2025 Re-evaluation of the recruits-per-spawner and CalCOFI SST relationship in Pacific sardine

Presentation for the PFMCC SSC CPS subcommittee

February 26, 2025

Caitlin I. Allen Akselrud, Alexander J. Jensen, and Kevin T. Hill

NOAA - NMFS Southwest Fisheries Science Center

Background: 2013 workshop

- Explored many model and data configurations and options
- Selected a GAM to assess the relationship between recruits-per-spawner and sea-surface temperature (SST)
- Spawners were represented by age 2+ biomass
- Spawner and recruit data were assembled from stock assessments 1984-2008
- The index of SST comes from CalCOFI quarterly survey estimates

Context

- The purpose of this analysis is to assess the relationship between recruits-per-spawner and the CalCOFI SST
- Use the best selected models from the 2013 workshop and apply the same method with updated data sets for biomass, recruitment, and CalCOFI SST

Data: biomass and recruits

- Recruits/spawner data for 1984-2004 were appended with the most recent stock assessment estimates of age 2+ biomass and recruits from 2005-2023 (Kuriyama et al, 2024)
- Two recruits/spawner time series:
 - one time series patching together the 1984-2023 data
 - one with only the most recent stock assessment data from 2005-2023.

Data: sea-surface temperature (SST)

- Reported workshop values slightly different from [current] standard generation methods
- Replaced workshop SST with reported SST from recent stock assessments and values generated consistent with the current method (Ed Weber)

GAM models

- Fitting to a log(recruits/spawner)

- Three GAM types:

- Configuration L – SST as a linear covariate:

$$\alpha + s(S_y, k = 3) + \beta T_y + \varepsilon_y$$

- Configuration G (consistent with the model chosen in the 2013 workshop) – smoothed SST (non-linear covariate):

$$\alpha + s(S_y, k = 3) + s(T_y, k=3) + \varepsilon_y.$$

- Configuration B – no SST covariate:

$$\alpha + s(S_y, k = 3) + \varepsilon_y.$$

Results

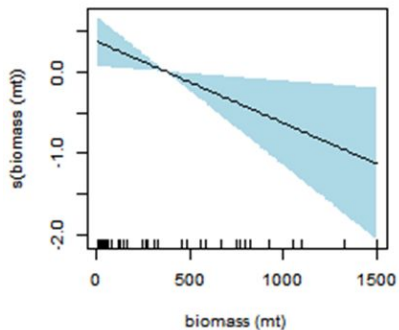

Analysis	Time series	GAM type	GAM	N	Resid. DF	EDF of SST	AIC	R ² adjusted	Squared Pearson corr. (R ²)
New	1984-2023	B	no SST covariate	40	38	0	122.2	0.11	0.13
New	1984-2023	G	smooth SST covariate	40	35.5	1.89	106	0.44	0.49
New	1984-2023	L	linear SST covariate	40	36.69	1	112.7	0.32	0.36
New	2005-2023	B	no SST covariate	19	17	0	66.49	-0.04	0.02
New	2005-2023	G	smooth SST covariate	19	15.33	1.67	63.42	0.18	0.3
New	2005-2023	L	linear SST covariate	19	16	1	65.18	0.07	0.17
Workshop	1984-2008	G	smooth SST covariate	25	21.73	1.27	44.49	0.741	0.762
Workshop	1984-2008	L	linear SST covariate	25	22	0	44.68	0.731	0.762

Results

Extended time series (1984-2023)

Short time series (2005-2023)

GAM B, recruit/spawner

GAM L, recruit/spawner

GAM B, recruit/spawner

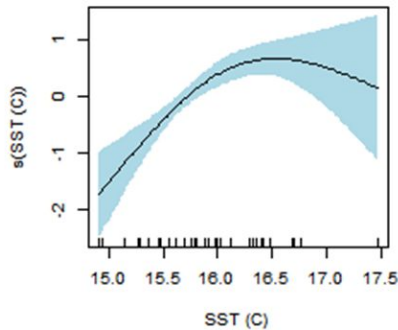

GAM L, recruit/spawner

GAM G, recruit/spawner

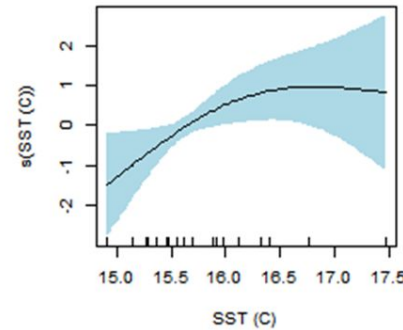

GAM G, recruit/spawner

GAM G, recruit/spawner

GAM G, recruit/spawner

Conclusion

The best fitting model is still the GAM with CalCOFI SST as a smoothed covariate (model G) for the extended time series (1984-2023).

The adjusted R^2 shows a decrease in the amount of variance explained in recruits/spawner by CalCOFI SST compared with the workshop findings.

The recent time series (2005-2023), which uses biomass and recruits generated in a consistent manner from the 2024 benchmark assessment, shows a much lower R^2 than the extended time series. However, AIC still suggests this is better than no SST covariate.
