## Executive Summary <br> 1

1 Introduction
2 Methods ..... 6
2.1 Sampling ..... 6
2.1.1 Design ..... 6
2.1.2 Acoustic ..... 8
2.1.3 Oceanographic ..... 13
2.1.4 Fish-eggs ..... 13
2.1.5 Species and Demographics ..... 14
2.2 Data processing ..... 19
2.2.1 Acoustic and oceanographic data ..... 19
2.2.2 Sound speed and absorption calculation ..... 19
2.2.3 Echo classification ..... 19
2.2.4 Removal of non-CPS backscatter ..... 20
2.2.5 Extraction of nearshore backscatter ..... 22
2.2.6 Quality Assurance and Quality Control ..... 22
2.2.7 Echo integral partitioning and acoustic inversion ..... 22
2.2.8 Trawl clustering and species proportion ..... 24
2.3 Data analysis ..... 26
2.3.1 Post-stratification ..... 26
2.3.2 Biomass and sampling precision estimation ..... 29
2.3.3 Abundance- and biomass-at-length estimation ..... 29
2.3.4 Percent biomass per cluster contribution ..... 29
3 Results ..... 30
3.1 Sampling effort and allocation ..... 30
3.2 Acoustic backscatter ..... 31
3.3 Egg densities and distributions ..... 31
3.4 Trawl catch ..... 32
3.5 Purse-seine catch ..... 32
3.5.1 Lisa Marie ..... 32
3.5.2 Long Beach Carnage ..... 32
3.5.3 Combined catch ..... 32
3.6 Biomass distribution and demographics ..... 39
3.6.1 Northern Anchovy ..... 39
3.6.2 Pacific Sardine ..... 47
3.6.3 Pacific Mackerel ..... 55
3.6.4 Jack Mackerel ..... 59
3.6.5 Pacific Herring ..... 64
4 Discussion ..... 68
4.1 Biomass and abundance ..... 68
4.1.1 Northern Anchovy ..... 68
4.1.2 Pacific Sardine ..... 68
4.1.3 Pacific Mackerel ..... 69
4.1.4 Jack Mackerel ..... 69
4.1.5 Pacific Herring ..... 69
4.2 Ecosystem dynamics: Forage fish community ..... 71
Acknowledgements ..... 75

A. 5 Pacific Herring ..... 84

## List of Tables

1 Wide-Bandwidth Transceiver (Simrad EK80 WBT; Kongsberg) information, pre-calibration settings, and post-calibration beam model results (below the horizontal line). Prior to the survey, on-axis gain ( $G_{0}$ ), beam angles, angle offsets, and $S_{A}$ Correction ( $S_{\mathrm{A}}$ corr) values from calibration results were entered into the WBT control software (Simrad EK80; Kongsberg). .

2 Wideband Transceiver (Simrad EK80 WBT; Kongsberg) and transducer information (above horizontal line) and beam model results (below horizontal line) estimated from calibration of the echosounders aboard Lisa Marie using a WC38.1 standard sphere.
3 General Purpose Transceiver (Simrad EK60 GPT; Kongsberg) and transducer information (above horizontal line) and beam model results (below horizontal line) estimated from a tank calibration, using a WC38.1 standard sphere, of the echosounders later installed and used aboard Long Beach Carnage

4 Miniature Wideband Transceiver (Simrad-Kongsberg WBT Mini) beam model results estimated from calibrations of echosounders using a WC38.1 standard sphere, of the echosounders aboard the two USVs.

5 Biomass estimates (metric tons, t) and their precisions (upper and lower $95 \%$ confidence intervals, $\mathrm{CI}_{95 \%}$; and coefficients of variation, CVs) for the northern stock of Northern Anchovy (Engraulis mordax) in the core and nearshore survey regions. Stratum areas are nmi ${ }^{2}$.
6 Abundance versus standard length ( $L_{S}, \mathrm{~cm}$ ) for the northern stock of Northern Anchovy (Engraulis mordax) in the core and nearshore survey regions.
7 Biomass estimates (metric tons, t) and their precisions (upper and lower $95 \%$ confidence intervals, $\mathrm{CI}_{95 \%}$; and coefficients of variation, CVs) for the central stock of Northern Anchovy (Engraulis mordax) in the core and nearshore survey regions. Stratum areas are nmi ${ }^{2}$.

8 Abundance versus standard length $\left(L_{S}, \mathrm{~cm}\right)$ for the central stock of Northern Anchovy (Engraulis mordax) in the core and nearshore survey regions.

9 Biomass estimates (metric tons, t) and their precisions (upper and lower $95 \%$ confidence intervals, $\mathrm{CI}_{95 \%}$; and coefficients of variation, CVs) for the northern stock of Pacific Sardine (Sardinops sagax) in the core and nearshore survey regions. Stratum areas are nmi ${ }^{2}$.
10 Abundance versus standard length ( $L_{S}, \mathrm{~cm}$ ) for the northern stock of Pacific Sardine (Sardinops sagax) in the core and nearshore survey regions.
11 Biomass estimates (metric tons, t) and their precisions (upper and lower $95 \%$ confidence intervals, $\mathrm{CI}_{95 \%}$; and coefficients of variation, CVs) for the southern stock of Pacific Sardine (Sardinops sagax) in the core and nearshore survey regions. Stratum areas are nmi ${ }^{2}$.

12 Abundance versus standard length $\left(L_{S}, \mathrm{~cm}\right)$ for the southern stock of Pacific Sardine (Sardinops sagax) in the core and nearshore survey regions.

13 Biomass estimates (metric tons, t) and their precisions (upper and lower $95 \%$ confidence intervals, $\mathrm{CI}_{95 \%}$; and coefficients of variation, CVs) for Pacific Mackerel (Scomber japonicus) in nearshore survey region. Stratum areas are nmi ${ }^{2}$.55

14 Abundance versus fork length ( $L_{F}, \mathrm{~cm}$ ) for Pacific Mackerel (Scomber japonicus) in the core and nearshore survey regions.
15 Biomass estimates (metric tons, t) and their precisions (upper and lower $95 \%$ confidence intervals, $\mathrm{CI}_{95 \%}$; and coefficients of variation, CVs) for Jack Mackerel (Trachurus symmetricus) in the core and nearshore survey regions. Stratum areas are nmi ${ }^{2}$.59
16 Abundance versus fork length $\left(L_{F}, \mathrm{~cm}\right)$ for Jack Mackerel (Trachurus symmetricus) in the core and nearshore survey regions. ..... 60

17 Biomass estimates (metric tons, t) and their precisions (upper and lower $95 \%$ confidence intervals, $\mathrm{CI}_{95 \%}$; and coefficients of variation, CVs) for Pacific Herring (Clupea pallasii) in the core and nearshore survey regions. Stratum areas are $\mathrm{nmi}^{2}$
18 Abundance versus fork length ( $L_{F}, \mathrm{~cm}$ ) for Pacific Herring (Clupea pallasii) in the core and nearshore survey regions.

## List of Figures

1 Conceptual spring (shaded region) and summer (hashed region) distributions of potential habitat for the northern stock of Pacific Sardine along the west coasts of Mexico, the United States, and Canada. The dashed and dotted lines represent, respectively, the approximate summer and spring positions of the $0.2 \mathrm{mg} \mathrm{m}^{-3}$ chlorophyll-a concentration isoline. This isoline appears to oscillate in synchrony with the transition zone chlorophyll front (TZCF, Polovina et al., 2001) and the offshore limit of the northern stock Pacific Sardine potential habitat (Zwolinski et al., 2011). Mackerels are found within and on the edge of the same oceanographic habitat (e.g., Demer et al., 2012; Zwolinski et al., 2012). The TZCF may delineate the offshore and southern limit of both Pacific Sardine and Pacific Mackerel distributions, and juveniles may have nursery areas in the SCB , downstream of upwelling regions.

2 Planned compulsory and adaptive transects sampled by Lasker and Carranza; interstitial and offshore transects sampled by USVs; and nearshore transects sampled by Lisa Marie and Long Beach Carnage. Isobaths (light gray lines) are 50, 200, 500, and 2,000 m.

3 Echosounder transducers mounted on the bottom of the retractable centerboard on Lasker. During the survey, the centerboard was extended, typically positioning the transducers $\sim 2 \mathrm{~m}$ below the keel at a water depth of $\sim 7 \mathrm{~m}$.

4 Transducers (Top-bottom: Simrad ES200-7C, ES120-7C, ES38-12, and ES70-7C, Kongsberg) in a pole-mounted multi-transducer array (MTA4) installed on Long Beach Carnage. . . . . .

5 Schematic drawings of the Nordic 264 rope trawl a) net and b) cod-end. . . . . . . . . . . . . 15
6 Example depths (m) of the trawl headrope (red line) and footrope (blue line) measured using temperature-depth recorders (TDRs) during the net deployment (dashed box) and when actively fishing (shaded region). The vessel speed over ground (kn, black line) was measured using the ship's GPS.

8 Two examples of echograms depicting CPS schools (red) and plankton aggregations (blue and green) at 38 kHz (top) and 120 kHz (bottom). Example data processing steps include the original echogram (a, d), after noise subtraction and bin-averaging (b, e), and after filtering to retain only putative CPS echoes (c, f).

9 Echoes from fishes with swimbladders (blue points, scaled by backscatter intensity) along an example acoustic transect (top) and the corresponding echogram image (bottom). In this example, the upper (blue) and lower lines (green) indicate boundaries within which echoes were retained. When the lower boundary is deeper than the seabed (black line), echoes above the seabed are retained. Echoes from deep, bottom-dwelling schools of non-CPS fishes with swimbladders, and from diffuse scatterers near the surface were excluded. The proximity of the echoes to the seabed was also used to define the lower limit for vertical integration.
10 a) Polygons enclosing 100-m acoustic intervals from Lasker, Lisa Marie, and USVs assigned to catches from each trawl cluster or purse-seine set, and b) the acoustic proportions of CPS in catches from trawl clusters or purse-seine sets. See Section 3.5.1 and Fig. 13 for a description of the method used for this survey to estimate species proportions and Jack Mackerel lengths in the area between Cape Flattery and Cape Mendocino. The numbers inside each polygon in panel a) are the cluster or purse-seine numbers, which are located at the average latitude and longitude of all trawls in that cluster or each individual purse-seine set. Black points in panel b) indicate trawl clusters or purse-seine sets with no CPS present in the catch

11 Biomass density $\left(\log _{10}\left(t \mathrm{nmi}^{2}+1\right)\right)$ versus latitude (easternmost portion of each transect) and strata used to estimate biomass and abundance (shaded regions; outline indicates stratum number) for each species in the core survey region. Data labels (blue numbers) correspond to transects with positive biomass $\left(\log _{10}(t+1)>0.01\right)$. Transect spacing (nmi; point color), and stock breaks for Northern Anchovy and Pacific Sardine (red dashed lines and text) are indicated.

12 Summary of all transects sampled throughout the survey by Lasker (red) and Lisa Marie (yellow) in relation to the probability thresholds of the updated model of potential habitat for the northern stock of Pacific Sardine (Zwolinski and Demer, In prep.). The shaded regions with probabilities higher than 0.29 and 0.18 contained $82 \%$ and $95 \%$ of all spring northern stock Pacific Sardine spawning stock biomass, respectively. The habitat-model output is averaged in areas, $\pm 2^{\circ}$ latitude and longitude, centered around the daytime location of each vessel throughout the survey. Areas without data (white), occurred in the analysis domain where and when clouds prevented satellite-sensed observations.
13 Maps of species proportions in Lasker's nighttime trawl-catch clusters during summer a) 2018 , b) 2019 , and c) 2021 depicting an analysis region between the Columbia River and Cape Mendocino (dashed line); d) a model of the acoustic proportions of Pacific Sardine versus latitude in Lasker's nighttime trawl-catch clusters between 2018 and 2021; e) species proportions in Lisa Marie's summer 2022 purse-seine catches; and f) the species proportions used in the estimation of summer 2022 CPS biomasses north of Cape Mendocino, replacing Lisa Marie's catches containing Pacific Sardine, in the analysis region, with the modeled proportion of Pacific Sardine, with its complement assigned to Jack Mackerel.

14 Proportion (top) and cumulative proportion (bottom) of biomass versus distance to the nearest positive trawl cluster. Dashed vertical lines (bottom) represent the cluster distance where cumulative biomass equals $90 \%$.
15 Spatial distributions of: a) $38-\mathrm{kHz}$ integrated backscattering coefficients $\left(s_{A}, \mathrm{~m}^{2} \mathrm{nmi}^{-2}\right.$; averaged over 2000-m distance intervals) ascribed to CPS; b) CUFES egg density (eggs $\mathrm{m}^{-3}$ ) for Northern Anchovy, Pacific Sardine, and Jack Mackerel; and c) acoustic proportions of CPS in trawl clusters (black outline) and purse-seine sets (white outline). Black points indicate trawl clusters or purse-seine sets with no CPS.

16 Nearshore survey transects sampled by Lisa Marie overlaid with the distributions of: a) $38-\mathrm{kHz}$ integrated backscattering coefficients ( $s_{A}, \mathrm{~m}^{2} \mathrm{nmi}^{-2}$; averaged over $2000-\mathrm{m}$ distance intervals) ascribed to CPS; and b) the proportions, by weight, of CPS in each purse-seine catch. Species with low catch weights may not be visible at this scale.
17 Nearshore transects sampled by Long Beach Carnage overlaid with the distributions of: a) $38-\mathrm{kHz}$ integrated backscattering coefficients $\left(s_{A}, \mathrm{~m}^{2} \mathrm{nmi}{ }^{-2}\right.$; averaged over 2000-m distance intervals) ascribed to CPS; and b) the proportions, by weight, of CPS in each purse-seine catch. Species with low catch weights may not be visible at this scale.

18 Spatial distributions of: a) $38-\mathrm{kHz}$ integrated backscattering coefficients ( $s_{A}, \mathrm{~m}^{2} \mathrm{nmi}^{-2}$; averaged over $2000-\mathrm{m}$ distance intervals) ascribed to CPS from nearshore sampling; and b) acoustic proportions of CPS in trawl clusters (black outline) and purse-seine sets (white outline)
19 Biomass densities (colored points) of the northern stock of Northern Anchovy (Engraulis mordax), per stratum, in the a) core and b) nearshore survey regions. Overlaid are the locations of trawl clusters with at least one Northern Anchovy (blue numbers) in each stratum (colored polygons). Thick gray lines represent acoustic transects.41

20 Abundance versus standard length ( $L_{S}$, upper panels) and biomass ( t ) versus $L_{S}$ (lower panels) for the northern stock of Northern Anchovy (Engraulis mordax) in the core and nearshore survey regions. This plot correctly shows the abundances and biomasses in the core region, which is based on one specimen resulting in the mode at 10 cm (see Cluster 60 in Appendix A.1). Abundance and biomass in the nearshore region is negligible relative to the core region
and not visible at this scale.

23 Biomass densities (colored points) of the northern stock of Pacific Sardine (Sardinops sagax), per stratum, in the a) core and b) nearshore survey regions. Overlaid are the locations of trawl clusters with at least one Pacific Sardine (blue numbers) in each stratum (colored polygons). Thick gray lines represent acoustic transects.

24 Estimated abundance (upper panel) and biomass (lower panel) versus standard length $\left(L_{S}\right.$, cm ) for the northern stock of Pacific Sardine (Sardinops sagax) in the core and nearshore survey regions.

25 Biomass densities (colored points) of the southern stock of Pacific Sardine (Sardinops sagax), per stratum, in the a) core and b) nearshore survey regions. Overlaid are the locations of trawl clusters with at least one Pacific Sardine (blue numbers) in each stratum (colored polygons). Thick gray lines represent acoustic transects.

26 Estimated abundance (upper panels) and biomass (lower panels) versus standard length $\left(L_{S}\right.$, $\mathrm{cm})$ for the southern stock of Pacific Sardine (Sardinops sagax) in the core and nearshore survey regions.

27 Biomass densities (colored points) of Pacific Mackerel (Scomber japonicus), per stratum, in the a) core and b) nearshore survey regions. Oyerlaid are the locations of trawl clusters with at least one Pacific Mackerel (blue numbers) in each stratum (colored polygons). Thick gray lines represent acoustic transects.

28 Estimated abundance (upper panels) and biomass (lower panels) versus fork length ( $L_{F}, \mathrm{~cm}$ ) for Pacific Mackerel (Scomber japonicus) in the core and nearshore survey regions. 58

29 Biomass densities (colored points) of Jack Mackerel (Trachurus symmetricus), per stratum, in the a) core and b) nearshore survey regions. Overlaid are the locations of trawl clusters with at least one Jack Mackerel (blue numbers) in each stratum (colored polygons). Thick gray lines represent acoustic transects.

30 Estimated abundance (upper panel) and biomass (lower panel) versus fork length ( $L_{F}, \mathrm{~cm}$ ) for Jack Mackerel (Trachurus symmetricus) in the core and nearshore survey regions.

31 Biomass densities (colored points) of Pacific Herring (Clupea pallasii), per stratum, in the a) core and b) nearshore survey regions. Overlaid are the locations of trawl clusters with at least one Pacific Herring (blue numbers) in each stratum (colored polygons). Thick gray lines represent acoustic transects.66

32 Estimated abundance (upper panel) and biomass (lower panel) versus fork length ( $\left.L_{F}, \mathrm{~cm}\right)$ for Pacific Herring (Clupea pallasii) in the core and nearshore survey regions.67

33 Differentiation of northern (blue) and southern (red) stocks of Pacific Sardine by: a) length distributions; b) individual (grey points) and catch-mean (colored points) lengths at the latitudes of their respective trawls; and c) geographic locations of trawls catches with (colored points) and without (black points) Pacific Sardine.
34 Distributions of species proportions in Lasker's nighttime trawl catches, summer 2015 through 2022. In 2015, the integrated CPS-hake survey sample northward of Vancouver Island. In 2017, there was no sampling in the SCB. In 2020, there was no survey due to the COVID-19 pandemic. In 2021, through a collaboration with Mexico, the CPS survey extended farther south into Baja California. In 2022, there was no nighttime trawl sampling north of Cape Mendocino, California.

35 a) Estimated and b) cumulative estimated biomasses ( $t$ ) of the eight most abundant CPS stocks of six species in the CCE during summer since 2008. Surveys typically span the area between Cape Flattery and San Diego, but in some years also include Vancouver Island, Canada (2015-2019) and portions of Baja CA (2021-2022).

## Executive Summary

This report provides: 1) a detailed description of the acoustic-trawl method (ATM) used by NOAA's Southwest Fisheries Science Center for direct assessments of the dominant coastal pelagic species (CPS; i.e.: Pacific Sardine Sardinops sagax, Northern Anchovy Engraulis mordax, Pacific Mackerel Scomber japonicus, Jack Mackerel Trachurus symmetricus, and Pacific Herring Clupea pallasii in the California Current Ecosystem off the west coast of the United States (U.S.) and portions of Baja CA, Mexico (MX); and 2) estimates of the biomasses, distributions, and demographics of those CPS encountered in the survey area between 27 June and 30 September 2022.
The core survey region, which was to be sampled by NOAA ship Reuben Lasker (hereafter, Lasker) and two wind-powered uncrewed surface vehicles (Explorer USVs; Saildrone, Inc.), spanned most of the continental shelf between Cape Flattery, WA and Punta Baja, Baja CA Norte. Planned transects were oriented approximately perpendicular to the coast, from the shallowest navigable depth $(\sim 20 \mathrm{~m})$ to either a distance of 35 nmi or to the $1,000 \mathrm{ftm}(\sim 1830 \mathrm{~m})$ isobath, whichever is farthest. In the SCB , transects in the core region were extended to approximately 75 nmi . However, after losing roughly half of the scheduled sea days aboard Lasker, the plan was modified for chartered fishing vessel Lisa Marie to survey Lasker's transects, 20 nmi apart, between Cape Flattery, WA and Cape Mendocino, but extended into the nearshore region to $\sim 5 \mathrm{~m}$ depth. Both Lisa Marie and Lasker sampled in the area between Cape Mendocino and Bodega Bay, and then Lasker sampled farther south, ending at Punta Baja. North of Cape Mendocino, where Lasker did not sample, species composition and CPS length distributions were estimated from Lisa Marie's daytime purse-seine catches, but adjusted to reflect the associations between Pacific Sardine and Jack Mackerel in this region during summer 2018-2021 (see Section 3.5.1). Between Cape Mendocino and Punta Baja, species composition and CPS length distributions were estimated, as usual, by the catches from nighttime surface trawls.

Because sampling by Lasker and the USVs in water shallower than $\sim 20 \mathrm{~m}$ was deemed inefficient, unsafe, or both, fishing vessel Long Beach Carnage sampled CPS in the U.S. nearshore region, along 2.5 to 5 nmi -long transects spaced 5 nmi apart off the mainland coast of the U.S., between Bodega Bay and San Diego, as well as around Santa Cruz and Santa Catalina Islands in the Southern CA Bight. In the nearshore region, the species composition and CPS length distributions were estimated using catches daytime purse-seine sets by Long Beach Carnage or nighttime surface trawls by Lasker, whichever was nearest to the acoustically sampled CPS.

The biomasses, distributions, and demographics for each species and stock are for the survey area and period, and therefore may not represent their entire population or stock. Nearshore sampling was not conducted off Baja CA, so nearshore biomass estimates are for U.S. waters only.

The estimated biomass of the northern stock of Northern Anchovy was $16,432 \mathrm{t}\left(\mathrm{CI}_{95 \%}=5,646-27,680\right.$ $\mathrm{t}, \mathrm{CV}=34 \%)$. In the core region, the biomass was $16,432 \mathrm{t}\left(\mathrm{CI}_{95 \%}=5,646-27,680 \mathrm{t}, \mathrm{CV}=34 \%\right)$, and in the nearshore region, biomass was $0.0934 \mathrm{t}\left(\mathrm{CI}_{95 \%}=0-0.285 \mathrm{t}\right.$, $\left.\mathrm{CV}=94 \%\right)$, or $0.00057 \%$ of the total biomass. The estimated nearshore biomass includes uncertainty associated with the assumed nearshore-area (see Section 3.5.1). The northern stock ranged from approximately Westport, WA to Cape Blanco, OR, and the distribution of their standard length $\left(L_{S}\right)$ ranged from 10 to 15 cm with a mode at 10 cm in both the core and nearshore regions.

The estimated biomass of the central stock of Northern Anchovy was 2,235,996 t $\left(\mathrm{CI}_{95 \%}=1,248,956\right.$ $3,051,863 \mathrm{t}, \mathrm{CV}=20 \%$ ), of which $6 \%$ was observed in Mexican waters. In the core region, the biomass was $2,197,812 \mathrm{t}\left(\mathrm{CI}_{95 \%}=1,231,227-3,002,630 \mathrm{t}, \mathrm{CV}=21 \%\right)$, and in the nearshore region, the biomass was $38,184 \mathrm{t}\left(\mathrm{CI}_{95 \%}=17,729-49,233 \mathrm{t}, \mathrm{CV}=21 \%\right)$, or $1.7 \%$ of the total biomass. The central stock ranged from approximately Bodega Bay to El Rosario, and the distribution of their $L_{S}$ ranged from 5 to 16 cm with modes at 9 and 12 cm in the core region and 9 cm in the nearshore region.

The estimated biomass of the northern stock of Pacific Sardine was $69,506 \mathrm{t}\left(\mathrm{CI}_{95 \%}=30,484-99,021 \mathrm{t}\right.$, CV $=21 \%)$. In the core region, the biomass was $53,741 \mathrm{t}\left(\mathrm{CI}_{95 \%}=29,672-84,749 \mathrm{t}, \mathrm{CV}=26 \%\right)$, and in the nearshore region, the biomass was $15,765 \mathrm{t}\left(\mathrm{CI}_{95 \%}=812-14,272 \mathrm{t}, \mathrm{CV}=23 \%\right)$, or $23 \%$ of the total biomass. The nearshore and total biomasses include uncertainties associated with the assumed nearshore-area (see

Section 2.2.5) and the estimated species proportions from the daytime purse-seine sets (see Section 3.5.1), respectively. Within the survey area, the northern stock ranged from approximately Westport, WA to Point Conception. The distribution of $L_{S}$ ranged from 11 to 27 cm with a mode at 16 cm in the core region and modes at 11 and 14 cm in the nearshore region.
The estimated biomass of the southern stock of Pacific Sardine in the surveyed area was 107,468 $\mathrm{t}\left(\mathrm{CI}_{95 \%}\right.$ $=47,994-178,947 \mathrm{t}, \mathrm{CV}=23 \%$ ), of which $0.9 \%$ was observed in Mexican waters. In the core region, the biomass was $40,206 \mathrm{t}\left(\mathrm{CI}_{95 \%}=4,741-79,328 \mathrm{t}, \mathrm{CV}=48 \%\right)$, and in the nearshore region, the biomass was $67,262 \mathrm{t}\left(\mathrm{CI}_{95 \%}=43,253-99,620 \mathrm{t}, \mathrm{CV}=23 \%\right)$, or $63 \%$ of the total biomass. Within the survey area, the southern stock ranged from approximately Point Conception to El Rosario. The distribution of $L_{S}$ ranged from 9 to 21 cm with modes at 13 and 18 cm in the core region and at 12 and 16 cm in the nearshore region.
The estimated biomass of Pacific Mackerel was $7,968 \mathrm{t}\left(\mathrm{CI}_{95 \%}=3,741-12,662 \mathrm{t}, \mathrm{CV}=22 \%\right)$, of which $27 \%$ was observed in Mexican waters. In the core region, the biomass was $5,619 \mathrm{t}\left(\mathrm{Cl}_{95 \%}=2,851-9,108 \mathrm{t}\right.$, CV $=29 \%$ ), and in the nearshore region, the biomass was $2,349 \mathrm{t}\left(\mathrm{CI}_{95 \%}=890-3,553 \mathrm{t}, \mathrm{CV}=30 \%\right.$ ), or $29 \%$ of the total biomass. The estimated nearshore biomass includes uncertainty associated with the assumed nearshore-area (see Section 2.2.5). Pacific Mackerel ranged from approximately Cape Mendocino to El Rosario, but was mostly south of Point Conception and around Santa Cruz and Santa Catalina Islands. The distribution of fork length $\left(L_{F}\right)$ ranged from 8 to 38 cm with modes at 11 and 15 cm in the core region, and at 18 and 27 cm in the nearshore region.

The estimated biomass of Jack Mackerel was $807,090 \mathrm{t}\left(\mathrm{CI}_{95 \%}=515,560-1,145,812 \mathrm{t}\right.$, $\mathrm{CV}=20 \%$, of which $0.06 \%$ was observed in Mexican waters. In the core region, biomass was $799,082 \mathrm{t}\left(\mathrm{CI}_{95 \%}=512,231\right.$ $1,132,052 \mathrm{t}, \mathrm{CV}=20 \%$ ), and, in the nearshore region, biomass was $8,009 \mathrm{t}\left(\mathrm{CI}_{95 \%}=3,328-13,761 \mathrm{t}, \mathrm{CV}=\right.$ $35 \%$ ), or $0.99 \%$ of the total biomass. The nearshore and total biomasses include uncertainties associated with the assumed nearshore-area (see Section 2.2.5) and the estimated species proportions from the daytime purse-seine sets (see Section 3.5.1), respectively. Jack Mackerel were present throughout the survey area from the Columbia River to El Rosario, but were most abundant in the core region between Astoria and Bodega Bay and around Santa Cruz Island in the nearshore region. The distribution of $L_{F}$ ranged from 3 to 51 cm with modes at 8 and 34 cm in the core region, and at 19 cm in the nearshore region.
The total estimated biomass of Pacific Herring was $50,718 \mathrm{t}\left(\mathrm{CI}_{95 \%}=14,460-99,700 \mathrm{t}, \mathrm{CV}=41 \%\right)$. In the core region, biomass was $47,024 \mathrm{t}\left(\mathrm{CI}_{95 \%}=13,306-93,207 \mathrm{t}, \mathrm{CV}=44 \%\right)$, and was distributed from approximately Cape Flattery to Cape Mendocino, but was most abundant from Cape Flattery to the Columbia River, and between Crescent City and Cape Mendocino. The distribution of $L_{F}$ ranged from 13 to 17 cm , with modes at 13 and 17 cm . In the nearshore region, biomass was $3,694 \mathrm{t}\left(\mathrm{CI}_{95 \%}=1,154-6,493\right.$ $\mathrm{t}, \mathrm{CV}=36 \%$ ), or $7.3 \%$ of the total biomass. The distribution of $L_{F}$ ranged from 13 to 17 cm , and had a mode at 14 cm .
The total estimated biomass of seven stocks of five species within the survey area was $3,295,179 \mathrm{t}$. Of this $68 \%(2,235,996 \mathrm{t})$ was from the central stock of Northern Anchovy. Proportions of other stocks, in decreasing order, were Jack Mackerel ( $24 \%$ ), southern stock of Pacific Sardine ( $3 \%$ ), northern stock of Pacific Sardine $(2.1 \%)$, Pacific Herring ( $1.5 \%$ ), northern stock of Northern Anchovy ( $0.5 \%$ ), and Pacific Mackerel ( $0.2 \%$ ). The biomass of the central stock of Northern Anchovy, which had been growing exponentially since 2015, decreased $\sim 20 \%$ from $2,721,689$ t estimated in summer 2021 (Stierhoff et al., 2023). Jack Mackerel, which were found mostly north of Cape Mendocino, included an abundance of apparently age-0 fish farther south, suggesting a strong recruitment. The southern stock of Pacific Sardine was found mostly north of the U.S.-Mexico border and more were found nearshore than in the core area. Even considering the additional uncertainties in the biomass estimates north of Cape Mendocino (see Sections 2.2.5 and 3.5.1) there is no indication that the biomasses of the northern stock of Pacific Sardine have changed significantly since summer 2021.

## 1 Introduction

In the California Current Ecosystem (CCE), multiple coastal pelagic fish species (CPS; i.e.: Pacific Sardine Sardinops sagax, Northern Anchovy Engraulis mordax, Jack Mackerel Trachurus symmetricus, Pacific Mackerel Scomber japonicus, and Pacific Herring Clupea pallasii) comprise the bulk of the forage fish assemblage. These populations, which can change by an order of magnitude within a few years, represent important prey for marine mammals, birds, and larger migratory fishes (Field et al., 2001), and are targets of commercial fisheries.

During summer and fall, the northern stock of Pacific Sardine typically migrates north to feed in the productive coastal upwelling off OR, WA, and Vancouver Island (Zwolinski et al., 2012, and references therein, Fig. 1). In synchrony, but separately, the southern stock of Pacific Sardine migrates from Northern Baja CA, Mexico to the Southern CA Bight (SCB) (Smith, 2005). The predominantly piscivorous adult Pacific and Jack Mackerels also migrate north in summer, but go farther offshore to feed (Zwolinski et al., 2014 and references therein). In the winter and spring, the northern stock of Pacific Sardine typically migrates south to its spawning grounds, generally off Central and Southern CA (Demer et al., 2012) and occasionally off OR and WA (Lo et al., 2011). These migrations vary in extent with population size; fish age and length; and oceanographic conditions (Zwolinski et al., 2012). For example, the transition zone chlorophyll front [TZCF; Polovina et al. (2001)] may delineate the offshore and southern limit of both Pacific Sardine and Pacific Mackerel habitat (e.g., Demer et al., 2012; Zwolinski et al., 2012), and juveniles may have nursery areas in the SCB, downstream of upwelling regions. In contrast, Northern Anchovy spawn predominantly during winter and closer to the coast where seasonal down-welling increases retention of their eggs and larvae (Bakun and Parrish, 1982). Pacific Herring spawn in intertidal beach areas (Love, 1996). The northern stock of Northern Anchovy is located off WA and OR and the central stock is located off Central and Southern CA and northern Baja CA. Whether a species migrates or remains in an area depends on its reproductive and feeding behaviors, affinity to certain oceanographic or seabed habitats, and its population size.

Acoustic-trawl method (ATM) surveys, which combine information collected with echosounders and nets, were introduced to the CCE more than 48 years ago to survey CPS off the west coast of the United States (U.S.) (Mais, 1974, 1977; Smith, 1978). Following a two-decade hiatus, the ATM was reintroduced in the CCE in spring 2006 to sample the then-abundant Pacific Sardine population (Cutter and Demer, 2008). Since then, this sampling effort has continued and expanded through annual or semi-annual surveys (Demer et al., 2012; Zwolinski et al., 2014). Beginning in 2011, the ATM estimates of Pacific Sardine abundance, age structure, and distribution have been incorporated in the annual assessments of the northern stock (Hill et al., 2017). ATM estimates are used in assessments of Pacific Mackerel (Crone et al., 2019; Crone and Hill, 2015) and the central stock of Northern Anchovy (Kuriyama et al., 2022). Additionally, ATM survey results have yielded estimated abundances, demographics, and distributions of epipelagic and semi-demersal fishes (e.g., Swartzman, 1997; Williams et al., 2013; Zwolinski et al., 2014) and zooplankton (Hewitt and Demer, 2000).

This document, and references herein, describes in detail the ATM as presently used by NOAA's Southwest Fisheries Science Center (SWFSC) to survey the distributions and abundances of CPS and their oceanographic environments (e.g., Cutter and Demer, 2008; Demer et al., 2012; Zwolinski et al., 2014). In general terms, the contemporary ATM combines information from satellite-sensed oceanographic conditions, multifrequency echosounders, probe-sampled oceanographic conditions, pumped samples of fish eggs, and trawl-net catches of juvenile and adult CPS. The survey area is initially defined with consideration to the potential habitat of the northern stock of Pacific Sardine for summer surveys (Fig. 1) or the central stock of Northern Anchovy for spring surveys, when they occur. The survey area is further expanded to encompass as much of the potential habitat as possible for other CPS present off the West Coast of the U.S. and Baja CA, as time permits.

Along transects in the survey area, multi-frequency split-beam echosounders transmit sound pulses downward beneath the ship and receive echoes from animals and the seabed in the path of the sound waves. Measurements of sound speed and absorption from conductivity-temperature-depth (CTD) probes allow accurate compensation of these echoes for propagation losses. The calibrated echo intensities, normalized to the range-dependent observational volume, provide indications of the target type and behavior (e.g., Demer

Figure 1: Conceptual spring (shaded region) and summer (hashed region) distributions of potential habitat for the northern stock of Pacific Sardine along the west coasts of Mexico, the United States, and Canada. The dashed and dotted lines represent, respectively, the approximate summer and spring positions of the 0.2 $\mathrm{mg} \mathrm{m}^{-3}$ chlorophyll-a concentration isoline. This isoline appears to oscillate in synchrony with the transition zone chlorophyll front (TZCF, Polovina et al., 2001) and the offshore limit of the northern stock Pacific Sardine potential habitat (Zwolinski et al., 2011). Mackerels are found within and on the edge of the same oceanographic habitat (e.g., Demer et al., 2012; Zwolinski et al., 2012). The TZCF may delineate the offshore and southern limit of both Pacific Sardine and Pacific Mackerel distributions, and juveniles may have nursery areas in the SCB, downstream of upwelling regions.

Echoes from marine organisms are a function of their body composition, shape, and size relative to the sensing-sound wavelength, and their orientation relative to the incident sound waves (Cutter et al., 2009; Demer et al., 2009b; Renfree et al., 2009). Variations in echo intensity across frequencies, known as echo spectra, indicate the taxonomic groups contributing to the echoes. The CPS, with highly reflective swim bladders, create high intensity echoes of sound pulses at all echosounder frequencies (e.g., Conti and Demer, 2003). In contrast, krill, with acoustic properties closer to those of the surrounding seawater, produce lower intensity echoes, particularly at lower frequencies (e.g., Demer et al., 2003). The echo energy attributed to CPS, based on empirical echo spectra (Demer et al., 2012), are apportioned to species using trawl-catch proportions (Zwolinski et al., 2014).

Animal densities are estimated by dividing the summed intensities attributed to a species by the lengthweighted average echo intensity, i.e., the mean backscattering cross-section, from animals of that species (e.g., Demer et al., 2012). Transects with similar densities are grouped into post-sampling strata that mimic the natural patchiness of the target species (e.g., Zwolinski et al., 2014). An estimate of abundance is obtained by multiplying the average estimated density in the stratum by the stratum area (Demer et al., 2012). The associated sampling variance is calculated using non-parametric bootstrap of the mean transect densities. The total abundance estimate in the survey area is the sum of abundances in all strata. Similarly, the total variance estimate is the sum of the variance in each stratum.

The primary objectives of the SWFSC's ATM surveys are to survey the distributions and abundances of CPS, krill, and their abiotic environments in the CCE. Typically, spring surveys are conducted during 25-40 days-at-sea (DAS) between March and May, and summer surveys are conducted during 50-90 DAS between June and October. In spring, the ATM surveys focus primarily on the northern stock of Pacific Sardine and the central stock of Northern Anchovy. In summer, the ATM surveys also include the northern stock of Northern Anchovy and Pacific Herring. During spring and summer, biomasses are also estimated for other CPS (e.g., Pacific Mackerel, Jack Mackerel, and Round Herring) present in the survey area.
In summer 2022, the ATM survey, spanning U.S. and Mexican waters, was conducted by fishing vessel Lisa Marie, between Cape Flattery and Cape Mendocino, and by Lasker from Cape Mendocino to Punta Baja. Between Newport, OR and Bodega Bay, along adaptive transects not sampled by Lisa Marie or Lasker, two wind-powered uncrewed surface vessels (Explorer USVs; Saildrone, Inc.) conducted acoustic sampling. From Cape Flattery to San Diego, sampling from fishing vessels Lisa Marie and Long Beach Carnage was used to estimate the biomasses of CPS in the nearshore regions, where sampling by Lasker was not possible or safe.

Presented here are: 1) a detailed description of the ATM used to survey CPS in the California Current Ecosystem (CCE) off the west coast of the U.S. and portions of Baja CA; and 2) estimates of the abundances, biomasses, size structures, and distributions of CPS, specifically the northern and southern stocks of Pacific Sardine; the central and northern stocks of Northern Anchovy, Pacific Mackerel, Jack Mackerel, and Pacific Herring for the core and nearshore survey regions in which they were sampled. Additional details about the survey may be found in the survey report (Renfree et al., 2023).
This survey was conducted with the approval of the Secretaria de Relaciones Exteriores (SRE, Diplomatic note UAN0807/2022), the Instituto Nacional de Estadística y Geografía (INEGI; Authorization: EG0022022, through official letters $400 . / 58 / 2022$ and 400./59/2022), Unidad de Planeación y Coordinación Estratégica de la Secretaría de Marina (SEMAR; Letter no AI/1223/22), Unidad Coordinadora de Asuntos Internacionales (UCAI) de la Secretaría de Medio Ambiente y Recursos Naturales (SEMARNAT; Letter UCAI/01314/2022), Universidad Nacional Autónoma de México (UNAM; Letter ICML/DIR/127/2022), Unidad de Concesiones y Servicios del Instituto Federal de Telecomunicaciones (IFT; Letter IFT/223/UCS/DG-AUSE/3059/2022), and the Comisión Nacional de Acuacultura y Pesca (CONAPESCA; Permit: PPFE/DGPPE.-05325/120722).

## 2 Methods

### 2.1 Sampling

### 2.1.1 Design

The summer 2022 survey was conducted principally using Lasker and Lisa Marie, but was augmented with acoustic sampling by two uncrewed surface vehicles (USVs), and nearshore sampling by Long Beach Carnage. The sampling domain, or core region, between Cape Flattery, WA and Punta Baja, Baja CA Norte, was defined by the conceptual distribution of potential habitat for the northern stock of Pacific Sardine in summer (Fig. 1), but also encompassed the anticipated distributions of the southern stock of Pacific Sardine and the central and northern stocks of Northern Anchovy off the west coasts of the U.S. and portion of Baja CA, Mexico. It also spanned portions of the Pacific Mackerel, Jack Mackerel, Pacific Herring, and Round Herring populations. East to west, the sampling domain extended from the coast to at least the $1,000 \mathrm{ftm}(\sim 1830 \mathrm{~m})$ isobath (Fig. 2). Considering the expected distribution of the target species, the acceptable uncertainty in biomass estimates, and the available ship time ( 75 days at sea, DAS), the principal survey objectives were to estimate the biomasses of the northern and southern stocks of Pacific Sardine and the northern and central stocks of Northern Anchovy in the survey region. Secondary objectives were to estimate the population biomasses of Pacific Mackerel, Jack Mackerel, Pacific Herring, and Round Herring in the survey region.

The core region transects were perpendicular to the coast, extending from the shallowest navigable depth $(\sim 20 \mathrm{~m})$ to either a distance of 35 nmi or to the $1,000 \mathrm{ftm}$ isobath, whichever was farthest (Fig. 2). Compulsory transects were spaced 10 nmi-apart in areas of historic CPS abundance (e.g., between Cape Flattery and Newport, and between San Francisco and San Diego) and 20-nmi apart elsewhere. When CPS were observed within the westernmost 3 nmi of a transect, that transect and the next one to the south were extended in 5 -nmi increments until no CPS were observed in the last 3 nmi of the extension, to a maximum extension of 50 nmi . If a transect was extended, the ensuing transect was extended by the same amount.
Leg I on Lasker was cancelled for reasons outside of the SWFSC's control, so Lisa Marie was directed to sample the transects between Cape Flattery, WA to Bodega Bay, CA using 20-nmi spacing, including the nearshore portions of those transects. Meanwhile USVs (SD-1076 and SD-1077) were directed to sample the interstitial transects, also spaced $20-\mathrm{nmi}$ apart, from Newport, OR to San Francisco (cyan lines, Fig. 2). Leg III on Lasker was delayed by 16 days for similar reasons, so the remaining four days were used to sample transects spaced 20-nmi apart, from San Diego northward into the Southern California Bight (SCB). During Leg IV on Lasker, transects were sampled southward from Monterey, CA to Punta Baja, Baja CA Norte. To progress as far south as possible, compulsory transects off Baja CA were shortened to 30-nmi, and adaptive transects were omitted.

To estimate the abundances and biomasses of CPS between Cape Flattery and San Diego, in the nearshore area where Lasker and the USVs could not efficiently or safely navigate or trawl, two fishing vessels conducted acoustic and purse-seine sampling (magenta lines, Fig. 2). Lisa Marie sampled transects to $\sim 5-\mathrm{m}$ depth, spaced 20 nmi apart between Cape Flattery and Bodega Bay. Long Beach Carnage sampled 5-nmi-long transects spaced 5 nmi apart between Bodega Bay and San Diego, and 2.5-nmi-long transects spaced 2.5 nmi apart around Santa Cruz and Santa Catalina Islands in the SCB.

Figure 2: Planned compulsory and adaptive transects sampled by Lasker and Carranza; interstitial and offshore transects sampled by USVs; and nearshore transects sampled by Lisa Marie and Long Beach Carnage. Isobaths (light gray lines) are 50, 200, 500, and $2,000 \mathrm{~m}$.

### 2.1.2 Acoustic

### 2.1.2.1 Acoustic equipment

2.1.2.1.1 Lasker Multi-frequency Wide-Bandwidth Transceivers (18-, 38-, 70-, 120-, 200-, and 333-kHz Simrad EK80 WBTs; Kongsberg) were configured with split-beam transducers (Simrad ES18-11, ES38B, ES70-7C, ES120-7C, ES200-7C, and ES333-7C, respectively; Kongsberg). The transducers were mounted on the bottom of a retractable keel or "centerboard" (Fig. 3). The keel was retracted (transducers at $\sim 5-\mathrm{m}$ depth) during calibration, and extended to the intermediate position (transducers at $\sim 7-\mathrm{m}$ depth) during the survey. Exceptions were made during shallow water operations, when the keel was retracted; or during times of heavy weather, when the keel was extended (transducers at $\sim 9-m$ depth) to provide extra stability and reduce the effect of weather-generated noise. In addition, acoustic data were also collected using a multibeam echosounder (Simrad ME70; Kongsberg), multibeam sonar (Simrad MS70; Kongsberg), scanning sonar (Simrad SX90; Kongsberg), acoustic Doppler current profiler and echosounder (Simrad EC150-3C, Kongsberg), and a separate ADCP (Ocean Surveyor OS75; Teledyne RD Instruments). Transducer position and motion were measured at 5 Hz using an inertial motion unit (Applanix POS-MV; Trimble).
2.1.2.1.2 Lisa Marie On Lisa Marie, multi-frequency Wideband Transceivers (Simrad 38- and 200kHz EK80 WBTs; Kongsberg) were connected to the vessel's hull-mounted split-beam transducers (Simrad ES38-7 and ES200-7C; Kongsberg). The transducers were at a water depth of $\sim 4 \mathrm{~m}$.
2.1.2.1.3 Long Beach Carnage On Long Beach Carnage, the SWFSC's multi-frequency General Purpose Transceivers (38-, 70-, 120-, and $200-\mathrm{kHz}$ Simrad EK60 GPTs; Kongsberg) were configured with the SWFSC's split-beam transducers (Simrad ES38-12, ES70-7C, ES120-7C and ES200-7C; Kongsberg) mounted in a multi-frequency transducer array (MTA4) on the bottom of a retractable pole (Fig. 4). The transducers were at a water depth of roughly 2 m .
2.1.2.1.4 USVs On the two USVs (SD-1076 and SD-1077), miniature Wide-Bandwidth Transceivers (Simrad WBT-Mini; Kongsberg) were configured with gimbaled, keel-mounted, dual-frequency transducers (Simrad ES38-18|200-18C; Kongsberg) containing a split-beam $38-\mathrm{kHz}$ transducer and single-beam $200-\mathrm{kHz}$ transducer with nominally $18^{\circ}$ beamwidths. The transducers were at a water depth of $\sim 1.9 \mathrm{~m}$.

Figure 3: Echosounder transducers mounted on the bottom of the retractable centerboard on Lasker. During the survey, the centerboard was extended, typically positioning the transducers $\sim 2 \mathrm{~m}$ below the keel at a water depth of $\sim 7 \mathrm{~m}$.

Figure 4: Transducers (Top-bottom: Simrad ES200-7C, ES120-7C, ES38-12, and ES70-7C, Kongsberg) in a pole-mounted multi-transducer array (MTA4) installed on Long Beach Carnage.

### 2.1.2.2 Echosounder calibrations

2.1.2.2.1 Lasker The echosounder systems aboard Lasker were calibrated on 23 June while the vessel was docked at 10th Avenue Marine Terminal, San Diego Bay ( $32.6956^{\circ} \mathrm{N},-117.15278^{\circ} \mathrm{W}$ ) using the standard sphere technique (Demer et al., 2015; Foote et al., 1987). Each WBT was calibrated in both CW (i.e., continuous wave or narrowband mode) and FM mode (i.e., frequency modulation or broadband mode). The reference target was a $38.1-\mathrm{mm}$ diameter sphere made from tungsten carbide (WC) with $6 \%$ cobalt binder material (WC38.1; Lasker sphere \#1); for FM mode, additional calibrations were conducted for the 120, 200 , and $333-\mathrm{kHz}$ echosounders using a $25-\mathrm{mm}$ WC sphere (WC25). Prior to the calibrations, temperature and salinity were measured to a depth of 10 m using a handheld probe (Pro2030, YSI) to estimate sound speeds at the transducer and sphere depths, and the time-averaged sound speed and absorption coefficients for the range between them. The theoretical target strength $\left(T S ; \mathrm{dB}\right.$ re $\left.1 \mathrm{~m}^{2}\right)$ of the sphere was calculated using values for the sphere, sound-pulse, and seawater properties. The sphere was positioned throughout the main lobe of each of the transducer beams using three motorized downriggers, two on one side of the vessel and one on the other. The WBTs were configured using the calibration results via the control software (Simrad EK80 v21.15.1; Kongsberg; Table 1). Calibration results for WBTs in FM mode are presented in the survey report (Renfree et al., 2023).

Table 1: Wide-Bandwidth Transceiver (Simrad EK80 WBT; Kongsberg) information, pre-calibration settings, and post-calibration beam model results (below the horizontal line). Prior to the survey, on-axis gain $\left(G_{0}\right)$, beam angles, angle offsets, and $S_{A}$ Correction ( $S_{\mathrm{A}}$ corr) values from calibration results were entered into the WBT control software (Simrad EK80; Kongsberg).

### 2.1.2.3 Data collection

On Lasker, the computer clocks were synchronized with the GPS clock (UTC) using synchronization software (NetTime ${ }^{1}$ ). The $18-\mathrm{kHz}$ WBT, operated by a separate PC from the other echosounders, was programmed to track the seabed and output the detected depth to the ship's Scientific Computing System (SCS). The 38-, 70-, 120-, 200-, and $333-\mathrm{kHz}$ echosounders were controlled by the EK80 Adaptive Logger (EAL ${ }^{2}$, Renfree and Demer, 2016). The EAL optimizes the pulse interval based on the seabed depth, while avoiding aliased seabed echoes, and was programmed such that once an hour the echosounders would record three pings in passive mode, for obtaining estimates of the background noise level. Acoustic sampling for CPS-density estimation along the pre-determined transects was limited to daylight hours (approximately between sunrise and sunset).

During daytime aboard Lasker, measurements of volume backscattering strength ( $S_{v}$; dB re $1 \mathrm{~m}^{2} \mathrm{~m}^{-3}$ ) and target strength ( $T S$; dB re $1 \mathrm{~m}^{2}$ ), indexed by time and geographic positions provided by GPS receivers, were logged to 60 m beyond the detected seabed range or to a maximum range of $500,500,500,300$, and 150 m for $38,70,120,200$, and 333 kHz , respectively, and stored, with a 50-GB maximum file size, in Simrad-EK80 .raw format. At nighttime, echosounders were set to FM mode to improve target strength estimation and species differentiation for CPS near the surface, and logged to 100 m to reduce data volume. For each acoustic instrument, the prefix for the file names is a concatenation of the survey name (e.g., 2207RL), the operational mode (CW or FM), and the logging commencement date and time from the EK80 software. For example, file generated by the EK80 software (v21.15.1) for a WBT operated in CW mode is named 2207RL-CW-D20220801-T125901.raw.

To minimize acoustic interference, transmit pulses from the EK80, ME70, MS70, SX90, EC150-3C, and ADCP were triggered using a synchronization system (Simrad K-Sync; Kongsberg). The K-Sync trigger rate, and thus echosounder ping interval, was modulated by the EAL (Renfree and Demer, 2016) using the seabed depth measured using the $18-\mathrm{kHz}$ echosounder. During daytime, the ME70, MS70, SX90, and ADCP were operated continuously, but only recorded at the discretion of the acoustician during times when CPS

[^0]were present. At nighttime, only the EK80 and ADCP were operated. All other instruments that produce sound within the echosounder bandwidths were secured during daytime survey operations. Exceptions were made during stations (e.g., plankton sampling and fish trawling) or in shallow water when the vessel's command occasionally operated the bridge's $50-$ and $200-\mathrm{kHz}$ echosounders (Furuno), the Doppler velocity $\log$ (SRD-500A; Sperry Marine), or both. Data from the ME70, MS70, and SX90 are not presented in this report.

On Lisa Marie and Long Beach Carnage, the EAL was used to control the EK80 software to modulate the echosounder recording ranges and ping intervals to avoid aliased seabed echoes. When the EAL was not utilized, the EK80 software recorded to 1000 m and used the maximum ping rate. Transmit pulses from the EK60s and fishing sonars were not synchronized. Therefore, the latter was secured during daytime acoustic transects.

On the USVs, the echosounders were programmed to transmit CW pulses to different ranges, dependent on the seabed depth. For deeper seabed depths, the ping interval was 2 s and the 38 and $200-\mathrm{kHz}$ echosounders recorded to 1000 and 400 m , respectively. For shallower depths, the ping interval was 1 s and both echosounders recorded to 250 m . Once an hour, the echosounders operated in passive mode and recorded data from three pings to obtain estimates of the background noise levels.

### 2.1.3 Oceanographic

### 2.1.3.1 Conductivity and temperature versus depth (CTD)

Conductivity and temperature were measured versus depth to 350 m (or to within $\sim 10 \mathrm{~m}$ of the shallower than 350 m ) with calibrated sensors on a CTD rosette (Model SBE911+, Seabird) or underway probe [UnderwayCTD (UCTD); Oceanscience] cast from the vessel. At least one cast was planned along each acoustic transect. These data were used to calculate the harmonic mean sound speed (Demer et al., 2015) for estimating ranges to the sound scatterers, and frequency-specific sound absorption coefficients for compensating signal attenuation of the sound pulse between the transducer and scatterers (Simmonds and MacLennan, 2005) (see Section 2.2.2).

### 2.1.3.2 Scientific Computer System

While underway, information about the position and direction (e.g., latitude, longitude, speed, course over ground, and heading), weather (air temperature, humidity, wind speed and direction, and barometric pressure), and sea-surface oceanography (e.g., temperature, salinity, and fluorescence) were measured continuously and logged using Lasker's Scientific Computer System (SCS). During and after the survey, data from a subset of these sensors, logged with a standardized format at 1-min resolution, are available on the internet via NOAA's ERDDAP data server ${ }^{3}$.

### 2.1.4 Fish-eggs

On Lasker, fish eggs were sampled during the day using a continuous underway fish egg sampler (CUFES, Checkley et al., 1997), which collects water and plankton at a rate of $\sim 640 \mathrm{l} \mathrm{min}^{-1}$ from an intake at $\sim 3-\mathrm{m}$ depth on the hull of the ship. The particles in the sampled water were sieved by a $505-\mu \mathrm{m}$ mesh. Pacific Sardine, Northern Anchovy, Jack Mackerel, and Pacific Hake (Merluccius productus) eggs were identified to species, counted, and logged. Eggs from other species (e.g., Pacific Mackerel and flatfishes) were also counted and logged as "other fish eggs." Typically, the duration of each CUFES sample was 30 min , corresponding to a distance of 5 nmi at a speed of 10 kn . Because the durations of the early egg stages are short for most fish species, the egg distributions inferred from CUFES indicated the nearby presence of actively spawning fish, and were used in combination with CPS echoes to select trawl locations.

[^1]
### 2.1.5 Species and Demographics

The net catches provide information about species composition, lengths, weights and ages of CPS sampled acoustically during the day. Nighttime trawls were conducted to sample the fish dispersed near the sea surface, because after sunset, schools of CPS and other fish tend to ascend and disperse and are less likely to avoid a trawl net (Mais, 1977). Daytime purse-seine nets were set nearshore to sample CPS schools where their depth is constrained by the seabed, and their vision is obscured by non-transparent, light-scattering water, due to primary production and suspended particulates. In summer 2022, Lisa Marie used daytime purse-seine sets to sample CPS schools nearshore, but also offshore in deeper, clearer water, and with mixed success (see Section 3.5.1). For example, fast swimming Jack Mackerel often avoided capture, resulting in unquantified species selectivity.

### 2.1.5.1 Trawl gear

2.1.5.1.1 Lasker A Nordic 264 rope trawl (NET Systems, Bainbridge Island, WA; Figs. 5a,b), was towed at the surface for 45 min at a speed of $3.5-4.5 \mathrm{kn}$. The net has a rectangular opening with an area of approximately $300 \mathrm{~m}^{2}$ ( $\sim 15-\mathrm{m}$ tall $\mathrm{x} 20-\mathrm{m}$ wide), a throat with variable-sized mesh and a "marine mammal excluder device" to prevent the capture of large animals, such as dolphins, turtles, or sharks while retaining target species (Dotson et al., 2010), and an $8-\mathrm{mm}$ square-mesh cod-end liner (to retain a large range of animal sizes). The trawl doors were foam-filled and the trawl headrope was lined with floats so the trawl towed at the surface. Temperature-depth recorders (TDRs; RBRduet ${ }^{3}$ T.D., RBR) were attached to the kite and footrope to evaluate trawl performance (Fig. 6).

### 2.1.5.2 Purse-seine gear

2.1.5.2.1 Lisa Marie and Long Beach Carnage Lisa Marie used an approximately 440-m-long and 40-m-deep net with 17-mm-wide mesh (A. Blair, pers. comm.). Long Beach Carnage used an approximately $200-\mathrm{m}$-long and $27-\mathrm{m}$-deep net with 17 -mm-wide mesh; a small section on the back end of the net had 25mm -wide mesh (R. Ashley, pers. comm.). Specimens collected by Lisa Marie and Long Beach Carnage were processed aboard the vessel by the WA Department of Fish and Wildlife (WDFW) and ashore by the CA Department of Fish and Wildlife (CDFW), respectively.

Figure 5: Schematic drawings of the Nordic 264 rope trawl a) net and b) cod-end.

Figure 6: Example depths (m) of the trawl headrope (red line) and footrope (blue line) measured using temperature-depth recorders (TDRs) during the net deployment (dashed box) and when actively fishing (shaded region). The vessel speed over ground (kn, black line) was measured using the ship's GPS.

### 2.1.5.3 Sampling locations

2.1.5.3.1 Lasker Up to three nighttime (i.e., 30 min after sunset to 30 min before sunrise) surface trawls, typically spaced at least $10-\mathrm{nmi}$ apart, were conducted in areas where echoes from putative CPS schools were observed earlier that day. Trawl locations were selected using one or more of the following criteria, in descending priority: CPS schools in echograms that day; CPS eggs in CUFES that day; and the trawl locations and catches during the previous night. Each evening, trawl locations were selected by an acoustician, who monitored CPS echoes, and a biologist, who measured the densities of CPS eggs in the CUFES. The locations were provided to the watch officers who charted the proposed trawl sites.

If no CPS echoes or CPS eggs were observed along a transect that day, the trawls were alternately placed nearshore one night and offshore the next night, with consideration given to the seabed depth and the modeled distribution of CPS habitat. Each morning, after the last trawl or 30 min prior to sunrise, Lasker resumed sampling at the location where the acoustic sampling stopped the previous day.
2.1.5.3.2 Lisa Marie and Long Beach Carnage On Lisa Marie, as many as three purse-seine sets were conducted each day. For each set, three dip-net samples, were collected, spatially separated as much as possible.
On Long Beach Carnage, as many as three purse-seine sets were conducted each day, including evenings. For each set, three dip-net samples were collected, spatially separated as much as possible.

### 2.1.5.4 Sample processing

2.1.5.4.1 Lasker If the total volume of the trawl catch was five $35-1$ baskets ( $\sim 175 \mathrm{l}$ ) or less, all target species were separated from the catch, sorted by species, weighed, and enumerated. If the volume of the entire catch was more than five baskets, a five-basket random subsample that included non-target species was collected, sorted by species, weighed, and enumerated; the remainder of the total catch was weighed. In these cases, the weight of the entire catch was calculated as the sum of the subsample and remainder weights. The weight of the $e$-th species in the total catch $\left(C_{T, e}\right)$ was obtained by summing the catch weight of the respective species in the subsample $\left(C_{S, e}\right)$ and the corresponding catch in the remainder $\left(C_{R, e}\right)$, which was calculated as:

$$
\begin{equation*}
C_{R, e}=C_{R} * P_{w, e} \tag{1}
\end{equation*}
$$

where $P_{w, e}=C_{S, e} / \sum_{1}^{s} C_{S, e}$, is the proportion in weight of the $e$-th species in the subsample. The number of specimens of the $e$-th species in the total catch $\left(N_{T, e}\right)$ was estimated by:

$$
\begin{equation*}
N_{T, e}=\frac{C_{T, e}}{\bar{w}_{e}} \tag{2}
\end{equation*}
$$

where $\bar{w}_{e}$ is the mean weight of the $e$-th species in the subsample. For Pacific Sardine and Northern Anchovy with 75 specimens or less, individual measurements of standard length $\left(L_{S}\right)$ in mm and weight $(w)$ in g were recorded. For Jack Mackerel, Pacific Mackerel, and Pacific Herring with 50 specimens or less, individual measurements of fork length $\left(L_{F}\right)$ and $w$ were recorded. In addition, sex and maturity were recorded for up to 75 Pacific Sardine and Northern Anchovy and up to 25 Jack and Pacific Mackerel. Ovaries were preserved for up to 10 specimens of each CPS species except Pacific Herring. Fin clips were removed from 50 Pacific Sardine and Northern Anchovy specimens from seven geographic zones (with boundaries at the Columbia River, Cape Mendocino, San Francisco Bay, Point Conception, San Diego, and San Quentin, Baja CA) and preserved in ethanol for genetic analysis. Otoliths were removed from all 50 Pacific Sardine in the subsample; for other CPS species except Pacific Herring, 25 otoliths were removed as equally as possible from the range of sizes present. The combined catches in up to three trawls per night (i.e., trawl cluster) were used to estimate the proportions of species contributing to the nearest samples of acoustic backscatter.
2.1.5.4.2 Lisa Marie For each dip-net sample, all specimens were sorted, weighed, and counted to provide a combined weight and count for each. Next, all three dip net samples were combined and up to 50 specimens of each CPS species were randomly sampled to provide a combined weight for each set. Length (mm), $L_{S}$ for Pacific Sardine and Northern Anchovy and $L_{F}$ for all others, and weight (g) were measured for up to 50 randomly selected specimens of each species. Otoliths were extracted, macroscopic maturity stage was determined visually, and gonads were collected and preserved from female specimens.
2.1.5.4.3 Long Beach Carnage For each dip net sample, all specimens were sorted, weighed, and counted to provide a combined weight and count for each, and as many as 20 fish of each CPS species were chosen randomly throughout the sample, and combined for a random sample of 50 fish collected throughout the catch. The fish were frozen for later analysis by CDFW biologists, yielding measures of individual fish and total sample weights (g); length (mm), $L_{S}$ for Pacific Sardine and Northern Anchovy and $L_{F}$ for all others; maturity; and otolith-derived ages. No female gonad samples were analyzed.
2.1.5.5 Quality Assurance and Quality Control At sea, trawl data were entered into a database (Microsoft Access). During and following the survey, data were further scrutinized and verified, or corrected. Missing length $\left(L_{\text {miss }}\right)$ and weight $\left(W_{\text {miss }}\right)$ measurements were estimated as $W_{\text {miss }}=\beta_{0} L^{\beta_{1}}$ and $L_{\text {miss }}=$ $\left(W / \beta_{0}\right)^{\left(1 / \beta_{1}\right)}$, respectively, where values for $\beta_{0}$ and $\beta_{1}$ are species- and season-specific parameters of the length-versus-weight relationships described in Palance et al. (Palance et al., 2019). To identify measurement or data-entry errors, length and weight data were graphically compared (Fig. 7) to measurements from previous surveys and models of season-specific length-versus-weight from previous surveys (Palance et al., 2019). Outliers were flagged, reviewed by the trawl team, and mitigated. Catch data were removed from aborted trawl hauls, or hauls otherwise deemed unacceptable.

Figure 7: Specimen length versus weight from the current survey (colored points, by sex) compared to those from previous SWFSC surveys during the same season (gray points, all sexes) and models [dashed lines; Palance et al. (2019)].

### 2.2 Data processing

### 2.2.1 Acoustic and oceanographic data

The calibrated echosounder data from each transect were processed using commercial software (Echoview v12.1; Echoview Software Pty Ltd.) and estimates of the sound speed and absorption coefficient calculated with contemporaneous data from CTD probes cast while stationary or underway (UCTD, see Section 2.1.3.1). Data collected along the daytime transects at speeds $\geq 5 \mathrm{kn}$ were used to estimate CPS densities. Nighttime acoustic data were not used for biomass estimations because they are assumed to be negatively biased due to diel-vertical migration and disaggregation of the target species' schools (Cutter and Demer, 2008).

### 2.2.2 Sound speed and absorption calculation

Depth derived from pressure in CTD casts was used to average samples in 1-m depth bins. Sound speed in each bin ( $c_{w, i}, \mathrm{~m} \mathrm{~s}^{-1}$ ) was estimated from the average salinity, density, and pH [if measured, else $\mathrm{pH}=8$; Chen and Millero (1977); Seabird (2013)]. The harmonic sound speed in the water column ( $\bar{c}_{w}, \mathrm{~m} \mathrm{~s}^{-1}$ ) was calculated over the upper 70 m as:

$$
\begin{equation*}
\bar{c}_{w}=\frac{\sum_{i=1}^{N} \Delta r_{i}}{\sum_{i=1}^{N} \Delta r_{i} / c_{w, i}} \tag{3}
\end{equation*}
$$

where $\Delta r$ is the depth of increment $i$ (Seabird, 2013). Measurements of seawater temperature $\left(t_{w},{ }^{\circ} \mathrm{C}\right)$, salinity $\left(s_{w}, \mathrm{psu}\right)$, depth, pH , and $\bar{c}_{w}$ are also used to calculate the mean species-specific absorption coefficients ( $\bar{\alpha}_{a}, \mathrm{~dB} \mathrm{~m}^{-1}$ ) over the entire profile using equations in Francois and Garrison (1982), Ainslie and $\operatorname{McColm}$ (1998), and Doonan et al. (2003). Both $\bar{c}_{w}$ and $\bar{\alpha}_{a}$ are later used to estimate ranges to the sound scatterers to compensate the echo signal for spherical spreading and attenuation during propagation of the sound pulse from the transducer to the scatterer range and back (Simmonds and MacLennan, 2005). The CTD rosette, when cast, also provides measures of fluorescence and dissolved oxygen concentration versus depth, which may be used to estimate the vertical dimension of Pacific Sardine potential habitat (Zwolinski et al., 2011), particularly the depth of the upper-mixed layer where most epipelagic CPS reside. The latter information is used to inform echo classification (see Section 2.2.3).

### 2.2.3 Echo classification

Echoes from schooling CPS and plankton (Figs. 8a,d) were identified using a semi-automated data processing algorithm implemented using Echoview software (v12.1; Echoview Software Pty Ltd). The filters and thresholds were based on a subsample of echoes from randomly selected CPS schools. The aim of the filter criteria is to retain at least $95 \%$ of the noise-free backscatter from CPS while rejecting at least $95 \%$ of the non-CPS backscatter (Fig. 8). Data from Lasker and Long Beach Carnage were processed using the following steps:

1. Match geometry of all $S_{v}$ variables to the $38-\mathrm{kHz} S_{v}$;
2. Remove passive-mode pings;
3. Estimate and subtract background noise using the background noise removal function (De Robertis and Higginbottom, 2007) in Echoview (Figs. 8b,e);
4. Average the noise-free $S_{v}$ echograms using non-overlapping 11 -sample by 3 -ping bins;
5. Expand the averaged, noise-reduced $S_{v}$ echograms with a 7 pixel x 7 pixel dilation;
6. For each pixel, compute: $S_{v, 200 \mathrm{kHz}}-S_{v, 38 \mathrm{kHz}}, S_{v, 120 \mathrm{kHz}}-S_{v, 38 \mathrm{kHz}}$, and $S_{v, 70 \mathrm{kHz}}-S_{v, 38 \mathrm{kHz}}$;
7. Create a Boolean echogram for $S_{v}$ differences in the CPS range: $-13.85<S_{v, 70 \mathrm{kHz}}-S_{v, 38 \mathrm{kHz}}<$ 9.89 and $-13.5<S_{v, 120 \mathrm{kHz}}-S_{v, 38 \mathrm{kHz}}<9.37$ and $-13.51<S_{v, 200 \mathrm{kHz}}-S_{v, 38 \mathrm{kHz}}<12.53$;
8. Compute the $120-$ and $200-\mathrm{kHz}$ Variance-to-Mean Ratios ( $V M R_{120 \mathrm{kHz}}$ and $V M R_{200 \mathrm{kHz}}$, respectively, Demer et al., 2009a) using the difference between noise-filtered $S_{v}$ (Step 3) and averaged $S_{v}$ (Step 4);
9. Expand the $V M R_{120 \mathrm{kHz}}$ and $V M R_{200 \mathrm{kHz}}$ echograms with a 7 pixel x 7 pixel dilation;
10. Create a Boolean echogram based on the $V M R \mathrm{~s}$ in the CPS range: $V M R_{120 \mathrm{kHz}}>-65 \mathrm{~dB}$ and $V M R_{200 \mathrm{kHz}}>-65 \mathrm{~dB}$. Diffuse backscattering layers have low $V M R$ (Zwolinski et al., 2010) whereas fish schools have high $V M R$ (Demer et al., 2009a);
11. Intersect the two Boolean echograms to create an echogram with "TRUE" samples for candidate CPS schools and "FALSE" elsewhere;
12. Mask the noise-reduced echograms using the CPS Boolean echogram (Figs. 8c,f);
13. Create an integration-start line 5 m below the transducer ( $\sim 10 \mathrm{~m}$ depth);
14. Create an integration-stop line 3 m above the estimated seabed (Demer et al., 2009a), or to the maximum logging range (e.g., 350 m ), whichever is shallowest;
15. Set the minimum $S_{v}$ threshold to -60 dB (corresponding to a density of approximately three 20-cm-long Pacific Sardine per $100 \mathrm{~m}^{3}$ );
16. Integrate the volume backscattering coefficients $\left(s_{V}, \mathrm{~m}^{2} \mathrm{~m}^{-3}\right)$ attributed to CPS over 5-m depths and averaged over $100-\mathrm{m}$ distances;
17. Output the resulting nautical area scattering coefficients $\left(s_{A} ; \mathrm{m}^{2} \mathrm{nmi}^{-2}\right)$ and associated information from each transect and frequency to comma-delimited text (.csv) files.

Data from Lisa Marie and the USVs were processed using the following steps:

1. Match geometry of the $S_{v, 200 \mathrm{kHz}}$ to the $S_{v, 38 \mathrm{kHz}}$;
2. Remove passive-mode pings;
3. Perform Steps 3-5 from Lasker processing;
4. For each pixel, compute: $S_{v, 200 \mathrm{kHz}}-S_{v, 38 \mathrm{kHz}}$;
5. Create a Boolean echogram for $S_{v}$ differences in the CPS range: $-13.5<S_{v, 200 \mathrm{kHz}}-S_{v, 38 \mathrm{kHz}}<9.37$
6. Perform Steps 8-9 from Lasker processing;
7. Create a Boolean echogram mask using $V M R>-57 \mathrm{~dB}$;
8. Performs Steps 11-17 from Lasker processing.

When necessary, the start and stop integration lines were manually edited to exclude reverberation due to bubbles, to include the entirety of shallow CPS aggregations, or to exclude seabed echoes. Also, echoes from putative rockfish schools were excluded based on their aggregation shapes and proximity to the rocky seabed.

### 2.2.4 Removal of non-CPS backscatter

In addition to echoes from target CPS, echoes may also be present from other pelagic fish species (Pacific Saury, Cololabis saira), or semi-demersal fish such as Pacific Hake and rockfishes (Sebastes spp.). When analyzing the acoustic-survey data, it was therefore necessary to filter "acoustic by-catch," i.e., backscatter not from the target species. To exclude echoes from mid-water, demersal, and benthic fishes, echograms were visually examined to exclude fish echoes where the seabed was hard and rugose, or where diffuse schools are observed offshore either near the surface or deeper than $\sim 250 \mathrm{~m}$ (Fig. 9). In areas dominated by Pacific Herring, for example off Vancouver Island, backscatter was integrated to a maximum depth of 75 m .

Figure 8: Two examples of echograms depicting CPS schools (red) and plankton aggregations (blue and green) at 38 kHz (top) and 120 kHz (bottom). Example data processing steps include the original echogram (a, d), after noise subtraction and bin-averaging (b, e), and after filtering to retain only putative CPS echoes (c, f).

2107RL_057_CPS-Final 38 kHz CPS.csv

Figure 9: Echoes from fishes with swimbladders (blue points, scaled by backscatter intensity) along an example acoustic transect (top) and the corresponding echogram image (bottom). In this example, the upper (blue) and lower lines (green) indicate boundaries within which echoes were retained. When the lower boundary is deeper than the seabed (black line), echoes above the seabed are retained. Echoes from deep, bottom-dwelling schools of non-CPS fishes with swimbladders, and from diffuse scatterers near the surface were excluded. The proximity of the echoes to the seabed was also used to define the lower limit for vertical integration.

### 2.2.5 Extraction of nearshore backscatter

In summer 2022, between Cape Flattery and Bodega Bay, Lisa Marie sampled along acoustic transects to a depth of $\sim 5 \mathrm{~m}$. Because there was not a separate nearshore survey in this area, as there was between 2016 and 2021, acoustic intervals in water shallower than the $20-\mathrm{m}$ isobath were assigned to nearshore strata, else to core strata, and biomasses were estimated as usual. The $20-\mathrm{m}$ isobath roughly corresponds to the shallowest depth in which Lasker can safely navigate, so this nearshore area roughly approximates those from previous surveys. However, a study of inter-annual variation in nearshore biomasses should use a standardized area across years.

### 2.2.6 Quality Assurance and Quality Control

The largest $38-\mathrm{kHz}$ integrated backscattering coefficients $\left(s_{A}, \mathrm{~m}^{2} \mathrm{nmi}^{-2}\right)$ were graphically examined to identify potential errors in the integrated data (e.g., when a portion of the seabed was accidentally integrated, not shown). If found, errors were corrected and data were re-integrated prior to use for biomass estimation.

### 2.2.7 Echo integral partitioning and acoustic inversion

For fishes with swimbladders, the acoustic backscattering cross-section of an individual $\left(\sigma_{b s}, \mathrm{~m}^{2}\right)$ depends on many factors but mostly on the acoustic wavelength and the swimbladder size and orientation relative to the incident sound pulse. For echosounder sampling conducted in this survey, $\sigma_{b s}$ is a function of the dorsal-surface area of the swimbladder and was approximated by a function of fish length $(L)$, i.e.:

$$
\begin{equation*}
\sigma_{b s}=10^{\frac{m \log _{10}(L)+b}{10}} \tag{4}
\end{equation*}
$$

where $m$ and $b$ are frequency and species-specific parameters that are obtained theoretically or experimentally (see references below). $T S$, a logarithmic representation of $\sigma_{b s}$, is defined as:

$$
\begin{equation*}
T S=10 \log _{10}\left(\sigma_{b s}\right)=m \log _{10}(L)+b \tag{5}
\end{equation*}
$$

$T S$ has units of dB re $1 \mathrm{~m}^{2}$ if defined for an individual, or dB re $1 \mathrm{~m}^{2} \mathrm{~kg}^{-1}$ if defined by weight. The following equations for $T S_{38 \mathrm{kHz}}$, were used in this analysis:

where the units for total length $\left(L_{T}\right)$ is cm and $T S$ is dB re $1 \mathrm{~m}^{2} \mathrm{~kg}^{-1}$.
Equations (6) and (9) were derived from echosounder measurements of $\sigma_{b s}$ for in situ fish and measures of $L_{T}$ and $W$ from concomitant catches of South American Pilchard (Sardinops ocellatus) and Horse Mackerel (Trachurus trachurus) off South Africa (Barange et al., 1996). Because mackerels have similar TS (Peña, 2008), Equation (9) is used for both Pacific and Jack Mackerels. For Pacific Herring and Round Herring, Equation (7) was derived from that of Thomas et al. (2002) measured at 120 kHz with the following modifications: 1) the intercept used here was calculated as the average intercept of Thomas et al.s spring
and fall regressions; 2) the intercept was compensated for swimbladder compression after Zhao et al. (2008) using the average depth for Pacific Herring of $44 \mathrm{~m} ; 3)$ the intercept was increased by 2.98 dB to account for the change of frequency from 120 to 38 kHz (Saunders et al., 2012). For Northern Anchovy, Equation (8) was derived from that of Kang et al. (2009), after compensation of the swimbladder volume (Ona, 2003; Zhao et al., 2008) for the average depth of Northern Anchovy observed in summer 2016 (19 m, Zwolinski et al., 2017).

To calculate $T S_{38 \mathrm{kHz}}, L_{T}$ was estimated from measurements of $L_{S}$ or $L_{F}$ using linear relationships between length and weight derived from specimens collected in the CCE (Palance et al., 2019): for Pacific Sardine, $L_{T}=0.3574+1.149 L_{S}$; for Northern Anchovy, $L_{T}=0.2056+1.1646 L_{S}$; for Pacific Mackerel, $L_{T}=$ $0.2994+1.092 L_{F}$; for Jack Mackerel $L_{T}=0.7295+1.078 L_{F}$; and for Pacific Herring $L_{T}=-0.105+1.2 L_{F}$. Since a conversion does not exist for Round Herring, the equation for Pacific Herring was used to estimate $L_{T}$.

The proportions of species in a trawl cluster were considered representative of the proportions of species in the vicinity of the cluster. Therefore, the proportion of the echo-integral from the $e$-th species $\left(P_{e}\right)$ in an ensemble of $s$ species can be calculated from the species catches $N_{1}, N_{2}, \ldots, N_{s}$ and the respective average backscattering cross-sections $\sigma_{b s_{1}}, \sigma_{b s_{2}}, \ldots, \sigma_{b s_{s}}$ (Nakken and Dommasnes, 1975). The acoustic proportion for the $e$-th species in the $a$-th trawl $\left(P_{a e}\right)$ is:

$$
\begin{equation*}
P_{a e}=\frac{N_{a e} \times \bar{w}_{a e} \times \bar{\sigma}_{b s, a e}}{\sum_{e=1}^{s_{a}}\left(N_{a e} \times \bar{w}_{a e} \times \bar{\sigma}_{b s, a e}\right)} \tag{10}
\end{equation*}
$$

where $\bar{\sigma}_{b s, a e}$ is the arithmetic counterpart of the average target strength $\left(\overline{T S}_{a e}\right)$ for all $n_{a e}$ individuals of species $e$ in the random sample of trawl $a$ :

$$
\begin{equation*}
\bar{\sigma}_{b s, a e}=\frac{\sum_{i=1}^{n_{a e}} 10^{\left(T S_{i} / 10\right)}}{n_{a e}} \tag{11}
\end{equation*}
$$

and $\bar{w}_{a e}$ is the average weight: $\bar{w}_{a e}=\sum_{i=1}^{n_{a e}} w_{a e i} / n_{a e}$. The total number of individuals of species $e$ in a trawl $a\left(N_{a e}\right)$ is obtained by: $N_{a e}=\frac{n_{a e}}{w_{s, a e}} \times w_{t, a e}$, where $w_{s, a e}$ is the weight of the $n_{a e}$ individuals sampled randomly, and $w_{t, a e}$ is the total weight of the respective species' catch.
The trawls within a cluster were combined to reduce sampling variability (see Section 2.2.8), and the number of individuals caught from the $e$-th species in a cluster $g\left(N_{g e}\right)$ was obtained by summing the catches across the $h$ trawls in the cluster: $N_{g e}=\sum_{a=1}^{h_{g}} N_{a e}$. The backscattering cross-section for species $e$ in the $g$-th cluster with $a$ trawls is then given by:

$$
\begin{equation*}
\bar{\sigma}_{b s, g e}=\frac{\sum_{a=1}^{h_{g}} N_{a e} \times \bar{w}_{a e} \times \bar{\sigma}_{b s, a e}}{\sum_{a=1}^{s_{g}} N_{a e} \times \bar{w}_{a e}}, \tag{12}
\end{equation*}
$$

where:

$$
\begin{equation*}
\bar{w}_{g e}=\frac{\sum_{a=1}^{h_{g}} N_{a e} \times \bar{w}_{a e}}{\sum_{a=1}^{h_{g}} N_{a e}} \tag{13}
\end{equation*}
$$

and the proportion $\left(P_{g e}\right)$ is;

$$
\begin{equation*}
P_{g e}=\frac{N_{g e} \times \bar{w}_{g e} \times \bar{\sigma}_{b s, a e}}{\sum_{e=1}^{s}\left(N_{g e} \times \bar{w}_{g e} \times \bar{\sigma}_{b s, g e}\right)} \tag{14}
\end{equation*}
$$

### 2.2.8 Trawl clustering and species proportion

Trawls that occurred on the same night were assigned to a trawl cluster. Biomass densities ( $\rho$ ) were calculated for $100-\mathrm{m}$ transect intervals by dividing the integrated area-backscatter coefficients for each CPS species by the mean backscattering cross-sectional area (MacLennan et al., 2002) estimated in the trawl cluster nearest in space. Survey data were post-stratified to account for spatial heterogeneity in sampling effort and biomass density in a similar way to that performed for Pacific Sardine (Zwolinski et al., 2016).
For a generic 100-m long acoustic interval, the area-backscattering coefficient for species $e: s_{A, e}=s_{A, c p s} \times P_{g e}$, where $P_{g e}$ is the species acoustic proportion of the nearest trawl cluster (Equation (14)), was used to estimate the biomass density ( $\rho_{w, e}$ ) (MacLennan et al., 2002; Simmonds and MacLennan, 2005) for every 100-m interval, using the size and species composition of the nearest (space and time) trawl cluster (Fig. 10):

$$
\begin{equation*}
\rho_{w, e}=\frac{s_{A, e}}{4 \pi \bar{\sigma}_{b s, e}} \tag{15}
\end{equation*}
$$

See Section 3.5.1 and Fig. 13 for a description of the method used for this survey to estimate species proportions and Jack Mackerel lengths in the area between Cape Flattery and Cape Mendocino. The biomass densities were converted to numerical densities using: $\rho_{n, e}=\rho_{w, e} / \bar{w}_{e}$, where $\bar{w}_{e}$ is the corresponding mean weight. Also, for each acoustic interval, the biomass or numeric densities are partitioned into length classes according to the species' length distribution in the respective trawl cluster.

Figure 10: a) Polygons enclosing 100-m acoustic intervals from Lasker, Lisa Marie, and USVs assigned to catches from each trawl cluster or purse-seine set, and b) the acoustic proportions of CPS in catches from trawl clusters or purse-seine sets. See Section 3.5.1 and Fig. 13 for a description of the method used for this survey to estimate species proportions and Jack Mackerel lengths in the area between Cape Flattery and Cape Mendocino. The numbers inside each polygon in panel a) are the cluster or purse-seine numbers, which are located at the average latitude and longitude of all trawls in that cluster or each individual purse-seine set. Black points in panel b) indicate trawl clusters or purse-seine sets with no CPS present in the catch.

### 2.3 Data analysis

### 2.3.1 Post-stratification

The transects were sampling units (Simmonds and Fryer, 1996). Because each species does not generally span the entire survey area (Demer and Zwolinski, 2017; Zwolinski et al., 2014), the sampling domain was stratified for each species and stock. Strata were defined by uniform transect spacing (sampling intensity) and either presences (positive densities and potentially structural zeros) or absences (real zeros) of species biomass. Each stratum has: 1) at least three transects, with approximately equal spacing, 2) fewer than three consecutive transects with zero-biomass density, and 3) bounding transects with zero-biomass density (Fig. 11). This approach tracks stock patchiness and creates statistically-independent, stationary, postsampling strata (Johannesson and Mitson, 1983; Simmonds et al., 1992). For Northern Anchovy, we define the separation between the northern and central stock at Cape Mendocino ( $40.5^{\circ} \mathrm{N}$ ). For Pacific Sardine, the northern and southern stocks present in the survey area (Felix-Uraga et al., 2004; Felix-Uraga et al., 2005; Garcia-Morales et al., 2012; Hill et al., 2014) were separated using the Pacific Sardine potential habitat during the survey (Fig. 12). This separation is further supported by different distributions of $L_{S}$ and a break in the distribution of Pacific Sardine biomass, which, in this survey, coincided geographically with Big Sur, CA $\left(36.2^{\circ} \mathrm{N}\right.$, Fig. 11).

Figure 11: Biomass density $\left(\log _{10}\left(\mathrm{nmi}^{2}+1\right)\right)$ versus latitude (easternmost portion of each transect) and strata used to estimate biomass and abundance (shaded regions; outline indicates stratum number) for each species in the core survey region. Data labels (blue numbers) correspond to transects with positive biomass $\left(\log _{10}(t+1)>0.01\right)$. Transect spacing (nmi; point color), and stock breaks for Northern Anchovy and Pacific Sardine (red dashed lines and text) are indicated.

Figure 12: Summary of all transects sampled throughout the survey by Lasker (red) and Lisa Marie (yellow) in relation to the probability thresholds of the updated model of potential habitat for the northern stock of Pacific Sardine (Zwolinski and Demer, In prep.). The shaded regions with probabilities higher than 0.29 and 0.18 contained $82 \%$ and $95 \%$ of all spring northern stock Pacific Sardine spawning stock biomass, respectively. The habitat-model output is averaged in areas, $\pm 2^{\circ}$ latitude and longitude, centered around the daytime location of each vessel throughout the survey. Areas without data (white), occurred in the analysis domain where and when clouds prevented satellite-sensed observations.

### 2.3.2 Biomass and sampling precision estimation

For each stratum and stock, the biomass $(\hat{B} ; \mathrm{kg})$ of each species was estimated by:

$$
\begin{equation*}
\hat{B}=A \times \hat{D} \tag{16}
\end{equation*}
$$

where $A$ is the stratum area $\left(\mathrm{nmi}^{2}\right)$ and $\hat{D}$ is the estimated mean biomass density $\left(\mathrm{kg} \mathrm{nmi}{ }^{-2}\right)$ :

$$
\begin{equation*}
\hat{D}=\frac{\sum_{l=1}^{k} \bar{\rho}_{w, l} c_{l}}{\sum_{l=1}^{k} c_{l}} \tag{17}
\end{equation*}
$$

where $\bar{\rho}_{w, l}$ is the mean biomass density of the species on transect $l, c_{l}$ is the transect length, and $k$ is the total number of transects. The variance of $\hat{B}$ is a function of the variability of the transect-mean densities and associated lengths. Treating transects as replicate samples of the underlying population (Simmonds and Fryer, 1996), the variance was calculated using bootstrap resampling (Efron, 1981) based on transects as sampling units. Provided that each stratum has independent and identically-distributed transect means (i.e., densities on nearby transects are not correlated, and they share the same statistical distribution), bootstrap or other random-sampling estimators provide unbiased estimates of variance.

The $95 \%$ confidence intervals $\left(\mathrm{CI}_{95 \%}\right)$ for the mean biomass densities ( $\left.\hat{D}\right)$ were estimated as the 0.025 and 0.975 percentiles of the distribution of 1000 bootstrap survey-mean biomass densities. Coefficient of variation (CV, \%) values were obtained by dividing the bootstrapped standard error by the mean estimate (Efron, 1981). Total biomass in the survey area was estimated as the sum of the biomasses in each stratum, and the associated sampling variance was calculated as the sum of the variances across strata.

### 2.3.3 Abundance- and biomass-at-length estimation

The numerical densities by length class (Section 2.2.8) were averaged for each stratum in a similar way for that used for biomass (Equation (17)), and multiplied by the stratum area to obtain abundance per length class.

### 2.3.4 Percent biomass per cluster contribution

The percent contribution of each cluster to the estimated abundance in a stratum (Appendix A) was calculated as:

$$
\begin{equation*}
\frac{\sum_{i=1}^{l} \bar{\rho}_{c i}}{\sum_{c=1}^{C} \Sigma_{i=1}^{l} \bar{\rho}_{c i}}, \tag{18}
\end{equation*}
$$

where $\bar{\rho}_{c i}$ is the numerical density in interval $i$ represented by the nearest trawl cluster $c$.

## 3 Results

### 3.1 Sampling effort and allocation

The summer 2022 survey spanned the area from Cape Flattery and El Rosario between 27 June and 30 September 2022, and included most of the potential habitat for the northern stock of Pacific Sardine at the time of the survey ${ }^{4}$. In the core survey region that spanned this area (Fig. 15), Lasker ( 40 days at sea, DAS), Lisa Marie ( 26 DAS), and the two USVs (108 mission days) sampled 96 east-west transects totaling $4,264 \mathrm{nmi}$. Catches from a total of 86 nighttime surface trawls and 41 purse-seine sets from Lisa Marie were combined into 73 trawl clusters. In the core area, one to six post-survey strata were defined by their transect spacing and the densities of echoes attributed to each species.

The nearshore region spanned an area from approximately Cape Flattery to San Diego, including around Santa Cruz and Santa Catalina Islands. Lisa Marie (26 DAS) surveyed from approximately Cape Flattery, WA to Stewarts Point, CA with 24 east-west transects totaling 18 nmi and 41 purse-seine sets. Long Beach Carnage (22 DAS) surveyed from approximately Stewarts Point to San Diego, and around the Santa Cruz and Santa Catalina Islands, with 129 east-west transects totaling 511 nmi and 53 purse-seine sets (Fig. 17). In the nearshore area, one to fourteen post-survey strata were defined by their transect spacing and the biomass densities.

Biomasses and abundances were estimated for each species in both the core and nearshore survey areas. The total biomass for each stock within the survey region was estimated as the sum of its biomasses in the core and nearshore areas.

## Leg I

Leg I on Lasker was canceled. Therefore, Lisa Marie was directed to sample the 20-nmi-spaced compulsory Transects, 178 to 143, between Cape Flattery and Port Orford, OR, but extending them shoreward to $\sim 5$ m depth. Two USVs (SD-1076 and SD-1077) sampled Transects 170 to 160, between Copalis Beach, WA to Tillamook Bay, OR, from 9 to 22 July.

## Leg II

On 21 July, Lasker departed from the 10th Avenue Marine Terminal in San Diego, CA at $\sim 1745$ (all times GMT). Prior to the transit north, a calibration of the Simrad-Kongsberg EC150-3C ADCP-echosounder was attempted northwest of the sea buoy outside San Diego Bay ( 32.6598 N, 117.3833 W) , but was not completed, due to GPS data-format incompatibilities. Throughout the northward transit, daytime sampling was conducted with CUFES, EK80s, ME70, MS70 and SX90 while personnel continued to troubleshoot GPS issues and test equipment. On 25 July, Lasker arrived at the waypoint offshore of Cape Mendocino, CA at ~1930 and conducted one tow before initiating acoustic sampling on transect 129 at sunrise. After encountering CPS echoes on the first transect, adaptive sampling was initiated. On 26 July, Simrad-Kongsberg representative David Barbee resolved the issues with GPS-attitude data inputs to the EK80s. ADCP calibrations were successfully completed on 27 July, taking advantage of good weather conditions, close proximity to the intended trawl locations, and the last two hours of daylight. On 29 July, after completing transect 119, Lasker ceased adaptive sampling. Small boat operations were conducted near Point Arena on 30 July at $\sim 0230$ to embark acoustician Scott Mau, biologist Rachel Backman, and Junior Officer Daniel Stofka. On 4 August, Lasker completed transect 103 off Monterey, CA, ceased acoustic sampling, and transited to Point Conception, CA to recover an acoustic lander. The lander was recovered on 5 August at $\sim 1400$ before Lasker continued south to San Diego. On 6 August, Lasker arrived at the 10th Avenue Marine Terminal in San Diego, CA at $\sim 1400$ to complete Leg II.

Meanwhile, Lisa Marie sampled core-region Transects 141 to 114, between Cape Sebastian, OR to Bodega Bay, CA, from 21 July to 1 August. On 2 August, on its transit north, Lisa Marie resampled Transect 133, which she had previously been sampled during Leg II, but without recording EK80 data. On 3 August, Lisa Marie returned to Westport, WA to conclude its portion of the 2022 Summer CCE survey.

[^2]The two USVs (SD-1076 and SD-1077) sampled core-region Transects 158 to 146, between Neskowin, OR to Bandon, OR, from 23 July to 13 August.
Long Beach Carnage sampled nearshore Transects 227 to 186, between Bodega Bay, CA to Morro Bay, CA, from 30 July to 5 August.

## Leg III

All but four days on Leg III were lost, so the remaining time was used for CPS reconnaissance in the SCB. At ~1400 on 26 August, after a 16-day delay, Lasker departed from the 10th Avenue Marine Terminal Pier in San Diego, CA. At $\sim 1930$ on 26 August, acoustic sampling was conducted along transect 72 . A total of five transects were completed in the SCB. On 29 August, acoustic sampling ceased after the completion of transect 78 off Long Beach, CA. On 30 August, after completing a compass calibration outside of the San Diego sea buoy, Lasker arrived at the 10th Avenue Marine Terminal in San Diego, CA at $\sim 1900$ to complete Leg III.

The two USVs (SD-1076 and SD-1077) sampled core-region Transects 144 to 122, between Cape Blanco, OR to Beaver Point, CA, from 9 to 31 August. Long Beach Carnage sampled nearshore Transects 185 to 138, between Point Buchon, CA to the U.S.-Mexico border, and the Santa Cruz and Santa Catalina Islands, from 20 August to 8 September.

## Leg IV

At ~1615 on 9 September, Lasker departed from 10th Avenue Marine Terminal in San Diego, CA. At ~1430 on 12 September, Lasker resumed acoustic sampling along transect 103 off Monterey, CA. At $\sim 0330$ on 16 September, an acoustic lander was deployed at $34.438635 \mathrm{~N}, 120.54667 \mathrm{~W}$. The lander, consisting of an autonomous echosounder (WBAT; Simrad-Kongsberg) and passive-acoustic recorder (AURAL-M2; MultiElectronique), is part of an ongoing project to utilize stationary platforms for monitoring the ecosystem off Point Conception, CA, and stocks of CPS that migrate past there. At 0330 on 17 September, scientists Dayv Lowry and Daniel Hernandez Cruz embarked via small craft in Santa Barbara Harbor, CA. At 0330 on 24 September, scientist Brittany Schwarzkopf disembarked and Lasker's XO embarked via small craft in Mission Bay, CA. At 0200 on 29 September, acoustic sampling ceased at sunset along transect 54 off Punta Baja, Baja California. At 0700 on 30 September, Lasker arrived at the 10th Avenue Marine Terminal in San Diego, CA to conclude the 2022 Summer CCE survey.

### 3.2 Acoustic backscatter

Acoustic backscatter ascribed to CPS was observed throughout the latitudinal range of the core survey area (Fig. 15a) and was present nearshore to the shelf break. Zero-biomass intervals were observed at the offshore end of each transect in the core region. The majority (greater than $90 \%$ ) of the biomass for each species was apportioned using catch data from trawl clusters conducted within 30 nmi (Fig. 14).

Acoustic backscatter ascribed to CPS was also observed throughout the nearshore survey area (Figs. 16a and 17a), but was most prevalent in transects sampled by Lisa Marie between Crescent City and Bodega Bay (Fig. 16a) and along transects sampled by Long Beach Carnage between Bodega Bay and San Francisco, between Big Sur and Long Beach, and around Santa Cruz Island (Fig. 17a).

### 3.3 Egg densities and distributions

Jack Mackerel eggs were predominant in CUFES samples collected north of Monterey, but were most abundant between Cape Mendocino and Fort Bragg (Fig. 15b). Northern Anchovy eggs were predominant in positive samples collected between Monterey and El Rosario (Fig. 15b). Some Pacific Sardine eggs were present in samples collected offshore between San Francisco and Half Moon Bay, CA and in a few samples throughout the SCB (Fig. 15b).

### 3.4 Trawl catch

Trawl catches from Lasker were comprised of mostly Jack Mackerel between Cape Mendocino and Point Arena, CA, and Northern Anchovy farther south (Fig. 15c). Pacific Herring were present in several trawl clusters off the coast of WA and OR. Pacific Sardine were caught in relatively small numbers between Cape Mendocino and Fort Bragg (Fig. 15c). Relatively few Pacific Mackerel and Pacific Herring were collected (Fig. 15c). Overall, the 86 trawls and 41 purse-seine sets captured a combined $7,356 \mathrm{~kg}$ of CPS ( $6,887 \mathrm{~kg}$ of Northern Anchovy, 213 kg of Pacific Sardine, 18 kg of Pacific Mackerel, 217 kg of Jack Mackerel, and 20.2 kg of Pacific Herring).

### 3.5 Purse-seine catch

### 3.5.1 Lisa Marie

North of the Columbia River, Pacific Herring were predominant, by weight, in the purse-seine samples (Fig. 13e). Between the Columbia River and Cape Mendocino, Pacific Sardine were predominant (Fig. 13e). On numerous occasions, however, Jack Mackerel were reportedly schooling with Pacific Sardine, but eluded capture, thereby biasing the species composition in those samples (K. Hinton, pers. comm.). Therefore, for the region between Astoria and Cape Mendocino, the acoustic proportions of Pacific Sardine in nighttime trawl clusters from Lasker between 2018 and 2021 (Fig. 13a-c) were used to create a generalized additive model (GAM) describing their acoustic proportion versus latitude (Fig. 13d), which was used to estimate the acoustic proportion of Pacific Sardine in the purse-seine catch in 2022 (Fig. 13f). The complement acoustic proportion in the 2022 purse-seine catch was assumed to be Jack Mackerel, based on the association of Jack Mackerel and Pacific Sardine in the summer 2021 nighttime trawl catches (Fig. 13f). Other species (e.g., Pacific Herring, Pacific Mackerel, saury, and smelt) that could have contributed to the CPS backscatter in this area were also observed or suspected to be avoiding the net (K. Hinton, pers. comm.), but those species comprised a small fraction (always $<5 \%,<1.4 \%$ on average, and mostly $<1 \%$ ) of the acoustic proportions in clusters that contained both Pacific Sardine and Jack Mackerel in 2021. The Jack Mackerel lengths in this region are those from the summer 2021 nighttime trawl clusters nearest to the CPS backscatter observed in summer 2022. The purse-seine was only deployed when schools were observed, so purse-seine sampling was sparse along portions of the WA and OR coast. Overall, the 41 seines captured a combined 62.4 kg of CPS ( 37.5 kg of Pacific Sardine, 12.1 kg of Jack Mackerel, 4.75 kg of Pacific Herring, 4.08 t of Pacific Mackerel, and 3.9 kg of Northern Anchovy).

### 3.5.2 Long Beach Carnage

Northern Anchovy were predominant, by weight, in purse-seine samples collected by Long Beach Carnage nearshore off central CA between Cape Mendocino and Monterey (Fig. 17b). Pacific Sardine were predominant between Big Sur and San Diego (Fig. 17b). Some Pacific Mackerel were collected between Oceanside, CA and San Diego and around Santa Cruz and Santa Catalina Islands. Jack Mackerel were collected between Big Sur and Morro Bay, and off San Diego (Fig. 17b). Overall, dip net samples from 53 seines totaled 151 kg of CPS ( 87 kg of Pacific Sardine, 46 kg of Pacific Mackerel, kg of Jack Mackerel, and 10 kg of Northern Anchovy; and no Pacific Herring).

### 3.5.3 Combined catch

In some areas, purse-seine sets were sparse (Figs. 16b and 17b). To estimate biomass in the nearshore region, acoustic intervals were assigned the species proportions from the nearest purse-seine set or trawl cluster, whichever was closest (Fig. 18b).

Figure 13: Maps of species proportions in Lasker's nighttime trawl-catch clusters during summer a) 2018, b) 2019, and c) 2021 depicting an analysis region between the Columbia River and Cape Mendocino (dashed line); d) a model of the acoustic proportions of Pacific Sardine versus latitude in Lasker's nighttime trawl-catch clusters between 2018 and 2021; e) species proportions in Lisa Marie's summer 2022 purse-seine catches; and f) the species proportions used in the estimation of summer 2022 CPS biomasses north of Cape Mendocino, replacing Lisa Marie's catches containing Pacific Sardine, in the analysis region, with the modeled proportion of Pacific Sardine, with its complement assigned to Jack Mackerel.

Figure 14: Proportion (top) and cumulative proportion (bottom) of biomass versus distance to the nearest positive trawl cluster. Dashed vertical lines (bottom) represent the cluster distance where cumulative biomass equals $90 \%$.

Figure 15: Spatial distributions of: a) $38-\mathrm{kHz}$ integrated backscattering coefficients ( $s_{A}, \mathrm{~m}^{2} \mathrm{nmi}^{-2}$; averaged over 2000-m distance intervals) ascribed to CPS; b) CUFES egg density (eggs $\mathrm{m}^{-3}$ ) for Northern Anchovy, Pacific Sardine, and Jack Mackerel; and c) acoustic proportions of CPS in trawl clusters (black outline) and purse-seine sets (white outline). Black points indicate trawl clusters or purse-seine sets with no CPS.

Figure 16: Nearshore survey transects sampled by Lisa Marie overlaid with the distributions of: a) $38-\mathrm{kHz}$ integrated backscattering coefficients $\left(s_{A}, \mathrm{~m}^{2} \mathrm{nmi}^{-2}\right.$; averaged over $2000-\mathrm{m}$ distance intervals) ascribed to CPS; and b) the proportions, by weight, of CPS in each purse-seine catch. Species with low catch weights may not be visible at this scale.

Figure 17: Nearshore transects sampled by Long Beach Carnage overlaid with the distributions of: a) $38-\mathrm{kHz}$ integrated backscattering coefficients ( $s_{A}, \mathrm{~m}^{2} \mathrm{nmi}^{-2}$; averaged over 2000-m distance intervals) ascribed to CPS; and b) the proportions, by weight, of CPS in each purse-seine catch. Species with low catch weights may not be visible at this scale.

Figure 18: Spatial distributions of: a) $38-\mathrm{kHz}$ integrated backscattering coefficients $\left(s_{A}, \mathrm{~m}^{2} \mathrm{nmi}^{-2}\right.$; averaged over 2000-m distance intervals) ascribed to CPS from nearshore sampling; and b) acoustic proportions of CPS in trawl clusters (black outline) and purse-seine sets (white outline).

### 3.6 Biomass distribution and demographics

The biomasses, distributions, and demographics for each species and stock are for the survey area and period and therefore may not represent the entire population. No nearshore sampling was conducted off Baja CA, so nearshore biomass estimates are for U.S. waters only.

### 3.6.1 Northern Anchovy

### 3.6.1.1 Northern stock

The total estimated biomass of the northern stock of Northern Anchovy was $16,432 \mathrm{t}\left(\mathrm{CI}_{95 \%}=5,646-\right.$ $27,680 \mathrm{t}, \mathrm{CV}=34 \%$; Table 5). In the core region, biomass was $16,432 \mathrm{t}\left(\mathrm{CI}_{95 \%}=5,646-27,680 \mathrm{t}, \mathrm{CV}=\right.$ $34 \%$; Table 5); the stock was distributed throughout the survey area from approximately Westport to Cape Blanco (Fig. 19a). $L_{S}$ ranged from 10 to 15 cm with modes at 10 and 13 cm (Table 6, Fig. 20). In the nearshore region, biomass was $0.0934 \mathrm{t}\left(\mathrm{CI}_{95 \%}=0-0.285 \mathrm{t}\right.$, $\mathrm{CV}=94 \%$; Table 5), comprising $0.00057 \%$ of the total biomass, and was located near the entrance to the Columbia River (Fig. 19b). $L_{S}$ had a single mode at $\sim 13 \mathrm{~cm}$ (Table 6; not visible in Fig. 20).

Table 5: Biomass estimates (metric tons, t) and their precisions (upper and lower $95 \%$ confidence intervals, $\mathrm{CI}_{95 \%}$; and coefficients of variation, CVs) for the northern stock of Northern Anchovy (Engraulis mordax) in the core and nearshore survey regions. Stratum areas are $n m i{ }^{2}$.

| Stratum |  |  |  |  | Trawl |  | Biomass |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Region | Number | Area | Transects | Distance | Clusters | Individuals | $\hat{B}$ | $\mathrm{CI}_{L, 95 \%}$ | $\mathrm{CI}_{U, 95 \%}$ | CV |
| Core | 4 | 3,287 | 8 | 352 | 1 | 1 | 16,321 | 5,556 | 27,583 | 35 |
|  | 5 | 6,558 | 13 | 659 | 2 | 9 | 111 | 2 | 319 | 76 |

Table 6: Abundance versus standard length $\left(L_{S}, \mathrm{~cm}\right)$ for the northern stock of Northern Anchovy (Engraulis mordax) in the core and nearshore survey regions.

Figure 19: Biomass densities (colored points) of the northern stock of Northern Anchovy (Engraulis mordax), per stratum, in the a) core and b) nearshore survey regions. Overlaid are the locations of trawl clusters with at least one Northern Anchovy (blue numbers) in each stratum (colored polygons). Thick gray lines represent acoustic transects.

Figure 20: Abundance versus standard length ( $L_{S}$, upper panels) and biomass ( t ) versus $L_{S}$ (lower panels) for the northern stock of Northern Anchovy (Engraulis mordax) in the core and nearshore survey regions. This plot correctly shows the abundances and biomasses in the core region, which is based on one specimen resulting in the mode at 10 cm (see Cluster 60 in Appendix A.1). Abundance and biomass in the nearshore region is negligible relative to the core region and not visible at this scale.

### 3.6.1.2 Central stock

The total estimated biomass of the central stock of Northern Anchovy was 2,235,996 t $\left(\mathrm{CI}_{95 \%}=1,248,956\right.$ $-3,051,863 \mathrm{t}, \mathrm{CV}=20 \%$; Table 7), of which $6 \%$ was observed in Mexican waters. In the core region, biomass was $2,197,812 \mathrm{t}\left(\mathrm{CI}_{95 \%}=1,231,227-3,002,630 \mathrm{t}\right.$, $\mathrm{CV}=21 \%$; Table 7$)$; the stock was distributed throughout most of the survey area from Bodega Bay to El Rosario (Fig. 21a). $L_{S}$ ranged from 5 to 16 cm with modes at 9 and 12 cm (Table 8, Fig. 22). In the nearshore region, biomass was $38,184 \mathrm{t}\left(\mathrm{CI}_{95 \%}=\right.$ 17,729-49,233 t, CV = 21\%; Table 7), comprising $1.7 \%$ of the total biomass, and was distributed between Bodega Bay and Los Angeles, CA (Fig. 21b). The nearshore length distribution had a single mode at 11 cm (Table 8, Fig. 22).

Table 7: Biomass estimates (metric tons, t ) and their precisions (upper and lower $95 \%$ confidence intervals, $\mathrm{CI}_{95 \%}$; and coefficients of variation, CVs) for the central stock of Northern Anchovy (Engraulis mordax) in the core and nearshore survey regions. Stratum areas are $\mathrm{nmi}^{2}$.

### 3.6.2 Pacific Sardine

### 3.6.2.1 Northern stock

The total estimated biomass of the northern stock of Pacific Sardine was $69,506 \mathrm{t}\left(\mathrm{CI}_{95 \%}=30,484-99,021 \mathrm{t}\right.$, CV $=21 \%$; Table 9). In the core region, biomass was $53,741 \mathrm{t}\left(\mathrm{CI}_{95 \%}=29,672-84,749 \mathrm{t}, \mathrm{CV}=26 \%\right.$; Table 9), was distributed from Westport to Point Conception, but was most abundant between the Columbia River and Newport (Fig. 23a). $L_{S}$ ranged from 11 to 27 cm with a mode at 16 cm (Table 10, Fig. 24). In the nearshore region, biomass was $15,765 \mathrm{t}\left(\mathrm{CI}_{95 \%}=812-14,272 \mathrm{t}\right.$, $\mathrm{CV}=23 \%$; Table 9 ), comprising $23 \%$ of the total biomass. It was distributed mostly between San Francisco and Point Conception, with some present near Crescent City (Fig. 23b). $L_{S}$ had two modes at 11 and 15 cm (Table 10, Fig. 24).

Table 9: Biomass estimates (metric tons, t) and their precisions (upper and lower $95 \%$ confidence intervals, $\mathrm{CI}_{95 \%}$; and coefficients of variation, CVs) for the northern stock of Pacific Sardine (Sardinops sagax) in the core and nearshore survey regions. ### 3.6.2.2 Southern stock

The total estimated biomass of the southern stock of Pacific Sardine was 107,468 t $\left(\mathrm{CI}_{95 \%}=47,994-178,947\right.$ $\mathrm{t}, \mathrm{CV}=23 \%$; Table 11), of which $0.9 \%$ was observed in Mexican waters. In the core region, biomass was $40,206 \mathrm{t}\left(\mathrm{CI}_{95 \%}=4,741-79,328 \mathrm{t}, \mathrm{CV}=48 \%\right.$; Table 11), and was distributed from approximately San Francisco to El Rosario (Fig. 25a). $L_{S}$ ranged from 9 to 21 cm with two modes, at 13 and 18 cm (Table 12, Fig. 26). In the nearshore region, biomass was $67,262 \mathrm{t}\left(\mathrm{CI}_{95 \%}=43,253-99,620 \mathrm{t}\right.$, $\mathrm{CV}=23 \%$; Table 11), comprising $63 \%$ of the total biomass. The nearshore biomass was distributed between Point Conception and San Diego, but was greatest near Santa Barbara, San Diego, and around Santa Cruz Island. The $L_{S}$ in the nearshore region ranged from 10 to 21 cm and had modes at 12 and 16 cm (Table 12, Fig. 26).

Table 11: Biomass estimates (metric tons, t ) and their precisions (upper and lower $95 \%$ confidence intervals, $\mathrm{CI}_{95 \%}$; and coefficients of variation, CVs) for the southern stock of Pacific Sardine (Sardinops sagax) in the core and nearshore survey regions. ### 3.6.3 Pacific Mackerel

The total estimated biomass of Pacific Mackerel was $7,968 \mathrm{t}\left(\mathrm{CI}_{95 \%}=3,741-12,662 \mathrm{t}, \mathrm{CV}=22 \%\right.$; Table 13), of which $27 \%$ was observed in Mexican waters. In the core region, biomass was $5,619 \mathrm{t}\left(\mathrm{CI}_{95 \%}=2,851\right.$ - $9,108 \mathrm{t}, \mathrm{CV}=29 \%$ ) and was distributed from approximately Cape Mendocino to El Rosario, but was primarily located south of Point Conception (Fig. 27a). The distribution of $L_{F}$ ranged from 8 to 38 cm with two modes at 11 and 15 cm (Table 14, Fig. 28). In the nearshore region, biomass was $2,349 \mathrm{t}\left(\mathrm{CI}_{95 \%}\right.$ $=890-3,553 \mathrm{t}, \mathrm{CV}=30 \%$; Table 13, Fig. 27b), comprising $29 \%$ of the total biomass. It was distributed from Point Conception to San Diego, but was most abundant around Santa Cruz and Santa Catalina Islands. The distribution of $L_{F}$ ranged from 8 to 35 cm and had modes at 18,27 , and 29 cm .

Table 13: Biomass estimates (metric tons, t) and their precisions (upper and lower $95 \%$ confidence intervals, $\mathrm{CI}_{95 \%}$; and coefficients of variation, CVs) for Pacific Mackerel (Scomber japonicus) in nearshore survey region. Stratum areas are $\mathrm{nmi}^{2}$.

### 3.6.4 Jack Mackerel

The total estimated biomass of Jack Mackerel was $807,090 \mathrm{t}\left(\mathrm{CI}_{95 \%}=515,560-1,145,812 \mathrm{t}, \mathrm{CV}=20 \%\right.$; Table 15), of which $0.06 \%$ was observed in Mexican waters. In the core region, the biomass was $799,082 \mathrm{t}$ $\left(\mathrm{CI}_{95 \%}=512,231-1,132,052 \mathrm{t}, \mathrm{CV}=20 \%\right.$; Table 15). It was distributed throughout the survey area from the Columbia River to El Rosario, but were most abundant between Astoria and Bodega Bay. (Fig. 29a). $L_{F}$ ranged from 3 to 51 cm , with modes at 8 and 34 cm . (Table 16, Fig. 30). In the nearshore region, the biomass was $8,009 \mathrm{t}\left(\mathrm{CI}_{95 \%}=3,328-13,761 \mathrm{t}, \mathrm{CV}=35 \%\right.$; Table 15), comprising $0.99 \%$ of the total biomass. It was distributed from Point Conception to San Diego, but was most abundant near Long Beach and around Santa Cruz Island (Fig. 29b), and had a length mode at 19 cm (Table 16, Fig. 30). A small amount of biomass was present in the nearshore region near Fort Bragg.

Table 15: Biomass estimates (metric tons, t ) and their precisions (upper and lower $95 \%$ confidence intervals, $\mathrm{CI}_{95 \%}$; and coefficients of variation, CVs) for Jack Mackerel (Trachurus symmetricus) in the core and nearshore survey regions. Stratum areas are nmi ${ }^{2}$.

### 3.6.5 Pacific Herring

The total estimated biomass of Pacific Herring was $50,718 \mathrm{t}\left(\mathrm{CI}_{95 \%}=14,460-99,700 \mathrm{t}\right.$, $\mathrm{CV}=41 \%$; Table 17). In the core region, biomass was $47,024 \mathrm{t}\left(\mathrm{CI}_{95 \%}=13,306-93,207 \mathrm{t}, \mathrm{CV}=44 \%\right.$; Table 17). It was distributed from approximately Cape Flattery to Cape Mendocino, but was most abundant from Cape Flattery to the Columbia River, and between Crescent City and Cape Mendocino (Fig. 31a). $L_{F}$ ranged from 13 to 17 cm , with modes at 13 and 17 cm (Table 18, Fig. 32). In the nearshore region, biomass was $3,694 \mathrm{t}\left(\mathrm{CI}_{95 \%}=1,154-6,493 \mathrm{t}, \mathrm{CV}=36 \%\right.$; Table 17, Fig. 31b), or $7.3 \%$ of the total biomass. It was distributed from Cape Flattery to Cape Mendocino (Fig. 32), and the distribution of $L_{F}$ ranged from 13 to 17 cm and had a mode at 14 cm (Table 18, Fig. 32).

Table 17: Biomass estimates (metric tons, t) and their precisions (upper and lower $95 \%$ confidence intervals, $\mathrm{CI}_{95 \%}$; and coefficients of variation, CVs) for Pacific Herring (Clupea pallasii) in the core and nearshore survey regions. Stratum areas are $\mathrm{nmi}^{2}$.

## 4 Discussion

The principal objectives of the 75 -day, summer 2022 CCE Survey were to estimate the biomasses and distributions of the northern and southern stocks of Pacific Sardine and the northern and central stocks of Northern Anchovy. Secondary objectives were to produce estimates for Pacific Mackerel, Jack Mackerel, and Pacific Herring within the survey area at the time of the survey.

Despite inclement weather conditions, mechanical limitations, staffing issues, and logistical challenges related to the COVID-19 pandemic, and the loss of nearly half of the allocated sea days aboard Lasker, the core region was surveyed by Lisa Marie and two USVs from Cape Flattery to Bodega Bay, and by Lasker between Cape Mendocino and El Rosario off Baja CA. Following the cancellation of Leg 1, the decision was made to forgo sampling off Vancouver Island to maximize the likelihood of surveying all of the transects in U.S. waters. To mitigate the loss of acoustic sampling effort north of Cape Mendocino, the decision was made to have Lisa Marie and two USVs acoustically sample along Lasker's compulsory transects in tandem, and daytime purse-seine sampling was conducted by Lisa Marie to provide information about the distribution, species composition, and length distribution of CPS. This approach deviated from the standard ATM surveys, which created additional challenges and uncertainty (see Section 3.5.1 and Fig. 13 ). For example, net avoidance by fast-swimming species, such as Jack Mackerel, required a novel method to adjust species proportions in that region to minimize uncertainty in the biomass estimates.

### 4.1 Biomass and abundance

### 4.1.1 Northern Anchovy

4.1.1.1 Northern stock The estimated biomass of the northern stock of Northern Anchovy in the survey region north of Cape Mendocino was $16,432 \mathrm{t}\left(\mathrm{CI}_{95 \%}=5,646-27,680 \mathrm{t}\right)$ in summer 2022. The northern stock biomass has comprised a small fraction ( 0.1 to $5.4 \%$ ) of the total biomass in the ATM surveys conducted in the CCE since at least 2015 (Stierhoff et al., 2021a).
4.1.1.2 Central stock The estimated biomass of the central stock of Northern Anchovy in the survey region was $2,235,996 \mathrm{t}\left(\mathrm{CI}_{95 \%}=1,248,956-3,051,863 \mathrm{t}\right)$ and comprised $68 \%$ of the total CPS biomass in summer 2022. The biomass represents a $\sim 20 \%$ decrease from the $2,721,689 \mathrm{t}$ estimated in summer 2021 (Stierhoff et al., 2023). In summer 2022, $6 \%$ of the central stock Northern Anchovy biomass was observed in Mexican waters. In 2015, the ATM survey documented a large recruitment to the central stock of Northern Anchovy, and since 2018, the central stock of Northern Anchovy has been the dominant forage fish species in the survey area (Figs. 35a,b).

### 4.1.2 Pacific Sardine

4.1.2.1 Northern stock The boundary between the northern and southern stocks of Pacific Sardine was Point Conception, based foremost on associations with potential habitat but corroborated by the distributions of biomass density north and south of Point Conception, and differences in length distribution (Fig. 33). The estimated biomass of $69,506 \mathrm{t}\left(\mathrm{CI}_{95 \%}=30,484-99,021 \mathrm{t}\right)$ in the survey region was a $46 \%$ increase in biomass compared to the $47,721 \mathrm{t}$ estimated in summer 2021 (Stierhoff et al., 2023). Since 2014, the ATM biomass of the northern stock of Pacific Sardine has remained less than the $150,000 \mathrm{t}$ rebuilding target adopted by the Pacific Fishery Management Council in $2020^{5}$ (Figs. 35a,b).

[^3]4.1.2.2 Southern stock The estimated biomass of the southern stock of Pacific Sardine in the survey region was $107,468 \mathrm{t}\left(\mathrm{CI}_{95 \%}=47,994-178,947 \mathrm{t}\right.$ ). In summer 2022, $106,930 \mathrm{t}$ (core stratum 2 and all nearshore strata; $99 \%$ of the total biomass) of southern stock biomass was observed in U.S. waters, and the remaining 376 t (stratum $1 ; 0.9 \%$ of the total biomass) was observed off Baja CA. Of the portion in U.S. waters in summer $2022,67,262 \mathrm{t}(63 \%)$ occurred in the nearshore region.

The southern stock was first observed in U.S. waters by the SWFSC's ATM surveys in 2016 (323 t, Stierhoff et al., 2021b). Since then, the southern stock biomass in U.S. waters has been increasing, from 33,093 t in summer 2018 (Stierhoff et al., 2021b) to 107,468 t in summer 2022. In summer 2017, the summer survey did not extend into the SCB (Zwolinski et al., 2019), and no summer survey was conducted in 2020 due to COVID-19.

### 4.1.3 Pacific Mackerel

In summer 2022, the estimated biomass of Pacific Mackerel in the survey region was $7,968 \mathrm{t}\left(\mathrm{CI}_{95 \%}=3,741\right.$ - $12,662 \mathrm{t}$ ), which is lower than recent estimates (21,998-42,423 between 2016 and 2021, and the lowest biomass observed since 2015 (1,224 t, Stierhoff et al., 2021a).

### 4.1.4 Jack Mackerel

In summer 2022, the estimated biomass of Jack Mackerel in the survey region, south of Cape Flattery, was $807,090 \mathrm{t}\left(\mathrm{CI}_{95 \%}=515,560-1,145,812 \mathrm{t}\right)$, which is 1.4 -fold higher than 569,793 t estimated in summer 2021 (Stierhoff et al., 2023). In summer 2022, Jack Mackerel was the second most abundant CPS overall, and comprised $24 \%$ of the total CPS biomass (Figs. 35a,b).

### 4.1.5 Pacific Herring

In summer 2022, the estimated biomass of Pacific Herring in U.S. waters south of Cape Flattery, was 50,718 $\mathrm{t}\left(\mathrm{CI}_{95 \%}=14,460-99,700 \mathrm{t}\right)$, which was $75 \%$ of the $67,920 \mathrm{t}$ estimated in summer 2021 (Stierhoff et al., 2023).

Figure 33: Differentiation of northern (blue) and southern (red) stocks of Pacific Sardine by: a) length distributions; b) individual (grey points) and catch-mean (colored points) lengths at the latitudes of their respective trawls; and c) geographic locations of trawls catches with (colored points) and without (black points) Pacific Sardine.

### 4.2 Ecosystem dynamics: Forage fish community

The acoustic-trawl method (ATM) has been used to monitor the biomasses and distributions of pelagic and mid-water fish stocks worldwide (e.g., Coetzee et al., 2008; Karp and Walters, 1994; Simmonds et al., 2009). In 2006, the SWFSC's ATM survey in the CCE focused on Pacific Sardine (Cutter and Demer, 2008), but evolved to assess the five most abundant CPS (Zwolinski et al., 2014): Pacific Sardine, Northern Anchovy, Jack Mackerel, Pacific Mackerel, and Pacific Herring. In the CCE, ATM surveys have been used to directly assess Pacific Hake (Edwards et al., 2018; JTC, 2014); rockfishes (Demer, 2012a, 2012b, 2012c; Starr et al., 1996); Pacific Herring (Thomas and Thorne, 2003); northern stock of Pacific Sardine (Hill et al., 2017); northern (Mais, 1974, 1977) and central stocks (Kuriyama et al., 2022) of Northern Anchovy; and Pacific Mackerel (Crone et al., 2019; Crone and Hill, 2015). The proportions of these stocks that are in water too shallow to be sampled by NOAA ships are estimated using samples collected from fishing vessels and USVs. Also, concurrent satellite- and ship-based measures of their biotic and abiotic habitats are used to provide an ecosystem perspective.
Collectively, these annual or bi-annual ATM surveys provide a unique insight into the dynamics of forage fishes in the CCE, including their distributions, abundances, interactions, and environments. For example, results from 2006 through 2013 indicate that Pacific Sardine dominated the CPS assemblage, but their biomass was declining (Demer and Zwolinski, 2012; Zwolinski and Demer, 2012) and their seasonal migration was contracting (Zwolinski et al., 2014). Meanwhile, harvest rates for the declining stock increased (Demer and Zwolinski, 2017), and the total forage-fish biomass decreased to less than 200,000 t in 2014 and 2015 (Figs. 35a,b). The U.S. fishery for Pacific Sardine was closed in 2015 (National Marine Fisheries Service, 2015), and there were reports of mass strandings, deaths, and reproductive failures in Brown Pelicans (Pelecanus occidentalis ${ }^{6}$ ), Common Murres (Uria aalge), Brandt's Cormorants (Phalacrocorax penicillatus), and California sea lions (Zalophus californianus ${ }^{7}$ ) (McClatchie et al., 2016), all of which depend on forage species. The National Marine Fisheries Service deemed the stock 'overfished' in 2019.
The biomass of the central stock of Northern Anchovy, which had been growing exponentially since 2015, decreased $\sim 20 \%$ from the $2,721,689$ t estimated in summer 2021 (Stierhoff et al., 2023). Jack Mackerel, which were found mostly north of Cape Mendocino, included an abundance of apparently age-0 fish farther south, suggesting a strong recruitment. The southern stock of Pacific Sardine was found mostly north of the U.S.-Mexico border and nearshore. Even considering the additional uncertainties in the biomass estimates north of Cape Mendocino (see Section 2.2.5, Section 3.5.1, and Fig. 13) there is no indication that the biomasses of the northern stock of Pacific Sardine and the northern stock of Northern Anchovy have changed significantly since summer 2021.

The survey time series of estimated CPS biomasses from summer 2008 to 2022 shows that the forage fish assemblage in the CCE was dominated by the northern stock of Pacific Sardine until 2013 and a low biomass of Jack Mackerel in 2014 and 2015 (Figs. 35a,b). Since 2016, the forage-fish biomass has increased, mainly due to resurgences of Jack Mackerel and the now dominant central stock of Northern Anchovy (Figs. 35a,b), whose biomass primarily ( $1,025,686 \mathrm{t}$, or $47 \%$ of the total estimate biomass) occurred in U.S. waters. In 2022, as it was a half century ago (Mais, 1974, 1977), the CPS assemblage is now mostly composed of Northern Anchovy and to a lesser extent Jack Mackerel. Between the summers of 2018 and 2021, the biomass of the southern stock of Pacific Sardine in U.S. waters has increased from 33,093 to $106,930 \mathrm{t}$.

Since the resurgence of the central stock of Northern Anchovy, beginning in 2015, there has been consistency in the regional distributions of the three dominant species: Northern Anchovy, Jack Mackerel and Pacific Herring (Fig. 34). Pacific Herring are caught mostly north of central Washington. Lower biomasses of northern stock Pacific Sardine and northern stock Northern Anchovy are resident off Oregon and Northern California. Jack mackerel are caught between central Washington and Cape Mendocino, often along with fewer northern stock Pacific Sardine in recent years. Central stock Northern Anchovy are caught south of Cape Mendocino and, with the exception of summer 2021, mostly south of Bodega Bay. The smaller northern stock is resident from central Washington to northern California. The summer 2022 distribution

[^4]of Northern Anchovy appears to have shifted south, better aligning with its distributions during 2015-2019. In contrast to earlier surveys in the time series, the southern stock of Pacific sardine has been persistently present during summer surveys in U.S. waters, mostly in the Southern California Bight (Fig. 34).

Figure 34: Distributions of species proportions in Lasker's nighttime trawl catches, summer 2015 through 2022. In 2015, the integrated CPS-hake survey sample northward of Vancouver Island. In 2017, there was no sampling in the SCB. In 2020, there was no survey due to the COVID-19 pandemic. In 2021, through a collaboration with Mexico, the CPS survey extended farther south into Baja California. In 2022, there was no nighttime trawl sampling north of Cape Mendocino, California.

Figure 35: a) Estimated and b) cumulative estimated biomasses ( $t$ ) of the eight most abundant CPS stocks of six species in the CCE during summer since 2008. Surveys typically span the area between Cape Flattery and San Diego, but in some years also include Vancouver Island, Canada (2015-2019) and portions of Baja CA (2021-2022).

## Acknowledgements

The authors greatly appreciate that the ATM surveys require an enormous effort by multiple groups of people, particularly the SWFSC's Advanced Survey Technologies group (Alice Beittel, Scott Mau, David Murfin, and Steve Sessions); CalCOFI and Ship Operations group (Noelle Bowlin, Nicolas Concha Saiz, Anne Freire, Emily Gardner, Amy Hays, Megan Human, Bryan Overcash, Andrew Thompson, Lanora Vasquez de Mercado, Bill Watson, and Ed Weber); Life History Group (Brad Erisman, Kelsey James, Brittany Schwartzkopf, Owyn Snodgrass, and Jon Walker); Stock Assessment (Peter Kuriyama); and their volunteers (Rachel Backman, Shannon Dolan, Morgan Illman, Dayv Lowry, Dan Palance, Kamran Walsh, and Jake Wood). We also thank biologists Daniel Hernandez Cruz and Selene del Carmen Morales Gutierrez (INAPESCA), the officers and crew of Lasker, and the SWFSC's Fisheries Resources Division administrative staff. The authors acknowledge that the methods used are the culmination of more than a half century of development efforts from numerous researchers from around the globe. We thank Capts. Rick Blair (Lisa Marie) and Rich Ashley and Tom Brinton (Long Beach Carnage), along with all the F/V crew members, for their coordination and cooperation during the nearshore sampling, and to Joel van Noord (CWPA) and Kristen Hinton and Patrick Biondo (WDFW) for leading the at-sea processing of purse seine specimens. We thank Diane PleschnerSteele (CWPA) for contracting the Long Beach Carnage to conduct the nearshore survey off central CA and in the SCB, and Greg Shaughnessy (Ocean Gold Seafoods) for contracting the Lisa Marie to conduct the nearshore survey of WA, OR, and northern CA. We thank Kelly Kloos, Trevor Stocking, Diego Aceituno, Dane McDermott, Kyle Mooers, Jax Mikkelsen, Leeanne Laughlin, Chelsea Protasio, and Michelle Horeczko (CDFW) for their efforts to coordinate with and process samples from Long Beach Carnage. Finally, reviews by [LIST OF REVIEWERS] and Annie Yau improved this report.

## Appendix

## A Length distributions and percent biomass by cluster

## A. 1 Northern Anchovy

Standard length $\left(L_{S}\right)$ frequency distributions of Northern Anchovy (Engraulis mordax) per nighttime trawl cluster, annotated with the number of individuals caught and their percentage contributions to the abundance in each stratum.

## A. 2 Pacific Sardine

Standard length $\left(L_{S}\right)$ frequency distributions of Pacific Sardine (Sardinops sagax) per nighttime trawl cluster, annotated with the number of individuals caught and their percentage contributions to the abundance in each stratum.

Cluster 52

Cluster 62
