approximately 245 species ascribed to two families (Ebert and Compagno 2007; McEachran 1990). Skates are benthic fish that are found in all coastal waters but are most common in cold temperatures and polar waters (Ebert and Compagno 2007).

There are about eleven species of skates from either of three genera (Amblyraja, Bathyraja, and Raja) present in the Northeast Pacific Ocean off California, Oregon and Washington (Ebert 2003). Of that number, just three species (longnose skate *Raja rhina*, big skate *Raja binoculata*, and sandpaper skate *Bathyraja interrupta*) make up over 95 percent of survey catches in terms of biomass and numbers, with the longnose skate leading in both categories (62% of biomass and 56% of numbers). Species compositions of fishery landings also show that longnose skate are the predominant skates in commercial catches. On average, longnose skate represents 75 percent of total skate landings in Oregon for the last 20 years and 45 percent in Washington for the last 10 years. There are no species composition data available for commercial landings in California, but anecdotal evidence suggests that the majority of skates landed there are longnose skates.

The distribution of the longnose skate is limited to the eastern Pacific Ocean. It is found from the southeastern Bering Sea to just below Punta San Juanico, southern Baja California, and Gulf of California at depths of 9-1,069 m (Love, *et al.* 2005). Longnose skates do not exhibit a size-specific pattern in distribution relative to bottom depth; average fish size does not vary greatly with depth.

Currently, there is no information available that indicates the existence of multiple breeding units in the Northeast Pacific Ocean. Several tagging studies have found that elasmobranchs, such as sharks and skates, can undertake extensive migrations within their geographic range (Martin and Zorzi 1993; McFarlane and King 2003). This behavior suggests the likelihood that there is a high degree of genetic mixing within the population, across its range. As a result, the longnose skate population off California, Oregon and Washington is modeled in this assessment as a single stock.

The life history of skates is characterized by late maturity, low fecundity and slow growth to large body size (King and McFarlane 2003; Moyle and Cech 1996; Walker and Hislop 1998). Skates invest considerable energy in developing a few large, well-protected embryos. These characteristics are associated with a K-type reproductive strategy, as opposed to r-type strategy, wherein reproductive success is achieved by high productivity and early maturity (Hoenig and Gruber 1990).

The longnose skate is oviparous. After fertilization, the female forms tough, but permeable egg cases that surround eggs and then deposits these egg cases onto the sea floor at daily to weekly intervals for a period of several months or longer (Hamlett and Koob 1999). The eggs within egg cases incubate for several months in a benthic habitat. Inside the egg cases, the embryos develop with nourishment provided by yolk. The longnose skate is known to have only a single embryo per egg case (David Ebert, Moss Landing Marine Laboratories, pers. com. as cited by Gertseva and Schirripa (2008)). When the yolk is depleted and the juvenile is fully formed, it exits in the egg case. Once hatched, the young skate is similar in appearance to an adult, but smaller in size. Upon reaching maturity, skates enter the reproductive stage, which lasts for the remainder of their lives (Frisk, *et al.* 2002; Pratt and Casey 1990). On average off the continental US Pacific Coast, female longnose skates mature between 11-18 years, which corresponds to 75-125 cm in total length (Thompson 2006). The life span of the longnose skate is not well known, although individuals up to 23 years of age have been found (Thompson 2006). Longnose skates attain a maximum length of about 145 cm, although individuals as large as 180 cm have been reported off the U.S. west coast (Thompson 2006).

The reproductive cycle of oviparous skates has been observed for a few species but not for longnose skate. These studies indicate that egg production generally occurs throughout the year although there have been some instances where seasonality in egg laying was observed (Hamlett and Koob 1999). Information on fecundity of longnose skate is extremely limited. Holden (1974) found that species of the family Rajidae are the most fecund of all elasmobranches and can lay 100 egg cases per year, although eggs may not be produced every year. Frisk et al. (2002) estimated that annual fecundity for skates similar in size with longnose may be less than 50 eggs per year; however, those eggs exhibit high survival rates due to the large parental investment. Overall, little is known about breeding frequency, egg survival, hatching success and other early life history characteristics of longnose skate.

Stock Status and Management History

Longnose skate was managed in a complex of dissimilar species, the Other Fish complex, from 1982, when the Groundfish FMP was implemented through 2008. In 2009, longnose skate was removed from the Other Fish complex and managed with stock-specific harvest specifications.

Gertseva and Schirripa (2008) assessed the west coast longnose skate stock in 2007. The spawning stock biomass was estimated to be at 66 percent of its unfished biomass at the start of 2007. Based on that assessment, a constant catch strategy (OY = 1,349 mt) was implemented in 2009 based on a 50 percent increase in the average 2004-2006 landings and discard mortality. The constant catch strategy was revised in 2013 by implementing an ACL of 2,000 mt to provide greater access to the stock and to limit disruption of current fisheries. This level of harvest was projected to maintain the population at a healthy level as projected in the 10-year forecast for longnose skate in the 2007 assessment (Gertseva and Schirripa 2008).

The SSC recommended changing the proxy F_{MSY} rate for longnose skate and other elasmobranchs from an SPR of 45% to an SPR of 50% beginning in 2015. This recommendation, driven primarily by conservation concerns for spiny dogfish (see section 1.1.4.18), was heeded by the Council when they adopted 2015 and 2016 OFLs consistent with this lower harvest rate.

Stock Productivity

Steepness of the stock-recruitment curve was fixed at a value of 0.4 in the 2007 assessment to reflect the K-type reproductive strategy of the longnose skate. Recruitments were deterministically provided using this steepness value and a Beverton-Holt stock-recruitment relationship since the data in the 2007 assessment was not informative of relative year-class strength. In general, elasmobranchs have relatively low productivity given the K-type reproductive strategy of producing few eggs per female with a significant parental energy investment to increase survival of those few eggs (e.g., production of egg cases and relatively large yolk masses).

Fishing Mortality

Historically, skates in general, and longnose skate in particular, have not been high-priced fishery products. They are taken mostly as bycatch in other commercially important fisheries (Bonfil 1994). Although skates are caught in almost all demersal fisheries and areas off the U.S. west coast, the vast majority (almost 97%) are caught with trawl gear.

Landing records indicate that skates have been retained on the U.S. Pacific Coast at least since 1916 (Martin and Zorzi 1993). Little is known about the species composition of west coast skate fisheries, particularly prior to 1990. With few exceptions, longnose skate landings have been reported, along with other skate species, under the market category “unspecified skates”, until 2009 when a sorting requirement for longnose skate was required.

Historically, only the skinned pectoral fins or “wings” were sold, although a small portion of catch would be marketed in the round (whole). The wings were cut onboard the boat and the remainder discarded. Currently, west coast skates are marketed both whole and as wings. Skates wings are sold fresh or fresh-frozen, as well as dried or salted and dehydrated, for sale predominantly in Asian markets (Bonfil 1994; Martin and Zorzi 1993). It appears that the demand for whole skates did increase greatly during the mid-1990s, as evidenced by the increase in the number of trips where skates were landed. While skates were encountered predominantly as bycatch previously, landings data from this period reveal greater targeting of skates by some vessels. After a few years, the whole-skate market cooled due to downturns in Asian financial markets (Peter Leipzig, Fishermen's Marketing Association, pers. com. as cited by Gertseva and Schirripa (2008).

Historically, the exploitation rate for the longnose skate has been low. It reached its maximum level of 4.02% in 1981 (Gertseva and Schirripa 2008). An exploitation rate of 1.25% was estimated in 2006.

A vulnerability score of 1.68 indicates a low concern for overfishing the stock.

1.1.4.12 Longspine Thornyhead

Distribution and Life History

Longspine thornyhead occur from the southern tip of Baja, California, to the Aleutian Islands (Jacobson and Vetter 1996; Orr, *et al.* 1998). There appears to be no distinct geographic breaks in stock abundance along the west coast (Fay 2006; Rogers, *et al.* 1997). Adult longspine thornyhead are bottom dwellers, and inhabit the deep waters of the continental slope throughout their range.

Longspine occur at depths greater between 201 and 1,756 m, most typically between 500 and 1,300 m (Love, *et al.* 2002), and a peak in abundance and spawning biomass in the oxygen minimum zone (OMZ) at about 1,000 m depth (Jacobson and Vetter 1996; Wakefield 1990). Longspine are better adapted to deep water than shortspine (Siebenaller 1978; Siebenaller and Somero 1982). Wakefield (Wakefield 1990) estimated that in Central California, 83% of the longspine population resides within an area of the continental slope bounded by 600 and 1,000 m depth.

Unlike shortspine thornyhead, the mean size of longspines is similar throughout the depth range of the species (Jacobson and Vetter 1996). Camera sled observations indicate that longspines do not school or aggregate, and are distributed relatively evenly over soft sediments (Wakefield 1990). Differences in density of individuals at depth do occur with latitude, with higher densities of longspine in deep water (1,000-1,400 m) off Oregon than off central California (Jacobson and Vetter 1996).

The strong relationship between depth and size found in shortspine thornyhead (Jacobson and Vetter 1996 is not observed for longspines, with the distribution of longspines being relatively uniform with depth {Rogers, 1997 #271). Unlike shortspines, longspine do not undergo an ontogenetic migration to deeper waters (Wakefield 1990).

Longspine thornyheads prefer muddy or soft sand bottoms in deep-water environments characterized by high pressure and low oxygen concentrations. These are low productivity (Vetter and Lynn 1997) and low diversity (Haigh and Schnute 2003) habitats where food availability is limited. Longspines have adapted to this environment with an extremely slow metabolism that allows it to wait up to 180 days between feedings (Vetter and Lynn 1997). They are not territorial, and do not school. They have no swim bladders; instead oil in the bones and spines provides floatation. Video observations from submersibles and ROVs indicate that thornyhead are sit-and-wait predators that rest on the bottom and remain motionless for extended periods (John Butler, NOAA Fisheries, Southwest Fisheries Science Center, CA, as cited in Jacobson and Vetter (1996)).

The spawning season for longspine thornyheads appears to be extended, and occurs over several months during February, March and April (Best 1964; Moser 1974; Pearcy 1962; Wakefield and Smith 1990). Both thornyhead species produce a bi- lobed jellied egg mass that is fertilized at depth and which then floats to the surface where final development and hatching occur (Pearcy 1962). An extended larval and pelagic juvenile phase follows, which is thought to be 18-20 months long (Jacobson and Vetter 1996; Moser 1974; Wakefield 1990). Juvenile longspine settle on the continental slope at depths between 600 and 1,200 m (Wakefield 1990). Moser (1974) reports a mean length at settlement of 4.2-6.0 cm, although pelagic juveniles up to 69 mm in length have been collected in midwater trawls off Oregon (J. Siebenaller unpublished data, as cited in Wakefield and Smith (1990)).

Following settlement, longspine thornyhead are strictly benthic (Jacobson and Vetter 1996). No apparent pulse in recruitment during the year was observed by Wakefield and Smith (1990), perhaps due to the long (4-5 months) spawning season, variation in growth rates, and variation in the duration of the pelagic period (Wakefield and Smith 1990). There is potential for cannibalism because juveniles settle directly on to the adult habitat (Jacobson and Vetter 1996).

Adult females release between 20,000 and 450,000 eggs over a 4-5 month period (Best 1964; Moser 1974). Wakefield (1990) and Cooper et al. (2005) both found linear relationships between fecundity and somatic weight. The data analyzed by Cooper et al. (2005) indicated that fecundity of longspine between 20 and 30 cm in length ranged from 20,000 to 50,000 eggs.

There is considerable uncertainty regarding age and growth of thornyheads (Jacobson and Vetter 1996), although data indicate that longspine thornyhead are long lived. Age estimates of over 40 years have been obtained from otoliths using thin-section and break- and-burn techniques (Ianelli, *et al.* 1994). High frequencies of large longspine thornyheads may be due to a strongly asymptotic growth pattern, with accumulation of many age groups in the largest size-classes (Jacobson and Vetter 1996).

Size-at-age data (Ianelli, *et al.* 1994) indicate that longspine grow to a maximum size of about 30cm TL at ages of about 25-45 years, with little or no sexual dimorphism in length at age – longspines in British Columbia, Canada also display no sexual dimorphism (Starr and Haigh 2000). Orr et al. (1998) report a maximum length for longspines of 38 cm, although individuals of this size are rare in both trawl surveys and commercial landings. Growth increments on otoliths suggest that juveniles reach 80 mm after 1 year of life as demersal juveniles {Wakefield unpublished data, as cited in Wakefield and Smith, \1990 #462}, which would correspond to an age of 2.5 - 3 years old.

Longspine thornyhead are ambush predators (Jacobson and Vetter 1996). They consume fish fragments, crustaceans, bivalves, and polychaetes and occupy a tertiary consumer level in the food web. Pelagic juveniles prey largely on herbivorous euphausiids and occupy a secondary consumer level in the food web (Love 1996; Smith and Brown 1983). Cannibalism in newly settled longspine thornyhead may occur, because juveniles settle directly onto adult habitat (Jacobson and Vetter 1996). Sablefish commonly prey on longspine thornyhead. Sablefish and shortspine thornyhead commonly prey on longspine thornyhead (Buckley, *et al.* 1999).

Stock Status and Management History

Longspine thornyhead are exploited in the limited entry deep-water trawl fishery operating on the continental slope that also targets shortspine thornyhead, Dover sole and sablefish (i.e., the DTS fishery). A very small proportion of longspine landings is due to non-trawl gears (gillnets, hook and line). Longspine and shortspine thornyhead make up a single market category; however, they were managed under separate harvest specifications since 1992. Beginning in 2011, trawl catches of longspine north of 34º27’ N lat. have been managed using individual fishing quotas.

The thornyhead fishery developed in Northern California during the 1960s. The fishery then expanded north and south, and the majority of the landings of longspine thornyhead have since been in the Monterey, Eureka, and Columbia INPFC areas, with some increase in landings from the Conception (southern CA) and Vancouver (northern WA) INPFC areas in recent years (Fay 2006).

The most recent stock assessment of west coast longspine thornyhead was done in 2013. This was the fifth assessment done for longspines, but only the second in which it was assessed individually (earlier assessments were of longspine and shortspine thornyheads in combination). Previous assessments were conducted by Jacobson (Jacobson 1990; 1991), Ianelli et al. (1994), Rogers et al. (1997), and Fay (2006). The 1990 and 1991 assessments were very similar. Important features included reviews of available biological data, and analyses of trends in mean lengths from port samples and catch rates calculated from logbook data. Swept-area and video biomass estimates were used to estimate average biomass levels and exploitation rates in the Monterey to US-Vancouver management areas. The available data were used to conduct per-recruit analyses of yield, revenue, and spawning biomass, and to develop estimates of the then target level of $F_{35\%}$.

Ianelli et al. (1994) assessed the coastwide abundance of longspine and shortspine thornyheads based on slope survey data, an updated analysis of the logbook data, and fishery length-composition data to estimate the parameters of length-based Stock Synthesis models, under different assumptions regarding discarding practices.

The Rogers et al. (1997) assessment used a length-based version of Stock Synthesis 1 to fit an age-structured model to data for the Monterey, Eureka, Columbia and Vancouver INPFC areas. Models were fitted to biomass estimates and length data from the AFSC slope surveys (1988-1996), a logbook CPUE index, discarded proportions by year, and length composition data from California and Oregon. Sensitivity to discard rates based on changes in prices and minimum size were explored.

The 2005 assessment of longspine thornyhead estimated spawning biomass in 2005 was approximately 71 percent of unfished spawning biomass (Fay 2006). The model assumed one coastwide stock with one coastwide trawl fishery. Results from the base model suggested that the length compositions from the slope surveys were influencing recruitment in the model, such that the model estimated slightly higher recruitment in the early 1990s, which then declined in the mid to late 1990s.

The 2013 longspine thornyhead assessment indicated a stock depletion of 75 percent at the start of 2013 (Stephens and Taylor 2013).

Stock Productivity

Stephens and Taylor (2013) estimated annual longspine recruitment using a Beverton-Holt stock-recruitment function and assuming a steepness value of 0.6. Most 2013 rockfish assessments used a steepness prior of 0.779, estimated from a meta-analysis of rockfish assessment results. This value might be expected in the 2013 longspine assessment; however, rockfish ecology and reproduction are quite different from those of thornyheads, which (for example) do not give birth to live young but rather spawn floating egg masses.

Steepness in the shortspine thornyhead assessment was fixed at 0.6 both in the 2005 and 2013 models (Hamel 2006c; Taylor and Stephens 2013). This value was justified based on consistency between the modeling approach and management targets, in addition to being within a range of biologically reasonable values. For consistency, therefore, steepness for the longspine model was also fixed at 0.6.

Annual deviations about this stock-recruitment curve were estimated for the years 1944 through 2012. Estimated recruitments do not show high variability, and the uncertainty in each estimate is greater than the variability between estimates. The 2013 longspine assessment is relatively uninformative of relative year class strength since ages were not used in the model (thornyheads are notoriously difficult to age). Therefore, a length-based assessment with an assumed steepness is used to determine recruitment.

Fishing Mortality

The estimated exploitation rate of longspine thornyheads was above the current F_{MSY} harvest rate through much of the 1990s and, in hindsight, given the current target harvest rate, overfishing was occurring. However, stock biomass was estimated to have never dropped below the target B_{MSY} level. There is very little risk of overexploitation of longspines given their deep distribution beyond the 700 fm limit to west coast bottom trawling implemented under Amendment 19.

The PSA vulnerability score of 1.54 for longspine thornyheads also indicates a low concern for potential overfishing of the stock.

1.1.4.13 Pacific Cod

Distribution and Life History

Stock Status and Management History

The west coast population of Pacific cod has never been formally assessed. Targetable amounts of Pacific cod occur off northern Washington infrequently since the west coast EEZ is at the southern limit of their distribution. The Pacific cod OFL has been set at the highest annual historical catch observed for the stock and ACLs/OYs have been set at half that amount.

Pacific cod is the only unassessed, data-poor groundfish stock currently managed with stock-specific harvest specifications on the west coast.

Stock Productivity

The PSA vulnerability score of 1.34 for Pacific cod indicates a low concern for potential overfishing of the stock.

Fishing Mortality

1.1.4.14 Pacific Whiting

Distribution and Life History

Stock Status and Management History

Stock Productivity

Fishing Mortality

Pacific whiting is managed consistent with the Agreement with Canada on Pacific Hake/Whiting. OYs, now called TACs (total allowable catches), for Pacific whiting are adopted on an annual basis after a stock assessment is completed just prior to the Council's March meeting . The most recent assessment was conducted in 2013 Hicks 2013 and was used to determine stock status and 2013 harvest specifications.

1.1.4.15 Sablefish

Distribution and Life History

Sablefish, or black cod, (*Anoplopoma fimbria*) are distributed in the northeastern Pacific ocean from the southern tip of Baja California, northward to the north-central Bering Sea and in the Northwestern Pacific ocean from Kamchatka, southward to the northeastern coast of Japan. Although few studies have critically evaluated issues regarding the stock structure of this species, it appears there may exist at least three different stocks of sablefish along the west coast of North America: (1) a stock that exhibits relatively slow growth and small maximum size that is found south of Monterey Bay (Cailliet, *et al.* 1988; Phillips and Inamura 1954); (2) a stock that is characterized by moderately fast growth and large maximum size that occurs from northern California to Washington; and (3) a stock that grows very quickly and contains individuals that reach the largest maximum size of all sablefish in the northeastern Pacific ocean, distributed off British Columbia, Canada and in the Gulf of Alaska (Mason, *et al.* 1983; McFarlane and Beamish 1983a). Large adults are uncommon south of Point Conception (Hart 1988; Love 1996; McFarlane and Beamish 1983b; NOAA 1990). Adults are found as deep as 1,900 m, but are most abundant between 200 m and 1,000 m (Beamish and McFarlane 1988; Kendall and Matarese 1987; Mason, *et al.* 1983). Off southern California, sablefish are abundant to depths of 1,500 m (MBC 1987). Adults and large juveniles commonly occur over sand and mud (McFarlane and Beamish 1983a; NOAA 1990) in deep marine waters. They were also reported on hard-packed mud and clay bottoms in the vicinity of submarine canyons (MBC 1987).

Spawning occurs annually in the late fall through winter in waters greater than 300 m (Hart 1988; NOAA 1990). Sablefish are oviparous with external fertilization (NOAA 1990). Eggs hatch in about 15 days (Mason, *et al.* 1983; NOAA 1990) and are demersal until the yolk sac is absorbed (Mason, *et al.* 1983). Age-zero juveniles become pelagic after the yolk sac is absorbed. Older juveniles and adults are benthopelagic. Larvae and small juveniles move inshore after spawning and may rear for up to four years (Boehlert and Yoklavich 1985; Mason, *et al.* 1983). Older juveniles and adults inhabit progressively deeper waters. Estimates indicate that 50 percent of females are mature at five years to six years (24 inches) and 50 percent of males are mature at five years (20 inches).

Sablefish larvae prey on copepods and copepod nauplii. Pelagic juveniles feed on small fishes and cephalopods—mainly squids (Hart 1988; Mason, *et al.* 1983). Demersal juveniles eat small demersal fishes, amphipods, and krill (NOAA 1990). Adult sablefish feed on fishes like rockfishes and octopus (Hart 1988; McFarlane and Beamish 1983a). Larvae and pelagic juvenile sablefish are heavily preyed upon by seabirds and pelagic fishes. Juveniles are eaten by Pacific cod, Pacific halibut, lingcod, spiny dogfish, and marine mammals, such as Orca whales (Cailliet, *et al.* 1988; Hart 1988; Love 1996; Mason, *et al.* 1983; NOAA 1990). Sablefish compete with many other co-occurring species for food, mainly Pacific cod and spiny dogfish (Allen 1982).

Stock Status and Management History

Formal stock assessments of sablefish began in 1984. The first coastwide assessment established regulations on the sablefish fishery off the U.S. Pacific coast which were implemented as trip limits in October 1982. Since 1982, the sablefish fishery has been managed intensively, with limited entry and open access programs used in various manners to limit catches.

In 2001, two assessments were completed and reviewed by a STAR Panel: one by NMFS (Schirripa and Methot 2001) and one by the Pacific Groundfish Conservation Trust (Hilborn, *et al.* 2001). The two assessments were in agreement, and the Council adopted the NMFS assessment for management purposes. Schirripa and Methot (2001) focused on evaluating the sensitivity of the model and the outcomes to changes in the survey data. These changes included the combining of the AFSC slope survey data and the NWFSC Industry Co-operative Survey data using a statistical Generalized Linear Models (GLM) procedure. This analysis made it possible to extend the southern boundary of the assessment south to Point Conception at 34°27' N lat. rather than 36° N lat., used in previous assessments. The assessment indicated a normal decline in biomass since the late 1970s due to the fishing down of the unfished stock and an unexpected decline in recruitment during the early 1990s. It introduced for the first time, the possibility that sablefish recruitment may be linked to environmental factors. A seemingly meaningful relationship was demonstrated between changes in northern and southern copepod abundances and sablefish recruitment. Conditions and projections in the model considered two competing "states of nature" to calculate the mean virgin recruitment: a "density-dependent" state that used the average of 1975-1991 recruitments, and a "regime shift" state that used the 1975-2000 recruitments. To account for this uncertainty, the Council adopted a 2002 ABC based on the proxy harvest rate ($F_{45\%}$) adjusted to reflect the distribution north and south of 36° N latitude. This was done because a plan amendment would be needed to change the management area since Groundfish FMP Amendment 14 specified only the area north of 36° N lat.

The Council also wanted to verify industry reports of a large abundance of juvenile sablefish, an observation that was confirmed to some extent by preliminary results from the 2001 NMFS slope survey. Based on these considerations, the Council recommended a new expedited assessment be done in 2002. This update assessment (Schirripa 2002), by definition, sought to document changes in the estimates of the status of the stock by only considering newly available data for 2001 while not considering any new changes in the model structure or model assumptions. The expedited assessment confirmed fishermen's anecdotal reports of a large 1999 year class, which was also apparent in the preliminary results of the 2001 slope survey.

The 2005 sablefish assessment estimated stock depletion at 34.3 percent of unfished biomass (Schirripa and Colbert 2006). The assessment fit a relationship between sea level and recruitment deviations for the period 1973-2003 and used that relationship to hindcast recruitment variability back to 1925. The 2005 assessment found that spawning stock biomass had steadily declined since 1900 and suggested that there was little evidence that recruitment from 2001-2005 was as high as that for the strong 1999 and 2000 year classes. As a result, the assessment's biomass projections indicate a short-term increase, followed by a continued decline.

The 2007 updated sablefish assessment estimated spawning depletion to be 38.3 percent of unfished biomass at the start of 2007 (Schirripa 2008). This increase from 2005 was attributed in part to the continued recruitment of the strong 1999 and 2000 year classes into the spawning stock biomass. The assessment also estimated a series of poor recruitments in the mid- to late-1990s, and if fished at the full OY level, depletion was forecasted to decrease for the next five years.

The 2011 sablefish assessment estimated spawning stock biomass to be at 33 percent of its unfished biomass at the beginning of 2011 (Stewart, *et al.* 2011). The resource was modeled as a single stock; however, there is some dispersal to and from offshore seamounts and along the coastal waters of the continental U.S., Canada, Alaska, and across the Aleutian Islands to the western Pacific which was not explicitly accounted for in this analysis. Environmental time-series including both sea-surface height (used in previous sablefish assessments) and zooplankton abundance were also investigated. These environmental indices were not used in the 2011 assessment in the interest of parsimony since they did not affect results.

Stock Productivity

It was not possible to estimate the steepness parameter of the Beverton-Holt stock-recruitment relationship in the 2011 sablefish assessment, so this quantity was fixed at a value of 0.6 and explored via sensitivity analyses.

Stewart et al. (2011) estimated sablefish were exploited at a modest level through the first half of the 20th century. Following a period of above-average recruitments, the spawning stock biomass increased to nearly unexploited levels. Large harvests in the 1970s and 1980s were believed to have caused the stock biomass to decline. Estimates of the stock's productivity were highly uncertain due to lack of information on mortality, absolute stock size, and productivity. Sablefish recruitment was estimated to be variable over the historical record, with substantial uncertainty in individual recruitment events. Recruitments during the 1980s were, on average, roughly an order of magnitude higher than the very poor recent cohorts estimated between 2002 and 2007.

Fishing Mortality

The sablefish fishery has been managed with a rich history of seasons, size-limits, trip-limits, and a complex permit system. Coastwide yield targets have been divided among the different gears (hook-and-line, pot and trawl), fishery sectors (including both limited entry and open access) as well as north and south of 36º N lat. Peak catches occurred in the late 1970s just prior to the imposition of the first catch limits. Since 2001, the total estimated dead catch has been only 79 percent of the sum of the OFLs (ABCs at the time) and 87 percent of the ACLs (OYs at the time). In only one year of the last 10, 2008, did the estimated dead catch exceed the ACL (and OFL) by 5% (3%).

The PSA vulnerability score of 1.64 indicates a relatively low concern for potential overfishing.

1.1.4.16 Shortbelly Rockfish

Distribution and Life History

Shortbelly rockfish (*Sebastes jordani*) range from Punta Baja in Baja California (Klingbeil 1976) as far north as La Perouse Bank off of British Columbia, and as far west as the Cobb seamount off the southern Washington coast (Pearson, *et al.* 1993). However, they are most abundant along the continental shelf break between the northern end of Monterey Bay and Point Reyes, California (particularly in the regions of Ascension Canyon and the Farallon Islands), and around the Channel Islands in the Southern California Bight (Love, *et al.* 2002; Moser, *et al.* 2000; Pearson, *et al.* 1991; Phillips 1964). Although stock structure is poorly understood, genetic analysis of fish collected between San Diego and Cape Mendocino suggest a single coastwide stock, with slight differences in allele frequencies across Point Conception (Constable 2006). The shortbelly rockfish is one of the most abundant rockfish species in the California Current and is a key forage species for many piscivorous fish, birds, and marine mammals.

Shortbelly rockfish feed primarily on juvenile and adult euphausiids, and are an important prey item to a wide range of piscivorous fishes, seabirds and marine mammals (Chess, *et al.* 1988; Lowry and Carretta 1999; Sydeman, *et al.* 2001). Merkel (1957) reported that juvenile shortbelly rockfish were important prey of Chinook salmon along the central California coast in late spring and summer, accounting for more than 60% of those identified to species. For many breeding California seabirds, as much as 90% of their diet is comprised of pelagic stages of juvenile (age 0) rockfish during the late spring and early summer breeding seasons, and unexploited species (such as shortbelly) generally account for more than two thirds of the juvenile rockfish identified (Ainley, *et al.* 1993; Miller and Sydeman 2004; Sydeman, *et al.* 2001). However there is considerable interannual and interdecadal variability in the frequency of rockfish in seabird diets. Throughout the 1990s, foraging rates on juvenile rockfish by central California seabirds declined for both exploited and unexploited rockfish species primarily in response to changes in ocean conditions associated with poor recruitment for rockfish (Miller and Sydeman 2004; Mills, *et al.* 2007; Sydeman, *et al.* 2001). Although rockfish have rarely been identified to the species level in the diets of many California Current marine mammals (Antonelis and Fiscus 1980; Morejohn, *et al.* 1978; Perez and Bigg 1986; Stroud, *et al.* 1981), shortbelly were among the five most significant prey items for California sea lion (*Zalophus californianus*) in the Channel Islands (Lowry and Carretta 1999) and are frequently encountered in sea lion food habits samples off of Central California (Weise and Harvey 2005). Shortbelly rockfish are also described as important prey to thresher sharks (Preti, *et al.* 2004), longnose skate (Robinson, *et al.* 2007), and jumbo squid (Field, *et al.* 2007), among others. Consequently, shortbelly rockfish are an important forage species to a wide range of predators throughout the California Current ecosystem, and generally have a trophic position and life history traits more similar to forage fishes than most other *Sebastes*.

Stock Status and Management History

The expectation of eventual development of a domestic commercial fishery (Kato 1981) led to past efforts to estimate stock abundance and productivity (Lenarz 1980, Pearson et al. 1989, Pearson et al. 1991) as well as evaluations of commercial potential. The first ABC for shortbelly rockfish was set by the Council at 10,000 mt for 1983 through 1989. A stock assessment by Pearson et al. (Pearson, *et al.* 1991) estimated that allowable catches for shortbelly might range from 13,900 to 47,000 mt per year, based on life history data and hydroacoustic survey estimates of abundance. Subsequently, the Council established an ABC of 23,500 mt, which was reduced to 13,900 mt in 2001 based on observations of poor recruitment throughout the 1990s and the continued lack of a targeted fishery. Yet despite several attempts to develop a commercial fishery for shortbelly, domestic fishery landings have never exceeded 80 mt per year along the west coast.

A shortbelly rockfish assessment was done as an academic exercise in 2007 to understand the potential environmental determinants of fluctuations in the recruitment and abundance of an unexploited rockfish population in the California Current ecosystem (Field, *et al.* 2008). The results of the assessment indicated the shortbelly stock was healthy with an estimated spawning stock biomass of 67 percent of its unfished biomass in 2005.

Shortbelly rockfish is an abundant species that is not targeted in any commercial or recreational fisheries or caught in substantial amounts. However, shortbelly rockfish is a valuable forage fish species in the California Current ecosystem with fluctuations in stock recruitment and biomass driven by environmental conditions. The consequence of fisheries, including high and low estimates of plausible discards, were estimated to be negligible ($P<0.01$) in all years with the exception of the foreign fisheries of the mid-1960s (Field, *et al.* 2008). Shortbelly rockfish were initially considered for an Ecosystem Component (EC) species categorization under Amendment 23. Rather than classifying shortbelly rockfish as an EC species, the Council chose to recommend a very restrictive ACL of 50 mt for 2011 and beyond. This ACL is a level of harvest meant to accommodate unavoidable incidental bycatch of shortbelly rockfish while allowing most of the harvestable surplus of the stock to be available as forage for species in the California Current ecosystem. Such ecological considerations are made when setting ACLs for west coast groundfish species.

Stock Productivity

Field et al. (Field, *et al.* 2008) assumed a steepness of 0.65 in a Mace-Doonan stock-recruitment relationship (Mace and Doonan 1988) in the 2007 shortbelly assessment. The data in the assessment model were insufficient for estimating steepness; therefore, an assumed value was used based on the Dorn (2002b) meta-analysis of rockfish steepness available at the time the assessment was conducted.
